Results: We did not observe differences with respect to hSLEDAI scores, clinical features, medication usage, or number and type of SLE-associated AutoAbs comparing pre-flare vs. pre-SNF time points, either in aggregate or by race. At follow-up, SLE patients experiencing a clinical disease flare (vs. SNF visit) had significantly elevated hSLEDAI scores ($p< 0.0001$), with an increased presence of arthritis ($p< 0.0001$), mucocutaneous ($p< 0.0001$), and serositis ($p=0.0066$) clinical features. Thirty-one immune mediators (**Figure [A]**) were altered in cases vs HC ($p\leq 0.05$), and altered in pre-flare vs. pre-SNF samples ($p\leq 0.02$ after adjusting for multiple comparison); inflammatory mediators were increased and regulatory mediators decreased in pre-flare samples. Variable importance of the 31 mediators was determined by random forest (**Figure [A]**) and confirmed by XG Boost. Forward selection/backward elimination drew 9-14 mediators that best differentiated pre-flare from pre-SNF (**Table**). A combination of the top 10 immune mediators best informed and maximized the performance of a newly refined LFPI (**Figure [B]**), achieving 87% sensitivity and 91% specificity. In addition to identifying impending clinical disease flare, the LFPI (and top mediators informing it) was significantly increased in SLE patients who went on to increased features of arthritis ($p< 0.0001$), mucocutaneous ($p< 0.0001$), or serositis ($p=0.0003$) clinical features at follow-up.

Conclusion: We verified the alteration of inflammatory and regulatory immune mediators with imminent lupus disease flare. A subset of mediators boosted the LFPI to identify SLE patients at risk of imminent flare who would benefit from early intervention strategies. Such an approach would be a game changer in prospective clinical trials and the management of lupus.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical II: Cardiopulmonary Involvement

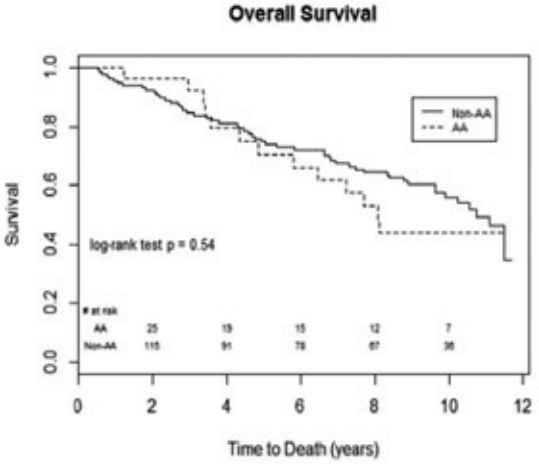

Figure 1a. Time to death in African American (dotted line) and non-African American participants of SLS I (solid line).

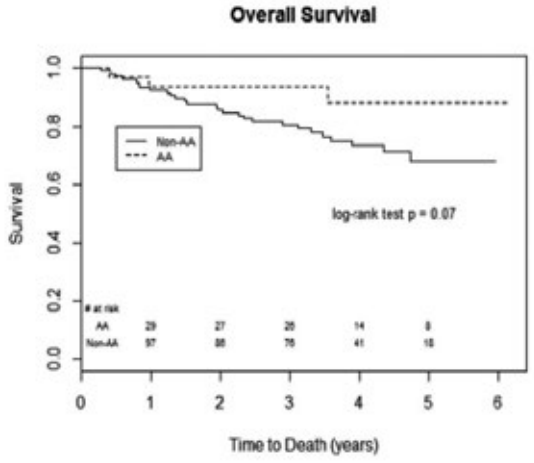

Figure 1b. Time to death in African American participants (dotted line) and non-African American participants of SLS II (solid line).

Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Observational studies have demonstrated that African American (AA) patients with systemic sclerosis (SSc) have a more unfavorable prognosis compared with non-AA. However, no studies have evaluated racial disparities using data from a randomized controlled trial (RCT) where all patients have equal access to care and standard treatment and follow-up during the trial. The objective of this study was to compare efficacy outcomes, as well as long-term morbidity and mortality, in AA and non-AA patients who participated in the Scleroderma Lung Study (SLS) I (Tashkin et al. NEJM 2006) and II (Tashkin et al. Lancet Resp Med 2016).

Methods: SLS I randomized 158 SSc participants (AA: N=26) with interstitial lung disease (ILD) from 13 US SSc centers to 1 year of oral CYC (cyclophosphamide) versus placebo, followed by 1 year off all treatment. SLS II randomized 142 SSc-ILD participants (AA: N=33) from 14 US SSc centers to 1 year of oral CYC, followed by 1 year of placebo, versus 2 years of mycophenolate (MMF). Both studies measured the forced vital capacity (FVC), diffusing capacity for carbon monoxide (DLCO) every 3 months during the study period. Up to 12 (SLS I) and 8 (SLS II) years after randomization, we contacted enrolled patients or designated surrogates to assess the following: mortality, cause of mortality, and development of organ failure. We created joint models to compare progression of ILD based on the course of the FVC and DLCO between AA and non-AA. We compared survival rates using a log-rank test and used Cox proportional hazard modeling to determine the variables associated with survival.

Results: Baseline demographic and disease characteristics of AA and non-AA were similar in SLS I and II, with the exception of age (AA were younger than non-AA [SLS I: 43.1 vs. 49.5 years; SLS II: 49.1 vs. 53.2 years], and extent of ILD (AA had a trend for more extensive quantitative radiographic ILD at baseline). In SLS I, there was no significant difference in the course of the FVC or DLCO over 24 months between AA and non-AA in CYC or placebo arms. In SLS II, AA had an improved course of FVC over 24 months compared with non-AA in the CYC arm (P=0.02); in the MMF arm, there was no difference in the course of the FVC. There was also no difference in the course of the DLCO over 24 months in either CYC or MMF arms. There was no difference in long-term survival (P=0.54; Figure 1a) or time to respiratory failure (P=0.37) between AA and non-AA in SLS I. There was a trend for improved long-term survival P=0.07; Figure 1b) and improved time to respiratory failure (P=0.10) in AA compared with non-AA in SLS II. The Cox models demonstrated AA race did not have any significant impact on long-term survival in SLS I or II participants.

Conclusion: Data from two large RCTs in SSc-ILD demonstrated that AA patients with SSc-ILD have similar morbidity and mortality outcomes compared with non-AA SSc-ILD patients when treated aggressively for SSc-ILD, even after adjusting for age and baseline disease severity. These findings contrast with the racial disparities described in previous observational studies and warrant further investigation.

FC = WHO Functional Class. 6MWT = six-minute walk test. Duration of follow up is from SSc physician diagnosis to last follow up or death. HAQ= Health Assessment Questionnaire. SHAQ = Scleroderma HAQ developed by Steen and Medsger. VAS = visual analog scale. Fischer's exact test was used if observations <5. PRO scores were averaged for each patient if multiple questionnaires were completed over follow up.

SESSION INFORMATION

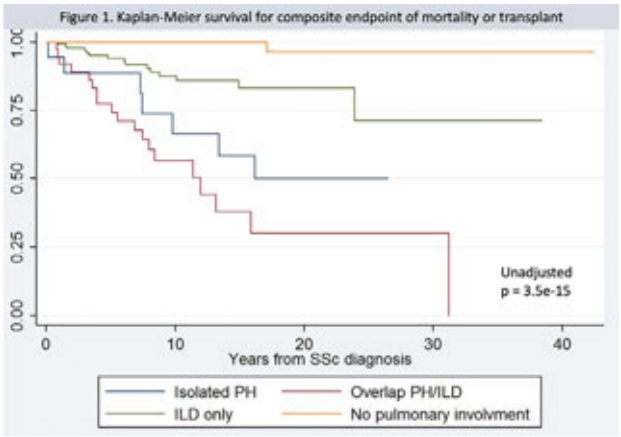
Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical II: Cardiopulmonary Involvement

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Pulmonary disease is a leading cause of mortality in scleroderma (SSc). Previous studies indicate that the coexistence of pulmonary hypertension (PH) and interstitial lung disease (ILD) is associated with worse survival. However, this has not been uniformly confirmed, in part due to lack of refined categorization of ILD extent and PH assessment by invasive testing. In addition, the clinical burden of disease has not been fully explored



in different SSc lung disease subtypes. Therefore, we sought to define outcomes related to type and severity of lung involvement in a well characterized SSc cohort enriched for pulmonary disease.

Methods: A retrospective analysis was conducted on 355 SSc subjects stratified into the following subgroups: isolated ILD, isolated pulmonary arterial hypertension (PAH, WHO Group I), overlap ILD/PH (WHO Group I and/or Group III), or SSc without pulmonary disease. PH was confirmed by right heart catheterization according to standard definition. PH due to left heart disease (Group II) was excluded. ILD was confirmed by chest CT. Biannual assessments of clinical and functional data and patient reported outcomes (PROs) were included. Hospitalization for heart or respiratory failure and mortality were ascertained by medical record review. Continuous variables were compared by Student's *t*-test or Wilcoxon's rank sum test. Categorical variables were compared using chi-square. A composite outcome of mortality or lung transplant was assessed by Kaplan-Meier analysis and adjusted Cox proportional hazard models.

Results: Differences among pulmonary subtypes characteristics are shown in Table 1. A significantly higher proportions of males in ILD/PH, of limited SSc and centromere positivity in PAH, of SCL70 in ILD and ILD/PH were noted. Baseline hemodynamics and PH therapy did not differ significantly between PAH and overlap ILD/PH. Subjects with PH/ILD showed more severe restrictive lung disease at ILD diagnosis compared to ILD only (FVC 1.99±0.71 vs 2.48±0.72, p=0.002) with ILD preceding PH onset more commonly (89.7%). Among pulmonary SSc sybtypes, overlap ILD/PH was significantly associated with worse functional capacity (WHO Functional Class and 6-minute walk distance), greater requirement for supplemental oxygen, greater SSc-related disability, and higher mean dyspnea PRO scores (Table 2). Notably, ILD/PH subjects compared to PAH and ILD also showed significantly increased rates of referral for lung transplant (69% vs 11% vs 13; p=< 0.001) as well as of transplant itself (33.3% vs. 5.6% vs 6.2%; p=< 0.001). This may explain the lack of difference in mortality between PAH and ILD/PH in this cohort. In fact, death or transplant free survival was significantly worse in the PH/ILD group (Figure 1; p = 3.5e-15).

Conclusion: The disease burden of lung involvement in SSc is significant, particularly in subjects with concurrent PH (Group I and III) and ILD. This subset manifests more advanced respiratory symptoms and functional decline compared to PAH and ILD alone. Referral for lung transplantation is confirmed as a life-saving intervention for patients with SSc lung involvement.

Abstract Number: 1832

Reliability of Traditional Cardiovascular Risk Calculators in Predicting Risk of Cardiovascular Disease in Systemic Sclerosis

Yasser Radwan ,[1] Reto Kurmann,[2] Avneek Singh Sandhu,[3] Cynthia Crowson,[4] Eric Matteson,[5] Thomas Osborn,[1] Kenneth Warrington,[2] Rekha Mankad,[1] and Ashima Makol[1], [1]Mayo Clinic Minnesota, rochester, MN, [2]Mayo Clinic Rochester, rochester, MN, [3]kettering health, dayton, OH, [4]Mayo Clinic Rochester, Rochester, [5]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical II: Cardiopulmonary Involvement
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Most cardiovascular (CV) risk calculators including the Framingham risk score (FRS) and American College of Cardiology (ACC) / American Heart Association (AHA) risk score underestimate CV risk in pa-

tients with chronic inflammatory diseases such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and sarcoidosis. It is unclear how these scores perform in estimation of CV risk in patients with SSc.

Methods: Medical records of patients in a geographically well-defined area were reviewed to identify incident cases of SSc (defined by physician diagnosis) from Jan 1, 1980 to Dec 31, 2016. Fulfillment of the 1980 and 2013 SSc classification criteria was ascertained. Cardiovascular disease (CVD) events including coronary artery disease (CAD), congestive heart failure (CHF), cerebrovascular disease (transient ischemic attacks and cerebrovascular accidents), and peripheral arterial disease (PAD) were abstracted. The 10 year general FRS for CVD was calculated and the office-based 10 year FRS, which does not include laboratory values, was used when lipid values were unavailable. The ACC/AHA atherosclerotic CVD (ASCVD) pooled risk score was also calculated using the ACC/AHA risk calculator. Patients were followed until death, migration from Olmsted County or June 30, 2017. Observed follow-up was truncated at 10 years after SSc incidence. For patients with < 10 years of follow-up, the predicted risk for CVD was adjusted proportionately. The standardized incidence ratio (SIR) was estimated as the ratio of the predicted and observed numbers of CVD events.

Results: In order to apply FRS to this cohort of 78 patients with incident SSc, 21 cases were excluded to fit FRS age limits (30-74 years) as were 7 patients with prior CVD; therefore data was available in 44 of 50 cases. The mean FRS was 7.1% (SD 5.2%). Among SSc cases, 2.2 CVD events were predicted and 9 CVD events observed, for a SIR of 4.16 (95% CI 2.16 to 7.99, p< 0.001). Only subjects aged 40 to 79 years were included in the ACC/AHA risk calculator; two patients with prior myocardial infarction or stroke were excluded. Because of missing data on lipids, the ACC/AHA risk score could only be calculated in 22 out of the remaining 42 SSc cases. The mean ACC/AHA risk score was 8.9% (SD 7.8%). The predicted CVD events were 1.2 and 7 CV events were observed, corresponding to an SIR of 5.69 (95% CI 2.71 to 11.94, p< 0.001).

Conclusion: This is the first population-based study using comprehensive individual medical record review to investigate the performance of FRS and ACC/AHA risk score among patients with SSc, of which both are strongly underestimating the risk of CVD events by about 4-fold and 5-fold, respectively. The poor performance of these risk scores in SSc is consistent with their poor performance in other chronic inflammatory conditions such as RA and SLE. While CVD risk calculators are meant to assist the clinician in identifying high risk patients for appropriate preventive strategies, our study suggests that these scoring systems are inadequate and may misclassify high risk patients as low risk, depriving them of preventive CVD interventions. Better CVD risk assessment tools are needed for CVD risk prediction in patients with SSc.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical II: Cardiopulmonary Involvement

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: In the SENSCIS trial in patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD), nintedanib reduced the annual rate of decline in forced vital capacity (FVC) vs placebo (-52.4 vs -93.3 mL/year; difference 41.0 mL/year [95% CI 2.9, 79.0]; p=0.04), with adverse events that were consistent with the profile observed in patients with IPF. In many countries, mycophenolate is commonly used in the treatment of SSc-ILD. We analyzed the efficacy and safety of nintedanib in the SENSCIS trial by use of mycophenolate at baseline.

Methods: Subjects with SSc-ILD with ≥10% fibrosis of the lungs on HRCT were randomized to receive nintedanib 150 mg bid or placebo. Patients who had received stable therapy with mycophenolate for ≥6 months prior to randomization were eligible to participate. We analyzed lung function outcomes and adverse events over 52 weeks in subgroups of patients who were and were not taking mycophenolate at baseline.

Results: In the nintedanib and placebo groups, respectively, 139 (48.3%) and 140 (48.6%) of patients were taking mycophenolate at baseline. In patients taking and not taking mycophenolate at baseline, respectively, mean (SD) FVC

Figure. Annual rate of decline in FVC (mL/yr) over 52 weeks in the SENSCIS trial in subgroups by use of mycophenolate at baseline

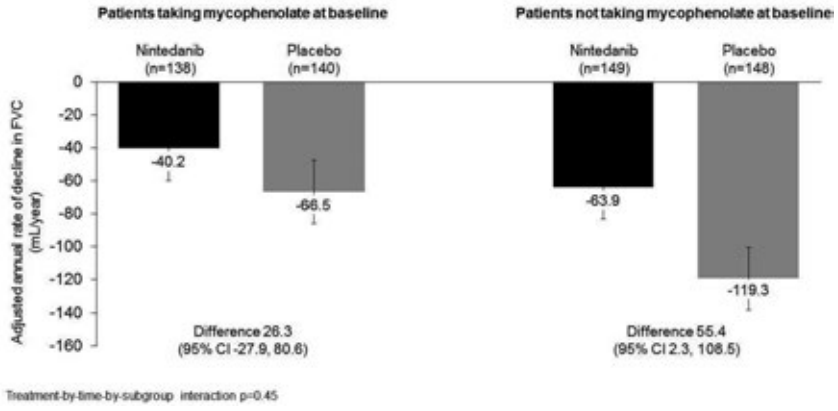

Table. Most frequent adverse events in the SENSCIS trial in subgroups by use of mycophenolate at baseline

	Patients taking mycophenolate at baseline		Patients not taking mycophenolate at baseline	
Adverse event	Nintedanib (n=139)	Placebo (n=140)	Nintedanib (n=149)	Placebo (n=148)
Most frequent adverse events*				
Diarrhea	106 (76.3)	48 (34.3)	112 (75.2)	43 (29.1)
Nausea	43 (30.9)	23 (16.4)	48 (32.2)	16 (10.8)
Skin ulcer	22 (15.8)	23 (16.4)	31 (20.8)	27 (18.2)
Vomiting	32 (23.0)	17 (12.1)	39 (26.2)	13 (8.8)
Cough	20 (14.4)	33 (23.6)	14 (9.4)	19 (12.8)
Nasopharyngitis	10 (7.2)	22 (15.7)	26 (17.4)	27 (18.2)
Upper respiratory tract infection	19 (13.7)	25 (17.9)	14 (9.4)	10 (6.8)
Abdominal pain	14 (10.1)	6 (4.3)	19 (12.8)	15 (10.1)
Fatigue	19 (13.7)	14 (10.0)	12 (8.1)	6 (4.1)
Headache	16 (11.5)	15 (10.7)	11 (7.4)	9 (6.1)
Urinary tract infection	16 (11.5)	11 (7.9)	8 (5.4)	12 (8.1)
Weight decreased	10 (7.2)	4 (2.9)	24 (16.1)	8 (5.4)
Decreased appetite	14 (10.1)	10 (7.1)	13 (8.7)	2 (1.4)
Adverse events leading to treatment discontinuation	15 (10.8)	9 (6.4)	31 (20.8)	16 (10.8)

Adverse events reported over 52 weeks (or until 28 days after last trial drug intake for patients who discontinued trial drug before week 52). Data are n (%) of patients with ≥1 such adverse event. Adverse events were coded according to preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA). *Adverse events reported in >10% of patients in any of the subgroups shown.

(mL) was 2539 (770) and 2463 (784) and FVC % predicted was 70.8 (16.0) and 74.2 (17.1). In patients who received placebo, the mean (SE) rate of decline in FVC over 52 weeks was -66.5 (19.3) mL/year in patients taking mycophenolate at baseline and -119.3 (19.0) mL/year in patients not taking mycophenolate at baseline. Nintedanib reduced the rate of FVC decline both in patients who were and were not taking mycophenolate at baseline. The treatment effect of nintedanib was numerically greater in patients who were not taking mycophenolate at baseline, but statistical testing did not indicate heterogeneity in the treatment effect between subgroups (p=0.45) (Figure). In post-hoc analyses, in the nintedanib and placebo groups, respectively, absolute declines in FVC >5% predicted were seen in 15.2% and 25.7% of patients taking mycophenolate at baseline (OR 0.52 [95% CI 0.29, 0.95]) and 25.5% and 31.1% of those not taking mycophenolate at baseline (OR 0.76 [0.46, 1.26]). The adverse event profile of nintedanib was similar irrespective of mycophenolate use at baseline (Table). The proportion of patients treated with nintedanib who had adverse events leading to discontinuation of trial drug was no higher in patients taking mycophenolate at baseline than in those who were not (Table).

Conclusion: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in FVC both in patients who had not taken mycophenolate and in patients who had taken a stable dose of mycophenolate for ≥6 months prior to randomization. The treatment effect of nintedanib was numerically greater in patients who were not taking mycophenolate at baseline. Careful interpretation of the data in the subgroups by use of mycophenolate is warranted as patients were not randomized by use of mycophenolate and the patients using mycophenolate at baseline had tolerated it for ≥6 months prior to entering the trial. The adverse event profile of nintedanib was similar irrespective of mycophenolate use.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical II: Cardiopulmonary Involvement

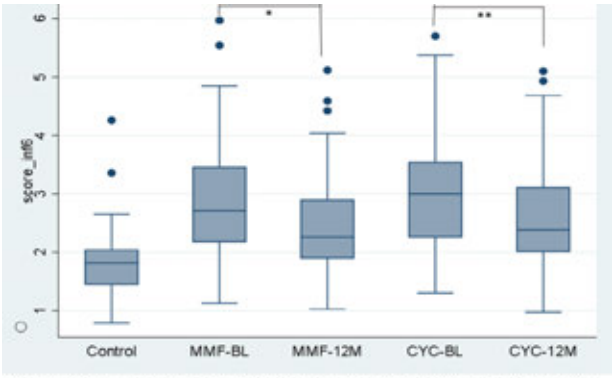
Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Response to immunosuppression is highly variable in systemic sclerosis (SSc) related interstitial lung disease (ILD), and there are no widely accepted clinical or biological parameters that predict response to treatment. The interferon (IFN) signature is the most prominent gene expression profile in the peripheral blood cells of SSc patients. We have previously identified 6 serum chemokines that highly correlate with the IFN transcript profile. Herein, we determined whether a composite serum IFN chemokine score has predictive significance for response to immunosuppression in SSc-ILD.

Methods: In the Scleroderma Lung Study (SLS) II (Tashkin et al. Lancet Resp Med. 2016), 142 SSc-ILD patients were randomized to receive either mycophenolate mofetil (MMF) for 2 years or oral cyclophosphamide (CYC) for 1 year followed by 1 year of placebo. The % predicted forced vital capacity (FVC%) was the primary clinical outcome and was measured every 3 months. Baseline serum samples were available in 135 participants. Serum from 45 unaffected controls matched for age, gender, and race in a 1 to 3 ratio to SLS II participants was also investigated. The serum levels of 6 IFN inducible chemokines (IP-10, MIG, MCP-2, B2M, MIP-3 beta, TNFR2) were measured using multiplex assays in a CLIA certified laboratory. A serum IFN composite score was calculated based on the levels of these six chemokines using a previously described method (Bauer et al. Arthritis Rheum. 2009). Similar to the primary outcome analysis in SLS II, a joint model of longitudinal measurements (serially obtained FVC%) and non-ignorable missing data was conducted in order to investigate the predictive significance of the baseline IFN chemokine score for response to treatment.

Results: In this study, 78 (57.8%) participants had diffuse cutaneous disease with a mean baseline FVC% of 66.3%. As shown in Figure 1, the IFN chemokine score was significantly higher in SSc-ILD (fold change= 1.62, $p< 0.001$) than in controls and decreased significantly in both treatment arms from baseline to 12-months. There was no significant correlation between baseline IFN chemokine score and baseline FVC% (p=0.197). As shown in Table 1, higher baseline IFN chemokine score predicted better response based on higher serial FVC% 3 to 12 months after initiation of treatment in CYC (b=0.91, p=0.009), and MMF (b=0.41, p=0.001) arms, after adjustment for baseline FVC%. In contrast, higher baseline CRP predicted progression of ILD based on significantly lower FVC% after treatment start in the CYC arm (b=-0.56, $p< 0.001$) and showed a similar trend for lower FVC% 3 to 12 months in the MMF arm (b=-0.15, p=0.091).



IFN chemokine score in controls, MMF patients at baseline (MMF-BL) and 12 months (MMF-12m), and CYC patients at baseline (CYC-BL) and 12 months (CYC-12M).
* P <0.05 in paired analysis
** p<0.001 in paired analysis

Figure 1. Boxplot of Interferon Chemokine Scores by Treatment

Table 1. Predictive Significance of IFN Chemokine Score for Subsequent Serial FVC%s

CYC Arm				
	Effect size	**2.5%**	**97.5%**	**P-value**
Predictive significance of baseline IFN chemokine score for serial FVC%s 3-12 months				
Baseline IFN sore	**0.91**	**0.56**	**1.13**	**0.009**
Baseline FVC%	0.87	0.84	0.9	<0.001
Predictive significance of 12-month IFN chemokine score for serial FVC%s 15-24 months				
12-month IFN score	**-0.61**	**-1.5**	**0.11**	**0.068**
12-month FVC%	1	0.96	1.08	<0.001
MMF Arm				
Predictive significance of baseline IFN chemokine score for serial FVC%s 3-12 months				
Baseline IFN score	**0.41**	**0.23**	**0.59**	**0.001**
Baseline FVC%	0.84	0.82	0.86	<0.001
Predictive significance of 12-month IFN chemokine score for serial FVC%s 15-24 months				
12-month IFN score	**0.28**	**0.11**	**0.69**	**0.029**
12-month FVC%	0.96	0.9	0.98	<0.001

Consistent with the different treatment approaches during the second year of SLS II, higher IFN chemokine score at 12 month showed a trend for predicting lower serial FVC% 15-24 months during the placebo treatment period of the CYC arm (b=-0.61, p=0.068) while it continued predicting better response to immunosuppression in the MMF arm (b=0.28, p=0.029).

Conclusion: Higher serum IFN chemokine score in SSc-ILD predicts better response to immunosuppression with MMF and CYC and could be potentially used for identify patients who may derive the most benefit from these two treatments.

Frequency and Predictors of Meaningful Decline in Forced Vital Capacity During Follow up of a Large Cohort of Systemic Sclerosis Associated Pulmonary Fibrosis Patients

Svetlana Nihtyanova ,[1] Emma Derrett-Smith,[1] Carmen Fonseca,[1] Voon Ong,[2] and Christopher Denton[3], [1]UCL Medical School, Royal Free Campus, London, United Kingdom, [2]UCL Medical School, Royal Free Campus, London, [3]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, UK, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical II: Cardiopulmonary Involvement
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Pulmonary fibrosis (PF) is common in systemic sclerosis (SSc) and serial pulmonary function tests (PFTs) are used for routine PF monitoring. Forced vital capacity (FVC) decline reflects progression in PF and FVC is frequently used as an endpoint in clinical trials assessing the effect of drugs on PF. We explore the changes in FVC over time in a cohort of patients with SSc-related PF receiving standard management, including immunosuppression.

Methods: Only SSc patients with CT-confirmed PF were included. FVC changes over the first 10 years from disease onset and the effects of age, sex, cutaneous subset and autoantibodies were assessed using linear mixed effect models. We analysed time to development of threshold FVC levels (FVC< 70% and FVC< 50%) on a time scale starting at first available FVC, if this was within the first 5 years of disease, using Kaplan-Meier estimates and Cox regression.

Results: From a single centre cohort of 1068 SSc patients with at least one PFT result available, we identified 505 (47.3%) who had PF. Of those 109 (21.6%) were male, average age of onset was 47 years and 249 (49.3%) had diffuse cutaneous subset (dcSSc). The most common autoantibody was anti-topoisomerase I (ATA) in 204 (40.4%) of the subjects, followed by anti-RNA polymerase in 59 (11.7%), anti-PmScl in 26 (5.2%), anti-centromere in 36 (7.1%) and anti-U3RNP in 15 (3.0%). In 83 (16.4%) of the patients ANA was positive, but no ENAs were identified (ANA+ENA-). FVC measurements on at least three occasions were available for 364 (72.1%) of the patients. Mean period between PFTs was 13 months.

Average FVC at 12 months from onset was 80.1% (SD 19.3). For most patients, FVC fluctuated over time, although there was a small but statistically significant absolute decline of approximately 0.32% per year (95%CI 0.09, 0.55; p=0.007) at a group level. There was no evidence for a significant correlation between baseline FVC

Table 3. Multivariable Cox regression analysis for predictors of time to development of FVC<70% and FVC<50% in systemic sclerosis patients with pulmonary fibrosis confirmed on CT.

	HR	95% CI		p-value
FVC<70% prediction				
Baseline FVC	0.84	0.79	0.89	<0.001
Male	1.92	1.16	3.16	0.011
Anti-topoisomerase antibody	1.68	1.05	2.69	0.030
Baseline FVC*Time (years)	1.02	1.01	1.03	<0.001
FVC<50% prediction				
Baseline FVC	0.91	0.89	0.94	<0.001

and subsequent change (correlation coefficient -0.13, 95%CI -0.26, 0.01). Multivariable analysis demonstrated significant associations between FVC and age at onset, sex, cutaneous subset and antibodies (Table 1).

In a multivariable model for change in FVC (difference between FVC measured in consecutive PFTs), only antibodies predicted future change with greatest drop observed in ANA+ENA- patients, followed by ARA+ and ATA+ ones (Table 2).

The proportion of PF subjects to develop FVC< 70%, if they had FVC≥70% at first available test, was 7.7% at 1 year, 13.6% at 2 years, 17.2% at 3 years, 18.7% at 4 years and 19.8% at 5 years from first FVC assessment. For FVC< 50% this was 2.1% at 1 year, 4.4% at 2 years, 5.8% at 3 years, 7.6% at 4 years and 10.5% at 5 years. In a multivariable model, factors that associated with increased risk for FVC drop below 70% were male sex, ATA positivity and low baseline FVC, while the only predictor of drop in FVC to 50% or lower was low baseline FVC (Table 3).

Conclusion: This study provides insight into long-term patterns of FVC change and develops a model that may help predict those most at risk of significant decline. We show that ATA positivity, male gender and diffuse subset are associated with greater long-term decline in FVC, while short-term change associated only with antibodies.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: Large Vessel Vasculitis Treatment

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: GiACTA, a randomized, double-blind, placebo (PBO)–controlled study, demonstrated the efficacy and safety of tocilizumab (TCZ) in patients with giant cell arteritis (GCA).[1] Growing evidence has shown that TCZ is also effective for the treatment of polymyalgia rheumatica (PMR); however, data on this are limited.[2,3] The purpose of this study was to evaluate the efficacy of TCZ in patients with GCA presenting with cranial symptoms only or PMR symptoms only in GiACTA.

Table 1. Patient Characteristics and Treatment at Study Baseline

	PMR Symptoms Only at Diagnosis (n = 52)	Cranial Symptoms Only at Diagnosis (n = 94)
Age, mean (SD), y	64.5 (8.3)	70.8 (7.8)
Female, n (%)	39 (75.0)	64 (68.1)
White, n (%)	51 (98.1)	91 (96.8)
Weight, mean (SD), kg	70.06 (14.09)	71.78 (16.10)
Body mass index, mean (SD), kg/m^2	24.81 (3.95)	26.36 (5.44)
GCA diagnosis, n (%)		
Newly diagnosed	27 (51.9)	41 (43.6)
Relapsing	25 (48.1)	53 (56.4)
Disease duration, mean (SD), days	327.04 (600.89)	239.05 (404.94)
ESR, mean (SD), mm/h	24.98 (20.21)	24.56 (19.92)
CRP, mean (SD), mg/L	6.51 (9.44)	7.73 (12.70)
Diagnosis, n (%)*

Annual flare rate, mean (SD)‡	0.64 (0.85)	0.95 (1.24)	0.40 (0.93)	0.93 (1.81)
Patients with flare following remission, n (%)	11 (35.5)	11 (52.4)	11 (19.0)	16 (44.4)
Cumulative prednisone dose, median, mg	1862.0	3671.5	1842.0	2965.5
Patients with ≥ 1 AE, n (%)§	30 (96.8)	20 (95.2)	55 (94.8)	36 (100)
Patients with ≥ 1 SAE, n (%)§	5 (16.1)	3 (14.3)	10 (17.2)	12 (33.3)

AE, adverse event; GCA, giant cell arteritis; PMR, polymyalgia rheumatica; SAE, serious adverse event; TCZ, tocilizumab.
* TCZ 162 mg weekly or every other week with a 26-week prednisone taper.
† Placebo with a 26-week or 52-week prednisone taper.
‡ Annualized flare rate is calculated as the number of flares between the first clinical assessment of GCA and the final clinical assessment prior to entry into Part 2, divided by the time period between the 2 days, multiplied by 365.25.
§ Multiple occurrences of AEs are included. Denominators are all AEs or SAEs.

Methods: GiACTA randomized 251 GCA patients to receive weekly or every other week TCZ plus a 26-week prednisone taper (TCZ + prednisone) or PBO plus a 26- or 52-week prednisone taper (PBO + prednisone).[1] In this post hoc analysis, baseline characteristics, sustained remission rate, number of flares, annual flare rate, time to flare, cumulative prednisone dose and safety were assessed in patients with PMR symptoms only and patients with cranial symptoms only at diagnosis. Disease flare was defined as the recurrence of signs or symptoms of GCA (including PMR) or an elevation in erythrocyte sedimentation rate attributable to GCA.

Results: Of 146 patients included in the analysis, 52 had PMR symptoms only and 94 had cranial symptoms only at diagnosis. Demographics and other patient characteristics are shown in **Table 1**. The hazard ratios for flare in patients receiving TCZ vs PBO were 0.77 (99% CI, 0.26-2.32) for patients with PMR symptoms only and 0.37 (99% CI, 0.13-1.01) for patients with cranial symptoms only. Of patients with PMR symptoms only, 18 flares occurred in 13/31 patients (41.9%) in the TCZ group and 20 flares occurred in 12/21 patients (57.1%) in the PBO group. Of patients with cranial symptoms only, 19 flares occurred in 12/58 patients (20.7%) in the TCZ group and 25 flares occurred in 17/36 patients (47.2%) in the PBO group (**Table 2**). For both the PMR and cranial symptoms only groups, annual flare rates were lower in patients receiving TCZ compared with those receiving PBO. The occurrence of adverse events and serious adverse events was similar between groups (**Table 2**).

Conclusion: TCZ improved clinical outcomes in patients who presented with PMR symptoms only or cranial symptoms only at diagnosis as indicated by a reduced incidence of flares. These findings suggest that TCZ is effective in patients with GCA with PMR or cranial symptoms.

Ustekinumab for the Treatment of Giant Cell Arteritis

Mark Matza ,[1] John Stone,[1] Ana Fernandes,[1] and Sebastian Unizony[1], [1]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: Large Vessel Vasculitis Treatment
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Disease flare despite high cumulative glucocorticoid exposure is one of the hallmarks of giant cell arteritis (GCA). Tocilizumab is effective in controlling disease activity in most patients, but up to 35% of them fail this treatment due to inefficacy or side-effects. Thus, additional remission maintenance and glucocorticoid-sparing options are greatly needed in GCA. Interleukins (IL)-12 and 23 are thought to play a pathogenic role in this disease. Therefore, we evaluated the efficacy of the IL-12/23 antagonist ustekinumab (UST) in GCA patients.

Methods: We conducted a prospective, single center, open-label pilot study (ClinicalTrials.gov NCT02955147) to evaluate the efficacy and safety of UST in combination with prednisone for new onset and relapsing GCA patients with active disease. GCA diagnosis required positive temporal artery biopsy or vascular imaging. Active disease for study enrollment was defined as the presence of cranial or PMR signs/symptoms along with elevation of ESR (≥40 mm/hour) or CRP (≥10 mg/L) within 6 weeks of baseline. UST 90 mg was administered subcutaneously at baseline and weeks 4, 12, 20, 28, 36 and 44. All patients received a pre-specified 6-month prednisone taper starting at 60 mg, 40 mg, or 20 mg based on investigators' clinical judgment. The primary endpoint, prednisone-free remission, was defined as the absence of disease flare from induction of remission up to week 52 and the concurrent normalization of ESR (< 40 mm/hour) and CRP (< 10 mg/L), while adhering to the protocol prednisone taper. Disease flare was defined as the recurrence of signs/symptoms of GCA (e.g., cranial or PMR) that required treatment modification, regardless of ESR and CRP levels. A sensitivity analysis eliminating ESR and CRP from the definition of prednisone-free remission was also completed.

Results: A sample of 20 consecutive patients was planned for the study. However, the study was prematurely terminated due to inefficacy. Here we report the outcomes of the first 11 patients that completed 52 weeks of treatment. Baseline patient characteristics are shown in **Table 1**. The mean age of the patients was 71 years, 82% were females, 27% had new-onset disease, and 91% had a positive temporal artery biopsy. The initial prednisone dose was 60 mg in 2 patients, 40 mg in 8 patients and 20 mg in 1 patient. Results are shown in **Table 2**. All patients achieved disease remission within 4 weeks of baseline. Only 2 patients (18%) achieved the primary

Table 1. Patient Baseline Characteristics

	GCA patients (n = 11)
Age, years: mean (SD)	71 (7)
Female sex	9 (82)
Caucasian ethnicity	11 (100)
New onset disease	3 (27)
Biopsy-proven disease	10 (91)
Imaging-proven disease	3 (27)
Cranial signs or symptoms	11 (100)
PMR symptoms	8 (73)
ESR, mm/hour: mean (SD)	43 (14)
CRP, mg/L: mean (SD)	44 (29)

Values represent number and (%) unless otherwise specified

ESR, erythrocyte sedimentation rate; CRP, C-reactive protein
UST, ustekinumab

outcome. Of the 9 patients (82%) who failed to achieve the primary outcome, 7 patients had a flare after a mean period of 23 weeks and 3-6 UST injections. The mean (SD) prednisone dose at the time of flare was 3 (3) mg/day. The other 2 patients who failed to achieve the primary outcome did not have a disease flare, but their inflammatory markers were elevated at week 52. Four patients (36%) met the alternative definition of prednisone-free remission at week 52 (sensitivity analysis). UST was well tolerated. Only 1 patient developed pneumonia, which resolved with oral antibiotics.

Conclusion: UST in combination with 6 months of prednisone was not associated with clinically significant rates of sustained disease remission in this cohort of GCA patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: Large Vessel Vasculitis Treatment

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Tocilizumab (TCZ) administered subcutaneously every week (QW) or every other week (Q2W) with 26-week prednisone tapering was superior to placebo (PBO) plus 26-week (PBO+26) or 52-week (PBO+52) prednisone tapering for achievement of sustained glucocorticoid-free remission in patients with giant cell arteritis (GCA) in part 1 of the 52-week, double-blind GiACTA trial.[1] In part 1, among patients with new-onset GCA at baseline, TCZ QW and TCZ Q2W treatment reduced the risk for GCA flare compared with PBO+26, whereas among patients with relapsing GCA, TCZ QW but not TCZ Q2W treatment reduced the risk for flare compared with both PBO groups, and there was separation in the time to flare between the TCZ QW and Q2W groups. The objective of the current analysis was to report time to first flare over 3 years of the GiACTA trial (part 1 plus 2-year open-label part 2) among patients with new-onset or relapsing GCA.

Methods: At the end of part 1, patients entered open-label part 2, in which GCA therapy (including initiation/termination of open-label TCZ and/or glucocorticoids) was given at the investigator's discretion according to disease status. Time to first GCA disease flare during the 3-year study period was assessed using Kaplan-Meier analysis for patients in the intent-to-treat population according to disease onset status at baseline (new-onset or relapsing) based on their originally assigned treatment groups: TCZ QW, TCZ Q2W, or pooled PBO (PBO+26 and PBO+52).

Table. Time to First Flare in Patients With New-Onset or Relapsing GCA

	TCZ QW		TCZ Q2W		Pooled PBO

Treatment groups refer to originally assigned treatment in part 1. Patients who were never in remission were censored at day 1 and patients who withdrew were censored from the time of withdrawal.

Results: Among patients randomly assigned in part 1, 47 of 100 (47%) in the TCZ QW group, 26 of 49 (53%) in the TCZ Q2W group, and 46 of 101 (46%) in the pooled PBO group had new-onset GCA at baseline; the rest had relapsing GCA. Median time to first flare over 3 years was longer for patients assigned to TCZ treatment in part 1 than for those assigned to PBO. Among patients assigned to TCZ, it was longer with QW than Q2W dosing for both the new-onset and the relapsing subgroups (Table 1). Higher proportions of patients in the TCZ QW group (new-onset, 49%; relapsing, 47%) than the pooled PBO group (new-onset, 28%; relapsing, 31%) and the TCZ Q2W group (new-onset, 27%; relapsing, 35%) remained flare-free during the entire 3-year study. Kaplan-Meier analysis showed a clear separation

between the TCZ QW and pooled PBO groups over 3 years for patients with new-onset and relapsing GCA (Figure 1). Separation between the TCZ QW and TCZ Q2W groups was also observed over 3 years in patients with new-onset and relapsing GCA, although this was more evident in patients with new-onset GCA during year 3 (Figure 2).

Conclusion: In this 3-year analysis of GiACTA parts 1 and 2, time to first flare favored TCZ QW over TCZ Q2W in patients with new-onset and relapsing GCA. TCZ QW delayed time to first flare compared with PBO in patients with new-onset and relapsing GCA, supporting TCZ QW dosing in patients with GCA regardless of disease onset.

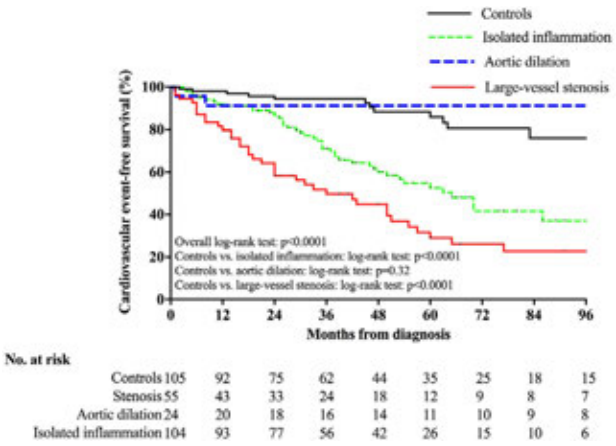
Different Patterns and Specific Outcomes of Large-Vessel Involvements in Giant Cell Arteritis

Hubert de Boysson ,[1] Eric Liozon,[2] Olivier Espitia,[3] Aurélie Daumas,[4] Mathieu Vautier,[5] Marc Lambert,[6] Jean-Jacques Parienti,[7] Alain Manrique,[7] David Saadoun,[8] Kim Heang Ly,[2] Christian Agard,[9] and Achille Aouba[10], [1]University Hospital of Caen, Caen, France, [2]Limoges University Hospital, Limoges, France, [3]Nantes University Hospital, Nantes, France, [4]Marseille AP-HM, Marseille, France, [5]Paris - Pitié salpétrière, Paris, France, [6]Lille University Hospital, Lille, France, [7]Caen University Hospital, Caen, France, [8]AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Internal Medicine and Clinical Immunology, F-75013, Paris, France, Paris, France, [9]CHU Nantes, Nantes, France, [10]CHU Caen, Caen, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: Large Vessel Vasculitis Treatment
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Large-vessel involvements (LVI) in giant-cell arteritis (GCA) include different clinical and imaging patterns that are often pooled together in the published cohorts under the generic term “large-vessel vasculitis”. The analysis of the different imaging patterns in GCA patients with LVI and their relationships with patients’ cardiovascular prognosis have been poorly investigated.

Methods: We conducted a nationwide retrospective study and included GCA patients with LVI demonstrated on imaging at diagnosis between 2007 and 2017. We analyzed the prognosis of three different imaging patterns of LVI



Kaplan-Meier curves of cardiovascular event-free survival in patients with three patterns of giant cell arteritis-related large-vessel involvement on imaging at diagnosis and in control patients without large-vessel involvement on imaging at diagnosis.

present at diagnosis, with some of them overlapping but with the first one present in all patients: 1) inflammation of the aorta and/or its branches; 2) dilation of the aorta; and 3) stenosis of the aortic branches. A control group of GCA patients without LVI was constituted.

A Cox proportional hazards model was used to assess predictive factors associated with new cardiovascular complications, ischemic events and aortic dilation. Hazard ratios (HRs) and 95% confidence intervals (CI) were computed for each predictor in the univariate analysis and in the multivariate model using the backward stepwise approach using variables that reached $p < 0.1$ in univariate analyses. We analyzed the cardiovascular event-free survival in patients with each different pattern of LVI and in controls, using life tables and the Kaplan-Meier method, and these were compared using the log-rank test.

Results: We included 183 patients with LVI and 105 controls without LVI. Altogether, among the 183 patients who all showed inflammation of the aorta and/or its main branches, concomitant aortic dilation and large-vessel stenosis were observed in 27 (15%) and 55 (30%) patients, respectively. During the follow-up period, new cardiovascular events occurred in 49% and 11% of LVI patients and controls, respectively ($p < 0.0001$). Inflammation of the aorta and/or its branches (HR: 3.42 [2.09-5.83], $p < 0.0001$) and large-artery stenosis (HR: 2.75 [1.80-4.15], $p < 0.0001$) were independent predictive factors of new cardiovascular events. Conversely, the use of an immunosuppressant besides corticosteroids was a protective factor against new cardiovascular events (HR: 0.44 [0.29-0.66], $p < 0.0001$) and the development of aortic dilation (HR: 0.43 [0.23-0.77], $p = 0.005$).). The cardiovascular event-free survival in the three patterns and in controls is shown in the Figure. Patients with large-vessel stenosis showed the worst outcomes (log-rank test: $p< 0.0001$).

Conclusion: This study highlights that large-vessel involvement in GCA includes different clinical and imaging patterns that might influence cardiovascular outcomes. The involvement of the aorta and its branches at diagnosis may increase the risk of aortic dilation and dissection, whereas stenotic involvement of large vessels may favor the occurrence of ischemic events. In this study, the use of immunosuppressants in patients with LVI showed a protective impact on the occurrence of new cardiovascular events. A validation of this finding in other studies is required.

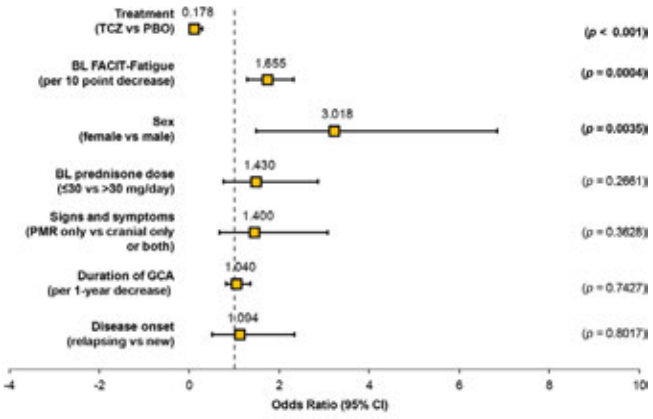
Statistical significance was assessed by $\chi 2$ tests (A) or 2-sample *t* tests (B). Significant *p* values are indicated by the asterisk, and corresponding values are shown in bold.

*EQ-5D scores: PBO group responders, 0.8 (0.2); PBO group treatment failures, 0.7 (0.2); TCZ group responders, 0.8 (0.2); TCZ group treatment failures, 0.7 (0.2).

Figure 2. Multivariate analysis of treatment failure



Odds ratio >1 indicates the first group has higher odds of treatment failure than its comparator based on a multiple logistic regression model including all variables selected in univariate analysis plus all possible treatment by BL covariate interactions. Significant *p* values are shown in bold.

Background/Purpose: Risk factors for treatment failure in patients with giant cell arteritis (GCA) are poorly understood. The objective of this analysis was to identify predictors of treatment failure in GCA patients receiving tocilizumab (TCZ) or placebo (PBO) in combination with prednisone in a randomized controlled trial (GiACTA).[1]

Methods: Two hundred fifty GCA patients received weekly or every-other-week TCZ plus a 26-week prednisone taper (TCZ+pred) or PBO plus a 26- or 52-week prednisone taper (PBO+pred). Patients who achieved and maintained clinical remission (CR) from week 12 to week 52 while adhering to the protocol prednisone taper were classified as responders. CR, adjudicated by investigators, was defined as the absence of disease flare (GCA signs or symptoms, and/or ESR elevation attributable to GCA that required further treatment [eg, rescue prednisone]) regardless of C-reactive protein (CRP) level. Treatment failure was defined as failure to achieve CR by week 12 or occurrence of flare between weeks 12 and 52. Both TCZ groups and both PBO groups were combined for this analysis. Potential predictors investigated included baseline demographics, disease- and treatment-related factors, and health-related quality of life (HRQOL) measures. Univariate and multivariate analyses were performed.

Results: Overall, 45% (113/250) of patients were responders: 27% (27/101) in the PBO+pred groups and 58% (86/149) in the TCZ+pred groups. In contrast, 44% (111/250) of patients experienced treatment failure: 66% (67/101) in the PBO+pred group and 30% (44/149) in the TCZ+pred group. The other 10% (26/250) of patients were nonresponders for reasons other than treatment failure: 7 in the PBO+pred group and 19 in the TCZ+pred group. In univariate analysis, female sex and lower baseline SF-36 Physical Component Summary (PCS), Mental Component Summary, and FACIT-Fatigue scores were associated with treatment failure among PBO+pred–treated patients, whereas higher patient global assessment of disease activity scores and lower SF-36 PCS, FACIT-Fatigue, and EQ-5D scores were associated with treatment failure among TCZ+pred–treated patients (Figure 1). Among TCZ+pred–treated patients, no treatment response difference according to sex was observed. Age, previous relapse, starting prednisone dose, and GCA clinical features (cranial or polymyalgia rheumatica symptoms) were not associated with treatment failure in either group based on univariate analysis. Multivariate logistic regression demonstrated that PBO+pred treatment, female sex, and worse FACIT-Fatigue scores at baseline increased the risk for treatment failure (Figure 2).

Conclusion: Female GCA patients responded particularly poorly if treated with prednisone alone according to univariate analysis. Female sex, impaired HRQOL at baseline, and treatment with prednisone alone are risk factors for treatment failure in GCA. These factors may be considered when determining which treatment would be best for a particular patient.

SESSION INFORMATION

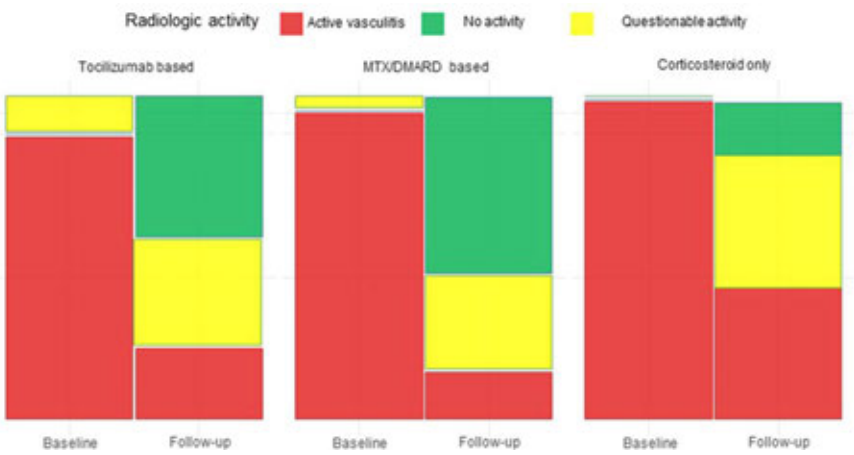
Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: Large Vessel Vasculitis Treatment

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: ^{18}F-FDG-PET/CT is a sensitive and comprehensive technique to diagnose giant cell arteritis (GCA). This technique may be also very useful to test whether vascular inflammation in GCA has disappeared or not, judging effectiveness of anti-inflammatory treatment. However, the role of ^{18}F-FDG-PET/CT in monitoring disease activity and judging disease remission is less well-established to date.



RIGA is an observational 2-center study that addresses the resolution of vascular inflammation in patients with new-onset GCA that are treated with either glucocorticoid monotherapy (GLC), GLC/methotrexate (MTX) or GLC/tocilizumab (TOC).

Methods: Patients with newly diagnosed GCA with large vessel involvement were clinically documented, subjected to sequential ^{18}F-FDG-PET/CT scanning and received treatment with GLC, MTX or TOC upon physicians' decision. Images were graded as active, questionable active and inactive according to nuclear medicine physician opinion and additionally graded by PETVAS score proposed by Grayson et al. (0-27) (1). We performed a mixed effects linear regression analysis to estimate the change in the PETVAS score adjusted by baseline CRP level and tested for treatment group interactions. We compared the proportion of radiologic activity states according to the activity tracer uptake in the follow up ^{18}F-FDG-PET/CT scan in three treatment groups with a chi-squared test.

Results: We included 48 patients (n=20 from Germany, n=28 from Italy) with a mean age of 66 years. At baseline, ^{18}F-FDG-PET/CT scan was graded as active in 46 patients while it was graded as questionable active in the remaining 2 patients. The mean CRP level was 66,8 mg/L (min 1,2; max 233,2 mg/l) and the mean PETVAS score was 21,1 (min=10 max=27). 12 patients received GLC, 27 MTX and 9 TOC as primary treatment. Follow-up PET/CT scans were graded as active in 11, questionable active in 16 and inactive in 21 patients. The mean CRP level at follow up was 12,4 mg/l (min 0,2; max 76,0) and the mean PETVAS score was 9,1 (min 0, max 27) with significant decreases in all 3 groups. The mean adjusted improvement in the PETVAS score (95%CI) was 13.0 (8.7 – 17.3) in GLC, 11.7 (8.9 – 14.6) in MTX and 11.8 (6.8 – 16.7) in TOC groups and interaction terms for treatment effect were not significant. However, only 17% of patients who received GLC showed no vasculitis activity in their follow up PET-CT compared to 53% of patients who received MTX or TOC (figure 1).

Conclusion: GLC, MTX and TOC significantly reduced vascular inflammation in GCA, but no significant differences between the three treatment strategies was found in this yet small population. However, when looking at complete resolution of vascular inflammation, MTX and TOC appear as being superior to GLC monotherapy, suggesting that addition of these agents right from the beginning of treatment of GCA may be beneficial to achieve complete control of vascular inflammation.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain, Anxiety, & Depression
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Relatives' and patients' adjustment to a chronic disease is complex, and there is room for improvement in the support provided to the dyad. So far, few studies have studied the impact of the characteristics of the caregiver and of the relationship within the couple simultaneously. Moreover, studies focused on rheumatoid arthritis (RA), not on spondyloarthritis (SpA), and were realized before biologics.

We aimed to analyze the impact of patient's caregiver and patient-caregiver relationship on functional impairment, mental health and self-efficacy of the patient with RA or SpA.

Methods: Study design: observational cross-sectional study.

Inclusion criteria: age ≥18 years old; diagnosis of RA or SpA; spouse consent. Exclusion criteria: major comorbidity. Participants were recruited by rheumatologists during their consultations in seven rheumatology departments and by a patient association.

Outcome criteria: functional impairment and mental health measured by the SF12 (Physical and Mental Component Summary scores) and self-efficay by the General Self-Efficacy Scale.

Potential determinants: Caregiver-patient relationship was assessed by the personal assessment of intimacy in relationships (PAIR) questionnaire (scores: communication, engagement, shared friends) and the Dyadic Adjustment Scale (DAS)(scores: degree of agreement, quality of the interactions), social support by the Social Support Questionnaire SQ6, burden by the Zarit questionnaire and comorbidities by the groll index.

Results: A total of 88 patient–relative dyads were included. Patients were mostly female (N=68, 77%), mean age 59 (SD 12.6) years old, 69% had RA, mean disease duration 16 (range 1-63) years, mean age of caregivers 60 (SD 13,5) years old, 35 (45%) were still in work.

	Patients Physical Component Summary Score (SF12)		Patients Mental Component Summary scores (SF12)		Patients General Self-Efficacy Scale [10,40]	
	Beta	P	Beta	P	Beta	P
Patients data						
Sex (women vs men)			-5,60	0,01		
IA (rheumatoid arthritis vs spondyloarthritis)	5,90	0,02	6,80	0,0002		
Comorbidities	-2,50	0,001			-0,8	0,04
Communication (PAIR)			0,50	0,04	0,4	0,04
Relatives data						
Social support (Satisfaction)			0,20	0,03		
Burden (ZARIT)					-0,2	0,003

In bivariate analyses, relatives' burden (and patients type of IA and comorbidities) were associated with patients functional impairment.

Patients' social Support (satisfaction scores), dyad relationship (PAIR communication and engagement scores, DAS degree of agreement and quality of the interactions scores assessed by patients) (and patients age, sex, IA), were associated with patients mental health.

Relatives burden, social support (satisfaction scores), relatives anxiety and depression, dyad relationship (PAIR communication score and DAS degree of agreement assessed by patients) (and patients comorbidities) were associated with self-efficacy.

In multivariate analyses (table), good communication in the couple, satisfaction with social support and low relative burden were independently associated with improved patients mental health and perceived self-efficacy.

Conclusion: This study has highlighted that mental health and self-efficacy of patients with IA are not only influenced by patient-relative relationship, but also by the perceived satisfaction of social support of the couple, the perceived burden of the relative and by relative anxiety and depression.

Intervention targeting relatives should be part of self-management programs of patients with IA.

Factors associated with functional impairment, mental health and self-efficacy of the patient with RA or SpA: multivariate analyses

Predictors of Mortality Among Black Women with Systemic Lupus Erythematosus: The Black Women's Experiences Living with Lupus (BeWELL) Study

Charmayne Dunlop-Thomas ,[1] Gaobin Bao,[2] Cristina Drenkard,[2] David Chae,[3] and S Sam Lim[2], [1]Emory University, Atlanta, Georgia, [2]Emory University, Atlanta, GA, [3]Auburn University, Auburn, AL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain, Anxiety, & Depression
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Mortality continues to be disproportionately high in Black women with SLE living in the South region of the United States. Recent studies suggest that as in other chronic conditions, psychosocial and patient-reported health domains might have a strong influence on the mortality of people with SLE. We examined psychosocial, general health, health care access/utilization, and indicators of disease severity in relation to mortality among Black women with SLE.

Methods: We examined data from the BeWELL study. A sample of 438 self-identified Black women was recruited between April 2015 and May 2017, from the Georgian's Organized Against Lupus (GOAL) cohort, a large population-

PROMIS Depression - T Score (per 5 points ?)	1.24 (1.01-1.53)	0.04	1.28 (1.01-1.62)	**0.04**
PROMIS Anxiety -T Score (per 5 points ?)	1.09 (0.89-1.34)	0.39	1.09 (0.87-1.38)	0.45
PROMIS Companionship – T Score (per 5 points ?)	0.78 (0.64-0.97)	0.022	0.78 (0.63-0.96)	**0.02**
PROMIS Pain – T Score (per 5 points ?)	1.23 (0.97-1.55)	0.082	1.22 (0.92-1.60)	0.16
PROMIS Fatigue – T Score (per 5 points ?)	1.09 (0.88-1.34)	0.43	1.07 (0.82-1.39)	0.63
Cohen's Perceived Stress (per 1 point ?)	1.16 (1.00-1.35)	0.049	1.20 (1.01-1.42)	**0.04**
*Multiple regressions were controlled for age, disease duration, education, insurance status, marital status, emergency room visit (yes/no), disease activity (SLAQ score) and organ damage (SA-BILD score)				

based cohort of patients from metropolitan Atlanta Georgia with validated SLE, fulfilling 3 or more ACR classification criteria with a final diagnosis by a board-certified rheumatologist. Inclusion criteria: 18-79 years of age, and lack of significant visual or physical impairment that would prohibit being able to respond to questions on a computer. Mortality was assessed prospectively through April 2019 based on notices from family, obituaries or clinical notes. For this study, we explored the associations of the following measures: Patient-Reported Outcomes Measurement Information System (PROMIS) Companionship SF4, PROMIS Depression SF6, Cohen's Perceived Stress Scale, the Systemic Lupus Activity Questionnaire (SLAQ) and the Self-administered Brief Index of Lupus Damage (SA-BILD). Multivariate Cox regression analysis was used to examine predictors of psychosocial and health-related factors on death, controlling for demographics, healthcare, and disease-related confounders.

Results: Twenty-four participants (mean age at enrollment = 45.5 years) died within the observation period (mean years from study entry to death = 1.3) (Table 1). Multivariate analyses (Table 2) showed that depression, perceived stress, and missed health care appointments increased the risk of death with p values ranging from 0.01 to 0.04,

while perceived availability of someone with whom to share social activities was associated with lower risk after controlling for other covariates (p=< 0.02).

Conclusion: During the observation period, five percent of the sample of Black women unexpectedly died. Findings suggest that psychosocial factors, including depression, stress, and barriers to show up for medical appointments may serve as indicators of declining health and death. Companionship may be a potential protective factor, as studies have shown psychological benefits and longer life related to regular companionship.

Abstract Number: 1844

The Contribution of Disease Activity, Depression, and Anxiety to Health-Related and Non-Health-Related Quality of Life in US and Filipino Patients with SLE

Alexandra Watts ,[1] Desiree Azizoddin,[2] Shadi Gholizadeh,[3] Sarah Mills,[4] Geraldine Zamora,[5] Daniel Wallace,[6] Meenakshi Jolly,[7] Michael Weisman,[8] and Perry Nicassio[9], [1]University of California, Los Angeles, Los Angeles, CA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]McGill University, Montreal, Canada, [4]Lineberger Comprehensive Cancer Center, Chapel Hill, NC, [5]Manila Doctors Hospital, Manila, Philippines, [6]Cedars-Sinai Medical Center/University California at Los Angeles, Los Angeles, CA, [7]Rush University Medical Center, Chicago, IL, [8]David Geffen School of Medicine at UCLA, Los Angeles, CA, [9]David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain, Anxiety, & Depression
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: It is well known that patients with SLE are often afflicted with deficits in quality of life and problems with physical impairment and psychosocial functioning. The present study sought to determine the variables associated with both health-related quality of life (HRQOL) and non-health-related quality of life (NHRQOL) in SLE.

Methods: Data from Patients with SLE from medical centers in an urban clinic in the United States and a rural-based clinic in the Philippines were analyzed. The US sample consisted of 136 patients from Los Angeles ages 18-81 (μ=49), and the Filipino sample was comprised of 100 patients ages 19-77 (μ=35) from Manila. Data on demographic factors (illness duration, age, income, and education), along with disease activity depression, anxiety, and quality of life (assessed using LupusPro) were collected. A series of multiple regression analyses were conducted to examine the contribution of demographic factors, disease duration and activity, and psychological factors to health-related quality of life (HRQOL) and non-health related quality of life (NHRQOL) in each sample.

Results: HRQOL. For the US sample, the regression equation was highly significant (F=22.88, p< .001), accounting for 57% of the variance. Anxiety (be=.-32, p< .001) and depression (be=-.46, p< .001) were each associated with lower HRQOL. No other variable was a significant predictor. For the Filipino sample, the regression equation accounted for 16% of the variance (F=2.49, p< .05). Depression was a significant predictor of lower HRQOL (be=-.28, p< .05). Disease activity (be=.20, p=.06) and anxiety (be=-.19, p=.08) both approached significance. NHRQOL. For the US sample, the regression equation accounted for 19% of the variance in NHRQOL (F=4.16, p< .001). Anxiety individually predicted lower NHRQOL (be=-.28, p< .001), while depression (be=-.16, p=.03) and age (be=-.19, p=.06) approached

significance. For the Filipino sample, the regression equation accounted for 10% of the variance in NHRQOL but was not significant (F=1.40, p=.22). Higher income was associated with higher NHRQOL (be=.23, p< .05) but since the overall model was not significant, the importance of income as an individual predictor could not be determined.

Conclusion: The findings illustrated the importance of depression in HRQOL for patients with SLE in the Philippines and the US, and anxiety for patients in the U.S. The results were more robust in general for the Cedars sample. More research on Filipino patients with SLE is needed to identify the predictors and potential intervention targets for quality of life in this population.

Physical Inactivity Is a Risk Factor for Incident Depression in Systemic Lupus Erythematosus

Laura Trupin ,[1] Sarah Patterson,[1] Louise Murphy,[2] Maria Dall'Era,[1] Jinoos Yazdany,[3] and Patricia Katz[1], [1]University of California, San Francisco, San Francisco, CA, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, [3]UCSF Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain, Anxiety, & Depression
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Physical activity can prevent and reduce depression, but there is little research on the relationship between physical inactivity and subsequent onset of depression in lupus. We examined physical inactivity as a predictor of incident depression in a cohort of individuals with SLE.

Methods: Data derive from the California Lupus Epidemiology Study (CLUES), a longitudinal cohort of 431 patients in the San Francisco Bay Area with confirmed SLE diagnoses, drawn from a variety of clinical sources and prior SLE studies. Participants complete an annual interview that includes sociodemographic questions and validated self-report measures of depression (Patient Health Questionnaire; PHQ-8), physical functioning (in Patient Reported Outcomes Measurement Information System; PROMIS), disease activity (Systemic Lupus Activity Questionnaire; SLAQ) and damage (Brief Index of Lupus Damage; BILD). A subset of participants also had physician assessed disease activity (SLE Disease Activity Index; SLEDAI) and damage (SLICC Damage Index; SDI). Physical inactivity was

Table. Risk of incident depression over 2 years, by physical activity at baseline, among SLE cohort participants with no depression at baseline.

Physical activity	n	Baseline PHQ-8	Incident depression, over 2 years	
			Cumulative incidence	Adjusted hazard ratio*
		(mean±sd)	% (95% CI)	HR (95% CI)
Total non-depressed at baseline	276		15% (11-19%)	
Inactive	42	3.98±3.78	36% (21-50%)	2.4 (1.2-4.8)
Active	234	3.44±3.12	11% (7-15%)	Ref
p-value		0.24	<0.001	0.02

*From Cox proportional hazards model, adjusted for age, gender, race/ethnicity, education, diagnosis age, and self-reported baseline disease activity (SLAQ), damage (BILD), and physical functioning (PROMIS).

assessed at baseline from a single item: "I rarely or never do any physical activities." Respondents were categorized as not depressed at baseline if their PHQ-8 scores were < 10, a validated cut-point. In that group, those with scores ≥ 10 in either of the next two annual interviews were considered to have incident depression. Using Cox proportional hazards regression, we modeled incident depression over a 2 year period as a function of baseline physical inactivity, controlling for sociodemographics, baseline physical functioning and disease status.

Results: 366 participants had ≥1 follow-up interview, of whom 256 (70%) had 2 follow-ups. At baseline, mean age of the sample was 47±14, 90% were female, 66% racial/ethnic minority. Among the 90 (25%) with PHQ-8 ≥10 at baseline, 33% were inactive vs. 16% of the 276 without baseline depression (p< 0.001). Those with baseline depression were excluded from further analysis. Mean PHQ scores for those without depression at baseline did not differ by activity status, but those who were inactive at baseline were more than 3 times as likely to develop depression over the next two years. After adjusting for baseline disease activity and damage (either by patient or physician assessment), physical function, and sociodemographics, the association remained moderately strong (hazard ratio, HR=2.4; see Table). Using physician assessed activity and damage reduced the sample size to 216 but did not appreciably change the results (HR=3.0; 95% CI= 1.4-6.7).

Conclusion: In this diverse cohort of patients with SLE, a simple question about low levels of physical activity was highly predictive of incident depression over the subsequent 2 years, after adjusting for sociodemographic and disease-related risk factors. Results support the importance of even low levels of physical activity and suggest an urgent need for approaches to increase physical activity in this high-risk patient population, such as health care providers' recommendation of SLE-appropriate low impact activities (e.g., walking and swimming) and referral to community-based physical activity programs designed for individuals with SLE.

Abstract Number: 1846

Does Cartilage Loss Cause Pain in Osteoarthritis?

Kathryn Bacon ,[1] Lavalley Michael,[2] and David Felson[3], [1]Boston University School of Medicine, Boston, MA, [2]Boston University, Boston, [3]Boston University School of Medicine, Department of Rheumatology, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain, Anxiety, & Depression
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Treatment development in osteoarthritis continues to focus on chondroprotection, but it is unclear if delaying cartilage loss would reduce joint pain. In published studies, less cartilage in a knee has not been consistently associated with more pain in the knee. Studies have not tested whether cartilage loss over time is associated with worsening pain and have not adjusted for other sources of pain. Further they have not examined whether synovitis, induced by cartilage loss, might mediate any effect on pain. Using observational data from the FNIH cohort within the Osteoarthritis Initiative, we tested whether cartilage loss was associated with worsening knee pain after adjusting for coexistent bone marrow lesions (BMLs) and synovitis and examined whether the association of cartilage loss with pain was mediated by worsening synovitis.

Association of change in WOMAC knee pain over 24 months with change in cartilage thickness loss over 24 months, adjusted for change in synovitis and BMLs			
MOAKS Factors over 24 months	**Model** Adjusted for BML only **Mean change (95% CI)**	**Model** Adjusted for Synovitis only **Mean change (95% CI)**	**Model** Adjusted for both BML and synovitis **Mean change (95% CI)**
Cartilage Thickness Loss over 24 months	0.15(-0.02,0.33)	0.10(-0.08,0.27)	0.09(-0.08,0.27)
BML change over 24 months	0.13(0.01,0.24)	-	0.10(-0.01,0.21)
Synovitis change over 24 months		0.84(0.53,1.14)	0.80(0.50,1.10)
All models adjusted for age, sex, BMI, race, depressive symptoms (CESD).			

Association of change in WOMAC knee pain over 36 months with change in cartilage thickness loss over 24 months, adjusted for change in synovitis and BMLs		
MOAKS Factors over 24 months	**Model** Adjusted for Synovitis only **Mean change (95% CI)**	**Model** Adjusted for both BML and synovitis **Mean change (95% CI)**
Cartilage Thickness Loss over 24 months	0.04(-0.15,0.23)	0.05(-0.14,0.24)
BML change over 24 months	-	-0.02(-0.15,0.10)
Synovitis change over 24 months	0.74(0.41,1.08)	0.74(0.40,1.08)
All models adjusted for age, sex, BMI, race, depressive symptoms (CESD).		

Association of change in WOMAC knee pain with change in cartilage thickness loss and synovitis, in strata defined by change in synovitis over 24 months				
	Outcome: WOMAC pain change over 24 months		Outcome: WOMAC pain change over 36 months	
	Strata: synovitis increased over 24 months **n=176**	**Strata: synovitis unchanged or decreased over 24 months** **n=424**	**Strata: synovitis increased over 24 months** **n=176**	**Strata: synovitis unchanged or decreased over 24 months** **n=424**
MOAKS Factors over 24 months	**Mean change (95% CI)**	**Mean change (95% CI)**	**Mean change (95% CI)**	**Mean change (95% CI)**
Cartilage Thickness Loss over 24 months	**0.46(0.13,0.78)**	**-0.06(-0.26,0.14)**	**0.31(-0.07,0.68)**	**-0.05(-0.28,0.18)**
Synovitis change over 24 months	**0.70(-0.22,1.62)**	**0.65(0.07,1.24)**	**0.63(-0.44,1.70)**	**0.81(0.15,1.46)**
All models adjusted for age, sex, BMI, race, depressive symptoms (CESD), and BML change. Cartilage loss by synovitis strata: n=105 of 176, cartilage loss in strata of increased synovitis; n=178 of 424, cartilage loss in strata of unchanged or decreased synovitis. Of knees with cartilage loss 178 of 283(63%) were in the stratum where cartilage loss was unrelated to worsening pain.				

Methods: 600 knee MRIs were scored for structural features of OA using the MRI Osteoarthritis Knee Score (MOAKS) at the baseline, 12-month, and 24-month OAI visits. We focused on loss of cartilage thickness as our measure of cartilage loss, because extent of cartilage area loss was unassociated with pain in initial analysis. For each visit we created summary scores for synovitis (range 0-6, sum of Hoffa-synovitis and effusion scores), cartilage thickness loss (range 0-42, sum of 14 regions), and BMLs (range 0-45, sum of 15 region scores) and computed change scores for MRI features from baseline to 24 months. We used the WOMAC knee pain score (range 0-20) from each visit and calculated change from baseline to 24 and 36 months. Linear models calculated mean change in pain associated with cartilage thickness loss, adjusted for BMLs and covariates. We used approaches by VanderWeele to examine whether synovitis change mediated the cartilage loss-pain association longitudinally at 24 and 36 months. Analyses explored effects of cartilage loss on pain in strata defined by synovitis change.

Results: Mean age and BMI were 61.6 years (8.9) and 30.7(4.8), respectively. 59% were female. In cross-sectional analyses, cartilage thickness was significantly associated with WOMAC pain (mean change in pain score=0.2, 95%CI=0.1,0.3 per unit change in predictor) but this association weakened when BML score was taken into account (mean change=0.1, 95%CI=0.0,0.2). In analyses adjusted for BMLs but not those adjusted for synovitis, change in cartilage thickness was weakly associated with pain change over 24 months (see upper table). Cartilage thickness change over 24 months was not predictive of pain change over 36 months after adjustment for BML or synovitis change (middle table). Most of the association of cartilage loss with pain was mediated by synovitis change (me-

diation proportion 52%), and we found a significant interaction between cartilage loss and synovitis change such that loss of cartilage was associated with worse pain only in those with increasing synovitis over time (lower table). However, in most knees with cartilage loss, there was no increase in synovitis.

Conclusion: Cartilage loss is, at most, weakly associated with knee pain, and this association with pain appears to be mediated by change in synovitis.

A National Needs Assessment of Males with SLE: Assessing Medical, Psychosocial, Support & Coping Needs

Priscilla Toral ,[1] Jillian Rose,[1] Roberta Horton,[1] Ambar Tavera,[1] and Natalia Irvine[1], [1]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain, Anxiety, & Depression
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: SLE mostly affects women; however, males represent 4-22% of patients. Research shows men tend to seek medical attention & supportive care < women & are underrepresented at self-management/support services for coping with SLE, despite having higher disease severity. Limited research exists regarding the specific medical, psychosocial, & support needs of men with SLE. Our hospital conducted a national survey to identify self-reported needs & concerns for men with SLE, as well as their interest in male specific support forums.

Methods: An 85-item survey with Likert scale & opened-ended questions was disseminated nationally to males with SLE over 18. The survey was advertised via online forums, at major hospitals serving SLE patients in NYC & at local & national SLE groups. The survey assessed 4 core areas: health status & quality of life, health behavior & lifestyle, access to care & interest in male specific programming. Surveys were completed via an online link.

Results: A total of 112 respondents participated in the survey, 61% identified as White, 21% Black/African-American, 15% Hispanic & 31% other. Mean age was 26 & mean year since diagnosis (DX) was 10. 49% of males were employed/self-employed & 46% unemployed/unable to work. 53% had an annual income of ˃ 50K, & 59% had some college or advanced degree. 94% reported having health insurance. Almost half (45%) reported living in an urban/city area, 34% suburban area & 20% rural area. Almost all (92%) were being treated by a Rheumatologist.

When respondents rated their overall health, 65% reported their health as fair/good, while 21% reported poor health. The majority (76%) reported worrying more about their future since DX. Most males (83%) reported that SLE limits their activities of daily living. When asked about the single most important way SLE affected daily life, responses included fatigue & pain, with 48% reporting feeling pain daily. 53% of men reported SLE affects their sexual health: 52% reported less sexual desire & satisfaction, 45% limited motion, & 47% impotence. When asked how often they followed medical advice, 59% said always, however reasons for not following medical advice included: worry about treatment side effects (44%) & that treatment would not help (43%).

Over half (58%) reported feeling depressed for several days/more than half the days in the last 2 weeks. Regarding support & coping with SLE, 52% reported receiving no support. 84% had never taken a class to learn self-management & coping skills. When asked if they would be interested in receiving support to help cope with SLE, 40% were interested/very interested, 44% reported being unsure &15% were not interested. When asked about the type of support platform they would prefer, 77% indicated online, 71% lupus app, 69% social group & 67% support & education group. When asked how likely they would be to participate in a male only support group, 50% reported likely/very likely, 27% unlikely/very unlikely & 23% unsure.

Conclusion: Despite our small sample, this study provides important information about the physical & emotional health of males with SLE as well as their interest in psychosocial support. A next step would be to conduct focus groups with males with SLE to better understand their specific support needs.

Racial Disparities in Septic and Aseptic Total Knee Replacement Revision Risk: A Study Using Four State-wide Inpatient Databases

Anne Bass ,[1] Huong Do,[2] Bella Mehta,[3] Lisa Mandl,[4] Jackie Finik,[5] Michael Parks,[3] Mark Figgie,[4] Haley Tornberg,[6] Stephen Lyman,[2] and Susan Goodman[1], [1]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [2]Hospital for Special Surgery, New York, [3]Hospital for Special Surgery/Weill Cornell Medicine, New York, [4]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY, [5]Hospital for Special Surgery, New York, NY, New York, NY, [6]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Approximately 4% of total knee replacement (TKR) patients require revision within five years. Blacks are 40% more likely to undergo TKR revision than whites,[1] but whether racial disparities exist for both septic and aseptic TKR revision risk is unknown.

Methods: This study used patient-level data from four diverse states representing the Northeast (NY), Southwest (AZ), South (AR), and Gulf Coast (FL) with ≥ 5 years of revisit files available from the Healthcare Utilization Project State Inpatient Databases (HCUP-SID) and New York Statewide Planning and Research Cooperative System (SPARCS). The index cohort was defined as black or white patients undergoing their first primary TKR. The reason for TKR revision was determined using ICD-9-CM diagnosis codes and categorized as septic, fracture, mechanical ("aseptic") or other. Kaplan-Meier survival curves were generated to assess the association between race and time to septic or aseptic TKR revision. Cox proportional hazards models were used to evaluate the association between demographic and clinical characteristics and septic or aseptic TKR revision.

Results: We identified 607,798 patients who underwent primary TKR. Mean (SD) age was 67 (10) years, 63% were female and 8.9% were black. Compared to whites, blacks were younger, more likely to be female, to have diabetes, obesity, renal disease and inflammatory arthritis, to have experienced a surgical complication during the index TKR, and to have Medicaid insurance ($p< 0.001$ for all). Median [IQR] duration of surveillance was 5.25 [2.25, 8.75] years. 26,268 (4.3%) of the patients underwent TKR revision, 1.3% septic, 0.1% fracture, 2.6% mechanical ("aseptic") and

0.3% other. In univariate analysis, the risk of septic revision was higher in blacks than whites, HR 1.4 (95% CI 1.3-1.5) (Figure 1a), as was the risk of aseptic revision, HR 1.7 (95% CI 1.6- 1.8) (Figure 1b). In multivariable models, the increased risk of TKR revision in blacks compared to whites was attenuated, but still present; HR 1.2, 95% CI 1.1-1.3 for septic and HR 1.3, 95% CI 1.3-1.4 for aseptic revision respectively (Table 1). In these models, Medicaid insurance

was a risk factor for septic TKR revision (HR 1.3; 95% CI 1.2-1.5) but not aseptic TKR revision (HR 0.9; 95% CI 0.8-1.0) (Table 1).

Conclusion: Blacks are at higher risk of both septic and aseptic TKR revision than whites. Medicaid insurance, a proxy for poverty, is associated with a higher risk of septic but not aseptic TKR revision. The interaction between race and poverty on the risk of septic TKR warrants study.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Medication access and adherence play key roles in determining outcomes. We investigated whether cost-related non-adherence (CRNA) to prescription medications was associated with worse patient-reported outcomes in a population-based SLE cohort.

Methods: This study utilized baseline data from the Michigan Lupus Epidemiology & Surveillance (MILES) Cohort. We collected detailed clinical, medication, and sociodemographic data through structured interviews and validated questionnaires. We used validated patient-reported outcome measures of SLE activity (Systemic Lupus Activity Questionnaire, SLAQ) and damage (Lupus Damage Index Questionnaire, LDIQ). CRNA was based on questions derived from the National Health Interview Survey and considered positive if participants reported any of the following actions to save money in the last 12 months: skipping doses, taking less medicine, and/or delaying filling prescriptions. We performed multivariable linear regression to examine the associations between CRNA and lupus activity

Table 1. Multivariable regression results for cost-related deviation from taking medication as prescribed and lupus-related activity and damage.

and damage, adjusted for the following covariates: age, sex, race, health insurance type, education levels, household income below the US median, PROMIS-Depression, PROMIS-Anxiety, fulfillment of fibromyalgia survey criteria, and SLE duration.

Results: 462 SLE participants completed the study visit: 430 (93.1%) female, 208 (45%) black, and mean age 53.3 years. Of the 462 SLE cases, CRNA was reported by 100 (21.7%) for the preceding 12 months. Based on multivariable models, CRNA was associated with both higher levels of SLE activity and damage scores, after adjustment for covariates (Table 1): those reporting CRNA had SLAQ scores that were on average 2.7 points higher compared those not reporting deviation [β coeff 2.7 (95% CI 1.3, 4.1), p< 0.001] and LDIQ scores that were 1.4 points higher [β coeff 1.4 (95% CI 0.5, 2.4), p=0.003]. Non-white race, having Medicaid/Medicare (compared to private insurance), and fulfilling FM survey criteria were also associated with both higher SLAQ and LDIQ scores; female sex was further associated with higher SLAQ scores (Table 1).

Conclusion: SLE patients with CRNA in the last 12 months had higher disease activity and damage scores. Asking patients about financial barriers, using tools such as motivational interviewing to discuss medication adherence, and incorporating cost-related factors in shared decision making are likely meaningful avenues for improving patient outcomes.

Abstract Number: 1850

Needs Assessment of Rheumatology Fellowship Program Directors on the Need for a Health Disparities Curriculum for Our Fellowship Programs

Irene Blanco,[1] Nevena Barjaktarovic,[1] and Cristina Gonzalez[1], [1]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Health disparities (HD) are pervasive in all fields of medicine including rheumatology. Low income patients as well as patients from racial and ethnic minority groups are disproportionately affected by the rheumatic diseases and have increased mortality. We previously conducted a needs assessment of rheumatology fellows that showed that while they felt the impact of the social determinants of the health on the well-being of their patients, they did not feel adequately trained to address these issues. Because of these findings, we now report a needs assessment of rheumatology fellowship program directors (PDs) to evaluate their views on the creation of a HD curriculum and to elucidate potential barriers to implementation.

Methods: We conducted an anonymous, survey-based study of rheumatology fellowship PDs at the annual PDs conference of the American College of Rheumatology held in March, 2019. Out of 74 unique fellowship programs that were registered to attend the conference, 49 completed the survey -- most from the Northeast (n=17) or Southeast (n=10). Our survey was modified from the 2016 survey that Cardinal et al. administered to internal medicine program directors assessing graduate medical education in disparities.

Results: 73% of the PDs reported that ≥ 10% of their fellows' patients are of limited English proficiency (LEP). 51% reported that ≥ 25% of patients were ≤ the US poverty level. At least 25% of the fellows' patients were from racial and ethnic minorities in 69% of programs and ≥50% in 39% of programs.

Overall 15 programs (30%) provided no training in cultural competency (CC), recognizing or addressing health disparities, or addressing health literacy in patients. Despite 51% of programs reporting that they train fellows to recognize (HD) in their populations, 71% give no training on how to address these HD. With regards to the care of LEP patients, 69% provided no training in how to care LEP patients, 75% offered no formal interpreter training, though interpreter services were widely available. In addition, 46% of PDs were neutral or disagreed with the statement that fellows had had prior training in HD and CC prior to fellowship, and 37% were unsure.

Barriers to the implementation of a curriculum that addresses CC, HD and LEP were:

- 78% of PD were neutral/disagreed that their faculty could assess their fellows providing CC care
- 88% were neutral/disagreed that they had the tools to assess fellows providing CC care

- 57% reported a lack of time in the curriculum
- 51% reported a lack of institutional resources

Conclusion: Our needs assessment of PDs shows that few programs are addressing HD and the social determinants of health despite the fact that HD are prevalent in rheumatology, and the fellows are caring for significant numbers of patients that are directly impacted by these disparities. While issues such as time and resources are commonly cited for many new initiatives, it is important to note that PDs feel that there is a paucity of faculty that can help address these issues. We, as a specialty, will need a two-pronged approach to implement a HD rheumatology curriculum, given we will have to train the faculty so that they can develop their skills in order to impart this education onto our trainees.

Abstract Number: 1851

The Association of Discrimination and Stress on Cardiovascular Disease in a Population-Based Cohort with Systemic Lupus Erythematosus

S Sam Lim ,[1] Gaobin Bao,[1] Charles Helmick,[2] Charmayne Dunlop-Thomas,[3] and Cristina Drenkard[1], [1]Emory University, Atlanta, GA, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA, [3]Emory University, Atlanta, Georgia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: African Americans (AA) are more likely to experience psychosocial and environmental stressors and develop SLE than whites. Increasing frequency of racial discrimination is associated with greater damage in SLE. Cardiovascular disease (CVD) is a leading cause of SLE morbidity and mortality. However, the increased CVD risk is not completely attributable to SLE activity and traditional CVD risk factors. We examined whether discrimination affects CVD risk after taking stress into account in patients with SLE.

Methods: The Georgians Organized Against Lupus (GOAL) is a population-based cohort of validated SLE patients in Atlanta derived from the Centers for Disease Control and Prevention supported Georgia Lupus Registry who consent to complete annual surveys across multiple domains. We analyzed 2 validated measures of psychosocial stress, Perceived Stress Scale (PSS) and Everyday Discrimination Scale (EDS), in the 2017 survey. Potential CVD events (ever) through 2016 were identified by patient report and by Georgia Hospital Discharge Database CVD-related codes. Medical records were reviewed by study physicians. CVD events (myocardial infarction, angina, transient ischemic attack, stroke, and/or peripheral vascular disease) were adjudicated using validated algorithms. Logistic regression was used to separately explore the association between PSS and CVD and EDS and CVD in univariate and multivariate analyses.

Results: The 2017 GOAL survey was comprised of 780 patients, of whom 621 (79.6%) were AA, 110 (14.1%) were white, and 49 (6.3%) from other racial/ethnic groups. A total of 179 (23%) patients were adjudicated as having had CVD. AA's had more CVD (24.8% vs. 15.7%, p=0.015), reported higher EDS score (1.8 vs 1.6, P=0.0002), but no difference in PSS level (6.4 vs 6.4, p=0.89) compared with non-AA's (Table 1). Multivariate logistic regression analysis demonstrated a significant association between both EDS and PSS with CVD after controlling for race; age; gender; SLE activity, dam-

Gender (female vs male)	0.58 (0.31-1.06)	0.078	0.50 (0.24-1.03)	0.06
Education (per year ↑)	0.92 (0.86-0.97)	**0.005**	0.97 (0.90-1.04)	0.42
Poverty	1.57 (1.11-2.21)	**0.011**	1.32 (0.84-2.07)	0.22
Disease activity (per unit↑)	1.04 (1.02-1.06)	**<.0001**	1.02 (0.99-1.04)	0.22
Organ damage Mild damage (vs. no damage)	2.02 (1.01-4.04)	**0.046**	1.24 (0.60-2.58)	0.12
Severe damage (vs. no damage)	6.37 (3.29-12.32)	**<.0001**	3.35 (1.64-6.87)	**<0.0001**
Taking medication for cholesterol	3.31 (2.28-4.82)	**<.0001**	2.37 (1.50-3.73)	**0.0002**
Taking medication for diabetes	2.62 (1.44-4.74)	**0.0015**	1.28 (0.63-2.60)	0.49
Taking medication for hypertension	1.91 (1.32-2.76)	**0.0006**	1.04 (0.67-1.62)	0.86
Currently smoking	1.79 (1.13-2.83)	**0.013**	1.29 (0.75-2.20)	0.36

Poverty: less than 100% Federal poverty level
*Logistic regression: multivariate model is adjusted by age, gender, race, disease duration, disease severity, education, poverty, currently smoking, and taking medication for high cholesterol, diabetes, or hypertension.

Table 3. Association of Cardiovascular Disease Risk with Discrimination and Stress

Model		Multiple regression*	
		OR (95% CI)	P value
Discrimination (per unit ↑)		1.43 (1.05-1.94)	**0.025**
Stress (per unit ↑)		1.16 (1.08-1.24)	**<0.0001**
Discrimination +	Discrimination (per unit ↑)	1.27 (0.91-1.76)	0.16
Stress	Stress (per unit ↑)	1.15 (1.07-1.23)	**0.0001**

*Adjusted by age, gender, race, disease duration, disease severity, education, poverty, currently smoking, and taking medication for high cholesterol, diabetes, or hypertension.
OR=odds ratio
Discrimination measured by the Everyday Discrimination Scale.
Stress measured by the Perceived Stress Scale.

age, and duration; being on medications for cholesterol, diabetes, and hypertension; currently smoking; and poverty (Table 2). The significance of the association was no longer present after including PSS in the model (Table 3).

Conclusion: Including PSS in the model of discrimination and CVD no longer made the association significant, suggesting the association between discrimination and CVD is principally through high stress levels. High stress is known to contribute to the development of atherosclerosis in the general population. In those with SLE, discrimination may result in greater CVD risk through higher stress rather than a result of being a certain race. In our study, the burden of psychosocial stress was higher in AA's than non-AA's, which may explain, in part, racial disparities in past CVD events along with poorer control of CVD risk factors. Including social determinants of health in the lupus health disparities framework provides a more comprehensive understanding of why low-income communities and communities of color experience poorer outcomes. Further research into related causal pathways, mitigating factors, and biologic mechanisms is also needed.

Abstract Number: 1852

Community-level Deprivation Index: Impact on Discharge Destination After Elective Hip Replacement

Bella Mehta ,[1] Susan Goodman,[2] Kaylee Ho,[3] Michael Parks,[1] and Said Ibrahim[3], [1]Hospital for Special Surgery/ Weill Cornell Medicine, New York, [2]Hospital For Special Surgery/Weill Cornell Medicine, New York, NY, [3]Weill Cornell University, New York

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: With the aging of the world population and the rising prevalence of Hip Osteoarthritis (OA), elective total hip arthroplasty (THA) has become one of the fastest growing procedures in the management of end-stage OA. Medicare, the largest payer in the US of joint replacement surgery, has introduced several payment reform models that target discharge destination and risk of readmission. In additional to clinical factors, social factors such as where one lives that might impact where patients go for post-op care and rehab following elective total hip replacement surgery.We sought to examine how the socioeconomic status of the community in which one lives influences discharge disposition and the odds of 90-day readmission after elective THA.

Methods: We used the Pennsylvania Health Care Cost Containment Council (PHC4) database to identify all patients who underwent elective THA between 2012 and 2016. We also derived Community level Area Deprivation Index

Table 1. Baseline characteristics and outcomes by Area Deprivation Index (ADI) and age group (N = 84 931).

[a] Data are presented as n(%).

[b] Variables are compared by ADI for each age group (years < 65, ≥ 65) using Pearson χ2 test or fisher's exact test, as appropriate. Significance levels: * = p<0.05, ** = p<0.01, *** = p<0.001.

[c] Clinical comorbidities were identified based on coding algorithms developed by Quan and colleagues (enhanced Elixhauser version), using either the ICD-9-CM or the ICD 10 coding system, as appropriate. The Elixhauser co-morbidity index score is calculated based on the cumulative number of comorbidity conditions.

a Data are presented as n(%). b Variables are compared by ADI for each age group (years < 65, ≥ 65) using Pearson χ2 test or fisher's exact test, as appropriate. Significance levels: * = p<0.05, ** = p<0.01, *** = p<0.001. c Clinical comorbidities were identified based on coding algorithms developed by Quan and colleagues (enhanced Elixhauser version), using either the ICD-9-CM or the ICD 10 coding system, as appropriate. The Elixhauser co-morbidity index score is calculated based on the cumulative number of comorbidity conditions.

(ADI) from the American Census Survey. We used binary logistic regression models to test the association between community ADI and the discharge outcome of Institution vs. Home. We also modeled the risk of 90-day readmission for patients sent to an institution compared to home for post-op care and rehab. We adjusted for important clinical, demographic, and facility level covariates. To evaluate whether patient race affects this relationship, we included into the models an interaction term for community ADI and patient race.

Results: Our analytic sample consisted of 84, 931 who underwent THA between 2012 and 2016 within the State of Pennsylvania. The study sample is stratified by < 65 (n = 40, 304) and ≥ 65 (n = 44, 627) years of age groups. In the years < 65 group, 17.1 % came from high ADI communities (above Q3), 46.5% from middle strata ADI (within Q2 and Q3) and 36.4% from low ADI communities (below Q2). The distribution for high, middle, and low ADI among patients ≥ 65 years of age were 13.8%, 47.1%, and 39.1%, respectively. Compared to low ADI community patients, patients from high ADI communities were more likely to be discharged to an institution compared to home ($p < 0.001$ in both age groups), after controlling for patient and facility level characteristics. The interaction effect of race and ADI on discharge destination was statistically significant in those ≥ 65 years of age ($p < 0.05$), but not in patients < 65 years. The association of ADI on 90-day readmission was not statistically significant. The interaction of ADI and race on 90-day readmission was also not statistically significant.

Figure 1. Pennsylvania zipcode level area deprivation index (ADI) with individual THA patient discharge status.

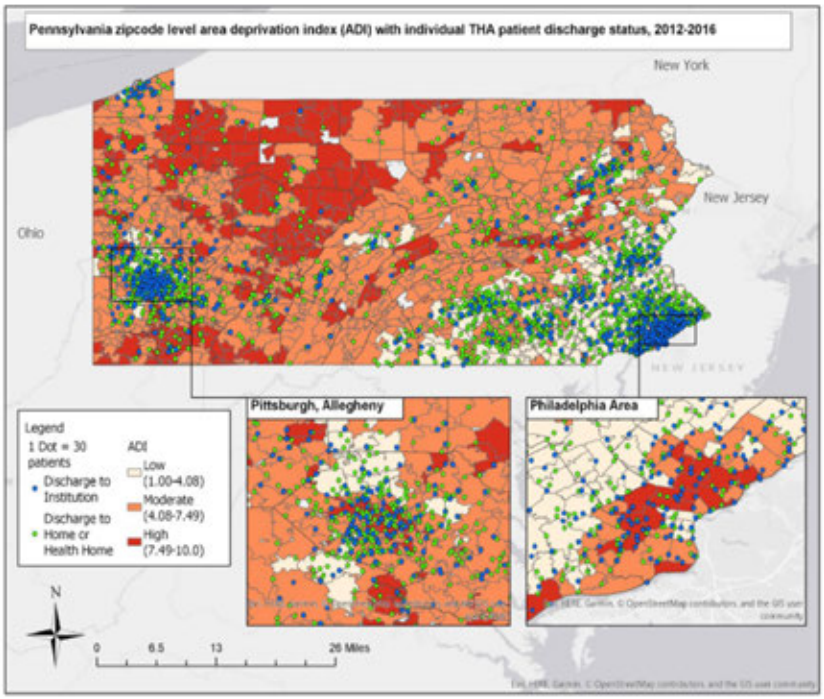

Figure 2. Odds ratio of referral to Institution for patients living in high area deprivation index (ADI) zipcode areas vs. low ADI areas.

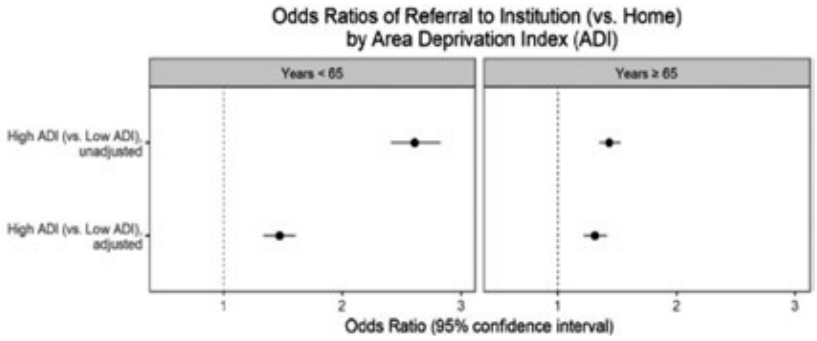

Conclusion: In this large sample of patients who underwent THA in the State of Pennsylvania, the level of deprivation of the community in the patient resides influences where patients go for post-op care and rehab after elective THA disposition.

Abstract Number: 1853

Racial Differences in Highly Effective Contraceptive Use Among Medicaid Beneficiaries with SLE

Jessica Williams ,[1] Chang Xu,[1] Karen Costenbader,[1] Bonnie Bermas,[2] Lydia Pace,[3] and Candace Feldman[3], [1]Brigham and Women's Hospital, Boston, MA, [2]UT Southwestern, Dallas, [3]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Highly effective contraception (HEC), which includes intrauterine devices, implants and sterilization, is safe for women with SLE and has a < 1% failure rate for preventing pregnancy. Prior studies have revealed low rates of contraceptive use among reproductive age women with SLE despite periods of high disease activity and frequent teratogenic medication use. Black and Hispanic women with SLE have higher rates of adverse outcomes, including pregnancy complications, compared to white women with SLE. Using U.S. nationwide data, we aimed to examine whether there are racial/ethnic differences in contraception use, and specifically HEC, among women with SLE.

Methods: Using Medicaid claims data from 2000-2010, we identified reproductive age women (18-50 years) with prevalent SLE (3 ICD-9 codes 710.0 separated by ≥30 days). We required 6 months of continuous enrollment prior to the 3rd SLE code (baseline) and 24 months of continuous enrollment after (follow-up). We excluded women ineligible for new contraceptive use (baseline codes for HEC, hysterectomy, or menopause). We examined uptake of contraception by race during follow-up. We used multivariable logistic regression adjusted for age, calendar year, region, and the SLE risk adjustment index (proxy for SLE severity), to estimate the odds (OR, 95% CI) by race/ethnicity of: A) any encounter for contraceptive management (vs. none), B) any contraception (vs. none), C) HEC (vs. no HEC), and D) HEC (vs. no HEC) in a subset with ≥1 teratogenic medication prescription during the baseline period. We also conducted sensitivity analyses excluding women with pregnancy codes.

Results: We identified 28,662 female Medicaid beneficiaries with SLE. The mean (SD) age was 36; 44% were black, 34% white, 15% Hispanic, 4% Asian, and 1% American Indian/Alaska Native. 15% had an encounter for contracep-

*Any contraception use includes sterilization, intrauterine devices, implants, oral contraceptives, estrogen patch, estrogen ring, and Depo Provera. Data on use of barrier methods was not available.
**Subpopulation (N=4,387) on methotrexate, mycophenolate mofetil, mycophenolic acid, cyclophosphamide, leflunomide, or warfarin

tive management, 16% received any form of contraception, and 5% received HEC (**Figure**). Among 4,387 women using a teratogenic medication, 4% received HEC. In multivariable models, compared to white women, despite 1.23 (95% CI 1.13-1.34) times higher odds of a contraceptive visit, black women had 0.72 (95% CI 0.63-0.82) times lower odds of HEC use. Asian women had significantly lower odds of both contraceptive visits and HEC use (**Table**). Younger age and living in the Midwest and South were associated with higher odds of HEC receipt; more severe SLE was associated with lower odds. Trends demonstrated significantly increased HEC uptake over time for white women, but not for other racial/ethnic groups. Findings were similar when women with pregnancy codes were excluded.

Conclusion: In this nationwide study of reproductive age women with SLE, HEC uptake was very low, even among women receiving teratogenic medications. Despite more encounters for contraception, black women had lower odds of HEC uptake; Asian women had fewer encounters and lower odds of HEC. With known disparities in pregnancy outcomes by race/ethnicity, further study is needed to understand whether racial/ethnic differences in HEC use among women with SLE are due to provider bias, patient preference, cultural factors, or variable access to reproductive counseling and care.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Imaging of Rheumatic Diseases I

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Bone marrow edema on MRI of the sacroiliac joints (SIJ) plays an important role in the ASAS (Assessment of Spondyloarthritis International Society) classification criteria for axial spondyloarthritis (axSpA). However, these lesions can also be seen in other conditions[1 2]. Structural SIJ MRI lesion characteristics may be of importance for differentiating patients with axSpA from other diagnostic entities with buttock/pelvic pain. The aim of this study was to investigate the diagnostic utility of the presence of fat lesions (FAT) in close relation to the joint space and other structural MRI lesions in order to differentiate patients with axSpA from other conditions.

Methods: This prospective cross-sectional study of 204 participants, included patients with axSpA (n=41), lumbar disc herniation (n=25), and women with postpartum buttock/pelvic pain (n=46) and a group of healthy participants consisting of women without postpartum buttock/pelvic pain (n=14), persons with hard physical work defined as hospital cleaning staff (n=26), long-distance runners (n=23) and healthy men (n=29). Participants with pain should all have VAS pain >2 (0-10) for ≥2 months. Non-axSpA participants were not allowed to have any clinical SpA features or rheumatological conditions. Participants underwent clinical, laboratory and MRI examination (semi-coronal STIR and T1W sequences) of the SIJs. MRIs were evaluated according to the SPARCC MRI definitions of lesions[1 2] by two independent readers. Analyses were based on "concordant reads", i.e. where both readers agreed on presence of the assessed pathology. In nine slices covering the entire cartilaginous compartment, each SIJ was separately assessed for the presence of FAT in relation to joint space (FAT@joint space), erosion (FAT@erosion), sclerosis (FAT@sclerosis) and ankylosis (FAT@ankylosis), respectively. Each of these "relation scores" had a total score range of 0-18 per patient.

Results: Table 1 shows the clinical characteristics of each group and table 2 shows the mean MRI FAT relation scores and the frequency of scores above various cut-off levels for each MRI relation score (concordant reads). FAT@joint space and FAT@sclerosis were seen in most groups, but higher scores were found in the axSpA group. FAT@erosion was almost only, and FAT@ankylosis exclusively, found in the axSpA group. A score above or equal to 1 (cut-

Cells with 1 row: Number (%) of patients with a score above a certain level. Cells with 2 rows: Mean (±SD) in upper row and median (min; max) in lower row.
Mann-Whitney test was applied, and all tests are patients with axSpA compared with the other groups. p<0.001***; p<0.01**; p<0.05*.
axSpA: axial spondylcarthritis; FAT: fat lesion; FAT@: fat lesions in relation to

off score ≥1) FAT@joint space was present in nearly all groups, however most frequent in the axSpA group followed by the group of healthy men. FAT@joint space was even present in both groups at high (≥10) cut-off scores. FAT@ sclerosis was present in axSpA, women with postpartum pain and healthy men, however, at higher thresholds, above ≥2, only in axSpA group.

Conclusion: Fat lesions in relation to other structural lesions were rarely recorded in the non-axSpA groups, in contrast to fat lesions in relation to the joint space. Assessment of structural sacroiliac joint lesions in anatomical relation to each other may be useful for differentiating axSpA from other conditions.

Abstract Number: 1855

Evaluating the OMERACT Definitions of Ultrasound Gout Structural Lesions in the Diagnosis of Gout

Sara Nysom Christiansen ,[1] Mikkel Østergaard,[2] Ole Slot,[1] and Lene Terslev[3], [1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Glostrup, Denmark, [2]Copenhagen Center for Arthritis Research, University of Copenhagen, Copenhagen, Denmark, [3]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging of Rheumatic Diseases I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To evaluate ultrasound (US) as a diagnostic tool for gout with positive urate crystal microscopy as the gold standard, using the OMERACT US working group definitions for crystal deposits.

Methods: US examinations (28 joints, 26 tendons) were performed in patients with clinically suspected gout. Joints (metacarpophalangeal, wrist, elbow, metatarsophalangeal, tibiotalar and knee joints) and tendons (extensor tendons of the wrist (scored as compartments (1-6)), triceps, quadriceps, patella, peroneus (longus and brevis scored as one), tibialis posterior and Achilles) were evaluated for the OMERACT gout structural lesions (double contour (DC), tophus, aggregates and erosions). Each of the structural lesions were registered as present/absent for each patient. The US assessment was compared to the gold standard reference for gout: presence/absence of monosodium-urate (MSU) crystals at joint fluid microscopy. The microscopies were performed by a rheumatologist blinded to US findings.

The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each US lesion, with microscopy as gold standard, were evaluated.

Results: 82 patients (70 males, 12 females), mean age of 61 years (19-88) were included. 57 had a positive microscopy for MSU crystals, 23 patients had a negative microscopy and in 2 patients joint aspiration was not possible (table 1).

All four structural lesions were statistically significant more frequent in patients with positive MSU microscopy compared to patients with negative microscopy (Fisher's exact test with p-values from < 0.0001 to 0.0049), and all lesions

Table 1: Ultrasound findings in patients with suspected gout

		Microscopy gold standard reference No. 82							
			Microscopy positive	Microscopy negative/not done	Sensitivity	Specificity	PPV	NPV	Fisher's Exact Test
Ultrasound lesions		No.	57	25					P-values
Double contour	Present	49	46	3	0.81	0.88	0.94	0.67	<0.0001
	Absent	33	11	22					
Tophus	Present	47	45	2	0.79	0.92	0.96	0.66	<0.0001
	Absent	35	12	23					
Aggregates	Present	69	54	15	0.95	0.40	0.78	0.77	0.0002
	Absent	13	3	10					
Erosions	Present	55	44	11	0.77	0.56	0.80	0.52	0.0049
	Absent	27	13	14					

were found to have high sensitivities for gout (ranges from 0.77-0.95). DC and tophus showed high specificities for patients with microscopically verified gout (0.88 and 0.92, respectively) and were also found to have high PPV (0.94 and 0.96, respectively). Low specificities were found for both aggregates and erosions (0.40 and 0.56). Negative predictive values were low to moderate for all lesions (ranges from 0.52-0.77).

Conclusion: The OMERACT set of US definitions of structural gout lesions seems to be a valid tool for diagnosis of gout in clinical practice. Particularly, DC and tophi seem to have a high specificity and high PPV for the disease, when joint fluid microscopy is considered as gold standard.

Tenosynovial Aspiration by Ultrasound Guidance: Correlation and Diagnostic Implications of Tenosynovial Analysis and Ultrasound Doppler Signal

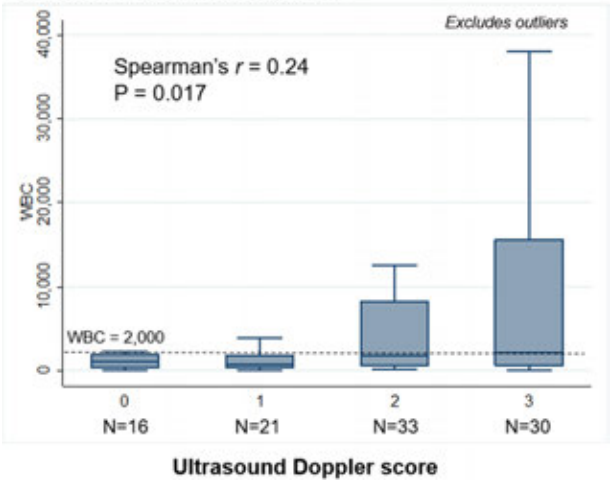
Fawad Aslam ,[1] Bryant England,[2] Amy Cannella,[3] Veronika Sharp,[4] Lily Kao,[5] Jon Arnason,[6] Jemima Albayda,[7] Catherine Bakewell,[8] Shruti Sanghvi,[8] Robert Fairchild,[9] Karina Torralba,[10] Amy Evangelisto,[11] Paul DeMarco,[12] Narandra Bethina,[13] and Eugene Kissin[14], [1]Mayo Clinic, Arizona, Scottsdale, AZ, [2]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, [3]University of Nebraska Medical Center, Omaha, [4]Santa Clara Valley Medical Center, San Jose, CA, [5]Evergreen Medical Group, Santa Clara Valley Medical Center, San Jose, CA, [6]University of Wisconsin Hospital and Clinics, Madison, [7]Johns Hopkins University, Baltimore, MD, [8]Intermountain Healthcare, Salt Lake City, UT, [9]Stanford University, Palo Alto, CA, [10]Loma Linda University School of Medicine, Loma Linda, CA, [11]Arthritis, Rheumatic and Back Disease Associates, Moorestown, NJ, [12]Arthritis & Rheumatism Associates PC, Wheaton, MD, [13]University of Vermont Medical Center, Burlington, VT, [14]Boston University, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging of Rheumatic Diseases I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Rheumatologists commonly use synovial fluid analysis and, more recently, US to establish a diagnosis in patients with joint effusions. Although tenosynovial (TS) effusions are common in rheumatic conditions, there is no guide on how to interpret the cell count of the fluid aspirated from tendon sheaths or how they correlate with US Doppler signal (DS). A multi-center collaboration was organized to prospectively analyze and correlate TS aspirate findings with US DS.

Methods: Patients with TS aspiration planned as part of routine care were enrolled. Tendon location, clinical diagnosis, synovial fluid analysis and Doppler US images were recorded. Doppler settings were standardized across sites and DS grading was performed blindly by 3 expert rheumatologists based on previously published methodology on a

Figure 1A. Correlation of Fluid WBC and Ultrasound Doppler Score in Tenosynovium

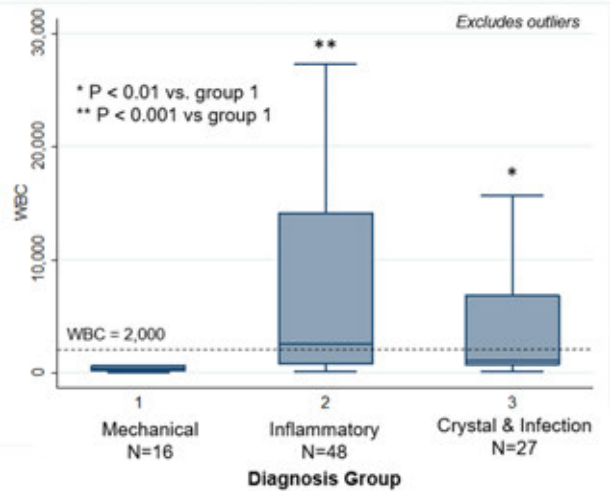


Correlation of tenosynovial fluid WBC count and ultrasound Doppler score in the tenosynovium

0-3 semiquantitative scale. Clinical diagnoses were categorized as non-inflammatory (group 1), inflammatory (group 2), or crystal/infection (group 3) related conditions. Inter-rater reliability was assessed using weighted kappa. Spearman's correlations of median DS with white blood cell (WBC) counts were determined. WBC counts and DS were compared between diagnostic groups using Kruskal-Wallis tests and logistic regression. Sensitivity and specificity calculations were used to discriminate between inflammatory and non-inflammatory conditions by WBC count or DS.

Results: 100 subjects with successful aspirations were enrolled at 14 participating sites. Subjects were primarily female (65%) and middle aged (mean 62 years). DS inter-rater reliability was substantial (kappa 0.74, 95% confidence interval 0.65-0.83). Fluid WBC count and DS correlated weakly (Figure 1A), and WBC counts were higher among diagnostic groups 2 and 3 (Figure 1B). There was substantial variability of TS WBC counts within diagnostic groups (ranges for groups 1, 2, and 3 were 4-7,734; 78-147,560; and 130-50,000 cells/μL respectively). Neither group 2 or 3 were significantly associated with higher DS, but notably, group 2 had only 3 (6%) subjects with a DS of 0. A DS of >1 had a sensitivity of 93.8% and specificity of 31.3% and a WBC count of >2000 cells/μL had a sensitivity of 58.3%

Figure 1B. Comparison of Tenosynovial Fluid WBC between Diagnosis Groups



Comparison of tenosynovial fluid WBC count between diagnosis groups

and specificity of 87.5% for discriminating group 2 vs. group 1. TS fluid WBC counts < 2000 cells/μL were observed in 41.7% of subjects with an inflammatory condition diagnosis (group 2). Crystals were observed in 22% of TS aspirates (CPPD 16% and monosodium urate 6 %).

Conclusion: DS and TS fluid WBC counts provide complementary information when evaluating TS effusions. DS may improve the sensitivity of detecting inflammatory tenosynovitis because TS fluid WBC counts from inflammatory arthritis are frequently in the range that would be considered non-inflammatory based on synovial fluid criteria for joints. While a negative DS strongly predicts a non-inflammatory condition, a positive DS is non-specific and should prompt aspiration for fluid analysis when possible. A TS fluid WBC count ≥2,000 cells/μL is highly specific for an inflammatory cause. TS fluid can also be used to identify crystal arthropathies.

High-resolution MRI Assessment of Flexor Tendon Pulleys in Psoriatic Arthritis for Disease Monitoring and Differentiation from Rheumatoid Arthritis Using a 16-channel Hand Coil

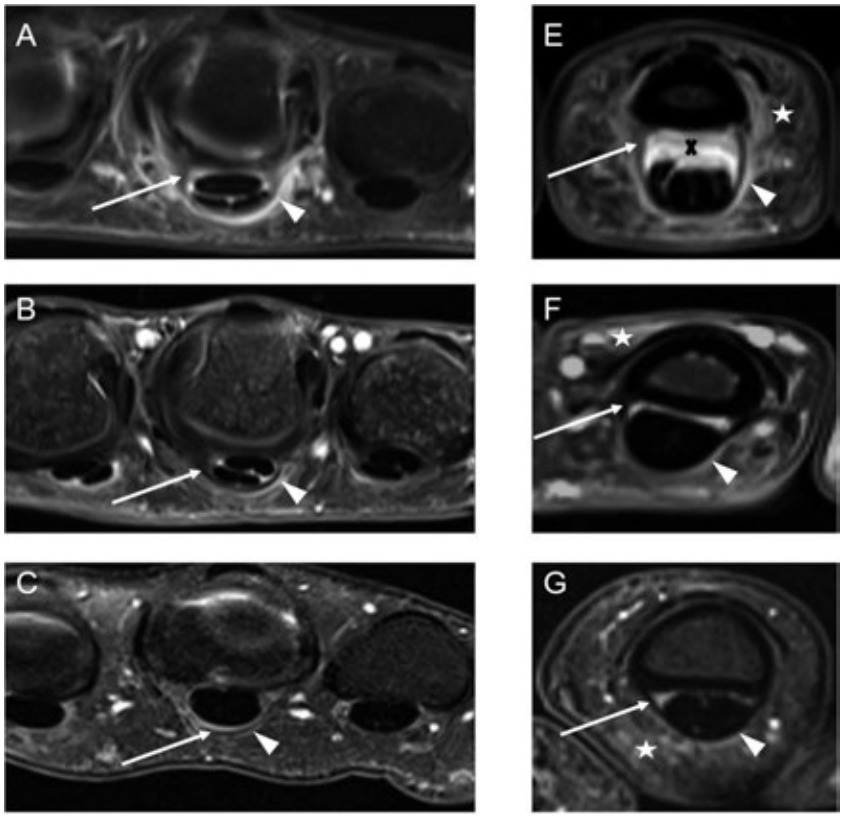
Philipp Sewerin ,[1] Daniel Benjamin Abrar,[2] Dennis McGonagle,[3] Miriam Frenken,[2] Karl Ludgar Ratke,[4] Stefan Vordenbaeumen,[5] Ralph Brinks,[6] Matthias Schneider,[7] Benedikt Ostendorf,[5] and Christoph Schleich[2], [1]Department of Rheumatology & Hiller Research Unit, University Hospital Düsseldorf,, Duesseldorf, Germany, [2]Institute for Diagnostic and Interventional Radiology, UKD, Heinrich Heine University, Duesseldorf, Germany, [3]University of Leeds, Leeds, United Kingdom, [4]Institute for Diagnostic and Interventional Radiology, UKD, Heinrich Heine University Düsseldorf, Duesseldorf, Germany, [5]Policlinic and Hiller Research Unit of Rheumatology, UKD, Heinrich Heine University, Duesseldorf, Germany, [6]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, [7]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging of Rheumatic Diseases I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To evaluate the value of 3 Tesla (T) magnetic resonance imaging (MRI) changes of flexor tendon pulleys for the differentiation of psoriatic (PsA) and rheumatoid arthritis (RA), as well as for potential disease detection and monitoring.

Methods: A total of 17 patients with active PsA, 20 patients with active RA and 16 healthy controls (HC) were evaluated by high-resolution 3T MRI using a dedicated 16-channel hand coil. Images were analyzed by three independent readers for the degree of inflammatory changes, the thickness of flexor tendon pulleys and comparison to the outcome measures for RA clinical trials (OMERACT) PsA MRI score (PsAMRIS) and to its sub-scores: synovitis, flexor tenosynovitis, bone edema, bone erosion, periarticular inflammation and bone proliferation.

Results: Flexor tendon pulleys were thicker in PsA than in RA patients (mean difference 0.16 mm, p< 0.001) and HC (mean difference 0.2 mm, p< 0.001) and showed a higher degree of associated inflammatory changes (mean difference RA: 4.7, p=0.048; mean difference HC: 14.65, p< 0.001). Additionally, there was a strong correlation of



Transversal fat-saturated T1w images after iv contrast administration. A1 (A-C) and A2 (E-G) flexor tendon pulleys of D3 in PsA (A & E) and RA (B & F) patients and in HC (C & G). A & E: 25 year old male with PsA. Flexor tendon pulleys at A1 and A2 level (white arrows) with increased contrast enhancement surrounding each pulley in its course and at ist attachment sites of the pulley (white arrowheads). White asterisk indicates periarticular inflammation within the soft tissue. Black X marks intense flexor tenosynovitis. B & F: 29 year old female with RA. A1 and A2 Flexor tendon pulleys appear thinner (white arrows) than in A & E, with less contrast enhancement (white arrowheads). There is also periarticular inflammation in the surrounding soft tissue (white asterisk). C & G: 37 year old healthy male. Flexor tendon pulleys (white arrows) appear thinner than in PsA and RA. There is only minimal contrast enhancement surrounding each pulley (white arrowheads). White asterisk indicates minimal periarticular inflammation.

pulley inflammation and total PsAMRIS and its acute-inflammatory sub-scores, flexor tenosynovitis, synovitis and periarticular inflammation (digitus (D) 2: synovitis r=0.72, flexor tenosynovitis 0.7, overall PsAMRIS r=0.72; D3: flexor tenosynovitis r=0.91, periarticular inflammation 0.62, overall PsAMRIS r=0.81; D4: flexor tenosynovitis r=0.7, periarticular inflammation r=0.77; D5: synovitis r=0.83, flexor tenosynovitis 0.76, periarticular inflammation r=0.6, overall PsAMRIS r=0.8. $p < 0.05$).

Conclusion: The assessment of MRI changes of flexor tendon pulleys is potentially beneficial for disease detection and monitoring in PsA, as well as for its distinction from RA and HC.

Abstract Number: 1858

Beta-2-Glycoprotein-I IgA Antibodies Predict Coronary Plaque Burden, Progression and Moderate the Effect of Inflammation on Atherosclerosis in Rheumatoid Arthritis

George Karpouzas ,[1] Sarah Ormseth,[1] Elizabeth Hernandez,[1] Viet Bui,[1] and Matthew Budoff[1], [1]Harbor-UCLA Medical Center and Los Angeles Biomedical Institute, Torrance, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging of Rheumatic Diseases I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Beta-2-glycoprotein-I(b2GPI), an apolipoprotein abundant in plasma, is readily expressed in human atherosclerotic plaque. Anti-b2GPI-IgA antibodies (Ab) have been previously reported in both rheumatoid arthritis (RA) patients and controls;they independently predicted cardiovascular events in general patients. We explored whether a-b2GPI-IgA presence predicted coronary plaque burden, its progression and potential interactions between a-b2GPI-IgA and inflammation on atherosclerosis load increase in RA.

Methods: One hundred-one participants with a baseline coronary computed tomography angiography (CCTA) underwent follow-up assessment within 83±3.6 months. Numbers of coronary segments with plaque andcumulative plaque stenosis were recorded.Coronary artery calcium (CAC) was quantified by the Agatston method. Subclasses (IgG, IgM and IgA) of a-b2GPI Ab, anticardiolipin-Ab and lupus anticoagulant were assessed at baseline and confirmed 12-weeks later, if positive. Serum interleukin-6 (IL-6) was measured at baseline, while CRP was assessed on every visit from baseline through follow-up. Multivariable robust linear regression models evaluated the effect of a-b2GPI-IgA presence onbaseline CACandCAC change. Negative binomial regression assessed plaque progression, defined as number of segments with new plaque or increase in stenosis of existing plaque.The effects of interactions between a-b2GPI-IgA and time-averaged CRP or baseline IL-6 on plaque progression were also explored.

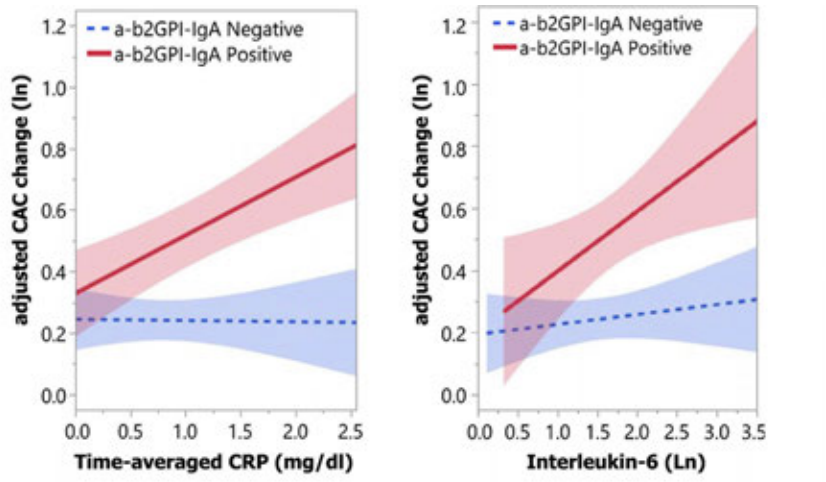

Figure 1. Associations of time-averaged CRP and baseline IL-6 with CAC change stratified by a-b2GPI-IgA presence. Models adjusted for age, hypertension, waist-to-height ratio, cumulative prednisone dose and time in-between scans.

Results: A-b2GPI-IgA was highly prevalent (34.7%) in contrast to other antiphospholipid-Ab subclasses (< 4%). Their presence predicted baseline CAC score independently of age, hypertension, statin use, and CRP [β=0.37 (0.04-0.71), p=0.029]. A-b2GPI-IgA further predicted CAC change [β=0.387 (0.06-0.71), p=0.019] and plaque progression [IRR=1.62 (1.03-2.56), p=0.039], independently of age, hypertension, time-averaged CRP, cumulative prednisone and methotrexate dose and duration of statin exposure. Similarly, Ab presence predicted incident CAC [OR=5.67 (1.10-29.23), p=0.038] as well as prevalent CAC progression [β=0.64 (0.02-1.26), p=0.044]. Notably, a-b2GPI-IgA moderated the effect of both time-averaged CRP and baseline IL-6 (Figure 1) on CAC change [p-interaction=0.01 and 0.017 respectively]; specifically, higher time-averaged CRP and higher baseline IL-6 promoted CAC progression only in a-b2GPI-IgA positive patients [β =0.47 (0.26-0.67), p< 0.001 and β=0.43 (0.05-0.81), p=0.028, respectively] but not negative ones [β=0.07 (-0.10-0.25), p=0.395 and β=-0.07 (-0.34-0.20), p=0.621, respectively].

Conclusion: A-b2GPI-IgA in RA independently contribute to higher baseline coronary atherosclerosis burden, accelerated plaque progression and remodeling, especially in the context of higher cumulative inflammation.

Abstract Number: 1859

Joint Tenderness and Ultrasound Inflammation in DMARD-naïve Early Rheumatoid Arthritis Patients

Nina Sundlisater ,[1] Anna-Birgitte Aga,[2] Hilde Hammer,[1] Till Uhlig,[3] Tore Kvien,[3] Espen Haavardsholm,[3] and Siri Lillegraven[4], [1]Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway, [2]Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Oslo, Norway, [3]Diakonhjemmet Hospital, Dept. of Rheumatology / University of Oslo, Faculty of Medicine, Oslo, Norway, [4]Diakonhjemmet Hospital, Dept. of Rheumatology, Oslo, Norway

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging of Rheumatic Diseases I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: A tender joint count is part of most disease activity scores and remission criteria in rheumatoid arthritis (RA). A recent study in established RA found that tender joint count might not reflect inflammatory activity assessed by ultrasound (1). Our objective was to explore if tender non-swollen joints is associated with subclinical inflammation, assessed by ultrasound, in DMARD-naïve early RA patients.

Methods: DMARD-naïve RA patients with < 2 years symptom duration from first swollen joint and indication for DMARD treatment were included in the ARCTIC trial (2). For the current analyses we used data from the baseline examination, including a tender joint count assessed by Ritchie Articular Index and a 44-swollen joint count. The Ritchie Articular Index treat certain joints as a single unit (as the MCP-joints), and scoring of tenderness in joints and joint groups is graded 0-3. All patients underwent an ultrasound examination of 32 joints, with a semi-quantitative 0-3 score for power Doppler in each joint. An ultrasound atlas was available for reference (3). We predefined the wrist and the MCP 1-5 joints as joint areas of interest since they are commonly involved in RA and were assessed both clinically and by ultrasound. We selected only joints that were clinically non-swollen, and assessed the association between joint tenderness and ultrasound power Doppler signal by mixed logistic regression models with patient-specific intercept to adjust for within-patient dependencies. The analyses were repeated using generalized estimating equations for robustness. The frequency and odds ratio (OR) of ultrasound power Doppler activity (yes/no) in tender

non-swollen wrists compared to non-tender non-swollen wrists were calculated. Similar analyses were performed for the MCP joints.

Results: A total of 222 patients with complete baseline data were included. 63% were female, median [IQR] age was 53.6 [41.2, 62.3] years, symptom duration 5.8 [2.9, 10.4] months, swollen joint count 9 [4, 15], joint tenderness 7 [4, 13] and power Doppler score 7 [3, 14]. Of 444 wrists, 268 were not swollen. The frequency of power Doppler signal >0 in tender non-swollen wrists were 50% (18/36), compared to 23% (53/232) in non-tender non-swollen wrists (p-value for comparison = 0.001). This corresponds to an OR of 4.32 (95% CI 1.47 to 12.65, p=0.008) for power Doppler signal if the wrist was tender but not swollen, compared to a non-tender non-swollen wrist. Similar results were found for the non-swollen MCP-joints (Table).

Table. The frequency and odds ratio (OR) of ultrasound power Doppler (PD) activity in Ritchie positive versus Ritchie negative non-swollen wrists and MCP joints.

	PD-signal positive if Ritchie positive	PD-signal positive if Ritchie negative	OR (CI)	p-value
Non-swollen wrist, n=268	18/36 (50%)	53/232 (23%)	4.32 (1.47 to 12.65)	0.008
Non-swollen MCP joints, n=165	15/35 (43%)	28/130 (22%)	4.84 (1.31 to 17.89)	0.02

Conclusion: Ultrasound power Doppler activity was more frequent in non-swollen wrists and non-swollen MCP joints if the joints had been scored as tender or painful by Ritchie Articular Index. Our findings indicate that in early RA patients, tenderness might reflect inflammation which is not detectable clinically.

Using Electronic Visits (E-Visits) to Achieve Goal Serum Urate Levels in Patients with Gout in a Rheumatology Practice: A Pilot Study

Chio Yokose ,[1] April Jorge,[1] Kristin D'Silva,[1] Naomi Serling-Boyd,[1] Mark Matza,[2] Mazen Nasrallah,[2] Sarah Keller,[1] Amar Oza,[1] Hyon K. Choi,[1] Marcy Bolster,[1] and Deborah Collier[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Measures of Healthcare Quality I: Digital Health Technologies – Tool for Improvement

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Gout is a highly prevalent form of inflammatory arthritis associated with increased morbidity and mortality, and the burden of gout on the healthcare system has continued to climb despite the widespread avail-

Figure 1. Gout E-Visit Questionnaire

Gout Questionnaire:

Overall, how have your gout symptoms been since your last visit (circle one)?
Better Same Worse

Have you experienced any gout attacks since your last visit? In the short term while you are being started on a medication to lower your uric acid, you are at an increased risk of a gout flare. Therefore, your doctor may also recommend taking another medication to prevent these flares.
Yes No

If yes, please answer the following 5 questions:
1. **How many flares have you had?** _____
2. **Which joints were affected?** _____
3. **How many days did the flares last, on average?** _____
4. **Did you have to visit the ER or hospital due to the flare?** _____
5. **How did you treat the flares (circle answers)** _____

Non-steroidal anti-inflammatory drugs (e.g., Indomethacin, naproxen(Aleve), ibuprofen (Motrin, Advil))
Colchicine (Colcrys, Mitigare)
Prednisone (Cortan, Orasone, Deltasone) or methylprednisolone (Medrol)
Ice packs
Other (please explain) _____
None of the above

Do you take a medicine to prevent gout flares? Yes No
If yes, which medicine do you take? _____ **Dose?** _____ **Number of times per day?** _____

General recommendations to ease or prevent gout attacks:
- Avoid foods that are high in purines (such as liver, organ meats, gravy, high-fat dairy products, tuna, anchovies).
- Avoid high-fructose corn syrup-sweetened beverages and foods.
- Drink plenty of water.
- Limit alcohol.
- Exercise regularly and maintain a healthy weight.
- If you're overweight, ask your doctor how to lose weight safely. Fast or extreme weight loss can raise uric acid levels.

Are you following these recommendations most of the time? Circle one. Yes No

Which uric acid-lowering drug are you taking for your gout? Select all that apply. Gout is caused by elevated uric acid levels in the blood. If the uric acid is lowered to target, then you can be cured of gout attacks. The medications listed below work by lowering uric acid levels. To be effective, they must be taken consistently and at the appropriate dose. Your doctor will adjust the dose of these medications to achieve the target uric acid level. The dose will likely need to be increased in several steps after lab checks over the next few months.
- Allopurinol (Zyloprim, Lopurin, Aloprim) Dose: _____
- Febuxostat (Uloric) Dose: _____
- Probenecid Dose: _____
- Other, please explain _____
- I have not been prescribed a uric acid-lowering drug

Are you taking the uric acid-lowering medication as prescribed?
Yes No

If no, then why? Select all that apply.
- Advice of another doctor. Please explain: _____
- Because my gout is mild and does not require preventive gout treatment
- Because I could not afford the treatment/medication co-pay
- Because I do not understand the medication instructions
- Because of side effects
- Other, please explain: _____

Are you experiencing any side effects from the medications?
Yes No
If yes, please explain: _____

Have there been any changes to your other prescription medications since your last visit?
Yes No
If yes, please explain: _____

Are you doing any non-medication therapy or taking any over-the-counter medicines for your gout?
Yes No
If yes, please explain: _____

Have you had your blood tests drawn since your last visit? It is important to have the uric acid level checked since this helps your doctor adjust the dose of your gout medication.
Yes No

Do you have other questions, concerns, or comments about your gout that you want your doctor to know?
Yes No
If yes, please explain: _____

Since your last visit, have you been: (Select all that apply)
- Told by a doctor that you have any new medical conditions? If yes, please explain: _____
- To the ER or hospital for a medical condition? If yes, please explain: _____
- None of the above

Table 1. Baseline Characteristics of Patients with Gout Enrolled in E-visits and Historical Controls

	E-visit Program (n=62)	Controls (n=62)
Age, years (mean, SD)[1]	58.3 (12.6)	56.5 (11.2)
Male sex (n, %)	52 (83.9%)	46 (76.7%)
White (n, %)	57 (91.9%)	52 (83.9%)
Black (n, %)	0	2 (3.2%)
Asian (n, %)	3 (4.8%)	4 (6.4%)
Other (n, %)	2 (3.2%)	4 (6.4%)
Hispanic (n, %)	3 (4.8%)	1 (1%)
Weight, kg (mean, SD)[1]	95.6 (18.9)	98.6 (20.7)
Height, cm (mean, SD)[1]	172.5 (10.8)	174.3 (10.6)
Body mass index, kg/m^2 (mean, SD)[1]	32.3 (6.7)	32.4 (6.3)
Creatinine, mg/dL (mean, SD)[1]	1.1 (0.3)	1.2 (0.4)
Mean glomerular filtration rate (mL/min/1.73m^2)[1,2]	103.4 (38.5)	99.0 (36.5)
Stage 3, 4, or 5 chronic kidney disease (n, %)[3]	11 (17.7%)	10 (16.1%)
New start of urate lowering therapy (n, %)	37 (59.7%)	29 (46.8%)

[1]Mean values are reported with standard deviation in parentheses
[2]Calculated by Cockroft-Gault Equation
[3]Stage 3 or worse chronic kidney disease defined as glomerular filtration rate < 60 mL/min/1.73m^2

Table 2. Comparison of Treat-to-Target in Gout Patients Enrolled in E-visits Compared to Historical Controls

	E-visit Program (n=62)	Controls (n=62)	P-value
Mean number of office visits in 6 months*	0.8 (0.8)	1.1 (1.0)	0.07
Mean number of E-visits in 6 months*	1.6 (1.5)	N/A	
Completed at least one E-visit (n, %)	43 (69.4%)	N/A	
Mean initial serum urate (mg/dL)*	8.3 (1.5)	8.1 (1.8)	0.50
Mean serum urate at 6 months (mg/dL)*	**5.5 (1.5)**	**6.6 (1.5)**	**<0.01**
Allopurinol (n, %)	55 (88.7%)	55 (88.7%)	1.00
Febuxostat (n, %)	6 (9.7%)	6 (9.7%)	1.00
Probenecid (n, %)	0	1 (1.6%)	0.5
Pegloticase (n, %)	1 (1.6%)	0	0.5
Mean allopurinol dose at 6 months (mg)*	273.5 (96.7)	263.2 (107.3)	0.58
Dose change/escalation over 6 months (n, %)	45 (72.6%)	40 (64.5%)	0.33

ability of effective medications. The American College of Rheumatology management guidelines for gout recommend a "treat-to-target" approach with a goal serum urate (SU) level < 6 mg/dL in most patients with gout with the use of urate-lowering therapy (ULT) such as allopurinol. However, achieving goal SU levels in patients with gout remains difficult in primary care and rheumatology practices. We hypothesized that an asynchronous electronic visit (E-visit) program could facilitate achieving a goal SU < 6 mg/dL among patients with gout on ULT.

Methods: Patients with rheumatologist-diagnosed gout and SU levels greater than 6 mg/dL either starting or continuing titration of ULT were eligible for the study and were enrolled in the E-visit program at the treating physicians' discretion between April 1, 2017 and May 31, 2018. The E-visit program consisted of an electronic questionnaire (Figure 1) that assessed medication compliance and recent symptoms and provided educational information on gout triggers and the "treat-to-target" approach for gout management. The E-visit also served as a reminder to the patient to have laboratory testing performed, as recommended by his/her physician. Once the E-visit was completed by the patient, the treating physician was notified to review the patient's responses (thus asynchronous) and recommend further action (including adjustment of ULT dose). We performed a retrospective cohort study, comparing patients who enrolled in the E-visit program with age- and sex-matched historical controls who received usual care and were seen within 12 months prior to E-visit program initiation. The primary outcome of interest was the proportion of patients achieving target SU level < 6 mg/dL at 6 months.

Results: Sixty-two patients were enrolled in the gout asynchronous E-visit program and were compared to 62 historical controls. Baseline characteristics including age, sex, body mass index, renal function, and initial SU were similar among patients enrolled in the E-visit program and controls (Table 1). At six months, E-visit patients had a lower mean SU level than the historical controls (5.5 mg/dL vs. 6.6 mg/dL, respectively, $p < 0.01$) (Table 2). The number of patients achieving a goal SU of < 6 mg/dL at the end of 6 months was higher in the E-visit group compared to control patients (61.3% vs. 29.0%, respectively, $p < 0.01$) (Table 2).

Conclusion: In this pilot study, a physician-initiated E-visit program led to a substantial improvement in the proportion of patients achieving goal SU in an academic rheumatology practice. E-visits may be a useful tool to improve gout management and achieve SU goals. Further studies should assess the generalizability and cost-effectiveness of an E-visit program in both academic and community rheumatology practice settings.

Abstract Number: 1861

Use of a Novel Electronic Auto-notification Process to Manage Transitions of Care in Rheumatic Patients on DMARD Therapy

Megan Bielawski ,[1] Eric Newman,[2] and Lisa Schroeder[1], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger, Danville, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures of Healthcare Quality I: Digital Health Technologies – Tool for Improvement
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Effective communication is essential in caring for medically complex patients with rheumatologic diseases. In our prior study of rheumatoid arthritis patients and hospital admissions, our rheumatologists were only notified 57.6% of the time. This project's goal was to integrate an auto-notification system into our clinical workflow, so that timely communication of sentinel events (Elective surgery, Hospital admission, or ER visit) in immunosuppressed rheumatic disease patients happens by design, not by accident.

Methods: We developed an algorithm that triggers an auto-notification to the Rheumatology Nurse Navigator when a patient of interest (POI) experiences a sentinel event. A POI has been seen by a rheumatologist at least twice within the past 14 months and takes a DMARD or glucocorticoid. The Nurse Navigator creates a telephone encounter that includes the event type, baseline glucocorticoid and DMARD therapy, and event date. That encounter is forwarded to the rheumatologist, who records recommendations based on current guidelines and returns it to the Nurse Navigator, who notifies the patient or other providers of the recommendations.

Results: During the four-month study period, 240 completed notifications were received - 57% for elective surgeries, 39% for ER visits, and 4% for admissions. The need for change in care plan was less common for ER visits (17%), but was 25% for hospital admissions and 44% for elective surgeries. A significant result is the time interval between receipt of the notification and the date of elective surgery. This is applicable to our patients taking biologic DMARDs and/or high dose glucocorticoids, as these medications may require holding or adjusting a dose weeks before surgery. The mean number of days in this interval was 23. Therefore, this notification process is useful in the case of medications that need to be held or adjusted three weeks or less prior to surgery. The time commitment by clinicians has been minimal. The nurse spent an average of 5 minutes for each patient and the physicians spent an average of 5.9 minutes. The percentage of time that clinicians were notified of sentinel events increased from 57.6% to 100%.

Conclusion: Without knowledge of the care team, and no communication process integrated into the clinical workflow, communication and care handoff failures are extremely common. We developed a process that "hardwires" notification of the specialist for a patient sentinel event, to facilitate timely and relevant care. The average number

of messages that clinicians received per week was 2.2. Since the average number of minutes clinicians spent per message was 5.9, this resulted in only 13 minutes of work for each clinician per week, making this a very manageable process. With this automated program, care communication failures fell from 42.4% to 0%. As changes to the care plan were needed 34% of the time, this notification is crucial to our patient care. The process is easy, reliable, and has been well-received. As the program has been effective in improving patient care and outcomes, other divisions in our institution, such as Pulmonary, are developing a similar program for their patient population.

Abstract Number: 1862

Treat to Target Opportunities – Design, Testing, and Adoption of a Novel EHR-Integrated Electronic System to Engage Rheumatologists and Capture Decision Making

Eric Newman ,[1] Jonida Cote,[1] and Joseph Chronowski[1], [1]Geisinger, Danville, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures of Healthcare Quality I: Digital Health Technologies – Tool for Improvement
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

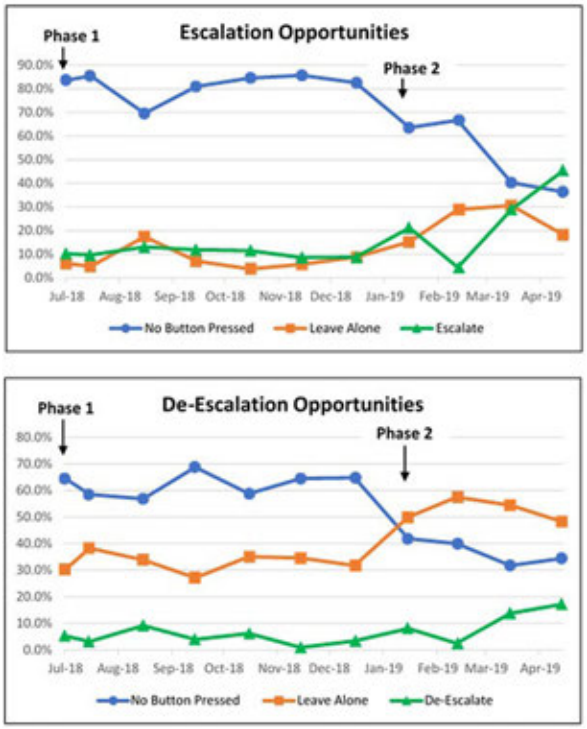
Background/Purpose: Treat to Target (T2T) opportunities and rheumatologist decision making are not defined, captured, or reportable within existing electronic health record (EHR) software. We developed a novel EHR-integrated electronic system that 1) signals rheumatologists in real time of an escalation or de-escalation treatment opportunity, 2) captures their decision making including exceptions, and 3) reports on those decisions.

Methods: Using the CDAI (Clinical Disease Activity Index - disease activity measure), we electronically defined an Escalation Opportunity (**E-Opp**) as the 2 most recent CDAIs in the moderate or high disease activity range and a De-escalation Opportunity (**D-Opp**) as every CDAI for the past year in the low or remission range.

Using EHR-integrated software that captures CDAI measures, we designed a T2T tab that displayed the E-Opp or D-Opp (Phase 1). The rheumatologist could choose to escalate/de-escalate therapy, or leave alone and why. The system then deactivated display of future T2T opportunities for that patient for a defined time period to minimize physician burden. Because of low adoption of navigation to the T2T tab, the software was redesigned (Phase 2) to give a visual cue upon completion of the CDAI, prompting in real time to address the T2T opportunity (Figure 1).

Figure 1. Clicking Treat to Target Opportunity displays "Escalate" or "Leave Alone" choices

Figure 2. Improvement in addressing T2T opportunities with Phase 2 redesign



Results: Between July 2018 and early May 2019, there were 1,428 T2T opportunities, representing 34.2% of the completed RA office visits during that time period. 11.3% of RA visits had an E-Opp and 22.9% of RA visits had a D-Opp. During Phase 1, rheumatologists used the T2T tab for only 18.1% of the E-Opp and 37.5% of the D-Opp. At the end of Phase 2, T2T tab use had risen to 63.6% for E-Opp and 65.5% for D-Opp (Figure 2). A decision to escalate rose from 10.2% to 45.5% of all E-Opp, and a decision to de-escalate rose from 5.3% to 17.2% of all D-Opp.

For opportunities where a decision was made, rheumatologists selected "leave alone" for 48.9% of E-Opp and 80.0% of D-Opp. When there was an E-Opp, reasons for "leave alone" included CDAI measure not accurate (33.9%), patient decision (14.5%), risk > benefit (14.5%), other (37.1%). When there was a D-Opp, reasons for "leave alone" included hard to control (46.1%), patient preference (29.4%), and poor prognostic factors (24.5%).

Conclusion: We designed and tested an EHR-integrated Treat to Target (T2T) tool that prompted rheumatologists about escalation/de-escalation opportunities and captured their medical decision making. Opportunities for escalation and de-escalation of therapy are common (34.2 % of RA visits), even in a well-managed RA population. Adoption of T2T tool use improved significantly with real-time visual notification. In parallel, decisions to escalate and de-escalate when opportunities existed also rose (10.2% to 45.5%, and 5.3% to 17.2%, respectively). Using this novel tool, the ability to reliably capture why escalation/de-escalation opportunities are deferred ("leave alone") will allow us to develop refined T2T care strategies. Now that it is embedded in routine RA care, next steps will be to use this tool to proactively drive value-concordant decision making and monitor the effect on disease control and cost of care.

Improving Pneumococcal Vaccination Rates in High Risk Rheumatology Patients

Heena Sheth ,[1] Grimes Vera,[2] Diana Rudge,[2] Gary Fischer,[2] Larry W. Moreland,[1] and Rohit Aggarwal[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]UPMC, Pittsburgh, [3]University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures of Healthcare Quality I: Digital Health Technologies – Tool for Improvement
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To improve Pneumococcal Vaccination rates in high risk Rheumatology patients on immunosuppressive therapy.

Methods: The study was a quality improvement project based on the pre-post-intervention design. The phase I of the project targeted all Rheumatoid Arthritis patients on immunosuppressive therapy for pneumovax vaccine (PV) seen in thirteen Rheumatology outpatient clinics (1/2013 to 7/2015). In the Phase II study (1/2015-10/2017) all Rheumatology patients on immunosuppressive medications irrespective of their diagnosis were intervened for pneumovax and prevnar vaccination as per current CDC guidelines. The electronic Best Practice Alert (BPA) for both PVs were developed with backend algorithm based on CDC guidelines. Based on patient eligibility checked electronically, the appropriate PV appeared on electronic medical records at the time of rooming of the eligible patient by the medical assistant. BPA was designed to inform the physician about vaccination status as well as enable physician to easily order PV or document refusal or deferral reasons (Figure 1). Education regarding vaccine guidelines, BPA, vaccination process, and regular feedback of results were important components of the project interventions. The vaccination rates during pre-post intervention phases during each study phase were compared using Chi square test.

Results: The PV rates reported as patients vaccinated among all eligible patients, improved significantly during both study phases. Phase I demonstrated 61.5% Pneumovax vaccination rate compared to pre-intervention rate of 27.9 % ($p < 0.0001$) (Figure 2). During Phase II 77% patients had received either pneumovax or prevnar compared to 49.6% patients in pre-intervention period ($p < 0.0001$) (Figure 3). The documentation rates (vaccine received, ordered, patient refusal and deferral reasons) also increased significantly in both phases.

Conclusion: Electronic identification of vaccine eligibility and implementation of BPA with capabilities to order and document reasons for non-compliance significantly improved PV rates. The process required minimal modification

Gaps in Care for Patients with SLE: Data from the ACR's RISE Registry

Gabriela Schmajuk ,[1] Zara Izadi,[2] Michael Evans,[3] and Jinoos Yazdany[4], [1]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA, [2]UCSF Division of Rheumatology, San Francisco, [3]University of California San Francisco, San Francisco, [4]UCSF Division of Rheumatology, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Measures of Healthcare Quality I: Digital Health Technologies – Tool for Improvement

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Although multiple national quality measures focus on the management and safety of rheumatoid arthritis, few measures address the care of patients with SLE. We used the ACR's RISE registry to assess na-

Table. Quality measures, number of eligible patients, and overall performance.

Quality measure	Number of patients eligible for the measure	Overall performance	Number of practices included in practice-level analysis†	25th-75th percentile practice-level performance
Proportion of patients with SLE with ≥1 documented urine study screening for lupus nephritis	22,171	26.2%	142	0 - 42.9%
Proportion of patients with SLE with ≥2 blood pressure readings recorded ≥30 days apart	22,171	90.3%	142	91.3 – 98.4%
Proportion of patients with SLE with blood pressure >140/90 mm Hg on ≥2 occasions ≥30 days apart	20,020	17.1%	131	8.1 – 24.7%
Proportion of patients with SLE prescribed ≥7.5 mg of prednisone (or equivalent) for > 90 days	22,171	14.9%	142	7.6 – 18.2%
Proportion of patients with SLE prescribed >6.5 mg/kg of hydroxychloroquine	2,176*	10.7%	35	5.6 – 14.4%

*Number of eligible patients, and therefore practices, is low because detailed HCQ prescription instructions could not be analyzed for many patients due to the unavailability of electronic prescription data.
† Practice-level analysis included only practices reporting on > 20 patients.

tionwide variations in SLE care around screening for renal disease; management of hypertension; medication safety related to prednisone and hydroxychloroquine (HCQ) use.

Methods: RISE is a national, EHR-enabled registry that passively collects data on all patients seen in participating practices, reducing the selection bias present in single-insurer claims databases. As of December 2017, RISE held validated data from 1,257 providers in 236 practices, representing ~36% of the U.S. clinical rheumatology workforce. Patients included this study were ≥18 years old and had ≥2 SLE codes ≥30 days apart between January 1 2017 and December 31 2017. Measures were assessed during this same period. We calculated 1) the proportion of patients with ≥1 documented urine study for screening for lupus nephritis (urinalysis; urine protein; or urine protein:creatinine ratio); 2) the proportion of patients with ≥2 blood pressure readings recorded ≥30 days apart; 3) the proportion of patients with systolic blood pressure >140 mm Hg or diastolic blood pressure > 90 mm Hg on ≥2 occasions, ≥30 days apart; 4) the proportion of patients prescribed ≥7.5 mg of prednisone (or equivalent) for > 90 days; 5) the proportion of patients prescribed >6.5 mg/kg of hydroxychloroquine. A practice-level analysis assessed performance on these measures among practices reporting on at least 20 patients. We also built a logistic regression model that included age, sex, race, insurance, and geographic region to assess independent predictors of performance on each measure.

Results: We included 22,171 unique patients from 142 practices; 92% were female, 51% white, with mean age 54±15. Additional characteristics of the SLE population included that 7,485 had at least 1 documented ANA (77.7% of these with titer > 1:40); 14,751 had at least 1 dsDNA Ab (46.4% of these with titer ≥ 1:40), and 9.7% had nephritis using ICD code definitions and 0.5% had ESRD. Performance on the proposed quality measures is shown in the Table: few patients had adequate screening for lupus nephritis. Although blood pressure screening was common, a meaningful fraction had untreated hypertension. Many were receiving long-term moderate-dose steroids, or excessive doses of hydroxychloroquine. Practice and regional variation were significant. Patients who were black were more likely to have uncontrolled hypertension (OR 1.79 (1.63, 1.97)) and high prednisone dosing (OR 1.35 (1.24, 1.49)) compared to whites.

Conclusion: Significant gaps in care exist for patients with SLE across the U.S. Although some performance variation may be explained by patient factors, dramatic differences suggest that developing quality measures to address these aspects of care in SLE may improve care.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Abstract Number: 1865

Improving Lupus Care Index Documentation in Patients with Childhood-Onset Systemic Lupus Erythematosus (cSLE)

Fatima Barbar-Smiley ,[1] Stephanie Lemle,[1] Cagri Yildirim-Toruner,[1] Edward Oberle,[1] Darby McDonald,[1] Vidya Sivaraman,[2] and Stacy Ardoin[1], [1]Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital and The Ohio State University, Columbus, OH

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Measures of Healthcare Quality I: Digital Health Technologies – Tool for Improvement

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) affects both adults and children with an estimated prevalence in children of 8/100,000. More than 1000 deaths related to SLE occur in a 5-year period, with most common causes attributed to active disease and organ failure. Adequate control of the disease reduces risk of organ damage, which is more common in children. Reliable measurement and documentation of disease activity is a key initial step for disease control. To achieve proper documentation of disease activity, our team developed a disease activity assessment tool called the Lupus Care Index (LCI). This index utilizes three existing metrics: SLE disease activity index (SLEDAI), Physician global assessment (PGA), and patient pain score. At our institution, we found that only one third of children diagnosed with SLE (cSLE) had proper documentation of all three components of LCI. We implemented a quality improvement (QI) project with aim to increase Lupus Care Index documentation, in children with SLE, from 38 % to 80%, by June 30, 2018.

Methods: We established a QI team including physicians, nurses, QI support staff. Patients with cSLE who received medical care in the pediatric rheumatology clinic from January 1, 2016 to November 31, 2016 were included in the baseline analysis. We excluded clinic visits scheduled for teaching purposes. Our process included a brainstorming session followed by development of a key driver diagram (Fig. 1). Our first PDSA cycle focused on establishing re-

Fig. 1

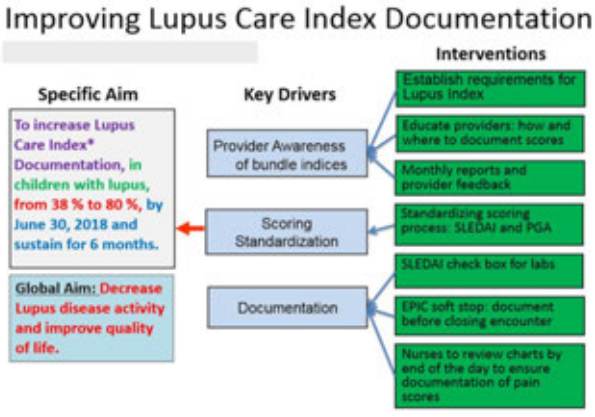

Figure 1. Key Driver Diagram (KDD)

Fig. 2

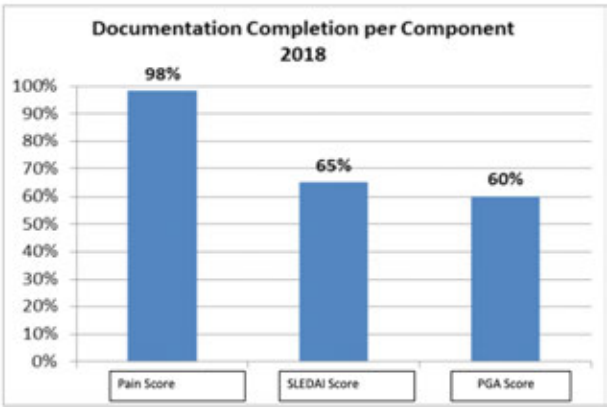

Figure 2. Pareto Chart

Fig. 3

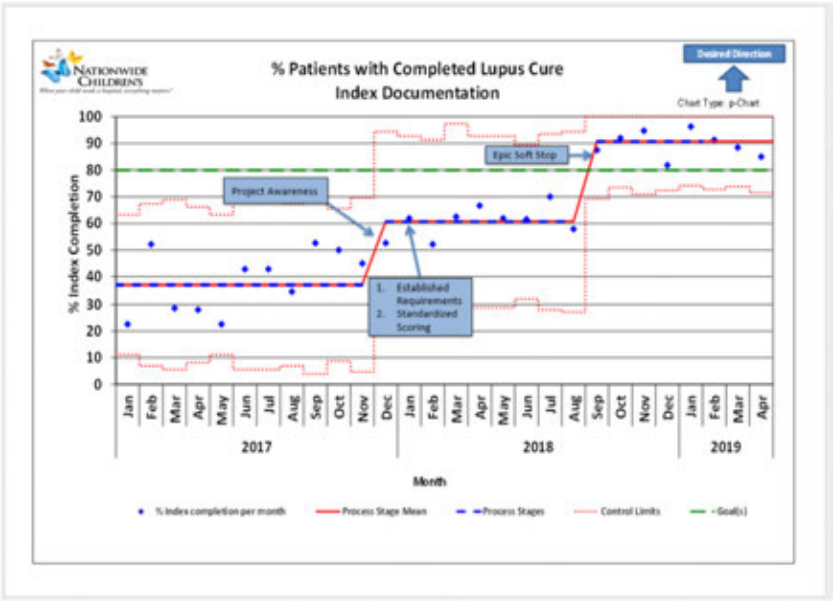

Figure 3. Control Chart

quirements for LCI and a team consensus for proper documentation. Next, we created a Pareto chart to assist with a targeted intervention approach focusing on least documented indices (Fig. 2). We ran monthly reports and provided timely feedback to providers, and developed EHR (electronic health medical record; EPIC) “soft stop” reminders for physicians to document disease activity prior to closing clinic encounters. We utilized control charts to show the monthly percentage of c-SLE patients who had complete documentation of all three components of LCI (Fig. 3).

Results: We noted initial improvement trend in documentation with project awareness, score standardization, and provider level monthly feedback. However, we were able to achieve and surpass our goal of 80% in Aug 2018 after establishing the EHR soft stop reminder. We have sustained the desired improvement for 8 months.

Conclusion: The results of this quality improvement initiative highlight the role of EHR reminders along with provider feedback and transparency in promoting quality of health care delivery. Future directions of this project aim at utilizing the documented disease activity indices to reduce disease activity and improve patient disease outcomes.

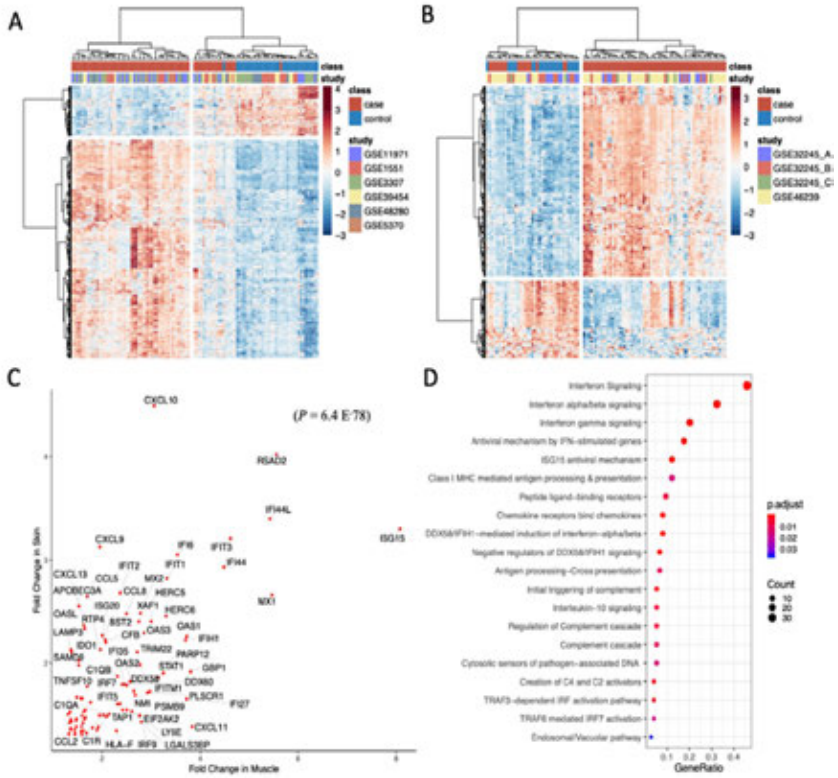
Gene Expression Meta-Analysis Reveals Commonalities in Gene Activation and Enrichment of Immune Pathways and Cell Types in Dermatomyositis Target Tissues

Jessica Neely ,[1] Dmitry Rychkov,[1] Manish Paranjpe,[1] Michael Waterfield,[2] Susan Kim,[1] and Marina Sirota[2], [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

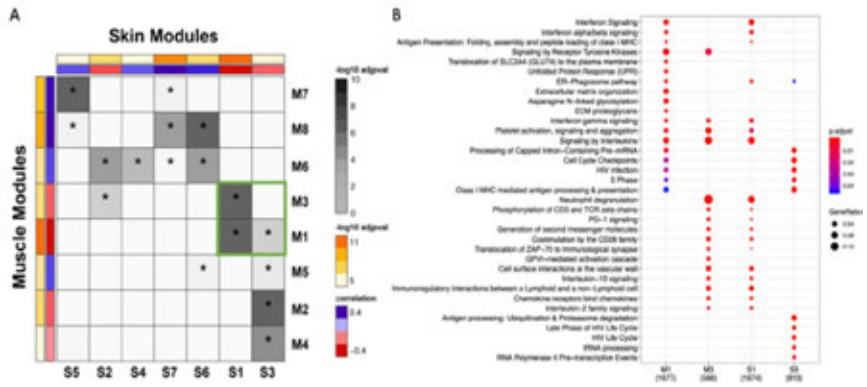
Background/Purpose: Dermatomyositis (DM) is a complex immune-mediated disease resulting in muscle and skin inflammation. Prior studies of gene expression in DM have revealed a type I interferon (IFN) signature, but less is known about alternative immune pathways involved. We conducted a comprehensive gene expression meta-analysis in DM muscle and skin to identify disease-relevant genes and pathways and elucidate a shared immune mechanism across tissues.

Figure 1



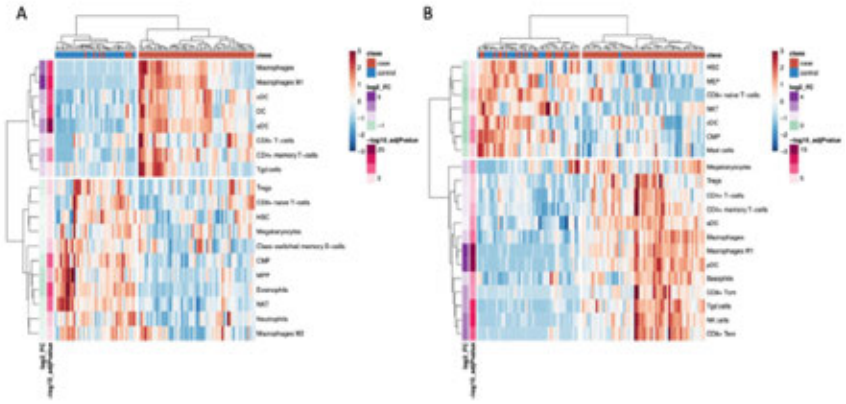
Heatmaps of differentially expressed genes (DEG) identified by SAM in muscle (A) and skin (B) using cut off of FDR p-value <0.05 and FC≥ 1.3. Hierarchical clustering demonstrates clustering of cases and controls and that the majority of DEGs in both tissues are up-regulated. C) Gene symbols of 94 overlapping differentially expressed genes plotted by fold change in muscle and skin. D) Enrichment of 94 overlapping genes by over-representation analysis using the Reactome Database. P-values are calculated using a hypergeometric distribution and corrected for multiple comparisons by the Benjamini Hochberg method.

Figure 2



A) Heatmap demonstrating hierarchical clustering of significant modules identified by WGCNA in each tissue based on gene overlap. Correlation between module eigengene and disease status is shown by the red to blue bar where red represents modules most positively-correlated with cases and blue represents modules negatively-correlated with cases. The color corresponds to a signed p-value: sign(correlation) * -log10(FDR p value). The -log10 adjusted p-value of this correlation is indicated by the yellow to orange bar. The degree of pairwise overlap in genes between muscle modules and skin modules computed using a hypergeometric test is denoted by grey coloring where modules with significant overlap in genes ($p < 0.05$) are denoted by an asterisk and the color range corresponds to –log10(pvalue) of the pairwise overlap. B) Plot showing over-representation analysis of pathways from the Reactome database across a cluster of highly overlapping and interesting modules (green box in pane A) in each tissue demonstrating enrichment of shared pathways across tissues.

Figure 3



Heatmaps of cell-type enrichment calculated using xCell demonstrates clustering of cases and controls based on cell types in both muscle (A) and skin (B). Enrichment was strongest for dendritic cells and M1 macrophages in both tissues.

Methods: Raw data from 6 publicly available datasets from DM muscle (71 cases, 36 controls) and 2 from skin (77 cases, 22 controls) were downloaded. Data were preprocessed, merged and batch-corrected, creating tissue-specific gene expression matrices. Significance Analysis of Microarrays was used to identify differentially expressed genes (DEG; cutoff FDR p-value < 0.05, FC≧1.3). A hypergeometric test was used to assess overlap between DEGs in skin and muscle. Weighted Gene Coexpression Network Analysis was used to construct muscle and skin networks and identify associations not detected on the single gene level. Disease-associated modules were identified by correlating module eigengene with case/control status. Network preservation was assessed by calculating gene overlap between muscle and skin modules using a hypergeometric test. Hub genes (gene significance >0.2 & module membership >0.8) in each network were identified. Cell type enrichment was performed using xCell.

Results: There were 544 significantly DEGs (FC≧1.3, q< 0.05) in muscle and 300 in skin (Fig 1A & 1B). There was significant overlap in upregulated genes across tissues with 94 shared genes (p=6.4xE-78) which were enriched in type I and II IFN signaling and MHC class I antigen processing pathways (Fig 1C & 1D). In a network analysis, we identified 8 significant muscle modules and 7 skin modules either positively or negatively correlated with case/control status (Fig 2A). Modules that were highly correlated with cases also shared significant overlap on the gene level (Fig 2A). These modules were enriched in pathways consistent with the single gene analysis and also in terms related to T cell activation and T cell receptor signaling (Fig 2B). Modules correlated with controls were enriched in processes related to energy metabolism. The top hub genes in each network included genes classically involved in type I IFN (STAT1, MX1, IFI44, ISG15), type II IFN (CXCL10, GBP1), class I MHC antigen processing (HLA-A, -B, -F, B2M, TAP1) and the immunoproteasome (PSMB8, PSMB9). In the cell type enrichment analysis, both tissues were enriched in antigen-presenting cells, including activated dendritic cells and M1 macrophages (Fig 3A & 3B).

Conclusion: This analysis demonstrates striking similarities in gene expression in target tissues in DM and simultaneous activation of innate and adaptive immune responses. Using an unbiased approach, we show enrichment of type I and type II IFN pathways, MHC class I antigen processing pathways, T cell activation, and antigen-presenting cells. These results suggest type II IFN contributes to the global IFN signature in DM and that altered autoantigen presentation through the class I MHC pathway may be important in disease pathogenesis.

Body Composition in Myositis Patients Is Negatively Changed Compared to Healthy Controls and the Changes Are Associated with Disease Activity and Duration, Skeletal Muscle Involvement and Physical Activity and Nutritional Status

Sabina Oreska ,[1] Maja Spiritovic,[2] Petr Cesak,[3] Ondrej Marecek,[3] Hana Storkanova,[4] Barbora Hermankova,[3] Katerina Kubinova,[5] Martin Klein,[4] Lucia Vernerová,[4] Olga Ruzickova,[4] Karel Pavelka,[1] Ladislav Senolt,[1] Herman Mann,[1] Jiří Vencovský,[1] and Michal Tomcik[1], [1]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2, Czech Republic, [2]Faculty of Physical Education and Sport, Department of Physiotherapy, Charles University, Prague, Czech Republic, Prague 2, Hlavni mesto Praha, Czech Republic, [3]Faculty of Physical Education and Sport, Department of Physiotherapy, Charles University, Prague, Czech Republic, Prague, Czech Republic, [4]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague, Czech Republic, [5]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Muscle Biology, Myositis & Myopathies I

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Skeletal muscle, pulmonary and articular involvement in idiopathic inflammatory myopathies (IIM) limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition. The aim of this study was to assess body composition and physical activity of IIM patients and healthy controls (HC) and the association with chosen inflammatory cytokines/chemokines and laboratory markers of nutrition and lipid metabolism.

Table 1: Body composition in IIM and HC.			
Parameters	**IIM (n=54)**	**HC (n=54)**	**p-value**
BF% (Body Fat %) (iDXA)	42.4±7.1	39.9±7.1	0.077
LBM (Lean Body Mass) (kg, iDXA)	40.6±7.2	45.6±8.1	0.001
LBM (Lean Body Mass) (kg, BIA)	48.7±9.0	52.6±8.8	0.023
ECM/BCM (Extracellular Mass/Body Cell Mass ratio)	1.44±0.42	1.06±0.15	<0.001
BMD (Bone Mineral Density) (g/cm^2)	1.1±0.1	1.2±0.1	<0.001

Table 2: Correlation of body composition parameters and clinical features of IIM: disease duration and activity, inflammation, muscle involvement, physical ability.		
Correlated parameters	**r**	**p-value**
BMD (Bone Mineral Density) (g/cm^2): Disease duration	-0.392	0.004

LBM (Lean Body Mass) (kg, iDXA): MITAX; MYOACT	0.341; 0.368	0.012; 0.007
BMR (Basal Metabolic Rate) (kcal): MITAX; MYOACT	0.336; 0.351	0.014; 0.010
FFM (Fat Free Mass) (kg): MITAX; MYOACT	0.338; 0.356	0.014; 0.009
BF% (iDXA); BF% (BIA): CRP (C-reactive protein) (mg/L)	0.276; 0.306	0.035; 0.025
ECM/BCM: MMT-8 (Manual Muscle Testing-8)	-0.385	0.006
BF% (iDXA): FI-2 (Function Index-2)	-0.311	0.026
BF% (iDXA): HAP (Human Activity Profile)	-0.292	0.032

Methods: 54 patients with IIM (45 females; mean age 57.7; disease duration 5.8 years; polymyositis (PM, 22) / dermatomyositis (DM, 25) / necrotizing myopathy (IMNM, 7)) and 54 age-/sex-matched HC (45 females, mean age 57.7) without rheumatic/tumor diseases were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. We assessed body composition (densitometry: iDXA Lunar, bioelectric impedance: BIA2000-M), physical activity (Human Activity Profile (HAP) questionnaire, serum levels of 27 cytokines/chemokines (commercial multiplex ELISA kit, Bio-Rad Laboratories) and serum levels of chosen parameters of nutrition and lipidogram. Disease activity (MITAX and MYOACT activity score) and muscle involvement (manual muscle test, MMT-8, and functional index 2, FI2) were evaluated. Data are presented as mean±SD.

Results: Compared to HC, patients with IIM had a trend towards significantly increased body fat % (BF%) as assessed by iDXA, but significantly decreased lean body mass (LBM) as assessed both by iDXA and BIA, and increased extracellular mass/body cell mass (ECM/BCM) ratio reflecting worse muscle predispositions for physical exercise, aerobic fitness/performance, and deteriorated nutritional status. Compared to HC, IIM patients had significantly lower bone mineral density (BMD) (Table 1). Disease duration negatively correlated with BMD and LBM-BIA. Disease activity assessed by both MITAX and MYOACT positively correlated with LBM (by BIA and iDXA), similarly as with basal metabolic rate (BMR) and fat free mass (FFM). CRP was positively associated with BF% (by iDXA and BIA). Higher BF%-iDXA was associated with worse physical endurance (Function Index-2, FI-2) and worse ability to perform physical activity (HAP). MMT-8 score negatively correlated with ECM/BCM ratio (Table 2). Serum levels of several inflammatory cytokines/chemokines (Table 3) and markers of nutrition and lipid metabolism were associated with alterations of body composition (Table 4 and 5).

Conclusion: Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease activity and duration, inflammatory status,

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Juvenile dermatomyositis (JDM) is an inflammatory myopathy characterized by prominent vascular and perivascular inflammation in affected skeletal muscles. The mechanisms of vessel injury in JDM remain unknown. Anti-endothelial cell antibodies (AECA) are frequently detected in inflammatory, infectious, and autoimmune diseases. We hypothesized that autoimmunity to blood vessel antigens may play a role in the pathology of JDM. We therefore, used proteomic approaches to identify target antigens for AECA in plasma from patients with JDM.

Methods: Proteins extracted from human aortic endothelial cells (HAEC) were separated by two-dimensional electrophoresis and transferred onto membranes. Western blotting using plasma from JDM and healthy controls was performed to detect antigens that were positive in JDM plasma, but not in healthy controls. Finally, the detected proteins were identified by peptide mass finger-printing. We next used ELISA assays to corroborate the mass spectrometry data, using plasma samples from 63 patients with JDM, 50 patients with polyarticular juvenile idiopathic arthritis (JIA) and 40 sex- and age-matched healthy controls. Nineteen patients with Kawasaki disease (KD) and 18 additional sex- and age-matched healthy controls were also used for ELISA assays. The differences in antibody levels and the frequency of autoantibodies between the groups were compared by Mann-Whitney U test and by Fisher's exact test, respectively. P values were determined with a two-tailed tests.

Results: Twenty-two proteins were identified as candidate targets of AECA in plasma from JDM patients. Among these antigens were molecular chaperones such as heat shock cognate 71 kDa protein (HSC70). On ELISA assays,

we found significant differences (p< 0.0001) in mean OD ± SD for autoantibodies against HSC70 when children with JDM were compared to healthy controls, and to children with JIA and KD. Autoantibodies to HSC70 were detected in 35% of patients with JDM, in 0% of healthy donors (P< 0.0001), 0% of patients with JIA (P< 0.0001), and 0% of patients with KD (P=0.002). The presence of autoantibodies against HSC70 correlated with the presence of other previously described myositis-associated autoantibodies (MAA). For example, antibodies against NT5C1A and Ro52 were more frequent in patients with autoantibodies against HSC70 than with these MAAs alone (69% vs. 29%, P=0.013 and 43% vs. 15%, P=0.027). The presence of skin ulcers was associated with autoantibodies against HSC70 (59% vs. 17%, P=0.0014). Use of wheelchairs and/or devices was associated with HSC70 autoantibodies (64% vs. 27%, P=0.007). We found significant differences (P=0.019) in mean serum levels of aspartate aminotransferase (AST) in JDM children with (32 ± 15 U/L) vs. without (25 ± 16 U/L) autoantibodies against HSC70.

Conclusion: Autoantibodies to HSC70 in the proteome of HAEC are present in the plasma of patients with JDM, implying that AECA may be involved in the pathophysiology of autoimmune inflammation of blood vessels in JDM. Larger studies will be required to determine the clinical utility of monitoring for these autoantibodies.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Dermatomyositis (DM) is an autoimmune disease affecting the skin, skeletal muscle, lungs, and/or other organs. While the pathogenesis remains poorly understood, it is thought to be driven largely by type 1 interferons (IFN-β) and involve CD4+ cells and dendritic cells. Plasmacytoid dendritic cells (pDCs) are considered major producers of type 1 interferons. Our objectives were as follows: 1) to quantify inflammatory cells and Type 1 IFN expression in skin and correlate with the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) skin activity score, 2) to identify cells contributing to refractoriness to hydroxychloroquine (HCQ), 3) to identify the major dendritic cell type producing IFN-β in DM.

Methods: In Aim 1, we evaluated lesional skin biopsies from 12 patients with moderate-severe cutaneous DM at baseline and from a nearby skin site after 12 weeks of treatment with lenabasum or placebo added to stable standard of care. Immunohistochemistry (IHC) was performed to assess expression of Type 1 IFN and various cell types [CD4+,

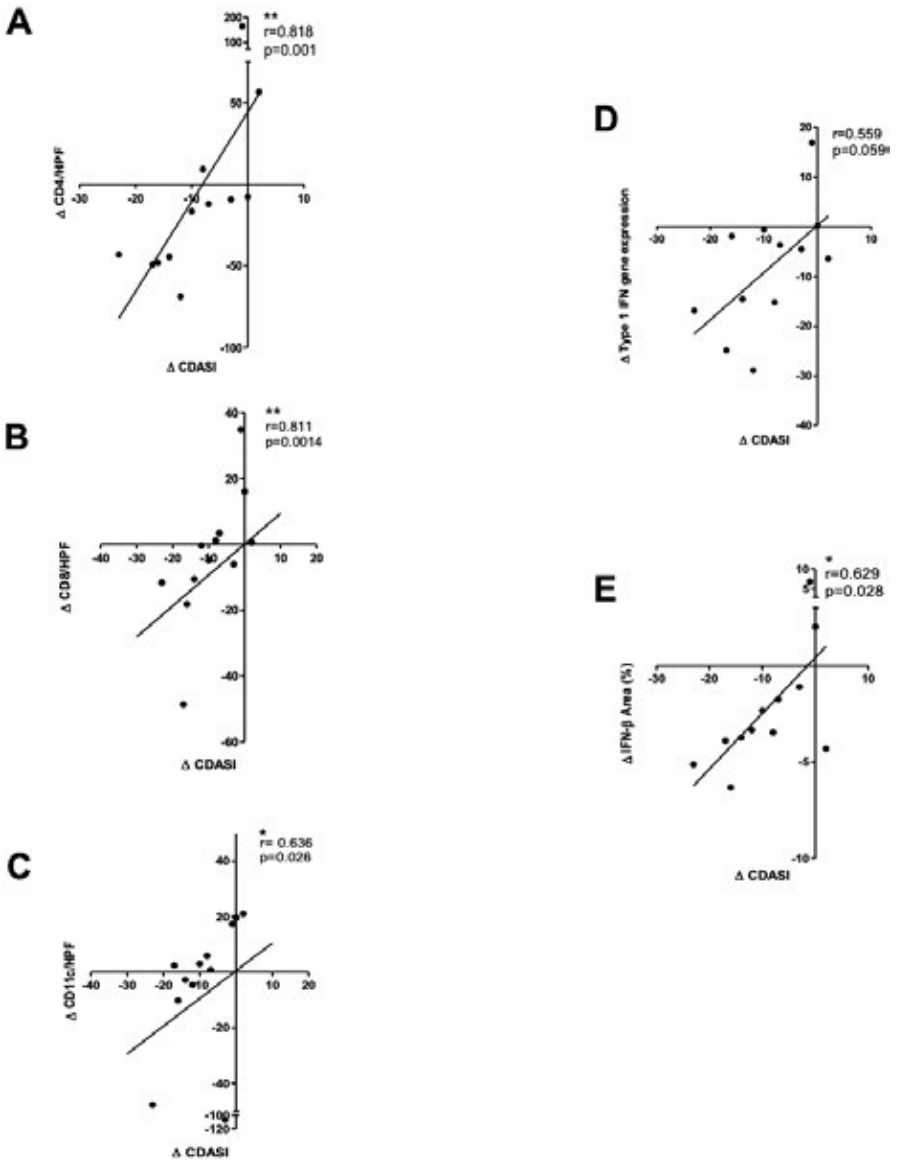

Figure 1. Change in CD4+/HPF, CD8+/HPF, and CD11c+/HPF significantly correlate with change in CDASI ($p < 0.05$). Change in Type 1 IFN gene expression and change in IFN-bβ protein expression correlate with change in CDASI.

macrophages, mDC (CD11c+), tissue-resident memory T (T_{RM}) cells (CD69+), CD8+, mast cells, and pDC (CD123+)] and relationship with CDASI activity scores. RT-PCR was performed to measure Type 1 IFN gene expression. In Aim 2, HCQ responders and HCQ nonresponders were identified from a longitudinal DM database where responsiveness to HCQ was defined as sufficient improvement in skin lesions so that further escalation of therapy was not needed. IHC was performed on lesional skin biopsies to compare mDC and pDC expression. In Aim 3, flow cytometry was performed on PBMCs from 5 healthy controls and 5 DM patients to identify whether mDCs or pDCs were predominant producers of IFN-β in the two study populations. PBMCs were stimulated with Resiquimod (R848). Analysis was performed using FlowJo software. Statistical analysis included the Spearman rank correlation test and the Mann-Whitney test.

Results: In Aim 1, we found CD4+, macrophages, mDCs, and T_{RM} cells were the most populous cells in DM lesional skin, followed by CD8+ cells, mast cells, and pDCs. Change in CD4+ cells/HPF, CD8+ cells/HPF, and mDCs/HPF significantly correlated with change in CDASI scores ($r = 0.818$, $p = 0.001$; $r = 0.811$, $p = 0.001$; $r = 0.636$, $p = 0.026$, respectively) (Fig. 1). Change in Type 1 IFN gene expression correlated with change in CDASI score ($r = 0.559$, p

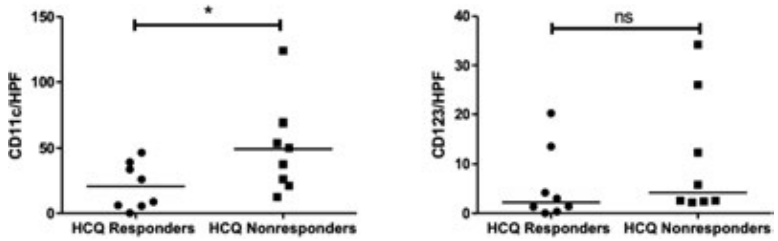

Figure 2. HCQ nonresponders have significantly more mDC (CD11c+)/HPF compared to HCQ responders ($p < 0.05$). There is no significant difference in pDC (CD123+)/HPF between HCQ responders and nonresponders.

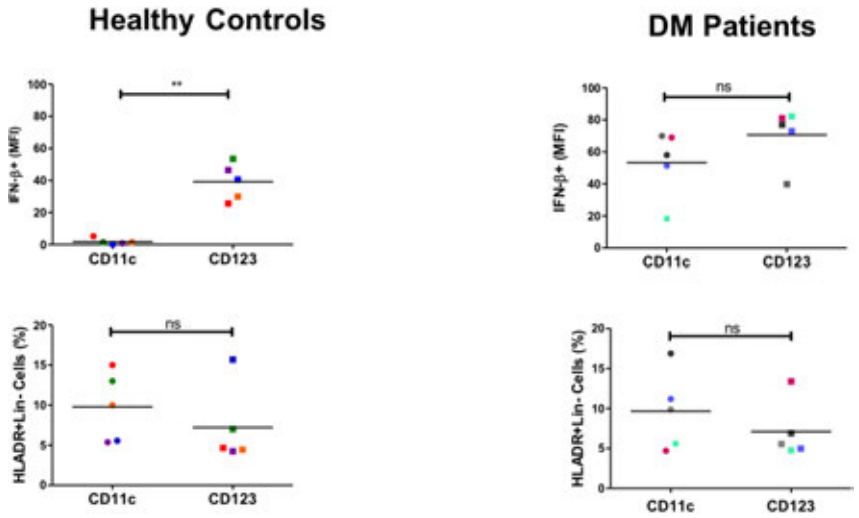

Figure 3. IFN-b β is produced by both mDCs (CD11c+)/HPF and pDCs (CD123+)/HPF in DM patients. IFN-bβ is produced predominantly by pDCs (CD123+)/HPF in healthy controls.

= 0.059) as did change in IFN-β protein expression ($r = 0.629$, $p = 0.028$) (Fig. 1). In Aim 2, significantly increased numbers of mDCs/HPF were found in skin of HCQ nonresponders ($p < 0.05$) (Fig. 2). In Aim 3, we found both mDCs and pDCs were major producers of IFN-β in DM patients; there was no significant difference in IFN-β production between the 2 cell types (Fig. 3). In contrast, in PBMCs from healthy controls, pDCs produced significantly more IFN-β compared to mDCs ($p < 0.01$) (Fig. 3). There was no significant different in percentage of mDCs vs. pDCs in healthy controls or DM patients (Fig. 3).

Conclusion: mDCs appear to play a significant role in DM pathogenesis. mDCs are major producers of IFN-β in DM patients but not in healthy controls. Increased numbers of mDCs are found in HCQ nonresponders.

Session Title: Muscle Biology, Myositis & Myopathies I

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

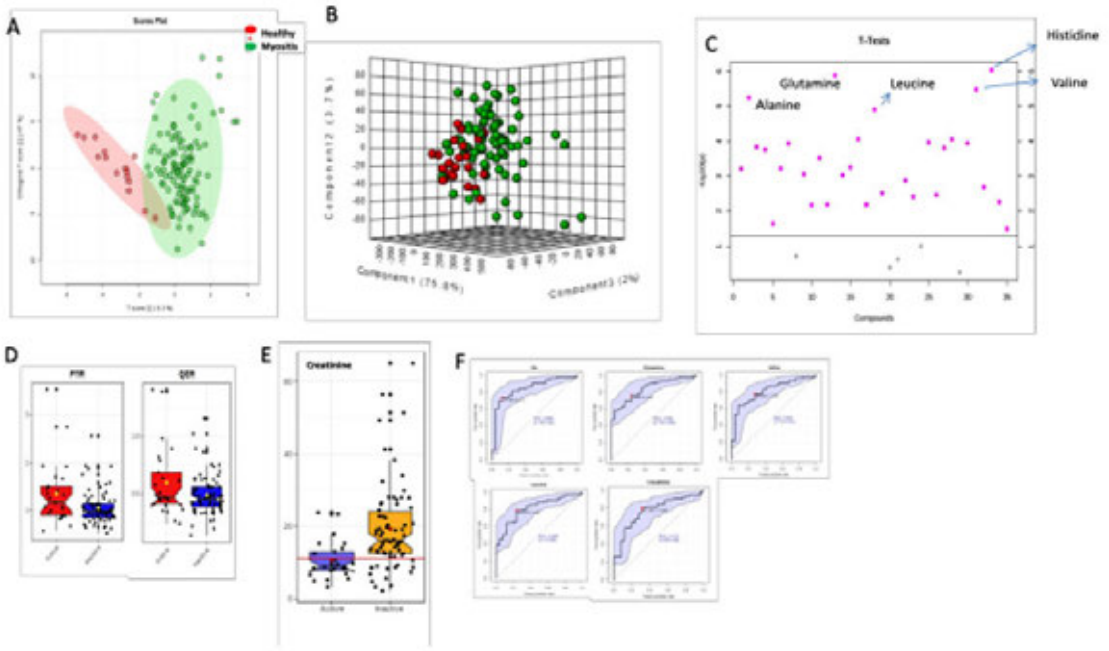

Figure 1: Serum metabolomics

(A) 3D score plot obtained from PCA analysis of 1D ^{1}H CPMG NMR based serum metabolic profiles showing clustering and separation between Healthy control and inflammatory myositis patients **(B)** 2D score plot after PCA analysis of sera from myositis patients with active and inactive disease **(C)** screening of metabolites responsible for the group separation in the score plot identified based on variable importance in projection (VIP) score > 2.0 **(D)** VIP projection suggesting elevated phenylalanine-to-tyrosine ratio (PTR) and Glutamate to Glutamine ration (EQR) **(E)** VIP projection suggesting creatinine is significantly decreased in the sera of active myositis patients **(F)** representative ROC curves of discriminatory metabolites

Background/Purpose: Differentiating smouldering disease activity from weakness due to fatty replacement of atrophied muscle can often be a challenge in Idiopathic Inflammatory Myositis (IIM). There is dearth of biomarkers that can distinguish active from inactive myositis.

To identify changes in metabolomics profiles in serum, urine and muscle of patients with myositis with active and inactive disease. Since we have previously found exquisite separation between paired serum samples obtained in fasting and non-fasting state, only sera collected in fasting state were taken for analysis.

Methods: Sera (n=116), urine (n=114) and muscle (n=11) from patients classifiable as myositis by the ACR-EULAR criteria [34 years (23.5 - 50.5 IQR), M/F 28:88] were compared with healthy controls [n=18 and 12 respectively, age= 44 (35-50) years, M/F-8:10]. For the muscle biopsies, two disease controls were used for comparison. To study effect of fasting state on urine metabolomics, 50 paired urine samples obtained in fasting and non-fasting states were analysed. Metabolic profiles were obtained at 800 MHZ NMR spectrometer and compared using multivariate partial least-squares discriminant analysis (PLS-DA). The discriminatory metabolites were identified based on variable importance in projection (VIP) statistics and further evaluated for statistical significance (p-value < 0.05). Paired T tests were done for metabolites in urine and muscle after normalizing for creatinine. MDAAT >=1 was used to define active myositis.

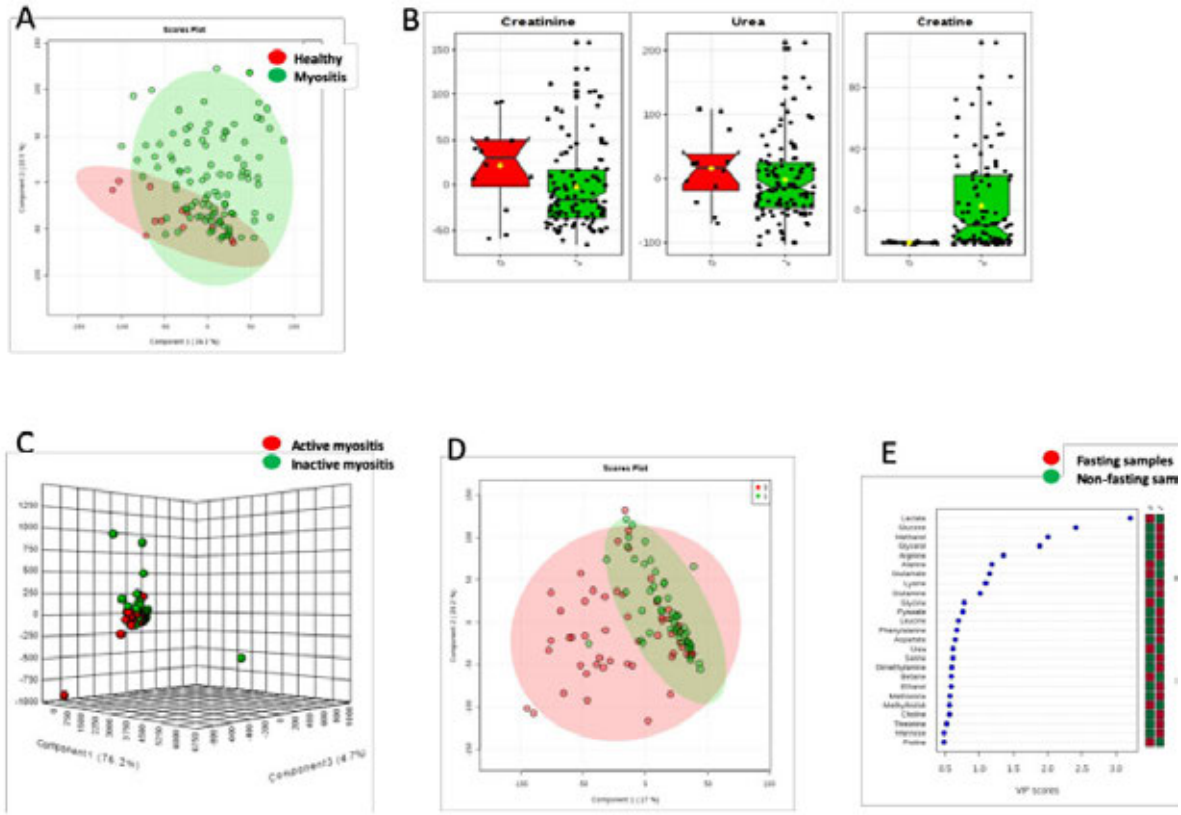

Figure 2: Urine Metabolomics
A) 3D score plot obtained from PCA analysis of 1D ^{1}H CPMG NMR based urine metabolic profiles showing clustering and separation between healthy control and inflammatory myositis patients **(B)** VIP projection suggesting elevated creatinine, and low urea and creatine in myositis versus healthy controls. **(C)** PCA suggests no differential clustering between active and inactive myositis. **(D)** In urine, paired samples obtained in fasting versus non-fasting state were fairly similar, **(E)** apart from differences in Creatine and Creatinine.

Results: Metabolomics profiles in IIM were distinct from healthy controls (Fig. 1A). Sera of patients with active myositis exhibited differential clustering from those with inactive myositis (Fig. 1B) with lower amino-acid metabolites (Fig. 1C) elevated phenylalanine-to-tyrosine ratio and glutamate to glutamine ratio (Fig. 1D) and low creatinine (Fig. 1E) with significant discriminatory potential (Fig. 1F). Urine of myositis patients exhibited higher creatine and lower urea and creatine than healthy controls (Fig. 1A, B). However, urine metabolomics exhibited similar clustering in active and inactive disease (Fig. 1C). In urine, paired samples in fasting and non-fasting state exhibited overlapping clustering (Fig. 1D) apart from higher creatine and creatinine (Fig. 1E) . Muscle of patients with inflammatory myositis exhibited almost absent levels of sucrose, mannose, uridine, histamine, inosineand carnitine compared with infection associated myositis.

Conclusion: Serum and urine metabolomics of myositis is distinctive. Serum metabolomic profiling using NMR has the potential to discriminate active from inactive myositis patients though urine metabolomics is largely non-contributory. Muscle metabolites holds potential to distinguish inflammatory myositis from infectious polymyositis.

Myositis-Specific Antibodies and Muscle Histopathology in Juvenile Dermatomyositis: New Insights into the Mechanism of Injury

MaiLan Nguyen ,[1] Vy Do,[1] Paul Yell,[1] Chanhee Jo,[2] Jie Liu,[2] Tracey Wright,[3] and Chunyu Cai[1], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Texas Scottish Rite Hospital for Children, Dallas, TX, [3]University of Texas Southwestern, Texas Scottish Rite Hospital for Children, Children's Health, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies I
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Myositis-specific antibodies (MSAs) are identified in over half of children with JDM and are associated with distinct clinical phenotypes. MSA subtype, in combination with clinical or muscle histopathology findings, may have prognostic value and implications for disease monitoring and treatment. The aim of this study is to define the relationships between MSAs and muscle histopathology as well as clinical markers of disease activity in children with JDM.

Methods: A retrospective chart review of subjects with JDM followed in the pediatric rheumatology clinic at a single center between October 2016 and November 2018 was performed. Markers of JDM disease activity, including muscle enzymes (creatine kinase (CK), aldolase, lactate dehydrogenase, aspartate aminotransferase, and alanine transaminase) and other clinical data were obtained at the initial visit and at 6 months. MSA serum levels were measured at a single point during the disease course. Muscle biopsy samples, routinely obtained at diagnosis, were reviewed and scored independently by 2 neuropathologists using a visual analog scale. Mann-Whitney tests were conducted to detect differences between the most prevalent MSA subtypes. Pearson correlation coefficient (r) was conducted to analyze the correlation between MSA subtype and CK.

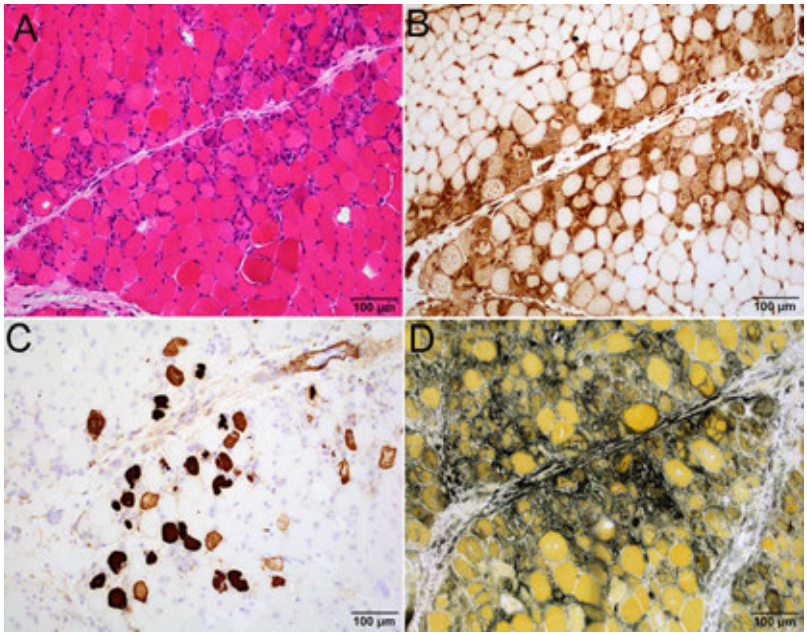

Figure 1. Twelve-year-old female with high anti-Mi-2 serum titer; quadriceps muscle shows prominent perifascicular necrotizing myopathy. (A) H&E shows abundant necrotic and regenerating fibers concentrated in perifascicular region. (B) MHC-1 is upregulated in perifascicular myofibers. (C) C5b-9 highlights necrotic fibers. There is no significant capillary deposition. (D) Alkaline phosphatase shows strong reactivity in regenerating fibers as well as in perimysial and endomysial connective tissue.

Results: Out of the 43 subjects in the study, 26 (60.5%) had a detectable MSA. The most common MSAs were anti-NXP-2 (13, 30.2%), anti-Mi-2 (7, 16.3%), and anti-MDA-5 (5, 11.6%). Other MSAs detected included anti-SRP, anti-Tif-1g, anti-OJ, and anti-PL-7.

Subjects with high titer anti-Mi-2 had more widespread perifascicular myofiber damage and perifascicular necrotizing myopathy (Figure 1). Subjects with high titer anti-NXP-2 had more prominent capillary C5b-9 deposition, indicative of vascular injury, and myofibers showed perifascicular atrophy and/or focal infarct but minimal perifascicular myofiber necrosis (Figure 2). All subjects with anti-MDA-5 had normal CK and normal muscle histology, consistent with previous reports of amyopathic or hypomyopathic disease. The subject with anti-PL-7 showed perifascicular necrotizing myopathy with diffuse MHC-1 upregulation on histopathology, consistent with the pattern seen in antisynthetase syndrome.

High titer anti-Mi-2 correlates with serum CK > 10,000 ($r=0.96$, $p=0.002$) (Figure 3). With the exception of a subject with anti-PL-7, no other MSA subtypes had a CK > 5000 at the initial visit. Anti-Mi-2 had a higher CK at initial visit compared to anti-NXP-2 ($p=0.04$) and anti-MDA-5 ($p=0.05$). In general, anti-Mi-2 was significantly associated with higher muscle enzymes, except for aldolase. There is no correlation between anti-NXP-2 titer and CK ($r=-0.21$, $p=0.49$) (Figure 3).

Conclusion: The mechanism of injury for patients with JDM differs based on MSA subtype: anti-Mi-2 is associated with direct myofiber damage; anti-NXP-2 is associated with vascular injury; and anti-MDA-5 is associated with minimal to no muscle injury. Serum CK, a clinical marker of disease activity, varies based on MSA subtype: anti-Mi-2 titer correlates with serum CK; anti-NXP-2 titer does not correlate with serum CK; and anti-MDA-5 is associated with normal serum CK.

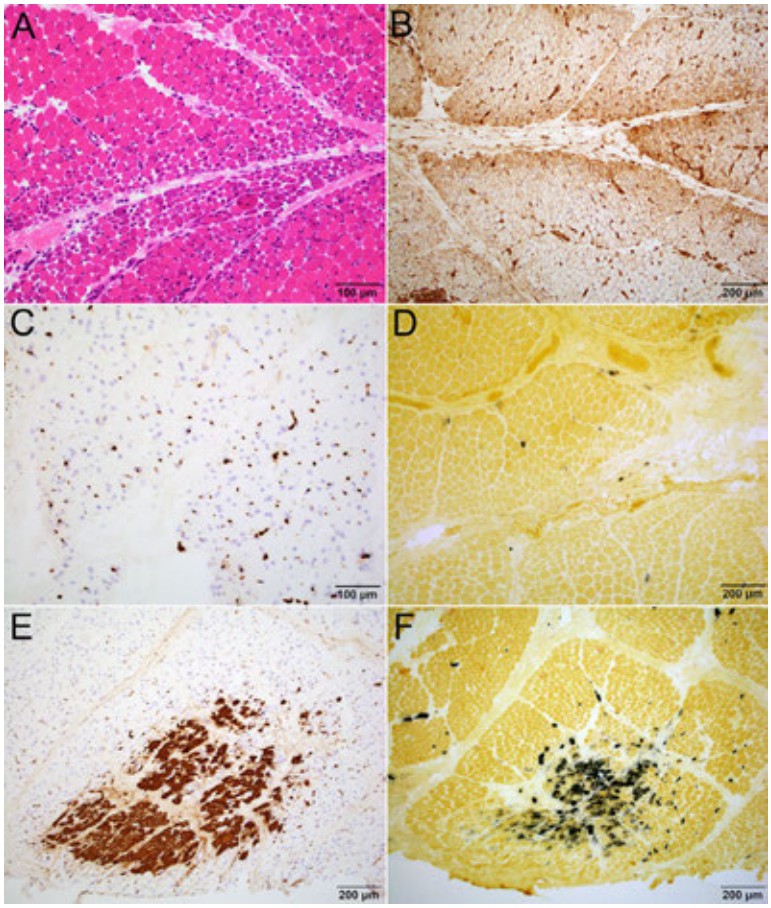

Figure 2. Two-year-old female with high anti-NXP-2 serum titer; thigh muscle shows prominent perifascicular atrophy, capillary C5b-9 deposition, and infarct. (A) H&E shows prominent perifascicular atrophy without significant myofiber necrosis. (B) MHC-1 is upregulated in perifascicular myofibers. (C) C5b-9 shows prominent capillary C5b-9 deposition. (D) Alkaline phosphatase shows no regenerating fibers or connective tissue reactivity. (E-F) Focal area of infarction is highlighted by C5b-9 stain (E) and alkaline phosphatase (F). The area of infarct is located in the center of a fascicle, and is composed of back-to-back, rather than scattered, necrotic fibers.

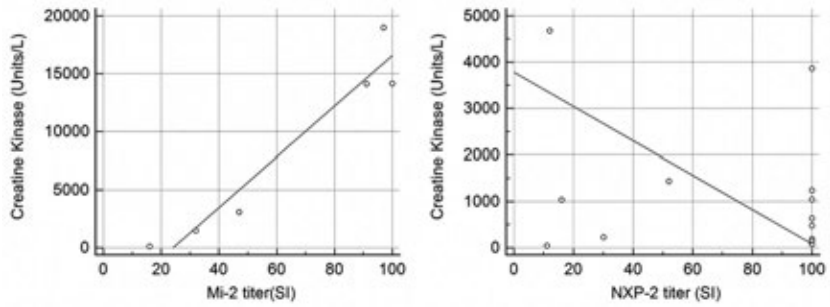

Figure 3. (left) Anti-Mi-2 titer strongly correlates with serum CK (r=0.96; p=0.002) and degree of myofiber damage. (right) Anti-NXP-2 titer does not correlate with serum CK (r=-0.21; p=0.49).

Worsening Trends in Osteoporosis Management in the Medicare Population: 2010-2014

Jeffrey Curtis ,[1] Shanette G. Daigle,[2] Setareh A. Williams,[3] Richard Weiss,[3] Yamei Wang,[4] and Tarun Arora[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]Radius Health, Inc, Waltham, [4]Radius Health, Inc, Waltham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Osteoporotic fractures are an important public health burden, and with an increasing aging population, the number of Americans at risk of fractures is projected to increase 33% by 2030. The objective of this study was to evaluate osteoporosis management in Medicare enrollees.

Methods: This study included Medicare fee-for-service (FFS) members with a closed fragility (or osteoporosis-related) fracture between 01/01/2010-12/31/2014. Cohort characteristics were computed yearly for 2010-2014 in order to examine secular trends in osteoporosis management. Inclusion criteria for cohort eligibility was age ≥65 at index date, continuous enrollment in Medicare FFS with medical and pharmacy benefits for ≥1 year before index date. Patients with Paget's disease or malignancy (except non-melanoma skin cancer) at baseline were excluded.

Results: Of 18,936,386 beneficiaries, 885,676 had fracture(s) and met eligibility criteria. Average age was 80.5(±8.4) years, 90.9% were white, and 93.8% female. Over half of patients in each yearly cohort had a comorbidity or a medication that increased fall risk, with approximately 50% of patients using opioids. Despite increased fall risk, osteoporosis diagnosis, screening, and treatment rates at baseline were low and decreased from 2010-2014: DXA: 25%, 24%, 23%, 22%,16%; diagnosis: 7%, 6%, 6%, 5%, 4%; treatment: 29%, 24%, 20%, 16%, 11%. A trend toward lower OP diagnosis and treatment utilization over time was observed.

Conclusion: These findings suggest continued and perhaps worsening osteoporotic fracture management over time. Opportunities exist to better identify and treat patients who have an increased risk of fracture.

Geisinger HiROC Performance 2017-2018: Continuing to Narrow the Post-Fracture Treatment Gap

Thomas Olenginski ,[1] and Karen Mackiewicz[2], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger, Danville, PA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: The morbidity and mortality of osteoporotic fractures threaten our aging population. Despite advances in new therapies for osteoporosis and technology to more effectively communicate, fewer than 20 % of patients who break a bone will receive a medical evaluation and/or treatment for osteoporosis. Since 2008, Geisinger has operated a Fracture Liaison Service (FLS) termed HiROC (High-Risk Osteoporosis Clinic). Descriptions of our program and performance have been published (References 1,2,3). We report our 2017-2018 performance and summarize a decade of successful FLS care.

Methods: All inpatient HiROC fracture consultations seen by Rheumatology at Geisinger Medical Center-Danville or Geisinger Wyoming Valley- Wilkes Barre from 1/1/2017 through 12/31/2018 were identified in our database. An excel spreadsheet was constructed and the following demographic and clinical variables were extracted: mean age; sex; fracture site; Geisinger Health Plan (GHP) insurance (%); early death (up to 6 months post-fracture); later death (> 6 months post-fracture); osteoporosis treatment given. Specifically, we were held 'responsible' to initiate treatment in a High-Risk patient if they were seen in our outpatient HiROC clinical pathway post-discharge and did not have a medical contraindication, as this is the highest quality metric in post-fracture care. We report the outcomes of this retrospective analysis and summarize our first decade of HiROC care and performance.

Results: 740 inpatient consultations were seen, of which 74 % were women and 26 % men. Fracture sites were hip (femoral neck or intertrochanteric) 77.6 %; vertebrae 5.3 %; distal femur 3.5 %; mid shaft/subtrochanter 2.8 %; pelvis 2.4 %; wrist 1.9 %; periprosthetic 1.9 %; and other 4.6 %. Early deaths comprised 14 % of cohort and 7 % were later deaths. HiROC followup was accepted by 336 patients, 45 % of cohort. Of 288 patients drug eligible, 207/288 patients or 72 % of HiROC followed patients were initiated on an FDA-approved medication. Treatments utilized included intravenous zoledronic acid in 73 (35 %); oral bisphosphonates in 70 (34 %); denosumab in 54 (26 %); and anabolic agents in 10 (5 %). GHP insurance accounted for 256 (35 %) of entire cohort (Tables 1,3).

