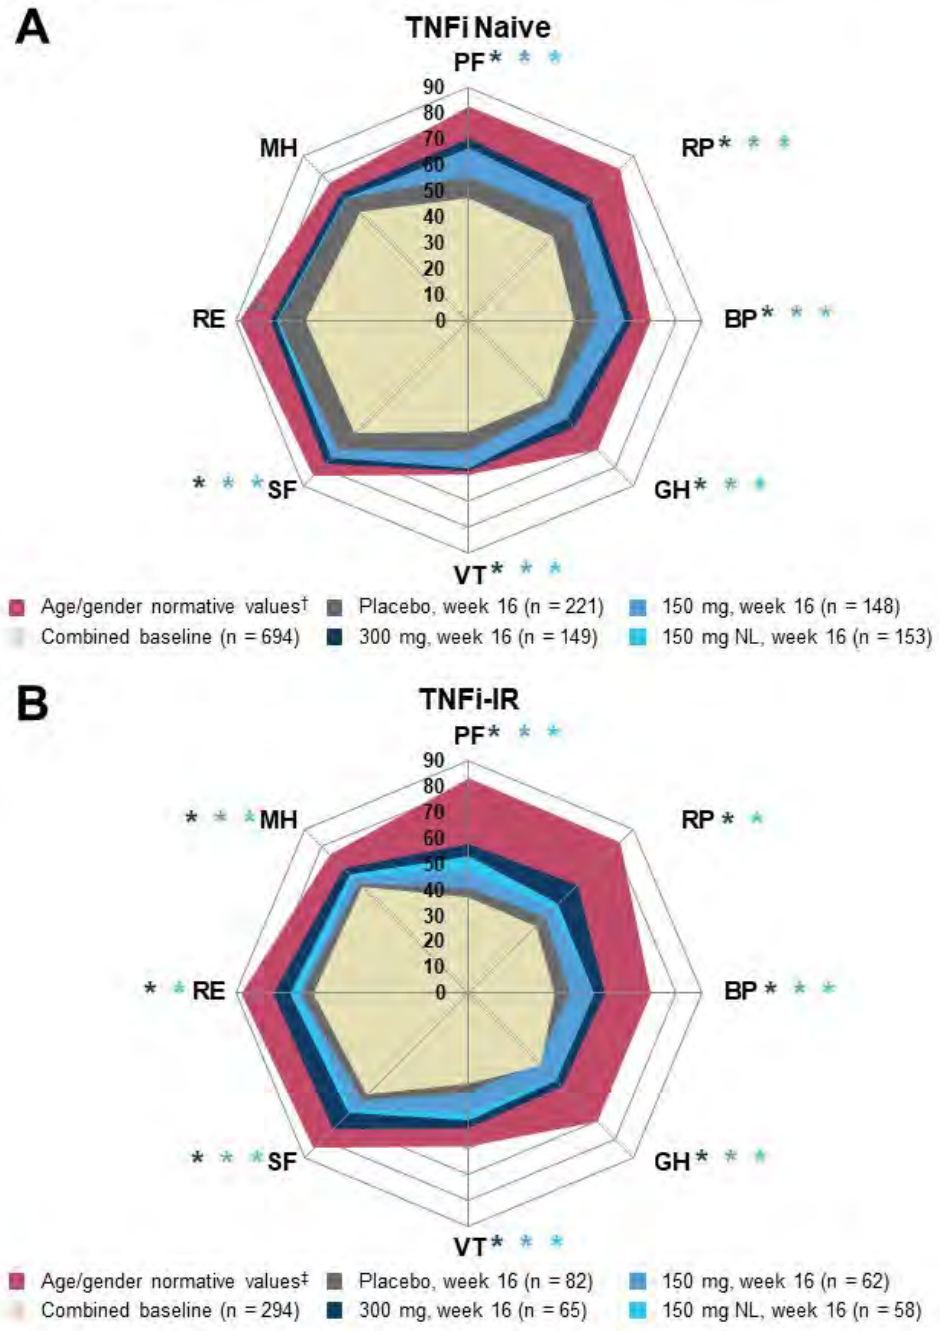
Methods: FUTURE 5 enrolled patients ≥ 18 years who met CASPAR with symptoms for ≥ 6 months at screening. Patients were randomized to receive SEC 300 mg, 150 mg, 150 mg no load (NL), or placebo (PBO) weekly from baseline to week 4 and every 4 weeks thereafter to week 16. Patients in the SEC 150 mg NL arm received PBO at weeks 1, 2, and 3. For this post hoc analysis, patients were stratified by prior TNFi use. PROs were assessed at baseline and selected visits through week 16. Mean changes from baseline in PROs and the proportions of patients reporting improvements ≥ minimum clinically important differences (MCIDs) and scores ≥ age/gender-matched normative values were assessed in each treatment group. PROs included patient global assessments of disease activity (PtGA) and psoriasis and arthritis (PtGA PsO/arthritis) visual analog scale (VAS), pain VAS, Health Assessment Questionnaire Disability Index (HAQ-DI), 36-item Short Form Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy (FACIT)–Fatigue, and Dermatology Life Quality Index (DLQI; patients with psoriasis only).

Results: Baseline PRO scores were generally worse in the TNFi-IR vs TNFi-naive population. TNFi-naive and TNFi-IR patients in all SEC treatment groups reported significantly greater improvements in PtGA, PtGA PsO/arthritis, pain, HAQ-DI, SF-36 physical component summary (PCS), and DLQI at week 16 vs PBO. Treatment responses were higher in the SEC 300-mg arm vs SEC 150-mg and 150-mg NL arms at week 16 across most PROs, including all SF-36 domains (**Figure 1**). Significantly higher proportions of both TNFi-naive and TNFi-IR patients receiving SEC reported improvements ≥ MCID as early as week 1 in HAQ-DI and at week 16 across all PROs except SF-36 mental component summary score vs PBO. The proportions of patients reporting improvement ≥ MCID in pain and HAQ-DI (**Figure 2**), as well as PtGA PsO/arthritis, SF-36 PCS, and DLQI, were higher in TNFi-naive than TNFi-IR patients. More SEC-treated patients reported scores ≥ normative values in HAQ-DI, SF-36 PCS, and FACIT-Fatigue at week 16 vs PBO, with more patients in the TNFi-naive than the TNFi-IR sub-population reporting scores ≥ normative values (**Figure 3**).

Conclusion: Initiation of SEC as a first-line biologic in patients with PsA resulted in early, statistically significant, and clinically meaningful improvements in PROs across all doses, and significant and meaningful improvements in

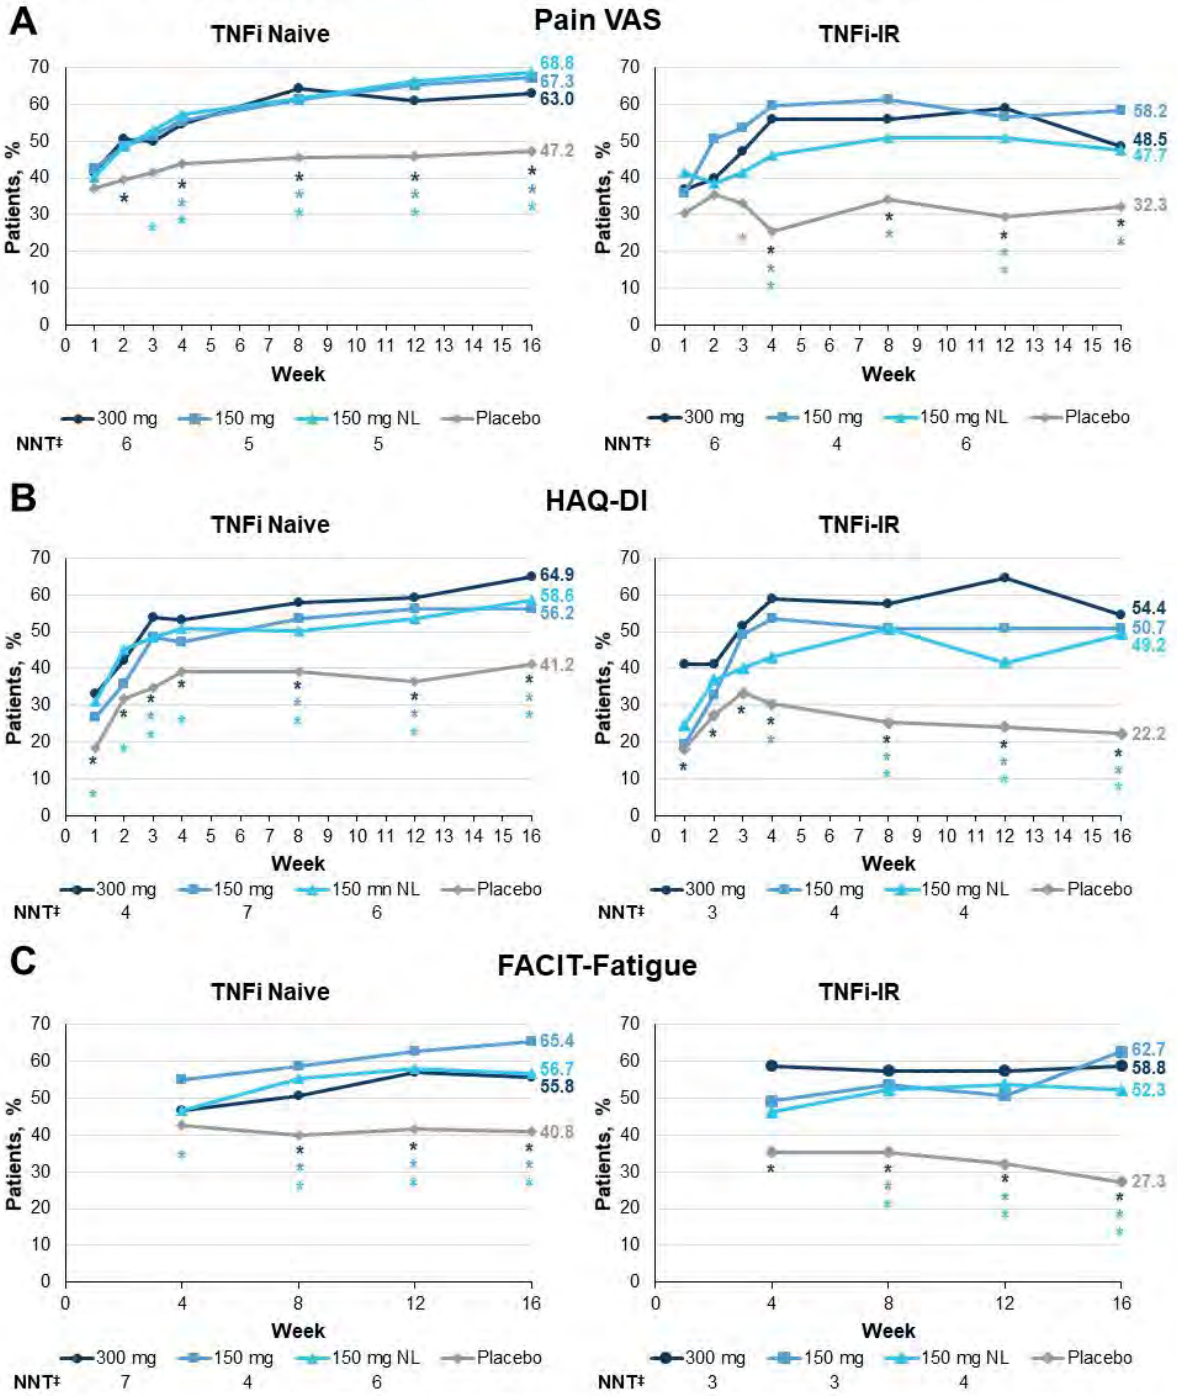
Figure 1. SF-36 Domain Scores at Baseline and Week 16 in **(A)** TNFi-Naive and **(B)** TNFi-IR Patients



BP, bodily pain; GH, general health; IR, inadequate response; MH, mental health; PF, physical functioning; RE, role-emotional; RP, role-physical; SF, social functioning; SF-36, 36-item Short Form Health Survey; TNFi, tumor necrosis factor inhibitor; VT, vitality.
* $P < 0.05$ compared with placebo.
† Age- and gender-matched normative values for SF-36 domains in TNFi-naive patients were defined as follows: PF, 82.5; RP, 83.2; BP, 73.0; GH, 70.45; VT, 59.0; SF, 85.2; RE, 88.5; MH, 75.9.
‡ Age- and gender-matched normative values for SF-36 domains in TNFi-IR patients were defined as follows: PF, 80.0; RP, 81.0; BP, 71.8; GH, 69.6; VT, 59.1; SF, 84.8; RE, 87.6; MH, 76.2.

TNFi-IR patients as later-line therapy. Treatment responses were higher in patients receiving SEC 300 mg vs 150 mg or 150 mg NL. TNFi-naive patients more frequently reported improvements ≥ MCID and scores ≥ normative values vs TNFi-IR patients, although TNFi-IR patients had lower baseline PRO scores and reported lower PBO responses.

Figure 2. Proportion of Patients Reporting Improvement from Baseline ≥ MCID† in **(A)** Pain, **(B)** HAQ-DI, and **(C)** FACIT-Fatigue Over 16 Weeks



FACIT, Functional Assessment of Chronic Illness Therapy; HAQ-DI, Health Assessment Questionnaire Disability Index; IR, inadequate response; MCID, minimum clinically important difference; NL, no load; NNT, number needed to treat; TNFi, tumor necrosis factor inhibitor, VAS, visual analog scale.

* $P < 0.05$ compared with placebo.

† MCIDs for PROs were defined as follows: pain VAS, ≥ 10; HAQ-DI, ≥ 0.35; FACIT-Fatigue, ≥ 4.

‡ NNT compared with placebo at week 16.

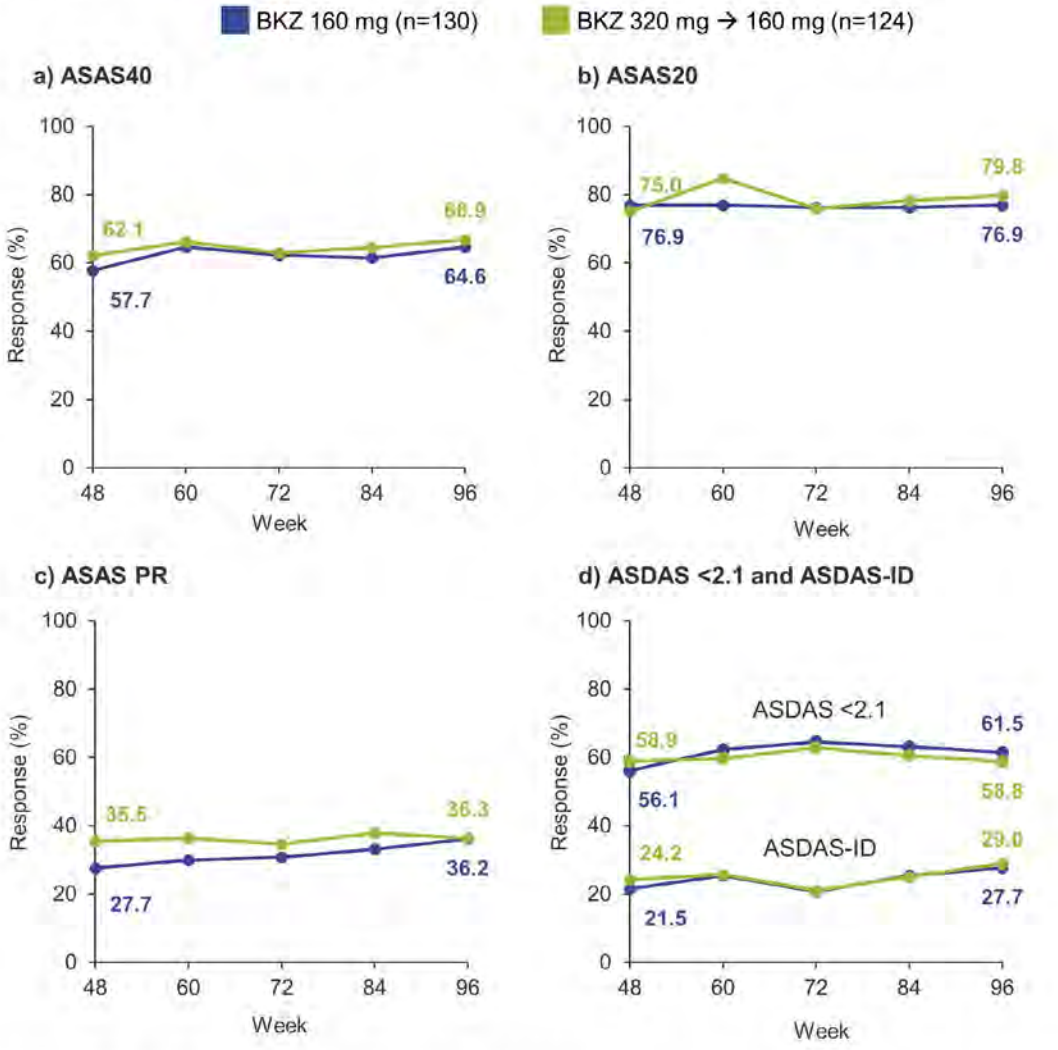
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ), a monoclonal antibody that selectively inhibits interleukin (IL)-17A and IL-17F, has demonstrated clinical efficacy in patients with ankylosing spondylitis (AS) treated over a period of 48 weeks.[1] We report 2-year interim efficacy and safety of BKZ in patients with active AS from a phase 2b dose-ranging study (BE AGILE; NCT02963506) and ongoing open-label extension (OLE; NCT03355573).

Methods: BE AGILE consisted of a 12-week dose-ranging period followed by a 36-week randomized period (BKZ 160 or 320 mg); full study design is described elsewhere.[1] Patients who completed 48 weeks' treatment in BE AGILE were eligible for entry into the OLE. All OLE patients received BKZ 160 mg every 4 weeks (Q4W) irrespective of previous dosing regimen. Efficacy and safety outcomes are presented from BE AGILE study baseline to Week 96. Efficacy outcomes are reported for the OLE Full Analysis Set (patients who had ≥1 dose of BKZ and ≥1 valid efficacy variable measurement since entry into the OLE), and include: Assessment of SpondyloArthritis international Society (ASAS) 40% and 20% response (ASAS40/20), ASAS partial remission (ASAS PR), Ankylosing Spondylitis Disease Activity Score (ASDAS) < 2.1, ASDAS inactive disease (ID: ASDAS < 1.3), ASDAS-CRP, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Metrology Index (BASMI) and Bath Ankylosing Spondylitis Functional Index (BASFI). Missing data were imputed using non-responder imputation (binary variables) or multiple imputation (continuous variables). Treatment-emergent adverse events (TEAEs) up to the 96-week treatment period cut-off and beyond are reported separately for the BE AGILE Safety Set and OLE Safety Set (patients who received ≥1 dose of BKZ on study entry).

Results: 262/303 (87%) patients randomized at BE AGILE study baseline completed Week 48, of whom 254/262 (97%) were included in the OLE Full Analysis Set, including 130 who continued on BKZ 160 mg Q4W and 124

Figure 1: Efficacy responses to Week 96 (OLE Week 48; non-responder imputation)



Full Analysis Set (N=254). ASAS: Assessment of SpondyloArthritis international Society; ASAS20/40: ASAS 20%/40% response; ASAS PR: ASAS partial remission; ASDAS: Ankylosing Spondylitis Disease Activity Score; BKZ: bimekizumab; ID: inactive disease (ASDAS<1.3); OLE: open-label extension.

dose-reduced from BKZ 320 mg Q4W to BKZ 160 mg Q4W. Of these, 238 (94%) had an efficacy assessment at Week 96. In BE AGILE, rapid improvements in efficacy outcomes were observed in BKZ-treated patients at Week 12; these further increased to Week 48 and were maintained during the OLE from Week 48–96 (**Figure 1, Table 1**). Responses were similar for patients on BKZ 160 mg and 320 mg at Week 48; and remained similar between patients continuing on BKZ 160 mg and those dose-reduced from BKZ 320 mg to 160 mg up to Week 96 (**Figure 1**). The exposure-adjusted incidence rate (EAIR) per 100 patient-years (PY) of TEAEs was 186.2 in BE AGILE (Weeks 0–48) and 111.7 in the OLE (Week 48 onwards); for serious TEAEs the EAIR/100 PY was 5.1 and 6.1, respectively (**Table 2**).

Conclusion: In patients with active AS who completed the first 48 weeks of BKZ treatment in BE AGILE, BKZ provides further sustained long-term improvements in key efficacy outcome measures over 96 weeks of treatment. Dose reduction from 320 mg to 160 mg Q4W was not followed by loss of response. There were no unexpected safety findings versus previous studies.

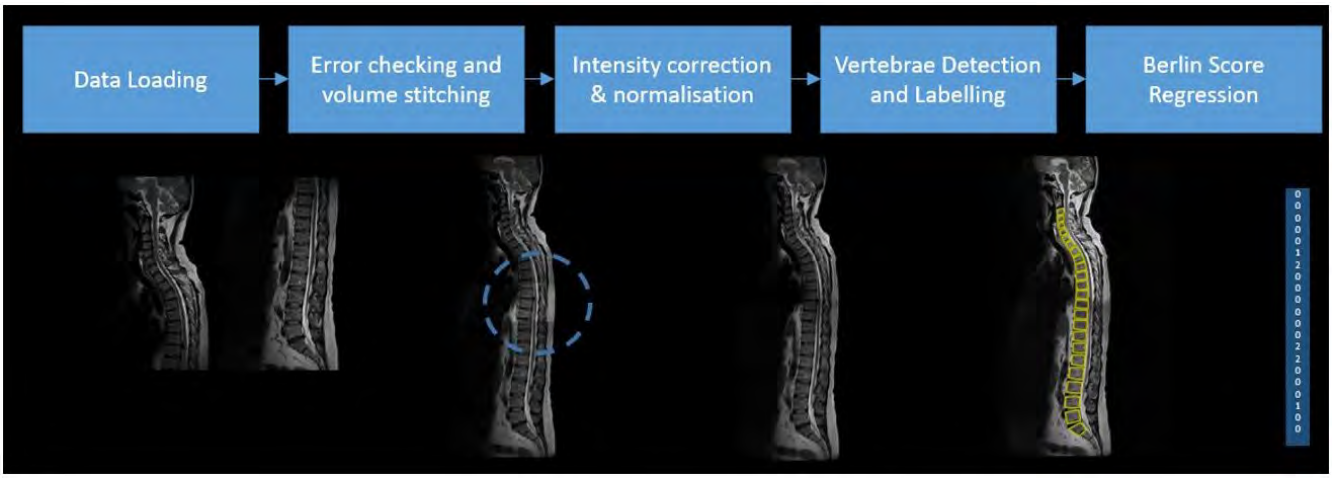
SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) offers a non-invasive and objective method of early diagnosis and classification, monitoring disease burden and treatment response for patients (pts) with axial spondyloarthritis (axSpA).[1] Numerous scoring schemes such as the Ankylosing Spondylitis (AS) Spine MRI Activity (ASspiMRIa) score are available for the quantitative assessment of MRI, but are subject to intra- and inter-rater variability, are labor intensive and costly. Nevertheless, quantification of MRI changes has become an important tool to demonstrate treatment success of biologic drugs in axSpA. In this study, we evaluate the performance of machine learning (ML) based software for the automated Berlin grading of spinal MRI bone marrow edema in pts with AS and compare with expert scoring.

Methods: Fully automated ML software (Figure) was developed to detect and label 23 vertebrae, define vertebral units (VU) as per the Berlin modification of the ASspiMRIa score, and score each VU as either 0 (score of 0) or 1 (score of 1, 2 or 3). The ML algorithm was based on the previously developed SpineNet software.[2] Analysis included 108 pts from the secukinumab MEASURE 1 study[3], in which imaging was done using T1 and STIR sagittal MRI at baseline and Weeks 16, 52, 104, 156 and 208. Two expert readers (R1 and R2), blinded to treatment and visit, evaluated all images by Berlin-modified ASspiMRIa score. The scores from both readers were binned or categorized into two groups: 0 vs 1, 2, or 3. As a result of multiple pt time points and expert reading sessions, the complete dataset comprised of 10,988 VUs, (8,954 graded by R1, 9,010 graded by R2). Ten-way cross-validation at the VU level was used to train and validate the ML software. The dataset was split into 10 randomly selected subsets, ensuring that each pt appears in only one subset, after which 8 subsets were used for training the ML software, one was used to check for correct training, and one was used for validation. The process was repeated 10 times such that all 10 subsets were used for validation. Area-Under-the-Curve (AUC), accuracy weighted for the frequency of each category, sensitivity and specificity were calculated. Intra- and inter-reader accuracy were also calculated.



Processing pipeline of automated Berlin scoring software

	Software Score = 0	Software Score = 1, 2 or 3	Total VU scored
R1 Score = 0	6505 (75%)	2177 (25%)	8682
R1 Score = 1, 2 or 3	70 (26%)	202 (74%)	272
R2 Score = 0	5862 (70%)	2514 (30%)	8376
R2 Score = 1, 2 or 3	190 (30%)	444 (70%)	634
Percentages calculated as a fraction over the total in each row. Overall accuracy is the average of the highlighted percentages.			

Confusion matrix between the software, R1 and R2

Results: Average AUC and accuracy of the software in relation to expert readers' scores was 0.80 and 72% with a sensitivity of 0.72 and specificity of 0.72. The intra- and inter-reader agreement was 75% (R1), 83% (R2) and 73% respectively. Individual VU scoring of the software vs. readers are presented in the Table as a confusion matrix.

Conclusion: Automated scoring of MR images in AS pts was comparable to that of expert reader-based assessments. ML software has the potential to provide an automated guided-reading approach to scoring MR images, which may enable further clinical insights.

Secukinumab Improved Signs and Symptoms in Patients with Non-radiographic Axial Spondyloarthritis: Results from a Randomized Controlled Phase III Study Stratified by Baseline Objective Signs of Inflammation

Juergen Braun[1], Ricardo Blanco[2], Helena Marzo-Ortega[3], Lianne Gensler[4], Filip Van den Bosch[5], Hideto Kameda[6], Denis Poddubnyy[7], Marleen van de Sande[8], Anna Wiksten[9], Brian Porter[10], Santiago Moreno[9], Abhijit Shete[9], Hanno Richards[9], Sibylle Haemmerle[9] and Atul Deodhar[11], [1]Rheumazentrum Ruhrgebiet Herne, and Ruhr-University Bochum, 44649 Herne, Germany, [2]Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, Spain, [3]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom, [4]University of California San Francisco, San Francisco, CA, [5]Ghent University Hospital, Ghent, Belgium, [6]Toho University, Tokyo, Japan, [7]Charité – Universitätsmedizin Berlin, Berlin, Germany, [8]Amsterdam UMC, AMC/University of Amsterdam, Department of Rheumatology and Clinical Immunology, Amsterdam Infection & Immunity Institute and Amsterdam Rheumatology and Immunology Center (ARC), Amsterdam, Netherlands, [9]Novartis Pharma AG, Basel, Switzerland, [10]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [11]Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Active non-radiographic axial spondyloarthritis (nr-axSpA) is often determined on the basis of objective signs of inflammation (elevated C-reactive protein [CRP] and/or evidence of sacroiliitis on MRI).[1] Secukinumab (SEC) significantly improved signs and symptoms in patients (pts) with nr-axSpA in the PREVENT study (NCT02696031).[2] Here, we report a pre-planned exploratory analyses of the efficacy of SEC from PREVENT stratified by CRP and MRI status (positive and/or negative) at study entry.

Methods: Pts (555) fulfilling ASAS criteria for axSpA plus abnormal CRP and/or MRI, without evidence of radiographic changes in sacroiliac joints according to modified New York Criteria for AS were enrolled. All images were assessed centrally before inclusion. Pts were randomized (1:1:1) to subcutaneous SEC 150 mg with loading (LD), without loading (NL), or placebo (PBO) at baseline (BL), Weeks (Wks) 1, 2, 3, and 4, then every 4 wks (q4wk). NL pts received SEC 150 mg at BL and PBO at Wks 1, 2, 3, and 4, then 150 mg q4wk. Exploratory efficacy assessments by CRP and MRI status (positive and/or negative) at Wk 16 included ASAS40, BASDAI50, ASAS-partial remission (PR), and ASDAS-CRP inactive disease (ID) responses. Missing values were imputed as non-response.

Results: Response rates for ASAS40, BASDAI50, ASAS-PR, and ASDAS-CRP ID with SEC 150 mg LD or NL by CRP and MRI status are shown in the Table. Numerically higher response rates for SEC were observed vs PBO for all endpoints across subgroups with the most notable differences vs PBO observed for ASAS-PR and ASDAS-CRP ID.

Endpoints, % responders	Subgroups	SEC 150 mg LD	SEC 150 mg NL	PBO
ASAS40	CRP+MRI+	53.7	50.9	21.8
	CRP+MRI−	34.6	31.4	29.4
	CRP−MRI+	34.2	39.5	31.3
BASDAI50	CRP+MRI+	46.3	43.9	12.7
	CRP+ MRI−	32.7	33.3	25.5
	CRP−MRI+	34.2	35.5	23.8
ASAS-PR	CRP+MRI+	29.6	21.1	5.5
	CRP+MRI−	21.2	19.6	7.8
	CRP−MRI+	16.5	22.4	7.5
ASDAS-CRP ID	CRP+MRI+	27.8	22.8	1.8
	CRP+MRI−	13.5	13.7	5.9
	CRP−MRI+	20.3	26.3	13.8

NRI data is presented for all the variables.
Number of patients in CRP+MRI+ subgroup were 54 (LD), 57 (NL), and 55 (PBO); in CRP+MRI− subgroup were 52, 51 and 51; and in CRP−MRI+ subgroup were 79, 76 and 80.
CRP, C-reactive protein; ID, inactive disease; LD, with loading; MRI, magnetic resonance imaging; NRI, non-responder imputation; NL, without loading; PBO, placebo; PR, partial response; SEC, secukinumab.

Summary of efficacy results at Week 16

Conclusion: SEC provided numerically higher response rates vs PBO in pts with nr-axSpA across CRP and/or MRI positive subgroups.

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

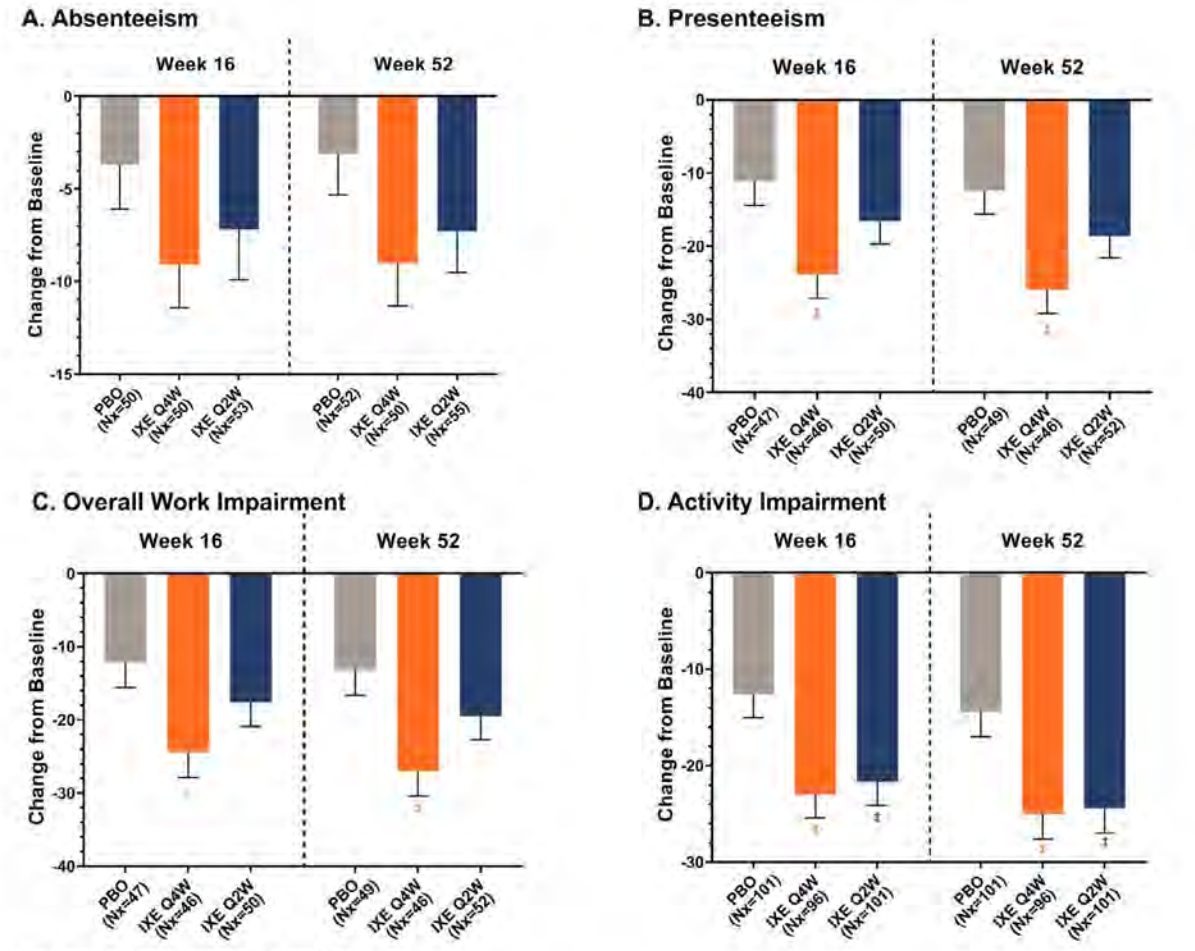
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with non-radiographic axial spondyloarthritis (nr-axSpA) experience impairments in health-related quality of life comparable to those seen in ankylosing spondylitis, including impacts on work productivity. Ixekizumab (IXE) is a high-affinity monoclonal antibody that selectively targets interleukin-17A and effectively treats axial spondyloarthritis.[1-3] This analysis evaluated the effect of IXE treatment for 52 weeks on work productivity and activity impairment as measured by absenteeism, presenteeism, overall work impairment, and activity impairment in patients with active nr-axSpA.

Methods: COAST-X (NCT02757352) was a phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group outpatient study investigating the efficacy and safety of 80 mg IXE every 2 weeks (Q2W) and every 4 weeks (Q4W) compared to placebo (PBO) in 303 patients naïve to biologic disease-modifying anti-rheumatic drugs with active nr-axSpA during a 52-week treatment period. From Weeks 16 through 44, if patients' disease activity required escalation of treatment at investigator discretion, patients were switched to open-label IXE Q2W or subsequent tumor necrosis factor inhibitor treatment. Analysis was performed for the intent-to-treat population, which included data up to the time of biologic switching. Patients who switched to open-label IXE were considered non-responders. Changes from baseline in work productivity were measured for patients reporting full- or part-time work at Weeks 16 and 52 with the Work Productivity and Activity Impairment (WPAI) Questionnaire for Spondyloarthritis and analyzed with an analysis of covariance model including treatment, geographic region, screening magnetic resonance imaging and C-reactive protein level status, and baseline value as factors. Missing data was imputed using the modified baseline observation carried forward.

Results: A majority of patients (63.5–65.7%) reported part-time or full-time paid work at baseline, with baseline scores for presenteeism and overall work activity slightly higher for patients in the PBO arm ($p< 0.05$). Patients treated with IXE Q4W had significantly greater improvement than PBO in activity impairment at Weeks 16 ($p=0.003$) and 52 ($p=0.004$), presenteeism at Weeks 16 ($p=0.007$) and 52 ($p=0.003$), and overall work impairment at Weeks 16 ($p=0.014$) and 52 ($p=0.005$; Figure). Patients treated with IXE Q2W had significantly greater improvement than PBO in activity impairment at Weeks 16 ($p=0.007$) and 52 ($p=0.006$; Figure). Patients treated with either IXE regimen had numeric improvements in all WPAI measures compared to those receiving PBO at Weeks 16 and 52 (Figure).

Figure. Changes from Baseline in A) Absenteeism, B) Presenteeism, C) Overall Work Impairment, and D) Activity Impairment.



Values are LSM (SE) from mBOCF ANCOVA.

COAST-X treatment groups: PBO (N=105); IXE Q4W (N=96); IXE Q2W (N=102). Absenteeism, Presenteeism, and Overall Work Impairment were measured in patients reporting full- or part-time work.

P-values were from ANCOVA (treatment vs. placebo). *=p<0.05, ‡=p<0.01, †=p< 0.001.

ANCOVA=analysis of covariance; IXE Q2W=80 mg ixekizumab every 2 weeks; IXE Q4W=80 mg ixekizumab every 4 weeks; LSM=least squares mean; mBOCF=modified baseline observation carried forward; N=number of patients in the treatment group; Nx=number of patients with non-missing values; PBO=placebo; SE=standard error.

Conclusion: Patients with nr-axSpA treated with either IXE regimen had significant improvements in activity impairment compared to PBO. Patients receiving IXE Q4W also had significant improvements in presenteeism and overall work impairment.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity anti–interleukin-23p19 monoclonal antibody approved in the US, EU, and Australia to treat moderate to severe plaque psoriasis.[1] A randomized, double-blind, placebo-controlled, multiple-dose, phase 2b study evaluating the efficacy and safety of TIL in psoriatic arthritis (PsA) was recently completed (NCT02980692). The objective of this analysis was to characterize and evaluate the rate of minimal disease activity (MDA) up to week (W)52 from the phase 2b study.

Methods: Patients (pts) ≥18 years old with active PsA[2] and ≥3 tender and ≥3 swollen joints were randomized 1:1:1:1:1 to receive TIL 200 mg every 4 weeks (Q4W) to W52, TIL 200 mg every 12 weeks (Q12W) to W52, TIL 100 mg Q12W to W52, TIL 20 mg Q12W to W24→TIL 200 mg Q12W to W52, or placebo (PBO) Q4W to W24→TIL 200 mg Q12W to W52. MDA was assessed throughout the study; an MDA response was achieved when 5 of 7 criteria were met.[3] Safety was assessed throughout the study and included treatment-emergent adverse event (TEAE) monitoring.

Results: Of 500 pts screened, 391 were randomized and received ≥1 dose of study drug. At baseline, mean age was 48.8 years, 55% were female, 97% were White, mean body mass index was 29.7 kg/m^2, and pts had PsA for a median (range) of 4.4 (0–42.8) years since diagnosis. Baseline disease characteristics related to MDA varied little between study arms (**Table 1**).

	TIL 200 mg Q4W n = 78	TIL 200 mg Q12W n = 79	TIL 100 mg Q12W n = 77	TIL 20→200 mg Q12W n = 78	PBO→TIL 200 mg Q12W n = 79
Swollen joint count	10.4 ± 7.4	10.0 ± 8.0	11.0 ± 8.2	9.4 ± 6.4	11.8 ± 9.8
Tender joint count	16.6 ± 11.9	19.5 ± 13.9	21.3 ± 14.8	19.0 ± 13.0	19.7 ± 14.7
Patient GADA score	57.8 ± 18.3	61.1 ± 20.7	60.3 ± 20.2	61.9 ± 17.4	65.2 ± 18.1
Patient pain assessment	55.4 ± 19.1	59.6 ± 23.5	59.2 ± 22.1	60.9 ± 19.7	64.2 ± 20.4
Enthesitis (LEI) score*	3.1 ± 1.7	2.8 ± 1.7	3.2 ± 1.8	3.1 ± 1.7	2.8 ± 1.8

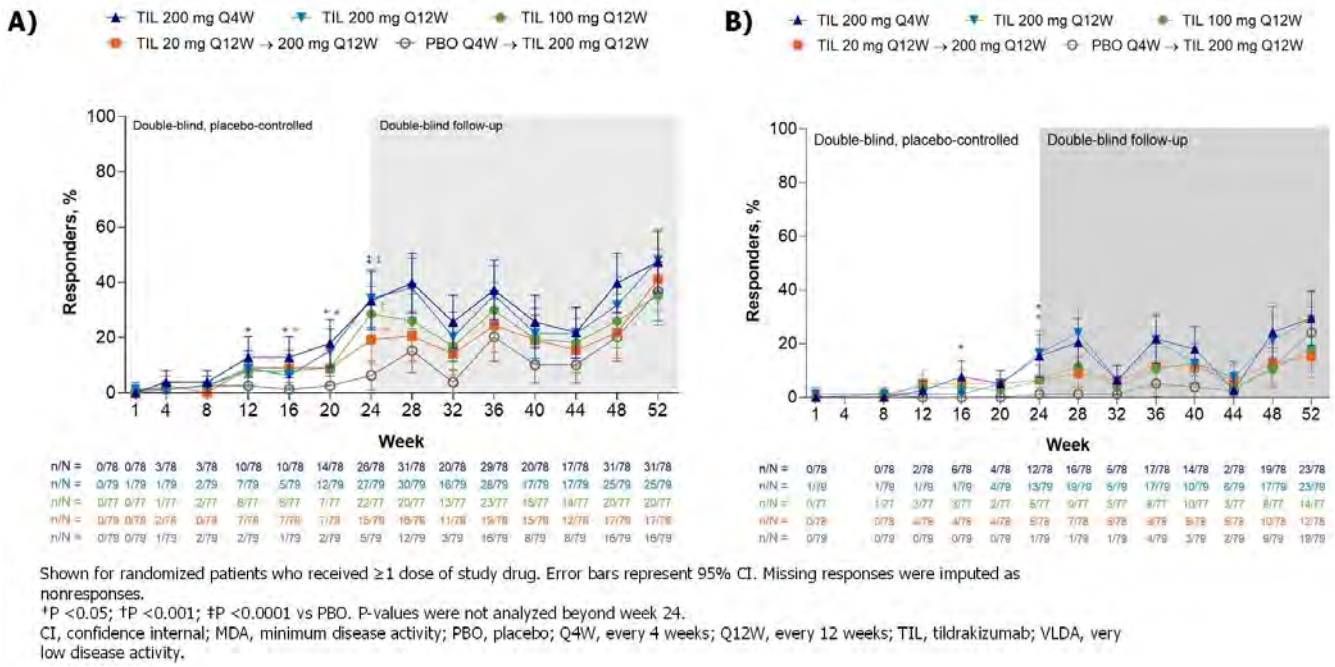
Data are shown as response rate (%) ± SE unless otherwise noted; numbers in parentheses indicate P-values.
Missing responses were imputed as nonresponses.
BSA, body surface area; HAQ-DI, Health Assessment Questionnaire-Disability Index; PASI, Psoriasis Area and Severity Index; PBO, placebo; PtGA, Patients Global Assessment; Q4W, every 4 weeks; Q12W, every 12 weeks; SE, standard error; TIL, tildrakizumab; VAS, visual analog scale.

Table 2. Efficacy outcomes related to minimal disease activity at week 24

Significantly more patients receiving TIL vs PBO achieved MDA (19%–34% vs 6%; P ≤0.0172) by W24; the proportion further increased with continued TIL treatment to W52 (35%–48%), including pts who switched from PBO to TIL (37%) (**Figure**). At W24, there was a greater proportion of responders in TIL 200 mg Q12W and Q4W arms vs PBO across all MDA subcomponents except for tender entheseal points ≤1 and Health Assessment Questionnaire-Disability Index ≤0.05 (**Table 2**).



Shown for randomized patients who received ≥1 dose of study drug. Error bars represent 95% CI. Missing responses were imputed as nonresponses.
*P <0.05; †P <0.001; ‡P <0.0001 vs PBO. P-values were not analyzed beyond week 24.
CI, confidence internal; MDA, minimum disease activity; PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; TIL, tildrakizumab; VLDA, very low disease activity.

Figure. MDA responders (A) over time and (B) VLDA responders by treatment and time point

Among the overall pt population 64.5% and 3.3% experienced a TEAE and serious TEAE, respectively. Two (0.5%) pts had a fungal skin infection (candida, TIL 200 mg Q4W arm). One (0.3%) malignancy (intraductal proliferative breast lesion) occurred in the TIL 20→200 mg Q12W arm. One serious infection (chronic tonsillitis) was reported in the TIL 20 mg Q12W arm during the first 24 weeks. There were no reports of systemic candidiasis, uveitis, inflammatory bowel disease, major adverse cardiac events, or deaths over the 52 weeks of the study.

Conclusion: TIL produced clinically meaningful improvement in pts with PsA, resulting in a large proportion of pts achieving MDA by W52, and was well tolerated through W52. A 2-trial phase 3 program is underway.

Data shown are n (%) for randomized patients who received ≥1 dose of study drug.
[a]AEs of special interest were major adverse cardiac events, malignancies, and severe infections.
[b]Any non-serious AEs of special interest.
PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; TEAE, treatment emergent adverse event; TIL, tildrakizumab.

Table 1. Summary of safety findings to week 52

Methods: Patients (pts) ≥18 years old with PsA2 and ≥3 tender and ≥3 swollen joints were randomized 1:1:1:1:1 to receive TIL (200 mg once every 4 weeks [Q4W], 200 mg every 12 weeks [Q12W], 100 mg Q12W, or 20 mg Q12W) or placebo (PBO Q4W) to W24. Thereafter, PBO Q4W and TIL 20 mg Q12W arms crossed over to TIL 200 mg Q12W to W52. Post hoc analyses were performed to evaluate the proportion of pts with Psoriatic Arthritis Disease Activity Score (PASDAS) < 3.2 (low disease activity), and remission in Disease Activity in Psoriatic Arthritis (DAPSA) (defined as scores between 0–4). Adverse events (AEs), including treatment-emergent AEs (TEAEs) and serious AEs (SAEs), were monitored throughout the study. Because this was a post-hoc analysis, no statistical analyses were performed to compare tildrakizumab groups to placebo.

Results: Overall, 391/500 pts screened met the inclusion criteria; demographics and baseline disease characteristics were comparable between treatment groups.

At 24 weeks, a numerically greater proportion of patients in the TIL vs PBO arms achieved DAPSA remission, with the proportion of patients in remission increasing thereafter to week 52 (**Figure 1**). At week 24, there was a numerically greater proportion of patients in the TIL vs placebo arms with low disease activity in PASDAS < 3.2. The proportion of patients with PASDAS < 3.2 continued to increase up to week 52 (**Figure 2**).

From W0–W52, 64.5% and 3.3% of pts experienced a TEAE and SAE, respectively. The most common TEAEs were nasopharyngitis (8.4%) and upper respiratory tract infection (6.4%). Two (0.5%) patients had a fungal skin infection (candida, tildrakizumab 200 mg Q4W arm). Most TEAEs, including infections, were mild. No deaths were reported.

Conclusion: PsA pts treated with TIL achieved desirable low disease activity and remission targets of treatment. TIL was well tolerated among patients in all groups through 52 weeks of treatment.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: There are inconclusive data on the effect of tumor necrosis factor inhibitors (TNFi) on radiographic spinal progression in axial spondyloarthritis (axSpA). Although inflammation and new bone formation are linked in axSpA, TNFi failed to show inhibition of radiographic spinal progression over two years compared to historical cohorts in pivotal studies in radiographic axSpA. Subsequent observational studies suggested that a longer treatment duration, earlier treatment initiation and effective inflammation suppression might be required to achieve inhibition of radiographic progression.

The aim of the current study was to evaluate the effect of TNFi on radiographic spinal progression in patients with early axSpA in a long-term inception cohort.

Figure 1. Cumulative probability plots depicting mSASSS change scores over 2 years in patients with axial spondyloarthritis treated vs. not treated with TNFi in the current (A) or previous (B) 2-year interval.

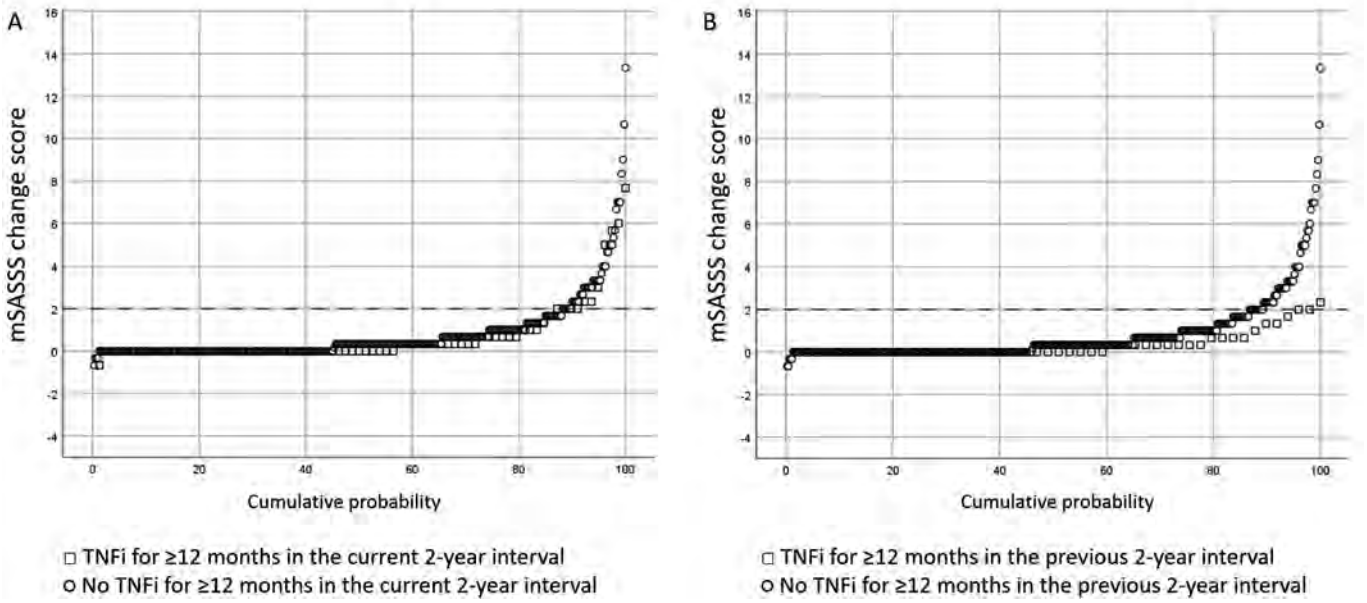

Figure 2. The mSASSS change scores over 2 years in patients with axial spondyloarthritis treated vs. not treated with TNFi in the current and/or previous 2-year interval.

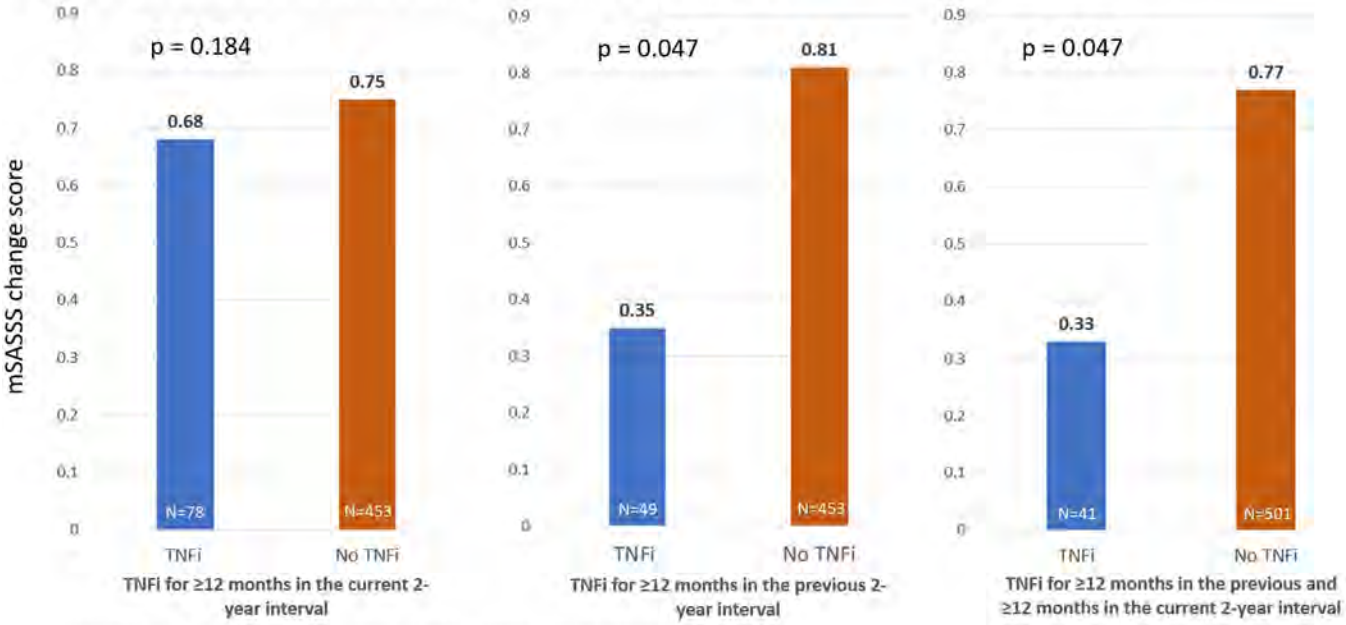

N corresponds to the number of the 2-year radiographic intervals with the information on TNFi intake.
P values are derived from the Mann-Whitney U test.

Table. The association between the change of the mSASSS over two years and current and/or previous treatment with TNFi in the longitudinal generalized estimation equation analysis.

TNFi treatment definition		Reference	β* (95% CI)
TNFi for ≥12 months in the previous 2-year interval	**TNFi for ≥12 months in the current 2-year interval**		
	Yes	No TNFi for ≥12 months in the current 2-year interval	-0.25 (-0.69 to 0.19)
Yes		No TNFi for ≥12 months in the previous 2-year interval	**-0.51 (-0.83 to -0.20)**
Yes	**Yes**	No TNFi for ≥12 months in the current and previous 2-year intervals	**-0.56 (-1.02 to -0.10)**

*Parameter estimates from the multivariable models adjusted for sex, symptom duration at the beginning of the current 2-year interval, time-averaged ASDAS in the current 2-year interval, smoking in the current 2-year interval and performing exercises in the current 2-year interval.

Methods: A total of 266 patients with early axSpA (with r-axSpA with symptom duration ≤10 years and nr-axSpA with symptom duration ≤5 years) from the German Spondyloarthritis Inception Cohort (GESPIC) with at least two sets of spinal radiographs obtained at least 2 years apart during a 10-year follow-up were included. These patients contributed with a total of 542 2-year radiographic intervals. Spinal radiographs were evaluated by three trained and calibrated readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). The final mSASSS was calculated as a mean of three reader scores. The association between the current TNFi, previous TNFi and radiographic spinal progression defined as the absolute mSASSS change score over 2 years was analyzed using longitudinal generalized estimating equations (GEE) analysis.

Results: Only 9 patients were treated with a tumor necrosis factor inhibitor (TNFi) at baseline, and a total of 77 patients received TNFi during the entire follow-up period that gave 103 2-year intervals covered by TNFi of any duration, and 78 intervals covered by TNFi with treatment duration of at least 12 months. Radiographic spinal progression in axSpA patients receiving TNFi in the current 2-year interval was not different from progression in patients not treated with TNFi, while TNFi in the previous 2-year interval was associated with lower progression compared to patients without TNFi in this interval (Figures 1 and 2). The latter was also evident for patients who received TNFi in both previous and current 2-year intervals, i.e. patients treated with TNFi over 4 years. The longitudinal GEE analysis confirmed no significant association between current TNFi treatment and radiographic spinal progression but a significant association between TNFi in the previous 2-year interval (especially if this was continued also in the current interval giving 4 years in total) and the progression in the current one (Table).

Conclusion: TNFi treatment exhibits a delayed inhibitory effect on radiographic spinal progression in axSpA that becomes evident after 4 years of treatment.

*$P<0.05$ for UPA vs PBO.
[a]Results presented at Week 16 as SAPS was not assessed at Week 12. [b]In subjects with psoriatic spondylitis at baseline. [c]Mean of BASDAI Q5 and Q6.
BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; EQ-5D-5L, EuroQoL-5 Dimension, 5 Level index score; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCS, mental component summary; NRS, numeric rating scale; PBO, placebo; PCS, physical component summary; PRO, patient-reported outcome; PtGA, Patient Global Assessment of Disease Activity; QD, once daily; SAPS, Self-Assessment of Psoriasis Symptoms; SF-36, 36-Item Short-Form Health Survey; UPA, upadacitinib; WPAI, Work Productivity and Activity Impairment.

Background/Purpose: The efficacy and safety of upadacitinib (UPA), a selective Janus kinase inhibitor, in patients with PsA is under investigation in Phase 3 clinical trials. Patient-reported outcomes (PROs) are an important component in the evaluation of efficacy for a new therapy. This *post hoc* analysis evaluated the impact of UPA vs placebo (PBO) on PROs in patients with active PsA and an inadequate response to biologic DMARDs (bDMARD-IR).

Methods: Patients in SELECT-PsA 2 (NCT03104374), a Phase 3, randomized, PBO-controlled trial, received UPA 15 mg or UPA 30 mg once daily or PBO for 24 weeks, with the primary endpoint assessment at Week 12. The following PROs were assessed: Patient Global Assessment of Disease Activity (PtGA), Patient's Assessment of Pain, HAQ-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue, 36-Item Short-Form Health Survey (SF-36), EQ-5D-5L, Self-Assessment of Psoriasis Symptoms (SAPS), Work Productivity and Activity Impairment, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and morning stiffness (items 5 and 6 from the BASDAI). BASDAI was assessed in patients with evidence of psoriatic spondylitis at baseline (BL). Least squares mean changes from BL to Week 12 (Week 16 for SAPS) were assessed. The proportions of patients reporting improvements ≥ minimal clinically important differences (MCID) from BL through Week 24 were compared between both doses of UPA and PBO. The number needed to treat (NNT) to achieve 1 additional MCID response for each PRO of interest with UPA vs PBO were calculated at Weeks 12/24.

Results: Data from 641 patients (UPA 15 mg: 211; UPA 30 mg: 218; PBO: 212) were analyzed. Significant improvements from BL to Week 12 were reported with both doses of UPA vs PBO across all PROs, including all SF-36 domains (**Table, Figure 1**). Significantly greater proportions of patients receiving either dose of UPA vs PBO reported improvements ≥ MCID as early as Week 2 (the first post-BL visit) in PtGA, pain, and HAQ-DI. Compared with PBO at Week 12, a significantly greater proportion of patients receiving either dose of UPA reported improvements ≥ MCID across all PROs except SF-36 mental component summary (UPA 30 mg) (**Figure 2**). Improvements were maintained or further improved through Week 24. NNTs with UPA 15 mg and 30 mg ranged from 3–10 across PROs at Week 12.

Conclusion: Among bDMARD-IR patients with active PsA, treatment with UPA 15 mg or 30 mg once daily for 12 weeks resulted in clinically meaningful improvements in PROs, which were maintained or further improved through 24 weeks.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) has demonstrated efficacy for the treatment of AS in patients (pts) who were NSAID inadequate responders (IR).[1] Pts with psoriatic arthritis (PsA) and axial involvment often exhibit greater disease activity and quality of life impairments compared with those without axial involvment. The aim of this analysis was to characterize PsA pts with and without axial involvement and compare efficacy of UPA vs placebo (PBO) in PsA pts with axial involvement.

Methods: In SELECT-PsA 1 (NCT03104400; N=1705, non-biologic DMARD IR) and SELECT-PsA 2 (NCT03104374; N=642, biologic DMARD IR), pts with active PsA (≥3 swollen and ≥3 tender joints), active or historical psoriasis, and

ASDAS, ankylosing spondylitis disease activity score; Δ, change from baseline; CII, clinically important improvement; MMRM, Mixed–Effects Model Repeated Measurement; QD, daily; ID, inactive disease; LDA low disease activity; MI, major improvement; NRI, non-responder imputation; UPA, upadacitinib. *P<0.0001, UPA vs placebo; nominal P values are presented and were not adjusted for multiple testing. MMRM analysis with unstructured variance–covariance matrix, including treatment, visit, treatment–by–visit interaction, study, and the stratification factor of current DMARD use (yes/no) as fixed factors and the continuous fixed covariates of baseline measurement. NRI analysis with nominal P value constructed using the Mantel-Haenszel estimation adjusting for study and the main stratification factor of current DMARD use (yes/no); 95% CI for response rate calculated based on normal approximation to the binomial distribution.

on ≤2 non-biologic DMARDs were randomized to once daily UPA 15 mg, UPA 30 mg, adalimumab 40 mg every other week (SELECT-PsA 1 only), or PBO. At baseline (BL), the presence of psoriatic spondylitis was assessed by the investigator based on the totality of information available, and characteristics were compared for pts with and without axial involvement. Efficacy was assessed in pts with axial involvement using pooled data from the 2 studies for pts on PBO, UPA 15 mg, or UPA 30 mg. Assessments included change from BL in overall BASDAI, BASDAI question 2 (neck/back/hip pain) and question 3 (joint swelling/pain), and the AS Disease Activity Score (ASDAS) based on CRP, and the percentage of pts with BASDAI 50 response, ASDAS inactive disease (ID), ASDAS low disease activity (LDA), ASDAS major improvement (MI), and ASDAS clinically important improvement (CII) responses. Adverse events were reviewed to identify new onset or worsening uveitis and inflammatory bowel disease (IBD). Data are presented through the end of the 24-week PBO-controlled period.

Results: Prevalence of axial involvment was 31.3% in SELECT-PsA 1 and 34.2% in SELECT-PsA 2. Demographics and disease activity for pts with and without axial involvement are presented in **Table 1**. Treatment with UPA 15 mg and 30 mg resulted in significantly greater improvements from BL in the overall BASDAI, BASDAI Q2 (neck/back/hip pain) and Q3 (joint swelling/pain) and ASDAS-CRP endpoints at weeks 12 and 24 vs PBO (**Table 2**). Similarly, significantly higher percentages of pts on UPA 15 mg and 30 mg achieved BASDAI 50, ASDAS ID, LDA, MI, and CII at weeks 12 and 24 vs PBO (**Table 2**). Uveitis was reported in 2 pts on PBO (1 new onset; 1 flare) and 1 pt on UPA 30 mg (new onset). 1 event of Crohn's disease (flare) was reported on PBO; no IBD events were reported on UPA. Except for the uveitis flare on PBO, all uveitis and IBD events were reported in pts with psoriatic spondylitis.

Conclusion: Pts with PsA and axial involvement were more likely to have higher BL disease burden compared with those without axial involvement. Consistent with results observed in pts with AS, UPA was efficacious in treating axial symptoms in pts with psoriatic spondylits. Uveitis rates did not increase with UPA treatment, and UPA has shown efficacy in phase 2 IBD studies[2,3] with no IBD events reported in UPA-treated PsA pts.

IL-23 Skin and Joint Profiling in Psoriatic Arthritis: Novel Perspectives in Understanding Clinical Responses to IL-23 Inhibitors

Alessandra Nerviani[1], **Marie-Astrid Boutet**[1], Wang Sin Gina Tan[1], Katriona Goldmann[1], Nirupam Purkayastha[1], Tamas Lajtos[1], Rebecca Hands[1], Myles Lewis[1], Stephen Kelly[2] and Costantino Pitzalis[3], [1]Centre for Experimental Medicine and Rheumatology, Queen Mary University of London, London, United Kingdom, [2]Mile End Hospital, Barts Health NHS Trust, London, United Kingdom, [3]Queen Mary University of London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: PsA is a chronic heterogeneous inflammatory condition affecting up to 30% of patients with skin and/or nail psoriasis and the IL-23/IL-17 axis is believed to be key in psoriasis and PsA pathogenesis. Several drugs targeting the IL-23/IL-17 axis have been successfully tested in the context of psoriasis and PsA but, while 50-60% of patients achieve almost complete psoriasis clearance upon treatment, the joint disease improvement is modest. To date, the mechanism for the divergent skin-joint response remains largely unexplained. This study aims to determine the relationship between synovial versus skin transcriptional/histological profiles in patients with active PsA and to explore mechanistic links between diseased tissue pathology and clinical outcomes.

Methods: Twenty-seven patients fulfilling the ClASsification for Psoriatic ARthritis (CASPAR) criteria with active peripheral joint disease (>3 tender and >3 swollen joints) despite an adequate trial of at least two conventional synthetic DMARDs and either biologic-naïve or failing one or more TNF-α-inhibitor (anti-TNF) were enrolled in an observational/open-label study. Patients underwent biopsies of synovium and paired lesional/non-lesional skin before starting anti-TNF (if biologic-naïve; n=18) or ustekinumab (anti-IL-12/IL-23p40; if anti-TNF inadequate responders; n=9). Molecular analysis of 80-inflammation-related genes and protein levels for IL-23p40/IL-23p19/IL-23R were assessed by real-time-PCR and immunohistochemistry, respectively.

Results: At baseline, all patients had persistent active disease as per inclusion criteria. At 16-weeks-post-treatment, skin responses favoured ustekinumab, while joint responses favoured anti-TNF therapies. Principal-component-analysis revealed distinct clustering of synovial tissue gene expression away from the matched-skin. While *IL12B-IL23A*-

IL23R were homogeneously expressed in lesional skin, their expression was extremely heterogeneous in paired synovial tissues. Here, IL-23 transcriptomic/protein expression was strongly linked to patients with high-grade synovitis who, however, were not distinguishable by conventional clinimetric measures.

Conclusion: PsA synovial tissue shows a heterogeneous IL-23 axis profile when compared to matched skin. Synovial molecular-pathology may help to identify among clinically indistinguishable patients those with a greater probability of responding to IL-23 inhibitors.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dactylitis is a key and frequent clinical manifestation of psoriatic arthritis (PsA)[1] associated with significant disease burden and impaired function.[2–3] Randomized controlled trials designed to evaluate the impact of biologics on resolution of dactylitis are limited.[3] We report results of a post hoc analysis evaluating the effect of secukinumab (SEC) on PsA patients with dactylitis, from the FUTURE 5 trial (NCT02404350).[4]

Methods: FUTURE 5 is a randomized, double-blinded, placebo-controlled, 2-year phase 3 trial in patients with active PsA. Patients (aged ≥18 years) were randomized 2:2:2:3 to s.c. SEC 300 mg or 150 mg with loading dose (LD), 150 mg without loading dose (NL) or placebo. All groups received SEC or placebo at baseline, weeks (wks) 1, 2 and 3 and then every 4 wks from Wk 4. Exploratory efficacy analysis at Wks 16 and 52 included time to resolution of dactylitis by dactylitis severity, proportion of patients with resolution of dactylitis, ACR 20/50 response and Psoriasis Area and Severity Index (PASI) 90.

Results: Of the 996 patients in the trial, 389 (39%) had dactylitis (SEC 150 mg NL [N=103], 150 mg LD [N=80], 300 mg LD [N=82], and placebo [N=124]). The mean (SD) tender joint count, swollen joint count and dactylitis count at baseline was: 24.0 (17.0), 14.5 (11.4) and 4.1 (4.16) and 19.1 (14.8), 9.5 (8.5) and 0, respectively, in patients with (N=389) and without (N=607) dactylitis at baseline. Higher presence of enthesitis, hsCRP and skin disease were also observed in the dactylitis subset. Median time to resolution of dactylitis (days) [95% CI] in patients on SEC 150 mg NL, 150 mg LD, and 300 mg LD, was 85 [61.0, 113.0], 85 [57.0, 119.0] and 57 [30.0, 85.0], respectively. A higher proportion of SEC treated patients achieved resolution of dactylitis, ACR 20/50 and PASI90 responses vs. placebo at Wk16 with further improvements through Wk 52 (**Table 1**). Resolution of dactylitis based on the number of dactylitis count at baseline (≤2 and ≥3) are shown in **Table 2**. SEC 300 mg LD was associated with a faster time to resolution of dactylitis and higher ACR50 and PASI90 responses compared to SEC 150 mg.

	SEC 150 mg (No Load) N = 103	SEC 150 mg (Load) N = 80	SEC 300 mg (Load) N = 82	Placebo N = 124

Stoenoiu[4], Patrick Durez[5], Laurent Meric De Bellefon[2] and Adrien Nzeusseu Toukap[6], [1]Rheumatology department, St-Luc university hospitals, Brussels, Belgium, [2]Rheumatology department; St-Luc University Hospitals, Brussels, Belgium, [3]Rheumatology, Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium, [4]1Department of Rheumatology, Cliniques Universitaires Saint-Luc, 2Institut de recherche expérimentale et cliniques (IREC), Brussels, Belgium, [5]Division of Rheumatology, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium, [6]1Department of Rheumatology, Cliniques Universitaires Saint Luc, 2Institut de recherche expérimentale et clinique (IREC), Brussels, Belgium

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Randomized-controlled trials (RCTs) done in axial spondyloarthritis (AxSpA) patients have shown that remission in Ankylosing Spondylitis and nonradiographic AxSpA patients treated without biologics (BIOL) occurs infrequently (Ref 1, 2). Few are known about remission rate (RR) in daily clinical practice. Our aim was to assess the remission rate (RR) in AxSpA patients in real life, and to compare the RR in AxSpA patients on NonSteroidal Anti-Inflammatory Drugs (NSAIDs) to RR for those on BIOL (anti-TNFα or IL-17A blockers).

Methods: This cross-sectional study reviewed clinical data from a single center (St-Luc university hospitals, UCLouvain, Brussels) from 01/2013 to 03/2019. Last visit available for clinical assessment was evaluated. Disease activity was measured using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score using the C-reactive protein (ASDAS-CRP). Remission was defined as BASDAI < 4 and ASDAS-CRP < 1.3.

Results: Data from 551 AxSpA patients were reviewed. 353 were men (64.3%). In the entire cohort, 478 BASDAI and 316 ASDAS-CRP were recorded. The RR according to the BASDAI was 46.7% (n = 223), and 17.4% for the ASDAS-CRP (n = 55). To look for the treatment-related RR, we stratified by the treatment (NSAIDs vs BIOL). We had 285 patients on NSAIDs (177 men, 62.5%) and 266 on BIOL (176 men, 66%). 245 BASDAI were available for NSAIDs and

Table. Distribution of ASDAS-CRP values in both groups (n = 316).

	ASDAS-CRP < 1.3	ASDAS-CRP ≥ 1.3 < 2.1	ASDAS-CRP ≥ 2.1 ≤ 3.5	ASDAS-CRP > 3.5
NSAIDs (n = 172)	N = 27 (15.7%)	N = 41 (23.8%)	N = 70 (40.7%)	N = 34 (19.8%)
BIOL (n = 144)	N = 28 (19.4%)	N = 30 (20.8%)	N = 57 (39.6%)	N = 29 (20.1%)

233 for BIOL. 110 patients on NSAIDs (44.9%) and 113 on BIOL (48.5%) were in remission for BASDAI. Regarding ASDAS-CRP (see table below), data from 172 patients on NSAIDs and 144 on BIOL were available. Out of them, 27 (15.7%) and 28 (19.4%) were in remission for NSAIDs and BIOL respectively. Chi-square test: p = 0.853.

Conclusion: In the real life, RR in AxSpA is higher on BIOL even if compared to NSAIDs the difference is not statistically significant. However, many patients on NSAIDs achieve the remission.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Data on the impact of body weight and body mass index (BMI) on the response to biological disease-modifying anti-rheumatic drugs (bDMARDs) in axial spondyloarthritis (axSpA) including ankylosing spondylitis (AS) are still contradictory. Data on the impact of different components of the body composition on the treatment response are lacking. The purpose of this study is to investigate the impact of body composition on the response to biological disease-modifying anti-rheumatic drugs (bDMARD) in patients with AS after 6 months of treatment.

Methods: Patients with AS (radiographic axSpA), fulfilling the modified New York criteria and starting a bDMARD therapy were recruited between 2015 and 2019 in an extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC-AS). All patients were required to be candidates for bDMARD therapy at baseline with high disease activity (BASDAI >=4 and/or ASDAS >=2.1) despite previous treatment with nonsteroidal anti-inflammatory drugs. Disease activity measures (BASDAI, CRP, ASDAS), as well as body composition parameters were assessed

*Adjusted for age, sex, HLA-B27 status, symptom duration, and ASDAS at baseline.
BMI: Body Mass Index; FMI: Fat Mass Index; SMM: Skeletal Muscle mass; VAT: Visceral Adipose Tissue; AS: ankylosing spondylitis; bDMARD: biological disease-modifying anti-rheumatic drug; CI: 95% confidence interval.

Table. Univariable and multivariable linear regression analysis of the association between response to bDMARD treatment (change in the ASDAS score after 6 months) and body composition parameters in patients with AS (n=77)

at baseline and after 6 months of bDMARD treatment. Body composition was assessed by the bioelectrical impedance analysis (BIA). Weight, body mass index (BMI), fat mass index (FMI), fat free mass index (FFMI), skeletal muscle mass value (SMM), visceral adipose tissue (VAT), total body water (TBW), and extracellular water (ECW) values were collected. The primary measure of the treatment response was ASDAS change at month 6 as compared to baseline.

Results: A total of 129 patients with AS were included in this cohort. BIA was performed in 77 patients. There were 71.4% males, and 85.7% were HLA-B27 positive. At baseline, BASDAI was 5.4±1.4, CRP was 12.8±16.5 mg/l, and ASDAS - 3.0±1.0. The baseline BMI was 25.0±4.3 kg/m^2. A total of 75 patients were treated with TNFi, 2 patients received an IL-17 inhibitor.

A higher BMI at baseline was associated with a worse response to bDMARD therapy that was attributable to both, the fat mass as reflected by FMI and to the fat-free mass reflected by FFMI, but not to SMM or VAT or water components – Table. This effect was independent of age, sex, symptom duration, HLA-B27 status and ASDAS at baseline.

Conclusion: Both fat mass and fat free mass have an impact on the response to bDMARDs after 6 months of treatment in patients with AS. Interestingly, skeletal muscle mass, visceral fat as well as water components showed no association with treatment response.

Raynaud's Phenomenon and Systemic Sclerosis in Post-9/11 Deployed Veterans Receiving Care Veterans Health Administration Care

Tracy Frech[1], Maureen Murtaugh[1], Megan Amuan[2] and Mary Jo Pugh[1], [1]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT, [2]Veterans Affair Medical Center, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this project was to describe Raynaud's phenomenon (RP), very early diagnosis of systemic sclerosis (VEDOSS), and systemic sclerosis (SSc) in Veterans who were deployed in support of Post-9/11 operations. We sought to describe the military occupation specialty, clinical features, and medication use across the three diagnoses.

Methods: Individual Veterans medical records were assessed for RP (ICD-9 443.0), VEDOSS with swelling of hands (ICD-9 729.81) and RP (ICD-9 443.0), and SSc (ICD-9 710.1). The distribution of sociodemographic, military service branch, job classification, vasodilator use, and comorbidities were examined across the three classifications of disease. The chi-squared test and Fisher's exact were used to compare frequency of these categorical variables. Logistic regression was used to assess the likelihood of characteristics of the three classifications of disease.

Results: In this population of 607,665 individual Veteran medical records, 857 had RP, 45 met possible VEDOSS criteria, and 71 had a diagnosis of SSc. The majority of RP, VEDOSS and SSc cases were white males, but the likelihood of having RP, VEDOSS or SSc was higher in white females. The vast majority of RP, VEDOSS, and SSc cases were found in the Army service, with a rank of enlisted with the most common occupation specialties of electronic repair. However, those in craftworks, engineering or maintenance, and healthcare had a greater likelihood of RP. The use of vasodilators was low among RP, VEDOSS, and SSc. The most common comorbidities were pain and depression. Gastrointestinal tract symptoms typical for SSc patients were found in RP patients.

Conclusion: This is a unique Veteran population of predominately-male patients. Our data suggests that vasodilator medications are potentially being under-utilized in this RP, VEDOSS, and SSc Veteran population. Our data highlights mood and pain management is an important aspect of SSc care.

Abstract Number: 1378

Understanding Diagnostic Pathways in Systemic Sclerosis and Systemic Sclerosis-Associated Interstitial Lung Disease (SSc-ILD)

Shervin Assassi[1], Nan Shao[2], Ziwei Yin[2], Elizabeth Volkmann[3], Donald Zoz[2] and Thomas Leonard[2], [1]University of Texas Houston McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX, [2]Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT, [3]University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common manifestation of SSc. SSc-ILD is usually detected in a patient known to have SSc, but ILD may be the initial presentation of SSc. Optum is a health insurance database covering >60 million patients, which is representative of the commercially insured population in the US. We used data from the Optum database to investigate the documentation of ILD prior to a diagnosis of SSc.

Methods: The study period was between 1 January 2007 and 30 June 2019. The "ICD-9 cohort" comprised patients aged ≥18 years, with an SSc index date (date of first insurance claim related to SSc) between 1 January 2010 and 30 September 2015 based on ICD-9-CM codes, ≥2 medical claims associated with SSc on different dates within a 1-year period, and ≥3 years of continuous enrollment in the database prior to the SSc index date. The "ICD-10 cohort" comprised patients aged ≥18 years, with an SSc index date between 1 October 2017 and 30 June 2019 based on ICD-10-CM codes, ≥2 medical claims associated with SSc on different dates within a 1-year period, and ≥2 years of continuous enrollment in the database prior to the SSc index date. ILD was defined as ≥2 medical claims associated with ILD on different dates. We identified patients who had their second claim associated with ILD prior to their SSc index date in the two cohorts. Analyses were descriptive.

Results: The ICD-9 and ICD-10 cohorts consisted of 1779 and 1032 patients with SSc, respectively. In these two cohorts, 7.6% and 9.3% of patients respectively, had their second claim associated with ILD prior to their SSc index date (Table). The second ILD claim occurred >1 year prior to the SSc index date in 4.3% of patients in the ICD-9 cohort and 5.6% of patients in the ICD-10 cohort.

Table. Patients who had claims for ILD prior to a claim for SSc in the Optum database

	Patients with SSc based on ICD-9 codes (n=1779)	Patients with SSc based on ICD-10 codes (n=1032)
ILD at any time prior to SSc	136 (7.6)	96 (9.3)
ILD >90 days prior to SSc	100 (5.6)	76 (7.4)
ILD >180 days prior to SSc	92 (5.2)	68 (6.6)
ILD >1 year prior to SSc	76 (4.3)	58 (5.6)
ILD >2 years prior to SSc	48 (2.7)	36 (3.5)

Data are n (%) of patients who had their second ILD claim prior to their SSc index date.

Conclusion: Based on data from a large US health insurance database, 4–6% of patients with SSc had claims for ILD more than 1 year prior to a claim for SSc. These data are consistent with previous studies showing that SSc can have an impact on the lung early in the course of SSc and demonstrate the importance of screening patients with ILD for SSc.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic sclerosis (SSc) may be at increased risk for severe outcomes with COVID-19, given the high rate of immunosuppressive medication use, underlying lung pathologies, and accompanying co-morbid conditions. Limited data are available on outcomes of COVID-19 infection in these patients.[1,2] The American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR) are collecting provider-entered COVID-19 cases in a registry of patients with rheumatic diseases.[3,4] We report number and outcomes of COVID-19 cases in regularly monitored diffuse cutaneous(dc) SSc patients followed in 2 open-label extension (OLE) studies of lenabasum, an orally-administered, non-immunosuppressive, selective cannabinoid receptor type 2 (CB2) agonist.

Methods: This cohort included participants satisfying ACR/EULAR criteria for SSc who were receiving lenabasum 20 mg BID in the OLE studies in a Phase 2 (NCT02465437) or Phase 3 trial (NCT03398837). Background therapy with immunosuppressive medications was allowed. COVID-19 infection rate was discerned by review of adverse events (AEs) and required a positive COVID-19 test. Outcome of COVID-19 was provided by treating physicians.

Results: Four/385 (0.11%) participants suffered a COVID-19 adverse event (AEs), including one serious AE (SAE). Mean age was 52 years (40-77), with 2 females, and all participants were white. Two had interstitial lung disease (ILD) and were being treated with mycophenolate mofetil (Table 1). One with ILD was asymptomatic and tested for Covid-19 because of contact with known COVID-19 positive individuals. This individual was treated with 5 days of hydroxychloroquine. During COVID-19 infection, 3 continued and 1 temporarily stopped lenabasum treatment due to hospitalization (SAE). This participant with ILD was hospitalized for 3 days and discharged home after 2 doses of experimental remdesivir, with full recovery 4 weeks after symptoms began. One received oxygen therapy in the emer-

Table 1. Summary of clinical characteristics of dcSSc study participants with COVID-19

Age/Sex/Race Serology	ILD (Yes/No) by CXR or HRCT, (Last ppFEV[1])	Concomitant Illness	Background Immuno-suppressive	Positive COVID-19 Test (Yes/No)	Status of Study Treatment	Patient Course	Anti-viral Treatment (Yes/No)	Serious AE (Yes/No)	Current Status of Patient
40/M/W ARA	No	Psoriasis	MMF*	Yes	Lenabasum 20mg BID* continued	Symptomatic with low grade fever, aches, nasal discharge, cough, and sweating. ER visit for chest tightness with a decreased aO^2 sat at 87% which increased to 94% on 1 L O^2 discharged home with O2 for 7 days	No	No	Recovered
77/F/W ARA	Yes by HRCT (81%)	Asthma	MMF, methyl-prednisolone	Yes	Lenabasum 20mg BID temporarily stopped for 22 days and then restarted after recovery	Symptomatic with fatigue, fever, chronic cough, myalgias, headache, vomiting; 3 days in hospital for hyponatremia, no ventilation.	Yes, on blinded trial with remdesivir	Yes	Recovered
45/F/W ARA	No	No	abatacept	Yes	Lenabasum 20 mg BID continued; abatacept held	Symptomatic with fatigue, myalgia, and cough; evaluated in ER without receiving oxygen and discharged to home with self quarantine	No	No	Recovered
47/M/W ATA	Yes by HRCT (77%)	No	MMF	Yes	Lenabasum 20mg BID continued; MMF held	Asymptomatic tested for positive contact; treated with home self-quarantine	Hydroxychloroquine	No	Asymptomatic

Abbreviations: dcSSc (diffuse cutaneous systemic sclerosis), ATA (anti-topoisomerase-1 antibody), ARA (anti-RNA polymerase III), ILD (interstitial lung disease), CXR (chest X-ray), HRCT (high resolution computed tomography), M (male), F (female), W (white), MMF (mycophenolate mofetil), BID (twice daily)

gency room (ER), then discharged home with oxygen for a week with subsequent full recovery. One symptomatic had an ER visit without requiring oxygen therapy and another asymptomatic did not have an ER visit; both did not require hospitalization and were self-quarantined.

Conclusion: The rate of confirmed COVID-19 infections (0.11%) in this cohort of dcSSc patients is about the same as the rate estimated from CDC data of June 5, 2020, adjusted for age (~0.1%). This suggests the diffuse cutaneous SSc subjects in this cohort are not more vulnerable to COVID-19 infection than the general population. All 4 trial participants despite 2 with confirmed ILD had acceptable outcomes, in the context of continued or resumed lenabasum treatments.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Vascular dysfunction is a key feature of systemic sclerosis (SSc), manifesting clinically as Raynaud's phenomenon (RP) with or without digital ischemia. Laser doppler flowmetry (LDF) with thermal challenge is a safe, noninvasive and reproducible technique to detect digital occlusive arterial disease (DOAD) with a high sensitivity and specificity of >90% (1). The presence and associations of DOAD in SSc are not well defined. We studied the prevalence and clinical correlates of DOAD on LDF in SSc patients referred for evaluation of RP at a tertiary referral center.

Methods: Medical records of all SSc patients meeting ACR/EULAR 2013 classification criteria that underwent upper extremity vascular study with LDF between Jan 2001-Dec 2018 at our institution were retrospectively reviewed to abstract the presence or absence of DOAD. The presence of DOAD on LDF was confirmed if pre- and post-warming skin blood flow was ≤206 arbitrary units. Severity of DOAD was assessed based on number of digits involved. Demographics, clinical characteristics, and outcomes were abstracted. Risk factors associated with presence of DOAD in SSc and correlation between presence and severity of DOAD with digital ischemic complications were studied.

Results: 304 SSc patients (mean age 57.1 ± 13.3 y, 81% female, 93% Caucasian) underwent LDF during the study period. Majority had limited cutaneous SSc (lcSSc) (79.6%) and 64.1% had a positive SSc specific antibody. Cohort characteristics are described in **Table 1**.

On LDF, presence of DOAD was noted in 243 (79.9%) SSc patients. Of these, 78.6% had lcSSc, 42.4% had a centromere antibody (Ab), 17.3% had a Scl-70 Ab, 53.5% had interstitial lung disease, 36.6% had pulmonary arterial hypertension, and 73.3% had gastrointestinal dysmotility (GID). Of 159 DOAD patients who had their digital nailfold examined, 70.4% had nailfold capillary abnormalities. After adjusting for age/sex, GID (OR: 2.73, $p < 0.001$) and telangiectasia (OR: 2.83, p 0.013) were significantly associated with DOAD on LDF.

Digital ischemic complications among SSc patients with DOAD were significantly higher than among those without DOAD (79.8% vs 41.0% had digital ulcers, 53.9% vs 26.2% had pitting/scars, 31.3% vs 8.2% had gangrene/amputation; $p < 0.001$). (**Figure 1**) Increasing severity of DOAD was associated with a statistically significant increase in incidence of digital ischemic complications as presented in **Table 2**.

Conclusion: To our knowledge, this is the first and largest study to describe the prevalence and predictors of DOAD on LDF in a well-defined cohort of SSc patients. The high prevalence of DOAD on LDF noted in SSc related RP makes it an important tool for evaluation of microangiopathy in SSc and distinguishing it from primary RP. The presence

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with PAH-CTD have a worse prognosis than patients with most other PAH etiologies. The OPsumit® USers (OPUS) Registry and OPsumit® Historical USers (OrPHeUS) study provide real-world evidence on the management of PAH-CTD patients newly treated with macitentan.

Methods: OPUS is a prospective, US, multicenter, drug registry ongoing since April 2014 (NCT02126943). OrPHeUS was a retrospective, US, multicenter chart review (NCT03197688); data collected October 2013–March 2017. Patient characteristics, safety and clinical outcomes are described by treatment pattern (mono-/double/triple therapy) at macitentan initiation (baseline) for PAH-CTD (WHO Clinical Classifications of PH Group 1) patients in the combined OPUS/OrPHeUS population. PAH etiology was investigator-assessed and not adjudicated.

Results: As of August 2019, the follow-up OPUS/OrPHeUS PAH population (N=4387) included 1130 PAH-CTD patients: 433 (38.3%) received macitentan monotherapy, 536 (47.4%) received double and 161 (14.2%) received triple combination therapy at baseline. Median (Q1, Q3) age was 63 (53, 70) years in mono-, 61 (50, 70) in double and 61 (51, 69) in triple therapy patients; most patients were female. In the monotherapy group, more patients were newly-diagnosed; median (Q1, Q3) time from diagnosis was 2.2 (0.6, 18.0) months in mono-, 8.7 (1.8, 37.1) in double and 34.8 (12.5, 80.4) in triple therapy patients. Of patients with WHO functional class (FC) recorded at baseline (49.2–57.3% of patients), 63.4% of mono-, 72.6% of double, and 68.2% of triple therapy patients were FC III/IV. Median (Q1, Q3) baseline 6-minute walk distance (reported in 32.1-40.7% of patients) was 274 (161, 366), 270 (194, 347), and 305 (226, 362) m in mono-, double and triple therapy patients. Treatment patterns at month 6 are shown in the Figure. Patients with ≥1 hepatic adverse event included 28 (6.5%), 36 (6.7%) and 21 (13.0%) on mono-, double and triple therapy. Macitentan was discontinued in 146/433 (33.7%) mono-, 188/536 (35.1%) double and 80/161 (49.7%) triple therapy patients: 59 (13.6%), 80 (14.9%) and 39 (24.2%) due to an adverse event. Kaplan-Meier (KM) estimates (95% CI) for mono-, double and triple therapy patients at macitentan initiation showed that 69% (64, 74), 62% (57, 66) and 61% (52, 69) of patients were free from hospitalization at 12 months; 12-month KM survival estimates (95% CI) were 94% (90, 96), 90% (87, 93) and 88% (81, 92).

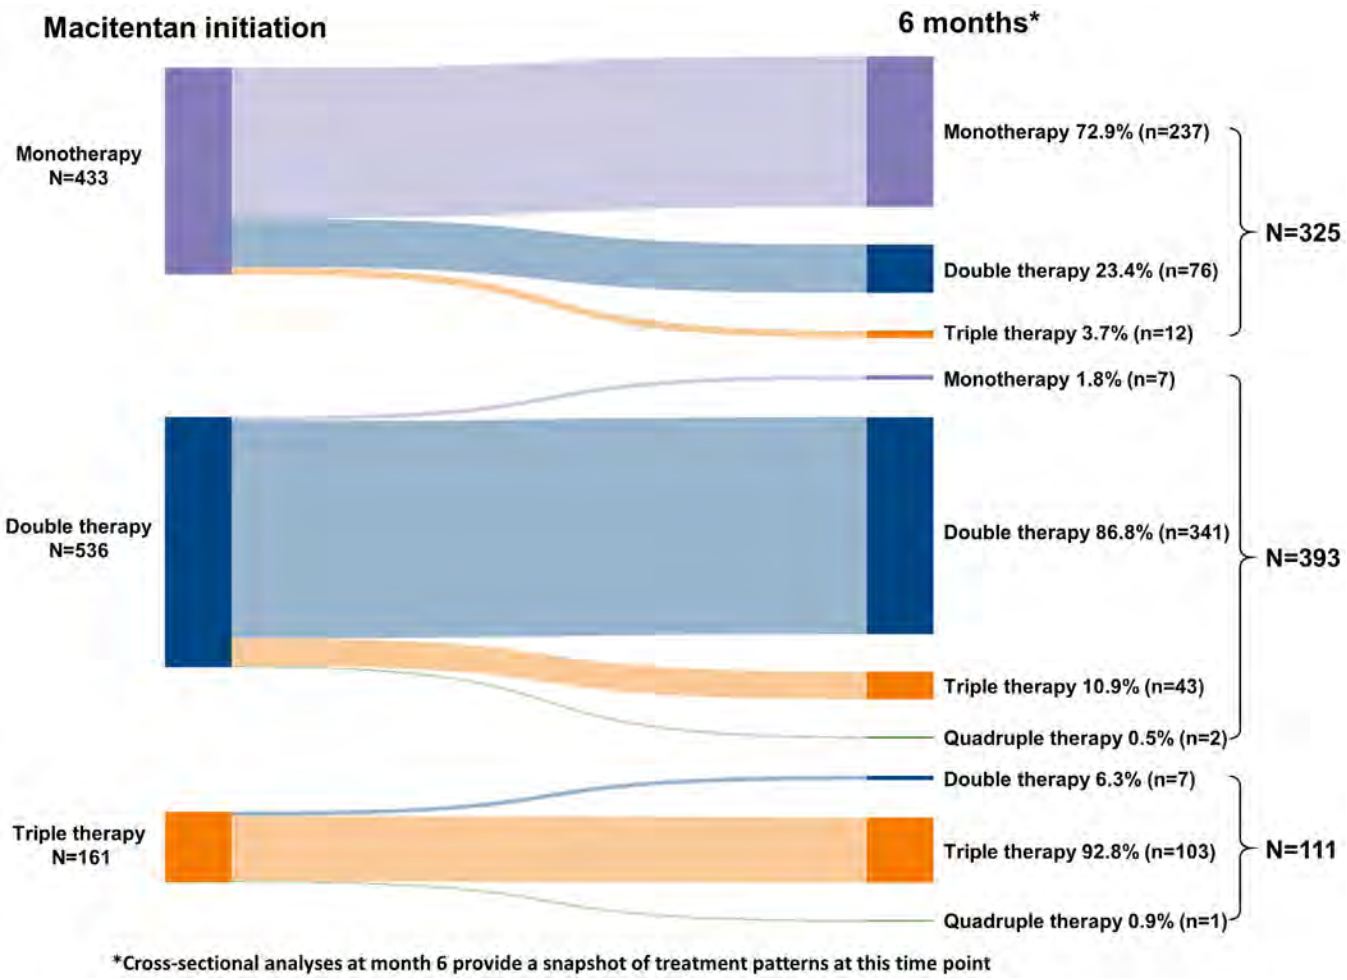

Figure. Treatment patterns at month 6

Conclusion: Despite the recommendation for combination therapy, a large proportion of patients received monotherapy at macitentan initiation and 6 months after initiation. For the vast majority of patients, combination treatment strategy did not change between baseline and 6 months.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks by 44% compared with placebo. The effects of nintedanib on markers of lung damage on high-resolution computed tomography (HRCT) were assessed in a sub-study.

Methods: Patients enrolled in the SENSCIS trial had SSc with onset of first non-Raynaud symptom ≤7 years before screening and an extent of fibrotic ILD ≥10% on HRCT (based on assessment of the whole lung). Patients were randomized to receive nintedanib or placebo. In a sub-study, HRCT images were assessed at baseline and at week 52 or 60. The extent of regions with evidence of abnormalities (honeycombing and/or reticulation and/or ground-glass opacity) was assessed in both lungs and changes from baseline were categorized by two radiologists as “much better”, “better”, “same”, “worse”, “much worse” or “unknown”. Disagreement between the radiologists in the categories “much better” or “better” and “worse” or “much worse” were considered “intermediate better” or “intermediate worse”. An ordinal logistic regression analysis (proportional odds model) adjusted for anti-topoisomerase antibody I status was used to compare changes between the treatment groups. Changes from baseline in a quantitative fibrosis score, a measure of the extent (%) of reticular patterns with architectural distortion, were assessed using data-driven texture analysis. Analyses were conducted in patients who received trial medication up to at least week 24 and had an evaluable HRCT scan at week 52/60.

Results: Of 576 patients who participated in the SENSCIS trial, 150 participated in the HRCT sub-study (nintedanib 73, placebo 77). The rate of decline in FVC over 52 weeks was similar in the overall trial population and in patients who participated in the HRCT sub-study (Figure). Compared with the placebo group (n=59), a lower proportion of patients in the nintedanib group (n=52) had a worsening in qualitative parameters (i.e., “worse”, “intermediate worse”, or “much worse”) from baseline to week 52–60 (40.4% vs 45.8%) (Table). Ordinal logistic regression analysis demonstrated a numerically greater risk of worsening in qualitative parameters in the placebo group compared with the nintedanib group (OR 1.24 [95% CI: 0.63, 2.47]; p=0.53). Adjusted mean (SE) changes from baseline in quantitative fibrosis score were 2.50 (0.88) % in the nintedanib group (n=23) and 2.80 (0.73) % in the placebo group (n=31) (difference: –0.31% [95% CI: –2.36, 1.75]; p=0.77).

Figure. Rate of decline in FVC (mL/year) over 52 weeks in the overall SENSCIS trial population and in the HRCT sub-study

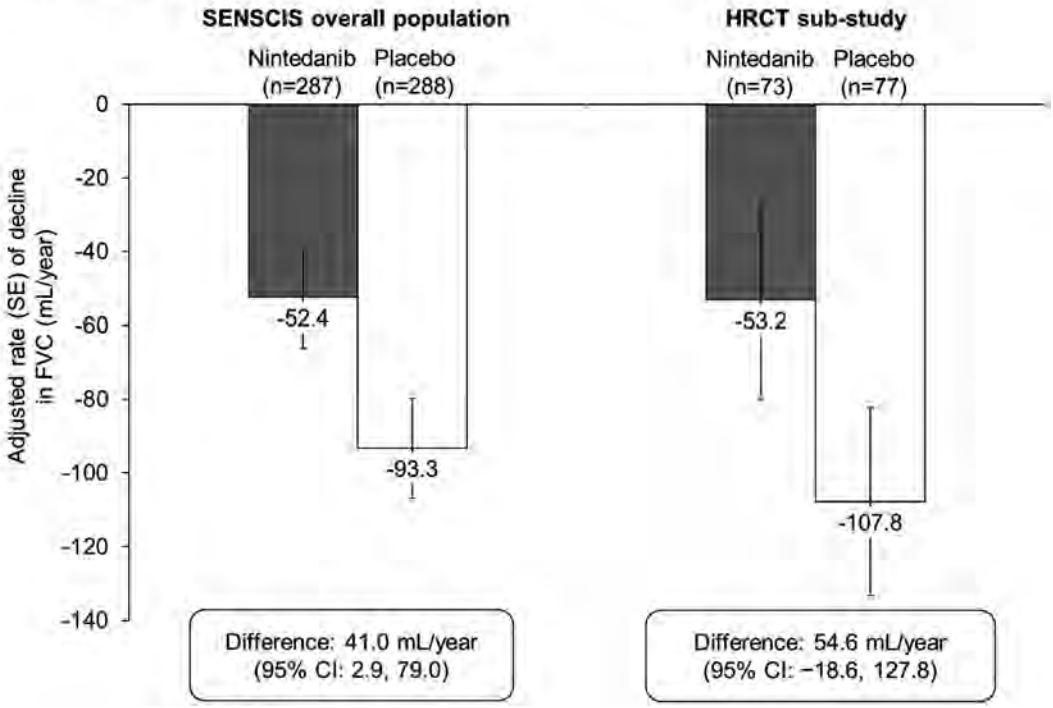

Table. Changes from baseline in the extent of regions with evidence of abnormalities (honeycombing and/or reticulation and/or ground-glass opacity) based on qualitative HRCT review

	Nintedanib (n=52)	**Placebo (n=59)**
Much better	0	0
Intermediate better	2 (3.8)	1 (1.7)
Better	7 (13.5)	8 (13.6)
Same	22 (42.3)	23 (39.0)
Worse	15 (28.8)	17 (28.8)
Intermediate worse	3 (5.8)	6 (10.2)
Much worse	3 (5.8)	4 (6.8)

Data are n (%) of patients with an evaluable HRCT scan. "Much better" = moderate decrease in honeycombing and/or reticulation and/or fibrotic ground glass opacity (GGO); decrease was >10%, as visually estimated. "Better" = definite but mild decrease in honeycombing and/or reticulation and/or fibrotic GGO; decrease was ≤10%, as visually estimated; decrease in extent of fibrosis, including change from fibrotic GGO to pure GGO, was considered improvement. "Same" = no change in honeycombing and/or reticulation and/or fibrotic GGO. "Worse" = definite but mild increase in honeycombing and/or reticulation and/or fibrotic GGO; increase was ≤10%, as visually estimated; increase in extent of fibrosis, including change from pure GGO to fibrotic GGO, was considered, worsening. "Much worse" = at least a moderate increase in honeycombing and/or reticulation and/or fibrotic GGO; increase was >10%, as visually estimated. Intermediate better" = the two radiologists disagreed between the categories "much better" and "better". "Intermediate worse" = the two radiologists disagreed between "worse" and "much worse".

Conclusion: In a sub-study of the SENSCIS trial, qualitative and quantitative changes on HRCT over 52–60 weeks were small. Numerical but non-significant trends towards less worsening were observed in patients treated with nintedanib versus placebo. These analyses were limited by the small number of patients who had an evaluable HRCT scan at the follow-up visit.

Tocilizumab Shows Potential in Preserving Lung Function in Systemic Sclerosis with Positive anti-topoisomerase-1 (Scl-70): A Single Centre Cohort Study

Yasir Suleman[1], Kristina Clark[2], Svetlana Nihtyanova[3], Voon Ong[4] and Christopher Denton[2], [1]Royal Free Hospital London NHS Trust, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Centre for Rheumatology, Royal Free Campus, UCL Division of Medicine, UK, London, United Kingdom, [4]UCL, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent Phase II (faSScinate) and Phase III (focuSSced) clinical trials of tocilizumab versus placebo in early dcSSc highlighted the potential impact of tocilizumab on lung function with preservation of forced vital capacity (FVC) in those treated with tocilizumab, despite only a trend of benefit for skin fibrosis. Tocilizumab is approved for SSc patients with inflammatory arthritis overlap and has been used in this context at our centre. We report here our experience of tocilizumab in SSc and the impact on lung function.

Methods: In our retrospective study, all SSc patients attending our centre who had ever been on tocilizumab were identified. Most of these patients had overlap inflammatory arthritis. Patients who had participated in the faSScinate trial were excluded, whilst those receiving tocilizumab on a compassionate basis following the phase 3 focuSSced trial were included. Statistical analysis was carried out using the Mann-Whitney-U test.

Results: Of the 32 patients identified, 68.8% (n = 22) were classified as diffuse SSc and 75% (n = 24) patients were female. The most common autoantibodies were ATA (anti-topoisomerase antibody) (34.3%) and ARA (anti-RNA polymerase-III antibody) (18.8%). 46.9% (n = 17) patients had known interstitial lung disease. 6 patients received tocilizumab on a compassionate basis following completion of the open label phase of the focuSSced clinical trial, the remainder had overlap inflammatory arthritis. Mean age of disease onset was 38.6 years, and the median disease duration to tocilizumab initiation was 7.9 years. 11 patients discontinued tocilizumab: 6 due to cessation of the compassionate use access, 2 due to side effects, 3 due to lack of benefit.

75% (n = 24) patients had serial lung function data to compare FVC and DLCO before and after initiation of treatment. Baseline FVC prior to tocilizumab was 3.09L (sd = 0.98) or 91% predicted (sd = 19.7). Baseline DLCO prior to tocilizumab was 5.55ml/min/mmHg (sd = 2.21) or 61.1% predicted (sd = 17). Median duration on tocilizumab was 7 months (IQR =9.5). To standardise results, the yearly change rate in FVC and DLCO was calculated. Median change in % predicted FVC was -1.5% (IQR=10.7) and median change in % predicted DLCO was -0.5% (IQR=6.1). Subgroup analysis revealed a significant difference between autoantibody groups and change in FVC while on tocilizumab. It was notable that there was an increase in median change in FVC in patients with ATA antibody (3.27%, IQR=13.55) whereas there was a decrease in median change in FVC in all other autoantibody groups (-4.7%, IQR=11.1, p = 0.0019). There was a near significant difference in change in DLCO between these antibodies at 12 months (-2.6%, IQR = 4.7, p = 0.056) in favour of improvement in ATA subgroup.

Conclusion: Our findings support potential benefit for lung function in SSc patients on tocilizumab compared to placebo particularly in those with the ATA, and this is consistent with previous trial results. Presence of ATA confers a higher risk of extensive lung fibrosis in SSc, regardless of extent of skin involvement, and so early identification of these cases and use of tocilizumab may prevent development of clinically meaningful lung fibrosis and improve long-term outcome.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The importance of non-pharmacologic interventions in systemic sclerosis (SSc) is increasingly recognized. Physical therapy is among the most frequently used interventions, but knowledge on its actual provision in daily practice and patients' perspectives on its delivery is absent. Therefore this study aimed to assess among patients with SSc the usage, contents, satisfaction, needs and preferences regarding the provision of physical therapy.

Methods: Four hundred and five SSc patients, fulfilling the ACR/EULAR 2013 criteria for SSc and participating in the multidisciplinary SSc care pathway of the Leiden University Medical Center were invited. They are seen by a physical therapist at the yearly assessment related to the care pathway, if treatment is needed they are referred to primary care. Between July-August 2019 they received a pen-and-paper questionnaire consisting of 39 questions regarding usage of physical therapy over the past two years (thirteen multiple-choice questions), contents (five multiple-choice

Table 1. Characteristics of the included systemic sclerosis patients (n=204)

questions), satisfaction (eight questions, 0-10 scale-based, multi-response, open field), and needs and preferences (thirteen questions, dichotomous, multi-response, open field).

Results: In total, 204 SSc patients (median age: 63 years, 80% female) were included (Table 1). Over the past two years, 62% (n=127) patients received physical therapy (PT-group; 94% in the primary care setting), whereas 38% (n=77) did not (No-PT-group). Regarding active treatment modalities, muscle strengthening (n=91, 71%), range of motion (n=88, 69%) and aerobic exercises (n=72, 56%) were most frequently mentioned (Table 2). Concerning passive modalities, 46% (n=59) of patients received massage and 16% (n=21) kinesiotaping. Twenty percent of patients reported SSc specific treatments including hand (n=20, 16%) and mouth (n=7, 6%) exercises. Thirty-one percent (n=40) of the patients were encouraged to spend time on physical activity at home. Seventy percent (n=142) of all

Table 2. Contents of physical therapy as reported by the systemic sclerosis patients (n=127)	
Active modalities	Number (percentages)
Aerobic exercises	72 (56%)
Muscle strengthening exercises	91 (71%)
Range of motion exercises	88 (69%)
Hand function exercises	20 (16%)
Mouth exercises	7 (6%)
Swallow exercises	1 (1%)
Balance exercises	55 (43%)
Passive modalities	
Relaxation exercises	10 (8%)
Massage	59 (46%)
Heat therapy	2 (2%)
Cold therapy	1 (1%)
Electrical therapy	7 (5%)
Dry needling	8 (6%)
Kinesiotaping	21 (16%)
Hydro therapy	7 (6%)
General	
Physical activity promotion	40 (31%)
Exercises to perform at home	100 (78%)
This table shows the contents of the received physical therapy as reported by the patients with systemic sclerosis who went to a physical therapist.	

Table 2. Contents of physical therapy as reported by the systemic sclerosis patients (n=127)

included patients indicated physical therapy as a valuable part of the standardized Care Pathway at the Leiden University Medical Center. Of the total group, 47% (n=96) patients preferred to receive more information regarding physical therapy and 63% (n=128) to continue/(re)start physical therapy in the near future, favoring individual continuous therapy (n=50/128, 39%) by physical therapist close to home (n=61/128, 48%). Eighty percent (n=163) stated that specific knowledge on systemic sclerosis and/or rheumatic diseases is necessary for physical therapists to treat systemic sclerosis patients.

Conclusion: Sixty-two percent of systemic sclerosis patients received physical therapy in a period of two years mostly consisting of active treatment.The use of passive treatment modalities and hand and mouth exercises was highly variable. Although all patients are seen once-yearly by a physical therapist in a multidisciplinary care pathway, more than half expressed an unmet need regarding physical therapy. These results could help improve content and patient education regarding physical therapy for SSc.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: As there is currently no cure available for systemic sclerosis (SSc), nonpharmacologic care is an essential element in the management of the disease. Physical therapy is often used by SSc patients, but evidence on its optimal content is scarce and practice highly variable. To improve the delivery of care perspectives of the health care professional are crucial. Therefore, this study aimed to assess the perspectives of physical therapists treating patients with SSc on their current practice and educational needs regarding physical therapy.

Methods: SSc patients who participated in a cross-sectional study on the use of physical therapy were asked to invite their treating physical therapist, if applicable, to complete a questionnaire. The questionnaire consisted of 37 questions regarding sociodemographic information (thirteen questions), the content of treatment employed (eight questions), perceived knowledge and skills (four questions) and educational needs (twelve questions). The survey consisted of dichotomous- (yes/no) or multiple-choice questions, and multiple-answer options.

Results: In total, 127 patients reported the use of physical therapy over the past two years, and 48 physical therapists returned the questionnaire. Their median age was 44 years, 52% was female and 50% had more than 20 years of working experience. The median number of SSc patients currently treated was 1 (range: 1 – 4). Eighty-three percent (n=44) of physical therapists received a referral, of whom two-third (n=30/44) from a rheumatologist. Seventy percent (n=32/44) stated a perceived lack of medical information concerning the patient's disease manifestations in the referral letter. Range of motion (n=42, 88%), muscle strengthening (n=41, 85%) and aerobic (n=34, 71%) exercises were most often reported, followed by hand (n=20, 42%) and mouth (n=5, 10%) exercises. Concerning passive modalities, massage (n=24, 50%) and relaxation exercises (n=21, 44%) were performed most frequently. Thirty-five percent (n=11) indicated that a lack of knowledge on SSc was a problem during the treatment, meanwhile 98% (n=47) had tried to get more information on the disease; Google (n=32/47, 67%), asking the patient (n=25/47, 52%) or Pubmed (n=19/47, 40%) were the most frequently mentioned sources of information. Eighty-five percent (n=41) expressed the need for an interactive website with information on treatment of SSc patients specifically designed for physical therapists and 77% (n=37) for additional courses on SSc, with online delivery preferred by most of them (n=28/37, 76%).

Conclusion: The large majority of physical therapists treating patients with systemic sclerosis used active treatment modalities, but passive modalities were also relatively frequent. Additionally, more than 75% expressed an unmet need regarding information and education on systemic sclerosis. The development of such educational activities could be a starting point to optimize the content and quality of physical therapy and therefore could contribute to improvement of quality of multidisciplinary care in systemic sclerosis.

Table 1. Factors associated with referral to EGD

Background/Purpose: Gastrointestinal (GI) tract involvement is the most common of all internal organ involvement in systemic sclerosis (SSc). The University of California at Los Angeles, Scleroderma Clinical Trial Consortium, Gastrointestinal Tract Instrument 2.0 (UCLA GIT 2.0) is validated to capture GI morbidity in patients with SSc (1). However, the routine clinical investigation of GI involvement in these patients is not standardized and there is no consensus about when and how frequently an esophago-gastro-duodenoscopy (EGD) should be performed.

The aims of this study were to determine in an unselected, real-life cohort of patients with SSc, 1) if the UCLA GIT 2.0 could discriminate patients for whom a rheumatologist with experience in SSc would recommend an EGD, and 2) if the UCLA GIT 2.0 could identify patients with endoscopic esophagitis.

Methods: We selected patients fulfilling the ACR/EULAR 2013 criteria for SSc from the Zurich EUSTAR cohort, having completed at least once the UCLA GIT 2.0 questionnaire at an EUSTAR visit. We reviewed the medical charts of the selected patients from 2013 to 2019 and recorded data on EGD performed in an interval of ±3 months from a

Table 2. Factors associated with endoscopic esophagitis

EUSTAR visit. We analyzed by general linear mixed effect models (GLMM) several parameters, including UCLA GIT 2.0 and its subscales, considered as potentially associated with 1) the referral to EGD and 2) endoscopic esophagitis.

Results: We identified 346 patients (82.7% female, median age 63 years, median disease duration 10 years, 23% with diffuse cutaneous SSc) satisfying the inclusion criteria, who filled in 940 UCLA GIT 2.0 questionnaires.

For the first objective, we excluded 31/940 visits because EGD was done shortly (< 3 months) before the EUSTAR visit. In the 909 remaining visits, EGD was recommended by the expert rheumatologists in 128 cases. The UCLA GIT 2.0 total score and some of its subscales (reflux, distention/bloating, social functioning score), but also the modified Rodnan skin score (mRSS) and esophageal and stomach symptoms by medical history were associated with the referral to EGD (Table 1).

For the second objective, we identified 177 EGD performed in 145 patients. In GLMM, esophageal symptoms and, to a lesser extent, mRSS, correlated with endoscopic esophagitis, while neither the total ULCA GIT 2.0 score nor any of its subscales showed any association with this finding (Table 2).

Conclusion: In a real-life setting, UCLA GIT 2.0 subscales (reflux, distention/bloating, social functioning) and total score strongly associated with expert interpretation of gastroesophageal symptoms and consecutive referral to EGD.

However, they showed no correlation with esophagitis on EGD. The main clinical association of esophagitis was the presence of esophageal symptoms.

Should Systemic Sclerosis Patients with Low Bicarbonate Have Replacement to Prevent Renal Dysfunction?

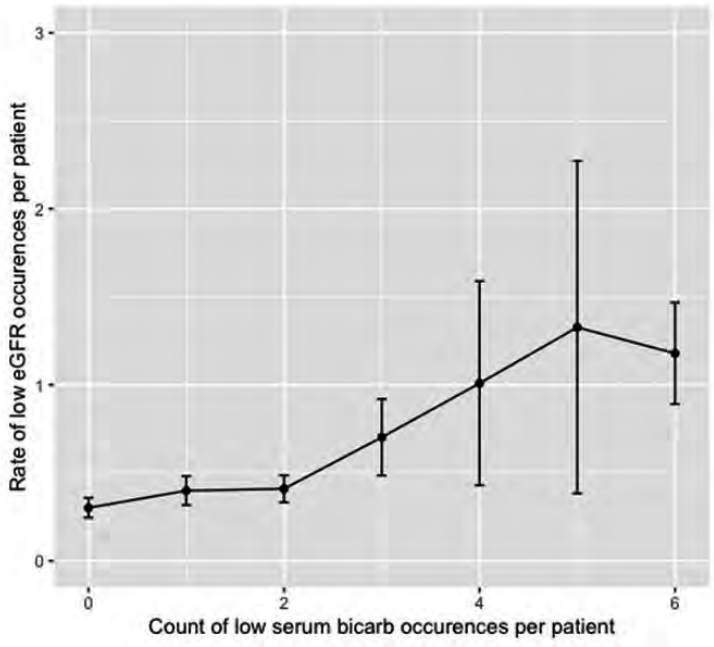
Megan Meier[1], Jacob Stever[2], Josephine Wright[1], Tracy Frech[3], Greg Stoddard[1] and Benjamin Tingey[1], [1]University of Utah, Salt Lake City, [2]University of Utah, SANDY, [3]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is a well-characterized condition in patients with systemic sclerosis, but systemic sclerosis patients frequently develop chronic kidney disease (CKD) without prior evidence of SRC. Retrospective analyses have shown that low serum bicarbonate predicts kidney failure and death in the general population. This study investigates the potential association of low serum bicarbonate levels (< 22 mmol/L) and the development of reduced kidney function in patients with SSc.

Methods: This was a retrospective cohort study comprised of patients with limited or systemic sclerosis (SSc) by 2013 ACR/EULAR criteria. Patients were recruited for participation from the University of Utah SSc Clinic from October, 2012 to March, 2017. Index and follow up bicarbonate levels and associated eGFR values were recorded. A serum bicarbonate level < 22 mmol/L and an eGFR < 60 ml/min/1.73m^2 were considered low values for the purposes of this study. Patients with normal versus low serum bicarbonate levels at index date were followed and compared longitudinally during the study period for the development of kidney dysfunction, manifested by low eGFR. A zero-inflated Poisson (ZIP) regressions model was applied to estimate the rate of predicted low eGFR labs associated with low serum bicarbonate occurrences per patient.

Figure 1. Rate of predicted low eGFR by low serum bicarbonate



The rate of predicted low eGFR occurrences, with error bars, plotted against the count of low serum-bicarbonate occurrences per patient .

Results: 143 patients met inclusion requirements for evaluation and had normal kidney function determined by eGFR at index date. In this SSc cohort, with each one count increase in low serum-bicarbonate labs, the rate of low eGFR labs increased (aIRR: 1.21; 95% CI: 1.05-1.40). This was a significant increase with P=0.01.

Conclusion: In a single center SSc cohort, low serial serum bicarbonate was associated with increased rates of reduced kidney function. Awareness of this association provides a means to screen for higher risk SSc patients and potentially intervene, given the reduction in morbidity and mortality seen with bicarbonate supplementation in patients with CKD in the general population.

A Systematic Assessment of Demographics, Clinical and Serological Features Associated with Colonic Hypomotility in Systemic Sclerosis

Jenice Cheah[1], Jamie Perin[2], Elizabeth Volkmann[3], Laura Hummers[4], Fredrick Wigley[5] and Zsuzsanna McMahan[6], [1]JHUSOM, Baltimore, [2]JHUSPH, Baltimore, [3]University of California, Los Angeles, Los Angeles, CA, [4]Johns Hopkins Univerisity, Ellicott City, MD, [5]Johns Hopkins University School of Medicine, Baltimore, MD, [6]Johns Hopkins University, Baltimore

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Colonic dysmotility affects up to 50% of patients with systemic sclerosis (SSc). While some patients have mild colonic disease, others experience severe complications, such as recurrent pseudo-obstruction and the requirement of total parenteral nutrition. Nevertheless, the clinical phenotype of patients with colonic hypomotility is not well-defined. We sought to identify the demographic, clinical, and serologic features that distinguish SSc patients with and without colonic hypomotility.

Methods: Patients with gastrointestinal (GI) symptoms from our Center who met SSc criteria were prospectively enrolled and underwent a scintigraphy-based whole gut transit (WGT) study. Eighty percent met 2013 ACR/EULAR criteria, 2% met ACR 1980 criteria, and 18% met CREST criteria. We performed a cross sectional analysis comparing

Table 1. Characteristics of the SSc patients with and without colonic hypomotility by WGT study in the Johns Hopkins Scleroderma Center cohort

demographic, clinical, and serologic features between SSc patients with and without colonic hypomotility by WGT. Clinical features were characterized using maximum severity scores recorded in the database. Univariate logistic regression was used to examine associations with colonic hypomotility. Multivariable models were then constructed using significant variables from the univariate analysis and potential confounders to determine whether the associations remained.

Results: One hundred patients with GI symptoms were enrolled and underwent WGT studies. Forty-eight percent had colonic hypomotility (i.e. < 67% colonic emptying by 72 hours of WGT study). Patients with colonic hypomotility were more likely to be female (98% vs. 80%; p< 0.01), have ever smoked (43% vs. 23%; p=0.04), have anti-centromere (CENP) autoantibodies (58% vs. 31%; p=0.02), have telangiectasias (89% vs. 67%; p = 0.01), and have a maximum Medsger GI Severity Score ≥3 (27% vs. 9%; p=0.03) compared to those without colonic hypomotility. Our univariate analyses found female sex [odd's ratio (OR)=12.02, 95% confidence interval (CI) 1.49-97.00; p=0.02], an-

Table 2. Cross-sectional univariate model evaluating the association between clinical, demographic, serologic features and colonic hypomotility in patients with SSc

Table 3. Multivariable model evaluating the association between clinical, demographic, and serological features and colonic hypomotility after adjusting for significant covariates from the univariate analysis.			
Covariate	Odds Ratio	95% Confidence Interval	p-value
Age at first symptom	1.02	0.96-1.09	0.53
Disease duration from first SSc-associated symptom (Raynaud's or non-Raynaud's) to date of WGT study	0.98	0.92-1.04	0.52
Female	50.06	2.59-968.37	**0.01†**
Ever smoker	3.88	0.75-20.11	0.11
GI involvement (≥3)	7.64	0.72-80.94	0.09
Telangiectasias	5.72	0.88-37.33	0.07
FVC‡	0.17	0.03-0.87	**0.03†**
Anti-centromere (CENP) autoantibody	0.88	0.17-4.45	0.88

† statistically significant

‡ Based on minimum value across all visits

GI = gastrointestinal; GI involvement = maximum Medsger GI severity score ≥3; FVC = forced vital capacity.

Table 3. Multivariable model evaluating the association between clinical, demographic, and serological features and colonic hypomotility after adjusting for significant covariates from the univariate analysis.

ti-CENP autoantibodies (OR=3.13, 95%CI 1.20-8.14; p=0.02), telangiectasias (OR=4.00, 95%CI 1.32-12.00; p=0.01), and smoking (OR=2.56, 95%CI 1.06-6.20; p=0.04) to be significantly associated with colonic hypomotility. Patients with colonic hypomotility were less likely to have signs of pulmonary fibrosis, defined as crackles on exam or a chest X-ray/chest CT suggesting fibrosis (OR=0.42, 95%CI 0.18-0.99; p=0.05), and a low FVC (OR=0.23, 95%CI 0.09-0.63; p< 0.01). After adjusting for significant covariates from the univariate analysis and potential confounders, our multivariable model determined that female sex (OR=50.06, 95%CI 2.59-968.37; p=0.01) remained strongly associated with colonic hypomotility, and confirmed that patients with colonic hypomotility were less likely to have a low FVC (OR=0.17, 95% CI0.03-0.87; p=0.03).

Conclusion: Distinct clinical features such as female sex, anti-CENP autoantibodies, telangiectasias, and smoking associated with colonic hypomotility. Our study also suggested that patients with colonic hypomotility were less likely to have restrictive lung disease. The identification of these features can inform the diagnostic evaluation and study of disease mechanism in SSc patients with colonic hypomotility.

Response: complete / sequels	10(35.7%)/18(64.2%)

[1]ECOG: Eastern Cooperative Oncology Group scale to assess the quality of life

imately 30%-50% of allogeneic transplant survivors. Although cGVHD can involve many organ systems, joint and fascial involvement is relatively common, little known and can cause significant functional impairment.

Describe the clinical/transplant related characteristics, the therapeutic management and the clinical outcome of a cohort of patients with joint and fascial involvement in the context of cGVHD.

Methods: Observational and retrospective study to describe the clinical characteristics of 28 patients affected by joint and fascial cGVHD. The usual demographic variables, the transplant reason disease, the type of transplant,laboratory parameters, rescue therapies and their response were collected. The statistical analysis was done with Microsoft Excel 2007.

Results: Seventeen (60.7%) patients were male and 11 (39.35%) were women with a mean age of 48.75 years (range from 10 to 74). Acute myeloid leukemia was the most frequent cause of the transplant in 11 patients (39.3%)

Transplant related characteristics are reflected in Table 1 and the clinical manifestations, therapies received and their response in Table 2.. Eighteen (64,3%) presented irreversible contracture due to sclerosis that negatively impacts their quality of life and physical function (11/39%).

Four (14.2%) patients died during their follow-up, being the cause of death in 2 cases due to sepsis, in 1 case due to leukemia relapse and in 1 case attributable to cGVHD.

Conclusion: Nonspecific joint symptoms such as stiffness, edema or arthromyalgia may be factors that predict the development of joint/fascial involvement in cGVHD.

They should be closely monitored in order to be able to perform early stage diagnoses and implementation of proper treatment, including rehabilitation, in order to restore function and improve the quality of life of these patients.

Outcomes of Systemic Sclerosis Patients Who Were Primarily Admitted for Acute Myocardial Infarction from 2016 to 2017: Insights from the National Inpatient Sample

Atefeh Vafa[1], Omid Behnamfar[2] and Yih Chang Lin[3], [1]University of South Florida, Tampa, FL, [2]University of California San Diego, La Jolla, CA, [3]University of South Florida, Morsani College of Medicine, Tampa, FL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Several systemic autoimmune rheumatic diseases have been shown to increase coronary artery disease (CAD) risk, notable rheumatoid arthritis and systemic lupus erythematosus. However, data on the risk of systemic sclerosis (SSc) and CAD is unclear. Although not a common finding, some studies have shown an increased prevalence of CAD in SSc patients. This has been attributed to the underlying vascular abnormalities. Other studies have failed to show a significant difference in the prevalence of CAD compared to the general population. The primary

Demographics and Outcomes of AMI hospitalizations in patients with and without Scleroderma in 2016-2017

Demographics/Outcomes	Scleroderma	No Scleroderma	P-value
Age (Mean) (Year)	66.7	66.9	0.786
Female (%)	82	37	<0.001
Caucasian (%)	71	73	0.540
Teaching Hospital (%)	74	66	0.013
Charlson Comorbidity Index ≥3 (%)	75	51	<0.001
Length of Stay (Mean) (Day)	5.3	4.4	0.038
Inpatient Mortality (%)	9.17	4.68	0.001

aim of this study was to assess the outcomes of SSc patients who were primarily hospitalized for acute myocardial infarction (AMI) from a nationally representative sample.

Methods: We used data from the National Inpatient Sample (NIS) for the period of 2016 to 2017 for adult AMI hospitalizations as a primary diagnosis and systemic sclerosis as a secondary diagnosis using ICD-10 codes. The proportion who met ACR classification criteria and disease activity status cannot be determined within the NIS database. We used STATA 15 for the data analysis and multivariate logistic regression to calculate the adjusted odds ratios for inpatient mortality in AMI hospitalizations.

Results: We identified a total of 1,305,889 AMI hospitalizations between 2016 and 2017 of which 1,145 (0.08%) had a diagnosis of SSc. Compared to the non-SSc group, patients with SSc were predominantly female (82.1% vs. 37.9%; p< 0.001). There was no statistically significant difference in the age between two groups of patients.

Compared to non-SSc hospitalizations with AMI, SSc hospitalizations had a higher unadjusted inpatient mortality rate (9.17% vs. 4.68%; p=0.001). After adjusting for gender, age, race, household income, hospital location, hospital teaching status, hospital bed size and Charlson Comorbidity Index, the odds ratio (OR) for hospital mortality due to AMI in SSC patients was higher and statistically significant (aOR=2.02; 95% CI= 1.28-3.19; p=0.002) compared to the non-SSc group. Length of stay was significantly longer in patients with SSc (5.3 vs 4.4 days; p=0.038).

Conclusion: In our study, unadjusted and adjusted inpatient mortality in SSc patients primarily hospitalized for AMI was higher than non-SSc patients with an adjusted odds ratio of 2.02. This finding indicates that patients with SSc may have worse outcomes for cardiovascular events when admitted for AMI. Further study in optimizing cardiovascular risk factors in SSc patients is paramount in order to minimize their cardiac morbidity and mortality.

Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies are useful in systemic sclerosis (SSc) for predicting disease course. Some autoantibodies have been associated with a close temporal relationship with cancer. We investigated the association between SSc-specific and SSc-associated autoantibodies and cancer in a national registry.

Methods: Subjects recruited between 2004 and 2019 in a national SSc registry were studied (96% fulfill 2013 ACR/EULAR SSc classification criteria). The exposure was presence of SSc-specific/associated autoantibodies, namely anti-centromere (ACA), -topoisomerase I (ATA), -RNA polymerase 3 (ARNAP), -fibrillarin, -Th/To, -PM-Scl, -Ku,

For continuous variables: median (interquartile range). For categorical variables: n (%). Autoantibodies include single-specificity and overlapping autoantibodies.
Disease onset is defined as time of first non-Raynaud disease manifestation of systemic sclerosis.

Table 2. Time interval between cancer diagnosis and systemic sclerosis onset in all subjects and stratified by autoantibodies

-U1RNP, -NOR90, -Ro52, -RNPC3 and -BICD2. The primary outcome was cancer-associated SSc, defined as cancer occurring within 2, 3 and 5 years of first non-Raynaud SSc manifestation. Univariate logistic regression was used to compare the odds of cancer-associated SSc between the autoantibody subgroups, using anti-centromere as reference. Descriptive statistics were used to compare clinical characteristics of subjects with cancer to those without cancer.

Results: Out of 1698 SSc subjects, 1474 (86.8%) had at least partially available autoantibody data. Mean (SD) age was 55.3 (12.3) years, 87% were female and 59% had a smoking history. Table 1 shows baseline characteristics

Table 3. Univariate logistic regression analyses for the risk of cancer within 2, 3 and 5 years of systemic sclerosis onset according to autoantibody status

	OR (95% CI) for cancer diagnosis within 2 years of SSc onset	OR (95% CI) for cancer diagnosis within 3 years of SSc onset	OR (95% CI) for cancer diagnosis within 5 years of SSc onset
Anti-centromere	1.00 (reference)	1.00 (reference)	1.00 (reference)
Anti-topoisomerase I	2.18 (0.62-7.32)	1.18 (0.37-3.28)	0.73 (0.26-1.73)
Anti-RNA polymerase III	1.75 (0.36-7.20)	1.46 (0.45-4.17)	0.91 (0.32-2.20)
Anti-Ro52	1.57 (0.38-5.99)	1.64 (0.47-5.50)	1.43 (0.55-3.60)
Anti-PM-Scl 75/100	–	–	0.59 (0.03-2.95)
Anti-U1RNP	1.56 (0.08-9.96)	0.86 (0.05-4.72)	0.48 (0.03-2.41)

Abbreviations: CI: confidence interval; OR: odds ratio.
Disease onset is defined as the time of first non-Raynaud disease manifestation of systemic sclerosis.
Subjects who are positive for both anti-centromere and the studied autoantibody were excluded.
Risk estimates could not be calculated due to the small number of events for anti-Nor90, anti-Th/To, anti-Ku, anti-Fibrillarin, anti-BicD2 and anti-RNPC3 protein autoantibodies.

Table 3. Univariate logistic regression analyses for the risk of cancer within 2, 3 and 5 years of systemic sclerosis onset according to autoantibody status

stratified by autoantibodies. Cancer was diagnosed in 231 (13.6%) subjects. Median (IQR) time between cancer and disease onset was 7.0 (-0.7 to 16.4) years.

Table 2 shows the prevalence of cancer diagnosed within 2, 3 and 5 years of SSc onset, stratified by autoantibodies. Among 207 cancer subjects with available time data, 27 (13.6%), 37 (17.9%) and 58 (28.0%) were diagnosed with cancer within 2, 3 and 5 years of SSc onset. The most frequent types of cancers diagnosed within 5 years were breast (n=13), non-melanoma skin (NMSC, n=12), cervical/uterine (n=9) and hematological (n=8) cancers.

Overall, among all SSc subjects, no autoantibody was predictive of cancer-associated SSc (Table 3). However, ATA-positive subjects were more likely to have a solid cancer excluding NMSC (OR 6.6, 95% CI 1.4-46.4), especially breast cancer (OR 7.9, 95% CI 1.0-159.2), within 2 years of SSc onset. The risk of cancer-associated SSc was not significantly increased among ARNAP-positive subjects, although for solid cancers excluding NMSC, the OR was 5.8 (95% CI 0.56-125.8). Furthermore, subjects positive for at least 3 autoantibodies were more likely to develop cancer within 5 years of SSc onset compared to subjects with 1 or 2 autoantibodies (OR 3.0, 95% CI 1.3-6.1). Subjects who developed cancer within two years of SSc onset were generally younger (51.8 vs 57.9 years) and more frequently had a history of smoking (72% vs 59%) and scleroderma renal crisis (11% vs 3%).

Conclusion: In this study, ATA and overlapping autoantibodies were predictive of cancer-associated SSc for solid cancers excluding NMSC. Breast cancer was the most frequent type of cancer detected within 5 years of first non-Raynaud manifestation. Autoantibodies may help guide the approach to cancer screening. Larger studies are needed to define the risk of cancer-associated SSc within rarer autoantibody subgroups.

Long-Term Tolerability of Aminaphtone in Raynaud's Phenomenon Secondary to Systemic Sclerosis

Alberto Sulli[1], Sabrina Paolino[1], Giorgia Ferrari[1], Carmen Pizzorni[1], Elvis Hysa[1], Maurizio Cutolo[1] and Emanuele Gotelli[1], [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic, Genoa, Italy

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Aminaphtone has been used for many years to treat microvascular disorders. *In vitro* Aminaphtone counteracts vasoconstriction downregulating endothelin-1 production and interferes with adhesion molecules and cadherin degradation thus defending vessels permeability (1-3). *In vivo* aminaphtone ameliorates clinical symptoms of several clinical conditions, including Raynaud's phenomenon (RP) (4).

The aim of the study was to evaluate long-term tolerability of standard dosage of Aminaphtone in a cohort of systemic sclerosis (SSc) patients with secondary RP.

Methods: Seventy-eight SSc patients (mean age 65±13 years; mean disease duration 9±7 years) treated with Aminaphtone due to active RP were enrolled (ACR/EULAR 2013 criteria). They were taking various concomitant treatments, including aspirin, calcium-channel blockers, cyclic intravenous iloprost, immunomodulators, endothelin receptor antagonists. SSc patients performed periodic clinical assessments and blood tests on average every four months per clinical practice. Duration of Aminaphtone administration, side effects, and self-assessment of Raynaud Condition Score (RCS) in a scale from 0 (absence of pain) to 10 (intolerable pain) were retrospectively taken into account.

Results: Duration of Aminaphtone administration (75 mg *bis in die* dosage, as standard initial posology) was between six and sixty-seven months (mean 31±20 months). During the follow-up, five patients (6.4%) referred headache as side effect: three of them had to reduce Aminaphtone posology to 75 mg per day, while maintaining clinical benefits. Periodic blood tests did not reveal any significant alteration attributable to Aminaphtone. No other side effects related to the drug appeared during the treatment period.

At baseline, mean RCS was 7.3±0.8. After 3 months of treatment sixty-four patients (82%) yet referred a subjective improvement of RCS (3.5±0.8, p=0.03), whereas 14 patients (18%) were clinically unsatisfied (RCS 6.1±0.4, p=0.12). In this last group, posology was increased to 75 mg *tris in die*, with a satisfactory amelioration in further nine patients (93.6%) (RCS 4.0±0.6 p=0.04), while five patients (6.4%) definitively discontinued therapy for subjective ineffectiveness within six months. Patients referred a sustained improvement of RCS along the observational period (31±20 months) (last RCS 3.7±0.7, p=0.03 vs baseline).

Conclusion: Aminaphtone shows an acceptable long-term tolerability along with sustained efficacy in the management of SSc-related RP, without disabling side effects. A randomized controlled trial for Aminaphtone use in the management of SSc-related RP is desirable.

Systemic Sclerosis: Subclinical Aterosclerosis and Morbimortality

Miriam Retuerto[1], Jose Luis Rosales[2], Maria Martin[1], Beatriz Joven[1] and Patricia E Carreira[1], [1]Hospital universitario 12 de octubre, Madrid, Spain, [2]Hospiten Rambla, Santa Cruz de Tenerife, Spain

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases are associated with accelerated atherosclerosis, and an increase in cardiovascular morbidity and mortality. This process is mediated by classic cardiovascular risk factors (CVRF), chronic inflammation and atherogenic treatments such as corticosteroids. In Systemic Sclerosis (SSc) cardiovascular complications have increased in recent decades, although the studies on subclinical atherosclerosis (sATS) in SSc show discordant results. Our objetive is to evaluate prospectively the relationship between subclinical atherosclerosis, cardiovascular morbidity and mortality in patients with SSc.

Methods: 120 consecutive patients with SSc who attended their medical regular review during November and December 2011 were included. We evaluated the presence of plaques and measured the right CCA IMT by B doppler US for the detection of sATS (IMT > 0.9mm and/or presence of plaque), review of classic CVRF and estimation of Medsger severity and EUSTAR activity index. Patients have been followed for 8 years, with at least annual consul-

	Absent n=78	Present n=42	
Diffuse cutaneous SSc	37.18%	26.12%	NS
mRSS	7.71 ± 6.32	6.38 ± 4.92	NS
High mRSS	9.69 ± 8.33	7.57 ± 4.74	NS
Arthritis	32.05%	28.57%	NS
Lung involvement	33.33%	30.95%	NS
PAH	10.26%	7.14%	NS
Cardiac involvement	15.38%	9.52%	NS
Digital ulcers	35.90%	35.83%	NS
AntiScl70	25.64%	21.43%	NS
ESR	20.12 ± 13.77	26.88 ±17.25	p =0.037*
CPR	0.65 ± 0.61	0.89 ± 0.7	p =0.041*
High activity index	11.54%	19.05%	NS
Damage index	6.67 ± 5.56	5.62 ± 4.9	NS
Σ Medsger index	5.37 ± 3.5	5.05 ± 3.45	NS

tation. In retrospect, the SCTC damage index, published in 2019, was obtained at the time of inclusion in the study. The clinical characteristics of the patients are collected since 1990 in a Prospective Longitudinal Observational Study (PLOS). Descriptive analysis was performed, using contigence tables for qualitative variables, and comparison of means for quantitative variables. The relationship between clinical characteristics, mortality, cardiovascular events (CVE), activity, severity and damage index, and sATS, was analyzed using binary logistic regression, adjusting for age and sex.

Results: 120 patients with SSc were included (93% female, age 60 ± 12 years). 42 of these patients (35%) had subclinical atherosclerosis. Age was statistically significant higher in patients with sATS compared to those without it (67.9±11.5 vs. 56.1±10.4 years, $p < 0.001$). We found no differences between groups in activity, damage and severity index (Table 1). Patients with sATS had higher levels of ESR and CRP, but the difference was not confirmed after adjusting for age (*). During the 8 years of follow- up, 9 CVE in 7 patients (5.8%): three myocardial infarction, one transient ischemic accident, one angor, one intermittent claudication and three refractory heart failure. The incidence of severe CVE was more than double in patients with SAtS (10.25% vs. 3.7%), but the difference was not significant. We found no relationship between the mortality of any cause, or the secondary to CVE, with sATS, in the 32 patients who died during the follow-up, 3 due to CVE (9.4%). The results are similar when we analyze only the presence of plaques.

Conclusion: In our study subclinical atherosclerosis is not related to higher mortality in patients with SSc, but it does seem to influence the occurrence of cardiovascular events. In addition, our results suggest that SSc does not influence the onset of accelerated atheromatosis.

Pathway to Systemic Sclerosis: Concerning Patients' Experiences During the Diagnostic Process

Fennell Patricia[1], Lee Shapiro[2], Nancy Dorr[3], Roberta Lukasiewicz[4], Frank Houser[5] and Madison Taylor[6], [1]Albany Health Management Associates, Steffens Scleroderma Foundation, Albany, NY, [2]Albany Medical College, Stillwater, NY, [3]The College of Saint Rose, Albany, NY, [4]Steffens Scleroderma Foundation, Albany, NY, [5]The College of Saint Rose, Nassau, NY, [6]The College of Saint Rose, Mississauga, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Receiving a diagnosis of systemic sclerosis (SSc) can be straightforward process for some, whereas others have a circuitous route. Given that complications can often arise early and lead to death, reducing the length of time until diagnosis is crucial (1). To the extent that understanding patients' experiences in the diagnostic process may help find ways to shorten it, we retrospectively examined the process patients with SSc experienced from the point of first symptoms through diagnosis.

Methods: Patients with SSc were approached to participate by their rheumatologist (specializing in scleroderma) during an office visit. Sixty-four patients (42% diffuse, 45% limited, 13% unknown) completed open-ended questions (e.g., what was your experience when you first felt unwell and when you were diagnosed with scleroderma).

Two researchers independently categorized responses; discrepancies were resolved by discussion. One researcher reviewed patients' records. All patients included met ACR-Eular criteria for diagnosis of systemic sclerosis.

Results: Regarding length of time from first symptoms to SSc diagnosis, 48% of patients reported being diagnosed within one year, 31% within 1-4 years, and 21% were diagnosed more than 4 years after the first symptoms appeared.

Overall, 75% of patients reported an initial symptom(s) involving their hands (53% Raynaud's). The 25% without symptoms involving hands commonly reported pain (50%), shortness of breath (31%), and gastrointestinal issues (19%).

Patients reported seeing up to seven health providers during the diagnostic process (*M* = 2.64). When patients first noticed symptoms, 33% saw their primary care physician (PCP) and/or a rheumatologist (27%), and 19% saw their PCP subsequently. Thirty-one percent of patients had a provider suspect SSc before it was diagnosed (13% of providers was a rheumatologist who referred them to a scleroderma specialist, 6% was their PCP). One-third of patients were diagnosed with another condition before receiving the scleroderma diagnosis. Some of these were a mis-diagnosis (e.g., carpal tunnel syndrome, lupus); others likely did have SSc as the underlying, but unrecognized, cause (e.g., arthritis, pulmonary arterial hypertension). Fifty percent of patients reported a SSc diagnosis from a scleroderma specialist, 38% from a different rheumatologist, and 3% from their PCP.

Conclusion: With 1 in 5 of patients being undiagnosed for more than four years, and only about 30% of patients having a health provider suspect a SSc diagnosis, educational efforts should make SSc a more salient diagnosis for providers. Three-quarters of patients reported initial symptoms involving their hands. About half of patients saw their PCP at some point in the diagnostic process, but only 9% reported their PCP suspected SSc.

Taken together, these data suggest educational efforts targeting PCPs and specialists to consider scleroderma more readily as a diagnostic possibility. SSc should be, but often is not, included in differential diagnosis of persistent hand complaints.

Poor Maternal and Fetal Outcome in Indian Women with Systemic Sclerosis: Interview-based Study at a Tertiary Center in India

Rajat Kharbanda[1], Naveen R[2], Durga P Misra[2], Latika Gupta[3] and **Vikas Agarwal**[4], [1]SGPGIMS, Lucknow, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Post graduate institute of medical sciences, Lucknow, Uttar Pradesh, India, [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India, [4]Sanjay Gandhi Post Graduate Institute of Medical Sciences, LUCKNOW, India

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Poor obstetric outcomes have been described in Systemic sclerosis (SSc) in the developed world. We assessed effect of the disease in Indian women and compared with world literature.

Methods: Women with SSc (>18 years, ACR/EULAR 2013 criteria)[1] registered at a tertiary care centre from 2010-2016 were contacted over the telephone. Apart from demographics, disease related features, obstetric history and social issues were recorded (Figure 1).

Results: Of 200 women, 94 (47%) could be contacted, 13 (of 94, 13.8%) deaths were recorded, and 75 (79.8%) agreed for an interview (baseline characteristics Table 1). Median age at diagnosis was 31 (22-38) years. Diffuse SSc was more common (56%).

127 conceptions before SSc were compared with 15 after the disease (Figure 2) to yield a higher odd of maternal [OR: 4.9] and foetal [OR: 9.9] complications, and low chances of a live births [OR: 0.23]. Pregnancies after SSc had higher spontaneous abortion, premature rupture of membrane (PROM), prolonged labor, oligohydramnios, maternal infection and intrauterine death (IUD), preterm delivery, low birth weight (LBW) (Table 1)]. Greater (66.7% vs 52%)[2] caesarean deliveries were recorded after disease onset. Social issues were reported by 12 (16%).

As compared to SSc in developed countries,[2,3,4] we found a similar caesarean (two-third) and preterm deliveries (one-fourth), whereas abortion rate was six times higher (26.6% vs 4%) and LBW was 20%, which was 1.5 times higher compared to IMPRESS cohort.[2]

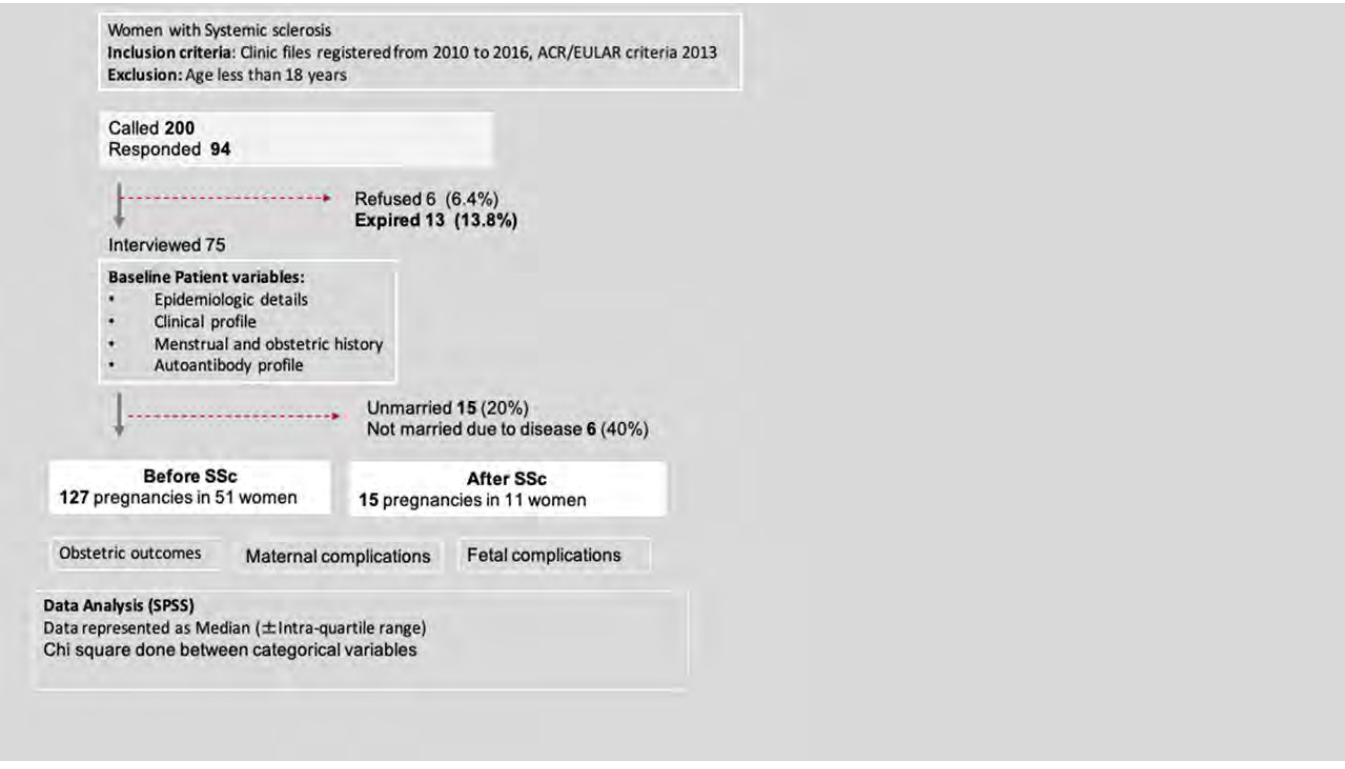

Figure 1. Detailed Methods

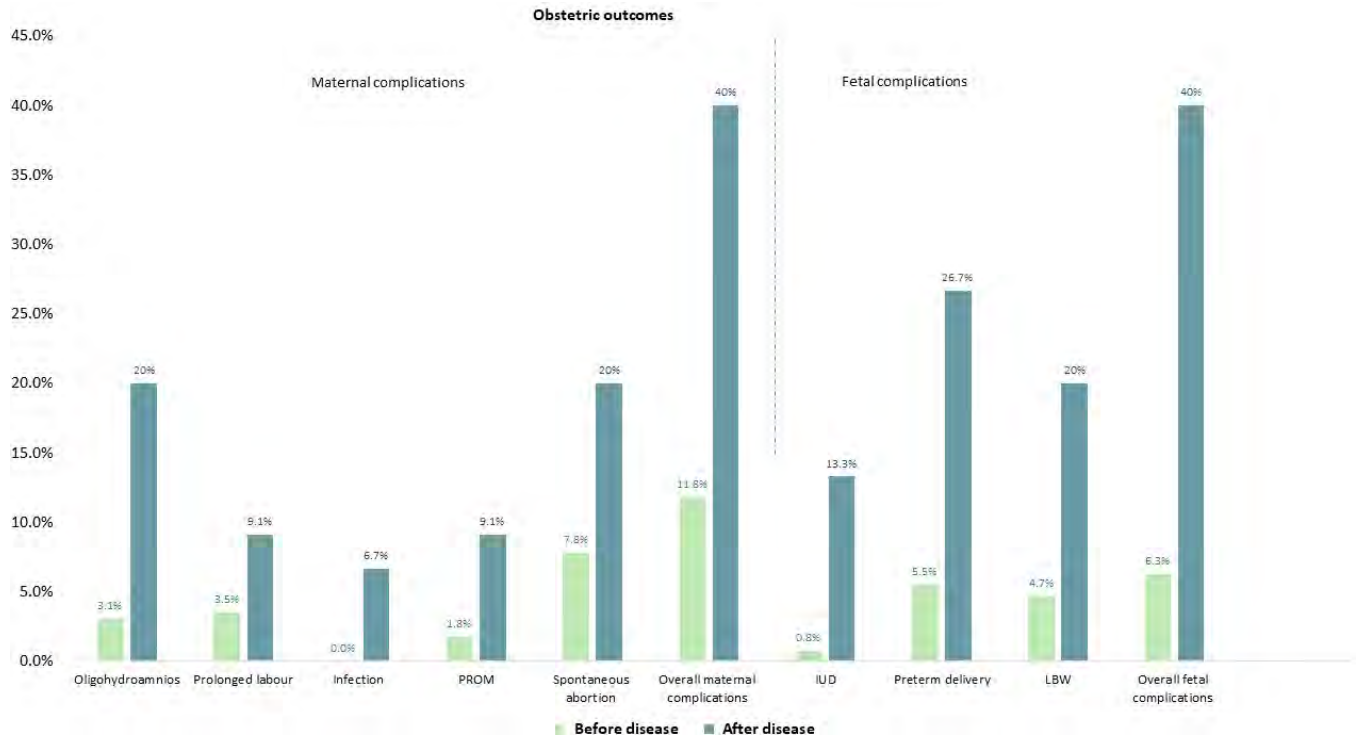

Figure 2. Maternal and fetal complications in Systemic sclerosis

Conclusion: SSc incurs high mortality, poor obstetric outcomes, greater maternal and foetal complications, and low birth weight in addition to social issues. The outcomes are worse in a low-middle income country than previously described from the developed world.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Neointima proliferation is a key pathologic feature of Systemic Sclerosis (SSc), causing arterial vessel narrowing. It is a recognised culprit pathological lesion in Digital Ulcers (DUs), pulmonary artery hypertension and renal crisis. Nevertheless, there are no validated imaging techniques to assess the severity of vascular involvement in SSc. This study presents Digital Artery Volume index (DAVIX ©), a novel quantitative MRI based scoring for the assessment of the blood flow in the arteries and its validation in predicting the onset of DUs in SSc patients.

Methods: This study enrolled 91 (78 female) consecutive patients with Raynaud's phenomenon, with median disease duration of 4 years (IQR=1.91-9). Complete historical and prospective follow-up data were available for 68 patients. 63 patients fulfilled the 2013 ACR/EULAR classification criteria for SSc; 28 had score < 9. The data collected included: pulmonary function tests (PFTs), nailfold capillaroscopy, modified Rodnan Skin Score (mRSS), and Scleroderma Health Assessment Questionnaire Disability Index (sHAQ-DI). DAVIX of the dominant hand was calculated as % mean of the 4 fingers, employing proprietary algorithm by IAG. The distribution was analysed with D'Agostino-Pearson normality test. The median scores were compared by Mann-Whitney-Wilcoxon test; correlation with clinical parameters was performed using Spearman's or Pearson test, as appropriate (Prism 7).

Results: DAVIX correlated with mRSS (r=-0.258, p=0.017), DLCO% (r=0.338, p=0.008) and capillaroscopy pattern (r=-0.388, p=0.001). In patients with DUs, DAVIX showed a stronger correlation with DLCO% (r=0.786, p=0.048). DAVIX predicted the worsening of HAQ-DI (r=-0.295, p=0.029), sHAQ (r =-0.333, p=0.029) and VAS pain (r=-0.269, p=0.038) independently of the presence of DUs. In the context of DU, 7 patients had DUs at baseline (5 with a positive history for DUs). 12 patients developed DUs within 12 months, 3 of them had DUs at baseline. 38 patients did not have either previous or current DUs, neither did they develop new DUs within 12 months. DAVIX of patients with current DUs was lower than DAVIX of patients without DUs (0.18 vs 0.63 p=0.0093). DAVIX of patients with positive history of DUs was lower than in patient with a negative history (median 0.34 vs 0.64, p=0.0052). In patients without current DUs, DAVIX of patients who developed new DUs within 12 months of follow-up was 3-fold lower than in patients who did not develop DUs (0.21 vs 0.65, p=0.0156). ROC curve analysis indicated that DAVIX threshold < 0.49 conferred a 4 times higher risk of developing new DUs (67%) compared to overall risk of our population 17.6%.

Conclusion: The study demonstrates that DAVIX© is a feasible surrogate outcome measure of neointima proliferation in SSc and a useful imaging biomarker of vascular disease activity. Its predictive value of the future onset of DU could be used to stratify patients in clinical trials. The value of DAVIX in predicting the worsening of PROs and clinical parameters in overall patients, may offer insights on the role of vascular disease activity in the overall progression of SSc.

Demographic and clinical characteristics by mucocutaneus involvement

Background/Purpose: Morphea is an autoimmune skin condition that produces skin and soft tissue sclerosis. While clinical manifestations of morphea have been well-described, mucocutaneous findings such as oral and genital lesions have not been well-characterized. Thus, the aim of our study was to determine the demographic and clinical characteristics of morphea patients with mucocutaneous lesions.

Methods: The present study was a cross-sectional study of 735 patients in the Morphea of Adults and Children Cohort (MAC Cohort) from 2007 to 2018. We included participants with sufficient demographic and clinical data for analysis. Patient disease activity and damage were assessed by the Localized Scleroderma Cutaneous Assessment Tool (LoSCAT), including the Localized Scleroderma Activity Index (LoSAI) and Damage Index (LoSDI). Physician Global Assessment of Disease Activity (PGA-A) and Damage (PGA-D) were recorded. Presence of extragenital and genital lichen sclerosus atrophicus (LsA) and oral mucosa changes were determined by physical exam, histology, and/or referral to relevant specialties. Differences between demographic and clinical variables of groups of interest were analyzed by chi-squared tests for dichotomous variables while Kruskall-Wallis and Mann-Whitney U tests were used for continuous variables.

Results: Of 735 morphea patients, linear comprised 49% (n=362) and generalized comprised 32% (n=232) **(Table 1)**. The median age of morphea onset was older in generalized morphea than linear morphea (55 versus 13 years, $p< 0.001$). Oral lesions were present in 2.4% (n=18) of patients overall, of which the majority (94%) had linear morphea. Genital lesions were present in 27 (3.7%) of patients overall, the majority of which (85%) had generalized morphea **(Table 2).** Patients with oral morphea lesions had a younger age of onset than those with genital involvement (11.5 versus 57 years, respectively; $p< 0.001$). Patients with oral involvement were majority female (78%) while genital involvement were all female and majority Caucasian (89%). Genital morphea patients had LsA overlap in 82% (n=22) versus 0% with oral involvement ($p < 0.001$). Deep morphea was seen in 100% patients with oral involvement versus 22% of patients with genital involvement ($p < 0.001$). Median LoSAI and PGA-A scores for patients with oral involvement (0, IQR 0-0 and 0, IQR 0-0, respectively) was lower than patients with genital involvement (6, IQR 0-12 and 13, IQR 0-30, respectively) ($p < 0.001$ and $p< 0.001$, respectively). PGA-D scores were higher in oral morphea (32.5, IQR 25.3-48.8) than in genital morphea (15, IQR 10-30) ($p =0.001$).

Conclusion: Our study demonstrates mucocutaneous involvement in morphea is uncommon but occurs in a substantial number of those with specific morphea subsets. The presence of mucocutaneous lesions is associated with substantial morbidity. Oral morphea lesions predominate in younger patients with overlying facial linear morphea while genital lesions predominate in post-menopausal women with overlying extragenital LsA. Our results underscore the need to look for mucocutaneous findings in morphea, particularly those with the clinical subsets associated with these findings.

The Isolated Nucleolar Pattern ANA Antibody in a Systemic Sclerosis Patient Cohort

Sabrina Elliott[1], Duncan Moore[2] and Virginia Steen[2], [1]MedStar Georgetown Hospital, Alexandria, VA, [2]Division of Rheumatology, Department of Medicine, MedStar Georgetown University Hospital, Washington, DC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) patients with an isolated nucleolar patterned ANA (NUC ANA) make up about 15% of the SSc population, although the specific nucleolar antibody is not easily identified. We sought to characterize patients with an isolated nucleolar pattern ANA without other SSc specific antibodies and describe the clinical and laboratory features associated with this SSc subset.

Methods: A single-center, retrospective study of SSc patients as previously described (Moore, 2019) was used. African American (AA) and non-African American (non-AA) SSc patients were matched 1:1 based on sex, age, date, and disease duration at the first visit, and extent of cutaneous disease. Demographic and clinical features were compared by the presence of the antibody and race. Mortality risks were assessed by a Cox proportional hazards model with covariates of race and the presence of the NUC ANA.

Results: NUC ANA was seen in 81 of the 402 (20%) of the SSc patient, 49 (60%) were AA in the NUC ANA group compared to 48% in the non-NUC ANA group ($p< 0.05$) (Table 1). The NUC ANA patients presented with shorter disease duration at their first visit ($p= 0.000$) and developed more severe upper GI problems ($p=0.041$). They had more cardiac involvement, but not more severe pulmonary fibrosis(Table 2). Comparing AA patients in the NUC ANA group to the non-AA patients, the non-AA patients were more likely to have Raynaud's with digital pitting scars ($p=0.031$) while African Americans were more likely to have pericardial effusions ($p=0.043$). Although survival was not different from NUC ANA compared to non-NUC ANA, more patients with the NUC ANA died of pulmonary hypertension($p= 0.033$) and kidney disease ($p=0.046$)(Table 3).

Table 1. Baseline Characteristics by Race and Antibody*

Characteristic	Antibody Comparison		
	Non-NUC ANA (321)	NUC ANA (81)	P

*Values are reported as number (%) unless indicated otherwise. The actual cohort sizes are 81 isolated nucleolar ANA patients, 321 non-isolated nucleolar ANA antibody patients and within the isoNucANA cohort, there were 49 African Americans (AA) and 32 non-African Americans (non-AA). Not all tests were performed in all patients. Forced Vital Capacity (FVC):74 isolated nucleolar patients (isoNucANA) and 265 non-isoNucANA; diffusing capacity for carbon monoxide (DLco). 74 isoNucANA and 263 non-isoNucANA; Pulmonary Artery Systolic Pressure (PASP) or right ventricular systolic pressure (RVSP). 54 isoNucANA patients, 209 non-IsoNucANA, 30 AA w/ isoNucANA, 24 non-AA w/isoNucANA; Left ejection fraction (LVEF): 61 isoNucANA patients, 235 non-isoNucANA, 35AA isoNucANA, 26 non-AA isoNucANA. GERD= Gastroesophageal reflux disease; CT= computed tomography; RP; Raynaud's Phenomenon; GI= gastrointestinal; PH= pulmonary hypertension; RHC= right heart catheterization; non-IsoNucANA: non-isolated nucleolar ANA Antibody group.

X- statistic could not be calculated because the variable 'no Raynaud's' is a constant between African Americans and non-African Americans in this cohort

** Severe involvement characterized by pericardial effusion, arrhythmias requiring treatment or heart failure requiring treatment

† Statistically significant

Conclusion: Scleroderma specific nucleolar antibodies have not been easily characterized commercially except as an ANA with a nucleolar pattern. This study shows that 20% of our SSc patients had a NUC ANA and that AA had a higher frequency of NUC ANA. However, previous studies have shown more meaningful clinical associations with the specific nucleolar antibodies including anti-U3 RNP, (or fibrillarin), anti-Th/To, and PmScl. This study was not able to

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inhibition of TNFα has emerged as an effective therapeutic approach for many autoimmune/inflammatory diseases.While the efficacy and safety profile of the five FDA-approved TNFis (etanercept, adalimumab,

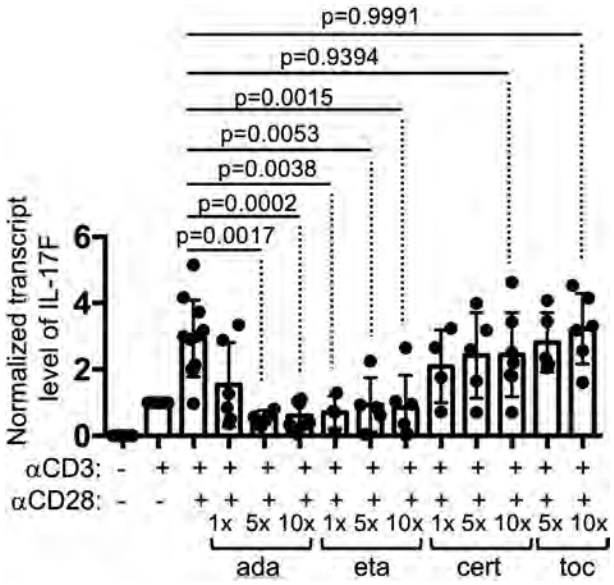

Figure 1. Drug-specific suppression of Th cytokine production by TNFis. PBMC of healthy donors were stimulated with anti-CD3 and/or anti-CD28 for 24 hours in the presence or absence of indicated TNFis at different concentrations (1X = 10 ug/ml for adalimumab, 25 ug/ml for etanercept, 10 ug/ml for certolizumab, and 20 ug/ml for tocilizumab). The transcript levels of IL-17F in the PBMC are shown. Statistical analysis was carried out with one-way ANOVA.

certolizumab, golimumab, and infliximab) are comparable in rheumatoid arthritis (RA), there exist some intriguing differences among them. For example, one RA patient may respond to one TNFi but not the others; etanercept is generally ineffective for inflammatory bowel diseases or uveitis. Post-hoc data have also uncovered several unexpected sided effects of TNFis, such as +ANA, lupus-like diseases, demyelinating diseases, and pustular psoriasis, which probably can be partly attributed to the induction of type 1 interferons. Interestingly, certolizumab may be less likely to induce lupus-like diseases. The mechanisms mediating such discrepancies among TNFis are still poorly understood. The goal of this project is to examine whether TNFis have differential impacts on the expression of Th cytokines.

Methods: PBMC from healthy donors were stimulated with anti-CD3/anti-CD28 for 24 hours in the presence or absence of adalimumab, etanercept, or certolizumab for 24 hours. The expression of Th cytokines in PBMC or subsequently purified Th cells was analyzed with qPCR as well as RNA-seq. Flow cytometry was used to examine the binding of TNFis to membrane TNFα.

Results: Adalimumab and etanercept, but not certolizumab, inhibited the expression of IL-17A/F and IL-2 in Th cells within anti-CD3-stimulated PBMC (Figure 1). This discordant effect between adalimumab and certolizumab was not due to neutralization of soluble TNFα or their differential binding to membrane TNFα. Instead, the unique effect of adalimumab required cell-cell contacts between Th cells and non-Th cells and was not recapitulated by cross-linking of the Fc of adalimumab. RNA-seq analyses further revealed that adalimumab also suppressed the expression of other effector Th cytokines, including IFNγ, IL-21, and IL-9, but reciprocally induced strong type 1 interferon signals and the expression of co-inhibitory molecules CD96 and PVRIG in Th cells.

Conclusion: Adalimumab, but not certolizumab, inhibits the expression of Th cytokines independently of neutralizing soluble TNFα. This phenomenon is very likely mediated by type 1 interferon signals and CD96/PVRIG co-inhibition. Elucidating the mechanism mediating the unique effect of adalimumab very likely will uncover novel mechanisms of action of TNFis and improve their efficacy and safety.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is a systemic autoimmune/inflammatory condition that primarily affects the skin, but also other organ systems. Effector $CD4^+$ T lymphocytes have been identified as a key contributor to inflammation and tissue damage, but underlying molecular mechanisms remain poorly understood.

The transcription factor CREMα plays a role in effector CD4+ T cell differentiation and activation in autoimmune/inflammatory conditions through altering cytokine gene expression, favoring effector T cells. The inhibitory surface co-receptor programmed death (PD-)1 plays a key role in controlling effector T cell generation and activation. This study investigated the involvement of CREMα in the regulation of PD-1 and effector T cell generation in psoriasis and psoriatic arthritis.

Methods: CD4+ T cells were isolated from peripheral blood of controls (N=13), psoriasis (N=13) and psoriatic arthritis patients (N=9) to examine effector cytokine expression (LUMINEX mRNA probe and MSD protein assays), and monitor CD4+ T cell subset distribution (flow cytometry) and co-inhibitory PD-1 mRNA and surface protein expression (flow cytometry, mRNA probes, qPCR). Using chromatin immunoprecipitation assays and luciferase reported assays, we investigated recruitment and *trans*-regulatory effects of CREMα on the *PDCD1* promoter in wild-type and genetically modified CD4+ Jurkat T cells (CREMα overexpressing and CREMα-deficient cells).

Results: CD4+ T cells from psoriasis and psoriatic arthritis patients exhibit effector CD4+ T cell phenotypes with increased IL-17, and reduced IL-2 and inhibitory PD-1 co-receptor (mRNA and protein) expression. In effector CD4+ T cells, expression of the transcription factor CREMα is increased. Recruitment of CREMα to the *PDCD1* proximal promoter results in its *trans*-repression and subsequently reduced PD-1 mRNA and protein expression. Expression of PD-1 associates with IL-2 expression and inversely correlates with IL-17A expression in wild-type and CREMα overexpressing Jurkat CD4+ T cells.

Conclusion: CREMα promotes effector CD4+ T cells in psoriasis and psoriatic arthritis through inhibition of PD-1 co-receptor expression. This contributes to imbalanced IL-2 and IL-17 expression in psoriasis and psoriatic arthritis and potentially may extend to other effector T cell mediated autoimmune/inflammatory conditions. This suggests CREMα:PD-1 axis is a promising target in the search for disease biomarkers and treatment targets.

Disease Mutation That Weakens ZAP70 Autoinhibition Enhances Responses to Weak and Self Ligands

Lin Shen[1], Mehrdad Matloubian[1], Theresa Kadlecek[2] and Arthur Weiss[1], [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ZAP70, a cytoplasmic protein tyrosine kinase, is critical for TCR signaling and T cell development. Complete loss of function of ZAP70 in humans causes severe immunodeficiency. Autoimmune disease due to mutant *ZAP70* alleles in humans has not been reported until recently. Our previous study has shown that compound heterozygous mutations R192W/R360P in *ZAP70* are responsible for a new familial autoimmune syndrome manifested by bullous pemphigoid, colitis, proteinuria and autoantibody to factor VIII in early life. Cell line data showed that the R192W allele leads to reduced binding of mutant ZAP70 to the phosphorylated TCR zeta-chain, thus functions as a null-allele. In contrast, the R360P allele in the catalytic domain causes weak constitutive activation of the TCR pathway that is suppressed by the wild type (WT) but not the R192W allele. Therefore, the R360P allele is likely responsible for the disease, but the mechanism remains unclear. We hypothesize that the R360P allele interferes with ZAP70 autoinhibition, results in an increase in T cell antigen sensitivity, enhanced follicular helper T (Tfh) cell differentiation, and excessive auto-reactive T helper cell activity for B cells, thereby leading to a primarily autoantibody mediated disease.

Methods: Using *Zap70* R360P knock-in mice we generated and biochemical and functional assays, we assessed how the R360P mutation affects lymphocyte development, TCR signaling, and Tfh cell differentiation following LCMV infection.

Results: The structural location and biochemical signaling effects of the R360P mutation were consistent with weakening of the autoinhibitory conformation of ZAP70. Mice with a ZAP70 R360P mutation and polyclonal TCR repertoires exhibited relatively normal T cell development but showed evidence of increased signaling, as evidenced in the increase in ZAP70 Y319 phosphorylation and faster calcium mobilization following TCR stimulation. Additionally, the R360P mutation resulted in enhanced follicular helper T cell expansion following LCMV infection. When R360P or WT $CD8^+$-OTI T cells were stimulated by antigen presenting cells preloaded with peptides of different agonist potency, we observed marked augmentation of CD69 induction in R360P cells relative to that of WT cells in the responses to weak (Q4H7, G4) agonists, contrasting with only slight to no enhancement in the responses to strong (OVA, Q4R7) agonists. There was also enhanced proliferation of R360P $CD8^+$-OTI T cell than WT controls in response to weak and self peptides.

Conclusion: Our findings suggest that the R360P mutation is a weak hypermorphic allele of ZAP70, resulting in enhanced TCR signaling through disruption of ZAP70 autoinhibition, and enhanced Tfh cell expansion. The R360P

mutation may allow increased mature T cell sensitivity to weak and self-antigens that would normally be ignored by WT T cells, a mechanism that may contribute to the break of tolerance in human patients with R360P mutation.

Galectin-3 Decreases the Activity of 4-1BB by Facilitating Its Decoy Surface Binding in Rheumatoid Arthritis

Morten Aagaard Nielsen[1], Kristian Juul-Madsen[2], John Stegmayr[3], Chao Gao[4], Tue Wenzel Kragstrup[1], Malene Hvid[1], Thomas Vorup-Jensen[1], Richard Cummings[5], Hakon Leffler[3] and Bent Deleuran[1], [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University, Aarhus, Midtjylland, Denmark, [3]Lund University, Lund, Sweden, [4]Beth Israel Deaconess Medical Center Harvard Medical School, Boston, MA, [5]Beth Israel Deaconess Medical Center Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Orchestration of immune checkpoints is central for the outcome of immune activation, especially in patients with rheumatoid arthritis (RA). We have previously shown that galectin-9 (Gal-9) binding to 4-1BB is central for the increased cytokine production in RA[1]. Here we extend these studies, showing that Gal-3 has the opposite effect, leading to decreased 4-1BBL signaling in RA.

We hereby aim to investigate the modulatory potential of Gal-3 on 4-1BB in RA.

Methods: Gal-3 and 4-1BB were measured in plasma, synovial fluid and synovial tissue samples from RA patients (n=8). Fluorescence polarization and surface plasmon resonance (SPR) analyses were used to evaluate the binding between 4-1BB, 4-1BBL and Gal-3. Synovial fluid mononuclear cells (SFMCs) from patients with RA were cultured for 24 hours and co-incubated with either 4-1BB, 4-1BBL, Gal-3, or combinations thereof. Nanoparticle Tracking Analysis (NTA) was used to detect Gal-3 and 4-1BB complexes in healthy control (HC) plasma (n=10), RA plasma, and synovial fluid samples (n=10). Flow cytometry and Imagestream analyses were performed to detect complex-depletion to the cell membrane and evaluate the functional implications of complex-depletion. Glycan dependence was shown by addition of a Gal-3-specific inhibitor, lactose, or using PNGase F pretreatment of the cells.

Results: In RA, Gal-3 and 4-1BB levels in synovial fluid were increased by a factor 4 and 12 compared with paired plasma ($p< 0.05$), ($p< 0.01$) respectively. Cells expressing 4-1BB also co-expressed Gal-3 in the inflamed RA synovial tissue. Gal-3 was capable of binding to both soluble and membrane bound 4-1BB with a K_D=1.79 m M, without interfering with the binding of 4-1BBL. In plasma, Gal-3 was detected as part of complexes > 300 nm in size. Activated 4-1BB$^+$ T cells and 4-1BB transfected HEK293 cells were both capable of depleting these complexes from plasma ($p< 0.01$) . After cell mediated depletion, expression levels of Gal-3 and 4-1BB complexes were increased on the cell surface compared with untreated cells ($p< 0.05$). T he increase in 4-1BB expression was accompanied by a 4-fold decreased in TNFa production ($p< 0.01$). Gal-3^{high}4-1BB^{high} T cells, were now found to be less responsive to 4-1BBL stimulation. In RA patients, complexes containing Gal-3 were dramatically reduced in both plasma and synovial fluid ($p< 0.01$). The level of Gal-3 complexes in RA plasma correlated inversely with disease activity (DAS28crp). Pro-

duction of MCP-1 in SFMC cultures stimulated with Gal-3, followed by 4-1BBL, decreased by 50% compared with untreated cultures or cultures stimulated with either 4-1BBL or Gal-3 alone ($p < 0.05$).

Conclusion: Gal-3 is a carbohydrate-dependent 4-1BB binding protein, which does not block the co-binding of 4-1BBL. In plasma and synovial fluid, Gal-3 binds to s4-1BB and forms complexes which again can bind to T cells, followed by a decreased cytokine production. These observations provide evidence that galectins control the effects of 4-1BB signaling in RA by decoy binding, highlighting the interplay between galectins and an important checkpoint molecule in RA.

Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: CXCR5+PD-1^{hi} follicular helper (Tfh) and CXCR5-PD-1^{hi} peripheral helper (Tph) T cells play an important role in the pathogenesis of Rheumatoid Arthritis (RA) by providing help to autoantibody secreting B cells. Whereas Tfh cells typically dwell in the germinal centers of lymphoid organs, Tph cells accumulate at inflamed tissues. An increased frequency of Tph cells and of circulating counterparts of Tfh cells have been described in the peripheral blood of patients with seropositive RA. Our objective was to examine the effect of treatment escalation using biological agents (TNF blockers or abatacept), on the frequency of circulating Tfh (cTfh) and Tph (cTph) cells in RA.

Methods: Peripheral blood was drawn from seropositive RA patients with an incomplete response to csDMARDS (n=29) who initiated biological therapy with TNF blockers (TNFb) (n= 17) or abatacept (n= 12), prescribed based on routine clinical practice. cTfh and cTph cell frequencies were determined by flow cytometry of freshly isolated PBMCs at the basal visit and 6 months after starting treatment escalation. For each patient, an age and gender-matched healthy control (HC) was also studied at both time points (n=29).

Results: As compared with HC, active RA patients receiving csDMARDs demonstrated a baseline increased frequency of both cTfh and cTph cells. A significant improvement of disease activity as determined by the DAS28 score

(ΔDAS28 >2.0) was apparent in all of the patients 6 months after initiating biologicals. At that time point, a significant reduction of the previously elevated cTph cell frequency was observed in both treatment groups. However, cTfh cells remained elevated in patients receiving TNFb notwithstanding a good therapeutic response, whereas subjects receiving abatacept experienced a significant abatement of their cTfh cell frequency. Experimental variation of the cTfh and cTph cell numbers in HC was minimal.

Conclusion: Abatacept but not TNFb, are able to bring down cTfh cell numbers in RA. This indicates that costimulation blockade can help attain an immunological remission, whereas TNF neutralization may allow a persistent pathogenic germinal center overactivity. At the same time, treatment with both abatacept and TNF blockers results in a downmodulation of the previouly elevated cTph cell numbers, in parallel with the remitting local joint inflammation.