Conclusion: Geisinger HiROC reports treatment in 72 % of post-fracture patients who were followed in their outpatient clinical pathway. Prior performance analyses show HiROC treatment rates of 75-80 % (Table 2). Despite

Table 1. 2017-2018 HiROC Demographics

N = 740 patients

Wrist	14	75
Other	34	512

our program's maturity, we face several ongoing barriers: patient activation/engagement and fear of FDA-approved medications; access to and/or cost of parenteral medications or anabolic agents; and inability to use database to capture care gaps in real time and correct/solve them. We hope that our work will inspire others in rheumatology to implement FLS care.

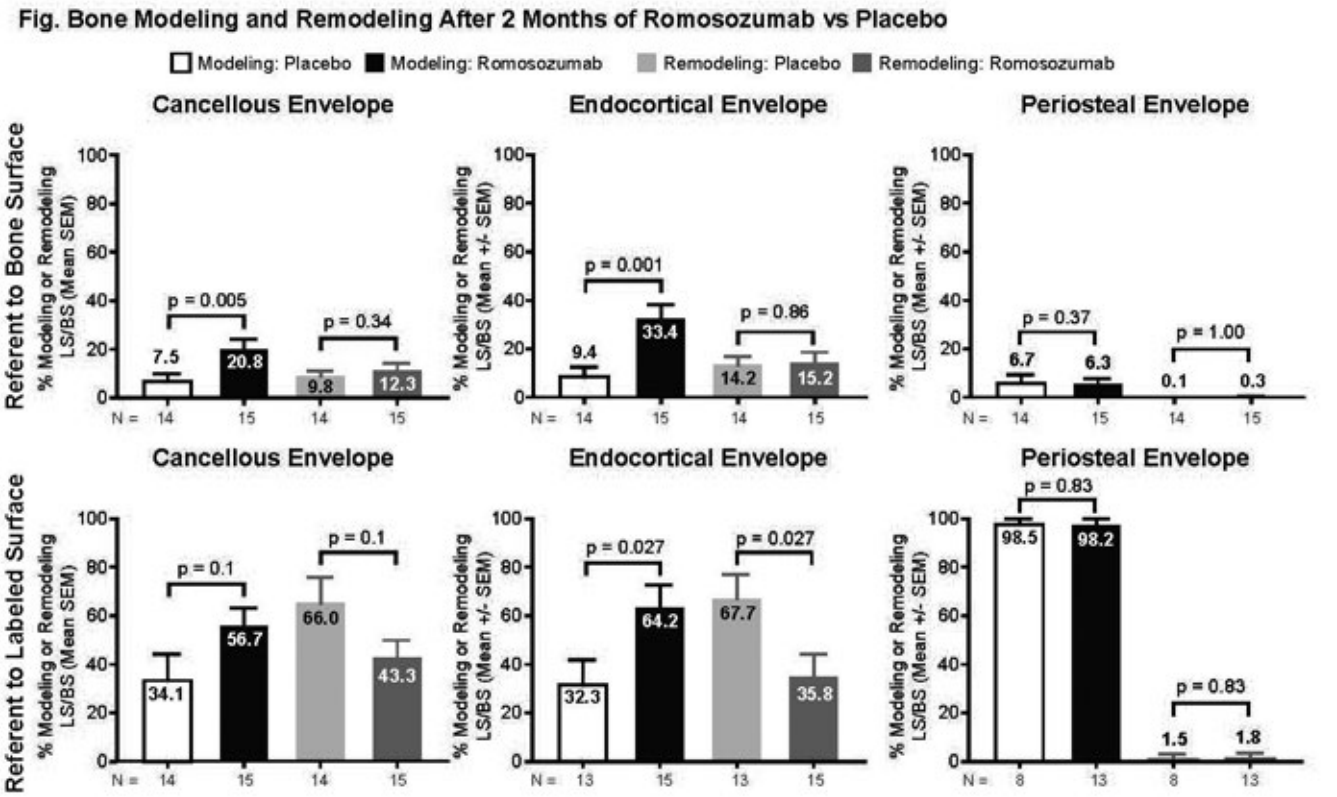
Abstract Number: 1874

Extensive Modeling-Based Bone Formation After 2 Months of Romosozumab Treatment: Results from the FRAME Clinical Trial

Erik Eriksen ,[1] Roland Chapurlat,[2] Rogely Boyce,[3] Jacques Brown,[4] Stéphane Horlait,[5] Cesar Libanati,[6] Yifei Shi,[3] Rachel Wagman,[3] and Pascale Chavassieux[2], [1]Department of Clinical Endocrinology, Oslo University Hospital and Institute of Clinical Medicine Oslo University, Oslo, Norway, [2]INSERM UMR 1033, Université de Lyon, Lyon, France, [3]Amgen Inc., Thousand Oaks, CA, [4]CHU de Quebec Research Centre and Laval University, Quebec, QC, Canada, [5]Amgen Inc., Boulogne Billancourt, France, [6]UCB Pharma, Brussels, Belgium

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The bone-forming agent romosozumab (Romo) is a monoclonal antibody that binds to/inhibits sclerostin, leading to increased bone formation and decreased bone resorption. The highest levels of bone formation markers in human subjects are observed in the first 2 months of treatment (McClung, NEJM 2014). Studies in cynomolgus monkeys demonstrated that most new bone formation following Romo treatment was modeling-based (MBBF; Ominsky, JBMR 2014). Histomorphometric analysis of bone biopsies in a substudy of the FRAME trial (NCT01575834) showed an early significant increase in bone formation with concomitant decreased resorption (Chavassieux, ASBMR 2017). Here we analyzed bone biopsies from FRAME to assess the effect of 2 months of Romo vs placebo (Pbo) on the surface extent of MBBF and remodeling-based bone formation (RBBF) on cancellous (Cn), endocortical (Ec), and periosteal (Ps) envelopes.



N = Number of subjects with evaluable histomorphometry data at timepoint of interest. Nominal p-values are the treatment difference (romosozumab vs placebo) and are based on the Wilcoxon rank-sum test without multiplicity adjustment. BS, bone surface; LS, labeled surface; SEM, standard error of the mean.

(3.28.19 all p values) FRAME Modeling ASBMR 2019 Fig

Methods: In FRAME, postmenopausal women aged ≥55 years with osteoporosis (BMD T-score ≤–2.5 and >–3.5 at the total hip or femoral neck) were randomized 1:1 to 210 mg Romo or Pbo SC QM for 12 months, followed by 60 mg denosumab SC Q6M for 12 months. Subjects in the bone biopsy substudy who had a transiliac biopsy at month 2 received quadruple labeling (double labeling at baseline and prior to biopsy). Unstained, 7 μm bone sections were analyzed by fluorescence microscopy. Histomorphometric parameters were measured separately at the Cn, Ec, and Ps envelopes using an ocular linear test system, randomly rotated between fields of view for unbiased sampling of bone surfaces. At each line intersection of the ocular sampling grid with either single or double tetracycline labels administered at month 2, the underlying cement line was classified as smooth (signifying bone modeling) or scalloped (signifying bone remodeling). The effect of 2 months of Romo vs Pbo on MBBF/RBBF at each envelope referent to bone surface and labeled surface was compared using the Wilcoxon rank-sum test, without multiplicity adjustment.

Results: After 2 months of Romo, MBBF referent to bone surface was significantly increased on Ec and Cn, but not Ps, surfaces with no significant difference in the surface extent of RBBF vs Pbo (Fig.). Romo at month 2 reversed proportions of MBBF/RBBF from approximately 33%/66% in Pbo to 66%/33% in Ec and Cn envelopes.

Conclusion: These data show that stimulation of bone formation in the first 2 months of Romo treatment is predominately due to increased MBBF on the Ec and Cn surfaces.

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: There are limited data on patients transitioning from denosumab (DMAb) to bisphosphonates (BPs). The Denosumab Adherence Preference Satisfaction (DAPS) study (NCT00518531) reported that alendronate (ALN) could maintain the gains in bone mineral density (BMD) achieved with 1 year of DMAb treatment (Freemantle *Osteoporos Int* 2012). Here, we investigate relationships between subject characteristics and their BMD responses after transitioning from DMAb to ALN.

Table. Selected baseline characteristics and percentage change in BMD for subjects who lost, maintained, or gained BMD after transitioning from denosumab to alendronate.

	Lumbar Spine (N = 82)			Total Hip (N = 92)			Femoral Neck (N = 92)		
Subjects stratified by BMD change category from M12 to M24[a]	Lost	Maintained	Gained	Lost	Maintained	Gained	Lost	Maintained	Gained
n (%)	13 (15.9)	52 (63.4)	17 (20.7)	7 (7.6)	75 (81.5)	10 (10.9)	20 (21.7)	56 (60.9)	16 (17.4)

ALN adherence at M24, n (%)	11 (84.6)	38 (73.1)	14 (82.4)	5 (71.4)	56 (74.7)	10 (100)	15 (75.0)	45 (80.4)	11 (68.8)

N = number of subjects with BMD values at M12 and M24; n = number of subjects in each BMD group with available data

BMD = bone mineral density; M = month; SD = standard deviation

[a] Based on a 3% BMD threshold. A BMD change ≤−3% indicated lost BMD; >−3% and <3% indicated maintained BMD; and ≥3% indicated gained BMD; [b] n = 16

Selected baseline characteristics and percentage change in BMD for subjects who lost, maintained, or gained BMD after transitioning from denosumab to alendronate.

Methods: DAPS was a 24-month, open-label, randomized, cross-over study designed to compare adherence to 12 months of DMAb treatment (60 mg Q6M SC) with ALN (70 mg QW PO) in treatment-naïve postmenopausal women with a T-score ≤—2.0 to ≥—4.0 at the lumbar spine (LS), total hip (TH), or femoral neck (FN). BMD was measured at baseline and months (M) 12 and 24. Here we evaluate subjects transitioning from DMAb to ALN at M12. A 3% BMD least significant change threshold identified subjects who lost, maintained, or gained BMD from M12 to M24 (change ≤—3%, >—3% and < 3%, or ≥3%, respectively); baseline, M12, and M24 characteristics were summarized using descriptive statistics.

Results: Of 126 subjects randomized to DMAb, 115 (91%) transitioned to ALN at M12. At baseline, subjects had a mean age of 65 years and mean BMD T-scores of —2.0, —1.6, and –2.0 at the LS, TH, and FN, respectively. BMD increased by 5.6%, 3.2%, and 3.1% with DMAb from M0 to M12 at the LS, TH, and FN, respectively, and changed by 0.6%, 0.4%, and –0.1% with ALN from M12 to M24. After transitioning from DMAb to ALN, most subjects showed maintained or increased BMD (Table); 15.9%, 7.6%, and 21.7% lost BMD at the LS, TH, and FN, respectively, and only 1 subject (1.2%) lost BMD at all 3 sites. Baseline characteristics, M12 BMD, and adherence to oral ALN showed no trend with the BMD change from M12 to M24. However, subjects who lost BMD from M12 to M24 on ALN showed greater gains in BMD from M0 to M12 on DMAb, and few who lost BMD fell below their pre-study baseline BMD value. No subject experienced clinical vertebral fracture.

Conclusion: ALN can effectively maintain the BMD gains accrued after 1 year of DMAb in most subjects. Those with larger BMD increases in year 1 are more likely to lose BMD in year 2, with other subject characteristics not predictive of the response in year 2. These data highlight the need for oral BP therapy following DMAb cessation and BMD monitoring of patients transitioning from DMAb to ALN.

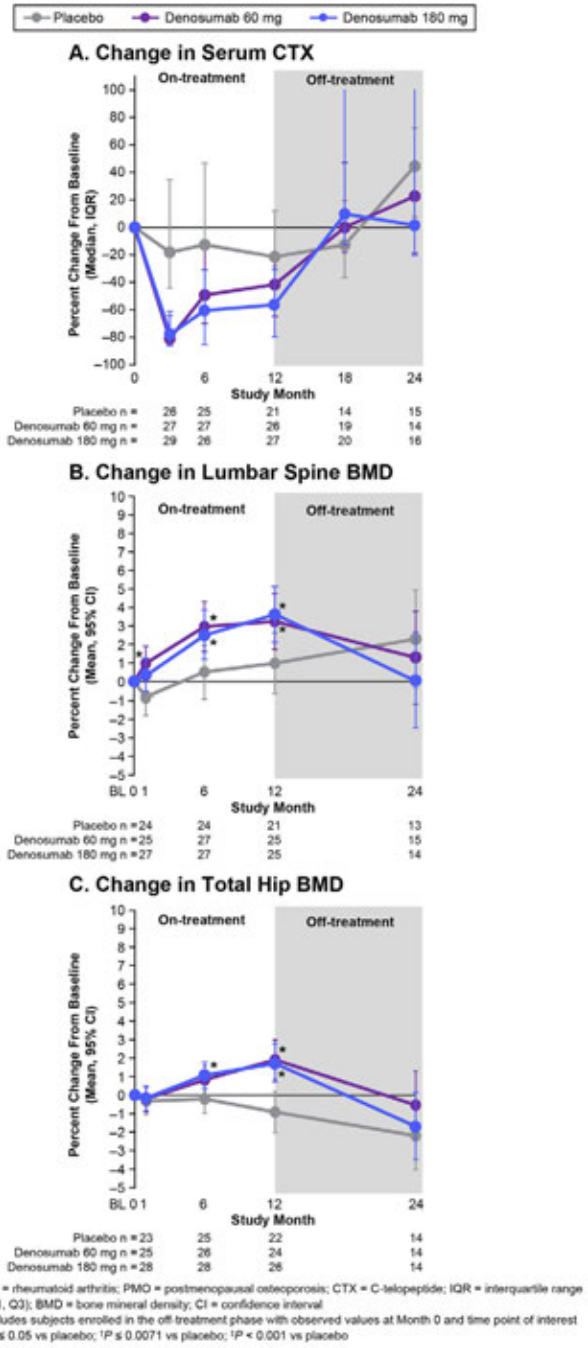
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Denosumab, a monoclonal antibody against RANKL, is approved for the treatment of glucocorticoid (GC) induced osteoporosis (GiOP). In postmenopausal women with osteoporosis, denosumab discontinuation leads to a transient increase in bone turnover above baseline, peaking at 12 months from the last dose, and a corresponding decline in bone mineral density (BMD). To better understand the effects of denosumab discontinuation



Change in CTX, Lumbar Spine BMD, and Total Hip BMD from Baseline Upon Denosumab Discontinuation in Patients with Rheumatoid Arthritis

in GC-treated patients, we analyzed a subgroup receiving GCs at baseline from a phase 2 study of denosumab in subjects with rheumatoid arthritis (RA), followed for 12 months after denosumab discontinuation, for changes in bone turnover and BMD. (Ann Rheum Dis, vol 8, suppl 2, yr 2019, pg A931)

Methods: This double-blind, placebo-controlled study enrolled subjects with RA who were randomized to receive denosumab 60 mg, denosumab 180 mg, or placebo subcutaneously for 12 months, and followed for progression of structural damage. Subjects were followed for an additional 12 months after denosumab discontinuation. Outcome measures in this subgroup analysis of subjects treated with GCs at study baseline included percent change from baseline in serum C-terminal telopeptide of type I collagen (CTX) and lumbar spine (LS) and total hip (TH) BMD on- and off-treatment. Baseline mean (SD) prednisone equivalent dose (mg/day) was 6.1 (2.4), 5.2 (2.1), and 6.1 (3.2) in

the placebo, denosumab 60 mg, and denosumab 180 mg groups, respectively. Data on CTX are reported as median and interquartile range. Percent changes in LS and TH BMD at each time point were assessed based on a repeated-measures model adjusting for treatment, baseline use of steroids, previous use of biologics, and baseline BMD value.

Results: Among 218 subjects in the phase 2 study, 82 (26 placebo, 27 denosumab 60 mg, and 29 denosumab 180 mg) were included in this analysis. After 12 months of denosumab treatment, CTX decreased from baseline in both groups (Figure); in the off-treatment period, CTX returned to baseline by 18 months and was overall similar to placebo at 24 months. BMD increased at the LS and TH at 12 months with denosumab treatment (Figure) and returned to baseline levels after 12 months of discontinuation.

Conclusion: Like all non-bisphosphonate medications for osteoporosis, denosumab is reversible with discontinuation. In this small subgroup of GC-treated subjects with RA, BMD gains achieved with denosumab were lost upon discontinuation, consistent with observations in postmenopausal women receiving denosumab for osteoporosis. In this analysis of short-term denosumab use in subjects with RA receiving GCs, bone turnover was reduced with denosumab and gradually returned to baseline upon discontinuation, without a clear increase to above-baseline levels in the off-treatment period.

SESSION INFORMATION

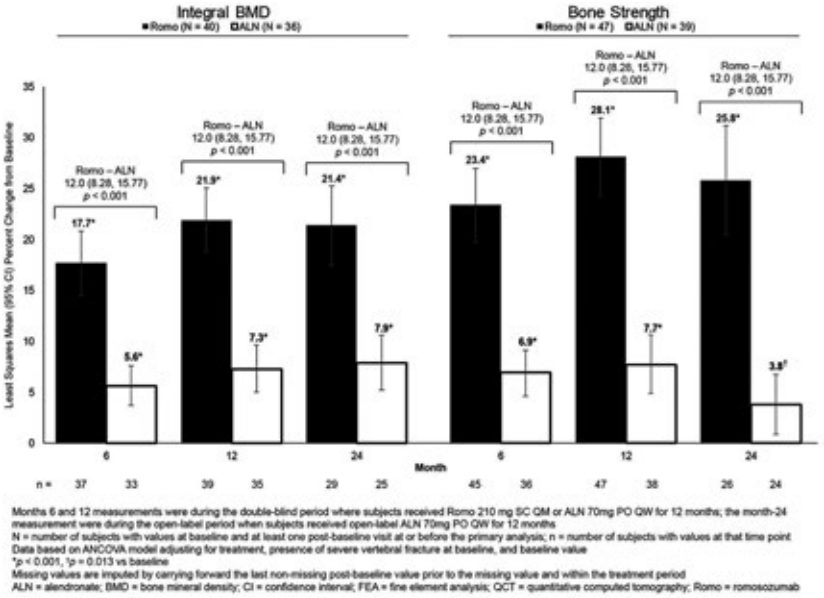
Session Date: Monday, November 11, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Recent evidence suggests BMD achieved during treatment is a reliable surrogate for fracture risk reduction (Bouxsein *JBMR* 2019). Romosozumab (Romo) is a bone-forming agent with a dual effect of



Percentage change from baseline and difference between romosozumab and alendronate treatment in integral BMD and bone strength at the lumbar spine through the primary analysis in ARCH

increasing bone formation and decreasing bone resorption. In ARCH (NCT01631214), Romo followed by alendronate (ALN) had greater efficacy in BMD gains and fracture risk reduction vs ALN alone (Saag *NEJM* 2017). Here we assessed improvements in lumbar spine (LS) BMD and bone strength with Romo vs ALN treatment by quantitative computed tomography (QCT) and Finite Element Analysis (FEA).

Methods: Postmenopausal women with osteoporosis and prior vertebral or hip fracture were randomized 1:1 to receive Romo 210mg SC monthly or ALN 70mg PO weekly for 12 months, followed by open-label ALN 70mg PO weekly. In an imaging substudy, LS BMD was assessed by QCT and vertebral-estimated bone strength by FEA using QCT images obtained at baseline and months 6, 12, and 24. Correlation analyses evaluated the relationship between changes in FEA, QCT, and DXA.

Results: This post-hoc analysis included 90 subjects (49 Romo, 41 ALN) with baseline and ≥1 post-baseline QCT/FEA assessment. At baseline, mean (SD) age was 73 (7) years; DXA T-scores were –3.08 (1.09), –2.70 (0.68), and –2.84 (0.45) at the LS, total hip, and femoral neck, respectively; and 97% had prior vertebral fracture, similar to core study subjects. 76 (40 Romo, 36 ALN) subjects had QCT assessments and 86 (47 Romo, 39 ALN) had FEA assessments at baseline and ≥1 post-baseline visit. Subjects in both groups experienced significant gains in integral and trabecular BMD from baseline at all time points (except ALN in trabecular BMD; Fig and data not shown). Differences between Romo and ALN were significant at months 6, 12, and 24. QCT BMD increases were accompanied by significant increases in LS bone strength in both groups at all time points, with significantly greater increases observed with Romo than ALN. With treatment arms combined, correlation between post-baseline percent change in FEA and BMD by QCT (integral and trabecular) and DXA was similar (r=0.69–0.87, all p< 0.001).

Conclusion: Compared with ALN, Romo significantly improved LS BMD by QCT and bone strength by FEA. These effects occurred rapidly (month 6), were sustained over 12 months, were preserved upon transition to ALN through 24 months—demonstrating maintenance of therapeutic effect achieved with Romo—and are consistent with greater fracture risk reduction observed in this trial with Romo-ALN vs ALN.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain Mechanisms – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In recent years, diverse compounds for intra-articular (IA) administration were brought into the market with a subsequent significant and heterogeneous literature production.

Understanding the efficacy of any drug to be delivered intra-articularly implies bearing in mind the placebo (PBO) effect of any medication that is placed where the pain is elicited, especially in the first weeks after the procedure. To date, most of the studies analyzing this effect were not focused specifically on the route of administration but on the treatment being administered. Thus, we aimed at evaluating the size of the PBO effect after IA injections.

Methods: For the upcoming EULAR recommendations/points to consider for IA therapies, an overview of systematic reviews (SR) was conducted, including SR of randomized-controlled trials (RCT) of IA therapies comparing an active treatment vs an IA control. We selected all SR in which the control arm was a saline solution. After assessing the risk of bias with the AMSTAR-2 tool, all SR showing high-confidence results were selected and the studies included in them, re-analyzed.

The analysis included data on the change in pain from the PBO arms, measured on continuous variables (different scales) from baseline to 3-6 and 12-16 weeks after the IA procedure. The standardized mean differences (SMD) from baseline were calculated as the ratio between the size of the intervention effect in each study and the variability observed in that study. A meta-analysis was performed using an inverse-variance random-effects model in Review Manager 5.3. The overall effect sizes obtained refer to versions of the SMD, which corresponds to the Hedges' (adjusted) g. e.g. a "g" of 1 indicates the two groups being compared differ by 1 standard deviation and so on.

Results: Two SR comprising 50 RCT were included, 44 had to be excluded: 26 due to not having PBO arms or not showing its data, 6 due to not measuring the target outcome or at the specified time-points, in 5 we could not obtain the target data, and 7 used a PBO different than saline.

Pain, measured by visual analog scale (VAS) and Lequesne index, was retrieved from 6 RCT. The effect of PBO IA administration from baseline to 3-6 weeks was pooled from 6 studies on VAS pain and 3 on Lequesne index; SMD

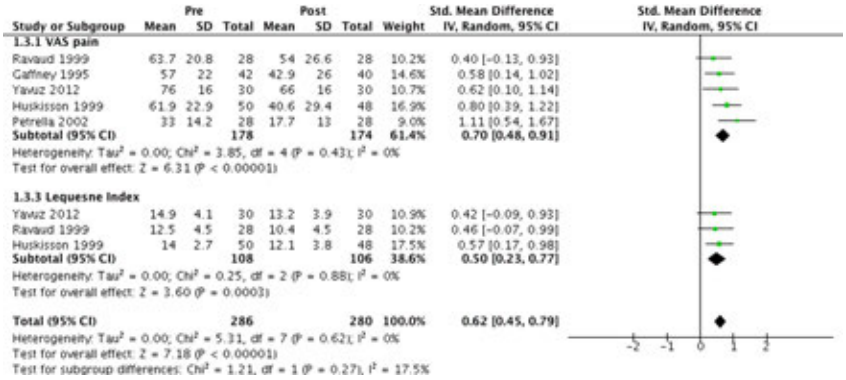

Figure 1. Forest plot for pooled effects of PBO arms on VAS pain and Lequesne Index at 3-6 weeks after injection.

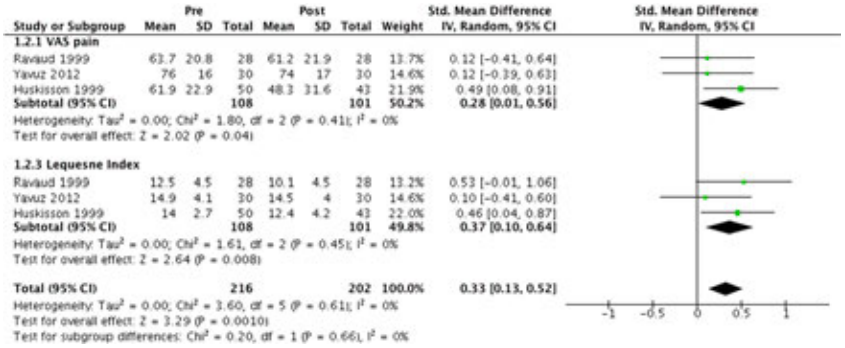

Figure 2. Forest plot for pooled effects of PBO arms on VAS pain and Lequesne Index at 12-16 weeks after injection

[95%CI] was 0,74 [0.47-1.00]. As one study had too large an effect, we performed a sensitivity analysis excluding it. This resulted in a notable reduction of overall heterogeneity both measured by I^2 and Tau^2 with a resultant SMD = 0.62 [0.45-0.79] (Figure 1).

The overall PBO effect at 12-16 weeks, measured by pooling data from 3 studies for VAS pain and for Lequesne, showed an SMD = 0.33 [0.14-0.52] (Figure 2).

Using the interpretation suggested by Cohen[1], our results would confirm a moderate to large effect of IA saline (PBO) at 3-6 weeks with a subsequent reduction to a small but persistent effect at 12-16 weeks. Therefore, IA PBO may have a clinically detectable and lasting effect.

Conclusion: Based on these findings we suggest that PBO effect should be taken into account not only when analyzing the efficacy of IA therapies in RCT but also in clinical practice, where this effect could be maximized, as well.

The Relation of Pain Sensitization and Conditioned Pain Modulation to Pain Patterns in Knee Osteoarthritis: The Multicenter Osteoarthritis Study

Lisa Carlesso ,[1] Laura Frey Law,[2] Na Wang,[3] Michael Nevitt,[4] Beth Lewis,[5] and Tuhina Neogi[3], [1]McMaster University, Hamilton, ON, Canada, [2]University of Iowa, Iowa City, IA, [3]Boston University School of Medicine, Boston, MA, [4]University of California at San Francisco, San Francisco, CA, [5]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain Mechanisms – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Intermittent pain progresses to constant pain in some, but not all, individuals with knee osteoarthritis (OA). Differing pain mechanisms may underlie these transitions. Later onset constant pain may represent pain sensitization or inadequate descending inhibitory modulation, while earlier intermittent pain may be due to peripherally-driven nociceptive input. We sought to examine the association of pain sensitization and conditioned pain modulation (CPM) to patterns and predictability of knee pain.

Methods: Subjects from the Multicenter Osteoarthritis (MOST) study, a NIH-funded longitudinal prospective cohort of older adults with or at risk of knee OA, at the 144-month visit were included in this cross-sectional analysis. Mechanical pressure pain threshold (PPT) at the wrist and patella were assessed with a handheld algometer. Lower PPTs indicate greater sensitization. Weighted mechanical punctate probes were used to assess temporal summation at the wrist, an indicator of central sensitization. Efficiency of CPM was determined by assessing PPT at the patella (test stimulus, PPT1) with forearm ischemia as the conditioning stimulus, followed by reassessment of PPT at the patella (PPT2). Adequate CPM is operationalized as PPT2:PPT1 >1. Knee pain patterns were defined using the Intermittent and Constant OA pain (ICOAP) scale as no intermittent or constant pain; intermittent pain only; constant pain only; or a mix of both. Unpredictable pain was assessed with a question regarding pain onset without warning. We evaluated the relation of pain sensitization and adequacy of CPM to pain patterns using logistic regression with general estimating equations to account for 2 knees within an individual. Analyses were adjusted for age, sex, BMI, race, clinic site, depressive symptoms and catastrophizing.

Results: There were 2817 subjects included (mean age 64 yrs, 57% female, mean BMI 29.4 kg/m^2). Higher patellar PPT (less sensitivity) was associated with lower likelihood of constant +/- intermittent pain than intermittent only (OR 0.80 (95% CI 0.69, 0.93) or no pain (OR 0.69 (95% CI 0.60-0.81)) and less unpredictable pain (OR 0.88 (95% CI 0.79-

Table 1.

	ICOAP Pain Pattern constant+/- intermittent vs. intermittent only OR (95% CI)†	ICOAP Pain Pattern constant+/-intermittent vs. intermittent only or no pain OR (95% CI)†	ICOAP Pain Comes on Without Warning Sometimes/often vs. rarely/never OR (95% CI)†
*PPT - patella	**0.80 (0.69, 0.93)**	**0.69 (0.60, 0.81)**	**0.88 (0.79, 0.97)**
*PPT – wrist	**0.80 (0.66, 0.97)**	**0.70 (0.59, 0.84)**	0.97 (0.86, 1.10)
**Temporal Summation – wrist (Y vs. N)	1.14 (0.48, 2.67)	1.63 (0.76, 3.49)	1.33 (0.55, 3.21)
***Adequate CPM (> 1 vs.≤ 1)	**1.45 (1.09, 1.91)**	**1.36 (1.05, 1.78)**	1.00 (0.81, 1.23)

†Adjusted for age, sex, BMI, depressive symptoms, catastrophizing, race and clinic site.

*PPT: per unit SD increase; higher PPT indicates less pain sensitization
**TS: dichotomous; present if pain increases at end of stimuli train compared with baseline; TS indicates central sensitization
***CPM: dichotomous; adequate CPM indicates descending inhibitory modulation

0.97)) (**Table**). Similar findings were noted for wrist PPT, but were inverse for adequate CPM (**Table**). No associations were noted for temporal summation.

Conclusion: Lower levels of pain sensitization (by PPT) were associated with lower likelihood of constant +/- intermittent pain than intermittent pain or no pain, and less unpredictable pain. Adequate CPM was unexpectedly associated with greater likelihood of constant +/- intermittent pain, perhaps reflecting activation of this pathway when constant pain is present. These findings support the hypothesis that different pain mechanisms underlie intermittent vs. constant pain. Pain patterns noted over the course of OA appear to be related to peripheral +/- central facilitated ascending pain mechanisms.

Baricitinib 4 Mg and 2 Mg Once Daily Reduced Pain in Both Patients Who Were Opioid Users and Non-users in Active Rheumatoid Arthritis: A Post-hoc Analysis of Phase 3 Trials

Janet Pope ,[1] Yvonne Lee,[2] Jeffrey Curtis,[3] Daojun Mo,[4] Terence Rooney,[4] Li Xie,[4] Christina Dickson,[4] Douglas Schlichting,[4] Amanda Quebe,[4] Anabela Cardoso,[4] Lee Simon,[5] and Peter Taylor[6], [1]Western University, London, ON, Canada, [2]Northwestern University Feinberg School of Medicine, Chicago, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Eli Lilly and Company, Indianapolis, IN, [5]SDG LLC, Cambridge, MA, [6]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain Mechanisms – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Opioid use in RA patients has increased over the past 2 decades in the US. Little is known about the combined effects of opioids and disease-modifying antirheumatic drugs (DMARDs) on pain in RA. To assess pain reduction in opioid users and non-users, we tested the effect of 1) 4 mg baricitinib (BARI), an oral JAK1/JAK2 inhibitor, vs. placebo (PBO) with data pooled from Phase 3 trials, RA-BEAM (NCT01710358, with RA patients with an inadequate response [IR] to MTX), RA-BUILD (NCT01721057, with those with IR to conventional DMARDs), and RA-BEACON (NCT01721044, with those with IR to ≥1 tumor necrosis factor inhibitors), 2) BARI 2 mg vs. PBO in RA-BEACON, and 3) subcutaneous 40 mg adalimumab (ADA) every other week vs. PBO in RA-BEAM.

Methods: Opioid users were patients who reported opioid use during the trials. The number of opioid users/the total number of randomized patients were: 171/891 BARI 4 mg and 153/892 PBO in the pooled analysis, 54/174 BARI 2 mg and 58/176 PBO in RA-BEACON, and 34/330 ADA and 50/488 PBO in RA-BEAM. Pain was measured by the Patient's Assessment of Pain visual analog scale (VAS, 0-100 mm). Last observation before treatment discontinuation or rescue was carried forward through Week 24. An ANCOVA model assessed differences in pain reduction at each time point between BARI 4 mg and PBO (pooled), BARI 2 mg and PBO (RA-BEACON), and ADA and PBO (RA-BEAM) by opioid users and non-users. Baseline pain VAS, age, BMI, and trial were covariates in the model. Heterogeneity of treatment effect (active vs. PBO) was evaluated across opioid users and non-users by interaction test. Analyses were not adjusted for multiplicity.

Results: BARI 4 mg had greater pain reduction vs. PBO in opioid users and non-users (P< 0.05) at all time points (Weeks 1, 2, 4, 8, 12, 14, 16, 20 and 24). Pain reduction in BARI 4 mg vs. PBO was similar between opioid users and non-users at all time points (interaction P >0.1 at all time points). At Week 24, the difference in pain VAS reduction between BARI 4 mg vs. PBO was -13.4 mm (95% CI: -19.0, -7.8) in opioid users and -14.3 mm (-16.7, -11.9) in non-users, interaction P=0.8. In RA-BEACON, BARI 2 mg had greater pain reduction vs. PBO in both opioid users and non-users (P< 0.05) starting at Week 12. Pain reduction with BARI 2 mg vs. PBO was similar between opioid users and non-users at all time points (interaction P >0.1 at all time points). At Week 24, the difference in pain VAS reduction between BARI 2 mg vs. PBO was -10.7 mm (-19.5, -1.9) in opioid users and -8.3 mm (-15.0, -1.6) in non-users, interaction P=0.8. In RA-BEAM, a significant difference in pain reduction was not observed for ADA vs. PBO in the opioid users; whereas, for non-users, a difference in pain reduction was observed for ADA vs. PBO at all time points (P< 0.05). At Week 24, the difference in pain VAS reduction between ADA vs. PBO was -4.9 mm (95% CI:-16.4, 6.6) in opioid users and -12.2 mm (-15.6, -8.9) in non-users, interaction P=0.2.

Conclusion: Pain reduction with BARI 4 mg was similar between opioid users and non-users and was observed at all time points. Pain reduction with BARI 2 mg vs. PBO was similar between opioid users and non-users from Week 12. In contrast, ADA did not result in pain reduction compared to PBO in opioid users.

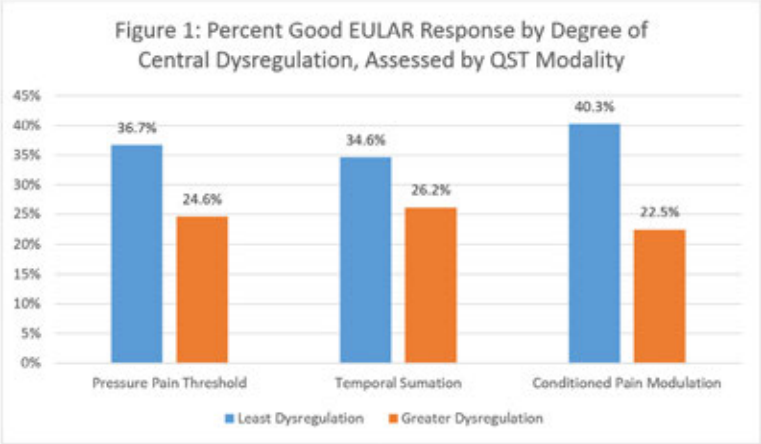
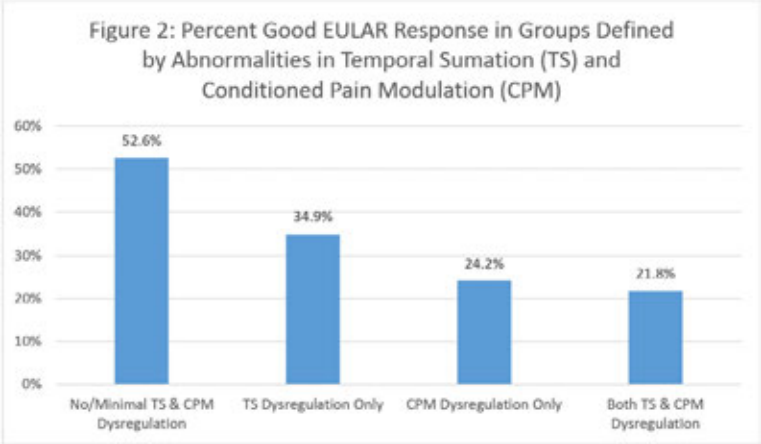
Association of Pain Centralization with DMARD Response in Active RA

Andrew Heisler ,[1] Jing Song,[2] Dorothy Dunlop,[1] Alyssa Wohlfahrt,[3] Marcy Bolster,[4] Wendy Marder,[5] Clifton Bingham,[6] Daniel Clauw,[7] Tuhina Neogi,[8] and Yvonne Lee[9], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Worthington, OH, [3]Brigham and Woman's Hospital, Boston, MA, [4]Massachusetts General Hospital, Boston, MA, [5]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, [6]Johns Hopkins University, Baltimore, MD, [7]Division of Rheumatology, Department of Internal Medicine and Division of Anesthesia, Michigan Medicine, Ann Arbor, MI, [8]Boston University School of Medicine, Boston, MA, [9]Northwestern University Feinberg School of Medicine, Chicago

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain Mechanisms – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Despite the availability of potent disease modifying anti-rheumatic drugs (DMARDs), a significant percentage of rheumatoid arthritis (RA) patients do not achieve low disease activity or remission de-





fined by composite disease activity measures (CDAMs). Although CDAMs are intended to reflect inflammation, non-inflammatory processes may also contribute to high scores. For instance, dysregulated central nervous system processing, termed “pain centralization”, is associated with high patient global assessment and tender joint count, both of which are components of CDAMs. The objective of this study was to assess the contribution of pain centralization to DMARD response.

Methods: One hundred and eighty-two RA patients with active disease necessitating DMARD initiation or change were included in this longitudinal prospective multicenter cohort. All patients met ACR criteria for RA. Patients were assessed before and approximately 12-weeks after DMARD initiation or change. The outcome was good response per the European League Against Rheumatism (EULAR) response criteria. Primary predictors were pain centralization assessed by quantitative sensory testing (QST). Overall pain centralization was measured by pressure pain thresholds (PPTs). Pain facilitation was assessed by temporal summation (TS). Impaired pain inhibition was measured by conditioned pain modulation (CPM). The secondary predictor was a combined measure of TS and CPM. Predictors were dichotomized into least central dysregulation and greater central dysregulation using a split between the 1st and 2nd sex-specific tertiles for each QST measure. Multiple logistic regression was used to calculate odds ratios (ORs) for good EULAR response.

Results: Mean age of the population was 55.2 years. 83% of patients were female, and 70.3% seropositive. Mean baseline Disease Activity Score in 28 joints (DAS28-CRP) was 4.3. Patients with greater central dysregulation had lower percentages of good EULAR response (PPT: 24.6% vs. 36.7%, TS: 26.3% vs. 34.6%, CPM: 22.5% vs. 40.3%) (Figure 1) and lower adjusted ORs of good EULAR response (PPTs: OR 0.59 (95% CI 0.28-1.23), TS: OR 0.60 (95% CI 0.27-1.34), CPM: OR 0.40 (95% CI 0.19-0.83)) than those with least dysregulation (Table 1). However, only the

Table 1: Odds Ratios (OR) for Good EULAR Response			
		Unadjusted OR (95% CI)	Adjusted[3] OR (95% CI)
Central Dysregulation Assessed by Individual QST Predictors[1]			
PPT	**Least**	1.00 (Referent)	1.00 (Referent)
	Greater	0.56 (0.29, 1.10)	0.59 (0.28, 1.23)
TS	**Least**	1.00 (Referent)	1.00 (Referent)
	Greater	0.67 (0.33, 1.34)	0.60 (0.27, 1.34)
CPM	**Least**	1.00 (Referent)	1.00 (Referent)
	Greater	**0.43 (0.22, 0.83)**	**0.40 (0.19, 0.83)**
Central Dysregulation Assessed by Combinations of TS and CPM[2]			
No/Minimal TS and CPM Dysregulation		1.00 (Referent)	1.00 (Referent)
TS Dysregulation Only		0.48 (0.16, 1.45)	0.49 (0.14, 1.67)
CPM Dysregulation Only		**0.29 (0.09, 0.96)**	0.31 (0.08, 1.13)
Both TS and CPM Dysregulation		**0.25 (0.09, 0.71)**	**0.23 (0.07, 0.73)**

1. Odds ratios are for good EULAR response for greater dysregulation compared to least dysregulation (referent) for each QST modality.
2. Odds ratios are for good EULAR response for each combination of dysregulation of TS and CPM compared to no/minimal TS and CPM dysregulation (referent).
3. Adjusted for age, sex, race, BMI, education, seropositivity, disease duration, PROMIS sleep disturbance, PROMIS depression, and modified Charlson comorbidity score.
* Bolded values indicate statistical significance.

OR for CPM reached statistical significance. Percent good EULAR response decreased with increasing number of abnormalities in pain centralization mechanisms (neither TS and CPM: 52.6%, only TS dysregulation: 30.8%, only CPM dysregulation: 24.4%, both TS and CPM dysregulation: 22.1%) (Figure 2). The adjusted OR for good EULAR response was 0.23 (95% CI 0.07-0.73) for patients with both TS and CPM dysregulation compared to those without TS and CPM dysregulation (Table 1).

Conclusion: In this study, high pain centralization, particularly impaired pain inhibition, was associated with poor DMARD response. Physicians should consider pain centralization as a possible reason why some patients fail to reach low disease activity or remission, despite treatment with DMARDs. Such patients may benefit from adjunctive therapy (e.g. serotonin norepinephrine reuptake inhibitors), rather than escalation of DMARD therapy.

Anti-CCP Antibody and Pain Sensitization in Rheumatoid Arthritis

Yoon Mun ,[1] Tuhina Neogi,[2] Jing Song,[3] Dorothy Dunlop,[1] Andrew Heisler,[1] Marcy Bolster,[4] Clifton Bingham,[5] Wendy Marder,[6] Alyssa Wohlfahrt,[7] and Yvonne Lee[8], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Boston University School of Medicine, Boston, MA, [3]Northwestern University Feinberg School of Medicine, Worthington, OH, [4]Massachusetts General Hospital, Boston, MA, [5]Johns Hopkins University, Baltimore, [6]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, [7]Brigham and Woman's Hospital, Boston, MA, [8]Northwestern University Feinberg School of Medicine, Chicago

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain Mechanisms – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Many patients with RA report persistent pain in the absence of clinically appreciable inflammation. In a mouse model of inflammatory arthritis, mice injected with anti-cyclic citrullinated peptide (CCP) antibody exhibited increased pain sensitivity and more pain behaviors in the absence of histological evidence of joint inflammation. These findings raise the possibility of an inflammation-independent pain pathway mediated by anti-CCP antibodies. In this study, we investigated the association between anti-CCP antibody and pain, assessed by quantitative sensory testing (QST) and patient-reported measures, in RA patients with active inflammation.

Methods: This cross-sectional analysis included study participants who met the ACR/EULAR 2010 classification criteria for RA, had active inflammatory disease, and required initiation of a disease-modifying antirheumatic drug (DMARD). Serum levels of anti-CCP antibody and high sensitivity C-reactive protein (hsCRP) were measured. Subjects also underwent QST, including assessment of pressure pain thresholds (PPTs) at wrist and knee joints to quantify peripheral sensitization. Self-reported pain measures were obtained and included average pain intensity on a numeric rating scale (NRS) and pain interference score assessed by the Patient Reported Outcomes Measurement Information System computerized adaptive test (PROMIS® CAT). We examined the cross-sectional relation of anti-

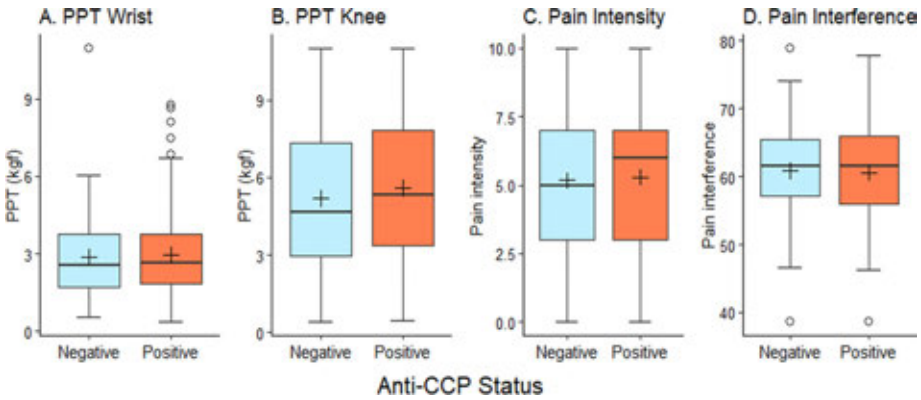

Figure 1. Pain sensitivity by QST and patient-reported pain measures grouped by anti-CCP seropositivity. The horizontal line in each box represents the median, the top and bottom of the boxes the interquartile range, and the whiskers the minimum and maximum observations within the lower and upper fences (1.5*IQR). The plus sign represents the mean.

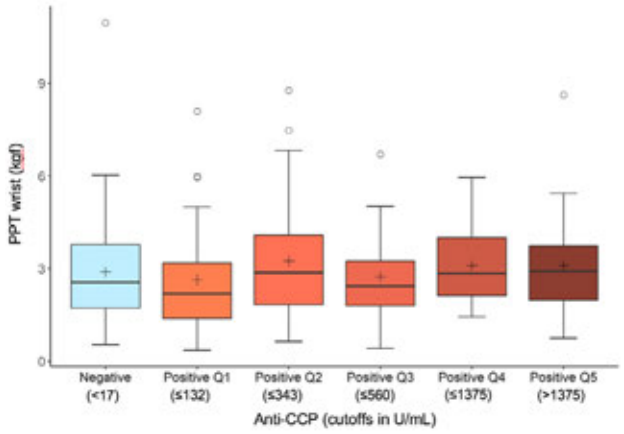

Figure 2. PPT at wrist grouped by anti-CCP-negative and anti-CCP-positive quintiles. The horizontal line in each box represents the median, the top and bottom of the boxes the interquartile range, and the whiskers the minimum and maximum observations within the lower and upper fences (1.5*IQR). The plus sign represents the mean.

Table 1: Association between anti-CCP positivity and pain measures

Outcome	Model	β coefficient	95% C.I.
Experimental Pain Sensitivity			
PPT, wrist	Unadjusted	0.07	-0.33 to 0.47
	Adjusted 1	0.16	-0.25 to 0.56
	Adjusted 2	0.16	-0.24 to 0.56
PPT, knee	Unadjusted	0.41	-0.31 to 1.13
	Adjusted 1	0.65	-0.06 to 1.37
	Adjusted 2	0.61	-0.10 to 1.31
Patient Reported Pain			
Pain intensity	Unadjusted	0.11	-0.46 to 0.68
	Adjusted 1	-0.14	-0.71 to 0.43
	Adjusted 2	-0.04	-0.58 to 0.50
Pain interference	Unadjusted	-0.31	-2.03 to 1.41
	Adjusted 1	-0.87	-2.63 to 0.88
	Adjusted 2	-0.52	-2.17 to 1.12

Adjusted 1: adjusted for age, race, gender, RA disease duration, current steroid/DMARD use, and study site. Adjusted 2: adjusted for covariates in Adjusted 1 + inflammation (hsCRP, swollen joint count) and fibromyalgia status.

CCP antibody seropositivity to PPT and self-reported pain measures using linear regression, adjusting for potential confounders. We also assessed for a dose-response relationship by categorizing anti-CCP as seronegative and as quintiles of seropositivity.

Results: There were 264 participants (mean age 54.6 years, average disease duration 10.2 years). On average, participants had 10.9 tender joints, 5.2 swollen joints, and a hsCRP level of 7.3 mg/L. Anti-CCP positivity was present in 164 patients (62.1%) and was not significantly associated with PPT at the wrist (b-coefficient 0.16, 95% confidence interval [CI] -0.24, 0.56) or knee (b-coefficient 0.61, 95% CI -0.10, 1.31) (Table 1, Figure 1). Similarly, there was no association between anti-CCP seropositivity and pain intensity (b-coefficient -0.04, 95% CI -0.58, 0.50) or pain interference (b-coefficient -0.52, 95% CI -2.17, 1.12). Categorizing seropositive anti-CCP into quintiles of increasing serum antibody did not show a dose-response relationship between anti-CCP and PPT at the wrist (Figure 2) or anti-CCP and any other pain measure (data not shown).

Conclusion: Among patients with active RA, anti-CCP seropositivity and higher levels of anti-CCP were not associated with experimental measures of pain sensitivity or patient-reported measures of pain. The possibility that untreat-

ed patients may demonstrate different findings cannot be ruled out. Nonetheless, these results contrast with data from animal models of inflammatory arthritis, as our data did not show evidence of an anti-CCP-antibody-mediated mechanism of joint pain as suggested in the animal models.

Elucidating Pain Mechanisms in Polyarticular Juvenile Idiopathic Arthritis Patients

Jaymin Upadhyay ,[1] Diana Sibai,[1] Robert Labadie,[2] Jordan Lemme,[3] Christine Sieberg,[2] Kirsten Ecklund,[4] David Borsook,[4] and Robert Sundel[4], [1]Boston Children's Hospital, Harvard Medical School, Boston, MA, [2]Boston Children's Hospital, Harvard Medical School, Boston, MA, [3]Boston Children's Hospital, Harvard Medical School, Boston, [4]Boston Children's Hospital, Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pain Mechanisms – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Despite a broad range of available therapeutics, pain remains poorly treated in many juvenile idiopathic arthritis (JIA) patients[1-2]. For some patients, the level of pain is not commensurate with the magnitude of detectable joint pathology (i.e., synovitis). In order to elucidate pain mechanisms in JIA, we have investigated the functionality of CNS circuitry in polyarticular JIA (pJIA) individuals (>5 affected joints) alongside peripheral joint pathology, markers of inflammation, subjective measures related to pain and clinical status. This strategy is projected to facilitate the identification of pain biomarker signatures and define mechanisms that underlie the observed pain-inflammation disconnect in JIA.

Methods: Consented, male and female pJIA patients (8-16 years) with and without pain were assessed using functional magnetic resonance imaging (fMRI), musculoskeletal MRI, Patient Reported Outcomes Measurement Information System (PROMIS) questionnaires, fluid markers informing on inflammation (i.e., CRP and ESR levels) and clinical status. All evaluated patients had either past or ongoing hand joint abnormalities. Patient enrollment is currently active.

FMRI data collected during a hand motor task involved a visually cued, opening and closing of the right or left hand (depending on location of joint pathology or clinical pain) in a 30 second off/10 second on manner for 5 cycles. Evoked stimulation was subsequently performed by applying cold stimuli (10°C) to hand and knee joints also in a 30 second off/10 second on block design (Medoc LTD, Israel). Immediately following fMRI, patients underwent hand MRI (index hand only). All imaging was performed on a Siemens 3T scanner (Siemens, Germany). fMRI data was analyzed using FSL 6.0, while hand MRI was clinically evaluated by a musculoskeletal radiologist (KE). This study was approved by the Institutional Review Board at Boston Children's Hospital.

Results: Hand motor task fMRI showed differential CNS activation profiles amongst patients with No Pain + No inflammation, Pain + No Inflammation and Pain + Inflammation (**Figure 1)**. Of these states, the pain without inflam-

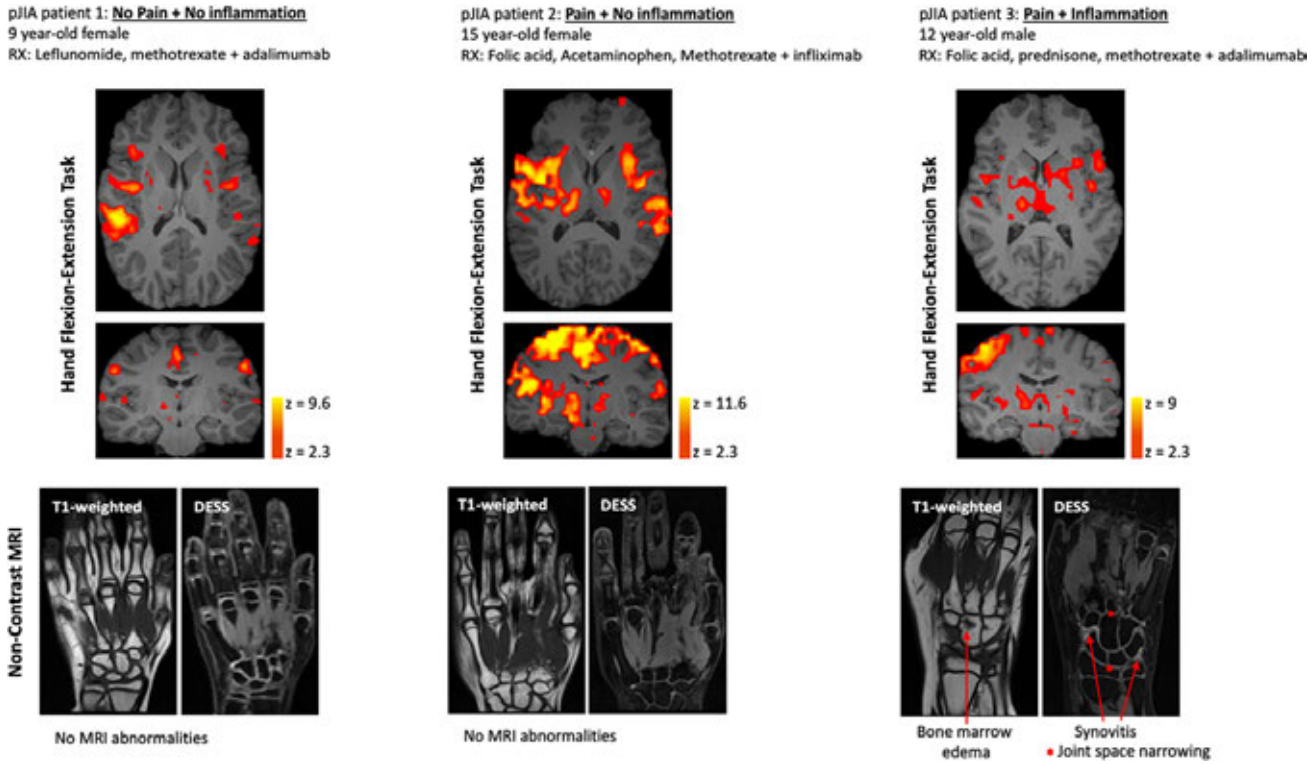

Figure 1. Evoked BOLD Response in pJIA Patients With and Without Pain During a Hand Motor Task. A. Single patient data showing CNS activity during a hand flexion and extension exercise. Statistical activation maps are depicted on axial (top row) and coronal (bottom row) planes on subject-specific, high-resolution anatomical MRI data. Patient 2 in particular reported pain and discomfort during the hand motor task. All pJIA patients had prior (Patient 1) or current (Patients 2 and 3) hand involvement in terms of clinical pain and/or inflammation. B. At the time neuroimaging evaluation, only one individual (Patient 3) had pathology detected in the hand as determined by non-contrast MRI. CRP and ESR levels were normal for Patients 1 and 2, but considered elevated in Patient 3 (CRP: 0.09 mg/dL and ESR: 24 mm/hr).

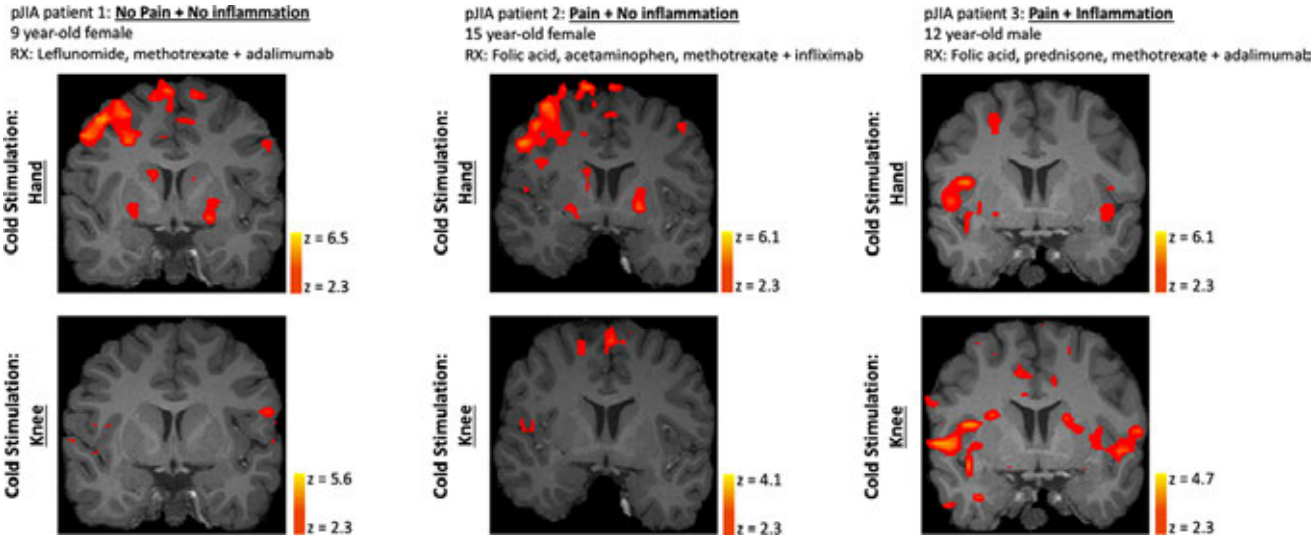

Figure 2. Evoked CNS Response in pJIA Patients With and Without Pain During Unilateral Cold Stimulation of the Hand (Top Row) and Knee (Bottom Row). Overall greater CNS activation was induced by cold stimulation of the dorsal side of the hand compared to the knee. Greater CNS activation for pJIA patient 3 for knee cold stimulation may have resulted from prior knee involvement. This patient reported pain during cold stimulation for both sites (hand and knee). Statistical activation maps are depicted on subject-specific, high-resolution anatomical MRI data.

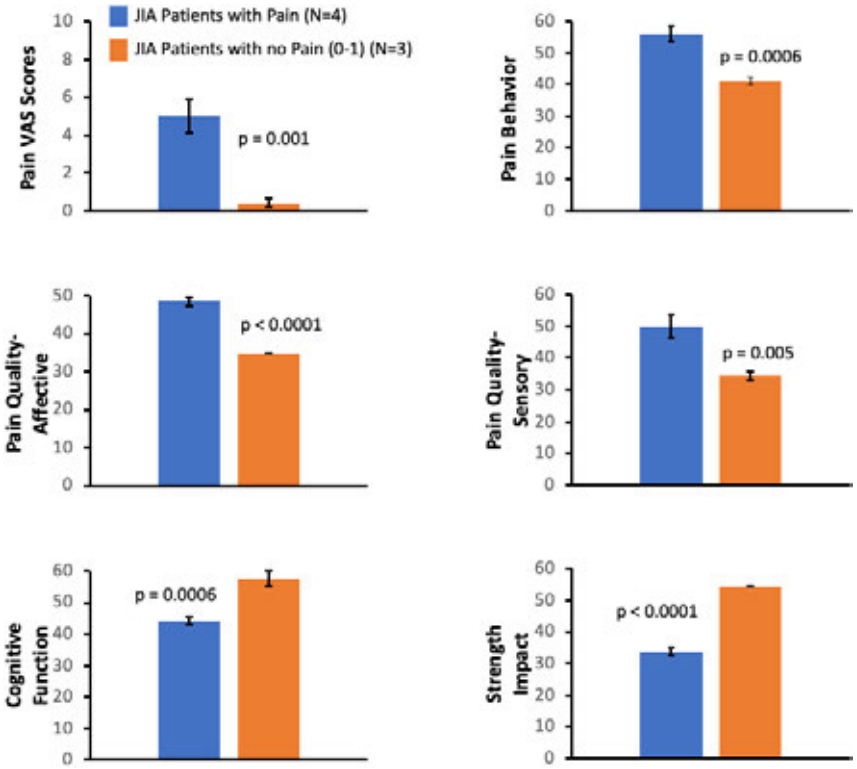

Figure 3. Group-Level Results Demonstrating the Impact of Pain in pJIA With and Without Pain. At the time of evaluation, pJIA patients reported clinical pain at a level of ~5 on a 0-10 scale. PROMIS-based questionnaires were used for all assessments, where higher T-score metrics represent more of the trait measured. The presence of pain in pJIA negatively impacted (loss of function) domains such as cognitive ability and strength. Two-tailed t-tests were performed for all comparisons.

mation (or other pathology) sub-type yielded the most robust CNS activation. MRI abnormalities detected in the hand in Patient 3 consisted of (teno-)synovitis, bone marrow lesions and joint space narrowing. Cold stimuli yielded comparable responses across pain and inflammation conditions (**Figure 2**). Interestingly, in the pJIA patient with current hand/wrist and past knee joint abnormalities, evoked CNS responses and pain scores to cold stimuli were similar at either site. Finally, from PROMIS-based questionnaires (**Figure 3**), pJIA patients with pain reported a greater extent of loss of functions (cognition) and gain of functions (behaviors altered by pain).

Conclusion: For the first time, a neuroimaging-based assessment of pJIA patients was executed. This allowed for novel insight to be gained regarding potential neurobiological factors driving pain in pJIA. The current multidisciplinary datasets are suggestive of non-inflammatory (centralized or neuropathic) and inflammatory pain mechanisms at play in pJIA.

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Diagnosis & Prognosis

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Previous work has demonstrated that malondialdehyde-acetalehyde (MAA) adducts, resulting from oxidative stress, are formed in synovial and lung tissues of patients with rheumatoid arthritis (RA). Moreover, MAA co-localizes in these tissues with citrulline and generates robust anti-MAA antibody responses, suggesting a pathogenic role for MAA-adducted antigens in RA (Thiele GM et al. 2015, England BR et al. 2019). In this study, we sought to examine whether anti-MAA antibody responses were detectable in pre-clinical RA.

	Pre-diagnosis			Post-diagnosis
	Earliest Pre-RA diagnosis Sample	Midterm Sample	Closest Pre-RA diagnosis Sample

Table

*MAA antibody measured in AU/ml; CCP U/ml; RF IU/ml; significant p-values (case vs. control for given time point) shown in bold; values shown as median (interquartile range). **The identification of specific products or scientific instrumentation is considered an integral part of the scientific endeavor and does not constitute endorsement or implied endorsement on the part of the author, DoD, or any component agency. The views expressed in this abstract are those of the author and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense, or U.S. Government.

Methods: Using the Department of Defense Serum Repository, we identified 214 RA cases and 210 matched controls. We tested a mean of 3 serial serum samples from pre-RA diagnosis, and 1 post-RA diagnosis sample, for anti-MAA immunoglobulin (Ig) isotypes A, IgG, and IgM, anti-CCP antibody (CCP2 and CCP3.1), and RF (IgM). The relative timing and trajectories of autoantibody isotypes were evaluated. Case-control samples were compared for each time point using Wilcoxon rank-sum tests.

Results: RA cases and controls were similar in age, sex, race, and smoking status ($p > 0.05$). The timespan of oldest to newest sample was similar in RA cases (mean 12.8±5.6 years) and control (12.3±5.4 years) ($p=0.4$). Anti-MAA, CCP2, CCP3.1, and RF-IgM concentrations by sample in cases and controls are shown in the Table. CCP2, CCP3.1 and RF were significantly elevated in cases vs. controls in the earliest pre-RA diagnosis samples while anti-MAA (IgA, IgM) became significantly elevated in the midterm and closest samples pre-RA diagnosis.

Conclusion: IgA and IgG autoantibodies to MAA are increased pre-RA diagnosis, supporting a potential pathogenic role of immune responses targeting MAA in RA. In contrast to RF and anti-CCP, anti-MAA antibodies appear to be increased later in the pre-clinical period closer to the time of disease onset with higher IgA and IgG anti-MAA appearing, on average, at least 2-3 years prior to RA diagnosis. This suggests that anti-MAA responses may play a role in disease amplification and/or the transition to clinically-apparent RA, potentially after other autoantibodies (e.g. CCP and RF) have become elevated.

A Search to the Target Tissue in Which RA-specific Inflammation Starts: A Detailed MRI Study to Improve Identification of RA-specific Features in the Phase of Clinically Suspect Arthralgia

Xanthe ME Matthijssen ,[1] Fenne Wouters,[2] Debbie Boeters,[2] Aleid Boer,[2] Yousra Dakkak,[2] Ellis Niemantsverdriet,[2] and Annette van der Helm-van Mil[3], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, Leiden, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]LUMC, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Diagnosis & Prognosis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Based on a unique cohort of clinically suspect arthralgia (CSA) patients, we analysed which combinations of MRI-features at onset were predictive for Rheumatoid Arthritis (RA) development. This was done to increase our comprehension of locations of RA-onset and improve the predictive accuracy of MRI in CSA.

Methods: In the discovery cohort, 225 CSA-patients were followed on clinical arthritis development. Contrast-enhanced 1.5T MRIs were made of unilateral MCP(2-5), wrist and MTP(1-5)-joints at baseline and scored for synovitis, tenosynovitis and bone marrow edema. Severity, number and combinations of locations (joint/tendon/bone) with subclinical inflammation were determined, with symptom-free controls of similar age category as reference. Cox

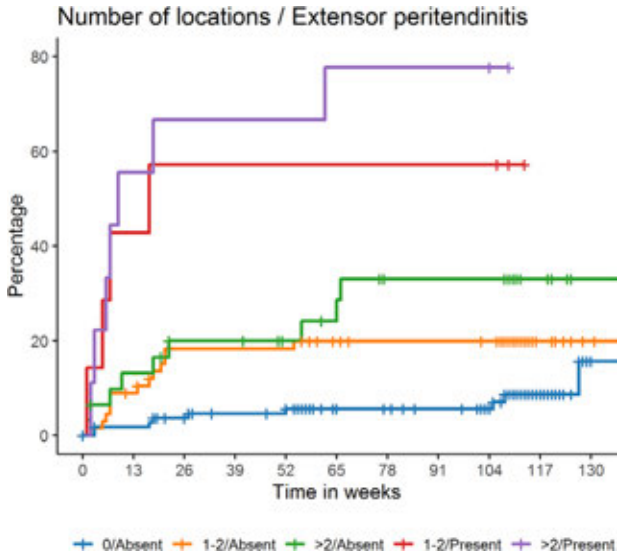

Figure 1. Kaplan Meijer curves showing the associations of the five risk-categories with inflammatory arthritis development in the discovery cohort. The five risk-categories are: 0/Absent: 0 locations with subclinical inflammation without MCP extensor peritendinitis; 1-2/Absent: 1-2 locations with subclinical inflammation without MCP extensor peritendinitis; >2/Absent: 3 or more locations with subclinical inflammation without MCP extensor peritendinitis; 1-2/Present: 1-2 locations with subclinical inflammation + MCP extensor peritendinitis; >2/ Present: 3 or more locations with subclinical inflammation + MCP extensor peritendinitis

regression was used for predictor selection. Predictive values were determined at 1-year follow-up. Results were validated in 209 CSA-patients.

Results: In both cohorts 15% developed arthritis < 1-year. The multivariable Cox model selected presence of MCP-extensor peritendinitis (HR 4.38 (2.07-9.25)) and the number of locations with subclinical inflammation (1-2 locations HR 2.54 (1.11-5.82); ≥3 locations HR 3.75 (1.49-9.48)) as predictors (Figure 1). Severity and combinations of inflammatory lesions were not selected. Based on these variables, five risk-categories were defined: no subclinical inflammation, 1-2 or ≥3 locations, with or without MCP-extensor peritendinitis. Positive predictive values (PPVs) ranged 5% (lowest category; NPV 95%)-67%(highest category). Similar findings were obtained in the validation cohort; PPVs ranged 4% (lowest category; NPV 96%)-63%(highest category).

Conclusion: Tenosynovitis, particularly MCP-extensor peritendinitis, is among the first tissues affected by RA. Incorporating this feature and number of locations with subclinical inflammation improved prediction making with PPVs up to 63-67%.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Diagnosis & Prognosis

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Novel antibody systems including anti-carbamylated protein antibody (anti-CarP IgG) and anti-peptidyl arginine deiminase antibody (anti-PAD4 IgG) are emerging as independent diagnostic and prognostic biomarkers for rheumatoid arthritis (RA) and may add value to rheumatoid factor (IgM) and anti-citrullinated peptide antibody (ACPA IgG), the hallmark antibodies in RA. We evaluated the diagnostic performance of these markers in combination.

Methods: The cohort consisted of 638 consented subjects with RA (fulfilling the 1987 or 2010 ACR classification criteria, mean age: 59.8±0.5 years [SEM], 80% females) and a control group of 775 subjects (mean age: 44.7±0.5 years, 85% females, including systemic lupus erythematosus [n=369], primary Sjogren's syndrome [n=64], primary fibromyalgia [n=85], other connective tissue diseases [n=63], and a group of normal healthy donors [n=194]). Autoantibodies titers from serum were measured using fluoroenzyme immunoassays (IgM RF and anti-CCP [IgG]; Phadia, Upsala Sweden), ELISA (anti-CarP [IgG], research use only [RUO], Inova Diagnostics, San Diego) and bead-based Aptiva™ technology (anti-PAD4 [IgG], RUO, Inova Diagnostics) in a clinical laboratory accredited by the College of American Pathologists. For each positive antibody (above each cutoff) a score of 1 was assigned and the cumulative presence of the 4 antibodies was determined [range 0-4]. The ability of the biomarkers to distinguish RA from controls was calculated using sensitivity, specificity and interval likelihood ratio (LR). Predictive value (PPV) was estimated at 10% pre-test probability. Statistics consisted of Mann-Whitney and Chi-square test.

Results: In this cohort anti-CarP (>20 Units) yielded 33.5% sensitivity and 77.9% specificity. Anti-PAD4 (>1000 Units) yielded 35.0% sensitivity and 95.0% specificity. RF IgM (>5 Units/ml) and anti-CCP (>10 Units/ml) were 67.4% and 66.5% sensitive, respectively (87.5% and 97.0% specific, respectively). RA presented 5-fold higher 4-antibody system scores (2.02±0.05) than controls (0.42±0.02) (p< 0.01). Scores greater than 2 yielded 42% sensitivity and 98.8% specificity. A total of 82 subjects presented with full-house 4 antibodies (score = 4) and 81 of them had RA (99.9% specific). Interval LR and PV for each of the 4-antibody score are presented in the Table. There was no difference in the 4-antibody score between RA who fulfilled the 1987 ACR or 2010 ACR criteria (1.99±0.07 vs 2.08±0.09; p=0.40). In the subset of subjects newly diagnosed (less than one year), average 4-antibody system score for RA (n=33) was 1.72±0.22 (36.3% with score greater than 2) and 0.58±0.12 for other diseases (0% with score greater than 2, 100% specific) (p< 0.01).

Table 1. Combination of RF IgM, anti-CCP (IgG), anti-CarP (IgG), and anti-PAD4 (IgG)

Score	RA (%, N)	CTL (%, N)	Likelihood Ratio [CI 95%]	Pre-test PPV	Post-test PPV	Change
0	20.5% (131/638)	65.8% (510/775)	0.31 [0.27 to 0.37]	10%	3.4%	-6.6%
1	11.6% (74/638)	27.2% (211/775)	0.43 [0.33 to 0.54]	10%	4.5%	-5.5%
2	25.5% (163/638)	5.8% (45/775)	4.40 [3.22 to 6.02]	10%	32.8%	22.8%
3	29.6% (189/638)	1.0% (8/775)	28.70 [14.26 to 57.77]	10%	76.1%	66.1%
4	12.7% (81/638)	0.1% (1/775)	98.39 [13.73 to 705.04]	10%	91.6%	81.6%

Conclusion: This cumulative combination of antibody systems targeting citrullinated, carbamylated, PAD4 and RF is highly specific for RA. It may be useful in diagnosing and classifying RA even in symptomatic patients who present early in the course of disease.

Abstract Number: 1887

Anti-Mitochondrial Antibodies Predict Severe Erosive Disease in Rheumatoid Arthritis

Richard Moore ,[1] Tiffany Pan,[1] J. Lee Nelson,[2] and Christian Lood[1], [1]University of Washington, Seattle, [2]Fred Hutchinson Cancer Research Center, Seattle

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Diagnosis & Prognosis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Mitochondria are key regulators of metabolism, inflammation and cell death, with mitochondrial dysfunction being associated with several diseases. Though mainly found intracellularly, we recently made the observation that mitochondria (Mt) were extruded upon formation of neutrophil extracellular traps (NETs), a neutrophil cell death process commonly observed in autoimmune rheumatic diseases, including rheumatoid arthritis (RA). Other than the inflammatory potential of mitochondria, they are highly immunogenic, evoking an immune response with development of anti-mitochondrial antibodies (AMA). Anti-mitochondrial antibodies are also found in RA patients, with reactivity towards the mitochondrial-specific phospholipid cardiolipin having major clinical significance given the capacity to predispose to thrombosis and miscarriage. However, the potential pathogenic role of other AMAs in RA pathogenesis has not been carefully addressed. The aim of the current study was to investigate prevalence and clinical utility of AMAs in RA patients.

Methods: Mitochondria (Mt) were isolated from the human hepatic cell line HepG2 and analyzed for binding of AMAs using a state-of-the art flow cytometry-based method developed in-house. Two cohorts of healthy controls (HC) and RA patients were used: one cross-sectional (HC, n=30; RA, n=101) and one longitudinal inception cohort (HC, n=100; RA n=247). Purified whole Mt lysate was used to detect proteins targeted by RA AMAs via Western Blot.

Results: Using Western blot analysis, several mitochondrial proteins were identified to which RA patients, but not healthy individuals had reactivity. Of note, most RA patients (67%) recognized a 70 kDa mitochondrial protein ($p< 0.05$). Also by flow cytometry, assessing binding of RA IgG to highly purified mitochondria, AMA IgG levels were markedly elevated in the two RA cohorts as compared to HCs ($p< 0.0001$ and $p=0.02$). In the cross-sectional RA cohort, levels of AMAs were associated with a severe erosive disease ($p=0.01$). We next asked whether AMA positivity

could predict development of erosive disease using the longitudinal inception cohort with a median follow-up of 8 years. Consistent with prior studies, ACPA positivity predicted future erosive disease (OR=6.7, p< 0.0001). Of note, AMA positivity could also predict erosive disease independent of ACPA positivity (OR=4.6, p=0.006). Being positive for either of the autoantibodies further increased the odds ratio (10.4, p=0.002), suggesting additive value of the two markers. Further, in contrast to ACPA (OR=1.5, p=0.43), AMA could also predict joint space narrowing (OR=3.3, p=0.02).

Conclusion: Our results demonstrate the presence of an important, yet to be identified, novel mitochondrial autoantibody prevalent in RA patients. Further, these AMAs, by themselves, as well as in combination with established biomarkers, e.g. ACPA, provide significant clinical value in identifying patients at risk of developing severe erosive disease, allowing for preventative therapeutic strategies.

Serum Calprotectin Is a Prognostic Marker for Drug-Free Remission in RA

Emma de **Moel** ,[1] Jürgen Rech,[2] Michael Mahler,[3] Johannes Roth,[4] Anne Schouffoer,[5] Karel Ronday,[6] Thomas Huizinga,[5] CF Allaart,[7] René Toes,[5] Georg Schett,[8] and Diane van der Woude[1], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Department of Internal Medicine 3, Friedrich-Alexander-University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany, [3]Inova Diagnostics, San Diego, CA, [4]University of Muenster, Muenster, Germany, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Haga Ziekenhuis, The Hague, Netherlands, [7]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, Leiden, Netherlands, [8]Department of Internal Medicine 3, Friedrich Alexander University Erlangen-Nuremberg, Erlangen, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Diagnosis & Prognosis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The ability to accurately predict whether RA patients will flare following DMARD-tapering would open doors in clinical decision-making for achieving drug-free remission (DFR). Calprotectin (S100A8/A9 or MRP8/14), an inflammatory protein released locally by monocytes, is a marker of disease activity in RA[1]. We hypothesized that circulating calprotectin could indicate residual subclinical inflammation in patients who are in remission on DMARDs, and that patients with high calprotectin levels might thus be more prone to flare after DMARD-tapering. As such, we investigated the value of calprotectin levels as a marker for disease flare after DMARD-tapering.

Methods: We used data from two randomized controlled trials: the IMPROVED2 study and the RETRO3 study. The IMPROVED included early (< 2 years) untreated RA, was steered at disease activity score-remission (DAS44< 1.6), and, for those achieving remission at 8 months, rapidly tapered and stopped methotrexate to attempt drug-free remission. The RETRO randomized patients with long-standing RA in stable remission (DAS44< 2.6) to three arms: continue, taper by 50%, or stop (biological or conventional) DMARDs. Only patients in the taper or stop arms were included for this analysis. Circulating calprotectin at the tapering timepoint was determined using a diagnostic calprotectin kit (Inova Diagnostics, Research use only) in IMPROVED and using an in-house sandwich ELISA4 in RETRO. Logistic regression and area under the receiver operating characteristic curves (AUC) analyses were conducted

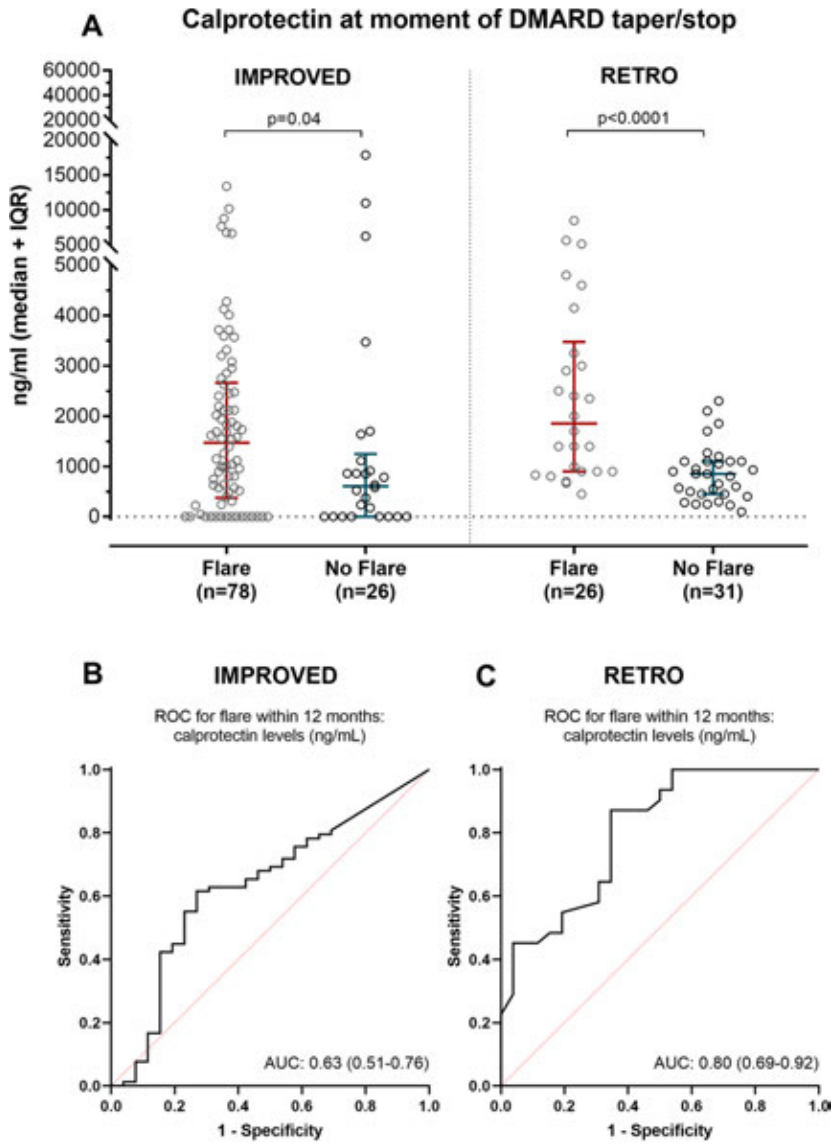

Figure 1. A) Circulating calprotectin levels (ng/mL) at the moment of DMARD tapering/stop, separated by whether patients experienced a disease flare within 12 months of tapering. p-values were calculated by Mann-Whitney-U tests. B-C) ROC-curves indicating the predictive value of circulating calprotectin levels (ng/mL) at the moment of DMARD-tapering/stop for disease flare within 12 months of tapering in the IMPROVED (B) and RETRO (C).

to evaluate the predictive value of calprotectin for flare (loss of remission) within 12 months of tapering/stopping DMARDs.

Results: In the IMPROVED and in the RETRO, respectively 104 and 57 patients were eligible to taper/stop DMARDs and had serum available. In both IMPROVED and RETRO, patients that flared within 12 months had higher calprotectin at the moment of DMARD-tapering/stop (Figure 1A). Two-fold higher calprotectin at the moment of DMARD-tapering/stop was associated with an increased risk (odds ratio) of flare of 1.1 (95% CI: 1.0-1.2) in the IMPROVED study and 3.6 (95% CI: 1.8-7.5) in the RETRO study. Correcting for clinical predictors of flare (body mass index, gender, anti-CCP2, and baseline DAS in IMPROVED; age and anti-CCP2 in RETRO) did not greatly alter these estimates: 1.1 (95% CI: 1.0-1.2) in the IMPROVED study and 4.0 (95% CI: 1.8 to 8.9) in the RETRO study. The AUC for

predicting flare within 12 months was 0.63 (95% CIs: 0.51-0.76) in the IMPROVED study and 0.80 (95% CIs: 0.69 to 0.92) in the RETRO study (Figure 1B-C).

Conclusion: Circulating calprotectin levels in RA patients in remission on DMARDs are associated with higher risk of disease flare upon DMARD-tapering. Calprotectin's ability to predict whether RA patients will flare following DMARD-tapering could aid in clinical decision-making for attempting drug tapering and discontinuation.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Diagnosis & Prognosis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To search biomarkers of clinical relapse and radiological progression in patients with RA in clinical remission

Methods: RA patients in clinical remission (defined as DAS28-ESR < 2.6 for > 6 months) were selected. Clinical, epidemiological and serological data were analyzed. A MRI of dominant hand and an ultrasound assessment of knees and hands were performed at baseline and at 48 weeks. Serum levels of inflammation and angiogenesis biomarkers were determined by Quantibody® Human Array at baseline and 48 weeks. A synovial biopsy was performed in patients with subclinical synovitis. Patients were followed up for 5 years. Clinical and radiological data (hands and feet

X-rays) were collected. Clinical relapse was defined as loss of remission status (DAS28 > 2.6) leading to a therapeutic intervention. Treatment change was defined as the change in csDMARD or biological therapy of RA. Radiographic progression was defined as the change in the SvH index at 5 years >10.47 (SDD).

Results: 60 patients fulfilling ACR 2010 criteria for RA and DAS28< 2.6 were included. 1/3 also met remission criteria for SDAI (33.3%), CDAI (31.6%) and ACR (35%). 78.3% of the patients were women. Mean age was 53 years and the disease duration was 110 months. 81.6% were ACPA +. 26% were taking oral prednisone, 76% DMARDs and 45% biological therapies. At baseline, 67% had PD signal and 48% met a more stringent criteria for subclinical synovitis (UdAS: SH > 2 + PD). After 5 years of follow-up, 44 (73.3%), 11 (18.3%), 9 (15%) and 10 (16.6%) patients remained in remission according to DAS28, SDAI, CDAI and ACR criteria, respectively. 29 patients (48.3%) had flares at any time during the 5 years of follow-up. In the multivariate analysis, the variables that were related to clinical relapse were BMI (OR 1.8 CI 95% 1.2-2.7), TNFalpha levels at baseline (OR 32.4, CI 95% 1.9-546.2), the fisrt year change in CXCL16 levels (OR 1.05 CI 95% 1-1.1) and ESR (OR 2.48 CI 95% 1-6.1). Patients who flared during the follow-up had a significantly higher number of mast cells (p=0.02). Regarding to change in treatment, 20 patients (33.3%) changed DMARDs or biological therapy at any time during the 5 years of follow-up. In the logistic regression analysis, BMI (OR 1.3 CI 95% 1-1.7), biological therapy (OR 24.7 CI 95% 2.3-257.2), progression of erosions by MRI during the first year (OR 1.2, CI 95% 1-1.3) and the rate of progression of calprotectin serum levels during the first year (OR 2.8, CI 95% 1-8.2) were the main factors that predicted the change in baseline therapy after 5 years of follow-up . Finally, only 6 patients (10%) had X-Ray progression according to the SvdH index. The number of macrophages and T cells in synovial tissue at baseline was much higher in patients with radiological progression. Likewise, the first-year rate of bone edema was significantly higher in patients with structural progression (p = 0.04)

Conclusion: 27% of RA patients lost clinical remission (DAS28) after 5 years of follow-up. BMI, serum TNFa levels, and first-year rate of CXCL16 and VSG levels were predictors of joint flares. Baseline BMI, use of biological therapy, MRI erosions and calprotectin levels predicted the change of baseline therapy for RA. Only 10% of patients had radiological progression along the study.

Neuro-psychiatric	78 (3.3)	83 (3.5)	0.70	0.96 (0.71, 1.31)
Musculoskeletal	155 (6.5)	135 (5.6)	0.22	1.16 (0.92, 1.46)
Notes: * N includes first events of a given type. The first mild, moderate, and severe are all included. As well, the first of each subtype of adverse event was included. ** The outcome labeled "all coded adverse events" includes all of the MedDRA coded events, not just the adjudicated events of interest.				

Background/Purpose: Prior observational studies have estimated the risk of adverse events with low dose methotrexate (MTX). However, prior randomized controlled trials (RCT) were too small to precisely estimate the risk of MTX-related adverse events (AEs). We investigated the risk of AEs in patients without rheumatic disease using MTX compared with placebo.

Methods: We conducted pre-specified secondary analyses of the CIRT randomized controlled trial (Ridker et al, NEJM, 2019). The trial was conducted in N. America among adults with known cardiovascular disease and diabetes or metabolic syndrome. Subjects were randomly allocated to low dose MTX (maximum 20mg/week) or placebo. All subjects received folic acid 1mg for six days/week. The "AEs of interest" were adjudicated blinded to study drug assignment; they included gastrointestinal (hepatic or other), pulmonary (COPD, bronchitis, or pneumonitis), infectious, hematologic (bleeding or cytopenias), malignant, mucocutaneous (skin, alopecia or oral lesions), renal (acute kidney insufficiency or nephrolithiasis), neuropsychiatric, and musculoskeletal. The frequency and relative rates of the specific AEs of interest, laboratory AEs (AST, ALT, and CBC) as well as all reported AEs were compared across treatment arms in intention to treat analyses. We estimated the hazard ratios (HR) using Cox proportional hazards regression. Skin cancers were further examined by sub-type using the same methods.

Results: 6,158 patients were enrolled and 4,786 randomized after a 5-8 week active run-in period and followed for a mean of 27 months on a median dosage of 16mg. Of the 2,391 subjects randomized to MTX, 2,104 (84.5%) experienced any AE and 1,968 (82.3%) experienced an AE of interest. This compared to 1,998 (78.0%) of the 2,395 randomized to placebo who experienced any AE and 1,796 (75.0%) who experienced an AE of interest. The relative rate of an AE of interest (**Table 1**) was 27% higher for those randomized to MTX (HR 1.27, 95% CI 1.19– 1.35) compared

Table 2: Frequency and Relative Risks of Skin Cancer Adverse Events (AEs) During the Randomized Phase of CIRT				
	MTX N=2391	Placebo N=2395	p-value	Hazard ratio (95% CI)
	N (%)*			
Skin Cancer Events	56 (2.3)	27 (1.1)	<0.01	2.20 (1.39, 3.50)
Basal cell	20 (0.8)	14 (0.6)	0.31	1.47 (0.74, 2.90)
Squamous cell	36 (1.5)	11 (0.5)	<0.01	3.55 (1.78, 7.05)
Melanoma	6 (0.3)	3 (0.1)	0.34	2.06 (0.52, 8.23)
* N includes first events of a given type.				

to placebo. The relative rates of gastrointestinal (HR 1.88, 95% CI 1.71-2.07), infectious (HR 1.16, 95% CI 1.03-1.31), pulmonary (HR 1.41, 95% CI 1.14-1.75), and hematologic (HR 1.17, 95% CI 1.09-1.26) events were elevated for those randomized to MTX. There was no difference between treatment arms for the risk of malignant, mucocutaneous, neuropsychiatric, musculoskeletal, or renal AEs. While there were no overall differences in malignancies, skin cancers were more common in patients randomized to MTX than placebo, with a composite skin cancer HR 2.20 (95% CI 1.39-3.50) and squamous cell cancer HR 3.55 (95% CI 1.78-7.05) (**Table 2**).

Conclusion: In this large RCT among patients with known cardiovascular disease, MTX was associated with a significantly increased risk of AEs compared with placebo. While the trial was conducted in non-rheumatic disease patients and only select adverse events were adjudicated, the elevated risks observed for infectious, pulmonary, gastrointestinal, hematologic and skin cancer events represent a broad range of clinical issues, requiring further examination. These results quantify risk of MTX for the many clinicians and patients considering treatment across the spectrum of systemic rheumatic diseases.

Hydroxychloroquine Use Is Associated with a Lower Risk of Major Adverse Cardiovascular Events in Medicare Recipients with Rheumatoid Arthritis

Priyanka Iyer,[1] Yubo Gao,[2] Saket Girotra,[2] Jeffrey Curtis,[3] Mary Vaughan-Sarrazin,[4] and **Namrata Singh** [4], [1]University of Iowa, Iowa City, IA, [2]University of Iowa Hospitals and Clinics, Iowa city, IA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Iowa, Iowa City

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments III: Cardiovascular Disease & Readmissions

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Hydroxychloroquine (HCQ) has known immunomodulatory effects and mechanistic actions that may provide cardioprotective effects. To date, cardiovascular (CV) outcomes in elderly patients receiving HCQ in clinical practice have not been evaluated. This is important since the majority of patients with CV disease in the U.S. are adults ≥ 65 years. We hypothesized that the use of HCQ is protective for major adverse cardiovascular events (MACE) defined as acute admissions for stroke, myocardial infarction or heart failure.

Methods: We compared the risk of MACE in a retrospective cohort of Medicare beneficiaries aged ≥65 years with rheumatoid arthritis (RA) who initiated HCQ (exposed) and who did not initiate HCQ (non-exposed) between 2014 and 2016. RA was defined by the following ICD codes – 714.0, 714.2, M05.xx, M06.4 and M06.1. Data sources included Medicare Parts A, B, and D claims for a 5% random sample of beneficiaries. The index date for the exposed was defined by the date of the first HCQ fill. Each exposed user was matched to 2 non-users of HCQ using propensity score derived from patient baseline characteristics including demographics, comorbid conditions like prior CV disease, and other medication use (cardioprotective agents like ACE inhibitors, antiplatelets, statins and beta blockers, NSAIDs, opioids, steroids, methotrexate, and tumor necrosis factor alpha inhibitors [TNFi]) (Table 1). Patient follow-up started at the index date and continued until the first MACE, end of HCQ use or the end of the observation period (December 31, 2016). We compared incident MACE using Kaplan-Meier analysis on matched patients. The primary outcome was the occurrence of MACE, and the secondary outcome was the composite of MACE and all-cause mortality. Cox proportional hazards model was used to compare the hazards of MACE events between HCQ users to non-users.

Beta Blocker	2.48	31.27	28.96	0.781	0.05

Results: We found 1602 eligible RA patients with incident HCQ use and matched them to 3204 RA patients who did not use HCQ over the study period. The mean age of HCQ user cohort was 74.37 years and of the non-users was 74.73. 75.41% of the HCQ users were females compared to 72.53% in the non-users. The mean follow-up time was 1.7 years in non-users and 1 year in HCQ users. During the observation period, 329 MACE events occurred, 54 in HCQ exposed (3.51 per 100 patient-years) and 275 in the non-exposed group (incidence rate of 5.38 per 100 patient-years. Multivariate Cox regression model showed a hazard ratio (HR) of 0.47 (95% CI: 0.35-0.63, p< 0.0001) for MACE for HCQ users versus non-users. Compared to people aged 85+ years, those aged 75 to <85 (HR 0.73, 95% CI: 0.51 – 1.04), or those aged 65 to <75 (HR 0.59, 95% CI: 0.42 – 0.84) years had a lower hazard of MACE. Similarly, the HR for composite outcome of MACE and all-cause mortality was 0.40 (95% CI: 0.32-0.51, p< 0.0001) for users compared to non-users.

Conclusion: Our study suggests that incident HCQ use is associated with a 53% lower risk of MACE events compared to non-users in an elderly population of patients with RA. Based on our study, future larger trials can be designed looking at the efficacy of a well-tolerated and relatively inexpensive drug on CV outcomes in the general population.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments III: Cardiovascular Disease & Readmissions
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The impact of immunosuppression on post-operative outcomes in rheumatoid arthritis (RA) has primarily been studied in patients undergoing joint replacement surgery. We aimed to evaluate the impact of glucocorticoids and biologics on outcomes after other major surgeries.

Methods: Using Medicare claims data 2006-2015 we identified adults with ≥2 diagnoses of RA who received methotrexate, a TNF inhibitor, abatacept, rituximab, tocilizumab, or tofacitinib within 6 months before major surgery and had 1 year of continuous prior Medicare enrollment (baseline). Hip fracture repair, abdominal surgeries (cholecystectomy, hysterectomy, hernia surgery, appendectomy, colectomy for diverticular disease), and cardiac surgeries (coronary artery bypass graft, mitral or aortic valve surgery) were identified based on primary ICD-9 procedure codes from inpatient hospitalization using established definitions. Patients with malignancy or HIV and patients with another major

Non-TNF biologic/tsDMARD	0.65 (0.31-1.39)	0.85 (0.41-1.75)	0.48 (0.21-1.08)	0.91 (0.48-1.72)	1.02 (0.69-1.50)	0.98 (0.58-1.65)

Odds ratios from inverse probability weighted logistic regression models. Propensity scores are re-calculated for each surgery type and include the same variables as the models shown in Table 2. Bold cells indicate $p < 0.05$.

surgery within 6 months were excluded. Inverse probability weighted logistic regression models assessed association between average glucocorticoid dose in the 90 days before surgery (none, ≤5mg, 5-10mg, >10mg) and risk of 90-day mortality and 30-day readmission (among patients discharged to home, skilled nursing facility, or inpatient rehabilitation). Propensity score models included surgery type, elective vs. non-elective surgery, demographics, and measures of healthcare utilization, comorbidities, and previous infection during the baseline period. Separate models with recalculated propensity scores compared risk of these outcomes in patients receiving a biologic or targeted synthetic DMARD (tsDMARD) vs. patients exposed to methotrexate without biologics/tsDMARDs, requiring patients to have an infusion or prescription within 8 weeks before surgery.

Results: We identified 13544 surgeries meeting all inclusion and exclusion criteria, including 4328 hip fracture surgeries, 6403 abdominal surgeries, and 2813 cardiac surgeries. Glucocorticoids were associated with a dose-dependent increase in the risk of 90-day mortality and 30-day readmission, although associations were partially attenuated in propensity weighted models (Table 2). Associations with mortality were strongest among patients undergoing cardiac surgery, while associations with 30-day readmission were similar across surgeries (Table 3). Among the 10677 (78.8%) of patients who received their biologic/tsDMARD or methotrexate within 8 weeks of surgery, we found no significant increase in the risk of 90-day mortality or 30-day readmission in patients receiving a TNF or patients receiving a non-TNF biologic/tsDMARD vs. patients receiving methotrexate, with similar results across surgery types (Tables 2-3).

Conclusion: Glucocorticoids are associated with greater risk of adverse outcomes after major surgery, especially at higher doses. Recent exposure to biologics/tsDMARDs, however, is not associated with increased mortality or readmission.

Abstract Number: 1893

Statin Exposure Moderates the Effects of Chronic Inflammation on Coronary Atherosclerosis Progression and Cardiovascular Events in Rheumatoid Arthritis

George Karpouzas ,[1] Sarah Ormseth,[1] Elizabeth Hernandez,[2] and Matthew Budoff[1], [1]Harbor-UCLA Medical Center and Los Angeles Biomedical Institute, Torrance, CA, [2]Harbor-UCLA and Los Angeles Biomedical Institute, Torrance, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments III: Cardiovascular Disease & Readmissions
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Chronic inflammation yields higher risk of cardiovascular events (CVE) in patients with rheumatoid arthritis (RA). We recently reported that occult atherosclerosis burden on coronary computed tomography

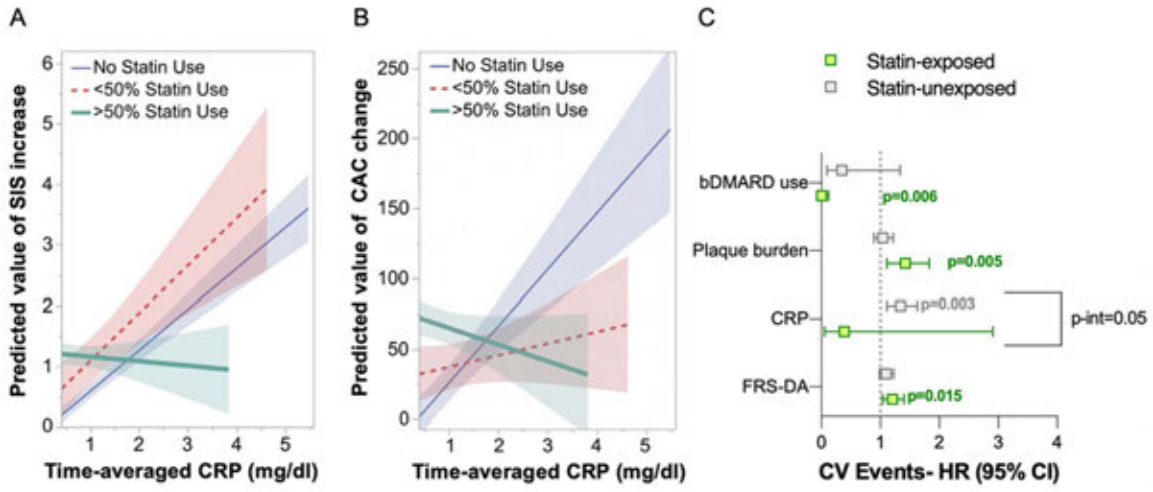

Figure 1. Statin exposure moderates the effect of cumulative inflammation on (A) coronary plaque, (B) CAC progression and (C) CVE risk in RA. FRS-DA: D'Agostino Framingham cardiovascular risk score.

angiography (CCTA) predicted CVE in RA beyond cardiac risk factors or scores. We further showed that that higher cumulative inflammation independently predicted coronary plaque progression. We here explored whether statin exposure impacted plaque progression or incident CVE in RA; we further evaluated potential interactions of statin treatment with cumulative inflammation on both outcomes.

Methods: One hundred-fifty RA patients underwent a baseline CCTA and followed thereafter; 101 had a repeat scan within 83±3.6 months. Coronary artery calcium (CAC) was reported as Agatston score. Segment involvement score (SIS) reported numbers of coronary segments with plaque; segment stenosis score (SSS) reflected the cumulative plaque stenosis. Plaque composition was defined as non-calcified (NCP), mixed or calcified. Cox proportional hazards regression models with time-varying covariates evaluated predictors of CVE. Negative binomial regression was used to assess count outcomes and a generalized linear model with a Tweedie (Poisson-Gamma) error distribution for CAC change.

Results: Longer statin exposure independently inhibited NCP progression [OR=0.72 (0.57-0.90), p< 0.01]. An interaction between cumulative inflammation and duration of statin exposure on total SIS increase (p=0.017) as well as CAC increase (p=0.006) was observed independently of age, dyslipidemia, total prednisone and methotrexate dose and bDMARD duration (Figure 1A and B respectively); higher time-averaged CRP yielded significant plaque progression in patients not on statin [RR=1.48 (1.05-2.09), p=0.025] or those receiving statins< 50% of the study period [RR=1.31 (1.01-1.69), p=0.040]. In contrast, in subjects with statin exposure >50% of study time, such risk was not observed [RR=1.07 (0.93-1.22), p=0.35]. Similarly for CAC, higher time-averaged CRP yielded greater progression risk in statin unexposed patients [OR=2.33 (1.29-4.22), p=0.005]; in contrast, any statin exposure mitigated that risk [OR=1.17 (0.81-1.68), p=0.41 for exposure< 50% and OR=0.96 (0.44-2.17), p=0.98 for exposure >50%]. Sixteen RA patients incurred 19 CVEs. Higher cumulative inflammation yielded significantly higher CVE risk in patients not receiving statins vs. those who do [HR=1.34 (1.11-1.63), p=0.003 and 0.39 (0.05-2.91), p=0.36 respectively, p-interaction=0.05, Figure 1C].

Conclusion: Statin exposure moderates the effect of cumulative inflammation on coronary atherosclerosis progression and CVE risk in RA. The atheroprotective effect of statins may highlight potential local anti-inflammatory attributes at the plaque level independently of systemic inflammation.

Session Title: RA – Treatments III: Cardiovascular Disease & Readmissions

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of venous thromboembolism (VTE, which includes pulmonary embolism [PE] and deep vein thrombosis [DVT]) compared with the general population. However, population-based data on the risk of VTE among patients with newly diagnosed RA and new users of disease-modifying anti-rheumatic drugs (DMARDs) are limited. The objectives of our study were: 1) to estimate the incidence rate of VTE, PE, DVT among new users of biologic DMARDs (bDMARDs) and conventional DMARDs (cDMARDs) in RA patients. 2) To compare risk of VTE, PE and DVT between new users of bDMARDs and cDMARDs.

Methods: We conducted a population-based cohort study using administrative data that included all visits to physician and hospital from Jan 1990 until Mar 2015 and all dispensed medication from Sep 1995 to Mar 2015. Our sample included all patients with newly diagnosed RA using a previously validated case definition from physician billing data; and who were new users of a DMARD (no prior use in the 365 days before the first DMARD). Date of first DMARD use was considered the index date. For discontinuation, the exposure risk window for each DMARD extended until 30 days after the expiration of the last fill. Our outcomes of interest were first ever VTE, PE, and DVT based on ICD-9 or ICD-10 codes plus dispensation of an oral anti-coagulant. Follow-up began on the index date and continued until the earliest occurrence of: 1) DAMRD discontinuation; 2) leaving the province; 3) death; 4) the end of the study period; 5) the outcome of interest; or 6) switching to another DMARD. We calculated incidence rates per 100 person-years for

60-64 yrs.	658	13.9	<5	1.26	830	0.36 (0.07, 1.06)
65+ yrs.	1,299	27.5	16	1.12	1,453	1.10 (0.63, 1.79)
Male	3,500	74.1	17	1.07	3,749	0.45 (0.26, 0.73)
Female	1,222	25.9	7	1.11	1,355	0.52 (0.21, 1.06)

Table 3. Relative risk of incident VTE, PE and DVT according to DMARDs use

	B-DMRADs	C-DMARDs
Venous Thromboembolism (VTE)	N = 4723	N = 14809
Cases, N	24	40
Incidence Rate/1000 Person-Years	0.47	0.36
Age-, Sex-, Entry Time-Adjusted Cox HR (95% CI)	1.58 (0.94, 2.65)	1
*Fully-Adjusted Cox HR (95% CI)	1.20 (0.67, 2.15)	1
Pulmonary Embolism (PE)	N = 4730	N = 14831
Cases, N	11	16
Incidence Rate/1000 Person-Years	0.21	0.15
Age-, Sex-, Entry Time-Adjusted Cox HR (95% CI)	1.76 (0.80, 3.85)	1
*Fully-Adjusted Cox HR (95% CI)	1.20 (0.49, 2.91)	1
Deep Vein Thrombosis (DVT)	N = 4730	N = 14826
Cases, N	16	31
Incidence Rate/1000 Person-Years	0.31	0.28
Age-, Sex-, Entry Time-Adjusted Cox HR (95% CI)	1.39 (0.75, 2.57)	1
*Fully-Adjusted Cox HR (95% CI)	1.04 (0.53, 2.04)	1

*adjusted for age, sex, number of outpatient and inpatient visits, charlson comorbidity index, obesity, alcoholism, hypertension, sepsis, varicosed vein, inflammatory bowel disease, trauma, fracture, surgery, glucocorticoid use, hormone replacement therapy, oral contraceptives, aspirin, cox-2 inhibitors

each outcome (Table 1). Incidence rates of VTE were also stratified by age and sex. Furthermore, we conducted Cox proportional hazard regression models to estimate the hazard ratio (HR) of incident VTE, PE, and DVT during periods of bDMARDs use relative to periods of cDMARDs use after adjusting for baseline covariates.

Results: 14,809 patients were new users of cDMARDs (74% female, mean age of 58 yrs) and 4,723 were new users of bDMARDs (74% female, mean age of 56 yrs). Among new users of cDMARDs and bDMARDs, 40 and 24 patients developed VTE, the incidence rate was 0.36 and 0.47 per 100 person-years (Table 1), respectively. Across cDMARDs and bDMARDs, risk of VTE increased with age and was also higher in men than women (Table 2). Comparing bD-

MARDs with cDMARDs, the fully adjusted HRs were 1.20 (95% CI, 0.67-2.15), 1.20 (95% CI, 0.49-2.91), 1.04 (95% CI, 0.53-2.04) (Table 3), for VTE, PE, DVT, respectively.

Conclusion: The incidence rate of VTE varies by age and sex among RA patients treated with different DMARDs. The point estimate suggests a potentially increased risk of VTE in bDMARDs compared to cDAMRDs, but the results were not statistically significant. Further studies with larger sample size and adjusting for confounding by indication are needed.

Biologics Prevent Cardiovascular Events in Rheumatoid Arthritis by Inhibiting Non-calcified Coronary Plaque Progression and Stabilizing Vulnerable Plaques

George Karpouzas ,[1] Sarah Ormseth,[1] Elizabeth Hernandez,[2] and Matthew Budoff[1], [1]Harbor-UCLA Medical Center and Los Angeles Biomedical Institute, Torrance, CA, [2]Harbor-UCLA and Los Angeles Biomedical Institute, Torrance, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments III: Cardiovascular Disease & Readmissions
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Biologic disease-modifying antirheumatic drugs (bDMARDs) may decrease cardiovascular events (CVE) in Rheumatoid arthritis (RA). We here evaluated whether bDMARDs reduce long-term CVE risk in RA; we further explored whether potential benefits were rendered by altering the trajectory of coronary plaque progression or stability.

Methods: One hundred-fifty patients without CV disease underwent a baseline coronary computed tomography angiography (CCTA) and followed thereafter; 101 underwent repeat CCTA within 83±3.6 months. Coronary artery calcium (CAC) was quantified by the Agatston method. Segment involvement score (SIS) reported numbers of coronary segments with plaque; segment stenosis score (SSS) reflected the cumulative plaque stenosis. Plaque composition

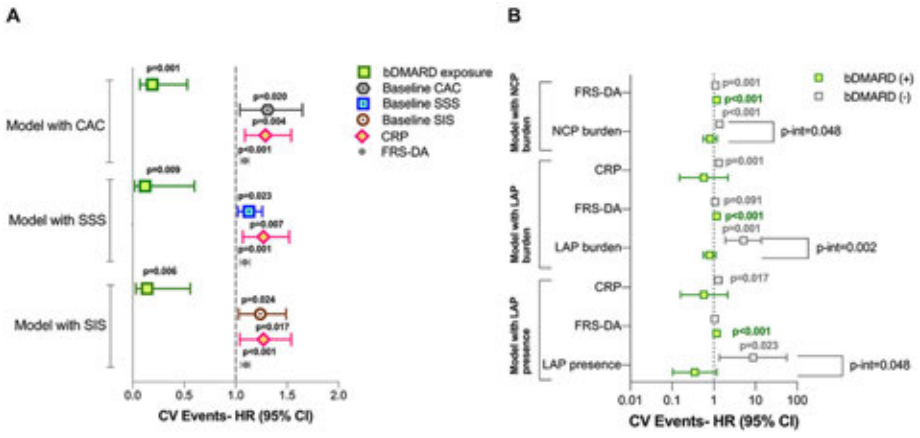

Figure 1. (A) bDMARD use independently lowers CV event risk in RA. **(B)** bDMARDs moderate the effect of soft, NCP burden as well as LAP presence and burden on long-term CVE risk.

was defined as non-calcified (NCP), mixed or calcified. Lesions containing necrotic cores (low attenuation plaques-LAP) were deemed vulnerable. Cox proportional hazards regression models with time-varying covariates evaluated predictors of CVE. Robust logistic regression was used to assess plaque progression, and a generalized linear model with a Tweedie (Poisson-Gamma) error distribution for CAC change.

Results: Sixteen RA patients incurred 19 CVEs. Use of bDMARDs lowered CVE risk independently of cardiac scores, baseline atherosclerosis burden and time-varying CRP (Figure 1A, all p< 0.009). bDMARD use moderated the effect of baseline NCP burden on CVE risk (p-interaction=0.048); higher NCP load yielded higher risk only in bDMARD unexposed patients [HR=1.37 (1.16-1.61)], but not in exposed ones [HR=0.82 (0.56-1.20), Figure 1B]. Indeed, longer bDMARD use inhibited NCP progression independently of statin exposure, cumulative prednisone and methotrexate doses [OR=0.77 (0.61-0.98)]. Moreover, bDMARD use moderated the effect of baseline LAP presence and burden on CVE risk [p-interaction=0.048 and 0.002 respectively, Figure 1B]. LAP presence yielded an 8.8-fold [(1.36-56.80)] higher risk of CVE in patients not on bDMARDs but not in those on bDMARDs [HR=0.35 (0.10-1.19)]. Similarly, higher baseline LAP burden yielded greater CVE risk exclusively in patients not on bDMARDs [HR=5.16 (1.90-13.99)] but not in those receiving bDMARD [HR=0.79 (0.56-1.10)]. Longer bDMARD use reduced the likelihood of LAP presence on follow-up [OR=0.22 (0.07-0.69)] after adjustment for cardiac scores. Indeed, patients with LAP loss or lower LAP burden on follow-up had longer exposure to bDMARDs compared to those without [differences of 3.75 years (0.46-7.04), p=0.028 and 6.08 years (3.02-9.13), p=0.001 respectively].

Conclusion: bDMARD use reduces CVE risk in RA, possibly by inhibiting non-calcified coronary plaque progression, remodeling and by stabilizing vulnerable plaques.

Abstract Number: 1896

Breastfeeding in Women with Rheumatic Diseases

Naira Ikram ,[1] Amanda Eudy,[1] and Megan Clowse[1], [1]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: For many women, breastfeeding is a central aspect of motherhood, but many worry that their rheumatic disease or treatment will interfere. Fortunately, most anti-rheumatic medications are compatible with breastfeeding. This study sought to identify the frequency and predictors of the desire to and actually breastfeeding in women with a range of rheumatic diseases.

Methods: All pregnant patients with rheumatic disease in a single center between 2008-2018 in a prospective study of pregnancy and the post-partum period. Women were grouped into 4 diagnosis categories: systemic lupus erythematosus (SLE), undifferentiated connective tissue disease (UCTD), inflammatory arthritis (including rheumatoid, psoriatic, juvenile idiopathic arthritis, and spondyloarthropathies) and other rare rheumatic diseases. Breastfeeding intention was collected at study entry and breastfeeding was recorded at the post-partum visit. Infant feeding was divided into those who exclusively formula-fed, compared to those who exclusively breastfed or fed with a combination of breastmilk and formula.

Table 1. Maternal and Infant Characteristics by Method of Infant Feeding at the Post-partum Rheumatology Visit.

	Formula Only N=92 (35%)	Breastfeeding N=173 (65%)	P-value
Maternal Diagnosis			
SLE	38 (41%)	50 (29%)	0.081
UCTD	7 (8%)	26 (15%)	
Arthritis	30 (33%)	70 (40%)	
Rare rheumatic diseases*	17 (18%)	27 (16%)	
Maternal Demographics			
Race (black)	30 (33%)	29 (17%)	0.005
Mean age	29.6 (5.9)	32.2 (5.1)	0.0004
Education: at least college graduate	47 (52%)	137 (81%)	<0.001
Income under $50,000	40 (47%)	32 (20%)	<0.001
Single	21 (24%)	15 (9%)	0.002
Feeding Plan during Pregnancy			
Plan to breastfeed	53 (58%)	158 (90%)	<0.001
Plan to use formula	29 (32%)	5 (3%)	
Unsure	10 (11%)	12 (7%)	
Health of the Baby:			
Gestational age			
- Preterm (>37)	28 (30%)	27 (16%)	0.007
- Very preterm (<34)	8 (9%)	11 (6%)	0.5
Neonatal intensive care unit admission	27 (31%)	22 (14%)	0.003

* Rare Rheumatic Diseases: Antiphospholipid Syndrome=3, cutaneous lupus=8, mixed connective tissue disease=4, scleroderma=5, myositis=2, Sjogen's Syndrome=6, vasculitis=1, other=15.

Results: A total of 265 pregnancies were included in the study, 88 with SLE, 33 with UCTD, 100 with arthritis, and 44 with other rheumatic diagnoses. Overall, most patients were white (70%), had at least a college education (71%), lived with a spouse/partner (85%), and had private health insurance (76%). While pregnant, % of all women indicated a desire and plan to breastfeed their infant.

Post-partum, an average of 7.5 weeks after delivery, 92 (35%) were feeding exclusively with formula, 110 (42%) exclusively breastmilk, and 63 (24%) a mix of breastmilk and formula. Of the women who planned to formula-feed only, 85% did so. On the other hand, 25% of the women who planned to breastfeed were not. Of these, 81 had tried to breastfeed, but stopped. The most common reasons for having breastfeeding were having a low milk supply, the baby being unwell, and concerns over the mother's medications.

In univariate analysis, exclusively feeding with formula was not associated with maternal diagnosis, but was significantly more common in women who were black, younger, had less than a college education, had an income under $50,000/year, and live without a partner (see Table 1). Babies that were admitted to the neonatal intensive care unit or were born preterm were more likely to be formula-fed. In analysis, formula feeding was only associated with preterm delivery (OR 2.97 (1.39, 6.35)), younger maternal age (OR 0.94 (0.88-1.00)) and the mother having a college degree (OR 0.33 (0.17, 0.66)). Maternal education trumped race: only 30% of black women and 25% of non-black women with a college degree fed exclusively with formula.

Conclusion: The large majority of women with rheumatic disease in this cohort planned to breastfeed and were breastfeeding at follow-up. Maternal education and preterm birth were the primary predictors of breastfeeding, while diagnosis and race did not significantly impact the frequency of breastfeeding. The majority of women with rheumatic disease want to breastfeed and, given the safety of our medications for lactation, the large majority can do so successfully.

Sexual Function and Health-related Quality of Life in Male Patients with Systemic Lupus Erythematosus, the Untold Story

Martín Valdez-López ,[1] Jonathan Campos-Guzmán,[1] Ana Barrera-Vargas,[2] Samuel Govea-Peláez,[1] Diana Gómez-Martín,[1] Jorge Alcocer-Varela,[1] Eduardo Aguirre-Aguilar,[1] Diana Padilla-Ortíz,[3] and Javier Merayo-Chalico[1], [1]Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Distrito Federal, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico, [3]Universidad De La Sabana, Bogotá, Cundinamarca, Colombia

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Abstract Session

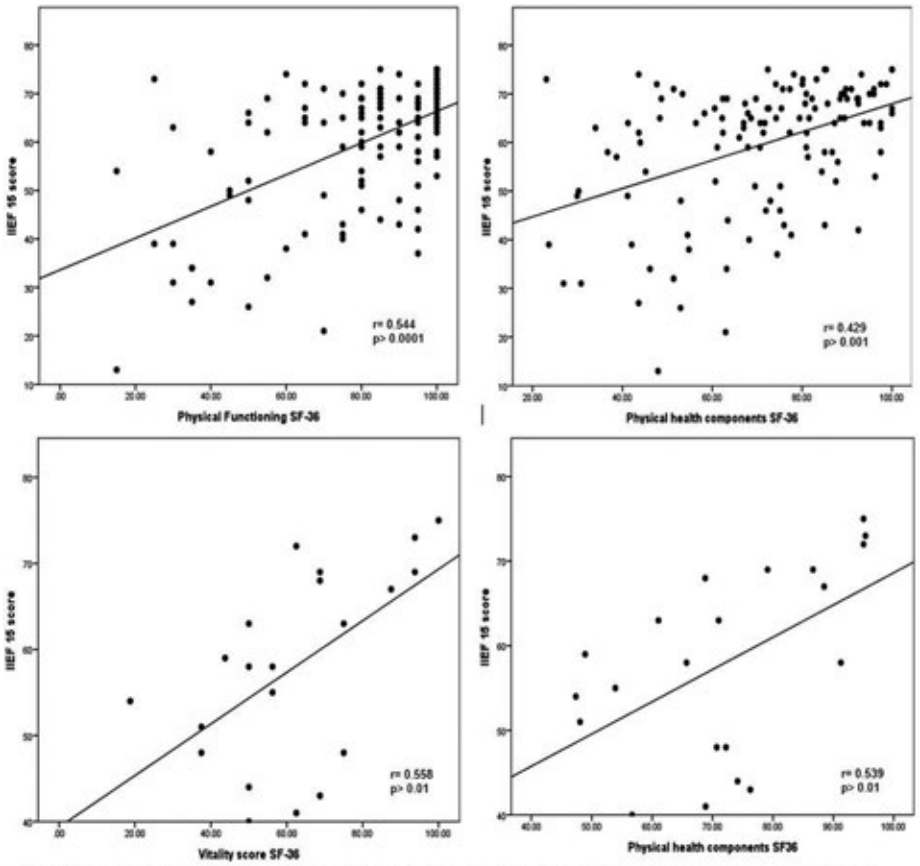

Image 1. All graphs show scatter plots comparing some of the different components of the Short Form-36 questionnaire, compared to the total International Index of Erectile Function. Pearson correlation coefficient r, and it's p value, are shown in each graph.

Table 1. Demographic, clinical and laboratory features (initial outpatient visit); p value <0.05 are shown in bold.

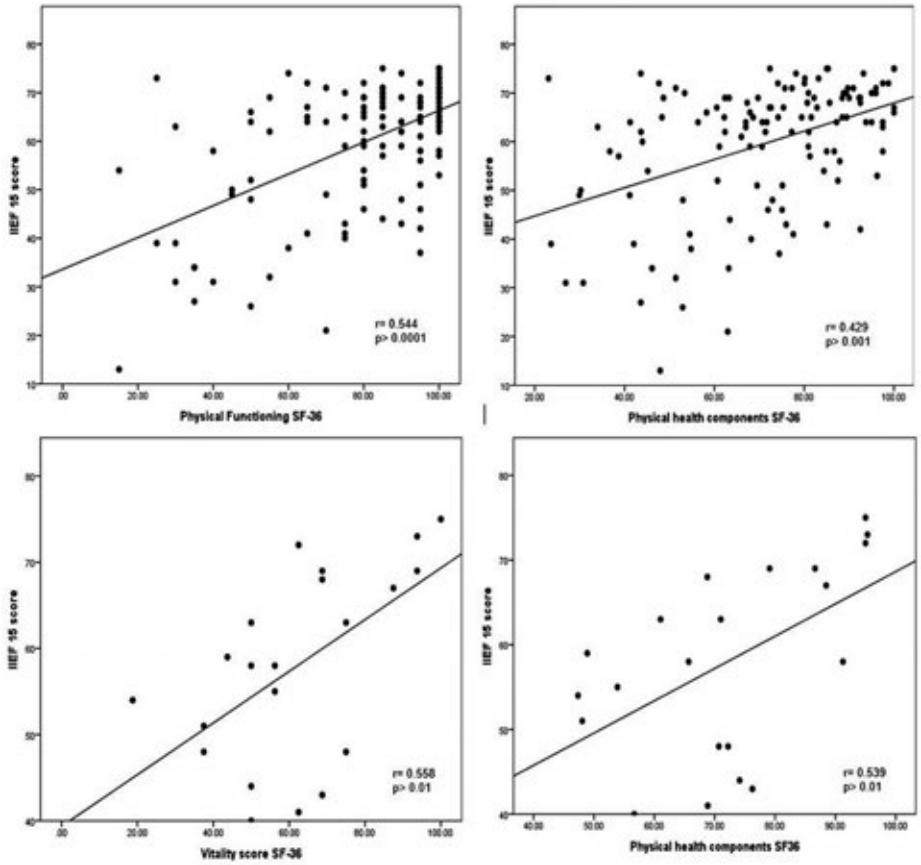

Figure 1. All graphs show scatter plot comparing some of the different components of the SF-36 questionnaire, compared to the total IIEF-15. Pearson correlation coefficient and p value, are shown in each graphic. The most representative graphs were selected (with the upper half being from the first visit, and the lower half corresponding to the third visit)

Session Time: 4:30PM–6:00PM

Background/Purpose: Although SLE is uncommon in men, the disease is usually more severe and requires more aggressive immunosuppression in male patients. There are multiple studies evaluating the association between SLE and sexual function in female patients and its impact on their quality of life, but information regarding male patients is practically non-existent.

Methods: We performed a longitudinal study in a referral center in Mexico City (2018- 2019). We included men aged ≥16 years who fulfilled ACR criteria for SLE and who were sexually active in the previous six months. All subjects answered the International Index of Erectile Function-15 (IIEF-15), the SF-36 (which determines generic health-related quality of life) and the HAQ questionnaire in the basal and subsequent visits. Other clinical, serological and demographic variables were measured. Statistical analysis was performed with SPSS v21.

Results: We included 124 male SLE patients. Mean age was 36.8 (±11.8) years and most patients (88%) were taking immunosuppressive therapy. There was some degree of sexual dysfunction in 58 (47.5%) of patients. Table 1 shows the different characteristics of patients with and without abnormalities in sexual function. Of note, men who presented some degree of sexual dysfunction had fewer years of schooling (p=0.010) and a higher HAQ score (p=0.011).

In the first visit, abnormalities in sexual function, as measured by IIEF-15, were associated with different spheres of the SF-36 score. The most relevant correlations between the different components of SF-36 and global IIEF-15 are shown in Fig 1. Other correlations were found between global IIEF-15 and the absolute neutrophil/lymphocyte ratio

(r= -0.259, *p*=0.004), as well as the SLICC score (r= -0.262, p= 0.003). Correlations between these same variables remained significant in subsequent visits.

When asked, 84.3% of patients said they would like to have specialized care if they were diagnosed with sexual dysfunction. Interestingly, only 22% of patients thought their disease could have repercussions on their sexual function.

Conclusion: To our knowledge, this is the first study to show that sexual function in male SLE patients seems to be closely associated with the patients quality of life, particularly with its physical aspects. Higher prevalence in patients with low education may reflect the importance of the psychological components in the development of this complication. The association of lymphopenia with an impaired sexual function could be related to its role in endothelial dysfunction and atherosclerosis. These findings highlight the need for rheumatologist to promote and coordinate a multidisciplinary approach for male SLE patients with sexual dysfunction.

Rheumatoid Arthritis in Pregnancy and Offspring School Performance. a Danish Nationwide Register-Based Study

Signe Knudsen ,[1] Julia Simard,[2] Jakob Christensen,[3] Thomas Lauersen,[4] Bent Deleuran,[5] and Bodil Bech[1], [1]Department of Public Health, Aarhus University, Aarhus, Denmark, Aarhus, Denmark, [2]Stanford University School of Medicine, Palo Alto, CA, [3]Department of Neurology, Aarhus University Hospital & The National Center for Register-based Research, Aarhus University, Denmark, Aarhus, Denmark, [4]The National Center for Register-based Research, Department of Economics and Business Economics, Business and Social Science, Aarhus University, Aarhus, Denmark, Aarhus, Denmark, [5]Department of Biomedicine; Department of Rheumatology, Aarhus University, Aarhus, Denmark

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Rheumatoid arthritis (RA) during pregnancy is a risk factor for several adverse pregnancy and child outcomes. Studies have found higher incidences of neurological and psychiatric diseases, including childhood epilepsy and autism spectrum disorders, in children born to mothers with RA. However, the overall long-term cognitive development of children exposed to maternal RA has scarcely been examined.

In this study, we examine the overall cognitive development of children born to mothers with RA by comparing their results in national standardized school tests, to those of their peers. The Danish national school tests are mandatory, annual tests conducted in all Danish public schools since 2010.

Methods: All singleton children born in Denmark between 1995 and 2008, who were listed in the Danish national school test register were included in this study (n=738,862). Children exposed to maternal RA in utero were identified through linkage of national registers. In subgroup analyses, we classified exposure according to maternal RA serostatus, and also included a maternal preclinical RA group (defined as the mother receiving a diagnosis of RA up to 3 years after birth of the child).

The Danish National School Tests are standardized, adaptive computer-based tests. Children are tested in reading in grades 2, 4, 6 and 8, and in mathematics in grades 3 and 6. Results from all reading and mathematics tests, from 2010 until 2018, were included. We compared adjusted differences of means by maternal RA exposure separately for each test. We adjusted for potential confounders, i.e. maternal age, maternal educational level, nationality and smoking during pregnancy. We also compiled school test results from all tests, in reading and mathematics separately, and analysed them as repeated measurements for each child, using multilevel regression models. Missing data was handled by multiple imputations.

Results: In total, 816 (0.1%) children were exposed to maternal RA in utero.

There were no differences in test scores in any of the reading tests between maternal RA exposed and unexposed children in grades 2, 4, 6 and 8.

In mathematics, exposed children scored marginally worse in both grades 3 and 6, compared to their unexposed peers (adjusted mean differences were -0.15 Standard Deviations (SD) (95% CI: -0.24; -0.07) and -0.17 SD (95% CI: -0.26; -0.07), respectively).

Results did not change when combining the tests for all grade levels in multilevel regressions (adjusted mean differences were: reading: -0.01 SD (95% CI: -0.08; 0.06) and mathematics: -0.13 SD (95% CI: -0.20; -0.05)).

Children exposed to preclinical RA in utero showed the same pattern of test performance as children exposed to diagnosed maternal RA. There was no appreciable differences between children by maternal RA serostatus.

Conclusion: In this long-term national follow-up study of cognitive development in children, maternal RA exposed children performed similar to their peers in national reading tests. We observed a small, but consistent association with poorer performance on mathematics tests among the exposed children. This was comparable to children exposed to preclinical RA, indicating that RA treatment may not be the underlying cause.

sFlt-1, PlGF and VEGF in the Differential Diagnosis Between Active SLE Nephritis During Pregnancy and Preeclampsia

Guilherme De Jesus ,[1] Marcela Lacerda,[1] Bruna Rodrigues,[1] Flavia dos Santos,[1] Adriana Nascimento,[1] Luis Cristóvão Porto,[1] Nilson Ramires de Jesús,[1] Roger Levy,[2] and Evandro Klumb[1], [1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [2]GlaxoSmithKline, Upper Providence, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Pregnancy in patients with SLE is associated with significant morbidity and mortality. SLE activity during pregnancy, specifically nephritis, makes the differential diagnosis with preeclampsia (PE) troublesome

Table 1. Demographic and gestational results of patients with Inactive SLE, SLE nephritis and SLE with Preeclampsia.

	Inactive SLE (n = 41)	SLE Nephritis (n = 15)	SLE with Preeclampsia (n = 15)	p value (C.I. 95%) (ANOVA)
Age at inclusion Mean ± SD	27.2 ± 6	29.4 ± 4.4	30.1 ± 5.8	0.17
Gestational age at blood collection Mean ± SD	36.8 ± 1.7	33.7 ± 4.2	34.5 ± 2.5	**<0.001**
Gestational age at delivery Mean ± SD	38.7 ± 1.9	35.7 ± 3.8	35.8 ± 2.5	**<0.001**
SLICC Damage Index (SDI) Mean ± SD	0.3 ± 0.6	0.3 ± 0.5	0.1 ± 0.4	0.45
Birth weight Mean ± SD	2976.8 ± 532.4	2448.4 ± 759.2	2174.3 ± 834.6	**<0.001**
Small for gestational age (SGA) newborn n (%)	5 (12.1%)	4 (26.6%)	9 (60%)	NA

Table 2. Mean values of VEGF, PlGF and sFlt-1 for patients with Inactive SLE, SLE nephritis and SLE with Preeclampsia.

	Inactive SLE (n = 41)	SLE Nephritis (n = 15)	SLE with Preeclampsia (n = 15)	p value (C.I. 95%) (Mann-Whitney's U test)
VEGF (pg/mL) Mean ± SD	5.6 ± 7	12.3 ± 10.1	4.1 ± 5	Inactive SLE x SLE nephritis: **0.006** Inactive SLE x PE: 0.45 SLE Nephritis x PE: **0.009**
PlGF (pg/mL) Mean ± SD	189.8 ± 146.1	198.7 ± 134.8	61.4 ± 127.3	Inactive SLE x SLE nephritis: 0.83 Inactive SLE x PE: **0.003** SLE Nephritis x PE: **0.007**
sFlt-1 (pg/mL) Mean ± SD	1804.2 ± 668.3	1832.1 ± 760.9	2517.0 ± 431.9	Inactive SLE x SLE nephritis: 0.90 Inactive SLE x PE: **<0.001** SLE Nephritis x PE: **0.006**
Ratio sFlt-1/PlGF Mean ± SD	22.9 ± 25.1	23.3 ± 35.5	781.1 ± 1211.3	Inactive SLE x SLE nephritis: 0.96 Inactive SLE x PE: **0.02** SLE Nephritis x PE: **0.02**

in clinical practice. The use of angiogenic factors, like vascular endothelial growth factor (VEGF) and placental growth factor (PlGF), and antiangiogenic factors, such as soluble Fms-like tyrosine kinase-1 (sFlt-1), has been proposed to help differentiate these two conditions, but there is no available data about these cytokines in this scenario. The ob-

jective of this study was to evaluate circulating levels of VEGF, PlGF and sFlt-1 in SLE pregnant women with inactive disease, active lupus nephritis and PE.

Methods: Patients with SLE (ACR criteria) with singleton pregnancies followed at a high risk prenatal care, without any other autoimmune disease, were included. They were divided according to disease activity using SLE*P*DAI (SLE Pregnancy Disease Activity Index), clinical and laboratory evaluation by a rheumatologist experienced in evaluating pregnant SLE patients and the occurrence of PE. Blood samples were collected at the third trimester of pregnancy, within 3 weeks of delivery, and frozen for subsequent blinded analysis by ELISA kits (PlGF – DRG Instruments, Marbug, Germany; sFlt-1 and VEGF – R&D systems, Minneapolis, United States).

Results: Seventy one women were included. Forty one patients had inactive SLE (Group 1, SLEPDAI < 4), 15 had active lupus nephritis (Group 2, SLEPDAI >4, including renal criteria) and 15 had PE (Group 3). Mean gestational age at blood collection was of 36.8, 33.7 and 34.5 weeks, respectively and delivery at 38.7, 35.7 and 35.8 weeks, respectively; statistically significantly higher in patients with inactive SLE (Table 1). Mean levels of VEGF, PlGF and sFlt-1 of each group are reported on Table 2. Patients with SLE and PE had statistically significantly lower mean serum levels of PlGF than SLE patients without PE, while sFlt-1 was significantly higher in patients with PE compared to pregnant patients with inactive SLE or lupus nephritis. The sFlt-1/PlGF ratio was also significantly higher in patients of Group 3 (PE) compared to other patients with SLE (Groups 1 and 2). VEGF was higher in patients with SLE nephritis compared to inactive SLE and SLE with PE, while PlGF and sFlt-1 were similar when both groups without PE were compared.

Conclusion: In this study, pregnant SLE patients with PE had similar angiogenic and antiangiogenic profile of patients with PE without SLE – low PlGF and high sFlt-1, with high sFlt-1/PlGF ratio. This pattern differs from patients with inactive SLE or active lupus nephritis, the main differential diagnosis during gestation. Evaluation of angiogenic and antiangiogenic factors, specially PlGF and sFlt-1, can be a new tool to differentiate PE from lupus nephritis during pregnancy in clinical practice.

Assessing Commercial Titers of anti-Ro60 and Ro52 Antibodies to Risk Stratify Surveillance of Anti-Ro/SSA Antibody Positive Pregnancies

Kimberly Robins,[1] **Rohit Bhan** ,[1] Catherine Trad,[1] Rebecca Cohen,[1] Miao Chang,[1] Benjamin Wainwright,[1] Mala Masson,[1] Shilpi Mehta-Lee,[1] Peter Izmirly,[1] Robert Clancy,[1] Bettina Cuneo,[2] and Jill Buyon[1], [1]NYU School of Medicine, New York, [2]Children's Hospital Colorado, Aurora

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Pregnancy counseling of all anti-Ro positive women includes advice regarding the development of congenital heart block (CHB), albeit the risk is only 2% for primigravida women or those with previously unaffected offspring. Despite this low risk, the prevailing surveillance recommendation is weekly echocardiography. While evidence from basic research laboratories support that "high" titers of antibodies confer clinically meaningful

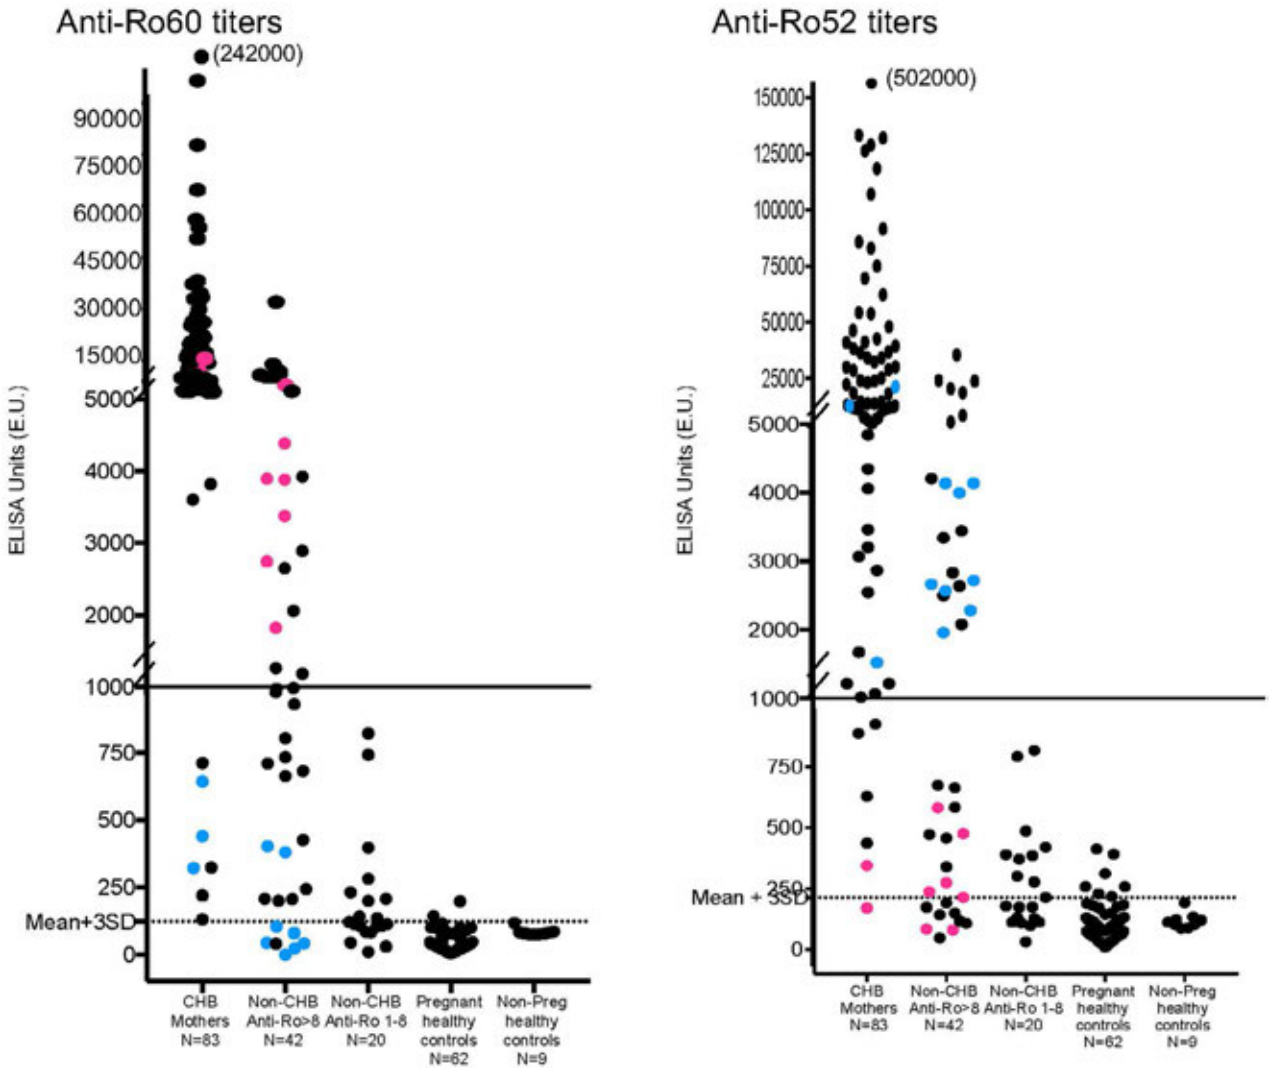

Figure 1. Anti-Ro60 and anti-Ro52 titers of mothers by CHB status and BioPlex assay results.

risk, unfortunately the majority of commercial laboratories use the BioPlex assay, which provides positive and negative values with limited information on actual levels because the sera or plasma are not diluted past a specified cutoff given cost (e.g. values of anti-Ro inclusive of Ro52 or Ro60 by laboratories such as Quest or LabCorp provide positive as 1-8 or > 8 units with no further information). The present study was initiated to assess whether the BioPlex assay used by many commercial laboratories provides adequate stratification of risk for counseling regarding management.

Methods: The study group comprised healthy non-pregnant donors (N = 9), healthy pregnant donors (N = 62), women testing positive for anti-Ro by commercial BioPlex but without CHB children (N = 60 SLE and 2 SS), and women with CHB children (N = 83). Anti-Ro60 reactivity was assessed using native antigen and anti-Ro52 using recombinant protein. Sera were applied to coated microtiter plates at serial dilutions ranging from 1:1000 – 1:50,000 for 1h at RT and run in duplicate. Tested samples were multiplied by the dilution factor which gives an OD in the range of 0.3-0.8. Results were considered positive at 123 ELISA units (EU) for Ro60 and 215 EU for Ro52 as this represented the mean +3 SD of the values obtained for healthy control sera.

Results: Of the 83 CHB mothers tested, 74 had titers of Ro60 and Ro52 > 1000 EU, in 1 anti-Ro60 was > 1000 EU and anti-52 Ro between 215 - 1000, in 3 anti-Ro52 was > 1000 EU and anti-Ro60 between 300 - 1000, and 1 mother had anti-Ro60 > 1000 EU and was negative for anti-Ro52. Albeit all positive, the sera from 4 CHB mothers obtained 15 years after the birth of the affected child were < 1000 EU for both anti-Ro60 and Ro52. With these results setting thresholds (> 1000 EU in either Ro60 or Ro52 for CHB risk), we assessed patients testing positive for anti-Ro based on the BioPlex assay. Of 42 patients with values of > 8 on BioPlex testing, 14 had titers > 1000 EU for both anti-Ro60 and Ro52, 7 had anti-Ro60 > 1000 EU, and 8 had anti-Ro52 > 1000 EU. Thus, 13 of 42 (25%) with commercial Ro > 8 did not meet the threshold EU for CHB risk. Of 20 patients considered positive for anti-Ro by BioPlex with values between 1-8, none had levels of either anti-Ro60 or Ro52 at 1000 EU. No patient or healthy control testing negative by the BioPlex assay was positive for CHB risk in our ELISA.

Conclusion: These data suggest that commercial testing using the BioPlex assay may fall short of stratifying risk for CHB. Women with positive values < 8 are not likely at risk, obviating the cost and burden of weekly fetal echo surveillance. Moreover, even those considered "high" titer on commercial testing may be at low risk supporting the need for more quantitative commercial testing than is currently available.

Serious Infections in Offspring Exposed in Utero to Non-TNFi Biologics and Tofacitinib

Evelyne Vinet ,[1] Yvan St-Pierre,[1] Cristiano S. Moura,[1] Jeffrey Curtis,[2] and Sasha Bernatsky[3], [1]McGill University Health Centre, Montreal, QC, Canada, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: During pregnancy, maternal circulating immunoglobulins G (IgG) are actively transported across the placenta through their Fc portion. Thus, TNFi and other biologics harbouring an Fc part have the potential to transfer across the placenta, often reaching higher fetal than maternal levels. In addition, it is postulated that small-molecule drugs may cross the placenta, although this remains unconfirmed. As fetuses could be exposed to therapeutic (or potentially supra-therapeutic) levels of biologics and small molecules, there are concerns that these agents could cause immunosuppression in exposed offspring. We compared the risk of serious infections in children born to mothers with chronic inflammatory diseases who used non-TNFi biologics or tofacitinib during pregnancy, versus unexposed offspring and children exposed to TNFi in utero.

Methods: We identified all women with ≥1 hospitalization for delivery after a diagnosis of rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriasis (PsO), psoriatic arthritis (PsA), or inflammatory bowel diseases (IBD), and a randomly selected group of unaffected mothers, matched ≥4:1 for age, year of delivery, and state of residence, using MarketScan database (2011-2016). Only women continuously enrolled within MarketScan for ≥12 months prior to

delivery and with available child linkage were included. We defined tofacitinib, TNFi and non-TNFi biologic (i.e. abatacept, rituximab, tocilizumab, ustekinumab, vedolizumab) exposure based on ≥1 filled prescription and/or infusion procedure code during pregnancy and/or the preconception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographics, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics).

Results: We identified 16,490 offspring of mothers with RA (4,142), AS (381), PsO/PsA (5,743), and IBD (6,731), as well as 164,553 children born to unaffected matched mothers. Among offspring whose mothers had inflammatory diseases, 105 were exposed to tofacitinib or non-TNFi biologics (tofacitinib 4, abatacept 33, rituximab 4, tocilizumab 12, ustekinumab 42, vedolizumab 10) and 1,611 to TNFi during pregnancy. We observed 2 cases of serious infections in children exposed to tofacitinib or non-TNFi biologics (1.9%; 95% CI 0.3, 7.4): one case was exposed to tofacitinib, while the other was exposed to abatacept. The percent of serious infections in offspring of inflammatory disease mothers with no TNFi exposure was 2.1% (95% CI 1.9, 2.3), while for those with TNFi in utero exposure, it was 2.3% (95% CI 1.6, 3.0). In children born to unaffected mothers, the percent of serious infections was 1.6% (95% CI 1.6, 1.7).

Conclusion: In the largest cohort of inflammatory disease offspring ever assembled, we detected very few serious infections in children exposed to non-TNFi biologics or tofacitinib. More studies are necessary to precisely determine the specific effects of individual non-TNFi biologic and small-molecule drugs.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

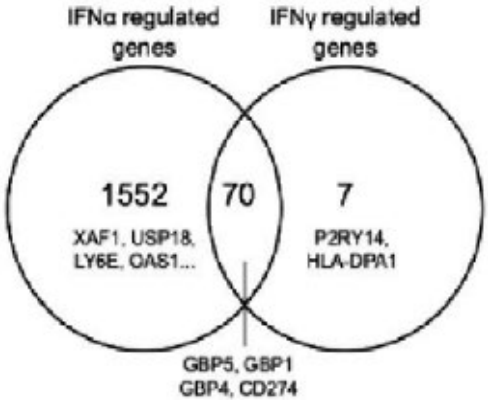

Figure.1 Venn diagram showing the number of genes transcriptionally controlled by IFNα, IFNγ, or both according to ultrasensitive digital ELISA of IFN alpha and IFN gamma

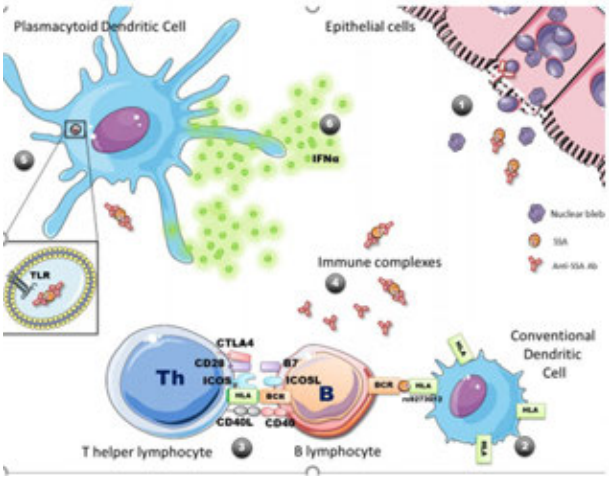

Figure 2. Proposed scenario underlying the association between HLA polymorphism and circulating IFNα. HLA predisposes to IFNα secretion by favoring classical presentation by cDCs of SSA peptides to T cells, leading to anti-SSA antibodies, and immune complexes stimulating IFNα secretion.

Background/Purpose: Primary Sjögren's syndrome (pSS) is the second most frequent systemic autoimmune disease affecting 0.1% of the general population. No specific immunomodulatory drug has demonstrated efficacy for this disease, and no biomarker is available to identify patients at risk of developing systemic complications. To enable a precision medicine approach, we explored the molecular stratification of the disease in an unsupervised systems biological manner.

Methods: Blood transcriptomes and genotypes of 351 pSS patients from a multi-center prospective clinical ASSESS cohort were analyzed. Clinical phenotype, immunological profile and yearly follow-up of disease course for 5 years of these patients were carefully assessed. Replication of the transcriptomic results was performed using 3 independent cohorts (n= 523 patients). Circulating IFN-alpha (IFNα) and IFN-gamma (IFNγ) protein concentrations were determined using ultrasensitive digital ELISA (SIMOA) and patients were genotyped using Immunochip in the ASSESS cohort.

Results: Transcriptomic analysis of the prospective cohort enabled patient stratification that matched clinical assessments, and showed a strong IFN gene signature in more than half of the patients. This finding was replicated in

three independent cohorts. As gene expression analysis did not discriminate between type I and II interferons, we applied digital ELISA to assess serum levels of IFNγ. The IFN transcriptomic signature was regulated by circulating IFNα, and not IFNγ, protein levels. 95% of the interferon-inducible genes (1552 genes) were specifically modulated by serum IFNα concentration, while only 7 genes were specifically regulated by serum IFNγ concentration. 70 genes were regulated by both IFNα and IFNγ concentrations (Figure 1).

IFNα protein levels, detectable in 75% of patients, were significantly associated with clinical and immunological features of disease activity at enrollment (association with anti-SSA: $p= 5.09*10^{-28}$, anti-SSB: $p= 2.45*10^{-14}$, RF: R=0.662, $p = 1.19 \times 10^{-41}$) . At enrolment, the mean ESSDAI was higher (4 [0-31] versus 2[1-18], p=0.0004) in patients with detectable IFNα blood levels. During the 5-year follow-up, patients with detectable IFNα blood levels more frequently developed systemic complications (OR 1.54 [1.14; 2.13]). Genetic analysis revealed a significant association between a specific MHC-II HLA-DQ locus genotype (HLA-DQA1*05:01 allele), anti-SSA antibody ($p=4.31 \times 10^{-12}$) and circulating IFNα protein ($p=1.70 \times 10^{-8}$). In multivariate analysis, both HLA DQA1*05:01 and anti-SSA positivity were independently associated with IFNα blood concentrations (OR 3.24 [1.78-5.88], p< 0.001, OR 3.08 [1.80-5.29], p< 0.001, respectively). Analyses in healthy controls, and in anti-SSA positive patients using Cytof, suggested that this HLA gene polymorphism acts through upregulation of HLA II molecules on conventional DCs (Figure 2).

Conclusion: This large systems biology analysis emphasizes the crucial role of circulating IFNα in pSS. In addition, we report a new pathogenic mechanism underlying the associations between HLA predisposition, autoantibody production, cytokine secretion and systemic complications of autoimmunity.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To identify a molecular signature associated with lymphomagenesis in primary Sjögren's Syndrome (pSS).

Methods: Whole peripheral blood samples were collected from 346 well-phenotyped pSS patients enrolled in the ASSESS prospective cohort. A transcriptomic analysis was performed using Clariom S Human Arrays (Affymetrix). Patients with a pSS-related Non-Hodgkin lymphoma (NHL) (historic or incident NHL) were compared with 3 control populations: i) Patients without lymphoma and without any risk factor, among 9 validated predictive factors of developing lymphoma (systemic complications, parotid swelling, purpura, lymphocytopenia, CD4/CD8≤0.8, rheumatoid factors, cryoglobulinemia, monoclonal component and low C4 levels) (this comparator limits the risk of including patients who might develop lymphoma later during follow-up); ii) Patients without lymphoma but with moderate or high systemic disease activity at enrolment (ESSDAI≥5) (this comparator allows to identify relevant predictors in an at-risk population); iii) All patients without lymphoma. We focused on genes that were significantly differentially expressed in patients with lymphomas compared to each of these control populations.

Results: At enrolment, 13 patients had a history of lymphoma. During the 10-year follow-up, 9 patients developed an incident lymphoma. A total of 324 pSS patients had no lymphoma, including 110 patients with an ESSDAI≥5 and 61 patients without any risk factor of lymphoma. Gene Set Enrichment Analysis (GSEA) identified an over-expression of B-cell activation related genes in NHL-pSS, such as BAFF (p=0.007), APRIL (p=0.0009), BCMA (p=0.02) or BTK (p=0.0003) compared to patients without any risk factor of NHL. APRIL and BCMA were significantly up regulated when NHL-pSS patients were compared to all patients without NHL (p=0.002, p=0.04, respectively) but not BAFF (p=0.1). However, the gene expression profile of NHL-pSS patients compared to patients with an ESSDAI ≥ 5 did not show significant over expression of BAFF (p=0.3), APRIL (p=0.2) and BCMA (p=0.2). Conversely, the Bruton Tyrosine Kinase (BTK) gene was over expressed at enrolment, before the occurrence of lymphoma in patients with an incident NHL, in patients with a history of NHL, and in all NHL-pSS patients (either history of or incident) when compared to patients without any risk factor of developing lymphoma (p=0.006, p=0.005 and p=0.0003, respectively), to patients without lymphoma but with an ESSDAI ≥ 5 (p=0.03, p=0.02, p=0.003, respectively) and to all patients without lymphoma (p=0.02, p=0.01, p=0.0008 respectively).

Conclusion: BTK, a pivotal transducer of B-cell receptor, is over expressed in the peripheral blood of pSS patients before the occurrence of lymphoma. Conversely to BAFF, APRIL, and BCMA, BTK over expression is not related to a higher disease activity since BTK is up regulated in patients with lymphoma even when compared to patients with a moderate or high systemic disease activity and no lymphoma. BTK might therefore represent a pivotal pathogenic player in the transition from B-cell polyclonal activation to a monoclonal malignant proliferation. The present results suggest that BTK might represent a therapeutic target of interest in pSS.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: IL-6 is suspected to play an important pathogenic role in primary Sjögren's syndrome (pSS) through its crucial roles in B-cell activation, and T-cell polarization, as shown in mice models and ex vivo studies. To investigate the relevance of IL-6 as a therapeutic target in patients with pSS, we performed a double- blind randomized placebo-controlled trial evaluating tocilizumab.

Methods: Inclusion criteria were pSS according to AECG criteria and an ESSDAI (score of systemic complications) ≥ 5. Patients received 6 monthly infusions of tocilizumab or placebo. Primary endpoint criteria was response to treatment evaluated at week 24. Response to treatment was defined by the combination of i) a decrease of at least 3 points in ESSDAI ; ii) no occurrence of moderate or severe activity in any new domain of the ESSDAI compared to enrollment ; iii) absence of worsening in physician's global assessment on visual numeric scale ≥ 1/10. Secondary endpoints included change in ESSPRI (mean of patient's fatigue, pain and dryness visual analogic scales), and in Schirmer's test. The data were analysed using Bayesian methods on an intent-to-treat basis.

Results: 55 patients (women : 98.2%, mean age : 50.9 [26 ; 76] years, anti-SSA antibody-positive : 84.7%) were randomized to tocilizumab and 55 patients to placebo (women : 90.3%, mean age : 54.9 [30 ; 80] years, anti-SSA positive : 87.6%). Mean ESSDAI was 11.5 [5 ; 25] and 12.4 [5 ; 39] and mean ESSPRI was 6.4 [2 ; 9] and 6.4 [1 ; 9] in the tocilizumab and in the placebo group, respectively.

The results on the primary outcome criteria were similar in both groups : 54.2% [41.3 ; 66.7%] of responders in the tocilizumab group, 62.1 %[49.0 ; 74.1] in the placebo group, OR = 1.6 [0.3 ; 3.3]

Mean ESSDAI at week 24 were 6.6 [4.7 ; 9.0] and 5.4 [3.7 ; 7.6] in the tocilizumab and placebo group, respectively, with a similar difference of the changes from baseline between groups (interaction, 0.9 [-1.3 ; 3.2]) (Figure 1).

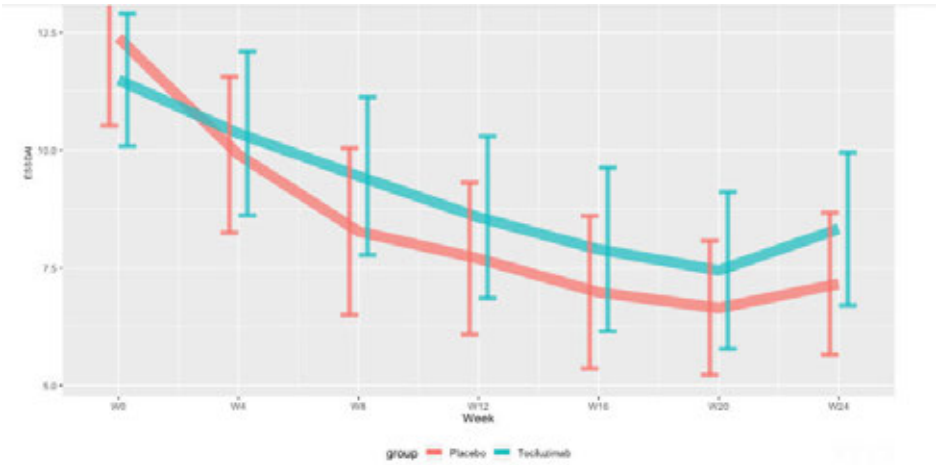

Figure 1. Change in ESSDAI.

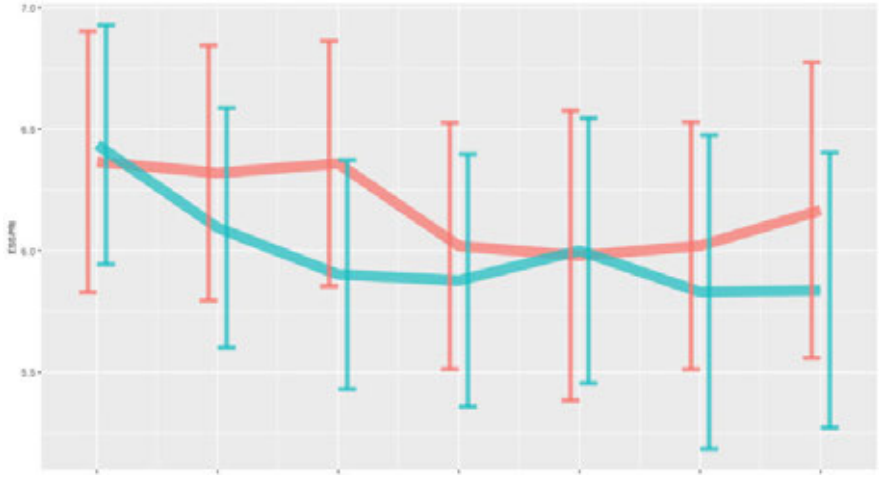

Figure 2. Change in ESSPRI

Mean ESSPRI at week 24 was 6.0 [5.0 ; 7.0] and 6.2 [5.2 ; 7.1] in the tocilizumab and placebo group respectivey, with a similar difference of the changes from baseline between groups (0.1 [-0.4 ; 0.7]) (Figure 2).

Change in Schirmer's test was similar in both groups.

Change from baseline in number of tender and swolllen joints was higher in the tocilizumab (from 7.4 [6.7 ; 8.1] to 3.6 [3.3 ; 3.9] and from 2.2 [1.8 ; 2.6] to 0.6 [0.5 ; 0.7], respectively) than in the placebo group (from 7.8 [7.1 ; 8.6] to 4.9 [4.6 ; 5.3] and from 2.4 [2.0 ; 2.8] to 1.3 [1.1 ; 1.5]) (interaction 1.2 [0.2 ; 2.7] and 0.8 [0.3 ; 1.4], respectively). Number of severe adverse events was similar in the 2 groups.

Conclusion: In this randomized placebo-controlled study, tocilizumab did not reach its primary outcome criteria and had no impact on main symptoms in pSS. Some improvement was observed in patients with articular involvement. Effect of tocilizumab on other subsets of patients and on immunological parameters is currently investigated and will be reported at ACR.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

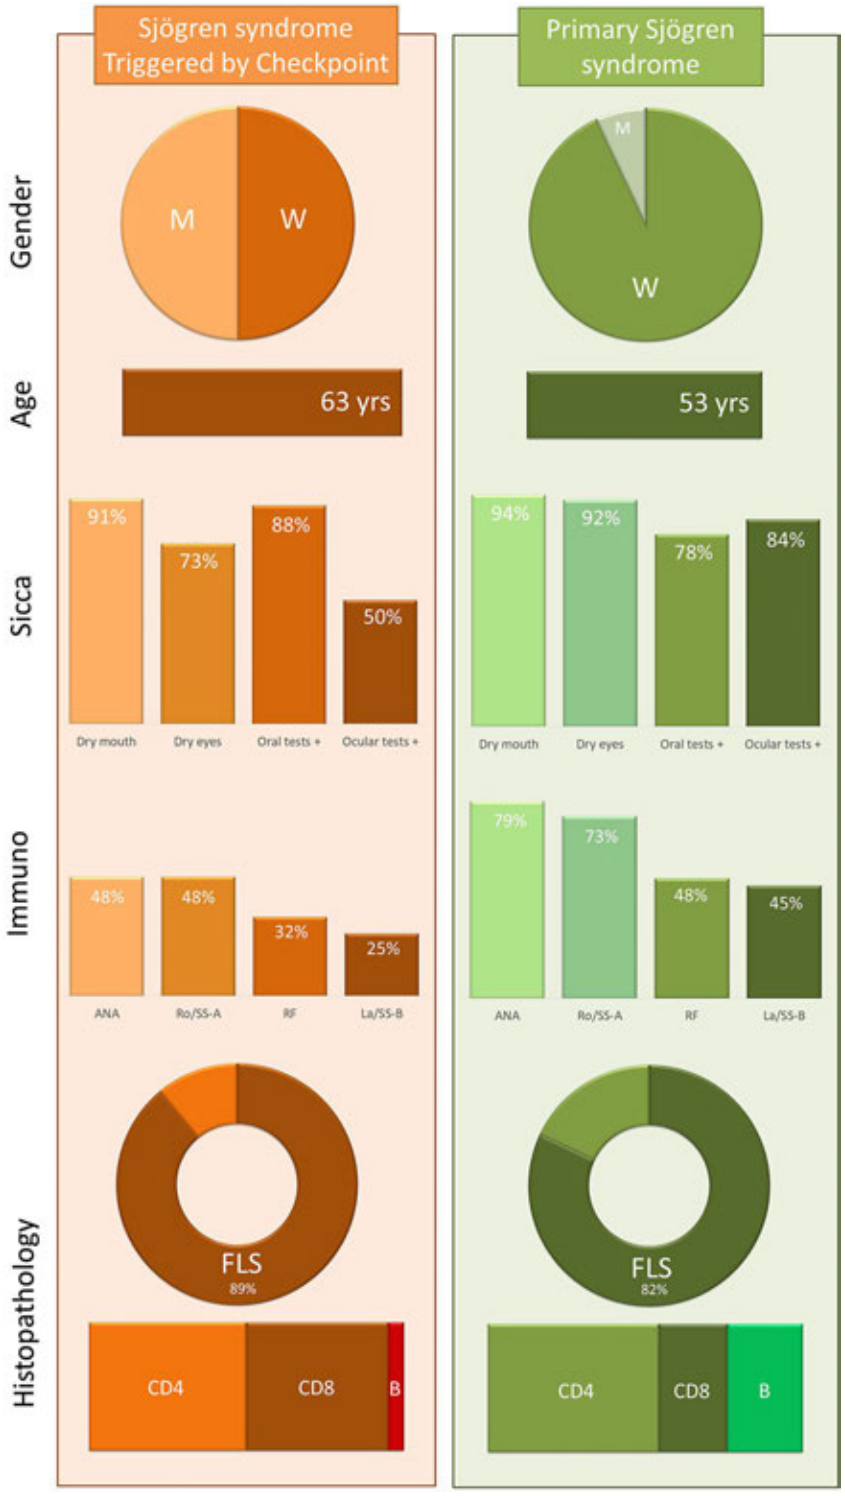
Session Title: Sjögren's Syndrome – Basic & Clinical Science

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: To analyse the worldwide occurrence of sicca/Sjögren (SjS) syndrome associated with the use of immune checkpoint inhibitors (ICI) in patients with cancer.

Methods: The ImmunoCancer International Registry (ICIR) is a Big Data-Sharing multidisciplinary network composed by 40 specialists in Rheumatology, Internal Medicine, Immunology and Oncology from 18 countries focused on the clinical and basic research of the immune-related adverse events (irAEs) related to cancer immunotherapies. For this study, patients investigating for a clinical suspicion of SjS after being exposed to ICI were included.



Results: We identified 26 patients (11 women and 15 men, with a mean age at diagnosis of 63,57 years). Underlying cancer included lung (n=12), renal (n=7), melanoma (n=4), and other (n=3) neoplasia. Cancer immunotherapies consisted of monotherapy (77%) and combined regimens (23%). In those patients receiving monotherapy, all patients were treated with PD1/PD1-L inhibitors (nivolumab in 9, pembrolizumab in 7 and durvalumab in 4); no cases associated with CTLA-4 inhibitors were identified. The main SjS-related features consisted of dry mouth in 25 (96%) patients, dry eye in 17 (65%), abnormal ocular tests in 10/16 (62%) and abnormal oral diagnostic tests in 12/14 (86%) patients. Minor salivary gland biopsy was carried in 15 patients: histopathological findings consisted of mild chronic sialadeni-

tis in 8 (53%) patients and focal lymphocytic sialadenitis in the remaining 7 (47%); a focus score was measured in 5 of the 6 patients (mean of 1.8, range 1 to 4). Immunological markers included positive ANA in 13/25 (52%), anti-Ro/SS-A in 5/25 (20%), RF in 2/22 (9%), anti-La/SS-B in 2/25 (8%), low C3/C4 levels in 1/17 (6%) and positive cryoglobulins in 1/10 (10%). Classification criteria for SjS were fulfilled by 10 (62%) out of 16 patients in whom the two key classificatory features were carried out. Among the 26 patients, there were only 3 (11%) who presented exclusively sicca syndrome without organ-specific autoimmune manifestations. Therapeutic management included measures directed to treat sicca symptoms and therapies against autoimmune-mediated manifestations (glucocorticoids in 42%, second/third-line therapies in 31%); therapeutic response for systemic features was observed in 8/11 (73%). No patient died due to autoimmune involvement.

Conclusion: Patients with Sjögren syndrome triggered by ICI display a very-specific profile different from that reported in idiopathic primary SjS, including more frequent occurrence in men, a higher mean age, a predominant immunonegative serological profile, and a notable development of organ-specific autoimmune involvement in spite of the poor immunological profile (Figure). The close association found between sicca/Sjögren syndrome and primarily PD1 blockade requires further specific investigation.

Abstract Number: 1906

Using Multi-modal Ultrasound to Assess Disease Activity Within the Salivary Glands of Patients with Primary Sjögren's Syndrome Treated with Ianalumab (VAY736)

Torsten Diekhoff,[1] Maximilian Posch,[2] Frank Wagner,[2] Thomas Fischer,[1] Quirino Schefer,[2] Thomas Dörner,[3] Didier Laurent,[4] Yue Li,[4] and **Stephen Oliver** [4], [1]Charité University Hospital, Berlin, Germany, [2]Charité Research Organisation, Berlin, Germany, [3]Charite Universitätsmedizin Berlin and DRFZ, Berlin, Germany, [4]Novartis Pharma AG, Basel, Switzerland

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To use ultrasound (US) to demonstrate that ianalumab, a monoclonal antibody with dual mechanisms-of-action of BAFF:BAFF-R blockade and enhanced, ADCC-mediated B cell depletion, can modulate the inflammation and morphology within salivary glands of patients with primary Sjögren's syndrome (pSS).

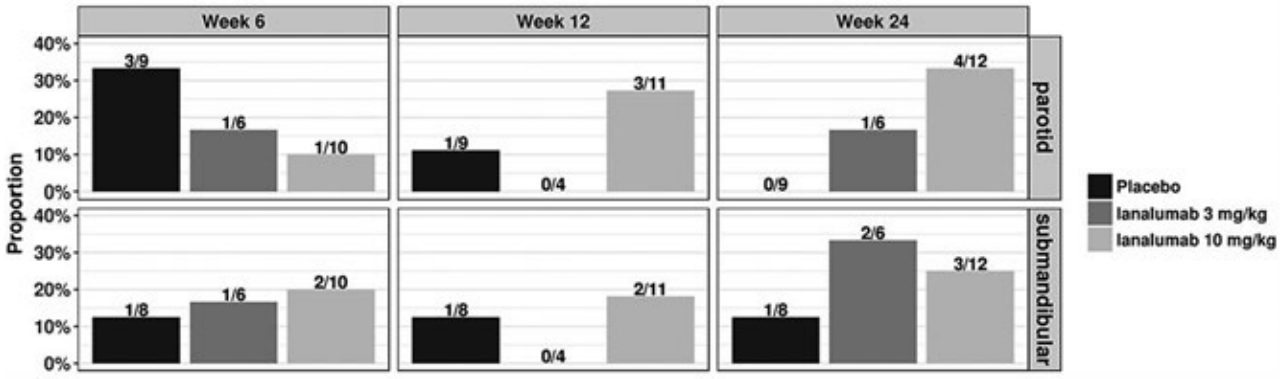

Figure 1. Proportions of de Vita responder by treatment group, week and gland type are shown in barchart. The responder is defined as one point reduction from baseline in de Vita score. The numbers on top of the bars, "m/n", indicates m responders out of n patients in a given group.

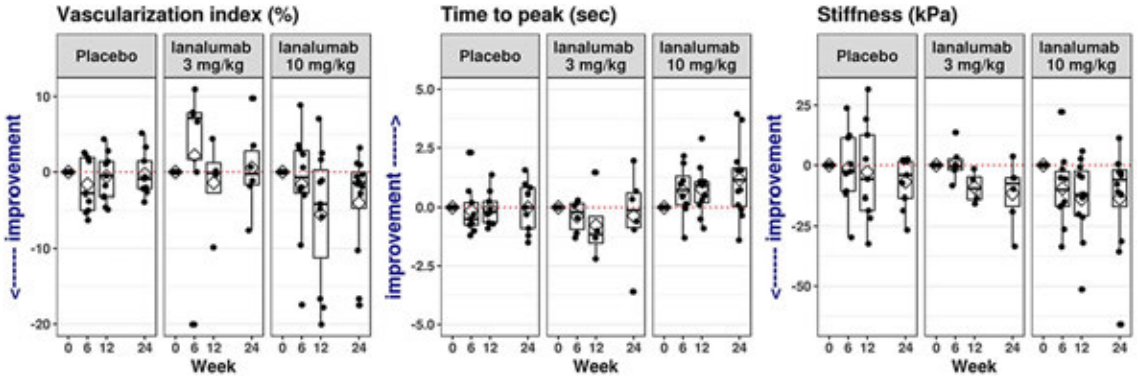

Figure 2. Change from baseline in a few ultrasound parameters are presented in boxplots by group over time, overlaid with individual data points. Median values are shown as the middle line within the boxes and mean values are indicated by diamonds. The direction of disease improvement is indicated by the arrow along the y axis. Two extreme data points greater than 70 are left out in the boxplot for the parameter of time-to-peak.

Methods: In a single-center study, 27 patients fulfilling the revised American European consensus criteria for pSS with stimulated whole salivary flow rate of >0 mL/minute and active disease (EULAR Sjögren's Syndrome Disease Activity Index; ESSDAI ≥6) were randomly assigned between three treatment groups in a 24-week double-blind treatment period to receive a single i.v. dose of either 3 mg/kg or 10 mg/kg ianalumab, or placebo[1]. Concurrent with clinical and laboratory outcomes that included ESSDAI, Physician's Global Assessment, and patient-reported outcomes for disease activity, fatigue and quality of life (EULAR Sjögren's Syndrome Patient Response Index, Multi-Dimensional Fatigue Index, Short Form-36, Patient's Global Assessment), multi-modal US images were acquired at baseline and weeks 6, 12, and 24. Using a single US device, applied modalities included: 1) echostructure by B-mode scored 0-4 in 5 categories according to de Vita classification[2,3], 2) large vessel blood flow by power Doppler (vascularity index, scored 0 for no vascularization and 1-3 for mild, moderate and high vascularization, respectively), and, limited to parotid glands (PG) only, 3) microvascularization using contrast-enhanced US (area under the curve, time to peak) and 4) gland stiffness by sonoelastography[4,5].

Results: The overall profiles of US data differed greatly between PG and submandibular glands (SMG) but were comparable between the respective left and right sides of these glands. A numerical improvement in both PG and SMG quality and declining inflammation in the glands were observed, including more de Vita responders (patients achieving ≥1 point reduction from baseline) in the VAY736 groups than in placebo (Figure 1), and changes in perfusion of both PG and SMG, as shown from large vessels and microvascular assessments (Figure 2), and a trend of decrease in PG stiffness (Figure 2). Change in some US parameters is observed to have correlation with some clini-

cal endpoints, including change in thickness with change in ESSDAI at week 12 (Spearman correlation coefficient = -0.63, p value = 0.0031), and change in TTP at week 12 correlated with change in patient global assessment (Spearmann cc=0.61; p=0.018) and with MFI-physical fatigue (Spearman cc = 0.61, p-value = 0.046).

Conclusion: Early signs of salivary gland improvement in response to an effective intervention can be shown using non-invasive, comprehensive, ultrasound-based approach at multiple time points without the need of biopsies.

Abatacept Reduces Serum CXCL13 and Disease-Relevant Immune Cell Phenotypes in a Double-Blind, Placebo-Controlled Primary Sjögren's Syndrome Clinical Trial

Jacques-Eric Gottenberg ,[1] Sumanta Mukherjee,[2] Marleen Nys,[3] Robert Wong,[4] Hendrika Bootsma,[5] and Neelanjana Ray[4], [1]Department of Rheumatology, Strasbourg University Hospital, Strasbourg, France, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Braine L'Alleud, Belgium, [4]Bristol-Myers Squibb, Princeton, [5]University of Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Chemokine (C-X-C motif) ligand 13 (CXCL13), produced by follicular helper T (Tfh) cells, plays a pivotal role in B-cell homing and activation in germinal centers in salivary glands.[1,2] CXCL13 is associated with systemic disease activity and clinical activity in primary Sjögren's syndrome (pSS) and increased risk of lymphoma.[1,2] In patients with pSS, in an open-label trial (ASAP), abatacept (ABA) treatment decreased Tfh and CD4 memory T (TEM) cells.[1] In the Phase III, double-blind, placebo-controlled study (NCT02915159), ABA significantly impacted biomarkers of disease activity, but did not improve clinical disease measures, vs placebo.[3] This analysis aimed to assess serum CXCL13 levels and immune cell phenotypes of study patients.

Methods: Adult patients meeting the 2016 ACR/EULAR criteria for pSS with EULAR Sjögren's Syndrome Disease Activity Index ≥5 were randomized to receive ABA 125 mg SC weekly or placebo for 168 days. Serum and whole blood samples were collected at follow-up. Serum CXCL13 was measured using the SIMOA™ assay from Myriad RBM (all patients). Immune cell phenotyping of whole blood samples in a subgroup of patients from participating countries with available samples (cellular phenotyping population [CPP]) was assessed by flow cytometry, with data analyzed using BD FACSDiva™ software. Estimates of adjusted mean change from baseline (BL) in immune cells were from a repeated measures mixed model with statistical significance determined by the Benjamini–Hochberg procedure.

Results: In total, 187 (ABA, 92; placebo, 95)[3] patients were randomized and received ≥1 dose of study drug. At BL, CXCL13 levels were comparable between treatment arms. At Days 85 and 169, ABA reduced levels of serum

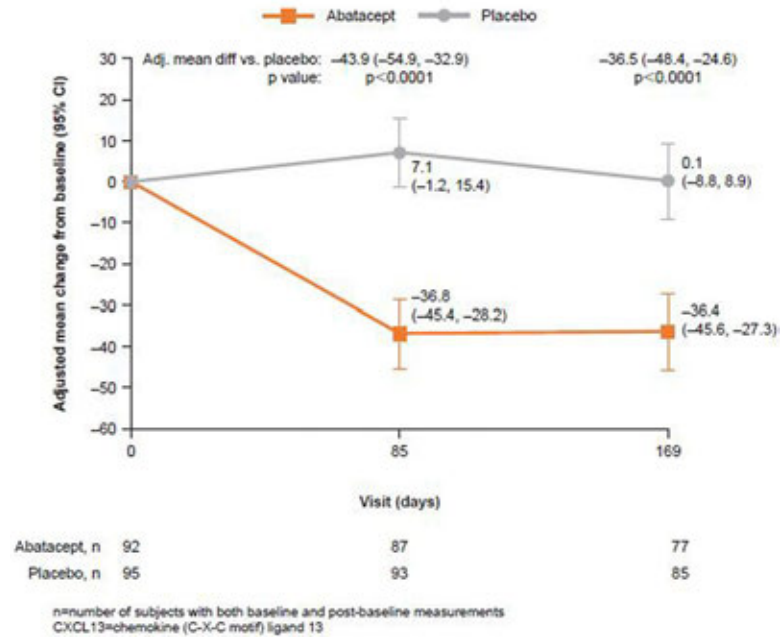
Table. Adjusted Mean Difference between Abatacept vs Placebo in Adjusted Mean Change From Baseline of Disease-Relevant Cell Subsets of Patients with pSS Treated With Abatacept, After 169 Days

Cell subtype	Adjusted mean difference from placebo (95% CI)	p value
Tfh	–1.38 (–2.23, –0.54)	0.0017*
ICOS-Tfh	–14.15 (–19.00, –9.30)	<0.0001*
Plasmablasts	–0.48 (–1.04, 0.09)	0.0957†
Treg	–1.80 (–3.00, –0.61)	0.0038*

*Statiscally significant based on Benjamini–Hochberg procedure with False Discovery Rate with alpha=10%; †nominal p-value

ICOS-Tfh=programmed death 1 inducible co-stimulator expressing activated follicular T helper cells; pSS=primary Sjögren's syndrome; Tfh=follicular T helper cells; Treg=regulatory T cells

Figure. Adjusted Mean Change From Baseline in Serum CXCL13



n=number of subjects with both baseline and post-baseline measurements
CXCL13=chemokine (C-X-C motif) ligand 13

CXCL3 from BL, and ABA-treated patients had significantly lower levels of serum CXCL13, compared with placebo ($p< 0.0001$; Figure). Seventy-eight (ABA, 32; placebo, 46) patients were included in the CPP, with no observed differences in BL characteristics between treatment groups or populations (CPP vs non-CPP). ABA-treated patients had significantly reduced proportions of disease-relevant cell subsets (Tfh, activated Tfh, CD4 TEM, helper T cell 1 [Th1] and regulatory T cells [Treg]) at Day 169 compared with BL (data not shown). At Day 169, there was a significant adjusted mean difference in adjusted mean change from BL for ABA vs placebo for Tfh, ICOS-expressing activated Tfh and Treg cells (Table), and CD4 TEM, Th1 cells and naïve CD4 T cells (data not shown), and a numerical difference for plasmablasts (Table).

Conclusion: A significant pharmacodynamic effect of abatacept was observed on disease-relevant serum (CXCL13) and pathogenic cell subpopulations. The disconnect between the effectiveness of abatacept in lowering serum CXCL13 (a relevant biomarker in pSS) and pathogenic cell subsets, and the previously-reported lack of demonstrable benefit (vs placebo) in clinical outcomes, warrants further investigation.

Preliminary Identification of Arthritis-Associated Microbiota in Experimental Spondyloarthritis

Tejpal Gill ,[1] Tri Tran,[2] Stephen Brooks,[3] and Robert Colbert[4], [1]NIAMS/NIH, Bethesda, MD, [2]NIAMS, NIH, Bethesda, MD, [3]Biomining and Discovery Section/NIAMS/NIH, Bethesda, MD, [4]Pediatric Clinical Trials Unit, Pediatric Translational Research Branch, NIAMS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Axial Spondyloarthritis Translational Research
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Gut microbiota are strongly implicated in the pathogenesis of spondyloarthritis (SpA). Previous studies from our lab have documented extensive gut microbial dysbiosis in rats expressing HLA-B27 and human b2-microglobulin (HLA-B27 TG). The relative abundance of individual microbes is highly dependent on host genetic and environmental differences despite common immune dysregulation, indicating a complex ecological model of dysbiosis that precedes the development of arthritis. Here, we aimed to determine whether HLA-B27 TG rats that develop arthritis have a distinct gut microbial signature and host immune response.

Methods: Cohorts of mixed background (SDM) HLA-B27 TG and wild type (WT) littermates were generated by crossing HLA-B27 TG Lewis with WT Sprague-Dawley rats. SDM animals were monitored for the development of arthritis and euthanized at 4 to 6 months of age. Inflammation in the cecum and colon was assessed by histological scoring. Microbiota profiles were determined using DNA isolated from the cecum lumenal contents by 16S rRNA gene sequencing with primers specified by the Earth Microbiome Project (V4) and Illumina MiSeq. Data were quality-filtered using Quantitative Insights Into Microbial Ecology (QIIME 2). Host gene expression profiles were determined from the cecum tissue samples. RNA was isolated using a standard phenol–chloroform extraction and single-end sequencing of 50 bases was performed using an Illumina HiSeq 2000 system. Transcript expression levels (in reads per kilobase million [RPKM]) were generated and differentially expressed genes were defined for various comparisons.

Results: HLA-B27 TG SDM rats displayed early onset gut inflammation with ~30% developing arthritis by 4 months of age. No arthritis or gut inflammation was seen in WT SDM rats. Cecal and colon histology scores were similar in arthritic vs. non-arthritic HLA-B27 TG rats. There were distinct arthritis-associated microbial that were largely different from gut inflammation associated microbiota found by comparing HLA-B27 TG with WT SDM rats. Arthritic HLA-B27 SDM rats have increased abundance of phylum *Bacteroides* and *Parabacteroides* at the expense of *Firmicutes*. At

the species level, the relative frequency of *Akkermansia muciniphila* and *Blautia* was increased, while *Lachnospiraceae* and *[Ruminococcus] gnavus* were decreased compared to non-arthritic HLA-B27 TG rats. In contrast, cecal host gene expression between HLA-B27 TG arthritic and non-arthritic rats was not significantly different.

Conclusion: We provide a preliminary identification of arthritis associated gut microbiota in HLA-B27 TG rats, which is largely distinct from gut inflammation-associated microbiota. These results may provide valuable insights into the relationship between HLA-B27, gut microbiota, and arthritis in experimental SpA although further studies to determine cause-and-effect relationships are needed.

miR-21-5p Expression as a Marker of Treatment Response in Psoriatic Arthritis Patients

Rohan Machhar ,[1] JustineYang Ye,[2] Remy Pollock,[1] and Dafna Gladman[3], [1]Krembil Research Institute, University Health Network, Toronto, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Axial Spondyloarthritis Translational Research
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis occurring in patients with psoriasis. Links between altered miRNA expression with the pathogenesis of several autoimmune disorders have been reported. We previously demonstrated that miR-21-5p was upregulated in PsA compared to psoriasis without arthritis (PsC) and healthy controls (HC) and is thus a potential biomarker for PsA. We also demonstrated that miR-21-5p modulates inflammation in psoriatic disease (PsD = PsA & PsC) through IL-17/IL-23 axis and CXCL10 and is a marker of inflammation. We aimed to 1) validate the results in a new set of patients, 2) examine the expression of miR-21-5p before and after 24 weeks of methotrexate (MTX) treatment 3) determine if miR-21-5p expression differs depending on route of MTX administration.

Methods: Serum & whole blood RNA samples were collected from 40 patients with early PsA (< 2 years' disease duration and not receiving biologic therapy), 40 patients with psoriasis who have been confirmed by a rheumatologist not to have PsA (PsC, >10 years disease duration, not receiving biologic therapy, and matched to PsA patients on age, sex, psoriasis duration, and age of psoriasis onset), and 40 HC (matched to patients based on age, sex), 15 PsA patients before and after 24 weeks of treatment with MTX. An additional 15 PsA patient samples were collected to compare oral vs subcutaneous MTX. RNA was extracted using the Tempus Spin RNA Isolation Kit. miR-21-5p was measured by droplet digital PCR (ddPCR). Serum IL-17, CXCL10, IL-23, TGFβ1 were measured by commercially available ELISA kits. One-way ANOVA, Pearson Chi Square test, paired t-test and Spearman correlations were performed.

Results: miR-21-5p was upregulated in PsA compared to PsC (Fold Change(FC)=2.32, p=0.001) and HC (FC=15.7, p=< 0.0001), validating the results observed in our previous studies. In PsA patients we found a correlation between expression of miR-21-5p and swollen joint count (SJ) (r=0.367, p= 0.022) and actively inflamed joint counts (AJTOT) (r=0.326, p=0.043). miR-21-5p was significantly down regulated 24 weeks post-MTX treatment in 12 patients (p=0.021) and correlated with AJTOT (r=0.421, p=0.036), SJ (r=0.420, p=0.037), TJ (r=0.418, p=0.037) and clinical

Table 1: Demographic, Clinical and Relative Expression Data of Validation cohort

Variable	PsA (N=40)	PsC (N=40)	HC (N=42)	P Value
miR-21-5p*	121.1 (99.2)	52.06 (27.4)	7.74 (5.98)	<0.001
Sex Male	21(53%)	21(53%)	21(53%)	0.96
Female	19(47%)	19(47%)	19(47%)	
Age*	45.7 (10.3)	43.9 (9.2)	45.7 (10.3)	0.19
PASI*	5.03 (6.9)	5.09 (3.2)	N/A	0.29
AJTOT*	4.6(3.6)	N/A	N/A	N/A

*Mean (standard deviation); PASI-psoriasis areas severity index; AJTOT-total actively inflamed (tender or swollen) joint count; CRP-C reactive protein; PsA - psoriatic arthritis; PsC – cutaneous psoriasis without arthritis; HC- healthy controls

Table 2

Variable	PsA (N=15)	
Sex Male	8(47%)	
Female	7(53%)	
Age*	50.6(12.6)	
PASI*	2(2.2)	
AJTOT *	3.0(3.8)	
miR-21-5p*	Pre Treatment	Post Treatment
	104.4 (63.7)	67.2 (56.3)

*Mean (SD); PASI-psoriasis areas severity index; AJTOT-total actively inflamed (tender or swollen) joint count; CRP-C reactive protein; PsA - psoriatic arthritis

disease activity in PsA (cDAPSA) (r=0.549, p=0.004). 3 patients showed an upregulation of miR-21-5p. These 3 patients had treatment escalation at subsequent visit. We also observed significant downregulation of miR-21-5p and significant correlation with AJTOT (r=0.964, p=0.002) and cDAPSA (r=0.811, p=0.035) in patients taking subcutaneous MTX but no downregulation of miR-21-5p in patients taking oral MTX. The MTX dosage in both groups were not significantly different (avg dose 15.5 mg/wk).

Conclusion: We have determined a role of miR21-5p as a potential biomarker for inflammation in psoriatic disease and response to methotrexate treatment. miR-21-5p levels appear to decrease in patients taking subcutaneous but not oral MTX.

Inflammatory Processes in Experimental Spondyloarthritis Are Accompanied by Formation of Ectopic Lymphoid Structures and B Cell Lineage Alterations in the Bone Marrow

Merlijn Kaaij ,[1] Jan Piet van Hamburg,[1] Jasper Rip,[2] George Kollias,[3] Leonie van Duivenvoorde,[1] Martijn Nolte,[4] Dominique Baeten,[1] and Sander Tas[1], [1]Amsterdam Rheumatology & immunology Center, Amsterdam UMC/University of Amsterdam, Amsterdam, Netherlands, [2]Department of Pulmonary Medicine, Erasmus MC, Rotterdam, Rotterdam, Netherlands, [3]Division of Immunology, Biomedical Sciences Center "Alexander Fleming", Vari, Greece, Vari, Greece, [4]Sanquin Research and Landsteiner Laboratory, Molecular & Cellular Hemostasis, Amsterdam UMC/University of Amsterdam, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Axial Spondyloarthritis Translational Research
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Tumour necrosis factor a (TNF) is important in immune-mediated inflammatory diseases such as spondyloarthritis (SpA). Transmembrane (tm)TNF-transgenic (tg) mice that overexpress tmTNF develop typical SpA symptoms, including inflammation, bone destruction and bone formation. Interestingly, these mice also develop lymphoid aggregates in the bone marrow (BM) of the axial and peripheral skeleton. We characterized the lymphoid aggregates in the context of angiogenesis and inflammation.

Methods: Ankles, femora, tibiae, vertebrae and spleens from tmTNF tg mice and wild-type (WT) littermates (6 weeks, 12 weeks, and 8 months old; n=5 per age per group) were dissected and analyzed by confocal microscopy. In addition, 12 week old mice (n=6 per group) were analyzed by flow cytometry. To study the importance of TNF-R signaling in these processes, tmTNF tg mice lacking TNF-RI (tmTNF tgxTNF-RI$^{-/-}$) or TNF-RII (tmTNF tgxTNF-RII$^{-/-}$) (n=5 per group) were investigated.

Results: Immunofluorescent (IF) evaluation demonstrated that BM of tmTNF tg mice contained extensive lymphoid aggregates, both in the vertebrae and the ankles, but not in the femurs. The aggregates in the BM progressed with age and contained characteristics of ectopic lymphoid structures (ELS) consisting of B220^{+} B cells, CD3^{+} T cells, expression of the germinal center marker peanut agglutinin (PNA) and FDC-M1^{+} follicular dendritic cells that are in close proximity of MECA79^{+} high endothelial venules (HEVs). Quantification showed a median of 2 aggregates per vertebra in the tmTNF tg mouse, while there were none in the WT (P=0.001). Flow cytometric analysis revealed that tmTNF tg vertebrae contained a significantly higher amount of B cells (P=0.002) and more IgD^{-}CD95^{+} germinal center B cells per B cell (P=0.002) with a higher expression of the costimulatory molecules CD80 (P=0.002) and CD86 (P=0.002) compared to vertebrae of WT animals. The vertebrae also contained significantly more CXCR5^{+}PD-1^{+}FoxP3^{-}CTLA4^{-} T follicular helper cells (P=0.026), CXCR5^{+}PD-1^{+}FoxP3^{+}CTLA4^{+} T follicular regulatory cells (P=0.02) and CXCR5^{-}PD-1^{-} FoxP3^{+} T regulatory cells (P=0.01) in tmTNF tg mice. Meanwhile, B cell development in the BM of tmTNF tg femurs and vertebrae was not altered. Furthermore, BM, spleen and vertebrae from tmTNF tg mice contained significantly more IgA^{+} plasma cells compared to WT littermates. Of note, tmTNF tgxTNF-RI$^{-/-}$ mice did not display lymphoid aggregates or HEVs in the BM, while tmTNF tgxTNF-RII$^{-/-}$ mice did, although to a lesser extent than tmTNF tg mice. Likewise, tmTNFa tgxTNF-RI$^{-/-}$ mice did not develop macroscopic inflammation in spine and ankle joints, while the tmTNF tgxTNF-RII$^{-/-}$ mice did.

Conclusion: tmTNF overexpression in mice induces ELS in BM and supports IgA^{+} plasma cell differentiation. These effects are critically dependent on TNF-RI signaling and may underlie SpA pathology, as BM edema and elevated serum IgA have also been described in SpA patients.

Targeting the Oxidative Stress Pathway in Experimental Spondyloarthritis Reduces Pro-inflammatory Response in Rat Macrophages and Modulates Their Metabolic Requirements

Fatemeh Navid ,[1] Francesca LiCausi,[1] Breanna Nguyen,[1] Antony Cougnoux,[2] Pierre-Christian Violet,[3] Mark Levine,[3] and Robert Colbert[1], [1]NIAMS/NIH, bethesda, [2]NICHDR/NIH, Bethesda, [3]NIDDK/NIH, Bethesda

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Axial Spondyloarthritis Translational Research
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: HLA-B27 is associated with the development of spondyloarthritis (SpA) and has a tendency to generate ER stress due to misfolding which can activate the unfolded protein response (UPR). UPR may contribute to SpA pathogenesis by promoting the production of pro-inflammatory cytokines like IL-23 and TNF. Under ER stress cells produce more reactive oxygen species (ROS), which further can worsen the UPR and promote inflammation. Our preliminary data indicate that IFNg and LPS treatment increases ROS and cytokine production to a greater extent in HLA-B27-expressing macrophages compared to wild type cells or cells expressing the non-disease associated allele, HLA-B7. Another important aspect of inflammation is that upon inflammatory activation immune cells have to change their metabolic requirements in order to meet the adequate response like producing pro-inflammatory cytokines. Here we examined whether reducing oxidative stress in HLA-B27+ macrophages affects pro-inflammatory cytokine production and UPR gene expression. Furthermore, we were interested whether targeting the oxidative stress pathway will modulate the metabolic requirements of the cells upon inflammatory activation.

Methods: Bone marrow derived macrophages from HLA-B27 and human b_2m (hb_2m) transgenic rats were examined with and without IFNg and LPS treatment. ROS levels were meseared with the ROS-sensitive dye MitoSOX for mitochondrial ROS production and 2',7'-dichlorofluorescein diacetate (DCFDA) for cellular ROS level detection. N-acetylcysteine (NAC) was used as an antioxidant, and differential gene expression was determined by RNASeq. For cytokine secretion, ELISAs were used and in order to measure metabolic activity the Seahorse Assay was performed. Wild type (WT) and HLA-B7/hb_2m transgenic rat macrophages were used as controls.

Results: Bone marrow-derived macrophages from HLA-B27-transgenic (Tg) showed increased baseline mitochondrial ROS production in the absence of UPR compared to HLA-B7-Tg and wild type (WT) control rats. Further stimulation of HLA-B27-Tg macrophages with IFNg and LPS (stimulated) showed increased ROS production compared to HLA-B7-Tg and WT control rats.This was accompanied by robust activation of the UPR only in HLA-B27-expressing cells. Treatment with NAC, an ROS scavenger, significantly reduced ROS levels in HLA-B27+ macrophages and strongly decreased the transcription of many pro-inflammatory cytokines including Il-23, Il-12, Tnf, Il-6, Il-1a and Il-1b. The effect of NAC was further verified by ELISA assays available for rat IL-6 and TNF. NAC treatment had minimal effect on UPR gene expression, with partially reduction of BiP expression and no changes in HLA-B27 expression. Interestingly, NAC reduced metabolic activity in stimulated macrophages to levels similar to untreated control cells as measured by the Seahorse Assay.

Conclusion: Our data demonstrate that reducing ROS levels with NAC ameliorates ER stress-related pro-inflammatory effects of HLA-B27 misfolding. Alteration of the oxidative stress pathway should be further explored for therapeutic intervention in SpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Axial Spondyloarthritis Translational Research

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Psoriasis (Pso) is a common chronic inflammatory skin disease. About 30% of Pso patients develop psoriatic arthritis (PsA), a chronic inflammation of joints and entheses with an additional negative impact on quality of life. Early detection of PsA patients is important to ensure timely treatment and prevention of structural joint damage. Unfortunately, PsA is markedly under-diagnosed by dermatologists; an unmet need for biomarker-profiles to screen Pso patients at-risk is obvious. The aim of our study was to assess whether high dimensional flowcytometric profiling can distinguish Pso and PsA patients.

Methods: A cross-sectional and case-control study recruited 25 Pso patients without arthritis and 33 patients with PsA, both not using biological therapy at baseline. Psoriasis was diagnosed by a dermatologist and all the included Pso patients had a Psoriasis Epidemiology Screening Tool (PEST) score of 2 or lower. All PsA patients were clinically diagnosed by a rheumatologist.

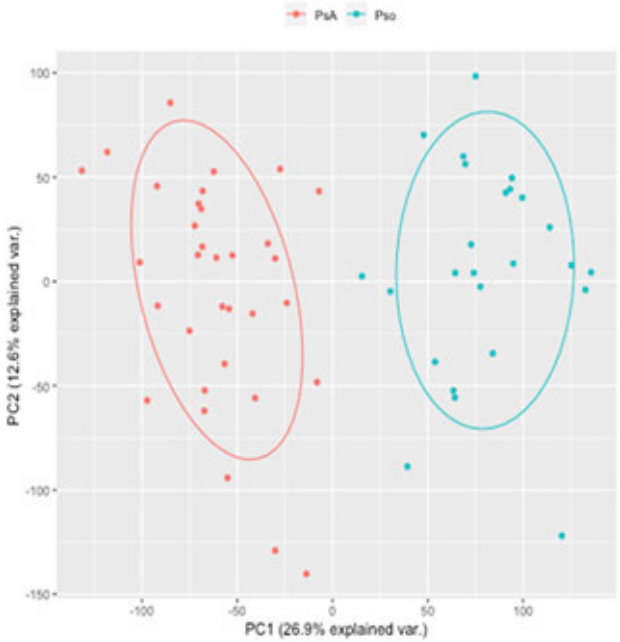

Figure 1. Semi-unsupervised clustering based on principal component analysis. Red dots represent PsA patients, blue dots represent Pso patients.

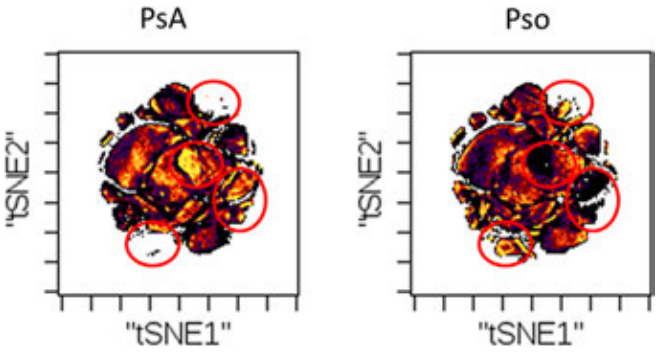

Figure 2. Density plots of different celsubsets in PsA and Pso based on viSNE analysis.

Peripheral blood samples were analyzed by high dimensional flowcytometry, consisting of five different and supplementary 10-color antibody panels, which enables the characterization of ~150 immune cell populations. Both semi-unsupervised and unsupervised computational flow cytometry analyses were performed. In case of semi-unsupervised analysis, the flow cytometry data was first manually analysed, followed by principal component analysis (PCA) and unsupervised hierarchical clustering of PCA (HCPC). For unsupervised computational flow cytometry, flowsom and viSNE analysis packages of Cytobank were used.

Results: The PsA and Pso population were comparable with regard to gender. In line with expectations, the PsA patients were slightly older compared to the Pso patients (57±15.4 vs 44±14.6). There was a significant difference in the use of methotrexate between the PsA patients (51%) and Pso patients (12%). Semi-unsupervised analysis of high dimensional flow cytometry data of peripheral blood from Pso and PsA patients clearly revealed differential clustering of Pso-vs-PsA patients as indicated by principal component analysis (Fig 1). This distinction between Pso and PsA patients was independent of age, gender, PASI scores and methotrexate use. Also unsupervised clustering showed a clear distinction between both diseases. Similar, unsupervised computational analysis utilizing flowsom and viSNE showed marked differences in the immune cell subset profiles between Pso and PsA patients (Fig 2).

Conclusion: High dimensional flowcytometric evaluation with semi-unsupervised and unsupervised analysis, can differentiate Pso and PsA patiens. Following validation, the obtained immune profiles might be used to support the timely diagnosis of PsA in Pso patients, as well as target finding to prevent this disease-shift.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Axial Spondyloarthritis Translational Research

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Recent studies have suggested that peripheral arthritis in patients with spondyloarthritis is associated with HLA-B*15. Studies of white patients with psoriatic arthritis (PsA) have demonstrated associations with HLA-B*27, B*38, B*08 and B*37, whereas B*44 was associated with presence of milder disease. The purpose of this study was to examine HLA-B allele associations with peripheral arthritis and enthesitis in a longitudinal study of outcome in ankylosing spondylitis (AS) where these factors were assessed not only historically but also by systematic clinical assessments.

Methods: This study focused on white patients enrolled in a longitudinal study of outcome in AS. All patients met modified New York Criteria for AS. Study visits were conducted every 4-6 months, and at baseline and every two years a history of peripheral arthritis (and which joints involved), heel pain, plantar fasciitis and Achilles tendonitis. Hip and shoulder involvement was not included in this analysis. Clinical evaluation was carried out by the study rheumatologist at each visit, including joint pain/tenderness/swelling and entheseal involvement by the UCSF Enthesitis Index. HLA-B typing was carried out by single stranded conformational polymorphism (SSCP) analysis. Statistical

Table 1.

HLA-B Alleles and Peripheral Arthritis in Patients with AS by History

B*57	1.6%	0.7%	0.13	2.2

Table 2

HLA-B Alleles and Peripheral Arthritis in Patients with AS by Clinical Assessment

HLA	Peripheral Arthritis by Clinical Assessment n=261	No Peripheral Arthritis N=569	P value	Odds Ratio
B*07	5.9%	5.8%	1.0	1.0
B*08	5.9%	5.4%	0.83	1.1
B*14	3.6 %	3.1%	0.72	1.2
B*15	4.8%	2.6%	0.025	1.9
B*27	41.4%	45.2%	0.16	0.9
B*35	5.2%	5.8%	0.16	0.9
B*37	1.5%	0.5%	0.07	2.9
B*38	3.7%	3.7%	1.00	1.0
B*40	4.2%	4.3%	1.00	1.0
B*44	5.8%	8.2%	0.10	0.7
B*51	3.1%	3.3%	0.96	0.9
B*57	1.0%	1.1%	0.90	0.8

analyses were carried out by chi square analysis using the EPI-INFO statistical program. In order to control for the high frequency of HLA-B27, relative predispositional effect (RPE) analysis was carried out with HLA-B27 alleles.

Results: There were 1009 white AS patients with HLA-B typing available included in this analysis. Of these, 158 were seen only once and comprehensive musculoskeletal exam not carried out, though a history of peripheral arthritis, heel pain, plantar fasciitis and Achilles tendonitis attributed to AS recorded. In those patients followed longitudinally, there was an average of 7 study visits conducted. Peripheral arthritis (excluding hips and shoulders) attributed to AS occurred in 64.7% by history. Peripheral arthritis found on clinical evaluation was found in 25.9%. Heel pain by self report occurred in 25.9%, and plantar fascia/Achilles tendon tenderness on clinical evaluation at study visits in 32%. Entheseal tenderness as defined by the UCSF Enthesitis index was observed at least once in 65.5%. No HLA-B associations were encountered with heel pain, plantar fasciitis, Achilles tendonitis by history or plantar/Achilles tendon tenderness. Neither were any associations were observed on the UCSF Enthesitis index or with peripheral arthritis by patient history. HLA-B*15 was increased in frequency in those with peripheral arthritis seen on clinical evaluation (Table 2), which was confirmed on RPE analysis, where a weak negative association with HLA-B*44 was also observed (9.8 vs. 14.9%, p=0.04, OR=0.6).

Conclusion: These data in a large cohort of patients with AS confirms the association of HLA-B*15 with peripheral joint involvement in AS. The HLA-B associations with peripheral joint and entheseal involvement previously reported in PsA are not confirmed in AS suggesting that different mechanisms may be in play in the pathogenesis of peripheral joint and entheseal involvement between AS and psoriatic arthritis.

Session Title: SLE – Clinical IV: Lupus Nephritis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Table 1. Patient Characteristics. 201 patients were included in the study. There were 113 patients with high IFN signature trait and 88 patients with low IFN signature trait. Gender, race, and age at SLE diagnosis are displayed for each group. The event of interest, development of lupus nephritis, is also included.

	All	IFN High	IFN Low
Total (n,%)	201 100%	113 56.22%	88 43.78%
Demographics			
Female (n,%)	180 89.11%	99 87.61%	81 92.05%
Race/Ethnicity (n,%)			
Asian	13 6.44%	12 10.62%	1 1.14%
Black/African American	47 23.27%	29 25.66%	18 20.45%
Hispanic/Latino	23 11.39%	17 15.04%	6 6.82%
Native American	23 11.39%	17 15.04%	6 6.82%
White/Caucasian	95 47.03%	38 33.62%	57 64.77%
Age at SLE Diagnosis (median, IQR)	32.00 [23.00-43.00]	27.65 [22.00-37.00]	37.5 [26.00-44.25]
Lupus Nephritis (n, %)	58 28.86%	48 42.48%	10 11.36%

Background/Purpose: The interferon (IFN) signature in SLE is well established, distinguishing lupus patients from healthy controls. Additionally, within lupus patients, higher levels of IFN-responsive gene expression associate with higher disease activity, elevated autoantibodies, greater number of SLE criteria, and higher damage indices. Despite these associations in SLE patients, an individual's IFN signature lacks responsiveness to acute changes in disease activity in longitudinal analyses. This stability is more reflective of a continuous trait, likely the result of known interferon pathway genetic associations. Elevated levels of IFN have been noted in lupus nephritis, which occurs in approximately half of SLE patients and is a major cause of morbidity and early mortality. Delay in diagnosis of lupus nephritis results in prolongation of renal inflammation, and often irreversible kidney damage. The ability to predict patients at greater risk of lupus nephritis may improve surveillance, reduce time to diagnosis and treatment, and potentially result in improved outcomes in lupus nephritis. We evaluated the prognostic significance of an individual having an elevated IFN-signature trait and progression to lupus nephritis.

Methods: The study included 201 lupus patients, all meeting both the ACR 1997 and SLICC 2012 classification criteria for SLE from a single institution. The open cohort had a median follow-up time of 14.14 years [IQR 10.96, 19.83]. Stored whole blood RNA (PAXgene) samples from the earliest longitudinal timepoint on these 201 patients were assessed for interferon signatures using an IFN-responsive four gene expression assay (Autoimmune Profile Assay, DxTerity Diagnostics) to define an individual's overall IFN-signature trait. Lupus nephritis status was defined by the date of attainment of the renal component of the SLICC SLE classification criteria. Cox proportional hazards modeling was utilized to determine the contribution of IFN signature trait, age at SLE diagnosis, gender, and race to the development of lupus nephritis.

Results: The cohort of 201 SLE patients included 58 patients who developed lupus nephritis and 113 with a high IFN signature trait. Characteristics of the complete group, as well as IFN-signature subgroups, are displayed in Table 1. High IFN signature trait was an independent predictor for earlier time to development of nephritis (Hazard Ratio 3.36, p=0.0008) after adjusting for age at SLE diagnosis, gender, and race (Figure 1). In our Cox proportional hazards model, younger age at diagnosis of SLE, male gender, and non-white race were also associated with higher likelihood of nephritis development. Racial subgroup analyses found that high IFN signature remained a significant predictor of earlier nephritis when evaluating either non-white patients (Hazard Ratio 3.41, p=0.021) or white patients (Hazard Ratio 2.97, p=0.031), adjusting for age at SLE diagnosis and gender.

Conclusion: Assessment of an individual's interferon signature phenotypic trait at the time of SLE diagnosis may be a useful tool to determine risk for development of lupus nephritis.

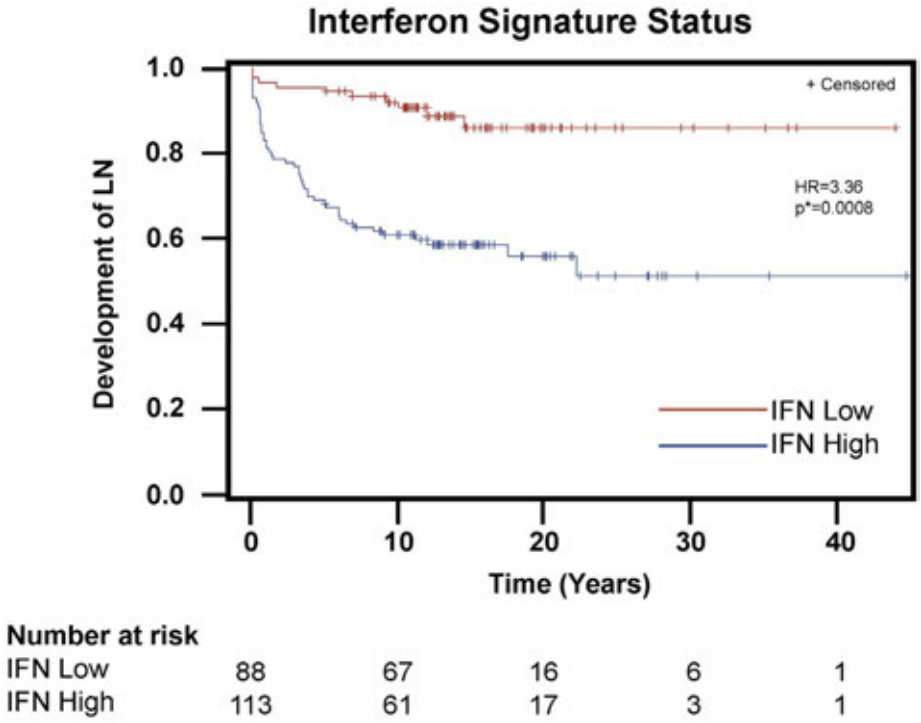

Figure 1. Kaplan-Meier Survival Analysis. Time to development of lupus nephritis is compared for patients with low interferon signature trait (red, upper) and those with high interferon signature trait (blue, lower). Cox Proportional Hazard Testing was utilized to adjust for covariates of age at lupus diagnosis, gender, and race (Hazard Ratio and p*).

Abstract Number: 1915

Validation of a Serologic Antibody Biomarker Against a Candidate Gut Pathobiont for the Diagnosis of Lupus Nephritis

Gregg Silverman ,[1] Doua Azzouz,[1] Caroline Grönwall,[2] Iva Gunnarsson,[3] and Elisabet Svenungsson[4], [1]NYU School of Medicine, New York, NY, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital and Institutet, Stockholm, Sweden., Stockholm, Sweden, [3]Karolinska Institute, Stockholm, Stockholms Lan, Sweden, [4]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

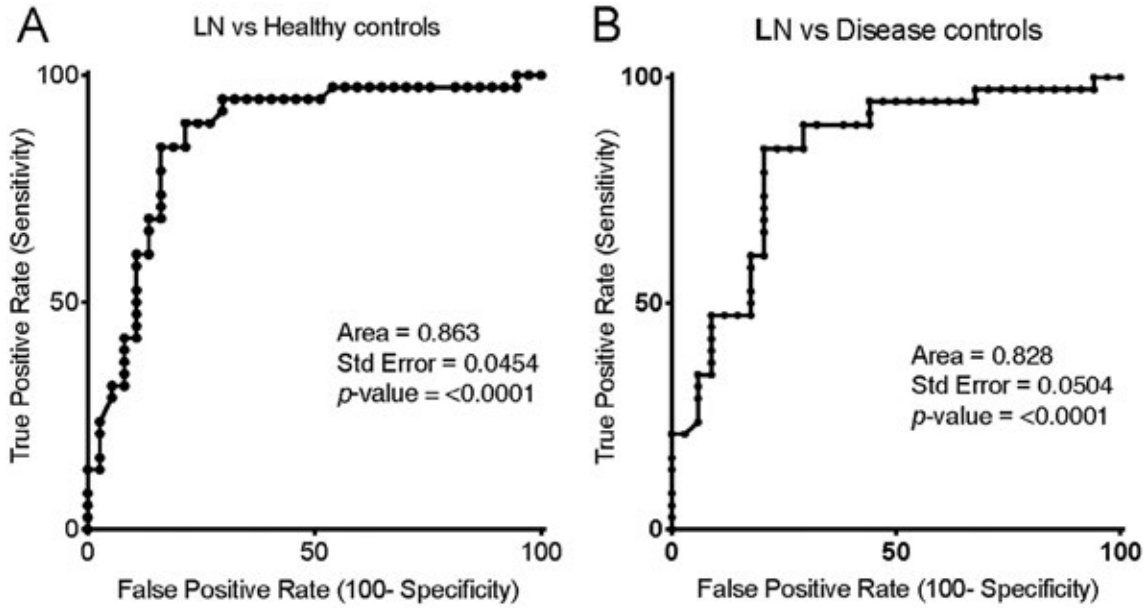
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical IV: Lupus Nephritis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is the archetypic systemic autoimmune disease, for which there is mounting evidence for roles for intestinal bacteria in the development of the systemic autoimmune responses, inflammation, and tissue injury. Whereas Lupus nephritis (LN) is amongst the most serious and potentially life-threatening complications of SLE, earlier diagnosis would speed clinical decision-making and initiation of definitive therapy. To characterize the interrelationships between Lupus host immunity and a candidate gut microbiome pathobiont, we have recently described an assay for detection of serum IgG responses to the commensal anaerobe, *Ruminococcus gnavus* (*RG*), for identification of individuals with active LN in three US adult Lupus cohort. In the current studies, we further validated this assay and investigated its potential utility in a Swedish cohort.

Methods: Patients were recruited and characterized at the Karolinska Hospital, based on ACR criteria, with 38 LN confirmed by renal biopsy, 38 non-renal SLE patients, with 37 age- gender- ethnicity- matched unaffected population (Healthy) controls, 20 ANCA-associated vasculitis (AAV) and 14 IgA Nephropathy (IgAN) patients, based on renal biopsy and/or standard clinical criteria. At our NYU lab, serologic studies were performed with a previously described custom bead-based serologic assay with nuclease-treated *RG2* extract and control analytes.

Results: LN patients had significantly higher levels of IgG anti-RG2 than Healthy subjects ($p < 0.0001$,) other non-renal Lupus patients ($p=0.0002$), or patients with IgAN ($p < 0.0001$) or AAV ($p < 0.0001$)(Wilcoxon rank-sum). There was a modest difference between non-renal Lupus patients, and Healthy subjects ($p=0.0283$), but no difference between Healthy with IgAN ($p=0.273$) or AAV ($p=0.433$). ROC analysis, when LN were compared to Healthy subjects gave an AUC of 0.863 and a Likelihood ratio (LR) of 5.6 at a cut-off of the mean+1 SD for control subjects ($p < 0.0001$); the LR was 5.8 for a cut-off of a mean+2SD ($p < 0.0062$), and LR of 7.8 for a cut-off of a mean+3SD ($p=0.0284$). For LN compared to the disease controls (AAV and IgAN) there was an AUC of 0.828 with a LR of 2.64 with a cut-off of a mean+1SD for disease controls ($p=0.01$), and the LR of 5.4 with a disease control mean+2SD ($p=0.0071$)(Figure 1A&B).

Conclusion: These findings further validate that serum IgG anti-*RG2* levels provide a robust biomarker for the identification of LN, unaffected by gender and age. Importantly, the assay displayed attractive performance characteristics



Area under the curve estimates for comparisons of Lupus nephritis patients to A) age- and gender-matched population (Healthy) controls, or B) Disease controls with AAV or IgA nephropathy that represent other forms of glomerulopathy often complicated by pathologic levels of proteinuria.

for discrimination of LN patients from population controls as well as those with pathologic proteinuria due to other forms of immune glomerulopathy (i.e., AAV and IgAN). Our findings also provide circumstantial evidence of a possible role for the *R. gnavus* pathobiont in patients in Sweden, suggesting this pathobiont may be involved in LN at sites geographically distant from the localities in which this association was first identified.

Abstract Number: 1916

Reduced DNASE1L3 Activity in Sporadic SLE Is Linked to Increased DNA Load of Microparticles, Reactivity to DNASE1L3-sensitive Antigens, and Lupus Nephritis

Johannes Hartl ,[1] Robert Clancy,[1] Peter Izmirly,[1] H Michael Belmont,[2] Catherine Trad,[1] Nicole Bornkamp,[1] Vanja Sisirak,[1] Benjamin Sally,[1] Jill Buyon,[1] and Boris Reizis[1], [1]NYU School of Medicine, New York, [2]NYU Langone Health, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical IV: Lupus Nephritis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Null mutations in *DNASE1L3* cause severe familial SLE with prominent anti-DNA antibodies (Abs), suggesting that DNASE1L3 is a key driver of tolerance to DNA. Indeed, DNASE1L3-deficient mice rapidly develop anti-chromatin and anti-DNA Abs followed by renal involvement. DNASE1L3 is a secreted DNase that has the preferential capacity to digest DNA within nucleosomes and/or encapsulated by membranes. Our previous studies suggest that chromatin carried by circulating apoptotic microparticles (MP) is an important physiological substrate of DNASE1L3. Accordingly, the present study was initiated to address the hypothesis that dysfunction of DNASE1L3 and its downstream consequences contribute to the development of sporadic human SLE.

Methods: Reactivity to DNASE1L3-sensitive antigens on MP was measured by incubating plasma samples with control or DNASE1L3-treated MP and analyzing IgG binding to MP by flow cytometry. DNASE1L3 activity was measured based on its preferential capacity to digest complex DNA substrates with the readout expressed as the fraction of activity measured in healthy control subjects. The DNA load of MP was measured by qPCR of genomic DNA purified from the MP and MP-depleted fractions of plasma. In considering a spectrum from benign to clinical autoimmunity, subjects included those with active biopsy proven lupus nephritis as well as those with anti-Ro antibodies absent SLE.

Results: IgG-binding to MP was assessed in 116 SLE patients, 45 anti-Ro Ab-positive mothers whose children have neonatal lupus (17 asymptomatic or having an undifferentiated autoimmune syndrome, 2 SLE, 12 SS, 14 SLE/SS) and 16 healthy controls. IgG-reactivity to MP was not detected in any healthy controls. In contrast, 36% of SLE patients showed IgG binding to MP reversed by DNASE1L3 pretreatment (DNASE1L3-senstive reactivity). Only two of these patients were heterozygous for the known hypomorphic DNASE1L3 (R206C) variant. DNASE1L3-sensitive reactivity correlated with anti-dsDNA Abs ($p< .0001$) but did not overlap, indicating that reactivity is directed to more complex DNA. DNASE1L3-sensitive reactivity correlated with active proteinuria ($p=.0003$), low complement levels ($p=.01$) and overall SLEDAI ($p< .0001$). Among 45 anti-Ro-positive mothers, all were unreactive except the only 2 SLE mothers that developed lupus nephritis. The DNA load of MP and DNASE1L3 activity were assessed in a subset of SLE pa-

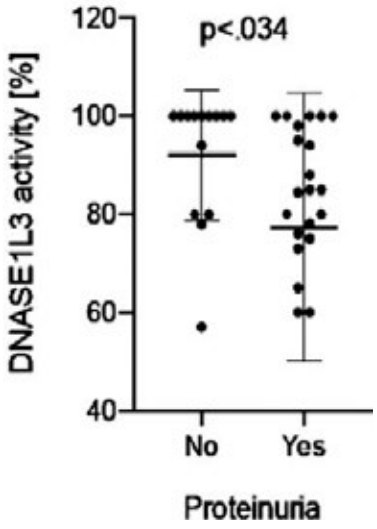

Figure 1. DNASE1L3 activity in SLE patients with and without proteinuria measured as a percentage of baseline activity in healthy controls.

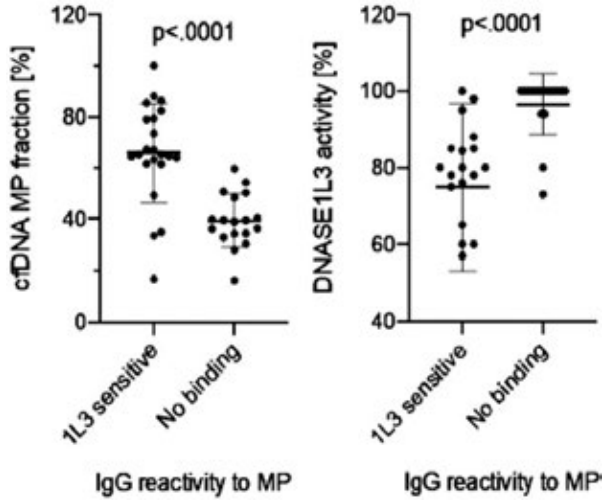

Figure 2. Cell-free DNA bound to microparticles (cfDNA MP fraction) as a percentage of total DNA in DNASE1L3-sensitive versus insensitive patient samples (left panel); DNASE1L3 activity in in DNASE1L3-sensitive versus insensitive patient samples measured as a percentage of baseline activity in healthy controls (right panel).

tients (n=40). Of these, patients with proteinuria showed lower plasma DNASE1L3 activity (p=.034) than those without proteinuria (Fig. 1). Moreover, increased partitioning of plasma DNA into MP correlated with reduced DNASE1L3 activity, and both parameters strongly correlated with DNASE1L3-sensitive IgG binding to MPs (p< 0.0001) (Fig. 2).

Conclusion: The activity of plasma DNASE1L3 is reduced in a significant fraction of SLE patients with renal disorder unrelated to a genetic explanation and is associated with DNA accumulation in MP targeted by Abs. Collectively, these data suggest that digestion of circulating chromatin by DNASE1L3 is a fundamental mechanism of tolerance to DNA which when disrupted may lead to sporadic SLE, particularly lupus nephritis.

Tubulointerstitial Inflammation Predicts Outcomes in Lupus Nephritis

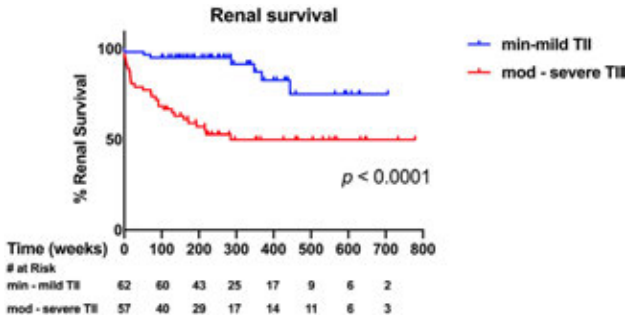
Charles Oshinsky ,[1] Mariam Siddiqui,[2] Vladimir Liarski,[3] Anthony Chang,[3] Marcus Clark,[4] and Kichul Ko[3], [1]University of Chicago, Department of Internal Medicine, Chicago, [2]Northwestern Memorial Hospital, Chicago, [3]University of Chicago, Chicago, [4]University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical IV: Lupus Nephritis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

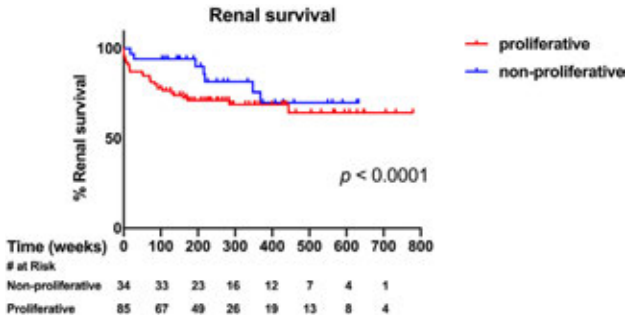
Background/Purpose: Lupus nephritis (LuN) causes significant morbidity and mortality, but predicting which patients will progress still remains imprecise. Current classification schema for LuN and its treatment are based exclusively or primarily on the glomerulus. Multiple studies have found that such classification schemes inconsistently predict outcomes, whereas tubulointerstitial inflammation (TII) has been shown to associate with poor renal survival. However, long-term data from a cohort with mostly African American (AA) patients with severe TII are still lacking. We aimed to determine the association between TII and long-term renal survival in LuN, and at-biopsy factors associated with moderate to severe TII.

Methods: Retrospective data from LuN subjects who had native kidney biopsies done from 2003 through 2014 were collected. Only those with at least 2 years of follow-up from the time of biopsy were included for analysis. Subjects were classified by International Society of Nephrology/Renal Pathology Society (ISN/RPS) criteria, and Class III and IV cases were combined into a proliferative class for analysis. TII was scored semi-quantitatively through light and immunofluorescence (CD45) microscopy by a blinded pathologist, and given scores from 0 – 3: 0 (< 10% of involvement, minimal), 1 (10 – 25%, mild), 2 (26 – 50%, moderate) and 3 (>50%, severe). Bivariate comparisons and multivariate logistic regression (MLR) analysis were performed to determine at-biopsy factors associated with moderate to severe TII. Renal survival analyses were done though Kaplan – Meier technique with time to end-stage renal disease (ESRD) with curves compared through the log-rank test.

Results: Among 122 subjects, 75.4% were AA, 84.4% were female, and 73.0% had proliferative LuN. The median follow-up period was 5.3 years (interquartile range 3.4 – 8.4 years). 60 subjects had moderate to severe TII, and they had higher percent of AA (91.7 vs 59.7%, $p < 0.0001$), higher median creatinine (1.5 vs 0.7 mg/dL, $p < 0.0001$), higher degree of proteinuria (3.8 g/day vs 1.8 g/day, $p < 0.0001$), and higher glomerular activity index ($p = 0.02$) and chronicity index (CI, both glomerular [$p = 0.0001$] and tubulointerstitial [$p < 0.0001$]) than those with minimal to mild TII. MLR analysis showed that moderate to severe TII was only associated with AA ethnicity (Odds Ratio [OR] 5.38, $p = 0.028$)



Higher degree of tubulointerstitial inflammation predicted worse renal survival



The ISN/RPS classification, stratified by proliferative (class III and class IV) vs nonproliferative, does not predict renal survival

and tubulointerstitial CI (OR 3.85, p = 0.001) but not with proliferative class or glomerular CI. Renal survival analysis found that subjects with moderate to severe TII had worse renal survival (approximately 50% with ESRD by 4th year) compared to those with minimal to mild TII (hazard ratio 5.01, $p < 0.0001$). There was no renal survival difference based on the presence of proliferative LuN (p = 0.2).

Conclusion: Higher degree of TII predicted worse renal survival, whereas ISN/RPS classification was not prognostic. Only AA ethnicity and tubulointerstitial CI were associated with moderate to severe TII at biopsy.

Urine CD163 Significantly Discriminates Active Lupus Nephritis and Strongly Correlates with Proliferative Glomerulonephritis

Ting Zhang ,[1] Ramesh Saxena,[2] Chi Chiu Mok,[3] Michelle Petri,[4] and Chandra Mohan[5], [1]Biomedical Engineering, University of Houston, Houston, TX, [2]UTSW, Dallas, [3]Department of Medicine, Tuen Mun Hospital, Hong Kong, China (People's Republic), [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]University of Houston, Houston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical IV: Lupus Nephritis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: CD163 is a marker for alternatively activated M2 macrophages, which have been implicated in the pathogenesis of lupus nephritis (LN). The potential of urine CD163 as a novel biomarker to reflect renal disease activities and pathological changes in LN was investigated.

Methods: Urine samples were obtained from LN patients with multiple ethnicities, assayed for CD163 using ELISA and then normalized to urine creatinine. Urine samples of healthy volunteers, inactive SLE, or active SLE patients without renal involvement were used as controls. CD163 was also measured in urine samples of an independent LN cohort with concurrent renal biopsies, and its correlation with renal pathology as well as clinical parameters were analyzed.

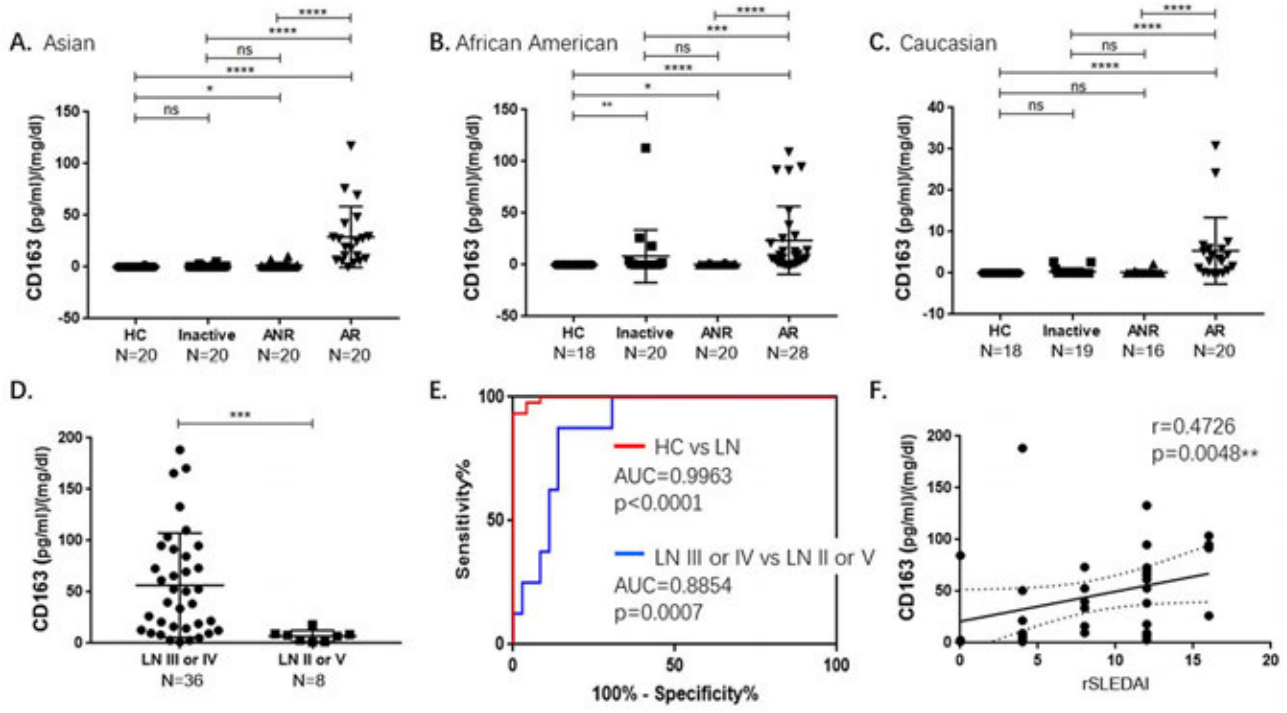

Figure 1. A-C, Cr-normalized urine CD163 was significantly elevated in active LN patients (AR) when compared with healthy controls (HC), inactive SLE patients or active SLE without renal involvement (ANR) in Asian, African American or Caucasian patients. D-E, Urine CD163 was significantly higher in LN patients with concurrent proliferative glomerulonephritis (LN III or IV). F, Urine CD163 significantly correlated with rSLEDAI.

Results: Urine CD163 was significantly elevated in active LN when compared with healthy controls, inactive SLE, or active SLE patients without renal involvement in Asian, Caucasian or African American patients (all $p< 0.001$). In 44 LN patients with concurrent renal biopsies, urine CD163 was dramatically increased in patients with proliferative glomerulonephritis (LN III or IV) when compared with that in other histological patterns (LN II or V) ($p< 0.001$) (Figure 1). Urine CD163 significantly correlated with SLEDAI, rSLEDAI, urine protein/creatinine and C3. It also strongly correlated with activity index of renal pathology, particularly fibrinoid necrosis, cellular crescents and interstitial inflammation (all $p< 0.01$).

Conclusion: Urine CD163 discriminates patients with active lupus nephritis from other SLE patients and is significantly elevated in LN with proliferative glomerulonephritis. It also excellently correlates with multiple clinical parameters reflecting lupus disease activities as well as renal pathological activity index.

Development of a Multi-Modality Imaging Approach to Evaluate Lupus Nephritis

Amit Saxena,[1] David Karp,[2] Brad Rovin,[3] Mikael Boesen,[4] Olga Kubassova,[5] Claire Dykas,[6] Anthony Yeo,[7] and **Peter Lipsky** [8], [1]New York University School of Medicine, New York, NY, [2]UTSouthwestern Medical Center, Dallas, TX, [3]The Ohio State University Medical Center, Columbus, OH, [4]Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark, [5]Image Analysis Group, London, United Kingdom, [6]AmpelBioSolutions, Charlottesville, VA, [7]RILITE Research Institute, Charlottesville, VA, [8]AMPEL BioSolutions, LLC, Charlottesville, VA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical IV: Lupus Nephritis
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Lupus nephritis (LN) remains a significant cause of morbidity and mortality in subjects with Systemic Lupus Erythematosus (SLE). The gold standard for evaluation of LN remains the kidney biopsy, whereas renal function is usually evaluated by eGFR and urinary protein:creatinine ratio. More effective and sensitive methodology is needed to assess LN and also the response to treatment. Functional imaging of the kidney using quantitative techniques has great potential, as it can assess kidney function and pathologic changes non-invasively by evaluating perfusion, oxygenation, cellular density and fibrosis. The objective of this study was to develop a multi-modality imaging approach for the evaluation of the spectrum of pathologic changes in LN.

Methods: In this multi-center study (NCT03180021), subjects who were having a standard of care renal biopsy for LN were asked to participate in the imaging evaluation. Local Institutional Review Board approval was obtained, and subjects signed an Informed Consent Form. Dynamic contrast enhanced MRI (DCE-MRI) was employed to detect changes in vascularization and perfusion, Diffusion Weighted Imaging (DWI) to assess interstitial diffusion, T2*Map/BOLD to evaluate tissue oxygenation and T1rho to evaluate fibrosis (Figure 1). Regions of interest were identified in the imaged kidneys and imaging parameters were correlated with measures of renal function, including eGFR and urinary protein: creatinine ratio. In DCE-MRI, we specifically focused on mean Maximum Enhancement (ME), mean Time to Peak Enhancement (TTP) and mean Time of Washout (Twashout) as indicators of renal perfusion.

Results: Nine subjects have been evaluated to date and their imaging data assessed for quality. Evaluation of mean data from DCE-MRI has shown a significant correlation between renal perfusion and renal function. For example, the 24 hour protein concentration negatively correlated with ME (r_s=-0.81, p=0.015), TTP (r_s=-0.83, p=0.01) and Twashout (r_s=-0.81.p=0.01, Spearman rank correlation). In addition, the protein:creatinine ratio also negatively correlated with ME (r_s=-0.79, p=0.02), TTP (r_s=-0.74, p=0.04) and Twashout (r_s=-0.79, p=0.02, Spearman rank correlation).

Conclusion: These initial results have established the feasibility of multi-modality imaging as a tool to evaluate LN in a multi-center study. Moreover, changes in perfusion detected by DCE-MRI significantly correlate with proteinuria and urinary protein:creatinine ratio. These results suggest that multiparameter imaging may contribute useful data in the evaluation of subjects with LN.

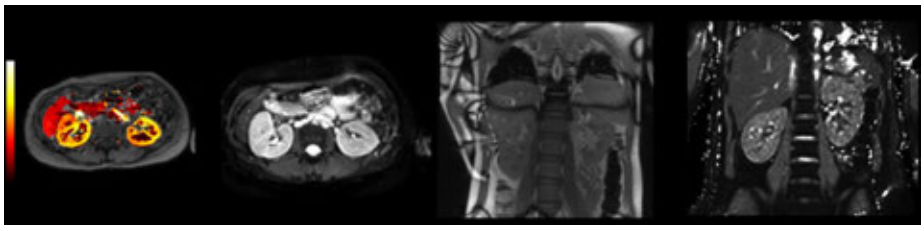

Figure 1. Multi-modality imaging from a representative LN patient. Left: Map of the initial rate of enhancement (DYNAMIKA™) from DCE-MRI showing the degree of perfusion (the white-yellow colors correspond to increased and the redder colors decreased perfusion) in which decreased perfusion can be seen in the anterior pole of the right kidney ; Left center: DWI sequence that shows diffusion; Right center: T1rho illustrating fibrosis; and Right:T2*Map/BOLD to investigate tissue oxygenation within the renal medullary tissue.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology: Outcomes & Quality of Life
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: There is a paucity of literature on the challenges children with JIA face at school. Despite treatment advances, children with JIA often rate their Quality of Life (QoL) and school experience as lower than healthy peers. Absences due to disease flares, office visits, medication administration, or side effects may impact school experience. Training of school nurses on other chronic diseases has led to increased knowledge and management skills as well as improvement in children's QoL and school experience. Due to the lack of data on school nurses' awareness about the care of children with JIA, we aimed to improve their knowledge.

Methods: A pediatric rheumatologist presented to school nurses from two large, urban school districts attending a yearly educational seminar. The talk focused on JIA symptoms, course, and treatment, described challenges children with JIA face at school, and recommended accommodations/resources for families and school personnel. Pretest and posttest surveys were administered. Surveys assessed nurses' knowledge of JIA, any prior experience caring for children with JIA or other chronic conditions, assessed acquired knowledge, and responses to hypothetical cases. The study was approved by the primary institution's IRB and the local school districts.

Results: Two hundred and ninety-four school nurses attended the talks. Two hundred and sixty-one nurses (83%) completed both pre and posttest surveys. Most nurses were experienced (mean experience in school setting, 8.8 years, $\pm$ 8.7) and were predominantly located at elementary schools. They had variable exposure to other pediatric disorders (Table 1). Only 18.3% of nurses had ever met with a caregiver of a child with JIA, and only 11.8% had implemented a JIA health plan. Over 80% of nurses reported no experience in treating JIA, but reported experience treating Diabetes Mellitus (DM). Nevertheless, nurses identified other resources for managing children with JIA in school, such as supportive care and contacting parents. Seventy percent of respondents reported feeling more prepared to treat DM (vs JIA). After the presentation, nurses felt significantly more prepared to care for a child with JIA at a level that was comparable to DM knowledge (Table 2). Nurses' reported takeaways from the talk included "being

Table 1: Demographic data of participants

Characteristic	Frequency (%)
Type of school currently working in (may work in multiple types), total/frequency	
Early Childhood/Pre-K	26 (11.1%)
Elementary	148 (63.2%)
Middle	44 (18.8%)
High School	40 (17.1%)
Special needs children at nurses' schools	206 (93.2%)
Have you even taken a course/training program that covered improving school experience of children with arthritis?	4 (1.7%)
Have you used any published resources to learn more about a child with arthritis?	55 (23.8%)
Have you received any training about working with students who have other medical problems? number/frequency	
Total:	192 (85.3%)
Disease:

Total	240 (100%)	241 (100%)	241 (100%)

*$P < 0.001$. There was a significant relationship between the feelings of preparedness of school nurses in caring for a child with JIA vs caring for a child with diabetes when comparing the pre-test responses. There is a significant difference in feeling of preparedness of school nurses in caring for a child with JIA when comparing the pre-test and post-test preparedness responses.

more prepared," "more observant," and not "dismissing joint complaints in a child with JIA." The majority (86.3%) of school nurses found the educational session to be useful.

Conclusion: This study highlights school nurses' knowledge gap regarding JIA in school-age children. We demonstrated the effectiveness of a single educational session to increase knowledge of JIA and influence future care of children with JIA in school. Additional data is necessary to assess nurses' knowledge retention and practice changes over time. Similar educational interventions for teachers, social workers, or administrators could be used for other autoimmune and autoinflammatory disorders. Efforts to improve the QoL of patients with JIA should involve interdisciplinary "front-line" team members (e.g., medical, mental health, and school personnel). This project can be continued by future trainees to provide community education.

Parent-Reported Medication Side-Effects and Their Impact on Health-Related Quality of Life in Children with Juvenile Idiopathic Arthritis: Results from the CAPRI Registry

Gaëlle Chédeville ,[1] Michelle Batthish,[2] Roberta Berard,[3] Roxana Bolaria,[4] Alessandra Bruns,[5] David Cabral,[6] Ciaran Duffy,[7] Kerstin Gerhold,[8] Tommy Gerschman,[6] Jean-Philippe Proulx-Gauthier,[9] Alan Rosenberg,[10] Dax Rumsey,[11] Heinrike Schmeling,[12] Natalie Shiff,[13] Gordon Soon,[14] Lori Tucker,[15] and Jaime Guzman[6], [1]The Montreal Children's Hospital, McGill University, Montreal, Canada, [2]McMaster University, Hamilton, Canada, [3]Children's Hospital, London Health Sciences Centre, London, Canada, [4]University of British Columbia, Victoria, BC, Canada, [5]Université de Sherbrooke, Sherbrooke, QC, Canada, [6]University of British Columbia, Vancouver, BC, Canada, [7]University of Ottawa, Ottawa, ON, Canada, [8]University of Manitoba, Winnipeg, MB, Canada, [9]Université Laval, Québec, QC, Canada, [10]University of Saskatchewan, Saskatoon, SK, Canada, [11]University of Alberta, Edmonton, AB, Canada, [12]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [13]University of Florida, Gainesville, FL, [14]University of Toronto, Toronto, ON, Canada, [15]British Columbia Children's Hospital, Vancouver, Canada

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology: Outcomes & Quality of Life

Session Type: ACR/ARP Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children and many medications are available to control the disease. While physician-reported adverse events (AE) are captured in clinical trials and registries, perceptions of parents about side-effects (SE) of anti-rheumatic medications are not well studied.

Using data from the Canadian Alliance of Pediatric Rheumatology Investigators (CAPRI) JIA registry, we describe the frequency and incidence of parent-reported medication SE in children with JIA, compare them to physician-reported AE, and assess their impact on health-related quality of life.

Methods: All children with JIA enrolled within 3 months of diagnosis who had at least one visit documented in the Registry as of May 9, 2019 were included in this analysis. At every clinic visit parents were asked "Is your child having any side effects from medications taken for his/her arthritis?" They selected SE from a 17-item list, added any not listed, and rated their overall severity on a 21-point numerical rating scale from 0=no problem, to 10=very severe. Physicians reported AE that required additional visits, tests or treatments (irrespective of their cause) and used a standard 18-item list, similar to other registries. Health-related quality of life was assessed using the parent's global assessment from Singh's Childhood Health Assessment Questionnaire (CHAQ) "Considering all the ways that arthritis affects your child rate how your child is doing", from 0=very well, to 10=very poor; and the child's answer to Feldman's Quality of My Life questionnaire (QoML) "Considering my HEALTH my life is" from 0=the WORST, to 10=the BEST (if the parent felt the child could answer the question).

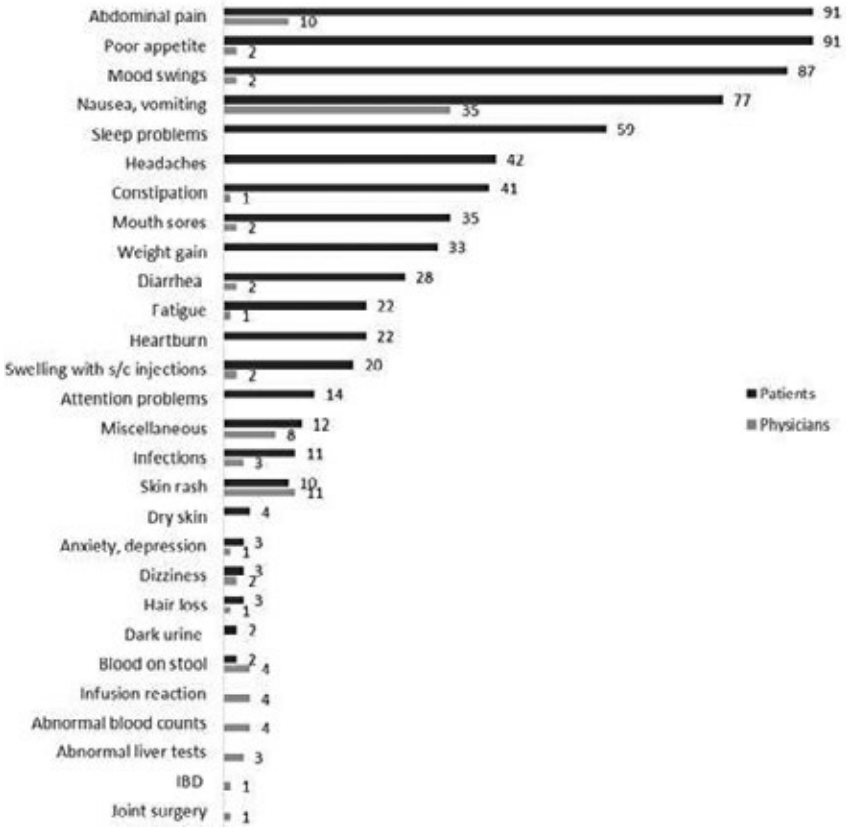
Results: The 226 included patients were typical of western JIA inception cohorts (Table 1). Parent reports were available for 718 of 760 visits (94.5%). Patients were receiving medications at 613 (85.4%) of those visits. Parents reported SE at 294 of 613 visits (48%) with a median of 2 SE per visit (IQR 1, 3). The corresponding incidence rate was 76 SE per hundred patient-years of follow-up with a 54% (CI 48-59) probability of experiencing at least one SE by 1 year after diagnosis. For physician-reported AE it was 25 events per 100 patient-years with a 24% (CI 19-30) probability of at least one AE by 1 year after diagnosis. The reported SE and AE are shown in Figure 1.

Table 1: Demographics

Number of patients	226
Median age at diagnosis, years (IQR)	8.1 (3.4, 12.5) *
Female sex	128 (59.3%) *
Median time diagnosis to enrollment, weeks (IQR)	4.6 (0, 9.3)
JIA subtype - number of patients (%)	
Oligoarticular	107 (47.3)
Polyarticular RF-	38 (16.8)
Polyarticular RF+	7 (3.1)
Psoriatic	10 (4.4)
ERA	37 (16.4)
Systemic	13 (5.8)
Undifferentiated	14 (6.2)
Medications - number of visits (%), out of 718 visits	
None	105 (13.8)
NSAIDs	446 (62.1)
Methotrexate	270 (37.6)
Other DMARDs	15 (2.1)
Biologics	71 (9.9)
Joint injections	95 (13.2)
Prednisone p.o.	79 (11)
Ocular corticosteroid	16 (2.2)

* Age information missing in 28 subjects and sex in 10 subjects.

Figure 1: Number of parent-reported SE and physician-reported AE in a total of 718 visits



The most common SE were gastro-intestinal. The severity of SE was a median of 3 out of 10 (IQR 1.5, 5) and 82% were mild with a score ≤ 5. The parent's global assessment was a median of 2 (IQR 0.5, 5.5) when SE were present, and a median of 0.5 (0, 2) when absent ($p < 0.0001$, median test). The patient's rating of their health-related quality of life was a median of 7 (5, 8.5) when SE were present, and a median of 8 (6.5, 9.5) when absent ($p < 0.0001$).

Conclusion: Parents of children with JIA report a very high frequency of medication SE, significantly higher than physician reported AE. SE have a measurable effect on the parent's global assessment and on the patient's assessment of health-related quality of life. Better addressing these SE may improve quality of life and adherence with medication regimens in children with JIA.

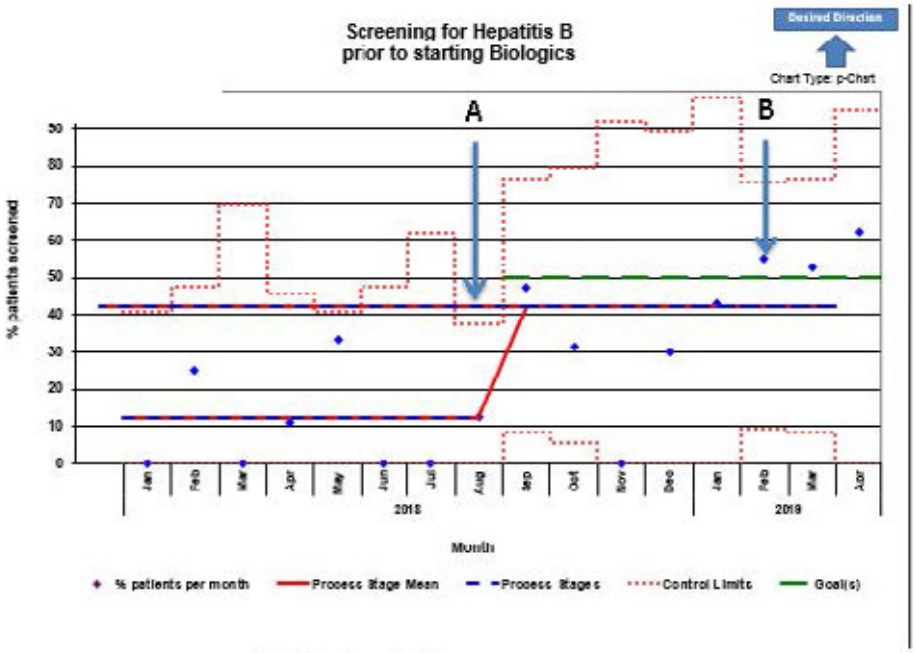
Improvement in Hepatitis B Screening Prior to Initiation of Biologic Therapy in the Pediatric Rheumatology Clinic

Vidya Sivaraman ,[1] Kelly Wise,[2] Elizabeth Bley,[3] M. Zachary Dawson,[4] Jennifer DeSalvo,[3] Samuel Lazaroff,[5] Michael Neiger,[3] Elizabeth Shisler,[4] Stephanie Lemle,[2] and Monica Ardura[2], [1]Nationwide Children's Hospital and The Ohio State University, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]The Ohio State University, Columbus, OH, [4]Rainbow Babies and Children's Hospital, Cleveland, OH, [5]Vanderbilt University, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology: Outcomes & Quality of Life
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Use of certain biologic medications increases the risk of reactivation of hepatitis B. Therefore, screening for hepatitis B viral (HBV) infection is recommended prior to initiation of biologic agents for the treatment of rheumatic diseases. Although children are routinely vaccinated for hepatitis B in the US, vaccine seroprotection may be reduced or lost in immunocompromised patients. We sought to evaluate our compliance with HBV screening before starting biologic therapies.

Methods: We used Quality Improvement methodologies with an aim to increase HBV screening rates in patients starting injectable biologic agents from 12.5% to greater than 50% in 6 months and to 80% in 1 year. Using a multidisciplinary team approach, we identified the root causes of incomplete HBV screening including: lack of provider awareness of guidelines, lack of access to vaccination records and prompts in the electronic health record (EHR), and concern about delay in therapy. To address these root causes, we performed multiple PDSA cycles including education of providers and engaging the clinical pharmacy staff, who were involved with the prior authorization for these Specialty medications. We created smart phrases for providers to use at the time of request for prior authorization for new injectable biologic medications, which included all required HBV screening tests. Another smart phrase enabled pharmacy staff to notify providers of patients missing screening. Flyers were posted in clinic rooms to remind prescribers and patients of the need to perform HBV screening.



A: Project Awareness
B: EPIC Smart phrase

Results: At the start of the project, only 1 of 7 providers (14%) stated that they routinely screened patients for HBV before starting a new biologic and only 12.5% of patients in the rheumatology clinic were screened for HBV with hepatitis B surface antigen prior to initiating biologic therapy. Through the PDSA cycles, monthly HBV screening rate for patients starting injectable biologics increased from 12.5% to 42.5% by 7 months. Further improvement is being seen with implementation of the EHR smart phrase. Since testing was incorporated in to the prior authorization process, initiation of therapy was not delayed.

Conclusion: Despite falling short of the initial project aim, our interventions resulted in a significant improvement in the number of patients screened for a potentially serious complication than in the pre-intervention period, as seen by the center line shift in the control chart (Fig 1). Inclusion of pharmacists in the improvement process was successful in reminding providers of missed opportunities for testing. Future directions include analysis for percentage of patients without evidence of immunity to hepatitis B with plans for booster vaccination when indicated.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology: Outcomes & Quality of Life

Session Type: ACR/ARP Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Tocilizumab (TCZ) was approved for the treatment of systemic juvenile idiopathic arthritis (sJIA) and polyarticular juvenile idiopathic arthritis (pJIA) based on the results of 2 large phase 3 clinical trials.[1,2] Physical function, measured by the Childhood Health Assessment Questionnaire–Disability Index (CHAQ-DI), and health-related quality of life (HRQOL), measured by the Child Health Questionnaire (CHQ), were evaluated in both trials. The objective of this post hoc analysis of data from both phase 3 trials of TCZ was to examine measures of disability and HRQOL in patients with sJIA or pJIA treated with TCZ for up to 2 years.

Methods: Eligible patients aged 2 to 17 years of age diagnosed with active (≥6 months) sJIA or pJIA according to International League of Associations for Rheumatology criteria received TCZ IV or placebo every 4 weeks (pJIA) or every 12 weeks (sJIA). For sJIA patients, changes within 3 months of treatment initiation with TCZ (baseline) were compared between TCZ- and placebo (PBO)-treated patients using CHAQ-DI, pain-global assessment, physician (MD) global assessment, and patient global assessment using analysis of variance adjusted for treatment group. Changes in CHAQ-DI overall and domain scores from baseline to 2 years were compared for sJIA and pJIA patients treated with TCZ using the unpaired *t* test; similarly, for sJIA patients treated with TCZ, changes in CHQ domain and summary scores between baseline and 2 years were assessed.

Results: sJIA patients experienced clinically relevant improvement of physical function (CHAQ-DI) and reduction in pain (pain-global). Mean (SD) CHAQ-DI scores for patients treated with PBO and TCZ were 1.7 (0.8) for both groups at baseline and 1.2 (1.0) and 0.9 (0.8), respectively, at week 12 (week 12 mean difference, –0.2; median [range] change from baseline to week 12 difference, –0.3 [–0.6 to 0.0]). sJIA patients treated with TCZ had significantly improved socialization, behavior, mental health, and CHQ-psychosocial summary scores after 3 months compared with those receiving PBO (Table 1). Marked improvement in all CHAQ-DI domains over 2 years was observed with TCZ treatment in both sJIA and pJIA patients (Table 2); improvement rates in patient well-being (patient-global) were 87.7% in sJIA patients and 83.4% in pJIA patients. There was also significant improvement ($p < 0.05$) in most domains of HRQOL (CHQ-domain scores) in patients with sJIA; of note, sJIA patients experienced marked improvement in mean scores from baseline to week 104 for pain/discomfort (31.7 to 75.3), self-esteem (61.0 to 76.0), mental health (62.1 to 76.8), and social limitation-emotional (52.6 to 86.2).

Table 1. Change in HRQOL and Disability Within 3 Months of Starting Therapy in sJIA Patients*

Variable	Placebo n = 37		Tocilizumab n = 75		Difference

Abstract Number: 1924

Assessing Psychosocial Needs in Juvenile Dermatomyositis Patients Across the United Kingdom

Polly Livermore ,[1] and Lucy Wedderburn[2], [1]ICH/UCL, Arlesey, United Kingdom, [2]ICH/UCL, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology: Outcomes & Quality of Life
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Juvenile Dermatomyositis (JDM) is a rare, autoimmune inflammatory condition primarily affecting the muscles and skin. With a mean age of onset of 7 years of age, and research suggesting that 70-80% of young people will have ongoing treatment into adulthood, a significant proportion of children and young people will live with chronic disease for over 10 years of their childhood. Whilst it is acknowledged from studies asking carers that children and young people with JDM suffer from a significant impairment in their health related quality of life, there is no current published research asking young people what their psychosocial needs are and how we can improve their coping with this condition, even after disease remission.

Methods: We surveyed all 246 8-19 year old young people with JDM in the United Kingdom through the Juvenile Dermatomyositis Cohort and Biomarker Study and Repository (JDCBS). Young people were asked to complete measures which have proved significant from previous qualitative interviews, these included perception of uncertainty, quality of life, benefit, burden, and emotional distress, with the opportunity to answer qualitative questions with commentary.

Results: There were no differences in demographics or disease characteristics between the 123 responders and the 119 non responders. 40% of patients scored over the recommended cut-off for emotional distress, which suggested that they should be referred for further psychological assessment. Quality of life scores were lower in children with JDM compared with scores for healthy UK norms. JDM physical and psychosocial summary scores: (75.64 + 24.47 and 76.89 + 18.55) healthy physical and psychosocial summary scores: (88.51 +11.62 and 81.58 + 11.84). Regression analysis indicated that children with increased feelings of uncertainty about their disease and increased perception of burden had lower quality of life in all domains (P value < 0.001). Furthermore, uncertainty and burden were correlated (r= 0.64 P = < 0.001), but equally significant and therefore independently related to quality of life, however burden was more closely related to quality of life after adjusting for other factors. Importantly there was no evidence that quality of life varied by gender, age or years since diagnosis, and no relationship between benefit and quality of life or emotional distress was observed.

Conclusion: This study found that perception of uncertainty and feeling a burden in children and young people with JDM were significantly related to reporting a lower quality of life and higher emotional distress, and 40% of the UK cohort of JDM patients scored over the recommended threshold for emotional distress. These findings can be used by clinicians and allied health professionals to consider the impact of uncertainty and perception of being a burden on children and young people with JDM, and consider ways to lessen this uncertainty. From the qualitative comments, we have ideas about improving psychosocial support for the future, such as the creation of a book for teachers about JDM to improve their education experience.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology: Outcomes & Quality of Life

Session Type: ACR/ARP Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: The assessment of disease activity plays a pivotal role in the management of children with juvenile idiopathic arthritis (JIA). Most recent recommendations require that the parents' and children's perception is incorporated in the evaluation of disease course and of effectiveness of therapeutic interventions. A new disease activity tool, named parent Juvenile Arthritis Disease Activity Score (parJADAS), based only on parent-centered outcome measures, is currently under development**.** Aim of the study is to demonstrate, in 2 large multinational datasets, the discriminant and predictiveability of the parJADAS

Methods: The parJADAS (range 0-40) is the sum of 4 measures: 1) parent assessment of disease activity on a 21-numbered circle 0-10 VAS; 2) assessment of pain intensity on a 21-numbered circle 0-10 VAS; 3) proxy assessment of joint disease up to a maximum of 10 joints; 4) assessment of morning stiffness (MS) on a Likert scale, ranging from no MS (0 points) to > 2 hours of MS (10 points). Discriminat ability was assessed on a dataset of 8,656 children with JIA from 49 countries, enrolled in the study of Epidemiology, treatment and Outcome of Childhood Arthritis (Consolaro A et al. Lancet Child Adolesc Health. 2019), who had all the variables included in the parJADAS available. Discriminant ability was evaluated by comparing parJADAS median levels among patients with inactive disease (ID), low disease activity (LDA), moderate disease activity (MDA), and high disease activity (HDA) according to cJADAS10 and in patients whose parents were satisfied or not satisfied with disease status. To assess the influence of damage on the parJADAS, the levels of the score in patients with or without damage (Juvenile Arthritis Damage Index > 0) were compared in subjects in ID and with at least 2 years of disease course (n = 2,423). Predictive ability was assessed in a longitudinal dataset of subjects included in the PharmaChild Registry (Swart J, et al Arthritis Res Ther 2018). Patients (n = 98) were retained if they had 2 years of follow up and at least 4 visits with parJADAS available during the first year since enrolment. The AUC of the parJADAS in the first year of registry participation was calculated and compared

in subjects with/without reduced functional ability (Juvenile Arthritis Functionality Scale, JAFS > 0) at 2 years and in subjects who achieved or did not achieve clinically ID at 2 years.

Results: The median levels of parJADAS in patients in ID, LDA, MDA, and HDA were 0, 3.0, 6.0, and 4.5, respectively (Kruskal-Wallis test, $p < 0.001$). Median parJADAS in patients whose parents were satisfied or not satisfied with disease course were 1.5 and 13.0, respectively (Mann-Whitney test $p < 0.001$). ParJADAS was not different in JIA patients in remission with or without damage measured with the JADI (Mann-Whitney test $p = 0.08$). Subjects JAFS > 0 at 2 years had greater parJADAS AUC in the first year ($p < 0.001$). Subjects in remission at 2 years had smaller parJADAS AUC in the first year ($p < 0.001$)

Conclusion: The parJADAS showed excellent discriminant and predictive ability in 2 large multinational cohorts. The score was not relevantly influenced by disease damage in JIA patients in remission.

Characterization of *DOCK8* as a Novel Gene Associated with Macrophage Activation Syndrome

Mingce Zhang,[1] Remy Cron,[2] Devin Absher,[3] Courtney Crayne,[2] Prescott Atkinson,[2] W. Winn Chatham,[2] and **Randy Cron** [1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]HudsonAlpha Institute for Biotechnology, Huntsville, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophage activation syndrome (MAS), also known as secondary hemophagocytic lymphohistiocytosis (HLH), is a life threatening condition that commonly presents with unremitting fever and shock like multi-organ dysfunction (MOD). Laboratory studies show pancytopenia, elevated liver enzymes, elevated ferritin, and hemophagocytosis. Familial forms of HLH result from homozygous defects in genes involved in perforin mediated cytolysis by NK cells and CD8 T cells. As many as 30-40% of MAS patient cohorts studied have heterozygous defects in the same HLH genes resulting in decreased cytolytic function, prolonged interaction with antigen presenting cells, and subsequent increased pro-inflammatory cytokines resulting in MOD. Since NK cell dysfunction is common in MAS, there are likely other genes that contribute to MAS via decreased cytolysis. Using gene sequencing, mutations in potentially novel HLH genes present in 2 or more MAS patients were explored.

Table. *DOCK8* rare mutations and polymorphisms identified in MAS patients.						
#	Age (yrs)	Sex	Disease	Trigger	Mutation	Frequency
1	16	M	Hyper IgE syndr.	Bartonella	c.782C>T, p.Ala261Val	novel
2	19	M	T cell leukemia	?	c.54-1G>T (splice acceptor)	0.03%
3	24	M	Still disease	?	c.187G>A, p.Asp63Asn	12%
4	36	F	Polyarteritis nod.	Streptococcus	c.187G>A, p.Asp63Asn	12%

Table 1. Age, sex, disease, trigger, genetic mutation and its frequency of 4 MAS patients expressing DOCK8 mutations or a less common polymorphism.

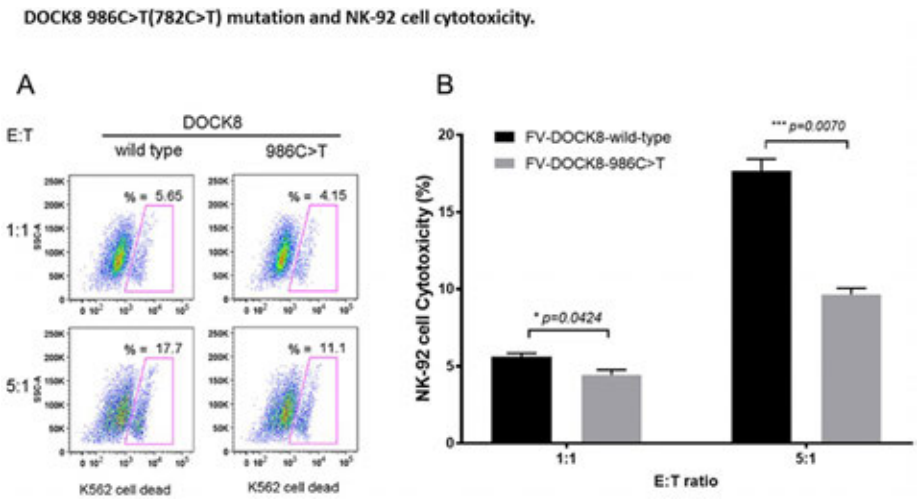

Figure 1. Cytolytic activity of NK-92 cell expressing (by foamy virus transduction) a novel DOCK8 mutation (c.782C>T, p.Ala261Val). A. A representative flow cytometry example of wild type (left columns) or mutant (right columns) DOCK8-expressing NK-92 cell lysis of K562 target cells at effector-to-target ratios of 1:1 (top row) and 5:1 (bottom row), with cell death noted along the X-axis. B. Mean +/- SEM cytoltyic activity of wild-type or mutant DOCK8-expressing NK-92 cells from 3 experiments.

Methods: Pediatric and adult patients with MAS at UAB were screened for genetic mutations, potentially contributing to MAS, via whole genome sequencing or a commercial immunodeficiency exomic genetic panel of 207 genes. Several patients were noted to have mutations in the guanine nucleotide exchange factor *DOCK8* critical to NK cell function. *DOCK8* mutations from this MAS cohort, or wild-type (WT) sequence controls, were introduced exogenously into human NK-92 NK cell lines by foamy virus (FV) transduction. Alternatively, the endogenous NK-92 *DOCK8* genes were cut and repaired to express WT sequence or patient derived *DOCK8* mutations by CRISPR/Cas9 technology. WT and mutant *DOCK8* expressing NK-92 cells were incubated with K562 target cells and compared for cytolytic activity, degranulation (CD107a), and cytokine [interferon-g (IFNγ), tumor necrosis factor (TNF)] production by flow cytometry.

Results: Two MAS patients were identified with rare heterozygous DOCK8 mutations, and 2 others with MAS were noted to have the same DOCK8 polymorphism (c.187G >A, p.Asp63Asn) present in 12% of the population (Table). One of the rare mutations was missense (c.782C >T, p.Ala261Val – novel), and one was a splice acceptor variant (c.54-1G >T, 0.03%). The novel DOCK8 mutant consistently decreased NK cell lytic activity when introduced by either CRISPR/Cas9 (n=2) or FV (n=3, decreased by ~50% compared to WT, p=0.007) (Fig. 1). Similarly, the novel mutant decreased degranulation by >50% (n=3, p=0.0129) (Fig. 2). During the incubation of the NK-92 cells with K562 targets, NK cells expressing the novel DOCK8 mutant increased expression of IFNγ and TNF by >200% (p=0.0192 & p=0.0027, respectively). Prolonged interaction of the DOCK8 mutant NK-92 cells with K562 cells is currently being explored as a cause of increased cytokine production. Also, the DOCK8 splicing mutation is currently being tested functionally by “exon trapping” to explore a potential hypomorphic mutation.

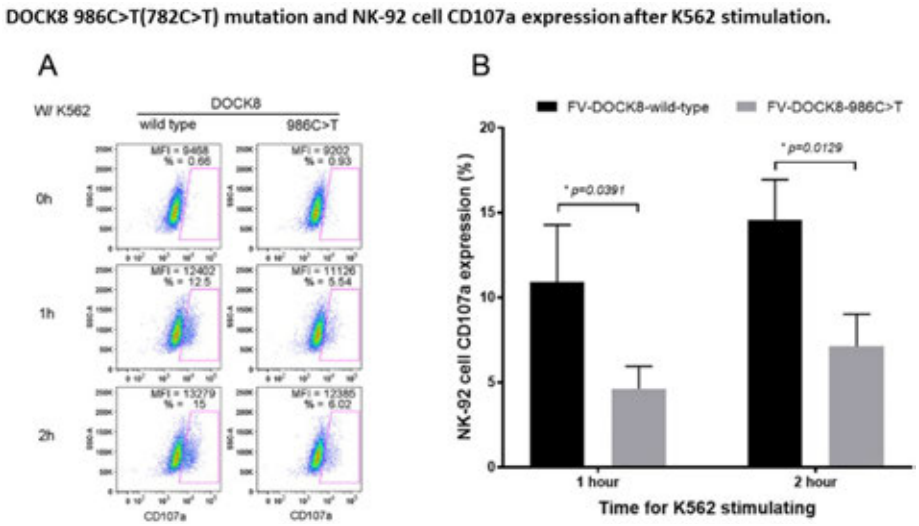

Figure 2. Degrantulation of NK-92 cell expressing (by foamy virus transduction) a novel DOCK8 mutation (c.782C>T, p.Ala261Val). A. A representative flow cytometry example of degranulation (CD107a expression) of wild type (left columns) or mutant (right columns) DOCK8-expressing NK-92 cells incubated with K562 target cells evaluated at 0 hr (top row), 1 hr (middle row), and 2hr (bottom row), with CD107a noted along the X-axis. B. Mean +/- SEM CD107a expression of wild-type or mutant DOCK8-expressing NK-92 cells from 3 experiments.

Conclusion: Heterozygous mutations in *DOCK8*, a novel MAS associated gene, likely contribute to pathology through a partial dominant-negative or hypomorphic effect resulting in decreased cytolysis and increased pro-inflammatory cytokine production.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: With the redefinition of Osteoarthritis (OA) and the understanding that the joint behaves as an organ, OA is now considered a systemic illness with a low grade of chronic inflammation. Chondroptosis, chondrosenescence and autophagy contribute to cell death and tissue damage in OA. The mitochondria are related with these three process implicated in the cartilage degeneration. Mitochondrial dysfunction is well documented in OA and has the capacity to alter chondrocyte and synoviocyte function contributing to cartilage degeneration. Trans-mitochondrial cybrids are a useful cellular model to study mitochondrial biology *in vitro*, since they carry different mitochondrial variants with the same nuclear background

Purpose: The aim of this work was to study apoptosis, senescence and autophagy using cybrids with mtDNA from healthy (N) and OA donors.

Methods: Cybrids were developed using 143B.TK$^-$ Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy (N) and OA donors. The mitochondrial depolarized and morphology were evaluated incubating cells with DilC1(5) and MitoTracker Red® respectively and these parameters were analyzed using Flow Cytometer. The percentage of apoptotic cells was measured by Flow Cytometry using Annexin-V and PI. Senescence level was measured by real-time PCR method. Autophagy was evaluated through the developed of Microtubule-associated protein 1A/1B-light chain 3 (LC3) WB. The WB quantification was developed using Image J software. Appropriate statistical analyses were performed with GraphPad Prism v6.

Results: OA cybrids showed higher increment depolarized mitochondria under negative stimuli (2.57±1.20; 1.76±0.99; $p \leq 0.05$ respectively). Mitochondrial distribution showed that in OA cybrids mitochondria were concentrated around the nucleus whereas in N cybrids were organized in extended tubular structures. The quantification of staining reflected a decrease of fluorescence intensity in OA compared to N cybrids (14.31±3.16; 33.00±4.20 respectively, $p \leq 0.005$). When the cells were submitted for a positive stimuli and an inflammatory environment the analysis of apoptotic levels were developed and reflected that OA cybrids had an increase in positive cells for Annexin-V in comparison to N cybrids (2μM Staurosporine 15.68±6.39; 6.41±4.88 respectively, $p \leq 0.05$. 10ng/ml IL-1β 0.924±0.19; 0.47±0.24 respectively, $p \leq 0.05$). The gene expression corresponding to senescence marker protein (SMP30) showed higher levels in OA cybrids than in N (4.535±1.63; 1.21±0.42 respectively, $p \leq 0.0005$). Autophagy was analyzed studying LC3 a marker for autophagosome formation and the results showed that LC3 activation was reduced in OA cybrids (1.19±0.24; 1.41±0.21 respectively, $p \leq 0.05$).

Conclusion: Mitochondria from OA donors was involved in three relevant processes related with OA as cellular apoptosis, senescence and autophagy.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept (CTLA4-Ig) is an approved biological therapy for the treatment of rheumatoid arthritis (RA). Similar to other biological agents, most patients (50-60%) respond significantly to this therapy. To date, however, the biological mechanisms underlying the lack of efficacy for this drug are unknown.The objectives of the present study were to generate insights into the biological processes that underly the differential response to abatacept and to evaluate the blood transcriptome as a valid source for drug response prediction.

Methods: A total of n=57 patients diagnosed with RA according to the ACR-EULAR criteria where recruited for this study from the rheumatology departments of 16 different university hospitals from Spain. All patients had >6 months of disease evolution and started therapy with a baseline DAS28 > 3.2. The primary clinical response was defined at week 12 of therapy using the EULAR criteria. Good and moderate responders were aggregated into a single response group and compared to the remaining (no response) group of patients. Whole blood RNA was collected from all patients at baseline using Paxgene tubes. From a subgroup of these patients (n=31), blood RNA was also obtained at weeks 12, 24 and 48 of treatment with abatacept. Gene expression levels were determined using paired-end RNA-seq with the NovaSeq 6000 platform (Illumina). Differential gene expression, association to biological processes, longitudinal association analysis and building of the multigenic predictor were performed using the R software. The Random Forest algorithm was used to build the predictor and the prediction accuracy was evaluated using the ROC AUC.

Results: From the 57 patients treated with abatacept, n=10 (17.5%) were good EULAR responders, n=24 (42%) moderate EULAR responders and n=23 (40.5%) non-responders at week 12 of therapy. Two significantly distinct biological profiles were identified between responders and non-responders to abatacept. In responders, we found an association to pathways associated with the effector phase of T cells (e.g. interleukin IL-15 and IL-22 signalling, adjusted $P < 0.05$). Non-responder patients showed instead a strong association to biological processes associated with antigen presentation and activation of T cells (adjusted $P < 0.005$). Using the baseline gene expression profiles, we built a multigenic predictor of response to abatacept with an AUC = 75%. In the longitudinal cohort, patients were stratified based on reaching an inactive state at week 48 (DAS28 < 3.2). Using this endpoint measure, the longitudinal analysis of the 4 time points corroborated the association with antigen presentation activation and the lack of response to this drug (adjusted $P < 0.01$).

Conclusion: The analysis of longitudinal blood RNA-seq profiles of RA patients starting abatacept therapy, has enabled the identification of specific immunological processes associated with the efficacy of B7 costimulation inhibition. Also, we demonstrate that blood expression profiles could be predictive of the response abatacept. The results

from this study contribute to the advancement of precision medicine in RA and the understanding of the underlying disease heterogeneity.

Identification and Validation of Transcriptional Genes Associated with Osteoporotic Vertebral Fractures by Microarray Study, in Community Elderly Women

Levi Jales Neto ,[1] Zofia Wicik,[2] Georgea Torres,[1] Liliam Takayama,[1] Neusa Lopes,[1] alexandre Pereira,[1] and Rosa Pereira[3], [1]University of Sao Paulo, Sao Paulo, Brazil, [2]University of Sao Paulo, São Paulo, Brazil, [3]Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The pathogenesis of osteoporosis, a common disease with high morbidity[1], comprises genetic and environmental factors[2]. Recent studies demonstrated that blood samples are a source of reliable biomarkers which could serve as drug targets in treating of multiple age-associated diseases. The aim of this study was analyze transcriptomes of elderly women with osteoporotic Vertebral Frature, comparing with women with no Vertebral Fracture. Applying bioinformatical tools enabled us to identify such biomarkers for further validation.

Methods: We conducted microarray assays for comparing RNA expression of female vertebral fracture patients and no vertebral fracture controls. Age, bone mineral density (BMD) at lumbar spine, total hip and femoral neck and bone turnover markers were similar between the groups. In statistical analysis of microarrays we applied logistic regression model with age used as a covariate. Bioinformatic analysis involved interactome network analysis in Cytoscape software and enrichment analysis of biological processes regulated by the candidate genes. Special focus was put on identification candidate genes showing also age related changes in expression in bone and muscle tissue according

Table 1. Genes chosen using bioinformatic tools for validation

Genes	Top 10 UP regulate	Down regulate	Interaction genes	Muscle expression	Bone expression	Gene Ontology (Biological process and molecular function)	Aging related
SNTG2	Yes	-	-	Yes	-	Yes	-
TRAF3IP2	Yes	-	Yes	Yes	-	Yes	Yes
PNO1	Yes	-	Yes	Yes	-	-	-
CD248	Yes	-	Yes	Yes	-	-	-
TNXB	-	-	Yes	Yes	-	Yes	-
ITGA6	-	-	Yes	Yes	-	Yes	-
PRDX5	-	Yes	Yes	Yes	Yes	-	-
UBXN6	-	Yes	Yes	Yes	-	-	-

Table 2. Validation of gene expression using qPCR-RT

Gene	Fold change	SD	P
SNTG2	2.74	1.68	0.024
TRAF3IP2	1.83	0.66	0.010
PNO1	1.14	0.28	0.319
CD248	1.54	0.92	0.203
TNXB	0.96	0.50	0.845
ITGA6	1.62	0.45	0.007
PRDX5	1.04	0.35	0.783
UBXN6	1.42	0.53	0.093

to public available data (GTEX, String database). Expression changes were validated using SYBR green based qPCR-RT (quantitative real-time polymerase chain reaction). We used Pfaff method for relative expression quantification. The geometric mean of 2 control genes (RPL27 and RPL6) was used to compare the gene expression between the groups. Genes with p≤ 0.01 were considered statistically significant in microarray study and p≤ 0.05 in qPCR.

Results: We identified 142 differentially expressed transcripts, 57 up regulated, 85 down regulated in microarray analysis. The transcripts SNTG2, TRAF3IP2, PNO1, CD248, TNXB, ITGA6, PRDX5 and UBXN6 were chosen for validation due to their significance in the analysis of enrichment and genetic interaction. qPCR validation confirmed increased expression in Vertebral Fracture group of TRAF3 Interacting Protein 2 (TRAF3IP2 with fold change = 1.83, SD = 0.66, p = 0.01), Integrin Subunit Alpha 6 (ITGA6 with fold change = 1.62, SD = 0.45, p = 0.007) and Sintrophyn (SNTG2 with fold change = 2.74, SD = 1.68, p = 0.024).

Conclusion: TRAF3IP2 plays a role in various autoimmune and inflammatory diseases and interacts with TNF receptor-associated factor 3[3]. ITGA6 recently was found as upregulated and potentially involved in activity of osteoblasts of rheumatoid arthritis[4]. SNTGβ2 transcript that encodes a protein belonging to the syntrophin family, highly expressed in the musculoskeletal system[5].

Our data support the association of these transcripts with osteoporotic vertebral fracture in elderly women, independently of bone mineral density. These transcripts could be used as biomarkers or therapeutic targets in osteoporotic vertebral fracture in futures studies.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: LN is a serious complication of SLE that affects about 20-40% of all lupus patients and leads to kidney damage, end-stage renal disease, and patient mortality. Despite advances in therapy, progression to end stage renal disease has not been affected. Therefore, it is important to re-consider the pathogenic mechanisms involved in LN as a basis for development of more effective therapies. Here we present a multi-pronged approach to characterize LN via bioinformatic analysis of gene expression data obtained from kidney biopsies.

Methods: Genomic expression profiling data of LN patient biopsies, microdissected into glomerulus and tubulonterstitium (TI), was sourced from GSE32591 via the GEO database. Differentially expressed genes (DEGs) detected in LN-derived samples relative to samples from healthy individuals were interrogated for cell infiltrate composition using gene set variation analysis (GSVA) against a curated database of immune and non-immune cell type signatures (I-SCOPE, T-SCOPE). Weighted gene co-expression network analysis (WGCNA) was used to generate gene modules correlated to clinical variables. DEGs were further functionally characterized using a curated immunity-specific gene functional category database (BIG-C) and IPA signaling pathway analysis software. Queries of the perturbation database (LINCS, Library of Integrated Network-Based Cellular Signatures) were used to identify possible upstream regulators of altered gene expression patterns in LN samples as well as to identify drugs that could reverse abnormal gene expression profiles.

Results: WGCNA produced 6 gene modules (3 glomerulus, 3 TI) positively correlated with disease stage as measured by WHO class. These modules were enriched in signatures for several immune cell types, including granulocytes, pDC, DC, myeloid cells, $CD4^+$/$CD8^+$ T cells, and B cells. Additionally, the presence of both IG-κ and -λ as well as V_L genes and detection of pre- and post-switch PCs as indicated by IgM, IgD, and IgG1 Ig Heavy Chain genes indicate polyclonal PC infiltration. Podocyte signatures were detected as enriched in WGCNA modules negatively correlated with WHO class. Chemokines and pathways that mediate lymphocyte proliferation, organization and/or recruitment into lupus kidney tissue were detected as enriched via BIG-C and IPA analysis, including the cytokines TNF, IL1β, IL2, IL6, IL12, IL17, IL23, and IL27 and signaling pathways including CD40L, PI3K, NF-κB, NF-AT, and p70S6K. IPA upstream regulator analysis indicated ongoing signaling by cytokines such as TNF, IFNγ, IFNα, CD40L, IL1β, IL2, IL6, and IL17. Interestingly, connectivity analysis using LINCS elucidated high priority drug targets such as IFNβ (PF-06823859), IL12 (Ustekinumab), and S1PR (Fingolimod) that may prove to be good options for therapeutic intervention.

Conclusion: Bioinformatic analysis of LN gene expression highlights several dysregulated signaling pathways that can form the targets of novel therapeutic strategies, and further elucidation of these signatures may enhance clinical surveillance and diagnosis of LN to improve patient outcomes.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The immune infiltrate of skin lesions of Cutaneous Lupus Erythematosus (CLE) patients is known to be rich and complex. Single cell RNAseq (scRNAseq) is a unique approach to understand the cell-specific transcriptional heterogeneity in a complex tissue. ScRNAseq analyses of CLE skin biopsies has the unique potential to improve our understanding of human disease tissues and provide critical biological insights into the CLE pathogenesis.

Methods: Skin punch biopsies were obtained from healthy skin or lesional skin from CLE patients. Skin storage conditions and tissue dissociation protocol were optimized using healthy skin biopsies. RNAseq protocol was tested with blood-sorted pDCs and monocytes. Skin biopsies were collected from patients with DLE or SCLE. After tissue dissociation and cell staining, single CD45+ immune cells were sorted using flow cytometry and scRNAseq was performed using the SMART-seq2 protocol for cDNA synthesis and library preparation prior to sequencing.

Results: The scRNAseq protocol showed a similar sensitivity as a state-of-the-art published protocol (Villani AC et al, Science 2017). Avoiding cryopreservation and digestion of the skin biopsies with collagenase provided the best immune cell yield. Approximatively 85% of the isolated single cells produced RNAseq data that passed quality control. Analysis of 5 biopsies provided transcriptomic characterization of B-cells, CD4 and CD8 positive T-cells, Macrophages, Dendritic cells, and pDCs from skin lesions and suggested immune infiltrate heterogeneity in CLE patients. RNAseq data was also leveraged to define cell type marker panel for scqPCR which allowed a more focused cost- and time- effective approach for follow-up/validation of gene expression analyses.

Conclusion: We developed a protocol that successfully identified and characterized the immune infiltrate from skin punch biopsies of CLE patients. Analyses from additional patients will be needed to further understand the immunological heterogeneity of CLE skin lesions.

Genetic Evidence for Recent Positive Selection of the *HLA-B*51:01* Allele in the Turkish Population, a Population with a High Prevalence of *HLA-B*51*-Associated Behçet's Disease

Elaine Remmers ,[1] Ahmet Gül,[2] and Daniel Kastner[1], [1]National Human Genome Research Institute, Bethesda, MD, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

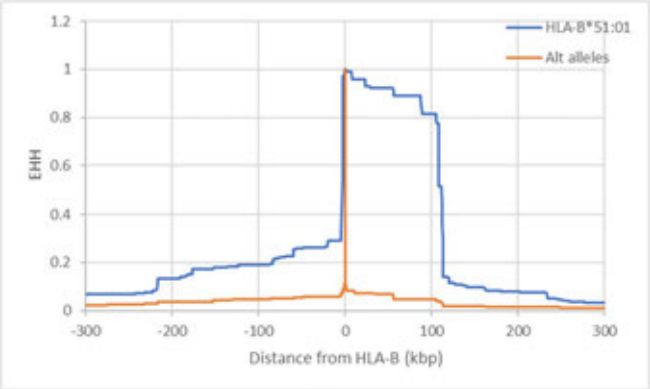

Figure 1. Extended haplotype homozygosity (EHH) of chromosome 6 markers flanking HLA-B*51:01. Decay of the ancestral HLA-B*51:01 bearing haplotype is shown by the frequency of chromosomes with the conserved haplotype at markers on either side of HLA-B, compared with haplotypes bearing all other HLA-B alleles (Alt alleles).

Background/Purpose: The Turkish population has one of the highest world-wide prevalence's of the genetically complex inflammatory Behçet's disease (BD), estimated as 4 affected per 1000 and also has one of the highest world-wide prevalence's of *HLA-B*51*, the strongest identified BD genetic risk factor, with the prevalence of *HLA-B*51:01* in healthy controls estimated as 25.6% and the prevalence in BD patients estimated as 55.6%. It has been proposed that the high frequency of *HLA-B*51* in this population is a result of a selective advantage that was provided to carriers of this HLA allele, for example, in response to some life-threatening infection. If recent positive selection occurred, haplotypes bearing the *HLA-B*51:01* allele should display unusually long-range linkage disequilibrium for their frequency, because selection would cause a rapid rise in the allele frequency over a short enough time that recombination does not substantially break down the selected haplotype. We looked for this genetic imprint of natural selection on *HLA-B*51:01* carrier chromosomes from the Turkish population.

Methods: Genome-wide SNP genotypes from 1,779 healthy Turkish subjects were obtained from a prior genome-wide association study. HLA alleles and MHC region SNP genotypes were imputed with the SNP2HLA application. Haplotypes were derived from genotypes with Eagle. Extended haplotype homozygosity (EHH) and frequency normalized iHS statistic values were computed for each marker in the combined marker set with the Selscan application.

Results: The chromosome 6 region flanking *HLA-B*51:01* exhibited extended haplotype homozygosity compared with other HLA-B alleles in the Turkish healthy control population (Figure 1). Of all the HLA-B alleles, *HLA-B*51:01* had the strongest evidence for recent positive selection with a frequency normalized iHS statistic = 3.87 (values greater than 2.00 are suggestive of recent positive selection).

Conclusion: *HLA-B*51:01* exhibits strong genetic evidence of recent positive selection in the Turkish population. An historical survival advantage provided by this allele could explain its current high frequency in the Turkish population, and as a strong BD risk factor, its high frequency could account for the high prevalence of BD in the Turkish population.

Session Date: Tuesday, November 12, 2019

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is a progressive, systemic autoimmune disease-causing inflammatory changes in the skin and skeletal muscles. DM is associated with carcinomas of the ovary, breast, lung and GI tract in a significant number of patients.

Methods: We employed the STARGEO platform to search the Gene Expression Omnibus and conduct meta-analysis on muscle biopsy (71 DM vs 22 healthy). We then analyzed the signature using Ingenuity Pathway Analysis, restricting genes that showed statistical significance ($p< 0.05$) and an absolute experimental log ratio greater than 0.1. We focused our analysis on tumorigenic gene expression.

Results: Our data demonstrate activation of several tumorigenesis associated genes: a) Immunoglobulin lambda constant 1 (IGLC1; p-value 4.48e-10, log ratio 2.62) is part of the innate immune response but is also upregulated in chronic myeloid leukemia, T-cell lymphoma, and T-cell non-Hodgkin disease, b) IFI44 (p-value 0.0377, log ratio 2.40) upregulated in both cutaneous and muscle samples of DM, is also upregulated in T-cell non-Hodgkin disease, and in peripheral and cutaneous T-cell lymphomas, c) Periostin (POSTN; p-value 0.0359, log ratio 2.15) is a secreted extracellular matrix protein part of the FAS1 domain, binds to integrins to support adhesion and migration of epithelial cells, and plays a role in cancer stem cell maintenance and metastasis and d) the MYC (p-value 0.0414, log ratio 1.28) proto-oncogene. Further tumorigenesis pathways identified in our dataset include CD44 (p-value 0.0343, log ratio 0.886), NPM1 (p-value 0.0295, log ratio 0.462), and IDO1 (p-value 0.0109, log ratio 0.543). CD44 is a cell surface adhesion receptor that is overexpressed in cancer cells and regulates metastasis and is considered a stem cell marker in ovarian cancer and an indicator of poor prognosis. Overexpression of NPM1 is a marker for progression in solid tumors such as hepatocellular and ovarian carcinomas and in some breast cancers. Indoleamine 2,3-dioxygenase 1 (IDO1) is a tryptophan catabolic enzyme that is also implicated in tumorigenesis via promotion of immune tolerance to tumor antigens.

Conclusion: Our results demonstrate novel tumorigenesis related pathways that are upregulated in Dermatomyositis that have largely not been studied previously in this disease. Additional studies need to be carried out to determine if this tumorigenic gene overexpression can serve as a predictive biomarker of malignancy risk in DM. Moreover, since some of the genes (e.g. IDO) are being studied as target for anticancer therapy, this should be explored in patients with DM associated malignancy also.

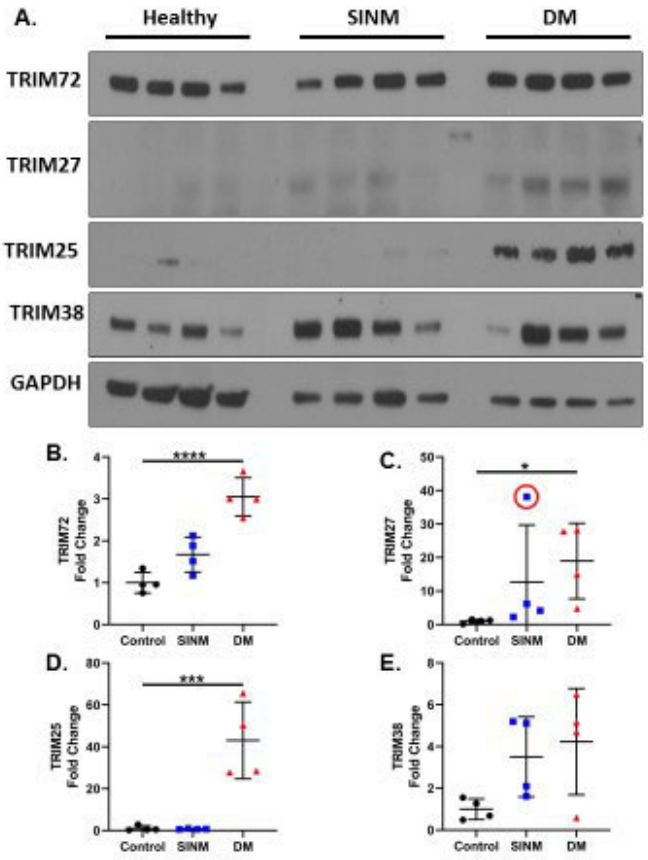
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is a progressive, systemic autoimmune disease causing inflammatory changes to the skin and skeletal muscles. TRIM family proteins are composed of approximately 80 E3 ubiquitin ligase proteins and some have a role in membrane resealing.

Methods: We employed the STARGEO platform to search the Gene Expression Omnibus and conduct meta-analysis on human skin (60 DM vs 34 healthy) and muscle biopsy (71 DM vs 22 healthy) samples. We analyzed the signature



using Ingenuity Pathway Analysis, restricting genes with significance ($p < 0.05$) and an absolute experimental log ratio greater than 0.1, focusing on TRIM family genes. We conducted similar analysis on rheumatoid arthritis (RA) blood (114 RA vs 90 healthy) and synovial samples (130 RA vs 68 healthy), sarcoidosis (SD) bronchoalveolar lavage (21 SD vs 20 healthy) and blood (216 SD vs 271 healthy) samples, systemic scleroderma (SSc) skin (63 SSc vs 31 healthy) biopsies, and Kawasaki (KA) blood (121 KA vs 40 healthy) for comparative TRIM activity analysis. Lastly, we conducted immunoblotting analysis on muscle biopsy specimens from 4 DM, statin-induced necrotizing myopathy, and healthy subjects. Bands of interest were visualized by chemiluminescence and fold change in TRIM72 protein levels evaluated by densitometry using ImageJ and Dunett's Test analysis.

Results: From our skin biopsy analysis in DM we found upregulation of TRIM genes TRIM5 (p-value 5.72e-12, log ratio 0.225), TRIM14 (p-value 3.36e-8, log ratio 0.132), TRIM34 (p-value 1.48e-6, log ratio 0.105), TRIM6 (2.97e-4, log ratio 0.212), TRIM21 (p-value 0.0111, log ratio 0.193), and TRIM38 (p-value 0.0189, log ratio 0.106). TRIM73 was downregulated (p-value 6.58e-13, log ratio -0.102). From our muscle biopsy analysis, we found upregulation of TRIM genes TRIM14 (p-value 0.0405, log ratio 1.02), TRIM22 (p-value 0.0361), TRIM25 (p-value 0.0287, log ratio 0.421), TRIM27 (p-value 0.00276, log ratio 0.298), and TRIM38 (p-value 0.0409, log ratio 0.949). Protein expression of TRIM 72, 25 and 27 protein expression were significantly upregulated and TRIM 38 trending although did not reach statistical significance in our DM cohort compared to healthy controls. Additional comparisons were made between DM and necrotizing myopathy and was significant for TRIM 25 only. Immunoblotting of human muscle proteins shown in Figure A and densitometry analysis shown in B-E. B.) TRIM72: Healthy vs. DM $p < 0.0001$. C) TRIM27: Healthy vs. DM $p=0.012$. D.) TRIM25: Healthy vs. DM $p=0.0006$. E.) TRIM38: Healthy vs. DM $p=0.064$. From our comparative analysis, there was no overlap in TRIM gene expression patterns in rheumatoid arthritis, sarcoidosis, systemic scleroderma, and Kawasaki with our skin and muscle biopsy DM analysis. The only overlapping expression was a similar upregulation of TRIM21 (p-value 3.97e-8, log ratio 0.158) in sarcoidosis blood samples.

Conclusion: TRIM protein family role in immune modulation is emerging. It has not been studied well in the context of DM. Our results suggest certain TRIM family members have a tissue and disease specific role in DM pathogenesis and may have diagnostic and therapeutic implications.

Multi-Organ System Meta-Analytic Approach to Investigating Sarcoidosis

Jihad Aljabban ,[1] Saad Syed,[2] Sharjeel Syed,[3] Nikhil Adapa,[1] Laith Hasan,[4] Zahir Allarakhia,[5] Dexter Hadley,[6] Mohamad Aljabban,[7] and Wael Jarjour[8], [1]Ohio State University College of Medicine, Columbus, [2]Stanford School of Medicine, Stanford, [3]Stanford School of Medicine, Stanford, CA, [4]Tulane School of Medicine, New Orleans, [5]Ohio State University College of Medicine, Columbus, OH, [6]Institute for Computational Health Sciences, San Francisco, [7]Genesys Health Systems, Grand Blanc, MI, [8]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis (SD) is a granulomatous inflammatory disease with a heterogenous presentation and no definite etiology. SD usually begins in the lungs, skin, or lymph nodes but can involve other organs such as the heart and lacrimal glands. A better understanding of pathogenesis can pave new therapeutic avenues.

Methods: We employed the STARGEO platform to tag samples from the Gene Expression Omnibus and performed three separate meta-analyses on 216 peripheral blood (216 SD vs 271 healthy), bronchoalveolar lavage (BAL; 21 SD vs 20 healthy), and lacrimal gland (22 SD vs 14 healthy) samples. We then analyzed the signature in Ingenuity Pathway Analysis.

Results: Lacrimal gland analysis revealed Th1 and Th2 activation and T helper cell differentiation as top canonical pathways. IFNG, TGFB1, and TNF were top upstream regulators. ADAMDEC1 was our top upregulated gene and is essential for dendritic cell differentiation. Additionally, we found upregulation of the metalloproteinase MMP12. MMP12 and ADAMDEC1 are potential markers of pulmonary SD activity and may be implicated in lacrimal glad involvement. GBP5, activator of the NLRP3 inflammasome, and osteopontin, associated in T cells in SD granulomas, were upregulated. Genes expressing antimicrobial peptides in secretions, such as HTN1 and STATH, were downregulated.

Blood analysis revealed TH1 activation, IFN, EIF2, TREM1, and pattern recognition receptor signaling as top canonical pathways. IRF7, IFNa, STAT1, and IFNL1 were top upstream regulators. We found upregulation of classical complement pathway related genes such as FCGR1B and SERPING1. Additionally, CARD17, regulator of IL1B, was upregulated and has activity linked to granulomatosis disease. The recently described transcription factor and immune regulator BATF2 was upregulated. Lastly, there was downregulation of TRABD2A, a metalloprotease and negative regulator or Wnt signaling.

BAL analysis revealed “role of macrophages, fibroblasts, and endothelial cells in rheumatoid arthritis” as the top canonical pathway, with TP53, hepatocyte growth factor, ERBB2, CTNNB1, and E2F7 as top upstream regulators. We found upregulation of sprout family gene SPRY2, a negative feedback regulator of tyrosine kinases. Additionally, there was downregulation of phospholipase D1, a regulator of signal transduction.

Conclusion: Sarcoidosis is a complex and likely multifactorial disease process. Our results emphasized the role of innate immune cell and Wnt activity in SD, among other signaling pathways, and suggest potential biomarkers and therapeutic targets. This approach to data analysis illustrates the importance of studying affected target organs to determine active pathways that are unique.

The Expression of the Interferon Inducible Gene SERPING1 Is Reduced by Rituximab and Correlates with Clinical Response in Systemic Lupus Erythematosus

Liliana Santos Ribeiro ,[1] Mariea Parvaz,[2] Su-Ann Yeoh,[2] and Michael Ehrenstein[2], [1]University College London, London, United Kingdom, [2]University College London, London, England, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Abnormalities in B cells and the interferon alpha (IFN) pathway have been separately implicated in the pathogenesis of systemic lupus erythematosus (SLE). B cell depletion therapy with rituximab is used to treat SLE but clinical response varies between patients. We hypothesized that the IFN inducible gene response may explain the difference in clinical responses to rituximab.

Methods: RNA was isolated from whole blood collected into Tempus tubes. Gene expression of the IFN signature genes (STAT 1, SERPING1, S100) was analysed in whole blood from 13 active SLE subjects (before and 2 months after Rituximab), and on age/gender-matched healthy controls, using real time PCR normalized to GADPH. Disease activity was evaluated according to the SLE Disease Activity Index (SLEDAI) score. Complement component C3 was measured by Nephelometry and anti-dsDNA antibodies by ELISA. Analysis of variance (ANOVA) was used to identify significant differences.

Results: Gene expression of SERPING1, but not other interferon inducible genes, was significantly higher in SLE patients before rituximab compared to healthy controls (p=0.0002) (Figure 1). Rituximab treatment led to a 25% decrease in SERPING1 expression in SLE patients (p=0.0131) (Figure 1C) which correlated with clinical response measured by SLEDAI (p=0.054), a reduction in anti-dsDNA antibodies after rituximab (p=0.037), and a trend towards an increase in C3 (p=0.062).

Conclusion: These data suggest that assessment of SERPING1 gene expression, an IFN inducible gene, is strikingly increased in SLE patients and correlated with clinical response to rituximab. These results could support therapeutic targeting of IFN to improve the efficacy of rituximab.

Mononuclear Leukocyte DNA Methylome Imprinting of Networked Signaling and Immunity Regulatory Pathways in Gout

Zengmiao Wang,[1] Ying Zhao,[1] Amanda Phipps-Green,[2] Ru Liu-Bryan,[3] Arnold Ceponis,[1] David Boyle,[4] Jun Wang,[1] Tony Merriman,[5] Wei Wang,[4] and **Robert Terkeltaub** [6], [1]UCSD, La Jolla, CA, [2]University of Otago, Otago, Otago, New Zealand, [3]San Diego VA/UCSD, La Jolla, CA, [4]University of California, San Diego, San Diego, CA, [5]University of Otago, Birmingham, AL, [6]San Diego VA/UCSD, San Diego, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout encompasses acute arthritis flares mediated by innate autoinflammatory responses to urate crystals, chronic granulomatous tophi, and synovitis promoting bone erosion and soft tissue damage. Here, we probed gout mediators in the circulating mononuclear leukocyte (PBMC) DNA methylome.

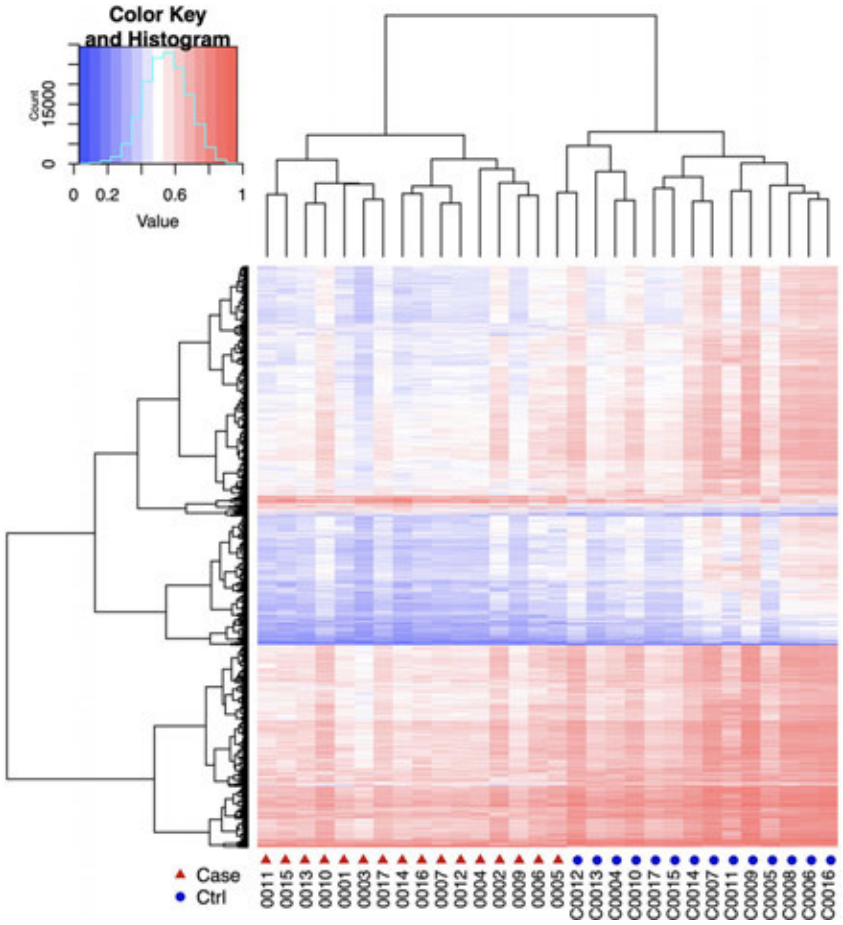

Figure 1. Hierarchical cluster analysis of gout vs. healthy controls in NA cohort.

Methods: PBMC DNA converted by Na+ bisulfite modification was hybridized to Illumina Infinium MethylationEPIC BeadChip arrays. Methylation data were processed with ChAMP in R. Our North American (NA) gout cohort (n=16), sampled between flares, all met ACR/EULAR criteria, and well-controlled urate overal. Healthy controls (n=14) were matched for age, gender, and BMI. Obese New Zealand (NZ) Maori, enriched in hypertension and diabetes, provided an independent validation cohort (n=13 gout; n=16 no gout). Transcription Factor (TF)-gene networks were built and combined from B and T cells, CD14+ monocytes, CD4+ and CD8+ T cells.

Results: By hierarchical clustering and PCA, gout DNA methylome signatures were significantly separable from controls in both the NA cohort (Fig. 1,2), and NZ validation cohort. Most (>85%) differentially methylated loci (DML) in gout were hypo-methylated in open sea regions, and gene body hypomethylation (which inhibits gene expression) was prominent. Gout DML included 23 from ~125 genetic risk loci from past GWAS (eg, urate transporter *SLC2A9* , B2 kinin receptor, and *IL-23R* , which bridges innate and adaptive immunity, and promotes granuloma formation). Numerous KEGG signaling pathways, but not the NLRP3 pathway, were enriched in DML (eg, circadian entrainment, and TRP ion channel signaling (which transduces pain in nerve fibers, and also activates phagocytes)), aligned with severe pain and nocturnal onset of background gout flares. We saw differential DNA methylation of myeloid cell signaling and function pathways (eg, FcgammaR phagocytosis, chemokine signaling, adhesion, PI3K-AKT, HIF-1), nutritional biosensing by NF-kB and NLRP3 inhibitor AMPK, and choline metabolism, which promotes gouty inflammation by modulating AMPK and mitophagy. In gout, *STAT2* , *IRF1* , nuclear factor of activated T cells (*NFATC2*), and major adaptive immunity pathways (T and B cell receptor signaling, Th17 differentiation) were differentially methylated. By far, most overlaps between gout cohorts were in transcription factors (TFs) with motifs enriched in hypo-methylated sequences, and enriched KEGG pathways based on TFs. Strikingly, DMLs of *NFATC2* , which blunts NF-kB hyper-

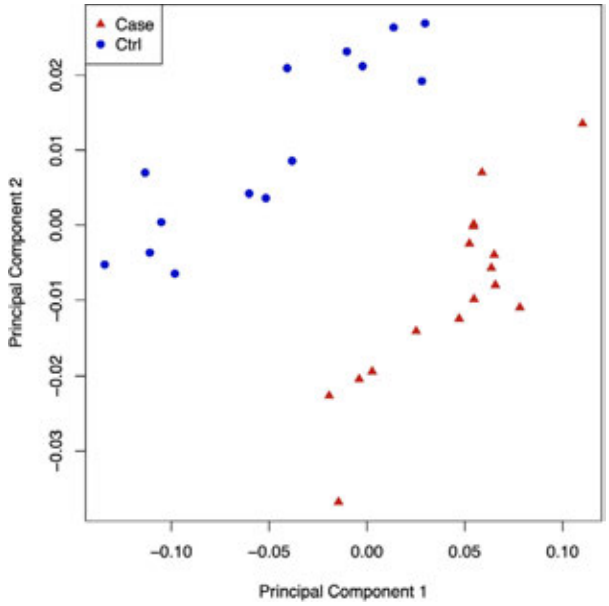

Figure 2. Principal component analyses of gout vs. healthy controls in NA cohort.

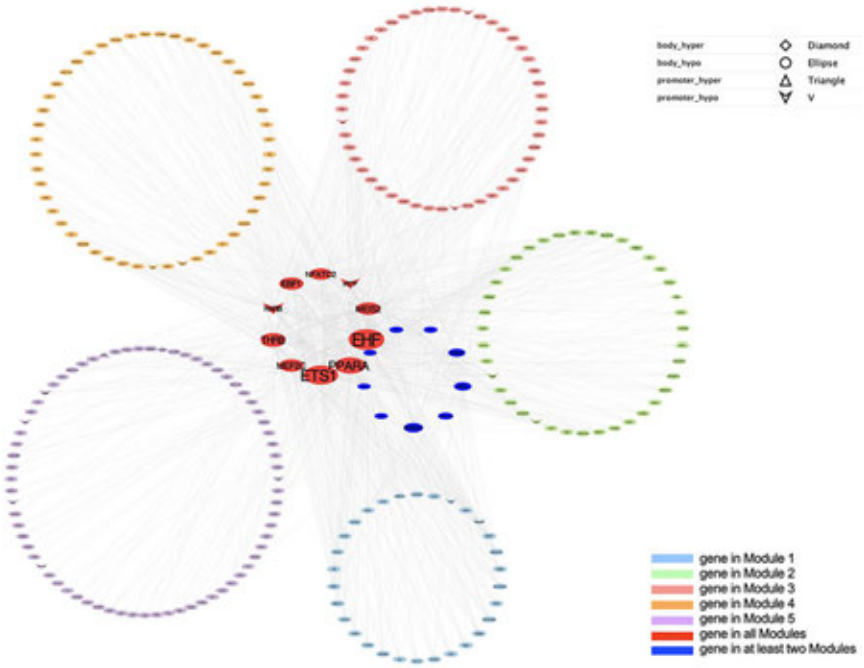

Figure 3. Integration of common gout-related DML-genes in both the NA and NZ cohorts with TF gene regulatory networks. Using ENCODE data, TF-gene networks were constructed in B-cells, T-cells, CD14+ monocytes, CD4+ helper T cells and CD8+ alpha-beta T cell respectively and then combined into one. After mapping common 361 DML-genes to the network, 256 DML-genes and 1053 edges were left (shown here). Five modules were identified using agmfit algorithm. The genes were colored based on the membership in a module. The 10 genes present in all Modules, which included NFAT2C and MEF2C, are depicted in red.

activation, and myocyte enhancer factor 2C *MEF2C* , which controls myeloid switching to granulocytopoiesis, were among 10 TFs propagated in all PBMC TF networks in both gout cohorts (Fig. 3).

Conclusion: A PBMC DNA methylome signature reflected trained immunity in gout, especially imprinting signaling and transcriptional pathways, and involving adaptive immunity. Such changes, and differential TF-gene network DNA methylation in all PBMCs, were in contrast to lack of NLRP3 pathway imprinting. The PBMC DNA methylome signature likely helps determine phenotypic outcomes of not only acute gouty arthritis, but also granulomatous tophaceous and chronic inflammatory synovitis, and potentially modulates comorbidities in the disease.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancy is known to induce a natural improvement of Rheumatoid Arthritis (RA) symptoms in 50-75% of patients as gestation progresses. However, the underlying mechanisms are not well understood and no biomarkers have been identified that predict whether a woman will improve or worsen during pregnancy. In this study, we aimed to identify RA-associated pre-pregnancy gene expression signatures to determine if they correlated with the subsequent improvement or worsening of RA during pregnancy.

Methods: Women with RA (n=11) and healthy women (n=5) were enrolled in our pregnancy cohort and followed prospectively. The women with RA were examined before pregnancy (T0) and at the third trimester (T3). Disease activity was assessed using Clinical Disease Activity Index (CDAI) scores. Blood was drawn from all women (RA and healthy) at both time-points. Total RNA was isolated and used to prepare cDNA libraries which were sequenced at an average depth of 60 million reads. The raw RNA sequencing (RNA-seq) data were pseudo-aligned to the reference Human transcriptome and quantified using kallisto. Genes differentially expressed between groups were identified with edgeR using a fold-change cutoff of 2 and significance threshold $q < 0.05$ (FDR corrected). Functional enrichment analysis was performed using Cytoscape.

Results: Of the 11 women with RA, 8 improved ($RA_{improved}$ group) by T3 while 3 worsened ($RA_{worsened}$ group). At the T0 baseline, however, the mean disease activity scores were similar in both groups of women ($RA_{improved}$: 3.2±0.7; $RA_{worsened}$: 3.5±1.4, p=0.7). When gene expression profiles of each RA subset was compared to the healthy women at T0, 94 genes were differentially expressed ($q< 0.05$; $FC\geq2$) between the $RA_{improved}$ and healthy women. These included CAMP, LGALS2, MAOA, S100A8, S100A9, S100A12 and a set of type I interferon inducible genes, many of which overlapped with previously reported RA expression signatures. A large proportion of the 94 differentially expressed genes clustered within 2 functional networks, one containing the over-expressed genes and the other containing the under-expressed genes. However, when the $RA_{worsened}$ women were compared to the healthy women at T0, a largely different RA-associated expression signature was identified. Of 83 genes that were differentially expressed, only 13 overlapped with those differentially expressed between $RA_{improved}$ and healthy women at T0. The majority of the 83 genes did not appear to be enriched in any relevant biological pathways.

Conclusion: In our pilot dataset, the RA-associated gene expression signatures identified before pregnancy correlated with, and were thus predictive of, subsequent improvement or worsening during pregnancy, even though mean disease activity scores at the pre-pregnancy baseline were similar between the two RA subsets. These different expression signatures suggest that there may be inherent genomic differences between women with RA that dictate how pregnancy can alter disease activity.

Analysis of Discoid Lupus Erythematosus (DLE) Gene Expression Reveals Dysregulation of Pathogenic Pathways Associated with Infiltrating Immune/Inflammatory Cells

Frances Harris ,[1] Sarah Heuer,[2] Robert Robl,[2] Prathyusha Bachali,[2] Adam Labonte,[2] Benjamin Chong,[3] Michelle Catalina,[2] Peter Lipsky,[2] and Amrie Grammer[2], [1]RILITE Research Institute, Charlottesville, VA, [2]RILITE Research Institute, Charlottesville, [3]University of Texas Southwestern, Dallas

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: DLE is a chronic, scarring inflammatory autoimmune disease of the skin. The precise molecular pathways underlying DLE pathogenesis have not been fully delineated. To obtain a more complete view of the pathologic processes involved in DLE, we undertook a comprehensive analysis of gene expression profiles from DLE affected skin.

Methods: Microarray gene expression data was obtained from skin biopsy samples of three studies (GSE81071, GSE72535, & GSE52471). Differentially expressed genes (DEGs) between DLE and control were identified by LIMMA analysis. Weighted gene co-expression network analysis (WGCNA) yielded modules of co-expressed genes. Modules correlating to clinical data were prioritized. Correlated modules were interrogated for statistical enrichment of immune and non-immune cell type specific gene signatures. Genes were functionally characterized using a curated immune-specific gene functional category database (BIG-C) and pathways elucidated using IPA®. Queries of a per-

turbation database (LINCS, Library of Integrated Network-Based Cellular Signatures) were used to identify drugs that could reverse the altered gene expression patterns in DLE.

Results: For each dataset, between 7-12 WGCNA modules had significant correlations to disease. Significant WGCNA module preservation was observed between all three datasets. Non-immune cell types (fibroblasts, keratinocytes, melanocytes) and also Langerhans cells are represented in WGCNA modules negatively correlated with disease. An immune cell signature was noted in WGCNA modules positively correlated to DLE, including DCs, myeloid cells, $CD4^+$ & $CD8^+$ T cells, NK cells, B cells as well as pre- and post-switch plasma cells (PCs). The presence of both Ig -κ & -λ as well as multiple VL genes suggests the presence of polyclonal PCs. Chemokines that mediate lymphocyte organization and/or recruitment into the skin were identified, including CCL5,7,8 & CXCL9-10,13. Cytokines (TNF, IFNγ, IFNα, IL1β, IL2, IL6, IL12, IL17, IL23 & IL27), signaling molecules (CD40L, PI3K, & mTOR) and transcription factors (NF-κB, NF-AT), as well as cellular proliferation, were evident. IPA® UPR analysis indicated that many of the expressed genes could be secondary to signaling by TNF, IFNγ, IFNα, CD40L, IL1β, IL2, IL6, IL12, IL17, IL23 & IL27. Interestingly, connectivity analysis using LINCS/CLUE identified high priority drug targets, such as IKZF1/3 (lenalidomide, CC-220), JAK1/2 (ruxolitinib) and HDAC6 (Ricolinostat) may prove to be options for therapeutic intervention.

Conclusion: Bioinformatic analysis of DLE gene expression has elucidated many dysregulated signaling pathways potentially involved in the pathogenesis of DLE that could be targeted by novel therapeutic strategies. Further investigation of these signatures may enhance our understanding of the pathogenesis of DLE.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with Rheumatoid arthritis (RA) tend to have a predictable flare of disease activity in the months after childbirth. The mechanism(s) underlying this post-partum flare are as yet unknown. Using our pregnancy cohort, we (a) examined gene expression changes associated with a flare of RA disease activity post-partum, (b) determined how those changes compare to post-partum changes observed among healthy women, and (c) examined whether expression profiles by 3 months post-partum differed from those before pregnancy.

Methods: Ten women with RA and five healthy women were enrolled in our pregnancy cohort and prospectively followed. Data on joint counts and global scores were collected from the women with RA before pregnancy (T0), at the third trimester (T3) and every 3 months post-partum (PP), and used to assess disease activity. Blood samples were drawn from all women at each time-point. Total RNA was isolated and used for RNA sequencing (RNA-seq). Pseudo-alignment and quantification of the raw RNA-seq reads were performed using kallisto. Differentially expressed (DE) genes were identified with edgeR using a significance threshold of $q \leq 0.05$ and fold-change≥ 2. Longitudinal mixed linear models were also used to test for associations between gene expression and disease activity post-partum. Functional analyses were performed using Cytoscape and ClueGO.

Results: Among the women with RA, 133 genes were DE between T3 and 3 months PP, when there was a flare of disease activity. These included genes encoding cell surface receptors CD24, CD177 and PD-L1, defensins, immunoglobulin receptors, S100 calcium binding proteins, and TRIM proteins. Functionally, these genes were enriched in the Gene Ontology (GO) terms neutrophil activation (q=1.1e-16) and antimicrobial humoral response (q=1.4e-5). Of the 133 DE genes, 118 were also DE among healthy women between T3 and 3 months PP, with expression changing in the same direction in both RA and healthy women. Similar results were obtained when the PP time-point with maximal disease activity during the flare was used (instead of 3 months PP). In the mixed linear model, 64 genes had expression patterns significantly associated with RA disease activity post-partum; these were enriched in various immune-related pathways including complement and coagulation cascades and systemic lupus erythematosus. At 3 months PP, the gene expression profile among the women with RA differed from that at T0, with 61 genes DE between the 2 time-points. Among healthy women, however, there were no statistically significant changes in gene expression between T0 and 3 months PP, although some immune-related genes (n=24) were under-expressed by at least two-fold at 3 months PP compared to T0.

Conclusion: The large majority of gene expression changes between 3rd trimester and 3 months post-partum in RA reflect normal post-partum changes also seen among healthy women. Nonetheless, there are a set of immune-related genes whose expression appear to be influencing disease activity during the post-partum flare. Further, our results show that the RA expression profile at 3 months post-partum is distinct from that before pregnancy.

Multiplicative Interaction: Current/Recent Smoking x wGRS			
p for interaction		0.18	0.2
*wGRS includes 86 SLE SNPs + 10 HLA alleles, dichotomized at median from controls distribution			

Table 3. Multiplicative Interactions for Individual SNPs and Current/Recent Smoking (Strongest Associations)		
Interaction of Current/Recent smoking with (p-value):	All SLE	Whites-only SLE
HLA-DRB1-0102	**0.002**	**0.02**
SPATA8 (rs8023715)	**0.004**	0.10
DRAM1	**0.05**	**0.02**
GPR78 (rs13116227)	0.06	**0.01**
Weighted *HLA* GRS for SLE	0.06	**0.04**

Background/Purpose: We have previously reported that current smoking (or having recently quit within 4 years) was associated with elevated risk of SLE, in particular anti-dsDNA+ SLE. Genetic and environmental factors, such as smoking, may interact in determining SLE risk. We investigated whether interactions between smoking and genetic risk factors may influence SLE risk.

Methods: We identified subjects with validated SLE and DNA samples within the Nurses' Health Studies (NHS) and Partners Healthcare Biobank (PHB). 673 SLE cases were matched to 3,276 controls without SLE on age, sex and race (matched on self-report race in NHS and by 1st 3 principle components of GWAS in PHB). All subjects had data on smoking prior to SLE diagnosis date or the matched index date in controls. DNA samples were genotyped and imputed using Haplotype Reference Consortium (Michigan) and SNP2HLA for *HLA*. SLE risk alleles were identified from published GWAS studies (mainly from White and Asian populations): https://www.ebi.ac.uk/gwas/. After pruning for linkage disequilibrium, 86 SNPs and 10 *HLA* alleles with genome wide significance $p \leq 5\times10^{-8}$ were included in a new weighted genetic risk score (wGRS), weighted by log OR from published GWAS. The wGRS for all markers and for HLA alleles only were studied. Smoking was classified as current/quit within 4 years at SLE diagnosis vs. past/never smoker. wGRS was dichotomized as ≤ vs. > the median value in controls. We employed conditional logistic regression models for SLE or anti-double stranded DNA antibody + SLE (dsDNA+ SLE), conditioning on matching factors and controlling for cohort. We examined additive interactions using the attributable proportion (AP) due to interaction and tested for multiplicative interactions using a 1 d.f. χ^2 test, for the wGRS as well as for individual risk alleles. We repeated analyses for risk of anti-dsDNA+ SLE. We examined interactions among all subjects and among Whites only.

Results: Characteristics of the cases and controls are shown in **Table 1**. High wGRS (OR 1.4, p 5.6×10^{-52}) and current smoking (OR 1.5, p 0.0006) were individually both strongly associated with SLE risk. SLE risk was highest in those with high wGRS and current smoking, OR 5.58 (95% CI 4.1-7.6) (**Table 2)**. A significant additive interaction between high vs. low wGRS and current/recent vs. past/never smoking was found (AP 0.37, p 1.5×10^{-4}). Findings were similar for interactions associated with anti-dsDNA+ SLE risk. Significant multiplicative interactions between smoking and genotypes were found with specific genotypes, including *HLA-DRB1-0102* (p 0.002) (**Table 3**), the weighted HLA GRS for SLE, but not with overall wGRS (p 0.18). Findings were similar when limited to Whites only.

Conclusion: These findings support the hypothesis that smoking predisposes to SLE in the presence of genetic factors, with a greater than additive interaction with overall genetic risk and potentially greater than multiplicative interaction with certain genotypes. Studies should now investigate the mechanisms of these interactions and whether smoking influences the function of these genes in SLE pathogenesis.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical and serological features of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are different across geographical regions and ethnicities, which strongly indicates significant roles of genetic factors in development of AAV. In AAV patients with Asian ethnicity, MHC and non-MHC genes associated with susceptibility or clinical characteristics of AAV were reported using the candidate-gene approach, but genome-

wide association study (GWAS) has not been reported. We implemented GWAS to identify single nucleotide variants (SNV) associated with AAV in the Japanese population.

Methods: GWAS was implemented using samples from 374 Japanese patients with AAV comprised of 214 with microscopic polyangiitis (MPA), 75 with granulomatosis with polyangiitis (GPA), and 45 with eosinophilic granulomatosis with polyangiitis (EGPA). Myeloperoxidase (MPO)-ANCA was positive in 300 patients and proteinase 3 (PR3)-ANCA was positive in 47 patients. Data were compared with those of 2,994 healthy Japanese owned by Japan PGx Data Science Consortium. The genotype data were obtained using HumanOmni 2.5-8 BeadChip Kits (Illumina, San Diego, CA, USA). From the genotypes of several SNVs around HLA regions, two alleles of each subject were predicted by HIBAG algorithm using the parameters tuned by Japanese population. The four-digit HLA alleles on six loci (HLA-A, HLA-B, HLA-C, HLA-DRB1, HLA-DQB1, HLA-DPB1) for ANCA subjects were predicted. For JPDSC data, alleles of HLA-DQB1 were also predicted and other *HLA* loci were genotyped using the Luminex assay as four digits *HLA* allele.

Results: GWAS revealed substantially different associations from those reported from populations of European ancestry. SNVs rs2858331 in a region between HLA-DQB1 and HLA-DQA2 was associated with MPO-ANCA (OR=1.649, P=9.504E-09) at the genome-wide significance level, and tended to be associated with the phenotype MPA as well (OR=1.631, P=1.373E-06). HLA association test showed significant association of HLA-B*51:01-C*14:02 haplotype in addition to the previously reported HLA-DRB1*09:01-DQB1*03:03 haplotype with MPA and MPO-ANCA. SNV rs749873 in a region near CXCR4 gene showed a trend toward association with GPA (OR=8.058, P=6.755E-08).

Conclusion: GWAS demonstrated multiple association signals in MHC class I and class II regions, as well as potential associations in the non-MHC regions, not previously reported from European populations.

The authors are the members of Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS) and Research Committee of Progressive Renal Disease, Ministry of Health, Labour, and Welfare of Japan. This study was performed in collaboration with Japan PGx Data Science Consortium.

The Emerging Regulatory Function of microRNA146a in Bone Biology and Osteoporosis

Victoria Saferding ,[1] Melanie Hofmann,[2] Julia S. Brunner,[2] Mihaela F. Militaru,[2] Antonia Puchner,[2] Silvia Hayer,[2] Melanie Timmen,[3] Richard Stange,[3] Josef Smolen,[2] and Stephan Blüml[4], [1]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria, [3]University Hospital Muenster, Muenster, Germany, [4]Medical University of Vienna, Vienna

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Micro RNAs (miRNAs) play a crucial role in the regulation of bone metabolism. MiR-146a, an important anti-inflammatory miRNA, was found to negatively impact osteogenesis and bone regeneration *in vitro*, by controlling the differentiation of mesenchymal stem cells. But to date the role of miR-146a in bone remodelling, its influence on bone stability and development of osteoporosis is not known.

Methods: Systemic bone, tibiae and femur, of wt, miR-146a$^{-/-}$ and miR- 146a$^{-/-}$ TRAF6$^{+/-}$ animals was assessed histologically and via µCT analysis, over a period of 3 to 18 months of age. Serum cytokine levels were analysed by Elisa. MRNA expression levels in bone were analysed by qPCR. To induce osteoporosis, ovariectomy (OVX) induced bone loss was performed.

Results: When we analysed bone volume of long bones histologically as well as with µCT analysis we detected significantly increased trabecular as well as cortical bone mass in miR-146a deficient compared to wt animals, starting at an age of 6 months. Dose reduction of TRAF6, a main target of miR-146a, using miR-146a$^{-/-}$ TRAF6$^{+/-}$ animals could not change the observed bone phenotype. Analysis of serum in aged miR-146a deficient animals displayed elevated activity of bone resorbing osteoclasts as amounts of CTX I in miR-146a$^{-/-}$ mice were significantly increased compared to wt animals. Q-PCR analysis of important osteoclast as well as osteoblast marker genes in bones *ex vivo* displayed elevated expression of signature molecules of both cell types in aged miR-146a deficient mice, suggesting a regulatory role of miR-146a in both cell types. Moreover, expression level of Wnt5a, a known target of miR-146a, influencing bone forming as well as bone resorbing cells, was strongly elevated in miR-146a$^{-/-}$ bones, possibly responsible for this deregulated bone growth. When we induced osteoporosis using the OVX disease model, histological analysis of long bones showed significant trabecular bone loss in ovariectomized wt mice. In contrast, we could not detect trabecular bone loss in ovariectomized miR-146a knock out animals, suggesting that loss of miR-146a deficiency protects bone loss induced by estrogen deficiency.

Conclusion: MiR-146a seems to control bone turnover and miR-146a deficient mice accrue bone over time. Moreover this miRNA has a negative influence on bone loss occurring during oestrogen loss induced osteoporosis. Therefore, miR-146a could be possibly used as a therapeutic target in the treatment of osteoporosis.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the most prevalent rheumatic disorder of the middle-age population. The lack of sensitive diagnostics methods led to an identification of the disease in advanced stages, where the only possible treatment is surgery. Therefore, the objective of this work was to validate and qualify the putative ability of 6 potential proteomic markers to predict the appearance of radiographic knee OA in the clinical routine.

Methods: In the *validation phase* 6 potential biomarkers were quantify in 540 sera at baseline belonging to participants from the Osteoarthritis Initiative (OAI) who will develop (incident group, n=209) or not (not-incident group, n=331) radiographic knee OA in a follow-up period of 96 months using custom sandwich immunoassays for bead-based xMAP technology. Non-parametric Mann-Whitney U test was carried out to look for statistical differences between the outcome groups. In the *qualification phase* significant association of the biomarkers with the risk of knee OA development was assessed by regression analysis. A clinical prognostic model was defined by stepwise

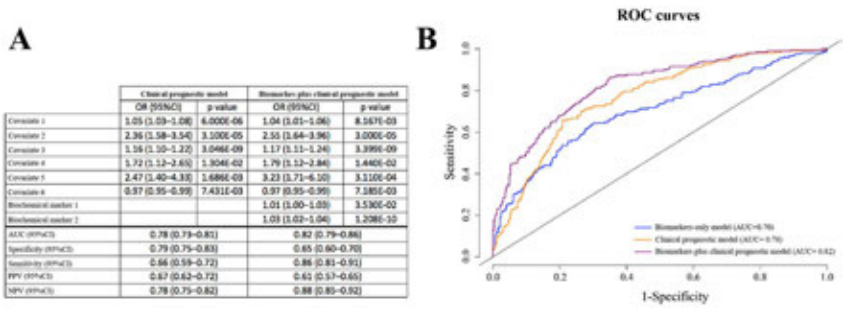

Figure 1. (A) Multivariate regression analysis comparing the clinical prognostic model with the biomarker plus clinical prognostic model. (B) Roc curves of the three models.

regression analysis using clinical non-radiographic variables significant associated with OA risk assessment. The utility of the potential biomarkers in the clinical routine, alone or in combination with other biomarkers included in the same multiplex sandwich immunoassay, was evaluated by comparing the Area Under the Curve (AUC) of the clinical prognostic model with the different biomarkers plus clinical models. Sensitivity, specificity and predictive coefficients were also assessed.

Results: The incident group showed significant higher serum concentrations of all the potential biomarkers analyzed ($p < 0.05$). We also found that 5 of the analytes were significant associated with the future appearance of radiographic knee OA, yielding Odd Ratios (OR) $\geq$ 10 per 10 µg/ml increase. Among all the possible combinations, the inclusion of 2 of the potential biomarkers to the clinical prognostic model showed a significant improvement of the predictive capacity (AUCs = 0.78 vs 0.82, p= 0,044) with 65% (60-70%) specificity and 88% (81-91%) sensitivity. The regression model and all metrics are listed in the Figure 1, comparing the biomarkers plus clinical model with the clinical prognostic model. The ROC curve of the biomarker-only model, clinical prognostic model and biomarker plus clinical model are also represented at the figure.

Conclusion: Significant association of higher concentrations of 5 of the potential biomarkers where found in people who are at risk of knee OA when analyzing 540 sera from the OAI cohorts by custom sandwich immunoassays. Among all of them, the combination of 2 of the analytes showed a putative utility in the clinical setting by improving the predictive capacity of a clinical prognostic model to predict who is in risk to develop radiographic knee OA.

Polymorphisms in Genes Involved in Methotrexate Pathway: Predictor of Response to Methotrexate Therapy in Indian Rheumatoid Arthritis Patients

Ankita Singh ,[1] Harikrishnan Nair,[2] Vikas Gupta,[2] Pradeepta Sekhar,[2] Ramnath Misra,[3] and Amita Aggarwal[4], [1]Sanjay Gandhi Post Graduate institute of medical science, Lucknow, India, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India, [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Lucknow, Uttar Pradesh, India, [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is first line therapy to treat rheumatoid arthritis (RA) patients. However, the response is variable with 50-60% showing response and this variability could be related to single nucleotide polymorphisms (SNPs) in genes involved in MTX metabolism or action. Thus we studied association of eight polymorphisms [rs2236225 (MTHFD1 1958G >A), rs17602729 (AMPD1 G >A), rs1127354 (ITPA C >A), rs1431131 (TGFBR2 A >T), rs244076 (ADA T >C), rs2372536 (ATIC C >G), rs11188513 (ENTPD1 C >T), rs5751876 (ADORA2A T >C)] in the genes involved in MTX pathway with response to MTX therapy in Indian RA patients.

Table 1: Allelic and genotypic associations of polymorphism with response to MTX.

Gene	SNP	Allele frequency		Allele association, P value*; OR (95% CI)	Genotype frequency		Genotypic association, P value
		(R=172)	(NR=35)		R	NR

CI, confidence interval; R, responders; NR, non-responders; MTX, methotrexate; OR, odds ratio; SNP, single nucleotide polymorphism.
*P value calculated using $\chi 2$ test.

Allelic and genotypic associations of polymorphism with response to Methotrexate.

Methods: Genotyping of RA patients (EULAR/ACR 2010 criteria), DMARD naïve with active disease (DAS 28 >3.2) was done using by TaqMan 5' nuclease assay. MTX monotherapy was given to the patients by gradually escalating the dose to a maximum of 25mg/week or maximal tolerated dose. Four months after therapy, based on EULAR response criteria patients were classified into responder and non-responder group. The association of SNPs with response to MTX therapy was assessed using Chi-Squared test.

Results: Two hundred seven patients (85.5% females; median-age 40 [17] years); median duration of disease 24 (40) months; median DAS28-CRP 4.82 (1.51) were enrolled. At 4 months, based on EULAR response 172 patients were classified as responders and 35 as non-responders. Assuming C dominance, recessive model of ITPA C >T [P = 0.004; OR (95% CI= 1.44 (1.05-1.97) associated with response to MTX. Assuming C dominance, dominant model [P = 0.019; OR (95% CI) = 4.07 (1.03-16.06)] and recessive model [P = 0.04; OR (95% CI) = 1.28 (0.96- 1.7)] of ATIC C >G associated with response to MTX. On multiple logistic regression analysis, ITPA C >T and DAS28-ESR at baseline were independent predictors of response to MTX.

Conclusion: Two polymorphisms i.e. ITPA C >T and ATIC C >G were associated with response to MTX therapy in Indian RA patients. Along with clinical variables only ITPA C >T had independent association with response to MTX.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose:: Osteoarthritis (OA) is the most frequent joint disease.The OA is a heterogeneous disorder. With acceptance of the joint as an organ, the pathogenesis of OA has been viewed as a complex process that involves all the joint structures. There are several metabolic pathways involved in cell metabolism, including glycolysis, tricarboxylic acid (TCA) cycle and fatty acid (FA) oxidation. Metabolic flexibility has been described as the ability to adapt fuel oxidation by fuel availability. During OA, it has been established a relationship between mitochondrial dysfunction and cellular damage due to impairments in mitochondrial function and metabolic flexibility. Several studies have suggested that fatty acids may play an important role in OA development and progression.

Purpose: The aim of this work was to examine the differences in glucose and fatty acid metabolism, with special focus on metabolic flexibility, in cybrids from healthy (N) or OA donors.

Methods: Cybrids were developed using 143B.TK$^-$ Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy (N) and OA donors. Glucose and FA metabolism were measured using D-[^{14}C(U)]glucose and [1-^{14}C]oleic acid respectively. Metabolic flexibility was evaluated by co-culturing with glucose and oleic acid acutely by using inhibitors against glucose and FA oxidation, 20μM UK5099 and 10μM etomoxir, respectively. Incorporation of FA into lipid droplet (LD) was evaluated by thin layer chromatography and LDs were stained by LD540 and analyzed by confocal microscope and flow cytometry. Appropriate statistical analyses were performed with GraphPad Prism v6.

Results: There were no changes in basal glucose metabolism between cybrids. N cybrids had higher acid-soluble metabolites, reflecting incomplete FA β-oxidation than OA cybrids (N: 127.9±9.5 nmol/mg protein, OA: 91.58±7.17 nmol/mg protein, $p \leq 0.005$). Comparing glucose and FA metabolism showed that both types of cybrids preferred to oxidize glucose. Co-culturing with glucose and Oleic acid, increased total cellular uptake and oxidation of glucose in N (oxidation: 1.28±0.09, uptake: 1.22±0.09, $p \leq 0.05$) compared to basal condition but no in OA cybrids. Inhibition of FA oxidation by etomoxir increased complete glucose oxidation of N cybrids (1.14±0.02, $p \leq 0.0001$) compared to basal condition. Combine these data indicate that N cybrids are more metabolically flexible than OA. Cybrids presented different lipid distribution patterns; N cybrids had higher incorporation into phospholipids (N: 24.36±0.93, OA: 20.64±1.02, $p \leq 0.05$) but lower into TAG (N: 64.07±1.17, OA: 70.03±0.84, $p \leq 0.005$), compared to OA cybrids. Lipid droplet (LD) formation increased in both groups incubated in presence of FA (2.07±0.09, 2.61±0.17, $p \leq 0.0001$). Furthermore, N cybrids showed less LD formation than OA ($p \leq 0.005$).

Conclusion: The results indicated that cybrids from OA patients had reduced metabolic flexibility compared to N cybrids. Furthermore, the results indicate that this is associated with mitochondrial impairments.

Integrating Genetic Risk Scores and Pre-Diagnostic Metabolomics to Infer Dysregulated Mechanisms in Rheumatoid Arthritis in Women

Su H. Chu ,[1] Jing Cui,[2] Jeffrey Sparks,[2] Bing Lu,[2] Clary Clish,[3] Jessica Lasky-Su,[1] Elizabeth Karlson,[2] and Karen Costenbader[2], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Broad Institute of MIT and Harvard, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis genetic risk scores (RA-GRS) improve RA risk prediction, but the added predictive value over lifestyle risk factors is modest. Several human leukocyte antigen (HLA) haplotypes are strongly related to seropositive RA. Recently, we identified a number of metabolites, including short-chain acylcarnitines and metabolites involved in polyamine metabolism, associated with RA risk. Integrating RA-GRS and metabolomics may provide insight into RA pathogenesis.

Methods: Plasma samples obtained prior to disease onset from 254 female participants who later developed validated RA in the Nurses' Health Studies were 1) genotyped, imputed to the 1000 Genomes reference panel, and imputed HLA haplotype using SNP2HLA, and 2) analyzed using untargeted liquid-chromatography tandem mass-spectrometry for metabolomic profiling. Genetic risk measures included: 93 weighted non-HLA single nucleotide variants (wGRS93), and 18 weighted HLA (wHLA) haplotypes previously associated with RA risk. For metabolomic measurements, three complementary methods were applied to detect amines and polar metabolites, polar and non-polar lipids, and free fatty acids, bile acids, and metabolites of intermediate polarity. After quality control, 360 unique metabolites were included for analysis. Associations between wGRS93, wHLA, and the cumulative sum of wGRS93 and wHLA and individual metabolite levels were tested using ordinary least squares to identify putative genetically

Table 1. Characteristics of the pre-RA cases in the Nurses' Health Study sample.

Characteristics	Pre-RA Cases (N=254)
Age at Blood Draw	
Mean (SD)	51.3 (8.0)
Age at Diagnosis	
Mean (SD)	61.2 (10.3)
Seropositive Status*, N (%)	
Seropositive, At Blood Draw	39 (15.6)
Seropositive, Ever	158 (62.2)
Time to RA From Blood Draw (Years)	
Median (IQR)	10 (5-13)
Range	0.3-23
Menopause and PMH at Blood Draw, N (%)	
Premenopausal, No PMH	97 (38.2)
Postmenopausal, No PMH	50 (19.7)
Postmenopausal, Past PMH	76 (28.9)
Postmenopausal, Current PMH	31 (12.2)

Putative associations of HLA-SE and cumulative HLS-SE and GRS93 with pre-RA plasma metabolites levels among 254 RA cases in the Nurses' Health Study. All metabolites reported above were significant at a false discovery rate adjusted p-value threshold of 0.1. Dashed lines indicate failure to meet nominal significance thresholds.

informed metabolites of RA. Adjustment for multiple comparisons was made using the pooled local index of significance, a false discovery rate approach which employs Hidden Markov Models to account for dependency structures in the data.

Results: After adjustment for multiple comparisons, no genetically informed metabolites for wGRS93 were found; however, 27 RA wHLA-SE associations were identified, including several short-chain acylcarnitines and metabolites involved in polyamine metabolism that we previously found to be associated with RA: C2 carnitine (β=0.120; p=0.018), C3 carnitine (β=0.122; p=0.007), C5:1 carnitine (β=0.120; p=0.016), 4-acetamidobutanoate (β=0.134; p=0.027), and N-acetylputrescine (β=0.119; p=0.011). In the combined wGRS93 and wHLA-GRS score, 21 associations were identified, also including several carnitines identified for wHLA-SE, as well as additional acylcarnitines: C4-OH carnitine (β=0.092; p=0.048) and C7 carnitine (β=0.105; p=0.017). In all results, higher genetic risk was associated with increased standardized metabolite expression levels.

Conclusion: We identified several novel associations between both 1) wHLA haplotypes and 2) combined wGRS93 and wHLA risk scores, with newly identified metabolite levels in pre-RA, but none for GRS93. These associations may point to new biologic pathways involved in RA development. However, further validation is required.

Abstract Number: 1948

The Mechanism of DC-STAMP-Mediated Signaling in Cell-Cell Fusion and Osteoclast Maturation

Ananta Paine ,[1] Kerstin Tiedemann,[2] Maria de la luz Garcia-Hernandez,[1] Svetlana Komarova,[2] and Christopher Ritchlin[1], [1]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY, [2]Faculty of Dentistry, McGill University, Montreal, Quebec, Canada; Shriners Hospital for Children-Canada, Montreal, Quebec, Canada, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoclasts (OC) are bone-resorbing, multinuclear cells that originate from myeloid progenitor cells through repetitive cycles of cell-cell fusion. Dendritic cell-specific transmembrane protein (DC-STAMP) is essential for cell-cell fusion and formation of fully functional OC, resulting in mild-moderate osteopetrosis in DC-STAMP$^{-/-}$ mice; however the molecular mechanisms of its action is not well understood. We examined how the complete absence of DC-STAMP in the osteogenic progenitor cells (OCPs) affects their ability to participate in cell-cell fusion, alters calcium (Ca^{2+}) signaling, and gene and protein expression in response to osteoclastogenic stimuli: macrophage colony-stimulating factor (MCSF) and receptor activator of nuclear factor kappa-B ligand (RANKL).

Methods: We isolated bone marrow macrophages (BMMs) from wild type (WT) and DC-STAMP knockout (KO) mice. To analyze cell-cell fusion, we labeled DCSTAMP$^{+/+}$ and DCSTAMP$^{-/-}$ BMMs with red (CellVue® Red) and green (CellVue® Jade) membrane dyes respectively, cultured them with MCSF (30 - 50 ng/ml) and RANKL (30 - 50 ng/ml) and monitored cell-cell fusion with live cell imaging. Calcium signaling was examined using microspectrofluorimetry of Fura-2 loaded OC precursors. Activation of osteoclastogenic transcription factor NFATc1 was assessed using immunoblotting and immunofluorescence. The effect of DC-STAMP knockout on gene and protein expression was examined using RNAseq, quantitative PCR (qPCR), and immunoblotting.

Results: DCSTAMP$^{+/+}$ cells were essential to initiate cell-cell fusion events; however DC-STAMP$^{-/-}$ BMMs were successfully incorporated into forming OC. RANKL-induced Ca^{2+} oscillations were still present in DC-STAMP$^{-/-}$ precursors, and increased in intensity compared to DC-STAMP$^{+/+}$ OCPs during the later stages of differentiation. NFATc1 protein levels in DCSTAMP$^{-/-}$ OCPs increased with time following RANKL exposure and were comparable to WT. However, nuclear translocation of NFATc1 was significantly decreased in DCSTAMP$^{-/-}$ osteoclast precursors at day 3 of differentiation. We further observed decreased expression of key osteoclastogenic genes (CTSK, ATP6V0D2, ACP5) in DCSTAMP$^{-/-}$ cells. RNAseq analysis of DCSTAMP$^{-/-}$ and WT OCPs identified differentially expressed genes indicating alterations in key molecular pathways, including RELA, NFκB, FOS, PKC, and TREM1 signaling.

Conclusion: Our findings indicate that while DC-STAMP$^{-/-}$ OCPs cannot form multinuclear OCs, they do fuse with DCSTAMP$^{+/+}$ OCPs and are incorporated into maturing OCs. We demonstrate that even though calcium oscillations are present in DC-STAMP$^{-/-}$ OCPs, NFATc1 nuclear translocation is deficient, suggesting that DC-STAMP acts in the NFATc1 pathway, but downstream of calcium signaling. Our RNAseq analysis identified multiple differentially expressed genes that are potentially involved in cell-cell fusion and maturation of OCs.

The p.R321C Mutation in P62 Associated with Paget's Disease of Bone Leads to a Change of Localization of the Protein in Human Osteoclasts

Nerea Gestoso-Uzal,[1] Ricardo Usategui-Martín,[1] Rogelio González-Sarmiento,[1] and **Javier Del Pino-Montes** [1],

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Paget´s disease of bone (PDB) is a chronic bone metabolic disorder. Currently, PDB is a focal disorder characterized by an increase in bone turnover in a disorganized way. Its cause is unknown, but it is clear that it is a multifactorial disease in which genetic and environmental factors are involved. The most important known genetic factor predisposing to PDB is mutation in Sequestosome1 (*SQSTM1*) gene. This gene encodes p62, a multifunctional protein involved in autophagy that binds ubiquitin and regulates activation of the nuclear factor kappa-B (NF-kB) signaling pathway, regulating autophagy. We detected for the first time the c.961C >T *SQSTM1* gene mutation localized in exon 6 of *SQSTM1* gene in three PDB patients. It causes the p.R321C mutation, localized in the LIR domain of p62 protein. The aim of this study is to characterize the effect of the p.R321C mutation in human osteoclasts.

Methods: First of all, the *SQSTM1* cDNA was cloned into the EcoRI site of the pCEFL-Flag vector to generate the pCEFL-Flag-cSQSTM1-321wt construct. The p.R321C mutation was introduced into this construct by mutagenesis using primers designed to introduce C >T base change at position +961 to generate pCEFL-Flag-cSQSTM1-321C construct. After that, PBMCs were isolated from venous blood samples for generating human osteoclasts in vitro, using Ficoll. Mononuclear cells were seeded in 6-well culture plates with glass cover slips and cultured with α-MEM medium supplemented with 10% fetal bovine serum and 1% penicillin-streptomycin at 37ºC in a humidified 5% CO2 atmosphere. Cells were differentiated with fresh α-MEM containing M-CSF and RANKL every 3 days for 3 weeks. After that, the cells were transiently transfected with total plasmid DNA (pCEFL-Flag-cSQSTM1-321wt and pCEFL-Flag-cSQSTM1-321C). 72 hours after transfection cells were fixed and we performed a Confocal Co-Immunofluorescence Assay, using as primary antibodies anti-Flag M2 and anti-p62. Also, cells were stained with DAPI (4', 6-diamidino-2-phenylindole), to select the ones with at least 3 nuclei. Fluorescence images were captured with a confocal microscope.

Results: Our results showed that, while endogenous p62 remains scattered though the cytoplasm, p.R321C p62 is concentrated in the periphery of human osteoclasts. Transfection with WT p62 showed the same localization that endogenous WT p62. This change of localization caused by the mutation detected in PDB patients could result in an alteration in autophagy that can have an important role in the development of PDB, since autophagy is a catabolic process that occurs in the cytoplasm. In fact, previous studies have associated other mutations in autophagy genes with the physiopathology of PDB. To confirm the effect of this mutation in autophagy functional studies are ongoing.

Conclusion: The mutation p.R321C in the LIR domain of p62 protein leads to a change of localization of the protein in human osteoclasts, reinforcing the hypothesis that autophagy is involved in PDB.

Apolipoprotein L1 Variant-Carrying Monocytes Exhibit Mitochondrial Respiration Defects

Ashira Blazer ,[1] Miao Chang,[1] Kimberly Robins,[1] Jill Buyon,[2] and Robert Clancy[2], [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In SLE Apolipoprotein L1 (APOL1) risk variants associate with cardiovascular and kidney damage. APOL1 is both a secreted and tissue intrinsic protein; the latter role mediates organ injury. Expression is driven by inflammatory stimuli which initially promotes survival through autophagy. At higher expression, APOL1 contributes to cell death partially by compromising mitochondria. The RV protein structure favors toxicity at lower thresholds. Macrophages express APOL1 and use metabolic plasticity to perform effector functions. We hypothesized that in activated macrophages, APOL1 expression impairs mitochondrial

Methods: Healthy controls were genotyped for APOL1 reference allele (G0) risk variants (RV) (n=15; G0/G0=8, RV/G0=4, RV/RV=3). Monocytes were isolated from PBMCs using a Miltenyi Biotec Pan Monocyte Isolation kit and differentiated into macrophages using GM-CSF. Cells were treated with SLE-relevant agonists ssRNA hY3 or IFNɣ; and APOL1 expression was observed by qPCR. As in-vivo correlates, APOL1 expression relative to IFN response gene, Siglec 1, in SLE patient monocytes (n=17); and expression in coronary artery tissue macrophages with (n=3) or without (n=3) atherosclerotic plaque were assessed through RNA seq data and immunohistochemistry respectively. To

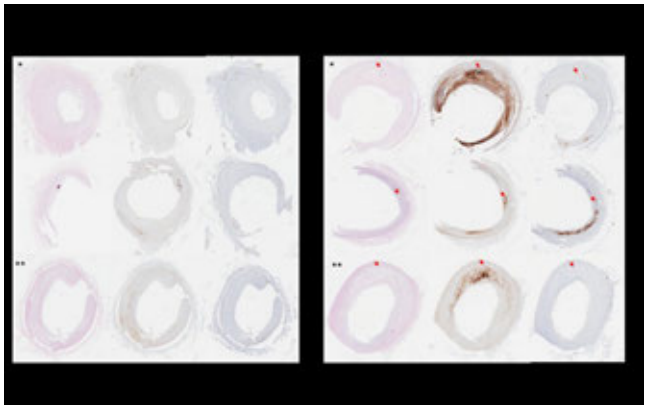

Figure 1. Axial sections of coronary arteries (explanted human hearts, magnification 1X). Sections denoted by * and ** represent samples taken from the same donor at a plaque free and plaque containing sites

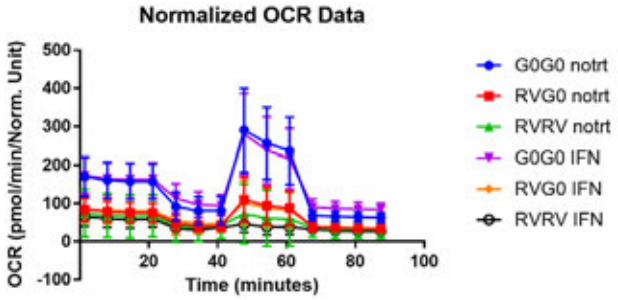

Figure 2. Representative mitochondrial oxygen consumption rate tracings by macrophage genotype and condition.

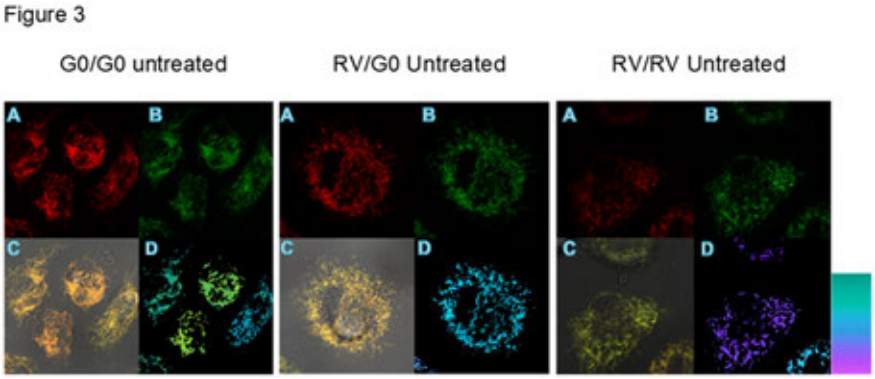

Figure 3. Representative montages of cells by genotype: A. MitoProbe Polarized mitochondria, B. MitoTracker All mitochondria, C. Composite Image. D. Masked Images showing MitoProbe/MiTotracker ratios.

test mitochondrial respiration, cultured HC macrophages were left untreated or IFNɣ treated, and bioenergetics were measured by the Seahorse assay. Confirmatory fluorescent microscopy was done by staining cells with Mitoprobe (polarized mitochondria) and Mitotracker (all mitochondria) and the ratio of Mitoprobe to Mitotracker staining was quantified using ImageJ software.

Results: Across the genotypes,hY3 and IFNɣ increased APOL1 mRNA expression 29.1±18.4 and 31.6±14.9 fold compared to untreated ($p< 0.001$ in each). In SLE monocytes, APOL1 significantly correlated with Siglec1 expression ($R=0.64$; $P=0.005$). APOL1 stained 4% of non-plaque containing and 18% of plaque-containing coronary arteries ($p=0.05$). APOL1 was apparent in multiple cell types including invading tissue macrophages (fig1). On the seahorse assay, there were genotype-dependent differences in Basal OCR (BO pmol/min), Spare Capacity (SC pmol/min), and total ATP production (ATP pmol/min) (G0/G0: BO: 99.4±11.3, SC:150.9±16.6, ATP: 88.1±9.5; RV/G0: BO: 46.1±4.5, SC: 52.1±8.8, ATP: 40.7±3.4; RV/RV: BO: 46±17.4, SC: 14.9±11.6, ATP: 36.7±9.5 each $p< 0.001$). Across genotype, these values fell with IFNɣ (G0/G0: BO: 73.9±6, SC: 129.4±17.3, ATP: 67.6±5.4; RV/G0: BO: 46±5.1, SC: 27.9±8.1, ATP: 39.5±3.9; RV/RV: BO: 42.1±8.6, SC: 9.5±8.3, ATP: 35.8±6.9) (fig2). Fluorescent microscopy confirmed findings with the mean respective MitoProbe/Mitotracker ratios in G0/G0, RV/G0, and RV/RV macrophages at rest 1.5±0.5, 0.86±0.3, and 0.89±0.3 and with IFNɣ 1.3±0.4, 0.74±0.3, and 0.6±0.2 (fig3).

Conclusion: Inflammation both in vitro and in vivo due to hY3, IFNɣ, and ischemia increase macrophage APOL1 expression across genotypes. In RV carrying macrophages, this results in diminished mitochondrial energy production—a potential underpin of variant-mediated toxicity.

Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have shown that therapeutic response in juvenile idiopathic arthritis (JIA) is a non-linear process invloving reorganization of gene expression networks. However, our earlier studies were performed on whole blood and neutrophils. Detailed descriptions of the lymphoid compartment have not been published. We undertook this study to gain a better understanding of treatment response in JIA using transcriptome analysis of peripheral blood CD4+ T cells.

Methods: This was a cross-sectional study of children with polyarticular, RF-negative JIA, who ranged in age from 5-13 years. Subjects included 12 patients with active disease on therapy with methotrexate (MTX) and etanercept (ADT), 10 patients also on MTX and etanercept who met crieria for clinical remission on medication (CRM),and 10 healthy control children (HC). CD4+ T cells were obtained from peripheral blood by positive selection and RNA purified and cDNA libraries prepared using conventional appproaches. Libraries were sequenced using 100 base pair (bp) paired-end reads on the Illumina HiSeq 2500 platform. We used standard statistical approaches to identify differentially expressed genes, and gene ontology (GO) analysis to identify common functional properties among groups of differentially expressed genes.

Results: We identified 4062 genes that were differentially expressed between ADT and HC, 3454 genes that demonstrated expression differences between ADT and CRM, and 22 genes that were expressed differently between HC and CRM. These findings differ from what we have seen in neutrophils, where transcriptional profiles of children who have achieved CRM differ significantly from those of HC. We next plotted all differentially expressed genes called between any pair of sample groups and used k-means clustering to group genes into gene clusters. We identified 5 distinct subgroups, representing different cellular functions. Cluster 1, which was characterized by increased expression in HC and CRM compared to ADT, was involved in metabolic processes. Clusters 2 and 4, representing genes that showed higher expression in the ADT group compared the HC and CRM groups, were enriched for genes involved in transcription and translation, indicating that in the active disease state, CD4+T-cells were more active in their transcriptional and translational processes. Cluster 3, which was characterized by higher expression in HC samples compared to CRM or ADT samples, was enriched for genes involved in immune activation and may represent genes that are suppressed by treatment. Cluster 5 contained genes that showed a wide variety of expression patterns across the samples but show a general increase in expression in the ADT samples compared to the CRM and HC samples; this cluster was represented by genes involved in RNA processing and RNA metabolism.

Conclusion: CD4+ T cells undergo significant re-organization of their transcriptional repertoires over the course of therapy. This re-organization involves fundamental cellular processes such as metabolism and the processing of RNA transcripts. Further research to determine whether these changes are necessary for or merely associated with therapeutic response is warranted.

Genes Associated with Nucleotide Oligomerization Domain-Like Receptor Signaling Pathway Are Upregulated in Discoid Lupus Erythematosus

Irene Calderon ,[1] Inhan Lee,[2] and Rina Mina[3], [1]SCDS, Cincinnati, OH, [2]mcore, Ann Arbor, MI, [3]University of Cincinnati, Cincinnati

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Discoid Lupus Erythematosus (DLE) is disfiguring autoimmune skin disorder, associated with defects in the adaptive immune system. The innate immune system is likely involved as seen in the presence of interface dermatitis, observed in viral exanthem, and improvement of DLE using inhibitors to membrane-bound Pattern Recognition Receptors (PRR).

Hypothesis: Genes associated with defects in the innate immune system would be upregulated in DLE skin compared to normal controls.

Methods: Datasets selected from the Gene Expression Omnibus (GEO), GSE109248, GSE81071, GSE52417, GSE95474, and GSE72535 were analyzed using GEO2R to compare the gene expressions between DLE and normal controls. Search Tool for the Retrieval of Interacting Genes/Proteins (STRING) database, Gene Card, and Kyoto Encyclopedia of Genes and Genomes (KEGG) Pathway analysis were used to identify the interaction and function of specific genes.

Results: There were a total of 54 DLE skin samples and 37 normal controls. Genes associated with the Nucleotide Oligomerization Domain-Like Receptor (NLR) signaling pathway were consistently differentially expressed in DLE skin samples in all datasets (p-value < 8.74e-05). Five genes associated with the NLR signaling pathway, STAT1, OAS1, OAS2, OAS3, and AIM2, were found to be upregulated in skin samples of DLE patients compared to normal controls in all datasets. These five genes are associated with transcription activation, regulation of viral infection, and interferon response.

Table 1. Gene Functions, Source: Gene-Cards

Gene	Function	Relevance to Study
STAT1 (Signal Transducer and Activator of Transcription1)	Mediates cellular responses to interferons (IFNs), cytokines, and growth factors. Transcription activators of IFN-stimulated genes	Acts dysfunctionally in systemic lupus (SLE), related to DLE. IFN signature in monocytes in SLE is upregulated compared to normal
OAS (2'-5'-Oligoadenylate Synthetase) 1,2,3	Induced by IFNs. OAS 1 and 3 activate RNase L by catalyzing the 2', 5' oligomers of adenosine, which results in viral RNA degradation and the inhibition of viral replication. Related pathway: Toll-like Receptor (TLR) Signaling Pathway	Related to IFN-1. Isoforms may be suggestive of disease activity in SLE patients
AIM2 (Absent In Melanoma 2)	May control cell proliferation. Related pathway: TLR Signaling Pathway	Closely correlated with severity of disease in SLE patients. Upregulated in aberrantly activated macrophages

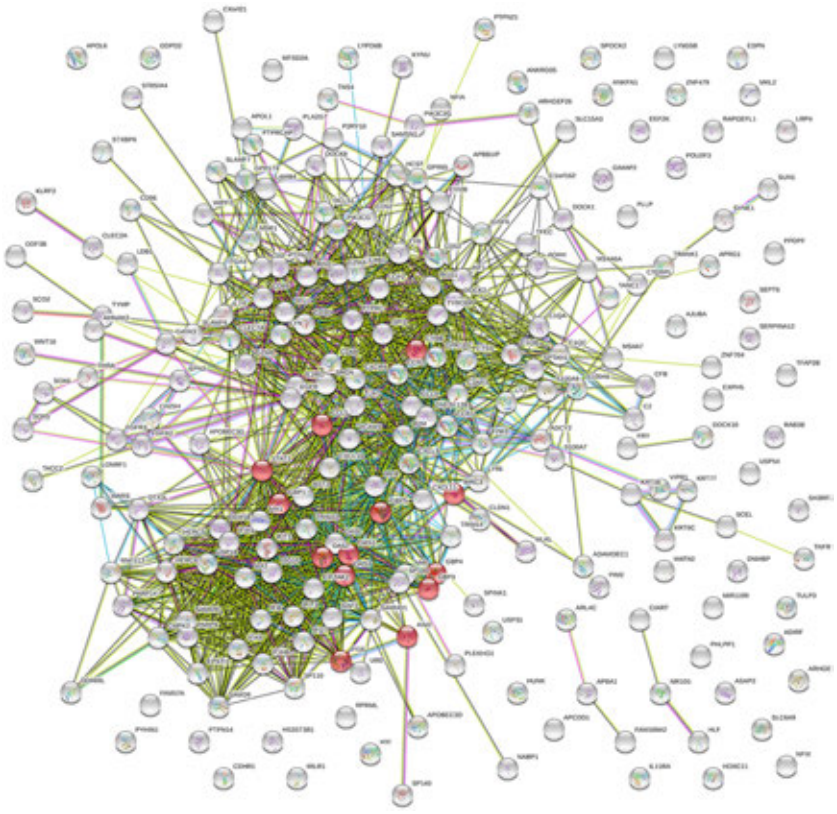

Image 1. NOD-Like Receptor Genes From GSE 81071

Conclusion: Genes associated with the NLR signaling pathway are differentially expressed in the skin of DLE patients compared to normal controls, supporting the role of the innate immune system in DLE. Further validation studies using experimental methods are needed.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

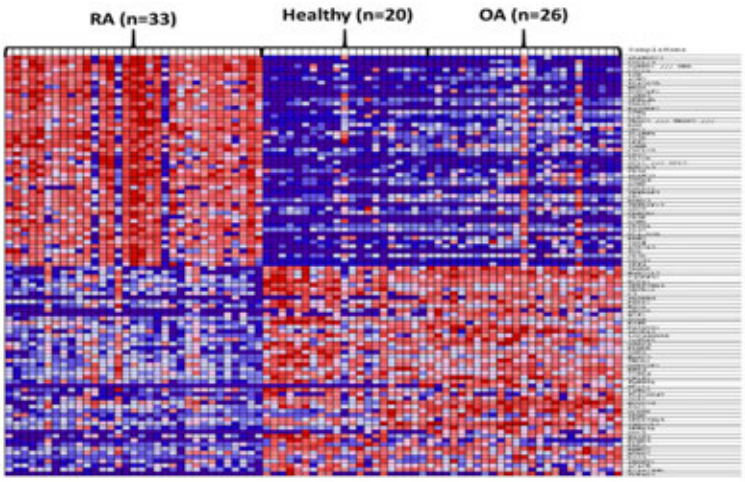

Figure 1. GSEA analysis on combined publicly available datasets (GSE55235, GSE55457, GSE55584) of synovium transcriptomic profiling showing the top 100 differentially expressed genes between RA (n=33), OA (n=26) and healthy controls (n=20). The figure was generated using GSEA software (http://software.broadinstitute.org/gsea)

Background/Purpose: Rheumatoid arthritis (RA) is one of the most prevalent autoimmune and prototypic inflammatory diseases. It is a heterogeneous autoimmune disease with local and systemic features. The molecular triggers for the synovium transition from healthy to inflammatory and then to rheumatoid arthritis are still not clearly defined. Recently, studying synovial tissue in RA is gaining more attention in order to have a better understanding of the early stages of the disease. Transcriptomic profiling of synovial samples is a promising approach to identify reliable biomarkers, assess the effects of medical interventions, and predict the outcomes. One limitation of such an approach is the masking effect of the local gene expression signature by the infiltrating immune cells, thus making it difficult to distinguish the trigger from the consequence. We aimed to establish a combined bioinformatical approach using in house pipeline to process, filter, and combine microarray transcriptomic data to identify novel synovium related biomarkers. The filtered transcriptomic profile was tested by ESTIMATE R package (Estimation of Stromal and Immune cells in MAlignant Tumor tissues using Expression data) to estimate the difference in immune cells infiltration in healthy, Osteoarthritis (OA) and RA.

Methods: Gene expression profile of synovial tissue from 33 RA, 26 OA, and 20 healthy controls from three datasets (GSE55235, GSE55457, GSE55584) were extracted using the Gene Expression Omnibus (GEO) public repository. Raw cell files were re-analyzed using in house pipeline for normalization and variant filtration. Gene Set Enrichment analysis was used to identify genes that are differentially expressed (DEG) between the three groups, as shown in Figure 1.

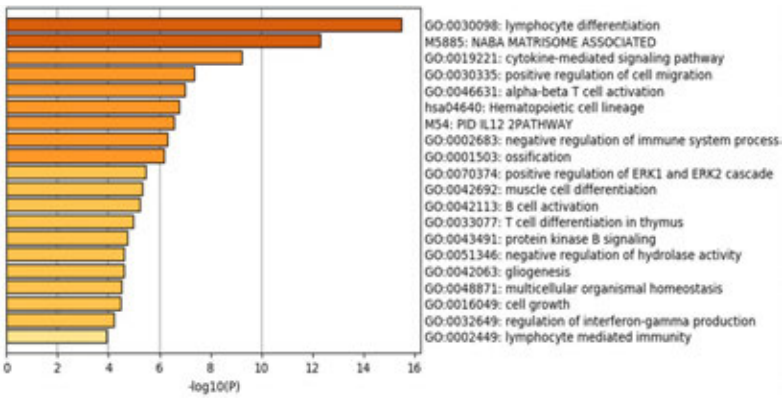

Figure 2. Top pathway enrichment for the top 100 Differentially expressed genes in RA synovium compared to OA and healthy controls. The figure was generated using metascape online tool (http://metascape.org)

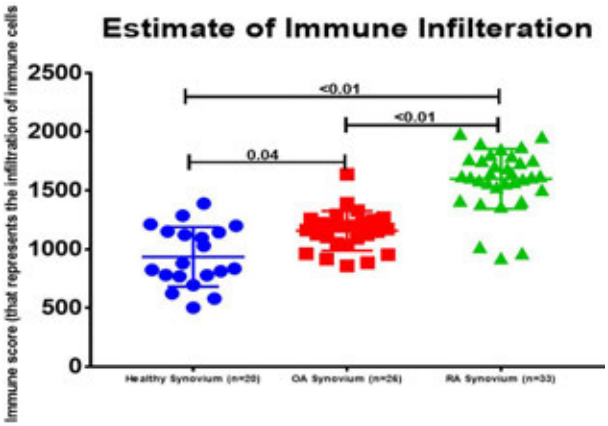

Figure 3. Using the transcriptomic profiling to estimate the infiltration of immune cells in synovium using ESTIMATE tool (https://bioinformatics.mdanderson.org/public-software/estimate/).

Results: In comparison to OA and healthy controls, RA synovium showed significant enrichment for immune-related pathways namely: lymphocytes differentiation, aβT cell activation, IL12 pathway, B cell activation, T cell differentiation, regulation of interferon-gamma production and lymphocytes mediated immunity, Figure (2). The most immune-related genes significantly altered in RA were chemokines (CXCL13, CXCL9, CCR2, CXCL10, XCL1, XCL2, and CXCL11), interleukins (IL7R, IL21R, IL32, and IRF4), and B cell related (TPD52, SLAMF8, IGHM, CD27, CD79A). Interestingly, NK related gene NKG7 (natural killer cell granule protein 7) was significantly upregulated in RA patients. Using ESTIMATE, it was shown that RA synovium contains more infiltrating immune cells than OA or healthy synovium, Figure (3). Healthy synovium contained the highest nonimmune cells (64±5%), compared to OA (58±2%), and RA (52±3%). One of the identified biomarkers to be synovium specific marker is CXCL13, a potent homing chemoattractant for B lymphocytes. CXCL13 was shown previously to be upregulated in RA synovium and can predict the recruitment of Follicular Dendritic Cells and synovial germinal centers formation, pathognomonic features in RA.

Conclusion: Using proper bioinformatical analysis of the synovium in RA to identify synovium specific biomarkers that are not masked by infiltrating immune cells may pave the way for understanding the molecular basis of RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Susceptibility genes which can account for the characteristic features of systemic sclerosis (SSc) such as fibrosis, vasculopathy and autoimmunity remain to be determined. A series of extensive studies by Asano and colleagues using genetically engineered mice convincingly demonstrated that deficiency of a transcription factor Fli1 can play a causal role in the development of SSc with all these characteristic features. Although previous genome-wide association studies (GWAS) have not reported association of single nucleotide polymorphisms (SNVs) in the *FLI1* gene, *FLI1* contains $(GA)_n$ microsatellite in its regulatory region, which has been shown to be associated with expression level of FLI1. Because microsatellite polymorphisms are not usually captured by GWAS unless they are in tight linkage disequilibrium with SNVs, we thought it is possible that *FLI1* microsatellite may partly account for the "missing heritability" of SSc. In this study, we directly genotyped *FLI1* $(GA)_n$ microsatellite and examined whether it is associated with susceptibility to SSc.

Methods: Genomic DNA from 639 Japanese SSc patients and 851 healthy controls (HCs) was genotyped for $(GA)_n$ microsatellite using the fragment assay. In the discovery stage, the genotype distribution was compared between 479 patients and 573 HCs, and the cut-off repeat number for the susceptibility to SSc was determined by receiver operating characteristic (ROC) analysis to classify the alleles into L (long) and S (short) alleles. In the replication stage, 160 patients and 268 HCs were examined, and the data from both stages were combined using meta-analysis. Association with susceptibility and clinical characteristics was examined using logistic regression analysis with the adjustment for sex. *FLI1* mRNA levels were determined using quantitative RT-PCR.

Results: In the discovery stage, genotype distribution of the $(GA)_n$ microsatellite alleles in SSc patients showed a trend towards extension as compared with that in the HCs (Cochran-Armitage test for trend, P=0.045)(Figure 1). Based on the ROC analysis, (GA)n alleles with ≥22 repeats were collectively defined as L alleles, and alleles with ≤21 repeats as S alleles. The same trend was observed in the discovery and replication stages, and when combined, $(GA)_n$

Table 1. Case-control study of *FLI1* $(GA)_n$ microsatellite with systemic sclerosis

	n	Genotype frequency L/L	L/S	S/S	Allele frequency L	Additive model (L vs S) P	OR (95%CI)	power*
Discovery stage								
SSc	479	66 (0.138)	227 (0.474)	186 (0.388)	359 (0.375)	**2.0E-03**	**1.37 (1.12-1.67)**	0.945
HCs	593	58 (0.098)	252 (0.425)	283 (0.477)	368 (0.310)	referent		
Replication stage								
SSc	160	34 (0.213)	68 (0.425)	58 (0.362)	136 (0.425)	0.10	1.27 (0.96-1.70)	0.386
HCs	258	33 (0.128)	118 (0.457)	107 (0.415)	184 (0.357)	referent		
Meta-analysis						**5.0E-04**	**1.34 (1.14-1.58)**	

L alleles: $(GA)_{22}$ or longer alleles, S:alleles: $(GA)_{21}$ or shorter alleles.
SSc: systemic sclerosis, HCs: healthy controls, OR: odds ratio, CI: confidence interval.
Comparisons with P<0.05 are shown in bold.
*Power to detect statistical association at the significance level of 0.05.

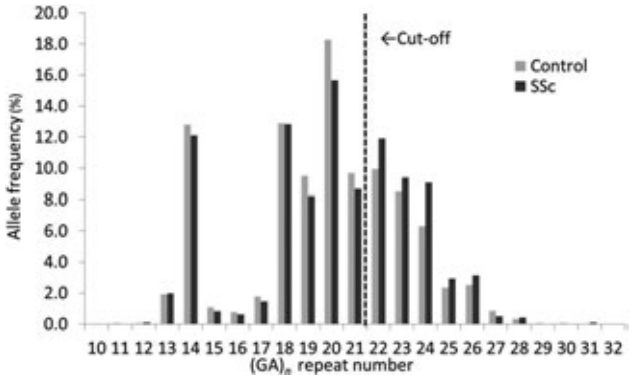

Figure 1. Distribution of FLI1 (GA)n microsatellite alleles in the patients with systemic sclerosis and healthy controls in the discovery stage. X and Y axes show the repeat number and allele frequency (%) of FLI1 (GA)n microsatellite, respectively. The distribution in SSc patients was significantly shifted to extended alleles when compared with healthy controls (Cochran-Armitage test for trend, P=0.045). The dotted line shows the cutoff value for the susceptibility to SSc derived from the receiver operating characteristic (ROC) analysis

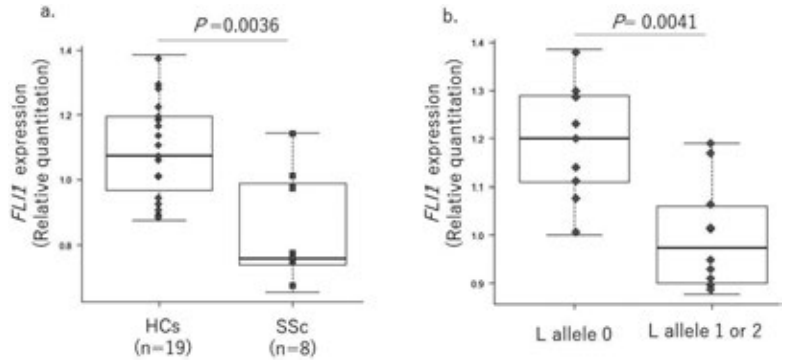

Figure 2. FLI1 mRNA expression in whole peripheral blood. The band and quartiles in the boxplot diagrams indicate median (Q2) and interquartile range (IQR) of FLI1 mRNA expression levels. P values were calculated by Mann-Whitney U-test. (a) Patients with SSc and HCs (all genotypes combined). HCs: n=19, Q2=1.07, IQR=0.23. SSc: n=8, Q2=0.76, IQR=0.24. (b) Healthy controls carrying (L alleles 1 or 2) and not carrying (L allele 0) (GA)n L alleles. (L allele 0: n=9, Q2=1.20, IQR=0.18, L allele 1or 2: n=10, Q2=0.97, IQR=0.14.)

L alleles were significantly associated with susceptibility to SSc (P=5.0E-04, odds ratio[OR]=1.34, 95% confidence interval 1,14-1.58, additive model)(Table 1). Significant association was observed both in diffuse cutaneous and limited cutaneous SSc. Among the SSc, $(GA)_n$ L alleles were significantly enriched in the patients with modified Rodnan total skin thickness score (mRSS)≥10 compared with those with mRSS< 10 (P=9.6E-03, OR=1.63). *FLI1* mRNA level in the whole blood was significantly reduced in SSc patients when compared with HCs(Figure 2a). When the mRNA levels were compared between the carriers and non-carriers of $(GA)_n$ L alleles among HCs, significant reduction was observed in individuals carrying $(GA)_n$ L allele (Figure 2b).

Conclusion: *FLI1* $(GA)_n$ microsatellite alleles with extended repeat numbers were associated with lower *FLI1* mRNA levels and susceptibility to human SSc.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Epidemiology of ANCA-associated vasculitis (AAV) is substantially different between East Asian and European populations. Microscopic polyangiitis (MPA) and MPO-ANCA positive AAV (MPO-AAV) are prevalent in Japan, while granulomatosis with polyangiitis (GPA) and PR3-ANCA positive AAV (PR3-AAV) are dominant in Europe. In addition, high prevalence of interstitial lung disease (ILD), a severe complication and a prognostic factor in AAV, is a striking feature in the Japanese population, suggesting a role for genetic background in the development and clinical features of AAV.

A proportion of patients with idiopathic pulmonary fibrosis (IPF) are positive for MPO-ANCA, and some of these patients develop MPA, suggesting that ILD in AAV and IPF may share some pathogenic processes. Recently, we reported that 5% of MPO-AAV patients with ILD carry *MUC5B* single nucleotide variant (SNV) rs35705950T, the risk allele for IPF, as compared with 1% among healthy controls, indicating that *MUC5B* is a shared susceptibility gene between IPF and MPO-AAV associated ILD (Namba et al, Ann Rheum Dis 2019). However, the allele frequency of rs35705950T

Table 1. Association of AAV subphenotypes with *TERT* and *DSP*

DSP rs2076295	total allele count	G allele	P (ILD+ vs. ILD-)	Pc	OR	95%CI
MPO-AAV with ILD	306	169 (0.552)	0.91	0.91	1.02	(0.75-1.37)
MPO-AAV without ILD	396	217 (0.548)				
			P (vs. HCs)	Pc	OR	95%CI
MPO-AAV	820	445 (0.543)	0.0026	0.0086	1.25	(1.08-1.44)
PR3-AAV	130	75 (0.577)	0.043	0.087	1.43	(1.01-2.03)
MPA	630	346 (0.549)	0.0029	0.0086	1.28	(1.09-1.51)
GPA	212	115 (0.542)	0.12	0.20	1.25	(0.95-1.64)
EGPA	136	73 (0.537)	0.26	0.34	1.22	(0.87-1.71)
HCs	8788	4286 (0.488)				

is much lower in general Japanese population as compared with European populations, and does not account for high prevalence of ILD in Japanese AAV. In this study, we performed association study of other IPF susceptibility genes, *TERT* and *DSP*, to examine whether these are associated with ILD in AAV patients.

Methods: The members of Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS) and Research Committee of Progressive Renal Disease, Ministry of Health, Labour, and Welfare of Japan contributed to this study.

Five hundred and twenty-three patients including 315 MPA, 108 GPA, 68 eosinophilic granulomatosis with polyangiitis (EGPA) and 32 unclassifiable AAV (412 MPO-ANCA positive [MPO-AAV] and 66 PR3-ANCA positive [PR3-AAV]) and 4394 controls were examined. Among MPO-AAV, 163 were positive for ILD and 264 were negative. Genotyping for *TERT* rs2736100 and *DSP* rs2076295 was performed by TaqMan SNP Genotyping Assays. Association was tested by chi-squared test.

Results: Allele frequencies of *TERT* rs2736100A and *DSP* rs2076295G were not significantly different between MPO-AAV with ILD and MPO-AAV without ILD (Table 1). However, when the association of *TERT* was tested in MPO-AAV regardless of the presence/absence of ILD, rs2736100A was significantly increased in MPO-AAV as compared with healthy controls (P=4.3E-05, Pc=5.2E-04, odds ratio [OR] 1.37). This association was also observed in MPA (P=2.2E-04, Pc=0.0013, OR 1.38). Similarly, *DSP* rs2076295G is increased in MPA (P=0.0029, Pc=0.0086, OR 1.28) and MPO-AAV (P=0.0026, Pc=0.0086, OR 1.25) as compared with healthy controls. Other AAV phenotypes were not significantly associated with both SNVs after correction for multiple testing, although a trend for association was observed between EGPA and *TERT* and between PR3-AAV and *DSP*.

Conclusion: *TERT* and *DSP* SNVs were found to be associated with MPO-AAV and MPA for the first time. These results suggest that some susceptibility genes to IPF may be associated with AAV regardless of the presence of ILD.

Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Monoclonal antibodies against CTLA-4 and PD-1 have revolutionized the field of immuno-oncology over the past decade. These therapies however are limited by immune related adverse events (irAEs) that can affect nearly every organ system. Inflammatory arthritis (irIA) is a common well-recognized irAE, but with a poorly understood pathophysiology that results in limited targeted treatments. Mechanistic insight into disease pathogenesis has been hampered by the lack of animal models, as mice treated with these drugs do not develop significant irAEs. We thus designed a translational study using human samples focused on identifying distinct cells types, and critical signaling pathways involved in promoting irIA.

Methods: We have established a specialty clinic that provides comprehensive clinical evaluation and long-term follow up of patients with suspected rheumatological irAEs. This clinic also enables serial sample collection of synovial fluid and matched blood samples at the time of the patient's first rheumatologic assessment and, when possible, serially before and after the initiation of immunosuppressive therapy. To define distinct cell populations that might be driving irIA pathogenesis and could be used as a diagnostic marker, we leveraged 10X Genomics droplet-based single-cell RNA-sequencing strategies that do not require an *a priori*knowledge of the specific cell populations or signaling components involved. Single-cell TCR analysis was performed in parallel on the same samples using the VDJ enrichment strategy.

Results: Approximately, 25,000 single cells from the synovial fluid of 5 patients with different irIA clinical phenotypes were analyzed. Findings shows that synovial fluid is highly heterogenous in composition and includes diverse

populations of myeloid and dendritic cells in high proportions. Furthermore, distinct CD8+ cytotoxic T cells across disease phenotypes were expanded. Paralleled single T cell receptor analyses identified diverse clonotypes within these expanded lymphocyte subsets, as well as clonotypic expansion within specific cytotoxic CD8+ populations across patients.

Conclusion: Our systems-level approach provides a better understanding of the biological basis of irIA. Importantly, because irIA provides a model to study mechanisms of immune-tolerance, we believe that our translational effort also represents a unique opportunity to study proximate events leading to autoimmunity in humans.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Genetic studies of common variants in scleroderma (systemic sclerosis, SSc) have identified several susceptibility loci increasing SSc risk. Most of these common variants are in the non-coding region and

Table 1. SKAT of the top 10 genes with functional variants in overall SSc

Chromosome	Gene Name	SKAT P-value	SKAT P-value$_{Corr}$	# Markers Used
6	NOTCH4	0.00099	0.032	49
12	SOX5	0.007	0.22	9
6	HLA-DQB1	0.01	0.3	33
6	HLA-DPA1	0.01	0.3	36
6	HLA-DRB1	0.01	0.3	2

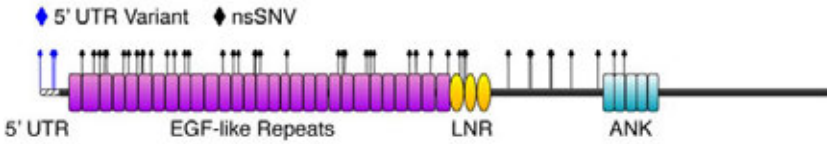
6	HLA-DQA1	0.05	1	29
6	PRDM1	0.05	1	25

Figure 1. Schematic of NOTCH4 gene and the SSc associated variants



thus have a relatively minor effect size and are not able to fully account for the heritability of SSc. The risk accorded by rare and functional variants is presumed to be higher and could be part of the missing heritability.

Methods: We selected all SSc-associated loci at p-value< 0.00001 from the GWAS catalog, an NHGRI-EBI catalog of published genome-wide association studies and genes identified in candidate gene studies that were independently replicated. 26 genes were selected and sequenced using next generation sequencing technology in 379 SSc patients and 411 unaffected controls of Africa. Variants were selected for testing if they were missense, splice site or InDels and based on CADD score < 15 for synonymous and UTR variants. Association testing was performed using sequence kernel association test (SKAT). Significance threshold for p-value (P) was set at P< 0.002 after Bonferroni's multiple testing correction.

Results: After multiple testing correction only *NOTCH4* (Neurogenic Locus Notch Homolog Protein 4) gene was statistically significantly associated with SSc (P=0.00099, P_{corr}=0.03) with an increased burden of functional variants (Table1). We used CMC test to confirm the *NOTCH4* association and the P remained significant (CMC P=0.01, 100000 permutations). Majority of the variants were present on the extracellular domain of NOTCH4 (Figure 1). On comparing the phenotypic subsets of SSc, the *NOTCH4* association was strongest in the diffuse skin subset (P=0.001) and interstitial lung disease subset of SSc (P=0.0003).

Conclusion: Aggregation of functional variants in genes previously implicated with SSc provides new approaches to understand SSc pathogenesis. Understanding the functional role of these *NOTCH4* functional variants will increase our understanding of SSc and SSc-associated interstitial lung disease.

Contribution of *MOCS* on Xanthinuria Type III and Its Clinical Significance for Screening

Sung Kweon Cho ,[1] and Blanka Stiburkova[2], [1]NCI, Frederick, MD, [2]Institute of Rheumatology; Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic, Prague, Czech Republic

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Xanthinuria is a rare inherited disorder of purine metabolism (1 in 69,000). In the first step, determination of serum and urinary uric acid and purine profile is

important to establish the diagnosis of xanthinuria. Second, xanthinuria is typed using urinary metabolomics. Finally, the results are confirmed by molecular genetics.[1] Here, we aimed to identify genetic variants in the xanthiuria patient using whole-exome sequencing (WES) and evaluated its functional variants.

To distinguish the types of HX, allopurinol loading test and invasive intestinal or liver biopsy have been traditionally used because XDH/XO activity in humans is expressed only in the small intestine and liver.

Methods: 43-year-old female (Roma ethnic group) visited the outpatient clinic. She was diagnosed as xanthinuria based on biochemical lab data (serum uric acid 70 μmol/L, FE-UA: 8.6%, urinary hypoxanthine 52.6 mmol/molCr and urinary xanthine 186.3 mmol/molCr). Conventional genotyping of *XDH*/*XO*, *AOX* and *MOCOS* does not find the causal variant. WES and corresponding downstream analyses were performed for the discovery of coding causal variants further evaluation and we compared the result to WES of 31 hypouricemia patients in Korean.

Results: Considering its prevalence and recessive inheritance, 34 candidate variants were identified after filtering out allele frequency threshold in Non-Finish European. Based on known gene list, homozygote mutation of p.Leu19Phe in *MOCS2* (MIM : 603708) was identified for the causal variants. Functional prediction tool indicated that the variants was found to be damaging (0.58, Polyphen2), disease causing (0.686, Mutation Taster) and CADD score of 16.62.

After investigating 31 hypouricemic Korean patients for the replication, we found a truncating p.Arg132* variant of *MOCS1* (MIM: 603707) in patients who have homozygous variants of *SLC22A12.*

Conclusion: This shows the value of *MOCS* genes for xanthinuria for the first time. Early genetic identification may prevent acute kidney injury or nephrolithiasis.

Pleiotropy of Systemic Lupus Erythematosus (SLE) Risk Alleles: Association with Increased Risk for Type 1 Diabetes (T1D) Complications Through a *PTPN22* Polymorphism

Vivian Kawai ,[1] Mingjian Shi,[1] Qiping Feng,[2] Cecilia Chung,[1] Ge Liu,[2] Nancy Cox,[2] Dan Roden,[2] C. Michael Stein,[1] and Jonathan Mosley[2], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE have increased risk of cardiovascular events and a higher prevalence of metabolic conditions compared to the general population. Inflammation is a strong component of the pathogenesis of SLE, cardiometabolic disorders, and other autoimmune diseases; thus, we examined the hypotheses that genetic predisposition to SLE may increase the risk for: 1) cardiometabolic outcomes and 2) other autoimmune diseases.

Methods: To test these hypotheses, we selected 47 independent SNPs ($R^2 < 0.10$) in 36 loci with significant associations with SLE ($P < 5x10^{-8}$) in the largest genetic study performed in Caucasians. In the Vanderbilt DNA biobank (BioVU), forty-one SNPs had a call rate ≥ 95% and were used to construct a weighted genetic risk score (wGRS) for SLE to: 1) test its association with 9 cardiometabolic disorders (Table 1) and 2) examine the relationship between the wGRS and all phenotypes present in 29,892 Caucasian patients in a global phenome wide association study (PheWAS) adjusting for median age in the electronic health record, sex, and 5 principal components. A P-value ≤ 0.006 was considered significant for the 9 selected cardiometabolic diseases, and a false discovery rate (FDR) < 0.1 was used in the global PheWAS. In addition, a set of independent SLE-associated SNPs ($R^2 < 0.05$) was used to perform a two-sample inverse-variance weighted regression (IVWR) meta-analysis using publicly available summary statistics

Table 1. Association of the wGRS for SLE with 9 clinical diagnosis (or proxies) using a PheWAS and IVWR approach

Figure 1. Clinical diagnoses associated with a wGRS for SLE

for the 9 cardiometabolic phenotypes of interest (or proxies). Egger regression was performed to test for horizontal pleiotropy with phenotypes in which the IVWR analysis was significant.

Results: There was no significant association between the SLE wGRS and the 9 selected cardiometabolic phenotypes (all P values >0.006, Table 1). In the global PheWAS the wGRS was associated with several autoimmune phenotypes including SLE (OR 1.6, $P=2x10^{-22}$), systemic sclerosis, hypothyroidism, Grave's disease, rheumatoid arthritis, and several T1D phenotypes (Fig. 1). The IVWR analyses comparing the genetics of SLE with that of the 9 selected phenotypes was significant for T1D (P=0.028, Table 1; Fig. 2). In the Egger analysis, the intercept term of the regression was not significant (P=0.49) suggesting no horizontal pleiotropy between SLE and T1D. Exclusion of the SLE-variant rs2476601, a SNP in *PTPN22*, in the T1D analysis (Fig. 2) attenuated the results of the IWVR analysis (P=0.06).

Conclusion: We found evidence suggesting pleiotropy between genetic predisposition for SLE and several autoimmune disorders as well as diabetic retinopathy and nephropathy. In the IVWR analysis, genetic predisposition to SLE was associated with increased risk of T1D, in part through a common missense variant in *PTPN22* known to be associated with several autoimmune phenotypes.

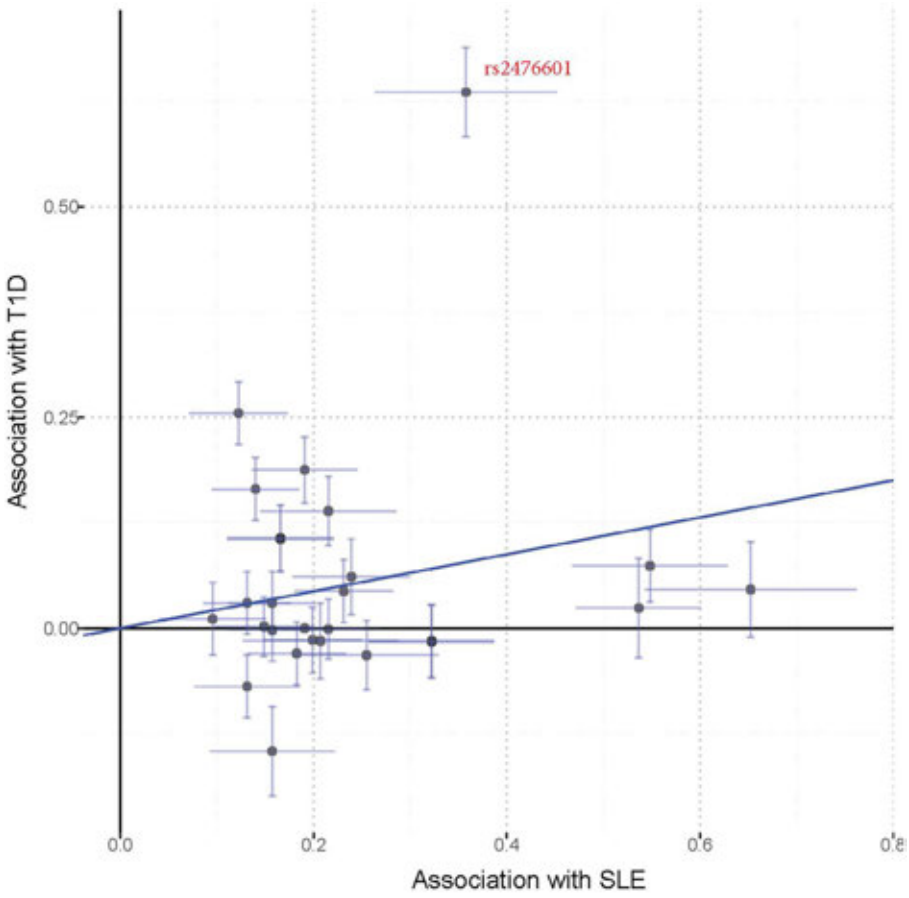

Figure 2. Scatter plot comparing the association between the genetic predisposition for SLE and the risk for T1D for 27 SNPs significantly associated with SLE in Caucasians.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disorder that is associated with increased risk of cardiovascular disease, cardiometabolic disorders, and autoimmune disease. Thus, we examined the hypothesis that genetic predisposition to RA increases the risk for cardiovascular disease, cardiometabolic disorders, and other autoimmune disorders.

Methods: To test this hypothesis, we selected 102 independent SNPs ($R^2 < 0.10$) that were significantly associated with RA ($P < 5x10^{-8}$) in the largest transethnic meta-analysis published. In the Vanderbilt DNA biobank (BioVU), ninety-five SNPs had a call rate ≥ 95% and were used to construct a weighted genetic risk score (wGRS) for RA to: 1) test its association with 9 cardiometabolic disorders (Table 1) and 2) perform a global phenome wide association study (PheWAS) examining the relationship between the wGRS and all phenotypes present in 29,892 Caucasian patients adjusting for median age in the electronic health record, sex, and 5 principal components. A P-value ≤ 0.006 was considered significant for the 9 selected cardiometabolic diseases and a false discovery rate (FDR) < 0.1 was used in the global PheWAS. In addition, a set of independent RA-associated SNPs ($R^2 < 0.05$) was used to perform a two-sample inverse-variance weighted regression (IVWR) meta-analysis using publicly available summary statistics for the 9 cardiometabolic phenotypes of interest (or proxies). Egger regression was performed to test horizontal pleiotropy with phenotypes in which the IVWR analysis was significant.

Results: Among the 9 cardiometabolic phenotypes selected, the wGRS for RA was significantly associated with type I diabetes (T1D) ($P=9.82x10^{-4}$, Table 1). In the global PheWAS, the wGRS was associated with increased risk for several autoimmune phenotypes including RA (OR=1.41, $P=1.54x10^{-27}$), thyroiditis, systemic sclerosis, and T1D phenotypes, and with protection against multiple sclerosis and demyelinating disorders (Fig. 1). In the IVWR analysis, RA was significantly associated with type 2 diabetes (T2D) ($P=4.04x10^{-4}$, Table1), but the association was abrogated when an RA SNP in the HLA region (rs9268839) was excluded from the analysis (P=0.133). T1D was also significantly associated with RA in the IVWR analysis ($P=1.93x10^{-10}$, Table 1, Fig. 2) with the Egger intercept term suggesting horizontal pleiotropy (P< 0.001). When rs2476601 (an RA SNP in *PTPN22*) was excluded, the IVWR analysis remained significant ($P=1x10^{-4}$) and the intercept term in the Egger regression no longer showed evidence of horizontal pleiotropy (P=0.611).

Conclusion: We found evidence suggesting pleiotropy between genetic predisposition for RA and several other autoimmune disorders including T1D. The IVWR analysis showed that genetic predisposition to RA was associated with increased risk of T1D, even after the exclusion of a common variant in *PTPN22* known to be associated with different autoimmune disorders.

Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a need to identify the rapid progressive phenotype of Osteoarthritis (OA). Our aim is to analyze the effect of mitochondrial haplogroups in the risk of suffering rapid progressive knee OA in patients from the Osteoarthritis Initiative (OAI).

Methods: Caucasian patients from the OAI were classified into three groups based on previous criteria: i) Rapid progressors (RP), with baseline KL grade 0-I in at least one knee and increase up to KL≥III during 48 month follow-

Table 1. Regression model with two categories (Rapid vs Non-rapid pool) with all the variables influencing the rapidly progressive knee OA phenotype in Caucasian patients of the OAI

Variables	P-Value	OR	95% CI	
Gender (Female)	0,004*	1,644	1,176	2,297
Age	<0,001*	1,044	1,025	1,063

H1 (72)	0,037*	1,797	1,036	3,117
H3 (19)	0,354	1,603	0,591	4,351
H5 (14)	0,684	0,776	0,228	2,638
H* (87)	0,943	1,019	0,6	1,732

WOMAC: Western Ontario and McMaster Universities Arthritis Index; BMI: body mass index; CI: Confidence Interval; OR: Odds Ratio; H*: includes minor haplogroup H subtypes; (*): statistical significance declared at $p < 0.05$

up; ii) Non-rapid progressors (NRP), with baseline KL grade 0-I in at least one knee and increase up to KL=II during 48 month follow-up; iii) Non-progressors (NP), with KL grade 0-I at baseline in at least one knee and bilaterally stable during the 48-month follow-up period.

Also, these groups were re-categorized into two groups: Rapid and Non-Rapid (pooling NRP and NP). Once selected, we performed regression models adjusting by clinical variables including gender, age, body mass index (BMI), contralateral OA, previous injury in the target knee and total WOMAC. mtDNA haplogroups and major H sub-haplogroups

(H1, H3, H5 and H*) were previously assigned using sequencing techniques. Analysis were performed with IBM SPSS Statistics v24.

Results: We analyzed data from 2092 patients splitted on 181 RP (8,7%), 321 NRP (15,3%) and 1590 NP (76%). The comparison between RP and NP revealed that all risk factors showed significant differences, including gender (female) (OR=1,934; 95%CI: 1,377 – 2,717; p< 0,001), age (OR=1,040; 95%CI: 1,021 – 1,060; p< 0,001), BMI (OR=1,113; 95%CI: 1,073 – 1,154; p< 0,001), contralateral OA (OR=2,710; 95%CI: 1,938 – 3,773; p< 0,001), previous injury of target knee (OR=2,849; 95%CI: 2,032 – 4,000; p< 0,001) and total WOMAC (OR=1,016; 95%CI: 1,008 – 1,023; p< 0,001); however, these significant differences were also observed between NRP and NP. Regarding mtDNA haplogroups, compared with haplogroup H, the haplogroup J showed a lower frequency in the RP in relation to NP, but this difference did not reach the statistical significance (OR=0,526; 95%CI: 0,251 – 1,101; p=0,088). When the analysis included major H subtypes, sub-haplogroup H1 appeared over-represented in the RP in relation to both NP (OR=1,533; 95%CI: 0,981 – 2,934; p=0,061) and NRP (OR=1,686; 95%CI: 0,984 – 2,889; p=0,057).

A second type of analysis included the re-categorized variable and, in addition to the significant association of the classical risk factors, the sub-haplogroup H1 appeared significantly associated as a risk factor for rapid progression (OR= 1,573; 95%CI: 1,017 – 2,435; p=0,042) (Table 1). Finally, we repeated this analysis but excluding NP from the Non-Rapid pool. Age was the only significant risk factor (OR=1,061; 95%CI: 1,036 – 1,086; p< 0,001), and the sub-haplogroup H1 remained significantly associated as a risk factor for rapid progression (OR=1,797; 95%CI: 1,036 – 3,117; p=0,037) (Table 2).

Conclusion: The mtDNA haplogroups, more specifically the major sub-haplogroup H1, increase the risk of rapidly progressive OA of the knee. The assignment of this mitochondrial genetic sub-haplogroup could be useful as complementary genetic biomarker for the early identification of this OA phenotype.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome is an autoimmune thrombophillia characterized by recurrent thromboembolism and or pregrancy morbidity in the presence of antiphospholipid antibodies (aPL), which recognize either a serum apolipoprotein, known as β2glycoprotein I (β2GPI), or other PL-binding proteins such as prothrombin. Complexes of anti-β2GPI/β2GPI activate platelets, monocytes and endothelial cells, probably by activating TLR4 and

TLR6 leading eventually to NFκB and MAPK activation resulting to Tissue Factor (TF) and proinflammatory cytokine expression. Therefore, we assessed the whole transcriptome of endothelial cells that have been stimulated with anti-β2GPI/β2GPI.

Methods: Human umbilical Vein Endothelial cells (HUVECs) were isolated from 4 Healthy control women upon delivery. Healthy donor HUVEC were stimulated with IgG isolated from APS patients with high anti-β2GPI titers or IgG from healthy individuals in the presence of β2GPI. Consequently, total mRNA was isolated, cDNA libraries were created and whole transcriptome sequencing (RNASeq) was performed. Gene expression data were validated in protein levels with immunocytochemistry and immunohistochemistry in placenta tissues from APS patients and healthy individuals. Data underwent KEGG Pathway Database and Gene Ontology analysis.

Results: Whole transcriptome analysis of HUVECs stimulated with anti-β2GPI/β2GPI complexes revealed 680 differentially expressed genes, among which 377 were upregulated and 303 downregulated in the aPL treated endothelial cells. Characteristic examples of the upregulated genes are IL-6, IL-8, VCAM1, SELE and TGFB2 and TGFBR1. Bioinformatics analysis revealed that the upregulated genes belong mainly to the cytokine-cytokine receptor interaction (hsa053323), MAPK signaling pathway (hsa04010), TNF signaling pathway (hsa04668) and NOD-like receptor pathway (hsa04621). Characteristic examples of the downregulated genes include the CBX4, CBX8, BCOR and HDAC7 genes. Several proteins encoded by these genes play role in the epigenetic modification of DNA. Immunohistochemical staining on placenta biopsies from APS patients and healthy individuals for IL-6, IL-8, IL-18, NFkB, TF, TNF-a, E-SELECTIN, MAPK8, TGFB2 and TGFBR1 showed increased intensity in the signal of endothelial cells on APS specimens validating thus the RNASeq results in the tissues.

Conclusion: RNASeq of endothelial cells treated with anti-β2GPI/β2GPI reveals a thoroughly analysed proinflamatory and procoagulant phenotype. Moreover, differential expression of DNA modifying proteins suggests the possible epigenetic regulation of gene expression on endothelial cells in APS syndrome. Ongoing experiments aim to analyze histone acetylation and methylation status of the promoters of the selected genes that were shown to be differentially expressed.

as leukopenia. Our ability to predict azathioprine-associated leukopenia is limited to the evaluation of the enzyme thiopurine methyl transferase (TPMT), either by functional assays or by the identification of variants in the gene *TPMT* which encodes it. We hypothesize that a risk score composed of multiple clinical factors and variants in selected candidate genes—in addition to TPMT—could improve the prediction of azathioprine-associated leukopenia.

Methods: This is a case-control study that used de-identified records from BioVU, a clinical practice-based biobank at a tertiary medical center to identify 425 Caucasian patients who received prescriptions for azathioprine. Subjects with a leukocyte count of less than 4,000 WBC/μL while receiving prescriptions for azathioprine were classified as cases. Subjects receiving prescriptions for azathioprine who did not develop leukopenia were classified as controls.

We reviewed the clinical records, collected clinical variables (age, sex, weight, clinical indication for azathioprine use, concurrent prescription of other medications, and azathioprine daily dose) and genotyped 71 genetic candidates identified through literature and database review. Genotyping of 60 single nucleotide polymorphisms passed quality control. We built two scores using the coefficients from multivariate regressions; leukopenia was the dependent variable. The first model was a logistic regression including TMPT status, age, and sex. The second model included TPMT status, age, sex, additional clinical variables listed above, and genetic candidates. To avoid overfitting, we used ridge regression, which uses a standard cross-validated penalty to shrink the coefficients of the covariates.

Results: 216 patients had azathioprine-associated leukopenia and 209 were control subjects. Younger age, lower weight, a diagnosis of systemic lupus erythematosus or organ transplant, and being a carrier of the *TPMT* haplotype corresponding to intermediate metabolizer status were significantly associated with leukopenia (Table 1). The area under the ROC curve (AUC) of a score based on a regression that included TPMT status, age, and sex was 0.59 (95% C.I.: 0.54-0.64). After shrinkage, the ridge model included 11 clinical and 47 genetic candidates (Table 2); the AUC of the score from that model increased to 0.77 (95% C.I.:0.73-0.82).

Conclusion: This proof-of-concept study investigates the utility of adding clinical and genetic variables to TMPT to improve discrimination of the risk for azathioprine-associated leukopenia. After shrinkage, we were able to show that a combined model, including clinical and genetic variants, improved our ability to predict leukopenia. Further studies in larger populations with independent replications are needed to further develop prediction scores that are useful for routine clinical practice.

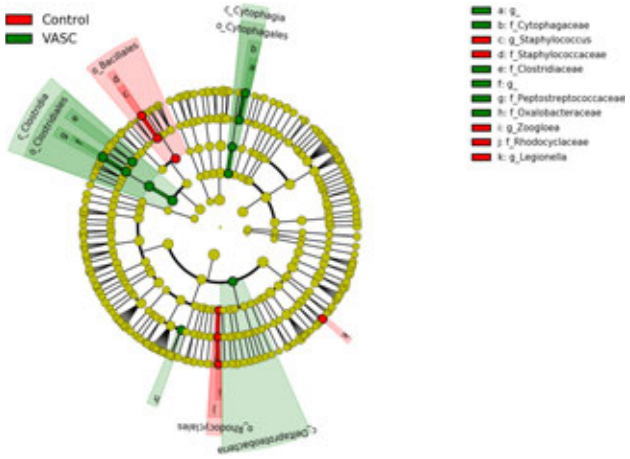
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM



Microbiome profile of TAK patients compared to HD

Background/Purpose: The pathogenesis of Large Vessel Vasculitis (LVV) is not well understood. There is increasing evidence of a close link between intestinal dysbiosis and systemic inflammatory/autoimmune diseases. Gut microbiota has never been studied in LVV. We aimed at comparing the blood microbiota profile of patients with LVV (TAK or GCA) and healthy donors (HD).

Methods: We studied the blood microbiome profile microbiota of 20 patients with TAK, 11 with GCA and 16 HD. The microbiome profile microbiota was assessed by sequencing of the 16S rDNA blood bacterial DNA. Linear Discriminant Analysis (LDA) coupled with effect size measurement (LEfSe) was used to analyse the differences in the microbiome profile between groups.

Results: TAK and GCA patients had a mean age of 45 (23.1; 70.6) and 74.5 (58; 84) years, and were of female gender in 55% and 85%, respectively. Among TAK patients 10 had an active disease and 10 were inactive; among GCA patients, 6 were active and 4 inactive. TAK patients compared to HD showed a specific blood microbiota profile with a significant higher level of the phyla Clostridia (Clostridium saudiense), Cytophagia (Pseudarcella Hirudinis) and Delta-proteobacteria (Bdellovibrio bacteriovorus particularly), whereas Bacillus and Staphylococcus were significantly more abundant in HD ($p< 0.05$) (Figure). Active compared to inactive TAK patients had significantly lower levels of Staphylococcus. TAK microbiota compared to GCA showed significant higher levels of Bacteroidia (LDA >2; $p< 0.05$). In TAK patients, differences in the blood microbiome were also associated with a shift of metabolic functions. TAK patients compared to HD showed a significant increase of porphyrin and chlorophyll pathways. Active compared to inactive TAK patients showed increase of the same pathways. GCA patients did not show a specific blood microbiota profile compared to HD, except for lower levels of Bacteroidia.

Conclusion: patients with TAK showed a specific blood microbiome profile as compared to healthy controls and GCA patients. Among TAK patients, significant changes of blood microbiome profile were found in active as compared to inactive patients, and it was associated with specific metabolic functions.

Session Date: Tuesday, November 12, 2019

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a potentially life-threatening autoimmune disease with no cure. The onset of SLE is thought to be the result of environmental events in a genetically susceptible host, yet the underlying genetic architecture of the disease is not fully understood. Pediatric SLE (pSLE) patients have early disease onset and incur more organ damage than adults, and thus may have a larger genetic burden. Confirmed genetic associations with common variants have been demonstrated in many SLE genome wide association studies (GWAS). Examining the polygenic disease score allows us to capture both the number of common SLE risk variants and the magnitude of influence of each genetic variant on SLE predisposition. While a few studies have used a polygenic risk score to explore genetic burden differences in adult SLE patients, this measure has not been reported in pediatric onset SLE.

Methods: All SLE patients included fulfilled at least four of the 11 American College of Rheumatology classification criteria for SLE; pSLE subjects met criteria prior to age 18. Samples collected from 81 SLE patients were sequenced via whole genome sequencing using Illumina HiSeq X Ten. Baseline demographics are reported in Table 1. GWAS data from 1169 juvenile idiopathic arthritis patient genotypes were used as pediatric controls, and publicly available GWAS data from adult SLE women and healthy controls were used as a disease specific comparison group. 238 SLE risk single nucleotide polymorphisms (SNPs) tagging independent previously published and established SLE genetic susceptibility loci were assessed in the study. The risk variants were pruned for SNPs in linkage disequilibrium with PLINK 1.9 software using an r^2 value of 0.2, resulting in 183 SLE risk loci shared between pSLE and JIA controls.

Table 1. Demographic data

	Number of patients	African Ancestry %, (n)	European Ancestry %, (n)	Asian ancestry %, (n)	Amerindian ancestry %, (n)	Median age of onset (years)
Pediatric SLE	81	20 (16)	26 (21)	26 (21)	28 (23)	12
Adult SLE	216	0	100 (216)	0	0	NR
Juvenile Idiopathic Arthritis	1169	NR	NR	NR	NR	NR
Adult Healthy Control	81	0	100 (81)	0	0	NR

For adults, a limited number of 63 risk loci were shared and used to compare pediatric and adult risk. A polygenic risk score was calculated for each subject based on the sum of the product of the natural logarithm of the odds ratio for each association and the number of alleles present in each individual at each risk locus. Cumulative scores were calculated for all subjects. The case and control means and distributions of polygenic risk score were evaluated with the Wilcoxon rank-sum test.

Results: Pediatric-onset SLE patients have a high burden of SLE common risk SNPs, with mean polygenic risk score of 35.9. Comparing to other children with autoimmune diseases, pediatric onset SLE patients also have a significantly higher polygenic risk score than children with juvenile idiopathic arthritis (35.9 vs. 29.9, p value 2.2×10^{-16}). PSLE patients have a similar mean polygenic risk score (11.9) as adult SLE (11.9, p value NS) and higher than healthy adult subjects (11.4, p value 0.002)

Conclusion: Patients with childhood onset SLE have an increased burden of common risk SNPs for SLE when compared to children with non-SLE autoimmune disease. SLE Both childhood and adult-onset SLE have a higher polygenic risk score than adult healthy controls subjects. Childhood onset SLE patients have a polygenic risk score similar to adult onset SLE patient. This may be due to limited number of shared SNPs available for assessment or limited sample size for comparison.

A Genome-Wide Association Study of Copy Number Variations Identifies the Deletion Associated with Efficacy of TNF-Alpha Blocker Therapy in Korean Patients with Rheumatoid Arthritis

Ki-Nam Gu,[1] **So-Young Bang** ,[2] Hye-Soon Lee,[3] Youngho Park,[2] Juyeon Kang,[2] Ji-Soong Kim,[2] Bora Nam,[2] Hyun-Seung Yoo,[4] Jung-Min Shin,[2] Yeon-Kyung Lee,[2] Tae-Han Lee,[2] Sehwan Chun,[1] Soo-Kyung Cho,[2] Chan-Bum Choi,[2] Yoon-Kyoung Sung,[5] Tae-Hwan Kim,[2] Jae-Bum Jun,[2] DaeHyun Yoo,[2] Kwangwoo Kim,[1] and Sang-Cheol Bae[2], [1]Kyung Hee University, Seoul, Republic of Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [3]Department of Internal Medicine, Hanyang University Guri Hospital,Hanyang University School of Medicine, Guri, Korea, Guri, Republic of Korea, [4]Hanyang University Hospital, Guri, Republic of Korea, [5]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Copy number variation (CNV) is the most common structural variation defined as large (>1 kb) genomic deletions and duplications and could yield a high impact on various traits including drug response. In this study, we performed a genome-wide association studies (GWAS) of CNV to investigate the efficacy of treatment with TNF-α blockers in patients with rheumatoid arthritis (RA).

Methods: The study was conducted in 357 Korean RA patients treated with TNF-α blockers. All the study subjects were classified into non-responders and responders based on the change in disease activity indexes at 6 months according to the EULAR response criteria. A multivariate logistic regression analysis performed to fit the response to

TNF-α blocker therapy with a CNV adjusting for the top 10 genetic principal components, body mass index, gender, baseline disease activity, and methotrexate use.

Results: The study subjects had 319 common CNVs with the frequency of abnormal-copy carrier ≥ 5% in autosomes and varied in their responses to TNF-α blockers with a wide range of 6-month changes in disease activity indexes. The CNV-response association analysis revealed that the copy number at 2q14.3 was associated with response to TNF-α blockers therapy in the patients with RA ($P \leq 3.2 \times 10^{-4}$) at a false discovery rate (FDR) threshold of 5%. The loss of copy number in the identified CNV was significantly more in the non-responders than in the responders ($7.3 \leq$ odds ratio ≤ 8.5), indicating worse response to TNF-α blockers in the deletion carriers. The 3.8-kb deletion at 2q14.3 is located in an intergenic region with the experimentally validated binding sites of two transcription factors, MAFF and MAFK.

Conclusion: This study conducted the first genome-wide CNV analysis to identify which structural variations associated with the varied response to the TNF-α blocker therapy. Here, we identified a novel CNV that explained a proportion of the inter-individual variance in efficacy of biologics based on the common response criteria.