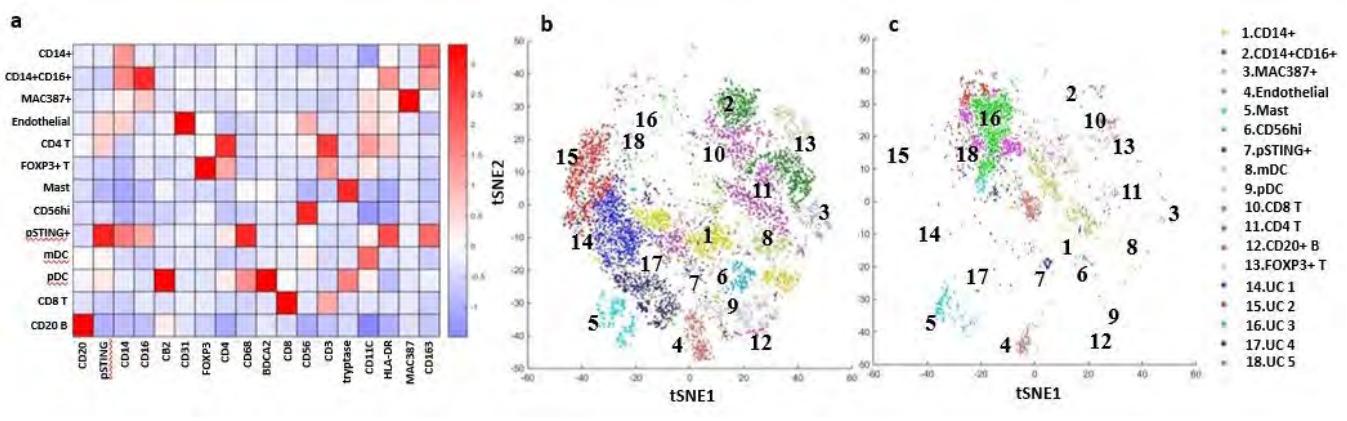
SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

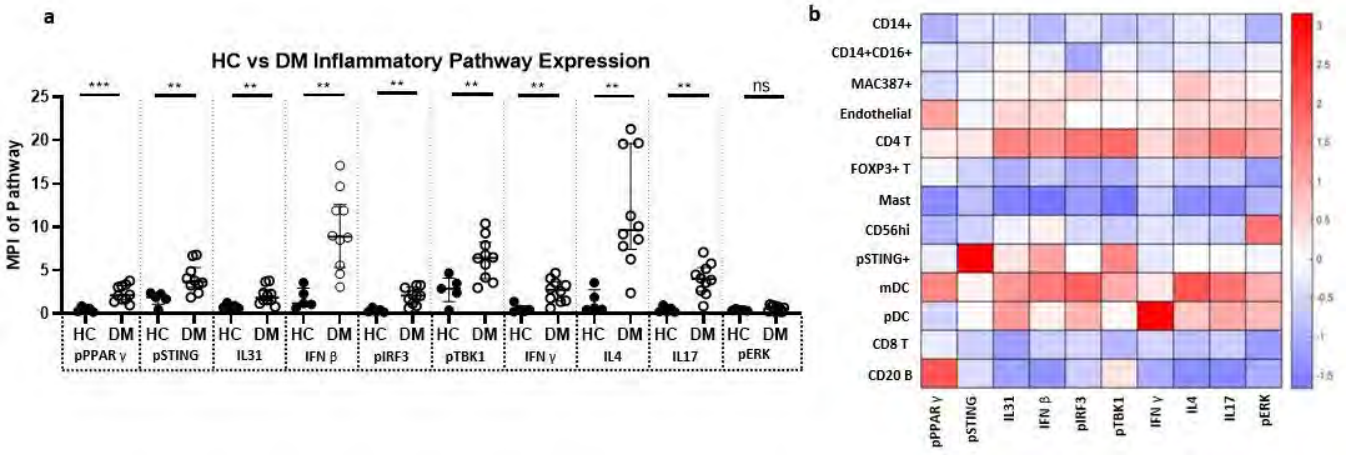
Background/Purpose: Dermatomyositis (DM) is a systemic autoimmune disease affecting the skin and muscles, among other organs. The inflammatory infiltrate in skin has not been fully characterized, but the type I interferon (IFN) system is thought to be a major contributor to disease and has the capacity to interact with multiple cell types. Previous studies have used single or double staining to characterize the complex inflammatory infiltrate, but we implemented image mass cytometry (IMC) and took an unbiased approach to identify possible cellular sources of the type I IFNs and other cytokines.

Methods: We evaluated skin biopsies from 10 patients with moderate-severe DM and 5 healthy controls (HC). IMC was implemented to identify the infiltrate at a single cell level using a diverse set of 37 metal conjugated antibodies. Biopsies were stained with a cocktail of the 37 markers and regions of 1mm x 2mm ablated using the Hyperion Imaging System. Cell were segmented using a nuclear app-based algorithm in Visiopharm. Per cell mean pixel intensity (MPI) analysis was performed using histoCAT. The Phenograph algorithm was used to cluster cells based on expression of cell type markers. Further gating for rare populations was performed using FlowJo and image based sliding scale gates. Statistical analysis included the Mann-Whitney and Spearman rank correlation tests.

Results: We identified CD14+, CD14+CD16+, MAC387+, Endothelial, CD4 T, FOXP3+ T, Mast cells, CD56+, myeloid dendritic (mDC), plasmacytoid dendritic (pDC), CD8+ T, pSTING+, and CD20+ B cells (Fig 1). Monocyte-macrophage diversity was observed with increased numbers of CD14+, CD14+CD16+, MAC387+, and pSTING+ macrophages in lesional DM skin ($p < 0.05$), with the CD14+ population correlating positively with the cutaneous dermatomyositis dis-

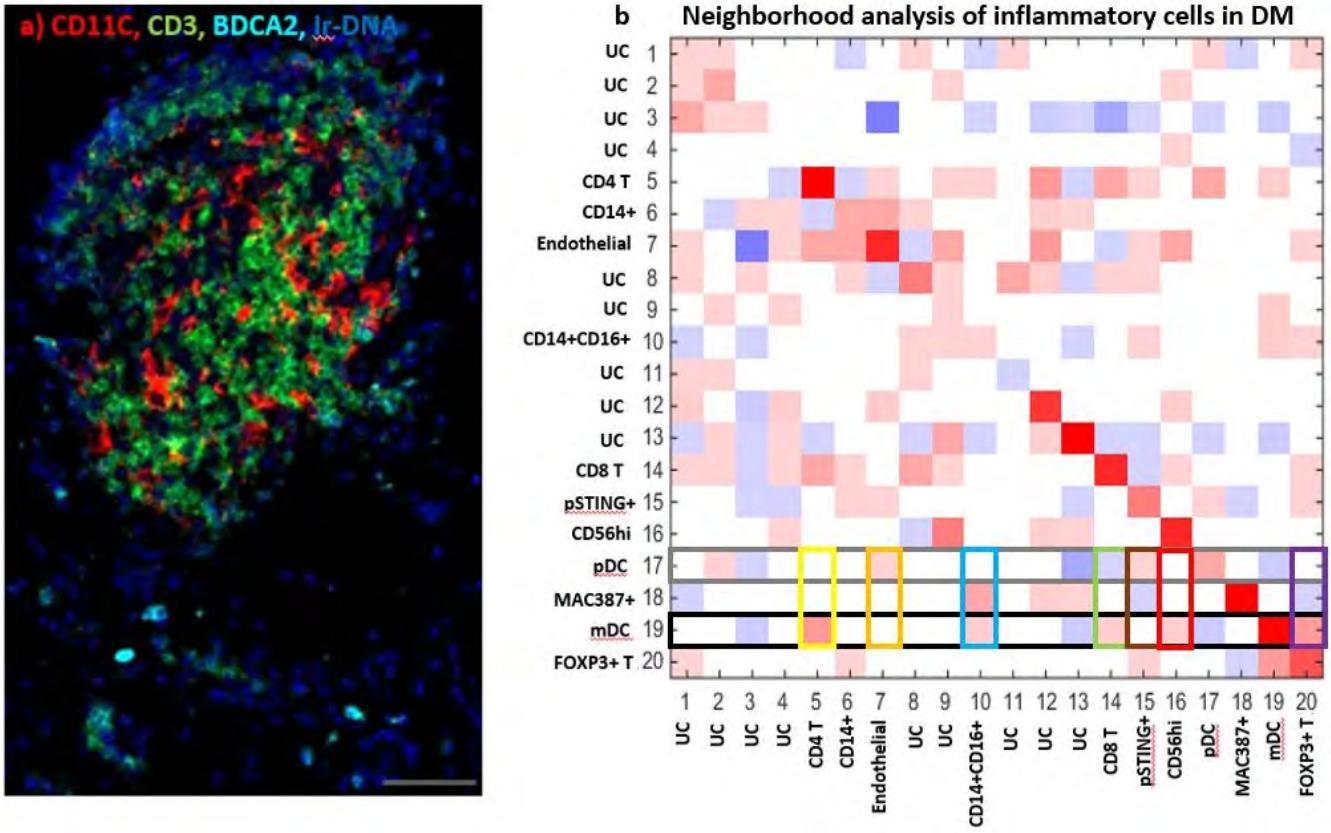


Immune Cells in Dermatomyositis Skin Lesions a) Heatmap of Different Cell Type Markers expressed the 13 cell populations identified: Monocytes (CD14+CD16-), mo-MAC (CD14+CD16+), Macrophages (MAC387+), Endothelial Cells (CD31+), CD4 T Cells (CD4+CD3+), Tregs (FOXP3+CD4+CD3+), Mast Cells (tryptase++), CD56+ Cells, pSTING+ mo-MAC (pSTING++,CD14+CD16+), mDC (CD11C+HLADR+), pDC (BDCA2+), CD8 T (CD8+CD3+), and CD20 B (CD20+). b) tSNE dimensional reduction plot of the different cell clusters identified in lesional DM skin c) tSNE dimensional reduction plot of the corresponding cell clusters in HC skin. Clusters 14-18 represent unidentified clusters (UC)



Inflammatory Pathway expression in Dermatomyositis Skin Lesions a) Expression of pPPARγ, pSTING, IL31, IFNβ, pIRF3, pTBK1, IFNγ, IL4, IL17 is increased in DM skin compared to HC skin. There is no significant difference between DM and HC skin pERK expression. b) Heatmap displaying the relative mean expression of each inflammatory pathway in each cell cluster * p<0.05, ** p<0.01, *** p<0.001

ease area and severity index (CDASI) (r=0.697, p=0.031). The T cell compartment revealed CD4, CD8, and FOXP3+ T cells with activated CD69+ circulating memory T cells correlating with CDASI scores (r=0.754, p=0.0151). Inflammatory pathways pPPARγ, pSTING, IL31, IFNβ, pIRF3, pTBK1, IFNγ, IL4, and IL17 were all upregulated compared to HC (p< 0.05, Fig 2); pERK did not differ. IFNβ protein is upregulated in T cell, macrophage, dendritic, and endothelial cell populations of DM skin (p< 0.05) with mDC IFNβ trending highest. IL4+ and IL31+ mDCs were found to correlate with a Skindex itch score (IL4+: r=0.6547, p=0.0448; IL31+: r=0.7310, p=0.0194). pDCs colocalize with IFNγ in addition to the known IFNβ. The endothelium, mDCs, and B cells in DM skin express pPPARγ. Neighborhood analysis reveals significant interactions between mDCs and CD4, CD8, FOXP3+ T cells while pDCs interact with pSTING+ macrophages (p< 0.05, Fig 3).



Neighborhood Analysis of Dermatomyositis skin infiltrate allowed for the visualization of different immune cells in DM skin and their spatial relationship to each other. CD11C+ mDCs (red, a) are seen to be intertwined with CD3+ T cells (green, a) whereas BDCA2+ pDCs are scattered throughout the tissue (cyan, a). Neighborhood analysis of n=7 DM lesional skin biopsies using histoCAT (b) reveals cell to cell interactions displayed as a heatmap with red representing a positive (neighbored) association ($p<0.05$), white as an insignificant association ($p>0.05$), and blue as a negative (avoided) association ($p<0.05$). Rows signify cells surrounding a cell type of interest. Columns signify the cell type of interest surrounding other cell types. The heatmap shows mDCs (black bar) may interact with CD4 T(yellow bar), CD14+CD16+ macrophages (cyan bar), CD8 T (green bar), CD56(NCAM) hi cells (red bar), and FOXP3+ T (purple bar) while pDCS (gray bar) may interact more with the endothelial cells (orange bar) and pSTING+ cells (brown bar). Scale bar (a) = 60 μm (gray).

Conclusion: The immune infiltrate in DM is complex and consists of a dominant monocyte-macrophage-myeloid cell axis that may contribute to IFNβ related pathogenesis and IL4, IL31 related pruritus. Findings of interest are CD14+ monocytes, pSTING+ macrophages, IFNγ+ pDCs, and pPPARγ+ endothelial cells and active mDCs, which requires further investigation. The use of IMC allows for single cell characterization of the immune cell population seen in DM skin and possible novel targeted therapeutics.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session C

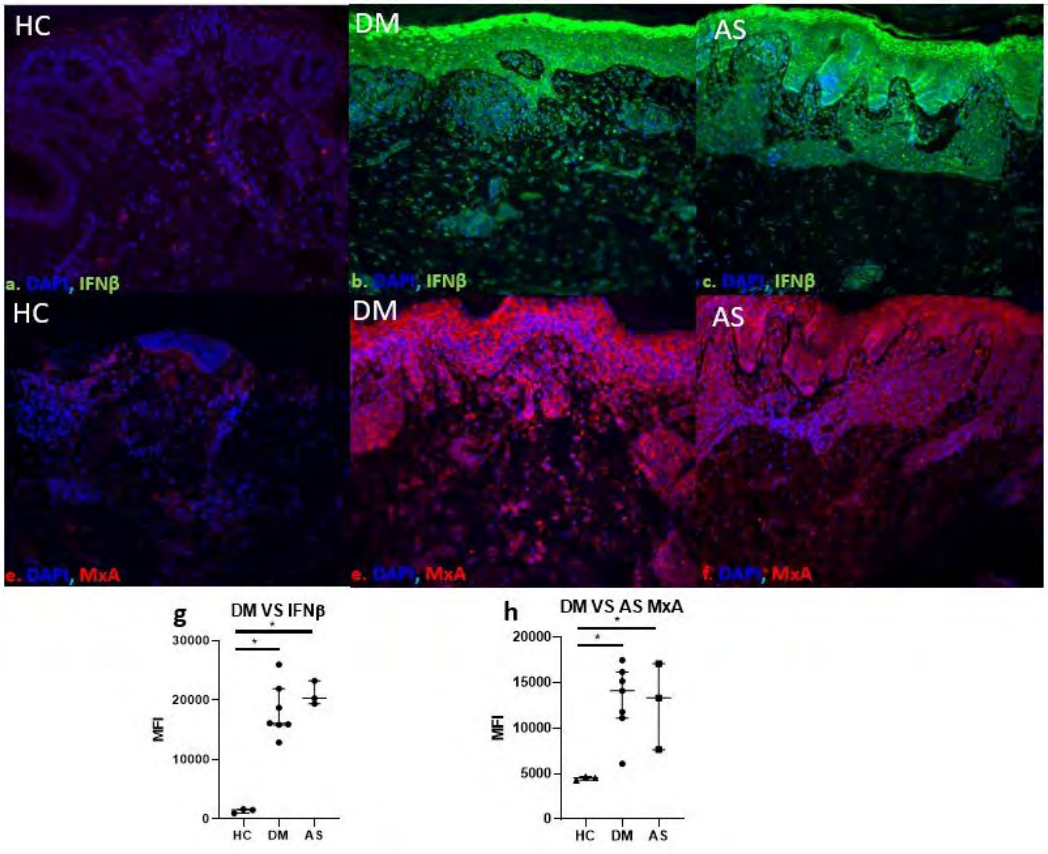
Session Time: 9:00AM–11:00AM

Background/Purpose: Antisynthetase syndrome (AS) is a systemic autoimmune disorder characterized by the presence of anti-aminoacyl-tRNA synthetase antibodies, myositis, interstitial lung disease (ILD), mechanics hands, and raynaud's phenomenon. Dermatomyositis (DM) is a similar autoimmune disorder with clinical features of muscle weakness, ILD, neoplasms, gottron's papules, and photosensitive cutaneous manifestations. Currently most clinicians see AS as a subclassification under DM due to the many similarities. Recently some studies have emerged identifying differences in the type I interferon system between AS and DM muscle and finger eruptions. Type I interferons are amplified in autoimmune diseases such as DM, as demonstrated by proteins such as MxA expression. To further characterize these differences, we investigated the cellular composition and inflammatory pathway profile using immunofluorescent staining (IF) and image mass cytometry (IMC).

Methods: We evaluated skin biopsies from back, arm, or leg of 7 DM patients, 3 AS patients, and 3 healthy control (HC). IF was performed on 3 biopsies from each group for IFNβ and MxA. Subsequently, IMC was implemented to further identify differences between DM and AS using metal conjugated antibodies. Biopsies were stained with a cocktail of markers and 1mm x 2mm regions were ablated using the Hyperion Imaging System. Cells were segmented using a nuclear app-based algorithm in Visiopharm. Per cell mean pixel intensity (MPI) analysis was performed using histoCAT. The Phenograph algorithm was used to cluster cells based on expression of cell type markers. The Kruskal Wallis test was used to identify immunofluorescence IFNβ and MxA differences between HC, DM, and AS groups corrected for multiple comparisons by controlling False Discovery Rate. The Mann Whitney test was used to identify differences in IMC cell populations and pathway expression between AS and DM skin lesions, including mDC IFNβ.

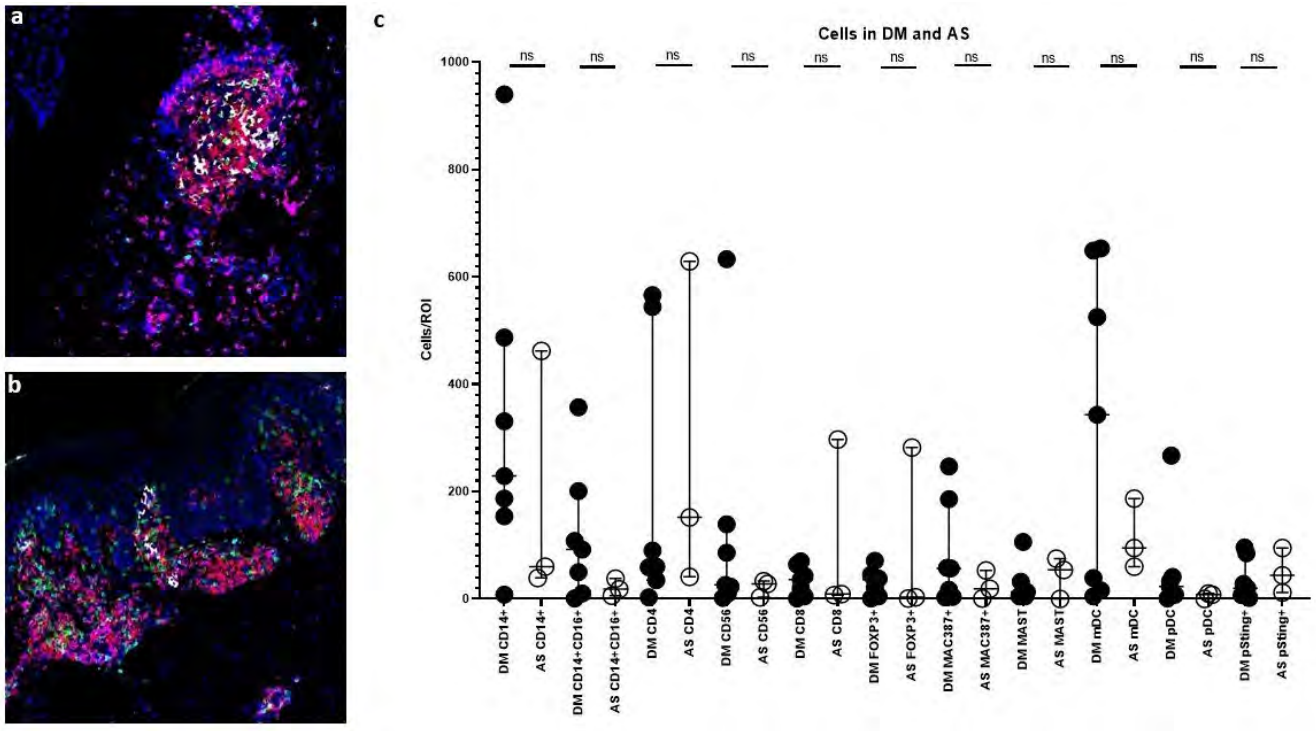
Results: IF of AS skin showed increased IFNβ and MxA compared to HC ($p < 0.05$, Fig 1) but there was no difference compared to DM IFNβ and MxA ($p > 0.05$, Fig 1). IMC cell clusters in AS and DM were similarly distributed and we identified no differences in the cell populations (macrophages, T cells, and dendritic cells) of AS and DM ($p > 0.05$, Fig 2). Despite no statistical differences in cells there is a trend for increased CD14+CD16+, mDCs, and pDCs in DM. Pathway expressions of pPPARγ, pSTING, IL31, IFNβ, MxA, pTBK1, IFNγ, and pERK also did not differ between AS and DM ($p > 0.05$, Fig 3). The pIRF3, IL4, and IL17 pathways were increased in DM compared to AS skin lesion ($p=0.04$, 0.01, and 0.01, Fig 3). Both AS and DM mDCs produced IFNβ (Fig3), but there was no difference in mDC IFNβ between AS and DM ($p > 0.05$, Fig 3).

Conclusion: A similar immune composition exists in AS and DM skin and there is a role for the type I interferon system in AS, however there may be differences in the extent of involvement due to decreased pIRF3,trends for decreased MxA, and dendritic cells. Additional differences in cytokines IL4 and IL17 exist with increased expression

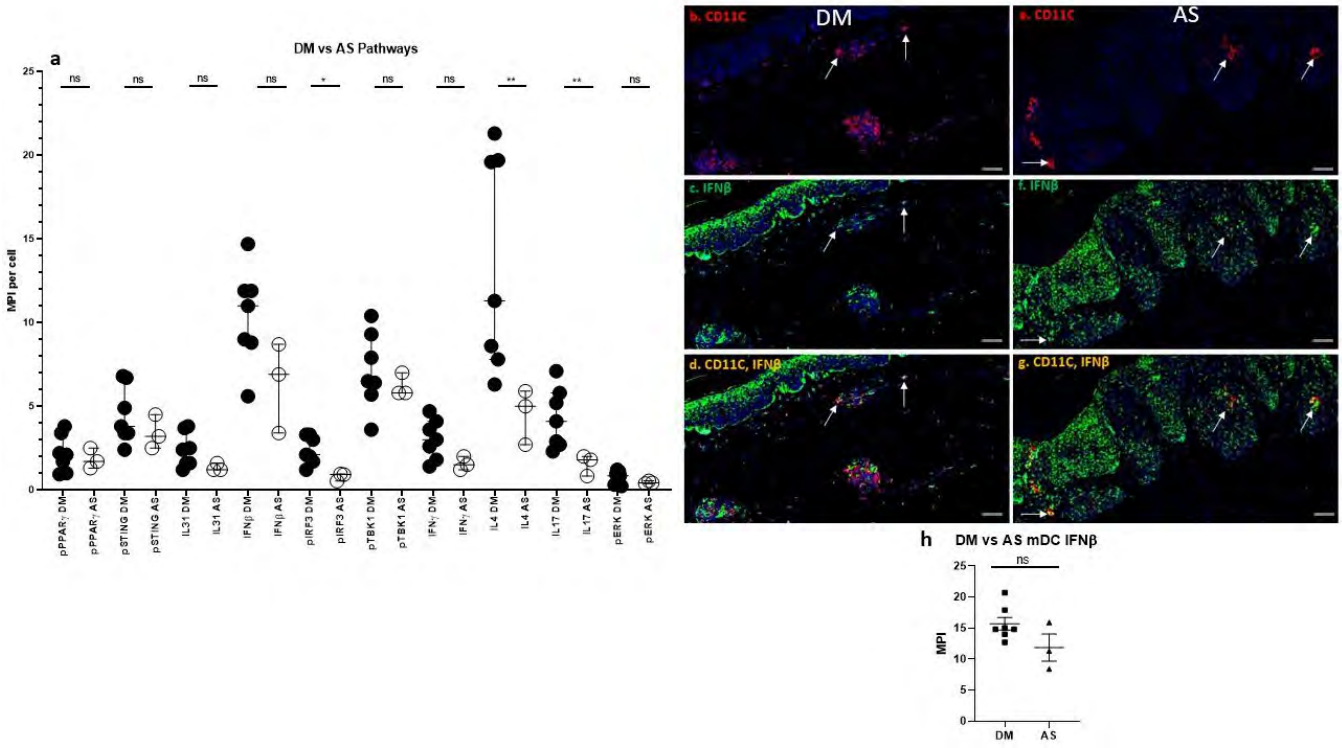


Immunofluorescence staining of IFNβ and MxA in HC, DM, and ASA skin a-c) HC skin has little IFNβ (green, a) compared to DM skin (b) and ASA skin (c). e-f) HC skin also has decreased MxA (red, d) compared to DM skin (e) and ASA skin (f) with DAPI in blue (a-f). Quantification of mean fluorescence intensity shows increased IFNβ in DM and ASA lesional skin compared to HC (g) and increased MxA expression in DM and ASA lesional skin compared to HC (h). Nuclei represented by DAPI (blue, a-f) * $p<0.05$

in DM. However, the two diseases overlap significantly supporting their current classification, but larger studies are still needed to clarify differences.



Immune Cell quantification between HC, DM, and AS patients using Image Mass Cytometry PhenoGraph populations. a-b) Multiplexed image of lesional DM(a) and AS(b) skin revealing similar cells CD4 (red), CD8(green), DNA (blue), CD11C+ (white), BDCA1+ (cyan), and CD14+ (magenta) cells. c) The cell counts of CD14+, CD14+CD16+, MAC387+, CD4+, FOXP3+, Mast, CD56+, pSTING+CD14+CD16+, mDC, pDC, and CD8 were compared between DM and AS skin lesions. No significant differences were found between DM and AS for all cell populations.



Mean Pathway Expression in skin lesions of DM and ASA patients a) The mean expression per cell of pathways pPPARγ, pSTING, IL31, IFNβ, pRF3, pTBK1, IFNγ, IL4, IL17, and pERK was compared between AS and DM skin lesions. No significant differences between DM and AS were observed for pPPARγ, pSTING, IL31, IFNβ, pTBK1, IFNγ, and pERK. DM skin had increased expression of pIRF3, IL4, and IL17. b-g) DM and AS mDCs express IFNβ. CD11C mDCs (red, b,e) overlap with IFNβ (green, c,f) as seen in yellow (d,g). Individual mDCs overlapping with IFNβ are highlighted with white arrows. Nuclei represented with Ir-Intercalator (blue, b-g). Scale bars (gray) = 50μm h) DM and AS mDCs do not differ in mean IFNβ expression at a single cell level. * p<0.05, ** p<0.01,

LAG-3$^+$ T Cells Are Diminished in Active Psoriatic Arthritis Patients and Their Restoration in Vitro Is Mediated by TNF Inhibitors

Smadar Gertel[1], Ari Polachek[2], Victoria Furer[3], David Levartovsky[3] and Ori Elkayam[4], [1]Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel, [2]Tel Aviv Sourasky Medical Center, Petah-Tikva, Israel, [3]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [4]Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis. Aberrant T cell regulation has been implicated in the process of inflammation in PsA. One of the regulatory receptors expressed on T cells is lymphocyte-activation gene (LAG)-3. We aimed to assess the surface expression levels of LAG-3 on CD4$^+$ T cells derived from PsA patients with low and high disease activity in comparison with healthy controls and to determine the in vitro effect of biologics on the LAG-3$^+$ T cell population.

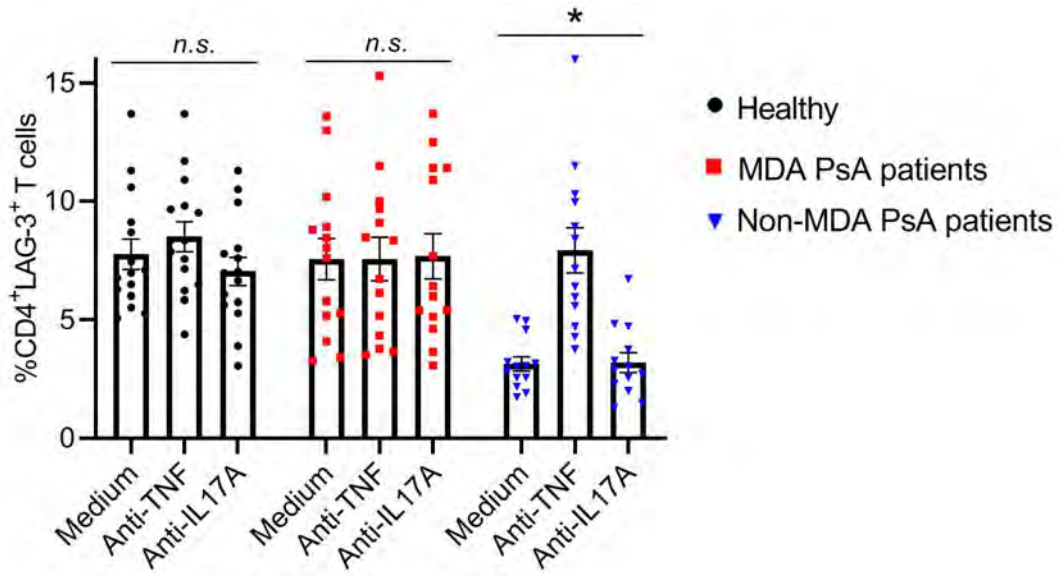

Figure 1. Levels of CD4+LAG-3+ T cells in PBMCs derived from healthy, MDA and non-MDA PsA patients and the ability of TNF and IL-17 inhibitors to modulate the CD4+LAG-3+ T cells in vitro. Freshly isolated PBMCs from healthy donors (n=15), MDA (n=14) and non-MDA (n=13) PsA patients were co-cultured for 5 days in RPMI medium alone or supplemented with TNF inhibitor (Adalimumab) or IL-17A inhibitor (Ixekizumab). Cells were subsequently stained with CD4 and LAG-3 Abs. Surface CD4 and LAG-3 expression was determined by flow cytometry. Graphs represent the mean percentages ±SEM of CD4+LAG-3+ T cells. Significance between groups was determined by Mann-Whitney U test, * $p < 0.0001$.

Methods: Consecutive patients with PsA were recruited to this study, clinically assessed and classified as having minimal disease activity (MDA) or non-MDA. healthy donors were included as controls. Peripheral blood mononuclear cells (PBMCs) were co-cultured with medium alone or with TNF or IL-17A inhibitors and their effect on $CD4^+LAG\text{-}3^+$ T cells proportion was determined.

Results: The basal levels of $CD4^+LAG\text{-}3^+$ T cells in fresh PBMCs was undetectable, we then used in vitro conditions to detect $CD4^+LAG\text{-}3^+$ T cells. In PBMCs derived from healthy controls (n=15) as well as from MDA PsA patients (n=14) the percentages of $CD4^+LAG\text{-}3^+$ T cells after 5 days of in vitro incubation with medium alone was (7.7±0.6 and 7.5±0.9, respectively). Supplementation of either TNF or IL-17A inhibitors to the culture had no effect on the percentages of $CD4^+LAG\text{-}3^+$ T cells (8.5±0.6, 7.0±0.6 and 7.6±0.9, 7.7±0.9, respectively) (Figure 1).

In contrast, significantly lower percentages of $CD4^+LAG\text{-}3^+$ T cells were found in non-MDA (n=13) (3.1±03, $p< 0.0001$) as compared to MDA PsA patients and healthy controls (7.7±0.6 and 7.5±0.9). In non-MDA PsA patients, incubation with TNF inhibitor restored the percentages of $CD4^+LAG\text{-}3^+$ T cells compared to medium control (7.9±0.9, $p< 0.0001$), to an equivalent levels as determined after incubation with medium alone in healthy and MDA PsA patients. On the other hand, after supplementation of IL-17A inhibitor the $CD4^+LAG\text{-}3^+$ T cells proportion remain low (3.2±0.4).

Moreover, there was a significant inverse correlation between percentages of $CD4^+LAG\text{-}3^+$ T cells after in vitro culture with medium alone and the clinical disease activity of the PsA patients in the cohort (CPDAI, r=-0.47, $p < 0.02$ and PASDAS, r=-0.51, $p < 0.008$).

Conclusion: Lower surface LAG-3 expression levels on $CD4^+$ T cells may reflect active PsA disease state. TNF inhibitors have potency to up-regulate this population. Larger studies are needed to verify this observation.

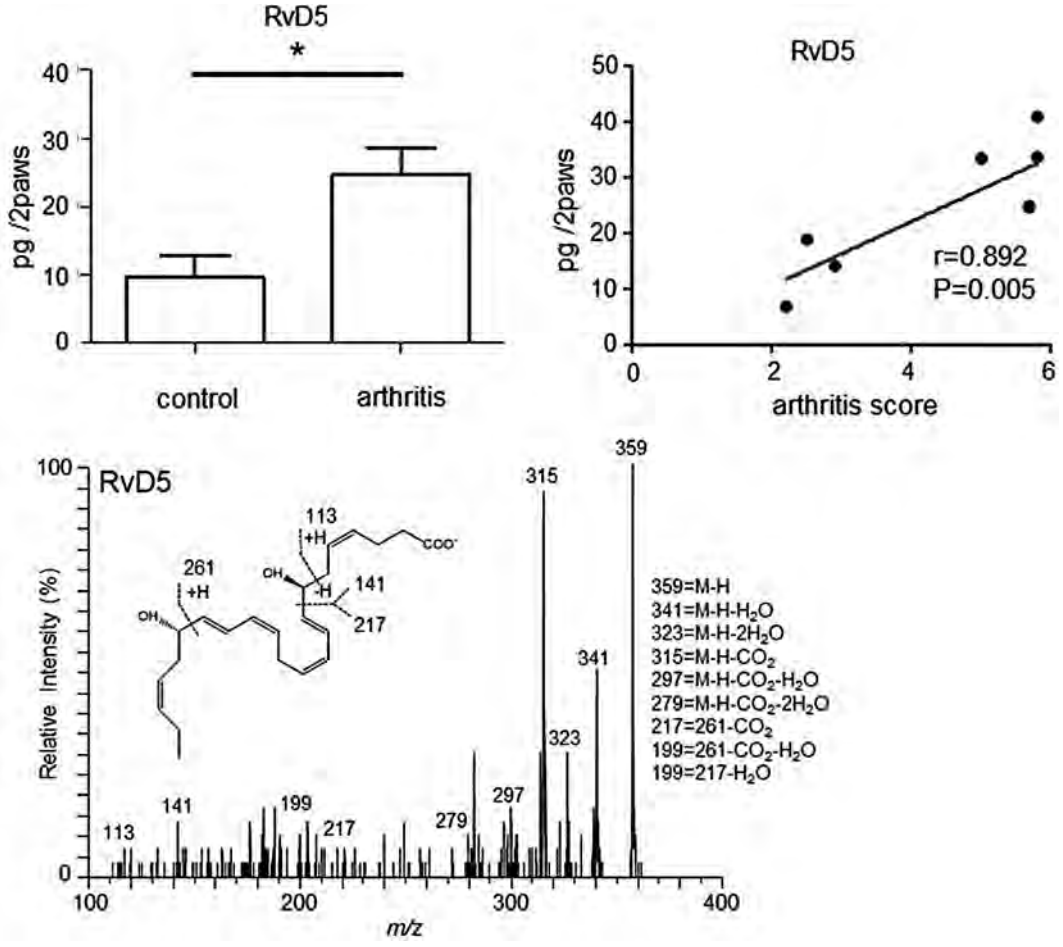
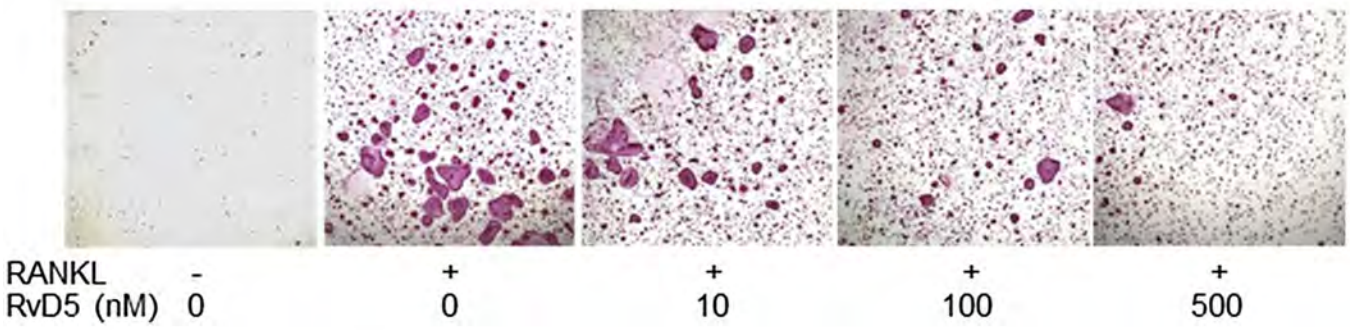
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

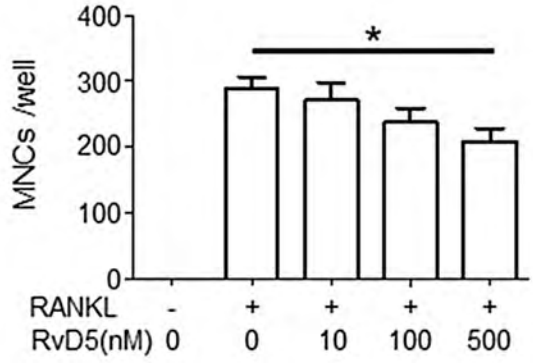
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Over the last two decades, it has become increasingly clear that resolution of acute inflammation is not a passive process, but requires active modulation. This is tightly regulated by families of novel potent bioactive lipid mediators (LM), which have been termed “specialized pro-resolving mediators” (SPMs), but little is known concerning their role in chronic inflammation, such as in rheumatoid arthritis (RA). This study was conducted to investigate whether LM are involved in the pathogenesis of RA.







Methods: We performed LM profiling on inflamed arthritic paws in a mouse model of RA by using lipid chromatography (LC) /mass spectrometry (MS) /MS-based LM metabololipidomics. $CD4^+$ T cells from splenocytes of SKG mice were cultured on anti-CD3/ CD28 mAbs precoated plate with IL-6/TGF-β, anti-IFNγ/IL-4 and SPMs were added daily from day 0. On day 3, cells were analyzed by flow cytometry. $CD4^+$ T cells were incubated with CFSE and RvD5 was added daily. On day 3, cell proliferation was analyzed by flow cytometry. Mouse bone marrow cells were cultured with M-CSF and RANKL and RvD5 was added daily. Tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells were defined as osteoclasts and counted under a microscope. Osteoclast differentiation markers were analyzed by quantitative RT-PCR.

Results: We found that RvE3, RvD1, RvD3, RvD5 and Maresin2 were significantly elevated in the arthritic paws. Of the elevated SPMs, levels of RvD5 correlated significantly with arthritis disease activity (Figure 1). We also found that RvD5 inhibited the differentiation of $Ror\gamma t^+$ Th17 cells and increased the population of $Foxp3^+$ regulatory T (Treg) cells. In addition, RvD5 inhibited $CD4^+$ T cell proliferation. Furthermore, RvD5 attenuated osteoclast differentiation and interfered osteoclastogenesis at the molecular level (Figure 2).

Conclusion: RvD5 is increased in the paws of arthritic mice, suppresses Th17 cell differentiation and $CD4^+$ T cell proliferation, facilitates Treg cell differentiation, and suppresses osteoclastogenesis.

Metabolic Reprogramming in Memory CD4+ T Cells Is Associated with Immune Cell Dysfunction During Aging

Yuling Chen[1], Yuanchun Ye[2], Hao Wu[3], Pierre-Louis Krauß[1], Pelle Löwe[1], Moritz Pfeiffenberger[1], Lisa Ehlers[1], Thomas Buttgereit[4], Paula Hoff[5], Frank Buttgereit[6] and Timo Gaber[1], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Hematology, Oncology and Tumor Immunology, Berlin, Germany, [3]Julius-Maximilians Universität Würzburg, Institut für Systemimmunologie, Würzburg, Germany, [4]Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Dermatology, Venerology, and Allergology, Berlin, Germany, [5]Endokrinologikum Berlin, Rheumatologie, Berlin, Germany, [6]Charité University Medicine, Berlin, Germany

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflamm-aging is a chronic, sterile, low-grade inflammatory status, characterized by an increase of proinflammatory cytokines which participate in the development of most age-related diseases such as cancer, Alzheimer's disease, type 2 diabetes mellitus, stroke, cardiovascular diseases, and rheumatoid arthritis (RA). As cellular metabolism modulates T cell function, it can be assumed that metabolic changes accompany the differentiation of memory CD4+ T cells into senescent CD4+ T cell and contribute to memory CD4+ T cells dysfunction during aging. Therefore, we hypothesized that metabolic reprogramming in memory CD4+ T cells might represent an essential factor promoting immune cell dysfunction during aging, thereby fueling to the pathogenesis of age-related diseases including RA

Methods: To this end, we analyzed memory CD4+ T cells isolated from PBMCs of young donors (20-32 years) and old donors (52-67 years) by using MACS™ technology. *Ex vivo* memory CD4+ T cells were analyzed by Seahorse™ Technology to determine proton efflux rate (PER) as a measure of glycolysis (glycPER) and oxygen consumption rate (OCR) as a measure of mitochondrial respiration (mitoOCR). Cytokine expression and secretion was measured by flow cytometry and multiplex assay. Finally, TCR-stimulated memory CD4+ T cell proliferation was determined using CSFE and Ki-67 after 3 days and 4 days by flow cytometry.

Results: In a quiescent state, memory $CD4^+$ T cells from elderly individuals demonstrated a decrease in basal glycolysis and compensatory glycolysis, and an increase in the ratio of basal mitochondrial oxygen consumption rate (mitoOCR) to glycolytic proton efflux rate (glycoPER) while their mitochondrial profile was equivalent to that of young donors. In comparison to the younger reference group, memory $CD4^+$ T cells from aged donors presented a greater spare respiratory capacity after TCR-activation. Interestingly, we did not observe an impact of aging on memory $CD4^+$ T cell proliferation as determined by CFSE and Ki-67. Although the capacity of intracellular cytokine expression did not differ between the compared groups, the levels of secreted IFN-γ, IP-10, IL-6, IL-9, and MCAF were significantly higher in the supernatants of memory $CD4^+$ T cells taken from aged donors.

Conclusion: These findings suggest that metabolic reprogramming in human memory $CD4^+$ T cells during aging results in an increased expression of proinflammatory cytokines. This process may culminate in T cell dysfunction

and thus contribute to the pathogenesis of inflamm-aging and the development of age-related diseases such as rheumatoid arthritis (RA).

Lack of Conventional Acinar Cells in the Salivary Gland Following Anti PD-L1 and anti-PD-1 Immune Checkpoint Inhibitor Therapy

Sarah Pringle[1], Bert van der Vegt[1], Xiaoyan Wang[1], Nico van Bakelen[1], Arjan Vissink[1], Frans Kroese[2] and Hendrika Bootsma[2], [1]UMCG, Groningen, [2]University Medical Centre Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Salivary glands (SGs) can be damaged by immune checkpoint inhibitor (ICI) therapy. In patients with ICI-induced SG dysfunction, 60% progress to fulfill the ACR-EULAR 2016 classification criteria for primary Sjögren's syndrome (pSS), owing to immune foci in SGs and/or anti-SSA autoantibody positivity. We report the SG tissue analysis of 2 patients with SG dysfunction after treatment with anti PD-L1 and PD-1 ICIs, compared to that of a dry mouth ("sicca") control and pSS patient.

Methods: Immunostaining for CD4, CD8, Keratin7 (K7), AQP5, Ki67, and PD-L1 was performed in two parotid SG biopsies from patients following ICI therapy, and in control and a pSS patient tissue. The first patient (male, 52 yrs) received fortnightly infusions of 10mg/kg durvalumab (anti-PD-L1 therapy), for non-small cell carcinoma (NSNLC). After 43 weeks (22 cycles) of treatment, the patient was not capable of producing stimulated or unstimulated whole saliva, and demonstrated SSA-positivity. The second patient (female, 74) received infusions of pembrolizumab (anti-PD-1) every 3 weeks for treatment of NSNLC, at a flat dose of 200mg. This patient was not capable of producing unstimulated whole saliva, and demonstrated reduced 0.12mL/min stimulated whole saliva production, after 15 weeks (5 cycles) of treatment. Both patients were SSA-positive following ICI treatment.

Results: In contrast to control and pSS tissue, following anti-PD-L1 and anti-PD-1 blockade, only few $AQP5^+$, classically shaped acinar cell clusters were observed in the parotid SG after treatment with anti-PD-L1 and anti-PD-1 biologicals (Fig. 1a-c). The parenchyma was dominated by hybrid epithelial structures containing a mixture of $AQP5^+$ (acinar cell marker) and $K7^+$ (intercalated duct marker) cells (Figure 1d-f). $AQP5^+K7^+$ cells were also detected. Cells with this unusual phenotype are not seen in control/pSS tissue. More $Ki67^+$ proliferating ID-like cells were detected following PD-L1 or PD-1 therapy, compared to control and pSS SGs. The SG post-PD-L1 and PD-1 therapy demonstrated focal and disperse lymphocytic sialadentitis. Infiltration was $CD4^+$ T cell-rich, although $CD8^+$ T cells were also present. $CD4^+$ and $CD8^+$ T cells were observed in-between and inside hybrid structures. $CD20^+$ B-cells were infrequent. No germinal centers, lymphoepithelial lesions or antibody class-switching following ICI therapy were observed. PD-L1 expression was detected in the SG parenchyma following anti-PD-L1 therapy.

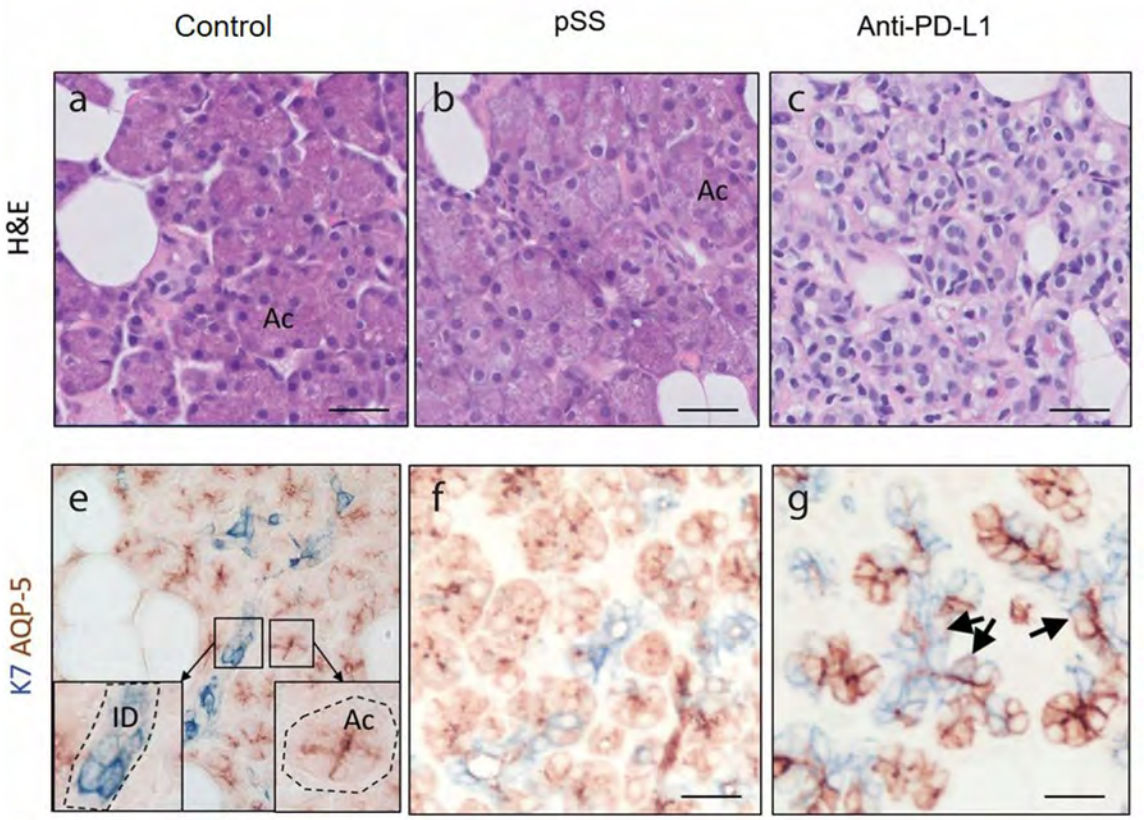

Figure 1. a-c) H&E staining of the parotid salivary gland in sicca control, pSS and post-PD-L1 ICI therapy, showing lack of conventional acinar cell morphology following ICI treatment. d-f) AQP5 and Keratin 7 (K7) double immunostaining, showing presence of unusual hybrid mixed AQP5+K7+ cells post-PD-L1 therapy.

Conclusion: Conventional SG acinar cells were lacking following both anti-PD-L1 and PD-1 ICI therapy. SGs demonstrated presence of hybrid intercalated duct-like structures. Understanding which mechanisms and dynamics underpin this aberrant parenchyma may be crucial to understand how SG dysfunction post-ICI therapy, and potentially other affected organs. Furthermore, although patients post-ICI therapy may fulfill the ACR-EULAR 2016 pSS criteria and demonstrate focal lymphocytic sialadentitis, the further histopathological characteristics do not resemble pSS.

Resident Memory T Cells Persist in Joints of Anakinra-Treated Mice in Spontaneous Arthritis Model

Anais Levescot[1], Margaret Chang[2], Alexandra Wactor[1], Rachel Blaustein[1], Nathan Nelson-Maney[1], Robert Fuhlbrigge[3] and Peter Nigrovic[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Boston Children's Hospital, Boston, MA, [3]University of Colorado, Denver, CO, [4]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory arthritis is characterized by chronic inflammation of joints which can be suppressed with immunomodulatory therapy. However, two-thirds of patients will have an arthritis flare when medication is stopped. We sought to understand how immune cells that persist in arthritic joints in remission may contribute to subsequent recurrence of disease.

Methods: Using IL-1 receptor antagonist (IL-1Ra)-deficient mice, a spontaneous model of T cell mediated arthritis, we identified animals early in arthritis who exhibit involvement of only one of paired major joints (ankle, wrist). We induced arthritis remission by administration of anakinra, an IL-1Ra analog, and then observed flare pattern when treatment was discontinued. Synovium was dissected from the mice and evaluated for the presence of T cell subsets by flow cytometry. Intraperitoneal injection of anti-Thy1.2 antibodies was utilized to deplete circulating T cells and assess tissue residency.

Results: In IL-1Ra deficient mice, unilateral joint inflammation is suppressed by treatment with anakinra. Intriguingly, subsequent discontinuation of therapy results in arthritis flare preferentially in the originally-inflamed joint, implying a mechanism of joint-specific memory. We identified a population of T cells with a cell surface protein signature consistent with resident memory T cells (CD44+CD62L-CD69+CD103+) is found in the synovium during remission. These cells are only present in joints that were previously inflamed, and persist in the synovium despite antibody-mediated depletion of circulating T lymphocytes, suggesting tissue residency.

Conclusion: Our data suggests that the persistence of T cells with a resident memory phenotype in the synovium of arthritic joints may contribute to arthritis flares when immunomodulatory medication is weaned.

CD8+ T Cell Subsets and Immune Checkpoint Profiles in Ankylosing Spondylitis Implicate Dysregulation of Cytotoxic T Lymphocytes (CTL)

Michael Tang[1], Zoya Qaiyum[2], Melissa Lim[1] and Robert Inman[2], [1]UNIVERSITY HEALTH NETWORK, TORONTO, Canada, [2]University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is characterized by chronic inflammation which underlies the pain and precedes spinal ankylosis. The strongest genetic association with AS is the HLA-B27, implicating involvement of CD8+ cytotoxic T cells (CTL) in AS pathogenesis. To date, the CTL compartment that underlies AS inflammation

has yet to be fully defined. Our lab recently reported altered cytotoxicity profiles in CTL from AS patients, suggesting that dysregulated CTL with a cytotoxic phenotype are recruited to the joints. These findings suggest a central role of dysregulated CTLs in AS pathogenesis, warranting further investigation. Here we sought to characterize CTL subsets and immune checkpoint (IC) expression on CTL from patients with AS.

Methods: We performed immunophenotyping of peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) by flow cytometry. A 21- marker mass cytometry time-of-flight (CyTOF) panel is currently being developed to comprehensively assess the CTL compartment in AS patients.

Results: We identified a sub-cohort of AS patients with an enriched population of terminally differentiated memory CTL (up to 46.2% of all $CD8^+$ T cells, expressing $CD45RA^+CCR7^-$) in the periphery and elevated expression of the IC molecules PD-1 (18.3% vs 10.2% of total $CD8^+$ T cells) & TIGIT (17.3% vs. 4.4% of total $CD8^+$ T cells) on AS CTL compared to healthy controls. Effector memory CTL ($CD45RA^-CCR7^-$) were highly enriched in the SF. PD-1 expression is also highly upregulated in the synovial CTL (up to 75% of $CD8^+$ T cells), suggesting local immune activation. Despite PD-1 upregulation in these CTL subsets, evidence of immune exhaustion, as assessed by EOMES expression, was not found.

Conclusion: We demonstrate that CTL from AS patients are highly activated, and are characterized by a distinct immune phenotype which implicates an intrinsic CTL dysregulation in AS pathogenesis.

A T Cell Intrinsic Role for Nod2 in Suppression of Th17-Mediated Experimental Arthritis and Uveitis: Implications for Blau Syndrome

Ruth Napier[1], Ellen Lee[1], Emily Vance[1], Sydney Lashley[2], Luke Uebelhoer[3], Christina Lancioni[3], Richard Vehe[4], Bryce Binstadt[4], Rachel Caspi[5] and Holly Rosenzweig[1], [1]Oregon Health & Science University and VA Portland Health Care System, Portland, OR, [2]VA Portland Health Care System, Portland, OR, [3]Oregon Health & Science University, Portland, [4]University of Minnesota, Minneapolis, MN, [5]NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Mutations in nucleotide-binding oligomerization domain-containing protein 2 (*NOD2*) cause Blau syndrome, an inflammatory disorder characterized by uveitis, dermatitis, and polyarthritis. The antimicrobial functions of NOD2 are well established; yet the mechanism by which dysregulated NOD2 causes sterile inflammation remain unknown. Here we utilized experimental models of autoimmune arthritis and uveitis, and PBMCs from Blau syndrome patients to dissect a T cell-specific role for NOD2 in uveitis.

Methods: Arthritis was induced in SKG and $NOD2^{-/-}$SKG mice with a single intraperitoneal 1.5mg injection of zymosan and assessed by clinical scoring, near infrared imaging and histology. Uveitis was induced in $NOD2^{+/+}$ and $NOD2^{-/-}$ C57BL/6 mice by immunization with the retinal antigen interphotoreceptor retinoid-binding protein (IRBP) and assessed by clinical scoring and histology. Mice were treated with IL-17A/F mAb (R&D systems) beginning 24h

prior to disease induction. Lymphopenic Rag1$^{-/-}$ mice were reconstituted with NOD2$^{-/-}$ or NOD2$^{+/+}$ (WT) CD4+ T cells and arthritis or uveitis was induced. IL-17 production by T cells was evaluated by flow cytometry and ELISA. For T cell homeostasis studies, purified naive (CD62L^{hi}CD44^{-}) CD4+ T cells were differentiated under Th17 polarizing conditions (CellXVivo) or purified memory (CD62L^{-}CD44^{hi}) CD4+ T cells from naive mice were stimulated with anti-CD3 and anti-CD28, and activation state (CD69) and pro-inflammatory cytokine production was determined by flow cytometry ($n \geq 6$ mice/group and repeated 3X). Peripheral blood mononuclear cells from Blau Syndrome patients or healthy controls were cultured for 5 d, stimulated with PMA/ionomycin, and IL-17 was measured. Data were analyzed by Mann-Whitney, and $p < 0.05$ were considered significant.

Results: Lymphopenic recipients of NOD2-deficient T cells developed significantly worse arthritis and uveitis, implicating T cell-intrinsic NOD2 in suppression of disease. CD4+ T cells purified from arthritic and uveitic mice produced significantly more IL-17, and blockade of IL-17 mitigated the enhanced disease caused by NOD2-deficiency, indicating a direct role for T cell-intrinsic NOD2 in suppressing autoreactive Th17 responses. NOD2 was dispensable for Th17 differentiation of naïve CD4+ T cells. However, NOD2$^{-/-}$ memory (antigen-experienced) CD4+ T cells isolated from naïve mice when stimulated with anti-CD3 and anti-CD28 had enhanced expression of IL-17, the IL-17-associated transcription factor (RORγt) and the activation marker CD69. Importantly, stimulation of CD4+ T cells from Blau syndrome patients resulted in significantly more IL-17 production than those from healthy control T cells, suggesting a similar function for NOD2 in human disease.

Conclusion: We have uncovered a novel, T cell-intrinsic function for NOD2 as a negative regulator of T cell homeostasis and autoimmunity. Our work suggests that a "loss-of-function" in NOD2 (i.e. NOD2$^{-/-}$ mice) results in a "gain-of-function" in the ability of T cells to produce IL-17 and cause arthritis and uveitis. These findings could potentially change the way we view the immunopathology of Blau syndrome and open up new therapeutic options for patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session C

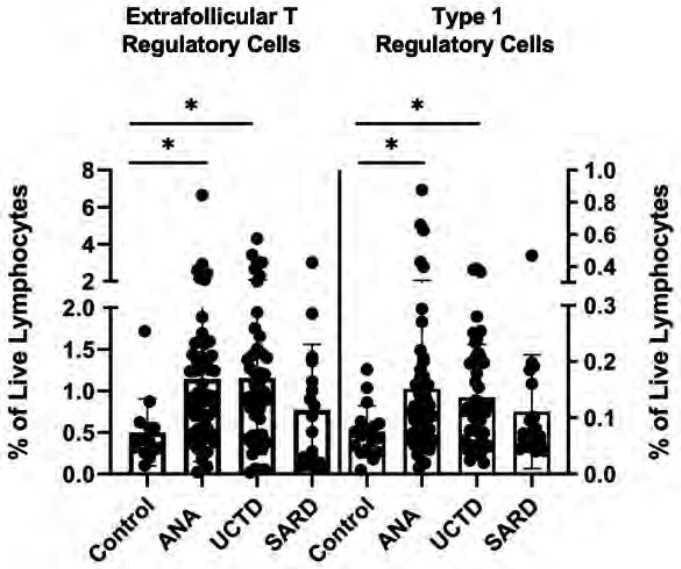
Session Time: 9:00AM–11:00AM

Background/Purpose: The anti-nuclear antibody (ANA)-associated systemic autoimmune rheumatic diseases (SARDs) are characterized by a prolonged preclinical phase in which ANAs are produced in the absence of symptoms. ANAs are also seen in healthy, non-symptomatic individuals (ANA^+NS), the majority of whom will not progress to SARD. Currently, the immunologic features that discriminate progressors from non-progressors are incompletely understood. Previous work has suggested that T regulatory (Treg) cell function may be disturbed in SARD. To determine whether alterations in these cell populations could contribute to SARD progression we investigated the balance between regulatory and inflammatory T cells in patient populations representative of the various stages in SARD development.

Methods: ANA^+ (IF ≥ 1:160) participants were recruited through the clinic and classified as ANA^+NS (n = 61), ANA^+ with ≥ 1 SARD classification criteria but lacking a SARD diagnosis (UCTD, n=54) or early SARD (SLE, n=10, SS, n=7, SSc, n=5, classified according to the 1997 ACR criteria, 2013 ACR-EULAR criteria, and the 2016 ACR-EULAR criteria, respectively). All SARD patients were within 2 years of diagnosis and not taking DMARDs (hydroxychloroquine allowed) or prednisone. ANA^- healthy controls (HC, n= 21) were recruited from clinical and laboratory staff. Peripheral blood mononuclear cells were isolated and stained with fluorochrome-labeled antibodies to identify immune cell populations via flow cytometry. Plasma aliquots retrieved from the same patients were used to measure TGF-ß1 levels (pg/ml) through ELISA. Statistical comparisons were made using the Kruskal-Wallis test.

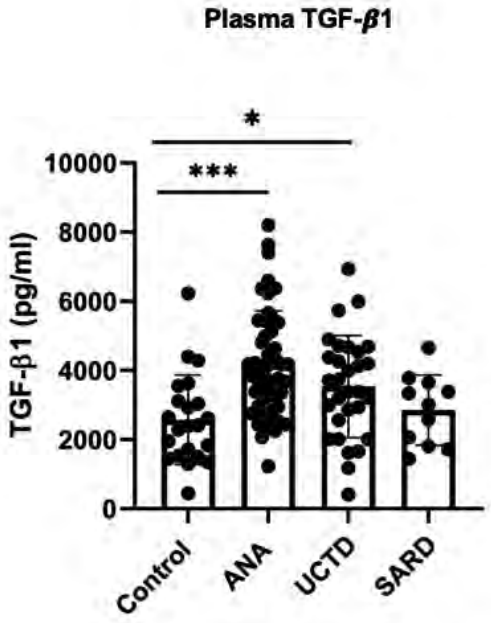
Results: ANA^+NS and UCTD patients had significant increases in the proportion of extrafollicular Tregs ($CD3^+CD4^+CXCR5^-PD1^{hi}FOXP3^+HELIOS^+$) and Type 1 ($CD3^+CD4^+CD45RA^-LAG3^+$) regulatory (Tr1) cells, relative to ANA^-HC, whereas the levels of these cells were similar to ANA^-HC in SARD patients (Figure 1). The same trends were observed for TGF-ß1 levels (Figure 2). In ANA^+NS individuals there was a moderate correlation between TGF-ß1 levels and the proportion of Tr1 cells (r=0.43, p=0.009), a population that has been previously shown to secrete this regulatory cytokine. To examine inflammatory T cell subsets, $CD3^+CD4^+CD45RA^-PD1^{hi}$ activated memory T peripheral ($CXCR5^-$, Tph) and

Figure 1 – Proportion of T Regulatory Subsets



* p ≤ 0.05, ** p ≤ 0.01, *** p ≤ 0.001

Figure 2 – Plasma TGF-β1 Measurements



* p ≤ 0.05, ** p ≤ 0.01, *** p ≤ 0.001

follicular ($CXCR5^+$, Tfh) helper cells were gated and the proportion of Th1 ($CXCR3^+CCR6^-$), Th2 ($CXCR3^-CCR6^-$) and Th17 ($CXCR3^-CCR6^+$) cells in each subset were determined. As shown in Figure 3, increased proportions of Tph2 cells were seen in all ANA^+ patient subsets as compared to ANA^-HC but were most pronounced for SARD patients (Figure 3). Although similar trends were seen for Tph17 cells, the increase was only significant in SARD patients. The same but less significant trends were seen for Tfh cells (data not shown).

Conclusion: Our findings suggest that expanded proportions of extrafollicular Treg and Tr1 cells may act to regulate the autoimmune response in asymptomatic ANA^+ individuals and that in SARD patients this becomes attenuated resulting in an imbalance between regulatory and inflammatory T cell subsets which promotes disease development.

Highly Polyfunctional Metabolically Altered Pathogenic T Cells Accumulate in the Synovial Tissue of RA Patients and Arthralgia Subject but Not Healthy Control Synovial Tissue

Achilleas Floudas[1], Barry Moran[2], Nuno Neto[3], Michael Monaghan[4], Vinod Krishna[5], Sunil Nagpal[6], Phil Gallagher[7], Conor Hurson[8], Douglas Veale[9] and Ursula Fearon[10], [1]Molecular Rheumatology Trinity Biomedical Sciences Institute, Dublin, Dublin, Ireland, [2]Trinity Biomedical Sciences Institute, Dublin, Ireland, [3]Department of Mechanical and Manufacturing Engineering, Dublin, Dublin, Ireland, [4]Department of Mechanical and Manufacturing Engineering, Dublin, Ireland, [5]Janssen R&D, Spring House, PA, [6]Janssen Research & Development, Collegeville, PA, [7]St Vincents University Hospital, UCD, Dublin, Ireland, [8]St Vincents University Hospital, UCD, Dublin, Dublin, Ireland, [9]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland, [10]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Effective treatment of Rheumatoid arthritis (RA) patients is achievable within a short window of opportunity following diagnosis. Identification of pathogenic immune mechanisms at a pre-RA stage would greatly benefit our understanding of the early events that govern disease progression and help identify early points of therapeutic intervention.

Characterization of pro-inflammatory T cell polyfunctionality in the periphery and synovial tissue of 'at-risk; subjects (Arthralgia) RA patients (RA) and healthy controls (HC).

Identification of pathogenic, synovial T cell subsets.

Characterization of metabolic status of pathogenic T cell populations.

Methods: Synovial biopsies from RA, AR and HC were obtained by arthroscopic surgery followed by RNAseq analysis (Guo et al., PLoS One, 2018). Single cell synovial tissue cell suspensions from RA, AR and HC and paired PBMC were stimulated *in vitro* and polyfunctional synovial T cell subsets examined by flow cytometric analysis, SPICE visualization and Flowsome unsupervised clustering. Flow-Imaging was utilised to confirm specific T cell cluster identification. Fluorescent Lifetime Imaging Microscopy (FLIM) was used to visualise metabolic status of specific T cell populations.

Results: T cell associated pro-inflammatory cytokines were increased in whole synovial tissue biopsy RNAseq analysis in RA patients and AR subjects compared to HCs. Flow cytometric analysis and SPICE revealed marked T cell polyfunctionality with similar pro-inflammatory cytokine profiles in RA and AR compared to HC, providing evidence of a dysregulated synovial T cell response that pre-dates clinical onset of disease. Cluster analysis led to the identification of highly polyfunctional T cell clusters and an accumulation of $CD4^{+}CD8^{+}$ double positive T cells in the synovial tissue of AR and RA but not in HC. Hybrid flow cytometry and imaging technique confirmed the cell membrane co-expression of CD4 and CD8 by a synovial T cell population. DP T cells do not share characteristics of NK T cells and their synovial accumulation correlates with DAS28(CRP). Initial studies utilising non-invasive FLIM technique and flow cytometric analysis revealed that DP T cells have an intermediate metabolic profile between CD4 and CD8 T cells and an activated mTOR pathway.

Conclusion: Highly polyfunctional pro-inflammatory T cell responses pre-date disease onset as demonstrated by the accumulation of polyfunctional T cells in the synovial tissue of pre-RA arthralgia subjects. These data highlight a key early pathogenic role for T cell plasticity and specific synovial T cell clusters including, DP T cells in RA.

Murine Roseolovirus Induces Autoimmune Disease and Development of Autoreactive T Cells and Autoantibodies

Tarin Bigley[1], Jose Saenz[2], Li-Ping Yang[2], Jason Mills[2] and Wayne Yokoyama[2], [1]Washington University in St. Louis, Saint Louis, MO, [2]Washington University in St. Louis, St. Louis, MO

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Murine roseolovirus (MRV) is a recently sequenced beta-herpesvirus that is a natural murine pathogen and is genetically highly related to HHV6 and HHV7. The human roseoloviruses, HHV6 and HHV7, have been associated with autoimmune disease. Demonstrating causality has been difficult due to the ubiquitous and chronic nature of roseolovirus infections. Herein we have demonstrated that neonatal MRV infection induces autoimmune disease and development of autoantibodies in adult mice.

Methods: To evaluate the role of MRV in autoimmune disease, mice were infected within the first 48 hours of life. At 12 weeks post infection we performed autoantibody screening as well as histology to identify organ specific tissue inflammation. We utilized flow cytometry and immunofluorescence to characterize the immune response, both systemically and within tissues. Antiviral treatment with ganciclovir was utilized to inhibit viral replication.

Results: Our studies show that autoimmune gastritis occurs in the absence of detectable virus in the gastric mucosa. Neonatal MRV infection results in a transient reduction in thymic and peripheral $CD4^+Foxp3^+$ regulatory T cells (Treg). Ganciclovir (GCV), a potent inhibitor of replication of other beta-herpesviruses, inhibits MRV replication as well as MRV-mediated $CD4^+$ T cell and Treg depletion. Treatment with GCV early in life also reduces autoimmune gastritis, suggesting that MRV replication is necessary for altering immunologic tolerance early in life. The inflammatory infiltrate in the gastric mucosa is characterized by an increase in T cells, neutrophils and eosinophils. Furthermore, the $CD4^+$ T cells in the gastric mucosa express IL-17 and IL-4, demonstrating a Th2 and Th17 response. The development of autoimmune gastritis was found to be T cell dependent. Interestingly, neonatal MRV infection results in the production of a wide array of autoantibodies in adult mice, including those associated with rheumatologic disease such as dsDNA, Scl-70, SSA, SSB, Jo-1, Smith, GBM and MPO.

Conclusion: This study shows that neonatal infection with MRV results in the development of autoimmunity later in life, after acute infection has been cleared. Taken together, these findings strongly suggest that infection with a roseolovirus infection early in life results in disruption of immunologic tolerance and development of autoimmune disease.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Vasculitis – ANCA-Associated Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic has the potential to impact how patients with vasculitis interact with health care systems due to concerns about infections. This study aimed to analyze the concerns and health-related behaviors in patients with vasculitis during early phase of the COVID 19 pandemic in North America.

Methods: Patients with vasculitis were invited to complete an online survey through Vasculitis Patient-Powered Research Network in collaboration with the Vasculitis Foundation and the Relapsing Polychondritis Awareness and Support Foundation. Questions focused on concerns and behaviors related to doctors' visits, laboratory and other tests, medication use, and telehealth use. Differences based on age, diagnoses, immunosuppressive drugs, daily glucocorticoid (GC) doses, urban vs. rural location, education, income, and COVID-19 infection rates in patients' county were compared with Kruskal-Wallis (for concerns) or logistic regression, with telehealth analyses adjusted for date of survey completion. This report details findings from April 8, 2020 through May 29, 2020.

Results: Data from 662 patients were included: 90% Caucasians, 78% women (**Table 1**). Seven patients reported a diagnosis of COVID-19. Most patients (83%) expressed moderate or high levels of concern about COVID-19; 87% reported their vasculitis "moderately" or "extremely" affected their level of concern (**Figure 1**). Age >60 years ($p< 0.01$), female sex ($p=0.01$), and lung disease ($p< 0.01$) were associated with higher levels of concern. Immunosuppressive drug use and lung disease were associated with a higher likelihood that underlying vasculitis significantly affected level of concern ($p< 0.01$ each).

66% of patients reported avoiding doctors' visits, 46% avoided laboratory tests, and 40% avoided other tests. Age < 60 years, urban location, higher COVID-19 activity, higher income, higher concern levels, and prednisone dose >10 mg/day were each associated with greater likelihood of avoiding visits or tests. 10% of patients on immunosuppression stopped drugs, especially patients with respiratory illnesses (39% vs 8% without respiratory illness, $p< 0.01$). The most common reasons for drug stoppage were concern about infection (57%) and physician's advice (40%). Among 225 patients on rituximab, 43 (29%) reported avoiding an infusion.

44% of patients had telehealth visits; more visits were reported in younger patients, those on GC, and in Canada vs the USA (**Table 2**). Patients with telehealth visits were more likely to report getting information about COVID-19 from healthcare providers (65% vs 38%, $p< 0.01$).

* $p < 0.05$ vs. the reference groups (granulomatosis with polyangiitis, rituximab, no glucocorticoid use, urban residence, lowest tertile of median household income, greater than high school education, or COVID-19 cases per capita, United States, age < 60) based on univariate logistic regression models except for telehealth visit analyses which were adjusted for date of entry into the study because of associations between calendar time and telehealth use; t tests were performed for continuous variables and chi square tests for categorical variables; p values are nominal in nature and should be interpreted in an exploratory manner

** Proportion stopping medications is among patients who were on immunosuppression/immunomodulatory therapy and did not report a respiratory illness or diagnosis of COVID-19

AAV: ANCA associated vasculitis, GPA: granulomatosis with polyangiitis, MPA: microscopic polyangiitis, EGPA: eosinophilic granulomatosis with polyangiitis, GCA: giant cell arteritis, JAKi: Janus kinase inhibitors, CYC: cyclophosphamide, AZA: azathioprine, MMF: mycophenolate, MTX: methotrexate, TAC: tacrolimus, CSP: cyclosporine; DMARD: Disease Modifying Anti-Rheumatic Drugs

Conclusion: In patients with vasculitis there were high levels of concern due to COVID-19 in the early months of the pandemic. Many patients avoided doctors' visits, laboratory and other tests, and stopped or delayed medications without consulting physicians. Healthcare utilization varied across demographics and geographies. Strategies to facilitate ongoing engagement with the health care system during the pandemic are warranted and should be tailored to specific subsets of patients with vasculitis.

Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) frequently occurs among older patients, with different clinical presentations than the younger. Little is known on the outcome of older patients presenting with AAV. We aim to study the risk of relapse of patients with an AAV diagnosed after the age of 75 years.

Methods: Data from patients aged ≥65 years were extracted from the prospectively completed French Vasculitis Study Group (FVSG) database and from a call for observation of patients aged ≥75 years sent to the FVSG members on June 2019. Patients were included if they had a diagnosis of granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) or unclassified AAV (EMA classification criteria) made after the age of 65 and were either followed-up for 6 months or deceased. Patients aged ≥75 years were compared to those aged 65-75 years. Data on comorbidities, demography, disease phenotype, treatment, and outcome were collected. Primary end-point was risk of first relapse among those who achieved remission. To assess relapse risk, univariate and multivariate analysis was performed, using both Cox (using cause-specific hazard ratios, CSHR) and Fine- Gray models (using sub-distribution HR, SHR), taking death into account as a competing risk for relapse.

Results: We included 299 patients, 219 patients aged ≥75 years (median 79, IQR [77-83], 79 from the database and 140 from the call for observations) and 80 patients aged 65-75 years (median 70 years, IQR [68-72]) from the database. Diagnosis was GPA for 155 patients (52%), MPA for 136 patients (45%) and unclassified for 8 patients (3%). When compared with patients aged 65-75 years, those aged ≥75 years had lower relapse risks in multivariate analysis (CSHR 0.54, 95% IC 0.33 to 0.89, p=0.016), as well as when death was taken into account as a competing event (SHR 0.46, 95% IC 0.29 to 0.74, p=0.001). Patients aged ≥75 years also had lower relapse risks when adjusting on diagnosis of GPA (CHSR 0.56, 95% IC 0.35 to 0.90, p=0.017; SHR 0.56 95% IC 0.34 to 0.91, p=0.019), on variables composing Five Factor Score (FFS) 1996, as well as on variables composing FFS 2011. Patients aged ≥75 years had a lower risk of being treated with immunosuppressive therapy in addition to glucocorticoids (versus glucocorticoids alone), after adjusting for FFS 1996 (HR 0.29, 95% IC 0.12 to 0.70, p=0.023) and FFS 2011 (HR 0.29, 95% IC 0.12 to 0.71, p=0.007). Patients aged ≥75 years, for whom a combination of immunosuppressants and glucocorticoids is usually recommended and who followed that treatment regimen, had significantly lower relapse rates than those who were treated with glucocorticoids alone (CSHR 0.29, 95% IC 0.12 to 0.68, p=0.005; SHR 0.31, 95% IC 0.13 to 0.71, p=0.006).

Conclusion: Patients with a diagnosis of AAV after the age of 75 years had a lower risk of relapse than patients aged 65-75 years, after adjusting for confounders and using death as a competing risk of relapse. Patients aged ≥75 years had lower probabilities of being treated with a combination of immunosuppressants and glucocorticoids. However, patients aged ≥75 years still benefit from being treated with immunosuppressants and glucocorticoids when recommended, with a lower relapse risk.

Clinical Presentations and Follow-up Results of Granulomatosis with Polyangiitis: An Analysis of 8 Years Clinical Experience with 220 Patients from a National Referral Center

Seyed Behnam Jazayeri[1], Farzaneh Kianifar[2], **Samira Alesaeidi**[2], Soheil Tavakolpour[3], Amir Teimourpour[4] and Sasan Dabiri[2], [1]Tehran university of medical scienses, Tehran, Iran, [2]Tehran university of medical sciences, Tehran, Iran, [3]Dana-faber cancer institute, Harvard Medical School, Boston, MA, [4]Department of epidemiology and bio-statistics, Tehran university of medical sciences, Tehran, Iran

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) is a rare and life-threatening autoimmune disease. Due to the extremely low prevalence of GPA, monitoring of clinical characteristics and outcomes is critical. The objective of this study was to analyze the clinical presentations and follow-up results of patients diagnosed with the GPA at a national referral center in Iran.

Methods: Between 2012 and 2020, all consecutive GPA-diagnosed patients at Tehran University of Medical Sciences (Amir A'lam Hospital) were included. All patients fulfilled the 1990 ACR criteria and/or revised Chapel Hill nomenclature for GPA. Patients' demographic information, laboratory findings, and clinicopathological manifestations were retrospectively recorded in the GPA registry system.

Results: Overall, 220 GPA patients, including 112 (50.9%) men and 108 (49.1%) women, with the mean age of 44.4 ± 15.9 years, were diagnosed. The mean follow-up time was 24.6 months. The mean interval between disease onset and diagnosis was 23.6 months (ranged 6-300). Regarding clinical manifestation at diagnosis, ear nose throat (ENT) (99.5%), pulmonary (76.8%), and renal (46.8%) were the most commonly involved organs (Table 1). Sera positivity for anti-proteinase 3 (PR3)-ANCA and myeloperoxidase (MPO)-ANCA were found in 138 (63.3%) and 29 (13.3%) patients, respectively. Histologic data obtained from 140 patients, revealed the classical triad of vasculitis, necrosis, and granulomatous inflammation in 29 specimens (19%). Regarding inflammatory serological markers, high levels of CRP (>10 mg/L) was observed in 137 (62.8%) and high ESR levels (>30 mm/h) in 122 (55.9%) patients (Table 2). Regarding disease severity, the mean BVAS/WG and PGA scores at the time of diagnosis were calculated as 9.5 ± 4.3 and 5.9 ± 1.8, respectively. Accordingly, based on the BVAS/WG classification, 141 (64%) patients fell into severe and 79 (36%) in limited disease activity categories. Based on the last recorded follow-up, ENT, pulmonary, and renal were increased to 100%, 85.9%, and 56.8%, respectively. Among 103 patients with a minimum follow-up of 24 months, 161 relapses occurred (mean relapse count for each patient: 1.56). Sixty-nine (31.3 %) patients expired during the follow-up period, 46 (66.6 %) less than 1 year, 16 (23.1 %) between 1 to 5 years and 7 (10.1 %) after 5 years post-diagnosis. There was a significant change in the main causes of death in the study timeframe (p-value = 0.001). During the first year after diagnosis of GPA, the most common cause of death was active vasculitis (19 Of 46; 41.3%), whereas from years 1 to 5 after the diagnosis, the most frequent cause was cardiovascular (CVD) disease (8 Of 16; 50%), and from years 5 to 10, malignancy and CVD were the most common causes (3 Of 7; 42.8% each).

Conclusion: GPA has a progressive nature, which, despite the continuous treatment, it moves to a more severe form. GPA-related death might occur either as the results of disease directly (organs involvement) or long-term side-effects related to treatments (e.g., malignancy). Thereby, early diagnosis of disease, regular follow-up, and using non-car-

Session Title: Vasculitis – ANCA-Associated Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: One of the controversial matters in ANCA associated vasculitis is the definition of disease based on clinical characteristics since there is a remarkable overlap between disease groups. For instance, single organ disease like renal limited vasculitis (RLV) is not take place most of the definitions or classification criteria.

The aim of this study to determine clinical subgroups that may incorporate different clinical phenotypes, including RLV in AAV patients, followed up in two tertiary centres.

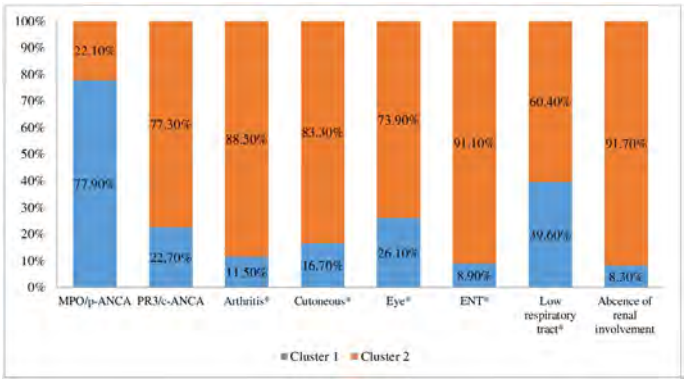

Table 1: Baseline characteristics of 165 patients with AAV

Age at diagnosis, mean years ± SD, (n)	51.6 ±15.2, 163
Male, n (%)	87 (52.7)
Labaratory results at diagnosis	
GFR =<60, n (%)	100/145 (69)
MPO-ANCA or p-ANCA	68 (41.2)
Pr3-ANCA or c-ANCA	97 (58.8)
Variants of AAV	
MPA	26 (15.8)
GPA	108 (65.5)
EGPA	11 (6.7)
RLV	20 (12.1)
Organ systems involved at diagnosis n (%)	
Cutaneous	24 (14.5)
Eye	23 (13.9)
Ear, nose and throat	90 (54.5)
Low respiratory tract	111 (67.3)
Cardiovascular system	5/163 (3.1)
Gastrointestinal system	10/164 (6.1)
Renal	129 (78.2)
Peripheral nervous system	16 (9.7)

GFR: glomeruler filtration rate; ANCA: antineutrophil cytoplasmic antibodies; Pr3: proteinase 3; MPO: myeloperoxidase; p-ANCA: perinuclear ANCA; c-ANCA: cytoplasmic ANCA; MPA: Microscopic Polyangiitis; GPA: Granulamatosis and Polyangiitis; EGPA: Eosinophilic Granulomatosis with Polyangiitis; RLV: Renal limited vasculitis

Methods: Baseline clinical features of AAV patients were studied. To analyse our data and identify sub-groups of AAV patients with similar clinical characteristics, a two-step cluster analysis using log-likelihood distance measures was performed. For clustering, we evaluated the following variables: gender, age at symptom onset, the presence of major organ involvement (renal, upper and lower respiratory tract, skin, joint, eye) and ANCA specificity

Results: In total 165 (87 [53%] male, age at diagnosis 51.6± 15.2 years) out of 238 (126 [53%] male, age at diagnosis 51.3± 15.6 years) AAV patients included in the analysis. Some of the demographic and clinical characteristics were summarized in table 1. There are two distinct clusters in AAV patients. Of 78% of those AAV patients with MPO/pANCA, 56% with renal involvement and 89% without ENT involvement were in Cluster 1. Of 77% those patients with PR3/cANCA, 89% with arthritis, 74% with eye involvement, 83% with skin, 91% with upper, and 60% with lower respiratory tract involvement and 92% of those without renal disease were in Cluster 2. Most of them (89%) classified as MPA and all as RLV were repositioned in Cluster 1, and 74% of GPA and 64% of EGPA patients were in Cluster 2.

Conclusion: Patients with AAV could be separated into two distinct categories. PR3 ANCA specificity and more organ/system involvement determine one and MPO ANCA specificity in renal disease define other subgroups.

Characterization of ANCA-Associated Vasculitis Among African American Patients

Sehris Khawaja[1], Saloni Godbole[1], Maryann Kimoto[2], Virginia Steen[3] and Kaitlin Quinn[4], [1]Georgetown University, Washington, DC, [2]UCLA, Los Angeles, CA, [3]Division of Rheumatology, Department of Medicine, MedStar Georgetown University Hospital, Washington, DC, [4]National Institutes of Health, Washington, DC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) comprises a group of disorders characterized by inflammation of small and medium-sized arteries. Prevalence and phenotype of these diseases appear to vary across geographic and racial subgroups and information pertaining to the African American population is sparse. The objective of this study was to characterize clinical features in a cohort of African American patients with AAV compared to a matched cohort of Caucasian patients with AAV.

Methods: A retrospective electronic chart review was performed from 2007-2019 to identify patients with AAV within a single hospital network. African American and Caucasian patients were matched based on age and gender. Differences in clinical characteristics between the two groups were assessed by the Chi-square test for categorical variables and Mann-Whitney test for continuous variables, as appropriate.

Results: Thirty-five African American patients and 35 Caucasian patients with AAV were identified. Median age at diagnosis was 48 years (IQR 38-66) in the African American group, and 44 years (IQR 31-60) in Caucasian group; p=0.15. Twenty-four (69%) patients in each group were female; p=1.0. At time of presentation, African-American patients with AAV more frequently required admission to the Intensive Care Unit (58% versus 31%, p=0.02), received pulse dose steroids (83% versus 51%, p< 0.01), had lower hemoglobin values (median 10 g/dL versus 12.8 g/dL, p< 0.01), and higher creatinine levels (3.05 mg/dL versus 1.1 mg/dL, p=0.01) compared to Caucasian patients with AAV. African American patients with AAV also more frequently had renal involvement (80% versus 57%, p=0.02) and required hemodialysis at presentation (31% versus 11%, p=0.04), compared to Caucasian patients with AAV. There was a higher frequency of PR3-ANCA positivity in the Caucasian patient population (57% versus 29%, p=0.03) and a trend towards African American patients having a higher frequency of MPO-ANCA, although this did not reach statistical significance. There were no statistically significant differences in cutaneous manifestations, eye involvement, ENT involvement, subglottic stenosis, lung nodules or diffuse alveolar hemorrhage, or nervous system involvement between the two groups (TABLE).

Conclusion: African American patients with AAV had more severe disease at time of initial presentation, as demonstrated by more frequent Intensive Care Unit admissions, more frequent administration of pulse dose steroids, higher creatinine, and increased need for hemodialysis, when compared to the group of Caucasian patients with AAV. The observed differences in disease severity are likely multifactorial with potential causes including heterogeneity of vas-

Table:

Clinical Features of African American and Caucasian Patients with ANCA-associated Vasculitis			
	African American (n=35)	Caucasian (n=35)	p-value

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Vasculitis – ANCA-Associated Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV), including Granulomatosis with Polyangiitis (GPA), Eosinophilic Granulomatosis with Polyangiitis (EGPA) and Microscopic Polyangiitis (MPA), affect mostly Caucasians of European descent. Clinical presentation, clinical features, and prognosis of AAV in African Americans (AAs) have not been well described. The objective of this study was to compare the clinical features and outcomes at time of diagnosis of AA patients with AAV to Caucasian patients. Our hypothesis was that AA patients with AAV present with a higher frequency of MPA, greater disease severity, and experience higher mortality compared to Caucasian patients.

Table 1. Demographics, clinical and ANCA serologies in AA and Caucasian patients with AAV between 2003-2018

	African Americans (N= 32)	Caucasian (N= 64)	P-Value

Table 2

Methods: We conducted a retrospective chart review of patients with ICD-9-CM and ICD-10 codes used for AAV (446.0, 446.4, 447.6 and M31.3, 31.7, M30.1, I77.6, M31.9, M31.8) between 1/2003 to 12/2018. Diagnosis was confirmed by two reviewers (one rheumatologist), and in case of discordance, a third reviewer was involved (rheumatologist). Race was verified through chart review. AA cases were randomly matched by year of diagnosis (± 4 years) in a 1:2 ratio with Caucasian controls. Demographics, clinical and laboratory features, disease activity and prognosis were abstracted by chart review using the Birmingham Vasculitis Activity Score (BVAS) 3 and Five-Factor Score (FFS). T-test, Chi-square and Fisher exact test were used for statistical analysis, when appropriate.

Results: 548 AA patients were identified using diagnostic codes. 56 AA patients were confirmed to have AAV via chart review but only 32 of these cases were confirmed using diagnostic criteria. We matched 64 similarly confirmed Caucasian controls. Compared to Caucasians, AA patients with AAV were younger (47.5 years [IQR 32.5] vs 61.0 years [IQR 19.5], p = 0.001). No other clinical or laboratory features were different compared to Caucasians (Table 1). In addition, we found no difference in frequency of GPA, MPA, or EGPA phenotypes between AA and Caucasians. Younger age at presentation was observed among AAs with GPA (35 [IQR 24] vs 55 [IQR 20), p = 0.006) and MPA (55.5 [IQR 20] vs 65.0 [IQR 13], p = 0.02) (Table 2). Compared with Caucasians, the proportion of women with GPA was higher among AAs (82.3% vs 47.8%, p = 0.008) but the proportion of AA men with MPA was higher (53.3% vs 15%, p = 0.03) (Table 2). There was no difference in disease activity, severity of manifestations or mortality.

Conclusion: In this single center retrospective study, AA patients with AAV presented at a younger age compared with Caucasians. No differences in mortality rates, clinical phenotypes, clinical and laboratory features, disease activity, prognostic scores, or mortality were observed.

Healthcare Utilization Among Patients Diagnosed with ANCA-Associated Vasculitis Between 2007 and 2014 in a Multi-Center Cohort Linked to Medicare Claims Data

Zachary Wallace[1], Xiaoqing Fu[2], John Stone[3], Hyon Choi[4] and Rochelle Walensky[2], [1]Massachusetts General Hospital, Newton, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Concord, MA, [4]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) leads to complications that contribute to poor quality of life and survival. Systemic vasculitis is associated with high healthcare utilization but little is known about healthcare utilization specifically in AAV, especially around the time of diagnosis when complications are common. Identifying utilization patterns is needed to define opportunities to improve care, to inform inputs for cost-effectiveness studies, and to support advocacy efforts to fund research in diseases that have a disproportionate impact on societal resources.

Methods: The Partners AAV Cohort is a consecutive inception cohort established at Partners HealthCare (PHS), a large healthcare system in New England. We included AAV cases diagnosed between 2007-2014 with available Medicare claims data who could be matched (by age, sex, and index date [AAV treatment initiation]) to a non-AAV control that received primary care at PHS and also had claims data available. Electronic health record data from cases and controls were linked deterministically to Medicare Parts A and B claims data, which contain details regarding ambulatory, inpatient, and emergency department visits and non-acute institutional visits (e.g., rehab). Healthcare utilization was compared using Chi Square tests and generalized estimating equations.

Results: We included 99 cases and controls. Age, sex, race, and baseline Charlson Comorbidity Index were similar between cases and controls (**Table 1**). There was an increase in emergency department (ED) and ambulatory visits (AV) and inpatient (IP) hospitalizations among AAV cases in the months preceding the index date (**Figure 1**). Compared to controls, cases were more likely to have at least one ED visit (67% vs 22%, P = < 0.001) and/or IP hospitalization (65% vs 15%, P= < 0.001) during the first six months following the index date (**Table 1**). AVs were more frequent among cases than controls throughout the study period (**Figure 1,** P< 0.001); in the first six months after the

Table 2. Healthcare Utilization Among AAV Cases and Controls Using Medicare Claims Data from 2007-2014

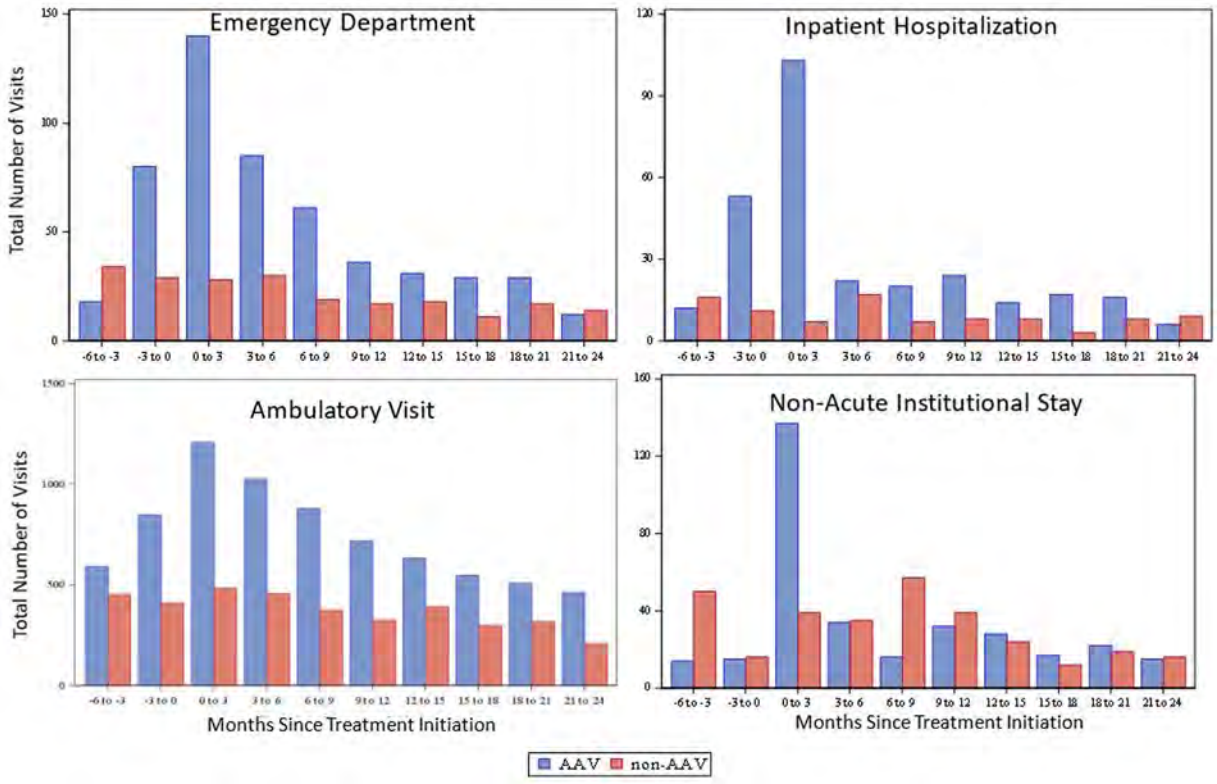

Figure 1. Healthcare Utilization in ANCA-Associated Vasculitis Before and After Treatment Initiation

index date, cases had a median of 22 [13, 33] AVs compared to 5 [1, 13] among controls (**Table 1**). Among cases, 33% had ≥ 2 IP hospitalizations in the six months after the index date while 35% had none. Following the index date, there was a gradual decrease in healthcare utilization among cases (**Figure 1**). More cases than controls had ≥ 1 non-acute institutional stay (24% vs 10%, P=0.02) in the first six months after the index date (**Table 1**).

Conclusion: Compared to controls, AAV patients have greater healthcare utilization in the period around diagnosis. These observations establish important benchmarks in AAV care and opportunities for improvement. First, increased utilization prior to diagnosis might reflect diagnostic delays that may be shortened with strategies that include better provider education and leveraging artificial intelligence in electronic health records. Second, high utilization appears to be concentrated in a subset of AAV patients (e.g., multiple hospitalizations) which may benefit from interventions to minimize readmission or unnecessary care. Studies are needed to identify modifiable risk factors associated with healthcare utilization in AAV.

Abstract Number: 1423

Declining In-Hospital Mortality in Vasculitis: A 17-year U.S. National Study

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To our knowledge, only a few population-based studies for vasculitis mortality exist; and most are limited to vasculitis sub-types. Therefore, our study objective was to assess time-trends in in-hospital mortality in vasculitis and compare it to the general population, using the U.S. National Inpatient Sample (NIS).

Methods: We included the data from the Healthcare Cost and Utilization Project (HCUP) NIS from 1998 to 2014. The NIS is a de-identified national all-payer inpatient health care database that has a 20% stratified sample of hospital discharges. NIS is used frequently for creating U.S. national estimates.

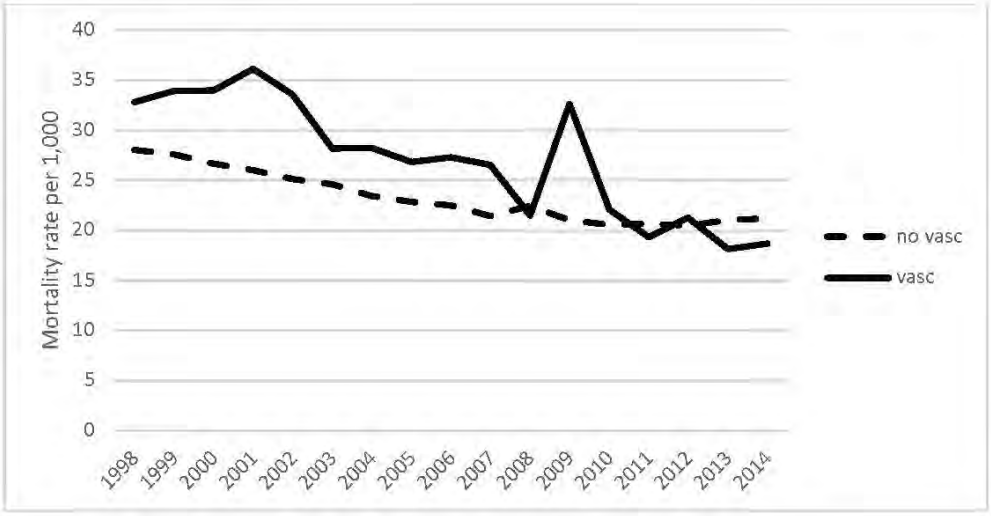
Cases of hospitalized vasculitis were defined based on the listing of 446.xx or 447.6 as the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) diagnostic codes in the primary diagnosis position. A previous study showed a sensitivity of 93% and specificity of 95% using this approach. We limited our study to 2014, the last year ICD-9-CM codes were used in the U.S. before switching to ICD-10-CM in 2015.

We calculated the unadjusted in-hospital mortality rates per 1,000 hospitalizations for people with versus without primary vasculitis hospitalizations, with the respective denominators. We calculated age-adjusted rates by grouping age in quintiles (< 20, 20-39, 40-59, 60-79, >79) and age- and sex-adjusted rates. We analyzed in-hospital mortality rate time-trends using the Cochran Armitage test, weighted by the number of hospitalizations each year.

Results: There were 266,461 primary vasculitis hospitalizations in 1998-2014 with 7,215 in-hospital deaths (2.7%). Mean age was 42.9 years, 57% were men, 50% were white, 30% had a Deyo-Charlson comorbidity score of ≥2 and 18% had a Medicaid payer (Table **1**).

Figure 1. Time-trends in unadjusted (A) and age- and sex-adjusted (B) in-hospital mortality rates per 1,000 population of hospitalizations in people with vasculitis compared to people without vasculitis.

A. Unadjusted



B. Age- and sex- adjusted

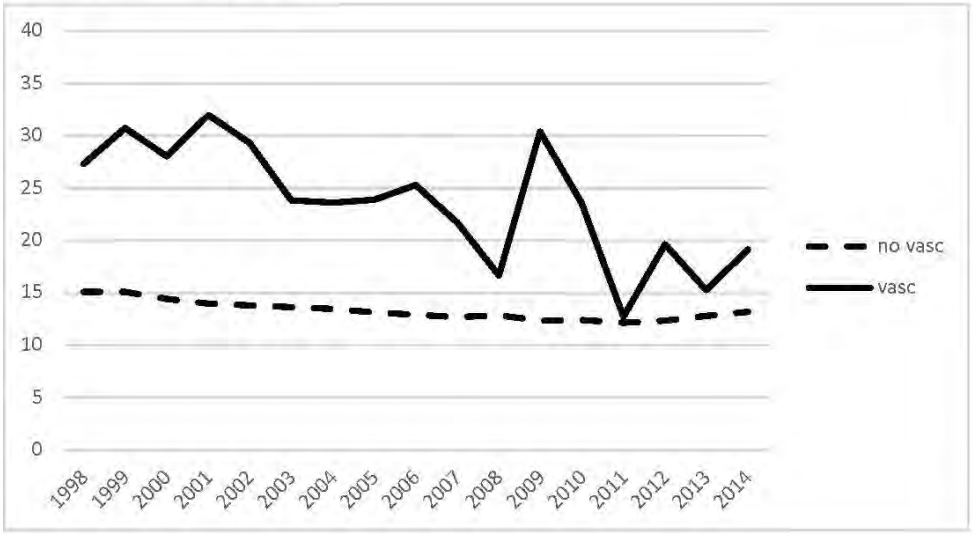


Figure 1 legend

The y-axis shows rate per 1,000 hospitalization claims with each respective denominator

Figure 1. Time-trends in unadjusted (A) and age- and sex-adjusted (B) in-hospital mortality rates per 1,000 population of hospitalizations in people with vasculitis compared to people without vasculitis. Figure 1 legend The y-axis shows rate per 1,000 hospitalization claims with each respective denominator

Unadjusted in-hospital mortality in primary vasculitis hospitalizations decreased by 43% from 32.8 per 1,000 in 1998 to 18.7 per 1,000 in 2014 ($p< 0.01$), compared to a 24.5% reduction in deaths for all NIS claims without vasculitis (28.1 to 21.2 per 1,000; $p< 0.01$; **Figure 1**).

Died during hospitalization	7,214 (2.71%)

Table 1. Demographic and clinical characteristics of people hospitalized with vasculitis in the U.S.

Age- and sex-adjusted in-hospital mortality decreased both in primary vasculitis hospitalizations from 27.3 per 1,000 claims in 1998 to 19.1 in 2014 and non-vasculitis hospitalizations from 15.1 to 13.2 per 1,000 in 2014, respectively ($p< 0.01$; **Figure 1**; Table **2**). The age- and sex-adjusted mortality rate gap between those with versus without vasculitis narrowed (**Figure 1**); vasculitis to non-vasculitis in-hospital mortality ratio was 1.81 in 1998-2000 and 1.45 in 2013-2014 (Table **2**). Primary vasculitis hospitalizations per year remained fairly constant from 1998-2014 at 14-18,000 per year; rate was 43 per 100,000 NIS claims in 1998-2000 versus 43.2 in 2013-14; i.e., 0.05% of claims per year.

Appendix 2. Mortality rates per 1,000 population in people hospitalized without versus with Vasculitis: unadjusted based on the NIS sample; age- and age- and sex-adjusted rates based on the NIS sample and the census data

	No Vasculitis			Vasculitis		
Year	Unadjusted	Age-adjusted	Age- and sex-adjusted	Unadjusted	Age-adjusted	Age- and sex-adjusted
1998	28.1	14.4	15.1	32.8	27.1	27.3
1999	27.6	14.5	15.1	33.9	31.9	30.7

2013	21.1	12.3	12.8	18.2	15.8	15.2
2014	21.2	12.7	13.2	18.7	18.1	19.1
% reduction - 1998 to 2014	**24.5%**	**11.8%**	**12.6%**	**43.0%**	**33.2%**	**30.0%**

Table 2. Mortality rates per 1,000 population in people hospitalized without versus with Vasculitis: unadjusted based on the NIS sample; age- and age- and sex-adjusted rates based on the NIS sample and the census data

Conclusion: Adjusted in-hospital mortality decreased significantly over time in both the general U.S. population and primary vasculitis hospitalization cohorts, and the absolute and relative reductions were larger for vasculitis hospitalizations. Age- and sex-adjusted in-hospital mortality was higher in vasculitis compared to the general population in both 1998 and 2014, but the gap narrowed over time.

Outcomes of Hospitalizations for Acute Myocardial Infarction in Patients with ANCA Associated Vasculitis from the National Inpatient Sample

Atefeh Vafa[1], Marielys Figueroa Sierra[1], Omid Behnamfar[2], Hamayon Babary[1], Suraiya Afroz[1] and Yih Chang Lin[3], [1]University of South Florida, Tampa, FL, [2]University of California San Diego, La Jolla, CA, [3]University of South Florida, Morsani College of Medicine, Tampa, FL

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Vasculitis – ANCA-Associated Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Several studies in the past have shown significantly increased risks of cardiovascular disease in patients with ANCA associated vasculitis (AAV). This association is thought to be secondary to systemic inflammation as well as glucocorticoid use and their role in premature atherosclerosis. In this study, we aimed to evaluate the

Demographics and Outcomes of AMI hospitalizations in patients with and without AAV in 2016-2017

Demographics/Outcomes	AAV	No AAV	P-value
Female (%)	46	38	0.01
Caucasian (%)	67	71	0.31
Age (Year) (mean)	67.23	66.97	0.78
Insurance (%) Medicare Medicaid Private	 67 08 21	 59 09 26	0.14
Hospital Region (%) NE MW South West	 18 25 38 17	 17 22 40 19	0.68
Hospital Bed size (%) Small Medium Large	 14 35 50	 16 30 53	0.24
Urban Hospital (%)	90	92	0.45
Teaching Hospital (%)	67	66	0.81
Charlson Comorbidity Index ≥3 (%)	72	51	<0.01

outcomes of patients hospitalized for acute myocardial infarction (AMI) in those with and without a history of AAV in a nationally representative sample.

Methods: We used data from the National Inpatient Sample (NIS) for the period of 2016 to-2017 for adult AMI hospitalizations as a primary diagnosis and AAV as a secondary diagnosis using ICD-10 codes. The proportion who met ACR classification criteria cannot be determined with the NIS database. We used STATA.15 for the data analysis and logistic regression was applied to calculate adjusted odds ratios (aOR) for inpatient mortality and length of stay (LOS) in AMI hospitalizations in patients with and without a history of AAV.

Results: We identified a total of 1305889 AMI hospitalizations over a 2-year period of 2016 to 2017 of which 1040 patients had a history of AAV. There was no statistically significant difference in the age between two groups of patients. Compared to the patient without AAV, a higher proportion of patients were female in the AAV group (46% vs 38%; p= 0.01). There was a statistically significant difference in Charlson comorbidity index between two groups of AMI with AAV vs without AAV (72% vs 51%; P< 0.01)

In-hospital mortality after MI in patients with a history of AAV compared with those without AAV was not different (5.3% vs. 4.7%; P= 0.66). In Multivariate logistic regression model after adjusting for age, sex, hospital teaching status, hospital bed size, insurance status, and Charlson comorbidity index, there was no difference in the odds of in-hospital mortality in patients with history of AAV compared with no history of AAV (OR 1.06; 95% CI 0.57-1.97).

Unadjusted mean LOS in AMI patients with a history of AAV was not statistically different from those without AAV (5.02 vs. 4.44; P=0.09). In multivariate Regression model; after adjusting for age, sex, household income, Hospital location, Hospital teaching status, Hospital bed size, and Charlson comorbidity index, mean LOS following MI in patients with AAV vs. no AAV was not different (P=0.73).

Conclusion: Inpatient mortality after AMI as well as LOS were similar in patients with and without AAV in the 2-year period of 2016-2017 despite previously known greater risk of Cardiovascular disease in patients with AAV. These findings may be related to better disease control with Rituximab and reduction in the use of glucocorticoids in these patients.

Table 1. Baseline Demographic and Disease-Specific Features

Background/Purpose: Granulomatosis with polyangiitis (GPA) is a common cause of glomerulonephritis and leads to end-stage renal disease (ESRD) in approximately 25% of patients. Both GPA and ESRD are associated with an increased risk of cardiovascular disease (CVD). In fact, CVD is the most common cause of death in GPA. Renal transplantation improves survival in GPA but its impact on risk of CVD events like myocardial infarction (MI) and cerebrovascular accident (CVA) is poorly understood in this unique population.

Methods: We identified all incident cases of ESRD due to GPA (ICD9=446.4) in the United States Renal Data System (USRDS) who were waitlisted for a renal transplant between 2000-2014. The USRDS captures nearly all patients with ESRD in the US and requires that nephrologists report the ESRD cause (ICD-9 code). The USRDS includes details regarding demographics, comorbidities, hospitalizations covered under Medicare Part A, and waitlist and transplant dates and statuses. All patients were followed to the earliest of: up to 3 years after transplant, end of Medicare coverage, death, or December 31, 2015. CVD outcomes of interested included non-fatal and fatal myocardial infarctions (MI) and ischemic cerebrovascular accident (CVA). We used a Cox regression model with transplantation as a time-varying exposure and accounted for the competing risk of non-CVD-related mortality to estimate the hazard ratio (HR) and 95% confidence intervals (CIs) of CVD events among those transplanted compared to those who remained on the waitlist. We adjusted for sociodemographics, comorbidities, and other covariates.

Results: During the study period, 985 patients with ESRD due to GPA were waitlisted for a renal transplant (**Table 1**); 640 (65%) received a renal transplant. The majority were male (59%) and white (87%). Mean age at waitlisting was 50.6 (±16.3) years. Among those who had a renal transplant, the mean age at transplant was 48.1 (±16.7) years.

Mean follow-up time was 2.8 years. During follow-up, 15 non-fatal MIs, 39 non-fatal CVAs, 13 fatal MIs, and 4 fatal CVAs occurred. In total, there were 68 CVD events. The incidence of a CVD event during follow-up was 13.8/1,000 person-years and 53.0/1,000 person-years in the group that did and did not receive a transplant, respectively. In fully-adjusted analyses, transplanted patients had a 70% lower risk of a CVD event compared to those who remained on the waitlist (HR 0.30, 95% CI 0.24-0.38). Our findings remained consistent when analyzing each CVD event individually in unadjusted analyses, accounting for the competing risk of death and other CVD events: non-fatal CVA (HR 0.34, 95% CI 0.27-0.43), non-fatal MI (HR 0.34, 95% CI 0.27-0.43), fatal CVA (HR 0.35, 95% CI 0.27-0.44), and fatal MI (HR 0.35, 95% CI 0.28-0.44).

Conclusion: In this nationwide study of ESRD due to GPA, renal transplantation was associated with a significantly reduced risk of non-fatal and fatal CVD events. Our findings highlight the importance of identifying barriers to transplantation in this patient population. Additionally, evaluating management strategies to reduce the risk of CVD events in patients on the waitlist will likely improve survival.

Values are expressed as number (percentage) or median (range). BVAS, Birmingham Vasculitis Activity Score; ENT, ear nose throat; FFS, Five Factor Score; MPO, myeloperoxidase; PR3, proteinase 3.

Background/Purpose: Studies addressing the epidemiology of ANCA-associated vasculitides (AAV) in different countries reported various prevalence rates and suggested that incidence may have increased over the past 30 years. Environmental factors may play an important role in the development of AAV. Exposure to silica, one of the strongest environmental substances causing overall autoimmunity, has particularly been associated with a higher risk of developing AAV. In the present work, we report the prevalence of granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and renal limited vasculitis (RLV) in Alsace, a French Northeast region, and demonstrated a geospatial association between these diseases and quarries leading to crystalline silica exposure.

Methods: We performed a capture–recapture analysis using three separate sources : 1) hospital records from departments of medical specialties that were likely to diagnose AAV, 2) ANCA positivity in publicly-funded reference immunology laboratories, and 3) the database from the French National Health Insurance System. A case was included if the patient was alive and resided in Alsace on January 1, 2016, and fulfilled either the ACR classification criteria for GPA, either the Chapel Hill Consensus Conference CHCC 2012 revised definition of systemic vasculitides for both GPA and MPA. The European Medicines Agency (EMA) algorithm was used to distinguish GPA and MPA. RLV was defined as pauci-immune glomerulonephritis without evidence for extrarenal disease. Capture-recapture was used to estimate the number of cases missed by any of the sources and therefore the total number of cases. The spatial association between the number of cases and the number of quarries in each administrative entity (French “communes”) was assessed using geographical weighted regression.

Results: 910 potential eligible cases were identified. After exclusion of duplicates and non-matching demographic or medical criteria cases, 185 patients were included from the three sources (Figure 1). 120 were classified as GPA, 35

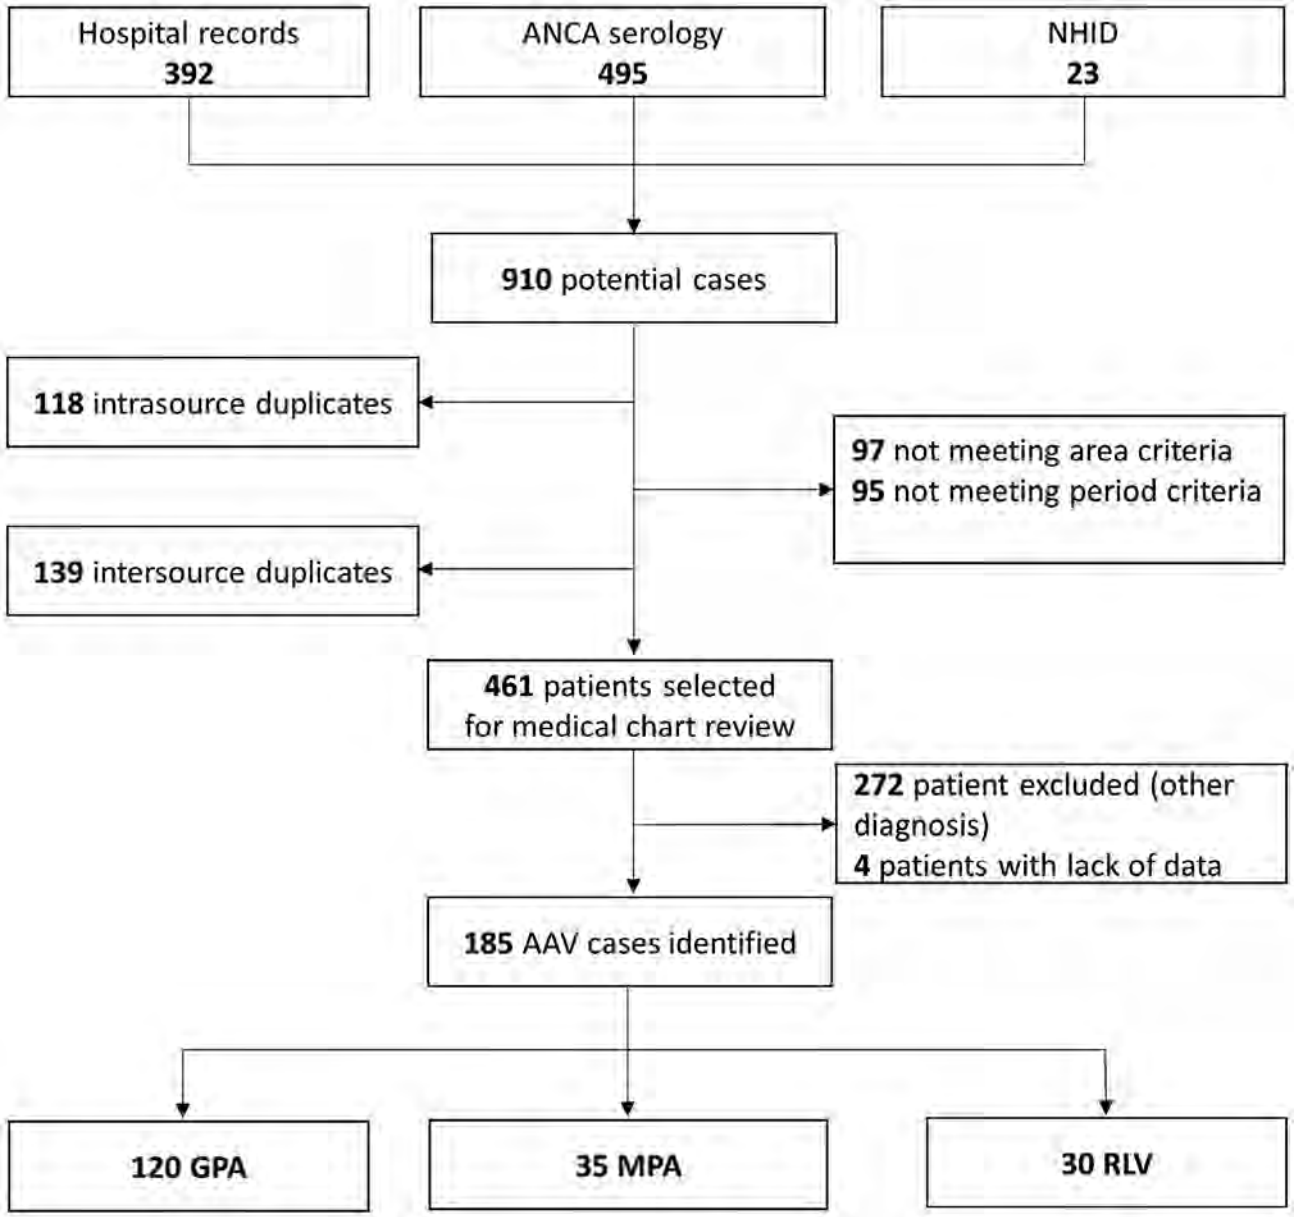

Figure 1. Flow chart of AAV cases identifications. AAV, ANCA-associated vasculitis; GPA, granulomatosis with polyangeitiis; MPA, micropolyangeitiis; NHID, National Health Insurance database; RLV, renal-limited vasculitis.

as MPA, 30 as RLV (Table 1). Capture-recapture estimated the number of cases missed by any source to 6.4 (95%CI 3.6-11.5), and the 2016 estimated prevalence in Alsace was 65.5 cases per million inhabitants (95%CI 47.3-93.0) for GPA, 19.1 (95%CI 11.3-34.3) for MPA, and 16.8 (95%CI 8.7-35.2) for RLV. This GPA prevalence was two times higher than that estimated in a North-eastern suburb of Paris in 2003. Geographical weighted regression models demonstrated a significant spatial association between presence of quarries and GPA cases ($p = 0.039$) but not MPA or RLV (Figure 2).

Conclusion: In a French region with a high density of extraction sites, the high prevalence of GPA and the spatial association between quarries and GPA supports the role of specific environmental etiologic factors. Further studies evaluating type and duration exposure should investigate the link between silica and AAV development.

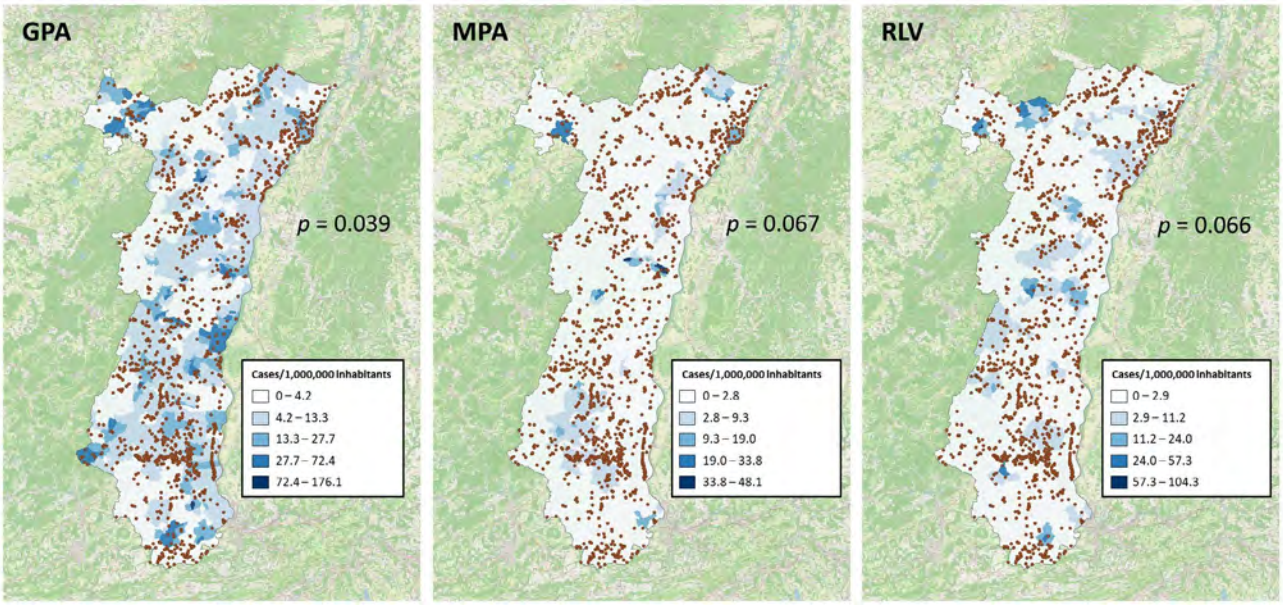

Figure 2. Spatial association between GPA cases and quarries in Alsace, France. Spatial association between the normalized prevalence of GPA, MPA and RLV (shown as the prevalence per 1,000,000 inhabitants with spatial Bayesian smoothing using Jenks natural breaks) and localization of quarries in Alsace, France.

ANCA titres at 12 months

Background/Purpose: EGPA is a small vessel vasculitis characterized by the presence of tissue eosinophilia, necrotizing vasculitis and granulomatous inflammation[1]. In the randomized, placebo-controlled MIRRA trial for relapsing and refractory EGPA, adjuvant therapy with 300mg anti-IL5 mAB Mepolizumab [MEPO], accrued longer times in remission, reduced steroid exposure and reduced relapse rates[2]. The aim of the study was to analyze the longer term outcome for EGPA patients who received MEPO monthly for 18 months [M] and beyond, at 100mg dosage.

Methods: This retrospective, descriptive study analyzed 13 patients with EGPA, who received 100mg s/c of MEPO therapy monthly. Time points of assessment included MEPO commencement [M0], month 12 [M12] and ≧ month 18 [M ≧ 18].

Results: This study demonstrates that anti-IL5 therapy serves as a favorable model for steroid minimization in EGPA, with an overall 50% reduction in steroid dosage. Adjuvant conventional immunosuppressants were stopped in 3 patients, and commenced in two. By 12 months, ANCA serology normalized in all four positive patients, BVAS reduced [n=13, mean±SD, 7.3±6.2 M0 to 2.23 ±1.69 M12], along with reduction in asthma Control questionnaire [n=5, mean ± SD, 2.92 ±1.27 M0 to 2.23±1.69 M12]. Well tolerated, at M≥18, anti-IL5 therapy demonstrated considerable clinical benefit, with 12 patients [92.3%] continuing anti-IL5 therapy beyond 18 months. Renal function was preserved. One patient had MEPO switched to Rituximab to treat both EGPA and new onset rheumatoid arthritis. Three patients were switched to alternative anti-IL5 therapies, benralizumab (x2) and Reslizumab (x1).

Conclusion: The relapsing nature of EGPA places a potential dependency of therapy on steroids, underscoring the importance of pathway specific biologics to minimize exposure, prevent tissue damage and ensure early response to therapy. There was a 50% reduction in steroid dosage in this study, with longer-term anti-IL5 therapy continued in 12/13 patients due to clinical benefits achieved. Adjuvant immunotherapy is well tolerated and reduced in some cases.

GCA, giant cell arteritis; IQR, interquartile range; IV, intravenous; N/A, not applicable; qw, every week; q2w, every 2 weeks; SC, subcutaneous; TAB, temporal artery biopsy; TCZ, tocilizumab.
*The SC TCZ qw and q2w treatment arms of the GiACTA trial were counted as separate studies.
†The unweighted mean proportion was calculated by calculating the proportion for each study individually and then averaging studies. The unweighted mean was calculated by computing the mean of individual reported study means.
‡The weighted population mean proportion or weighted population mean was estimated by adjusting the mean in each case for the number of patients in each study.
§Not all patients undergo TAB, but the number of patients who did undergo TAB was not known for each study; therefore, the proportion of abnormal TAB was underestimated.
‖Methylprednisolone 1000 mg IV was converted to 1250-mg/day equivalent oral prednisone dose. Patients who reported taking 0 mg of prednisone are not included in the summary statistic calculations.

Background/Purpose: Tocilizumab (TCZ) has been proven to be safe and effective for the treatment of giant cell arteritis (GCA) in 2 randomized controlled trials; however, data from additional types of studies provide valuable information related to the treatment of GCA with TCZ. The objective of this study was to review and analyze efficacy and safety data for TCZ in GCA based on peer-reviewed publications to date.

Table 2. Summary of Remission, Relapse and Adverse Events

	Across GCA Studies*; Unweighted† (n = 36 studies)	Weighted‡ Population Mean (n = 519 patients)
Percentage of patients in investigator-defined remission at the end of the study§		
N	35	411
Mean (SE) [95% CI]	86.3 (4.3) [77.6 to 94.9]	79.3 (6.0) [67.2 to 91.4]
Percentage of patients who relapsed while receiving TCZ‖		
N	31	39
Mean (SE) [95% CI]	2.6 (1.3) [−0.18 to 5.31]	12.0 (4.5) [2.8 to 21.2]
Percentage of patients who relapsed after TCZ discontinuation¶		
N	20	41
Mean (SE) [95% CI]	26.4 (7.8) [10.1 to 42.7]	14.8 (5.8) [2.7 to 26.9]
Percentage of patients receiving no steroids at the end of follow-up		
N	31	170

Percentage of patients with SAEs after TCZ initiation		
N	35	72
Mean (SE) [95% CI]	14.0 (4.1) [5.5 to 22.4]	14.3 (1.3) [11.7 to 17.0]

CRP, C-reactive protein; ESP, erythrocyte sedimentation rate; GCA, giant cell arteritis; qw, every week; q2w, every 2 weeks; SAE, serious adverse event; TCZ, tocilizumab.
*The subcutaneous TCZ qw and q2w treatment arms of the GiACTA trial were counted as separate studies.
†The unweighted mean proportion is calculated by calculating the proportion for each study individually and then averaging studies. The unweighted mean was calculated by computing the mean of individual reported study means.
‡The weighted population mean proportion or weighted population mean was estimated by adjusting the mean in each case for the number of patients in each study.
§Investigator-defined remission included absence of signs and symptoms and normal acute-phase reactant levels (n = 13 [36%]); normal acute-phase reactant levels (n = 5 [14%]), absence of signs and symptoms (n = 4 [11%]); absence of signs and symptoms, normal acute-phase reactant levels and glucocorticoid taper (n = 4 [11%]); normal imaging and acute-phase reactant levels (n = 3 [8%]); absence of signs and symptoms and normal imaging (n = 2 [6%]); glucocorticoid taper and normal acute-phase reactant levels (n = 2 [6%]); absence of signs and symptoms and glucocorticoid taper (n = 1 [3%]); patient global assessment (n = 1 [3%]) and missing (n = 1 [3%]).
‖Investigator-defined relapse included recurrence of signs and symptoms and/or increase/re-increase in acute-phase reactant levels (n = 14 [38.9%]); recurrence of signs and symptoms (n = 6 [16.7%]); recurrence of signs and symptoms and inability to taper glucocorticoids (n = 3 [8.3%]); signs and symptoms, raised acute-phase reactant levels and active large-vessel vasculitis on positron emission tomography/computed tomography upon decrease in the prednisone dose (n = 1 [2.8%]); worsening or emergence of ≥ 2 of the following: signs and symptoms, increased erythrocyte sedimentation rate or C-reactive protein levels (CRP), polymyalgia rheumatica signs and symptoms, large-vessel vasculitis signs and symptoms (n = 1 [2.8%]); worsening or recurrence of clinical symptoms, increase in CRP levels attributable to vasculitis; need for glucocorticoid and/or immunosuppressant (n = 1 [2.8%]) and missing (n = 10 [27.8%]).
¶Data on follow-up of patients after TCZ discontinuation were not available. Thus, the estimate of the proportion of patients who relapsed after discontinuation of TCZ is potentially biased.

Methods: A systematic literature review was conducted according to the PRISMA guidelines. Publications were retrieved from the MEDLINE, Embase, Cochrane, Scopus and Web of Science databases. Publications of clinical trials and retrospective or prospective observational studies (April 11, 2005-October 8, 2019) including patients with GCA (classified based on ACR criteria and/or positive biopsy vs imaging) treated with TCZ and reporting a measure of efficacy were eligible for inclusion. Extracted data included year of publication, year(s) when the study was conducted, number of patients with GCA, method of GCA diagnosis, age and sex, TCZ treatment details (dose, route of administration, frequency, duration), clinical outcome (remission, relapse), serious adverse events (SAEs) following treatment

with TCZ, corticosteroid dose before and following TCZ initiation and imaging data following TCZ treatment. Results are presented for the studies (unweighted) and as the weighted population mean. Unweighted mean proportions were calculated as the average of the proportions reported from each study; unweighted means were calculated by computing the mean of individual reported study means. The weighted population proportion was estimated by calculating the total number of patients achieving an outcome and dividing by the total number of patients in all of the studies. The weighted population mean was equivalent to the sum of the individual patient's outcome values divided by the total number of patients in all of the studies.

Results: The search retrieved 664 references; 55 full-text articles were reviewed for eligibility, and 36 studies were included in the meta-analysis (**Figure 1**); the once-weekly and every-2-weeks subcutaneous (SC) TCZ arms of the GiACTA trial were counted as separate studies. A total of 519 patients were included. The median (IQR) duration of treatment with intravenous and SC TCZ was 26.0 (20.0-37.3) and 52.0 (26.0-52.0) weeks, respectively, across all studies in the unweighted analysis and 25.8 (20.8-41.9) and 38.9 (32.4-45.5) weeks in the weighted analysis (**Table 1**). The mean (SE) proportion of patients achieving investigator-defined remission at the end of the study was 86.3% (4.3%) and 79.3% (6.0%) in the unweighted and weighted analyses, respectively (**Table 2**). The mean (SE) proportion of patients who relapsed while receiving TCZ was 2.6% (1.3%) and 12.0% (4.5%) in the unweighted and weighted analyses, respectively. The median prednisone dose at the end of the study was < 5 mg/day, and the mean proportion of patients with SAEs after TCZ initiation was ≈ 14.0%.

Conclusion: A high proportion of patients with GCA treated with TCZ were in investigator-defined remission at the end of the study across all studies analyzed. These meta-analysis findings add to the evidence of the efficacy and safety of TCZ in GCA.

Abstract Number: 1429

An Evaluation of Real World Use of Biologics in Rare Systemic Vasculitides During Routine Clinical Care in the US

Kathryn Starzyk[1], Kimberly Milberg[1], Ashish Deshpande[1] and Gary Curhan[1], [1]OM1, Inc, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The mainstay of treatment for vasculitis has been corticosteroids and other cytotoxic and immunosuppressive medications (e.g., cyclophosphamide, methotrexate) to promptly achieve and maintain remission. Novel treatment options for giant cell arteritis and some forms of polyangiitis have recently become available, however unmet need remains. The purpose of this study is to explore the real world use of biologic agents with different mechanisms of action in patients with Behçet's disease and other rare systemic vasculitides, despite a paucity of regulatory-approved options.

Methods: The OM1 Real World Data Cloud (OM1, Boston, MA), which collects, links and leverages structured and unstructured data from electronic medical records (EMR), claims and other sources in an ongoing and continuously

Abbreviations: Behcets disease (BD), Takayasu arteritis (TA), polyarteritis nodosa (PAN), mixed cryoglobulinemia (MC), granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) and microscopic polyangiitis (MPA)

*At the time of this analysis, rituximab was indicated for adult patients with MPA and GPA forms of vasculitis only and mepolizumab was indicated for adult patients with EGPA

updating manner in the US, was used for the analysis. Use of anti-TNFs, anti-IL-6 agents and other select biologic disease-modifying anti-rheumatic drugs (DMARDs) and monoclonal antibodies between January 2013 and April 2020 were evaluated in patients diagnosed with Behcet's disease (BD), Takayasu's arteritis (TA), polyarteritis nodosa (PAN), mixed cryoglobulinemia (MC), granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) and microscopic polyangiitis (MPA). For the DMARDs, patients with a documented diagnosis of one or more FDA-approved indications for each DMARD were excluded. By excluding patients with comorbidities (e.g., rheumatoid arthritis) included in the marketed indications for each agent, some patients for whom the agent was specifically used for vasculitis may have been omitted. Patients may have been treated with more than one biologic of interest.

Results: Overall, > 50,000 patients diagnosed with the vasculitides of interest were identified, with GPA and BD the most common (Table 1). Across the conditions of interest, the majority were female (62.7%). A small proportion of pediatric patients were identified. Amongst patients with BD, anti-TNFs were the most commonly used biologic (n=532, 4.4% of BD patients) followed by rituximab. While rituximab was frequently used in its indicated forms (GPA and MPA), it was also used across the other forms of vasculitis. Anti-TNF and anti-IL-6 use was noted in 140 (4.0%) and 64 (1.8%) of TA patients, respectively; rituximab was less commonly used. The other DMARDs evaluated were rarely observed.

Conclusion: If left untreated (or under-treated), systemic vasculitides can result in substantial multisystem morbidity. As the proinflammatory activity in the vasculitides involves many aspects of the immune system, it remains unclear

which mechanism of action is best suited in an individualized treatment setting. Harnessing real world experience may help inform clinical practice, including decisions to switch therapies, and clinical trial design.

Abstract Number: 1430

The Role of Lung Biopsy in Pediatric ANCA-associated Vasculitis

Edouard Sayad[1], Tiphanie Vogel[1], David Moreno McNeill[1], Nahir Cortes-Santiago[1], David Spielberg[1], Kalyani Patel[1] and Manuel Silva Carmona[1], [1]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anca-associated vasculitis (AAV) is characterized by vascular inflammation in multiple organs. The diagnosis can be made clinically using a number of different criteria. The lungs are commonly affected, with a broad range of manifestations described including cough, dyspnea, respiratory failure, and pulmonary hemorrhage. Multiple pulmonary histopathologic patterns have been described in AAV, which requires invasive tissue sampling through lung biopsy and is not without risk. Here, we have reviewed the histopathologic findings in a series of pediatric AAV, and discuss procedural outcomes and yield of lung biopsies in this population.

Methods: After IRB approval, we performed a retrospective chart review of all patients < 18 years of age presenting to our institution with a diagnosis of AAV who underwent lung biopsy. We reviewed histopathologic features, serologies, timing of biopsy, and complications.

Results: 14 patients met inclusion criteria, 9 patients with a diagnosis of microscopic polyangiitis (MPA), and 5 patients with granulomatosis with polyangiitis (GPA). 10/14 (71%) of the biopsies were performed between 2009 and 2013, and only 4 (29%) from 2015 to present. 13/14 patients required initial admission on presentation for respiratory symptoms. 11/14 required respiratory support. All patients had abnormal chest imaging at presentation. 11/14 had concerns for pulmonary hemorrhage. All 5 patients with GPA had an elevated serine protease-3 (PR3). Mean PR3 level was 703 AU/mL (range 49-1353 AU/mL). Myeloperoxidase (MPO) was elevated in all MPA patients. Mean MPO level was 109 AU/mL (range 24-186 AU/mL). The indication for biopsy was to confirm the diagnosis prior to initiating therapy in 11 patients (78%), as part of an infectious work-up in 2 (14%), and as part of an interstitial lung disease work-up in 1 (7%). 9/14 (64%) biopsies had findings consistent with a diagnosis of AAV, 4/9 (44%) of the MPA patients compared to 5/5 (100%) of the GPA patients. The most common findings on histopathology in GPA patients were vasculitis (100%), granulomatous changes (20%), and alveolar hemorrhage (60%). Only 44% of MPA patients had signs of vasculitis, but 100% showed signs of alveolar hemorrhage. The main post-procedure complication was pneumothorax, in 28% of patients.

Conclusion: We found that lung biopsy had a higher diagnostic yield in GPA compared to MPA. On histology, confirmation of vasculitis and pulmonary hemorrhage were the most common findings. In our cohort, the diagnosis of AAV was able to be made with clinical features and a positive serology in all cases. Therefore, considering the risks associated with obtaining a lung biopsy, they should not be routine and reserved for uncertain cases.

Abstract Number: 1431

Interstitial Lung Disease in Patients with ANCA Associated Vasculitis – a Prospective Single Centre Study

Alojzija Hocevar[1], Katja Perdan Pirkmajer[1], Matija Tomsic[1] and Ziga Rotar[1], [1]University Medical Center Ljubljana, LJUBLJANA, Slovenia

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, an association between anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and interstitial lung disease (ILD) has been uncovered. We aimed to determine the rate of ILD in our AAV patient cohort and to compare clinical characteristics of AAV patients with and without associated ILD.

Characteristic	ILD-AAV (13)	non-ILD- AAV (89)	p	Characteristic	ILD-AAV (13)	non-ILD-AAV (89)	p
Female	46.2	62.5	0.225	ENT	0	59.6	<0.001
Age*	76 (67;77)	66 (55;77)	0.163	Heart	0	6.7	1.0
Smoking	61.5	38.2	0.137	GI tract	15.4	7.9	0.322
Fever	61.5	52.8	0.767	Kidney	53.8	59.6	0.767

Eye	0	27.0	0.035	a-PR3	7.7	46.1	0.013

Legend: * median (IQR)); ENT ear-nose-throat; GI gastrointestinal tract; PNS peripheral nervous system; CNS central nervous system;

Table 1. Clinical characteristics of ILD-AAV and non-ILD-AAV group

Methods: We analysed medical records of prospectively diagnosed and followed AAV patients at our secondary/tertiary rheumatology centre between January 2010 and May 2020. The diagnosis of ILD was based on lung HRCT findings.

Results: During the observation period, we identified 102 incipient AAV patients (50 had granulomatosis with polyangiitis, and 52 microscopic polyangiitis). Thirteen (12.7%) patients had ILD (ILD-AAV group). 12/13 had usual interstitial pneumonia (UIP) pattern and 1/13 non-specific fibrosis on HRCT. ILD was diagnosed in tandem with AAV in 9/13 patients, and 9 months to 5 years prior to AAV in 4/17 patients. Characteristics of ILD-AAV, and non-ILD-AAV groups are presented in Table 1. ILD-AAV patients more commonly reported of weight loss, less frequently had ENT involvement, and were predominantly a-MPO ANCA positive (92.3%). Follow up data were available for 90 AAV patients (88.2%; 13 ILD-AAV and 77 non-ILD-AAV). During the median (IQR) follow up of 30.6 (11.4; 62.8) months, 5/13 (38.5%) ILD-AAV patients died, compared to 7 (9.1%) deaths registered in non-ILD-AAV group. The crude mortality rate evaluated by Cox proportional hazards regression was significantly higher for AAV-ILD group (HR 5.5 (95%CI 1.7-17.3), p=0.004).

Conclusion: In our incipient AAV cohort 13% of patients presented with ILD. The AAV patients with ILD had a higher mortality rate than the rest of the cohort.

Thyroid Disease in Patients with ANCA-Associated Vasculitis

Tanaz Kermani[1], David Cuthbertson[2], Simon Carette[3], Nader Khalidi[4], Curry L. Koening[5], Carol Langford[6], Carol McAlear[7], Paul Monach[8], Larry Moreland[9], Christian Pagnoux[10], Philip Seo[11], Ulrich Specks[12], Antoine Sreih[13], Kenneth Warrington[12] and Peter Merkel[13], [1]University of California Los Angeles, West Hills, CA, [2]University of South Florida, Tampa, [3]Division of Rheumatology, Mount Sinai Hospital and University Health Network, University of Toronto, Toronto, ON, Canada, [4]McMaster University, Hamilton, ON, Canada, [5]University of Utah, Salt Lake City, [6]Cleveland Clinic, Moreland Hills, OH, [7]University of Pennsylvania, Philadelphia, [8]Brigham and Women's, Boston, [9]University of Pittsburgh, Denver, CO, [10]Vasculitis Clinic, Canadian Network for Research on Vasculitides (CanVasc), Department of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [11]Johns Hopkins University, Baltimore, MD, [12]Mayo Clinic, Rochester, MN, [13]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior studies have found increased prevalence of thyroid disease in patients with ANCA-associated vasculitis (AAV), especially positive myeloperoxidase (MPO)-ANCA, but a majority of the patients in the studies had microscopic polyangiitis (MPA). The aim of this study was to evaluate the risk of thyroid disease between the different forms of AAV, and, to compare the clinical features of AAV in patients with and without thyroid disease.

Methods: Patients with the 3 forms of AAV (granulomatosis with polyangiitis (GPA), MPA and eosinophilic granulomatosis with polyangiitis (EGPA)) enrolled in a prospective, multicenter, longitudinal study were included. All patients were followed with standardized data collection. Information on thyroid disease was systematically collected. Logistic regression was used to evaluate the association of thyroid diseases with different clinical and laboratory variables.

Table 1: Characteristics of ANCA-associated vasculitis in patients with and without hypothyroidism.

Variable	With hypothyroidism, N= 145	Without hypothyroidism, N= 1170	OR* (95% CI)
Mean age±(SD), years	57.4 (14.03)	51.8 (15.9)	
Female sex, N (%)	113 (78%)	616 (53%)	
Clinical diagnosis			
GPA	93 (11)	773 (89)	1.10 (0.76, 1.61)
MPA	29 (17)	138 (83)	1.41 (0.89, 2.25)
EGPA	23 (8)	259 (92)	0.64 (0.40, 1.02)
ANCA status			
p-ANCA, N (%)	49 (33)	255 (22)	1.52 (1.03, 2.23)
c-ANCA, N (%)	54 (37)	525 (45)	0.87 (0.60, 1.25)
MPO, N (%)	61 (42)	282 (24)	1.89 (1.39, 2.76)
PR3, N (%)	59 (41)	598 (51)	0.79 (0.54, 1.14)
Negative, N (%)	21 (15)	223 (19)	0.69 (0.42, 1.14)

N=Number, OR=Odds ratio, CI=Confidence intervals, SD=standard deviation, GPA=granulomatosis with polyangiitis, MPA=microscopic polyangiitis, EGPA=eosinophilic granulomatosis with polyangiitis, p-ANCA=perinuclear ANCA, c-ANCA=cytoplasmic ANCA, MPO=myeloperoxidase, PR3=proteinase 3; *adjusted for age, sex

Results: The study included 1,315 patients with AAV, 55% female. Clinical diagnosis was GPA in 866 (66%), MPA in 167 (13%) and EGPA in 282 (21%). Mean age at entry into the cohort was 52.5 ±15.8 years. Thyroid disease was present in 163 patients (13%) including hypothyroidism in 145 (11%) and hyperthyroidism in 18 (1.4%). Women were more likely to have thyroid disease (OR 3.22, 95% CI 2.19, 4.75).

The age- and sex-adjusted risk of hypothyroidism by type of AAV and ANCA are in **Table 1.** Hypothyroidism was associated with positivity for p-ANCA or MPO, but not type of AAV (**Table 1**). Analyses in the subset of patients with GPA demonstrated that hypothyroidism was associated with MPO-ANCA positivity (OR 3.01, 95% CI 1.80, 5.02 compared to positive PR3) and p-ANCA (OR 2.32, 95% CI 1.27, 3.94 compared to c-ANCA).

The clinical features of AAV were compared between patients with and without hypothyroidism (**Table 2**). Patients with AAV and hypothyroidism had an increased risk of venous thrombosis.

Conclusion: This study confirms an association of hypothyroidism with p-ANCA/MPO in patients with AAV. Further strengthening this observation is the association of thyroid disease with MPO ANCA in the subset of patients with

Table 2: Comparison of organ involvement from ANCA-associated vasculitis in patients with and without hypothyroidism.

N=Number, OR=Odds ratio, CI=Confidence intervals, SD=standard deviation, GPA=granulomatosis with polyangiitis, MPA=microscopic polyangiitis, EGPA=eosinophilic granulomatosis with polyangiitis, p-ANCA=perinuclear ANCA, c-ANCA=cytoplasmic ANCA, MPO=myeloperoxidase, PR3=proteinase 3
** adjusted for age, sex, type of ANCA vasculitis and any ANCA positivity

GPA. Previously hypothesized mechanisms for this finding include homology between thyroid peroxidase antibodies and MPO, or, general loss of tolerance to peroxidases. The increased risk of venous thromboembolism in patients with AAV and hypothyroidism warrants further investigation and may be due to additional effects of hypothyroidism on endothelial dysfunction or hypercoagulability.

Thyroid Disease in ANCA-associated Vasculitis. a Population-based Study

Anna Wilding[1], Rona Smith[2], David Jayne[3], Mårten Segelmark[4] and Aladdin Mohammad[5], [1]Lund University, Staffanstorp, Sweden, [2]University of Cambridge, Cambridge, United Kingdom, [3]Department of Medicine, Vasculitis and Lupus Research Group, University of Cambridge, Cambridge, UK, Cambridge, United Kingdom, [4]Lund University, Lund, [5]Lund University, Lund, Sweden. Department of Medicine, Vasculitis and Lupus Research Group, University of Cambridge, Cambridge, UK, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A higher incidence of thyroid disease has been seen in patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). We aim to assess the incidence rate, patients' characteristics and predictors of thyroid disease in patients with AAV.

Methods: Patients were included from two well characterized cohorts of AAV: (i) a population-based cohort from Southern Sweden and (ii) a cohort from a specialized centre; the Vasculitis and Lupus clinic, Addenbrookes Hospital, Cambridge, UK. Diagnosis of AAV was confirmed by review of medical records and patients were classified into AAV disease phenotypes according to the European Medicines Agency Algorithm 2007. The medical records were reviewed to identify patients with thyroid disease. The diagnosis of thyroid disease was supported by clinical characteristics, laboratory data and medication history and in some cases histopathology and radiological findings when available. Demographics, laboratory and clinical data from the date of AAV diagnosis were collected. Cases

Table 1. Characteristics of patients with and without thyroid disease

	No thyroid disease n=515	All Thyroid disease n=134	p
Sex, Female, n (%)	237 (46)	94 (70)	<0.001
Diagnosis GPA/MPA/EGPA	253/242/20	69/59/6	0.8
PR3-ANCA +, n (%)	249 (48.3)	54 (40.3)	0.2
MPO-ANCA +, n (%)	215 (41.7)	69 (51.5)	0.003

PR3-ANCA+	0.42 (0.18-0.96)	0.04	0.32 (0.09-1.04)	0.05
S-creatinine**	1.03 (0.81-1.31)	0.78	1.12 (0.87-1.44)	0.36

*Age increments by 10 years; **S-creatinine increments by 100 μmol/l

of thyroid diagnosis after AAV onset were included in incidence and predictor analyses. Patient-years of follow up were calculated from AAV diagnosis to the earliest of thyroid diagnosis, death or end of study (Southern Sweden 01/ Jan/2019, Cambridge 01/Oct/2019. Vasculitis disease activity was assessed by the Birmingham Vasculitis Activity score. Irreversible organ damage was evaluated according to the Vasculitis Damage Index. Cox regression analysis was employed to study predictors of thyroid disease. The following variables from the time of AAV diagnosis were studied: Age, sex, ANCA specificity (proteinase-3 and myeloperoxidase) and serum creatinine.

Results: A total of 649 patients were included in this study (Lund = 325, Cambridge. = 324). 134 (21%) patients were diagnosed with thyroid disease, 29 (4.5%) were diagnosed after the onset of AAV. Table 1 summarizes clinical and outcome characteristics of all patients. Thyroid disease was more common in females and patients positive for MPO-ANCA. The incidence of all thyroid disease rate per 100 000 person-years of follow-up after AAV diagnosis was 608 for the whole study population, 781 in Lund-Sweden and 478 in Cambridge, UK, Table 2. The incidence rate for hypothyroidism was 344 /100 000 person-years and for hyperthyroidism 144/100 000 person-years. In Cox regression analysis a positive PR3-ANCA was associated with a lower risk of being diagnosed with thyroid disease even after adjustment for age and sex, Table 3.

Conclusion: After an AAV diagnosis the incidence of thyroid disease is higher than in the general population (incidence of hyperthyroidism in Sweden 25.8-43/100 000 person-years and incidence of hypothyroidism in UK, up to 297/100 000 person-years(1)). PR3-ANCA positivity is associated with less risk for thyroid disease after an AAV diagnosis, this is also true after adjustment for age and sex.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Vasculitis – ANCA-Associated Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Vasculitis of the peripheral nervous system is seen mainly in systemic vasculitis involving small and medium sized vessels and in cases of single-organ vasculitis affecting the peripheral nerves. There are no pathognomonic tests to confirm a diagnosis of vasculitis other than histopathological findings of vasculitis affecting the vasa nervorum. However, the diagnostic yield of biopsies from affected peripheral nerves and the correlation of pathological confirmation with clinical features is largely unknown. The aims of this study were to (i) characterize patients undergoing sural nerve biopsy in the search of vasculitis, (ii) estimate the diagnostic yield, (iii) correlate biopsy findings with demographic, laboratory and clinical parameters, (iv) estimate the rate of surgical complications and (v) to study possible predictors of a positive biopsy.

Methods: A retrospective cohort study was conducted at Skåne University Hospital (Sweden) and Addenbrooke's Hospital (Cambridge, United Kingdom). Patients that underwent sural nerve biopsy between 2005 and 2019 in the region of Skåne were identified by search in the regional pathology database and by search on the surgical procedure code in the clinical register. Patients that underwent sural nerve biopsy between 2015-2019 at Addenbrooke's Hospital were identified by search in the local pathology database. A structured review of the medical case records and pathology reports was performed. Patients with a suspected vasculitis were included in the study. Histopathologic biopsy findings were recorded as definite, probable or non-vasculitis in accordance with validated guidelines. Definite and probable histopathologic biopsy findings were regarded as a positive biopsy. Surgical complications were recorded when available in the medical case record.

Results: Out of 94 identified patients, vasculitis was diagnosed in 40 (43%) patients based on findings in the sural nerve biopsy (definite =14, probable =26). (Table 1) A positive biopsy finding was associated with ANCA-positivity (p=0.029), a higher white blood cell count (p=0.007) and organ involvement other than from the nervous system at the time of the biopsy (p=0.039). A positive biopsy finding was associated with a longer median length of the biopsy sample (p=0.042). The biopsy sample length was 30 mm (IQR: 18-42.5) and 21 mm (IQR: 14-33) for positive and negative biopsies respectively. (Table 2) However, no parameter was shown to be an independent predictor of a positive biopsy after a multivariate adjustment of the regression model. Post-surgical follow-up was available in 60 patients with a reported sural nerve surgical complication rate of 17%. The most common presentations were wound infection (10%), wound dehiscence (7%), and delayed wound healing (5%). A concomitant muscle biopsy was performed in 11 patients. None of the muscle biopsies added to the diagnostic yield. (Table 1)

	All patients (n=94)
Demography	
Cambridge, Skåne	60 (64%), 34 (36%)
Age at biopsy, years	59 (SD: 15.05; range: 20-84)
Male sex	52 (55%)
Duration of symptoms prior to biopsy, months [1]	10 (IQR: 4.75-24)
Organ involvement	
BVAS [a], (median) [2]	8 (IQR: 6-11)
Laboratory	
White blood cell count, $x10^9/L$ [3]	8.75 (IQR: 7.4-12.9)
Erythrocyte sedimentation rate, mm/h [4]	28 (IQR: 9-43)
C-reactive protein, mg/L [5]	6 (IQR: 1.1-18)
ANCA-positivity, ELISA [6]	20 (28%)
Neurophysiology	
Pure sensory neuropathy [7]	14 (17%)
Pure motor neuropathy [7]	4 (5%)
Sensorimotor neuropathy [7]	62 (76%)
No neuropathy [7]	2 (2%)
Axonal neuropathy [8]	64 (74%)
Asymmetric pattern [b, 9]	42 (62%)
Multifocal mononeuropathy [c, 10]	30 (33%)

Prognostic Factors for Mononeuritis Multiplex Associated with ANCA-associated Vasculitis

Yutaro Hayashi[1], Satoshi Hama[2], Keisuke Izumi[2], Mari Ushikubo[1], Misako Konishi[3], Yutaka Okano[4] and Hisaji Ohshima[2], [1]Tokyo medical center, Tokyo, Japan, [2]Department of Connective Tissue Diseases, National Hospital Organization Tokyo Medical Center, tokyo, Japan, [3]Tokyo medical center, toukyouto Meguroku, Japan, [4]Department of Connective Tissue Diseases, National Hospital Organization Tokyo Medical Center, Kawasaki, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) sometimes presents mononeuritis multiplex which worsens the prognosis and activity of daily living in patients. This study aimed to determine theprognostic factorsand clinical feature of mononeuritis multiplex associated with AAV.

Methods: Consecutive patients with AAV who visited Tokyo Medical Center between April 2006 and February 2020 were included in this study. We examined the following clinical features: prevalence of neuropathy, age of onset, sex, the worst blood test values before the initial therapy (WBC, Eo, MPO-ANCA, PR3-ANCA, and CRP levels), MMT score of 20 muscles (Max 100 points), and time (days) from the initial neuropathy to the initial induction therapies. Fisher's exact test, univariate analysis of variance, and logistic regression analysis were applied for evaluation of the risk.

Results: A total of 89 patients with AAV were identified. Among them, 19 patients had eosinophilic granulomatosis with polyangiitis (EGPA) (8 males and 11 females, mean age 59.3 ± 22.0), 9 patients had granulomatosis with polyangiitis (GPA) (0 males, 9 females, meanage 75.6 ± 3.9), and 61 patients had microscopic polyangiitis (MPA) (17 males, 44 females, mean age 78.2 ± 1.5). Of the 89 AAV patients, 26 had sensory neuropathy (15/19 EGPA (78.9%), 11/61 MPA (18.0%), and 0/9 GPA (0%)). Motor neuropathy was observed in 19 patients (EGPA 14/19 (73.7%), MPA 5/61 (8.2%), GPA 0/9 (0%)). 15 patients had both sensory and motor neuropathies (EGPA 12/19 (63.2%), MPA 3/61 (4.9%), GPA 0 (0%)).In patients with both sensory and motor neuropathy, sensory impairment preceded in all cases. AmongThe time from initial sensory neuropathy to initial induction therapy in patients with and without motor neuropathy was 34 ± 10.1 days and 30 ± 10.8 days (p = 0.77) respectively. Also, when comparing those who were treated within 3 days from the onset of motor neuropathy with those who were treated later, MMT score two weeks after the start of treatment were 92.15 ± 1.47 vs. 91.25 ± 2.65 (p = 0.77).

Between the patients with EGPA with and without sensory neuropathy, there were no significant differences in the following: highest WBC (19620.0 ± 2082.6 vs. 19350.0 ± 4033.5 cells/uL (p = 0.953)), highest Eo (10790.6 ± 1774.8 vs 12440.8 ± 3436.9 cells/uL (p = 0.6750)), and highest CRP levels (4.46 ± 0.96 vs 2.70 ± 1.85 mg/dL (p = 0.41)) before the initial therapy. On the other hand, comparing the EGPA patients with and without motor neuron disorder, CRP levels were significantly higher in those with motor impairment than those without (WBC 20978.6 ± 2049.8 vs. 15600.0 ± 3429.9 cells/uL (p = 0.20); Eo 12213.4 ± 1775.5 vs. 8127.0 ± 2971.0 cells/uL (p = 0.25); CRP 5.13 ± 0.89 vs. 1.20 ± 1.48 mg/dL (p = 0.04)). And in patients with motor neuropathy, the decrease in MMT score was significantly correlated with the worst levels of CRP (p = 0.001) while the decrease was not correlated with the other blood tests. In similar analyses of patients with MPA, there were no significant findings.

Conclusion: Worst CRP levels before the initial therapy are a poor prognosis factor for motor neuropathy in patients with EGPA. EGPA patients with high CRP levels need to be paid more attention to because of possible development of motor neuropathy.

Incidence Rate, Predictors and Outcome of Stroke in Patients with ANCA Associated Vasculitis - A Population-based Study

Dennis Tabakovic[1], Rona Smith[2], David Jayne[3] and Aladdin Mohammad[4], [1]Lund University, Lund, Skane Lan, Sweden, [2]University of Cambridge, Cambridge, United Kingdom, [3]Department of Medicine, Vasculitis and Lupus Research Group, University of Cambridge, Cambridge, UK, Cambridge, United Kingdom, [4]Lund University, Lund, Sweden. Department of Medicine, Vasculitis and Lupus Research Group, University of Cambridge, Cambridge, UK, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To study the incidence rate, predictors and outcome of stroke in patients with ANCA-associated vasculitis (AAV) within a defined population in southern Sweden.

Table 1 Standardized incidence ratio (SIR) of stroke in AAV-patients

	Observed	Expected	SIR	95% CI
All patients	20	14.2	1.41	(0.86-2.18)
<65 years	8	2.5	3.23	(1.39-6.36)
>65 years	12	11.7	1.03	(0.53-1.79)
Male	11	8.4	1.32	(0.66-2.36)
Female	9	5.8	1.55	(0.71-2.94)
GPA	11	7.9	1.40	(0.70-2.51)
MPA*	8	5.8	1.37	(0.59-2.70)
PR3-ANCA*positive	9	6.9	1.31	(0.60-2.49)
MPO-ANCA positive	10	6.5	1.54	(0.74-2.84)

SIR: Standardized incidence ratio, GPA: granulomatosis with polyangiitis, MPA: microscopic polyangiitis, PR3: proteinase-3, MPO: myeloperoxidase, ANCA: Antineutrophil cytoplasmic antibody. *1 patient had a diagnosis of Eosinophilic granulomatosis with polyangiitis and was ANCA-negative. This patient was therefore not included in the SIR-calculation of stroke in GPA/MPA and PR3/MPO-positive patients.

Table 2 Predictors of stroke in patients with ANCA associated vasculitis using Cox-regression analysis

	Univariate analysis		*Multivariate analysis*	
Predictors	**HR (95% CI)**	**P-value**	**HR (95% CI)**	**P-value**
Age at AAV diagnosis*	1.31 (0.94-1.81)	0.10	1.42 (0.97-2.08)	0.06
Sex, male	1.18 (0.49-2.86)	0.70	0.80 (0.31-2.06)	0.64
MPO-ANCA	1.35 (0.56-3.24)	0.50	0.52 (0.06-4.26)	0.54
PR3-ANCA	0.76 (0.31-1.89)	0.56	1.08 (0.12-9.26)	0.94
Platelet count**	1.05 (1.00-1.11)	0.04	1.06 (1.01-1.12)	0.01
MucMembeyes	2.84 (0.95-8.54)	0.06	3.14 (0.95-10.30)	0.06

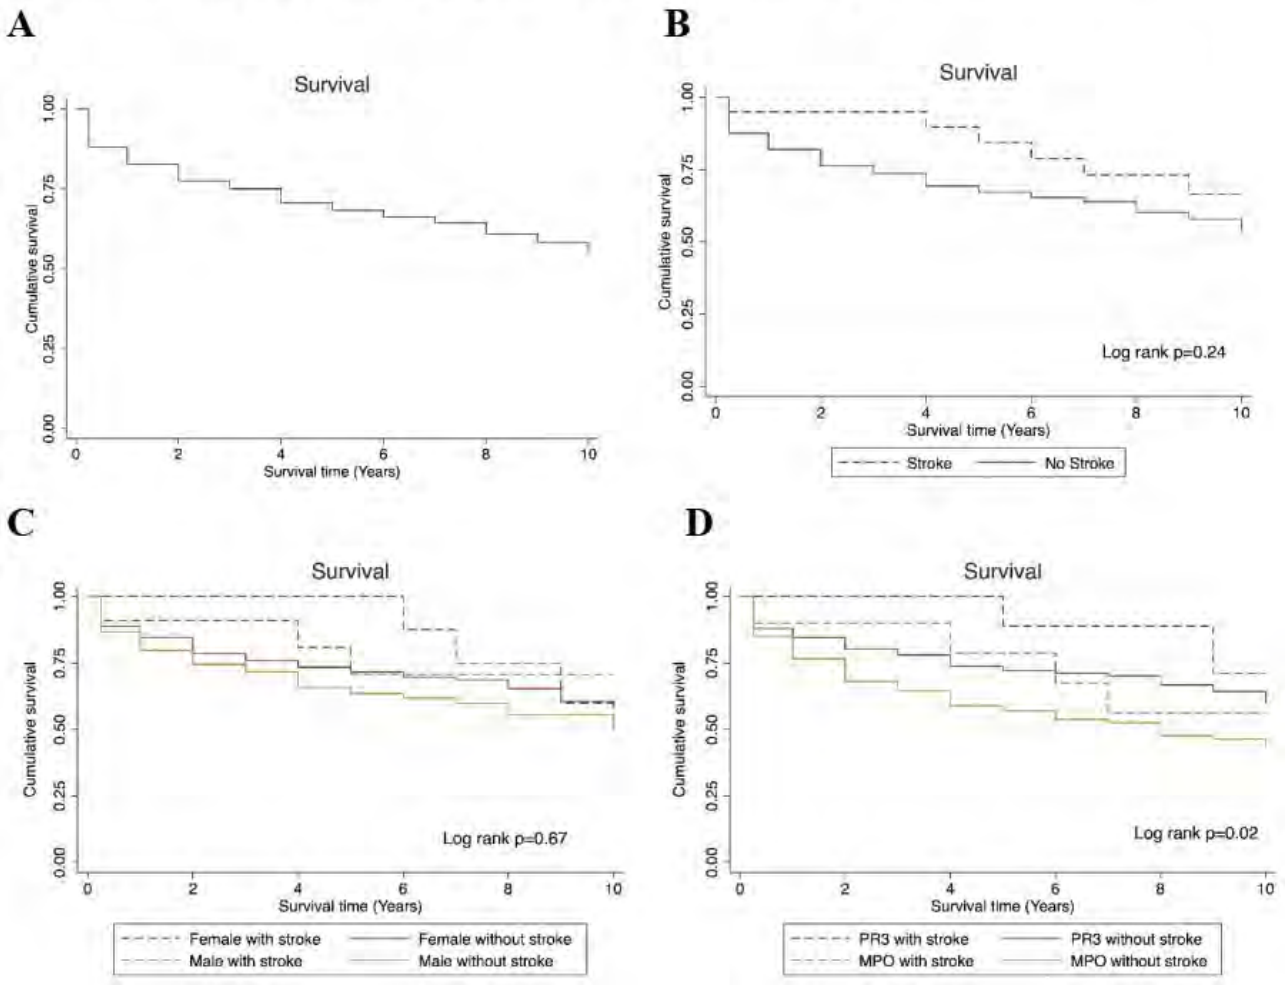
*: age increased by 10 years, **: platelets increased by 20, PR3: Proteinase-3, MPO: Myeloperoxidase, ANCA: Antineutrophil cytoplasmic antibody, HR: Hazard ratio, Mucmembeyes: Mucocutaneous/eyes involvement. Hazard-ratios were calculated by using Cox-regression analysis. P-value of <0.05 was regarded as statistically significant.

Methods: The study included a total of 325 patients diagnosed with AAV within a defined geographical area in Sweden (1997-2016). The diagnosis and classification of AAV was confirmed by case record review using the European Medicines Agency (EMA) algorithm. To identify AAV cases with stroke, two sources were used: (i) The Swedish Stroke Register (Riksstroke): a national stroke register operated since 1994 which includes all cases of stroke diagnosed at stroke-units in Sweden , (ii) The Skåne healthcare register (SHR), an administrative local register of all healthcare services provided to the population in Skåne, was used to identify patients diagnosed at departments not specialized in stroke-care. Diagnosis of stroke for cases identified by the SHR were verified by case record review. From the Riksstroke register we identified 10 controls for each AAV-patient, matched for age, sex and years of stroke diagnosis. Incidence rate of stroke in AAV-patients was calculated per 1000 person-years of follow-up. The person-year was calculated from date of AAV-diagnosis to either date of stroke, death or end of study, December 2018. Using data from the Swedish background population, standardized incidence ratio (SIR) of stroke was estimated. Cox-regression analysis was utilized to investigate predictors of stroke in AAV.

Results: Out of 325 AAV-patients, 20 (6%) suffered a stroke during the follow-up period. The incidence rate of stroke in AAV was 9.7 per 1000 person-years (95% CI 5.5-14.0) and was highest within the first year after AAV-diagnosis,

Figure 1

Survival curves in AAV according to Kaplan–Meier analysis. **(A)** Overall survival in 325 patients with AAV. **(B)** Survival in stroke vs non-stroke patients (P=0.24). **(C)** Survival according to gender (P=0.67). **(D)** Survival according to ANCA-serology (P=0.02) AAV: ANCA associated vasculitis, ANCA: ANCA: Antineutrophil cytoplasmic antibody, PR3: proteinase-3, MPO: myeloperoxidase. Log-rank test was used to calculated differences between groups. P-value of <0.05 was regarded as statistically significant.



20.5 per 1000 person-years of follow-up (95% CI 4.1-36.9). Patients diagnosed with AAV at age < 65 years had 3.2-fold increased risk of stroke compared with background population (Table 1). Platelet count at AAV diagnosis was identified as an independent predictor of stroke (Table 2). There were no differences in survival rates or other outcome measures of stroke between AAV patients and their controls. While comparing AAV patients with and without stroke, a higher survival rate in PR3-positive patients compared to MPO-positive patients was observed (Figure 1).

Conclusion: Incidence rate of stroke in AAV is highest during first year after AAV diagnosis and significantly higher than that of the background population among patients younger than 65 years at AAV diagnosis. An elevated platelet count at AAV-diagnosis was able to predict an increased risk of stroke. Prophylactic treatment with antithrombotic and anticoagulant drugs to prevent stroke-occurrence requires further exploration.

Abstract Number: 1437

Measuring Disease Activity and Functional Status in Patients with Granulomatosis with Polyangiitis (Wegener's) (GPA)

Kinanah Yaseen[1], Isaac Briskin[1] and Rula Hajj-ali[2], [1]Cleveland Clinic Foundation, Cleveland, [2]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Variable association between vasculitis activity and patient reported outcomes was reported in small groups of Granulomatosis with polyangiitis (GPA) patients in the literature so far. In this study we evaluated the utility of PROMIS (Patient-Reported Outcomes Measurement Information System) as potential indirect tool for predicting disease activity in patients with GPA.

Methods: A retrospective chart review study in GPA patients who were seen two or more times at the Cleveland Clinic vasculitis center was conducted between July 2016 and March 2019 to compare disease activity and damage measured by BVAS-WG and VDI scores with PROMIS data. BVAS-WG activity and vasculitis damage index (VDI) scores were calculated at each visit where PROMIS data was obtained. Further, glucocorticoids dose, and immuno-

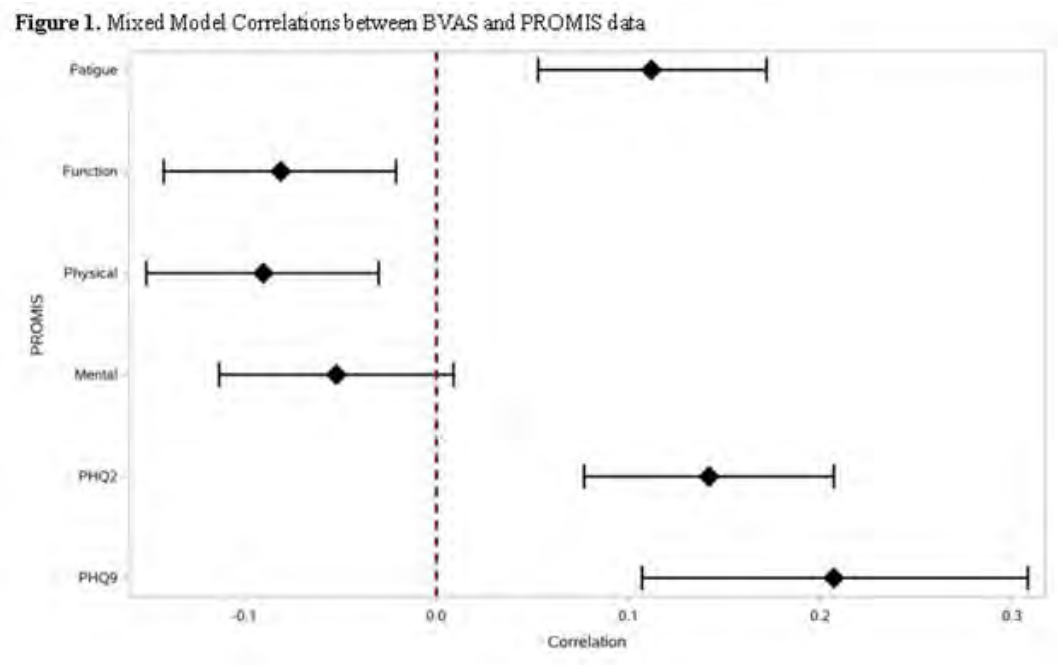

Figure 1. Mixed Model Correlation between BVAS and PROMIS data

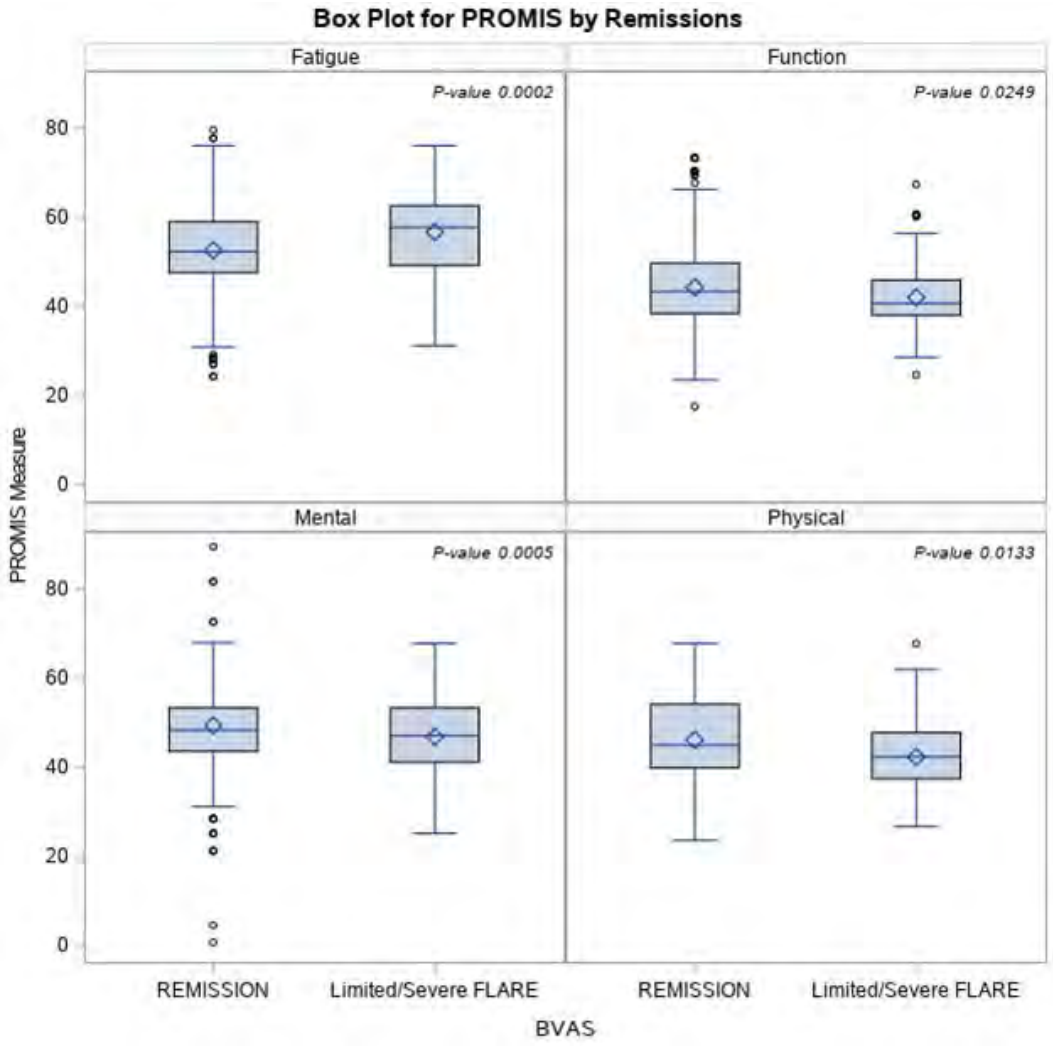

Figure 2. Box Plot for PROMIS by Remissions

suppressive medications were also recorded per each data set. Mixed effect models were used to calculate repeated measures correlations.

Results: 286 patients (median age at first visit 60 years, 53.8% females) with GPA were included in final analysis. Total 85 disease flares were reported (62 limited, 23 severe), median BVAS- WG score was 0 with a range (0-10).

BVAS-WG score was found to be positively correlating with fatigue ($r = 0.112$, $p < 0.001$), PHQ2($r = 0.142$, $p < 0.001$) and PHQ9 ($r = 0.207$, p-value< 0.001) respectively. However, BVAS -WG score seems to be negatively correlating with function ($r = -0.081$, $p = 0.009$) and physical score ($r = -0.090$, $p = 0.003$) (**Figure 1).** More interestingly, patients with flares had fatigue scores > by 4.1 units (p- value =0.001), PHQ2 scores > by 0.75 units (p- value = 0.001), Function scores < by 2.2 units (p- value= 0.025), physical scores < by 3.84 units (p-value= 0.001), and mental scores < by 2.54 units (p-value = 0.013) comparing to those were in remission (**Figure 2)**

Not surprisingly, as VDI score increases, fatigue ($r = 0.142$) and PHQ2 ($r = 0.145$) increase while function ($r = -0.295$) and physical scores decrease ($r = -0.213$).