Abstract Number: 1967

Adenosine A2A Receptor Signals Through AMPK and SIRT1 to Increase Chondrocyte Homeostasis

Benjamin Friedman ,[1] and Bruce Cronstein[2], [1]Department of Medicine, Division of Rheumatology NYUSoM, NYC, [2]NYU Langone, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: OA is characterized by loss of cartilage and chondrocyte dysfunction. Our lab has shown CGS21680 (CGS, 1μM) activation of adenosine A2AR leads to chondrocyte homeostasis. We have demonstrated *in vitro* and *in vivo* activation of FoxO1/3 in human TC28α2 chondrocytes and in obesity-OA mice treated with liposomal injections of adenosine or CGS. In this study, we sought to identify an upstream mechanism to explain A2AR related FoxO1/3 activation and cartilage homeostasis.

Methods: WB or IF was done for AMPK, phos-AMPK, LKB1, Sirt1, p53, Lys 382 Acetyl-p53, and Acetyl lysine in human TC28α2 cells ± CGS (1μM). Autophagy inhibitor hydroxychloroquine (HCQ, 25μM), Sirt1 inhibitor nicotinamide (NAM, 5mM) and peptide PKA inhibitor (15μM) were added *in vitro* as indicated. Sirt1 and acetyl lysine *in vivo* levels were measured by IHC in 1yr old A2ARKO, CD73KO, or WT mice.

Results: vs 1.0±0.2, p=0.02, n=4). Sirt1 is a homeostatic deacetylase that increases nuclear retention of deacetylated Foxo1/3. Further, it can indirectly activate AMPK via deacetylation of nucleus-sequestered LKB1 kinase so it can exit the nucleus to phosphorylate/activate AMPK. IF exhibited bimodal Sirt1 nuclear elevation based on average cell

intensity from 3 experiments both at 10m (5.3±0.4 vs 1.0±0.2, p=0.001) and 30m (8.2±0.8 vs 1.0±0.2, p=0.01). LKB1 cytoplasmic fraction increased with in vitro CGS at 15m (1.34±0.22 vs 1.0±0.14, p< 0.01, n=3) and 30m (1.5±0.2 vs 1.0±0.14, p< 0.01, n=3). Sirt1 proved to be a key mediator in the signaling pathway as its inhibitor NAM blocked CGS-induced activation of Sirt1 and Foxo proteins. In joint sections, Sirt1 was visibly decreased in A2ARKO and CD73KO mice (lower extracellular adenosine) with an increase in total cartilage acetylated lysine. To assess Sirt1 function we evaluated known target p53, which when deacetylated undergoes proteasomal degradation. Prior results in our lab show CGS decreases p53 in vitro. This decrease may be related to a chondroprotective increase in autophagy that occurs with A2AR activation, but we found cells treated simultaneously with starvation to induce autophagy plus autophagy inhibitor HCQ exhibited much higher p53 levels by IF and CGS treatment dramatically reduced p53 despite +HCQ. To test the alternative hypothesis that Sirt1 deacetylates and degrades p53, we performed IF for Ac-Lys-382 p53 and noted clear decrease at 30m post-CGS. Lastly, we identified an in vitro role for PKA in this A2AR pathway by demonstrating a PKA inhibitor blocked normal CGS-mediated activation of Sirt1 and FoxO1/3 assessed by IF.

Conclusion: These early results provide a viable mechanism by which A2AR can activate Sirt1 and AMPK through PKA, explaining the A2AR-associated chondroprotective effect with activation of FoxO1/3 and related increase in autophagy. Both AMPK and Sirt1, which reciprocally activate each other, are important for maintenance of healthy cartilage as evidenced by the fact that knockdown of these proteins is associated with OA. This AMPK/Sirt1 mechanism lends further support to the importance of A2AR activation in chondrocyte homeostasis that our lab has demonstrated *in vivo*.

A Drug Repurposing Story: New Therapeutic Tools Ready to Block Innate Immune Responses in Osteoarthritis

Eloi Franco-Trepat ,[1] Ana Alonso-Pérez,[1] Maria Guillán-Fresco,[1] Alberto Jorge-Mora,[2] Ana Lois Iglesias,[3] Oreste Gualillo,[4] and Rodolfo Gómez[1], [1]Institute IDIS - Musculoskeletal Pathology Group, Santiago de Compostela, Spain, [2]Institute IDIS - Musculoskeletal Pathology Group, Santiago de Compostela, [3]Institute IDIS - Musculoskeletal Pathology Group, Santiago de Compostela, Galicia, Spain, [4]Institute IDIS - NEIRID Lab - SERGAS, Santiago de Compostela, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases, also known as musculoskeletal pathologies, are steadily rising their prevalence. This worldwide phenomenon is depriving our society of their life quality and has become a grave economic burden. Among musculoskeletal pathologies, osteoarthritis (OA) stands as the major rheumatic disease, in fact, the World Health Organization (WHO) included OA within the TOP10 most disabling diseases.

The activation of Toll-like receptors (TLRs) by damage-associated molecular patterns (DAMPS) promotes critical innate immune responses (IIR). Although TLR4 and OA IIR are linked, no drugs are available to block TLR4 in rheumatology. Interestingly, TLR4 share downstream signaling with interleukin 1 receptor (IL1R). The development of new

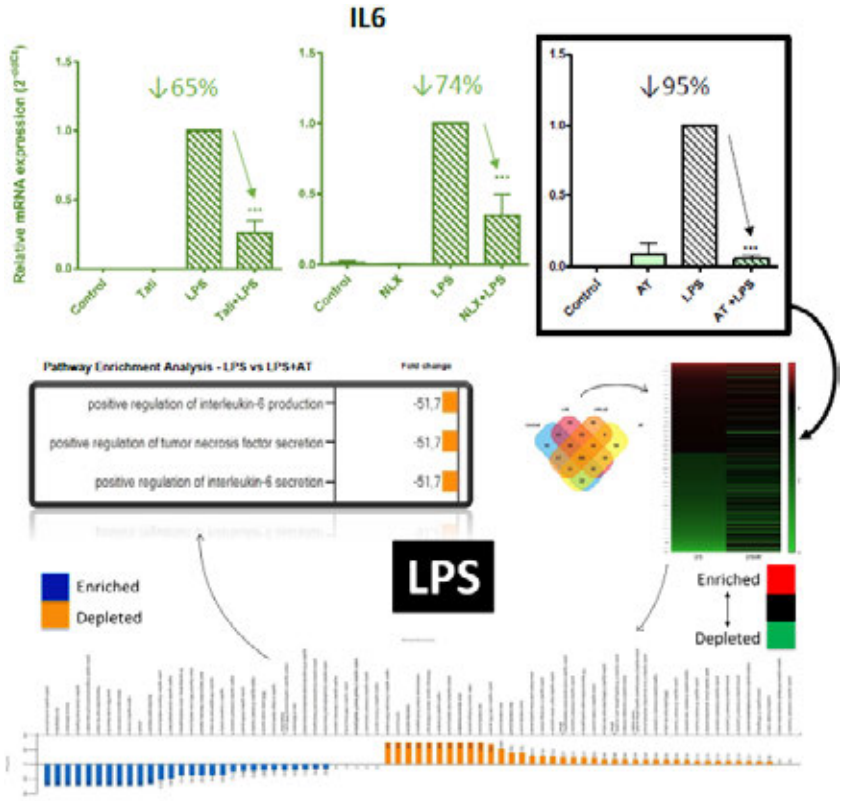

Figure 1. Effect of amitriptyline on TLR4-mediated and IL1R-mediated innate immune responses. OA human chondrocytes were stimulated with thalidomide (TALI) [500µM], naloxone (NLX) [100 µM] or amitriptyline (AT) [1µM], and TLR4 agonist LPS [100ng/ml] or the IL1R agonist IL1B [0,1ng/ml]. Pro-inflammatory factor interleukin-6 (IL6) was studied in human primary OA chondrocytes by RT-PCR and protein profiling MALDI/TOFF. A 4-way Venn diagram, differential Heatmap profile selection, a biological processes enrichment was done. Several cut-offs were carried out: 1st - false discovery rate (FDR) of 5% + p-value ±20% (Heatmap), 3rd augmented relevant immune IIR biological processes (Pathway enrichment analysis). Results are presented as mean ± SEM of four independent experiments. *p < 0.05; **p < 0.01; ***p < 0.001 versus stimulated control (LPS or IL1B). Statistical significance was determined by One-Way ANOVA analysis followed by a Tukey Post-Test.

drugs is necessary but requires decades of work and billions in investment. An alternative exists, the search for anti-TLR4 properties in currently available drugs.

Amitriptyline (AT) is a tricyclic antidepressant currently in-use for neuropathies. Naloxone (NLX) swiftly reverse opioid overdose thanks to its antagonist design. Thalidomide (TALI) initially used as a sedative was found to be teratogenic. In the present, it is used as an anti-neoplastic and to combat leprosy.

Recent studies indicate that AT, NLX and TALI might have anti-TLR4 activity, and could be repurposed to the rheumatology field.

Methods: AT [1µM], NLX [100µM] and TALI [500µM] effect on IIR was initially studied in mouse chondrocytes (ATDC5) and human synoviocytes (SW982) to evaluate the drug effects in the whole joint. Next, it was validated in human OA chondrocytes (hOAC) isolated from knee-joint replacements. Gene expression was evaluated by RT-PCR. Protein levels were determined by ELISA and MALDI/TOFF. Cell viability was evaluated by MTT assay.

Results: At the studied concentrations, AT reduced cell culture nitrite accumulation (Griess assay) and did not affect cell viability (MTT assay). NLX and TALI also reduced cell culture nitrite accumulation (Griess assay).

Stimulation with TLR4 agonist LPS [100ng/ml] or IL1R agonist IL1B [0,5ng/ml] increased IIR gene expression (LCN2, IL6, MCP1, COX2, NOS2, MMP9, MMP13, and ADAMTS4) in chondrocytes (hOAC & ATDC5) and synoviocytes (SW982). Inhibition of TLR4 by CLI95 [3μM] reduced IIR gene expression in LPS and IL1B-treated chondrocytes.

Upon treatment with AT, NLX or TALI, the observed IIR processes (mRNA) were significantly inhibited in synoviocytes and chondrocytes (Figure 1). AT showed the highest anti-TLR4 effect (↓95%) and was selected to perform a proteomic profile (MALDI-TOF) in hOAC. AT treatment depleted IIR-related pathways, including IL6 (Figure 1). To further validate the proteomic results, IL6 protein secretion was evaluated (ELISA) and showed reduced levels after AT treatment.

Conclusion:

We show in chondrocytes and synoviocytes

1. TLR4 receptor is involved in IL1β-mediated innate immune responses (IIR).
2. Amitriptyline, thalidomide, and naloxone blocked TLR4 and IL1R –mediated IIR gene expression.
3. Amitriptyline inhibited the expression of multiple TLR4 and IL1R –mediated IIR proteins.

The rheumatologists have a new therapeutic tool to manage innate immune responses in osteoarthritis.

Abstract Number: 1969

FOXO1 Is Required for Human Osteoclast Differentiation

Sabarinadh Chilaka,[1] Yannick Degboe,[1] Iain McInnes,[2] and **Carl Goodyear** [3], [1]Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom., Glasgow, Scotland, United Kingdom, [2]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dysregulation of osteoclast differentiation and function is a feature of inflammatory arthropathies (IA). Multiple genes and signalling pathways have been associated with regulation of osteoclastogenesis. In particular, FOXO1, a member of the forkhead box O family of transcription factors, is implicated in many cell processes, including metabolism, signalling, ageing, stress, cell cycle, cell differentiation and as such is an intriguing candidate for osteoclast dysregulation in IA. Recent murine studies however provided conflicting data with regard to the role of FOXO1 in osteoclast differentiation (1, 2) and no data are available in human osteoclastogenesis. We therefore investigated the role of FOXO1 in human osteoclast differentiation.

Methods: Human CD14+ monocytes were isolated from human buffy coat samples using magnetic separation kit (Stemcell). Monocytes were differentiated into osteoclasts with M-CSF (25 ng/ml) and RANK-L (25 ng/ml) either in the presence or absence of a highly specific FOXO1 inhibitor (AS1842856; 0.5 uM for 3 days). To mimic

inflammation-driven osteoclastogenesis, monocytes were grown in suboptimal RANK-L (1 ng/ml) medium for 4 days and on the 4th day TNF or supernatants from activated CD3+ T cells, were added in the presence or absence of FOXO1 inhibitor. Mature osteoclasts were stained with tartrate-resistant acid phosphatase and quantified by light microscopy. Mineral-coated plates were used to assess the resorption activity. Gene expression was assessed by RT-qPCR.

Results: Inhibition of FOXO1 completely blocked both RANK-L driven and inflammation-driven (TNF or activated CD3^{+}supernatant), osteoclast differentiation of human CD14+ monocytes and strongly inhibited osteolytic activity. FOXO1 inhibited cells were viable and had a macrophage-like phenotype. Kinetic studies revealed that FOXO1 plays a role in both the early cell fate decision and the late commitment phase of osteoclastogenesis; both inhibition during the first three days (pre-osteoclast stage) or later stage (day 4-7; committed osteoclast pre-cursors) was observed. Moreover, selective addition of AS1842856 on only day 1, clearly implicated FOXO1 during the earliest stages of osteoclast differentiation. Finally, gene expression analysis of major osteoclastogenesis-associated genes (*M-CSFR*, *RANK* and *NFATC1*) showed reduction upon treatment with AS1842856.

Conclusion: Our results suggest that FOXO1 is an essential transcription factor for human osteoclast differentiation. The ability to inhibit inflammation-driven osteoclastogenesis and osteolytic function indicates that this pathway may be viable therapeutic target in inflammatory arthropathies.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

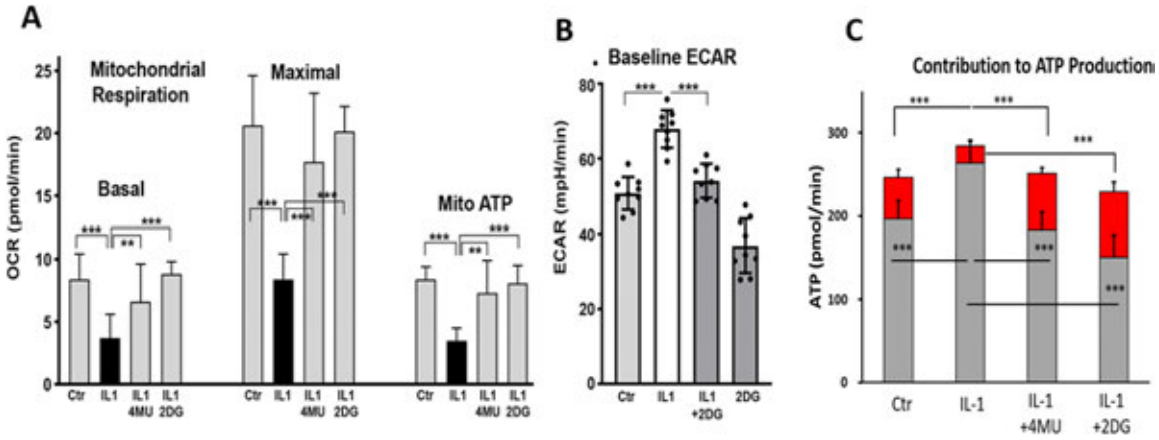

Figure 1. Bovine chondrocytes were incubated 24h ± IL1β (2 ng/ml) and without or with 4MU (1.0mM) or 2DG (2.0 mM). Panel A depicts a representative Mito Stress Test wherein bars represent basal and maximal mitochondrial respiration as a corrected OCR value. Panel B shows summaries of ECAR data representative of changes in basal glycolysis rates as labeled. Panel C shows a representative ATP rate assay wherein the contribution of glycolysis (grey bars) and mitochondrial respiration (red bars) to ATP production. (**: p<0.01 ***: p<0.001)

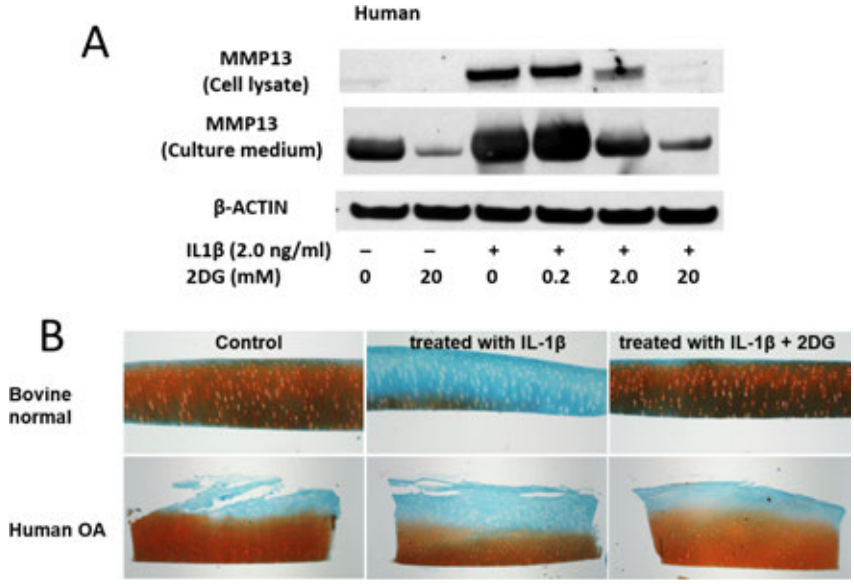

Figure 2. Effect of 2DG on chondrocytes activated with IL-β. Panel A represents the experiment with human OA chondrocytes treated ± 2 ng/ml IL1β in the absence or presence of 0.2, 2.0 or 20 mM 2DG for 24h. Panel B depicts representative examples of bovine and human OA cartilage explants stained by Safranin O.

Background/Purpose: We recently reported that the inhibitor of hyaluronan (HA) biosynthesis, 4-methylumbelliferone (4-MU) blocked IL-1β activation of MMP13 mRNA and protein expression in human osteoarthritic (OA), bovine as well as bovine or OA cartilage explants [1]. This was a somewhat counterintuitive observation because we have also demonstrated that the overexpression of HAS2 (HAS2-OE) exerted the same chondroprotective effects on human and bovine chondrocytes. Others [2] have reported that HAS2-OE in tumor cells generates a flux in intracellular UDP-sugar pools that resulted in changes in cell metabolism; switching from a dependence on glycolysis to aerobic respiration. HAS2-OE and 4-MU likely also cause dramatic fluxes in intracellular UDP-GlcUA pools. From these results, we hypothesized that the effect of HAS2-OE and 4-MU relate to changing metabolism and the possibility of inhibition of glycolysis induce chondroprotective effect. To determine that, we used the glycolysis inhibitor, 2-Deoxyglucose (2DG) as an alternative agent to change metabolism in chondrocytes.

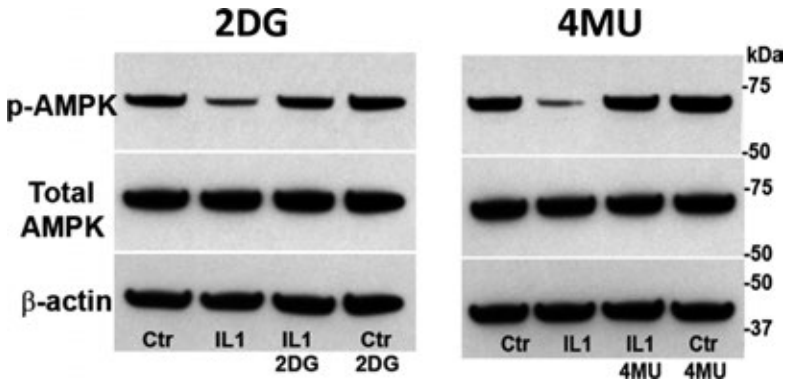

Figure 3. The effect of 4MU and 2DG on p-AMPK changes in IL1β activated chondrocytes. Bovine chondrocytes were treated for 24 h without (Ctr) or with IL1β (2 ng/ml) and ±2DG (2.0 mM), ±4MU (0.5 mM).

Methods: Bovine and human chondrocyte were stimulated with IL-1β (2ng/ml) in the presence or absence of 4MU (1.0 mM), 2DG (0.2-20 mM). Bovine chondrocytes were tested using Seahorse Flux Analyzer (Agilent Tech) to determine rate changes in medium accumulation of +H protons (indicative of lactic acid accumulation: ECAR) and for O2 consumption (indicative of mitochondrial respiration: OCR). Accumulation of MMP13 and phosphor AMPK (pAMPK) protein was quantified with Western blotting. Human and Bovine cartilage explants were cultured with L-1β in the presence or absence of 2DG (20 mM) for 7 days and stained with Safranin O.

Results: Reduced mitochondrial potential and enhanced dependence on glycolysis was observed in IL-1β stimulated chondrocytes. Co-treatment with 4-MU and 2DG returned the cell metabolism to levels at or below baseline (Fig 1A, B). The Seahorse ATP Rate Assay means the contributions of glycolysis and mitochondrial respiration to chondrocyte ATP production (Fig 1C). In control chondrocytes, the use of glycolysis contributes to the majority of ATP produced (grey bars) approximately 1/5th from the TCA cycle (red bars). IL1β-activated chondrocytes display increase in glycolysis and decrease in mitochondrial contributions. These changes are reversed by co-treatment with 4MU and 2DG. As shown in Figs 2A, 2DG reversed the IL1β-induced increases accumulation of MMP13 protein in human OA chondrocytes by Western blotting analysis. Although IL-1β lost safranin O staining in human and bovine samples, co-incubation with 2DG blocked in the loss of proteoglycan (Fig 2B). pAMPK is associate with energy homeostasis in chondrocytes. IL-1β treatment decreased accumulation of phosphor AMPK. Co-treatment with 4-MU and 2DG resulted in a rescue of the pAMPK status.

Conclusion: 4-MU and 2DG have chondroprotective effect by changing metabolism and upregulate AMPK. We propose that 4MU and 2DG become useful when these endogenous responses are not enough to rescue cells from a pro-catabolic phenotype.

CD39 Produced from Human Gingiva-Derived Mesenchymal Stem Cells Regulates the Balance of Osteoclasts and Osteoblasts Through Wnt / β-catenin Pathway in Osteoporosis

Wenbin Wu ,[1] Julie Wang,[2] feng huang,[1] limin Rong,[1] and Song Guo Zheng[3], [1]Sun Yat-sen University, Guangzhou, [2]Ohio State University, columbus, [3]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis led to severe bone-related diseases and increased mortality and health care costs. Existing treatments failed to reduce the risk of fractures in patients, so it is urgent to search new therapeutic methods for regulating bone resorption and formation.

Methods: 2×10^6 GMSC were intravenously injected to the ovariectomy (OVX) mice, trabecular bone parameters, dynamic bone formation and the frequency of osteoclasts were assessed. GMSC were pretreated with CD39 inhibitor, CD73 inhibitor or adenosine receptors to evaluate osteogenesis function in vitro and in vivo.

Results: OVX was performed in adult C57BL/6J mice after complete skeletal remodeling, and GMSC therapy was given 2 weeks after OVX. After 8 weeks of treatment, the distal femoral trabecular bone was sparse and discontinuous in OVX group, and GMSC treatment showed a clear therapeutic effect on bone density, trabecular BV/TV, trabecular numbers. GMSC treatment also resulted in a dramatically decreased frequency of osteoclasts and increased dynamic bone formation in vivo. To identify the mechanism, we found CD39 inhibitors (POM-1) inhibited the osteogenic potential of GMSC in vitro. Interestingly, POM-1 almost completely abolished the therapeutic effect of GMSC on osteoporosis. At the molecular level, we further observed that CD39 of GMSC exert their osteogenic capacity through Wnt / β-catenin pathway.

Conclusion: GMSC regulate the balance of osteoclasts and osteoblasts in osteoporosis by CD39 depending Wnt / β-catenin pathway. Our data suggests that application of GMSC represents a potential therapeutic approach for patients with osteoporosis, and highlight the key role of CD39 in the GMSC function.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of inflammatory arthritis is associated with improved patient outcomes. However, accurate diagnosis can be challenging because of their complexity and heterogeneous nature. Synovitis is a common pathological event undergoing arthritis which causes severe histological changes in the synovium. In this work, we evaluated the lipid signature of the synovium from different forms of inflammatory arthropathies using mass spectrometry imaging, in order to identify novel biomarkers that may enable an accurate and differential diagnosis and patient classification.

Methods: Synovial membrane biopsies of patients affected by osteoarthritis (OA, n=13), rheumatoid arthritis (RA, n=6), psoriatic arthritis (PsA, n=12) and healthy controls (n=10) were compared by matrix-assisted laser desorption ionization mass spectrometry imaging (MALDI-MSI). Tissue sections were deposited on conductive slides and coated with different matrices for lipid extraction. Lipid measurements were acquired in duplicate on a rapifleX MALDI Tissuetyper™ time-of-flight instrument in both ion modes. On-tissue MS/MS was performed on a MALDI-enabled Orbitrap Elite to confirm the molecular identity of lipids. Principal component analysis (PCA) and discriminant analysis (DA) were employed to classify lipids specific for each disease. Statistically significant changes were established at $p < 0.05$.

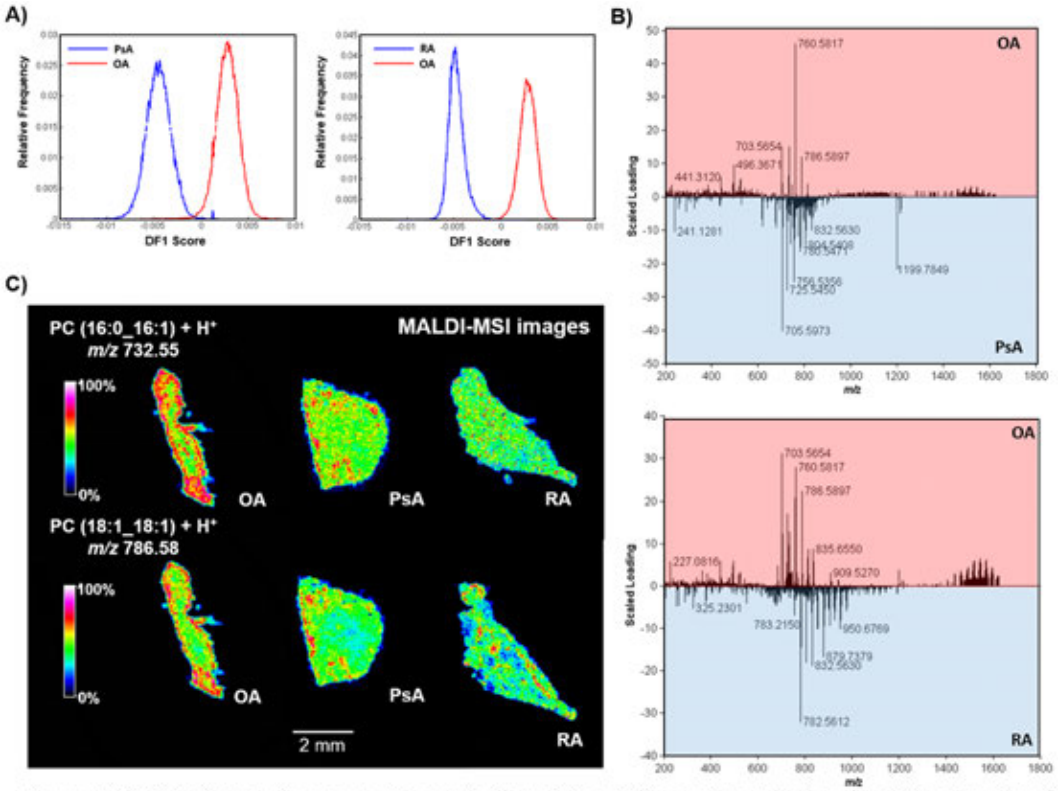

Figure 1. A) PCA-DA analysis separates OA samples from PsA and RA according to lipid profile. B) Loading plot of PCA-DA analysis representing the lipid masses characteristic to OA (positive side) and PsA/RA (negative side) samples given by MALDI-MSI. C) MALDI-MSI images showing the differences in the abundance and spatial distribution of two phosphatidylcholines (PC) in OA synovium compared to PsA and RA.

Results: MALDI-MSI in combination with PCA-DA showed a good separation of OA patients and controls pointing out a differential lipid profile between OA and control biopsies. OA tissues showed higher lipid content in the mass/charge (*m/z*) range 600-800, relative to controls. OA lipid intensities were normalized to healthy tissues to determine disease-associated lipidomic profiles of synovium. This analysis showed 35 phospholipids significantly different between OA and controls. These were mainly phosphatidylcholines (PC, 30%), phosphatidylethanolamines (PE, 26%), phosphatidylinositols (PI, 26%), phosphatidylserines (PS, 14%) and lysophosphatylcholines (LPC, 6%). PCA-DA analysis displayed a clear separation between OA and highly inflammatory arthritis (PsA and RA) based on lipid profiles (Figure 1A). Particularly, PC (*m/z* 732.5, 760.5 and 786.5) and sphingomyelins (*m/z* 703.5) were significantly upregulated in OA (Figure 1B). Some of them also showed a specific spatial distribution within the tissue. For instance, PC *m/z* 732.5 and *m/z* 786.5 were localized in the lining layer of hyperplastic OA synovium (Figure 1C). In contrast, most of PE were significantly more abundant in PsA, whereas phosphatidic acids distinguished RA synovium from OA.

Conclusion: OA synovial tissues were characterized by a higher content of PCs and sphingomyelins compared to healthy controls and other inflammatory joint diseases such as PsA and RA. These molecules may have an important role in the synovitis associated with the pathogenesis of OA, and constitute relevant molecular disease classifiers for the OA diagnosis.

Protective Effects of Intra-Articular Formulated Liraglutide in Osteoarthritis: Preclinical Studies

Francis Berenbaum ,[1] Coralie Meurot,[2] Margot Vieubled,[2] Laure Sudre,[3] carole bougault,[4] revital rattenbach,[2] celine martin,[2] and claire jacques[5], [1]Sorbonne Université-Inserm CDR Saint-Antoine, AP-HP, Paris, France, [2]4P Pharma, Lille, France, [3]Sorbonne Université-Inserm CDR Saint-Antoine, paris, France, [4]Université de Lyon - CNRS, lyon, France, [5]Sorbonne Université-Inserm CDR Saint-Antoine, Paris

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a degenerative joint disease affecting millions of individuals worldwide. Its development has been reported to be associated with cartilage degradation and inflammatory responses leading to pain, swelling and reduced function. Liraglutide, a Glucagon-Like-Peptide 1 Receptor (GLP-1R) agonist, is clinically used as a subcutaneous treatment for type 2 diabetes. Interestingly, immunomodulatory and anti-inflammatory properties of the GLP-1 pathway have been recently described in various diseases but its role in the pathogenesis of OA remains to be elucidated. The objective of this study was to evaluate the effects of intra-articular (IA) Liraglutide in *in vitro* and *in vivo* models of OA by evaluating surrogate markers of inflammation and cartilage matrix proteolysis, cartilage degradation and pain.

Methods: IL-1β-stimulated mouse articular chondrocytes were treated with different concentrations of Liraglutide for 24h. Production of matrix metalloproteinases (MMP) and prostaglandin E2 (PGE2) was measured by ELISA. IA injections of Liraglutide or vehicle were performed in two chemically-induced inflammatory knee OA models: the mouse

monosodium iodoacetate (MIA) model and the rat collagenase type II model. Paw withdrawal threshold and weight bearing distribution were performed for pain behavior assessment. Histopathological analyses (OARSI score) were conducted blindly by one observer in the rat collagenase OA model for evaluating cartilage degradation.

Results: Liraglutide significantly reduced the IL-1β-induced production of PGE2 (1341±86 vs 1766±145 pg/ml for vehicle, p≤0.05, 50nM dose) and cartilage matrix catabolic enzymes MMP-3 (294±23 for vehicle vs 204±15 ng/ml, p≤0.01, 3nM dose; vs 197±23 ng/ml, p≤0.001, 50nM dose) and MMP-13 with a dose response (127±14 for vehicle vs 90±18 pg/ml, p≤0.01, 3nM dose; vs 70±10 ng/ml, p≤0.001, 10nM dose; vs 52±6 ng/ml, p≤0.001, 50nM dose) in murine chondrocytes. In both *in vivo* OA models, Liraglutide IA injections significantly attenuated pain symptoms. Indeed, in the mouse MIA model, single injection of IA Liraglutide increased paw withdrawal threshold (0.37±0.39 vs 0.13±0.11 g for vehicle, p≤0.05, day 7) and improved weight distribution to the affected limb (80±7% at day 7 and 83±4% at day 10, p≤0.001) compared to vehicle (71±6% at day 7 and 74±4% at day 10). The response was found similar to the one after an IA injection of dexamethasone (79±8% at day 7 and 81±4% at day 10). In the rat collagenase OA model, repeated IA injections of Liraglutide improved weight bearing deficit at multiple time-points (50±4 at week 1, 66±5 at week 3 and 66±4% at week 6, p≤0.001) compared to vehicle (42±4 at week 1, 57±4 at week 3 and 59±3% at week 6). Histological assessment of rat collagenase-injected knee joint revealed a significant (p≤0.05) decrease of the total joint score in the IA Liraglutide treated group (8±4) compared to vehicle (11±4).

Conclusion: IA injection of Liraglutide has demonstrated anti-catabolic, anti-inflammatory and pain-relieving effects in preclinical OA models, opening the wave to considering now this molecule as a potential disease-modifying OA drug.

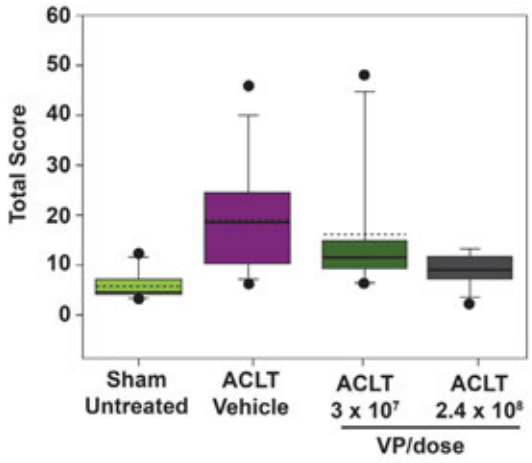
The Rat Homolog to FX201, a Gene Therapy in Development for the Treatment of Osteoarthritis, Demonstrates Dose-Dependent Decreases in the Severity of Cartilage and Bone Lesions Following Anterior Cruciate Ligament Transection

Rebecca Senter,[1] **Rogely Boyce** ,[2] Monika Chabicovksy,[3] Emily Walsh Martin,[1] Geneviève Langevin-Carpentier,[4] and Neil Bodick[1], [1]Flexion Therapeutics, Burlington, [2]Beechy Ridge ToxPath LLC, Clay, [3]MC Toxicology Consulting, Vienna, Austria, [4]Charles River Laboratories, Senneville, Canada

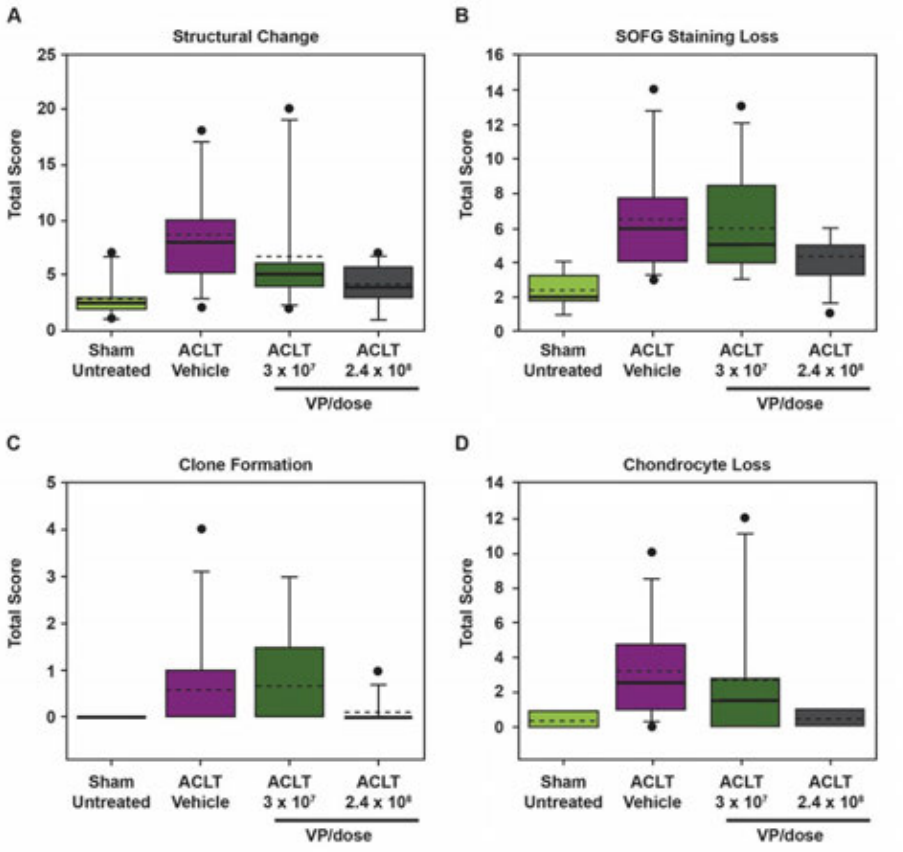
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Acute injury to the anterior cruciate ligament (ACL) is a common cause of posttraumatic OA in humans, and ACL transection (ACLT) in rats is an established animal model of traumatic injury-induced OA. FX201, a helper-dependent adenovirus (HDAd)-based intra-articular (IA) gene therapy candidate designed to induce the production of an Interleukin (IL)-1 receptor antagonist (IL-1Ra) in the presence of inflammation, is in development as a potential therapeutic agent for OA. Here, we evaluated the effects of HDAd-ratIL-1Ra, the rat surrogate of FX201, when administered as a single IA injection in rats 1 week following ACLT surgery.



Dashed line = mean; solid line = median; dots = outliers; box extremities = quartile 1 (bottom) and quartile 3 (top); end of whiskers = min and max.
ACLT, anterior cruciate ligament transection; Min, minimum; Max, maximum; SOFG, Safranin O fast green; VP, viral particle.

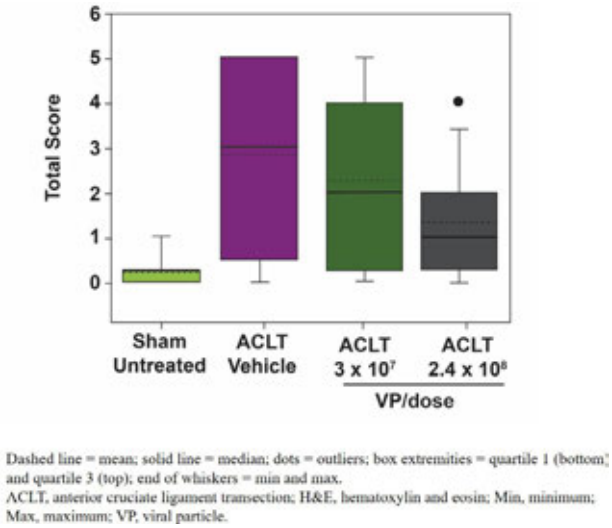
Figure 1. Composite (Total) Scores by Group for Cartilage/Bone Evaluation (SOFG Staining) in Sham- and ACLT-Operated Rats



Dashed line = mean; solid line = median; dots = outliers; box extremities = quartile 1 (bottom) and quartile 3 (top); end of whiskers = min and max.
ACLT, anterior cruciate ligament transection; Min, minimum; Max, maximum; SOFG, Safranin O fast green; VP, viral particle.

Figure 2. Total Scores by Group for (A) Structural Change (B) SOFG Staining Loss (C) Clone Formation and (D) Chondrocyte Loss in Sham- and ACLT-Operated Rats

Methods: A total of 46 Sprague Dawley rats were assigned to 1 of 4 study groups: high-dose HDad-ratIL-1Ra (ACLT/HDAd-ratIL-1Ra; 2.4×10^8 viral particles [VP]/dose; n=12), low-dose HDAd-ratIL-1Ra (ACLT/HDAd-ratIL-1Ra; 3×10^7



Dashed line = mean; solid line = median; dots = outliers; box extremities = quartile 1 (bottom) and quartile 3 (top); end of whiskers = min and max.
ACLT, anterior cruciate ligament transection; H&E, hematoxylin and eosin; Min, minimum; Max, maximum; VP, viral particle.

Figure 3. Composite (Total) Scores by Group for Synovial Membrane Evaluation (H&E Staining) in Sham- and ACLT-Operated Rats

VP/dose; n=12), vehicle (ACLT/vehicle; n=12), or sham/untreated (n=10). Rats underwent ACLT surgery in the right knee (except sham animals) under isoflurane anesthesia on Day -7. Seven days postsurgery (Day 1) rats received a single IA injection of HDAd-ratIL-1Ra or vehicle in the right knee joint under anesthesia. At Week 12, animals were sacrificed and whole right knee joints were harvested and analyzed for histopathology. For histopathological evaluation, whole right knee joints were stained with Safranin O fast green (SOFG) and hematoxylin and eosin and assessed using a semi-quantitative grading system (OARSI score) to score cartilage/bone and synovial membrane, respectively. Individual scores were recorded, and composite scores for each parameter were generated by the sum of all individual scores.

Results: In sham-operated rats, microscopic changes at Week 12 were limited to low incidence of superficial articular cartilage changes graded minimal in severity as assessed by surface irregularities with focal fibrillation/clefts/fissure, chondrocyte loss, and/or SOFG staining. All ACLT-operated rats developed OA microscopic changes that were minimal-to-severe in 1 or more of the examined articular compartments at Week 12. Among ACLT-operated rats, HDAd-ratIL-1Ra resulted in a dose-dependent decrease in composite scores for cartilage/bone compared with vehicle (**Figure 1**); these decreases are likely due to reduced severity of structural changes and chondrocyte loss with HDAd-ratIL-1Ra treatment compared with vehicle (**Figure 2**). Slight decreases in severity of SOFG staining loss and incidence of clone formation were also observed with HDAd-ratIL-1Ra treatment compared with vehicle (**Figure 2**). Furthermore, HDAd-ratIL-1Ra demonstrated dose-dependent decreases in composite scores of OA microscopic changes to the synovial membrane compared with vehicle (**Figure 3**); all synovial microscopic findings were minimal in severity.

Conclusion: A single administration of HDAd-ratIL-1Ra, the rat surrogate of FX201, resulted in a dose-dependent decrease in the incidence and severity of OA-related lesions to cartilage/bone and the synovial membrane 12 weeks postsurgery; these results support further development of FX201 as a potential therapeutic agent for OA.

Session Date: Tuesday, November 12, 2019

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Increasing evidence suggest that osteoarthritis (OA) is associated with hallmarks of ageing, including cellular senescence or defective autophagy, that could promote disease onset. *The objective of this study was to identify small molecules with senolytic and pro-autophagy activity to prevent cartilage degeneration and OA.*

Methods: Senescence and defective autophagy were induced in human chondrocytes (T/C28a2) by treatment with IL-6, a SASP factor, at 20ng/ml for 72 or 18 hours, respectively. Chondrocytes were incubated with compounds from Prestwick Chemical Library to identify potential senotherapeutics, using SA-β-gal activity imaging as fluorescence reporter. To identify molecules activating autophagy flux, LC3 reporter stably expressed in chondrocytes was imaged and analyzed. Confirmatory assays for senescence, autophagy, FoxO signaling pathway and inflammation were performed in primary human chondrocytes. The potential protection from degeneration was evaluated by Safranin O staining and Nitric Oxide (NO) production in human cartilage. Moreover Senolytic index was determined. PPARα was evaluated as a target mechanism in both spontaneous aging and surgically-induced OA in mice and in blood and cartilage from human OA Cohort. Furthermore, the consequences of PPARα silencing was investigated in human chondrocytes.

Results: The cell-based screen yielded 279 potential senotherapeutic compounds, 14 of which show pro-autophagy activity. Fenofibrate (FN), a PPARα agonist approved for dyslipidemia was selected as a candidate. FN reduced senescence and increased autophagic flux ($p < 0.0001$) in response to IL-6, and protects against senescence, defective autophagy and inflammation in human OA and aging primary chondrocytes. This protective effect was confirmed in human aging articular cartilage explants by a reduction of proteoglycans loss and NO production ($p < 0.05$) in response to IL-1b. Interestingly, FN present a senolytic activity represented by a reduction of the senescent cells and the total number of cells ($p < 0.05$). Moreover, this selective elimination was mediated by apoptosis. Furthermore, FN upregulates key homeostasis markers, such as LC3 and FoxO1 and CPT1A, gen involved in mitochondrial fatty acid beta-oxidation. These effects were also observed for structurally distinct PPARα agonists, suggesting that pharmacological modulation of PPARα may provide therapeutic benefits in OA. Interestingly, PPARα silencing induced senescence, altered homeostasis mechanisms or increases inflammation at both basal conditions or in response to

IL-6 or IL-1b at 48 hours ($p < 0.05$). Moreover, PPARα expression was reduced with aging and OA in mice and in blood and cartilage from OA Cohort ($p < 0.01$). Remarkably, in a retrospective study, fibrate treatment improved OA clinical conditions in human patients from Osteoarthritis initiative (OAI) Cohort.

Conclusion: These results demonstrate that FDA-approved fibrate drugs targeting lipid metabolism protect against cartilage degeneration with aging and OA. Thus, these drugs could have immediate clinically utility for the treatment of OA and age-related cartilage degeneration.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a chronic degenerative joint disease caused by synovial inflammation and cartilage degradation primarily driven by interleukin-1beta (IL-1β). Studies suggest that TNF-stimulated gene 6 (TSG6) plays an important role in reducing IL-1β-induced tissue destruction in arthritis. In the present study, we evaluated the role of guanylate binding protein 5 (GBP5), an interferon gamma regulated gene, in regulating TSG6 expression, and IL-1β-induced COX-2 expression and IL-6 and MMP-1 production in human osteoarthritis synovial fibroblasts (OASFs).

Methods: Primary OASFs were isolated from synovial tissues obtained after joint replacement surgeries from OA patients under an approved IRB protocol and cultured in RPMI1640 with 10% FBS. Human OASFs were treated with IL-1β (10 ng/ml) or TNF-α (20 ng/ml) for 24 hours to study the expression of inflammatory proteins using Western immunoblotting, qRT-PCR, or ELISA method. The potential crosstalk and association of GBP5 with IL-1β stimulated signaling proteins was studied by the immunoprecipitation (IP) method. Small-interfering RNA (siRNA) mediated knockdown of GBP5 was conducted to study its effect on IL-1β-induced inflammatory mediators in human OASFs.

Results: Western blot analysis showed that the expression of GBP5 is significantly increased upon IL-1β or TNF-α stimulation in human OASFs ($p< 0.05$; n=3). Knockdown of GBP5 significantly increased the expression of IL-1β-induced COX-2 and the production of IL-6 and MMP-1 in human OASFs ($p< 0.05$; n=3). Our qRT-PCR and Western blotting results showed that the knockdown of TNF-stimulated gene 6 (TSG6) significantly upregulates IL-1β-induced MMP-1 expression in human OASFs ($p< 0.05$; n=3). Surprisingly, GBP5 knockdown by siRNA significantly lowered the expression of IL-1β-induced TSG6 at mRNA and protein levels ($p< 0.05$; n=3), which suggests GBP5 a novel reg-

ulator of TSG6 in human OASFs. Supporting evidence showed that the overexpression of GBP5 via lentiviral delivery resulted in the upregulation of TSG6 expression and a concomitant decrease in IL-1β-induced COX-2 expression and IL-6 and MMP-1 production in human OASFs ($p< 0.05$; n=3). Furthermore, the results from IP analysis showed that IL-1β stimulation led to enhanced association between TSG6 and GBP5 in human OASFs in vitro, thereby selectively amplifying phosphorylation of JNK/SAPK MAPK and its downstream substrate c-Jun.

Conclusion: Our study suggests that GBP5 suppresses IL-1β-induced tissue destruction primarily through TSG6, whereas it elicits anti-inflammatory actions that are independent of TSG6 in human OASFs.

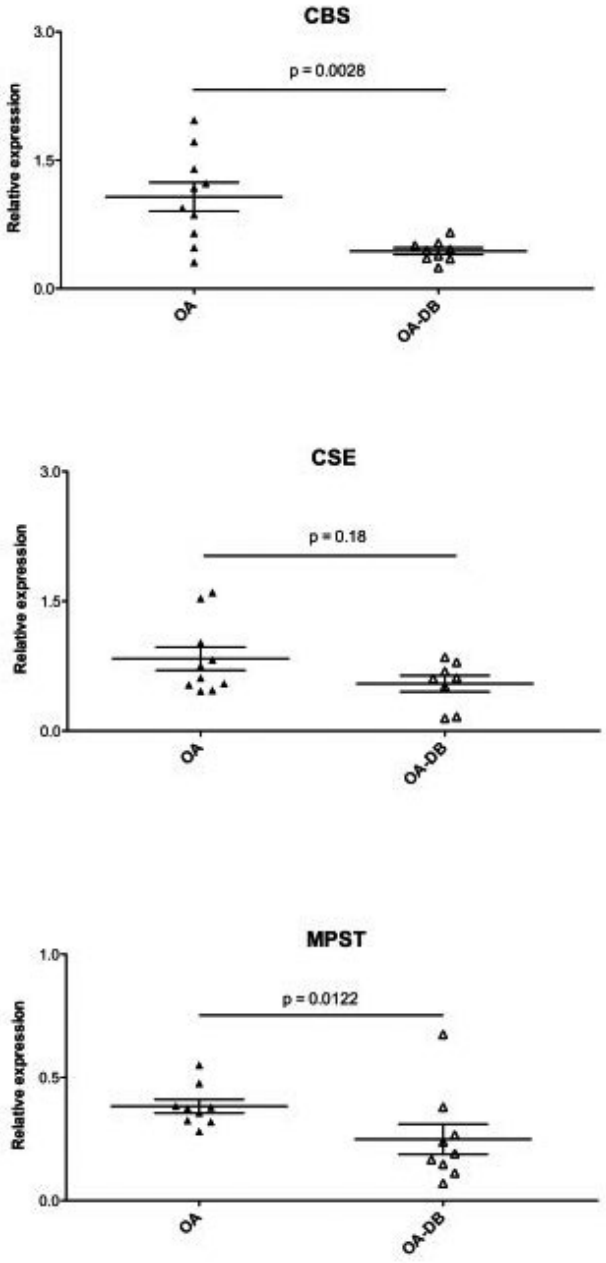
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A growing number of findings indicates that type 2 diabetes is an independent risk factor of osteoarthritis (OA). However, the mechanisms underlying the connection between both diseases remain unclear. Hydrogen sulfide (H2S) plays an important role in the pathogenesis of diabetes and its complications. In relation, we and other authors have observed a protective impact of H2S induction on activation of pathological pathways in osteoarthritic chondrocytes. In this study we examined the modulation of H2S levels in serum and chondrocytes from OA/non-OA diabetic (DB) or non-diabetic (non-DB) patients and in cell under glucose stress, in order to elucidate whether impairment in H2S-mediated signaling could participate in the onset of diabetes-related OA.

Methods: Serum and chondrocytes were isolated from OA/non-OA cartilage of diabetic (DB) or non-diabetic (non-DB) patients. Serum levels of H2S were measured by an ion-selective microelectrode. Primary chondrocytes and T/C28a2 were stimulated w/o IL-1β (5 ng/mL) under a normal (5.5 mM; NG) or a high (25 mM; HG) glucose environment. Gene and protein expression of enzymes involved in H2S synthesis (cystationine γ-liase [CSE], cystationine β- synthase [CBS], and 3-mercaptopyruvate sulfurtransferase [3-MT]) and heme oxygenase 1 (HO-1) were assessed by RT-qPCR and WB, respectively. To determine the involvement of H2S in catabolic pathways activated by HG in chondrocytes, NaSH and GYY 4137 (500 μM), a fast and slow-releasing H2S donor respectively, were employed.

Results: H2S levels in serum from OA-DB patients were significantly lower than in those from non-OA-DB patients ($p< 0.05$). Likewise, fresh isolated chondrocytes from OA cartilage of diabetic patients showed lower levels of H2S synthesizing enzymes (CSE, CBS and 3-MT) than those of non-DB patients (Figure 1). T/C28a2 cells exposed to HG



Protein expression of enzymes involved in H2S synthesis in freshly isolated chondrocytes from OA or non-OA diabetic (DB) patients

stress expressed lower mRNA and protein levels of these 3 enzymes after 3 days of incubation than in those incubated in NG conditions (0.41- fold and 0.83-fold [CSE], 0.42-fold and 0.66-fold [CBS], and 0.52-fold and 0.79-fold [3-MT] for mRNA and protein expression, respectively; n=6, $p< 0.05$). Similar results were found in primary chondrocytes incubated in HG in the presence of IL-1β ($p< 0.05$). Additionally, the expression of IL-6 and COX-2 induced by IL-1β was significantly higher in primary chondrocytes under HG than NG condition (n=5, $p< 0.05$); whereas protein levels of anti-oxidant enzyme HO-1 were reduced in HG exposed cells. GYY 4137 and NaSH co-treatment recovered HO-1 expression and attenuated IL-6 and COX-2 expression in cells under HG+IL-1β condition (n=3; $p< 0.05$).

Conclusion: The results indicate a reduction of H2S synthesis as a critical feature involved in hyperglucidic-mediated dysregulation of articular chondrocytes. The impairment of H2S signaling could participate in the mechanisms un-

derlying the predisposition to OA development in diabetic individuals and may open new opportunities for treating patients with a diabetes-related OA phenotype.

Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In osteoarthritis (OA) defects in Autophagy are evident and precede joint damage. *Therefore, identifying biomarkers associated with autophagy defects could facilitate the development of personalized therapeutic strategies to prevent OA progression.*

Methods: A comparative analysis of 35 autophagy genes was performed in blood from a Prospective OA Cohort of A Coruña (PROCOAC) of non-OA and knee OA patients. Non-OA patients (Age: 61,44 ± 1,16 years; BMI: 25,25 ± 0,52; Females, n=18) and Knee OA patients (Age: 65,50 ± 1,05 years; BMI: 29,55 ± 0,67; Females, n=18, OA grade III-IV) were profiled using an autophagy gene expression array. Confirmatory studies of the candidate genes were performed in blood from Non-OA patients (Age: 60,13 ± 1,12 years; BMI: 24,85 ± 0,59; Sex: Females; n=30) and Knee-OA patients (Age: 68,4 ± 1,11 years; BMI: 29,65 ± 0,55; Females; n=30, OA grade III-IV) by using Taqman Technology. Moreover, the candidate gene was evaluated as a potential biomarker in human cartilage from Normal (n=19) and OA (n=20) patients and in both spontaneous aging (2, 6, 12, 18, and 30 months old, n=3/each time) and surgically-induced OA (10 weeks after surgery, n=4/each) in mice by immunohistochemistry. Remarkably, the consequences of candidate gene silencing on autophagy, FOXO signaling, inflammation, senescence, oxidative stress and cell death by apoptosis was investigated by gene expression and flow cytometry.

Results: 15 autophagy-related genes were downregulated in blood from knee OA patients compared to non-OA patients ($p < 0.05$). No upregulation was found. although a trend towards upregulation was found for several genes involved in the mTOR signaling pathway. Importantly, key autophagy-related genes, including ATG16L2, ATG12, ATG4B and MAP1LC3B were significant downregulated in knee OA patients ($p < 0.05$). Interestingly, HSP90AA1 and HSPA8, chaperone-mediated autophagy genes involved in stress response and protein folding, were significant downregulated ($p < 0.001$). Confirmatory studies for MAP1LC3B and HSP90AA1, showed a significant downregulation ($p < 0.001$) in blood from knee OA patients. Remarkably, total proteome screening of human OA chondrocytes

with defective autophagy, showed a significant reduction of HSP90AA1 ($p< 0.05$). Moreover, pharmacological inhibition of HSP90 chaperone reduces chondrocyte homeostasis. Remarkably, HSP90AA1 expression was reduced in OA cartilage ($p < 0.01$) and in spontaneous aging and surgically-induced OA in mice ($p< 0.05$). Interestingly, HSP90AA1 silencing increased LC3 and FOXO1 expression ($p < 0.01$) and increased NFkB and p16 expression ($p< 0.05$) at 48h post-transfection. In addition, HSP90AA1 silencing increased cell death by apoptosis and mitochondrial ROS production 72h post-transfection ($p < 0.05$). These data indicate that HSP90AA1 might be a potential biomarker associated with defective autophagy in OA.

Conclusion: We identified biomarkers of defective autophagy as a mechanism of central homeostasis, which gives us a general vision of the disease mechanisms linked to OA clinical reality.

What Is the Pathogenic Meaning of Chondrocyte Hypertrophy in Osteoarthritis? Effect of Evc Deletion Through Hedgehog Signaling

Ana Lamuedra ,[1] Paula Gratal,[1] Víctor Luis Ruiz-Perez,[2] Adrián Palencia-Campos,[3] Sergio Portal-Nuñez,[4] Gabriel Herrero-Beaumont,[5] and Raquel Largo[5], [1]IIS - Fundacion Jimenez Diaz, Madrid, Madrid, Spain, [2]Instituto de Investigaciones Biomédicas 'Alberto Sols', Madrid, Madrid, Spain, [3]Adrián Palencia Campos [apalencia@iib.uam.es], Madrid, Madrid, Spain, [4]Applied Molecular Medicine Institute (IMMA), Universidad San Pablo-CEU, Alcorcón, Madrid, Spain, [5]IIS-Fundación Jiménez Díaz, Madrid, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is mainly characterized by the progressive damage of articular cartilage, where chondrocytes acquire a hypertrophic-like phenotype. Indian Hedgehog levels are increased in OA cartilage. An induction of Hedgehog (Hh) signaling pathway induces OA-like cartilage lesions, whereas its pharmacological down-regulation prevents articular destruction in animal models. Mutations in *EVC* or *EVC2* genes disrupt Hh signaling, and are responsible for the Ellis-van Creveld skeletal dysplasia. Hence, *Evc* deletion would hamper the expression of Hh target genes, Runx2, ColX and MMP13 among others, preventing the expression of hypertrophic mediators and protecting cartilage against OA progression. Our aim was to study whether Hh pathway inhibition restrains chondrocyte hypertrophy and the effect of *Evc* deletion on joint damage in an Evc tamoxifen induced conditional knock out (cKO) ($Evc^{cKO-/-}$) model of OA in mice.

Methods: C57BL6 wild-type (WT) and $Evc^{-/-}$ primary murine chondrocytes were isolated from cartilage explants from E18.5 embryos and cultured in micromass. Hypertrophy was induced with insulin for 14 days ($n\geq6$). Cyclopamine (5-10 μM) was used for Hh pharmacological inhibition. Gene expression of hypertrophic markers and Hh genes was measured by qRT-PCR, and proteoglycan content visualized by Alcian Blue staining. To study the effect of Evc deletion *in vivo*, OA was induced by surgical knee destabilization in WT (n=6) and $Evc^{cKO-/-}$ (n=6) adult mice and let evolve for 8 weeks. Healthy WT (n=8) and $Evc^{cKO-/-}$ (n=3) mice were used as controls. Cartilage damage and chondrocyte size were evaluated in Safranin-O and haematoxylin/eosin stained joint sections. MMP levels were assessed by western blot and hypertrophic markers gene expression by qRT-PCR.

Results: Cyclopamine prevented the expression of ColX, alkaline phosphatase (ALP), Adamts5 and Runx2 ($p< 0.05$) and reduced proteoglycan content ($p=0.004$) evoked by insulin in cultured WT chondrocytes. $Evc^{-/-}$ chondrocytes showed a partial inhibition of insulin-induced hypertrophy, with a decrease in ALP and Runx2 gene expression ($p=0.03$) and in proteoglycan content ($p=0.02$). However, Evc deletion did not modify articular cartilage damage in OA mice, since similar OARSI scores were observed in OA WT and OA $Evc^{cKO-/-}$ mice ($p=0.64$). MMP13, MMP1 and MMP3 protein levels were increased in OA WT knees ($p< 0.01$ vs Healthy WT), and reduced levels of MMP3 ($p=0.09$) and MMP13 ($p=0.18$) were found in OA $Evc^{cKO-/-}$ mice when compared to OA WT. However, gene expression of Hh genes was induced in OA WT knees, and completely inhibited in OA $Evc^{cKO-/-}$. Furthermore, ColX ($p=0.002$), ALP ($p=0.13$) and Runx2 ($p=0.21$) gene expressions were decreased in OA $Evc^{cKO-/-}$ mice in comparison with OA WT. Likewise, chondrocyte size was increased in the OA WT calcified cartilage ($p=0.098$ vs. Healthy WT), while it was diminished in OA $Evc^{cKO-/-}$ ($p=0.11$ vs OA WT).

Conclusion: Although the inactivation of Hh signaling pathway prevented chondrocyte hypertrophy, it was not able to prevent cartilage damage progression in OA $Evc^{cKO-/-}$. Therefore, our results suggest that chondrocyte hypertrophy is not a pathogenic event in the progression of articular cartilage damage in OA.

Disorganization of Chondrocyte Columns in the Growth Plate During Experimental Osteoarthritis in Mice

Ana Lamuedra ,[1] Víctor Luis Ruiz-Perez,[2] Paula Gratal,[1] Raquel Largo,[3] and Gabriel Herrero-Beaumont[3], [1]IIS - Fundacion Jimenez Diaz, Madrid, Madrid, Spain, [2]Instituto de Investigaciones Biomédicas 'Alberto Sols', Madrid, Madrid, Spain, [3]IIS-Fundación Jiménez Díaz, Madrid, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a biomechanical joint disease mainly affecting articular cartilage and subchondral bone. A great variety of animal models, especially mice, are used trying to mimic human disease and its pathogenesis. Unlike in humans, mouse growth plates (GP) do not completely fuse and disappear. GP chondrocytes arrange in columns, where Hedgehog (Hh) pathway plays a key role orchestrating chondrocyte differentiation. In fact, we have previously shown that *Evc*$^{-/-}$ mouse embryos exhibit loss of columns in the GP, premature hypertrophy and shorter bones due to the disruption of the Hh pathway. In neonatal mice, an altered mechanical joint loading due to hemiplegia induces disorganization of chondrocyte columns in the GP. However, it is unclear whether joint biomechanical alteration modifies GP structure in adult mice. Our aim was to study whether OA can disturb GP organization in adult mice and to assess whether the GP alteration may have an additional deleterious effect on the articular cartilage damage.

Methods: Knee OA was induced by medial meniscus sectioning in wild-type (WT) adult mice and let evolve for 8 weeks. We used an Evc tamoxifen (Tx) induced conditional knock out (cKO) model to achieve intermediate (*Evc*$^{cKO+/-}$, +Vehicle) or null (*Evc*$^{cKO-/-}$, +Tx) Evc levels in adult mice, as a control for GP disorganization. Mice were randomly assigned to different groups: healthy WT (n=8), OA WT (n=6), healthy *Evc*$^{cKO+/-}$ (n=4), OA *Evc*$^{cKO+/-}$ (n=5), healthy *Evc*-

$^{cKO-/-}$ (n=3) and OA *Evc*$^{cKO-/-}$ (n=6). GP organization assessment was performed at the central region of the tibia, and expressed as Column Index (CI). CI was calculated as the percentage of GP chondrocytes in columns, with at least 3 cells less than 20 pixels apart, angles ranging from 155° to 180°, and corrected by column length[1]. Articular cartilage damage was evaluated by OARSI score and GP thickness measured in Safranin-O stained sections.

Results: GP column measurements revealed that CI decreased by 50% in OA WT mice, showing altered columnar structure and clusters of cells (Healthy WT: 2225±125; OA WT: 682±69; p=0.0001). Healthy *Evc*$^{cKO+/-}$ mice exhibited a low CI (1015±130; p=0.0004 vs Healthy WT) while a complete Evc deletion showed a significant loss of GP organization (Healthy *Evc*$^{cKO-/-}$: 462±76; p=0.005 vs Healthy *Evc*$^{cKO+/-}$). In *Evc*$^{cKO-/-}$ mice, OA drastically reduced CI (229±55; p=0.0002 vs OA WT). No changes were observed regarding GP thickness or proteoglycan content between groups. Neither a partial deletion nor a complete loss of Evc induced cartilage damage in mice (p=0.73 and 0.11 vs Healthy WT respectively). In addition, OA WT and OA *Evc*$^{cKO-/-}$ mice showed equally severe lesions in the articular cartilage (p=0.64).

Conclusion: Profound GP chondrocyte disorganization occurred in OA adult mice due to joint instability. However, the altered GP column structure in *Evc*$^{cKO/-}$ mice did not exacerbate articular cartilage damage. Although OA leads to the loss of GP chondrocyte column structure, this alteration in the GP does not seem to void mouse experimental models of OA. Further studies are needed to confirm the lack of interference of GP pathological state on articular cartilage damage in mouse OA.

Functional Differences Between Osteoclasts and Osteoclast-like Cells Differentiated from Peripheral Blood Mononuclear Cells in Patients with Rheumatoid Arthritis

Kazuhiro Yokota ,[1] Yoshimi Aizaki,[1] Shinya Tanaka,[2] Kojiro Sato,[3] Yasuto Araki,[1] Noritsune Kouzu,[4] Yuho Kadono,[2] Hiromi Oda,[5] and Toshihide Mimura[1], [1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [2]Department of Orthopaedic Surgery, Saitama Medical University, Saitama, Japan, [3]Division of Rheumatology and Clinical Immunology, Department of Medicine, Jichi Medical University, Tochigi, Japan, [4]Medical Kouzu orthopedic and Yachiyo radiation center, Chiba, Japan, [5]Department of Orthopedic Surgery, Faculty of Medicine, Saitama Medical University, Saitama, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoclasts (OCs) are giant multinucleated cells formed from precursors of the monocyte/macrophage lineage and are believe to play a major role in the bone destruction associated with rheumatoid arthritis (RA). Previously, we have reported that osteoclast-like cells (OLCs) are differentiated from mouse bone marrow macrophages stimulated with TNFα and IL-6; they show bone resorption activity both *in vitro* and *in vivo*. The purpose of

the present study is to investigate the functional differences between OCs and OLCs differentiated from peripheral blood mononuclear cells (PBMCs) from patients with RA or healthy controls (HCs).

Methods: PBMCs and $CD14^+$ monocytes from 9 RA patients and/or HCs were stimulated with RANKL or TNFα and IL-6. The number of tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells (OCs/OLCs) and bone resorption activity were assessed. Quantitative RT-PCR was used to measure the mRNA expression levels of *cathepsin K* and *matrix metalloproteinases (MMPs)*. The relationship between the number of OCs/OLCs and the modified total Sharp score (mTSS) or whole-body bone mineral density (BMD) was also examined.

Results: The number of OCs/OLCs differentiated from PBMCs in RA patients was significantly higher than that in HCs (RA OCs, 30.7±7.3 vs. HCs OCs, 10.0±4.0, $p< 0.01$; RA OLCs, 16.0±6.1 vs. HCs OLCs, 2.3±0.7, $p< 0.01$). These cells showed bone resorption activity on dentin slices. Moreover, CD14+ monocytes-differentiated OCs and OLCs showed significantly increased expression of *cathepsin K* mRNA compared with osteoclast precursors (OCPs) (OCs 9.4±3.5-fold, OLCs 2.3±0.5-fold vs. OCPs 1.0±0.0-fold, $p< 0.01$, respectively). In addition, the expression levels of *MMP-3* mRNA was significantly higher in OLCs than in OCs and OCPs (OLCs, 35.7±12.8-fold vs. OCs 2.8±0.5-fold, OCPs 1.0±0.0-fold, $p< 0.01$, respectively). The number of OLCs differentiated from PBMCs in RA patients was significantly positively correlated with the mTSS, erosion score, and joint space narrowing score ($r=0.82$, $r=0.79$, and $r=0.68$, respectively, $p< 0.05$), while the number of OCs was not. On the other hand, the number of OCs was significantly negatively correlated with the whole-body BMD ($r=-0.67$, $p< 0.05$), while the number of OLCs was not.

Conclusion: Our results demonstrated that the PBMCs of RA patients showed a higher OC/OLC differentiation potential than those from HCs. The bone resorption activity of PBMC-differentiated OLCs could likely have a potential role in the joint destruction, whereas OC activity plays an important role in the development of osteoporosis in RA patients. OLCs could form a subpopulation of OCs; possibly, this is one of the functional differences between OLCs and conventional OCs.

Senescent Synoviocytes in Knee Osteoarthritis Correlate with Disease Biomarkers, Synovitis, and Knee Pain

Christopher Yohn,[1] Robert O'Brien,[1] Stephanie Lussier,[1] Casey Berridge,[1] Rathi Ryan,[1] Ali Guermazi,[2] Mahru An,[1] Remi-Martin Laberge,[1] **Benjamin Hsu** ,[1] Carl Millward,[1] Kate Doherty,[1] and Jamie Dananberg[1], [1]Unity Biotechnology, Brisbane, CA, [2]Boston Medical Center, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cellular senescence is a natural state in which a cell permanently halts division through upregulation of a set of intracellular proteins including p16INK4A in response to various cellular stressors. Senescent cells secrete factors collectively referred to as the Senescence Associated Secretory Phenotype (SASP) that are proinflammatory and degradative in the local tissue environment. With aging, senescent cells accumulate in multiple tissues, and senolytic therapies are being developed to address age-related diseases. We conducted a clinical study

to evaluate the relationship between the accumulation of senescent cells in OA knee synovial tissue and SASP/OA biomarkers, OA severity, and knee pain.

Methods: This was a non-drug, cross-sectional, single-center study of 30 patients with symptomatic, radiographic, femoro-tibial knee OA (defined by a modified version of the American College of Rheumatology Criteria) for ≥6 months. Synovial biopsies were obtained arthroscopically and analyzed for the presence of p16Ink4A positive cells by immunohistochemistry. Blood, urine, and synovial fluid were collected for measurement of candidate biomarkers. Fixed-flexion, standing radiographs of the knees and gadolinium contrast-enhanced (CE)-MRI scans were performed and analyzed respectively for Kellgren-Lawrence (KL) grade and 11-point semiquantitative synovitis score. Patients completed the Knee Injury and Osteoarthritis Outcome Score (KOOS) Survey, from which were derived WOMAC pain subscale scores. Correlation analyses of senescence burden (i.e. percent of p16Ink4A positive synoviocytes) to candidate biomarkers in synovial fluid, plasma, serum and urine, and to MRI-based synovitis scores, KL grades, WOMAC pain scores, were done. Partial correlation coefficients after adjustment for age, BMI, and KL grade were determined.

Results: The study cohort had a mean age of 59 yrs, 47% were women, 77% white, and 93% had a KL grade of 2 or higher. Consistent with findings in ex vivo studies of human OA knee specimens and a surgically-induced OA model in mice, we detected p16Ink4A positive, senescent cells in synovial biopsies from OA patients. Moreover, the percent of p16Ink4A positive synoviocytes correlated significantly with a number of protein biomarkers in synovial fluid and plasma; the most strongly correlated was synovial fluid interleukin-6 (IL-6). Senescent synoviocytes also correlated significantly with the degree of synovitis (range 0-2) at the site of biopsy as assessed by the MRI-based synovitis score. A trend for the correlation between senescent synoviocytes and KL grade 1 to 4 was observed; when restricting to patients with KL grades 1 to 3, the correlation was statistically significant. Interestingly, the percent of senescent synoviocytes was also moderately correlated with pain as measured by the WOMAC-A pain subscale.

Conclusion: This cross-sectional study provides further evidence for a relationship between the accumulation of senescent cells in the OA joint, SASP secretion, pain symptoms, and structural changes of knee OA. It supports investigation of senolytics as a therapy for OA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The absence of effective disease-modifying drugs remains an important unmet need in the treatment of osteoarthritis. In recent years, novel pharmacological treatments including targeting TGF-beta signaling in subchondral bone (Zhen *et al.*, Nat Med 2013) or senescence of joint tissues (Jeon *et al.,* Nat Med 2017) have demonstrated promising efficacy in experimental osteoarthritis. However, the translation from experimental models to humans has not been pursued to date. Here, we determined therapeutic and deleterious side effects of these treatment strategies in a preclinical explant model of human knee and facet joint osteoarthritis.

Methods: Osteochondral tissue explants of osteoarthritic human knee tibial plateaus (*n*=10) or lumbar facet joints (*n*=10) were cultured for one week in the presence and absence of an inflammatory stimulus (1 μg/mL LPS). Specimens were left untreated (control) or treated with a senolytic agent (4.5 mg/mL quercetin) or inhibitor of TGF-beta receptor signaling (10μm SB-505124). Subchondral bone turnover (Pro-Collagen-Iα) and tissue inflammation (IL-6, MCP-1) was assessed by ELISA. Tissue viability was determined by MTT staining. Data was analyzed by one-way ANOVA.

Results: Explanted tissues showed no appreciable loss of viability during culture and drug treatment. LPS challenge led to a 4- and 3-fold induction of IL-6 and MCP-1 tissue secretion, respectively. Subchondral bone turnover was not affected by inflammatory conditions. The therapeutic effect of TGF-beta signaling inhibition was revealed by a drastic reduction of pro-Col-I (~75%) and IL-6 (~50%) secretion. Unexpectedly, MCP-1 secretion was significantly elevated (~200%) revealing a TGF-beta-dependent negative feedback mechanism. This side effect was specific for knee osteoarthritis and not observed in facet joint specimens. Senolytic treatment with quercetin did not affect bone turnover, yet strongly induced IL-6 tissue secretion under control (~400%) and inflammatory conditions (~200%).

Conclusion: Taking advantage of a preclinical model of human osteoarthritis, we established therapeutic efficacy of TGF-beta signaling inhibition on subchondral bone turnover in knee and spine. Elevated MCP-1 secretion upon TGF-beta targeting and increased tissue inflammation using senolytic drugs prompt careful evaluation of these potential disease-modifying agents transitioning from experimental to human osteoarthritis. Osteochondral explant models are highly valuable for determining joint-specific tissue responses.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Implant loosening due to loss of bone is the most common cause of total joint replacement revision surgeries. One of the main cause of osteolysis is the shed of wear particles from the implant as it causes an increased local inflammation and osteoclast number and activity. It is known that an A_{2A} adenosine receptor selective ago-

nist (CGS21680, CGS) prevents bone loss in wear particle-induced osteolysis model in mice. But frequent administration requirements and its potential to cause side effects make it a less than optimal treatment. We therefore generated and tested a novel alendronate-CGS conjugate (MRS7216) that specifically localizes to bone targeting the agonist to the site of tissue injury and thereby diminishing the frequency of administration and curtailing systemic side effects.

Methods: The conjugate was synthesized from CGS by sequential activation of the carboxylic acid moiety and reacting with the appropriate amino acid under basic conditions. A PEG_6 linker was incorporated to alendronic acid by direct coupling. Osteolysis in 6–8-week-old C57BL/6J (WT) or A_{2A} KO mice was induced by surgical implantation of 3mg of ultrahigh-molecular-weight-polyethylene particles over the calvaria. Mice received a weekly 10mg/kg intraperitoneal dose of MRS7216 conjugate, starting at the time of surgery. Other groups of mice were treated with equivalent weekly doses of alendronate-PEG_6 (AlenP) or saline respectively. An additional control group underwent sham surgery. New bone formation was studied by Calcein/Alizarin Red-labeling. After 2 weeks, animals were sacrificed and microCT and histology analyses were performed. The studies were approved by the Institutional Animal Care and Use Committee of NYU School of Medicine.

Results: Receptor binding studies demonstrate that the Ki for CGS, 7216 conjugates and the control AlenP molecules were 21.5 nM, 69.2 nM and >10,000 nM respectively, indicating that MRS7216 efficiently binds the A2A adenosine receptor. MicroCT studies showed that WT mice treated with weekly doses of MRS7216 had a significant reduction in bone damage of 40% (p=0.04) compared to saline treated mice. In contrast, AlenP molecules did not prevent bone erosion. Similarly in A_{2A} KO mice MRS7216 treatment did not prevent bone damage. Histological analysis of TRAP stained samples showed a significant decrease of osteoclast number/high-power field (HPF) of 55% (p=0.03) in AlenP treated WT mice compared to the saline treated group. The osteoclast depletion was more dramatic in MRS7216 treated group with an 81% reduction of osteoclasts number/HPF (p=0.002). Additionally alkaline phosphatase staining in MRS7216 treated group, showed a significant increase in osteoblast number per HPF compared to saline (55%, p=0.01) and to AlenP group (45%, p=0.03). Furthermore Double bone labeling with calcein/alizarin red showed a significant increase on femurs bone formation of MRS7216 treated group compared to saline and to Alendronate group (p=0.0092 and p=0.0345).

Conclusion: Alendronate-CGS conjugates represent a novel and specific therapeutic approach to inhibit osteolysis and stimulate new bone formation to prevent prosthetic failure in patients with prosthetic joints or other bone pathologies.

Divergent Mononuclear Cell Participation and Cytokine Release Profiles Define Hip and Knee Osteoarthritis

Ricardo Grieshaber-Bouyer ,[1] Till Kämmerer,[2] Nils Rosshirt,[2] Philipp Koniezke,[2] Sebastien Hagmann,[2] Elena Tripel,[2] Johannes Kirsch,[2] Tobias Gotterbarm,[2] and Babak Moradi[2], [1]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Department of Orthopedics, Heidelberg University Hospital, Heidelberg, Germany, Boston, MA, [2]Department of Orthopedics, Heidelberg University Hospital, Heidelberg, Germany, Heidelberg, Germany

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a progressive joint disease driven by a blend of inflammatory and biomechanical processes. Studies using human samples to understand inflammatory mechanisms in OA frequently recruit OA patients with different affected joints, even though recent evidence indicates that OA is a heterogeneous disease which only culminates in a common end point. Differences in age of onset and the dynamics of disease progression suggest that different joints may represent different disease entities, thereby diluting the discovery potential in a combined analysis. We hypothesized that different OA joints may also differ in immunopathology within the synovium.

Methods: We profiled the immune cell composition (flow cytometry) and cytokine release profiles (ELISA) in purified mononuclear cells from the synovial membrane from 51 patients undergoing either hip (n = 34) or knee (n = 17) replacement surgery. Peripheral blood was collected simultaneously and profiled using flow cytometry. Overall, 48 different cytokines were assayed. Unsupervised computational approaches were used for disease deconstruction.

Results: Hip and knee osteoarthritis were not identical with respect to the inflammatory processes that take place in the synovial membrane. The mononuclear cell infiltration pattern in the synovial membrane was highly variable between individuals, ranging from a CD4+ T cell predominant phenotype to a macrophage predominant phenotype. When directly comparing hip and knee samples, we found that macrophages and CD8+ T cells were expanded fourfold in the synovial membrane of patients with knee OA compared to hip OA, while CD4+ T cells, B cells and NK cells were found at comparable quantities. In contrast, there were no differences in immune cell abundance in the peripheral blood.

Consistent with differences in mononuclear cell infiltration into the joints, we identified differences in the cytokine release profile of cultured cells. Upon isolation and culture of cells from synovial membrane over 24 hours, isolates from hip OA released higher concentrations of Eotaxin (CCL11), G-CSF, GM-CSF, IFN-γ, IP-10 (CXCL10), TNF-α, MIP-1α (CCL3), MIP-1β (CCL4), IL-4, IL-10, IL-17 and lower concentrations of stem cell factor (SCF), thereby highlighting the difference in nature of hip and knee osteoarthritis.

Conclusion: Osteoarthritis affecting different joints has often been regarded as the same disease. This study provides evidence that hip and knee OA are immunologically distinct types of OA, warranting further investigation of different subtypes of OA. Further, this public resource of the cytokine expression landscape and mononuclear cell infiltration pattern of patients with hip and knee osteoarthritis will help accelerate research on the immunobiology of osteoarthritis.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Bone marrow multipotential stromal cells (MSC) are widely used in clinical trials to treat bone and cartilage diseases. However, there is limited information on the role of MSC in the pathogenesis in humans. As osteoarthritis (OA) severity is often associated with an abnormal movement and load distribution on the medial compartment of the knee, the aim of this study was to determine differences in MSC topography and gene expression between the diseased medial and more "macroscopically normal" lateral femoral condyles. Also, we investigated the miRNA profiling of cargo from extracellular vesicles (EVs) secreted by medial OA MSCs (OAMSC-EVs) compared with the ones secreted by healthy MSCs (HMSC-EVs).

Methods: OA MSCs were obtained from femoral condyles of total knee replacement patients and were extracted from subchondral bone after digestion and sorted using the CD271+CD45- phenotype for gene expression analysis. MSCs from healthy donors were isolated from bone marrow aspirate by density gradient centrifugation using Lymphoprep and culture expanded for EV isolation. EVs were isolated from medial and healthy MSCs by differential centrifugation and characterized before miRNA profiling using NanoString technology.

Results: Medial condyles presented higher degree of cartilage damage (OARSI score 20) compared to lateral condyles (OARSI score 3) and sclerotic subchondral bone area was higher in the medial condyles (64.3±7.0% vs 27.6±7.4% area in lateral condyles). CD271+ cells in medial and lateral femoral condyles did not show differences in topography or numbers, and cultured MSCs also presented similar growth rates and trilineage capacities *in vitro*. Three genes were significantly upregulated in medial condyle CD271+ MSCs: GREM1 (lateral MSCs below detection), PTHLH (2.4-fold, p=0.02) and STMN2 (10.5-fold, p=0.02), all of them implicated in osteogenic differentiation and mineralisation. miRNA profiling showed 46 miRNA differentially expressed between OAMSC-EVs and HMSC-EVs.

Conclusion: Despite the apparent differences in cartilage damage and bone sclerosis, no major differences were found between medial and lateral condyles. However, there was upregulation of genes implicated in osteogenic differentiation and mineralisation in medial condyle MSCs that can be associated with sclerotic-plate formation. Also,

there was differences in miRNA between medial and healthy MSCs and MSC-EVs, for which the target genes and implicated pathways need further investigation.

CCN3 Regulates Macrophage Function in MSU-induced Inflammation

Lihua Duan ,[1] Jie Chen,[1] and Jixin Zhong[2], [1]Department of Rheumatology and Clinical Immunology, Jiangxi Provincial People's Hospital, Nanchang, Jiangxi, China (People's Republic), [2]Cardiovascular Research Institute, School of Medicine, Case Western Reserve University, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most common metabolic disease in which monosodium urate (MSU) crystals form and deposit in the joints and soft tissues of patients. While several lines of evidence support the importance of MSU-induced macrophage activation in the inflammatory response in gout, the mechanism remains unclear. Recent studies implicate CCN3 matricellular signaling protein as emerging player in the regulation of inflammation, reactive oxygen species production and angiogenesis. Additional data suggest that CCN3 regulates macrophage polarization and foam cell formation in diabetes and atherosclerosis. However, information regarding the role of CCN3 in gout remains unclear. Therefore, the objective of this investigation was to decipher the role of CCN3 in the pathogenesis of gout.

Methods: A total of 41 gout patients and 41 healthy control subjects, matched for age and sex ratio, were enrolled. PBMCs and serum were harvested and subjected to real-time PCR and ELISA analysis. MSU-induced peritonitis was conducted in LysM-Cre CCN3$^{fl/fl}$ mice with a macrophage-selective deletion of CCN3. In addition, the IL-1β production of bone marrow derived macrophage (BMM) and peritoneal macrophage with CCN3 deletion or not were investigated.

Results: Levels of CCN3 were predominantly increased in gout patients when compared to healthy controls. Furthermore, the sera CCN3 levels showed a positive correlation with inflammatory response protein CRP, while no significant correlation with lipids level were observed. To further address the role CCN3 in the pathogenesis of gout, MSU-induced peritonitis was conducted in LysM-Cre CCN3$^{fl/fl}$ mice with a macrophage-selective deletion of CCN3. As expected, LysM-Cre CCN3$^{fl/fl}$ mice showed a decreased cell infiltration in the peritoneal cavity. In addition, decreased levels of IL-1β in the peritoneal lavage fluid and caspase1 activity in peritoneal macrophage were observed in LysM-Cre CCN3$^{fl/fl}$ mice. Similarly, bone marrow derived macrophage (BMM) and peritoneal macrophage with CCN3 deletion showed an impaired caspase1 activation and IL-1β production in vitro.

Conclusion: These results indicate that CCN3 in macrophage plays a critical role in the development of MSU-induced inflammation.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Knowledge and research results in the field of hand osteoarthritis (hOA) are currently limited, mainly due to the unavailability of tissue samples to develop *in vitro* studies and lack of animal models of this disease. Cellular *in vitro* models are important tools to elucidate the molecular mechanisms and pathways that are involved in hOA, but current cell sources present disadvantages. Induced Pluripotent Stem cells (iPSc) generated by genetic reprogramming of somatic cells are considered ideal tools for these purposes, since they allow the use of unlimited cells with chondrogenic differentiation potential. Therefore, the aim of this study was to generate iPSc-lines from patients with hOA and healthy donors, to evaluate the presence of at-risk single nucleotide polymorphisms (SNPs), and to assess their chondrogenic differentiation potential in order to use them as cellular models of hOA.

Methods: Patients with hOA (non erosive hOA with thumb OA) and a healthy donor were selected for the study. Fibroblasts from 3mm skin biopsies of these patients were isolated. For the reprogramming, transcriptional factors Oct4, Sox2, Klf4 and c-Myc were introduced in these cells by using Sendai virus modified vectors. Cell lines obtained were morphologically, phenotypically and functionally characterized (Fig 1A). To evaluate weather these iPSc lines could be used as cellular model of hOA, presence of 10 SNPs within genes previously associated with hOA was studied by Sanger sequencing. Finally, chondrogenic differentiation capacity of the “healthy” and “ill” iPSc-lines was studied by means of histological techniques after 21 days in micromass culture.

Results: Fibroblasts were isolated from skin biopsies of two patients with radiographic hOA and one healthy donor. Embryonic stem cell-like colonies emerged in culture three weeks after reprogramming, which fulfilled the morphologic and phenotypic criteria to be considered pluripotent cells. This means, positivity for alkaline phosphatase activity (Fig 1B) and the pluripotency markers Tra1-81 and Nanog (Fig 1C), high relative expression levels of the pluripotency-related genes OCT4, SOX2, NANOG and CRIPTO, and capacity to give rise to cells from the three germ layers. Regarding SNPs studies, we found sequence variants in 6 out of the 10 genes studied. Interestingly, the at-risk allele within the genes SMAD3 and IL1-R1 was just detected in the “ill” iPSc-lines (Fig 1D). Finally, The “ill” iPSc-line

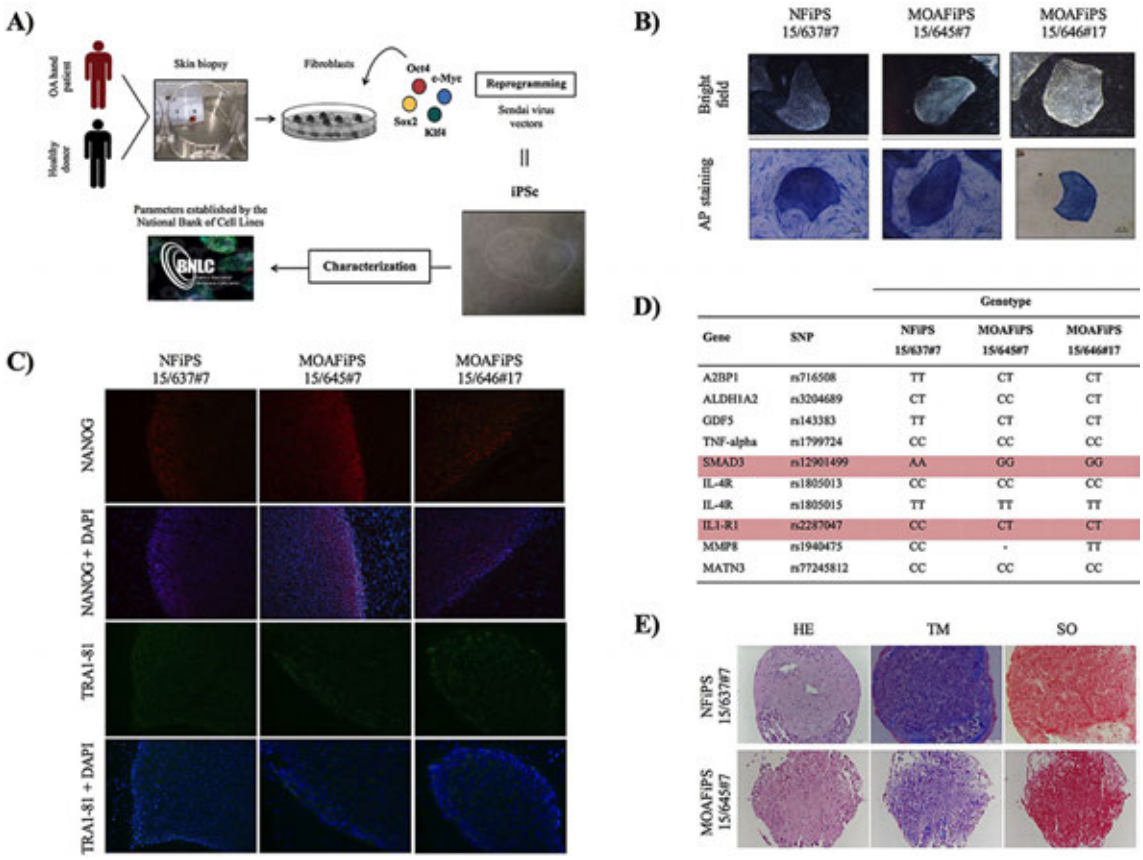

Figure 1. (A) General scheme of the followed process to generate iPSc-lines. (B) Bright field images of one representative iPSc-colonie from each donor and alkaline phosphatase (AP) activity staining. (C) Immunofluorescence images of pluripotency markers (NANOG and TRA-1-81) of representative clones from each cell line. Scale 100 μm. (D) Summarize of the results obtained after single nucleotide polymorphism analysis. (E) Haematoxilin-Eosin (HE), Masson's Tricromic (TM) and Safranin-O (SO) staining after chondrogenic differentiation of the iPSc lines. x10 magnification.

(MOAFiPS 15/645#7) showed worse chondrogenic differentiation than the "healthy" iPSc-line (NFiPS 15/637#7), as shown by the micromasses collagen and proteoglycan content (Fig 1E).

Conclusion: To our knowledge, the generation of iPSc-lines form patients with hOA is reported for the first time. The presence of sequence variants within the studied genes was maintained after fibroblast reprogramming. The generated iPSc-lines showed differences in their chondrogenic differentiation capacity, demonstrating their usefulness to model hOA *in vitro*, and to deeper study the role of these genetic variants in the pathogenesis of hOA.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteopenia and fragility fractures have been associated with HIV infection. Tenofovir, a common antiviral in HIV treatment, also leads to increases in bone catabolism markers and decreased bone mineral density (BMD) in children and young adults. In murine models and human cell lines, tenofovir inhibits ATP release and decreases extracellular adenosine levels. We have recently reported that Netrin-1 is an autocrine and paracrine regulator of osteoclast differentiation with unique role for Netrin-1 in osteoclast biology and inflammation. We have also described that blosckade of adenoine uotaken with dipyridamole, prevent bone loss caused by tenofovir in mice. We hypothesized that Netrin1 might be involved in bone resorption induced by tenofovir, and if we increase adenosine levels, we could revert the deleterious effect of tenofovir.

Methods: Male C57Bl/6 mice were treated as follows: IP injection of saline (control), tenofovir 75mg/Kg/day, dipyridamole 25mg/Kg/day, combination tenofovir/dipyridamole (n=10, 4 weeks) and after sacrifice, long bones were prepared for histology. Primary murine M-CSF/RANKL-induced were challenge with Tenofovir 1mM alone or in combination with Dipyridamole 1mM, and expression of Netrin-1 and its receptors Unc5B and DCC were study by Western Blot.

Results: Mice treated with tenofovir showed an increased expression of Netrin-1 and its receptor Unc5b when compare to control mice, and treatment with Dipyridamole partially reverting the expression of these molecules. In vitro, tenofovir tenofovir increases Netrin1 expression (44±4% increased vs. basal, $p< 0.05$) and secretion (16±5% increased vs. basal, p=ns) and Unc5b expression (74±18% increased vs. basal, $p< 0.05$) 24 hours after stimulation, and pre-treatment with dipyridamole reverted the effect. No changes in DCC expression were observed.

Conclusion: These results suggest that Netrin-1/Unc5b might be involved in bone resorption mediated by tenofovir, and treatment with agents that increase local adenosine concentrations, like Dipyridamole, might prevent this bone loss.

Tenofovir Modulates Semaphorin 4D Signaling and Regulates Bone Homeostasis, Which Can Be Counteracted by Dipyridamole and Adenosine A2A Receptor

Aranzazu Mediero ,[1] Patricia Llamas-Granda,[2] Bruce Cronstein,[3] Raquel Largo,[4] and Gabriel Herrero-Beaumont[4], [1]IIS-FUNDACION JIMENEZ DIAZ, Madrid, Spain, [2]IIS-FUNDACION JIMENEX DIAZ, Madrid, Spain, [3]Department of Medicine, Division of Rheumatology NYUSoM, NYC, [4]IIS-Fundación Jiménez Díaz, Madrid, Madrid, Spain

Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Semaphorins (Sema) are a family of proteins associated with neuronal development and guidance. Sema4D/CD100 was first identified as a regulator of immune response in resting T cells and NK cells. It has been recently found that loss of CD100 expression plays an important role in dysfunctional immunity in HIV infection. Osteopenia has been associated with HIV infection. Tenofovir, one of the most commonly used antivirals in HIV, increases in bone catabolism markers and decreased bone mineral density (BMD). Sema4D is secreted by osteoclasts (OC) in the presence of RANKL and binds to its receptor PlexinB1 on osteoblasts (OB) to inhibit their differentiation and function by activating RhoA/ROCK. Adenosine A2AR activation inhibits Sema4D-mediated OC activation and diminishes inflammatory osteolysis. We have recently described that treatment with agents that increase local adenosine concentrations, like dipyridamole, prevent bone loss following tenofovir treatment *in vivo* and *in vitro*. We hypothesized that Sema4D signaling might be regulated by tenofovir to alter bone turnover, and dipyridamole may counteract this effect.

Methods: Male C57Bl/6 mice were treated as follows: IP injection of saline (control), tenofovir 75mg/Kg/day, dipyridamole 25mg/Kg/day, combination tenofovir/dipyridamole (n=10, 4 weeks) and after sacrifice, long bones were prepared for histology. Primary murine M-CSF/RANKL-induced OC and stimulated OB were challenge with Tenofovir 1mM alone or with dipyridamole 1mM, and expression of Sema4D/PlexinB1, RhoA/ROCK and b-catenin were study by Western Blot and inmmunostaining (n=3-4). OB differentiation was studied by alizarin red staining.

Results: Mice treated with tenofovir showed an increased expression of Sema4D and its receptor PlexinB1 when comprare to control mice, and treatment with dipyridamole reverted the expression of these molecules. In vitro, tenofovir inhibits OB differentiation and treatment with dipyridamole reversed this effect. In OC, tenofovir increases Sema4D expression (1191±32% increase vs basal, $p< 0.05$) and secretion (51±20% increase vs basal, $p< 0.05$) 24 hours after stimulation, and pretreatment with dipyridamole reverted this effect. No changes in PlexinB1 expression were observed in OB. Both total b-catenin and de-phospho b-catenin (active) were increased in the cytoplasmic fraction and decreased in the nuclear fraction in OB 15 minutes after treatment with tenofovir and this was reverted in the presence of dipyridamole. Phosphorilation of RhoA was increased in OB by tenofovir 10 minutes after treatment (32±11% increase vs. basal, $p< 0.05$) and reverted by dipyridamole, and ROCK1 was increased by tenofovir 15 minutes after treatment (83±35% increase vs. basal, $p< 0.05$), and dipyridamole decreases the expression as well.

Conclusion: These results suggest that tenofovir increases bone loss by activation Sema4D/PlexinB1 signaling that inhibis OB differentiation. Treatment with agents that increase local adenosine concentrations, like dipyridamole, might prevent this bone loss following inhibition of the pathway and increase of OB differentiation.

Inhibition of CD44 Intracellular Domain Production Suppresses Bovine Articular Chondrocyte De-differentiation Induced by Excessive Mechanical Stress Loading

Yasumori Sobue ,[1] Nobunori Takahashi,[2] Naoki Ishiguro,[2] and Toshihisa Kojima[2], [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Department of Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

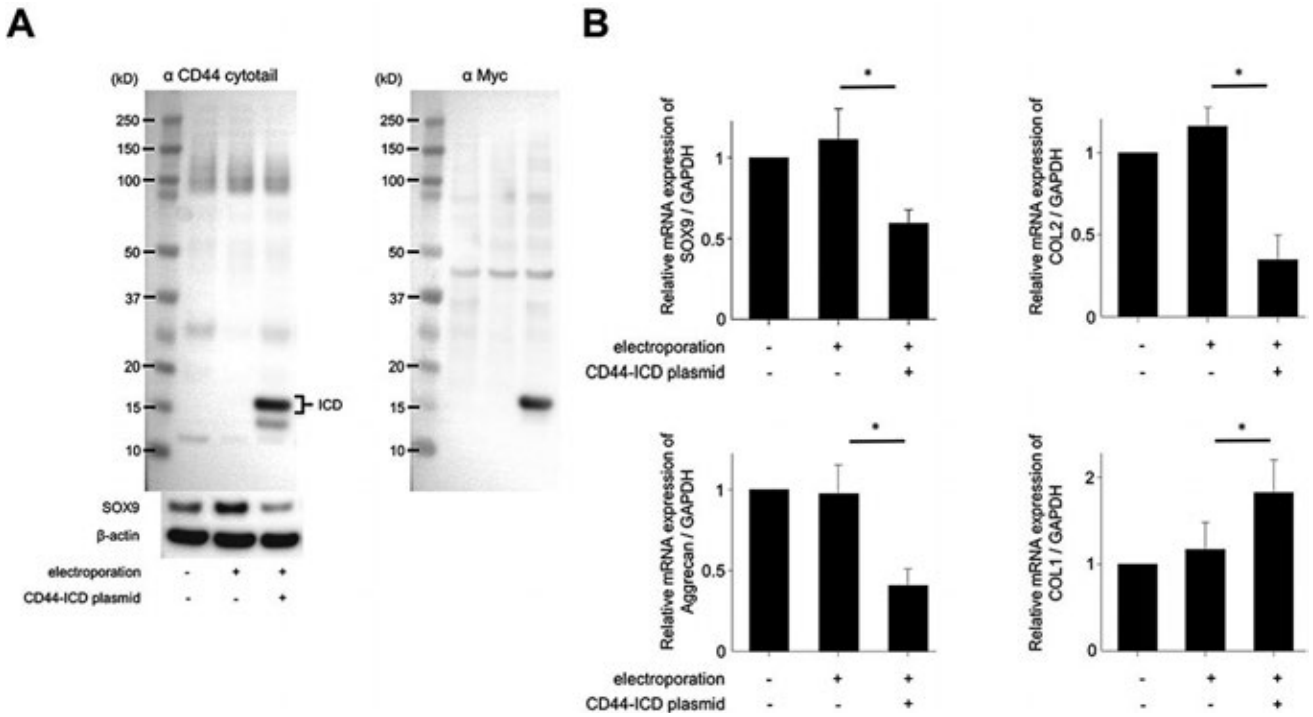
Background/Purpose: CD44 fragmentation is enhanced in chondrocytes of osteoarthritis (OA) patients. Excessive mechanical stress loading is a risk factor for OA, but the molecular mechanism underlying the relationship is unclear. We hypothesized that mechanical stress-induced enhancement of CD44-ICD production plays an important role in the de-differentiation of chondrocytes and OA. This study aimed to assess the relationship between CD44-ICD and chondrocyte gene expression.

Methods: Monolayer cultured primary bovine articular chondrocytes (BACs) were subjected to cyclic tensile strain (CTS) loading using a stretching system (STB-140) at various intensities. An ADAM10 inhibitor (GI254023X) and γ-secretase inhibitor (DAPT) were used to inhibit CD44 cleavage. In overexpression experiments, BACs were electroporated with a plasmid encoding CD44-ICD(pCMV/myc/cyto-CD44ICD).

Results: CTS loading increased the expression of ADAM10 and subsequent CD44 cleavage, while decreasing the expression of SOX9, aggrecan, and type 2 collagen (COL2) in an intensity-dependent manner. Both GI254023X and DAPT reduced the production of CD44-ICD upon CTS loading, and significantly rescued the reduction of SOX9 expression by CTS loading in a dose-dependent manner. Chemical inhibition of CD44-ICD production also rescued aggrecan and COL2 expression following CTS loading.

Induction of chondrocyte de-differentiation by CD44-ICD overexpression

The effect of CD44-ICD overexpression on the expression of chondrogenic differentiation-related genes was also assessed. As shown in Fig. A, two CD44-ICD bands of about 15 kD (a strong band and weak band) were observed in lysates of BACs transfected with the CD44-ICD plasmid by Western blot, while corresponding bands were absent in BACs that were not transfected or were transfected with control plasmid. SOX9 protein expression was reduced in BACs transfected with CD44-ICD, but not in controls (Fig. A). CD44-ICD significantly decreased the mRNA expression of SOX9, aggrecan, and COL2, while increasing the expression of COL1 mRNA (Fig. B). This suggests that the ability to maintain the chondrocyte phenotype was disrupted by CD44-ICD overexpression. These results suggest



Effect of CD44-ICD overexpression on bovine articular chondrocytes (BACs) de-differentiation. (A) BACs were transfected with plasmid DNA expressing CD44-ICD (pCMV/myc/cyto-CD44ICD) or empty plasmid as a control using an electroporator (NEPA21). A strong band of about 15 kD was observed in BACs transfected with the CD44-ICD plasmid, which was consistent with the addition of anti-Myc antibody, and SOX9 levels were reduced in these cells. (B) CD44-ICD overexpression significantly decreased the mRNA expression of chondrocyte differentiation markers (SOX9, aggrecan, and collagen type 2 [COL2]). In contrast, CD44-ICD overexpression significantly increased the mRNA expression of a chondrocyte de-differentiation marker (collagen type 1 [COL1]). N = 6, *p < 0.05.

that CD44-ICD overexpression or CD44-ICD production upon excess mechanical stress loading can promote the de-differentiation of articular chondrocytes.

Conclusion: Our findings suggest that CD44-ICD is closely associated with the de-differentiation of chondrocytes. Excessive mechanical stress loading promoted the de-differentiation of BACs by enhancing CD44 cleavage and CD44-ICD production. Suppression of CD44 cleavage has potential as a novel treatment strategy for OA.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis, affecting nearly 10% of the US population and one of the contributing factors in OA pathogenesis is inflammaging, chronic low grade inflammation. With injury and aging there is dysfunction of chondrocyte mitochondria, thought to be a central event in inflammaging, resulting in reduction of intracellular and extracellular ATP and extracellular adenosine. Reductions in extracellular adenosine or loss of A2AR leads to the development of OA. We therefore explored determined whether A2AR ligation regulates mitochondrial health *in vivo* and *in vitro.*

Methods: Primary murine WT and A2ARKO as well as primary human chondrocytes were isolated from neonatal mice or differentiated from surgical discard, treated with medium (CTRL) or IL-1β (5ng/mL for 4h) with and without the A2AR agonist, CGS21680 (1uM for 1h, CGS) or CGS alone and then stained with TMRM to evaluate mitochondrial length, network volumes and membrane polarity. RNAseq, RT-PCR and transmission electron microscopy (TEM) were performed in untreated murine chondrocytes and proteins of interest were evaluated by WB. Mitochondrial markers were also evaluated in rat post-traumatic OA (PTOA) and mouse obesity-induced OA (OB-OA) models*in vivo.* Human chondrocytic cells (T/C28-a2) were grown in culture, treated as stated above and submitted for TEM to study mitochondrial ultrastructure. Primary human chondrocytes were cultured from discarded surgical specimens.

Results: WT chondrocytes treated with CGS +/- IL-1β had increased mitochondrial lengths than cells that received medium or IL-1β alone ($p< 0.0001$, ONE-Way ANOVA). There were no significant differences in mitochondrial lengths of untreated WT or null chondrocytes but loss of A2AR signaling prevented mitochondrial length expansion after stimuli ($p< 0.04$, ONE-Way ANOVA). Depolarization upregulates total PINK1 expression in A2AR-/- ($p< 0.005$, unpaired, two-tailed t-test) but not Parkin levels. ROS burden was reduced and mitochondrial markers were improved in PTOA and OB-OA models in vivo. In fully differentiated human chondrocytes, A2AR ligation after stimulation with IL-1β increased TMRM and mitochondrial volumes ($p< 0.0001$, ONE-Way ANOVA). T/C28-a2 cells treated with CGS after IL-1β exposure had significantly reduced cristae widths ($p< 0.0001$) and an increased number of cristae junctions per mitochondria ($p=0.02$, ONE-Way ANOVA).

Conclusion: A2AR ligation enhances mitochondrial function and biomass in murine chondrocytes *in vitro*and *in vivo* in models of OA and, thereby diminishes the signs of inflammaging, maintains chondrocyte homeostasis and reverses OA *in vivo*.

Session Date: Tuesday, November 12, 2019

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a disease of the whole joint, affecting cartilage, ligaments, menisci, bone and synovial tissue. We previously found that choline kinase alpha (ChoK) expression was upregulated in human OA synovial and cartilage tissues, and inhibition of ChoK decreased production of proinflammatory cytokines by OA synovial fibroblasts and inhibited chondrocyte catabolic responses to IL-1b *in vitro*. In this study, we evaluated the effects of ChoK inhibition on OA development *in vivo* in two animal models of OA.

Methods: Collagenase-induced osteoarthritis (CIOA) was done in 12-week old male C57BL/6 mice (intraarticular injection of 1 U of collagenase in left knee and PBS in the contralateral knee). MN58b (a ChoK inhibitor) was administered daily via intraperitoneal injection (i.p) at a dose of 2.5mg/kg. The control group received PBS i.p. Mice were sacrificed at 2 weeks. The destabilization of the medial meniscus (DMM) surgery-induced OA was performed in 12 weeks old male C57BL/6 mice on the right knee with sham surgery performed on the contralateral knee (control). PBS or MN58b (2.5mg/kg) i.p. was administered daily for 2 weeks and then every other day until 12 weeks when mice were sacrificed. Joints were graded for synovitis (1 none to 5 severe). Micro-computed tomography (μCT) at $(9\ \mu m)^3$ voxel size was used to evaluate associated bone damage in the DMM model. The medial and lateral femoral condyle (MFC, LFC) and medial and lateral tibial plateau (MTP, LTP) of the arthritic and contralateral knees were registered and visualized in tri-plane orthogonal views, centered in each region, and also in periodic 2-D planes (150 per knee). Joint sections were analyzed by histology with H&E and Saf-O/FG and scored for cartilage damage and osteophyte size and maturation, as well as by immunohistochemistry, probing for ChoK, CD86 and iNOS.

Results: In CIOA, synovitis was reduced from 2.0±1.5 (range 1–5, N=13) in control mice to 0.5±1.0 (range 0–3, N=11, p=0.03) in MN58b-treated mice. Compared to the control group, the MN58b-treated CIOA joints had a lower number of infiltrating cells in the synovial membrane that were positive for ChoK, iNOS and CD86. In the DMM model, cartilage damage in the control group (4.0±2.0, range 2–6, N=9) was reduced by MN58b treatment (1.8±1.3, range 0–4, N=10, p=0.018). Furthermore, medial osteophytes in the control group (1.04±0.59, range 0–1.9) tended to be reduced

in size by MN58b (0.72±0.6, range 0–1.7, p=0.1), although no difference was observed in the degree of maturation. μCT indicated that MN58b treatment reduced medial osteophyte size (by 28%, p=0.04) and medial subchondral plate thickness (by 12%, p< 0.01).

Conclusion: Our results show that ChoK inhibition reduces the degree of synovitis in CIOA animal model of OA, and cartilage damage and osteophyte size in the DMM model of OA. These findings suggest that ChoK may mediate multiple pathways of joint damage in the pathogenesis of OA and be a potential therapeutic target.

Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While smoking is an important environmental risk factor for rheumatoid arthritis (RA) development, only a small proportion of Korean patients with RA were found to have tobacco exposure. Since Helicobacter pylori (HP) infection is not only highly prevalent among Korean adult population but also causes chronic gastric inflammation, we aimed to test potential interaction between shared epitope (SE) and HP infection for the risk of anti-citrullinated protein antibody (ACPA)-positive RA in a Korean population.

Methods: SE distribution and HP infection status were compared between ACPA-positive patients (n=202 for cases) who met 1987 ACR classification criteria for RA and age- and sex-matched healthy controls (n=187 for controls). SE

Table 1. Association between rheumatoid arthritis and shared epitope (SE) or Helicobacter pylori (HP) infection

Model 1[a]			Model 2[a]		
	OR [95% CI]	p		OR [95% CI]	p
SE	7.40 [4.60-11.90]	<0.0001	SE	7.08 [1.96-25.49]	0.003
HP infection	2.72 [1.42-5.21]	0.003	HP infection	2.62 [0.85-8.12]	0.093
			SE x HP infection	1.05 [0.27-4.15]	0.94

[a]Both models included age and sex in addition to the dependent variables presented above.

SE x HP infection is the interaction variable generated by a product of SE (0, 1) and HP (0, 1).

was considered positive for HLA-DRB1*01:01, *01:02, *04:01, *04:04, *04:05, *04:08, *04:10, *10:01, *14:02, and *14:06. HP infection was assessed by ELISA based anti-HP IgG titers (cut-off value of 20 U/mL). Logistic regression analysis was used to estimate the odds ratio (OR) and 95% confidence interval (CI). The relative excess risk due to interaction (RERI) based on OR was estimated to assess additive interaction.

Results: Patients with RA showed a mean (standard deviation, SD) age of 41 (11.7) years with 63.3% female. The anti-HP IgG titer was significantly higher among RA patients than controls (mean±SD, 6832±6406 vs. 3539±5238, $p < 0.0001$). RA patients showed a higher prevalence of HP infection and SE than controls (90.1% vs. 75.9%, $p < 0.0001$ for HP infection; 75.2% vs. 35.1%, $p < 0.0001$ for SE). SE and HP infection were independently associated with RA, adjusting for age and sex (Table 1, Model 1). The magnitude of association between HP infection and RA was similar between SE carriers (2.63 [1.17-5.88]) and non-carriers (2.72 [0.90-8.47], adjusting for age and sex. We found no multiplicative interaction between HP infection and SE for the risk of RA (measure of interaction [95% CI] = 1.05 [0.27-4.15, $p = 0.94$) (Table 1, Model 2). Although the additive interaction was positive ($RERI_{OR}$ [95% CI] = 9.87 [-3.73-23.48], $p = 0.15$), it was not statistically significant possibly due to limited power.

Conclusion: There was a significant association between RA and HP infection independent of SE status. We found no multiplicative interaction but positive, albeit statistically not significant, additive interaction between HP infection and SE for the risk of RA. Whether the association derives from causal relationship or merely suggests a higher susceptibility towards HP infection among RA patients remains to be determined.

Gingival-Derived Mesenchymal Stem Cells Alleviate Cartilage Damage in Collagen-Induced Arthritis via Suppressing Activities of Inflamed Synovial Fibroblast

Ximei Zhang ,[1] Julie Wang,[2] Nancy Olsen,[3] Wael Jarjour,[4] and Song Guo Zheng[4], [1]Ohio State College of Medicine, Columbus, [2]Ohio State University, columbus, [3]Penn State University, Hershey, PA, [4]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dysfunction of immunology and inflammatory responses is crucial in initiating and promoting bone/cartilage destruction in rheumatic arthritis (RA). Inflamed synovial fibroblast cells (ISFs) are the most prominent player in both inflammation and joint destruction in RA. ISFs not only produce pro-inflammatory cytokines that promote the differentiation and activation of osteoclasts and bone erosion but also expresses matrix metalloproteinases (MMPs) that contribute to matrix degradation. In addition, ISFs have a tumor-like behavior that directly attaches to articular cartilage and invades the extracellular matrix. Gingiva-derived mesenchymal stem cells (GMSC) are a unique population of mesenchymal stem cells(MSCs) with the intrinsic ability of self-renewal, potential for multilineage differentiation and potent immunoregulatory ability. Our preliminary data and many studies from other groups have demonstrated that infusion of MSCs significantly suppressed the disease development in various animal models of autoimmune diseases including RA model, nonetheless, it is unknown whether GMSC can target ISFs in rheumatoid arthritis.

Methods: To explore whether GMSCs suppress cytokines production of ISFs derived from patients with RA, ISFs were co-cultured with GMSC or control cells with different ratios (1:2-1:50 of GMSCs to ISFs) and the production of the pro-inflammatory factors TNF-α, IL-6, IL-12, IL-18, IL-1β, IL-11, IL-15, monocyte chemoattractant protein (MCP)-1, MMPs as well as anti-inflammatory cytokines IL-10, IL-1R were measured by qPCR or ELISA. ISFs were also co-cultured with GMSCs for 1-3 days and detected by CCK-8 (proliferation) or crystal violet staining (migration and invasion) to study whether GMSCs inhibit the tumor-like biologic behaviors of ISFs. To determine whether GMSC target ISFs in vivo, GMSC were adoptively transferred into CIA mice and humanized animal model.

Results: Our results showed that GSMC but not control cells significantly inhibited the production of the pro-inflammatory factors and matrix metalloproteinases, as well as proliferation, migration and invasion of ISFs isolated from RA patients in vitro. In line with these results in vitro, infusion of GMSCs reduced the activation of osteoclasts and bone erosion in CIA mice. ISFs isolated from CIA treated with GMSCs showed reduced expression of pro-inflammatory factors and matrix metalloproteinases and suppressed tumor-like biologic behaviors, with lower proliferation, migration and invasion. Moreover, infusion of GMSC markedly controlled the migration and invasion of RA-ISFs in a humanized animal model.

Conclusion: GMSC target RA-ISFs that implicates GMSC may have a potential promise to treat patients with RA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disorder, characterized by joint inflammation and bone destruction. The fibroblast-like synoviocyte(FLS) contributes to the pathogenesis of RA through cellular proliferation and production of cytokines or chemokines. Recently, blockade of the bromodomain and extra-terminal domain (BET) family protein was reported to be a potential therapeutic target by inhibiting epigenetic interaction between bromodomains and acetylated histones. This study aimed to investigate the effects of bromodomain-

containing protein 4 (BRD4) inhibition on tumor necrosis factor (TNF)-α-stimulated RA-FLS and osteoclast using BRD4 inhibitor, I-BET762.

Methods: RA-FLSs were treated with TNF-α in the presence of I-BET762 for 48 h. The cell viability and proliferation were measured after 24, 48, and 72 h in I-BET762-treated RA-FLS using CCK-8 colormetric assay. We then screened pro-inflammatory mediators by using the human inflammation antibody array. The levels of interleukin (IL)-6, IL-8 and CXCL-10 were measured in culture supernatants of TNF-α-stimulated RA-FLS by ELISA. Migrations were analyzed by the wound healing assay. We compared the expression of BRD2, BRD3 and BRD4 level by BRD4 specific inhibition in RA. Expression of c-Myc was detected by using Western blot. PBMC isolated from buffy coat were cultured with M-CSF and RANKL for 14 days in the presence or absence of I-BET762. Cells were stained with tartrate-resistant acid phosphatase (TRAP) and the number was counted by light microscopy. The ability of actin formation in osteoclast was evaluated by immunofluorecent stain.

Results: I-BET762 had no effect on cytotoxicity and proliferation of RA-FLS. I-BET762 reduced the secretion of IL-6, CXCL-10 and regulated upon activation, normal T cell expressed, and secreted (RANTES) from RA-FLS in the antibody array. Level of IL-6, IL-8 and CXCL-10 were significantly decreased after treatment with I-BET762 by ELISA. The number of migrated cells decreased in response to I-BET762 compared with the vehicle. The expression levels of BRD2, BRD3 and BRD4 proteins did not change with I-BET762. Expression of the target molecule, c-Myc, was decreased in I-BET762 treated RA-FLSs. TRAP-positive multinucleated (more than three nuclei) cells were reduced in a dose-dependent manner. The actin formation of podosome, actin belt and actin ring were inhibited in the presence of I-BET762.

Conclusion: Inhibition of BRD4 by I-BET762 led to down-regulation of pro-inflammatory mediators, migration and expression of c-Myc in RA-FLSs. The differentiation of osteoclast and resorption activity was inhibited by I-BET762. These data suggest that the I-BET762 may have anti-inflammatory properties and prevent bone loss in RA.

Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The AMP-RA network applies cutting edge molecular single cell technologies to study synovial tissue obtained from rheumatoid arthritis (RA) patients using US guided synovial biopsy (USGSB). Ultrasound can provide objective joint level measures of synovial inflammation, including hypertrophy (greyscale ultrasound, GSUS) and hyperemia (Power Doppler ultrasound, PDUS). Phase 1 AMP-RA demonstrated that USGSB was effective and safe for obtaining synovial tissue in the United States in patients with RA. In Phase 2 RA patients with active disease were recruited based on treatment exposure. We examined the relationship between joint level US variables, clinical characteristics, and synovial histology in Phase 2 patients.

Methods: In this multi-center study, eligible AMP-RA Phase 2 subjects had classifiable RA, ≥2 actively inflamed joints including the biopsied "sentinel" joint, a CDAI >10, and a GSUS of ≥2 of the biopsied joint. Biopsies were done using either QuickCore™ needle or Portal and Forceps. Subject Groups defined by treatment exposure were: (1) DMARD naïve/ minimally exposed (≤ 4 weeks of MTX)((n=40), (2) MTX-IR despite ≥3 months of MTX (n=29), (3) TNF-IR despite ≥3 months of anti-TNF therapy. US scanned sentinel joints were scored using a 4-point semi-quantitative scale of GSUS and PDUS alongside composite RA disease activity measures. Retrieved tissue was fixed, stained and paraffin embedded, then sectioned and stained by H&E. Tissues were assessed for quality based on presence of and quantity of lining layer and synovium. Tissues were scored using 2 of 3 Krenn domains: lining layer (Krenn L) (0-3) and inflammatory infiltrate (Krenn I)(0-3) by three pathologists (BB, ED, EG).

Results: Of 119 synovial biopsies obtained from 13 sites across the USA and UK, 93 (83%) were of good quality. Clinical Groups 1, 2, and 3 had similar disease activity and US scores but the expected differences in disease duration (Table 1). GSUS, PDUS, CDAI, and Disease Duration were similar between the samples regardless of histology quality. Krenn scores differed between the Groups: Group 1 biopsies had higher mean Krenn(I) and Krenn(L) scores and a greater proportion with Krenn(L) and Krenn(I) scores of >1 (Table 2). PDUS grade correlated with the Krenn(L) and the Krenn(I) scores (p=0.003, r=0.32). GSUS grade failed to correlate with either histological measure (p=0.55, p=0.43 respectively).

Conclusion: In this cohort, the clinical and ultrasound characteristics did not correlate with tissue quality. Ultrasound measures of synovial hyperemia correlate with histologic joint infiltrates. Group 1 subjects had the shortest disease duration and least medication exposure. Despite such, Group 1 had higher mean Krenn(I) scores when compared to the MTX-IR (Group 2) and TNF-IR (Group 3) subjects.

Table 1. Clinical, Ultrasound and Histology correlates for 3 clinical groups.

Table 1: Clinical, Ultrasound and Histology correlates for 3 clinical groups.

	Number of Samples	CDAI Mean(SD)	Disease Duration Years Mean (SD)	GSUS Mean(SD)	PDUS Mean(SD)
Group 1	40	30.32(16.33)	1.30 (3.93)	2.03(0.76)	1.18(0.95)

Major Histocompatibility Antigen HLA-DQB1*0601 Is Associated with Rheumatoid Arthritis Among Indians in a Replication Study: Evidence of Gene-Environment Interaction with LPG Stove Use

Able Lawrence ,[1] Anshul Dhar,[2] Swayam Prakash,[3] Suvrat Arya,[4] Amita Aggarwal,[5] and Suraksha Agrawal[6], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Lucknow, Uttar Pradesh, India, [2]SGPGIMS, Lucknow, India, [3]Cellular and Molecular Immunology Laboratory University of California Irvine, School of Medicine USA, Irvine, CA, [4]Sanjay Gandhi Postgraduate Institute, Lucknow, India, Lucknow, India, [5]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India, [6]SGPGIMS, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Shared epitope smoking interaction does not fully explain MHC association in Rheumatoid Arthritis (RA). We have previously shown HLA-DQB1*0601 (DQ6.1) to be a susceptibility allele in India1. It has a restricted geographic distribution being common in Japan, India and parts of middle-east while absent in Africa and western Europe (Fig 1 heat map of DQ6.1 distribution). In Pristane induced arthritis, susceptibility is determined by rat ortholog of DQ locus RT1-B. Thus it is possible that HLA-DQ6.1 may have an interaction with hydrocarbons. We therefore planned this study to confirm the association of DQ6.1 with RA and explore interactions with smoking and household fuel use.

Methods: Patients with RA (ACR 2010 criteria) and healthy controls of similar ethnic background were included. Data on environmental exposure like tobacco use, active and passive smoking and exposure to household smoke during cooking including biomass fuels (wood, coal, cow-dung cake) and hydrocarbon fuels LPG and kerosene was collected. Patients sex, age of onset, duration of exposure, birth year, RF, anti-CCP were also recorded. HLA-DQB1*0601, DQB1*0603 and DQA1*0103 were typed using Sequence specific PCR. The association of Chi-squared test was used to test the strength of association. Gene environment interaction was studied using Cox regression after stratifying by genotype.

Results: 175 patients (21 males) and 263 healthy controls were included. The median age of onset of RA was 37(range 17-67 years) and median duration of disease was 9 years(range 2mo to 35 years). Of these 138/172 (80%) were RF positive and 104/126 (82.5%) were anti-CCP positive. Overall 165 were seropositive and 7 seronegative. Among patients DQB1*0601 was present in 45/175 (25.7%) while DQB1*0603 in 27/175(15.4%) and DQA1*0103 in 35/175(20%). Among controls, DQB1*0601 was present in 47/263 (17.9%) while DQB1*0603 was present in 31/263(11.8%) and DQA1*0103 in 42/263(16%). The putative risk allele DQB1*0601 was significantly associated with RA with an Odds Ratio of 1.59 (P< 0.005) confirming the association. There was no significant association be-

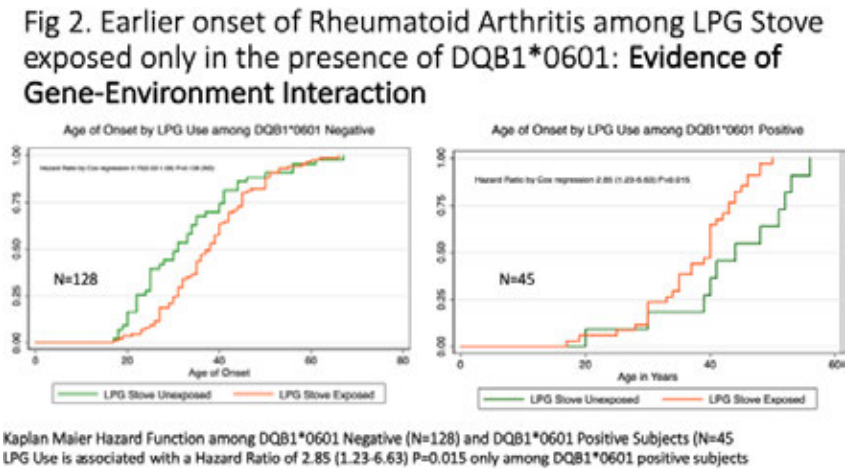
Figure 1. Heat map of DQB1*0601 prevalence



Kaplan Maier Hazard Function among DQB1*0601 Negative (N=128) and DQB1*0601 Positive Subjects (N=45
LPG Use is associated with a Hazard Ratio of 2.85 (1.23-6.63) P=0.015 only among DQB1*0601 positive subjects

tween serological status with presence of DQ6.1. Smoking was rare among Females (4/154 versus 9/21 in males). 116/175 had exposure to biomass fuels (wood 107, cow-dung cake 72) while LPG stove was used by 121/175 subjects. Exposure to LPG was associated with earlier age of onset of RA (median 40 years versus 44 years) in the presence of DQ6.1 with a hazard ratio of 2.5 (CI 1.2-5, P=0.014, Figure 2) but not in DQ6.1 negative patients.

Conclusion: This replication study confirms the association of DQB1*0601 with RA. Smoking is rare among Indian women with RA. There is signal of gene-environment interaction between DQ6.1 and exposure to LPG stoves.

NADPH Oxidase 4 Regulates the Migration and Invasion of Synoviocytes in Rheumatoid Arthritis Through Pro-angiogenic Factor Secretion

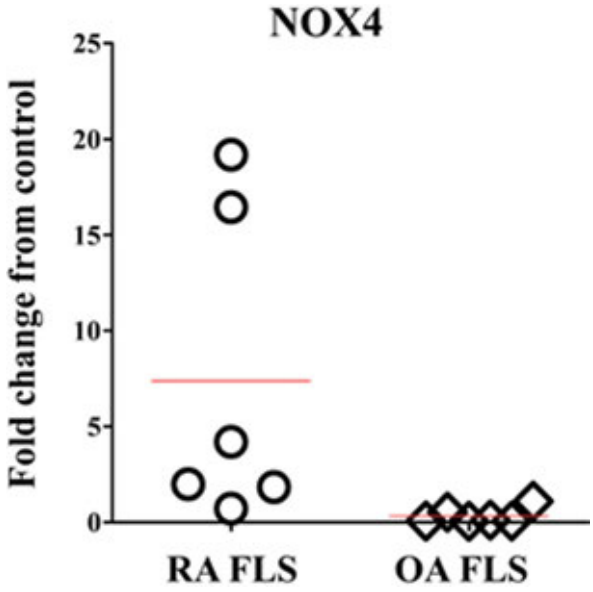
Ha-Reum Lee ,[1] Su-Jin Yoo,[2] Chan-Geol Park,[2] Jinhyun Kim,[2] In Seol Yoo,[2] and Seong Wook Kang[2], [1]Chungnam National University Hospital, Daejeon, Republic of Korea, [2]Chungnam National University Hospital, Daejeon, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

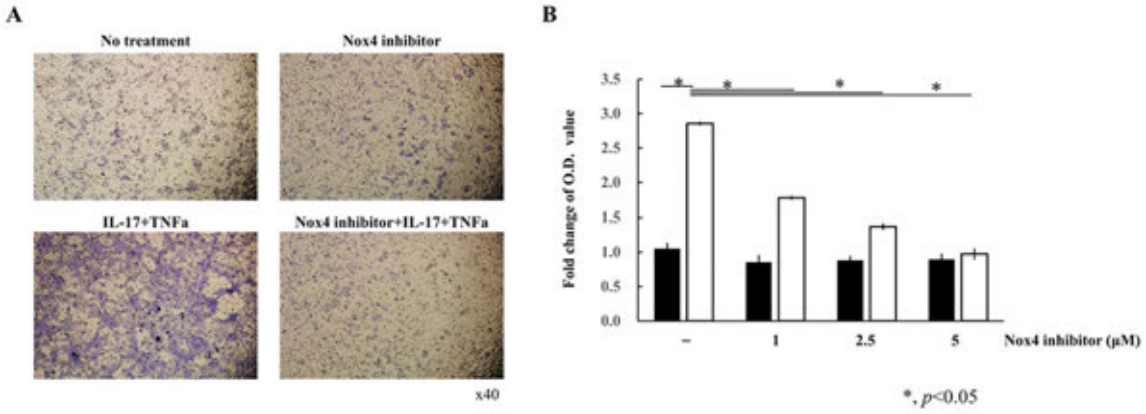
Background/Purpose: Fibroblast-like synoviocytes (FLS) are key effector cells in the pathogenesis of rheumatoid arthritis (RA) through the increased cell migration, degradation of extracellular matrix, and cartilage destruction. Reactive oxygen species (ROS) also have been known to be involved in the initiation and progression of RA, such as secretion of immunoregulatory and pro-angiogenic factors. Despite the important interrelationship between RA FLS and ROS, the mechanism of interaction and signaling is not clear.

Methods: In this study, the differential expression of six NADPH Oxidase subunits was analyzed after stimulation with recombinant interleukin-17 (IL-17) and tumor necrosis factor-alpha (TNFa) in FLS from RA and osteoarthritis (OA) patients. In particular, NADPH Oxidase 4 (NOX4) was highly increased by cytokine stimulation in RA FLS. So, we investigated whether Nox4 has a critical role in the migration and invasion of synoviocytes in RA. This study was performed according to the recommendations of the Declaration of Helsinki and approved by the Institutional Review Board of Chungnam National University Hospital in Republic of Korea. Synovial tissues were obtained from 5 RA patients (female 4, male 1, average age 55.6 ± 11.8) and 5 OA patients (female 4, male 1, average age 64.8 ± 16.1) who received synovectomy or joint replacement. For detection of ROS, MitoSox (mitochondria specific probe) was used according to the manufacturer's instructions. The cell migration assay was performed using transwell chamber (8 μm pore) and matrigel coating was added to transwell for the cell invasion assay. The migrated cells were stained with crystal violet and quantified.

Results: After the stimulation with recombinant IL-17 (10 ng/ml) and TNFa (10 ng/ml), the expression of Nox4 mRNA was higher by 8.73 folds in RA FLS compared to OA FLS. Following cytokine stimulation for 24 hours, the level of mitochondria-specific ROS was increased by 2 folds in RA FLS compared to OA. When the cells were treated with various concentrations of Nox4 inhibitor GLX351322 (1, 2.5, or 5 μM) for 1 hour, the level of ROS was significantly decreased in a dose dependent manner. On transwell migration assay, cytokines-stimulated RA FLS showed enhanced migratory ability by 3 folds compared to those without stimulation. Pretreatment with 5 μM of Nox4 inhibitor decreased the movement of RA FLS to the baseline level. The expression of pro-angiogenic factors, vascular endothelial growth factor (VEGF) and granulocyte macrophage colony stimulating factor (GM-CSF), was significantly reduced by Nox4 inhibition.



NADPH Oxidase 4 (NOX4) was the higher expression by cytokine stimulation for 1 hr in RA FLS than OA FLS.



Nox4 inhibition significantly decreased the cytokine-induced-migratory ability than no treatment in RA FLS

Conclusion: From these data, we suggest that Nox4 may modulate the migration and invasion of synoviocytes and contribute to progression of RA. Nox4 among NADPH Oxidase subunits can be an attractive therapeutic target of RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by bone and cartilage destruction with leukocyte infiltration and activation at synovial tissue. The fibroblast-like synoviocytes (FLS) have a central role in disease pathogenesis and in vitro FLS invasiveness which correlates with articular damage in RA patients. Spleen tyrosine kinase (SYK) is a non-receptor tyrosine kinase known to have a crucial role in immune receptor signaling. Recently, a number of studies have revealed that aberrant SYK activation is associated with diverse allergic disorders and antibody-mediated autoimmune diseases such as rheumatoid arthritis, asthma and allergic rhinitis. A novel small-molecule SYK inhibitor, SKI-O-592, was designed and synthesized. The aim of this study is to evaluate the inhibitory effect of SYK inhibitor on inflammation and migration in RA FLS and THP-1 cell.

Methods: Selectivity of SKI-O-592 was evaluated by KinaseProfiler platform consisting of 293 human purified kinases using ATP Km for each kinase. A series of concentrations of ATP ranged from 10 to 1,500 μM were simultaneously incubated with cell-free kinase reaction. FLS were isolated from synovial tissues of RA patients, and treated with SKI-O-592 under tumor necrosis factor alpha (TNF-α). FLS were stimulated with TNF-α for 48 hr after 1 hr treatment of SKI-O-592. After stimulation, cell viability were measured using CCK-8 assay. The levels of IL-6, CXCL10, MMP-3 and TNF-α were measured in culture supernatant of RA FLS and THP-1 cell by ELISA. Wound healing assay were performed to evaluate cell migration ability. The expression of α-tubulin, phosphorylated SYK and phosphoinositide 3-kinase (PI3K) were determined by Western blotting.

Results: SKI-O-592 inhibited the activity of recombinant human SYK enzymes with an IC_{50} of 5.1 nM. The kinases with more than 75% inhibition by 0.1 μM SKI-O-592 were SYK, YES and ROCK-II. The number of migrated cell to wound region was decreased in SKI-O-592 treated RA FLS without the change in cell viability. SKI-O-592 reduced the levels of cytokine and chemokine secretion including IL-6, CXCL10 and MMP-3 in RA FLS. Secreted TNF-α levels were decreased in THP-1 cell by SKI-O-592. Phosphorylation of PI3K was decreased after 30min of SKI-O-592 treatment. The viability and proliferation of the cells were not affected.

Conclusion: The novel SYK inhibitor, SKI-O-592 decreased the production of pro-inflammatory cytokine, chemokine and metalloproteinase in RA FLS. SKI-O-592 decreased the phosphorylation of PI3K. SKI-O-592 may provide a new therapeutic strategy in RA patients.

Survivin Controls the Transcriptional Activity by Changing the Pattern of Histone H3 Marks on Chromatin

Karin Andersson,[1] Malin Erlandsson,[1] Anastasius Damdimopoulos,[2] Robin Bremer,[1] Maja Jensen,[3] Maria-José Garcia-Bonete,[3] Gergely Katona,[3] and **Maria Bokarewa**[1], [1]Department of Rheumatology and Inflammation Research, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden, [2]Department of Biosciences and Nutrition, Karolinska Institute, Solna, Sweden, Stockholm, Sweden, [3]Department of Chemistry and Molecular Biology, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The oncoprotein survivin coded by the BIRC5 gene was described as an important marker in rheumatoid arthritis (RA). Survivin participates in cell division being a member of the chromosomal passenger complex, while its role in gene transcription remains unknown. The purpose of this study was to identify survivin-specific transcription pattern in $CD4^+$ T-cells.

Methods: CD4+ T cells of RA patients and healthy females were isolated from the perpheral blood, activated and treated with a survivin inhibitor YM155. Chromatin was immunoprecipitated using polyclonal antibodies to survivin and to histone H3 trimethylation H3K27me3, H3K4me3 and acetylation H3K27ac marks. DNA libraries were prepared for all ChIP material using ThruPLEX (Rubicon) and **high throughput sequencing** was performed using Hiseq2000 (Illumina) and aligned to the human reference genome (Ensembl GRCh38) using the STAR aligner. Transcriptional analysis was done by RNAseq (Illumina) and conventional qPCR.

Results: Genome-wide analysis of survivin binding to chromatin in activated primary CD4+ T cells was enriched ($p< 10\text{-}5$) and annotated to RNA polymerase II-specific DNA binding transcription factor activity (GO:0000981) with known roles in developmental processes (GO:0032502), and cell communication (GO:0010646, GO:0098742). A search in the ENDCODE ChIP database identified colocalization of survivin with the enhancer of zeste homolog 2 (FDR< 10-33) and Suz12 (FDR< 0.001%), the subunits of the Polycomb-repressive complex 2 responsible for the trimethylation of H3K27. The analysis of histone H3 bound chromatin in CD4 cells revealed colocalisation of H3K27ac, H3K27me3 and H3K4me3 marks to 3784 common peaks. A surplus of the activation marks H3K4me3 and H3K27ac was found in 74%, while 25.6% genes had a surplus of the repressive mark H3K27me3, which was in agreement with the activated cell phenotype. Alignment of survivin peaks with histone H3 marks revealed a co-localization of survinin-ChIP with H3K27me3 (82.7%) mark rather than H3K4me3 (66%) ($p=0.042$). Depletion of survivin in cultured CD4 cells resulted in a significant general increase in deposition of the repressive H3K27me3 mark on chromatin (FC 1.98; $p< 10\text{-}24$) and shifted a balance from H3K27ac and H3K4me3 marks. Only 4% of the H3K4me3 surplus peaks kept it after survivin depletion. mRNA analysis of CD4 cells showed that survivin depletion changed the transcription of the genes controlled by H3K27me3 and EZH2. Among those we found the the genes of HOX-B cluster and their partners MEIS, PKNOX and PBX1 controlling the development of anatomical structures including joints.

Conclusion: This genome-wide study suggest that survivin has important transcription regulating function. It preserves optimal levels of the repressive histone H3K27me3 mark with a potential impact on the function of HOX genes and limb pathology in RA patients.

Presence of the MerTK Receptor on Human Synovial Tissue Macrophages Lowers Inflammatory Cytokine Production and Activation of the MerTK^{+}CD206^{+} Subpopulation Limits the Inflammatory Response of Synovial Fibroblasts

Samuel Finlay,[1] Stefano Alivernini,[2] Aziza Elmesmari,[3] Barbara Tolusso,[2] Luca Petricca,[2] Clara Di Mario,[4] Annunziata Capacci,[2] Andrew Filer,[5] Gianfranco Ferraccioli,[2] Iain McInnes,[1] Elisa Gremese,[2] and Mariola Kurowska-Stolarska[1], [1]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom, [2]Division of Rheumatology - Fondazione Policlinico Universitario A. SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A substantial proportion of Rheumatoid Arthritis patients do not respond to treatment and only a small proportion achieve sustained disease remission. We showed previously that human synovial tissue macrophages (STMs) are heterogeneous; and a sub-population of CD206^{+}MertK^{+} positive STMs predominates in RA patients in sustained remission as compared to patients with active RA. Their surface receptors, *e.g.* MerTK, and distinct transcriptome suggest that they may play a role in re-enforcing joint homeostasis (1). *Thus, we hypothesise that activation of CD206^{+}MerTK^{+} human synovial tissue macrophages contributes to the resolution of inflammation.*

Objectives: We aimed to investigate whether activation of MerTK in STM sub-population promotes an anti-inflammatory environment in the synovium.

Methods: Using flow cytometric techniques and with a specific antibody panel design (1), STMs from digested RA synovial biopsies were phenotyped and/or harvested for functional studies. The study included patients with active disease and patients in remission (DAS28 ESR< 2.6 and power doppler negative). After excluding all other cell types, macrophages were gated based on the expression of CD64 and CD11b (CD45posCD64posCD11bposHLA-DRpos) (1). Two distinct subpopulations: CD206+MerTK+ and CD206-MerTK- were sorted and cultured on a collagen coated 96-well plate at 1000 cells per well in the presence of with LPS (10ng/ml) ± Gas 6, a MerTK ligand (100ng/ml), for 24h. Cytokine production was measured using a high sensitivity UPLEX assay. To test the role of MerTK expressing macrophages on the activation of synovial fibroblasts, a trans-well membrane coculture system was used. Macrophages were pre-treated with LPS (1ng/ml) ± MertK inhibitor (UNC1062, 100um-250um) for 4 and 2 hours respectively, and then co-cultured with fibroblasts for 48hours. MMPs production were measured by multiplex.

Results: As previously shown (1), RA patients in sustained remission have a majority $CD206^{+}MerTK^{+}$ STMs, whilst patients with active RA show an increased number of $CD206^{-}MerTK^{-}$ macrophages. The percentage of $CD206^{+}MerTK^{+}$ macrophages negatively correlated with the disease activity score in RA. Stimulation of FACS-Aria sorted $CD206^{+}MerTK^{+}$ and $CD206^{-}MerTK^{-}$ macrophages with TLR4 ligand induced a different cytokine pattern: the $CD206^{-}MerTK^{-}$ macrophages mostly produced TNF, IL-6 and IL-1b while $CD206^{+}MerTK^{+}$ produced IL-10. Inhibition of MerTK in macrophages increased the production of MMP1 and MMP3 by synovial fibroblasts in the co-culture system.

Conclusion: $CD206^{+}MERTK^{+}$ macrophages, which predominate in RA patients in remission, have Gas6-mediated negative feedback mechanism limiting inflammatory cytokine production and activation of synovial fibroblasts. Thus, Gas6/MerTK pathway in synovial tissue macrophages could drive the resolution of inflammation and synovial tissue homeostasis.

Abstract Number: 2003

Anti-Polygalacturonic Acid Antibody (PGA-Ab) Induced Bone Destruction in Rheumatoid Arthritis by Promoting Osteoclastogenesis via Integrin Beta 5

Jiawei Xie,[1] and Hui Dai[1], [1]Peking University, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-polygalacturonic acid antibody (PGA-Ab) is a new rheumatoid arthritis (RA)-related autoantibody first identified by our group. The sensitivity and specificity of PGA-Ab is even higher than anti-cyclic peptide containing citrulline (anti-CCP) and rheumatoid factor (RF). However, the pathogenesis of PGA-Ab has never been investigated.

Methods: Rabbits were immunized with PGA for PGA-Ab production followed by joint structure analysis by HE staining and micro-CT. Bone resorption index of RA patients were detected to analyze the comparation of PGA-Ab with bone loss. Osteoclasts were induced *in vitro* from peripheral blood mononuclear cells (PBMC) by M-CSF and RANKL with or without PGA-Ab treatment followed by RNA-Sequence for transcriptome analysis and then confirmed by real

Figure 1

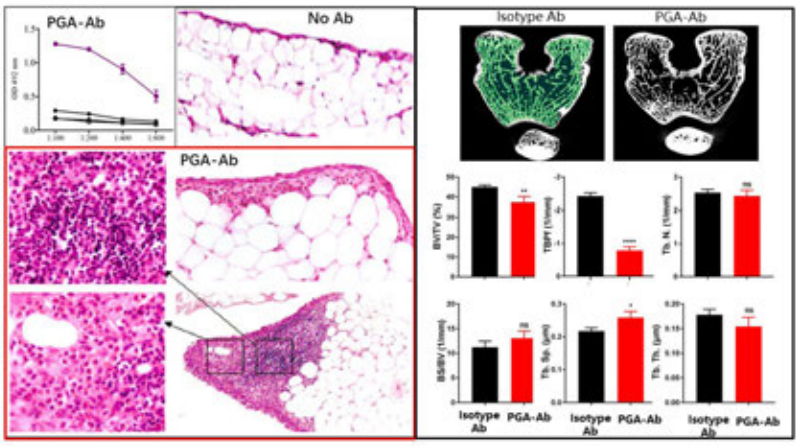

Figure 1 Knee joint inflammation and bone loss following induction of PGA-Abs in rabbits. Two month-old female white rabbits (3 per group) were subcutaneous injected with PGA and boosted 2 weeks and 4 weeks later. The mice were bled on 6th week and the sera were assayed for PGA-Abs. Hind knee joints from rabbits without PGA-Ab (B) and with PGA-Ab (C) were fixed with 4% formaldehyde solution and then decalcificated, followed by paraffin section preparation and HE staining. Microscopic observation found obvious inflammatory changes, including synovial hyperplasia, small vessels proliferation and inflammatory cell infiltration, in the joint sections from rabbits with PGA-Ab. (D) Micro-CT images of the distal femur and analysis of BV/TV, bone volume/tissue volume; BMD, bone mineral density; TbTh, trabecular thickness; TbN, trabecular number; Tb.sp, bone separation. Data are presented as the mean ± standard deviation (n=5 for each group). *P<0.05 vs. control.

Figure 2

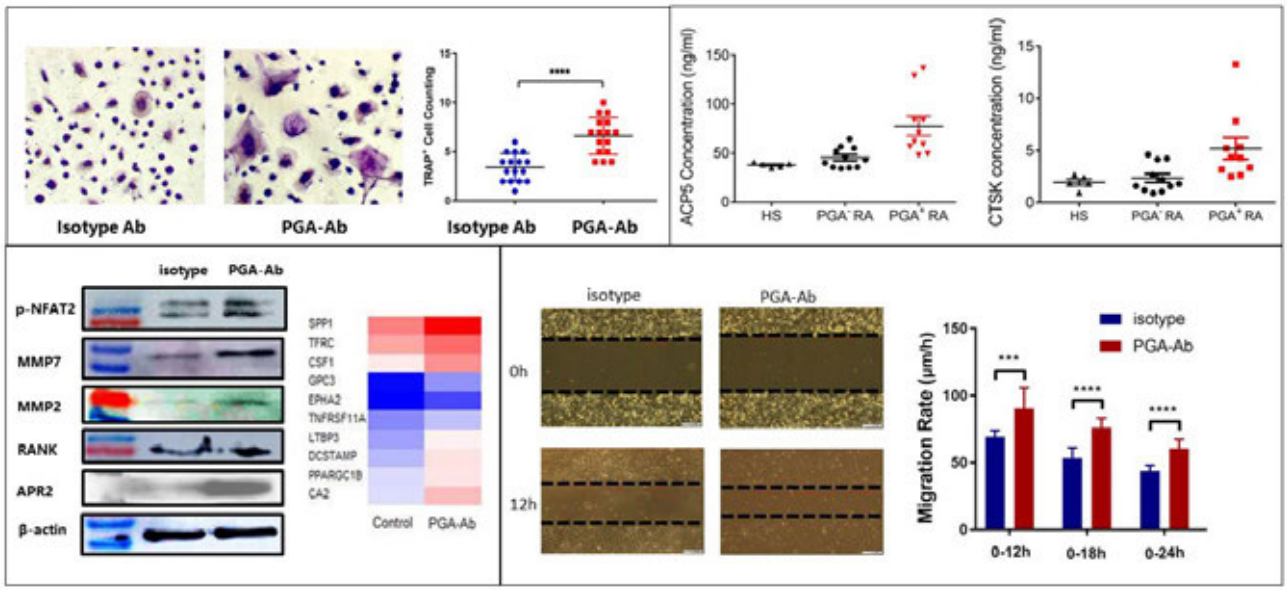

Figure 2 Effect of the PGA-Ab on osteoclastogenesis and migration (A) Osteoclasts were induced in vitro from peripheral blood mononuclear cells (PBMC) by M-CSF and RANKL with or without PGA-Ab treatment Representative images of osteoclastic TRAP staining and osteoclast cell number count were shown. (B) Bone turnover biomarker (ACP5 and CTSK) in healthy subjects and RA patients with or with PGA-Ab. (C) Protein extracts were isolated from osteoclasts after treatment with the isotype antibody or PGA-Ab (0.05mg/ml) for 48h and analyzed by immunoblotting with anti-NFAT2, beta-actin, and histone-1 antibodies. After treatment with isotype antibody or PGA-Ab for 48h, mRNA extracts were analyzed by RNA-seq for transcriptome analysis and representative heat map of osteoclastgenesis-related gene expression was shown. (D) Cells were treated by isotype antibody or PGA-Ab for 48h followed by migration assay by wound healing.

time quantitative PCR or western blot. Potential receptors were also identified by immunoprecipitation and protein spectrum sequencing (IP-MS).

Figure 3

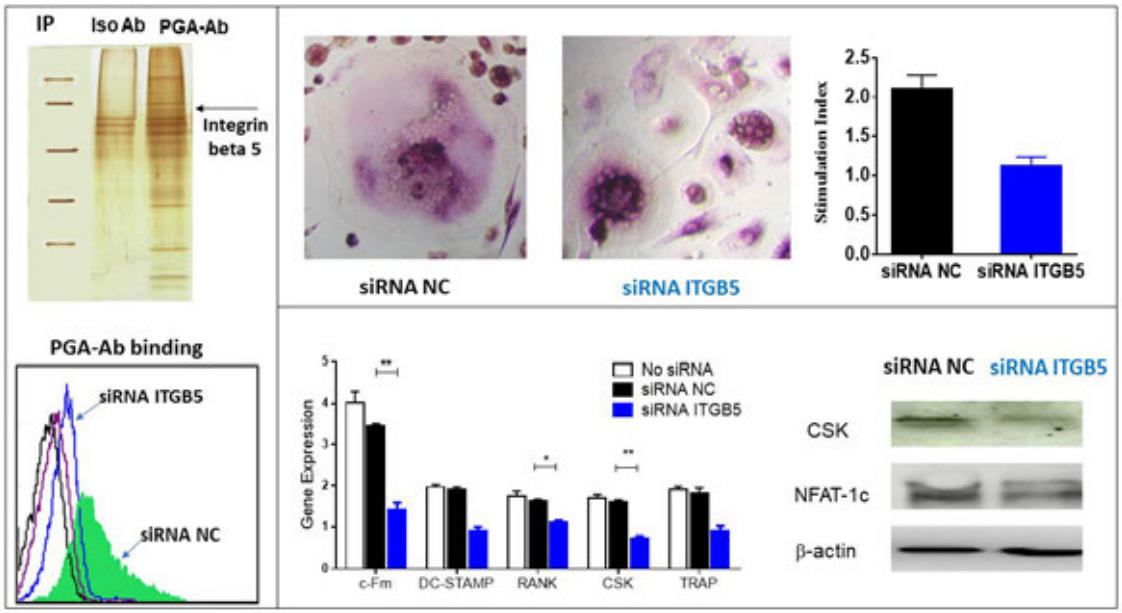

Figure 3 Integrin beta 5 was identified as a potential receptor of PGA-Ab on osteoclast (A) Protein extracts were isolated from osteoclasts followed by incubated with PGA-Ab or isotype Ab for immunoprecipitation. After protein spectrum sequencing for differential bands, integrin beta 5 was identified as PGA-Ab-binding protein. After knock down ITGB5 expression by siRNA, the binding of PGA-Ab and osteoclast were detected by flow cytometry. (B) ITGB5 knock down followed by osteoclastogenesis induced by M-CSF and RANKL. TRAP staining were used for osteoclast cell number count. (C) Gene and protein expression of osteoclasts after ITGB5 silence were detected by real time quantitative PCR and western blot, respectively.

Results: After PGA immunization, severe joint inflammation and damage were shown in PGA-Ab positive animals, including increasing synovium thickness, neutrophils and lymphocytes infiltration and reducing bone mineral density of femoral trabecula. Cathepsin k (CSK) and Tartrate Resistant (ACP5) in PGA-Ab positive RA patients were significantly higher than in PGA-Ab negative RA patients. *In vitro* culture, PGA-Ab treatment increased mature osteoclast numbers, CSK or metalloproteinases (MMPs) releasing and NFAT1c and AP-1 activation. Rho-GTPase signaling pathway-related protein RhoA, RhoD-GTP and ARP2 expression were also increased and PGA-Ab treatment increased wound healing, indicating increased cell migration and motility induced by PGA-Ab. Integrin beta5 (ITGB5) were identified as receptor of PGA-Ab on osteoclasts. Knockdown of ITGB5 eliminated the binding of PGA-Ab with osteoclasts and reduced PGA-Ab-induced osteoclastogenesis significantly.

Conclusion: PGA-Ab is a new RA-related autoantibody, which has pathogenic effect on arthritis bone erosion by inducing osteoclast differentiation through receptor integrin beta 5 via Rho-GTPase signaling pathway.

Protein Profiling and Network Enrichment Analysis in Individuals Before and After the Onset of Rheumatoid Arthritis

Mikael Brink,[1] Anders Lundquist,[1] Andrey Alexeyenko,[2] Kristina Lejon,[1] and **Solbritt Rantapää-Dahlqvist**[1], [1]Umeå University, Umeå, Sweden, [2]SciLife lab, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antibodies and up-regulated cytokines and chemokines predate the onset of symptoms of rheumatoid arthritis (RA). The aims with this study was to identify pathways related to the early processes leading to RA development, and potential novel biomarkers, using multiple proteins analysis.

Methods: A case-control study was conducted within the Biobank of northern Sweden. Plasma samples from 118 pre-symptomatic individuals (207 samples, median predating time 4.1 years), 79 early RA patients and 74 matched controls were analysed. The levels of 122 unique proteins with acknowledged relation to autoimmunity were analysed using 153 antibodies in a bead-based multiplex system (FlexMap3D, Luminex Corp.). Data was analyzed using ANOVA, Random Forest and Network Enrichment analysis (NEA), on the basis of the ten most significantly differentially expressed proteins for each two-by-two group comparison, using the MSigDB collection of Hallmarks.

Results: There was high agreement between the different statistical methods for identifying the most significant proteins. Levels of 22 proteins differed significantly between pre-symptomatic individuals and controls, 93 between RA-patients and controls and one between pre-symptomatic individuals and RA after adjustment for multiple testing. The area under curve for proteins discriminating pre-symptomatic individuals from controls was 0.75, between pre-symptomatic individuals and RA 0.80 and between RA and controls 0.93. Of the 30 proteins with the highest discriminatory capacity 27 differed between pre-symptomatic individuals vs. controls ($p< 1.9e-7$ to 0.05), 29 between RA-patients and controls ($p< 5.5e-26$ to $1.7e-4$) and 29 between pre-symptomatic individuals and RA ($p< 7.4e-4$ to 0.05). The Adipogenesis and Interferon alpha response hallmarks, included proteins involved in innate immunity, differentiated pre-symptomatic individuals from controls. Between pre-symptomatic individuals and RA-patients three hallmarks were identified, involving Apical Junction, Epithelial Mesenchymal Transition and TGF-β signaling including proteins suggestive of cell interaction, re-modulation and fibrosis. The Adipogenesis and Heme metabolism hallmarks differentiated RA-patients from controls.

Conclusion: We confirm the importance of Interferon alpha signaling as well as of lipids in the early phases of RA development. Network Enrichment Analysis provides a tool for a deeper understanding of molecules involved at different phases of the disease progression.

Abstract Number: 2005

Circulating Mitochondrial Danger-Associated Molecular Patterns as Novel Biomarkers of Disease Activity and Inflammation in Rheumatoid Arthritis

Bhargavi Duvvuri,[1] and Christian Lood[1], [1]University of Washington, Seattle

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune inflammatory disease causing erosive and disabling joint damage. We recently found that mitochondria are extruded upon formation of neutrophil extracellular traps (NETs). The extruded mitochondria can be a source of danger-associated molecular patterns (DAMPs) that include highly unmethylated CpG motif content, oxidized mitochondrial DNA (mtDNA) and N-formylmethionyl (N-fMet) peptides. In RA, elevated levels of cell-free mtDNA have been reported in both synovial fluid and plasma. However, the clinical utility of mtDNA in RA is yet to be explored. Nothing has been reported on levels of N-fMet peptides in RA patients. The aim of the current study was to quantitate circulating levels of mitochondrial components in RA patients, and investigate their utility as novel non-invasive biomarkers in monitoring disease activity and severity in RA.

Methods: DNA isolated from plasma samples of healthy individuals (HC, n=20) and RA patients (n=100) was analyzed for mtDNA (Cytochrome C Oxidase Subunit II) and nuclear (nu) DNA (Ribosomal Protein Lateral Stalk Subunit P0) content using qPCR. NETs were analyzed by an in-house MPO-DNA ELISA. Levels of circulating human N-fMet and DNA damage (8-OHdG) were analyzed by ELISA.

Results: Seropositive RA patients had elevated levels of mtDNA compared to seronegative patients ($p=0.03$). However, no difference was observed for nuDNA ($p=0.11$). Further, RA patients had extensive DNA oxidation ($p=0.0009$). Oxidation, mainly seen in mtDNA, is known to increase the inflammatory capacity of DNA. Of note, cfDNA from RA patients had higher inflammatory potential upon in vitro incubation with PBMCs, as compared to cfDNA from HC ($p< 0.0001$). The inflammatory capacity of DNA correlated with mtDNA levels ($r=0.36$, $p=0.0004$), but not with nuDNA levels ($r=0.06$, $p=0.57$), suggesting circulating mtDNA as the pro-inflammatory component of cfDNA. Consistent with our hypothesis that NETs could be a potential source of mtDNA, we found a correlation between levels of cf-mtDNA and NETs ($r=0.025$, $p=0.03$). RA patients also had significantly elevated levels of circulating N-fMet as compared to controls ($p< 0.0001$). N-fMet levels correlated with markers of inflammation, including CRP ($r=0.56$, $p< 0.0001$), ESR ($r=0.32$, $p=0.01$), and calprotectin, ($r=0.42$, $p< 0.0001$). Both circulating mtDNA levels and N-fMet levels were elevated in patients with active disease ($p=0.001$ and $p=0.007$, respectively). Further, a distinct group of RA patients (n=20) with predominant levels of mtDNA, showed significant correlation between mtDNA levels and CDAI ($r=0.56$, $p=0.03$). Circulating N-fMet levels also correlated with joint involvement (N-fMet vs. swollen joints, $r= 0.23$, $p=0.03$; N-fMet vs. tender joints, $r= 0.22$, $p=0.04$).

Conclusion: Mitochondrial DAMPs are elevated in RA, indicating abnormal mitochondrial extrusion and/or clearance occurring in RA. Levels of mitochondrial DAMPs are related to inflammation and disease activity, suggesting an instrumental role in the RA pathogenesis. In all, pathways involved in mitochondrial extrusion could be considered as novel therapeutic targets as well as biomarkers in RA.

Pyruvate Kinase M2 May Contribute to the Inflammation and Joint Destruction in Rheumatoid Arthritis

Dong Woo Han,[1] Yong Seok Choi,[1] **You-Jung Ha**,[2] Eun Hye Park,[2] Eun Ha Kang,[2] Yeong-Wook Song,[3] and Yun Jong Lee[1], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, Seongnam, Republic of Korea, [3]Seoul National University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pyruvate kinase M2 (PKM2), one of glycolytic enzymes, is an emerging molecule that plays significant roles in tumor growth as well as inflammatory process. However, the role of PKM2 in the RA pathogenesis has not been well evaluated. The aim of this study is to investigate the expression of PKM2 in RA patients and to find their clinical implications. Also, we tried to determine the role of PKM2 in the biologic processes of RA fibroblast-like synoviocytes (FLSs) and osteoclast *in vitro*.

Methods: To determine expression and localization of PKM2 in RA synovial tissue, immunohistochemistry and double IF was performed. The levels of PKM2 in SF and plasma were measured by ELISA and their relations with clinical variables including modified Sharp/van der Heijde (SHS) scores and circulating levels of TNF-α, IL-6, and VEGF were analyzed. In RA FLSs and THP-1 cell lines stimulated with LPS, TNF-α, or IL-6, the PKM2 levels in the conditioned media were also investigated. The effect of recombinant PKM2 on osteoclast differentiation was examined in

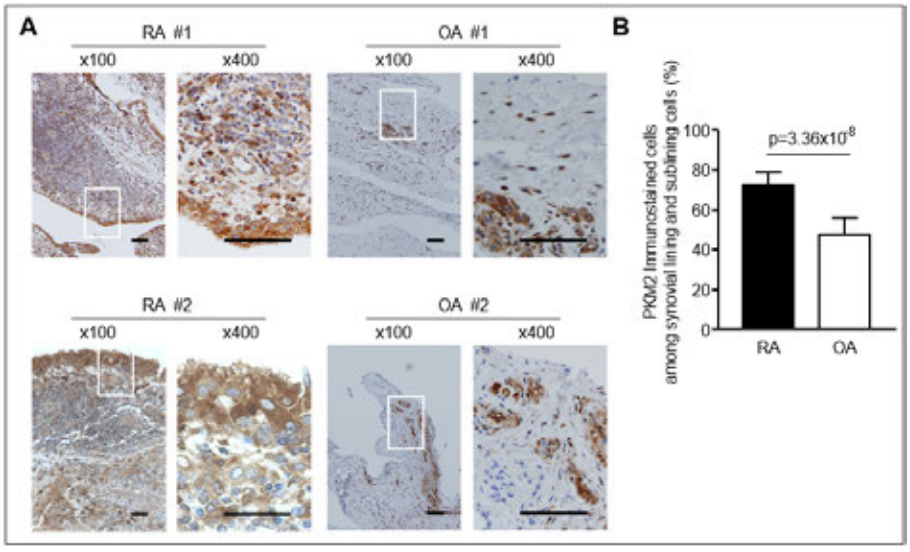

Figure 1. PKM2 expression in the synovial tissue. The number of PKM2 immunostained cells was significantly increased in RA synovium. RA = rheumatoid arthritis; OA = osteoarthritis.

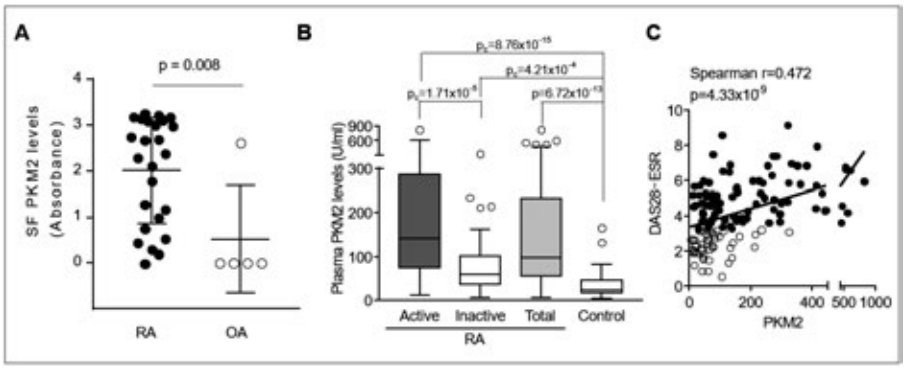

Figure 2. SF and circulating PKM2 levels in RA. (A and B) PKM2 levels in SF and plasma samples were significantly increased in RA patients, especially RA patients with active disease. (C) Plasma PKM2 levels were correlated with DAS28-ESR.

Raw264.7 cell line. Additionally, the impact of PKM2 down-regulation on migration and proliferation in RA-FLSs were determined using small-interfering RNA.

Results: In the synovial tissues of RA patients, PKM2 was more immunostained than in OA synovium and mainly expressed in the fibroblasts. The levels of SF PKM2 in RA patients were significantly higher than those in OA patients and correlated with SF inflammatory cell counts. Compared with healthy controls, the plasma PKM2 levels were significantly elevated in RA patients and correlated with DAS28. The circulating levels of PKM2 were positively correlated with IL-6 and VEGF levels, but not with TNF-α. Elderly onset RA patients with high PKM2 levels (≥ 90th percentile of the controls) were more likely to have radiographic progression (Δ SHS ≥1 unit/year) than those with low PKM2 levels. In early RA (disease duration ≤12 months) subgroup, plasma PKM2 levels were independent predictors for subsequent progression of radiographic damage. *In vitro*, PKM2 release was enhanced in stimulated macrophages, but not in stimulated RA-FLSs. The number of tartrate resistant acid phosphatase-positive multinuclear cells was dose-dependently increased by recombinant PKM2 in Raw264.7 cell, even without RANK ligand. PKM2 knockdown by siRNA transfection significantly decreased TNF-α induced migration and proliferation of RA-FLSs.

Conclusion: PKM2 was upregulated in RA synovium and the elevated PKM2 levels in plasma and SF were associated with inflammatory burden as well as radiographic progression. Intracellular PKM2 could be involved in the migration and proliferation of RA-FLSs, whereas extracellular PKM2 released from activated macrophages could promote osteoclastogenesis. These findings suggest that PKM2 might be a novel regulator in the pathogenesis of RA.

Periodontal Pockets as a Potential Source of Circulating TREM-1 and Its Ligand PGLYRP1 in Patients with Rheumatoid Arthritis

Nevsun Inanc,[1] Gonca Mumcu,[2] Meryem Can,[3] Haner Direskeneli,[4] and Nagihan Bostanci[5], [1]Marmara University, Faculty of Medicine, Division of Rheumatology, Istanbul, Turkey, ISTANBUL, Turkey, [2]Marmara, University, Department of Health Management, Marmara University School of Health Sciences, Istanbul, Turkey, ISTANBUL, Turkey, [3]Marmara University, Division of Rheumatology, Istanbul, Turkey, Istanbul, Turkey, [4]Marmara University, School of Medicine, Division of Rheumatology, Istanbul, Turkey, [5]Section of Periodontology and Dental Hygiene, Division of Oral Diseases, Department of Dental Medicine, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: PGLYRP1, a member of peptidoglycan recognition proteins is a putative ligand as a ligand for triggering receptor expressed on myeloid cells-1 (TREM-1) which is involved in amplifying pro-inflammatory processes in chronic inflammatory diseases. However, the presence of circulating PGLYRP1 in patients with rheumatoid arthritis (RA) who suffer from periodontal disease is currently unknown.

The aim of the study was to investigate the association of circulating TREM-1 and its ligand PGLYRP1 with oral inflammatory/infection burden among patients with rheumatoid arthritis (RA).

Methods: The study population was recruited among individuals diagnosed with RA who were under sDMARD treatment for more than 6 months and never used biologic treatment (n=65, (F/M: 45/17) at the Department of Rheuma-

Table 3. Serum TREM-1 and PGLYRP-1 Levels According to Severe Periodontitis in RA

tology, Faculty of Medicine, Marmara University, Turkey. 43 patients with Behcet syndrome (BS, F/M: 31/12) and 59 systemically healthy subjects (HC, F/M: 40/19) were assessed as controls. Serum and saliva samples were collected on the same day of oral health and musculoskeletal examination. RA disease activity was assessed using 28- joint disease activity score (DAS-28). Oral health was evaluated by dental and periodontal indices. Salivary levels of cumulative bacterial load and individual species including *S.oralis, A.oris, F.nucleatum, P.intermedia, A.actinomycetemcomitans, T.denticola, P.gingivalis,* and *T.forsthia* were analyzed by quantitative real-time polymerase chain reaction (qPCR). sTREM-1 and PGLYRP1 levels in serum were analyzed by ELISA.

Results: Elevated sTREM-1 and PGLYRP1 levels in serum was observed in RA (167,1±95,0 pg/ml; 157,5±228,8 pg/ml) than BD (102,8±44,4 pg/ml; 52,4±26,01pg/ml) and HC (90,7±56,5 pg/ml; 68,8±37,7 pg/ml) ($p< 0.05$)(Table 1). RA patients presented with significantly higher total bacterial load ($p< 0.05$) compared to the HC group. Tooth loss was significantly higher in RA (18.67±8.45) compared to those of BD (24.02±3.7) and HC (25.36±3.83)($p=0.001$ and $p=0.000$) (Table 2). In RA, sTREM-1 and PGLYRP1 levels were significantly higher in patients with severe periodontitis (219,1±107,9 pg/ml and 265,6±336,7 pg/ml) than the others (133,9±68,9 and 87,1±55,3 pg/ml) ($p=0.006$; $p=0.01$, respectively) (Table 3).

Conclusion: Serum sTREM-1 and its ligand PGLYRP1 levels were higher in patients with RA than BD and HC and especially were higher in patients with severe periodontitis. In addition, increased tooth loss and higher total bacterial load were associated with RA.

Histone Lysine Methyltransferase MLL1 Regulates the Expression of Cytokines and Chemokines in Rheumatoid Arthritis Synovial Fibroblasts

Yasuto Araki,[1] Keita Okamoto,[1] Yoshimi Aizaki,[1] Hiromi Oda,[2] and Toshihide Mimura[1], [1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [2]Department of Orthopedic Surgery, Faculty of Medicine, Saitama Medical University, Saitama, Japan

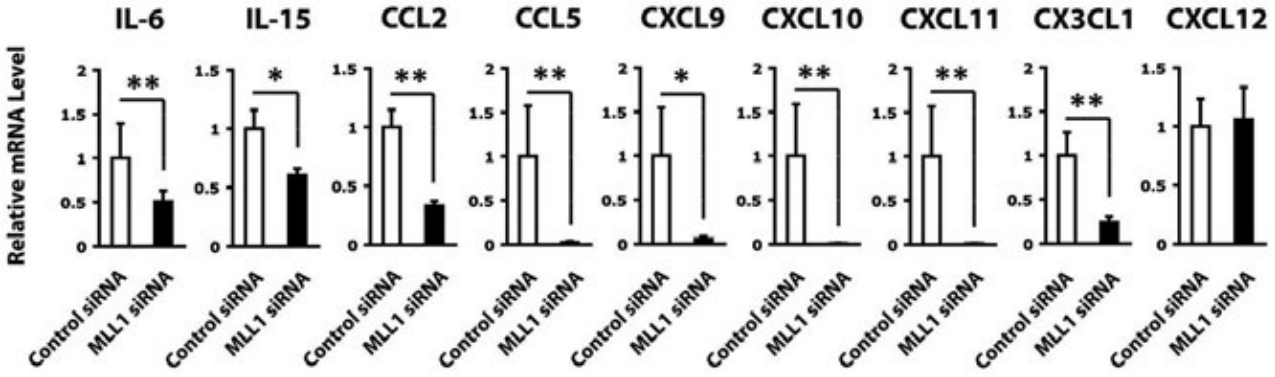
SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

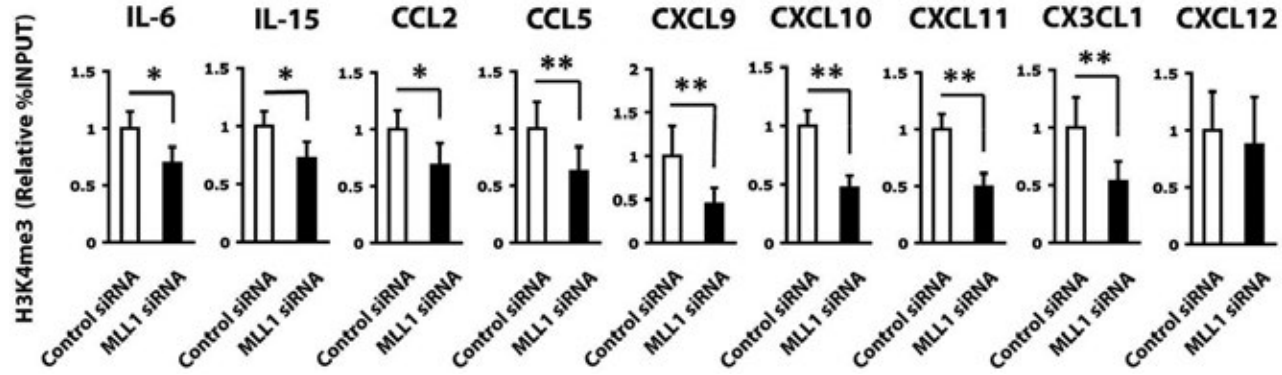
Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

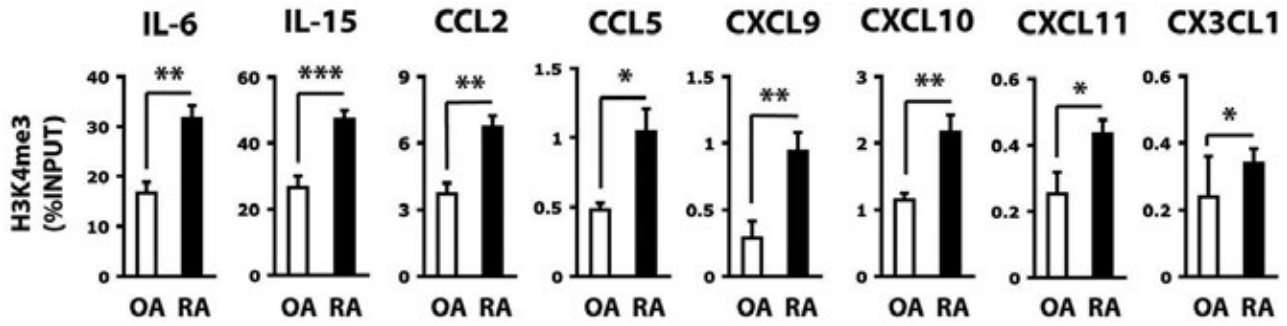
Session Time: 9:00AM–11:00AM



The silencing of MLL1 significantly decreased the mRNA levels of two cytokines (IL-6, IL-15) and six chemokines (CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1) in RASFs (N=12, *P<0.05, **P<0.01).



The H3K4me3 levels in two cytokines (IL-6, IL-15) and six chemokines (CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1) genes were significantly decreased in MLL1 siRNA-treated RASFs (N=7, *P<0.05, **P<0.01).



The H3K4me3 levels in two cytokines (IL-6, IL-15) and six chemokines (CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1) promoters were significantly higher in RASFs than OASFs (OA: N=8, RA: N=14, *P<0.05, **P<0.01, ***P<0.001).

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that primarily affects the joints. The inflammatory process causes the activation of synovial fibroblasts (SFs) and the destruction of articular cartilage and bone, resulting in disability of the joints. Both genetic and environmental factors have been shown to be associated with the pathogenesis of RA. However, these factors are unable to explain the pathogenesis of RA completely. Epigenetic factors such as histone lysine methylation are suggested to be associated with the pathogenesis of RA. Epigenetics refers to heritable phenotypic changes that influence gene expression independently of the DNA sequence. Aberrant gene expression of MLL1, which catalyzes methylation of histone H3 lysine 4 (H3K4), has been reported in RASFs. The aim of this study is to elucidate the involvement of MLL1 in the pathogenesis of RA.

Methods: SFs were isolated from synovial tissues obtained from patients with RA or osteoarthritis (OA) during total knee joint replacement. MLL1 expression in the cultured SFs was evaluated after stimulation with tumor necrosis factor α (TNFα). We examined the changes in the expression of RA-associated genes, including matrix metalloproteinases (MMP-1, MMP-3, MMP-9, and MMP-13), cathepsins (CTSK and CTSL), cytokines (IL-6, IL-8, IL-15, and IL-23A), and chemokines (CCL2, CCL3, CCL5, CXCL1, CXCL5, CXCL6, CXCL9, CXCL10, CXCL11, CXCL12, CXCL13, and CX3CL1), as well as the trimethylation of H3K4 (H3K4me3) levels in the promoters upon siRNA-mediated depletion of MLL1 in RASFs. The changes in the gene expression were also investigated by the treatment with an MLL1 inhibitor MM-102. The H3K4me3 levels in the cytokine and chemokine promoters were also examined in RASFs and OASFs.

Results: The levels of MLL1 mRNA and protein were higher after TNFα stimulation in RASFs versus OASFs. The mRNA levels of IL-6, IL-15, CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1 genes were significantly decreased in MLL1 siRNA-treated RASFs. Correspondingly, the H3K4me3 levels in the promoters were significantly repressed. MM-102 significantly decreased CCL5, CXCL9, CXCL10, and CXCL11 mRNA levels in RASFs. MM-102 also repressed the H3K4me3 levels in the promoters in RASFs. In addition, the H3K4me3 levels in the IL-6, IL-15, CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1 promoters were significantly higher in RASFs than OASFs.

Conclusion: Study findings suggest that MLL1 regulates expression of the cytokines and chemokines that are involved in the pathogenesis of RASFs. MLL1 may be a new target for RA therapy.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease modifying antirheumatic drugs (b-DMARDs) have revolutionized the management of Rheumatoid Arthritis (RA). Despite this success, a high percentage of the patients undergoing biologic treatment respond insufficiently. There is thus an urgent need to identify effective biomarkers to guide treatment selection. The aim of this study was to identify several specific reliable clinical and molecular predictors of the response of RA patients to TNF-α inhibitors (TNFi) and to B-cell depletion by anti-CD20 antibody (Rituximab, RTX).

Methods: In a prospective RA cohort study, we collected serum from RA patients with moderate or high disease activity prior to treatment with TNFi or RTX and analyzed baseline levels of 27 proteins that constitute a multibiomarker test of inflammatory profile of these samples using a multiplex immunoassay. The patients' response was determined 24 weeks after starting bDMARDs treatment, according to the EULAR response criteria (good vs. moderate/no). We compared the inflammatory molecules between the response and non-response patient groups and analyzed their discriminative ability. Logistic prediction models were created to assess the added value of potential inflammatory predictors.

Results: Among 91 total RA patients, 45 of 66 patients in the TNFi group and 20 of 25 patients in the RTX group responded to the biologic treatment. As previously reported both, high DAS28 and CRP levels at baseline were predictive of response to TNFi. High rheumatoid factor titers and DAS28 at baseline were predictive of response to RTX. Instead, smoking habit and hyperlipidemia at baseline were predictors of a worse response to any of these b-DMARDs. Of the molecules analyzed by the multiplex assay, we identified seven molecules as potential predictors of TNFi response [fibroblast growth factor basic (FGFb), interleukin (IL)-10, IL-13, IL-15, IL-2, IL-8, and monocyte chemotactic protein -1 (MCP-1)] mainly involving molecules related to leukocyte's activation and recruitment to inflammatory tissues. On the other hand, three highly expressed cytokines/chemokines in RA serum were identified as predictors of RTX response [IL-9, interferon-inducible protein 10 (IP10) and macrophage inflammatory protein 1 beta (MIP1b)]. Receiver operating characteristic analyses for those multiple biomarkers revealed areas under the curve (AUC) ranging from 0.78 to 0.94, with a sensitivity of 100% and specificity varying from 80 to 90% for TNFi, and AUC

from 0,76 to 0,97 with a sensitivity of 96% and specificity varying from 79 to 88% for RTX. Combinations of these 7 and 3 biomarkers, respectively, significantly increased the accuracy of prediction.

Conclusion: By analysis of serum inflammatory profile, we identified specific and distinctive serum biomarkers that, in coordination with known clinical and serological profiles, have a high ability to predict the response of RA patients to TNFi or RTX treatments. Individual Functions of Histone-acetyltransferases CBP and p300 in Regulating Autophagy and Proteasomal Degradation in Synovial Fibroblasts

Monika Krošel,[1] Marcel Gabathuler,[2] Matija Tomšič,[1] Oliver Distler,[3] Caroline Ospelt,[4] and Kerstin Klein[5], [1]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, Ljubljana, Slovenia, [2]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Switzerland, Schlieren, [3]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland, [4]University Hospital Zürich, Zürich, Switzerland, [5]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Switzerland., Zürich, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tight control of the two major catabolic pathways proteasomal degradation and autophagy is critical for the maintenance of cellular homeostasis and cell survival. Here we analyzed the individual functions of the two homolog histone acetyltransferases cAMP-response element binding protein binding protein (CBP) and p300 in regulating catabolic pathways in rheumatoid arthritis (RA) synovial fibroblasts (SF).

Methods: SF were obtained from knee, shoulder and hand joints of RA patients undergoing joint replacement surgery. The expression of CBP and p300 was silenced by transfection of antisense LNA gapmeRs (12,5 nM). 24 hours later, cells were stimulated with TNF-α (10 ng/ml, 24 hours). Transcriptomes were determined by RNA-seq (Illumina NovaSeq 6000, n=6). Pathway enrichment analysis (fold change >1.5, FDR < 0.05) was performed using DAVID Bioinformatic Resources. Autophagy was assessed by Western blotting using LC3B conversion and p62 as autophagy markers (n=5) in presence and absence of the lysosomal inhibitor bafilomycin A1 (100 nM, 4h). Cell death (n=6) was analyzed using the CytoTox-Glo cytotoxicity assay. Proteasome activities were analyzed using Proteasome-Glo chymotrypsin-like, trypsin-like and caspase-like cell-based assays (n=5).

Results: The top pathway identified after silencing of p300 in SF in presence (p=3.57-14) of TNF-α was 'proteasome', which was also among the top three pathways in unstimulated SF (p=6.77x10-5). The expression of most

genes encoding proteasome subunits was increased after silencing of p300 but unaffected by silencing of CBP. In contrast, chymotrypsin-like and trypsin-like proteasome activities were decreased by silencing of p300, indicating a compensatory upregulation of transcription of proteasome subunits under conditions of impaired proteasome function. Caspase-like proteasome activity was not affected by silencing of p300. Genes contributing to the biological process 'autophagy' (p=0.031) were enriched after silencing of CBP in presence of TNF-α, whereas genes contributing to 'regulation of mitophagy' were enriched after silencing of p300 in absence (p=0.02) and presence of TNF-α (p=0.06). In line with RNA-seq data, silencing of CBP reduced the conversion of LC3B and the protein expression of p62 in presence and absence of TNF-α. Results were similar in presence of bafilomycin A1, indicating a decrease in autophagosome synthesis. In contrast, the conversion of LC3B and p62 expression were increased after silencing of p300 in unstimulated SF, indicating increased autophagy. This effect was lost for LC3B after treatment with TNF-α, and LC3B conversion was even decreased in presence of bafilomycin A1. This indicates a late stage block of autophagy after silencing of p300 in TNF-α-stimulated SF. In line with this, silencing of p300 in SF ($p < 0.05$) increased cell death only in presence of TNF-α. Viability of SF was not affected by silencing of CBP.

Conclusion: Our data provide the first evidence that p300 but not CBP regulates proteasome activity in SF by post-translational modifications. CBP and p300 have diverging functions in regulating autophagy.

Novel Somatic Mutations Identified by Whole Genome Sequencing of Rheumatoid Arthritis (RA) Fibroblast-Like Synoviocytes (FLS)

Richard Ainsworth,[1] Deepa Hammaker,[2] David Boyle,[1] **Rizi Ai**,[2] Jeremy Sokolove,[3] Wei Wang,[1] and Gary Firestein[2], [1]University of California, San Diego, San Diego, CA, [2]University of California, San Diego, San Diego, [3]AbbVie Immunology Clinical Development, Redwood City

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Somatic mutations caused by reactive oxygen and nitrogen species in inflamed joints, have been implicated in the destructive nature of RA. Mutation analysis also helps identify mechanisms contributing to the aggressive behavior of RA FLS. However, previous analyses focused on candidate gene approaches. This work represents the first whole genome sequencing study of RA FLS.

Methods: Next generation sequencing of the whole genome was carried out for 10 RA and 10 osteoarthritis (OA) human FLS cell lines at 100X. Reads were aligned, sorted according to chromosome and position, duplicates and those with a MAQ score < 30 removed. Base quality score recalibration of aligned reads was then performed with GATK 3.8. Variant calling was performed using VarScan2 with low quality base calls of < Q20 filtered out. Finally, we removed low coverage and low confidence sites. To account for a lack of a germline reference for each line and potential culture effects, we used a novel approach by filtering for sequences with mutation frequencies (MF) in >2% and < 5-8% of reads and discarding those found in at least >92% of the reads to remove putative germline polymorphsms and identify somatic mutations. For each set of mutations, single nucleotide variants (SNV) and insertion/deletion (Indel) locations were overlapped with gene bodies and promoters to identify the associated genes or with gene exons only. Genes specific to RA were analyzed for enriched functions and pathways.

Results: Indel and Missense SNV somatic mutations in the range 2%< MF< 5% were overlapped with gene bodies and promoters. Mutated genes unique to RA were identified and ranked by the number of RA cell lines with the mutant gene. Only 43 genes had mutations in > 5/10 RA lines and 0/10 OA lines. The top ranking genes, which had 7/10 RA lines with intronic mutations included MTMR3, which plays a role in autophagosome formation and CLNK which plays a role in immunoreceptor signaling. Other RA-specific mutated genes included multiple E3 ubiquitin ligases and DNA repair genes. Using the same filter and overlapping somatic mutations only with exons yielded additional RA-specific genes. Of the 33 exon-only mutations in 3/10 or more RA lines and 0/10 OA lines, 5 are also unexpectedly involved ubiquitination. We then extended the mutation range to 2%< MF< 6% and only considered missense somatic mutations in exons. 260 and 207 genes unique to RA or OA, respectively, were identified. Pathway analysis on these gene sets identified 11 significant pathways ($p< 1 x10^{-5}$) for the RA genes but no significant pathways for OA suggesting that the latter were not functionally relevant. 3 of the mutant RA pathways involved antigen processing including “Antigen Presentation: Folding, assembly and peptide loading of class 1 MHC” ($p< 1 x10^{-16}$).

Conclusion: Whole genome sequencing of RA and OA human FLS lines identified somatic mutations unique to RA in genes consistent with immune deregulation. Our novel computational approach corrected for potential tissue culture effects and showed a high mutation rate in RA. The unbiased analysis showed significant mutant pathways enriched in RA and suggests that the mutations play a role in disease pathogenesis.

FIL 200 mg vs Placebo	-0.96 (0.22)	**<0.0001**
FIL 200 mg vs FIL 100 mg	-0.33 (0.22)	0.28

FIL, filgotinib, SE, standard error.

Table. Filgotinib dose-dependent reduction of the composite IFN-based signature

FINCH-2 ClinicalTrials.gov Identifier: NCT02873936). RA pts with high IFN scores have shown a diminished clinical response to first-line treatments (Rodríguez-Carrio *et al.* 2018; Cooles FAH *et al*. 2018) and differential responses to second-line treatments (Mavragani *et al*. 2010; Thurlings R *et al.* 2010). Baseline IFN scores have been associated with a week 12 FIL-specific ACR-N response in the DARWIN Phase 2 trials (Taylor *et al*. 2018). The value of baseline gene expression for predicting therapeutic response to FIL in a bDMARD experienced RA population was explored in an RNA sequencing study using FINCH-2 pts.

Methods: Blood samples from RA pts in FINCH-2 on either a stable dose of MTX and placebo (n = 144), or once daily FIL 100 mg (n = 151), or 200 mg (n = 143) were analyzed at baseline and weeks 4 and 12. To evaluate the relationship between baseline IFN activity and change in disease activity after 12 weeks, we tested two IFN-based signatures: a 4-gene panel (Rodríguez-Carrio *et al.* 2018) and a FINCH-2 composite score derived from IFN response genes and clinical assay results. The association of these two signatures at baseline with the week 12 change in disease activity score 28 CRP (DAS28-CRP) or ACR-N response were evaluated using a linear regression model. The main effect of signature activity on clinical response represents a prognostic effect (i.e. independent of treatment), while a multiplicative interaction between signature activity and FIL is predictive. A linear mixed-effects model determined the FIL-specific change in signature activity across 2 time-points post-baseline (weeks 4 and 12).

Results: Baseline Rodriguez-Carrio IFN signature score showed no significant association with week 12 clinical response ($P > 0.05$ for all comparisons). In contrast, the baseline FINCH-2 derived composite IFN-based signature was significantly associated with an increase of DAS28-CRP after 12 weeks ($P = 0.0026$), independent of treatment. The composite IFN-based signature score was significantly associated with a FIL-specific improvement in DAS28-CRP (FIL 100 mg, $P = 0.0045$; FIL 200 mg, $P = 0.0005$) and ACR-N responses (FIL 100 mg, $P = 0.036$) after 12 weeks. The composite signature was significantly reduced in a dose-dependent manner after FIL treatment at weeks 4 and 12 (Table).

Conclusion: Expression of 4 IFN-stimulated genes at baseline was not significantly associated with week 12 clinical response in FINCH-2, suggesting that IFN signalling alone is not sufficient to predict response to MTX in a bDMARD experienced population. However, an expanded FINCH-2 derived composite IFN signature demonstrated a treatment-specific significant association at week 12. Validation of this signature or its sub-components will be performed in the FINCH-1 (MTX-experienced) and FINCH-3 (MTX-naïve) clinical trials, and retrospectively in the DARWIN clinical trials.

Session Title: RA – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are approximately two-fold more likely to develop cardiovascular disease (CVD). Prior reports have suggested that "dysfunctional" HDL may explain at least part of this enhanced risk profile. It has been suggested that post-translational modifications of HDL, including those characteristic of RA, may attenuate relevant protective properties of this lipoprotein. Specifically, studies have suggested that the irreversible post-translational modification of proteins with malondialdehyde-acetaldehyde (MAA) that are prevalent in RA synovium are also present in atherosclerotic plaque. Moreover, antibodies to MAA correlate with the development and progression of both RA and CVD. Therefore, the purpose of this study was to examine the biologic effects resulting from the exposure of MAA-modified HDL to human macrophages that have been implicated in CVD pathogenesis.

Methods: HDL was incubated with 2mM malondialdehye and 1mM acetaldehyde for 3 days to form the MAA adduct. PMA activated human THP-1 macrophages were subjected to 0.1, 1, 10 μg/ml of native or modified HDL in via-

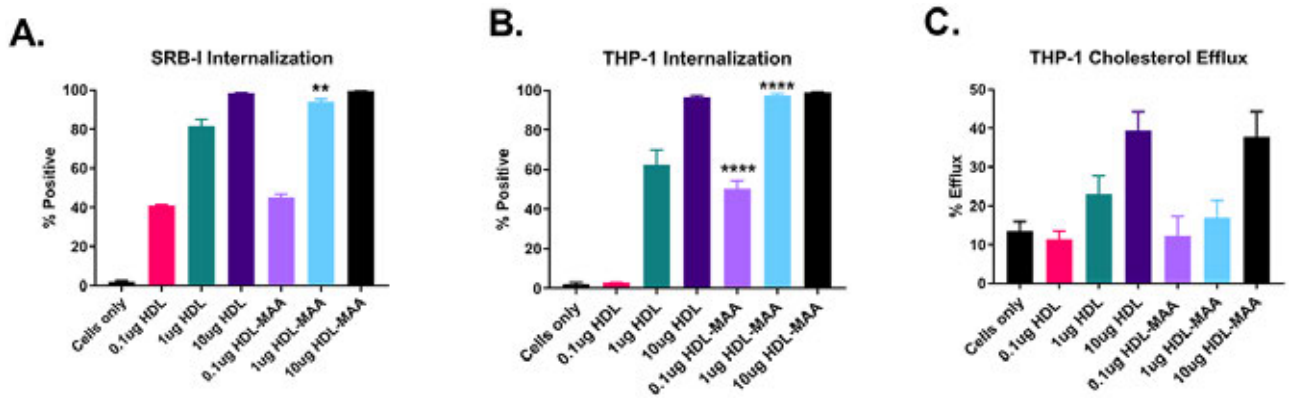

Figure 1 Internalization of MAA Modified HDL Proteins and Cholesterol Efflux. (A) CHO cells transfected with SRB-I internalize HDL-MAA significantly more ($p<0.01$) than native HDL at 1 ug. (B) THP-1 cells internalize HDL-MAA at 0.1 and 1 ug significantly more than native HDL ($p<0.0001$) (C) THP-1 cells demonstrated no significant change in the cholesterol efflux despite HDL particles being modified by MAA. (N=5)

bility assays for 4 hours and ligand internalization studies for 90 minutes. Internalization studies were also performed using Chinese Hamster Ovary (CHO) cells transfected with the B-I scavenger receptor (SRB-I) shown in prior studies to mediate cellular uptake of MAA-modified protein. Measurement of modified HDL function was tested using a fluorescent labeled cholesterol efflux assay using THP-1 cells.

Results: MAA modification of HDL was evident after 72 hours by fluorescence of the dihydropyridine ring at 398nm. THP-1 cell viability remained >95% after 4 hours of exposure to HDL-MAA. HDL-MAA was internalized at increasing concentrations compared to native HDL in both CHO cells transfected with the SRB-I receptor ($p< 0.01$) (A) and THP-1 cells ($p< 0.0001$) (B). However, cholesterol efflux (C) was not significantly different between native HDL and HDL-MAA, indicating that cholesterol binding is not MAA-dependent.

Conclusion: Post-translational modification of HDL may contribute to the development and progression of RA and CVD comorbidity. Increased internalization of HDL-MAA in the absence of meaningful effects on cholesterol efflux suggests that MAA modification does not alter the physiological rate of reverse cholesterol transport. However, the preferential accumulation of HDL in THP-1 cells following MAA modification suggests that this post-translational modification (demonstrated in RA to result from inflammation and increased oxidative stress) could impact the development and progression of comorbid CVD.

Loss-of-function of the DNA Repair Nuclease MRE11A Induces Mitochondrial Failure and Tissue Inflammation in Rheumatoid Arthritis

Yinyin Li,[1] Yi Shen,[1] Ke Jin,[1] Zhenke Wen,[1] Wenqiang Cao,[1] Bowen Wu,[1] Ru Wen,[1] Lu Tian,[1] Gerald Berry,[1] Jorg Goronzy,[1] and **Cornelia Weyand**[1], [1]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) accumulate tissue-invasive, pro-inflammatory $CD4^+$ T cells. Such T cells are metabolically reprogrammed, favoring cytokine production, lipogenesis and membrane formation while reducing ATP production. Also, such T cells have low expression of the DNA repair nuclease MRE11A, have a defect in DNA repair and are prematurely aged. How defective DNA repair, metabolic rewiring and the propensity to induce tissue inflammation are mechanistically linked is unknown.

Methods: $CD4^+$ T cells from seropositive RA patients and age-matched controls were isolated from human peripheral blood mononuclear cells. Nucleolytic activity of the DNA repair protein MRE11A was inhibited by gene knockdown or the pharmacologic inhibitor Mirin. Metabolic profiles and mitochondrial activity were examined by the Seahorse Analyzer and by quantifying metabolites. Inflammasome activation and lytic T cell death were measured by caspase-1 activation, IL-1β production and LDH release. Tissue inflammatory propensity of T cells was quantified in NSG mice engrafted with human synovial tissue and reconstituted with genetically or pharmacologically manipulated T cells.

Results: MRE11A^{low} CD4^{+} T cells from RA patients had low oxygen consumption and low ATP production, indicative of impaired mitochondrial function. The phenotype was reproduced with MRE11A knockdown in healthy T cells. Immunoblotting and imaging analysis localized MRE11A to the mitochondria. Pharmacologic and genetic inhibition of MRE11A resulted in leakage of mitochondrial DNA (mtDNA) into the cytoplasm, where it triggered assembly of the NLRP3 and AIM2 inflammasome and induced caspase-1-dependent pyroptotic cell death. Caspase-1 activation was a feature of T cells in lymph node biopsies of RA patients. MRE11A loss-of-function was associated with high propensity of T cells to induce synovial tissue inflammation in vivo, including the deposition of mtDNA in inflamed tissue sites. MRE11A overexpression was sufficient to restore mitochondrial function and prevent mtDNA leakage into the cytosol. Also, restoration of MRE11A expression suppressed pyroptotic T cell death and protected synovial tissue against inflammatory attack.

Conclusion: The DNA repair defect in RA T cells extends to mitochondrial DNA, impairing mitochondrial oxygen consumption and ATP generation and damaging mtDNA containment. The mitochondrial stress program associated with loss-of-function of the repair nuclease MRE11A triggers inflammasome assembly, caspase-1 activation and pyroptotic T cell death. The mechanistic connection between DNA repair, bioenergetic failure and pro-inflammatory T cell death provides novel therapeutic opportunities to manage immune aging and restore tissue homeostasis in rheumatoid arthritis.

Abstract Number: 2015

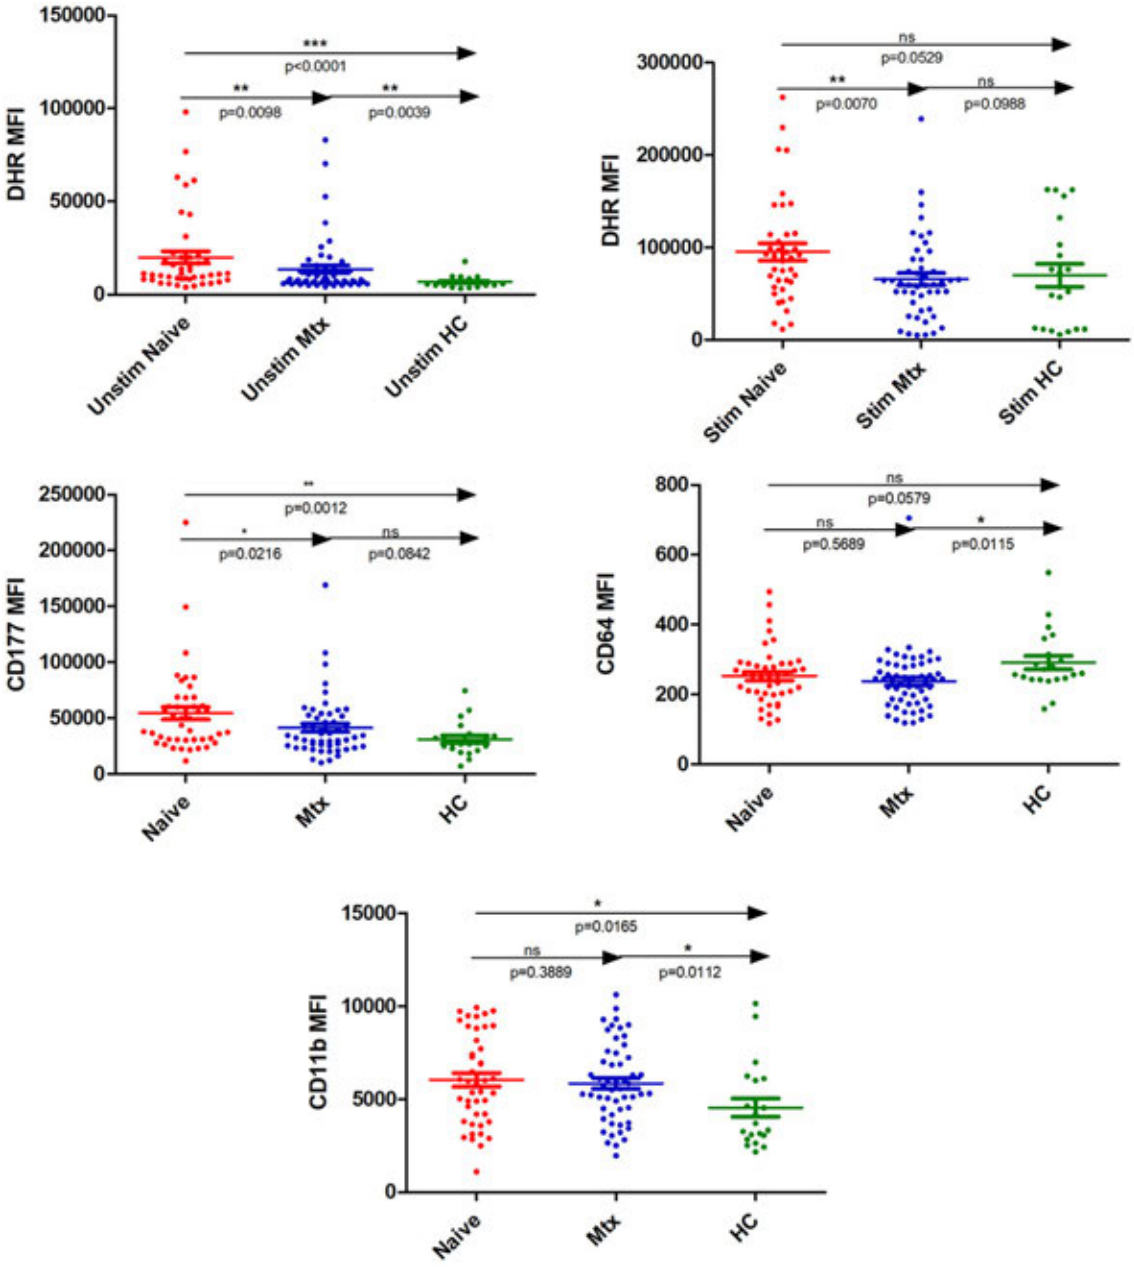
Methotrexate Treatment Is Associated with Reduction of Neutrophil Reactive Oxygen Species and CD177 in RA Patients

Urvashi Kaundal,[1] **Varun Dhir**,[1] Biman Saikia,[1] and Aastha Khullar[1], [1]Post Graduate Institute of Medical Education and Research, Chandigarh, India

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is the gold-standard DMARD in rheumatoid arthritis, however, it is unclear how exactly it works. Its effects on neutrophils may involve reduction in ROS production and neutrophil activation markers like CD177, CD11b and CD64.

Methods: This was a single-center cross-sectional study, which recruited patients with rheumatoid arthritis (RA) and healthy controls. RA patients included naïve (could be on low dose steroids) and MTX treated patients (at least 15 mg/week for 6 months), labeled as naïve-RA and MTX-RA groups. Neutrophils were separated from blood using Hetasep and Ficoll density-gradient centrifugation. Reactive oxygen species (ROS) by dihydrorhodamine (DHR) was detected using flow cytometry after PMA stimulation (1.62 ug/ml) as Median Fluorescent Intensity (MFI). ROS by Luminol was detected after adding PMA (0.4 ug/ml) and Luminol (50 uM) and using a luminescence detector (area under curve over 30 mins). Activation markers CD177, CD11b and CD64 were detected by surface staining of neutrophils using FACS.



Top panel shows scatter-plots showing higher reactive-oxygen species detected using dihydrorhodamine in naive-RA than MTX-RA, but no differnce between MTX-RA and healthy controls (both unstimulated and pMA stimulated). Middle panel shows higher level of CD177 expression in neutrophils of naive-RA than MTX-RA, but no difference in CD64. Lower panel shows higher expression of CD11b in both RA groups than healthy controls.

Results: This study included 53 (F:M= 43:10) patients of rheumatoid arthritis on methotrexate (MTX-RA), 47 (F:M=39:8) naïve (naïve-RA) and 21 healthy controls. There was no significant difference in the mean age (44.5, 47.6 years, p=0.17) between RA groups. There was a significant difference in the DAS28-3 between the naïve-RA and MTX-RA group (6.2, 4.9., p< 0.001). At baseline, there was higher level of ROS by DHR (MFI) in neutrophils of naive-RA compard to MTX-RA (11049, 7301, p=0.009). ROS levels by DHR (MFI) remained higher in naive-RA than MTX-RA (88805, 59637, p=0.0070) even after PMA stimulation. However there was no significant between MTX-RA and healthy controls after PMA stimulation. No significant difference was found in ROS by luminol between Naive-RA and MTX-RA patients. CD177 was found higher expressed (MFI) in naïve-RA compared to MTX-RA patients (46620, 34475, p=0.0216) and healthy controls (46620, 26855, p= 0.0012). No significant change for CD11b and CD64 levels

was observed between naive and MTX treated patients. However, in comparison to healthy controls, MTX-RA patients had lower levels of CD64 (260, 241, p= 0.0115) while both MTX-RA and naïve-RA patients had higher levels of CD11b (3708, 5560, p= 0.0112 and 3708, 5978, p=0.0165).

Conclusion: MTX treatment in RA patients was associated with reduction (reaching healthy control levels) of ROS production in neutrophils. In addition, CD177 expression was also significantly reduced (reaching healthy controls) in MTX- treated patients. One of the ways MTX acts in RA may be through reducing neutrophil activation and ROS.

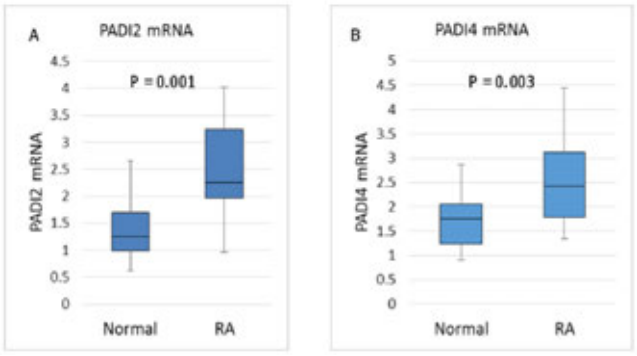
Expression of Peptidyl-arginine Deiminases in Peripheral Blood Neutrophils and Its Association with Single Nucleotide Variants in Patients with Rheumatoid Arthritis

Masayoshi Harigai,[1] Ryoko Sakai,[2] Takahiko Sugihara,[3] and Akihito Ishigami[4], [1]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Department of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [3]Tokyo Medical and Dental University, Tokyo, Japan, [4]Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan

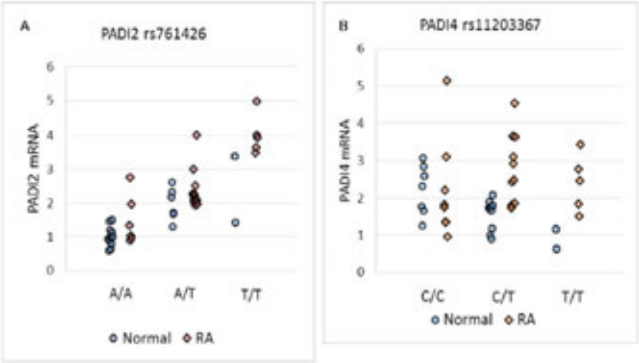
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Figure 1. Expression of PADI2 and PADI4 mRNA in patients with RA and healthy controls



Peripheral blood neutrophils were separated by using magnetic beads and total RNA was extracted. PADI2 and PADI4 mRNA were measured by using real-time RT-PCR and normalized by beta-actin mRNA.

Figure 2. Expression of PADI2 and PADI4 mRNA in patients with RA and healthy controls stratified by the numbers of risk alleles



Patients and healthy controls were stratified by numbers of risk allele of the PADI2 or PADI4 single nucleotide variant, and mRNA levels of PADIs were compared across the groups.

Background/Purpose: Peptidyl-arginine deiminases (PADIs) are enriched in neutrophils and considered to be responsible for citrullination of proteins *in vivo*. Autoantibody against citrullinated proteins are frequently detected in patients with rheumatoid arthritis (RA) and are highly diagnostic for the disease. PADI activity is detected in synovial fluid, and citrullinated proteins are found in synovium of patients with RA. Genetic evidence has shown that single nucleotide variants (SNVs) of PADI2 and PADI4 genes are associated with RA susceptibility. We aimed to elucidate association of SNVs of PADIs and their expression in peripheral blood neutrophils from patients with RA.

Methods: We enrolled 23 patients who fulfilled the 2010 American College of Rheumatology / European League Against Rheumatism classification criteria for RA and 20 healthy controls. Peripheral blood neutrophils were separated by using magnetic beads and applied to *in vitro* culture and extraction of genomic DNA. Neutrophils were cultured with or without stimulation for 48 hours and supernatants were collected to measure PADI2 and PADI4 by using enzyme-linked immunosorbent assay. SNVs of PADI2 and PADI4 were determined by using TaqMan SNP Genotyping Assays. Quantitative real-time RT-PCR was used to measure mRNA levels of PADI2 and PADI4.

Results: Fresh neutrophils from patients with RA expressed significantly larger amounts of PADI2 (p = 0.001) and PADI4 (P = 0.003) mRNA, than healthy controls (Figure 1). Neutrophils spontaneously released PADI2 and PADI4. Upon stimulation with PMA (20 and 200 microM), secretion of PADI2 significantly increased in patients with RA (p = 0.003 for 20 microM; p = 0.001 for 200 microM), but not in healthy controls. On the contrary, secretion of PADI4 significantly decreased in healthy controls at both PMA concentrations (p = 0.001 for 20 microM; p = 0.003 for 200 microM), but only at 20 microM in patients with RA (p = 0.05 for 20 microM, p = 0.5 at 200 microM). Patients and healthy controls were stratified by numbers of risk allele in SNVs of PADI genes, and mRNA levels of PADIs were compared (Figure 2). Multiple linear regression analyses revealed that RA (versus healthy controls) [nonstandardized partial regression coefficient (NPRC) = 1.29, 95% confidence interval (95% CI) 0.67 – 1.91, p = 0.001] and numbers of the risk allele of PADI2 rs761426 (A - >T) (NPRC = 0.20, 95% CI = 0.010 – 0.39, p = 0.04) were significantly associated with the levels of PADI2 mRNA in neutrophils. RA (versus healthy controls) was also associated with the levels of PADI4 mRNA in neutrophils (NPRC = 0.95, 95% CI = 0.36 – 1.55, p = 0.002), but not numbers of the risk allele of PADI4 rs11203367 (C - >T).

Conclusion: Expression levels of PADI2 and PADI4 mRNA were higher in patients with RA compared to healthy controls, but their association with SNVs are different. Secretion of these PADIs upon stimulation with PMA were different, which may suggest their independent physiological and pathological roles *in vivo*.

Beyond Genes—a Multi-omic Analysis of Monozygotic Twins Discordant for Rheumatoid Arthritis

Julia Manasson,[1] Jeremy Sokolove,[2] Lauren Lahey,[2] Adriana Heguy,[1] Carles Ubeda,[3] and Jose Scher[1], [1]New York University School of Medicine, New York, NY, [2]Stanford University School of Medicine, VA Palo Alto Medical Center, Stanford, CA, [3]Centro Superior de Investigación en Salud Pública - FISABIO, Valencia, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although a number of genetic factors, including susceptibility alleles, have been identified in rheumatoid arthritis (RA), the concordance rate in monozygotic (MZ) twins is only 15% (Silman AJ et al, Br J Rheumatol 1993). Given this relatively low rate, environmental factors (including smoking, the microbiome and others) likely play a significant role in disease pathogenesis. Several prior studies have highlighted this relationship. Two examples include oral *Porphyromonas gingivalis*, which has been implicated in the citrullination of peptides (Hitchon CA et al, J Rheumatol 2010), and intestinal *Prevotella copri*, which is significantly increased in new-onset RA (Scher JU et al,

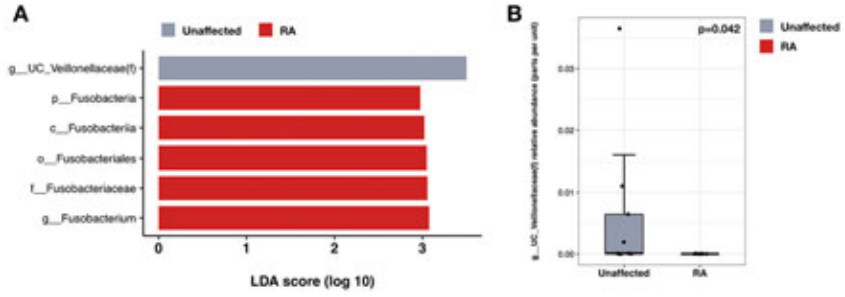

Figure 1 Linear discriminant analysis Effect size (LEfSe) identifies bacterial taxa that differentiate unaffected from RA twins. (A) Unaffected twins demonstrate differentially higher abundance of Unclassified Veillonellaceae, whereas RA twins demonstrate differentially higher abundance of Fusobacterium and other taxa within the Fusobacteria phylum. Linear discriminant analysis (LDA) score is on a log10 scale. Log10 LDA is >2 for all taxa. None of the identified taxa achieve FDR <0.1. (B) Boxplot of Unclassified Veillonellaceae relative abundance comparing unaffected and RA twins. Statistical significance calculated using the Wilcoxon signed-rank test.

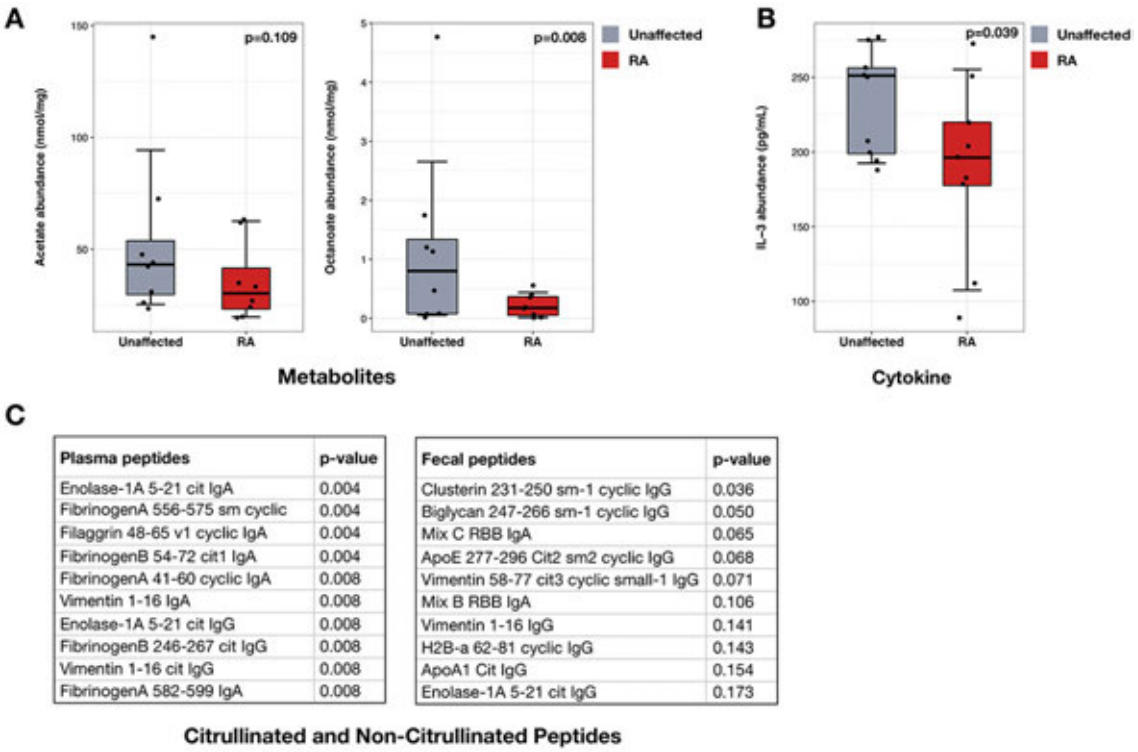

Plasma peptides	p-value
Enolase-1A 5-21 cit IgA	0.004
FibrinogenA 556-575 sm cyclic	0.004
Filaggrin 48-65 v1 cyclic IgA	0.004
FibrinogenB 54-72 cit1 IgA	0.004
FibrinogenA 41-60 cyclic IgA	0.008
Vimentin 1-16 IgA	0.008
Enolase-1A 5-21 cit IgG	0.008
FibrinogenB 246-267 cit IgG	0.008
Vimentin 1-16 cit IgG	0.008
FibrinogenA 582-599 IgA	0.008

Fecal peptides	p-value
Clusterin 231-250 sm-1 cyclic IgG	0.036
Biglycan 247-266 sm-1 cyclic IgG	0.050
Mix C RBB IgA	0.065
ApoE 277-296 Cit2 sm2 cyclic IgG	0.068
Vimentin 58-77 cit3 cyclic small-1 IgG	0.071
Mix B RBB IgA	0.106
Vimentin 1-16 IgG	0.141
H2B-a 62-81 cyclic IgG	0.143
ApoA1 Cit IgG	0.154
Enolase-1A 5-21 cit IgG	0.173

Citrullinated and Non-Citrullinated Peptides

Figure 2 Unaffected twins demonstrate higher levels of octanoate and IL-3, whereas RA twins have significantly higher levels of fecal and plasma citrullinated/non-citrullinated peptides. (A-B) Boxplots of fatty acid metabolites and IL-3 abundance comparing unaffected and RA twins. (C) Tables of plasma and fecal citrullinated/non-citrullinated peptides comparing unaffected and RA twins. Only the top ten peptides by p-value are listed. For all panels, statistical significance calculated using the Wilcoxon signed-rank test.

Elife, 2013). In our study, we sought to further understand this relationship by exploring the microbial, metabolomic and cytokine differences in MZ twins with discordant disease.

Methods: Fecal and blood samples were collected from nine pairs of MZ twins where one sibling was diagnosed with RA and the other unaffected. Fecal samples underwent bacterial DNA extraction, amplification and 16S rRNA gene sequencing. Additionally, gas chromatography mass spectrometry (GC-MS) was used to quantify fecal metabolites and multiplex assays were used to quantify fecal and plasma ACPA autoantigens as well as other cytokines (Sokolove J et al, PLoS One, 2012.). Analysis was performed using R, Quantitative Insights into Microbial Ecology (QIIME) and Linear discriminant analysis Effect Size (LEfSe).

Results: Microbiome analysis revealed no significant differences in overall bacterial alpha or beta diversity between unaffected and RA twins. On average, RA twins had higher relative abundance of Bacteroidales (RA 56.6% vs Unaffected 47.9%) and lower abundance of Clostridiales (RA 34.5% vs Unaffected 42.8%). LEfSe analysis showed differentially higher abundance of *Unclassified Veillonellaceae* in unaffected twins ($p=0.042$). Unaffected twins also demonstrated higher levels of fecal octanoate ($p=0.008$), a medium-chain fatty acid with beneficial immune effects, as well as significantly increased levels of plasma IL-3 ($p=0.039$). Conversely, several fecal and plasma citrullinated/non-citrullinated peptides were significantly higher in RA twins compared to their unaffected siblings ($p< 0.05$).

Conclusion: We characterized differences in the bacterial microbiome, metabolites, cytokines and citrullinated/non-citrullinated peptides in MZ twins discordant for RA. We found changes in the abundance of particular taxa, as well as higher levels of octanoate and IL-3 in unaffected twins, further suggesting the possibility that the initial citrullination and autoimmune events in this disease may occur in the intestinal mucosa. Understanding the immune mechanisms

orchestrated by the gut microbiota and their downstream effects may ultimately shed light on the pathogenesis of RA beyond genetic susceptibility and allow us to potentially alter the course of disease development and progression.

Elevated Serum Levels of Tie-1 in Patients with Rheumatoid Arthritis

Dylan Lee,[1] Chandra Mohan,[2] Danielle Feger,[3] Nancy Olsen,[4] and Rayford June[4], [1]Pennsylvania State M.S. Hershey Medical Center, Hershey, PA, [2]Department of Biomedical Engineering, University of Houston,, Houston, [3]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health,, Baltimore, [4]Pennsylvania State M.S. Hershey Medical Center, Hershey

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease that primarily affects patients' peripheral joints and can lead to severe personal disability from progressive articular joint destruction. The cause of RA is unknown. Recent studies have shown that collagen formation as well as angiogenesis are important in the pathophysiology of this disease. Specifically, serum vascular endothelial factor (VEGF) levels have been shown to be elevated in patients with RA and were correlated with the degree of radiographic joint damage. In addition to VEGF, a related angiogenic factor Tie-1 has been found to be elevated in RA synovial fluid. The objective of this study was to determine serum levels of Tie-1 in patients with RA and investigate associations with RA disease activity and RA clinical features.

Methods: 94 patients with RA and 21 healthy controls from the Penn State Hershey Investigation of Remission in Rheumatoid Arthritis (IRRA) cohort at Pennsylvania State M.S. Hershey Medical Center had measurement of serum Tie-1 levels using ELISA. High levels of Tie-1 were considered to be greater than 35,000. Mean Tie-1 levels were compared by T-test. Further analysis was performed using other available data including DAS 28 ESR/CRP, age, disease duration and mHAQ using Pearson's correlation and linear regression. Further chart review analysis was done to correlate radiographic findings. Data are expressed as mean (standard deviation).

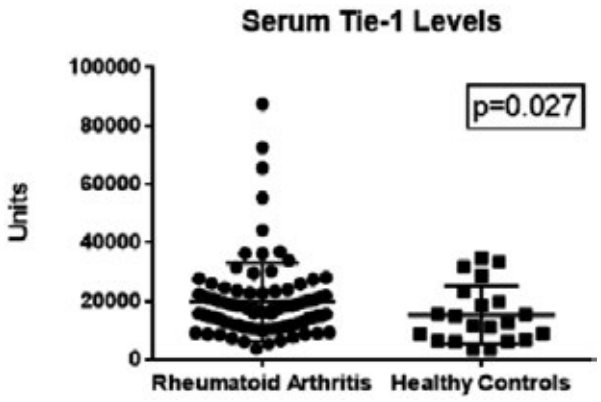

Figure 1. Serum Levels of TIE-1

Table 1a: Demographics			
	RA Patients (N=96)	Healthy Controls (N=21)	p-Values
Age (yrs)	55.57 (13.47)	48.48 (15.42)	0.035
Gender (% of female)	71 (74.0%)	16 (76.2%)	0.832
Seropositive for RF or CCP	89.4% (N=85)	-	-
DAS 28 CRP	3.33 (1.39) N=74	-	-
DAS 28 ESR	3.46 (1.59) N=64	-	-
Disease Duration (yrs)	11.09 (10.11) N=94	-	-
MHAQ (median, IQR)	0.125 (1.250) (N=90)	-	-
X-Ray erosions	41.8% (N=79)	-	-
BMI	29.57 (7.16)	25.15 (5.95)	0.010
Tie-1 level (units)	19794.91 (13373.99) N=94	15388.67 (9935.25)	0.027
Table 1b: High Tie-1 vs. Low-Tie 1			
	High TIE patients (levels >35,000) (N=8)	Low TIE patients (levels ≤35,000) (N=107)	p-Values
Age (yrs)	61.76 (7.82)	53.84 (14.20)	0.123
Gender (% of female)	7 (87.5%)	79 (73.3%)	0.390
Seropositive for RF or CCP	8 (100%)	67 (88.2%) (N=76)	0.590
DAS 28 CRP	3.97 (0.85) (N=6)	3.24 (0.17) (N=67)	0.209
DAS 28 ESR	4.21 (1.09) (N=5)	3.35 (1.60) (N=58)	0.246
Disease Duration (yrs)	17.96 (8.84)	10.50 (10.09) (N=84)	0.047
MHAQ	0.688 (0.625)	0.125 (1.250) (N=80)	0.036
X-Ray erosions	5 (83.3%) (N=6)	27 (38.0%) (N=71)	0.076
BMI	33.48 (8.25)	28.41 (7.04)	0.055
Tie-1 level (units)	54393.53 (19312.95)	16343.33 (7238.54)	<0.001

Results: The 94 subjects with RA had significantly higher serum Tie-1 levels compared to the healthy controls (19,794.91 (13,373.99) vs. 15,388.67 (9,935.25), p=0.027, Table 1a). There was a mild association between Tie-1 and DAS28ESR (β estimate 0.072; p=0.069). Eight subjects had high levels of Tie-1; 6 of these 8 patients had erosions on their x-rays (Table 1b). Patients with erosions had higher Tie-1 levels, but this was not statistically significant (P=0.125).

Conclusion: RA patients have higher levels of Tie-1 compared to healthy controls (Figure 1). High Tie-1 levels had a mild correlation with RA disease activity in this cross-sectional analysis. The etiology for the reason for higher levels of this angiogenesis factor in RA is unknown but may be related to synovial proliferation and other features of uncontrolled disease. Further research is needed to investigate the mechanism and source of the increase in serum and synovial fluid levels of TIE-1 and study as a biomarker of disease will be also of interest. These findings, combined with the previously described correlation between VEGF and RA activity, support the need to further understand the role of angiogenesis in the pathogenesis of RA.

Tenosynovitis at the Metatarsophalangeal Joints, a Novel Feature of RA: Results from an Anatomical and Large Magnetic Resonance Imaging Study of Tendon Sheaths of the Forefoot

Yousra Dakkak,[1] Friso Jansen,[1] Marco DeRuiter,[1] Monique Reijnierse,[1] and Annette van der Helm-van Mil[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]LUMC, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent magnetic resonance imaging (MRI)-studies revealed that tenosynovitis in the hands is associated with rheumatoid arthritis (RA). Although the forefoot is a preferential location for RA-inflammation, it is unknown whether MRI-detected tenosynovitis at the level of metatarsophalangeal (MTP)-joints is associated with RA. In addition anatomic literature leaves it undetermined if tendons at MTP-joints are surrounded by a synovial sheath. These questions were investigated.

Methods: Macroscopically, 14 forefeet of donated bodies were examined at the flexor-tendons and extensor-tendons for the presence and course of tendon sheaths. Tissue surrounding tendons was injected with blue-dyed resin or silicon. Presence of a sheath was also studied by light-microscopy. 624 persons (157 patients presenting with RA, 284 with other early arthritides and 193 symptom-free persons from the general population) underwent 1.5T MRI of unilateral MTP(1-5)-joints. Images were scored by two readers for tenosynovitis, synovitis and bone marrow oedema.

Results: Macroscopically, all extensor and flexor tendons crossing MTP-joints demonstrated clearly demarcated sheaths surrounding tendons. Microscopy revealed a synovial sheath. MRI-detected tenosynovitis occurred in 42% of RA-patients, 22% with other arthritidesand 1.6% of symptom-free controls. Compared to other arthritides, MRI-detected tenosynovitis was associated with RA, OR 2.38 (95%CI 1.5-3.8) for flexor and OR 3.13 (95%CI 1.9-5.2) for extensor tendons. The sensitivity of tenosynovitis in RA was 42%. The specificity compared to other arthritideswas 78%, and compared to symptom-free controls 98%.

Conclusion: Tenosynovium is present surrounding flexor and extensor tendons at MTP-joints. MRI-detected tenosynovitis of MTP-joints is specific for RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Malondialdehyde (MDA) is highly reactive compound produced by lipid-peroxidation in situations associated with oxidative stress. MDA can irreversibly modify proteins (e.g. lysine, arginine and histidine residues), which can lead to the generation of immunogenic neo-epitopes that are recognized by autoantibodies. In fact, anti-MDA IgG antibodies are significantly increased in the serum of patients with autoimmune diseases, such as rheumatoid arthritis (1). Recently, anti-MDA IgG antibodies have been shown to promote osteoclast (OC) differentiation *in vitro* (1). In this study, we decided to further elucidate the molecular mechanisms triggered by these autoantibodies during osteoclastogenesis.

Methods: OCs were generated from monocyte-derived macrophages in the presence of the cytokines RANK-L and M-CSF. The development of OCs was monitored by light microscopy following tartrate-resistant acid phosphatase (TRAP) staining. Three different recombinant human monoclonal anti-MDA antibodies, generated by single-cells cloning from synovial RA B cells, or control antibodies were added to OC cultures. Cellular metabolism was monitored using Seahorse XF Analyzer (extracellular acidification rate and oxygen consumption) and a colorimetric L-Lactate assay. Genes expressions were assessed by RT-PCR.

Results: Lactic acid production correlated with stimulatory effect of anti-MDA antibodies on OCs, suggesting an antibody-mediated regulation of glycolysis. Moreover, extracellular acidification rate and oxygen consumption of the developing OCs were increased by the osteoclastogenic anti-MDA clone but not by control antibodies. We have also observed the upregulation of genes encoding the glucose transporter GLUT1 and the down-regulation of the pyruvate dehydrogenase kinase (PDK)2 and PDK4 enzymes by anti-MDA antibodies. The glycolysis inhibitor 2-deoxyglucose eliminated the stimulatory effect of anti-MDA clone on OCs at drug concentrations that did not influence baseline OC development.

Conclusion: Our study further confirmed that IgG autoantibodies against MDA/MDA-acetaldehyde posttranslational modifications might have pathological roles in RA. We showed that certain anti-MDA clones induced an early boost of glycolysis and mitochondrial respiration in developing OCs and these metabolic changes led to an increased OC differentiation. Our study thus described a new type of autoantibody-induced cellular mechanism that can contribute to bone abnormalities.

Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multifactorial autoimmune disease with diverse heterogeneous phenotypes. Although many studies of SLE presented estimates of high heritability, impact of complex genetic variants on the clinical manifestations and antibodies profiles of SLE was not fully understood. The aim of this study is to identify the genetic load by genetic risk score (GRS) that influence the clinical and serological manifestations according to ACR criteria in patients with SLE.

Methods: A total of 781 Korean patients from the Hanyang BAE lupus cohort were genotyped by genome-wide association study array. Weighted genetic risk score (GRS) were calculated from 45 well-validated non-HLA SNPs and HLA SLE-risk loci. Individual GRS was tested for associations with the clinical subphenotypes based on ACR criteria of SLE and the development of autoantibody by using a multivariable linear regression or a logistic regression.

Results: We identified weighted GRS calculated from non-HLA and HLA SLE-risk loci with significant associations in various SLE subphenotypes defined by the ACR criteria (mean number 5.74) among 11 criteria. Individual's weighted GRS showed significantly positive correlation with the number of ACR criteria in a linear regression model (β coefficient = 0.13, $p = 9.00\times10^{-3}$). Consistently, a significant positive correlation with the number of ACR in both non-HLA GRS ($\beta = 0.11$, $p = 0.027$) and HLA GRS (β 0.06, $p = 0.021$) was observed, respectively.

In a clinical subphenotype analysis, weighted GRS from non-HLA and HLA risk loci were significantly related to malar rash (OR 1.23, $p = 2.68\times10^{-3}$), renal disorder (OR 1.15, $p = 4.41\times10^{-2}$), and thrombocytopenia (OR 1.21, $p = 7.55\times10^{-3}$) using a multivariable logistic regression. Weighted GRS were strongly associated with production of anti-DNA antibody (OR 1.38, $p = 2.18\times10^{-3}$).

Conclusion: In conclusion, genetic risk load of SLE is significantly higher in individuals with more diverse clinical and serological manifestations. Several subphenotypes (malar rash, renal disorder, thrombocytopenia and anti-dsDNA antibody) might be influenced by cumulative genetic risk load.

Analysis of Gene Expression from Systemic Lupus Erythematosus Synovium Reveals Unique Pathogenic Mechanisms

Erika Hubbard,[1] Michelle Catalina,[2] Sarah Heuer,[1] Prathyusha Bachali,[2] Nicholas Geraci,[3] Peter Lipsky,[3] and Amrie Grammer[1], [1]AMPEL BioSolutions and RILITE Research Institute, Charlottesville, VA, [2]AMPEL BioSolutions and the RILITE Research Institute, Charlottesville, VA, [3]AMPEL BioSolutions, LLC, Charlottesville, VA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis is a common manifestation of SLE and the ability of a new lupus therapy often depends on its ability to suppress joint inflammation. Despite this, an understanding of the underlying pathogenic mechanisms driving lupus synovitis remains incomplete. We, therefore, interrogated gene expression profiles of SLE synovium to gain insight into the nature of joint inflammation in lupus arthritis.

Methods: Biopsied knee synovia from SLE and OA patients were analyzed for differentially expressed genes (DEGs) and also by Weighted Gene Co-expression Network Analysis (WGCNA) to determine similarities and differences between gene profiles and to identify modules of highly co-expressed genes that correlated with clinical features of lupus arthritis. DEGs and correlated modules were interrogated for statistical enrichment of immune and non-immune cell type-specific signatures and validated by Gene Set Variation Analysis (GSVA). Genes were functionally characterized using BIG-C and canonical pathways and upstream regulators operative in lupus synovitis were predicted by IPA®.

Results: DEGs upregulated in lupus arthritis revealed enrichment of numerous immune and inflammatory cell types dominated by a myeloid phentoype, whereas downregulated genes were characteristic of fibroblasts. WGCNA revealed 7 modules of co-expressed genes significantly correlated to lupus arthritis or disease activity (SLEDAI or anti-dsDNA titer). Functional characterization of both DEGs and WGCNA modules by BIG-C revealed consistent co-expression of immune signaling molecules and immune cell surface markers, pattern recognition receptors (PRRs), antigen presentation, and interferon stimulated genes. Although DEGs were predominantly enriched in myeloid cell transcripts, WGCNA also revealed enrichment of activated T cells, B cells, CD8 T and NK cells, and plasma cells/plasmablasts, indicating an adaptive immune response in lupus arthritis. Th1, Th2, and Th17 cells were not identified by transcriptomic analysis although IPA® predicted signaling by the Th1 pathway and numerous innate immune signaling pathways were verified by GSVA. IPA® additionally predicted inflammatory cytokines TNF, CD40L, IFNα, IFNβ, IFNγ, IL27, IL1, IL12, and IL15 as active upstream regulators of the lupus arthritis gene expression profile in addition to the PRRs IRF7, IRF3, TLR7, TICAM1, IRF4, IRF5, TLR9, TLR4, and TLR3. Analysis of chemokine receptor-ligand pairs, adhesion molecules, germinal center (GC) markers and T follicular helper (T_{fh}) cell markers indicated trafficking of immune cell populations into the synovium by chemokine signaling, but not *in situ* generation of fully-formed GCs. GSVA confirmed activation of both myeloid and lymphoid cell types and inflammatory signaling pathways in lupus arthritis, whereas OA was characterized by tissue repair/damage.

Conclusion: Bioinformatic analysis of lupus arthritis reveals a pattern of immunopathogenesis in which myeloid cell-mediated inflammation dominates, leading to further recruitment of adaptive immune cells that contribute to the ongoing inflammatory synovitis.

Gene-Expression Analysis of Male and Female SLE Patients Reveals Candidate Pathogenic Pathways

Mikhail Olferiev,[1] David Fernandez,[2] Dina Greenman,[1] Mary Peng,[1] Kyriakos Kirou,[1] and Mary Crow[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Mary Kirkland Center for Lupus Research, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The female predisposition for development of multiple autoimmune diseases is well recognized. The female to male ratio reaches a maximum during the reproductive years among SLE patients, suggesting a link between sexual development and disease. Additional epidemiologic data indicate an effect of sex chromosomes. To gain insight into molecular mechanisms of SLE, we investigated gene expression in PBMC of SLE patients and corresponding healthy donors of both genders using RNA-seq.

Methods: SLE samples were selected at a time of relative disease quiescence from a longitudinal cohort of patients. To minimize variation between male and female patients only demographically matched adults receiving low doses of steroids, hydroxychloroquine and mycophenolate motifil were selected and matched to healthy donors (HD). The analysis focused on identification of functional pathways affected in male and female SLE patients and abnormal gene expression from sex chromosomes.

Results: Principal component analysis differentiated the 4 donor groups, with PC1 and PC3 reflecting disease and PC2 reflecting gender. Male SLE patients received the highest score on PC1 and were placed closer to both SLE and healthy females than healthy males on PC2. We identified 796 and 99 differentially expressed genes in male and female SLE patients respectively, compared to HD ($p< 0.05$, logFC=1.5). Fewer genes (20 vs. 27) differed between genders in SLE vs. HD ($p< 0.05$, logFC=1.5). Weighted Gene Co-expression Network Analysis (WGCNA) identified 24 clusters of co-expressed genes in male and female patients. The most intriguing were clusters that differed in male and female HD and were upregulated in SLE of both genders. Those clusters include genes related to EGF receptor ligands (AREG, EREG, HBEGF), transcription factors (ATF3, NR4A1, NR4A2, NR4A3), cytokines and chemokines (CCL3, CXCL2, CXCL8, CCL3L3, IL1A, IL1B). We also identified a group of X-chromosomal genes strongly upregulated in male SLE patients, including CXorf21.

Conclusion: Despite being clinically similar, male SLE patients showed a higher level of affected genes and had a lower divergence from females based on gender-related genes. Male HD had the lowest basal level of pro-inflammatory genes and EGF receptor ligands. The signaling through the EGF receptor has been shown to modulate the type I interferon response and may predispose females to autoimmune disease. The effect of X-chromosomal genes, including those that can escape inactivation in females, should be further investigated. We propose that gender-specific differences in gene expression reveal immunopathogenic mechanisms in autoimmune disease.

Session Title: SLE – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Genetics influences kidney function (estimated glomerular filtration rate (eGFR)), systemic lupus erythematosus (SLE) and lupus nephritis (LN) risk. Genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) associated with eGFR in the general population as well as SLE. However, few loci have been identified and replicated for LN risk, in part due to heterogeneity with LN. Using quantitative, repeated eGFR measures as opposed to binary LN may be more informative in detecting LN genetic loci. Our objective was to demonstrate repeated eGFR measures as potentially informative measures in GWAS by showing an association exists between SNPs associated with eGFR and SLE on (1) mean and (2) variance of eGFR.

Patient-Level Covariates	All SLE Patients (n = 1167)	LN SLE Patients (n = 434)	Non-LN SLE Patients (n = 733)
Sex			
Female	1012 (86.7)	354 (81.6)	658 (89.8)
Age at Diagnosis (years)‡	19.61 [14.30, 31.71]	17.07 [13.21, 28.54]	21.92 [14.78, 33.64]
Total Follow-Up Time (years)‡	7.52 [3.92, 15.25]	8.72 [5.06, 16.25]	6.87 [3.52, 14.51]
Ancestry			
European	564 (48.3)	164 (37.8)	400 (54.6)
East Asian	236 (20.2)	105 (24.2)	131 (17.9)

No. of aSLE Measures (CKD-EPI)	23,926 (66.0)	9,788 (60.0)	14,138 (70.9)
No. of cSLE Measures (Schwartz)	12,332 (34.0)	6,526 (40.0)	5,806 (29.1)
Within-Person No. eGFR Measures‡	24 [13, 41]	30 [17, 50]	21 [11, 35]
Within-Person Mean eGFR†	98.60 (21.86)	93.57 (26.75)	101.57 (17.72)
Within-Person eGFR Variance†	11.11 (5.95)	13.67 (7.40)	9.59 (4.23)

Categorical variables, frequency (proportion in %)
†Continuous variables, mean (standard deviation), ‡Continuous variables, median [interquartile range]
SLE = systemic lupus erythematosus, LN = lupus nephritis, eGFR = estimated Glomerular Filtration Rate, No. = number,
aSLE = adult-onset SLE, cSLE = childhood-onset SLE, CKD-EPI = Chronic Kidney Disease Epidemiology Collaboration

Summary statistics of patient-level laboratory, demographic and clinical characteristics collected during follow-up between LN and non-LN patients.

Methods: We included 1167 patients followed in Toronto Lupus Clinics from SickKids and/or the Toronto Western Hospital. Patients met ≥4 ACR and/or SLICC criteria for SLE and were genotyped on the Illumina MEGA or Omni1-Quad arrays. Ungenotyped SNPs were imputed. Non-HLA additive genetic risk scores (GRS) were calculated for SLE, and for eGFR, using published GWAS weights for loci that met $p < 5x10^{-8}$. LN was confirmed by renal biopsy. Longitudinal, prospectively collected clinical and laboratory data, including serum creatinine, were extracted from lupus databases. eGFR was calculated using the CKD-EPI (≥18y), and Schwartz equations (< 18y). We tested the effect of SLE-GRS and eGFR-GRS with respect to (1) eGFR mean using linear mixed models and (2) eGFR variance through Gamma regression of squared-ordinary least squares jackknife residuals in R. Models included a time-varying indicator for eGFR taken as a child or adult.

Results: Our cohort included 567 (47%) patients with childhood-onset SLE (cSLE) and 615 (53%) adult-onset SLE (aSLE) with a total of 36,258 eGFR measures (23,926 measures (66%) during aSLE). Median follow-up time was 7.52 years [IQR: 3.92, 15.25 years] (Table). The majority were female (87%) and of European ancestry (48%). There was a median lag of 77 days [IQR: 0, 1193 days] between SLE diagnosis and first visit. Under a t-test of independence, we observed lower within-person mean eGFR ($p < 0.001$) and higher within-person eGFR variance ($p < 0.001$) in patients with LN compared to those without LN. From linear mixed models and Gamma regression, a unit increase in eGFR-GRS was associated with a 0.60 mL/min/1.73 m^2 increase in eGFR (0.60; 95% CI: [0.24, 0.96]; $p = 0.001$) and a 2% increase in eGFR variance (1.02; 95% CI: [1.02, 1.03]; $p < 0.001$). A unit increase in SLE-GRS was associated with a 1.28 mL/min/1.73 m^2 decrease in eGFR (-1.28; 95% CI: [-2.42, -0.13]; $p = 0.029$) and a 4% increase in eGFR variance (1.04 95% CI: [1.01, 1.06]; $p < 0.001$).

Conclusion: Using a large number of repeated eGFR measures taken from people with aSLE and cSLE, we observed that as expected, patients with LN had both lower mean eGFR and higher variability in eGFR, when compared to patients without LN. We demonstrated that eGFR and SLE loci are influencing (1) eGFR mean and (2) eGFR variance in SLE patients. This suggests that longitudinal eGFR measures may be more informative outcomes than binary LN categories for identifying genetics of kidney disease in SLE.

Ancestry Influences the Gene Expression Profile in Systemic Lupus Erythematosus and Contributes to Transcriptomic Heterogeneity in Lupus Patients

Michelle Catalina,[1] Prathyusha Bachali,[2] Anthony Yeo,[3] Nicholas Geraci,[2] Michelle Petri,[4] Amrie Grammer,[2] and Peter Lipsky[2], [1]AMPEL BioSolutions, LLC, harvard, MA, [2]AMPEL BioSolutions, LLC, Charlottesville, VA, [3]Rilite Foundation, Charlottesville, VA, [4]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

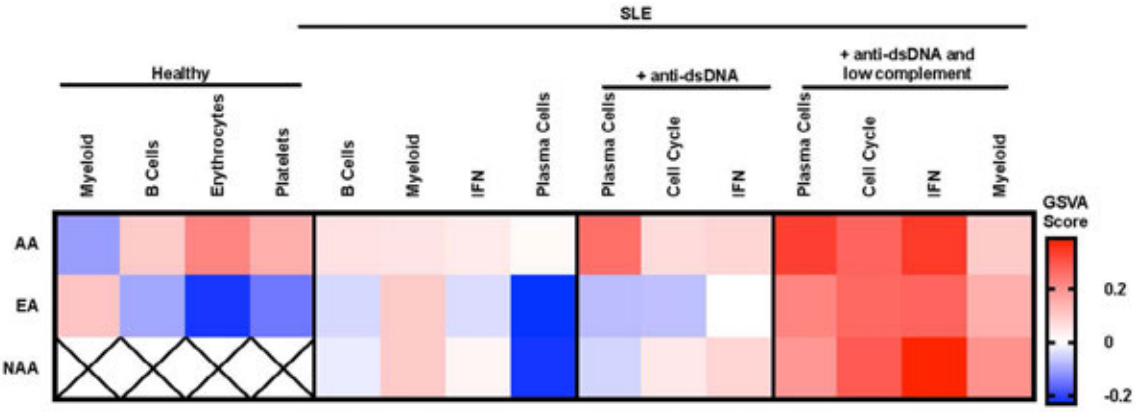

Figure 1. Gene Expression is Affected by Ancestry, SLE Autoantibodies and SOC Drugs. Average difference in GSVA enrichment scores are shown for Healthy. Average GSVA enrichment scores are shown for Lupus patients.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease with both sex and ancestral bias. Gene expression analysis has revealed complex heterogeneity between SLE patients, making deconvolution of the data difficult and delineation of the impact of different disease drivers uncertain. We, therefore, sought to understand the individual contributions of ancestry, gender and medications to gene expression heterogeneity, as well as to determine the association of gene expression profiles with various SLE manifestations.

Methods: Bulk Differential Expression (DE) analysis and Gene Set Variation Analysis (GSVA) were carried out on 1903 SLE patients of African (AA), European (EA) and Native American (NAA) ancestry. Modules of genes defined by co-expression in patients and representing either functional or cell specific groups were used to determine the relationship between drugs, SLE manifestations and individual patient gene expression. Logistic regression analysis was used to understand the relative contribution of ancestry, drugs and SLE manifestations to gene expression signatures.

Results: Gene expression analysis between female disease-matched SLE patients of AA, EA, and NAA revealed thousands of DE transcripts between ancestries, but none within a single ancestry. AA, EA and NAA SLE patients had significantly different cellular contributions to gene expression and these differences were related to significantly different percentages of patients in each ancestry with specific signatures. GSVA showed an increase in plasma cells, B cells and T cells in the majority of AA patients and an increase in myeloid cells in most EA and NAA patients. Corticosteroids and immunosuppressives significantly changed gene expression and contributed to the disparate signatures between and within ancestries. Anti-dsDNA autoantibodies and low complement, but not other clinical features of SLE, were significantly associated with gene expression in AA, EA and NAA SLE patients. Despite the impact of medications, ancestry made a significant contribution to gene expression profiles. Notably, we found that differences between AA and EA SLE patients are similar to those between healthy people of these ancestries, and that there were fewer differences between males and females of the same ancestry, than between ancestries.

Conclusion: Combinations of different ancestries, specific medications and autoantibody production associate with gene expression profiles (Figure 1). Importantly, ancestry contributes unique features of gene expression, implying differences in the molecular basis of SLE in these populations. Understanding the contributions of the gene expression signature components may permit a better interpretation of the signatures and their relationship to disease status.

MicroRNA-27a Can Contribute to Interferon Signatures in Systemic Lupus Erythematosus via the Suppression of Tripartite Motif-containing Protein 27

Daiga Kishimoto,[1] Ryusuke Yoshimi,[1] Yosuke Kunishita,[1] Yumiko Sugiyama,[2] Takaaki Komiya,[1] Natsuki Sakurai,[3] Reikou Kamiyama,[1] Yohei Kirino,[4] and Hideaki Nakajima[4], [1]Department of Stem Cell and Immune Regulation / Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Department of Rheumatic Diseases / Yokohama City University Medical Center, Yokohama, Japan, [3]Department of Stem Cell and Immune Regulation / Yokohama City University Graduate School of Medicine, Yokohama City, Japan, [4]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Type I interferons (IFN) contribute to antiviral innate immune responses. Upon viral infection, pattern recognition receptors trigger TANK-binding kinase 1 (TBK1) activation and lead to activation of the transcription factor IFN regulatory factor (IRF) 3 to induce type I IFN production. Because high expression of typeI IFN inducible genes, called IFN signature, is observed in systemic lupus erythematosus (SLE), the excessive IFN production has been thought to have the important role in SLE pathogenesis.

Recently, it has been reported that silica acid-binding immunoglobulin-like lectin (Siglec) 1 suppresses antiviral innate immune response by inducing TBK1 degradation by the E3 ubiquitin ligase, tripartite motif-containing protein (TRIM) 27. It has also been reported that type I IFN-induced downregulation of microRNA (miR)-27a can increase TRIM27 expression, and then inhibit the type I IFN production in antiviral innate response.

Here, we report that downregulation of TRIM27 by miR-27a can contribute to IFN signature in SLE.

Methods: Human peripheral blood mononuclear cells (PBMC) and sera were obtained from SLE patients and healthy controls (HC). All of the patients fulfilled the revised 1997 ACR Criteria for Classification of SLE. The quantitative real-

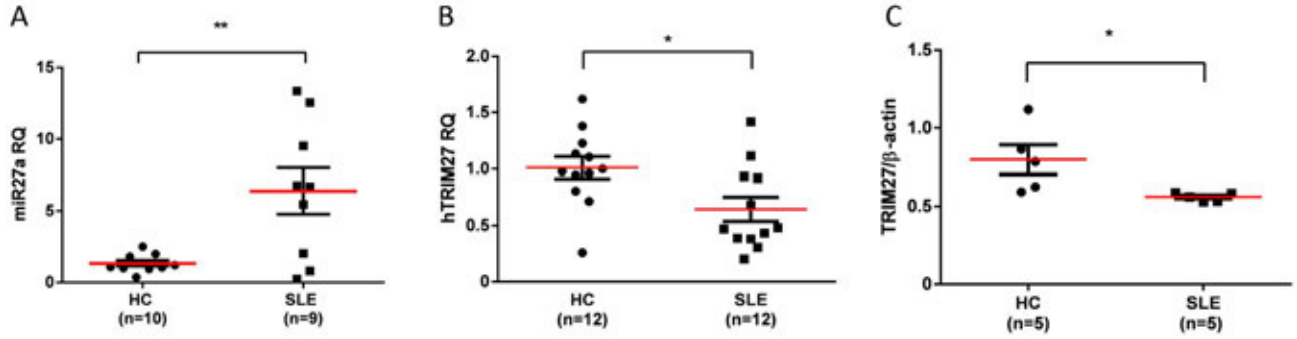

Figure 1 Increased miRNA-27a expression may induce downregulation of TRIM27 in SLE patients (A)The expression level of miR-27a in sera of SLE patients was higher than that of HC (p=0.0043). The expression levels of mRNA (B) and protein (C) of TRIM27 in PBMC of SLE patients were lower than those of HC (p=0.020, p=0.038, respectively). Data are presented as mean ± SEM. Statistically significant data (*, p< 0.05 and **, p < 0.01) by Student's t-test or two-tailed Mann-Whitney U test.

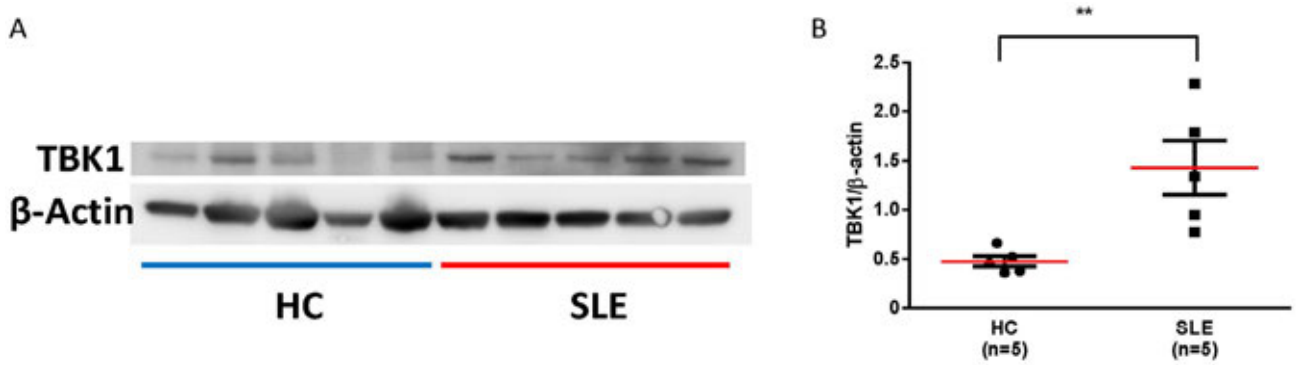

Figure 2. TBK1 protein level is higher in SLE patients. (A) Western blot analysis was performed with extracts from PBMC of SLE patients and HC using anti-TBK1 Ab. β-actin was used as a loading control. (B) TBK1 protein level was higher in SLE patients as compared to HC (n=5 in each groups). Data are presented as mean ± SEM. Statistically significant data (**, $p < 0.01$) by Student's t-test.

time PCR (qPCR) and western blotting were performed to assess the mRNA and protein expression levels of TRIM27 and TBK1, respectively. Serum miR-27a levels were investigated by qPCR. Statistical analysis was performed by using the GraphPad Prism. Data are presented as mean ± SEM. We used a Student's *t*-test or the two-tailed Mann-Whitney *U* test. The *p*-values < 0.05 were considered statistically significant.

Results: The expression level of miR-27a in sera of SLE patients was higher than that of HC (p=0.0043; Figure 1A). The expression levels of mRNA and protein of TRIM27 in PBMC of SLE patients were lower than those of HC (p=0.020, p=0.038, respectively; Figure 1B, C). On the contrary, TBK1 protein level was higher in SLE patients as compared to HC (p=0.0079; Figure 2A, B).

Conclusion: In SLE patients, increased miR-27a expression may induce downregulation of TRIM27, which leads to reduction of the TBK1 ubiquitination and degradation. The results suggest that miR-27a can contribute to interferon signatures in SLE via the suppression of TRIM27.

Dysregulation of Granulopoiesis in Systemic Lupus Erythematosus

Neelakshi R. Jog,[1] Teresa Aberle,[1] Cristina Arriens,[2] Stefania Gallucci,[3] and Judith James[2], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Lewis Katz School of Medicine, Temple University, Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by autoantibody production and periods of elevated disease activity. Recent studies indicate that along with dysfunctional adaptive immune responses, neutrophils are also important in disease pathogenesis. SLE patients have higher numbers of low-density granulocytes (LDGs) in peripheral blood that express neutrophil markers and are hyper-

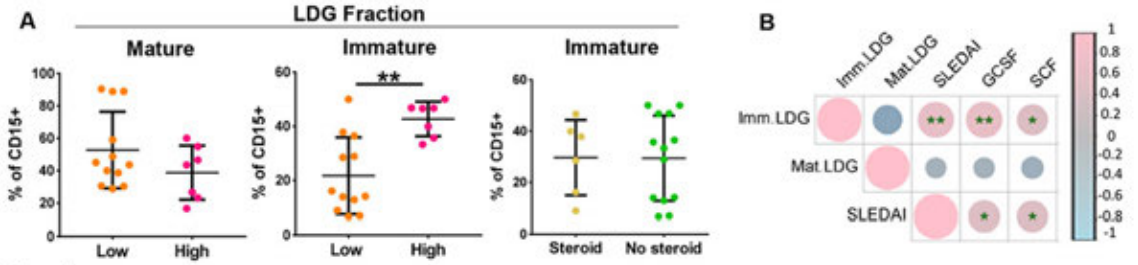

Figure 1

A. LDG fraction of SLE patients with elevated disease activity has higher frequencies of immature cells. PBMCs from SLE patients were enriched by density gradient centrifugation. Cells were stained, acquired on BD LSRII and analyzed by FlowJo. Low=SLEDAI<4 (*n=12*), High=SLEDAI>4 (*n=7*). **p<0.01* by Mann-Whitney. Immature neutrophil frequencies were independent of steroid use.

B. Immature LDGs correlate with SLEDAI, SCF, and GCSF. Spearman correlation coefficients were calculated and correlogram generated in R. The color represents direction and size of circles represents strength of association. **p<0.05, **p<0.01.* Imm.LDG=immature neutrophil in LDG fraction, Mat.LDG=mature neutrophil in LDG fraction. Pink=positive correlation, Blue=negative correlation.

responsive to external stimuli. LDGs also have an enhanced ability to form neutrophil extracellular traps (NETs), and are suggested to be pathogenic in lupus. This study was carried out to determine whether the LDG fraction consists of immature cells and whether these cells differ with disease activity.

Methods: Peripheral blood mononuclear cells from 19 SLE patients with varying disease activity and 11 controls were enriched by density gradient centrifugation. Neutrophils were enriched by dextran sedimentation and density gradient centrifugation. LDG numbers were determined by flow cytometry. Plasma cytokines were measured by xMAP assays. Neutrophils were cultured for 3h and cytokines in supernatants were measured by xMAP assays. Levels of microRNA (miRNA) were determined by quantitative PCRs. SLE disease activity indices (SLEDAI) were obtained from medical records. Immature and mature neutrophil frequencies in bone marrow from 9-11 months old B6.NZM/Sle1/Sle2/Sle3 (Sle123) or C57BL/6J (B6) mice were determined by flow cytometry.

Results: SLE patients with elevated disease activity had significantly higher frequency of immature LDGs as determined by surface marker expression (p=0.0053) (Figure 1A). The frequencies of immature LDGs correlated with the SLE disease activity index (SLEDAI) and plasma G-CSF (Spearman r=0.651, *p*=0.0025, r=0.663, *p*=0.002, respectively) (Figure 1B). Compared to their wild type B6 counterpart, the spontaneous lupus mice Sle123 showed increased immature neutrophils (p=0.0079), similar to our data from lupus patients. SLE neutrophils spontaneously secreted higher levels of BAFF (p=0.043) and IL-21 (p=0.0394), but not IL-8 or MMP9. SLE neutrophils expressed significantly different levels of select miRNA compared to healthy neutrophils, as was previously reported for neutrophils generated by G-CSF induced emergency granulopoiesis.

Conclusion: Our data suggest that SLE patients may have dysregulated development of myeloid cells in the bone marrow due to the cytokine milieu present during elevated disease activity. The functional responses of these newly generated neutrophils may differ due to differences in the bone marrow transit time. The dysregulation of granulopoiesis therefore may generate neutrophils that further exacerbate autoimmune response.

Inhibited Expression of Hematopoietic Progenitor Kinase 1 in Tfh Cells Contributes to Autoimmunity in Systemic Lupus Erythematosus

Qing Zhang,[1] and Huilin Zhang[2], [1]Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China (People's Republic), [2]Clinical Nursing Teaching and Research Section, Second Xiangya Hospital, Central South University, Changsha, Hunan, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: T follicular helper cells (Tfh cells) are a newly discovered subset of $CD4^+$ T cells, which play a mainly role in inducing B cells to produce antibody. Tfh cells are over activated in systemic lupus erythematosus (SLE) patients, consequently bring about immune damages. Hematopoietic progenitor kinase 1 (HPK1) can inhibit T cell-mediated immune responses, but the role that HPK1 plays in Tfh cells from SLE patients remain elusive. The aim of this study is to investigate whether HPK1 plays roles in SLE Tfh cells.

Methods: Naïve $CD4^+$ T cells and B cells were isolated from healthy controls and SLE patients. Then Naïve $CD4^+$ T cells were induced to differentiate into Tfh cells by stimulating with anti-CD3 antibody, anti-CD28 antibody, IL-6, IL-12, IL-21, and TGF-β. HPK1 mRNA and protein levels in Tfh cells were determined by real-time RT-PCR and western blotting. Detection of IL-21, CXCL13, IFNγ, IL-17A, IgM, IgG1, IgG2a, IgG2b and IgG3 levels were performed by ELISA. Tfh cells proliferations were analyzed with MTT assay.

Results: We identified HPK1 mRNA and protein levels were significantly decreased in Tfh cells from patients with SLE. Moreover, HPK1 mRNA levels were found to negatively correlated with SLE disease activity as measured by SLE Disease Activity Index (SLEDAI). Down-regulation of HPK1 in healthy Tfh cells significantly accelerated Tfh cells proliferation and productions of IL-21, CXCL13, IFNγ, IgG1, IgG2a, IgG2b, and IgG3. There were no marked changes in IL-17A and IgM amounts. Consistent with these findings, overexpressing HPK1 in SLE Tfh cells caused significant decrease in Tfh cells proliferation and productions of IL-21, CXCL13, IFNγ, IgG1, IgG2a, IgG2b, and IgG3. And there were no significant alters in IL-17A and IgM levels.

Conclusion: Our results show for the first time that inhibited expression of HPK1 in SLE Tfh cells contributes to Tfh cells overactivation and B cells overstimulation, which lead to the development of SLE at last.

Aberrant H3K9me3 Modification in Promoter Region Up-regulates cAMP Response Element Modulator Alpha in Systemic Lupus Erythematosus

Huilin Zhang,[1] and **Qing Zhang**[2], [1]Clinical Nursing Teaching and Research Section, Second Xiangya Hospital, Central South University, Changsha, Hunan, China (People's Republic), [2]Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years, accumulating evidences have demonstrated that increased cAMP response element modulator α (CREMα) which can inhibit IL-2 and induce IL-17A in $CD4^+$ T cells plays an essential role in the pathogenesis of systemic lupus erythematosus (SLE). However, the molecular mechanisms that result in CREMα over expression remain poorly understood. The aim of this study is to investigate the mechanisms that regulate CREMα expression in SLE.

Methods: $CD4^+$ T cells were isolated from healthy controls and SLE patients. Histone H3 lysine 9 trimethylation (H3K9me3, a hallmark associated with transcription inhibition) enrichments at various gene promoters in $CD4^+$ T cells from 5 healthy controls and 5 SLE patients were analyzed by chromatin immunoprecipitation (ChIP) microarray. Amounts of H3K9me3, H3K9 methyltransferases SUV39H1 and SUV39H2 within the CREMα promoter were subsequently assessed by ChIP and real-time PCR in $CD4^+$ T cells from 15 healthy controls and 15 SLE patients. And CREMα mRNA levels were determined by real-time RT-PCR.

Results: From the ChIP microarray data, we identified sharply decreased H3K9me3 enrichment at the CREMα promoter of SLE $CD4^+$ T cells compared to healthy controls. Then by ChIP and real-time PCR experiments, we confirmed this finding. In addition, H3K9me3 enrichment at the promoter was negatively correlated with CREMα mRNA level in SLE $CD4^+$ T cells. Moreover, a markedly decrease was observed in SUV39H1 binding, but no significant change in SUV39H2 enrichment at the CREMα promoter region in SLE $CD4^+$ T cells. We also proved SUV39H1 binding was positively correlated with H3K9me3 amount at the CREMα promoter, and negatively correlated with CREMα mRNA level in $CD4^+$ T cells from SLE patients.

Conclusion: Our findings suggest for the first time that decreased SUV39H1 binding down-regulates H3K9me3 enrichment at the CREMα promoter, which induces CREMα overexpression in SLE $CD4^+$ T cells, and results in the development of SLE at last.

Staphylococcus Aureus Colonization Is Increased on Lupus Skin Lesions and Is Promoted by Interferon-Mediated Barrier Disruption

Sirisha Sirobhushanam,[1] Navya Parsa,[2] Tamra Reed,[1] Celine Berthier,[1] Mrinal Sarkar,[1] Grace Hile,[1] Lam Tsoi,[1] Alexander Horswill,[3] Johann Gudjonsson,[1] and J Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Toledo, Toledo, OH, [3]University of Colorado, Denver, CO

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous inflammation is recurrent in systemic lupus erythematosus (SLE) and is often triggered by exposure to ultraviolet B (UVB) light. Type I interferons (IFN) play a critical role in SLE skin inflammation and are increased in non-lesional SLE keratinocytes. Mechanisms that drive cutaneous inflammation in SLE are not well-defined and may involve microbial dysbiosis, an underexplored source of cutaneous IFNs. *Staphylococcus aureus*, known to induce IFN production, could play a role in cutaneous inflammation in SLE. This study thus evaluated the colonization of lupus skin by *S. aureus* and the extent to which IFNs drive increased colonization rates by S. aureus.

Methods: Patients with SLE who fulfilled ≥4 ACR criteria for diagnosis were recruited from the Michigan Lupus Cohort. Nares, chest, and lupus related skin lesions were swabbed and analyzed for *S. aureus* colonization. To define the impact of IFNs on *S. aureus* colonization, we examined the effect of type I and type II IFNs (1000U/ml) on barrier gene expression in N/TERTs (a keratinocyte cell line) by real time quantitative PCR (RT-qPCR). Adhesion and invasion of log-phase *S. aureus* was assessed using confluent N/TERTs treated with IFNα or IFNγ. Adhered *S. aureus* were quantified by counting colony forming units (CFUs). Cells were treated with gentamicin (200 μg/ml) for invasion assays prior to CFU quantification. Keratinocytes were exposed to baricitinib (10 μg/ml) prior to IFN exposure to block IFN signaling. Primary keratinocytes were isolated from non-lesional skin of SLE patients and matched healthy adults and utilized for RNA-seq analysis as well as adhesion and invasion assays.

Results: We show here that active lupus lesions are highly colonized (~50%) by *S. aureus*. Microarray data from SLE lesional skin revealed lower expression of various cutaneous barrier genes such as filaggrin (FLG). IFN-exposed keratinocytes demonstrated lower expression of barrier related genes such as FLG, loricrin and involucrin. This repression of barrier genes was also seen in primary SLE keratinocytes without additional IFN treatment via RNA-seq. We next examined the role of IFN exposure on *S. aureus* colonization by adhesion and invasion assays. *S. aureus* adherence was significantly higher in keratinocytes that were exposed to IFNα but not IFNγ. RT-qPCR analysis showed higher expression of α-integrin in IFNα but not IFNγ exposed keratinocytes, indicating a possible mechanism for higher *S. aureus* adherence. In addition, IFNγ exposure appeared to inhibit invasion of *S. aureus* into keratinocytes. Confirming a role for IFNs in primary cells, *S. aureus* adhered better to SLE keratinocytes than healthy control keratinocytes. Exposure to baricitinib reduced IFNα-promoted *S. aureus* adherence, thus confirming specificity of the IFN activity.

Conclusion: SLE lesional skin is highly colonized by *S. aureus* and exhibits lower barrier gene expression indicating barrier compromise. IFN exposure inhibits barrier gene expression and IFNα promotes *S. aureus* adhesion. Together, these data suggest that chronic exposure to IFNs induces barrier disruption that allows for higher *S. aureus* colonization in SLE skin.

Interferon Alpha Promotes Caspase-Dependent Apoptosis Independently of Reactive Oxygen Species in Ultraviolet B-Exposed Keratinocytes

Shannon Estadt,[1] and J. Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by increased sensitivity to ultraviolet radiation (UVR). UVR can trigger cutaneous and systemic disease fares, yet mechanisms driving these responses are not well characterized. Type I interferons (IFNs), which have been previously implicated in driving apoptosis of cancer cells, are expressed at higher levels at baseline in non-lesional skin of SLE patients and drive hyperinflammatory responses after UVR. In addition, these type I IFNs promote increased death of SLE keratinocytes after UVR; however, the manner in which they regulate cell death after UVR is currently unknown. This study explores the cell death pathways activated in keratinocytes by type I IFNs and UVR.

Methods: Immortalized human keratinocytes (N/TERTs) were treated overnight with IFNα (0-1000 U/ml) prior to UVB exposure (0-50 mJ/cm^2). Reactive oxygen species (ROS) production was measured using the cell-permeable oxidative stress indicator CM-H_2DCFDA and fluorescence was measured 5 minutes post UVB exposure. Annexin V (AV) and propidium iodide (PI) staining was performed 4 hours post UVB exposure and cells were analyzed by flow cytometry. Cells were pretreated with apoptosis, necroptosis, and pyroptosis inhibitors to examine activated death pathways. Caspase-3 cleavage was measured by flow cytometry.

Results: Intracellular ROS were significantly increased by 5 minutes after UVB exposure. Surprisingly, priming with IFNα resulted in a dose-dependent decrease in ROS production. IFNα priming prior to UVB exposure also resulted in a significant increase in the percentage of AV^+PI^- cells, indicative of early apoptosis. In addition, IFNα treatment promoted apoptosis at a lower dose of UVB (20 mJ/cm^2). IFNα treatment prior to UVB exposure resulted in a significantly higher percentage of both cleaved-caspase-3^+ and AV^+PI^-, but not AV^+PI^+, cells compared to treatment with UVB alone. Pre-treatment with Z-VAD-FMK (pan-caspase inhibitor) or Z-IETD-FMK (caspase-8 inhibitor) significantly reduced AV^+PI^- cells following IFNα and UVB treatment while treatment with Z-LEHD-FMK (caspase-9 inhibitor) did not, suggesting enhanced activation of the extrinsic apoptosis pathway. Further, use of Necrostatin-1 (RIPK1 inhibitor) or AC-YVAD-CMK (caspase-1 inhibitor) showed no effect on death at 4 hours post UVB exposure in the presence of IFNα suggesting that enhanced death of type I IFN treated cells after UVB likely does not involve necroptosis or pyroptosis.

Conclusion: Treatment of keratinocytes with IFNα results in increased sensitivity to UVB-mediated cell death, which takes the primary form of caspase-8 driven apoptosis, independently of ROS. It is well documented that SLE skin is rich in type I IFNs and that high circulating IFNs are a feature of the disease. Together, these data suggest that pho-

tosensitive responses exhibited by lupus patients are likely due to type I IFN priming of keratinocytes that sensitizes the cells to undergo increased apoptosis after exposure to minimal amounts of UVB. Continued investigation into the mechanism by which IFN drives UVR-mediated cell death will be crucial for developing novel preventative strategies for photosensitivity.

Enhanced IFN a Production and STING Pathway in Monocytes in Systemic Lupus Erythematosus Is Suppressed by the Inhibition of mTOR Activation

Goh Murayama,[1] Asako Chiba,[2] Ayako Makiyama,[3] Taiga Kuga,[4] Ken Yamaji,[4] Naoto Tamura,[4] and Sachiko Miyake[2], [1]Department of Internal Medicine and Rhumatology, Juntendo University School of Medicine, Tokyo, Japan, [2]Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan, [3]Juntendo University School of Medicine, Tokyo, Japan, [4]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interferona (IFNa) is increased and plays an important role in the pathogenesis of systemic lupus erythematosus (SLE). Overexpression of type I IFN regulated genes has been reported in patients with SLE. Plasmacytoid dendritic cells (pDCs) are thought as the main producer of IFNa upon activation of TLR pathway. However, IFNa producers by the stimulation of cyclic GMP-AMP synthase (cGAS) and stimulator of interferon genes (STING) in SLE still remains unknown. In this study, we investigated the IFNa producing capacity of myeloid cells under stimulation of cGAS-STING pathway.

Methods: Peripheral blood mononuclear cells from patients with SLE and healthy controls were stimulated with 2'3'c-GAMP, a stimulator of cGAS-STING pathway, or a TLR-7 agonist, imiquimod, and IFNa-producing capacity of myeloid cells was examined by intracellular cytokine staining and flow cytometry. The expression and co-localization of STING with TBK1 were examined by intracellular staining and flow cytometry or confocal microscopy. The effect of *in vitro* IFNa exposure on IFNa production and STING expression was examined. Monocytes were treated with rapamycin *in vitro*, and IFNa production and the expression of STING, pTBK1, IRF3 were examined.

Results: As previously reported, IFNa was produced from only pDCs upon activation of TLR7 pathway. However, IFNa was produced from monocytes, conventional dendritic cells (cDCs) and pDCs upon activation of cGAS-STING pathway. The frequency of IFNa-producing monocytes stimulated with 2'3'c-GAMP positively correlated with disease activity of SLE. The expression of STING and its co-localization with TBK1 were increased in lupus monocytes. Prior exposure to IFNa enhanced the IFNa-producing capacity of monocytes. Inhibition of mechanistic target of rapamycin (mTOR) pathway by using rapamycin suppressed IFNa production from monocytes and downregulated the enhanced expression of STING pathway.

Conclusion: We demonstrate that lupus monocytes are potent to produce IFNa in association with the augmentation of cGAS-STING pathway. Production of IFNa and enhancement of cGAS-STING pathway was suppressed by the

inhibition of mTOR pathway. These findings indicate that enhanced IFNa from lupus monocytes owing to augmented STING pathway is associated with the pathogenesis of SLE. The blockade of the cGAS-STING pathway may serve as a promising therapeutic target for SLE.

IRAK4 Inhibition Suppresses TLR7, TLR9, and SLE Serum-Induced IFNA Production in Primary Human Plasmacytoid Dendritic Cells

Angie Hammond,[1] Sean Parghi,[1] Nathan Wright,[1] Ethan Grant,[1] James Taylor,[1] and Matthew Warr[1], [1]Gilead Sciences, Inc., Foster City, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A hallmark of lupus is the presence of antinuclear autoantibodies, including those against RNA-protein complexes and double-stranded DNA (dsDNA).[1,2] FcγR-mediated internalization of these nucleic acid:autoantibody immune complexes results in endosomal activation of TLR7 and TLR9, respectively, and the production of IFNα from plasmacytoid dendritic cells (pDC).[3,4] The importance of this pathway is underscored by the majority of systemic lupus erythematosus (SLE) patients having a peripheral interferon-stimulated gene (ISG) signature.[5] IRAK4 is a serine/threonine kinase at the top of the signaling cascade downstream of TLRs, including TLR7 and TLR9. As such, inhibition of IRAK4 represents a promising therapeutic target for lupus. The objective of this study is to investigate the effect of a highly selective IRAK4 inhibitor on IFNα production from pDCs stimulated with TLR7 and TLR9 agonists, SLE serum, and nucleic acid:autoantibody immune complexes.

Methods: Primary human pDCs were precultured with an IRAK4 inhibitor followed by stimulation for 24 hours. Stimulation agents included TLR7 and TLR9 agonists, human SLE serum, and nucleic acid:autoantibody immune complexes. Culture supernatants were then assessed for secretion of IFNα by MSD.

Results: TLR7 and TLR9 stimulation of pDCs resulted in the secretion of IFNα from pDCs as expected. Treatment with an IRAK4 inhibitor resulted in dose-dependent inhibition of TLR7- and TLR9-induced IFNα with high potency. Human SLE serum was tested to extend findings to physiological SLE-relevant stimuli. Several SLE serum samples, which had positive ELISA titers to the antinuclear antibodies, stimulated production of IFNα in pDCs after 24 hours in culture. No induction of IFNα was observed with healthy volunteer serum samples. Treatment with an IRAK4 inhibitor effectively blocked secretion of IFNα from SLE serum-stimulated pDCs in a dose-dependent manner. Additional antigen (either RNP or dsDNA) was added to SLE samples that yielded titers for autoantibodies but failed to elicit IFNα

production. Addition of RNP or dsDNA to anti–RNP and anti–dsDNA-positive SLE sera induced strong IFNα production, and this response was blocked with IRAK4 inhibition. No induction was seen with SLE serum that was negative for both anti–RNP and anti–dsDNA.

Conclusion: This work demonstrates the effects of IRAK4 inhibition on IFNα production in primary pDCs downstream of disease-relevant stimuli and highlights the potential for IRAK4 inhibition as a promising treatment for lupus.

Identification of IL-17$^+$ and IL-10$^+$ TCR$\alpha\beta^+$ CD4$^-$ CD8$^-$ Double Negative (DN) T Cell Subsets in Lupus-prone Mice and Patients with SLE and Their Significance in Predicting Renal Involvement

Yi Li,[1] Hao Li,[2] Shui Lian Yu,[3] Vasileios Kyttaris,[4] and George Tsokos[4], [1]BIDMC, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, [3]The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou, China (People's Republic), [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously shown that DN T cells are expanded in both lupus-prone mice and patients with SLE and we have demonstrated that this population is an essential component of the immunopathogenesis of the disease. It still remains unknown whether the DN T cell pool consists of functionally heterogeneous subpopulations. In this study we ask whether DN T cells comprise distinct functional subsets.

Methods: Flow cytometry analysis was applied for the expression of cytokines and T cell receptor (TCR) repertoire etc. IL-17-GFP B6 mice were crossed to MPL/lpr mice for 8 generations to generate IL-17-GFP MPL/lpr mice which were used to track IL-17$^+$ DN T cells *in vivo* and sort IL-17$^+$ DN T cells *ex vivo*. Cytokine capture assay was applied for *ex vivo* isolation of either IL-17$^+$ or IL-10$^+$ DN T cells from MPL/lpr mice and SLE patients. The mTOR pathway was assessed using RT2 profiler PCR array and verified by RT-PCR.

Results: Two distinct DN T populations were identified in both mice and humans based on the expression of two cytokines, IL-17 and IL-10. As expected, IL-17+ DN T cells were significantly increased in aging MRL/lpr mice (20 wks old) compared to either age matched control MRL/mpj mice or young MRL/lpr mice (12 wks old), a finding which is

consistent with our previous report that DN T cells contribute to lupus pathogenesis by producing IL-17. Interestingly, the numbers of IL-10+ DN T cells in aging (20 wks old) mice were reduced compared to young (12 wks old) MRL/lpr mice. Flow cytometry analysis revealed the different TCR V beta usage of V β 5, 6, 8.1/8.2, 12 in IL-17+ DN T cells while V β 14 and 15 in IL-10+ DN T cells. Consistently, increase of IL-17+ DN T cells (7.9 ± 0.7% vs 4.6 ± 0.6%, p=0.01) and reduction of IL-10+ DN T cells (1.5 ± 0.24% vs 4.6 ± 0.6%, P< 0.001) were observed in the peripheral blood from the subjects with SLE compared to healthy subjects. Interestingly, the ratio of IL17+/IL10+ DN T cells displayed a significant positive association with SLEDAI (p = 0.02) but negative association with C3 level (p = 0.01). Additionally, the ratio is found remarkedly higher in lupus patients with proteinuria (4.4 ± 1.2% vs 2.4± 0.4% p= 0.03) and positive anti- dsDNA (3.3± 0.3% vs 1.79 ± 0.2% p= 0.02). Of note, IL17+ DN Tc actively express most mTOR pathway associated genes compared to IL10+ DN Tc.

Conclusion: We present evidence that two distinct subsets exist within the DN T cell population in lupus prone mice and patients with SLE. The ratio of IL-$17^+/10^+$ DN T cells increases as the disease progresses in MRL/lpr mice, in lupus patients with more severe disease and renal involvement. The two subsets appear to utilize different TCR repertoire and metabolic enzyme patterns. We demonstrate that the ratio between the two subsets represents a valid disease biomarker and particularly of kidney involvement.

Abstract Number: 2035

Systemic Lupus Erythematosus (SLE) Is Caused by Expanded DOCK8-Positive Autoantibody-Inducing CD4 T (*ai*CD4 T) Cell

Shunichi Shiozawa,[1] Ken Tsumiyama,[1] Yumi Miyazaki,[2] Keiichi Sakurai,[3] Takahiko Horiuchi,[4] Motohiro Oribe,[5] Takashi Yamane,[6] Hidetoshi Kagawa,[7] and Kazuko Shiozawa[8], [1]Institute for Rheumatic Diseases, Ashiya, Japan, [2]Kyushu University Beppu Hospital, Tokyo, Japan, [3]Rheumatology and Allergology, St. Marianna University School of Medicine, Tokyo, Japan, [4]Department of Internal Medicine, Kyushu University Beppu Hospital, Beppu, Japan, Beppu, Japan, [5]Oribe Rheumatology Clinic, Oita, Japan, [6]Department of Rheumatology, Kakogawa Central City Hospital, Kakogawa, Japan, [7]Rheumatology, Red Cross Society Himeji Hospital, Himeji, Japan, [8]Rheumatic Diseases Center, Hyogo Prefectural Kakogawa Medical Center, Ashiya, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously found in reproducible experiments in which the mice not prone to autoimmune disease were immunized repeatedly with antigen that overstimulation of CD4 T cells led to the development of autoantibody-inducing CD4 T cell (*ai*CD4 T cell) which had undergone TCR revision capable of inducing varieties of autoantibody and antigen-specific CTL *via* antigen cross-presentation, after which they caused SLE (Tsumiyama K et al. PLoS ONE 4(12): e8382, 2009). Here we show that the *ai*CD4 T cell is DOCK8-positive, and this DOCK8+CD4 T cell caused SLE in the mice not prone to autoimmune disease when adoptively transferred. Further, the SLE as induced in the mice was cured by anti-DOCK8 antibody treatment. The DOCK8+CD4 T cells were found to be expanded in association with patients' disease activity (SLEDAI).

Methods: The *ai*CD4 T cell was identified by transferring different CD4 T cell subsets of x12 OVA-immunized BALB/c mice into naïve mice and testing generation of autoantibodies in the recipients, where DOCK8 was identified by

extraction of membrane proteins, electrophoresis, mass spectrometry of isolated subsets. The DOCK8+CD4 T cell was then transferred into naïve mice to confirm generation of classical SLE features. The number of DOCK8+CD4 T cell was measured in the PBMC of SLE patients and evaluated with reference to clinical manifestation.

Results: Transfer of DOCK8+CD4 T cells into naïve mice induced autoantibodies including anti-dsDNA and anti-Sm antibodies and organ diseases such as WHO IV/V lupus nephritis, skin liquefaction degeneration, and splenic periarteriolar fibrosis with amyloid-like deposits known as Onion-skin lesion classical to SLE. The lesion such as pericholangitis, pneumonitis, thyroiditis, perineuritis or panniculitis was also induced. Such manifestations subsided after anti-DOCK8 Ab treatment. The DOCK8+CD4 T cell was a large lymphocyte with abundant ER and mitochondria, expressing ICOS, PD1, Ly6C and LFA1 but not CXCR5. The DOCK8+CD4 T cell produced increased amounts of IFNg, IL-4, IL-6, IL-17, IL-21 and IL-22, but not IL-2. The TCR repertoire of DOCK8+CD4 T cell was significantly deviated. In the PBMC of active patients with SLE, DOCK8+CD4 T cells were significantly increased, whereas they were negligible in inactive disease, other rheumatic diseases, or healthy control.

Conclusion: We prove the self-organized criticality theory explaining that autoimmunity, i.e., SLE, arises as a natural consequence of routine but exaggerated immune response against antigen when stimulated maximally beyond immune system's self-organized criticality, where expanded DOCK8+CD4 T cell was responsible for inducing SLE.

Mitochondrial DNA: A Potential Trigger of Cyclic GMP-AMP Synthase Activation in Systemic Lupus Erythematosus

Jie An,[1] Bhargavi Duvvuri,[1] Xizhang Sun,[1] Lena Tanaka,[1] Christian Lood,[1] and Keith Elkon[1], [1]University of Washington, Seattle

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 70% of patients with Systemic Lupus Erythematosus (SLE) show a striking Type I Interferon (IFN-I) signature in peripheral blood. Although we have some understanding of how this signature can be generated *in vitro* (by immune complex activation of Toll-Like Receptors, TLRs), we have little understanding of mechanisms operative in SLE patients. Cyclic GMP-AMP (cGAMP) synthase (cGAS) is a cytosolic DNA sensor that is triggered by both microbial as well as self DNA and has been shown to be the most important cytosolic DNA sensor responsible for IFN-I production. Using PBMC samples from patients, we have shown that the cGAS-STING (stimulator of interferon genes) pathway is activated in ~15% of patients with SLE. In a separate study, we also reported that oxidized mitochondrial DNA (Ox-mtDNA comprising 8-hydroxydeoxyguanine or 8-OHdG) released from neutrophils undergoing NETosis stimulates IFN-I via the cGAS-STING pathway. The aim of our study was to determine the relationship between Ox-mtDNA and activation of the cGAS-STING pathway in SLE patients.

Methods: Cell-free DNA was isolated from the plasma of SLE patients (n=16) and Healthy Controls (HC, n=12) by standard procedures. Genes unique to mitochondria (COXII and MT-TL1, abbreviated MtDNA) in plasma were quantified by Real time qPCR. 8-OHdG was quantified by DNA Damage ELISA. Multiple Reaction Monitoring (MRM) by

Ultra-Performance Liquid Chromatogram coupled with tandem Mass Spectrometer (UPLC-MS/MS) was used to quantify cGAMP in peripheral blood mononuclear cells (PBMC). Disease activity was assessed using SLEDAI and defined as either low (SLEDAI< =2) or high (SLEDAI >4). Statistical analyses were performed with GraphPad Prism 7.

Results: Levels of mtDNA were increased in plasma from SLE patients compared to HC ($p< 0.01$), and related to disease activity, e.g. patients with active disease (n=8) had higher levels of mtDNA in plasma as compared to patients with low disease activity (n=8, $p< 0.05$) as well as HC ($p< 0.0001$). Further, SLE patients with active disease had higher concentrations of 8-OHdG DNA as compared to patients with low disease activity ($p< 0.05$) as well as HC ($p< 0.05$). Patients that were cGAMP+ (n=5) had higher concentrations of 8-OHdG compared to cGAMP- (n=11) SLE patients although the difference was not statistically significant. Of interest, the levels of mtDNA was significantly higher in cGAMP+ patients compared to HC ($p< 0.01$) whereas the levels of mtDNA in cGAMP- patients was not statistically different from HC ($p=0.1$).

Conclusion: SLE patients, in particular those with active disease, have elevated levels of mtDNA and 8-OHdG DNA in peripheral blood. The increased levels of mtDNA in cGAMP positive SLE plasma is consistent with a role of mtDNA in activation of the cGAS pathway in SLE patients although other ligands cannot be excluded.

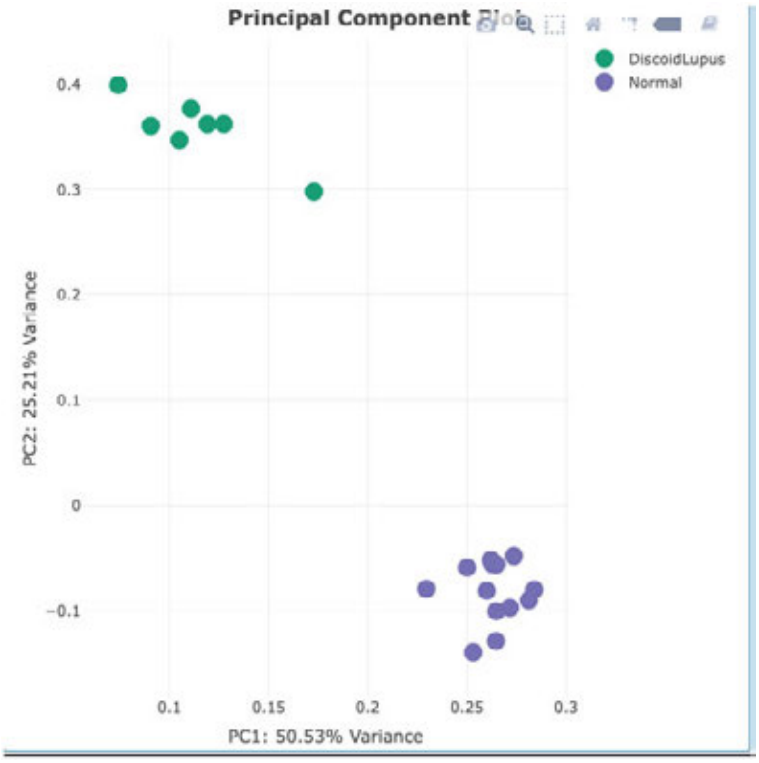
Understanding Langerhans Cell ADAM17 Levels in Systemic Lupus Erythematosus: Potential Contributor to Photosensitivity

Theresa Lu,[1] Noa Schwartz,[2] Thomas Li,[2] William Shipman,[3] Dragos Dasoveanu,[3] Yong Liu,[4] Niroshana Anandasabapathy,[4] Henry Lee,[4] Ali Jabbari,[5] James Krueger,[5] Bebak Mehrara,[6] Keila Veiga,[2] Kira Minkis,[4] and David Oliver[2], [1]Hospital for Special Surgery, Weill Cornell Medicine (**Microbiology and Immunology)**, New York, [2]Hospital for Special Surgery, New York, [3]Hospital for Special Surgery; Weill Cornell Medicine, New York, [4]Weill Cornell Medicine (Dermatology), New York, [5]Rockefeller University, New York, [6]Memorial Sloan Kettering Cancer Center, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Photosensitivity resulting in inflammatory skin lesions is a hallmark of cutaneous lupus. Lesions can be disfiguring and have a negative impact on patients' quality of life. Understanding photosensitivity is critical to developing better treatment. Prior research by our lab showed that ADAM17, a metalloprotease found on Langerhans cells (LCs), is activated by ultraviolet radiation (UVR) and is critical for limiting UVR-induced keratinocyte apoptosis and skin inflammation through cleavage and activation of epidermal growth factor receptor (EGFR) ligands. Two photosensitive lupus models showed reduced LC ADAM17 expression with evidence for dysfunction in human lupus, suggesting that photosensitivity is at least in part due to dysfunctional LCs. We propose a cross-sectional study to evaluate the hypothesis that LC ADAM17 expression and activity are reduced in the epidermis of lupus patients, contributing to photosensitivity. Our secondary hypothesis addresses whether reduced ADAM17 expression and increased photosensitivity is associated with lupus disease activity and severity. As part of our secondary hypothesis, we will correlate reduced ADAM17 levels with increased type I interferon (IFN) in lupus.

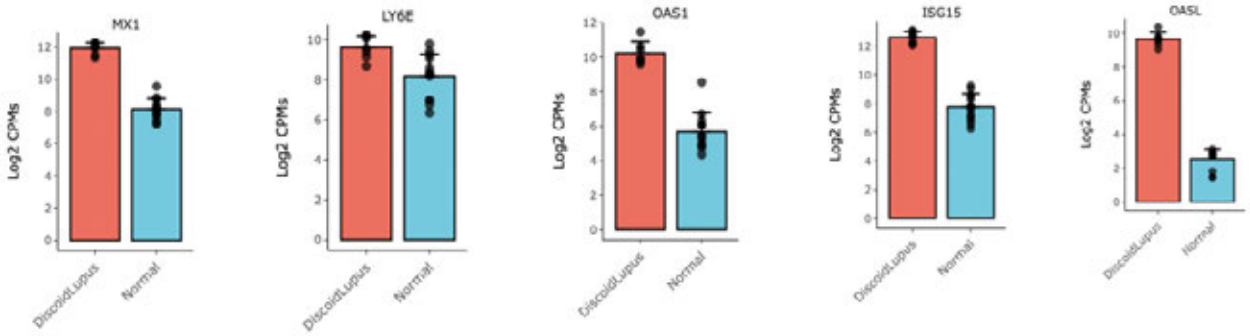


Principal Component Analysis comparing non lesional skin from discoid lupus patients (n=7) and controls (n=13)

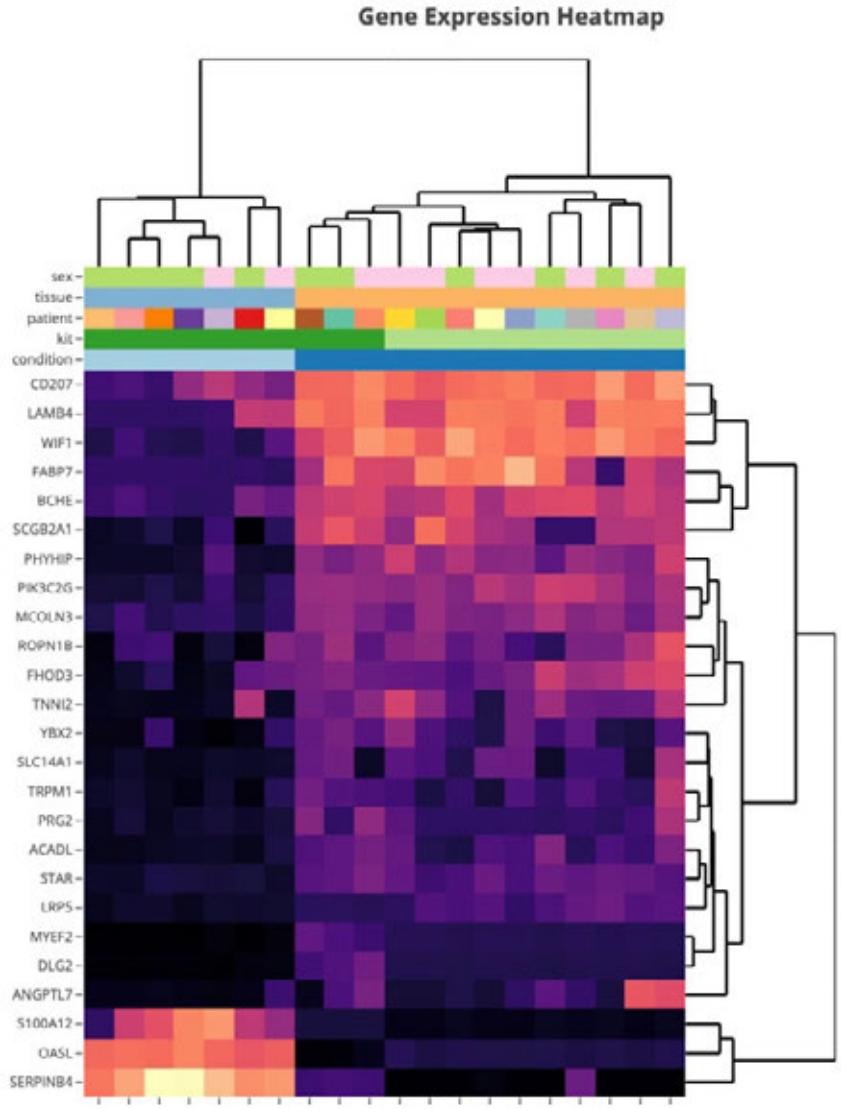
Methods: Transcriptomics of non-lesional skin from discoid lupus (DLE) and healthy controls were compared using microarray. Data was gathered from unpublished data from Krueger et al (2014) looking at immune related pathways present in DLE lesions compared to psoriasis and healthy skin. This study showed an enrichment of IFN gamma associated genes in DLE. We plan to collect punch biopsies of non-lesional, non-sun exposed skin from 10 patients who meet ACR/SLICC criteria for lupus nephritis as well as 5 healthy controls, at a single visit. We will perform flow cytometry on LCs from these biopsies to assess ADAM17 expression and activity. We will collect the SLE Disease Activity Index (SLEDAI) and will evaluate the correlation between ADAM17 activity with disease activity. Lastly, we will perform RNA sequencing to evaluate the IFN signature and correlate IFN expression with ADAM17 levels.

Results: Principal component analysis of microarray results demonstrated the variance between non lesional DLE skin and controls (Fig 1). Expression of IFN related genes were found to be elevated in non-lesional skin versus controls (Fig 2). Genes found to be highly expressed in non-lesional DLE skin included S100A12 and OASL(Fig 3). These results suggest an elevated IFN signature and inflammatory markers in non-lesional skin of DLE patients. We also demonstrate we can successfully assay for LC ADAM17 levels by 13 parameter flow cytometric analysis of human skin biopsies, and preliminary results from analysis of SLE patients are expected in the next several months.

Conclusion: Microarray results suggest an elevated IFN signature in non-lesional skin of DLE patients. If we find ADAM17 expression is reduced in non-lesional skin of SLE nephritis patients in comparison to controls, this would support a role of ADAM17 and perhaps type I IFN in SLE photosensitivity. These findings could lead to targeting of ADAM17 and potentially of type I IFN for treating the photosensitive rash seen in patients with lupus.



Expression of Interferon related genes in non-lesional skin from discoid lupus patients versus controls via microarray



Gene expression heat map showing elevated levels of S100A12, OASL and SerpinB4 in the skin of discoid lupus patients (N=7).

Antibodies to Malondialdehyde-acetaldehyde (MAA) Protein Adduct as a Biomarker for Cardiovascular Manifestations in Systemic Lupus Erythematosus

Yangsheng Yu,[1] Michelene Hearth-Holmes,[2] Tammy Wang,[1] Perio D Lopez,[3] Carmen Tineo,[4] G Paulino,[4] Michael Duryee,[2] Geoffrey Thiele,[5] Ted Mikuls,[5] Esthela Loyo,[4] and **Kaihong Su**[2], [1]University of Nebraska Medical Center, Omaha, [2]University of Nebraska Medical Center, Omaha, NE, [3]Georgetown University, Washington DC, [4]Hospital Regional Universitario José Ma Cabral Baez, San Diego, Dominican Republic, [5]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by devastating end-organ manifestations. Cardiovascular disease (CVD) is a leading cause for premature death in SLE patients across different ethnicities. While the traditional Framingham risk factors likely contribute to CVD in SLE, they cannot fully account for the highly increased risk of CVD in SLE. Malondialdehyde-acetaldehyde (MAA) protein adduct (a byproduct of oxidative stress) and antibodies to MAA have been suggested to mediate early inflammation in atherosclerotic disease. The purpose of this study is to determine whether SLE patients develop anti-MAA antibodies and whether anti-MAA antibodies identify SLE patients with cardiovascular manifestations.

Methods: 201 SLE patients who fulfilled the 1997 revised American College of Rheumatology criteria for the classification of SLE and 205 non-diseased healthy controls (matched in age, sex, and ethnicity) were recruited from the Dominican Republic for the study. Enzyme-linked immunosorbent assay (ELISA) was performed to determine the serum levels of anti-MAA IgG antibodies. Data were analyzed using Mann Whitney test. A p value of < 0.05 was considered significant.

Results: The mean anti-MAA IgG levels in SLE patients was 0.13 (in optical density units; SD 0.27, 95% CI 0.09-0.17), which is significantly higher than that in healthy controls (mean: 0.06; SD 0.07, 95% CI 0.05-0.07; p=0.041). SLE patients with pericarditis or myocarditis have higher levels of anti-MAA IgG antibodies than SLE patients without pericarditis or myocarditis (mean: 0.24 versus 0.07; p=0.018).Â SLE patients with vasculitis have significantly higher levels of anti-MAA IgG antibodies than SLE patients without vasculitis (mean: 0.22 versus 0.08; p=0.019).

Conclusion: SLE patients with CVD (such as pericarditis, myocarditis, or vasculitis) have significantly higher anti-MAA IgG antibodies than SLE patients without CVD. These results suggest that anti-MAA antibodies may be a biomarker for CVD in SLE. Future studies will determine if MAA and/or anti-MAA antibodies play a role in the pathogenesis of CVD in SLE.

Abstract Number: 2039

High Prevalence and Disease Correlation of Autoantibodies Against p40 Encoded by Long Interspersed Nuclear Elements (LINE-1) in SLE

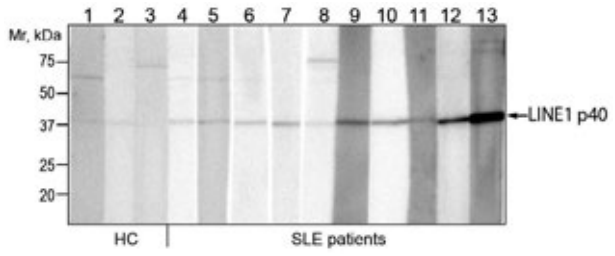
Kennedy Ukadike,[1] Victoria Carter,[1] John LaCava,[2] Martin Taylor,[3] Anders Bengtsson,[4] Christian Lood,[1] and Tomas Mustelin[1], [1]University of Washington, Seattle, WA, [2]The Rockefeller University, New York, NY, [3]Massachusetts General Hospital, Boston, MA, [4]Lund University, Lund, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

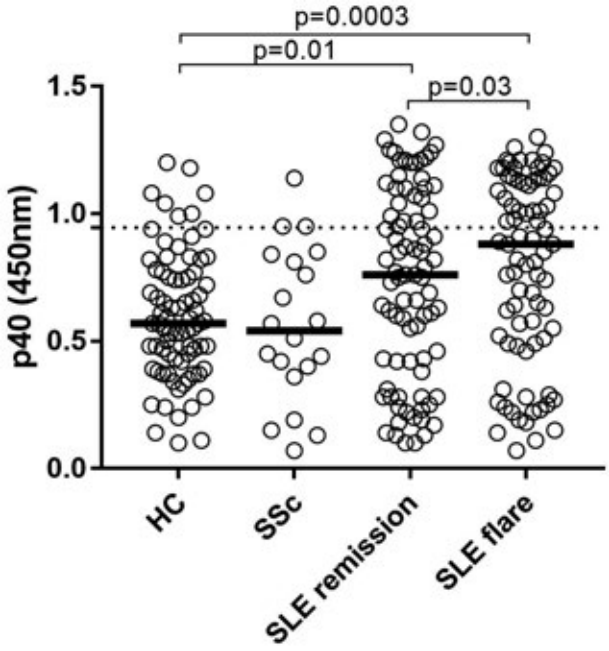
Background/Purpose: The long interspersed nuclear element 1 (LINE-1) has two major open reading frames (ORFs): ORF1 encodes the RNA-binding p40 protein, and ORF2 encodes the endonuclease and reverse transcriptase; both are required for LINE-1 to retrotranspose. In cells expressing LINE-1, these proteins assemble with the LINE-1 RNA and additional RNA-binding proteins, some of which are well-known autoantigens in patients with systemic lupus erythematosus (SLE). We asked whether SLE patients also make autoantibodies against the LINE-1 p40.

Methods: Highly purified p40 protein was used to quantitate IgG autoantibodies in the serum of SLE patients (n=172 total), disease controls (systemic sclerosis, n=20), and age-matched healthy subjects (n=78) by immunoblotting and ELISA. To determine the relationship between disease activity and LINE-1 p40 antibodies, the same SLE patients (n=80) were recruited at two time-points: low disease activity (median SLEDAI 2) and high disease activity (median SLEDAI 8.5). The patients were primarily female (89%), Caucasian (100%), with a median age of 44. An additional cross-sectional SLE cohort (n=12) was included to study LINE-1 p40 reactivity using Western blot. Preparations of p40 that also contained associated proteins were analyzed by immunoblotting with patient sera. Serum type I interferon (IFN) activity was analyzed using a cell reporter system (WISH). The 90th percentile of healthy controls was used as a cut-off for LINE-1 p40 positivity. GraphPad Prism and IBM SPSS were used for statistical analyses, and all analyses were considered statistically significant only if $p < 0.05$.

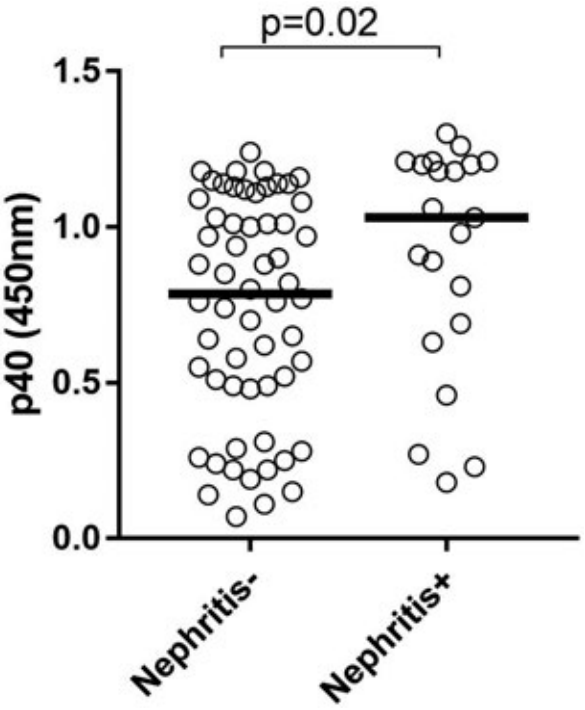
Results: Antibodies reactive with p40 were detected in the majority of patients and many healthy controls (Figure 1): they were higher in patients with SLE, but not systemic sclerosis, compared to healthy subjects (p=0.01, Figure 2). The anti-p40 reactivity was higher in patients during a flare than in remission (p=0.03, Figure 2), correlated with SLEDAI (p=0.0002), type I IFN score (p=0.006), complement C3 decrease (p=0.0001), anti-DNA antibodies ($p < 0.0001$), anti-C1q antibodies (p=0.004), current or past history of nephritis (p=0.02 and 0.003, Figure 3), and they correlated inversely with age (r=-0.49, $p < 0.0001$). SLE patient sera also reacted with p40-associated proteins.



Immunoblot



Disease State



Renal Disease Status

Conclusion: Autoantibodies reacting with LINE-1 p40 characterize a population of SLE patients with severe and active disease. These autoantibodies may represent an early immune response against LINE-1 p40 that does not yet by itself imply clinically significant autoimmunity, but may represent an early, and still reversible, step towards SLE pathogenesis.

BATF2 Contributes to Interferon Dysregulation in SLE Keratinocytes

Jessica Turnier,[1] Celine Berthier,[1] Lam Tsoi,[1] Danielle Barnes,[1] Grace Hile,[1] Tamra Reed,[1] Jianhua Liu,[1] Johann Gudjonsson,[1] and J. Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Skin inflammation can drive systemic disease in SLE, thus it is essential to understand the key regulators of the aberrant inflammatory response in lupus skin. We have previously identified BATF2 as a transcription factor that is highly overexpressed in lupus keratinocytes following type I IFN exposure. The objective of this study was to determine the role of BATF2 in regulating keratinocyte responses to type I and type II interferons.

Methods: After generating BATF2 knockouts (BATF2 -/-) in a human keratinocyte cell line (N/TERTs) using CRISPR/Cas9 technology, we treated both BATF2 -/- and control N/TERTs (CTL) with either media or 1000 units/milliliter of IFN alpha (α) or gamma (γ) for 6 hours. We subsequently isolated RNA from biological triplicates of each treatment condition and completed Illumina HiSeq analysis through the University of Michigan Sequencing Core. We performed RNA sequencing (RNA-seq) analysis to identify differentially expressed genes (DEGs; p-adjusted ≤ 10% and log2|FC| ≥ 1) and differences in transcriptional profiles between treatment conditions. We then utilized Ingenuity Pathway Analysis (IPA) to highlight enriched biological pathways within regulated genes and Genomatix Pathway System (GePS) to display transcriptional targets of regulated genes. To validate our RNA-seq findings, we performed RT-PCR of candidate genes and BATF2 immunostaining of cutaneous lupus (CLE) biopsies.

Results: RNA-seq analysis revealed an overall higher number of DEGs in CTL compared to BATF2 -/- with both type I and II interferon stimulation (905 and 1542 genes versus 536 and 947, respectively). DEGs unique to CTL upon IFNα stimulation included *IFNK*, *IL-16* and *HLA-DRB1*, and with IFNγ, *MX2*, *TNF*, *TLR5* and *CASP5*. Of identified DEGs, 408 were common to CTL and BATF2 -/- with IFNα and 744 with IFNγ stimulation, including the majority of IFN-responsive genes. Within common DEGs upon IFNα and γ stimulation, 127 and 215 genes were 1.5-fold increased or decreased in BATF2 -/- relative to CTL. IFN-responsive genes less expressed in BATF2 -/- with IFN stimulation compared to CTL included *CXCL10*, *OASL*, *CCL5*, *IFIT1/2/3, CASP1, IFI30 and ICAM1*, with some genes common and unique to IFNα and γ stimulation **(Figure 1)**. Not all IFN-responsive genes were differentially regulated by BATF2, and some were even more expressed in BATF2 -/- (*CXCL9*, *MX1*). Transcription factor analysis showed enrichment for key genes in the IFN response with a potential binding site for BATF2 in their promoter, including *CXCL9/10*, *IRF1*, *JAK2*, *MX1* and *TLR2,* many of which were identified as differentially regulated by BATF2. To validate RNA-seq data, we confirmed candidate differentially regulated genes between BATF2 -/- and CTL using RT-PCR, notably decreased *IFNK* expression in BATF2 -/-, and demonstrated increased BATF2 expression in CLE biopsies compared to healthy control skin.

Conclusion: BATF2 -/- keratinocytes respond similarly to CTL upon IFN stimulation with respect to expression of many IFN-responsive genes; however, critical genes dysregulated in CLE lesions, including *CXCL10, CCL5* and *CASP1* require BATF2 for peak induction by IFNs. Thus, BATF2 may be a specific target for blocking IFN-induced inflammatory responses in SLE skin.

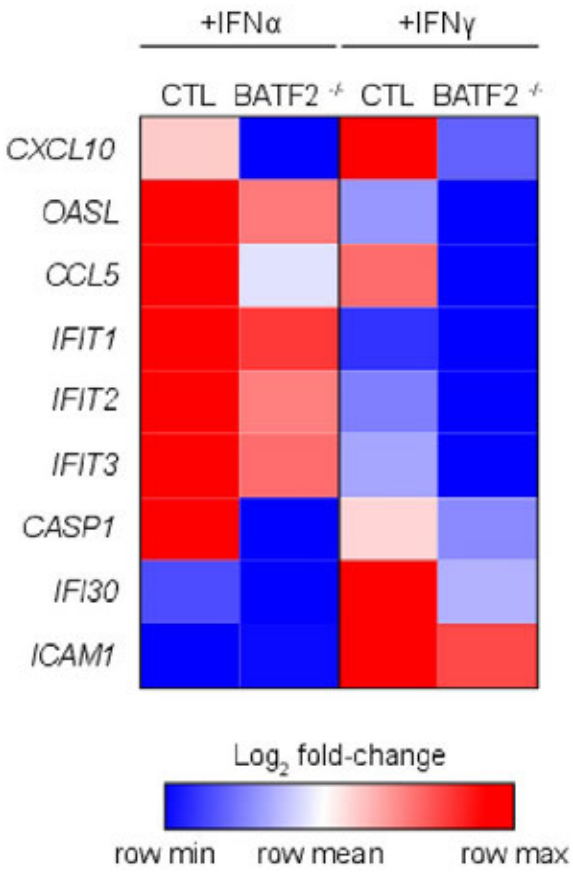

Figure 1 IFN-responsive genes less expressed in BATF2 -/- upon IFN stimulation compared to CTL

Epigenome-wide Association Study Reveals Differential DNA Methylation in Systemic Lupus Erythematosus Patients with a History of Ischemic Heart Disease

Juliana Imgenberg-Kreuz,[1] Christopher Sjöwall,[2] Martina Frodlund,[2] Iva Gunnarsson,[3] Elisabet Svenungsson,[4] and Dag Leonard[1], [1]Department of Medical Sciences, Section of Rheumatology and Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [2]Department of Clinical and Experimental Medicine, Rheumatology/Division of Neuro and Inflammation Sciences, Linköping University, Linköping, Sweden, [3]Department of Medicine Solna, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [4]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of ischemic heart disease (IHD). Altered methylation patterns have been reported both in SLE, including hypomethylation of interferon (IFN) regulated genes, and in individuals with a history of IHD in the general population. We performed a matched case-case epigenome-wide association study (EWAS) for IHD in patients with SLE to identify phenotype-specific differences in DNA methylation.

Methods: DNA methylation profiles from peripheral blood samples of 33 SLE patients with a history of IHD (myocardial infarction and or angina pectoris) and 66 matched (ethnicity and age) SLE patients without any prior cardiovascular events were generated on the HumanMethylation450k array (Illumina). All patients were female, fulfilled ≥ 4 ACR-82 SLE criteria and were recruited at the Uppsala, Linköping and Karolinska University hospitals, Sweden. Association was tested using a logistic regression model including age at sampling, blood cell type distribution and HM450k BeadChip as covariates. Differentially methylated CpG sites (DMCs) were defined as p< 1.3×10-7 based on Bonferroni correction and an absolute average difference in methylation beta of $|\Delta\beta| > 0.05$. Functional gene-set enrichment analyses were conducted using the ToppGene Suite database and for classification of IFN regulated genes the Interferome v2.01 database was queried.

Results: We identified 210 DMCs in SLE IHD, with a majority (84.3%) of DMCs showing decreased methylation levels in IHD. The strongest differentially methylated DMCs were located at Complement component 4 binding protein alpha (*C4BPA*) ($|\Delta\beta|$=-0.06, $p=1.1\times10^{-13}$), Membrane spanning 4-domains A3 (*MS4A3*) ($|\Delta\beta|$=-0.07, $p=3.7\times10^{-13}$) and Triggering receptor expressed on myeloid cells 1 (*TREM1*) ($|\Delta\beta|$=-0.07, $p=8.7\times10^{-13}$). Further, a differentially methylated region with multiple DMCs was observed in the promoter region of Programmed cell death 1 gene (*PDCD1*). DMCs in SLE IHD were annotated to 155 unique genes, of which 63.9% were characterized as interferon-induced. Gene-set enrichment analysis revealed response to oxidative stress ($p=1.0\times10^{-5}$), vesicle-mediated transport ($p=1.1\times10^{-6}$) and inflammasomes ($p=6.4\times10^{-6}$) as the most significantly enriched pathways in SLE IHD.

Conclusion: The results of this study highlight genes and pathways that may be implicated in the pathogenesis of and/or recovery from IHD in patients with SLE. The identified DMCs can serve as candidates for functional studies and as potential biomarkers for IHD in patients with SLE.

Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Intestinal microbiota dysbiosis has been implicated in the pathogenesis of autoimmune disease. How the microbiota affects the peripheral immune system leading to the development of systemic autoimmune disease is elusive. Herein, we generated germ-free (GF) BXD2 mice, a complex lupus mouse model, to dissect the impact of microbiota on disease associated peripheral B and T cell signatures in these mice.

Methods: GF BXD2 mice were generated and maintained at UAB gnotobiotic core facility. Sera autoantibody levels were assessed by ELISA in special pathogen free (SPF) BXD2, GF BXD2, SPF B6, and GF B6 mice. The frequencies and absolute numbers of GC B ($CD19^+GL\text{-}7^+Fas^+$), Tfh ($CD4^+PD1^+ICOS^+$) and Treg ($CD4^+Foxp3^+CD25^+$) in spleen were determined by FACS. Immunostaining and confocal imaging were applied to assess the immune architecture of the spleens from each strain of mice. Antibodies against bacterial lysates from the intestine were measured by western blot. Histology was performed to evaluate disease development in the kidney, lung, liver and intestine. The microbiome in 4 strains of mice were comprehensively assessed by 16S rRNA V4 gene sequencing. GC B ($CD19^+GL\text{-}7^+Fas^+$) and Tfh ($CD4^+PD1^+CXCR5^+$) cells from SPF BXD2 and GF BXD2 were FACS sorted for RNA-seq transcriptome analysis.

Results: Deep 16S rRNA V4 gene sequencing revealed two distinctive clusters of microbiome compositions between GF and SPF. Serum levels of IgG against bacteria lysates of cecal content from SPF or GF BXD2 mice were lower in GF BXD2 than in SPF BXD2 mice. Surprisingly, the GF status did not diminish sera levels of IgG or IgM autoantibodies against dsDNA, BiP, histone, rheumatoid factor (RF), MARCO, SR-AI, and SSA in BXD2 mice. The differences of frequency and absolute numbers of GC B cells, $CD4^+$ T cells, Tfh cells were also undistinguishable between SPF BXD2 spleen and GF BXD2 mouse spleen although GF BXD2 mice exhibited a higher number of $CD19^+$ B cells, compared to the SPF counterpart. Interestingly, upstream pathway analysis of the transcriptomes of Tfh and GC B cells indicated that the GF status has favored the programs of Tfh-IFNɣ over Tfh-IL-17. There was also an increased *IL10RA* program in GF BXD2 Tfh cells and this was further supported by an increased follicular T-regulatory (Tfr) cells in GF BXD2 mice. Immunofluorescent staining demonstrated similar spleen follicle structures and enlarged GCs in both SPF and GF BXD2 mice, compared to normal B6 mice. Histologic study in the organs that are most affected in lupus showed similar disease scores in kidney and lung between SPF and GF BXD2 mice.

Conclusion: This study provided the fundamental evidence that the commensal microbiome is not the main driver for the development of systemic autoimmune disease in BXD2 mice. Since the Tfh-IFNɣ/Tfh-IL-17 balance and the Tfr programs were altered in GF mice, the results suggest that certain immune phenotypes may be modulated through leaky intestine, yet they are not sufficient to alter the autoimmune responses in BXD2 mice.

Large Joint Arthritis in Systemic Lupus Erythematosus Is Characterized by TH17 Cells Rather Than B Cell Accumulation

Natalie Sippl,[1] Francesca Faustini,[1] Karine Chemin,[1] Iva Gunnarsson,[2] and Vivianne Malmström[3], [1]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [2]Division of Rheumatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Department of Medicine, Karolinska University Hospital and Institutet, Stockholm, Sweden., Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis is a common clinical feature of systemic lupus erythematosus (SLE), that can be present either at the onset or in later disease course. SLE-related arthritis is usually non-erosive and non-deforming as opposed to rheumatoid arthritis (RA). While RA synovial pathology has been extensively studied, little is known about the pathophysiology of arthritis in SLE. Here, we aimed to explore the cytokine and cellular compartments in synovial fluids (SF) of SLE patients with arthritic manifestations.

Methods: Paired synovial fluid mononuclear cells (SFMC) from large joint aspiration and peripheral blood samples (PBMC) from three SLE patients were analyzed by three different lineage-specific multicolor flow cytometry panels for B cells and T cells (cytotoxic and helper). SLE-derived SFMCs were further stimulated in vitro to measure T cell production of IFN gamma and IL-17. Since the majority of SF samples from SLE patients were not cellular, we analyzed the acellular SF samples (n=19) with cytokine bead array for Th1, Th17 and Th2 associated cytokines (BD Bioscience). The patients fulfilled the ACR 1982 classification criteria for SLE. Clinical records were reviewed in order to exclude the presence of comorbidities such osteoarthritis or overlap with RA.

Results: The overall frequency of CD4+ and CD8+ T cells among CD3+ T cells was similar across SFMC and PBMC samples, while CD19+ cells (B-lymphocytes) were scarcely present in the joint of SLE patients as opposed to the peripheral blood. In SF, we could identify an increased frequency of CCR6+ cells among CD4+ T cells, a marker associated with Th17 cells. IL-17-production could be validated in the (CD4+CCR6+) compartment following in vitro stimulation of SFMCs. Also, a strong IFN gamma production was seen, which may originate from the increased frequency of cytotoxic EOMES+ Granzyme A+ T cells that were also recorded in the SLE-SFMC. IFN gamma was not found in the acellular synovial fluid samples, while the TH17-associated cytokines IL-17 and IL-6 were abundant.

Conclusion: Although SLE is usually considered to be a B-cell driven disease, its common clinical features like arthritis could be driven in situ by T cells, namely TH17 cells and CD4+ T cells with cytotoxic profile.

Session Title: SLE – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

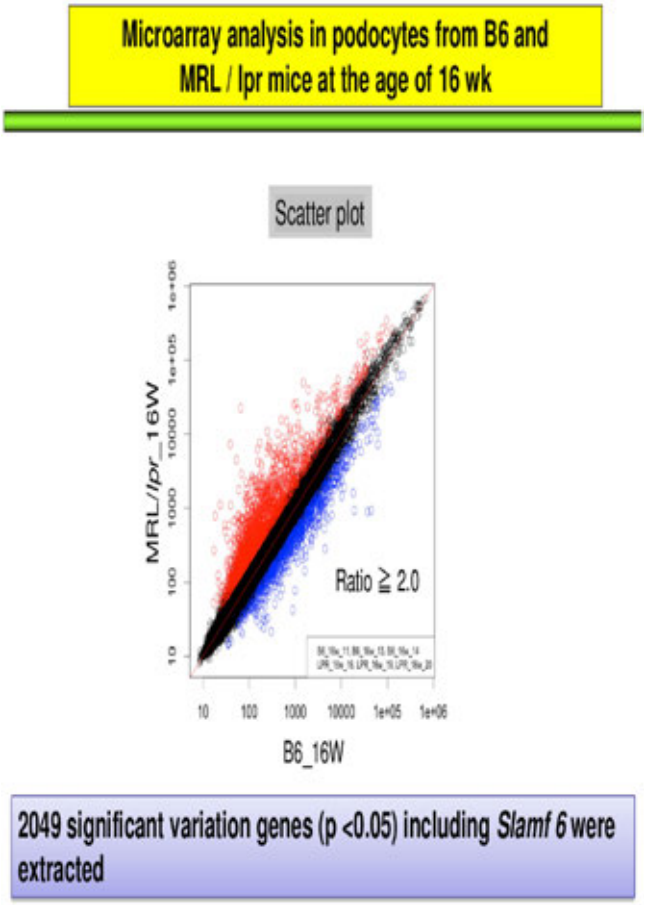

Figure 1 Microarray analysis in podocytes from B6 and MRL / lpr mice at the age of 16 wk

Background/Purpose: Lupus nephritis (LN) is one of the most serious complication of SLE. The alteration of the structural protein in podocytes is known as a mechanism of proteinuria in LN. The signaling lymphocyte activation molecule family(the SLAM family) of typeItransmembrane receptors consists of nine related members of the immunoglobulin superfamily and has been reported to mediate important regulatory signals between immune cells (Nat Rev Immunol. 2003 Oct;3(10):813-21).The 1q23 region on human chromosome 1 including the SLAMF cluster of genes, containing SLAMF6 has been identified as a lupus susceptibility locus(Nat Rev Rheumatol. 2010 Jun;6(6):348-57). We sought to examine the functional role of SLAMF6 in lupus podocytes.

Methods: We evaluated the co-expression of nephrin, a podocyte marker and SLAMF6 in kidney of normal controls and LN patients, also in B6 and MRL/*lpr* mice by immunofluorescence analysis. We also examined nephrin positive SLAMF6 expression in isolated podocytes from B6 and MRL/*lpr* kidneys. Then, we analyzed the expression of SLAMF6 in CD4+T cells of isolated kidney and spleen in B6 and MRL/*lpr* mice. We treated human podocytes with IgG from healthy individuals and LN patients for 24 h and 48h and analyzed the expression of SLAMF6 by real-time PCR. We isolated podocyte from B6 and MRL/*lpr* mice by cell sorter, then extracted mRNA, and performed microarray analysis.

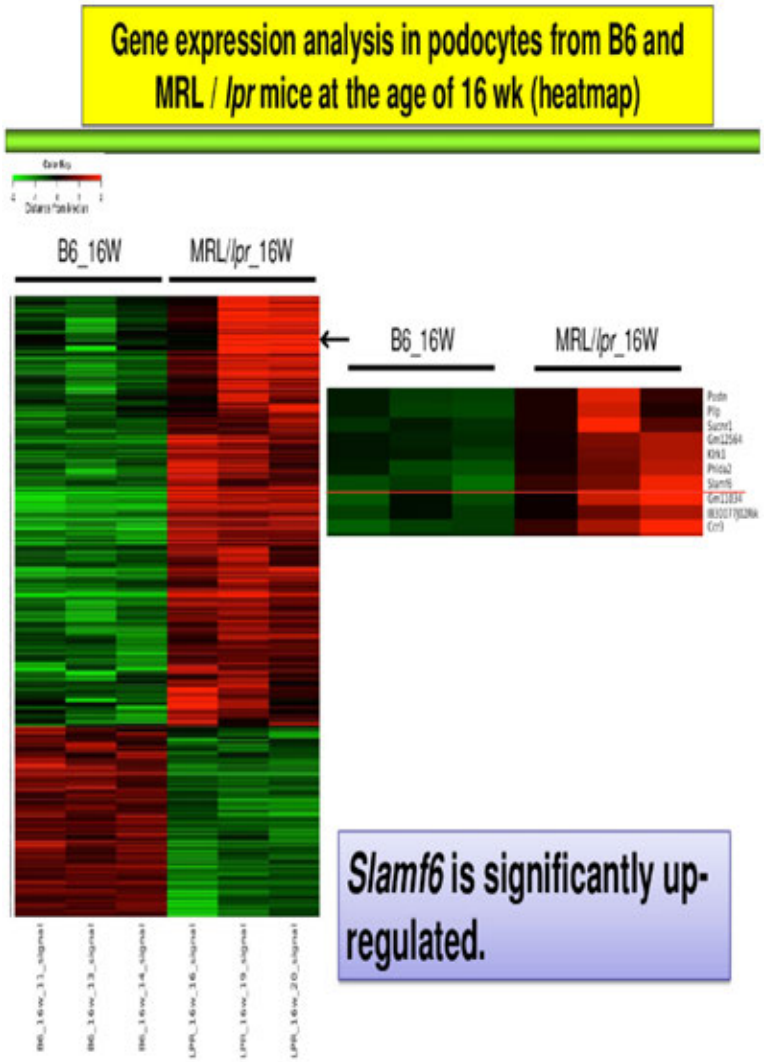

Figure 2 Gene expression analysis in podocytes from B6 and MRL / lpr mice at the age of 16 wk (heatmap)

Results: In the histopathology, the expression of SLAMF6 was increased in LN patients and MRL/*lpr* mice compared to control. Although the expression of nephrin in MRL/*lpr* mice kidney at 16 wk old decreased compared to B6 mice at same age, the expression of SLAMF6 in podocytes increased in diseased MRL/*lpr* mice compared to B6 mice. Similarly, the expression of SLAMF6 in CD4+ T cells increased in diseased MRL/*lpr* mice kidney and spleen compared to B6 mice. The level of SLAMF6 mRNA elevated in human podocytes exposed to LN-derived IgG compared to healthy control derived IgG.

When an arbitrary difference of 2.0-fold (or greater) change was selected, 1420 genes were identified as being up-regulated and 629 as down-regulated in podocytes derived from MRL/*lpr* mice as compared to B6 mice (Figure 1). Above all, the expression level of SLAMF6 in podocytes was significantly increased in MRL/*lpr* mice (ratio 3.22, P=0.0017) (Figure 2). The expression of the gene encoding the adapter protein, which is required for SLAMF signal transduction, was also confirmed in mice, and the fluctuation of some genes was confirmed. We also confirmed a decrease in several podocyte-related genes including *nphs1* (gene encoding nephrin) and an increase in apoptosis-related genes.

Conclusion: The expression of SLAMF6 is enhanced in LN podocytes, suggesting that the possibility of cooperating with CD4+T cells contributing to its dysfunction. Here, we compared the gene expression and signal transduction of podocytes in B6 mice and MRL /*lpr* mice by microarray. Further examination is needed to investigate in detail how SLAMF6 on downstream signals, specifically, the expression of nephrin and apoptosis markers are involved in the development of LN in the future.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus is an autoimmune disease characterized by chronic inflammation. We have previously shown that TLR7 and TLR8 are significantly upregulated in PBMCs of Lupus patients. Recent studies have discovered that miR-21, mir-29a, and miR-29b packaged and secreted in extracellular vesicles (EVs) can also bind to these receptors.

Methods: Twenty four lupus patients meeting the revised ACR criteria and 15 healthy controls provided informed consent to participate in this IRB-approved study. Plasma- and urine-derived EVs were isolated from 16 lupus patients including lupus nephritis (LN) and 6 healthy subjects by differential ultracentrifugation and validated by Nanosight and ELISA. Moreover, urine and plasma EVs from an additional 5 LN patients and 9 healthy subjects were subjected to RNA sequencing to identify RNA species including lnRNA, miRNA, and mRNA. A novel human-mouse chimeric model for testing therapeutics in SLE was created by adoptively transferring PBMCs from 3 active lupus patients into immunodeficient mouse recipients. Prior to transfer, PBMCs were incubated with synthetic liposomal EVs containing miR antagonists to miR-21, mir-29a, and miR-29b, or a control. After 21 days, PBMCs were collected for immunophenotyping and ELISA; tissues were collected for histopathological analysis by H&E staining and immunohistochemistry (IHC) for human CD3.

Results: There was a significant upregulation of EVs detected in the plasma of lupus patients relative to healthy controls. Additionally, the lupus nephritis patients that had RNAseq data resulted in a collection of statistically significant small RNA reads, such as miR-142-3p and let-7b-5p. The unique RNA signature observed by volcano plots showed multiple RNA species significantly upregulated and downregulated in lupus nephritis plasma samples. Furthermore, principal component analysis of both plasma and urine derived EVs revealed distinct lupus nephritis and healthy populations. Finally, in the adoptive transfer model, human CD4+, CD8+, B-cells, monocytes, and NK cells were successfully recovered from whole blood of chimeric mice at similar levels, but levels of human IL-2, IL-6, IL-10, and TNF-α were reduced with miR inhibition. Moreover, miR inhibition significantly reduced the inflammatory histopathology in the small intestine, liver, and kidney, demonstrated by H&E and digital quantitation of positive human CD3 IHC staining.

Conclusion: Our data shows elevated levels of EVs in lupus patients and reveals unique EV-derived RNA signatures in both urine and plasma that may be targeted therapeutically or used as diagnostic biomarkers for Lupus.

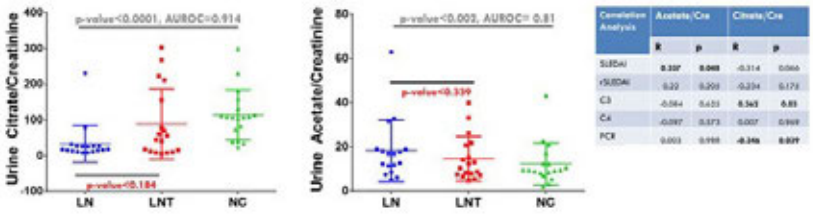
Session Title: SLE – Etiology & Pathogenesis Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM



Correlation Analysis	Acetate/Cre		Citrate/Cre	
	R	p	R	p
SLEDAI	0.337	0.048	-0.314	0.066
rSLEDAI	0.22	0.203	-0.234	0.173
C3	-0.064	0.633	0.362	0.03
C4	-0.097	0.573	0.007	0.969
PCR	0.003	0.988	-0.346	0.039

Figure: The box plot representation of Urinary Citrate/Cre and Acetate/Cre ratios obtained for different study groups: LN (in blue), LNT (in red) and NC (green). The significantly higher p-values and area under the ROC curve (AUROC) between LN and NC groups demonstrated the diagnostic potential of these urinary ratios. The table on the right side shows the correlation analysis parameters between urinary metabolic profiles and clinical parameters.

Background/Purpose: Metabolomics, the study of global alterations in small metabolites is a useful tool to look for novel biomarkers. Recently, we reported a reprogramming of the serum metabolomic profile on nuclear magnetic resonance(NMR) spectroscopy following treatment in Lupus Nephritis (LN).(1)We explored urinary parameters using NMR Spectroscopy in patients with biopsy proven proliferative lupus nephritis. Change in parameters after 6 months Cyclophosphamide induction treatment and its correlation with disease activity was assessed.

Methods: Urine obtained from Lupus Nephritis (n=18, F=16,M=2) at diagnosis and following induction therapy with cyclophosphamide, and healthy controls (n=18, median age 35,all females) were stored at -80 °C. Metabolomic profiling was done using high resolution 800 MHz 1D 1H NMR spectroscopy. Urinary ratio of metabolites was calculated-(Metabolitex1000)/Creatinine. Disease activity was measured using SLEDAI. Metabolomic profiles were compared between groups and correlated with clinical parameters using SPSS

Results: Urinary metabolomic fingerprint of LN patients differed from healthy controls by having significantly raised urinary acetate/creatinine(LN=41.84±100.6, HC=12.36±9.40, p=< 0.002) and reduced urinary citrate/creatinine. (LN=34.22±54.8, HC=114.5±70.09, p=< 0.0001). Urinary citrate (88.68±98.33) increased after 6 months of Cyclophosphamide, while urinary acetate showed a trend towards decrease(14.77±9.98). AUC for urinary citrate/creatinine and acetate/creatinine were 0.9136 and 0.8086. The urinary acetate levels correlated with SLEDAI (r=0.337,p=0.048). Urinary citrate levels correlated with C3 (r=0.362,p=0.03) and negatively correlated with uPCR (r=0.346, p=0.039).

Conclusion: The decreased urinary citrate mirrors the finding seen in serum of the patients done earlier which reflects dampened aerobic glycolysis and oxidative phosphorylation.(1) Raised urinary acetate levels possibly reflects renal tubular injury and decreased entry into TCA cycle. Urinary metabolomics parameters are potential noninvasive biomarkers for diagnosis and monitoring treatment response in LN.

Time-trends in Opioid Use Hospitalizations in Common Musculoskeletal Conditions: Gout, Osteoarthritis, Rheumatoid Arthritis, Fibromyalgia, and Low Back Pain

Jasvinder Singh,[1] and John Cleveland[2], [1]University of Alabama Medical Center, Birmingham, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rates of opioid abuse and associated mortality is a problem of epidemic proportion in the U.S. To our knowledge, limited data are available on opioid use disorder (OUD)-related hospitalizations in people with common musculoskeletal diseases

Methods: We used the U.S. National Inpatient Sample (NIS) data from 1998-2014 to examine the rates of OUD hospitalizations without opioid overdose, detoxification or rehabilitation services, based on the presence of any of the following International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) diagnostic codes for opioid dependence or abuse in the primary diagnosis position: 304.0x, 304.7x, 305.5x, 965.0x, E850.0, or E935.05. Five key rheumatic diseases were assessed using the respective ICD-9-CM diagnostic codes in a secondary position: Gout, rheumatoid arthritis (RA), fibromyalgia, osteoarthritis (OA), and low back pain (LBP). Incidence of OUD claims was assessed per 100K NIS claims overall.

Results: The incidence of OUD-related primary hospitalizations was low in 1998-2000 for the five musculoskeletal conditions and increased over the 19-year study period (**Table1**). The increase was 3.5- fold higher in people with LBP to 24-fold higher in people with gout. Rates of OUD per 100K total NIS claims showed similar trends namely, with increased ranging 5-fold higher in people with LBP to 35-fold higher in people with gout (**Table 2**). There was a plateauing of OUD claims for LBP and gout, but the increase seems to continue for OA, fibromyalgia, and RA (**Figure 1**).

Conclusion: The rate of increase in OUD-hospitalizations occurred in all 5 musculoskeletal conditions, but the rate differed by the condition. Providers, policy makers and patients with these conditions need to be aware of these trends, so the OUD-associated morbidity and mortality can be prevented.

Opioid Prescription Use Among Patients with Rheumatic Disease: A Population Based Cohort Study

April Jorge,[1] Na Lu,[2] and Hyon K. Choi[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hosptial, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases can be associated with pain and disability. An international opioid epidemic is ongoing, and prescription opioid use has been linked with increased risks of addiction, abuse, and mor-

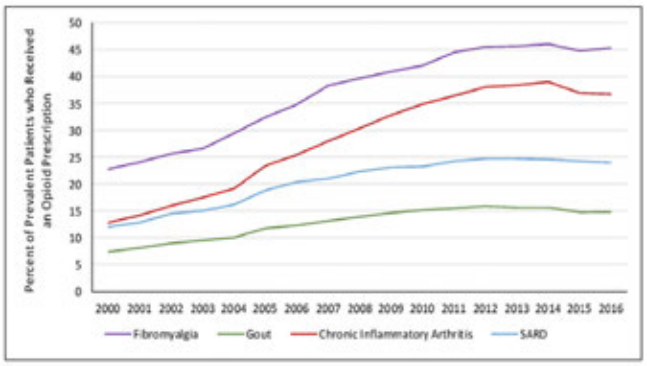

Figure 1 Annual Prevalent Opioid Prescriptions Among Patients with Rheumatologic Disease. Systemic Autoimmune Rheumatic Disease (SARD) includes systemic lupus erythematosus, Sjogren's syndrome, systemic sclerosis, dermatomyositis, polymyositis, mixed connective tissue disease, ANCA-associated vasculitis, and Behcet's disease. Chronic inflammatory arthritis includes rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis.

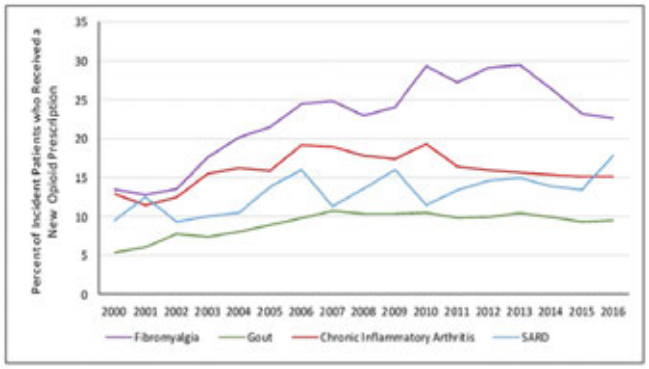

Figure 2 New Opioid Prescriptions Among Patients with Incident Rheumatic Disease. Systemic Autoimmune Rheumatic Disease (SARD) includes systemic lupus erythematosus, Sjogren's syndrome, systemic sclerosis, dermatomyositis, polymyositis, mixed connective tissue disease, ANCA-associated vasculitis, and Behcet's disease. Chronic inflammatory arthritis includes rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis.

tality. We assessed contemporary opioid prescription patterns among patients with rheumatic diseases in a general population context.

Methods: Using a United Kingdom general population database, we identified cohorts of fibromyalgia, chronic inflammatory arthritis (including RA, ankylosing spondylitis [AS], and psoriatic arthritis [PsA]), systemic autoimmune rheumatic diseases (SARDs) (including SLE, Sjogren's syndrome, systemic sclerosis, dermatomyositis, polymyositis, mixed connective tissue disease, ANCA-vasculitis, and Bechet's disease), and gout by Read codes and examined opioid prescriptions between January 1, 2000 and December 31, 2016 within these cohorts. We estimated the annual prevalence of opioid prescriptions among prevalent cases in each disease cohort. We also estimated the annual incidence of new opioid prescriptions among incident patients in each disease cohort, as determined by the percentage who received an opioid prescription within one year following their diagnosis and were free of opioid prescriptions in the antecedent 6 months. We examined secular trends by prescription opioid (e.g., tramadol, codeine) and strong opioids including morphine, oxycodone, fentanyl, hydromorphone, and methadone) within each disease cohort.

Results: Among incident cohorts, we identified 26,267 with fibromyalgia, 39,954 with inflammatory arthritis, 9,800 with SARDs, and 135,130 with gout. Prevalent opioid prescriptions increased in each disease cohort, reaching a plateau between 2012 and 2016 (**Figure 1**). In 2016, 45.2% of patients with fibromyalgia, 36.7% with inflammatory

arthritis, 24.0% with SARD, and 14.8% with gout received opioid prescriptions. Tramadol was the most commonly prescribed individual opioid (19.4%, 13.0%, 8.7%, and 5.2% prevalence, respectively), whereas 20.1%, 15.2%, 10.1%, and 3.6% of patients received strong opioid prescriptions, respectively. Patients with fibromyalgia were the most likely to receive new opioid prescriptions; annual rates rose from 12.8% in 2000 to 22.6% in 2016 (**Figure 2**). This was followed by incident inflammatory arthritis and SARDs, and the annual incidence was lowest among gout patients, rising from 5.3% to 9.5%.

Conclusion: In this general population-based study, we identified a substantial rise in the rates of opioid prescriptions among patients with rheumatic disease. Between 2012 and 2016, nearly half of patients with fibromyalgia, over one-third of patients with RA, PsA, and AS and nearly one-fourth of patients with SARDs received opioid prescriptions. These findings highlight the importance of increased awareness, as this population may be at risk for opioid-related complications.

Abstract Number: 2049

National Estimates of Pain Medication Use in Patients with Osteoarthritis

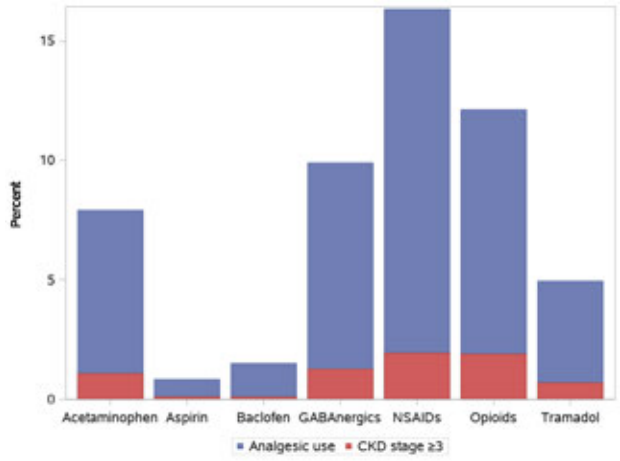
Mohammed Saeed[1], [1]Capital Health, Trenton, NJ

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The epidemiology of pain medication use among patients with osteoarthritis is not well explored. Chronic kidney disease (CKD) modifies choice of analgesics. The aim of this study was to explore real world use of pain medications in a nationally representative sample of patients with osteoarthritis.

Methods: The CDC's National Health and Nutrition Examination Survey (NHANES) 2013-2016 data were used, which is nationally representative of the non-institutionalized civilian resident population of the United States. The survey includes at-home questionnaires and health examination with laboratory testing. The study sample included adults (age ≥20 years) with a self-reported physician-made diagnosis of osteoarthritis. Prescription pain medication use in the past month was classified into groups: acetaminophen, aspirin, NSAIDs, tramadol, opioids, GABAnergics, and baclofen. eGFR was calculated using the CKD-EPI formula. Demographics including age and gender were identified. Survey-specific statistical methods were used to account for sample design and weighted frequencies and percentages were calculated with 95% confidence intervals (CI).

Results: There were 1,212 adults with osteoarthritis in the NHANES 2013-2016 sample, which represented 30,918,356 people when weighed. The sample was 65.0% female with a mean age of 61.5 years (95% CI, 60.6-62.4). eGFR was < 60 mL/min per 1.73 m2 (CKD stage ≥3) in 13.7% of study sample. The most commonly used prescription pain medications were NSAIDs, n=5,051,211 (16.3%); opioids, n=3,745,128 (12.1%); and GABAnergics, n=3,059,324 (9.9%). The prevalence of CKD stage ≥3 was 11.8% in NSAID users, 15.6% in opioid users, 12.8 in GABAnergic users, and 14.0% in tramadol users (See figure). Commonly used NSAIDs were meloxicam, n=1,648,619 (5.3%); celecoxib, n=965,139 (3.1%); and ibuprofen, n=947,035 (3.1%). Commonly used opioids were hydrocodone, n=2,088,939 (6.8%); oxycodone, n=967,814 (3.1%); and morphine, n=425,875 (1.4%). Use of more than one class of



Weighted Percentages of Prescription Pain Medication Use and CKD stage ≥3 in Patients with Osteoarthritis

Weighted Frequencies and Percentages of Prescription Pain Medication Use and CKD stage ≥3 in Patients with Osteoarthritis

	N (%)	CKD ≥3, N (Row %)
Acetaminophen	2,451,919 (7.9)	332,259 (13.6)
Aspirin	254,601 (0.8)	29,701 (11.7)
NSAIDs	5,051,211 (16.3)	594,373 (11.8)
Tramadol	1,529,572 (4.9)	214,330 (14.0)
Opioids	3,745,128 (12.1)	582,912 (15.6)
GABAnergics	3,059,324 (9.9)	392,824 (12.8)
Baclofen	462,480 (1.5)	29,136 (6.3)

pain medication included: NSAIDs and Opioids, n=1,158,653 (3.7%); NSAIDs and GABAnergics, n=1,136,693 (3.7%); Opioids and Gabanergics, n= 1,201,136 (3.9%); and NSAIDs, opioids, and GABAnergics, n=464,595 (1.5%).

Conclusion: Using nationally representative data, we described the epidemiology of prescription pain medication use, CKD prevalence, and use of combinations of pain medications in patients with osteoarthritis.

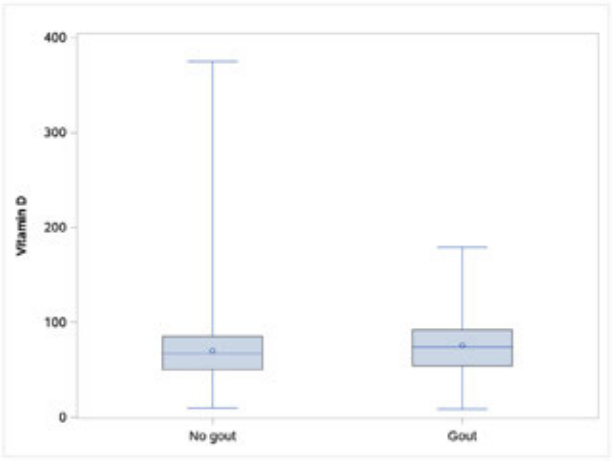
Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases



Mean vitamin D level in patients with gout compared to the nongout group

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior research showed conflicting results about the association of vitamin D with gout. We aimed in this study to quantify vitamin D levels in patients with and without gout using nationally representative data.

Methods: The National Health and Nutrition Examination Survey (NHANES) is a nationally representative sample of the non-institutionalized population in the United States. We analyzed data from 2011 to 2014 for adults (age ≥20 years). Gout was defined as a "yes" to: "Has a doctor or other health professional ever told you that you had gout?". Gender, age, vitamin D level, and vitamin D supplement use in the past 30 days were identified. Vitamin D deficiency was defined as < 50 nmol/L and high vitamin D level was defined as >125 nmol/L. Survey-specific statistical methods were used to account for sample design. Mean vitamin D levels (with 95% CI) and low/high vitamin D prevalence were calculated for people with and without gout. The Chi-square test was used to test the difference between categorical variables with alpha=0.05.

Results: There were 10,907 adults in our sample, which represented 226,559,243 people when weighted. Gout was reported in 8,705,906 (3.8%) of the sample. The mean age was 60.8 (95% CI:59.0-62.6) in those with gout compared to 49.9 (CI:46.0-47.8) in those without gout. 67.3% of those with gout were male compared to 47.2% in those with no gout. Mean vitamin D level was 75.7 (95% CI:71.4-80.1) in people with gout compared to 69.9 (95% CI:67.8-72.1) in those without gout (see Figure 1). The prevalence of low vitamin D in people with and without gout were 25.2% and 27.7%, respectively (P value 0.3945). While the prevalence of high vitamin D level in people with and without gout were 6.4% and 4.3, respectively (P value 0.1265). Vitamin D supplement use was more common in people with gout (50.3%) compared to people without gout (40.4%, P value 0.0025). Among people with gout who took vitamin D supplements, 40.0% reported being advised by a doctor to take the supplement.

Conclusion: In this large nationally representative population-based cross-sectional study, vitamin D was not associated with gout. The prevalence of vitamin D deficiency was similar in people with and without gout. Vitamin D supplement use was more common in people with gout.

Factors in Achieving Serum Uric Acid Target and the Occurrence of Gouty Arthritis: A Cross-sectional Study Based on Japanese Health Insurance Claim Data

Ruriko Koto,[1] Akihiro Nakajima,[1] Hideki Horiuchi,[1] and Hisashi Yamanaka[2], [1]Teijin Pharma Limited, Chiyoda-ku, Tokyo, Japan, [2]Sanno Medical Center, Minato-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The number of gout attacks can be reduced by achieving and maintaining serum uric acid (sUA) at or below 6.0 mg/dL, a level uniformly recommended by international guidelines. However, although urate-lowering therapy (ULT) can reliably achieve such reductions, many gout patients fail to reach their sUA target, and such patients tend to experience recurring gouty arthritis in real-world clinical practice. The present study assessed factors related to achieving target sUA levels and the occurrence of gouty arthritis in Japanese clinical practice, to better understand the underlying reasons for suboptimal treatment of gout.

Methods: We analyzed Japanese health insurance claims and medical check-up data from April 2016 to March 2017, and assessed factors that were associated with target sUA in gout and asymptomatic hyperuricemia and with the occurrence of gouty arthritis in gout. We also conducted subgroup analysis of ULT prescriptions and outcomes, stratified by renal function, to determine effects on achieving target sUA. Data were obtained from the JMDC Claims Database, including diagnostic codes, names of prescription drugs prescribed, and data from physical examinations of company employees and their dependents.

Results: Patients who reached their target sUA tended to be older, to be female, to receive higher doses of ULT, to achieve higher treatment adherence (medication possession ratio), to have more comorbidities, and/or to be prescribed antidiabetic drugs. We found that renal dysfunction and/or diuretic prescriptions were predictive of reduced achievement of target sUA. This was obvious in severe renal dysfunction (OR 0.22 [95% CI 0.10-0.48] for < 15 and 0.15 [0.10-0.23] for ≥15 to < 30, compared with eGFR ≥90 mL/min/1.73m2) (Figure 1). Notably, the mean prescribed ULT dose was low (febuxostat 17.0-21.0 mg/day, allopurinol 123.1-139.6 mg/day) a cross all renal function categories. We also found that lower renal function was associated with lower achievement of target sUA for every ULT dosage category. Our data showed that gouty arthritis attacks occurred more often among patients with a prior history of gouty arthritis and less often in patients who had higher ULT adherence, sUA measured at medical facilities, and/or more comorbidities (Figure 2).

Conclusion: Our analysis showed renal dysfunction as an important predictor for failure to achieve target sUA; within our dataset, most renal dysfunction patients with gout or asymptomatic hyperuricemia did not reach target sUA. These findings imply suboptimal disease management, especially in this population. Our findings also suggested the importance of regular clinic visits and sustained adherence to ULT in the control of gouty arthritis attacks.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Traumatic knee joint injuries, such as injuries to the anterior cruciate ligament and menisci, are associated with early onset osteoarthritis (OA), but our understanding of the epidemiology of this association is limited. The effect of knee injury on patient-reported outcomes (PROs) of knee function and symptoms is understudied in military populations, despite their high risk of knee injury and knee OA. This study of a cohort of military officers examined the association of traumatic knee injury with knee function, symptoms, and radiographic OA (rOA).

Methods: Participants were recruited from an existing cohort of 6452 military officers enrolled between 2004 and 2009, at the time of their matriculation as cadets at the United States Air Force Academy, Military Academy, or Naval Academy. Officers with a history of ligament and meniscal injuries prior to, during, or after their 4-year academy career (knee injury subcohort; n=176) were compared to site-matched officers with no history of knee injury (non-injured subcohort; n=261). All participants completed a questionnaire between August 2015 and December 2017 that included PROs assessed with Knee Injury and OA Outcome Score (KOOS) scales (range 0-100=extreme to no deficits) and a single-item measure of knee symptoms (pain, aching, or stiffness in the past 30 days, 4-point Likert scale). Radiographic evidence of knee OA was evaluated using standardized fixed-flexion bilateral knee radiographs (available in n=117 injured, n=143 non-injured). These were read by a single highly-experienced musculoskeletal radiologist for Kellgren-Lawrence grade (KLG), presence of osteophytes (OST), and joint space narrowing (JSN). Data were analyzed using descriptive statistics, contingency table methods (radiographic data), and ANOVA (KOOS).

Results: Mean age was 28 years for both injured and non-injured participants; 39% were women (injured: 37%; non-injured: 40%). Mean weight was 78 kg and body mass index was 25 kg/m2. Mean time from first knee injury to follow-up assessment was 8.7 years. Among officers with a history of knee injury, 16% had knee rOA (KLG $\geq$ 2), 40% had OST, and 22% had JSN, compared to only < 1%, 9%, and 3% of non-injured participants ($p < 0.001$). Compared with non-injured participants, injured participants also had clinically relevant deficits on KOOS symptoms, KOOS pain, KOOS sports/recreation, and KOOS quality of life scales (mean score differences of -13.3, -9.6, -14.8, -19.6 respectively; all $p < 0.001$). Deficits on KOOS activities of daily living scale were also statistically significant (mean difference -4.6; $p < 0.001$) but were smaller and less clinically-relevant. Average scores on the single-item symptom scale were worse in the injured (1.1 vs. 0.4; $p < 0.001$).

TABLE 1. Mean Patient-Reported Outcome Measure Scores in Knee Injury and Non-Injured Subjects.

Patient-Reported Outcome Measure	Non-Injured Referent Subcohorts		Knee Injury Subcohort

Table 3. Radiographic Evidence of Osteoarthritis in Knee Injury and Non-Injured Subjects.

Conclusion: At the midpoint of an anticipated 20-year military career, officers with a history of ACL/meniscal injury have deficits in knee-related symptoms, QOL, and knee function. Approximately 1 in 6 officers with prior knee injury progressed to rOA before mean age 30. This progression rate is highly concerning given the physically-demanding nature of their profession and their young age.

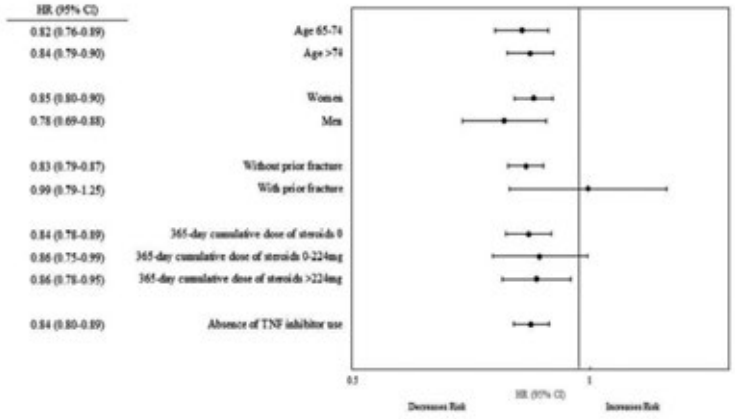
Table 2. Risk of non-vertebral or hip fracture in the gout group compared with the RA group

Adjustment	Hazard ratio (95% CI)
Non-vertebral fracture	
Model 1	0.69 (0.66-0.72)
Model 2	0.78 (0.75-0.82)
Model 3	0.75 (0.72-0.79)
Final model	0.84 (0.80-0.88)
Hip fracture	
Model 1	0.62 (0.59-0.66)
Model 2	0.72 (0.67-0.76)
Model 3	0.68 (0.64-0.73)
Final model	0.76 (0.71-0.82)

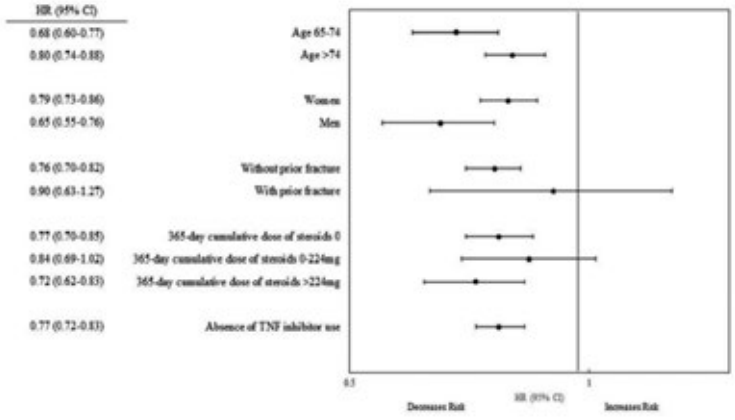
Model 1: Age, sex-adjusted
Model 2: Calendar year, bone mineral density test, Fall, obesity, prior fracture, bisphosphonates, use of non-bisphosphonate osteoporosis medications, recent use of steroids, and 365-day cumulative dosage of steroids in addition to model 1
Model 3: Race, frailty index, comorbidity index, and number of different prescriptions in addition to model 2
Final model: All other comorbidities, medication use, and intensity of health care utilization in addition to model 3

Figure. Risk of fracture in the gout group compared with the RA group according to stratification

A. Non-vertebral fracture



B. Hip fracture



Background/Purpose: Gout is a common inflammatory arthritis, characterized by hyperuricemia leading to crystallization of uric acid in joints. Proinflammatory cytokines have been known as an increasing factor for osteoporotic fractures, and chronic inflammatory diseases such as rheumatoid arthritis (RA) are considered to be a risk factor for

osteoporosis and fractures. However, association between hyperuricemia and osteoporotic fractures, and relationship between gout and osteoporotic fractures has shown conflicting results. We hypothesized that older patients with gout would have a similar risk of osteoporotic fracture compared with older patients with RA.

Methods: Using claims data from Medicare Parts A/B/D (2008-2015), we conducted a cohort study. We selected gout with ≥2 diagnosis codes and ≥1 dispensing for gout treatment. Similarly, RA were identified with ≥2 diagnosis codes and ≥1 dispensing for disease-modifying antirheumatic drugs. Gout patients were 1:1 matched to RA patients on age, sex, and index date. The primary outcome was non-vertebral fractures, a composite endpoint of humerus, wrist, pelvis or hip fracture, based on previously validated claims-based algorithms (PPV > 93%). The secondary outcome was hip fracture. We calculated the incidence rate (IR) of non-vertebral fracture and hip fracture in each group. Cox proportional hazards regression estimated the hazard ratio (HR) with 95% confidence intervals (CI) for the primary and secondary outcomes in gout versus RA, adjusting for 45 baseline risk factors for osteoporosis.

Results: We included a total of 134,157 matched pairs of gout and RA patients with mean age of 73.7 years. 70.4% were female. Risk factors of osteoporotic fracture such as receipt of a bone mineral density test, diagnosis of osteoporosis, prior fracture, use of osteoporosis medication, and steroid use were more prevalent in RA than gout. However, other comorbidities including obesity, coronary heart disease, heart failure, hypertension, hyperlipidemia, diabetes, and chronic kidney disease were more frequently noted in gout than RA (**Table 1**). Over the mean 2.8-year follow up, the IR per 1,000 person-year (PY) of non-vertebral fractures was 10.42 in gout and 15.01 in RA, and the IR per 1,000 PY of hip fracture was 4.86 in gout and 7.73 in RA. The IR of non-vertebral fractures was more than twofold higher in patients aged ≥75 years than patients aged 65-74 years, and about threefold higher in the patients with prior fracture than the patients without prior fracture in both groups. Multivariable HR associated with gout versus RA was 0.84 (95% CI 0.80-0.88) for non-vertebral fractures and 0.76 (95% CI 0.71-0.82) for hip fractures (**Table 2**). Subgroup analyses by age, sex, history of prior fractures, 365-day cumulative dose of steroids and absence of TNF inhibitor use showed similar results (**Figure**).

Conclusion: In this large cohort of older patients enrolled in Medicare, the absolute rate of non-vertebral fractures or hip fractures was high in both gout and RA. However, gout was associated with a decreased risk of non-vertebral and hip fractures regardless of age, sex, steroid use and prior fracture, compared to RA.

2014	1,801	2,727	899	3.0
2015	2,005	3,026	1,009	3.0

Background/Purpose: Gout is the most common inflammatory arthritis that results from chronic elevation of uric acid levels above the saturation point for monosodium urate crystal formation. However, data on gout incidence, prevalence and management, are sparse, especially in Korean populations. We reevaluated the recent prevalence and incidence of gout in Korean people after our previous study in 2011 (1).

Methods: The National Health Insurance Corporation (NHIC) Database was used to identify patients with gout. We selected the gout patients who were coded as having gout (KCD M10.0) from main diagnosis to 4th additional diagnosis. And we estimated the prevalence (from 2002 to 2015) and the incidence (from 2006 to 2015) for each calendar year.

Results: Prevalence of gout was 0.39% in 2002 and 2.00% in 2015. There was a 5.17 fold increased during over 13 years. Prevalence have increased at all ages, especially at the age of 80 and over. Also, incidence per 100,000 was 361 in 2006 and 797 in 2015, there was 2.21 fold increased during over 10 years. Sex ratio (male:female) was 3.0~3.8:1. When monthly incidence was examined, except for December, it increased as the day warmed and peaked in July and August. In the southern provinces, especially Busan, prevalence and incidence were high. Of those diagnosed with gout in 2012, a total of 30% of those who had been prescribed uric acid lowering agent (allopurinol or febuxostat or benzbromarone) within three years.

Conclusion: In Korea, prevalence and incidence of gout are rapidly increasing. Incidence was higher for males, for older age, for warmer days, and for southern regions. Management of gout in Korea is poor, with only three in ten affected people who have ever been treated with uric acid lowering therapy.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A high sodium intake has been reported to adversely affect bone health and to be associated with an increased inflammatory response. However, the relationship between dietary sodium intake and OA has not been established. This study aimed to analyze the association between sodium intake and OA in Korean population using the fifth Korean National Health and Nutrition Examination Survey (KNHANES V).

Methods: We included participants aged 50 to 75 years who completed urinary sodium evaluation, plain knee radiographs, health interview and nutritional surveys in the 2010 to 2011 KNHANES V. Knee OA (KOA) was defined as the presence of radiographic features of Kellgren-Lawrence grade ≥2. We used the Tanaka formula to estimate 24-hour urinary sodium excretion from a fasting morning specimen as a surrogate for daily sodium intake. All of the statistical analyses were performed on the basis of a sampling weight to represent the entire Korean population. The association between symptomatic KOA and the dietary indices was statistically analyzed using univariate and multivariate logistic regression methods.

Results: Among study population, 10.5% (weighted n=1,214,665/11,610,574) had symptomatic KOA, of which 80.7% was female. Of the total, 86.8% of study participants had sodium intake levels well above the recommendation of World Health Organization (2,000 mg of sodium per day). Compared to the non-KOA group, the KOA group was older, more obese, less educated, and less earned. The percentages of subjects with depression or taking antihypertensive medications, and non-smokers in KOA were higher than those in non-KOA. Although total energy intake in KOA group was lower than in non-KOA group, the mean estimated 24-hour urinary sodium excretion level in KOA group was significantly higher than in non-KOA group. After adjusting for covariates, the statistical significance of the estimated 24-hour urinary sodium excretion was lost in total participants. However, subgroup analysis in subjects with high sodium intake (daily sodium intake ≥2,000 mg) demonstrate that 24-hr urinary sodium excretion was positively associated with symptomatic KOA even after adjustment with confounding factors (Odds ratio 1.165, 95% confidence interval 1.019-1.331, $p < 0.001$).

Conclusion: The present study suggested that sodium intake levels could be dose-dependently associated with symptomatic knee OA in subjects consuming dietary salt intake ≥2,000 mg/day.

Abstract Number: 2056

Opioids Use Among Medicare Beneficiaries with Knee Osteoarthritis: Prevalence and Correlates of Chronic Use

Elena Losina,[1] Shuang Song,[2] and Jeffrey Katz[3], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital/Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) of the knee is prevalent among Medicare beneficiaries. Effective pain control is critical for managing this chronic disease. In the last decade, opioids became widely available for persons with knee OA. We sought to identify knee OA patients that use opioids chronically and occasionally, and determine factors associated with greater risk of occasional and chronic opioid use among knee OA patients ≥ 65years of age.

Methods: We used the Medicare Beneficiary Survey (MCBS) of a nationally representative sample of Medicare beneficiaries administered in 2015. MCBS survey data are linked to Medicare claims. We selected a knee OA cohort from community-dwelling MCBS respondents age ≥ 65 who had at least one outpatient visit in Medicare Parts A or B with an ICD-10-CM code of a) M17.9 or b) M25.569 (Pain in unspecified knee) plus M15.x or M19.90. We obtained data on demographics, smoking, marital status, comorbidities and prescribed medications from survey data and claims. We included all prescribed medication records classified as opioids under the First Databank therapeutic analgesics category. We stratified knee OA subjects into three opioid use groups: 1) none, 2) occasional (1-5 prescriptions/year), 3) chronic (6+ prescriptions/year). We built several multivariable logistic regression models to determine independent correlates of any opioid use vs non-use; chronic vs. non-use and chronic vs. occasional use.

Results: We identified a cohort of 620 persons with knee OA. Mean age was 78.5 (SD 7.3), 65% were female. 31% of the cohort had at least one opioid prescription during 2015. 10% of the overall cohort were identified as chronic opioid users, and 21% of the overall cohort as occasional users. Multivariable analyses that compared any opioid use to no use identified several patient features associated with greater risk of opioid use: ≥ 1 fall in the prior year (OR 1.96, 95% CI 1.16-3.30; ≥ 2 comorbidities (OR 2.62, 95% CI: 1.30, 5.29) and use of NSAIDS (OR 3.74, 95% CI: 2.09-6.71). Married beneficiaries had 0.50 odds of using opioids compared to those who were not married (95% 0.30-0.84). When we compared chronic opioid users to no users, features associated with chronic use included low household income (< 30K/annually; OR 6.13, 95% CI: 2.39-15.7; ≥ 2 comorbidities (OR 3.27, 95% CI: 1.25-8.55) and NSAID use (OR 2.77, 95% CI: 1.14-6.71). Comparing chronic users with occasional opioid users, features associated with chronic use included low income (OR 6.15, 95% CI: 2.04-18.44) and current smoking (OR 5.83, 95%CI: 1.15-29.45).

Conclusion: Over 30% of Medicare beneficiaries with knee OA use opioids and 10% use them chronically. Low income, NSAID use and higher burden of comorbidities are associated with greater risk of opioid use, while marriage was associated with lower risk of use. The causal relationship between prior falls, low income and marital status and risk of current opioid use requires further study. Efforts to find non-opioid regimens for knee OA would be especially useful for patients with risk factors identified in this study.

Table 1 Cross-sectional associations of MJOA

Background/Purpose: Multiple joint osteoarthritis (MJOA) may represent a unique phenotype of osteoarthritis related to systemic factors associated with pathologic aging. We tested the hypothesis that metabolic syndrome and its components, frailty and its components and lower levels of bone density are associated with MJOA.

Methods: Participants in the Osteoarthritis Initiative (N=3325) had hand, hip and knee xrays performed and centrally read for osteoarthritis. Hand osteoarthritis (OA) was defined as at least one joint with Kellegren-Lawrence(KL) $\geq$2 on at least two rays; Hip OA was defined as modified Croft grade $\geq$2 in ether hip; Knee OA was defined as KL $\geq$2 in either knee. MJOA was defined as hand OA and either hip or knee OA. A metabolic syndrome score was developed based upon the presence of hypertension, diabetes, lipid disorder, and increased waist circumference. Frailty was defined as one positive on the Song Frailty index and evaluating waking speed, chair stands and self-reported energy. Cortical thickness of metacarpal bones digits 2-4 and femoral bone density (FMD) in a smaller sub-sample based upon DEXA estimated the effect of bone mineral density (BMD). Prevalence ratios and 95% confidence intervals were estimated using poisson regression.

Results: Of the 3325 participants, 933 had MJOA and 2392 did not. The average age of the analytic cohort was 60.9 years, 56.8% were female, 82.1% were white, 15.4% were black and 2.4% were hispanic, and 11% had incomes < $25,000. Age, female gender, BMI, abdominal circumference, hypertension, lipid disorder, diabetes, metabolic syndrome score, Song Frailty index, slow walking speed, using hands during chair stands were associated with higher prevalence of MJOA. Higher levels of physical activity,bone mineral density, walking speed, chair stand pace, extensor and flexor strength of lower extremities were inversely associated with MJOA. In multiple variate analysis adjusting for age, gender, and BMI metabolic syndrome and its components were no longer associated with MJOA, thinner cortical thickness was only associated with MJOA in those < 65 years of age, and only slow walking speed as a measure of Frailty was associated with MJOA. Faster chair stand pace and dominant lower extremity extensor strength remained inversely associated with MJOA. (See Table 1)

Conclusion: Age is a strongly associated with MJOA. Low bone density as measured by metacarpal cortical thickness at age less than 65, impaired walking speed, lower chair stand pace, decreased lower extremity extensor strength may reflect pathologic aging and are associated with MJOA in this cross-sectional analysis. Prospective analysis and exploring the underlying pathobiologic pathways associated with impaired BMD and muscle strength could lead to effective prevention and treatments of MJOA.

Table 1 Selected characteristics (weighted column %) of patients with gout by pharmacological treatment in office-based outpatient care visits

Background/Purpose: Studies show that gout treatment remains suboptimal in the United States (US). Despite clear benefits for urate-lowering therapy (ULT) for chronic gout, surveyed physicians in the US are less likely to continue prescribing ULT after the first prescription. Prophylactic therapy was also infrequently prescribed concurrently with initial ULT. Our study investigates rates and trends of pharmacological treatments for gout in ambulatory office-base care from 2009 to 2016, along with factors associated with use.

Methods: We used data from 2009-2016 National Ambulatory Medical Care Surveys (NAMCS), a nationally representative sample of US office-based outpatient care. We included visits in which gout was diagnosed among adults age 18 or older (n=827 unweighted). We estimated prevalence and trends from 2009 to 2016 for the following medication classes for pharmacological treatments of gout: non-steroidal anti-inflammatory drugs (NSAIDs), colchicine, oral steroids, ULT, and opioids. Using a multivariable-adjusted logistic regression analysis, we examined associations between demographic and clinical characteristics and pharmacological treatments for gout.

Results: Between 2009-2016, there were 827 gout-diagnosed outpatient visits, representing 2.5 million office-based visits. Medication prescriptions occurred in 74.8% of these visits. Patients receiving prescriptions were predominantly aged 45 or older, male, and non-Hispanic white. When stratified by medication class, prescribing of opioids

Table 3 Multivariable-adjusted analysis of factors associated with gout-related medication prescribing among adults with gout in office-based outpatient care visits

has monotonically increased from 9.1% in 2009-2010 to 34.7% in 2015-2016 (odds ratio [OR] for trends=1.73; 95% CI=1.04, 2.88); prescribing of oral steroids similarly increased from 10.7% in 2009-2010 to 27.5% in 2015-2016 (OR for trends=1.48; 95% CI=1.04, 2.08). Over the same period, prescription of ULT remained steady OR=1.16; 95% CI=0.92, 1.45). Patient factors independently associated with a higher likelihood of prescribing medications for gout were being male (adjusted odds ratio [AOR]=2.36; 95% CI=1.20, 4.65) and those with six or more medications concomitantly prescribed (AOR=5.93; 95% CI=2.74, 12.82). Studied medications were also less likely prescribed during visits pre and post surgery (AOR=0.12; 95%CI=0.02, 0.70).

Conclusion: Opioids and oral steroids were increasingly prescribed at initial gout visits while prescriptions of ULT and colchicine were unchanged over time. This suggests a concerning trend toward use of opiates in gout patients. Also, despite surgical intervention being a risk factor for gout flare, ULT may be underutilized in this population. Overall, our findings support the need for better understanding of optimal gout treatment among US clinicians and further research is needed to support improved treatment of gout.

Abstract Number: 2059

Usage of Predicting Out-of-Office Blood Pressure Calculator in Hispanic Patients with Rheumatic Diseases

Dionicio Galarza-Delgado,[1] Jose Azpiri-Lopez,[1] Iris Colunga-Pedraza,[1] **Carolina Marlene Martinez-Flores**,[1] Marielva Castro-Gonzalez,[1] Ileana Cecilia Reynosa-Silva,[1] Karla Paola Cuellar-Calderon,[1] and Raymundo Vera-Pineda[2], [1]Universidad Autonoma de Nuevo Leon, Hospital Universitario "Dr Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico, [2]Universidad Autonoma de Nuevo Leon, Hospital Universitario "Dr. Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Subjects with rheumatic diseases have an increased risk of cardiovascular (CV) morbimortality. Hypertension (HTN) is a key modifiable risk factor for CV events. A recently published and validated prediction model (Predicting Out-of-Office Blood Pressure, PROOF-BP) has been proposed as a tool to improve diagnosis of HTN, and detection of out-of-office HTN in subjects with a previous diagnosis, with a *c*-statistic (AUC) of 0.86 in non-rheumatic subjects. This model has not been explored in rheumatic patients. Therefore, the objective of this study was to evaluate the diagnostic performance of the PROOF-BP algorithm for the prediction of HTN in subjects with/without rheumatic diseases.

Table 1. Diagnostic performances.

	Sensitivity (%)	Specificity (%)	PPV (%)	NVP (%)
Low risk	100	55	58	100
High risk	29	95	80	68

Predicting Out-of-Office Blood Pressure calculator.TABLE
PPV- Positive predictive value; NPV- Negative predictive value.

Methods: A cross-sectional, observational trial was designed. Subjects with/without rheumatologic conditions were recruited at a rheumatology outpatient clinic. Complete history with somatometry of each subject was registered. BP was measured by a physician 3 times to each participant using current recommendations, with an OMRON HEM-7121 BP monitor. Calculations using the PROOF-BP online site were done, and risk categories were assigned to each subject: low (< 130/80 mmHg), medium (130/80-145/90 mmHg) and high risk (>145/90 mmHg). Subjects in the medium and high risk strata were then asked to return for further evaluation and additional BP measurement, to define each diagnosis of HTN. We used frequencies (%) and median (q25-q75) for descriptive analysis. Diagnostic accuracy of each category was determined using 2 x 2 tables.

Results: A total of 217 subjects were included. The most frequent rheumatic disease was RA (35.9%), followed by OA, SLE and Sjögren syndrome (13.4%, 2.8% and 2.3%, respectively). Using PROOF-BP, 84 (38.7%) subjects were stratified as medium or high risk. Of these, only 36 (42.8%) returned for evaluation. A final diagnosis of HTN was attained in 14 (38.8%) of those who returned. In 21 (67.7%) cases of the medium risk category the diagnosis of HTN was finally discarded, and in the remaining 10 (32.2%) diagnosis of HTN was finally ascertained. The high risk category had a specificity of 95% and a PPV of 80% for the diagnosis of HTN.

Conclusion: In a cohort of Mexican-mestizo subjects with rheumatic diseases, 38.7% were classified as medium or high-risk for HTN. Only 42.8% of patients that required further evaluation followed medical recommendations. More than 30% of patients in the medium-risk category had a final diagnosis of HTN. Using the BP-PROOF algorithm, none of the patients in the low-risk stratum had a final diagnosis of HTN (sensitivity= 100%); the high-risk category had a high specificity (95%) for the diagnosis of HTN.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Big data are defined as data sets that are too large or complex for traditional data-processing application software to adequately deal with. Artificial Intelligence (AI) includes various statistical techniques which can deal with big data. The current use of these concepts in publications related to rheumatic and musculoskeletal diseases (RMDs) is unknown. Therefore, the aim of this literature review was to assess the current use of big data and AI in the field of RMDs.

Methods: A systematic literature review was performed in PubMed MEDLINE in November 2018, with key words referring to big data, artificial intelligence and RMDs. All original reports published in English were analyzed. A mirror literature review was also performed outside of RMDs on the same number of articles. The number of data analyzed, data sources and statistical methods used (traditional statistics, AI or both) were collected. The analysis compared findings within and beyond the field of RMDs.

Results: Of 567 articles relating to RMDs, 55 met the inclusion criteria and were analyzed, as well as 55 articles in other medical fields. The mean year of publication was 2014 for the RMDs SLR, with 72% of the articles published between 2013 and 2018; whereas the articles included in the mirror non-RMD review were all published in 2018 or 2019. Among RMDs, the most represented fields were inflammatory joint diseases (N=22, 40%) and osteoarthritis (N=16, 29%). The 3 most represented diseases were: knee osteoarthritis (N=13, 24%), rheumatoid arthritis (N=12, 22%) and post-menopausal osteoporosis (N=6, 11%). Outside of RMDs, the most represented medical fields were: oncology (N=14, 25%), neurology (N=8, 15%), infectious diseases (N=6, 11%), ophtalmology (N=5, 9%) and psychiatry (N=5, 9%).

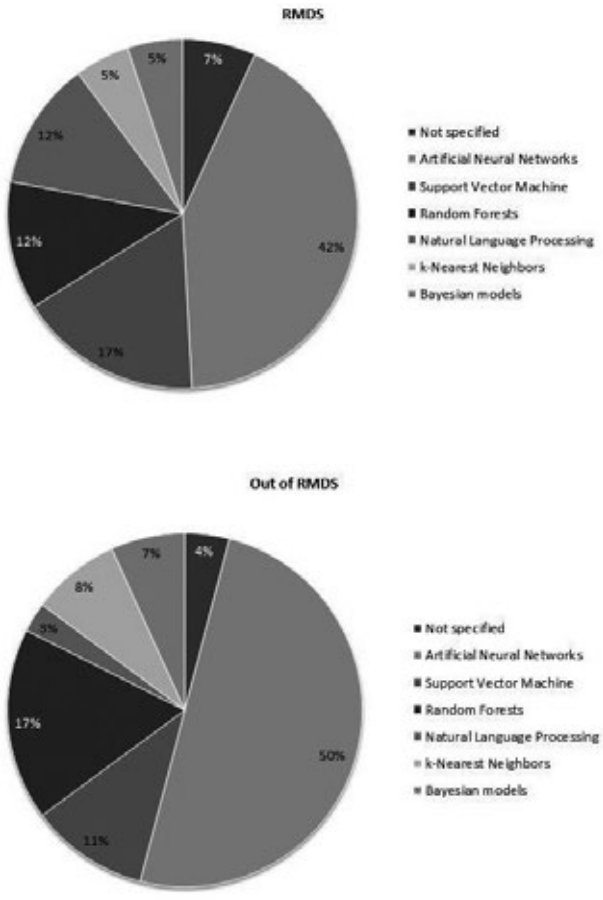

Figure 1 Distribution of machine learning methods in RMDs and outside of RMDs

Only two articles in the field of RMDs (4%) and seven articles out of the field of RMDs (13%) mentioned a clear definition of big data. The mean number of data points was 746 million [range 2000–5 billion] in RMDs, and 9.1 billion [range 100,000 – 200 billion] outside of RMDs.

Data sources were varied: in RMDs, 26 (47%) were clinical, 8 (15%) biological and 16 (29%) radiological; whereas outside of RMDs, the distribution was quite homogenous between clinical, biological and imaging sources (respectively 31%, 31% and 29%).

Both traditional and AI methods were used to analyze big data (respectively 10 (18%) and 45 (82%) in RMDs and 8 (15%) and 47 (85%) out of RMDs). Machine learning was used in almost all AI papers (44/45 in RMDs and 47/47 outside of RMDs), and among machine learning methods, the most represented was artificial neural network (20/44 in RMDs, and 24/47 out of RMDs). More details are provided in Figure 1.

Conclusion: Big data sources and types are varied within the field of RMDs, and methods used to analyze big data were heterogeneous. These findings informed a EULAR taskforce developing recommendations for big data in RMDs.

Table 3. Multivariable logistic regression analysis showing the odds ratio of the relationship between rheumatic disease and periodontitis.

Rheumatic diseases	OR*	CI	P
Rheumatoid arthritis	1.2	0.8-1.8	0.45
Osteoarthritis	0.7	0.5-0.97	0.03
Osteoporosis	0.8	0.6-1.2	0.2
Gout	1.1	0.6-1.9	0.8
SLE	2.1	0.5-8.3	0.3

OR= Odds Ratio, CI: 95% Confidence interval
*: Adjusted for age, gender, race-ethnicity, smoking, and history of diabetes mellitus.

key oral bacteria may play a role in the pathogenesis of autoimmune diseases. This study aims to determine the association between periodontal health and various rheumatic diseases by examining data from the Third National Health and Nutrition Examination Survey (NHANES III).

Methods: The NHANES III is a nationally representative survey of U.S. noninstitutionalized civilians and was conducted from 1988-1994. We included participants aged 13 years and older who had a periodontal examination (Table 1). We used assessments of self-declared physician diagnosis of the following diseases: RA, osteoarthritis (OA), gout, osteoporosis,and systemic lupus erythematosus (SLE). We also included smoking and diabetes mellitus as these have been shown to be significant risk factors for periodontitis. Periodontitis was defined using criteria recommended by the American Academy of Periodontology.

Results: The prevalence of periodontitis and the mean attachment loss increased with age and was significantly higher in males, African-Americans, smokers, and in persons with high HbA1c (Table 2). The regression analysis using mean periodontal attachment loss showed that the association of periodontitis with rheumatic diseases, including rheumatoid arthritis, was not statistically significant except for osteoarthritis (p=0.003). Similarly, using the diagnosis of periodontitis as the outcome variable, the logistic regression model showed no significant relationship between periodontitis and rheumatic diseases, except for osteoarthritis which showed a negative relationship with periodontitis (OR= 0.7, p=0.03), after controlling for the effect of other co-variates (Table 3).

Conclusion: This study shows positive associations of periodontitis with known risk factors, such as demographics, smoking, and diabetes mellitus, but it failed to show statistically significant positive association with systemic rheumatic diseases including RA. This is in contrast with other studies showing positive association of many rheumatic diseases especially RA with periodontitis. There was a trend toward an association of periodontitis with SLE but the number of SLE patients was very small. The negative association between osteoarthritis and periodontitis is unexplained. More prospective studies are needed to confirm or refute the association between periodontitis and rheumatic diseases.

Arthritis, Physical Function, and Disability Among Older Mexican Americans over 20-Years of Follow-up

Martin A Rodriguez,[1] Lin-Na Chou,[1] Jaspreet K Sodhi,[1] Kyriakos S Markides,[1] Kenneth J Ottenbacher,[1] and Soham Al Snih[1], [1]The University of Texas Medical Branch, Galveston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hispanics are the fastest growing group of older adults in the US, with older Mexican Americans the largest segment of US Hispanics (65%), a population with high rates of disability. The objective of this study was to examine the effect of arthritis on physical function and disability among non-disabled older Mexican Americans over time.

Methods: Data are from a 20-year prospective cohort study of 2254 non-institutionalized Mexican American aged 65 years and older from the Hispanic Established Population for the Epidemiological Study of the Elderly (1993/94-2012/13) who were non-disabled at baseline. Data on self-reported arthritis, socio-demographic variables, medical conditions (hypertension, diabetes, stroke, heart attack, cancer or hip fracture), pain on weight-bearing, activities of daily living (ADLs), instrumental activities of daily living (IADLs), short physical performance battery (balance, repeated chair-stand, and timed walk tests), handgrip muscle strength, body mass index (BMI), and Mini Mental State Examination (MMSE) were collected at each the eighth waves of interview. Any ADL disability was defined as limitation in one or more of the seven ADL activities, and any IADL disability was defined as limitation in one or more of the IADL activities. General equation estimation were fitted to estimate the odds ratio (OR) of ADL and IADL disability and as a function of arthritis. General linear mixed models were performed to estimate change in short physical performance battery (SPPB) tests and handgrip muscle strength. All variables were used as time-varying except for gender and education.

Results: Thirty eight percent of the participants reported arthritis at baseline, 58% were female, and the mean years of education was 4.9. Participants with arthritis were at greater risk of any ADL [OR=1.37, 95% Confidence Interval (CI)=1.12-1.67) and IADL disability over time (OR=1.31, 95% CI=1.16-1.48) after controlling for all covariates. The total SPPB score declined 0.23 points per year among those with arthritis compared with those without arthritis (p-value =0.0105) after controlling for all covariates. The decline in handgrip muscle strength as a function of arthritis was not statistical significant.

Conclusion: Older Mexican Americans with arthritis were at higher risk of developing ADL and IADL disability and experience decline in physical function over 20-years of follow-up. Early prevention of disability will improve the quality of life in this at risk and underserved population.

Arthritis, Upper-Lower Extremity Functional Limitations, and Disability in American Older Adults: Findings from the National Health and Aging Trends Study (NHATS)

Martin A Rodriguez,[1] Jaspreet K Sodhi,[1] and Soham Al Snih[1], [1]The University of Texas Medical Branch, Galveston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To examine the effect of arthritis on upper-lower extremity (UE-LE) functional limitations and disability over 6-years of follow-up among American older adults.

Methods: Data are from a 6-year prospective cohort study of 5716 American older adults aged 65 years and older residing in the community from the National Health and Aging Trends Study (NHATS 2011-2016). Data on self-reported arthritis, socio-demographic variables, medical conditions (hypertension, diabetes, stroke, heart attack, cancer or hip fracture), overall pain, activities of daily living (ADLs), body mass index (BMI), and UE-LE activities (able to put a heavy object or reach above the head, able to open a jar or grasp small objects, able to carry 20 or 10-pounds, able to walk 6 or 3-blocks, able to walk up 20 or 10-stairs, get down on knees, and able to bend over) were collected. UP-LE functional limitation was defined as limitation in one or more of the four activities for UE and one or more of the six activities for LE. ADL disability was defined as limitation in one or more of the six ADL activities. General estimation equation model was fitted to test the effect of arthritis on UE-LE disability over time. All variables were analyzed as time-dependent variable except gender, education and race/ethnicity. Analysis for any UE-LE functional limitations where performed among those who reported no limitations in UE-LE at baseline. Analysis for any ADL disability were performed among those who reported no ADL disability at baseline. Interaction effect between arthritis and race/ethnicity was performed.

Results: At baseline, 53% reported arthritis, 54.8% were female, 85.3% were Non-Hispanic White, 8% were Non-Hispanic Black, 7% were Hispanic, 17.8% reported UE functional limitations, 68.9% reported LE functional limitations, and 10% reported ADL disability. Participants with arthritis were at greater risk for any UE functional limitations [OR=1.72, 95% Confidence Interval (CI)=1.44-2.06), any LE functional limitations (OR=1.47, 95% CI=1.17-1.83), and any ADL disability (OR=1.59, 95% CI=1.32-1.90) after controlling for all covariates. Hispanics with arthritis were at greater risk for any ADL disability (OR=2.84, 95% CI=1.34-6.01) compared with Non-Hispanic Whites.

Conclusion: American older adults with arthritis were at higher risk of developing upper and lower extremity functional limitations, and ADL disability than those without arthritis over 6-years of follow-up. Hispanic older adults were at higher risk of developing ADL disability than Non-Hispanic White older adults.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Comparing the outcomes of an intervention in a clinical trial versus an observational study might help identify challenges in translating results from clinical trials to clinical practice. We aimed to describe differences in follow-up data of a clinical trial and an observational study using an empirical example and to evaluate selected methods to account for differences in missing data patterns.

Methods: We used data from two Norwegian rheumatoid arthritis (RA) cohorts, the ARCTIC randomized controlled trial (RCT) and the NOR-VEAC observational study. Both included treatment-naïve patients, implementing treat-to-target strategies. The outcome in the current study was achievement of remission according to the Disease Activity Score in 28 joints at 6, 12 and 24 months. For all analyses, we balanced the cohorts on baseline covariates using inverse probability of treatment weights. As a naïve analysis, we used unadjusted logistic regression in a subset of patients with complete follow-up data. Then, we analyzed the full dataset, combining multiple imputation by chained equations (MICE) to handle missing variables at existing visits and inverse probability of censoring weights (IPCW) to handle missing data due to drop-out. Further, we used three different approaches to handle intermittent missing visits, i.e. missing visits in patients with subsequent study visits: I) Censoring each patient at the first missing visit, II) Ignoring the missing data from single intermittent missing visits and III) Imputing the outcome variables of intermittent missing visits using MICE.

Results: We included 183 patients from the ARCTIC trial and 277 patients from the NOR-VEAC study. During follow-up, missing data in the ARCTIC trial were mainly a result of missing visits due to patients dropping out of the study, whereas missing data in the NOR-VEAC study were a result of missing variables at existing visits, intermittent missing visits or missing visits due to drop-out (**Figure 1**). The naïve complete case analyses resulted in estimates favoring outcomes in the ARCTIC trial at all study visits during follow-up (**Table 1**). Combining MICE and IPCW with three different approaches to handle intermittent missing visits yielded similar estimates at 6 months and attenuated estimates at 12 and 24 months (**Table 1**). At 24 months, odds ratios (ORs) with 95% confidence intervals for reaching remission in the ARCTIC trial vs. the NOR-VEAC study were 1.6 (0.9-2.7) for the complete case analyses and for the combination of MICE and IPCW, 1.4 (0.8-2.6) for the strict censoring approach, 1.6 (0.9-2.8) for the approach ignoring intermittent missing visits and 1.4 (0.8-2.5) (**Table 1**).

Conclusion: We observed more complex missingness patterns during follow-up in an observational study than in a RCT. The use of methods to account for missing data became more important with longer follow-up time. Compared to complete case analyses, the precision of the effect estimates improved using MICE and IPCW in combination with

Figure 1 Patterns of missing data in the ARCTIC trial and the NOR-VEAC observational study

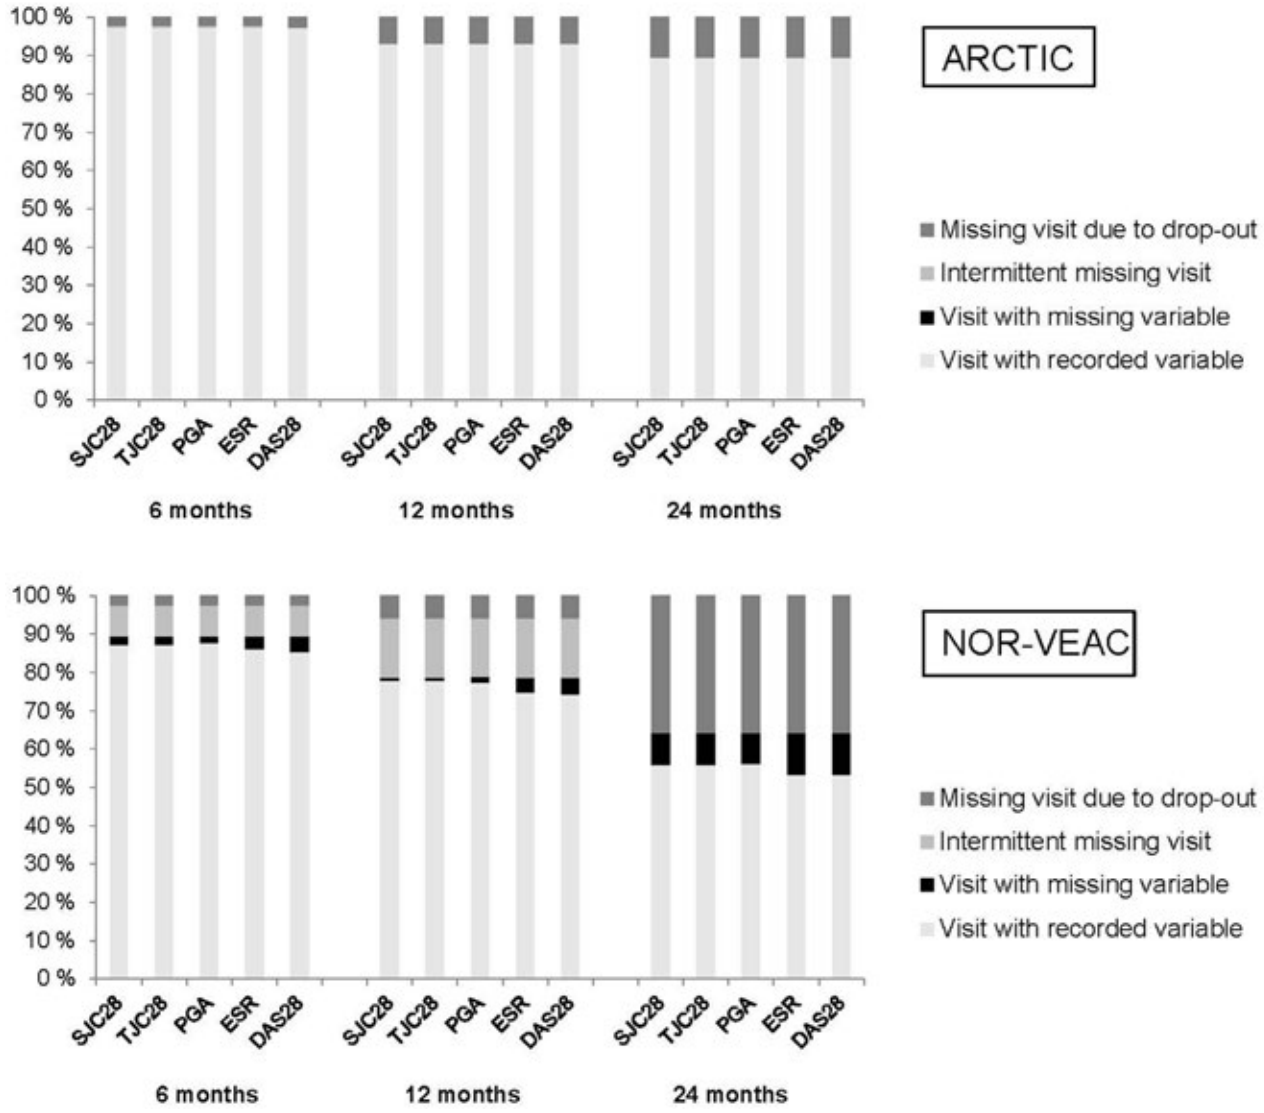

Figure 1 Patterns of missing data during follow-up in the ARCTIC trial and the NOR-VEAC observational study

three different approaches to account for intermittent missing visits. The strict censoring approach might be preferable due to the balance of more precise estimates and simplicity of implementation.

Table 1 Achievement of DAS28 remission at 6, 12 and 24 months in the ARCTIC trial compared to the NOR-VEAC study[3]

	6 months		12 months		24 months	
	OR (95% CI)	*p*-value	OR (95% CI)	*p*-value	OR (95% CI)	*p*-value
Complete case analyses[2]	1.46 (0.96 – 2.21)	0.08	2.15 (1.30 – 3.56)	0.003	1.60 (0.93 – 2.74)	0.09
Combining MICE and IPCW with 3 approaches for intermittent missing visits:[3]						
I: Strict censoring	1.43 (0.91 – 2.26)	0.13	1.73 (1.03 – 2.91)	0.04	1.42 (0.79 – 2.55)	0.24
II: Ignoring intermittent single missing visits	1.47 (0.94 – 2.29)	0.08	1.72 (1.04 – 2.84)	0.04	1.60 (0.93 – 2.76)	0.09
III: Imputing intermittent missing visits	1.45 (0.94 – 2.23)	0.10	1.67 (1.01 – 2.76)	0.05	1.42 (0.83 – 2.45)	0.20

[1]All analyses were performed after balancing the cohorts on baseline covariates using inverse probability of treatment weighting on the propensity scores.
[2]Unadjusted logistic regression model.
[3] Logistic regression models with inverse probability of censoring weights (IPCW). Multiple imputation by chained equations (MICE) was used to impute missing variables at existing visits. Approaches to account for intermittent missing visits: I, censoring at first missing visit; II, ignoring single intermittent missing visits by only including a missing indicator, but censoring if >1 subsequent intermittent visits missing; III, imputing intermittent missing visits using MICE.
DAS28, Disease Activity Score 28 joints; OR, odds ration; CI, confidence interval.

Association Between Anemia and Hyperuricemia: Korean National Health and Nutrition Survey 2016-2017

Seulkee Lee,[1] Yeonghee Eun,[1] Jiwon Hwang,[2] Hoon-Suk Cha,[1] Eun-Mi Koh,[1] Jaejoon Lee,[1] and Hyungjin Kim[1], [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia and anemia may be related in terms of sharing comorbidities such as chronic kidney disease (CKD) and cardiovascular disease. However, to our knowledge, no studies have been conducted on the relationship between two conditions. The purpose of this study was to investigate the association between hyperuricemia and anemia using data from Korean National Health and Nutrition Examination Survey (KNHANES VII; 2016-2017), which is representative of the Korean population.

Methods: The present study included 10794 participants aged ≥ 19 years from KNHANES VII. Logistic regression was used to examine the association between anemia and hyperuricemia. Subgroup analysis was performed to confirm whether the association between two conditions varies according to participant characteristics.

Results: Because there were significant differences in baseline characteristics with and without hyperuricemia between subjects with CKD and subjects without CKD, we analyzed the association between hyperuricemia and anemia separately in subjects with and without CKD. The association between anemia and hyperuricemia was not evident in subjects without CKD, but the risk of hyperuricemia in patients with CKD was 2.2 times higher in patients with anemia. This association was also maintained when the glomerular filtration rate was adjusted (HR 2.34, 95% CI 1.20-4.56). In subgroup analysis, the association of anemia with hyperuricemia was significant in subjects aged 65 years and older, in men, in subjects with diabetes or hypertension, and in subjects with CKD. Subgroup analysis of subjects with CKD showed similar results.

Conclusion: In a Korean representative sample, the association of anemia with hyperuricemia was evident in CKD patients, which remained significant when GFR was adjusted. In addition, anemia and hyperuricemia were well correlated with older age, men, and comorbidity such as diabetes or hypertension.

Clinical, Serologic and Morphologic Features of Interstitial Pneumonia with Autoimmune Features (IPAF): A Single Center Experience

Michael Allen,[1] Emily Press,[1] Aditi Mathur,[1] Sakshi Dua,[2] Maria Padilla,[2] and Ioannis Tassiulas[2], [1]Icahn School of Medicine at Mt Sinai, New York, [2]Icahn School of Medicine, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) encompasses a group of disorders that are classified together based on similar clinical, radiographic and pathologic findings. ILD is highly associated with autoimmune connective tissue diseases (CTD), and the diagnosis of ILD necessitates investigation into the possibility of an occult CTD. In a substantial number of cases, this investigation reveals evidence of autoimmunity, serologically, clinically or in both domains, without fulfilling criteria of a specific CTD. This disease category has been termed interstitial pneumonia with autoimmune features (IPAF). The goal of this study was to describe the characteristics of a cohort of ILD patients that fulfil the IPAF criteria.

Methods: The study patients were identified from a Mount Sinai Hospital-Department of Pulmonary Medicine registry of patients with ILD. All of the patients were diagnosed with ILD based on either a high resolution CT (HRCT) of the chest or a lung biopsy. The electronic medical records were reviewed to determine if they fulfilled clinical and/or laboratory IPAF criteria. The radiology report from each patient's HRCT was reviewed as well as pathology reports from lung biopsies when available. Patients were excluded if they fulfilled classification criteria for a specific autoimmune CTD, or if there was insufficient data to evaluate their case in each of the three domains in which IPAF is assessed (clinical, serologic, morphologic).

Results: Of 429 patients in the ILD registry, 32 met criteria for IPAF. Nineteen were female (59%) and 13 were male (41%). Twenty-nine out of 31 patients (91%), met serologic criteria for IPAF, with the most common being an ANA >1:320 in a diffuse, speckled or homogeneous pattern (16/32). The next most common serologic criterion was anti-

CCP positivity (6/32). Other serologic criteria that were present in the study cohort included anti-Ro positivity (4/32), anti-RNP (3/32), ANA< 1:320 in a nucleolar pattern (2/32) and anti-tRNA synthetase (1/32). Fifteen of the 32 patients (47%) met clinical criteria for IPAF. Presence of Raynaud's phenomenon was the most common (11/32) followed by inflammatory arthritis (5/32), digital edema (2/32) and palmar telangiectasia (2/32). Twenty-eight of the 32 patients (88%) met morphologic criteria for IPAF. Non spesific interstitial pneumonia (NSIP) on HRCT or on biopsy was the most common morphologic criterion (20/32). Other morphologic criteria included unexplained: pleural thickening (3/32), intrinsic airway disease (2/32), pulmonary vasculopathy (1/32), diffuse lymphoplasmacytic infiltrates on lung biopsy (1/32), and pericardial effusion or thickening (1/32).

Conclusion: In a single center, retrospective cohort of patients who meet the IPAF criteria, the great majority of patients have serologic and morphologic findings that support the diagnosis (91% and 88%, respectively). However, less than half of the patients in this cohort (47%), demonstrated clinical features of a systemic autoimmune disease. Identifying patients with IPAF early during the disease course may be important since there is evidence of a favorable response to immunosuppressive therapy.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: New user designs are typically preferred in pharmacoepidemiology to avoid bias. The optimal implementation of a new user design in electronic medical record (EMR) data, where the concept of 'enrollment' does not necessarily exist, has not been well studied.

Methods: We used data from PCORnet, a large U.S. comparative effectiveness research network consisting of multiple EMR data sources from both academic and community practices, to compare various new user definitions in 5 PCORnet datamarts, focusing mainly on rheumatoid arthritis (RA) but examining other conditions (e.g. vasculitis) as exemplar use cases. The first prescription appearing in the data for medications of interest (e.g. methotrexate [MTX], biologic, targeted therapy) was identified in the EMR prescribing data. Five new user definitions with varying requirements for the amount and type of prior EMR data needed to construct a 'baseline' period were evaluated. New user definitions tested included 0) no requirement for any prior data; 1) >6 months (m) from first medical inpatient or outpatient medical encounter of any type; 2) >6m from first prescription [Rx] for any medication; 3) >6m from first medical encounter for disease indication (e.g. RA, vasculitis); 4) >6 m from first prescription for any disease-specific

rheumatologic therapy. The rate of hospitalized infection, where a time-dependent hazard was expected, and herpes zoster, where minimal time-dependent hazard was expected, was examined according to various new user definitions. Infections were ascertained over 6- and 12-month follow-up periods, using a first-exposure carried forward approach.

Results: A total of 6621 RA patients initiated one of 9 unique DMARDS, biologics or targeted medications. Mean (SD) age was 55(16) years, 78% women, 43% MTX, 38% TNFi biologics; 19% non-TNFi therapy, 38% oral glucocorticoids. The proportion of person-time represented in the new user analysis across the five definitions was: 100% (base case, 1st Rx is index date with no prior data required), 83% (>6m from first visit), 57% (>6m from first Rx of any type), 71% (>6m from first RA visit), and 29 % (>6m from first RA drug), respectively. The rate of hospitalized infection generally was numerically higher, although < 1-2/100py difference, using 6 month vs. 12 month followup. The crude rate of serious infections by exposure was sometimes but not always numerically higher using the more specific new user definitions (3 and 4) but meaningfully reduced exposure time, especially for 1st line therapies (e.g. methotrexate) and in diseases where sample size was small to begin with (e.g. vasculitis). In contrast, rates of herpes zoster varied minimally by new user definition.

Conclusion: A range of tradeoffs exist in how to best apply new user definitions to multi-specialty EMR data that will affect patient selection and outcome ascertainment. More rigorous and specific definitions are likely preferred for most pharmacoepidemiology studies to avoid bias but must be balanced against feasibility and may need to differ by disease and by outcome.

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Certolizumab pegol (CZP) is an anti-TNF drug approved for rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA), psoriasis (PSO) and Crohn's disease (CD). Older age, comorbidities and corticosteroid (CS) use have been linked to increased risk of serious infectious events (SIEs) in CZP-treated patients (pts) with RA.[1] However, the impact of overall disease burden on the risk of serious adverse events (SAEs) has not been fully examined for other CZP indications. High body mass index (BMI) has been linked to systemic inflammation and comorbidity risk.[2,3] Greater disease burden in these pts may lead to increased CS use – a known risk

Table: Cox proportional hazards models of time to first SAE of interest

The above variables result from a stepwise selection procedure with p>0.25 for entry and retention into the model. A covariate was defined as a risk factor if p≤0.05. All p values are nominal and should be interpreted in an exploratory manner. axSpA: axial spondyloarthritis; BMI: body mass index; CD: Crohn's disease; CI: confidence interval; CS: corticosteroid; HR: hazard ratio; MACE: major adverse cardiovascular events; MTX: methotrexate; PsA: psoriatic arthritis; PSO: psoriasis; RA: rheumatoid arthritis; Ref.: reference category used as denominator in the hazard ratio calculations; SIE: serious infectious event; yrs: years.

factor for SAEs.[1] This study aimed to examine the contribution of BMI and CS use to the risk of SIEs, malignancies and major adverse cardiovascular events (MACE) in CZP-treated pts across indications.

Methods: Safety data were pooled across 49 CZP clinical trials (27 RA, 1 axSpA, 1 PsA, 5 PSO, 15 CD). SAEs of potential concern were medically reviewed by an external expert committee using predefined case rules.[4] Incidence rates (IR) were calculated per 100 pt-years (PY). Multivariate Cox modeling was used to estimate relative risk (hazard ratio [HR]) of time to first SIE, malignancy or MACE by baseline BMI (< 18.5, 18.5–< 25, 25–< 30, ≥30 kg/m^2) and CS use (yes, no). The model was adjusted for baseline age, sex, disease duration, methotrexate (MTX) use, prior anti-TNF drug use, and CZP indication.

Results: Across indications, 11,317 pts received CZP (21,695 PY total exposure; max: 7.8 years [yrs]; exposure for RA: 13,542 PY; axSpA: 978 PY; PsA: 1,316 PY; PSO: 1,481 PY; CD: 4,378 PY). Mean BMI was 27.8 kg/m^2 in RA, 27.6 kg/m^2 in axSpA, 29.8 kg/m^2 in PsA, 30.1 kg/m^2 in PSO, and 24.0 kg/m^2 in CD. Overall, 4,132 pts (37%) used CS at baseline, more so in RA (46%) and axSpA (51%). Across indications, IRs were 0.82/100 PY for all malignancies (0.66/100 PY excluding non-melanoma skin cancer [NMSC]), 0.47/100 PY for MACE, and 3.62/100 PY for SIEs. According to the Cox model, age ≥45 yrs, disease duration < 1 yr (compared with ≥5 yrs), and no MTX use were risk factors for malignancies (including NMSCs); BMI and CS use did not have a detectable impact (**Table**). MACE risk was higher in RA and PsA; BMI ≥30 kg/m^2 was a risk factor for MACE, in addition to age ≥45 yrs and male sex (**Table**). Compared with RA, SIE risk was higher in CD and lower in PSO and PsA; key risk factors included age ≥65 yrs, disease duration ≥10 yrs and CS use. Without CS use, BMI did not impact SIE risk, but among CS users, SIE risk was higher for obese pts (**Table**)

Conclusion: In CZP-treated pts across indications, malignancy risk was not influenced by BMI or CS use. As expected, obesity and CS use increased the risk of MACE. The SIE risk associated with CS use was compounded in obese pts, which may reflect the contribution of comorbidities, disease activity or other factors not examined here.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Alcohol consumption is a common, but declining, lifestyle behaviour of UK adults. Previous research has shown that among people with rheumatoid arthritis (RA) moderate drinkers report reduced symptom severity (e.g. pain) compared to non-drinkers, leading some to argue that moderate alcohol consumption may be beneficial for the management of chronic pain conditions. Little is known whether alcohol consumption may also reduce fatigue severity despite fatigue and pain sharing a number of common risk factors and possible mechanisms. This study sought to determine whether alcohol consumption was associated with levels of fatigue severity.

Methods: 270 participants recruited to the QUAlity of life, Sleep and rheumatoid ARthritis study (QUASAR) recorded fatigue and pain severity, measured on an ordinal scale from 1 (none) to 5 (very severe), daily for 30 days using a smartphone app. Average weekly alcohol consumption (in units) was reported at baseline and categorised as none- (0), moderate- (1-15) and heavy-drinkers (16+). Participants also reported an assessment of disease activity (Routine Assessment of Patient Index Data 3; RAPID-3), number of co-morbidities and medications and mental health (Hospital Anxiety and Depression (HAD) scale). Ordinal probit models with random effects tested the independent relationship between alcohol consumption and fatigue severity over time. The model was cumulatively adjusted for disease activity, pain, medications and co-morbidities, and mental health, and marginal effects were calculated. Results are presented as percentage point change in the probability of reporting severe or very severe fatigue and 95% confidence intervals (95%CI).

Table – Marginal effects for the probability of fatigue severity reporting (95% confidence intervals) †Referent category 0 units. ‡adjusted for age, sex and day(time). Bold denotes statistical significance

Results: Of 267 participants who provided alcohol and fatigue data, 107 (40%) were non-drinkers, 139 (52%) were moderate-drinkers and 21 (8%) were heavy-drinkers. Compared to non-drinkers, moderate- and heavy-drinkers were 11 (95%CI:-0.18—0.03) and 12 (-0.22—0.01) percentage points less likely to report severe fatigue, respectively. Both groups were 1 percentage point less likely to report very severe fatigue compared to non-drinkers (-0.02—0.002; -0.02—0.001, respectively). The relationship between alcohol consumption and fatigue severity was attenuated and became non-significant upon adjustment all co-variates. Fatigue severity was predicted by concurrent pain reports, depressive mood and the number of medications, but not RAPID-3 (Table).

Conclusion: In contrast to previous research, we did not find alcohol consumption, at a moderate or heavy level, to be independently associated with fatigue severity over time. It is unlikely that moderate consumption of alcohol will be directly beneficial for those seeking to manage fatigue. Instead, greater benefits may be obtained through the use of management strategies which target pain, medication use, and mood.

Co-morbidities in Patients with OA and RA: Results from a Large US Rheumatic Disease Registry

Sofia Pedro,[1] Rebecca Schumacher,[1] Alyssa Dominique,[2] Yomei Shaw,[1] Kristin Wipfler,[1] and Kaleb Michaud[3], [1]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [2]Bristol-Myers Squibb, Princeton, NJ, [3]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The burden of co-morbid conditions can impact the overall quality of life in patients with RA and OA. However, the presence of common co-morbidities in inflammatory and degenerative arthritis is not well described. We sought to compare overlapping co-morbidities in the two patient groups.

Methods: We identified patients with physician-diagnosed OA and RA in FORWARD, The National Databank for Rheumatic Diseases, a large US registry with comprehensive 6-month questionnaires from 1998 through 2018, with patients primarily recruited through rheumatology clinics. Each patient with OA was age- and sex-matched to two patients with RA at study entry. We compared demographics, clinical characteristics and current and past co-morbidities between the OA and RA groups. Patient status at the last observation was further categorized as active (if they had a full follow-up questionnaire collected in the last 2 years), not active, or lost to follow-up/deceased. *T*-tests and Chi-square tests were used as appropriate to assess differences.

Results: Overall, 9463 patients with OA were matched to 18,926 patients with RA. Patients with OA experienced more pain compared with patients with RA (4.6 vs 4.2), but patients with RA had slightly worse HAQ scores (1.0 vs 1.1; Table 1). Higher use of NSAIDs was reported for patients with OA. Except for pulmonary and liver disorders,

Table 1. Clinical Measures and Treatment of Patients With OA and Age- and Sex-Matched RA, Characterized at Last Observation

Variable	Patients with OA n=9463	Patients with RA n=18,926	p value

Gall bladder disorder	29.8	44.6	38.7	25.8	37.7	33.8	<0.001
Fracture	21.7	38.5	35.5	18.6	37.7	30.9	<0.001
Cancer	18.0	43.5	35.5	16.1	38.4	31.8	<0.001
Asthma	26.0	32.3	34.1	20.4	27.7	30.1	<0.001
Renal disease	17.4	31.9	28.5	16.5	25.8	26.6	<0.001
Diabetes	18.3	30.7	25.9	16.0	25.8	23.5	<0.001
Myocardial infarction	8.7	25.4	15.7	8.3	23.6	15.5	0.82
Liver disease	9.7	15.7	18.4	11.6	14.6	19.5	<0.001
Cerebrovascular accident	8.3	20.0	16.6	7.4	18.9	14.2	0.18
Neurological disorder	10.0	16.4	23.5	7.5	11.7	15.1	<0.001

which were more prevalent among patients with RA, patients with OA had a higher prevalence of the majority of co-morbidities, with an average overall disease co-morbidity index of 2.3 vs 2.1 for patients with RA. Presence of overlapping autoimmune disease was also higher for patients with OA (OA vs RA: 8.4% vs 3.1%). The most frequently reported co-morbidities (OA vs RA) were hypertension (69% vs 66%), gastrointestinal disorders (67% vs 63%) and psychiatric disorders (55% vs 48%) (Figure 1). As expected, patients who were lost to follow-up/deceased had worse outcomes and more co-morbidities than active and non-active patients both with OA and RA. Patients who were not active had more co-morbidities than active patients, revealing an informative drop-out (Table 2).

Conclusion: Patients with OA reported more overlapping co-morbidities than patients with RA, even after age- and sex-matching. Although RA has a much more complex etiology, affecting more organ systems, our data suggest that the burden of having OA in terms of overlapping symptoms and other problems is not negligible in comparison. It is possible that the advancement of medications for RA has aided in lessening the burden of disease or other co-morbidities when compared with OA. Also, this OA cohort may have increased disease severity due to seeking care from a rheumatologist.