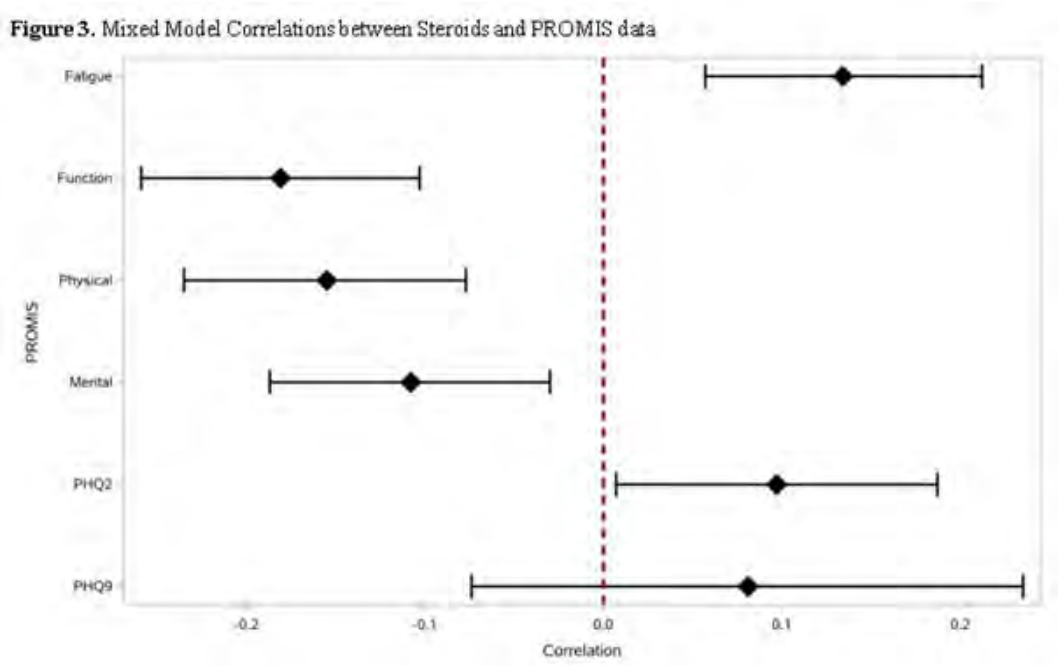

Figure 3. Mixed Model Correlation between Steriods and PROMIS data

In comparing for different glucocorticoids dose, and immunosuppressive medications, patients who received methotrexate and cyclophosphamide had higher PHQ2 scores on average by 1.03 and 0.76 units, respectively. Furthermore, methotrexate was found to be correlating negatively with function scores (b = -2.66, p-value=0.028).

Higher doses of glucocorticoid were positively associated with fatigue (r = 0.134, p-value = 0.001), and PHQ2 (r=0.097, p- value = 0.034) while higher doses were negatively associated with function (r = -0.181, p- value < 0.001), physical score (r = -155, p- value = < 0.001), and mental score (r = -0.108, p- value = 0.009). (**Figure 3)**

Conclusion: PROMIS weakly correlates with disease activity as measured by BVAS-WG and may successfully differentiate between different disease statutes.

Larger studies are needed to validate our study outcomes and the use of PROMIS as indirect tool in predicting disease activity in patients with GPA.

Abstract Number: 1438

Rituximab Immunogenicity in ANCA-associated Vasculitis (RITUXIMAV)

Jason Springer[1] and Ryan Funk[2], [1]University of Kansas Medical Center, Overland Park, KS, [2]UNIVERSITY OF KANSAS, Kansas City, KS

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

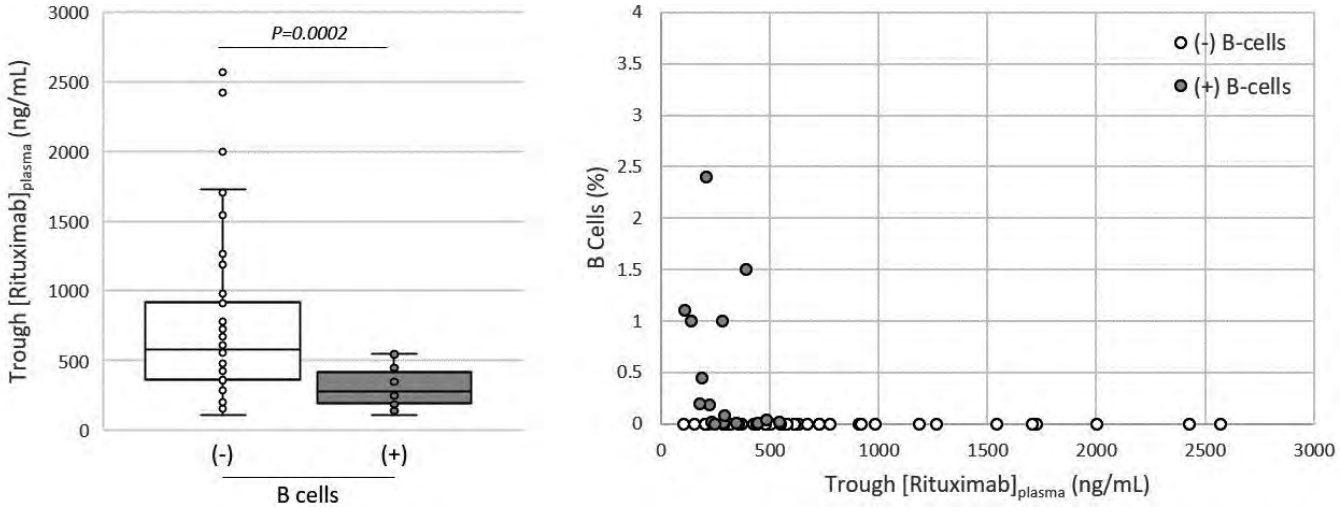

Figure 1. B-cell counts based on trough rituximab levels

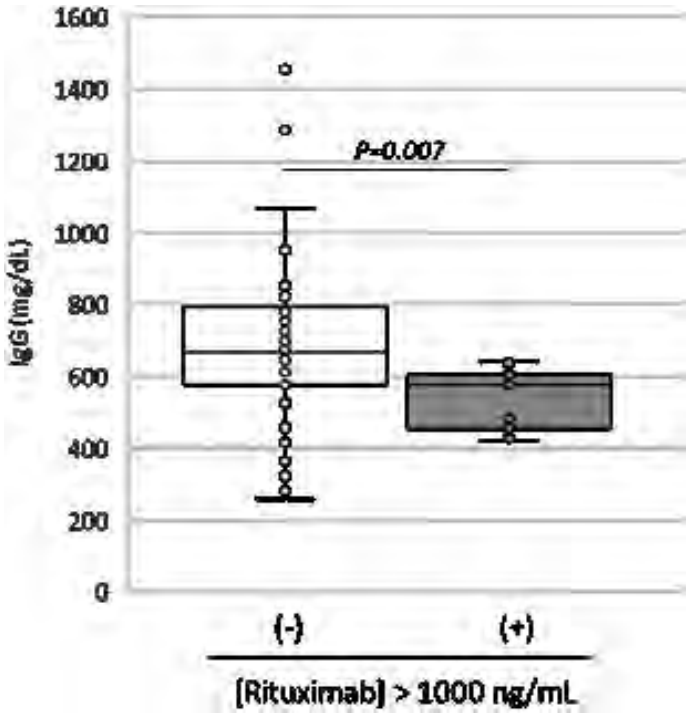

Figure 2. IgG based on trough rituximab levels.

Background/Purpose: Rituximab (RTX), an anti-CD20 chimeric monoclonal antibody, has been shown to be an effective maintenance therapy for granulomatosis with polyangitiis (GPA) and microscopic polyangiitis (MPA). There is very little data on the development of immunogenicity in patients with GPA/MPA receiving RTX for maintenance therapy. The purpose of this study is to determine a) the rate of anti-RTX antibody development, and b) if peripheral RTX and anti-RTX levels can be predictive of B-cell depletion, ANCA negativity and hypogammaglobulinemia in GPA/MPA patients receiving RTX for maintenance therapy.

Methods: Thirty patients with a diagnosis of GPA (n=25) or MPA (n=5) were recruited from a single center. Inclusion criteria included: a) previously received RTX within the last 8 months; b) in remission and c) receiving RTX maintenance therapy. Labs including trough peripheral RTX levels and anti-RTX antibodies were checked serially just before

infusions. The mean age at enrollment was 62.5 years (IQR 46.5-67.5), 70% were female, and 67% had undetectable B-cells at baseline. P-values were calculated using z-test and students t-test as appropriate.

Results: B-cell depletion was found to be more likely when the RTX trough level was greater than 500 ng/mL (93% versus 56% when trough < 500 ng/mL; p=0.002) (Figure 1). There was a non-significant trend toward a higher likelihood for both B-cell depletion and ANCA negativity by EIA when the RTX trough level was greater then 500 ng/mL (61% vs 41% when < 500 ng/mL, p=0.1354); however, the study was likely underpowered to find significance. Trough RTX levels > 1,000 ng/mL were associated with lower mean IgG levels (Figure 2).

Overall, 70% of samples had detectable anti-RTX levels. Anti-RTX levels did not correlate with B-cell depletion (p=1.0) or the combination of B-cell depletion and ANCA negativity (p=0.38). The presence of detectable anti-RTX levels were protective against the development of hypogammaglobulinemia (56% versus 83% without anti-RTX antibodies; p=0.041).

Conclusion: Some authors have supported dosing of RTX based on B-cell counts and ANCA testing, however a clear benefit of this approach has not been demonstrated. In addition, these approaches are reactionary to presumed under-dosing of RTX (i.e. either based on dose or frequency of dosing). Establishing target levels of RTX exposure offers the potential of an *a priori* precision dosing approach to RTX therapy in comparison to responsive monitoring of the effect of RTX. Establishing target RTX trough levels would allow for dosage determinations and adjustments based on population pharmacokinetic estimates to maximize the probability of clinical response and minimize the risk of toxicity. Based on the results of this study a RTX dosing algorithm personalized to the patient could be established. This would be a critical step towards personalized medicine in these forms of primary systemic vasculitis, and potentially other RTX treated diseases such as rheumatoid arthritis.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In ANCA-associated vasculitis (AAV) B cells play a central pathogenic role and are instrumental for the production of ANCA, which are thought to mediate disease activity by triggering the activation and degranulation of neutrophils.

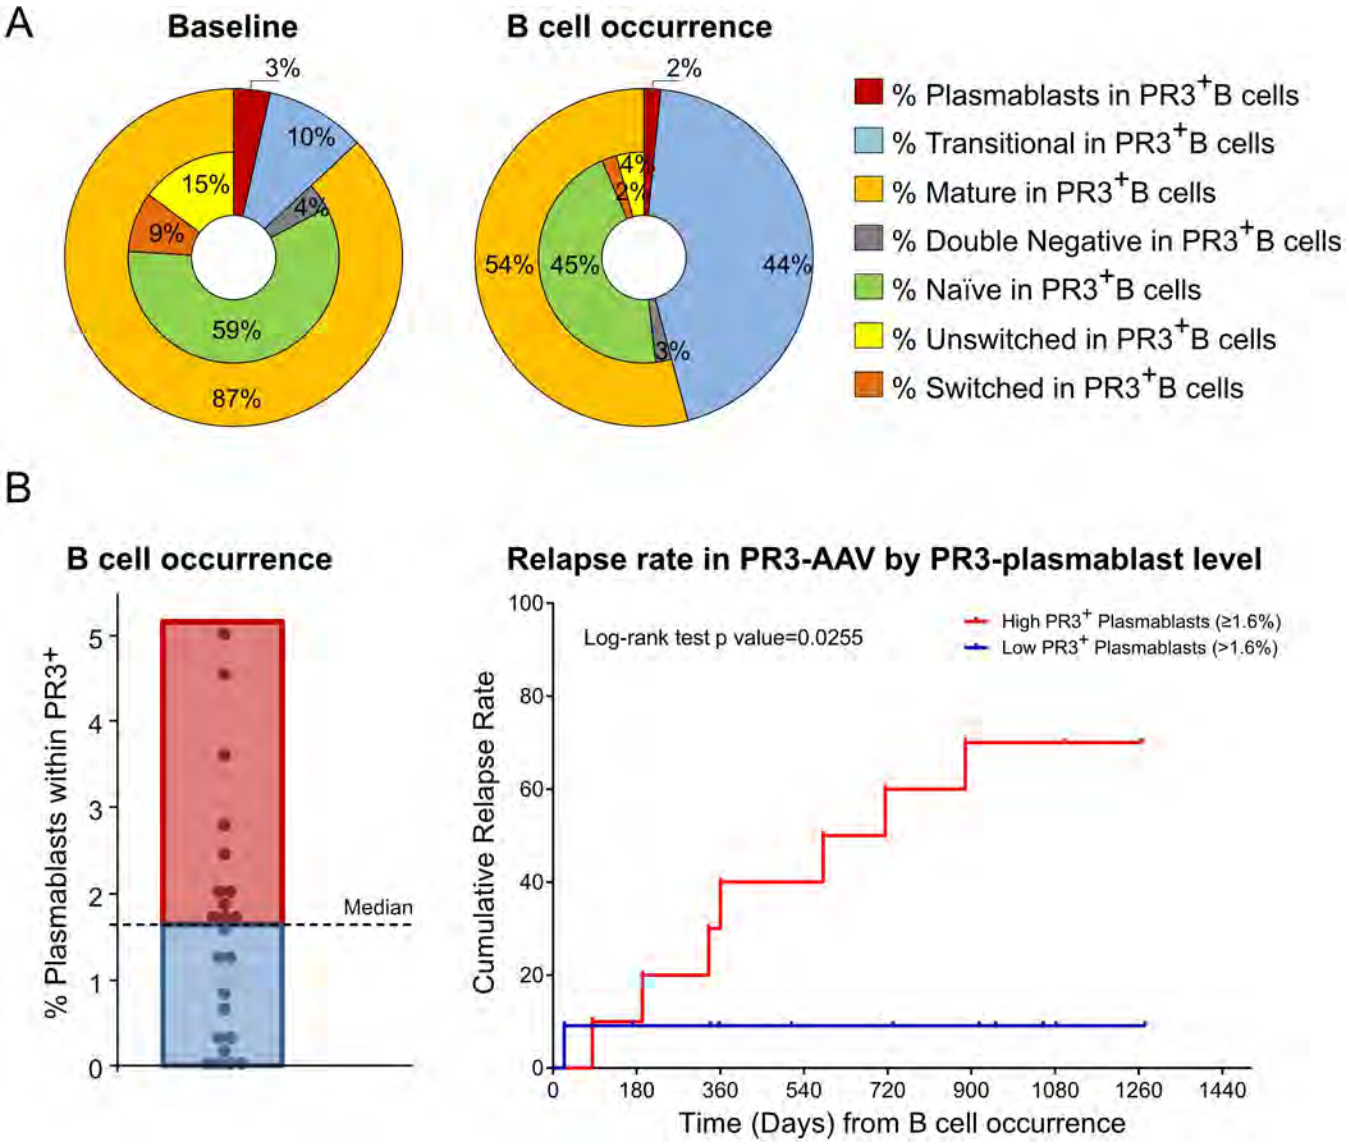

Figure 1. PR3+ B cells at baseline and B cell recurrence (A) and plasmablasts among the PR3+ B cell pool at B cell recurrence (B) among subjects with ANCA-associated vasculitis treated with rituximab.

We hypothesized that changes in the circulating proteinase 3 (PR3) reactive B cell ($PR3^+$ B cell) pool at the time of B cell recurrence after treatment with rituximab (RTX) and/or during the subsequent follow-up mirror disease course and relapses of PR3-AAV.

Methods: We performed sequential flow-cytometry on 148 samples of peripheral blood mononuclear cells (PBMC) from 23 well-characterized participants in the Rituximab for ANCA-Associated Vasculitis (RAVE) trial, treated with RTX for induction of remission and during long-term follow-up off therapy. Clinical data and outcomes were correlated with numbers of B cells and $PR3^+$ B cells; survival analyses and case-time-control analysis were performed by conditional logistic regression.

Results: Ten (43%) patients relapsed during the follow-up, 8 (35%) with severe disease. At baseline, clinical features, PR3-ANCA levels, $PR3^+$ B cells, and $PR3^+$ B cell subsets were similar between patients who relapsed (relapsers) and who did not relapse during the observation period (non-relapsers). All patients were studied for ≥18 months (observa-

tion period of the trial), for a mean of 44 months (25-75%IQR 31-54), without significant difference between relapsers and non-relapsers (p=0.98).

Two patients repopulated their B cells at 6 months; one relapsed and one did not during the follow-up. Total B cell counts and frequency were lower at B cell recurrence compared to baseline ($p< 0.01$). In contrast, the frequency of $PR3^+$ B cells was higher at B cell recurrence ($p< 0.01$), and pairwise comparisons showed that both B cell and $PR3^+$ B cell frequencies of transitional and naïve B cells were higher, while mature, unswitched and switched memory B cells were lower at the time of B cell recurrence compared to baseline ($p< 0.001$ in all comparisons) (**Figure 1A**).

At B cell recurrence, B cell subpopulations did not differ between relapsers and non-relapsers, while plasmablasts within the $PR3^+$ B cell pool were higher in relapsers, and associated with a shorter time to relapse (**Figure 1B**). Increased numbers of PR3+ plasmablasts were more likely to be found in patients that relapsed in the following 12 months ($p< 0.05$), and this increase was 50% more likely to occur in relapsers when compared to non-relapsers.

Conclusion: Our findings describe the restructuring of B cell and $PR3^+$ B cell compartments after B cell depletion with rituximab in PR3-AAV, and contribute to clarifying how early changes within the $PR3^+$ B cell pool associate with the future outcome of the patients with PR3-AAV. Our results highlight the importance of the expansion of peripheral blood $PR3^+$ B cells, which are linked to subsequent relapses. These findings contribute to a better understanding of the mechanisms governing the reconstitution of antigen-specific B cells after treatment with RTX in AAV.

The Myeloperoxidase (MPO) Anti-Neutrophilic Cytoplasmic Antibody (ANCA) Binding Epitope, $MPO_{447-459}$ Induces CD4 T-cell Proliferation in Patients with MPO-ANCA-associated Vasculitis

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Vasculitis – ANCA-Associated Poster
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In Myeloperoxidase (MPO) Anti Neutrophilic Cytoplasmic Antibody (ANCA)-Associated Vasculitis (MPO-AAV), murine and human studies suggest that the $MPO_{435-465}$ region, which includes ANCA-binding $MPO_{447-459}$, the CD4 $MPO_{435-454}$ epitope and CD8 $MPO_{457-465}$ epitope; is an immunogenic hotspot within the MPO heavy chain. To map the MPO peptide proliferative response in peripheral blood (PB) of MPO-AAV, we developed a T cell proliferation assay based on CFSE dilution, and assayed responses to MPO heavy chain peptides in participants with MPO-AAV, and age and sex-matched healthy controls.

Methods: MPO-AAV participants were included if they had a positive MPO-ANCA and Birmingham Vasculitis Activity Score (BVAS) ≥ 1 at diagnosis. We collected PB, isolated and froze mononuclear cells, thawed and stained them with CFSE, and cultured them for 7 days with no peptide, anti-CD3, tetanus toxoid, MPO peptides or pools of 10 overlapping 15mer MPO peptides derived from the $MPO_{279-745}$ heavy chain. The % proliferating CD3+CD4+ and CD8+ T cells in response to antigen or anti-CD3 was calculated by flow cytometry. The cell division index (CDI) was calculated as % divided in peptide-stimulated relative to % divided in unstimulated samples. All were genotyped for HLA-DR, DP and DQ.

Results: Nineteen participants with MPO-AAV were included, with mean age 65.32 (95% CI: 57.36- 73.27) and 14/19 were male (11 MPA, 3 GPA, 5 renal limited disease). Five had active disease. Of the healthy participants, mean age was 56.70 (95% CI: 43.32- 70.08), and 7/9 were male. MPO-AAV patients had a significantly greater CD4+ T cell CDI to MPO447-459 than healthy controls (p=0.015), with median CDI 3.20 (95% CI: 0.96- 5.80) in MPO-AAV and 0.67 (95% CI: 0.07- 0.89) in controls. CDI was greater in patients with remitted disease (median CDI 3.93, 95% CI: 0.52- 13.00), than in patients with active disease (median CDI 1.72, 95% CI: 0.96-3.89), but CDI did not correlate with ANCA titre. Within the MPO heavy chain, there was no significant increase in CDI among MPO-AAV patients towards any epitope other than $MPO_{447-461}$. CDI to $MPO_{435-365}$ among MPO-AAV patients with remitted disease was increased relative to patients with active disease. No peptide stimulated a significantly increased CD8+ proliferative response. HLA-DPB1*04:01 was enriched among patients with MPO-AAV (10/13; 76.92%) relative to controls (2/6; 33.33%), odds ratio 6.67 (95% CI: 0.79- 56.21). Carriage of this allele did not influence CDI to $MPO_{447-459}$.

Conclusion: CD4+ T cells from patients with MPO-AAV proliferate specifically to the $MPO_{447-459}$ epitope within the MPO heavy chain, and this response is greater after remission. An increased CDI to $MPO_{435-465}$ suggests that $MPO_{447-459}$ can be processed in culture from the longer peptide. T cell immunomodulation may be a suitable strategy for remitted MPO-AAV.

Session Date: Sunday, November 8, 2020

Session Title: Plenary Session III

Session Type: Plenary Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Belimumab (BEL) has demonstrated efficacy in systemic lupus erythematosus (SLE) in 4 positive pivotal trials. This study assessed the efficacy and safety of intravenous (IV) BEL plus standard therapy (ST) in patients (pts) with active lupus nephritis (LN).

Methods: This Phase 3, double-blind, placebo (PBO)-controlled study (GSK Study BEL114054; NCT01639339) randomized (1:1) adults with SLE and biopsy-proven LN (class III, IV, and/or V) to monthly BEL 10 mg/kg IV or PBO, plus ST. Randomization was stratified by race and treatment regimen (high-dose corticosteroids + either cyclophosphamide followed by azathioprine, or mycophenolate mofetil [MMF] followed by MMF). Primary endpoint: Primary Efficacy Renal Response (PERR; urine protein-creatinine ratio [uPCR] ≤0.7; estimated glomerular filtration rate [eGFR] no worse than 20% below pre-flare value or ≥60 ml/min/1.73m^2; no rescue therapy) at Week (Wk) 104. Key secondary endpoints: Complete Renal Response (CRR; uPCR < 0.5; eGFR no worse than 10% below pre-flare value or ≥90 ml/min/1.73m^2; no rescue therapy) at Wk 104; Ordinal Renal Response (ORR; CRR, PRR or no response) at Wk 104; PERR at Wk 52; time to renal-related event (defined in **Table 1**) or death. Wk 104 PERR/CRR were analyzed in subgroups: treatment regimens, LN class, race. Additional evaluations included: time to first severe SFI flare (defined in **Table 2**); proportions of pts with SLEDAI-S2K (defined in **Table 2**) score < 4 and with prednisone dose ≤7.5/5 mg/day, both at Wk 104; changes from baseline in biomarkers (anti-dsDNA, anti-C1q, C3, C4) at Wk 104; safety.

Results: Randomized pts: 448 (efficacy: 223/group; safety: 224/group). The study met its primary and key secondary endpoints (**Table 1**). Risk of a renal-related event or death was lower over the study with BEL vs PBO (HR [95% CI] 0.5 [0.3, 0.8]; p=0.001). **Table 2** displays additional endpoints. The odds of PERR/CRR responses at Wk 104 on BEL vs PBO were numerically greater for listed subgroups, except pure class V LN (**Figure**); however, in class V, a numerically greater proportion of BEL vs PBO pts achieved PERR/CRR response at Wk 52 (PERR: 44.4% vs 33.3%; CRR: 36.1% vs 27.8%, respectively).

At Wk 104, in pts with baseline autoantibodies, median (IQR) percent change from baseline (BEL vs PBO) in anti-dsDNA was –74.2 (–85.1, –49.5) vs –36.6 (–69.7, 28.6); and anti-C1q was –73.2 (–84.1, –59.0) vs –57.9 (–76.1, –33.2).

Table 1. Primary and key secondary endpoints

Endpoint, n (%)	PBO (n=223)	BEL 10 mg/kg IV (n=223)	Observed difference (%) vs placebo	OR/HR (95% CI) vs PBO	p-value
PERR at Wk 104*	72 (32.3)	96 (43.0)	10.8	OR 1.6 (1.0, 2.3)	0.031
CRR at Wk 104*	44 (19.7)	67 (30.0)	10.3	OR 1.7 (1.1, 2.7)	0.017

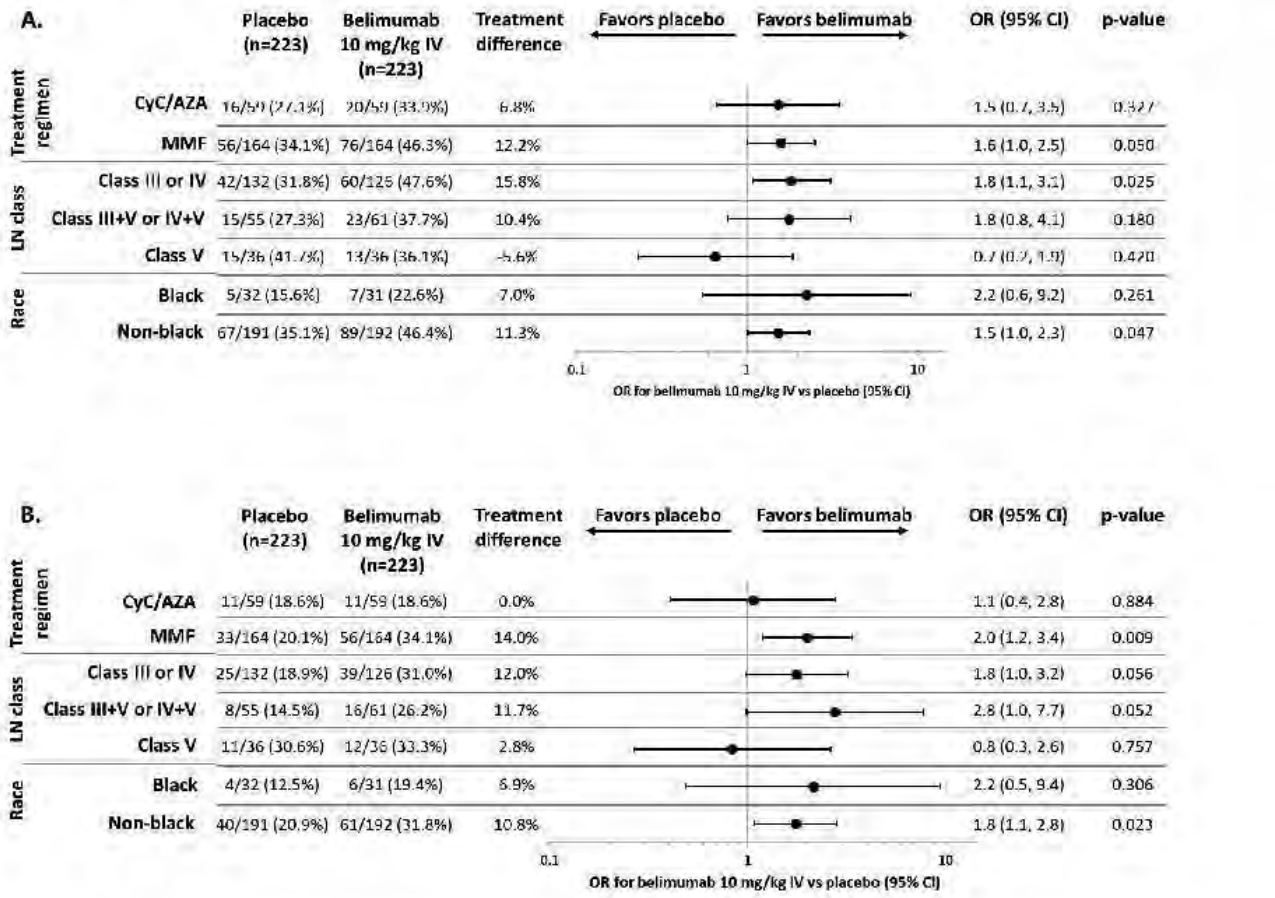
Prednisone dose ≤5 mg/day at Wk 104§	62 (27.8)	82 (36.8)	OR 1.5 (1.0, 2.3)	0.044

*Defined as (event date − treatment start date) + 1; †number/proportion of pts reporting the event; ‡SLEDAI-S2K defined as SELENA-SLEDAI with proteinuria scoring as per SLEDAI-2000 rules; §pts required to taper steroids to ≤10 mg/day by Wk 24

BEL, belimumab; CI, confidence interval; HR, hazard ratio; IV, intravenous; OR, odds ratio; PBO, placebo; pts, patients; SELENA-SLEDAI, Safety of Estrogens in Lupus National Assessment-SLE Disease Activity Index; SFI, SELENA-SLEDAI Flare Index; SLE, Systemic Lupus Erythematosus

Figure. PERR at Wk 104 (A), and CRR at Wk 104 (B), both by treatment regimen, LN class, and race



AZA, azathioprine; CI, confidence interval; CRR, Complete Renal Response; CyC, cyclophosphamide; IV, intravenous; LN, lupus nephritis; MMF, mycophenolate mofetil; OR, odds ratio; PERR, Primary Efficacy Renal Response; Wk, week

In pts with low baseline complement levels, median (IQR) percent change from baseline (BEL vs PBO) in C3 was 43.8 (17.1, 88.9) vs 30.0 (13.5, 59.8) and in C4 was 115.5 (60.0, 177.8) vs 66.7 (22.2, 166.7).

Adverse events (AEs; ≥1) were reported for 95.5% of BEL and 94.2% of PBO pts; 12.9% of pts in each group had ≥1 AE resulting in study treatment discontinuation. Serious AEs (≥1) were reported for 25.9% of BEL and 29.9% of PBO pts, most commonly infections and infestations (13.8% of BEL vs 17.0% of PBO pts); 1.8% of BEL and 1.3% of PBO pts developed on-treatment fatal AEs (mainly due to infections).

Conclusion: In this large 2-year LN study, compared with ST alone, BEL plus ST improved renal outcomes, overall SLE disease activity, and biomarker levels, while reducing steroid use, with a favorable safety profile.

Denosumab versus Oral Bisphosphonate for Osteoporosis in Long-term Glucocorticoid Users: A 12-month Randomized Controlled Trial

Chi Chiu Mok[1], Ling Yin Ho[1] and Kwok Man Ma[1], [1]Tuen Mun Hospital, Hong Kong, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Plenary Session III
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: To compare the efficacy of denosumab (DEN) and oral alendronate (ALN) on spinal bone mineral density (BMD) in long-term glucocorticoid users.

Methods: Patients receiving long-term prednisolone treatment for medical illnesses were recruited. Inclusion criteria: (1) adult patients ^{3}18 years of age; (2) prednisolone ^{3}2.5mg/day for ^{3}1 year. Exclusion criteria: (1) previous use of DEN, teriparatide; (2) plan for pregnancy; (3) metabolic bone disease or unexplained hypocalcemia; (4) renal insufficiency. Participants were randomized to receive either: (1) DEN (60mg subcutaneously every 6 months); or (2) ALN (70mg/week). Calcium (Caltrate 3000mg/day) and vitamin D3 (cholecalciferol 1000IU/day) was given. BMD (femoral neck, total hip, lumbar spine) at month 0, 6 and 12 months were performed. Markers of bone turnover (serum P1NP and CTX) were also assayed at the same time points. The primary outcome was the difference of lumbar spine BMD change at month 12 between the two groups.

Results: 139 subjects were recruited (age 50.0±12.7 years): 69 assigned DEN and 70 assigned ALN. Underlying medical diseases: SLE (81%), RA (9.4%) and myositis (5%). Prednisolone dose at entry was 5.7±2.1mg/day. 56% of female patients were postmenopausal. 73(53%) of patients were osteoporotic (T score < -2.5) at the hip, femoral neck or lumbar spine. The mean body mass index (BMI) was 23.1±4.1kg/m^2 (11% patients had BMI< 18kg/m^2). 82(59%) patients were naive to bisphosphonates. Pre-existing fragility or vertebral fracture was present in 19 (14%) patients and 18 patients (13%) had a family history of fractures. Baseline demographic data, osteoporotic risk factors, and BMD at various sites were not significantly different between the two groups at entry. At month 12, a significant gain in BMD at the lumbar spine (+3.5±2.5%; p< 0.001) and the hip (+0.9±2.8%; p=0.01) was observed in DEN-treated patients, whereas the corresponding change was +2.5±2.9% (p< 0.001) and +1.6±2.7% (p< 0.001) in the ALN group. The spinal BMD at month 12 was significantly higher in the DEN than ALN group after adjustment for BMD values at baseline, age, sex and other osteoporosis risk factors that included smoking, drinking, cumulative steroid doses in one year, BMI, menopausal status and personal history of fracture (p=0.045). The differences in hip and femoral neck BMD were not significantly different between the two groups after adjustment for the same confounding factors. No new symptomatic fractures occurred in any participants at month 12. Adverse events were similar in frequency between the two treatment arms. Major infective episodes were uncommon (0.06/patient/year) and similar in the two groups. Minor upper gastrointestinal symptoms and non-specific dizziness were numerically more common in the ALN but arthralgia, minor infections (eg. upper respiratory tract) and new hypertension was more commonly reported in the DEN group. Three patients from ALN and 2 patients from DEN group were withdrawn from the study because of non-compliance but none withdrew because of adverse events.

Conclusion: In patients receiving long-term glucocorticoids, DEN is superior to ALN in raising the spinal BMD after 12 months' treatment. Both DEN and ALN were well tolerated.

High-dimensional Analyses of Checkpoint-inhibitor Related Arthritis Synovial Fluid Cells Reveal a Unique, Proliferating CD38^{hi} Cytotoxic CD8 T Cell Population Induced by Type I IFN

Runci Wang[1], Karmela Kim Chan[2], Amy Cunningham-Bussel[1], Gregory Vitone[3], Aidan Tirpack[2], Caroline Benson[2], Gregory Keras[4], Anna Helena Jonsson[5], Michael Brenner[5], Laura Donlin[6], Anne Bass[7] and Deepak Rao[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Hospital For Special Surgery, New York, NY, [3]Hospital for Special Surgery, New York, [4]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, MA, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [6]Hospital for Special Surgery, Weill Cornell Medicine, New York, [7]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Plenary Session III
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Checkpoint inhibitors (CI) used to treat cancer frequently trigger immune-related adverse events, including inflammatory arthritis. CI-related arthritis (CIrA) occurs in ~5% of treated patients, with clinical manifestations resembling rheumatoid arthritis (RA) and spondyloarthropathies (SpA). However, the cellular and molecular features of CIrA remain unknown, calling for a deeper understanding of its pathogenesis.

Methods: We conducted detailed immunophenotyping of synovial fluid (SF) mononuclear cells to compare CIrA, seropositive RA, and SpA using mass cytometry (CyTOF) (CIrA n=10, anti-PD-1-treated; 5 mono/oligoarthritis, 5 polyarthritis; RA n=11; SpA n=9). Significantly altered populations ($p< 0.05$) were identified using FlowSOM and validated by flow cytometry in additional SF and blood samples (CIrA n=15; RA n=15). SF CD8 T cell subpopulations were sorted for RNA-seq and intracellular staining. Transcriptomic features were recognized by identifying differentially expressed genes and by Gene Set Enrichment Analysis (GSEA) ($q< 0.25$). RA SF cells were cultured with cytokines (IFNα 1kU/mL or IFNγ 50ng/mL) and anti-CD3/CD28 for 72 hours and analyzed by flow cytometry.

Results: FlowSOM analysis of SF CyTOF revealed a CD38^{hi}CD127^{-} PD-1^{+} CD8 cell population uniquely expanded in CIrA (~25% of CD8 in CIrA, a 3.4-fold increase over RA/SpA), which was confirmed in additional SF samples by flow cytometry. In contrast, T cells with the converse CD38^{-}CD127^{+} phenotype were reduced in CIrA compared to RA/SpA. CD38^{hi}CD127^{-} CD8 cells were also expanded in blood of CIrA patients (5% of CD8 in CIrA, a 2.8-fold increase over RA) (Fig. 1).

RNA-seq analysis of the expanded CD38^{hi}CD127^{-} subset revealed significantly increased expression of inflammatory and cytotoxic molecules including granzyme A/B/H/K, perforin and IFNγ, with expression levels of these genes comparable to those in sorted KLRG1^{+} cytotoxic T cells. Flow cytometry of ex vivo stimulated T cells confirmed a higher frequency of granzyme B^{+} and perforin^{+} cells in the CD38^{hi}CD127- population (Fig. 2). GSEA revealed an increased proliferation signature in CD38^{hi}CD127^{-} cells compared to CD38^{-}CD127^{+} cells, with upregulation of genes involved in DNA replication, mitosis and cell division ($q< 0.1$, FC >1.5 over CD38^{-}CD127^{+} cells). This feature was not shared

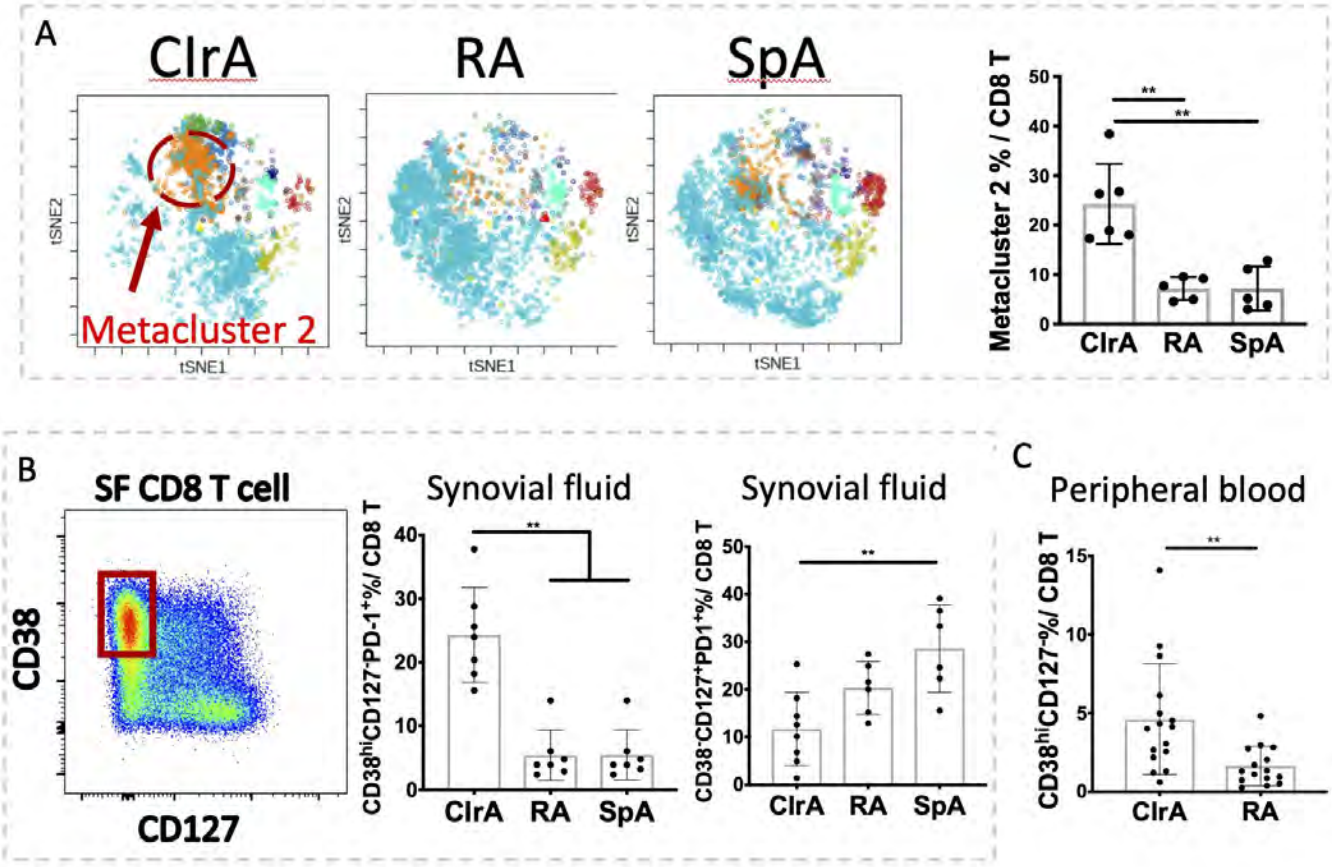

Figure 1. FlowSOM analysis of CD8 T cells revealed the expansion of a PD-1+CD38hiCD127- population in synovial fluid and peripheral blood of checkpoint inhibitor-related arthritis (ClrA). A) FlowSOM analysis of CyTOF CD8 T cells highlighted an expanded metacluster 2 in ClrA SF (Kruskal-Wallis test, ClrA n=6, RA/SpA n=5). B) Biaxial gating of flow cytometry data confirmed expanded CD38hiCD127-PD1+ cells and reduced CD38-CD127+ CD8 T cells in ClrA SF (Kruskal-Wallis test, n=7). C) CD38hiCD127- CD8 cells are expanded in blood of ClrA patients (t-test, n=15). Mean±SD shown, **p<0.01.

by PD1$^-$ cells or KLRG1$^+$ cells (Fig 3). CyTOF confirmed >40% of CD38^{hi} CD127$^-$ PD-1$^+$ CD8 T cells expressed Ki67. GSEA of SF T cells also revealed a marked enrichment of IFN-inducible genes in ClrA compared to SpA/RA. Treatment of RA SF T cells with IFNα, but not IFNγ, induced CD8 T cells to acquire a CD38^{hi}CD127$^-$ phenotype resembling that seen in ClrA (Fig. 3).

Conclusion: CyTOF analysis of SF mononuclear cells revealed a highly expanded PD-1$^+$CD38^{hi}CD127$^-$ CD8 T cell population in ClrA that is not shared by RA or SpA. This T cell subset shows cytotoxic and proliferative features at both the gene and protein expression level. CD38^{hi}CD127$^-$ CD8 T cells in ClrA samples showed an IFN signature, and treatment of T cells with IFNα induced this phenotype in vitro. This work reveals a unique T cell phenotype in ClrA and suggests type I IFN may be a pathologic driver in this condition.

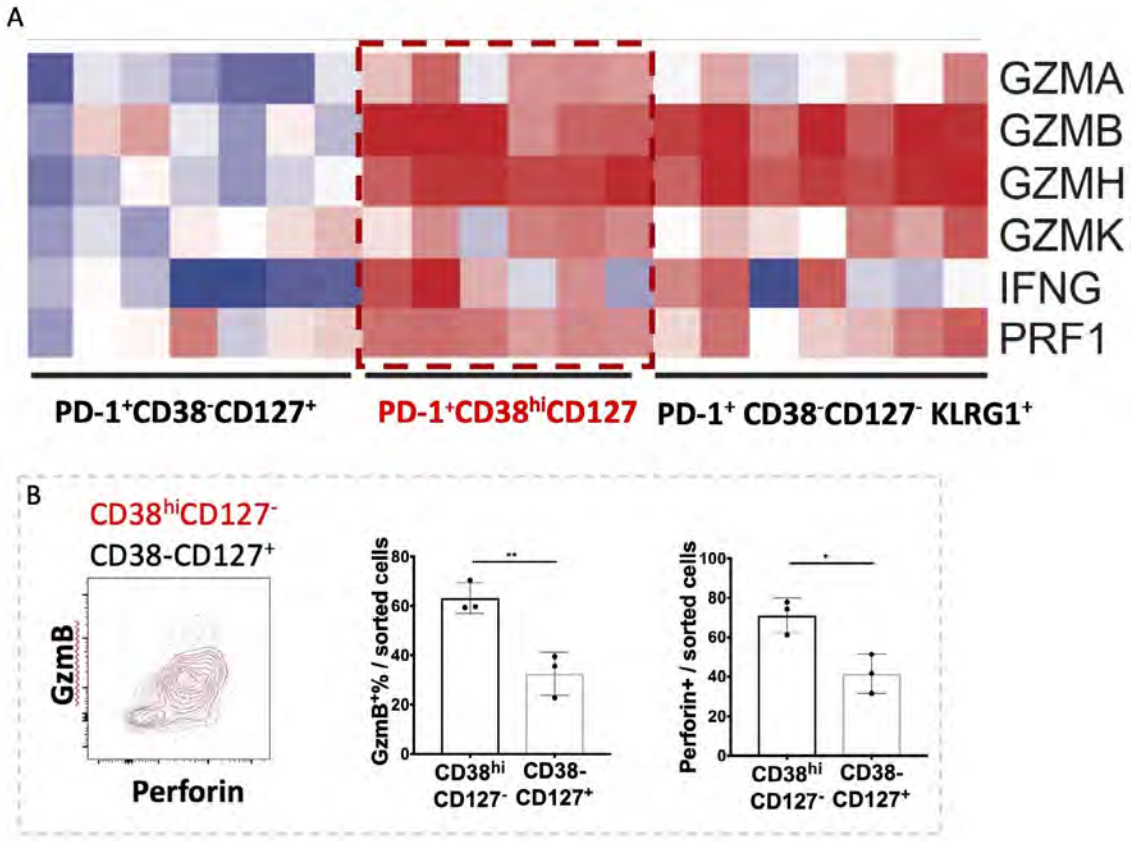

Figure 2. RNA-seq analysis and flow cytometry staining of CD38hiCD127- CD8 T cells in ClrA SF demonstrated cytotoxic and inflammatory features. A) Heatmap of cytotoxic molecules enriched in CD38hiCD127- cells. B) Enrichment of intracellular granzyme B and perforin in sorted CD38hiCD127- CD8 T cells. Mean±SD shown, *p<0.05, **p<0.01.

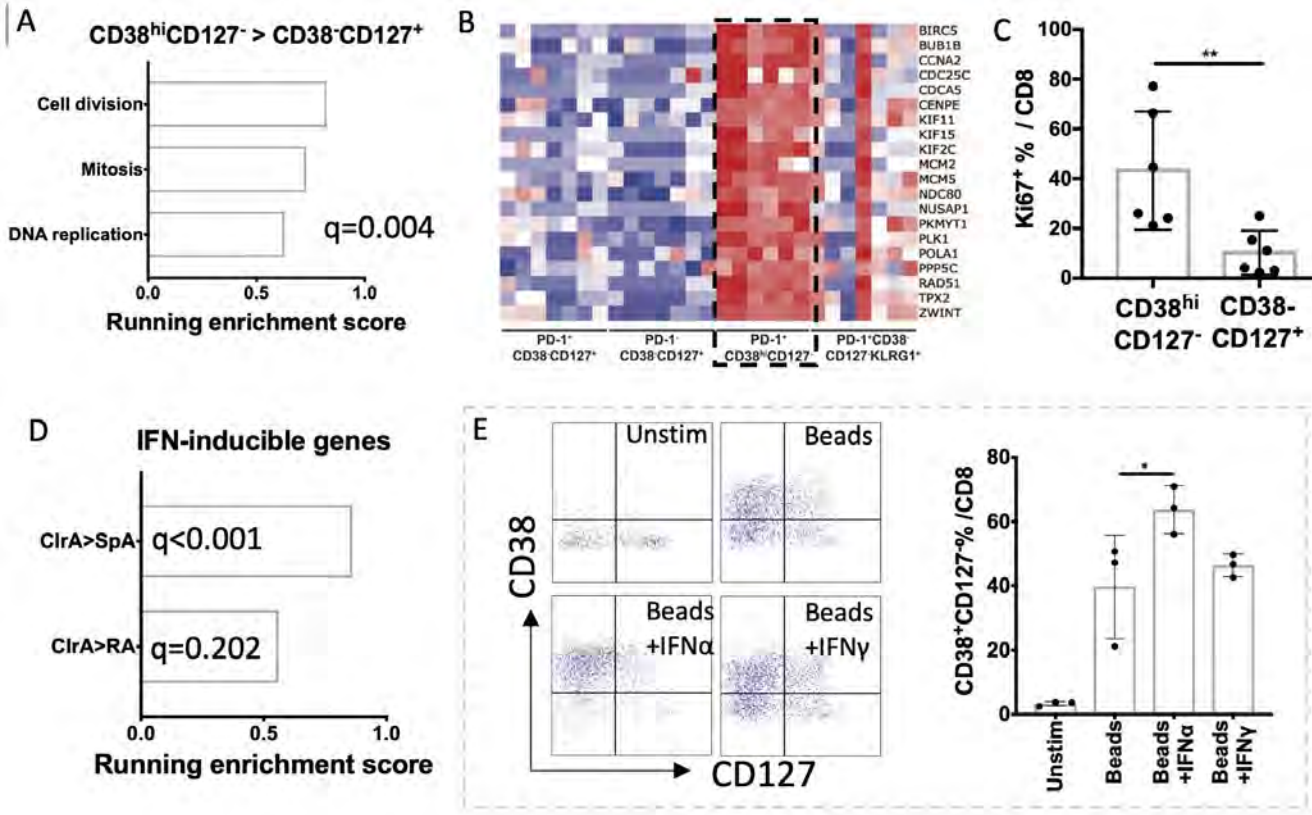

Figure 3. CD38hiCD127- CD8 T cells in ClrA SF showed a proliferation feature, and a phenotype induced by IFNα. A) GSEA identified enrichment of proliferation gene sets in CD38hiCD127- CD8 T cells; B) Heatmap of proliferation genes enriched in CD38hiCD127- CD8 T cells. C) CyTOF showed increased expression of Ki67 in CD38hiCD127- CD8 T cells. D) GSEA showed an IFN signature in ClrA cells. E) RA SF cells were cultured unstimulated or stimulated with anti-CD3/28 activation beads with or without IFNα or IFNγ as indicated for 72 hours. CD38hiCD127- phenotype resembling that seen in ClrA was induced by IFNα but not IFNγ. Mean±SD shown, *p<0.05, **p<0.01.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Plenary Session III
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Recommendations for axial spondyloarthritis (axSpA) management include tight control and treat-to-target (TC), but no study has evaluated its potential benefit. The objective of this trial was to evaluate the benefit of TC strategies in comparison to usual care (UC) in patients with axSpA.

Methods: *Study design:* Pragmatic, prospective, cluster-randomized controlled (2 arms), one-year trial (NCT03043846). *Centers*: 18 axSpA expert centers randomly allocated (1:1) to the treatment arm: TC vs. UC. *Patients*: axSpA diagnosis and ASAS criteria, non-optimally treated with NSAIDs, bDMARD-naïve, and ASDAS > 2.1 at inclusion. *Study treatment*: a) TC: the strategy was pre-specified by the scientific committee based on current axSpA recommendations and aiming at a target (ASDAS < 2.1); visits every 4w; b) UC arm: treatment decisions were at the rheumatologist's discretion with visits every 12w. *Outcomes:* the % of patients with a significant (>30%) improvement in the ASAS-HI score over one-year follow-up was the main outcome. Other outcomes (disease activity, quality of life, treatment, …) over follow-up were evaluated (Table 1). The number/type of adverse events were collected. *Statistical analysis*: this was an intention-to-treat analysis. To take into account the cluster-randomization design, for all outcomes, two models were performed: first a two-level mixed model with 2 random effects was used to estimate the % of responders/the change of the outcome over follow-up (i.e. mod1); in a second step, the imbalanced variables observed at baseline were included in the model (i.e.mod2). Cost-effectiveness was assessed by estimating the (baseline- and cluster-adjusted) incremental cost per quality-adjusted life-year (QALY) gained for TC vs. UC.

Results: 160 patients were included (80 in TC and 80 in UC). Mean age was 37.9(11.0) years with a disease duration of 3.7(6.2) years, 51.2% were males. A radiographic damage of the SI-joints, a (ever) positive MRI sacroiliitis and HLA-B27+ were seen in 46.9%, 81.9% and 75.0% patients respectively. Mean ASDAS at inclusion was 3.0 (0.7) and

	Estimated outcomes at week 48		Cluster-adjusted	Cluster and imbalance -adjusted
	TC	UC		
ASAS HI significant improvement (Main Outcome)	47.3%	36.1%	-	-
ASDAS LDA*	76.5%	59.5%	<0.01	0.03
ASDAS ID	25.9%	18.7%	-	-
ASDAS CII	61.2%	46.0%	<0.01	0.02
ASDAS MI	16.5%	14.9%	-	-
ASAS40	52.3%	34.7%	<0.01	0.01
ASAS20	94.9%	85.9%	<0.01	0.03
BASDAI 50	79.0%	43.8%	0.01	0.03
Physician Global (0-10)	2.0 (0.2)	1.8 (0.2)	-	-
CRP (mg/L)	3.9(1.4)	3.5 (1.5)	-	-
BASG (0-10)	2.6 (0.5)	3.4 (0.5)	0.09	-
BASFI (0-10)	1.7(0.5)	2.4 (0.5)	-	-
EQ5D	0.7(0.1)	0.8(0.1)	0.02	-
ASAS-NSAID score	1.5(2.2)	- 4.9 (2.9)	-	-

Legend: - : not statistically significant.

mean ASASHI was 8.6 (3.7). 72 patients per group attended the one-year visit. Although 47.3% vs. 36.1% patients in the TC and UC arms achieved a significant improvement in ASASHI at the one-year visit, the difference was not statistically significant, with either model. Across all other outcomes a trend was observed in favor of the TC arm (Table 1). The number of bDMARDs was significantly higher in TC arm (56.2% vs. 27.2%). The number of infections was comparable in both groups (15 vs. 16 in the TC and UC, respectively), with only 2 severe infections occurring in the UC arm. From a societal perspective, TC resulted in an additional 0.04 QALY and saved €265 when compared to UC and a 67% probability of being cost-effective at a cost-effectiveness threshold of €20,000 per QALY.

Conclusion: In this setting of SpA expert centers, UC resulted in a good outcome in a substantial number of patients but the TC was not superior for the primary outcome despite a greater number of bDMARDs prescription. Nevertheless, a general trend in favor of the tight control was observed, with a comparable safety profile and was found to be favorable from a societal health economic perspective.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Plenary Session III
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Structural changes, increased tissue citrullination, signs of local inflammation and anti-citrullinated protein autoantibodies (ACPA) are present in the pulmonary compartment of early untreated seropositive

rheumatoid arthritis (RA). These findings provide evidence of a potential role for the lungs in generation and initiation of RA-associated autoimmunity. Here we aimed to investigate the presence of citrulline-reactive B cells in the lung compartment of early untreated RA patients by single-cell cloning of monoclonal antibodies (mAbs) from lung-derived B cells.

Methods: Bronchoalveolar lavage (BAL) fluid cells were obtained from ACPA positive individuals with arthralgia (n=4), early untreated ACPA positive RA (n=3) and ACPA negative RA (n=5) patients at the time of diagnosis. CD19+ B cells were single cell sorted by flow cytometry. Immunoglobulin heavy and light chain variable regions were PCR amplified, sequenced, and analyzed by V-Quest and IgBLAST towards the IMGT database to annotate variable gene usage. Sequences having high somatic hypermutations (SHM) and Fab N-glycosylation sites were selected to be cloned and expressed as human IgG1 recombinant mAbs. Citrulline reactivity was determined by CCP2 assay and in-house ELISA against citrullinated and native peptides from vimentin, a-enolase, fibrinogen and filaggrin. Polyreactivity was determined by reactivity against double stranded DNA, bacterial lipopolysaccharides (LPS) and insulin. The functional properties of mAbs were analyzed in osteoclastogenesis assay, fibroblast migration assay and neutrophil binding assay.

Results: Significant higher proportion of CD19+ B cells were found in ACPA positive compared to ACPA negative BAL (median 6.7% vs 0.79%). PCR amplification and subsequent BCR sequencing from 8 individuals yielded 581 paired heavy and light chain sequences. 49 monoclonal antibodies (from 5 individuals) were selected for expression based on high number of SHM and predicted Fab N-linked glycosylation. Notably, four of these selected mAbs (8%; 2 antibodies from each patient, one risk RA and one early untreated RA) were determined to be ACPAs by CCP2 ELISA. The 4 ACPAs had varying ACPA fine-specificity against citrullinated a-enolase, filaggrin, vimentin and fibrinogen peptides without any native peptide binding. All the 4 monoclonal ACPAs were negative in polyreactivity test. Clone L204:01A01 and L201:11C11 but not clone L201:10D07 and L204:05E10 bound to activated neutrophils (49.75% for clone A01 and 22.3% for clone C11). Clone L204:01A01 and L204:05E10 but not L201:10D07 and L201:11C11 induced osteoclastogenesis with a fold increase of 1.5 and 1.9 respectively. Clone L204:01A01 and L201:10D07 but not L201:11C11 and L204:05E10 promoted fibroblasts migration with a fold increase of 1.4 and 1.5 respectively.

Conclusion: We demonstrate for the first time that citrulline-reactive B cells producing pathogenic ACPAs are present in the lung compartment of seropositive individuals at risk for or having early untreated RA. This provides a strong link between the lung and the adaptive autoreactive response in RA, and support the hypothesis of the lung as one of the key sites of initiation and propagation of disease in RA.

Pregnancy Outcomes in Patients with Interstitial Lung Disease

Aardra Rajendran[1], Stephanie Giattino[2], Amanda Eudy[3], Aparna Swaminathan[4] and Megan Clowse[5], [1]Duke University, Lewisville, NC, [2]Duke University, Media, PA, [3]Duke University, Durham, NC, [4]Duke University, Durham, [5]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Plenary Session III
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Patients with interstitial lung disease (ILD) are often recommended to avoid conception or terminate pregnancy despite limited data on pregnancy outcomes and complications. Studies to date have only been conducted in small samples of 9-15 patients with mixed results. This study aims to retrospectively analyze pregnancy outcomes in the largest-to-date cohort of patients with ILD secondary to autoimmune disease to further inform providers and patients on the risks of pregnancy. We hypothesize that patients with more severe ILD as classified by physiologic measures will have worse pregnancy outcomes and increased complications.

Methods: Medical records in the Duke University Health System (1/1/1996 - 7/1/2019) were reviewed for pregnancies in patients with a diagnosis of ILD secondary to autoimmune disease. Pregnancies were classified according to severity of ILD based on percent predicted forced vital capacity (FVC % pred) or percent predicted diffusion capacity for carbon monoxide (DLCO % pred). Cutoff values included normal (DLCO % pred ≥ 80% and FVC % pred ≥ 80%), mild (DLCO % pred 61-79% or FVC % pred 60-79%), moderate (DLCO % pred 40-60% or FVC % pred 40-59%), and severe (DLCO % pred < 40% or FVC % pred < 40%). Adverse outcomes were defined using the composite PROMISSE-APO (preeclampsia, pre-term delivery < 36 weeks, small for gestational age (SGA) infant < 5th percentile, fetal death > 12 weeks, or neonatal death) and PROMISSE-APO SEVERE (preeclampsia and preterm delivery < 34

DELIVERY OUTCOMES	Total	No PFTs	Severe	Moderate	Mild	Normal	p-value[1]
	N=94	n=30	n=7	n=16	n=32	n=9	
PROMISSE APO[2]	25/73 (34%)	5/24 (21%)	5/5 (100%)	5/12 (42%)	7/24 (29%)	3/8 (38%)	0.03
PROMISSE APO-SEVERE[3]	11/73 (15%)	1/24 (4%)	3/5 (60%)	2/12 (17%)	4/24 (17%)	1/8 (13%)	0.2
Non-Live Births	28 (30%)	7 (23%)	4 (57%)	5 (31%)	11 (34%)	1 (11%)	0.3
Termination	9 (10%)	3 (10%)	1 (14%)	2 (13%)	3 (9%)	0 (0%)	0.7
Miscarriage	17 (23%)	4 (13%)	2 (29%)	3 (19%)	7 (22%)	1 (11%)	0.8
Stillbirth	2 (2%)	0 (0%)	1 (14%)	0 (05)	1 (3%)	0 (0%)	0.4
Live Births:	66 (70%)	23 (77%)	3 (43%)	11 (69%)	21 (66%)	8 (89%)	0.3
Gestational age at delivery (mean ± S.D.) (weeks)[4]	37.8 ± 2.6	38.2 ± 2.2	33.7 ± 4.2	37.9 ± 1.9	38.0 ± 2.8	37.5 ± 2.6	0.08
Preterm birth[4]	9/62 (15%)	2/21 (10%)	2/3 (67%)	1/11 (9%)	2/21 (10%)	2/6 (33%)	0.06
SGA < 10th percentile[4]	10/61 (16%)	3/21 (14%)	1/3 (33%)	0/11 (0%)	3/20 (15%)	3/6 (50%)	0.04
Preeclampsia	10/65 (15%)	1/22 (5%)	2/4 (50%)	4/11 (36%)	2/20 (10%)	1/8 (13%)	0.1

1. p-value comparisons are only made between pregnancies in the severe, moderate, mild, and normal groups. Pregnancies in patients without PFTs were not included in statistical analysis.
2. PROMISSE-APO: preeclampsia, pre-term delivery < 36 weeks, small for gestational age (SGA) infant < 5th percentile, fetal death > 12 weeks, or neonatal death. Pregnancy losses < 12 weeks were excluded as in the PROMISSE study (Kim et al., 2016).
3. PROMISSE-APO SEVERE: preeclampsia and preterm delivery < 34 weeks, preterm delivery < 30 weeks, fetal death > 12 weeks, or neonatal death. Pregnancy losses < 12 weeks were excluded as in the PROMISSE study (Kim et al., 2016).
4. Only singleton pregnancies included for analysis of gestational age at delivery, preterm birth and SGA < 10th percentile.

Figure 1. Delivery Outcomes

weeks, preterm delivery < 30 weeks, fetal death > 12 weeks, or neonatal death). Fisher's Exact Test and ANOVA was used to compare outcomes among patients in different severity groups.

Results: This study included 67 patients with 94 pregnancies (5 twin pergnancies). The average maternal age was 32.1 ± 6.0 years with 83% identifying as Black. Overall, 69% of pregnancies were diagnosed with sarcoidosis and the remaining 31% had a connective tissue disease associated ILD (CTD-ILD). Of the pregnancies with available measures to classify ILD severity (n=64), 11% were severe, 25% were moderate, 50% were mild, and 14% were normal. All the pregnancies in the severe group had CTD-ILD while 89% of pregnancies in the normal group had sarcoidosis (p=0.001 across groups).

Overall, 70% of pregnancies resulted in live births and 9 pregnancies (10%) were terminated (Fig. 1). There was a 15% rate of pre-eclampsia, 34% rate of PROMISSE-APO, and 15% rate of PROMISSE-APO SEVERE. Patients with severe disease had the highest rates of PROMISSE-APO (p=0.03 across groups).

There were no maternal deaths and only 2 pregnancies required intensive care unit care. Overall, 4 pregnancies experienced volume overload at the time of delivery, of which 1 patient developed postpartum heart failure. A total of 8 pregnancies required oxygen at the time of delivery, and 1 patient was intubated during pregnancy.

Conclusion: While adverse pregnancy outcomes are common in ILD pregnancies, especially in patients with more severe disease, overall maternal morbidity and mortality is low. Patients with ILD do not necessarily have to terminate pregnancies provided they have close monitoring before, during, and after pregnancy and appropriate subspecialist involvement.

Vitamin D Deficiency Enhances Antiphospholipid Antibody-Mediated Thrombosis in a Passive Immunization Mouse Model

Rohan Willis[1], Karen Roye-Green[2], Zurina Romay-Penabad[1], Elizabeth Papalardo[1], Alvaro Schleh[3], Vijaya Murthy[4], Monica Smikle[2] and Emilio Gonzalez[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of the West Indies, Kingston, Jamaica, [3]Antiphospholipid Standardization Laboratory, GALVESTON, TX, [4]University of Texas Medical Branch, League City, TX

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Abnormal vitamin D levels occur frequently in antiphospholipid (APS) patients and are correlated with thrombosis. It remains unclear however if vitamin D deficiency observed in APS occurs as a part of disease pathogenesis, as a consequence of disease activity or as an incidental disease-modifying factor. This study aims to determine if induction of antiphospholipid antibody (aPL) induces changes in vitamin D levels (Phase I) and to evaluate the effect of vitamin D deficiency on aPL-mediated thrombosis in APS mouse models (Phase II).

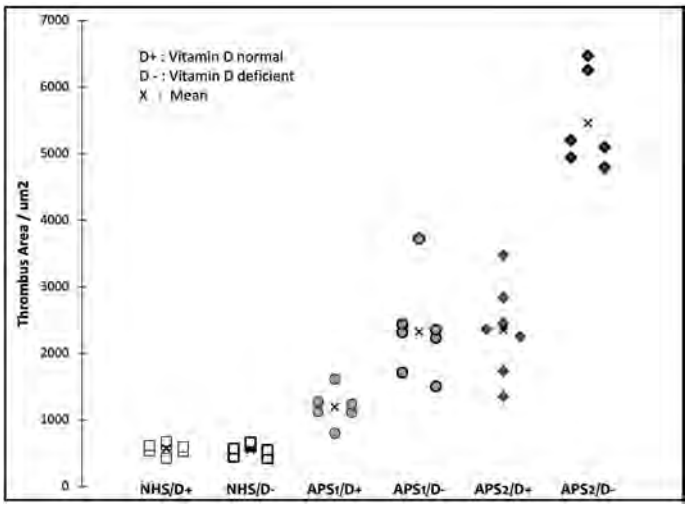

Figure 1. Cross-sectional area of induced thrombi in femoral vein of vitamin D deficient and normal mice treated with antiphospholipid and normal IgG

Methods: In Phase I, CD1 male mice (n= 5 to 7 per group) fed normal diets were immunized with either human β2GPI of varying doses (0.5ug, 1ug, 10ug or 150ug with adjuvant) once weekly for 3 doses to induce different levels of aPL activity or ovalbumin (OA) (10ug or 150ug). Serum was collected 4 weeks following initial immunization to measure 25 hydroxy vitamin D (25OHVD), aCL and anti-β2GPI levels by ELISA. In Phase II, CD1 male mice (n=5 to 7) were fed either a vitamin D normal (VDnorm) or deficient (VDdef) diet supplemented with calcium for 6 weeks until 25OHVD levels were stable. After stable 25OHVD levels, mice were then inoculated (2 doses over 48hrs) with either purified whole IgG from a primary APS (PAPS) patient (IgG APS 1), β2GPI-affinity purified IgG from a second PAPS patient (IgG APS 2) or whole IgG from normal human serum (IgG NHS) prior to thrombosis induction in the femoral vein. Blood was collected weekly after start of diet, immediately prior to IgG treatment and at time of thrombosis analysis.

Results: Phase I – IgG aCL and anti-β2PI levels were significantly higher in β2GPI immunized mice compared to control mice and increases were dependent on dose of antigen. However, there was no significant difference in 25OHVD levels among all the groups and all were normal (range 61.2±15.1 to 78.5±9.6 ng/ml, p=0.220). In phase II, VDdef mice developed vitamin D deficiency (< 20ng/ml) by W3, which continued until W6. Thrombus experiments were subsequently done at W4 and mean 25OHVD was significantly less in VDdef vs VDnorm mice (17.7±2.9 vs 36.1±7.8 ng/ml,p< 0.0001). Mean IgG anti-β2GPI levels were similar for VDdef vs VDnorm mice treated with IgG NHS (2.5±0.6 vs 2.8±0.4 G units), IgG APS 1 (75.9±0.2 vs 75.9±0.4) and IgG APS 2 (42.8±0.3 vs 42.3±0.3) at the time of surgery. Mean thrombus sizes in these 3 treatment groups were (555.9±89.5 vs 574.3±82.8 μm^2,p=0.902), (2327.8±709.8 vs 1195.6±265.5,p< 0.001) and (5461.8±715.8 vs 2353.7±694.7,p< 0.001) for VDdef vs VDnorm mice (Figure 1).

Conclusion: We provide the first mechanistic data indicating that vitamin D deficiency amplifies the thrombogenic effect of IgG aPL. This effect was demonstrated for aPL derived from 2 different primary APS patients. However, induction of aPL activity of varying strength in an active immunization model seemingly had no effect on vitamin D production and storage in the face of normal dietary intake. Future studies will focus on the immunomodulatory changes underlying the effect of vitamin D on the thrombogenic capacity of aPL and mechanisms that lead to abnormal vitamin D levels in APS patients.

Abstract Number: 1448

Single-cell RNA Sequencing of Livedo Reticularis Skin Reveals Endothelial Pathology in Antiphospholipid Syndrome

Hui Shi[1], Allison Billi[1], Rachael Wasikowski[1], Kelsey Gockman[1], Alex Tsoi[1], Johann Gudjonsson[2] and Jason Knight[3], [1]University of Michigan, Ann Arbor, [2]University of Michigan, Ann ArborUniversity of Michigan, [3]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Antiphospholipid syndrome (**APS**) is a thromboinflammatory disease that can present with a variety of clinical phenotypes. Livedo reticularis is the most common skin manifestation of APS, representing a netlike pattern of reddish-blue skin discoloration indicative of superficial vessels that have swollen in response to sluggish flow in the deeper vascular network. Interestingly, livedo reticularis is predictive of APS patients at higher risk of cerebrovascular events. Although the interaction between antiphospholipid antibodies (**aPL**) and endothelial cells are likely key mechanistic drivers of livedo reticularis, these cells have rarely been directly studied. Here, we used single-cell RNA sequencing to begin to characterize APS endothelial cells.

Methods: We applied single-cell RNA sequencing to skin biopsies of two APS patients with livedo reticularis and three matched controls with neither APS nor livedo; t-distributed stochastic neighbor embedding (**t-SNE**) was then

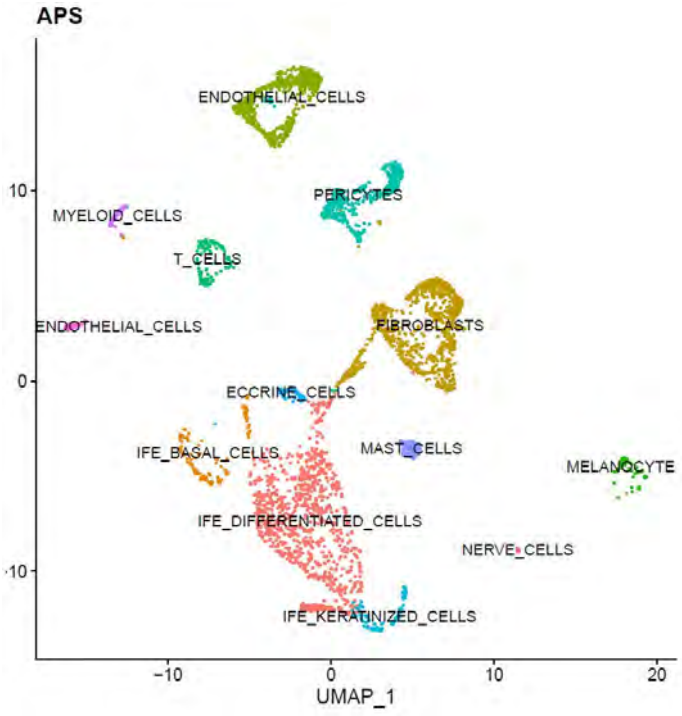

Figure 1. t-SNE analysis of the cells isolated from the antiphospholipid syndrome (APS) skin with livedo reticularis. Defined number of 13 clusters with every cluster represented by a different color.

used to identify the various cell types. We performed GO and pathway enrichment by using Database for Annotation, Visualization, and Integrated Discovery (**DAVID**) analysis.

Results: By combining the t-SNE analysis with the expression of known endothelial cell markers, we identified three subpopulations of endothelial cells among the sorted cells (**Figure 1**). Subsequently, we compared expression profiles between endothelial cells from healthy and APS skin and found significant upregulation of CD36 (a scavenger receptor) and TXNIP (a mediator of oxidative stress) in APS endothelial cells. Using DAVID analysis, we revealed that the APS endothelial cell expression profile is enriched for processes associated with cell adhesion, angiogenesis, and type I interferon signaling.

Conclusion: To our knowledge, this is the first direct analysis of gene expression in APS endothelial cells. These data suggest that APS endothelial cells from skin affected by livedo reticularis demonstrate a pattern of gene expression associated with endothelial activation and damage. We are actively recruiting additional patients into the study in pursuit of providing a foundation for future studies of vascular injury in APS.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: To identify shared and differential changes in the splicing machinery of immune cells from antiphospholipid syndrome (APS), systemic lupus erythematosus (SLE) and antiphospholipid syndrome with lupus (APS plus SLE) patients, and their involvement in the activity and clinical profile of these autoimmune disorders.

Methods: Monocytes, lymphocytes and neutrophils from 70 patients (14 APS, 36 SLE and 20 APS plus SLE) and 23 healthy donors (HD) were purified by immunomagnetic selection. Then, 45 selected elements of the splicing machinery were evaluated using a microfluidic qPCR array (Fluidigm). In parallel, extensive clinical/serological evaluation was performed, comprising renal, obstetric and cardiovascular (CV) involvement, along with autoantibodies and inflammatory molecules. Correlation/association studies and logistic models among those clinical and analytical parameters were developed. Mechanistic *in vitro* studies were performed by incubation of HD-leukocytes with purified

aPL-IgG or anti-dsDNA-IgG. Overexpression of selected components was further performed to evaluate their role in the leukocytes' activity.

Results: Compared with HD, 35, 31 and 14 splicing machinery components were differentially expressed in monocytes, lymphocytes and neutrophils, respectively, from SLE patients; 25, 17 and 21 on APS patients, and 18, 29 and 23 in APS plus SLE patients.

Although a number of spliceosome components were found commonly deranged in the leukocyte subsets of the three disorders, each disease displayed an specific alteration, further associated with distinctive clinical features. Hence, in APS, altered expression of PRPF8 was linked to heightened CV-risk factors (HTA and dyslipidemia), thrombotic recurrences, and the CV events number. In APS plus SLE patients, RNU4 and SF3B1 were associated to CV-related parameters (HTA, microvascular endothelial dysfunction and apoB/A ratio). Besides, levels of these spliceosome components correlated with those of several plasma inflammatory mediators.

Lastly, in SLE patients, levels of key splicing machinery components (RNU6, PRPF8, RAVER1 and TCERG1) were associated to positivity for anti-dsDNA, activity of the disease (SLEDAI), the inflammatory plasma profile, and enhanced CV-risk factors (carotid-intimae media thickness, endothelial dysfunction and atherogenic index), along with obstetric complications and nephropathy.

Finally, *in vitro* treatment of HD lymphocytes with aPL-IgG or anti-dsDNA-IgG changed specific spliceosome components found altered *in vivo* in the three autoimmune diseases. The overexpression of selected spliceosome components in leukocytes further modulated the expression of inflammatory cytokines.

Conclusion: 1) The splicing machinery is profoundly altered in leukocytes from APS, APS plus SLE and SLE patients, and closely related to the activity of these diseases, their autoimmune and inflammatory profiles. 2) The analysis of the splicing machinery allows the segregation of APS, APS plus SLE and SLE, with specific components explaining the CV risk and organ involvement in these highly related autoimmune diseases.

Integrative Analysis of DNA Methylation and Gene Expression in Monocytes from Primary Antiphospholipid Syndrome Patients Identifies a Gene Expression Signature Associated with Their Atherothrombotic Phenotype

Carlos Pérez-Sánchez[1], M Angeles Aguirre[2], Alejandra Maria Patiño-Trives[1], Laura Pérez-Sanchez[3], Maria Luque-Tevar[1], Iván Arias de la Rosa[1], María-Carmen Abalos-Aguilera[1], Pedro Segui[4], Javier Rodriguez-Ubreva[5], Esteban Ballestar[5], Nuria Barbarroja[1], Eduardo Collantes-Estévez[2] and Chary Lopez-Pedrera[1], [1]Rheumatology Department, Reina Sofia University Hospital/ Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC)/ University of Cordoba, Cordoba, Spain, Cordoba, Spain, [2]Rheumatology Department, Reina Sofia University Hospital/ Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC)/ University of Cordoba, Cordoba, Spain, Córdoba, Spain, [3]Hospital Universitario Reina Sofía, Córdoba, Spain, [4]IMIBIC/University of Cordoba/Reina Sofia Hospital, Cordoba, [5]Josep Carreras Institute (IJC), Badalona, Spain

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Antiphospholipid Syndrome

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: 1. To develop integrated analyses of the genome-wide DNA methylation and gene expression profiles in monocytes from APS patients and assess their involvement in cardiovascular pathology. 2. To evaluate the role of antiphospholipid antibodies (aPL) in the regulation of these processes.

Methods: Thirty-three APS patients were included in the study. Monocytes were isolated from peripheral blood by positive immunomagnetic selection. The Illumina Infinium Methylation EPIC Beadchip was used to obtain DNA methylation profiles across approximately 850,000 CpGs. Total RNA was processed for sequencing library preparation using 75bp paired-end NextGen sequencing (Illumina NextSeq 500 instrument). To examine the impact of DNA methylation on the local regulation of gene expression, the Pearson correlation (r) was calculated between the beta values (β) of CpGs located in promoter regions and the normalized expression values of the corresponding genes. Functional classification of these genes was carried out by gene ontology analysis. Gene expression of selected genes was evaluated by RT-PCR. CV-risk parameters were further assessed, and correlation/association studies were developed with clinical/analytical variables. The effects of aPLs were also evaluated by *in vitro* studies.

Results: Integrative analysis of DNA methylation and gene expression identified 4727 mRNAs whose expression was linked to methylation levels. Functional classification of these genes revealed signatures associated with biological processes and pathways related to immune response, adhesion, oxidative stress and vascular signaling. Thus, correlation and association studies showed that altered mRNA expression of several genes whose altered expression was linked to aberrant methylation levels were further related to the CV-risk score, -aGAPSS- (TGFB1, SERPINB6, NFKB1, SLC25A24, IFNAR2, CXCL8, SOD2), the vascular involvement -type of thrombosis and thrombotic recurrences- (IFI52, IL18BP, IL6R, ITGA5, SLC25A26, STAT5A) and the microvascular endothelial dysfunction (HLA-DPA1, SLS25A26,SLC25A45, SERPINB9). Abnormal methylation and transcription levels of several genes were further associated with a pathological increase of the CIMT.

Lastly, expression levels of several genes related to cytokine-mediated signaling pathway, oxidative stress and mitochondrial dysfunction (PLXND1, CXCR4, PDE4A, TNFRSF1A, IL17RA, MMP17, CXXC1, IL10RA, TNFRSF1B, SER-

PINB6, NFKB2, SFPQ, ILF3, STAT5A, JAK2) correlated with aPL titers. In vitro studies further supported the role of aPLs as key players in the altered methylation and transcriptomic profiles of APS patients.

Conclusion: APS patients showed coordinately impaired methylation and gene expression profiles in monocytes of genes associated with clinical features of the disease such as autoantibody titers, CV risk score -aGAPSS-, thrombotic recurrences and early atherosclerosis. These results offered a map to the monocytes methylome and their influence on gene expression, and shed light on the pathophysiology of APS, paving the way for the development of effective biomarkers and therapeutics.

Abstract Number: 1451

Longitudinal Assessment of Anti-beta 2 Glycoprotein in SLE

Michelle Petri[1], Laurence Magder[2] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Although anti-beta2 glycoprotein is one of the three antiphospholipid antibodies recognized in the Sydney APS classification criteria, it is one of the least studied. Lupus anticoagulant, the antiphospholipid antibody most associated with both thrombosis and adverse pregnancy outcomes, can be divided into two subsets: those that target beta2 glycoprotein I and those that target prothrombin (Blood 1995;86:617-23). In SLE, lupus anticoagulant can fluctuate over time, making it difficult to define which patient is “persistently positive”. Fluctuation could reflect change in SLE activity, change in SLE treatement, or both. We looked at two definitions of “positive”: 20 (medium) as in the classification criteria; or 40 as part of “triple positivity”. We sought to address some of these questions in our prospective SLE cohort.

Methods: The SLE patients met revised ACR and/or SLICC classification criteria. Anti-beta 2 glycoprotein IgG, IgM, and IgA were measured by ELISA (INOVA) at 2,393 visits in 1,417 patients. The patients were 92% female, 50% Caucasian, and 40% African-American. Forty-three percent of the patients had more than 1 assessment (57% had 1, 26% had 2, 10% had 3, and 7% had 4 or more assessments).

Results: Anti-beta 2 glycoprotein IgG > 20 (medium positive) or > 40 (high positive) was more common in Caucasians than in African-Americans (p=0.0012, 0.0089) but IgA > 20 or > 40 was more common in African-Americans (p=NS). Table 1 shows that about 40-76% of the time a patient who was positive at the first check became negative at the second check (but the converse was not true: most patients initially negative remained negative). Table 2 shows the effect of testing over multiple visits. IgA remained the most frequent isotype. There was minimal incremental value in serial testing overall. Table 3 shows a multiple variable model for the isotype (IgG) most associated with thrombosis. IgG anti-beta 2 glycoprotein was clearly less frequent in African-Americans and was also clearly reduced in those tak-

Isotype/cutoff	Of those positive on first visit, proportion negative on second visit	Of those negative on first visit, proportion positive on the second visit
IgA>20	39/97 (40%)	11/407 (3%)
IgA>40	26/53 (49%)	8/451 (2%)
IgG>20	12/23 (52%)	7/481 (1%)
IgG>40	8/14 (57%)	5/490 (1%)
IgM>20	47/62 (76%)	5/442 (1%)
IgM>40	13/20 (65%)	6/484 (1%)

Proportion who changed status from first to second visit.

Isotype	Number of visits	Ever >20	Ever>40
IgA	1 (n=810)	144 (18%)	71 (9%)
	2 (n=371)	79 (21%)	47 (13%)
	3 (n=142)	37 (26%)	18 (13%)
	4+ (n=92)	12 (25%)	8 (9%)
IgG	1 (n=810)	46 (6%)	33 (4%)
	2 (n=371)	23 (6%)	18 (5%)
	3 (n=142)	8 (6%)	3 (2%)
	4+ (n=92)	6 (7%)	3 (3%)
IgM	1 (n=810)	107 (13%)	34 (4%)
	2 (n=371)	41 (11%)	15 (4%)
	3 (n=142)	20 (14%)	9 (6%)
	4+ (n=92)	18 (20%)	7 (8%)

Number (%) ever positive, by number of assessments.

ing hydroxychloroquine. There was borderline evidence, in contrast, that it might be reduced by immunosuppression

Predictor and comparison	Odds Ratio (95% CI)	P-value
Black (vs. White)	0.42 (0.24, 0.75)	0.0032
Other (vs. White)	0.86 (0.39, 1.92)	0.72
Plaquenil	0.62 (0.41, 0.93)	0.022
Aspirin	1.97 (1.31, 2.98)	0.0013
Anticoagulant	2.97 (1.77, 5.00)	<0.0001
Immunosuppressant	0.65 (0.41, 1.02)	0.060

Multivariate model for association between predictors and Anti-beta 2 IgG

treatment (p=0.06). A similar multivariate model of IgA anti-beta 2 glycoprotein showed that hydroxychloroquine also reduced IgA (OR 0.72, 95% CI 0.58, 0.90; p=0.004).

Conclusion: Anti-beta 2 glycoprotein IgG is more common in Caucasian than African-American SLE, but the opposite is true for the IgA isotype. As with other antiphospholipid antibodies in SLE, there is considerable fluctuation over visits, with 40-76% becoming negative at a second check. Hydroxychloroquine use reduced both the IgG and IgA isotypes, again reinforcing the benefit of hydroxychloroquine in thrombosis reduction. The IgA anti-beta 2 glycoprotein finding is particularly important, in that hydroxychloroquine did not reduce IgA anticardiolipin (Lupus Sci Med 2016;3:e000107).

Transcriptomic Meta-analysis Reveals a Core Transcriptional Program in Murine B Cell Anergy and Implicates Immunometabolic Regulation as a Central Pathway in Maintaining Non-responsiveness of Autoreactive B-cells in Both Mouse and Man

Isaac Harley[1], Bergren Crute[2], Andrew Getahun[2] and John Cambier[3], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Colorado – Anschutz Medical Campus, Aurora, [3]Univ, Aurora

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The mechanisms self-tolerance loss that lead to autoantibody-mediated autoimmune disease remain underdefined. The rapid reversibility of peripheral B-cell tolerance in murine models suggests that non-durable biochemical mechanisms predominate to enforce this state, termed anergy. However, transcriptomic differences between anergic B-cells and their naïve non-anergic counterparts have also been described in murine models. Current understanding holds that B-cell anergy is maintained through chronic antigen receptor stimulation. This suggests that a core transcriptional program might extend across B-cell anergy in autoantigen systems of differing specificity. Here, we sought to understand whether such a core transcriptional program exists and performed initial functional characterization of one implicated pathway.

Methods: Data used in this analysis was from a combination of publicly available microarray/RNA-Seq data and a previously unpublished RNA-Seq experiment. All experimental conditions compared anergic B-cells to their naïve non-anergic counterparts. Data were analyzed using the NetworkAnalyst platform. Following normalization and batch effect correction, meta-analysis comparing anergic to naïve non-anergic B cells was carried out using Fisher's method with a threshold of $P < 1E-8$. Pathway analysis was performed using Enrichr. For confirmatory studies, murine splenocytes or human PBMC were stained with CD36 along with B-cell subpopulation markers. For functional experiments, Ramos cells were pre-treated with palmitoyl-carnitine and calcium flux was determined kinetically following B-cell receptor crosslinking.

Results: Meta-analysis revealed 185 differentially expressed genes with this stringent significance threshold between anergic and naïve non-anergic B cells. Pathway analysis indicated expected enrichment of antigen receptor signaling pathway gene expression in anergic B cells. Surprisingly, genes involved in several metabolic pathways were differentially expressed. Of these, *Cd36* stood out as one of the genes with lowest relative expression in anergic B-cells. We focused on its role as a key regulator of several metabolic pathways. Indeed, flow cytometry confirmed decreased CD36 protein expression on anergic B cells in comparison to their naïve non-anergic counterparts within the wild type repertoire. Similar decreases were observed in BCR-transgenic mouse models of anergy and the peripheral

blood anergic human B-cell compartment. Ramos cells pre-treated with palmitoyl-carnitine, a metabolic intermediate downstream of CD36 exhibited dose-dependent suppression of calcium influx upon BCR-crosslinking.

Conclusion: Taken together, our results define a core transcriptional program of murine B-cell anergy and highlight metabolic pathways in the maintenance of tolerance in autoreactive B-cells. These findings are likely to inform our understanding of the long-term effects of therapies targeting metabolic pathways on the maintenance of tolerance in autoreactive B-cells. Further defining these mechanisms will nominate novel potential therapeutic approaches for autoimmune diseases.

A First in Class Therapeutic Nanoparticle for Specific Targeting of Anti-citrullinated Protein Antibody Ameliorates Serum Transfer and Collagen Induced Arthritis

Sangita Khatri[1], Jonas Hansen[1], Mads Clausen[1], Tue Wenzel Kragstrup[2], Shu-Chen Hung[3], Elizabeth Mellins[4] and Kira Astakhova[1], [1]Technical University of Denmark, Copenhagen, Denmark, [2]Aarhus University, Aarhus, Denmark, [3]Amgen, Thousand Oaks, [4]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Rheumatoid arthritis (RA) is an immune mediated inflammatory disease with autoimmune features, including antibodies to citrullinated proteins and peptides (ACPAs). Several in vitro studies have suggested a pathogenic role of ACPAs in RA. However, in vivo proof of this concept has been hampered by the lack of therapeutic strategies to reduce or deplete ACPA in serum and synovial fluid. Previously, we constructed a chitosan-hyaluronic acid nanoparticle formulation with the ability to use neutrophil recruitment as a delivery mechanism to inflamed joints.[1] We hypothesized that reducing ACPA levels would have a therapeutic effect by blocking cytokine production. In this study, we prepared and tested a series of therapeutic nanoparticles for specific targeting of ACPA in synovial fluid.

Methods: Nanoparticles were prepared by the microdroplet method and then decorated with synthetic cyclic citrullinated peptide aptamer PEP2, PEG/hexanoic acid and fluorophore (Cy5.5). Nanoparticles were characterized by dynamic light scattering (DLS), scanning electron microscopy (SEM) and high-performance liquid chromatography (HPLC). Nanoparticles were then used in a series of in vitro assays, including cell uptake with flow cytometry (FACS) detection, and in vivo studies including disease activity scores, cytokine measurements and near-infrared imaging.

Results: We screened a series of citrullinated peptide epitopes and identified a fibrinogen-derived 21-amino-acid-long citrullinated peptide showing high selectivity toward autoantibodies in RA samples. We incorporated this aptamer in the chitosan-hyaluronic acid nanoparticle formulation previously described. Average nanoparticle size was 230 nm ± 10 nm by DLS and SEM; z potential was -0.0012. Attachment efficiency of aptamer was 92% by HPLC. FACS study showed selective uptake of Cy5.5 labelled aptamer-nanoparticle conjugates by neutrophils in the concentration range 0.5 nM-4 nM. In vitro, the aptamer-nanoparticles dramatically decreased Ly6C expression in mouse

bone marrow cells analyzed by FACS. In vivo, over 50% reduction of disease activity was achieved in three weeks treatment using as little as 1 nM drug candidate (dosed every 48 hours) in the collagen-induced (CIA) mouse model of RA (N=30; $p< 0.001$ for treated vs placebo). The aptamer-nanoparticle conjugate, significantly reduced IL-6 and TNFα levels in the mouse sera ($p< 0.01$). Importantly, this effect was confirmed in the serum transfer arthritis model (N=10). The effects was not inferior compared with tocilizumab treated controls (N=30). To confirm mode of action, we applied Cy5.5-labelled aptamer-nanoparticles in the collagen induced mouse model (N=10), and analyzed the resulting uptake by near-infrared imaging. We confirmed over 6-fold higher accumulation of the signal in inflamed vs healthy joints ($p< 0.01$), which strongly supports the fact that the aptamer is highly specific to the inflammatory process.

Conclusion: Overall, we have designed a first in class therapeutic nanoparticle drug for specific targeting of anti-citrullinated protein antibodies. The marked effect of this nanoparticle observed in vivo holds promise for targeting ACPAs as a therapeutic option in RA.

Abstract Number: 1454

B Cell-specific TLR7 Regulates Lupus in TLR9 Deficient Mice

Haylee Baxendell[1], Minjung Kim[2], Jeremy Tilstra[2] and Mark Shlomchik[2], [1]University of Pittsburgh, Cranberry Twp, PA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that results in significant morbidity and mortality. In SLE, endosomal TLR7 and TLR9 are known to mediate the anti-self response. We found that TLR9 deletion in the MRL.Fas^{lpr} model of SLE exacerbates disease, despite the requirement of TLR9 for the formation of anti-DNA antibodies. This is dependent on TLR7, suggesting that TLR9 is protective while TLR7 drives pathology. Recently, we found that TLR9 mediates protection specifically in B cells; however, it is unknown whether TLR9 regulates TLR7 in the same cell (*cis*) or in different cells (*trans*). For example, while TLR9 regulates disease in B cells, TLR7 may exacerbate disease in DCs. Thus, a major goal of our lab is to understand the B cell-specific role of TLR7 to inform the development of targeted therapeutics for SLE.

Methods: The MRL.*Fas*^{lpr} model replicates many features of human SLE including ANA production, dermatitis, and renal disease starting from 9-11 weeks of age. MRL.*Fas*^{lpr} mice were generated with a B cell specific deletion of TLR7 (CD19-Cre TLR7$^{fl/fl}$) and compared to Cre- littermates. Deletion was assessed via cell sorting and qPCR of genomic DNA. Lupus pathology was analyzed in female and male mice at 19 and 22 weeks of age, respectively, with parameters including proteinuria, renal histology for interstitial and histologic disease, dermatitis, organ weight, and immune cell activation. CD19-Cre TLR7$^{fl/fl}$ mice were also crossed to TLR9$^{-/-}$MRL.*Fas*^{lpr} mice and analyzed at 16 and 19 weeks of age for females and males, respectively, to study B-cell intrinsic interactions between TLR7 and TLR9.

Results: Validation via qPCR showed specific but incomplete deletion of TLR7, with a 78.60% deletion efficiency in B cells, which was further reduced in plasmablasts. CD19-Cre TLR7$^{fl/fl}$ mice had reduced proteinuria but no analogous

decrease in kidney pathology or other disease parameters. Given the interaction between TLR9 and TLR7, and that TLR9 deficiency accelerates disease, we then studied the effects of B cell-specific TLR7 deficiency in TLR9$^{-/-}$ mice. The CD19-Cre TLR7$^{fl/fl}$ TLR9$^{-/-}$ mice exhibited reduced spleen weights (p=0.002) and an increased proportion of splenic naïve CD4+ T cells. More importantly, they exhibited a significant reduction in proteinuria (p=0.005), glomerulonephritis (p=0.0001), and interstitial nephritis (p=0.0002).

Conclusion: The inefficient deletion of TLR7 suggests that activated, "escapee" B cells could preferentially expand and explain the lack of disease regulation in the CD19-Cre TLR7$^{fl/fl}$ cohort. Conversely, a lack of regulation by TLR9 could allow B-cell specific TLR7 to exacerbate disease to an even greater degree than it could when TLR9 is present. This is suggested by the CD19-Cre TLR7$^{fl/fl}$ TLR9$^{-/-}$ cohort which shows a marked reduction in TLR9-driven lupus exacerbation when TLR7 is deleted in B cells. This supports the hypothesis that TLR9 regulation acts in *cis*, and that B cell specific TLR signaling is a major mediator of SLE. Ongoing studies will continue to address the cell specific roles of TLR7 via a mixed bone marrow chimera and DC specific deletion. Overall, these results indicate that targeting TLRs in B cells could be a viable therapeutic strategy in SLE.

Functional Characterization of *PLCG2* Mutations Found in Subjects with Autoinflammation and *PLCG2*-Associated Antibody Deficiency and Immune Dysregulation (APLAID) Reveals Both Hypermorphic and Hypomorphic Mutants

Kathleen Baysac[1], Charles Fisher[2], Hiroto Nakano[2], Joshua Milner[3] and Michael Ombrello[4], [1]NIAMS, NIH, Bethesda, MD, [2]NIAMS, NIH, Bethesda, [3]Division of Allergy, Immunology and Rheumatology Columbia University Medical Center, New York, NY, [4]Translational Genetics and Genomics Unit, NIAMS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: *PLCG2*-associated antibody deficiency and immune dysregulation (PLAID) and autoinflammatory PLAID (APLAID) are autosomal dominant diseases caused by mutations of *PLCG2.* APLAID is clinically characterized by episodic fever, severe interstitial lung disease (ILD), antibody deficiency and inflammation of the eyes, skin and gut. To date, 3 mutations have been reported to cause APLAID (S707Y, L848P, M1141K), each leading to increased PLCg2-dependent signaling following stimulation. Since our initial descriptions of PLAID/APLAID, we have received >100 referrals of patients with severe forms of immune dysregulation and mutations in *PLCG2*. Here, we leverage this cohort to expand our understanding of *PLCG2* variants that cause autoinflammatory phenotypes.

Methods: Subjects with immune dysregulation and mutations in *PLCG2* were referred to our group for evaluation; those with autoinflammatory features (episodic fever or ILD) were identified and their mutations were investigated. Characteristics of *PLCG2* variants, including allele frequencies, metrics of evolutionary conservation and predicted functional consequences, were assessed using Annovar. Mutant forms of *PLCG2* were generated for *in vitro* studies by site-directed mutagenesis of a GFP-tagged PLCg2 construct. Constructs were overexpressed in *Plcg2*-deficient DT40 B cells. Cells were assayed for BCR-induced calcium flux and ERK phosphorylation. Cells were stained with

the calcium-binding fluorophore, Indo-1, and intracellular calcium levels were observed by flow cytometry at baseline and following BCR cross-linking with anti-IgM antibody. Similarly, ERK phosphorylation was measured by flow cytometry before and after BCR-stimulation.

Results: We identified 16 subjects with autoinflammatory features bearing 16 ultra-rare/novel missense mutations of *PLCG2.* The most common autoinflammatory features were episodic fever (81%), cutaneous inflammation, including blistering, granulomatous or nodular skin lesions (63%) and ILD (38%). Arthritis and gastrointestinal inflammation were each present in 25% of patients, while half of patients had antibody deficiency. All mutations were located at evolutionarily conserved residues, each was predicted to alter protein function and 14 were previously unreported. Overexpression studies identified 3 groups of variants that produced distinct responses to BCR cross-linking: 1) 5 variants whose response was indistinguishable from wild type *PLCG2;* 2) 5 variants with hypermorphic responses consistent with S707Y; and 3) 6 variants with hypomorphic responses, 1 of which was amorphic. In all, we identified signaling alterations in 11/16 *PLCG2* mutations found in these patients.

Conclusion: This study describes 14 new mutations of *PLCG2* found in 16 APLAID patients with clinical features consistent with published cases. A third of the mutations produced a typical hypermorphic pattern in our *in vitro* system of B cell activation, but surprisingly, another third of variants reproducibly produced hypomorphic or amorphic responses. Future investigations should focus on the interrogation of primary patient cells and specific examination of differential effects in different *PLCG2*-expressing cells.

Exploring the RA Bone Marrow Niche by Single-cell Technology to Identify Long Lived ACPA+ Plasma Cells

Khaled Amara[1], Aase Hensvold[2], Radha Thyagarajan[1], Lena Israelsson[1], Johanna Steen[1], Heidi Wähämaa[1], Monika Hansson[1], Marianne Engström[1], Annika van Vollenhoven[1], Anca Catrina[2], Vivianne Malmström[3] and Caroline Grönwall[1], [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden, [3]Karolinska Institutet, Stockholm, Stockholms Lan, Sweden

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Autoantibodies is a hallmark of rheumatoid arthritis, placing the adaptive immune system and B-cells centrally in the pathogenesis. The anti-citrullinated autoantibodies (ACPA) detected in the serum can be produced either by circulating plasma blasts, locally residing plasma cells the joint, or long-lived plasma cells in the bone marrow (BM). Here we use different single cell methods to investigate the bone marrow niche.

Methods: Bone marrow samples from proximal femur in RA patients undergoing hip joint replacement was processed to isolate mononuclear cells. In total four CCP2+ and one CCP2- RA patients were investigated. All patients were HLA shared epitope positive. Firstly, CD138+ plasma cells were single cell sorted by flow cytometry followed by BCR sequencing. For two of the RA patients, MACS enriched BM B cell and peripheral B cells were further investigated by 10X Genomics Chromium methodology for single-cell RNAseq profiling and immunoglobulin sequencing.

Selected paired heavy-light Ig-chains with N-glycosylation sites and high somatic hypermutation level were subsequently expressed as recombinant IgG and investigated for citrulline reactivity using an autoantigen array.

Results: For the single-cell sorted CD138+ cells, in total 509 complete IgG+ BCR sequences were generated and 44 monoclonal IgG were expressed (36 from CCP+ RA). Among the mAbs, two clones from two different patients were identified as CCP2+. One of these originated from an IgG4+ plasma cell and had strong reactivity and multi-specificity for different cit-peptides (e.g. cit-fibrinogen, cit-tenascin C, cit-hnRNP derived). 10X cell capture of 8391 BM B-cells from the same patient, generated 856 Ig with a RNAseq plasma cell profile (i.e. CD27+ XBP1+ MZB+ DERL3+ JCHAIN+ SSR4+) from 832 unique clones defined by paired HCDR3-LCDR3, occurring 1-6 times. Five 10X clones whereof two in plasma cell clusters were overlapping with the single cell sort (N=92). We observed a high frequency of both Fab glycosylation (31% of IgG+ plasma cells) and IgG4+ cells (6% of IgG+ plasma cells). Notably, also IgA+ plasma cells could be identified (37% IgA1+ 3% IgA2+). In comparison, by 10X, 24% BM IgG+ plasma cells from the CCP2- patient had Fab N-glyc sites and no IgG4+ were detected. We found no direct BCR overlap with the BM plasma cells in investigated paired peripheral B cells.

Conclusion: ACPA+ long lived plasma cells can be found in the bone marrow niche and BM-derived ACPA display multi-reactivity profiles as also seen in synovial ACPA+ plasma cells [1-2]. However, they may be relatively rare and no large clonal expansions were found. In the bone marrow, similar to blood, B-cell repertoire skewing with increased N-glycosylation and IgG4 frequencies can be observed.

Two Minute Walking Distance and Other Timed Function Tests Are Superior to MMT-8 in Assessing Outcomes in Polymyositis and Dermatomyositis

Sai kumar Dunga[1], Chengappa G Kavadichanda[2] and VS Negi[2], [1]Jawaharlal institute of postgraduate medical education and research, puducherry, India, [2]Jawaharlal institute of postgraduate medical education and research, Puducherry, Puducherry, India

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Clinical Practice II
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Inflammatory myositis are heterogenous group of diseases affecting skeletal muscles and multiple different organs. Assessing improvement in disease activity is done by Manual muscle testing (MMT) and Functional index 2(FI-2). These are time taking and need expertise to administer. Several Timed function tests (TFTs) like the 2- minute walk test (2MWT) or 30s raise from a chair test and 30s 1kg arm rise test may be better alternatives and less time taking. Moreover these tests can be self-administered by patients themselves. In the current world of accountability for treatment response and improvement in technology, these TFTs upon self-administration in particular time intervals have the potential to provide objective data on diseases status enabling the physician to make therapeutic decisions. We undertook a study with objective to evaluate the performance of TFT in assessing muscle diseases at baseline and to evaluate the performance of TFTs to detect change in muscle power and endurance with treatment.

Methods: This is an observational cohort study which included 29 patients with polymyositis and dermatomyositis satisfying ENMC classification criteria. Patients with inclusion body myositis, overlap myositis, chronic kidney disease, coexisting myocarditis, sepsis, malignancy, pregnancy were excluded. MMT8, FI-, EQ-5D and Timed function tests were done at baseline and after 3 months.

Results: The study had 29 patients of which 6 were polymyositis and 23 were dermatomyositis. Male to female ratio was 1:2.1. Anti-cell antibody was positive in 20 patients. Out of 29 patients, 11 had active disease and rest 18 had stable disease. Mean scores of MMT8, Fi-2 and TFTs are shown in table 1. The 3 TFTs had moderate to high correlation with MMT8 and FI-2 at baseline in inactive disease group but only with FI-2 in active disease as shown in Table 2. At 3 months, change in all 3 TFTs significantly correlated with change in Fi-2 in active disease, but in stable disease only 2MWD had moderate correlation with MMT8. (Table 3)

Conclusion: 2 Minute walk distance is a better alternative to the conventional muscle testing as it measures both power and endurance. This score can overcome the ceiling effect of MMT-8. Besides, owing to the ease of administration 2MWD may be used as a patient reported outcome measure in IIM.

Abstract Number: 1458

Slower Current Walking Speed Is Associated with Progression in Radiographic Knee Osteoarthritis: The Johnston County Osteoarthritis Project

Lindsey Duca[1], Liubov Arbeeva[2], Yvonne Golightly[3], Louise Murphy[4], Charles Helmick[4] and Kamil Barbour[5], [1]Centers for Disease Control and Prevention, Chamblee, GA, [2]University of North Carolina at Chapel Hill Thurston Arthritis Research Center, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill Dept of Epidemiology, Chapel Hill, NC, [4]Centers for Disease Control and Prevention, Atlanta, GA, [5]CDC, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Clinical Practice II
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Poorer physical functioning as a single baseline measurement has been associated with increased risk of radiographic knee osteoarthritis (rKOA) progression, but it is unknown whether reduced physical functioning as well as its change over time is associated with rKOA progression. Slower walking speed, suggestive of

decreased physical functioning, or reductions in walking speed may be an early indicator of worsening osteoarthritis or contribute to underlying disease advancement.

Methods: We analyzed Johnston County Osteoarthritis Project data from baseline (1999-2004) and up to three follow up visits (2006-2010; 2013-2015; 2017-2018). Walking time was evaluated over an 8-foot walk distance in two trials; walking speed was calculated as the average of the trials and log-transformed. Progression of rKOA was defined as an increase of one Kellgren-Lawrence (K-L) grade or more in at least one knee between two visits. A joint statistical model (JM), incorporating a linear mixed effects model for repeated walking speed measures and a Cox proportional hazards model for time-to-event outcome of K-L grade increase, was used to evaluate the association between longitudinal walking speed measures and rKOA progression. Two separate JMs were run evaluating 1) change in walking speed (slope) over time (model 1) and 2) current walking speed adjusting for the slope (model 2) on risk of K-L grade increase. Both models were adjusted for sex, race, education, BMI and age at baseline.

Results: Our final sample consisted of 1,606 participants with at least one measurement of walking speed and a minimum of two visits with knee radiographs (average follow-up time was 8 ± 3 years). At baseline, mean age was 62 ± 9 years, over two-thirds of participants were women (67%), and mean walking speed was 3.5 ± 1.8 seconds per 8-foot walk distance. During follow-up, 1,077 (67%) participants had rKOA progression in at least one knee. Application of JM demonstrated model 2 incorporating both the current level and slope of walking speed had the best model fit (model 1 Bayesian Information Criterion [BIC] 6767 vs. model 2 BIC 5661). In model 2, slower current walking speed but not slope was associated with rKOA progression adjusted for sex, race, education, BMI and age at baseline. Specifically, a 50% slower walking speed was associated with 2-fold higher risk for progression (hazard ratio [HR] = 1.99; 95% CI, 1.08-3.67).

Conclusion: rKOA progression is associated with an individual's current level of walking speed and not on the reduction in walking speed over time. Treatment and interventions for individuals with knee OA aimed at improving physical function may help maintain or increase walking speed and slow rKOA progression regardless of the rate of decline.

Session Date: Sunday, November 8, 2020
Session Title: Clinical Practice II
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Frequent bending increases loading at the knee and is a risk factor for worsening knee pain associated with knee osteoarthritis (OA). Knee bending is also common during activities of daily living, such as climbing stairs, and beneficial for lower extremity strength. Presently, it is unclear if frequent knee bending is helpful or harmful for trajectories of pain and function, thus understanding this association is important to help weigh its costs

^adjusted for BL age, sex, BMI, presence of comorbidity, and Physical Activity Scale for the Elderly (PASE) score

Table 1. Odds ratios and 95% confidence intervals for the association between frequent knee bending and pain and gait speed trajectory group membership

and benefits. Therefore, the purpose of this study was to investigate the association of knee bending and 8-year trajectories of pain and function in adults with or at risk for knee OA.

Methods: We used data from the Osteoarthritis Initiative, a prospective cohort study of adults with or at risk for knee OA. Knee bending activities over the previous 30 days were collected at baseline (BL) via two yes/no questions: (1) climbing up 10+ flights of stairs in 1 day (stair use) and (2) lifting/moving objects weighing 25+ lbs by hand in 1 day (lifting). Pain and function were assessed at BL and six follow-up (FU) visits (1, 2, 3, 4, 6, 8 years). Knee pain severity in the past 30 days was determined via a Visual Analogue Scale (VAS; 0-10). Function was assessed using self-selected gait speed over 20m. Samples were restricted to those with low pain (< 3/10) or good function (≥ 1.22m/s) at BL and trajectories were identified using group-based modeling. To determine the association between each knee bending activity and group membership for pain and function trajectories, we calculated odds ratios (OR) and 95% confidence intervals (95% CI) using multinomial logistic regression, adjusted for confounders.

Results: Of those with complete data at BL and at least 2 FU visits, two separate trajectory models were run for both pain (age: 61.9 ± 9.0 years, sex: 56.7% female, BMI: 27.7 ± 4.6 kg/m^2) and function (age: 60.1 ± 8.8 years, sex: 54.7% female, BMI: 27.8 ± 4.5 kg/m^2). We identified 3 pain trajectory groups: Minimal Pain, Low Pain, and Worsening Pain. The Worsening Pain trajectory group exceeded the Patient Acceptable Symptom State (> 3/10) by 24 months, while the other trajectories remained at 0 or 1 (Figure 1). However, no associations were found between knee bending activities and pain trajectory group membership. We identified 3 function trajectory groups: No Decline, Minimal Decline, and Fast Decline. The Fast Decline trajectory dropped below 1.22 m/s by 24 months, while the other trajectories remained above this cutoff with little decline over 8 years (Figure 2). Those who reported no stair use had 40% [1.40 (1.06, 1.84)] greater odds of being in the Fast Decline group relative to those who reported stair use. Those who reported no lifting had 49% [1.49 (1.18, 1.89)] and 61% [1.61 (1.17, 2.21)] greater odds of being in the No or Minimal Decline groups, respectively, relative to those who reported lifting.

Conclusion: Adults who did not engage in knee bending activities at BL had greater odds of membership in the slowest gait speed trajectory group, relative to those who did. Additionally, knee bending was not associated with any of the pain trajectories. This indicates that stair use and lifting may be unrelated to pain and favorably associated with gait speed trajectories in adults with or at risk for knee OA.

Abstract Number: 1460

"Can I Help You with Your RA Today?": A Pilot Study on the User Experience with a Voice-Enabled Smartphone App to Virtually Monitor Disease Activity and Collect ePROs in Rheumatoid Arthritis

Meredith Murray[1], Stephen Penney[2], Adam Landman[3], Josephine Elias[2], Emma Richard[4], Bert Hartog[4] and Daniel H. Solomon[5], [1]Brigham and Women's Hospital, Medfield, MA, [2]Partners Healthcare, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Janssen Research & Development, LLC, Boston, MA, [5]Brigham & Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Clinical Practice II
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic disease that involves frequent patient-provider interaction and self-monitoring, both integral to successful disease management. We developed a novel mobile health smartphone app with a voice-enabled feature to help patients virtually track disease activity and ask general questions about RA. A user-centered design-based approach was used to develop and test the app. This abstract will present information from several phases of development and sources of information including: exit interviews from the previous (V1.0) trial, focus groups, adherence with a revised app (V2.0), outcome data (V2.0), and satisfaction surveys (V2.0).

Methods: We recruited patients with RA who participated in a prior trial of the same app (V1.0). They were asked to help design and test V2.0. We conducted exit interviews from the prior trial and used these results to develop a new prototype of V2.0 that included voice enablement and a question & answer (Q&A) function. The prototype was tested in two focus groups of patients (N=8) and one with providers (N=4). Based on focus group feedback, the V2.0 app was built and given to 26 patients to test for 60 days. The V2.0 app asks patients to fill in patient reported outcomes

Figure 1. Overall adherence during a 4-week period with daily PRO surveys on disease activity, mood, fatigue, sleep, function and pain.

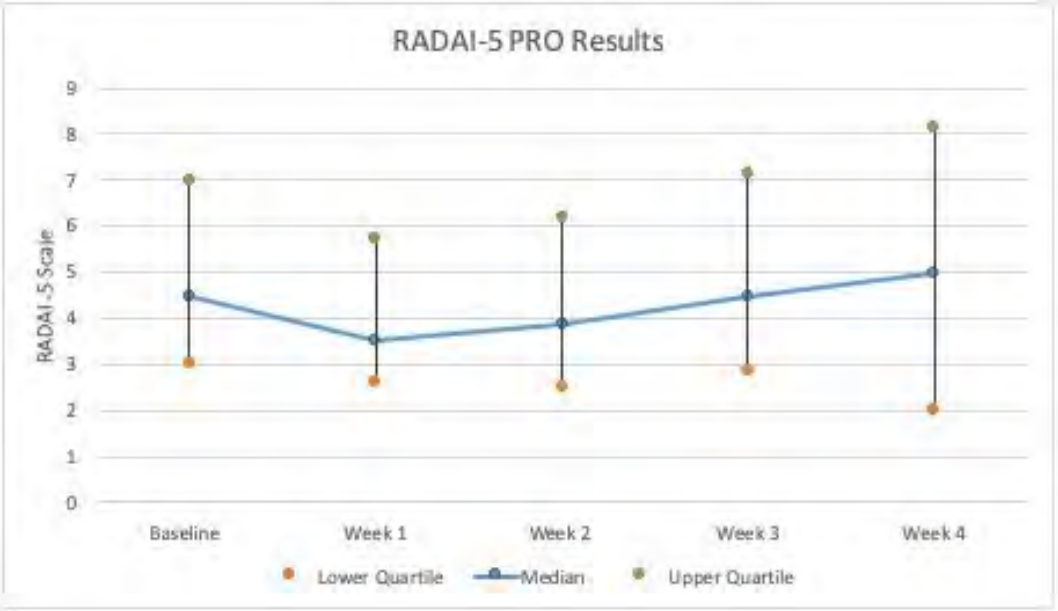

Figure 2. Results from the RADAI-5 PRO surveys, disseminated twice weekly, over a 4-week period with median values and interquartile ranges.

Patient Satisfaction	N, (%)
Overall Experience with App	
Very satisfied	7 (35)
Satisfied	10 (50)
Neither satisfied or dissatisfied	3 (15)
Dissatisfied	0 (0)
Experience Filling Out Surveys	
Very satisfied	10 (50)
Satisfied	9 (45)
Neither satisfied or dissatisfied	1 (5)
Dissatisfied	0 (0)
Experience Filling Out Surveys with Voice Assistant	
Very satisfied	3 (15)
Satisfied	3 (15)
Neither satisfied or dissatisfied	9 (45)
Dissatisfied	5 (25)
Patient Perception of Most Used Survey Method	
Voice more often	0 (0)
Touch more often	20 (100)
Not sure	0 (0)
Experience Using Voice Assistant For Q&A	
Very satisfied	3 (15)
Satisfied	3 (15)
Neither satisfied or dissatisfied	11 (55)
Dissatisfied	3 (15)

Table Patient satisfaction survey results after a 60-day trial testing the V2.0 app (N=20).

(PROs) daily; PROs rotate between disease activity, mood, fatigue, sleep, function and pain. After the trial, subjects completed satisfaction surveys to provide feedback on their experience. Adherence to PROs was defined as questions answered over total daily app questions.

Results: The exit interviews with V1.0 trial participants revealed several priorities for V2.0 including voice enablement and Q&A function. Focus groups showed the majority of participants found these functions helpful and also helped refine the Q&A library. These RA patients made suggestions regarding diction, speed and options embedded within the voice assistant. The 26 V2.0 trial patients were 77% female and 35% were aged 45-54 years. Interim analyses of adherence to daily PROs during the first 28-day period was 58% (95% CI ± 4.2) (Figure 1). Less than 1% of PROs were completed with the voice-enabled feature. Disease activity, measured twice weekly by the RADAI-5, was stable over four weeks, remaining within the moderate disease activity range (3.2 to 5.4) (Figure 2). Of the 20 patients who completed a satisfaction survey after a full 60-day trial, 85% of subjects were satisfied with their experience (Table). It appeared that only half of the patients had used the voice assistant; not all were satisfied with the voice assistant. The voice assistant had an overall 49% success rate at understanding and answering a user's request. Most questions focused on simple medication issues (dosage, interactions, time of day, etc).

Conclusion: We developed a novel mobile health PRO app (V2.0) with a voice assistant employing a user-centered design and conducted preliminary user testing. While adherence was moderate and disease activity was reported as stable, the voice assistant was not tried by all patients limiting feedback. While the Q&A library was widely used, not all patient questions could be answered and some participants were dissatisfied. Exit interviews will further examine patient experience to plan for the next iteration.

Abstract Number: 1461

Implementation, Feasibility and Acceptability of *Take Charge*, an Email Series to Increase Knowledge of Lupus Self-Management Skills

Karin Tse[1], Mary Crimmings[2], Mike Donnelly[2], Reid Dossinger[2], Lauren Metelski[2] and Latifa Boyce[2], [1]Lupus Foundation of America, DC, WA, [2]Lupus Foundation of America, WASHINGTON, DC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Clinical Practice II
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The Lupus Foundation of America developed and launched an educational email series, *Take Charge,* to provide people with lupus educational information, tools and resources on lupus self-management skills to increase knowledge of self-management skills, particularly in newly diagnosed individuals (diagnosis within past 12 months). Topics include: managing day-to-day challenges, explaining lupus to others, building social support, identifying and tracking lupus symptoms, preparing questions for medical appointments, and managing medications. Related skills are: increased self-awareness, communication and coping skills, and symptom and medication management. This abstract describes initial implementation and assessment of feasibility and acceptability of *Take Charge* measured through email campaign analytics and a post-series survey.

Self-Management Skill	Diagnosed within the past 12 months (n=107)	Diagnosed more than 1 year ago (n=347)
Developed my own coping strategy	40.2% (43)	38.0% (132)
Made an elevator speech to explain what lupus is to others	29.9% (32)*	17.6% (61)
Started building a social support network or logged into LupusConnect	28.0% (30)*	13.3% (46)
Identified and tracked my symptoms	59.8% (64)*	43.8% (152)
Got some questions ready for the next appointment with my doctor	62.6% (67)*	49.9% (173)
Started to track my medications or other treatments	32.7% (35)	23.3% (81)
None of the above	5.6% (6)	10.4% (36)

Table 1. Self-management skills reportedly tried, by diagnosis status; *indicates $p<0.05$

Methods: 8 total messages were distributed weekly to self-subscribed participants through an online communications platform, Luminate Online. 6 of the 8 messages focus on self-management topics and present additional resources, including worksheets and trackers, to further develop skills. The series ends with a 9-question post-series survey programmed in Qualtrics and summary of additional lupus resources. Participants reported time of lupus diagnosis and all self-management skills tried through multiple choice, and rated how interesting and helpful the series was on a scale of 1-10, with 10 being the most interesting and helpful. Open-text responses elicited feedback on likes/dislikes of the series and topics for future inclusion. Cross-tabulation analysis was conducted in Qualtrics.

Results: Nearly 6,500 individuals subscribed to *Take Charge*, with 45,792 emails sent at an average email open rate of 44.5% and click-through rate to provided resources of 11.8%. 494 participants completed the post-series survey, with 22% (n=107) reporting being newly diagnosed in the past 12 months, 70% (n=347) diagnosed more than 1 year ago, and the remaining were not yet diagnosed, indirectly connected or not connected to lupus at all. Top reported skills tried after series participation were preparing questions for medical appointments (55%, n=268), identifying and tracking symptoms (48%, n=238), and developing a coping strategy (39%, n=190). Newly diagnosed individuals were significantly more likely ($p< 0.05$) to report preparing questions for appointments, identifying and tracking symptoms, building a social support network, and making an elevator speech on lupus compared to those diagnosed more than 1 year ago (**Table 1**). Participants rated the series an average of 7.83 for interesting content and 7.96 for helpfulness. Lifestyle topics, such as diet and exercise, were highly recommended.

Conclusion: *Take Charge* is feasible to distribute through email communication platforms such as Luminate Online, with open and click-through rates higher than industry standards. *Take Charge* appears acceptable in interest, helpfulness, and delivering actionable self-management skills to newly diagnosed individuals with lupus. Future updates should include additional topics and updated evaluation tools to measure changes in knowledge, such as pre-post testing.

Abstract Number: 1462

Intensity and Duration of Silica Exposure Increase Rheumatoid Arthritis Risk Among Coal Miners

Laura Trupin[1], Gabriela Schmajuk[2], Edward Yelin[1] and Paul Blanc[1], [1]UCSF, San Francisco, CA, [2]University of California, San Francisco, Atherton, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health I: RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Exposure to inhaled mineral dust, particularly silica, has been associated with increased risk of rheumatoid arthritis and other autoimmune diseases. Coal mining, which can involve substantial silica exposure, was strongly linked to risk of RA in our initial survey in the Appalachian region of the U.S.[1] Using additional survey data, we further analyzed the intensity and duration of coal mining-related exposure, in particular from silica, on the risk of RA.

Methods: We conducted a random digit dial telephone survey in 2019 within selected counties in the Appalachian region with the highest coal workers' pneumoconiosis mortality rates identified by NIOSH, based on our previously validated methods. Eligibility was limited to males age ≥50, with any work history. Structured telephone interviews included demographics, history and details of coal mining work, other occupational dust exposures, and self-reported physician diagnoses of arthritis, including RA. RA was defined 2 ways: based on a reported physician diagnosis and either glucocorticoids or DMARDS prescribed for joint symptoms. We used logistic regression analyses to estimate the risks of any type of arthritis and RA (by each definition), associated with coal mining and other occupational exposures to silica. Additional models estimated risks associated with extensive time worked in underground coal mining and coal mining jobs with high intensity silica exposure, based on data from occupational health analyses. All models controlled for age and smoking status (current/former/never). The models of RA risk excluded those reporting a diagnosis of arthritis but who did not meet the given study definition of RA.

Results: We interviewed a population sample of 2,008 men, average age 67±10 years, of whom 93% were white and 58% ever smokers. Coal mining work was reported by 409 (20%) and 557 (28%) reported work-related silica exposure outside of coal mining. Among coal miners, 258/409 had specific job tasks with likely high-intensity silica exposure and 263 worked underground. Arthritis was highly prevalent: 1171 (58%) reported a physician diagnosis of any type of arthritis, RA with glucocorticoids in 202 (10%), and RA with DMARDs in 88 (4%). Coal mining and other occupational silica exposure were associated with an increased odds of arthritis, with increased risk for RA using

Table 1. Arthritis and RA associated with coal and silica exposure from logistic regression models adjusted for smoking and age

	Model outcomes		
Coal and Silica exposure	Arthritis (any type) (n=2008)	RA (definition 1) (n=1039)	RA (definition 2) (n=925)
	Odds ratios (95% confidence intervals)		
No exposure to coal mining or other occupational silica	ref.	ref.	ref.
Model 1: Any exposure			
Coal mining exposure	2.3 (1.8, 2.9)	3.6 (2.4, 5.5)	3.4 (1.8, 6.5)
Silica exposure from non-coal occupations only	1.9 (1.5, 2.3)	3.2 (2.2, 4.6)	4.6 (2.7, 7.9)
Model 2: Intensity of exposure			
High silica coal mining exposure	2.5 (1.8, 3.4)	4.1 (2.6, 6.7)	3.9 (1.9, 8.0)
All other coal mining exposure	2.0 (1.4, 2.8)	2.9 (1.6, 5.2)	2.7 (1.1, 6.8)
Model 3: Underground mining exposure			
≥18 years	3.3 (2.1, 5.1)	5.9 (3.2, 11.0)	4.9 (1.9, 12.4)
1-18 years	1.9 (1.3, 2.9)	3.4 (1.9, 6.2)	3.8 (1.6, 9.0)
No underground work	1.9 (1.3, 2.8)	2.4 (1.3, 4.5)	2.4 (0.9, 6.1)

For all models, odds ratios shown are in reference to the unexposed group, and control for non-coal mining silica exposure, age, and smoking (never/former/current).
Models of RA exclude respondents who report arthritis not meeting the given definition.
Definition 1 based on report of doctor's diagnosis of RA, plus treatment with glucocorticoids.
Definition 2 based on report of doctor's diagnosis of RA, plus treatment with DMARDs, including methotrexate, sulfasalazine, hydroxycholoroqine, azathioprine, leflunomide, tofacitinib, etanercept, adalimumab, infliximab, golimumab, certulizumab, tocilizumab, abatacept, rituximab.
High silica coal mining jobs included roof bolter, slope or shaft construction work, and bulldozer, dragline, or scraper operator.

either definition (Table 1). Coal mining jobs with high intensity silica exposure and individuals with ≥18 years of underground mining manifested a further step-up in risk of RA.

Conclusion: This study provides further confirmatory evidence for coal mining as a significant risk factor for RA, most saliently by showing increasing risk with increasing exposure intensity and duration.

Abstract Number: 1463

Threshold Level for Long-term Healthy Diet Adherence to Reduce the Risk of Rheumatoid Arthritis Among Women in a Prospective Cohort Using a Marginal Structural Model Approach

Nathalie Marchand[1], Yu-Han Chiu[2], Kazuki Yoshida[3], Susan Malspeis[4], Jeffrey Sparks[5], Karen Costenbader[6], Elizabeth Karlson[1] and Bing Lu[7], [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [4]Brigham and Women's Hospital, Boston, [5]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [7]Brigham and Women's Hospital and Harvard Medical School, Newton, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health I: RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Previous analyses in the Nurses' Health Study (NHS) cohorts have shown that eating a healthier diet, as measured by the Alternative Healthy Eating Index (AHEI), is associated with a reduced risk of rheumatoid arthritis (RA) particularly seropositive RA, among younger women. Here, we used a marginal structural model (MSM) approach to determine potential thresholds of dietary improvement on the risk of RA in women.

Methods: We followed 83,585 women in the NHS II (1995-2017) prospective study cohort, where information on lifestyle, diet, and health was obtained biennially through validated questionnaires. We fitted an MSM via weighted pooled logistic regression with inverse-probability-of-censoring and exposure weights to approximately calculate risk ratios (RR) and 95% confidence intervals (CI). The models were adjusted for baseline and time-varying covariates including age,body mass index, smoking, age at menarche, parity and breastfeeding status, menopausal status and hormone use, census tract median family income, prior diet, and total energy intake. Diet quality and risk of incident RA were investigated using dichotomous cut-points of AHEI score (cut-points: 60, 65, 70, 75; AHEI score ranged from 0, which represented the least healthy diet, to 110, which represented the healthiest diet) (**Table 2**).

Results: Over 1,475,223 person years, there were 337 confirmed incident cases of RA. At baseline, the mean age was 40.3 years (SD ±4.6) and the mean AHEI score was 57.1 points (SD ±13.8). During 22 years of follow-up there was a mean AHEI score improvement of 9.1 points (SD ±12.7). The risk of RA, comparing long-term adherence to an AHEI score of at least 75 points with maintaining dietary quality below this threshold, was reduced by more than 50% (RR 0.43; 95% CI 0.27, 0.67) (**Table 1**). Risk reduction was similar for seropositive RA (RR 0.41; 95% CI 0.22, 0.74) and seronegative RA (RR 0.47; 95% CI 0.25, 0.91) (**Table 1**). Maintaining AHEI scores below the threshold of 75 was not associated with a reduced risk of RA.

Conclusion: Our results suggest that adherence to higher diet quality at an AHEI threshold score of ≥75 points may lower the risk of RA by more than 50% in women. Such an improvement could be achieved by increasing fruit, vegetable, nut, legume, whole grain, omega-3, or polyunsaturated fat consumption, or by decreasing sodium, sugar-sweetened beverage, or red/processed meat consumption.

Table 1. Dietary changes required to improve Alternative Healthy Eating Index (AHEI) diet score.

AHEI Components	Change required to achieve 1-point improvement in AHEI diet score
Fruit	Adding 0.4 servings per day
Vegetables	Adding 0.5 servings per day
Nuts and legumes	Adding 0.1 servings per day
Whole grains	Adding 7.5 grams per day
Long-chain omega-3 fatty acids	Adding 25 mg per day
Polyunsaturated fat	Adding 0.8% of total energy
Trans fat	Eliminating 0.35% of total energy
Red and processed meat	Eliminating 0.15 servings per day
Sugar-sweetened beverages	Eliminating 0.1 servings per day
Sodium	Eliminating 222 milligrams per day
Alcohol	Eliminating 0.2 drinks per day

Table 2. Estimated risk of rheumatoid arthritis following long-term adherence to Alternative Healthy Eating Index (AHEI) diet score[1] in the Nurses' Health Study II (1995-2017).

Long-term AHEI diet score adherence models[1]	Percentage of women with long-term adherence to diet score at or above cut-point	All RA		Seropositive RA		Seronegative RA	
		RR	95% CI	RR	95% CI	RR	95% CI
Model 1: AHEI score ≥ 60 v. <60 *Least healthy diet*	40.3%	0.92	(0.59, 1.44)	1.04	(0.62, 1.75)	0.74	(0.32, 1.72)
Model 2: AHEI score ≥ 65 v. <65	28.6%	0.94	(0.62, 1.43)	1.13	(0.69, 1.84)	0.63	(0.29, 1.37)
Model 3: AHEI score ≥ 70 v. <70	18.6%	0.72	(0.48, 1.06)	0.75	(0.45, 1.26)	0.63	(0.35, 1.12)
Model 4: AHEI score ≥ 75 v. <75 *Most healthy diet*	11.1%	**0.43**	**(0.27, 0.67)**	**0.41**	**(0.22, 0.74)**	**0.47**	**(0.25, 0.91)**

1. Higher score indicates healthier diet (AHEI diet score range: 0-110) 2. Adjusted for baseline pervious AHEI score (continuous), age at menarche (12 months breastfeeding), menopausal status and hormone use (pre-menopausal, post-menopausal with never use, current use and past use), census tract median family income (quartiles), and total energy (quintiles).

Multi-Variate Approach Including Serology and Genetics for an Improved Identification of Patients at Risk of Developing Rheumatoid Arthritis

Céline Lamacchia[1], Maresa Grundhuber[2], Isabel Gehring[2], Pascale Roux Lombard[3], Michael John Nissen[1], Andrea Rubbert Roth[4], Ruediger Mueller[5], Ulrich Walker[6], Burkhard Moeller[7], Diego Kyburz[8], Adrian Ciurea[9], Sascha Swiniarski[10] and **Axel Finckh**[11], [1]Geneva University Hospital, Geneva - 14, Switzerland, [2]Thermo Fisher Scientific Phadia GmbH, Freiburg, Germany, [3]Geneva University Hospital, Geneva, Switzerland, [4]Klinik für Rheumatologie, Kantonsspital St Gallen, St Gallen, Sankt Gallen, Switzerland, [5]KSA: Aarau Hospital, Aarau, Switzerland, [6]Basel University Hospital, Basel, Switzerland, [7]Inselspital - University Hospital Bern, Bern, Switzerland, [8]University Hospital Basel, Basel, Switzerland, [9]University Hospital Zurich, Zurich, Switzerland, [10]Phadia GmbH / Thermo Fisher Scientific, Freiburg, Germany, [11]Division of Rheumatology, University Hospitals of Geneva, Geneva, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health I: RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: First-degree relatives of RA patients (FDR-RA) have an increased prevalence for rheumatoid arthritis (RA) [1] and joint symptoms [2]. Identification of individuals with imminent RA is key to achieve prevention in pre-clinical stages.

We developed a two-step approach combining established biomarkers including different isotypes, genetics and first symptoms (step 1) followed by multiple and high positivity for serologic marker (step 2) to identify FDR-RAs with a high risk to develop RA. Using this approach to identify patients before onset of disease could improve patient management in the future.

Methods: 1227 FDR-RAs from the Swiss multicenter cohort study SCREEN-RA were included in this study [3]. The established serologic biomarkers anti-CCP IgG/A, RF IgM/A (CE-IVD) and the prototype assay anti-RA33 IgM/A/G were measured. The NGS technology AmpliSeq™ on the Ion GeneStudio™ instruments (Thermo Fisher Scientific, USA) was used covering 320 variants specific for RA in a targeted sequencing run. Symptoms of the patients were

Figure 1

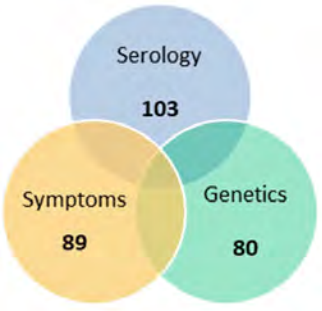

Figure 2

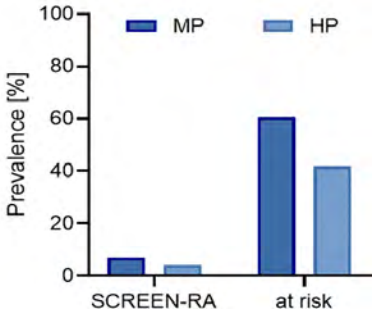

Figure 1. Venn diagram showing the identified individuals for each criterion and the individuals with ≥2 criteria positive. During step 1 of the approach, 51 individuals (4%) were highlighted as at risk. Fig 2: Additional 35 individuals (3%) were flagged during step 2 of the approach showing high or multiple positivity for the measured biomarkers

included using information from the Clinical Suspected Arthralgia (CSA) questionnaire. An algorithm based on Naïve Bayes was developed to combine serology, genetics and symptoms and in addition multiple and high positivity to define risk scores for each criterion for the included individuals. Individuals which had a high risk score for ≥2 criteria were flagged, as well as individuals with high or multiple positivity for the included biomarkers.

Results: For each individual the risk score for the three criteria (serology, genetics and symptoms) was calculated. 86 individuals (7%) were identified at high risk for developing RA including 51 individuals being positive for ≥ 2 criteria (step 1; Fig 1) and additional 35 individuals showed multiple positivity and/or high positivity for serologic markers (Fig 2). Individuals which were flagged during step 1 of the approach were not included in the numbers for step 2. Among 13 individuals diagnosed with incident clinical RA by rheumatologists, 9 of them (70%) were correctly identified by our approach.

Conclusion: The newly created algorithm including various risk factors could support the identification of individuals at risk to develop the disease in the near future and could allow a tight control. The highlighted individuals (n=86) will be followed up to identify imminent RA.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health I: RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Respiratory infections are among the leading causes of hospitalization in rheumatoid arthritis (RA) and Streptococcus Pneumoniae (SP) is one of the most frequent pathogens involved. For these patients, the CDC recommends a combined vaccination scheme (CVS) using two types of vaccines but evidence on its effectiveness in this specific population remains insufficient.

Objectives: To assess the impact of the combined vaccination scheme on the incidence of SP infections in patients with RA treated with bDMARD and tsDMARD.

Methods: A cohort was nested in a register including patients with RA who were prescribed a bDMARD or tsDMARD (either naïve or switch) from October 1999 to November 2018. The stem register, BIOBADASER 3.0, is a national multicenter prospective register established in 1999 which recruits patients from 28 tertiary Spanish centers with an estimated national coverage of bDMARD and tsDMARD treatment in RA of 25%.

Vaccination Status assessment

Each center informed about the date when they implemented a systematic SP vaccination protocol and whether they were using the CVS. Those not adopting the latter were excluded from the analysis.

Outcomes

Invasive pneumococcal disease (IPD) and all-cause community-acquired pneumonia (CAP) were the main outcomes. However, since it is estimated that in a significant proportion of lower respiratory tract infections, SP presence is underdiagnosed, we also included all events reported using relevant MedDRA® codes related to this type of infection. Demographic and clinical features were also retrieved.

Statistical Analysis

Crude incidence rates (IR) were calculated for each outcome and its combination ("All SP-related infections"). Exposure was split into two periods, pre and post-vaccination, considering the date when the CVS was officially recommended in Spain (May 2015).

Variable	Study population n=1704
Age, years	60.57 (12.49)

Female	1.22 (0.58-2.57)	0.603
Age		
≤65 years	ref	
>65 years	1.40 (0.57-3.435)	0.456
Charlson Index	1.29 (1.02-1.62)	0.03
Current smoking	0.91 (0.39-2.13)	0.827

Table 3. Adjusted Poisson regression model comparing pre-vaccination and post-vaccination periods adjusted for sex, age, Charlson Index and active smoking

Poisson regression modelling was carried out to estimate the incidence rate ratio (IRR) comparing both periods. Models were adjusted for potential confounders available such as sex, age, smoking and burden of comorbidity assessed with the Charlson Index which includes conditions such as diabetes mellitus, chronic respiratory diseases, chronic kidney disease, etc.

Results: Study population baseline features

A total of 1704 patients were included, their main features are shown in table 1. All participating centers reported using the CVS except for one that was, therefore, excluded from the analysis.

Incidence Rates

One-hundred and sixty-seven events were found; 2 for IPD, 136 for CAP and 29 for other lower respiratory tract infections. No IPD events were found in the pre-vac period. The IRs were higher in the pre-vac period for the remaining outcomes. Results are shown in Table 2

Crude and adjusted Incidence Rate Ratios

The IRR for all SP-related infections in the post- vac period was 0.25 (95% CI: 0.13 - 0.47) in the multivariable analysis. (table 3).

Conclusion: The incidence of infections due to SP experienced a decrease in RA patients taking bDMARD or tsDMARD after the introduction of the stepwise combined vaccination scheme that was independent of age, sex, smoking or comorbidities.

Multimorbidity in Rheumatoid Arthritis, Psoriatic Arthritis, Gout, and Osteoarthritis Within the Rheumatology Informatics System for Effectiveness (RISE) Registry

Bryant England[1], Huifeng Yun[2], Lang Chen[3], Kaleb Michaud[1], Ted Mikuls[1] and Jeffrey R Curtis[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health I: RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Rheumatic and musculoskeletal diseases (RMDs) often predispose the development of other chronic conditions, resulting in multimorbidity. While multimorbidity is increasingly being recognized and examined within individual RMDs, few studies have directly compared the burden and pattern of multimorbidity across RMDs.

Table 1. Patient Characteristics by Rheumatic and Musculoskeletal Disease from the RISE Registry

Table 2. Multivariable Adjusted Associations of Rheumatic and Musculoskeletal Diseases with Multimorbidity in the RISE Registry

Therefore, we aimed to compare multimorbidity between rheumatoid arthritis (RA), psoriatic arthritis (PsA), gout, and osteoarthritis (OA) within the Rheumatology Informatics System for Effectiveness (RISE) registry.

Methods: We conducted a cross-sectional study within the RISE registry, the largest EHR-enabled rheumatology registry in the U.S. We selected patients >18 years of age, with ≥2 RISE encounters over ≥30 days, and who fulfilled algorithms for RA, PsA, gout, or OA (≥2 consecutive visits with corresponding ICD-10 codes) in a hierarchical fashion to avoid patients contributing to multiple disease groups. Multimorbidity was assessed using the RxRisk, a medication-based index of chronic conditions, assessed using all available preceding data before the 2nd visit. We compared the frequency of multimorbidity (defined as receiving medications from ≥5 different RxRisk categories; Wallace E. et al. *BMJ Open*, 2016) across disease groups using multivariable logistic regression and the burden of multimorbidity (defined as the number of RxRisk categories) using multivariable negative binomial regression.

Results: We included 356,820 patients from the RISE registry (n=152,214 RA, n=33,156 PsA, n=19,781 gout, n=151,669 OA) with characteristics shown in **Table 1**. Patients with PsA were younger and more frequently Caucasian while male sex was more frequent in patients with gout or PsA. The odds of multimorbidity (35 RxRisk categories) were 1.29-fold higher in gout than RA (95% CI 1.23-1.34; **Table 2**). Compared to patients with RA, the prevalence of multimorbidity was similar in PsA (p=0.15) but less frequent in OA (OR 0.78, 95% CI 0.76-0.79). Similarly, a higher burden of multimorbidity (# of RxRisk categories) was observed in gout compared to RA (B=0.054, P< 0.001; **Table 2**). Both PsA (B=-0.008, P=0.02) and OA were associated with a lower burden of multimorbidity than RA (B=-0.086, P< 0.001). Distinct patterns of multimorbidity were noted across disease groups. Specifically, metabolic and cardiac RxRisk categories were most closely associated with gout, while thyroid and osteoporosis categories were most closely associated with RA and OA.

Conclusion: In this large, national, U.S. rheumatology EHR-based registry, multimorbidity was highly prevalent in RA, PsA, gout, and OA. Recognizing the tremendous burden and unique patterns of multimorbidity accompanying these conditions is an essential step for optimizing the management of RMDs in real-world populations.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health II: Risk Factors & Outcomes

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Arthritis often leads to presenteeism (decreased at-work productivity) and permanent work disability, the worst occupational outcome of a disease, leading to reduced quality of life and cost to society. Yet, health services addressing employment needs of people with arthritis are lacking. We evaluated the effectiveness of the Making-it-Work™ (MIW), an online program developed to help people with inflammatory arthritis (IA) deal with employment issues.

Methods: A multi-center RCT evaluated the effectiveness of MIW at improving presenteeism and work cessation (WC) over two years. Participants were recruited from rheumatologist practices, consumer organizations and arthritis programs, in three provinces. Eligibility criteria: diagnosis of IA, employed, age 18-59, and concerned about ability to work. Participants were randomized 1:1 to MIW or usual care plus printed material on workplace tips. MIW consists

Table 1. Sample characteristics

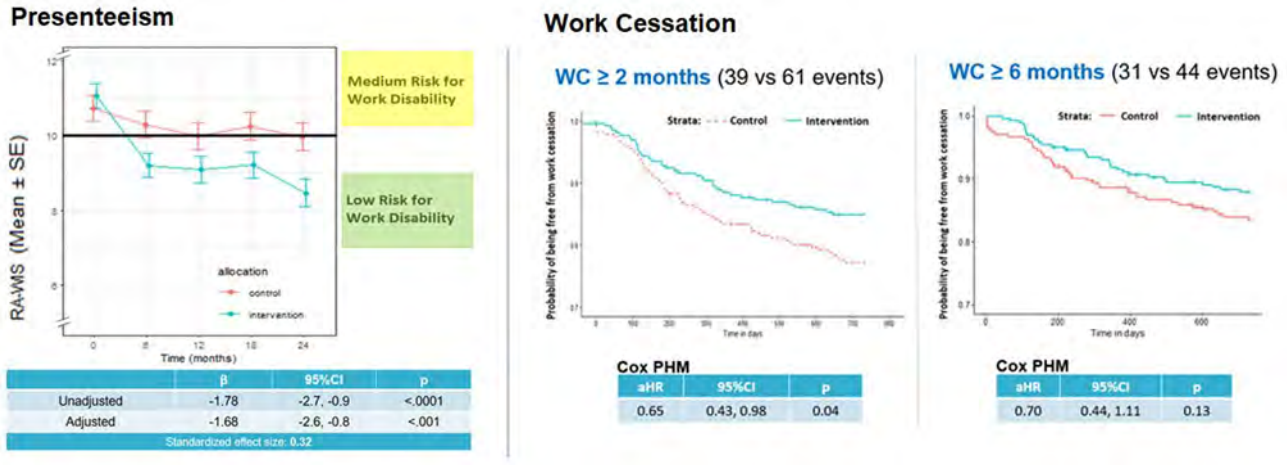

Figure 1. Effectiveness of the Making-it-Work(TM) program on Presenteeism and Work Cessation over 2 years

of five online self-learning modules and group meetings, and individual vocational counselling and ergonomic assessments. Questionnaires were administered every 6 months. Outcomes were presenteeism [Rheumatoid Arthritis Work Instability Scale (RA-WIS)], time to WC of ≥6 months duration, and time to WC ≥2 months (secondary outcome). Baseline characteristics (age, gender, ethnicity, occupation, education, disease duration and self-employment) were collected. Intention-to-treat longitudinal analysis of RA-WIS using linear mixed effect regression models with 2-year comparison as primary endpoint and survival analysis for time to WC using Kaplan-Meier and Cox Proportional Hazard models were performed. Sensitivity analyses were conducted with missing values imputed using last observation carried forward and worse possible outcomes; with square root transformation of RA-WIS outcome; and adjusting for baseline covariates. SAS version 9.4 was used.

Results: A total of 564 participants were recruited, with 85% completing 2-year follow-up. Baseline characteristics were similar between groups. Difference in means of RA-WIS scores was significantly lower in the intervention group from 6 months onwards, with the greatest difference observed at 2 years (-1.78, 95%CI: -2.7, -0.9, p< .0001), yielding a standardized effect size of 0.32. Sensitivity analysis revealed satisfactory robustness of results. Work cessation occurred less often in intervention than control groups, but only reached statistical significance for WC duration ≥2 months (WC ≥6 months: 31 vs 44 events, aHR 0.70, 95%CI: 0.44, 1.11, p-value: 0.13; WC ≥2 months: 39 vs 61 events, aHR: 0.65, 95%CI: 0.43, 0.98, p-value: 0.04).

Conclusion: Results of the RCT reveal the program was effective at improving presenteeism and preventing short-term WC. Effectiveness at preventing long-term work disability will be assessed at 5 years. This program fills one of the most important unmet needs for people with inflammatory arthritis.

[a]Adjusted for baseline age, body mass index, sex, race, education, comorbidities, depression (≤ vs. >16), and symptomatic knee OA (yes or no);
[b]LR χ^2 values are obtained from unadjusted Cox models for (A) and from Cox model stratified by study orgin was used in (B);
[c]Cox model stratified by study oirigin (OAI or MOST) was used when the data from OAI and MOST cohorts were combined into one sample;
[d]Approach states that higher chi-square values represent greater concordance between the threshold and mortality;
[e]Model that yielded a maximum χ^2 value;
aHR=adjusted hazard ratio, CI=confidence interval

Background/Purpose: Patients with radiographic knee OA (rKOA) are at increased risk of mortality and walking difficulty may mediate this relation. Walking speed may be used to objectively assess walking difficulty. However, there is little consensus on the specification for testing distance, which may affect the values of walking speed. Subsequently, this difference may limit the ability to generalize results between different test distances. It is not known if speed measured from short (2.4-meter) and standard (20-meter) distance walk tests similarly predict mortality risk. Therefore, the purpose of the study was to investigate the association of walking speed measured via short and standard distances to mortality risk in adults with rKOA using three large longitudinal cohort studies in the United States.

Methods: We included participants with rKOA (presence of Kellgren Lawrence grade ≥2 in either knee) from the Johnston County Osteoarthritis Project (JoCoOA) which is longitudinal population-based cohort, Osteoarthritis Initiative (OAI) and Multicenter Osteoarthritis Study (MOST), latter two being cohorts of individuals with or at high risk of knee OA. Walking speed was measured via 2.4-meter walk test (short-distance) in JoCoOA and 20-meter walk test (standard-distance) in OAI and MOST. The data from OAI and MOST were combined because they measured walking speed in a similar fashion. To examine the association of baseline walking speed specific to each test with mortality risk over nine years, hazard ratios (HR) and 95% confidence intervals (CI) were calculated from Cox regression models adjusted for potential confounders. To identify an optimal threshold of walking speed specific to each test that best discriminiated mortality risk, Maximal Likelihood Ratio Chi-square Approach was utilized.

Results: Deaths after 9 years of follow-up occurred in 23.3% (290/1244) of JoCoOA (age [mean±sd] 65.2±10.8 years, BMI 31.9±7.7 kg/m^2, 67% female) and 5.9% (249/4215) of OAI and MOST (age 63.1±8.6 years, BMI 30.6±5.6 kg/m^2, 59% female). Walking 0.1 meters/second slower during short- and standard-distance walk tests was associated with 11% (HR[95%CI]; 1.11[1.05, 1.18]) and 12% (1.12[1.05, 1.20]) higher risk of mortality, respectively. Walking slower than 0.5 meters/second on short-distance walk test, and slower than 1.2 meters/second on standard-distance walk test, best discriminated those with and without excess mortality risk (Table).

Conclusion: Slower walking speed measured via short- and standard-distance walk tests was associated with increased mortality risk in adults with rKOA. The study findings on optimal thresholds should be viewed with caution because the short- and standard-distance walk tests were administered in different cohorts. However, a plausible explanation for the differences in the optimal thresholds between different walk tests may be due to the variability in test distances, which may affect the acceleration and deceleration walking phases to achieve a self-selected usual pace.

Characteristics of Adult Patients with Rheumatic Diseases During the COVID-19 Pandemic: Data from an International Patient Survey

Jonathan Hausmann[1], Kevin Kennedy[2], Salman Surangiwala[3], Maggie Larche[4], Mitchell Levine[2], Jean Liew[5], Zachary Wallace[6] and Emily Sirotich[4], [1]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Cambridge, MA, [2]McMaster University, Hamilton, Canada, [3]Queen's School of Medicine, Kingston, Canada, [4]McMaster University, Hamilton, ON, Canada, [5]University of Washington, Seattle, WA, [6]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health II: Risk Factors & Outcomes
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Patients with rheumatic diseases are at increased risk of infection due to immune dysregulation and the use of immunosuppression. It is unknown whether they are also at increased risk of SARS-CoV-2 infection or of COVID-19-related complications. Using real-world data from the COVID-19 Global Rheumatology Alliance (C19-GRA) Patient Experience Survey, we describe the demographic and clinical characteristics of adult respondents and investigate risk factors related to COVID-19 infection.

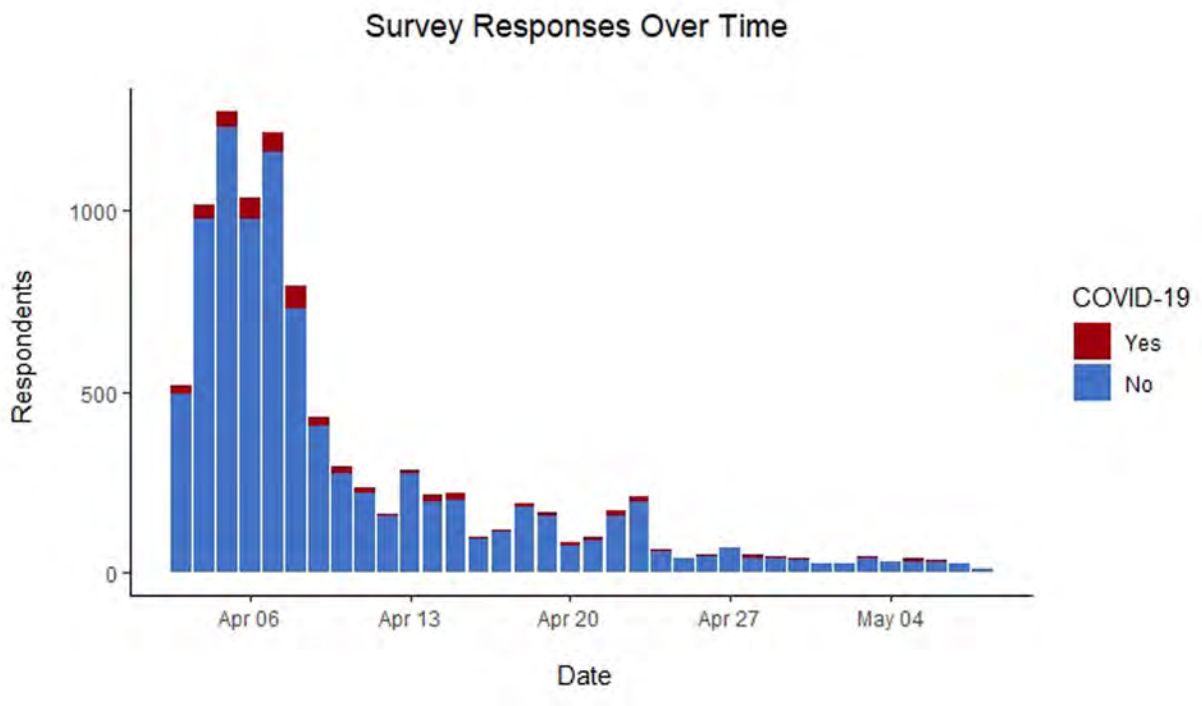

Figure 1. Survey respondents during the study period April 3 - May 8, 2020.

Not hospitalized but with some difficulties performing ADLs	329 (63.39)
Hospitalized but did not require a ventilatory support	59 (11.37)
Hospitalized and required ventilatory support	6 (1.16)
Missing	7 (1.35)

ADLs: activities of daily living such as bathing, eating, dressing, etc.

Table 2. Symptoms and hospitalization status of adults with COVID-19 (n=519).

Methods: We distributed a patient-reported outcomes survey for adults and parents of children with rheumatic diseases, regardless of COVID-19 status, to all six WHO regions and available in nine languages. The survey was disseminated through patient support organizations and on social media. Patients answered questions regarding their demographics, rheumatic disease diagnosis, medications, as well as COVID-19 diagnosis and its complications. We evaluate the demographics of adults within this study and describe the clinical characteristics of COVID-19 infection from April 3-May 8, 2020.

Results: A total of 9,393 adults completed the survey during the study period (Figure 1). Respondents represented all six WHO regions; most were female (90.0%) with a mean age of 46.1 (SD 12.8) (Table 1). Common diagnoses included rheumatoid arthritis (38.6%), systemic lupus erythematosus (SLE) (30.7%), and Sjogren's syndrome (13.7%). The majority of patients were taking conventional synthetic DMARDs (70.9%), while 34.7% and 30.8% were on steroids and biologic DMARDs, respectively. Comorbidities included pain syndromes (23.2%), hypertension (22.8%), and pulmonary diseases (21.4%).

Out of the patients surveyed, 519 (5.5%) endorsed having COVID-19 (Table 2). Frequently-reported COVID-19 symptoms included malaise/fatigue (87.1%), cough (78.6%), and headache (78.0%). Only 65 patients (12.5%) required hospitalization. When compared to the population without COVID-19, those with COVID-19 more often had diagnoses of SLE (38.3% vs. 30.2%, $p< 0.001$) and pulmonary comorbidities (36.0% vs. 20.5%, $p< 0.001$).

Conclusion: These results demonstrate the feasibility of conducting an international patient-reported outcomes survey to address the impact of the COVID-19 pandemic among patients with rheumatic diseases. Only 5.5% of patients with rheumatic diseases developed COVID-19 and the majority did not require hospitalization, even though most

were on immunosuppressive drugs. Patients with SLE and pulmonary comorbidities were overrepresented among those with COVID-19. Future subgroup analyses will explore the relationships between disease states and diagnosis of COVID-19.

** WORMS MRI features: cartilage morphology, osteophytes, bone marrow lesions, synovitis or effusion, meniscal tears and extrusion.

Algorithms included: Bayesian adaptive regression trees (BART), extreme gradient boosting, generalized linear models with convex penalties (that consisted least absolute shrinkage and selection operator [LASSO], ridge regression, and elastic net), logistic regression, random forest, and support vector machine.

Table 2. Frequency of runs (out of 100) in which the listed variables were in the top 10 of contributors to the prediction of knee replacement within 7 years.

Background/Purpose: Prior studies of predictors of knee replacement (KR) have often included only a limited set of risk factors, been conducted primarily in knees with radiographic OA (ROA), and with short follow-up. Further, it is uncertain if addition of MRI data would improve prediction. We therefore evaluated clinical and imaging features of OA for their ability to predict KR over a 7-year period, including knees with and without ROA, and assessed the utility of adding MRI data.

Methods: We included data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded cohort of persons with or at risk of knee OA. We first limited the model to baseline demographics, clinical (e.g., WOMAC, other symptom questionnaires) and radiographic (KL, JSN, OST grades) data. In the full model, WORMS knee MRI features were added. KRs were confirmed by medical records and/or radiographs up to year 7. We used a random 80% of the sample for model development and training, and the remaining 20% for testing. We used an ensemble stacking approach, i.e., super learning, to combine multiple machine learning algorithms to develop a predictive model, which selects the optimal combination of algorithms to achieve a minimum mean square error in a multi-fold cross-validation to provide the highest predictive accuracy. See tables for algorithms included. We also developed stacked predictive models for knees with and without ROA at baseline. We repeated the random split of data into training and testing sets 100 times, and for each run, we repeated model development and training, and evaluated performance in the independent 20% test set. We then listed the top 10 variables that contributed most to the prediction of KR across 100 runs by calculating a variable importance measure

Results: Our study sample included 2357 participants (mean age 61.6 [SD: 7.8] years, 62% female). The median area under the receive operating characteristic curves (AUCs) across 100 runs with and without MRI data were similar (Table 1). MRI features improved prediction of KR in knees without ROA. Prediction performance was higher in the sample as a whole as opposed to knees with and without ROA due in part to sample size (Table 1). Several variables were important contributors to KR prediction, even in knees free of ROA, including malalignment, race, and certain functional limitations. MRI features contributed to KR prediction based on the variable importance measures across 100 runs (Table 2).

Conclusion: Clinical and radiographic structural features as well as MRI features predict KR within 7 years with substantial accuracy, including in knees that had no ROA at baseline. The super learning-based predictive model development performed well and models that included MRI features did not substantially improve AUC over the models that included only clinical and radiographic data. Malalignment appeared to be an important target. Certain functional limitations were important contributors to the prediction of KR, while WOMAC pain symptoms (pain with stairs) only featured prominently in the clinical and radiographic model for ROA-free knees, suggesting that function may be a more important driver than previously recognized.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health II: Risk Factors & Outcomes

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Many potentially modifiable biobehavioral factors have been associated with the risk of developing rheumatoid arthritis (RA), but the benefit of adopting an overall healthy lifestyle has not yet been examined. We investigated whether a healthy lifestyle, defined by a healthy lifestyle index score (HLIS), was associated with the risk of developing RA, overall and for seropositive or seronegative subtypes. We hypothesized that an increasingly healthy lifestyle, as measured by the HLIS, would be associated with reduced risk of RA, and we aimed to estimate the population attributable risk of these behaviors for RA.

Methods: We analyzed female nurses in the Nurses' Health Study (NHS) (1986-2016) and NHSII (1991-2017). Behavioral, demographic, and medical information were assessed on biennial questionnaires. Incident RA was confirmed

Table. Hazard ratios (95% CIs)[a] for risk of incident RA according to continuous and categorical healthy lifestyle index score (HLIS) among women in Nurses' Health Study (1986-2016) and Nurses' Health Study II (1991-2017).

Abbreviations: CI, confidence interval; RA, rheumatoid arthritis.

[a]Hazard ratios were calculated by using time-varying Cox proportional hazards models.

[b]Age-adjusted model adjusted for age, questionnaire cycle, cohort.

Multivariable model adjusted for age, questionnaire cycle, cohort, census tract median family income (quartiles), parity and breastfeeding (nulliparous, parous/no breastfeeding, parous/1–12 mo breastfeeding, or parous/>12 mo breastfeeding), hormone use (premenopausal, postmenopausal with never use, current use, or past use).

[c]Healthy lifestyle index score (HLIS) as a continuous score from 0 (no low-risk factors) to 5 (all low risk factors), where a higher score reflects a healthier lifestyle.

[d]Low-risk factors were defined as: never smoking; moderate alcohol consumption (5-15g/day); healthy body weight (body mass index 18.5–24.9 kg/m^2); healthy diet (AHEA in top 40th percentile); and healthy level of physical activity (at least 19 Met-hours/week).

by medical record review. We created a healthy lifestyle index score (HLIS), following previous work and using 5 established biobehavioral RA risk factors: smoking, alcohol consumption, BMI, physical activity, and diet. For each factor, we created a binary variable with the "healthy" categories: never smoking; moderate alcohol use (5-15g, or about one drink/day), normal body weight (BMI 18.5–24.9 kg/m$^{2)}$); regular exercise (at least 19 MET-hours/week, equivalent to at least 30 minutes of brisk walking every day); and healthy diet (in the top 2/5ths of the Alternative Healthy Eating Index). These were summed to create a HLIS, ranging from 0-5. Cox proportional hazards models, adjusted for confounders, modeled associations between HLIS (as continuous or categorical variables) and incident RA, overall and by serostatus. We calculated the population attributable risk (PAR) to estimate the proportion of incident RA in this population that would be prevented if all participants had adopted 4 or 5 healthy lifestyle factors.

Results: Among 107,090 women (mean age 43.7 years), we identified 1,219 incident RA cases (776 seropositive and 443 seronegative) in 4,467,872 person-years of follow-up (mean 24.0 years/participant). Higher continuous HLIS score was associated with a lower risk of RA (HR 0.87, 95% CI 0.83-0.91 per unit increase) overall, as well as with a lower risk of both seropositive RA (HR 0.86, 95% CI 0.81-0.92) and seronegative RA (HR 0.88, 95% CI 0.81-0.96) (**Table**). Women with all 5 healthy lifestyle factors had the lowest risk of developing RA (HR 0.42, 95% CI 0.22-0.80) and seropositive RA (HR 0.25, 95% CI 0.09-0.69), compared to those with no healthy lifestyle factors. The PAR for adhering to 4 or 5 lifestyle factors was 35% for overall RA.

Conclusion: In this large prospective cohort with lengthy follow-up, women who had a larger number of healthy lifestyle biobehaviors had a corresponding lower risk of both seropositive and seronegative RA. A large proportion of RA risk reduction may be attributable to healthy lifestyle independent of other confounders.Table. Hazard ratios (95% CIs)a for risk of incident RA according to continuous and categorical healthy lifestyle index score (HLIS) among women in Nurses' Health Study (1986-2016) and Nurses' Health Study II (1991-2017).

Assessing Causal Associations of Urate Levels with Type 2 Diabetes and Related Glycemic Traits Using Bidirectional Mendelian Randomization

Natalie McCormick[1], Mark O'Connor[1], Shelby Marozoff[2], John Choi[3], Aaron Leong[1] and Hyon Choi[4], [1]Massachusetts General Hospital, Boston, MA, [2]Arthritis Research Canada, Vancouver, Canada, [3]Massachusetts General Hospital, Boston, [4]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health III: Risk Factors & Outcomes
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Type 2 diabetes (T2D) and gout/hyperuricemia frequently coexist, but the nature and direction of this relationship is unclear. Observational studies have reported positive associations between gout/SU levels and risk of T2D but are subject to residual confounding or reverse causality bias. We used bidirectional two-sample Mendelian randomization to obtain unconfounded evidence of these potential causal effects.

Outcome: Insulin resistance (HOMA-IR: log units)		
Analysis	**Effect size (95% CI)**	**p-value**
Inverse weighted variance (Primary)	0.0091 (-0.0136 to 0.0318)	0.43

Table 1. Causal effect estimates for genetically-determined serum urate levels (per 1 mg/dL) on type 2 diabetes risk and other glycemic trait levels

Methods: Aggregate data from three large genome-wide association studies were used to identify genetic variants (SNPs) associated with SU levels (CKDGEN Consortium (*Nat Genetics* 2019; n=288,649 European-ancestry individuals; 123 SNPs)), T2D (DIAbetes Genetics Replication And Meta-analysis consortium (DIAGRAM: >34,000 T2D cases and >114,000 controls)), and related glycemic traits (Meta-Analyses of Glucose and Insulin-related traits Consortium

All risk SNPs for fasting insulin, including pleiotropic SNP mapped to *GCKR*		
Analysis	**Effect size, mg/dL (95% CI)**	**p-value**
Inverse weighted variance (Primary)	0.37 (0.15 to 0.58)	< 0.001
MR-Egger	-0.14 (-0.75 to 0.47)	0.66
Weighted Median	0.58 (0.45 to 0.71)	< 0.0001
Weighted Mode	0.67 (0.48 to 0.86)	< 0.0001
MR-PRESSO (outlier-corrected)	0.55 (0.44 to 0.66)	< 0.0001
All risk SNPs for fasting insulin, excluding pleiotropic SNP mapped to *GCKR*		
Analysis	**Effect size, mg/dL (95% CI)**	**p-value**
Inverse weighted variance (Primary)	0.51 (0.35 to 0.66)	< 0.0001
MR-Egger	0.45 (0.00 to 0.90)	0.18
Weighted Median	0.58 (0.45 to 0.71)	< 0.0001
Weighted Mode	0.67 (0.47 to 0.86)	< 0.0001
MR-PRESSO (outlier-corrected)	0.57 (0.46 to 0.69)	< 0.0001

Table 2. Causal effect estimates for genetically-determined levels of fasting insulin (ascertained in non-diabetics) on levels of serum urate (mg/dL)

(MAGIC): >200,000 in people without diabetes). These SNPs served as instrumental variables for the genetically determined exposures at conception, thus free of confounding by all factors after birth (e.g., lifestyle factors).

We first assessed the association between genetically-determined SU levels and T2D and levels of 3 glycemic traits, insulin resistance (HOMA-IR), fasting insulin (FI), and HbA1c, using inverse variance weighted (IVW) meta-analysis methods. We also separately examined the effects of SNPs from genes which regulate SU levels, *SLC2A9* and *ABCG2,* estimating Wald ratios for these individual SNPs.

We then assessed the effects of genetically-determined T2D and glycemic traits on changes in SU levels, including and excluding a pleiotropic SNP (rs1260326) mapped to the *GCKR* gene.

In addition to the main IVW analyses, we generated MR-Egger, weighted median and mode, and MR-PRESSO estimates to account for potential heterogeneity and horizontal pleiotropy.

Analyses were performed with the TwoSampleMR and MR-PRESSO packages in R.

Results: Estimated effects of genetically-determined SU levels on each of the four outcomes (HOMA-IR, FI, HbA1c, and T2D) were small and non-significant (**Table 1**); this was consistent across MR estimates. The *SLC2A9* and *ABCG2* SNPs were strongly associated with SU levels (beta=0.33 mg/dL, R^2=2.4% and beta=0.25 mg/dL, R^2=0.7%, respectively; both p< 0.001), but neither were associated with T2D or any glycaemic traits (**Table 1**).

In the opposite direction, there was a strong association between genetically determined levels of FI and SU (beta=0.37 mg/dL, p=0.001) (**Table 2**), which strengthened after excluding the pleiotropic SNP in *GCKR* (beta=0.52 mg/dL (95% CI 0.35 to 0.66), p< 0.001).

Conclusion: Evidence from this Mendelian randomization analysis suggests that genetically raised fasting insulin, a measure of insulin resistance and precursor to T2D, is causally associated with hyperuricemia. Results are consistent with cross-sectional/observational studies and corroborate physiologic evidence for insulin's anti-uricosuric property. Conversely, our data do not support a causal association of SU with FI levels or T2D risk. Interventions targeting SU levels are unlikely to lower T2D risk, whereas lowering insulin resistance would lower risk of gout.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health III: Risk Factors & Outcomes
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: While the association between lifestyle factors such as alcohol consumption, smoking, and body mass index (BMI) and risk of SLE have been previously investigated, it is unclear how these behaviors may combine to reduce SLE risk. We prospectively evaluated whether a healthy lifestyle was associated with the risk of incident SLE and its subtypes, dsDNA positive (+) versus dsDNA negative (-) SLE. We hypothesized that greater adherence to a healthier lifestyle would be inversely associated with SLE risk.

Methods: We included 217,623 female nurses in the Nurses' Health Study (NHS) (1976-2016) and NHSII (1989-2017). Lifestyle and environmental were collected at baseline and on subsequent biennial questionnaires. Incident SLE was confirmed by medical record review. Healthy Lifestyle Index Score (HLIS) was calculated at baseline and approximately every 4 years in follow-up, using three lifestyle behaviors: alcohol consumption, BMI and smoking. For

Table. Incident SLE risk among women in Nurses' Health Study (1976-2016) and Nurses' Health Study II (1989-2017) according to Healthy Lifestyle Index Score (HLIS[1]) behaviors defined as drinking alcohol in moderation (5g/day to 15g/day), maintaining a healthy body weight (body mass index in 18.5–24.9 kg/m^2), and never smokers and past smokers (quit more than 4 years ago).

Abbreviations: CI, confidence interval; HR, hazard ratio; MV, multivariable; PY, person-years.
[1]Healthy lifestyle index score (HLIS) as a summed score from 0 (no healthy behaviors) to 3 (all healthy behaviors) or continuous score (per 1 unit of behavior change)
[2]Multivariable (MV)-adjusted hazard ratios (HR) from time-varying Cox proportional hazards models, adjusted for age (months), questionnaire cycle, cohort, race, census-tract median household income, oral contraceptive use, age at menarche, menopausal status

each factor, we created a binary low risk or healthy variable, defined as drinking alcohol in moderation (5g-15g/day), normal body weight (BMI 18.5–24.9 kg/m^2), and never or past smokers (quit >4 years), each previously associated with reduced SLE risk. A time-varying Cox hazards regression model estimated hazard ratios (HRs [95% confidence intervals]) for SLE risk, overall and by dsDNA subtype. The HLIS was modeled both categorically and continuously for number of healthy behaviors. We also calculated the partial population attributable risk (PAR%), an estimate of the percentage of incident SLE cases in this population during follow-up that would not have occurred if all participants had been in the lowest risk HLIS group (3 healthy behaviors).

Results: There were 283 incident SLE cases (120 anti-dsDNA positive and 163 anti-dsDNA negative) during 5,815,233 person-years of follow-up. In multivariable-adjusted models, we found that a higher continuous HLIS score was associated with a lower SLE risk overall (HR 0.75 [95%CI 0.64-0.88]) and both dsDNA subtypes (positive HR 0.67 [95%CI 0.53-0.85] and negative HR 0.82 [95%CI 0.67-1.00]) (**Table**). Women with all 3 healthy SLE behaviors had the lowest risk (overall HR 0.45 [95%CI 0.24-0.85] and dsDNA-positive HR 0.39 [95%CI 0.16-0.94]) of developing SLE compared to women with no healthy behaviors. Women who consumed moderate amounts of alcohol had a lower risk of developing SLE overall compared to those who consumed less alcohol (HR 0.62 [95%CI 0.46-0.83]). In addition, women who were never and past smokers were less likely to develop anti-dsDNA positive SLE (HR 0.55 [95%CI 0.36-0.85]) compared to current smokers and those who quit within last 4 years. PAR% revealed that 43.7% of SLE risk in this cohort could be attributable to healthy behaviors not in the lowest risk HLIS group.

Conclusion: Adherence to a healthy lifestyle was associated with a lower risk of SLE development overall and by dsDNA subtype compared to less healthy lifestyle. A larger reduction in risk was seen with each additional healthy behavior. Over 43% of SLE risk could be reduced if everyone had adhered to all three healthy lifestyle behaviors.

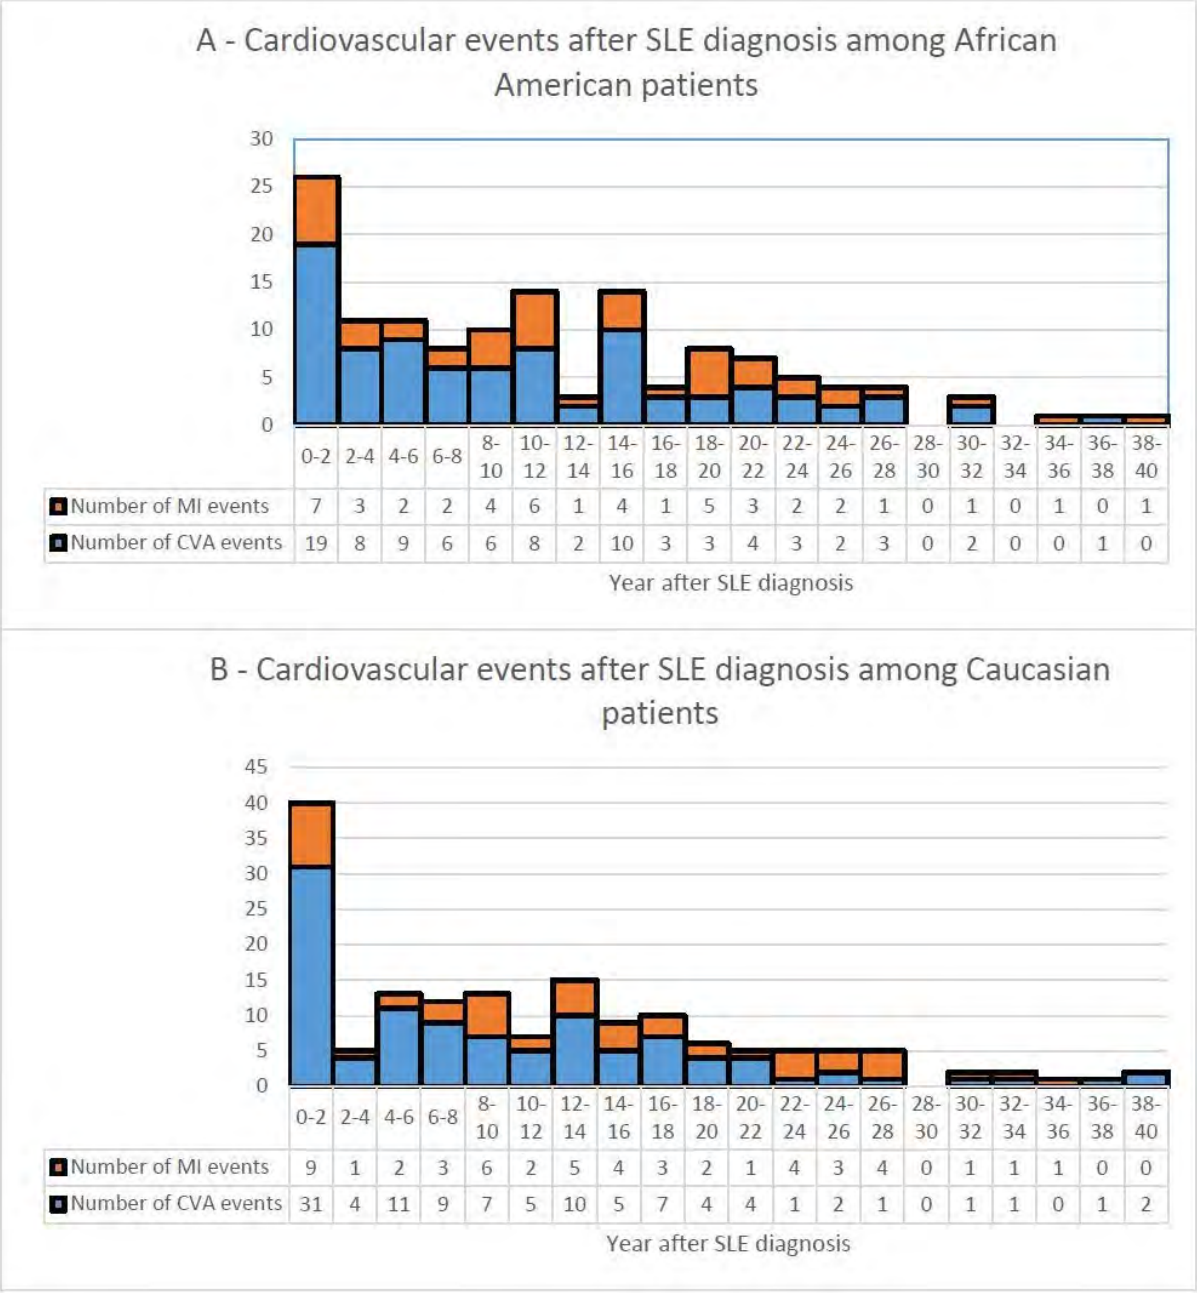
Abstract Number: 1474

Early Peak of Cardiovascular Events Occurs Equally in Caucasians and African-American SLE but Is Attributed to Different Risk Factors

Michelle Petri[1], Jessica Li[2] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health III: Risk Factors & Outcomes
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

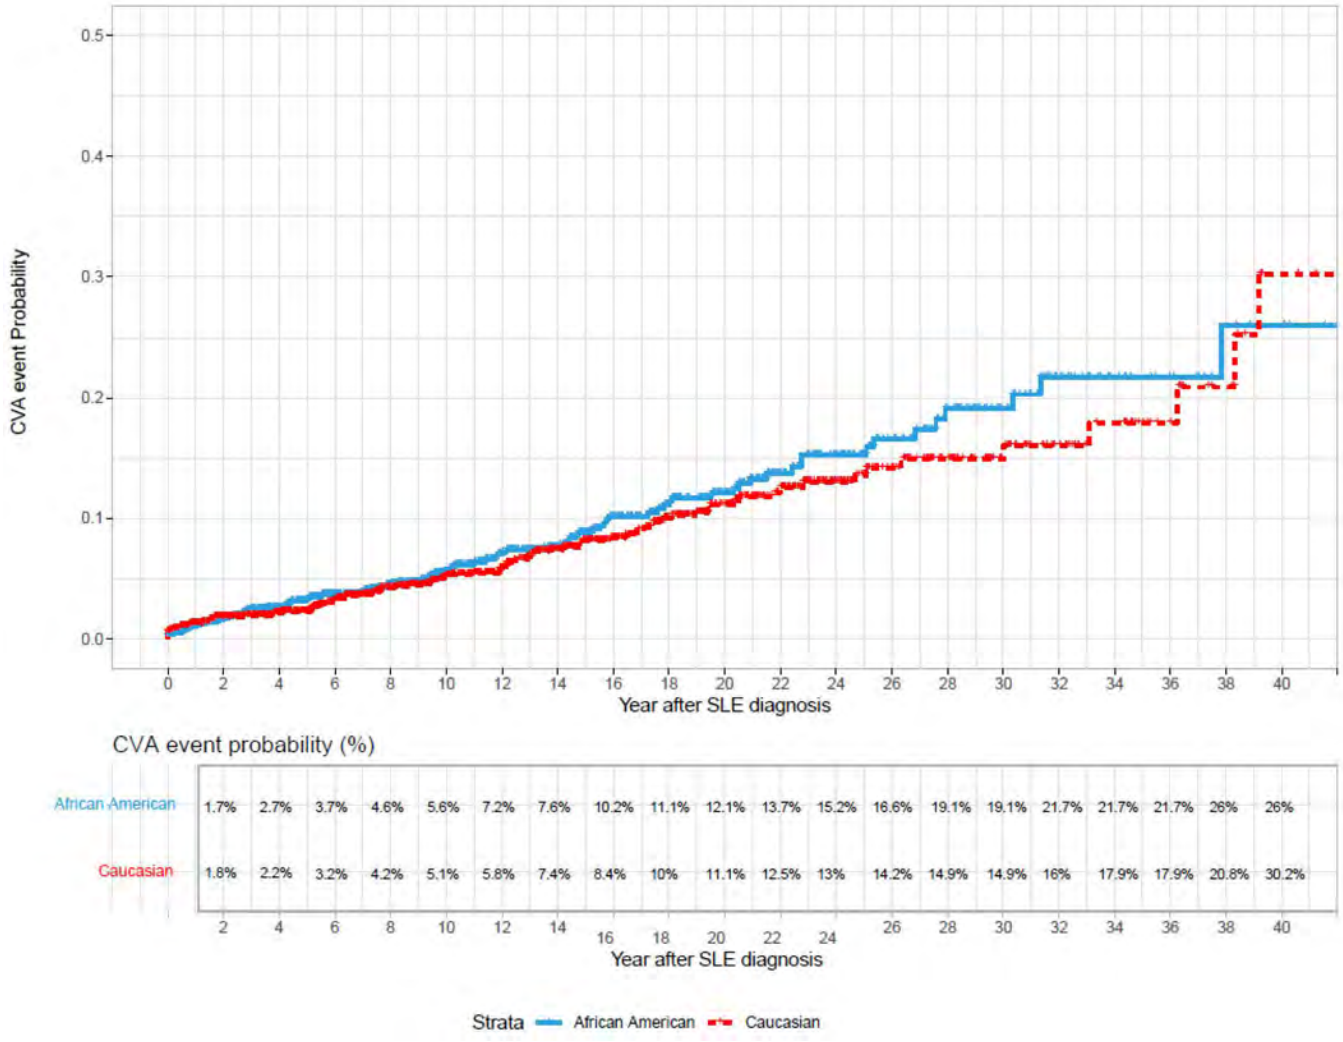
Background/Purpose: The classic bimodal pattern of morbidity/mortality in SLE highlighted that cardiovascular events occurred later in the natural history of SLE (Urowitz & Gladman. J Rheumatol 1980;7:412-16). This paradigm has now been challenged by the SLICC international inception cohort that found cardiovascular events early in the disease course (Urowitz et al. Lupus Sci Med 3:e000143, 2016). Furthermore, in the Georgia Lupus Registry, cardiovascular deaths peaked 1-2 years after diagnosis, with African-American ethnicity as the strongest predictor. We



Cardiovascular events (CVA and MI) by year after SLE diagnosis among African-American patients (A) and among Caucasian Patients (B)

examined the timing of cardiovascular events in a different U.S. cohort, balanced for Caucasian and African-American ethnicities.

Methods: SLE was defined by the revised ACR or SLICC classification criteria. Cardiovascular events were defined as myocardial infarction (MI) or stroke (ACC/AHA definition). In our cohort of 2,398 patients, 1,029 were African-American and 1,369 Caucasian. Nineteen were missing a SLE diagnosis date and 9 had missing data on events. There were 230 strokes and 116 myocardial infarctions.



Estimated Probability of Remaining Stroke Free for Caucasians and African Americans, by Year After SLE Diagnosis

Results: Figure 1A (African-American) and Figure 1B (Caucasian) show the number of cardiovascular events by ethnicity. The peak was years 0-2 after diagnosis for both ethnicities. Figure 2 is a Kaplan-Meier showing stroke probability by year after SLE diagnosis, with no difference found between African-American and Caucasian SLE. Similarly, there was no difference for MI. Table 1 shows that African-American and Caucasian SLE patients differed significantly in their risk factors for MI or for stroke. For example, hypertension was a significant risk factor in Caucasians for MI, while lupus anticoagulant was a significant risk factor in Caucasians for stroke.

Conclusion: In agreement with recent studies, we found an early peak of cardiovascular events (MI and stroke). Contrary to the Georgia Lupus Registry, we saw no difference for MI or storke in Caucasian vs. African-American patients by year after diagnosis. Instead, we found important differences in risk factors for stroke and MI in African-American vs Caucasian SLE patients.

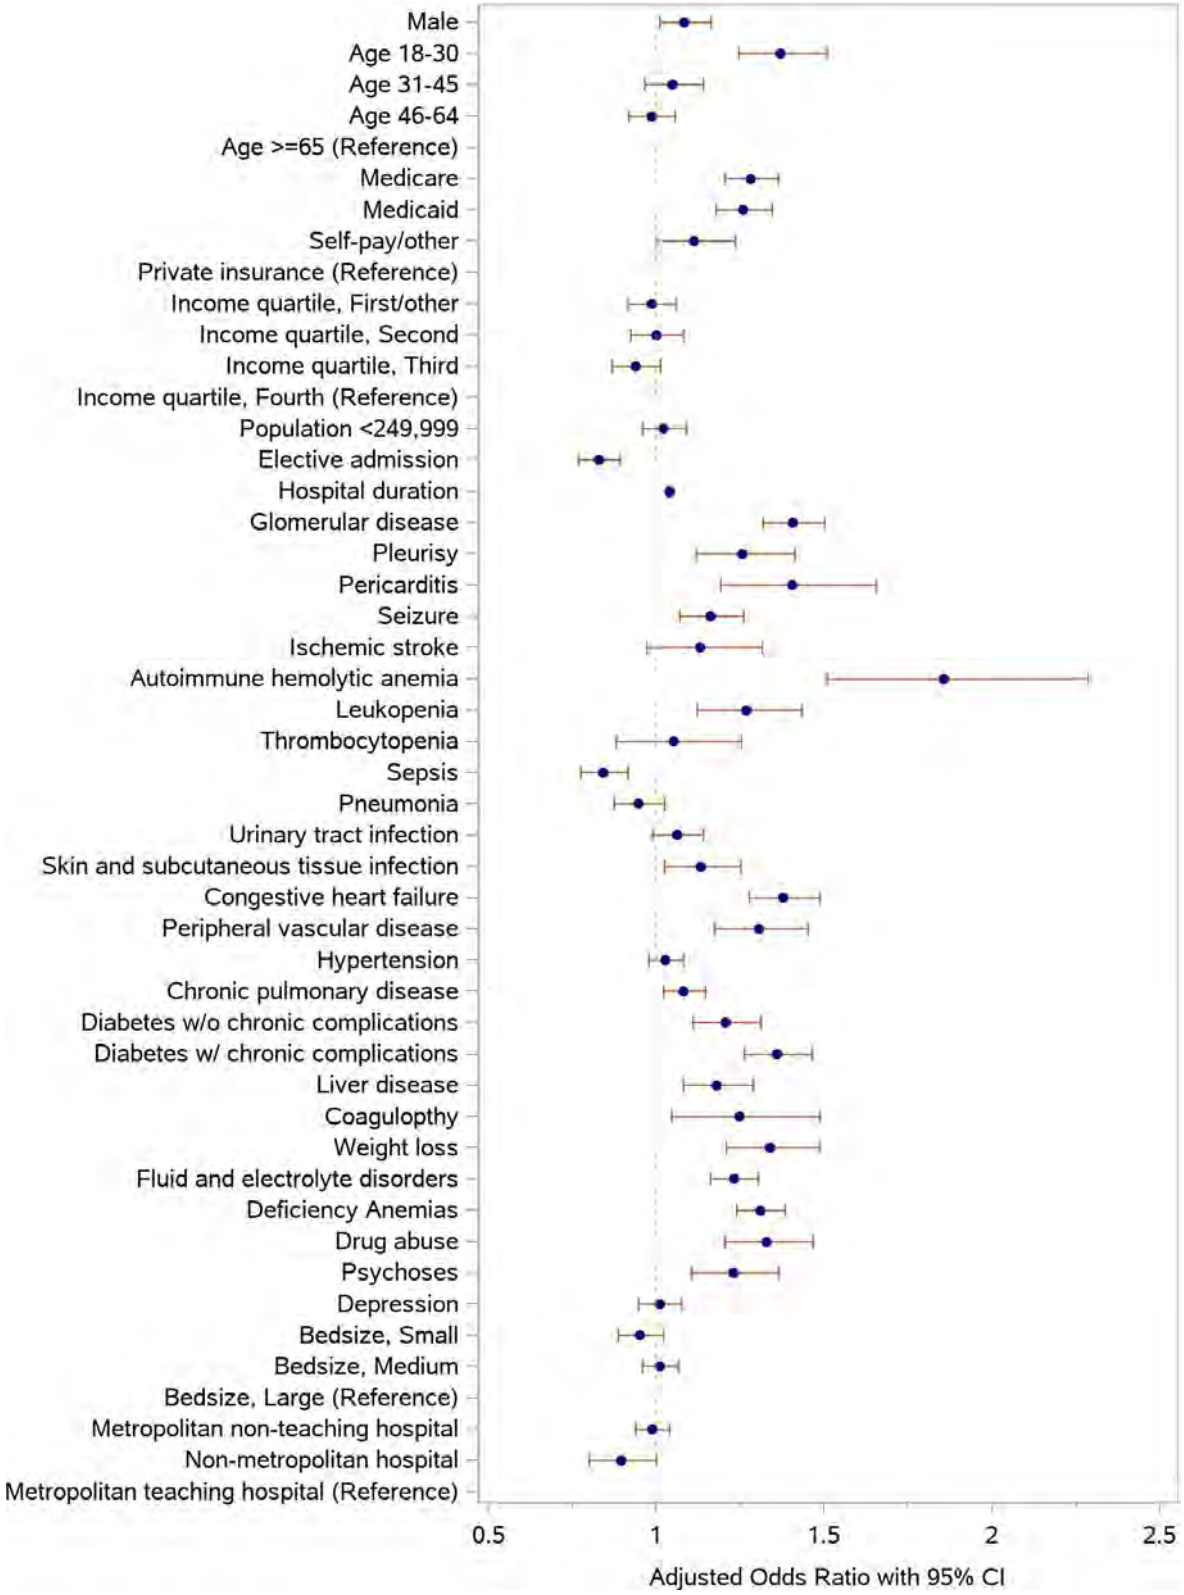
Predictors of Thirty-Day Hospital Readmissions in Systemic Lupus Erythematosus in the US: A Nationwide Study

Rayan Najjar[1], Swetha Ann Alexander[2], Grant Hughes[1], Jinoos Yazdany[3] and Namrata Singh[4], [1]University of Washington, Seattle, WA, [2]University of Connecticut, Hartford, CT, [3]UCSF, San Francisco, CA, [4]University of Washington, Bellevue, WA



Multivariable Logistic Regression Model for Risk of 30-day Readmission in US Adults with Systemic Lupus Erythematosus, 2016-2017

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health III: Risk Factors & Outcomes
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: For individuals with systemic lupus erythematosus (SLE), hospital readmission rate is associated with quality of care and prognosis. Our objective was to evaluate independent risk factors for readmission and determine the major reasons for readmission in a contemporary and nationally representative sample of SLE patients.

Methods: We used the Nationwide Readmissions Database (NRD) from the Healthcare Cost and Utilization Project (HCUP), which includes all-payer nation-wide data from US non-federal hospitalizations across 28 states, to identify adults with SLE who were discharged from hospital to home during January-November of 2016 and 2017. Subjects were identified using SLE ICD-10-CM primary and secondary diagnosis codes (M32.1-M32.9). 30-day all-cause readmissions were identified. Comorbidities were defined using the Elixhauser classification. Demographics (gender, age group, insurance, median income quartile by ZIP code, and population density), hospital-level variables (bedsize and teaching hospital), and SLE manifestation-related ICD-10-CM diagnosis codes (glomerular disease, pleurisy, pericarditis, seizure, ischemic stroke, autoimmune hemolytic anemia, leukopenia, and thrombocytopenia) were recorded. Survey-specific statistical methods were used to obtain weighted frequencies and percentages of study covariates. A multivariable survey-specific logistic regression model was used to identify factors associated with readmission adjusting for the covariates mentioned above. We identified the main cause of readmission using primary ICD-10-CM diagnosis codes for readmission and the HCUP Clinical Classifications Software, Refined.

Results: There were 132,400 hospitalized adults with SLE discharged home during the study period. 88.3% were female, with median age of 51.0 years (IQR 38.7-61.9). 18,973 (14.3%) people were readmitted within 30 days of discharge from their index hospitalization. Median hospital stay was 3.3 days (IQR 1.7-5.9) for readmitted patients and 2.5 (IQR 1.3-4.3) in patients without readmission. The predictors with largest magnitude of effect for readmission in an adjusted regression model were autoimmune hemolytic anemia [odds ratio (OR) 1.86, 95% CI 1.51-2.29], glomerular disease (OR 1.41, 95% CI 1.32-1.50), pericarditis (OR 1.40, 95% CI 1.19-1.66), heart failure (OR 1.38, 95% CI 1.28-1.49), and age 18-30 (OR 1.37, 95% CI 1.24-1.51, vs age ≥65) (Figure 1). The most common causes for readmission were sepsis (n=1,446, 7.6%), SLE (n=1,407, 7.4%), heart failure (n=668, 3.5%), pneumonia (n=605, 3.2%), and complication of surgical/medical care, injury (n=565, 3.0%) (Table 1).

Table 1. Frequencies and Percentages of Top 10 Reasons for Readmission in US Adults with Systemic Lupus Erythematosus, 2016-2017

Condition	Frequency	Percent
Sepsis	1,446	7.6
Systemic lupus erythematosus and connective tissue disorders	1,407	7.4
Heart failure	668	3.5
Pneumonia	605	3.2
Complication of other surgical or medical care, injury	565	3.0
Acute and unspecified renal failure	542	2.9
Chronic kidney disease	414	2.2
Skin and subcutaneous tissue infections	404	2.1
Fluid and electrolyte disorders	393	2.1
Complication of cardiovascular device, implant or graft	361	1.9

Conclusion: In this first nationally representative study of SLE readmissions, we identified independent risk factors for readmission in adult SLE patients discharged to home. The strongest identified risk factors were related to select SLE manifestations such as cytopenias and comorbidities such as diabetes and cardiopulmonary disease. Certain demographic features also contributed to risk, such as young age and public insurance.

Trends in Mortality and Cause-specific Mortality Among Patients with Psoriasis and Psoriatic Arthritis in Ontario, Canada

Keith Colaco[1], Jessica Widdifield[2], Jin Luo[3], Cheryl Rosen[4], Raed Alhusayen[5], J. Michael Paterson[6], Willemina Campbell[7], Karen Tu[4], Sasha Bernatsky[8], Dafna Gladman[9] and Lihi Eder[10], [1]Institute of Medical Science, University of Toronto; Women's College Research Institute, Women's College Hospital; and Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [2]University of Toronto - Toronto, Toronto, ON, Canada, [3]ICES, Toronto, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada, [5]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada, [6]ICES, University of Toronto, Toronto, ON, Canada, [7]University Health Network, University of Toronto, Toronto, ON, Canada, [8]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada, [9]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [10]Women's College Research Institute, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health III: Risk Factors & Outcomes
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Several studies have consistently demonstrated that psoriasis is associated with an increased risk of mortality compared to the general population. However, the excess risk of mortality in psoriatic arthritis (PsA) is unclear, with observational studies yielding conflicting evidence. We aimed to compare overall and cause-specific mortality rates and their trends over time among patients with psoriasis, PsA and general population comparators without psoriatic disease living in Ontario, Canada.

Methods: We performed a population-based study using health administrative data among adult Ontario residents between 1996 and 2016. Patients diagnosed with psoriasis (from 1996 onward) and PsA (from 2008 onward) were identified using validated case definitions and compared with individuals without psoriatic disease. All-cause and cause-specific age- and sex-standardized mortality rates, standardized mortality ratios (SMRs) and excess mortality rates were computed for the years 1996 to 2016.

Results: A total of 176,858 psoriasis patients (2,524 deaths) and 15,430 PsA patients (221 deaths) were identified in 2016. All-cause mortality rates were greater among patients with psoriasis and PsA compared with the general population. The standardized mortality rate per 1000 (95% confidence interval [CI]) in 2016 was 8.26 (7.92, 8.62) among those with psoriasis and 9.25 (7.97, 10.69) among those with PsA compared to 6.82 (6.78, 6.86) in the general population. Patients with psoriasis and PsA had excess mortality rates of 5.70 (95% CI 5.20, 6.21) and 5.75 (95% CI 3.98, 7.71) per 1000 population, respectively. All-cause SMRs in 2016 were elevated for psoriasis: 1.18 (95% CI 1.13, 1.23); and PsA: 1.34 (95% CI 1.16, 1.52) (**Figure 1**). Standardized mortality rates decreased by approximately 30% over the study period in both disease groups, but remained elevated compared to the general population (**Figure 2**).

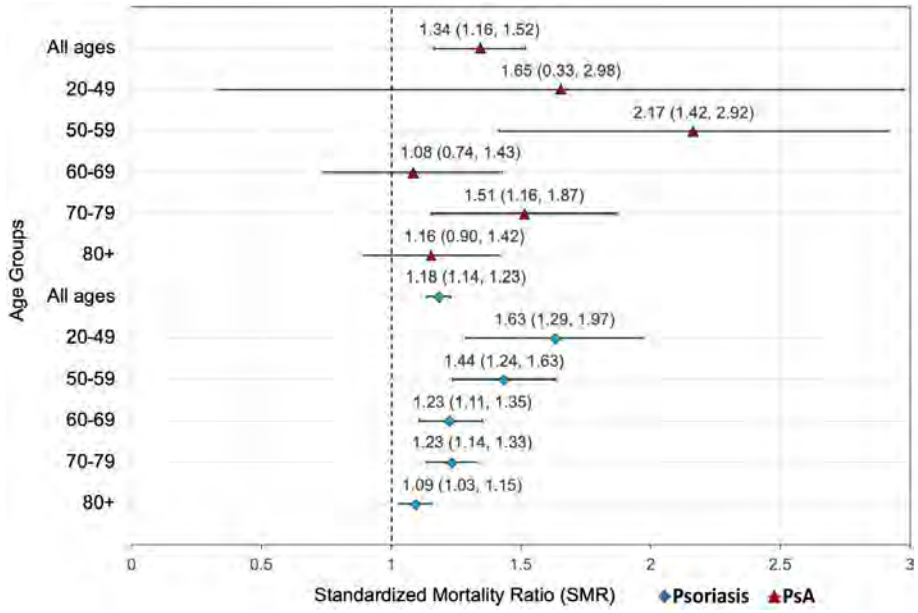

Figure 1. Age-specific Standardized Mortality Ratios (with 95% CI) in psoriatic arthritis (PsA) and psoriasis patients (2016).

The leading causes of death and corresponding SMRs in psoriasis patients were cancer (26.0%, SMR 1.11), circulatory diseases (25.6%, SMR 1.12), and respiratory conditions (11.7%, SMR 1.32) (**Figure 3**). In those with PsA, circulatory disease (26.2%, SMR 1.35) was the leading cause of death, followed by cancer (21.7%, SMR 0.96), and respiratory conditions (12.7%, SMR 1.69).

Conclusion: This study, the largest one to date that assessed trends in mortality rates and their underlying causes, showed that mortality rates in psoriasis and PsA have decreased over the past decade, but remain significantly elevated compared to the general population. Cardiovascular diseases, cancer and respiratory diseases remain the leading causes of mortality in psoriasis and PsA.

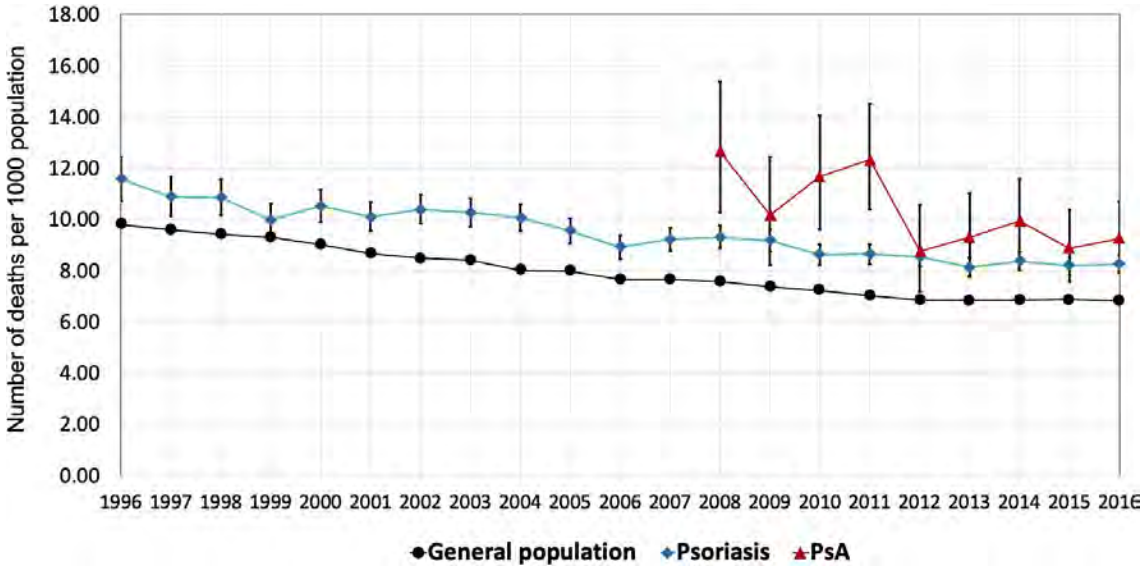

Figure 2. Annual age- and sex-standardized all-cause mortality rates among patients with psoriatic arthritis (PsA), psoriasis, and general population comparators (with 95% CI) from 1996 to 2016.

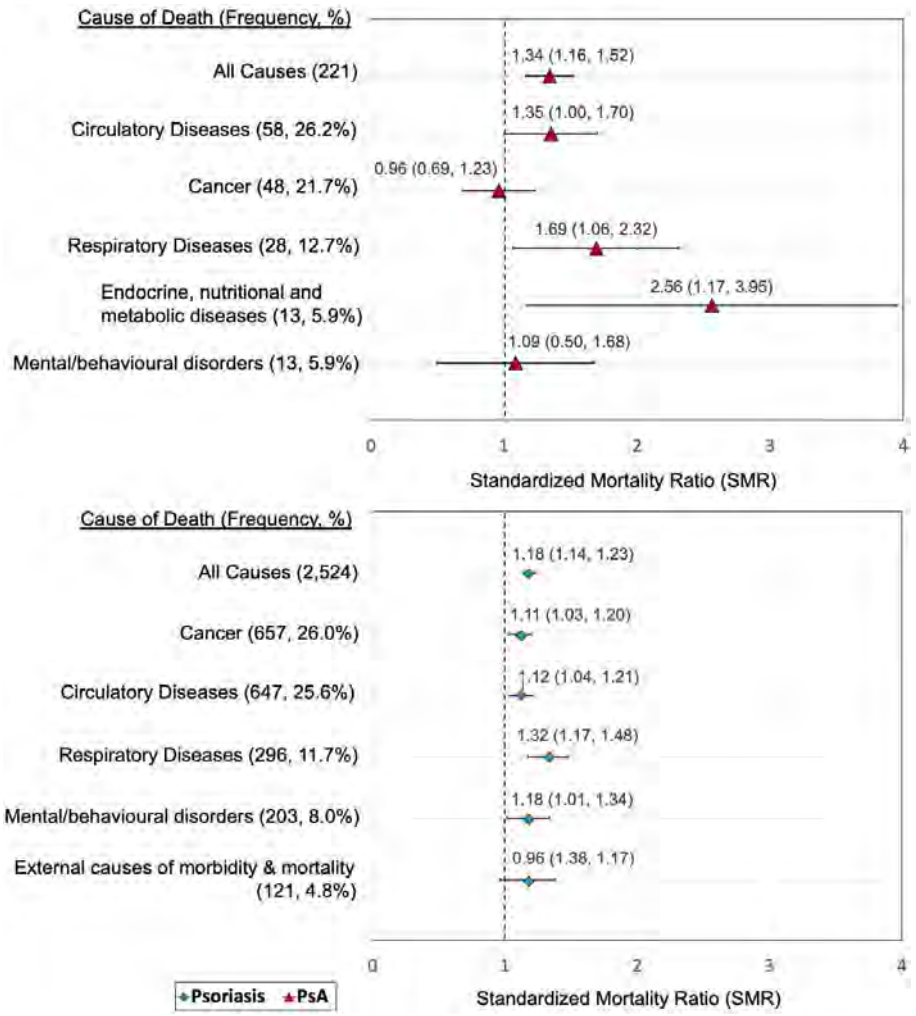

Figure 3. Standardized Mortality Ratios (with 95% CI) for the five leading causes of death in individuals with psoriatic arthritis (PsA) (top plot) and psoriasis (bottom plot) (2016). Causes of death are listed by chapter of the International Classification of Diseases, Tenth Revision.

Adherence in Patients with Chronic Rheumatic Diseases Treated with Biological and Synthetic Targeted Therapies During COVID-19 Pandemic

Patricia Castro Pérez[1], Alberto Onteniente González[1], Angel Aragón Díez[1], Angel Gallegos Cid[1], Jesús Garcia-Arroba Muñoz[1] and Jose Manuel Rodriguez heredia[1], [1]Hospital de Getafe, Madrid, Spain

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases II: Evaluating Drug Therapies for COVID-19

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Adherence to treatments for chronic rheumatic diseases is influenced by many factors, including the patient's belief in the development of adverse effects such as increased susceptibility to infection. It seems logical to think that immunosuppressive therapy increases the risk of severe affectation if SARS-CoV2 infection occurs and that many patients may tend to stop their biological treatment, especially in areas with a high incidence of COVID-19

The OBJECTIVE is to determinate the adherence in patients with rheumatic diseases treated with biological therapies during COVID-19 health crisis period in Madrid.

Methods: Prospective observational study. Telephone interviews were conducted between April 22 and May 15, 2020 (either by the rheumatologist or the hospital pharmacist) in patients with rheumatic diseases such us rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA) treated with any subcutaneus biological (bDMARD) or targeted synthetic disease-modifying antirheumatic drug (tsDMARD)

Patients were asked about continuation or discontinuation of any medication received for their chronic rheumatic disease, possible reasons that led to drug discontinuation (including fear of immunosuppresion and lack of resources/drug shortage), whether advise was received from a clinician or other sources. We also asked if they knew by the media channels that treatments for rheumatic diseases were being used in severe forms of COVID-19 infection. Patients were considered non-adherent if they had missed or delayed any of the prescribed doses. All patients received the medication through a home delivery system.

Results: We telephone-interviewed 400 patients followed-up in our centre (196 RA, 115 PsA and 89 SpA) during confinement period due to the coronavirus pandemic. 32 (8%) patients discontinued their treatment, 14 of them (43.75%) due to the fear of suffering the infection, 9 (28.12%) due to COVID-19 infection symptomatology , 4 (12.5%) for some reasons not related to COVID-19, 3 (9.38%) due to lack of resources/shortage of drug and 2 (6.25%) due to confirmed COVID-19 infection. 222 patients (58.57%) knew about the use of anti-rheumatic drugs for the treatment of COVID-19 infection.

Conclusion: Adherence to treatment for rheumatic diseases during the COVID-19 health crisis period was very high in Madrid, despite of being one of the cities hardest hit by the SARS-CoV-2.

A high Knowledge of the use of anti-rheumatic drugs for the treatment of COVID-19 on the media channels and the better access to treatments through a home delivery system has contributed to this adherence.

The main reasons that led to drug discontinuation was the fear of suffering the infection or for having COVID-19 infection symptomatology.

Although the presence of COVID-19 infection was not the reason for the survey, we only found 2 patients diagnosed of COVID-19 with positive PCR test for SARS-CoV-2, and 9 posible patients, due to the symptoms they reffered, among our 400 patients. However, these findings point in the direction that COVID-19 course and mortality in patients with chronic rheumatic diseases treated with b/tsDMARD do not differ from the general population. Doubtlessness, additional studies are still needed.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases II: Evaluating Drug Therapies for COVID-19

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: National health authorities reported a prevalence of SARS-CoV-2 infection around 7% of the general population in Barcelona county (1). A recent report focused on autoimmune and immune-mediated inflammatory disease (AI/IMID) in Spain reported a slightly higher prevalence than in general population, especially in patients under targeted therapies and patients with systemic disease (2). Our aim was to analyze clinical characteristics and outcomes in a multidisciplinary cohort of patients with AI/IMID and symptomatic COVID-19 infection in a single tertiary center.

Methods: We included confirmed cases with RT-PCR SARS-CoV-2 test positive after nasopharyngeal swab according to Microbiology registry from Hospital Clinic of Barcelona from the 1st of March until May 29th, 2020. Data was matched with our registry of AI/IMID diseases. Additionally, patients under clinical follow-up for AI/IMID underwent a telephone survey to establish probable cases according CDC classification. We evaluated clinical characteristics and COVID-19 outcomes including clinical complications, need for ICU admission, and death as well as markers of systemic inflammatory response.

Results: From a total of 1,709 patients who gave positive for RT-PCR SARS-CoV-2, we identified 1,448 single patients. Around 5.000 patients with AI/IMID are under follow-up in our center. Thirty-one patients (23 female) with AI/IMID were identified, with a median age of 53 (IQR 25) years. Twenty-six cases were confirmed by PCR and 5 were diagnosed as probable cases. Main comorbidities included hypertension in 32% of cases and chronic pulmonary disease in 16%. Rheumatoid arthritis and inflammatory bowel disease were the most common diseases in 29% and 22%, respectively. Clinical characteristics of COVID-19 patients with AI/IMID are summarized in **Table 1**. Nine (29%) out of 31 patients were under glucocorticoid treatment (mean dose 7.0 ± 5.5 mg/d), 4 (12.9%) under hydroxychloroquine (HCQ), 9 under methotrexate (29%), and 8 (25.8%) under targeted synthetic/biologic DMARDs (mainly TNF inhibitors). A total of 16 (51%) patients had pneumonia and required admission. There were no differences between admission rates according to age, gender, underlying diagnosis, or baseline treatment. Most patients (87%) received the institutional standard treatment for COVID-19 with Lopinavir/ritonavir, HCQ and azithromycin. One patient had renal insufficiency and a pulmonary complication that resolved before discharge. Only 1 patient required ICU admission

Table 1. General characteristics of symptomatic COVID-19 patients with AI/IMID

and another patient died due to COVID-19 infection. Characteristics and clinical outcomes of patients admitted due to COVID-19 are summarized in **Table 2**. During admission, immunosuppressive therapies were stopped in 7 (43%) cases and ts/bDMARDs in 3 (18%) cases. Four patients presented a clinical flare.

Conclusion: In our center, less than 1% of patients with AI/IMID had symptomatic COVID-19 infection. Most patients had a satisfactory outcome; including patients under ts/bDMARDs and clinical fares during admission and follow-up were uncommon. We are running comparative analysis with other populations and evaluating the prevalence of asymptomatic COVID-19 infection in patients AI/IMID.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases II: Evaluating Drug Therapies for COVID-19

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: In the treatment of monogenic autoinflammatory diseases (AID), a heterogeneous group of diseases with excessive interleukin (IL)-1β release and severe systemic and organ inflammation, the anti-IL-1 inhibitor canakinumab (CAN) has been associated with rapid remission of symptoms in clinical trials as well as in real-life.[1,2]

The aim of the RELIANCE registry is to explore long-term effectiveness and safety of CAN under routine clinical practice conditions in patients with CAPS (cryopyrin-associated periodic syndromes, including Muckle-Wells syndrome [MWS], familial cold autoinflammatory syndrome [FCAS], neonatal onset multisystem inflammatory disease [NOMID]/chronic infantile neurological cutaneous and articular syndrome [CINCA]), FMF (familial Mediterranean fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

[1]Kuemmerle-Deschner et al. Rheumatology (Oxford). 2016;55(4):689-96

[2]De Benedetti et al. N Engl. J Med. 2018;378(20):1908-1919

Methods: This prospective, non-interventional, observational study based in Germany has a 3-year follow-up and enrolls pediatric ≥2 years and adult patients with clinically confirmed diagnoses of CAPS, FMF, TRAPS and HIDS/MKD routinely receiving CAN. In 6-monthly visits, clinical data and patient-reported outcomes are assessed. Study endpoints are long-term effectiveness and safety of CAN. Here, the CAPS cohort was analyzed.

Results: This 18-month interim-analysis includes 78 CAPS patients (49% females) enrolled by September 2019. Mean age at baseline was 25 years and mean duration of prior CAN treatment was 5.7 years. 64 patients (82%) had MWS, 2 FCAS, 7 NOMID/CINCA, 3 atypical CAPS and 2 lacked subtype diagnosis. Preferred CAN doses and inter-

vals (% of all injections) were 300 mg q4w (every 4 weeks; 10.4), 150 mg q4w (16.9), 150 mg q8w (13.7) and 150 mg more than q9w (9). Disease activity, fatigue and social impairment by patients' assessment, days absent from school/work, inflammatory markers, and remission by physician assessment were evaluated at 6-monthly intervals starting at baseline with last update at 18 months of follow-up (Table 1). The patient–reported AIDAI score of disease activity revealed inactive disease in 9 out of 12 months (Table 2). The results demonstrate sustained remission and disease control to remain stable over time. The incidence rate per 100 patient years was 25.67 for any serious adverse event (SAE) including 15.21 for serious drug-related adverse events (drSAE; Table 3). DrSAE were reported for 10/78 patients including cardiovascular disorder, pyrexia (3), chest pain, appendicitis, tonsillitis (2), haemophilus test positive,

circulatory collapse, febrile convulsion, skin disorders (3), tonsillectomy, and preterm delivery. No deaths were reported. 3/78 patients discontinued CAN, 2 due to inefficacy, 1 due to loss of efficacy.

Conclusion: The 18-month interim analysis of the RELIANCE study, the longest running real-life CAN registry, demonstrates that long-term CAN treatment is well tolerated and effective in CAPS patients.

Abatacept for the Treatment of IgG4-Related Disease

Mark Matza[1], Cory Perugino[1], Liam Harvey[2], Zachary Wallace[3], Hang Liu[4], Shiv Pillai[5] and John H. Stone[6], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Newton, MA, [4]Massachusetts General Hospital, Cambridge, MA, [5]Harvard Medical School, Cambridge, MA, [6]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases II: Evaluating Drug Therapies for COVID-19
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: To assess the efficacy and safety of abatacept (ABA) for the treatment of IgG4-related disease (IgG4-RD). To date, there are no FDA-approved treatments available for IgG4-RD. The efficacy of ABA in the context of IgG4-RD has been reported in a single case report but not yet studied further.

Methods: We conducted a prospective, open-label trial of ABA in 10 patients with active IgG4-RD. All subjects met the ACR/EULAR Classification Criteria for IgG4-RD and had active disease based on an IgG4-RD responder index (RI) of ≥2 with disease manifestations in at least one organ system at the time of screening. Patients received subcutaneous ABA 125 mg weekly for 24 weeks. Concurrent glucocorticoid treatment was permitted but was required to be discontinued by week 4. The primary endpoint, complete remission at 24 weeks, was defined as an IgG4-RD RI score of 0 and a secondary endpoint, disease response, was defined as improvement of ≥ 1 point in the IgG4-RD RI score from baseline. Achieving either outcome required no glucocorticoid use beyond week 4 and no disease flares. PBMCs were collected at baseline, 1-month and 3-month time points and B and T cell subsets were quantitated using a 25-parameter flow cytometry panel.

Results: Ten subjects were enrolled in the study between December 2018 and August 2019. Median age was 67.5 years, 70% were male and 90% Caucasian. Eight subjects had both orbital and salivary gland involvement, while five subjects had lung involvement. All patients had elevated serum IgG4 concentrations of at least 2-fold the upper limit of normal (range 170 to 1,359.5 mg/dL, median 480.5 mg/dL). Two subjects received prednisone with ABA. Three subjects (30%) achieved the primary endpoint of complete remission and two subjects (20%) had a disease response at week 24. ABA was stopped early in the remaining five subjects (50%) due to flare (N=1) or lack of response by week 12 (N=4). Although serum IgG4 concentrations declined in only two of the five subjects with any response, serum IgE concentrations declined in all five (baseline median 802 IU/mL, IQR 260-4981 IU/mL, 24 week median 470

IU/mL, IQR 138-2417 IU/mL). Response to treatment correlated most strongly with a reduction in circulating plasmablasts (p=0.016) with a trend towards significant reduction in HLA-DR$^+$ CD4$^+$ T cells (p=0.056). There was also a trend toward significant correlation between the change in plasmablast numbers and serum IgE but not with IgG4. Surface expression of CD86 on memory B cells was less detectable among responders as compared to non-responders (p=0.016). PD1$^+$CXCR5$^+$CD4$^+$ T cells did not correlate with clinical response, plasmablasts, serum IgE or serum IgG4. There was one adverse event (grade 2 thrombocytopenia) attributed to ABA.

Conclusion: Although subcutaneous ABA was associated with a high rate of treatment failure in patients with IgG4-RD, some patients had excellent clinical responses that correlated well with measures of immunologic response. Correlates of clinical response included reductions in serum IgE, circulating plasmablasts, activated CD4$^+$ T cells, and detectable surface expression of CD86. It is possible that the higher dose of ABA offered by intravenous administration may be more effective.

Abstract Number: 1481

A Systematic Review to Quantify the Extent of Pharmaceutical Company Involvement in Rheumatology Consensus-Based Recommendations

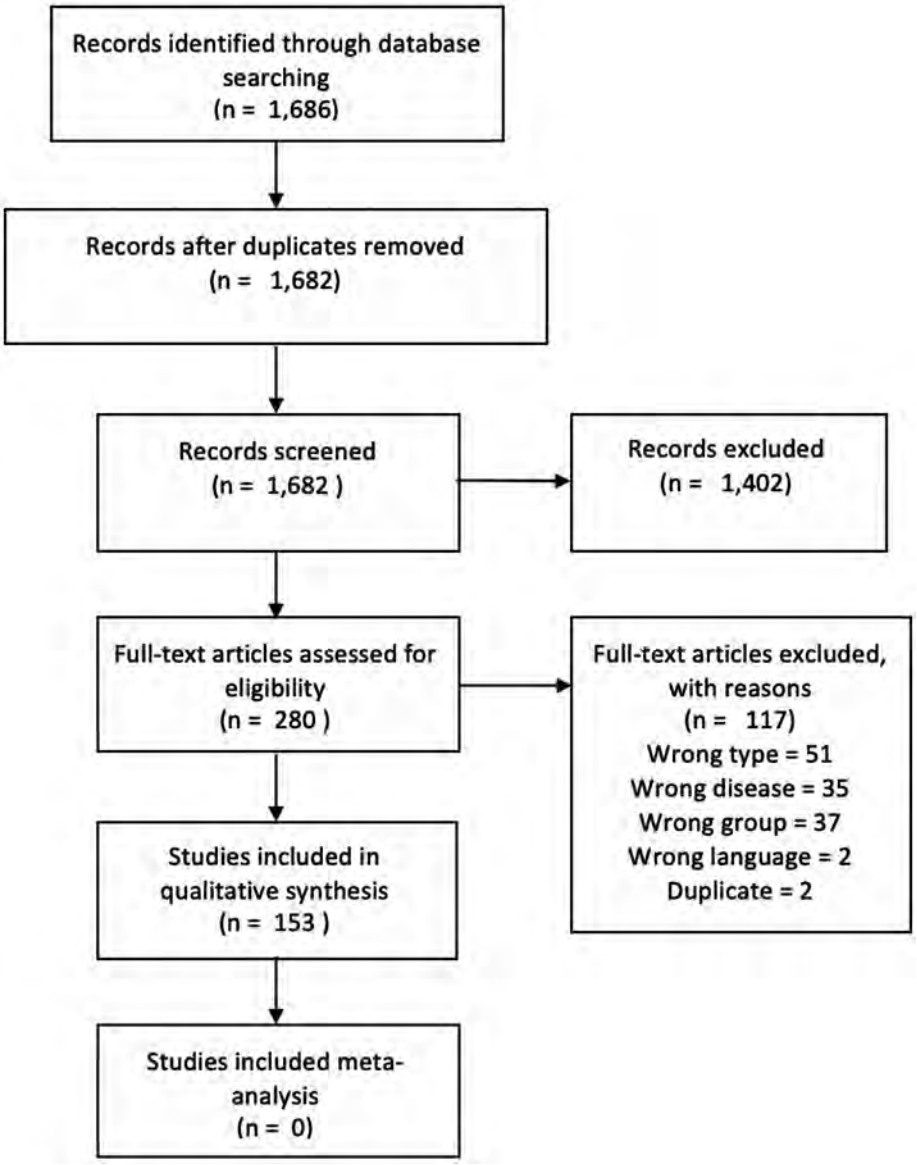
Dominique Feterman Jimenez[1], Garret Duron[2], Ali Duarte-Garcia[3], Paul Sufka[4], Samuel Whittle[5], Philip Robinson[6], Larry Prokop[3] and Michael Putman[7], [1]UConn Health Center, Farmington, CT, [2]HCA Memorial Health University Medical Center, Savannah, GA, [3]Mayo Clinic, Rochester, MN, [4]Healthpartners, St Paul, [5]Rheumatology Unit, The Queen Elizabeth Hospital, Springfield, South Australia, Australia, [6]University of Queensland, Herston, Queensland, Australia, [7]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases II: Evaluating Drug Therapies for COVID-19
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Consensus-based recommendations guide standards of care for clinical practice. Pharmaceutical-industry involvement in producing such recommendations may undermine their objectivity. We performed a systematic review to quantify the extent of pharmaceutical company involvement in rheumatology consensus based recommendations in the field of rheumatology.

Methods: A comprehensive search of several databases from their inception to April 21st, 2020 was conducted. The search strategy was designed by an experienced librarian with input from the study's investigators. Eligibility criteria included (1) English language (2) consensus-based recommendations that assessed (3) pharmacotherapy of (4) rheumatic diseases after (5) January 1st, 2000. Pairs of reviewers screened articles and extracted data. Categorical variables were assessed using Fisher's exact test; yearly publications were analyzed using a linear regression.

Results: The search identified 1,686 articles, of which 153 were included. The most common subjects were rheumatoid arthritis 31/153 (20%), spondyloarthritis 18/153 (12%), osteoarthritis 10/153 (7%), crystal arthropathies 9/153 (6%), and vasculitis 9/153 (6%). The most common consensus-based methodologies were Delphi processes 77/187 (41%) and consensus conferences 69/187 (37%) (Figure 2A). Major societies (ACR, EULAR, BSR) endorsed 37/153 (24%), other organizations (professional societies or governments) endorsed 74/153 (48%), and 42/153 (28%) were



PRISMA Diagram

not endorsed (Figure 2B). Major society-endorsed guidelines were less likely to accept industry funding (5% vs. 31% other organizations vs. 67% not endorsed, $p < 0.001$), allow pharmaceutical involvement in the consensus process (3% vs. 9% other organizations vs. 21% not endorsed, $p = 0.03$), or allow an industry funded medical writer (0% vs. 3% other organizations vs. 19% not endorsed, $p = 0.006$). The percent of authors who declared any conflicts of interest increased over time across all consensus-based recommendations ($p < 0.001$) (Figure 2C). With regard to the projects that accepted funding from pharmaceutical companies, the industry sponsor was involved in the consensus based process in 16/53 (30%), provided a medical writer in 10/53 (19%), and was allowed to approve the final draft in 1/53 (2%) (Figure 2D).

Conclusion: The yearly production of consensus-based recommendations has significantly increased over time. Consensus-based recommendations that are not endorsed by major rheumatology societies frequently receive funding from pharmaceutical companies, which may be involved in the consensus-finding process or provide editorial support. Rheumatologists should be aware of this potential influence and policymakers should consider strategies to mitigate their impact.

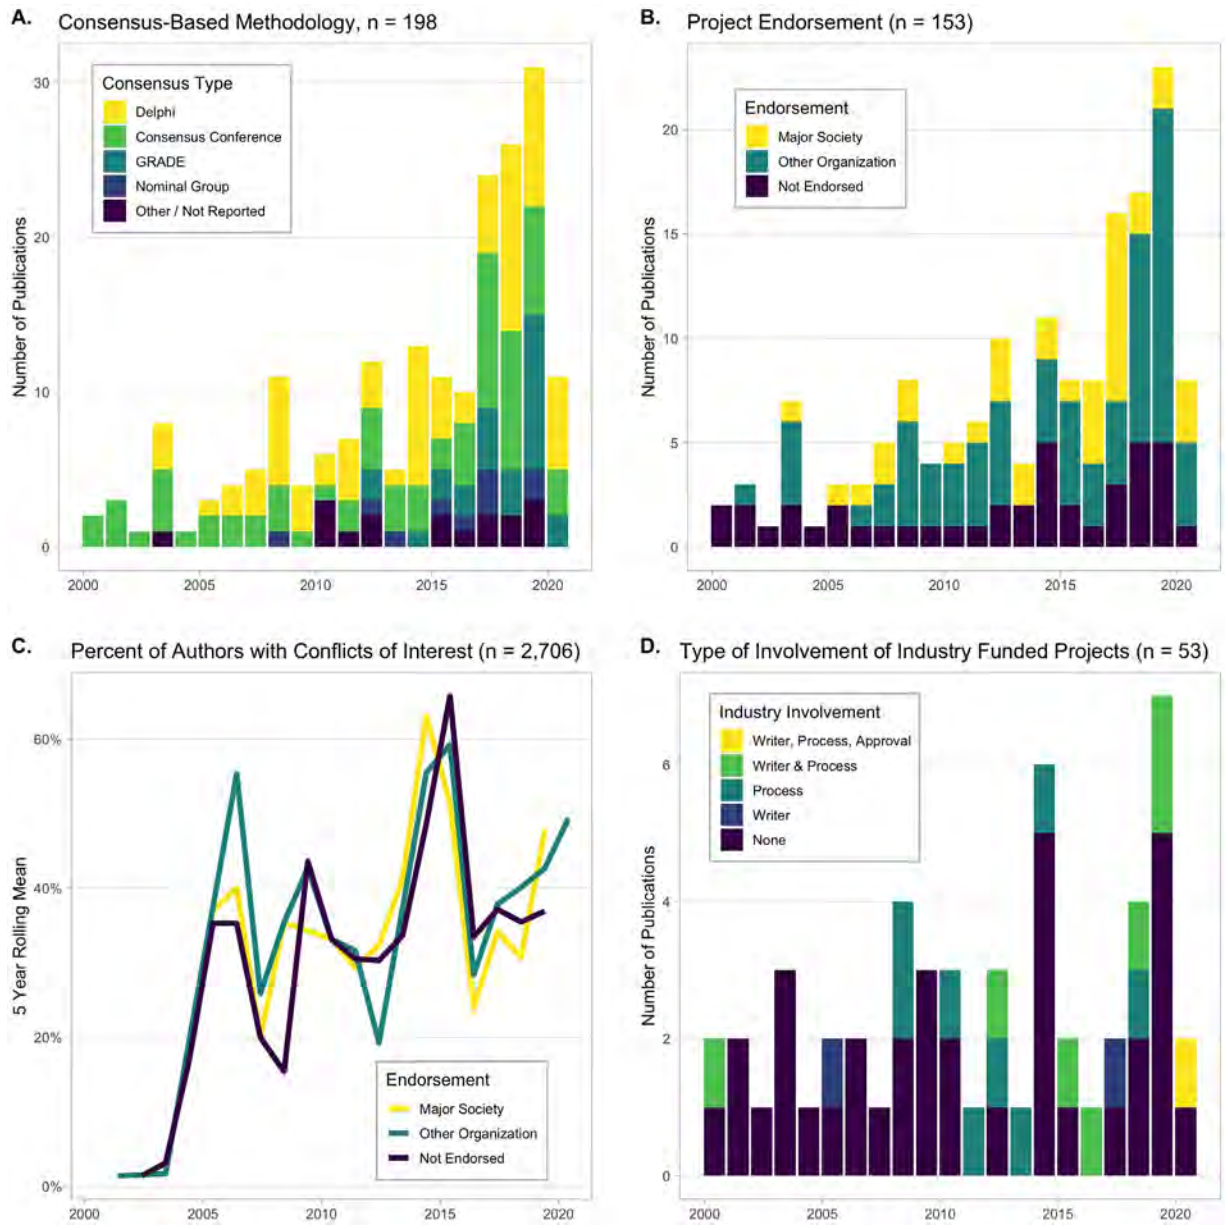


Figure 2. A. Number of publications utilizing major consensus-finding methodologies, n = 198. Number exceeds total number of publications because of studies that utilized mixed methods. B. Project endorsement by major society (ACR, EULAR, BSR), other organization (other professional societies, government groups), or not endorsed, n = 153. C. Percentage of authors per year who declared conflicts of interest, stratified by project endorsement. Data displayed as five year rolling mean for reporting clarity. D. Types of involvement by industry in industry funded projects over time, n = 53. Involvement categories were "Writer" (medical writer or editorial support), "Process" (involvement in the consensus-finding process), and "Approval" (pharmaceutical company having right to edit or approve the final manuscript).

OA, osteoarthritis
Primary outcome for each subject is shown, according to the following hierarchy: primary osteonecrosis, rapidly progressive OA type 2, subchondral insufficiency fracture, pathological fracture, rapidly progressive OA type 1,not enough information to determine rapid vs. normal progression of OA, other, normal progression of osteoarthritis.
(1) The primary composite joint safety endpoint includes any subject with an adjudicated outcome of primary osteonecrosis, rapidly progressive OA type 1 or type 2, subchondral insufficiency fracture, or pathological fracture.
*Includes post-traumatic/post-procedure events and pre-existing conditions.

Table 2. Adjudicated joint safety outcomes, n (%)

ses summarized here include baseline population characteristics, adjudicated joint safety outcomes and sub-group analyses in the combined randomized, controlled, phase 3 OA tanezumab studies.

Methods: In study 1 (NCT02697773) patients received placebo, tanezumab 2.5 mg, or 2.5 mg then 5 mg (tanezumab 2.5/5 mg) over 16 weeks. In study 2 (NCT02709486) patients received placebo, tanezumab 2.5 mg, or tanezumab 5 mg over 24 weeks. In study 3 (NCT02528188) patients received tanezumab 2.5 mg, tanezumab 5 mg, or nonsteroidal anti-inflammatory drug (NSAID) over 56 weeks. Joint safety outcomes were adjudicated by a blinded external Adjudication Committee. The adjudicated composite joint safety endpoint (CJSE) included: primary osteonecrosis (ON), rapidly progressive OA type 1 (RPOA1) or type 2 (RPOA2), subchondral insufficiency fracture (SIF), or pathological

Table 3. Subgroups analyzed for potential association with adjudicated composite joint safety endpoint

Subgroups	Details	Association with CJSE
Demographic factors	Age: <65 versus ≥65, <75 versus ≥75), gender, BMI: <25, 25 to <30, 30 to <35, ≥35	No association
Baseline disease severity	Maximum KL Grade at baseline (2, 3, or 4), Number of joints with baseline KL Grade ≥2, Prior history of TJR, WOMAC Pain subscale score at baseline (<7, ≥7), WOMAC Physical Function subscale score at baseline (<7, ≥7), Patient's Global Assessment at baseline (Fair, Poor/Very Poor)	Possible association for maximum KL grade of 3 at baseline and WOMAC pain and physical function score ≥7 at baseline
Adverse events	Selected adverse events up to end of study: arthralgia, joint swelling, abnormal peripheral sensation, fracture, lower limb fracture, fall, and peripheral edema	Possible association for arthralgia and joint swelling
Efficacy Response: WOMAC Pain and Physical Function	≥50% change from baseline in WOMAC Pain response at Week 16, Patients with WOMAC Pain subscale scores ≤2 at two or more consecutive visits, Patients with ≥50% change from baseline in WOMAC Physical Function response at Week 16	No association
Sensory examinations in lower extremities	Standardized neurologic examinations carried out by investigators or designated physicians at each study site	No association
Concomitant medications (non-NSAID)	Use of intra-articular hyaluronic acid in the year prior to the study, use of intra-articular corticosteroid in the year prior to the study, concomitant cardiovascular prophylactic aspirin use, concomitant intra-articular corticosteroid use, concomitant bisphosphonate use, and concomitant acetaminophen use	No association
Concomitant NSAID use	Use of NSAID prior to occurrence of joint safety endpoint	No association
Baseline bone health	Including: history of osteopenia, history of osteoporosis	No association

BMI, Body mass index; KL, Kellgren-Lawrence; TJR, Total joint replacement; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index

Table 3. Subgroups analyzed for potential association with adjudicated composite joint safety endpoint

fracture. Subgroups were cross-tabulated to investigate potential associations with outcomes descriptively with no formal statistical analysis.

Results: At baseline, maximum Kellgren-Lawrence (KL) grade of any joint and number of joints with KL grade ≥2 were similar across treatment groups (Table 1). A total of 451 patients were evaluated by the blinded adjudication committee; 145 were adjudicated to have a primary outcome which was a component of the CJSE: RPOA1 (69% 100/145), RPOA2 (17% 24/145), SIF (12% 18/145), and ON (2% 3/145) (Table 2). The proportion of patients with adjudicated

CJSE was higher in tanezumab-treated patients relative to placebo or NSAID and the incidence increased with increasing dose of tanezumab. RPOA1 typically occurred in the knee and in joints with KL grade 2 or 3 OA at baseline, although there were four events in joints that were KL grade 0 at baseline (two each in the tanezumab 2.5 mg and 5 mg treatment groups). For RPOA2, the affected joint was approximately evenly split between the hip and knee with two patients having shoulder as the affected joint (one each in the tanezumab 5 mg and NSAID groups). Most RPOA2 events occurred in joints with KL grade 3 or 4 OA at baseline. RPOA2 was more often associated with a total joint replacement than RPOA1. Multiple subgroups were investigated to assess potential associations with CJSE, with possible associations noted for baseline disease severity and adverse events of arthralgia and joint swelling (Table 3).

Conclusion: Patients enrolled in the combined phase 3 OA tanezumab studies had moderate to severe OA. The proportion of patients with adjudicated CJSE was higher in tanezumab-treated patients relative to placebo or NSAID and the incidence increased with increasing dose of tanezumab. Subgroup analyses did not reveal an association of CJSE with efficacy response.

Abstract Number: 1483

A Randomised Controlled Trial Evaluating the Efficacy of Internet-based Exercises Aimed at Treating Knee Osteoarthritis (iBEAT-OA)

Sameer Gohir[1], Abhishek Abhishek[2], Anthony Kelly[2] and Ana M Valdes[3], [1]NIHR Nottingham Biomedical Research Centre, GRAYS ESSEX, England, United Kingdom, [2]University of Nottingham, Nottingham, United Kingdom, [3]NIHR Nottingham Biomedical Research Centre, School of Medicine, University of Nottingham, Nottingham, England, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis I: Clinical Trials
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Osteoarthritis (OA) is the commonest cause of pain and disability in the general population and is usually managed by family doctors and physiotherapists. This study aimed to explore the benefits of digital delivery of exercises on pain, function, and other health-related outcomes in individuals with painful knee OA.

Methods: iBEAT-OA was a primary-care based randomised controlled trial in which participants with knee OA were 1:1 randomised to web-based exercises or usual care. The study was designed to ascertain whether, after 6 weeks, i-BEAT-OA was more effective to reduce the pain than continued usual care. The eligibility criteria are shown in Figure 1.

An app-based exercises platform known as Joint Academy (JA) was used as an intervention given to treatment arm. There were two face-to-face sessions with a physiotherapist for both arms, at enrolment and six weeks. Visual Analogue Score (VAS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), The Arthritis Research UK Musculoskeletal Health Questionnaire (MSK-HQ), Pittsburgh Sleep Quality Index (PSQI), 30-second sit to stand

Figure 1: Inclusion and Exclusion Criteria for iBEAT-OA trial

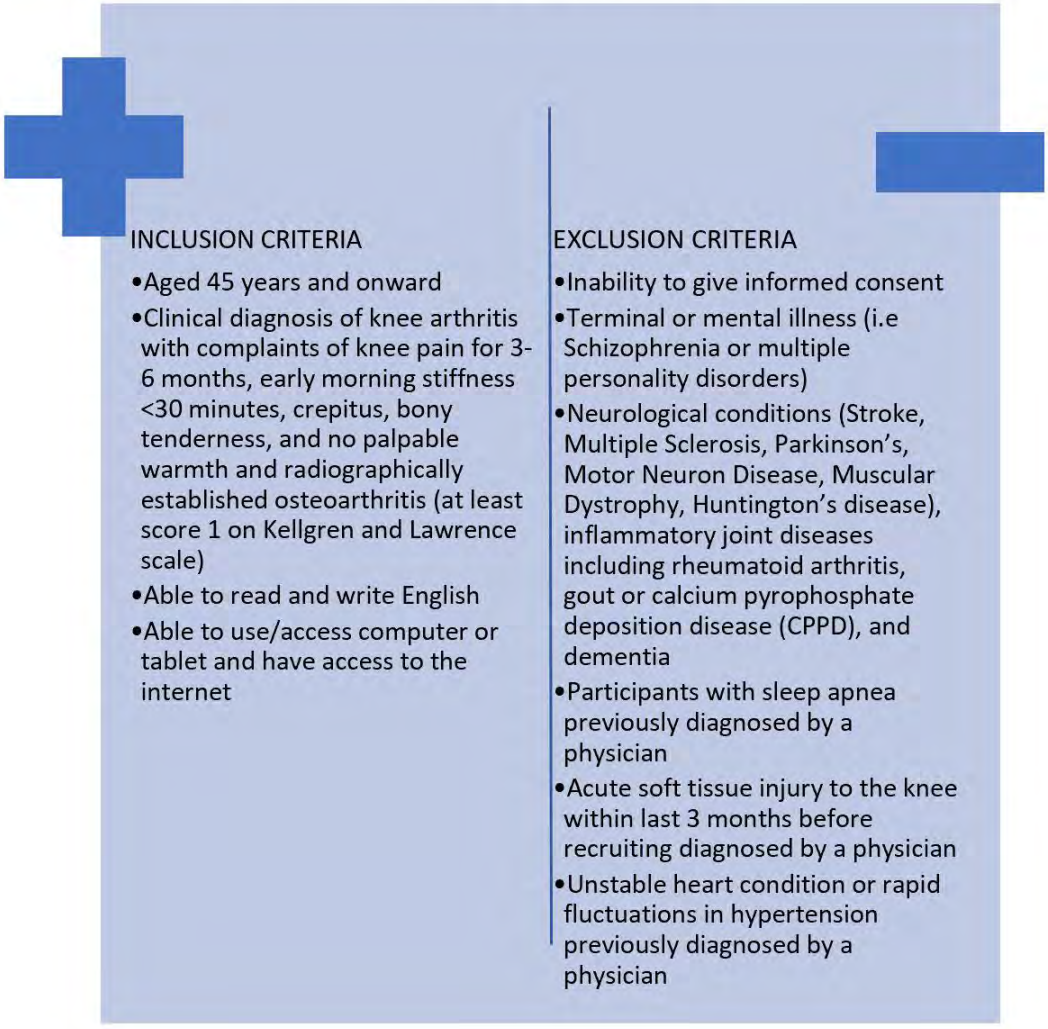

Figure 1. Inclusion and Exclusion Criteria for iBEAT-OA trial

test (30CST), Time up and go test (TUG), Quantitative Sensory Testing (QST), Maximum Voluntary Contraction (MVC)-isokinetic contraction of Quadriceps / Hamstring muscle, urine and blood samples were taken at baseline and at six weeks follow up. Participants were given an actigraphy device.

We compared groups at baseline and after 6 weeks by intention to treat.

The primary outcome was the change in pain (mean difference) assessed by visual analogue scores (VAS) between baseline and follow-up between the treatment and control arms. The difference within arms between baseline and follow-up was assessed using a paired t-test. A similar model was used for other variables. Regression analysis models were used to assess confounding factors. The threshold for statistical significance was set at level .05 with 2-sided testing.

Results: The recruitment was stopped in March 2020 due to COVID-19 lockdown instructions. In total, 105 participants (48 participants in the intervention arm and 57 participants in the control arm) had completed data for both baseline and follow-up assessments. No significant differences in baseline characteristics were seen (Table 1).

	Control Group	Intervention Group	P values
Age	67.96 (8.6)	65.23 (9.7)	P= 0.132
Women / Men	37 (64.91%) / 20 (35.09%)	34 (70.83%) / 14 (29.16%)	P= 0.518
BMI	31.9 (5.9)	30.4 (5.5)	P= 0.193
K/L Score	2.09	2.04	P= 0.643
1	18 (31.58%)	19 (39.58%)	
2	22 (38.6%)	13 (27.08%)	
3	11 (19.3%)	11 (22.9%)	
4	6 (10.5%)	5 (10.4%)	

Table 1: Baseline Characteristics

Table 1. Baseline Characteristics

The mean difference in pain as measured by a visual analogue scale (0-10) from baseline minus follow-up for the treatment arm was a drop of -1.79 [95%CI -1.16 to -2.41], for the control arm it was -0.39 [95%CI -0.97 to 0.18]. The mean difference between the treatment and control arms was 1.39 [95%CI 0.55-2.2] p< 0.0014 favouring the treatment arm.

Conclusion: Among participants with knee pain from OA, use of the Joint Academy app compared with control group resulted in an improvement in pain, function and muscle strength at 6 weeks follow-up that was statistically significant. Furthermore, there was improved muscle strength of hamstring and functional activities in intervention group. With COVID-19 pandemic, when social distancing is a vital prerequisite of staying safe, apps such as Joint Academy can be useful tools to manage knee OA at home.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Osteoarthritis I: Clinical Trials

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: To evaluate the efficacy of tocilizumab, an antibody against interleukin-6 receptor (IL-6R), in patients with hand osteoarthritis.

Methods: This was a multicenter, 12-week, randomized, double-blind, placebo-controlled study. Patients with symptomatic hand osteoarthritis (pain ≥ 40 on a 0–100-mm visual analogic scale [VAS] despite analgesics and non-steroidal anti-inflammatory drugs; at least 3 painful joints, Kellgren–Lawrence grade ≥ 2) were randomized to receive two infusions 4 weeks apart (week 0 and week 4) of tocilizumab (8 mg/kg IV) or a placebo. The primary endpoint was the change in VAS pain at week 6. Secondary outcomes included the number of painful and swollen joints, duration of morning stiffness, patients' and physicians' global assessment and function scores.

Results: Of 104 patients screened, 91 (82% women; mean age, 64.4 years) were randomly assigned and 79 completed the 12-week study visit. The mean change between baseline and week 6 on VAS pain (primary outcome) was -7.9 (SD 19.4) and -9.9 (SD 20.1) in the tocilizumab and placebo group (p=0.7). No significant treatment differences were observed at weeks 4, 6, 8 or 12 for any secondary outcomes. Overall, adverse events were slightly more frequent in the tocilizumab than placebo group.

Conclusion: Tocilizumab was no more effective than placebo for pain relief in patients with hand osteoarthritis.

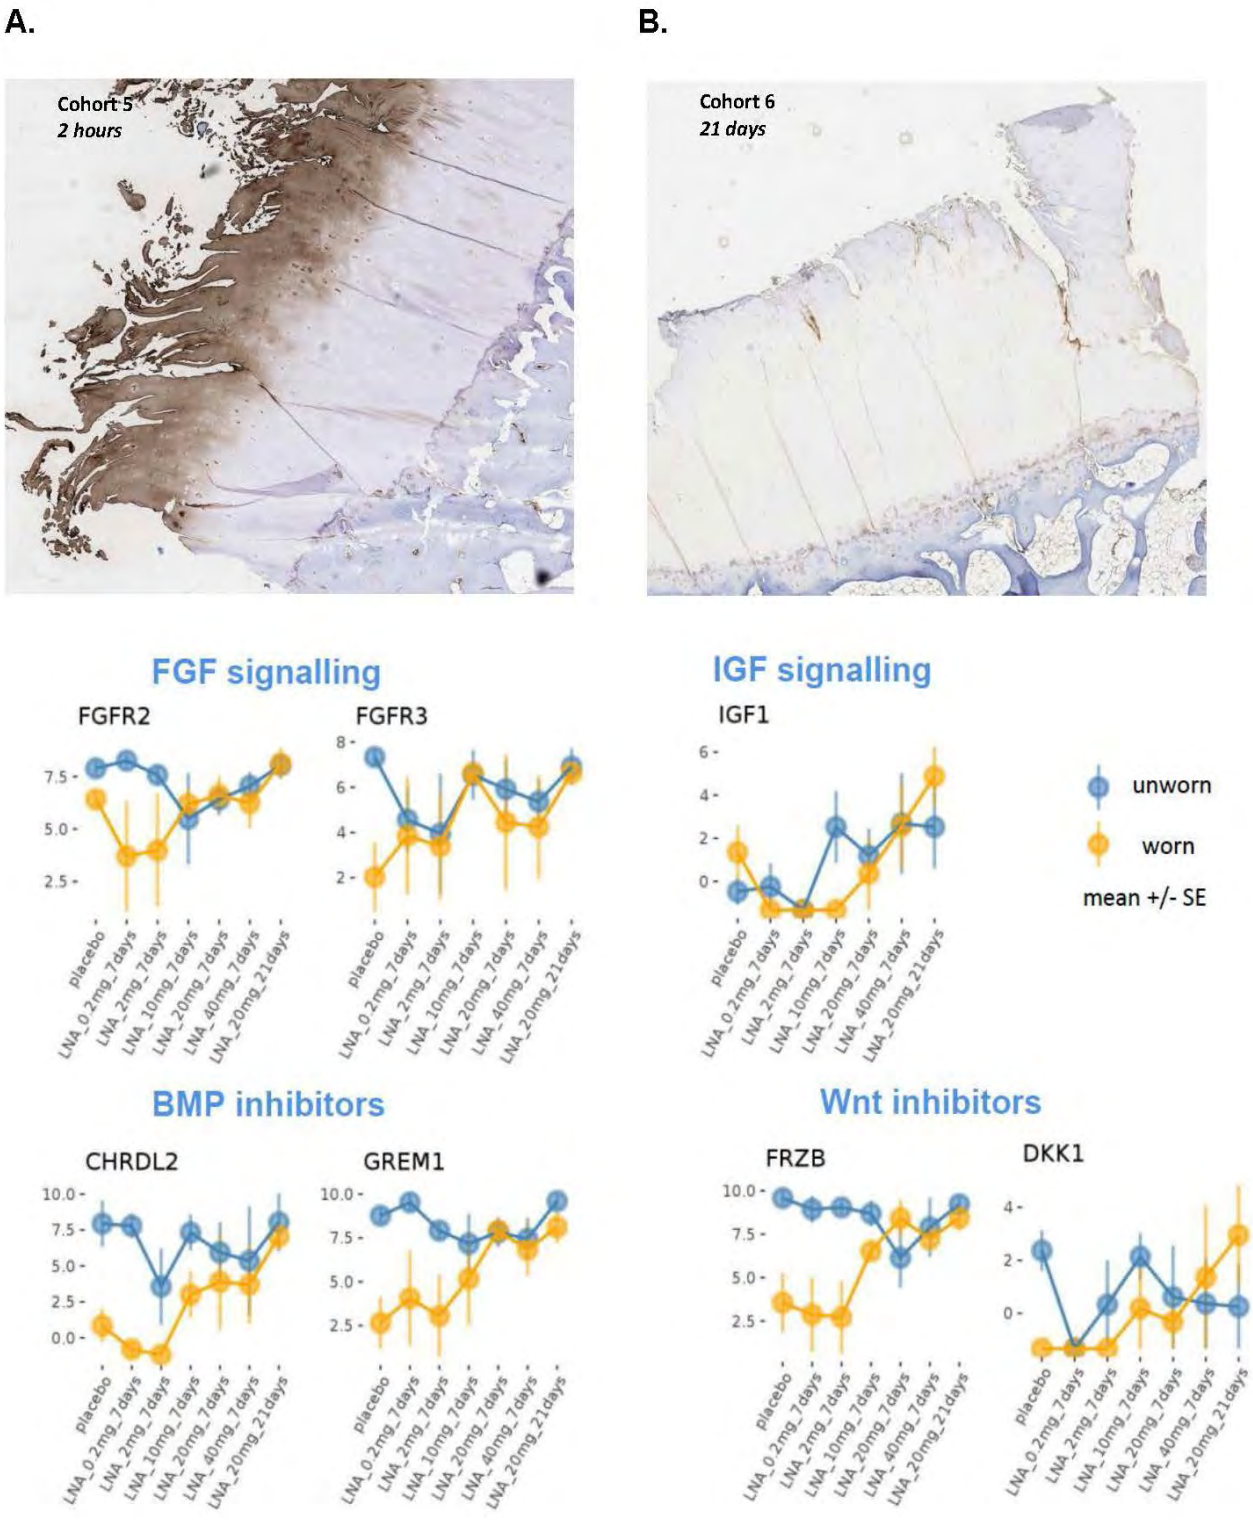
SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis I: Clinical Trials
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: LNA043 is a modified human angiopoietin-like 3 (ANGPTL3) protein identified in a phenotypic screen for inducers of chondrogenesis and cartilage repair. The primary objective of this trial (NCT02491281) was to assess safety and tolerability of single intraarticular doses of LNA043 into the knee of patients with knee osteoarthritis (OA).

Figure 1.



Methods: A first-in-human, randomized, single-center, placebo-controlled, double-blind, single ascending dose trial was conducted in patients aged 50–75 years with knee OA scheduled for total knee replacement (TKR). Patients were randomized 3:1 (LNA043 to placebo) in each of 7 cohorts consisting of 4 patients each. The 5 increasing intraarticular dose levels ranging 0.2–40 mg (0.2 mg, 2 mg, 10 mg, 20 mg, 40 mg) administered 7 days before TKR. Two additional

20 mg dose levels were also administered 2 hours or 21 days before TKR. Key safety parameters included adverse events (AEs), injection-site reactions and detection of anti-drug antibodies against LNA043. Knee tissues were obtained during the TKR procedure to assess local exposure to LNA043 through immunohistochemical (IHC) staining, and cartilage biopsies were harvested from worn and unworn areas of the knee to perform RNA-Seq analysis.

Results: 30 patients were randomized to LNA043 (n=21) or placebo (n=7), 2 withdrew consent prior to treatment. Pertinent demographic information included: a mean age of 63 years, 68% female (n=19), and 96% Caucasian (n=27) participants. A total of 19 (14 on LNA043 and 5 on placebo) patients experienced at least one AE. The overall incidence of AEs for LNA043 was 66.7% (14/21). The overall incidence of AEs for placebo was 71.4% (5/7). One case of dry mouth/dysgeusia was reported in the 40 mg cohort, which resolved spontaneously and was considered mild. Ten non-study drug-related, serious AEs were reported in five patients (LNA043, n=3; placebo, n=2). Anti-LNA043 antibodies were not detected in the patients. After intraarticular injection, LNA043 was dose-dependently distributed from the joint to systemic circulation with C_{max} typically reached between 2 to 6 hours after the intraarticular injection. IHC demonstrated that LNA043 penetrated the articular cartilage shortly after injection (2 hours), with more pronounced penetration into the damaged areas (Figure 1A). LNA043 was not detectable in the articular cartilage or synovial-fluid 7 days post intraarticular injection. RNA-Seq analysis demonstrated modulation of several genes involved in cartilage homeostasis and repair, suggesting a broad effect by LNA043 up to 21 days post-injection (Figure 1B). These effects were both dose-dependent and mostly present in the worn cartilage tissue.

Conclusion: In this study, LNA043 displayed a favorable safety profile without any clinically significant drug-related safety signals or immunogenicity. In addition, LNA043 penetrated transiently into the articular cartilage; was quickly cleared locally and systemically; and elicited a chondroanabolic response as shown by modulating several pathways in chondrocytes involved in OA and cartilage repair at the RNA level. Further studies of LNA043 for treatment of knee OA are now in progress.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Osteoarthritis I: Clinical Trials

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: The 5-year Phase II FORWARD study assessed the efficacy and safety of the potential disease-modifying osteoarthritis drug (DMOAD) sprifermin (recombinant human fibroblast growth factor 18) in patients with symptomatic, radiographic knee osteoarthritis (OA). Here, we report the long-term 5-year efficacy and safety results of FORWARD.

Methods: Patients were randomized 1:1:1:1:1 to intra-articular sprifermin 100 or 30 µg q6mo, 100 or 30 µg q12mo, or placebo (PBO), for 18 months. The treatment period-related analysis for the primary endpoint was at Year 2, with an extended 3-year observation period. The intent-to-treat (ITT) population included all randomized patients; the modified (m)ITT population all patients with a baseline and ≥1 qMRI reading up to Year 2. Post-hoc exploratory analysis was conducted in a 'subgroup at risk' (SAR, n=161), with minimum medial or lateral joint space width of 1.5–3.5 mm and WOMAC pain 40–90 at baseline. Treatment differences vs PBO were estimated using a repeated measures model controlling for baseline, treatment, time, pooled country and treatment by time interaction. Confidence intervals (CIs) were adjusted for multiplicity of treatments using Dunnett adjustment. Linear dose-effect trend tests were performed exploratively at each timepoint.

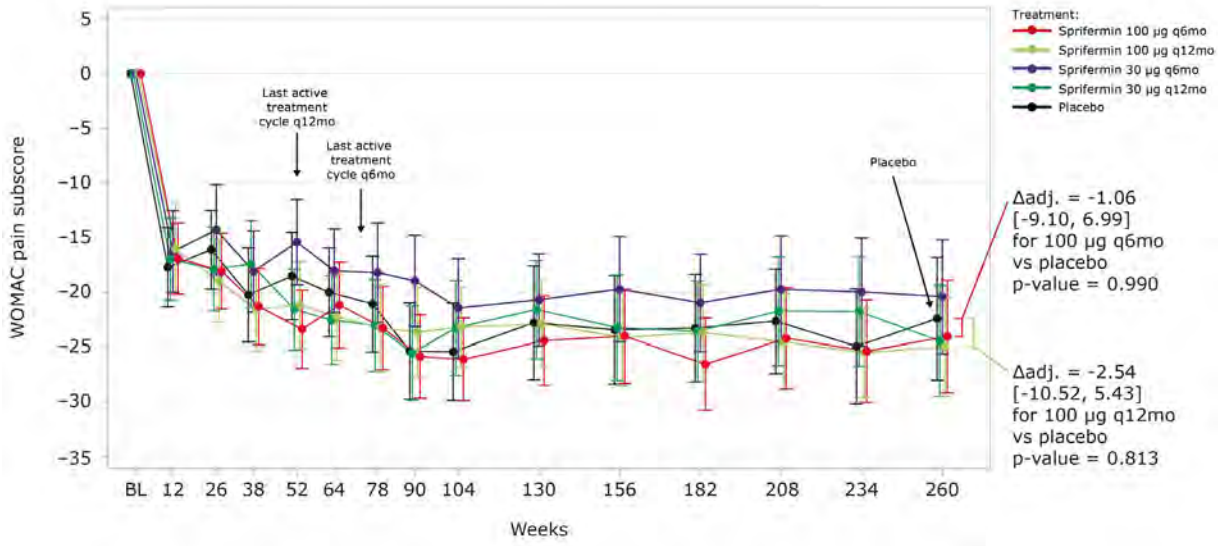
Results: 474 (86.3%) patients completed the primary 2-year observation period; 442 (80.5%) and 378 (69%) patients completed the 3- and 5-year extended follow-up periods, respectively. The significant dose-response effect of sprifermin on longitudinal change in total femorotibial joint (TFTJ) cartilage thickness (trend test, p< 0.001), and the 0.05 mm mean increase in TFTJ cartilage thickness with sprifermin 100 µg q6mo (highest dose) vs PBO (95% CI 0.004, 0.095; p=0.015; **Table 1**) observed at Year 2 were sustained to Year 5. WOMAC pain scores improved by ~50% from baseline to Year 5 in all cohorts, including PBO (**Figure 1**). Post-hoc analysis of the SAR identified a differentiation in WOMAC pain scores between the sprifermin 100 µg q6mo and PBO groups at Year 2 (–5.82; 95% CI –18.87, 7.23), Year 3 (–8.75; 95% CI –22.42, 4.92) and Year 5 (–10.08; 95% CI –25.68, 5.53; **Figure 2**). AEs were mostly moderate in severity. 181 patients (33%) reported serious AEs, none of which were deemed related to treatment. AE-related study withdrawals were < 10%, the majority of which were musculoskeletal and soft tissue disorders. At Year 5, there was no notable difference in the incidence of adverse events (AEs), serious AEs or study discontinuation due to AEs in any sprifermin group vs PBO.

Table 1. Cartilage thickness in the total femorotibial joint based on qMRI from Year 2 through to Year 5: mean change from baseline and adjusted difference vs placebo with sprifermin (mITT population; n = 494)

	Sprifermin 100 µg q12mo (N=99)		**Sprifermin 100 µg q6mo (N=101)**		**Trend test**
	Number of observations	Adjusted mean difference to placebo (95% CI; p)	Number of observations	Adjusted mean difference to placebo (95% CI; p)	
Year 2	90	**0.041** (0.014, 0.067; <0.001)	86	**0.050** (0.023, 0.077; <0.001)	***p<0.001***
Year 3	86	**0.021** (-0.013, 0.055; 0.332)	79	**0.054** (0.019, 0.089; <0.001)	***p<0.001***
Year 4	81	**0.033** (-0.009, 0.075; 0.127)	78	**0.055** (0.013, 0.098; 0.002)	***p<0.001***
Year 5	74	**0.024** (-0.021, 0.070; 0.406)	72	**0.049** (0.004, 0.095; 0.015)	***p<0.001***

p-values at time points other than Year 2 are nominal

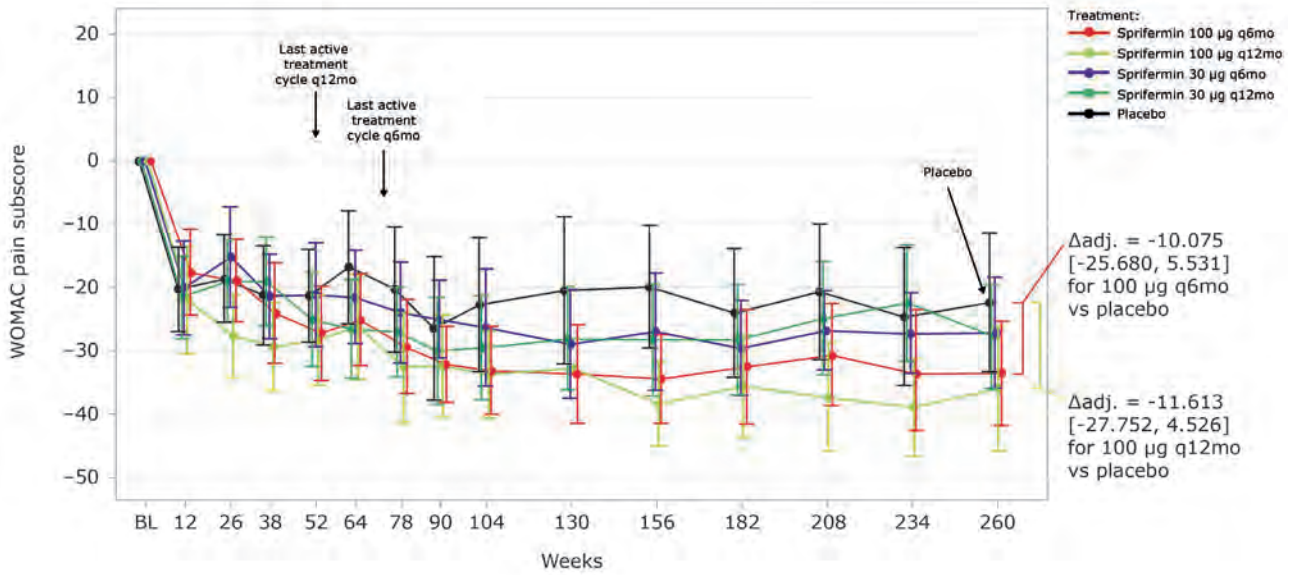
Figure 1. Change from baseline in WOMAC pain scores (ITT population; n=549)



Dose response p-value at Year 5 = 0.673

Abbreviations: **Δadj.**, adjusted mean difference [95% CI] to placebo at Year 5; **BL**, baseline; **CI**, confidence interval; **q6mo**, every 6 months; **q12mo**, every 12 months; **ITT**, intent-to-treat; **WOMAC**, Western Ontario and McMaster Universities Osteoarthritis Index.

Figure 2. Change from baseline in WOMAC pain scores in the "subgroup at risk" (n = 161) (post-hoc analysis)



Dose response p-value at year 5 = 0.046

Abbreviations: **Δadj.**, adjusted mean difference [95% CI] to placebo at Year 5; **BL**, baseline; **CI**, confidence interval; **q6mo**, every 6 months; **q12mo**, every 12 months; **WOMAC**, Western Ontario and McMaster Universities Osteoarthritis Index.

Conclusion: In FORWARD, the longest DMOAD study ever reported, sprifermin maintained long-term structural modification of articular cartilage vs PBO despite a 3.5-year treatment-free period, with no new safety signals. Pain improvement vs PBO was sustained in a subgroup at risk of structural and symptomatic progression. This suggests potential disease modification with sprifermin, with delayed knee OA structural progression and translation of structural modification to clinical benefit. It also identifies a potential target dose and patient population for future Phase III trials.

Biclustering Reveals Potential Knee Osteoarthritis Phenotypes in Exploratory Analyses: Data from the Osteoarthritis Initiative

Amanda Nelson[1], Thomas Keefe[2], Todd Schwartz[3], Richard Loeser[1], Yvonne Golightly[4], Liubov Arbeeva[1] and J Marron[2], [1]University of North Carolina at Chapel Hill Thurston Arthritis Research Center, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill Dept of Biostatistics, Chapel Hill, NC, [4]University of North Carolina at Chapel Hill Dept of Epidemiology, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis II: Clinical Aspects
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: To utilize novel methodologies to explore subgroups within the OAI clinical data.

Methods: From the OAI baseline dataset (n=4796 individuals with or at risk of knee OA/9592 knees; 116 clinical and demographic features; https://nda.nih.gov/oai/; *AllClinical00*), we excluded uninformative variables and features/knees with missing data leaving 86 features from 3322 people (6461 knees) for analyses. Continuous variables were transformed using a procedure to remove skewness and standardized (Feng 2016; https://doi.org/10.1002/sta4.104).

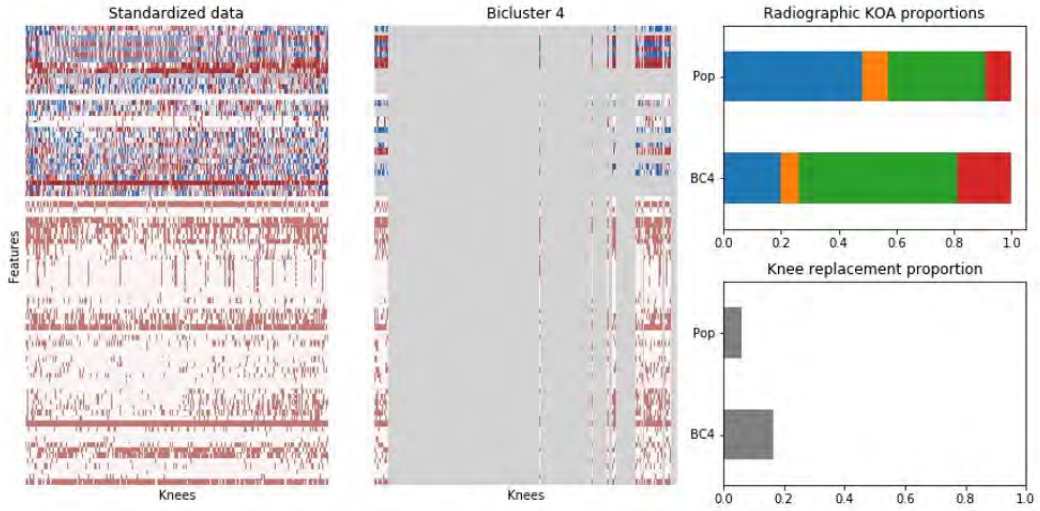
Biclustering (Cheng 2000; PMID 10977070) is particularly useful when different subsets of features are informative for some, but not all, knees. This method allows simultaneous clustering of the rows (knees) and columns (features) of the matrix, and automated discovery of similarities based on these attributes. A bicluster is then defined as a sub-matrix that is well-fit (i.e., larger R^2) by two-way ANOVA, in that the entries are close to a common value with adjustments for the rows and columns. We chose the parameters of the algorithm to balance competing desires for biclusters: strongly similar knees and sufficient sample size to provide potentially useful phenotypes.

Table 1. Summary of identified biclusters, number of knees and features included, and prognosis

Bicluster	n (knees)	N (people)	D (features)	R^2	Prognosis*
1	1425	960	80	0.37	Better for bicluster
2	2415	1649	69	0.30	Similar
3	1822	1294	63	0.31	Similar
4	188	147	70	0.64	Poorer for bicluster
5	238	191	64	0.53	Poorer for bicluster
6	258	194	63	0.31	Similar

*Summary prognosis for those knees in each bicluster compared to the full cohort of knees, based on outcomes shown in Figure 1, including knees without radiographic OA (rOA), knees developing incident rOA (baseline KLG=0-1 increasing to 2+), knees with prevalent rOA (baseline KLG=2+ without progression), knees with progressive rOA (baseline KLG=2+ with worsening KLG), and the proportion of knees undergoing TKR over 96 months.

Figure 1: Composite image showing **A**) heatmap of standardized OAI data (n=6461 knees; 86 features); **B**) heatmap of bicluster 4 (n=188 knees), **C and D**) outcomes for knees in the overall cohort compared with bicluster #4

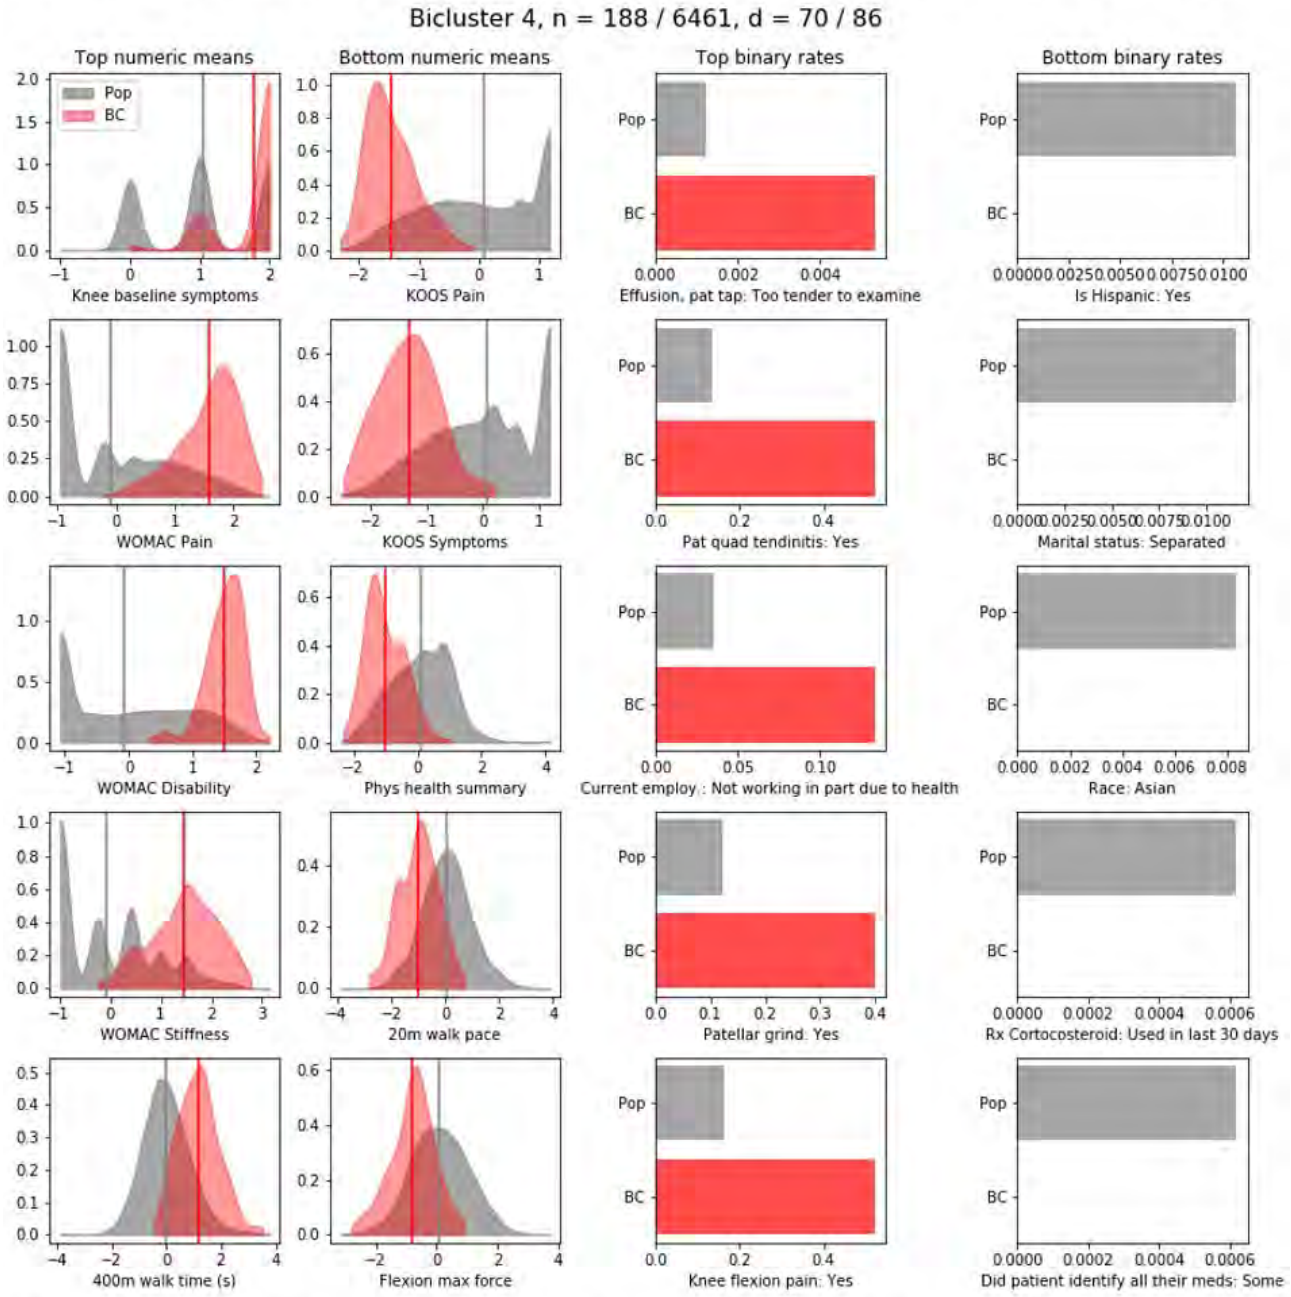


***A and B**: Red = positive standardized values, blue = negative standardized values, white = zero, gray = features not identified in bicluster 4. **C**: Blue: baseline KLG=0-1 without progression; Gold: baseline KLG=0-1 with progression; Green: baseline KLG=2+ without progression; Red: baseline KLG=2+ with progression. **D**: Proportion of TKR over 96 months in the cohort (top) and in the bicluster (bottom).*

After identifying potential biclusters, we characterized them by comparing the knees within the bicluster to the overall population of knees based on marginal distributions of features as well as outcomes (defined in **Table 1**) such as prevalent, incident, and progressive knee OA and provision of knee replacement (TKR) from baseline to 96 months.

Results: We found 6 biclusters (chosen until the clusters became too small to be useful, **Table 1**). As an example, bicluster #4 contained 188 knees (from 147 people) and 70 features (**Fig 1B**) and was characterized by greater frequency of both progressive OA (**Fig 1C**) and TKR (**Fig 1D**). We then compared the distribution of baseline features between the knees in bicluster #4 and the total population of knees (**Fig 2**). Features that were higher among the knees in bicluster #4 versus the overall population of knees included knee symptoms, WOMAC scores, 400-meter walk time, knee tenderness on exam, patellar quadriceps tendinitis, inability to work for health reasons, presence of

Figure 2: Distributions or proportions of main features differentiating knees in bicluster #4 from the total group of knees



Continuous or multi-level variables (post-standardization) are shown using density estimates (gray=distribution for whole population; red=distribution within the bicluster); binary variables are studied using bar graphs (note difference in scales). The top and bottom 5 of each type are explicitly shown.

patellar grind, and knee flexion pain. In contrast, knees included in the bicluster had lower values for KOOS (to be expected as the coding is opposite that of WOMAC), SF-12 physical summary scale, 20-meter walk speed, and maximal isometric flexion strength. These knees were less likely to be from Hispanic or Asian participants, individuals who were separated (versus any other marital status), and less frequently reported IA corticosteroids in the last 30 days.

Conclusion: We identified several biclusters (groups of features and knees) within the baseline OAI data with varying prognoses. Such biclusters may represent potential phenotypes (e.g., progressor phenotype(s)) within the larger cohort. Application of novel methodologies can provide new insights into OA phenotypes and development or progression of disease.

Abbreviations: ADL = activities daily living, KOOS = Knee Injury and Osteoarthritis Outcome Score, SD = standard deviation

Background/Purpose: The interpretation of patient-reported outcomes, such as the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire, can prove difficult if benchmarks are lacking. Therefore, we recently developed KOOS percentile curves with data from a Dutch population-based cohort (Loef et al. 2020. https://doi.org/10.1016/j.

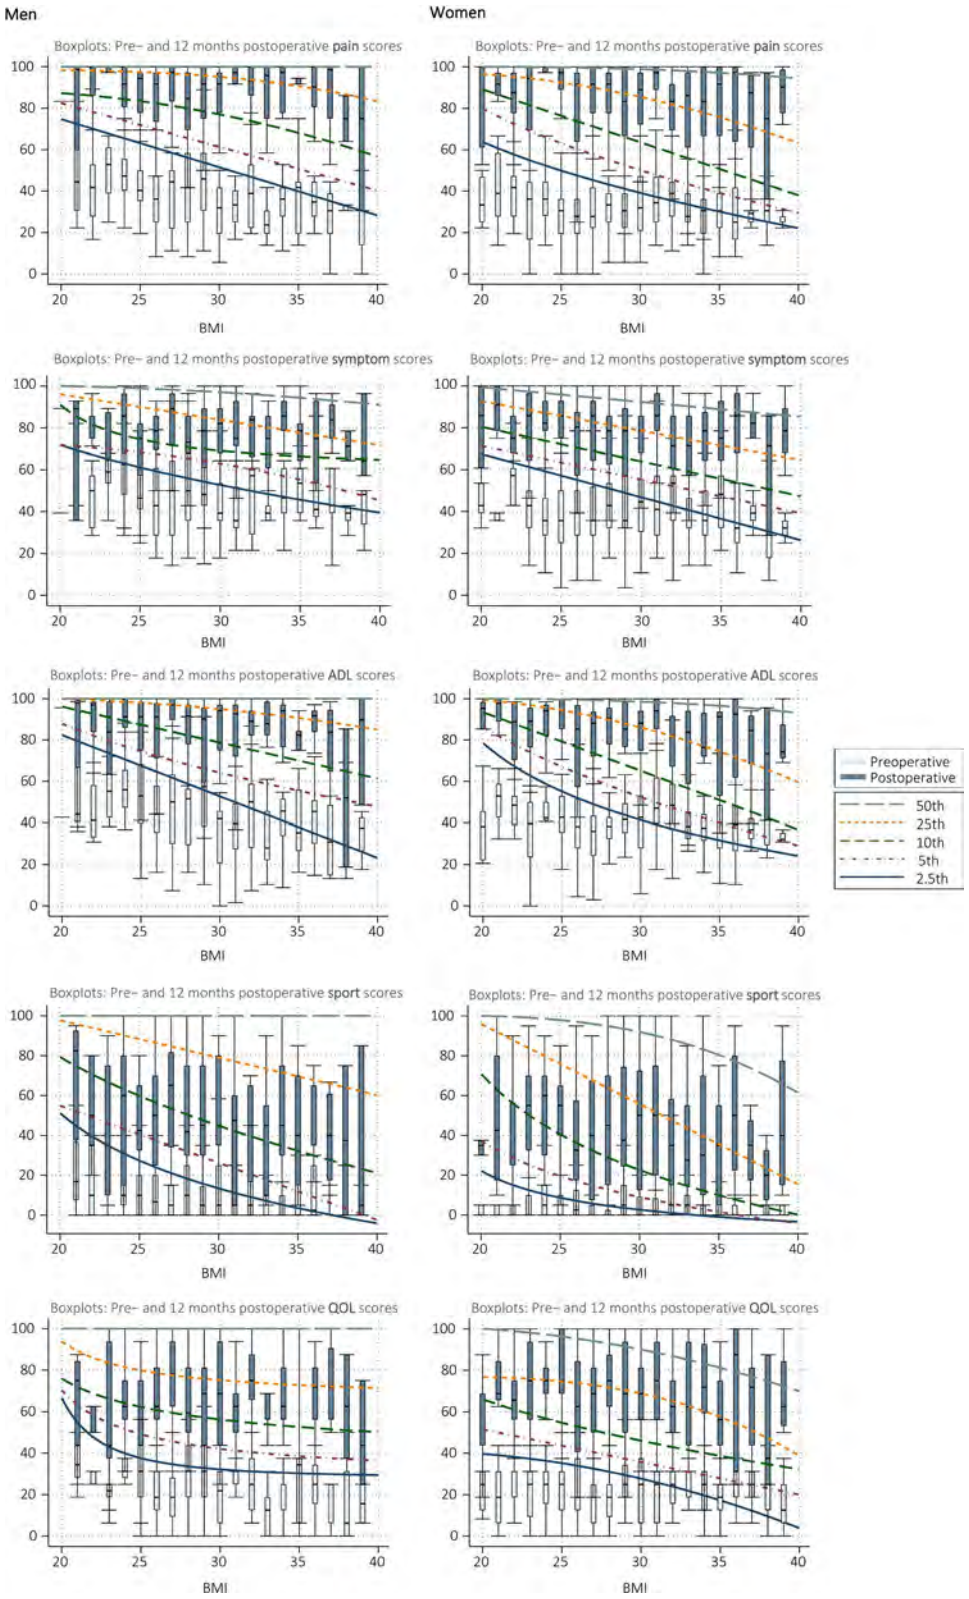

Figure 1. Preoperative and 12 months postoperative KOOS pain, symptoms, activities of daily living (ADL) function, sport and recreation function, and quality of life (QOL) subscale scores of men and women with knee OA undergoing TKA plotted on the KOOS percentile curves.

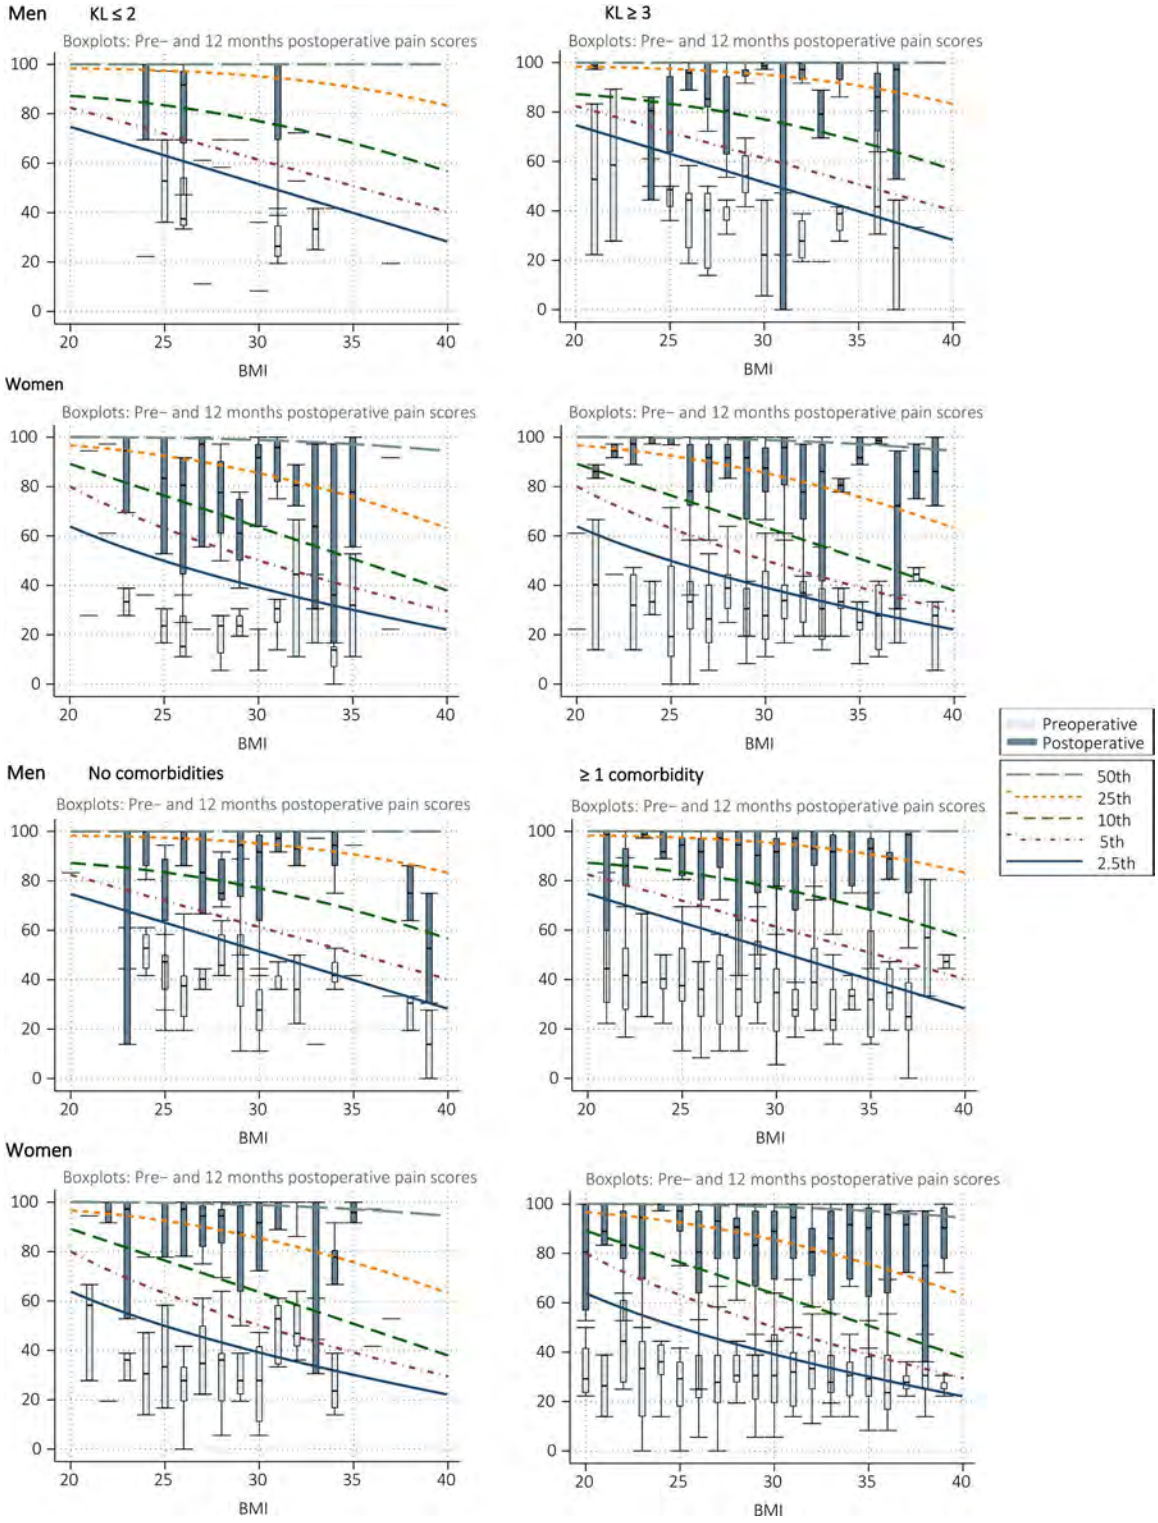

Figure 2. Preoperative and 12 months postoperative KOOS pain subscale scores of men and women with knee OA undergoing TKA, stratified by Kellgren-Lawrence score (upper quadrant), and by presence of comorbidities (lower quadrant).

joca.2020.03.014). With the present study, we aimed to investigate the application of the KOOS percentile curves using pre- and postoperative data of patients with knee osteoarthritis (OA) undergoing total knee arthroplasty (TKA).

Methods: We used data of the Longitudinal Leiden Orthopaedics Outcomes of Osteo-Arthritis study (LOAS) (van de Water et al. 2019. https://doi.org/10.2106/JBJS.18.00642). The current analyses are comprised of patients who have been included from June 2012 until June 2017, who were between 45 and 65 years of age, and undergoing primary TKA.KOOS subscale scores (0-100) were obtained preoperatively and 6, 12 and 24 months after TKA. Preoperative radiographs of the operated knee were assessed for radiographic OA severity according to the Kellgren-Lawrence (KL) grading system by an experienced musculoskeletal radiologist in a subset (37%) of patients. Comorbidities were self-reported using a standardized questionnaire. We stratified all analyses by sex. We plotted the median (interquartile range) population-level KOOS scores of all subscales on the previously developed population-based KOOS percentile curves(1). Additionally, we investigated differences in score trajectories between patients with preoperative KL scores ≤2 to ≥3, and presence (versus absence) of comorbidities.

Results: The study population consisted of 853 knee OA patients, of whom 62% were women. The mean (SD) age was 59 (5) years, mean BMI was 30 (5) kg/m2). Overall, 74% of the population had moderate to severe radiographic OA, a minority had no (4%), doubtful (6%) or minimal but definte (17%) radiographic OA. Comorbidities were present in 75% of patients. We observed poor KOOS scores across all subscales, which improved greatly postoperatively, with stabilization of scores after 12 months (table 1). Preoperatively, median KOOS scores of all subscales were at or below the 2.5th percentile. Scores increased to approximately the 25th percentile 12 months postoperatively. Greater improvements were observed in the subscale pain, and less improvements in the subscales sport and recreational function, and quality of life (figure 1). Patients with higher preoperative KL scores and without comorbidities showed greater improvements in KOOS scores (figure 2).

Conclusion: We applied KOOS data of knee OA patients undergoing TKA on the KOOS percentile curves, showcasing multiple ways these curves may be used in research and clinical care. In comparison to the general population, we observed poor preoperative KOOS scores, with large interpatient variation. Although major improvements were observed postoperatively, median population scores did not normalize to scores of the general population. The percentile curves may aid patient-clinician communication, improve management of treatment expectations and support shared-decision making.

Relation of Quantitative Sensory Testing Measures of Ascending Facilitation and Descending Modulation to Risk of Developing Knee Pain or Knee Pain Worsening Over Two Years

Background/Purpose: Whether altered nociceptive signaling, such as pain sensitization and abnormal descending pain modulation, impact the risk of developing knee pain, more pain severity, and/or change in pain patterns from intermittent to more persistent pain over time is not clear. We used quantitative sensory testing (QST) to evaluate the relation of pain mechanisms to development and change in pain over 2 years.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of people with or at risk of knee OA. The current analysis focusing on the 12th-year visit as the baseline for this analysis as this was the first visit at which descending pain modulation was assessed. All participants had pain questionnaires, knee radiographs, and QST at this baseline visit, and were assessed for pain outcomes every 8 months x3. QST comprised temporal summation (TS), pressure pain threshold (PPT), both of assess ascending pain facilitation, and conditioned pain modulation (CPM), a measure of descending pain modulation. TS was assessed with a set of weighted mechanical punctate probes. Degree of TS was defined as the difference in pain rating from the end of the train of 10 stimuli vs. the baseline. PPT at the wrist and patellae was assessed with an algometer as the point at which pressure first changed to slight pain. CPM was assessed using PPT at the wrist as the test stimulus pre- and post-conditioning stimulus (forearm ischemia); CPM was computed as the post-PPT: pre-PPT ratio. We evaluated the relation of each QST measure to the risk of development of: frequent knee pain (FKP) among those free of FKP at baseline, development of more frequent intermittent knee pain (indicated as at least “often”) or constant pain among those with no constant pain or only infrequent intermittent pain (occurring no more than “sometimes” based on the ICOAP) at baseline, and WOMAC worsening of ≥2/20 (MCID) over 2 years. We used logistic regression with GEE, adjusting for age, sex, BMI, race, catastrophizing, and depressive symptoms.

Results: 2794 participants were included (mean age 64, mean BMI 29.5, 57% female). More pain sensitization assessed by TS was associated with increased risk of developing more intermittent or constant pain over two years (**Table**). More pain sensitization by PPT at the patella and wrist were associated with higher risk of developing more intermittent or constant pain, and with WOMAC pain worsening. Lower PPT at the patella was additionally associated with higher risk of developing FKP. In contrast, inefficient CPM was not associated with development of any of these pain outcomes over two years.

Conclusion: Pain sensitization measures that reflect ascending pain facilitation were associated with increased risk of developing more frequent and/or more severe knee pain. In contrast, descending pain modulation did not appear to play a role in changing pain frequency or severity over time. These findings provide insights into the role of neurobiological pain mechanisms in the transition from acute to chronic pain in knee OA.

Pain Rating Variability and Response to Treatment in Osteoarthritis Clinical Trials

Camila Pinto[1], Joana Barroso[2] and Thomas Schnitzer[3], [1]Department of Physiology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Department of Physiology, Northwestern University, Feinberg School of Medicine, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis II: Clinical Aspects
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Despite the known high inter- and intra-patient variability in analgesic responses in chronic pain, most interventional pain studies rely on single time point pain reports and do not take in consideration the dynamic effects of daily pain on the response to treatment. In this study we examined the between- and within-subject variability in pain ratings and their value as a predictor of treatment response.

Methods: Three hundred and eighty-nine osteoarthritis patients (OA) enrolled as part of a clinical trial (NCT00809783) were randomized in two groups: Naproxen 500 mg twice a day (NAP; n=113) and Placebo (PBO; n=276). All participants were to complete daily pain intensity diaries using a numeric rating scale (NRS; 0 to 10 points) for a period of 127 days (15 days before + 112 days during treatment). A logistic regression analysis of responders (30% pain improvement) and a linear longitudinal model were performed to determine whether the pre-treatment pain variation (standard deviation of pain, SD) was associated with treatment response and decreases in pain intensity.

Results: Longitudinal pain decrease was observed over time (NRS SD) with both treatments ($p< 0.001$); pain variability (PV) within subjects was stable over time (Pearson's R, pre/post treatment SD: PBO $r= 0.37$, $p< 0.00$; NAP=0.21 $p=0.03$). Pre-treatment pain variability significantly predicted response after 4, 8, 12 and 16 weeks (Table 1, $p< 0.05$). Next, we investigated the treatment effects subclassifying treatment groups based on their pain variability. The high

Predictor	Estimate	Std. Err.	Odds Ratio	P>|z|
at 4 weeks				
pain variability	0.710	0.214	2.034	0.001
at 8 weeks				
pain variability	0.833	0.228	2.301	0.000
at 12 weeks				
pain variability	0.548	0.235	1.730	0.019
at 16 weeks				
pain variability	0.492	0.249	1.635	0.049
* The following regression model: logit (responder -30 % pain decrease: 0,1) log(pain variability index [standard deviation before baseline]). OR odds ratio				

Table 1. Results of logistic regression analysis of clinical pain responders*

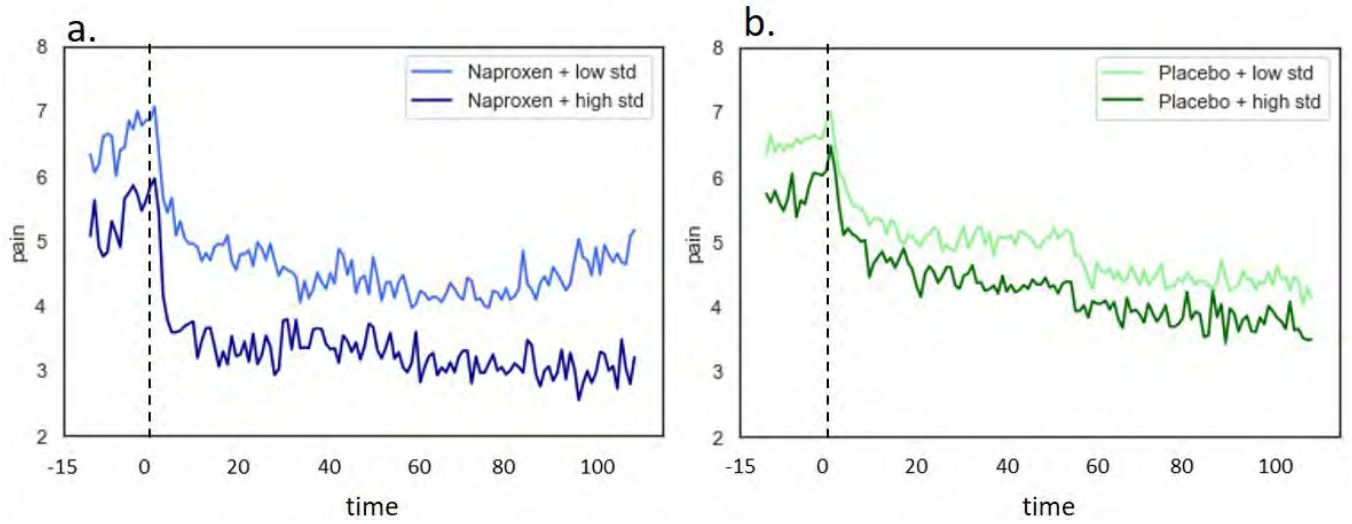

Figure 1. Longitudinal daily pain decreases over time. a. There is significant difference in pain decrease over time between high and low Naproxen groups (p<0.001). b. There is a significant decrease of pain over time, but not significant difference between high and low Placebo groups (p=0.09).

variability NAP subgroup presented significantly larger improvement in pain than the low variability subgroup (p< 0.001), and a similar trend was observed for the placebo group (p=0.09) (Figure 1).

Conclusion: Pain variability in patients with OA seems to be stable over time and independent of mean pain reduction. Pre-treatment higher pain variability associates both with categorical response to treatment (30% recovery), and linear pain reduction, thus constituting a marker of treatment response and a possible important effect to control for in OA clinical trials.Table 1. Results of logistic regression analysis of clinical pain responders*

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis II: Clinical Aspects
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: To test the hypothesis that an altered gut microbiota (dysbiosis) plays a causal role in the obese OA phenotype (obesity with both hand and knee OA).

Methods: Stool and blood samples were collected from 92 participants with BMI ≥ 30 and age ≥ 55 yrs recruited from the Johnston County Osteoarthritis Project. OA cases (n=50) had clinical and/or radiographic hand OA, defined as

Table 1.

Participant Characteristic	Cases (N=50)	Controls (N=42)	p-value
Age, years	73.7 (6.9)	70.8 (6.4)	0.04
Female, N (%)	43 (86%)	26 (62%)	0.01
African American, N (%)	17 (34%)	18 (43%)	0.39
BMI, kg/m^2	36.3 (4.4)	33.4 (3.1)	0.001
WOMAC Pain Score, left knee	5.2 (5.1)	2.2 (3.7)	0.002
WOMAC Pain Score, right knee	5.3 (4.9)	1.8 (3.3)	0.0001
Maximum KL Grade			
0	0	1 (2.4%)	
1	0	32 (76.2%)	
2	2 (4.0%)	9 (21.4%)	
3	13 (26.0%)	0	
4	21 (42.0%)	0	
Total knee replacement	14 (28.0%)	0	

BMI, body mass index

WOMAC, Western Ontario and McMaster Universities Arthritis Index (range 0-20)

involvement of at least 3 joints across both hands, and had Kellgren-Lawrence (KL) grade 2-4 knee OA (or TKR) in at least one knee on preliminary reading. Controls (N=42) had no hand OA and KL grade 0-1 knees. Exclusions included consumption of antibiotics/probiotics or intestinal surgery within the past 6 weeks, known bowel disease or prior fecal microbiota transplantation. Compositional analysis of the gut microbiome was carried out by 16S rRNA bacterial amplicon sequencing. Data was analyzed using QIIME 1.9.0. Shannon index, Chao1, and Phylogenetic Diversity (PD) were estimated from sequencing data. Beta diversity estimates were calculated using weighted and unweighted Unifrac approaches. Permutation Multivariate Analysis of Variance (PERMANOVA) and Analysis of Similarities (ANOSIM) were used to test the null hypothesis that case and control microbial communities share the same distribution. The Wilcoxon tests adjusted for multiple comparisons were used to determine differences in relative genera abundances between case and control groupsl. Blood samples were used for a multiplex cytokine analysis (n=73) and measures of LPS and LPS binding protein (n=78). To test for causality, pooled fecal transplant from 5 cases and 5 controls were gavaged every 4 weeks to 31 germ-free mice (n=16 cases; n=15 controls). Mice were on a Western Diet (40% fat, high sucrose) for 40 weeks. Fecal samples were collected 2 weeks after each gavage. Knee OA was evaluated histologically (grading of cartilage damage, osteophytes and synovitis) at week 40.

Results: OA cases were slightly older with more females, higher BMI, greater WOMAC pain and KL grades (Table 1). Nine participants recruited as controls had KL grade 2 in one knee after final readings by the study radiologist. A sensitivity analysis was performed assigning these participants to the case group and this did not change any of the results. There were no significant differences in diversity between cases and controls. Likewise, there were no significant compositional differences between groups at the genus level. Cases had higher levels of osteopontin (a pro-inflammatory cytokine originally isolated from bone) and LPS (a sign of a leaky gut) (Fig 1).

Mice transplanted with case or control microbiota gained similar weight but exhibited a significant difference in microbial diversity (p=0.02, Fig.2). Both groups developed histologic findings of OA without any differences in OA severity between the groups.

Conclusion: The lack of differences in the gut microbiota yet increased serum LPS levels in obese humans with hand and knee OA suggest that a leaky gut allowing for greater absorption of LPS (and potentially other bacterial products), rather than a dysbiotic microbiota, may contribute to development of OA. This was supported by the failure to promote more severe OA in mice by microbial transplant from humans with OA.

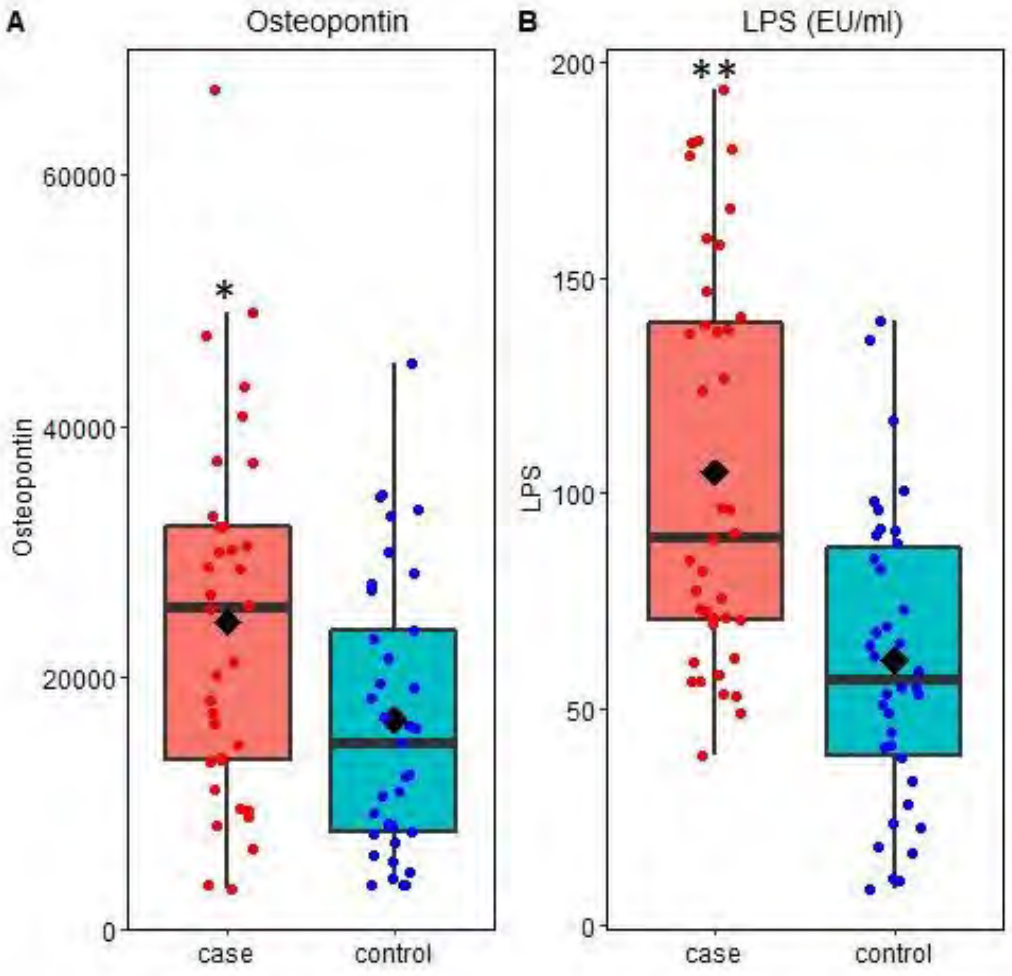

Fig.1 Osteopontin (A) and LPS (B) levels in OA cases and controls. Osteopontin measured in plasma shown as RFU values. LPS measured in serum shown as EU/ml. *p=0.01, **p<0.0001

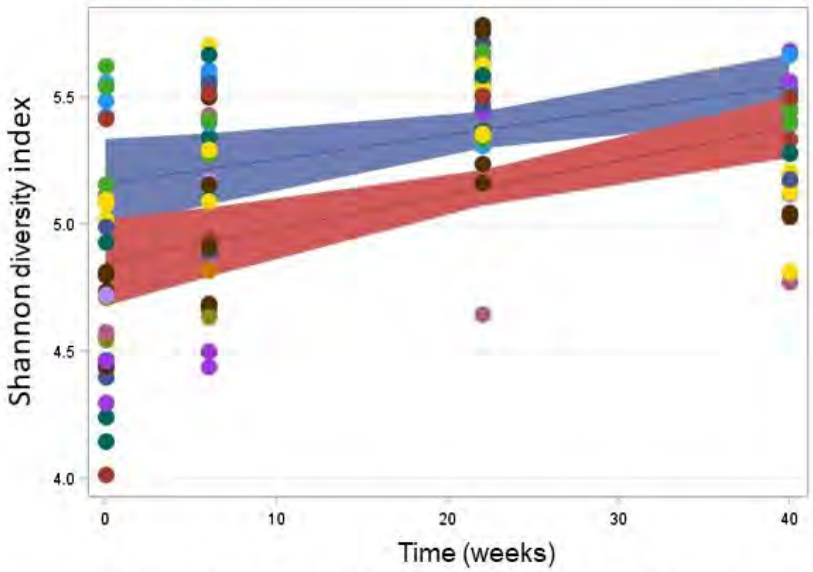

Fig.2 Longitudinal change in Shannon (alpha) diversity index over time in mouse fecal microbiota after pooled fecal transplants from human OA cases and controls. Colored dots indicate mice from the same cage. p=0.02 for difference between case and control over time.

Session Title: Pediatric Rheumatology – Clinical I: Treatment of JIA

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: There is uncertainty regarding when to start biologic medications for polyarticular juvenile idiopathic arthritis (P-JIA). The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed consensus treatment plans (CTPs) that reflect the most commonly used strategies for starting biologic treatment in untreated

P-JIA patients. The CARRA STOP-JIA study compared the effectiveness of the CARRA CTPs in achieving clinical inactive disease (CID) using a prospective, observational study design.

Methods: STOP-JIA compared 3 CARRA CTPs: 1) Step Up – starting non-biologic disease modifying anti-rheumatic drug (DMARD) monotherapy, adding biologic medication if needed after ≥ 3 months; 2) Early Combination - DMARD and biologic medication started together; and 3) Biologic First – starting biologic monotherapy, adding DMARD if needed after ≥ 3 months. There was no randomization. Data were collected approximately every 3 months using the CARRA Registry. The primary outcome was the proportion of children achieving CID off glucocorticoids (GC) at 12 months. The primary analysis was intention-to-treat. Propensity score (PS) weighting was used to balance baseline differences in potential confounders between CTPs. Multiple imputation was used to address missing data. Secondary outcomes included comparison of clinical Juvenile Arthritis Disease Activity Score based on 10 joints (cJADAS10) scores, patient-reported outcomes (PROs) and serious adverse events (SAEs).

Results: 400 participants were enrolled across 56 Registry sites. 64% chose Step Up, 25% Early Combination, and 11% Biologic First. There were significant baseline differences between CTP groups for several variables, including JIA categories, number of active joints, Physician Global Assessment of Disease Activity, and Juvenile Arthritis Dis-

Table 1. Baseline Patient Characteristics

Early Combination vs Step Up	9.5 (-4.1, 23.2) p=0.17	**16 (1.8, 30.2) p=0.02**
Biologic First vs Early Combination	-13.7 (-35.7, 8.2) p=0.22	-11.7 (-36.7, 13.3) p=0.43

*Clinical Juvenile Disease Activity Score based on 10 Joints (cJADAS10). Defined as score ≤ 2.5.

ease Activity Score (cJADAS10) scores (Table 1). Proportion of patients achieving CID at 12 months was 32% for Step Up, 37% Early Combination, and 24% Biologic First, with no statistically significant difference between groups. The differences remained not significant after PS weighting and multiple imputation (Table 2). Comparison of cJADAS10 levels of remission (≤ 2.5) at 12 months significantly favored Early Combination over Step Up after PS weighting and multiple imputation (66.6% versus 42.4%; p=0.02). There were no significant differences in either pain interference or mobility (PROMIS®) measures between CTPs over time, although both measures showed improvement over time (Figure 1). Seventeen SAEs were reported, most commonly infections.

Conclusion: Although there were no significant differences between CARRA P-JIA CTP groups in the primary endpoint of CID off GC, all CTP groups had improved disease activity during the study, and cJADAS10 scores showed significant differences. Planned secondary analyses, including subgroup analyses, timing of medication initiation/discontinuation, and reclassifying groups by CTP actually used, are underway and will generate additional information about the comparative effectiveness of the CTP approaches.

Distinct Patient-level Patterns of Response to Methotrexate in Juvenile Idiopathic Arthritis

Stephanie Shoop-Worrall[1], Kimme Hyrich[2], Lucy Wedderburn[3], Wendy Thomson[4] and Nophar Geifman[5], [1]Centre for Health Informatics, Centre for Epidemiology Versus Arthritis, The University of Manchester, Manchester, United Kingdom, [2]Centre for Epidemiology Versus Arthritis, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [3]UCL, UCLH, GOS Institute of Child Health, London, United Kingdom, [4]Centre for Genetics and Genomics Versus Arthritis, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [5]Centre for Health Informatics, The University of Manchester, Manchester

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical I: Treatment of JIA
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Treatment response in JIA is often viewed as a binary outcome: response or non-response, usually assessed using composite, multidimensional measures, such as the juvenile arthritis disease activity score (JADAS). Within a composite outcome, there are likely different, identifiable patterns of response that cluster within subgroups of children and young people (CYP). Identifying these subgroups could assist the tailoring of stratified treatment approaches in JIA and offer further insights into understanding treatment response.

This study aimed to identify subgroups of CYP defined by different trajectories of individual JADAS components in the first year following initiation of methotrexate (MTX).

Methods: The discovery cohort for subgroup identification included MTX-naïve CYP with JIA at the point of MTX initiation, enrolled prior to January 2018 to either the BSPAR Etanercept Cohort Study (BSPAR-ETN) or the Biologics for Children with Rheumatic Diseases Study (BCRD), nationwide pharmacological registers. The Childhood Arthritis Prospective Study (CAPS), a multicentre JIA inception cohort, was used for verification. JADAS components (active joint count, physician's global assessment (PGA, 0-10cm), parental global evaluation (PGE, 0-10cm) and standardised ESR (0-10) were calculated based on data collected in the year following MTX initiation and log1p transformed for analysis.

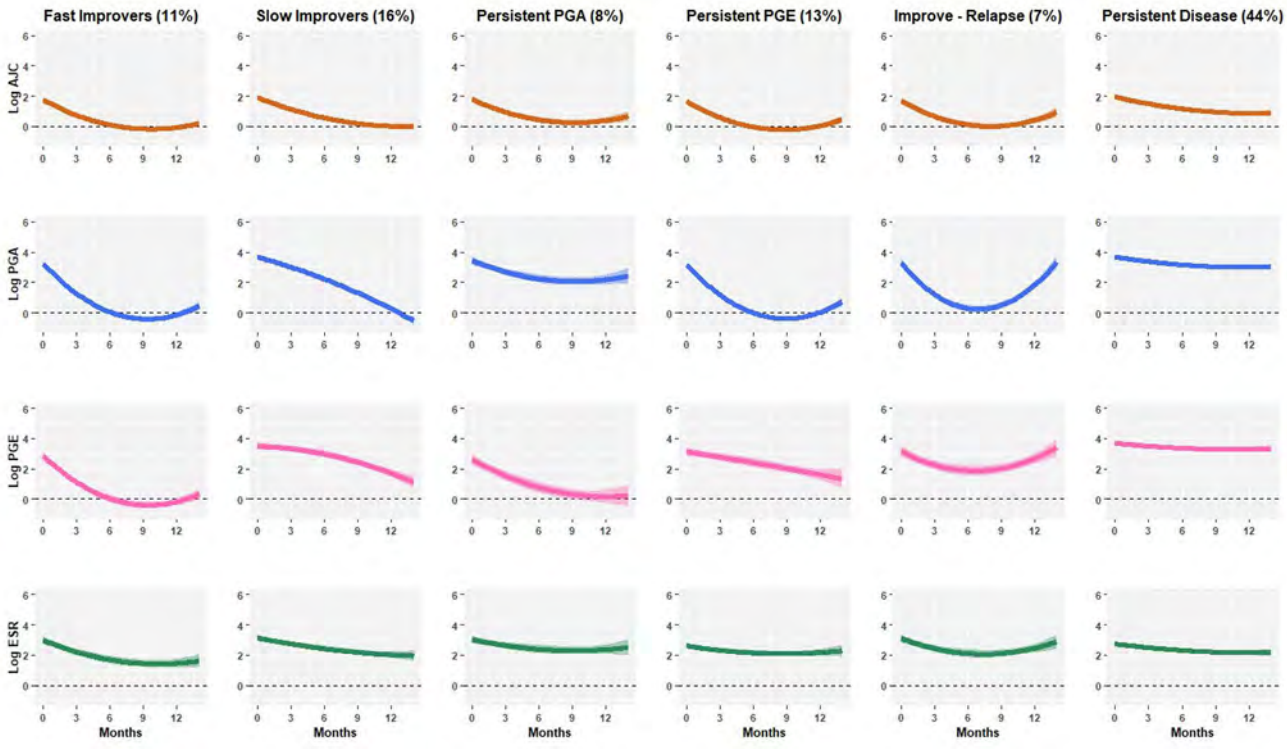

Figure 1. Clusters of MTX response identified in children and young people with JIA enrolled to the BSPAR-ETN or BCRD studies

Multivariate group-based trajectory models were used to explore MTX response clusters. Optimal models were selected based on a combination of model fit (BIC, relative entropy, average posterior probabilities), parsimony and clinical plausibility. Model development and selection were repeated independently in the verification cohort.

Results: The discovery cohort included 658 CYP, and in the verification cohort n=537. The majority were female (68%, 70%) and of white ethnicity (86%, 82%), with RF-negative JIA (35%, 33%), respectively.

Six disease trajectories following MTX were identified in the discovery cohort: Two groups improved across all JADAS components: Fast improvers (11%) and Slow Improvers (16%). A large group maintained persistent disease overall (44%). Two groups maintained one persistent disease feature despite otherwise improvement: Persistent PGA (8%) and Persistent PGE (13%). A final group experienced disease relapse (7%) (Figure 1). These results were verified in the CAPS cohort, with similar subgroups and group proportions identified, except for the relapse group, which was not evident in the CAPS cohort.

Conclusion: We identify six clusters of CYP following initiation of MTX, each with differing patterns of disease activity, suggesting a simple responder/non-responder analysis at a set point may be over-simplistic. Common patterns were identified across multiple, large, UK cohorts. Understanding both clinical factors associated with, and biological mechanisms underpinning, these subgroups would aid stratified treatment decisions in JIA.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical I: Treatment of JIA
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) patients may experience significant medication-related adverse effects (AEs), which may adversely affect health-related quality of life (HRQOL), daily activities and treatment compliance. The study aims to investigate Patient-Reported Adverse Events (AEs) and their effects on HRQoL, school activity and therapeutic adherence, as captured by patient- and parent-reported outcome measures (PROMs).

Methods: Data on 13704 visits of 8402 patients were obtained from two large multi-center international studies, the pharmacovigilance registry Pharmachild and The EPidemiology, treatment and Outcome of Childhood Arthritis (EPOCA) cohort. Subjects who were on medications at the time of visit were included. PROMs were collected through the Juvenile Arthritis Multidimensional Assessment Report (JAMAR) and included checklists of AEs (18

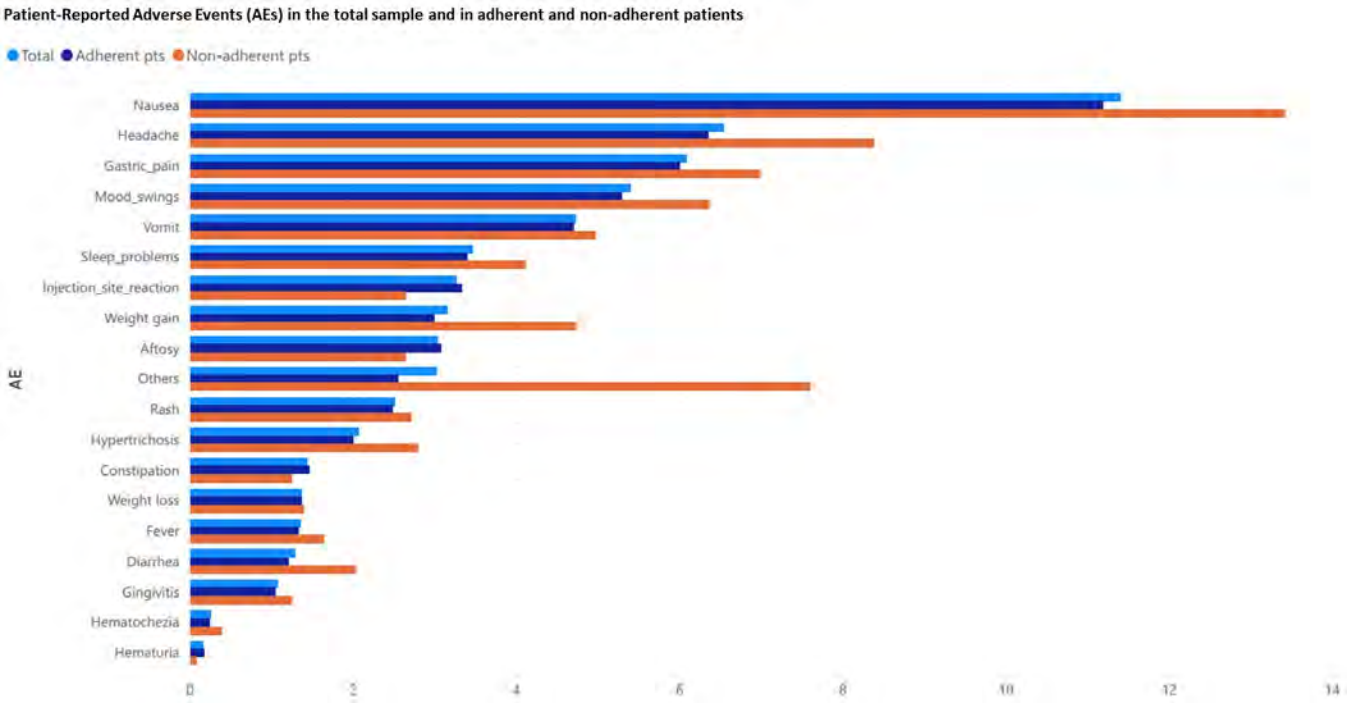

Figure 1. Frequencies (percentages) of Patient-Reported Adverse Events (AEs) in the total sample (light blue), adherent (dark blue) and non-adherent patients (orange).

items), disease-related school problems (5 items), self-reported treatment adherence (as a dichotomous variable) and reasons for non-compliance (5 items). Pain and overall well-being (PGA) were measured by 21-numbered circle visual analog scales. HRQoL was assessed through a ten-items Likert-type HRQoL scale encompassing a physical health (PhH) and psychosocial health (PsH) subscale, with higher scores indicating worse outcomes. The effects of

Figure 2. Results from linear mixed-effects regression models show the effects of the most commonly reported AEs (frequency > 3%) on Patient Global Assessment (PGA) and Psychosocial Health subscale score (PsH). The model for PGA is adjusted for pain levels and physician global assessment; the model for PsH is adjusted for physical health quality of life as measured by Physical Health subscale score (PhH).

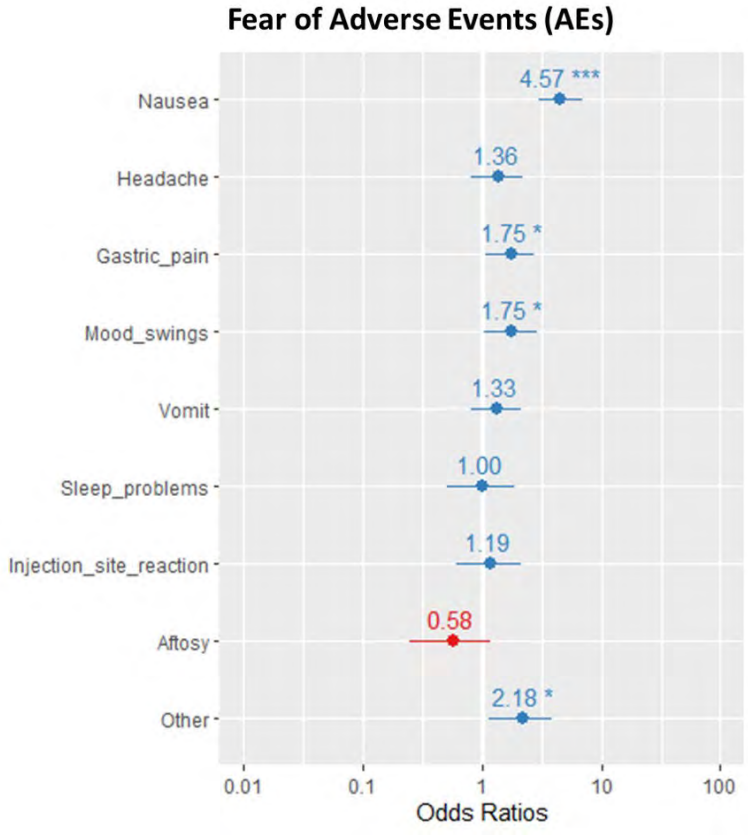

Figure 3. Risk (expressed as odds ratios) of self-reported non-adherence due to fear of Adverse Events (AEs) for individual AEs. * $p \leq 0.05$, *** $p \leq 0.001$

AEs on PGA, PsH scale, school problems, and self-reported non-adherence were analyzed using General Linear and Generalized Mixed Effects Models with random intercepts per individual.

Results: AEs were reported by 29,49% of patients. Frequencies of individual AEs are shown in Fig.1. Experiencing one or more AEs was associated to worse PGA (OR 1,46 95%CI 1.38-1.45, η^2 0.011, $p < .001$) and PsH score (OR 1.85, 95%CI 1.72-2.00, η^2 0.024, $p < .001$) and school problems (OR 1.82, 95%CI 1.64-2.01, $p < .001$) after adjustment for physician global assessment, PhH and pain levels. The effects of individual AEs on outcomes are reported in Fig. 2; mood swings, sleep problems and weight gain showed the highest impact on psychosocial health. Treatment non-adherence was reported by 9,27% of subjects; the most frequently cited reasons were drug refusal by the child (15,4%) and fear of adverse events (10,9%). Subjects reporting more than two AEs had a higher risk of non-adherence (OR 1.47, 95%CI 1.21 - 1.76, $p < .001$). Nausea was associated with non-compliance specifically due to fear of AEs, as shown in Fig. 3 (OR 4.57, 95%CI 2.98-6.92, $p < .001$).

Conclusion: AEs have a substantial impact on patients' quality of life, functioning and treatment adherence in JIA. The understanding treatment-related burden is vital to achieve good therapeutic compliance and improve outcomes in JIA.

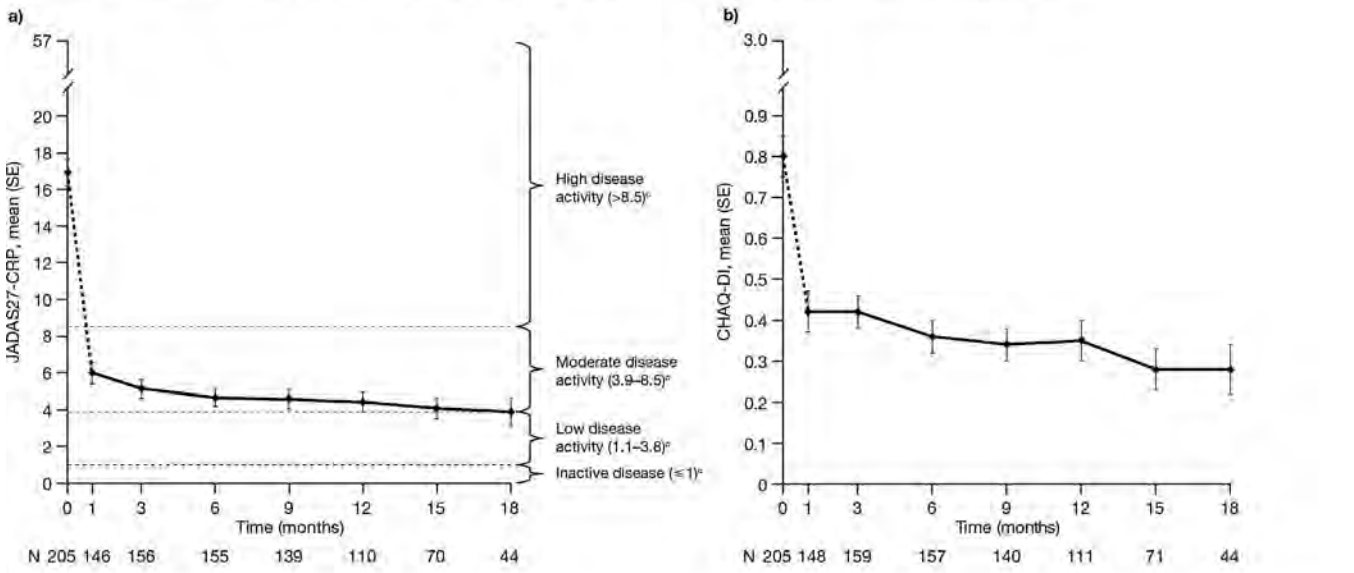
Session Title: Pediatric Rheumatology – Clinical I: Treatment of JIA

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Figure 1. Observed efficacy of tofacitinib[a] in pts with JIA through M18: a) mean JADAS27-CRP[b] and b) mean CHAQ-DI[b]



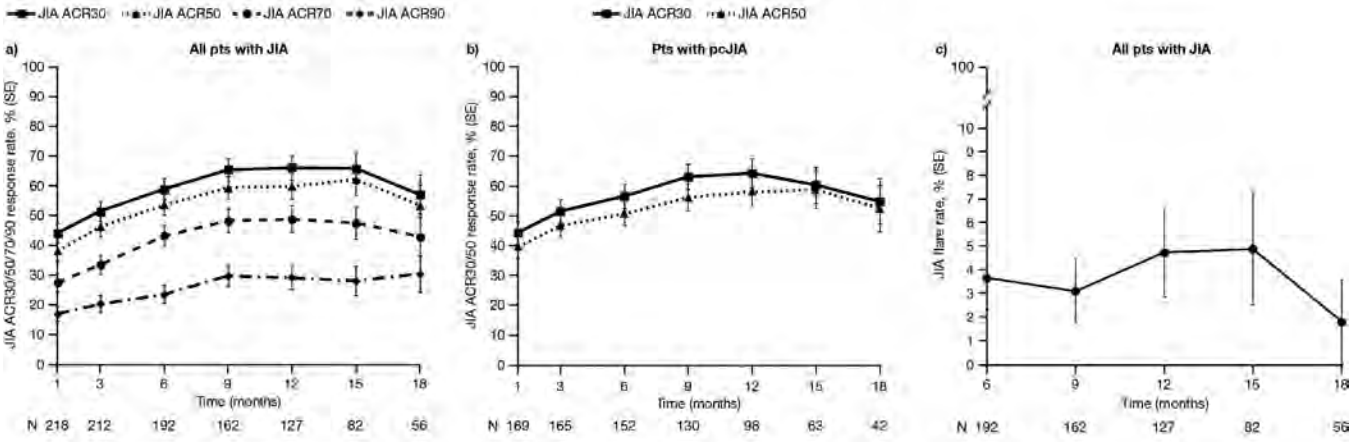
Missing values were not imputed

[a]Tofacitinib 5 mg BID or equivalent weight-based lower dose in pts <40 kg; [b]The dotted line represents the time between baseline (M0) and M1, as baseline values were those of the qualifying index study except for pts who enrolled more than 14 days after the end of study visit of the qualifying index study, whose baseline values were those of the LTE study; [c]Disease activity cut-offs shown in Figure 1a are for pts with >4 active joints ie all pts with pcJIA and some pts with PsA/ERA. In pts with PsA/ERA with ≤4 active joints, disease activity cut-offs are as follows: inactive disease ≤1; low disease activity, 1.1–2; moderate disease activity, 2.1–4.2; high disease activity >4.2 (Consolaro A et al. Pediatr Rheumatol Online J 2016; 14: 23)

BID, twice daily; CHAQ-DI, Childhood Health Assessment Questionnaire-Disability Index; ERA, enthesitis-related arthritis; JADAS27-CRP, Juvenile Arthritis Disease Activity Score in 27 joints, C-reactive protein; JIA, juvenile idiopathic arthritis; LTE, long-term extension; M, month; N, number of pts evaluated at each time point; pcJIA, polyarticular course JIA; PsA, psoriatic arthritis; pts, patients; SE, standard error

Figure 1

Figure 2. a) JIA ACR30/50/70/90 response rates[a] through M18 in all pts with JIA, b) JIA ACR30/50 response rates[a] in pts with pcJIA, and c) JIA flare rate[b] in all pts with JIA



Missing values were not imputed

[a]JIA ACR30/50/70/90 response criteria are defined as: 3 out of 6 JIA core set variables improving by ≥30/50/70/90%, respectively, with ≤1 variable worsening by ≥30%.[2] In pts with systemic JIA, the absence of fever due to systemic JIA in the preceding seven days is also required. Baseline values for determining JIA ACR30/50/70/90 response rates were those of the qualifying index study, except for pts who enrolled more than 14 days after the end of study visit of the qualifying index study, whose baseline values were those of the LTE study. As such, M1 was the first time point at which it was possible to calculate the JIA ACR30/50/70/90 response rates for all pts with available data; [b]Flare is defined as a worsening of ≥30% in ≥3 out of 6 JIA core set variables, with ≤1 variable improving by ≥30%.[3] Baseline values for determining JIA flare rate were those of the M3 visit of the LTE study. As such, M6 was the first time point at which it was possible to calculate the JIA flare rate

ACR, American College of Rheumatology; JIA, juvenile idiopathic arthritis; LTE, long-term extension; M, month; N, number of pts evaluated at each time point; pcJIA, polyarticular course JIA; pts, patients; SE, standard error

Figure 2

Background/Purpose: Tofacitinib is an oral JAK inhibitor that is being investigated for JIA. We report the safety, tolerability, and efficacy of tofacitinib in patients (pts) with JIA in an open-label, long-term extension study with up to 66 months of observation.

Methods: We performed an interim analysis of this ongoing study (NCT01500551; data cut-off: June 4, 2019; database not locked and subject to change). Eligible pts aged 2–≤ 18 years with polyarticular course (pc)JIA, juvenile (j)PsA, or ERA were enrolled after completing a Phase (P)1 (NCT01513902) or P3 (NCT02592434) tofacitinib index study, or after discontinuing from the index studies for reasons other than treatment-related serious adverse events (SAEs). Pts received open-label tofacitinib 5 mg BID or an equivalent weight-based lower dose. Safety endpoints, reported up to Month (M)66 for the overall cohort, were AEs (including AEs of special interest and laboratory test abnormalities) and active uveitis. Efficacy endpoints, reported through M18 for the overall cohort, included mean JADAS27-CRP, JADAS27-CRP minimal disease activity (scores ≤ 3.8 and ≤ 2 in pts with > 4 and ≤ 4 active joints, respectively[1]) rate, mean CHAQ-DI, JIA ACR30/50/70/90 response[2] rates, JIA ACR30/50 response rates for pts with pcJIA, JIA ACR clinical remission (ie inactive disease for 6 months continuously), and JIA flare[3] rate.

Results: 223 pts with pcJIA (n=172), jPsA (n=19), or ERA (n=21) were enrolled and received open-label tofacitinib (total follow-up 265.8 pt-years). Most pts were female (74.9%) and mean (range) age was 12.3 (3–18) years. Mean (median; range) tofacitinib exposure was 402.4 (347.0; 20.0–1,983.0) days. Over 66 months, 160 (71.7%) pts had AEs; 15 (6.7%) pts had SAEs; 13 (5.8%) pts discontinued due to AEs (Table). The most common AEs by MedDRA preferred term were upper respiratory tract infection (16.1% of pts), JIA exacerbation (8.5% of pts), and nasopharyngitis (8.5% of pts). Five (2.2%) pts had serious infections. Two (0.9%) pts had herpes zoster: one case was non-serious; the other case was serious and adjudicated as opportunistic. Laboratory test abnormality rates were ≤ 2.7% (Table).

Table. Summary of treatment-emergent AEs, AEs of special interest, and laboratory test abnormalities

	Tofacitinib[a] (N=223)
Pts with events, n (%)	
AEs	160 (71.7)
SAEs	15 (6.7)
Permanent discontinuations due to AEs	13 (5.8)
Dose reductions or temporary discontinuations due to AEs	43 (19.3)
Most common AEs (≥5% occurrence, by MedDRA preferred term)	
Upper respiratory tract infection	36 (16.1)
JIA exacerbation	19 (8.5)
Nasopharyngitis	19 (8.5)
Arthralgia	16 (7.2)
Viral infection	14 (6.3)
Headache	14 (6.3)
Sinusitis	12 (5.4)
Vomiting	12 (5.4)
AEs of special interest	
Death	0
Gastrointestinal perforation	0
Hepatic event	0
HZ (non-serious and serious)[b]	2 (0.9)
Interstitial lung disease	0
Major adverse cardiovascular event	0
Malignancy (including non-melanoma skin cancer)	0
Macrophage activation syndrome[c]	0
Opportunistic infections (excluding tuberculosis)[d]	1 (0.4)
Serious infection	5 (2.2)
Thrombotic event[e]	0
Tuberculosis	0
Pts with laboratory test abnormalities, n (%)[f]	
Hemoglobin	
<0.8× LLN	4 (1.8)
Lymphocytes	
<0.8× LLN	6 (2.7)
>1.2× ULN	1 (0.5)
Aspartate aminotransferase	
>3.0× ULN	0
Alanine aminotransferase	
>3.0× ULN	1 (0.5)
Cholesterol	
>1.3× ULN	0

Safety events were assessed from baseline through the data cut-off date
[a]Tofacitinib 5 mg BID or equivalent weight-based lower dose in pts <40 kg; [b]One serious case, one non-serious case; [c]Applicable to pts with systemic JIA without active systemic features only (N=11); [d]The serious HZ case was an opportunistic infection; [e]Includes deep vein thrombosis, pulmonary embolism, and arterial thromboembolism; [f]220 pts were evaluated for laboratory abnormalities, except cholesterol which was evaluated in 204 pts
AE, adverse event; BID, twice daily; HZ, herper zoster; JIA, juvenile idiopathic arthritis; LLN, lower limit of normal; MedDRA, Medical Dictionary for Regulatory Activities; N, number of pts evaluated; n, number of pts with event; pts, patients; SAE, serious AE; ULN, upper limit of normal

Table 1

One (0.4%) pt at M12 had active uveitis. Improvements in disease activity (JADAS27-CRP; Figure 1a) and physical functioning (CHAQ-DI; Figure 1b) were maintained through M18. In M1–18, JADAS27-CRP minimal disease activity rates were > 50%. JIA ACR30/50 response rates overall, and in pts with pcJIA, increased from M1 and were > 50%

from M6–18 (Figure 2a/b). JIA ACR70/90 response rates overall increased from M1 and were > 40% and > 20%, respectively, from M6–18 (Figure 2a). None of the 223 pts achieved JIA ACR clinical remission by M18. JIA flare rate was < 5% through M18 (Figure 2c).

Conclusion: In this open-label, long-term extension study of tofacitinib in pts with JIA, no new safety findings were observed over 66 months. Clinical efficacy was maintained over 18 months.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical I: Treatment of JIA
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Rapid identification of HLH/MAS coupled with a multidisciplinary approach to management is essential to improve patient outcomes. We describe our experience with a newly instituted Evidence Based Guideline (EBG) for HLH/MAS at Boston Children's Hospital (BCH).

Methods: A diagnostic and therapeutic algorithm for HLH/MAS was developed at BCH based on literature review and expert opinion. This EBG was activated in 1/2018 with the goal to review quality metrics after implementation. An electronic medical record search algorithm (patients with an oncology and/or rheumatology note, fever ≥38.2°C, and ferritin ≥500 ng/mL) was developed to retrospectively identify all hospitalized patients in the EBG from 1/2018-4/2019. For comparison, patients with HLH/MAS treated at BCH before implementation of the EBG (3/2016-4/2018) were identified with the same search algorithm. The selected medical records were reviewed by an attending rheumatologist to confirm the HLH/MAS diagnosis and collect clinical data. Subjects with a previously known diagnosis of HLH/MAS before hospitalization were excluded.

Results: After initiation of the EBG, 12 girls and 15 boys with an average age of 8.8 years were identified by house staff as potential HLH/MAS patients and rheumatology was consulted for management. After rheumatology consult, 10 patients were diagnosed with HLH/MAS by the treating team. Of these, 6 met HLH 2004 criteria, and 9 met 2016 MAS classification criteria for systemic juvenile idiopathic arthritis (sJIA). In the comparison group, 20 patients were identified as having HLH/MAS prior to the start of the EBG (pre-EBG). Fifteen pre-EBG patients were diagnosed with HLH/MAS by the treating team during the hospital admission and 5 were identified during retrospective chart review by the study team. The 20 pre-EBG patients had an average age of 8.9 years (9 boys, 11 girls). Of these patients, 7 met HLH 2004 criteria and 18 met 2016 MAS classification criteria for sJIA.

The mean time to HLH/MAS diagnosis by the treating team was 8.4 days in the pre-EBG group at 2.8 days in the post-EBG group. The average hospital stay among pre-EBG patients was 34.0 days with a mean time to HLH/MAS directed treatment of 7.4 days. The same metrics in the post-EBG group were 29.9 days and 3.1 days, respectively. The most common first line treatments for both groups (pre-EBG, post-EBG) were IVIG (35.0%, 53.3%), Anakinra (30.0%, 20.0%), and glucocorticoids (15.0%, 20.0%). 30.0% of pre-EBG patients responded completely to first line treatment, compared to 40.0% post-EBG. The mortality rate during hospitalization was 25.0% in the pre-EBG group and 6.7% in the post-EBG group.

Conclusion: Implementation of an EBG for HLH/MAS was associated with superior outcomes in the post-EBG cohort compared to patients treated before the EBG was established. Notably, overall survival increased from 75.0% in the pre-EBG group to 93.3% in the post-EBG group. While improvements may be partially attributed to increased recognition and advances in treatment of HLH/MAS that have accumulated over time, this analysis also suggests that a multidisciplinary treatment pathway for HLH/MAS contributed to favorable outcomes.

COVID-19 in Pregnant Patients with Rheumatic Disease: Data from the COVID-19 Global Rheumatology Alliance

Bonnie Bermas[1], Megan Clowse[2], Milena Gianfrancesco[3], Jonathan Hausmann[4], Pedro M Machado[5], Emily Sirotich[6], Helen Robinson[7], Anja Strangfeld[8], Jinoos Yazdany[9] and Philip Robinson[10], [1]UTSouthwestern.edu, Dallas, TX, [2]Duke University, Chapel Hill, NC, [3]University of California, San Francisco, San Francisco, CA, [4]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Cambridge, MA, [5]University College London, London, United Kingdom, [6]McMaster University, Hamilton, ON, Canada, [7]University of Queensland School of Medicine, HERSTON, Queensland, Australia, [8]German Rheumatism Research Center, Berlin, Germany, [9]UCSF, San Francisco, CA, [10]University of Queensland, Herston, Queensland, Australia

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Rheumatic Disease Diagnosis	
Systemic Lupus Erythematosus	6 (55%)
Rheumatoid arthritis	2 (18%)
Anti-phospholipid Antibody Syndrome	2 (18%)
Axial Spondyloarthritis	1 (9%)
Other Inflammatory Arthritis	1 (9%)
Inflammatory Myopathy	1 (9%)
COVID-19 Treatments	
No treatment except supportive care	6 (55%)
Anti-malarials (e.g. hydroxychloroquine)	4 (36%)
Oseltamivir	1 (9%)
Azithromycin	1(9%)
Glucocorticoids 10 mg/day	2 (18%)
Rheumatic Disease Medications	
No therapy	2 (18%)
Anti-TNF	2 (18%)
Anti-Malarials Alone	5 (45%)
Azathioprine	1 (9%)
Sulfasalazine & antimalarial	1 (9%)
Rheum Disease Medication Stopped	5 (45%)
Antimalarial alone	1
Anti-TNF	2
Azathioprine	1
Sulfasalazine & antimalarial	1

Table. Details of diagnoses and treatments

Background/Purpose: The impact of COVID-19 on pregnancy in patients with rheumatic disease is unknown. We describe COVID-19 outcomes in pregnant rheumatic disease patients reported to an international rheumatic diseases COVID-19 registry between March and June 2020.

Methods: Pregnant patients reported to the COVID-19 Global Rheumatology Alliance physician registries, which includes the COVID-19 EULAR registry, were included. The registry includes cases of COVID-19 in people with rheumatic diseases entered between 24 March 2020 to 22 May 2020.

Results: Eleven cases of pregnant women were reported: eight were white, one black, one Latin American, and one of other ethnicity. The mean age was 33 years (+ 6.5), range 20-45. Diagnoses included systemic lupus erythematosus (n=6), rheumatoid arthritis (n=2), inflammatory arthritis (n=1), inflammatory myositis (n=1), and axial spondyloarthritis (n=1). Two patients had coexisting antiphospholipid syndrome. None were smokers. Most patients' rheumatic disease was either low or in remission based on physician global assessment (n=9), although 2 had moderate disease activity. Background rheumatic disease treatment is shown in the table. Five of the 11 patients stopped their anti-rheumatic treatments at the time of their infection. Seven patients had COVID-19 diagnosed by polymerase chain reaction testing, two by symptoms alone, two unknown, and one each by computed tomography scan and chest x-ray (multiple responses allowed). Five cases were reported to have close contact with a confirmed or probable case of COVID-19 infection, and one had a history of travel to an area with documented cases of COVID-19 infection. The other cases had unknown or community-acquired COVID-19. Symptoms of COVID-19 infection included cough (n=8), fever (n=7), shortness of breath (n=4), diarrhea, anosmia, and arthralgia (each n=3). Most patients (n=6) received only supportive treatment (table). Forty-five percent of patients were hospitalized; the maximum care received by hospitalized patients was supplemental oxygen (n=1). There were two COVID-19 complications, one co-infection with *C. difficile* and one pneumonia. None of the patients died. The outcome of pregnancies is not yet known.

Conclusion: We report on 11 pregnant women with diverse rheumatic diseases and medications who developed COVID-19 infection. Five patients were hospitalized but only one required supplemental oxygen. There were two co-infections and no deaths. In this small series, outcomes of COVID-19 infected pregnant patients with rheumatic disease were favorable.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Axial spondyloarthritis (axSpA) can affect women in their childbearing age. Data on pregnancy in axSpA patients are mainly retrospective and highly heterogeneous [1]. The aim of this analysis was to investigate pregnancy outcomes and health of live born children in women with axSpA in four prospective cohort studies.

Table 1: Maternal and disease characteristics

	EGR2 (FR)	RePreg (CH)	RevNatus (NO)	Rhekiss (DE)
No. of pregnancies	45	31	160	92
No. of patients	44	31	125	88
Age in years	32.0 ± 4.2	31.4 ± 4.0	30.5 ± 4.5	33.2 ± 4.4
Disease duration in years	6.0 ± 5.6	7.7 ± 4.6	3.2 ± 3.3	6.2 ± 5.3
HLA-B27 positive	26 (66.7)	23 (74.2)	79 (71.2)	54 (73.0)
Pre-gestational diabetes	0	0	1 (0.6)	1 (1.4)
Inflammatory bowel disease	0	0	4 (2.6)	5 (7.2)
Uveitis	0	0	3 (1.9)	3 (4.3)
BMI	26.5 ± 4.8	22.6 ± 2.5	24.4 ± 4.3	23.4 ± 4.3

Results are presented as mean ± SD or number (percentage)

Table 2: Pregnancy characteristics, obstetric and neonatal outcomes

	EGR2 (FR)	RePreg (CH)	RevNatus (NO)	Rhekiss (DE)
WGA at the first visit in pregnancy	11.9 ± 8.15	19.7 ± 9.4	12.9 ± 5.7	13.4 ± 5.4
Patients with 1 pregnancy	43 (95.5)	31 (100.0)	101 (80.8)	84 (95.5)

Congenital malformation	0	0	n.a.[#]	4 (5.1)

*Results are presented as mean ± SD or number (percentage). WGA: gestational age in weeks. *Data for twins are not shown. [#]Malformations can be retrieved by national birth registry with a lag time of 2 years. [$]Missing information for 7 infants.*

[1] Giovannopoulou E et al. Curr Rheumatol Rev. 2017;13(3):162-9.

Methods: Data of four European pregnancy registries that collect data prospectively and collaborate in the European Network of Pregnancy registries in Rheumatology (EuNeP) were compiled and compared according to a pre-defined study protocol: EGR2 (France), RePreg (Switzerland), RevNatus (Norway) and Rhekiss (Germany). Women with a diagnosis of axSpA enrolled in one of the registries and with a known pregnancy outcome reported until June, August and September 2019, respectively, were eligible for the analysis. Each registry analysed their data descriptively and provided the results to the coordinating centre.

Results: A total of 328 pregnancies in 288 women were investigated. Mean age of patients was comparable between registries ranging from 31 to 33 years. However, disease duration (3-8 years) and proportion of patients with a positive HLA-B27 (64-74%) varied (Table 1). The axSpA diagnosis was either classified by ASAS criteria (fulfilment in EGR2: 93%, RePreg: 65%, RevNatus: 86%) or by ASAS criteria for axial/ peripheral SpA (Rhekiss: 81/ 34%). Preeclampsia occurred in 0-4% and gestational diabetes in 6-9% of patients. Rates for preterm birth were ≤5%, and congenital malformations were reported in 4 out of 287 neonates (Table 2).

Conclusion: Differences in study design and classification criteria result in slightliy different patient populations in each registry. The outcome of pregnancies was favourable. Preterm birth rates are within rates reported by the WHO for the EU general population. However, a selection bias of rather planned and well-controlled pregnancies cannot be ruled out. This is the first collaborative analysis of four European pregnancy registries in rheumatology. Descriptive data were combined, and will be – in a next step – pooled together.

Funding: This work was supported by a research grant from FOREUM Foundation for Research in Rheumatology.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Several of the most commonly prescribed anti-rheumatic medications for women with rheumatic disease are known teratogens, posing a risk for pregnancy loss and birth defects if taken during pregnancy. Despite the importance of avoiding pregnancy while taking a teratogenic medication, within the U.S. an estimated 10-15% of pregnancies to women with rheumatic disease are conceived while the mother is using a teratogen. We

sought to understand the frequency of contraception documentation for women with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) in a large U.S. electronic-health-record (EHR) based registry, and to identify disparities by teratogen prescription and patient race and ethnicity.

Methods: RISE (Rheumatology Informatics System for Effectiveness) is a national EHR-enabled rheumatology registry that passively collects data on all patients seen by participating practices. As of 2018, RISE held validated data from 1,113 clinicians in 226 practices, representing an estimated 32% of the U.S. clinical rheumatology workforce. Women of childbearing age (18-45 years) in 2018 and at least 2 visits with ICD-9 or -10 diagnosis codes for SLE or RA (at any time) were assessed for anti-rheumatic medication prescriptions and contraception documentation within a structured data field. The proportion of patients with documented contraception was compared by teratogen prescription and patient age and race/ethnicity.

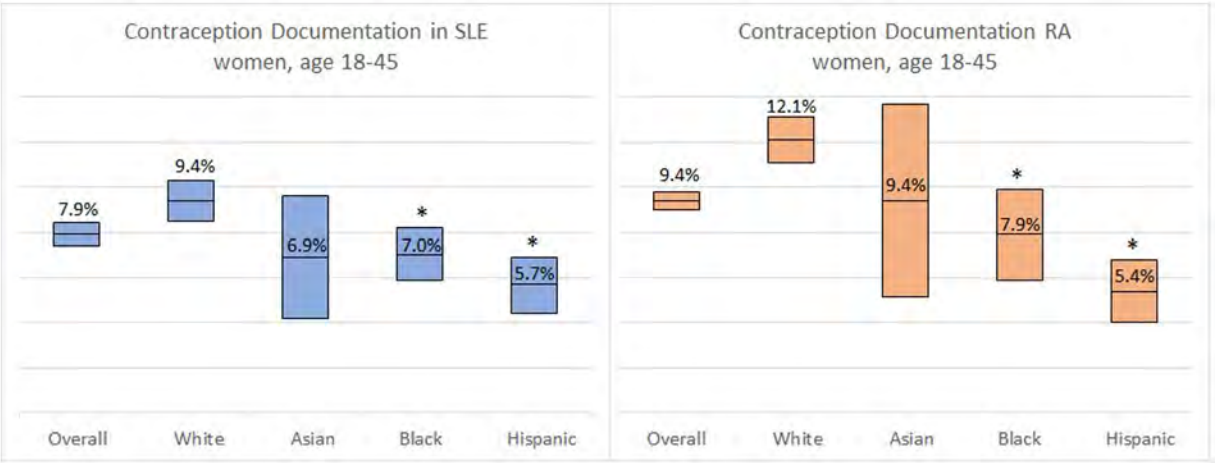
Results: In 2018, 110,359 women between the ages of 18-45 had at least 1 visit: 9,826 with SLE and 19,009 with RA. Overall, 8.9% had any contraception documented.

More women with RA than SLE had documentation of contraception (SLE 7.9%, RA 9.4%, p< 0.001). Among SLE patients, the rate of contraception documentation was similar whether or not the woman was prescribed a teratogenic anti-rheumatic medication. Among women with RA, however, contraception documentation was greater among women prescribed a teratogen than those prescribed only pregnancy-compatible medications (10.3% vs 9.1%, p=0.02).

The rate of contraception documentation was higher in white women (SLE 9.4%, RA 10.9% (see figure) compared to Hispanic women (SLE 5.7%, p=0< 0.001; RA 5.4%, p< 0.001) or black women (SLE 7.0, p< 0.001; RA 6.3, p< 0.001).

For women with SLE and RA, 1.5-1.7% of women used highly effective contraception (i.e., tubal ligation, intrauterine device, subdermal implant) and 5.0-5.6% had documentation of other forms of effective contraception (i.e., pill, patch, ring, or injection).

Conclusion: We found large gaps in contraception documentation within the RISE registry. While roughly 70% of women in the U.S. report using contraception, contraception was documented in < 10% of eligible women in RISE. While these data likely underestimate contraception use, they also highlight that many rheumatologists do not have a systematic approach to collecting and recording this information in the EHR. The racial disparities noted within this study require additional study, and may suggest that implicit bias plays a role in ascertaining and recording contraception use within the RISE Registry.



Contraception documentation among women with SLE and RA by race and ethnicity (mean noted, range is 95% CI; *p-value<0.001 compared to white women)

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

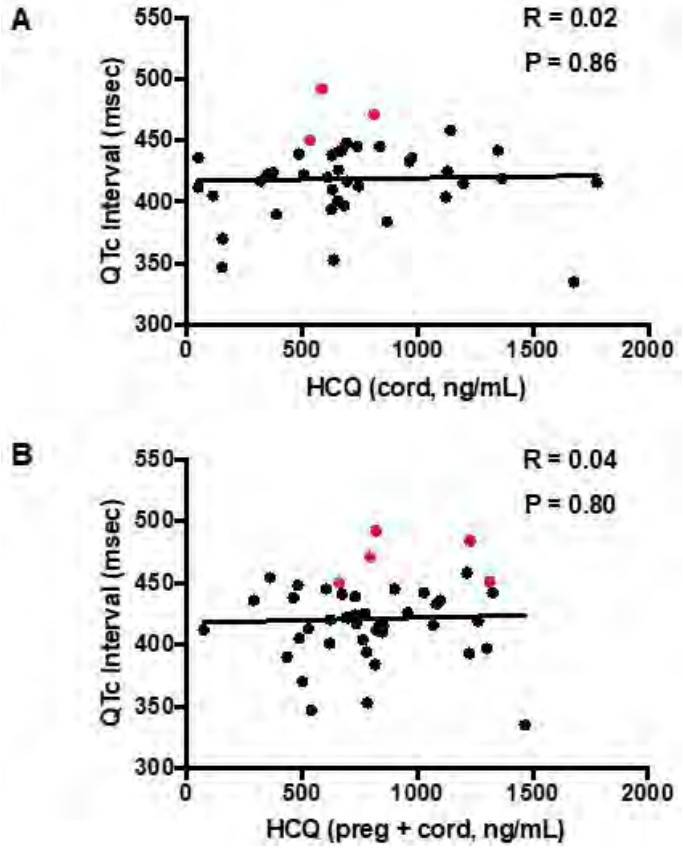

Figure 1. Correlation between blood HCQ levels and neonatal QTc. (Panel A) Cord HCQ is plotted against QTc. (Panel B) Overall mean HCQ levels (obtained by averaging all HCQ levels throughout an individual pregnancy and cord blood level) are plotted against QTc. Subjects with an abnormally prolonged QTc are designated with red bold circles. All QTc intervals were calculated using the Bazett formula (QTcB).