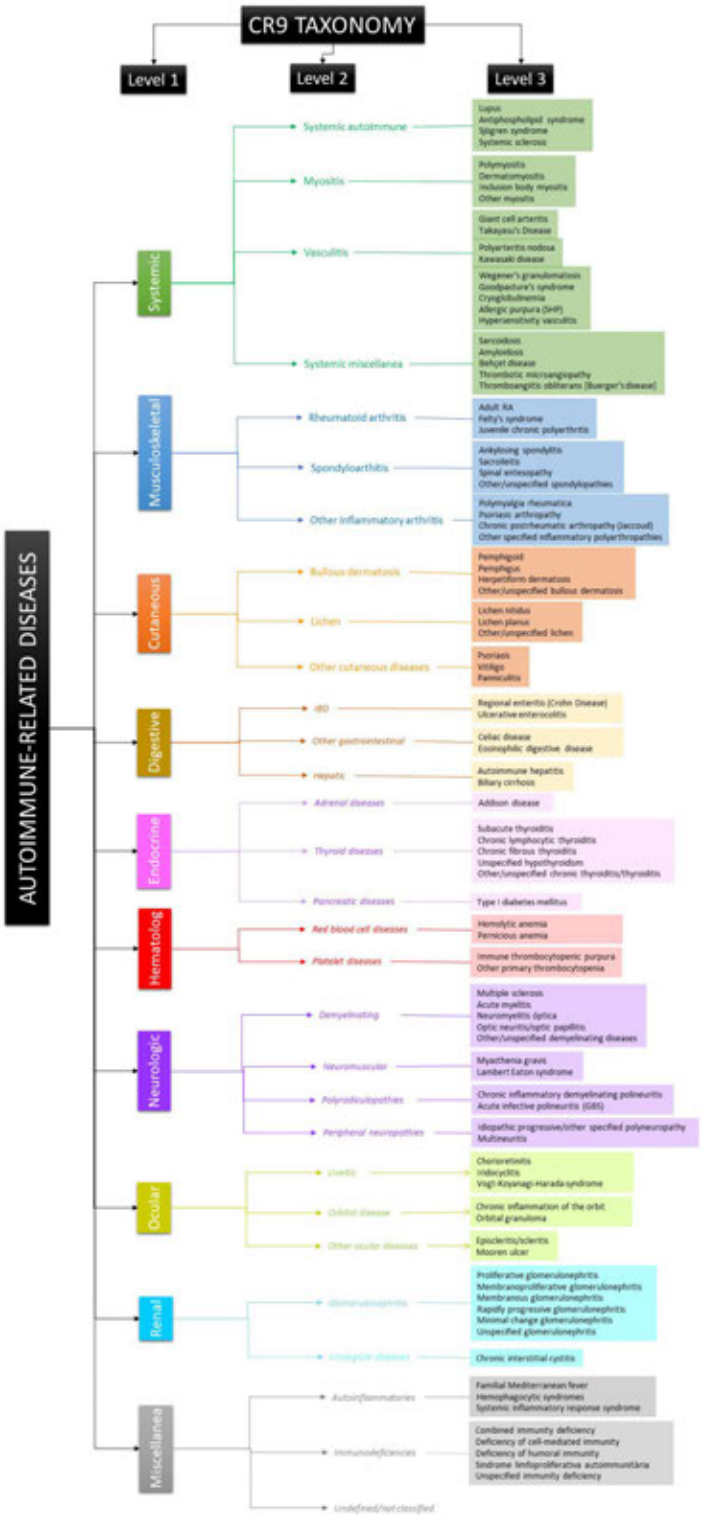
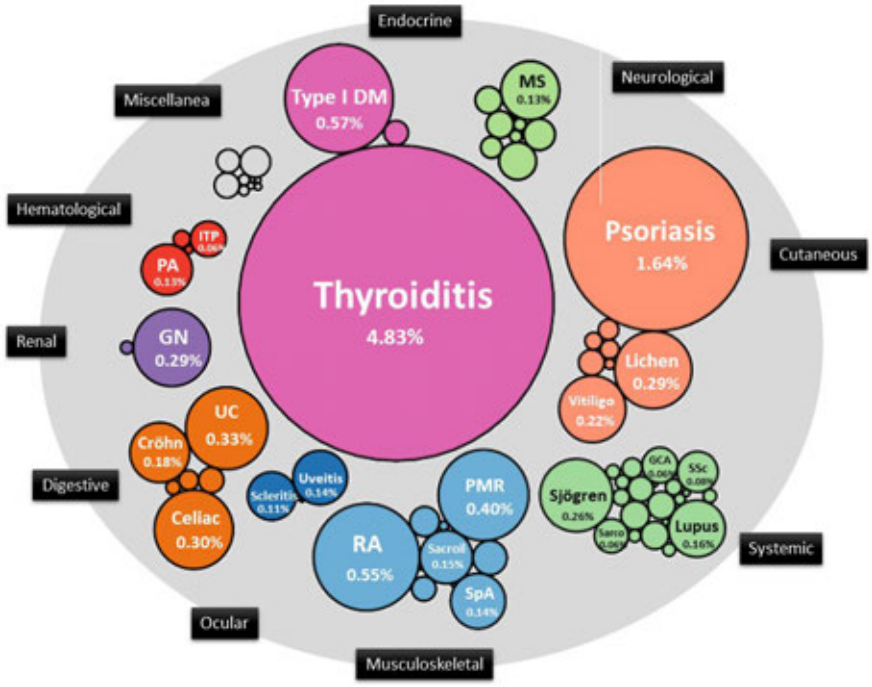
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

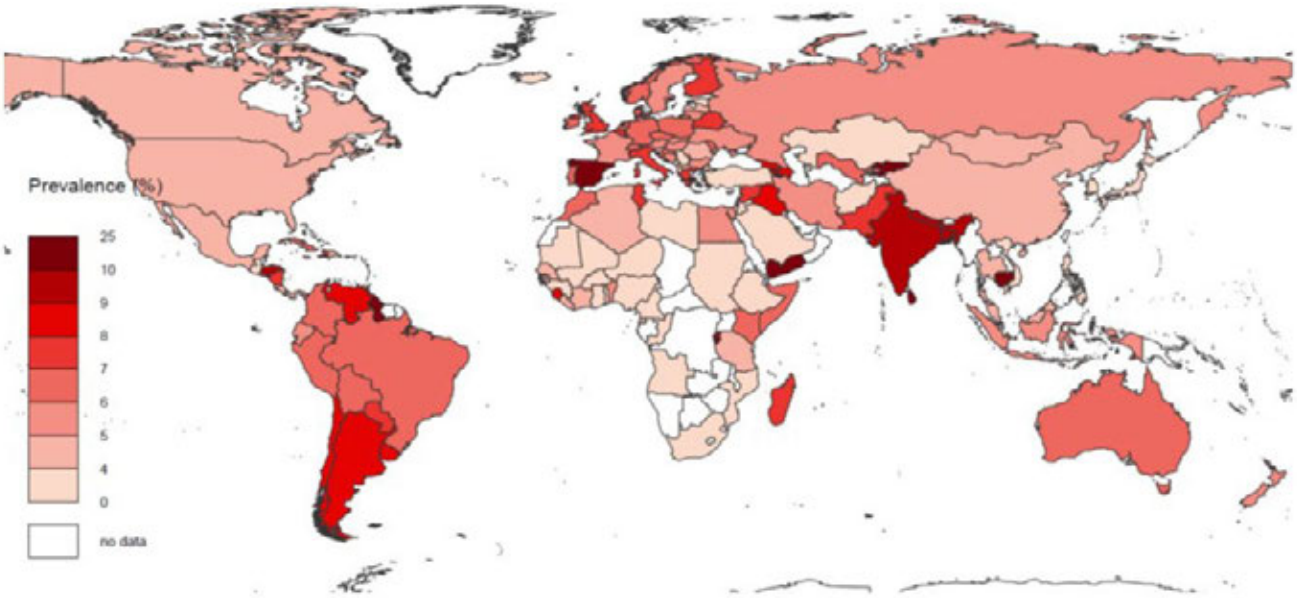
Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM





Prevalence by nationality (%) (population census > 0 habitants)



Background/Purpose: To analyze the prevalence of autoimmune diseases (ADs) in Catalonia, a Mediterranean region with nearly 8 million inhabitants using a public administrative big data program.

Methods: The MASCAT-PADRIS Project was designed in 2017 to take a "high-definition" picture of ADs in Catalonia. Individuals with ≥ 1 ICD-9-CM code for an AD recorded during the study period (January 1st, 2012 – December 31st, 2017) to be included. The prevalence rates were estimated for the main subgroups of ADs after grouping the 234 ICD-9-CM ADs codes into a 3-level taxonomy classification that included 78 individual diseases (Level 3), 28 AD subgroups (Level 2) and 10 main AD groups (Level 1) (**Figure 1**). We assumed that a patient with an AD will visit a primary care center and/or hospital at least once during the 6-year study period. Therefore, the lifetime prevalence for each individual AD was estimated as the number of individuals with ≥ 1 ICD-9-CM code during the study period divided by the mean number of people with public health coverage in Catalonia during the study period and expressed per 100,000 inhabitants.

Results: A total of 799,003 individuals had a diagnosis of AD during the 2012-2017 study period, representing a prevalence of 10.61%. Among the main individual ADs, 25 (32%) were classified as non-rare diseases (prevalence >5/10,000 inhabitants), 26 (33%) as rare diseases (prevalence 1-5/10,000 inhabitants) and the remaining 27 (35%) as very rare diseases (prevalence < 1/10,000 inhabitants). The 10 main individual ADs with the highest prevalence rates were thyroiditis (4.83%), psoriasis (1.64%), type I diabetes mellitus (1.90%), rheumatoid arthritis (0.58%), polymyalgia rheumatica (0.40%), ulcerative colitis (0.33%), lichen planus (0.31%), celiac disease (0.31%), glomerulonephritis (0.29%) and Sjögren syndrome (0.26%) (Figure 2). Of the 799,003 Catalans with ADs, 531,064 (66.46%) were women, with a female:male ratio of 2:1; only 20 (16 were rare diseases) out of the 78 main ADs (26%) were more frequently reported in men. The ADs most frequently reported in woman were Sjögren syndrome (ratio 6:1) biliary cirrhosis (ratio 5.5) and systemic lupus erythematosus (ratio 4.8:1), while ankylosing spondylitis (ratio 1.7:1), type I diabetes mellitus (1.3:1) and psoriasis (1.3:1) were more frequently reported in men. With respect to the country of birth, a south-to-north gradient of higher frequencies was found. For the main individual ADs, some countries had at least three ADs with a higher prevalence than native-born Catalans (India, Pakistan, Paraguay, Honduras, Morocco and the UK). Some ADs showed a geographically-driven higher prevalence: inflammatory bowel disease and multiple sclerosis in European countries, sarcoidosis in India, Pakistan, Morocco and Paraguay, vitiligo in India, Pakistan, Morocco and all Latin American countries, and thyroiditis in India, Honduras and Argentina (Figure 3).

Conclusion: Autoimmune diseases, although sharing a common etiopathogenic basis, are characterized by wide individual heterogeneity in their frequency, organ-specific phenotype, gender ratio, age predominance and ethnic influence.

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Thyroid dysfunction (TD) is known as a common complication of rheumatological diseases (RD). Treatment for TD is important not only in clinical TD for controlling symptom but also in some patients with subclinical ones especially for cardiovascular events in the future. But the data about prevalence of hypothyroidism or hyperthyroidism requiring treatment and it's changes with follow up in patients with RD is limited.

Methods: We retrospectively reviewed charts of consecutive patients with RD and healthy controls who checked TSH (thyroid stimulating hormone) level at least once at immuno-rheumatology center and preventive medicine center, in St. Luke's International Hospital, Tokyo, Japan, from January 2004 to July 2018. We investigated basic demographics, underlying diseases, blood tests including thyroid functions and treatment with thyroid hormone or antithyroid medications. We compared the number of TD requiring treatment (TSH ≧10 μU/mL, TSH ≦0.1 μU/mL or

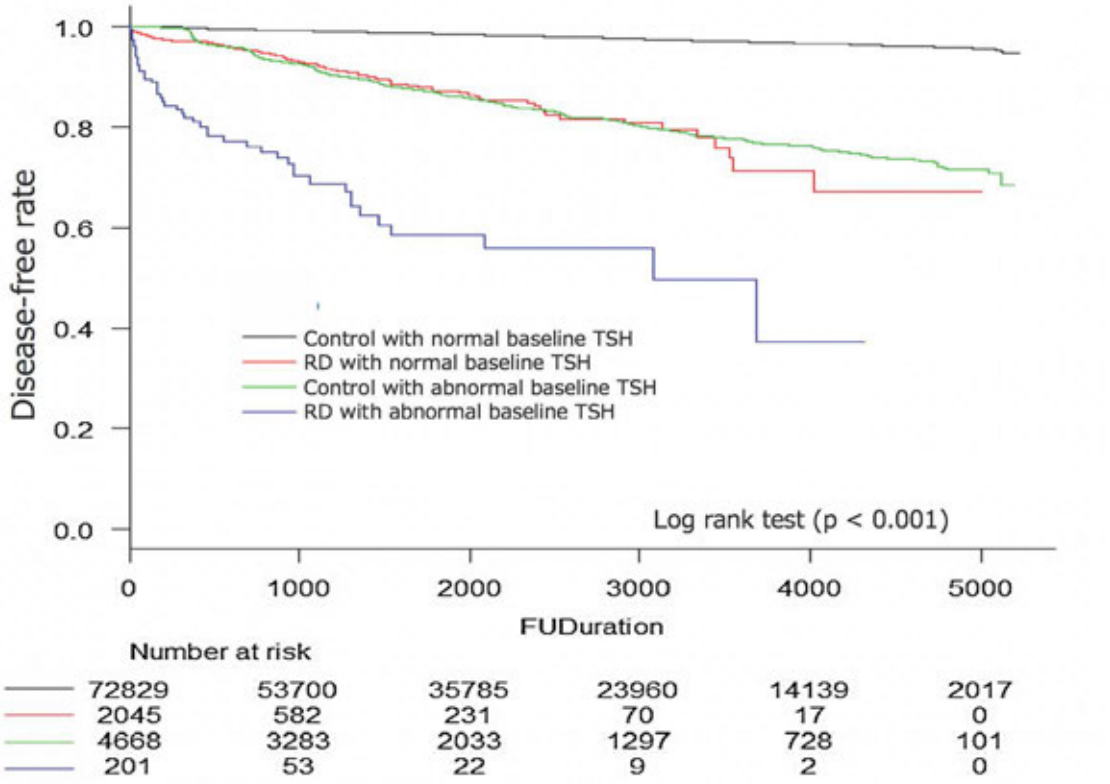
Figure1. Kaplan–Meier curve of TD with treatment indication and RD with or without baseline abnormal TSH level in patients without treatment indication at baseline



physician started treatment) and it's changes in follow up using univariate analysis and Kaplan–Meier method with log rank test. The risk of TD which needs treatments was assessed with Cox proportional hazard model in all subjects and logistic regression analysis in RD patients.

Results: 2307 RD patients and 78251 controls without past medical history of TD requiring treatments are included. Newly-detected TD requiring treatments are significantly frequent in RD patients (214, 9.3% vs 2828, 3.6%, P< 0.001). When focused on patients without TD requiring treatment at baseline, Kaplan–Meier method and Cox's proportional hazards model revealed hazard ratio of TD with indication of treatment is significantly higher in RD patients with baseline abnormal TSH(≦0.45 or ≧4.5 μU/mL) (HR=32.6; 95%CI 24.3-43.9, p< 0.001), RD with normal baseline TSH (HR=7.5; 95%CI 6.1-9.2, p< 0.001), control with abnormal TSH (HR=8.5; 95%CI 7.8-9.3, p< 0.001) when compared to controls with normal TSH at baseline after adjusting confounders. When focus on RD patients, female, patients with ANA(anti-nuclear antibody) related disease, baseline abnormal TSH level, and positive thyroid-related antibodies at baseline have statistically significant higher risk of TD requiring treatment after adjusting confounders in multivariate analysis.

Conclusion: TD with therapeutic indication are much more frequent in RD patients, especially with abnormal baseline TSH level, and about 1 out of 10 RD patients has TD requiring treatment. We encourage active routine measurement of thyroid function tests in RD patients especially with above risk factors.

The Association of Serum Uric Acid Levels and the Risk of Lower Urinary Tract Symptoms in Korean Healthy Adults

Jiwon Hwang,[1] Seung-ho Ryu,[2] and Joong Kyong Ahn[3], [1]Division of Rheumatology, Department of Internal Medicine, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon-si, Republic of Korea, [2]Department of Occupational and Environmental Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Along the aging process, men frequently appeal lower urinary tract symptoms (LUTS). The impact of LUTS on quality of life and mental health was apparent regardless of the East and West. Recently, uric acid (UA) has emerged as a modulator of prostate cells. Because UA acts like two-faced Janus, antioxidants or pro-oxidants, depending on its chemical microenvironment, hyperuricemia has been proposed to link to various diseases independent of crystal formation. Although UA has been shown to play a role in prostate pathology, there has been scarce investigation between UA and LUTS, irrespective of prostatic hyperplasia and prostate cancer. Therefore, we performed this study to assess the relationship serum uric acid (SUA) levels and the incidence of LUTS using a large sample of Korean middle-aged men who underwent comprehensive health screening exams.

Uric acid level (mg/dl)	Person-years	Incident case	Incidence Density (per 1000 person-years)	Age-adjusted HR (95% CI)	Multivariate-adjusted HR[a] (95% CI)	
					Model 1	Model 2
<5.5	96,895.1	3,994	41.2	1.00 (reference)	1.00 (reference)	1.00 (reference)
5.5-6.4	125,703.0	4,715	37.5	0.98 (0.94-1.02)	0.99 (0.95-1.03)	1.00 (0.96-1.05)
6.5-7.4	88,701.7	3,134	35.3	0.96 (0.92-1.01)	0.97 (0.92-1.02)	1.00 (0.95-1.06)
7.5-8.4	35,049.3	1,216	34.5	0.98 (0.92-1.04)	0.99 (0.93-1.06)	1.03 (0.96-1.11)
8.5-9.4	9,626.9	291	30.2	0.88 (0.78-0.99)	0.90 (0.80-1.02)	0.98 (0.86-1.12)
≥9.5	3,006.6	74	24.6	0.73 (0.58-0.92)	0.74 (0.58-0.93)	0.77 (0.59-0.99)
P for trend				0.008	0.039	0.850

Hazard ratios (95% CI) of significant lower urinary tract symptom by uric acid level

Methods: A cohort study was performed in 101,091 Korean men, free of LUTS at baseline, who underwent health check-ups from 2011 to 2016. LUTS were assessed using the International Prostate Symptom Score (IPSS) and clinically significant LUTS were defined as an IPSS score ≥8. Men are divided into 6 groups according to SUA level in mg/dl (< 5.5, 5.5–6.4, 6.5–7.4, 7.5–8.4, 8.5–9.4, and ≥9.5). Hazard ratios (HRs) and 95% confidence intervals (95% CIs) for incident LUTS were estimated using Cox proportional hazards regression analysis. Stratified analyses were also conducted in pre-specified subgroups: age (< 50 vs. ≥50 years), smoking (none vs. ever smoker), alcohol consumption (< 20 g/day vs. ≥20 g/day), physical activity (health enhancing physical activity; no vs. yes) and body mass index (BMI) (< 25 kg/m^2 vs. ≥25 kg/m^2).

Results: During a total of 358,982.6 person-years of follow-up, 13,424 people developed significant LUTS (incidence rate, 37.3 per 1,000 person-years). In a multivariable model adjusted for age, center, year of screening examination, education level, BMI, alcohol intake, regular exercise, hypertension, diabetes mellitus, and estimated glomerular filtration rate, the highest level of SUA (< 9.5mg/dl) was associated with decreased risk of significant LUTS. The multivariable-adjusted HR for significant LUTS in the highest SUA categories compared with the reference category (< 5.5mg/dl) was 0.77 (95% CI 0.59-0.99). The association of the SUA levels with the risk of significant LUTS was examined by pre-specified subgroups, and the trend of decreasing risk for significant LUTS along the increasing SUA levels was predominant in age < 50 years.

Conclusion: In this large cohort of middle-aged men, higher SUA level was predictive of decreased risk of LUTS. This suggests another important role of SUA for preventing LUTS. A further study is warranted to elucidate the biological mechanisms underlying this association.

Automated Diagnosis Extraction from Electronic Medical Records with Machine Learning Classifiers

Tjardo Maarseveen,[1] Thomas Huizinga,[1] Marcel J.T. Reinders,[1] Erik van den Akker,[1] and Rachel Knevel[1], [1]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of Electronic Medical Records (EMR) for research purposes has led to an increasing interest in Natural Language Processing (NLP) for text classification. Little preparation is required as the NLP-methods are capable of automatically interpreting the data. Classification is often accomplished with naïve word-matching. An alternative to word-matching is the usage of a Machine Learning (ML) classifier. Rather than providing a set of patterns, an ML-model only requires the outcome and then formulates the patterns itself. The purpose of this study is to build a reliable classifier with machine learning techniques that can identify the Rheumatoid Arthritis (RA) cases based on the provided EMR entry.

Methods: Data was acquired from the HiX-EMR database consisting of 2,771 patients that visited the rheumatology outpatient clinic from the Leiden University Medical Centre between 2007 and 2018. This database featured a total of 38,216 entries. The first entry (if available) was selected per patient for annotation, resulting

Table 1: Overview of the different characteristics for each classifying method

Classifying Method	*Probabilistic*	*Multiclass*	*Description*
Naïve Bayes	+	+	Simple probabilistic model that treats every feature independently
Neural Networks	-	+	Utilizes multiple 'hidden' layers with weighted connections in between to form a 'response'
Gradient Boosting	+	+	Composition of multiple weak learners (decision trees in this case)
Decision Tree	-	+	Builds a flowchart-like structure and classifies based on multiple binary decisions
SVM	-	+	Defines the most optimal boundary (hyperplane) between classes

Note: Probabilistic = model returns probabilities, Multiclass= model can be applied to data with multiple classes, Description= classifying approach of model.

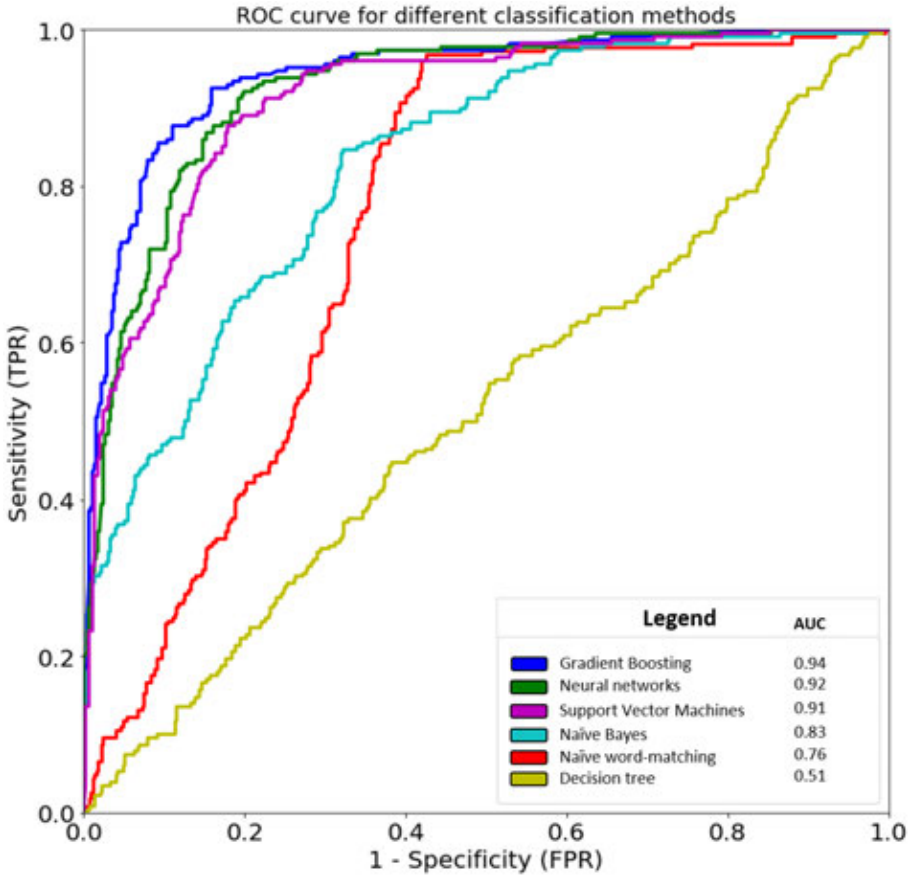

Figure 1: ROC-curve applied on both the Machine Learning models and the naïve word-matching method.

in a total of 1,361 entries. The annotated sample was then randomly split into an equally sized training and test set. Both sets were preprocessed and then classified with the following Methods naïve word-matching, Naive Bayes (NB), Decision Tree, Gradient Boosting (GB), Neural Networks and Support Vector Machines (SVM), see table 1 for more information. Default Scikit-learn implementations[2] were used to create the models, except for the word-matching model of which the classification is based on the presence of RA-defining strings like 'Reumatoide Artritis'.

Finally, the performance of the models was evaluated with a receiver operating characteristic (ROC) curve analysis via the pROC package[3]. The Delong test was used to assess the 95% confidence intervals (CI) and to determine the difference between the performance of the word-matching method and the ML-models.

Results: The naïve word-matching approach resulted in a high area under the curve (AUC=0.76). Likewise, the ML-models resulted in relatively high AUC-scores as well: NB=0.83, SVM=0.91, Neural Networks=0.92 and the GB-method with a 0.94. The Decision Tree showed the worst performance with an AUC-ROC of only 0.51. In comparison to the naïve word-matching ROC-curve, all the ML-models showed a significant difference: Decision Tree ($p< 2.2e-16$; CI=0.49-0.56), NB ($p= 4.4e-3$; CI=0.80-0.86), Neural Networks ($p< 2.2e-16$; CI=0.90-0.94), GB ($p< 2.2e-16$; CI=0.92-0.96) and the SVM ($p=4.0e-16$; CI=0.89-0.93).

Conclusion: The Gradient Boosting, Neural Networks, SVM and Naïve Bayes models all showcased a significantly better performance than the Naïve word-matching algorithm, which establishes these ML-methods as an efficient approach for data extraction from EMR.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune diseases (AD) are complex diseases associated with both genetic and environmental risk factors. In the last 10 years major advances have been made in the characterization of the genetic basis of AD. To date, very little is known on the environmental factors associated to AD. The objective of the present study was to characterize the dietary patterns of six of the most prevalent ADs, and evaluate the effect of disease on the observed changes.

Methods: A total cross-sectional cohort of 11,621 individuals from Spain encompassing six prevalent ADs (RA n=1,949; psoriasis (PS) n=2,186; PsA n=1,437; SLE n=699, ulcerative colitis (UC) n=1,415; Crohn's disease (CD) n=1,952) and healthy controls (n=1,983), was recruited through the IMID-Consortium from 2,007 to 2,012. Dietary habits were registered through a common epidemiological questionnaire, including biometric, socio-demographic and lifestyle information. For each individual, the weekly consumption frequency of 13 main food categories was recorded. Disease-specific main effects and moderation by disease activity were tested for statistical significance. Multivariate linear models were used to test for association with adjustment for main confounding covariates (e.g. age, gender, geographic region, BMI). In a subset of patients and controls with GWAS data (n=7,402) mendelian randomization (MR) was used to support the causality of disease on the observed diet variation.

Results: As expected, patients with ADs targeting the digestive system -UC and CD- showed the largest food consumption differences in comparison to healthy controls. This included a highly significant increase in bread, pasta and sweets ($P< 1e-8$ in CD, $P< 1e-5$ in UC). Like IBDs, SLE and PsA patients had a higher ingestion of sweets, and RA patients showed a higher consumption of bread ($P< 0.05$). Specifically, chronic arthritis RA and PsA had a reduced consumption of meat ($P< 5e-4$) compared to controls. RA and UC (but not CD) incorporated more fruit in their diet. Testing for association between disease activity in the three rheumatic diseases -SLEDAI for SLE and DAS28 for RA and PsA- did not support a direct association between the previous food groups with severity but revealed a positive association between dairy and disease activity in RA. Using a MR approach, we provide evidence that several of the observed dietary changes are caused by the disease. High smoking cessation rates were observed in UC, CD and SLE, but not in Ps, RA and PsA. Alcohol consumption was significantly lower in all ADs compared to healthy subjects. MR analysis showed that disease was the main cause for this change of habit in SLE ($P< 5e-11$) and RA ($P< 5e-7$), but not in PsA ($P=0.21$).

Conclusion: Using a large cross-sectional cohort of patients and controls from the Spanish population we provide, for the first time, a simultaneous analysis of the dietary habits of six autoimmune diseases. Our results confirm the high impact of IBD on diet alteration but also show multiple previously unreported associations with food categories and rheumatic ADs. Mendelian Randomization analyses support the causal effect of disease on multiple of the observed dietary changes but also suggest the presence of reverse causation.

Abstract Number: 2076

The Opioid Epidemic: The Rheumatology Response to Management of Chronic Pain

Michael Grant,[1] Alysia Kwiatkowski,[1] and Najia Shakoor[1], [1]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is the hallmark symptom of many rheumatologic conditions and chronic pain management is a major part of clinical practice in rheumatology. Therefore, as the country and medical community evaluate and respond to the opioid epidemic, rheumatologists should be in the forefront of these discussions and response. In rheumatoid arthritis (RA), chronic opioid use doubled from 2002 to 2015, with peak use in 2010 (Curtis JR et al, *Arthritis Rheum*, 2017). However, it is still unclear in which diseases in rheumatology opioid use is most prevalent and how rheumatologists have changed their management in response to the crisis. Recent studies suggest an inclination for providers to seek alternate methods of pain control, and focus on the treatment of concomitant psychiatric disease (Yvonne LC et al, Arthritis Rheum, 2018). The purpose of this study was to evaluate changes in opioid and other medication use in the management of chronic pain for common rheumatologic conditions in an outpatient rheumatology clinic of an academic medical center.

Methods: Institutional review board approval was obtained and a retrospective electronic medical chart review was performed. Patients with the primary diagnosis of fibromyalgia (FMS), osteoarthritis (OA), and RA seen in the outpatient rheumatology clinic were randomly selected from 2011 and 2017. Records were reviewed to confirm primary diagnosis, demographic information, and medication use. Specifically, opioid use with consecutive prescriptions for at least 3 month duration, and gabapentin, pregabalin, tramadol, muscle relaxant, and selective serotonin reuptake

Table. Prevalence of Medication use for Chronic Pain in Rheumatology, 2011 vs 2017

Primary Diagnosis	Year	Opioid	Tramadol	Gabapentin	Pregabalin	SSRIs	Muscle relaxers
FMS	2011	11 (22%)	**17 (34%)***	**10 (20%)***	**17 (34%)***	36 (72%)	10 (20%)
	2017	5 (10%)	**8 (16%)***	**21 (42%)***	**6 (12%)***	32 (64%)	8 (16%)
OA	2011	**17 (34%)***	**22 (44%)***	5(10%)	3 (6%)	5 (10%)	6 (12%)
	2017	**7 (14%)***	**12 (24%)***	12(24%)	1 (2%)	8 (16%)	9 (18%)
RA	2011	15 (30%)	**10 (20%)***	4 (8%)	2 (4%)	5 (10%)	**1 (2%)***
	2017	8 (16%)	**1 (2%)***	6 (12%)	2(4%)	5 (10%)	**7 (14%)***
Total Pts	2011	**43 (29%)***	**49 (33%)***	**19 (13%)***	**22 (15%)***	46 (31%)	17 (11%)
	2017	**20 (13%)***	**21 (14%)***	**39 (26%)***	**10 (7%)***	45 (30%)	24 (16%)

*p less than or equal to 0.05 (when comparing 2011 to 2017)

inhibitor (SSRI) use were evaluated. Chi squared tests were used to analyze differences in medication use prevalence between 2011 and 2017.

Results: A total of 300 patients were evaluated, 50 in each diagnosis group from 2011 and 2017. Results are summarized in the Table. In 2011, prevalence of opioid use was 34% in OA, 30% in RA, and 22% in FMS. In the groups overall, there was a significant decrease in opioid ($p< 0.001$), tramadol ($p< 0.001$) and pregabalin ($p=0.022$) use from 2011 to 2017. There were also significant increases in gabapentin use ($p=0.028$). These trends were fairly similar for all groups. Interestingly, no significant changes in prevalence were found for SSRI use any group and muscle relaxant use significantly increased in the RA group only.

Conclusion: The opioid epidemic is a national crisis. In the medical community, rheumatologists are primary contributors to the management of chronic pain and directly affected by this crisis, considering that nearly 30% of these patients were on chronic opioids in 2011. It appears that the clinical community has responded to this epidemic quite dramatically over a 6 year period by decreasing use of opioids, and interestingly tramadol, by nearly 50%, as well as increasing gabapentin use by 50%. Notably, SSRI use did not increase, but remained relatively high at 30%. Rheumatologists should be major contributors to the discussions regarding management of chronic pain and we should continue to evaluate optimal chronic pain management regimens that provide improved quality of life for our patients without substantial risk.

Population Impact Attributable to Modifiable Risk Factors for Hyperuricemia and the Fallacy of the Variance Explained

Natalie McCormick,[1] Na Lu,[2] Sharan Rai,[3] Chio Yokose,[4] Yuqing Zhang,[4] and **Hyon K. Choi**[4], [1]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [2]Massachusetts General Hosptial, Boston, MA, [3]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA, [4]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In a seminal *BMJ* paper (Prior 1986), the Tokelau Island migrant study for gout and hyperuricemia concluded preventive strategies to modify body mass, diet and patterns of alcohol use were needed to prevent gout in this migrant population living in urban New Zealand (9 times higher risk of gout vs. their non-immigrant counterparts). This and other multiple layers of epidemiologic and trial evidence suggesting the importance of obesity epidemics and lifestyle factors, are at odds with a recent *BMJ* paper (Major et al 2018) about minimal variance explained by isocaloric diets and an accompanying conclusion "Gout is genetic, and 'drinking too much beer' has very little influence on serum urate". To resolve this issue, we examined key modifiable risk factors in relation to the presence of hyperuricemia and estimated the theoretical proportion of hyperuricemia cases that could be prevented through risk factor modification. For comparison, we also estimated the variance explained for the same risk factors, which does not incorporate an exposure's prevalence in the population.

Methods: Using lifestyle, medical and diet data collected in NHANES III, we calculated adjusted prevalence ratios for hyperuricemia, adjusted population attributable risks (PAR) and the variance explained (partial R^2 from linear

Risk Factor	N of Individuals (%)	N of hyperuricemia	Multivariable prevalence ratios for hyperuricemia (95% CI)*	Multivariable serum urate level difference, mg/dL (95% CI)*
Body Mass Index (kg/m²)				
<25.0	5,789 (40)	607	1.0	0.0
25.0-29.9	5,133 (35)	1,090	1.85 (1.69 to 2.03)	0.48 (0.44 to 0.53)
30.0-34.9	2,378 (16)	729	2.72 (2.48 to 3.00)	0.84 (0.78 to 0.89)
≥35.0	1,324 (9)	508	3.53 (3.19 to 3.91)	1.11 (1.04 to 1.19)
DASH Diet Score				
1st Quintile	2,602 (18)	544	1.0	0.0
2nd Quintile	2,908 (20)	612	1.08 (0.98 to 1.19)	0.01 (-0.06 to 0.07)
3rd Quintile	3,499 (24)	706	1.11 (1.00 to 1.22)	0.04 (-0.02 to 0.10)
4th Quintile	3,075 (21)	593	1.16 (1.05 to 1.29)	0.07 (0.01 to 0.14)
5th Quintile	2,540 (17)	544	1.22 (1.09 to 1.37)	0.13 (0.05 to 0.20)
Alcohol Use (serving/day)				
0	7,564 (52)	1,555	1.0	0.0
0.01 to 0.09	1,428 (10)	237	0.95 (0.85 to 1.07)	0.00 (-0.07 to 0.07)
0.1 to 0.49	3,398 (23)	637	1.18 (1.09 to 1.28)	0.16 (0.11 to 0.21)
0.5 to 0.99	1,313 (9)	284	1.37 (1.23 to 1.53)	0.32 (0.25 to 0.40)
≥1	921 (6)	221	1.40 (1.23 to 1.58)	0.37 (0.29 to 0.46)
Diuretic Use				

Table 1. Multivariable serum urate level difference and prevalence ratio for hyperuricemia according to modifiable risk factors in the NHANES III

Modifiable Risk Factors	Exposure prevalence, %	PAR for hyperuricemia (95% CI), %	Serum urate variance explained, %	Serum urate variance explained, %*
BMI >25 kg/m²	60	44 (41 to 48)	8.3	8.9
DASH Diet Score (Bottom 4 Quintiles)	82	9 (3 to 16)	0.1	0.1
Alcohol Use	48	8 (5 to 11)	0.9	0.5
Diuretic Use	8	12 (11 to 14)	5.0	5.0

Abbreviations: BMI, body mass index. CI, confidence interval. DASH, Dietary Approaches to Stop Hypertension. PAR%, Population attributable risk percent.
*Calculated based on continuous variables except for diuretic use.

Table 2. Population attributable risk of hyperuricemia and serum urate variance explained for serum urate level according to modifiable risk factors in the NHANES III

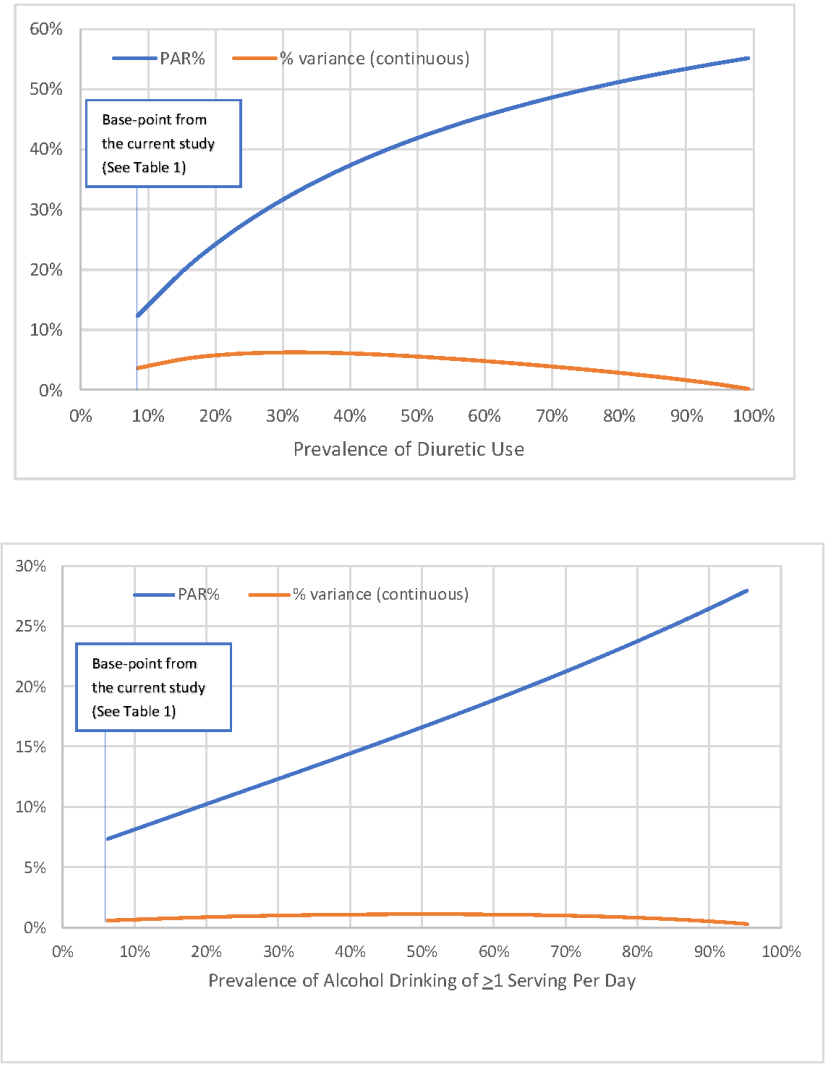

Figure 1. Population Attributable Risk vs Variance Explained According to the Prevalence of Diuretic Use (top) and Alcohol Use (bottom).

regression models) according to the following four factors: body mass index (BMI ≥25 kg/m^2), alcohol intake, non-adherence to a DASH-style diet (bottom 4 quintiles of the DASH diet score) and diuretic use. Hyperuricemia was defined as serum urate > 7.0 mg/dL among men and > 5.7 mg/dL among women. We also conducted simulation analyses to evaluate the impact on PAR and variance explained when varying the prevalence of exposure in the study population.

Results: We included 14,624 adults (mean age 47 years); 20% were hyperuricemic, 60% overweight/obese. BMI, alcohol intake, adherence to DASH-style diet, and diuretic use were all independently associated with serum urate levels and presence of hyperuricemia in a dose-response manner (**Table 1**). PARs of hyperuricemia cases for overweight/obesity, non-adherence to a DASH-style diet, alcohol use, and diuretic use were 44%, 9%, 8%, and 12%, respectively, while corresponding variances explained were 8.9%, 0.1%, 0.5%, and 5.0% (**Table 2**). Using the top half, decile and percentile of the DASH diet score as the reference group, PAR%s were 6%, 14% and 40%, respectively. Excluding those with self-reported history of gout or taking hyperuricemia drugs did not materially alter our results, nor did using an alternative definition of hyperuricemia (> 7.0 mg/dL in both sexes). Our simulation study showed the variance nearing zero with exposure prevalence's nearing 100% (**Figure**).

Conclusion: In this national sample of US men and women, four modifiable risk factors (BMI, DASH diet, alcohol use and diuretic use) independently accounted for a large proportion of hyperuricemia cases, suggesting a substantial role for modification intervention. However, the corresponding serum urate variance explained by these risk factors was far smaller and paradoxically masked their high prevalences, providing real-life empirical evidence for its limitations in assessing common environmental risk factors.

Transitions in Lumbar Spine Osteoarthritis: The Johnston County Osteoarthritis Project

Adam Goode,[1] David Hu,[2] Rebecca Cleveland,[3] Steven George,[4] Virginia Byers Kraus,[5] Todd Schwartz,[6] Richard Gracely,[7] Joanne Jordan,[8] and Yvonne Golightly[9], [1]Duke University, Department of Orthopedic Surgery, Duke Clinical Research Institute, and Department of Population Health Sciences, Durham, NC, [2]Thurston Arthritis Center, University of North Carolina - Chapel Hill, Chapel Hill, NC, [3]Thurston Arthritis Research Center, Chapel Hill, NC, [4]Duke University, Department of Orthopedic Surgery and Duke Clinical Research Institute, Durham, NC, [5]Duke University, Department of Orthopedic Surgery, Duke Molecular Physiology Laboratory, Durham, NC, [6]University of North Carolina at Chapel Hill Department of Biostatistics, Chapel Hill, NC, [7]Department of Endodontics, Adams School of Dentistry, University of North Carolina, Chapel Hill, Chapel Hill, NC, [8]University of North Carolina at Chapel Hill Thurston Arthritis Research Center, Chapel Hill, NC, [9]University of North Carolina at Chapel Hill Department of Epidemiology and Thurston Arthritis Research Center, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Spine osteoarthritis (SOA) has been defined by the presence of: 1) disc space narrowing (DSN) and vertebral osteophytes (OST), or 2) facet joint OA (FOA). Anatomical differences between these structures suggest they may have different etiologies. Furthermore, a current clinical paradigm is that SOA leads to lumbar spine instability and subsequent FOA, suggesting a transition pathway. The purpose of this study was to 1) describe the participants with SOA and FOA over time 2) describe the proportion that transitioned from neither SOA nor FOA at baseline to either FOA only or SOA only at follow-up and 3) describe the proportion that transitioned from FOA only or SOA only at baseline to both SOA and FOA at follow-up. Elucidating these transitions would improve our understanding of the underlying pathophysiological processes and may indicate the potential for separate clinical phenotypes.

Methods: These analyses used baseline (2006-2010) and follow-up (2013-2015) data from the Johnston County Osteoarthritis Project. Paired (baseline and follow-up) lumbar spine radiographs were graded using the Burnett Atlas for OST (0-3), DSN (grade 0-3), and FOA (present or absent). SOA was defined as the presence of at least ≥ 1 DSN and the presence of at least a ≥1 OST at the same lumbar level. Participants were categorized into those with 1) FOA only 2) SOA only 3) neither FOA nor SOA and 4) both FOA and SOA (excluded at baseline). Starting with neither FOA nor SOA at baseline, we describe the transition to SOA only and to FOA only at follow-up. Starting with prevalent FOA only or SOA only at baseline, we describe the transition to both SOA and FOA. Counts and percentages with 95% confidence intervals (CI) were used to describe the prevalence at baseline and incidence of transitions occurring at follow-up. The mean follow-up time was 5.5 years.

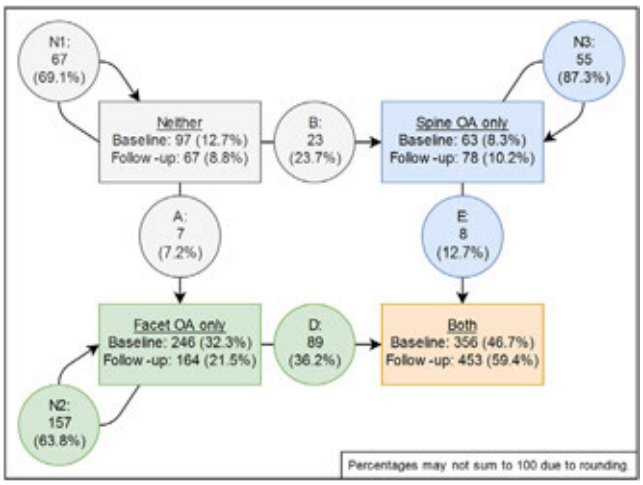

Figure illustrating the counts and percentages of participants that remain within subgroups (N1-3), transition to incident spine osteoarthritis (OA) or facet OA (A&B), or transition from prevalent facet OA or spine OA to both (D&E).

Results: A total of n=762 participants had complete data for these analyses. The mean age and body mass index (BMI) were 66.2 (SD 10.2) years and 30.9 (SD 6.5) kg/m2, respectively; 65.7% were women, and 32.6% were African American (AA).

The figure illustrates the counts and proportions of those with prevalent SOA only or FOA only at baseline and those that transition from either SOA (blue) or FOA (green) to both SOA and FOA (orange) at follow-up. At baseline, 13% of participants had neither SOA nor FOA, 32.3% had FOA only, 8% had SOA only, and 47% had both. At follow-up, a large proportion of participants remained within the same subgroup as baseline and did not transition: 69.1% neither SOA nor FOA (N1), 64% of those with FOA only (N2) and 87% of those with SOA only (N3). Among those with neither SOA nor FOA at baseline, 7% (95% CI 3% to 16%) transitioned to FOA only (A) and 24% (95% CI 16% to 36%) transitioned to SOA only (B). Among those with baseline SOA or FOA only, 36% (95% CI 30% to 42%) transitioned from FOA only to both (D) compared to 13% (95% CI 5% to 21%) that transitioned from SOA to both (E).

Conclusion: Participants in this study tended to remain within these subgroups over time. The most common transitions were from neither SOA nor FOA to SOA only and prevalent FOA only to both SOA and FOA. These findings suggest a different etiological process may exist between SOA and FOA and supports the potential for separate clinical phenotypes.

Impact of Eliminating the Bouted Minutes Requirement in the New 2018 Physical Activity Guidelines for Americans on Gender Disparity in Guideline Attainment for Persons with or at High Risk of Knee Osteoarthritis

Alison Chang,[1] Jing Song,[2] Julia (Jungwha) Lee,[3] Rowland Chang,[3] Pamela Semanik,[1] and Dorothy Dunlop[3], [1]Northwestern University Feinberg School of Medicine, Chicago, [2]Northwestern University Feinberg School of Medicine, Worthington, OH, [3]Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2018 Physical Activity (PA) Guidelines no longer require PA to occur in bouts of ≥ 10 minutes for meeting the weekly 150-min moderate-to-vigorous PA (MVPA) recommendations. In persons with lower limb joint symptoms, attaining 60-min weekly MVPA is linked to maintaining disability-free status over 4 years. This benchmark serves as an achievable intermediate step toward meeting guidelines and motivates those with chronic knee pain and/or function limitations to engage in PA. In persons with radiographic knee OA (KOA), 13% men and 8% women met the legacy 2008 PA Guidelines. It is unknown what proportions of men and women with or at high risk for KOA meet the updated 2018 Guidelines (150-min weekly MVPA) and the disability-free threshold (60-min weekly MVPA). Factors associated with meeting each threshold have not been examined. We aimed to (1) describe the prevalence of attaining ≥ 150-min and ≥ 60-min weekly MVPA; and (2) determine factors associated with attaining each of the PA recommendations, in persons with or at high risk for KOA.

Methods: 1922 OAI (Osteoarthritis Initiative) participants with valid accelerometer monitoring at 48-month OAI visit were included in the analysis sample. We computed weekly unbouted MVPA minutes for each participant. Radiographic KOA was defined as ≥ K/L 2 in at least 1 knee; symptomatic KOA defined as aching or stiffness for at least half of the days of a month (in the past year) in at least 1 knee. Descriptive summaries of weekly MVPA minutes are presented separately for men and women. To identify factors associated with attaining 150-min and 60-min MVPA respectively, we performed multivariate ordered logistic regressions, controlling for age, sex, BMI, race, education, depression, comorbidity, and radiographic/symptomatic KOA.

Results: In those with or at high risk for KOA, 44% men vs. 22% women had ≥ 150 weekly MVPA minutes; 67% men vs. 50% women had ≥ 60 minutes. In those with radiographic KOA, 41% men vs. 20% women had ≥ 150 minutes; 62% men vs. 47% women had ≥ 60 minutes. In those with symptomatic KOA, 41% men vs. 16% women had ≥ 150 minutes; 65% men vs. 45% women had ≥ 60 minutes (Table 1). Being a woman, older, obese, overweight, non-White, depressed; and having ≥ 2 comorbidities and both radiographic and symptomatic KOA was each associated with reduced likelihood of attaining the 150-min threshold. Being a woman, older, obese, overweight, non-college graduate, depressed; and having any comorbidity was each associated with reduced likelihood of attaining the 60-minute threshold.

Conclusion: The proportion of men and women meeting guidelines tripled based the updated 2018 PA Guidelines vs. the legacy 2008 Guidelines. The disparity between sexes widened; twice as many men attained the updated guidelines than women. PA interventions may explore strategies to engage women, non-Whites, and non-college graduates and target modifiable factors of BMI, depression, and symptom managements.

Table 1. Physical activity levels based on 150-min and 60-min weekly MVPA thresholds, among men and women

Characteristics (n)	Weekly time spent in MVPA		
	< 60 min	60 to 150 min	≥ 150 min
	n (row %)		
Men			
Overall (n=861)	283 (32.9%)	198 (23.0%)	380 (44.1%)

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Young adults with rheumatic disease who are employed frequently report presenteeism (i.e., working while unwell). Workplace supports including extended health benefits, job accommodations and work modifications have the potential to minimize presenteeism and promote long-term labor market engagement. Study objectives are to examine the most needed workplace supports reported by young adults with rheumatic disease, and to determine the relationship between meeting workplace support needs and presenteeism.

Methods: Baseline findings from an ongoing three-year longitudinal study of the transitional work experiences of Canadian young adults (18-35 years) with rheumatic disease are presented. Participants were recruited from rheumatology clinics, community-based patient organizations and a survey research firm. All participants completed an online survey that asked about sociodemographic (e.g., age, gender), health factors (e.g., pain, fatigue, disease activity) and work context (e.g., work hours, job demands). Participants were also asked about need for and use of twelve workplace supports. Participants were categorized as having workplace support needs met or exceeded when workplace supports used were equal or greater than the number of workplace supports needed, respectively. Presenteeism was assessed using one item from the Work Productivity and Impairment Questionnaire that asked about the effect of health on work (0= no effect; 10= completely prevented from working). A multivariable proportional odds model was used to examine the relationship between meeting workplace support needs and presenteeism.

Results: 412 young adult participants with rheumatic disease completed the baseline survey. Mean age of participants was 29 years (±4.2) and over half were female (51%). A majority of participants had rheumatoid arthritis (36%) or juvenile arthritis (20%). Participants indicated moderate pain, fatigue and disease activity. The most needed workplace supports included scheduling flexibility (92%), drug coverage (91%), paid sick leave (86%) and modified job duties (81%). Just over half of participants reported that their workplace needs were met (41%) or exceeded (16%); 43% reported unmet need. The sample's mean presenteeism score was 5.3 (±2.3). Those who reported that their workplace support needs were exceeded indicated significantly lower presenteeism (mean = 4.2 ± 2.8) compared to those who reported workplace support needs met (mean = 5.4 ± 2.5) or unmet (mean = 5.4 ± 2.4). When controlling for sociodemographic and health factors, those whose workplace support needs were exceeded showed 50% lower risk of reporting presenteeism (RR = 0.50, 95% CI 0.29-0.87). Having workplace needs met or unmet were not significantly associated with presenteeism.

Conclusion: For young adults, the workplace plays an important role in fostering work productivity. By providing diverse workplace supports and encouraging their use, employers can attenuate the relationship between rheumatic disease and presenteeism at the early career phase.

The Health-promoting Potential of Everyday Activities: Preliminary Results from an Exploratory Study of Adults with and Without Inflammatory Arthritis

Flora To-Miles,[1] Sue Forwell,[1] Eli Puterman,[1] and Catherine L. Backman[1], [1]University of British Columbia, Vancouver, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory arthritis (IA) can disrupt a person's valued life activities but little is known about the potential health benefits of activities other than physical activity. This study explores (a) differences in activity characteristics between adults with and without IA, and (b) the relationships between activity characteristics and health and well-being. Understanding how people characterize their activities and how these activities impact health can help advance arthritis care.

Methods: We conducted a cross-sectional study (as the first phase of a larger longitudinal study) with 40 non-smoking adults, 20 with IA (confirmed by a rheumatologist) and 20 healthy controls (HC). Participants were recruited via clinic and community advertising. Demographic data included age, sex, diagnosis, and employment status. Activity characteristics were measured using Personal Projects Analysis: participants identify 10 salient, goal-directed activities and rate them on 19 characteristics (e.g., creative, absorbing, stressful) using a 11-point scale (e.g., 10=highly creative, 0=not at all creative). Health status indicators were the SF-36 health survey and telomere length (TL), measured from dried blood spots using the monochrome multiplex qPCR method. Descriptive statistics, t-tests, and correlation coefficients were calculated.

Results: Participants' mean age was 54 (SD=15.6); 82.5% were women. Mean age and proportion of women did not differ between groups. In the IA group 65% had RA, 20% lupus, 5% JIA, and 10% had both RA and lupus. In the IA group the highest ranked activity characteristics were value, time adequacy, and outcome, and in the HC group they were outcome, progress, and challenge. Significant between-group differences include creativity, value, control, and absorption. See Table 1. In the total sample, the SF-36 physical component score (PCS) was most strongly associated with value ($r = -0.56$, $p < 0.001$) and creative ($r = -0.38$, $p = 0.02$) activity characteristics. The SF-36 mental component score (MCS) was most strongly associated with stress ($r = -0.48$, $p = 0.002$) and difficulty ($r = -0.43$, $p = 0.006$). TL was most strongly associated with importance ($r = -0.33$, $p = 0.04$) and value ($r = -0.33$, $p = 0.04$). The correlation between TL and MCS ($r = -0.36$, $p = 0.02$) was stronger than TL and PCS ($r = 0.22$, $p = 0.17$). PCS score was significantly higher in the HC group than the IA group. See Table 2 for health outcomes between groups.

Conclusion: There are differences in how adults with and without IA characterize their daily activities. Our results show that people with IA engage in more activities of positive characteristics than those without IA. Perhaps having arthritis compels patients to engage in more valued activities; however, this requires further exploration. A better understanding of these differences may provide insight to future activity recommendations to support physical and

Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Knee osteoarthritis (OA) is the leading cause of functional limitation in older adults, e.g., slow walking. Physical activity (PA) is beneficial for those with knee OA, as those who walk more or engage in more moderate-to-vigorous PA (MVPA) have better physical function than their less-active counterparts. However, it is unclear to what extent work may modify this association. Over half of all PA occurs in a work context, i.e. preparing for

Table 1: Descriptive statistics and risk ratios for incident slow gait speed by PA and employment

*adjusted for baseline age, sex, BMI, presence of knee pain, presence of radiographic knee OA

Table 1. Descriptive statistics and risk ratios for incident slow gait speed by PA and employment

work, commuting, and engaging in employment-based tasks. Therefore, the purpose of this study was to determine to what extent employment status may modify the association of physical activity with incident slow walking in adults with or at risk for knee OA.

Methods: We used data from the Osteoarthritis Initiative (OAI), a large cohort study of individuals with or at risk for knee OA. Objectively-measured PA (steps/day and MVPA) and employment status (yes or no) were collected at the 48-month visit (baseline). PA was measured with an Actigraph GT1M accelerometer worn at the hip for at least 4 days, 10 hours/day and MVPA was defined as ≥ 2020 counts/min. Employment status was obtained from the Physical Activity Scale for the Elderly (PASE) when asked whether they worked for pay or as a volunteer in the past 7 days. Gait speed from a 20m walk test was collected at the 48-month and 96-month visits. PA metrics were separately dichotomized into Active and Inactive using 6000 steps/day and 45 min/week of MVPA. Gait speed was dichotomized using 1.22 m/s as the cutoff to identify slow gait speed as walking less than that represents the inability to safely cross a timed street intersection. To determine to what extent employment status modifies the association between PA and incident slow gait speed at the 96-month visit, we first used binary logistic regression to calculate risk ratios and 95% confidence intervals (95% CI), adjusting for potential confounders at baseline. Next, we evaluated the interaction effect of PA and employment status on FL in a separate binary logistic regression model.

Results: Of the 1305 individuals with valid accelerometry data who were free of FL at the 48-month visit (age: 63.4 ± 8.6 years old, sex: 51.6% female, BMI: 28.0 ± 4.5 kg/m^2), 1133 had gait speed data at the 96-month visit. For both steps/day and MVPA, inactive individuals had greater risk of incident slow gait speed relative to active individuals. Risk for incident slow gait speed was similar based on employment status in both models. In a separate model, the interaction effect of PA and employment status on FL was not significant (p = 0.11).

Conclusion: Regardless of employment, those who were inactive throughout the day, either in terms of daily walking or MVPA, had greater risk for incident slow walking relative to those who were active. This suggests that PA is a driving factor in the development of slow walking habits and that simply whether an individual was previously employed does not impact future slow walking.

Abstract Number: 2083

Understanding Knee Function and Symptom Management in Individuals with Risk Factors for Knee Osteoarthritis

Jason Jakiela,[1] Daniel White,[2] Hiral Master,[2] Meredith Christiansen,[1] Dana Voinier,[1] Lauren Neely,[1] and Louise Thoma[3], [1]University of Delaware, Newark, [2]University of Delaware, Newark, DE, [3]University of North Carolina at Chapel Hill, Newark

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Worse knee function and frequent use of knee symptom management strategies are common in people with symptomatic knee osteoarthritis (SxOA). There are several risk factors for SxOA, with the most common being overweight/obese (OW/OB) or having a previous knee injury/surgery (KISHx). Prior to the onset of SxOA, individuals likely are not seeking care, however the presence of risk factors may help identify those experiencing signs of early knee dysfunction and need for symptom management. Therefore, the purpose of this study was to describe the association of knee OA risk factors with knee function and symptom management. We stratified by frequency of knee pain since this is strongly related to knee function and use of symptom management strategies.

Methods: We used data from the Osteoarthritis Initiative (OAI). Our analytic sample was limited to those who had at least one risk factor for knee OA and were free of SxOA at baseline. Risk factors were: OW/OB as determined by age- and sex-specific cutoffs for weight, KISHx, family history (FmHx) of end-stage knee OA, presence of bilateral Heberden's nodes, frequent knee bending, and knee symptoms in the past 12 months. Outcomes were obtained from self-report questionnaires, including: knee function via the WOMAC Physical Function score and symptom management strategies, i.e. activity limitation due to knee symptoms in the past 30 days (yes/no), use of medications in the past year due to knee symptoms (yes/no). To assess the associations of the risk factors with each outcome, we used a general linear model and logistic regression to calculate effect estimates/odds ratios with 95% confidence intervals (CI). Analyses were stratified by knee pain frequency and adjusted for potential confounders.

Results: Of the analytic sample (n=2987, age 61.1 ± 9.3 years old, 59% female, BMI 28.3 ± 4.7 kg/m^2), 988 were OW/OB, 1475 had KISHx, 500 reported knee OA FmHx, 755 had bilateral Heberden's nodes, and 2182 reported frequent knee bending. Regardless of frequency of knee pain, those who were OW/OB or with KISHx had significantly worse knee function than those without each risk factor (Table). In those with infrequent knee pain, KISHx was associated with use of both symptom management strategies, while FmHx was only associated with activity limitation and presence of bilateral Heberden's nodes was only associated with use of medications. In individuals with frequent knee pain, OW/OB and KISHx were associated with use of both symptom management strategies.

Conclusion: KISHx and OW/OB were consistently associated with worse knee function regardless of the presence and frequency of knee pain. KISHx was also consistently associated with use of knee symptom management strategies when any knee pain was present, yet OW/OB was only associated in the presence of frequent knee pain. Other risk factors were not independently related to knee function, and inconsistently related to symptom management. These results emphasize the two most common risk factors for knee OA, OW/OB and KISHx, are also the most strongly related to knee function and symptom management. Early monitoring of people with these risk factors may allow for early intervention when symptoms present and delay the consequences of knee OA.

Table: Associations of risk factors with knee function and symptom management strategies, stratified by frequency of knee pain

Why so Fast? A Focus on Reasons for an Increase in Arthritis-Attributable Activity Limitation Trends, 2002-2017

Kristina Theis,[1] Michael Boring,[2] and Ross Wilkie[3], [1]Centers for Disease Control and Prevention, Atlanta, [2]Johnson Consulting dba Cutting Edge Technologies and Solutions, Atlanta, [3]Keele University, Keele, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

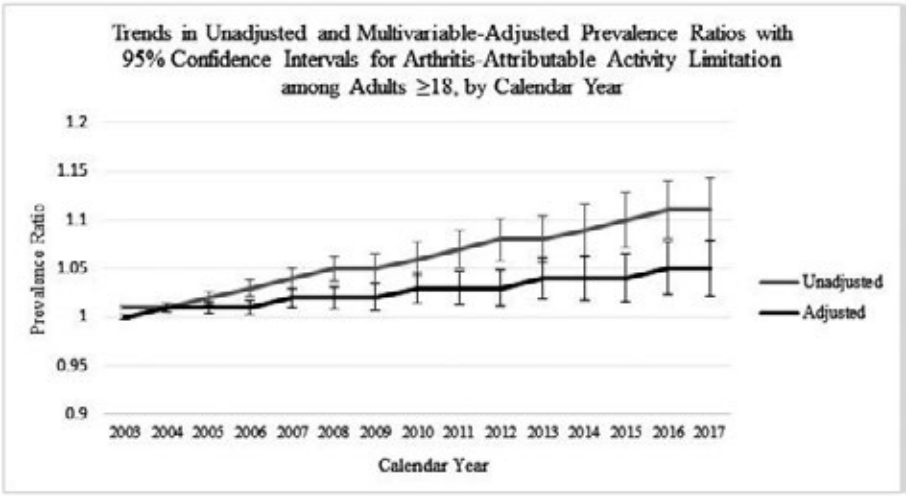
Background/Purpose: "Arthritis-attributable activity limitation" (AAAL) is linked to many potentially modifiable characteristics (e.g., work disability, physical inactivity, obesity). By 2015, prevalence of AAAL among adults ≥18 with arthritis had increased by almost 20% compared with that reported in 2002, and the observed annualized prevalence of AAAL in 2010 had outpaced projections for 2020 (22.7 vs. 22.1 million). Our objective was to investigate the extent to which trends in AAAL prevalence can be explained by changes in characteristics associated with AAAL among U.S. adults with arthritis.

Methods: Cross-Sectional data were obtained for participants ≥18 years from years 2002-2017 of the National Health Interview Survey (NHIS, average unweighted sample n=30,076), an ongoing, multistage probability survey designed to be nationally representative of the civilian, non-institutionalized U.S. population. Analyses were restricted to those with self-reported doctor-diagnosed arthritis. AAAL was defined as "yes" to "Are you now limited in any way in any of your usual activities because of arthritis or joint symptoms?" Demographic, health, function, and health care access measures were assessed across 30 variables.

We used unconditional logistic regression to estimate prevalence ratios (PR) with 95% confidence intervals (CI) to examine the associations between *a priori* selected variables and AAAL, modeled the prevalence of AAAL (dependent variable), and estimated a prevalence ratio (PR) for each independent variable in a model containing only that variable and (continuous) calendar year. Next, for 7 variables significantly associated with AAAL (identified with the overall Wald test of model coefficients) we estimated 2 PRs for AAAL trend: 1) average annual increase in AAAL, and 2) overall AAAL increase, (2017 prevalence less 2002 prevalence). Finally, we calculated a series of multivariable-adjusted (MV) models to test changes in the estimated effect of calendar year on AAAL post-adjustment, i.e., addition of a covariate which reduced the significance of the existing trend identified a variable with a significant role in the observed trend relationship.

Results: Between 2002 and 2017, prevalence of AAAL among adults with arthritis significantly increased (37.6% (95% CI=36.1-39.1) to 42.9% (41.4-44.4), p-value < 0.0001 test for trend). Initial model PR=1.11 (1.08-1.15). Only 4 variables reduced the PR, driven by: comorbidities (increased number), employment status (increased retired and not in labor force), body mass index (increased overweight), and race/ethnicity (increased non-Hispanic White). The final MV PR was 1.05 (1.02-1.08). The temporal trend in AAAL is largely explained by the temporal trends of the characteristics accounted for in this analysis (Figure).

Conclusion: In addition to identifying specific variables which explain some of the trend in increased AAAL between 2002-2017, we rejected many others as contributors. Still, unknown/unmeasured variables (e.g., zip code, urbaniza-



Adjusted for: Number of comorbidities, employment status, body mass index, and race/ethnicity.

tion, neighborhood) may account for some of the trend. Meanwhile, interventions can be directed at the subgroups identified here to reduce AAAL impact.

Too Soon to Say: Promising Results from a Community-Delivered RCT Examining Work-Related Outcomes of the Chronic Disease Self-Management Program

Kristina Theis,[1] Teresa Brady,[2] and Shawn Kneipp[3], [1]Centers for Disease Control and Prevention, Atlanta, [2]Clarity Consulting and Communications, Atlanta, GA, [3]School of Nursing, The University of North Carolina at Chapel Hill, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: More than two-thirds of U.S. adults with arthritis are working-age (< 65), and arthritis is a leading cause of work disability. The Chronic Disease Self-Management Program (CDSMP) has evidence for improving physical and mental health outcomes, but few studies specifically address employment. We examined work-related outcomes following participation in CDSMP.

Methods: From 6/2016-9/2017, we recruited participants through flyer, e-mail, and digital advertisements in communities, worksites, and other channels. No reference was made to CDSMP; participation was described in either a “health self-management program” or a “financial self-management program” (FSMP). Potential participants consented and enrolled through a website which screened for age (40-64 years), being employed, income, ≥1 chronic condition, English fluency, and living/working in the study area (5 North Carolina counties). Study design was a randomized controlled trial: intervention group=CDSMP, attenuated attention-control group=FSMP. Our primary study outcome was percent work productivity loss due to health-related presenteeism using the Work Limitations Ques-

tionnaire (WLQ) 4 Question Time Loss Module and the WLQ 25 Item Online Version. Baseline sample characteristics were summarized using descriptive statistics. Analyses of primary outcomes were conducted using simple t-tests, paired t-tests, and multivariate generalized linear models using an intent-to-treat (ITT) approach. We also did a post hoc analysis comparing CDSMP completers (attended ≥4 of the 6 sessions) to the FSMP group using α=0.10 due to the small sample size of CDSMP completers (n=41).

Results: A total of 327 enrolled and were randomized to CDSMP (n=160) or FSMP (n=167). The sample was predominantly white (54%), female (89%), and college educated (73%), with an average 2.89 chronic conditions, and average household income of $62,009. There were no significant group differences at baseline. Participation rates (attending any portion of program) were 35% (n=56) CDSMP and 25% (n=41) FSMP.

ITT analysis: There were no significant between-group differences in work-related outcomes (e.g., percent work productivity loss, time management, work output, or work self-efficacy) from baseline to 6 or 12-month follow up. In the CDSMP group (vs FSMP) depressive symptoms improved at 6 months (p=0.04) but not at 12 months; general health significantly improved at 12 months (p=0.02) but was clinically negligible.

CDSMP Completer Analysis: Compared to the FSMP group, CDSMP completers reported a greater reduction in percent work productivity loss (p=0.06) and subscales mental/interpersonal tasks (p=0.05) and work output (p=0.07) using α=0.10.

Conclusion: Low participation rates decreased power to find significant differences in the ITT analysis. However, the CDSMP completer analysis suggested a positive effect of CDSMP on work productivity among those who completed ≥4 sessions. A larger sample size of CDSMP completers is necessary to confirm these promising findings.

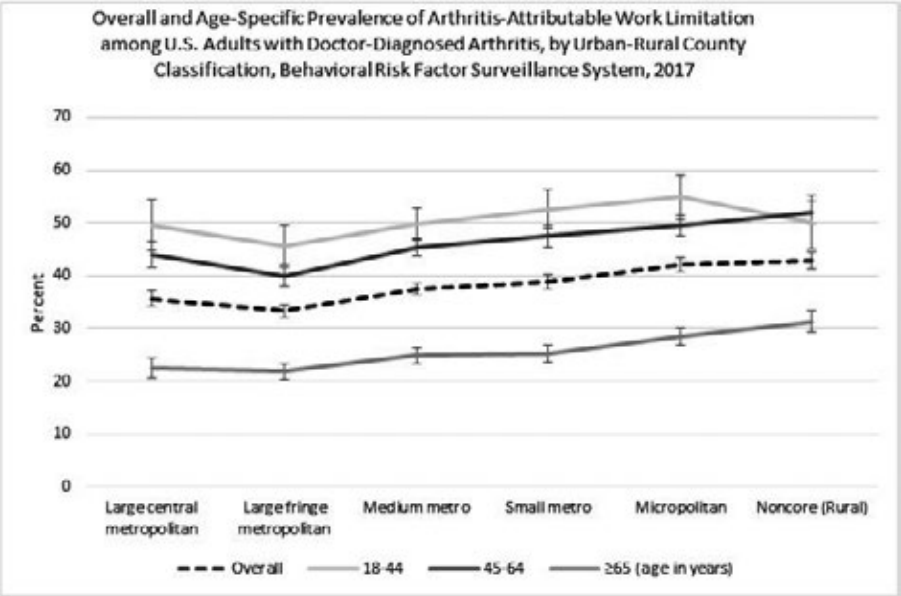
Arthritis-Attributable Work Limitation Variation by U.S. County Classifications and Selected Characteristics, 2017

Kristina Theis,[1] Yong Liu,[2] Michael Boring,[3] and Kerry Souza[4], [1]Centers for Disease Control and Prevention, Atlanta, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA, [3]Cutting Edge Technologies and Solutions (Cetechs), Atlanta, GA, [4]Centers for Disease Control and Prevention, Washington, D.C., DC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis prevalence ranges from 1-in-5 to 1-in-3 across U.S. counties, and its prevalence and effects vary by county economic grouping, metropolitan status, and uneven population density. It is a leading cause of work disability, which research suggests is sometimes linked to specific occupations/industries or job tasks. We examined the prevalence and variation of arthritis-attributable work limitation (AAWL) by overall county classification and selected characteristics.

Methods: Cross-Sectional data were from the 2017 Behavioral Risk Factor Surveillance System, an annual, state-based, random-digit–dialed landline/cellphone health survey of non-institutionalized U.S. adults ≥18 years. Among



adults with self-reported, doctor-diagnosed arthritis (145,776 respondents in 50 states and D.C.), AAWL was defined as "yes" to "In this next question, we are referring to work for pay. Do arthritis or joint symptoms now affect whether you work, the type of work you do, or the amount of work you do?" Analyses were restricted to those with AAWL, age, and county data (n=141,183). The National Center for Health Statistics 2013 Urban-Rural Classification Scheme for Counties was used to classify respondents in counties from most-urban to most-rural: large central metropolitan; large fringe metropolitan; medium metropolitan; small metropolitan; micropolitan; and noncore (smallest rural). Age-Specific estimates of AAWL prevalence by urban-rural status and selected characteristics were calculated with 95% confidence intervals (CIs). Pairwise comparisons tests for statistically significant differences between county classifications were conducted at α=0.05.

Results: Overall prevalence of AAWL among adults with arthritis ranged from 36% in large central metropolitan to 43% in the smallest rural (noncore) counties, with considerable variation by age group (Figure). Among 18-44 year olds, AAWL prevalence varied little by county classification, e.g., no statistical differences for less than high school education, unable to work/disabled, or having 0 or 1 comorbid conditions. For those ages 45-64, unemployed respondents in the 3 smallest county classifications reported higher prevalence of AAWL (range: 70-72%) vs the 3 largest county classifications (range: 54-57%). Prevalence of AAWL was highest among those 45-64 unable to work/disabled in noncore (rural) counties (76%) vs the 3 largest county classifications (69.0%, 70.8%, and 71.8%, respectively). AAWL prevalence and significance by county varied for physical activity obesity in this age group. Magnitude of AAWL prevalence was lowest among those ≥65, but all characteristics examined displayed variations by county classification.

Conclusion: Observed variations in AAWL prevalence are not fully understood. Some may be explained by distributions of arthritis-associated industries/occupations in more rural areas (e.g., farming, forestry), demographic shifts, and limited access to health care. Overall, county-specific AAWL prevalence was ≥1-in-3, indicating widespread need for evidence-based interventions to reduce negative personal and societal economic consequences of arthritis.

Abstract Number: 2087

Prevalence of Corticosteroid Use in Incidental Vertebral or Hip Fractures

Gurjit Kaeley,[1] Julie Ferm,[2] and **Lanh Dang**[2], [1]University of Florida, Gainesville, FL, [2]UF Health Jacksonville, Jacksonville, FL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-traumatic vertebral and hip fractures are detrimental complications of osteoporosis and those with a previous fracture have double the risk of subsequent fractures. The objective of this quality improvement (QI) project was to determine the baseline characteristics that may have contributed to the vertebral or hip fracture and determine if bone health was optimized subsequent to the fracture. As corticosteroids can increase the risk of osteoporotic fractures, the initial focus of this analysis was on patients who had an outpatient prednisone prescription prior to admission.

Methods: Data was retrospectively collected from the electronic health record for patients aged 45 and older admitted to UF Health Jacksonville for an active vertebral or hip fracture diagnosis between January 1, 2017 and January 31, 2019. Traumatic injuries were excluded. Retrospective chart review could occur dating back to January 2014 for completeness. Data on patient demographics, any medication that may affect bone health (e.g. steroids, calcium and vitamin D products, bisphosphonates, etc.), DEXA scans, and pertinent labs were collected.

Results: A total of 287 patients were admitted 296 times between January 1, 2017 and January 31, 2019. Of these, 24 patients (8.4%) had an outpatient order for prednisone on at least one occasion prior to admission. Over half of the patients, 58.3%, had an outpatient order for prednisone with an associated diagnosis of chronic obstructive pulmonary disease. A majority, 79.2%, were female with a median age of 70.5 years old (range: 57 – 98 years old). More admissions were due to hip fractures (54.2%) than vertebral fractures (45.8%). Chronic prednisone use ≥ 15 mg/day prior to admission was noted in 9.1% of patients. The remaining 22 patients had prednisone bursts with 9.1% of patients having cumulative burst doses between 10-100 mg, 68.2% patients between 101-500 mg, 18.2% patients between 501-1000 mg, and 4.5% patients > 1000 mg. Of the 24 patients, six patients had a DEXA scan prior to admission and of these DEXA scans, 2 showed osteoporosis and 3 showed osteopenia in the affected fracture area at baseline. Only 8.3% of patients were on a bisphosphonate prior to admission. Baseline Vitamin D 25-OH levels were available in 12 patients with an average level of 30.365 ± 11.35 ng/mL.

Conclusion: In this convenience sample of patients who had an outpatient order for prednisone prior to admission, more hip fractures occurred than vertebral fractures. A small percentage of patients (9%) were on prednisone chronically. The rate of baseline DEXA scan was low as only 25% of patients had one available despite approximately 68% of patients having a cumulative prednisone dose exposure between 101 – 500 mg. The rate of bisphosphate use prior to admission was also low at 8.3%. Data collection for the patients not on prednisone is ongoing. The goal of this QI project is to create a care pathway for patients admitted to the hospital for vertebral or hip fractures to optimize bone health by mitigating modifiable risk factors and increasing appropriate osteoporosis medication prescriptions to reduce the future risk of fractures. No correlation can be made at this time between prednisone use, osteoporosis, and fracture incidence.

When It Just Won't Stop: Chronic Pain and High Impact Chronic Pain Among U.S. Adults with Arthritis

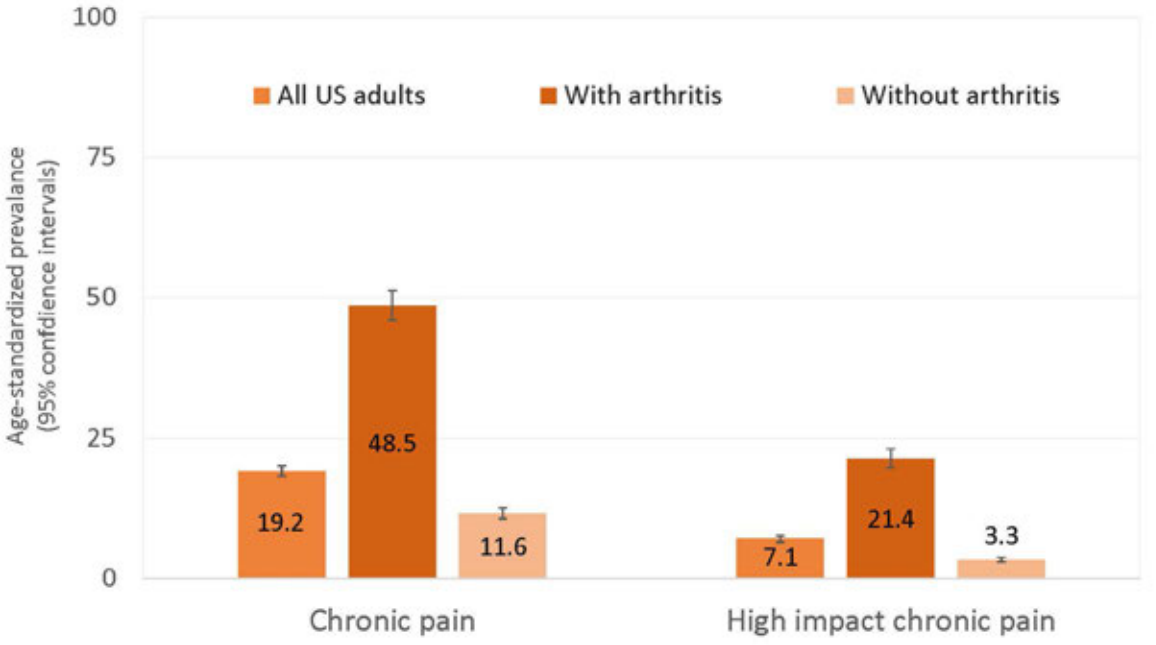
Louise Murphy,[1] Kristina Theis,[2] Dana Guglielmo,[2] Kamil Barbour,[3] Charles Helmick,[2] and Janet Croft[2], [1]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA, [3]Centers for Disease Control and Prevention, Atlanta

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a hallmark of arthritis. Despite growing attention to chronic pain (CP), surprisingly little is known about its magnitude and impact among the 54.4 million US adults with arthritis. We studied two pain outcomes, CP and high impact chronic pain (HICP), among US adults age ≥18 years with a focus on those with arthritis.

Methods: We analyzed 2016/2017 data from the population-based US National Health Interview Survey (NHIS) (59, 696 participants). Arthritis was a "yes" (n=16,732) to "Have you **ever** been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" We calculated crude and age-standardized prevalence of CP (pain most/all days in past 6 months) and HICP (CP that limited life or work

Figure: Age-standardized prevalence of chronic pain and high impact chronic pain among US adults age ≥ 18 years, overall and by arthritis status, 2016-17 National Health Interview Survey



Crude chronic pain prevalence: all US adults (20.3%), adults with arthritis (48.4%), and adults without arthritis (11.5%)
Crude high impact chronic pain prevalence: all US adults (7.6%), adults with arthritis (21.6%), and adults without arthritis (3.2%)

Table: Multivariable-adjusted prevalence ratios (PR) for associations between each pain outcome and 14 selected chronic conditions*

	Chronic pain		High impact chronic pain	
Chronic Condition	PR	95% CI	PR	95% CI
Low back pain	2.2	(2.1 - 2.3)	2.3	(2.1 - 2.5)
Arthritis	**2.1**	**(2.0 - 2.2)**	**2.2**	**(2.0 - 2.4)**
Neck pain	1.8	(1.7 - 1.9)	1.9	(1.7 - 2.1)
Serious psychological distress	1.6	(1.5 - 1.7)	1.7	(1.6 - 1.9)
Asthma	1.2	(1.2 - 1.3)	1.2	(1.1 - 1.3)
Chronic obstructive pulmonary disease	1.2	(1.1 - 1.3)	1.2	(1.1 - 1.4)
Hypertension	1.2	(1.1 - 1.2)	1.2	(1.1 - 1.4)
Liver	1.2	(1.1 - 1.4)	1.2	(1.1 - 1.4)
Cancer	1.1	(1.1 - 1.2)	1.0	(0.9 - 1.2)
Diabetes	1.1	(1.0 - 1.2)	1.1	(1.0 - 1.1)
Heart disease	1.1	(1.1 - 1.2)	1.1	(1.0 - 1.2)
Hepatitis	1.1	(1.0 - 1.2)	1.1	(1.0 - 1.3)
Kidney	1.1	(1.0 - 1.2)	1.1	(1.1 - 1.2)
Stroke	1.1	(1.0 - 1.2)	1.2	(1.1 - 1.3)

*Multivariable logistic regression model for each pain outcome contained 14 chronic conditions and age, sex, race/ethnicity, highest educational attainment, employment status, sexual identity

CI, confidence interval

activities on most/all days in the past 6 months) among US adults overall and by arthritis status. Then, among all US adults, we estimated the multivariable-adjusted association with prevalence ratios (PR) from logistic regression models between each pain outcome and 14 chronic conditions and 6 socio-demographic characteristics. Finally, we calculated CP and HICP prevalence among adults with arthritis across socio-demographic characteristics, health status, and comorbidities.

Results: Crude CP and HICP prevalence among adults with arthritis was 48.4% and 21.6%, respectively (Figure). Both CP and HICP age-standardized prevalence for adults with arthritis was higher than for US adults overall and those without arthritis, respectively (CP=48.5%, 19.2%, and 11.6%; HICP=21.4%, 7.1%, and 3.3%). In multivariable modelling, across all conditions examined, arthritis had the second strongest association with CP (PR=2.1; 95% CI=2.0-2.2) and HICP (PR=2.2; 95% CI=2.1-2.4); low back pain was the most strongly associated with CP (PR=2.2; 95% CI [confidence interval]=2.1-2.3) and HICP (PR=2.3; 95% CI=2.1-2.5) (Table). Among adults with arthritis, 5 subgroups had CP prevalence >70%: serious psychological distress (82.2%), unable to work/disabled (80.8%), neck pain (74.1%), fair/poor self-rated health (73.3%), and arthritis-attributable activity limitations (71.7%). At least 40% in these 5 subgroups had HICP: unable to work/disabled (63.4%), serious psychological distress (59.7%), American Indian/Alaskan Native (43.0%), kidney disease (41.1%), and neck pain (40.3%).

Conclusion: Approximately one in two and one in five adults with arthritis live with CP and HICP, respectively; among them, both CP and HICP prevalence was even higher for those living with other challenges, including work disability and psychological distress. Despite unknown temporality, our study results combined with clinical evidence suggests that arthritis may be a leading cause of CP and HICP among US adults. Integrated approaches to pain management that include evidence-based non-pharmacologic strategies (e.g., cognitive behavioral therapy, physical activity, and self-management education) can reduce CP and its adverse effects, such as psychological distress, and may help reduce prescribed opioid use.

Abstract Number: 2089

Restricting Activity to Evade Knee Symptoms Is Associated with Worse Physical Function and Radiographic Osteoarthritis

Louise Thoma,[1] Jason Jakiela,[2] Hiral Master,[1] Dana Voinier,[2] Meredith Christiansen,[2] and Daniel White[1], [1]University of Delaware, Newark, DE, [2]University of Delaware, Newark

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Activity restriction (i.e. limiting or avoiding normal activity) is a common strategy to reduce, and sometimes eliminate, knee symptoms. Knee symptoms, such as pain, aching, or stiffness, may be indicative of knee osteoarthritis (OA), thus are a common reason that individuals seek health care services. One concern is that activity restriction may indicate in deteriorating function and development of OA, even if the knee remains symptom free. It is unclear how activity restriction is associated with physical function and knee OA, in the presence or absence of knee symptoms. The purpose of this analysis was to examine the associations of pain and activity restriction with physical function and OA in adults with or at risk for knee OA.

Methods: We conducted a cross-sectional analysis using baseline data from the Osteoarthritis Initiative, a cohort study of individuals with or at risk for knee OA. We defined people using activity restriction to manage knee symptoms as those who reported that they "avoid/reduce pain, aching, or stiffness by changing or cutting back on normal activities" in the past 30 days. We defined people with knee symptoms as people reporting "knee pain, aching, or stiffness on more than half of the past 30 days". We created a four-category exposure by combining the answers to activity restriction (yes/no) and knee symptoms (yes/no). The outcomes of interest were physical function and radiographic knee OA (ROA). Physical function was assessed with the Short Form 12 Physical Component Score (SF-12 PCS), Western Ontario and McMaster Universities Osteoarthritis Index for function (WOMAC-function), and gait speed (m/s) from the 20-m walk test. ROA was defined as Kellgren-Lawrence grade ≥ 2 in either limb. To examine the association of the exposure groups with physical function, we used a general linear model to calculate effect estimates with 95% confidence intervals (95% CI), adjusting for potential confounders. To examine the association of

	Group	n	Mean ± SD	Mean difference* (95% CI)

*Adjusted for age (years), sex (men vs. women), BMI (kg/m^2), race (white vs. non-white), education (college graduate vs. some college or less), comorbidity (none vs. at least 1), ROA in either knee(yes vs. no)

Table 1. Association of Exposure Groups with Physical Function

Group	n	% with ROA (n)	Odds Ratio* (95% CI)
Neither	2174	50% (1081)	1.00 [REF]
Activity restriction only	174	54% (309)	1.27 (1.04, 1.54)
Knee symptoms only	817	59% (482)	1.33 (1.12, 1.28)
Both	1202	66% (790)	1.85 (1.58, 2.2)

*Adjusted for age (years), sex (men vs. women), BMI (kg/m^2), race (white vs. non-white), education (college graduate vs. some college or less), comorbidity (none vs. at least 1)

Table 2. Association of Exposure Groups with ROA

the exposure groups with ROA, we used binomial logistic regression to calculate odds ratios with 95% CI, adjusting for potential confounders.

Results: Of the full sample (N=4796, 58% women, 61±9 years old, 28.6±4.8 kg/m^2), 45% reported neither activity restriction nor knee symptoms, 12% reported activity restriction only, 17% reported knee symptoms only, and 25% reported both activity restriction and knee symptoms. Compared to people reporting no activity restriction or knee symptoms, those who reported activity restriction and/or knee symptoms had worse self-reported and performance-based physical function (Table 1). Similarly, those reporting activity restriction and/or knee symptoms had higher odds of more (unilateral or bilateral) ROA compared to those reporting no activity restriction or knee symptoms (Table 2).

Conclusion: Individuals who restrict normal activities to avoid knee symptoms, or have knee symptoms, have worse physical function and higher prevalence of ROA compared to those who have neither. Identifying people who restrict normal activities to avoid pain may be a marker of early symptomatic progression.

Abstract Number: 2090

Differences in Stepping and Standing Based on Self-reported Exercise Identity in Persons Following Total Knee Replacement

Nicholas Mook,[1] Katherine DeVivo,[1] Deborah Brown,[2] Amanda Rebar,[3] and Christine Pellegrini[1], [1]University of South Carolina, Columbia, [2]Prisma Health, Columbia, [3]Central Queensland University, North Rockhampton, Queensland, Australia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health Poster III: OA, Gout, & Other Diseases – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Following knee replacement, patients see an improvement in both function and pain, but physical activity often remains at pre-operative levels. One possible influence on an individual's physical activity may be their exercise identity. Exercise identity is the degree to which one views themselves as an exerciser. This is used to assess the importance of identifying with exercise as an integral part of each person's self-concept. Those who identify themselves as exercisers could potentially be more active than those who do not identify with exercise. The purpose of this study was to determine if there is a difference in objectively measured steps per day and minutes

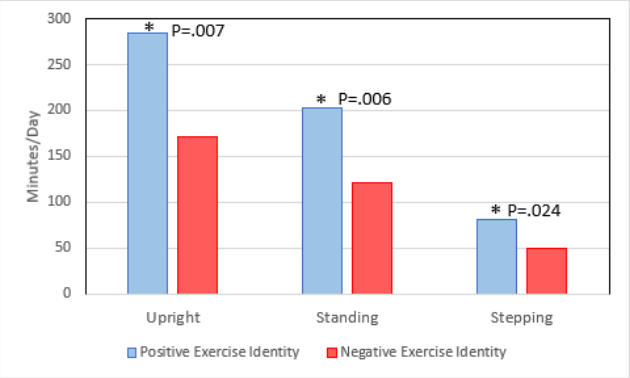

Figure 1. Means by group of time/day spent upright, standing, and stepping based on exercise identity categorization.

per day spent upright, standing, and stepping between participants with positive exercise identity and those with negative exercise identity.

Methods: Participants were aged 40-79 years and were recruited at their first out-patient physical therapy appointment following knee replacement. Participants completed an online self-reported exercise identity survey and wore an activPAL monitor for 7 days. The activPAL monitor assessed the number of steps/day and average minutes/day spent upright, standing, and stepping. Only valid days consisting of 24 hours of wear time were used for analyses. The self-reported exercise identity survey (Wilson & Muon, 2008) asked participants 9 questions to rate their feelings about exercise on a 1 (Strongly Disagree) to 5 (Strongly Agree) Likert scale. All 9 items were summed to create an exercise identity score. Participants median score of exercise identity (29) was used to separate the sample into groups. Analysis was done comparing the two groups as those who have a positive exercise identity (30) and those who have a negative exercise identity (≤29). Independent t-tests were used to compare means of the two groups to see if there was a difference in objectively measured physical activity outcomes based on exercise identity.

Results: Participants (n=19) were an average age of 63.0±7.4 years and body mass index of 32.8±6.2 kg/m^2. As a full sample, participants averaged 5.6±1.4 valid days with the activPAL. Participants in the positive exercise identity group (n=9) had significantly higher steps/day (5145±2034 vs 3128±1578; p=.027), time spent upright (283.9±96.8 vs 170.7±61.4 mins/day; p=.007), time spent standing (203.4±70.2 vs 121±40.8 mins/day; p=.006), and time spent stepping (80.6±31.6 vs 49.7±22.3 mins/day; p=.024) compared to the negative exercise identity group. (Figure 1).

Conclusion: Participants with knee replacement with positive exercise identity took significantly more steps and spent more time per day upright, standing, and stepping than those with negative exercise identity. Future researchers should consider using this information to tailor physical activity interventions based on the participant's exercise identity. If a participant identifies negatively with exercise, different strategies may be required to increase activity than if the participant identified positively with exercise.

SC: seroconversion. SD-QIV: standard-dose quadrivalent inactivated vaccine. HD-TIV: high-dose trivalent inactivated vaccine. The difference between two strata was calculated by prevalence fraction.

Table-Age

the immune response to vaccination compared to a quadrivalent standard dose influenza vaccine (SD-QIV). It is unknown whether among RA patients, the increased immunogenicity of the HD-TIV is restricted to a specific age subgroup.

Methods: Between 2016 and 2018, we conducted a treatment-stratified, randomized, modified double-blind, active-controlled trial in adult seropositive RA patients (rheumatoid factor and/or anti-cyclic citrullinated peptide antibodies) to assess antibody responses to either SD-QIV (15 μg of hemagglutinin per strain) or HD-TIV (60 μg of HA per strain) (NCT02936180). Seroconversion (SC) rates were assessed using pre- (Day 0 – D0) and post-vaccine (D28) titers determined by serum hemagglutination inhibition (HI) and microneutralization (MN) assays. In both cases, SC was defined as at least a four-fold HI or MN antibody titer increase from D0.The effect of age (adults versus elderly, cutoff age 65+ years) on SC rates were evaluated using logistic regression analysis.

Results: A total of 279 seropositive RA patients were enrolled. 140 (50.2%) received SD-QIV and 139 (49.8%) received HD-TIV. The mean age (±SD) was 61.0±12.9 and 80% were female. Results of seroconversion rates based on hemagglutination and microneutralization assays, per vaccine strain and according to RA age groups are presented in Table 1.

Conclusion: The benefit of the HD-TIV regarding immune protection is not restricted to elderly seropositive RA patients. The HD-TIV substantially improves immune responses to all influenza strains in adults living with RA.

Abstract Number: 2092

Efficacy and Safety of the Adjuvanted Recombinant Zoster Vaccine in Adults with Pre-existing Potential Immune Mediated Diseases: A Pooled Post-hoc Analysis on Two Parallel Randomized Trials

Alemnew Dagnew,[1] Debora Rausch,[2] Caroline Hervé,[3] Toufik Zahaf,[4] and Anne Schuind[1], [1]GSK, Rockville, MD, [2]GSK, Philadelphia, PA, [3]GSK, Wavre, Belgium, [4]GSK, Rixensart, Belgium

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The increased risk of herpes zoster (HZ) in older adults is attributable to age-related decline in immunity. In 2 pivotal studies, ZOE-50 (NCT01165177) and ZOE-70 (NCT01165229), the adjuvanted recombinant zoster vaccine (RZV) proved to be efficacious against HZ in adults ≥50 years of age (YOA), with no identified safety concerns, irrespective of the pre-existing medical conditions at enrollment.[1] This post-hoc analysis was performed to evaluate the impact of any pre-existing potential immune mediated diseases (pIMDs) on RZV efficacy (VE) against the first or only episode of HZ and on RZV safety. pIMDs included autoimmune diseases and other inflammatory and/or neurologic disorders of interest, which may or may not have an autoimmune etiology.

Methods: The ZOE-50 and ZOE-70 studies were phase 3, observer-blind, placebo-controlled, randomized trials conducted in 18 countries. Adults ≥50 YOA (ZOE-50) and ≥70 YOA (ZOE-70) received 2 intramuscular doses of RZV or placebo 2 months apart. This post-hoc analysis was performed on the pooled ZOE 50/70 population to evaluate

Conditions	n	RZV group (N=983) % (95% CI)	n	Placebo group (N=960) % (95% CI)

≥80 YOA **	128	1	464.8	2.2	121	6	397.0	15.1	86.2 (-13.5–99.7)

mTVC, modified total vaccinated cohort; YOA, years of age; N, number of participants included in each group; n, number of participants with one confirmed herpes zoster (HZ) episode; person-year, cumulative follow-up period (censored at the first occurrence of a confirmed HZ episode) expressed in years; number/1000 person-year, incidence rate of participants reporting at least one event. Efficacy (VE) was calculated by means of the Poisson method. *VE adjusted by age strata and region; **VE adjusted by region.

Table 2. Vaccine efficacy against first or only HZ episode during the entire study period overall and by age strata (mTVC, pooled ZOE 50/70 population with pre-existing pIMDs at enrollment)

VE overall and by age strata, and safety in participants that had at least 1 pIMD at enrollment. Participants with pre-existing pIMDs were identified by querying the global medical history of the participants included in the total vaccinated cohort (TVC) with a customized MedDRA query for pIMDs.[2] VE was estimated in the modified TVC, which excluded participants who did not receive the second RZV dose or who had a confirmed HZ episode within 1 month after the second dose. Safety was evaluated in the TVC, which included all participants who received at least 1 RZV dose or placebo. Here, we present serious adverse events (SAEs) and SAEs with fatal outcome reported up to 1 year post-last vaccination.

Results: The pooled TVC included 14,645 RZV and 14,660 placebo recipients. Of TVC, 983 (RZV) and 960 (placebo) participants had pre-existing pIMDs, the majority of these (59.9%, RZV; 60.8%, placebo) were females. Table 1 summarizes the most frequent pIMDs in both groups at study enrollment. VE for participants ≥50 YOA with at least 1 pIMD at enrollment was 90.5% (95% confidence intervals: 73.5–97.5%) for the modified TVC (Table 2). High VE against HZ was maintained in all age groups: 50–59 YOA (92.8%), 60–69 YOA (100%), 70–79 YOA (84.4%) and ≥80 YOA (86.2%) (Table 2). SAEs were reported by 144 (14.6%) RZV and 112 (11.7%) placebo recipients and SAEs with

	n	RZV group (N=983) % (95% CI)	n	Placebo group (N=960) % (95% CI)
SAEs*	144	14.6 (12.5–17.0)	112	11.7 (9.7–13.9)
Infections and infestations				
Pneumonia	9	0.9 (0.4–1.7)	9	0.9 (0.4–1.8)
Urinary tract infections	5	0.5 (0.2–1.2)	5	0.5 (0.2–1.2)
Cardiac disorders				
Myocardial infarction	7	0.7 (0.3–1.5)	3	0.3 (0.1–0.9)
Cardiac failure	5	0.5 (0.2–1.2)	1	0.1 (0.0–0.6)
Fatal SAEs**	12	1.2 (0.6–2.1)	9	0.9 (0.4–1.8)

N, number of participants with at least 1 administered dose; n/%, number/percentage of participants reporting the event at least once. SAEs are presented by System Organ Class and Preferred Term. *Only events reported by ≥0.5% of RZV recipients are presented here. None of the fatal SAEs were reported by >0.5%. **RZV = 1 of each of the following events: acute myocardial infarction, myocardial infarction, large intestinal obstruction, sudden death, neutropenic sepsis, pneumonia, skull fracture, ovarian cancer, prostate cancer, rectal adenocarcinoma, cerebrovascular accident, pneumonia aspiration, and 2 pancreatic carcinomas. Placebo = 1 of each of the following events: acute myocardial infarction, chronic hepatic failure, large cell lung cancer, metastases to central nervous system, cerebrovascular accident, azotemia, pulmonary fibrosis, and 2 pancreatic carcinomas.

Table 3. Serious adverse events (SAEs) and SAEs with fatal outcomes reported up to 1 year post-last vaccination (TVC, pooled ZOE 50/70 population with pre-existing pIMDs at enrollment)

fatal outcome were reported for 12 (1.2%) RZV and 9 (0.9%) placebo recipients with pre-existing pIMDs at enrollment (Table 3).

Conclusion: This analysis demonstrated that RZV efficacy in adults ≥50 YOA is not impacted by the presence of pre-existing pIMDs at enrollment. There were no differences in the proportion of reported SAEs or fatal SAEs between RZV and placebo recipients with pre-existing pIMDs.

Both conventional and biologic/targeted DMARDS use: 12 (25)

Background/Purpose: HZ/su has been in use since 2017 and is recommended by the advisory committee on immunization practices (ACIP) as the preferred shingles vaccine due to more than 90% efficacy in preventing shingles and postherpetic neuralgia. Centers for Disease Control and Prevention (CDC) recommends that healthy adults 50 years and older get two doses of HZ/su separated by 2 to 6 months. However, patients with immune-mediated inflammatory diseases were all excluded from HZ/su trials. HZ/su is reported to have high reactogenicity due to the presence of a novel adjuvant which has never been used before in humans. Given the high immunogenicity, rheuma-

tologists are concerned about the aggravation or potentially induction of autoimmune inflammatory diseases. Given the sparsity of data regarding the safety of HZ/su among rheumatology patients, we looked at the safety of the vaccine among subjects who are being treated with synthetic and biologic DMARDs.

Methods: This a retrospective study involving subjects from university-affiliated rheumatology practice who received HZ/su in 2018. Data were extracted from the electronic medical record. In addition to demographic details and medication use, Rapid 3 score and CRP level (mg/dl) before and after the series of vaccine administration were recorded. Any patient-reported adverse reactions related to HZ/su and provider documented flare-up of disease, after vaccination, were also recorded. Statistical analysis using paired T-test was conducted in order to see if there was a difference between Rapid 3 and CRP scores before and after vaccination. The analysis was done with SPSS 25.0.

Results: A total of 47 patient had received both doses of HZ/su. The mean age of patients was 65.9 and of all 76.6 % of the patients had rheumatoid arthritis as a primary diagnosis. The CRP, Rapid 3 for all patients, and Rapid 3 for RA patients were compared before and after vaccinations and were found to have no statistically significant differences. Average prednisone dose was similar before and after vaccination. Of all patients, 6.4% reported adverse reactions. Adverse reactions were non-severe and included fever, myalgia, fatigue, and stomach upset. None of the adverse events led to hospital admission, major organ failure or death. There were 4 events of underlying rheumatic disease flare-ups. All of the 4 patients had RA, and the 2 had self-discontinued the DMARDs (Methotrexate and Leflunomide). There was one event of herpes zoster occurred in a patient with SLE on Hydroxychloroquine and rituximab after receiving the first dose of vaccine.

Conclusion: HZ/su was well tolerated in our subjects. There was no statistically significant difference in CRP values in all patients, Rapid 3 scores in all patients, and Rapid 3 scores among rheumatoid arthritis patients before and after the HZ/su.

Evaluation of Influenza and Pneumococcal Vaccination Rate in Patients with Rheumatoid Arthritis and Spondyloarthritis, and the Attitudes of Rheumatologists About Vaccination

İdil Kurut Aysin,[1] Murat Aysin,[2] Dilek Solmaz,[3] Nazmiye Baş Tomas,[4] Filiz Koç,[4] Elif Durak Ediboğlu,[4] Gokhan Kabadayi,[5] Onay Gercik,[3] Sercan Gücenmez,[4] and **Servet Akar**[6], [1]Izmir Katip Celebi University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, İzmir, Turkey, [2]University of Izmir Katip Celebi Faculty of Medicine, Public Health, İzmir, Turkey, [3]Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, İzmir, Turkey, [4]University of Izmir Katip Celebi Faculty of Medicine, Rheumatology, İzmir, Turkey, [5]Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, İzmir, Turkey, [6]Izmir Katip Celebi University, Faculty of Medicine, Division of Rheumatology, İzmir, Turkey

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with inflammatory arthritis have increased risk of infections which may lead to morbidity and mortality. Some of those infections could be prevented by vaccination. The main objectives of the present study were to investigate (a) the uptake rate of influenza and pneumococcal vaccination among patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) attending a rheumatology outpatient clinic, (b) the factors associated with their vaccination rate and, (c) the attitudes of Turkish rheumatologists about vaccination.

Methods: Patients, followed-up in a tertiary rheumatology outpatient clinic with the diagnosis of RA and SpA, volunteered for participating to study, were included in this cross-sectional study. Data regarding the socio-demographic and disease-related characteristics (including disease duration, medications used, and comorbid conditions) of the patients, vaccination history, the knowledge about the vaccination, and the factors potentially associated with the uptake of vaccination were collected by face-to-face interview using a standardized questionnaire. 102 out of 345 rheumatologists have participated in a web-based survey.

Results: In total, we collected data from 199 patients (145 with SpA and 54 with RA; 101 [50.8%] female and mean age 45.4 ± 12.2 years) (Table 1). Only 55 (27.6%) of our patients were responded that their disease or treatment might be related to the increased risk for infectious diseases. Influenza and pneumococcal vaccines were administered to 38 (19.1%) and 8 (4%) patients, respectively. Vaccination for influenza was recommended by family physicians in 16 patients and by rheumatologists in 6 patients. Rate of influenza vaccination was significantly higher in patients >65 years (p=0.031) and with any co-morbid conditions (p=0.027). The main reasons reported by unvaccinated patients were (a) the belief that they did not need the vaccine (58.4% for influenza and 30.9% for pneumococcal vaccine), (b) the absence of recommendation from their physicians (24.8% for influenza and 25.1% for pneumococcal vaccine), (c) fear of adverse event of vaccination (24.8% for influenza and 4.7% for pneumococcal vaccine), and (d) lack of knowledge vaccination (3.7% for influenza and 14.6% for pneumococcal vaccine). Even though 50% of rheumatologists who responded to the survey were aware of the presence of national vaccination recommendations, all of them stated that patients with inflammatory arthritis need to be vaccinated for both influenza and pneumococcal infections.

Conclusion: Although the knowledge and awareness about influenza and pneumococcal vaccinations were seemed to be high among rheumatologists, vaccination rates for both were insufficient in RA and SpA patients. There remains significant effort to improve vaccination rates and to prevent morbidity and mortality due to vaccine-preventable infections in inflammatory rheumatic diseases.

Abstract Number: 2095

A Quality Improvement Intervention to Improve Influenza and Pneumococcal Vaccination Rates in Immunosuppressed Inflammatory Arthritis Outpatients

Kieran Murray,[1] Candice Low,[1] Francis Young,[1] Anna O'Rourke,[1] Ian Callanan,[2] Eoin Feeney,[1] and Douglas Veale[3], [1]Saint Vincent's University Hospital, Dublin, Ireland, [2]Saint Vincent's University Hospital, Dublin, Dublin, Ireland, [3]EULAR Centre For Arthritis And Rheumatic Diseases and The Conway Institute, Dublin, Ireland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The ACR and CDC recommend influenza ("flu") and 23-valent pneumococcal polysaccharide (PPSV23) vaccination for inflammatory arthritis (IA) patients on immunosuppression. This study aimed to: 1). assess barriers to vaccination and 2). increase PPSV23 (5 yearly) and "flu" (annual) vaccination uptake in immunosuppressed IA outpatients through a multifaceted quality improvement (QI) intervention.

Methods: The primary outcome was adequate "flu" and PPSV23 vaccination uptake of immunosuppressed IA outpatients. Consecutive outpatients in 2017 were invited to complete an anonymous 23 question paper questionnaire including demographic, diagnostic, medication and vaccination (knowledge, status and barriers) data. Patients taking oral steroids, biologic disease modifying antirheumatic drugs (bDMARDs) or immunosuppressant conventional synthetic agents (csDMARDs) were included. Simultaneously, a low cost multifaceted QI intervention was performed (Figure 1).

In 2018, post-intervention, the clinic was re-assessed. Binary logistic regression analysis was used to assess for independent predictors of up-to-date vaccination.

Results: In 2017-2018, 163 and 262 patients, respectively, met inclusion criteria. Patients were typical of an IA clinic (74% women; 45.4% ≥60 years old; 72.7% RA; 61.1% using csDMARDs; 46.6% using bDMARDs; 23.1% using combination csDMARD plus bDMARD; 32.5% using oral steroids).

In 2017, 104 (65.4%) knew of the increased infectious risk with IA. In 2018, 168 (65.6%) were aware. In 2017, 111 (69.8%) were aware of increased infection risk with medications;172 (66.9%) in 2018.

Vaccination awareness was higher for "flu" (Table 1). General practitioners (GPs) informed and vaccinated most patients. The most common reason for non-vaccination was lack of awareness. This decreased post intervention. 70% of patients had smart phone access. 78% were willing to use this for vaccination reminders.

PPSV23 vaccination rates increased from 41.0% to 47.2% (P=0.29. Pearson Chi squared), and "flu" from 61.8% to 62.1% (P=0.95, Pearson Chi squared).

Age, bDMARD use and up-to-date influenza vaccination were significant predictors of PPSV23 vaccination (Table 2). Only, up-to-date PPSV23 vaccination predicted "flu" vaccination.

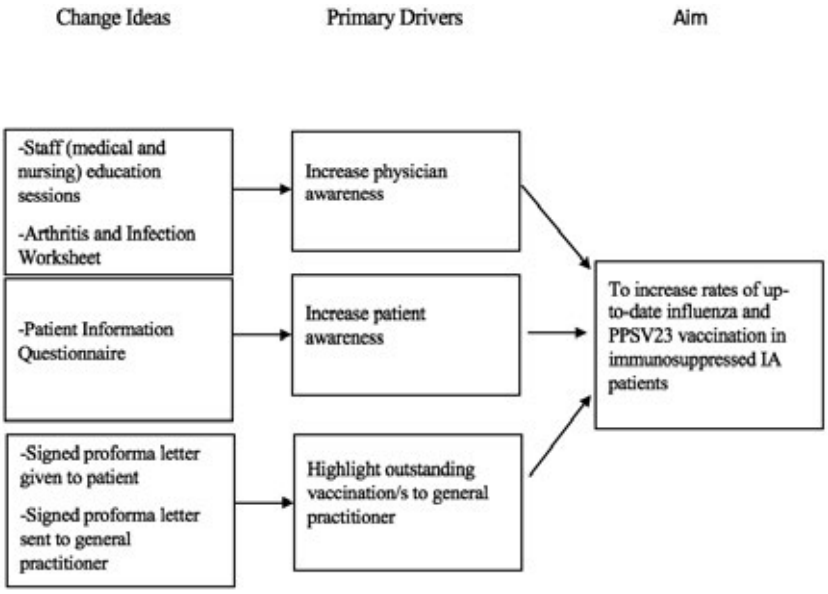

Figure 1. Quality improvement intervention

	Influenza		PPSV23	
	2017	2018	2017	2018

Table 2. Predictors of adequate vaccination

Conclusion: "Flu" and PPSV23 vaccination rates were suboptimal and increased marginally post intervention. Overall, < 5% of vaccinations were in hospital. New strategies to increase vaccination including point-of-care vaccination in clinic and guidelines advocating specialists sharing responsibility with GPs are required.

An Intervention Bundle Increases Uptake of Influenza Vaccine by Rheumatoid Arthritis Patients

Valeria Valerio,[1] Maria Bazan,[1] Mianbo Wang,[2] Bruce Mazer,[1] Elizabeth M. Hazel,[3] Christian Pineau,[4] Sasha Bernatsky,[5] Brian Ward,[6] and Ines Colmegna[6], [1]The Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [2]Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada, [3]McGill University Health Centre, Montreal, Canada, [4]McGill University Health Centre, Montreal, QC, Canada, [5]McGill University Health Center, Montreal, Canada, [6]McGill University Health Center, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Annual vaccination with inactivated influenza vaccine is recommended for adults with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA). Despite this, influenza immunization coverage among those patients is suboptimal. Interventions proven to enhance immunization rates in other at-risk groups include letters to patients, physician reminders, and home visits providing vaccines. We tested the effectiveness of an intervention bundle to enhance influenza vaccination uptake among adults living with RA and JIA.

Methods: Between 10/2018 and 12/2018, an influenza vaccine intervention bundle was implemented at a large academic center in North America. This consisted of: (i) a letter from the Division of Rheumatology mailed to RA/JIA patients reminding them of the benefits of vaccination and need to plan for it; (ii) providing influenza vaccine at the rheumatology clinics; and (iii) placing posters in rheumatology clinics targeting patients and their providers. Between 01/2019 and 05/2019, a post-intervention anonymous survey was completed by RA/JIA patients at the time of a routine rheumatology appointment. Baseline influenza vaccination rates had been established in 2015 using the same survey. The effectiveness of the intervention was determined by comparing patient reported vaccination rates in 2015 and 2019. During the intervention period, there were no changes in the public health program promoting vaccination in RA/JIA. Multivariate logistical regression analyses were performed to evaluate reasons of non-vaccination.

Results: On 10/2018**,** 254 letters were mailed to RA/JIA patients who had a rheumatology appointment in the previous 4 months. During the intervention period in which 343 RA/JIA patients had rheumatology appointments, 116 received the influenza vaccine. Most (107/116, 92.2%) were vaccinated at the time of a previously scheduled appointment while the remainder (9/116, 7.7%) presented for vaccination in response to the mailed letter. The post-intervention survey conducted in 2019, showed that the influenza vaccination rate in RA/JIA was 62.6% (67/107) increased from 48.5% (65/136) in 2015 (p=0.03). Over a third (26/67, 38.8%) of the surveyed patients received the vaccine at the rheumatology clinic in 2019. In multivariate analysis, age (OR 1.07, 95% CI 1.03-1.11), and biologic use (OR 3.45, 95% CI 1.04-11.4) independently predicted vaccination uptake. Physician recommendation was the strongest independent predictor of vaccination (OR 6.56, 95% CI 1.54-27.97). Vaccine hesitancy and refusal were reported reasons for non-vaccination in 35.5% (38/107) of the patients that completed the 2019 post-intervention survey.

Conclusion: An influenza vaccine bundle, with recall interventions directed at both patients and providers, and that facilitated vaccination access, was associated with an increase in vaccine coverage among adults with RA/JIA. Vaccine hesitancy and refusal remain high among RA/JIA patients. Rheumatologists have a key role in promoting vaccination in this population.

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Screening for and the treatment of latent tuberculosis is recommended in patients with inflammatory arthritides prior to biologic treatments, particularly the TNF inhibitors. The aim of this study is to evaluate the performance of tuberculin skin test (TST) with respect to Quantiferon®-TB Gold In-Tube test (QFT-GIT) in patients with rheumatoid arthritis (RA) and spondyloarthropathies (SpA) who are candidates for biologic treatments in a BCG-vaccinated population.

Methods: Data were collected from TReasure, a national-scale, multicenter registry of patients with inflammatory arthritis under biologic treatments[1]. Patients older than 18 years of age, with a diagnosis of RA or SpA, meeting 2010 ACR/EULAR and ASAS criteria, respectively, who had both TST and QFT-GIT prior to initiation of biologic treatments were included in the study. Exclusion criteria were the presence of active tuberculosis, HIV infection, diabetes, chronic kidney disease, chronic obstructive pulmonary disease or asthma, and malignancy. Sensitivity, specifity, and positive and negative predictive values of TST with respect to QFT-GIT were calculated at 5, 10, and 15 mm cutoffs in RA and AS groups.

Results: Among 2690 patients with RA and 4995 patients with SpA, 3468 (45.1%) and 3922 (51%) patients underwent testing with TST and QFT-GIT, respectively. Numbers of eligible patients with both tests performed were 206 for RA, and 392 for SpA. Features of these study groups were given in Table 1. Although the positivity rates of QFT-GIT did not differ substantially between RA and SpA groups, rates of positive TST at 5, 10, and 15 mm cutoffs were signif-

Continuous variables were given as means±SDs. cDMARD = conventional DMARD; TST = tuberculin skin test; QFT-GIT = Quantiferon®-TB Gold In-Tube; LTB = latent tuberculosis

Table 1. General features of the study groups

	RA (n=206)			SpA (n=392)		
TST cutoff	**5 mm**	**10 mm**	**15 mm**	**5 mm**	**10 mm**	**15 mm**
QFT+TST+	5%	3%	2%	13%	10%	6%
QFT-TST-	51%	75%	84%	29%	56%	75%
QFT+TST-	5%	7%	8%	2%	5%	9%
QFT-TST+	39%	15%	5%	56%	29%	9%
Disagreement	44%	22%	13%	58%	34%	18%
Sensitivity	52%	33%	23%	88%	68%	40%
Specifity	56%	83%	94%	34%	65%	89%
PPV	12%	18%	31%	19%	26%	40%
NPV	91%	91%	91%	94%	92%	89%
Cohen's κ	0.02	0.09	0.16	0.08	0.19	0.29

TST = tuberculin skin test; QFT-GIT = Quantiferon®-TB Gold In-Tube; PPV = positive predictive value; NPV = negative predictive value

Note that a TST cutoff of 10 mm in SpA gave slightly better results compared to a 5 mm cutoff in RA in terms of sensitivity, specifity and agreement with respect to QFT-GIT (grey columns)

Table 2. Performance of TST with respect to QFT-GIT in the study groups

icantly higher in SpA group. Treatment rate of latent tuberculosis was also higher in SpA group (Table 1). Distributions of steroid and conventional DMARD use were different between groups (Table 1).

Performance of TST with respect to QFT-GIT for 5, 10, and 15 mm cutoffs were represented in RA and SpA groups in Table 2. The two tests poorly agreed in both groups at a TST cutoff of 5 mm. Increasing the TST cutoff only slightly increased the agreement between the two tests at the expense of decreased sensitivity (Table 2). For all cutoffs, SpA group had higher disagreement rates as compared to RA. Notably, a TST cutoff of 10 mm in SpA gave slightly better results compared to a 5 mm cutoff in RA in terms of sensitivity, specifity and agreement with respect to QFT-GIT (Table 2, grey columns).

Conclusion: Agreement of TST with QFT-GIT for latent tuberculosis was poor in patients with RA and SpA before the initiation of biologic treatments. TST positivity and the disagreement rates were more pronounced in SpA. Increasing the TST cutoff only slightly increased the agreement between the two tests at the expense of decreased sensitivity.

Abstract Number: 2098

Distinctive Pattern of LTBI Screening Parameters in Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA) in Endemic Areas

Andrea Shimabuco,[1] Ana Cristina de Medeiros Ribeiro,[2] Renata Miossi,[3] Karina Bonfiglioli,[3] Julio Cesar Bertacini Moraes,[3] Celio Gonçalves,[3] Percival Sampaio-Barros,[3] Claudia Goldenstein-Schainberg,[3] Fernando Henrique Souza,[3] Leandro Prado,[3] Michelle Remião Ugolini-Lopes,[4] Emily Yuki,[5] Eloisa Bonfa,[6] and **Carla Gonçalves Schahin Saad**[3], [1]Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [3]Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [4]Rheumatology Division - Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo (FMUSP), Sao Paulo, Sao Paulo, Brazil, [5]Rheumatology Division, Hospital das Clinicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Brazil., São Paulo, Brazil, [6]Rheumatology Division, Hospital das Clinicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Brazil., Sao Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite late tuberculosis infection (LTBI) screening before anti-TNF treatment, TB reactivation/new exposure in endemic areas remains a relevant problem. The specific analysis of Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA) screening parameters has not been evaluated previously and may provide clues to improve risk assessment for these diseases. Our objective is to evaluate retrospectively the efficacy of LTBI screening for anti-TNF therapy in AS and PsA in endemic areas and further determine the possible distinguishing features of the LTBI parameters in each disease.

Methods: A total of 218 Spondyloarthritis patients (135 AS and 83 APS) were screened for LTBI before receiving anti-TNF treatment using the tuberculin skin test (TST), chest X-ray and history of previous TB exposure. Patients were regularly followed assessing infectious symptoms/new exposure every 2-3 months. LTBI patients were treated with isoniazid for 6 months.

Results: From June 2014 to June 2018, 135 AS and 83 PsA were referred to Immunotherapy Infusion Center to initiate anti-TNF treatment. LTBI screening was more often positive in AS than in PsA (42% vs. 30%, p=0.043). LTBI parameters were distinct in both diseases with a higher frequency of TST-positive (93% vs. 64%, p=0.002) and lower frequency of history of exposure (18% vs. 52%, p=0.027) and previous TB (0.7% vs, 6%, p= 0.03) in AS than PsA. During follow-up, 7 (4%) AS (71% LTBI-) and 4 (5%) PsA (50% LTBI-) patients developed active TB (ADA, INF and ETA) and 45% were extrapulmonary. Four cases (3 AS and 1 PsA) occurred within the first year of anti-TNF and 2 (50%) in LTBI+ patients, suggesting reactivation. Seven cases (4 AS and 2 PsA) occurred after the first year (4 AS and 1 PsA were LTBI-) probably due to re-exposure.

Conclusion: We report a distinct pattern of LTBI screening parameters in AS and PsA, with a higher frequency of LTBI in the former, mainly identified by TST. For PsA, TST and a history of exposure have similar relevance for LTBI diagnosis. The frequency of screening failure remains a problem and it was comparable in AS and PsA. Availability of non anti-TNF therapies, that are not associated with an increased risk of TB reactivation, may be safer for patients with high risk of TB. Furthermore the annual periodic rescreening may benefit the re-exposure group.

Comparison of Single and Dual Latent Tuberculosis Screening Strategies Before the Initiation of Biologic and Targeted Therapy in Rheumatological Patients in Hong Kong

Yan Ki Tang,[1] Ho So,[2] Weng Nga Virginia Lao,[2] Hin Ting Pang,[2] Tak Lung Victor Wong,[2] Tsz Ho Luk,[2] and Man Lung Ronald Yip[3], [1]Department of Medicine and Geriatrics, Kwong Wah Hospital, Hong Kong, Hong Kong, [2]Department of Medicine & geriatrics, Kwong Wah Hospital, Hong Kong, Hong Kong, [3]Tung Wah Group of Hospitals Integrated Diagnostic and Medical Centre, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Screening for latent tuberculosis infection (LTBI) before the initiation of biologic and targeted synthetic disease modifying anti-rheumatic drugs (b/tsDMARDs) is recommended internationally especially in tuberculosis (TB) endemic areas like Hong Kong. However, there is no gold-standard. The local guideline recommends the use of either tuberculin-skin-test (TST) or interferon-gamma-release-assay (IGRA) before starting b/tsDMARDs for rheumatic diseases. Both tests have reduced sensitivity in immunosuppressed patients and a previous local study has demonstrated that the two tests had fair level of agreement only. We conducted this study to determine whether the dual LTBI screening strategy could reduce the incidence of TB.

Methods: This is a retrospective cohort study. Consecutive patients who have received b/tsDMARDs for rheumatic diseases in a regional hospital in Hong Kong from July 2007 to December 2018 were reviewed. All patients underwent LTBI screening, either with single testing by TST/ IGRA or dual testing by both. They were categorized into single or

dual testing group. Background demographics, concurrent medications and choices of biologic were documented. All patients were followed-up regularly since the initiation of biologic agents for at least 6 months. Isoniazid chemoprophylaxis was prescribed if the patient was tested positive for LTBI. The primary outcome of this study was the incidence of TB during the b/tsDMARDs therapy in the single and dual testing groups. The secondary outcomes included the associated factors of TB, the agreement between TST and IGRA, and the safety of the TB chemoprophylaxis.

Results: Two hundred and seventeen patients were included in this study. One hundred and twenty one patients underwent single LTBI testing with either TST (115) or IGRA (6) and 96 patients underwent dual testing. There was no significant difference in the demographic variables between the two groups. The major indication of biologic agents was rheumatoid arthritis (57% in the single test group and 56% in the dual test group). TB occurred in 9 patients in single testing group and one patient in dual testing group (7.43% versus 1.09%, p=0.045 by Fisher's exact test). Thirty five patients in the single testing group and 36 patients in the dual testing group were tested positive for LTBI and given isoniazid chemoprophylaxis (28.9% versus 45.8%, p=0.007). The agreement between IGRA and TST was 74.5% with the Cohen's kappa value 0.413. However, in patients on prednisolone at screening, the kappa value was reduced to 0.378 and further to 0.346 in patients on at least 10mg prednisolone daily. Among all the b/tsDMARDs, infliximab use was significantly associated with the incidence of TB (p< 0.001). Reversible hepatotoxicity occurs in 7 out of 71 courses of isoniazid given, which was not significantly different between the two groups.

Conclusion: Dual testing strategy with both TST and IGRA appears to be an effective and safe way to reduce the incidence of TB in patients on biologic agents for rheumatic diseases. It should be considered in TB endemic areas especially in patients who are on prednisolone when undergoing LTBI screening or if infliximab therapy is anticipated.

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab is used to treat a variety of rheumatic diseases. In 2015, the American Gastroenterological Association (AGA) categorized rituximab as high-risk in terms of hepatitis B virus (HBV) reactivation. Specifically, patients that are hepatitis B surface antigen (HBsAg) negative and total hepatitis B core antibody (anti-HBc) positive or HBsAg and anti-HBc positive are at high risk of reactivation when receiving rituximab, and therefore, should receive antiviral prophylaxis. This study aims to evaluate rates of HBV screening prior to rituximab.

Methods: A retrospective chart review was conducted on 228 patients at a single tertiary center. Patients were included who had received rituximab for a rheumatologic indication, were seen by the rheumatology department, and received the first rituximab infusion between January 1, 2008 and February 28, 2019. Charts were reviewed for dates of HBsAg, anti-HBc, IgM antibody to hepatitis B core antigen (IgM anti-HBc), and hepatitis B surface antibody (anti-HBs) laboratory tests. If patients were found to be HBsAg or anti-HBc positive, charts were reviewed for any referral to hepatology or infectious disease specialties as well as for any antiviral prophylaxis initiation.

Results: Out of 228 patients meeting criteria, indications for rituximab varied, with the majority being rheumatoid arthritis (65 [28.5%]) and granulomatosis with polyangiitis (44 [19.3%]). One hundred ninety (83.3%) had HBsAg tested and 133 (58.3%) were tested for anti-HBc before first rituximab infusion. Out of these patients, all 190 were HBsAg negative and eight of the 133 tested for anti-HBc were positive. Six of these patients were referred to either infectious disease or hepatology and initiated on tenofovir or entecavir for antiviral prophylaxis. No action was taken on the remaining two patients with positive anti-HBc. An additional two patients were found to be anti-HBc positive after receiving rituximab and both were started on entecavir. No documented HBV reactivation occurred in any of the patients.

Conclusion: This chart review identified inadequate screening of HBV prior to the administration of rituximab. The majority of patients were properly screened for HBsAg; but only slightly more than half had testing for anti-HBc prior to first rituximab infusion. This study identifies areas to implement system changes to improve rates of HBV screening.

Hepatitis C Affects More Than Just the Liver: A Retrospective Chart Review on the Prevalence of Connective Tissue Diseases and Autoantibodies in Hepatitis C Virus Infections in an Academic Rheumatology Clinic

Matthew Malus,[1] Ly-Elaine Pham,[1] Hrishikesh Samant,[1] and Mamatha Katikaneni[2], [1]Louisiana State University Health Sciences Center in Shreveport, Shreveport, LA, [2]LSUHSC- Shreveport, Shreveport, LA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic Hepatitis C virus infection (HCV) has been shown to be associated with connective tissue diseases (CTD). It has been hypothesized that HCV can itself induce a clonal B-cell expansion leading to extrahepatic manifestations of HCV such as arthralgia which brings the question of whether the HCV or CTD is the cause of the arthritis. This determination is very important to help guide treatment decisions. Prior studies of CTD in Patients with HCV was on interferon-based immunomodulator therapy, which has inherent immunogenicity resulting in autoimmune diseases. Current therapy for eradication of HCV includes Direct-Acting Antivirals (DAA) which are not immunomodulators. Hence, we wanted to explore the association between HCV and CTD in the current era of DAA therapy.

Methods: This study is a retrospective chart review of 619 patients seen in the Rheumatology Clinic at Ochsner LSU Helath Hospital in Shreveport, LA with a diagnosis of HCV and CTD.

Results: Out of the 9,604 patients seen in Rheumatology clinic, 619 were found to have a positive Hepatitis C Antibody (6.4%), but only 61 patients had chronic HCV infection determined by a positive viral load. In the 61 patients with HCV, the CTD was Osteoarthritis (OA) in 36 % of cases, Rheumatoid Arthritis (RA) in 21.3%; Psoriatic Arthritis (PSA) in 13.1%; Systemic Lupus Erythematosus (SLE) in 6.5% and Seronegative Inflammatory arthritis in 4.9%. There

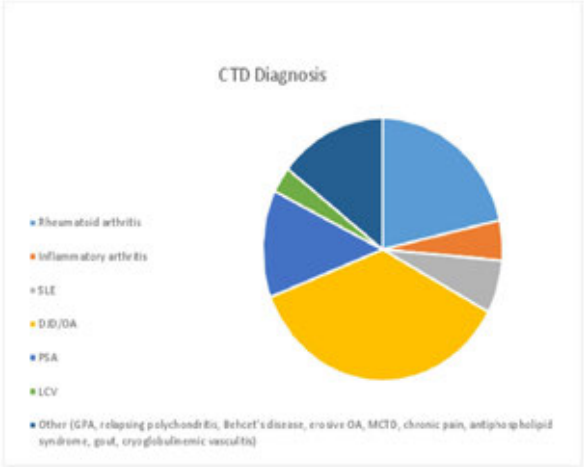

Figure 1. CTD Diagnosis in patients with HCV. SLE = Systemic Lupus Erythematosus; DJD = Degenerative Joint Disease; OA = Osteoarthritis; PSA = Psoriatic Arthritis; LCV = Leukocytoclastic Vasculitis; GPA = Granulomatosis with Polyangiitis; MCTD = Mixed Connective Tissue Disease

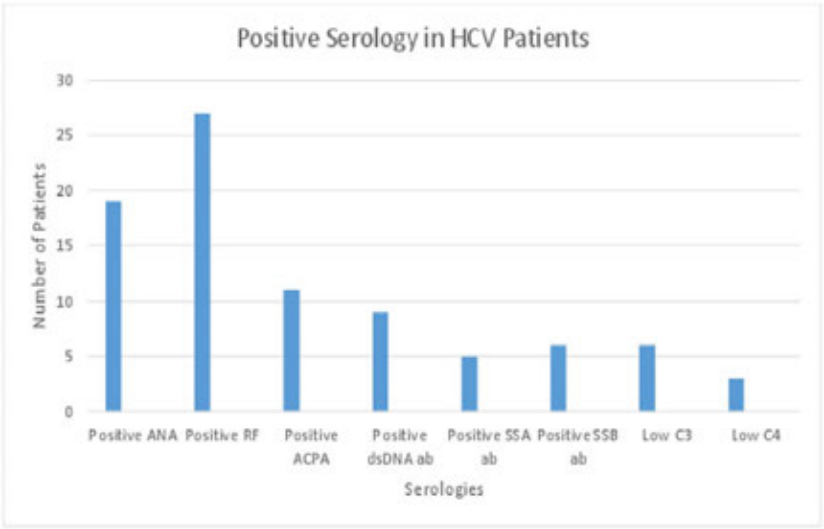

Figure 2. Positive serologies in patients with CTD and HCV.

were 1-2 cases of HCV associated with other CTDs (Figure 1). Positive Rheumatoid Factor (RF) and Antinuclear Antibody (ANA) were the most prevalent positive serological markers present in 44% and 31%, respectively (Figure 2). The RF was found to be a false positive (patients did not meet American College of Rheumatology-ACR diagnostic criteria for RA) in 25% of cases with the highest level being 106 IU/ml. Two out of 13 patients diagnosed with RA had a poor response to therapy and both patients were noted to have a high viral load and high anti-citrullinated protein antibody (ACPA). The HCV genotype most commonly associated with CTD was 1A in 61 % of patients. Joint pain was the presenting symptom in 51% of patients that were subsequently diagnosed with HCV. Hydroxychloroquine and Sulfasalazine (18%) were the most commonly prescribed Disease modifying agents and Tumor Necrosis Factor inhibitors (Etanercept and Adalimumab) were used in 16% of patients without relapse of HCV (Figure 3). Corticosteroids were used in 18% of patients.

Conclusion: HCV infection even without the interferon based therapy is associated with a variety of CTDs with RA and OA being the two most prevalent. Patients with CTD would benefit from a 2-stage HCV screening with HCV anti-

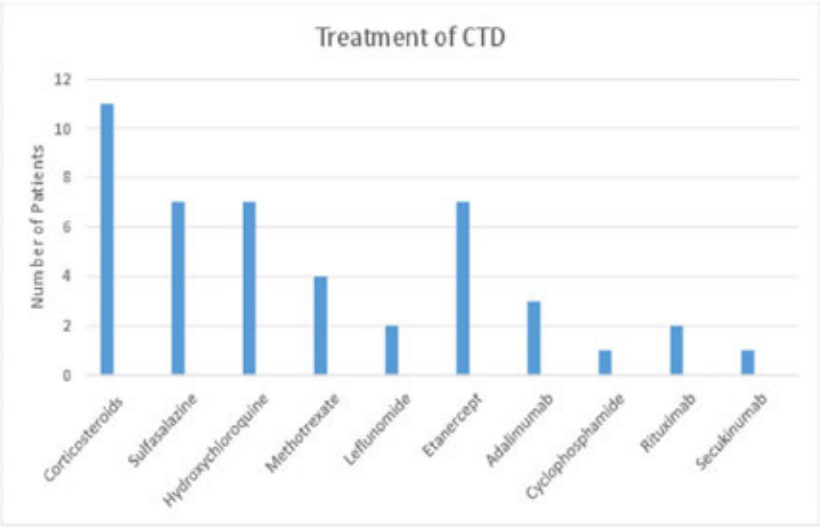

Figure 3. Treatments used for CTDs in patients with HCV.

body followed by HCV RNA on same serum sample due to high false positive antibody test in this subset of population. The presence of ACPA and erosions in addition to the ACR diagnostic criteria help diagnose RA in patients with HCV that have a higher incidence of false positive RF and joint pain. Further long term studies are needed to study the response of treating HCV with DAA to the disease course of CTD.

First-line Antiretroviral Therapy with Tenofovir Produces Deleterious Effects on Bone and an Increase in Proinflammatory Cytokines Expression After 12 Months of Treatment in Naïve HIV Patients

Francisco Conesa-Buendia,[1] Patricia Atencio,[1] Alfonso Cabello,[2] Patricia Llamas-Granda,[3] Ignacio Mahillo-Fernández,[4] Raquel Largo,[5] Gabriel Herrero-Beaumont,[5] Miguel Gorgolas,[1] and Aranzazu Mediero[1], [1]IIS-FUNDACION JIMENEZ DIAZ, Madrid, Spain, [2]IIS FUNDACION JIMENEZ DIAZ, Madrid, Spain, [3]IIS-FUNDACION JIMENEX DIAZ, Madrid, Spain, [4]IIS-FUNDACION JIMENEZ DIAZ, Madrid, Spain, [5]IIS-Fundación Jiménez Díaz, Madrid, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: For almost two decades, bone alterations have been observed in the course of HIV infection, characterized by a marked decrease in bone mineral density (BMD) and an increase in the frequency of fractures as a result of fragility. It is not clear if it is HIV infection per se that contributes to the decrease in BMD, osteoporosis and bone fagility, or if the risk factors associated with the disease (malnutrition, low body weight, high smoking rate and alcohol consumption or low vitamin D levels). In adults, the decrease in BMD has also been associated with prolonged treatment with antiretrovirals and more specifically therapy with tenofovir. The aim of this study was to evaluate the deleterious effects in bone metabolism, produced by tenofovir vs other HIV treatment in naïve patients.

Cytokines measured by ELISA on serum samples for HIV-patients. Median (% increment) and interquartile range (Q1 and Q3) are represented.

Methods: A cohort of 114 HIV-naïve patients were included in the study. Patients were separated by treatment: 1) Tenofovir Disoproxil Fumarate (TDF), 2) Tenofovir Alafenamide (TAF), 3) Abacavir/Dolutegravir/Lamivudin combo (ADL), 4) Protease Inhibitors (PI). Epidemiological, immunological, and metabolic parameters, as well as BMD were evaluated. Bone markers, proinflammatory and anti-inflammatory cytokines were analyzed in serum at basal and 12 months post-treatment by MILLIPLEX® MAP Luminex® Technology. The diagnosis of osteopenia/osteoporosis was made according to the WHO criteria.

Results: The mean age was 34.7 years (range 19-50 years). 91% was on CDC stage A. The median CD4 was 481 cell/μL (IQR=339.5), 10% had CD4 under 200 cell/μl, and 42% had CD4/CD8 under 0.4. 71% (71/143 p) had low Vitamin D levels, 4% low BMI (< 18.5). Osteopenia or osteoporosis was found in 53% and 11% respectively. In the serum/plasma we found differences at molecular level among different treatments (Table 1). We observed that both TDF and TAF presented a more aggressive resorptive profile than other antiretroviral drugs. We observed that there are no significant differences between the TDF and TAF group at 12 months. However, we have observed an increase in CTX, P1NP and DKK1 for TDF being greater than for TAF and the other treatments. All antiviral presented a pro-inflammatory profile with no significant differences among groups (Table 2).

Conclusion: HIV-naïve patients under 50 years have a high prevalence of bone fragility and osteoporosis, and patients treated with tenofovir (both TDF and also TAF) had greater bone deterioration and proinflammatory state than other patients at 12 months of treatment.

Abstract Number: 2103

Anti-TNF Therapy in Patients with HIV Infection

Joanna Marco,[1] and Alison Bays[2], [1]University of Washington, Seattle, WA, [2]University of Washington Division of Rheumatology, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Human Immunodeficiency Virus (HIV) infection may benefit from the use of anti-Tumor Necrosis Factor (TNF) therapy in the setting of inflammatory disease, but the safety of this therapy in patients with HIV infection has not been well established.

Methods: All patients seen at an academic medical center with HIV infection who were prescribed anti-TNF therapy from 1/1/2014-5/1/2019 were identified through retrospective chart review. 11 patients met these criteria. Clinical characteristics, CD4 counts, HIV viral loads, and adverse outcomes including Emergency Department visits, hospitalizations, major infections, malignancies, and death are reported. IRB approval was obtained.

Results: The mean age of patients in this cohort was 48.4, and 90.9% of these patients were male. Indications for anti-TNF use included inflammatory bowel disease (45.4%), psoriatic arthritis (27.2%), rheumatoid arthritis (27.2%), psoriasis (9.1%), and hidradenitis suppurativa (9.1%). The mean duration of anti-TNF use was 52.3 months (range 7-168 months, standard deviation 54.9 months). There were 13 uses of anti-TNF therapy among 11 patients. There were 4 uses of infliximab, 4 uses of etanercept, 4 uses of adalimumab, and 1 use of certolizumab.

All patients were on antiretroviral therapy (ART) at the time of initial anti-TNF prescription, and remain on ART. 72.7% of patients received at least one DMARD in conjunction with anti-TNF use.

There was no significant change in CD4 count during anti-TNF therapy (mean change 103, $p = 0.34$). At the initiation of anti-TNF therapy, 72.7% of patients had undetectable HIV viral loads and 27.3% of patients had detectable viral loads. At the most recent check, all patients had undetectable viral loads. There were no instances of development of a detectable viral load once it became undetectable.

No major infections occurred over 47.9 person-years on anti-TNF therapy. There were 20 ED visits and 10 hospitalizations over this time course, but none were for infections, heart failure, or other complications of anti-TNF therapy.

Two malignancies were diagnosed over 47.9 person-years: an abdominal leiomyosarcoma diagnosed after 12 months of infliximab therapy for Crohn's disease, and a metastatic cholangiocarcinoma diagnosed after 168 months on etanercept for rheumatoid arthritis.

Conclusion: In 11 HIV-infected patients receiving anti-TNF therapy along with ART, anti-TNF therapy did not impact CD4 counts or viral load. No major infections were seen in this population. Two malignancies developed but they not clearly related to HIV infection, anti-TNF therapy, or the underlying disease requiring anti-TNF therapy. We suggest that with appropriate monitoring and consistent use of ART, patients with HIV infection may safely receive anti-TNF medications.

Vasculitis in HIV-Infected Individuals: Making the Case for an Antigen Driven Process

Courtney McCray,[1] Gloria Salazar,[2] Ryan Valicek,[1] Binh Nguyen,[3] Benjamin Naovarat,[4] Francis Williams,[2] and John Reveille[2], [1]University of Texas McGovern Medical School, Houston, TX, [2]University of Texas McGovern Medical School, Houston, [3]University of Texas McGoven Medical School, Houston, [4]University of Texas-McGovern Medical School, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A large spectrum of vasculitides affecting small, medium, and large vessels have been reported in HIV-infected individuals. Although vasculitis is a rare manifestation of HIV, it is a clinically important complication to recognize that requires immunosuppressive treatment. The purpose of this study was to examine the clinical features and treatment outcomes of HIV-infected individuals with vasculitis referred to a rheumatic disease clinic specialized in the treatment of HIV-related disorders.

Features of HIV-Associated Vasculitis

Age At Diagnosis	Gender/ Ethnic	Diagnosis	Treatment	Year of Diagnosis	Absolute CD4/ HIV viral load	Last Seen/Status
46	M/Black	Polyarteritis Nodosa	None	1996	Unknown	1997 - Deceased
51	F/Hisp	Polyarteritis Nodosa	Prednisone 60mg taper	2006	220/136,270	2019 - Alive, remission
57	M/White	Polyarteritis Nodosa	Prednisone 40 mg taper /Azathioprine	2008	187/208,571	Followed until 2015 – Lost to follow-up
21	M/Hisp	IgA Vasculitis (Henoch-Schoenlein purpura)	Prednisone 40 mg taper	2007	Unknown	2019 – Alive, remission
46	M/Hisp	Primary Angiitis of the CNS	Prednisone 60 mg taper	1998	Unknown	2019 – Alive, remission
53	F/Hisp	Primary Angiitis of the CNS	Prednisone/Mycophenolate Mofetil	2005	60/158,182	2012 - Deceased
44	F/Black	Granulomatosis with Polyangiitis	Prednisone 60 mg taper/Cyclophosphamide	1997	Always CD4 >500. (CD4 1767, viral load <400 in 2002)	2003 – Deceased
38	F/Hisp	Granulomatosis with Polyangiitis	Prednisone 60mg taper,azathioprine, cyclophosphamide	2002	146/ <400	2017 – Deceased
42	F/Hisp	MPO-associated Vasculitis	Prednisone 40 mg taper/Azathioprine	2006	27/ >750,000	2018 – Alive, remission
39	M/Black	HCV-related cutaneous vasculitis	Prednisone 40 mg taper	2007	511/10,176	2019 – Alive, remission

Methods: A retrospective chart review of HIV-infected patients evaluated at an outpatient rheumatology clinic from 1994-2019 was performed. Pertinent demographic data, disease features, laboratory data, treatment, and adverse events were collected.

Results: Ten of 1127 HIV-infected patients were diagnosed with the following: systemic vasculitis/polyarteritis nodosa (n=3), granulomatosis with polyangiitis (n=2) primary angiitis of the CNS (n=2), MPO-associated vasculitis (n=1), IgA vasculitis (n=1), HCV-associated cutaneous vasculitis (n=1). Ten patients were treated with prednisone, and 5 patients required additional immunosuppression with azathioprine (n=3), cyclophosphamide (n=2) and mycophenolate mofetil (n=1). Nine patients had sustained remission for several years. Five patients are currently alive, 3 patients died of non-vasculitis related complications, and 1 vasculitis-related death occurred in a patient who did not undergo treatment. One patient is lost to follow up. Of particular interest, no new cases of vasculitis were referred or diagnosed after 2008, despite no changes on the clinic physicians and no alternative clinical referral sites having become available.

Conclusion: Patients treated for vasculitis in the setting of HIV do well with sustained remission suggesting this is a milder form of disease. Additionally, the absence of new cases over the past 10 years is likely result of more effective antiretroviral treatment. This supports the hypothesis that the development of vasculitis in HIV-infected individual is an antigen or viral (i.e. HIV) driven process

Background/Purpose: Trimethoprim-sulfamethoxazole (TMP-SMX) is recommended as a first-line agent of pneumocystis pneumonia (PCP) prophylaxis for those who receive prolonged high-dose glucocorticoids. Alternative agents can be used, but relative efficacy of PCP prophylactic regimens are unknown. We investigated the prophylactic effect of TMP-SMX and other agents for PCP in patients with connective tissue diseases (CTDs) receiving high-dose glucocorticoids.

Methods: Patients with CTDs aged ≧ 18 years who were treated with a prolonged course (≧ 4 weeks) of steroids (≧ 20 mg/day prednisone) in a Japanese tertiary center between January 2013 and December 2017 were included. The

Lymphocyte ≦ 800/ml	28 (40.6)	161 (54.4)	86 (74.8)	<0.01
Chronic lung disease	10 (10.5)	115 (38.9)	60 (52.2)	<0.01

Categorical values were analyzed using Mantel-Haenszel chi-square test.
Continuous values were analyzed using one-way ANOVA.
*In other prophylactic drugs group, 107 cases received atovaquone and 8 cases received aerosolized pentamidine.
**Including Takayasu's arteritis and giant cell arteritis.
TMP-SMX, trimethoprim-sulfamethoxazole; ANCA, anti-neutrophil cytoplasmic antibody.

patients were categorized into three groups; TMP-SMX, other prophylactic drugs (atovaquone or aerosolized pentamidine), and no prophylaxis group. One-year incidence rate of PCP among the three groups was compared using a cox proportional hazards model.

Results: A total of 480 patients were identified. Two hundred ninety six patients received TMP-SMX while 115 received other prophylactic drugs (107 atovaquone and 8 aerosolized pentamidine). Compared with the no prophylaxis group, patients in the TMP-SMX and other prophylactic drugs group were older, more likely to have chronic lung disease and to be treated with cyclophosphamide and higher dose of glucocorticoids. During a total of 418.95 patient-years, 11 PCP cases (2 in the TMP-SMX, 6 in other prophylactic drugs, and 3 in the no prophylaxis group) occurred with a mortality rate of 54.5%. As compared with no prophylaxis, TMP-SMX significantly reduced the PCP incidence (adjusted HR=0.009, 95%CI 0.0005 to 0.15, p< 0.01) while other prophylactic drugs also reduced the PCP incidence (adjusted HR=0.034, 95%CI: 0.003-0.47, p=0.01).

Conclusion: Not only TMP-SMX but other PCP prophylactic drugs, atovaquone and aerosolized pentamidine, significantly reduced the PCP incidence in CTDs patients receiving prolonged high dose glucocorticoids. TMP-SMX seems to be more effective as a primary prophylaxis against PCP than other prophylactic drugs.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 6% of adults with idiopathic inflammatory myopathy (IIM) develop Pneumocystis jirovecii pneumonia (PJP), and PJP confers higher mortality in IIM patients compared to other connective tissue diseases. There are few studies examining PJP in juvenile IIM (JIIM). Our purpose was to characterize the clinical features associated with PJP infections in JIIM.

Methods: An electronic REDCap survey of 215 questions regarding JIIM disease course, medication usage, and PJP infection was sent to members of the Pediatric Rheumatology Bulletin Board, an electronic list-serv, and members of the Childhood Arthritis and Rheumatology Research Alliance. Retrospective chart review of JIIM patients who developed PJP was completed by the primary treating physician.

Results: Survey data were completed for nine juvenile dermatomyositis and one juvenile polymyositis patients who developed PJP infection between ages 1.7-18 years. Of these, 6/10 were male and the median age of IIM disease onset was 5.9 years (range 1.6-17.2 years). At IIM disease onset, 9/10 had weakness, 8/10 had Gottron's papules or heliotrope rash, 6/10 had dysphonia, and 5/10 had skin ulcers. Myositis specific autoantibodies (MSA) were obtained in 9 patients: 4 were positive for anti-MDA5, 1 was positive for anti-p155/140, and 4 were MSA negative. Anti-Ro (SSA) autoantibodies were present in 5/9 patients. The median duration from IIM onset to PJP diagnosis was 3.7 months (IQR 1.7-6.9 months). At PJP diagnosis, IIM disease severity was moderate in 7/10 and severe in 2/10 patients. At the time of PJP infection, 2 patients had interstitial lung disease, one of whom also had pulmonary hypertension. The average white blood cell count at PJP diagnosis was 12.7 thousand cells/μl and 3/10 patients had a low absolute lymphocyte count (range 76-590 cells/μl). Symptoms at PJP presentation included dyspnea on exertion (10/10), hypoxia (9/10), fever (8/10), cough (8/10), and tachycardia (8/10). Mean time from symptom onset to initiation of treatment for PJP was 1 week. The average daily dose of oral prednisone was 30mg (1.1 mg/kg/day) with 8/10 patients on ≥20mg prednisone daily, and 7/10 receiving IV pulse steroids the month prior. Only 2 patients received cyclophosphamide and/or rituximab prior to PJP. Eight patients required ICU admission and 6/10 required mechanical ventilation for an average of 49 days. Two patients required extracorporeal membrane oxygenation, both of whom died secondary to complications of PJP infection. None of the patients had received PJP prophylaxis prior to infection.

Conclusion: PJP affects JIIM patients receiving systemic immunosuppression. Most patients with PJP had moderate to severe disease at diagnosis. Skin ulcerations and anti-MDA5 autoantibodies were commonly reported. Infection with PJP occurred in the first 6 months of disease in the majority of patients, and most patients were receiving high doses of prednisone (≥20 mg) and IV pulse steroids. Due to the high mortality associated with PJP, prophylaxis may be warranted in a subset of JIIM patients with these disease features, especially early in the disease course when higher doses of steroids are required to control disease.

Clinical characteristics

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pneumonia is a common cause of death not only in the general population but also in patients with rheumatoid arthritis (RA). In particular, patients with RA have an increased risk for pneumonia due to rheumatoid lung disease and the use of some DMARDs. No studies have assessed differences in the management and prognosis of pneumonia in patients with RA compared to the general population. This study aimed to examine the prognosis of pneumonia and its management in patients with RA compared to the general population.

Methods: This study utilized the Diagnosis Procedure Combination database, a nationwide inpatient database in Japan. We reviewed abstract data and medical procedures to identify patients with pneumonia with or without RA between 2014 and 2016. We assessed differences in medical actions: examinations (such as imaging examination, bacteria culture, and antigen testing), interventions (such as oxygen supplementation, use of mechanical ventilation, and ICU admission), and treatment (such as type of antibiotic and duration of antibiotic therapy) between patients with and without RA. We compared the prognosis of pneumonia (mortality, length of hospitalization, aggravation of activities of daily living (ADL), and readmission) between patients with RA and those without RA. We examined the association between RA and pneumonia prognosis using multivariate analysis, adjusting for patients' background data, comorbidities, and pneumonia severity at admission.

Association of patients' background with 30-day hospital mortality

Results: For this study, 178,994 patients from 1,570 hospitals were eligible. Of these patients, 2,951 (1.6%) were diagnosed with RA. The severity of pneumonia in patients WITH RA was mild-to-moderate compared with patients without RA (p< 0.01). Patients with RA had more CT scans performed (84.6% vs 82.3%, p< 0.01) and more sputum culture tests (80.9% vs 47.7%, p< 0.01). Furthermore, broad-spectrum antibiotics (e.g., carbapenem) were frequently administered (16.1% vs 13.2%, p< 0.01) and the antibiotic administration period was slightly longer (8.9 days vs 7.6 days, p< 0.01) in these patients. Patients with RA had lower 30-day in-hospital mortality than those with RA (2.7% vs 5.1%, p< 0.01), but the length of hospital stay was longer (12.6 vs 11.4, p< 0.01). Multiple logistic regression analysis revealed that patients with RA did not have an associated increased risk of in-hospital mortality after adjusting for covariates in each pneumonia severity class (OR 1.36, 95% CI: 0.86-2.14). Lengthened hospitalization period was observed in patients with RA by Cox regression analysis (OR 0.78, 95% CI: 0.75-0.82).

Conclusion: Although pneumonia in patients with RA is not as severe as that in general patients, the rates of examination were high and broad-spectrum and long-term antibiotic treatment were administered more frequently in patients with RA. RA does not affect the prognosis of pneumonia but affects the hospitalization period. It is necessary to consider the implementation of appropriate medical practices according to the severity and the patient background for pneumonia in patients with RA.

Risk Factors for Pulmonary Nontuberculous Mycobacterial Disease in Rheumatoid Arthritis Patients

Yoichi Nakayama,[1] Eisaku Tanaka,[2] Masakuni Ueyama,[3] Satoru Terada,[2] Takashi Inao,[2] Yusuke Kaji,[2] Takehiro Yasuda,[2] Seishu Hashimoto,[2] Takashi Hajiro,[2] and Yoshio Taguchi[2], [1]Tenri Hospital, Department of General Internal Medicine, Tenri, Nara, Japan, [2]Tenri Hospital, Department of Respiratory Medicine, Tenri, Nara, Japan, [3]Tenri Hospital, Department of Respiratory Medicine, Tenri, Japan

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients have increased susceptibility to infection by pulmonary nontuberculous mycobacterial disease (pNTM) compared with the healthy population. The reason for this increased susceptibility to pNTM in RA patients is still unclear and few studies have been conducted to identify risk factors.

Methods: Medical records for all the RA patients who attended our hospital from March 2017 to March 2018 were retrospectively reviewed. pNTM was diagnosed by the criteria of the American Thoracic Society and the Infectious Diseases Society of America. Clinical factors such as age, gender, BMI, smoking history, diabetes, Charlson Comorbidity Index (CCI), rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), DMARDs, and chest CT findings were collected and compared between RA patients with and without pNTM.

Results: Data from 868 RA patients (205 males, 663 females) were analyzed. Among those patients, 37 patients were diagnosed with pNTM. Patients with pNTM were significantly older and had lower BMI than those without (72 +/- 10.6 vs 66.9 +/-13.5, p=0.014, and 20.0 +/-3.9 kg/m^2 vs 22.5 +/-4.5 kg/m^2, p=0.016, respectively). RF positivity was significantly higher in patients with pNTM (100% vs 83.6%, p=0.014). Percentages of MTX or bDMARDs use were significantly lower in patients with pNTM (48.9% vs 69.0%, p=0.016, 10.8% vs 30.0%, p=0.020). For chest CT findings, consolidation, cavitary lesion, pleural effusion, nodular lesion, and bronchiectasis were significantly higher among patients with pNTM (71.4% vs 8.0%, 14.3% vs 1.1%, 17.1% vs 2.0%, 85.7% vs 16.2%, and 62.9% vs 14.2%, respectively, with all p< 0.001). Multiple logistic regression analysis revealed ACPA and lower BMI to be independent risk factors of pNTM in RA patients (OR=4.9, 95% CI 1.1-21.0 and OR=0.8, 95% CI 0.7-0.9, respectively).

Conclusion: As is consistent with patients without RA, lower BMI is a risk factor for pNTM in RA patients. We identified ACPA positivity as a novel risk factor for pNTM in RA patients.

Are Immunosuppressants a Risk Factor Associated with *Mycobacterium Tuberculosis* Infection in Colombian Patients with Systemic Lupus Erythematosus? A Case-control Study

Jaime Coral-Enriquez,[1] Mauricio Restrepo,[2] Gloria Vasquez,[3] Carlos H Muñoz-Vahos,[4] Daniel Jaramillo,[5] Adriana Vanegas-García,[4] Ruth Eraso,[6] Johanna Hernández,[7] Fabian Jaimes,[8] and **Luis Gonzalez**[2], [1]Grupo de Reumatología, Universidad de Antioquia, Medellin, Colombia, [2]Grupo de Reumatología, Division of Rheumatology, Department of Internal Medicine, School of Medicine Universidad de Antioquia, Medellín, Colombia, [3]University of Antioquia, Medellin, Antioquia, Colombia, [4]Grupo de Reumatología, Universidad de Antioquia, Medellín, Antioquia, Colombia, [5]Rheumatology unit, Hospital Universitario San Vicente Fundación, Medellin, Colombia, [6]Grupo de Reumatología, Universidad de Antioquia; Pediatric rheumatology unit, Hospital Pablo Tobón Uribe, Medellin, Colombia, [7]Division of Rheumatology, Pediatric Department, School of Medicine, Universidad de Antioquia, Medellín, Colombia, [8]Department of Epidemiology, Hospital Universitario San Vicente Fundación, Universidad de Antioquia, Medellín, Colombia, Medellín, Colombia

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

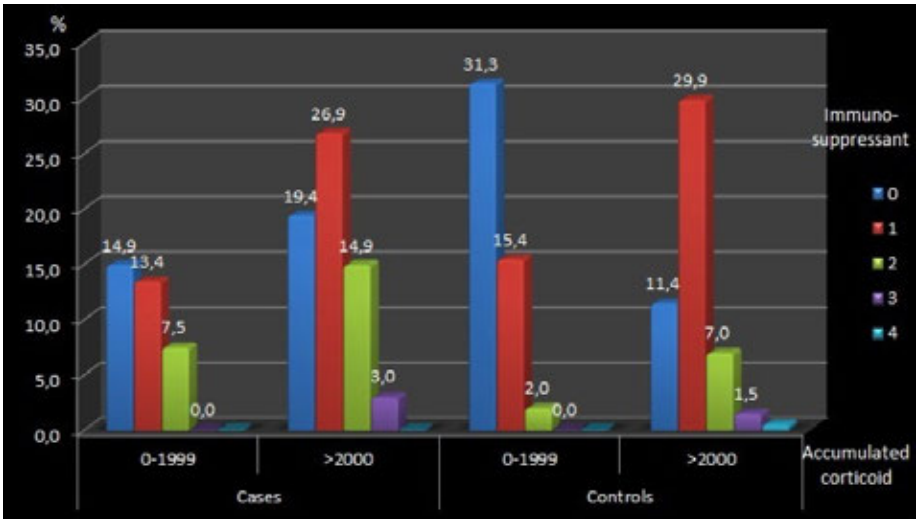

Figure 1. Number of immunosuppressants received within the last year in both, cases and controls, discriminated by the cumulative dose of glucocorticoids (<2 grams or ≥2 grams).

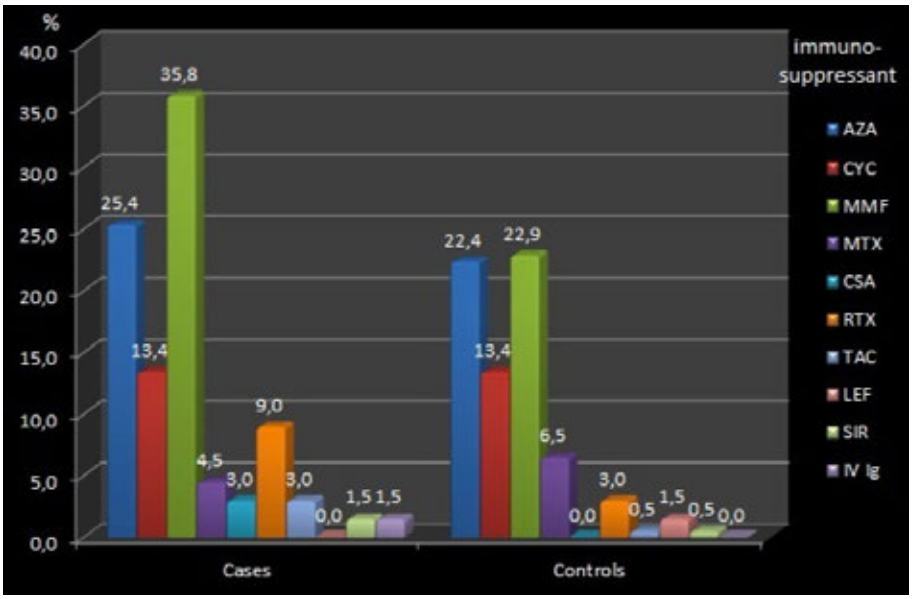

Figure 2. Frequency of immunosuppressants used in cases and in controls. AZA: azathioprine. CYC: cyclophosphamide. MMF: mycophenolate mofetil. MTX: methotrexate. CSA: ciclosporin A. RTX: rituximab. TAC: tacrolimus. LEF: leflunomide. SIR: sirolimus. IV Ig: intravenous immunoglobulin.

Background/Purpose: Tuberculosis (TB) infection is an important cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients, especially in developing countries. Previous studies have shown that higher cumulative doses of glucocorticoids within the last year are a risk factor for *Mycobacterium tuberculosis* infection. However, the role of conventional immunosuppressants in TB development is controversial. The aim of this study was to identify the factors associated with TB infection in SLE patients.

Methods: A retrospective case-control study. From January 2007 to December 2017, a total of 268 patients who met the 1997 ACR revised classification criteria for SLE were included. Cases were SLE patients diagnosed with TB by clinical, radiological, microbiological, molecular and/or histopathological criteria (SLE-TB). TB infection was classified as pulmonary, extrapulmonary or disseminated. Controls were SLE patients without TB infection (SLE-non-TB). In

total 67 cases and 201 controls were assessed. The quantitative variables are expressed as means or medians with their respective measure of dispersion and the qualitative variables as absolute number and percentage. Univariable and multivariable logistic regression analyses were performed.

Results: Females were more frequent in cases (83.5%) and controls (86%). The mean age was 34 years (range 13-84 years) for cases and 36 years (range 10-87 years) for controls. No significant differences in the frequency of comorbidities [diabetes, cirrhosis and Charlson comorbidity index (CCI)], disease duration and disease activity (SLEDAI) between cases and controls were found. Pulmonary TB occurred in 46.3%, extrapulmonary TB in 16.4% and disseminated TB in 37.3% of cases. Miliary pattern on chest X-ray was found in 23.8% of cases. In the univariable analyses, kidney transplantation, cumulative glucocorticoid dose (>2 grams) and ≥2 immunosuppressants received within the last year were associated with TB infection (11.9% in cases vs. 4.4% in controls; p= 0.04; 3.7 grams in cases vs. 2.1 grams in controls, p = 0.02; 22.7% in cases and 8.9% in controls, p= 0.02, respectively) (figure 1). By multivariable analysis, after adjusting for age, gender, disease duration, nephritis, antimalarials, immunosuppressants and CCI, cumulative glucocorticoid dose (OR 1.00; 95% CI 1.00-1.01; p=0.02) and kidney transplantation (OR 4.1; 95% CI 1.06-16.1; p=0.04) were significantly associated with TB infection occurrence. The most commonly immunosuppressants used were mycophenolate mofetil (MMF), azathioprine and cyclophosphamide, with a higher prevalence of MMF and rituximab in SLE-TB compared with SLE-non-TB patients (35.8% vs. 22.9% and 9% vs. 3%, respectively) (Figure 2).

Conclusion: Besides cumulative glucocorticoid dose (>2 grams), kidney transplantation was found to be significantly associated with an increased risk of Mycobacterium tuberculosis infection. Although, the exposure to ≥2 immunosuppressants was more than twice in cases than in controls, it was not significant in multivariable analysis. Prospective studies are needed to clarify the potential risk of immunosuppressants for TB infection development in SLE.

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fungal infections are an important cause of morbidity and mortality in patients with rheumatic diseases. Invasive aspergillosis (IA) is a fungal infection potentially fatal, which has been primarily described in patients with profound neutropenia such as those with hematologic malignancies. There is limited information in patients with rheumatic diseases. We describe herein clinical characteristics and outcomes of IA diagnosed in patients with rheumatic diseases.

Methods: At first, we identified from microbiological records of a national referral center for rheumatic diseases, patients with *Aspergillus spp.* isolated and/or positive galactomannan (January 2014-December 2018); then patients

Steroids, (%)	28 (84.8)	7 (77.8)	21 (87.5)	0.00	
Immunosuppresor non steroid, n (%)	28 (84.8)	7 (77.8)	21 (87.5)	0.00	
Activity disease	26 (78.8)	8 (88.9)	18 (75)	0.39	
Hepatic failure	12 (36.4)	3 (33.3)	9 (37.5)	0.8	
Time to initiate antifungal therapy, median (IQR) days	10 (4-20)	9(3-21)	10(4-20)	0.8	

obtained, including the disease activity status and its severity. Descriptive statistics was used along with multivariate analysis to investigate 6-weeks mortality predictors.

Results: Thirty-three patients with a rheumatic disease and IA were identified; of them, 14 patients (42.4%) had SLE, 9 (27.3) had polyangiitis with granulomatosis, 4 (12%) had dermatomyositis, 3 (9.1%) had RA, 2 (6%) had adult onset Still disease and 1 patient (3%) has primary antiphospholipid syndrome. The majority of the patients (29 [87.9%]) had probable IA, meanwhile, 3 (9%) had putative IA and 1 patient left (3%) had proven IA; also, 14 patients (42.4%) had a bacterial co-infection. Demographical, clinical characteristics, treatment and relevant laboratory parameters from the population are summarized in **Table 1. Table 2** summarizes IA clinical presentations, radiological findings and treatment. Fifteen (45.4%) patients had ≥1 culture with *Aspergillus* growth, the most frequent species were: *A. fumigatus* 10 /19 (53%), *A. niger* 3 (15.7%), *A.flavus* 1 (5%) and 5(26.3%) *Aspergillus sp*. Galactomannan antigen was tested on 27 (82%) of which 20/27 (74%) were positive: 14(70%) serum, 12(60%) in broncoalvoelar lavage samples and 3 cases had both. Six-week mortality was 27%. **Table 3** summarizes risk factors associated to mortality. In the multivariate analysis platelets counts below 100.0 K/uL was the only risk factor identified.

Conclusion: In this study we found specifics characteristics among the rheumatologic patients. The six week mortality of 27% was lower than has been reported in non neutropenic patients. Finally only thrombocytopenia was found as a risk factor of mortality in this group. It is necessary an increased knowledge of IA characteristics in these group of patients for early diagnosis and treatment.

Symptomatic Coccidioidomycosis Infections in Patients on Biologic Therapies

Alexander Peck,[1] Ella Starobinska,[2] Gilbert Ortega,[1] Travis Maestas,[1] Jaclyn Leong,[1] Phan Saligrama,[1] Jawad Bilal,[1] and Dominick Sudano[3], [1]University of Arizona College of Medicine, Tucson, AZ, [2]University of Arizona College of Medicine, Tucson, AL, [3]Banner University Medical Center Tucson, Tucson

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies have shown an increased risk of *coccidioidomycosis* infection in immunosuppressed patients. However, relationship of *coccidioidomycosis* infections with different immunosuppressive medication is not well established. This study was aimed to examine the characteristics of symptomatic *coccidioidomycosis* infections in patients with rheumatic diseases on biologic infusions.

Methods: A retrospective study was conducted between 2013 and 2017 at two infusion centers affiliated with the University of Arizona. Patients with rheumatic diseases on biological infusions for the diagnosis of symptomatic *coccidioidomycosis* were identified. The data related to method of infection identification, subsequent management, and concurrent steroid.

Results: Out of 548 patients, 21/548 (3.8%) had symptomatic *coccidioidomycosis.* Mean age was 54 years. 15/21 (71.4%) were female and 6 (28.6%) were male. 1/21 had disseminated disease, 17/21 had primary pulmonary disease, and 3/21 had unclear disease status. 6/21 (28.6%) patients were on rituximab therapy, 4/21 (19%) were on infliximab, 4/21 (19%) were on tocilizumab, 2/21 (9.5%) were on abatacept, 2/21 (9.5%) on golimumab 1/21 (4.8%) on canakinumab, and 1/21 (4.8%) on IVIG. Total of 15/21 (71.4%) patients used glucocorticoids with average dose being 14.5mg. 7/15 (46.7%) of patients were on chronic glucocorticoids treatment.

10/21 (47.6%) were diagnosed with a positive qualitative immunodiffusion assay. 4/21 (19%) patients had a serum enzyme-linked immunosorbent assay with positive titers > 1:2. 4/21 (19%) patients had a positive complement fixation test. 3/21 (14.3%) patients were diagnosed with a positive fungal culture, 2/3 being from a respiratory source.

15/21 (71.4%) patients had an abnormal chest x-ray, with the most common finding being a nodule (6/15). 12/21 (57%) patients had an abnormal chest CT, with the most common finding being a nodule as well (6/12). 17/21 (80.9%) were started on antifungal therapy, with 16/17 (94%) being started on fluconazole. 9/21 (42.9%) patients had their biologic therapy stopped, with 3/9 (33.3%) eventually having their biologic therapy restarted. 12/21 patients continued their therapy without interruption.

Conclusion: This study showed that occurrence of symptomatic *coccidioidomycosis* infection was more prevalent in patients using concurrent glucocorticoids with biologics. Among biologics, rituximab had the highest rate of symptomatic infections. Qualitative immunodiffusion assay was commonly utilized test to diagnose coccidioidomycosis infection. The vast majority of patients were treated with fluconazole, but continued the antirheumatic therapy.

Real Life Serious Infections in Patients with Chronic Inflammatory Arthritis on Treatment with TNF Inhibitors

Alazne Ruiz,[1] Juan Ramón De Dios,[2] Belen Alvarez,[1] Margarida Vasques Rocha,[2] Claudia Stoye,[2] Susana Gil,[1] Orlando Pompei Fernández,[2] and **Jaime Calvo-Alen**[3], [1]Hospital Universitario Araba, Vitoria, Pais Vasco, Spain, [2]Araba University Hospital, Vitoria, Pais Vasco, Spain, [3]Hospital Universitario Araba, Vitoria-Gasteiz, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To study frequency and associated factors for serious infections in patients with inflammatory arthritis treated with TNF inhibitors

Methods: All the medical records of the patients with inflammatory arthritis being treated with TNF inhibitors at the beginning of 2016 were reviewed. All seroious infections suffered for these patients until the end of 2018 were recorded. Serious infections were defined as those which required to admitted at the hospital for intraveous treatment. Potential variables associated with the development of these infections including: demographic and clinical characteristics, concomitant treatments or comorbidity (by Charlson index) were studied. Standard statistical tests for descriptive and univariate analyses were used and a multivariable logistic regression model was built to check independent associations.

Results: Overall 334 patients (50.3% women) with a mean age of 56.67 (±12.853) were studied: 140 (41.92%) Rheumatoid arthritis (RA), 55 (16.46%) psoriatic arthritis (PsA) and 138 (41.62%) spondyloarthritis (Sp). Forty five serious infections were observed in 30 patients, being respiratory (40%) and urinary (8.8%) the most frequent localizations. Only one patient died. By univariate analysis, disease duration, age, concomitan use of glucocorticoids (GC) (but not of synthetic DMARDs), Charlson index and specifically Diabetes Mellitus were associated with infection ($p< 0.05$). The type of arthritis was not associated and the results in the subset of RA patients were overall similar. In the multivariate analysis the use of GC [OR: 5.31 (1.98.14.26)] and the Charlson index [OR:2.48 (1.70;3.60)] were found to be independently associated to infection.

Conclusion: In patients with inflammatory arthritis and treated with TNF inhibitors around a 10% developed any serious infection along three years of follow up. Use of GC and comorbidity emerged as the main risk factors for this complication.

Biological Therapy Is Associated with Faster Recovery and Lower Frequency of Switch Treatment in Patients with Chikungunya Fever

Aline Razolin,[1] Claudia Marques,[1] **Laurindo Rocha Jr**,[2] Hugo Lima,[3] Lays Martins,[1] Anderson Almeida,[1] Priscila Oliveira,[1] Angela Duarte,[1] Moacyr Rego,[1] Maira Pitta,[4] and Ieda Laurindo[5], [1]Universidade Federal de Pernambuco, Recife, Brazil, [2]Instituto de Medicina Integral Professor Fernando Figueira - IMIP, Recife, Brazil, [3]Instituto de Medicina Integral Professor Fernando Figueira - IMIP, Recife, Pernambuco, Brazil, [4]Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil, [5]BIOBADABRASIL comittee, São Paulo

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The first chikungunya fever outbreak in Brazil had its peak in the first half of 2016 and many patients with rheumatologic disease using biological disease-modifying antirheumatic drugs (bDMARD) and conventional synthetic disease-modifying antirheumatic drugs therapy (csDMARD) were affected by the disease. Although there was initially concerns about the use of drugs with immunosuppressive potential in patients with a viral infection, the clinical practice and a few case reports demonstrated that there were no major complications and the clinical course seems to be similar to healthy population. The aim of this study was to compare the clinical course of rheumatic patients with rheumatic diseases treated with bDMARD or csDMARD.

Methods: The patients included in this study was select from two centers in Pernambuco, participating in the Brazilian cohort of patients with rheumatic diseases using bDMARD or csDMARD. Data about the disease therapy for the rheumatic disease and the symptoms of Chikungunya fever were collected. All the patients had the rheumatic disease diagnosis before the Chikungunya fever Brazilian outbreak and underwent serologic testing for chikungunya virus (CHIKV) IgG. The clinical data and blood sample for serology testing was taken from July 2017 until July 2018.

Results: We included 103 patients in the study and 74.7% were women; the most frequent previous rheumatologic diagnosis was rheumatoid arthritis (76.1%); 50.5% of the sample was on bDMARD therapy combined or not with csDMARD, of which 21% exclusively on biological use. The overall soroprevalence of CHIKV IgG was 40.8%; on bDMARD patients it was 36.5% and on csDMARD 46.4% (p=0.437). Among patients with positive CHIKV IgG, 26.2% had no typical Chikungunya fever symptoms (fever and joint pain). No differences were observed among the two groups regarding the number of patients with asymptomatic infection. There was no clinically significant difference in acute phase symptoms between the two groups of patients. Regarding the persistence time of Chikungunya fever musculoskeletal symptoms in CHIKV IgG positive group, 85.7% of patients using bDMARD recovered up to 3 months compared to 47.1% in the non bDMARD group (p=0.029). In addition, the bDMARD group switched the treatment less frequently after CHIKV infection (p=0.0001).

Conclusion: The bDMARD seems to be associated with a shorter period of Chikungunya fever symptoms and lower frequency of flare triggered by CHIKV infection comparing to csDMARD. No difference was observed between the severity of the symptoms in both groups.

Risk Factors for Cytomegalovirus Infection in Patients with Autoimmune Diseases

Daisuke Kobayashi,[1] Sayuri Takamura,[2] Yoko Wada,[3] Takeshi Kuroda,[4] and Ichiei Narita[1], [1]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Niigata, Japan, [2]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Japan, [3]Niigata Rinko Hospital, Niigata, Niigata, Japan, [4]Health administration office, Niigata University, Niigata, Niigata, Japan

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Intensive immunosuppressive treatment is often required for patients with autoimmune diseases, and those who are thus treated have a high risk of opportunistic infections. It is therefore important to investigate the risk of opportunistic infections to ensure appropriate management of patients with autoimmune disease. Cytomegalovirus (CMV) infection is one of the most common opportunistic infections. Since 2011 we have been performing routine weekly evaluation of CMV pp65 antigen for such patients. Here we investigated the predictive risk factors for CMV infection under remission-induction therapy in patients with autoimmune disease.

Methods: We enrolled 96 patients (male 34, female 62) with autoimmune disease who received remission-induction therapy with prednisolone at over 0.5 mg/kg/day in Niigata University Hospital between January 2017 and December 2018. We retrospectively analyzed their clinical features and laboratory data at the baseline, the treatment regimens used, and the results of CMVpp65 antigen analysis. The presence of more than 5 CMVpp65 antigen-positive cells/2 slides was defined as a positive result. We conducted univariate and multivariate analyses to identify risk factors for CMV positivity.

Results: The enrolled patients included 26 systemic lupus erythematosus (SLE), 18 anti-nucleolar cytoplasmic antibody-associated vasculitis (AAV), 8 interstitial pneumonia with anti-aminoacyl tRNA synthetase antibody, 6 mixed connective tissue disease (MCTD), 6 rheumatoid arthritis, 5 clinically amyopathic dermatomyositis (CADM), 5 adult-onset Still's disease (AOSD), 5 Takayasu's aortitis, and 17 other conditions. Methylprednisolone pulse therapy, intravenous cyclophosphamide, oral calcineurin inhibitor, methotrexate, azathioprine, and mycophenolate mofetil were applied in 36 (37.5%), 17 (17.7%), 7 (7.29%), 4 (4.17%), 4 (4.17%), and 3 (3.13%) patients, respectively. The median follow-up duration was 62.5 days, and 21 patients became CMV antigenemia-positive (SLE 9, AOSD 4, AAV 2, CADM 2, MCTD 2, and others 2). Univariate analysis showed that the positivity was associated with a low total lymphocyte count (TLC) (710/μl vs 1330/μl; $p< 0.001$), a low serum albumin level (2.70 g/dl vs 3.50 g/dl; $p< 0.001$), a high HbA1c level (6.4% vs 5.9%; $p< 0.001$), and a high initial prednisolone dosage (0.97 mg/kg/day vs 0.86 mg/kg/day; $p< 0.001$). Fifteen of the 21 patients in the positive group received steroid pulse therapy ($p< 0.001$). The Cox hazard regression model indicated that a higher age by decade (OR; 1.46 [95%CI 1.06- 2.00]), a lower TLC per 100/mL (OR; 0.827 [95%CI 0.731-0.935]), a higher HbA1c level per 1% (OR; 2.37 [1.25-4.53]), and mPSL pulse therapy (OR; 3.92 [1.33-11.5]) were independent risk factors for CMV positivity.

Conclusion: Lower TLC, lower serum albumin, higher HbA1c, and receiving steroid pulse therapy were risk factors for CMV pp65 antigen positivity. Careful monitoring is therefore necessary for such patients.

Abstract Number: 2115

BK Polyomavirus Viremia and Viruria in Patients with Autoimmune Connective Tissue Diseases: Impact of Immunosuppressants

Mamatha Katikaneni,[1] Madeline Davis,[1] Carolyn Smith,[2] and John Vanchiere[2], [1]LSUHSC- Shreveport, Shreveport, LA, [2]LSUHSC- Shreveport, Shreveport

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The human polyomaviruses, such as the BK and JC virus, are highly prevalent in humans but appear to cause clinical disease only in immunocompromised patients. BK virus (BKV) is the primary cause of tubulointerstitial nephritis and ureteral stenosis in kidney transplant recipients and hemorrhagic cystitis in bone marrow transplant recipients. Among transplant recipients, it has been hypothesized that the intensity of immune suppression, rather than the specific immunosuppressive agent used, determines the risk for BKV replication and progression to clinically significant disease.

Patients with autoimmune connective tissue diseases (CTD) like Systemic Lupus Erythematosus (SLE) and Rheumatoid arthritis (RA) have been shown to have increased polyomavirus levels in blood and urine. The treatment for these autoimmune diseases include medications like corticosteroids and disease modifying anti-rheumatic drugs (DMARDS), including biologics and cytotoxic agents which have been shown to increase the frequency of virus reactivation/excretion in prior studies. The purpose of this study was to determine the prevalence of BK virus in the blood and its excretion in urine in immunosuppressed patients with CTDs. We hypothesized that subjects on DMARDS plus steroids would have the highest prevalence of BKV viremia and viruria.

Methods: Sixty-six patients with CTD on various immunosuppressive regimens (including Prednisone, Mycophenolate Mofetil, Methotrexate, Leflunomide, Azathioprine, Sulfasalazine, Hydroxychloroquine, Tumor necrosis factor inhibitors, Tocilizumab, Rituximab, Cyclophosphamide) and control subjects were enrolled after informed consent was obtained. Urine and serum specimens were collected at each clinic visit and analyzed qualitatively and quantitatively for BK virus by PCR. Subjects' demographic data, diagnosis and medications were recorded at the time of each clinic visit. The frequency of BKV viruria and viremia was compared for clinical and demographic factors using Chi-square analysis. Multivariate analysis is planned once the study population reaches 100.

Results: The average age of study subjects was 53.5 +/- 12.4 years and 46 (69.7%) were African-American. Fifty-six (84.8%) subjects were female. Twenty subjects had RA, 15 had SLE, 31 had other diagnosis like Psoriatic arthritis, myositis, scleroderma. Serum and Urine specimens were collected from study subjects at 239 clinical visits. 155 (64.8%) of 239 urine specimens and 106 (45.1%) of 239 serum specimens were positive for BKV. There was no difference in the frequency of BKV viremia or viruria based on the subject's diagnosis (RA (49.2% and 62.9%) vs SLE (43.1% and 68.4%) vs other (43.6% and 69.6%)) Figure 1, or medication regimen (none vs. steroids vs. DMARDS vs. DMARDS + steroids) Figure 2.

Conclusion: Contrary to our hypothesis, there was no statistical difference between the frequency of BK-positive serum or urine by medication group. Likewise, there was no statistical difference in the frequency of BKV viremia or

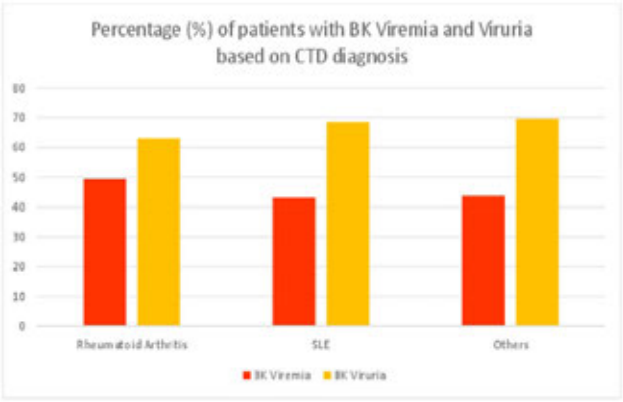

Figure 1. Percentage (%) of patients with BK Viremia and Viruria based on CTD diagnosis

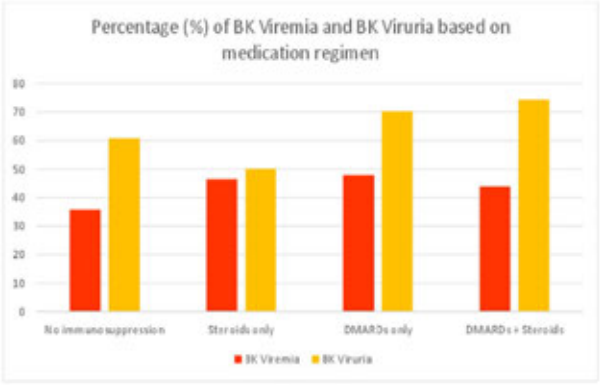

Figure 2. Percentage (%) of BK Viremia and BK Viruria based on medication regimen

viruria by subject's CTD diagnosis. These data suggest that immunologic control of BKV viremia and viruria may be dysregulated in CTD, independent of immunosuppressive regimens.

Serious Infection in Patients with Systemic Lupus Erythematosus, Lupus Nephritis and Rheumatoid Arthritis Compared to the General Population: Incidence Rates Using Real-World Claims Data

Lisa Lindsay,[1] Ching-Yi Chuo,[2] Nicholas Jones,[2] Joshua Galanter,[2] Anna McGregor,[2] and Katie Tuckwell[2], [1]Genentech Inc, SOUTH SAN FRANCISCO, CA, [2]Genentech Inc, SOUTH SAN FRANCISCO

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE), lupus nephritis (LN) and rheumatoid arthritis (RA) are at risk of serious infections (SIs) due to the impact of the disease itself and treatments that modulate immune function. Rates of SIs resulting in hospitalization among these patients have not been compared to the general population. The objective of this study was to compare the rates of SIs resulting in an inpatient claim in adult patients with SLE/LN, RA and the general population using population-based claims data.

Methods: We conducted a retrospective cohort study using the US-based Truven Healthcare MarketScan® Claims database for individuals aged 18-64 years enrolled between January 2007 and September 2015. Patients were required to have continuous enrollment for ≥ 90 days pre- and ≥ 365 days post-index date. Patients with SLE/LN (including non-renal SLE and LN) and RA were identified using modifications to algorithms developed for use in registry and/or claims data. The general population included individuals without SLE/LN or RA. Index date for the SLE/LN and RA cohorts was the date when patients fulfilled the diagnostic algorithms for SLE/LN, or RA. Index date for the general population occurred after 90 days of continuous enrollment. Patients were excluded from all cohorts if they had: an auto-immune (AI) condition other than SLE/LN or RA; cancer; received a solid-organ transplant; or HIV/AIDs. First incident SIs were identified as those that resulted in an inpatient claim for a pre-specified set of ICD-9 codes within 365 days of index date. Incidence rates (IRs) and standardized incidence ratios (SIRs) were calculated along with 95% confidence intervals (CI) adjusted for age, gender, index year, prevalent SI and glucocorticoid use.

Results: The SLE/LN, RA, and general population cohorts included 58,105, 183,229, and 50,530,269 patients, respectively. Table 1 provides a summary of cohort-specific patient characteristics. As anticipated, the SLE/LN and RA cohorts were predominantly female. The RA cohort was generally older than the other cohorts. Index date was fairly consistent across study year and cohort. In all cohorts, the unadjusted SI IRs increased with age, were higher among patients who had a prior SI (claim ≤ 90 days prior to the index date), and were slightly increased in patients who received systemic glucocorticoids ≤ 365 days after their index date. Adjusted SI IRs (95% CIs) were 21.2 (21.1, 21.2) in SLE/LN patients, followed by 15.8 (15.8, 15.8) in RA patients, and 3.8 (3.7, 3.8) in the general population

Table 1. Description of study population.

	SLE/LN* (n=58,105) n (%)	RA** (n=183,229) n (%)	General Population (n=50,530,269) n (%)
Age (years)			
18-34	11,177 (19.2)	17,298 (9.4)	18,790,240 (37.1)
35-44	14,389 (24.8)	31,873 (17.4)	11,218,925 (22.2)
45-54	18,352 (31.6)	63,702 (34.8)	11,677,603 (23.1)
55-64	14,187 (24.4)	70,356 (38.4)	8,837,501 (17.5)
Gender			
Female	52,316 (90.0)	136,341 (74.4)	26,188,302 (51.8)
Male	5,789 (10.0)	46,888 (25.6)	24,341,967 (48.1)

* SLE/LN = patients with non-renal systemic lupus erythematosus and lupus nephritis

** RA = patients with rheumatoid arthritis

Table 2. Adjusted* incidence rate (IR) and standardized incidence ratios (SIR) (95% confidence interval) for serious infections (SIs) for individuals with systemic lupus erythematosus(SLE) / lupus nephritis (LN), rheumatoid arthritis (RA) and the general population.

	SLE/LN**	RA***	General Population
SI event within 365 days of index	1,435	3,360	189,602
Person-years	57,037.10	180,919.70	50,433,745.24
Direct adjusted rate per 1000 person-year (95% CI)	21.2 (21.1, 21.2)	15.8 (15.8, 15.8)	3.8 (3.7, 3.8)
Adjusted SIR (95% CI)	4.4 (4.2, 4.6)	2.8 (2.7, 2.9)	Ref

* Adjusted for age, gender, index year, prevalent SI and glucocorticoid use within 365 days of index date.
** SLE/LN = patients with non-renal systemic lupus erythematosus and lupus nephritis
*** RA = patients with rheumatoid arthritis

(Table 2). Adjusted SIRs were 4.4 and 2.8 times higher among patients with SLE/LN and RA compared to the general population, respectively.

Conclusion: In this population-based analysis of claims data, adjusted SI IRs were highest in SLE/LN patients. Both AI cohorts experienced excess SI rates compared to the general population. These rates were based on inpatient claims from patients with varying disease severity and treatment patterns. Further characterization of the role of treatment and type of infection is warranted. Findings demonstrate the important contribution of SIs on the burden of disease among SLE/LN and RA patients.

Adjusted incidence rate (IR) and standardized incidence ratios (SIR) (95% confidence interval) for serious infections (SIs) for individuals with systemic lupus erythematosus(SLE)/lupus nephritis (LN), rheumatoid arthritis (RA) and the general population.

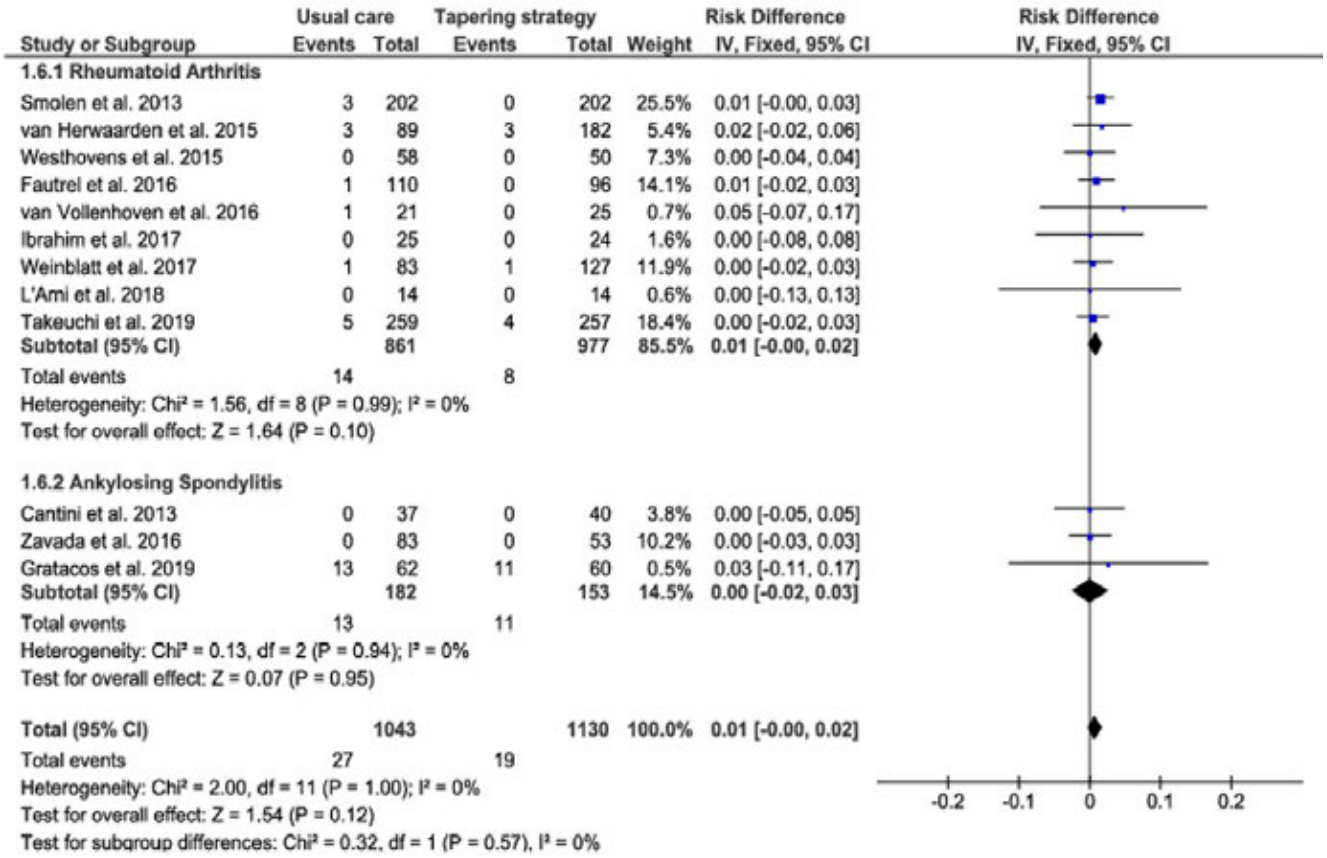
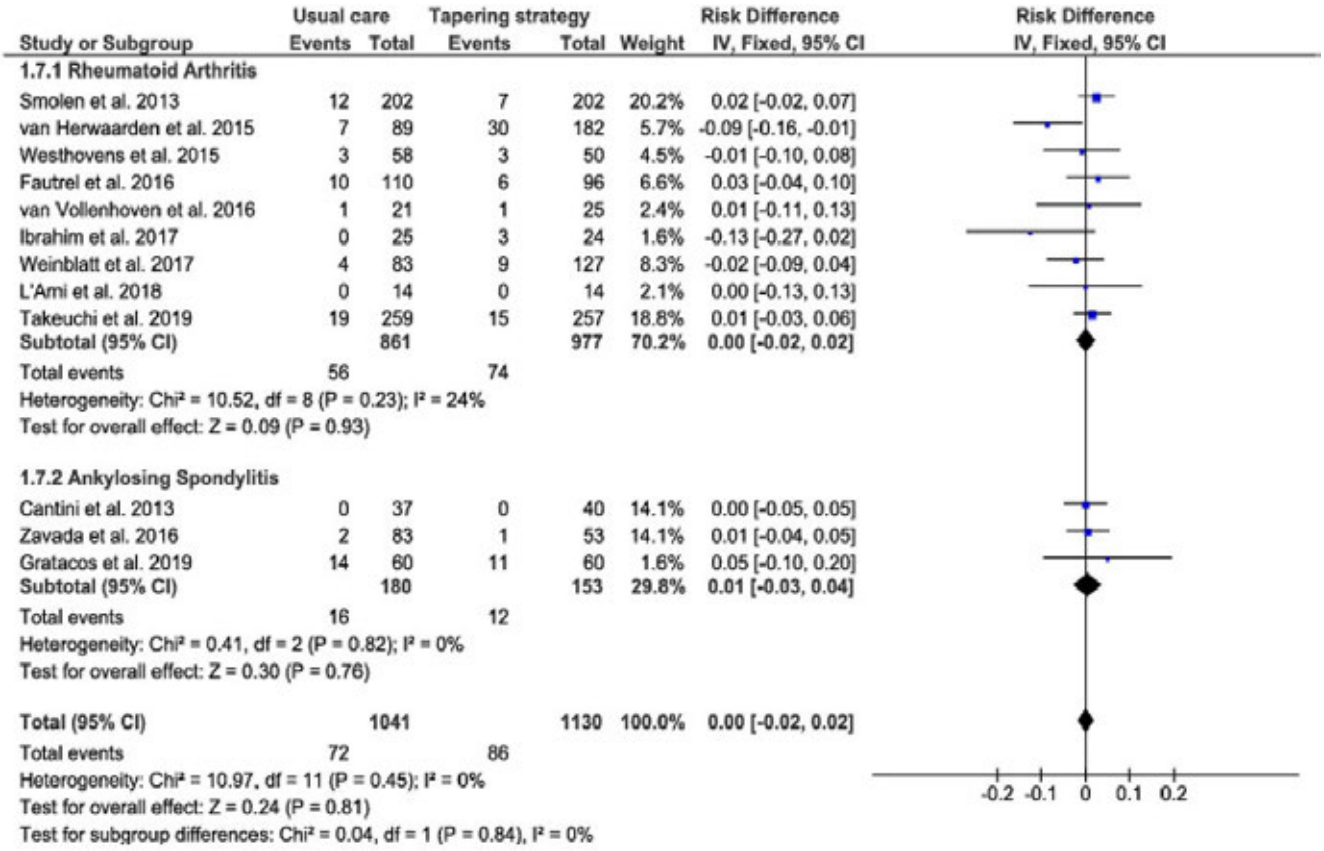
Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: A previous meta-analysis[1] showed that tapering of bDMARDs does not increase the risk of relapse in rheumatoid arthritis (RA) patients with remission or low disease activity (LDA). In the present meta-analysis



Risk difference of serious infections



Risk difference of serious Adverse Event

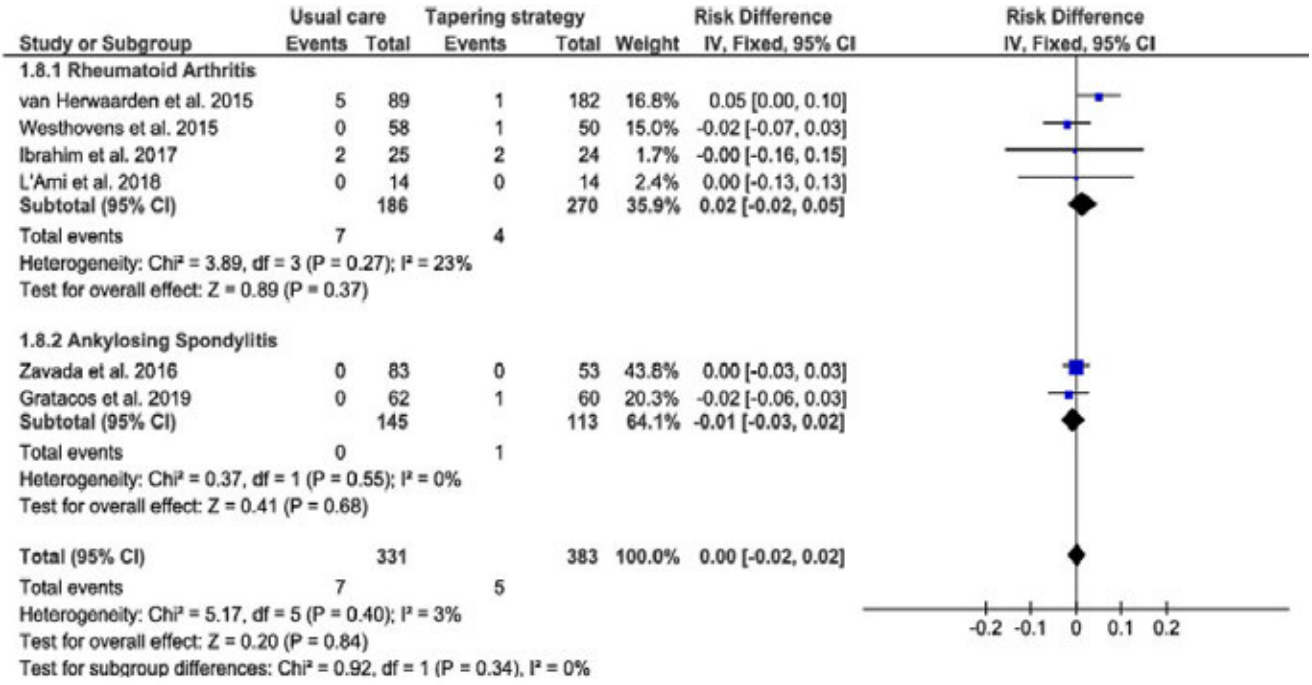
we assessed the impact of tapering targeted therapies (bDMARDs or Jakinibs) on the risk of adverse events (AEs) of special interest in patients with RA or spondyloarthritis (SpA) in remission or (LDA).

Methods: A systematic literature analysis was carried out through May 2019 on PubMed, Embase, Cochrane and international meeting databases, selecting controlled trials comparing tapering (dose reduction or spacing) versus continuation of the initial treatment regimen, in patients with RA or SpA in remission or LDA. The meta-analysis assessed the risk difference and 95% confidence interval (95%CI) of serious infections, serious AEs, malignancy or cardiovascular AEs after tapering versus continuation of bDMARDs or Jakinibs.

Results: 1922 records were screened in our systematic analysis of literature. 1826 records were excluded after title and abstract reading leaving 96 articles eligible. After full text assessment, 84 references were excluded. Twelve references were finally included in our systematic review and meta-analysis among which 9 trials refered to RA and 3 trials to SpA.

There were 1129 patient-year studied in the targeted therapy tapering group (TG) versus 1041 in the usual care group (UC). The study period lasted 6 months in 2 trials, 12 months in 7 trials and around 18 months in 3 trials. Mean years from diagnosis was 8 years and extended from 2.6 years to 16.6 years, the sex ratio was 67% and mean age was 51 years in both groups.

The meta-analysis comparing targeted therapy tapering versus continuation performed on twelve trials showed no decreased risk of serious infections (Risk difference (95% CI) = 0.01 (-0.00 to 0.02), P = 0.12), serious AEs (Risk difference (95% CI) = 0.00 (-0.02 to 0.02), P = 0.81), malignancy (Risk difference (95% CI) = -0.01 (-0.02 to 0.01), P



Risk difference of Cardiovascular Adverse Event

= 0.33) or cardiovascular AEs (Risk difference (95% CI) = 0.00 (-0.02 to 0.02), P = 0.84). There was no difference in subgroup analysis (RA and SpA).

Conclusion: In this meta-analysis focused on controlled trials in RA and SpA patients in remission or LDA, tapering bDMARDs or Jakinibs does not lead to a decreased risk of serious infections, serious AEs, malignancy or cardiovascular AEs in comparison with continuation of the initial treatment regimen.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The asymptotic individuals with the human T lymphotropic virus type I (HTLV-I) infection rarely develop adult T cell leukemia/lymphoma (ATL) or HTLV-I–associated myelopathy (HAM). In addition, HTLV1 infection is also associated with rheumatic disease such as HTLV-I–associated arthropathy, rheumatoid arthritis (RA), and Sjogren's syndrome. The HTLV-I virus infects not only primarily CD4+ T lymphocytes but also synovial fibroblasts and salivary gland epithelial cells, and the HTLV-I infections modify the functions of these cells and induce various inflammatory conditions. Therefore, it is important clinical issue whether HTLV-I infection changes the pathological condition and the therapeutic response in patients with rheumatic disease.

Our previous study has showed that the efficacy of tumor necrosis factor inhibitor (TNFi) was attenuated in anti–HTLV-I antibody–positive patients with RA. However, no previous reports have examined the comparative efficacy and safety between anti–HTLV-I antibody–negative and –positive RA patients when they are treated with non-TNFi biologics.

We aimed to evaluate the efficacy and safety of tocilizumab (TCZ) in anti–HTLV-I antibody–positive patients with RA compared with those negative patients using a multicenter retrospective cohort.

Methods: The present study reviewed Japanese RA patients who TCZ was newly introduced as a first biologics between April 2008 and September 2018 at 7 participating rheumatology centers in Nagasaki and Miyazaki Prefecture in Japan, which are known as endemic areas of HTLV-I infection. Patients with unclear anti–HTLV-I antibody status and patients with remission at baseline were excluded. Overall, the outcomes of 184 patients treated with TCZ were analyzed. The primary end point was the change in the patients' clinical disease activity index (CDAI) between entry and 6 months after the initiation of TCZ treatment. We also analyzed the occurrence of ATL or HAM during TCZ treatment periods for 6 months.