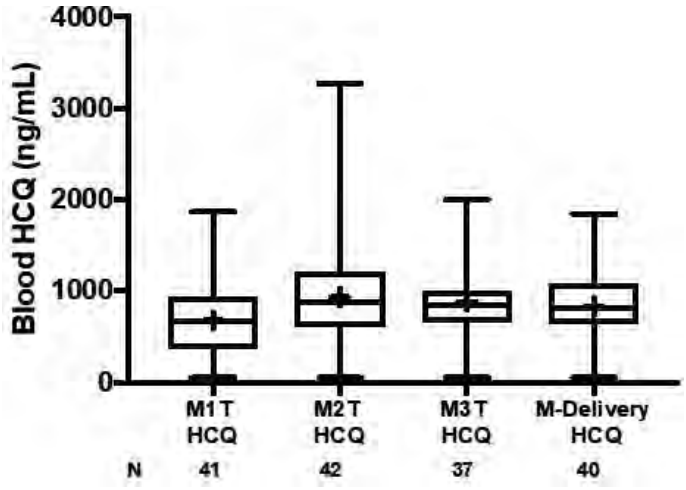

Figure 2. Box plots of maternal blood levels of HCQ during each trimester of pregnancy and delivery. M1T is baseline first trimester. M2T is second trimester. M3T is third trimester. M-Delivery is at the time of delivery. Median levels of HCQ (interquartile range) for M1T: 669 ng/mL (363-941); M2T: 877 ng/mL (604-1212); M3T: 849 ng/mL (652-1000); M-Delivery: 815 ng/mL (645-1080). Mean values denoted by + in box plot.

Background/Purpose: Based on inhibition of viral replication and limited reports on clinical efficacy, hydroxychloroquine (HCQ) was initially considered as a prophylaxis and treatment of COVID-19. Despite this optimism, more extensive reports have significantly dampened the promise of efficacy, however cardiac toxicity has surfaced raising attention to this complication. Although HCQ is generally considered safe during pregnancy based on studies in patients with systemic lupus erythematous and other rheumatic conditions, this initiative leveraged a unique opportunity to evaluate neonatal electrocardiograms (ECGs) in the context of HCQ levels to address any potential cardiotoxicity.

Methods: Neonatal ECGs and HCQ blood levels were available in a recently completed study evaluating the efficacy of HCQ 400mg daily to prevent the recurrence of congenital heart block associated with anti-SSA/Ro antibodies. The ECGs of affected newborns who met the primary outcome of advanced block were not included in this safety study so that the results only reflect those infants with no clinical cardiac disease. Using the Bazett formula to correct for heart rate, corrected QT (QTc) intervals were calculated and compared to age-matched normal values. For reference, the median (2^{nd} percentile – 98^{th} percentile) values for QTc were 413 (378-448) msec in males, and 420 (379-462) msec in females. QTc intervals were recorded in the absence of knowledge of the HCQ levels. Values exceeding 448 msec for males and 462 msec for females were considered abnormal. Levels of HCQ were assessed during each trimester of pregnancy and in the cord blood, providing unambiguous assurance of drug exposure.

Results: There were 45 ECGs available for interpretation within the first 4 months of life in unaffected infants. Overall, there was no correlation between cord blood levels of HCQ and the QTc (R = 0.02, P = 0.86) or the average value of HCQ levels obtained during each individual pregnancy and cord blood and the QTc (R = 0.04, P = 0.80), as shown in **Figure 1A and Figure 1B**. Likewise there was no correlation between the average of the maternal HCQ levels obtained at each trimester and delivery plus cord levels and the QTc on the ECGs of the 31 infants evaluated on day of life 1-4 (R = 0.08, P = 0.63) or those of the 14 children older than 4 days (R = 0.01, P = 0.95). Maternal values of HCQ were sustained throughout pregnancy and delivery (**Figure 2**). Mean QTc values were nearly identical between those in the highest and lowest quartiles of cord blood HCQ levels (P = 0.57) and between the highest and lowest quartiles of average HCQ levels during pregnancy (P = 0.54) (**Figure 3A and 3B**). Among these 45 infants, only 5 had prolongation of the QTc (11%; 95% CI: 4% - 24%), 2 marked and 3 marginal. No arrhythmias occurred in any neonate that was not known to have heart block.

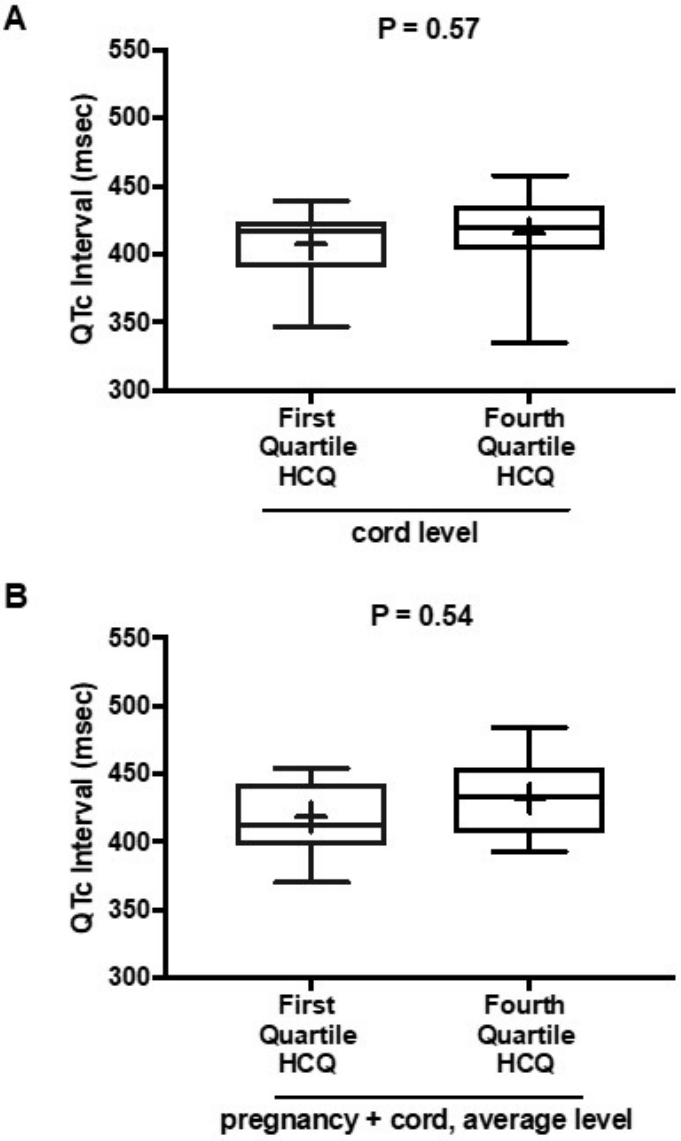

Figure 3. Box plots of QTc interval data for subjects in first and fourth quartiles of cord blood HCQ levels and average HCQ levels during pregnancy. (Panel A) Comparison of QTc between the first and fourth quartiles of HCQ cord blood levels. Median QTc (interquartile range) in first HCQ quartile: 417 msec (390- 424); in fourth HCQ quartile: 419 msec (404-436). (Panel B) Comparison of QTc between the first and fourth quartiles of HCQ levels averaged over pregnancy and cord blood. Median QTc (interquartile range) in first HCQ quartile: 413 msec (398, 443); in fourth HCQ quartile: 433 msec (407, 455). Mean values denoted by + in box plots. All QTc intervals were calculated using the Bazett formula (QTcB).

Conclusion: In aggregate, these data provide reassurances that the maternal use of HCQ is not associated with a high incidence of QTc prolongation in the neonate.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: According to APS classification criteria[1], clinical manifestations of antiphospholipid syndrome (APS) consist in thrombotic and obstetric events, including severe preeclampsia (PE). Because little is known on this topic, our aim was to describe severe PE in a cohort of APS patients and to report the thrombotic and obstetrical outcomes in these patients.

Methods: Retrospective study of female patients referred to 5 French Internal Medicine departments and 1 Italian Rheumatology Unit with a severe PE according to standard definition[1], that occurred before 34 WG between 2000 and 2018 in patients with APS[2]. In case of more than one episode of severe PE in one given patient, we defined the index pregnancy as the first episode. We considered that women had been treated during pregnancy if they were prescribed low-dose aspirin (LDA) and/or low-molecular-weight heparin (LMWH) before the diagnosis of severe PE.

Results: The study included 40 women with APS, with a median follow-up after the index pregnancy with PE of 3 years. 12 (30%) had an associated SLE. 33 women (82.5%) had a positive LAC and 21 women (52.5%) had triple positivity anti-phospholipid (aPL) positivity.

- During the index pregnancy, PE occurred at a median term of 25.5 WG. 29 pregnancies (72.5%) led to a live birth but 5 severely premature neonates died (i.e. a total of 24 pregnancies resulted to a living child). Data on PE are described Table 1.
- Thrombotic criteria: 16 women (40%) had at least one thrombotic event. Their first thrombosis occurred before (n=14) or after the index pregnancy (n=2). Thromboses were venous (n=6), arterial (n=12), and/or micro-thrombotic (n=5). Four patients experienced a catastrophic APS (CAPS), 3 of them simultaneously with PE.

Table 1: Characteristics of the index pregnancies complicated with severe Preeclampsia in 40 patients with APS	
Patient's characteristics	**(N=40, %)**
Age of index pregnancy (first severe PE), (median, IQR)	30.5 (27-33)
Primiparous	21 (52.5)
Associated SLE	12 (30)
Abs profile	
Triple positivity for aPL antibodies	21 (52.5)
IgG/IgM anti-cardiolipin antibodies	34 (85.0)
IgG/IgM anti-β2GPI antibodies	25 (62.5)
LAC	33 (82.5)
Treatment (during index pregnancy, prior to PE)	
LDA	19 (47.5)
LMWH	19 (47.5)
Antimalarials	7 (17.5)
Corticosteroids	8 (20)
Immunosuppressants	3 (7.5)
None	17 (42.5)
Severe PE characteristics	
Live births	29 (72.5)
Neonatal deaths	5 (12.5)
PE term, WG (median, IQR)	25.5 (23-29)
Birth term, WG (median, IQR)	25.5 (23.7-30.3)
Preterm delivery (<37th WG)	22 (55)
Associated maternal complications	
HELLP	18 (45)
Eclampsia	6 (15)
Catastrophic APS	3 (7.5)
Placental abruptions	3 (7.5)
Associated fetal complications	
IUGR	18 (45)
IUFD	11 (27.5)

Legend to Table 1: APS: antiphospholipid syndrome; PE: preeclampsia; IQR: interquartile range; WG: weeks of gestation; SLE: systemic lupus erythematosus; Abs: antibodies; aPL: antiphospholipid; LAC: lupus anticoagulant; LDA: low dose aspirin; LMWH: Low Molecular Weight Heparin; HELLP: Hemolysis, elevated liver enzymes, low platelet; IUGR: intrauterine growth restriction; IUFD: intrauterine fetal death.

- Obstetrical criteria: when considering all their pregnancy (n=122), 17 patients (42.5%) had at least one intra-uterine fetal death (IUFD), and 19 women (47.5%) had at least one HELLP syndrome. None of the 40 patients presented 3 or more consecutive miscarriages.

Conclusion: During the 40 index pregnancies, severe PE occurred early in the pregnancy with a high rate of in utero (n=11) or neonatal (n=5) mortality of the offspring.

APS was characterized by a strong autoimmune anti-phospholipid serology and SLE was frequent (30%).

Among these 40 APS patients with severe PE, almost half also experienced at least one thrombosis, a HELLP syndrome and/or an IUFD. However, no overlap with the «three consecutive miscarriages" classification criterion was found in our cohort suggesting that the underlying physiopathology of these 2 obstetrical phenotypes are completely different.

Composite of Relevant Endpoints for Sjögren's Syndrome (CRESS)

Suzanne Arends[1], Liseth de Wolff[2], Jolien van Nimwegen[3], Gwenny Verstappen[2], Jelle Vehof[2], Arjan Vissink[4], Neelanjana Ray[5], Frans Kroese[2] and Hendrika Bootsma[2], [1]University Medical Centre Groningen and Medical centre Leeuwarden, Groningen, Netherlands, [2]University Medical Centre Groningen, Groningen, Netherlands, [3]University Medical Center Groningen, Groningen, Netherlands, [4]University Medical Centre Groningen, Leek, Netherlands, [5]Bristol-Myers Squibb, Lawrenceville

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Several recent randomized controlled trials that used the validated ESSDAI as primary endpoint failed, partly explained by relatively large response rates in the placebo group. Since primary Sjögren's Syndrome (pSS) is a very heterogeneous disease, a composite endpoint including multiple disease aspects may be more appropriate to demonstrate clinical efficacy. Therefore, our objective was to develop a composite endpoint for pSS based on expert opinion and analysis of trial data.

Methods: According to expert opinion, 5 items were found to be most relevant to assess the effect of treatment in pSS: systemic disease activity, patient-reported symptoms, tear gland, salivary gland and serological items. These items were tested using data from the randomized, double-blind, placebo-controlled ASAPIII trial at week 24.[1] Cut-off points were based on ROC analysis to assess discrimination of effect between patients on abatacept (n=40) and placebo (n=39) and on expert opinion.

Table 1: Overview of the Composite of Relevant Endpoints for Sjögren's Syndrome (CRESS): definition of response of the 5 complementary items		
Item	**Measurement**	**Definition of response**
Systemic disease activity	ClinESSDAI	Score <5 (low disease activity)
Patient-reported symptoms	ESSPRI	Decrease of ≥1 point or ≥15% from baseline
Tear gland*	Schirmer/OSS**	If abnormal score at baseline: • Or increase of ≥5 mm in Schirmer • Decrease of ≥2 points in OSS Or if both normal at baseline: • No change to abnormal in Schirmer and OSS
Salivary gland*	UWS/SGUS	• Increase of ≥25% or if score is 0 at baseline any increase in UWS • Or decrease of ≥25% in total Hocevar score
Serological	RF/IgG	• Decrease of ≥25% in RF • Or decrease of ≥10% in IgG
Total CRESS responder		Response on ≥3 items of 5
*CRESS can also be used without OSS and SGUS if these tests are not available **Mean of both eyes Abbreviations: ClinESSDAI: Clinical EULAR Sjögren's syndrome disease activity index; ESSPRI: EULAR Sjögren's syndrome patient reported index; OSS: Ocular Staining Score; UWS: unstimulated whole saliva; SGUS: salivary gland ultrasonography; RF: rheumatoid factor; IgG: Immunoglobulin G		

Table 1. Overview of the Composite of Relevant Endpoints for Sjögren's Syndrome (CRESS): definition of response of the 5 complementary items

Table 2: CRESS response rates at week 24 of abatacept and placebo groups			
Item	**Measurement**	**Responders abatacept**	**Responders placebo**
Systemic disease activity	ClinESSDAI	45%	27%
Patient-reported symptoms	ESSPRI	58%	22%
Tear gland	Schirmer/OSS	58%	36%
Salivary gland	UWS/SGUS	58%	41%
Serological	RF/IgG	64%	19%
Total CRESS responder	**Response on ≥3 items of 5**	**65%**	**18%**
Abbreviations: see Table 1			

Table 2 CRESS response rates at week 24 of abatacept and placebo groups

Results: The 'Composite of Relevant Endpoints in Sjögren's Syndrome' (CRESS) consists of 5 complementary items. The definition of response for each item is presented in Table 1. For measuring systemic disease activity, ClinESSDAI[2] is used as it showed higher discrimination compared to ESSDAI and because the biological domain is separately in-

Table 3: Response and non-response on individual items in CRESS responders		
Measurement	Abatacept n=26 CRESS responders	Placebo n=7 CRESS responders
ClinESSDAI	16 vs. 10	5 vs. 2
ESSPRI	18 vs. 8	4 vs. 3
Schirmer/OSS	19 vs. 7	5 vs. 2
UWS/SGUS	19 vs. 7	4 vs. 3
RF/IgG	18 vs. 8	4 vs. 3
Abbreviations: see Table 1		

Table 3. Response and non-response on individual items in CRESS responders

cluded in the CRESS. ROC analysis for absolute or relative change in ClinESSDAI showed no discrimination between treatment groups (AUC 0.534 and 0.565), therefore low disease activity (< 5) in ClinESSDAI was used. Patient-reported symptoms are measured with ESSPRI. As ROC analysis showed optimal cut-off points of -0.83 and -13.8% (AUC 0.621 and 0.629), the previously validated definition of ESSPRI response (≥15% or 1 point)[3] was used. Tear and salivary gland items include both glandular function and imaging. Cut-off points were based on expert opinion, taking measurement variation into account. The CRESS can also be used without OSS and SGUS if these tests are not available, leaving Schirmer's and UWS for assessing the tear and salivary gland item with similar response rates in both treatment groups. The serological item includes serum levels of RF-IgM and IgG. ROC analysis showed optimal cut-off points of -23% and -2.2% (AUC 0.861 and 0.615), respectively, which were set to ≥25% and ≥10% decrease to minimize placebo response due to natural variation. Total CRESS response was defined as response on ≥3 of the 5 items. The CRESS response per item for abatacept and placebo treatment groups is presented in Table 2. The total CRESS response rate was 65% vs. 18% (p< 0.001). As shown in Table 3, response to the 5 CRESS items is well-balanced.

Conclusion: The newly developed 'Composite of Relevant Endpoints for Sjögren's Syndrome' (CRESS) enables discrimination between active treatment (abatacept) and placebo treatment in pSS patients. All items contribute equally to CRESS response. Validation analyses in independent, global, multi-center, placebo-controlled trials in pSS patients will be performed.

Ultra High-resolution Ultrasound (UHFUS) of Labial Salivary Glands Might Help to Avoid Unnecessary Lip Biopsy in Patients with Sicca Syndrome

Chiara Baldini[1], Francesco Ferro[1], Rossana Izzetti[2], Saverio Vitali[3], Giacomo Aringhieri[3], Silvia Fonzetti[4], Marta Mosca[1], Valentina Donati[5], Stefano Bombardieri[1] and Davide Caramella[3], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Department of Surgical Pathology, Medicine, Molecular and Critical Area, University of Pisa, Pisa, Italy, Pisa, [3]Diagnostic and Interventional Radiology, Department of Translational Research and of New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, Pisa, [4]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, [5]Pathology Unit, AOUP, Pisa

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Major salivary gland ultrasonography (SGUS) has an established role as a first-line imaging tool in the diagnosis of primary Sjögren's syndrome (pSS). Nowadays, however, interest is also arisen in last-generation ultra high-resolution ultrasound (UHFUS) transducers, which can produce frequencies up to 70 MHz and achieve tissue resolution up to 30 μm, opening up new possibilities for the study of labial salivary glands (LSG).Purpose: to compare the diagnostic accuracy of LSG-UHFUS with SGUS and to investigate the usefulness of UHFUS in LSG biopsy preoperative planning.

Methods: Consecutive patients undergoing a LSG for clinically suspected pSS were included in this study from January 2018 to March 2020. UHFUS of LSG was performed by using VEVO MD, equipped with a 70 MHz probe, scanning first the central compartment of the inferior lip, and then both peripheral compartments. The following parameters were evaluated: distribution of the glands, parenchymal inhomogeneity (score 0-3, from normal to evident), and fibrosis. UHFUS imaging was used to help locate the LSG for the US-guided biopsy. SGUS findings were defined according to previous studies exploring both parotid and submandibular glands.

Results: We included a total of 138 patients with suspected pSS: out of them, 61 (44.2%) received a diagnosis of pSS (ACR 2016 criteria) and 77 (55.8%) were diagnosed as no-SS sicca controls. The two groups did not differ in their demographic features, USFR and ESSPRI. With respect to no-SS sicca controls, pSS patients presented both a higher SGUS scores and a higher UHFUS scores in both central and peripheral labial compartments ($p< 0.001$). UHFUS scores significantly correlated with parotid SGUS scores ($r=0.385$, $p=0.001$), submandibular SGUS scores ($r=0.463$, $p=0.001$), and with the minor salivary gland focus score ($r=0.407$, $p=0.001$); moreover, UHFUS scores were significantly associated with anti-Ro/SSA, anti-La/SSB, RF and hyper-IgG ($p< 0.05$). By using a cut-off score$\geq$2, UHFUS sensitivity was slightly higher than SGUS (63.9% vs 60.7%) whereas UHFUS specificity was lower (71.4% vs 79.2%). However, by using a cut-off score$<$ 1, UHFUS sensitivity raised up to 98.4% with a negative predictive value of 93.8%. In our cohort, the sequential combination of the two US techniques (UHFUS followed by SGUS) and the use of different UHFUS cut-off scores would have avoided unnecessary lip biopsy in 46/77 (59.7%) patients with sicca syndrome and no-pSS.

Conclusion: UHFUS of LSG appeared feasible and sensitive in pSS, potentially offering unique advantages in LSG biopsy preoperative planning to avoid unnecessary lip biopsy in patients with sicca symptoms.

Four Distinct Symptom-Based Clusters Identified from the Sjögren's Foundation Survey

Sara McCoy[1], Christie Bartels[2], Miguel Woodham[1], Noah Maerz[1], Esen Akpek[3], Ian Saldanha[4], Matthew Makara[5] and Alan Baer[6], [1]University of Wisconsin, Madison, [2]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI, [3]Johns Hopkins University, Baltimore, [4]Brown University, Providence, [5]Sjogren's Syndrome Foundation, Reston, [6]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Relief of symptoms is a *sine qua non* for successful drug development in Sjögren's syndrome (SS). However, symptom-based patient experience is understudied, particularly how these symptoms cluster in patients, potentially impacting immunosuppressive agent selection or outcome definitions. Recently, 4 distinct symptom-based groups with unique ESSDAI and lab profiles were identified by analyzing the UK Primary SS Registry cohort of 608 patients (Tarn et al. 2019). Our objective was to determine the generalizability of these findings in a larger US population and report medication use, quality of life, symptoms, and systemic manifestations unique to these clusters.

Methods: A survey, conducted by the Sjögren's Foundation, was completed by 2,961 adults with self-reported SS. Unsupervised hierarchical clustering was applied using Ward's method to identify the optimal phenotypically similar clusters based on self-reported severity of: 1) anxiety (never-daily), 2) depression (never-daily), 3) pain (visual analogue scale [VAS] 0-10), 4) fatigue (VAS), and 5) dryness (VAS). We tabulated demographic features, medications, quality of life, and SS-specific symptom frequency and systemic manifestations within each cluster. We used ANOVA or Chi-square to identify cluster differences, controlling for age, sex, race, and social security disability (SSD).

Results: The analysis yielded 4 clusters among 2,806 participants with complete data on the 5 key symptoms (Figure 1), as previously described. Clusters were characterized by low symptom burden (LSB; 14% prevalence) and high symptom burden (HSB; 30%) in all categories; high dryness and fatigue but low anxiety and depression (HDF; 34%) and high anxiety and depression but low dryness and fatigue (HAD; 22%). Diagnosis age and sex were similar but SSD significantly differed between clusters (1% in LSB and 15% in HSB) (Table). Analgesic use was significantly different between groups and highest in the HSB group (35% used opioids). HSB and HDF groups used more prescription eye drops (54% and 51%) and secretagogues (39% both), than other groups. Significant differences in systemic medication use included highest corticosteroid use in the HSB group (22%) and HCQ use in the HAD group (47%). The HSB group had more emotional burden (94%) than the LSB group (43%). The groups differed in all SS-specific symptoms (Figure 2A). Systemic manifestations differed significantly by clusters for inflammatory arthritis, interstitial lung disease, and neuropathy, but other systemic manifestations, like leukopenia and lymphoma, demonstrated no difference (Figure 2B).

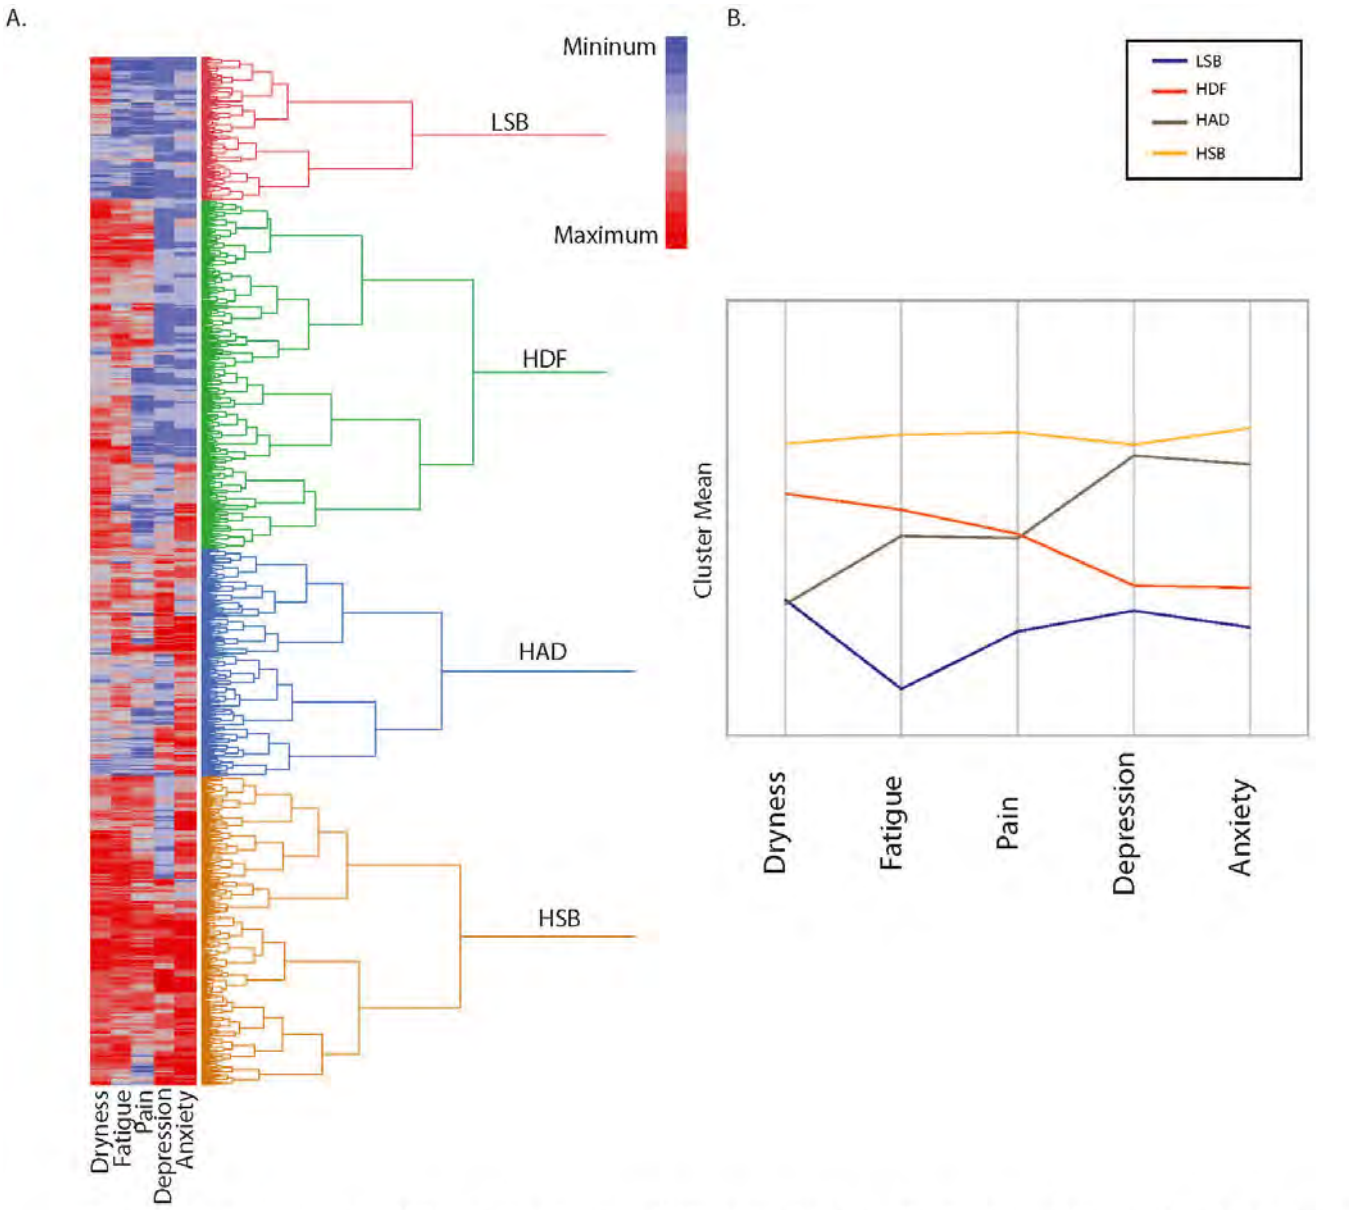

Figure 1. Four symptom based SS hierarchical clusters. A) Heat map demonstrating hierarchical clusters based on dryness, fatigue, pain, depression and anxiety. B) Cluster means of dryness, fatigue, pain, depression and anxiety. LSB= Low Symptom Burden; HDF=High Dryness and Fatigue; HAD=High Anxiety and Depression; HSB=High Symptom Burden

Conclusion: We verified the observation by Tarn et al. that 5 key symptoms can define 4 distinct clusters in SS patients. The HSB group is associated with more disability, symptomatic medication use, SS-specific symptoms and lower quality of life, but not as consistently with systemic manifestations. Findings highlight unique SS disease cluster profiles independent of age, sex, and some classical disease manifestations. We propose future phenotypic cluster research to better define subsets of this heterogeneous disease, and ultimately inform targeted therapies.

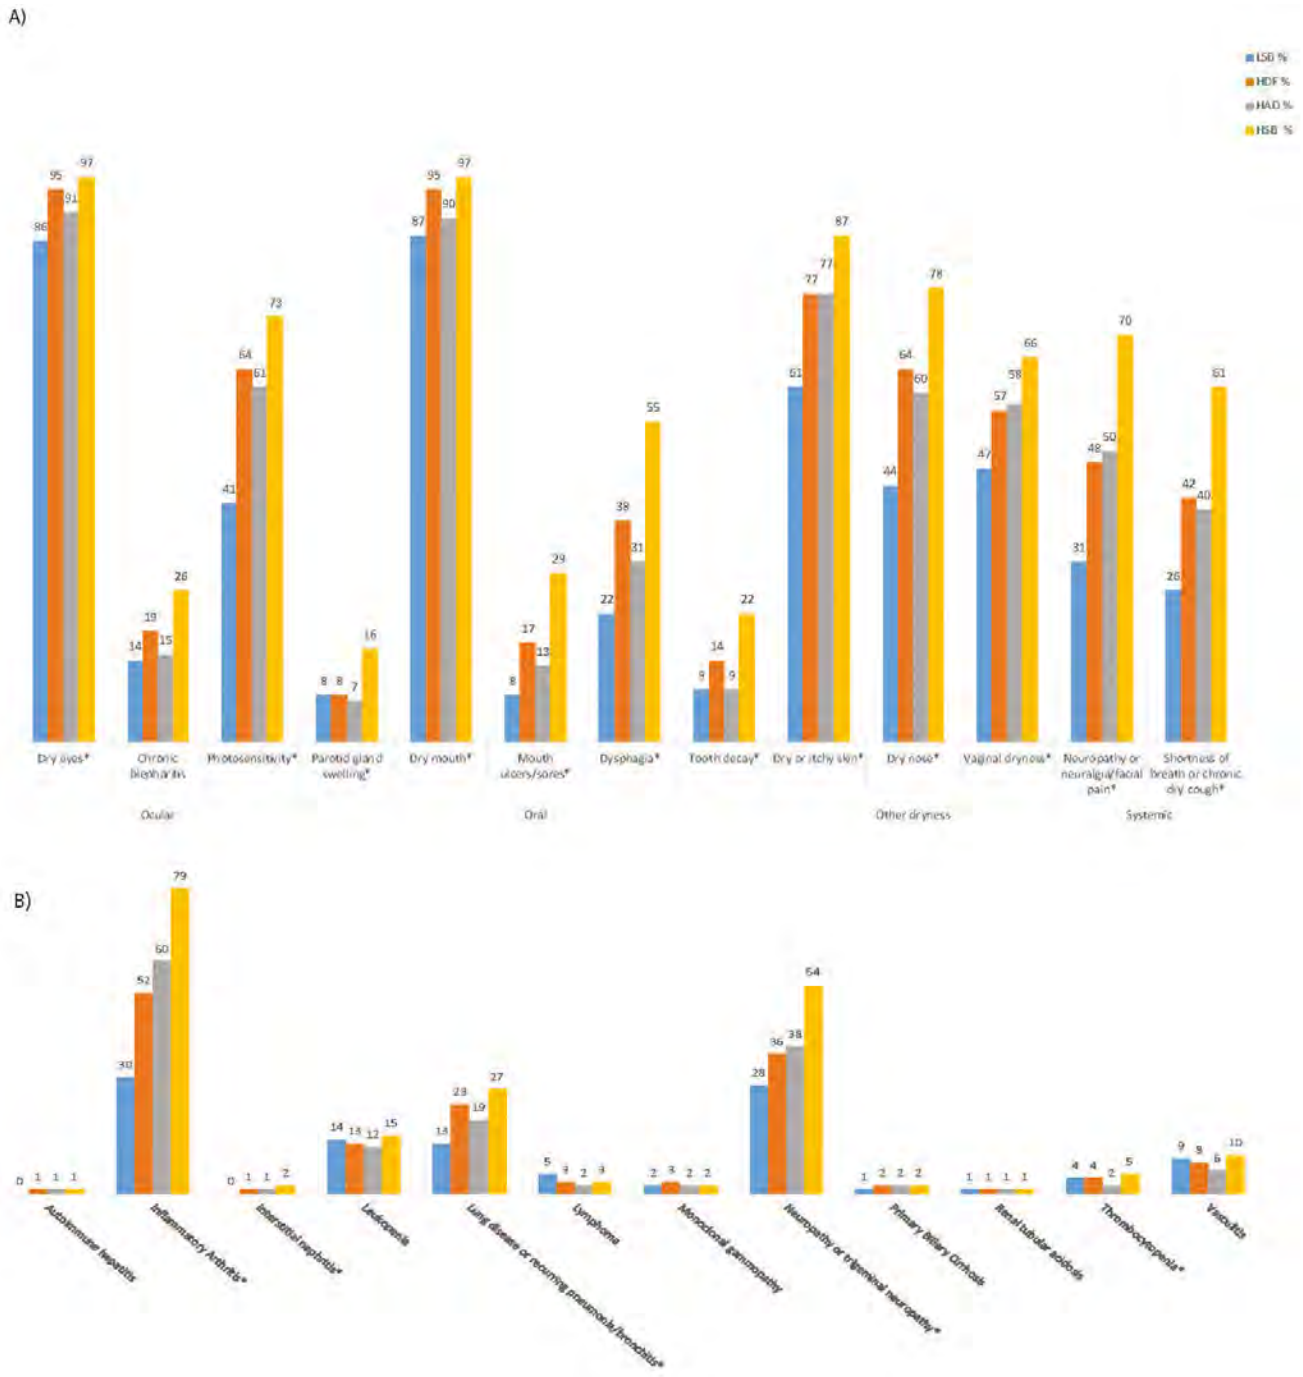

Figure 2. Frequency of reported symptoms and signs among symptom-based hierarchical clusters. A) Percent prevalence is reported for each symptom (present if experienced weekly or daily) within LSB, HDF, HAD, and LSB groups. B) Percent prevalence is reported for each sign within LSB, HDF, HAD, and LSB groups. LSB=low symptom burden; HDF=high dryness & fatigue; HAD=high anxiety and depression; LSB=low symptom burden. *p<0.05. Model is adjusted for age, sex, race,and social security disability.

Table. Symptom-Based Cluster Baseline Demographics (n=2806)

Antibodies Binding Ro/SSA and Muscarinic 3 Receptor in Sjogren's Syndrome

R. Scofield[1], Syed Quadri[2], Valerie Harris[2], Biji Kurien[2] and Kristi Keolsch[2], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Sjögren's syndrome is characterized by exocrine gland dysfunction and autoantibody production. Some data suggest autoantibodies binding the muscarinic 3 receptor (M3R) mediate poor function of the salvary gland. We have previously produced recombinant human monoclonal antibodies (rhMab) from antibody-se-

creting B cells (ASC) infiltrating the salivary glands of Sjögren's syndrome subjects. We undertook this study to determine anti-M3R properties of these rhMab.

Methods: Minor salivary gland biopsies were obtained in a comprehensive sicca evaluation clinic. ABCs were single cell purified with heavy and light genes amplified by PCR. These genes were then expressed in 239 cells with production of monoclonal IgG or IgM. The rhMab were assayed for anti-Ro, Ro peptide and M3R extracellular loop (ECL) peptides by ELISA. Ability to act as an agonist or antagonist of M3R was assessed via GeneBlazer™ M3-NFAT-bla CHO-K1 (M3R) cell line (K1716).

Results: We studied 47 rhMabs from SS subjects and 18 from non-SS sicca subjects. There were 10/47 and 0/18 hrMab from the SS and non-SS sicca subjects, respectively, that were positive for binding to M3R ECL2 (p=0.05) and 5/47 SS vs. 0/18 non-SS sicca subjects that were positive for M3R ECL3 (p=0.311). Four of the rhMabs (1-G04k, 1-E06k, 2-D06k and 5-E04k) from one SS patient (pSS-3) bound both M3R ECL2 and ECL3. When we considered positivity to either M3R ECL2 or ECL3, 11 of 47 rhMabs from SS subjects bound, while 0 of 18 rhMabs from non-SS sicca subjects bound (p=0.03 by 2-tailed Fisher's Exact Test). Several rhMab that bound M3R ECL2 showed high affinity binding (Kd values ranging from 10-7 to 10-9). Among the Ro60-binding rhMab derived from SS subjects, 8/23 (34.8%) also bound M3R ECL2. and 4/23 (17%) bound the M3R ECL3 by ELISA. None of the anti-Ro60 rhMab from the non-SS sicca subjects bound either M3R ECL2 or ECL3. Of 65 rhMab, 4 from the SS group (all from pSS-3) and 2 from the non-SS sicca group (1 from NSS-1 and 1 from NSS-4) showed M3R antagonist activity.

Conclusion: Recombinant monoclonal antibodies derived from salivary gland infiltrating antibody secreting cells bind M3R extracellular loop. Some of these antibodies show M3R inhibitory activity; and, thus, may be directly involved in salivary gland dysfunction.

Correction of Sjögren's Syndrome Fluid Secretion Deficits in Salivary Gland Acinar Cells by Aquaporin-1 Gene Transfer

Paola Perez[1], Blake Warner[2], Sandra Wainer[1], Youngmi Ji[1], Thomas Pranzatelli[1] and Jay Chiorini[1], [1]Nidcr, National Institute of Health, Bethesda, MD, [2]National Institute of Dental and Craniofacial Research, Bethesda

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: The hallmark clinical complaints in Sjögren's syndrome (SS) are dry mouth and dry eyes related to salivary and lacrimal glands dysfunction. Reduced salivation reflects underlying fluid secretion deficits in the membrane permeability of acinar cells. In several animal models, including SS, increasing the membrane permeability using gene transfer of human aquaporin 1 (hAQP1) effectively restores fluid secretion. Indeed, hAQP1 gene transfer improved salivation and dry mouth in patients with radiation-induced xerostomia. Presently, there are no long-term effective therapies for most patients with dry mouth. To address this unmet clinical need we tested the ability of ex vivo adeno-associated virus serotype-2 (AAV2)-hAQP1 gene transfer to restore fluid secretion in human labial salivary

glands (LSG) from SS patients and identify predictive molecular signatures of responsiveness. We hypothesize that by restoring water permeability in acinar cells of salivary glands it is possible to correct salivary hypofunction in SS.

Methods: Sixteen (N=16) subjects provided informed consent and were evaluated in the NIDCR Sjögren's Syndrome Clinic. Subjects received comprehensive rheumatologic, ophthalmologic, and oral/salivary evaluations including LSG biopsies; nine subjects met the 2016 American College of Rheumatology SS criteria. LSG biopsies were divided into RNA*later* for storage or immediately micro-dissected into lobule preparations for ex vivo culture. Lobules were transferred to 24-well transwell plates and cultured at the air-media interface. Two hours after equilibration, LSG lobules were transduced with 6.25E+11 particles of AAV2-hAQP1 and 1.35E+11 AAV2-mCherry or 1.35E+11 AAV2-mCherry alone as a control. After 24 hours of transduction, the volume change response to 2uM carbachol was measured. Remaining lobules were fixed in 4% paraformaldehyde for immunofluorescence (IF) or preserved in RNA*later* for RNA sequencing.

Results: AAV2-hAQP1 transduction corrected both SS ($p = 0.02$) and non-SS ($p < 0.01$) LSG fluid secretion deficits up to 80% of normal. AAV2-hAQP1 transduction was confirmed using IF for hAQP1 expression and mCherry fluorescence in the acinar tissues. The RNA-sequencing analysis showed that responders to AQP1 transduction have a lower molecular signature for mesenchymal markers.

Conclusion: Our data suggest that, in the context of SS pathophysiology with sufficient secretory parenchyma in the glands of patients, SS salivary hypofunction can be recovered using AAV2-hAQP1.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes II: Bench to Bedside

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Anti-nuclear antibodies (ANA) are important biomarkers for the diagnosis and classification of systemic lupus erythematosus (SLE). However, emerging data from cross-sectional studies suggest variation in the performance between ANA assays. The purpose of this project was to compare the performance of three different ANA assays in a longitudinal analysis of samples from the Systemic Lupus International Collaborating Clinics (SLICC) Inception Cohort.

Methods: We used demographic, clinical, and serological data of SLICC patients who fulfilled the 1997 Updated ACR SLE Classification Criteria and were enrolled within 15 months of diagnosis. Samples from enrolment and follow-up visits at years 3 and 5, were assayed using three FDA-approved ANA tests, including two HEp-2 indirect immuno-fluorescence assays, IFA1 (BioRad, Hercules, USA) and IFA2 (NovaLite, Inova Diagnostics, San Diego, USA), and an

enzyme-linked immunosorbent assay (ELISA) (Inova Diagnostics, San Diego, USA), at one central laboratory (Calgary, AB). A positive test was defined as a titer of ≥1:80 for IFA1 and IFA2 and ≥20 chemiluminescent units (CU) for the ELISA. The frequency of positivity, titer and patterns among different ANA assays were compared using weighted kappa statistics (κ) and McNemar tests. Longitudinal analysis of ANA titers was assessed for IFA1 and IFA2 using a mixed-effects restricted maximum likelihood regression model fitting a quadratic trend with unstructured co-variance. ANA patterns were categorized into three groups: 1) pure nuclear (e.g. homogeneous, speckled), 2) cytoplasmic and mitotic patterns (e.g. dense fine speckled and centrosome), and 3) mixed nuclear, cytoplasmic and mitotic patterns.

Results: 806 patients were included; 88.7% were female and mean age at diagnosis was 35.2 (SD 13.6) years. At enrolment, the frequency of ANA positivity by IFA1, IFA2, and ELISA was high (99.6%, 98.3%, and 96.7% respectively) (**Table**) and there was strong agreement between IFA1 and IFA2 (99.6% agreement) and IFA1 and ELISA (98.4%), but significant differences were detected for IFA2 and ELISA (95.7% agreement, $p< 0.05$ on McNemar's test). Over five years of follow-up, the prevalence and agreement in ANA positivity remained high for IFA1 and IFA2, decreasing slightly only for ELISA (91.5% positivity and 91.4% agreement with IFA2 at year 5). There was fair to moderate agreement between IFA1 and IFA2 titres at enrolment (84.7% agreement, κ=0.52), year 3 (77.0%, κ=0.32), and year 5 (80.1%, κ=0.37). A quadratic trend model revealed that IFA1 titers decreased more rapidly compared to IFA2 ($p< 0.001$) (**Figure 1**). There was fair to moderate agreement between IFA1 and IFA2 ANA patterns at enrolment (75.4% agreement, κ=0.45), year 3 (66.7%, κ=0.28), and year 5 (69.4%, κ=0.37) (**Figure 2**). Pure nuclear patterns were the most common, followed by mixed patterns.

Table. ANA positivity and inter-test percentage agreement among indirect immunofluorescence assays (IFA) 1 and 2 and enzyme-linked immunosorbent assay (ELISA) at enrolment, year 3 and year 5

	Enrolment (%)			Year 3 (%)			Year 5 (%)		
	IFA1	IFA2	ELISA	IFA1	IFA2	ELISA	IFA1	IFA2	ELISA
Positivity	99.6	98.3	96.7	96.8	98.6	92.6	98.4	98.8	91.5
Agreement									
IFA1	-	-	-	-	-	-	-	-	-
IFA2	99.6	-	-	97.2	-	-	98.4	-	-
ELISA	98.4	95.7*	-	94.8	92.4**	-	97.6	91.4**	-

**p<0.001, *p<0.05 using McNemar's Test

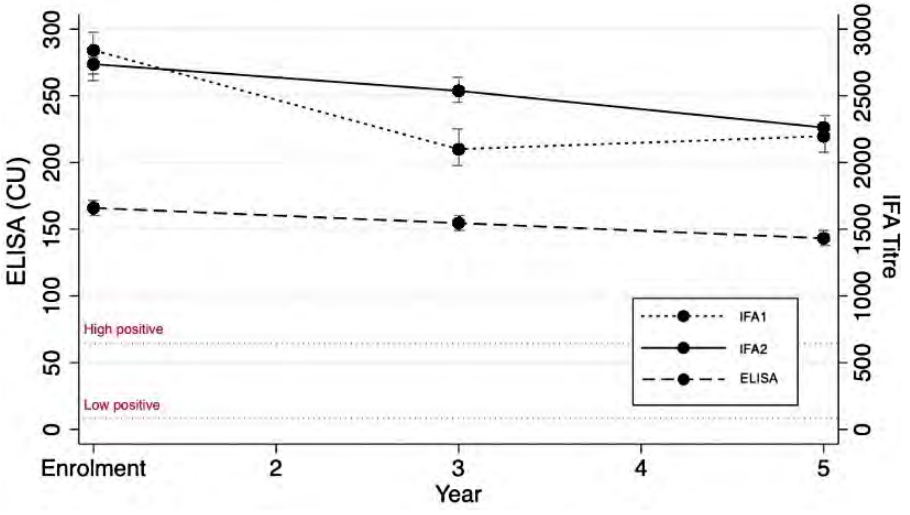

Figure 1. ANA titres decrease over time with indirect immunofluorescence assay (IFA) 1, IFA2, and enzyme-linked immunosorbent assay (ELISA) in chemiluminescent units (CU).

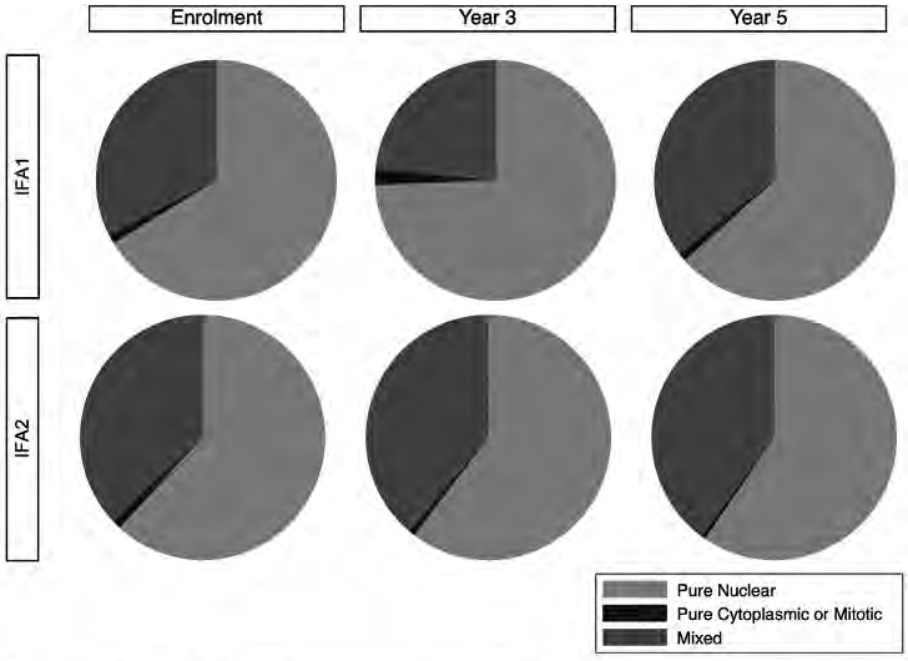

Time	Enrolment	Year 3	Year 5
%Agree (kappa)	75.4 (0.45)**	66.7 (0.28)**	69.4 (0.37)**

Figure 2. ANA patterns over time with indirect immunofluorescence assays (IFA) 1 and 2. **p<0.0001 using weighted kappa statistics.

Conclusion: In recent-onset SLE, early ANA positivity is 96.7-99.6% depending on the test. Agreement between the two IFA's was high at diagnosis and sustained over five years but was lower between one of the IFA's and ELISA. While titers did decrease slightly over time, ANA patterns remained largely unchanged. A future study with a longer follow-up period and clinical correlation is underway.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes II: Bench to Bedside
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Cognitive impairment is the most frequent manifestation of neuropsychiatric systemic lupus erythematosus (NPSLE), yet the mechanisms underlying it remain poorly understood. The purpose of our study was to examine the association between blood-brain barrier (BBB) integrity, brain volume and cognitive dysfunction in adult patients with systemic lupus erythematosus (SLE).

Methods: A total of 65 ambulatory SLE patients and 9 healthy controls underwent dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) scanning, for quantitative assessment of blood-brain barrier (BBB) permeability. Volumetric data was extracted using the VolBrain pipeline. Global cognitive function and performance in five individual cognitive domains was compared between patients with normal versus extensive BBB leakage.

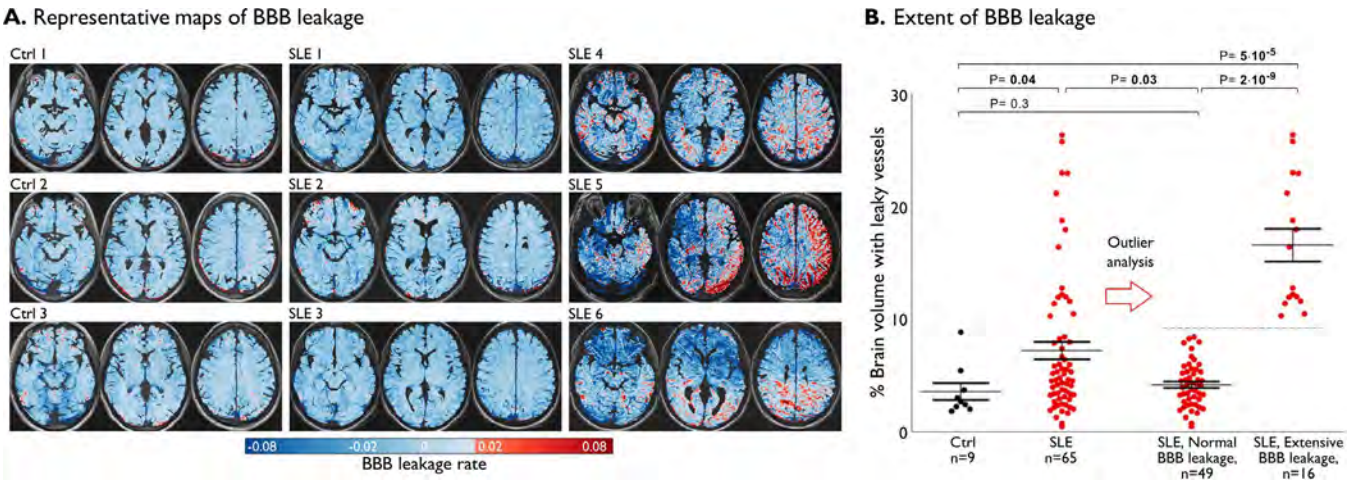

Figure 1. A sub-group of SLE patients have extensive BBB leakage. A. The rate of BBB leakage was quantified for every brain voxel. Shades of blue represent tissue with non-permeable BBB and shades of red represent contrast agent accumulation due to BBB leakage. A qualitative review of leakage maps in these selected cases illustrates that some SLE patients are visually comparable to controls, while others exhibit visibly higher number of voxels with BBB leakage. B. The percent of brain volume with BBB leakage was quantified for each subject, revealing a significant difference between SLE patients and controls (p=0.04). Outlier analysis of all 74 participants identified a group with "extensive BBB leakage", consisting of 16 SLE patients; and a group termed "normal BBB leakage", consisting of 9 controls and 49 SLE patients.

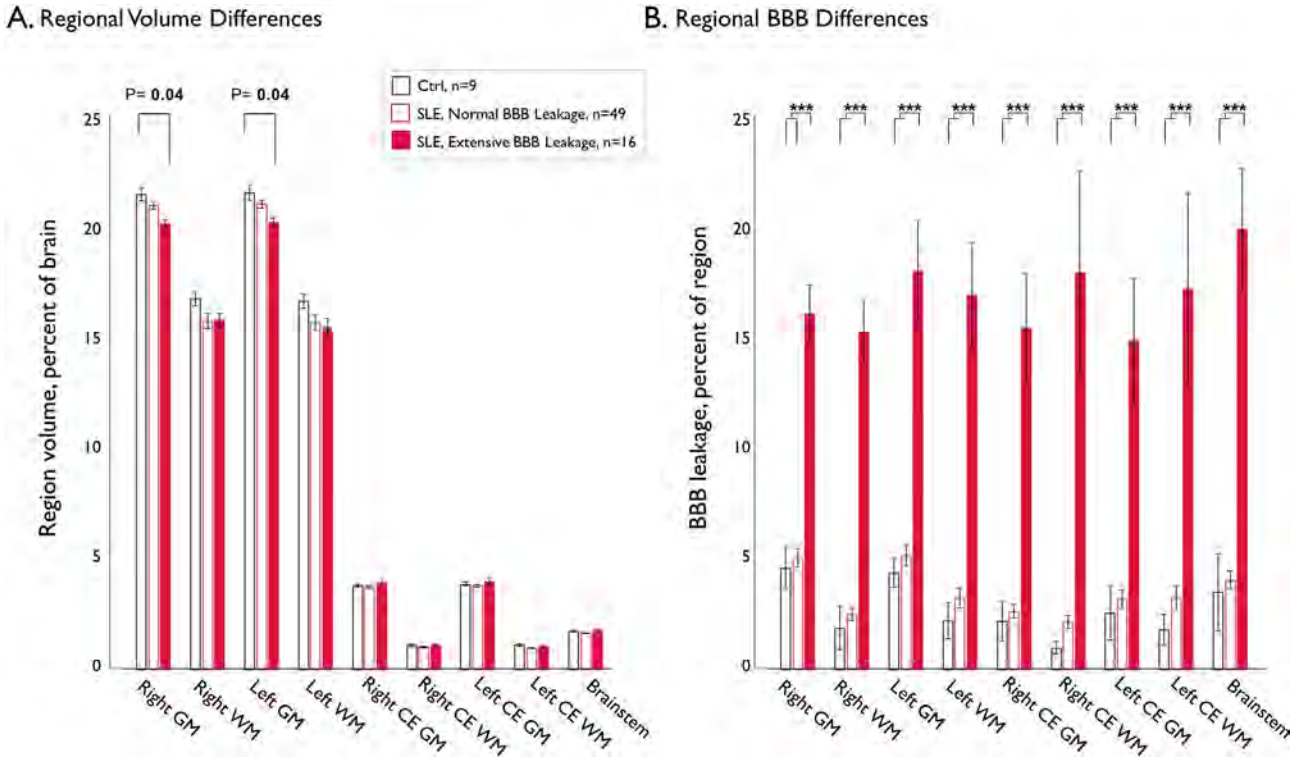

Figure 2. Extensive BBB leakage in SLE patients is associated with smaller gray matter volume. A. Depiction of the nine largest brain structures (of the 23 regions compared between the groups) illustrates the reduced right- and left- gray matter volumes in patients with extensive BBB leakage compared to controls (p=0.04, corrected for multiple comparisons). There were no volumetric differences in any other regions. B. Comparison of BBB leakage in the same 23 brain structures revealed that the 'extensive BBB leakage group' had higher levels of leakage in all regions (the same nine regions are depicted in B and A), compared to patients with normal BBB leakage and controls (p≤0.001, corrected for multiple comparisons). The Wilcoxon rank sum test was used to compare between the groups, and the false discovery rate algorithm was used to correct for multiple comparisons. Error bars denote standard error of the mean. Asterisks denote level of significance, with ***p≤0.001. GM, gray matter; WM, white matter; CE, cerebellum.

Results: Patients were predominantly female (87.7%) and Caucasian (89%) with a mean±SD age of 48.9 ± 13.3 years and disease duration of 15.1 ± 10.5 years. All patients had quiescent SLE and prior NP events attributable to SLE were present in 23% of patients. Impairment in at least one of five cognitive domains was found in 47.7% of patients. SLE patients had significantly higher levels of BBB leakage compared to controls (p=0.04). Extensive BBB leakage (affecting over >9% of brain volume) was identified only in SLE patients (16/65; 24.6%), who also had smaller right and left cerebral gray matter volumes compared to controls (p=0.04). Extensive BBB leakage was associated with lower global cognitive scores (p=0.02), and with the presence of impairment in one or more cognitive domains (p=0.01).

Conclusion: Our findings provide evidence for an association between extensive BBB leakage and changes in both brain structure and cognitive function in SLE patients. Future studies should investigate the mechanisms underlying BBB-mediated cognitive impairment, the diagnostic utility of BBB imaging, and the potential of targeting the BBB as a therapeutic strategy in SLE patients.

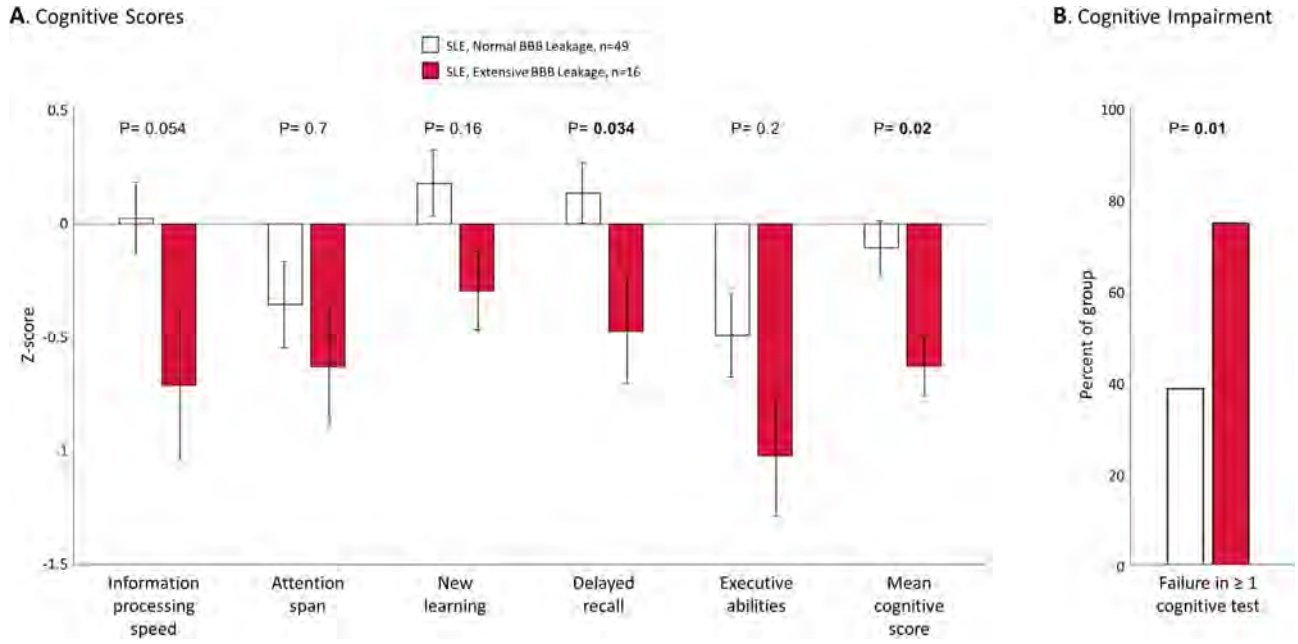

Figure 3. Extensive BBB leakage in SLE patients is associated with cognitive impairment. A. SLE patients with extensive BBB leakage had worse delayed recall and lower mean cognitive scores (averaged Z-scores of the five examined cognitive domains) compared to patients with normal BBB leakage (p=0.02, Wilcoxon rank sum test). B. The extensive BBB leakage group also had a significantly higher percent of subjects failing at least one cognitive test (p=0.01, chi-square test). Error bars denote standard error of the mean.

Leukocyte Telomere Length and Childhood Onset of Systemic Lupus Erythematosus in the Black Women's Experiences Living with Lupus (BeWELL) Study

John Bridges[1], Kara Chung[2], Connor Martz[2], Emily Smitherman[1], Cristina Drenkard[3], S. Sam Lim[4] and David Chae[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Auburn University, Auburn, AL, [3]Division of Rheumatology, Department of Medicine, Emory School of Medicine, Atlanta, GA, [4]Emory University, Atlanta, GA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes II: Bench to Bedside

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Childhood-onset SLE is generally more aggressive than adult-onset SLE. Leukocyte telomere length (LTL) has been posited to reflect immune system aging. Short LTL in particular has been associated with chronic health conditions mediated by inflammatory pathways as well as all-cause mortality. Prior studies have found evidence for shorter LTL among patients with SLE compared to healthy controls. However, no studies to date have compared LTL among SLE patients diagnosed in childhood vs. adulthood.

Table 1: Descriptive Characteristics of Black Women with SLE in the Black Women's Experience Living with Lupus (BeWELL) Study

Characteristic	Childhood-Onset SLE (n=40)	Adult-Onset SLE (n=375)	Total Sample* (n=415)

Methods: Data are from the Black Women's Experiences Living with Lupus (BeWELL) Study. A total of 438 Black women living in the Atlanta, Georgia metropolitan area with a validated diagnosis of SLE (≥ 4 American College of Rheumatology SLE criteria or 3 criteria with a diagnosis of SLE by a board-certified rheumatologist) were recruited between April 2015-May 2017. Multivariable linear regression analyses were conducted examining childhood diag-

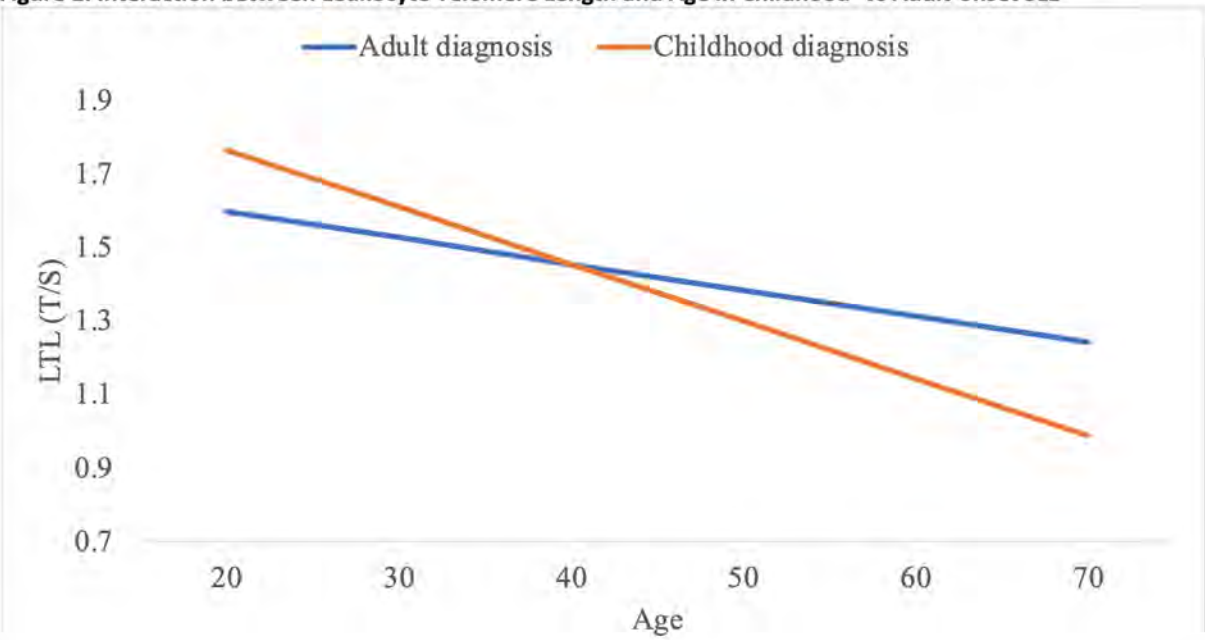
Age*childhood diagnosis			0.008	(0.016, 0.001)	-0.009	(-0.016, -0.001)	0.007	(-0.015, 0.001)
≥ 10-year disease duration					0.063	(-0.002, 0.127)	--	--
Disease duration (continuous)					--	--	-0.002	(-0.006, 0.002)

Note: Total sample was age-restricted to participants < 70 years.

All models adjust for the following covariates: relationship status, education, income-poverty ratio category, insurance status, disease damage (BILD), body mass index, and smoking status.

Table 2

Figure 1: Interaction between Leukocyte Telomere Length and Age in Childhood- vs Adult-onset SLE



LTL (T/S) = leukocyte telomere length (telomere to single copy gene ratio)

Figure 1

nosis of SLE (< 18 years of age derived from self-reported age and disease duration) in relation to LTL assayed from dried blood spots, measured as the relative telomere to single copy gene (T/S) ratio.

Results: Seven participants without a valid measure of LTL were excluded from analyses. Among those diagnosed in childhood, the oldest participant was 69 years of age. Analyses were restricted to those < 70 years of age resulting in a total analytic sample size of 415. A total of 40 participants (9.6%) were diagnosed in childhood. Multivariable linear regression analyses were conducted adjusting for a range of demographic, socioeconomic and health-related

covariates, including smoking status, body mass index, and disease damage measured using the Brief Index of Lupus Damage (Table 2). Results indicated no main effect of childhood diagnosis on LTL (Model 1: b=0.007, 95% CI: -0.089, 0.103). However, the interaction between age and childhood diagnosis was significant (Model 2: b—0.008, -0.016, -0.001), indicating a steeper inverse association between age and LTL among those diagnosed in childhood compared to those diagnosed in adulthood (Figure 2). This interaction continued to be significant at p=0.024 (Model 3) after controlling for disease duration measured dichotomously (< 10 years vs. >= 10 years); and was marginally significant at p=0.083 (Model 4) when examined continuously.

Conclusion: This cross-sectional analysis suggests that Black women with childhood-onset SLE may undergo accelerated LTL shortening compared to their adult-onset counterparts. We found that this relationship persisted even after controlling for differences in SLE damage and disease duration. Future longitudinal research modeling within-person change in LTL over time that includes larger samples of those diagnosed in childhood may help to uncover if this finding is an artifact of cohort effects, or if there are other mechanisms involved in more rapid LTL shortening in this population. Despite limitations, these findings inform research on immunosenescence mechanisms of SLE.

Platelet-bound C4d Is Associated with Platelet Activation and Arterial Thrombotic Events

Yevgeniya Gartshteyn[1], Adam Mor[2], Daichi Shimbo[2], Leila Khalili[3], Teja Kapoor[4], Laura Geraldino-Pardilla[5], Roberta Vezza Alexander[6], Thierry Dervieux[7] and Anca Askanase[2], [1]Columbia University College of Physicians and Surgeons, Glen Rock, NJ, [2]Columbia University College of Physicians and Surgeons, New York, NY, [3]Columbia University Medical Center, New Haven, CT, [4]Columbia University College of Physicians and Surgeons, Leonia, NJ, [5]Division of Rheumatology, Columbia University Vagelos College of Physicians and Surgeons, New York, [6]Exagen Inc, Vista, CA, [7]Prometheus Biosciences Inc, Irvine, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes II: Bench to Bedside
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Platelets have a well-defined role in arterial thrombosis, and platelet-bound complement activation products (PC4d) correlate with vascular thromboses in patients with Systemic Lupus Erythematosus (SLE). The mechanistic link between PC4d and thrombosis has not been studied to date.

Methods: Using a cross-sectional design, we evaluated the associations between PC4d and arterial thrombosis, as well as between PC4d and platelet volumetric measures (count and volume). Platelet reactivity was assessed using the gold-standard technique of light-transmittance aggregometry (LTA). Decreasing doses of adenosine diphosphate (ADP) were used to induce platelet aggregation; a dose-response curve for ADP vs maximal aggregation was constructed for each patient. The ADP concentration at which 50% of maximal aggregation defined the EC_{50}. Patients on anti-platelet agents were excluded.

Results: 150 SLE patients were included; their average age was 40±13 years, 38% were antiphospholipid antibody (aPL) positive, 18% were taking prednisone ≥7.5mg/day, 29% had hypertension, 19% were smokers, 5% had di-

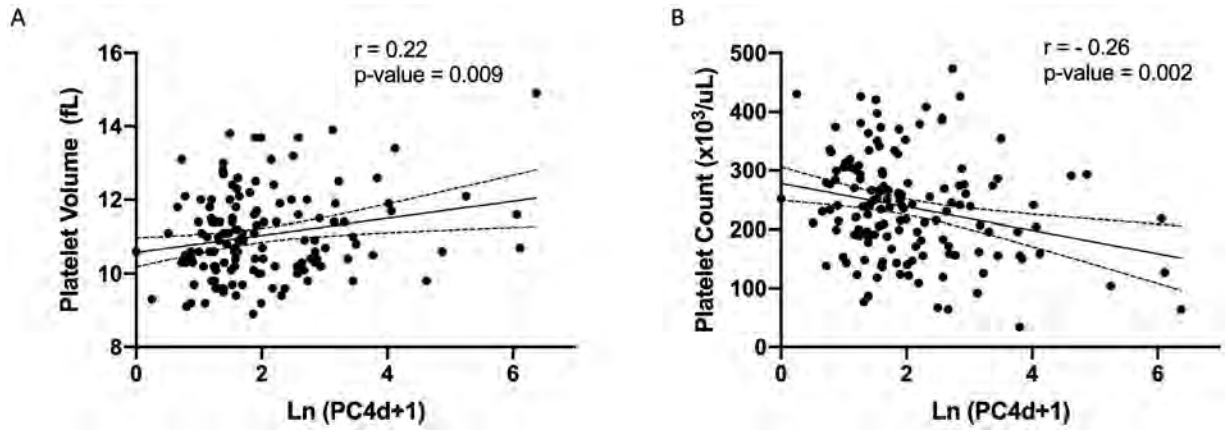

Figure 1. PC4d levels correlate with mean platelet volume and count. Correlation between PC4d levels, natural log transformed (Ln), and A, mean platelet volume and B, platelet count. r is the Pearson's correlation coefficient.

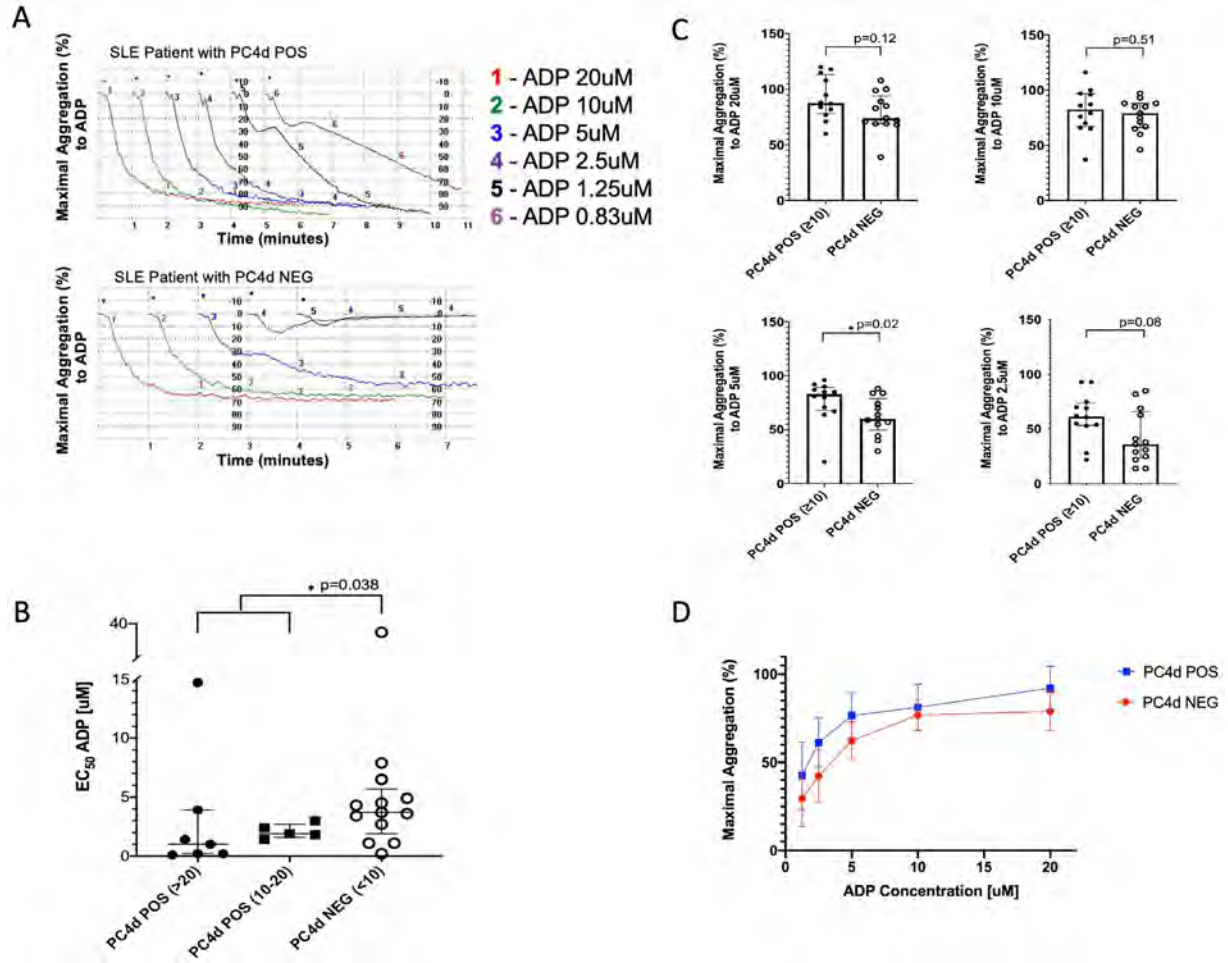

Figure 2. PC4d POS (PC4d≥10) platelets, as compared with PC4d NEG (PC4d≤10) platelets, aggregate more in response to addition of ADP agonist. A, Representative platelet aggregation curves from a PC4d POS patient (top) and a PC4d NEG patient (bottom). Decreasing concentrations of ADP agonist were added to platelet rich plasma and the aggregation response was recorded for six minutes. B, Platelet aggregation was analyzed as EC50, expressed as the ADP concentration [uM] that achieves 50% of the maximal aggregation. A lower EC50 indicates greater platelet sensitivity to the addition of the platelet aggregation agonist. C and D, Maximal platelet aggregation response after the addition of 20, 10, 5 and 2.5uM ADP agonist. Bars show the median ± IQR; Patients on aspirin were excluded. *p-value≤0.05.

abetes, mean total cholesterol and LDL 173±52 and 93±41 respectively. Thirteen arterial events (5 myocardial infarctions, 8 strokes) occurred within 5 years of enrollment. Arterial events were associated with PC4d levels (log transformed given positive skewness): for every one unit increase in log PC4d the odds of an arterial even increased by 70% (OR 1.7, p< 0.05) when adjusting for the significant covariates identified on the univariable analysis (aPL, smoking, and prednisone ≥7.5mg/day use). A PC4d cutoff of 10MFI had the greatest area under the curve of 0.71±0.08 for detecting arterial events.

PC4d levels correlated with lower platelet counts (r=-0.26, p=0.002) and larger platelet volumes (r=0.22, p=0.009). Platelet aggregation was tested in 12 patients with PC4d net MFI and 13 patients with PC4d< 10; aPL were present in 5/12 and 7/13 patients in each group. EC_{50} values were significantly lower in patients with PC4d10 net MFI compared with PC4d< 10 (1.6 vs. 3.7, p=0.038). The maximal aggregation response in PC4d positive patients, as compared to PC4d negative patients, trended towards greater aggregation at all concentrations of ADP agonist, and was statistically significant at 5 µmol.

Conclusion: PC4d is associated with arterial events in SLE. PC4d platelets were fewer in number, larger, and hyper-aggregable, suggesting that PC4d may be a mechanistic marker for vascular disease in SLE.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes II: Bench to Bedside
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Identifying populations at risk of SLE is essential to curtail inflammatory damage and identify individuals for prevention trials. Unaffected blood relatives (BRs) of lupus patients have increased risk of SLE. Some BRs have autoantibodies (AutoAbs) or SLE clinical features, but do not progress, some progress, but do not meet the

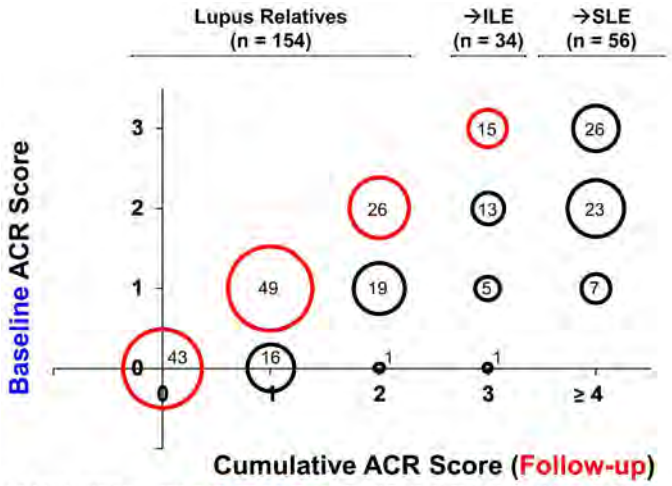

Fig. 1 ACR Criteria **Progressors** vs. **Non-progressors** Comparing Baseline (BL) and Follow-up (FU) Visits in LAUREL Cohort. Bubble plot of number of ACR criteria (ACR Score) at BL (y-axis, 0-3) vs. FU (x-axis, 0- ≥4). Lupus relatives with no change in number of ACR Score between BL and FU are **Non-progressors** (**red** circles), while all other lupus relatives met additional ACR classification criteria (**Progressors, black** circles). Incomplete Lupus (ILE) = 3 ACR criteria; SLE = ≥ 4 ACR criteria (1997 Update of the 1982 American College of Rheumatology Revised Criteria). Bubble size based on number of lupus relatives (within or adjacent to bubble) representing intersection of ACR Scores between BL and FU.

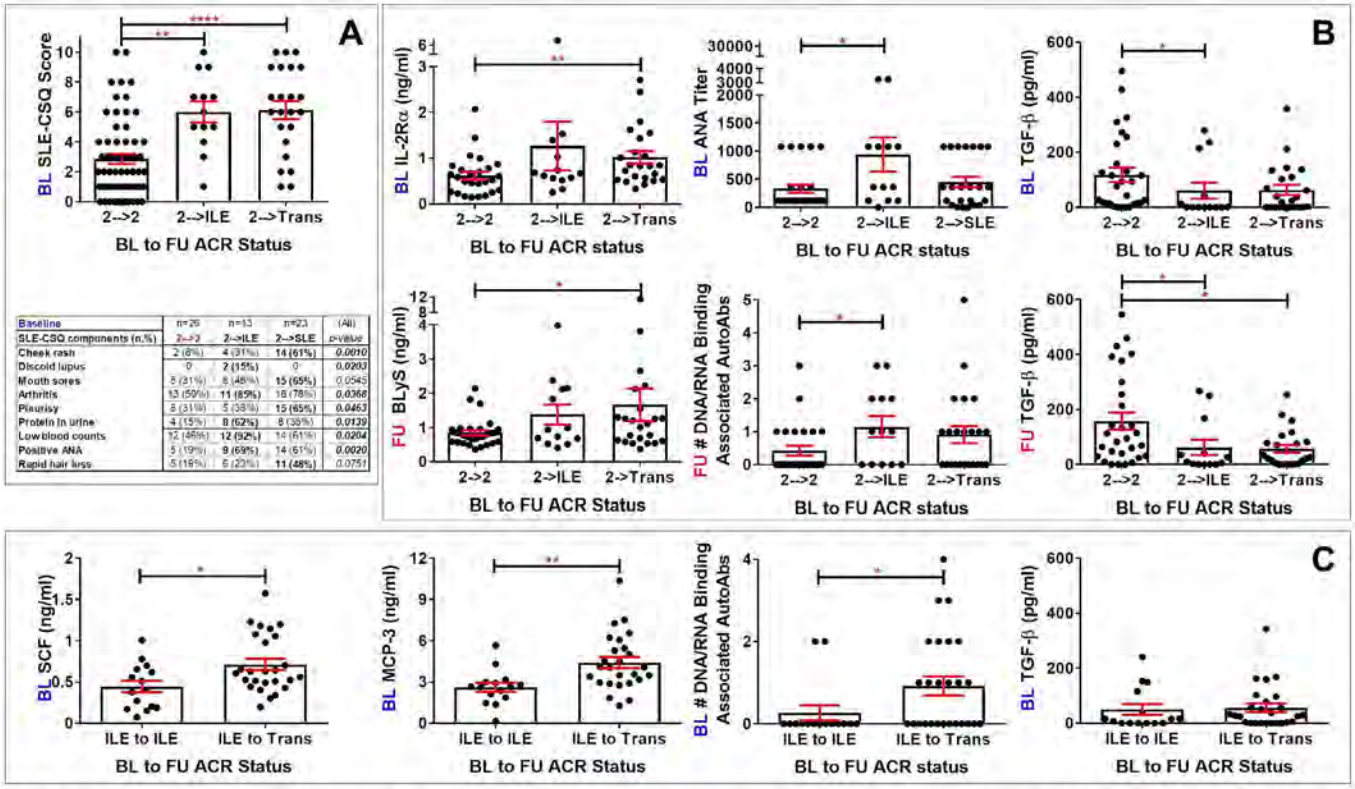

Baseline	n=26	n=13	n=23	(All)
SLE-CSQ components (n,%)	2-->2	2-->ILE	2-->SLE	p-value
Cheek rash	2 (8%)	4 (31%)	14 (61%)	*0.0010*

required ≥ 4 ACR classification criteria (incomplete lupus, ILE), while others progress to classified SLE. The goal of this study is to determine factors that distinguish previously healthy BRs who remain stable or subsequently progress to ILE or SLE.

Methods: This is a nested study of re-enrolled BRs of SLE patients (n=436) who previously enrolled in a genetics study (mean time to follow-up = 6.3 yrs) and did not meet SLE classification at baseline (BL). Of the 177 (41%) and 259 (59%) who did/did not meet additional ACR criteria at follow-up (FU) in this cohort, we compared the 56 BRs who transitioned to SLE (≥4 ACR criteria) to 34 BRs who met 3 ACR criteria (ILE) at FU and 154 race/sex/age (± 5 years) matched BRs with < 3 ACR criteria at FU. BRs provided clinical and demographic information, and completed the SLE-specific portion of the CTD Screening Questionnaire (CSQ) at BL and FU. Medical records were reviewed for ACR classification criteria. BL and FU plasma samples were assessed for autoantibody production (ANA, anti-dsDNA, aCL, Ro, La, Sm, nRNP, and ribosomal p antibodies) and for 52 soluble inflammatory and regulatory mediators by xMAP and ELISA assay.

Results: 133/244 (55%) of BRs evaluated in this nested cohort did not have any change in ACR criteria between BL and FU (**Fig. 1**, red circles, Nonprogressors [NP]), while the remaining 111 BRs accrued ≥1 classification criteria (**Fig. 1**, black circles, Progressors). There was no difference in time to FU between NP and Progressor BRs. No significant differences were seen in ACR criteria, either at BL or FU, between BRs with ILE at BL who were NP vs. those who progressed to SLE at FU. Yet, a number of differences were seen at BL in BRs meeting 2 ACR criteria at BL who were NP vs. those who progressed to ILE or SLE at FU. NP BRs with BL ACR Score = 2 were more likely to meet immunologic criteria ($p< 0.0001$), while those BRs with ACR score ≤ 2 who progressed to ILE or SLE were more likely to meet clinical criteria at BL, particularly malar rash ($p=0.0126$) or arthritis ($p=0.0054$). In addition, these same NP had significantly lower SLE-CSQ scores and features at BL (**Fig. 2A**), with lower plasma levels of IL-2Rα and lower ANA titers. At FU, ACR Score = 2 NP had lower levels of BLyS and accumulated fewer AutoAbs (**Fig. 2B**). At both BL and FU, levels of the regulatory mediator Native TGF-β were significantly higher in ACR Score = 2 NP (**Fig. 2B**). For those BRs with ILE at BL, those who progressed to SLE at FU had higher BL levels of SCF, MCP-3, and more AutoAb specificities than BL ILE NP BRs, with no difference in levels of Native TGF-β (**Fig. 2C**).

Conclusion: BRs of known SLE patients who progress to ILE or SLE compared to BRs who remain stable are more likely to have elevated inflammatory mediators, reduced regulatory mediators, and meet as few as one clinical ACR classification criterion. This suggests that ANA or serologic positivity alone is not predictive of progression to ILE or SLE in lupus relatives.

Abstract Number: 1512

Trajectory Analysis of Repeat Renal Biopsies Identified Previous Endocapillary Proliferation as Predictor of Damage and End Stage Renal Disease in Pure Membranous Lupus Nephritis

Andrea Fava[1], Avi Rosenberg[2], Serena Bagnasco[2], Paride Fenaroli[2], Jessica Li[1], Jose Monroy-Trujillo[2], Derek Fine[2] and Michelle Petri[3], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, [3]Johns Hopkins University School of Medicine, Baltimore

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes III: Lupus Nephritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Pure membranous (class V) lupus nephritis is considered a less aggressive phenotype, but renal fibrosis and chronic kidney disease may develop. Whether this chronic damage is related to previous inflammatory changes before the biopsy date has not been adequately studied.

Methods: All patients met the revised ACR and/or SLICC SLE classification criteria. We analyzed data from 220 patients with lupus nephritis (543 biopsies) with at least two renal biopsies obtained for clinical purposes. The median time between biopsies was 4 years [IQR 2-9 years]. Patients with pure membranous lupus nephritis on the second biopsy were observed for a median of 7.5 years [IQR 4-12 years]. New onset of end stage renal disease (ESRD) was defined estimated glomerular filtration rate (eGFR) < 15 ml/min/1.73m^2, initiation of dialysis, or renal transplantation. Histological chronic changes in pure class V lupus nephritis biopsies were scored by 2 nephropathologists using the NIH chronicity index and averaged when discordant.

Results: Lupus nephritis transitioned to a different class in 136/220 (62%) on repeat biopsy. Pure class V transitioned to proliferative lupus nephritis in 41.5% (**Figure 1A**). In patients with pure class V on the second biopsy, proliferative lupus nephritis was detected in 52% of the first biopsies (**Figure 1B)**. Surprisingly, the NIH chronicity index did not differ between class V vs. class III and IV (p=0.5) and it was numerically higher **(Figure 2A**). The chronicity index in repeat biopsies was higher than in first biopsies. In particular, patients with proliferative lupus nephritis in the first biopsy who transitioned to class V had numerically worse chronicity index than those with class V in the first biopsy

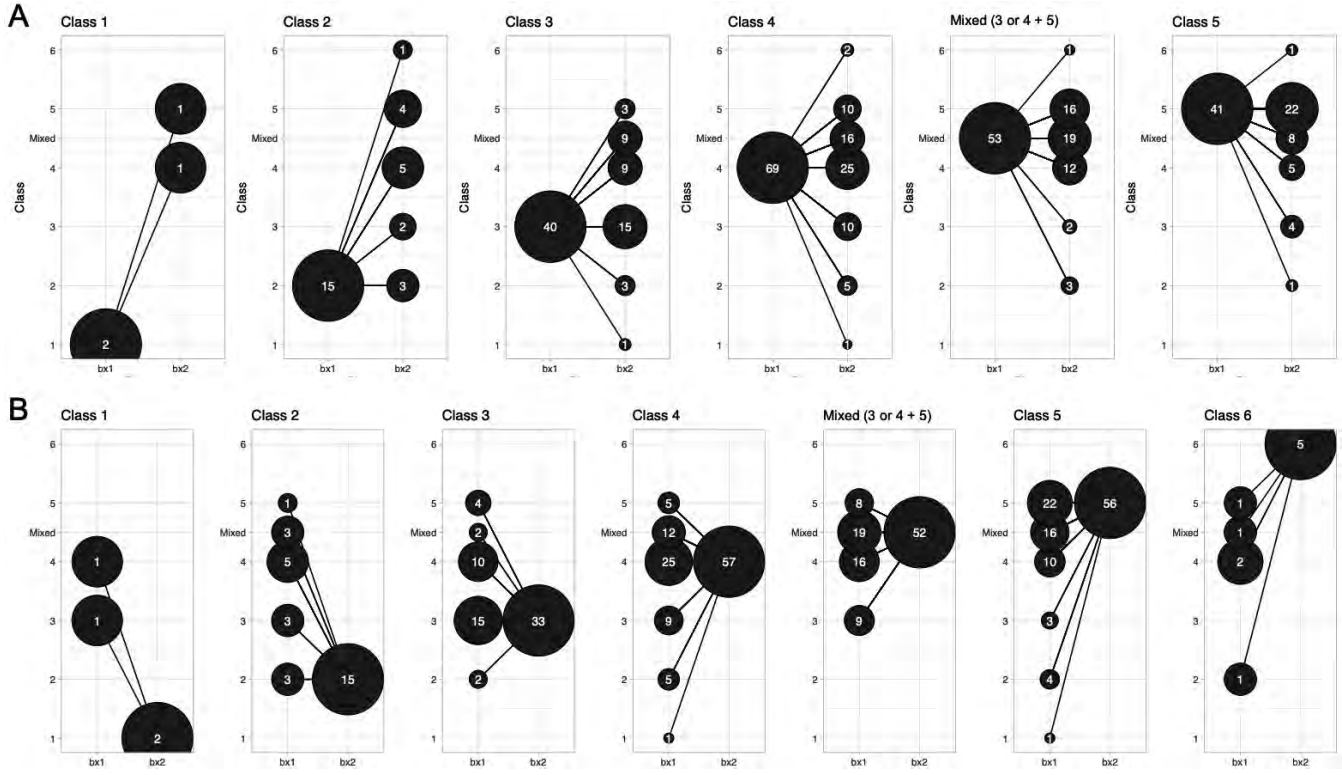

Figure 1. Transition across lupus nephritis classes in repeat renal biopsies. Change of ISN class from first (bx1) to second (bx2) biopsy according the class of the first (A) or the second biopsy (B). Numbers in the circles indicate the number of biopsies. The size of the circle indicates the proportion of biopsies within each ISN class for each plot.

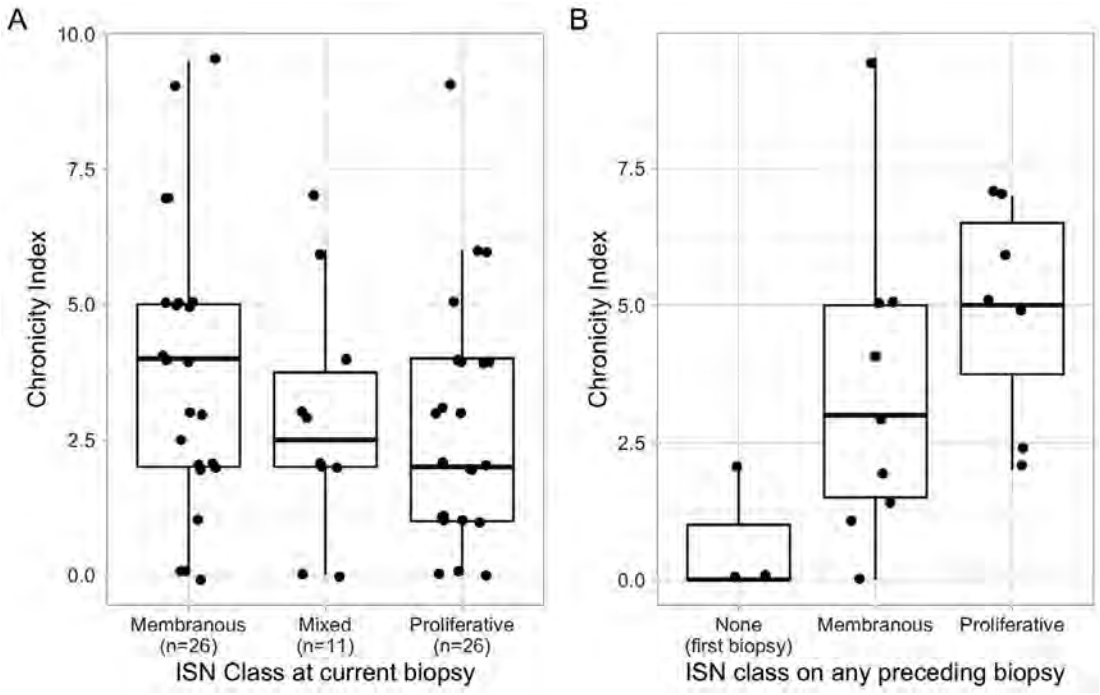

Figure 2. Chronic renal damage is observed in pure class V lupus nephritis and is associated with previous episodes of proliferative disease. (A) NIH chronicity index in the nephritis cohort. There was no statistically significant difference across groups. (B) NIH chronicity index in pure class V renal biopsies according to the class of the preceding renal biopsies.

(5 [3.75-6.5] vs. 3 [1.5-5], p=0.13) (**Figure 2B**). New onset ESRD was observed in 5/52 (9.6%) patients with pure class V. All 5 patients (100%) had proliferative lupus nephritis in the first biopsy (p=0.04) (**Figure 3**).

Conclusion: Lupus nephritis is a dynamic disease, with the separation of membranous and proliferative an artificial division based on a kidney biopsy. Non-proliferative lupus nephritis may be preceded by proliferative disease which is associated with risk of ESRD. Chronic damage, a known negative prognostic factor, is commonly observed in pure membranous nephritis and it is associated with previous proliferative disease. The management of membranous lupus nephritis should involve immunosuppression to address the high frequency of proliferative nephritis on repeat (or preceding) biopsies to proliferative disease and quantification of chronic damage should be pursued in all classes.

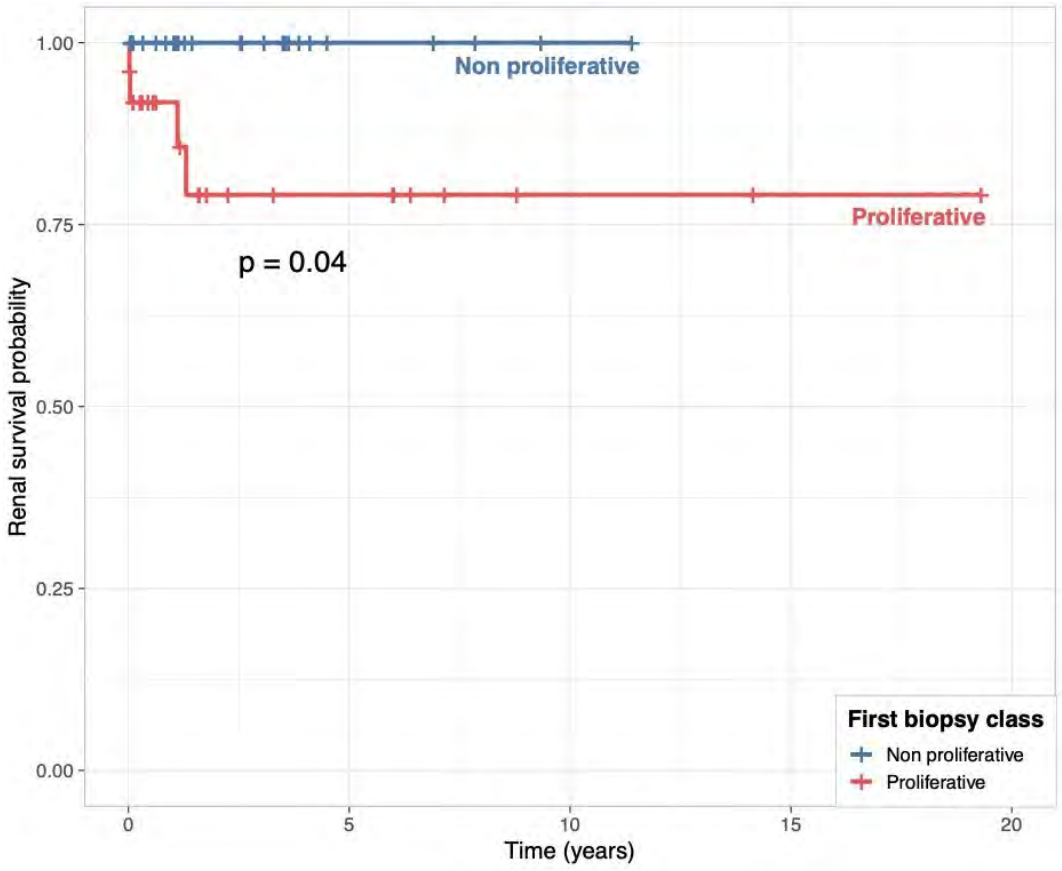

Figure 3. Renal survival of patients with pure class V lupus nephritis in a repeat renal biopsy according the histological class of the initial biopsy. P value was calculated using the log rank test.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes III: Lupus Nephritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Disease activity	Estimated difference in each disease activity item (relative to a person's average) as a function of differences in a person's Platelet C4d levels (relative to that person's average Platelet C4d levels)	
	Mean difference (95% CI)	**P-value**
PGA	0.01 (-0.005, 0.03)	0.1661
Total SLEDAI	0.05 (-0.01, 0.10)	0.1197
Specific items		
C3 level	-0.12 (-0.65, 0.41)	0.6642
C4 level	-0.03 (-0.15, 0.09)	0.6469
Log anti-dsDNA	0.001 (-0.03, 0.03)	0.9413
Urine protein/cr ratio	0.022 (0.01, 0.03)	0.0005

Estimated difference in disease activity variables at each visit per 10 unit difference in between the patient's Platelet C4d at that visit and the person's average Platelet C4d.

Pc4d level categories	% of visits with pr/cr>=0.5
<5	12/201 (6.0%)
5-<10	8/77 (10.4%)
10-<20	8/56 (14.3%)
20-<30	15/79 (19.0%)

Pr/cr ratio were missing in 10 visits

Percentage of patient visits with urine protein/cr ≥ 0.5 g at each platelet C4d level.

Background/Purpose: The SLE thrombosis risk equation contains three components: lupus anticoagulant (dRVVT), low C3 and C4d bound to platelets (platelet C4d). We examined the role of platelet C4d in association with thrombosis and proteinuria.

Methods: A total of 150 patients, consented to the study, were enrolled with a maximum of 3 visits per patient (424 visits): baseline, 6 month follow up, and 12 month follow up. Platelet C4d was measured by flow cytometry and expressed as net mean Fluorescence intensity (MFI). An abnormal platelet C4d was defined as a net MFI >20. GEE models were used to assess the relationship between disease activity measures and platelet C4d, accounting for within patient correlations. Linear mixed effects model was used to evaluate the within-patient associations.

Results: This analysis included 150 patients: 86% were female; 34.7% were African-American; and 55.3% were Caucasian. The mean age at diagnosis was 30.7 years (SD=14.1 years). 206 visits had a platelet C4d net MFI< 5, 77 visits had a net MFI between 5 and 10, 59 visits were 10-< 20, 27 were 20-< 30, and 54 were 30 or above. Adjusting for age at visit, race, and sex, platelet C4d was associated with low complement (OR 3.65 (2.11, 6.32), p< 0.0001) and increased anti-dsDNA (OR 1.77 (1.16, 2.72), p=0.0083). In a comparison of intermittent or persistently positive vs normal platelet C4d, positive platelet C4d was associated with deep vein thrombosis (OR 6.14 (1.43, 26.31), p=0.0144), any venous thrombosis (OR 12.3 (2.48,61.53), p=0.0022), and any venous or arterial thrombosis (OR 5.54 (1.84, 16.66), p=0.0023). A "within patient" analysis was also done (Table 1), showing a significant increase in urine protein/cr (p=0.0005). The percentage of patient visits with urine protein/cr ≥ 0.5 g at each platelet C4d level is shown in Table 2.

Conclusion: Platelet C4d represents the importance of immunothrombosis in SLE: that thrombosis reflects cross-talk between coagulation, complement and platelets. In our between patient analyses, platelet C4d was associated with serologies (low complement and anti-dsDNA) and both arterial and venous thrombosis. In our within patient analyses, it was associated with proteinuria. The association with proteinuria is novel and may be one of the ways that serologies – which are more common in lupus nephritis – act to effect thrombosis risk and organ damage.

Abstract Number: 1514

The Impact of Renal Transplantation on Cardiovascular Events Among Patients with End-State Kidney Disease Due to Lupus Nephritis: A Nationwide Cohort Study

April Jorge[1], Xiaoqing Fu[2], Yuqing Zhang[3], Hyon Choi[4] and Zachary Wallace[5], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Harvard Medical School, Boston, [4]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA, [5]Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes III: Lupus Nephritis
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: A major complication of systemic lupus erythematosus (SLE) is the progression of lupus nephritis (LN) to end-stage kidney disease (ESKD). Both SLE and ESKD are associated with increased risks of cardiovascular disease (CVD). Renal transplantation improves survival among patients with LN-ESKD. We sought to assess the potential impact of renal transplantation on CVD events in LN-ESKD.

Methods: We identified all incident cases of ESKD due to SLE (ICD9 710.0) in the United States Renal Data System (USRDS) between 2000 and 2014. The USRDS captures nearly all patients with ESKD in the US and includes the cause of ESKD by ICD9 code as well as demographics, comorbidities, and dates of waitlist entry, transplantation and death including the cause of death. Hospitalizations are additionally captured under Medicare Part A. We restricted our study population to patients who were waitlisted for transplant to limit the potential bias of confounding by indication and required Medicare enrollment. To account for time-varying variables, we performed sequential cohort matching on the basis of age, sex, and time since initiation of dialysis.We sequentially matched patients on their transplant date (index date) 1:1 with comparators who remained active on the waitlist on that date. Follow-up began at the date of transplant or matching and ended at the time of death, end of Medicare coverage, three years following the index date, transplantation (control group only, at which point a participant would be matched and begin follow-up time in the transplant group), or January 1, 2015, whichever came first. The outcomes of interest were CVD events, including non-fatal and fatal myocardial infarctions (MI) and non-fatal and fatal cerebrovascular accidents (CVA). We determined CVD event rates in the groups that did and did not have transplants, accounting for competing risk of death, and calculated hazard ratios (HRs) using a stratified Cox proportional hazards model, additionally adjusting for race/ethnicity, time on waitlist, first ESKD treatment modality, ESKD-specific comorbidity score, Organ Procurement and Transplant Network region, and history of any organ transplant.

Results: We identified 1,250 patients who had a transplant and 1,250 matched comparators. These groups were well-balanced by age, sex, time since initiation of dialysis, and time since entry onto the waitlist (**Table 1**). Over mean 2.26 years of follow up, 24 patients who had a transplant and 68 who did not have a transplant had a CVD event,

HR, hazard ratio; ESKD, end-stage kidney disease
*Per 1,000 Person Years; †Additionally adjusted for race/ethnicity, mean time on waitlist, first ESKD treatment method, comorbidity score, Organ Procurement and Transplant Network region, and history of organ transplant; ‡Numbers of events are too few to display among non-African American and Hispanic patient subgroups (not shown) and for myocardial infarction.

Table 2. Cardiovascular Events According to Transplant Status Among Matched Patients with End-Stage Kidney Disease Due to Lupus Nephritis

Conclusion: In this nationwide study of ESKD due to LN, renal transplantation was associated with a reduced risk of CVD events, including MI and CVA. Our findings highlight the importance of identifying barriers to transplantation in this population, as improved access could reduce CVD morbidity and mortality.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes III: Lupus Nephritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Poor therapeutic response rates contribute to the increased morbidity and mortality associated with lupus nephritis. Early identification of patients likely to respond is crucial as delays in treatment associate with worse outcomes. This study evaluated response using prospectively collected data obtained from the multi-ethnic/racial, multi-center Accelerating Medicines Partnership (AMP) lupus nephritis cohort. This cohort represents a real-world clinical setting using provider chosen standard of care and uniform collection of data.

Table 3. Change in laboratory values at 12 weeks compared to baseline by response status. Data are presented as median [IQR], 2-way p-values compare nonresponders to complete responders. *Includes only patients who had low complement at baseline.

tions recorded at each visit. Follow up data were available for 136 patients at 26 wks and 118 at 52 wks. Complete response was defined as a reduction in UPCR to < .5, a normal serum creatinine or no greater than 125% of baseline, and < 10 mg prednisone at time of response assessment. Patients were partial responders if UPCR decreased > 50% but remained >.5 and nonresponders if < 50% reduction in UPCR and/or did not meet the other response criteria.

Results: Medications were reported at 12 wks (Table 1). The complete response rate was 26% at both 26 and 52 wks. For patients undergoing a first biopsy, the rates were 37% and 40% and for those with repeat biopsies, the rates were lower at 21% and 19% respectively (p=0.042 at 26 wks; p=0.015 at 52 wks). The complete response at 26 wks was generally sustained with only 4 of 27 patients experiencing a relapse at 52 wks. At 26 wks, patients with membranous histology were less likely to be complete responders than patients with proliferative histology.

This trend was observed regardless of biopsy number and persisted for response status at 52 wks. Although baseline activity score did not predict responder status, complete responders had a significantly lower chronicity index than nonresponders (mean + SD, 2.26 + 2.22 vs 3.83 + 2.57, p=0.016) at 26 wks with similar results at 52 wks. Responder status at 26 and 52 wks whether first or repeat biopsy was independent of extrarenal disease at entry (Table 2). Complete responder status was associated with positive anti-dsDNA serology at baseline for repeat biopsy patients. Complete responders had a greater change in C3, hemoglobin, lymphocyte count, albumin, and UPCR at 12 wks compared to baseline values than nonresponders (Table 3). Similar trends were observed when considering response status at 52 wks.

Conclusion: The low complete response rates reported in the AMP cohort are consistent with findings in blinded controlled trials of standard-of-care therapies and support the critical need for new therapeutics particularly in patients undergoing repeat biopsies and those with increased chronicity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes III: Lupus Nephritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Lupus nephritis continues to be the complication with the highest standardized mortality ratio in Systemic Lupus Erythematosus (SLE), and a late diagnosis associates with worse outcomes. Clinicians traditionally rely on proteinuria to drive decisions regarding renal biopsy and subsequent management. Since threshold levels for such determinations are variable but critically important, this study leveraged the well-phenotyped multi-center multi- racial Accelerating Medicines Partnership (AMP) lupus nephritis cohort, to address whether urine protein to creatinine ratios (UPCR) between .5 and 1 differ from higher ratios with regard to clinical, serologic and histologic variables.

Methods: 239 patients fulfilling ACR or SLICC criteria for SLE with a random or 24 hr uPCR > or = .5 and histologic biopsy Class III, IV, V, or mixed were consecutively enrolled in AMP at the time of renal biopsy and demographics, clinical history, medications, disease activity as assessed by the hybrid SELENA-SLEDAI were recorded. Patients with biopsy Classes I, II and VI were ineligible. Patients were followed at 3, 12, 26 and 52 weeks.

Results: At baseline, 38 patients had a UPCR < 1 (A), 113 had a UPCR 1-3 (B) , and 88 had a UPCR > 3 (C). There were 14 additional patients with UPCR < 1, and 11 patients with UPCR > 1 who had biopsy class I or II. In group A, there were significantly more male patients (44% A; 23% B; 26% C, p=0.012) with no differences in age, race or ethnicity. Neither the SLEDAI nor serologic parameters (anti-dsDNA, C3, or C4) distinguished among the groups. Those in group C had a significantly increased creatinine and decreased hemoglobin and albumin compared to the other two groups (Table 1). Patients in group A trended toward having an increased frequency of proliferative histology (Table 2). This trend was not observed when considering patients for whom this was their first biopsy, but was significant for repeat biopsy patients (56% A; 41% B; 24% C, p=0.03). The activity index was independent of UPCR regardless of biopsy number. However, those in group C had a significantly higher chronicity index than those with lower UPCR. This correlation was shown for patients with a repeat biopsy (r=0.2299, p=0.003) but not first biopsy patients (r=0.0891, p=0.45). Although medications did not differ at baseline among the groups, at 12 weeks, for each group significantly more patients were taking Mycophenolate Mofetil than at the time of biopsy (Table 3).

Table 2. Biopsy characteristics by UPCR group.

Conclusion: A significant proportion of both first and recurrent biopsies in patients with a UPCR < 1 have proliferative histology and accompanying activity scores similar to that of patients with nephrotic range proteinuria. These results support renal biopsy at thresholds lower than a UPCR of 1 since histologic findings can inform therapeutic decisions.

Metabolic Regulation of Type 3 Innate Lymphoid Cells by Intestinal Bacteria-Derived Indoles in Ankylosing Spondylitis

Adam Berlinberg[1], Adam Lefferts[2], Emilie Regner[3], Andrew Stahly[4] and Kristine Kuhn[4], [1]University of Colorado, Denver, CO, [2]University of Colorado, Anschutz Medical Campus, Denver, CO, [3]University of California San Francisco, San Francisco, CA, [4]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Intestinal microbial dysbiosis, intestinal inflammation, and Th17 immunity are all linked to the pathophysiology of ankylosing spondylitis (AS); however, the mechanisms linking them remain unknown. Using three

unbiased approaches, we hypothesized that microbial dysbiosis in AS results in altered bacterial metabolites that expand IL-17-producing immune cells.

Methods: Healthy controls (HC, N=23) and patients with AS (N=24) were recruited while undergoing standard-of-care colonoscopy. Thirty distal colon biopsies and rectal swabs were obtained from each subject. Four biopsies were submitted for metabolomics screening via LC-MS while the remaining were homogenized and analyzed by single cell RNA sequencing (scRNA-seq, 2 subjects per group) and flow cytometry (remaining) to validate findings. Bacterial DNA was extracted from the rectal swabs, underwent shotgun sequencing, and analyzed using the HumanN2 software suite.

Results: ScRNA-seq identified a unique population in AS versus HC that transcriptionally segregated with T cells but lacked traditional T cell markers. Flow cytometry validated a significant expansion of type 3 innate lymphoid cells (ILC3s) in the intestinal tissue from patients with AS. By LC-MS, multiple metabolites within the tryptophan pathway were found to be significantly increased in AS vs HC, including indole-3-acetate (relative tissue concentration 153,583±156,338 vs 36,124±29,764, $p< 0.0003$) and indole-3-acetaldehyde (relative tissue concentration 2,615,095±1,890,967 vs 1,068,847±1,158,350, $p< 0.0005$), which are bacteria-specific products of tryptophan metabolism. Metagenomic analysis of the bacterial populations in AS identified altered metabolic pathways involving amino acid synthesis/degradation. In particular, there was a predilection towards tryptophan synthesis in HC while other tryptophan metabolism pathways were altered in AS.

Conclusion: In this study we identified altered tryptophan metabolism with a corresponding increase in ILC3s in intestinal tissue from patients with AS, which may link intestinal pathology to Th17 immunity in AS. Future studies will focus on the mechanistic pathways between tryptophan metabolism and ILC3 development.

The Role for Neutrophils in the Early Phases of Enthesitis in Spondyloarthritis

Zheni Stavre[1], Charles Bridgewood[2], Qiao Zhou[2], Yukiko Maeda[3], Jozsef Karman[4], Dennis McGonagle[5] and Ellen Gravallese[6], [1]University of Massachusetts Medical School-Rheumatology Division, Worcester, MA, [2]University of Leeds, Leeds, United Kingdom, [3]University of Massachusetts Medical School, worcester, MA, [4]Abbvie Inc., Worcester, MA, [5]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom, [6]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Neutrophils are present in the early phases of spondyloarthritis (SpA)-associated uveitis, skin and intestinal disease, but their role in enthesitis remains unknown. We investigated the role of neutrophils in the experimental SKG mouse model and in human axial enthesis tissue.

Methods: SKG mice have been shown to manifest multiple features of SpA. Arthritis in 9-week old female SKG mice was synchronized via intraperitoneal injections of curdlan and peripheral arthritis was scored weekly. Histology of ankles and spine were performed at serial time points. Formalin-fixed, paraffin-embedded (FFPE) tissue samples from entheseal sites around ankles and proximal tail vertebrae were obtained 2-3 weeks after curdlan injection (representing early inflammation) and subjected to laser capture microscopy. Whole transcriptome analysis was carried out using Affymetrix gene array MTA 1.0 and data was analyzed via IPA. Immunohistochemical staining for S100A8, a neutrophil product, and for MPO, a neutrophil marker, were performed at both sites. In conjunction with murine experimental work, normal human spinous process entheses were obtained from patients undergoing spinal decompression or thoracic or lumbar scoliosis surgery. IHC for MPO was performed on human FFPE enthesis to confirm the presence of neutrophils. Isolated neutrophils from peri-entheseal bone were stimulated with the fungal adjuvant zymosan and IFNγ and supernatants were probed for IL-23 secretion by ELISA.

Results: SKG mice developed early inflammation at enthesial sites around ankles and proximal tail vertebrae that included many neutrophils. The highest expression of transcripts arising from neutrophils included the alarmins S100A8 and S100A9 (calprotectin) and IL-23-associated genes, identified in both peripheral and axial enthesitis. In normal human axial enthesis, occasional neutrophils were evident. Upon fungal stimulation in vitro, these produced IL-23 protein, while isolated human entheseal fibroblasts stimulated with the fungal adjuvant mannan produced chemokines including IL-8, an important in the recruitment of neutrophils.

Conclusion: Neutrophil genes and pathways (including S100A8/9, cathepsin S, clec4d, clec7a) are upregulated early in the inflammatory infiltrate at entheseal sites. Neutrophils obtained from human entheses can be induced to produce IL-23 and may be an important early source of this cytokine that is critical for early SpA pathogenesis.

Abstract Number: 1519

Interleukin-17D, a Cytokine Derived from Stromal Cells, Attenuates Joint Inflammation

Sijia Chen[1], Catherine Manning[2], Melissa van Tok[3], Yukiko Maeda[4], Daniel Montoro[5], Jung-Min Kim[6], Jeroen den Dunnen[3], Nataliya Yeremenko[3], Jae-Hyuck Shim[4], Dominique Baeten[7] and Ellen Gravallese[8], [1]Brigham and Women's Hospital, Boston, [2]Brigham and Women's Hospital, Boston, [3]Amsterdam University Medical Centers, Amsterdam, Netherlands, [4]University of Massachusetts Medical School, worcester, MA, [5]Broad Institute of Massachusetts Institute of Technology and Harvard, Boston, [6]University of Massachusetts Medical School, Worcester, [7]UCB Pharma / Amsterdam University Medical Centers, Amsterdam, Netherlands, [8]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Interleukin(IL)-17D is a little recognized member of the IL-17 family of cytokines. While the activities of IL-17A and IL-17F in the pathogenesis of spondyloarthritis (SpA) are established, a role for IL-17D in SpA and tissue inflammation has not yet been demonstrated.

Methods: In order to identify the cell types that express IL-17D in SpA synovial tissue and in primary human cells, we performed RNA sequencing, qPCR and IF analyses. We isolated fibroblast-like synoviocytes (FLS) from inflamed SpA synovial tissues, and stimulated cultured FLS with cytokines or subjected FLS to osteogenic differentiation. To determine a potential role for IL-17D in bone, femurs from *il17d*$^{-/-}$ mice were assessed by micro-computed tomography analysis. Serum transfer arthritis (STA) was also induced in *il17d*$^{-/-}$ mice and we performed subsequent Luminex assays to assess circulating cytokine expression at peak inflammation.

Results: In SpA inflamed synovial tissues, we demonstrate that *IL-17D* mRNA is more highly expressed than any other IL-17 family member, and that IL-17D is expressed by FLS that stain positive for markers of multipotent mesenchymal stromal cells (MSCs). *In vitro,* FLS express *IL-17D* at baseline. Osteogenic differentiation upregulates *IL-17D* mRNA in FLS when differentiated to osteoblast-like cells. *In vivo*, cells with the morphologic appearance of osteoblasts in bone sections also express IL-17D. However, *Il17d*$^{-/-}$ mice fail to demonstrate a bone phenotype, suggesting that IL-17D deletion does not impact bone homeostasis. Importantly, there is an inverse correlation between IL-17D expression and inflammation *in vitro and in vivo.* Anti-IL-17A treatment in SpA patients decreases synovial inflammation, and correlates with an increase in synovial *IL-17D* mRNA expression. Additionally, *Il17d*$^{-/-}$ mice demonstrate a more severe arthritis than littermate controls, and show elevated levels of pro-inflammatory cytokines at peak inflammation in STA, including TNFα, MCP-1 and MIP-1α.

Conclusion: These data demonstrate that IL-17D is the most highly-expressed IL-17 family member in inflamed SpA synovium. We localized IL-17D expression to stromal cells, including FLS. Furthermore, *IL-17D* expression is downregulated during human and experimental SpA inflammation, and evidence from STA indicates that this cytokine may exert an anti-inflammatory effect on joint inflammation.

Characterisation of Rheumatoid and Psoriatic Arthritis Synovial Fibroblasts

Clare Cunningham[1], Sharon Ansboro[1], Sarah Wade[1], Candice Low[2], Ronan Mullan[3], Douglas Veale[4] and Ursula Fearon[5], [1]Trinity College Dublin, Dublin, Ireland, [2]EULAR Centre for Arthritis and Rheumatic diseases, St Vincents University Hospital, UCD, Dublin, Ireland, [3]Adelaide and Meath Hospital, Dublin, Dublin, Ireland, [4]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland, [5]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: The synovial inflammation observed in Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) is characterised by synovial fibroblast hyperplasia, leukocyte infiltration, neoangiogenesis and hypoxia. These features cause the inflamed synovium to adopt a tumour-like phenotype which facilitates the invasion of adjacent cartilage. Pathogenic differences between RA and PsA are observed in the vascular morphology pattern, synovial tissue (ST) cellular infiltrates and lining-layer thickness. While synovial fibroblasts (FLS) have generally been considered as

a heterogeneous population of cells with specific functions, recent studies have identified distinct FLS subsets which differentially contribute to disease pathogenesis. $CD34^{-}THY1^{+}$ FLS are increased in RA synovial sublining compared to that of OA, and are reported to sustain synovitis. In contrast, $CD34^{-}THY1^{-}$ FLS were elevated in the OA synovial lining layer and are thought to contribute to cartilage and bone degradation. The aim of this study was to compare the phenotypic, metabolic and functional profiles of PsA-FLS compared to RA-FLS.

Methods: Single cell analysis of PsA and RA ST cell suspensions were analysed for specific synovial fibroblast subsets and metabolic markers by 14-colour flow cytometry. Fibroblasts were defined as CD45-CD146-CD31-podoplanin+. Subsets were further defined according to CD34 and THY1 expression and analysed for pmTOR, pS6, GLUT1 and pSTAT3 expression. The metabolic profiles of primary RA- and PsA-FLS were analysed using the XFe96-Extracellular Flux Analyzer. Gene expression for metabolic and inflammatory mediators was determined by quantitative-PCR. Cell migration and invasion were determined by wound repair scratch assays and Transwell Matrigel™ invasion chambers. All patients satisfy ACR classification criteria for RA and CASPAR criteria for PsA.

Results: A significant increase in the $podoplanin^{+}CD34^{-}THY1^{+}$ FLS subset was demonstrated in RA synovial tissue single cell suspensions compared to that of PsA ($p=0.0003$). In contrast, a significant increase in $podoplanin^{+}CD34^{-}THY1^{-}$ FLS subset was observed in PsA ($p< 0.0001$). In both RA and PsA, GLUT1 and pSTAT3 were slightly elevated in the $THY1^{+}$ subset, while pmTOR and pS6 were slightly elevated in the $THY1^{-}$ subset. Expression of glycolytic genes HK2, GAPDH, PKM2 and LDHA and the glucose receptors GLUT-1 and GLUT-3 were significantly increased in cultured RA-FLS compared to PsA-FLS. This was paralleled by an overall increase in the ECAR:OCR ratio in RA-FLS compared to PsA-FLS, demonstrating a shift to a more glycolytic phenotype in RA, an effect associated with an increase in disease activity score, DAS28. Finally, a significant increase ICAM-1 and MMP-1 expression was demonstrated in RA-FLS compared to PsA-FLS, in addition to an increase in their migratory and invasive capacity.

Conclusion: This study demonstrates, for the first time, distinct differences in FLS subsets in RA synovial biopsies compared to PsA, with an increase in the more invasive, $podoplanin^{+}CD34^{-}THY1^{+}$ FLS observed in RA. This was consistent with an increase in their metabolic profile and functional capacity and reflects the clinical observations of disease activity.

A Novel Gut-joint Migratory TCRab+ Cell Subset Relies on sphingosine-1-phosphate for Tissue Localization

Adam Lefferts[1], Emilie Regner[2], Eric Norman[3], David Claypool[4], Hannah Schultz[4], Danielle Sansone-Poe[4] and Kristine Kuhn[5], [1]University of Colorado, Anschutz Medical Campus, Aurora, CO, [2]University of California San Francisco, San Francisco, CA, [3]University of Colorado, Anschutz Medical Campus, Denver, [4]University of Colorado, Anschutz Medical Campus, Aurora, [5]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Despite findings of similar immune cellular phenotypes in the gut and joint of patients with spondyloarthritis, the mechanistic linkage between intestinal immunology and the subsequent pathogenic targeting of the enthesis by gut-originating cells have not been defined. Prior work in our lab demonstrated a correlation between the numbers of colon intraepithelial lymphocytes (IELs) and circulating lymphocytes, leading us to hypothesize that IELs migrate from the colon to the enthesis as one mechanistic link between the colon and joint.

Methods: We used the KikGR transgenic mouse in which colonoscopy guided violet light allows labeling of cells in the distal colon, termed photo-conversion. Following photo-conversion, we evaluated the Achilles enthesis for the presence and characteristics of labeled cells by flow cytometry in two models: the TNF^{DARE} model of spontaneous inflammatory bowel disease and arthritis and hock injection of complete Fruend's adjuvant (CFA). IEL recruitment to the colon epithelium was evaluated using microarray and confirmed by qPCR, the pan spingosine-1-phosphate receptor (S1PR) antagonist FTY720 to interrupt cellular trafficking, and LysM-Cre x $MyD88^{fl/fl}$ mice.

Results: Following photo-conversion of the distal colon, we identified colon-labeled CD3+TCRab+ cells in the Achilles enthesis within 72 hours. The numbers of trafficked T cells significantly increased in the entheses during inflammation caused by either CFA or in TNF^{DARE} mice compared to non-arthritic controls; however, the percentage of gut-derived cells remained at ~10% regardless of the presence of arthritis. Following this discovery, we hypothesized that the function of IELs may be affected by their interactions in the gut. Therefore, we investigated how IELs localize and interact with the colon epithelium. By microarray and qPCR, we identified that the trafficking receptor S1PR1 was significantly expressed on IELs compared to lamina propria T cells. The S1PR inhibitor FTY720 blocked IEL localization to the colon epithelium, and gut-joint trafficking was ablated. Finally, we identified that MyD88 expression by myeloid cells was critical for IEL localization via S1P, and treatment of bone marrow derived dendritic cells (BMDCs) with cecal contents induces *sphk1* expression in a MyD88 dependent fashion, which was sufficient to induce T cell migration in an S1P-dependent fashion.

Conclusion: Altogether, our data demonstrate a model of gut-joint trafficking. Bacterial signals through MyD88 in myeloid cells stimulate the S1P pathway to recruit IELs to the colon epithelium. Although the specific interaction with the epithelium and impact on T cells is yet to be elucidated, we hypothesize that this interaction functionally alters IELs. The colon IELs then traffic to the joint, where their role in inflammation likely depends upon the functional programming they receive in the intestine. These findings may shed light into pathogenic mechanisms connecting the gut and joint in spondyloarthritis.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: To investigate alterations in the serum proteome of patients with systemic sclerosis (SSc)-associated pulmonary hypertension (PAH), to identify proteins that correlated with hemodynamic severity and to determine their possible role in the pathogenesis of the disease.

Methods: Eligible patients were recruited from Boston, Lille, Kremlin-Bicêtre and Grenoble SSc and PH referral centers. Patients were included if they fulfilled the following criteria: diagnosis of SSc according to 2013 ACR/EULAR criteria, limited cutaneous subtype, no extensive interstitial lung disease (ILD) according to Goh criteria, and no treatment with PAH-specific therapy. Patients were classified as cases if they had a definitive diagnosis of PAH confirmed by right heart catheterization (RHC) and a serum sample collected on the same day as RHC. They were classified as controls if they had no sign suggestive of PAH on echocardiography.

Results: In a first exploratory step, serum expression of 1129 proteins was assessed in 15 cases and 16 controls by a high-throughput proteomic assay (SOMAscan). We identified 53 proteins differentially expressed between the 2 groups. Among these 53 candidates, only 2 correlated significantly with pulmonary vascular resistance (PVR): chemerin (p=0.01, ρ=0.62) and SET nuclear proto-oncogen (SET) (p=0.01, ρ=0.62).

To validate these results, serum levels of chemerin and SET were measured by ELISA assay in 25 additional cases and 19 additional controls. Chemerin levels were confirmed to be significantly higher in cases (p=0.01) and correlated with PVR (p=0.01, ρ=0.46) in this independent cohort.

In a second step, to study the potential pathophysiological role of chemerin, we performed confocal immunofluorescence analyses on explanted lungs of healthy controls, SSc-ILD without PAH and SSc-PAH patients. Chemerin receptor, CMKLR1, was significantly increased on SSc-ILD and SSc-PAH pulmonary artery smooth muscle cells (PA-SMC).

We then tested the effect of chemerin on PA-SMC proliferation by stimulating PA-SMCs from idiopathic pulmonary arterial hypertension (iPAH) patients with serum from SSc patients with and without PH, in the presence or absence of a CMKLR1 inhibitor. PA-SMCs from iPAH were confirmed to have higher mRNA expression of CMKLR1 than controls (p=0.03). Serum from SSc-PH patients induced a significantly higher PA-SMC proliferation (p=0.005) than serum from controls. This difference was no longer significant (p=0.69) when adding the CMKLR1 inhibitor aNETA.

Conclusion: Chemerin is a surrogate biomarker for PVR in SSc-PAH. Increased chemerin and its receptor, CMKLR1, contribute to the SSc-PAH pathogenesis by inducing PA-SMC proliferation.

Pulmonary Cytokine, Chemokine and Growth Factor Profiles of Distinct Radiographic Patterns of Interstitial Lung Disease in Systemic Sclerosis

Elizabeth Volkmann[1], Donald Tashkin[2], Ning Li[2], Mei Leng[2], Grace Kim[2], Jonathan Goldin[2], Airi Harui[2] and Michael Roth[2], [1]University of California, Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: The radiological hallmarks of systemic sclerosis-related interstitial lung disease (SSc-ILD) include interstitial inflammation (ground glass opacity) with reticular changes (fibrosis). The precise pathobiology of these radiographic manifestations is unknown. We hypothesized that certain cytokines, chemokines and growth factors may uniquely associate with distinct radiographic patterns of ILD in SSc.

Methods: We measured the concentrations of 68 chemokines, cytokines and growth factors from bronchoalveolar lavage (BAL) fluid of 103 patients with SSc-ILD who participated in Scleroderma Lung Study I (1). SLS I randomized SSc-ILD participants to 1 year of oral cyclophosphamide versus placebo, followed by 1 year off all treatment. Bronchoscopy was performed at baseline in SLS I. Quantitative imaging analysis (QIA) was used to calculate the extent of radiographic fibrosis (QLF) and ground glass opacity (GGO) on the baseline HRCT of the chest. Kendall tau's correlations were calculated to examine the relationship between BAL proteins and QLF and GGO scores, separately, for the whole lung. Multivariable linear regression models were created to determine the key BAL proteins associated with QLF and GGO scores using a backward selection process in combination with evaluation of the Akaike information criterion (AIC). The bootstrap procedure was employed for internal validation.

Table 1. BAL proteins associated with quantitative extent of radiographic fibrosis in the whole lung based on a multivariable linear regression model.*

BAL Protein	Estimate	Standard Error	P-value
IL-4	-4.86	2.04	0.0198
MCP-3	4.23	1.56	0.0082
RANK	1.71	0.68	0.0140
TNF-α	-2.40	0.84	0.0057
HGF	1.87	1.13	0.1029
Endoglin	-0.01	0.01	0.0748
VEGF	-1.28	0.90	0.1594
TGF-α	2.67	2.25	0.2396

*Adjusted R-square for the model = 0.38; AIC = 472.39.

Table 2. BAL proteins associated with quantitative radiographic extent of ground glass opacity in the whole lung based on a multivariable linear regression model.*

BAL Protein	Estimate	Standard Error	P-value
IL-15	-1.88	0.84	0.0271
IL-5	-5.26	2.41	0.0318
IFN-γ	4.10	2.04	0.0484

*Adjusted R-square for the model = 0.10; AIC = 484.73.

Results: QLF scores correlated significantly with 25 different proteins from several biologic pathways including pro-fibrotic factors (transforming growth factor beta [TGF-β], platelet-derived growth factor [PDGF]), proteins involved in tissue remodeling (Matrix metallopeptidase [MMP]-1,7,8,9; Hepatocyte growth factor [HGF]), and those involved in monocyte/macrophage migration and activation (Monocyte chemoattractant protein [MCP]-1,3; macrophage colony-stimulating factor [MCSF]). GGO scores correlated with 7 different proteins that are mediators of immune response and inflammation (interleukin [IL]-5, IL-15, IL-1 receptor antagonist and interferon gamma [IFN-γ]) with limited overlap to proteins that related to fibrosis. Vascular endothelial growth factor (VEGF) levels were lower in patients with more extensive GGO and QLF, suggesting that vascular changes are an important feature of SSc-ILD. In the multivariate models, IL-4, MCP-3, receptor activator of NF-κB (RANK), tumor necrosis factor alpha (TNF-α) were independently associated with QLF (Table 1); whereas, IL-15, IL-5 and IFN-γ were independently associated with GGO (Table 2).

Conclusion: In a diverse and comprehensive analysis of BAL proteins from a well-characterized SSc-ILD cohort, the findings suggest that specific biological signatures underlie distinct radiographic features of ILD in SSc. These proteins may represent important therapeutic targets and serve to help define specific phenotypes of SSc-ILD (inflammation predominant versus fibrosis predominant), which may ultimately lead to the development of personalized treatment approaches in this patient population.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Basic Science

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: To explore the pathogenic potential of lymphocytes in systemic sclerosis (SSc) and granulomatosis with polyangiitis (GPA), a humanized mouse model was generated by transferring human peripheral blood mononuclear cells (PBMC) into immunocompromised mice.

Methods: PBMC derived from patients with SSc and GPA were isolated, characerized by flow cytometry and infused into RAG2/IL2rg double- deficient mice. PBMC from healthy donors (HD) and from rituximab-treated SSc patients served as controls. Twelve weeks later, peripheral blood and tissues from recipient mice were collected and the latter examined by histology and immunohistology. Autoantibodies were analyzed in peripheral blood using ELISA or immunofluorescence assay on HEp-2 cells.

Results: Following transfer of PBMC derived from patients with SSc, total IgG and, in particular, SSc-related autoantibodies such as anti-AT1R, anti-ETAR antibodies and ANA were detected in recipient mice. In addition, infiltration of human lymphocytes was observed in multiple organs of recipient mice. In addition, infiltrations of human lymphocytes were observed in multiple organs of recipient mice, particularly lung, kindey and muscles. By contrast, although PBMC derived from HD or GPA patients also survived in recipient mice, no production of human autoantibodies and only marginal infiltration of human immune cells in lung, kidney, or muscles was found. Furthermore, transfer of PBMC derived from SSc patients predominantly featured an infiltration of human B cells in lung, kidneys and muscles, while no such cells were detected following transfer of PBMC derived from rituximab-treated SSc patients.

Conclusion: The humanized mouse model using adoptive transfer is indicative for intrinsic immune cell defects and argues for a pivotal role of B cells in the pathogenesis of SSc. It provides a powerful tool to study interstitial lung disease as so far under-recognized disease manifestations such as myositis and interstitial nephritis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Systemic Sclerosis & Related Disorders – Basic Science

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Genome-wide association study (GWAS) from the Genome Research in African American Scleroderma Patients (GRASP) cohort has identified the human leukocyte antigen (*HLA*) region as the strongest genetic risk factor in SSc. The functional roles of *HLA* variants in SSc susceptibility are largely unknown. We hypothesize that SSc-associated HLA variants overlap with one of the classes of *cis*-regulatory modules (CRMs) such as enhancer to regulate gene expression. CRMs can be mapped using DNase I hypersensitive site sequencing (DNase-Seq) or assay for transposase-accessible chromatin with high throughput sequencing (ATAC-Seq) giving information regarding chromatin accessibility. Thus, chromatin accessibility in the SSc-relevant cell types would be crucial in interpreting the function of these variants.

Methods: Genotyping data using the Illumina Multi-Ethnic Global array (MEGA) from the GRASP cohort were analyzed to identify the top *HLA* variant. Expression quantitative trait loci (eQTL) analysis was performed for the risk variants using RNA sequencing data from the Genotype-Tissue Expression (GTEx) project. Epstein-Barr virus-transformed B (EBV-B) cells with wild type, heterozygous and homozygous alleles for the most highly associated *HLA* variant were used to confirm the expression of *HLA-II* genes using RNA-sequencing. Protein expression was confirmed by flow

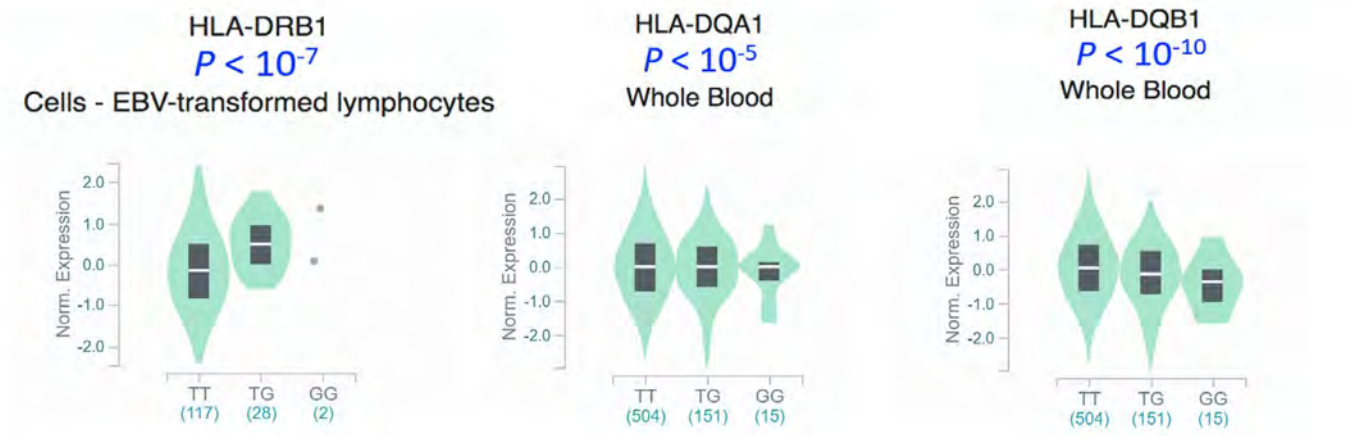

Figure 1. GTEx HLA-DRB1, HLA-DQA1 and HLA-DQB1 expression by rs9469201 variant

cytometry and confocal microscopy. Chromatin accessibility at the variant position in EBV-B cells is being identified using ATAC-seq.

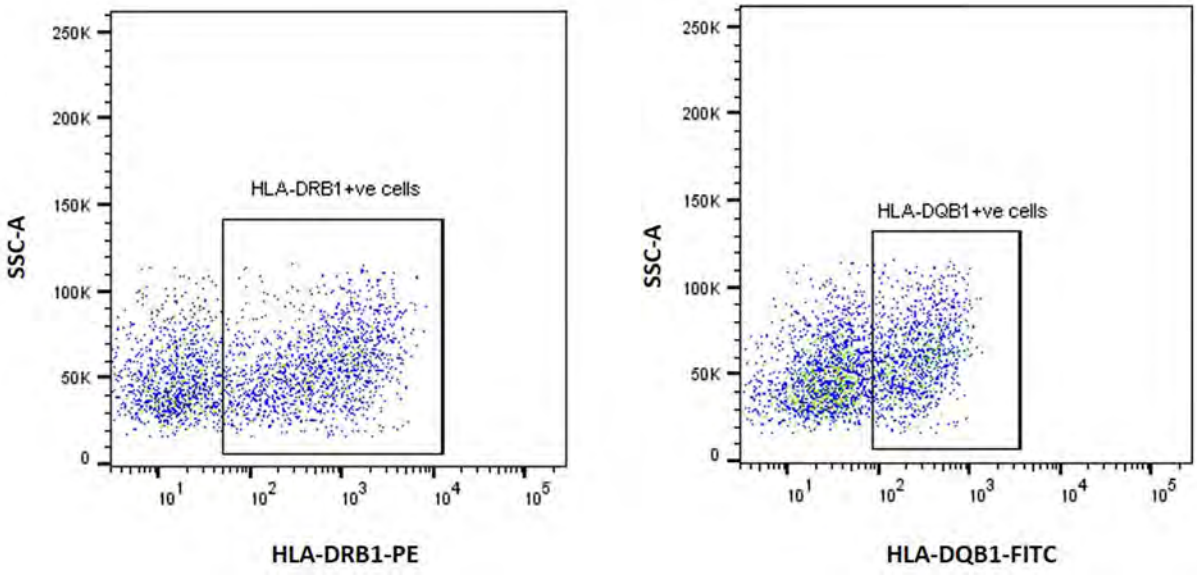

Figure 2. Flow cytometry plots for EBV-B cells with wild type allele stained for HLA-DRB1 and HLA-DQB1 protein using fluorochrome conjugated antibodies.

Results: The top variant in the African American GWAS was rs9469201, near the *HLA-DQA1* gene with an odds ratio of 2.13 (P=4.5x10^{-20}). eQTL analysis suggested decreased expression of *HLA-DQA1/-DQB1* (in whole blood) and increased expression of *HLA-DRB1* (in EBV-B cells) for the risk allele (Figure 1). This is particularly intriguing because we have previously reported two HLA-DRB1 alleles (*HLA-DRB1*08:04* and *-DRB1*11:02*) as independent risk factors in African American SSc. The rs9469201 variant was found not to be in linkage disequilibrium with the *HLA-DRB1*08:04* allele. Flow cytometry (Figure 2) and confocal microscopy (Figure 3) confirmed the expression of HLA-DRB1 and HLA-DQB1. ATAC-Seq analysis of the EBV-B cells is currently ongoing.

Conclusion: Our preliminary findings suggest that peptide presentation by HLA molecules as well as the relative expression of the specific HLA molecule presenting the peptide are both important in SSc pathogenesis. Future direc-

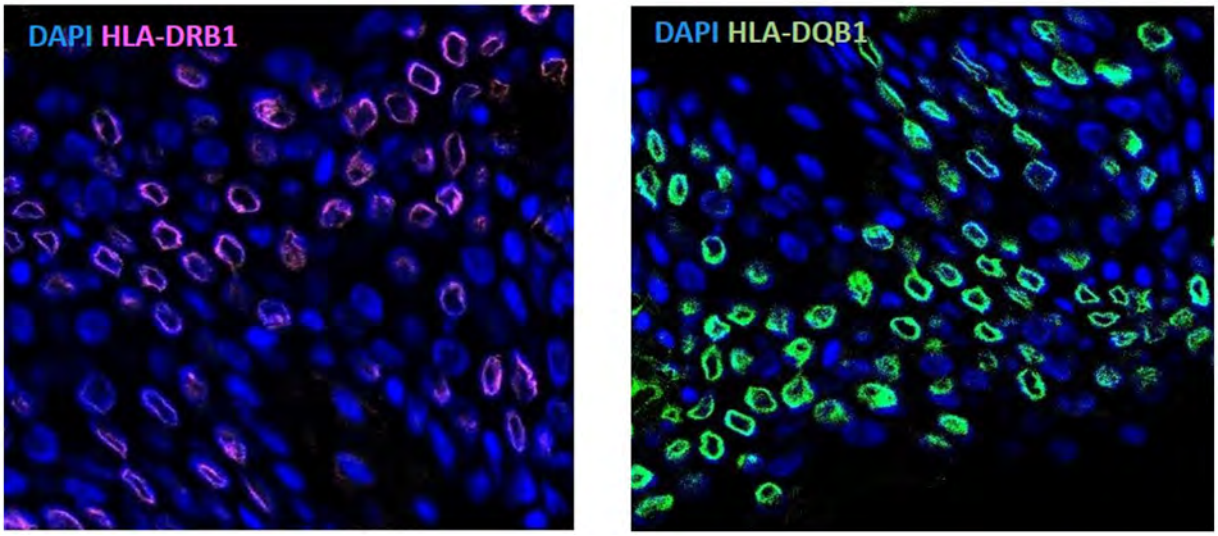

Figure 3. Confocal microscopy image for HLA-DRB1 and HLA-DQB1 stained cells for the wild type allele.

tions will involve CRISPR/Cas9 based deletion of CRMs-with overlapping *HLA* variants, and subsequent evaluation of the changes in *HLA-II* gene expression. Transcription factor binding at the *HLA* variant site will be accessed using chromatin immunoprecipitation with sequencing (ChIP-seq) in EBV-B cells. This study will elucidate the functional role of the *HLA* variants in allele-specific *HLA-II* gene expression in SSc.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Systemic sclerosis (SSc) is characterized by fibrosis, microangiopathy and immune dysregulation. Despite many years of research, the pathogenesis of SSc is poorly understood; there is no approved therapy and biomarkers for early diagnosis, assessment of disease activity, prediction of complications and prognosis. Current technologies that investigate bulk populations of cells lack the depth and resolution needed to define the small skin stromal and immune subsets that drive SSc progression. Advances in the field of single-cell RNA has opened the way for unbiased dissection of complex niches into single cells, and identification of unique cell subtypes, pathways, markers and target genes. Our aims are to understand SSc pathogenesis by comprehensive characterization of stromal and immune cells in the skin and blood of SSc patients and detection of specific intra-skin cell states, pathways, and cell-cell interactions in SSc patients compared to healthy controls.

Methods: We applied the massively parallel single cell RNA-seq (MARS-seq) technique developed in our lab to conduct a comprehensive single-cell analysis of skin stromal and immune cells obtained from punch biopsy together with blood immune cells from 79 SSc patients (44 dSSc, 35 lSSc) at different stages of disease progression, and 35 healthy controls. The perturbed signaling pathways, pathogenic stromal or immune cell subsets are characterized using CyTOF, Immunohistochemistry, **P**hysical **I**nteracting **C**ell sequencing (**PIC**-seq), and *in vitro* functional assays.

Results: We collected data from a total of 49,831 high-quality skin stromal cells, and 61,365 high-quality blood and skin immune cells. Our MetaCell analytical method resulting in a detailed map of 389 meta cells in the immune cell compartment organized into 14 broad lineages (e.g skin T, B and NK cells, Dendritic cells, Monocyte). In the stromal cell compartment, we found 294 meta cells organized into 17 broad lineages including: Fibroblasts, Pericytes, Vascular cells, and other cells. To our surprise, analysis of the immune cell compartment revealed only minor changes in the cell composition and gene expression in patients compared with controls. In the dermal fibroblast lineage we found a small cluster of cells that were significantly diminished in the SSc patients compared with control. This subset expressed genes associated with fibrosis, vascular remodeling, and most importantly, display stem cell-like phenotypic markers that are different from other known skin stem cells located in the hair follicle and subcutaneous fat. We further found significant increased number of subsets of pericytes and vascular cells in SSc patients compared with controls. Finally, we found known and novel pathways that play crucial roles in SSc pathogenesis.

Conclusion: Our study provides the most comprehensive dataset in single cell resolution in SSc, and suggests a paradigm shift in the understanding of SSc. The MARS-seq can serve as a vehicle for discovering immune-stromal

cell crosstalk, for finding new biomarkers for early SSc diagnosis and for tailoring and identification of new therapeutic targets.

Tofacitinib Inhibits Angiogenesis Through Its Opposite Effects on Pro- and Anti-angiogenic Factors

Devy Zisman[1], Maya Rahat[2], Elina Simanovich[2], Elizabeth Mellins[3], Amir Haddad[1], Tal Gazitt[1], Joy Feld[2] and Michal Rahat[2], [1]Carmel Hospital, Haifa, Israel, [2]Carmel Medical Center, Haifa, Israel, [3]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Angiogenesis plays a key role in the progression of rheumatoid arthritis (RA), but the mechanisms regulating this process are not fully elucidated. EMMPRIN is a multi-functional protein that can induce the expression of matrix metalloproteinases (MMPs) and vascular endothelial growth factor (VEGF), which are pro-angiogenic. Tofacitinib, a small molecule inhibitor of Janus Kinase (JAK) 1 and JAK3, in use for treatment of RA, has been shown to inhibit production of cytokines. However, its effects on angiogenesis, and specifically on EMMPRIN expression and activity, are not yet clear.

Methods: To determine the effects of Tofacitinib on the expression of EMMPRIN, MMP-9 and VEGF, as well as on the expression of the anti-angiogenic proteins endostatin and thrombospondin-1 (Tsp-1).

Results: The co-culture increased the secretion of MMP-9 and VEGF compared to the single culture of HT1080 cells (by 1.5-fold and 1.4-fold respectively, $p< 0.05$) and decreased the secretion of endostatin and Tsp-1 (by ~45%, $p< 0.05$); however, EMMPRIN secretion was unaffected. Tofacitinib significantly inhibited the secretion of EMMPRIN, VEGF and MMP-9 (by 16%, 39%, 29% respectively, $p< 0.01$), whereas secretion of endostatin, but not of Tsp-1, was increased (1.7-fold, $p=0.0074$). The ratio between VEGF and endostatin, a measure of the overall angiogenic potential, was reduced by 54% by the addition of Tofacitinib ($p=0.0005$). Likewise, CM from the co-cultured cells after incubation with Tofacitinib demonstrated reduction (12.7%, $p=0.0441$) in the ability of endothelial cells to migrate and to form closed lumens (17%, $p=0.0002$).

Conclusion: We suggest that the interactions between monocytes and fibroblasts lead to an angiogenic switch, as they enhance pro-angiogenic factors and decrease anti-angiogenic mediators. Tofacitinib reversed these effects by enhancing endostatin secretion and reducing the accumulation of EMMPRIN, VEGF and MMP-9. Thus, the inhibitory effect of tofacitinib on angiogenesis may contribute to its efficacy in treating inflammatory arthritis.

Abstract Number: 1528

Filgotinib Inhibits Monocyte Differentiation and Pro Inflammatoly Cytokine Production in Osteoblasts

Takeo Isozaki[1], Yuzo Ikari[1] and Tsuyoshi Kasama[2], [1]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan, [2]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Koutou-ku Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammation and joint destruction. Filgotinib is a selective small molecule inhibitor of JAK 1 enzymes, and is currently in clinical development for the treatment of rheumatoid arthritis (RA). However, a direct role of filgotinib for osteogenesis has not been demonstrated. Here, we examined filgotinib inhibited monocyte differentiation and proinflammatoly cytokine production in osteoblasts.

Methods: To determine if the JAK-STAT enzyme was expressed in RA osteoblasts and MG63 (human osteosarcoma cell line), we performed immunohistochemistry. In order to confirm that filgotinib inhibited STAT signaling phosphorylation, interleukin (IL)-6 and IL-6 receptor (IL-6R) stimulated MG63 was used for western blotting. To determine whether filgotinib was involved in proinflammatoly cytokine production, monocyte chemotactic protein-1(MCP-1)/CCL2, IL-8/CXCL8, receptor activator for nuclear factor -κB ligand (RANKL) and CXCL16 in filgotinib treated MG63 conditioned medium was measured using enzyme-linked immunosorbent assay (ELISA). Finally, to confirm if monocyte was differentiated with filgotinib, THP-1 (human acute monocytic leukemia cell line) was cultured with filgotinib treated MG63 conditioned medium.

Results: JAK1, 2 and 3 was expressed in osteoblast and MG63. We found that phosphorylated STAT1 and STAT3 signaling in IL-6 and IL-6R stimulated filgotinib treated MG63 was significantly decreased at 10 minutes compared to nontreated MG63. MCP-1/CCL2 in filgotinib treated MG63 conditioned medium was significantly decreased compared with in nontreated MG63 conditioned medium (12.8 ± 0.6 pg/ml and 41.6 ± 0.0 pg/ml, $p < 0.05$, respectively). CXCL16 in in filgotinib treated MG63 conditioned medium was also significantly decreased compared with in nontreated MG63 conditioned medium (12.8 ± 0.6 pg/ml and 41.6 ± 0.0 pg/ml, $p < 0.05$, respectively). Additionally, THP-1 with IL-6 and IL-6R treated MG63 conditioned medium differentiated into multinuclear cells. On the other hand, THP-1 with filgotinib treated MG63 conditioned medium did not differentiate into multinuclear cells.

Conclusion: Filgotinib inhibited proinflammatory cytokine production and monocyte differentiation. These data indicate that filgotinib acts on bone metabolism, suggesting that filgotinib may prevent bone destruction.

Differentially Expressed Chemokines and Cytokines in Peripheral Blood Mononuclear Cells (PBMCs) of Rheumatoid Arthritis (RA) Patients

Noha Elemam[1], Mahmood Hachim[2], Suad Hannawi[3] and Azzam Maghazachi[4], [1]University of Sharjah, Sharjah, United Arab Emirates, [2]Mohammed Bin Rashid University Of Medicine and Health Sciences, Dubai, [3]Ministry of Health and Prevention, Dubai, United Arab Emirates, [4]University of Sharjah, Sharjah

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most prevalent autoimmune disease, where various immune cells are associated such as monocytes, natural killer (NK) cells, B cells, and T cells. Additionally, soluble mediators aid in the interaction between immune and non-immune cells. Cytokines are soluble mediators that play a crucial role in the inflammatory processes that could lead to joint destruction associated with RA, while chemokines play a major role in the migration of various cell types into inflammatory sites in RA (Brennan and McInnes 2008, Szekanecz, Vegvari, et al. 2010, Elemam, Hannawi, et al. 2020). In this study, we aimed at exploring chemokines and cytokines that could possibly be used to aid in evaluating the differences between healthy controls and RA patients.

Methods: Publicly available transcriptome dataset (GSE64708) of peripheral blood mononuclear cells (PBMCs) of RA patients and healthy controls were analyzed using the GEO2R tool. Then, the cytokines and chemokines were selected from the top 250 significant genes. Whole blood samples were collected from the recruited 17 RA patients (satisfying the 2010 ACR/EULAR classification criteria for RA) and 16 healthy controls (with no diagnosis of autoimmune diseases). Then, blood was separated to obtain PBMCs using the Ficoll density gradient method. RNA was extracted and gene expression was assessed using qRT-PCR. Statistical analysis was done using the unpaired t-test or Mann-Whitney test, after the assessment of data distribution. P-value < 0.05 was considered statistically significant.

Results: In silico analysis showed that several chemokines, cytokines, and innate receptors such as toll-like receptors were differentially expressed between RA patients and healthy controls. Hence, some of these cytokine and chemokine ligands and receptors were validated and assessed in PBMCs of RA patients and healthy controls. Regarding the chemokines, CCR4, CCL2, CKLF, and CXCL10 were found to be upregulated in RA patients (Figure 1). Similarly, the proinflammatory chemokine IL-1β, IL-1 receptor antagonist (IL1RN) as well as the cytokine receptor

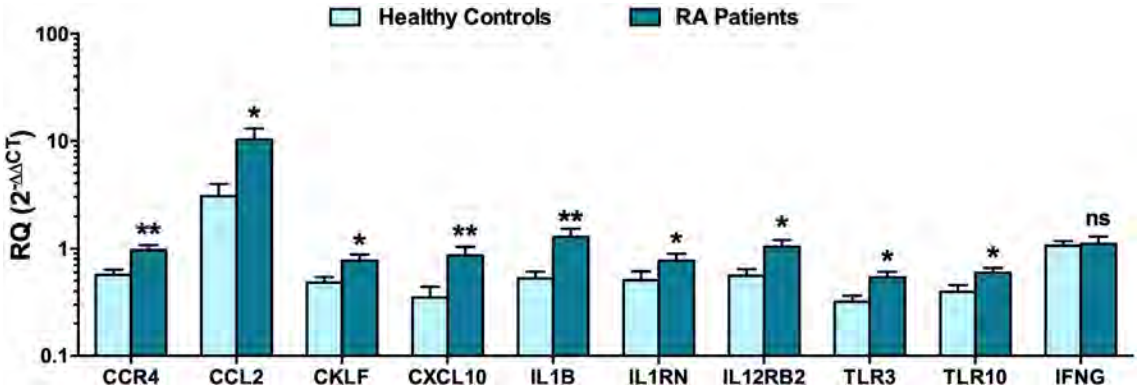

Figure 1. Assessment of gene expression of chemokines, cytokines, and toll-like receptors in the PBMCs of RA patients and healthy controls.

component IL12RB2 exhibited an upregulation in the PBMCs of RA patients while the T helper 1 cytokine IFN-γ did not display any differential expression in PBMCs of RA patients. Furthermore, the innate toll-like receptors TLR3 and TLR10 were upregulated in PBMCs of RA patients.

Conclusion: In conclusion, certain chemokines and cytokines seem to play a major role in the pathogenesis of RA disease. Gene expression of these molecules; CCR4, CCL2, CKLF, CXCL10, IL-1β, IL-1RN, IL12RB2, TLR3, and TLR10 in PBMCs could be used as promising biomarkers for RA disease.

Activin a and Follistatin Alter Endothelial Cell and Rheumatoid Arthritis Synovial Fibroblast Adhesion and Interaction

Helge Scholz[1], Iris Aykara[1], Klaus Frommer[2], Stefan Rehart[3], Ulf Müller-Ladner[4] and Elena Neumann[1], [1]Department of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus Liebig University Giessen, Bad Nauheim, Germany, [2]Justus-Liebig-University Giessen, Campus Kerckhoff, Dept. of Rheumatology and Clinical Immunology, Bad Nauheim, Germany, [3]Department of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt, Frankfurt, Germany, [4]Department of Rheumatology, Immunology, Osteology and Physical Medicine, Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, Bad Nauheim, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Activin A and follistatin belong to an anti-inflammatory auto-regulatory cycle. Patients with rheumatoid arthritis (RA) have increased activin A levels in the synovial fluid and tissue. During inflammation, activin A is released systemically, then inducing its antagonist follistatin. This negative feedback is active in different cell types but not RA synovial fibroblasts (SF). Fibroblasts are known to interact with endothelial cells in inflamed tissues. Objective: Evaluation of the role of activin A and follistatin on RASF and endothelial cell interactions.

Methods: RA synovium was used for RASF isolation, HUVEC were commercially obtained. RASF and HUVEC were stimulated in mono- and coculture. Direct: RASF together with HUVEC; indirect: inserts with HUVEC separated by a membrane from RASF in the lower chamber. Stimuli: 15ng/ml activin A, 500ng/ml follistatin, 1ng/ml IL-1. Proteins were measured by ELISA. Proliferation was analyzed by BrdU assay. RASF were Calcein-AM stained for short-term cell adhesion assays in direct coculture. Cells were transferred to 24-well plates after 18h stimulation. After adhesion for 1h, non-adherent cells were removed by shaking 3x 5 min. Afterwards, cells were quantified. For the flow-adhesion assay, HUVEC were cultured on rat tail collagen coated capillary slides. HUVEC and RASF were stimulated for 4h with TNF, TNF+activin A or TNF+follistatin. After stimulation, 1x10^6 RASF were resuspended in 20ml medium. Two 1min videos were recorded at 18.4ml/h and 30.5ml/h using TNF-stimulated HUVEC or TNF-stimulated RASF on activin A or follistatin stimulated HUVEC.

Results: IL-1 induced activin A in RASF and HUVEC monoculture (8-fold, $p< 0.01$, 4-fold, $p< 0.05$) and direct and indirect coculture (5-fold, $p< 0.05$; 4-fold, $p< 0.05$). IL-1-induced activin A release was reduced by follistatin in HUVEC monoculture (12-fold, $p< 0.01$, n=5), direct and indirect coculture (10-fold, $p< 0.01$; 5-fold, $p< 0.01$) compared to IL-1 alone but not in RASF monoculture. IL-1-induced IL-6 release was reduced by activin A in HUVEC (42.6%, $p< 0.05$)

and indirect coculture (31.8%, p< 0.05) but not in RASF monoculture and direct coculture. Follistatin did not alter IL-6 responses. IL-1 induced VEGF in RASF but not in HUVEC and was not altered by activin A. Proliferation of RASF, HUVEC or both was not altered by activin A or follistatin. Short-term adhesion showed no significant influence of activin A or follistatin (n=3). Flow adhesion assay showed reduced adherence / rolling of RASF on HUVEC stimulated with TNFα and activin A.

Conclusion: In direct and indirect coculture of HUVEC with RASF the effect on HUVEC is dominant leading to reduced IL-1-induced activin A release. However, the IL-1-induced IL-6 release in RASF or HUVECs was decreased by activin A in HUVEC monoculture and indirect coculture but not during cell-contact of both cell types. The direct interaction of RASF with HUVEC seems to prevent the reducing activin A effect on IL-6 release in HUVECs. Activin A seems to not to have an impact on short-term cell adhesion but first observations show that activin A has an influence on selectin-mediated adhesion under flow conditions.

Abstract Number: 1531

Characterization of Cytokine/chemokine Profile in Patient-derived M1/ M2 Macrophages to Identify Biomarkers for Genetically-defined Systemic Autoinflammatory Diseases

Farzana Bhuyan[1], Adriana Almeida de Jesus[2], Kim Johnson[3], Jacob Mitchell[4], Yan Huang[5] and Raphaela Goldbach-Mansky[5], [1]NIH, bhetesda, MD, [2]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, [3]NIH, NIAID, Bethesda, [4]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, MD, [5]NIH, Bethesda

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Genetic mutations in key regulatory molecules of the innate immune system cause autoinflammatory diseases through propagation of hyperinflammatory responses. Monocytes/ macrophages regulate inflammatory processes during infection and homeostasis by secreting a wide range of cytokines and chemokines that control recruitment and migration of immune cells to inflamed tissue, and their biological functions through immune cell differentiation and polarization. We characterized the cytokine/chemokine profile of peripheral blood monocyte-derived M1-, and M2-macrophages (M1-, M2-MDMs) from patients (pts) with genetically defined systemic autoinflammatory diseases (SAIDs) and controls.

Methods: Whole blood from pts enrolled in the IRB approved study (NCT 02974595) with IL-1 mediated SAIDs NOMID (n=3), DIRA (n=4), Majeed Syndrome (n=1); interferon-mediated diseases CANDLE (n=3) SAVI (n=3); IL-18 mediated diseases NLRC4-MAS (n=2), IL-18PAP-MAS(n=1), Blau syndrome (n=4), NEMO-NDAS (n=3); and healthy controls (HC) (n=6) were assessed. M1-, M2-MDMs) from culture with GM-CSF or M-CSF for 6 days were assessed with and without LPS+ATP stimulation. Human Cytokine Array and ELISA were used for cytokine/chemokine profiling. SAVI monocytes died upon in vitro M1-M2 MDM differentiation. Differentiation into rounded and flat shaped M1-MDMs and elongated or spindle shaped M2-MDMs was 80-90% and 70-80% respectively for all samples.

Results: IL-1β secretion from M1-MDMs was higher in NOMID, DIRA and Majeed syndrome pts upon stimulation with LPS and ATP compared to HC and other SAID pts. In NOMID pts, IL-1b was equally elevated in M1-and M2 MDMs, whereas IL-18 was produced in M1- and M2-MDMs in NLRC4-MAS and in M2-MDMs in IL-18PAP-MAS. TNF and IL-6 were highest in stimulated M1-MDMs in NOD2 and NLRC4 MAS pts. compared to HC ($p< 0.05$) and in stimulated M2-MDMs in Majeed, CANDLE, NOD2 and NLRC4 pts. Among chemokines, CCL2/MCP-1 which recruit monocyte into inflamed tissues was constitutively expressed in M1/M2-MDMs of CANDLE and NOD2 and M1-MDM of NLRC4-MAS pts. M2-MDMs derived from Majeed and DIRA pts. produced significantly higher levels of CCL5/RANTES and CXCL10/IP-10 ($p< 0.05$). IP-10 secretion was not seen in CANDLE or NEMO-NDAS. IL-8 and CXCL1, two neutrophil-attracting chemokines were high in most autoinflammatory disease groups, moreover, M2-MDMs of CANDLE and Majeed pts constitutively released IL-8. As expected, IL-1ra was absent in unstimulated and stimulated DIRA M1-, and M2-MDSs. Moreover, CANLDE MDMs did not show an upregulation of IL-1ra distinct from IL-1 mediated diseases.

Conclusion: Taken together, differentiation of monocytes into M1 and M2 MDMs leads to variable but disease-specific regulation of pro-inflammatory cytokine and chemokine production. The value of this system in assessing monocyte and macrophage polarization defects and in assessing the proinflammatory dysregulation in various SAIDs need to be further explored. Particularly, whether such systems proof useful in conditions where more than one cytokine/chemokine are dysregulated and in suggesting treatment targets needs to be evaluated in the future.

The Non-psychotropic Phytocannabinoids Cannabigerol and Tetrahydrocannabinolic Acid Inhibit Rheumatoid Arthritis Synovial Fibroblast Function by Targeting the Wasabi Receptor TRPA1

Torsten Lowin[1], Matthias Schneider[2] and Georg Pongratz[3], [1]Department of Rheumatology and Hiller Research Unit Rheumatology, Heinrich Heine University, Duesseldorf, Germany, Düsseldorf, Germany, [2]Department of Rheumatology and Hiller Research Unit Rheumatology, Heinrich Heine University, Duesseldorf, Germany, Duesseldorf, Germany, [3]Department of Rheumatology and Hiller Research Unit Rheumatology, Heinrich Heine University, Duesseldorf, Germany, D sseldorf, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: While medical cannabis is available for german patients since 2017, its use to alleviate symptoms of rheumatic diseases is not recommended due to a lack of clinical studies. While cannabis might be beneficial to treat neuropathic pain, the impact on inflammation has not been assessed adequately. In this study, we investigated the effects of the two non-psychotropic plant cannabinoids, cannabigerol (CBG) and tetrahydrocannabinolic acid (THCA) on the function of rheumatoid arthritis synovial fibroblasts (RASF).

Methods: RASF were treated with THCA and CBG together with TNF or vehicle. After three days, proliferation and cytokine production (IL-6, IL-8 and MMP-3) were assessed. Furthermore, intracellular calcium mobilization and cell death were investigated.

Results: CBG and THCA decreased the proliferation of RASF *in vitro* ($p < 0.001$), which was dependent on concentration of cannabinoids and fetal calf serum content of the culture medium. This was accompanied by reduced production of IL-6, IL-8 and MMP-3 ($p < 0.001$). CBG and THCA increased intracellular calcium ($p < 0.001$) levels and the uptake of the viability dye PoPo3 ($p < 0.001$), which was inhibited by antagonizing the wasabi receptor TRPA1 (transient receptor potential type ankyrin). In addition, we observed significant cell death in response to THCA and CBG, which was inhibited by the mitochondrial transition pore inhibitor cyclosporin A. In contrast to TNF pre-stimulated RASF, the effects of CBG and THCA on cytokine production, proliferation, cell death and calcium mobilization were absent or less pronounced in unstimulated RASF.

Conclusion: CBG and THCA showed robust anti-inflammatory effects preferentially in TNF-activated RASF by targeting the wasabi receptor TRPA1. This ion channel might be a novel therapeutic target since it exerts a crucial influence on the function of RASF, which, *in vivo* contribute to the pro-inflammatory environment in the rheumatoid joint.

Ultrasound Joint Inflammation but Not Disease Activity Score at 28 Joints Is Reflective of the Severity of Joint Damage in Patients with Rheumatoid Arthritis

York Kiat Tan[1], HuiHua Li[2], John Allen Jr[3] and Julian Thumboo[1], [1]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, Singapore, [2]Health Services Research Unit, Singapore General Hospital, Singapore, Singapore, Singapore, [3]Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore, Singapore

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: With increased use of musculoskeletal ultrasound (US) among rheumatologists, it will be necessary to understand what additional clinical information may be derived from US joint assessment versus routine clinical assessment in patients with rheumatoid arthritis (RA). Our study aims to gain further insight into this by studying the severity of joint damage in RA patients classified based on their US joint inflammation findings and their disease activity score at 28 joints (DAS28). By comparing with DAS28, this cross-sectional study mimics what happens in routine clinical practice, whereby clinicians often rely on routine clinical measures (like DAS28) for RA disease activity assessment.

Methods: US power Doppler (PD) and grey scale (GS) joint inflammation were graded semi-quantitatively (0-3), while bone erosion was scored dichotomously (Yes=1 or No=0) at each joint recess. Patients were categorized into 4 US patient groups: group 1 (PD positive and GS ≥median score of 35.5); group 2 (PD negative and GS ≥ median score);

Ultrasound erosion score Mean (95% CI)		Differences (95% CI) between		P-value Group 4 vs.	
Group 1: PD positive and GS ⩾ median score	9.75 (6.69, 12.81)	**Groups 1 and 4**	**6.35 (0.78, 11.83)**	**Group 1**	**0.026***
Group 2: PD negative and GS ⩾ median score	7.33 (-4.11, 18.78)	Group 2 and 4	3.93 (-19.95, 27.81)	Group 2	0.572
Group 3: PD positive and GS < median score	3.3 (2.17, 4.43)	Group 3 and 4	-0.10 (-2.58, 2.38)	Group 3	0.932
Group 4: PD negative and GS < median score	3.4 (1.11, 5.69)				

Statistically significant: *P<0.05.

Table 1. Comparison of ultrasound erosion scores between the ultrasound patient groups.

Ultrasound erosion score Mean (95% CI)		Differences (95% CI) between		P-value Remission vs.	
HDA: DAS28 > 5.1	5.25 (2.32, 8.18)	HDA and remission	-0.08 (-6.74, 6.58)	HDA	0.978
MDA: 3.2 ≤ DAS28 ≤ 5.1	7.93 (4.63, 11.24)	MDA and remission	2.60 (-3.67, 8.87)	MDA	0.396
LDA: 2.6 ≤ DAS28 < 3.2	3.4 (1.81, 4.99)	LDA and remission	-1.93 (-7.46, 3.59)	LDA	0.449
Remission: DAS28 < 2.6	5.33 (1.2, 9.47)				

HDA, high disease activity; MDA, moderate disease activity; LDA, low disease activity; DAS28, disease activity score at 28 joints.

Table 2. Comparison of ultrasound erosion scores between the DAS28 disease severity categories.

group 3 (PD positive and GS < median score); group 4 (PD negative and GS < median score). US erosion scores were compared (a) between patients in groups 1 vs. 4, groups 2 vs. 4 and groups 3 vs. 4 and (b) between patients with high (> 5.1), moderate (≥ 3.2 and ≤ 5.1) and low (≥ 2.6 and < 3.2) DAS28 scores versus those in DAS28 remission (< 2.6). All comparative analyses were performed using the unpaired student's T-test.

Results: 1080 joints and 1800 joint recesses from bilateral elbows, wrists, ankles and small joints of the hands and feet were scanned in 30 adult RA patients with the following baseline characteristics: 76.7 % Chinese; 93.3% female; mean (SD) DAS28 of 3.58 (1.20); mean (SD) disease duration of 70.3 (61.2) months; 90% on conventional DMARD (methotrexate, sulfasalazine, hydroxychloroquine and/or leflunomide). Table 1 summarizes the comparison of US erosion scores between the 4 ultrasound patient groups. The mean (95% CI) US erosion scores were significantly higher (p=0.026) for groups 1 vs. 4 (9.75 (6.69, 12.81) vs. 3.4 (1.11, 5.69), respectively) with a difference (95% CI) of 6.35 (0.78, 11.83). US erosion scores were, however, not significantly different (P-values all >0.05) for patients in groups 2 vs. 4 and 3 vs. 4. Table 2 summarizes the comparison of US erosion scores between the DAS28 disease severity categories. The US erosion scores of patients with high, moderate and low DAS28 disease severity categories were not significantly different (P-values all >0.05) from that of patients in DAS28 remission.

Conclusion: US joint inflammation assessment – and not DAS28 – is reflective of the severity of joint damage in RA patients. Specifically, the severity of US-detected bone erosions was significantly greater when both positive PD and a greater degree of GS joint inflammation were present. This association was not observed when either component was absent. Given this advantage of US joint inflammation assessment over DAS28 assessment, the former may po-

tentially help identify RA patients with a more aggressive disease course requiring more intensive treatment, although this will need to be further evaluated in future studies.

Combined Thermal and Ultrasound Imaging in Rheumatoid Arthritis Is Superior to Either Imaging Alone in Terms of Correlation with the 28-joint Disease Activity Score

York Kiat Tan[1], Cassandra Hong[1], HuiHua Li[2], John Allen Jr[3] and Julian Thumboo[1], [1]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, Singapore, [2]Health Services Research Unit, Singapore General Hospital, Singapore, Singapore, Singapore, [3]Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore, Singapore

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Combined thermal and ultrasound (US) imaging modalities in detecting joint inflammation in rheumatoid arthritis (RA) has not been evaluated relative to thermal or US imaging alone. Therefore, we aim to compare outcomes of the combined imaging modalities versus single imaging modality using the routinely performed 28-joint disease activity score (DAS28).

Methods: Thermography and ultrasonography were performed on 22 joint sites (bilateral hands and wrists) at the same study visit. Maximum (Tmax), minimum (Tmin) and average (Tavg) temperatures at each joint were recorded. For each patient, the lowest Tmin temperature among all joints testing negative for joint inflammation by both US power Doppler (PD) and grey-scale (GS) was defined as the patient's control temperature and subtracted from Tmax, Tmin and Tavg temperatures at all 22 joints for that patient. Differences with the control temperature for the respective parameters (Tmax, Tmin and Tavg) were then summed across all joints to obtain MAX, MIN and AVG values for each patient. US PD and GS joint inflammation scores (graded semi-quantitatively 0-3 at each joint recess), respectively, were summed for the 22 joints to obtain Total PD and Total GS scores per patient. MAX (PD), MIN (PD) and AVG (PD) represent the results of combined thermal and US PD imaging. As a greater PD vascularity indicates more inflammation at the joints, when a patient's Total PD score was greater than the median value, to increase its weightage to the combined imaging scores, the patient's MAX (PD), MIN (PD) and AVG (PD) were derived by multiplying MAX, MIN and AVG by a factor of 2. Otherwise, the patient's MAX (PD), MIN (PD) and AVG (PD) remained the same as the MAX, MIN and AVG (without multiplying by 2).

Results: In this cross-sectional study, 814 joints were studied in 37 RA patients with the following patients' baseline characteristics: mean (SD) age, 56.5 (13.8) years; majority female, 28/37 (75.7%); majority Chinese, 28/37 (75.7%); mean (SD) disease duration of 30.9 (45.3) months; mean (SD) DAS28 of 4.43 (1.12); 31/37 (83.8%) patients were on one or more DMARDs (methotrexate, sulfasalazine, hydroxychloroquine and/or tofacitinib). Table 1 summarizes results of the correlation analysis between the imaging parameters and DAS28. Specifically, only MAX (PD) and AVG (PD) exhibited statistically significant correlation with DAS28 scores (MAX (PD): correlation coefficient (95% CI) 0.393 (0.079, 0.636), P=0.016; AVG (PD): 0.376 (0.060, 0.624), P=0.022). Figure 1 shows the scatter plots for the combined thermal and US imaging parameters versus DAS28. Table 2 summarizes the results of the simple linear regressions

Parameter	Correlation coefficient (95% CI)	P- value	Parameter	Correlation coefficient (95% CI)	P- value
MAX	0.258 (-0.072, 0.537)	0.123	Total GS	0.186 (-0.147, 0.481)	0.270
MIN	0.141 (-0.192, 0.445)	0.406	**MAX (PD)**	**0.393 (0.079, 0.636)**	**0.016***
AVG	0.235 (-0.096, 0.52)	0.161	**AVG (PD)**	**0.376 (0.060, 0.624)**	**0.022***
Total PD	0.247 (-0.084, 0.528)	0.141	MIN (PD)	0.298 (-0.029, 0.567)	0.074

*Statistically significant at P<0.05

Table 1. Correlation between imaging parameters and DAS28.

	Prediction of DAS28	
Parameter	Coefficient (95% CI)	P-value
Total PD	0.0978 (-0.0295, 0.2252)	0.1411
Total GS	0.0304 (-0.0228, 0.0836)	0.2704
MAX	0.0133 (-0.0032, 0.0298)	0.1231
AVG	0.0150 (-0.0056, 0.0356)	0.1613
MIN	0.0113 (-0.0150, 0.0375)	0.4060
MAX (PD)	0.0086 (0.0019, 0.0153)	**0.0161**
AVG (PD)	0.0112 (0.0021, 0.0203)	**0.0217**
MIN (PD)	0.0122 (-0.0008, 0.0251)	0.0736

Statistically significant: * p<0.05

Table 2. Results of linear regression between the imaging parameters and DAS28.

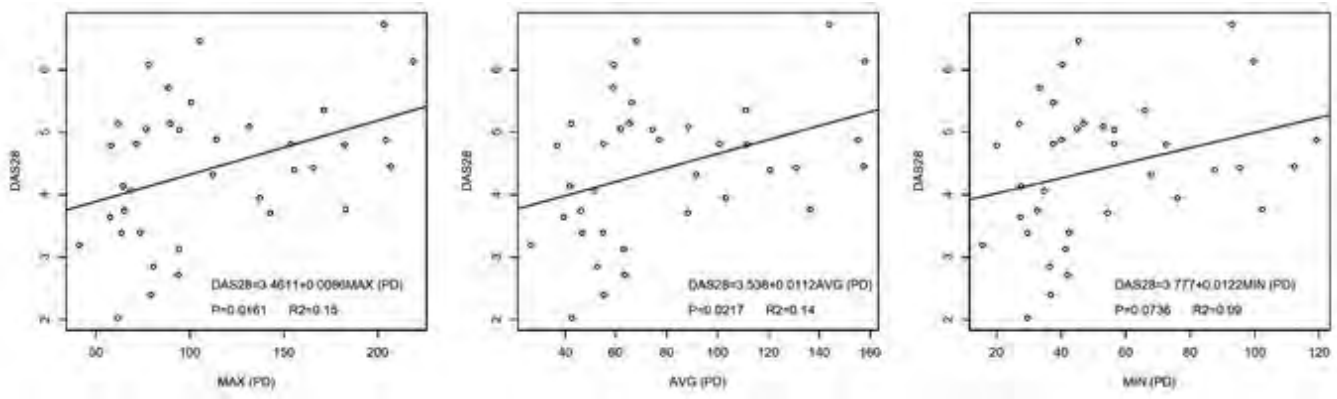

Figure1. Scatter plots for the combined thermal and ultrasound imaging parameters versus DAS28.

between the imaging parameters and DAS28. Specifically, only MAX (PD) and AVG (PD) were shown to be significantly correlated with DAS28 (MAX (PD): coefficient (95% CI), 0.0086 (0.0019, 0.0153); P=0.0161); AVG (PD): coefficient (95% CI), 0.0112 (0.0021, 0.0203); P=0.0217).

Conclusion: For the first time ever, combined thermal and US imaging in RA have been shown to be superior to either imaging modality alone in terms of correlation with DAS28. Longitudinal studies testing the use of combined thermal and US imaging in RA will be required.

Abstract Number: 1535

Frequency and Anatomic Distribution of Magnetic Resonance Imaging Lesions in the Sacro-iliac Joints of Healthy Subjects and Patients with Spondyloarthritis

Sophie Hecquet[1], Jean-Philippe Lustig[2], Frank Verhoeven[1], Mickaël Chouk[1], Sébastien Aubry[2], Daniel Wendling[3] and Clement Prati[1], [1]Rheumatology, University Teaching Hospital, Besançon, France, [2]Radiology, University Teaching Hospital, Besançon, France, [3]CHU Besançon, department of rheumatology, Besancon, France

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Lesions detected by magnetic resonance imaging (MRI) of the sacroiliac joints are critical to the diagnosis of non-radiographic axial spondyloarthritis. However, some lesions, such as bone marrow edema (BME), usually observed in patients with spondyloarthritis may be encountered in other conditions. BME have been described in patients with nonspecific back pain, healthy subjects, women with postpartum and in athletes. Moreover, it has recently been shown that structural lesions of the sacroiliac joint, such as erosions and fat metaplasia, may be present in healthy subjects.

To evaluate and compare the frequency and location of lesions (BME, subchondral condensation, fat metaplasia, erosions and ankylosis) on MRIs of the sacroiliac joint of healthy individuals and patients with spondyloarthritis.

Methods: This is a retrospective study conducted at the University Hospital of Besançon including 200 patients, each having received an MRI of the sacroiliac joints in coronal section and in T1 and Semicoronal short tau inversion recovery sequences. Two experienced readers evaluated the whole set of images to detect erosions, subchondral condensation, fat metaplasia, BME and ankylosis according to the definitions established by the Assessment of SpondyloArthritis MRI working group. We subdivided a sacroiliac joint into three segments, upper, medium and lower along the cranio-caudal axis. Within the middle segment, we retained 3 portions: anterior, intermediate, posterior along the ventro-dorsal axis. Overall, one sacroiliac joint contained five quadrants on the iliac side and five quadrants on the sacral side. Thus, there were 20 quadrants defined for the two sacroiliac joints of each patient.

Results: Collected MRI of 200 patients (62% female), 96 patients had spondyloarthritis (mean age 37.4±11.8 years, 48% HLA-B27+), 104 subjects were unaffected by the disease (mean age 39.9±11.6 years, 11% HLA-B27+). Of the 96 spondyloarthritis patients, 62 (65%) had inflammatory buttock pain compared to 26 (25%) in the group without spondyloarthritis. BME was seen in 62 (65%) patients with spondyloarthritis mainly in the iliac quadrant of the intermediate middle segment and in 21 (20%) patients without spondyloarthritis predominantly in the antero-middle quadrant. There were equal BME in women and men with spondyloarthritis. Subchondral condensation occurred in 45% of patients without spondyloarthritis, mostly in the antero-middle quadrant and in 36% of patients with spondyloarthritis. Fat metaplasia was present in 35% of spondyloarthritis patients and in 23% of control patients. Erosions were seen in 31% of healthy patients and in 61% of patients with spondyloarthritis.

Conclusion: In this large retrospective cohort, we observed a significant frequency of inflammatory but also structural lesions on MRIs of sacroiliacs joints from healthy patients, which could lead to the misdiagnosis of spondyloarthritis. Fine identification of the location of these lesions is crucial to avoid erroneous diagnosis.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The combination of methotrexate (MTX) and tocilizumab (TCZ) has been proven to be superior to MTX alone in early rheumatoid arthritis (RA)[1] and was able to prevent radiographic progression. Ultrasound (US) has become a valid imaging modality in managing RA. Together with clinical examination, US may allow a comprehensive monitoring of response to therapy. So far, few data are available concerning the early response to TCZ plus MTX in very early RA (VERA).

In this study we aimed to assess the early US response to TCZ plus MTX in VERA, DMARD-naïve patients.

Methods: In this open-label, single-arm study, VERA patients received TCZ (162 mg/week, subcutaneously) and MTX (15-20 mg/week, *per os*) for 24 weeks as induction therapy, followed by MTX as maintenance therapy. RA was diagnosed according to the 2010 ACR/European league against rheumatism (EULAR) criteria. All patients who fulfilled the inclusion criteria (ClinicalTrials.gov: NCT02837146) underwent blood tests, clinical and ultrasound examinations at the predefined time-points: 0,2,4,8,12,24,32,48,54 weeks (w). Ultrasound examination of 34 joints (elbows, wrists, MCP [1-5, bilateral], PIP ([2-5, bilateral], knees, ankles and MTP [2-5, bilateral]) was performed blindly to clinical data. Gray-scale (GS), power-Doppler (PD) scores, and the global *OMERACT*-EULAR synovitis score (*GLOESS*) were assessed in each joint. The sum of individual scores was calculated for 17-joint score (JS) (whole joint set), 10-JS (wrists, MCP, ankles and MTP joints), 12-JS[2], and 7-JS[3].

Results: Forty-four patients (77% women), aged 46.7 ± 12.4 years, completed the 24-week period. Two-thirds (72.7%) were positive for anti-citrullinated protein antibody (ACPA) and 18.2% had bone erosions. At baseline, the mean 28 swollen joints count (28-SJC) was 7.55± 4.5, mean disease activity score (DAS28)-CRP score was 5.2 ± 0.15, mean simplified clinical activity score (SDAI) was 31.4 ± 1.9, mean clinical activity score (CDAI) was 29.1 ± 1.8 and mean health assessments questionnaire (HAQ) score was 1.3 ± 0.1. The C-reactive protein (CRP) decreased significantly at 2w ($p< 0.05$) and, accordingly DAS28-CRP score decreased significantly at 4w ($p< 0.05$). The 28-SJC and CDAI scores decreased significantly at 8w ($p< 0.05$). The HAQ and visual analogue scale (VAS) disease activity reported by patients decreased significantly at 8w ($p< 0.05$) and VAS fatigue at 12w ($p< 0.05$).

The GLOESS and GS scores allowed us detecting the earliest significant treatment response at 2w and PD scores at 4w ($p< 0.05$). Among US joint subsets, 17-JS ($p< 0.01$), 12-JS ($p< 0.05$) and 10-JS ($p< 0.05$) were able to detect the earliest treatment response at 2w. The 7-joint score detected the earliest response at 4w, both in GS and PD ($p< 0.05$).

Conclusion: US scores were able to detect therapeutic response to TCZ plus MTX earlier than clinical scores and may therefore be a promising imaging biomarker.

Abstract Number: 1537

Usefulness of Ultrasound Assessment of Sarcopenia in Patients with Rheumatoid Arthritis

Takeshi Yoshida[1] and Yoshitaka Kumon[1], [1]Chikamori Hospital, Kochi, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcopenia, the age-related loss of muscle mass and function, is associated with numerous risk factors, including rheumatoid arthritis (RA). Although standard diagnostic tool for sarcopenia include dual-energy X-ray absorptiometry and bioelectrical impedance analysis (BIA), ultrasound (US) has a unique advantage to measure muscle quantity as well as muscle quality. Muscle echogenicity reflect intramuscular lipids and fibrosis, and it can be used as a marker of muscle quality. We sought to determine usefulness of US in discriminating patients with RA with sarcopenia from those without. We also assessed correlation between US echogenicity and various clinical measures of physical function and muscle volume.

Methods: 50 female patients with RA, aged 50 years or older, who fulfilled 2010 ACR/EULAR RA Classification Criteria were recruited and cross-sectionally studied. Clinical parameters such as age, BMI, CDAI, pharmacological treatments including corticosteroid and biologics, as well as comorbidities such as diabetes mellitus were assessed. Diagnosis of sarcopenia was based on 2019 updated Asian Working Group for Sarcopenia definition. Because handgrip test is often difficult for RA patients, chair-stand test was selected as primary assessment tool of physical function. BIA was used for the measurement of muscle volume. For US analysis, we used LOGIQ S8 (GE, USA; linear-array transducer) equipment. Cross sectional images of biceps brachii (BB), vastus lateralis (VL), and rectus femoris (RF) were obtained at predetermined position bilaterally. Mean US echogenicity was then calculated. On measuring US

	Sarcopenia	Non-sarcopenia	P value
Number	14 (28%)	36 (72%)	
Age (years)	77.5 ± 6.42	65.89 ± 8.87	**0.00005**
BMI	23.48 ± 2.76	23.77 ± 4.4	0.824
Duration (months)	196.08 ± 217.98	80.12 ± 84.25	**0.0117**
ACPA (%)	34 (68%)	16 (32%)	0.309
RF (%)	10 (71.43%)	31 (75.61%)	0.202
CDAI	6.2 ± 5.91	2.84 ± 2.34	**0.006**
Current CS use (%)	4 (28.57%)	5 (14.28%)	0.254
Current Biologics use (%)	13 (92.86%)	16 (45.71%)	**0.0031**
Joint surgery (%)	6 (42.86 %)	7 (20%)	0.152
SARC-F	4.14 ± 2.07	1.4 ± 1.48	**0.000004**
BB echogenicity	80.89 ± 17.89	73.67 ± 17.74	0.218
VL echogenicity	78.37 ± 18.14	62.67 ± 16.05	**0.0061**
RF echogenicity	89.18 ± 17.82	73.63 ± 16.45	**0.0071**

Table 1. Clinical and imaging features of RA patients with or without sarcopenia. Abbreviation. ACPA: anti-citrullinated peptide antibodies. BMI: body-mass index. CS: corticosteroid. RF: rheumatoid factor.

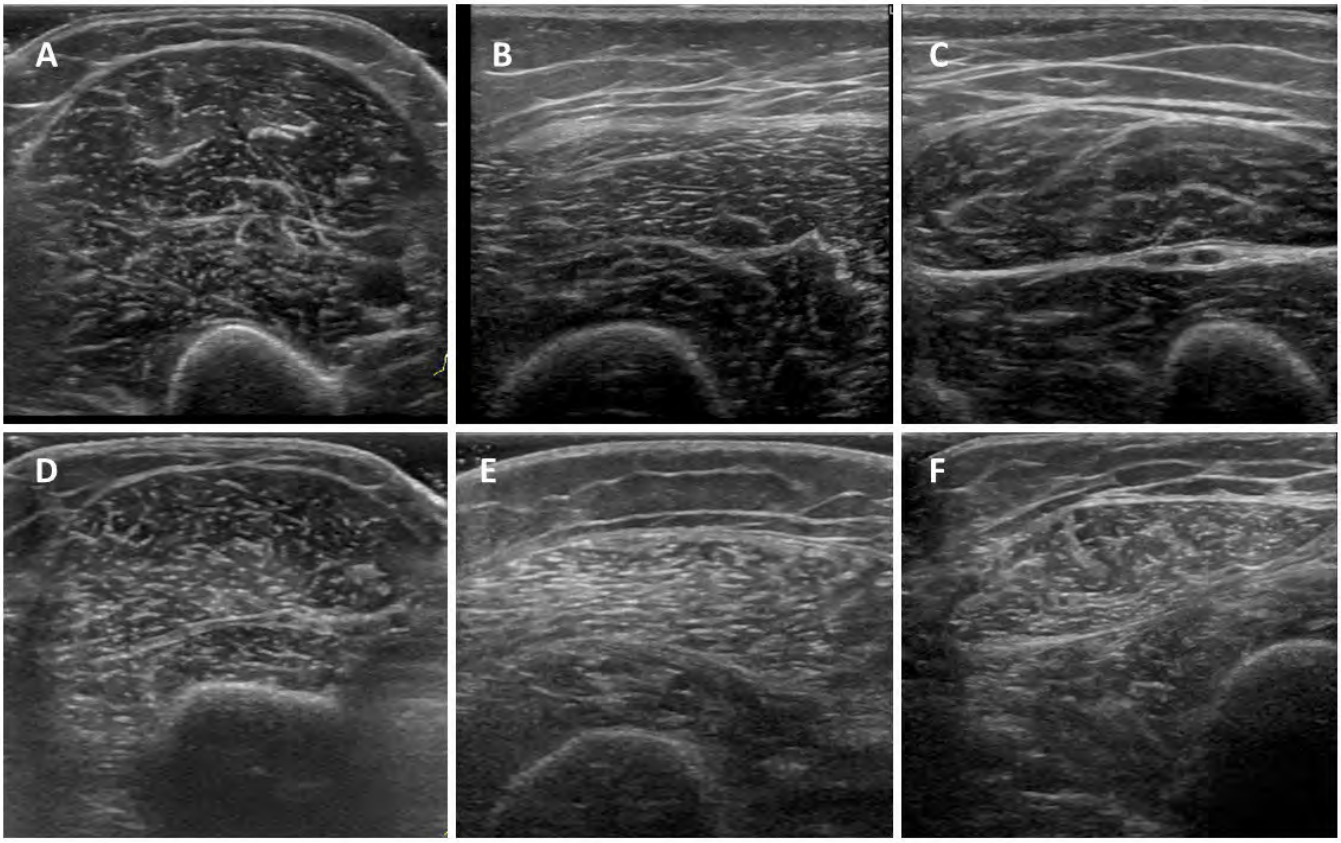

Figure 1. US image of biceps brachii (A, D), vastus lateralis (B, E), and rectus femoris (C, F). A-C. A 60 year old patient with normal physical function and muscle volume. D-F. A 84 year old patient with sarcopenia. The latter patient showed higher intramuscular echogenicity of vastus lateralis and rectus femoris.

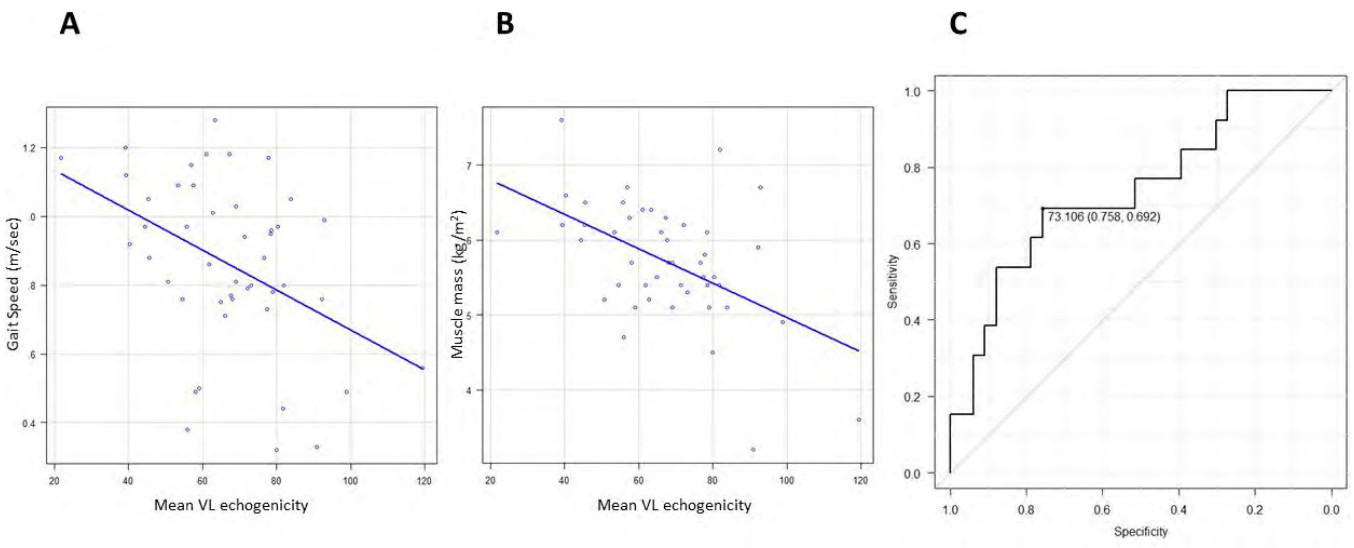

Figure 2. Significant correlation between US echogenicity of VL and gait speed (A), and muscle volume (B). US echogenicity of VL showed moderate discriminative capacity with the area under the ROC curve of 0.737 (95% CI, 0.569 – 0.904).

echogenicity, regions of interest were manually drawn by using ImageJ. All statistical analyses were performed using EZR, a graphical user interface for R. The p value of < 0.05 was determined as the cutoff for statistical significance.

Results: Mean age was 69.7 ± 7.23. 14 patients (28 %) were diagnosed as sarcopenia. 34 patients (68%) were positive for anti-CCP antibody. Age, disease duration, SARC-F, CDAI, current biologics use were significantly associated with presence of sarcopenia. Patients with sarcopenia had significantly increased US echogenicity of VL compared to those without (78.4 ± 18.15 vs 62.7 ± 16.05, p = 0.006). US echogenicity of VL showed the area under the ROC curve of 0.737 (95% CI, 0.569 – 0.904). In addition, US echogenicity showed significant negative correlation between gait speed (r = -0.507, p = 0.0003) and muscle volume (r = -0.423, p = 0.003).

Conclusion: US echogenicity of VL was useful in discriminating the RA patients with sarcopenia from those without. In addition, it showed significant correlation with both muscle volume and physical function. We suggest muscle US can be used as an assessment tool of sarcopenia in patients with RA and further studies incorporating more patients and longitudinal follow up would be needed.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: There is an increasing interest in tapering or even discontinuing biological disease-modifying anti-rheumatic drugs (bDMARDs) in rheumatoid arthritis (RA) patients in sustained remission. The aim was to assess the potential role of ultrasound (US) for predicting successful tapering and successful discontinuation.

Methods: Patients with RA on bDMARDs in sustained disease activity score remission (DAS28-CRP < 2.6) and no radiographic progression the previous year were included(1). At baseline, clinical assessment, MRI and x-ray were performed as part of a standardized tapering regimen. Further, synovitis in 24 joints was scored 0-3 by US using the OMERACT scoring system for synovitis. At patient level, greyscale (GS), Doppler and the Global OMERACT/EULAR US Synovitis Score GLOESS synovitis sum scores were calculated. The bDMARD was reduced to 2/3 of standard dose at baseline, ½ dose after 16 weeks, and discontinued after 32 weeks. If flare occurred (defined as either DAS28-CRP≥2.6 and ΔDAS28-CRP≥1.2 from baseline, or erosive progression on X-ray and/or MRI) tapering was stopped and the dose escalated to the previous level. Final state of treatment was assessed after 2-years.

Logistic regression analyses were used to identify factors associated with successful tapering and successful discontinuation at 2 years follow-up. For all models, variables shown in Table 1 except MRI were included (separate models for ultrasound “24-joint-score” and “hands-only score”). Additional analyses including MRI variables (combined inflammation and combined damage) were performed. Missing data in independent variables were imputed with multiple imputation by chained equations (50 imputed datasets). Variables with p< 0.25 in univariate analyses were included in the initial multivariate model. Backward selection was performed to derive the final multivariate models using a significance level of 0.05.

Table 1 Baseline characteristics

	All patients n=125	Successful tapering n=76	Full dose n=47	p-value	Discontinued n=19	Not discontinued n=104	p-value

Doppler sum score - 24-joints (0-72), median (IQR)	0 (0-1)	0 (0-1)	1 (0-2)	0.121	0 (0-0)	0 (0-2)	**0.007**
GLOESS hands-only (0-30), median (IQR)	2 (0-5)	2 (0-5)	3 (1-5)	0.257	1 (0-2)	3 (1-5)	**0.017**
GLOESS - 24-joints (0-72), median (IQR)	5 (2-9)	5 (2-9)	5 (3-9)	0.632	3 (2-6)	5 (3-9)	0.074

Successful tapering: patients on less than full dose of bDMARD at 2-year follow-up. Full dose: patients on full dose of bDMARD at 2-year follow-up. Discontinued: patients that discontinued of bDMARDs at 2-year follow-up. Not discontinued: patients that were not discontinued of bDMARDs at 2-year follow-up. p-values for differences between treatment groups by Kruskal-Wallis test for numeric measures and chi-squared test or Fisher's exact test, as appropriate, for binary and categorical measures; bold indicates p-values<0.05. Anti-CCP: Anti-Cyclic Citrullinated Protein antibodies; ACR: American College of Rheumatology; bDMARD: biological Disease-Modifying Antirheumatic Drug; CRP: C-Reactive Protein; DAS28-CRP: 28-joint Disease Activity Score with CRP; DMARD: Disease-Modifying Antirheumatic Drug; EULAR: European League Against Rheumatism; GLOESS: Global OMERACT/EULAR Ultrasound Synovitis Score; HAQ: Health Assessment Questionnaire; IQR: Interquartile Range; RF: IgM- Rheumatoid Factor; MRI combined inflammation score (the sum of synovitis(0-3), tenosynovitis(0-3), bone marrow oedema (0-3)); MRI combined damage score (the sum of bone erosions (0-10) and joint space narrowing (0-4)); TSS: Total Sharp van der Heijde score. 24 joints: bilateral wrist, metacarpophalangeal joint 2-5, elbow, knee, ankle and metatarsophalenageal joint 2-5.

Results: One-hundred-and-twenty-five patients completed 2-year follow-up. At 2 years, 47 patients (38%) were back on full dose, 59 (46%) tapered to 2/3 or ½ dose and, 19 (15%) had discontinued the bDMARD. A lower number of previous bDMARDs was an independent predictor for successful tapering (OR=0.54; p=0.006) (table 2). Negative

Table 2 Multivariate logistic regression analyses for successful tapering and successful discontinuation in imputed data after applying backward selection (MRI not included). 123 patients were available for analyses.

	Successful tapering					
	Ultrasound			Ultrasound (hands only)		
	OR	95% CI	p-value	OR	95% CI	p-value
Number of previous bDMARDs	0.54	(0.33 - 0.84)	0.006	0.54	(0.33 - 0.84)	0.006
	Successful discontinuation					
	Ultrasound			Ultrasound (hands only)		
	OR	95% CI	p-value	OR	95% CI	p-value
RF positive	0.26	(0.09 - 0.74)	0.012	0.20	(0.07 - 0.56)	0.002
Doppler sum score	0.44	(0.15 - 0.87)	0.013			

p-values by likelihood ratio tests. bDMARD: biological Disease-Modifying Antirheumatic Drug; CI: confidence interval; OR: odds ratio; RF: IgM-Rheumatoid Factor.

IgM-RF (OR=0.26; p=0.012) and low Doppler sum score for 24 joints (OR=0.44; p=0.013) but not for hands alone, predicted successful discontinuation. Including MRI variables in the model did not affect the predictive value of Doppler sum score. GLOESS sum score was unable to predict successful tapering or discontinuation.

Conclusion: A low Doppler 24-joint sum score and negative IgM-RF at baseline were independent predictors for successful discontinuation of bDMARDs at 2-years' follow-up. Low number of previous bDMARD, but not baseline US, predicted successful tapering.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US) of temporal (TA) and axillary arteries is recommended as the first imaging modality in patients with suspected predominantly cranial giant cell arteritis (GCA) and recently, two US scoring systems, the halo count and Halo Score, have been proposed to quantify the extent of vascular inflammation. We aim to assess the diagnostic value of both scoring systems and its association with systemic inflammation in patients with GCA seen in routine clinical practice.

Methods: This is a retrospective observational study including patients suspected of having GCA over a 9-month period. Baseline clinical and laboratory parameters were retrieved from the electronic health records. All patients underwent bilateral US examination of the three TA segments and extracranial (carotid, subclavian and axillary) arteries as part of a diagnostic fast track pathway (FTP). The FTP is offered to all patients with suspected GCA who will receive an appointment for the US examination within 24 hours. The extent of vascular inflammation was quantified according to the halo count (number of TA segments and axillary arteries with a halo) and the Halo Score (a composite index that incorporates the thickness of each halo). TA biopsy (TAB) was performed according to the treating clinician criteria. The gold standard for GCA was the clinical diagnosis after 6 months of follow-up by the treating clinician. Differences between groups were determined by Chi-squared and Student-t tests, validity was analyzed by receiver operating characteristic (ROC) curves and correlations were determined by Spearman's rank correlation coefficient (rho).

	Total n=58	Patients with GCA n=15	Patients without GCA n=43	p

Table 1. Clinical, laboratory and ultrasound findings of patients included in the fast track pathway

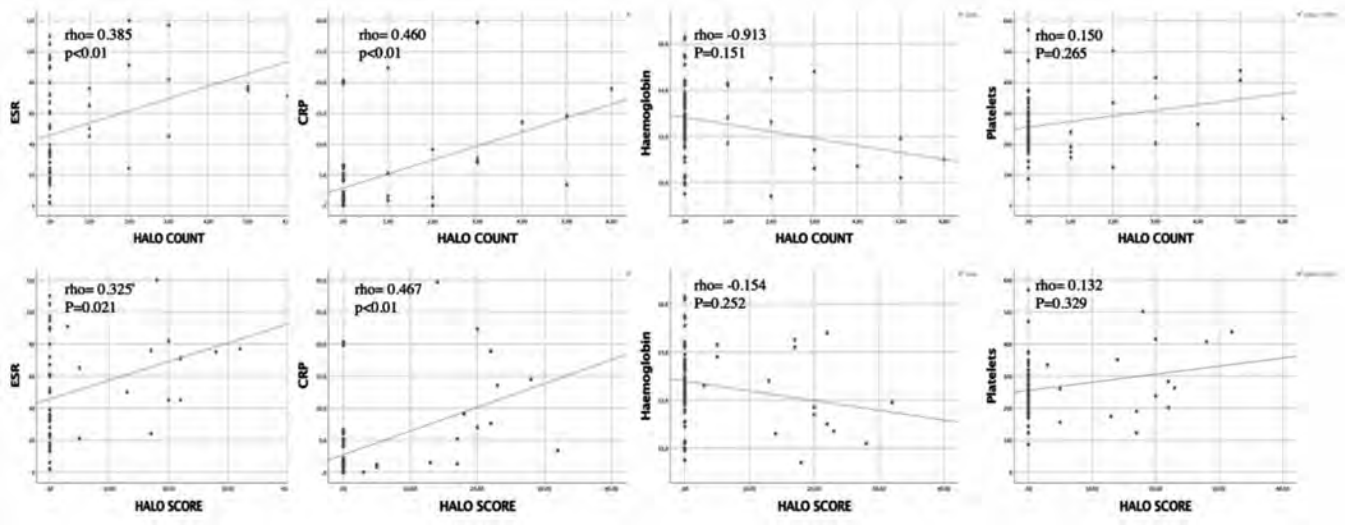

Figure 1. Correlations between halo count and Halo Score with markers of systemic inflammation (ESR CRP, haemoglobin and platelets)

Results: A total of 58 patients were evaluated in the FTP. Mean age was 74.7 years and 65.5% females. Clinical characteristics and US variables of patients with and without GCA are shown in Table 1. A clinical diagnosis of GCA was established in 15 (25.9%) patients. Only 4.7% patients without GCA versus 86.7% with GCA had positive US findings according to the ultrasonographer criteria (sensitivity (Sens) 86.7%, specificity (Spec) 95.3%, positive likelihood ratio (LR+) 18.4 and negative likelihood ratio (LR-) 0.14). Halo count and Halo Score showed similar diagnostic accuracy for a clinical diagnosis of GCA (area under the ROC curve of 0.892 and 0.921 respectively). The optimal cut-off point for halo count was ≥1 (Sens 80%, Spec 95.3, LR+ 17.02, LR- 0.21) and for Halo Score ≥2 (Sens 86.7%, Spec 95.3%, LR+ 18.4, LR- 0.14). Statistically moderate positive correlations were found between halo count and Halo Score and ESR (rho 0.385 and 0.325, p< 0.05) and CRP (rho 0.460 and 0.467, p< 0.01), but not with haemoglobin and platelet count (p >0.05) (Figure 1).

Conclusion: The extent of vascular inflammation by US halo count and Halo Score can help to support the diagnosis of GCA in routine care as they correlate with laboratory markers of systemic inflammation, mainly CRP. Although both scoring systems need further validation, they can be easily implemented in FTP of patients with GCA.

Association Between Disease Activity and Left Ventricular Systolic Function in Patients with Rheumatoid Arthritis: A Case-Control Study

Elías Abraham Rodríguez[1], Dionicio Ángel Galarza-Delgado[2], José Ramón Azpiri López[3], Iris Jazmín Colunga Pedraza[4], **Salvador Lugo Pérez**[3], Itzel Corina Zárate Salinas[3], Paola Fernanda Frausto Lerma[4], Alejandra Pérez Villar[4], Mayra Alejandra Reyes Soto[4] and Raymundo Vera[5], [1]Hospital Universitario "José Eleuterio González", Monterrey, Mexico, [2]Rheumatology Service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Nuevo Leon, Mexico, [3]Cardiology Service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Mexico, [4]Rheumatology service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Mexico, [5]Cardiology Service Hospital Universitario "José Eleuterio González", Monterrey, Mexico

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis(RA) have a higher prevalence of Cardiovascular Disease (CVD), which is the most common cause of death in this group. Disease activity seems to be an independent risk factor for CVD, but there is controversy at the impact on left ventricular systolic function (LVSF). LVSF may be assessed by conventional methods like left ventricular ejection fraction (LVEF) and myocardial shortening or by novel techniques evaluating myocardial strain such as speckle tracking echocardiography (STE).

Methods: Observational, cross-sectional study. RA patients aged 40-75 years that fulfilled the 2010 ACR/EULAR classification criteria and matched controls were included. Patients with a poor US window, history of previous CVD (ischemic heart disease, cerebrovascular accident or peripheral arterial disease), and pregnancy were excluded. Individuals were evaluated using two-dimensional speckle tracking echocardiography performed and reviewed by 2 certified echocardiographers. LVEF and myocardial strains (circumferential, longitudinal, and radial) were measured; differences were solved by consensus. Descriptive analysis was done with measures of central tendency and dispersion. Student-t and Mann-Whitney U tests were used for comparisons.

Table 1. Demographic and clinical characteristics.

	RA (n= 70)	Control (n= 70)	*P*
Female, n (%)	67 (95.7)	69 (98.6)	NS
Age, mean ± SD	52,4±6,7	52,0±6,1	NS
Type 2 Diabetes Mellitus, n (%)	9 (12.9)	7 (10)	NS
Hypertension, n (%)	14 (20)	16 (22.9)	NS
Dyslipidemia, n (%)	16 (22.9)	17 (24.3)	NS
Active smoking, n (%)	11 (10.9)	8 (16.3)	NS
Disease duration, years, median (q25 –q75)	8.0(3.0-15.0)	-	-
DAS-28-PCR, median (q25 –q75)	3.2(2.1-3.9)	-	-

Table 2. Echocardiographic findings

	LVEF	***P***	**CS**	***P***
RA, mean ± SD	63.0±4.3	**0.022**	-16.4±4.5	NS
Controls, mean ± SD	64.7±3.8		-16.2±4.1	
	LVEF	***P***	**CS**	***P***
Remission or low disease activity, median (q25 –q75)	64.0(60.0-66.0)	NS	-15.1(-17.2- -12.2)	**0.006**
Moderate and high diseases activity, median (q25 –q75)	63.0(60.0-66.0)		-18.1(-22.0- -13.9)	

***LVEF**= Left ventricular ejection fraction*
***CS**= Circumferential strain*

Results: A total of 140 subjects were included. Demographic and clinical characteristics are shown in Table 1. RA patients were divided into 2 groups, according to disease activity by DAS 28-CRP (remission or low activity and moderate or high activity). Echocardiographic parameters were compared between the RA group and controls also between the 2 groups in which RA patients were divided by disease activity Table 2. The LVEF was lower in RA subjects compared with controls (p= 0.022), however, LVEF was normal (> 52% in men and >54% in women) in both groups. There was a significant difference in the circumferential strain (CS) between RA patients based on the disease activity by DAS 28-CRP (p= 0.006).

Conclusion: The decrease in circumferential strain depends on disease activity. Myocardial strain by speckle tracking echocardiography may detect early myocardial dysfunction in RA. The rheumatologist needs to establish an appropriate treatment to achieve the disease remission or low disease activity, as there is an impact of the disease activity on the myocardial function.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Radiography is the most widespread imaging technique used in the evaluation of knee osteoarthritis (KOA), and MRI is known to be specific in characterization of cartilage disease. However, both modalities have their limitations, and there remains need for a reproducible and widely available imaging technique for characterization of KOA disease severity. The utility of ultrasound (US) in inflammatory arthritis is well documented. In KOA, however, the typical sonographic findings are less clear, and can be operator dependent. This study aims to describe sonographic features of KOA, assess reader reliability, and correlate to radiographic findings.

Methods: 161 patients with end stage KOA were prospectively enrolled two weeks prior to knee replacement to undergo knee ultrasound. 31 sonographic features pertinent to KOA were assessed, including osteophyte size, meniscal extrusion (Figure 1), synovial thickness and cartilage erosion. Bangdiwala's B statistic and intraclass correlation coefficient (ICC) were used to assess rater agreement and interrater reliability, respectively, for 2 raters in 75 knees. Spearman's rank correlation (ρ) was used to assess for association between US and radiographic findings.

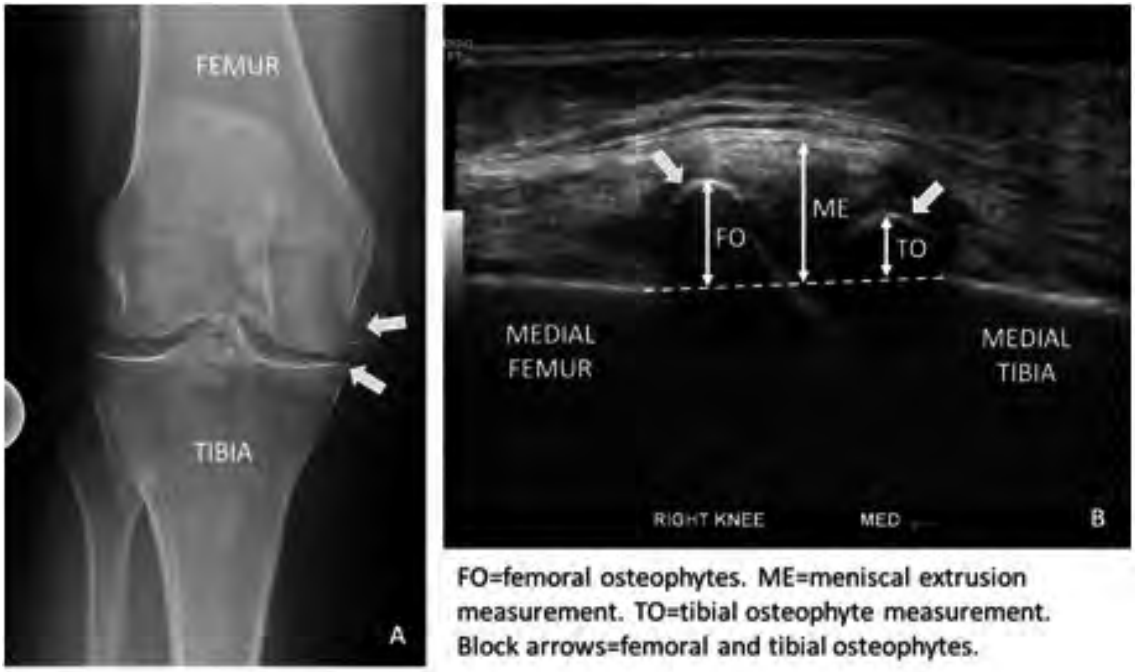

Figure 1. Radiograph of the right knee (A) with corresponding sonographic image of the medial knee (B) in end stage knee osteoarthritis. Measurement technique for femoral and tibial osteophyte and meniscal extrusion depicted.

Ultrasound Metric	X-Ray Metric	N	Spearman's ρ	95% CI	p-value
Medial Joint Line Meniscal Extrusion	KL Grade of Knee OA	144	0.31	(0.15, 0.45)	<.001
Medial Joint Line Meniscal Extrusion	Degrees of Varus	81	0.24	(0.03, 0.44)	0.028
Medial Joint Line Meniscal Extrusion	Degrees of Valgus	62	-0.48	(-0.65, -0.26)	<.001
Lateral Joint Line Meniscal Extrusion	KL Grade of Knee OA	143	0.17	(0.01, 0.33)	0.037
Lateral Joint Line Meniscal Extrusion	Degrees of Valgus	65	0.44	(0.22, 0.62)	<.001
Medial Joint Line Osteophytes on Tibial Joint Line	KL Grade of Knee OA	137	0.31	(0.15, 0.45)	<.001
Medial Joint Line Osteophytes on Tibial Joint Line	Degrees of Varus	80	0.21	(-0.01, 0.41)	0.06
Medial Joint Line Osteophytes on Femoral Joint Line	KL Grade of Knee OA	141	0.38	(0.23, 0.51)	<.001
Lateral Joint Line Osteophytes on Femoral Joint Line	KL Grade of Knee OA	139	0.3	(0.13, 0.44)	<.001
Lateral Joint Line Osteophytes on Femoral Joint Line	Degrees of Valgus	63	0.42	(0.19, 0.60)	<.001

Table 1: Significant correlations between ultrasound and radiographic metrics in patients with end stage knee osteoarthritis.

Results: In this cohort of 161 knees, 94 (58%) revealed no to mild suprapatellar synovial thickness. Joint line osteophytes tended to be larger medially, and on the femoral side. The degree of meniscal extrusion was worse at the medial side. There was almost perfect to perfect (0.81-1) rater agreement for 14 of 24 features assessed, includ-

ing presence of effusion, synovial hyperemia, degree of synovial thickening, patella tendinopathy. Substantial rater agreement (0.70-0.80) was found for medial/lateral joint line synovial thickening, degree of cartilage erosion, presence of Baker's cyst, and quadriceps tendinosis. Measures of synovial thickness, osteophyte size, degree of meniscal extrusion showed excellent interrater reliability (0.73-0.99), while interrater reliability of Baker's cyst wall thickness measurement was fair (0.53). Degree of medial and lateral meniscal extrusion correlated with the degree of knee varus and valgus, respectively. Degree of medial and lateral meniscal extrusion, medial tibial and femoral osteophyte size, and lateral femoral osteophyte size correlated with the Kellgren-Lawrence (KL) grade of KOA. However, significant correlations between US and x-ray findings were fair at most (Table 1). Presence or degree of synovial thickening did not correlate with KL grade of KOA, or with the degree of knee varus/valgus.

Conclusion: Patients with KOA had larger medial side osteophytes, and worse degrees of medial meniscal extrusion, compared to the lateral side. The majority of patients presented with no to mild suprapatellar synovial thickening. The majority of sonographic measurements performed in the knee demonstrates high agreement and reliability across raters. Sonographic features of meniscal extrusion and osteophyte size correlated with radiographic measures of knee alignment, and with radiographic K-L grade of KOA. Ongoing studies will correlate these sonographic features of KOA with clinical and histologic findings.

The Role of Dual Energy Computed Tomography (DECT) in the Differentiation of Gout and Calcium Pyrophosphate Deposition Disease

Dmitrij Kravchenko[1], Pantelis Karakostas[2], Peter Brossart[3], Charlotte Behning[4], Carsten Meyer[1] and **Valentin Schaefer**[5], [1]Department of Interventional and Diagnostic Radiology, University Hospital Bonn, Bonn, Germany, Bonn, Germany, [2]Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Bonn, Germany, Bonn, Germany, [3]Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [4]Institute for Medical Biometrics, Informatics and Epidemiology (IMBIE), University Hospital Bonn, Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [5]Clinic ofInternal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Bonn, Germany, Bonn, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Differentiation of gout and calcium pyrophosphate deposition disease (CPPD) is sometimes difficult as patients often present with a similar clinical picture. Arthrocentesis and subsequent polarization microscopy (PM) remains the gold standard but novel diagnostic approaches such as non-invasive dual energy computed

	DECT	US	Conventional radiographs	Suspected clinical Diagnosis
Gout	n=30	n=30	n=26	n=30
Sensitivity	59.1% (0.36-0.79)	90.9% (0.71-0.99)	55.6% (0.31 - 0.79)	81.8% (0.60-0.95)
Specificity	100% (0.63-1.00)	75% (0.35-0.97)	100% (0.63 - 1.00)	87.5% (0.47-1.00)
CPPD	n=30	n=30	n=26	n=30
Sensitivity	37.5% (0.09-0.76)	87.5% (0.47-1.00)	25% (0.01 - 0.81)	75.0% (0.35-0.97)
Specificity	81.8% (0.60-0.95)	90.1% (0.71-0.99)	72.3% (0.50 - 0.89)	100% (0.85-1.00)

Table 1. Sensitivities and specificities of examinations in gout and calcium pyrophosphate deposition disease (95% CI in brackets).

tomography (DECT) have recently been validated for gout. Currently, limited data is available on DECT in patients with CPPD. Our objective was to analyse the diagnostic impact of DECT in gout and CPPD when compared to the gold standard of PM. We further compared the results of PM to ultrasound (US), conventional radiographs (CR), and suspected clinical diagnosis (SCD). Additionally, 12 laboratory parameters were analysed.

Methods: Thirty patients with suspected gout (n = 22) or CPPD (n = 8) were included. Two independent readers assessed colour coded, as well as 80 and 120 kV DECT images for signs of monosodium urate (MSU) crystals or CPP deposition. US, CR, and the SCD were also compared to PM results. US examinations were performed by certified musculoskeletal ultrasound specialists. The association of up to 12 laboratory parameters such as uric acid, thyroid stimulating hormone, and C-reactive protein (CRP) with the PM results was analysed.

Results: Sensitivity of DECT for gout was 59.1% (95% CI 0.36-0.79) with a specificity of 100% (95% CI 0.63-1.00). Concerning CPPD, the sensitivity and specificity of DECT was 37.5% (95% CI 0.09-0.76) and 81.8% (95% CI 0.60-0.95) respectively. US had the highest sensitivity of 90.9% (95% CI 0.71-0.99) with a specificity of 75% (95% CI 0.35-0.97) for gout, while the sensitivity and specificity for CPPD were 87.5% (95% CI 0.47-1.0) and 90.1% (95% CI 0.71-0.99) respectively. The SCD had the second highest sensitivity for gout at 81.8% (95% CI 0.60-0.95) with a comparable sensitivity of 75% (95% CI 0.35-0.97) for CPPD. Uric acid levels were elevated in 26% of gout patients and 25% of CPPD patients. While elevated CRP levels were observed in 60% of gout patients and in 88% of CPPD patients. None of the 12 laboratory parameters were found to be significantly linked to either disease.

Conclusion: DECT is a non-invasive imaging tool for gout but might have a lower sensitivity than published by previous studies (59.1% vs 90%[1]). DECT sensitivity for CPPD was 37.5% (95% CI 0.09-0.76) in a sample group of eight patients. Both US and the SCD had higher sensitivities than DECT for gout and CPPD. Further studies with larger patient cohorts are needed in order to determine the diagnostic utility of DECT in CPPD.

Prevalence of Ultrasound Findings Suggestive of Inflammatory Arthritis in Children with Skin Psoriasis (ChildEchoPso)

Luis Coronel[1], Tania Gudu[2], Sophie Ruel-Gagné[1], Helen Gouze[3], Francois Vidal[4], Ilaria Padovano[4], Felice Constantino[2], Maxime Breban[4], Emmanuel Mahe[5] and Maria Antonietta D'Agostino[6], [1]Hôpital Ambroise-Paré, Boulogne-Billancourt, France, [2]Hôpital Ambroise-Paré, Bolougne-Billancourt, France, [3]helene.gouze@aphp.fr, Bolougne-Billancourt, France, [4]Hôpital Ambroise-Paré, Bolougne-Billancourt, [5]Centre Hospitalier Victor Dupouy, Argenteuil, France, [6]Paris-Saclay Versailles University, Hôpital Ambroise Paré, Boulogne-Billancourt, France

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of psoriasis in children is estimated between 0.5-1% (1), and can be associated with musculoskeletal involvement, althought the prevalence and typology of such involvement is unknown. (2)

Over the last years ultrasound associated with Doppler (PDUS) has become an important tool for evaluating joint involvement in children. Several studies have shown the high sensitivity of this technique for detecting joint involvement, as well as high acceptability, due to the lack of radiation or of sedation (3).

To the best to our knowledge this is the first study aiming to evaluate the prevalence of ultrasound involvement of joints and entheses in children with PsO.

Methods: Observational cross-sectional study aiming at evaluating 150 consecutive children (≤16 years) with skin PsO. For each child a standardized clinical and ultrasound evaluation of joint and entheses was performed at the following bilateral sites: a) Entheses: quadriceps tendon, proximal and distal patellar ligament, Achilles tendon, plantar fascia and extensor elbow tendon), b) joints: metacarpophalangeal, proximal and distal interphalangeal, wrist, elbow,

Table 2. PDUS Findings.

knee, ankle, and metatarsophalangeal. The presence of spontaneous pain was also recorded. Ultrasound was performed by an independent assessor, blinded to clinical assessment and symptoms.

Results: 49 patients were included until now. Thirteen patients (26%) presented some painful joint or enthesis, 27 patients (55%) had family history of PsO and none of them had family history of psoriatic arthritis. Demographic and clinical characteristics are shown in Table1, whilst PDUS findings in Table 2.

Conclusion: Presence of ultrasound abnormalities was higher in the symptomatic group and the most prevalent inflammatory ultrasound findings were synovitis and enthesitis. Ultrasound may be useful to detect subclinical involvement in children with PsO and musculoskeletal symptoms.

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis **(**RA) is a serious and potentially debilitating disease, but low disease activity and even clinical remission can be obtained if an effective therapy can be identified early in the course of the disease. Imaging with Tc99m tilmanocept, a high affinity ligand to CD206 expressed on activated macrophages, offers the potential to meet this need by providing an objective, quantifiable readout of changes in macrophage density in the joints of patients undergoing initiation or change of bDMARD therapy. These macrophage density changes may be observable weeks before disease modification can be detected with standard clinical assessments. This earlier

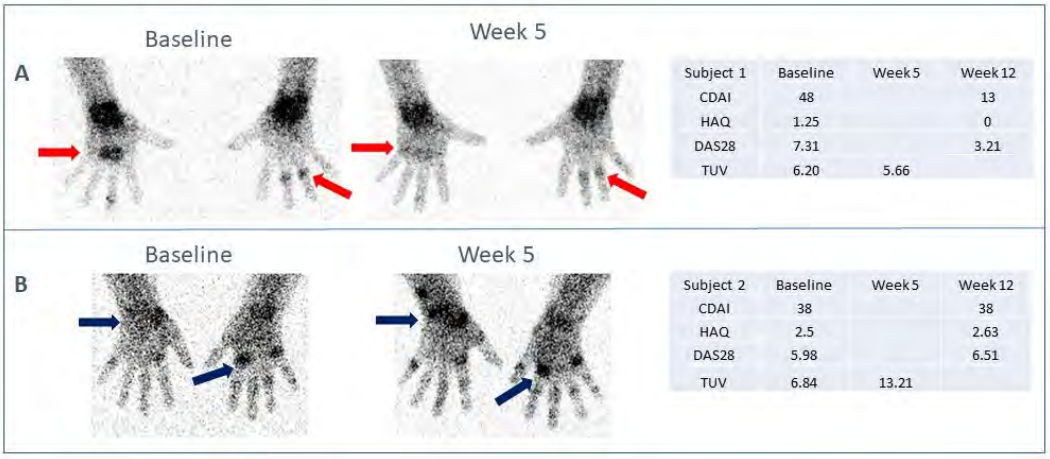

Figure 1. Quantification of Tc99m tilmanocept at Baseline and Week 5 is predictive of clinical efficacy at Week 12. Representative Baseline and Week 5 images and Tc99m tilmanocept quantification (Tilmanocept Uptake Value; TUV) demonstrate changes in localization that are sensitive to and predictive of clinical response at Week 12. Images show decrease in signal localization predictive of clinical response (Panel A) and increase in signal localization predictive of clinical non-response (Panel B) at Week 12.

readout would allow for more timely modifications of the treatment strategy and earlier identification of an effective therapy, thus reducing the likelihood of permanent joint damage associated with ineffective therapy and the potential for side effects from exposure to these ineffective therapies.

Methods: An interim analysis of our Phase 2b trial (NCT03938636) was performed using data from 15 subjects with active RA (DAS28 ≥ 3.2; ACR/EULAR 2010 Classification Criteria ≥ 6) set to begin a new or first-time treatment regimen with an anti-TNFα therapy. Hand/wrist planar gamma camera images were obtained at baseline prior to initiation of new treatment, 5 weeks post-therapy initiation, and 12 weeks post-therapy initiation for 11 of the 15 subjects at the time of the analysis. The remaining subjects had completed baseline and 5-week imaging only at the time of this analysis. Images were quantitatively assessed to detect localization within synovial spaces of bilateral hands and wrists by determining average pixel intensity in each region of interest relative to average pixel intensity in an adjacent reference region. Additionally, a panel of established clinical assessments (CDAI, DAS28, HAQ-DI) was performed at each time point in order to compare imaging results with clinical evaluations over the 12-week time course.

Results: In 9 out of 11 subjects with 12-week clinical data available at the time of analysis, Tc99m tilmanocept imaging from baseline to week 5 was predictive of clinical outcome at 12 weeks (Figure 1). Global Tc99m tilmanocept signals declined by an average of 46% from baseline to week 5 in those subjects correctly predicted as responding significantly to anti-TNFα treatment by week 12. In subjects correctly predicted by imaging not to have a significant clinical response by week 12, Tc99m tilmanocept signals increased by an average of 44% from baseline to week 5. Combined data from all 15 subjects demonstrated that baseline global Tc99m tilmanocept uptake values in joints with RA-involved inflammation spanned a range of values of over an order of magnitude. These preliminary results indicate that marked changes in Tc99m tilmanocept global uptake values by week 5 presage clinical efficacy evaluations at week 12 of treatment.

Conclusion: These interim data are supportive of the hypotheses that Tc99m tilmanocept imaging can provide quantifiable imaging assessment of RA-involved joints that enables early prediction of clinical response as well as longitudinal monitoring of clinical status.

Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Diffuse idiopathic skeletal hyperostosis (DISH) is a non-inflammatory condition most classically seen in the spine, and is characterized by ossification of the spinal ligaments and entheses. DISH may be asymptomatic, but in some cases is associated with back pain and stiffness. Risk factors include male sex, increasing age, obesity and metabolic syndrome. Important radiographic mimics of DISH include osteoarthritis and ankylosing spondylitis There are multiple classification criteria for DISH, though the 1976 Resnick and Niwayama classification criteria are best known (1).

While xrays are used to identify DISH, it can still be challenging for trainees and primary care health professionals to distinguish it from its mimics. We conducted a pilot study to develop an Artificial Intelligence (AI) assistant, trained to identify DISH from 'non-DISH' on xrays by using convolution neural network (CNN). CNN is the most popular model for imaging classification in deep learning.

Methods: DISH patients were identified from our university's radiology database, using word search 'DISH' or 'Diffuse idiopathic skeletal hyperostosis' in all cervical, thoracic or lumbosacral radiographs in the year 2015. Diagnosis of DISH was confirmed by 2 board certified radiologists, and either completely fulfilled Resnick criteria or incompletely fulfilled Resnick criteria but were still felt to have DISH based on radiologists' expert opinion. We also compiled a list of age and sex-matched patients with spinal x-rays from 2015 who lacked DISH based on the radiologists' read.

All image data were imported into R statistical language/Rstudio. We used a CNN to train a classification rule for spinal xrays of DISH vs. non-DISH using the keras and tensorflow R packages. 90% of each group was used as training data and the rest were used as test data to evaluate the accuracy of the classification rule.

Results: 116 patients with DISH and 262 matched controls were included. The image size was cropped from 601x524 pixels to 461 x 345 pixels to remove unnecessary solid background and add-on information before the CNN training. The trained CNN was a sequential model with 2 convolution layers (64 or 32 rectified linear units), 2 dense layers (one layer with 16 rectified linear units and the other with 1 sigmoid unit), and others. The network was trained by the RMSprop optimizer and validation split = 0.2 with 100 epochs. The overall training accuracy of the classification rule

by CNN was 92% (sensitivity 75% and specificity 100%). The overall test accuracy was 89% (sensitivity 70% and specificity 98%).

Conclusion: The trained AI-assistant has reasonable sensitivity and very high specificity. In this pilot study, we demonstrated that a CNN-based AI-assist for identifying DISH xrays could be trained from scratch with a moderate size of images that seemed to perform reasonably well. The future research will be focusing on improving the accuracy of the AI-assistant with more images.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US), magnetic resonance imaging (MRI) and conventional radiography are the leading imaging modalities for musculoskeletal (MSK) assessment in PsA. However, little is reported about the discrepancies between these tools in PsA patients. The aim of this study is to examine the agreement between these modalities and to evaluate the sensitivity and specificity of US and X-ray with MRI as gold standard in PsA patients.

Methods: The study population included consecutive PsA patients (CASPAR criteria) that were prospectively recruited. All patients underwent clinical assessment including complete history taking, physical examination, questionnaires for disease activity and quality of life assessment and blood test for acute phase reactants. US (gray scale and Doppler), contrast enhanced MRI and AP and oblique radiographs of MCP, PIP and DIP joints of one most clinically involved matched hand. US and MRI evaluated synovitis, flexor tenosynovitis and extensor paratenonitis. US, MRI and radiography evaluated erosions and bone proliferations. The time interval between the US and MRI was maximum 3 days and the US, MRI and X-ray readers were blinded to clinical data. NSAIDs were hold for 3 days before US and MRI assessment. The US images were scored according to the EULAR-OMERACT, the MRI images according to the PsAMRIS scoring system and the X-ray according to the Psoriatic Arthritis Ratingen Score (PARS) method. Positive values for comparison were ≥1. Agreement between MRI and US was calculated based on kappa and prevalence-adjusted bias-adjusted kappa (PABAK) values. Sensitivity and specificity of US and X-ray with MRI as gold standard was calculated as well.

Table 1: Prevalence of lesions for each group of joints

		US Value ≥1	MRI Value ≥1	X-Ray Value ≥1	P-Value
Synovitis*					
MCP, n (%)		101 (20.2)	79 (15.8)		0.07
PIP, n (%)		43 (8.6)	38 (7.6)		0.6
DIP, n (%)		16 (4)	14 (3.5)		0.7
Extensor paratenonitis					
MCP, n (%)	Gray scale	20 (4)	19 (3.8)		0.9
	Doppler	5 (1)			
PIP, n (%)	Gray scale	37 (7.4)	23 (4.6)		0.06
	Doppler	3 (0.6)			
DIP, n (%)	Gray scale	6 (1.5)	8 (2)		0.6
	Doppler	2 (0.5)			
Flexor tenosynovitis					
MCP, n (%)	Gray scale	32 (6.4)	33 (6.6)		0.9
	Doppler	7 (1.4)			
PIP, n (%)	Gray scale	24 (4.8)	16 (3.2)		0.2
	Doppler	5 (1)			
DIP, n (%)	Gray scale	7 (1.8)	5 (1.2)		0.6
	Doppler	0			
Erosions					
MCP, n (%)		20 (4)	24 (4.8)	3 (0.9)	*0.005*
PIP, n (%)		11 (2.2)	9 (1.8)	7 (2.5)	*0.71*
DIP, n (%)		4 (1)	4 (1)	8 (2.9)	*0.13*
Bone proliferations					
MCP, n (%)		41 (8.2)	8 (1.6)	25 (7.1)	<0.001
PIP, n (%)		81 (16.2)	12 (2.4)	57 (16.3)	<0.001
DIP, n (%)		117 (29.2)	3 (0.8)	74 (26.4)	<0.001

*According to the EULAR-OMERACT definition

Table 1. Prevalence of lesions for each group of joints

Results: One hundred PsA patients were included (mean age: 51.2 years with 59% females) and 29 patients were in minimal disease activity. The prevalence of synovitis, flexor tenosynovitis, extensor paratenonitis were similar between the US and MRI assessments. Erosions were significantly increased in US and MRI compared to X-RAY in MCPs level (p=0.005), while bone proliferations were significantly increased in US and X-ray compared to MRI (p< 0.001) (Table 1). The absolute agreement between US and MRI was good-very good for synovitis (85%-96%, PABAK=0.7-0.92), flexor tenosynovitis (93%-98% PABAK=0.87-0.96) and for extensor paratenonitis (95%-98%, PABAK=0.9-0.97) (Table 2). Agreement between US, MRI and X-Ray for erosions was very good (96%-98%, PABAK=0.92-0.97) and for bone proliferations good-very good (71%-93%, PABAK= 0.47-0.87). Sensitivity of US with MRI as gold standard was higher for synovitis 0.5-0.86, extensor paratenonitis (0.63-0.85) than for flexor tenosynovitis (0.1-0.75), while the specificity was high in each evaluated domain (0.89-0.98) (Table 3).

Conclusion: There is very good agreement between US and MRI for the detection of finger inflammatory changes. US, X-ray and MRI have good to very good agreement for structural changes.

Table 2: Agreement between the different imaging modalities with both Kappa and prevalence adjusted biased adjusted Kappa (PABAK)

	US vs MRI			X-Ray vs US			X-Ray vs MRI

SESSION INFORMATION

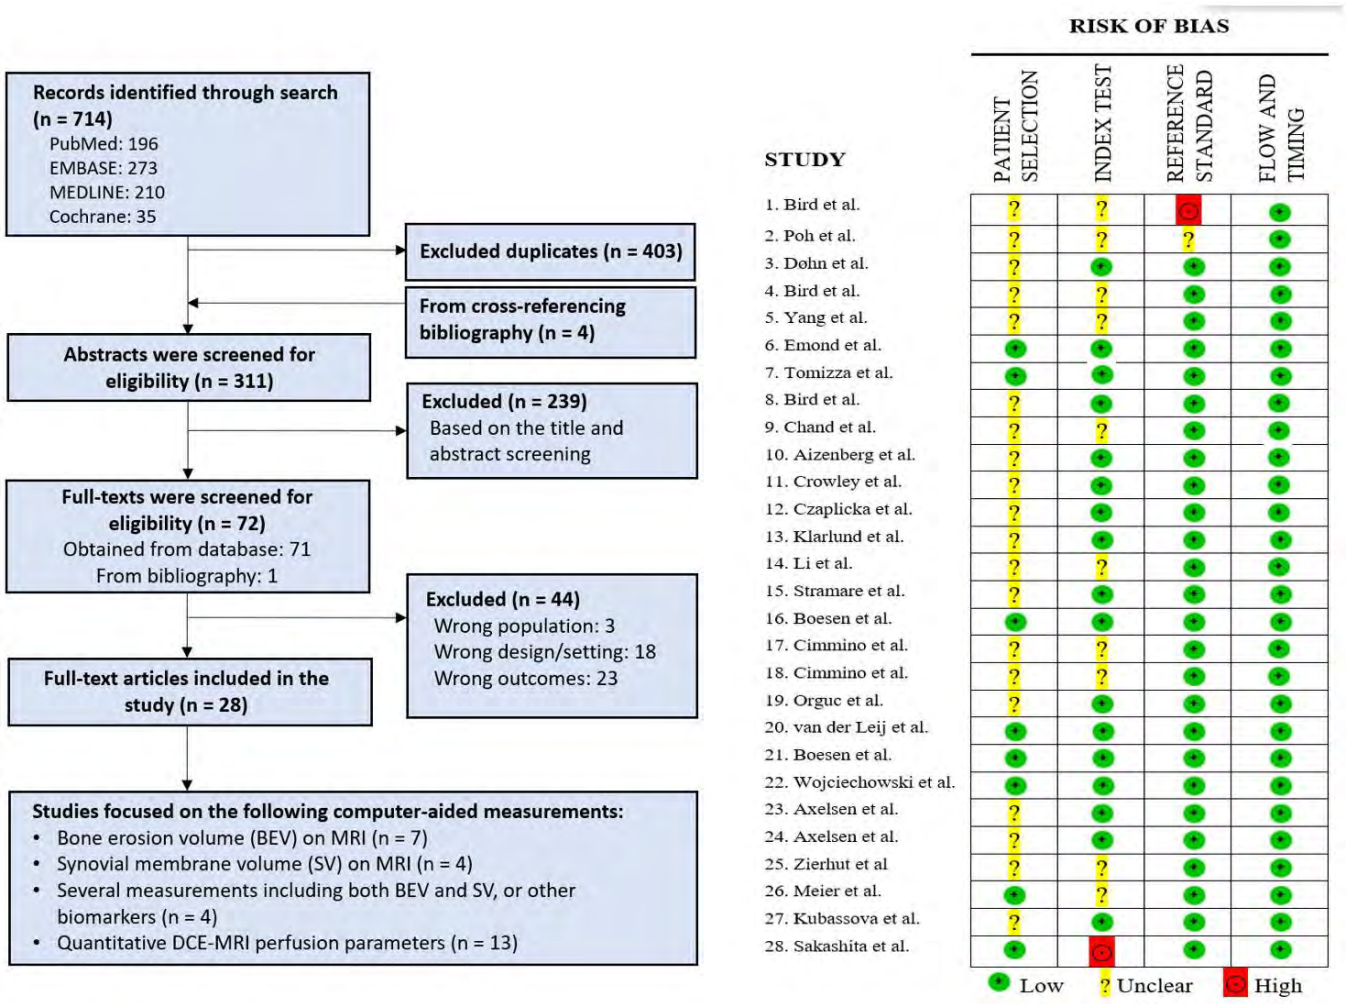
Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To summarize the feasibility, reliability, and validity of computer-aided quantification of joint destruction and synovitis on MRI using artificial intelligence (AI) based methods in patients with inflammatory arthritis.



PRISMA flowchart diagram for study selection and risk of bias assessment using the QUADAS-2 tool. No concern was detected regarding the applicability of patient selection, index test, and reference standard.

Methods: A systematic literature search was performed on PubMed, EMBASE, SCOPUS, and Cochrane databases for original articles published from January 01, 1985 to June 02, 2020. We selected studies in which patients with inflammatory arthritis were enrolled, and arthritis-related structural damage/synovitis in peripheral joints were assessed on non-CE, CE, or DCE-MRI using (semi)automated methods. Data were pooled using random-effects model. Publication bias was addressed using the Begg and Mazumdar test and the trim and fill method. Subgroup analysis and meta-regression were performed.

Results: 28 studies consisting of 1342 MRIs were included (age=54.8; 66.7%female; duration of arthritis=3.6years). Pooled analysis showed an overall excellent intra- and inter-reader reliability for computer-aided quantification of bone erosion volume (BEV) (*r*=0.97(95%CI:0.92–0.99) and 0.93(0.87–0.97)), synovial membrane volume (SV) (*r*=0.98(0.90–0.99) and 0.86(0.78–0.91)), and DCE-MRI perfusion parameters (*r*=0.99(0.82–1) for maximum enhancement, *r*=0.99(0.94–1) for initial rate enhancement, *r*=0.96(0.85–0.99) for and total number of enhancing voxels (N-total)). Meta-regression analysis showed that computer-aided and manual methods provide comparable reliability for quantification of bone erosion, synovitis, and perfusion parameters (*P*>0.05). Computer-aided measurement of BEV (*r*=0.92), SV (*r*=0.82), and DCE-MRI biomarkers (*r*=0.72 N-total; *r*=0.74 N-plateau; *r*=0.64 N-washout) were significantly correlated with the OMERACT RAMRIS scores (*P*< 0.01). Among clinical and laboratory factors, SV was mod-

Results of pooled analysis and meta-regression: Pooled ICC values for intra- and inter-reader realibility of each computer-aided measurement, correlation values between computer-aided measurements and manual scores/ clinical findings, and time needed to perform each image analysis method (Table). Meta-regression analysis for the association between the field-strength of MR scanner (tesla of MRI) and intra-reader (Fig A) and inter-reader (Fig B) reliability of computer-aided measurement of bone erosion volume (BEV) on MRI. Meta-regression analysis for the association between the duration of disease, form the onset of inflammatory arthritis (years), and intra-reader (Fig C) and inter-reader (Fig D) reliability of computer-aided measurement of synovial membrane volume (SV) on MRI.

erately correlated with ESR level (r=0.52, P< 0.01). On average, (semi)automated analysis of BEV/SV and DCE-MRI takes 17mins (vs. 9mins for OMERACT RAMRIS method) and 4mins (vs. 33mins for manual reading), respectively.

Conclusion: AI-based methods demonstrate feasibility, reliability and validity when utilized to quantify MRI pathologies of peripheral joints in patients with inflammatory arthritis; this provides a sound basis for future research. Computer-aided evaluation of inflammatory arthritis on non-CE and CE-MRI, and DCE-MRI could be considered as an alternative to conventional observer-based methods.

Blood Pressure, BMI and Sex Affect Optical Spectral Transmission Imaging Measurements of the Hands

Annelies Blanken[1], Conny van der Laken[2] and Mike Nurmohamed[3], [1]Amsterdam Rheumatology and immunology Center location Reade, Amsterdam, Netherlands, [2]Amsterdam Rheumatology and immunology Center, location Amsterdam UMC, VU medical center, Amsterdam, Netherlands, [3]Amsterdam Rheumatology and immunology Center, location Reade and Amsterdam UMC, VU medical center, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Optical spectral transmission imaging (OST) is a new imaging method designed to measure inflammation in the hands of rheumatoid arthritis (RA) patients. The device uses a pressure cuff to occlude venous blood flow, resulting in an increased blood pool in the hands of the patient. In inflamed joints transmission of light through this blood pool is altered due to higher blood content, lower oxygenation and stronger hemodynamics at the location of inflammation. However, altered hemodynamics not related to inflammatory arthritis might also influence OST measurements. In this study we investigated whether hemodynamic and other cardiovascular parameters affect OST in healthy participants.

Methods: OST measurement was done in 37 healthy participants using the HandScan device (Hemics, the Netherlands). Carotid intima media thickness (IMT), pulse wave velocity (PWV) and augmentation index (AIx) were measured with ultrasound and SphygmoCor tonometry. Age, sex, diastolic and systolic blood pressure, pulse, hypertension (defined as systolic blood pressure >140 mmHg or diastolic blood pressure > 90 mmHg or antihypertensive treatment), total cholesterol, HDL, LDL, total/HDL cholesterol ratio, body mass index (BMI), European SCORE risk assessment, smoking status, cardiovascular history and medication use were collected during the same visit. Associations were investigated using univariate linear regression and multivariate regression adjusting for age and sex.

Results: Participants were 53 ± 8 years old and 65% was female. Systolic and diastolic blood pressure was 129 ± 19 mmHg and 80 ± 9 mmHg respectively and 22% used antihypertensive treatment, 8% an anticoagulant and 11% a statin. In total 38% had hypertension and 8% had a history of cardiovascular disease.

Table 1. Cardiovascular and hemodynamic parameters associated with higher OST measurement

	Univariate			Adjusted for age and sex		
	B	95%CI	p	B	95%CI	p
Hypertension (y/n)	2.39	0.12 - 4.67	0.04	2.41	0.37 - 4.45	0.02
Systolic blood pressure	0.08	0.03 - 0.14	0.005	0.07	0.02 - 0.12	0.01
Diastolic blood pressure	0.20	0.08 - 0.32	0.001	0.19	0.09 - 0.29	0.001
BMI	0.24	-0.01 - 0.48	0.06	0.26	0.05 - 0.47	0.02
Sex (male/female)*	3.67	1.56 - 5.78	0.001	3.54	1.29 - 5.79	0.003
European SCORE**	1.24	0.09 - 2.39	0.04	n/a		

*Adjusted for age only, **Not adjusted because age and sex are included in the European SCORE

Mean OST value was 12.69 ± 3.47 and all values were between 5.00 and 20.78. Cardiovascular and hemodynamic parameters that were associated with higher OST measurement were: hypertension (14.18 ± 1.12 versus 11.79 ± 0.69), systolic and diastole blood pressure, BMI and European SCORE (table 1). Also, male sex was associated with a higher OST with and without adjustment for age (15.05 ± 1.04 versus 11.41 ± 0.62 for females). Other parameters (age, cholesterol, pulse, IMT, having carotid plaque, PWV, AI, cardiovascular history, smoking status and statin, anti-hypertensive drug and/or anticoagulant use) were not associated with the OST measurement (p >0.13).

Excluding the 5 (14%) participants with hand osteoarthritis showed comparable results, except for BMI and hypertension. BMI was also significantly associated with OST in the univariate analysis (B 0.24, 95%CI 0.01-0.47, p=0.039), while hypertension lost its statistical significance (uni B 1.74, 95%CI -0.69-4.17, p=0.15; multi B 1.44, 95%CI -0.61-3.48, p=0.16).

Conclusion: High blood pressure, BMI, male sex and European SCORE are associated with increased OST values in healthy participants. This indicates that differences in OST measurements of RA patients might not only reflect inflammatory burden but is also dependent on sex, blood pressure and body composition. This should be taken into account when using optical spectral transmission imaging for the assessment of inflammation in RA patients.

Joint Damage and Malalignment Determine Articular Tenderness More Than Inflammation in Rheumatoid Arthritis, Psoriatic Arthritis or Osteoarthritis in Established Disease

Mihaela Popescu[1], Victoria Schimpl[2], Gabriela Supp[3], Martina Durechova[3], Paul Studenic[3], Michael Zauner[3], Josef Smolen[3], Daniel Aletaha[4], Peter Mandl[3] and **Irina Gessl**[3], [1]Hôpital Maisonneuve-Rosemont, Montreal, Canada, [2]Medical University of Vienna, Vienna, Austria, [3]Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, [4]Division of Rheumatology, Department of Medicine III, Medical University of Vienna,, Vienna, Austria

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

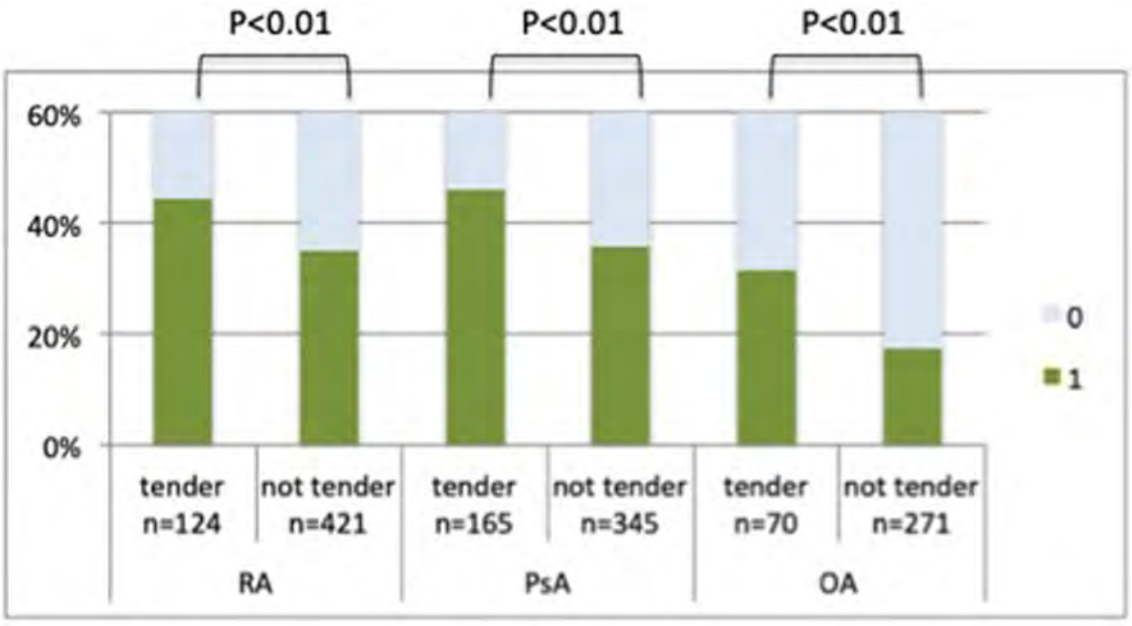

Figure 1. Difference of damage score (0 vs. ≥1) in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and osteoarthritis (OA).

Background/Purpose: To determine whether clinical tenderness can be considered a sign of inflammatory joint activity in patients with rheumatoid arthritis (RA), osteoarthritis (OA) or psoriatic arthritis (PsA).

Methods: Patients diagnosed with RA, PsA and OA underwent clinical and ultrasound examination of wrists and finger joints. Gray scale signs of synovitis (GS) and Power Doppler signal (PD) were evaluated using a semiquantitative grading system. Radiographs of the hands were scored for erosions, joint space narrowing, osteophytes and malalignment and a binary damage score was calculated. Differences in PD and GS between tender non-swollen (TNS) vs. non-tender non-swollen joints (NTNS) were calculated by Chi-Square test and prediction of tenderness was assessed by sex- and age-adjusted binary logistic regression analysis.

Results: There was no difference in the frequency of PD positivity between TNS and NTNS joints in RA (p=0.18), PsA (p=0.59) or OA (p=0.96) (Fig. 1). However, PD had a significant impact on tenderness in non-swollen joints in patients with a disease duration of less than 2 years, both in RA (OR 2.22, 95%CI 1.12-4.43, p=0.02) and in PsA (OR 3.26, 95%CI 1.21-8.81, p=0.02). The radiographic damage score had a significant impact on tenderness in non-swollen joints in RA (OR 1.8, 95%CI 1.17-2.86, p< 0.01), PsA (OR 1.84, 95%CI 1.18-2.86; p< 0.01) and OA (OR 1.89, 95%CI 1.03-3.46; p=0.04) (Fig. 2).

Conclusion: Tenderness might not always be a sign of active inflammation in RA, PsA and OA. While inflammation may play a role in early disease, tenderness in established disease may be better explained by joint damage and malalignment.

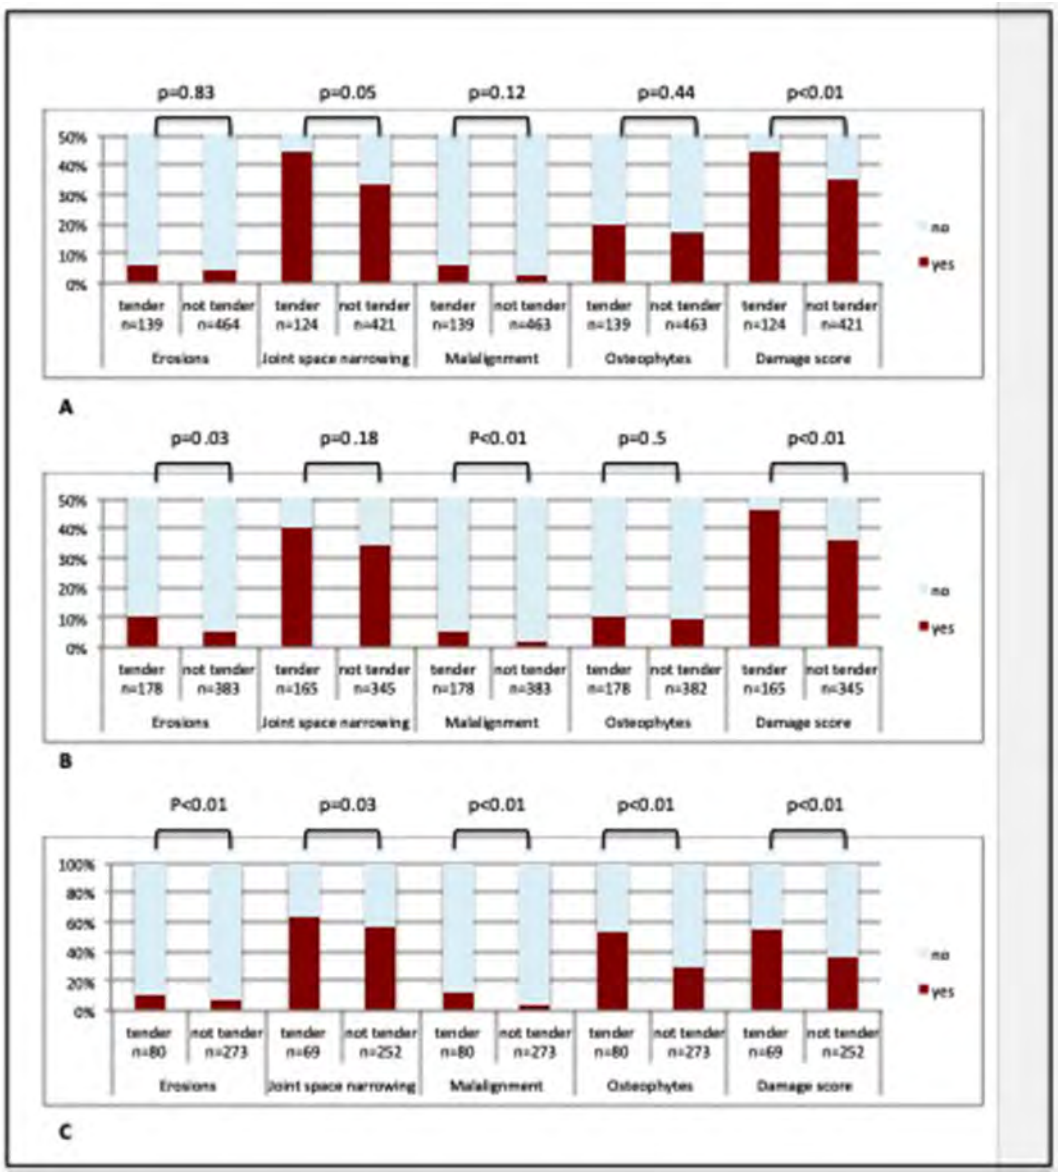

Figure 2. Difference of detected erosions (0 vs. ≥1), joint space narrowing (0 vs. ≥1), malalignment (presence/ absence), osteophytes (presence/ absence) and damage score (0 vs. ≥1) in patients with rheumatoid arthritis (A), psoriatic arthritis (B) and osteoarthritis (C). Impact of erosions (semiquantitatively), joint space narrowing (semiquantitatively), malalignment, osteophytes and damage score on tenderness in non-swollen joints was calculated by age- and sex-adjusted binary logistic regression.

Change in Tophus Size Measured with Dual-energy CT and Ultrasound: A 1-year Multicenter Follow-up Study

Tristan Pascart[1], Pascal Richette[2], Sebastien Ottaviani[3], Laurène Norberciak[1], Hang Korng EA[4], Frédéric Lioté[5], Jérémy Ora[6], Julie Legrand[1], Valérie Bousson[6], Elyas Mahdjoub[7] and Jean--Francois Budzik[8], [1]GHICL, Lomme, France, [2]Department of Rheumatology, Lariboisière Hospital, Paris, France, [3]Rheumatology Department, Bichat hospital, APHP, Paris, France, [4]Universite de Paris, AP-HP, INSERM, paris, France, [5]AP-HP, Paris, France, [6]Lariboisière Hospital, Paris, France, [7]Bichat Hospital, Paris, France, [8]University of Lille, Lille, France

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Dual-Energy computed tomography (DECT) and ultrasound are the two techniques able to identify and measure monosodium urate (MSU) crystal deposition, and both are considered for monitoring crystal depletion during urate lowering therapy (ULT). Particularly, both techniques are able to measure tophi, but it is unknown if their assessment of tophus size are correlated throughout follow-up. The objective of this study was to determine if the evolution of tophus volume measured with DECT and ultrasound were correlated during the first year of ULT.

Methods: Gout patients naïve of ULT and presenting with at least 1 ultrasound tophus of the knees or ankles/feet were recruited in three French referral centers to undergo DECT scans, and were followed-up with ultrasound and

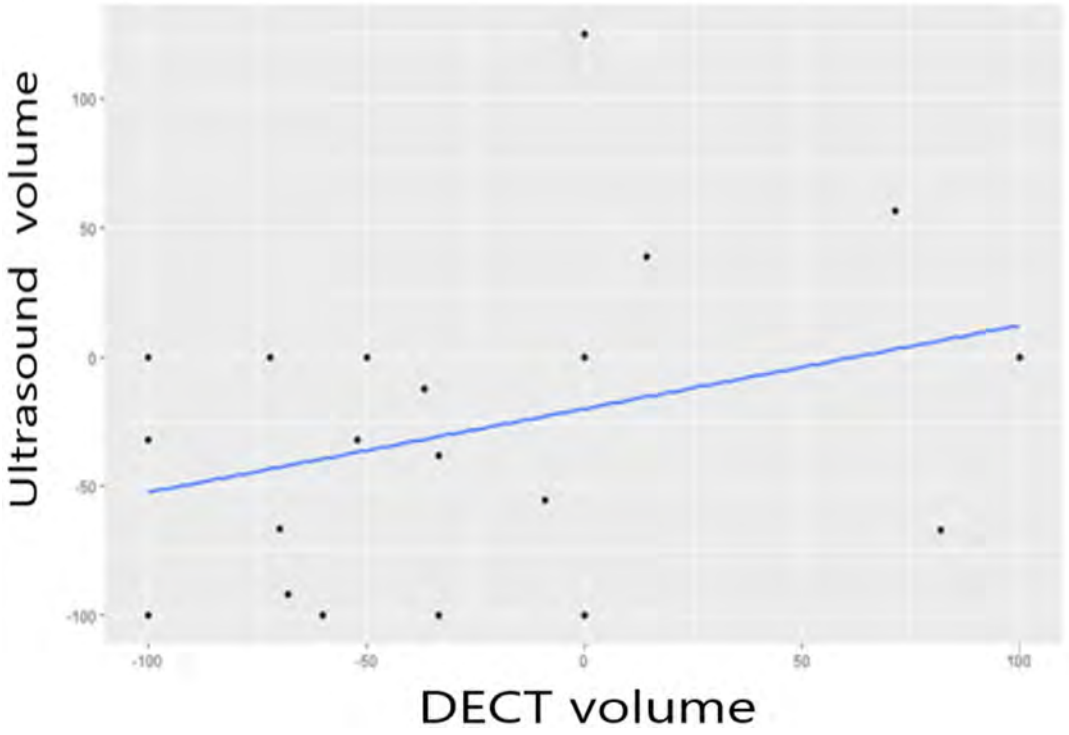

Figure 1. Evolution (in % from baseline) at month 6 of the index tophus measured with dual-energy computed tomography (DECT) and ultrasound.

DECT scans at months 6 and 12. The largest tophus in ultrasound was considered as the index tophus and measured with both techniques. The primary endpoint was the correlation between the evolution of the volumes of the index tophus measured with DECT and ultrasound assessed by the Spearman coefficient correlation (ρ) and its 95% confidence interval at months 6 and 12.

Results: A total of 41 patients were included; they were mostly males (83.3%) and aged in average 63.7 years (±12.3). Baseline serum urate levels were 515.2 µmol/L (±85) (=8.6mg/dL) and 58.3% had subcutaneous tophi. Most index tophi were localized at the 1st MTP joint (53.9%) and had a volume of 0.87 cm^3 (±1.39). 17 patients were lost to follow-up and 4 patients had index tophi that were not detected by DECT at baseline. The relative decrease of the volume of the index tophi at months 6 and 12 measured with ultrasound was -50% [-79.2%;0%] and -75.6% [-94.2%;-25%], respectively, while the decrease measured with DECT was -32.1% [-85.8%;0%] and -37.1% [-88.5%;0%], respectively.

The correlation between the volumes of the index tophi measured with ultrasound and DECT was poor with ρ=0.29 [-0.22;0.65] at month 6 and ρ=-0.03 [-0.66;0.65] at month 12. The correlation between the decrease of the DECT tophus index volume and the global volume of MSU crystal deposition measured with DECT was very good at both months 6 and 12 with ρ=0.82 [0.55;0.93] and 0.83 [0.5;0.96]. The correlation between the decrease of the volume of the index tophus measured with ultrasound and the decrease of the volume of overall MSU crystal deposition measured with DECT was at best moderate with ρ=0.35 [-0.16;0.75] at month 6 and 0.42 [-0.44 ; 0.82] at month 12.

Conclusion: Ultrasound and DECT do not provide the same assessment of MSU crystal depletion during the first year of ULT. The two techniques are not inter-changeable when considering monitoring gout treatment with imaging, especially when considering the follow-up of a target tophus.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To explore the effects of tofacitinib (Tofa) on US lesions in a consecutive series of patients with active RA MTX and/or bioDMARDs -IR.

Methods: In this observational, open label, longitudinal, m*ulticenter* study, patients received Tofa 5 mg twice daily ± MTX ± corticosteroids for 24 weeks. All patients underwent clinical, laboratory and US examinations in a standardized manner according to the EULAR guidelines for musculoskeletal US in rheumatology. Inclusion criteria required an OMERACT-EULAR composite US score for grading synovitis of ≥2 in at least two MCPs. US examinations were performed at baseline (T0), 2w (T1), 4w (T2), 12w (T3) and 24w (T4) for bilateral 20 joint sites and bilateral 20 tendon sites. For each patients we obtained two US joint scores (GS score and PD score) summing up the value of a 0-3 semiquantitative scale for each joint and a cumulative joint score summing up the values of the OMERACT combined joint score. Moreover we calculated two tenosynovitis scores (GS and PD) by summing the 0-3 score for each tendon. US examination were done in each centre, by the same sonographer, with the same US equipment (Esaote My Lab 70 Class, 12–18 MHz transducers) after a reliability test between the sonographers. Sonographers were blinded to clinical evaluations. Clinical and US data obtained at T0, T1, T2, T3 and T4 examinations were compared (T-test for paired samples) and correlated (Spearman's Rho).

Results: In total, 37 patients were enrolled and completed the 6 month period study (F 30 (81%), mean age : 58.5±12.6y), mean disease duration : 8.4+6.4y, ACPA + : 24 (66%) , baseline DAS28 : 4.8±1.2, HAQ : 1.3±0.7, CRP : 2.25±3.1 mg/dl). Joint (GS, PD and combined-PDUS) and tendon US scores (GS and PD) were significantly reduced as early as T1 examination as well as at T2, T3 and T4 visits as compared to baseline values ($p < 0.001$ for all comparisons). There was a statistical significant correlation between reduction of PD and GS teno-score at T1 examination and HAQ improvement at T4 visit (rho 0.607, $p < 0.001$ and rho 0.408, $p = 0.017$ respectively). Improvement of joint US scores (GS, PD and PDUS-combined) correlated at T4 examination with the reduction of serum CRP levels (rho 0.418, $p = 0.036$, rho 0.495, $p=0.004$ and rho 0.454, $p=0.009$ respectively). We did not found any correlation between the variations of DAS28 and any US scores at any visits.

Conclusion: These preliminary results provide evidence that Tofa treatment leads to early (two weeks) and persistent reduction of US signs of inflammation both at tendon and joint level.

Table 2. Clinical, laboratory and MASEI evaluation at baseline, 3- and 6-month follow-up visits aWilcoxon test between time visits

Background/Purpose: The assessment of activity in spondyloarthritis (SpA) and psoriatic arthritis (PsA) involves several domains, including enthesitis. Clinical enthesitis has shown low sensitivity, specificity and reliability. The MAdrid Sonographic Enthesitis Index (MASEI) is a feasible and reliable ultrasound score, but its responsiveness to treatment has not yet been evaluated. Our aim was to explore the sensitivity to change of power Doppler (PD) enthesitis in active spondyloarthritis (SpA) and psoriatic arthritis (PsA) patients.

Methods: Longitudinal study in patients with SpA and PsA with active disease (defined as patients who were going to start or switch biologic disease modifying antirheumatic drugs (bDMARD) therapy). The MAdrid Sonographic Enthesitis Index (MASEI) was performed at baseline, 3- and 6-months visits. MASEI and Outcome Measures in Rheumatology (OMERACT) PD enthesitis definitions were checked. A reliability analysis among three readers was performed with ultrasound (US) recorded videos.

Results: US examinations of 25 patients were included, of whom 13(52%) were ankylosing spondylitis (AS) patients, 9(36%) PsA and 3(12%) non radiographic axial spondyloarthritis (nr-axSpA). Median age was 49 (41-61) years and 13(52%) patients were females. Median DAS28 3.6 (2.3-4.2), median BASDAI 6.7 (6.1-7.4), and CRP values 8.2 (1.6-20), reflect moderate-high disease activity at baseline. Both MASEI and OMERACT PD enthesitis improved significantly at 3- and 6-month follow-up visits ($p< 0.05$) (Table 1) and showed sensitivity to change with a standard error of measurement (SEM) of 0.47 and 0.61 respectively. Improvement in clinical activity outcomes was significantly associated with a decreased of the MASEI and OMERACT PD enthesitis count ($p< 0.05$). Reliability of MASEI and OMERACT PD definitions among the three readers was excellent (kappa 0.918 and 0.865 respectively).

Conclusion: PD enthesitis significantly improves at 3- and 6- months of follow up in patients under bDMARD treatment. Both MASEI and OMERACT PD definitions of US active enthesitis reflect treatment response.

Optical Tomography Can Accurately Diagnose Lupus Arthritis

Wei Tang[1], Alessandro Marone[2], Youngwan Kim[2], Tommy Chen[1], Cathy Guo[1], Leila Khalili[1], Andreas Hielscher[2] and Anca Askanase[3], [1]Columbia University Medical Center, New York, NY, [2]Columbia University, New York, NY, [3]Columbia University College of Physicians & Surgeons, New York, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Incapacitating inflammatory arthritis occurs in up to 88% of patients with systemic lupus erythematosus (SLE). Arthritis is present in 70-80% of lupus patients in clinical trials. There is continued debate as to whether tenderness in the absence of swelling constitutes active lupus arthritis and should be scored on activity instruments. The confusion over arthritis scoring impacts clinical care and trials. There is an unmet need for a simple tool that can objectively assess lupus arthritis; near-infrared optical imaging has the potential to address this need. Over the last decade the technology has been optimized for use in brain imaging, breast cancer, and peripheral ischemia. Studies have also shown its utility in rheumatoid arthritis. Near-infrared light illuminates the tissues and transmitted and reflected light intensities are measured. Maps computed from these measurements show the spatial distribution of physiological parameters. Changes in optical properties caused by physiologic changes form the basis for its diagnostic capabilities. Using a so-called frequency-domain optical imaging (FDOI) system[1] we evaluated the proximal interphalangeal (PIP) joints of 16 SLE patients and 10 healthy volunteers.

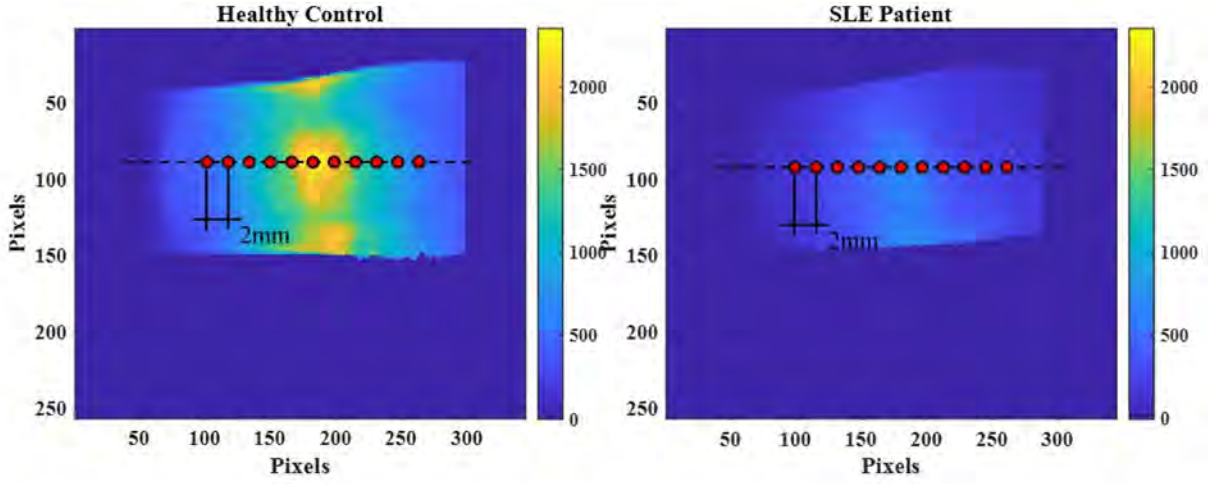

Fig. 1. Examples of amplitude images obtained from the index finger of a healthy volunteer (PIP2) (left) and the index finger of a SLE patient (PIP2) with lupus arthritis joint (right). The images were generated by a frequency-domain optical imaging (FDOI) system. The red dots indicate the positions of the 11 sources used in this study. The images shown above are the mean value from 11 amplitude images, one per source position. The bright yellow area on the left panel corresponds to the PIP joint, a similar region in light blue is also visible in the right panel. Note that the amplitude of the transmitted light intensity is much lower in the SLE patients compared to the healthy volunteer.

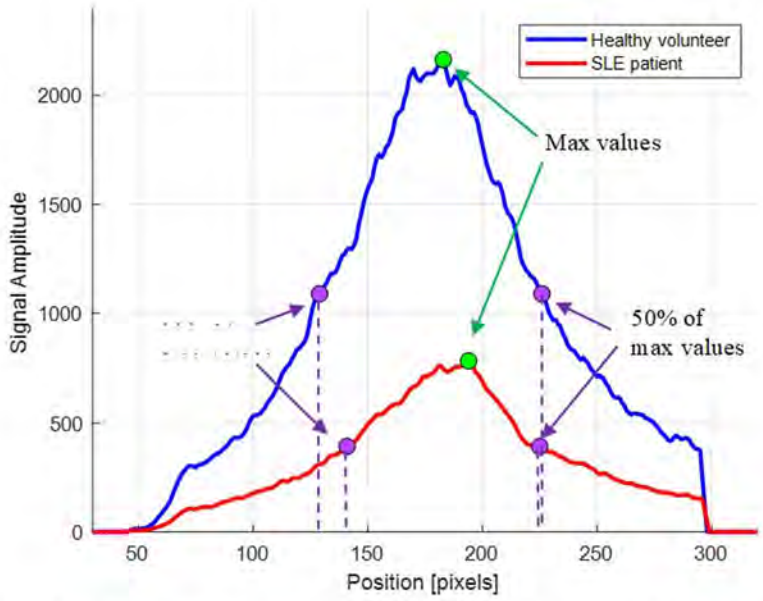

Fig. 2. Example of mean amplitude obtained along the length of the finger shown in Fig.1 from the same control subject (blue) and SLE patient (red). The maximum value is highlighted in green. The points at 50% of the max value are highlighted in purple; the number of pixels between them was selected as the third parameter for the linear discriminant analysis.

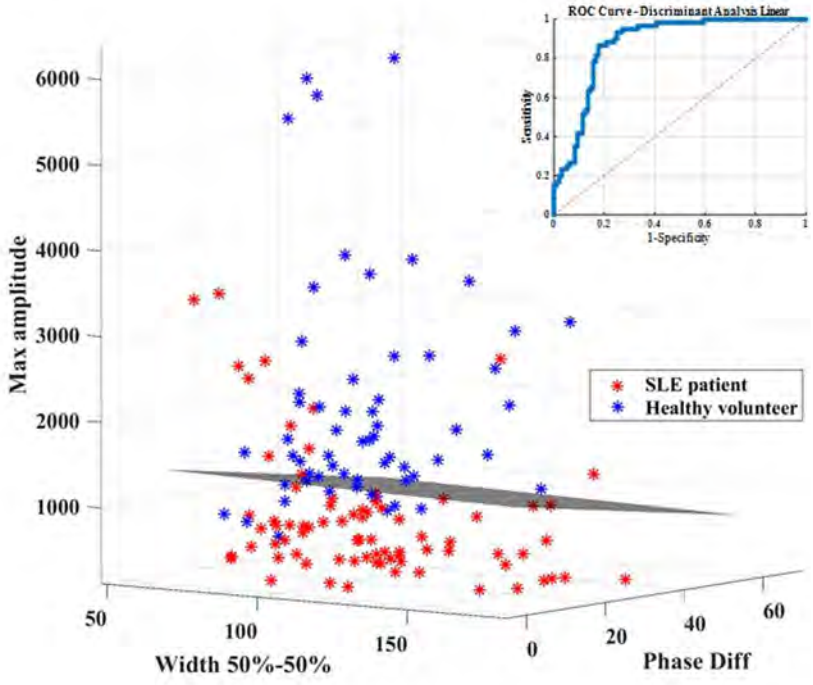

Fig. 3. Linear discriminant analysis of the three parameters for the 2nd, 3rd, and 4th PIP joints. The healthy volunteers are represented by blue dots, SLE patients with swollen and/or tender fingers by red dots. The black plane is the cut-off for evaluating sensitivity and specificity, which maximizes J-value. The upper right corner shows the corresponding ROC curve.

Methods: The FDOI system consists of a laser diode projecting a 1-mm - 670nm optical beam at 11 different positions along the PIP joints, 2mm apart, lengthwise. Fig.1 shows with the positions of the source. At each point, 16 images are acquired at different phases by a camera. The FDOI system is operated at a frequency of 300 MHz. PIPs 2-4 bilaterally were evaluated. A total of 60 healthy joints from 10 healthy volunteers and 96 joints from 16 patients with SLE arthritis were analyzed. Amplitudes and phases signals were generated using a demodulation algorithm.[1] The fingers' sizes (width and thickness) were measured using a caliper.

Results: The 16 patients with SLE arthritis (94% women, mean age 43±10 years, disease duration 14±8 years) had 74 swollen and/or tender PIP joints. Considering the mean signals from the 11 illumination positions (see Figs. 1 and 2), a discriminant analysis was done considering three variables: the maximum amplitude at the peak of the curve obtained, the maximum difference of the phase signals, and the number of pixels between 50% of the maximum value on the left and on the right of the peak. A receiver-operating curve (ROC) analysis showed an area under the curve (AUC) of 0.88 with correspondent sensitivity of 87% and specificity of 80% (Fig. 3).

Conclusion: These pilot data show that FDOI measurements of the PIP joints provide a clear difference between SLE patients and healthy subjects. If confirmed in a larger clinical study, FDOI could bring objectivity to the quantification of SLE arthritis. Compared to joint counts, US, and MR imaging, the advantages of FDOI are non-invasiveness, objectivity (eliminates inter-rater variability and operator dependency), low cost, and high speed of performance (~5 min).

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: ^{18}F-fluodeoxyglucose positron emission tomography (^{18}F-FDG PET/CT) is useful to establish the presence and extent of large vessel vasculitis (LVV). Tocilizumab (TCZ) has shown efficacy in the management of LVV. However, it is unknown if the extent of FDG vascular uptake may influence the clinical response to TCZ.

Our aim was to assess whether the extent of baseline FDG vascular uptake in PET/CT scans correlates to clinical and serological evolution in patients with LVV under TCZ therapy.

TABLE 1

	1-2 vascular affected areas (n=13)	≥3 vascular affected areas (n=17)	P
Demographic data			
Age, *mean ± SD*	66.0 ± 10.8	64.8 ± 10.7	0.77
Sex (women), *n (%)*	11 (84.6)	13 (76.5)	0.67
Evolution time before TCZ therapy (months), *median [IQR]*	26.0 [3.5-34.0]	5.0 [1.5-10.0]	0.02
Laboratory markers			
ESR (mm/1st hour), *mean ± SD*	30.0 ± 27.3	34.8 ± 27.6	0.64
CRP (mg/dL), *mean ± SD*	1.3 ± 1.2	1.8 ± 1.7	0.28
Previous treatment			
Prednisone dose (mg/day), *mean ± SD*	9.4 ± 6.2	7.9 ± 6.9	0.53
TCZ therapy			
Intravenous infusions, n *(%)*	10 (76.9)	11 (64.7)	0.47
Combined with MTX, n *(%)*	6 (46.2)	8 (47.1)	0.96

TABLE 2

	1-2 vascular affected areas (n=13)	≥ 3 vascular affected areas (n=17)	P
Complete clinical improvement, *n/N (%)*			
- 6 months	11/13 (84.6)	12/17 (70.6)	0.43
- 12 months	12/13 (92.3)	13/17 (76.5)	0.36
- 18 months	10/11 (90.9)	11/12 (91.7)	0.99
- 24 months	8/8 (100)	9/10 (90.0)	0.99
Normalization of ESR and/or CRP, *n/N (%)*			
- 6 months	13/13 (100)	16/17 (94.1)	0.99
- 12 months	13/13 (100)	16/17 (94.1)	0.99
- 18 months	11/11 (100)	11/12 (91.7)	0.99
- 24 months	8/8 (100)	10/10 (100)	0.99
Dose of Prednisone (mg/day), *median [IQR]*			
- 6 months	5.0 [1.3-5.0]	5.0 [0.0-5.0]	0.98
- 12 months	2.5 [0.0-3.8]	0.0 [0.0-5.0]	0.97
- 18 months	0.0 [0.0-2.5]	0.0 [0.0-1.9]	0.72
- 24 months	0.0 [0.0- 2.2]	0.0 [0.0-2.5]	0.77

Methods: Comparative single-center study of 30 patients with LVV treated with TCZ who were divided into two groups depending on the extent of FDG vascular uptake in the baseline PET/CT scan: **a)** 1-2 affected areas, **b)** ≥affected 3 areas. Vascular FDG uptake was qualitatively assessed by two experienced nuclear medicine physicians in five areas (supra aortic trunks, thoracic aorta, abdominal aorta, iliac arteries, femorotibial arteries). We assessed clinical improvement (no improvement/partial/complete), normalization of acute phase reactants (CRP ≤0.5mg/dL and/or ESR ≤ 20 mm/1st hour) and reduction of prednisone dose (mg/day).

Results: We included 30 (24 women/6 men); mean age 65.3±10.6 years. 13 patients exhibited FDG vascular uptake in < 3 areas whereas 17 patients had ≥3 affected areas. There was a trend to higher ESR/CRP and shorter evolution of clinical symptoms before TCZ onset in patients with ≥3 affected areas (**TABLE 1**). Most of the patients received TCZ as intravenous infusions and almost half of them received combined therapy with MTX in both groups. Clinical and serological evolution and reduction of prednisone dose is shown in the **TABLE 2**. No statistical differences were found between both groups. However, patients with ≥ 3 affected areas tended to experience a slower clinical response.

Conclusion: TCZ therapy was effective in patients with LVV regardless the extent of FDG vascular uptake in the baseline PET/CT scan. However, a trend to a slower clinical response was observed in patients with ≥3 affected areas.

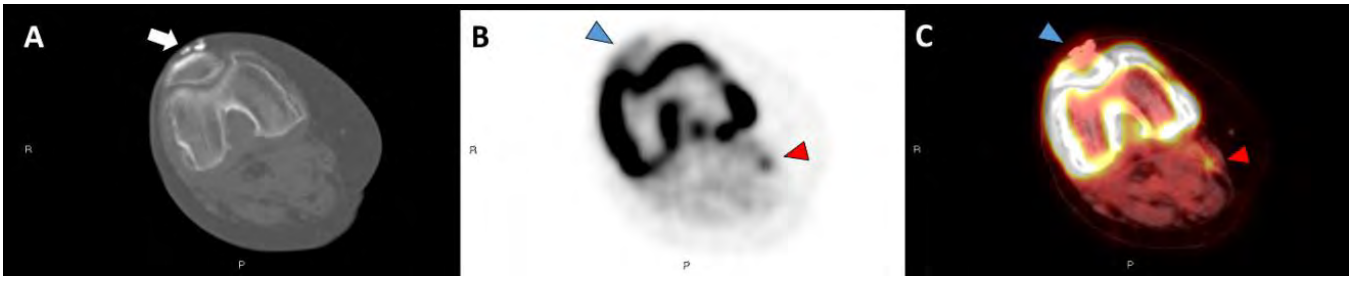
^{18}F-NaF PET/CT Identifies Active Calcium Uptake in Calcinosis Due to Dermatomyositis and Scleroderma

Carrie Richardson[1], Mehrbod Javadi[2], Ami Shah[3], Lilja Solnes[2], Fredrick Wigley[4], Laura Hummers[5] and Lisa Christopher-Stine[6], [1]Rush University Medical Center, Chicago, IL, [2]Johns Hopkins University, Baltimore, [3]Johns Hopkins University School of Medicine, Ellicott City, MD, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]Johns Hopkins Univerisity, Ellicott City, MD, [6]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ectopic soft tissue deposition of hydroxyapatite (calcinosis) is a frequent and morbid complication of dermatomyositis and scleroderma with no known effective pharmacologic treatment. ^{18}F-NaF PET/CT detects active hydroxyapatite deposition in benign and malignant bone disorders and may identify subclinical and actively calcifying lesions in scleroderma- and dermatomyositis-related calcinosis.

Methods: In this pilot study, we enrolled three adults with dermatomyositis and three adults with scleroderma, all with new calcinosis deposits within the past six months. Each participant underwent ^{18}F-NaF PET/CT as well as a clinical examination for assessment of calcinosis. We recorded the number, locations, and standardized uptake values (SUVs) of deposits for each ^{18}F-NaF PET/CT.



Axial CT image in bone windows (A) demonstrates calcinosis involving the quadriceps and patellar tendon complex overlying the left patella. Axial 18F-NaF PET/CT images (B and C) demonstrate mild activity along this calcified complex (blue arrowheads). However, there is focal PET signal activity located along the semimebranosus muscle without associated calcification on CT (red arrowheads). These findings may suggest increased sensitivity of 18F-NaF PET imaging in detecting pre-calcified disease involvement.

Full-body coronal 18F-NaF PET image of Patient 6 demonstrating the distribution and intensity of 18F-NaF uptake. Note the intense activity in the upper arms and around the knees as well as widespread uptake in the thighs and pelvic girdle. There is also increased uptake in the axial skeleton, indicating increased systemic bone turnover

Results: ^{18}F-NaF PET/CT detected heterogeneous uptake in calcinosis deposits appearing homogeneous on CT. ^{18}F-NaF PET/CT also detected calcium uptake where there was no visible calcification on CT. We noted increased uptake of ^{18}F-NaF in the axial skeleton of one patient with multiple actively calcifying deposits, consistent with increased systemic bone turnover. Some joints also demonstrated increased ^{18}F-NaF uptake, consistent with arthritic remodeling.

Conclusion: ^{18}F-NaF uptake on PET/CT is heterogeneous, even in radiographically homogeneous deposits, and identifies actively calcifying and subclinical deposits not apparent on CT. ^{18}F-NaF uptake on PET/CT may be an early and sensitive marker of disease activity in calcinosis due to scleroderma and dermatomyositis.

Assessing Calcinosis in Dermatomyositis with Computed Tomography and Calcium Scoring

Prateek Gowda[1], Briana Cervantes[2], Lisa G. Rider[3], Frederick W. Miller[4], Marcus Chen[4] and Adam Schiffenbauer[4], [1]NIBIB, Baltimore, MD, [2]NIEHS, Silver Spring, MD, [3]Environmental Autoimmunity Group, Clinical Research Branch, NIEHS, NIH, Garrett Park, MD, [4]National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis is a condition in which calcium salts are deposited in and around soft tissue and is observed in up to 30% of adult dermatomyositis (DM) patients and up to 70% of juvenile dermatomyositis (JDM) patients. Clinical assessment of calcinosis is usually conducted with a physical assessment or through radiographic imaging consisting of plain X-rays. However, due to the two-dimensional nature of these X-ray images, much is still not known about the spatial properties of calcification and the relative densities of the lesions. The objective of the study was to utilize whole-body computed tomography (CT) imaging and calcium scoring techniques as tools for calcinosis assessment in a prospective cohort of patients with DM and JDM.

Methods: Thirty-one patients (14 DM and 17 JDM) who fulfilled Bohan and Peter Classification criteria as probable or definite DM, the EULAR-ACR for definite DM, and with calcinosis identified by physical examination or prior imaging studies were included. Non-contrast whole-body CT scans were obtained using generic and ultra-low dose radiation procedures. Scans were read qualitatively and quantitated using imaging software. We calculated the sensitivity and specificity of calcinosis detection against a physician physical exam. We quantified calcinosis burden using the Agatston scoring technique.

Results: We identified five distinct calcinosis patterns: Clustered, Disjoint, Interfascial, Confluent, and Fluid-filled. Patients often exhibited multiple types of calcification. The most common patterns were the Clustered and Interfascial type seen in 19 and 7 patients, respectively. Novel locations of calcinosis were observed, including the cardiac tissue, pelvic and shoulder bursa, and the spermatic cord. The regions of highest and lowest calcinosis occurrence were the proximal legs (86.7%) and head & neck (40%), respectively. There was moderate agreement for calcinosis detection between the physical exam and CT ($\kappa = 0.45$, 95% confidence interval [95% CI] 0.38, 0.52). Physician physical exams had a sensitivity of 59% and a specificity of 90% compared to CT detection. Quantitative measures using Agatston scoring for calcinosis were used in regional distributions across the body. Total average Agatston score, normalized by patient height, was 3128.52 ± 5868.52 (adult DM: 1741.93 ± 2347.21, JDM: 4630.67 ± 8024.76), with no difference by clinical subgroup. A higher calcium score correlated with higher Physician Global Damage, Calcinosis Severity scores, and disease duration.

Conclusion: Whole-body CT scans and the Agatston scoring metric define distinct calcinosis patterns and provide novel insights relating to calcinosis in DM and JDM patients. Physician physical examinations underrepresented the presence of calcium. Calcium scoring of CT scans correlated with clinical measures, which suggests that this method may be used to assess calcinosis and follow its progression.

Lymphatics as a Biomarker of Joint Physiology: Near-Infrared Imaging of Indocyanine Green Identifies Novel Routes of Lymphatic Drainage from Metacarpophalangeal Joints in Healthy Human Hands

H. Mark Kenney[1], Gregory Dieudonne[1], Ronald Wood[1], Edward Schwarz[1], Christopher Ritchlin[2] and Homaira Rahimi[3], [1]University of Rochester Medical Center, Rochester, [2]Department of Medicine, University of Rochester Medical Center, Rochester, NY, [3]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Imaging of Rheumatic Diseases Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: In our previous work, we discovered that patients with active hand RA have reduced lymphatic drainage of indocyanine green (ICG) from the web spaces adjacent to metacarpophalangeal (MCP) joints visualized by near-infrared (NIR) imaging.[1] We also noted an associated decrease in draining lymphatic vessels (LVs) on the basilic surface of the hand as one of many potential mechanisms mediating the impaired lymphatic function.[1] While these changes represent important biomarker potential in identifying RA patients with active disease, we wanted to more directly assess MCP joint-specific lymphatic drainage in a pilot study of healthy subjects utilizing NIR-ICG imaging. In addition, we aimed to validate the lymphatic tributaries identified via NIR-ICG imaging using a novel

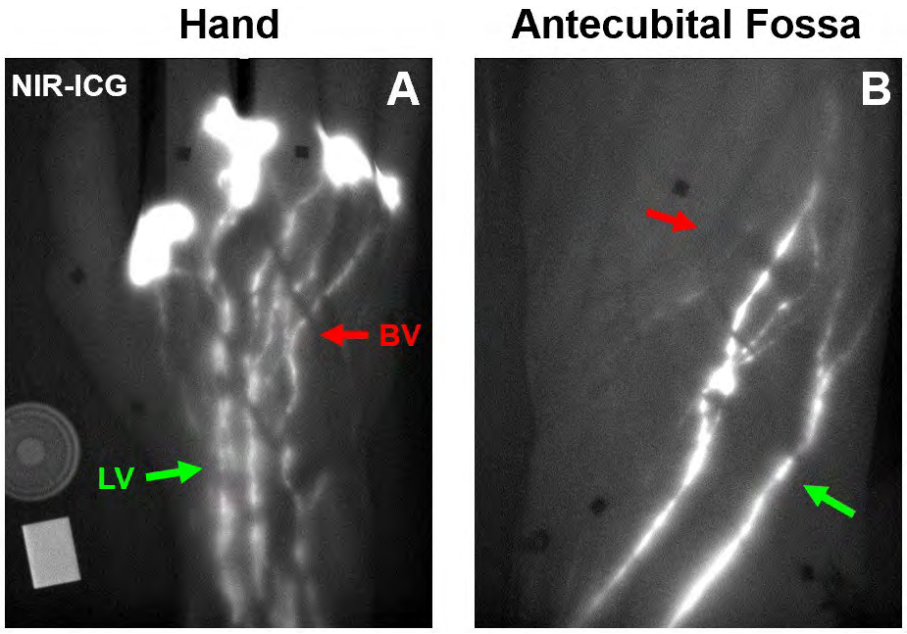

Figure 1. Lymphatic vessels identified by dynamic NIR imaging following ICG web space injections in healthy human hands. Representative images of web space draining lymphatic vessels (white, green arrows) adjacent to blood vessels (dark, red arrows) in the hand (A) and antecubital fossa (B).

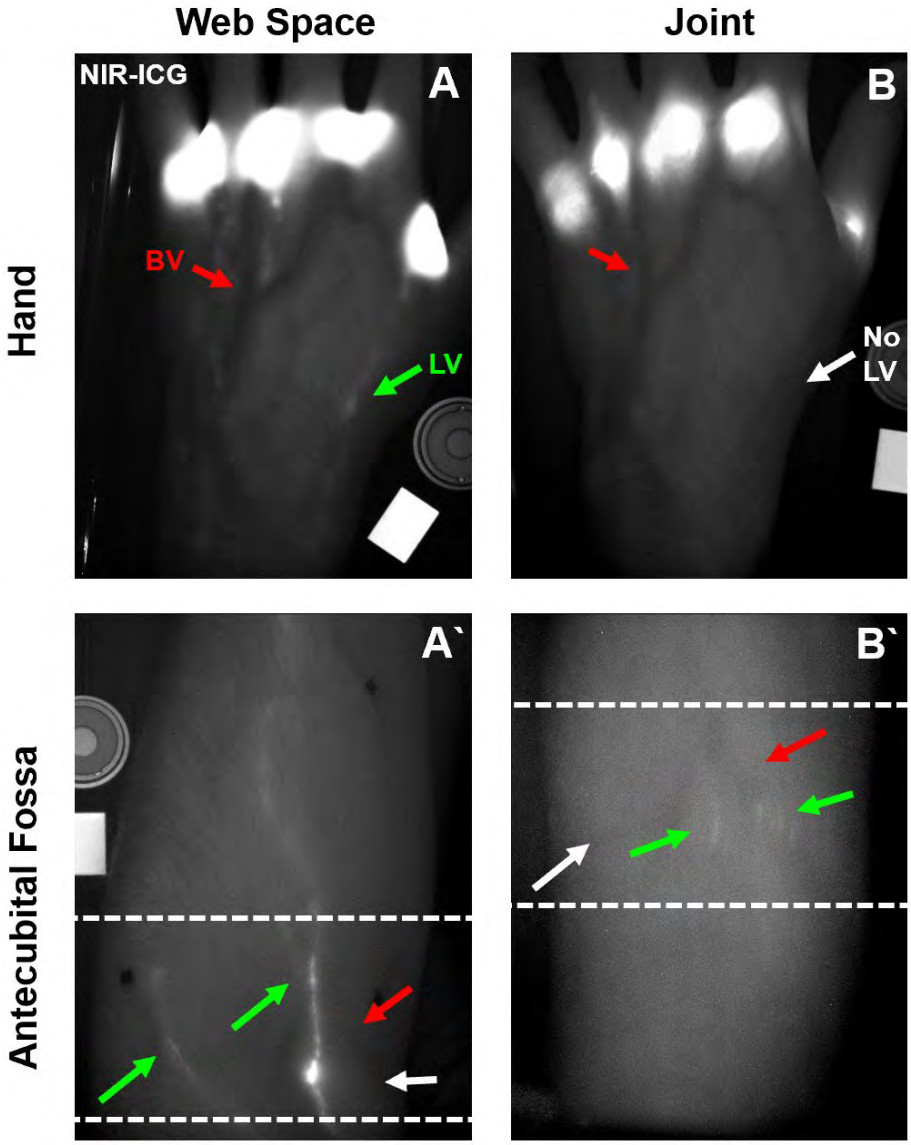

Figure 2. Dynamic NIR-ICG imaging reveals distinct lymphatic vessels draining the MCP joint versus the adjacent web space. NIR-ICG imaging showing verified LVs (white vessels, green arrows) and adjacent superficial BVs (dark vessels, red arrows) in the hand (A) and antecubital fossa (A`, dashed lines) following ID ICG web space injections. In contrast, IA MCP joint injections of ICG show no identifiable LVs (white arrows) in the hand (B) and different draining LVs in the antecubital fossa (B`, dashed lines) of the same subject.

dual-agent relaxation contrast magnetic resonance lymphography (DARC-MRL) technique successful in identifying lymphatic vessels in patients with lymphedema.[2]

1. Bell et al. 2020 *Arthritis & Rheumatology*. https://doi.org/10.1002/art.41311.
2. Ripley et al. 2017 *Radiology*. 286(2):705-714.

Methods: All of the experiments were approved by the University of Rochester IRB and the FDA (NCT02680067). A total of ten healthy subjects will be recruited for this pilot study. We conducted lymphatic imaging of the hands and forearms at four visits using different methods of imaging and routes of contrast administration: 1) NIR-ICG web spaces, 2) NIR-ICG MCP joints, 3) DARC-MRL web spaces, and 4) DARC-MRL MCP joints. For NIR-ICG imaging, 0.1 mL of 100 μM ICG was injected intradermally (ID) into the web spaces or intra-articularly (IA) into the MCP joints. To capture the DARC-MRL imaging, subjects received intravenous ferumoxytol diluted in normal saline to 60 mL total

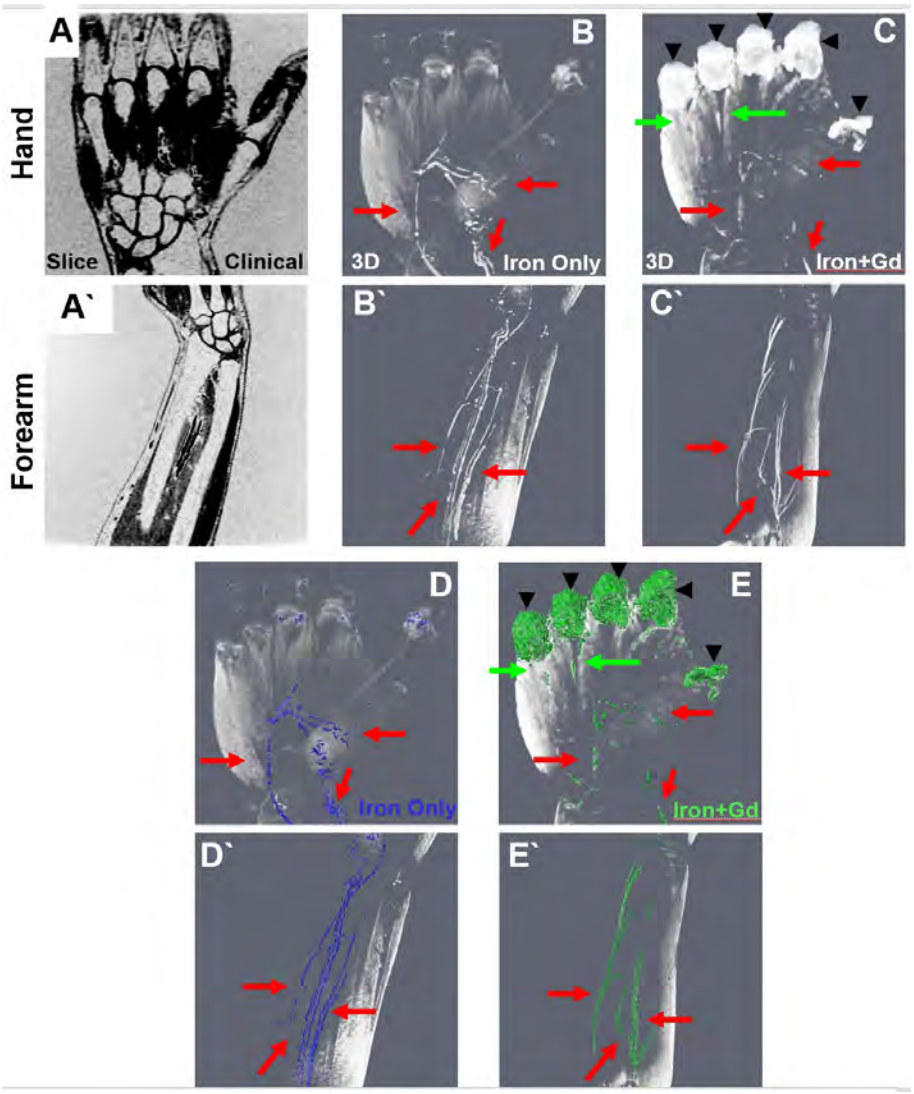

Figure 3. MCP joint draining lymphatic vessels using DARC-MRL. To assess the distinct lymphatic drainage of the MCP joints throughout the hand and forearm, DARC-MRL following IV iron infusion and gadolinium joint injections was performed on the same healthy subject. Prior to the joint injections, intravenous iron was administered and utilized as contrast enhancement to generate a scout image of the blood vasculature. Following the gadolinium joint injections, image sequences were captured at TR 11.2 and TE 8.5; under these conditions, the iron infused blood should quench, while the lymphatic vessels are enhanced by the gadolinium based on previous DARC-MRL methods. Inverted representative images of the hand (A) and of the forearm (A`) in a healthy subject are shown for orientation. Note that the background is white, demonstrating that the sequence was inverted. 3D renderings of the iron scout sequence showing the hand (B) and forearm (B`) demonstrate contrast enhanced blood vessels (red arrows). The images following the gadolinium joint injections indicate successful administration of the gadolinium into the MCP joint space (arrow heads) with contrast enhanced lymphatic vessels draining directly from the joint (green arrows) that are not visualized thereafter in the hand (C) or forearm (C`). The blood vessels remain partially enhanced in this sequence (red arrows) demonstrating incomplete quenching using this method (C, C`). Automated segmentation using thresholding of the contrast enhanced vasculature before (D, D`) and after (E, E`) gadolinium administration to the MCP joint shows the similar blood vessels (red arrows) and the unique lymphatic vessels (green arrows).

volume at 5 mg iron/kg body weight at a rate of 0.1 mL/sec. Subjects were then administered 0.5 mL of gadolinium-diethylenetriamine pentaacetic acid (Gd-DTPA) either ID in the web spaces or IA in the MCP joints.

Results: The results from two healthy subjects thus far indicate that MCP joint-draining LVs travel deep to the superficial LVs associated with the web space **(Figures 1 & 2)** and may follow novel routes shuttling lymph unexpectedly retrograde from the MCP to the proximal interphalangeal (PIP) joint. In addition, our current methods of DARC-MRL

do not have the appropriate resolution or suppression of the blood vessels (BVs) to accurately identify small healthy LVs **(Figure 3)**.

Conclusion: This is the first study to date that has directly visualized MCP joint-draining LVs and performed DARC-MRL in healthy subjects. Our analysis thus far suggests that LVs draining MCP joints represent an entirely distinct lymphatic vascular network than those draining the adjacent web spaces. In addition, improvement in the DARC-MRL technique will provide a valuable understanding of the lymphatic architecture draining MCP joints and alterations in this lymphatic anatomy in patients with RA. As future studies continue to evaluate the joint-draining LVs, and their function during RA progression, we will be able to better define the lymphatic system as a biomarker of active arthritis towards beneficial clinical application.

Cinematic Rendering Enables Depiction of Bone Anabolic Effects in Patients Treated with Baricitinib

Sara Bayat[1], David Simon[2], Louis Schuster[2], Georg Schett[3] and **Arnd Kleyer**[2], [1]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany, [2]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Bayern, Germany, [3]Friedrich-Alexander-Universität Erlangen- Nuremberg, Erlangen, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Preclinical studies show that tsDMARDs such as baricitinib may be a therapeutic agent for bone anabolic effects by increasing osteoblast function in inflammatory conditions.[1] High-resolution CT imaging (HR-pQCT) allows the determination of volumetric, peripheral bone mineral density of trabecular and cortical bone

Table 1
Patient characteristics and volumetric bone density of the radial bone

demographics	patient 1	patient 2	patient 3
age (y)	63	59	80
sex	w	m	w
CCP status	+	+	+
Baricitinib treatment 12 months	4 mg	4 mg	2 mg
DAS28-CRP after 12 months	- 1,03	- 1,34	- 1,26

Dtotal (% after 1 year)	+ 41,8 %	+ 3,8 %	+ 16,4 %
D trab (% after 1 year)	+ 49,9%	+ 5,9 %	+ 18,1 %
Dcort (% after 1 year)	+ 0,0 %	+ 0,5 %	+ 0,5 %

*volumetric bone mineral density of the radius (vBMD) in mg hydroxylapatite / mm³; Dtotal (total vBMD); Dtrab (trabecular vBMD); Dcort (cortical vBMD)

Figure 1

a) 2018 b) 2019

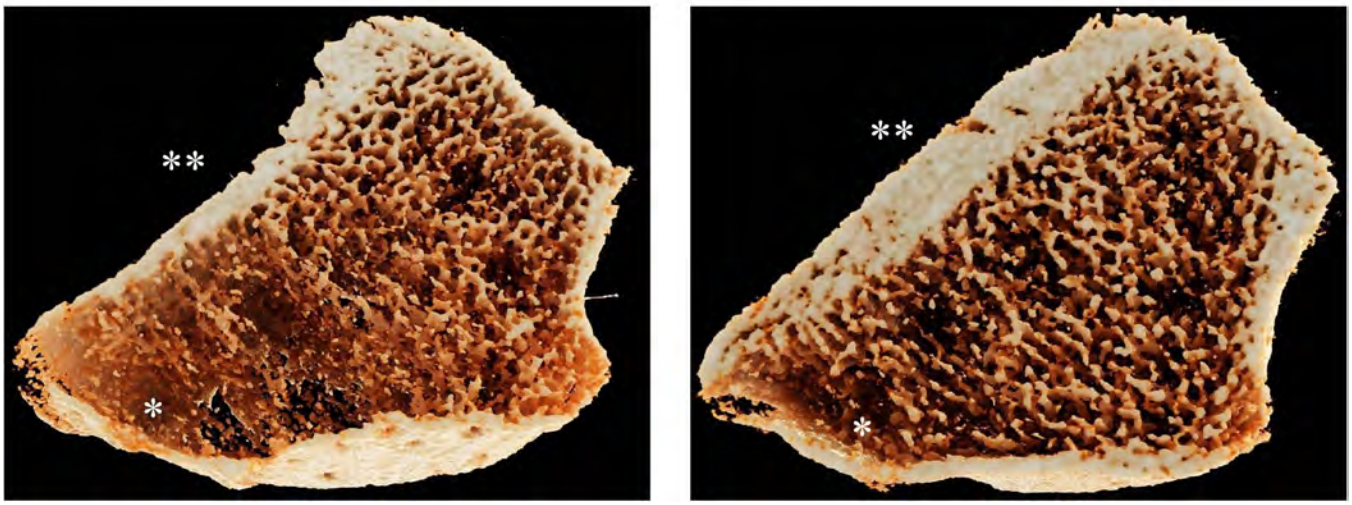

Figure 1. High resolution CT images of the radius from patient 1 are visualized with Cinematic Rendering at two time points (figure 1a and figure 1b). * illustrates changes in trabecular bone.

in patients with rheumatic diseases in vivo with a resolution of 82 micrometers voxel size. [2] Recently introduced rendering techniques such as cinematic rendering, developed by Siemens Healthineers allow a fotorealistic- insight into the bone on microstructural level in vivo.(3)

To test whether HR-pQCT images, segmented by cinematic rendering depict changes in bone mineral density in patients treated with baricitinib.

Methods: Bone density measurements of two time points of the radial bone from patients with active rheumatoid arthritis who are part of an ongoing, prospective cohort (ethics 19_18B;324_16) receiving baricitinb were analyzed. Volumetric bone density (vBMD) of the entire radius (Dtotal) in mg/hydroxyapatite / cm^3 was determined as well as the cortical (Dcort) and trabecular (Dtrab) part of the bone. The measurements were registered using the software supplied by the manufacturer Scanco to determine the percentage change of vBMD. Images were post-processed using cinematic rendering technique to visualize pathologies in detail.

Results: Clinical characteristics are shown in table 1. We included three patients as a proof of concept analysis. All patients showed an improvement in clinical scores. We were able to display bone microstructure using cinematic rendering technique in great detail (figure 1) proving the feasibility to visualize bone microstructure with cinematic rendering at two time points. Furthermore, our preliminary data regarding vBMD shows that anabolic effects were observed for trabecular bone in particular. One patient displayed an increase of 49%.

Conclusion: The preliminary data reported here underline the potential impact of tsDMARDs therapy on secondary peripheral osteoporosis in patients with rheumatoid arthritis. These observations led to a prospective clinical trial, investigating effects of tsDMARDS (baricitinib) on bone metabolism(EUDRA-CT 2018-001164-32).

Fully Automatic Assessment of Nail Fold Capillaroscopy Software - Early Results

Olga Brzezińska[1], Krzysztof Rychlicki-Kicior[2] and **Joanna Makowska**[1], [1]Department of Rheumatology, Medical University of Lodz, Poland, Lodz, Lodzkie, Poland, [2]University of Economics and Human Sciences in Warsaw, Poland, Lodz, Poland

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Changes in capillaroscopy nailfold image are a valuable element in the diagnostic procedure and monitoring of systemic sclerosis as well as other systemic diseases. However, manual image assessment is time consuming and the classification of observed changes is subjective. This makes it difficult to compare the results of tests evaluated by different physician, as well as to thoroughly analyse the progression that occurs between repeated tests. The aim of the study is to validate an automated software for classification of nailfold capillary image as normal or disturbed

Methods: From among the available resources, 100 normal capillaroscopy images and 100 with varying severity of pathological changes were selected. manual image analysis was performed twice. In the teaching program prepared for this purpose (Figure 1), region of interest (ROI) was determined and individual capillaries were marked, images were classified as correct and changed. The neural network was trained using the fast.ai library (based on PyTorch).

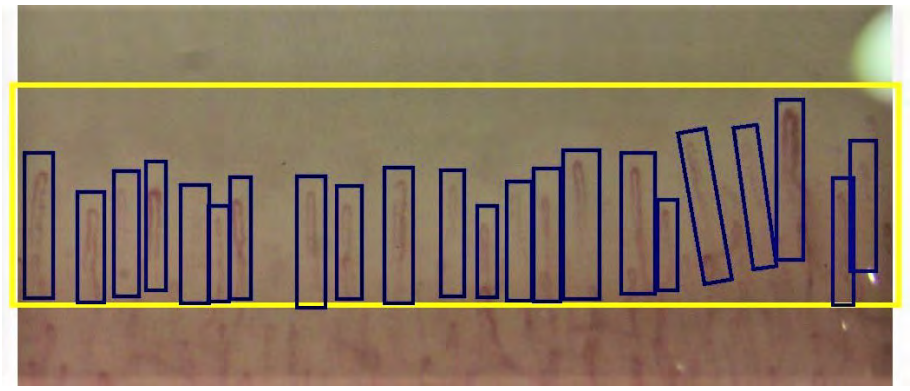

Figure. 1 Screen from training capillaroscopy software with manually marked region of interest (ROI) and individual capillaries

The ResNet-34 deep residual neural network was chosen, as it is widely known to perform image recognition and classification. The dataset was split on training, validation and test sets, using a proportion 70/20/10. Due to a small number of images, 10-fold cross-validation with validation and test set was performed.

Results: The manual annotations (normal/disturbed) of images were treated as ground truth. Sensitivity and the specificity of validation set (the 20% subset of images used for validation during the neural network training process) were, respectively, 89.0% and 89.4%, while for test set, these metrics were reported as 89.0% and 86.9%, respectively

Conclusion: Pilot software for the fully automatic assessment of capillaroscopic image can be a useful tool for quick classification of correct and changed capillaroscopy pattern. In the course of further work on the software, additional functionalities allowing for capillary counting, shape and clinical pattern classification will be developed

Measuring Asymmetry in Facial Morphea via 3D Stereophotogrammetry

Laila Abbas[1], Jennifer Day[2] and Heidi Jacobe[3], [1]UT Southwestern Medical Center, Dallas, TX, [2]University of Colorado, Denver, CO, [3]University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Morphea is an autoimmune disorder causing sclerosis and inflammation of the skin and subcutaneous tissue. Facial morphea can cause substantial disfigurement and negative impact on quality of life. Existing clinical measures such as the LoSCAT likely fail to capture the severity of facial morphea due to their body site driven approach and difficulty in quantifying tissue loss making it difficult to assess severity and response to treatment. 3D stereophotogrammetry is a non-invasive, readily available modality that has been used measure facial asymmetry in disorders such as cleft palate. The aim of this pilot study was to investigate the feasibility of use of this

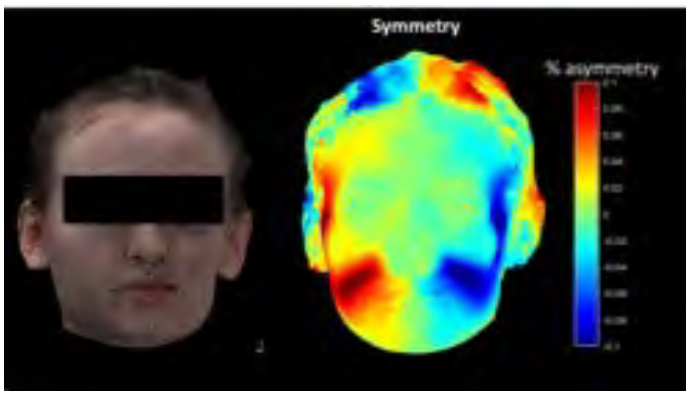

Figure 1 shows a 3D image and heat map created by the 3D stereophotogrammetry technique, which demonstrates pathologic asymmetry in a morphea patient.

Table 2 provides asymmetry values in millimeters of study patients as determined through 3D stereophotogrammetry.

modality in identifying asymmetry in facial morphea, and to compare 3D stereophotogrammetry to clinical assessment.

Methods: 23 participants with facial morphea were recruited from the Morphea in Adults and Children Cohort at UT Southwestern Medical Center. They were evaluated by a single dermatologist (HJ), at which time they were assigned

a LoSCAT score, a clinical morphea subtype, and completed validated quality of life questionnaires. Participants then underwent 3D stereophotogrammetry. Facial asymmetry (mm) was determined by calculating the distance between layers of stereolithography images using an in-house written mathematical model in MATLAB, thus quantifying the amount of atrophy (Figure 1 gives an example of a 3D image and heat map generated from this technique). In order to analyze asymmetry in specific anatomical regions of interest, established anatomical landmarks were used to segment facial subunits of interest, and both mean and maximum 5% values were calculated in order to account for dilution.

Results: The majority of patients were children (70%), female (74%), Caucasian (61%), and had linear morphea (en coup de sabre) (52%). Table 1 provides demographic and clinical information of participants. Based on a previously published standard of 1.2mm to define pathologic asymmetry, 22 of 23 patients showed pathologic asymmetry in every facial subunit (Table 2 provides asymmetry values). In order of greatest to least asymmetry, the facial subunits were ranked as follows: forehead, cheek, nose, then mouth. While LoSDI scores did not correlate with asymmetry values, PGA-D values correlated significantly to mean mouth (p=0.0021) and cheek asymmetry (p=0.04). Quality of life measures also showed correlation with asymmetry in the lower face (p=0.013).

Conclusion: Results of this pilot study indicate that the majority of facial morphea lesions produce asymmetry that can be quantified using 3D stereophotogrammetry. Interestingly, we found that both physicians and patients attributed greater severity to lesions affecting the lower part of the face while actual percent asymmetry was greatest in the forehead, indicating that percent asymmetry alone does not drive impact on patients. Taken together, these results confirm that the LoSCAT alone is an inadequate measure of facial morphea and the use of 3D facial imaging maybe a valuable addition to evaluation. Further studies using this modality are needed to determine clinically important difference in facial asymmetry and sensitivity to change.

Findings Compatible with Axial Spondyloarthritis in Radiologist Reports

Rouhin Sen[1], Emmeline Kim[2], Evan Manning[3], Eric Anderson[4], Kyle Maier[5], Elizabeth Cheng[6] and Liron Caplan[6], [1]University of Colorado - Division of Rheumatology, Denver, CO, [2]University of Colorado School of Medicine, Denver, [3]University of Colorado - Department of Medicine, Denver, [4]Washington University - Division of Rheumatology, St. Louis, [5]United States Air Force, San Antonio, TX, [6]Rocky Mountain Regional Veterans Affairs Medical Center, Aurora, CO

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The sacroiliac joint (SIJ) has a distinct anatomical shape that can pose challenges to standard planar imaging techniques making the detection of subtle changes difficult[1]. SIJ radiographs are a very important tool for the evaluation of disease in patients with suspected axial spondyloarthritis (axSpA). With lack of a reliable biomarker and limitations in physical examination, clinicians are reliant on the interpretation of plain films by radiologists, who may or may not be trained in musculoskeletal radiology[2]. This study characterizes the details reported by radiologists in their reports of SIJ radiographs and compares their scoring with formal interpretations by trained readers.

Methods: SIJ 3-view (Ferguson and obliques) radiographs of US Veterans enrolled in the Program to Understand Long-term Outcomes of Spondylarthritis (PULSAR) registry were evaluated by three trained readers using the scoring from the modified New York (mNY) criteria. Corresponding radiology reports were then evaluated for the presence of terms used to apply mNY scores (erosions, sclerosis, joint narrowing or widening, ankylosis, and blurring), descriptions regarding the severity of any abnormality (no abnormality, mild/possible abnormality, clear abnormality), and the presence of sacroiliitis or axSpA. Classification of sacroiliitis based on consensus mNY grade by trained readers was compared with corresponding radiologist interpretation. Radiograph interpretations were evaluated for association with HLAB27 status.

Results: Reports from 90 radiographs (180 joints) revealed that among patients described as having sacroiliitis or axSpA by the radiologist report, no particular finding was described more frequently than 20% when considering laterality separately and no finding was present more than 31% of the time when assessing either side for abnormalities. Similarly, among patients classified as axSpA by consensus of the three readers, no particular finding was described more frequently than 32% of the time when assessing either side. The most frequent described findings were ankylosis (31.2%) and erosions (29.0%). Compared with the gold-standard consensus interpretation by three trained readers, the radiologist report demonstrated a sensitivity of 57.6% (95% CI 44.1-70.4) and specificity of 93.3% (95% CI 68.1-99.8) for identifying sacroiliitis/axSpA. The strength of the association between HLAB27 status and classification of AS was also greater for the consensus of three readers (ß=0.465, R^2=0.288) than the radiologist report (ß=0.319, R^2=0.090).

Conclusion: In patients likely to have axSpA, radiology reports only describe specific findings suggestive of axSpA in a minority of cases. Classification of axSpA by radiology reports is less well associated with HLAB27 status than a consensus of trained readers. Rheumatologists should consider training to read SIJ radiographs themselves, rather than relying exclusively upon radiology reports.

Legend:

PsA – psoriatic arthritis, MRI-magnetic resonance imaging, BMI – body mass index, BSA – body surface area; PASI - psoriasis area severity index; DAPSA - Disease Activity Index for Psoriatic Arthritis (DAPSA); HAQ, health assessment questionnaire; IL – interleukin; MCP – metacarpophalangeal, PIP – proximal interphalangeal, DIP – distal interphalangeal, PsA – psoriatic arthritis; sDMARD – synthetic disease modifying anti-rheumatic drug; TNF – anti-tumor necrosis factor; VAS – visual analogue scale

Table 1. Clinical characteristics and hand MRI findings in the PsA cohort.

is unknown. The purpose of this study is to estimate the MRI-detected prevalence and distribution of subclinical inflammatory changes of hands joints in patients with PsA in remission based on physical examination in comparison to active disease and to determine the sensitivity and specificity of physical examination findings using MRI-verified pathology as the standard of reference.

Methods: One-hundred consecutive, prospectively recruited patients with peripheral PsA (CASPAR criteria) underwent clinical evaluation and MRI of a predominantly involved hand performed within 72 hours from the clinical examination. Metacarpophalangeal (MCP), proximal (PIP) and distal interphalangeal (DIP) joints were scored according to the OMERACT PsAMRIS performed by an expert musculoskeletal radiologist, blinded for clinical data.

Results: Clinical characteristics and prevalence of MRI findings of the whole study cohort (n=100) and subgroups stratified by normal (TJC and/or SJC=0) (n=43) and abnormal clinical examination (n=57) are presented in Tables 1 and 2, respectively. Patients with active disease were older, had higher BMI, and longer duration of PsA compared to patients in clinical remission, 53.6±11.8 vs 48±13.0 years, p=0.025; 28.6±4.9 vs 26.3±4.9, p=0.021; 11.6 ±12.9 vs 8.1 ± 8.1 years, p=0.085, respectively. Otherwise, both subgroups were comparable in severity of psoriasis and treatment modalities. Total PsAMRIS and PsAMRIS of PIP joints were significantly higher in patients with active disease compared to patients in clinical remission, 9.8±18.4 vs 2.74±4.7, p=0.016 and 3.1±7.2 vs 0.6±1.4, p=0.026, respectively, with the same, though non-significant, trend for PsAMRIS of MCP and DIP joints. The overall prevalence of MRI inflammatory lesions in patients in clinical remission was low. Yet, subclinical synovitis was detected in 37.2% of patients, predominantly distributed in the MCP joints (37.2%), followed by equally affected PIP and DIP joints (11.6%). Flexor tenosynovitis and bone marrow edema were equally present in 11.6%, and periarticular inflammation in 2.3 %. The prevalence of MCP synovitis and flexor tenosynovitis was higher in patients with active disease but did not reach a statistical significance, whereas the difference was significant for other inflammatory MRI parameters (Table 2).

Bone proliferation, n [%]	3 [7.0%]	5 [8.8%]	1.000

Table 2. Clinical characteristics in PsA patients and hand MRI findings stratified by normal versus abnormal clinical examination of hand joints.

The sensitivity and specificity of physical examination of hand (TJC and/or SJC ≥1) for the corresponding MRI-detected synovitis were 66% and 51%, respectively, and for a combined MRI global inflammation score, including a summation of all the PsAMRIS components, were 69% and 63%, respectively.

Conclusion: MRI-detected subclinical synovitis, represented mainly as synovitis of MCP joints and flexor tenosynovitis was detected in up to third of PsA patients with a normal clinical hand examination. Further research is required to assess the pathogenetic role of subclinical hand inflammation for structural progression.

High Impact Sports Leads to Inflammatory Responses at Entheseal Sites Results of the BEAT Study (Badminton Enthesitis Arthrosonography Study)

David Simon[1], **Arnd Kleyer**[1], Koray Tascilar[1], Sara Bayat[2], Johannes Knitza[3], Larissa Valor-Mendez[4], Marina Schweiger[5], Georg Schett[6] and Axel Hueber[7], [1]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Bayern, Germany, [2]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany, [3]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander University Erlangen-Nürnberg, University Hospital Erlangen, Erlangen, Germany, Erlangen, Germany, [4]Department of Internal Medicine 3, Rheumatology and Immunology, University Hospital Erlangen, Erlangen, Bayern, Germany, [5]Department of Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany, [6]Friedrich-Alexander-Universität Erlangen-Nuremberg, Erlangen, Germany, [7]Sektion Rheumatologie, Sozialstiftung Bamberg, Bamberg, Germany

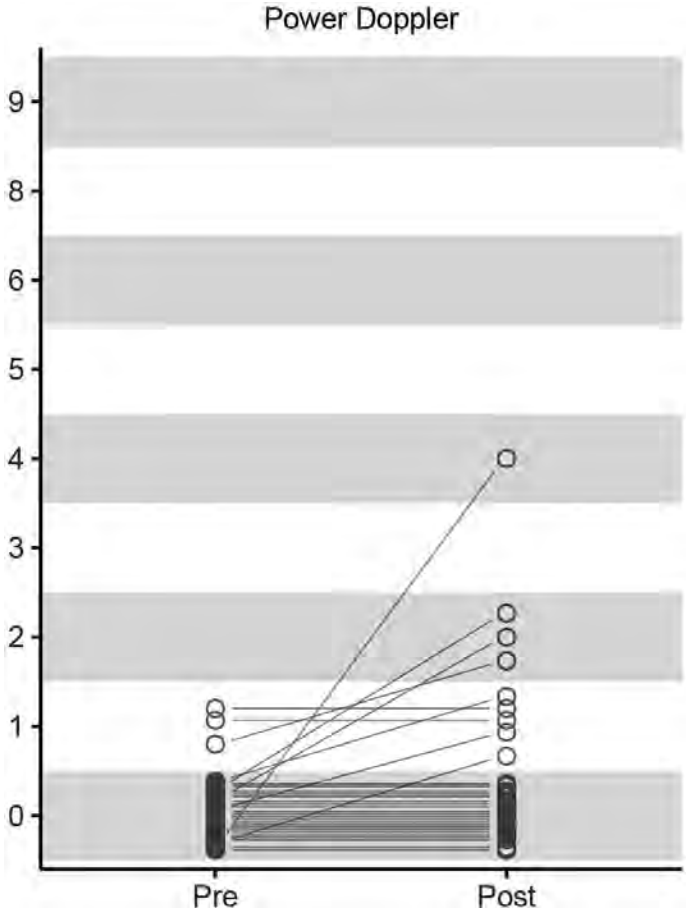
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Biomechanical stress triggers entheseal inflammation in psoriatic disease [1,2]. However, there is only limited data on the impact of mechanical stress on entheseal sites in healthy subjects. Musculoskeletal ultrasound can detect acute inflammatory changes at entheseal sites using power doppler (PD) technology. Competitive badminton is a demanding stop-and-go sport that puts strain especially on entheseal sites and is therefore an ideal sport to assess the impact of physical activity on the synovial-entheseal complex. Thus, we aimed to test whether intensive pyhsical stimulation of the musculoskeletal system by badminton training leads to an immediate inflammatory response at entheseal sites measured by PD ultrasound.

Methods: In this interventional study (BEAT, **B**adminton **E**nthesitis **A**rthrosonography **S**tudy), competitive players from two different badminton clubs were recruited. Only subjects without chronic inflammatory diseases were included. A physical examination comprising an examination of 29 entheses (SPARCC, LEI, MASES) of all players was performed just before and after 60 minutes of intensive training. Ultrasound of entheseal sites (achilles tendon, patella tendon at the tibial insertion, epicondylus humeri lateralis; all both sides) was also performed immediately before and after the training by an independent assessors using a Samsung HS50 machine with a linear probe (16 MHZ). The presence of inflammatory entheseal components was assessed using a validated scoring system. [3] Scores at each site were summed to derive an empirical total score for each participant for visual comparison. Pre- and post-match scores were compared using linear mixed effects models. We used interaction terms to assess possible differential effects on patella, elbow or achilles entheses. The study was approved by the ethics committee and all subjects provided informed consent.

Results: 32 players (22 men, 10 women) with an average age of 31.1±13.0 years were included. On average they had been playing badminton for 16.2±10.1 years. 192 entheseal sites were examined twice. The respective empirical total scores for PD examination were 0.1 (0.3) before and 0.5 (0.9) after training. Overall 7 participants (22%) showed an increased empirical total PD score as shown in the figure. A mixed effects model shows that there was an increase in PD scores after the game, with a mean increase per region of 0.06 (95%CI 0.01 to 0.12, p=0.017).

Conclusion: Ultrasonographic assessment of entheses after an hour of high-impact exercise in healthy individuals show a significant increase in PD activity at entheseal sites. The magnitude of these changes however seems rather



small and only in a subset of individuals. However, these results underline the concept of mechano-inflammation and needs to be further assessed in a population with known risk factors for developing spondyloarthritis or psoriatic disease. Linearity assumption for the bounded discrete ultrasound scores is a shortcoming of this analysis.

Feasibility of Ultra-low-dose, Short-duration, Total-body Evaluation of Inflammatory Arthritis Using uEXPLORER 18F-FDG PET/CT

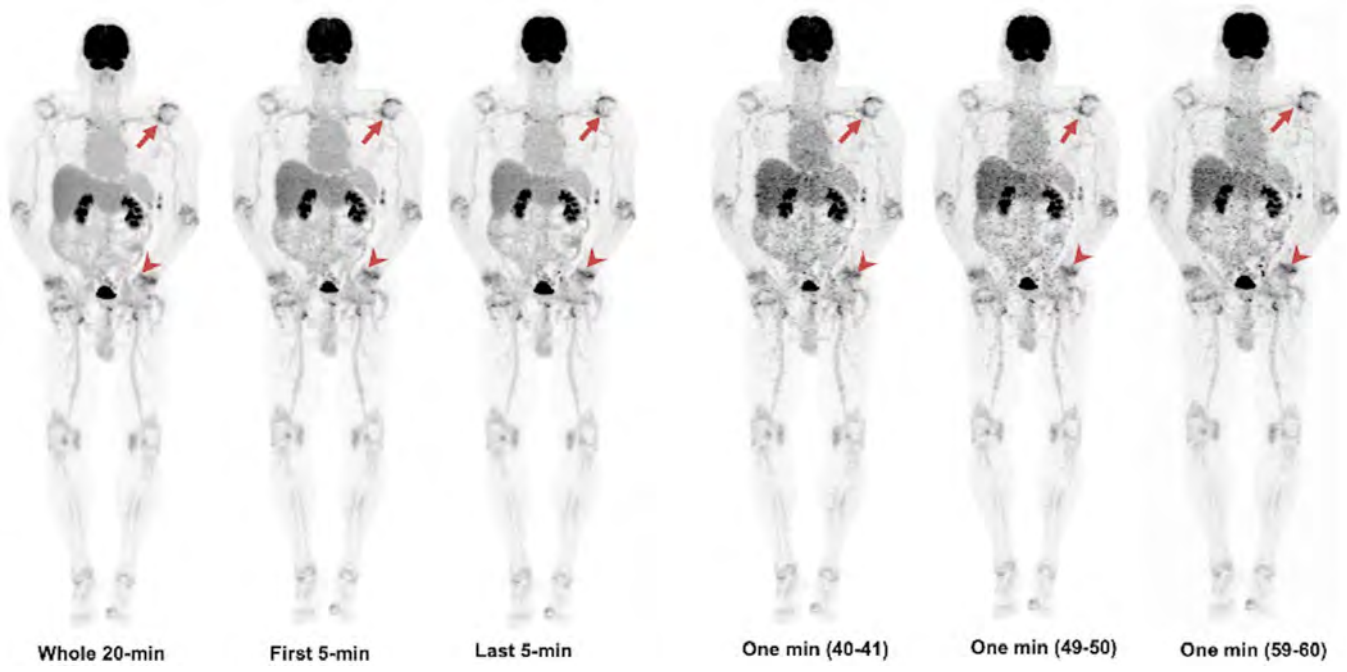
Soumajyoti Sarkar[1], Siba Raychaudhuri[2], Lorenzo Nardo[3], Heather Hunt[3], Denise Caudle[4], Mike Nguyen[4], Simon Cherry[4], Ramsey Badawi[4], Abhijit Chaudhari[5] and **Yasser Abdelhafez**[3], [1]University of California, Davis, Davis, [2]Division of Rheumatology, Allergy & Clinical Immunology, University of California School of Medicine, Davis, and VA Medical Center Sacramento, Sacramento, CA, [3]University of California Davis, Sacramento, CA, [4]University of California Davis, Sacramento, [5]University of California, Davis, Sacramento, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The uEXPLORER system enables the unique, simultaneous acquisition of PET data over the entire adult human body with a high-sensitivity, alongside concurrent CT data. We hypothesized that these unique characteristics of the uEXPLORER system will yield shorter scan time and reduction in radiation dose, both crucial to an arthritic population. We aimed to prospectively (1) document the glucose uptake patterns – using the radiotracer ^{18}F-FDG – in arthritic lesions across the entire body of participants with established rheumatoid arthritis (RA), psoriatic arthritis (PsA) and osteoarthritis (OA); and (2) evaluate the influence of shortening the scan time or dose reduction on image quality.

Methods: An ultra-low-dose 18F-FDG scanning protocol was employed in 14 patients (all males, 59±13 yrs) with RA (n=3), PsA (n=8) or OA (n=3) (injected radiotracer dose 75.5±4.4 MBq (1/5th of standard clinical dose)). PET/CT scans were acquired for 20-min starting at 40-min after the injection of 18F-FDG; data were then reconstructed as a single frame (20-min long), four 5-min frames, and twenty 1-min frames, using the same standard protocol. A single volume of interest (VOI) >3cm3 was drawn on the ascending aorta as a background blood pool [BP], and on arthritic lesions to calculate target-to-background ratio (TBR). Coefficient of variation (COV%) was used to estimate image noise and was calculated from the VOIs in the BP.

Results: uEXPLORER scans were successfully conducted for the 14 participants. The entire body was in the field-of-view in all participants. The effective dose from the PET radiotracer and ultra-low-dose CT was approximately 2.7



Maximum intensity projection total body images of a 72-year-old male (172 cm, 85 kg) with established diagnosis of psoriatic arthritis. Images were acquired for 20-min duration starting at 40-min after IV injection of 77.6 MBq of 18F-FDG. Images were further subsampled in software into 5-min and 1-min frames. Note that changes in tracer intensity in the left shoulder (arrow) and wrist (arrowhead) are preserved over the different frames.

mSv compared to typically ~14-15 mSv for clinical PET/CT scans on standard scanners. When evaluating the most active lesion, the average TBR was 1.3±0.4. The COV for the 20-min, 5-min, and 1-min scans were (median [range]): 8 [6,13], 15 [8,25], 31 [16, 57]. Qualitatively, all lesions detected on 20-min images could also be seen on 5-min images. Although lesions were still visualized on 1-min frames (TBR=1.4±0.5), the surrounding tissue background was elevated, and the image quality was sub-optimal.

Conclusion: All joints of the body could be visualized simultaneously and assessed in the same phase of radiotracer uptake on uEXPLORER PET/CT scans. Scan times as short as 5-min, with 1/5th of the standard 18F-FDG dose, appeared to be feasible and provide image quality not inferior to the full 20-min PET/CT scan. Further work is warranted to evaluate the methods on more participants, and further develop software-based methods to enhance the image quality of shorter duration scans.

Joint Cartilage Damage Evaluated by Ultrasound in Patients with Systemic Lupus Erythematosus

Takehisa Ogura[1], Ayako Hirata[2], Yuki Inoue[2], Takaharu Katagiri[2], Yuto Takakura[2] and Hideto Kameda[3], [1]Division of Rheumatology, Department of Internal Medicine, Toho University, Meguro-ku, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Toho University, Tokyo, Japan, [3]Toho University, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Imaging of Rheumatic Diseases Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis in systemic lupus erythematosus (SLE) is typically non-erosive, although some patients with SLE show erosive destruction or Jaccoud's arthropathy. Previously we have confirmed the usefulness of the direct imaging of finger joint cartilage by ultrasound (US) in patients with rheumatoid arthritis. In this study, we aimed to examine cartilage lesions in patients with SLE by US.

Methods: We enrolled 44 SLE patients with an episode of joint symptoms and 42 healthy subjects. The cartilage thickness of bilateral metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints of the 2nd to 5th fingers were visualized from a dorsal view with joints in approximately 90 degrees flexion and measured at the middle portion. Furthermore, one US examiner performed the semiquantitative scoring of the recorded cartilage images in a blinded manner on a scale of 0–2. Continuous variables from the two groups were analyzed using the Mann–Whitney U test. The relationships among the continuous variables were assessed using the Spearman's rank correlation coefficient.

Results: Female predominance, height and weight were similar between the two groups, although patients with SLE were younger than healthy subjects. The total cartilage thickness of 16 joints tended to be decreased in SLE patients as compared with healthy control (the median 7.0 versus 7.5, p=0.057; and 4.1 versus 4.4 in MCP joints and 2.9 versus 3.0 in PIP joints, respectively). The cartilage thickness of MCP joints was significantly correlated with that of PIP joints (rho=0.40, p=0.007), and the cartilage thickness of MCP/PIP was independent of patients' age, height

and disease duration. The total semi-quantitative score of 16 joints was comparable between patients with SLE and healthy subjects (the median 4.0 versus 4.0, p=0.395; and 2.0 versus 2.0 in MCP joints and 2.0 versus 2.0 in PIP joints, respectively).

Conclusion: The evaluation of finger joint cartilage damage by US is valid and the cartilage damage is limited in most of the patients with SLE.

Abstract Number: 1566

Onset and Disease Course of Inflammatory Arthritis in Patients Receiving Immune Checkpoint Inhibitor Therapy at a Single Institution

Christina Boutsicaris[1], Angelo Ciliberti[2], Elizabeth Lockerman[1], Faizah Siddique[3] and Rochella Ostrowski[1], [1]Loyola University Medical Center, Maywood, IL, [2]Loyola University Medical Center, Oak Park, IL, [3]Loyola University Medical Center, Lombard, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have improved outcomes for many types of cancer, but the therapy is known to cause immune-related adverse events (IRAE). ICI can cause early or late onset inflammatory arthritis, which can continue after stopping ICI[1,2]. Many cases are negative for RF and ACPA. Timely recognition and treatment may improve symptoms and facilitate continuation of cancer therapy.

Methods: We reviewed the Loyola University Medical Center database to identify patients who had new-onset arthritis in the setting of ICI cancer therapy. We collected data on clinical and diagnostic features and outcome measures. Patients received at least one dose of ICI (atezolizumab, durvalumab, ipilimumab, nivolumab, pembrolizumab) between January 1, 2011 and October 31, 2019 and were identified on manual review by two rheumatologists. Definite inflammatory arthritis was based on the presence of documented diagnosis by a physician, exam, or imaging findings. Probable diagnosis was based on clinical description. Arthritis course was described as resolved or sustained, with sustained defined as at least 3 months of arthritis symptoms or treatment. Tumor response was categorized according to the Response Evaluation Criteria for Solid Tumors on oncology follow up. We used descriptive statistics, with frequency and percentage for categorical variables.

Results: A total of 801 patients received ICI. Among these, 28 patients were identified as having ICI-induced arthritis (Table 1, Fig. 1). Median age was 57.5 years. Most common tumor types were melanoma, renal, non-small cell lung, and bladder. Mean follow up time from ICI start was 24.3 months (range 4-62).

RF and ACPA were negative in all 5 patients for whom they were measured. One patient had a positive RF that pre-dated cancer therapy. 32% of patients had severe IRAE (hepatitis, hypophysitis, adrenal insufficiency, ITP, pancytopenia, severe colitis). Patients with a resolved course of arthritis were more likely to have a favorable cancer outcome than those with a sustained course (100% of 8 vs. 67% of 15), but this did not reach statistical significance. Of

Demographics of patients in case series (n = 28)

	Partial response	3 (11%)
	Stable disease	7 (25%)
	Progressive disease	9 (32%)

Table 1

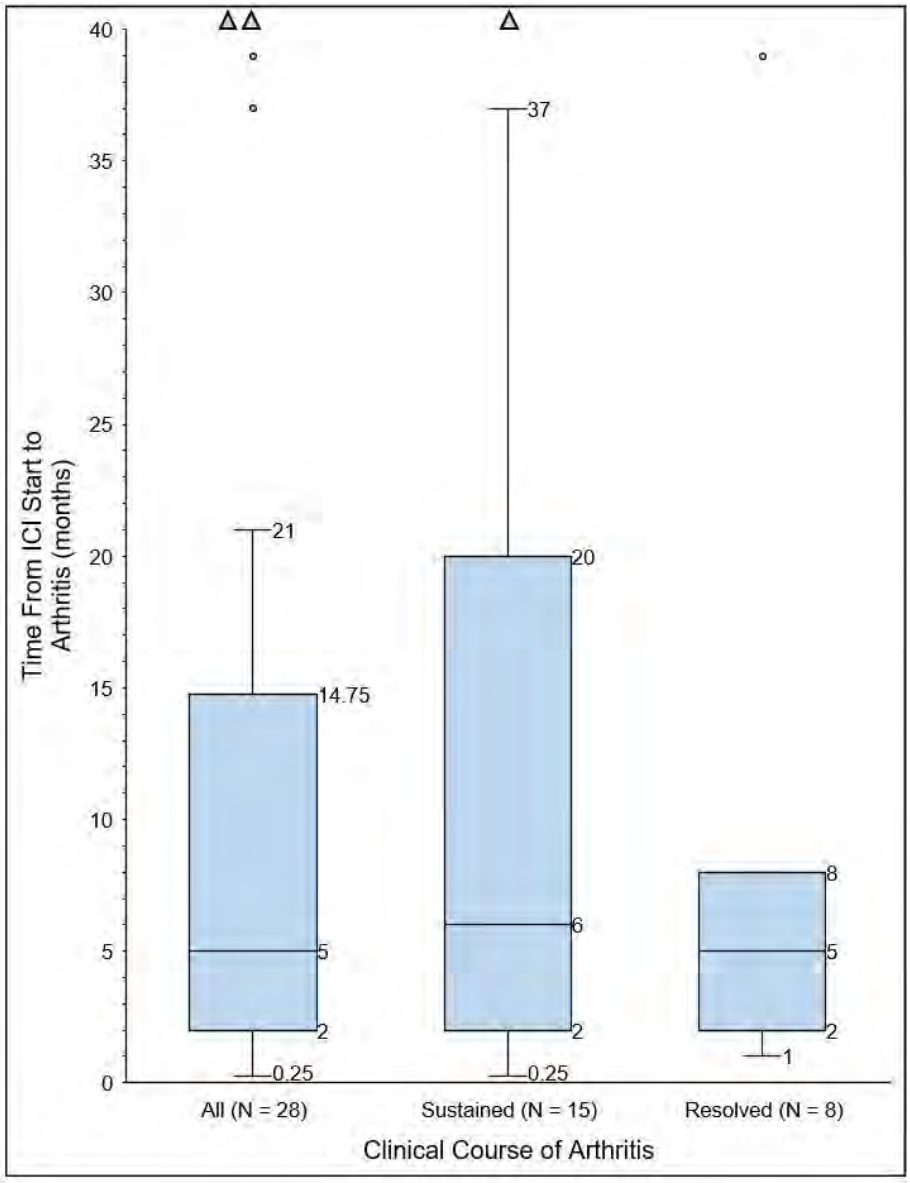

Figure 1. Delay from Immune Checkpoint Inhibitor Start to Arthritis

7 patients who were treated with DMARD or biologic, cancer outcomes included 6 who had no evidence of disease or have stable disease. Of the 8 patients who received combination ICI, 5 had a sustained course. Five patients did not have enough follow up data to define their arthritis course.

Conclusion: Our case series shows that patients can develop IRAE arthritis beyond six months of ICI therapy and that later onset IRAE arthritis trends towards a sustained arthritis course. Patients with a resolved IRAE arthritis course were more likely to have a favorable cancer outcome. IRAE interrupting cancer treatment may contribute to our observations and warrants further study into identifying predictors of IRAE development. Additionally, a concern about treating IRAE with immunosuppression is that treatment could diminish the effects of cancer therapy. However, many patients treated for IRAE arthritis in this series had favorable cancer outcomes.

Abstract Number: 1567

Association of Blood Count Biomarkers and Clinical Features with Immune Related Adverse Events (irAEs) in Patients with Cancer Treated with Checkpoint Inhibitors (CPI)

Despina Michailidou[1], Ali R Khaki[2], Guangyu Wang[3], Leonidas Diamantopoulos[2] and Petros Grivas[2], [1]Division of Rheumatology, University of Washington, Seattle, Washington, Seattle, WA, [2]Division of Oncology, University of Washington, Fred Hutchinson Cancer Research Center, Seattle, Washington, Seattle, WA, [3]Department of Biostatistics, University of Washington, Seattle, Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with cancer treated with CPI can develop irAEs. Since immune changes may impact blood counts and ratios, we hypothesized that those would be associated with irAEs. We also investigated the asso-

ciation between irAEs and personal or family history of autoimmune disease (AD), combination of CPI and/or history of chronic infection.

Methods: We performed a retrospective cohort study and identified patients with solid and hematologic malignancies who started CPI (anti-PD1/PDL1 and anti-CTLA-4) in 2018. We defined irAEs as both rheumatologic and non-rheumatologic. The association between irAEs, baseline absolute neutrophil (ANC), lymphocyte (ALC), monocyte count (AMC), neutrophil to lymphocyte (NLR), monocyte to lymphocyte (MLR), platelet to lymphocyte ratio (PLR), was assessed by logistic regression (LR) with robust standard errors adjusting for age, sex, smoking history, cancer type, ECOG performance status (PS), concomitant systemic therapy, personal or family history of AD and chronic infection. LR with robust standard errors was also used to examine the relationship between irAEs and personal or family history of AD, combination of CPI and chronic infection adjusting for age, sex, smoking history, cancer type, ECOG PS, and concomitant systemic therapy. After Bonferroni correction, alpha level was set to 0.005 for all statistical testing.

Results: A total of 193 patients were identified with median age 64 (range 23-92), 47% women; 49% with smoking history; 23% had lung cancer, 21% skin cancer, 56% other cancers; 19% received concomitant CPI and 32% other systemic therapy plus CPI. Rheumatologic irAEs were reported in 10%, and non-rheumatologic irAEs in 23% of patients. Association between irAEs, blood biomarkers and clinical features are described in **Table.** Development of irAEs was significantly associated with higher baseline ALC (OR: 2.43, 95%CI: 1.39-4.22, p=0.002) and lower baseline MLR (OR: 0.09, 95%CI: 0.02-0.42, p=0.002). Patients with pre-existing AD (OR: 5.14, 95%CI: 2.18-12.15, p< 0.001) were also more likely to experience irAEs during treatment with CPI.

Table. Association of lab biomarkers as continuous variables and clinical features with irAEs

	OR	95% CI	p-value
Absolute neutrophil count (ANC)	1.06	0.96 – 1.18	0.25
Absolute lymphocyte count (ALC)	2.43	1.39 – 4.22	0.002
Absolute monocyte count (AMC)	1.93	0.40 – 9.34	0.42
Neutrophil:Lymphocyte ratio (NLR)	0.90	0.82 – 0.99	0.03
Monocyte:Lymphocyte ratio (MLR)	0.09	0.02 – 0.42	0.002
Platelet:Lymphocyte ratio (PLR)*	0.96	0.94 – 0.99	0.01
Personal history of autoimmune disease	5.14	2.18– 12.15	<0.001
Family history of autoimmune disease	4.02	1.45 – 11.13	0.008
Combination of CPIs vs single agent	2.92	1.19 – 7.16	0.02
Chronic infection	0.51	0.18 – 1.44	0.20

*PLR was calculated at (platelet count/10)/absolute lymphocyte count

Conclusion: In patients with cancer treated with CPI, irAE development was associated with higher baseline ALC, lower MLR and pre-existing history of AD. Further validation is required to test our generated hypothesis that blood count subsets could be used as inexpensive and easily obtained biomarkers to predict the development of irAEs in clinical practice.

Abstract Number: 1568

Impact of the SARS-CoV-2 Pandemic on a Cohort of Patients with Rheumatic Complications of Immune Checkpoint Inhibitors: A Registry Survey Study

Nilasha Ghosh[1], Aidan Tirpack[2], Caroline Benson[3], Gregory Vitone[3], Karmela Kim Chan[2] and Anne Bass[1], [1]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: It is not known whether cancer patients being treated with immune checkpoint inhibitors (ICI) and/or immunosuppression are more vulnerable to SARS-CoV-2 or more apt to have severe manifestations of the disease. We aimed to describe oncology and rheumatology treatment practices in ICI-treated patients with a history of rheumatic immune-related adverse events (irAE) during the March-April 2020 “surge” in SARS-CoV-2 infections in the New York Tri-State area, and to determine the frequency of SARS-CoV-2 infection in these patients.

Methods: A 23-question email survey was administered via RedCap on April, 16 2020 to all living patients enrolled in our institutional ICI rheumatic irAE registry, who had consented to future studies. Participants who did not fill out the form electronically were contacted via telephone and if they agreed, completed the survey verbally. The survey included questions about current cancer status, ICI and immunosuppressant medication use, irAE status, history of SARS-CoV-2 symptoms or diagnosed infection, as well as a free text question asking, “Is there anything else you would like to tell us about how coronavirus has affected you personally?”

Results: The survey was sent to 92 registry patients. Thirty-nine completed the survey electronically and 26 by telephone (response rate 71%). After excluding 2 patients who never received ICI, 63 patients were analyzed (**Table 1**). Patients who had been on ICI within the last 6 months (n=25) and those who discontinued ICI because of the pandemic (n=7) were identified as patient subsets. There were no significant differences between the groups, although there was a trend toward ICI therapy more often being held in female patients, those on ICI monotherapy and those with a good cancer response. None of the patients who had their ICI held had active arthritis or other irAE requiring immunosuppression. In patients on immunosuppression for irAE, none had changes made in these medications pre-emptively as a result of the pandemic. **Table 2** highlights characteristics of patients with proven or presumed SARS-CoV-2 infection. Four of 5 were men, and 3 had renal cell carcinoma (RCC), proportionally higher than the

Table 1. Patient Characteristics

Characteristics	Entire cohort (n=63)	Patients on ICI at outset of SARS-CoV-2 pandemic (n=25)

Any arthritis medication changes due to SARS-CoV-2?	No	No	No

Key: ICI = immune checkpoint inhibitor; NSCLC = non-small cell lung cancer; CR = complete response; PR = partial response; irAE = immune-related adverse effect; OA = osteoarthritis; PMR = polymyalgia rheumatica; NSAIDs = nonsteroidal anti-inflammatory drugs; HCQ = hydroxychloroquine; MTX = methotrexate; Anti-TNF = Anti-tumor necrosis factor.
*Totals do not add up to 100% given that patients can be on multiple medications at a given time

Table 1. Patient Characteristics

overall cohort both for gender and cancer type. The 2 patients still on active ICI were on combination therapy and prednisone at the time of infection. The other 3 were no longer on either ICI or immunosuppression. 37/63 (59%) responded to the free-text question and, of those, 30 (81%) expressed depression, anxiety/fear, frustration and economic hardship while 7 (19 %) remained optimistic and positive **(Table 3)**.

Conclusion: Oncologists held ICI in a quarter of registry cancer patients in the context of the SARS-CoV-2 pandemic, particularly women on ICI monotherapy who had had a good cancer response. Five patients (8%) developed SARS-CoV-2 infection during the NY Tri-state "surge" of March-April 2020, but all were able to recover uneventfully despite their advanced age. Four of 5 with SARS-CoV-2 infection were male, 3 had RCC and 2 were on combination ICI. Larger studies are needed to determine whether RCC and/or combination ICI are risk factors for SARS-CoV-2 infection.