Table 1. Baseline participant characteristic by positivity or negativity of anti–HTLV-I antibody (univariate analysis)

Variables	All patients (n = 184)	Anti–HTLV-I antibody–negative patients (n = 167)	Anti–HTLV-I antibody–positive patients (n = 17)	p-value
Patient characteristics at baseline				
Age (years)	62.5 (55.0 – 71.0, n = 184)	62.0 (54.0 – 71.0, n = 167)	70.0 (62.5 – 78.0, n = 17)	0.009
Disease duration (month)	68.5 (15.0 – 175.7, n = 184)	68.0 (15.0 – 180.0, n = 167)	72.0 (11.5 – 145.8, n = 17)	0.86
Male gender (%)	45/184 (24.5%)	41/167 (24.6%)	4/17 (23.5%)	1.00
Medication at baseline				
Concomitant prednisolone use (%)	114/184 (62.0%)	105/167 (62.9%)	9/17 (52.9%)	0.44
Doses of concomitant prednisolone (mg/day)	3.0 (0.0 – 5.0, n = 184)	3.0 (0.0 – 5.0, n = 167)	2.5 (0.0 – 6.3, n = 17)	0.67
Concomitant methotrexate use (%)	81/184 (44.0%)	70/167 (41.9%)	11/17 (64.7%)	0.08
Doses of concomitant methotrexate (mg/week)	0.0 (0.0 – 8.0, n = 184)	0.0 (0.0 – 8.0, n = 167)	8.0 (0.0 – 9.0, n = 17)	0.04
Laboratory findings at baseline				
Baseline RF positive (%)	147/184 (79.9%)	133/167 (79.6%)	14/17 (82.4%)	1.00
Baseline ACPA positive (%)	144/176 (81.8%)	29/159 (81.1%)	15/17 (81.2%)	0.74
Clinical disease activity at baseline				
Tender joint count in 28 joints	5.0 (2.0 – 10.0, n = 184)	5.0 (2.0 – 9.0, n = 167)	9.0 (5.0 – 14.0, n = 17)	0.02
Swollen joint count in 28 joints	4.0 (2.0 – 6.0, n = 184)	4.0 (2.0 – 6.0, n = 167)	6.0 (3.5 – 9.5, n = 17)	0.09
ESR (mm/hour)	43.0 (27.0 – 69.0, n = 181)	41.0 (26.3 – 67.8, n = 164)	62.0 (41.5 – 80.5, n = 17)	0.06
CRP (mg/dl)	1.2 (0.4 – 2.9, n = 184)	1.2 (0.3 – 2.9, n = 167)	1.8 (0.56 – 2.65, n = 17)	0.37
Patient's global assessment score (1–100-mm VAS)	50.0 (20.3 – 68.0, n – 184)	50.0 (20.0 – 68.0, n – 167)	50.0 (29.0 – 65.0, n – 17)	0.77

Table 1. Baseline participant characteristic by positivity or negativity of anti–HTLV-I antibody (univariate analysis)

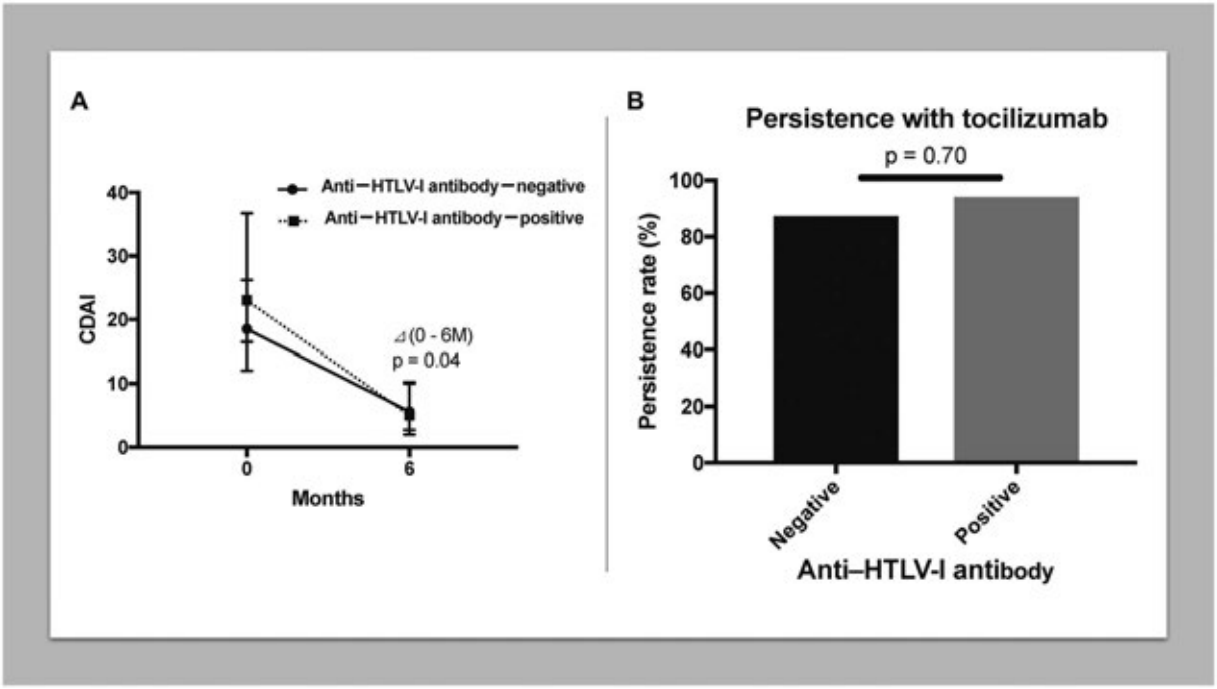

Figure 1. Clinical disease activity index and persistence with tocilizumab at 6 months by positivity or negativity of anti–HTLV-I antibody (univariate analysis)

Results: Enrolled total 184 patients were divided into anti–HTLV-I antibody–negative and –positive groups of 167 (90.8%) and 17 (9.2%). The median age at baseline and doses of concomitant methotrexate were significantly higher in anti–HTLV-I antibody–positive group ($p = 0.009$, $p = 0.04$, respectively). In addition, each indicator of clinical disease activity score at baseline was also significantly higher in anti–HTLV-I antibody–positive group. The CDAI score decreased significantly at 6 months in anti–HTLV-I antibody–positive group compared with anti–HTLV-I antibody–negative group ($p = 0.05$), and persistence with TCZ tended to be higher in anti–HTLV-I antibody–positive group. Multiple regression analysis demonstrated that anti–HTLV-I antibody status tended to be associated with the CDAI score's improvement but was not significant. No patients developed ATL or HAM during TCZ treatment periods for 6 months.

Conclusion: Our results indicate that TCZ treatment tend to confer prefer response in anti–HTLV-I antibody–positive patients with RA, but further investigations are desired.

Impact of Day of Admission and Time to Diagnostic Arthrocentesis on Mortality and Other Outcomes in Septic Arthritis: A Nationwide Analysis

Gustavo Contreras,[1] Ana B Arevalo,[1] Shane Murray,[1] Faris Haddadin,[1] and Yiming Luo[1], [1]Mount Sinai St. Luke's - West/ Icahn School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple studies have been done assessing the "weekend effect" and outcomes for hospitalized patients [1,2,3,4], however, there is no data evaluating the outcome of patients with septic arthritis of a native joint (SANJ) who are admitted on the weekend compared to the rest of the week. We evaluated whether important outcomes in SANJ, including in-hospital mortality, differ between patients admitted on weekends versus weekdays and the time to diagnostic arthrocentesis.

Methods: The National Inpatient Sample (NIS) database of the year 2016 was utilized for patients admitted to the hospital with a principal discharge diagnosis of SANJ. This was a retrospective cohort study of patients hospitalized in 2016 with SANJ in hospitals across the US. Patients were included if they were adults with a principal diagnosis of SANJ based on ICD-10 codes. Admissions between midnight Friday and midnight Sunday were classified as weekend admissions. Early arthrocentesis was defined as percutaneous arthrocentesis performed within 24 hours of admission. The proportion of patients with SANJ admitted over weekends versus weekdays was determined. Odds ratios (OR) were calculated for primary and secondary outcomes including in-hospital mortality rate, rates of diagnostic arthrocentesis and early arthrocentesis, length of stay and total hospital charges, These

results were compared after multivariable logistic regression adjusted for age, gender, race, day of admission, Charlson comorbidity index and median household yearly income in the patient's zip code. We used STATA-15 for statistical analysis.

Results: The study included 12819 patients with SANJ. Compared with patients admitted on weekdays, patients with SANJ admitted on weekends had increased in-hospital mortality rates (adjusted odds ratio[aOR] 3.67; 95% [CI] 1.52 – 8.86, p< .005), but similar early arthrocentesis rates ([aOR] 1.14; 95%, [CI] 0.90 – 1.45 p >0.05), length of stay (p >0.05) and hospital charges ($ 2751.11; 95% [CI] -4449.6 – 9951.8; P >0.05). However, regardless of the day of admission those who received an early arthrocentesis had lower length of stay (-1.46, p< 0.05), and lower total hospital charges ($ -6527 $; p< 0.05).

In-hospital mortality rates based on day of admission					
	Total	Weekend	Weekday	*Weekend as independent predictor of mortality	P value
SANJ	105/12819	46/105 (43.8%)	59/105 (56.2%)	(aOR 3.67; 95% CI 1.52 – 8.86)	P <0.005
*Adjusted for age, gender, race, day of admission, Charlson comorbidity index, median household yearly income in the patient's zip code; aOR= Adjusted odds ratio.					

Table 1

Adjusted* total hospital charges based on day of admission and time to arthrocentesis					
	Mean total hospital charges	Adjusted difference for arthrocentesis within 24 h	P value	Adjusted difference for arthrocentesis > 24 h	P value
SANJ	$ 64699.27; 95% CI (61321.48 – 68077.06)	$ -6527; 95 % CI (-13090.00 – -165.00)	P <0.05	$ 2751.08; 95% CI (-4449.6 – 9951.8)	P >0.5
*Adjusted for age, gender, race, day of admission, Charlson comorbidity index, median household yearly income in the patient's zip code					

Table 2

Adjusted* median length of stay (days)				
	Arthrocentesis within 24 h of admission	Arthrocentesis > 24 h after admission	P Value	Difference in length of stay (P value)
SANJ	7.11 (6.61 – 7.61)	8.61 (7.51 – 9.71)	<0.05	-1.46 (< 0.05)
*Adjusted for age, gender, race, day of admission, Charlson comorbidity index, median household yearly income in the patient's zip code				

Table 3

Conclusion: This study showed that compared with patients admitted on weekdays, patients with SANJ admitted on weekends had increased mortality rates but similar length of stays and total hospital charges. However, patients who received an early arthrocentesis had significantly lower length of stay and hospital charges regardless of the day of admission. This results add weight to the hypothesis of negative outcomes in weekend admissions. Moreover, we believe that our findings require further investigation to establish the role of early arthrocentesis in the management of septic arthritis.

No Evidence of an Increased Risk of Serious Infections Among 3 Classes of Biologics for Psoriasis or Psoriatic Arthritis: A Retrospective Real-World Cohort Study

Xintong Li,[1] **Kathleen M Andersen**,[2] Hsien-Yen Chang,[3] G. Caleb Alexander,[4] and Jeffrey Curtis[5], [1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health,, Baltimore, MD, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, [4]Johns Hopkins Bloomberg School of Public Health. Center for Drug Safety and Effectiveness, Baltimore, MD, [5]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The real-world risk of serious infections associated with interleukin (IL) and tumor necrosis factor-alpha (TNF-α) inhibitors for patients with psoriasis (PsO) and psoriatic arthritis (PsA) is unclear. The objective of this study was to examine whether initiation of IL-17, IL-12/23, or TNF-α, was associated with increased risk of serious infection among PsO and PsA patients.

Methods: We built a cohort of commercially insured adults diagnosed with PsO or PsA between 2015–2018 using data from the OptumLabs® Data Warehouse. Exposure was new use of IL-17 (ixekizumab or secukinumab), IL-12/23 (ustekinumab), or TNF-α (adalimumab, certolizumab pegol, etanercept, golimumab, or infliximab). The main outcome was hospitalized infection after date of biologic initiation. Incidence rates (IR) per 100 person-years were computed, and hazard ratios (HR) with 95% confidence intervals (CI) were estimated using Cox proportional hazards regression models, adjusted for inverse probability of treatment weighted propensity scores to control for confounding. In sensitivity analyses, we varied the permissible gap between prescriptions, and to restrict to infection listed as the first diagnosis code position.

Results: A total of 11,560 new treatment episodes were included (19% IL-17, 25% IL-12/23, 56% TNF-α inhibitors). Overall, 190 serious infections (2% of treatment episodes) were identified in 9,264 person-years of follow-up (Table). Class-specific IR were similar among IL-17 and TNF- α, and significantly lower for IL-12/23. After adjustment for propensity scores, there was no evidence of an increased risk of serious infections with IL-17, as compared to either TNF-α (HR=0.89, 95% CI 0.48-1.66) or IL-12/23 (HR=1.12, 95% CI 0.62-2.03). By contrast, IL-23/23 were associated with a lower risk of infections than TNF-α (HR=0.59, 95% CI 0.39-0.90). In the subgroup of patients with PsA, we observed a similar risk of serious infections between the three biologics exposure groups. Indeed, compared to the PsA cohort, the PsO cohort patients were younger, more likely to be male, had fewer comorbidities, fewer physician

Table. Incidence of serious infections among biologic users with psoriasis or psoriatic arthritis, overall and by drug class.

	All biologic classes	IL-17	IL-12/23	TNF- α
Total cohort				
Number of treatment episodes	11,560	2,148	2,882	6,530
Total person-years of follow-up	9,264	1,528	2,461	5,275
Incident serious infections, n (%)	190 (2%)	32 (1%)	32 (1%)	126 (2%)
Incidence rate (95% confidence interval), per 100 person-years	2.1 (1.8-2.4)	2.1 (1.5-2.9)	1.3 (0.9-1.8)	2.4 (2.0-2.8)
Psoriasis				
Number of treatment episodes	9,691	1,903	2,644	5,144
Total person-years of follow-up	8,010	1,406	2,311	4,293
Incident serious infections, n (%)	156 (2%)	26 (1%)	29 (1%)	101 (2%)
Incidence rate (95% confidence interval), per 100 person-years	2.0 (1.7-2.3)	1.9 (1.2-2.7)	1.3 (0.9-1.8)	2.4 (1.9-2.8)
Psoriatic arthritis				
Number of treatment episodes	5,517	944	888	3,685
Total person-years of follow-up	4,159	605	647	2,907
Incident serious infections, n (%)	105 (2%)	14 (1%)	13 (1%)	78 (2%)
Incidence rate (95% confidence interval), per 100 person-years	2.5 (2.1-3.1)	2.3 (1.3-3.7)	2.0 (1.1-3.3)	2.7 (2.1-3.3)
Biologic-naive				
Number of treatment episodes	5,995	332	1,344	4,319
Total person-years of follow-up	5,019	237	1,217	3,565
Incident serious infections, n (%)	*	*	11 (1%)	80 (2%)
Incidence rate (95% confidence interval), per 100 person-years	2.0 (1.6-2.4)	3.4 (1.6-6.3)	0.9 (0.5-1.6)	2.2 (1.8-2.8)
Biologic experienced				
Number of treatment episodes	5,565	1,816	1,538	2,211
Total person-years of follow-up	4,246	1,292	1,244	1,710
Incident serious infections, n (%)	91 (2%)	24 (1%)	21 (1%)	46 (2%)
Incidence rate (95% confidence interval), per 100 person-years	2.1 (1.7-2.6)	1.9 (1.2-2.7)	1.7 (1.1-2.5)	2.7 (2.0-3.5)

*As per OptumLabs data confidentiality policies, cells with 10 or fewer events are not reported.

office visits, lower proportions of DMARD use, and less glucocorticoid exposure during baseline. Nevertheless, we note that the effect estimate even in the PsA patients for IL-12/23 exposure was numerically lower (0.74 , 95% CI 0.40 - 1.36) and compatible with the significantly protective association observed in the psoriasis patients (0.59, 95% CI 0.38 - 0.92).

Conclusion: We did not find empirical evidence of an increased risk of serious infection with the IL-17 inhibitors, and observed a significantly lower infection risk with IL-12/23 biologics, compared to TNF- α therapy. Given the relatively small magnitude of absolute effect (difference less than 1 per 100 person-years) yet strong relative risk reduction compared to TNF-a, these results may inform clinical decision-making regarding the safety of the available choices.

Hospitalization Trends for Bacterial Septic Arthritis in the United States from 1997 to 2014

Soumyasri Kambhatla,[1] Estefania Gauto-Mariotti,[2] and Augustine Manadan[3], [1]John H. Stroger Hospital of Cook County, Chicago, [2]Cook County Health, chicago, [3]Rush University Medical Center, chicago

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Bacterial septic arthritis is a serious cause of morbidity and mortality, constituting one of the true musculoskeletal emergencies. In this abstract, we describe hospitalization trends for patients with bacterial septic arthritis in the USA over multiple years.

Table: Septic Arthritis Trends

Year	Total number of discharges: N	Rate of discharges per 100,000 persons	Age (mean)	LOS (length of stay), days (mean)	Charges, $ (mean)	In-hospital deaths: N	In-hospital deaths: %
2014	25,065	7.9	53.2	6.5	52,878	115	0.46
2012	24,875	7.9	53.13	6.5	49,899	125	0.5
2005	24,852	8.4	48.21	7.2	29,840	217	0.87
2013	24,200	7.7	52.94	6.6	52,341	120	0.5
2010	23,755	7.7	51.19	7.1	45,851	108	0.46
2011	23,716	7.6	53.4	7.1	51,019	160	0.67
2006	23,640	7.9	50.71	7.2	33,178	183	0.78
2008	23,443	7.7	52.74	7.1	39,332	157	0.67
2009	22,802	7.4	52.46	6.7	40,535	175	0.77
2007	22,726	7.5	51.47	7.2	35,901	198	0.87
2003	22,460	7.7	50.12	7.3	27,849	239	1.06

2001	20,596	7.2	50.73	7.9	22,391	321	1.56
2000	19,364	6.9	49.67	7.7	20,543	238	1.23
1999	18,626	6.7	48.09	7.3	17,168	196	1.05
1998	18,345	6.7	47.45	7.1	15,323	208	1.13
1997	17,300	6.3	47.38	7.5	15,381	184	1.07

Methods: Data were abstracted from the National Inpatient Sample Databases. This database is the largest longitudinal collection of inpatient admission data in the USA. It is a nationally representative sample of 20% of admissions from approximately 1000 hospitals pertaining to approximately 7 million inpatient hospital admissions. The numbers in the databases are weighted to optimize both national estimates and longitudinal analysis. The databases were searched for patients admitted from 1997 to 2014 with an ICD-9 septic arthritis codes 711.0 -711.09 listed as the principal diagnosis. Codes for fungal, mycobacterial and viral arthritis were not included. The total number of septic arthritis discharges, number of in-hospital deaths, percentage of in-hospital deaths, rates of discharges, length of stay (LOS), hospital charges and ages were recorded.

Results: An average of 22,179 hospital discharges per year (range 17,300-25,065) had an ICD-9 bacterial septic arthritis code listed as the principal diagnosis from 1997 to 2014. The average rate of discharges was 7.45/100,000 persons (range 6.3-8.4). The average age was 50.8 years. The average hospital charges was $33,549 (range 15,323-52,878). The average LOS was 7.2 days (range 6.5-7.9). The in-hospital deaths averaged 0.87% of those admissions. The annual trend for in-hospital deaths for septic arthritis seemed to both improve and parallel the overall improvement for deaths for all hospital discharges during same time period. This type of analysis is greatly limited by inability to determine actual cause of death.

Conclusion: This data gives us valuable information on the magnitude, cost, and temporal trends of septic arthritis hospitalizations in the USA. Our analysis shows septic arthritis resulted in an average of 22,179 hospital admissions per year. The rate of discharges per 100,000 was very low and stable from 1997 to 2014. Septic arthritis admissions averaged a LOS of 1 week and had an average hospital charge of $33,549. For a condition thought of as a rheumatologic emergency, it had a surprisingly low in-hospital mortality and has been trending in a favorable direction.

Outcomes and Risk Factors in Septic Arthritis with Underlying Rheumatic Conditions

Soumyasri Kambhatla,[1] Estefania Gauto-Mariotti,[2] and Augustine Manadan[3], [1]John H. Stroger Hospital of Cook County, Chicago, [2]John H Stroger Hospital of Cook County, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Septic arthritis is known to cause significant morbidity due to joint destruction and mortality if timely and adequate treatment is not given. In this study, we aim to describe outcomes of septic arthritis, focusing on comparison between the patients with and without underlying rheumatic disease.

Methods: Using the National Inpatient Sample database from 2016, we identified patients admitted with a principal diagnosis of septic arthritis based on ICD10 codes. Separate cohort was created for patients with secondary diagnoses of various rheumatic conditions including rheumatoid arthritis, psoriatic arthritis, osteoarthritis, osteonecrosis, lupus, ankylosing spondylitis, gout, polyarteritis nodosa, dermatopolymyositis, scleroderma, and

Descriptive data of septic arthritis patients with and without rheumatologic disease

Variable	Patients with septic arthritis and underlying Rheumatologic process	95% Confidence interval/ p-value	Patients with septic arthritis without rheumatologic disease	95% Confidence Interval/p-value
Mean age(years)	62.6	61.1-64.2	56.6	55.7-57.4
Proportion of females	40.9%	35.8%-46.1%	38.6%	36.4%-40.9%
Mean Length of stay(days)	5.30	4.9-5.6	5.74	5.4-6.02
Mean total hospitalization charge ($)	48,075	P<0.05	53,683	P<0.05
Mortality	0%	P<0.05	0.004%	P<0.05

Descriptive data for septic arthritis

Multivariable regression model to build adjusted risk factors

Risk factors for development of septic arthritis	Odd's ratio	P-value
Age- with increase in 1 year	1.028	<0.001
Race (compared to Caucasian)		
African American	1.004	0.94
Hispanic	1.11	0.16
Asian/ Pacific Islander	0.68	0.02
Native American	1.72	0.03
Obesity	1.24	0.006
Female sex	0.49	<0.001
Rheumatoid arthritis	3.77	<0.001
Psoriatic arthritis	3.13	<0.001
Osteonecrosis	7.74	<0.001
Osteoarthritis	2.41	0.002
SLE	1.93	0.006

PMR	0.80	0.634

Multivariable regression model

vasculitis. We identified risk factors for development of septic arthritis and compared the outcomes of patients admitted for septic arthritis with and without underlying rheumatic disease. STATA software was used to analyze the data.

Results: Study included 10,808 patients admitted in the year 2016 with septic arthritis, of which 1759 patients had underlying rheumatic disease and 9049 patients did not. For patients who did not have underlying rheumatic disease the mean age was 56.6 years, mean length of stay (LOS) was 5.74 days, and mean charges for hospitalization was $53,683. In comparison, for patients with underlying rheumatic disease, the mean age of patients was 62.6 years, mean LOS was 5.3 days and mean charges of $48,075. Both groups had higher proportion of Caucasians compared to other races (68.3% in those with rheumatic disease vs 69.1% in those without, both $p< 0.05$). There were no deaths in septic arthritis group with rheumatic disease whereas mortality rate was 0.004% in septic arthritis without rheumatic diseases. The following factors increased the risk of overall septic arthritis with the multivariable regression model: Obesity (OR=1.2), Rheumatoid arthritis (OR=3.7), Psoriatic arthritis (OR=3.13), Osteonecrosis (OR=7.7), Osteoarthritis (OR=2.4), SLE (OR=1.9), Arthroplasty (OR=2.13) with P values < 0.05. Female sex, Asian race and ankylosing spondylitis seemed to lower the risk (OR=0.49, 0.68 and 0.8 respectively) with P values < 0.05. Gout, PAN, Dermatopolymyositis, CKD and smoking were removed in the final analysis as they were found to be collinear variables.

Conclusion: In patients with septic arthritis, those with underlying rheumatic conditions seemed to be older with slightly higher proportion of females compared to those without. People with underlying rheumatic disease are more likely to develop septic arthrits but when they do, they seemed to have lower mortality, LOS and hospitalization charge compared to those without a rheumatic disease. This is likely because of better interdisciplinary care. Further studies are needed to establish various factors resulting in this outcome.

Abstract Number: 2123

Clinical Features of Prosthetic Joint Infections in Patients with Rheumatic Diseases vs Osteoarthritis

Susan Goodman,[1] Milan Kapadia,[2] Andy Miller,[2] Laura Donlin,[3] Michael Henry,[2] Linda Russell,[2] Mark Figgie,[4] Allina Nocon,[2] and Peter Sculco[2], [1]Hospital For Special Surgery/Weill Cornell Medicine, New York, NY, [2]Hospital for Special Surgery, New York, [3]Hospital For Special Surgery, New York, NY, [4]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic disease (RD) patients are at increased risk for prosthetic joint infections (PJI), however, diagnosis is challenging because active RD may mimic joint infection and definitive microbiologic diagnosis may be delayed. We aimed to identify the clinical and microbiological features of total hip (THA) and total knee arthroplasty (TKA) PJI in RD and OA patients, using an institutional PJI registry and compare the incidence of culture negative (CN) PJI in RD vs OA. Baseline clinical differences between CN-RD and culture positive (CP)-RD and OA PJI as well as the relationship of infection free survivorship of the prosthesis were also evaluated.

Methods: A retrospective cohort of THA/TKA PJIs, from 2009 to 2016, were identified by ICD codes, and confirmed by chart review. RD cases were also confirmed by use of RD-specific medications. CN cases were defined as PJIs with no evidence of microbial growth in intraoperative cultures and CP PJI cases were defined by positive microbial growth in intraoperative cultures. Treatment failure was defined as subsequent surgical treatment for infection after the index procedure- debridement, antibiotics and implant retention (DAIR), one stage or two stage exchange. Demographics, medications, microbiology, surgical therapy and outcome were abstracted. Baseline characteristics were evaluated using Fisher's exact and Chi-Square tests.Kaplan-Meier estimates were used to calculate infection free survivorship.

Results: 807 PJI cases were identified including 36 RD (33 RAand 3 SLE) and 771 OA. A higher proportion of RD PJI were CN (N=10, 27%) vs. OA PJI (N=109, 14%, p=0.02). Fewer CN-RD cases met PJI histopathology criteria compared to CN-OA, (p=0.08). On average, RD-CN were younger than OA-CN (59 vs 69, p=.01), but no different than RD-CP cases. One year survivorship of CN-OA and CN-RD were 87% and 66%, respectively and 47% for CP-RD. Comparing CN-RD vs. CP-RD, no difference was observed in age, smoking, diabetes, or Charlson comorbidities, but a trend towards higher prevalence of prior PJI in the CN-RD group. No differences were found in surgical treatment (p=0.92) or use of biologics and DMARDs (p=0.12) between CN and CP RD patients. Among CP cases, there was no difference in diabetes, comorbidities, smoking, or history of PJI, but more RD were female (p=.0003) and used glucocorticoids (p=.0001). Across all CP cases, 57.4% were Staphylococcal, with no differences between groups.

	CN-RD (N=10)	CP-RD (N=26)	CN-RD vs CP-RD p-value	CP-OA	CP-RD vs CP-OA p-value
Age	59.04 (10.21)	58.35 (12.02)	0.986	66.33 (12.16)	.0003
Body mass index	25.88 (9.81)	27.16 (12.23)	0.697	28.31 (9.73)	.904
Sex			.842		.0003
Female	8 (80)	20 (76.92)		275 (41.54)	
Male	2 (20)	6 (23.08)		387 (54.46)	
Joint			0.285		.509
Knee	6 (60)	10 (38.46)		298 (45.02)	
Hip	4 (40)	16 (61.54)		364 (54.98)	
History of Smoking	1 (10)	3 (11.54)	1.000	78 (11.78)	1.000
Diabetes	0 (0)	5 (19.23)	0.293	137 (20.73)	.8535
History of prior PJI	2 (20)	0 (0)	0.071	49 (7.4)	.247
Glucocorticoids	2 (20)	8 (30.77)	.518	31 (4.68)	.0001
DMARD			.397		
Biologic	5 (50)	9 (34.62)		NA	
Synthetic only	5 (50)	17 (65.38)		NA	
Surgical Therapy			0.791		.760
One Stage Exchange	0 (0)	1 (3.85)		30 (4.53)	
Two Stage Exchange	7 (70)	17 (65.38)		360 (54.38)	
DAIR	3 (30)	8 (30.77)		262 (39.58)	

RD- rheumatic disease; CP- culture positive; CN-culture negative; DAIR- debridement, antibiotics and implant retention; PJI -prosthetic joint infection; DMARD – disease-modifying anti-rheumatic drugs

Table 1. Baseline Characteristics

Overall surgical treatment included 2-stage exchange (54.8%), DAIR (39.24%) and 1-stage exchange (4.51%), with no differencebetween groups (p=0.76). Treatment failure was more frequent for CP-RD (30.4% vs 42.3%), but the difference was not significant (p=0.19).

Conclusion: RD PJIs are more likely to be culture negative than OA PJIs, but small numbers limit our analysis. Prior PJI, histopathology and better outcomes suggest biologic differences between CN and CP PJI that should be explored further.

Figure 1 The Kaplan-Meier curve representing implant survivorship after prosthetic joint infection treatment for rheumatic disease(RD) was 66% at 1 year for culture negative (red) and 47% for culture positive (blue), p=0.163.

Session Date: Tuesday, November 12, 2019

Session Title: Infection-Related Rheumatic Disease Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: American Trypanosomiasis or Chagas Disease (CD) is a zoonotic infection, endemic in Latin America. It is a major cause of morbidity, mortality and economic burden in developing countries. Because of population movements, it has spread out around the globe. CD behavior has been well-described in patients with HIV infection, oncologic and organ transplant-related immunosuppression, but little is known in rheumatic diseases (RD) with rheumatologic treatments (RT).

The purpose of this research is to screen and follow up (clinical and serologically) patients with RD under RT, with concomitant CD. To detect clinical and serological reactivation.

Methods: Prospective, observational study. A systematic screening for CD in the Rheumatology and Internal Medicine Departments was conducted for eighteen months in a third-level Hospital in Argentina. Patients with CD and concomitant RD under RT were included for follow up. Assessments were done before and after RT and if it was already established, subsequently. Clinical features were examined by anamnesis, physical examination, Electrocardiogram, Echocardiogram and Chest X-ray. In order to detect parasitemia, two methods were performed: Strout and Polymerase chain reaction (PCR). Levels of antibodies were evaluated by three techniques: enzyme-linked immunosorbent assay (ELISA), indirect hemagglutination assay (IHA) and indirect immunofluorescence assay (IFA). Every patient received, at least, two assessments. A descriptive analysis was performed.

Results: From the population screened, 46 patients with RD under RT, infected with Trypanosoma Cruzi were detected by two of three techniques (ELISA, IHA, IFA).

Table 1:

Demographics	N=46 (%)	N=46 (%)
Sex	Females	41 (89,13%)
	Males	5 (10,87%)
Mean Age (standard deviation)	51 years (SD:10)	
Birthplace	Argentina	42 (91,30%)
	Other countries	4 (8,70%)
Rheumatic Diseases	Rheumatoid Arthritis	26 (56,52%)
	Systemic lupus erythematosus:	4 (8,70%)
	Systemic Sclerosis	5 (10,87%)
	Vasculitis	2 (4,35%)
	Psoriatic Arthritis:	2 (4,35%)
	Uveitic	1 (2,17%)
	Other rheumatic diseases (Sjogren, Osteoarthritis, Mixed Connective Tissue Disease, Overlap Syndrome):	6 (13,14%)
Treatment (n and % do not reach 100%)	Classic DMARD	40 (68,98%)
	Biologic DMARD	4 (8,70%)
	Synthetic DMARD	2 (4,35%)
	Azathioprine	3 (6,52%)
	Cyclophosphamide	2 (4,35%)
	Steroids < 20 mg/day (prednisone equivalent)	22 (47,83%)
	Steroids > 20 mg/day (prednisone equivalent)	2 (4,35%)

Disease modifying antirheumatic drugs (DMARD). Classic: Methotrexate, Leflunomide, Hydroxychloroquine. Biologic: Adalimumab, Certolizumab, Abatacept. Synthetic: Tofacitinib.

Table 2:

Clinical aspects		First evaluation (n=46)	Follow up (n=46)
With Demonstrable Disease	Chagas Cardiomyopathy	5 (10,87%)	5 (10,87%)
	Gastrointestinal Disease	0 (0%)	0 (0%)
	Neurologic Disease	0 (0%)	0 (0%)
Without Demonstrable Disease		41 (89,13%)	41 (89,13%)
Serological aspects			
Strout and PCR	Positive	2 (4,35%)	0* (0%)
	Negative	44 (95,65%)	46* (100%)

* After Trypanosoma Cruzi Treatment

Table 1: Population characteristics, Rheumatic Diseases and Treatments.
Table 2: Clinical and Serological Follow up.

In search of reactivation, two patients with parasitemia (both Strout and PCR positive) and concomitant signs and symptoms were detected. They had chagasic cardiomyopathy. A 64-years old lady with Microscopic Polyangiitis, under prednisone 60 mg/day and a 57-years old lady with Systemic Lupus Erythematosus under prednisone 40 mg/day and hydroxychloroquine. They developed high fever, myalgias, arthralgias and asthenia. Other infections were ruled out. They received Benznidazole and Nifurtimox respectively. After one-week treatment, Strout and PCR became negative, with clinical improvement.

Conclusion: Of the 46 patients detected in the screening, 2 (4,35%) had parasitemia and clinical features suggestive of reactivation, in context of high doses of steroids. As they were sisters, a genetic relationship may be present. In the rest of the patients, no clinical or serological variation in the follow up was recognized, considering all treatments. As reactivation is possible, parasite´s screening before and during rheumatologic immunosuppression should be performed routinely in endemic countries and suspected in non-endemic countries with epidemiological nexus. CD specific antibodies determination, Strout and PCR are economic and practical techniques. The benefits of this measures would outweigh morbidity and mortality costs. Further studies are required to broaden our knowledge and make recommendations.

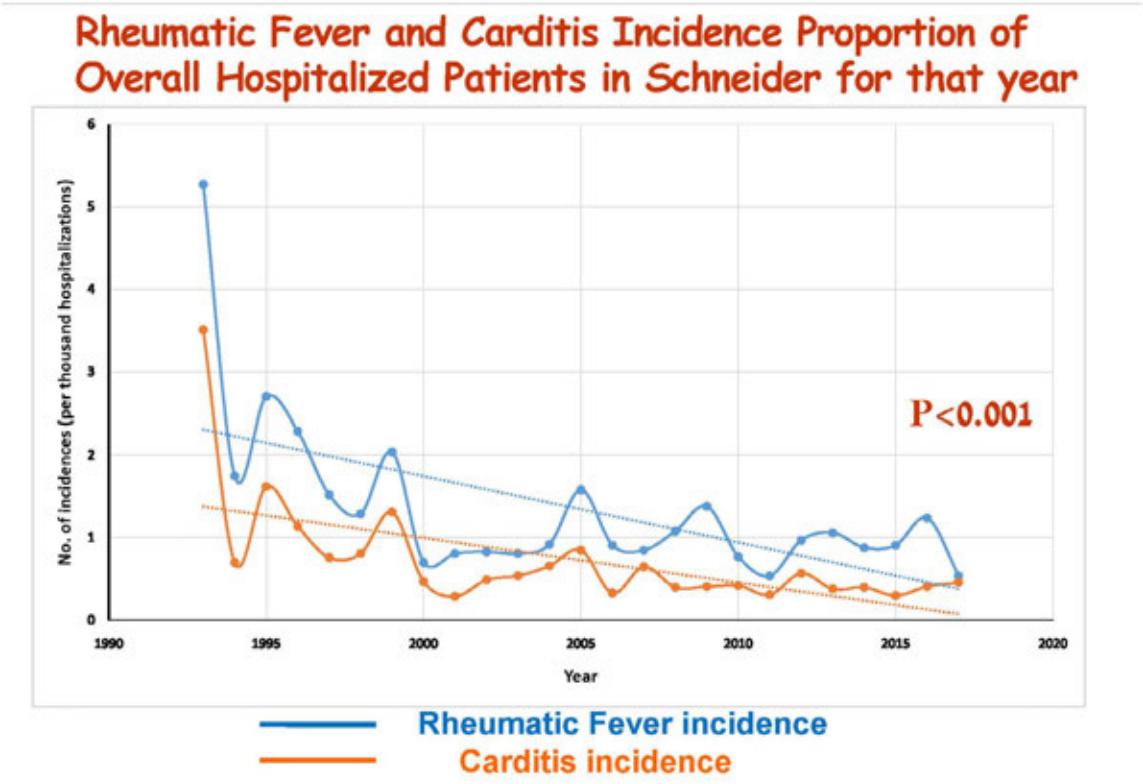
Rheumatic Fever in a Tertiary Medical Center - 25 Years of Follow Up

Mohammad Hammad Saied,[1] Liora Harel,[2] Gil Amarilyo,[3] Rotem Tal,[4] and Razi Zidani[5], [1]schneider medical center, kaboul village, Israel, [2]Tel Aviv University, Tel Aviv, Israel, [3]schneider medical center, petach tekva, [4]schneider medical center, ramat gan, Israel, [5]tel aviv university, Tamra, Israel

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

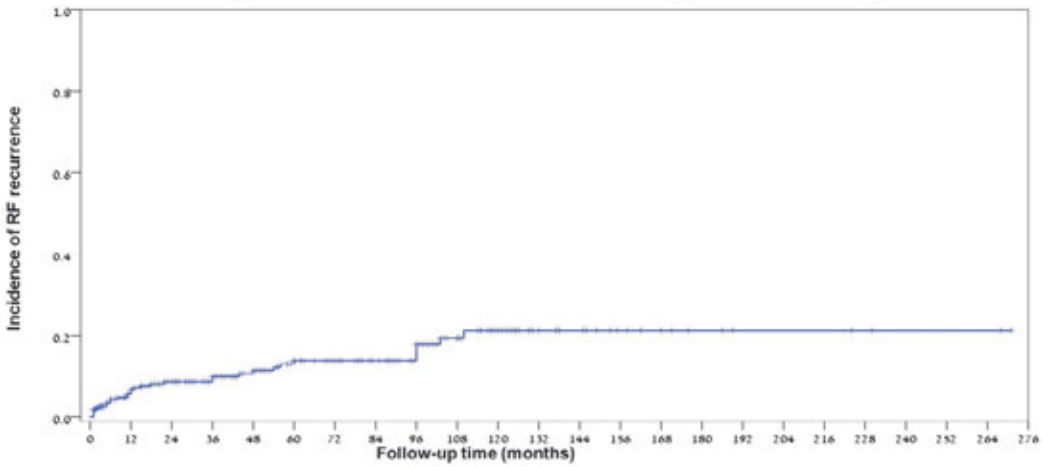
Background/Purpose: Rheumatic Fever (RF) occurs after a pharyngeal infection caused by group A-B-hemolytic streptococci.Its principal clinical significance is causing carditis at the acute phase of the disease, and valvular impairment, leading to a significant hemodynamic disturbance, as a late sequela.

Aim: To examine the number of cases of Rheumatic fever in Schneider Children's medical center, and to find whether it has declined during the years of its existence. In addition, to characterize the patient population, clinical characteristics, risk factors and asses the course of the disease. In addition, we will address the relapse rates, with an emphasis on cardiac relapses, with a correlation to preventive treatment.



Rheumatic Fever - Overall Recurrence Rate

•12% developed disease recurrence (32 of 268)



•15% of the children receiving oral prophylaxis developed recurrences, compared with 9% receiving IM injections [HR (IM) = 0.5 , 95% CI 0.25-1.06, P=0.076]

Methods: Retrospective cohort study was conducted, collecting data of patients with rheumatic fever who were admitted to the Schneider Medical Center from 1993 to 2017.

Results: 307 patients met the inclusion criteria. During the acute phase,64% presented with arthritis, 52% carditis, 15% chorea, 5% erythema marginatum, and 0.7% with subcutaneous nodules. 19.5% developed severe carditis, 13% of whom developed heart failure signs. There was a decrease in incidence of rheumatic fever and rheumatic heart disease during the study period. Median follow-up time was 49 months, 12% of all patients developed a relapse of the disease and 11 of whom (4% of all patients) developed a cardiac relapse. 15% of the patients who received oral prophylaxis experienced relapse, compared to 9% of those who received intramuscular injection therapy.

Conclusion: Despite the reduction in incidence of rheumatic fever and rheumatic heart disease during the study period, the disease remains a significant cause of general and cardiac morbidity among children despite being completely preventable, therefore, It should remain in the mind of every doctor, pediatricians in particular.

Combined Detection of Cytokines and Biomarkers Improve the Diagnostic Performance of Bacteria Infection in Rheumatoid Arthritis

Yan Qin,[1] Xiangcong Zhao,[1] and Jing Luo[1], [1]the Second Hospital of Shanxi Medical University, Taiyuan, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) suffer a high susceptibility to infection, and many inflammatory cytokines are prognostic in RA, but currently the role of cytokines in identifying infection individuals is rarely studied. We assessed the performance of serum inflammatory cytokines to discriminate bacteria infection from non-infections in RA, and setted up a bioscore system to evaluate the significance of these biomarkers in identifying bacterial infection.

Methods: A total of 168 RA patients were enrolled and divided into the bacterial infection (INFE) group and non-INFE group from January 2018 through January 2019, and were quantitatively measured the expression level of cytokines

Table 1. The demographic data and biomarkers of the INFE and the non-INFE group in RA patients

IL-2 (pg/mL)	5.66 (3.37, 9.37)	4.84 (2.85, 8.00)	0.206
IL-4 (pg/mL)	6.59 (2.32, 15.93)	5.04 (2.20, 10.64)	0.249
IL-6 (pg/mL)	54.53 (19.30,105.96)	31.79 (12.69, 58.08)	0.006
IL-10 (pg/mL)	9.64 (7.14, 16.47)	8.07 (5.61, 13.29)	0.019
IL-17 (pg/mL)	43.08 (13.63, 91.66)	53.22 (7.03, 91.90)	0.084
IFN-γ (pg/mL)	12.67 (6.82, 32.22)	8.98 (4.51, 25.55)	0.033
TNF-α (pg/mL)	9.00 (4.95, 21.61)	9.04 (3.92, 18.48)	0.437

***All data were described as the medians (IQR) or M ± SD except gender and smoke**

by flow cytometry. The discriminating value of C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), white blood cell count (WBC), lymphocyte subsets, complement C3 and complement C4 also were assessed. Bacterial infection was confirmed through bacterial culture, image study, response to antibiotic therapy and typical clinical symptom. The diagnostic value for bacterial infection was evaluated by the areas under the receiver operating characteristic (ROC) curves (AUC) and a novel bioscore system combining multiple biomarkers.

Results: In INFE group, the levels of IL-6 (p=0.006), IL-10 (p=0.019), IFN-γ (p=0.033), CRP (p< 0.001), ESR (p< 0.001), B cell (p< 0.001) and T cell (p=0.031) were higher than in non-INFE group. The IL-2, IL-4 and TNF-α also increased in INFE group, but no statistical significance (IL-2, p=0.206; IL-4, p=0.249; TNF-α, p=0.437), IL-17 decreased (p=0.084). However, it was remarkable that the AUC yielded 0.820 (95%CI: 0.753, 0.876), with sensitivity of 64.38%

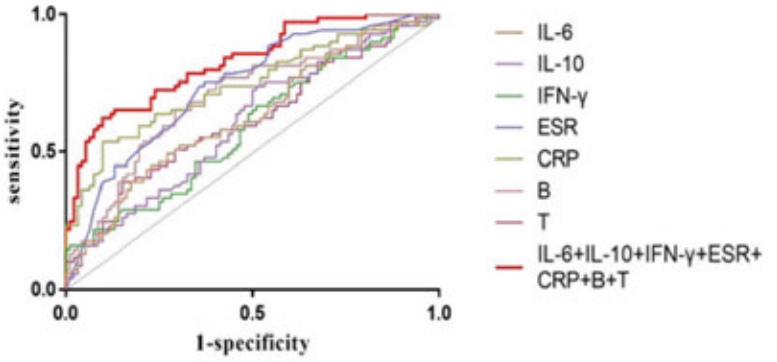

Figure.1 Receiver operating characteristic curves (ROC) of IL-6, IL-10, IFN-γ, ESR, CRP, B cells, T cell and their combination. ROC curves of the above biomarkers were plotted based on the differentiation between bacterial infection and non-infection in RA patients.

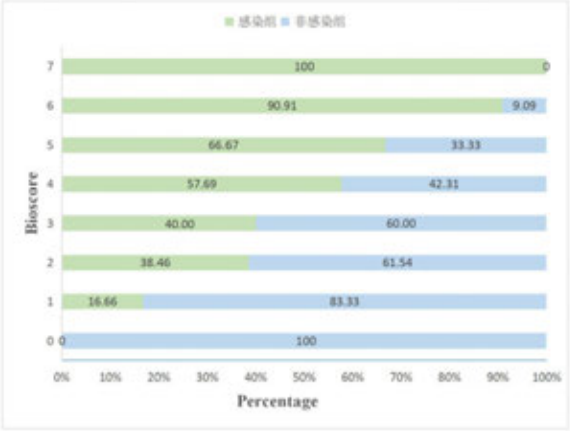

Figure.2 Distribution of the INFE group and the non-INFE group in bioscore range 0-7. As the score went up, so did the infection rate.

and specificity of 88.03%, when combined with IL-6, IL-10, IFN-γ, ESR, CRP, B and T cell. The above seven biomarkers were included in the bioscore system, the whole of patients with bioscore of 0 (n=18) were in the non-INFE group. When the score was 7, all patients (n=6) were in the INFE group.

Conclusion:

Serum cytokines are markers for detection of bacterial infection in RA. The combination of ESR, CRP, IL-6, IL-10, IFN-γ, B and T cell may be a valuable diagnostic score to early diagnose infection in RA, and provide certain reference basis for clinical treatment and prognosis evaluation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Infection-Related Rheumatic Disease Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of inflammatory rheumatic diseases (IRD), as axial Spondyloarthritis (axSpA), Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) represents in our days a major clinical challenge. Increasing evidence has determined that early diagnosis, prompt treatment initiation and early achievement of remission are the main predictors of long-term clinical, functional and radiographic outcomes. Therefore, identification of sensitive markers is important for the early detection and precise therapy for IRD patients. Taking into consideration that metabolomics is a post-genomics technology that offers the closest characterization of the phenotype, this methodology can constitute a key tool for discriminating patients with IRD. This study aims to identify differences in the urinary metabolic profile and develop a feasible clinical approach for axSpA, RA and SLE diagnosis.

Methods: A cross-sectional non-targeted mass spectrometry-based metabolomics study was performed in 111 individuals composed by: axSpA (n=27, according to ASAS criteria), RA (n=22, according to ACR/EULAR criteria for RA) and SLE (n=23, according to ACR classification criteria for SLE) patients and healthy controls (HC; n=39). Patients with co-occurrence of other IRD or having received biotechnological therapies were excluded. Urine samples were analyzed by liquid chromatography high-resolution mass spectrometry (LC-HRMS) and data was subsequently preprocessed with the open-source software MZmine. The resulting matrix was normalized by total area and analyzed by multivariate analysis with the SIMCA software.

Results: Patients with RA were significantly older than controls [RA: 58±12 years old (yo); HC: 43±13yo; axSpA: 36±7yo; SLE: 49±12yo]. RA and SLE groups contained significantly more women (RA: 90%; SLE: 91%; HC: 49%; axSpA: 33%). However, Principal Component Analysis showed that the metabolic profile was not influenced by gender or age. Additionally, metabolic differences were identified between RA and SLE *vs* HC, but not between axSpA and HC. Importantly, the metabolic profile of SLE and RA patients was significantly different from the one displayed by axSpA patients.

Conclusion: Urine metabolomics demonstrated to be a useful tool to discriminate SLE and RA patients from axSpA patients. Further studies will validate the potential use of urine metabolomic profile for Inflammatory rheumatic diseases diagnosis in clinical practice.

Anti–MDA5 Antibody Positive Dermatomyositis Is Not Always Associated with Recalcitrant Lung Disease or Mortality

Dipekka Soni,[1] David Maniscalco,[2] Srihari Veeraraghavan,[3] Justin Cheeley,[3] and Arezou Khosroshahi[1], [1]Emory University, Atlanta, GA, [2]Emory University, Altanta, [3]Emory University, Atlanta

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with autoantibodies against melanoma differentiation-associated protein 5 (MDA-5) are reported to have a significant risk of developing rapidly progressive and fatal interstitial lung disease (ILD). It is important that as new DM-specific antibodies emerge, the associated phenotype be carefully defined as this can greatly impact the choice of treatment and prognostication of patients. The goal of this study is to describe the clinical and radiologic features of anti-MDA-5 antibody-positive patients in a North American cohort, and in doing so, we contrast the existing literature by highlighting that ILD was less severe than previously reported and most patients had more favorable outcomes with treatment.

Methods: This retrospective study characterized the clinical characteristics, lung function, HRCT findings, treatment and outcomes of MDA5-positive patients seen at at Emory University and affiliated hospitals.

Results: Fourteen MDA5-positive and two borderline-positive cases were identified between 2013 to 2019. Median disease duration is 18 months (range: 4-84). 15/16 (92%) had clinically amyopathic dermatomyositis, 7/16 (40%) had cutaneous ulcers and 14/16 (87%) had ILD. 6/16 subjects (37%) developed severe ILD of which 3 died from hypox-

emic respiratory failure. Of the three patients that died from hypoxemic respiratory failure, one had severe pneumomediastinum.

Conclusion: Our data supports that MDA5 Ab-associated ILD can be severe and/or progressive in a significant number of patients, however, it is can be treatable and stabilized in most cases. Borderline positive anti-MDA5 patients manifest a phenotype consistent with strong positive MDA5 patients. Finally, an association with spontaneous mediastinum may contribute to mortality rates in more severe cases.

Thyroperoxidase Antibodies in Patients with Positive ANA

ChiChi Lau,[1] Scott Legunn,[2] Alana Nevares,[2] and Turner Osler[3], [1]UVM Larner College of Medicine, Burlington, VA, [2]UVM Larner College of Medicine, Burlington, VT, [3]UVM Larner College of Medicine, Colchester, VT

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune thyroid disease, which is defined by the presence of thyroid antibodies, is the most common organ specific autoimmune disorder, affecting 11% of the general population[1]. There is a reported higher prevalence of thyroiditis in older women, and patients with systemic lupus (SLE), Sjogren's, or RA. Antinuclear antibodies (ANA) are present in 45% of patients with thyroid antibodies, but there are no studies looking at the prevalence of thyroiditis in ANA positive (ANA+) patients. Our goal was to report the prevalence of thyroperoxidase antibodies (TPO ab) in ANA+ patients, and define associations with disease specific autoantibodies, gender, age, and thyroid dysfunction.

Methods: Lab data from 1/1/2010 to 8/1/2018 on ANA+ rheumatology patients followed at an academic center was evaluated for the presence of the most recent TPO, dsDNA, Smith, RNP, Ro/SSA, La/SSB, RF, and CCP antibodies, and for the highest or maximum thyroid stimulating hormone (TSH) level reported for each patient over the study period . Antibody positivity, existence of elevated highest TSH, and gender were compared between TPO ab groups by Chi square or Fisher's exact test. ANA titers within 1 year of TPO ab testing, and age were analyzed relative to TPO ab titers using regression analyses or Kruskal-Wallis. Upper reference values for TPO ab were >35 or 61 IU/mL depending on year of testing and >5 mU/L for TSH.

Results: Of 690 ANA+ adults who had TPO ab testing, 196 (28.4%) had positive TPO ab (+TPO), and consisted of 184 (93.9%) females at a mean age of 47.5 years, see Table 1. There was no age difference between +TPO and -TPO groups. There was no significant difference in the prevalence of autoantibodies between TPO groups, Table 2. There was no relationship between ANA titer (p=0.265) or age (p=0.136) to TPO titer. There was a significant correlation between +TPO status and history of elevated TSH.

Table 1. Characteristics of 690 Adult Rheumatology patients with positive ANA.

	Positive TPO	Negative TPO	P
Female, n (%)	184 (30.0)*	428 (69.9)	*0.007
Male, n (%)	12 (15.4)*	66 (84.6)

Table 2. Autoimmune antibodies and Thyroperoxidase (TPO) antibody status in patients with positive ANA.

Conclusion: TPO antibodies, which are specific for thyroiditis, were present in 30% of ANA+ female patients, higher than the 16-20% prevalence reported in the general female population for the same age group[1]. Serologic markers for RA, Sjogrens, and SLE, were not higher in the +TPO group despite reports of increased TPO ab prevalence in these autoimmune conditions; additional workup for these autoimmune markers should not be routine in +TPO ab patients due to the low yield. This study did not compare the presence of TPO ab in patients with or without positive ANA, therefore no conclusion can be drawn as to the effect of ANA positivity on TPO ab positivity, although this study found no correlation between TPO and ANA titers. The strong association between TPO ab and TSH elevation justifies screening ANA+ patients for thyroiditis due to the increased risk of hypothyroidism. Future work will look at the presence of TPO ab and symptoms that may define thyroiditis with subclinical hypothyroidism.

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are associated with immune-related adverse events (irAEs), including arthritis (arthritis-irAE). Understanding the pathophysiology of arthritis-irAE is critical to treating it without impeding antitumor immunity; however, these mechanisms remain elusive. As a first step in elucidating these mechanisms, we characterized functional immune cell profiles in synovial fluid from patients with arthritis-irAE.

Methods: We collected and performed immunoprofiling of synovial fluid from seven patients with active arthritis-irAE who received ICIs and three control patients with osteoarthritis who did not receive ICIs.

Results: Four patients developed arthritis after PD-1 inhibitor monotherapy and three after combination therapy with CTLA-4 and PD-1 inhibitors. Two patients in the combination therapy group required interleukin (IL)-6 receptor inhibitor therapy in addition to steroids, compared with one patient in the monotherapy group (sulfasalazine). IL-17-producing $CD4^+$ T cells (Th17) were enriched in the combination therapy group (1.01±0.73% live $CD4^+$ T cells in the monotherapy group compared with 3.19±0.31% in the combination therapy group; P=0.005). Synovial fluid levels of IL-6 and IL-17A, key cytokines for Th17 cell differentiation and function, were higher in the combination therapy group than in the monotherapy group, although this difference was not statistically significant.

Conclusion: Our results demonstrate that combination therapy with CTLA-4 and PD-1 inhibitors may result in enhanced incidence of steroid-resistant arthritis-irAE. Th17 cells were enriched in the synovial fluid of arthritis-irAE patients with combination therapy, suggesting their role in disease pathophysiology. Further studies with more cases and controls are needed to better understand the mechanisms underlying arthritis-irAE.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX), an anti-CD20 monoclonal antibody inducing B cell depletion, is used as therapy for diverse systemic autoimmune diseases (SAIDs), but is associated with adverse events (AE) such as infusion reactions, infections and others, which may lead to therapy suspension. We aim to evaluate the safety profile and persistence of RTX in SAIDs and factors that influence on the development of infections in real-life practice.

DISEASE	N (%)
Rheumatoid arthritis (RA)	24(40%)
Vasculitis	11(18.3%)
Systemic lupus erythematosus (SLE)	9 (15%)
Systemic sclerosis (SSc)	5 (8.3%)
Antisynthetase syndrome	3 (5%)
Mixed connective tissue disease (MCTD)	2 (3.3%)
Overlap syndrome	2 (3.3%)
Others	4 (6.7%)

Methods: A retrospective observational study was conducted including patients diagnosed of SAIDs treated in a tertiary hospital between 2007 and 2018, who received at least 1 RTX infusion. At RTX initiation we collected clinical and demographic data including: age, sex, Charlson score, comorbidities, previous use of immunosuppressants (IM), biologic therapy and/or JAK inhibitors, use/dose of concomitant glucocorticoids (GC) and/or immunosuppressants and RTX dose. During treatment we analyzed: serum immunoglobulin (Ig) levels, number of RTX cycles and adverse events.

Results: 60 patients were included (73.3% women, mean age 52.8 ± 14.9 years), with median Charlson score of 3 (P25–75 1-4) and median disease evolution of 7.5 years (P25–75 1.2-12.6). Table 1 shows distribution of SAIDs.

Prior to RTX 85% of patients received IM, 48.3% biologic agents (16.7% >1) and 5% JAK inhibitors. Associated to RTX 58.3% of patients received IM and 81.7% GC (median dose 12.5mg, P25–75 7.5-15). Total RTX cycles registered were 215.5 with a median of 2.25 (P25–75 1.3-5) cycles per patient.

In terms of AE: 18 patients presented infusion reaction (72.2% were mild, 61.1% related to first cycle and 27.8% had recurrent infusion reactions). 28 patients presented infections (75% had >1), total number of infections was 64 (35 respiratory, 11 urinary, 6 skin and soft tissue, 4 gastrointestinal, 3 non-diseminated herpes zoster, 2 septic shock, 1 Pneumocystis Jiroveci pneumonia, 1 head and neck and 1 gynecological), 10 of them were serious and 1 was an opportunistic infection. There were 4 neoplasia (2 non-melanoma skin cancer, 1 bladder carcinoma and 1 ampullary carcinoma). 2 patients presented neutropenia and 1 presented an intersticial pneumonitis.

During RTX treatment 35% of patients had low Ig G and 48.3% low Ig M levels. None developed low Ig A levels. RTX was suspended in 26 patients (10 AE and 16 other reasons). 5 deaths were reported (2 infections, 2 unknown and 1 pulmonary fibrosis progression).

Low Ig G levels during RTX treatment were associated with the presence of infection ($p< 0.042$). Patients who had infection received more RTX cycles and higher doses of GC than those who did not, but there wasn't association on statistical analysis.

Kaplan Meier analysis showed less probability of continuing RTX therapy among SSc patients ($p< 0.0095$).

Conclusion: RTX therapy was safe and the presence of serious AE infrequent. Low Ig G levels were associated with the presence of infection. SSc patients showed less probability of continuing RTX than the rest of SAIDs.

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic diseases have an increased risk of cardiovascular disease (CVD). Cardiometabolic disease includes an alteration in metabolic organs and CV system that might contribute to the development of CVD. Complement factors have recently been associated with metabolic events such as metabolic syndrome.

Objectives: 1) To evaluate the levels of complement C3 in rheumatic diseases with increased prevalence of cardiovascular risk and 2) to analyze the relationship of the complement C3 with the different cardiometabolic risk factors in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE).

Methods: 570 subjects: cross-sectional study including 200 RA, 150 AS, 60 PsA, 60 SLE patients and 100 healthy donors (HD) recruited from the Rheumatology department of Reina Sofia Hospital, Cordoba (Spain). The prevalence of traditional cardiovascular risk factors was analyzed in the different rheumatic diseases. Inflammatory markers (C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), complement C3 and insulin resistance (HOMA-IR) was measured. Serum glucose, insulin, triglycerides (TG), total cholesterol, low density lipoprotein (LDL) cholesterol, high-density lipoprotein (HDL) cholesterol, apolipoprotein A (apo-A), apoliprotein B (apo-B) were measured in overnight fasting conditions.

Kruskall wallis tests were performed for multiple comparisons. Chi-squared test were performed to analyze qualitative data. ROC analysis was carried out to identify biomarkers for cardiometabolic comorbidities. Spearman's rho correlation coefficient was used for correlation studies.

Results: All patients had significant increase in the prevalence of obesity, insulin resistance, hyperlipidemia and hypertension. PsA patients showed the worst cardiometabolic profile followed by RA, SLE and AS. Levels of complement C3 were significantly elevated in RA, AS and PsA patients. Although complement C3 levels were not increased in SLE patients, complement C3 levels were associated with HOMA-IR index in all the diseases, due to the strong correlation with insulin levels. ROC analyses showed that C3 levels could be a marker of IR in RA, PsA and SLE patients. Besides, complement C3 levels were strongly correlated with CRP in all the diseases. On the other hand,

in RA, AS and PsA patients, levels of complement C3 correlated with ERS and altered lipid profile. Hard clustering analysis identified two distinctive phenotypes in our cohort of rheumatic disease patients depending on the complement C3 levels. Patients from cluster 1 presented higher levels of complement C3 alongside increased prevalence of cardiometabolic comorbidities (obesity, diabetes, IR, hyperlipidemia, hypertension, apoB/apoA ratio, atherogenic risk) compared to cluster 2.

Conclusion: 1) Complement C3 could be a marker of IR in the rheumatic diseases most associated with cardiometabolic risk. 2) Complement C3 could be considered a cardiometabolic risk factor in RA, PsA and AS.

Acute Myocardial Infarction in Rheumatoid Arthritis, Gout, and Osteoarthritis: A Retrospective Study Using the National Inpatient Sample from 2002-2016

Rouhin Sen,[1] Sarah Aurit,[2] Luay Sarsam,[3] Osman Bhatty,[4] Mukund Kumar,[1] and Joseph Nahas[1], [1]Creighton University Medical Center, Omaha, NE, [2]Creighton University Medical Center, Omaha, [3]Arnot Health, Elmira, NY, [4]Montefiore Medical Center Wakefield Campus, Bronx, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation is a risk factor in the development of cardiovascular disease. The proposed etiology centers around accelerated atherosclerosis involving various cytokines in the TNF and IL families. As a result, chronic inflammatory diseases such as RA and gout are thought of as risk factors for the development of cardiovascular disease. There is limited data on comprehensive nationwide analysis of mortality, incidence, and demographic features in patients admitted for acute myocardial infarction (AMI) with underlying RA and gout. Our objectives are to describe the demographics associated with these admissions and report any differences between the inflammatory conditions of RA and gout to the non-inflammatory disease, OA.

Methods: We used the national inpatient sample (NIS) to capture all adult patients (> 18 years) hospitalized between 2002-2016. Using ICD-9 and -10 codes, we identified hospitalizations with primary diagnosis of AMI and further delineated these patients as having secondary diagnosis of RA, gout, or OA. The NIS is the largest publicly available multi-year hospital care dataset. Incidence and mortality rates were calculated and means/medians were used to describe demographic features. SAS v9.4 was used for all analyses and $p < 0.05$ was used to determine statistical significance.

Results: We identified 603,359 hospitalizations between 2002-2016 with a primary diagnosis of AMI and secondary diagnoses of RA, gout, or OA. Patients with AMI and secondary diagnosis of RA or gout had higher incidence of ad-

Table 1. Characteristics for Acute Myocardial Infarction Admissions Stratified by Rheumatic Disease

Average Age in Years			
Average Age of Admission in Years (95% Confidence Interval)	70.9 (70.0-71.1)	71.7 (71.5-71.9)	75.4 (75.3-75.6)
Average Age of Death in Years (95% Confidence Interval)	77.2 (76.5-77.9)	79.0 (78.4-79.6)	82.4 (82.1-82.8)

Table 1. shows characteristics of admissions with acute MI and underlying RA, gout, and OA.

mission at a younger age and significantly younger average age of admission for AMI (RA 70.9, 95% CI [70.0-71.1], gout 71.7, 95% CI [71.5-71.9]) compared to those with secondary diagnosis of OA (75.4, 95% CI [75.3-75.6]). Hospitalizations associated with African American race had disproportionally higher incidence of admission for AMI with secondary diagnosis of gout compared to other races. There was a female predominance in those with admission for AMI and secondary diagnosis of RA and OA. The average age of death in those with admission for AMI was significantly lower in those with secondary diagnosis of RA (77.2, 95% CI [76.5-77.9]) or gout (79.0, 95% CI [78.4-79.6]) compared to OA (82.4, 95% CI [82.1-82.8]). Full demographic data is found in Table 1.

Conclusion: Patients with an underlying diagnosis of RA or gout are admitted for AMI at a younger age compared to those with a secondary diagnosis of OA; these same patients also die at a younger age compared to their counterparts with OA. This could reflect the pro-inflammatory disease state in RA and gout predisposing them to accelerated atherosclerosis. A Cleveland Clinic study showed increased prevalence of suboptimal treatment in the African American population likely leading to a higher vascular risk which may contribute to the higher incidence of admission with

AMI as we saw in our subgroup. RA is usually diagnosed at an earlier age in women; this longer disease course may also contribute to higher vascular risk manifested by higher incidence of admissions for AMI. Continued awareness and modification of the cardiovascular risks through disease control agents is needed in those with RA and gout to optimize cardiovascular outcomes.

Abstract Number: 2134

Extracellular Adenosine Increases IL-6 Production by Aging Tenocytes and May Contribute to the Age-related Pattern of Polymyalgia Rheumatica

Charmi Shah,[1] Thomas Garvey,[2] Claudia Gohr,[1] Elizabeth Mitton-fitzgerald,[3] and Ann Rosenthal[3], [1]Medical College of Wisconsin, Milwaukee, WI, [2]Mayo Clinic, Rochester, MN, [3]Medical College of Wisconsin, Milwaukee

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a common disease preferentially affecting elderly patients. Characteristically, PMR involves large tendons and muscles around the hips and shoulders. While corticosteroids remain the mainstay of PMR therapy, IL-6 inhibitors have been shown to be effective alternatives to corticosteroids in PMR. Recent work suggests that IL-6 levels in hip and shoulder regions of PMR patients are higher than circulating levels, thus suggesting local IL-6 production. The factors stimulating IL-6 release in tendon and muscles of PMR patients are not well defined. An explanation of the strong association of PMR with age also remains unclear. Adenosine levels are higher with age in some tissues. In myocardial tissue, for example, dysfunction of cellular adenosine transporters leads to accumulation of adenosine in the extracellular space. While adenosine is often considered to be anti-inflammatory, extracellular adenosine increases IL-6 production in some connective tissue cells. We sought to determine if elevated levels of adenosine promote IL-6 production in tenocytes, whether this is age-dependent, and whether levels of the adenosine transporter, equilibrative nucleoside transporter 1 (ENT1), vary with age.

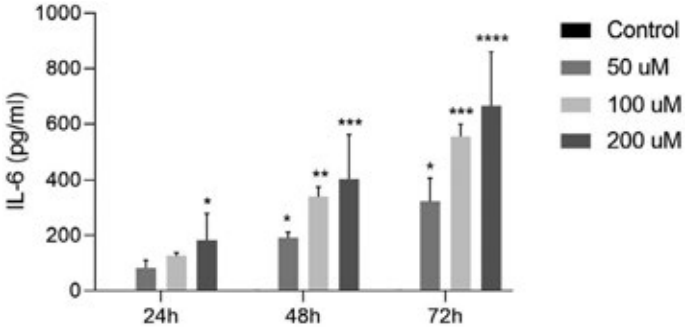

Figure 1. Effect of adenosine on tenocyte IL-6 levels. Old tenocytes were incubated with no additives (Control) or 50,100 or 200 uM adenosine. IL-6 levels were measured by ELISA in the media after 24-72 hours. IL-6 levels were not measurable at any time point in the controls. IL-6 levels were significantly increased at 24 hours by 200 uM adenosine (n=6, *= p<0.01) and at 48 and 72 hours by all concentrations of adenosine (n=6, **=p<.001, ***=p=.0002). IL-6 levels were not measurable in young tenocytes at any time point or with any concentration of adenosine (Data not shown.)

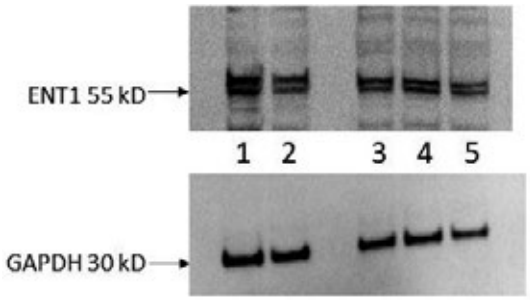

Figure 2. Levels of ENT1 in old and young chondrocytes. Two cultures of old and three cultures of young tenocytes were lysed with RIPA buffer, and similar quantities of protein were run on a 4-12 % Bis-Tris gel. Proteins were transferred to a nitrocellulose membrane and probed with ENT1 antibody. The loading control was GAPDH. There were no differences in the density of the ENT1 bands between old and young tenocytes. Lanes 1 and 2 are old tenocytes, Lanes 3,4 and 5 are young tenocytes.

Methods: Primary tenocytes were obtained from the patellar tendons of old (3-5 year old) and young (6 month old) pigs using digestion with collagenase. Cells were plated at $4.5x10^5$ cells/cm^2 in DMEM with 10 % fetal calf serum and used within 5 days of culture. After two days in culture, tenocytes were exposed to fresh DMEM with 0.35 % BSA with no additives (control) or 50 to 200 μM adenosine. IL-6 levels were measured in the conditioned media with both Western blotting using IL-17 as a positive control and an IL-6 ELISA (R&D Systems) with dose and time response. ENT1 levels were measured in the cell layer of young and old tenocytes using Western blotting and GAPDH as a loading control.

Results: In old tenocytes, 100 μM of adenosine and 10 ng/mL IL-17 increased media IL-6 levels by Western blot. The IL-6 ELISA showed no measurable amounts of IL-6 in the control of either young or old tenocytes. In old tenocytes, IL-6 levels rose to 666.3 +/- 194.3 pg/ml with 200 μM adenosine at 72 hours ($p< 0.002$) (Figure 1). In young tenocytes, there was no measurable IL-6 with any amount or time of adenosine exposure. (Data not shown.) Similar levels of ENT1 were present in both old and young tenocytes (Figure 2).

Conclusion: As tenocytes age, they may become increasingly responsive to adenosine leading to IL-6 production and an inflammatory response. While levels of ENT1 protein are similar in old and young tenocytes, additional work will be necessary to determine whether there are differences in adenosine metabolism in old and young tendon. Further studies of the pro-inflammatory effects of adenosine in older tissues may ultimately result in a better understanding of the pathways underlying the strong association of PMR with advanced age.

Therapeutic Strategies and Survival in Patients with Interstitial Pneumonia with Autoimmune Features

Marco Sebastiani,[1] Giulia Cassone,[2] Caterina Vacchi,[1] Lisa De Pasquale,[1] Stefania Cerri,[3] Giovanni Della Casa,[4] Carlo Salvarani,[1] and Andreina Manfredi[1], [1]Rheumatology Unit, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria Policlinico di Modena, MOdena, Emilia-Romagna, Italy, [2]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Emilia-Romagna, Italy, [3]Respiratory Disease Unit, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Emilia-Romagna, Italy, [4]Radiology Unit, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Emilia-Romagna, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently the term “interstitial pneumonia with autoimmune features” (IPAF) has been proposed to identify patients with interstitial lung disease and autoimmune characteristics, not fulfilling the criteria for specific connective tissue diseases (CTD). Until now, only few data are available about the clinical and serological features of IPAF patients, their survival and the possible evolution in a CTD.

The aim of the study was to investigate the therapeutic choices in IPAF patients, their efficacy and safety.

Methods: Fifty-two patients (mean age at diagnosis 65.5±11.0 years, female/male ratio 29/23) were consecutively enrolled and prospectively followed for 45±31.6 months. Data about therapies, disease onset, serological, clinical and therapeutic features, pulmonary function tests and high-resolution computed tomography were periodically repeated. A worsening of lung function was defined as a reduction of 10% compared to baseline of forced vital capacity (FVC) and diffusion lung capacity of CO (DLCO).

Results: An immunosuppressive therapy was prescribed in 15 patients (namely cyclophosphamide in 4, mycophenolate mofetil in 6 and azathioprine in 6, respectively), while 6 patients were treated with anti-fibrotic therapies (pirfenidone or nintedanib). Thirty-three patients taken corticosteroids, associated to other drugs in 18 patients, and alone in 15. Finally, no therapies were prescribed in 16 patients. At the end of follow-up FVC remained stable in 35% of patients, worsened in 50% and increased in 15%; DLCO remained stable in 25.8% of patients, worsened in 58.1% and increased in 16.1%. Mean survival was 94.2±8.5 months, and no differences were recorded according to the kind of therapy, while survival was significantly associated to the lung function at baseline (FVC and DLCO were confirmed to be significantly associated to death at multivariate analysis).

Conclusion: The therapeutic strategy in IPAF patients reflects the etherogeneity of the disease. Waiting for specific trial in this population, treatment is empyrical and based on the baseline features of the patients. Despite well tolerated, both anti-fibrotic and immunosoppressive therapies seem to not influence the evolution of the diseas.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

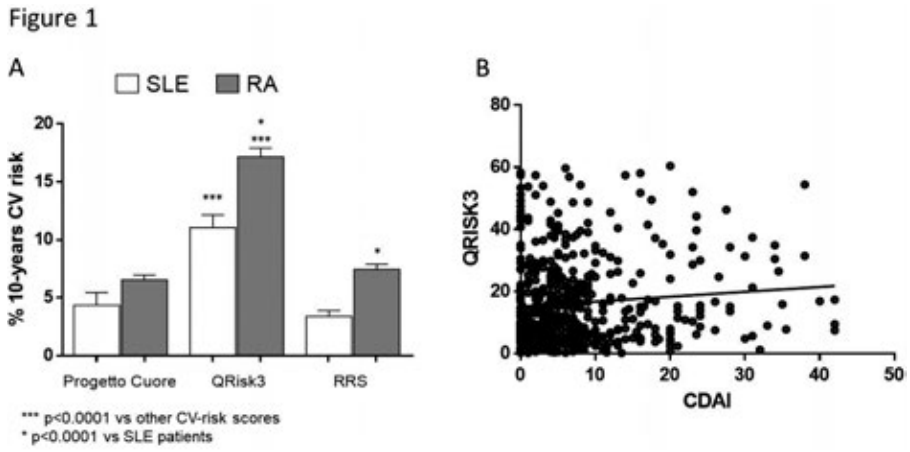
Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) patients present high cardiovascular (CV) morbidity and mortality. International guidelines suggest estimating CV-risk in these patients, but no indications about the strategy to use are specified. This multicentre cross-sectional study aimed to investigate the performance in real-life setting of three different 10-years CV-risk estimating algorithms in SLE and RA.

Methods: Data of 989 patients with SLE (140 patients; female 85.7%; age 40±16 years; disease duration 155±106 months) and RA (849 patients; female 79.3%; age 61±12 years; disease duration 133±110 months), according to specific classification criteria, were collected since January 2019 in 10 rheumatologic University Hospitals. Clinical and laboratory parameters were registered, and individual CV-risk was calculated using the "Progetto Cuore", QRisk3 and Reynolds risk scores (RRS), as stated by suitable algorithms. Statistical analysis was performed with appropriate tests using the Statistical System Prism (Graphpad Instat 6.0 - San Diego CA-USA).

Results: Fifty-six (6.6%) RA and 14 (10%) SLE patients had experienced a previous CV event (mainly myocardial- infarction). Among traditional CV-risks RA patients were significantly older ($p< 0.0001$), hyperlipidaemia was more prevalent in RA then SLE (57.8% vs 37.1%; $p< 0.001$), and similar prevalence of hypertension and diabetes was recorded. Mean BMI was not significantly different between groups, nevertheless a BMI >25 Kg/m2 was more prevalent in RA than SLE (47.8% vs 14.2% - $p< 0.0001$). RA patients were more frequently smokers (23.7% vs 13.6% - $p=0.007$). C-reactive protein was significantly higher in RA compared to SLE patients (6.8±1.1 vs 3.8±0.4 mg/l – $p=0.01$). Median (IQR) CDAI and SLEDAI were 7 (3-12) and 2 (0-2) in RA and SLE, respectively, and low-disease or remission according to CDAI (< 10) and SLEDAI (< 4) was similar. Sixty-eight percent of SLE patients were on a mean prednisone-dose of 5.9±2.6 mg/day whereas 41% of RA patients took 5.0±2.8 mg/day of prednisone ($p< 0.01$). All SLE patients were on



A. Estimated % 10-years cardiovascular risk in SLE and RA patients according to "Progetto Cuore", QRisk3 and Reynolds risk scores. B. Correlation between CDAI and QRisk3 score in RA patients.

hydroxychloroquine, 78 (55.7%) were co-treated with an immunosuppressant agent and 9 (6.4%) with belimumab or rituximab. Seventy percent of RA patients were on csDMARDs, mainly methotrexate, and 49.5% used also a biologic agent. CV-risk with QRisk3 results 2 to 3-fold higher compared to RRS and "Progetto Cuore" score in both patient groups. Moreover, QRisk3 and RRS resulted significantly higher in RA compared to SLE (Figure1A). Interestingly, only in RA a positive correlation between CDAI and QRisk3 (r=0.1; p=0.03) was detected (Figure1B).

Conclusion: This multicentre study showed a different performance in SLE and RA patients of the commonly used algorithms to estimate CV-risk in clinical practice. With a good disease activity control, traditional CV-risk factors may differently impact on predictable CV-risk using the "Progetto Cuore" scores, QRisk3 or the RRS. These findings should be considered when CV-risk is estimated routinely in such patients.

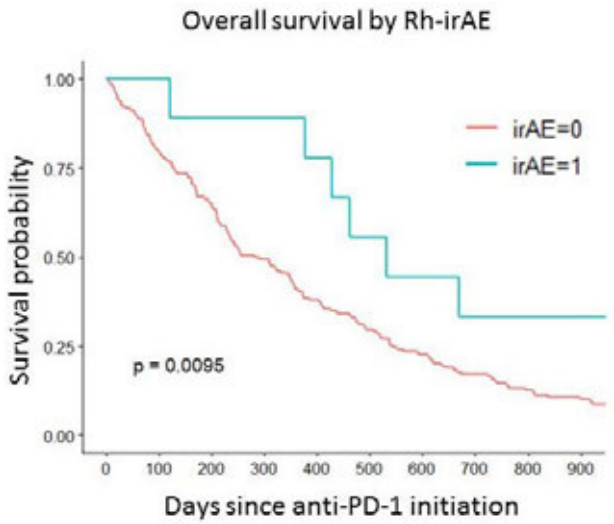
Overall Survival in Patients with PD-1 Inhibitor-related Inflammatory Arthritis and Metastatic Melanoma

Michael Richter,[1] Jacob Orme,[2] Heidi Finnes,[3] and Uma Thanarajasingam[4], [1]Division of Rheumatology, University of Washington, Seattle, WA, [2]Department of Hematology and Oncology, Mayo Clinic, Rochester, MN, [3]Department of Pharmacy, Mayo Clinic, Rochester, [4]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM



Overall survival based on the development of inflammatory arthritis.Abbreviations: Rh-irAE; rheumatic immune-related adverse effect.

Background/Purpose: The development of *de novo* inflammatory arthritis (IA) occurs in 2-4% of all patients with cancer treated with programmed cell death protein 1 (PD-1) inhibitors. (1) Prognosis remains a major concern for managing physicians, particularly given the potential for immunosuppressive medications to impact the anti-tumor response. The objective of this study is to assess the overall survival of patients with melanoma who develop anti-PD-1 associated IA.

Methods: From a database of all patients who received any PD-1 inhibitor at the Mayo Clinic Rochester, Minnesota campus between January 1st, 2011 and May 1st, 2018, we identified those with metastatic melanoma and new-onset inflammatory arthritis using diagnostic codes, search terms, and manual chart review. A Cox proportional hazard model was used to examine overall survival using R statistical software.

Results: Of the 394 patients with stage IV melanoma who received any PD-1 inhibitor, 27 (6.9%) were diagnosed with inflammatory arthritis representing a rheumatic immune-related adverse effect (Rh-irAE). Mean age upon starting anti-PD-1 therapy was 62.4 (SD=13.9) and 39% of patient were female. There were no statistically significant differences in age or sex between patients with and without IA. Average duration of anti-PD-1 therapy was 225 days (SD=279) with no significant differences between groups. IA was most often polyarticular (74%) and was treated with systemic glucocorticoids in 82% of cases for a mean duration of 210 days (SD=221). Six patients (22%) were treated with disease modifying drugs and three patients (11%) required permanent anti-PD-1 discontinuation due to severe symptoms. The development of IA correlated significantly with increased overall survival (HR 0.39, 95% CI=0.19-0.81).

Conclusion: This study shows a significant survival benefit associated with the development of anti-PD-1 associated IA in patients with metastatic melanoma. The prevalence of IA was higher than previous reports on rheumatic irAEs.

Rheumatic Immune-related Adverse Effects from Checkpoint Inhibitor Immunotherapy in Patients with Solid Tumors in a Latin American Population

Alain Sánchez-Rodríguez,[1] Elina Alexandra Rodriguez-Melendez,[2] Alonso Turrent-Carriles,[3] Paola Bermúdez-Bermejo,[3] José Fabián Martínez-Herrera,[2] and Raquel Gerson-Cwilich[2], [1]Hospital General de Mexico, Mexico City, Distrito Federal, Mexico, [2]ABC Medical Center, Oncology Department, Ciudad de Mexico, Distrito Federal, Mexico, [3]ABC Medical Center, Rheumatology Department, Ciudad de Mexico, Distrito Federal, Mexico

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cancer immunotherapy is a newly-approved approach in the management of advanced malignancies. Immune checkpoint inhibitors (ICIs) are the most commonly used type of cancer immunotherapy and have been associated with an increasingly number of immune-related adverse events (irAEs), including a variety of rheumatologic manifestations, however information regarding prevalence and incidence of irAEs in Latin American population is scarce.

Methods: We designed a retrospective, cross-sectional study to identify the prevalence of rheumatologic irAEs in patients with cancer receiving ICIs during the study period, ranging from January 2014 to February 2018 in a single center.

Results: Data from 140 subjects was included with a global prevalence of irAES of 38.6%, from which Rheumatic irAES were identified in 20 patients (14.3%). None of the patients had history of previous autoimmune disease. Mean age was 63 (+/- 11.3) years, 50% were female. The most common solid tumors were Lung and melanoma in 45 and 30%, respectively and 85% had metastatic disease. Patients received the following ICIs or combinations: Pembrolizumab in 45%, Nivolumab in 30%, Ipilimumab in 15% or Nivolumab + Ipilimumab in 10%. In order of frequency the following Rheumatologic irAEs were observed: Cutaneous (80%) (including lupus-like erythema), inflammatory arthritis (20%), myositis (5%), interstitial lung disease (5%), episcleritis (5%), nephritis (5%); Only four patients had available antinuclear antibodies with positive result. One patient developed a lupus-like syndrome with cutaneous, articular and renal involvement with negative antinuclear antibodies. Additionally, other concomitant non-rheumatologic irAES were observed: conjunctivitis in 4 patients, thyroiditis in 1 patient, and severe thrombocytopenia in 1 patient. Of notice, only 2 of the rheumatologic irAES were considered severe and 80% were mild or moderated. And most patients were treated with topic or low dose systemic glucocorticoids and symptomatic treatment and none required treatment with DMARDs.

Conclusion: We performed one of the first epidemiologic reports of rheumatologic irAES in a Latin American Population. Patients showed a predominantly mild and moderated cutaneous and articular involvement. Emphasis on serological assessment may improve identification of these newly described manifestations in Latin American populations.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) against CTLA-4 or PD- 1/PD-L1 and more recently TIM3, have demonstrated efficacy in improving the survival of patients with diverse advanced malignancies including melanoma, lung and urothelial cancer, among others.

Because of its mechanism of action, ICI are prone to produce different immune-related adverse events (irAEs), including musculoskeletal manifestations.

Our aim was to describe the experience with rheumatic irAEs in three tertiary centers.

Methods: All adult patients referred to the rheumatology departments of three tertiary centers from 2015 to 2018 because of the onset of musculoskeletal symptoms following treatment with an ICI were included.

Data collected comprised demographic features as well as ICI indication and type, history of rheumatic disease, musculoskeletal manifestations at the irAE onset, laboratory tests, ultrasound findings and treatment. Diagnostic and treatment approach was done according to clinical judgment in daily clinical practice settings.

Results: 38 patients were included, 39.5% female, mean age was 64 years (range 32-83). The indication for ICI was lung cancer in 20 cases, 10 melanoma, 3 urothelial and 1 for acute myeloid leukemia, squamous skin, breast, head and neck and rectum cancer.

Pembrolizumab was the most used ICI with 17 cases (1 combined with epacadostat), 12 were treated with Nivolumab (4 combined with Ipilimumab), 6 Atezolizumab (1 combined with Ibatasertib) whereas Durvalumab, Ipilimumab and MBG453 (a TIM3 inhibitor) were used each in 1 patient.

A history of rheumatic disease was reported in 12 patients 3 gout, 2 chondrocalcinosis and 1 case for each RA, Spondyloarthritis, SLE, psoriasis, fibromyalgia and osteoarthritis.

The most frequent irAE presentations were arthritis with 20 cases (52.3%) and arthralgia in 12 cases (31.6%). After the assessment, 15 patients were diagnosed as undifferentiated arthritis, 4 psoriatic-like arthritis, 2 PMR-like,1

leukocytoclastic vasculitis, 1 small-vessel vasculitis, 1 tenosynovitis, 2 gout and 12 were classified as having non-inflammatory symptoms.

Antibody status was analyzed in 33 patients, ACPA were positive in 1 patient with known RA, ANAs were positive in 4 (including 1 patient with previous SLE) but without any specificities (i.e. ENAs) and ANCA were negative in one case with small-vessel vasculitis.

Ultrasonography assessment was performed in 11 patients, 3 did not show signs of inflammation. Among the remaining ones, 6 presented either synovial hypertrophy with/or positive power Doppler, 1 a peritendinous fluid collection and 1 an elbow joint effusion.

Most patients were treated with glucocorticoids and NSAID 23 (60.5%) and 13 (34.2%) respectively. Only 4 patients required csDMARD (Methotrexate or Hydroxychloroquine) and 4 had to withdraw ICI treatment due to irAEs.

Conclusion: Our results were in line with previous studies showing that MSK-irAEs associated with ICI may present as a flare of a previous known rheumatic disease or as a de novo symptom.

Most patients presented with asymmetric mono or oligoarthritis and responded to GC and NSAID with only a few requiring DMARD or ICI withdrawal

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy by harnessing the immune system to fight cancer, but are associated with significant immune-related adverse events (irAEs). Limited data is available on the safety of ICIs in patients with preexisting autoimmune diseases and on concomitant use of immunosuppressive drugs. CanRIO is a network of Canadian rheumatologists with experience in the management of rheumatic irAEs secondary to ICIs. In this case series, we describe the clinical course of patients with preexisting autoimmune diseases who were treated with ICIs at 7 CanRIO sites.

Methods: Patients referred for rheumatological evaluation in the context of immunotherapy between 2013 and March 2019 at participating CanRIO sites with preexisting autoimmune disease were identified. Standardized data were extracted by retrospective chart review. Descriptive statistics were used to summarize the data.

Results: A total of 25 patients with preexisting autoimmune disease who received ICI treatment were identified. Their age was 62.9 ± 11.9 (mean ± SD), 13 (52%) were male, and 23 (92%) were White. Mean (SD) follow-up was 13.1 (9.2) months. The most common indications for ICI were advanced lung cancer (n=13, 52%) and melanoma (n=9, 36%); 96% had stage 4 disease. Most patients received ICI monotherapy (Pembrolizumab: n=17, 68%; Nivolumab: n=6, 24%).

Preexisting autoimmune diseases included rheumatoid arthritis (RA, n=8), psoriasis (n=4), psoriatic arthritis (n=3), axial spondyloarthropathy (SpA, n=3), systemic lupus erythematosus (SLE, n=2), dermatomyositis (n=1), polymyalgia rheumatica (PMR, n=1) and other non-rheumatic diseases (n=3).

Of 8 patients with RA, 71% (5/7) were seropositive (RF ±anti-CCP) and 43% (3/7) had erosive disease. 50% (4/8) were in remission at time of ICI initiation, 29% (2/7) had their DMARDs stopped, 29% (2/7) continued their DMARD(s) and 43% (3/7) had new DMARD(s) started prophylactically. Overall, 50% (4/8) experienced grade ≤ 2 flares of their polyarthritis, 13% (1/8) developed PMR *de novo*and 38% (3/8) did not have any rheumatic irAE. Of those who developed rheumatic irAEs, 80% (4/5) received Nivolumab, 80% (4/5) had seropositive disease, 63% (5/8) were on DMARDs at time of ICI initiation and 80% (4/5) events occurred after a single dose of ICI.

Of 4 patients with psoriasis but without arthritis, 3 (75%) experienced a flare (both mild and major) of their skin disease and 3 (75%) developed *de novo* arthritis (grade 2-3) within the first 4 months of ICI treatment. Of 3 patients with axial SpA, two experienced new peripheral arthritis (grade 2) after receiving ICI.

Inflammatory arthritis responded to oral corticosteroids (up to 50 mg, tapered over 4-9 months) and/or addition of DMARDs (methotrexate, hydroxychloroquine and/or sulfasalazine), and required ICI discontinuation in 27% (3/11) of patients. Two patients with SLE remained in remission (on hydroxychloroquine).

Conclusion: This is the largest multicentered study of patients with rheumatic autoimmune diseases exposed to immunotherapy. Arthritis flares in patients with RA exposed to ICI are frequent despite DMARD background therapy. New onset of peripheral arthritis is frequent in SpA and psoriatic patients.

*ANA considered positive if titer ≥1:320
**Percentage of patients with a given pattern out of the 9 patients with positive ANA.
***RF counted as positive if ≥2 times the upper limit of normal
****No patients had a positive ANA in a nucleolar pattern, ANCA, anti-RNA polymerase III, anti-CCP, anti-PM/Scl, anti-melanoma differentiation-associated protein 5, or other myositis-associated or myositis-specific antibodies except as noted in the table.

Table 2. Baseline laboratory values of patients with interstitial pneumonia with autoimmune features (IPAF) prior to treatment with rituximab.

Background/Purpose: Interstitial lung disease (ILD) is a major cause of morbidity and mortality in patients with connective tissue diseases (CTD). Approximately one-third of patients with ILD have autoimmune manifestations not classifiable as a CTD, designated as interstitial pneumonia with autoimmune features (IPAF). To our knowledge, there are no studies examining the efficacy of rituximab (RTX) in IPAF. Here, we describe a case series of 19 patients with IPAF treated with RTX.

Methods: An institution-wide registry of patients seen consecutively at a large academic medical center from 2000-2018 was queried for patients aged ≥18 years with diagnostic codes for ILD, treatment with RTX, and positive autoantibodies (including ANA, RF, anti-CCP, anti-dsDNA, anti-Ro, anti-La, anti-Smith, anti-Scl-70, anti-tRNA synthetase, anti-PM-Scl, anti-melanoma differentiation-associated protein 5). Patients included met the 2015 classification criteria for IPAF (N=19) (Fischer A, et al., *Eur Respir J* 2015; 46:976-87). Patients were excluded if they had received RTX for a known autoimmune disease or malignancy. Clinical data and pulmonary function tests (PFTs) were collected by medical record review. Chest computed tomography (CT) scans were reviewed independently by 2 radiologists. Clinical improvement was based on a composite of clinician assessment, oxygen requirements, hospitalization, and survival. Only those subjects with PFTs within 3 months prior to or 1 month after RTX initiation and 6-18 months af-

Outcome	Patients with IPAF (N=19 for clinical assessment, N=10 for pulmonary function testing)

Clinically stable (%)*	**8 (42%)**
Clinically worsened (%)*	3 (16%)
Absolute change in percent predicted of forced vital capacity, mean % (SD)	8% (13%)
Absolute change in percent predicted of diffusion capacity of carbon monoxide, mean % (SD)	3% (13%)
Pulmonary function testing improved (%)**	**5 (50%)**
Pulmonary function testing stable (%)**	**3 (30%)**
Pulmonary function testing worsened (%)**	2 (20%)
Tapered off corticosteroids completely (%)	6 (32%)

*Definition based on composite of clinician assessment, change in oxygen requirements, need for hospitalization, and survival.
**Improvement defined as ≥10% improvement in forced vital capacity. Stable defined as forced vital capacity within +/- 10% of prior measurement. Worsening defined as ≥10% decline in forced vital capacity.

Table 3. Outcomes after treatment with rituximab in patients with interstitial pneumonia with autoimmune features (IPAF).

ter RTX initiation were included in the PFT analysis (N=10); PFT improvement was defined as ≥10% improvement in forced vital capacity (FVC).

Results: To date, we have identified 19 patients with IPAF treated with RTX, with median follow up time of 24 months (**Table 1**). Several patients had inflammatory arthritis, myalgia, esophageal symptoms, and Raynaud phenomenon at the time of diagnosis. Sixteen patients had chest CT features of non-specific interstitial pneumonia (NSIP), organizing pneumonia (OP), or a combination of NSIP and OP. The creatine kinase, aldolase, ESR, and CRP levels were elevated (**Table 2**). The average number of RTX doses received was 7, over a median follow up time of 24 months (range 8-120 months).

After treatment with RTX, sixteen patients (84%) were improved or stable based on clinical parameters (**Table 3**). Among the ten patients with PFTs within the designated timeframe, the absolute changes in FVC percent predicted was +8% (SD 13%) and diffusion capacity of carbon monoxide (DLCO) was +3% (SD 13%). No patients stopped therapy due to adverse events. One patient died due to respiratory failure. Six patients were tapered off glucocorticoids completely after 1 year of treatment with RTX.

Conclusion: In this case series of 19 patients with IPAF treated with RTX, most patients appear to have had improvement or stability. These findings call for prospective studies, including potential randomized controlled trials, to further determine the risks and benefits of RTX use in IPAF.

Frailty in Systemic Rheumatic Diseases: A Systematic Review

Sarah Lieber,[1] Abigail Schmucker,[2] and Lisa Mandl[3], [1]Hospital for Special Surgery, New York, [2]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA, [3]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty, a state of decreased homeostatic reserve, is well studied in the elderly and is independently associated with increased morbidity and mortality. Many systemic rheumatic diseases are increased in the elderly and can similarly be associated with poor outcomes. To our knowledge, there are no systematic reviews evaluating frailty in inflammatory rheumatic conditions. Thus, we performed a systematic review to evaluate the prevalence of frailty and the association of frailty with health-related outcomes in patients with systemic rheumatic disease.

Methods: A search of Ovid MEDLINE, Ovid Embase, the Cochrane Library, the Cumulative Index to Nursing and Allied Health Literature, AgeLine, and Scopus was conducted from database inception to January 2019 to identify original research articles and abstracts about frailty and inflammatory rheumatic conditions. Studies addressing frailty, using all definitions, and any inflammatory rheumatic disease were eligible. Data extracted included study design, patient characteristics, frailty instruments, and health-related outcomes. Risk of bias was assessed using the Newcastle-Ottawa scale for cohort and cross-sectional studies and the Cochrane Risk of Bias Tool for randomized controlled trials (RCTs). Two investigators reviewed each study. Disagreements were resolved by a third reviewer. The study was registered prospectively in PROSPERO and conducted according to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.

Figure 1. PRISMA flow diagram

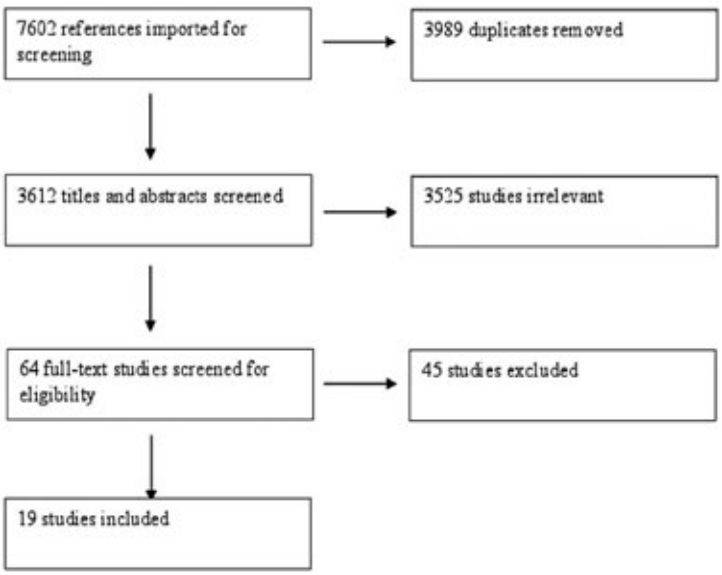

Table 1. Characteristics of included studies

Source	Study Design	N	Rheumatic Condition	Frailty Scale	Results
Andrews et al. 2017* (United States)	Cross-sectional study	124	RA	Fried phenotype	Frailty was associated with increased disability in RA as measured by Valued Life Activities after adjustment for confounders.
Bagshaw et al. 2016* (Canada)	Prospective cohort study	197	Rheumatoid/connective tissue disease	Canadian Study of Health and Aging Clinical Frailty Scale	Rheumatoid/connective tissue disease was associated with prehospital frailty in patients admitted to the intensive care unit.
Bernelli et al. 2015* (taly)	Case series	6	SSc	Not defined	Frailty was evaluated in all patients with SSc in whom transaortic valve implantation was performed.
Blunn KJ et al. 2010 (United Kingdom)	Prospective cohort study	207	RA	Subjective assessments in combination with age and Health Assessment Questionnaire	Frailty was identified as a reason for RA monotherapy or lack of therapy.
Cano-Garcia et al. 2014 (Spain)	Cross-sectional study	16	RA, SLE, SSc, PsA	Barthel Index	87.5% of participants with rheumatic diseases were frail.
Chang et al. 2010* (United States)	Cross-sectional study	620	RA	Fried phenotype	RA was associated with increased odds of frailty.
Cleutjens et al. 2018 (Netherlands)	Cross-sectional study	Unspecified	RA	Groningen Frailty Indicator	Frail patients with RA were more often female and reported lower health status and worse social and psychological domains.
Guler et al. 2017* (Canada)	Cross-sectional study	86	SSc-associated interstitial lung disease	42-Item Frailty Index	Dyspnea was associated with the frailty index

Results: Of 7602 abstracts identified, 64 full-text abstracts and articles were available for review, and 19 were included (Figure 1). These included 1 RCT, 9 prospective cohort studies, 7 cross-sectional studies, 1 retrospective cohort study, and 1 case series. Eleven studies included participants with RA, 4 studies included participants with SSc, 2 studies included participants with SLE, 3 studies included participants with vasculitis, 1 study included participants with PsA, and 2 studies included participants with non-specific “connective tissue disease.” Given study heterogeneity, meta-analysis was not conducted. Risk of bias varied across studies. Frailty was prevalent in multiple systemic rheumatic diseases and associated with poor clinical outcomes, including increased disability and mortality (Table 1).

Conclusion: To our knowledge, this is the first systematic review exploring the relationship between frailty and systemic rheumatic diseases. Frailty is prevalent in multiple systemic rheumatic diseases and is often associated with poor clinical outcomes. Further study is needed to determine risk factors for frailty in systemic rheumatic disease, including risks for progressing from pre-frail to frail. Using standardized frailty instruments will facilitate comparisons between diseases and patient populations.

Neuromyelitis Optica Overlaps Frequently with Systemic Rheumatic Diseases in African-Americans: Experience at a Large US Academic Medical Center

Michael Belsky,[1] Sunita Dia,[2] Hassan Amer,[2] Christopher Collins,[1] and Konstantinos Loupasakis[1], [1]MedStar Washington Hospital Center, Department of Rheumatology, Washington, DC, [2]MedStar Washington Hospital Center, Department of Internal Medicine, Washington, DC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Neuromyelitis optica (NMO) and neuromyelitis optica spectrum disorders (NMOSD) are immune-mediated demyelinating disorders of the central nervous system, primarily characterized by optic neuritis and longitudinal extensive transverse myelitis. Antibodies to aquaporin-4 (AQP4-IgG) are highly specific markers of NMOSD. The coexistence of NMOSD with systemic rheumatologic autoimmune disease has been well documented, especially systemic lupus erythematosus (SLE) and Sjogren syndrome (SS) [1]. Several recent studies have demonstrated that NMOSD may disproportionately affect black patients [2,3]. Our objective was to characterize African-Americans diagnosed with NMO at our academic medical center, and identify any associated systemic rheumatologic autoimmune diseases.

Methods: We conducted a retrospective chart review of adult African-American patients diagnosed with NMO at a single academic medical center between 2011 and 2017. The charts reviewed were identified using ICD codes for NMO, transverse myelitis and optic neuritis. The diagnosis of NMO was then confirmed as per the 2015 International Consensus Diagnostic Criteria. The diagnosis of SLE and SS were also confirmed based on existing diagnostic criteria.

Results: Of the 60 charts reviewed, 25 patients (41.7%) met criteria for NMO, and of those, 21 patients (84%) were African-American. Of the 21 African-American NMO patients, 89.5% (n=19) were AQP4-IgG positive, 95.2% were women, and 38.1% had an associated systemic rheumatologic autoimmune disease (SLE 62.5% and primary SS 37.5%). In 60% of the NMO patients with SLE, the diagnosis of NMO preceded the SLE diagnosis. Conversely, in 100% of the NMO patients with SS, the diagnosis of NMO either followed, or was made simultaneous to, the SS diagnosis. Notably, 80% of the SLE patients had primarily hematologic manifestations. ANA was positive in 78.6% of the African-American patients in whom ANA testing was performed (n=14), with anti-SSA (64.3%, n=14) and anti-SSB

(50%, n=11) the next most prevalent autoantibodies. Mean age of NMO onset was 46.7 years (SD 13.6). Transverse myelitis was the most common presenting manifestation (71.4%), followed by optic neuritis (61.9%).

Conclusion: Our population had a higher mean age of onset (46.7 vs 33 years) compared with other cohorts of seropositive NMO African-Americans [2]. Additionally, African-Americans with NMO at our institution had a higher female:male distribution than has been documented[3]. Not surprisingly, SLE was the most common associated systemic rheumatic disease in our cohort, however the frequency of SLE and ANA positivity in our NMO cohort was higher than has been reported (23.8% and 78.6%, respectively) [4]. Additional larger studies are needed to further explore how NMOSD in African-Americans may differ from other populations.

Musculoskeletal Immune-Related Adverse Events After Immune Checkpoint Inhibitor Therapy: Single Center Experience

Didem Saygin,[1] Melissa Bastacky,[1] Gerard Mascara,[1] Timothy L Brenner,[1] Chester Oddis,[1] Siamak Moghadam-Kia,[1] Dana Ascherman,[1] Diwakar Davar,[1] and Rohit Aggarwal[1], [1]University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are new anti-cancer agents used for lung cancer, melanoma, renal cell and urothelial carcinoma, and head and neck cancers. They activate anti-tumor immunity which hampers self-tolerance leading to many immune related adverse events (irAE) commonly affecting the skin, endocrine organs and GI tract. Historically, rheumatologists report limited experience and confidence in the management of irAEs. We report our single-center experience with musculoskeletal irAEs.

Table. Characteristics of melanoma patients and immune related adverse events

#	IrAEs	Grade	IrAE treatment	Interruption of ICI	Cycle	Freq	ICI	Combo or mono	Other IrAE	Prior autoimmune disease	Age	Sex	Race
1	Arthritis (Seronegative RA)	2	MTX	No	1	3 wks	Pembro	Mono	None	No	75	M	Caucasian
2	Arthralgia or arthritis	2	Prednisone	Yes	6	3 wks	Pembro	Mono	Rash, hyperthyroidism	No	81	F	Caucasian
3	Arthralgia or arthritis	2	Prednisone	No	7	3 wks	Pembro	Mono	Rash	No	81	M	Caucasian
4	Arthralgia	2	None	No	2	3 wks	Ipilumumab	Mono	Rash	No	26	F	Caucasian
5	Arthralgia	2	None	Yes	15	3 wks	Pembro	Mono	Rash, pneumonitis	No	62	M	Caucasian
6	Arthritis	2	Prednisone	No	4	2 wks	Ipilumumab	Mono	Autoimmune adrenalitis	No	73	M	Caucasian
7	Myalgia	2	Prednisone	Yes	1	3 wks	Ipi+Nivo	Combo	Hypothyroidism	No	80	M	Caucasian
8	Myositis	3	Prednisone	Yes	2	3 wks	Pembro	Mono	Hepatitis	Yes (MS)	66	M	Caucasian
9	Arthritis	2	Prednisone	No	4	3 wks	Pembro	Mono	Colitis, rash	Yes (RA)	62	F	Caucasian
10	Myalgia	2	None	Yes	19	3 wks	Pembro	Mono	Rash	No	62	F	Caucasian
11	Arthritis (Seronegative SPA)	3	Tocilizumab	Yes	9	2 wks	Nivolumab	Mono	Rash	No	45	F	Caucasian
12	Arthralgia	N/A	Prednisone	No	2	3 wks	Pembro	Mono	None	No	65	M	Caucasian

ICI: immune checkpoint-inhibitor, RA: rheumatoid arthritis, MS: multiple sclerosis, SPA: spondyloarthropathy, MTX: methotrexate, Pembro: pembrolizumab, Combo: combination, Ipi: ipilumumab, Nivo: nivolumab, N/A: not available, wks: weeks

Methods: University of Pittsburgh melanoma patients treated with ≥1 dose of a PD-1 inhibitor between 2011-2018 were analyzed. Demographic data, cancer diagnosis and treatment and the type and treatment of irAEs were obtained via retrospective chart review.

Results: The melanoma cohort included 130 patients with 12 (9.2%) developing ≥ grade 2 arthralgia, arthritis, myalgia or myositis. The mean age was 64.8 (± 16.1) and included 7 males and 5 females. Nine subjects developed ≥ grade 2 arthralgia/arthritis (6.9%) and two had grade 2 myalgias (1.5%) while there was 1 case of myositis (0.7%). Fifty percent of patients had their cancer treatment interrupted and the patient developing myositis was hospitalized. IrAEs occurred after a median of 4 (IQR 2-7.5) cycles and 66 (IQR 20.2-145) days after initiation of cancer treatment and was grade 2 in 81% of cases. Cancer treatment included pembrolizumab (n:8), ipilimumab (n:3) and nivolumab (n:1) in subjects with irAEs, and was single agent in 92% of the cases. Eighty-three percent of the cases developed other non-musculoskeletal irAEs, with rash (80%) the most common followed by thyroid abnormalities (20%). One melanoma patient with pre-existing rheumatoid arthritis (RA) flared with synovitis after 19 ICI cycles and was treated with a short course of prednisone. Treatment of the irAEs included prednisone alone in 58% and at least one additional agent in in 2 (17%) of the cases, all of whom significantly improved. Of the latter 2 cases, 1 was diagnosed with seronegative RA that responded to methotrexate while the other patient had a new diagnosis of seronegative spondyloarthropathy treated with sulfasalazine (discontinued due to rash), methotrexate (ineffective) and later responded to tocilizumab. The subject with myositis was hospitalized with muscle weakness and an elevated creatine kinase (CK) of 1058 U/L and responded to glucocorticoids. Two patients with myalgias and a normal CK improved with ICI discontinuation in one and a short course of prednisone with ICI monotherapy in the second case.

Conclusion: In summary, approximately 10% of melanoma patients receiving immunotherapy developed musculoskeletal irAEs with 50% requiring interruption in cancer treatment, and most (75%) requiring glucocorticoids or other immunosuppressive therapy. Musculoskeletal irAEs responded well to prednisone alone in 80% of cases, while 20% required an additional immunosuppressive agent. As more ICIs are used, it will be necessary to conduct prospective assessments of toxicity in order to better ascertain the frequency as well as to optimally manage the irAES to allow for continuation of effective cancer therapy.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity anti–interleukin-23p19 monoclonal antibody approved for the treatment of moderate-to-severe plaque psoriasis. The objective of this study was to evaluate severe infections in the phase 3 reSURFACE 1 (NCT01722331) and reSURFACE 2 (NCT01729754) trials.

Methods: This is a post hoc pooled analysis of adult patients with moderate-to-severe plaque psoriasis from two 3-part, parallel group, double-blinded, randomized, controlled trials; reSURFACE 1 (64 week) and reSURFACE 2 (52 week). Detailed methodology has been previously published.[1] Safety data over 148 weeks, pooled across trials and treatment groups, were included. Groups were defined as placebo, etanercept (until week 28), TIL 100 mg (100 mg-only in at least 1 part of the study), TIL 200 mg (200 mg-only in at least 1 part of the study), continuous TIL 100 mg (100 mg throughout the 3 double-blind parts plus open-label extension), continuous TIL 200 mg (200 mg throughout all parts), TIL 100/200 mg (any TIL dose in at least 1 part), and continuous TIL 100/200 mg (consistently exposed but dose could change throughout all parts). Severe infections were defined as any infection meeting the regulatory definition of a serious adverse event (SAE) or requiring intravenous antibiotics, irrespective of whether it was reported as an SAE. Exposure-adjusted incidence rates (EAIR) were reported.

Results: Overall, 928 patients on TIL 200 mg, 872 on TIL 100 mg, 316 on continuous TIL 200 mg, 352 on continuous TIL 100 mg, 543 on placebo, 1646 on TIL 100/200 mg, 808 on continuous TIL 100/200 mg, and 313 on etanercept were included. The EAIR of severe infections was 1.12/100 subject-years of exposure among TIL 200 mg, 1.14 (TIL 100 mg), 0.88 (continuous TIL 200 mg), 0.64 (continuous TIL 100 mg), 0.97 (placebo), 1.11 (TIL 100/200 mg), 0.86 (continuous TIL 100/200 mg), and 1.96 (etanercept). Most commonly reported types of severe infections included appendicitis, cellulitis, diverticulitis, and sinusitis.

Conclusion: Tildrakizumab had a favorable long-term safety profile as demonstrated by a low rate of severe infections (lower than etanercept and comparable to placebo) in patients with moderate-to-severe plaque psoriasis.

Editorial support was provided by Puneet Dang, PhD, of AlphaBioCom, LLC.

Complications of Immune Checkpoint Inhibitor Therapy in Patients with and Without Pre-existing Rheumatologic Disease

Emily Carroll,[1] Amanda Leiter,[2] Danielle Brooks,[1] Jennifer Ben Shimol,[3] Elliot Eisenberg,[1] Matthew Galsky,[4] Emily Gallagher,[5] and Margrit Wiesendanger[3], [1]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, [2]Division of Endocrinology, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, [3]Division of Rheumatology, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, [4]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, [5]Division of Endocrinology, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are effective therapies in the treatment of many cancers, but their use has been linked with immune-related adverse events (irAEs). As use of ICIs becomes more widespread, more patients are developing irAEs including rheumatologic manifestations. Thus, it is important that clinicians monitor for irAEs and identify patients who may be at increased risk for developing them. We sought to describe the prevalence and presentation of irAEs, both in general and specifically rheumatologic, in order to better characterize their clinical manifestations and recognize potential predisposing risk factors. We hypothesized that patients with preexisting rheumatologic disease would experience irAEs at an increased rate compared to those without preexisting conditions.

Methods: We performed an IRB approved retrospective review using an EMR database of patients treated with ICIs at our institution from January 2011 to April 2017. We reviewed charts to assess for the presence of preexisting rheumatologic disease as well as the development of irAEs during ICI treatment. In patients who experienced an irAE, we determined whether they required additional work up, glucocorticoid treatment, hospitalization, or cessation of ICI therapy. To see if there was an association between preexisting rheumatologic disease and developing irAEs, we did comparative analysis using the Fisher exact test.

Results: Of 420 patients treated with ICIs, 4.8% (n=20) experienced rheumatologic irAEs. As a result, 4 were referred for rheumatology consultation, 7 were treated with glucocorticoids, 3 had to delay or stop ICIs, and 0 required hospitalization. Preexisting rheumatologic disease was present in 4.8% (n=20). In this subgroup, 65% (n=13) developed any irAE compared to 43% (n=172) of those without preexisting rheumatologic disease (p=0.065). 15% (n=3) developed a rheumatologic irAE compared to 4.25% (n=17) of those without preexisting rheumatologic disease (p=0.063).

Conclusion: We did not detect a statistically significant difference in the rates of irAEs in patients with preexisting rheumatologic disease; however, this study was limited by its retrospective design and relatively small sample size. Given that p-values neared significance, it is possible that this study was underpowered to detect a true relationship and thus additional, larger studies would be beneficial to further investigate. Overall, the majority of rheumatologic irAEs did not require treatment or lead to cessation of ICI therapy. This suggests that even if there is found to be a significant relationship between preexisting rheumatologic disease and the development of irAEs, this risk factor should not preclude this population from receiving ICI therapy but would require careful monitoring and collaboration between these patients' oncologists and rheumatologists.

Musculoskeletal Ultrasound Enhances the Evaluation of Checkpoint Inhibitor Associated Musculoskeletal Immune Related Adverse Events

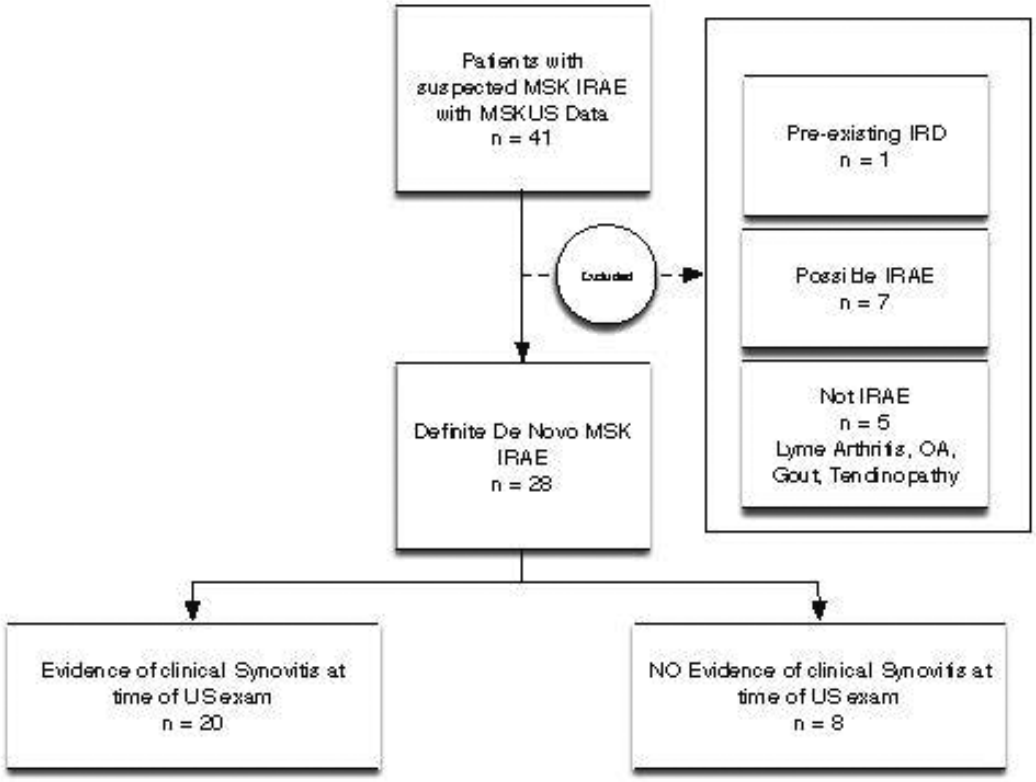
Mazen Nasrallah,[1] Sara Schoenfeld,[2] Mark Matza,[1] Donald Lawrence,[2] Justine Cohen,[2] Meghan Mooradian,[2] Kerry Reynolds,[2] Ryan Sullivan,[2] and Minna Kohler[2], [1]Massachusetts General Hospital, Boston, [2]MGH, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cancer immunotherapy with monoclonal antibodies that antagonize molecular checkpoint pathways in immune activation, the PD-1/PDL1 axis and CTLA-4, have revolutionized the treatment of solid cancers. These therapies however are limited by immune related adverse events (irAEs), including inflammatory arthritis (irIA). Presentations can be subtle, and recognition delayed. Here we describe point-of-care musculoskeletal ultrasound (MSKUS) findings in patients with solid cancer treated with checkpoint inhibitors.

Methods: Patients >18 years treated with an ICI at our tertiary care center from 2011-2019 were seen by rheumatology for evaluation of musculoskeletal symptoms following ICI. Forty-one patients with suspected MSK irAEs had MSKUS performed and interpreted by the same ultra-sonographer. Findings were reviewed and confirmed by a blinded US reader. US findings in patients with confirmed de novo MSK irAEs were reviewed and correlated with the presence or absence of documented clinical synovitis and with available synovial fluid analysis.

Results: Twenty-eight out of forty-one patients had definite de novo MSK irAE, five patients had an alternative etiology identified with assistance of diagnostic MSKUS, 1 patient had pre-existing rheumatoid arthritis, and 7 patients were classified as possible MSK irAE when diagnosis was uncertain (Figure 1). Twenty out of the twenty-eight patients with definite de novo MSK irAE had clinical evidence of synovitis at the time of initial MSKUS examination, while 8 did not. Among patients with clinically evident synovitis, MSKUS examination confirmed inflammatory pathology in all patients. The most common MSKUS features identified were grade 2 or higher synovial thickening (80%), hyperemia measured by color power Doppler (CPD) signal (70%), tenosynovial proliferation (60%), and moderate or large effusion (45%). Among the 8 patients without clinically evident synovitis, the initial US examination identified inflammatory synovial or tenosynovial pathology in 6 patients (75%); in 2 patients, inflammatory features evolved only on follow up and were identified by MSKUS examination. Fourteen patients with definite de novo MSK IRAE had synovial fluid analysis; 6 patients had synovial fluid cell counts < 2000 cells/μl. Of these 6 patients with synovial analysis



NOT IRAE	An alternative explanation for patients symptoms and signs identified and more likely cause of symptoms.
POSSIBLE IRAE	MSK pathology potentially though not unequivocally correlating with ICI therapy and/or insufficient follow up data to assess for evolution in equivocal cases. Alternative diagnosis is felt to be equally possible.
DEFINITE IRAE	MSK pathology unequivocally correlating with ICI therapy and alternative etiology excluded based on history/exam/imaging/labs

Figure 1. Overview of Patients on Immunotherapy and MSK Symptoms with MSKUS Data

within the 'non-inflammatory' range, all patients had grade 2 or higher synovial thickening, 50% had moderate or large effusions, 50% had tenosynovial proliferation, and 33% had evidence of hyperemia (+CPD). All 6 patients required steroids (intra-articular or oral) and initiation of DMARD therapy at first or subsequent visits with improvement in symptoms.

Conclusion: Point-of-care MSKUS is a valuable tool for confirming inflammatory pathology and expediting early identification of subclinical synovitis or tenosynovitis among patients with ICI-therapy associated MSK symptoms. Additionally, MSKUS helps identify patients with inflammatory features when synovial fluid analysis is within the traditional non-inflammatory range and assists in excluding alternative etiologies.

Muscle Involvement Revealed by 18F-PET-CT in Polymyalgia Rheumatica

Daniel Wendling,[1] Maxime Sondag,[2] Nicolas Giraud,[2] Mickael Chouk,[2] Hatem Boulahdour,[2] Clément Prati,[2] and Frank Verhoeven[3], [1]Rheumatology, University Teaching Hospital (CHRU), Besançon, France, [2]University Teaching Hospital (CHRU), Besançon, France, [3]CHU Besancon, BESANCON, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Imaging techniques in polymyalgia rheumatica (PMR) have revealed mainly bursitis, tenosynovitis, capsulitis and enthesitis. This is also the case for 18F-FDG-PET-CT. This technique, which has shown its interest for the diagnosis of PMR, allows an assessment of the metabolic activity of the entire musculoskeletal system and in particular of muscle structures.

The aim of this study was to evaluate muscle damage using 18F-FDG-PET-CT in PMR.

Methods: This is a retrospective study including patients with PMR (ACR/EULAR 2012 criteria) seen in our department, who had an 18F-FDG PET-CT examination between September 2012 and November 2018. A control group consisting of subjects without rheumatologic manifestations who had such an examination as part of neoplastic research or neoplastic disease control was also evaluated. PET evaluation included 17 sites suggestive of PMR, as previously reported [1], leading to a global PET score ranging from 0 to 51. Muscle hyper metabolism areas were similarly rated according to the same Goerres classification [2](0 = no uptake; 1 = slight uptake, less than liver; 2 = uptake like liver; 3 = uptake higher than liver). Muscle activity sites have been identified. A comparison of PMR patients with and without muscle involvement was performed using the Mann Whitney or Fisher's exact test.

Results: 134 cases were reviewed, concerning 80 PMR (mean age 67.9) and 54 "controls" (mean age 68.1). Overall, PET muscle damage was observed in 27 cases (34%) in PMR and 6 cases (11%) in controls (p=0.004). The damage is bi or multi-focal in 16/27 cases. The affected muscular sites are: thighs and ischium-leg (n = 10), spinal (11), piriform/buttocks (7), pectoral (5), large serrated (4), subspinatus/subscapular (3), deltoid (1), trapezius (1). Fasciitis was found in 4 cases. As expected, PMR patients exhibited higher TEP scores than controls ($p< 0.001$). In PMR patients, PET muscle involvement was associated with higher ESR values ($p< 0.05$), but not with age, CRP or global PMR PET score.

Conclusion: Muscle involvement assessed by 18F-Fluorodeoxyglucose PET-CT is frequent in PMR (1/3 of cases), located at usual sites of symptoms of the disease, without association with age, CRP levels or global PET score for PMR. Muscle should be carefully evaluated during PET in cases of PMR; these pictures may be a new diagnosis feature of the disease.

Principal Components Analysis as a Tool to Identify Lesional Skin Patterns in Cutaneous Lupus Erythematosus

Smriti Prasad,[1] Justin Raman,[1] Motolani Ogunsanya,[2] and Benjamin Chong[3], [1]University of Texas Southwestern Medical Center, Dallas, [2]OU College of Pharmacy, Oklahoma City, [3]University of Texas Southwestern, Dallas

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) has multiple subtypes that account for a broad range of presentations. The preferential locations of skin lesions have only been described based on clinical experience, and statistical approaches are lacking. The principal component analysis is a dimension reducing test that seeks to describe variability amongst observed, correlated variables through a set of latent, or unobserved, variables called factors.[1] We propose that an analysis of this type will better characterize CLE subtypes in an objective way, particularly with regards to clinical aspects and location of skin lesions.

Methods: We conducted a cross-sectional analysis of patients enrolled in the Cutaneous Lupus Registry at the University of Texas Southwestern Medical Center from November 2008 to July 2018. Components of the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) were scored by one dermatologist (BFC) for 303 patients. We then ran a principal components analysis on these patients using IBM SPSS v. 25.

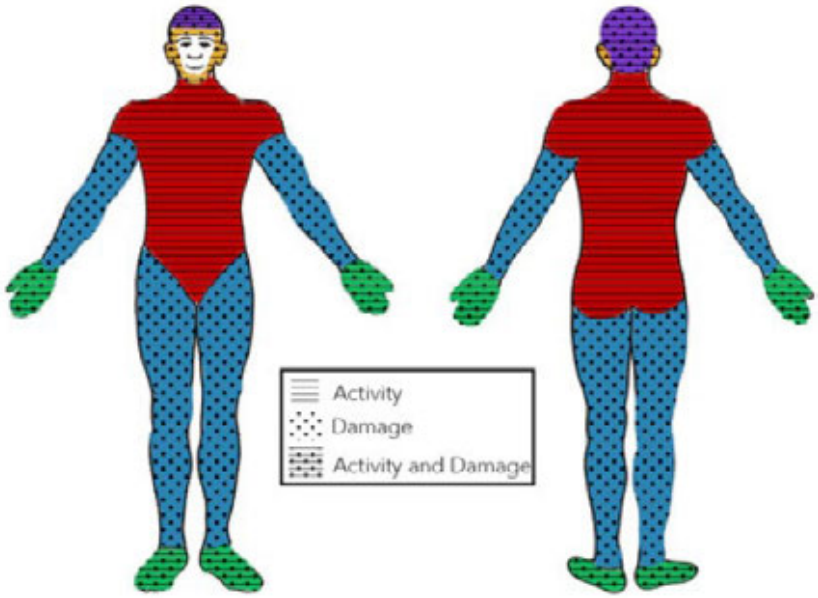

Figure 1. CLE skin lesion patterns identified by PCA. We extracted five factors with significant associations of body sites and clinical features in this cohort of CLE patients. Each color corresponds to the distribution described by each factor - red for factor 1, orange for factor 2, blue for factor 3, green for factor 4 and purple for factor 5. The overlying patterns represent the CLASI components that loaded highly for that factor – stripes for activity, dots for damage, and stripes and dots for both. Of note, factor 1 also had involvement of arms and factor 3 had involvement of chest, back and buttocks, which are not depicted here.

Results: Our results showed that around half of the variance was explained in the first five factors alone (F1 through F5). The factors correlated with well-known subtypes. F1 delineated patients with high CLASI activity scores in the neck, chest, arms and back, and resembled patients with subacute CLE, based on the trunk and arm preference with high activity scores (**Figure 1,** *red***).** F2 described patients with high CLASI damage scores on the scalp, ears and face (**Figure 1,** *orange***).** while F3 characterized patients with damage on the posterior neck, back/buttocks, arms and legs (**Figure 1,** *blue***)**. Because of their predilection for higher damage scores, F2 and F3 resembled localized and generalized discoid lupus, respectively. F4 characterized damage only predominately on acral surfaces, favoring chilblains lupus (**Figure 1,** *green***)**. F5 described patients with activity and damage in the scalp, which could resemble patients with discoid lupus limited to involvement of the scalp (**Figure 1,** *purple***)**.

Conclusion: The principal component analysis helps characterize where on the body lesions of CLE tend to occur, in terms of activity and damage, in certain patient demographics. These results further clinical knowledge about the nature of CLE lesions, and may help guide clinical decisions in the future.

Frequency of Polyautoimmunity in a Tertiary Hospital

Elena Grau García,[1] José Ivorra Cortés,[1] Jorge Juan Fragio Gil,[1] Roxana Gonzalez Mazarío,[1] Marta de la Rubia Navarro,[1] Cristóbal Pavez Perales,[1] Cristina Alcañiz Escandell,[1] Inmaculada Chalmeta Verdejo,[1] Luis González Puig,[1] Isabel Martínez Cordellat,[1] Rosa Negueroles Albuixech,[1] José Eloy Oller Rodríguez,[2] Francisco Miguel Ortiz-Sanjuán,[1] Elvira Vicens Bernabeu,[1] Carmen Nájera Herranz,[1] Inés Cánovas Olmos,[1] Samuel Leal Rodriguez,[1] and José Andrés Román Ivorra[1], [1]Rheumatology Department. HUP La Fe, Valencia, Comunidad Valenciana, Spain, [2]Rheumatology Department. HUP La Fe, v, Comunidad Valenciana, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polyautoimmunity (PAI) is the presence of more than one Autoimmune Disease (AID) in one patient. PAI have been reported in different AIDs as systemic lupus erythematosus (SLE) (33-45%), rheumatoid arthritis (RA) (13-23%), systemic sclerosis (SSc) (10-43%) or Sjögren Syndrome (SS) (32-52%). On the other hand, Multiple Autoimmune Syndrome (MAS) where three or more AIDs coexisting in one patient has been reported.

The aim of the present study is to determine PAI frequency in the context of AIDs reported in a tertiary hospital.

Methods: Cross-sectional observational study with systematic revision of patients' electronic clinical records with AIDs (from 2014 to 2018). We selected those patients who had two or more diagnosis of AIDs. Demographic, clinical and immunological data were collected.

Results: Of 1854 patients with AIDs, 96 (5.17%) had PAI. Mean age was 56±15 years and 93.75% were female. 7 patients from the 96 (0.4%) also had MAS.

The mean age at diagnosis of the first AID was 39.03±15.93 years and mean age at diagnosis of the second AID was 48.16±15.04 years. A mean difference of 9.17±10.18 years between first and second AIDs debut was observed.

RHEUMATIC AUTOINMUNE DISEASES	TOTAL CASES	POLYAUTOIMMUNITY CASES	FREQUENCY (%)
APS	70	23	32.86
SS	154	42	27.27
SLE	261	41	15.71
SSc	88	5	5.68
RA	926	46	4.97
Vasculitis	83	4	4.82
Psa	371	7	1.89

NON RHEUMATIC AUTOINMUNE DISEASES	POLYAUTOIMMUNITY CASES
IBD	12
AHyp	9
CD	7
DM-1	2
AHep	1

The most frequent AIDs registered are shown in table 1.

Antiphospholipid syndrome (APS), Sjögren syndrome (SS), Systemic lupus erythematosus (SLE), Systemic sclerosis (SSc), Rheumatoid arthritis (RA), Psoriasic arthritis (PsA), Inflammatory bowel disease (IBD), Autoimmune hypothyroidism (AHyp), Celiac disease (CD), Diabetes mellitus type 1 (DM-1), Autoimmune hepatitis (AHep).

The most frequent PAI cases registered were RA-SS (N=23), SLE-APS (N=17), SLE-SS (N=11), AR-IBD (N=7), RA-SLE (N=5), RA-CD (N=5), SS-SSc (N=4) and PsA-IBD (N=4).

In the total group of 1854 patients with AIDs, SLE with PAI was present in 41 (2.21%) patients, SS with PAI in 42 (2.26%), RA with PAI in 46 (2.48%) and APS with PAI in 23 (1.2%). Moreover, SS was present in the 4.21% of SLE patients and in the 2.48% of RA patients. In contrast, APS was present in the 6.51% of SLE patients, being de of 7.64 (17.62) years the difference between the onset of the first AID and the second AID.

In the MAS group an AHyp-SLE-APS in 2 patients was observed, as well as 1 patient with SLE-SS-Aps, 1 with SS-RA-APS, 1 with RA-vasculitis-AHyp and 1 with SS-Ahyp-Ahep.

Conclusion: A 5.17% frequency of patients with PAI in our group of AID patients was observed, mostly women. APS, SS and SLE respectively were the diseases that most PAI showed. The most frequent association of AID diseases in PAI cases were RA-SS, APS-SLE and SS-SLE.

We found a rather lower frequency compared with those published in the literature, possibly due to the putative bias of retrospective studies and the geographical differences of PAI patients.

Patient Reported Outcomes and Factors Predicting Clinical Disease Activity in Patients with Immune-Checkpoint Inhibitor Inflammatory Arthritis

Caoilfhionn Connolly,[1] Tawnie Braaten,[1] Ami Shah,[1] Clifton Bingham,[2] and Laura Cappelli[2], [1]Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) enhance anti-tumor immunity by stimulating a patient's immune system to fight cancer. ICIs have demonstrated unprecedented response rates in a wide array of cancers, but have a unique side effect profile known as immune-related adverse events (irAEs) that can result in significant morbidity and mortality. Inflammatory arthritis (IA) is one of the most commonly encountered rheumatic irAEs and can persist after ICI cessation. Early recognition and appropriate treatment is critical to avoid erosive joint damage. Clinical Disease Activity Index (CDAI) is a commonly used scale for disease severity and guides therapeutic strategy in rheumatoid arthritis, which can also be utilized in ICI-induced IA to inform clinical approach. Additionally, other patient-reported outcome measures (PROs) are used to evaluate pain, physical function, and quality of life in rheumatic diseases. In this study, we evaluate PROs and disease activity to establish the impact of ICI-induced IA. We also evaluate the factors correlating with CDAI, so that management can be optimized to facilitate the goal of achieving remission.

Variable	Median (IQR)
Age	59 (IQR 52-69)
Patient Global Assessment (0-100)	35 (15-50)
Patient Fatigue (0-100)	40 (10-60)
Patient Pain (0-100)	50 (20-76)
Patient Stiffness (0-100)	53 (40-75)
mHAQ (0-3)	0.31 (0-0.72)
Physician Global Assessment (0-100)	24.5 (12.5-33.8)
Tender Joints (0-28)	2 (0.25-3.8)
Swollen Joints (0-28)	6 (2.3-10.5)
CDAI	14.2 (7.4-21.5) Remission: n =0 (0%) Low: n=21 (35%) Moderate: n= 26 (43.3%) High: n=13 (21.7%)

Oncologic diagnosis	Melanoma: 20 (33.3%) Non-SCLC: 11(18.3%). (Other tumor types included pancreatic cancer, basal cell carcinoma, endometrial cancer and renal cell carcinoma)
Cancer stage	Stage III: 14 (13.0%) Stage IV: 46 (86.8%)
ICI therapy	Anti-PD1 monotherapy: 39 (65%) Anti-CTLA4/PD1 combination: 15 (25%) Anti-CTLA4 monotherapy: 3 (5%) Anti-PDL1 monotherapy: 3 (5%)
Number of irAE	Median: 1 (IQR 1-3) • 1 irAE: 34 (56.7%) • >1 irAE: 26 patients (43.3%)

Methods: Patients evaluated at an academic Rheumatology clinic with confirmed ICI-induced IA who were enrolled in our prospective cohort study of rheumatic irAEs were included. Patient and physician data from questionnaires at the baseline visit were analyzed to obtain median and interquartile range (IQR) values. CDAI and Modified Health Assessment Questionnaire (mHAQ) scores were calculated. Univariate analysis was completed to assess factors that impacted CDAI score. Multivariate linear regression analysis was performed with variables that were significant in univariate analysis to identify the factors that yielded the greatest impact upon CDAI.

Results: Sixty patients were included in the analysis. 33 patients (55%) were female. Clinical characteristics and PROs are summarized in Table 1.

Oncologic history, immunotherapy regimen, and irAE are detailed in Table 2.

Univariate analysis revealed a significant relationship between CDAI and patient stiffness (p 0.001), patient fatigue (p 0.019), mHAQ score (p 0.03) and patient pain (p 0.0001), while age (p 0.212), cancer stage (p 0.9), number of irAEs (p 0.575) were not significant. In multivariate analysis, pain exerted a significant influence on CDAI (0.001).

Conclusion: Patients with ICI-induced IA have high levels of disease activity and experience significant impairment. The majority of patients have moderate or high disease activity. This is significant given the increasing incidence and prevalence of this disease entity. Furthermore, patient-reported pain, fatigue, and stiffness correlated with CDAI in these patients. Physicians should recognize and address these primary symptoms in order to optimize management. Assessment of a wider range of PROs may provide additional insight into the factors that could be modified to maximize health-related quality of life, enhance physical function, and reduce disease activity.

NSCLC:non-small cell carcinoma; anti-PD1: anti-programmed cell death protein-1; anti-PDL1: anti-programmed cell death ligand-1; anti-CTLA4: anti- cytotoxic T-lymphocyte-associated protein-4

Safety of Immune Checkpoint Inhibitors in Patients Treated for Cancer with Pre-existing Autoimmune Diseases

Aneet Kaur,[1] Umang Swami,[1] Munazza Fatima,[1] Meredith Ginn,[1] Jill Stein,[1] Yubo Gao,[1] Yousef Zakharia,[1] and **Namrata Singh**[2], [1]University of Iowa Hospitals and clinics, Iowa city, IA, [2]University of Iowa, Iowa City

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with pre-existing autoimmune diseases (AID) have been traditionally excluded from clinical trials of immune checkpoint inhibitors (ICI), so the data on risk of flare of pre-existing AID with ICI therapy is very limited. As we encounter more patients in clinical practice with pre-existing AID who have been treated with ICI therapy, there is a growing need for understanding the management of autoimmune complications from ICI therapies. The aim of our study was to investigate the safety of immune checkpoint inhibitors in patients who have pre-existing AID.

Methods: After approval from the University of Iowa Hospitals and Clinics (UIHC) IRB, we performed a retrospective chart review of all the patients with pre-existing AID who received any kind of ICI therapy at UIHC through September 1st, 2018. Data collection included- the nature of the pre-existing AID, treatments previously given or currently being given for the AID, type of ICI therapy given, course and duration of ICI therapy, effects of ICI therapy on the AID, timeline of development of flares of pre-existing AID (if applicable), grade and severity of any new immune related adverse events (irAE's) seen, progression free survival, overall survival and vital status at the time of last documentation available in the chart. Predictors of developing a flare were determined using logistic regression.

Results: A total of 42 patients with pre-existing AID were identified who received ICI therapy. Out of these, 25 patients had metastatic melanoma, 11 patients had lung cancer, four patients had genitourinary cancer, one patient had diffuse large B cell lymphoma and one patient had head and neck cancer. Twelve patients had flares of their pre-existing AID including three patients with rheumatoid arthritis (RA), two patients with psoriatic arthritis, two patients with polymyalgia rheumatica (PMR), and one patient each with skin psoriasis, Crohn's disease, bullous pemphigoid, inflammatory arthritis and myasthenia gravis. All of the flares were treated with oral or topical corticosteroids. In addition, one patient with RA flare was treated with tofacitinib and one Crohn's flare was treated with infliximab. Female sex, older age and non-smoker status were predictors of flare although these were not statistically significant **(Table 1)**. Five patients developed new irAE's, which were managed with corticosteroids as well. ICI therapy was stopped in four patients due to AID flare but continued in the rest. The median progression-free survival (PFS) in melanoma and lung cancer cohort was 943 and 158 days and median overall survival (OS) was undefined and 361 days respectively.

Table 1: Predictors of flare of pre-existing AID

Variable	Odds Ratio	95% Confidence intervals
Sex (F vs M)	1.394	0.33-5.83
Smoking status (Non vs ever smoker)	1.765	0.314-9.93
Age at start of ICI therapy (70.7 vs 66.9)	1.018	0.964-1.08

Conclusion: In patients with pre-existing AID treated with an ICI therapy, flare of AID happened in a small proportion of patients (28%). Even among those who flared, they were managed safely with corticosteroids alone or with additional disease modifying therapies. Immunotherapy could be safely continued in majority of the patients with close monitoring and multidisciplinary collaboration.

Ocular Scleral Pathology and Relationship with Autoimmune Diseases: Study of 101 Patients from a Single Universitary Centre

Lara Sanchez-Bilbao,[1] Iñigo Gonzalez-Mazon,[2] Mónica Calderón-Goercke,[3] Diana Prieto-Pena,[2] Jose Luis Martín-Varillas,[1] Belén Atienza-Mateo,[1] Rosalia Demetrio,[4] Miguel A Gonzalez-Gay,[1] and Ricardo Blanco[1], [1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [3]Hospital Marqués de Valdecilla, Santander, Cantabria, Spain, [4]Hospital Universitario Marqués de Valdecilla, Santander, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ocular scleral pathology may be associated with autoimmune diseases. Our aim was to assess **a)** the epidemiological and clinical features and **b)** the relationship with immune-related diseases.

Methods: Observational study of unselected consecutive patients studied in a single reference University Hospital during the last ten years with**: a)** diagnosis of episcleritis and **b)** diagnosis of scleritis (Watson and Hayreh classification system, P. G. Watson, S. S. Hayreh, Br J Ophthalmol. 1976 Mar; 60(3): 163–191).

Patients were studied in a reference multidisciplinary unit (rheumatologist and ophthalmologist). Demographics features, clinical findings, complementary tests and treatment were recorded.

Results: We studied 101 (65 women/38 men) patients /202 eyes with diagnosis of scleral pathology (episcleritis=75; scleritis =26); mean age at diagnosis, 49.0±14.17 years. The mean follow-up was 3.68±5.30 years.Demographic baseline characteristics and clinical manifestations of these patients are shown in **TABLE 1.**

Diffuse anterior scleritis (n=17; 16.8%) was the most common type of scleritis, followed by nodular. In case of episcleritis, the most common was simple-form (n = 71; 70.3%).

Etiology was as follows: idiopathic (n=59, 58.4%), associated to systemic disease (SD-group) (n=32, 31.7%), and infectious (n=10, 9.9%). In SD-group, the main association was with Crohn's disease (n=8; 7.9%), rheumatoid arthritis (n=6; 5.9%) and psoriatic arthritis (n=4; 3.9%).

Laboratory tests were also performed in all patients, mainly as screening of systemic diseases. Antinuclear antibodies (ANA) and rheumatoid factor (RF) were positive in 9 patients, followed by HLA-B27 7; 6.9%).

	Patients diagnosed with episcleritis/scleritis (n=10)
DEMOGRAPHIC PARAMETERS

- Left eye limited, n (%)	36.0 (35.6)
- Right eye limited, n (%)	49.0 (48.5)
- Both, n (%)	16.0 (15.8)
Persistence / Recurrence	
- Persistent, n (%)	16.0 (15.8)
- Recurrent, n (%)	41.0 (40.6)
Complications, n (%)	**19.0 (18.8)**
- Keratitis, n (%)	6.0 (5.9)
- Uveitis, n (%)	5.0 (4.9)
- IOP, n (%)	5.0 (4.9)
- Cataract, n (%)	3.0 (2.9)
- Cystoid macular edema, n (%)	0.0 (0.0)
- Optic disc swelling, n (%)	0.0 (0.0)

Attending to the treatment, 100% of patients received topical treatment as first-line therapy and 81.2% (n=81) NSAIDs. Another conventional immunosuppressor and biological treatment were required in 27.7% (n=28) and 6.9 (n=7) respectively. The main indication for biological therapy was the presence of concomitant systemic disease.

Some complications were reported, being keratitis (n=6; 5.9%) the most common.

Conclusion: The results obtained are reproducible to those published in international series, except a more frequent of Crohn's disease and a less frequent of vasculitides. Scleral pathology is a frequent entity and it is necessary to exclude underlying systemic pathology.

Role of Insulin Resistance and Inflammation on Resting Energy Expenditure in Patients with Rheumatoid Arthritis

Beatriz Hanaoka,[1] and Barbara Gower[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with rheumatoid arthritis(RA), elevated resting energy expenditure(REE) is associated with rheumatoid cachexia and protein catabolism driven by pro-inflammatory cytokines. IR is also associated with elevated REE in adults without RA, independent of inflammation. Given the high prevalence of IR in RA, our goal was to investigate the association between IR and REE in patients with RA.

Methods: 35 individuals meeting the 2010ACR/EULAR criteria for RA and 17 non-RA controls comparable in age, sex and race were selected. Body composition was determined by dual energy x-ray absorptiometry (DEXA). REE was measured using indirect calorimetry. Insulin sensitivity was measured using the Matsuda index. Linear regression model was used to study the relationship among REE, insulin sensitivity and CRP, as well as an interaction between IS and CRP. Statistical significance is defined by a p-value < 0.05.

Results: RA and non-RA controls had comparable body mass index, total fat free mass index, CRP and REE levels. Insulin sensitivity was lower in the RA group (median=2.9, IQR=5.4) compared to the non-RA group (median=5.9, IQR=4.1). The median DAS28-CRP among individuals with RA was 1.8 (IQR=1.7). Among individuals with RA, we found a statistically significant relationship between REE and CRP levels [R^2= 41.0 %, adjusted R^2=33.9%, estimate coefficient (SE)= 46.7 (13.7), p=0.0022], while insulin sensitivity was not significantly associated with REE after adjusting for CRP level [estimate (SE)=-57.4 (43.3), p=0.256]. Among individuals with RA, there was also no significant interaction between IR and CRP [estimate (SE)=-40.0976(22.746), p=0.146]. In the non-RA control group, neither insulin sensitivity nor CRP level were significantly associated with REE.

Conclusion: CRP was significantly and independently associated with REE among RA individuals, but not non-RA controls. IS was not independently related to REE in either group. These results suggest that, in RA, inflammation may be a common antecedent leading to both elevated REE and insulin resistance.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) occurs in approximately 15% of patients with autoimmune diseases (AD) [1]. Its presence is associated with an increased risk of morbidity and mortality [2]. In the present study, we aimed to determine the frequency of ILD associated with AD (AD-ILD) among patients sent for assessment to a clinic of lung transplantation from a referral center. The different types of AD-ILD were described.

Methods: Clinical records of patients seen at the ILD clinic of Hospital Universitario Marqués de Valdecilla, Santander, Spain between May 2016 and May 2019 were reviewed. A diagnosis of ILD was made by the pneumologists based on clinical and radiological findings and pulmonary function test abnormalities. A definitive histological confirmation by transbronchial biopsy, surgical lung biopsy or cryobiopsy was performed according to the pneumologist consideration. All patients with ILD seen at the clinic were also assessed by an experienced rheumatologist to exclude the presence of an underlying AD.

Results: During the period of assessment, 384 patients were diagnosed with ILD in this referral clinic (**Table**). The diagnosis of ILD was histologically confirmed in 208 (54.2%) patients. Among the 384 ILD patients, 129 were diagnosed as having idiopathic pulmonary fibrosis (33.6%). Other frequent conditions unrelated to AD were chronic hypersensitivity pneumonitis (n= 40; 10.4%), non-classifiable interstitial pneumonia (n= 44; 11.5%) and non-specific interstitial pneumonia (n=20; 5.2%). Ninety-one (23.7%) of the ILD patients fulfilled definitions for AD. Most cases with AD-ILD were due to rheumatoid arthritis (n= 25/91; 27.5%); systemic sclerosis (n=24/91; 26.4%), antisynthetase syndrome (n= 16/91; 17.6%) and Sjogren's syndrome (n= 6/91; 6.6%). Interestingly, 15 of 91 patients with AD-ILD (16.5%) were diagnosed as having an interstitial pneumonia with autoimmune features. Other AD associated with ILD are shown in **Table**. The predominant radiological pattern in patients with rheumatoid arthritis was usual interstitial pneumonia. In contrast, a predominant non-specific interstitial pneumonia pattern was found in the remaining patients with AD.

Conclusion: Almost a quarter of patients with ILD seen at a referral clinic center have an underlying AD. Close assessment of patients with ILD by rheumatologists is of main importance to identify AD in patients with ILD.

Table. Characteristics of 384 patients with ILD unrelated and associated with AD included in this study.

					Pulmonary function tests			
	Women, n (%)	Age at study[1]	Age at diagnosis[1]	Smoking, n (%)	FVC, %[2]	FEV1, %[2]	FEV1/FVC, %[2]	DLCO, %[2]

Abstract Number: 2156

Expanding the Phenotypic and Genotypic Spectrum in Yao Syndrome

Qingping Yao,[1] and Apostolos Kontzias[1], [1]Stony Brook University, Stony Brook, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Yao syndrome (YAOS, OMIM 617321), formerly termed nucleotide-binding, oligomerization domain 2(*NOD2)*-associated autoinflammatory disease, has become increasingly recognized. The disease has been reported in America, Europe and Asia, and seems not uncommon. This study aimed to report novel phenotypic and genotypic findings in the disease.

Methods: This is a retrospective review of electronic medical records (EMRs) of 11 patients with YAOS, and the study was approved by the Stony Brook University (SBU) Institutional Research Board. These patients after an extensive workup without a unified diagnosis were referred to our Center of Autoinflammatory Disease at SBU, and followed up, and the charts were well documented by the lead author who has a vested interest in the disease. All

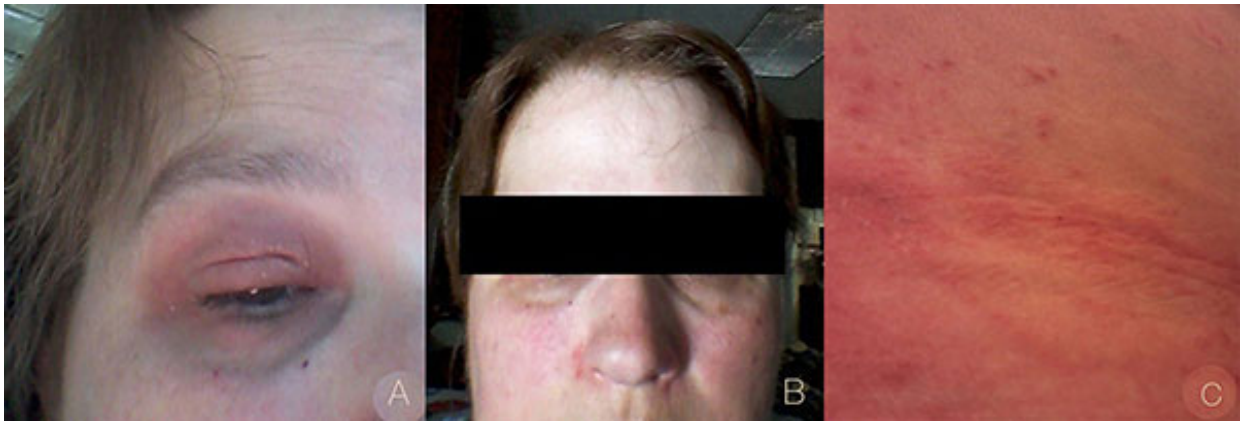

Table 1. Baseline Demographics, Clinical and Laboratory Characteristics of YAOS Patients

Eyelid swelling with discoloration and patchy erythema and plagues on the face and abdominal wall.

these patients underwent genetic testing for periodic fever syndrome 6-gene panel (MEFV, TNFRSF1A, NLRP3, MVK, NLRP12 and NOD2) or targeted gene sequencing for NOD2. These patients were included in the study because they fulfilled the diagnostic criteria for YAOS and had either eyelid swelling as corroborated by i-phone photographs and/or NOD2 variants that were not identified previously for the disease. Continuous variables were expressed as median, interquartile range, and frequency for descriptive statistics.

Results: All YAOS patients (10 females, 1 male) were Caucasians with the mean age of 25.9 at disease onset. They shared such known common phenotype for YAOS as fever, rash, arthritis/arthralgia, gastrointestinal, and sicca-like symptoms (Table 1). Three patients had a family history of the similar symptoms. Of note, 7 of the 11 patients developed unilateral or bilateral eyelid swelling with or without discoloration or eye redness (Figure 1). The symptom recurred and concurred with other clinical manifestations during disease flares and each episode lasted several hours to a few days with resolution. Six of the 7 patients carry the common NOD2 variants associated with YAOS. Of the 11 patients, 5 patients had clinical characteristics of YAOS and carry the rare NOD2 variants. These data support eyelid swelling as a new clinical feature of YAOS, and the spectrum of NOD2 variants associated with YAOS is extended.

Conclusion: This study indicates that the eyelid swelling and rare NOD2 variants are added clinical and genetic characteristics of YAOS. Recognition of the expanded disease spectrum will foster prompt diagnosis and management of the disease.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies suggest that steroid dose[1]and rheumatoid factor positivity[2] impact cancer survival in checkpoint inhibitor (CI)-treated patients (with CI-associated hypophysitis, and in all-comers with non-small cell lung cancer patients respectively). In this study we describe CI-associated arthritis phenotypes in patients enrolled in a CI registry, and measure the impact of phenotype, steroid dose, and serologic status on survival.

Methods: Patients referred to rheumatology at Hospital for Special Surgery (HSS) for CI-associated immune-related adverse events were enrolled in our registry. Demographics, cancer types, treatment and outcomes, musculoskeletal findings, labs and serologies were collected prospectively. We defined four categories of arthritis: (1) "small joint" swelling ± large joint involvement, (2) exclusively "large joint" swelling, (3) joint pain without joint swelling ("arthralgia"), and (4) polymyalgia rheumatica ("PMR"). For this analysis, we excluded patients with non-articular conditions, crystal disease, or mechanical disorders. Distribution of continuous variables was assessed using the Shapiro-Wilk test and summarized as median [IQR]; categorical variables are summarized as frequencies. Progression-free survival (PFS), measured from CI initiation until documented radiographic progression, is presented in Kaplan-Meier curves compared by 2-sided log rank test. Hazard ratios were estimated using Cox proportional hazards regression analysis.

Results: Of 50 registry patients enrolled between 5/1/18-4/1/19, 37 had articular complaints. Median [IQR] age was 67 [59,77], 22 (59%) were female, 17 (49%) had a smoking history, 14 (38%) had metastatic melanoma and 25 (68%) received anti-PD-1/PD-L1 monotherapy (**Table 1**). Median time to symptom onset was 2.8 [0.9,12] months after CI initiation. 22 (59%) had small joint involvement, 5 (14%) large joint, 8 (22%) arthralgia and 2 (5%) PMR. 9 (24%) had concomitant enthesitis/tenosynovitis and 11 (31%) were RFand/or CCP positive. The large joint phenotype was notable for prevalent combination CI (80%) and tenosynovitis (60%), high ESR of 90 [28,99], and no RF/CCP positivity. Overall, 17 (46%) patients required > 20mg prednisone, and 6 (16%) required a biologic DMARD (**Figure 1**). Overall median PFS was 100 [64,151] weeks, and did not differ between melanoma vs. non-melanoma, patients treated with >20mg vs. ≤20mg prednisone, RF/CCP pos vs. neg, or small joint vs. other phenotypes (**Figure 2**).

Conclusion: In our cohort, neither steroid dose nor seropositivity were associated with progression-free survival in CI-treated patients with symptomatic musculoskeletal syndromes. However, our findings are limited by the small size and heterogeneity of our cohort.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have revolutionized cancer therapy by harnessing the immune system to fight cancer. They are associated with the development of autoimmune toxicities, referred to as immune-related adverse events (irAE). Rheumatic irAE (Rh-irAE), particularly arthralgias and arthritis are common and optimal management remains unknown. The Canadian Research Group of Rheumatology in Immuno-Oncology (CanRIO) is an emerging network of Canadian rheumatologists with an interest in Rh-irAE secondary to ICI.

Methods: Patients presenting with rheumatic symptoms associated with ICI therapy between 2013 and January 2019 at participating CanRIO sites were identified. Cases were stratified based on the presence or absence of pre-existing autoimmune disease (PAD). Standardized data were extracted by chart review. The data were pooled and analyzed descriptively.

Results: A total of 118 patients without PAD who developed 140 Rh-irAE were identified, 59% were male with a mean age of 62 years. The most common indications for ICI were melanoma (n=57, 48.3%), lung (n=30, 25.4%), and genitourinary (n=19, 16.1%) with stage 4 disease seen in 79%. ICI included nivolumab (n=30, 25.6%), pembrolizumab(n=38, 32.5%), ipilimumab (n=1, 0.9%), durvalumab (n=3, 2.6%), atezolizumab (n=4, 3.4%) or combination therapy (n=29, 24.8%). Common Rh-irAE included symmetric polyarthritis (n=45, 32%), arthralgias/myalgias or acute flare of

Characteristic, n (%)	Patients without PAD (n=118)	Patients with PAD (n=20)
Age, mean (SD)	62.3 (13.9)	63.9 (9.2)
Female	48 (40.7)	10 (50.0)
White	105 (89.0)	18 (90.0)
Tumor Type		
Melanoma	57 (48.3)	8 (40.0)

Time to first Rh-irAE, mean (SD) (months)	6.8 (8.6)	1.8 (1.9)
ICI therapy stopped	62 (52)	7 (35)
Investigations at diagnosis (%)		
ANA positive	13 (11.0)	NA
RF positive	7 (5.9)	NA
Anti-CCP positive	3 (2.5)	NA
X-ray abnormalities	30 (25.0)	2 (33.3)

PAD = pre-existing autoimmune disease; CTCA = common terminology criteria for adverse events; SD = standard deviation; ICI = immune checkpoint inhibitors; ANA = anti-nuclear antibody; RF = rheumatoid factor; anti-CCP = anti-cyclic citrullinated peptide

Table 2. Rh-irAE and selected Investigations

osteoarthritis (n=20, 16.9%), polymyalgia rheumatica-like presentation (n=17, 12%), tenosynovitis/enthesitis (n=17, 12%), sicca (n=11, 9.3%) and myositis (n=9, 7.6%).

The majority of cases experienced at least one other non-rheumatic irAE (O-irAE) (n=63, 53%). Mean time from first ICI exposure to onset of Rh-irAE was 6.8 months. ICI was either held or discontinued in 65% (n=77). Despite this, (n=81, 68.6%) had favorable tumor response, while (n=14, 12%) had tumor progression. There were no deaths related to Rh-irAE.

Characteristic	Patients with PAD (n=20)
Autoimmune disease	
Rheumatoid arthritis	8 (40.0)
Systemic lupus erythematosus	2 (10.0)
Spondylitis	2 (10.0)
Psoriasis/Psoriatic arthritis	6 (30.0)
Inflammatory bowel disease	3 (15.0)
Other connective tissue disease	1 (5.0)
Vasculitis	0 (0)
Other	3 (15.0)
PAD Response to ICI	
Unchanged	9 (45.0)
Mild Flare	7 (35.0)
Major Flare	3 (15.0)
Treatment of PAD Flare	
Responded to low dose prednisone	1 (10.0)
Responded to increasing DMARD	1 (10.0)
Required high dose Prednisone	2 (20.0)
Required change in DMARD	5 (50.0)
New Rh-irAE events	4
New O-irAE events	7

PAD = pre-existing autoimmune disease; ICI = immune checkpoint inhibitors; DMARD = disease-modifying antirheumatic drug; Rh-irAE = Rheumatic immune-related adverse events; O-irAE = other immune-related adverse events

Table 3. Effects of ICI on pre-existing autoimmune disease

The majority of patients without PAD had either a partial or complete response to either mono- or combination therapy with oral prednisone (n=77; maximum dose 60 mg/d), non-steroidal anti-inflammatories (NSAID; n=52), intra-articular corticosteroids (n=29), hydroxychloroquine (n=26), methotrexate (n=17), or tumor necrosis factor alpha inhibitors (n=9).

Twenty patients with pre-existing autoimmune diseases were identified 70% of whom were in remission prior to starting ICI. 50% (n=10) had flares, 15% (n=3) developed a new Rh-IrAE and 20% (n=4) developed O-irAE.

Conclusion: This is the largest multi-centered cohort of Rh-irAE described to date. Seronegative inflammatory polyarthritis was the most common Rh-IrAE although a broad range of conditions were identified. The most common first-line treatment was systemic corticosteroids followed by NSAID and intra-articular steroid injections. Prednisone was effective, however high doses were required. Disease-modifying antirheumatic drugs (DMARD) and biologic therapy were well tolerated and effective, with hydroxychloroquine being the most commonly used DMARD. Despite moderate to high doses of immunosuppression, the majority of patients had favorable tumor responses.

Abstract Number: 2159

Pachymeningitis in Rheumatic Disease

Rachel Kneeland,[1] John Berry,[2] Sydney Brandwein,[2] and Monika Starosta[2], [1]Department of Internal Medicine, Advocate Lutheran General Hospital, Park Ridge, IL, [2]Advocate Lutheran General Hospital, Park Ridge, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Miscellanous Rheumatic & Inflammatory Disease Poster III: Autoimmune Conditions and Therapies
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pachymeningitis is a rare complication of rheumatic disease. Patients present with hearing loss or other neurologic complications. Diagnosis is made by thickening of dura or leptomeninges on MRI-imaging or histopathologically with biopsy of the dura. The prevalence pachymeningitis in rheumatic disease is unknown, and there is no standard of care.

Methods: We retrospectively identified nine patients diagnosed with pachymeningitis based on clinical symptoms, MRI findings, and in three cases, dural biopsy. We assessed the rheumatologic diagnoses, presenting symptoms, treatment modalities, and outcomes.

Results: There were two males and seven females, with a mean age of 63 for males and 60 for females. Five patients had rheumatoid arthritis, two had sarcoidosis, one had undifferentiated connective tissue disease and Sjogren's syndrome, and one had blastomycosis who developed rheumatoid arthritis one year later. The presenting symptoms were hearing loss (three), unilateral weakness (two), unilateral numbness (two), seizure (two). Additional symptoms included headache, confusion, memory loss, tinnitus, scleritis, optic neuritis, unilateral hemineglect, foot flaccidity, and gait disturbance. Diagnosis was confirmed in three patients with dural biopsy. MRI images were obtained on all patients. Six patients were treated solely with prednisone or pulse-dose methylprednisolone. Two patients were treated with anti-TNF agents and one patient with rituximab. Pre- and post-treatment MRI demonstrated resolution of leptomeningeal abnormality in two patients. Six out of nine patients reported resolution of symptoms with treatment. Three had persistent deficits, including hearing loss, visual impairment, and slight residual hemiplegia.

Conclusion: Rheumatoid arthritis was the most common rheumatological diagnosis, and hearing loss was the most common presenting symptom. Most patients had resolution of symptoms with prednisone, pulse methylprednisolone, anti-TNF agents, or rituximab. We hope this case series will assist clinicians with the diagnosis and management of pachymeningitis.

Age	Sex	Dx	Presenting Symptoms	Treatment and Outcomes
68	M	RA	R-sided hearing loss Synovitis, Scleritis	HD Prednisone Partial improvement in hearing loss
56	M	SD	R foot flaccidity	HD Prednisone Resolution of symptoms
51	F	RA	Optic neuritis L sided hearing loss	PD methylprednisolone Mild improvement but persistent visual loss
65	F	RA	Unilateral L hemiparesthesias and weakness	PD methylprednisolone Prednisone taper Leflunomide Rituximab Improvement in symptoms
51	F	RA	Headache, Tinnitus, R sided hearing loss	HD Prednisone Improvement in symptoms, chronic R hearing loss
67	F	BM UC	Focal seizure L sided numbness	Voriconazole Dx with RA one year after treatment
63	F	UCTD CREST SJ	Gait disturbance Memory loss	
47	F	SD	Ptosis	PD methylprednisolone Prednisone taper Remicaide Resolution of symptoms
76	F	RA	Acute Confusion, seizure, L hemiplegia, L sensory loss, L hemineglect	HD Prednisone Remicaide Slight residual hemiplegia

Table 1. Age, sex, rheumatologic diagnosis (Dx), presenting symptoms, outcomes and treatments of nine patients identified to have pachymeningitis based on clinical symptoms, magnetic resonance imaging (MRI) findings, and in three instances, dural biopsy. Rheumatologic diagnoses include rheumatoid arthritis (RA), Sarcoidosis (SD), Undifferentiated Connective Tissue Disease (UCTD), Limited cutaneous Systemic Sclerosis (CREST), Sjogren's Disease (SJ), Blastomycosis (BM), Ulcerative Colitis (UC). Lateralization of deficits abbreviated by L (Left) and R (Right). Treatment of patients was typically with high dose (HD) prednisone defined as 50 to 60 mg daily, pulse dose (PD) methylprednisolone of 500 mg to 1000 mg daily for three to five days.

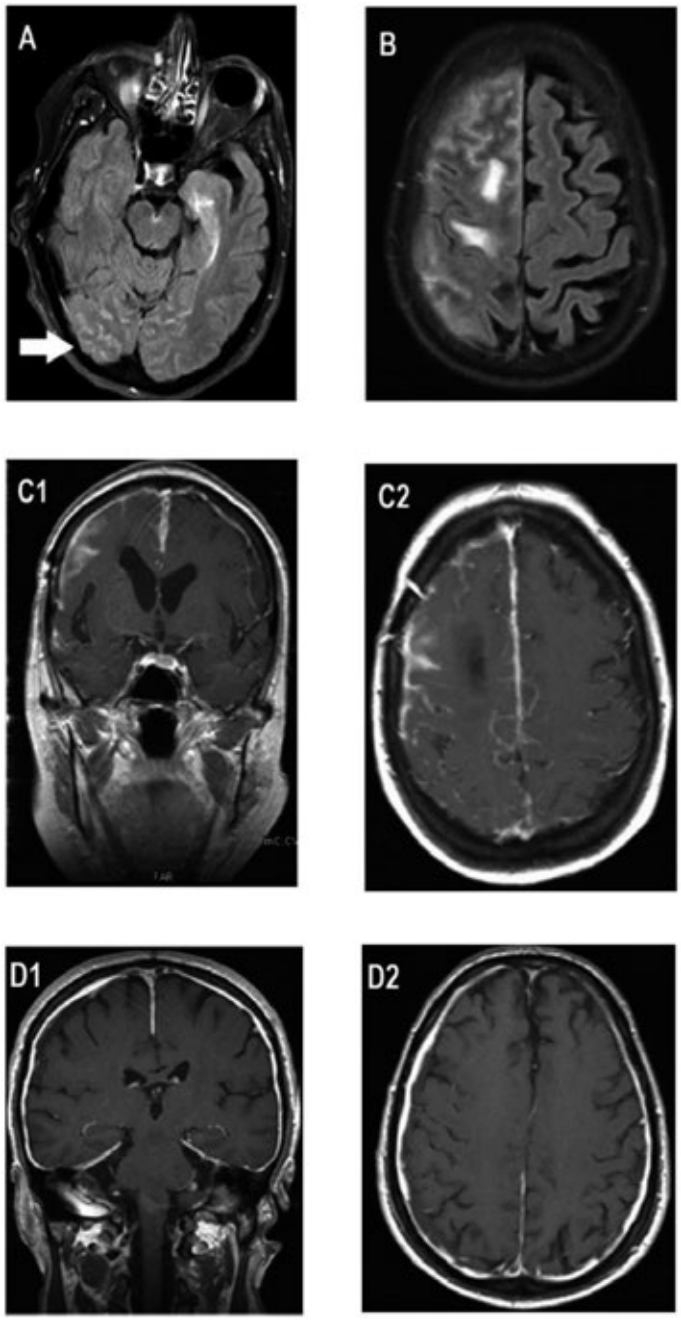

Figure 1. Magnetic resonance imaging (MRI) of the brain from individuals with pachymeningitis. (A) pachymeningitis with leptomeningeal enhancement overlying the occipital lobe (arrow) in a patient with RA presenting with optic neuritis; (B) Unilateral dural and leptomeningeal thickening and enhancement over superior R frontal lobe convexity and sulci extending into interhemispheric fissure in R medial frontal lobe in a patient with blastomycosis who developed focal seizure and L sided numbness who ultimately developed RA one year later; (C1, C2) Coronal and transverse plane images (respectively) demonstrating R cerebral dural, leptomeningeal enhancement seen in patient with RA presenting with acute confusion and L hemiparesis, L sided sensory loss, and L hemineglect; (D1, D2) Coronal and transverse plane images (respectively) demonstrating diffuse bilateral meningeal enhancement after gadolinium in a patient with RA presenting with R unilateral hearing loss, scleritis, and synovitis.

Myopenia Is an Independent Risk Factor for Rotator Cuff Tear and Shoulder Dysfunction in Elderly People : Data from NAMGARAM Cohort

Yun-Hong Cheon,[1] Young Sun Suh,[2] Mingyo Kim,[1] Ki-Soo Park,[3] and Sang-Il Lee[1], [1]Divison of Rheumatology, Gyeongsang National University Hospital, Jin-Ju, Republic of Korea, [2]Divison of Rheumatology, Gyeongsang National University Hospital, Changwon, Changwon, Republic of Korea, [3]Preventive Medicine, Gyeongsang National University Hospital, Jin-Ju, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Myopenia refers to decline in muscle mass with age, causing significant impairment in the ability to carry out normal daily functions. Rotator cuff tear (RCT) is a localized tendon disease, however, it is known to be related with systemic inflammation. The aim of this study is to determine whether there is correlation between myopenia and RCT in elderly people. In addition, we investigate the relationship between myopenia and severity of shoulder dysfunction.

Methods: Using data from NAMGARAM cohort which consisted of a group of people living in three rural communities in Korea, 510 participants who were ≥ 60 years and who underwent bioimpedance analysis, magnetic resonance imaging of shoulder, and completed shoulder function questionnaire such as Korean shoulder score (KSS), Constant Shoulder Score (CSS) were enrolled. Myopenia was defined according to the criteria set by the Asia Working Group for Sarcopenia (7.0 kg/m2 in men and 5.7 kg/m2 in women). RCT was diagnosed by MRI

Results: The prevalence of RCT was 62.5 % (n = 319). Multivariate logistic regression analysis showed myopenia (OR 1.77, 95% CI 1.12-2.8), hand osteoarthritis (OR 1.96, 95% CI 1.25 - 3.07), and waist circumference (OR 1.05, 95% CI 1.01 - 1.1) were related with RCT after adjustment for age, education level, solitude, body mass index, grip strength, dyslipidemia, hand osteoarthritis, and waist circumference, and myopenia. Subgroup analysis among patients with RCT (n = 319), patients with myopenia showed more severe shoulder dysfunction (KSS, 83.73 ±16.44; CSS, 78.22 ± 14.30) than those of patients without myopenia (KSS, 87.88 ± 11.60; CSS, 81.25 ± 11.00, $P < 0.001$). These results remained after multivariate analysis.

Conclusion: Myopenia is an independent risk factor of RCT and it is related to severe shoulder dysfunction. Keeping skeletal muscle mass is important to maintain shoulder function.

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Over 7 million Americans are estimated to suffer from inflammatory rheumatologic diseases and the rate of joint arthroplasties are nearly 50 % higher among this population as compared to controls. Many of these patients are on glucocorticoids around the time of their joint surgeries. The optimum perioperative management of glucocorticoid dosing is not known and there is no established clinical practice. The most recent recommendation by American College of Rheumatology/ American Association of Hip and Knee Surgeons to continue home steroid dose rather than administer supraphysiologic stress dose for patients undergoing elective arthroplasties was based on a low level of evidence. The aim of our study was to compare the rates of peri- and postoperative outcomes after elective joint arthroplasties with continuing home glucocorticoid dosing versus administering stress dose steroid.

Methods: The study is a retrospective case-control study done at the Reading Hospital. Hospital records were used to select patients who were had elective joint arthroplasties (in 5 years period from February 2013- July 2018) and concomitant rheumatologic diseases on chronic steroids. The patients with rheumatologic diseases that received stress dose steroid in the perioperative period (cases) and did not receive stress dose steroid (control) were identified. Patient-specific demographic and clinical data and information on perioperative and postoperative outcomes were extracted.

	Overall (n=78)	Stress dose steroids (n= 38, 48.72%)	No stress dose steroids (n=40, 51.28%)	P value
Baseline demographic characteristics				
Age, Years- Mean (SD)	71.73 (10.56)	70.16 (12.18)	73.23 (8.65)	0.20
Sex, Female- n (%)	64 (82.05)	32 (84.21)	32 (80)	0.63
Race				
Caucasian- n (%)	73 (93.59)	36 (94.74)	37 (92.50)	0.32
African American- n (%)	2 (2.56)	0	2 (5)	
Hispanic- n (%)	3 (3.85)	2 (5.26)	1 (2.5)	
Baseline clinical characteristics				
BMI, kg/m^2- Mean (SD)	30.94 (7.18)	32.30 (7.06)	29.65 (7.16)	0.10
Current smoking- n (%)	11 (14.10)	4 (10.53)	7 (17.5)	0.38
Depression- n (%)	24 (30.77)	12 (31.58)	12 (30)	0.88
Hypertension- n (%)	47 (60.26)	22 (57.89)	25 (62.5)	0.68
HbA1c, % - Mean (SD)	6.58 (1.01)	6.45 (1.02)	6.69 (1.02)	0.49
Age adjusted CCI- Mean (SD)	5.04 (2.21)	4.61 (1.88)	5.45 (2.43)	0.09
Use of additional immunosuppressives - n (%)	36 (46.15)	19 (50)	17 (42.5)	0.51
Pre-procedure steroid dose- Mean (SD)	6.51 (4.49)	7.53 (4.99)	5.55 (3.77)	0.05
In-hospital steroid dosing				
DOS prednisone equivalent dose, mg- Mean (SD)	25.25 27.27)	47.62 (23.03)	4.01 (3.76)	< 0.001
Postop. prednisone equivalent dose, mg- Mean (SD)	8.77 (8.68)	12.38 (10.04)	5.35 (5.334)	0.0002
Hospitalization outcomes				
In hospital glucose level, mg/dl- Mean (SD)	143.31 28.77)	145.77 (26.98)	140.58 (31.2)	0.59
DOS glucose level, mg/dl- Mean (SD)	139.74 (34.4)	147.07 (36.9)	132.08 (30.53)	0.14
Postop. Glucose level - Mean (SD)	137.04 (32.65)	141.18 (30.65)	132.78 (6.01)	0.30
Hypoglycemia	0	0	0	
Infection- n (%)	4 (5.13)	2 (5.26)	2 (5)	0.96
Hypotension- n (%)	27 (34.62)	11 (28.95)	16 (40)	0.31
Intraoperative hypotension- n (%)	14 (17.95)	4 (10.53)	10 (25)	0.09
Disease flare- n (%)	2 (2.56)	1 (2.63)	1 (2.5)	0.97

Table 1. Comparison of baseline characteristics, steroid dosing, and perioperative outcomes after elective joint surgeries in patients with rheumatologic diseases

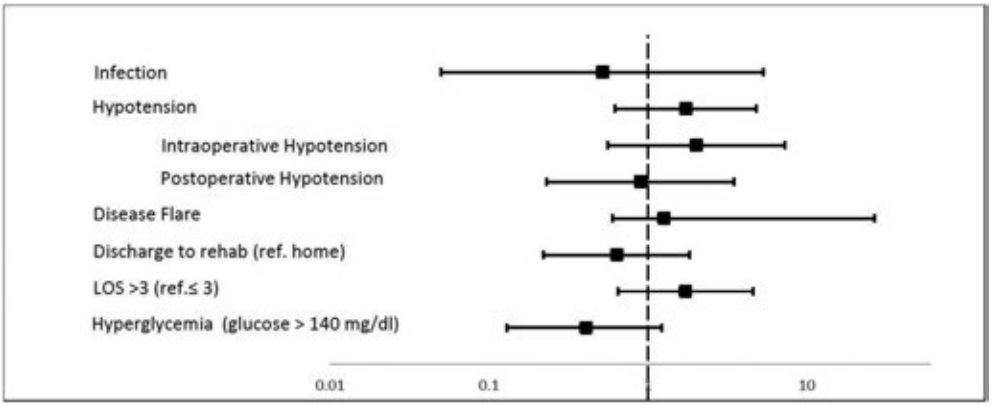

Figure 1. Odds of postoperative outcomes with no stress dose steroids (versus stress dosing) in the perioperative period * Odds adjusted for age, home steroid dose, use of other immunosuppressive and age-adjusted Charlson comorbidity index)

Results: 78 patients met the inclusion criteria, among which about 49 % received stress dose steroids perioperatively. Baseline characteristics were similar between the cases and controls (Table 1). The rate of peri- and postoperative outcomes were not significantly different between the two groups (Figure 1). Intraoperative hypotension was slightly higher in the control group versus those who received stress dose steroid (25 % vs 10.5%, p=0.09). Slight hyperglycemia was noted in the stress dose steroid group (mean in-hospital glucose 142 mg/dl vs 129mg/dl, p=0.07). No perioperative hypoglycemia was noted in either group (Table 1).

Conclusion: Although there is no clear guideline on perioperative glucocorticoid management for patients on chronic steroids, the recommended approach has been to treat patients with a high risk of secondary adrenal dysfunction (patients on > 20 mg prednisone equivalent daily for 3 weeks or with features of Cushing's syndrome). In our study of elective joint surgeries, no stress dose steroid group had a slightly increased tendency toward intraoperative hypotension and stress dose steroid group had increased hyperglycemia. No significant hemodynamic difference was noted between the two groups. Our study had a small size and is underpowered to make conclusions, however, the paucity of evidence necessitates more adequately powered studies to compare perioperative steroid strategies.

Characteristics of Patients with Rheumatoid Arthritis Undergoing Primary Total Joint Replacement: A 14-year Trend Analysis (2004-2017)

Shuji Asai,[1] Toshihisa Kojima,[1] Nobunori Takahashi,[1] and Naoki Ishiguro[1], [1]Department of Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Total joint replacement (TJR) is performed when severe large joint destruction causes functional disability in patients with rheumatoid arthritis (RA). Biologics were approved in Japan for use in patients with RA in July 2003. We hypothesized that newer medications including biologics and more aggressive treatment strategies to suppress disease activity might have led to a delay in TJR in patients with RA. This study aimed to examine time

trends in the characteristics of patients with RA undergoing primary TJR since the approval of biologics, and to determine factors associated with time from RA onset to TJR.

Methods: A total of 403 large joints (266 knees, 89 hips, 40 elbows, 5 shoulders, and 3 ankles) in 282 patients who underwent TJR at our institute between January 1, 2004 and December 31, 2017 were retrospectively examined. Time trends over the study period were assessed using the Jonkheere-Terpstra trend test for continuous variables and the Cochran-Armitage trend test for categorical variables. Moreover, patients were divided into two groups according to year of surgery: 2004-2010 and 2011-2017. Data at the time of surgery were compared between the two groups with the Mann-Whitney U test for continuous variables and the chi-square test for categorical variables. Multiple regression analysis was performed to assess whether serum C-reactive protein (CRP) levels at surgery and age at RA onset were associated with time from RA onset to TJR, with sex as an additional variable.

Results: A significant decreasing trend was observed in the number of TJRs performed from 2004 to 2017 ($P = 0.013$) (Fig. 1). Both age at surgery and age at RA onset showed a significant increasing trend ($P = 0.002$ and 0.034, respectively) (Fig. 2A). Time from RA onset to TJR showed no significant trend ($P = 0.294$) (Fig. 2B). Serum CRP levels showed a significant decreasing trend ($P < 0.001$) (Fig. 2C), and the proportion of subjects with negative CRP (defined as ≤0.3 mg/dl) showed a significant increasing trend ($P < 0.001$) (Fig. 2D). Relative to the 2004-2010 group (n =234), the 2011-2017 group (n =169) was more likely to be older at surgery [median (IQR), 66 (60-73) vs. 63 (57-69) years, $P = 0.005$], older at RA onset [51 (41-61) vs. 48 (37-57) years, $P = 0.013$], have lower serum CRP levels [0.30 (0.07-0.95) vs. 0.88 (0.29-2.22) mg/dl, $P < 0.001$], and have a higher rate of negative CRP (50% vs. 27%, $P < 0.001$) (Table 1). With respect to RA treatment, a significant increasing trend was observed in the proportion of subjects receiving MTX ($P = 0.004$) and biologics ($P < 0.001$) (Figs. 2E, 2F). Multiple regression analysis revealed that negative CRP [partial regression coefficient (B) =1.56, $P = 0.046$] and age at RA onset (B =-0.51, for a 1-year increase, $P < 0.001$) were independently associated with time from RA onset to TJR.

Conclusion: The number of TJRs decreased since the approval of biologics in Japan, and changes were observed in the characteristics of RA patients undergoing TJR. Negative CRP, defined as ≤0.3 mg/dl, was associated with longer times from RA onset to TJR independently of age. Newer medications and more aggressive treatment strategies to suppress disease activity can reduce the number of and delay TJR in patients with RA.

Prevalence of Postoperative Anemia in Patients with Rheumatoid Arthritis and Psoriatic Arthritis Undergoing Total Knee Arthroplasty: A Study of National Inpatient Sample 2010-2014

Karan Jatwani,[1] Karan Chugh,[2] Bikramjit Bindra,[3] and **Shraddha Jatwani**[2], [1]Mount Sinai West - St Luke's Hospital, New York, [2]St. Vincent Evansville, Evansville, [3]Government Medical College & Hospital, Chandigarh, India

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Total knee arthroplasty (TKA) is a valuable option for improving function and pain control in patients with end-stage arthritis, especially those with inflammatory arthritis like Rheumatoid arthritis (RA) or Psoriatic arthritis (PsA). RA and PsA have been associated with an overall increased risk of peri-operative complications, including infections and cardiovascular mortality. There is limited information comparing short-term inpatient complications like post-operative anemia and wound dehiscence in patients with RA or PsA. Anemia has been associated with delayed functional recovery for patients undergoing arthroplasty as well as higher postoperative morbidity and mortality. We aim to assess the prevalence of short term inpatient complications like post-operative anemia and wound dehiscence in patients undergoing TKA with RA and PsA.

Table 1: Comparison of hospitalizations for TKA: National Inpatient Sample 2010-2014

Characteristic	Adult TKA without RA or PsA	Adult TKA with RA	p value	Adult TKA with PsA	p value
Mean Age (in years)	65.985	64.852	<0.001	62.345	<0.001
Gender (%)			<0.001		
Male	38.2	22.17		37.67	
Female	61.8	77.83		62.33	
Race (%)			<0.001		<0.001
White	83.12	76.48		89.76	
Black	7.75	11.65		2.23	
Hispanic	5.22	7.33		4.94	
Asian or Pacific Islander	1.13	1.23		0.98	
Native American	0.51	0.7		0.36	
Other	2.26	2.6		1.73	
Mean Charlson Comorbidity Index	0.603	1.652	<0.001	0.803	<0.001
Total charges per hospitalization (in dollars)	52365	54808	<0.001	54141	0.05
Length of stay (in days)	3.0835	3.2257	<0.001	3.118	0.51

Methods: National Inpatient Sample (NIS)is the largest all-payer inpatient care database in the United States, with approximately 8 million hospitalizations each year. We extracted data for all the adult admissions for TKA from NIS database from 2010-2014 and stratified it into groups based on the status of RA and PsA; using ICD-9 CM diagnostic codes. The baseline characteristics, mortality, the prevalence of post-operative infections, wound dehiscence, and postoperative acute hemorrhagic anemia were compared, using appropriate statistical tools. Stata version 15 (College Station, TX) was used to perform the statistical analysis.

Results: An estimated total of 3172824 hospitalizations for TKA were identified, with around 3157706 TKA and 15117 revision TKA. Amongst these hospitalizations 108101 had an underlying diagnosis of RA and 7421 had an underlying diagnosis of PsA. No difference in postoperative mortality, postoperative infections, or risk of wound dehiscence was noted in these subgroups. But these subgroups were found to have significantly higher rates ($p< 0.05$)of postoperative acute hemorrhagic anemia. The Odds Ratio for patients admitted for TKA with an underlying diagnosis of RA was estimated as 1.295(95% confidence interval=1.249-1.342). 27.92% hospitalizations for TKA with underlying RA were found to have post-operative anemia (p-value < 0.001). The admissions for TKA with psoriatic arthritis also had significantly higher odds of post-operative acute hemorrhagic anemia (Odds Ratio 1.13, 95% confidence interval 1.012-1.282).

Conclusion: The study estimates that admissions for TKA with underlying RA or PsA have significantly higher rates of postoperative anemia. It may represent pre-existing anemia worsening with surgery, as RA and PsA are associated with anemia of chronic disease. Another explanation can be concomitant use of medications like NSAIDs, DMARDs, or steroids for treatment of RA and PsA. We suggest that besides pre-operative cardiovascular and infection risk assessment, patients with RA and PsA should also be screened for anemia, to avoid postoperative morbidity and mortality.

Lumbar Spinal Stenosis in Patients with Wild-type Transthyretin Cardiac Amyloidosis

Ana B Arevalo,[1] Faris Haddadin,[1] Shane Murray,[1] Gustavo Contreras,[1] Yiming Luo,[1] and Yousaf Ali[1], [1]Mount Sinai St. Luke's - West/ Icahn School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Senile systemic amyloidosis (SSA) derived from wild-type transthyretin (TTR) is a debilitating autosomal dominant disease leading to motor disability within 5 years and fatal within a decade without treatment. It is a common condition of old individuals, especially men. The main presentation is by cardiac involvement. SSA is, however, a systemic disease, and amyloid deposits may appear in many other tissues such as cartilage and ligaments[1]. Lumbar spinal stenosis is also a condition of elderly individuals in whom narrowing of the lumbar spinal canal leads to nerve compression of the lower extremities. Neuropathy caused by TTR amyloidosis had been frequently misdiagnosed as CIDP, paraproteinaemic peripheral neuropathy and other causes of acquired neuropathy[2].

Relation between Cardiac Amyloidosis and Lumbar Spinal Stenosis: adjusted for age, gender and race.				
Subgroup	n (%)	Odds Ratio (OR)	Confidence Interval (CI)	p value
Mean Age (years)	78.8	1.09 (per year of age)	95% CI 1.06-1.12	< 0.001
Female	25 (27.77)	0.028	95% CI 0.1-0.77	< 0.01
Race: -African American	25 (27.77)	3.8	95% CI 1.37-10.6	< 0.01
-Non-African American	65 (72.2)	2.07	95% CI 0.045-9.49	0.36
(n= 90; OR: 1.70; 95%-CI 1.03-2.82; p value <0.04)				

Table 1. Relation between cardiac amyloidosis and lumbar spinal stenosis, adjusted for age, gender and race.

Methods: This is a retrospective cohort study using the 2016 National Inpatient Sample (NIS) of adults hospitalized for Cardiac Amyloidosis (CA) as the admitting diagnosis and lumbar spinal stenosis (LSS) as a secondary diagnosis based on ICD-10 codes. Multivariate linear regression adjustment for confounders of age, gender and race was made. STATA 15 was used for data analysis.

Results: 1068 patients were admitted with cardiac amyloidosis in 2016, of which 90 patients had lumbar spinal stenosis (8.42%), 25 were females (27.77%), 65 males (72.2%), 65 were non-African American (72.2%) and 25 individuals were African American (27.77%). Mean age was 78.8 for those with CA and LSS, compared to 72.37 for CA and 68.3 for LSS alone. Univariate linear regression showed a significant relation between these two conditions (OR: 2.48; 95%-CI 1.49-4.12; p value: < 0.001). Multivariate linear regression adjusted to age, race and gender also showed a significant correlation (OR: 1.70; 95%-CI 1.03-2.82; p value: < 0.04). Subgroup analysis demonstrated an increased risk for developing LSS along with CA with the increase of age (OR: 1.09 per year of age; 95%-CI 1.06-1.12; p value: < 0.001) and for African-Americans (OR: 3.8; 95%-CI 1.37-10.6; p value: < 0.01). However, this association is less frequent in the female gender (OR: 0.028; 95%-CI 0.1-0.77; p value: < 0.01).

Conclusion: We conclude that LSS is quite frequent in patients with CA due to TTR-deposit therefore patients with lumbar back pain in the setting of restrictive cardiomyopathy deemed to be secondary to TTR, need a confirmatory tissue biopsy to avoid misdiagnosis because diverse treatment options are available, including tafamidis or patisiran, which all appear to be effective in early disease stages.

Relation between cardiac amyloidosis and lumbar spinal stenosis, adjusted for age, gender and race.

Stakeholder Feedback on Novel Behavioral Intervention Targeting Comorbid Chronic Back Pain and Depression in Older Adults

Ailing Yang,[1] Wei Yuet,[2] LaDonna Saxon,[3] James LePage,[3] Liana Fraenkel,[4] Manney Reid,[5] and Una Makris[6], [1]UT Southwestern Medical Center, Dallas, [2]UNT Health Science Center, Fort Worth, [3]Dallas VA Medical Center and UT Southwestern Medical Center, Dallas, [4]Yale School of Medicine and VA Connecticut Healthcare System, New Haven, [5]Weill Cornell Medicine, New York City, [6]UT Southwestern Medical Center and Dallas VA Medical Center, Dallas

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic low back pain (cLBP) is the 2nd most common reason for physician visits; annual related costs exceed $100 billion and are expected to rise with the aging population. Older adults with cLBP experience significant physical, psychological, and social consequences. We also know that depression frequently co-exists with cLBP and complicates management. A feasible, effective behavioral intervention targeting cLBP and comorbid depression in older adults is needed. Existing interventions are not adequate or sufficient, as they have not been specifically focused on older adults, nor have they targeted both cLBP and depression simultaneously.

We developed a novel 8-session, 12-week, telephone delivered behavioral intervention targeting older adults with cLBP and comorbid depression. MOTIVATE (Moving to Improve Chronic Back Pain and Depression in Older Adults) is delivered by a health coach who uses motivational interviewing and value concordant goal setting to capture individual motivations to increase physical activity. The ultimate goal is to improve both back pain-related disability and depression.

Table 1: Illustrative Quotes from Stakeholders Providing Feedback on MOTIVATE

Stakeholder	Theme	Illustrative Quotes
Veteran Participants	Rapport with health coach	"Before I had thoughts that stopped me from doing things. [Health coach] helped me overcome those thoughts." "Telephone calls were good. Some of the sessions were too long. I was fatigued, and [health coach] respected that and split the sessions up." "Being able to see my coach on video might be helpful."
	Motivation to follow through with goals related to physical activity	"[Health coach] motivated me a lot, once I got the idea and process of being more active to reduce depression and pain, then I got motivated by that." "This program helped me think differently about physical activity and depression…it changed me."
	Future role of health coaching within Patient Aligned Care Team	"It would be helpful to have someone who knows my values/goals call me and check in on me. Not every week! That would be a nuisance!"
Primary Care Providers including Clinic Director	Importance of health coach and goal setting in the context of pain and depression in primary care	"Goals would be valuable to know, especially if certain activities/modalities help alleviate their pain and improve their emotions. We could reinforce them." "It is very dependent on the health coach…They need to have the right personality." "Having adjunct health coach would be helpful, since we don't have time to do these types of sessions."
Health Coach	Perception of goal setting	"Goal setting … was the component the Veterans were most excited about…many at some point in their lives were very active…[this intervention] jump-started or augmented their current physical activity."
	Patient activation to improve outcomes	"Patient activation got patients out of the vicious cycle of severe depression and back pain."
	What successful implementation requires	"…requires education of staff and clinicians about what a health coach is and does…and examples of how they might help e.g. quit smoking, losing weight, exercising more."

Figure 1. Inelastic compression garment system

Methods: This single-arm pilot study of MOTIVATE was conducted to refine future intervention content, procedures, and delivery based on stakeholder feedback. The PARiHS (Promoting Action on Research Implementation in Health Services) framework was used to develop the discussion guide and facilitate individual in-depth interviews with the following key stakeholder groups: Veteran participants (n=4) over the age of 65 with comorbid cLBP and depression who received MOTIVATE, primary care providers (PCP) (n=4), clinic director (n=1), and health coach (n=1).

Results: We enrolled 8 Veterans in the pilot study who were predominately white (75%), male (87%), with a mean age of 70 years. The mean pain intensity score was 7.3/10; back pain-specific Roland Morris Disability Scale was 16.5/24; and depression (PHQ-9) score was 16.7/27. Upon completion of the intervention, semi-structured interviews with stakeholders provided valuable feedback on how to modify MOTIVATE moving forward (Table 1). Briefly, Veterans who completed MOTIVATE engaged well with the health coach, were motivated to walk with a pedometer and coaching, and felt that being more active reduced pain and depression. Of the four PCPs interviewed, all attributed the success of the intervention to the personal qualities and engagement of the health coach; we also learned about the variability in how PCPs would like results relating to patient-identified values and goals to be communicated to them. The health coach noted that Veterans were able to identify value concordant goals and easily link these to physical activities. All stakeholders stated that the individual health coach plays a critical role in activating and motivating older Veterans with complex medical and psychiatric issues.

Conclusion: This pilot study showed that we were able to effectively recruit older Veterans with cLBP and depression and deliver MOTIVATE via telephone. Feedback from key stakeholders regarding the iterative refinement of recruitment, study procedures, and content will aid the future evaluation and implementation of MOTIVATE.

Abstract Number: 2166

Multimodal Edema Management After Total Knee Arthroplasty: A Pilot Study

Joel Carmichael,[1] Michael Bade,[1] and Jennifer Stevens-Lapsley[1], [1]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The ideal treatment of swelling after TKA is unclear. The purpose of this pilot study was to determine the feasibility and initial efficacy of a multimodal edema management (MEM) program including inelastic gradient compression garment, manual lymph drainage massage and home exercise for patients presenting with swelling after TKA.

Methods: This was a prospective pilot study with retrospective historical cohort comparison. Ten patients (mean ± SD, 68 ± 2 years; 6 female) were consecutively enrolled 2 weeks prior to primary TKA. Patients were excluded if they: (1) had a chronic lower extremity swelling condition including congestive heart failure; (2) had BMI > 40; (3) had a history of thrombolytic therapy > 14 d. The multimodal therapy consisted of using an inelastic compression garment (Figure 1) 12 hours daily, self-administered manual lymph drainage massage once daily for 10 minutes, and a home exercise

program (toe curling, calf pumps and knee range of motion exercises). The daily MEM program continued for 3 weeks. Primary outcomes were MEM adherence, patient satisfaction, and knee swelling quantified by bioelectrical impedance spectroscopy (BIS). Outcomes were assessed preoperatively and at 2 and 3 weeks. Secondary outcomes included quadriceps strength and activation. These outcomes were assessed preoperatively and at 3 weeks. All outcomes were

Figure 1. Inelastic compression garment system.

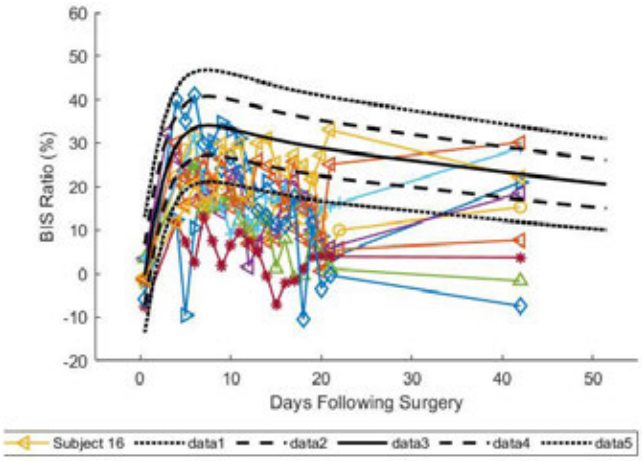

Figure 2. Plotted swelling percentiles of MEM intervention group vs. historical Controls (expected values for swelling after TKA at the 10th, 25th, 50th, 75th and 90th percentiles shown.)

re-assessed at 6 weeks. Data were compared to an historical Control group (n = 56) who met the same inclusion and exclusion criteria and who received standard physical therapy twice weekly. MEM and Control outcomes were compared using independent-samples t-tests. Preliminary effect sizes were obtained by calculating Cohen's d statistic.

Results: Mean compression garment adherence was 81.5% for hours worn per 12-hour daily goal, and 98% for all possible days of wear. Adherence to manual lymph drainage massage and home exercise program were 100% in all patients. MEM patients were similar at baseline to Control for age, sex, body mass index, ROM, quadriceps strength and quadriceps activation (all, P >.05). Mean swelling measures for MEM were 12% lower than Control at 2 weeks (P < 0.005), and 8 of 10 patients were below the 10th percentile of Control swelling at the conclusion of the 3-week intervention period (Figure 2). At 6 weeks mean swelling reductions for MEM were 7% lower than Control (P < 0.033). Mean quadriceps activation for MEM improved 17.5% at week 6 compared to 9.4% for Control (P < 0.106) with effect sizes of 0.82 and 0.38 respectively. MEM showed smaller losses in postoperative quadriceps strength at 6 weeks compared to Control (8.2 N-m vs. 21.7 N-m; P < 0.529) with effect sizes of -0.15 and -0.40 respectively. Mean loss in active knee flexion ROM was greater for MEM than Control at 2 and 6 weeks (range 16.1 to 17.4 degrees; all, P < 0.03) but effect sizes for MEM and Control at 6 weeks for this outcome were similar at 1.11 and 1.05 respectively.

Conclusion: Use of the MEM program is feasible for treating swelling after TKA and produces improvements in swelling and quadriceps activation. Future larger randomized controlled trials are needed to determine efficacy of the MEM program and determine optimal patient characteristics for success.

A Randomised Controlled Clinical Trial Comparing the Effectiveness of 6 and 12 Weeks of a Shoulder Specific Exercise Programme for Patients with Rotator Cuff Related Shoulder Pain

Sandra Keyes,[1] Noreen Walsh,[1] and Mark Phelan[1], [1]South Infirmary Victoria University Hospital, Cork, Ireland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Research has shown loaded exercise programmes to be beneficial for patients with rotator cuff related shoulder pain in terms of improving shoulder function, self-reported disability and pain[1,2]. The optimal duration for which these patients should complete a loaded exercise programme to achieve beneficial effects remains unclear. The purpose of this study is to determine if 6 weeks of a supervised shoulder specific exercise programme is as effective as 12 weeks of the same programme, for improving shoulder function, self-reported disability and pain, in patients with rotator cuff related shoulder pain.

Methods: In this randomised controlled single-blinded study patients with a history of lateral upper arm pain with MRI confirmation of rotator cuff pathology or positive testing on a cluster of clinical rotator cuff tests were included. Patients with a recent history of shoulder surgery or a shoulder fracture were excluded. Participants were randomly assigned to complete either 6 weeks (short group) or 12 weeks (long group) of the exercise programme. Both groups performed the same specific set of loaded exercises daily at home and attended 6 clinic-based group exercise sessions. Participants were assessed by a blinded assessor at 6 weeks, 3 and 6 months. Shoulder function was assessed using the Constant-Murley (CM) score. Disability was assessed using the QuickDash and the Shoulder Pain and Disability Index (SPADI). Pain was assessed using a visual analogue scale. Group comparisons were made using univariate generalised linear models.

Results: 85 patients were included in this study as per Table 1. An independent samples *t* test showed the two groups did not differ significantly in any of the outcome measurements at baseline ($p > .05$). Within each group all outcomes improved significantly at 3 months ($p < .05$). The mean difference between groups for each of the outcome measures are shown in Table 2. Results indicated that the long group had significantly lower pain scores at 3 months ($p = .02$). At 3 months there was no significant difference between the two groups in the CM score ($p = .415$), the SPADI score ($p = .053$) and the QuickDash score ($p = .249$). However, at 6 months, the long group had significantly greater changes in both the CM score ($p = .007$) and the SPADI score ($p = .002$). The results at six months indicate that receiving a corticosteroid injection in the three months prior to inclusion in the study did not influence participants' results within each group ($p = .97$).

Conclusion: In the management of patients with rotator cuff related shoulder pain the findings of this study indicate that a 12 week exercise programme results in better outcomes for pain at 3 months and self-reported disability and shoulder function at 6 months.

Characteristics	Short group (n = 45)	Long group (n = 40)

Abstract Number: 2168

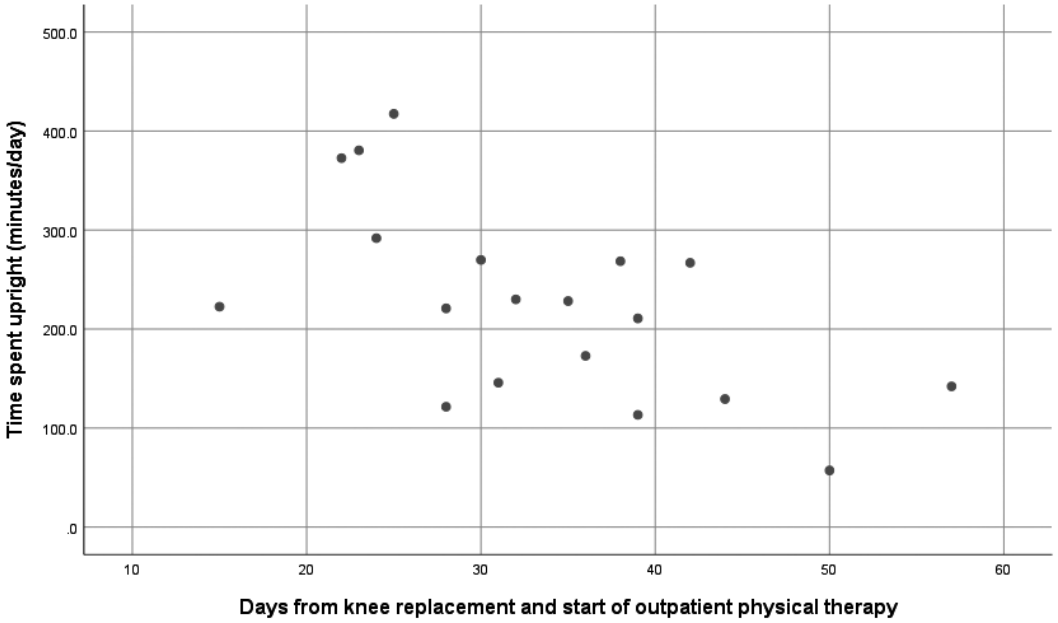
Early Start of Outpatient Physical Therapy After Knee Replacement Is Associated with More Objectively-measured Steps and Time Spent Upright

Christine Pellegrini,[1] Nicholas Mook,[2] Katherine DeVivo,[2] and Deborah Brown[3], [1]University of South Carolina, Columbia, SC, [2]University of South Carolina, Columbia, [3]Prisma Health, Columbia, SC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: After knee replacement, patients often receive physical therapy in-home or at a rehabilitation facility shortly after surgery and then transition to outpatient physical therapy. Physical activity is typically limited at this time, but little is known about how much time is spent upright prior to the start of outpatient therapy. The purpose of this study was to determine whether the timing of outpatient physical therapy is associated with objectively-measured steps and upright time following knee replacement.

Methods: Adults 40-80 years were recruited at the first outpatient physical therapy visit following total knee replacement. Participants completed an online survey assessing demographics, a brief medical and surgical history, and wore an activPAL monitor for 7 days. The activPAL monitor assessed the number of steps/day and average minutes/day spent upright, standing, and stepping. Only valid days consisting of 24 hours of wear time were used for analyses. Linear regression, adjusting for age and body mass index (BMI) was used to determine whether the start of outpatient physical therapy was predictive of steps/day, upright, standing, or stepping time.



Relationship between the number of days from the start of outpatient physical therapy and time spent upright after knee replacement

Results: Participants (n=19) were 63.2% female, 57.9% white, with an average age of 63.0±7.4 years and body mass index of 32.8±6.2 kg/m2. Participants started outpatient physical therapy 33.6±10.3 days from surgery. On average, participants had 5.6±1.4 valid days of activPAL monitor wear. Over a 24 hour day, participants spent 224.3±97.1 minutes upright, with 160.0±30.7 minutes/day of that time standing and 64.3±30.7 minutes/day stepping. Participants took 4083.7±2038.5 steps/day. The start of outpatient physical therapy, adjusting for age and BMI, significantly predicted the time spent upright ($F(3,15) = 3.46$, $P< 0.05$, $R2 = 0.41$) (Figure 1) and stepping ($F(3,15) = 3.45$, $P< 0.05$, $R2 = 0.41$). The start of outpatient physical therapy, age, and BMI did not statistically predict the time spent standing ($F(3,15) = 3.07$, $P=0.06$, $R2 = 0.38$) and number of steps/day ($F(3,15) = 2.76$, $P=0.08$, $R2 = 0.36$).

Conclusion: The timing of the start of outpatient physical therapy predicts the number of steps/day and time spent upright in patients after knee replacement. Specifically, starting outpatient therapy sooner from surgery was associated with greater steps and time spent upright. Physical therapists may want to consider the timing of starting outpatient physical therapy in developing personalized activity plans especially among those who started late and take fewer steps/day and spent less time upright.

Relationship between the number of days from the start of outpatient physical therapy and time spent upright after knee replacement

Abstract Number: 2169

Reporting of Adverse Events in Randomized Controlled Trials of Therapeutic Exercise for Knee Osteoarthritis: A Systematic Review

Johan vonHeideken,[1] and **Maura D. Iversen**[2], [1]Karolinska Institutet, Stockholm, Sweden, [2]Northeastern University, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CONSORT guidelines recommend the reporting of adverse events (AEs) and drop outs, along with a description of each**.** However, the application of these guidelines in clinical trials of exercise is unknown. This study aimed to identify how AEs and drop outs are reported in clinical trials of therapeutic exercise for adults with KOA.

Methods: Cochrane Library, EMBASE, MEDLINE, and CINAHL databases were searched to identify randomized controlled trials of therapeutic exercise for patients with KOA published in English from January 1, 1980 through December 31, 2016. The American Physical Therapy Association operational definition of therapeutic exercise was used. Databases were searched using the following search terms: knee osteoarthritis AND exercise OR exercise therapy OR strengthening OR aerobics OR anaerobic OR dynamic OR isotonic OR isometric OR isokinetic OR strengthening OR aquatic OR physical therapy AND clinical trial NOT modalities. Studies which compared non-pharmacologic interventions to therapeutic exercise were eligible as long as the therapeutic exercise intervention arm included only therapeutic exercise. Studies which included patients with other forms of arthritis or with non-specified knee pain were excluded. We focused on studies which reported outcomes related to impairments, functional limitations and participation. Four researchers independently examined each study and eliminated studies which did not meet our inclusion criteria. The reference list for each chosen article was also screened for eligible studies. In instances where the eligibility of the study was unclear, the researchers deliberated and came to a consensus regarding inclusion. Using a standardized form, we extracted information regarding participant and intervention characteristics, whether there was a clear statement of AEs and drop outs and reasons for AEs and drop outs. Study quality was assessed using the PEDRO scoring method and descriptive and inferential statistics were used to characterize results.

Results: One hundred two studies from 21 countries met the inclusion criteria with 6,654 subjects exercising. Of these 102 studies, 32 studies (31%) included a statement of AEs and 14 of these studies (44%) reported AEs. Eighty-five studies (83%) had a clear statement regarding drop outs and 20 studies (23%) gave reasons for drop out that could be classified as AEs. Forty percent of studies published in North America and Western Europe had a statement of AEs compared to 25% of studies from the rest of the world (p=0.13). Adverse events were reported for 59 patients and 55 individuals dropped out for reasons that could be considered an AEs, yielding 114 patients (2%) experiencing an AE-related to exercise.

Conclusion: Overall the quality of included studies was good. Geographic variations existed in statements about AEs. AEs and drop outs may be underreported and not sufficiently represent the risk associated with therapeutic exercise. Greater clarity regarding definitions of AEs and adherence to the CONSORT reporting guidelines are needed to best determine safe dosing of therapeutic exercise for KOA.

Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Low energy hip fractures are feared harbingers of morbidity and mortality. However, many older adults are high functioning and cognitively intact at the time of fracture, and thus death or loss of health-related quality of life post-hip fracture is unexpected and particularly devastating. Whether patient reported outcome meas-

TABLE 1. BASELINE DATA

White (%)	85.6
Age (years) [IQR]	81.7 [74.9, 87.3]
College educated or higher (%)	66.7
Pre-fracture Scores	**T-score**
PROMIS Physical Function [IQR]	45.3 [37.9, 56.9]
PROMIS Anxiety [IQR]	40.3 [40.3, 55.8]
PROMIS Depression [IQR]	41.0 [41.0, 51.8]
PROMIS Fatigue [IQR]	43.1 [33.7, 53.1]
PROMIS Sleep Disturbance [IQR]	48.4 [41.1, 52.4]
PROMIS Ability to Participate in Social Roles [IQR]	64.1 [51.6, 64.1]
PROMIS Pain Interference [IQR]	41.6 [41.6, 53.9]
PROMIS Pain Intensity* [IQR]	0 [0, 4]
*Pain Intensity = 0-10 Visual Analog Scale. All other PROMIS scores are T-scores (population mean=50). Higher PROMIS score = MORE of the domain being measured. PROMIS scores are reported as MEDIAN [INTERQUARTILE RANGE]	

ures (PROMs), collected at time of fracture, might provide risk stratification in these patients is unknown. This study evaluates the association of pre-operative PROMs with adverse events, death, and function in a cohort of robust, cognitively intact elderly patients 1-year after surgery for a low energy hip fracture.