Abstract Number: 1569

Immune Related Adverse Events Related to Check Point Inhibitors Among Outpatients in an Academic Center

Bushra Akram[1], Aleena Itani[1], Mohammad Razaq[2], Samera Vaseer[1], Sara Vesely[1] and Pawan Acharya[1], [1]University of Oklahoma Health Sciences Center, Oklahoma City, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK

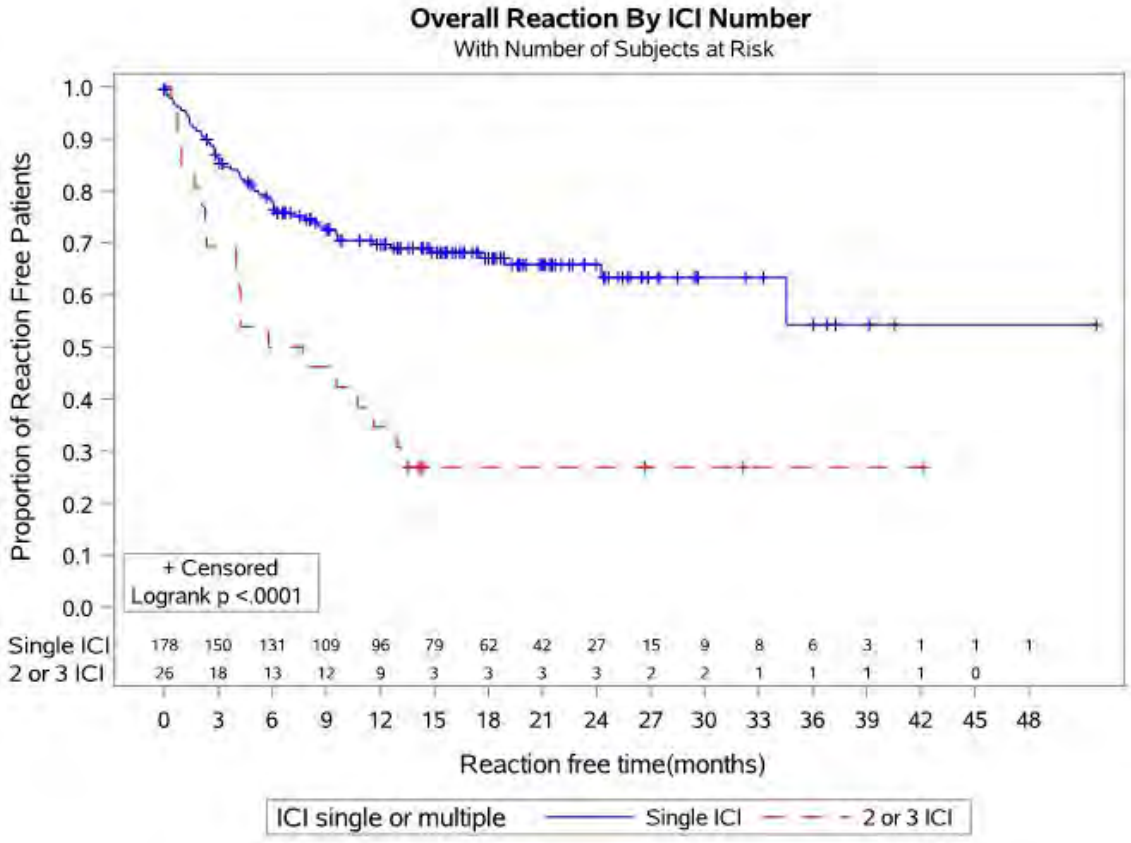
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune check point inhibitors (ICIs) allow the body to recognize tumor cells as non-self, resulting in immune-cell mediated tumor cell destruction. These therapies have the potential for adverse reactions secondary to excessive immune activation. Retrospective studies have identified several immune related adverse effects (irAE) and less commonly rheumatic immune related adverse effects (RhirAE). Little is known about factors that predispose patients to irAE, their treatments and correlation of irAE with response. Our study aimed to classify irAEs,

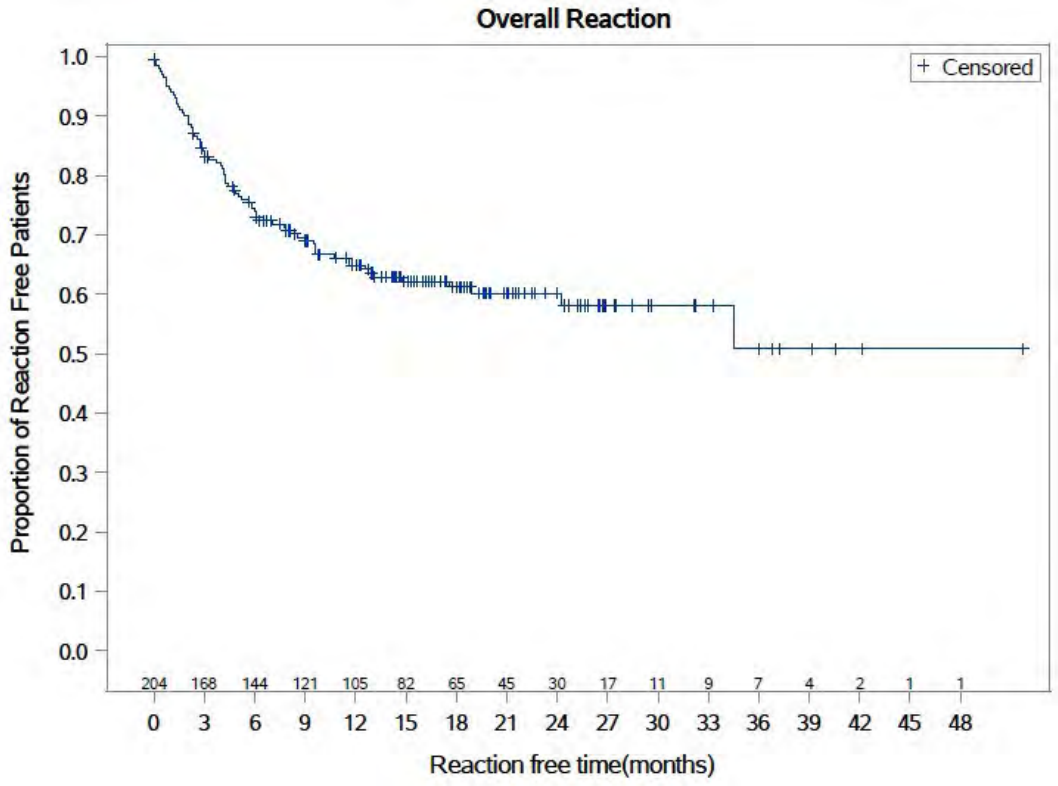
especially those related with rheumatic diseases, including their timing and risk factors. Additionally, we aim to collect data regarding current referral and management practices in a single academic center to improve knowledge gaps.

Methods: Retrospective chart review was performed evaluating patients at Stephenson Cancer Center exposed to at least 3 months of ICI therapy between 1/1/19 and 6/30/19. Patients under the age of 18, those with Type I DM or pregnancy were excluded. Demographic data, data regarding irAE and treatment, and disease outcomes were obtained through manual chart review.

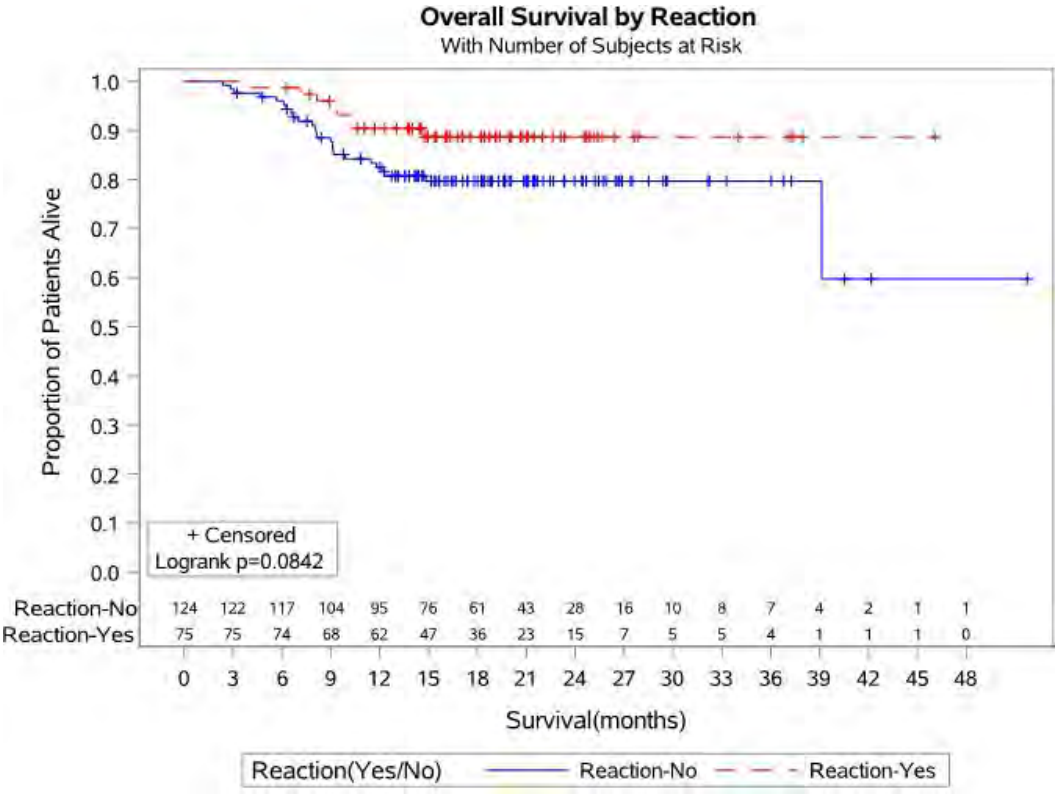
Results: 206 patients met study inclusion criteria, of which 78 had an irAE related to ICI with 7 patients having more than one reaction. The average time to onset of irAE after initiation of ICI was 164.2 days (3-1036 days). Non-small cell lung cancer (26.9%) was the most common cancer followed by melanoma (21.8%) and renal cell carcinoma (17.9%) that were equally distributed in the two groups. Pembrolizumab was the most used agent followed by nivolumab and atezolizumab. There were no significant differences between gender, age, underlying cancer type, cancer stage, and different ICI among patients who developed irAE (37.9%) and those who did not (62.1%). However, combination therapy was more likely to cause an irAE (Reaction rate: 71.42% $p < 0.0001$). Thyroiditis (30.6%) and rash (25.9%) were most common adverse reactions. RhirAE were rare with one patient with myositis, two with uveitis and one patient with arthritis. 93.6% of patients developed irAE requiring treatment, with 63% requiring steroids and 5.4% requiring disease-modifying antirheumatic drugs (DMARDS). Treatment with ICI was interrupted/stopped in 127 patients (61.6%) of which 19 patients stopped treatment due to irAE (14.9%) with 1 patient referred to rheumatology for evaluation.



IrAE in single vs multiple ICIs.



Average Lag period between ICI therapy and iRAE



IrAE and over all survival

Conclusion: Our study shows that irAE are common among patients treated with ICI. Treatment is continued in majority of patients and only 14.9% requiring change in therapy due to reactions. Our study did not have enough patients with prior rheumatic conditions to determine if these agents worsen underlying disease. Majority of reactions required treatment, often with steroids. There was no significant difference in age or gender between two groups, suggesting that these are not unique risk factors. Most irAE occurred around 5.3 months after starting ICI. Sustained ICI therapy and combination therapy is more likely to result in an irAE,suggesting that clinicians should monitor patients for reactions at all times.

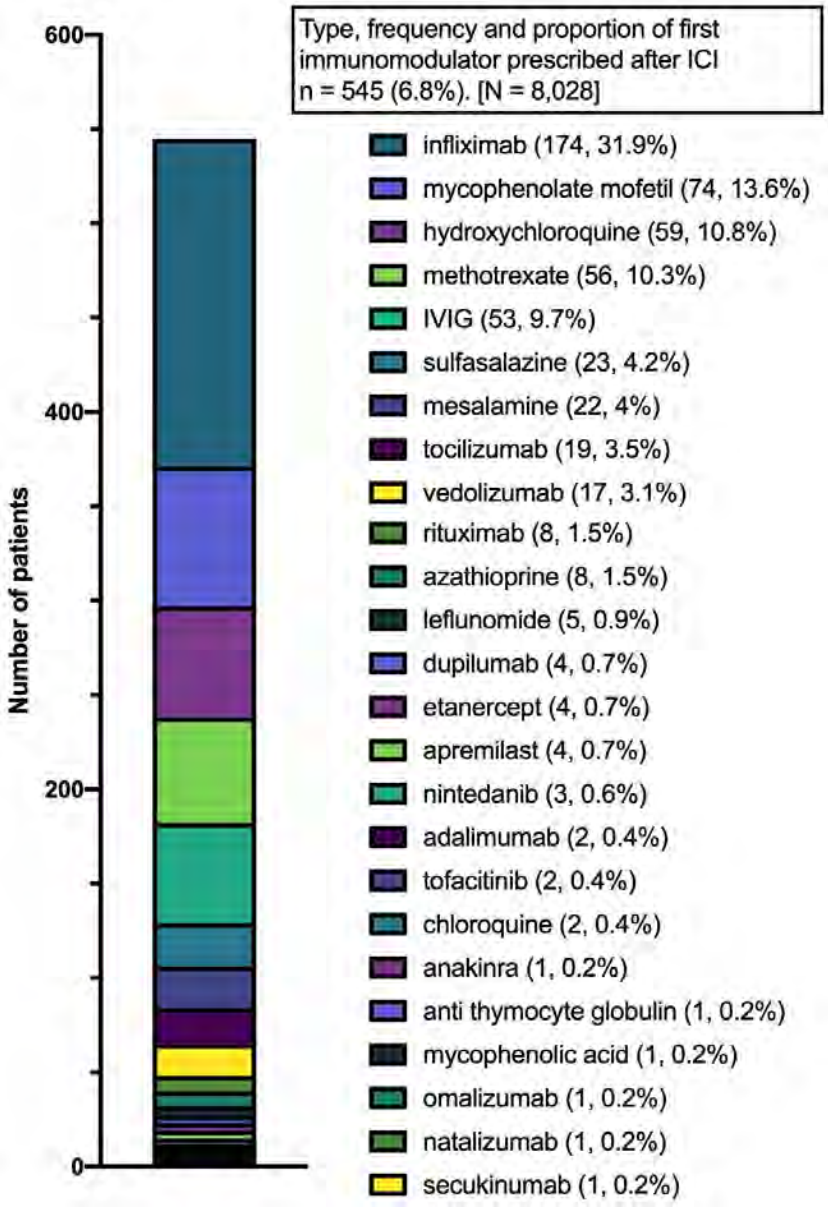
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are used to treat an expanding number of cancers. Many cancer patients treated with ICI develop immune-related adverse events (irAE) or flares of pre-existing autoimmune disease. These can be severe and/or refractory and may require treatment with immunomodulators (IM), commonly prescribed by rheumatologists. The aim of this study was to determine the frequency of IM use, specific initial IM drugs used, and involvement of rheumatology in the care of cancer patients treated with ICI.

Methods: We performed a descriptive study of all cancer patients initiating an ICI in a large tertiary academic health care system and cancer center. Patients receiving prescriptions of IM drugs after ICI were identified through an electronic query of prescriptions and clinical encounters. IM drugs were considered a proxy for the occurrence of an irAE or flare of a pre-existing autoimmune disease. We did not study NSAIDs or glucocorticoids since these medications are commonly prescribed for many indications and are non-specific for irAEs or pre-existing autoimmune disease flares. All prescriptions for IM that could also be used for cancer, organ rejection or stem cell transplant indications (methotrexate, rituximab, and mycophenolate mofetil) were manually reviewed to include only patients who received these drugs for treatment of an irAE or autoimmune disease flare. If multiple IMs were prescribed after ICI, we only included the initial IM, to avoid counting a single patient more than once. We also identified all clinical encounters with a rheumatologist in our healthcare system occurring after ICI initiation and reported the proportion and frequency of ICI- and IM-treated cancer patients who were evaluated by rheumatology.

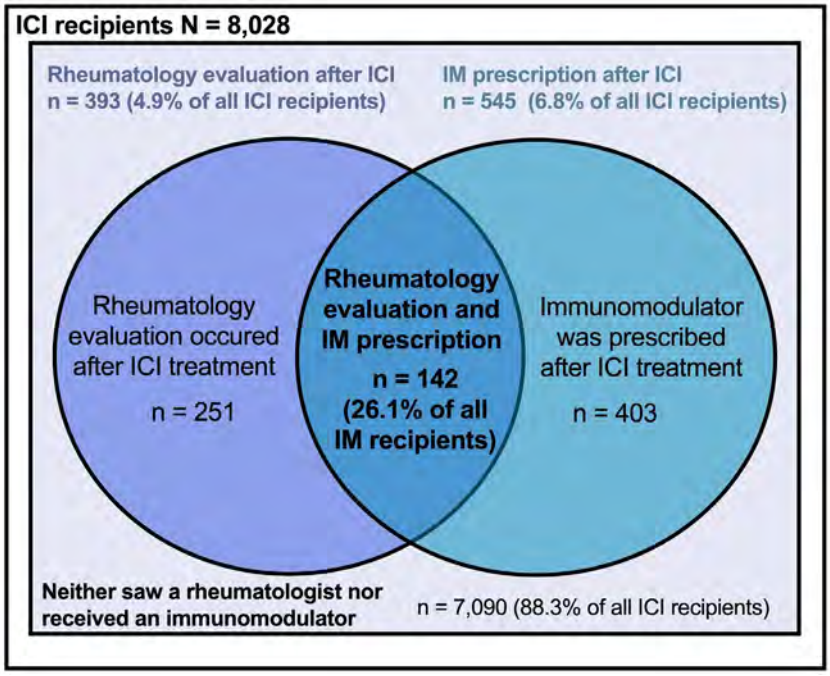
Results: We identified 8,028 cancer patients who initiated an ICI (mean age 64.4 years, female 43%). The most common ICIs were: pembrolizumab (47%), nivolumab (28%), ipilimumab (8.0%) and combination ipilimumab/nivolumab (8.0%), (**Figure 1**). Among ICI recipients, 6.8% subsequently received a prescription for an IM. Among all patients who received an IM following ICI treatment, the most common initial IMs were: infliximab (32.0%), mycophenolate mofetil (13.6%) hydroxychloroquine (10.8%), and methotrexate (10.3%). Among all ICI recipients, 4.9% (n = 393)



Frequency and proportion of initial immunomodulator (IM) prescribed (n=545).

were evaluated by rheumatology of which 1.8% (n = 142) received an IM after ICI start. Of all ICI-treated patients who received an IM, 26.1% were evaluated by a rheumatologist (**Figure 2**).

Conclusion: In this large single-center study, 6.8% of ICI-treated cancer patients had severe/refractory irAEs or underlying autoimmune disease flares that required treatment with IM. While determination of the indication for IM use in these patients is underway, these results provide a summary of which IM are initially considered after glucocorticoids, in cancer patients receiving ICI. While not all types of irAEs require rheumatology involvement, notably, only one-fourth of ICI-treated patients who received an IM were also evaluated by a rheumatologist suggesting that oncologists and other specialists prescribe most IM in these patients.



Frequency and proportion of patients with rheumatology evaluation and immunomodulator (IM) use among immune checkpoint inhibitor (ICI)-treated cancer patients (N=8,028).

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite of unprecedented clinical success in cancer therapeutics, immune checkpoint inhibitors (ICIs) are associated with immune-related adverse events (irAEs), including arthritis (arthritis-irAE). Arthritis-irAE can not only cause bone erosions but also warrant early termination of ICI treatment. Further, treatment for the arthri-

tis-irAE can mitigate anti-tumor immunity revived by the ICI treatment. To overcome such clinical challenges, understanding the pathophysiology of arthritis-irAE is critical; however, these mechanisms remain unknown.

Methods: We collected and performed immunoprofiling of synovial fluid from seven patients with active arthritis-irAE and three control patients with osteoarthritis. In parallel, we examined the impact of ICIs on collagen induced arthritis (CIA).

Results: Four patients developed arthritis after PD-1 inhibitor monotherapy and three after combination therapy with CTLA-4 and PD-1 inhibitors. Two patients in the combination therapy group required interleukin (IL)-6 receptor inhibitor therapy in addition to steroids, compared with one patient in the monotherapy group (sulfasalazine). IL-17-producing $CD4^+$ T cells (Th17) were enriched in the combination therapy group compared to monotherapy group (1.01±0.73% in live $CD4^+$ T cells in the monotherapy group compared with 3.19±0.31% in the combination therapy group; P=0.005). Synovial fluid levels of IL-6 and IL-17A, key cytokines for Th17 cell differentiation and function, were higher in the combination ICI therapy group than in the monotherapy group, suggesting the role of Th17-related cytokines in disease pathogenesis. Like humans, ICIs, especially in combinations, facilitate the development and progression of CIA. Importantly, although not reached statistical significance, like humans, collagen-specific Th17 cells were enriched in CIA mice receiving combined ICI treatment.

Conclusion: Our data suggests that Th17 cells, especially in post combination ICI therapy, play a critical role in the disease pathogenesis. Comprehensive studies with more patients/controls along with recapitulating mouse models will unmask underlying mechanisms of arthritis-irAE. Further, understanding of altered immunity in the arthritis-irAE will provide insights of inflammatory arthritis secondary to the classical autoimmune diseases.

Histology		DLBCL 15 HL 5 FL 1 PTCL 1 AILT 1 MALT 3 THRLBCL 1 Polymorphic 1 Reactive 4 Unknown 12 No biopsy 19	DLBCL 20 HL 4 IVL1 TCL 1 TCRLBCL1 MCL 1 Unknown 1	

Patients profile of MTX-LPD cases.

ing various clinical manifestation and histological finding. Therefore, we need more information about MTX-LPD. In addition, it has not been established for RA treatment after the onset of MTX-LPD. We investigate the clinical characteristics of MTX-LPD and RA treatment after the onset of MTX-LPD.

Methods: We enrolled 92 MTX-LPD patients from Kagawa Prefecture, Japan between June 2005 and March 2020. Patients were diagnosed RA according to American College of Rheumatology (ACR) 1987 classification criteria or ACR/European League Against Rheumatism (EULAR) 2010 classification criteria, and treated with disease modifying antirheumatic drugs (DMARDs) including MTX. We collected as follow information; age, gender, duration of RA, laboratory data (LDH and sIL-2R) and treatment of MTX-LPD. We divided 92 MTX-LPD cases into spontaneous regression cases (SR group) and cases that treated with chemotherapy after MTX discontinuation (CTx group), and compared the difference between two groups. In addition, we investigated RA treatment after the onset of MTX-LPD.

Results: Characteristics of 92 MTX-LPD patients are as follow; mean age 66.2±10.9 years, 64 female, duration of RA 13.1±9.1 years. 62 patients (67.4%) were spontaneously improved by discontinuing MTX. The level of sIL-2R was significantly lower in SR group ($p< 0.0001$). Furthermore, the rate of extranodal lesion was more in SR group compared with CTx group (56.5% vs 41.4%). 73 patients (76.1%) were proven MTX-LPD histologically. In these patients, diffuse large B-cell lymphoma (DLBCL) was the most frequent histological diagnosis of MTX-LPD (38.0%). As regards RA treatment after MTX-LPD onset, conventional synthetic DMARDs alone, biologics or JAK inhibitors and NSAIDs or PSL alone treatment were 34, 20 and 10 cases respectively. The remaining cases were untreated, or unknown due to transferred to another hospital.

Conclusion: We indicated clinical characteristics of MTX-LPD with RA patients. In this study, we suggested that the serum sIL-2R level may predict SR of MTX-LPD. Additionally, biologics and JAK inhibitor have been used in many cases to control of RA activity after the onset of MTX-LPD. However, the association of JAK inhibitor and LPD onset is not clarify, and we need to accumulate the cases in the future.

Gout as an Immune-Related Adverse Event from Immune Checkpoint Inhibitors

Kevin Lee[1], Carrie Ye[2] and Shokrollah Elahi[3], [1]Internal Medicine, University of Alberta, Edmonton, AB, Canada, [2]Rheumatology, University of Alberta, Edmonton, AB, Canada, [3]Medical Microbiology and Immunology, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are novel treatments approved for various tumours including melanoma, lung and kidney. By interacting with immunoregulatory molecules (programmed death-1 (PD-1), PD-1 ligand (PD-L1), or cytotoxic T-lymphocyte associated protein (CTLA-4)), ICI prevent inhibition of T-cells and thereby increase immune activity. However, this T-cell activation also dysregulates immune self-tolerance and causes immune-related adverse events (irAE) such as inflammatory arthritis, myositis, and polymyalgia rheumatica. Despite increases in ICI use, reports of crystal arthropathies as a potential irAE remain rare with only 2 cases of pseudogout and 2 cases of unspecified crystalline arthritis. Furthermore, despite reports of tumor lysis syndrome and hyperuricemia from ICI, gout was not specifically reported. We report our center's experience with ICI-associated gout and explore the potential pathophysiology behind this entity.

Methods: We reviewed all patients referred to the university adult rheumatology clinic between 2017 and 2020 for acute gout flares after receiving mono- or combination-ICI. After receiving individual informed consent, their electronic medical chart was reviewed for history relevant to their cancer and gout. Gout was confirmed by combination of imaging, classic podagra history, and joint aspirations.

Results: We identified 6 patients. They were all diagnosed at a mean age of 63 years with solid tumours (squamous cell carcinoma of the larynx or skin, lung adenocarcinoma, renal cell carcinoma, melanoma) and received a PD-1 inhibitor. Three patient also received an additional ICI as a combination therapy: 1 received CTLA-4 inhibitor (ipilimumab) while 2 received ipilimumab or placebo as part of clinical trials.

All patients previously had gout. Their last flare was at least 1 year prior to first ICI dose. While patients had risk factors for gout exacerbation including alcohol, hypertension, thiazide diuretic use, obesity, dyslipidemia, and elevated baseline creatinine and urate levels, these factors were non-contributory to post-ICI gout flares.

Four patients experienced gout flares after their first ICI infusion while 2 patients flared after multiple ICI infusions. Patterns of gout flares were not typical of classical gout with only 1 patient presenting with acute monoarticular involvement and 5 patients presenting with acute, acute-on-chronic, or chronic oligoarticular involvements. Affected joints included first metatarsophalangeal joint, knees, elbows, and smaller joints (wrist, hands, feet). All patients responded well to usual gout therapies and tolerated continuation of ICI with positive cancer response.

Conclusion: Although many irAE have previously been described, this is the first to report gout as a potential irAE. Potential mechanisms include loss of T-cell inhibition by ICI leading to unchecked inflammation from uric acid crystals; increased white blood cell turnover rates; and consequence of tumour lysis syndrome. With increased survival of stage four cancer patients with ICI, early identification and management of gout is an important aspect of improving patient quality of life.

Over Half of Patients with Immune Checkpoint Inhibitor-related Myositis, Myasthenia Gravis and/or Myocarditis Have Autoantibodies: Results from a Systematic Literature Review

Nilasha Ghosh[1], Karmela Kim Chan[2], Bridget Jivanelli[3] and Anne Bass[1], [1]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [2]Hospital For Special Surgery, New York, NY, [3]Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Although immune checkpoint inhibitor (ICI) cancer treatments are known to activate cytotoxic T-cells, autoantibodies may also contribute to the development of immune-related adverse events (irAE). Patients with ICI-associated myositis are said to rarely have autoantibodies. We performed a systematic literature review of irAE cases and case series to determine the prevalence of autoantibodies in patients with ICI-induced myositis, myasthenia gravis (MG) and/or myocarditis, and to identify characteristics of seropositive and seronegative patients.

Methods: PubMed, Embase and Cochrane databases were searched for reports of ICI-induced irAE. Publications were included if they provided results of autoantibody testing at the individual patient level. Here we report on the subset of publications describing ICI-induced myositis, MG and/or myocarditis. Descriptive statistics were used to summarize results.

Results: We screened 12,207 articles and subsequently, 1249 full texts. We included 69 publications that described autoantibody testing in 150 patients with myositis, MG and/or myocarditis. Eighty-nine patients (59%) had at least one autoantibody, including 4 of 5 tested patients with myocarditis alone, and 5 of 6 with the combination of myositis, MG and myocarditis (**Table 1**). The prevalence of autoantibodies was the same across ICI and cancer types. Seropositive patients had a higher median creatinine phosphate kinase (CPK) (4300 u/L vs. 1959 u/L), a slightly earlier time of irAE onset (3.6 weeks vs. 4.1 weeks) and were less likely to resolve their irAE (27% vs 45%). Sixty percent of tested patients had a muscle-specific antibody (MSA) (25%) and/or MG-specific (56%) antibody (**Table 2**). Only 1/15 tested

Any MSA or MG-specific Ab	73	121	**60**
Paraneoplastic Ab panel	1	15	6.7
Anti-nuclear Ab, any	20	54	37
- Anti-nuclear Ab, only	4	--	--
Other[1], any	7	17	41

Key: Ab= antibody, MSA = Muscle-specific antibody (specific antibodies: Jo-1, PL-7, PL-12, KS, Mi-2, p155/p140, EJ, Ku, OJ, PM/Scl, SRP, Smith/RNP (ENA), Ro50/Ro60, SAE, NXP2, MDA5, TIF1-y, 3-hydroxy-3methylglutaryl-coenzyme A reductase)
ACh Ab = Acetylcholine-related antibodies (Acetylcholine receptor binding, blocking, modulating antibodies, acetylcholinesterase antibody); Striated Ab (specific antibodies: titin, striated muscle, Kv1.4 (voltage-gated Potassium channel), ryanodine receptor, myosin, alpha-actin); MuSK = Muscle specific kinase antibody; MG = myasthenia gravis; MG-specific Ab include: Anti-ACh, anti-striated, anti-MuSK
[1]Other antibodies include: anti-nuclear antibody, ANCA, RF, anti-CCP, dsDNA, smooth muscle antibody, anti-thyroglobulin, anti-thyroid receptor, anti-thyroid peroxidase

Prevalence of autoantibodies

patients had a paraneoplastic autoantibody, while 20/54 (37%) tested were ANA positive. Over 90% of patients with MSA or striated antibodies presented with myositis, whereas 17/22 (77%) with only Acetylcholine-related antibodies (ACh) presented with MG (**Table 3**). A subset of patients (n=14) with both anti-striated and anti-ACh presented with variable myositis and MG symptoms. Patients with anti-ACh had worse irAE outcomes - only 10% with symptom resolution and 48% died.

Conclusion: Almost two-thirds of patients with ICI-induced myositis, MG and/or myocarditis have autoantibodies. Patients with myositis typically have MSA or striated antibodies. The presence of anti-ACh in isolation is found almost exclusively in patients presenting with MG and these patients tend to have a worse prognosis. Prospective studies are needed to determine whether autoantibodies are present prior to ICI and could serve as biomarkers of future serious irAE.

Table 3. Comparison of patients with specific autoantibody profiles

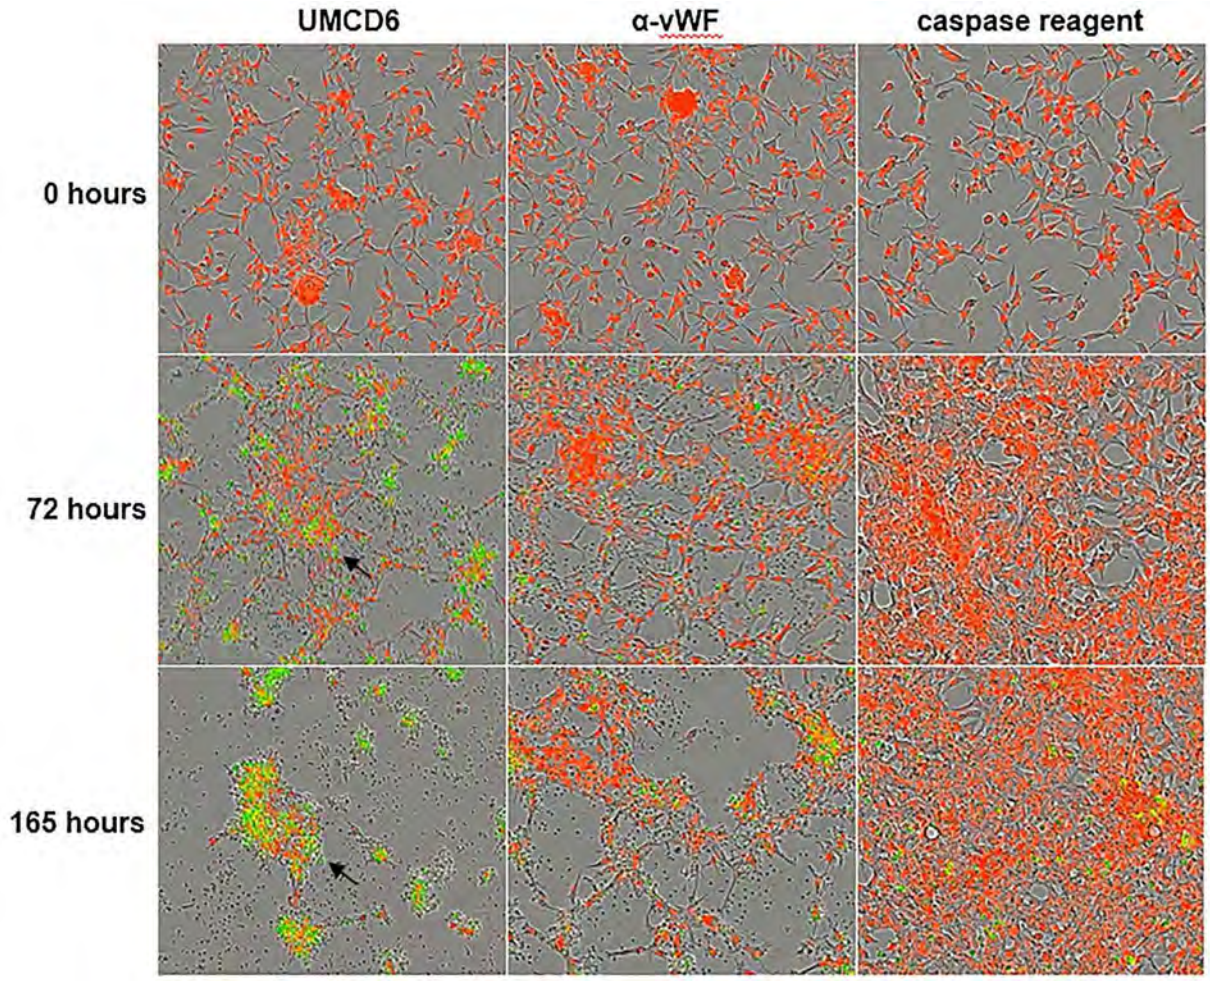
SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Immunological Complications of Therapy Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM



Supplemental Figure S2. ***UMCD6 enhances LNCaP prostate cancer cell killing in vitro by human PBMCs.*** In the absence of mAbs and/or PBMCs (right column – untreated wells), LNCAP proliferation was unimpeded (fluorescent red cells). LNCAP prostate cancer cells co-cultured with UMCD6-treated PBMCs displayed profound clumping and caspase expression (fluorescent green dye) at 72 hours and were almost completely eliminated by 165 hours (see arrows). In the presence of control antibody and PBMCs modest killing of LNCaP cells was observed, but viable cancer cells persisted. The experiment was performed using the IncuCyte imaging device and the pictures were taken directly from a movie of this assay that is included in the supplementary material.

The anti-CD6 monoclonal antibody UMCD6 induces lymphocytes to kill cancer cells.

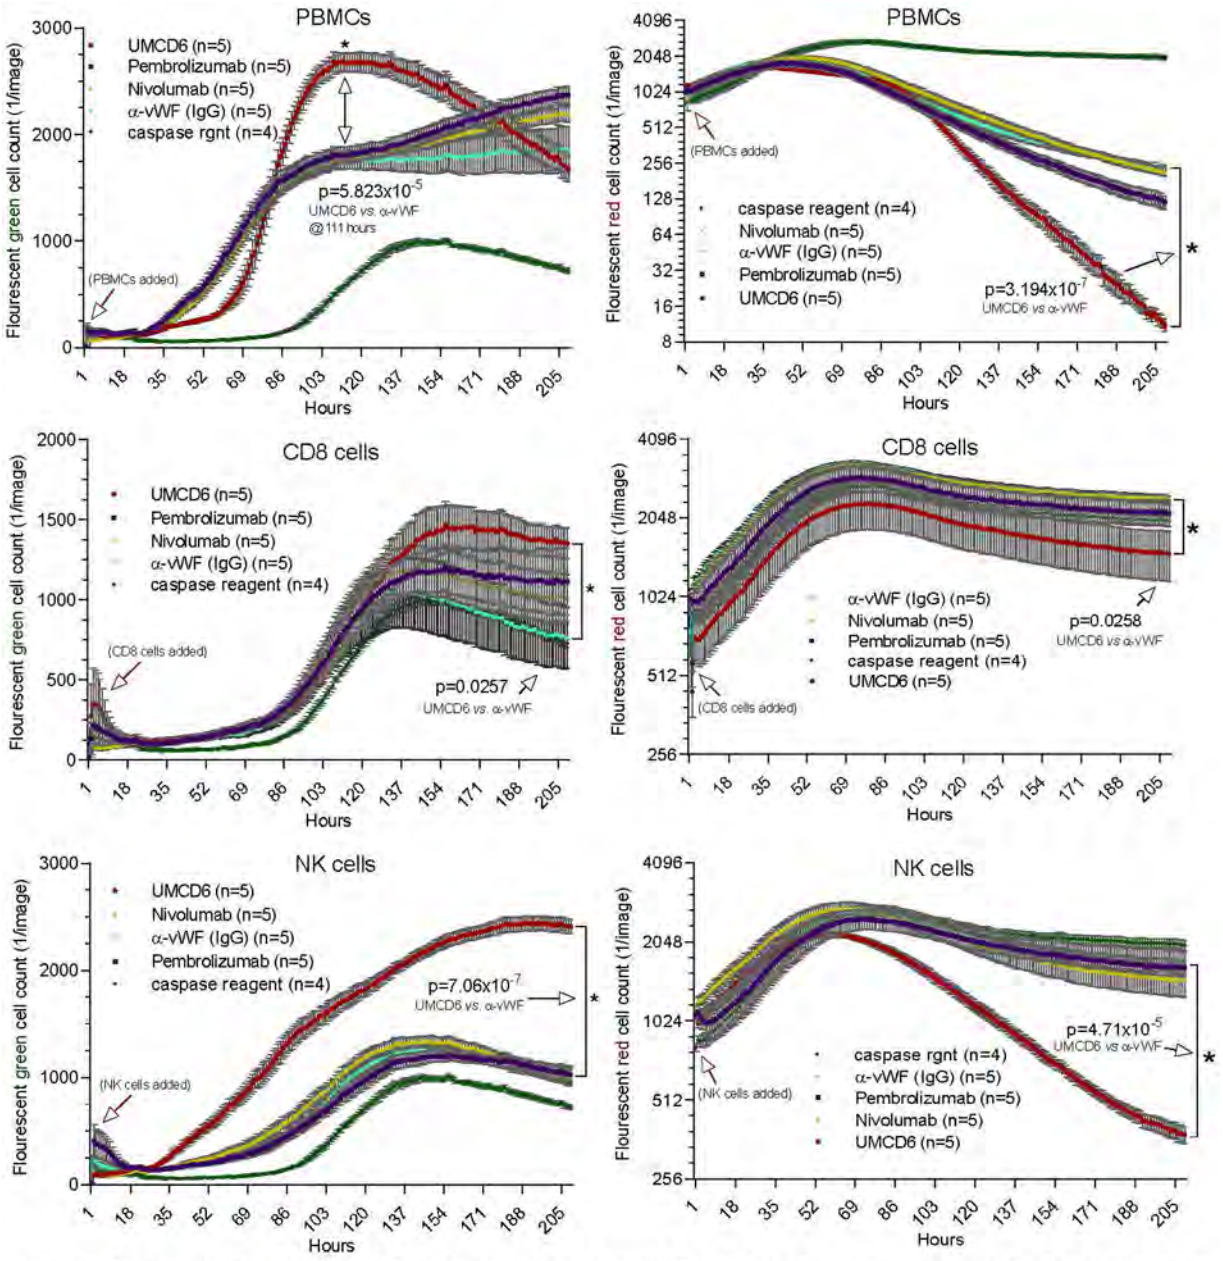


Figure 5. ***CD6+ NK cells treated with UMCD6 are highly effective at killing MDA-MB-231 tumor cells.*** **Upper panel:** Tumor cell killing assays were set up using 50,000 immune cells and 20,000 MDA-MB-231 HBCCs and antibodies at 10ug/mL. PBMCs pre-incubated with UMCD6 killed tumor cells much more effectively than PBMCs pre-incubated with IgG control antibody, pembrolizumab or nivolumab (right panels, red fluorescence tumor cell survival with *y-axis* $\log_2$) and cell death (left panels, green fluorescence, caspase sensitive with *y-axis* linear). **Middle panel:** Isolated CD8+ cells showed enhanced killing and lower tumor cell survival in co-cultures with UMCD6, compared to the other antibodies. **Lower panel:** Only UMCD6 induced tumor cell killing by purified NK cells.

UMCD6 directly activates cytotoxic lymphocytes and is more potent than conventional checkpoint inhibitors.

Background/Purpose: Limitations of checkpoint inhibitor immunotherapy include induction of autoimmune syndromes and resistance of many cancers. Definition of additional molecular targets is required. CD6, expressed by most human T lymphocytes and a subset of natural killer (NK) cells, engages the ligands CD166/ALCAM and CD318. Interrupting CD6 interaction with its ligands prevents or reverses mouse models of rheumatoid arthritis, multiple sclerosis and uveitis, due to suppression by UMCD6 of differentiation of effector Th1 and Th17 cells. As CD6 ligands are broadly expressed on cancer cells and high expression of CD318 is associated with aggressive and metastatic

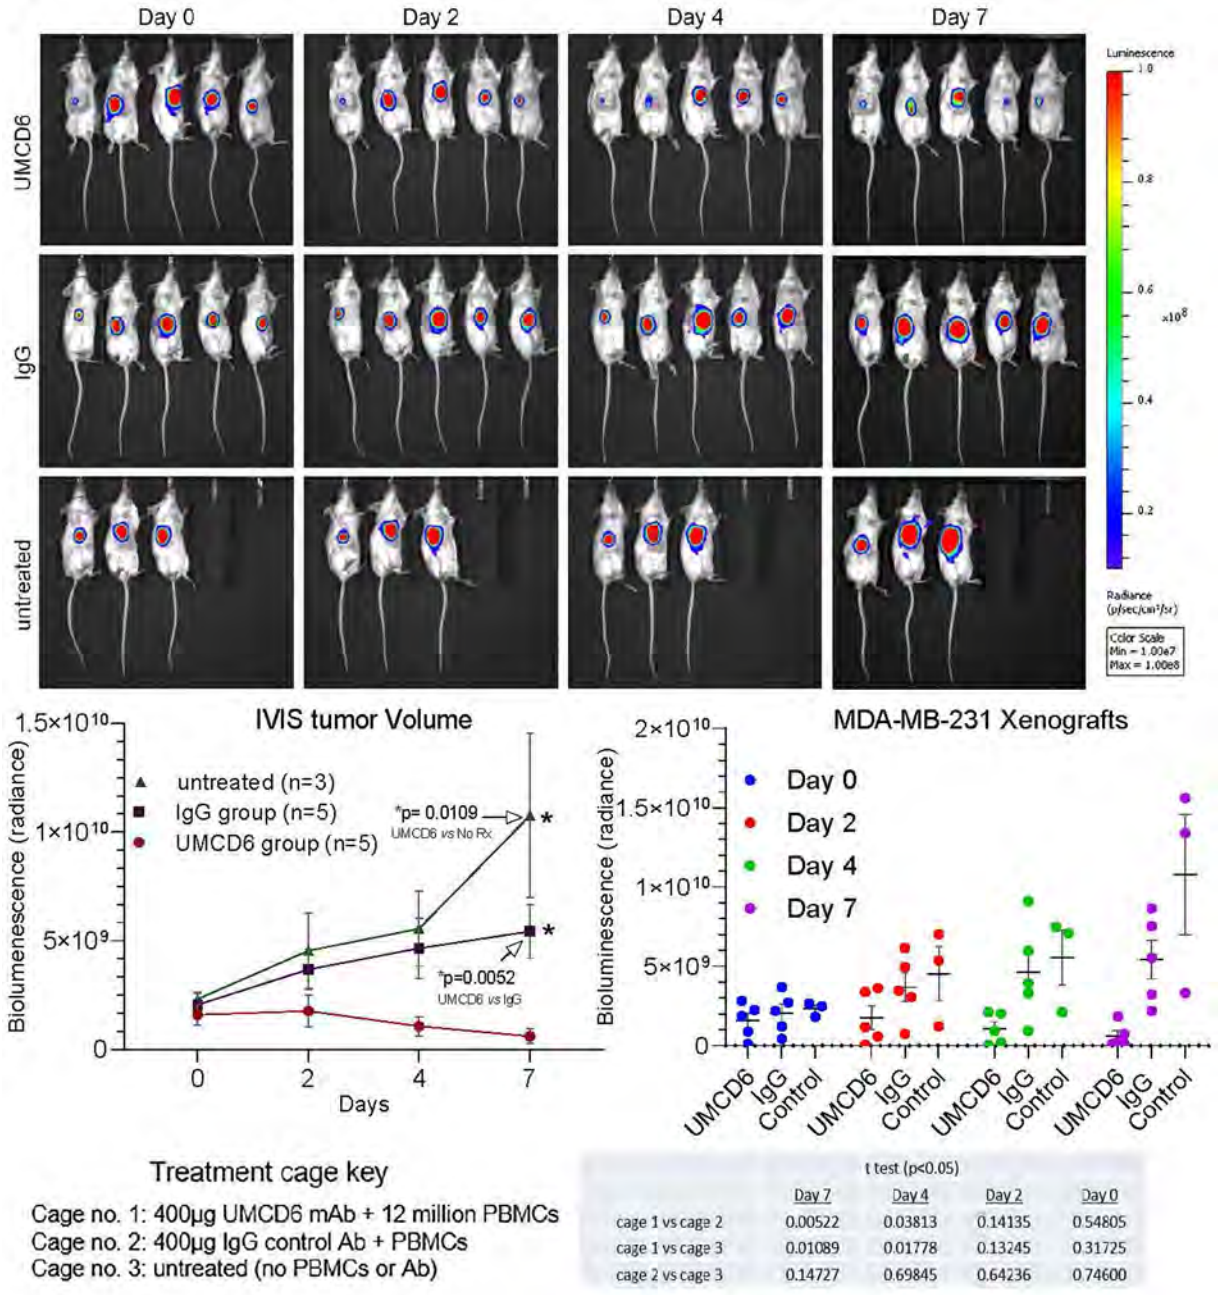

Figure 6. ***UMCD6 reduces tumor size in SCID beige mice.*** Human breast cancer cells (MDA $5x10^6$ cells) were inoculated s.c. in the ventral aspect of the abdomen of female SCID beige mice. Once tumors reached a size of about $100mm^3$ some mice were administered $12x10^6$ human PBMCs by tail vein (considered day 0). The next day mice that had received PBMCs were injected i.p. with either 0.4 mg control IgG or UMCD6. Mice not administered PBMCs received no antibodies (untreated). Tumors were measured by IVIS (*in vivo* imaging) thereafter. The effect of UMCD6 on tumor volume can be seen at day 4 and 7 after UMCD6 administration (*p<0.05) compared to both the IgG and no-treatment groups. Data represents mean of 3-5 animals ± sem.

UMCD6 induces lymphocyte-mediated cancer regression in vivo.

cancer, we hypothesized that interruption of CD6/CD6 ligand interactions would enhance lymphocyte killing of cancer cells.

Methods: Flow cytometry was used to define expression of CD6 ligands on human breast, lung and prostate cancer cell lines. Soluble CD318 was measured by ELISA. To develop cell lines with nuclear red fluorescence for live imaging,

cancer cells were transfected with an mKate2 2X nuclear localization fusion construct. Co-cultures of cancer cells with peripheral blood mononuclear cells (PBMC) or purified CD4+, CD8+ and NK cells were imaged in an IncuCyte® S3 Live Cell Analysis System every 30-60 minutes for 5 to 7 days. A caspase-sensitive green fluorescent dye detected dying cancer cells. To monitor tumor growth by bioluminescent imaging i*n vivo*, MDA-MB-231 breast cancer cells were transduced with a luciferase lentivirus reporter. SCID/beige mice were injected sc with 5×10^6 luciferase-transfected breast cancer cells. Tumors were imaged by bioluminescence and at day 26 mice received 1.2×10^7 PBMCs iv. The next day mice received a single dose of UMCD6 or an IgG control antibody (400µg/mouse ip). Tumor growth was measured by bioluminescence, using a Xenogen IVIS 200 instrument. Tumors were removed at day 36 and examined by fluorescent immunohistology.

Results: Most human cancer cell lines were strongly positive for both CD318 and CD166. CD318+ lines shed soluble CD318 at concentrations that were chemotactic for CD6+ lymphocytes. UMCD6 strikingly augmented killing of breast, lung or prostate cancer cells in co-cultures with human lymphocytes, through direct effects on both CD8+ T cells and NK cells, increasing cancer cell death and lowering cancer cell survival more robustly than checkpoint inhibitors that interrupt PD-1/PD-L1. UMCD6 also augmented *in vivo* killing by PBMC of a human breast cancer line xeno-transplanted into immunodeficient mice. A single injection of 0.4 mg per mouse one day after infusion of PBMC led to near disappearance of tumors in mice that received UMCD6 but not control IgG. Histology showed extensive infiltration and activation of T lymphocytes and NK cells, with the NK cells over-represented in the tumor-infiltrating lymphocytes

Conclusion: The combined capabilities of UMCD6 to control autoimmunity through effects on CD4+ lymphocyte differentiation, while enhancing killing of cancer cells through distinct effects on CD8+ and NK cells, open a potential new approach to cancer immunotherapy that would suppress rather than instigate autoimmunity.

Session Title: Immunological Complications of Therapy Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 threatens the health of people worldwide, although it remains unclear to what extent antirheumatic disease therapies increase susceptibility to complications of viral respiratory infections. We conducted a scoping review of available evidence regarding the frequency and severity of acute respiratory viral adverse events (AEs) related to antirheumatic disease therapies.

Methods: Studies reporting primary data on acute respiratory viral AEs in patients using antirheumatic medications were identified via systematic search of MEDLINE, Scopus, Embase, Proquest Dissertations and Theses, Cochrane Database of Systematic Reviews, and OpenGrey databases and supplemental hand search of PubMed for additional

Lower respiratory tract infection only	67		37.22%	
Both upper and lower respiratory tract infection	56		31.11%	
Other viral infection	3		1.67%	
Hospitalization	11		6.11%	
Mortality	4		2.22%	

Table 1. Summary of general characteristics of included studies

relevant clinical trials. Data from eligible studies were charted by pairs of independent reviewers using a data abstraction tool.

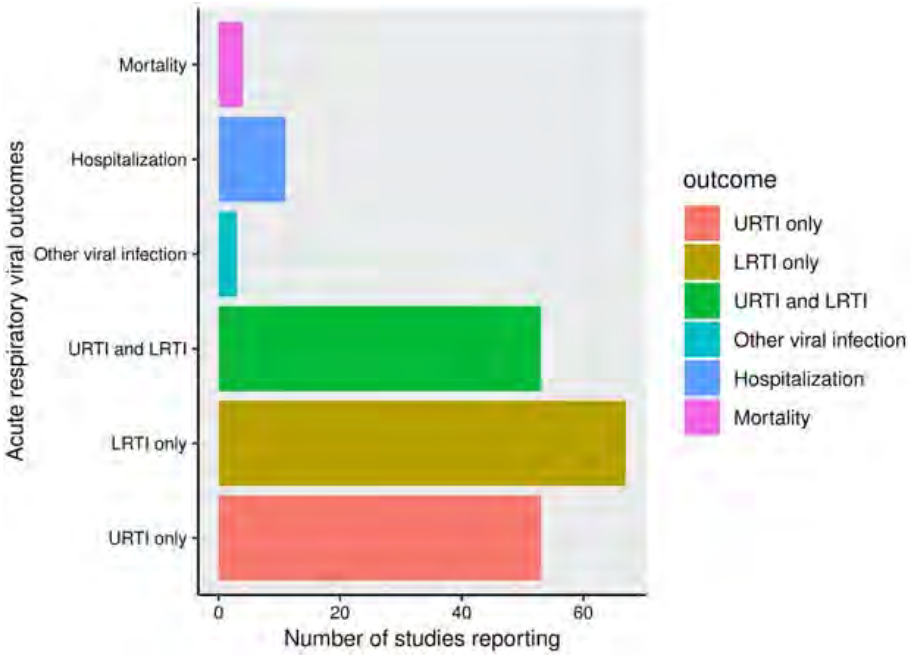

Figure 2. Acute respiratory viral outcomes reported in included studies. Mortality represents mortality secondary to an acute respiratory infection (including viral); Hospitalization represents hospitalization secondary to an acute respiratory infection (including viral); URTI, upper respiratory tract infection, includes sinusitis, nasopharyngitis, pharyngitis; LRTI, lower respiratory tract infection, includes bronchitis, pneumonia.

Results: 9,686 unique references were screened (Figure 1). After title and abstract screening, full-text screening, and the supplemental hand search, 180 studies (Table 1) were identified for data charting. The majority of studies were recently published (since 2011), of observational design, and from North America. 52% of studies focused on use of cytokine-directed bDMARDs; diseases of interest were most commonly RA (40%) and SLE (15%).

Domains of reported acute respiratory viral events and associated outcomes are shown (Figure 2). While the data are limited with regard to specific viral outcomes, they suggest that use of glucocorticoids, JAK inhibitors (especially high-dose), TNF inhibitors, and IL-17 inhibitors may be associated with a higher frequency of respiratory viral AEs compared to placebo. Available data suggest no increased frequency or risk of respiratory viral AEs with NSAIDs, hydroxychloroquine, sulfasalazine, methotrexate, azathioprine, mycophenolate mofetil, cyclophosphamide, or apremilast. One large cohort study demonstrated an association with leflunomide use and increased risk of acute viral respiratory AEs compared to non-use.

Conclusion: This scoping review identified that some classes of antirheumatic medications may be associated with increased risk of acute respiratory viral AEs in patients with rheumatic diseases. However, definitive data are lacking and future studies should address this knowledge gap. More granular reporting of viral respiratory AEs in future study designs would be helpful for rheumatology patients and practitioners to better interpret the risks of individual medications. In the context of the COVID-19 pandemic, increased widespread respiratory viral PCR testing offers immediate research opportunities to clarify the safety of antirheumatic therapies in terms of viral respiratory complications.

Immune Checkpoint Inhibitor-Induced Inflammatory Arthritis Impact on Function and Patient-Reported Quality of Life Measures Varies Depending on Pattern of Arthritis

Jeffrey Sarazin[1], Ann Impens[2], Nada Abdulaziz[1], Stacey Anderson[3], Leslie Fecher[1], Christopher Lao[1] and Elena Schiopu[1], [1]Michigan Medicine, Ann Arbor, MI, [2]Midwestern University, Ann Arbor, IL, [3]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have emerged as a paradigm shift in the treatment of malignancies, but can have significant side effects, termed immune related adverse events (IRAEs), that resemble autoimmune diseases. Inflammatory arthritis (ICI-IA) has significant impact on function, but little is understood about these patterns of arthritis and the specific quality of life impairment.

Methods: We performed a retrospective review of patients at one academic center who experienced ICI-IA and required referral to a rheumatologist in the collaborative Oncology-Rheumatology clinic. All patients were evaluated and completed a Health Assessment Questionnaire Disability Index (HAQ-DI). The pattern of ICI-IA was classified by a single rheumatologist based on the arthritis pattern as: inflammatory symmetrical polyarthritis (RA-like, IA), polymyalgia rheumatica-like (PMR), seronegative spondyloarthritis-like (SpA) and exacerbation of osteoarthritis-like (OA). Demographics (gender, age, and race) and malignancy (type, IRAE, type of ICI) data was collected. HAQ-DI, pain and patient global activity (PGA) visual analogue scores were compared based of the type of inflammatory arthritis using average and mean scores.

Results: Our review included 30 patients with ICI-IA: 12 with IA, 4 with PMR, 3 with SpA and 11 with OA. As expected for this age group, a majority, specifically 23, had pre-existent degenerative joint disease (DJD) and 5 had inflammatory arthritis (1 with rheumatoid arthritis (RA), 2 with psoriatic arthritis (PsA), and 2 with gout). Most patients were male (23, 76.6%), and all were Caucasian. The malignancy data and type of ICI are in Table 2. In terms of the patient reported outcomes, the overall HAQ-DI score was 0.57 ± 0.47, indicating that there was little effect of these arthropathies on overall functionality. The pain visual analogue scale had an average score of 41.8 ± 31.4 mm and the Patient Global Assessment had an overall score of 25.6 ± 26.7 mm.

Conclusion: The overall results suggest that the PMR-like pattern of ICI-IA is the most impactful based on the total HAQ scores. In contrast, the pain scores are higher in the SpA group, followed by the IA group. The overall PGA is highest in the IA group, followed by the SpA group. Interestingly, the HAQ scores were lower than the reported average scores of degenerative (0.8) or inflammatory arthritis (1.2). Our sample sizes for the subgroups are currently too small to allow for further statistical analyses of association or subgroup comparisons. Continued patient recruitment and further follow up will allow for understanding of the ICI-IA phenotypes will help understand and improve functionality and quality of life.

Rituximab Hypersensitivity in Rheumatic and Inflammatory Diseases: Role of Skin Testing

Sravani Penumarty[1], Javier Quintero Betancourt[2], Eugenio Capitle[2] and Reena Khianey[2], [1]Rutgers, Eastvale, CA, [2]Rutgers, Newark, NJ

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Infusion-related reactions have been reported with rituximab, a monoclonal antibody targeting the CD20 antigen on B cells, and may result in discontinuation of the medication and/or changing to a potentially less effective alternative agent. A positive skin testing with a non- irritating dose of a medication is thought to predict an IgE mediated reaction which includes life-threatening anaphylaxis. Furthermore, rituximab skin testing in lymphoma patients may correlate with the severity of IgE hypersensitivity[1].

To our knowledge, there is no data establishing the value of rituximab skin testing in patients with rheumatological conditions who have a presumed IgE mediated hypersensitivity reaction. We present our observational analysis on

#	Diagnosis	Immunosuppresant Medications use at the time of skin testing	Severity of reaction and manifestations	Medications used to treat reaction	Skin testing Results: Positive/Negative
1	Granulomatous polyangitis	Prednisone 3mg daily	Mild: Hives and Skin rash	IV Decadron 10mg and Benadryl 25mg IV	Negative
2	Rheumatoid arthritis	None	Mild: Shortness of breath, tightness in throat and chest, and dizziness	IV Solumedrol and Benadryl 25mg IV	Negative
3	Rheumatoid arthritis	Leflunomide 20mg daily	Mild: Tightness in chest and shortness of breath	IV Decadron 10mg and Benadryl 25mg	Negative
4	Neuromyelitis optica	Methotrexate	Mild: Diffuse Skin rash	IV Solumedrol and Benadryl 25mg IV	Negative
5	Pemphigus Vulgaris	Prednisone 20mg daily	Mild: Shortness of breath	IV Solumedrol and Benadryl 25mg IV	Negative
6	Rheumatoid arthritis	Certolizumab pegol	Mild: Rash on scalp, shortness of breath	IV Solumedrol and Benadryl 25mg IV	Could not complete testing due to poor histamine response (control)
7	Rheumatoid arthritis	Certolizumab pegol	Severe: Shortness of breath and rash	IV Solumedrol and Benadryl 25mg IV and Intramuscular Epinephrine	Negative
8	Systemic Lupus Erythematosus	Prednisone 20mg daily	Severe: Shortness of breath, skin rash, throat tightness and abdominal pain	IV Solumedrol and Benadryl 25mg IV and Intramuscular Epinephrine	Positive

Table 1

skin testing results in rheumatology patients who previously developed presumed IgE hypersensitivity reactions to rituximab, and whether the skin testing results correlated to the severity of the clinical reaction.

Methods: We present the skin testing results from a retrospective review of 8 patients followed from January 2000 through September 2019 with systemic rheumatologic conditions who developed presumed IgE mediated hypersensitivity reactions while receiving rituximab. Patients previously underwent epi-cutaneous prick testing using rituximab at a concentration of 10 mg/mL. If negative testing resulted at 10mg/ml concentration (defined as a wheal diameter measured less than 3mm), testing proceeded to intradermal injections of 1:1000, 1:100, and 1:10 dilutions of the full strength. Testing was discontinued and defined as a positive with a wheal 3mm or greater than the histamine control. We defined a “mild” IgE mediated reaction as that involving one organ system which did not require epinephrine. A “severe” IgE reaction has two or more organ system involvement which required epinephrine administration.

Results: Regardless of background immunosuppressive agents, all patients except one mounted an appropriate histamine response. Patients 1-5 and 7 developed “mild” IgE reactions and had negative skin testing. Patient 8 had severe IgE reactions requiring epinephrine IM and on testing mounted a positive intradermal test. A summary of patient characteristics and skin testing results are provided in Table 1.

Conclusion: Rituximab skin testing has not been studied in patients with underlying rheumatic and inflammatory diseases. Our preliminary analysis demonstrates mild presumed IgE reactions can possibly predict negative skin testing. A negative test may then allow clinicians to have discussions with patients on the possibility of re-challenging the medication if no alternative medications are suitable. Additionally, our analysis demonstrates that patients are able to mount an adequate histamine response despite immunosuppression by their disease and current medications.

Further studies will be needed to evaluate the utility in the evaluation of skin testing in rheumatic and inflammatory conditions.

Abstract Number: 1579

Assessing the Effect of Calcineurin Inhibitors for Immune-related Adverse Event Management on Tumor Response

Pankti Reid[1], Daniel Olson[2] and Thomas Gajewski[2], [1]University of Chicago, Chicago, IL, [2]University of Chicago Medical Center, Department of Medicine, Section of Hematology Oncology, Chicago

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: High grade immune-related adverse events (irAEs) to cancer immune checkpoint inhibitors (ICI) require considerable immunosuppression (IS) with high-dose steroids and steroid-sparing IS (SSIS) for steroid-dependent cases. T lymphocyte-specific IS has generally been avoided or used with significant caution due to the fear that these agents may negatively impact ICI efficacy. We sought to determine whether T cell-specific IS agents, such as calcineurin inhibitors (CNIs), have an adverse effect on tumor control when compared to primarily immunomodulatory drugs (IMDs) such as hydroxychloroquine and sulfasalazine..

Methods: We retrospectively analyzed clinical annotations of adult patients treated with ICIs for malignancy from 1/1/2000-12/31/2019, highlighting patients who were managed with SSIS, specifically those most commonly used for autoimmune disease therapy. Topical IS use was excluded. Patients were categorized as tumor responders or non-responders, and irAEs were graded according to National Cancer Institute's Common Terminology Criteria for Adverse Events (CTCAE). Progression-free survival (PFS) was assessed via Kaplan-Meier curve.

Results: 1331 unique individuals were prescribed > = 1 ICIs, with 526 prescribed systemic steroids (39.5%) and 90 (6.8%) patients prescribed SSIS agents (25 patients with > 1 SSIS): mycophenolate (39), methotrexate (26), leflunomide (5), azathioprine (3), rituximab (24), tocilizumab (3), infliximab (8), etanercept (1), adalimumab (1), golimumab (1) and CNIs (18): cyclosporine, tacrolimus. IMDs hydroxychloroquine (6) and sulfasalazine (5) were also prescribed. The objective response rate was 50.0% in the CNI group compared to 45.5% in the IMD cohort and 45.4% in the irAE group (CTCAE grade matched) with steroids alone without any SSIS. Median PFS was compared between CNI cohort (5.4 months, range 1.3-34 months) to IMD (1.1 months, range 0.4-6.4, p = 0.02) and steroid alone (2.4 months, range 0.69-17.7, p = 0.48). Multiple regression analysis identified irAE presence as an independent correlate to tumor response (p = 0.02).

Conclusion: T cell-specific IS should not be excluded from irAE treatment algorithm as we observed that PFS was comparable to immunomodulators and similar efficacy was observed compared to steroids alone. Rapid identification and management of irAEs can help mitigate morbidity but there are virtually no reliable clinical trials to guide irAE management with SSIS. These findings support the need for larger, prospective evaluation of immunosuppression use for high grade irAE therapy.

Generalized Immune Activation in Structures Related to PMR or GCA on PET/CT Assessment Does Not Occur in Immune Checkpoint Inhibitor-Treated Patients Who Do Not Go on to Develop Rheumatic Immune-Related Adverse Events

David Liew[1], Aurora Poon[2], Christopher McMaster[3], Claire Owen[4], Jessica Leung[5], Albert Frauman[2], Jonathan Cebon[6], Andrew Scott[6] and Russell Buchanan[7], [1]Austin Health, Melbourne, Victoria, Australia, Heidelberg, Victoria, Australia, [2]Austin Health, Melbourne, Victoria, Australia, Melbourne, Victoria, Australia, [3]Austin Health, Melbourne, Victoria, Australia, Pascoe Vale South, Victoria, Australia, [4]Austin Health, Melbourne, Victoria, Australia, Ashburton, Victoria, Australia, [5]Austin Health, Melbourne, Victoria, Australia, Melbourne, [6]Austin Health, Melbourne, Victoria, Australia, Melbourne, Australia, [7]Austin Health, Melbourne, Victoria, Australia, Heidelberg, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The pathogenesis of rheumatic immune-related adverse events (irAEs) from checkpoint inhibitor cancer immunotherapy directed against programmed cell death protein 1 (PD-1) and programmed death ligand 1 (PD-L1) remains unknown, even though they are a consequence of pharmacologic inhibition of a specific immune mechanism. Given that some irAEs resemble polymyalgia rheumatica (PMR) or giant cell arteritis (GCA), a disease whose pathogenesis is poorly understood, observations regarding the pathogenesis of PMR-like or GCA-like irAEs are of significant interest. One proposed pathogenic mechanism involves generalized immune activation leading to a spectrum of subclinical disease. Interrogation of this hypothesis may be aided by PET/CT, which is frequently utilized for oncological staging purposes but is also useful in classical PMR or GCA diagnosis. If PMR or GCA irAEs merely represent a spectrum of generalized immune activation, low-grade subclinical PMR or GCA-related changes on PET/CT might be expected to be seen in patients who receive immunotherapy, irrespective of whether they develop clinically evident rheumatic irAEs. This study investigated whether such changes occurred in patients receiving immunotherapy who did not develop clinically evident rheumatic irAEs.

Methods: Consecutive patients exposed to PD-1 or PD-L1 inhibitor immunotherapy at a single center had scintigraphic uptake calculated by a nuclear medicine physician experienced in assessment of vasculitis. Patients were included if they had had ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET/CT imaging both within the two weeks prior to immunotherapy initiation and after at least eleven weeks of immunotherapy. Patients who went on to develop a rheumatic irAE were excluded, as were patients with scintigraphic evidence of liver metastases owing to their potential influence on scoring of uptake. Quantification of ^{18}F-FDG uptake by maximum standardized uptake values (maximum standard unit value, SUV_{max}) was performed at sites relevant to PMR or GCA (17 sites relevant to PMR, 17 sites relevant to GCA) in paired scans, and the difference calculated.

Results: Twenty-four patients receiving nivolumab, pembrolizumab or avelumab met the inclusion criteria, primarily for melanoma, non-small cell lung cancer, or lymphoma. The mean age at the time of the first scan was 67, 71% were male, and 66% had a complete or partial oncological response at best response. No statistically or clinically significant difference in SUV_{max} was noted at any PMR or GCA-relevant anatomical site interrogated. Latent class analysis did not reveal clusters identifiable by cancer type, best response, or presence of combination therapy.

Conclusion: Patients treated with PD-1/PD-L1 inhibitors without clinically evident rheumatic irAEs do not develop subclinical PMR or GCA-like changes on PET/CT. This supports the proposition that PMR-like and GCA-like irAEs are a distinct entity with stochastic onset, and do not simply represent generalized immune activation induced by immunotherapy.

Neutrophil to Lymphocyte Ratio as a Predictor of Immune-Related Adverse Events in CTLA-4 Treated Patients: A Retrospective Review

Michael Cunningham[1], Carolina Alvarez[2], Shruti Saxena Beem[3], Todd Schwartz[4] and Rumey Ishizawar[5], [1]UNC Hospitals, Durham, NC, [2]University of North Carolina at Chapel Hill Thurston Arthritis Research Center, Miami, FL, [3]University of North Carolina at Chapel Hill, Chapel Hill, [4]University of North Carolina-Chapel Hill, Chapel Hill, NC, [5]University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Immunological Complications of Therapy Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) target checkpoint proteins PD-1/PD-L1 and CTLA-4 to activate and enhance the cytotoxic effects of T lymphocytes against tumor cells [1-2]. This systemic effect disrupts immune homeostasis and can result in immune-related adverse events (irAEs) affecting a wide variety of organs, including rheumatic presentations. Interestingly, irAEs are also reflective of anti-tumor efficacy [3].

There are currently no biomarkers that predict impending irAEs. Several studies demonstrated an association between low neutrophil-to-lymphocyte ratio (NLR) and the risk of irAEs in patients treated with PD-1/PD-L1 blockade (Table 1). To date, the literature is limited on whether NLR may serve as a marker for irAEs in patients undergoing CTLA-4 blockade. As CTLA4 blockade affects a separate and distinct checkpoint pathway, we sought to understand the utility of NLR in this treatment group.

NLR cut off	OR	p value	Cancer Type	Immunotherapy	Reference
<3	2.2 (1.1-4.1)	0.018	NSCLC	Nivo > Pembro	[4]
>3	0.37 (0.17-0.81)	0.012	Lung CA, Melanoma, Lymphoma mainly	Pembro	[5]
<5	0.97 (0.39-2.39)	0.939	NSCLC	Nivo	[6]
<5	0.051(0.02–0.14)	<0.001	NSCLC	PD-1 (nivo, pembro, Toripalimab, Sintilimab)	[7]

Table 1. Previously published data on NLR and odds ratio for irAE. NLR cut off values to determine "low" vs. "high" were variable across the papers, as was cancer subtype.

Methods: Under IRB approval, we conducted a retrospective electronic medical record review of oncology patients treated with ipilimumab (anti-CTLA4) at UNC Chapel Hill from 1/2004 to 7/2017. NLR was calculated from CBCs prior to initiation of ICI and compared against irAE type and incidence using logistic regression models to obtain odds ratios adjusted for age, sex, and ICI therapy type.

		RHEUM/MSK		
NLR<4	NLR<4 vs NLR≥4		1.33 (0.35, 5.07)	
NLR<5	NLR<5 vs NLR≥5		4.34 (0.52, 36.4)	

Table 3: Odds ratio for irAE based on NLR cut off (4 and 5) first with relation to the entire patient population and then stratified by organ system. Effect modification for the association between NLR and irAE incidence was assessed and reported if two-way interactions between NLR and age, sex, or ICI therapy were p<0.10. A statistically significant association between a low pre-ICI treatment NLR value and risk of irAE was found. This statistically significant effect is lost when stratifying by organ system. A strong estimate of association was observed between NLR<5 and rheum irAE, this estimate is notably imprecise.

Results: 112 patients received ipilimumab (35.7% monotherapy with 64.3% in combination with other ICIs) and irAEs occurred in 72.3% of patients (Table 2). Lower NLR was shown to be associated with an increased risk of irAEs of any severity in patients treated with ipilimumab (Table 3). When stratifying irAEs by organ system, there was no statistically significant effect found. Despite this, the data suggest an association of NLR< 5 with rheumatologic irAEs. In addition, we noted an association of low NLR with dermatologic irAEs among women. While an exploratory endpoint, this difference between women and men is an intriguing finding not previously reported.

Conclusion: Our data investigating low NLR as a predictor for irAEs in CTLA-4 treated patients shows a similar association to that reported with PD-1 blockade. Furthermore, the effect size in our population is similar to previously published data with PD-1 blockade [4-7], suggesting this effect is not unique to cancer type or ICI type. The statistical significance was lost when stratified by organ system, suggesting a lack of power. Also of note is the difference in effect size based on NLR cut off value. To date, there is no standard value. While the data suggests NLR may be a predictor for irAE, it also encourages further investigation into organ specific irAEs, sex differences, and setting a standard for NLR cut off.

Average Follow-up Time After Telemedicine Visit Is Longer Than Conventional Face-to-Face Visit in Outpatient Rheumatology Practice During COVID-19 Pandemic

Deepan Dalal[1], Tzu-Chun Chu[2], Brad Crough[3], Janine Molino[2], David Hemendinger[4] and Bharat Ramratnam[2], [1]Brown University, East Providence, RI, [2]Brown University, Providence, RI, [3]Brown Physicians Incorporation, East Providence, RI, [4]Brown Physicians Incorporation, Providence, RI

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In the era of recent COVID-19 crisis, outpatient rheumatology practices resorted to telemedicine to deliver longitudinal care, a fundamental component of chronic disease management. However, little is known regarding time to follow up after telemedicine visits as compared to conventional face-to-face encounters as a marker of longitudinal care.

Methods: We used electronic medical records (EMR) data from 1/1/2020 to 5/20/2020 to capture all encounters in the outpatient rheumatology practice. On March 12, when Rhode Island approved telemedicine visits as payable by insurers, telemedicine visits were captured in EMR like face-to-face visits. For both telemedicine and face-to-face visits, we captured data for patient demographics, date of visit, key diagnoses addressed at the visit identified by ICD-10 billing codes, complexity of visit based on CPT codes and scheduled follow-up in rheumatology clinic. The CPT codes for complexity of visit were 99201 to 99215 for initial and subsequent visits by either modality of care. CPT codes unique to telemedicine were transformed into their equivalent CPT codes from 99201 to 99215 based on their time factor.

Time to follow-up was calculated as the difference between scheduled follow-up and date of the current visit and expressed in days. We assessed the variation in time to follow-up by reporting mean with standard deviation across key rheumatic diagnoses and complexity of visits. Due to non-normality of the distribution of follow-up time, the Mann-Whitney U test was used to compare differences of follow-up time between face-to-face and telemedicine encounters across rheumatic diagnoses and complexity of visits.

Results: A total of 2,356 visits were completed by the rheumatology division between 1/1/2020 and 5/20/2020, of which 621 (26.4%) were via telemedicine. There was higher uptake of telemedicine amongst women and older patients. Telemedicine encounters were billed lower CPT codes as compared to face-to-face encounters (Table 1). The follow-rate between the 2 groups was similar (30.8% v. 32.4%). The time to follow-up was longer with telemedicine visits as compared to face-to-face visit (86.6 ± 52.1 v. 73.2 ± 45.6 days, $p < 0.01$). This was also noted for encounters with higher complexity billing codes (Table 2).

Conclusion: In the face of COVID-19 pandemic, the follow-rate after telemedicine was similar to that of face-to-face encounter with longer follow-up time with telemedicine across all complexities of visits. While the fear of COVID-19 pandemic may be reason for this observation, it also suggests that telemedicine could be a useful adjunct to face-to-face visits for longitudinal care of patients with rheumatic illnesses.

Impact of Telehealth Implementation on Practice Patterns and Electronic Health Record Utilization During COVID19

Mithu Maheswaranathan[1], Philip Chu[1], Andrew Johannemann[1], Megan Clowse[2], Lisa Criscione-Schreiber[3] and David Leverenz[1], [1]Duke University, Durham, NC, [2]Duke University, Chapel Hill, NC, [3]Duke University School of Medicine, Durham, NC

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID19 pandemic necessitated practice changes throughout health systems worldwide. Our academic rheumatology practice rapidly adopted telehealth (telephone or video visits), with unknown consequences regarding providers' time spent in the electronic health record (EHR) and ability to maintain patient care. We therefore analyzed changes in EHR utilization with telehealth implementation within our practice during COVID19.

Figure 1: Number of Rheumatology Visits as In-Person vs Telemedicine over Time, Pre/Post Telehealth Implementation

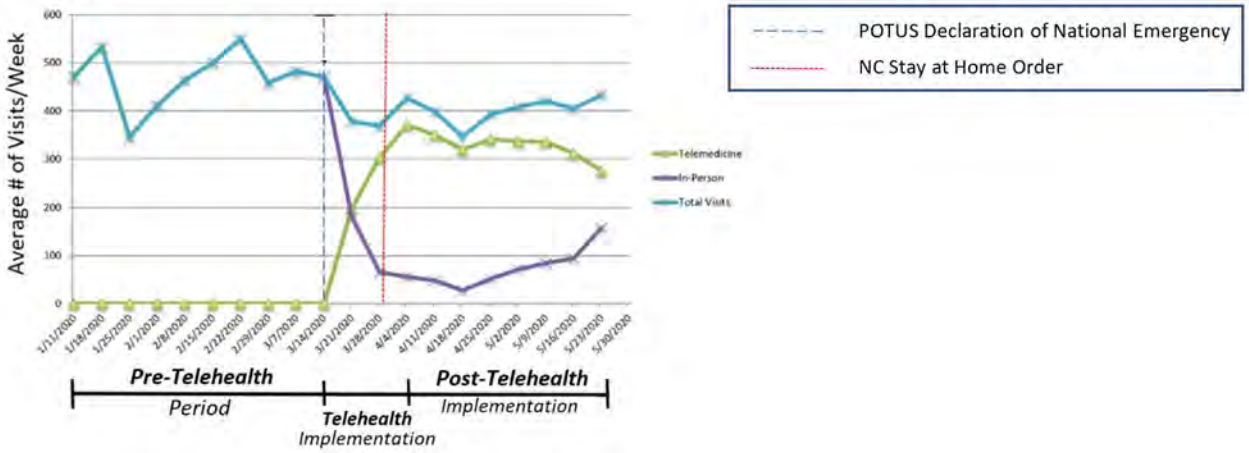

Figure 2: Average Time in the Electronic Health Record (EHR) per Appointment, Pre/Post Telehealth Implementation

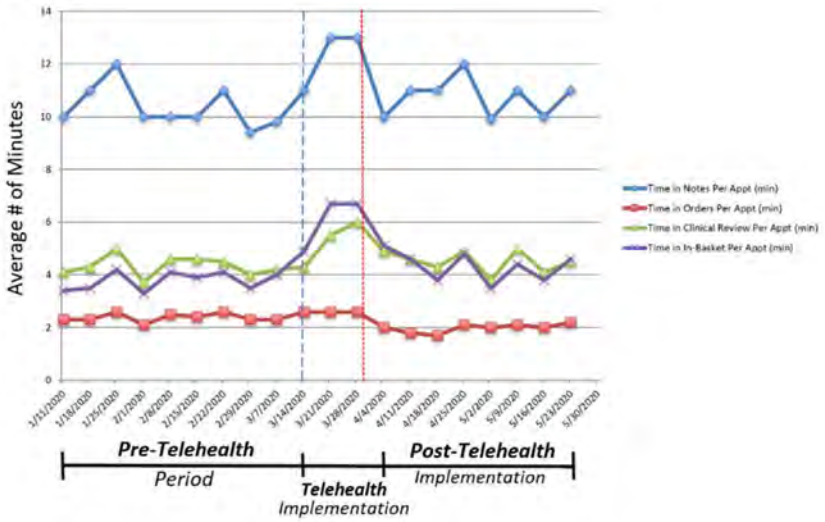
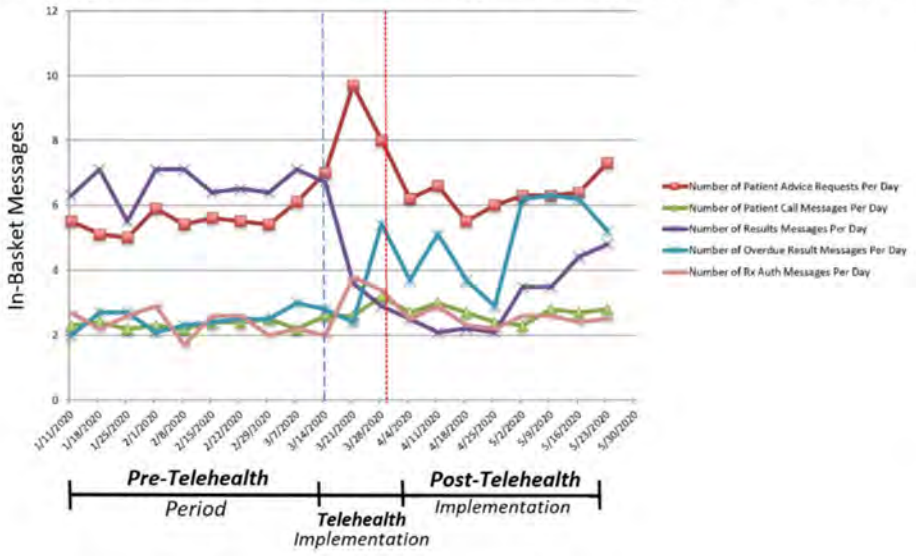


Methods: Data were obtained using Slicer Dicer and Signal, analytic data tools in our EHR to evaluate practice patterns. We evaluated changes in the proportion of in-person versus telehealth visits, physician time spent per scheduled appointment in EHR activities (notes, orders, clinical review, and in-basket), and number of in-basket messages per day. Data were analyzed using descriptive statistics.

Results: In response to the COVID-19 pandemic and national emergency declared on March 13, 2020, our practice (28 providers) began transitioning to telehealth on March 15. During the Pre-Telehealth Period (Jan 5 - Mar 14), there was an average of 468 in-person visits/week and 0 telehealth visits. During the Telehealth Implementation Period (Mar 15 - Apr 4), the proportion of total visits completed via Telehealth expanded rapidly: 52% in Week 1, 82% in Week 2, and 87% in Week 3 (**Figure 1**). Post-Telehealth Implementation (Apr 4 - May 23), telehealth visits peaked at 92% (Apr 18) followed by a gradual decline to 63% (May 23). The average number of total visits per week in the Post-Telehealth Implementation Period was 400, a 15% decline compared with the Pre-Telehealth Period.

Figure 3: Average Number of In-Basket Messages Per Day, Pre/Post Telehealth Implementation



During the Telehealth Implementation Period, we observed increased average EHR time per appointment in notes, in-basket and clinical review while time in orders remained stable (**Figure 2**). The average number of in-basket messages/day for patient advice requests, prescription authorization requests, and overdue lab result messages all increased (**Figure 3**). During the Post-Telehealth Implementation Period, patient advice and prescription authorization requests approached Pre-Telehealth levels, with a delayed increase in overdue lab result messages/day (**Figure 3**).

Conclusion: During the COVID-19 pandemic, our practice's clinical volume only declined by 15% by rapidly shifting from all in-person visits to 87% of visits (>300/week) by Telehealth over 3 weeks. This transition required more time spent in multiple EHR activities and more in-basket requests (especially patient advice and prescription requests) during telehealth implementation. We hypothesize that this reflects increased time spent coordinating care, answering patient questions about COVID19, and refilling hydroxychloroquine and other DMARDs in advance of potential shortages. Subsequently, our overall EHR utilization returned near baseline, suggesting sustainability of this practice pattern. During telehealth implementation, we observed a decrease in result messages per day, highlighting the difficulty of obtaining medication toxicity monitoring and other laboratory testing during telehealth. We plan to continue monitoring this data with future shifts in practice.

Telemedicine Visits During COVID-19 Improved Clinic Show Rates

Reem Alkilany[1] and Raymond Hong[2], [1]MetroHealth medical center, lakewood, OH, [2]Metrohealth Medical center, Richfield, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic has tremendously affected the healthcare sector. State of Ohio officials recommended to hold in-person outpatient visits and elective procedures to limit virus spread. Many patients with chronic illnesses had reduced access to healthcare, this prompted the necessity to take active steps to continue delivering healthcare while ensuring safety for both patients and healthcare providers.

The MetroHealth System is an academic, public health care institution that services the population of Cuyahoga County in Cleveland, OH. Within 1 week of the State of Ohio issuing a statewide order limiting gatherings in March 2020, the Rheumatology outpatient clinics implemented telemedicine by video or telephone limiting in person visit sonly when deemed medically necessary. Anecdotally, Rheumatology providers reported improved clinic show rates with telemedicine visits, prompting this quality improvement project.

Our aim is to investigate and compare completed visit, no show, and cancellation rates between in-person and telemedicine appointments to see if telemedicine has a beneficial impact on access to Rheumatology ambulatory clinics

Methods: Using Reporting Workbench in our Epic electronic health record, we collected data retrospectively pertaining to rheumatology outpatient appointments at the MetroHealth System between Jan 3-May 31, 2020 - a 20-week period. Appointments were allocated into 3 categories: canceled; no-show; and completed. Data was segmented into in-person versus telemedicine, weekly stratified. figures 1-3.

	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6	Week 7	Week 8	Week 9	Week 10
Cancelation % (In-Office visits, Period 1)	41.82%	31.54%	35.96%	28.02%	32.77%	30.98%	29.38%	23.75%	27.04%	32.42%
Cancelation % (In-Office visits, Period 2)	70.88%	84.85%	68.00%	73.91%	72.73%	61.82%	39.64%	45.22%	33.33%	31.37%
Cancelation % (Telemedicine, Period 2)	0.00%	0.86%	0.00%	0.00%	0.00%	0.00%	0.00%	0.00%	0.00%	0.00%

This graph illustrates overall cancelation rates: # canceled/ appointment activity (cancels + no shows + completed) - Period 1 is between Jan 3rd to Mar 15th, before the initial State of Ohio executive order responding to the COVID-19 pandemic - Period 2 is between Mar 16th - May 31st, immediately following the initial State of Ohio executive order responding to the COVID-19 pandemic

	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6	Week 7	Week 8	Week 9	Week 10
Complete % per Clinic Activity (In-Office visits, Period 1)	73.96%	79.78%	80.70%	83.21%	80.67%	81.89%	82.30%	82.79%	86.21%	75.61%
Complete % per Clinic Activity (In-Office visits, Period 2)	50.79%	60.00%	68.75%	66.67%	66.67%	66.67%	82.09%	71.43%	75.71%	72.86%
Complete % per Clinic Activity (Telemedicine, Period 2)	91.67%	91.30%	85.98%	94.79%	99.01%	91.57%	90.00%	83.33%	94.12%	87.88%

This graph illustrates completed visit rate per on-schedule appointments: # completed visits/ on-schedule appointments (completed visits+ no show). - Period one is between Jan 3rd to Mar 15th, before the initial State of Ohio executive order responding to the COVID-19 pandemic - Period two is between Mar 16th - May 31st, immediately following the initial State of Ohio executive order responding to the COVID-19 pandemic

For analysis, the data was divided into two 10-week periods: period 1, the pre-COVID19 interval (Jan 3-Mar 15, 2020) and period 2, during COVID19 pandemic (Mar16-May 31, 2020). During period 1, the only modality was in-person visits, while during period 2 telemedicine started taking place in addition to in-person visits. Appointment Activity denoted the sum of cancellations, no shows, and completed visits. On-Schedule appointment totals summed no show and completed visits. Rates of cancelations, no shows, and completed visits were compared to Appointment Activity totals as well as On-Schedule totals.

Results: Telemedicine appointment cancellations were nearly zero (1 out of 825 telemedicine appointments offered) in the 10-week During COVID-19 period as compared to the pre-COVID-19 period where 527 appointments were cancelled, all in-person appointments. No shows also trended down in period 2 when there were 191 no shows (121 in-person and 70 telemedicine) versus 220 no shows in period 1 where only in-person visits were offered. This led to a slight increase in completed visits During COVID-19 when 1038 had a completed appointment (754 telemedicine and 284 in-person); whereas, pre-COVID-19 resulted in 930 completed in-person.

Conclusion: Barriers to accessing in-person healthcare because of transportation or other issues has been a challenge that might be conquered by telemedicine. The offering of telemedicine had seemingly favorable impacts on access to Rheumatology ambulatory clinics at our academic, public health system. We encourage examining the incorporation of telemedicine in our routine clinic visits to improve patient's appointment adherence.

	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6	Week 7	Week 8	Week 9	Week 10
No Show% per Clinic Activity (In-Office visits, Period 1)	26.04%	20.22%	19.30%	16.79%	19.33%	18.11%	17.70%	17.21%	13.79%	24.39%
No Show% per Clinic Activity (In-Office visits, Period 2)	49.21%	40.00%	31.25%	33.33%	33.33%	33.33%	17.91%	28.57%	24.29%	27.14%
No Show% per Clinic Activity (Telemedicine, Period 2)	8.33%	8.70%	14.02%	5.21%	0.99%	8.43%	10.00%	16.67%	5.88%	12.12%

This graph illustrates no-show rate per on-schedule appointments: # no show/on-schedule appointments (completed+ no show) - Period 1 is between Jan 3rd to Mar 15th, before the initial State of Ohio executive order responding to the COVID-19 pandemic - Period two is between Mar 16th - May 31st, immediately following the initial State of Ohio executive order responding to the COVID-19 pandemic

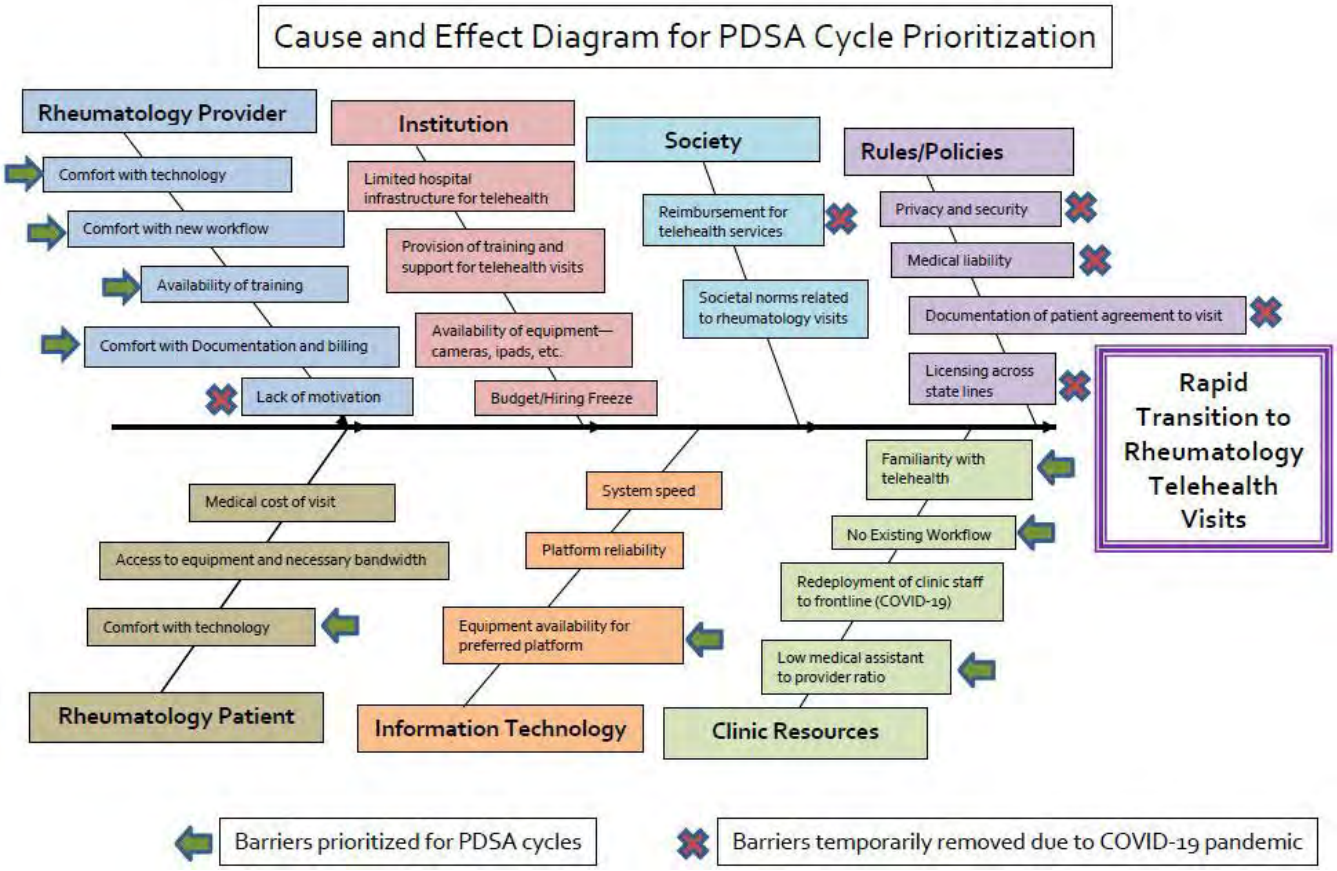
Abstract Number: 1585

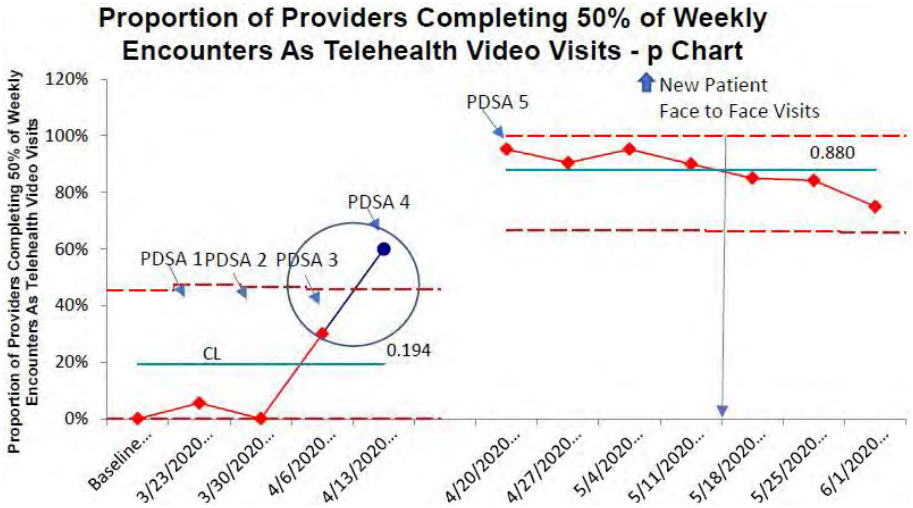
Lessons Learned Through Rapid Quality Improvement for Telehealth Implementation in an Academic Rheumatology Practice During the COVID-19 Pandemic

Julie Thomas[1], Dorota Lebiedz-Odrobina[1], Kyle Register[1], Francesca Ferrara[1], Danielle Barlow[1], Alicia Riddle[1] and Karla Miller[2], [1]University of Utah, Salt Lake City, UT, [2]Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

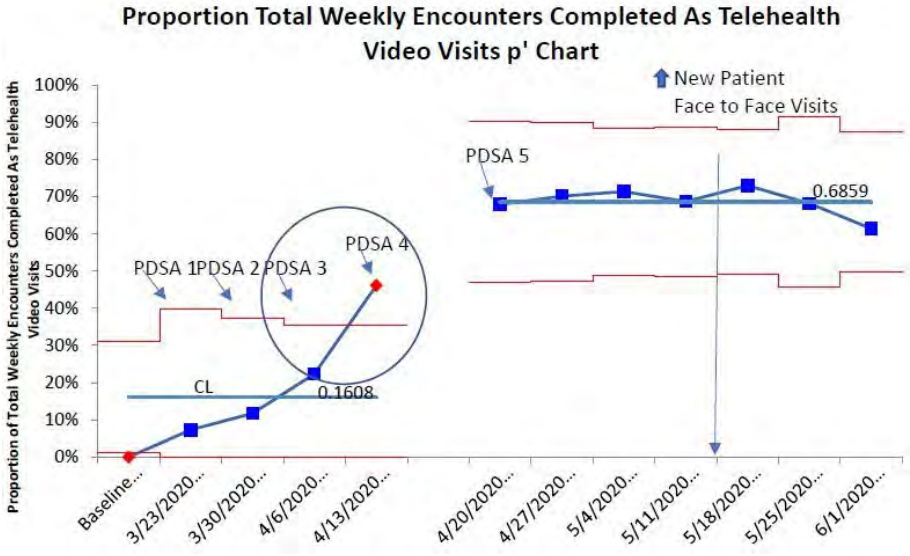
Background/Purpose: The COVID-19 pandemic created an urgent need for access to care while preserving patient safety through social distancing. Prior to the pandemic, patients were seen solely face to face for all visits in our aca-





demic practice, consisting of 17 rheumatologists and 5 advanced practice providers. We utilized quality improvement (QI) methods in rapid cycles to accelerate telehealth implementation and report our outcomes and lessons learned in this process to guide future telehealth efforts.

Methods: An inter-professional rheumatology telehealth team was established. We utilized the Define-Measure-Analyze-Improve-Control framework, Lean Six Sigma tools, and project charter to design this project. The primary impact measures were to increase the percentage of rheumatology providers utilizing [3]50% video for patient visits from 0 to 90% and to increase the percentage of video visits from 0 to 70% between 3/23/20 and 4/20/20. We aimed to



maintain the measures while social distancing policies remained in effect (6/1/2020). Balancing measures included provider patient satisfaction scores and visit volume. Baseline data were obtained between 1/7/20 and 3/13/20. We used a cause and effect diagram and voice of the customer (point-of care observations and provider survey) to prioritize Plan-Do-Study-Act (PDSA) cycles and statistical process control p-charts for primary impact measure analysis using QI macros for Microsoft Excel.

Results: Cause and effect analysis indicated provider, staff, and patient education and restructuring of clinic resources as high priority areas for PDSA cycles, while policy barriers were temporarily removed (Figure 1). Weekly PDSA cycles included telehealth education, live demonstration, pre-visit workflow development, simplification, and standardization, respectively. In the baseline period, no telehealth visits occurred, weekly visit average was 473, and patient satisfaction score was 95 of 99. We achieved 95% of providers conducting ≥ 50% of visits as video and 70% of total weekly visits conducted by video by week 5, with the greatest increase attributed to PDSA cycles 3 and 4 (Figures 2 and 3). Measures were maintained for three additional weeks before a slight decline after new patient face-to-face visits were added 5/15/20. Provider patient satisfaction scores remained stable and total rheumatology visit volume decreased by 60% in the first week followed by a steady increase to baseline with video visits as the primary visit type. Provider survey identified three major barriers to telehealth implementation: patient access/ability to use telehealth, interstate licensing, and clinic staff support.

Conclusion: The temporary removal of policy barriers and use of QI methods facilitated rapid and robust telehealth implementation in our academic practice in the face of a pandemic. This process identified the development, simplification, and standardization of pre-visit telehealth workflow as crucial factors for rapid and sustained success and allowed recovery of visit volume, while maintaining patient satisfaction and safety. Future efforts will focus on hybrid clinic workflows that can be rapidly scaled while addressing patient and provider barriers to telehealth.

Abstract Number: 1586

Rheum Service: Comprehensive Virtual Care During COVID-19

Stephanie Gottheil[1] and Joseph Carson[1], [1]London Rheumatology, London, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: During COVID-19, patients require timely access to rheumatologists while adhering to physical distancing guidelines. In this quality improvement project, we developed a comprehensive virtual pathway for rheumatology consults in a new community practice. We aimed to deliver a virtual experience, called "Rheum Service", which rivaled or exceeded traditional in-person care.

Methods: We used quality improvement methods to implement a virtual process with three phases: pre-visit, visit, and post-visit. In the pre-visit phase, we emailed appointment details and digital questionnaires to patients, and offered training for video-calls. In the visit phase, we enlisted multiple secure video platforms in case of technical difficulties. In the post-visit phase, we offered patients a digital consultation report and access to secure physician messaging.

Our outcome measures were the percentage of 1) consults using video-calling; 2) patients interested in future video appointments; and 3) video-visit diagnoses that changed after in-person visits. We collected data for all new consults between April 8 - June 11, 2020, and we emailed anonymized patient experience surveys one week after all video consults.

Results: Pre-visit, we scheduled 135 new patients in the 10 week study period; 119 (88%) by video, 15 (11%) by phone, and 1 (1%) by office visit. Twenty-one patients (16%) did not have a video-enabled device, 6 of whom borrowed a device. Prior to their appointment dates, 88% (119/135) of all patients completed questionnaires, and 10% (12/119) of the video cohort participated in video training.

We completed 98% (116/119) of scheduled video consults. During these visits, 6% (7/116) suffered technical difficulties, requiring a switch to phone or another video platform.

Post-visit, all patients with email (125/135, 93%) received a secure message containing a summary report. Of these patients, 38% (48/125) sent their rheumatologist at least one question through the secure messaging system. Our post-visit survey was completed by 38% (48/125) of patients, most of whom were satisfied with their virtual experience (Figure 1). When asked if they would like to have another appointment by video, 68% (32/48) said 'yes', 28% (13/48) were 'not sure', and 4% (2/48) declined. Within the study period, 38 patients had an in-person follow-up visit; 84% (32/38) maintained the same diagnosis from their video consult, while 16% (6/38) had a revised diagnosis.

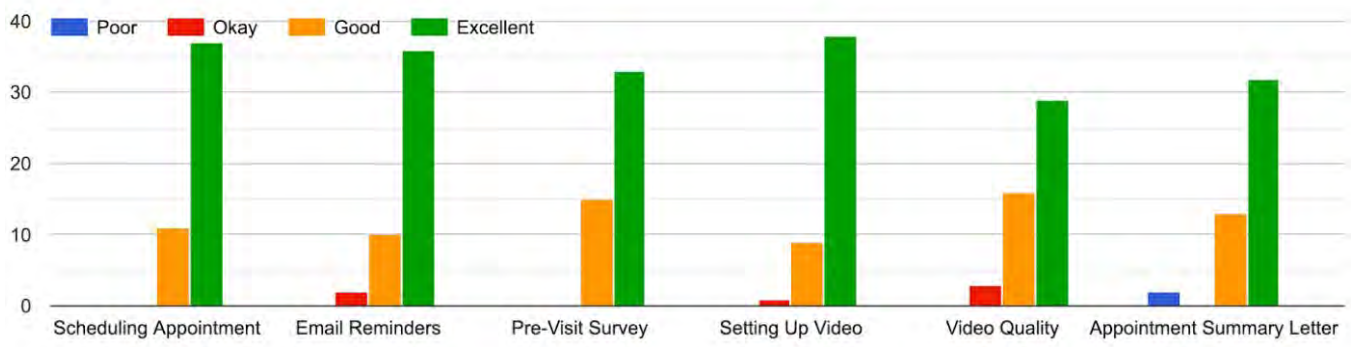

Figure 1. Patient Experience Survey Results (n = 48).

Conclusion: We delivered high quality virtual care to new rheumatology patients during the COVID-19 pandemic. Our interventions reduced barriers to video consults and increased communication through digital channels. We believe that more patients could benefit from virtual care by improving access to video-enabled devices and providing pre-visit training.

Improving Cardiovascular Risk Assessment in Patients with Rheumatoid Arthritis and Systemic Lupus Erythematosus in an Internal Medicine Resident Clinic: A Quality Improvement Initiative

Anna Falls[1], Peta-Gay Ricketts[1], Kelli Fox[1], Teresa George[1] and Chelsey Petz[1], [1]OhioHealth Riverside Methodist Hospital, Columbus, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease is one of the leading causes of death in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients. Its risk in RA and SLE is comparable to that of diabetes. Observational studies show that RA patients frequently have unidentified and untreated risk factors due to gaps in screening. There are currently no guidelines in the United States on cardiovascular risk reduction for patients with autoimmune diseases. EULAR guidelines have suggested multiplying 10-year ACC/AHA atherosclerotic cardiovascular disease (ASCVD) risk scores by 1.5. A 2015 study by Ozen et al. found that screening for 10-year ASCVD risk scores of >5% led to increased detection of subclinical atherosclerosis. Our aim is to increase the rate of annual lipid screening in RA and SLE patients at our resident clinic. We also aim to increase the use of statin therapy in patients with 10-year ASCVD risk scores ≥5%.

Methods: Baseline data was established by reviewing electronic medical records (EMRs) of patients with SLE and RA in the internal medicine resident clinic. Two plan-do-study-act (PDSA) cycles were performed over a four-month period. First, we developed a custom EMR note template for the resident rheumatology clinic that prompted residents to review lipid screening, calculate 10-year ASCVD risk score, determine if patients were on appropriate statin therapy, and notify the patient's primary care provider as needed. We also provided resident education on ASCVD risk assessment and utilization of note template. Second, we adjusted the note template to prompt residents to notify clinic staff to schedule an office visit for cardiovascular risk assessment if indicated and provided additional resident education.

Results: We reviewed 79 patients in the pre-intervention period (73.4% RA, 20.3% SLE, 6.3% SLE and RA). Ninety-two percent of patients were ≥ 40 years old, 82% were female, and 41% had comorbid conditions of diabetes mellitus, coronary artery disease, or cerebrovascular accident. After PDSA cycle 2, 88 patients with similar baseline characteristics were reviewed. Rates of documented lipid screening (92.4% vs 93.2%, p = 0.846) and annual lipid screening (62.0% vs 60.2%, p = 0.812) did not show improvement. The proportion of patients with 10-year ASCVD risk scores ≥ 5% on statin therapy in the current population (33.3% vs 57.9%, p = 0.038) showed improvement; a subgroup analysis of the original 79 patients (33.3% vs 58.3%, p = 0.038) also showed improvement.

Conclusion: In our clinic, there was a statistically significant increase in the proportion of patients on statin therapy with 10-year ASCVD risk scores ≥5% in the current and baseline populations. The rate of yearly lipid screening remained unchanged despite the use of a custom EMR template. Future PDSA cycles will focus on improving the rate of annual lipid screening.

Abstract Number: 1588

A Quality Improvement Project to Improve Bone Densitometry Ordering in Adult Patients on Chronic Glucocorticoids

Katherine Kaufman[1], Philip Chu[1], Mithu Maheswaranathan[1], Andrew Johannemann[1], D Ryan Anderson[1], Isaac Smith[1], Akrithi Udupa[1], Mary Buckley[1], Laura Cannon[1], Rachel Randell[1] and David Leverenz[1], [1]Duke University, DURHAM, NC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2017 ACR guideline for glucocorticoid-induced osteoporosis (GIOP) recommends DXA testing in patients aged ≥40 years on chronic glucocorticoids. We performed a quality improvement project to measure and improve provider adherence to this guideline in an academic adult rheumatology practice.

Methods: This project was led by adult and pediatric rheumatology fellows at our institution as part of our annual quality improvement curriculum. Our primary aim was to increase the percentage of patients aged ≥40 on prednisone with a DXA scan in the last 2 years from 15% to 30%. A secondary measure was the percentage of visits containing prednisone orders in which a DXA scan was ordered. Additional analyses were performed by patient age, sex, and ordering provider. Data were obtained with Slicer Dicer, an analytic data tool within our electronic health record (EHR), and validated by manual review of charts over a two-week period in 10/2019. Data were analyzed using descriptive statistics. We conducted these cycles using Plan-Do-Study-Act (PDSA) methodology: (1) combined pediatric and

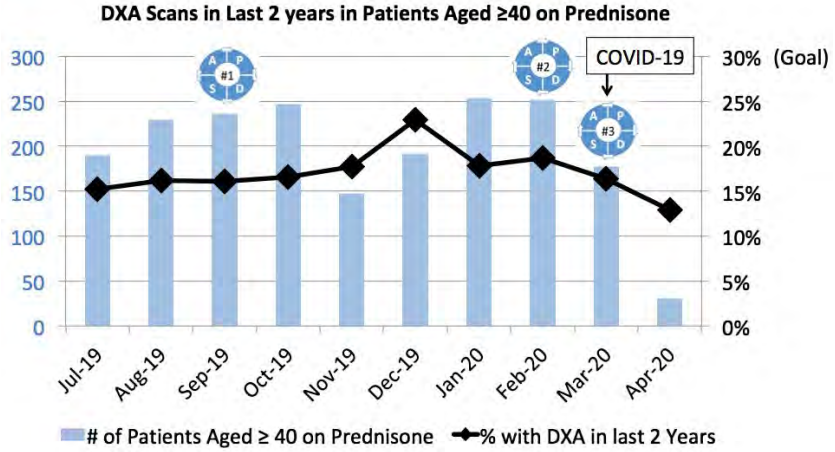

Figure 1. Percentage of patients with a DXA scan in the last 2 years (line) among patients aged ≥40 on prednisone seen in rheumatology clinic each month (bars).

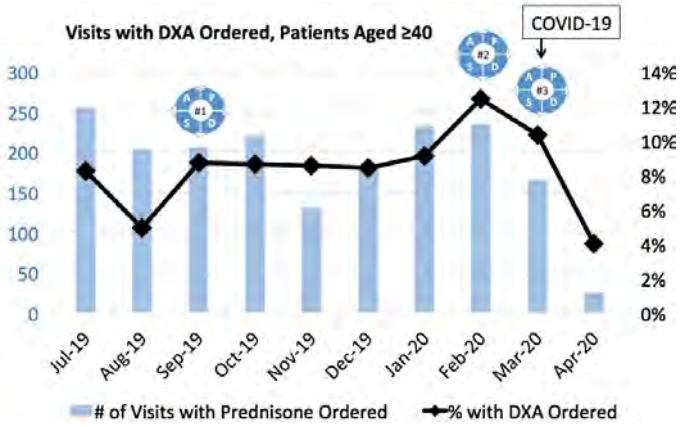

Figure 2. Percentage of visits with DXA scan ordered (line) among rheumatology visits with a prednisone order and patient aged ≥40 each month (bars).

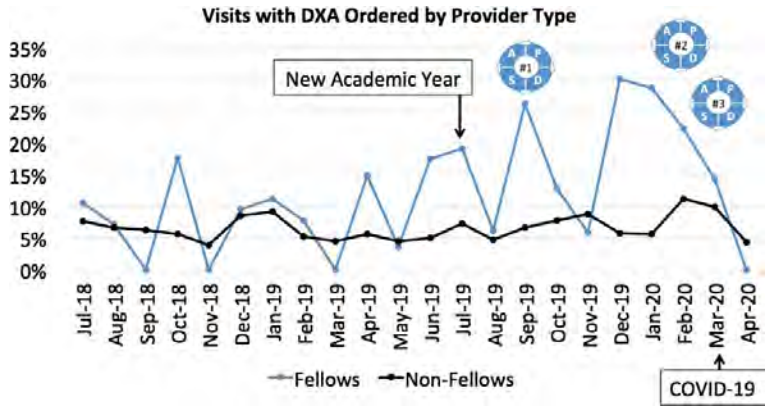

Figure 3. Percentage of visits with DXA scan ordered by provider type

adult rheumatology grand rounds describing the project, (2) presentation on GIOP by an endocrinology expert, and (3) data feedback on DXA scan ordering rates and distribution of EHR tools for easily identifying the last DXA scan.

Results: The percentage of patients aged ≥40 on prednisone with a DXA scan in the last 2 years increased from 15.2% among patients seen in 7/2019 to a maximum of 22.9% by 12/2019 after PDSA 1, was 18.7% after PDSA 2 in 2/2020, then declined despite PDSA 3 with onset of COVID19 (Figure 1). Among all patients seen from 7/1/19 – 4/30/20 (n = 1629), the highest percentage was in women aged ≥ 65 (31.6%, n = 443), followed by women aged 40 – 65 (18.2%, n = 752), men aged ≥ 65 (16.1%, n = 211), and men aged 40 – 65 (15.7%, n = 223).

The percentage of visits containing prednisone orders in which a DXA scan was ordered increased from 8.2% in 7/2019 to a maximum of 12.4% after PDSA 2 in 2/2020, then declined with onset of COVID19 (Figure 2). Among all visits with prednisone orders from 7/1/19 – 4/30/20, DXA scan ordering rates varied among 30 providers from 0.0% - 29.2% (IQR 4.3% - 18.4%). Compared with the 2018 – 2019 academic year, DXA scan ordering rates increased among fellows throughout the project (Figure 3).

The manual chart review included 93 patients and 82 visits. Chronic prednisone use (≥ 2.5mg daily for ≥ 3 months) occurred in 65.6% of patients and 59.6% of visits. The rest were on less prednisone or only took short courses. The manual chart review also demonstrated that our search for patients with a DXA scan in the last 2 years only identified scans done at our institution; 29% of all DXA scans occurred outside our institution.

Conclusion: We have not yet met our primary aim of increasing the percentage of patients aged ≥ 40 on prednisone with a DXA scan in the last 2 years from 15% to 30%; initial improvements were negated with onset of COVID19. However, we succeeded in validating a method for tracking this data over time, enabling ongoing efforts to improve adherence to the 2017 ACR GIOP guidelines. Furthermore, the large variability in DXA scan ordering rates and substantial improvement among fellows leading this project suggest that change is possible.

An Initiative to Improve Timely Glucocorticoid Tapering in Vasculitis

Arielle Mendel[1], Daniel Ennis[2], Shirley Lake[3], Simon Carette[4] and Christian Pagnoux[5], [1]Division of Rheumatology, McGill University, Montreal, QC, Canada, [2]Division of Rheumatology, Vancouver General Hospital, University of British Columbia, Vancouver, BC, Canada, [3]Division of Rheumatology, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada, [4]Division of Rheumatology, Mount Sinai Hospital and University Health Network, University of Toronto, Toronto, ON, Canada, [5]Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Vasculitis guidelines recommend scheduled glucocorticoid (GC) tapering to avoid toxicity. In an audit of 130 consecutive new patients on GC assessed in our tertiary Vasculitis Clinic (July 2017-October 2018), 33 (25%) were taking prednisone >10mg above target dose, based on GC initiation date. We aimed to increase the proportion of new patients taking appropriate GC doses to >90% by August 2019.

Methods: Interventions were (1) triaging patients on prednisone >20 mg to be seen in < 2 months (2) "fax- back" tapering suggestions based on current ANCA-associated vasculitis (AAV) and large vessel vasculitis (LVV) recommendations, sent to all physicians referring patients on GC. For the first several months, referring physicians' offices were contacted 1-2 weeks following the "fax-back" to determine if physicians had seen the suggestions. The primary outcome was the proportion of patients taking "appropriate" GC (< or =10 mg above target prednisone dose) at first visit, measured through interrupted time series. Other measures included clinic wait times, the proportion of patients starting to taper GC, and disease flares during tapering.

Results: Following physician triaging (December 2018), mean wait times for new patients on GC decreased from 81 days (95% CI 70-92) in the preceding 6 months to 64 days (95%CI 57-70). After introduction of "fax-back" in February 2019, only 29% of referring physicians were personally seeing the GC tapering suggestions. Following iterative modifications to the "fax-back" format, this increased to 73% by May 2019. Among patients referred for AAV/LVV, comparing pre-intervention (July 2017-January 2019) to post-intervention (February-October 2019) periods, the proportion of patients who had started to taper GC by their first visit increased from 71% (95%CI 62-78; n=83/117) to 94% (95%CI 84-98; n=49/52), and mean prednisone dose at first visit decreased from 30 mg (95%CI 27-33) to 22 mg (95%CI 18-26). Among non-AAV/LVV referrals, GC tapering trajectories did not change during the same periods. The proportion of patients ultimately taking "appropriate" GC doses at their first visit, overall and among the AAV/

Table: GC tapering trajectories among patients referred to the Vasculitis Clinic, before and after a "fax-back" intervention with tapering suggestions for AAV and LVV

GC, glucocorticoid; CI, Confidence Interval; AAV, ANCA-associated vasculitis; LVV, Large Vessel Vasculitis

LVV subset, did not significantly increase after the interventions. Potential/definite disease flares during tapering were similar before and after the "fax-back" intervention.

Conclusion: In this novel "GC stewardship" initiative to limit avoidable harm in vasculitis, we decreased wait times among GC-users. After introducing "fax-back" tapering suggestions, we observed increased tapering and lower GC doses at first visit among patients referred for AAV/LVV. Alternative knowledge dissemination strategies are needed to further improve timely GC tapering in vasculitis.

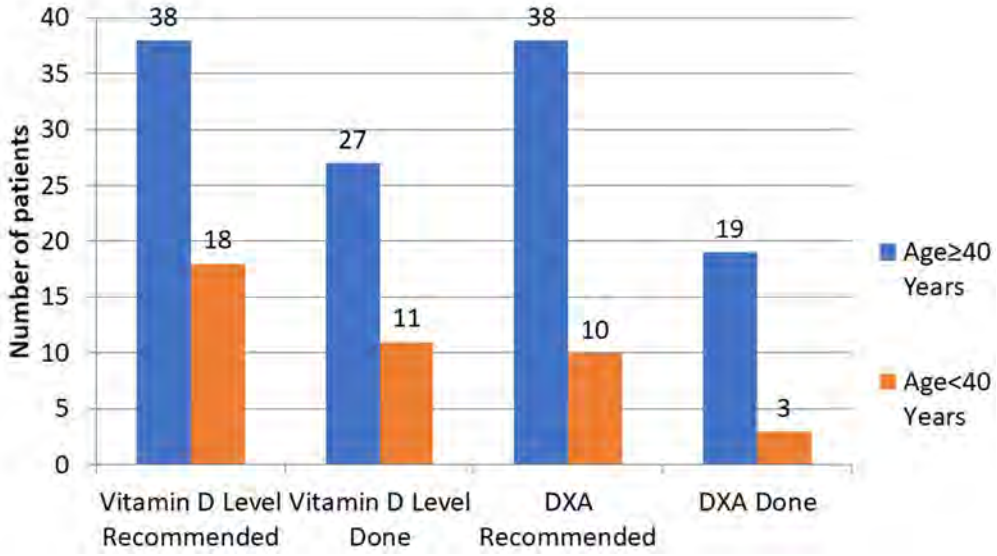
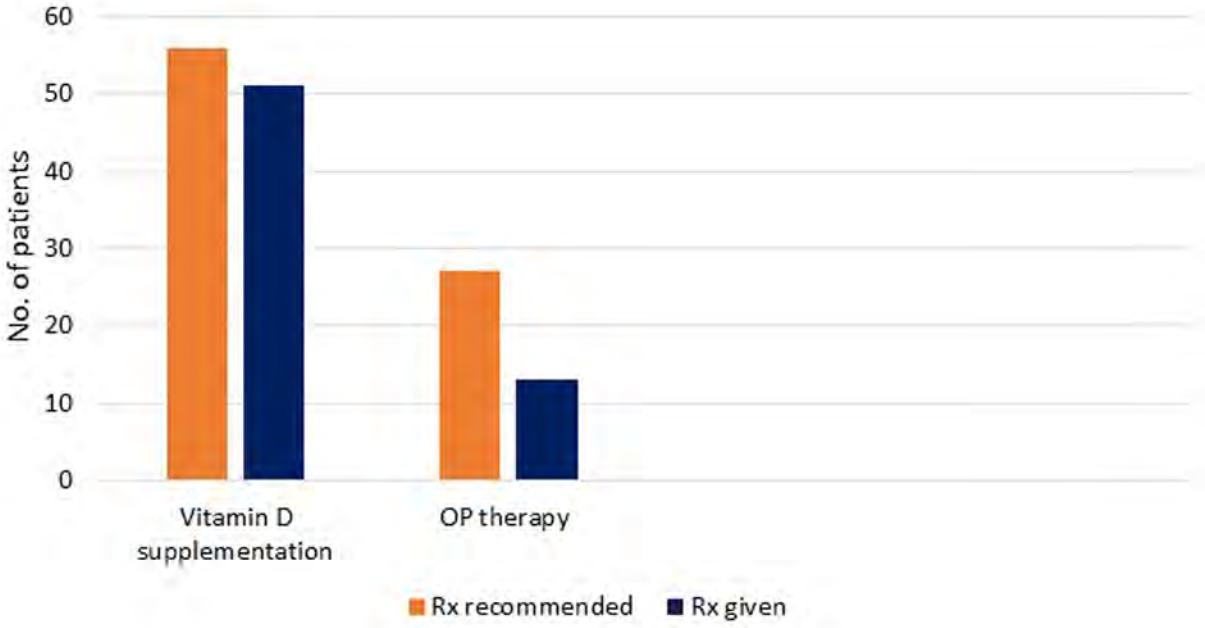
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Graph 1



Graph 2



Background/Purpose: Glucocorticoids (GC) are an important mode of therapy in ANCA associated vasculitis (AAV), and osteoporosis (OP) and fractures are potential adverse effects seen. The revised 2017 Glucocorticoid-induced osteoporosis guidelines by the American College of Rheumatology (ACR) categorizes patients into low, moderate and high fracture risk groups and provides recommendations. Our aim was to analyze the implementation of the guideline in AAV patients. This was a quality improvement (QI) initiative to identify potential targets for improving practice.

Comparison of tests done in patient groups (Table 1)

	Age≥40 Years n=38	Age<40 Years n=18	Fisher's Exact Test p-value
Vit D Level ordered	71% (27)	61% (11)	0.545
DXA ordered	50% (19)	30% (3)	0.307

Methods: Patients with vasculitis (AAV) were identified in 2 academic centers by generating an electronic medical record query during the period of 2012-2019. Patients with inadequate information at baseline and follow up, steroid use of < 3 months and steroid naive patients were excluded. 56 patients were included in the study. Demographics, OP risk factors, duration and dose of GC, bone mineral density (BMD) results were collected. Guideline adherence was assessed by analyzing the following: obtaining baseline DXA, testing of vitamin D levels, calcium and vitamin D supplementation and initiation of OP therapy. Fisher's exact test was used to determine if proportional differences existed in tests ordered between patients ≥ and < 40 yrs

Results: The mean age of the patients was 52.16 yrs (range 16 - 84 yrs) with 67.8 % (n=38) being females. Majority (n= 31, 59.6%) were on steroids for > 1 yr; with minimum duration of 3 months and minimum initial dose of 5 mg. Six (11.5%) had prior OP fracture. Though DXA is recommended in all patients ≥ 40 yrs, only 50% (n=19) had BMD tested (graph 1). 50 % (n=10) had OP and 64.7% were treated with bisphosphonates, 20% by denosumab and 10% by teriparatide. No prior OP fracture was seen in patients < 40 yrs. 56% (n= 10) met criteria based on OP risk factors for BMD testing at baseline and only 30% (n=3) were tested (graph 1). 43.7% also met BMD screening criteria based on cumulative steroid dose, however none of them underwent testing. There was no significant difference in ordering of DXA tests between the 2 age groups (p=0.307, table 1). 92.3% were advised calcium and vitamin D supplementation, however only 67.8 % had the levels checked (see graph 1) and there was no statistically significant difference in ordering of Vitamin D levels between the age groups (Table1). 69.2% of patients were in high and moderate fracture risk group that met criteria for OP therapy and only 33.3% received pharmacologic therapy (see graph 2). Patients < 40 yrs on continued GC dose of ≥ 7.5mg/day for > 6 months have moderate fracture risk based on BMD (z score < 3, rapid bone loss >10%). Due to inadequate BMD testing in patients < 40 yrs, risk stratification for pharmacologic therapy could not be done.

Conclusion: GIOP is a potentially reversible condition. In the study however, adherence to the guideline was inadequate in regards to ordering baseline DXA, checking vitamin D levels and starting OP therapy in high and moderate risk patients, especially in patients < 40 yrs. Hence this project identifies a potential QI initiative that can be implemented to improve the above practice methods in patients treated with long term steroids for many rheumatological conditions not just limited to vasculitis.

A Quality Improvement Project to Increase Vitamin D Prescribing for Pediatric Patients on Glucocorticoids

Katherine Kaufman[1], Mary Buckley[1], Laura Cannon[1], Rachel Randell[1], Philip Chu[1], Mithu Maheswaranathan[1], Andrew Johannemann[1], D Ryan Anderson[1], Isaac Smith[1], Akrithi Udupa[1] and David Leverenz[1], [1]Duke University, DURHAM, NC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic glucocorticoid treatment in children increases the risk of bone loss, fractures, and reduced adult skeletal mass. The 2017 ACR Glucocorticoid-Induced Osteoporosis (GIOP) guidelines recommend optimizing vitamin D intake to mitigate these risks. We performed a quality improvement project to measure and improve provider adherence to this guideline in an academic pediatric rheumatology clinic.

Methods: This project was led by pediatric and adult rheumatology fellows at our institution as part of our annual quality improvement curriculum. Our primary aim was to increase the percentage of pediatric patients treated with glucocorticoids prescribed a vitamin D supplement from less than 30% to 50%. A secondary measure was the percentage of patients on glucocorticoids with a vitamin D level checked in the preceding year. Using Plan-Do-Study-Act (PDSA) methodology, we conducted these cycles: (1) a combined pediatric and adult rheumatology divisional grand rounds describing the project, (2) a pediatric rheumatology conference focused on discussion of the project, and (3) a presentation on bone health by a pediatric endocrinologist. Data were obtained using Slicer Dicer, an analytic data tool available within our electronic health record (EPIC). Data were validated at baseline by manual chart review of all patients taking glucocorticoids

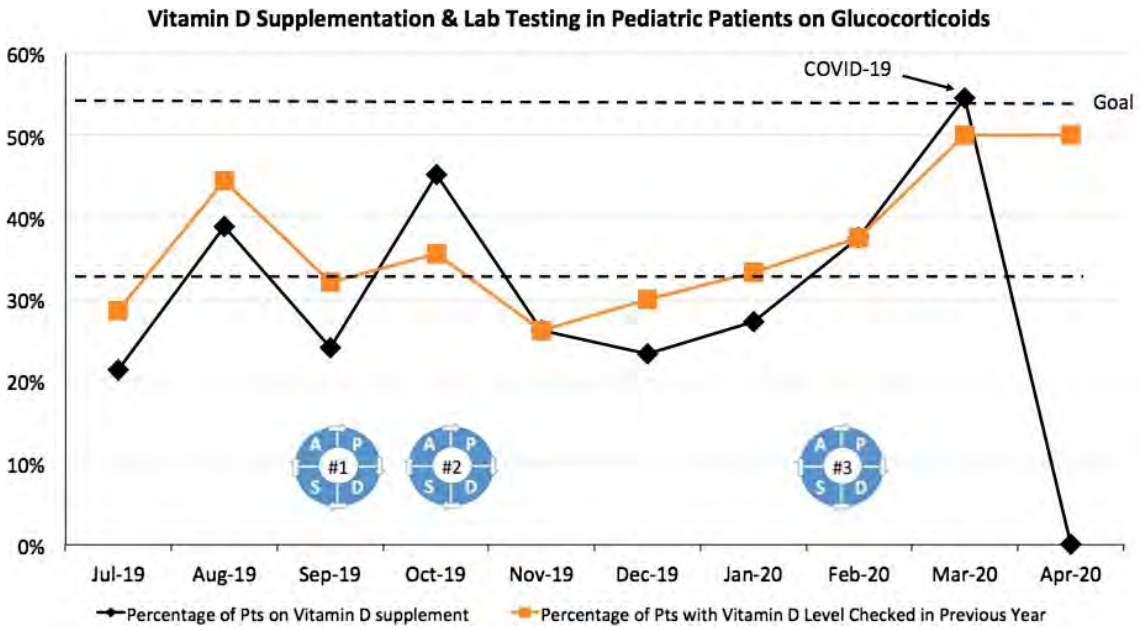

Figure 1. Run chart for vitamin D supplementation (black) and vitamin D levels checked (orange) by month in pediatric patients on glucocorticoids. The PDSA cycles are as follows: 9/17/2019- Combined Adult and Pediatric Rheumatology QI Introductory Grand Rounds; 10/3/2019- Pediatric Divisional QI Introduction; 2/6/2020- Pediatric Endocrinology Bone Health Educational Lecture. Our academic center started seeing an impact from the COVID-19 infection in mid-March 2020.

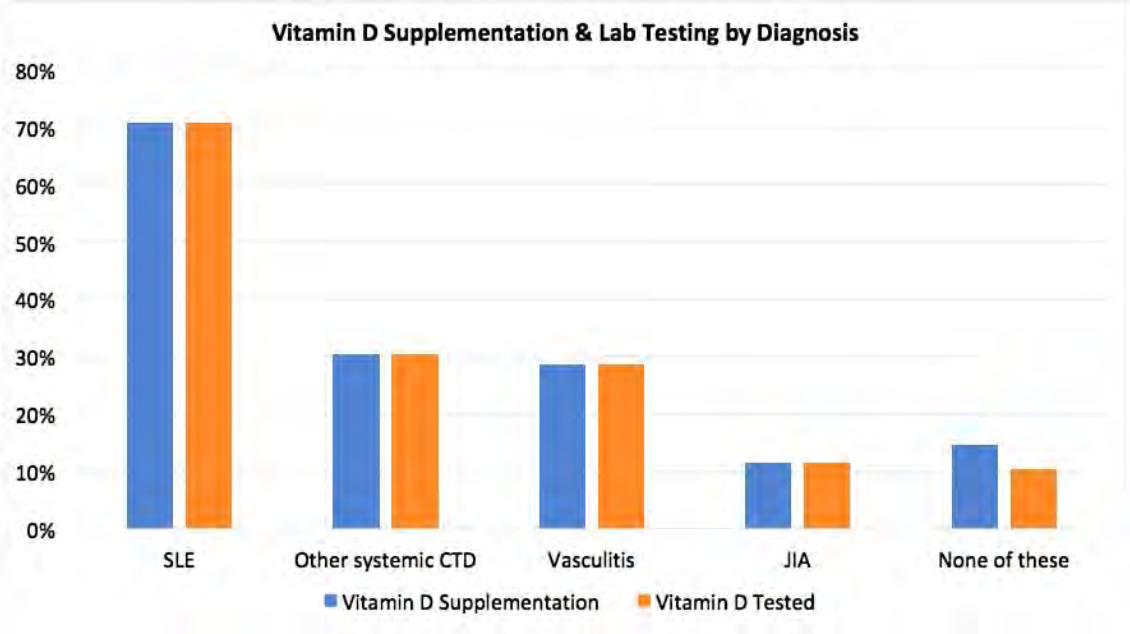

Figure 2. The percentage of patients on glucocorticoids who have an active prescription for a vitamin D supplement (blue) and who have had a vitamin D level checked in the preceding year (orange) by diagnosis. Other CTDs = JDM, localized scleroderma, SS, SSc, UCTD.

in pediatric rheumatology clinic in October 2019. Additional analyses were performed based on rheumatologic diagnosis (defined by ICD-10 codes) and age. Data were analyzed using descriptive statistics.

Results: The Slicer Dicer search at baseline in July 2019 revealed that 21.4% of patients on glucocorticoids were prescribed a vitamin D supplement, and 28.6% had a vitamin D level checked in the preceding year. By March 2020, vitamin D supplementation increased to 54.5% (Figure 1), and the percentage of patients with a vitamin D level checked increased to 50%. The largest rise in vitamin D prescriptions occurred following PDSA cycle 3.

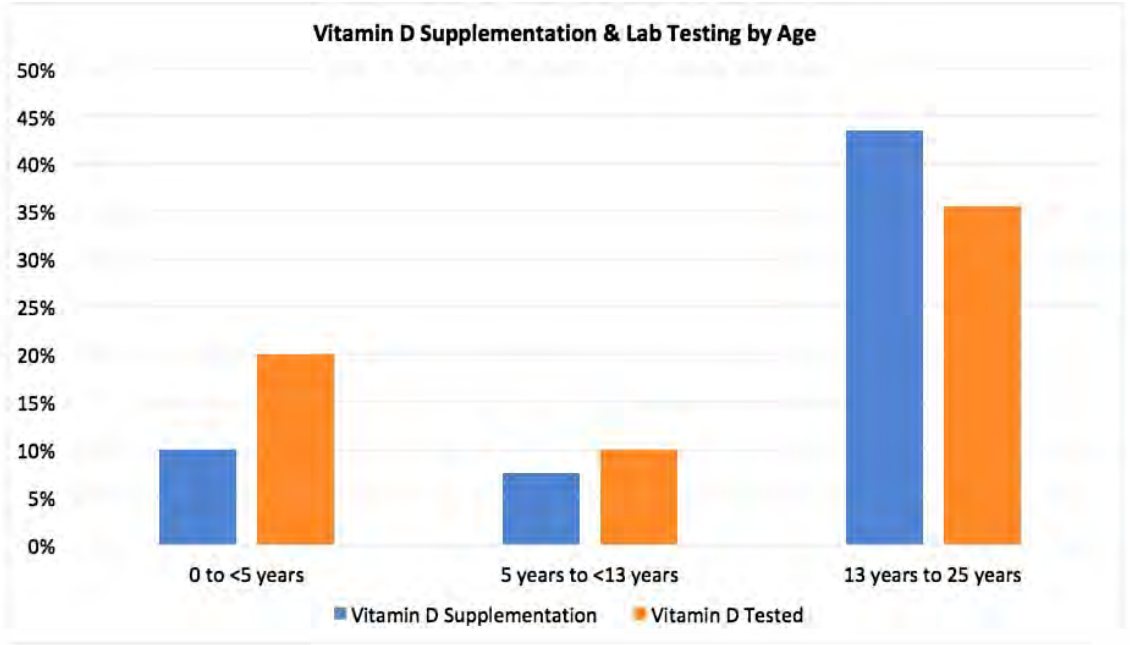

Figure 3. The percentage of patients on glucocorticoids who have an active prescription for a vitamin D supplement (blue) and who have had a vitamin D level checked in the preceding year (orange) by age. Other CTDs = JDM, localized scleroderma, SS, SSc, UCTD.

Throughout the project, vitamin D supplementation in patients with SLE was 70.6% (n=34), other connective tissue diseases 30.4% (n=23), vasculitis 28.6% (n=7), and JIA 11.5% (n=26) (Figure 2). When stratifying by age, vitamin D supplementation was 10% in patients < 5 (n=10), 7.5% in patients 5 to 13 (n=40), and 43.4% in patients ≥13 (n=83) (Figure 3). Rates of vitamin D levels checked were similar to vitamin D supplementation rates in each group.

Manual review of 31 patient charts in October 2019 revealed that 69% were prescribed glucocorticoids for >3 months. Of the patients prescribed chronic glucocorticoids, 45% had an active vitamin D prescription, and 37.5% had a preceding vitamin D level. Analysis by Slicer Dicer found that 45% were prescribed vitamin D and 35.5% had a preceding vitamin D level in October 2019.

Conclusion: We met our aim of increasing the percentage pediatric rheumatology patients on glucocorticoids taking vitamin D supplementation from 30% to 50%. The largest rise occurred after education from pediatric endocrinology. The highest levels of vitamin D supplementation were seen in patients with SLE and patients aged 13 to 25. Future interventions could focus on other diagnoses and age groups.

Abstract Number: 1592

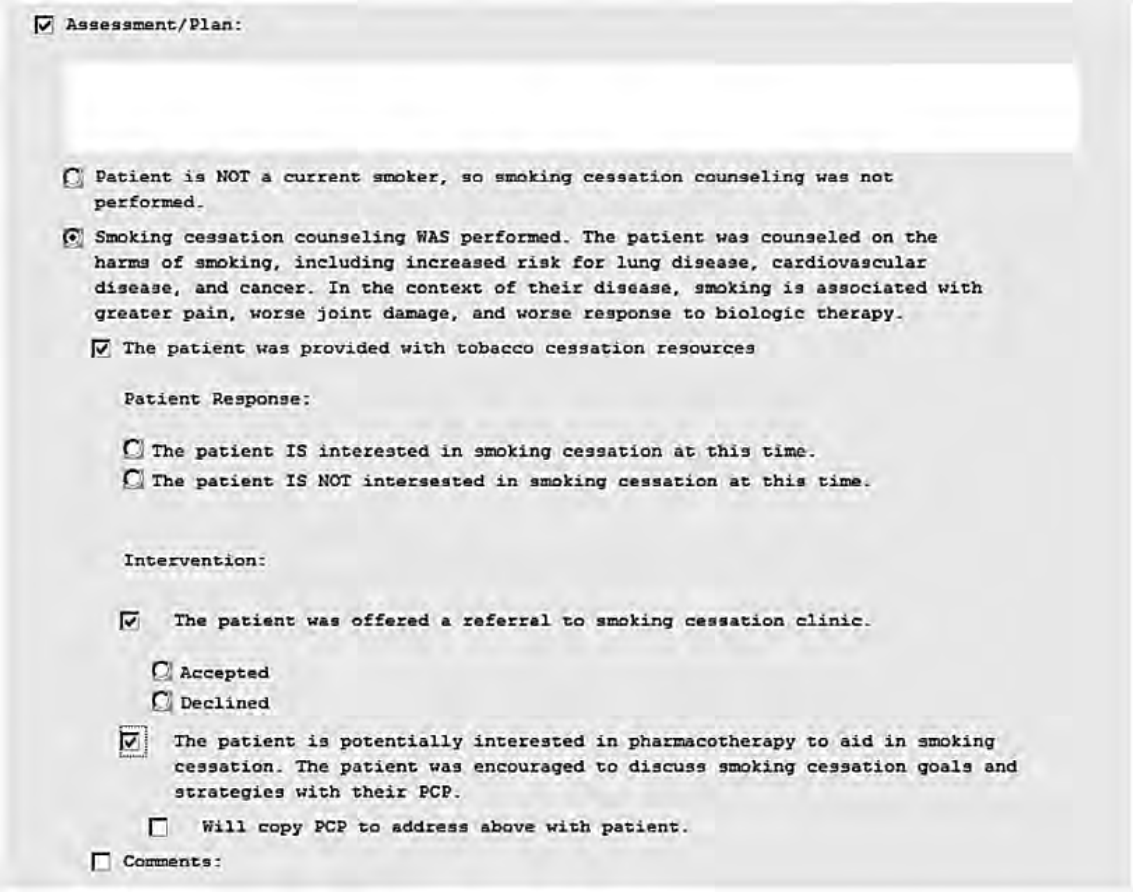
Improving Documentation of Smoking Cessation Counseling Among Spondyloarthropathy Smokers

Yusuf Chao[1], Jake Hutto[2], Elena Joerns[2], Rashmi Arora[3], Una Makris[1] and Swathi Reddy[3], [1]UT Southwestern Medical Center, Dallas, TX, [2]Division of Rheumatic Diseases, UT Southwestern Medical Center, Dallas, TX, [3]Veterans Affairs North Texas Healthcare System / UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking is prevalent among patients with spondyloarthropathies (SpA) and is associated with higher disease activity, poorer quality of life, and dampened response to biologic therapy. Despite the strong recommendation for smoking cessation in the 2018 American College of Rheumatology guidelines for management of psoriatic arthritis, providers do not routinely counsel smokers in the context of their disease (SpA). The goal of this quality improvement project was to improve documentation of smoking cessation counseling for SpA smokers at a busy Veteran Affairs (VA) Medical Center rheumatology clinic. The VA is an ideal setting to conduct this project since robust, evidence-based tobacco cessation modalities can be integrated into primary and specialty clinic care settings.

Methods: Baseline documentation rates of smoking status and smoking cessation counseling were obtained via chart review of patients diagnosed with ankylosing spondylitis, inflammatory bowel disease (IBD)-associated arthritis, and psoriatic arthritis who were current smokers seen for follow-up (8/2017-6/2018). We implemented a four step multi-modal intervention that included: a) a modified clinic note template (effective 1/2020) with specific prompts to address tobacco use (Figure 1), b) educating providers and nurses regarding the importance of counseling and template adherence, c) introducing a paper slip on top of intake documents to remind providers to inquire about smoking,



and d) equipping the clinic with brochures on cessation resources. Preliminary post-intervention data from follow-up visits were collected until the novel coronavirus disease 2019 (COVID-19) outbreak altered clinic workflow (1/2020-3/2020). Differences in documentation rates pre- and post-intervention were analyzed using Fischer's exact test.

Results: In the pre-intervention phase, 50 smokers were identified among 498 SpA patients, indicating a 10% baseline smoking rate. Rheumatologists documented smoking status for 92% of smokers and smoking cessation counseling for 12% of smokers. In the early post-intervention phase, we identified 13 smokers (15%) among 87 SpA patients. Utilization of the modified clinic note template was 30% (26/87). With our multi-modal intervention, the smoking status documentation rate remained at 92%, while the counseling documentation rate increased to 38.5% (Figure 2).

Conclusion: The baseline documentation rate of smoking cessation counseling for SpA smokers is low among rheumatology providers. Because of the COVID-19 outbreak, reduced outpatient volumes and unanticipated changes in clinic workflow have imposed limitations on post-intervention data collection. Nevertheless, our preliminary data suggest that a multi-modal intervention can improve documentation of smoking cessation counseling; this improvement may be sustainable with continued staff education on counseling and consistent template use. Our next steps will involve evaluation of receipt of smoking counseling and further reduction in smoking rates.

Abstract Number: 1593

Adherence to Weight-Based Dosing Guidelines in Patients Receiving Hydroxychloroquine for Rheumatoid Arthritis and Systemic Lupus Erythematosus: Results of a Quality Improvement Initiative

Tara Skorupa[1] and Robert Shmerling[2], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Division of Rheumatology, Mashpee, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a commonly prescribed medication for systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and other rheumatic diseases. HCQ may rarely cause retinopathy. This risk correlates with both daily dose and duration of use[1]. In addition to screening ophthalmologic examinations, the most recent guidelines by the American Academy of Ophthalmology recommend limiting the dose of HCQ to 5mg/kg/day of actual body weight[1]. After reviewing our practice's dosing of HCQ and adherence to these guidelines in 2018, we assessed the impact of sharing prescribing data with individual providers and implementing nurse-aided decision support for HCQ refill requests.

Methods: We previously performed a single-center retrospective analysis of 801 adult patients receiving HCQ for SLE or RA in our rheumatology practice at Beth Israel Deaconess Medical Center between January 1, 2018 and De-

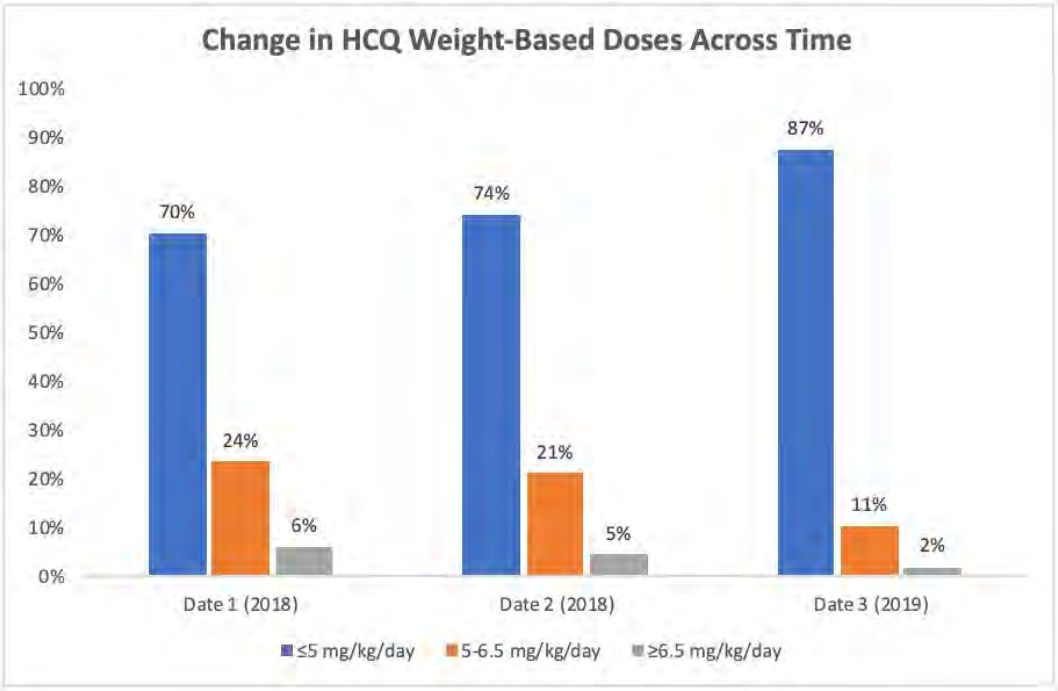

Figure 1. Change in HCQ Weight Based Doses Across Time. Date 1 and Date 2 represent the "pre-intervention" time points in 2018. Date 3 represents the "post-intervention" time point in 2019.

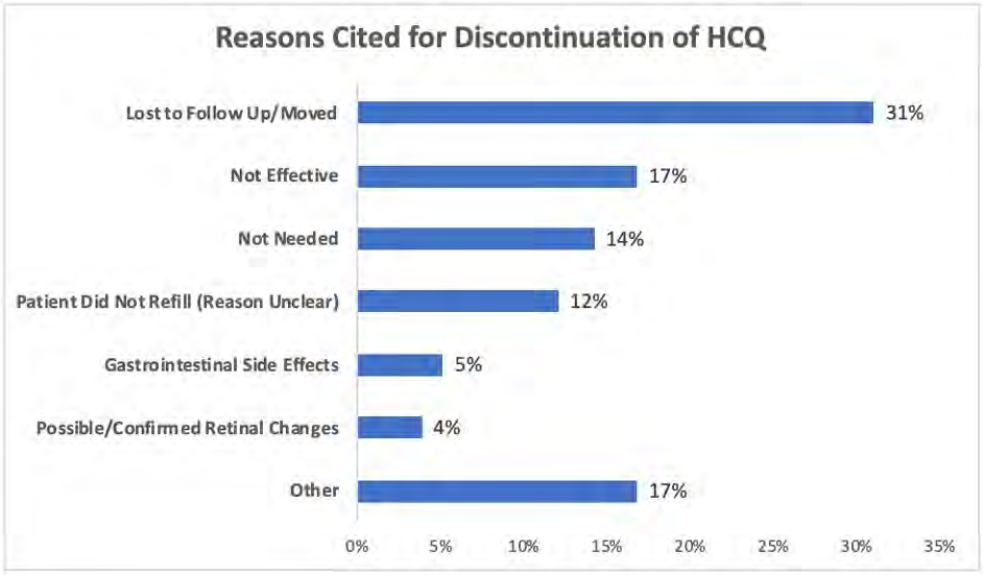

Figure 2. Reasons Cited for Discontinuation of HCQ. "Other" less common reasons for discontinuation included: non-ophthalmologic neurologic side effect, medication interaction, rash, rethinking diagnosis, death of patient, pregnancy, macular degeneration (concern for inability to safely monitor for retinal toxicity), hair loss, hyponatremia, G6PD deficiency, pill size, polypharmacy, tongue swelling, and mood.

cember 31, 2018. We calculated the weight-based dose of HCQ at two separate time points, separated by at least 6 months to allow for "loading dose" adjustments. In mid-2019, we implemented a two-pronged quality improvement intervention:

1. We shared aggregate dosing averages with all providers in the practice, then privately shared individual prescribing data with each provider, including a list of patients dosed >5mg/kg/day at both recorded time points in 2018.

2. We introduced nurse-aided decision support for HCQ refill requests. For each request, nurses calculated the weight-based dose before sending the request to the prescribing physician along with an alert if the dose was >5mg/kg/day.

One year after the initial analysis, we reviewed the same 801 patients included in the initial analysis, and recorded the current weight and HCQ dose. We used this data to calculate aggregate dosing averages for the practice, and dosing changes for individual patients. We used McNemar's test to assess for statistical significance of the changes.

Results: Of 801 patients included in the 2018 analysis, 674 continued to receive their care within our practice and remained on HCQ through the end of 2019. 154 patients were dosed >5mg/kg/day at both measured time points during 2018, and of those patients, 93 (60%) were dose-reduced to £5mg/kg/day by date 3. Between Date 2 in 2018 ("pre-intervention") and Date 3 in 2019 ("post-intervention"), there was a statistically significant increase in the proportion of patients dosed < 5mg/kg/day, from 74% to 87% (p< 0.0001) (*Figure 1*). HCQ was discontinued in 232 patients between 2018 and 2019. Of those patients, the most commonly cited reasons were "loss to follow up/moved away" (31%), "not effective" (17%), and "no longer needed" (14%) (*Figure 2*). In 9 patients (4%), HCQ was discontinued due to possible or confirmed retinopathy identified by ophthalmologic screening exam.

Conclusion: Our quality improvement intervention led to a statistically significant increase in the proportion of patients taking HCQ dosed according to the current recommended guidelines. These findings highlight provider feedback and nurse-aided decision support as two potentially effective strategies for improving adherence with the guidelines.

Hydroxychloroquine Prescribing Habits and Provider Opinion on Dosing Guidelines in the Rheumatology and Dermatology Practices of an Academic Institution

Rebecca Overbury[1], Jakrapun Pupaibool[2], Christopher Hansen[2] and Dorota Lebiedz-Odrobina[2], [1]University of Utah and Primary Children's Hospital, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: One rare but devastating adverse event related to the use of hydroxychloroquine (HCQ) is retinal toxicity. Retinal toxicity rates from HCQ can be as high as 7.5% and is dose-related. In 2016, the American Academy of Ophthalmology (AAO) issued weight-based guidelines recommending that daily dosing not exceed 5 mg/kg/day. However, there are concerns from those prescribing this medication that dose reduction might decrease the benefit of this medication. We wanted to analyze HCQ prescribing habits and opinions on these guidelines in our academic institution. We also conducted a prospective, non-controlled, quality improvement study to examine if a tool in the electronic medical record (EMR) affected compliance with these guidelines or affected provider's perspectives on these guidelines.

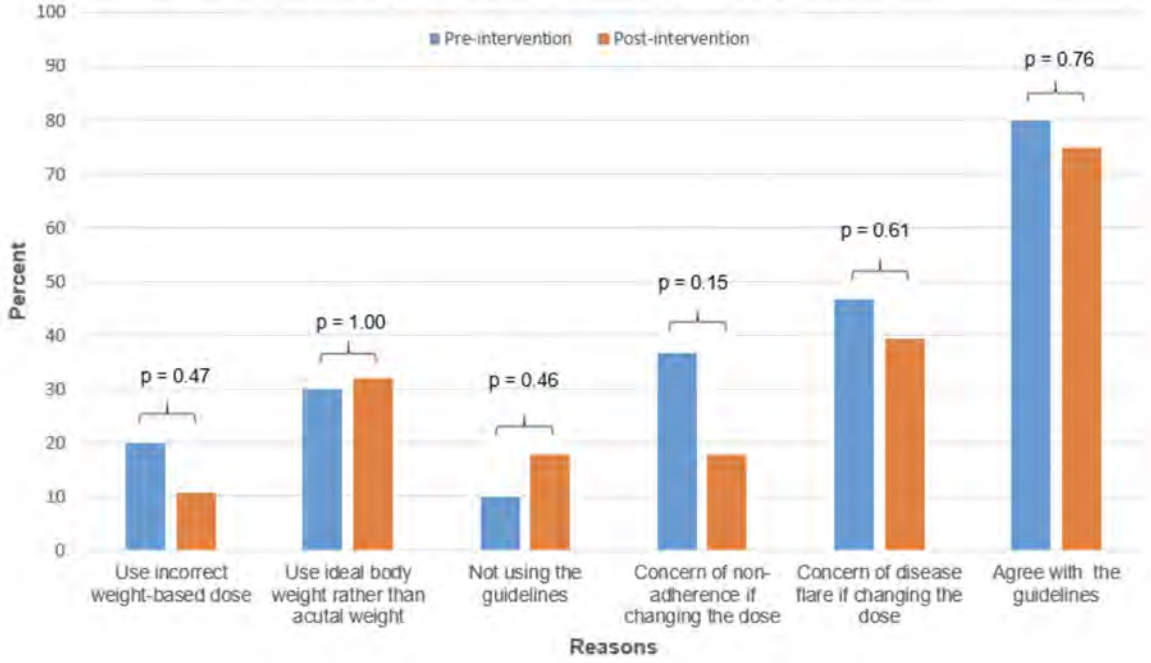
Table 1. Hydroxychloroquine Dosing Before Intervention

HCQ Dose (mg/kg/day)	Rheumatology [n (%)]			Dermatology [n (%)]		
	Female	Male	Total	Female	Male	Total
≤5	626 (80.5)	152 (19.5)	778 (69.0)	122 (71.8)	48 (28.2)	170 (60.3)
5.1 - 6.5	256 (92.4)	21 (7.6)	277 (24.6)	65 (83.3)	13 (16.7)	78 (27.7)
≥6.6	70 (95.9)	3 (4.1)	73 (6.5)	32 (94.1)	2 (5.9)	34 (12.1)
Total	952 (84.4)	176 (15.6)	1128 (100.0)	219 (77.7)	63 (22.3)	282 (100.0)

Table2 Hydroxychloroquine Dosing After Intervention

HCQ Dose (mg/kg/day)	Rheumatology [n (%)]			Dermatology [n (%)]		
	Female	Male	Total	Female	Male	Total
≤5	705 (79.1)	186 (20.9)	891 (76.9)	53 (67.9)	25 (32.1)	78 (73.6)
5.1 - 6.5	197 (88.7)	25 (11.3)	222 (19.2)	19 (86.4)	3 (13.6)	22 (20.8)
>6.6	42 (93.3)	3 (6.7)	45 (3.9)	4 (66.7)	2 (33.3)	6 (5.7)
Total	944 (81.5)	214 (18.5)	1158 (100.0)	76 (71.7)	30 (28.3)	106 (100.0)

Figure 1. Reasons for Incorrect Hydroxychloroquine Dosage and Opinions on The Guidelines Before and After the Intervention



Methods: Survey data was collected from prescribers. Chart review on patients prescribed HCQ, was collected. Survey data included: awareness of guidelines, self-reported compliance with guidelines, and opinion of guidelines. All data were collected pre-intervention (June 2017 - January 2019) and post-intervention (March 2019 - April 2020). In January 2019 we released an EMR tool which prompted guideline-based weight-based dosing whenever HCQ was prescribed. Results were analyzed using descriptive statistics for demographic data and Fisher's exact tests for comparisons of proportions between groups.

Results: Pre-intervention: We reviewed 1,128 rheumatology charts. 350 (31.0%) rheumatology patients were prescribed HCQ >5.0 mg/kg/day. We reviewed 282 dermatology charts. 112 (39.7%) dermatology patients were prescribed HCQ >5.0 mg/kg/day. Combining rheumatology and dermatology patients, 462 (32.8%) were prescribed HCQ >5.0 mg/kg/day (Table 1). Post-intervention: We analyzed 1,158 rheumatology charts. 267 (23.1%) rheumatology patients were prescribed HCQ >5.0 mg/kg/day. We reviewed 106 dermatology charts. 28 (26.4%) dermatology patients were prescribed HCQ >5.0 mg/kg/day. Combining rheumatology and dermatology patients, 295 (23.3%) were prescribed HCQ >5.0 mg/kg/day (Table 2). Post-intervention, there was a 9.5% increase in patients prescribed HCQ ≤5 mg/kg/day (p-value < 0.0001). Pre-intervention, we compiled 18 surveys from rheumatology and 12 surveys from dermatology; post-intervention, we compiled 16 surveys from rheumatology and 12 surveys from dermatology (Fig 1). Post-intervention, there were reductions in the number of rheumatologists who incorrectly identified the guideline-based weight-based dosing recommendation of HCQ; there was no change in dermatologists. Combined, there was an overall reduction but not of statistical significance (p=0.47).

Conclusion: Our research finds ongoing hesitation towards compliance with the 2016 AAO recommendations for HCQ weight-based dosing. There is ongoing unfamiliarity with the details of the recommendations therein. Prescribed HCQ doses in practice often exceeded the recommended daily dose. Finally, our research shows that appropriate EMR intervention, prompting appropriate and safe weight-based dosing of HCQ, can improve compliance with these guidelines. We believe that this will lead to improved patient safety over the lifetime.

Abstract Number: 1595

Using Rheumatoid Arthritis Communication Tool Developed by the RISE Learning Collaborative to Promote Shared Decision-Making

Joad Eseddi[1], Puneet Bajaj[2], Gabriela Schmajuk[3], Jinoos Yazdany[4] and Salahuddin Kazi[5], [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Dallas, TX, [3]University of California, San Francisco, Atherton, CA, [4]University of California, San Francisco, San Francisco, CA, [5]Veterans Affairs North Texas Healthcare System / UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient care is moving from physician directed treatment to a co-design framework that focuses on creating a partnership between patients and physicians. This new framework is centered on patients' values, with the aim of enhancing care by improving mutual understanding, goal alignment and patient-physician shared decision making (SDM). Our objective was to implement and evaluate the impact of a Rheumatoid Arthritis (RA) SDM tool, with the goal of improving SDM between RA patients and their providers.

Methods: A vital component to effectively improve outcomes in RA patients is by establishing personalized treatment plans and targets through SDM. An SDM tool (Figure 1) developed by the RISE Learning Collaborative (RISE-LC), a learning network established in March 2019 to coordinate quality improvement (QI) efforts in adult rheumatology practices across multiple centers, was introduced into our academic rheumatology clinic workflow (Figure 2) in January 2020.

We conducted a retrospective chart review of 99 patients: 50 of them with visits in September – December, prior to implementation of the SDM tool and 49 of them with a visit between January-March 2020, following tool implementation. The patients in each group categorized based on their CDAI scores: Remission: 0-2.8, Low disease activity (LDA): 2.9–10, Low-moderate disease activity (LMDA): 10.1–16, high-moderate disease activity (HMDA): 16.1–22 and high disease activity (HDA): >22. We used Minitab (Version 19.2020.1) for statistical analysis, and used two-sample t-test and two-proportion test to compare the 2 cohorts' demographics, goals for the visit, CDAI scores, number of medications patients were on, number of associated co-morbidities and whether patients had a change in therapy.

Results: 89.9% (89/99) of the included patients were females (see Table 1). Among the patients who used the SDM tool, 65.3% used less than 2 lines to answer the question 'what's on my mind for today's visit?'. Having less pain was the most common goal (65.3%) overall and this did not vary with the level of disease activity. The second most common goal was to avoid medication side effects (40.8%), which was listed more frequently for patients in LDA (47.3% or 9/19) and LMDA (50% or 6/12) groups. The patients who had a change in therapy in the non-SDM cohort were younger and had higher CDAI scores. Comparing other parameters did not reach statistical significance. See Table 1

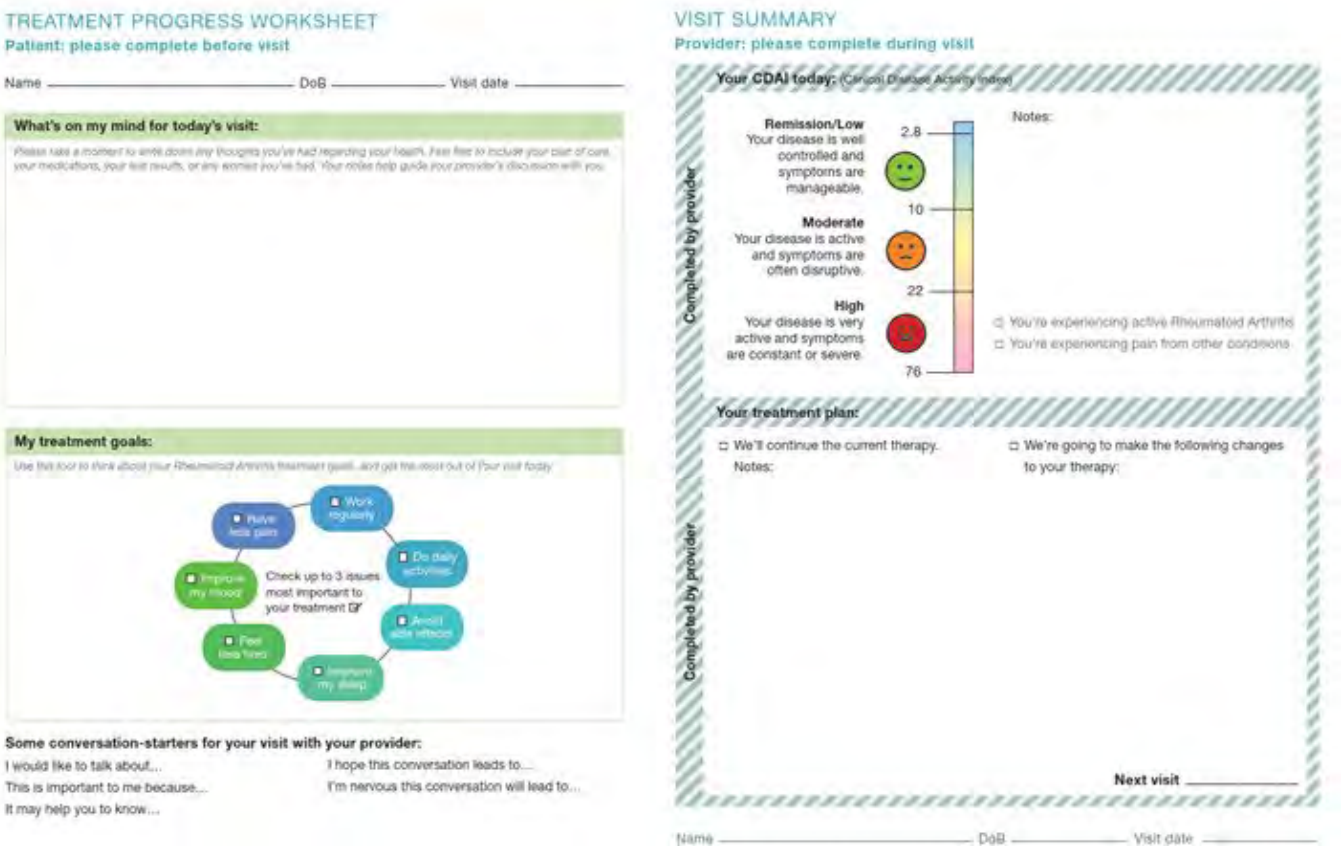

Figure 1 SDM Tool

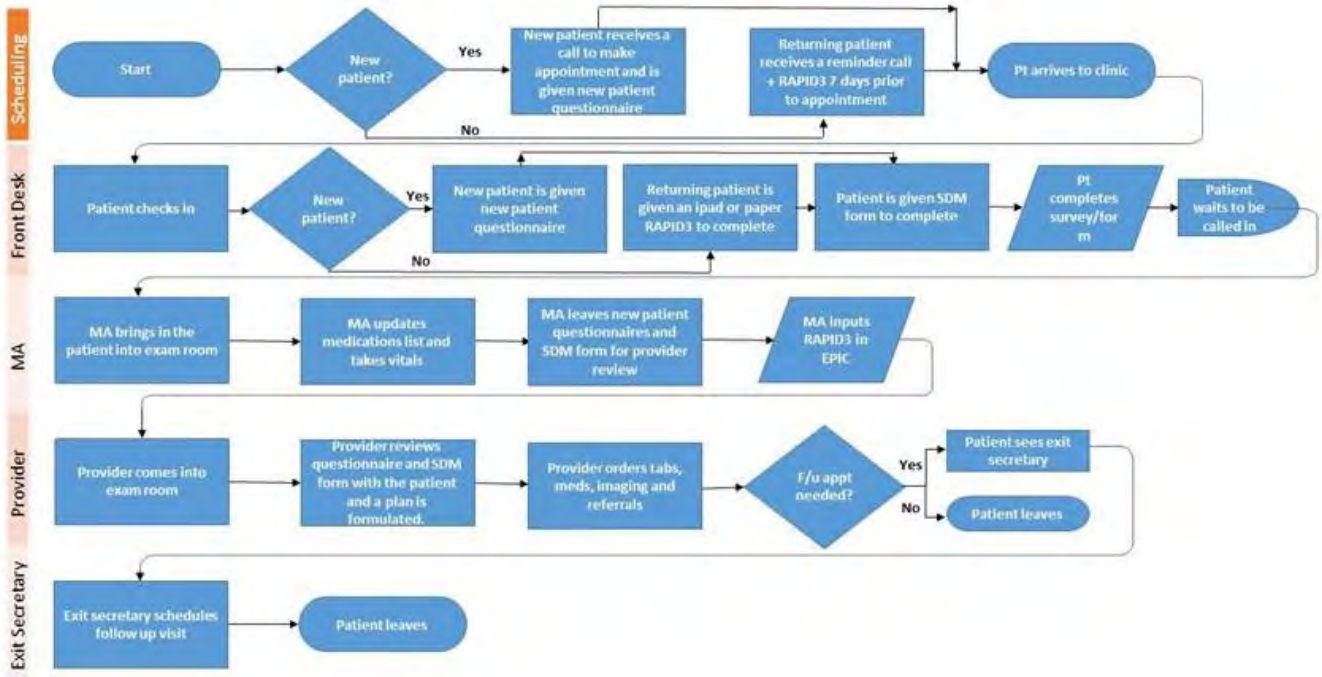

Figure 2. UT Southwestern Rheumatology Clinic Workflow

	SDM Tool Cohort N=49			Non-SDM Tool Cohort N=50			
Average age	61			62.2			p-value: 0.733
Sex	Female: 45 Male: 4			Female: 44 Male: 6			
Race	African American: 19 White: 19 Asian: 2 Other: 1 Unknown: 7			African American: 18 White: 23 Asian: 1 Other: 2 Unknown: 6			
Patients Making Change to Therapy	38.8%			40%			p-value: 0.901
Therapy changed?	Yes	No	p-value	Yes	No	p-value	
Average clinical disease activity (CDAI) scores	10.4	9	0.514	12.8	8.15	0.039	
Average number of medications	10.2	9.6	0.656	9.5	9.4	0.982	
Average Age (years)	60.68	61.2	0.905	56	60	0.030	
Average number of comorbid conditions	4.15	4.33	0.826	4.45	4.6	0.823	

Table 1. Comparing SDM Tool Cohort With Non-SDM Tool Cohort

Conclusion: Implementation of a SDM tool was feasible in our practice. Analysis of SDM tool content revealed that most patients had focused goals; less pain was the most common goal followed by having fewer medication side effects. As the disease activity increased, patients were willing to make changes to therapy. No early differences in treatment escalation were seen among those using the SDM tool, but larger studies are ongoing to assess the impact of tool implementation. Next steps also include incorporating SDM tool components into a rheumatology dashboard in our electronic health record.

Coproduction of Care for Veterans with RA: Improving Elicitation and Documentation of Patient Goals

Swathi Reddy[1], Kyawt Shwin[1], Rashmi Arora[1], Sarah Homann[2], Lisa Johnson[3], Yusuf Chao[4], Aricca Van Citters[3], Brant Oliver[5], Guy Eakin[6], Eugene Nelson[3], Andreas Reimold[1] and Salahuddin Kazi[1], [1]Veterans Affairs North Texas Healthcare System / UT Southwestern Medical Center, Dallas, TX, [2]Veterans Affairs Tennessee Valley Healthcare System / Vanderbilt University Medical Center, Nashville, TN, [3]The Dartmouth Institute for Health Policy & Clinical Practice, Lebanon, NH, [4]UT Southwestern Medical Center, Dallas, TX, [5]The Dartmouth Institute for Health Policy & Clinical Practice / Veterans Affairs National Quality Scholars Fellowship in Healthcare Quality & Safety, Lebanon, NH, [6]Arthritis Foundation, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Coproduction of healthcare services offers a pathway to increase patient engagement in care. Patients and clinicians coproduce care by working together to: (1) co-assess health status; (2) co-decide next steps in the care plan based on the patient's goals; (3) co-design the care plan to fit the patient's goals, context, and capabilities; and, (4) co-deliver self-care and professional services to achieve goals of care. This initiative aimed to increase patient engagement by eliciting their goals and concerns, incorporating them into the clinic discussion, and documenting coproduced goals as part of the care plan in the electronic health record (EHR) for at least 50% of veterans with RA by December 2019.

Methods: Our multi-phase intervention included: (1) creation of a new intake form to elicit patient's main goals and concerns; (2) adaptation of the clinical work flow to incorporate patient goals and concerns as part of the clinic visit discussion, supported by a motivational interviewing course to educate clinicians in patient-centered counseling; and, (3) modification of the after visit summary (AVS) template in the EHR to document coproduced goals and next steps to support patient self-management. We used the Plan-Do-Study-Act methodology to test, evaluate, and modify the patient prompt through four cycles of revisions. Input was obtained from patients and clinical care team members (5 attending physicians, 1 fellow physician, 1 nurse practitioner, and 4 nurses). The final patient prompt asked of all RA outpatients contains three questions (**Figure 1**). Modifications to the AVS include a text box entitled "Your Goal is" followed by "Next Steps to Achieve Goal." Process and outcome data were collected from a random sample of 30% of the RA population seen at the Rheumatology clinic in the baseline (November-December 2017, n=70) and post-intervention (November-December 2019, n=65) periods.

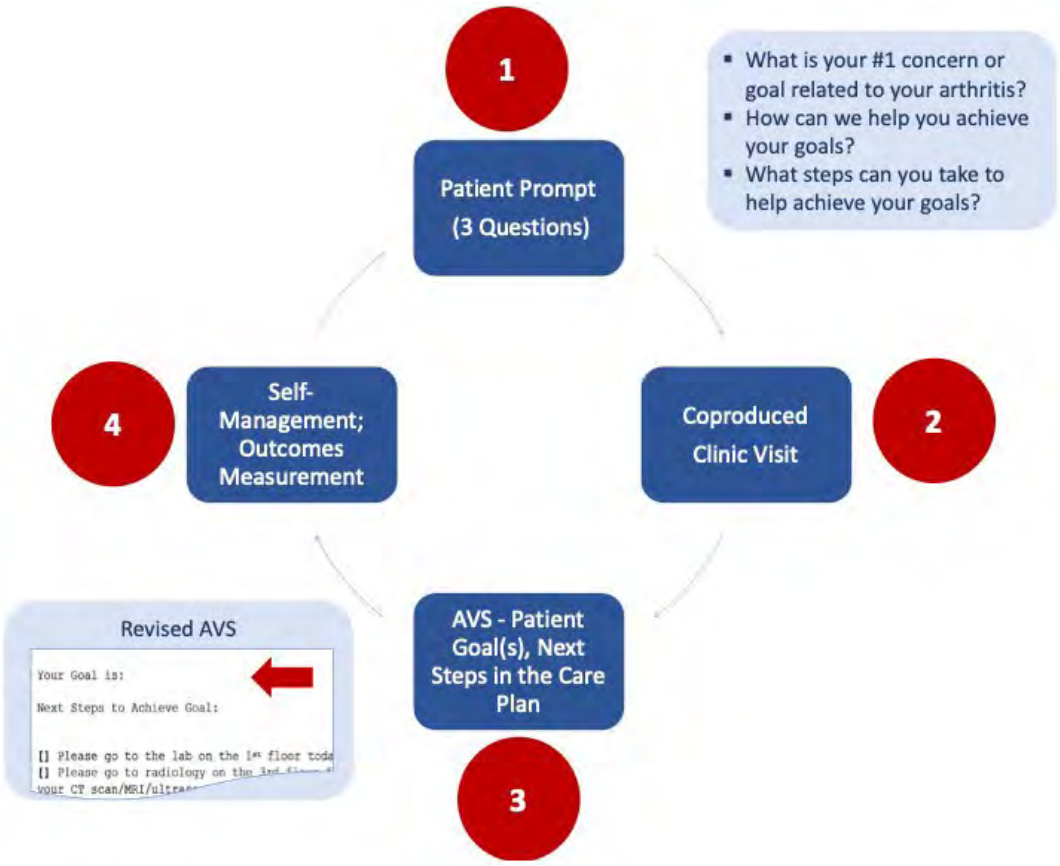

Figure 1. Coproduction of Care Initiative for Veterans with RA

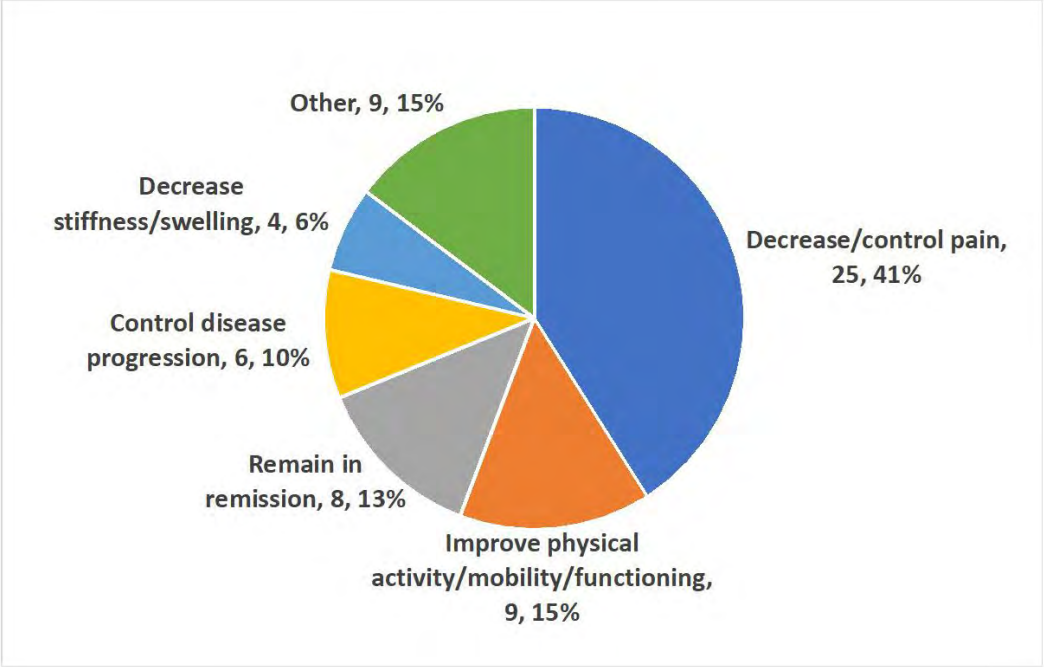

Figure 2. Coproduced Goals of Care Documented in the AVS (Post-Intervention: November-December 2019; n=61 goals, identified by 48 patients)

	Baseline: Nov/Dec 2017 n=70	Post-Intervention: Nov/Dec 2019 n=65
Age, years (mean, SD)	62.4 (11.1)	69.3 (10.8)
% Male	93% (65/70)	77% (50/65)
Disease Activity (% low or in remission)		
Clinical Disease Activity Index (CDAI)	66% (46/70)	71% (46/65)
Disease Activity Score-28 (DAS-28)	54% (38/70)	64% (35/55)
Functional Status (mean, SD)		
Health Assessment Questionnaire (HAQ) 0-3	1.2 (0.7) (n=60)	1.1 (0.7) (n=48)
Joint Exam (mean, SD)		
Total tender joint count 0-28	4.0 (6.9) (n=59)	2.9 (4.8) (n=56)
Total swollen joint count 0-28	0.7 (2.4) (n=59)	1.5 (3.9) (n=58)
Clinical Lab Markers (mean, SD)		
CRP mg/dL	1.2 (1.6) (n=69)	1.3 (2.1) (n=55)
ESR mm/hr	24.2 (18.4) (n=70)	24.1 (20.3) (n=55)
Patient Global Score 0-100mm (mean, SD)	46.6 (25.8) (n=61)	41.5 (28.2) (n=48)
Physician Global Score 0-100mm (mean, SD)	27.6 (21.0) (n=44)	23.7 (18.1) (n=50)
Documentation of Goals of Care	n/a	87% (48/55)

Table 1. Patient Data Comparison – Baseline and Post-Intervention Periods

Results: Coproduced goals of care were documented in 87% of the available AVS (n=55) in the post-intervention period, exceeding our aim. The most frequent coproduced goal was to decrease/control pain (41%, n=25), followed by improve physical activity/mobility/functioning (15%, n=9), and remain in remission (13%, n=8) (**Figure 2**). Data collection included patient characteristics, measures of disease activity, functional status, tender and swollen joint counts, patient and physician global scores, and clinical lab markers (**Table 1)**. A trend towards increased percentage of patients in disease remission, decreased tender joint count, and improved patient and physician global scores was noted.