Methods: Patients ≥ 65 at a single center who underwent surgical repair of a low trauma hip fracture were enrolled. Patients with active cancer, dementia, previous or bilateral hip fracture, or with a non-U.S. address were excluded. American Society of Anesthesiologists (ASA) risk score was recorded. The Lubben Social Networks Scale, a validated instrument designed to measure social isolation in the elderly, PROMIS29 and the Lower Extremity Activity Scale (LEAS) were administered 2-4 days post-op. to assess pre-fracture status, and again at 1-year. Adverse events (AEs) were recorded at 30 days, 3-months, and 1-year. Multivariable exact logistic regression was used to generate odds ratios and Wald 95% confidence intervals. Multivariable linear models were specified for each PROM of interest and each outcome, adjusting for confounders identified a priori using a directed acyclic graph approach. All analyses used SAS 9.4.

Results: 956 patients were screened; 140 excluded for dementia, 85 for cancer, 66 for previous/bilateral hip fracture, 211 for other reasons, and 319 consented to enroll. Subjects had less PROMIS29 anxiety, depression, fatigue, sleep disturbance, and better ability to participate in social roles than population means, though slightly worse physical function (Table 1). 31.9% were socially isolated pre-fracture. 19 subjects died, and of 189 patients eligible for follow up, 140 (74.1%) provided 1-year data.

There was no statistically significant association between pre-fracture social isolation and any PROMIS29 domain, or cumulative AEs at 1-year. In an analysis controlling for ASA score, social isolation predicted cumulative 1-year mortality, OR 2.9 (95% CI 0.95-9.4; p=0.06); this estimate is imprecise, however, as only 19 deaths were observed. In a multivariable linear regression controlling for PROMIS29 scores, age, race, sex, and ASA score, an increase in PROMIS29 physical function (β =0.18 p< 0.001) and male sex (β =1.4 p=0.03) were associated with an increase in 1-year LEAS function.

Conclusion: Although these results are imprecise due to the small number of deaths, our observations suggest pre-fracture social isolation could be associated with an almost 3x increase in 1-year mortality in these robust, cognitively intact, elderly hip fracture patients. Further research needs to verify these estimates. Identifying actionable risk factors, such as social isolation, which can be feasibly elicited at point of care, could help direct resource-intense interventions to high priority patients.

Data are expressed as the mean (standard deviation); T0, baseline; T6, evaluation after 6 weeks – end of the treatment; T12, evaluation after 12 weeks; T24, evaluation after 24 weeks – follow-up.

Background/Purpose: To assess the effectiveness of a functional exercise program for pain, functional capacity, general health, kinesiophobia, medication consumption and patient satisfaction in adults with chronic nonspecific low back pain.

Methods: A randomized controlled clinical trial with intention-to-treat analysis and 24-week follow-up was performed. Eighty-four patients were randomly assigned to an experimental group (EG) or control group (CG). The EG participated in the functional exercise program performed twice a week for twelve weeks. The functional exercise program was composed of global exercises that worked the group of muscles in the trunk and lower and upper limbs with progression every 4 weeks. The two groups received an informative class on the disease and were advised to use analgesics if necessary. Evaluations were performed at baseline, after 6, 12 and 24 weeks by a blinded evaluator. The primary outcome was low back pain measured by the numeric rating scale (NRS). Secondary outcomes included functional capacity by the Oswestry and Roland-Morris questionnaires, 6-minute walk and TUG tests, kinesiophobia (FABQ), general health (SF-36), medication consumption and satisfaction with treatment (Likert scale). Sample size was calculated. The tests were used: Kolmogorov-Smirnov, Chi-square, Student's-T and Mann-Whitney. We used the Generalized Linear Models (GLM) with Bonferroni adjustments and the intention-to-treat analysis were performed.

Results: The groups were homogeneous for all parameters at baseline. Compared with the CG, the EG significantly improved pain ($p< 0.001$), functional capacity (Oswestry, Roland Morris ($p< 0.001$) and TUG ($p=0.005$), FABQ ($p< 0.001$) and most of the SF-36 parameters.

Conclusion: The functional exercise program was effective in improving pain, functional capacity, kinesiophobia and general health in adults with chronic nonspecific low back pain.

Depression of Vitamin D Levels After Adult Primary Posterior Spinal Fusion: Are We Adding Insult to Injury?

Isabel Smith,[1] Samuel Golenbock,[1] Gerald Miley,[2] and Scott Tromanhauser[2], [1]New England Baptist Hospital, Boston, MA, [2]New England Baptist Hospital, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D is a steroid hormone metabolized to its active form in the presence of parathyroid hormone in the kidney. Vitamin D is essential in the process of bone formation which in turn is vital for achieving spinal arthrodesis. Previous studies have indicated that 43% of patients who undergo orthopedic surgery are vitamin D deficient (Bogunovic et al. 2010). Animal studies demonstrated that vitamin D modulates consolidation of bone after grafting for spinal posterolateral fusion in rats (Metzger et al 2015). Low vitamin D levels and increased inflammatory markers have been found following total knee arthroplasty (Henriksen et al 2013). Studies have suggested that spinal fusion patients presenting with vitamin D deficiency achieved lower fusion rates and had higher rates of recurrent persistent back pain compared with patients with normal vitamin D levels (Rodriguez and Gromelski 2013). If patients are deficient in vitamin D preoperatively and their levels decrease postoperatively, do they ever attain the preoperative baseline and, if not, does this have any bearing on successful spinal fusion? To our knowledge no large prospective study has been published that measures changes in vitamin D levels immediately after surgical spinal fusion. We share this data as part of an ongoing study investigating the relationship between serum 25-hydroxyvitamin D 25(OH) D levels and spinal fusion outcomes 1 year after surgery.

Methods: In total, 103 participants were enrolled in this prospective cohort study of patients undergoing one or two-level primary posterior lumbar spinal fusion with four surgeons between 2016 and 2018. The current study describes a preliminary analysis of all patients who had serum 25(OH)D measured at baseline, postoperative day 1 (POD-1) and at a follow-up visit within six weeks after surgery (n=70, mean follow-up time=31.9 ± 20.0 days). Average age and BMI of participants were 64.1 ± 10.7 years and 28.7 ± 6.2 kg/m^2, respectively. 54% of patients were taking vitamin D supplements at baseline, and were on average older (p=0.005) and more likely to be female (p=0.001) than those who did not take supplements. Median differences in 25(OH)D were calculated at each time point and tested by Wilcoxon signed rank test.

Results: Median 25(OH)D was 35.3 ng/mL at baseline (range, 9.5-95.0 ng/mL) and 27.8 ng/mL at POD-1 (range, 7.0-63.5 ng/mL). Median change in 25(OH)D from baseline to POD-1 was -7.1 ng/mL or -20.9% (p< .0001). The majority (63%) of patients who had been taking vitamin D supplements at baseline had normal (>30ng/mL) levels at POD-1, while this was true for only 19% of patients who were not taking vitamin D (p=0.001).

Conclusion: The results of this study suggest that many patients who undergo posterior spinal fusion have inadequate 25(OH)D levels at the time of surgery. These results raise the question of whether or not ultimate success of fusion could be affected by low vitamin D levels. Given the high prevalence of vitamin D insufficiency and deficiency in patients not taking supplements as well as in those that do, we suggest that it might be beneficial to optimize 25(OH) D levels prior to surgery. Further research examining the effect of low 25(OH)D levels and 25(OH)D optimization on fusion success is recommended.

Descriptive Analysis of Patient-Reported Home Exercise and Physical Activity and Their Associations with Patient Baseline Characteristics Following Total Knee Replacement

Carol Oatis,[1] Nikko Mendoza,[2] William Murray,[3] Bailey Novak,[4] Wenjun Li,[5] Hua Zheng,[6] and Patricia Franklin[7], [1]Arcadia University, Philadelphia, PA, [2]Fox Rehabilitation, Cherry Hill, NJ, [3]Physical Therapy and Wellness Institute, Hatfield, PA, [4]ATI Physical Therapy, Warrington, PA, [5]Department of Medicine, University of Massachusetts Medical School, Worcester, MA, [6]Department of Orthopedics and Physical Rehabilitation, University of Massachusetts Medical School, Worcester, MA, [7]Department of Medical Social Sciences, Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster – ACR/ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Total knee replacement (TKR) is one of the most common elective surgeries and is effective for managing knee pain in osteoarthritis. However functional outcomes post TKR are variable. Exercise and physical activity (PA) improve functional outcomes post TKR, but little is known about the role of specific content and dosage of exercise and PA on outcomes. While most patients receive some physical therapy (PT) post TKR, PT exercise content and dosage vary widely and are poorly documented. Importantly, trends in healthcare show more patients are receiving less direct PT and are instructed to perform exercise and PA with no supervision or with "virtual" supervision at home. Our study describes the content and dosage of exercise and PA that patients performed at home post TKR and assesses patient attributes that may influence patient engagement in exercise and PA.

Methods: Patients from 3 US states and multiple outpatient PT sites post-TKR recorded home exercises and PA performed using daily logs. Logs included exercise name, repetitions, sets, resistance, perceived difficulty (RPE), and PA per day. Three independent reviewers identified exercise type, total and weekly average of exercises, total and weekly average of progressions and total and weekly average of PA. Patient demographics, health status and joint-specific symptoms were collected at baseline through patient-reported assessment surveys. Descriptive statistics of patient and exercise factors are reported. Chi^2 and Fisher's exact tests and linear regressions are used to identify patient factors associated with characteristics of exercise and PA.

Table 1. Patient characteristics (mean (s.d.)

Total strength volume (no. of ex X no. of days)	113.8 (74.19); 106.0 (103.5)
Ave strength volume per week	30.0 (18.8); 26.7 (27.75)
Total CC volume (no. of ex X no. of days)	38.8 (35.65); 28.5 (51.5)
Ave CC volume per week	10.2 (9.03); 7.6 (12.87)
Total OC volume (no. of ex X no. of days)	75.0 (51.8); 74.5 (79.0)
Ave OC volume per week	19.5 (13.2); 18.6 (19.83)
Ratio of CC to OC	0.76 (.96); 0.44 (.75)
Total number of strengthening Progressions	5.2 (4.1); 4.0 (6.0)
Ave strengthening progressions per week	1.4 (1.1); 1.1 (1.75)
Total flexibility exercise volume (no. of ex X no. of days)	59.2 (36.0); 57.0 (51.0)
Ave flexibility volume per week	16.4 (9.15); 15.6 (11.75)
Total number of flexibility progressions	2.0 (3.7); 1.0 (3.0)
Ave flexibility progressions per week	0.6 (1.0); 0.25 (0.75)
Ratio of strengthening to stretching volume	2.71 (2.55); 1.9 (2.7)
Total exercise volume (strength plus flexibility)	173.0 (90.6); 168.5 (115.5)
Average total exercise volume per week	45.39 (23.3); 43.25 (31.38)
Total progressions	7.2 (5.5); 6.0 (7.5)
Average progressions per week	1.95 (1.59); 1.5 (2.0)
Total PA volume in minutes	1040.0 (1063.9); 690.0 (940.)
Average PA minutes/week	264.0 (264.0); 189.2 (231.25)

Table 2. Exercise and Physical Activity Factors (mean (s.d.); median (IQR))

Results: 74 patients returned exercise logs, 15 were excluded for incomplete or unclear responses; 50 records included 4 weeks of exercise logs; 9 included < 4 weeks. Patient characteristics are similar to those in a national registry of total joint replacement patients (FORCE-TJR) (Table 1). Amount of weekly exercise and PA varied widely (Table 2). On average (s.d.) patients performed 45.4 (23.3) exercises weekly, more strengthening than stretching (30.0 (18.8) vs 16.4 (9.2)). More strengthening exercises were non-weight bearing (OC) than weight bearing (CC). Average PA was 264.0 (264.0) minutes per week. We found no statistically significant associations between patients' clinical attributes and types or quantity of exercise and PA, although trends existed suggesting sex, presence of low back pain (LBP) and pre-operative function may affect home exercise engagement**.**

Conclusion: Patient-reported amount of at-home exercise and PA varied widely. Exercise logs often overstate patient engagement, but our data show wide variations in quantity, with some patients reporting few exercises and little PA and others reporting extreme amounts. Patients' clinical attributes did not help explain this variation. As post TKR rehabilitation trends suggest more dependence on home exercise and PA than on face-to-face PT, it is essential that we understand the source of variation in the type and quantity of at-home exercise and PA. Future research will examine the influence of patient engagement and variation in home exercise and PA on long term functional outcomes post TKR in order to optimize functional outcomes.

Test-Retest Reliability and Validity of a Mobile Health Application to Automate the 30 Seconds Chair Stand Test – Preliminary Data to Create a Contemporary Instrument for Randomized Clinical Trials

Lucas Dantas,[1] Matthew Harkey,[2] André Dantas,[3] Lori Lyn Price,[4] Jeffrey Driban,[5] and Timothy McAlindon[1], [1]Tufts Medical Center, Boston, MA, [2]Tufts Medical Center, University of Massachusetts Medical School, Boston, MA, [3]CI&T, Tokyo, Japan, [4]Tufts Medical Center, Tufts University, Boston, MA, [5]Tufts Medical Center, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Contemporary technologies offer potential solutions to improve and automate data collection of randomized clinical trials by transitioning assessments from the clinic to the real-world. Mobile health (mHealth) applications (Apps) associated with smartphone embedded sensors offer the possibility to automate objective physical function tests by tracking, recording, and analyzing quantitative participant data. An automated mHealth app brings to clinicians and researchers the opportunity to reliably monitor physical function at more frequent intervals within a real-world setting. To create this tool, we collected preliminary data to establish the test-retest reliability and validity of an automated mHealth app to assess performance on a 30-second chair-stand test when compared with the gold standard assessment technique.

Methods: We recruited 10 healthy individuals to participate in two data collection sessions separated by 7 days. Individuals were at least 21 years old, able to comfortably walk 20 meters without an assistive device, and had an iPhone 5 or higher. We developed a mHealth App that uses algorithms associated with the smartphone's embedded motion sensors (gravitometer and accelerometer) to automate the count of the repetitions during the 30-seconds chair-stand test. During the test, the participant's smartphone was positioned inside an elastic strap at the chest level. Participants performed three trials in which they completed as many repetitions of standing and

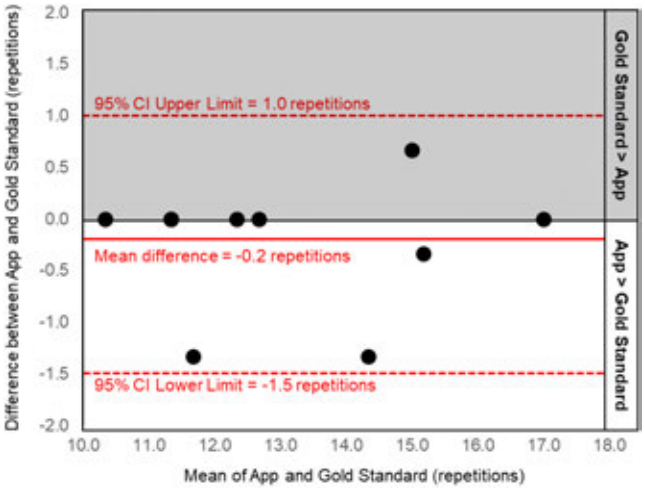

Figure 1. Bland-Altman Plot for the 30-second Chair Stand Test.

sitting from a standard chair during 30 seconds. For each trial, the mHealth app counted the number of repetitions completed by the participants. During the same three trials, an assessor manually counted the number of repetitions as the gold standard for assessing performance. The number of repetitions between the three trials was averaged for the mHealth app and the gold standard. Bland-Altman plots and Intraclass Correlation Coefficients (ICC) were used to establish agreement and inter-rater reliability between the gold standard and the mHealth app, respectively. ICCs were used to assess test-retest reliability between the two different sessions for the gold standard and the mHealth app.

Results: The majority of our sample was female (80%) with a mean ± standard deviation age of 30 ± 7 years, and body mass index of 24.7 ± 5.4 kg/m^2. The Bland-Altman plots demonstrate good agreement between the gold standard test and the mHealth app since no data points fell outside the 95% limits of agreement (upper limit:1.0 and lower limit -1.5 chair stands; **Figure 1**). Additionally, there is excellent reliability between the gold standard and the mHealth app ($ICC_{2,k}$ = 0.98). When comparing across the two different sessions, the gold standard ($ICC_{2,k}$ = 0.93) and mHealth app ($ICC_{2,k}$ = 0.89) demonstrate similar test-retest reliability.

Conclusion: The results suggest that our mHealth app is a reliable and valid tool to objectively quantify performance during the 30-second chair-stand test in healthy individuals. This data will lay the foundation for further development of algorithms to automate other objective physical function tests, as well as future implementation in clinical trials.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a serious disease characterized by progressive joint failure and cartilage degeneration. In OA, ADAMTS-5 protease is upregulated, resulting in enhanced cleavage of joint cartilage aggrecan into fragments (e.g. the aggrecan neo-epitope family [ARGS]) and subsequent stimulation of synovial inflammation. M6495 is an anti-catabolic, bivalent, bifunctional Nanobody® that selectively inhibits ADAMTS-5 *in vitro*, reducing aggrecan cleavage. This Phase I, single-center, randomized, double-blind, placebo-controlled, single ascending dose (SAD), first-in-human (FIH) study (NCT03224702) was conducted in healthy male subjects to explore the safety, tolerability, immunogenicity, pharmacokinetics (PK), and pharmacodynamics (PD) of single subcutaneous doses of M6495, with the aim to guide clinical development.

Table 1. Most common treatment-emergent adverse events by preferred term (safety analysis set)

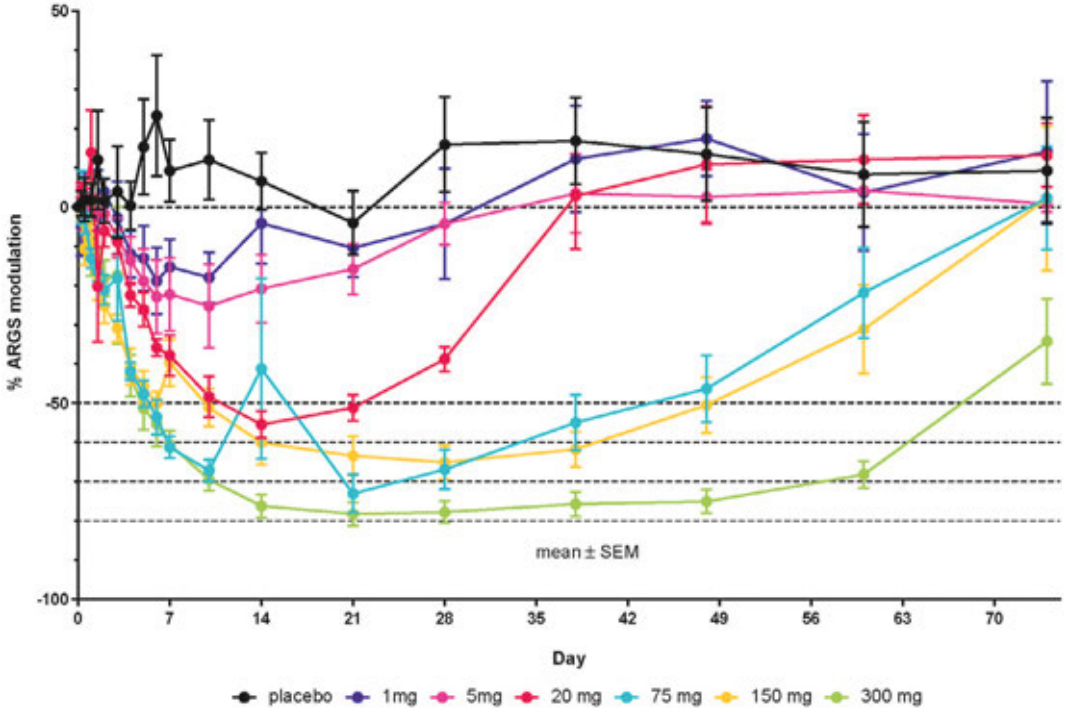

Figure 1. Mean M6495 serum-concentration profiles for all treatments (PK analysis set)

Methods: Male subjects (18–55 years old, body mass index of ≥18.5–≤29.9 kg/m^2) were randomized 2:1 to either M6495 or placebo in 6 dose-level (DL) cohorts (1 mg, 5 mg, 20 mg, 75 mg, 150 mg, 300 mg). Primary endpoints were safety and tolerability. Secondary endpoints were serum-based M6495 PK parameters and PD parameters, including percent change from baseline in ARGS. Exploratory endpoints included the effects of M6495 on versican degradation fragment (VCANM) and high-sensitivity C-reactive protein (hsCRP).

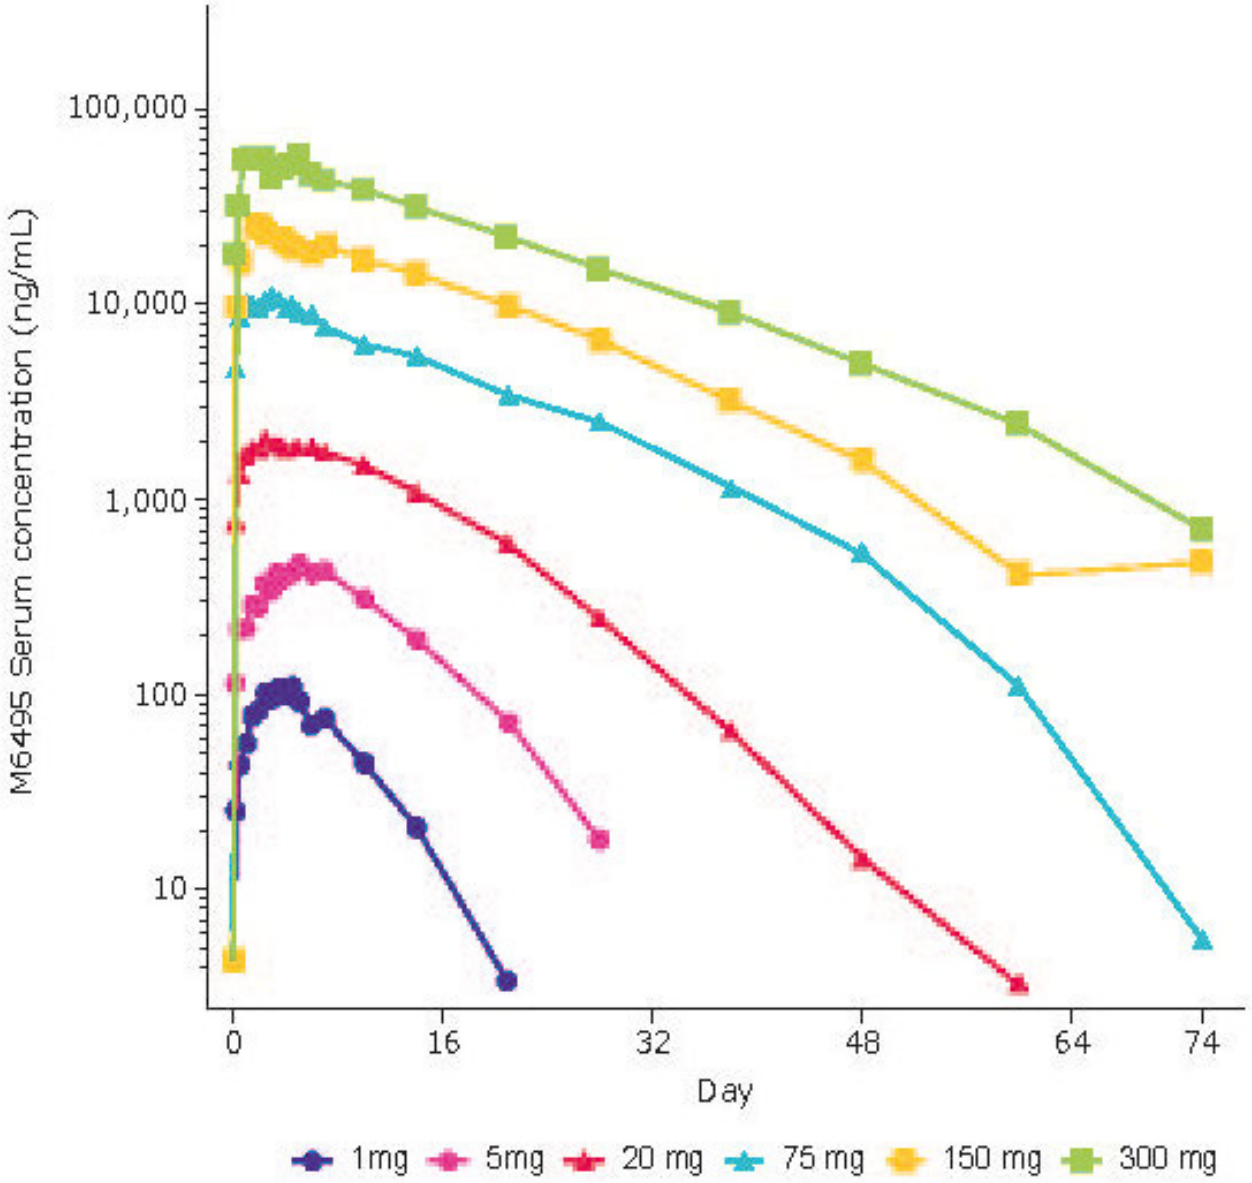

Figure 2. Mean (± standard error of the mean) percentage ARGS modulation (PD analysis set)

Results: 53/54 randomized healthy subjects completed the study; 1 discontinued due to an internship in Africa. Overall, there was minimal difference in treatment-emergent adverse event (TEAE) rate either between each M6495 DL cohort or between M6495 and placebo; 28 (77.8%) subjects receiving M6495 and 12 (66.7%) receiving placebo experienced TEAEs. The most common TEAEs are shown in **Table 1**; the majority were of mild intensity. Observed injection site reactions were mainly mild in nature and within expectations for a therapeutic protein. No deaths or safety signals emerged based on reported TEAEs or laboratory measurements. Based on serum AUC and C_{max}, M6495 exposure increased in a slightly greater-than-dose-proportional manner across the dose range (**Figure 1**). Median M6495 t_{max} ranged from 24–120 hours following administration of M6495. ARGS levels were reduced from baseline in a dose-dependent manner (**Figure 2**). Overall, 6 subjects had anti-drug antibodies (ADA); 2 in the placebo cohort and 1 each in the 5 mg, 20 mg, 75 mg and 300 mg cohorts. In 1 subject, ADA occurred at Day -1. Presence of ADA did not affect PK. In the 300 mg cohort, ARGS levels decreased by up to 78% vs baseline (95% CI = [54, 100]) and up to 93% vs placebo (mean [95% CI]: 93% [65, 120]) by electrochemiluminescence immunoassay. Following administration of 300 mg M6495, an ~45% decrease in mean percentage change from baseline

serum ARGS was maintained through 74 days (last planned time point) vs placebo, whereas reductions of >30% were maintained up to 60 days in the 75 mg and 150 mg cohorts. No significant modulation of hsCRP or VCANM were detected.

Conclusion: The observed safety profile of M6495 at single doses up to 300 mg appeared to be acceptable for further clinical development. M6495 dose-dependently inhibited release of the ARGS aggrecan fragment family.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While knee osteoarthritis (KOA) leads to cumulative damage to a diarthrodial joint there are also more dynamic processes that fluctuate throughout the disease process (e.g., bone marrow lesions [BMLs], effusion-synovitis). To monitor the different constructs of structural progression, we recently validated 2 magnetic resonance (MR)-based composite scores. First, the cumulative cartilage damage score represents hyaline cartilage damage throughout the knee, relates to radiographic severity, and reflects the damage attributable to KOA over the

Table. Disease Activity is Associated with Knee Replacement Over the Subsequent 9 Years in Univariate Analyses

Variable	No Knee Replacement (REFERENCE) mean (SD)	Knee Replacement mean (SD)	Odds Ratio (95% CI) OR per SD
Primary Analysis: All Groups	**n = 355**	**n = 19**	
Baseline Cumulative Damage (SD = 3.65)	0.02 (3.62)	-0.34 (4.29)	0.91 (0.58 to 1.42)
Baseline Disease Activity (SD = 2.71)	-0.13 (2.24)	1.98 (6.95)	**1.47 (1.11 to 1.95)**
1-Year Change Cumulative Damage (SD = 0.61)	0.29 (0.58)	0.33 (0.99)	1.07 (0.69 to 1.66)
1-Year Change Disease Activity (SD = 4.61)	0.71 (3.16)	4.81 (14.81)	**1.51 (1.08 to 2.1)**
Sensitivity Analysis: Only AKOA Group	**n = 101**	**n = 18**	
Baseline Cumulative Damage (SD = 3.89)	0.01 (3.85)	-0.65 (4.19)	0.85 (0.52 to 1.38)
Baseline Disease Activity (SD = 3.82)	0.18 (2.83)	2.12 (7.13)	1.44 (0.96 to 2.16)
1-Year Change Cumulative Damage (SD = 0.79)	0.47 (0.74)	0.35 (1.01)	0.84 (0.49 to 1.46)
1-Year Change Disease Activity (SD = 7.31)	1.51 (4.53)	5.08 (15.19)	1.45 (0.93 to 2.25)

Note: SD = standard deviation, OR = odds ratio, AKOA = accelerated knee osteoarthritis

course of the disease. Secondly, the disease activity score is a composite of BMLs and effusion-synovitis volumes that relates to knee pain and reflects a patient's current state of disease and symptoms. It is unknown if these composite scores predict poor clinical outcomes (e.g., knee replacement). Hence, we assessed adults without radiographic KOA to determine if baseline and 1-year change in cumulative cartilage damage or disease activity predicted knee replacement over the subsequent 9 years.

Methods: We performed a secondary analysis using existing MR-based data from a sex-matched nested case-control study of 3 groups from the Osteoarthritis Initiative without radiographic KOA at baseline (Kellgren-Lawrence (KL)< 2): 1) accelerated KOA: developed KL 3 or 4 within 48 months; 2) typical KOA: increase in KL grade within 48 months; 3) no KOA: no change in KL grade within 48 months. We quantified tibiofemoral cartilage damage, BML volume, and effusion-synovitis volume with semi-automated programs. All MR-based measures were normalized to bone width and standardized, so all measurements were on the same scale. The cumulative cartilage damage score was the sum of standardized cartilage damage for the medial and lateral tibia and femur. The disease activity score was the sum of the standardized volumes of effusion-synovitis (single volumetric measure) and BML (4 locations: medial and lateral tibia and femur). The outcome was knee replacement (partial or total) that was reported or observed between the 1- and 9-year follow-up (>96% adjudicated). For the primary analyses we combined the 3 groups and used logistic regression models to assess if baseline or 1-year change in cumulative cartilage damage or disease activity predicted knee replacement. We performed a sensitivity analysis limited to those who developed accelerated KOA.

Results: The groups were mostly female (63%) and overweight, 33% reported frequent knee pain within a year of baseline, 23% developed radiographic KOA during the first year (KL >1), and 19 people received a knee replacement between the 1- and 9-year follow-up. Greater baseline and 1-year change in disease activity, but not cumulative cartilage damage, was statistically associated with greater chance of receiving a knee replacement (Table). These findings were consistent among adults who developed accelerated KOA.

Conclusion: Prior to the onset of radiographic KOA, disease activity was associated with a knee replacement over the subsequent 9 years. This supports the construct validity of disease activity, which relates to knees symptoms that are the main reason a person would receive a knee replacement.

Sarcopenia and the Likelihood of Incident Knee Osteoarthritis and Knee Pain Among Older Adults in the Health ABC Study

James Andrews,[1] Laura Gold,[1] Michael Nevitt,[2] Patrick Heagerty,[1] and Peggy Cawthon[3], [1]University of Washington, Seattle, [2]University of California at San Francisco, San Francisco, CA, [3]University of California San Francisco, San Francisco

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) disproportionately affects older adults. Sarcopenia, or reduced muscle mass and strength, is strongly associated with reduced physical function and poor clinical outcomes among older adults. Prior studies of knee OA and sarcopenia used varied measures of muscle mass and strength, and results are conflicting. We tested whether two components of sarcopenia, lean mass and muscle strength, are associated with increased risk of incident knee OA and knee pain among older adults.

Methods: Data derived from the first 6 annual assessments of the Health ABC Study, a study of body composition and physical function in community dwelling adults aged 70-79 years. At baseline, appendicular lean mass (ALM) was measured by whole-body dual energy x-ray absorptiometry and grip strength by hand-held dynamometry. Incident OA by year 5 of follow-up was defined by participants' report A) that a doctor told them that they have osteoarthritis or degenerative arthritis of the knee, AND B) of having knee pain most days of the last month OR lasting >1 month in the past 12 months. Separate logistic regression analyses modeled the relationship of low ALM (low vs not low) (men < 19.75kg, women < 15.02kg[1]); and low grip strength (low vs not low) (men < 26kg, women < 16kg[1]) with the development of 1) incident knee OA and 2) incident knee pain (defined per B) above) over follow-up, adjusting for gender, race, baseline age, and baseline BMI. Participants who were lost or died prior to the end of follow-up were considered as not having developed the outcome, and those with the outcome at baseline were excluded. Secondary analyses modeled relationships of ALM and grip strength as continuous measures with the odds (per standard deviation (SD) decrement in exposure variable) of incident knee OA and knee pain.

Results: Table 1 presents baseline characteristics (n=2182). Forty-one (3.7%) and 300 (26.9%) men, and 94 (4.3%) and 367 (16.8%) women developed incident knee OA and knee pain, respectively. Neither low ALM (compared to not low ALM) nor low grip strength (compared to not low grip strength) was significantly associated with incident knee OA or incident knee pain. However, each SD decrement in grip strength was statistically significantly associated with increased likelihood of knee pain (OR per SD: 1.18, 95%CI: 1.03-1.35), Table 2); but the association between grip strength (as a continuous variable) and knee OA did not reach significance. ALM (as a continuous variable) was not significantly associated with either knee OA or knee pain.

Conclusion: Our findings suggest that weaker grip strength may be associated with development of incident knee pain, but not incident knee OA, in older adults. That those with low grip strength (compared to those without low grip strength) were not statistically more likely to develop incident knee pain suggests that published grip strength cut-points may be inadequate to identify older adults at increased risk of developing knee pain. Those with low ALM (compared to those without low ALM) were not statistically more likely to develop either incident knee OA or knee pain. Grip strength may, thus, be a useful tool to identify older adults at increased risk of knee pain.

Table 1: Participant Baseline Characteristics (n=2182)	
Age, years	73.6 ± 2.8
Female, n (%)	1067 (48.9%)
White, n (%)	1295 (59.3%)
BMI, kg/m^2	26.8 ± 4.5
ALM, kg	20.1 ± 5.0
Grip Strength, kg	30.5 ± 10.5
Low ALM[1], n (%)	547 (25.1%)
Low Grip Strength[1], n (%)	145 (6.6%)

All values are mean SD unless otherwise specified.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To quantify associations between baseline and change in computer-assisted hip quantitative joint space width (qJSW) with incident radiographic (rHOA) or symptomatic (sxHOA) hip OA.

Methods: The Johnston County OA Project (JoCoOA) is a longitudinal study of African American and white men and women. We analyzed individuals with anteroposterior pelvis x-rays from baseline and 3 follow up timepoints, approximately 6 years apart. Per protocol, women < 50 years did not have pelvis radiography. An expert musculoskeletal radiologist (JBR) assigned all hips a Kellgren-Lawrence grade (KLG). At all timepoints, participants reported presence of hip symptoms (On most days, do you have pain, aching, or stiffness in your (right, left) hip?"). Incident rHOA was KLG ≥ 2 at follow up, while incident sxHOA required both rHOA and symptoms in the same hip, among those without baseline rHOA or sxHOA, respectively. An independent reader (JD), blinded to all other data, measured qJSW (at 50 degrees, **Figure 1**) using a previously validated method. Analyses were in two steps. First, we used latent class modeling to identify clusters of hips with different patterns of qJSW change from baseline. Second, incident rHOA and sxHOA were modelled using logistic regression with generalized estimating equations to account for correlated hips; the independent relationship of baseline qJSW and identified cluster membership by sex with each outcome

Figure 1. Fixed location qJSW measurements

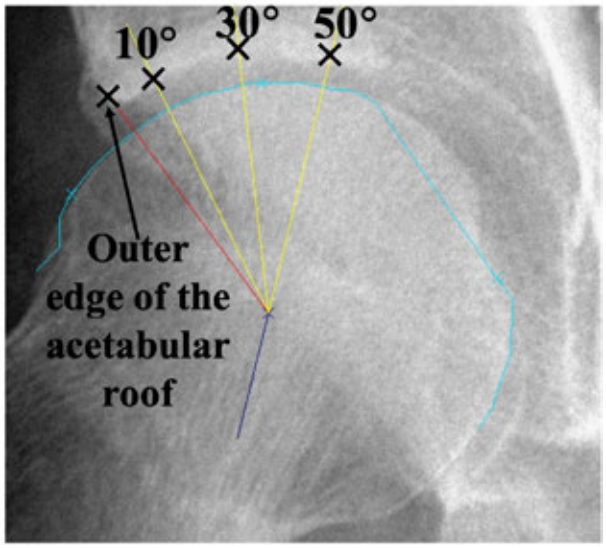

Figure 2. Identified groups and patterns of quantitative joint space width (qJSW) change over time among women (A) and men (B). Results are for the radiographic hip osteoarthritis (HOA) analytic samples (similar results were seen for the symptomatic HOA samples).

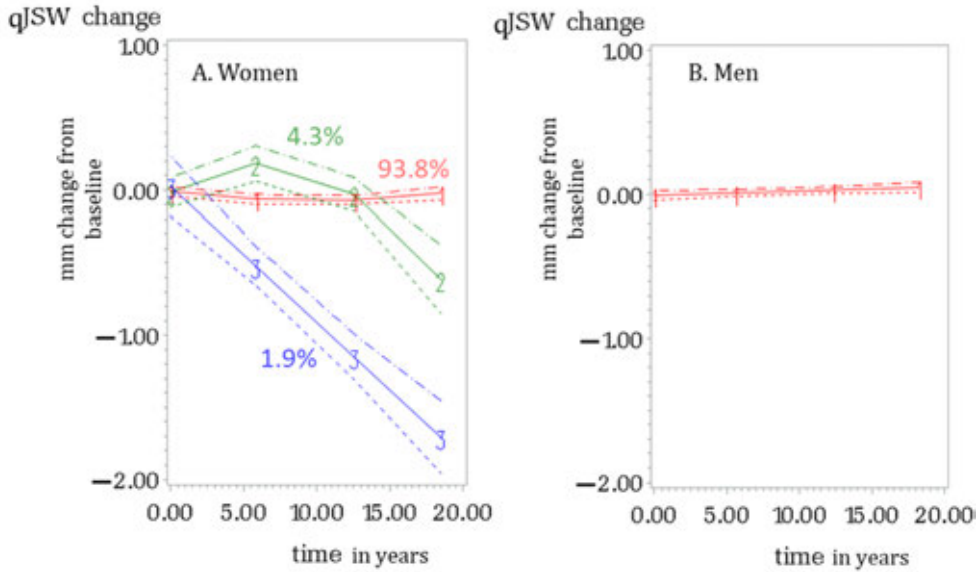

was estimated using adjusted (for age, race, education, height, body mass index [BMI], weight gain or loss [5% BMI change], and hip injury) odds ratios and 95% confidence intervals.

Results: Of 577 participants with 1154 hips meeting above criteria, 397 participants and 784 hips remained (59% women, 24% African American, average age 56 years) after excluding those missing hip films or with hip replacement. Baseline BMI was 28.6 (5.1) kg/m^2; 52% experienced >5% BMI increase over follow-up.

Among women, after exclusions for missing qJSW at 50 degrees and prevalent HOA, 360 and 410 hips were included in the incidence analysis of rHOA and sxHOA, resulting in an overall incidence of 25% and 13%, respectively. Three

Table 1. Adjusted* odds ratios and 95% confidence intervals [aOR (95% CI)] for the association of baseline quantitative joint space width (qJSW) and non-constant change in qJSW over time with incident radiographic (rHOA) or symptomatic hip osteoarthritis (sxHOA), separately for women (top) and men (bottom).

Sex	Main effect(s) for each model	Incident rHOA (H=number of hips in model)	Incident sxHOA (H=number of hips in model)
Women	*Overall effect*	*(H=360)*	*(H=410)*
	Loss of qJSW over time group (vs constant qJSW over time group)	**3.56 (1.73, 7.32)**	**3.28 (1.01, 10.7)**
	1 mm narrower (1SD) at baseline	**2.04 (1.43, 2.91)**	**2.71 (1.70, 4.33)**
Men	*Overall effect*	*(H=261)*	*(H=297)*
	1 mm narrower (1SD) at baseline	**1.63 (1.11, 2.37)**	**1.61 (1.04, 2.52)**

*Adjusted for: baseline age, race, education, BMI, height, 5% weight loss over time, any hip injury over time;
BOLD=statistically significant

patterns were seen in qJSW change over time; a constant qJSW group (**Figure 2.A**=1 red; n=394 [94%]), and two groups with loss over time (**Figure 2.A**=2 green and 3 blue; n=26 [6%]), combined for analysis. Narrower baseline qJSW and loss of qJSW over time were independently associated with increased odds of incident rHOA and sxHOA (**Table 1**).

Among men, after exclusions for missing qJSW at 50 degrees and prevalent HOA, 261 and 297 hips were included in the incidence analysis of rHOA and sxHOA, resulting in an overall incidence of rHOA and sxHOA of 21% and 10%, respectively. Men had only one qJSW pattern--constant over time (**Figure 2.B** red). In adjusted models, narrower qJSW at baseline was associated with increased odds of incident rHOA and sxHOA (**Table 1**).

Conclusion: Narrower qJSW at baseline predicts incident rHOA and sxHOA in both men and women, although more strongly in women; qJSW loss over time predicted incident HOA only in women. QJSW assessment may identify individuals at increased risk for HOA, allowing for earlier intervention to try to reduce HOA progression.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Erosive hand osteoarthritis (EOA) is often considered a more severe form of hand OA. However, more data are needed regarding this phenotype to conclude if represents a different subset of hand OA or a different degree of affectation of the same disease. The purpose of this work is to compare the clinical pattern of patients with EOA with those that do not show this phenotype

Methods: This cross-sectional study was conducted in the Prospective Cohort of Osteoarthritis A Coruna (PROCOAC). The cohort consists of 1136 subjects, of which 877 were diagnosed of hand OA following ACR criteria. After reviewing the x-rays, we split the cohort into patients with and without EOA, and subsequently analyzed both clinical and demographic data within each group, together with the assessment of the AUStralian CANadian Osteoarthritis Hand (AUSCAN) index. The study consisted in a Univariate analysis comparing different variables between both groups, followed by a stepwise regression logistic regression analysis.

Results: The mean age of the cohort was 63.61±9.03 years and consisted of 718 females and 159 males. Of the 877 OA patients, 167 had EOA. The Univariate analysis revealed that patients with EOA were younger (59.85±7.95 vs 64.43±9.04;p< 0.001), smokers (p=0.008), with lower BMI (p=0.007), increased inflammatory episodes (p< 0.001), more presence of nodal OA (p=0.001), with family history or suffering psoriasis (p=0.046) and less number of damaged joints (p< 0.001), specially the knee (p< 0.001). In addition, despite the higher number of females suffering from hand OA, no significant differences between erosive and non-erosive phenotypes in terms of gender were detected.

The regression model (Table 1) confirmed the strong association of age (OR=0.964;95%CI=0.939-0.991;p=0.008), inflammatory episodes (OR=4.367;95%CI=2.489-7.663;p< 0.001) and increased prevalence of nodal OA (OR=2.249;95%CI=1.159-4.363;p=0.017) with the EOA. Interestingly, the model also showed MetS as a risk factor too, specifically over 64 years (OR=2.194;95%CI=1.249-3.854;p=0.006), with the tryglicerides content as the metabolic component most involved in this association (p=0.082). In addition, EOA patients show a lower prevalence of knee OA (OR=0.437;95%CI=0.259-0.739;p=0.002) and to carry this phenotype at baseline does not confer a significant increased risk for radiographic knee OA progression over time (p=0.515). The AUSCAN score showed significantly higher mean values in patients with the EOA: pain (58.66±28.78 vs 41.83±32.26; p< 0.001), function (56.19±27.44 vs 39.22±30.01; p< 0.001) and stiffness (55.47±32.34 vs 39.28±36.41;p=0.001).

Conclusion: EOA is associated with more inflammation in younger patients, and worst AUSCAN score. Contrarily to the non-erosive phenotype, the presence of erosions associates with a lower occurrence of other forms of OA,

Table 1. Logistic regression analysis describing all the variables influencing the erosive hand OA phenotype in the Spanish cohort PROCOAC

Variable	B	Adjusted OR	95% CI	p-value
Gender (female)	-0.250	0.779	0.423 – 1.433	0.422

High Molecular Weight Intraarticular Hyaluronic Acid for the Treatment of Knee Osteoarthritis: A Network Meta-Analysis

Charles Hummer,[1] Felix Angst,[2] Emil Schemitsch,[3] Craig Whittington,[4] Colleen Manitt,[5] and **Wilson Ngai**[6], [1]Premier Orthopaedics and Sports Medicine, Media, PA, [2]Research Department, Rehabilitation Clinic ('RehaClinic'), Bad Zurzach, Switzerland, [3]London Health Sciences Centre, London, Ontario, Canada, [4]Doctor Evidence, Santa Monica, CA, [5]International Centre for Professional Development in Health and Medicine, Quebec, Canada, [6]Sanofi, U.S. Medical Affairs, Bridgewater

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2013 American Academy of Orthopaedic Surgeons (AAOS) clinical practice guideline (CPG) on the treatment of knee OA made a strong recommendation not in favor of the use of intraarticular hyaluronic acid (IAHA) because, though statistically significant, improvement in pain did not meet the threshold for a minimal clinically important difference (MCID). The AAOS CPG, and publications since, suggest there may be clinically important differences in the effectiveness of high vs. low molecular weight (MW) IAHA. We aimed to update the evidence-base since the guideline publication and use a network meta-analysis (NMA) to incorporate both direct and indirect evidence on this issue.

Methods: MEDLINE, Embase and CENTRAL were systematically searched to identify RCTs evaluating non-surgical interventions for people with knee OA. Trials were selected based on the AAOS CPG eligibility criteria. Effect sizes from each trial were computed using a pain measure hierarchy and longest follow up. The mean difference between intervention and comparator was converted to the standardized mean difference (SMD) before incorporating into the NMA using a random-effects Bayesian framework. To assess the impact of MW, high MW (HMW; defined as at least 6000 kDa) and low MW (LMW; < 750 kDa) nodes were created. Studies of IAHA which fell outside this definition were excluded. Sensitivity analyses were used to examine the robustness of the findings.

Results: The base-case analysis included a total of 14 RCTs (N=2,793), creating a network with 5 therapeutic nodes (Figure 1). Trials on NSAIDs, acetaminophen, and oral opioids were excluded as they lacked network connectivity. The results indicated that compared to IA placebo, HMW IAHA had a statistically significant effect on pain, which was "possibly clinically significant" according to the AAOS definition (SMD -0.57 [95% Credible Interval: -1.0, -0.11]) (Figure 2). In contrast, LMW IAHA resulted in a small, non-statistically significant improvement in pain relative to IA placebo (-0.23 [-0.67, 0.20]). The Bayesian model showed that HMW IAHA had the highest probability (71%) of ranking 1st with regard to improvement in pain score. Back-transforming the SMD to the WOMAC 0-100 pain scale indicated a 14.65 [13.93, 15.62] point improvement over IA placebo, substantially better than the AAOS minimum clinically important improvement threshold of 8.3. Sensitivity analyses confirmed these findings were robust.

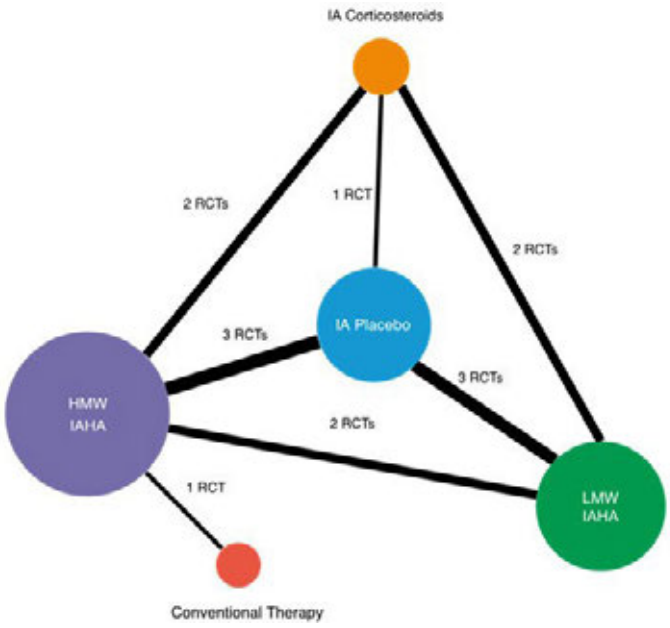

Figure 1. Network of trials comparing improvement in pain scores using nonoperative treatment for patients with knee osteoarthritis. The size of the nodes is proportional to the total number of participants and the width of the lines is proportional to the number of trials comparing every pair of treatments.

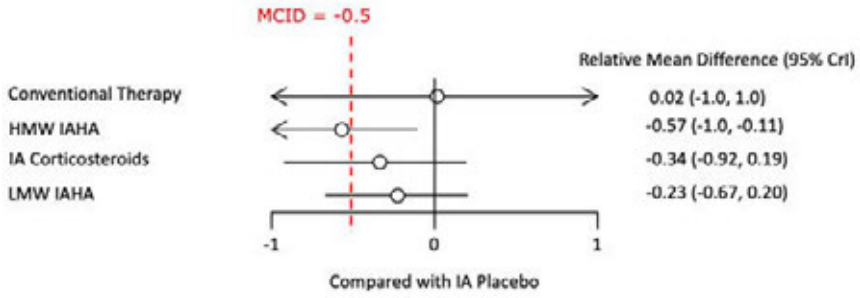

Figure 2. Relative standardized mean differences for each intervention compared to IA placebo based on network meta-analysis.

Conclusion: Based on direct and indirect evidence, stratified data of HMW IAHA (≥6000 kDa) revealed a pooled effect in pain relief which exceeded even the most conservative threshold for a MCID. Meaning, on average, the improvement can be subjectively perceived by the affected persons under therapy. In contrast, the pooled effect of LMW IAHA (< 750 kDa) is neither statistically significant nor clinically relevant. Amalgamation of data of LMW and HMW IAHA may have blurred the benefits of IAHA, which have led to negative therapy recommendations in the past. Differentiation according to the molecular weight offers refined insight into the IAHA treatment. The sub class of HMW IAHA's should be further evaluated in new focused RCTs.

Natural Disease Progression in Hand Osteoarthritis: Results from a Belgian Ten-years Prospective Cohort Study

Lisa Pardaens,[1] Tine Vanhaverbeke,[1] Jordy Vandercruyssen,[1] and **Ruth Wittoek**[2], [1]Ghent University, Gent, Belgium, [2]Ghent University Hospital, Gent University, Gent, Belgium

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Limited evidence is available about natural disease progression in hand osteoarthritis (HOA). A previous study of the Ghent HOA cohort showed a positive association between soft tissue swelling, tenderness upon pressure and pain with radiographic progression (1). The aim of the study is to study natural radiographic and clinical disease progression in HOA after 10 years of follow up.

Methods: From 2007 to 2009 (baseline, T0), 270 patients with HOA were included in a Belgian HOA register. On average, the disease was already ongoing for > 12 years at baseline. A first follow up visit (T1) occurred after approximately 5 years (n = 154) and a 2nd (T2) after 10 years (n= 106). Presence of tender and swollen joints was assessed. Grip strength was measured. FIHOA and AUSCAN were completed. Pain was scored on visual analogue scale (VAS pain, 0 -100). Radiographs of hands were taken and scored according to the scoring system by Verbruggen and Veys (2). Patients were categorized into 'non-significant radiographic progression', 'erosive ('E') progression only', "E' progression and remodeling ('R') occurring simultaneously' and "R' progression only'. Changes from N to S were considered non relevant. Longitudinal analyses were performed for patient related outcome measures from follow up (T1 or T2) to baseline (T0).

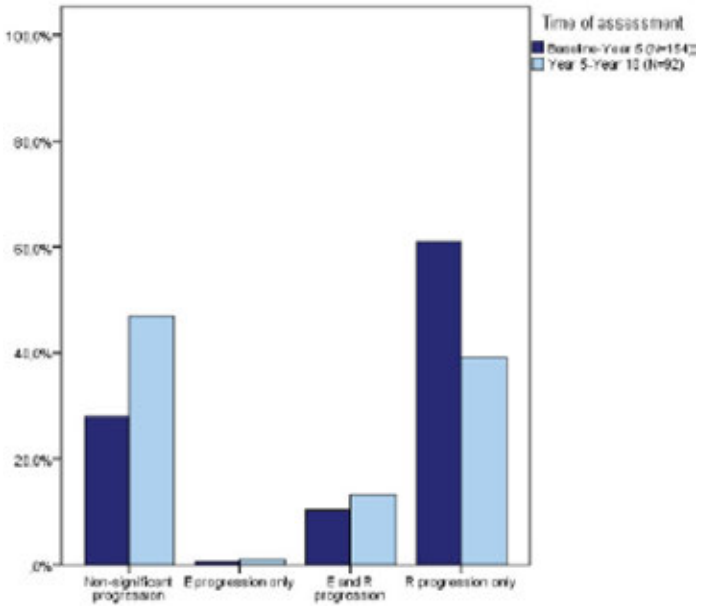

figure 1 Radiographic progression in HOA from baseline to T1 and T1 to T2

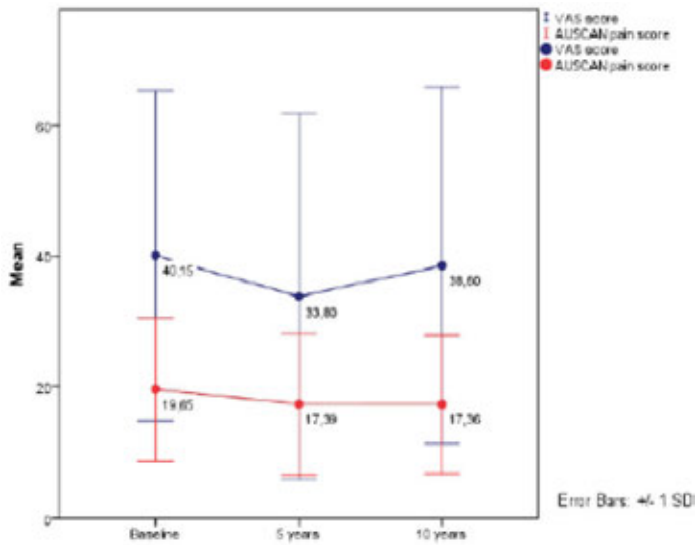

Figure 2 Longitudinal changes in functional status (FIHOA and AUSCAN function)

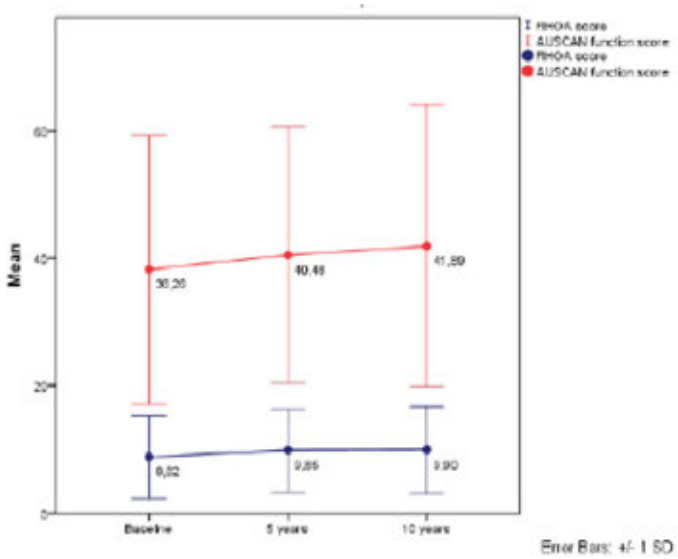

Figure 3 Longitudinal changes in pain (VAS pain and AUSCAN pain)

Results: After a mean follow-up of 9.7 years at T2, the majority of the patients (73.3%) showed any radiographic progression compared to baseline (figure 1). Exclusive 'E' progression is rare (0.6% from T1 to T0, and 1.1% from T2 to T1). Any 'E and R progression' is seen in 11% and 14.1%, resp. from T1 to T0, and T2 to T1. 'R' progression only is seen more often from T1 to T0 (61.1%) compared to T2 to T1 (39.2%)($p< 0.05$). FIHOA and AUSCAN, increased numerically over time and statistically significant after visit T2 ($p = 0.035$ for AUSCAN and $p = 0.017$ for FIHOA) (figure 2). Pain (measured by VAS and AUSCAN pain subscale) did not consistently nor significantly change over time (figure 3).After a mean follow-up of 9.7 years at T2, the majority of the patients (73.3%) showed any radiographic progression compared to baseline (figure 1). Exclusive 'E' progression is rare (0.6% from T1 to T0, and 1.1% from T2 to T1). Any 'E and R progression' is seen in 11% and 14.1%, resp. from T1 to T0, and T2 to T1. 'R' progression only is seen more often from T1 to T0 (61.1%) compared to T2 to T1 (39.2%)($p< 0.05$). FIHOA and AUSCAN, increased numerically over time and statistically significant after visit T2 ($p = 0.035$ for AUSCAN and $p = 0017$ for FIHOA) (figure 2). Pain (measured by VAS and AUSCAN pain subscale) did not consistently nor significantly change over time (figure 3).

Conclusion: HOA is a disease where significant radiographic progression is seen over time, with erosive progression being relatively rare and remodeling occurring frequently. While levels of pain remain similar over time, functional status does decrease. Future treatment goals in HOA should focus on preserving the functional status of HOA patients. Research is required to confirm this pattern of disease progression in a 'early' HOA cohort and amongst several subtypes of HOA.

Relation of MRI-detected Structural Damage in the Knee to Anterior Knee Pain: The MOST Study

Joshua Stefanik,[1] Tuhina Neogi,[2] Mohamed Jarraya,[3] Ali Guermazi,[4] Irina Tolstykh,[5] John Lynch,[6] James Torner,[7] Cora Lewis,[8] and Erin Macri[9], [1]Northeastern University, Boston, [2]Boston University School of Medicine, Boston, MA, [3]Mercy Catholic Medical Center, Darby, [4]Boston Medical Center, Boston, [5]UCSF, San Francisco, [6]University of California at San Francisco, San Francisco, CA, [7]University of Iowa at Iowa City, Iowa City, [8]UAB, Birmingham, [9]Erasmus MC, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Discordance between knee osteoarthritis (OA) and knee pain is common yet not well understood. Specifically, anterior knee pain (AKP) is widely held to be associated with patellofemoral (PF) joint structural damage. However, little is known about the relation of MRI-detected structural damage to AKP. A key challenge to identifying determinants of AKP relates to the high interpersonal variability in pain perception caused by psychosocial or central mechanisms, which can be difficult to account for with traditional methods. To address this challenge, we compared within-person, between-knee MRI-detected structural damage in individuals with unilateral frequent isolated AKP.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH-funded cohort of individuals with or at risk for knee OA. Individuals were eligible if, in one knee only, they (i) reported pain, aching, or stiffness on most days of the 30 days prior to the study visit; and (ii) completed a knee pain map that indicated pain was isolated to the anterior knee (i.e., AKP). Frequent knee pain was absent in the contralateral knee. We used data from the 60-month visit, the first visit at which the knee pain map was available. If individuals were not eligible at 60-months but were at 84-months, we included eligible individuals from the 84-month visit. This within-person, knee-matched approach removes the effects of person-level characteristics that could otherwise explain pain variability between individuals (psychosocial factors, BMI, sex, genetics, etc.). 4 PF subregions (medial/lateral patella and trochlea) and 10 tibiofemoral subregions were scored semi-quantitatively using the WORMS method on bilateral MRIs. We assessed medial and lateral PF and TF compartments separately and dichotomized scores into: full-thickness cartilage damage, any bone marrow lesions (BMLs), small osteophytes, any infrapatellar synovitis, and at least moderate whole knee joint effusion. We

Table. Association between PFOA and TFOA features and frequent isolated anterior knee pain				
	Painful knee prevalence	Contralateral knee prevalence	Odds Ratio (95% CI)	p
Tibiofemoral joint				
Full thickness TF cartilage damage				
Medial	23/71 (32%)	19/71 (27%)	1.4 (0.6, 3.4)	0.40
Lateral	26/71 (37%)	20/71 (28%)	2.0 (0.8, 5.3)	0.17
Any TF BMLs				
Medial	25/71 (35%)	23/71 (32%)	1.2 (0.5, 2.5)	0.70
Lateral	17/71 (24%)	9/71 (13%)	3.0 (0.97, 9.3)	0.06
Def TF osteophytes				
Medial	57/71 (80%)	54/71 (76%)	1.5 (0.5, 4.2)	0.44
Lateral	33/71 (46%)	33/70 (47%)	0.9 (0.4, 2.1)	0.83
Patellofemoral joint				
Full thickness PF cartilage damage				
Medial	28/71 (39%)	28/71 (39%)	1.0 (0.5, 2.2)	1.00
Lateral	26/71 (37%)	26/71 (37%)	1.0 (0.4, 2.9)	1.00
Any PF BMLs				
Medial	29/71 (41%)	32/71 (45%)	0.8 (0.4, 1.7)	0.55
Lateral	34/71 (48%)	34/71 (48%)	1.0 (0.5, 2.2)	1.00
Def PF osteophytes				
Medial	35/71 (49%)	31/71 (44%)	1.4 (0.6, 3.2)	0.42
Lateral	35/71 (49%)	19/71 (27%)	5.0 (1.7, 14.6)	**<0.01**
Infrapatellar synovitis	21/69 (30%)	12/71 (17%)	2.8 (1.0, 7.8)	**0.05**
Moderate whole knee effusion	20/71 (28%)	9/71 (13%)	4.7 (1.3, 16.2)	**0.02**

evaluated the association between MRI-detected structural damage and the presence of AKP using conditional logistic regression.

Results: 71 individuals met eligibility criteria and had bilateral MRIs (mean [SD] age and BMI 69 [8] and 30.2 [5.3], respectively; 47 [66%] women). Lateral PF osteophytes were most strongly associated with AKP, followed by whole knee effusion and infrapatellar synovitis (see Table). PF cartilage damage and BMLs were not associated with AKP. There was no relation between TF MRI structural damage and AKP.

Conclusion: In individuals with unilateral frequent isolated AKP, odds of having AKP were higher in the presence of lateral PF osteophytes, joint effusion, and synovitis. AKP was not associated with PF cartilage or BMLs or any TF structural damage. While this within-person knee-matched design may limit generalizability, it does contribute to our understanding of which pathologic features of PFOA may contribute to AKP.

Relation of Intra-Articular Knee Mineralization on CT to Knee Pain in People with or at Risk of Knee Osteoarthritis

Tuhina Neogi,[1] John Lynch,[2] Mohamed Jarraya,[3] David Felson,[4] Na Wang,[1] Michael Nevitt,[2] James Torner,[5] Beth Lewis,[6] and Ali Guermazi[1], [1]Boston University School of Medicine, Boston, MA, [2]University of California at San Francisco, San Francisco, CA, [3]Mercy Catholic Medical Center, Darby, [4]Boston University School of Medicine, Department of Rheumatology, Boston, [5]University of Iowa at Iowa City, Iowa City, [6]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Table: Relation of i.a. mineralization on knee CT to knee pain severity, frequent knee pain, and knee pain patterns

	WOMAC pain score beta **(95%CI)	Frequent knee pain OR (95% CI)	ICOAP Pain Pattern 3-level* OR (95% CI)
Any mineralization	0.11 (-0.28, 0.52)	1.11 (0.81, 1.53)	0.85 (0.59, 1.21)
Any Cartilage mineralization	0.12 (-0.30, 0.56)	1.20 (0.83, 1.74)	0.94 (0.52, 1.49)
Any meniscus mineralization	0.09 (-0.31, 0.50)	1.23 (0.87, 1.75)	0.87 (0.59, 1.28)

*ICOAP 3-level pain pattern: Constant+/- intermittent, intermittent only, or none
**per unit increase in WOMAC pain (0-20 scale) related to i.a. mineralization.

Background/Purpose: Intra-articular (i.a.) calcium crystal deposition is common in knee osteoarthritis (OA), particularly in end-stage disease. It is possible that low-grade inflammation related to crystals may contribute to knee pain, including pain fluctuation. However, in prior studies, results on this matter have been conflicting. Detection of chondrocalcinosis has relied on radiographs to date, which has low sensitivity, and this may have limited the ability to adequately assess the relation of chondrocalcinosis to knee pain. We used CT to identify i.a. mineralization to overcome this limitation.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort study of persons with or at risk of knee OA. Participants from the existing cohort underwent bilateral knee CT scans at the 144-months study visit (the first visit at which CTs were acquired), and completed standardized questionnaires to ascertain presence of frequent knee pain, knee pain severity using WOMAC, and patterns of knee pain using ICOAP (Intermittent and Constant OA Pain). A musculoskeletal radiologist scored multiplanar CT images (axial native images with coronal and sagittal 2D reformats) using a new CT scoring system that has high reliability, the Boston University Calcium Knee Score (BUCKS). The degree of mineralization in each of WORMS-defined subregions of cartilage and menisci was assessed using an ordinal score (0-3). Ligament and joint capsule mineralization were scored as present or absent. We evaluated the relation of presence of i.a. mineralization to WOMAC knee pain severity using linear regression, to presence of frequent knee pain with logistic regression, and to constant +/- intermittent pain versus intermittent pain only or no pain using ordinal logistic regression. Analyses were conducted with GEE and adjusted for age, sex, BMI, race, and KL grade.

Results: There were 633 persons (1261 knees) included (mean age 72, 57% female, mean BMI 29.9). Overall, 23.3% of knees had any i.a. mineralization; 16.7% had cartilage mineralization and 19.5% had meniscal mineralization. In terms of pain, 33% had frequent knee pain, 6.2% had constant +/- intermittent pain, 23.9% had intermittent pain only, and 46.2% had unpredictable knee pain that comes on without warning. Presence of i.a. mineralization anywhere in the joint, in the cartilage, or in the meniscus were not associated with WOMAC pain severity, frequent knee pain, or ICOAP pain pattern (i.e., constant +/- intermittent pain versus intermittent or no pain) (**Table**).

Conclusion: Despite greater sensitivity with CT, we did not find an association between i.a. mineralization and knee pain in these cross-sectional analyses. We were not able to differentiate type of crystal at this stage. Younger patients at earlier stages of disease may be a more relevant sample to study. Nonetheless, these cross-sectional analyses indicate that deposits of i.a. mineralization appear to be asymptomatic, though we cannot rule out subclinical inflammatory episodes not captured with these CT images that may contribute to symptoms.

Severe	0.38	-0.13-0.88	

*Results of linear mixed regression model adjusting for repeated measures over time, age, BMI, sub-cohort, baseline radiographic OA severity, and contralateral knee score.

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis. Knee OA is often accompanied by a knee flexion contracture (FC), but the impact of FC on OA-related outcomes is not well-described. We evaluated whether the presence and/or severity of a knee FC were risk factors for increased OA incidence, clinical outcomes, radiographic progression and the need for and time to total knee arthroplasty (TKA).

Methods: The cohort design was based on 9-year longitudinal data from the osteoarthritis initiative (OAI) database. Participants (n=4,796) were divided into 3 sub-cohorts: at-risk of knee OA (n=3284), radiographically-established knee OA (n=1390), and low-risk controls (n=122). We categorized knee FCs as none, mild, moderate or severe, based on maximum knee extension at enrollment. The incidence of radiographic knee OA was based on those with Kellgren and Lawrence (KL) score < 2 at enrolment, but ≥2 on follow-up xray. Clinical outcomes (pain, stiffness and function) were evaluated using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scale. KL radiographic scores, and time to TKA were extracted from the database. Effect size of FC was evaluated using a linear mixed regression model.

Results: Participants with knee FC without radiographic OA at enrolment did not have increased incidence of radiographic OA over the duration of data collection. The WOMAC pain, stiffness and function scores were worse in the FC group in a FC severity-dependent manner at nearly all timepoints (Figure 1). Effect estimates were significant for all 3 outcomes comparing FC vs no FC (0.17 [95% C.I. 0.12-0.22]) for pain, 0.12 [95% C.I. 0.09-0.14] for stiffness, 0.64 [95% C.I. 0.48-0.80] for function, all p< 0.001; Table 1). Those with knee FC had higher KL scores across all timepoints (effect size 0.38, p< 0.001, [95% C.I. 0.35-0.41]; Figure 2) with KL scores increasing with worsening FC severity (p< 0.001). Those with FC were more likely to undergo TKA (266/2819 or 9.4% with FC vs 246/5848 or 4.2% without FC, odds ratio 2.4 [95% C.I. 2.0-2.8], p< 0.001; Figure 2). After correcting for demographic variables, cohort, and baseline KL score, FC remained an independent predictor of TKA, in a severity dependent manner (Table 1). A FC was also a risk factor for having a TKA at an earlier timepoint (mean 279 days, p=0.024; Figure 2).

Conclusion: The presence of a knee FC at enrollment was a risk factor for worse clinical outcomes, radiographic progression, need for, and earlier time to TKA. Pain and OA-related structural changes may also lead to knee FC.

Further research using MRI to define the anatomic/structural factors that contribute to FC and the link to OA progression are needed. Early and aggressive treatment of a knee FC may represent a treatment option for improving clinical outcomes and slowing OA progression in knee OA. Longitudinal evaluation of such treatment is needed.

MRI-detected Abnormalities in Prediction Models of Incident Radiographic Knee Osteoarthritis over 10 Years of Follow-up

C. Kent Kwoh,[1] Frank Roemer,[2] Erin Ashbeck,[3] ChengCheng Hu,[1] Edward Bedrick,[1] Leena Sharma,[4] and Ali Guermazi[5], [1]University of Arizona, Tucson, AZ, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]The University of Arizona Arthritis Center, University of Arizona, Tuccson, AZ, Tucson, AL, [4]Northwestern University, Chicago, IL, [5]Boston Medical Center, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: MRI Osteoarthritis Knee Score (MOAKS) is a semi-quantitative scoring system used to assess MRI-detected structural abnormalities including over 100 raw scores representing multiple joint tissues, different ordinal grades and joint subregions or locations. Our objective was to compare 8 different representations of MOAKS in terms of prediction performance for time to incident radiographic OA over 10 years of follow-up.

Methods: We randomly selected 859 OAI participants with at least one knee at risk of developing ROA (i.e., KL 0,1 at baseline). 3T knee MRIs were assessed by expert readers using MOAKS. Radiographs were centrally read for KL grade, with ROA defined as KL³2. The 8 representations of MOAKS included features summarized at the whole knee level, the tibiofemoral and patellafemoral (PF) level, and the medial, lateral, subspinous, and PF level, with either maximum scores or sums for ordinal scores of the same feature/type (e.g., maximum number of BML lesions in a subregion (maxBMLLes]); additionally, raw scores as linear predictors and raw scores with indicators for each category were also included.

For each MOAKS representation, we fit lasso penalized Cox models and selected the penalty parameter that achieved a partial log-likelihood deviance within one standard error of the minimum in 10-fold cross validation. Performance of the optimal regularized model was then evaluated with a .632+ bootstrap estimate of the time-dependent Brier score, a weighted mean squared error for predicted survival probability and observed survival status, as well as area under the time-dependent ROC curve.

Results: A total of 244 knees developed incident ROA over the 10 year follow-up. Prediction error based on the area under the estimated prediction error curve was similar for the 8 representations of MOAKS. Variables selected under 6 of 8 representations of MOAKS are shown in Table 1. Performance and model interpretation for the whole knee maximum score model are shown in Figures 1 and 2. Prediction error increased over the course of follow-up (Figure 1a), with the greatest area under the time-dependent ROC curve achieved at 1 and 2 year follow-up (Figure 1b). The nomogram shows the MOAKS variables selected in the model, with the point values for each score, and the correspondence between the total points from these features out of a maximum

Whole Knee, maximum scores

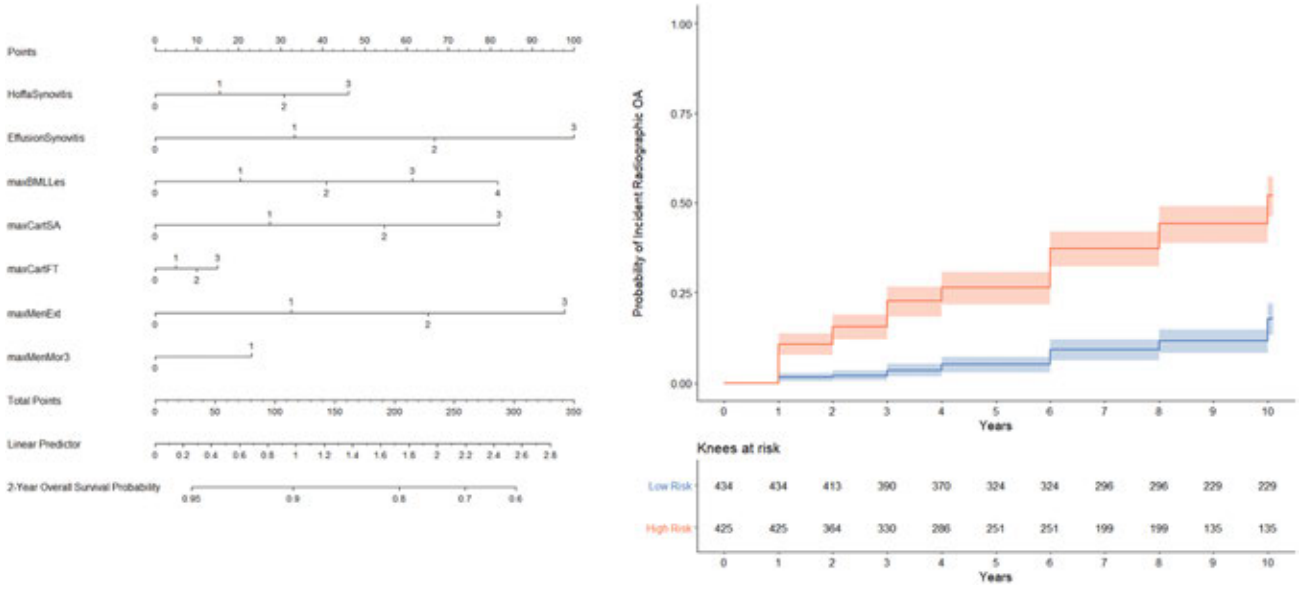
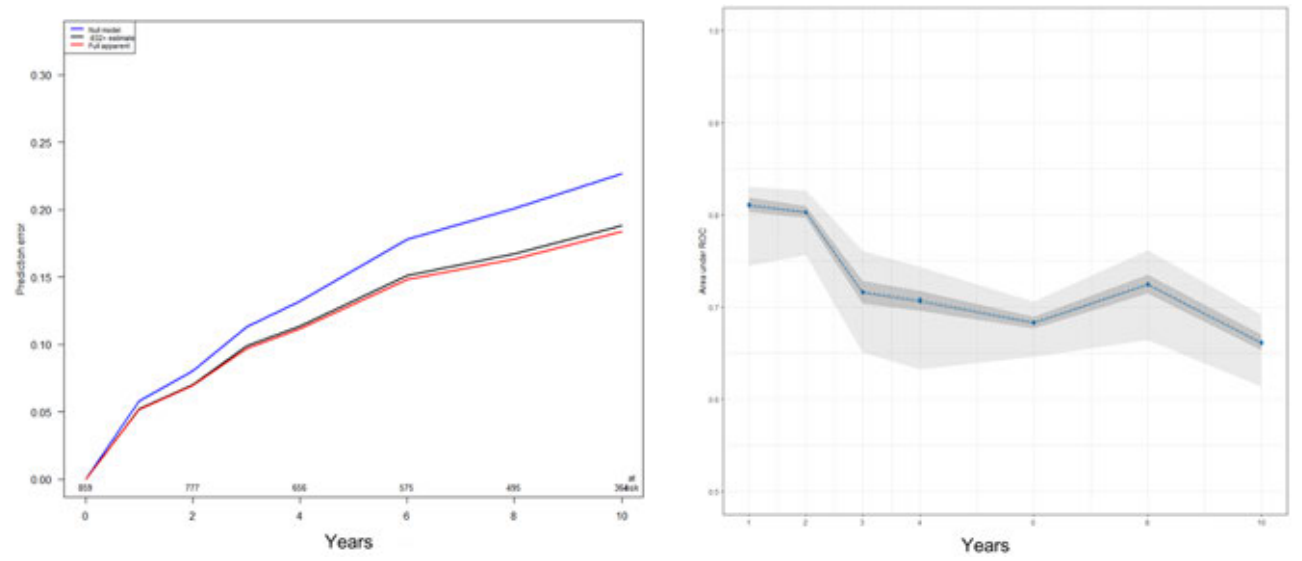
Sum of surface area cartilage damage (medial TF)

Table 1 Selected Feature Scores for 6 of 8 representations of MOAKS

of 350 points and the 2 year probability of survival from ROA (Figure 2a). For example, a total of 260 points from the 7 variables in the whole knee maximum score model corresponds to a .7 probability of not having ROA 2 years later. Estimated probability of ROA over 10 years is shown for knees with risk scores above and below the median total risk score (Figure 2b).

Conclusion: Different representations of MOAKS, whether maintaining granular-level information or summarizing at the whole knee level with maximum scores or sums of scores, have similar prediction performance for





incident ROA. MRI-detected abnormalities provide the greatest discrimination between knees that do and do not develop ROA in the short term (1-2 years), while providing the greatest improvement in prediction over long-term follow-up.

1a Prediction error for whole knee maximum scores model The blue line is the estimated prediction error curve over 10 years based on the Kaplan-Meier survival estimate, without incorporating any MOAKS data The black line is the .632+ bootstrap estimate of prediction error based on the Cox model with MOAKS predictors The red line is the apparent estimate of prediction error (in the full sample) based on the Cox model with MOAKS predictors 1b Area under time-dependent ROC curve for whole knee maximum scores model with bootstrapped 95% confidence bands

2a Nomogram for whole knee maximum scores model 2b Predicted Probability of ROA for low risk and high risk knees based on the whole knee maximum scores model; knees with risk scores below the median are “low risk”, while knees with risk scores above the median are “high risk”.

What Is an Important Difference in Gait Speed in Adults with Knee Osteoarthritis?

Jing Song,[1] David Cella,[2] **Abigail Gilbert**,[3] Rowland Chang,[2] and Dorothy Dunlop[2], [1]Northwestern University Feinberg School of Medicine, Worthington, OH, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

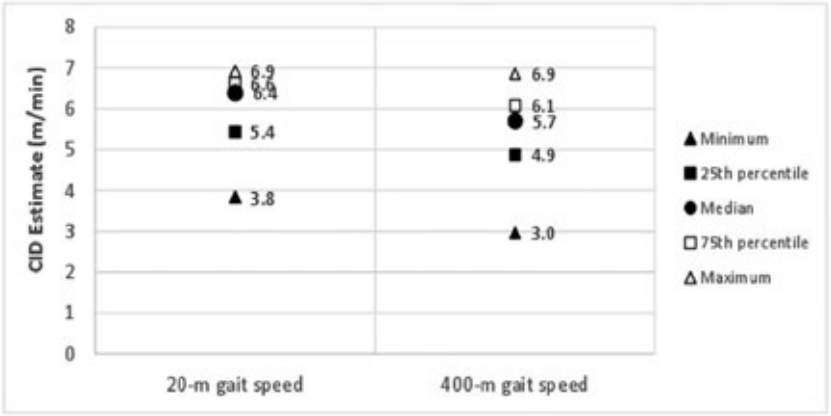
Background/Purpose: Little is known regarding what difference in functional performance measures are clinically significant in individuals with a chronic medical disease. This study examines the important differences in gait speed in adults with knee osteoarthritis.

Table: Baseline characteristics.

	All participants (n=2527)
Age (years), mean (SD)	62.6 (9.0)
Sex (% female)	57.8%
BMI[1] category (%)	
<25 kg/m²	16.6%
Overweight: 25-29.9 kg/m²	38.8%
Obese: >30 kg/m²	44.6%
K/L Grade (%)	
K/L Grade 2	53.6%
K/L Grade 3	35.0%
K/L Grade 4	11.4%
WOMAC function[3], mean (SD)	12.9 (12.7)
SF-12 function[4], mean (SD)	47.7 (9.3)
Chair stand rate (stand/sec)[5], mean (SD)	0.5 (0.1)
20-meter gait speed, mean (SD)	78.7 (12.9)
400-meter gait speed[6], mean (SD)	77.8 (13.0)

1. BMI: Body mass index, n=2523 participants
2. K/L Grade: Kellgren and Lawrence Grade, scale ranges from 0-4 with 0 no radiographic knee OA and 4 most severe radiographic knee OA
3. N=2521 participants. WOMAC physical function: Western Ontario and McMaster Universities Osteoarthritis Index range from 0 (best function) to 68 (most functional limitations)
4. N=2499 participants, SF-12 function: Medical Outcomes Study Short Form 12 Physical Component Summary Scale Score range from 0 (worst function) to 100 (best function)
5. N=2382 participants
6. N=2425 participants

Figure: Summary of usable* anchor-based important difference estimates



* An anchor was considered usable if the correlation between the anchor and gait speed was at least 0.3 and the corresponding effect size was within a plausible range of 0.2-0.8

Methods: Functional performance was objectively measured by gait speed using 20-meter and 400-meter walk tests among adults with radiographic knee osteoarthritis participating in the Osteoarthritis Initiative at baseline and 2 years later. Distribution-based methods were used to frame the range of gait speed likely to be considered important. We then utilized anchor-based methods using chair stand rate and self-reported physical function as anchors to calculate important gait speed differences.

Results: We included 2527 participants with radiographic knee osteoarthritis. Mean age was 62.6 years. Just over half (58%) of participants were female. Most participants were either overweight (39%) or obese (45%). Half (54%) had Kellgren Lawrence (K/L) grade 2 knee OA, 35% had K/L grade 3 knee OA and 11% had K/L grade 4 knee OA. Calculation of the distribution-based estimates resulted in a range from 4.1 to 6.4 meters/minute for 20-meter walk and 2.9 to 6.5 meters/minute for 400-meter walk. Anchor-based estimates ranged from 5.4 to 6.9 meters/minute for 20-meter walk and 3.0 to 6.9 meters/minute for 400-meter walk. Combining distribution-based and anchor-based methods we found the important gait speed difference for 20-meter walk is between 4.1 and 6.9 meters/minute and for 400-meter walk is between 2.9 and 6.9 meters/minute.

Conclusion: Our results found the important difference in gait speed for 20-meter walk and 400-meter walk are consistent with previous important difference estimates for older adult populations. These findings can provide benchmarks for assessing and understanding functional performance outcomes when comparing exposure groups and can be used in designing future studies targeting adults with knee osteoarthritis.

A Low Cartilage Formation & Repair Endotype Predicts Radiographic Progression in Symptomatic Knee Osteoarthritis Patients and Identifies Optimal Responders to a Potential OA Treatment

Yunyun Luo,[1] Jonathan Samuels,[2] Svetlana Krasnokutsky,[3] Inger Byrjalsen,[1] Jeppe Andersen,[4] Asger Bihlet,[5] Yi He,[1] Morten Karsdal,[6] Steven Abramson,[7] Mukundan Attur,[3] and **Anne Bay-Jensen**[1], [1]Nordic Bioscience, Herlev, Denmark, [2]NYU Langone Medical Center, New Yort, NY, [3]NYU School of Medicine and NYU Langone Orthopedic Hospital, New York City, NY, [4]Nordic Bioscience, Clinical development, Herlev, Denmark, [5]Nordic Bioscience Clinical Development, Herlev, Denmark, [6]Nordic Bioscience, Copenhagen, Denmark, [7]NYU School of Medicine and NYU Langone Orthopedic Hospital, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a highly heterogeneous disease, which suggest that multiple endotypes exist. Identification and characterization of such endotypes may assist in precision medicine for identification of faster progressors whom may benefit from a given type of intervention. Recent published data have shown that SNPs in growth factors such as TGFbeta and GDF are associated with OA, which indicate that cartilage formation and repair play an important role in progression of OA. The aim was to determine whether a biomarker of type II collagen formation measured in serum, as a potential surrogate measure of cartilage formation, could predict radiographic progression in knee OA population. Subsequently, we investigated if such a proposed low cartilage formation/repair endotype was more responsive to a potential treatment of OA.

Methods: hsPRO-C2, a measurement of the type II collagen pro-peptide, was measured in blood samples of two independent knee OA cohorts: 106 recruited at New York University (NYU cohort) and 147 from the phase III OA trial SMC021-2301 (clinicaltrial.gov: NCT00486434) evaluating the efficacy and safety of oral salmon calcitonin. Patients were dichotomized based on their baseline level of hsPRO-C2 and the mean difference in two-year radiographic progression (joint space narrowing (JSN)) was analyzed using ANCOVA adjusting for baseline demographics and clinical characteristics.

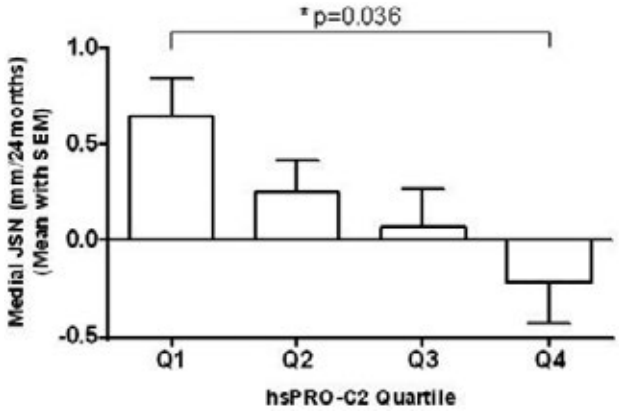

Figure 1. Two-year joint space narrowing in OA patients divided into quartiles based on baseline levels of plasma PRO-C2.

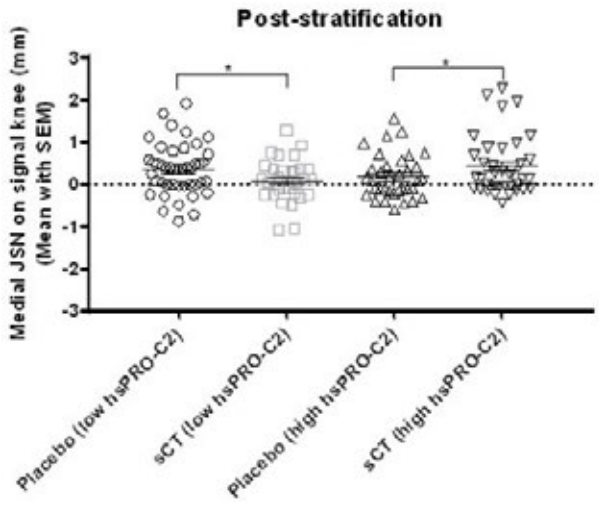

Figure 2. Two-year joint space arrowing in stratified patients treated with placebo or sCT.

Results: In the NYU cohort, baseline plasma hsPRO-C2 levels were negatively correlated with the progression of radiographic JSN ($r = -0.26$, $p = 0.009$). Quartile analysis demonstrated a significant difference in mean JSN from quartile 1 to 4 (0.51 mm versus -0.07 mm, $p = 0.036$, fig. 1). Knee OA patients with low hsPRO-C2 levels ($\leq$ 1.48 ng/mL) revealed significantly larger JSN compared to the individuals with high hsPRO-C2 levels (> 1.48 ng/mL) at 24 months (0.37 mm vs 0.02 mm, $p = 0.042$). In the SMC cohort, there was no significant treatment effect on the medial JSN over 2 years before stratification by hsPRO-C2; however, as observed in the NYU cohort, JSN was on average higher in the low hsPRO-C2 ($\leq$ 1.96 ng/mL) group compared to the high group (> 1.96 ng/mL). Furthermore, in the low baseline hsPRO-C2 subgroup, sCT-treated patients on average had a lower JSN compared to placebo patients ($p < 0.05$, fig. 2). The opposite trend was observed in patients with high baseline hsPRO-C2.

Conclusion: Here we show that low levels of cartilage formation, measured by PRO-C2, were associated with radiographic progression and greater likelihood of response to a salmon calcitonin. Low PRO-C2 may provide a measure of an OA endotype with low background cartilage formation (at baseline) and higher capacity for repair when treated with a potential cartilage anabolic drug.

The Association of Plasma Fatty Acids Levels with Hand and Knee Osteoarthritis

Marieke Loef,[1] Andreea Ioan-Facsinay,[1] Dennis O Mook-Kanamori,[2] Ko Willems van Dijk,[1] Renée de Mutsert,[1] Margreet Kloppenburg,[1] and Frits R Rosendaal[1], [1]Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity is one of the most important risk factors for osteoarthritis, and is strongly associated with increased levels of circulating fatty acids, which may result in lipotoxicity. However, our knowledge about the effect of different fatty acids on osteoarthritis is sparse. Therefore we aimed to investigate the association of plasma saturated fatty acids (SFAs), monounsaturated fatty acid (MUFAs), polyunsaturated fatty acids (PUFAs), omega-3 and omega-6 PUFAs with clinically defined hand and knee osteoarthritis.

Methods: In the population-based Netherlands Epidemiology of Obesity study, hand and knee osteoarthritis were defined by the ACR clinical classification criteria. Clinical hand and knee OA were defined by the ACR clinical classification criteria. Hand OA, knee OA and concurrent hand and knee OA were defined in 7%, 10% and 4% of participants, respectively. Plasma was sampled fasted and after a standardized meal (containing 600kCal, with 16% of energy (En%) derived from protein, 50 En% from carbohydrates and 34 En% from fat), and subsequently analysed using a nuclear magnetic resonance metabolomics platform. Since we are in a postprandial state most of the day, the postprandial samples were used for the primary analyses. All fatty acid concentrations were standardized (mean 0, SD 1). We excluded participants who reported to have inflammatory rheumatic disease or fibromyalgia, with missing physical examination, who were non-fasting at baseline, or reported using lipid-lowering medication. Logistic regression analyses were used to investigate the association between total fatty acids, SFAs, MUFAs, PUFAs, omega-6 PUFAs and omega-3 PUFAs and clinical osteoarthritis phenotypes. All analyses were stratified by sex and corrected for age, education, ethnicity and total body fat percentage.

Table 1. Characteristics of the weighted study population (n = 5,328), stratified by clinical OA phenotype

	No OA	Hand OA	Knee OA	Hand and knee OA
	79%	7%	10%	4%
General patient characteristics				
Age (year)	54.8 (6.1)	57.7 (5.3)	56.8 (5.1)	57.9 (4.5)
Women (%)	54	76	63	90
Ethnicity (% Caucasian)	95	93	95	91
Education (% high)	49	42	39	38
Body morphology measures				
Height (cm)	174 (10)	170 (9)	172 (10)	168 (7)
Weight (kg)	78.2 (15.5)	75.8 (16.0)	81.8 (17.4)	76.7 (15.1)
BMI (kg/m^2)	25.8 (4.1)	26.2 (4.6)	27.5 (5.2)	27.0 (4.8)
Total body fat (%)	30.5 (8.5)	34.4 (7.7)	33.8 (9.3)	37.3 (7.2)

Patients with missing physical examination, who were non-fasting at baseline, reported inflammatory rheumatic diseases or fibromyalgia or using lipid lowering medication are excluded. Numbers represent mean (SD) unless otherwise specified. † = median (IQR), BMI= body mass index.

Table 2. Association between postprandial plasma fatty acids and clinical OA phenotypes

		Clinical		
		Hand OA	Knee OA	Hand and knee OA

	Women	0.98 (0.80; 1.20)	0.92 (0.78; 1.08)	0.81 (0.60; 1.10)
PUFA	(SD=0.75)			
		1.21 (1.02; 1.42)	0.90 (0.78; 1.03)	0.95 (0.74; 1.21)
	Men	1.26 (1.00; 1.58)	0.90 (0.74; 1.09)	1.31 (0.84; 2.04)
	Women	1.13 (0.91; 1.41)	0.88 (0.73; 1.06)	0.86 (0.64; 1.14)
Omega-3 PUFA	(SD=0.13)			
		1.17 (0.99; 1.38)	0.94 (0.82; 1.09)	1.02 (0.81; 1.29)
	Men	1.24 (1.01; 1.52)	1.06 (0.86; 1.29)	1.24 (0.83; 1.85)
	Women	1.13 (0.90; 1.40)	0.85 (0.70; 1.04)	0.96 (0.74; 1.26)
Omega-6 PUFA	(SD=0.67)			
		1.19 (1.01; 1.40)	0.90 (0.78; 1.03)	0.94 (0.73; 1.20)
	Men	1.24 (0.98; 1.56)	0.87 (0.72; 1.06)	1.29 (0.85; 1.97)
	Women	1.12 (0.91; 1.39)	0.89 (0.74; 1.08)	0.85 (0.64; 1.13)

Results are based on weighted analyses of the study population. Fatty acid levels have been standardized (mean = 0, SD = 1), OR represents increased odds for every increase in SD. Analyses have been adjusted for age, fat percentage, education and ethnicity. Abbreviations: SFA= saturated fatty acid, MUFA= monounsaturated fatty acid, PUFA= polyunsaturated fatty acid.

Results: In the current analysis 5,328 NEO participants were included, with a mean age of 56 years and 58% were women (table 1). Unstratified analyses showed positive associations with OR (95% CI) of total PUFA concentrations 1.21 (1.02; 1.42), omega-3 1.17 (0.99; 1.38) and omega-6 PUFA concentrations 1.19 (1.01; 1.40) with clinical hand OA, but not with clinical knee OA. In men, total fatty acids 1.24 (1.01; 1.53), SFA 1.23 (1.00 – 1.50), total PUFA 1.26 (1.00 – 1.58) and omega-3 PUFA levels 1.24 (1.01 – 1.52) were positively associated with clinical hand OA. Similar effect estimates were observed with concurrent hand and knee OA, but not for clinical knee OA alone. In women no associations were seen of any of the fatty acids with clinical hand or knee OA (table 2).

Conclusion: Quantitively measured plasma postprandial SFA and PUFA levels were significantly associated with hand OA in men. Intriguingly, although SFA and omega-3 PUFAs are deemed to have opposing effects on inflammation, both were positively associated with hand OA. Future research is warranted for replication and to determine whether there is a causal role for plasma fatty acid levels in hand OA.

Abstract Number: 2189

Reference Curves for the Knee Injury and Osteoarthritis Outcome Score in the Middle-aged Dutch Population

Marieke Loef,[1] Féline PB Kroon,[1] Stephan Böhringer,[1] Frits R Rosendaal,[1] and Margreet Kloppenburg[1], [1]Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire is a widely used patient-reported outcome tool, developed to evaluate short- and long-term knee symptoms and function. Previous studies evaluating knee complaints in the general population have shown that individuals in the general population do not report the best possible score on knee-specific questionnaires, stressing the need for benchmarks for adequate interpretation of these patient-reported scores. Therefore, we aimed to improve the interpretation of the KOOS by developing reference curves in a large population-based cohort.

Methods: We used cross-sectional data of middle-aged individuals from the Netherlands Epidemiology of Obesity study. We obtained questionnaires regarding demographic and clinical characteristics, including previous knee injuries and surgery, as well as the KOOS questionnaire. In addition, a standardized physical examination of the knee was performed, allowing the classification of participants with clinical knee osteoarthritis according to the ACR criteria, which were fulfilled in 15% of participants. Associations of demographic and clinical characteristics with KOOS were explored using ordered logistic regression and sex- and body mass index-specific reference curves were developed using quantile regression with fractional polynomials. Subsequently, KOOS scores of participants classified with knee osteoarthritis were compared to the reference curves.

Results: The NEO study population consisted of 6,643 participants (56.4% women) with a mean (SD) age of 55.7 (6.0) years. KOOS subscale scores (median; IQR) were high: pain (100; 94-100), symptoms (96; 86-100), ADL (100; 96-100), sport (100; 80-100), QOL (100; 75-100). Age was not independently associated with KOOS scores. We observed that scores of all KOOS subscales were lower in women compared to men, and in individuals with a higher body mass index. A history of leg fractures or knee surgery was not associated with KOOS scores. In contrast, knee osteoarthritis was associated with lower KOOS scores on all subscales. Plotting the scores of participants with knee OA shows that these scores are low relative to the general population.

Conclusion: In the middle-aged Dutch population KOOS subscale scores were generally high and were lower in women and in individuals with a higher body mass index. Reference curves developed in the general population can be used as benchmarks in research and clinical practice to aid the appropriate interpretation of scores from patients with knee complaints.

Table 1. Characteristics of the weighted study population (n = 6,643), stratified by sex

	Men	Women
General patient characteristics		
Prevalence, %	43.6	56.4
Age, year	56.1 (6.0)	55.4 (6.0)
Ethnicity, % Caucasian	95.0	94.6
Education, % high	47.7	44.0
BMI, kg/m^2	26.9 (3.7)	25.9 (4.9)
Clinical knee OA, %	10.4	18.3
Self-reported inflammatory rheumatic disease, %	4.5	3.7
Self-reported fibromyalgia, %	0.3	3.0
History of knee surgery, %	20.8	13.8
History of leg fracture, %	9.3	6.2

Numbers represent mean (SD) unless otherwise specified, † = median (IQR).
KOOS subscores are transformed to a 0–100 scale, with zero representing extreme knee problems and 100 representing no knee problems.
BMI= body mass index

Multi-vendor Multi-site $T_{1\rho}$ and T_2 Quantification of Knee Cartilage

Jeehun Kim,[1] Kenji Mamoto,[2] Richard Lartey,[1] Kaipin Xu,[1] Matthew Tanaka,[3] Emma Bahroos,[3] Carl Winalski,[2] Thomas Link,[3] Peter Hardy,[4] Qi Peng,[5] Angie Botto-van Bemden,[6] Kecheng Liu,[7] Robert Peters,[8] Can Wu,[9] and **Xiaojuan Li**[10], [1]Program of Advanced Musculoskeletal Imaging, Cleveland Clinic Foundation, Cleveland, [2]Cleveland Clinic Foundation, Cleveland, [3]University of California, San Francisco, San Francisco, [4]University of Kentucky, Lexington, [5]Albert Einstein College of Medicine, New York City, [6]Arthritis Foundation, Atlanta, [7]Siemens Medical Solution Inc, Malvern, [8]GE Healthcare, Milwaukee, [9]Philips Healthcare, Andover, [10]Program of Advanced Musculoskeletal Imaging, Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a degenerative joint disease characterized by deterioration of articular cartilage in the joints. MRI $T_{1\rho}$ and T_2 relaxation times have been proposed as potential biomarkers for early detection of cartilage degeneration. However, few studies examined their reliability in a multi-site multi-vendor setting, which is critical for future large-scale trials and clinical translation of such quantitative measures. The purpose of this study was to evaluate the intra-site repeatability and inter-site reproducibility of knee cartilage $T_{1\rho}$ and T_2 data acquired by multiple sites and multiple vendors in phantoms and human subjects.

Methods: Four 3T MR systems from four different sites and three vendors (Siemens, GE, and Philips) with dedicated knee coils were used for this study (**Table 1a**). Five subjects were scanned with same day rescan at each site, includ-

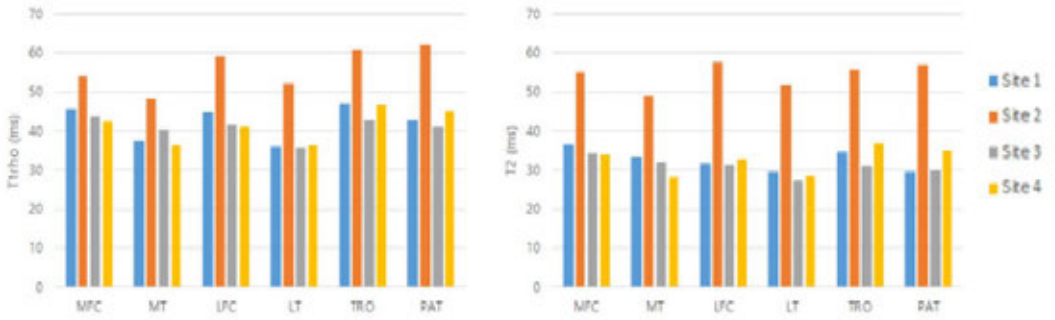

Figure 2. Bar graph of mean $T_{1\rho}$ and T_2 values of the traveling volunteers in each ROI. Note: Site 2 used a $T_{1\rho}$ and T_2 imaging sequence with segmented GRE and constant flip angle; while the other three sites used MAPSS $T_{1\rho}$ and T_2 imaging sequence with variable flip angles and RF cycling.

resolution DESS/GRE images, and the segmentation was overlaid on $T_{1\rho}$ and T_2 maps after registration to calculate means and standard deviations of $T_{1\rho}$ and T_2 values in each compartment.

Results: For phantoms, all sites showed excellent intra-site repeatability of $T_{1\rho}$ and T_2 values with an average CV of 2.24% for $T_{1\rho}$ and of 2.53% for T_2 (**Table 2, Fig. 1**). The average inter-site CVs were 7.67 % and 10.21 % for $T_{1\rho}$ and T_2 respectively with both sequences included (four sites); and 7.64% and 6.62% for $T_{1\rho}$ and T_2 respectively with the MAPSS sequence only (three sites).

For human subjects, excellent intra-site repeatability was observed for all sites with an average CV of 2.33% for $T_{1\rho}$ and of 2.91% for T_2, **Table 3**. The average inter-site CVs were 13.50% and 28.15% for $T_{1\rho}$ and T_2 respectively with both sequences included (four sites); and 8.2% and 10.17% for $T_{1\rho}$ and T_2 respectively with MAPSS sequences only (three sites). **Fig. 2** shows the $T_{1\rho}$ and T_2 values of each defined cartilage compartment for the traveling volunteers.

Conclusion: Cartilage $T_{1\rho}$ and T_2 imaging, after standardization of data acquisition and post-processing, demonstrates excellent intra-site repeatability, and inter-site reproducibility, suggesting great promise that $T_{1\rho}$ and T_2 may serve as reliable imaging biomarkers for future multi-site and multi-vendor studies, after standardization of data acquisition and post-processing. Factors that could introduce variations in $T_{1\rho}$ and T_2 values such as temperature, B0 and B1 inhomogeneity will be investigated further in future studies.

Construct Validity of OMERACT Ultrasound Knee Scores with Pain, Other Symptoms, Radiographic and MRI Findings

Win Min Oo,[1] James Linklater,[2] Kimberly Bennell,[3] Shirley Yu,[1] Xia Wang,[1] Vicky Duong,[1] and David Hunter[1], [1]Rheumatology Department, Royal North Shore Hospital and Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Australia, Sydney, New South Wales, Australia, [2]Department of Musculoskeletal Imaging, Castlereagh Sports Imaging Center, St. Leonards, Sydney, Australia, Sydney, New South Wales, Australia, [3]Centre for Health, Exercise and Sports Medicine, Department of Physiotherapy, School of Health Sciences, Faculty of Medicine Dentistry & Health Sciences, The University of Melbourne, Melbourne, VIC, Australia., Parkville, Victoria, Australia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the construct validity of Outcome Measures in Rheumatology (OMERACT) ultrasound scores for knee osteoarthritis (OA) with pain, other symptoms, and OA severity on radiographs and magnetic resonance imaging (MRI) counterparts.

Methods: A subgroup of community-recruited participants with symptomatic and mild-moderate radiographic knee OA participating in a randomized controlled trial of platelet-rich plasma were included in this study. At baseline, participants underwent dynamic ultrasound assessment using Aplio Platinum 500 machine, Toshiba, with a multi-frequency linear transducer (6-18MHz) according to the OMERACT scanning protocol. Using the published ultrasound image atlas by OMERACT group, a physician operator obtained semi-quantitative scores for synovitis, cartilage thinning, osteophytes and medial meniscal extrusion, and a dichotomous score for power Doppler (PD) signals, effusion and synovial hypertrophy. Clinical outcomes included the severity of pain on an 11-point numerical rating scale and Knee Injury and Osteoarthritis Outcome Score (KOOS) symptoms and pain sub-scores. The Likert responses of KOOS ranged from “none” to “extreme”. and scores ranged from 0 to 100, with lower scores indicating worse symptoms. OA severity was assessed using the Kellgren-Lawrence grade (KLG) on plain radiograph.

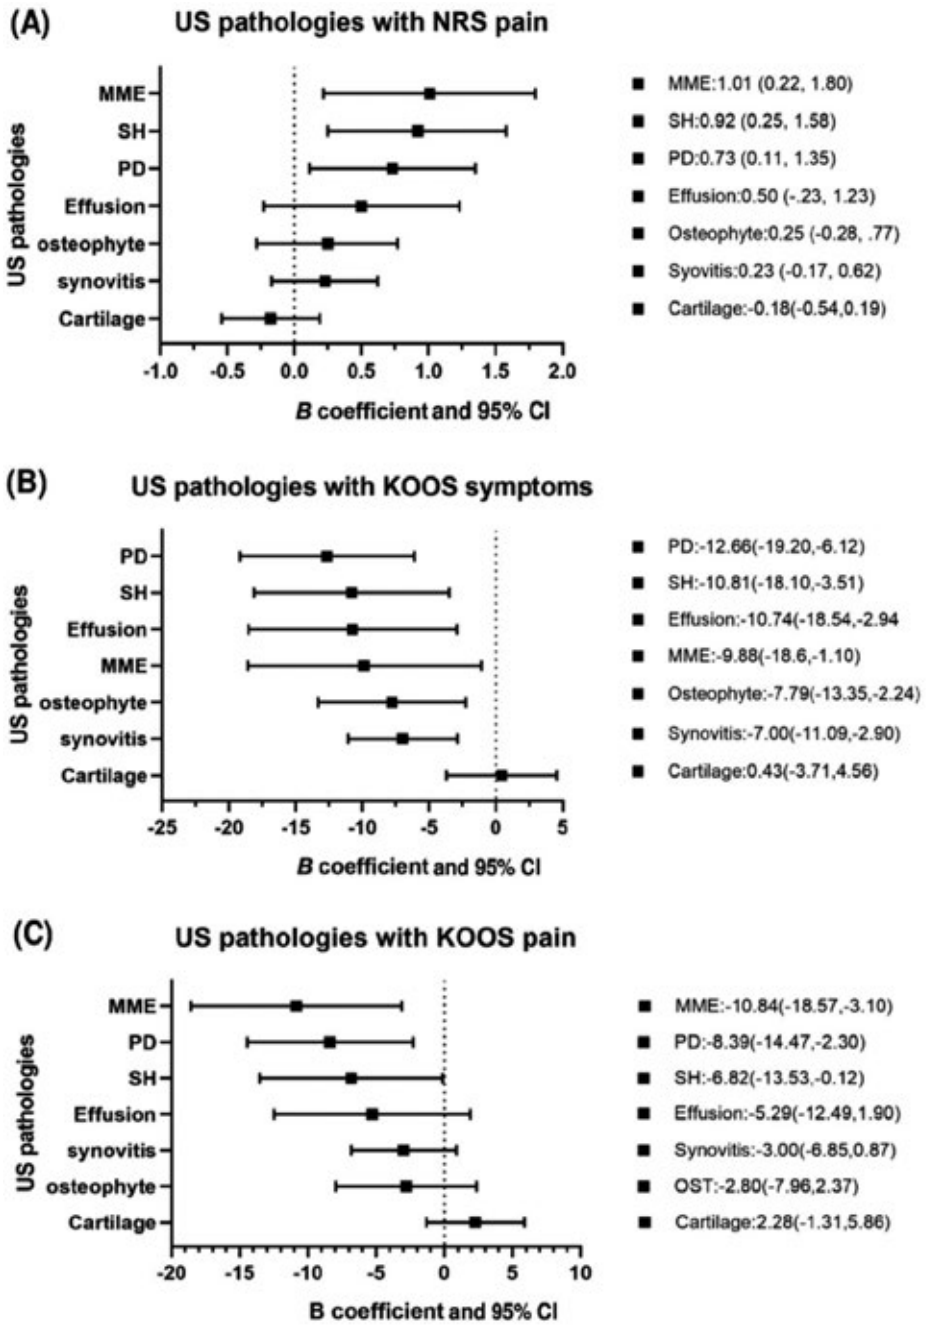

Figure 1. The association of OMERACT ultrasound OA scores with (A) NRS pain (B) KOOS symptoms (C) KOOS pain

KOOS= Knee Injury and Osteoarthritis Outcome Score; MME=Medial Meniscal Extrusion; NRS=Numerical Rating Scale; OST=Osteophyte; PD=Power Doppler; SH= Synovial Hypertrophy; US=ultrasound; CI=Confidence interval

MRI osteoarthritis knee score (MOAKS) was used on non-contrast-enhanced MRI sequences to evaluate cartilage loss (any or full thickness) from patellofemoral, medial and lateral tibiofemoral compartments, osteophytes from 12 different sites, medial meniscal extrusion, effusion-synovitis and Hoffa's synovitis. Linear regression was used to determine the associations of ultrasound OA pathologies with pain and KOOS sub-scores adjusting for confound-

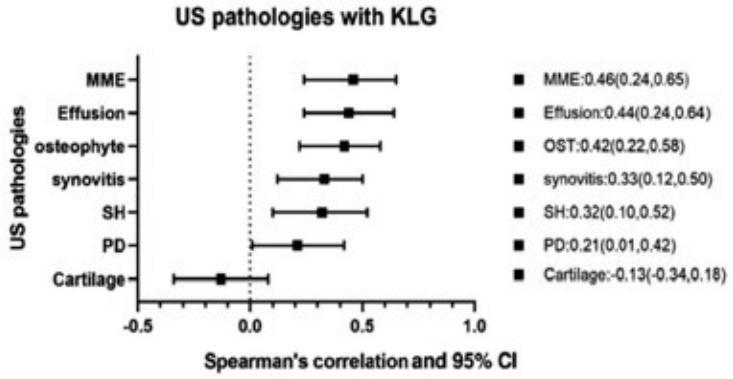

Figure 2. The association of OMERACT ultrasound OA scores with KLG on radiograph

KLG= Kellgren and Lawrence grade; MME=Medial Meniscal Extrusion; PD=Power Doppler; SH= Synovial Hypertrophy; US=ultrasound; CI=Confidence interval

ers such as age, gender, disease duration and KLG as appropriate, and Spearman's correlation was used for the relationship with KLG and MOAKS.

Results: Eighty-nine participants (female, 53.9%; body mass index, mean= 27.5±6.4) were included in the analysis. Synovial hypertrophy, PD signals and meniscal extrusion scores were associated with increased pain severity (*B* = 0.92, 95% confidence interval CI 0.25, 1.58); *B* = 0.73(95% CI 0.11, 1.35) and *B* = 1.01(95% CI 0.22, 1.80) respectively (**Figure 1A**). All ultrasound scores, except for cartilage grade, demonstrated associations with KOOS symptoms (**Figure 1B**) while only PD signals and meniscal extrusion were associated with KOOS pain (**Figure 1C**). All ultrasound scores, except for PD signals, were significantly correlated with KLG (**Figure 2**). Most ultrasound pathologies revealed moderate to good correlation with their MRI counterparts with ultrasound synovitis having the greatest correlation [0.69(95% CI 0.60, 0.78)] (**Figure 3**).

Conclusion: OMERACT ultrasound scores revealed good construct validity against commonly used measurement tools such as pain, function, and radiographic and MRI features, providing evidence to support its use as a standardized tool for determining ultrasound OA phenotypes.

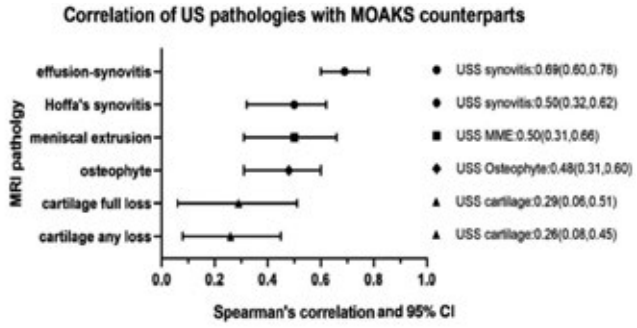

Figure 3. The association of OMERACT ultrasound OA scores with MOAKS on magnetic resonance imaging

Stabilization of Patellar Bone-Shape Correlates Significantly with Reduced Knee Pain Frequency After IA TPX-100 in Subjects with Bilateral Patellofemoral OA

Dawn McGuire,[1] Michael Bowes,[2] Alan Brett,[2] Neil Segal,[3] Meghan Miller,[4] David Rosen,[4] and Yoshinari Kumagai[4], [1]OrthoTrophix, Orinda, CA, [2]Imorphics, Manchester, England, United Kingdom, [3]University of Kansas Medical Center, Kansas City, KS, [4]OrthoTrophix, Oakland, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Based on data from the Osteoarthritis Initiative (OAI), MRI-based analyses of bone shape changes in the knee predict symptomatic and radiographic progression of knee OA and risk of joint replacement (Neogi 2013; Barr 2016). In a 12-month, double-blind, placebo-controlled trial of MRI-confirmed bilateral patellofemoral OA, TPX-100, administered in 4 weekly injections (200 mg/injection), markedly improved knee physical function (KOOS/WOMAC) compared with identical placebo injections (McGuire 2017). At 12 months, there were no significant treatment differences in overall knee pain; however, pain frequency significantly decreased in TPX-100-treated knees compared with placebo-exposed knees, and overall analgesic use declined by >60%. In the current retrospective study, we investigated patellar bone-shape change from baseline to 12-months among subjects who participated in TPX-100-1 and analyzed the strength of association between patellar bone shape change and changes in knee pain frequency.

Methods: Patellar bone shape changes from baseline were analyzed centrally by an automated method (Imorphics, Inc.) blind to treatment assignment and clinical results. MRI image quality permitted analysis in 79 of 93 subjects (85%) using active appearance model (AAM). Bone shape scores were computed to discriminate normal (non-OA) shapes versus bone surface deformations associated with radiographic and symptomatic OA. Changes in pain frequency were determined using Question 1 from the KOOS pain domain: "How often do you experience RIGHT/LEFT knee pain?" Spearman analysis was performed to investigate correlations between patellar shape change and change in knee pain frequency.

Results: Pain frequency was significantly improved in TPX-100-treated knees compared with placebo-exposed knees. Patellar bone shape delay correlated significantly with pain frequency reduction (r=.411; p=.0002; Table 1). Knees with stabilized or reduced bone-shape changes at 12 months had the greatest reductions in pain frequency, with statistically significant differences between quartiles (Fig 1).

Conclusion: In subjects with MRI-confirmed bilateral PFOA, a single series of IA TPX-100 is associated with statistically significant and clinically meaningful reductions in knee pain frequency at 12 months, significantly correlated with reduced or stabilized pathologic patellar bone shape change compared with placebo. Quartile analysis suggests a "dose-response" relationship between reduced patellar bone shape change and reduced knee pain frequency in TPX-100-treated knees. These concordant structural and symptomatic benefits support

development of TPX-100 as a candidate DMOAD as well as further study of bone shape change as an imaging biomarker in knee OA.

"If It Was Unicorn Dust I'd Have It Again." Patient Experiences of Hip Osteoarthritis and Treatments in the Hip Injection Trial

Clare Jinks,[1] Ashley Hawarden,[1] **Edward Roddy**,[2] Zoe Paskins,[3] Christian Mallen,[4] and Melanie Holden[5], [1]Research Institute for Primary Care and Health Sciences, Keele University, Keele, England, United Kingdom, [2]Research Institute for Primary Care and Health Sciences and Keele Clinical Trials Unit, Keele, United Kingdom, [3]Research Institute for Primary Care and Health Sciences, Keele University, Keele, United Kingdom, [4]Research Institute for Primary Care and Health Sciences, Keele University, UK, Keele, United Kingdom, [5]Research Institute for Primary Care and Health Sciences and Keele CTU, Keele University, Keele, England, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence of the effectiveness of intra-articular corticosteroid injection for hip osteoarthritis (OA) is limited and conflicting. The HIT trial compared the clinical effectiveness of an ultrasound-guided intra-articular hip injection (USGI) of triamcinolone acetonide and 1% lidocaine hydrochloride combined with best current treatment (BCT) with (i) BCT alone (primary objective) and (ii) an USGI of 1% lidocaine only combined with BCT (EudraCT: 2014–003412-37). BCT comprised advice and written information on exercise, weight loss, footwear, walking aids and pain management. This qualitative study investigated patient experiences of hip OA and impact of trial treatments.

Methods: Semi-structured interviews were undertaken with a purposeful sample of participants in each arm after 2-month follow-up. Interviewers knew whether participants had received an injection but were unaware of which injection (to minimise patients becoming un-blinded to treatment allocation). Sampling ceased when inductive thematic saturation had been achieved. Thematic analysis was undertaken blind to the clinical results to facilitate an interpretive and inductive approach.

Results: 34 trial participants were interviewed (males n=13, females n=19, aged 53 to 83 years). 13 participants were in USGI triamcinolone/lidocaine group, 11 in the lidocaine only arm and 8 in BCT. Preliminary findings indicate wide-ranging impacts of living with hip OA. Participants in all arms talked of physical, social, psychological and work-related impacts and difficulties with sleep and undertaking valued activities. Participants in BCT reported receiving an examination, information/explanation and exercises, providing evidence of intervention fidelity in this arm. Despite this, most felt that they had not received any treatment indicating that advice/exercise was not perceived as treatment for hip pain. Adherence was low in this group. Participants described little or no benefit in pain or function. Thoughts about the future were negative, focusing on inevitable decline and future need for surgery.

Experiences of having an injection were positive overall, and impacts described in both injection groups included "getting my life back" and having "a new lease of life". Perceived benefit appeared to be greater in the triamci-

nolone/lidocaine group, although length of benefit varied in both injection groups and there was uncertainty about the longer-term benefits of injection. Participants in the injection groups were more hopeful and optimistic about the future than those in BCT only.

Conclusion: Hip OA remains burdensome, affecting many aspects of life. The findings complement the trial results that showed superiority of USGI of triamcinolone/lidocaine combined with BCT over 6 months compared with BCT alone, but no significant difference between injection groups raising the possibility of a placebo effect. Participants' narratives outlined benefit in pain and function in both injection groups, strengthening the interpretations of the trial clinical results. Importantly, participants in BCT reported receiving BCT but did not feel they had treatment, indicating the need for future work highlighting the value of self-management.

Surgical and Medical Weight Loss Threshold Dictates Decreases in Knee Osteoarthritis Pain but Not Reductions in Inflammatory Biomarkers

Fernando Bomfim,[1] Shannon Chen,[1] Stephen Zak,[2] Taylor Jazrawi,[1] Madeline Kundler,[2] Vivienne Qie,[2] Laura Peralta,[2] Jose Aleman,[2] Christine Ren-Fielding,[2] Holly Lofton,[2] Jyoti Patel,[2] Mukundan Attur,[3] Steven B. SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Weight loss in obese patients can reduce knee osteoarthritis (OA) pain, even when physical therapy and intra-articular injections have failed. The impacts of either non-surgical or surgical weight loss on knee OA pain have been reported separately, but few studies have assessed them conjointly. While the decrease in mechanical load helps, the contribution of metabolic changes is less clear. We aimed to compare biomarker changes with weight loss as predictors of knee pain improvement, and consider a threshold of total weight loss necessary for these changes.

Methods: Patients from the NYU Langone Weight Management program were screened for knee pain prior to bariatric surgery or the start of a medical weight loss (MWL) regimen. We excluded patients with autoimmune disease, recent malignancy, recent intra-articular knee injections, and lack of OA by Kellgren-Lawrence (KL) x-ray grading. The BMI, Knee Injury and Osteoarthritis Outcome Score (KOOS) for pain, and blood samples were obtained at baseline and 1, 3, 6 and 12 months for evaluation of pain and biomarker levels.

Results: Of 140 patients screened, 81 were eligible and enrolled (82.7% female; BMI 45.2±9.6 kg/m2, 31-74; age 52±12 years, 30-80). A total of 49 patients had surgery (10 bypass, 30 sleeve, 9 LapBand) and 24 medical weight loss. 33 patients completed visits up to 6 months (2 bypass, 18 sleeve, 6 LapBand, 7 MWL). By 1 month, the surgical patients had lost much more total weight than the MWL group (9.8% vs 4.1 %, p=0.001), and realized marked pain relief (p< 0.001). By 6 months both groups had continued to lose weight, proportionately greater for surgical patients with further pain improvement. (Figure 1) Leptin levels dropped at 1 and then 6 months with both methods of weight loss.

Table 1.

The pro-inflammatory protein IL-1Ra decreased significantly by 6 months in the bariatric patients, but increased with the medical regimen across both time points. Soluble vascular adhesion protein 1 (sVAP-1), another pro-inflammatory protein that facilitates leukocyte infiltration, decreased at both the 1 and 6 month intervals – but much more in MWL than in surgical patients. Consistent with the literature, the anti-inflammatory soluble receptor for advanced glycation endproducts (sRAGE) mirrored KOOS pain improvement only in surgical patients and stabilized after 1 month, but did not change in the MWL group. (Table 1) In a subgroup analysis, the 14 surgical patients who lost at least 10% of

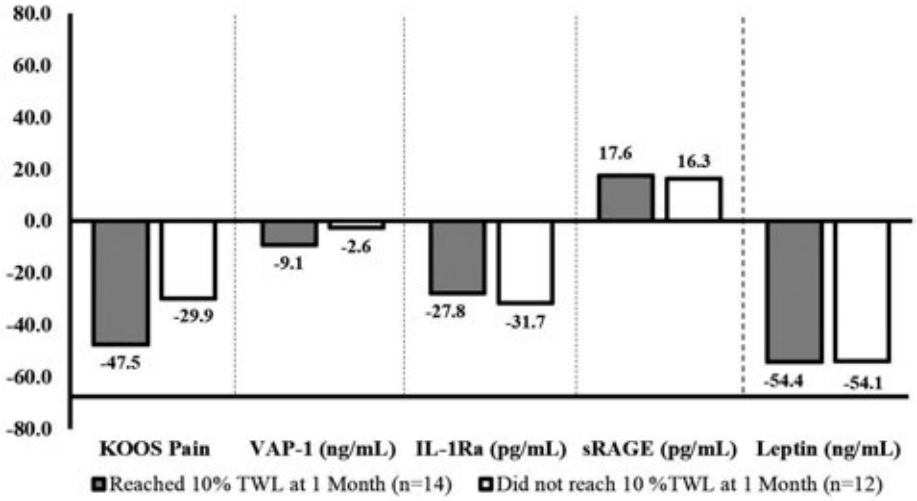

Figure 2. Percent change in biomarkers at 6 months in patients who reached threshold for one month total weight loss of 10%

total weight by 1 month had significantly less pain at 6 months than the 12 who did not meet the threshold (ΔKOOS 47.5 vs 29.9) but the biomarker levels were similar. (Figure 2)

Conclusion: Surgical and medically supervised weight loss both lead to significant decreases in adiposity, but only those having bariatric surgery realize significant pain relief. The anatomical changes of surgical (vs. medical) weight loss result in different metabolic cascades given divergent biomarker trends. Bariatric patients who lose more than 10 percent of total body weight within the first month are more likely to have better pain relief by 6 months, but the biomarker changes reflect anatomic intervention – and are not dependent on the degree of surgical weight loss.

BMI Has Minimal Effect on Reduction of Symptoms in Patients with Osteoarthritis of the Knee Treated with Diclofenac 1% Gel

Joel A. Block,[1] Bharat Patel,[2] and Sandy Yacoub Garas[3], [1]Rush University Medical Center, Chicago, IL, [2]GlaxoSmithKline Consumer Healthcare, Weybridge, United Kingdom, [3]GlaxoSmithKline Consumer Healthcare, Warren, NJ

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical trials demonstrate that diclofenac sodium gel 1% (DSG 1%), a topical NSAID, provides significantly better pain relief than vehicle placebo for patients with osteoarthritis (OA) of the knee. As patient BMI may affect the systemic availability and the volume of distribution of topical therapeutics, a post-hoc analysis was conducted to determine whether BMI has any clinical impact on the efficacy of DSG 1% in patients with OA of the knee.

Methods: This analysis pooled data from 3 vehicle-controlled studies of DSG 1%, VOSG-PN-304, VOSG-PN-310 and VOSG-PN-316, all double-blind studies with similar design and efficacy end-points, including Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) pain, function, and stiffness and pain on movement (POM). Efficacy data were analyzed as change from baseline and stratified by 3 BMI groups, (< 25, ≥25 to < 30, ≥30 kg/m2) at each visit (1, 4, 8 and 12 weeks). Populations included the Intention to Treat (ITT) efficacy population (all patients randomized and treated), and the Modified Efficacy Subset (MES) (patients with no decline in POM score between the screening and baseline visits and a score of 0-1 on the WOMAC abridged pain index for the contralateral knee). The treatment by BMI interaction from an analysis of covariance model was used for assessment.

Results: Improvement from baseline was larger for DSG 1% compared to vehicle in all 3 BMI groups for all 4 efficacy measures at each time point in both the ITT and MES populations. There were no significant differences in treatment effects between the 3 BMI groups at any time point for all 4 efficacy measures for both the ITT and MES population. Mean treatment effect (DSG 1% minus vehicle) at Week 12 and P-value for difference between < 25 (n=203), ≥25 to < 30 (n=460), ≥30 (n=751) kg/m2 BMI groups, respectively were: WOMAC pain, 1.01, 0.87, 0.79 (P=.94); POM, 9.66, 7.13, 6.06 (P=.71); WOMAC function, 2.38, 2.97, 3.77 (P=.78); WOMAC stiffness, 0.30, 0.47, 0.45 (P=.84) in the ITT population and WOMAC pain, 0.75, 1.48, 1.23 (P=.69); POM, 8.80, 10.39, 8.79 (P=.91); WOMAC function, 1.78, 4.99, 5.30 (P=.40); WOMAC stiffness, 0.22, 0.68, 0.66 (P=.37) in the MES population.

Conclusion: In this pooled analysis, patients treated with DSG 1% showed larger improvement from baseline in all 3 BMI groups, for all 4 efficacy measures, and at each time point compared to vehicle. There were no significant differences in efficacy between the 3 BMI groups, indicating that DSG 1% is efficacious regardless of BMI in patients with OA of the knee and that dose adjustments based on body size are not necessary.

Machine Learning Defines the Relationship Between Structural Knee Osteoarthritis and Patient-Important Outcomes: An 8-year Study of 47,858 Knee MRIs from the Osteoarthritis Initiative (OAI)

Michael Bowes,[1] Katherine Kacena,[2] Oras Alabas,[3] Alan Brett,[1] Bright Dube,[4] Neil Bodick,[5] and Philip G Conaghan[6], [1]Imorphics, Manchester, England, United Kingdom, [2]BioBridges, Wellesley Hills, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom, [4]University of Leeds, LEEDS, England, United Kingdom, [5]Flexion Therapeutics, Burlington, [6]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a slowly progressing disease which may be asymptomatic for many years. Therapy development has been hampered by poor understanding of both structural progression and outcomes, largely based on imprecise radiographic assessment. A statistical shape model (SSM), a form of machine

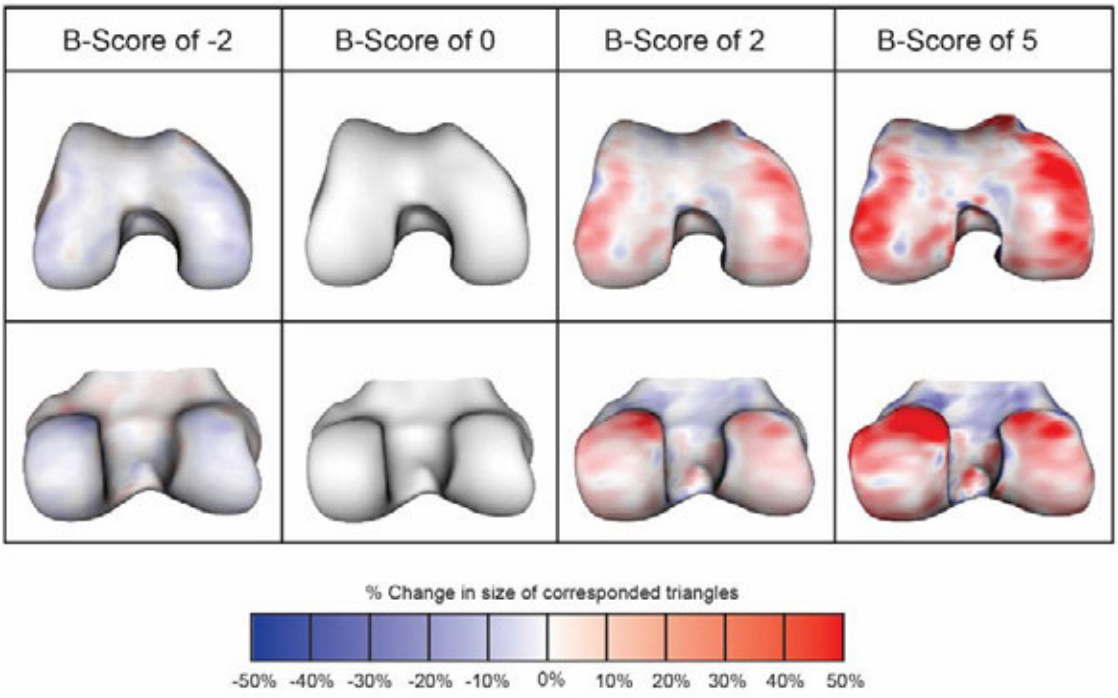

Figure 2. Change in Bone Shape with Increasing B-Score. Figure shows change in shape for the anterior femur (top row) and posterior femur (bottom row), for various B-scores. Red indicates where there is an increase in size, blue indicates decrease in size; scale shows percentage in local area size change.

learning, identified a characteristic 3D OA bone shape from MR images, enabling investigation of the relationship between structure and clinical outcomes in the largest musculoskeletal MRI study to date.

Methods: Construction of an SSM produces a "shape space," spanned by principal components used to describe the training set of examples. Within this space, we constructed an "OA vector" passing through the mean shape of an "OA Group" (all knees KLG ≥2 at all 0, 1, 2, and 4 years), and the mean shape for a "Non-OA Group" (KLG = 0 at the same time points). Distances along the OA vector are normalized to a z-score ("B-score"), with the mean shape of the Non-OA Group for each sex represented as the OA vector origin; 1 unit represents 1 SD of the Non-OA Group along the OA vector (+ve values toward the OA Group). Each femur bone shape was projected orthogonally onto the OA vector to specify the corresponding B-score. Representative examples of the femur bone shape are shown in Fig. 1.

The B-score was automatically measured at multiple time points up to 8 years in the OAI (9,433 knees; 5,031 without OA; 47,858 MRI images). WOMAC-A (pain) on the 20-unit scale was dichotomized, first by presence of moderate or higher pain (score ≥4) and then again by presence of severe pain (score ≥8). Knee Replacement Surgery (KRS) was defined as having either total or partial knee arthroplasty within the follow-up period, adjudicated using post-surgery radiographs. Logistic regression analysis was performed modeling any reporting of pain or KRS at any single time-point over the follow-up period for an individual knee by baseline B-score. This logistic regression was then repeated using baseline age.

Results: B-score was strongly associated with current and future pain; Fig. 2 displays the enhanced predictive power of B-score compared to age. Males and females were analyzed separately. However, an additional model combining both sexes was produced: for baseline B-scores of 0 and 6 (incipient and advanced disease), future risk of painful knee within an average follow-up of 5 years was 36.0% (95% CI: 34.9 to 37.1) and 75.1% (72.6 to 77.5), respectively. Males had 210 KRS, females had 318. Although both baseline B-score and baseline age were both sta-

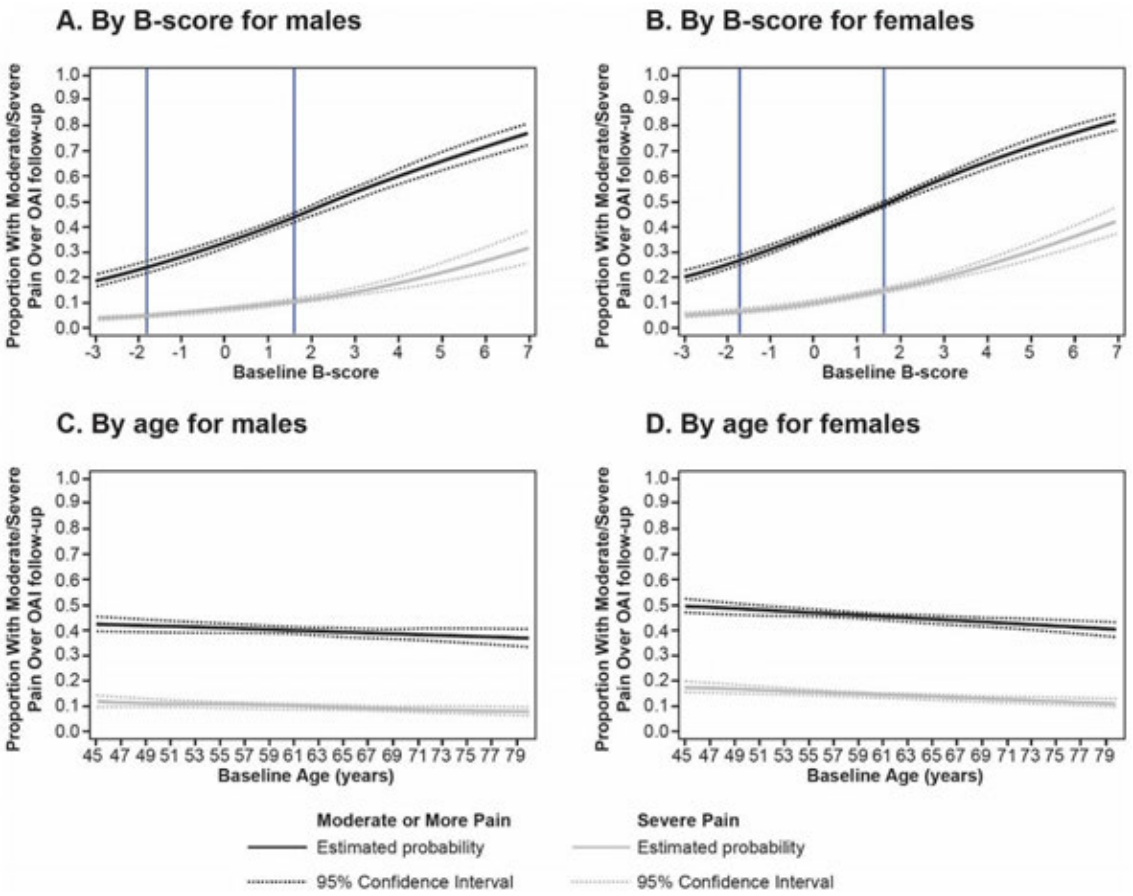

Figure 2. Knee Pain by B-Score for A) Males and B) Females and by Age for C) Males and D) Females. Moderate or more pain was defined as WOMAC-A (pain) ≥4 on the 20-unit scale; severe pain was defined as WOMAC-A (pain) ≥8 on the 20-unit scale. The average follow-up was 5 years. Vertical lines on B-score axis display Non-OA Range.

tistically significant at P< 0.001, Fig. 3 displays the enhanced predictive power of B-score compared to age for KRS. Using a combined model, future risk of KRS at B-scores of 0 and 6 was 2.3% (2.0 to 2.7) and 36.7% (32.5 to 41.1), respectively. Age had minimal utility in predicting pain or KRS.

Conclusion: By providing a continuous metric for OA, machine learning applied to a large dataset has for the first time demonstrated simple and strong relationships between bone shape and the current and future clinical outcomes. B-score provides accurate stratification for interventions and improved personalized assessment and is analogous to the T-score developed for osteoporosis.

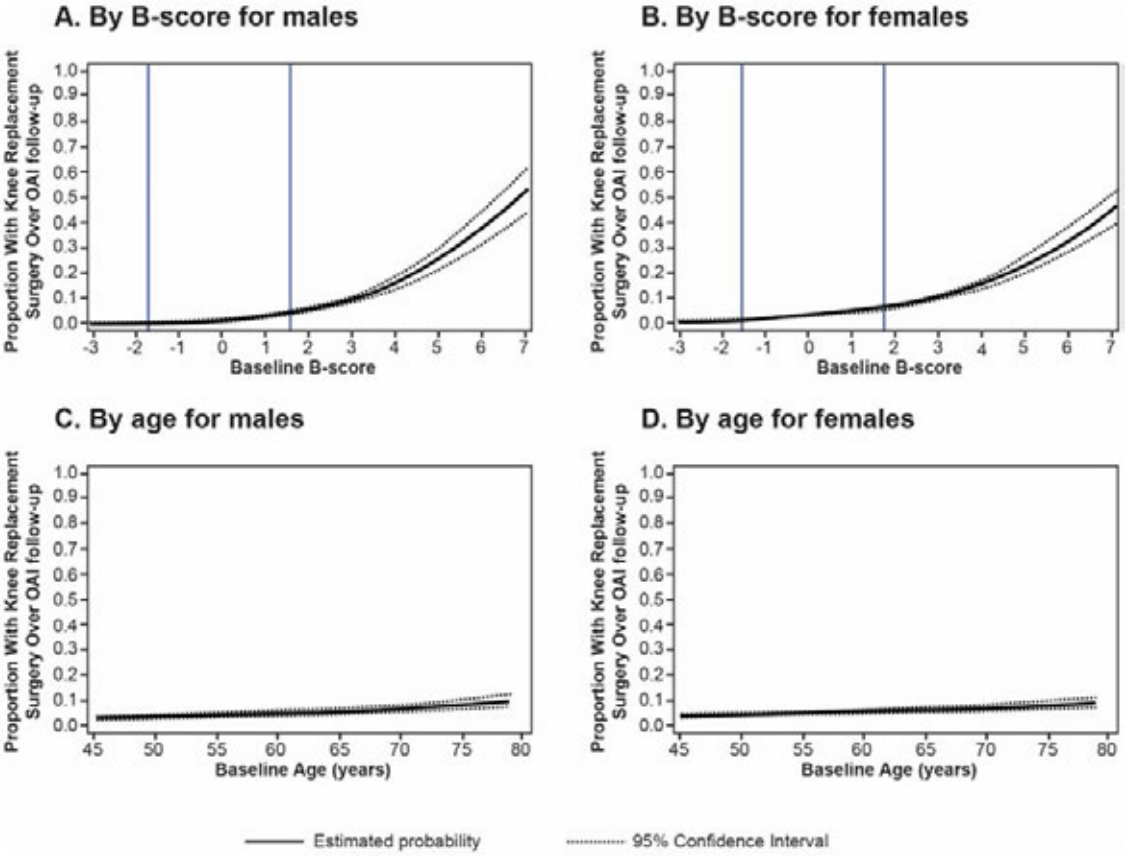

Figure 3. Risk of Knee Replacement Surgery by B-Score for A) Males and B) Females and by Age for C) Males and D) Females. Vertical lines on B-score axis display Non-OA B-score range.

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Topical agents are recommended for the initial treatment of patients with knee osteoarthritis (OA). Diclofenac sodium gel 1% (DSG 1%), a topical nonsteroidal anti-inflammatory drug (NSAID), demonstrated significant improvements in the signs and symptoms of knee OA and a higher percentage of patients meeting the Osteoarthritis Research Society International criteria for a response relative to a vehicle placebo in a trial of patients with OA of the knee. This post-hoc analysis was conducted to determine the percentage of patients in this study achieving a minimal clinically important improvement (MCII, the smallest improvement considered meaningful by an individual patient) in OA signs and symptoms.

Methods: This study was a 12-week, prospective, randomized, double-blind, multicenter, parallel group study that compared DSG 1% with placebo in subjects with OA of the knee. MCII responders were defined as having an improvement of ≥20% over baseline in Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) pain, function, and stiffness and in pain on movement (POM) per the definition used by Tubach F et al. (*Arthritis Care Res* (Hoboken). 2012;64(11):1699-707). The percentage of responders was analyzed using logistic regression with treatment and stratification factors (number of knees treated and Kellgren-Lawrence grade) included in the model. Time to MCII response was analyzed using the log-rank test with the same stratification factors.

Results: This analysis included 207 DSG 1%-treated and 212 vehicle-treated patients. Significant differences in the percentage of patients reaching an MCII were evident at Week 1 (DSG 1% vs vehicle, odds ratio [95% confidence limits]): WOMAC pain, 74.9% vs 61.8%, OR 1.87 [1.23, 2.85], *P*=.004; POM, 71.5% vs 59.9%, OR 1.71 [1.13, 2.59], *P*=.011; WOMAC function, 69.6% vs 58%, OR 1.70 [1.13, 2.56], *P*=.011; WOMAC stiffness, 75.4% vs 64.6%, OR 1.70 [1.11, 2.60], *P*=.015. Time to first MCII response was lower with DSG 1% for all measures: WOMAC pain, *P*=.001; POM, *P*=.013; WOMAC function, *P*=.018; WOMAC stiffness, *P*=.01. Significant differences in responder rates between groups were evident at most subsequent time points, with a higher percentage of patients with an MCII response with DSG 1% at Week 12 for all endpoints.

Conclusion: The MCII, a metric that considers patient perspectives on clinical improvements, was applied to data from a published clinical trial first time. In this analysis, most patients treated with DSG 1% achieved clinically meaningful relief within 1 week that was sustained for ≥12 weeks. Despite a relatively high vehicle response rate, a significantly higher percentage of patients had MCII responses with DSG 1%.

Severe Acute Localized Reactions Following Intra-Articular Hyaluronic Acid Injections in Knee Osteoarthritis

Kevin Ong,[1] Maria Runa,[1] Wilson Ngai,[2] Zhimin Xiao,[3] Edmund Lau,[4] and Roy Altman[5], [1]Exponent, Inc., Philadelphia, [2]Sanofi, U.S. Medical Affairs, Bridgewater, [3]Sanofi US, Cambridge, [4]Exponent, Inc., Menlo Park, [5]University of California, Los Angeles

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Some concerns have been raised about subsequent severe acute localized reactions (SALR) (flares, pseudoseptic reactions, etc.) following hyaluronic acid (HA) injections for pain relief of knee osteoarthritis (OA). SALR has been speculated to be possibly related to the crosslink of hylan or an allergic reaction to hyaluronan of avian origin, but similar reactions have been reported following the use of non-crosslinked, non-animal, and/or naturally derived HA. We compared surrogate SALR measures between hylan G-F 20 and non-hylan G-F 20 patients and evaluated the corresponding risk factors for hylan G-F 20 patients in a real-world setting.

Methods: Knee OA patients were identified from the Optum Clinformatics (UnitedHealth Group private payer) dataset (Jan 2006-June 2016) and stratified into hylan G-F 20 and non-hylan G-F 20 users. The occurrences of surrogate SALR measures including inflammation/infection, corticosteroid (CS) injections, arthrocentesis/aspiration, and office visits were evaluated within three days of HA use. Logistic regression was used to evaluate risk factors.

Results: The study cohort involved 748,428 HA patients with 23.2% in the hylan G-F 20 group. Knee OA-related inflammation/infection rate was 0.001% for hylan G-F 20 and 0.002% for non-hylan G-F 20 groups (Fig. 1). Knee OA-related arthrocentesis/aspiration rate was 1.6% for hylan G-F 20 and 2.1% for non-hylan G-F 20 groups, with comparable risk for both groups ($p=0.201$; Table 1). The rate of CS injection (any diagnosis) was 0.48% for hylan G-F 20 patients compared to 0.41% for non-hylan G-F 20 patients, with 28% greater risk greater for hylan G-F 20 patients ($p< 0.001$), but the combined rates of CS injection and arthrocentesis/aspiration (any diagnosis) was comparable for both groups (hylan G-F 20: 2.2%; non-hylan G-F 20: 2.6%). The risk of any visit or studied responses was lower for the hylan G-F 20 cohort by 12% (unadjusted rate of 3.1% versus 4.3%; $p< 0.001$). Clinical characteristics, such as CS injections or arthroscopy within 1 week before HA and ultrasound imaging, were associated with 84%, 289%, and 35% increased risk of any studied clinical encounter, respectively. Concomitant CS and HA injections, and fluoroscopic imaging were associated with 35% and 42% lower risks, respectively (all $p< 0.001$).

Conclusion: Our study of almost 750,000 knee OA patients who had HA injections, of which about a quarter were only given hylan G-F 20, demonstrated that the diagnosis of inflammations or infections within three days of the HA injection was extremely rare. The occurrence was 1 out of 100,000 hylan G-F 20 patients and 2 out of 100,000 non-hylan G-F 20 patients for those events that had a corresponding knee OA diagnosis, and increased to 2 out of 10,000 for both cohorts when all inflammation or infections were included regardless of diagnosis. The overall risk of surrogate SALR measures was not greater for hylan G-F 20 patients.

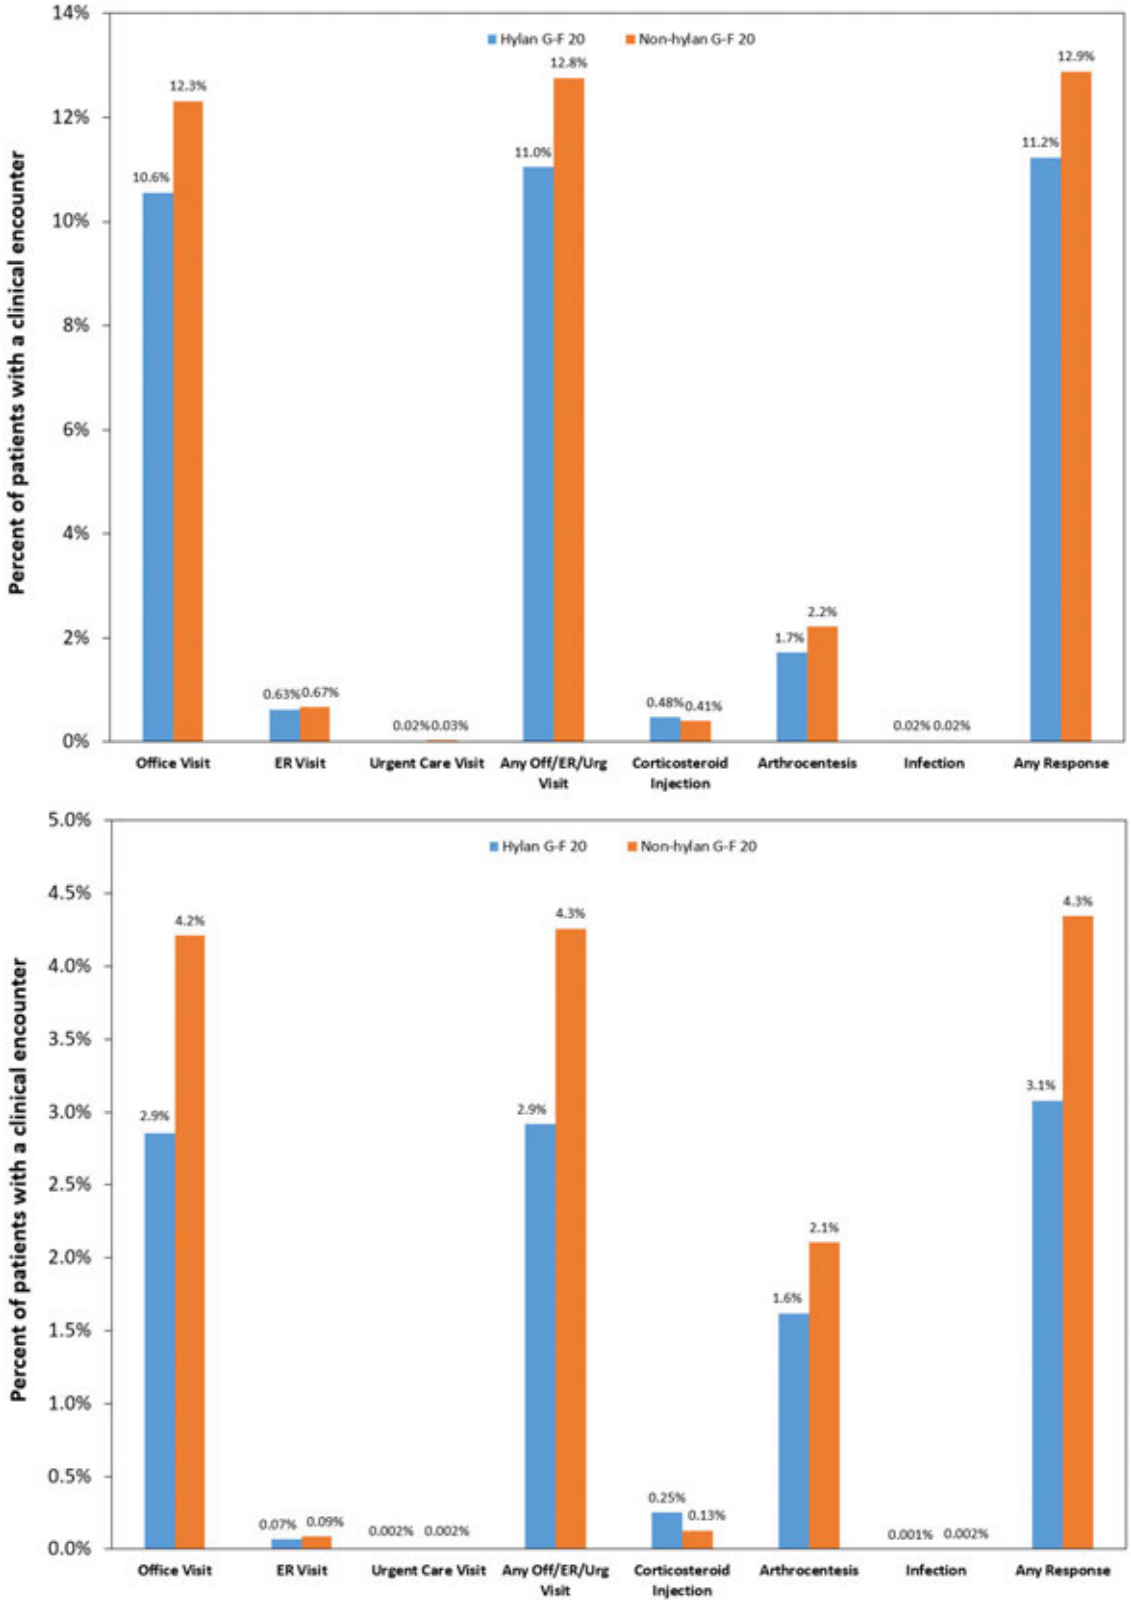

Figure 1. Clinical encounters (top: for any diagnosis; bottom: with knee OA diagnosis) within 3 days post-HA injection.

Table 1. Relative risk of clinical encounters within 3 days post-HA injection between hylan G-F 20 and non-hylan G-F 20 (reference) cohorts

Is There an Association of Serum LDL, HDL and Total Cholesterol with the Development of Knee Osteoarthritis?

Jessica Barlow,[1] Xianbang Sun,[2] Michael Nevitt,[3] James Torner,[4] Beth Lewis,[5] Nirupa Matthan,[6] Alice Lichtenstein,[6] and David Felson[7], [1]Boston University School of Medicine, Department of Rheumatology, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]University of California at San Francisco, San Francisco, CA, [4]University of Iowa at Iowa City, Iowa City, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Tufts University, Boston, MA, [7]Boston University School of Medicine, Department of Rheumatology, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent data have suggested an association between elevated serum cholesterol levels, particularly low density lipoprotein (LDL), and the development of osteoarthritis (OA). Within the joint, circulating LDL is taken up by the synovium and oxidized, activating macrophages and leading to the release of inflammatory medi-

ators. Further, mice with high LDL levels have high rates of OA compared with controls. In this study, we sought to comprehensively and longitudinally evaluate whether circulating total cholesterol, LDL, and high density lipoprotein (HDL) are associated with the risk of radiographic and symptomatic knee OA. We hypothesized that elevated levels of LDL increase the risk of developing knee OA.

Methods: We performed a nested case control study within the Multicenter Osteoarthritis study (MOST) cohort to examine the relationship between total cholesterol, LDL, and HDL and OA. MOST is an NIH-funded longitudinal study which followed 3,026 subjects with or at risk of developing OA for a seven year period, during which knee x-rays and MRIs were obtained and knee symptoms were queried at baseline, 30, 60, and 84 months. Baseline fasting blood samples were also drawn. We defined cases as those developing either radiographic OA (on plain film x-rays, N=283) or symptomatic OA (knee pain and radiographic OA, N=336) at follow-up. To identify cases with incident radiographic OA, we excluded those with prevalent radiographic OA at baseline and then followed subjects for the development of incident disease. Controls were selected randomly from those who were eligible to develop OA but did not. We carried out an identical case and control selection procedure for incident symptomatic OA. Additionally, we examined cartilage loss and synovitis on MRI and knee pain using the WOMAC scale. We carried out person-specific analyses using Cox Proportional Hazards regression adjusting for age, sex, BMI and educational attainment. When analyzing pain outcomes, covariates included depressive symptoms. We tested cholesterol as a continuous measure and did sensitivity analyses examining whether commonly used thresholds for high cholesterol (>=200mg/dl), LDL (>=130 mg/dl) or low HDL (< =60mg/dl) increased risk.

Results: Mean age at baseline was 62 years and 55% were women. The hazard ratio for incident radiographic OA and incident symptomatic OA according to total cholesterol, LDL, and HDL cholesterol levels as well as the mean cholesterol values showed no significant associations with OA (see table). Additionally, we found no significant association of total cholesterol, LDL and HDL with cartilage loss, worsening synovitis or worsening knee pain. We also examined whether persons with high cholesterol, LDL or low HDL had an increased risk of OA, and did not find a significant association.

Association of Cholesterol, LDL and HDL with Incident Knee OA in the MOST Study

	Mean (mg/dl)		HR with 95% CI (per SD)	P value
	Cases	Controls		
Incident Knee Radiographic OA(cases/controls=283/329)				
Total Chol	229	229	1.00 (0.88,1.14)	0.97
LDL	136	138	0.98 (0.87, 1.12)	0.80
HDL	62	61	1.11 (0.96, 1.29)	0.16
Incident Symptomatic Knee OA(cases/controls=336/559)				
Total Chol	224	229	0.91 (0.80, 1.03)	0.12
LDL	132	137	0.89 (0.79, 1.01)	0.06
HDL	62	61	1.09 (0.95, 1.24)	0.24

Conclusion: We did not find an association between LDL cholesterol, total cholesterol, or HDL cholesterol levels with incident osteoarthritis or other osteoarthritis outcomes. While LDL may have local deleterious effects on joint structure, elevated systemic levels do not confer risk of disease.

Magnetic Resonance Imaging of Knee Joint Protection Following an Intra-Articular Injection of Lipid-Based Dexamethasone Sodium Phosphate Sustained Release Formulation on Subjects with Knee Osteoarthritis

Sheue-Fang Shih,[1] Carl Brown,[1] Tien-Tzu Tai,[1] and Wing Chuang[1], [1]Taiwan Liposome Company, Ltd., Taipei, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The most commonly used intra-articular (IA) corticosteroid for osteoarthritis (OA) is triamcinolone acetonide (TA), but its potential chondrotoxicity restricts injection frequency to 3-4 injections per year. TLC599 is a liposomal formulation of dexamethasone sodium phosphate (DSP) designed for intra-articular injection in the treatment of knee osteoarthritis (OA). Based on a Phase 2a multi-center, randomized, double-blind, placebo-controlled clinical trial (ClinicalTrials.gov ID: NCT03005873), TLC599 has demonstrated durable pain relief and improved function over 24 weeks in patients with knee OA pain. Also, TLC599 possess the potential to protect articular cartilage from damage, making it potentially a beneficial therapy for OA with less risk of chondrotoxicity. To evaluate the effect of TLC599 on knee cartilage, magnetic resonance imaging (MRI) was utilized in this trial.

Methods: In the current Phase 2a study, subjects were eligible if they met the American College of Rheumatology Criteria for knee OA, with Grade 2 to 3 Kellgren-Lawrence severity. A total of 75 patients were randomized to receive 1 of the 3 regimens in the index knee in 1:1:1 ratio (TLC599 with 12 mg DSP and 100 μmol phospholipid (PL); TLC599 18 mg DSP with 150 μmol PL; or normal saline placebo). Patients were followed 24 weeks post injection. MRI was conducted on both knees before dosing and at the end of study, and cartilage was evaluated by a blinded radiologist at each center using the MRI Osteoarthritis Knee Score (MOAKS) instrument, with 14 articular subregions individually evaluated with 2 categorical scores, indicating the size of cartilage damage (surface area loss) and depth of cartilage damage (full thickness loss).

Results: Index knees were compared with non-index knees by number of sub-regions with worsening from baseline to the end of 24 weeks (≥ 2 sub-regions worsening representing significant worsening), regardless of the individual sub-region severity. Table 1 shows the MOAKS score pattern for placebo group index and non-index knees, representing the natural course of the disease, and the TLC599 group knees. For the placebo group, the index knee displayed similar or more significant cartilage damage (≥ 2 sub-regions with worsening) than the non-index knee, for both joint cartilage surface area and thickness. However, both TLC599 patient groups displayed lower proportions of significant cartilage damage in the index knee than the non-index knee. Figure 1 shows that the pattern of knee

Treatment group	Proportion of subjects with ≥2 cartilage sub-regions with worsening in:	Index knee	Non-index knee	Index knee minus non-index knee	Interpretation
Placebo (n=22)	Surface area loss	5%	5%	0%	Placebo group represents the natural course of cartilage degeneration. Assuming that index knee might be more severe and degenerate faster than non-index knee, the percentage with significant worsening was actually higher in the index knee than in the non-index knee.
	Full thickness loss	14%	5%	9%	
TLC599 12 mg (n=24)	Surface area loss	42%	50%	-8%	TLC599-treated subjects showed that the percentage of significant worsening was lower in index knee than non-index knee, which indicates that TLC599 might be able to slow down the natural course of cartilage degeneration.
	Full thickness loss	29%	33%	-4%	
TLC599 18 mg (n=21)	Surface area loss	14%	29%	-15%	
	Full thickness loss	5%	14%	-9%	

Table 1. Comparison of significant cartilage damage by MOAKS between placebo- and TLC599-treated patients

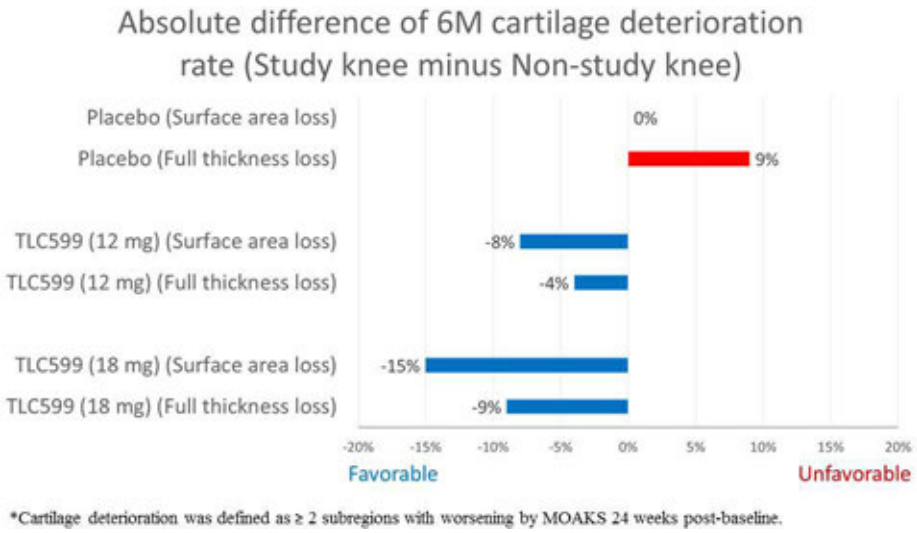

Figure 1. Difference in proportions with cartilage deterioration between index knee and non-index knee

joint cartilage damage change between treated groups was reflected by the difference between the proportions of subjects displaying ≥2 worsening cartilage sub-regions in index vs. non-index knee. These findings suggest there may be protection from cartilage degeneration by TLC599 IA injection.

Conclusion: The exploratory MRI evaluation of knee cartilage using semi-quantitative MOAKS indicated that, comparing index to non-index knees, patients treated with TLC599 IA injection displayed relatively less cartilage loss in the treated knee than placebo patients, suggesting a lack of cartilage damage or potentially a chondroprotective effect.

Developing a Comprehensive Patient-Specific Disease Progression Prediction Model for Knee Osteoarthritis Using Machine/Deep Learning Methods

Afshin Jamshidi,[1] Mickael Leclercq,[2] Jean-Pierre Pelletier,[3] Aurèlie Labbe,[4] François Abram,[5] Arnaud Droit,[6] and **Johanne Martel-Pelletier**[7], [1]University of Montreal Hospital Research Centre (CRCHUM); Laval University Hospital Research Centre, Québec, QC, Canada, [2]Laval University Hospital Research Centre, q, QC, Canada, [3]University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, Canada, [4]Department of Decision Sciences, HEC Montréal, Montreal, QC, Canada, [5]ArthroLab Inc., Montreal, QC, Canada, [6]Laval University Hospital Research Centre, Québec, QC, Canada, [7]University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Current assessment of knee osteoarthritis (OA) is primarily based on a patient's personal and familial history, clinical features, and on radiographies. However, such information does not provide enough evidence to lead to a robust prediction/prognosis of OA fast progressors. This study aims to identify early significant predictors of knee OA progression using advanced machine learning (ML) and deep learning (DL) algorithms and propose a prediction model based on a short number of selected predictors and outcomes.

Methods: We used six feature selection models, including LASSO (Least Absolute Shrinkage and Selection Operator), Elastic Net, GBM (Gradient Boosting machine), RF (Random Forest), IG (Information Gain), and DL-based Multi-Layer Perceptron [MLP]. In addition, more than 100 classification methods were tested on five outcomes: incidence of cartilage volume loss in medial plateau at 48 and 96 months (Prop_CV_48-96), knee replacement (TKR) at 48-96 months, Kellgren-Lawrence (KL) grade ≥2 and medial joint space narrowing (JSN) ≥1 mm at 48 months. Data were retrieved from the Osteoarthritis Initiative and quantitative magnetic resonance imaging (MRI) assessment. This study included 1044-1598 individuals/outcome, as well as 1107 variables and 135 MRI data at baseline. The classification was done using auto-ML tools by calculating the area under curve (AUC) and Matthews correlation coefficient (MCC) for the imbalanced TKR data. To prioritize the selected variables and outcomes, we used the multi-label Sparse Partial Least Square (sPLS) regression method.

Results: Feature selection and sPLS revealed MRI-based variable cartilage thickness and outcome cartilage volume loss at 96 months (Prop_CV_96) as the best predictors of knee OA progression. Moreover, medial joint space width along with pain were among the top predictors. The LASSO method outperformed other feature selection methods (AUC, 0.75-0.91). For the 1-label classification of top common variables between the models, MLP achieved the highest AUC in Prop_CV_96, KL, and JSN (0.80, 0.99, 0.95). For Prop_CV_48 and TKR outcomes, GBM was the best classifier (AUC, 0.70, 0.99).

Conclusion: This is the first time that such a comprehensive study is performed for identifying the best predictors of knee OA rapid progressors. Importantly, data showed that MRI-based variables and outcome have the most significant impact in identifying OA progressors, and could be applied for early prognosis in clinical practice.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) and opioids are commonly prescribed for patients with osteoarthritis (OA). However, both types of medication are associated with serious side effects. As a result, guidelines for the treatment of OA have changed substantially over the past 2 decades. Our purpose in this study was to describe the trends in prescribing of NSAIDs (including COX-2 inhibitors) and opioids among patients with OA in the general population.

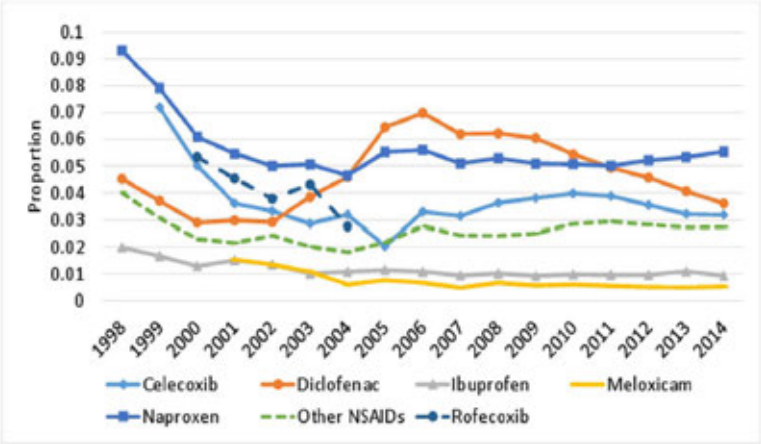

Figure 1. Prescriptions for NSAIDs in patients newly diagnosed with OA in British Columbia, Canada, 1998 - 2014

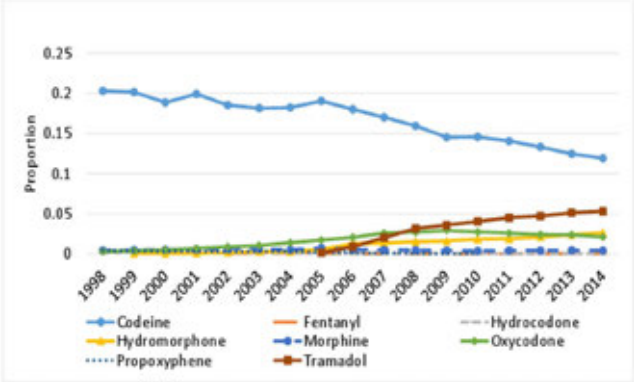

Figure 2. Prescriptions for opioids in patients newly diagnosed with OA in British Columbia, Canada, 1998 - 2014

Methods: We analyzed data from a large, population-based administrative database (PharmaNet) that included all prescriptions for persons aged 50+ processed by pharmacies in the province of British Columbia (BC), Canada, linked to diagnostic codes for visits to physicians and hospitalizations between 1990 and 2014. We identified all incident cases of OA, defined as at least 2 codes within 2 years, with a run-in period of 7 years. We identified all new prescriptions (no prescription in 6 months prior to diagnosis) for each NSAID and opioid available in BC and calculated the proportion of people starting NSAID or opioid medication. We performed similar analyses for prevalent (any) prescriptions among all prevalent cases of OA.

Results: Between 2000 and 2014, the proportion of new OA patients with an NSAID prescription declined from 19.8% to 16.5%. For most NSAIDs (Figure 1), prescriptions declined from 1998 till 2004 and were relatively stable until 2014, with the exception of diclofenac, which increased substantially from 2002 to 2006 and decreased afterwards. In 2014, the most common NSAID was naproxen (5.5%) followed by diclofenac (3.6%), celecoxib (3.2%), ibuprofen (0.9%) and meloxicam (0.5%). For opioids (Figure 2), the overall trend was relatively flat from 1998 to 2004, peaked in 2008 at 24.0%, and declined slightly thereafter. Codeine was by far the most commonly prescribed opioid throughout the study period, but declined from 20.3% of new OA patients in 1998 to 11.9% in 2014. Tramadol increased steadily from its introduction in 2005 and has been the second most common opioid since 2008, reaching 5.3% in 2014. Prescriptions for oxycodone started to decline around 2009 and reached 2.1% in 2014, whereas those for hydromorphone steadily increased to 2.6%. Other opioids were rarely prescribed in patients with OA. The results of prevalence analyses were essentially similar.

Conclusion: There have been important changes in the pattern of prescribing analgesics in BC during the study period. Declines in NSAIDs may have been compensated by increased prescriptions for opioids. This is likely to change as new guidelines discourage the long-term use of opioids as a consequence of the opioid crisis.

Abstract Number: 2203

Impact of Hypothetical Changes in the Use of Analgesics on the Burden of Osteoarthritis: A Population-based Microsimulation Study

Jacek Kopec,[1] Eric Sayre,[2] Anya Okhmatovskaia,[3] Jolanda Cibere,[4] Linda Li,[5] Nick Bansback,[6] Hubert Wong,[5] and John Esdaile[7], [1]Arthritis Research Canada and the University of British Columbia, Vancouver, BC, Canada, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]McGill University, Montreal, QC, Canada, [4]Arthritis Research Canada and the University of British Columbia, Vancouver, Canada, [5]University of British Columbia, Vancouver, BC, Canada, [6]University of British Columbia, Vancouver, Canada, [7]Arthritis Research Canada and the University of British Columbia, Richmond, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Analgesics are the cornerstone of medical treatment of osteoarthritis (OA) but are associated with serious side effects. A more optimal use of analgesics in OA is one strategy to reduce the population health burden of OA. The purpose of this simulation study was to assess the impact of hypothetical changes in the use of analgesics on the quality-adjusted life years (QALYs) among persons with OA in the general population.

Methods: We used a previously validated population-based microsimulation model of OA in Canada, POHEM-OA. Model parameters were derived from a large administrative database in British Columbia, Canadian national surveys,

and the scientific literature. The model included data on OA incidence, frequency of use of 4 classes of medication (acetaminophen, traditional non-steroidal anti-inflammatory drugs [NSAIDs], COX-2 inhibitors [coxibs], and opioids), treatment benefits in terms of pain reduction, frequency and quality-of-life (QOL) impact of adverse effects associated with each medication type (dyspepsia, ulcer, cardiovascular disease [CVD], stroke, and "other") and overall QOL measured by the Health Utilities Index 3. We assessed the impact of changes in medication use on overall QALYs. In the base-case scenario we assumed that the relative risk of adverse effects due to medication is doubled among persons aged 70+ compared to those < 70 years of age. Alternative assumptions were tested in sensitivity analyses. The scenarios involved increases and decreases in the use of all medications and each medication type individually.

Results: Under the base-case scenario, an average person with OA accumulated about 13.3 QALYs from OA diagnosis till death. Increasing the odds of using analgesics by 50%, 100% and 200% resulted in incrementally greater improvements in overall QALYs. However, the improvements were small (0.05-0.15 QALYs) and were observed only for opioids and acetaminophen. Increasing NSAIDs had virtually no effect on overall QALYs. Targeting persons with moderate or severe pain (>2 or >3 on a 5-point scale) for aggressive treatment (increasing the odds of treatment 3-fold) achieved a greater overall benefit than targeting all OA patients. Reducing the odds of using all analgesics by 50% among older (70+) patients with OA did not affect QALYs, whereas eliminating NSAIDs in this group had a slight beneficial effect at the population level. These results were sensitive to the assumptions about the relative risk of adverse effects among the elderly.

Conclusion: We found a beneficial but relatively small impact on QALYs of more aggressive treatment of OA with acetaminophen and opioids, and no benefit from increasing NSAIDs. For coxibs, even though gastrointestinal complications were reduced compared to traditional NSAIDs, the benefits of pain reduction were virtually nullified by the increased risk of CVD and stroke. Overall, the results seem plausible and support the validity of the simulation model. A limitation of the current model is that it does not consider the long-term harmful effects of opioids, including addiction and overdose.

Fragility Fractures in a Community Setting: Clinical Characteristics, Care Gaps, and Outcomes

Rachel Kneeland,[1] Keile Wahle,[1] Ishwar Gill,[1] Yangyang Liu,[2] and Monika Starosta[3], [1]Department of Internal Medicine, Advocate Lutheran General Hospital, Park Ridge, IL, [2]Russell Center for Research & Innovation, Advocate Lutheran General Hospital, Park Ridge, IL, [3]Department of Rheumatology, Advocate Lutheran General Hospital, Park Ridge, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis-related fragility fractures contribute to significant morbidity and mortality. The risk of subsequent hip fracture is significantly increased after initial fracture, with some reports suggesting rates of recurrent fractures in hip and spine to be 41% and 45% at 1-year, respectively[1]. Hip fractures plateaued between 2002-2012, yet increased between 2013-2015 resulting in an estimated 11,000 additional fractures[2]. Despite widely available access to Dual-energy X-ray absorptiometry (DEXA) and treatment, this effect may be due to low rates of

screening and treatment[3]. The purpose of this study was to identify the most common initial and secondary fractures, associated mortality, and frequency of screening and treatment.

Methods: Adults aged 65 and older diagnosed with fragility fracture at Lutheran General Hospital from January 2012 to January 2017 were included in this analysis. Fragility fractures, defined as wrist, humerus, vertebral, hip, and pelvis, were identified with ICD9/ICD10 codes, along with demographic and clinical characteristics from the Advocate Health Care EMR system. Univariate analysis for continuous and categorical variables were conducted. Logistic regression was applied to examine the association of demographic characteristics and risk of fragility fractures. A two-tailed *P* level of .05 was considered statistically significant in all analyses. All analyses were performed using SAS 9.4.

Results: A total of 1,424 initial and 137 secondary fragility fractures were identified. For initial fractures, vertebral was most common (607, 42.63%), closely followed by hip (592, 41.92%), and pelvis (153, 12.08%). The majority of initial fracture patients were females (1021, 71.7%), Caucasians (1209, 84.9%) and the mean age was 82.1-years-old (range: 66-105). DEXA and treatment with anti-resorptive medications were recorded at time of initial fracture among 17.6% and 1.9% of patients, respectively. DEXA and treatment for patients with recurrent fractures were recorded among 27% and 31% of patients, respectively. There were no statistically significant differences for in-hospital all-cause mortality among vertebral, hip, and pelvic fractures.

Conclusion: Vertebral, hip, and pelvic fractures are a common cause of initial fragility fracture in those over age 65. Pelvic fractures may represent an under-reported cause of initial fragility fracture with similar rates of morbidity com-

	All Initial Fractures (N=1424)	Vertebral (N=607)	Hip (N=592)	Pelvis (N=153)

Dual Femur Bone Density Measurements with Novel Sonographic Approach - Radiofrequency Echographic Multi Spectrometry

Elena Kirilova,[1] Nikola Kirilov,[2] **Martin Nikolov**,[1] Nikolay Nikolov,[1] Iliya Popov,[3] and Stoyanka Vladeva[4], [1]UMBAL "Dr. Georgi Stranski" EAD, Pleven, Bulgaria, [2]Medical University of Sofia, Sofia, Bulgaria, [3]University Prof. Assen Zlatarov, Burgas, Bulgaria, [4]Trakia University, Stara Zagora, Bulgaria

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A novel, non-ionizing approach - Radiofrequency Echographic Multi Spectrometry (REMS) was recently introduced for diagnosis of osteoporosis on both sites-lumbar spine and femoral neck. In the previous studies, bone mineral density (BMD) assessed by REMS technique highly correlated with BMD obtained by dual X-ray absorptiometry (DXA). However, there is no previous study, which investigated the diagnostic role of the dual femur BMD measurements based on REMS technology. The aim of this study is to compare the REMS-$_{based}$ BMD values of both femora-left and right in postmenopausal women and to identify the number of the women, in which the inclusion of bilateral hip in BMD measurement changed the diagnosis to more severe.

Methods: Dual femur was assessed in 72 postmenopausal women with mean age 61 years ± 13 standard deviations (SD), (range 40-66 years). Data was analyzed with SPSS version 21.0. Patients were classified as osteopenic if -2.5 SD < T-score< -1.0 SD, as osteoporotic if T-score ≤ -2.5 SD and healthy if T-score ≥-1.0. Linear regression analysis was used to compare the REMS-based BMD values of both femora.

Results: Based on the unilateral (left) hip BMD measurements, 22 women were diagnosed with normal BMD, 35- with osteopenia and 15 - with osteoporosis. The mean left femoral neck BMD was 0.879 g/cm^2 ± 0.100 g/cm^2 in the women with normal BMD, 0.685 g/cm^2 ± 0.056 g/cm^2 in the women with osteopenia and 0.507 g/cm^2 ± 0.054 g/cm^2 in the women with osteoporosis. The mean right femoral neck BMD was 0.873 g/cm^2 ± 0.095 g/cm^2 in the women with normal BMD, 0.677 g/cm^2 ± 0.046 g/cm^2 in the women with osteopenia and 0.507 g/cm^2 ± 0.054 g/cm^2 in the women with osteoporosis. A strong correlation between left and right femoral neck BMD values was observed (r^2=0.978, p=0.000), (figure 1). 63.6% (14/22) of the women with normal BMD had a T-score discordance equal to

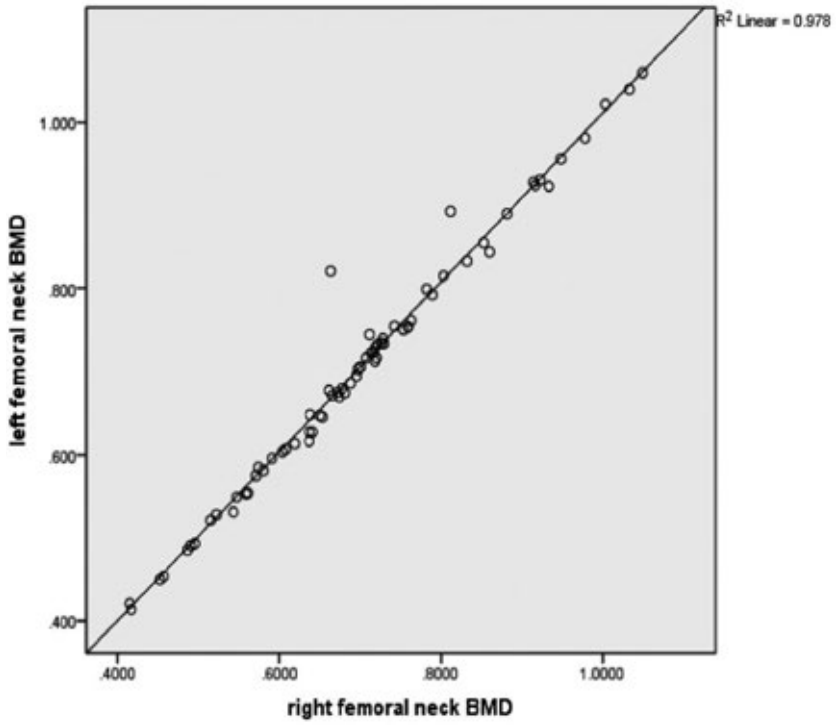

Figure 1. Linear regression analysis for comparison of the REMS-based BMD values of both femora.

0.1 and 4.6% (1/22) – equal to 0.2. 31.8% (7/22) of the women with normal BMD were attributed to a more severe diagnosis - osteopenia after assessing the dual femur. 48.6% (17/35) of the women with osteopenia had a T-score discordance equal to 0.1, 8.6% (3/35) – equal to 0.2 and 2.9% (1/35) – equal to 0.5. 2.9% (1/35) of the women with osteopenia were attributed to a more severe diagnosis – osteoporosis after assessing the dual femur. 33.3% (5/15) of the women with osteoporosis showed a T-score discordance equal to 0.1.

Conclusion: In women with femoral neck BMD values, which correspond to borderline T-scores, dual femur BMD measurements could be crucial for obtaining a more accurate diagnosis and decision about the treatment.

MRI-based Textural Analysis of Trabecular Bone: A Novel Method for the Opportunistic Screening of Bone Quality

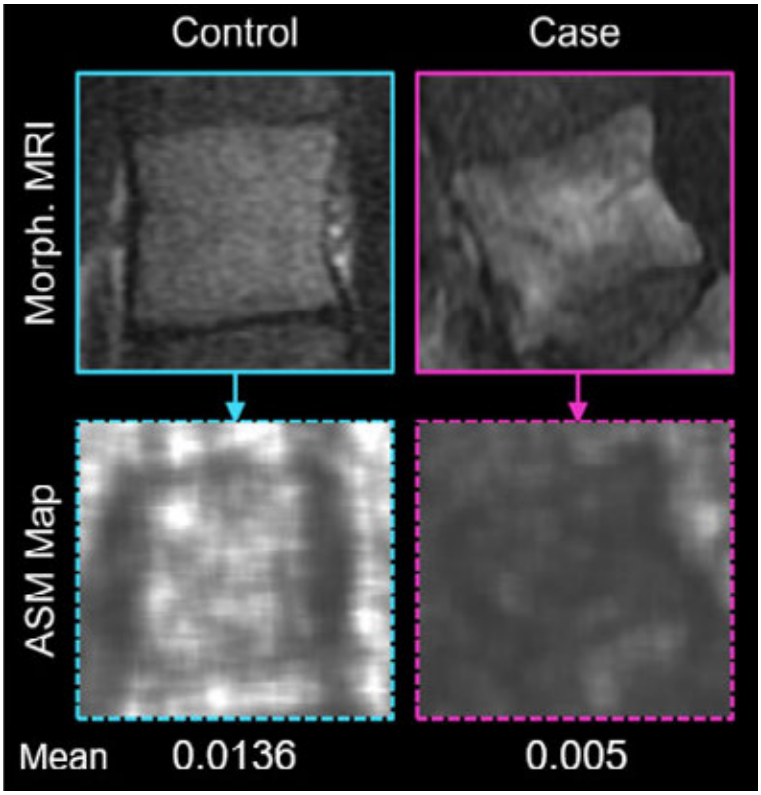
Jonathan Cheah,[1] Matthew Koff,[1] Ryan Breighner,[1] Bin Lin,[1] Conor Jones,[2] Janice Havasy,[2] Mikas Grewal,[1] and Emily Stein[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A major obstacle to the treatment of osteoporosis and prevention of fractures is that many at-risk patients are never screened. Dual energy x-ray absorptiometry (DXA) measurements of bone mineral density, the gold standard for diagnosis of osteoporosis, are only performed in a minority of patients. Therefore, opportunistic methods using imaging obtained for other clinical purposes are needed to foster identification and treatment. The aim of this pilot study was to investigate textural analysis of MRI scans of the lumbar spine (LS) as a measure of bone quality. We hypothesized: 1) similar to trabecular bone score (TBS) derived from DXA, textural analysis of MRI would provide an assessment of bone quality based upon trabecular (Tb) bone distribution and 2) Tb bone heterogeneity measured by MRI texture analysis would be higher in those with a history of fragility fracture compared to healthy controls.

Methods: In this study, we analyzed LS MRI scans of 30 patients. Cases (n=15) were postmenopausal women with a radiographically confirmed fragility fracture. Controls (n=15) were healthy women aged 25-35 years. Tb bone from the lumbar vertebrae was segmented to create regions of interest (ROIs). Fractured or previously instrumented vertebrae were excluded. A gray level co-occurrence matrix (GLCM) was then created to quantify the distribution and spatial organization of pixels within the Tb bone ROI. Heterogeneity in Tb bone texture was assessed by the following independent parameters, both globally as well as in anatomic directions: contrast (variability), entropy (disorder) and angular second moment (homogeneity) [figure]. Texture measures were compared using the Wilcoxon rank-sum test.

Results: Measures of Tb bone heterogeneity were worse in fracture patients, who had 139% higher contrast, 14% higher entropy and 60% lower angular second moment compared to controls (all $p < 0.05$). Contrast was the measure that most effectively discriminated between groups: fracture patients had 128-161% higher values in the vertical, horizontal, diagonal and through planes (all $p < 0.05$).



Comparison of output map and mean value for angular second moment (ASM)

Conclusion: In summary, textural analysis of Tb bone discriminated between patients with known osteoporotic fractures and controls. Our results demonstrate the feasibility of applying this technique to MRI to evaluate Tb bone quality. Further investigation is required to validate this promising methodology, which has the potential to greatly expand the number of patients screened for skeletal fragility.

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate alterations of bone mineral density and microarchitecture in patients with rheumatoid arthritis (RA). We also aimed to identify potential factors associated with these alterations.

Methods: In this case-control study, patients with RA were recruited from the PUMC Hospital site of the Chinese Registry of rhEumatoiD arthrITis (CREDIT). The primary outcomes were high-resolution peripheral quanitative computed tomography (HRpQCT)-related measures at the distal radius and tibia (Scanco XtremeCT II), and data from age- and gender-matched healthy controls were included for comparison. Additional diagnostic imaging examinations included thoracolumbar X-ray and DXA. Data regarding demographic and clinical characteristics, osteoporosis-related risk factors, and RA-related diagnosis and treatment history were collected. Finally, grip srength, serum bone turnover markers, TNF-α and IL-6 were also measured. Correlation between HRpQCT parameters and potentially related covariates were analyzed using univariate and multivariate linear regression analysis.

Results: A total of 81 patients (69 women, aged 57.9±8.7y, RA duration 5.7(1.4-11.2)y) and 81 matched healthy controls were included. Compared with controls, patients had significantly larger bone area and lower total and trabecular vBMD at both distal radius and tibia. HRpQCT measures at the distal tibia also showed lower cortical bone thickness in patients with RA. Further analyses were conducted among RA patients. aBMD at both the lumbar spine and total hip was positively correlated with vBMD, trabecular bone volume fraction, trabecular number and cortical thickness, and was negatively correlated with trabecular separation and inhomogeneity. Trabecular thickness and

cortical porosity were not correlated with aBMD at any sites. vBMD was positively correlated with body mass index, grip strength and ever being treated with HCQ, and was negatively associated with age, RA duration and DAS28-ESR. Age and RA duration were significant factors in multivariate analysis. In contrast, parameters reflecting impairment of microarchitecture (trabecular inhomogeneity and separation) were negatively correlated with BMI and grip strength, and was positively related to age, disease duration and activity. Duration and activity remained significant in multivariate regression. Current treatment with glucocorticoids was related to decreased vBMD, trabecular number and increased trabecular separation and inhomogeneity. No correlations were observed with regards to dose or duration of GCs. Patients with fragility fractures had significantly lower vBMD in both trabecular and cortical bone, thinner cortical bone as well as impaired trabecular bone microstructure (fewer in number, larger separation and increased inhomogeneity). Bone turnover markers, TNF-α and IL-6 were not related to any HRpQCT parameters in this study.

Conclusion: Patients with RA have alterations in bone density and microarchitecture compared to healthy population, which may impair bone strength and lead to increased risk of fractures. Both traditional risk factors for osteoporosis and RA-associated factors need to be considered in the assessment of bone quality in RA.

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with elderly-onset arthritis have greater comorbidity than young patients, with a higher incidence of osteoporosis (OP), probably mediated by increased bone resorption. However, there are few data on bone metabolism mediators in this population.

Methods: Longitudinal observational study that included patients with elderly-onset arthritis (> 65 years) without diagnosis of OP or on antiosteoporotic treatment. Phospho-calcium metabolism, quantification of bone remodeling mediators (DKK1, sclerostin, OPG and RANKL; ELISA, R&D systems) and bone densitometry were determined in all patients at diagnosis and at 12 months. The results were compared with a control group of the same age and sex (n=14). The statistical study was performed using SPSS.

Results: We included 73 patients (37F: 36M), with a mean age of 75±7 years. Most were diagnosed with rheumatoid arthritis (RA) (n=43), followed by polymyalgia rheumatica (n=16) and others (n=14). Fifteen patients were rheumatoid factor (RF) positive and 23 were ACA positive. Five patients had erosions at the diagnosis. 88.64% of patients with RA had an initial DAS28-ESR >5.1. Only 3 patients had previous fragility fractures (2 vertebral and 1 femur fractures). At diagnosis, patients with elderly-onset arthritis had higher levels of DKK1 and CTX than the control group, with no statistically significant differences in sclerostin, OPG, and RANKL values (table 1). In addition, DKK1 values were negatively correlated with sclerostin (r=-0.286, p=0.016) and OPG (r=-0.276, p=0.020). 31.9% had densitometric OP at baseline. We found no significant differences in bone remodeling mediators between patients with/without basal OP. At 12 months, DAS28-ESR was < 2.6 in 38.1%. The mean corticosteroid dose was 5.5 mg/day with a cumulative dose of 1630±426 mg. 45.8% received antiosteoporotic treatment (28 patients' bisphosphonates and 5 denosumab). The prevalence of OP at 12 months was 31.3% and 4 patients had new fractures (4 vertebral and 1 femur fractures). We observed a marked decrease in the values of DKK1 (-18.89%, p< 0.001) and sclerostin (-46.76%, p< 0.001) and an increase in OPG (11.97%, p=0.018). We didn´t found relationship between bone metabolism mediators and cumulative corticosteroid dose. There were not differences in terms of diagnosis (RA or PRM), ACA positivity, activity scores or treatment with bisphosphonates.

Conclusion: Patients with elderly-onset arthritis have higher Dkk1 values than the control group, and this correlate negatively with sclerostin and OPG. The marked decrease in Dkk-1 and sclerostin at 12 months, and the increase in OPG, suggests a role for these mediators in the bone metabolism of this population. It is important to note the high prevalence of OP in this group of patients.

Table 1: Clinical and analytical variables and values of bone metabolism mediators at baseline, at 12 months and in the control group.

Study of Vertebral Fracture Prevalence and Scanographic Bone Attenuation Coefficient of the First Lumbar Vertebra (SBAC-L1) in Patients with Rheumatoid Arthritis and Ankylosing Spondylitis vs. Controls

Marine Fauny,[1] Eliane Albuisson,[2] Elodie Bauer,[1] Julia Perrier-Cornet,[1] Isabelle Chary-Valckenaere,[2] and Damien Loeuille[3], [1]CHRU Nancy, VANDOEUVRE, France, [2]Centre Hospitalier Universitaire de Nancy, VANDOEUVRE, France, [3]Rheumatology, Nancy University Hospital and and UMR 7365 CNRS-UL IMoPA, Université de Lorraine, VANDOEUVRE, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a common disease whose prognosis can be seriously impacted by the development of fractures that lead to functional limitations and may even have life-threatening sequelae. This disease is often under-screened, especially in at-risk populations that require multidisciplinary care such as patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Moreover, a recent study showed that the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) with a threshold at 145 Hounsfield Units (HU) identified 96.6% of patients in the general population with a vertebral fracture (VF), whereas DEXA (with a T-score ≤ -2,5) identified only 39% of these patients.

The objective of the study was to identify the prevalence of vertebral fractures (VF) and to measure the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) based on CT-scan examinations of patients with rheumatoid arthritis (RA), patients with ankylosing spondylitis (AS) and in a control group.

Methods: This monocentric and retrospective study included patients who were evaluated between 2009 and 2017 with a diagnosis of RA based on the ACR/EULAR criteria, those with a diagnosis of AS based on the New-York criteria, and a RA-matched control group. All of the patients received a CT-scan. The osteoporosis risk factors, data from dual energy X-ray absorptiometry (DEXA) and clinical characteristics were collected. VFs were determined via CT-scans according to the Genant classification, and the SBAC-L1 was measured in Hounsfield units (HU). SBAC-L1 ≤ 145 HU (fracture threshold) defined patients at risk of VF.

Results: A total of 244 patients were included (105 RA, 83 AS, 56 controls). The AS group was younger and primarily consisted of males. Of the 4,365 vertebrae studied, 66 osteoporotic VF were found in 36 patients: 18 (17.1%) patients with RA, 13 (15.7%) patients with AS and 5 (8.9%) controls. The SBAC-L1 was 142.2 (±48.4) HU for the RA group and 142.8 (±48.2) for the AS group, both of which were significantly lower than that of the control group (161.8 (±42.7) HU). Of the 36 patients with VF and rheumatism, 28% had a T-score ≤ -2.5 SD, and 71.4% had a SBAC-L1 ≤ 145 HU. A T-score ≤ -2.5 SD and a SBAC-L1 ≤ 145 HU were associated with the presence of a VF (OR = 2.35 [CI95%: 1.12-4.92] and 2.06 [CI95%: 1.04-4.10]), respectively.

Conclusion: The SBAC-L1 was significantly lower in the RA and AS groups than in the control group. Furthermore, SBAC-L1 ≤ 145 HU was associated with a higher risk of VF, with an odds ratio similar to that of a DEXA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Thoracic and/or thoraco-abdomino-pelvic (TAP) Computed Tomography (CT) may be performed during the follow up of patients with ankylosing spondylitis (AS) and are able to assess vertebral fracture and recently to assess bone fragility thought the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1).

The objective is to evaluate the correlation between the risk of bone fragility measured by the SBAC-L1 and spine structural severity assessed by the S (Modified stoke ankylosing spondylitis spinal score) in patients with AS.

Methods: This monocentric retrospective study included patients with spondyloarthritis followed from 2009 to 2017 at the University hospital of Nancy. Patients should fulfill New-York or ASAS 2009 criteria with radiographic sacroiliitis and a thoracic or TAP CT scan and radiographies (spine, pelvis) performed with a delay which did not exceed 2 years. Osteoporotic risk factors, Dual Energy X-ray Absorptiometry (DXA) measurements and clinical characteristics were collected. The mSASSS was performed by two readers with adjudications in case of discordance. The definition of structural spine involvement is retained for a mSASSS ≥ 2. Vertebral fractures were studied on sagittal spine radiographies according to Genant classification. The SBAC-L1 was measured in Hounsfield Units (HU) on axial L1 section in trabecular bone on CT. Intra- and inter-reader reliabilities for mSASSS and vertebral fractures were calculated. A SBAC L1 ≤ 145 HU (fracture threshold) defines patients at risk of VF.

Results: A total of 73 AS patients were included (age median: 60 (53-68.5) years, 8 women (11%)), disease duration median: 24 years (12-34)). Sixty patients (82.2%) have a mSASSS ≥ 2, with a mean score of 20.7 (±21.2). Presence of partial ankylosis is observed in 37 patients (50.7%). Fifty-three patients (72.6%) presented at least one clinical risk factor of osteoporosis. Assessment of osteoporosis was explored by DXA of the spine in only 16 patients (21.9%) and 3 (18.8%) of them presented a T-score ≤ -2.5 SD. T-score of AS patients with mSASSS + tended to be higher in comparison to AS patients with mSASSS – (p=0.051). Thirteen VFs were detected in 9 patients (12.3%) of the total population, 8 from them have a mSASSS ≥ 2 and 5 have de SBAC-L1 ≤ 145 HU. The mean SBAC-L1 was 141.1 HU (±45) in the whole population, 138.1 HU for mSASSS + and 154.8 for mSASSS – respectively. Forty-two patients (57.5%) presented a SBAC-L1 ≤ 145 HU: 60% in mSASSS + and 46.2% in mSASSS-. Patients with bone bridge have a lower SBAC-L1 (123.96 ± 41.1 HU) than patients mSASSS + without vertebral ankylosis (160.4 ± 41.9 HU) (p=0.02). The number of AS patients under the fracture threshold was higher in mSASSS+ in comparison to mSASSS - (73% vs 41.9%, p=0.006). The reproducibilities are very good (over 0.8) for mSASSS, poor to moderate for VF (0.3 to 0.6) and good to excellent for radiographic sacroiliitis.

Conclusion: There is no relation between the risk of bone fragility measured by the SBAC-L1 and spine structural severity assessed by the mSASSS in patients with AS, however patients with bone bridge have significantly lower SBAC-L1 and more of them are under the fracture threshold compared to patients without bone.

***p<0.05 comparison with the control vertebrae status (vertebra without structural lesion),** L1, L2, L3, L4 and L5: lumbar vertebra 1, 2, 3, 4 and 5; N : number ; SBAC : Scanographic bone attenuation coefficient in Hounsfield units

Background/Purpose: Computed Tomography (CT) is sometimes performed during the follow up of patients with ankylosing spondylitis (AS) to screen comorbidities or complications. Thoracic or thoraco-abdomino-pelvic (TAP) CT have demonstrated their ability to depict vertebral fracture and recently to assess trabecular bone fragility though the scanographic bone attenuation coefficient (SBAC) on lumbar vertebrae (L1 to L5). To your knowledge, no study has assessed the impact of partial or complete vertebra ankylosis on the trabecular bone.

The principal objective was to characterize the SBAC on normal lumbar spine or spine with partial or total ankylosis.

Methods: This monocentric retrospective study included patients with AS followed from 2009 to 2017 at Nancy university hospital, fulfilling New-York criteria for AS and who underwent a thoracic or TAP CT and X-rays (spine, pelvis) within 2 years. Clinical characteristics were collected. Modified stoke ankylosing spondylitis spinal score (mSASSS) was scored by two readers, adjudication for one syndesmophyte discordance. Presence of one syndesmophyte defined mSASSS+ (mSASSS ≥ 2). Moreover, each lumbar vertebra was studied according to its level of ankylosis, 0: no lesion, 1: syndesmophyte(s), 2: partial ankylosis (superior or inferior) and 3: total ankylosis (both inferior and superior). The SBAC was measured in Hounsfield Units (HU) on L1 to L5 vertebrae, and a fracture threshold was defined at ≤145 HU.

Results: On 1503 spondyloarthritits, 73 AS patients were included (mean age: 60.3 (±10.7) years, 8 women (11%)). Sixty patients (82.2%) had a mSASSS ≥ 2, with a mean score of 20.7 (±21.2). Presence of ankylosis of at least one disco-vertebral unit in cervical or lumbar segments of the spine on mSASSS was observed in 37 patients (50.7%) and 6 (8.2%) have total lumbar spine ankylosis. Concerning the lumbar spine, the details of number of vertebrae without structural lesion, with syndesmophyte(s) or with partial and complete ankylosis are presented in table 1. The SBAC for each lumbar vertebra were not significantly different between patients with mSASSS < 2 versus mSASSS ≥ 2 (p = 0.24 to 0.99). However, the SBAC was lower for patients with mSASSS≥ 2 and bone bridge than for patients with mSASSS≥ 2 without bone bridge (p = 0.02 to 0.0001). The risk of SBAC ≤ 145 HU was higher in presence of total ankylosis on at least one lumbar vertebra (HR: 4.95(CI95% :1.104-17.36, p = 0.04 to 0.001)). Partial lumbar ankylosis of L3 and L4 affected also the SBAC with higher risk to have a SBAC ≤145 HU (HR :11.8 (CI95% :1.822-25.67) and 15 (CI95%: 2.54-30.85)) respectively.

Conclusion: Only AS patients with ankylosed vertebra on mSASSS presented lower values of SBAC. We showed that complete ankylosis of any lumbar vertebra and partial ankylosis of L3 and L4 were associated with lower values of SBAC, suggesting deterioration of the trabecular bone structure ankylosed.

Patients with Axial Spondyloarthritis Have Abnormal Microarchitecture Despite Normal Areal Bone Mineral Density and Trabecular Bone Score by DXA

Dalit Ashany,[1] Susan Goodman,[2] Haley Tornberg,[1] Donald McMahon,[3] Douglas Mintz,[4] Linda Russell,[5] and Emily Stein[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital For Special Surgery/Weill Cornell Medicine, New York, NY, [3]Donald J.McMahon Statistical Consulting, South Nyack, NY, [4]Hospital for Special Surgery, Division of Radiology and Imaging, New York, [5]Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis (axSpA) is characterized by abnormal bone formation that produces syndesmophytes, while paradoxically, inflammation causes increased bone resorption and skeletal fragility. Detection of osteoporosis using DXA can be challenging as syndesmophytes falsely elevate spine areal bone mineral density (aBMD). In contrast, high-resolution peripheral QCT (HRpQCT) measures volumetric BMD (vBMD) and microarchitecture and is not subject to this artifact. This study investigated skeletal health in a cohort with axSpA using aBMD, trabecular bone score (TBS), a method for estimation of spine trabecular bone quality, and HRpQCT. We hypothesized that TBS and HRpQCT would reveal skeletal abnormalities in axSpA, while aBMD by DXA would appear normal.

Methods: Patients fulfilling the imaging arm of the ASAS criteria who were enrolled as part of an ongoing longitudinal study had DXA measurements of aBMD of spine, hip and1/3 radius, and TBS. Trabecular (Tb) and cortical (Ct) vBMD and microarchitecture were measured by HRpQCT (Xtreme CT2, voxel size ~61 μm) at the distal radius and tibia. DXA in axSpA were compared with normative populations of age and sex matched individuals (Z-Scores). HRpQCT values were compared to a healthy reference population of young sex-matched adults. T-tests compared skeletal parameters in subjects and normative populations. Spearman correlations related skeletal parameters to disease features.

Results: 18 subjects were enrolled; 56% male, age 42+13 yrs. On average, subjects had symptoms for 14 yrs and had received a diagnosis of axSpA 6 yrs prior to study enrollment. BASDAI and other criteria reflected high disease activity (Table 1). The majority of subjects had normal aBMD by DXA. TBS was normal in the majority (67%). By HRpQCT at the radius, axSpA had lower Tb vBMD (-0.9 SD) and Tb thickness (-1.7 SD) than the reference population. At the tibia, axSpA had lower total (-0.9 SD), Ct (-1.5 SD) and Tb vBMD (-1.2 SD) and Tb thickness (-1.4 SD; $p< 0.01$ for all). Longer duration of symptoms was related to worse vBMD and microarchitecture, tibia: total vBMD ($r=-0.83$; $p< 0.0001$), Tb density ($r=-0.76$; $p< 0.0005$), Tb number ($r=-0.51$; $p< 0.04$) and Tb separation ($r=0.61$; $p< 0.01$) and radius: Tb density ($r=-0.64$; o< 0.1), Tb number (-0.50; $p< 0.04$) and Tb separation ($r= 0.57$; $p< 0.02$). Current disease activity did not relate to HRpQCT abnormalities.

Conclusion: Subjects with active axSpA had low vBMD and microarchitectural abnormalities by HRpQCT despite normal DXA and TBS. Abnormalities were most pronounced at the tibia and related to duration of symptoms. Larger studies are needed to confirm our findings, which suggest that long-term impairment in mobility may contribute to skeletal abnormalities in patients with axSpA.

Evaluation of Factors Associated with Bone Structure in an SLE Cohort Measured by Clinical 3T MRI and DEXA

Amit Saxena,[1] Peter Izmirly,[2] Jill Buyon,[2] Stephen Honig,[2] Xiaoliu Zhang,[3] Punam Saha,[4] H. Michael Belmont,[5] and Gregory Chang[2], [1]New York University School of Medicine, New York, NY, [2]NYU School of Medicine, New York, [3]University of Iowa, Iowa City, [4]University of Iowa Healthcare, Iowa City, [5]New York University School of Medicine, Ney York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis and bone fractures are a frequent cause of morbidity in systemic lupus erythematosus (SLE), and are felt to be related both to disease activity and glucocorticoid (GC) exposure. Dual energy X-ray absorptiometry (DEXA) is the standard tool to assess bone density, but it does not measure bone quality or strength and is not a robust predictor of fractures in SLE. Clinical 3T MRI scans have been shown to assess information about bone not captured by DEXA. This study aims to evaluate factors associated with bone structure measured by DEXA and MRI in an SLE cohort.

Methods: DEXAs were performed on 31 women with SLE and 3T MRI of the non-dominant hip were performed on 29 of these cases. Results were associated with multiple demographic, clinical and laboratory measures. MRI parameters measured included trabecular plate width (PW), trabecular plate to rod ratio (PRR), plate volume fraction (PVF), rod volume fraction (RVF), trabecular bone thickness (Tb.Th), trabecular spacing (Tb.Sp) and trabecular network area (TNA). DEXA BMD was measured, and osteoporosis (OP) was defined as hip, spine or femoral neck Z score < -2.0 in premenopausal women, and T score < -2.5 in others, and low bone density (LBD) as Z score < -2.0 in premenopausal women and T score < -1.0 in others.