Conclusion: Clinicians in a high-volume clinic can successfully partner with their RA patients to coproduce care by eliciting their goals, engaging in shared decision making about next steps, and documenting coproduced goals and care plans in the EHR. Areas of further exploration include: (1) monthly collection and tracking of health outcomes and patient satisfaction data over time, (2) measurement of patient self-reported effort towards meeting their goal(s) and identification of ways to bolster goal achievement, and (3) application of the coproduction process to telemedicine visits.

Abstract Number: 1597

Use of a Clinical Dashboard Improves the Documentation of Disease Severity Scores and May Facilitate the Implementation of Treat to Target Therapy

Taylor Nelson[1], Gary Kunkel[2] and Grant Cannon[2], [1]University of Utah, Salt Lake City, [2]Salt Lake City VA Medical Center and University of Utah, Salt Lake City

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) management guidelines recommend the collection of Disease Activity Measures (DAMs) to direct therapy as a component of a "treat-to-target" (T2T) strategy. A goal of the Veterans Affairs Rheumatoid Arthritis (VARA) registry is to systematically collect 6 clinical DAMs and two laboratory DAMs at each visit using note templates (Table 1). The real-time calculation of disease severity scores such as DAS28 is not part of the standard VARA protocol. We developed an on-line clinical dashboard that collects real-time DAMs and displays them longitudinally to calculate disease activity scores including DAS28 in real-time. In this study, we evaluated the association of clinical dashboard utilization with 1) DAS28 capture in the medical record and 2) the frequency of major changes in RA therapy.

Methods: Clinical notes from initial clinic visits for each US Veteran enrolled in VARA from a single site (between 10/2012 and 6/2018 - when the dashboard became available) were evaluated for documentation of 8 possible DAMs and whether major therapeutic changes (MTCs) were undertaken. We compared clinic notes for visits where the clinical dashboard was deployed for data collection with visits where the clinical dashboard was not used. MTC was defined as: initiation of synthetic or biologic disease-modifying antirheumatic drug (DMARD); DMARD dose escalation ≥25%; prednisone use (new agent or after 90-day gap); prednisone dose increased 25%; and/or corticosteroid injection in ≥2 joints. We also recorded changes and/or escalation in therapy even if it did not meet MTC criteria. Each MTC or lack of MTC was classified as being consistent or not consistent with ACR guidelines and our previously published potential optimal DAS28 threshold for MTC (See Table 2 Footnote).

Results: The 146 RA patients with a visit using the dashboard were similar to the 201 patients in whom the dashboard was not used referent to age, disease duration, clinical RA features, DAMs and overall DAS28 (Table 1). Clinic notes for patient visits using the dashboard were significantly more likely to record a DAS28 (75.3%) than visits not using the dashboard (2.0%) ($p < 0.001$) (Table 2). There was no significant difference in likelihood of an MTC, (20.5% vs 16.4%) or any therapeutic escalation (33.6% vs 27.4%) (Table 2). Management decisions to escalate therapy as recommended in ACR guidelines were more common at DAS28 >3.2 threshold for change (70.5% vs 60.2%, $p=0.046$) and DAS28 >3.8 threshold for change (77.4% vs. 66.7%, $p=0.029$).

Conclusion: Utilization of a clinical dashboard can improve documentation of disease activity scores such as DAS28 in real time. Further study is needed to determine if the use of a clinical dashboard will improve the implementation of care that is concordant with best practices and whether this leads to improvements in long-term patient outcomes.

Abstract Number: 1598

Efficacy of Universal Depression Screening in a Rheumatology Clinic

Osman Bhatty[1] and Michael Lucke[1], [1]Allegheny Health Network, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression has long been viewed as a comorbid condition in rheumatic diseases. Population studies have confirmed an increased incidence in patients with rheumatoid arthritis, systemic lupus erythematosus and systemic sclerosis. Additionally, studies have shown worse disease outcomes including increased mortality in patients with rheumatoid arthritis underscoring the need to identify and address depression in these populations.

Provider Perspectives on Co-morbid Depression (table 3)			
Question Asked	**Agree**	**Disagree**	**Neither**
Does it change management?	75% (9/12)	8% (1/12)	8% (1/12)
Does we play a role?	83% (10/12)	8% (1/12)	8% (1/12)
If not notified of screen, assume negative?	17% (2/12)	25% (3/12)	58% (7/12)
	Most or sometimes	**Seldom or Never**	
I have enough time during the visit to address screens	42% (5/12)	58% (7/12)	

This study assesses rates of screening and identifying depression after implementation of universal PHQ9 depression screening in an outpatient rheumatology clinic. We further evaluate any impact of rheumatologic diagnosis on rates of screening and explore provider beliefs on the role of the rheumatologist in addressing comorbid depression.

Methods: Universal PHQ9 screening was implemented in an outpatient rheumatology clinic consisting of physicians, physician assistants, and rheumatology fellows. Medical assistants would perform PHQ2 screens on all patients prior to their encounters and if positive would then perform full PHQ9 screens. If these were positive then the provider responsible for the encounter was notified and further triaging was left to their discretion.

A retrospective chart review of 16 random clinic dates between January 2020 and March 2020 was conducted. Race, age, gender and reason for clinic visit were collected. Each patient's PHQ9 score was identified as well as their "established rheumatic disease" defined as what was entered into their reason for follow up by the provider or documented as such in the note. The chart was then reviewed to see if the provider responded to the screen by referring to a behavioral health liaison, adding this to the problem list, or discussing it in their assessment and plan. If none of these actions were done then the screen was considered to be "Not Addressed".

Also, an anonymous survey was performed to assess rheumatology provider beliefs pertaining to co-morbid depression screening.

Results: Out of 530 patient visits, 432 had PHQ9 completed. 26/432 PHQ9 screens were positive (6%). Among positive screens, only 27% (7/26) were addressed (table 1). Out of the 18 patients with rheumatic disease that screened positive only 4 were addressed. There were also a large number of patients with rheumatic disease (43) who did not have screening performed at all despite clinic protocol (table 2). Out of the 12 providers that completed the survey the majority felt that co-morbid depression changed management (75%) and that they played a role (83%). 58% of providers felt they seldom or never had time to address the screens (table 3).

Conclusion: In spite of universal screening and the in office presence of a behavioral health liaison, the majority of positive PHQ9 results were not addressed. This trend remained true in patients with established rheumatic diseases suggesting that although providers recognize the importance of co-morbid depression there remains a care delivery gap in this subset of patients even with the addition of extra protocols and resources.

Table 1. Patient Reported Outcome Workflow Survey Results from 12 RISE PRO LC Centers

Background/Purpose: The use of patient reported outcomes (PROs) during rheumatology visits may facilitate shared decision making and encourage patients to share their health goals. However, few studies have analyzed how PROs are collected, stored, and discussed with patients in clinical practice. The Rheumatology Informatics System for Effectiveness Patient Reported Outcome Learning Collaborative (RISE PRO LC) launched in March 2019 as a national coalition of 15 medical centers from 10 states to exchange quality improvement ideas, such as how to leverage the electronic health record (EHR) to utilize PROs for patient care. We surveyed participating sites about PRO workflows and potential barriers to using PROs to engage patients in decisions about their RA treatment during office visits.

Methods: During the first quarter of 2020, 12 RISE PRO LC site physician champions completed a survey about PRO workflows. The survey collected information on the PROs used routinely in practice, the EHR systems employed, and also qualitative information about when and how PROs were collected, how the data were stored and retrieved, and how PROs were shared with patients. Descriptive statistics and thematic analysis using an inductive approach were used to analyze the survey data. Responses were coded, grouped into themes, and summarized.

Results: Of the 12 centers with responses, 2 were Veterans Affairs sites, and 10 were clinics associated with an academic medical center or county health system. EPIC systems was the most commonly reported EHR, followed by NextGen® and CPRS. For PRO collection, 10 of 12 sites used paper forms solely to collect PROs from patients in waiting rooms or exam rooms, while 1 used tablets alone. One site used paper forms, tablets, and an online patient portal for collection. Frequently cited challenges for PRO collection included inconsistent staffing, busy workflows for medical assistants, and language barriers. For PRO documentation in the EHR, 6 sites relied on structured data fields, while the remaining sites required providers to type PROs in the free-text of clinical notes. The sites that captured PROs in structured fields reported EHR capacity to review prior PRO scores longitudinally. Nine centers reported that clinicians regularly shared PROs with each patient during clinical visits. Only 1 site had capacity for patients to view PRO results between clinical encounters. Four of 6 sites that recorded PROs in structured EHR fields reported regularly sharing PROs with patients either during or after a clinical encounter (Table 1).

Conclusion: Although RA PROs were routinely collected in the participating rheumatology clinics surveyed, processes to gather, access and share PROs with patients highly varied. A vast majority of practices still employ paper surveys to collect PROs, and only half reported having structured data fields in their EHRs to store and longitudinally track PROs over time. PRO results were inconsistently shared with patients. These findings suggest significant opportunities to optimize workflows to collect, longitudinally store, and share PROs with patients to promote shared decision-making during rheumatology encounters.

Table 2. Association of EHR type with PRO documentation.

Background/Purpose: Routine collection of disease activity and patient reported outcomes (PROs) such as functional status assessment in rheumatoid arthritis (RA) are nationally endorsed quality measures and an important component of tracking outcomes and improving care. However, little is known about the health information technology barriers and facilitators to the routine collection of disease activity and PROs in rheumatology practice: there may be features of specific electronic health record (EHR) systems used by rheumatologists that facilitate collection of RA outcomes. Using the American College of Rheumatology's RISE registry of practices across the U.S., we analyzed the relationship between EHR type and performance on RA disease activity and functional status quality measures.

Methods: We analyzed 2018 data from practices enrolled in RISE. Our primary outcome was practice-level performance on 2 quality measures: (1) Disease activity assessment for patients with RA (the percentage of patients in a practice whose disease activity was assessed using a standardized tool at ≥ 50% encounters during 2018); (2) Functional status assessment for patients with RA (the percentage of patients in a practice whose functional status was assessed using a standardized tool at least once during 2018). Multivariable linear regression models were used to examine the independent effect of EHR type on practice-level performance after adjusting for practice characteristics (practice type, size, and geographic region). To account for differences in case mix, we also adjusted for aggregate characteristics of patients seen in the practice (proportion of patients≥65 years, proportion female, proportion non-White, and proportion with non-commercial insurance).

Results: We included 220 practices who cared for 314,793 patients; the median (IQR) number of patients per practice was 982 (397, 1993). Most were single-specialty group practices (53.2%). NextGen was the most commonly used EHR vendor (48.1%), followed by eClinicalWorks (15.8%; Table 1). Overall, mean (SD) practice-level performance was 39% (37) for disease activity and 34% (38) for functional status. Even after adjusting for practice characteristics and patient case mix, performance on disease activity and functional status assessments was dramatically lower in some practices with less commonly used EHRs (Table 2).

Conclusion: Among practices participating in RISE in 2018, we found significant variation in performance on RA disease activity and functional status PRO measures across EHRs, even after adjusting for practice characteristics and case-mix. Although a causal relationship cannot be determined here, future research should investigate whether

features of EHRs that facilitate rheumatology practice, such as the ability to enter PRO data into structured fields, may facilitate higher quality of care. Sharing features and developing rheumatology-specific standards for EHRs could help promote the routine collection of RA measures, which in turn could improve RA outcomes.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

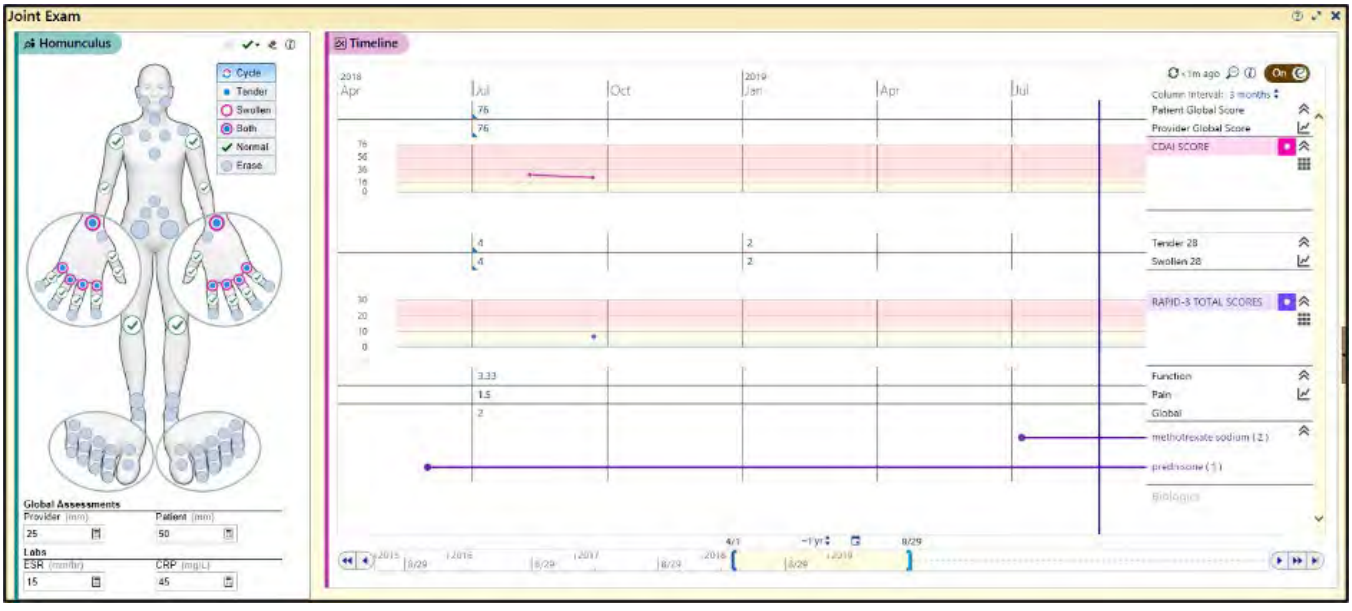

Figure 1. Rheumatology Dashboard (Epic Electronic Health Record) © 2020 Epic Systems Corporation. Used with Permission.

Background/Purpose: Increasing evidence exists that health outcomes are improved when people living with a chronic condition partner with their clinicians to coproduce their care based on their values, preferences, goals, and the best scientific evidence. This partnership may be aided by a data display tool, or dashboard, that presents longitudinal patient-reported outcomes (PROs), clinical data, and medications and is reviewed together to co-assess health status and co-decide next steps in the plan of care. This study assesses the utility of a dashboard to support coproduction of care for adults with RA.

Methods: We pilot tested the rheumatology dashboard with two rheumatologists and their adult RA patients at a rural academic health system. The dashboard resides within the Epic electronic health record and aggregates PROs and clinical data in real-time for review by the patient and clinician together (**Figure 1**). PRO data include the Routine Assessment of Patient Index Data (RAPID3); and, clinical data include the Clinical Disease Activity Index. RA-specific medications (Biologics, DMARDs, steroids, NSAIDs) map to the dashboard. Consecutive RA patients completed a a 19-item survey following their clinic visit to assess the impact of the dashboard on communication and shared decision making with their clinicians. Data were collected between January and March 2020. Feedback from clinicians was collected during biweekly meetings with the research team.

Results: Nineteen consecutive adult RA patients completed the post-visit survey. Mean (SD) age was 57 (12), 79% were female, 56% had a greater than high school education, and 39% had actively flaring RA (self-assessed). Three-quarters of patients (14 of 19) submitted pre-visit questionnaires (RAPID3) prior to their visit. Of those patients, 74% discussed the RAPID3 results with their clinician, and the clinician shared the dashboard in almost every visit that they discussed the RAPID3 (13 of 14). Two-thirds of patients (9 of 14) felt that the data and information in the dashboard was useful in discussions with their clinicians, helped them talk about what matters most, and helped them work with their clinician to make healthcare decisions. Half (7 of 14) felt that the dashboard helped them create a care plan that they could act on at home. Less than a third (4 of 14) thought that the data and information changed the content or focus of the discussion. Two thirds of patients (9 of 14) would recommend the dashboard to a friend or colleague with RA. Clinicians valued the ability to review and discuss with patients their disease activity over time and the impact of medications on their health status. Limitations included the small sample size as a result of decreased in-clinic visits during the study timeframe due to Covid-19.

Conclusion: Our study demonstrates that the rheumatology dashboard supports in-person review and discussion of PROs and clinical data and facilitates a meaningful dialogue and shared decision making between RA patients and their clinicians. Additional efforts are ongoing to spread the dashboard use to other clinicians in the department and to determine optimal use of the dashboard during telehealth visits.

Abstract Number: 1602

Assessing the Psychometric Properties of a Measure of Patient Empowerment with Patients with Arthritis

Erin Knight-Zhang[1], Kathleen Carluzzo[1], Karen Schifferdecker[1], Emily Creek[2], Rebecca Butcher[1] and Guy Eakin[2], [1]Dartmouth College, Lebanon, NH, [2]Arthritis Foundation, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The Health Care Empowerment Questionnaire (HCEQ) was developed for use in a general sample of patients to measure individual empowerment in health care and services (Gagnon et al., 2006), which can be considered an aspect of experience of care. The aim of this study was to validate the HCEQ, a patient-reported experience measure (PREM), for use with patients with arthritis and other rheumatic diseases by assessing its psychometric properties.

Methods: Data were collected from a convenience sample of adults with arthritis through online surveys administered between March 2019 to March 2020 through the Arthritis Foundation's LiveYes! INSIGHTS program. Experiences and importance of patient empowerment were measured using two domains of the HCEQ: Involvement in Decisions (6 items), which we call Patient Information Seeking, and Involvement in Interactions (8 items), which we call Result of Self-Advocacy. A larger sample was used to assess HCEQ internal consistency through Cronbach's alphas for each of the two subscales, as well as its measure structure through a confirmatory factor analysis (CFA; n=9229). A sub-sample of participants meeting inclusion criteria, including having completed the survey twice within 7 to 14 days, was used to assess test-retest reliability through Pearson correlation coefficients (n=186). Information on face validity was gathered from another sample of patients through qualitative data collection methods (n=5-59).

Results: After appropriate modifications, the CFA indicated good fit to the data for the two-factor structure of the HCEQ with this population, according to model fit indices (RMSEA = .047; CFI = .997; TLI = .993; SRMR = .012). The exception was the chi square, which was significant ($X^2 = 214.150$, $p < .001$), though this is susceptible to error when there are large sample sizes, as is the case here. Internal consistency was strong, with a Cronbach's alpha of .94 for both Patient Information Seeking and Result of Self-Advocacy. Test-retest reliability was moderate for Patient Information Seeking (r=.67) and good for Result of Self-Advocacy (r=.77). Qualitative data analysis indicated adequate face validity of the HCEQ for patients with arthritis.

Items by Subdomain	Lead-in and Response Options*	
	During the last 6 months, did you feel that...	*During the last 6 months, how important is it that...*
Patient Information-Seeking	Not at all (1)	Not important at all (1)
You asked for explanations	Somewhat (2)	Slightly important (2)
You asked questions	Quite a bit (3)	Very important (3)
You asked for advice	Very much (4)	Extremely important (4)
Result of Self-Advocacy		
You were able to talk to a professional to answer your questions		
Your choices were respected		
You obtained all the information you wanted		
You got the help you needed		

Note: Respondents rated feeling and importance of each item. Scores are calculated by summing the cross-product of feeling and importance ratings for items within the subdomain. There are three items in the Involvement in Decision subdomains and four items in the Involvement in Interactions, so the possible ranges are 3-48 points and 4-64 points, respectively.

Subdomains of the HCEQ, including items on each subdomain, lead-in to the items, and response options.

Conclusion: The HCEQ demonstrates promising psychometric properties when used with a sample of patients with arthritis and other rheumatic diseases. This lays the foundation for future work assessing additional psychometric properties of the HCEQ and examining patients' experiences with and desire for empowerment both for individuals with arthritis and in comparison to individuals with other conditions.

P4 Index Correlates with RAPID3 and Disease-Specific Indices in Rheumatoid Arthritis (RA) and Axial Spondyloarthritis (axSpA)

Abhijeet Danve[1], Betty Hsiao[2] and **Phillip Zhang**[3], [1]Yale University, Rocky Hill, CT, [2]Yale Rheumatology, New Haven, [3]Yale University, New Haven, CT

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: RAPID3 scores correlate well with disease-specific indices, including the Clinical Disease Activity Index (CDAI) in RA and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in axSpA, and are being widely used in clinical practice[1,2]. However, being a patient-reported outcome, RAPID3 can be affected by additional sources of pain, including fibromyalgia, prior joint damage, and psychosocial reasons such as anxiety or depression. Adding a physician global estimate (MD Glob) to RAPID3 (we termed it P4 index: pain, physical function, patient global, and physician (MD) global) may add an objective component and help filter out extraneous factors affecting disease activity measurements. In this observational study, we assessed performance of P4 index by comparing it against RAPID3 and CDAI in RA and RAPID3 and BASDAI in axSpA patients.

Methods: Consecutive patients with RA and axSpA under the care of three clinicians at one academic Rheumatology center completed the Multidimensional Health Assessment Questionnaire (MDHAQ) during their clinic visits with RAPID3 scores subsequently calculated. CDAI and BASDAI scores, respectively, were also recorded at the same visit and the clinician would separately report a physician global estimate (MD Glob) in the Electronic Medical Record. P4 score was calculated by adding MD Glob to the RAPID3 score (score range 0 to 40). Statistical significance between all scores was analyzed using Spearman correlation coefficients. Subgroup analysis was performed including only RA and axSpA patients with concomitant osteoarthritis, fibromyalgia, or anxiety/depression.

Results: We enrolled 40 patients with RA and 17 patients with axSpA; additional enrollment was limited by the coronavirus pandemic. Among RA patients, the mean (SD) CDAI was 8.8 (10.1), mean (SD) RAPID3 was 8.48 (7.9), and mean (SD) P4 was 11.2 (9.7). CDAI and RAPID3 correlated significantly (rho=0.91, $p< 0.001$). CDAI and P4 also correlated significantly and at somewhat higher levels than RAPID3 (rho=0.95, $p< 0.001$). Similar results were noted in subgroup analysis for RA patients (Table 1). Among axSpA patients, the mean (SD) BASDAI was 4.6 (2.5), mean (SD) RAPID3 was 12.7 (8.1), and mean P4 was 16.7 (9.9). BASDAI and RAPID3 correlated significantly (rho=0.81, $p< 0.001$). BASDAI and P4 also correlated significantly at a similar level (rho=0.82, $p< 0.001$). Subgroup analysis of axSpA patients showed similar results (rho=0.87 vs 0.88, see Table 2).

Table 1a. Spearman correlation coefficients for CDAI, RAPID3, and P4 indices in patients with RA (n=40)		
p<0.001 for all comparisons	CDAI	RAPID3
P4	0.9460	0.9838
RAPID3	0.9087	
Table 1b. Spearman correlation coefficients for CDAI, RAPID3, and P4 indices in RA patients with concomitant osteoarthritis, fibromyalgia, or anxiety/depression (n=30)		
p<0.001 for all comparisons	CDAI	RAPID3
P4	0.9459	0.9773
RAPID3	0.9040	

Table 2a. Spearman correlation coefficients for BASDAI, RAPID3, and P4 indices in patients with axSpA (n=17)		
p<0.001 for all comparisons	BASDAI	RAPID3
P4	0.8196	0.9933
RAPID3	0.8134	
Table 2b. Spearman correlation coefficients for BASDAI, RAPID3, and P4 indices in axSpA patients with concomitant osteoarthritis, fibromyalgia, or anxiety/depression (n=14)		
p<0.001 for all comparisons	BASDAI	RAPID3
P4	0.8845	0.9923
RAPID3	0.8711	

Tables 1 and 2

Conclusion: Our study demonstrates a high degree of correlation between P4 index and RAPID3 as well as validated disease-specific activity indices in both RA and axSpA patients. P4 index has an objective component in the form of MD Glob that may help to adjust for extraneous factors affecting disease activity measurement and management decisions. It would be important to confirm our findings in subsequent larger studies. Overall, using the P4 index may be a quick and practical way to more reliably trend disease activity in RA and axSpA.

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To date, information about the impact of the Coronavirus Disease (COVID-19) pandemic on rheumatology practice and on rheumatologists is limited.

The primary objective of the study was to evaluate the impact of the COVID-19 pandemic on rheumatology practice in the Arab countries. Secondary objectives were to evaluate the impact of COVID-19 on the rheumatologists and to develop recommendations to improve the rheumatology practice.

	Levant	Gulf	North Africa	All	p

Table 2. Factors associated with a higher impact on the outpatient clinic activity

Methods: A cross-sectional 21-items web survey was designed by members of the Arab League of Associations for Rheumatology (ArLAR) and validated by its scientific committee in English and in French. The survey was disseminated by e-mail and on social media to all rheumatologists in the 15 ArLAR countries. It comprised 19 close-ended questions about demographic characteristics, impact of the pandemic on the activities (in percentage, where 100% corresponds to complete suspension), attitude towards telemedicine, and two open-ended questions about the unmet needs and the ways to improve the practice. Recommendations were developed to improve practice during the pandemic.

Results: Between May 9 and May 24, 2020, 858 rheumatologists were included in the analysis (27.3% of registered rheumatologists in the ArLAR countries), 37% were in the 35-44 years age category, 60% were females and 48% worked in the private sector (Table 1). The impact of COVID-19 on the rheumatology practice was significant (Figure 1), with a decrease of 69% on hospitalization, 65% on outpatient clinic, 56% on infusion centers and 43% on income. A higher impact on the outpatient clinic activity was associated with the region (highest impact in North Africa, lowest

in the Levant), using telemedicine, and impact on income, The higher impact was negatively associated with working in the private sector (compared to the public sector and university teaching hospitals) (Tabl2 2). Telemedicine was used in 70% of cases, but mostly based on traditional telephone contacts and e-mails, and was reimbursed in only 12%. The mental impact related to the stress caused by COVID-19 was reported in 77% of the respondents (minor in 60.4%, major in 16.7% of cases). Fifteen rheumatologists (1.8%) were personally infected. The participants reported 156 cases of COVID-19 among their patients, of whom 22% died. The top-cited unmet needs were: access to drugs and a telemedicine platform.

Conclusion: The COVID-19 pandemic had a significant negative impact on the rheumatology practice in the Arab countries. Accordingly, better access to drugs and providing telemedicine platforms are recommended to improve rheumatology practice in the region.

Abstract Number: 1605

Knowledge of Biosimilars and Perceptions of Biosimilar Naming Conventions in Clinical Practice

Criswell Lavery[1], Marianna Olave[2], Charles Leonard[1], Vincent Lo Re[1], Jonathan Kay[3] and Joshua Baker[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, [3]University of Massachusetts Medical School, Worcester, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The market introduction of biosimilars has generated the need for novel biologic naming conventions, in part to support pharmacovigilance. We evaluated the familiarity of health care practitioners and other clinical professionals with biosimilars and their perceptions regarding the Food and Drug Administration's (FDA's) nomenclature for biologics in clinical practice. We hypothesized that health care providers would be unfamiliar with key concepts surrounding biosimilars and the FDA four-character suffix and would vary in their perceived value of the naming guidance in clinical practice.

Methods: A survey was emailed every two weeks over a two-month period to health care professionals within two large health care systems in the Philadelphia area: University of Pennsylvania Health System and the Corporal Michael J. Crescenz VA Medical Center. The survey was sent to prescribers and other health care administrators such as pharmacists, nurses, and medical coders. Prescribers received a survey if they had previously prescribed at least one biosimilar therapy from a query of prescription data from the electronic medical record. The survey assessed knowledge of key aspects of biosimilar therapies and the perceived utility of the FDA naming convention in practice. Differences in responses across prespecified sub-groups were tested using c^2 and Fisher's exact tests.

Results: The survey was sent to 506 prescribers and other clinical staff; 50 were returned from inactive email addresses. Of the remaining 456, 83 (~18%) responded. Most were from the University of Pennsylvania, with the highest number of responses coming from the Divisions of Hematology/Oncology and Rheumatology, and the Department of Pharmacy. Of respondents that identified being 'out of training', 14 (45%) had >10 years of clinical experience. Of

Table 1. Biosimilar

	Answered Correctly	Answered Incorrectly	p-value
K1. A biosimilar that has been approved by a regulatory body through a highly regulated pathway has a similar efficacy and comparable safety and immunogenicity compared to the originator product. (True)			
Overall	67 (81%)	16	
Prescribers	51 (77%)	15	0.17
Administrators	16 (94%)	1	
Those who use biosimilars	48 (96%)	2	<0.001

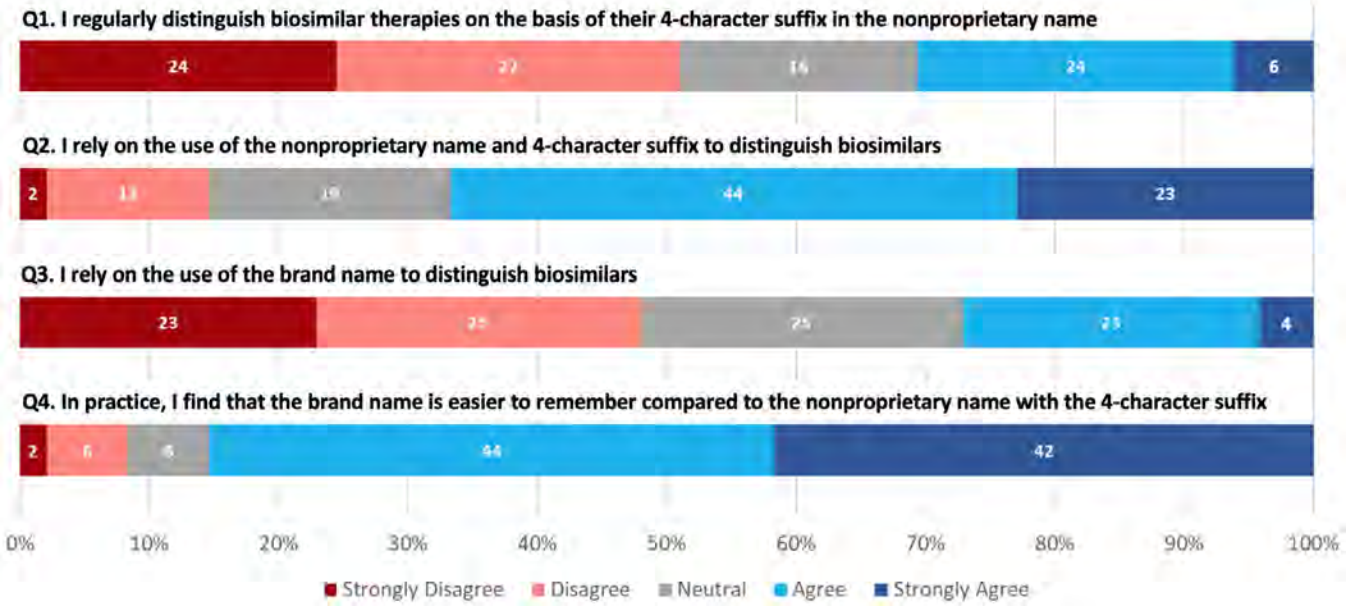
K2. Biosimilars are generics of originator biologic drugs. (False)			
Overall	43 (52%)	40	
Prescribers	28 (42%)	38	<0.001
Administrators	15 (88%)	2	
Those who use biosimilars	31 (52%)	29	0.04
Those who don't use biosimilars	12 (36%)	21	
K3. A biologic must have the exact amino acid sequence as the originator product. (True)			
Overall	26 (31%)	57	
Prescribers	21 (32%)	45	1
Administrators	5 (29%)	12	
Those who use biosimilars	22 (44%)	28	0.003
Those who don't use biosimilars	4 (12%)	29	
K4. Biosimilars are "interchangeable" with the originator product. (False)			
Overall	29 (35%)	54	
Prescribers	20 (30%)	46	0.14
Administrators	9 (53%)	8	
Those who use biosimilars	19 (38%)	31	0.63
Those who don't use biosimilars	10 (30%)	23	
K5. There is similar variability between originator product lots as there is a variability between biosimilars and originator products. (True)			
Overall	43 (52%)	40	
Prescribers	34 (52%)	32	1
Administrators	9 (53%)	8	
Those who use biosimilars	33 (66%)	17	0.003
Those who don't use biosimilars	10 (30%)	23	

This table includes the results of True and False questions designed to test knowledge of basic concepts of biosimilar therapies. All respondents are stratified by Prescribers vs. Administrators, and Those who use biosimilars vs. Those who don't use biosimilars in practice. For the purposes of these questions, "Those who use biosimilar drugs" includes both Prescribers as well as Administrators who encounter biologics. The correct answer is included at the end of the question. Total correct answers shown alongside in percentages. Incorrect totals include any marked 'Unsure' responses.

those still 'in training', 27 (93%) were residents or fellows. Although respondents had a general understanding of the regulatory criteria for approval, knowledge about biosimilars was generally poor (**Table 1**). For example, only 52% of all respondents correctly identified that a biosimilar differed from a generic drug. When asked about biosimilar

Figure 1. Biosimilar Use

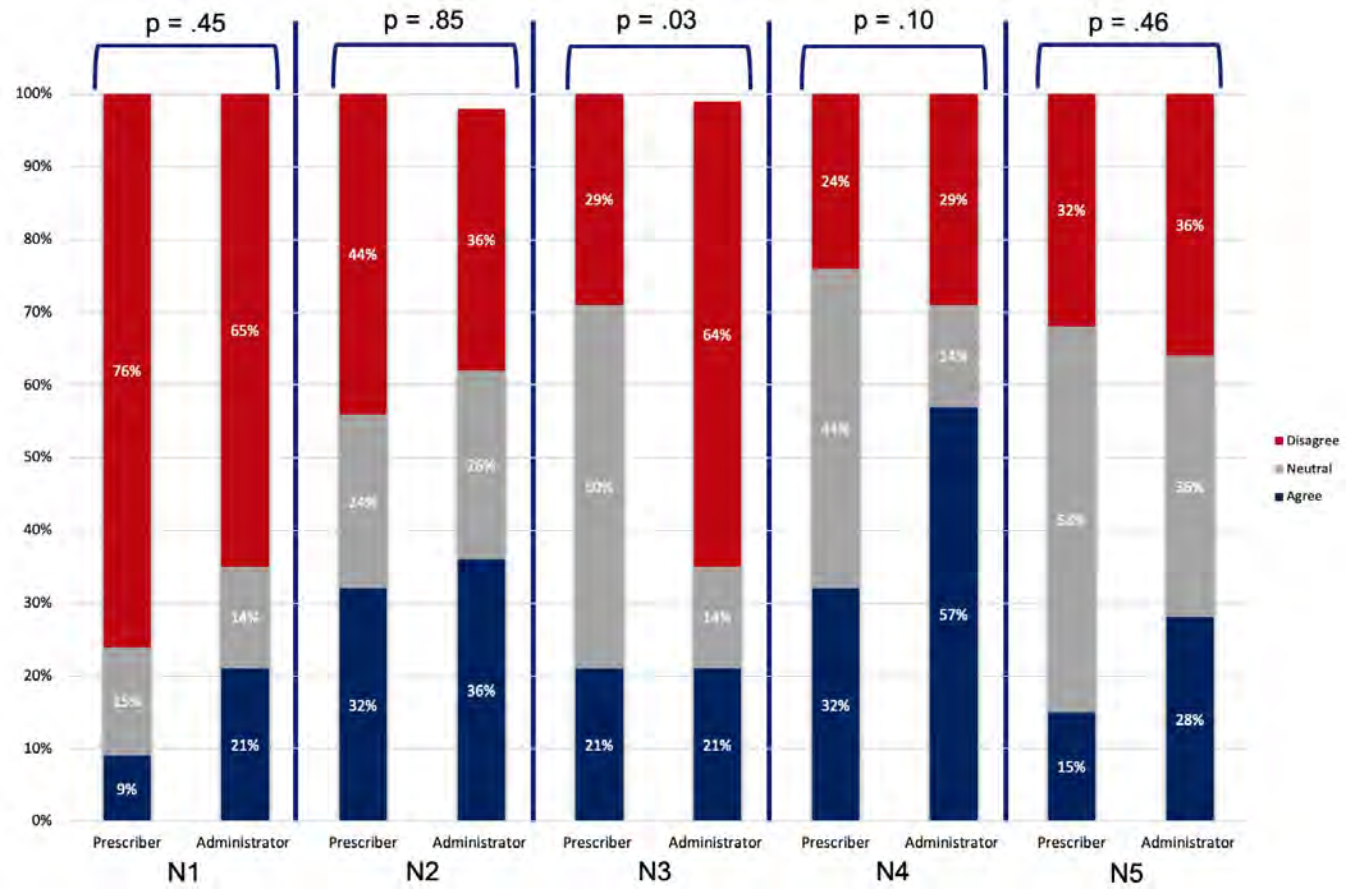


Questions related to general use of biosimilar identifiers in clinical practice. All questions included: To what degree do you agree with the following?

naming conventions, 67% reported using the brand name in clinical practice to distinguish between biosimilars and reference products. In contrast, as shown in Figure 1 (**Q1**), only a minority of respondents reported regular use of the four-character suffix to identify biologic therapies. Overall, there was little agreement on the utility of the four-character suffix in many aspects of care. For example, a majority of respondents (68% overall) indicated a neutral response when asked if the four-character suffix promoted medical errors (**Figure 2, N5**). Most prescribers (76%) disagreed that the 4-character suffix affected their decision to use biosimilars.

Conclusion: These survey findings suggest a knowledge gap with regard to biosimilars and lack of consensus about the usefulness of employing the four-character suffix in clinical practice. The lack of overall familiarity with biosimilars may also have contributed to a lack of comfort with the naming convention.

Figure 2. Naming Preference



Questions regarding naming preferences. All questions included: To what degree do you agree with the following? The questions are detailed below: N1. I am less likely to use biosimilars compared to the originator product because the nonproprietary names of biosimilars are different from the originator product. N2. I have experienced that the use of brand names to distinguish biosimilars introduces commercial bias in clinical practice. N3. The 4-character suffix in the non-proprietary name influences patients to think there are important differences between biosimilars and the originator products. N4. The 4-character suffix in the nonproprietary name causes inefficiencies due to inconsistencies with other naming systems in practice. N5. The use of the 4-character suffix in the nonproprietary name to distinguish biosimilar therapies in practice promotes medication errors in the ordering of biologics.

Mortality with Idiopathic Inflammatory Myositis in an Academic Hospital Setting: A Five-year Retrospective Study

Jaspreet Kaler[1], Zareen Vaghaiwalla[2], Gurjit Kaeley[3] and Myint Thway[4], [1]University of Florida - Jacksonville, Jacksonville, FL, [2]University of Florida Jacksonville, Jacksonville, FL, [3]University of Florida College of Medicine - Jacksonville, Jacksonville, FL, [4]University of Florida- Jacksonville, ponte vedra, FL

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myositis is a diverse group of muscle diseases characterized by muscle inflammation and dysfunction. Approximately 3-7/100,000 cases are diagnosed per year in the United States. Eight major subgroups were defined in the 2017 EULAR/ACR classification criteria including polymyositis and dermatomyositis. Recent availability of specific antibodies has helped to further phenotype myositis. Historically, these diseases have been associated with poor prognosis as many patients suffer interstitial lung disease, malignancies,

Table 1. Characteristics of Myositis Patients Admitted (n=20)	
Mean Age	53

ILD associated	4/5 (80%)
Swallow Study Completed	1/5 (20%)
Spirometry Completed	4/5 (80%)

Table 2. Characteristics of Deceased Myositis Patients

and infections. In fact, 10-year survival rates for myositis varies from 57-71% depending on the cohort analyzed. A low threshold for diagnosis, treatment and medication escalation is important due to the significant morbidly and mortality.

The aim of our study was to assess prevalence and mortality rate of patients with inflammatory myositis admitted to University of Florida Health-Jacksonville in the past 5 years. The goal was to determine factors associated with mortality in this patient population that could be modified in future. Ultimately, this study is to aid in the development of institutional protocols to improve survival of patients with inflammatory myositis.

Methods: Retrospective evaluation of patients admitted with inflammatory myositis and mortality during the hospitalization was completed by electronic medical record review from 1/1/2014-12/31/2018. Patients were generated by providing the Information Technology department with a list of International Classification of Disease (ICD) 9 and 10 diagnosis codes related to myositis.

Results: The search generated yielded 1489 charts, of which 46 patients were identified as idiopathic inflammatory myositis. Of these patients, 20 were specifically admitted for worsening myositis features with a mortality of 5 patients, yielding a 25% mortality rate. Characteristics of myositis patients admitted and deceased are given in Tables 1 and 2. The major causes of death were respiratory failure and dysphagia. We noted 3/5 patients had mortality related to dysphagia and 2/5 patients had mortality related to respiratory failure. We also noted 4/5 deceased patients suffered from interstitial lung disease and only 1/5 had a swallow study, 4/5 had spirometry completed, and 3/5 patients had myositis-specific-antibodies tested.

Conclusion: Although dysphagia and interstitial lung disease are known features of myositis clinical syndromes, they portended a worse prognosis for our myositis population. This study highlighted the importance of aspiration and respiratory monitoring in patients suffering from inflammatory myositis as related to mortality. Process improvement should include routine evaluation of swallowing, precautions for aspiration as well as monitoring negative inspiratory function in patients admitted with myositis. In addition, obtaining myositis-specific-antibodies may be beneficial to risk stratify patients that may be resistant to treatment, leading to mortality.

Abstract Number: 1607

Effectiveness of Dietary Counseling on Gout Management and Risk Factors for Metabolic Syndrome in Gout Patients

Juliana Chang[1], Jonathan Tsui[2] and Maida Wong[3], [1]Division of Rheumatology, Department of Medicine, University of California Irvine, Irvine, CA, [2]Geisinger Medical Center, Danville, PA, [3]Division of Rheumatology, Department of Medicine, VA Long Beach Healthcare System, Long Beach, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most prevalent inflammatory arthritis globally. Despite treatment advances, the prevalence of gout has continued to increase over the last several decades. There has also been increasing evidence

that gout has a strong association with the metabolic syndrome. This suggests that gout is likely both an inflammatory and a metabolic disease that has a significant effect on quality of life and healthcare costs. While current recommendations support aggressive medical therapy for gout treatment, dietary counseling is less emphasized. We hypothesize that emphasis on nonpharmacological therapy will likely improve management and the metabolic syndrome in gout patients.

Methods: A retrospective cohort study was created from 2009-2016 involving Long Beach Veterans Affairs Hospital gout patients (n= 130) based on International Classification of Disease version 9 or 10. Patients were then stratified into two cohorts: received diet counseling (n=100) and no diet counseling (n=30). Data was reviewed for 24 months following initial gout diagnosis or intervention. Management was evaluated based on frequency of flares and related ED visits, change in creatinine clearance, serum uric acid levels (sUA), and changes to risk factors for metabolic syndrome including blood pressure, body mass index (BMI), cholesterol panel and hemoglobin A1c levels (HA1c) at six-month intervals.

Results: Although patients in both cohorts had a trend of fewer gout attacks with time, those who received diet counseling had a significant decrease in number of attacks by 12 months ($p = 0.002$), and more so in 18 months ($p = 0.001$). After diet counseling, more patients reached their target sUA (sUA< 6 for nontophaceous gout and sUA< 5 for tophaceous gout) ($p = 0.002$) in 6 months and remained at goal at 24 months ($p < 0.001$), with improved creatinine clearance ($p = 0.06$) and HDL ($p = 0.08$). Patients with improved LDL and HDL values were more likely to have improved sUA levels (R^2=0.4, slope 0.03 and R^2=0.4, slope 0.16, respectively) by 6 months. Patients with improved HA1c and LDL values had fewer ED visits within the first 6 months (R^2=0.4, slope 0.14 and R^2=0.4, slope 0.05, respectively). Patients with improved HA1c were associated with decreased sUA at18 months (R^2=0.5, slope 0.2).

Conclusion: Gout patients who receive diet counseling had better control of sUA and a lower rate of future attacks and ED visits. Risk factors associated with metabolic syndrome improved in these patients, with better control of their HA1c, LDL and HDL, and they achieved lower sUA levels. This implies that controlling diabetes and hyperlipidemia in patients may help improve gout management. Given the serious complications and increased cardiovascular risks that can be associated with metabolic syndrome, optimization of gout through a nonpharmacologic intervention such as diet counseling can enhance clinical outcomes and optimize healthcare resources.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound-guided synovial biopsy (USGSBx) is a well-established minimally-invasive alternative to arthroscopy for sampling synovial tissue. Adverse event rates in published studies are favourable by comparison with arthroscopy, but a large-scale evaluation of the safety of these procedures is required.

Methods: A survey of USGSBx safety and practice was devised within the European Synovitis Study Group (ESSG). Respondents were asked to complete either an online web-form, or a spreadsheet data-collection tool encompassing centre-level information regarding facilities and training for USGSBx, anonymised information about USGSBx practitioners, and a comprehensive list of USGSBx procedures with any resultant complications. A systematic literature search was performed and email survey invitations sent to individuals featuring on publications reporting the use of USGSBx. ESSG members, and those known to be involved in USGSBx as part of a network or collaboration were also invited, and respondents asked to identify any other centres in their country believed to be performing USGSBx. One response was requested per centre.

Results: The first 15 responses from centres in 11 countries and encompassing 35 practitioners are presented. 10 centres reported performing USGSBx needle biopsies, and 7 using the portal & forceps technique. 8 centres arranged for routine patient follow-up face-to-face, with 5 centres following patients by telephone. 8 centres routinely issued patients with an alert card after their procedure.

1874 biopsies were reported, 1252 (67%) performed primarily for research, and 622 (33%) for a clinical indication. Intra-articular steroid was administered after 162 (8.6%) of the procedures. Procedures performed on 15 anatomical structures were reported, with the most commonly sampled being the knee (54%), wrist (29%), metacarpophalangeal (6%), ankle (5%), elbow (1%), shoulder (1%), metatarsophalangeal (1%), hip (1%) and proximal interphalangeal (1%)

	Frequency of complications	
	n	%
No reported complication	**1671**	**89.2%**
Total of reported complications	**210**	**11.2%**
Resolving arthralgia or local pain requiring analgesia	132	7.0%
Reaccumulation of fluid requiring review	24	1.3%
Presyncopal episode	13	0.7%
Prolonged superficial bleeding	9	0.5%
Post-procedure flare of arthritis	6	0.3%
Mild superficial haematoma	5	0.3%
Nerve damage - transient	4	0.2%
Wound infection	3	0.2%
Haemarthrosis	3	0.2%
Transient erythema	3	0.2%
Wound leakage	2	0.1%
*Tendon limitation without rupture	2	0.1%
Anxiety	1	0.1%
*Instrument failure	1	0.1%
Mild muscular haematoma	1	0.1%
*Nerve damage - persistent	1	0.1%

Table 1. Complications arising from minimally-invasive ultrasound-guided synovial biopsy procedures (1881 reports from 1874 procedures); major complications marked with asterisk (*)

joints. Other structures sampled included tendon sheaths, subacromial and subdeltoid bursae, acromioclavicular, sternoclavicular, and naviculocuneiform joints (all < 1%).

210 complications were reported from 1874 USGSBx procedures (see Table 1). For 5 procedures, 2 complications were reported, and for one 1 further procedure, 3 complications were reported. 4 major complications (marked with asterisk) were reported (0.21%), with no report of joint infection, thrombophlebitis, or deep venous thrombosis. 8 complications (none major) were reported in 162 procedures (4.9%) during which intra-articular steroid was used, and 202 complications reported in 1517 procedures (11.8%) in which intra-articular steroid was not used. Structures in which complications rates exceeded the average of 11.2% included the naviculocuneiform joint (1/1, 100%), elbow (8/27, 30%), MTP (4/16, 25%), and knee (123/1010, 12%) joints, although the sample size for some procedures is low.

Conclusion: Preliminary results of this survey of over 1,800 procedures, support the safety and tolerability of the minimally-invasive ultrasound-guided approach as an alternative to arthroscopy for synovial biopsy procedures.

Abstract Number: 1609

The Accuracy of Administrative Health Data for Identifying Patients with Rheumatoid Arthritis: A Validation Study Using Medical Records in Western Australia

Khalid Almutairi[1], Johannes Nossent[1], David Preen[1], Helen Keen[1], Katrina Rogers[2] and Charles Inderjeeth[1], [1]The University of Western Australia, Perth, Western Australia, Australia, [2]Sir Charles Gairdner Hospital, Perth, Western Australia, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of large administrative health datasets is increasingly important in Rheumatology for disease trends and outcome research. We established the West Australian Rheumatic Disease Epidemiological Registry containing longitudinal health data for over 10000 patients with Rheumatoid Arthritis (RA) in Western Australia (WA). Accuracy of coding for RA is essential to validity of the datasets. We investigated the diagnostic accuracy of International Classification of Diseases (ICD) based discharge codes for RA at WA's largest tertiary hospital.

Methods: Medical records for RA patients randomly selected from the hospital discharge database with ICD 10 codes (M05.00–M06.99) from 2008–2020 were retrospectively reviewed. Rheumatologist-reported diagnosis and ACR/EULAR classification were used as gold standards to determine positive predictive value (PPV) with 95% Confidence Interval (CI) for RA primary diagnostic codes.

Results: Medical chart review was completed for 87 patients (mean age 64.7 years, 67% female). Total of 80 (92%) patients had specialist confirmed RA diagnoses, while seven patients (8%) had alternate clinical diagnoses providing a PPV of 93.5% (95%CI: 89.9 to 95.86). Overall, 69 out 87 patients (79.3%) fulfilled ACR/EULAR classification criteria

Table 1: Accuracy measures of different algorithms for random sample of RA patients with one or more RA codes.

	Rheumatologist-reported diagnosis				ACR/EULAR classification criteria			
Administrative data	SN	SP	PPV	NPV	SN	SP	PPV	NPV
One or more RA primary codes	90%	28.5%	93.5%	7.6%	89.8%	16.6%	80.5%	30%
One or more RA biological infusion codes	25%	71.4%	90.9%	7.7%	20.3%	55.5%	63.6%	15.3%
Two or more RA codes including biological codes	60%	85.7%	97.9%	15.8%	56.5%	44.4%	79.6%	21%

SN=Sensitivity, SP=Specificity, PPV= positive predictive value, NPV= Negative predictive value.

Table 1. Accuracy measures of different algorithms for random sample of RA patients with one or more RA codes.

based on RA primary diagnostic codes with a PPV of 80.5% (95%CI: 76.81 to 83.7). A combination of a diagnostic RA code with biologic infusion codes in two or more codes increased the PPV to 97.9%.

Conclusion: Hospital discharge diagnostic codes in WA identify RA patients with a high degree of accuracy. Combining a primary diagnostic code for RA with biological infusion codes can further increase the PPV.

Cutaneous Side Effects of Hydroxychloroquine in Rheumatic Diseases –Combination of "Traditional" Multivariate Analysis for Risk Factors AndClassification Model Development Using Supervised Machine Learning –Single Centre Retrospective Cohort Study in India

Sandeep Surendran[1], Mithun CB[1], **Arun Tiwari**[2], Vishal Marwaha[1] and Sekhar Easwar[1], [1]Amrita Institute of Medical Sciences, Kochi, Kerala, India., Kochi, Kerala, India, [2]Amrita Institute of Medical Sciences, Kochi, Kerala, India., Kochi, India

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is associated with varied cutaneous side effects but only few studies in literature characterizing the risk factors for this. Recently machine learning tools have emerged as a promising option for predicting various outcomes. The aim of our study was to use "traditional" multivariate analysis along with novel machine learning (ML) methodology to analyze and predict for the occurrence of cutaneous side effects with HCQ usage.

Methods: Demographic, clinical details, laboratory parameters, treatment details of HCQ (dose/mg/kg, cumulative dose, duration of therapy) and coexistent DMARD prescription were collected for patients who were treated with HCQ for autoimmune rheumatic diseases from 2015 to 2019. Development of cutaneous side effects was the primary outcome of the study and the subtypes of cutaneous side effect were also noted (hyperpigmentation, photosensitivity and pruritus) retrospectively. Univariate and multivariate logistic regression for the primary outcome was done using SPSS 20.0. To develop the ML classification models for prediction of the primary outcome, we used Random Forest, Logistic Regression and K-nearest neighbour (KNN) algorithms from Python-3.0's scikit library. Hyperparameter tuning and five-fold cross validation were done for all three ML classifiers. After the three classifer models were trained, they were compared using accuracy scores on the test dataset. Precision and area under 'receiver operating curve' (AUC) of the highest accuracy model were also analyzed.

Results: Baseline characteristics of the 430 participants recruited are shown in Figure 1(A). 198 patients (46.04%) developed cutaneous side effects of which the most common was hyperpigmentation (n =182, 42.3%).15 patients stopped HCQ due to the cutaneous side effects. Figure 1(A) also shows the results of the univariate and multivariate regression analysis for development of cutaneous side effects. The risk factors identified were the cumulative dose of HCQ > 216,000 mg (OR 1.82, 1.22-2.73), combination treatment with MMF(OR 2.13, 1.10-4.09), or AZA(OR 2.05,

Identified risk factor	p-value (odds ratio and confidence intervals of multivariate analysis)
Cumulative dose (216000 mg or more)	**p= 0.004** (OR 1.82, 1.22-2.73)
ANA positivity	**p= 0.027** (OR 1.72, 1.06-2.8)
RF positivity	**p= 0.000** (OR 2.38, 1.51-3.76)
MMF combination	**p= 0.024** (OR 2.13, 1.10-4.09)
AZA combination	**p= 0.036** (OR 2.05, 1.04-4.01)

Abbreviations: OR Odds ratio, CAD coronary artery disease, CVA cerebro vascular accident

Figure 1

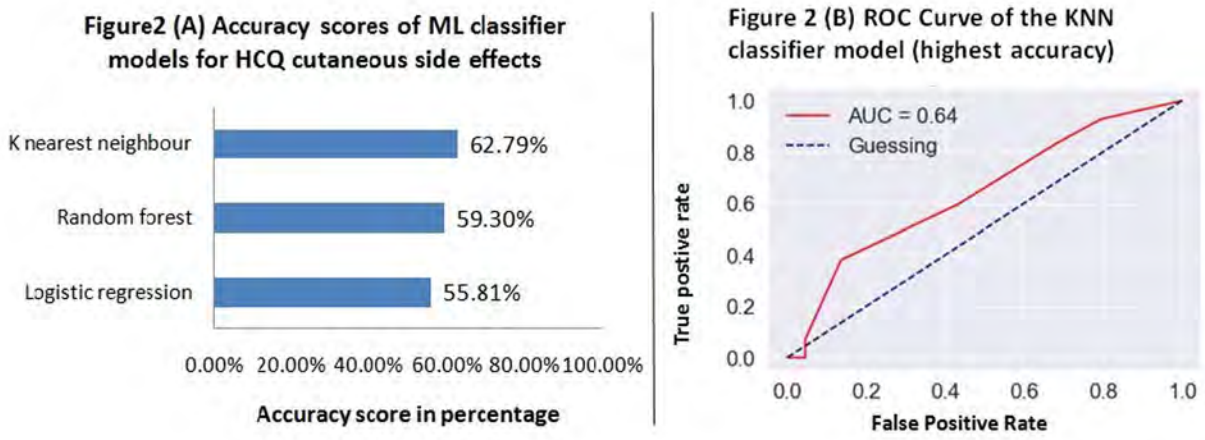

Figure 2

1.04-4.01) ANA positive (OR 1.72, 1.06-2.8), and RF positive(OR 2.38, 1.51-3.76) . Accuracy scores of three ML models are shown in figure 2A, with the KNN classifier model having the best performance. It achieved a 62.79% accuracy with precision of 0.6 and AUC of 0.64 (figure 2B).

Conclusion: Cutaneous side effects are common with HCQ treatment. While traditional statistical methods can help identify the risk factors, usage of supervised ML methods could help predict development of cutaneous side effects in an individual patient. Larger dataset analysis could allow for development of tailored therapeutic regimens avoiding adverse events.

Abstract Number: 1611

Documentation of Pregnancy Counseling in SSA-Positive Patients of Childbearing Potential: A Cross-Sectional Study

Heinrich-Karl Greenblatt[1] and Elena Weinstein[1], [1]University of Colorado School of Medicine, Aurora, CO

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) and primary Sjogren's Syndrome (SS) are highly associated with anti-SSA (anti-Ro) seropositivity. Anti-SSA autoantibodies may cross the placenta, causing a range of cutaneous and cardiac manifestations in the neonate. Approximately 2% of SSA-positive pregnancies result in complete congenital heart block, which is often fatal. Echocardiographic monitoring and early treatment with hydroxychloroquine may improve outcomes in SSA-positive pregnancies. Published data suggest that the majority of rheumatology clinic patients with the potential for high-risk pregnancies do not receive pre-pregnancy counseling, possibly due to provider anxiety or uncertainty in this area. We examined the rate of documentation of pre-pregnancy counseling in the specific case of SSA seropositivity.

Methods: We performed a cross-sectional study of 213 SSA-seropositive female patients age < 45 at a large, academic Rheumatology clinic. The majority of patients had a diagnosis of SLE or SS. We excluded 40 patients with a history of surgical birth control (e.g., tubal ligation or hysterectomy). For the remaining 173 patients, we manually reviewed electronic medical records to determine whether a discussion about the risks of SSA-seropositive pregnancy had ever been documented. We further ascertained several co-variates, including: lifetime history of normal, healthy pregnancy; lifetime history of spontaneous abortion and gender of the primary rheumatologist

Results: 67 out of 173 patients (39 percent) had documented counseling by a Rheumatologist regarding the risks of SSA-positive pregnancy. 84 patients (49 percent) had a history of at least one pregnancy; 35 of these had a history of at least one spontaneous abortion. . The rate of documented counseling was similar among patients with a primarily female Rheumatologist (39 percent) as compared to a primarily male Rheumatologist (34 percent).

Conclusion: Less than half of SSA-seropositive patients of childbearing potential have documented evidence of relevant pre-pregnancy counseling. Provider gender was not associated with a difference in the rate of counseling. These results corroborate previous data suggesting that high-risk Rheumatology clinic patients may not receive adequate pre-pregnancy counseling. Notably, these findings suggest that pre-pregnancy counseling is also underutilized in the specific instance of SSA seropositivity. Dedicated quality improvement initiatives are needed to increase the rates of SSA-specific pre-pregnancy counseling, as well as to ensure that such counseling is documented appropriately.

Assessing Patient Self-Reported Transition Readiness in a Large Pediatric Rheumatology Center

Alexander Alexander[1], Mary Robichaux[2], Priyanka Moolchandani[1], Cristina Saez[1], Ariel Coleman[3], JaLeen Rogers[3], Danielle Guffey[1], Anne Dykes[3], Miriah Gillispie-Taylor[1] and Tiphanie Vogel[4], [1]Baylor College of Medicine, Houston, [2]Baylor College of Medicine, Houston, TX, [3]Texas Children's Hospital, Houston, [4]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric rheumatology patients need effective transition from pediatric to adult providers. Texas Children's Hospital (TCH) rheumatology clinic providers have developed a transition pathway, the BRIDGE (Baylor Rheumatology Initiative: Developing and Guiding Engagement), based on defined elements of transition and utilizing an electronic medical record-based transition planning tool (TPT) to help with transition preparation.

Methods: The validated, self-administered Adolescent Assessment of Preparation for Transition (ADAPT) survey generates 3 composite scores (out of 100) for counseling on transition self-management and prescription medications, and on transfer planning. Return adolescent patients aged 14-19 years were surveyed regardless of diagnosis. Surveys were emailed via a REDCap database on the morning of clinic appointments between August-December 2018 and November 2019-May 2020. Surveys were scored and analyzed against demographics.

Results: 302 patients completed at least 1 survey. Serial surveys were collected on 59 respondents. Most respondents were female (71%) and white (75%); 42% were Hispanic. Most patients were privately insured (57%) or covered by Medicaid/Children's Health Insurance Program (38%). The most common diagnosis was juvenile arthritis (30%). Average initial ADAPT scores for all respondents were 37/100 for transition self-management, 66/100 for medication management, and 17/100 for transfer planning. Scores in all three domains increased with increasing patient age at first ADAPT survey ($p< 0.001$). Survey scores in self-management increased by 17 for each year since the first survey ($p< 0.001$), medications increased by 16 for each year since the first survey ($p< 0.001$), and transfer planning by 23 for each year since the first survey ($p< 0.001$). For transfer planning, higher patient age at first ADAPT survey was associated with larger increases in score over time. We noted that, on average, privately insured patients had 11-point lower initial scores in self-management than publicly insured patients ($p=0.029$). Further, we noted that, on average, English speaking patients scored 22 points lower on self-management and 20 points lower on medications than non-English speakers ($p=0.001$).

Conclusion: Our clinic has developed a method to assess patient self-reported transition readiness. Our data indicates that participating patients improved over time in all domains measured by the ADAPT survey. Going forward, we plan to analyze outcomes of transitioned patients to assess the efficacy of our pathway. Our ultimate goal is to create a sustainable and successful BRIDGE between pediatric and adult rheumatology care.

Improving Transition Policy Dissemination and Care Team Communication in Pediatric Rheumatology Clinic Through Standardization of Workflow and Electronic Health Record Documentation

Rosemary Peterson[1], Emily Liebling[1], Beth Rutstein[2], Julie Chase[1], Atiye Bilgic Dagci[3], Melissa Argraves[3], Jon Burnham[1], Lisa Wiater[3], Deborah Bieniakowski[3], Danielle Dodson[3], Jane Kennedy[3], Cora Sears[3] and Joyce Chang[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Morbidity and mortality increase when young adults with chronic disease transfer from pediatric to adult care. Structured healthcare transition processes improve outcomes, yet are rarely successfully implemented by pediatric rheumatology practices. Our goal was to standardize transition preparation and communication within a pediatric rheumatology care team to facilitate safe and timely transfer of patients to adult care.

Methods: This study was completed by a multi-disciplinary team of physicians, nurses and social worders within the Division of Rheumatology at a tertiary care pediatric hospital. Two of 4 key drivers were selected: 1) communication within the care team and 2) transition preparation (Figure 1). Standardizing review of the practice's transition policy with patients and families, a core component of the Got Transition Six Core Elements of Health Care Transition™

national guidelines, was selected as the initial secondary driver to improve. We included youth age 14 and older, with a clinical diagnosis of juvenile idiopathic arthritis, systemic lupus erythematosus, Sjogren's syndrome, mixed connective tissue disease, vasculitis, or juvenile dermatomyositis, and ^{3}2 Rheumatology follow-up visits. Consensus on revisions to a pre-existing transition policy was obtained through regular QI and staff meetings. Baseline patient surveys to assess awareness of the transition policy and transfer timing were collected 1 week per month from November 2019 to January 2020. In December 2019, nurses began to review printed transition policies with eligible patients during clinic visits and document review in the electronic health record (EHR) utilizing a standardized template

Table 1. Baseline Characteristics and Pre-implementation Survey Results (n = 57)

Age group	n (%)
14 to 15 years-old	19 (33%)
16 to 17 years-old	13 (23%)
≥ 18 years-old	25 (44%)

Figure 1.

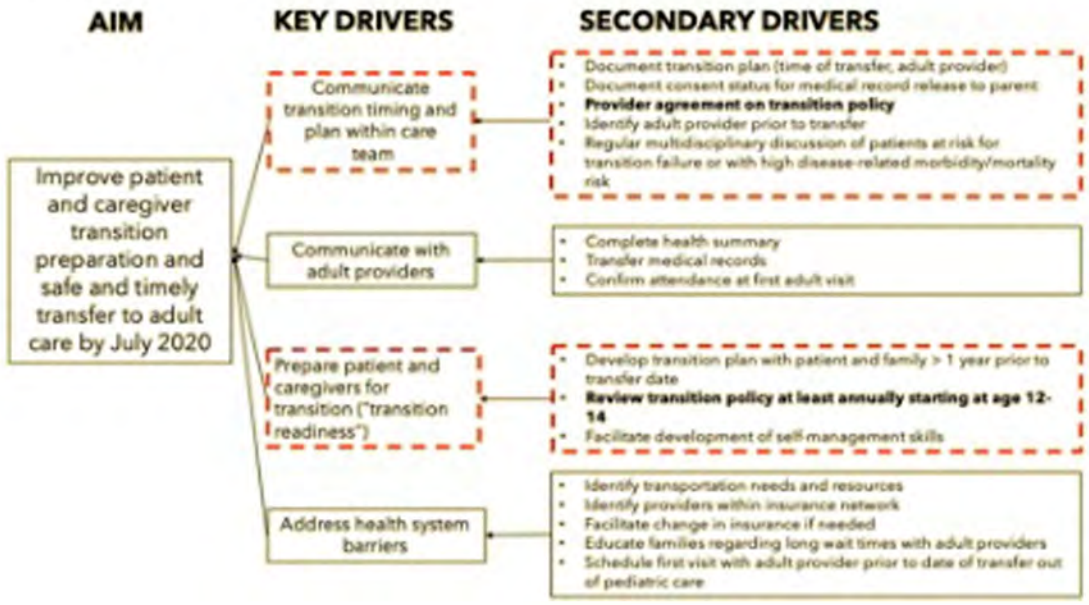

Figure 2.

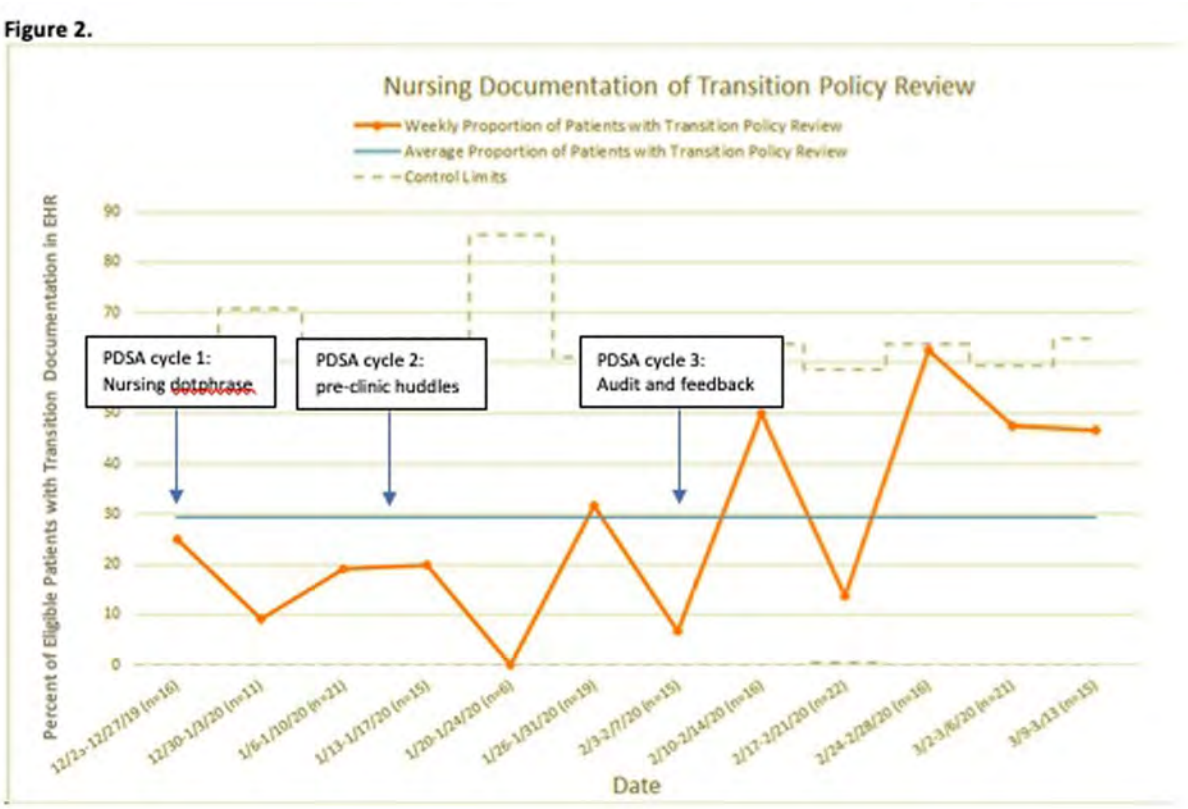

(Plan-Do-Study-Act (PDSA) cycle 1). In January 2020, pre-clinic team huddles were initiated to more consistently identify eligible patients (PDSA cycle 2). In February 2020, audit and feedback with review of monthly performance with the nursing team was added to monthly QI meetings (PDSA cycle 3).

Results: Table 1 summarizes baseline characteristics and survey data for all 57 respondents. Prior to implementation, 16% of patients reported prior transition policy receipt. Of patients age 18 and older (n = 25), only 32% had received the transition policy and 68% had discussed transfer timing with their care team. The proportion of eligible patients with EHR documentation of transition policy review was trending toward improvement at the time of project interruption in March 2020 due to COVID-19 (18% pre-implementation versus 42% post-implementation; Figure 2). Only 1 week of patient surveys reflecting the impact of interventions on awareness and understanding of the transition policy were able to be obtained prior to temporary cessation of routine in-person visits.

Conclusion: A minority of youth report receiving a transition policy or discussing timing of transfer to adult care with their care team. Workflow and EHR standardization, enhanced care team communication, and performance audit and feedback, may be effective strategies to implement transition processes. Future work is needed to determine the effect of regular transition policy review on patient preparation and safe and timely transfer to adult care.

Use of a Best Practice Alert to Encourage Transition Planning and Readiness

Bernard Danna[1], Monique Maher[1], Marietta DeGuzman[2], Andrea Ramirez[1], Eyal Muscal[2], Amanda Brown[2], Martha Curry[2], Maria Pereira[2], M. Brad Nelson[2], Pooja Patel[2], Ugo Awa[2], LeeGee Huang[3], Blanca Sanchez-Fournier[3], JaLeen Rogers[3], Ariel Coleman[3], Anne Dykes[3], Miriah Gillispie-Taylor[2] and Tiphanie Vogel[4], [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, Houston, [3]Texas Children's Hospital, Houston, [4]Baylor College of Medicine/ Texas Children's Hospital, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Transitioning children with chronic diseases from pediatric to adult care can be challenging. Patients are faced with the emotional shock of entering a new healthcare environment, along with the many technical burdens of learning how to navigate a complex new system. It is no wonder that both morbidity and mortality are higher in the time surrounding transition to adult care.

Fortunately, there is a movement to create standardized processes which empower patients to take ownership of their care. At our institution, rheumatology is a leader in this space. We have utilized the 6 core elements from "Got-Transition" to develop a transition pathway. This included the creation of a transition policy (element 1), as well as a data registry to track patients (element 2). The utilization of a transition planning tool, or TPT, allows for progress on readiness and planning (elements 3 and 4). The TPT is an electronic medical record (EMR) based flowsheet which helps guide providers in preparing patients for transition across multiple domains including medications, appointments, refills and insurance.

The aim of this project was to increase transition readiness and planning by increasing TPT use. We did this by tracking and encouraging TPT use or acknowledgement by providers in our rheumatology clinic.

Methods: In January 2019, a best practice alert (BPA) was created and embedded into the EMR to serve as a reminder for rheumatology providers to use the TPT with their transition aged patients (1567 patient encounters). Providers could also acknowledge why they didn't use the TPT. Use of the tool was refined through a series of PDSA cycles. The first PDSA cycle was used to gather baseline data to determine how the BPA influenced TPT use. The second cycle involved encouraging providers to utilize the tool at regular section meetings. In the third cycle, we worked to optimize integration of the BPA into the EMR. In the fourth cycle, transition coordinators were present at a majority of clinic sessions, serving as a reminder to use the TPT.

Results: There was a statistically significant increase in TPT use over time from the beginning to the end of the year ($p < 0.001$). TPT use plateaued around July 2019, with usage at 45% of eligible patient visits, up from only 16% of visits in January. If both use *and* acknowledgement are considered, the TPT was addressed in 95% of patient visits in July, up from only 24% in January. The two most common acknowledgements from providers who did not use the TPT were an active disease flare, in which the provider focused on acute issues (15% of acknowledgements), and clinic being too busy to utilize the TPT (32% of acknowledgements).

Conclusion: Our data suggests that a BPA incorporated into provider workflow is an effective means to promote transition planning using a TPT. As providers frequently cited time constraints as a key limitation in utilization of the TPT, we are working on securing dedicated transition support to achieve standardized transition readiness and planning. Going forward, we plan to finalize our transition pathway (transfer and completion, elements 5 and 6), and monitor outcomes, such as whether increased TPT use correlates with more successful transition into adult care.

Assessing Preparation for Care Transition Among Adolescents with Rheumatologic Disease: A Quality Assessment with Patient Survey

Jordan Roberts[1], Olha Halyabar[2], Carter Petty[3] and Mary Beth Son[1], [1]Boston Children's Hospital, Boston, MA, [2]Children's Hospital/Boston Medical Center, Boston, MA, [3]Boston Childrens Hospital, Institutional Centers for Clinical and Translational Research, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the risk for poor outcomes and gaps in care in the transition from pediatric to adult care, most pediatric rheumatology centers lack formal pathways for transition. We evaluated preparation for transition with a validated quality measure in a single pediatric rheumatology center.

Methods: Patients 16 and older were sent the ADolescent Assessment of Preparation for Transition (ADAPT) survey via email. This quality measure assesses preparation for transition in three domains: (1) self-management, (2) prescription medications, and (3) transfer planning using specific questions about transition counseling received (Table 2). Responses were converted to composite scores and analyzed using descriptive statistics. The association of patient illness and demographic factors with composite transition scores were assessed using t-tests, ANOVA and linear regression. Logistic regression was used to evaluate for independent predictors of transition readiness.

Results: 78 of 337 patients completed the survey (response rate of 23%), of whom 77 had a visit within 1 year and were eligible to complete the assessment tool. Demographics and disease types are reported in Table 1.

Patients most frequently endorsed receiving counseling on taking charge of their health and remembering to take medications, but less than half reported receiving specific counseling about transitioning to an adult provider (Table 2).

Patients ages 16-18 had significantly lower scores in all domains as compared to those 19 years and older (Table 3). Patients with lower education attainment compared with those who had attended some college or higher had lower scores in self- management (1.51 vs 2.52, p=0.0002), prescription medication counseling (1.96 vs 2.41, p= 0.029), and transfer planning (0.27 vs 1.62, p< 0.001). Patients with a diagnosis of MCTD, Sjogrens or SLE had higher

Table 1. Patient Characteristics

Table 2. Selected Transition Preparation Measures

Survey Question	Yes n (%)	No n (%)
In the last 12 months, did you talk with this provider without your parent or guardian in the room?	46 (59.7%)	31 (40.3%)
In the last 12 months, did you and this provider talk about you being more in charge of your health?	53 (68.8%)	24 (31.2%)
In the last 12 months, did you and this provider talk about whether you may need to change to a new provider who treats mostly adults?	31 (40.8%)	45 (59.2%)
In the last 12 months, did this provider ask if you had any questions or concerns about changing to a new provider who treats mostly adults?	22 (71.0%)	9 (29.0%)
In the last 12 months, did you and this provider talk about a specific plan for changing to a new provider who treats mostly adults?	14 (45.2%)	17 (54.8%)
In the last 12 months, did you and this provider talk about remembering to take your medicines?	37 (75.5%)	12 (24.5%)
Composite scores	Mean (SD)	
Self-management (n=77; score out of 4)	2.0 (1.2)	
Medication counseling (n=49; score out of 3)	2.2 (0.7)	
Transfer planning (n=76; score out of 4)	1.0 (1.4)	
Total transition composite score (n=77; % of items answered yes)	0.45 (0.25)	

Table 2. Selected Transition Preparation Measures

self-management scores than those with other diagnoses (2.6 vs 1.9; p=0.048). Non-white patients indicated they had received more thorough medication counseling than white patients (2.71 vs 2.07, p=0.027).

When controlling for age, educational attainment remained an independent predictor of transfer planning (Beta=1.00, 95% CI [0.06, 1.95], p=0.037), but not of other measures. Patients with longer duration of seeing their physician had higher transition preparation scores (r=0.26, p=0.021).

Conclusion: Few adolescents in our cohort endorsed receiving comprehensive transition counseling, including discussion of transfer planning. Patients who were younger and with lower levels of education had lower preparation scores. A long-term relationship with providers was associated with higher transition preparation scores. Further research including longitudinal assessment of transition preparation is needed to evaluate effective processes to assist vulnerable populations.

Systematic Review of Effectiveness Outcomes Reported in Rheumatology Transition Literature

Heather Bannerman[1], Karen Beattie[1], Avanti Patel[2], Milica Tanic[2], Michelle Batthish[3] and Mark Matsos[2], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster University, Hamilton, Canada, [3]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In young patients with rheumatologic disease, transition from pediatric to adult care is a complex process. Poor transitional care leads to health deterioration, loss to follow-up and increased morbidity. The "best" transition care model remains elusive and is complicated by how effectiveness and/or success of transition programs are defined and measured. In this review, we aimed to identify: 1) outcomes used in rheumatology transition literature to measure a "successful transition", and 2) tools used to determine these outcomes.

Methods: A systematic review was conducted by adapting a previously published search strategy using OVID Medline and Embase. The search was conducted in duplicate and discrepancies were reconciled. English articles meeting the following criteria were selected: 1) primary study; 2) pediatric-to-adult rheumatology transition program; 3) quantifiable outcomes reported. Of 506 abstracts reviewed, 69 were selected for full text review and 28 met the final inclusion criteria.

Results: Outcomes reported in rheumatology transition literature were divided into categories. The following categories of outcomes were used to measure a "successful transition" among the 28 studies that met the inclusion criteria: transfer completion (13 studies, 46.4%), transition readiness (5 studies, 17.9%), patient satisfaction (9 studies, 32.1%), disease activity/ functional ability (22 studies, 78.6%), and quality of life (10 studies, 35.7%).

Transfer completion was measured by various definitions of attendance at an adult appointment. Transition readiness was measured using 2 tools: SLE Transition Readiness Questionnaire (SLE-TRQ), and Transition Readiness Assessment Questionnaire (TRAQ). Patient satisfaction was measured using 3 tools, with the most frequently used being the "Mind the Gap" instrument. Disease activity/ functional ability was measured using 9 tools, with the most frequently used being the Child Health Assessment Questionnaire (CHAQ). Quality of life was measured using 6 tools, with the most frequently used being the 36-Item Short Form Health Survey (SF-36). Of the tools identified among the 28 studies, 11 were rheumatology-specific and the remaining were not specific to one disease or clinical area.

Conclusion: This rheumatology transition literature review identified several outcomes and tools used to report transition success and experiences. Variability in outcome measures makes comparisons between studies and between transition programs challenging. There is need for consensus on which outcomes are most meaningful for patients to allow for effectiveness of models to be determined.

April Bingham[23], [1]Children's Mercy Kansas City, Overland Park, KS, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Atrium Health Levine Children's Hospital, Charlotte, NC, [4]Medical University of South Carolina, Charleston, SC, [5]Nationwide Children's Hospital, Houston, TX, [6]Cincinnati Children's Hospital Medical Center, Cincinnati, [7]Pediatric Rheumatology Care and Outcomes Improvement Network, Cincinnati, [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [9]Cincinnati Children's Hospital Medical Center, University of Cincinnati, Cincinnati, [10]Children's Hospital of Philadelphia, Philadelphia, PA, [11]McMaster Children's Hospital, Hamilton, ON, Canada, [12]Cohen Children's Medical Center, Lake Success, NY, [13]University of Minnesota, Minneapolis, MN, [14]Boston Children's Hospital, Boston, MA, [15]The Hospital for Sick Children, Toronto, ON, Canada, [16]Stanford University School of Medicine, Palo Alto, CA, [17]University of Alabama at Birmingham, Birmingham, AL, [18]Medical College of Wisconsin, Milwaukee, WI, [19]Hospital for Special Surgery, New York, NY, [20]Phoenix Children's Hospital, Phoenix, AZ, [21]University of Mississippi, Jackson, MS, [22]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [23]Penn State Children's Hospital, Allentown, PA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a learning network to support pediatric rheumatology centers in improving care delivery and patient outcomes. This growing network, now 21 centers, was established in 2011 and has tracked outcome and process measures over time. PR-COIN recently modified its quality measure (QM) set that coincided with a registry migration of 5,905 patients to a new platform to support optimal data reporting. This report highlights the network's new QMs and provides some performance on these measures from a large JIA cohort enrolled in the network registry.

Methods: The network's initial process measures were based on a published set of QMs for JIA that was developed utilizing an evidence-based approach and consensus methodology. Outcome measures were created using published, validated JIA outcome assessments. Taking into consideration 3 main measure attributes – clinical health importance, scientific validity, and feasibility – in addition to new best practices, PR-COIN modified the QM set in 2019 with parent input and developed operational definitions. QMs were tested using patient data for validation. Network teams enter and/or auto-upload patient data into the PR-COIN registry to populate the measures, and statistical process control charts are utilized to display monthly performance.

Results: PR-COIN's QM set consists of 20 measures, including 16 clinical and 4 data quality measures (**Table 1**). Outcome measures for disease control include evaluation of the clinical Juvenile Arthritis Disease Activity Score (cJADAS10), clinically inactive disease, the active joint count, and the time to inactive disease. Patient-reported outcomes are comprised of optimal physical function, low or no pain, low patient global assessment of overall well-being, and low pain interference. Treat to Target interventions, including setting a treatment target and use of clinical decision support, will be tracked as process measures in addition to the use of self-management support and appropriate medication safety monitoring. A new balancing measure regarding infection-related hospitalizations rounds out the QM set. **Figure 1** is an example run chart of a disease control outcome measure – mean disease activity score by cJADAS10 (scale 0-30) of all JIA patients – demonstrating the aggregate performance of 8 PR-COIN sites. This cu-

Measure Group	Measure Classification	Measure Subgroup	Measure Title
Clinical Measures	Outcome Measures	Disease Control	Percent of JIA patients with oligoarthritis or polyarthritis with inactive disease or low disease activity by cJADAS10
			Mean cJADAS10 score
			Percent of all JIA patients with clinical inactive disease
			Mean active joint count for all JIA patients
			Percent of JIA patients with oligoarthritis or polyarthritis who achieve inactive or low disease activity by 6 months
		Quality of Life	Percent of patients with optimal physical function
			Percent of patients with pain score ≤3
			Percent of patients with patient global assessment ≤2
			Mean patient global assessment of well-being
			Percent of patients with pain interference T score <60
	Process Measures	Model Treatment	Percent of polyarticular course patients with treatment target set
			Percent of visits with provider attestation of disease activity status for Treat to Target
			Percent of visits where treatment was provided using clinical decision support
			Percent of patients who received self-management support
			Percent of patients who received appropriate medication safety monitoring
	Balancing Measure		Time between hospitalization for infections for all patients
Data Quality Measures			Percent of visits with all critical data recorded
			Percent of patients with a visit recorded in last 13 months
			Percent of JIA population that is enrolled in PR-COIN
			Percent of patients enrolled within 120 days of diagnosis

cJADAS10, clinical juvenile arthritis disease activity score

Table 1. PR-COIN Quality Measures for Juvenile Idiopathic Arthritis.

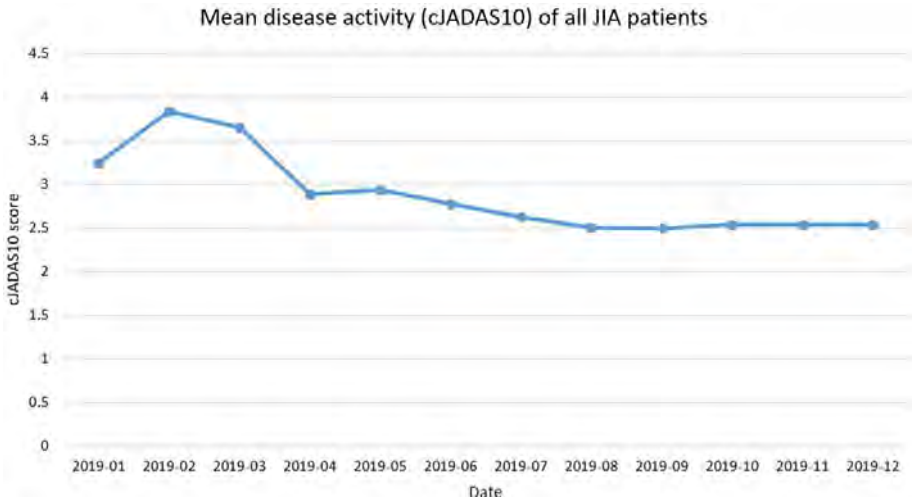

Figure 1. Mean disease activity score by cJADAS10 of JIA patients in PR-COIN.

mulative measure has been stable at 2.5 over the last 5 months. **Figure 2** is an example run chart using collaborative data of a patient-reported quality of life outcome measure, the mean patient global assessment of well-being (scale 0-10). This score has been around 1.26 for the last several months.

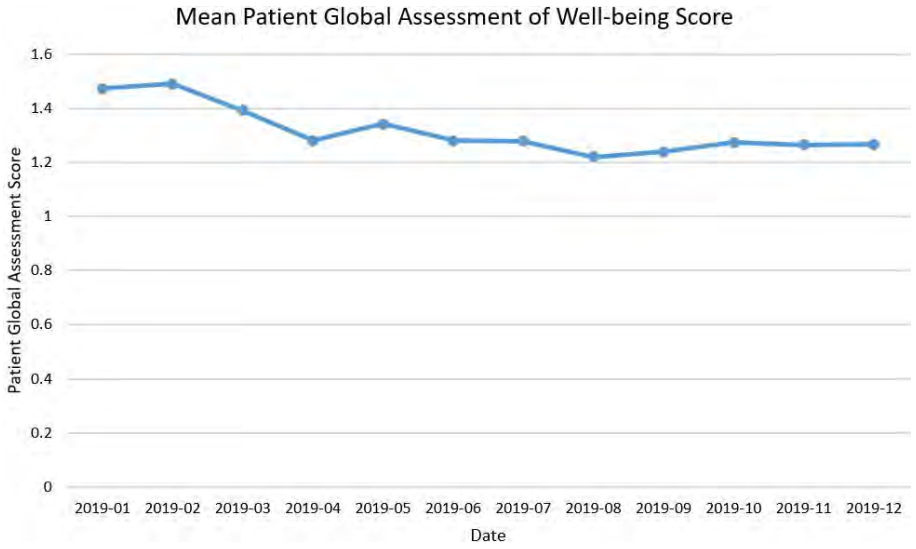

Figure 2. Mean patient global assessment of well-being score for JIA patients in PR-COIN.

Conclusion: PR-COIN has enhanced its comprehensive and varied QM set for the care of patients with JIA. Having clinically important measures that are tested for feasibility on a large cohort of patients with JIA can maximize quality improvement efforts to optimize care delivery.

Abstract Number: 1618

Frequency and Cost of Repeat HLA-B27 Testing Within the National Capital Consortium over a Calendar Year

Anna Stein[1], Caleb Anderson[2] and Angelique Collamer[3], [1]Walter Reed National Military Medical Center, Takoma Park, MD, [2]Walter Reed National Military Medical Center, Bethesda, MD, [3]Walter Reed National Military Medical Center, Silver Spring, MD

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Human leukocyte antigens (HLAs) are proteins encoded for by the major histocompatibility complex located on the short arm of chromosome six. One such allele, HLA-B27 is known to have a strong association with ankylosing spondylitis (AS) and is present in over 90% of Caucasian AS patients. The National Capital Consortium's (NCC) HLA-B27 testing is conducted as a polymerase chain reaction (PCR), sequence-specific oligonucleotide probe analysis. As this is a genetic test, repeating the assay multiple times for the same individual patient is

of limited diagnostic utility. The intent of this project was to determine the number of repeat HLA-B27 tests that occur within the NCC during a calendar year and the approximate cost associated with this repeat testing.

Methods: A record of all HLA-B27 tests ordered in the NCC between January 1 2019 and December 31 2019 was obtained. Chart reviews were performed to identify whether these patients had prior HLA-B27 testing conducted over the lifetime of the patient in the electronic medical record (EMR) and the number of prior tests. Ordering location of the testing (primary care, ophthalmology/optometry, rheumatology, other specialty clinic, inpatient, and outside provider) was also recorded. The cost of repeat testing was then estimated per the facility's contract with LabCorp.

Results: Between January 1 2019 and December 31 2019, 460 HLA-B27 tests were conducted for patients within the NCC. Of these, 33 (7%) represented repeat tests associated with a cost of approximately 5,610 dollars. Five of the thirty-two HLA-B27 tests ordered by outside providers (16%) represented repeat studies associated with a cost of approximately 850 dollars. The specialty with the second highest percentage of repeat tests was ophthalmology and optometry (8 repeat tests, 13% of all tests ordered by the specialty, $1,360 spent in repeat tests), followed by pediatric rheumatology (5, 11%, $850), other specialty clinics (6, 5%, $1,020), primary care (7, 5%, $1,190), and adult rheumatology (2, 5%, $340).

Conclusion: In this review of ordering practices, repeat HLA-B27 testing accounted for 7% of tests ordered in the NCC over one calendar year. While the majority of HLA-B27 tests were ordered in the primary care setting, the highest rates of repeat testing were conducted by outside providers, ophthalmology/optometry, and pediatric rheumatology. This repeat testing is not insignificant; when extrapolated it represents an estimated ten year cost of over $56,000 to our facility. We hypothesize that lack of access to our facility's EMR, use of order sets, and insufficient time to review the EMR represent major factors contributing to repeat HLA-B27 testing. Our findings suggest that efforts to reduce HLA-B27's inclusion in order sets and introduction of EMR "flags" to prevent repeat ordering may reflect reasonable interventions to lower repeat testing within our system.

Immunoglobulin G Subclass Ordering Patterns for IgG4-Related Disease at an Academic Medical Center

Lena Eder[1] and David Leverenz[2], [1]Duke University Hospital, Chapel Hill, NC, [2]Duke University, DURHAM, NC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: We have noticed an increasing number of serum IgG4 levels ordered over the last several years at our institution. This study was performed to better understand the clinical indications for IgG4 testing among inpatient general medicine providers and how those trends have changed from 2015 to 2019. We also sought to determine if there was any comparative change in rheumatology providers' behavior regarding IgG4 testing.

Methods: We used SlicerDicer, an analytic tool in our EHR, to identify patients with IgG subclasses ordered by inpatient general medicine or rheumatology providers in 2015 and 2019. Charts were manually reviewed to determine

Table 1. Statistical analysis of proportion of patients tested for IgG4-RD.

	Inpatient General Medicine IgG4 Testing				
	2015		2019		
	n	%	n	%	*p* value
Total patients with IgG4 level sent	60	-	133	-	
IgG4 level sent for suspected IgG4-RD	31	52%	79	59%	
IgG4 level sent for other reason	29	48%	54	41%	
Known IgG4-RD at time of testing	0	0%	2	2%	
No known IgG4-RD at time of testing	31	52%	77	58%	
Total patients with any lab test sent	26076	-	29100	-	
Patients tested for IgG4-RD among all patients with any lab test sent	31/26076	0.12%	77/29100	0.26%	< 0.001
	Outpatient Rheumatology IgG4 Testing				
	2015		2019		
	n	%	n	%	*p* value
Total patients with IgG4 level sent	24	-	67	-	
IgG4 level sent for suspected IgG4-RD	18	75%	50	75%	
IgG4 level sent for other reason	6	25%	17	25%	
Known IgG4-RD at time of testing	1	4%	11	16%	
No known IgG4-RD at time of testing	17	71%	39	58%	
Total patients with any lab test sent	5216	-	9246	-	
Patients tested for IgG4-RD among all patients with any lab test sent	17/5216	0.33%	39/9246	0.42%	0.4059

Table 2. Proportion of patients with elevated IgG4 levels, biopsies performed, and ultimate diagnosis of IgG4-RD.

Inpatient General Medicine IgG4 Testing					
	2015		2019		
	n	%	n	%	*p* value
Among patients tested for IgG4-RD	31		77		
IgG4 levels elevated	5	16%	6	8%	0.2891
Biopsy performed	9	29%	32	42%	0.2762
Diagnosed with IgG4-RD	1	3%	1	1%	0.4936
Outpatient Rheumatology IgG4 Testing					
	2015		2019		
	n	%	n	%	*p* value
Among patients tested for IgG4-RD	17		39		
IgG4 levels elevated	3	18%	5	13%	0.6876
Biopsy performed	9	53%	24	62%	0.5691
Diagnosed with IgG4-RD	2	12%	7	18%	0.7072

clinical indications for IgG subclass testing as determined by provider documentation at the time of ordering. Using a pre-specified adjudication algorithm, patients were excluded if IgG subsets were sent for an indication other than IgG4-Related Disease (IgG-RD) or if they already had a known diagnosis of IgG4-RD. For included patients, we also evaluated IgG4 levels, imaging, biopsies, and final diagnoses. Fisher's exact test (Social Science Statistics open software) was used to compare 2015 and 2019 data. Other data were analyzed using descriptive statistics.

Results: Among general medicine providers, there was a significant increase in patients tested for suspected IgG4-RD with serum IgG subclasses from 2015 (n = 31, 0.12% of all patients with any lab order) to 2019 (n = 77, 0.26%), p< 0.001 (table 1). There were no changes in the proportion of patients with elevated IgG4 levels, biopsies obtained, or a diagnosis of IgG4-RD from 2015 to 2019 (table 2). Notably, only 1 general medicine patient was diagnosed with IgG4-RD in 2015 and 1 in 2019. There was a significant decrease in the proportion of general medicine patients tested

	INPATIENT GENERAL MEDICINE IgG4 TESTING				
	2015 (n = 31)		2019 (n = 77)		
Clinical indications for IgG4 testing	**n**	**%**	**n**	**%**	***p* value**

Lymphadenopathy	0	0%	0	0%	-
Pulmonary disease	0	0%	1	1%	1.0
Kidney disease	0	0%	0	0%	-
Pericardial disease	1	3%	0	0%	0.287
Mediastinal disease	0	0%	1	1%	1.0
Other indications	1	3%	3	4%	1.0
	OUTPATIENT RHEUMATOLOGY IgG4 TESTING				
	2015 (n = 17)		2019 (n = 39)		
Clinical indications for IgG4 testing	**n**	**%**	**n**	**%**	***p* value**
Pancreatic disease	1	6%	2	5%	1.0
Hepatobiliary disease	1	6%	0	0%	0.3036
Aortitis /other large vessel disease	3	18%	5	13%	0.6876
Retroperitoneal fibrosis	2	12%	7	18%	0.7072
Salivary/lacrimal gland enlargement	3	18%	8	21%	1.0
Orbital inflammatory disease	2	12%	4	10%	1.0
Lymphadenopathy	1	6%	4	10%	1.0
Pulmonary disease	0	0%	2	5%	1.0
Kidney disease	0	0%	3	8%	0.5456
Pericardial disease	2	12%	1	3%	0.287
Mediastinal disease	0	0%	0	0%	-
Other indications	3	18%	9	23%	0.7378

Table 3. A review of clinical characteristics and indications of patients tested for IgG4-RD.

with IgG subclasses for IgG4-RD due to retroperitoneal fibrosis (10% in 2015 vs 0% in 2019, p=0.022) and a trend towards more patients tested due to hepatobiliary disease (13% vs 30%, p=0.0861) and orbital inflammatory disease (0% vs 9%, p=0.0571), table 3. There were no significant changes in IgG subclass testing patterns by rheumatology providersfrom 2015 to 2019.

Conclusion: Despite a more than two-fold increase in IgG subclass testing for IgG4-RD by inpatient general medicine providers from 2015 to 2019, the number of patients ultimately diagnosed with IgG4-RD did not change. The trend towards increased IgG subclass testing for hepatobiliary disease and orbital inflammatory disease suggests increased provider awareness of some of this condition's protean manifestations beyond the pancreas; however, the decrease in IgG subclass testing for retroperitoneal fibrosis and the minimal testing for other major clinical manifestations of IgG4-RD in either 2015 or 2019 suggests that this condition remains under-recognized. In contrast, there were no major changes in IgG subclass testing by rheumatologists from 2015 to 2019. Overall, this study reveals potential knowledge gaps regarding the workup of IgG4-RD among inpatient internal medicine providers and highlights the need for an educational intervention to address appropriate indications for IgG subclass testing in different clinical scenarios.

Hepatitis B Screening Practices When Prescribing Tocilizumab or Tofacitinib in Real World Practice

Naomi Serling-Boyd[1], Amir Mohareb[2], Arthur Kim[2], Emily Hyle[2] and Zachary Wallace[3], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hepatitis B virus (HBV) reactivation can complicate treatment with immunosuppressive medications. Reactivation risk varies by the status of HBV infection but has been reported in up to one third of patients receiving immunosuppression. While HBV screening is indicated prior to initiation of tumor necrosis factor inhibitors, recommendations are inconsistent regarding HBV screening when prescribing tocilizumab (TCZ) or tofacitinib (TOF),

Table 1: Baseline characteristics of subjects initiating tocilizumab or tofacitinib

Variable	Tocilizumab (N=764)	Tofacitinib (N=495)
Age (years), median (IQR)	64 (51-73)	60 (51-70)
Female sex, n (%)	596 (78)	435 (88)
Race/Ethnicity, n (%)*		
White, non-Hispanic	643 (84)	416 (84)
Black, non-Hispanic	33 (4)	21 (4)
Asian, non-Hispanic	27 (4)	11 (2)
Hispanic	28 (4)	20 (4)
Other or not reported	21 (3)	27 (5)
Diagnosis, n (%)		
Rheumatoid arthritis	393 (51)	381 (77)
Vasculitis	189 (25)	3 (1)
Psoriatic arthritis	9 (1)	30 (6)
Other inflammatory arthritis	73 (10)	26 (5)
Juvenile Idiopathic Arthritis or Adult-Onset Still's Disease	36 (5)	6 (1)
Other diagnosis	64 (8)	49 (10)
Medication History		
Prior DMARD	531 (70)	424 (86)
Prior biologic	485 (63)	383 (77)
Prior DMARD and biologic	426 (56)	348 (70)
No prior DMARD or biologic	174 (23)	36 (7)

IQR: interquartile range; DMARD: disease-modifying anti-rheumatic drug
*Numbers in tocilizumab group do not add up to 100% due to rounding

Table 1. Baseline characteristics of subjects initiating tocilizumab or tofacitinib

and scant data exist regarding real-world practice. Our objective was to determine providers' HBV screening practices when prescribing TCZ and TOF.

Methods: We identified patients initiating TCZ or TOF in the Mass General Brigham (MGB) Healthcare System from retrospective review of electronic health records. Adult patients were included if they had ≥ 1 prescription for either TCZ or TOF and an outpatient rheumatology encounter in MGB. We characterized all available HBV screening data

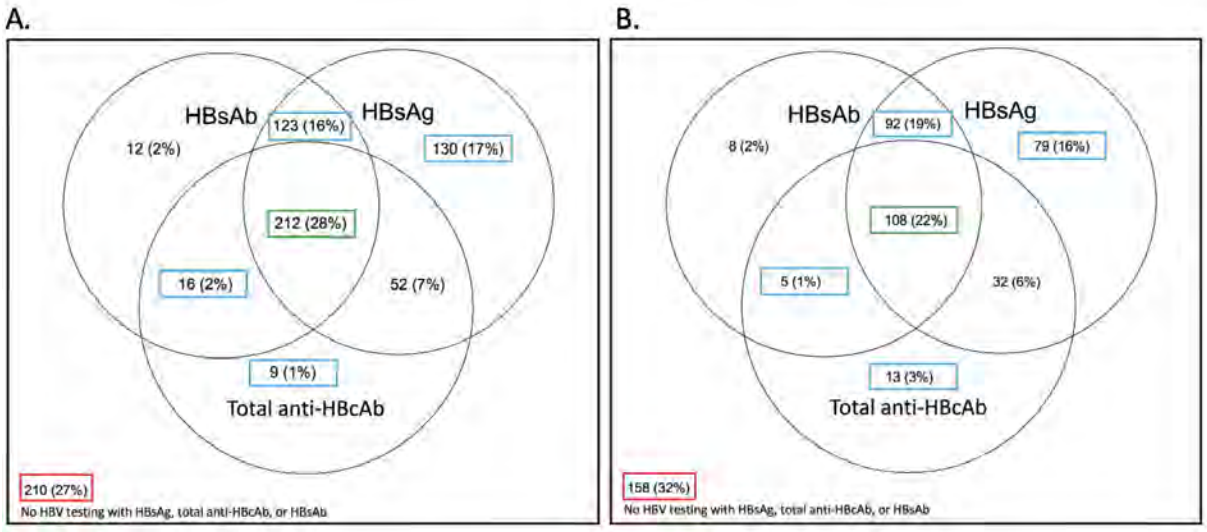
Table 2: Complete, partial, and inappropriate hepatitis B virus (HBV) screening among patients initiating tocilizumab and tofacitinib

Variable	Tocilizumab (N=764), n (%)	Tofacitinib (N=495), n (%)
Complete	212 (28)	108 (22)
Partial	278 (36)	189 (38)
Absent	210 (27)	158 (32)
Inappropriate*	163 (22)	177 (36)

*Inappropriate screening refers to anyone with testing for HBV e-antigen, HBcAb IgM, or HBV deoxyribonucleic acid (DNA) without a positive HBsAg or total anti-HBcAb, regardless of whether they had complete, partial, or absent HBV testing. Thus, percentages do not add up to 100%.

Table 2. Complete, partial, and inappropriate hepatitis B virus (HBV) screening among patients initiating tocilizumab and tofacitinib

Figure 1: Complete, partial, and absent hepatitis B virus screening among patients initiating (A) tocilizumab (n=764) and (B) tofacitinib (n=495)



Green boxes indicate complete HBV screening.
Blue boxes indicate partial HBV screening.
Red boxes indicate absent HBV screening.
Inappropriate HBV screening includes additional laboratory testing and therefore is not represented in the figure above.

Figure 1. Complete, partial, and absent hepatitis B virus screening among patients initiating (A) tocilizumab (n=764) and (B) tofacitinib (n=495)

(1995-2018) prior to or within 30 days of the first TCZ or TOF prescription as: complete (HBV surface antigen [HBsAg], HBV total core antibody [total anti-HBcAb], and HBV surface antibody [HBsAb]), partial (HBsAg or total anti-HBcAb but not both), and inappropriate (HBV e-antigen, HBcAb IgM, or HBV deoxyribonucleic acid [DNA] without a positive HBsAg or total anti-HBcAb).

Results: Among 913 patients prescribed TCZ and 630 prescribed TOF, we identified 764 patients prescribed TCZ and 495 prescribed TOF who had an outpatient rheumatology encounter in MGB. Median age was 64 years and 60 years in the TCZ and TOF groups, respectively; most were white and female. Rheumatoid arthritis was the most common indication (TCZ [51%] and TOF [77%]) (**Table 1**). Complete HBV screening was performed in 212 (28%) TCZ patients and 108 (22%) TOF patients (**Table 2** and **Figure 1**). Partial HBV screening was performed in 278 (36%) TCZ patients and 189 (38%) TOF patients. Inappropriate HBV testing was performed in 163 (22%) TCZ patients and 177 (36%) TOF patients. No appropriate HBV screening was performed in 210 (27%) TCZ patients and 158 (32%) TOF patients.

Conclusion: Fewer than 30% of patients prescribed TCZ or TOF for rheumatologic indications had complete HBV screening, which underscores the lack of consistent guidelines regarding HBV screening for this population. More than a quarter had inappropriate HBV screening, which contributes to medical errors and healthcare resource waste. The frequency of partial, inappropriate, or absent HBV screening among patients prescribed TCZ or TOF suggests that provider education and electronic health record system alerts could improve HBV screening practices.

Cervical Cancer Screening Among Women with Systemic Lupus Erythematosus or Prescribed Tumor Necrosis Alpha-inhibitors Who Receive Outpatient Rheumatology Care

Mehret Birru Talabi[1], Kwonho Jeong[1], Kaleab Abebe[1], Megan Clowse[2], Robyn Domsic[3] and Sonya Borrero[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]Duke University, Chapel Hill, NC, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Cervical cancer screening is important for women with systemic lupus erythematosus (SLE) and women prescribed TNF-alpha inhibitors (TNFi), as they have an increased risk of cervical dysplasia and cancer due to immune dysfunction and/or suppression. We describe receipt of guidelines-concordant cervical cancer screening among women receiving rheumatology care in a large Pennsylvania healthcare system. We explored whether women with SLE or prescribed TNFi would be more likely to receive guideline-concordant screening than women with average risk of cervical cancer.

Methods: Cervical cancer screening was compared between women ages 18-50 who had ≥ 2 rheumatology visits between 2007 and 2014, ≥ 1 documented screening test, and diagnosis of SLE or usage of TNFi's (cases) vs. fibro-

Table 1. Cervical cancer screening guidelines

Cervical Cancer Screening Guidelines	Change in Guidelines	Definition of Guideline-Concordant Screening
1. American College of Obstetricians and Gynecologists (ACOG)	Prior to 2009: Cervical cancer screening required annually After 2009: Every two years if younger than 30 years old, and every 3 years if 30 years of age or older	Women were required to meet at least one set of screening criteria (ACOG or USPTF) contemporaneous with the screening service
2. United States Preventive Task Force (USPTF)	In 2012: Cervical cancer screening every 3 years among women younger than 30 years old if negative cytology and screen every 5 years among women 30 years and older with negative human papillomavirus (HPV) co-testing.	

myalgia only (control). Outcomes and predictors were identified in the electronic health record by medication lists, ICD-9 and procedure codes. Guideline-concordant screening was defined as adherence with contemporaneous U.S. guidelines (Table 1), with six-month buffers added to each testing interval to account for potential scheduling constraints. Descriptive statistics were calculated and compared between groups using Chi-square or two-sample t-tests. Logistic regression was used to evaluate associations between each key predictor and the outcome variable; adjusted models included age, race/ethnicity, health insurance, and documented cervical dysplasia. Women without screening data (SLE: n=108; TNFi: n= 270) were excluded as they may have received screening outside of the health-care system; however, as some may not have had any screening tests completed, we also performed a separate sensitivity analysis categorizing these women as non-adherent with guidelines.

Results: Table 2 describes characteristics of controls (n=867), SLE cases (n=160), and TNFi cases (n=415). Guideline-concordant screening was conducted for 84% for controls, and 81% for SLE and 77% for TNFi cases. SLE cases were as likely as controls to receive guideline-concordant screening (OR 1.04, 95% CI: 0.49, 2.2) (Table 3), whereas TNFi cases were significantly less likely (aOR 0.56, 95% CI: 0.33, 0.95). As compared to whites, guideline-concordant screening was also less likely among non-white TNFi cases (aOR 0.55, 95% CI: 0.31, 0.99) and marginally less likely among non-white SLE cases (aOR 0.61, 95% CI: 0.32, 1.2). Having health insurance was associated with guideline-concordant screening among cases. Primary care or gynecology visits did not explain differences in screening. In sensitivity analyses, the relationship between SLE and guideline-concordant screening was unchanged but was attenuated for TNFi cases.

Conclusion: Women at increased risk of cervical dysplasia/cancer were not more likely to receive guideline-concordant cervical cancer screening than women with average risk, and women who used TNFi were significantly less likely. Rheumatologists should help to ensure that patients with elevated cervical cancer risk are informed about their risks and referred for appropriate screening; additional strategies to ensure screening equity for marginalized populations must also be identified.

Table 2. Patient Characteristics

Abstract Number: 1622

Determining the Zoster Vaccination Rate Among Veterans on Chronic Immunosuppressive Therapy at the Southeast Louisiana Veterans Healthcare System – a Quality Indicator

Hannah Kenninger[1], Rachel Dayno[1], Nkechinyere Emejuaiwe[2], Ileannette Robledo-Vega[3], Whitney Bembry[1], Myriam Guevara[4] and Soham Mahato[5], [1]Tulane University School of Medicine, New Orleans, LA, [2]Southeast Louisiana Veterans Healthcare System, New Orlenas, LA, [3]Louisiana State University Health Sciences Center, New Orlenas, LA, [4]Lousiana State University Health Sciences Center, New Orleans, LA, [5]LSUHSC School of Public Health, New Orleans, LA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes Zoster (HZ) causes an infection commonly known as shingles. Patients with HZ are at increased risk for post-herpetic neuralgia, which is painful for patients and costly for the United States (US) healthcare system. Certain medications and diseases such as RA, SLE, and IBD weaken the immune system making the body more susceptible to HZ. Two vaccines are available in the US. Zostavax, a live-attenuated vaccine (ZVL), was approved by the FDA in 2006 and Shingrix, an adjuvanted recombinant zoster vaccine (RZV), was approved in 2017. ZVL reduces the risk of HZ by 65% in patients aged 50-59, and by 50% in patients aged 60-69. Despite the relative

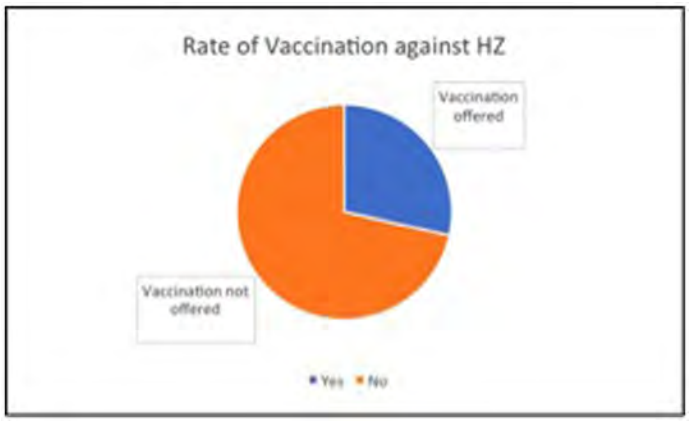

Figure 1. Rate of Vaccination against HZ

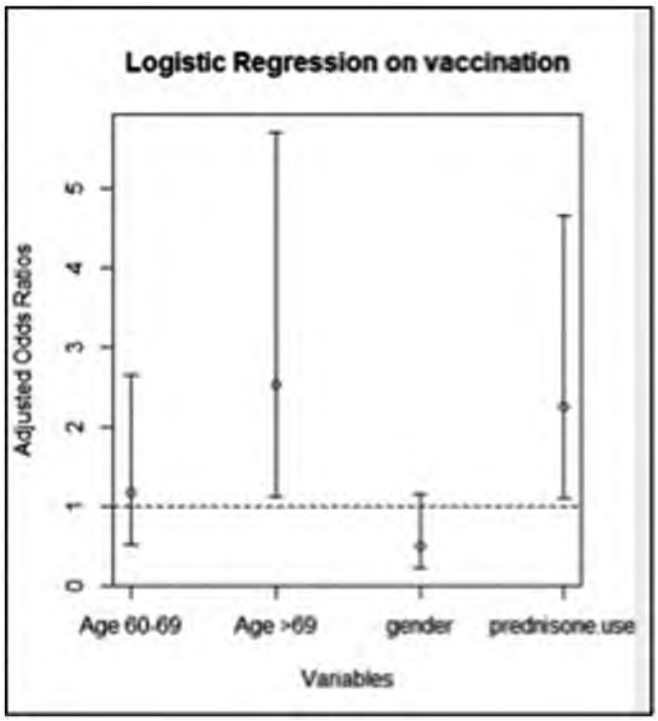

Figure 2. Vaccination Offered: Odds Ratios with 95% Confidence Interval

reduction of HZ with vaccination, rates in the general population remain low. Vaccination rates in 2016 were estimated at 33.4% among adults 60 years and older and 37.4% among adults 65 years and older.

The objective was to determine zoster vaccination rates of ZVL or RZV in patients on chronic immunosuppressive therapy at the Southeast Louisiana Veterans Healthcare System. We describe the correlation between vaccination rate and age, race, immunosuppressive medication and diagnosis.

Methods: This was a descriptive study with a retrospective review of records in the Computerized Patient Record System (CPRS). We included veterans 50 years and older treated with the following immunosuppressive medications: AZA, MMF, cyclosporine, MTX, LEF, tofacitinib, infliximab, adalimumab, etanercept, abatacept, rituximab or certolizumab from January 1, 2016 through December 31, 2018 (n= 601). Veterans with a history of malignancy, diabetes

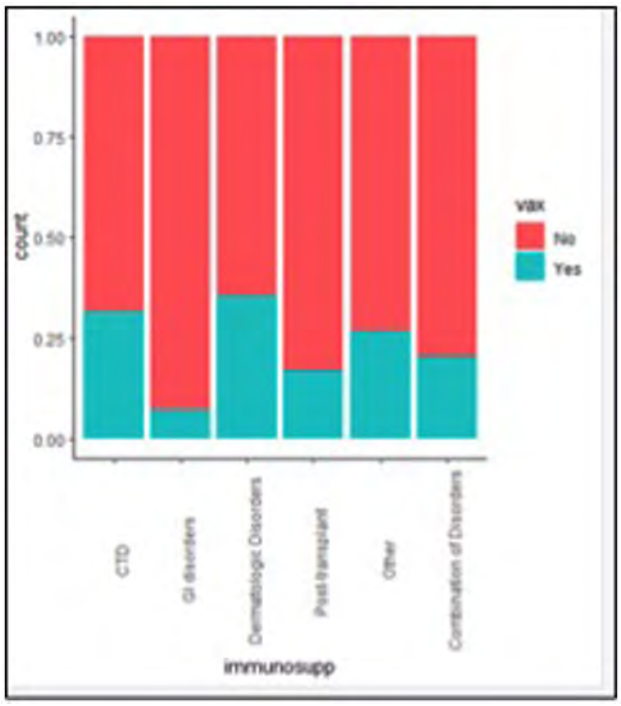

Figure 3. Rate vaccination was offered with respect to the diagnosis requiring immunosuppression

mellitus, HIV infection or death during the study period were excluded (n= 369). Charts were reviewed to determine receipt of ZVL or RZV and identify concurrent glucocorticoid therapy.

Results: 31 (13.4%) patients in our study population were vaccinated against HZ (Figure 1). Of the 232 patients included in the study, 66 (28.4%) were offered vaccination and 166 (71.6%) were not. Of the patients offered vaccination, 35 (53%) refused or had no documentation of receipt of vaccination. Of those vaccinated, 24 (77.4%) received RZV and 7 (22.6%) received ZVL.

Age and glucocorticoid therapy had a significant effect on whether vaccination was offered (Figure 2). Patients 70 years and older were 2.52 times more likely to be offered vaccination than patients less than 60 years of age (reference group). Patients on prednisone therapy were 2.26 times more likely to be offered vaccination than those not on prednisone therapy.

Patients on immunosuppressive therapy for gastrointestinal disorders were less likely to receive vaccination against HZ (Figure 3).

Race, gender and immunosuppressive medication did not influence the offer of vaccination against HZ in our study cohort.

Conclusion: The rate of vaccination against HZ in patients on immunosuppressive therapy in our study population was low despite the accessibility of vaccines. This is concerning given the risk of infection in this population and the proven efficacy of zoster vaccination. An extension of this study will explore factors that influencevaccination ratesand investigate interventions to improve vaccination rates. Interventions should include both provider and patient education.

Abstract Number: 1623

Improving Pneumococcal Vaccination Rates Among Immunosuppressed Adults in an Academic Rheumatology Clinic Utilizing a Nurse Driven Protocol

Elena Joerns[1], Bonnie Bermas[2], Puneet Bajaj[3], Nagendra Pokala[1], Reuben Arasaratnam[4], Joan Reisch[1] and Dan (Clarie) Wang[1], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UTSouthwestern.edu, Dallas, TX, [3]UT Southwestern, Dallas, TX, [4]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatology patients are particularly vulnerable to pneumococcal infection due to both their underlying disease and immunosuppressive therapy. Thus, quality improvement metrics include increasing pneumococcal vaccination rate in rheumatology patients. Our goal was to implement a nurse driven protocol to increase by 10% the pneumococcal conjugate and polysaccharide vaccination rate during a three month period among immunosuppressed patients aged 19-64 years old followed at an academic adult rheumatology clinic.

Table 1 Pneumococcal vaccination for significantly immunosuppressed patients aged 19 years and older

For all adult patients

1) **On immunosuppressive therapy or with intent to start immunosuppressive therapy or**
2) **Significant immunocompromising conditions:** CSF leaks, cochlear implants Congenital or acquired asplenia, Sickle cell disease, Chronic renal failure, congenital or acquired immunodeficiency, generalized malignancy, HIV infection, Hodgkin's disease, Iatrogenic immunosuppression, leukemia, lymphoma, multiple myeloma, nephrotic syndrome, solid organ transplant

-Absolute contraindication: Allergy to PCV13/PPSV23 or Tdap vaccination
-Consider deferring pneumococcal vaccination for patients on Rituximab or receipt of Rituximab in the last 6 months (see below for further guidance*)

Prior Pneumonia vaccination status	Recommendation
No pneumococcal vaccinations or Unknown vaccination history	- Give PCV13 then PPSV23 at least 8 weeks later - 5 years later, repeat PPSV23 unless previous PPSV23 given at age ³ 65
1 dose PPSV23	- Give PCV13 at least 1 year after PPSV23 - Repeat PPSV23** at least 5 years after previous PPSV23 and at least 8 weeks after PCV13 if the previous PPSV23 was administered at age <65
2 doses PPSV23	- Give PCV13 at least 1 year after last PPSV23
PCV13 only	- Give PPSV23 at least 8 weeks after PCV13 - Repeat PPSV23 at least 5 years later
PCV13 and 1 dose PPSV23	- Repeat PPSV23 at least 5 years after previous PPSV 23** and at least 8 weeks after PCV13 if the previous PPSV23 was at age <65 - Nothing to do if the previous PPSV23 was at age ³ 65
PCV13 and 2 doses PPSV23	- Nothing to do if patient is under 65 years old at time of completion of vaccination. If over age 65 see recommendations below ***

*For patients undergoing consideration for Rituximab therapy it is optimal to give pneumococcal vaccines at least two weeks prior to therapy. For patients currently receiving Rituximab therapy, wait at least 6 months after the last dose of Rituximab before administering pneumococcal vaccination

**Revaccination of PPSV 23 before the age of 65 is not required in patients with CSF leaks or cochlear implants and in immunocompetent patients (includes those with alcoholism, chronic heart, liver, lung disease, cigarette smoking and diabetes mellitus).

Table1. Pneumococcal Vaccination For Significantly Immunosuppressed Patients Aged 19 Years And Older

ACR 2020 Abstract

Figure 1:

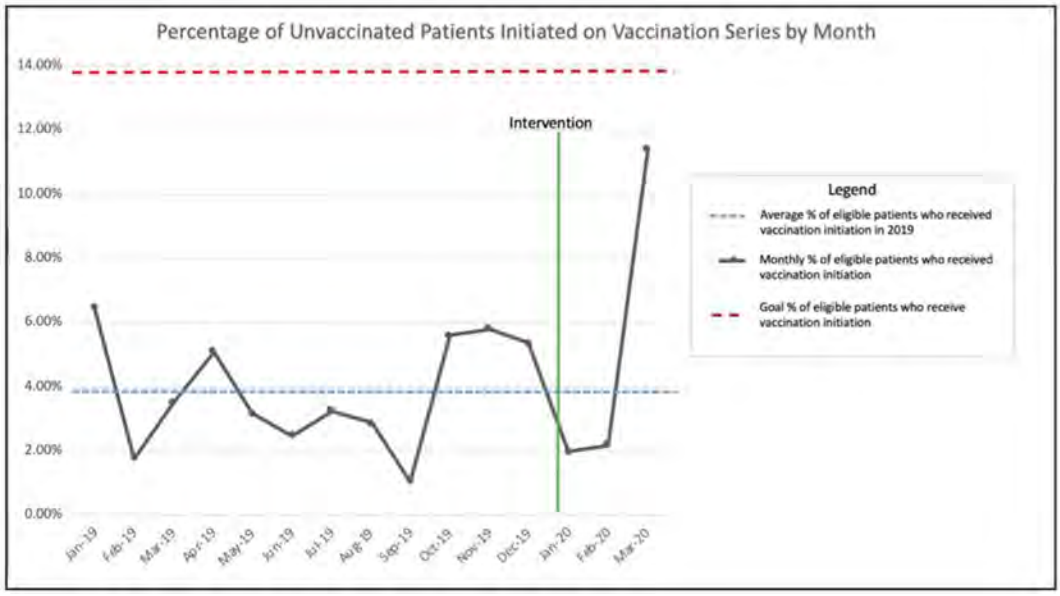

Figure 1. Percentage Of Unvaccinated Patients Initiated On Vaccination Series By Month

Methods: Eligible adults aged 19-64 years old were identified in the Electronic Medical Record (EMR) using a search protocol based on pre-set immunosuppressive medication group. We calculated baseline vaccination rate by assessing whether patients had received either the Pneumovax23 (PPSV23) or Prevnar13 (PCV13) or both vaccines from January 1, 2019 - December 31, 2019. We developed a nurse-driven workflow for vaccination implementation in the clinic. Using Center for Disease Control (CDC) guidelines, we created a pneumococcal vaccination protocol (Table 1) and converted it into a university approved Standing Medical Order (SMO) to be used by the nursing staff. We held educational sessions for the nursing staff to review the protocols and workflow. Staff re-training was implemented mid-way through the cycle. Post-intervention pneumococcal vaccination rates were calculated on a monthly basis.

Results: Baseline rate of both PCV13 and PPSV23 immunization (full immunization) for immunosuppressed rheumatology patients aged 19-64 years in 2019 was 6.6%. Baseline rate of unique patients within the target population who had received any type of immunization in our clinic (either PCV13, PPSV23, or both) was 25.3%.

Average monthly percentage of unvaccinated patients within target population seen in our clinic in 2019 was 73.2%. Percent of eligible patients who had pneumococcal vaccination series initiated, on average per month, in our clinic was 3.9% for 2019.

Start date for the intervention phase of project was January 1, 2020. We obtained post-intervention vaccination data for Jan-March 21, 2020 [a truncated three month time period due to COVID-19 pandemic clinic changes]. While the percentage of initiation of vaccination series continued to be low in Jan and Feb 2020, we achieved 11.4% vaccination rate of previously unvaccinated patients in March 2020 (Figure 1), which represents a nearly three fold increase over baseline vaccination rate.

Conclusion: During a three month cycle of nurse-driven SMO protocol to implement pneumococcal vaccination, we were able to increase our pneumococcal vaccination initiation rate of eligible immunocompromised patients from

baseline of 3.9% to 11.4%. Overall vaccination rates of eligible patients remain low, but we anticipate that continued use of a nurse driven protocol will improve this rate. Our study suggests that using a nurse-driven SMO protocol is a useful tool in improving vaccination rate amongst immunocompromised rheumatology patients. The post-intervention data is currently scarce; however, we hope to obtain four months more worth of data after the clinics are anticipated to re-open in June 2020.

Abstract Number: 1624

Improving Pneumococcal Vaccination in Veterans with Rheumatic Diseases

Sarah Homann[1], Michelle Ormseth[2], Christianne Roumie[2] and Robert Dittus[2], [1]Veterans Affairs Tennessee Valley Healthcare System / Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

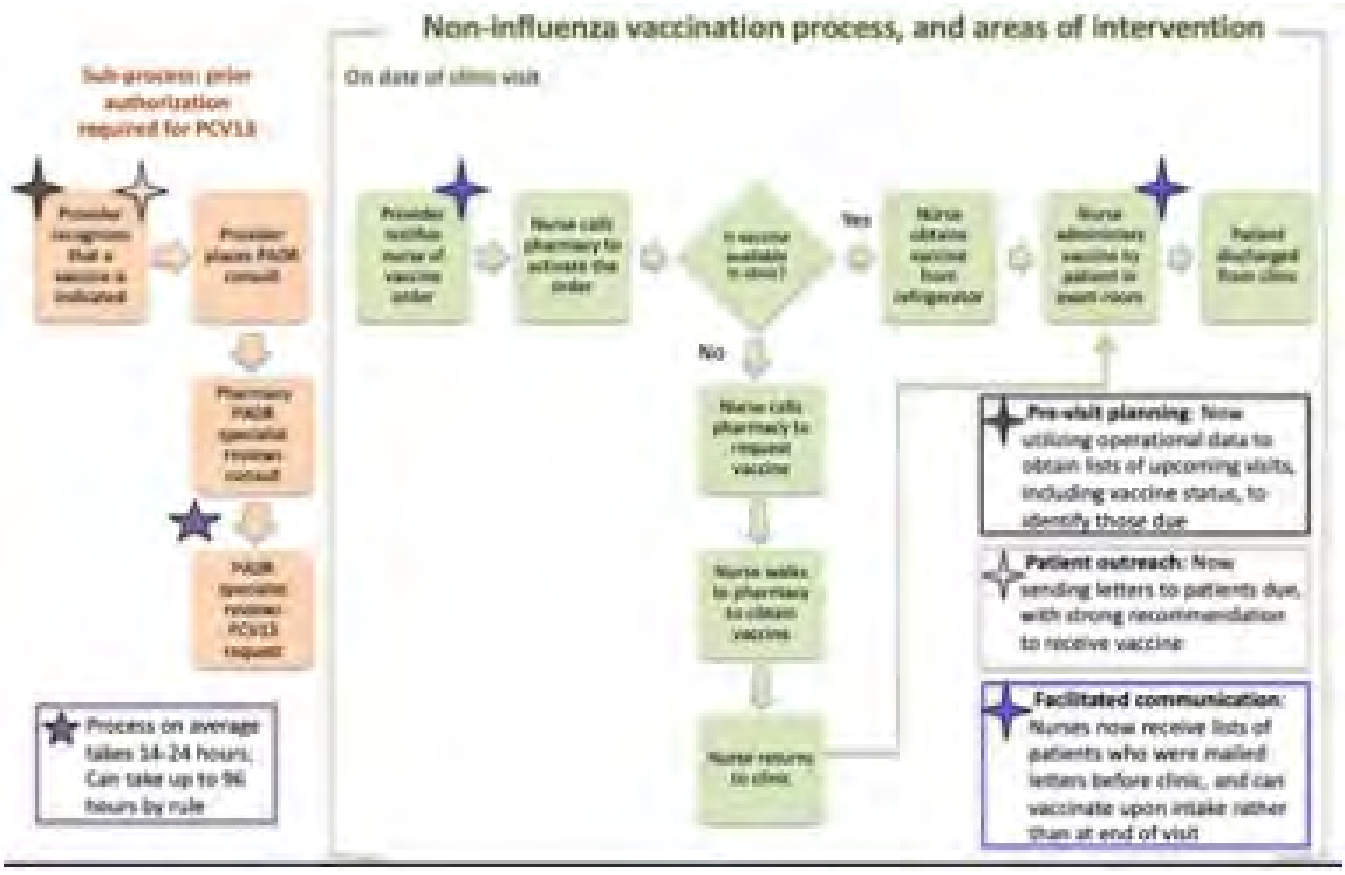

Figure 1. Process Map and Intervention

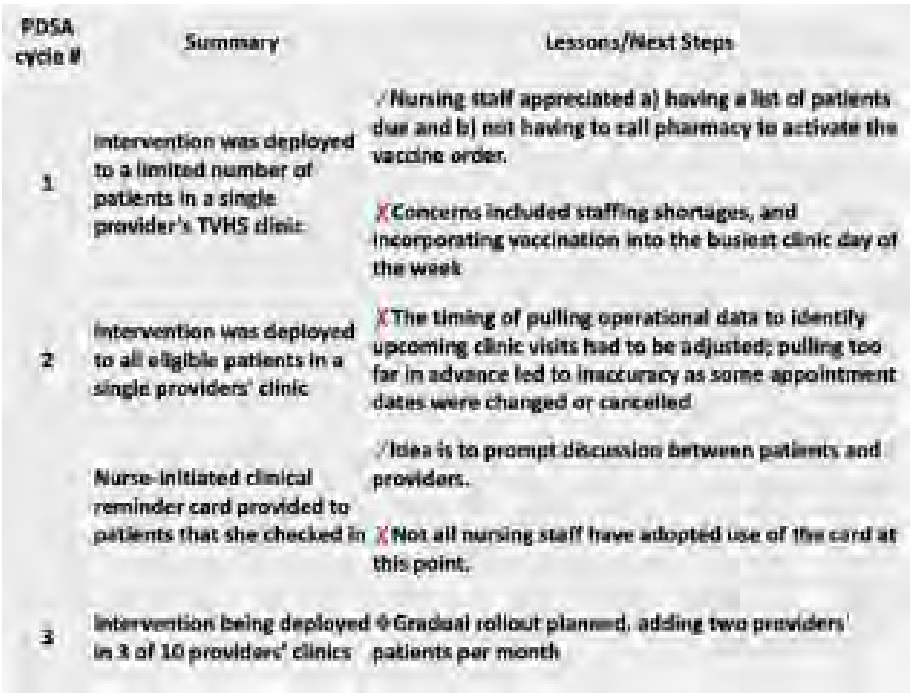

PDSA cycle #	Summary	Lessons/Next Steps
1	Intervention was deployed to a limited number of patients in a single provider's TVHS clinic	✓Nursing staff appreciated a) having a list of patients due and b) not having to call pharmacy to activate the vaccine order. ✗Concerns included staffing shortages, and incorporating vaccination into the busiest clinic day of the week
2	Intervention was deployed to all eligible patients in a single providers' clinic	✗The timing of pulling operational data to identify upcoming clinic visits had to be adjusted; pulling too far in advance led to inaccuracy as some appointment dates were changed or cancelled
	Nurse-initiated clinical reminder card provided to patients that she checked in	✓Idea is to prompt discussion between patients and providers. ✗Not all nursing staff have adopted use of the card at this point.
3	Intervention being deployed in 3 of 10 providers' clinics	✧Gradual rollout planned, adding two providers' patients per month

Figure 2. PDSA Summary

Background/Purpose: Patients with rheumatic diseases are at increased risk of invasive pneumococcal disease. Both pneumococcal conjugate vaccine (PCV13) and pneumococcal polysaccharide vaccine (PPSV23) are recommended for patients on immunosuppressant medications. However, under-vaccination of this population is common. The aim of this quality improvement project was to decrease the percent of patients in Tennessee Valley Healthcare System (TVHS) Rheumatology clinic due for vaccination in a given month from the baseline of 36% to a goal of 28% within 6 months.

Methods: Barriers to vaccination were identified and an intervention was designed incorporating patient outreach, provider outreach, and health system components (Figure 1). The primary outcome measure was the percent of randomly sampled patients due for a pneumococcal vaccination, assessed monthly. Process measures include the number of vaccinations administered in rheumatology clinic each month. Balancing measures included qualitative feedback from staff. The Plan Do Study Act (PDSA) cycle methodology was used to test and analyze process changes (Figure 2).

Results: Statistical process control (SPC) charts were used to visualize results (Figure 3). Post-implementation, the overall percent of patients due for a pneumococcal vaccination is statistically unchanged thus far, though trending downwards. The number of pneumococcal vaccines administered in clinic was steadily rising with a special cause signal seen in January 2020, however this change was not sustained. In the 9 month pre-intervention period, 38 vaccinations in total were administered in Rheumatology clinic, whereas in the post-intervention implementation period 54 vaccines were given in just 5 months.

Conclusion: A combination of operational data use, pre-visit planning, and patient outreach can lead to increased pneumococcal vaccination rates in a rheumatology clinic setting. The lack of statistically significant change in our primary outcome measure is likely explained by our sampling strategy, which samples from all providers' clinics, though the intervention had only been rolled out in about half of the providers' clinics before the COVID-19 pandemic. A more upstream process measure is the number of pneumococcal vaccinations administered in clinic each month, where

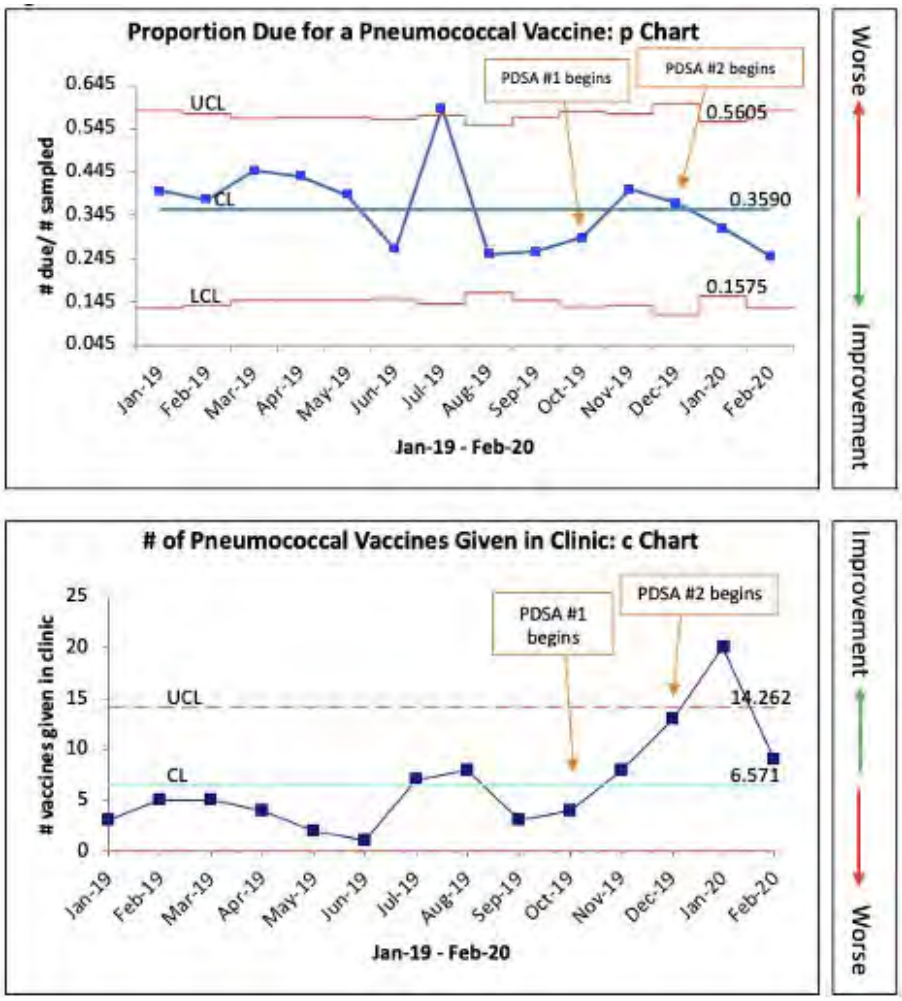

Figure 3. SPC Charts

we have seen signs of improvement. Next steps include 1) ongoing rollout to the clinics of all rheumatology providers, 2) development of an educational intervention for providers regarding the complex pneumococcal vaccination schedule, and 3) adaptations to the clinic templated note to include reminders and facilitate ordering.

Abstract Number: 1625

Pneumocystis Jiroveci Pneumonia in Immunocompromised Patients with Rheumatologic Disease in a Single, Tertiary Medical Center

Zahra Rehman[1], Megan Krause[1], Jessica Newman[2] and Pooja Bhadbhade[1], [1]The University of Kansas Medical Center, Kansas City, KS, [2]The University of Kansas Medical Center, Kansas City

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Measures & Measurement of Healthcare Quality Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Pneumocystis jiroveci pneumonia (PJP) is rare, but can be fatal among immunocompromised. There is no consensus on indications for PJP prophylaxis in rheumatologic patients. The challenge involves the benefit of prophylaxis with antimicrobials versus the risk of adverse events caused by the prophylactic medication.

Methods: A retrospective chart review was conducted to identify patients with PJP and a rheumatologic disease including rheumatoid arthritis (RA), Sjogren's syndrome, systemic lupus erythematosus (SLE), granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), microscopic polyangiitis (MPA), giant cell arteritis, polyarteritis nodosa, Takayasu's arteritis, dermatomyositis (DM), polymyositis, and systemic sclerosis (SSc) at a single, tertiary academic medical center between 1/1/2007 and 1/1/2019. Electronic medical records were reviewed to confirm diagnoses. PJP was based on clinical symptoms, laboratory studies (bronchoalveolar lavage PCR, Fungitell, beta 1,3 glucan, lactate dehydrogenase), radiographic findings, and infectious disease assessment. Data regarding immunosuppressants, prednisone use, lymphocyte count, interstitial lung disease (ILD), and use of prophylaxis was abstracted. PJP prophylaxis recommendations commonly used in rheumatologic patients were reviewed and indications for prophylaxis were determined.

Results: Fifteen patients were confirmed with a diagnosis of a rheumatologic disease and PJP. Diseases noted were RA in 5 patients, GPA in 3 patients, MPA in 2 patients, SLE in 1 patient, DM in 1 patient, psoriatic arthritis in 1 patient, antiphospholipid syndrome and autoimmune hemolytic anemia in 1 patient, and limited cutaneous SSc and necrotizing myopathy in 1 patient. Of these patients, 1 with SLE developed PJP despite prophylaxis with atovaquone. The other 14 patients did not receive prophylaxis. Fourteen of the 15 patients were on prednisone and 13 of these patients were on at least one additional immunosuppressant. Twelve of the 15 patients had lymphopenia at the time of PJP diagnosis, and 5 had ILD.

Four of the 15 patients who developed PJP were on low dose prednisone with at least one immunosuppressant. One of the 15 patients was on 3 immunosuppressants and no steroids. Three of these 5 patients had RA without ILD, 1 had PsA, and 1 had SSc with ILD and necrotizing myopathy. These 5 patients are considered low risk and prophylaxis would not be indicated due to current recommendations.

The remaining 10 patients would have been candidates for prophylaxis due to their dose and duration of prednisone, concurrent immunosuppression, or underlying disease.

Conclusion: Based on recommendations commonly used for PJP prophylaxis in patients with rheumatologic diseases, 10 of the 15 patients would have been candidates for prophylaxis and PJP may have been prevented, but 5 patients were considered low risk with no prophylactic indication. Although rheumatologists need to improve on utilizing PJP prophylaxis for high risk patients, this study indicates that further research is needed to determine individualized risk for initiating prophylaxis in rheumatologic patients who are not considered high risk for developing PJP.

Long-Term Follow-Up of Renal Transplantation Due to Lupus Nephritis. Single Universitary Center Experience

Lara Sanchez-Bilbao[1], Marina De Cos-Gomez[2], Inigo Gonzalez-Mazon[3], David Martinez-Lopez[4], Juan Carlos Ruiz-San Millan[2], Miguel Ángel González-Gay[5] and Ricardo Blanco[1], [1]Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, Spain, [3]Hospital Universitario Marques de Valdecilla, Bezana, Spain, [4]Hospital Universitario Marques de Valdecilla, Santander (SPAIN), Spain, [5]Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a severe complication of systemic lupus erythematosus (SLE). Approximately 10-20% of LN develop end stage renal disease (ESRD) and need replacement therapy. Renal transplantation may be a good option. However, concerns about LN recurrence after renal transplantation have been reported.

In a series of 23 patients with first renal transplantation due to LN our aim was to assess **a)** clinical features, **b)** renal transplantation as replacement therapy, **c)** SLE flares after transplantation.

Methods: Observational study of unselected all consecutive patients studied in a single reference University Hospital with**: a)** diagnosis of SLE by ACR/SLICC 2012 criteria. **b)** diagnosis of NL by performing biopsy (according to the World Health Organization and International Society of Nephrology/Renal Pathology Society classification), **c)** first renal transplant. Cumulative survival rates after transplantation were estimated by the Kaplan-Meier method.

Results: We studied 23 (16 women/7 men) patients with first renal transplantation due to LN; mean age at SLE diagnosis of 26.37±12.70 years and mean age at kidney transplantation of 39.80±11.27 years. Mean follow-up of 12.18±9.02 years. Demographic baseline characteristics and clinical manifestations of these patients are shown in **TABLE 1.**

The main clinical manifestations at diagnosis were articular (n= 12; 52.17%) and cutaneous (n=13; 56.52%). On the other hand, 16 patients (69.6%) presented impaired renal function at diagnosis. In the other 7 patients (30.4%), this manifestation appeared with a delay of diagnosis from the onset of symptoms of 13.17±7.73 years.

Renal biopsy had been performed in 21 patients with LN: type II LN (n=2; 9.1%), type III (n=8; 36.4%), type IV (n=9; 40.9%) and type V (n=2; 9.1%).

Graft and patients survival function after transplantation is represented in **Figure 1 and 2.**

Regarding lupus flares after transplantation, 3 patients (13.04 %) developed a lupus flare: 2 cases presented as extrarenal disease (one of them was a pneumonitis and the other one was a cutaneous and articular flare) and only 1 case with histological recurrence in the graft (Mean follow-up 15 ±9.84 years).

Conclusion: Renal transplantation is a safe alternative therapy for ESRD in this population and can provide a long-term survival. However, it is very important to consider the occurrence of flares even in the long-term post-transplant.

TABLE 1. Demographic baseline characteristics and clinical manifestations of patients with renal transplantation due to LN.

Phase I Trial of High-dose Hydroxychloroquine for the Treatment of Ambulatory Patients with Mild COVID-19: A Study in the Effects of Shifting Public Opinion on Patient Enrollment

Patrick Onkka[1], Pankti Reid[1], Iazsmin Bauer Ventura[1], Brian Labadie[2] and Reem Jan[1], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Coronavirus disease 2019 (COVID-19) was first recognized in December 2019 and quickly became a global pandemic within months. Amidst a myriad of uncertainties, early data from in-vitro analysis and a small-population retrospective study demonstrated promise for hydroxychloroquine (HCQ), a small molecule oral drug prevalently used for rheumatic diseases and previously in malarial therapy. The news of HCQ and its use in COVID-19 disseminated through social media channels and rose to international attention before proper conduct of large population, prospective clinical studies. It is within this capricious global environment that we discuss the unique pharmacokinetic (PK) reasoning for use of high dose HCQ in mild COVID-19 and subsequent proceedings of our phase I clinical trial and associated challenges.

Methods: We conducted a single-center, single-arm tolerability study for ambulatory patients with mild COVID-19 and risk factors for progression to moderate or severe disease. Physiologically based PK modeling suggests HCQ loading doses between 400 mg BID and 600 mg BID are effective in achieving desired lung tissue concentration, potentially enabling a faster clinical effect. Enrollment and consent were obtained remotely through a telephonic interaction between a physician and participant while the participant utilized the REDCap electronic consent platform. Participants took HCQ 600 mg twice daily for 5 days. Changes in symptoms and side effects were assessed via daily telephone questionnaire, with tolerability of HCQ at day 14 as the primary endpoint. Tolerability of the regimen was deemed acceptable if 80% of patients completed the protocol. Figure 1 shows the timeline of media releases with HCQ study recruitment.

Results: Ultimately, only 7 patients were enrolled in the study and 6 completed the 5 day course. Five patients (71%) tolerated the course without any side effects. One patient developed headaches, while another had nausea, vomiting, and diarrhea, was lost to follow up, and later hospitalized. After numerous reports in the media of potential severe side effects and ineffectiveness of HCQ for COVID-19 treatment, public opinion of HCQ shifted and potential participants became unwilling to be enrolled in the study, leading to its termination on 5/29/2020.

Conclusion: While a limited number of participants enrolled, no serious side effects were noted with use of high dose HCQ in mild COVID-19. We demonstrate that a large cohort prospective trial properly assessing HCQ in mild COVID-19 has many challenges in the current atmosphere, but given the tolerability of high doses HCQ, future research should give consideration of studying the potential benefit of this dose in rheumatic disease. (clinicaltrials.gov, *NCT04351620*)

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase is approved for severe gout in patients that are intolerant to, or whose disease is ineffectively controlled by, other uric acid lowering therapies (ULTs). The positioning of pegloticase as the last therapeutic option begs the question, how is gout managed once pegloticase is discontinued? Here we examine treatment following pegloticase for patients in US clinical care.

Methods: The ARN-TRIO Rheumatology registry contains EMR (fielded and open text), lab, procedure, infusion, medical claims, and specialty pharmacy data generated in care of >75,000 patients by ARN, a network of independent practices with >200 rheumatologists across the US. This study included data for gout-diagnosed patients who initiated their last pegloticase course between Jan 2015 and Dec 2019 with >90 days follow-up from pegloticase discontinuation (index). Comparisons were made using t-test for continuous variables and chi-square or Fischer's exact tests for categorical variables. Time to event analyses were by Kaplan-Meier and log-rank test. To assess consistency of control of sUA < 6 mg/dL, evaluations were limited to patients with 2+ sUA measures within the period of interest.

Results: 70 of 213 pegloticase-treated patients met study criteria; by time of assessment which was ≥90 days past pegloticase discontinuation, 49/70 (70%) initiated a ULT. [FIGURE 1] Median time from index to ULT initiation was 13 days; 76% (37/49) of initiations occurred within 30 days, 90% (44/49) 90 days, and 96% (47/49) 180 days. Median follow up for patients who did not initiate a subsequent ULT was 404 days, greater than but not significantly different from patients that did initiate ULT post-pegloticase (322 days, p=0.270). The absence of kidney disease was significantly associated with ULT initiation (39/47, 83% v. 14/23, 61% non-initiators, p=0.043). Variables NOT associated with ULT initiation within 180 days post-pegloticase included age, gender, race, ethnicity, payer, CVD, diabetes, non-gout rheumatic diseases, duration of prior pegloticase, and serum uric acid (sUA) ≥6 mg/dL during pegloticase or at pegloticase discontinuation. Of the 47 patients that initiated subsequent ULT within 180 days, 22 of 47 had 2+ sUA measures during treatment, and 9/22 (41%) had 2+ sUA ≥6 mg/dL. Two or more sUA results post-pegloticase were provided for 6/23 patients that did not initiate ULT within 180 days; 5/6 (83%) had 2+ sUA ≥6 mg/dL. [FIGURES 2 & 3]

Conclusion: After pegloticase discontinuation, most patients quickly initiated allopurinol. Consistent sUA < 6 ml/dL was not maintained post-pegloticase for half (14/28) of the evaluable patients. As the new 2020 ACR Guidelines for

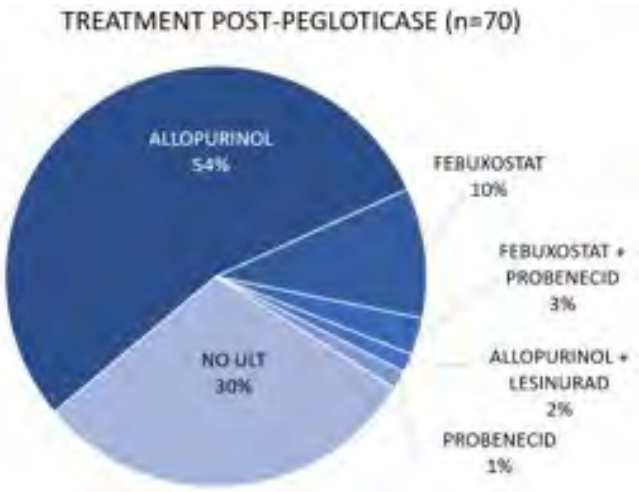

Figure 1. Treatment after pegloticase discontinuation (n=70)

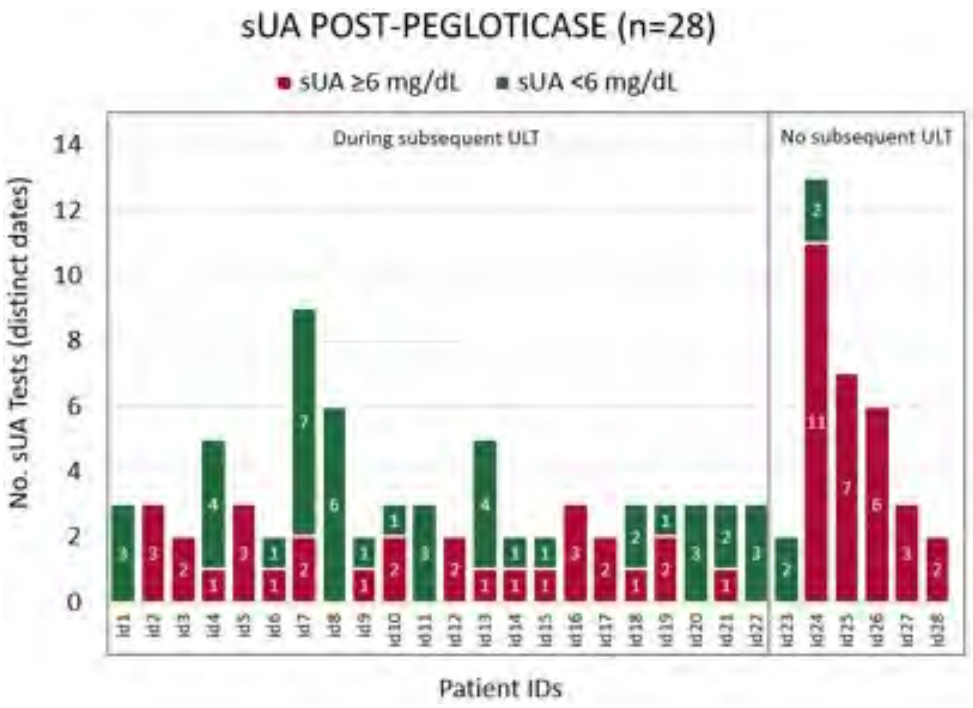

Figure 2. sUA test counts and results during ULT following pegloticase discontinuation (n=28)

the Management of Gout advises the treat to target approach to maintain sUA < 6 ml/dL, our results highlight the need for new ULTs and/or better strategies to maximize benefit with available therapies.

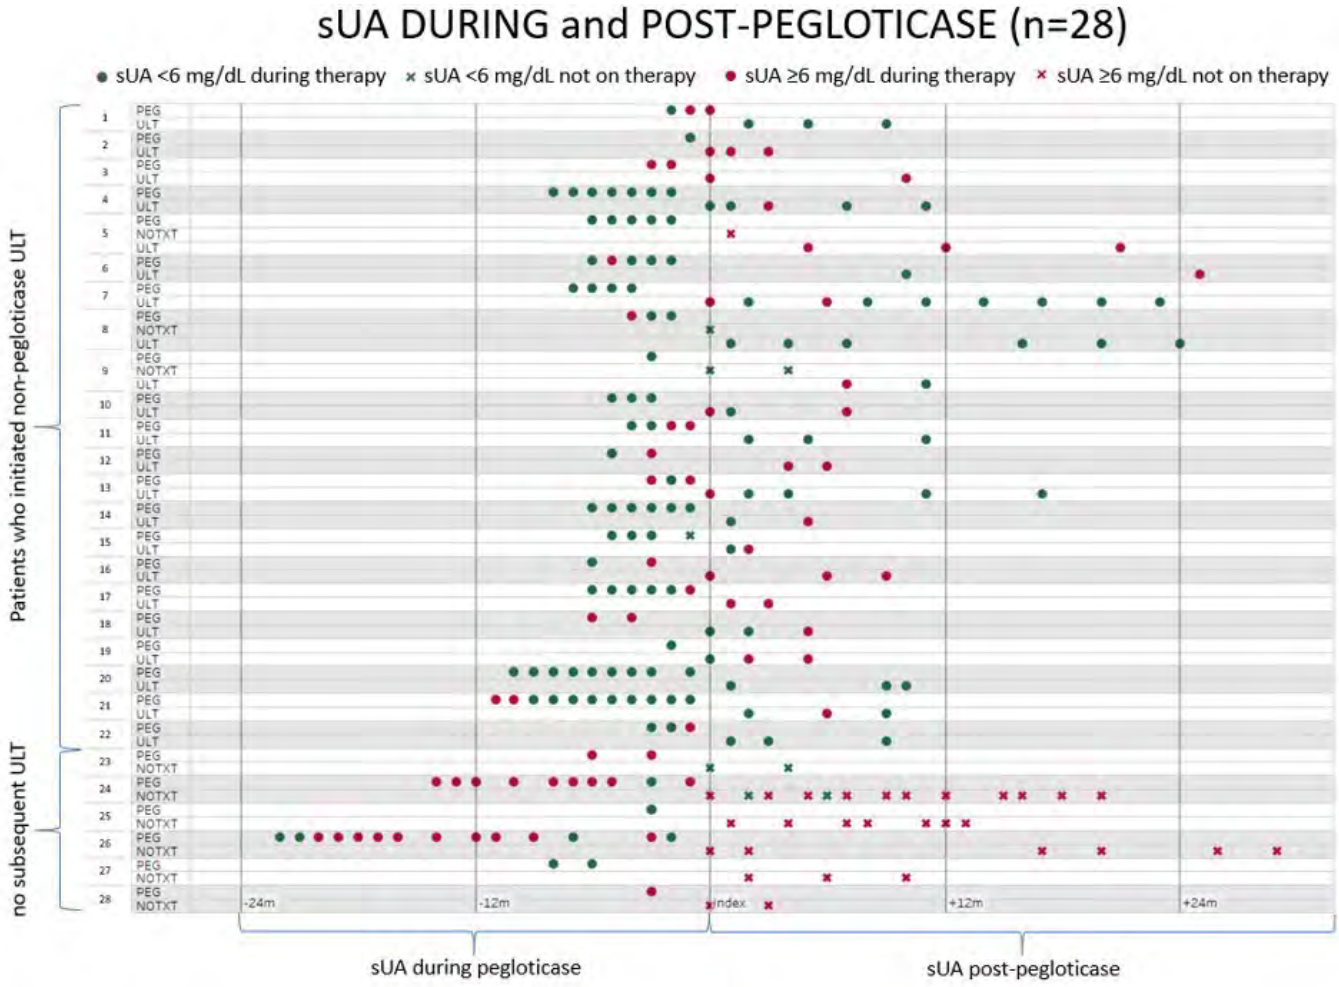

Figure 3. Alternative view of the patients in Figure 2, including sUA results during and after pegloticase treatment (n=28)

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Infusion reactions and other adverse events associated with pegloticase may lead to discontinuation of treatment in patient populations that have already failed or are intolerant to other uric acid lowering therapies (ULTs). Maximizing the benefit of pegloticase is critical in the absence of other suitable ULTs. Here, we examine use of pegloticase for patients in US clinical care and identify variables associated with longer time on therapy.

Methods: The ARN-TRIO Rheumatology registry contains EMR (fielded and open text), lab, procedure, infusion, medical claims, and specialty pharmacy data generated in care of >75,000 patients by ARN, a network of independent practices with >200 rheumatologists across the US. This study included data for gout-diagnosed patients who

Table 1. Study population characteristics

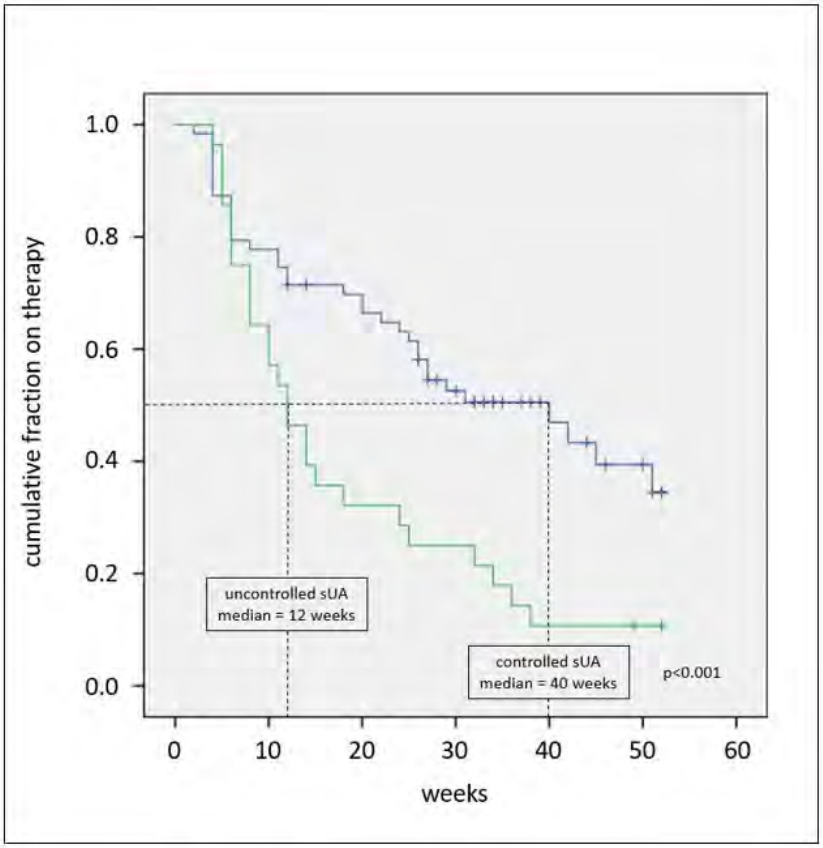

Figure 1. Time to unplanned pegloticase discontinuation stratified by uncontrolled (2+ sUA ≥ 6 mg/dL , green, n=28) or controlled (<2 sUA ≥ 6 mg/dL, blue, n=63) sUA

initiated their last pegloticase course between Jul 2015 and Oct 2019 with >180 days follow-up from pegloticase initiation (index). A course was defined as pegloticase infusions spaced < 90 days apart. Chart reviews were conducted for all study patients to determine treatment status (ongoing vs. discontinued) and reasons for discontinuation. To assess consistency of control of sUA < 6 mg/dL, evaluations were limited to patients with 2+ sUA measures during treatment. Time to event analyses were by Kaplan-Meier and log-rank or Wilcoxon test.

Results: 110 of 213 pegloticase-treated patients met study criteria. [TABLE 1] At time of assessment, 84% (95) had discontinued treatment; 19% (18/95) discontinued as intended upon meeting treatment goals, 39% (37/95) lack or loss of efficacy, 16% (15/95) adverse events, 8% (8/95) lost to follow up, 2% (2/95) each for cost or payer denial and unrelated health issues, and 17% (16/95) unknown. Of the 15 patients who discontinued therapy due to adverse events, 80% (12) cited infusion and/or allergic reactions. Median times to discontinuation were 20 weeks overall and 22 weeks for non-planned discontinuation. Controlled sUA (< 2 sUA ≥6 mg/dL) and concurrent use of immune-modulating therapies (predominantly methotrexate) were associated with a significantly longer pegloticase duration. [FIGURES 1 & 2] Variables NOT associated with unplanned discontinuation were race, gender, age, payer type, kidney disease, osteoarthritis or osteoporosis, baseline sUA, and pegloticase infusion schedule. None of the 12 patients who discontinued due to infusion or allergic reactions received concurrent immune-modulating therapies.

Conclusion: These observations suggest that treatment with pegloticase may be lengthened with concomitant use of immune-modulating therapies; however, a larger scale prospective study should be done to further elucidate the benefits of immunomodulation beyond durability of treatment, including safety benefits such as minimal to no infusion reactions.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity anti–interleukin-23p19 monoclonal antibody that is approved for the treatment of moderate to severe plaque psoriasis. The objective of this study was to evaluate major adverse cardiovascular events (MACE) in two phase 3 trials: reSURFACE 1 (NCT01722331) and reSURFACE 2 (NCT01729754).

Methods: This is a post hoc pooled analysis of adult patients with moderate to severe plaque psoriasis from two 3-part, parallel-group, double-blinded, randomized controlled trials: reSURFACE 1 (64 week) and reSURFACE 2 (52 week). Detailed methodology has previously been published. Safety data over 148 weeks, pooled across trials and treatment groups, were included. Groups were defined as placebo, etanercept (until week 28), TIL 100 mg (100 mg only in ≥1 part of the study), TIL 200 mg (200 mg only in ≥1 part of the study), continuous TIL 100 mg (100 mg throughout the three double-blinded parts plus open-label extension), continuous TIL 200 mg (200 mg throughout all parts), TIL 100/200 mg (any TIL dose in ≥1 part), and continuous TIL 100/200 mg (consistently exposed to TIL, but dose change possible throughout all parts). Exposure-adjusted incidence rates (EAIR) for confirmed MACE (including non-fatal myocardial infarction, non-fatal stroke, unstable angina, coronary revascularization, resuscitated cardiac arrest, and cardiovascular deaths that were confirmed as “cardiovascular” or “sudden”) were reported.

Results: Overall, 928 patients on TIL 200 mg, 872 on TIL 100 mg, 316 on continuous TIL 200 mg, 352 on continuous TIL 100 mg, 543 on placebo, 1646 on TIL 100/200 mg, 808 on continuous TIL 100/200 mg, and 313 on etanercept were included. EAIR for MACE were 0.54 (TIL 200 mg), 0.40 (TIL 100 mg), 0.29 (continuous TIL 200 mg), 0.36 (continuous TIL 100 mg), 0.49 (placebo), 0.47 (TIL 100/200 mg), 0.35 (continuous TIL 100/200 mg), and 0.65 (etanercept) per 100 patient-years of exposure.

Conclusion: Tildrakizumab had a favorable long-term safety profile as demonstrated by a low rate of MACE (comparable to etanercept and placebo) in patients with moderate to severe plaque psoriasis.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity, humanized, immunoglobulin G1κ, anti–interleukin-23p19 monoclonal antibody approved for the treatment of moderate to severe plaque psoriasis. We evaluated adverse events related to liver function in the clinical development program for TIL.

Methods: This post hoc analysis included patients with moderate to severe chronic plaque psoriasis in 1 phase 2b (P05495, NCT01225731) and 2 phase 3 trials (reSURFACE 1 and 2, NCT01722331 and NCT01729754). In P05495, patients received placebo (PBO) or TIL 5, 25, 100, or 200 mg. In reSURFACE 1 and 2, patients received PBO or TIL 100 or 200 mg; reSURFACE 2 had an additional etanercept (ETN) 50 mg arm up to week (W)28. Patients were treated at W0 and W4 and then every 12 weeks, and were followed for up to W52 (P05495/reSURFACE 2) or 64 (reSURFACE 1). The primary safety population was all subjects as treated (≥1 dose of study treatment). We evaluated liver function test (LFT) findings in patients receiving TIL 100 or 200 mg using pooled safety data from the base studies (P05495, n = 355; reSURFACE 1, n = 771; reSURFACE 2, n = 1090). LFT events of clinical interest were defined as elevated aspartate or alanine transaminase (AST or ALT) levels ≥3 times the upper limit of normal (ULN) and elevated total bilirubin (BILI) levels ≥2 times the ULN combined with alkaline phosphatase levels (ALP) < 2 times the ULN. Extension study data are also provided.

Results: In the PBO-controlled periods, 2 patients (0.6%) in the PBO and 1 (0.1%) in the TIL 200 mg group discontinued due to elevated LFT. In the base study periods, the numbers of patients (patients with events/100 patient-years) with elevated LFT leading to treatment discontinuation were similar between PBO (2 [0.91]) and TIL (4 [0.21]) groups. No patients discontinued in the ETN group due to elevated LFT. Two patients had elevated LFT events of clinical interest not related to study treatment. During the extension, no patients met the criteria for elevated LFT events of clinical interest. In the base study safety pool, there were no patterns of worsening in AST, ALP, and BILI levels over the study course for patients with continuous TIL 100/200 mg exposure. Of patients with normal ALT levels at baseline, 26% had a high ALT result at some point during the study. Similar patterns were seen in the extension.

Conclusion: Patients receiving TIL had low rates of increased liver function or drug-induced liver injury, similar to patients receiving PBO or ETN. There were no consistent signals for LFT worsening over the study course.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoinflammatory periodic fever syndromes characterized by excessive interleukin(IL)-1ß release and severe systemic and organ inflammation have been successfully treated with the anti-IL-1ß inhibitor canakinumab. In clinical trial situations and real life, rapid remission of symptoms and normalization of laboratory parameters were observed in most patients.[1-3]

The present study explores long-term effectiveness and safety of canakinumab under routine clinical practice conditions in pediatric and adult patients with CAPS (cryopyrin-associated periodic syndromes), FMF (familial Mediterranean fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

[3]De Benedetti et al. N Engl J Med. 2018;378(20):1908-1919

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up period. Pediatric (age ≥2 years) and adult patients with clinically confirmed diagnoses of CAPS, FMF, TRAPS and HIDS/MKD that routinely receive canakinumab are enrolled in order to evaluate effectiveness and safety

	FMF				TRAPS	HIDS

Table 1. Baseline characteristics of the FMF/TRAPS/HIDS-subgroup and preliminary 6-month interim data of 16 FMF patients *Baseline of FMF patient subset (N=16) with preliminary 6 and 12-month data

of canakinumab under standard clinical practice conditions. Evaluation of disease activity and fatigue by patients' assessment, days absent from school/work due to study indication, inflammatory markers and physician assessment of disease remission was performed at baseline and will be further assessed at 6-monthly intervals within the 3-year observation period of the study.

Results: This first interim analysis of 41 patients enrolled by September 2019, diagnosed with FMF (n=29), TRAPS (n=10) and HIDS/MKD (n=2), includes baseline data as well as preliminary 12-month data of a FMF subset (N=16). Mean age at baseline for FMF-TRAPS-HIDS/MKD patients was 26-22-11 years and mean duration of prior canakinumab treatment was 2.2-1-3 years.

Preliminary results of the FMF subset of N=16 patients diagnosed with FMF indicate stable remission and disease control during observation period. Within the first study interval, no major changes were observed regarding physician ratings, patient reported outcomes and inflammatory markers (Table 1). The AIDAI score of disease activity revealed inactive disease in 9 out of 12 months (Table 2). Preferred canakinumab doses and intervals (% of all injections) were 150 mg every 4 weeks (24), 150 mg every 6 weeks (11), and 150 mg every 8 weeks (21). Any serious adverse events were reported for 2 patients including tonsillectomy (drug-related) and arthritis. No study discontinuations were observed.

Conclusion: Baseline characteristics of the FMF-TRAPS-HIDS/MKD-subgroup are reported. In addition, first interim data of FMF patients available from the RELIANCE registry show that long-term CAN treatment is well tolerated and effective in FMF patients.

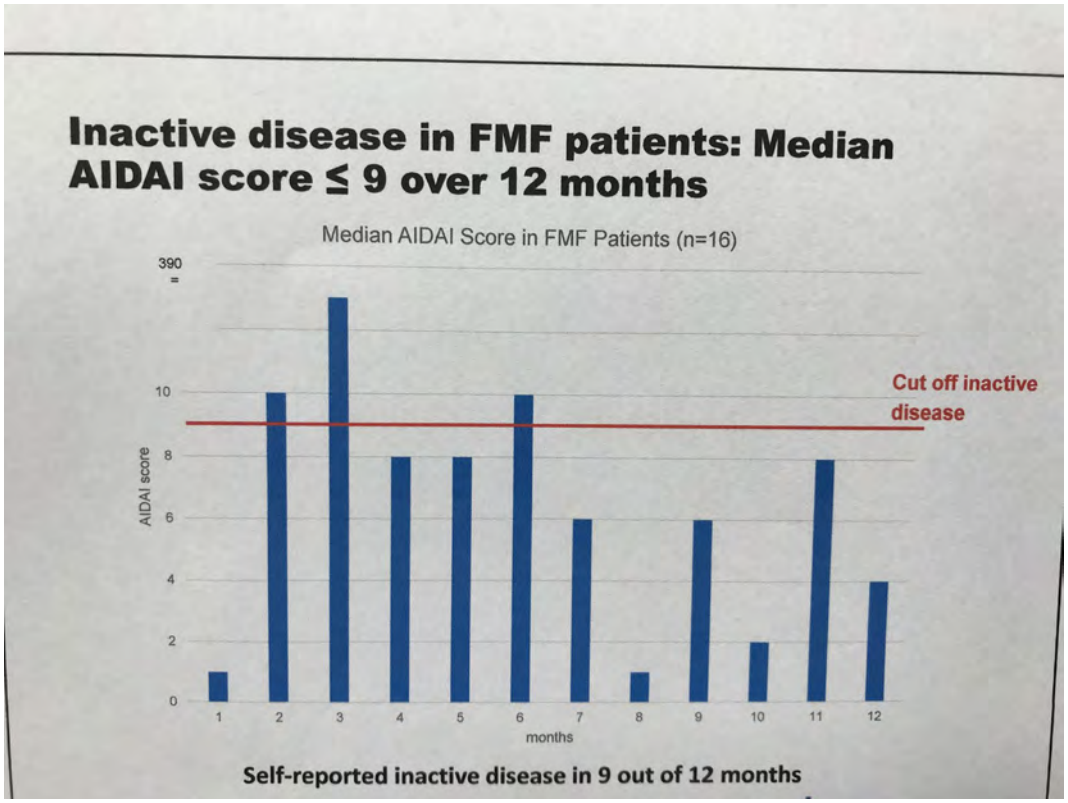

Table 2. Median AIDAI Score of the FMF subgroup (n=16) Over 12 Months

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Still's disease, including both systemic juvenile idiopathic arthritis (SJIA) and adult-onset Still's disease (AOSD), is a rare systemic auto-inflammatory disorder associated with an activated IL-1 pathway. The purpose of the anaSTILLs study (anakinra in Still's disease) was to build on earlier evidence and evaluate, in a controlled setting, the efficacy and safety of anakinra (IL-1 receptor antagonist), in patients with active, newly diagnosed Still's disease across all age groups.

Methods: The anaSTILLs study (NCT03265132) was a randomized, double-blind, placebo-controlled, 12-week study including patients with active and newly diagnosed Still's disease (adapted ILAR criteria if < 16 years of age, Yama-

● Bullets indicate ACR90 response at the particular week.
Patient 1 had sustained ACR70 response but not ACR90.

guchi criteria if ≥16 years of age at disease onset). Patients were randomized to anakinra 2 mg/kg (max 100 mg/day), 4 mg/kg (max 200 mg/day) or placebo. The primary objective was to demonstrate the efficacy of anakinra versus placebo as assessed by ACR30 response with absence of fever at Week 2. Secondary objectives included: early onset of efficacy, sustained efficacy, time to study drug discontinuation, safety, pharmacokinetics (PK), clinical signs and biomarkers.

Results: Twelve patients were randomized and received study treatment: 6 to anakinra (2 mg/kg n=2, 4 mg/kg n=4) and 6 to placebo. Due to slow recruitment the study was terminated early. One patient was excluded from the efficacy analyses since he/she was later diagnosed with lymphoma, not Still's disease. 11 patients were analyzed for efficacy (anakinra n=6, placebo n=5), 8 children (median [range] age=4.0 [1-11] years) and 3 adults (median [range] age=32.0 [25-51] years). 55% were male and the mean (range) symptom duration was 74.2 (12-222) days. All patients on anakinra but none on placebo achieved ACR30 response with absence of fever at Week 2 (p-value=0.0022). The efficacy of anakinra was supported by superiority to placebo in ACR50/70/90 responses with absence of fever at Week 2. All placebo patients discontinued the study within 6 weeks, 2 due to progressive disease, 2 due to lack of efficacy and 1 due to withdrawal by the patient. A numerically greater proportion of patients in the anakinra group had early onset of efficacy (Week 1) compared to placebo, as assessed by ACR30. ACR30/50/70/90 responses in anakinra-treated patients were sustained throughout the study period. No unexpected safety findings were observed. Based on serum anakinra concentrations Week 12, Cmax was 2920 ng/mL at 4.0 hours (dose: 4.1 mg/kg) in a 1-year-old patient, and Cmax was 1060 ng/mL at 2.1 hours (dose: 1.5 mg/kg) in a 6-year-old patient.

Conclusion: Anakinra is superior to placebo in the treatment of Still's disease. The safety and PK results are consistent with previous anakinra experience. These results confirm the benefits of anakinra treatment in patients with active, newly diagnosed Still's disease across ages.

Etiologies and Management of Hemophagocytic Lymphohistiocytosis: Is It Time for an Updated Protocol and Targeted Treatments?

Therese Posas-Mendoza[1], Cara McLeod[1], William Davis[2] and Robert Quinet[2], [1]Ochsner Medical Center, New Orleans, LA, [2]Dept of Rheumatology, Ochsner Medical Center, New Orleans, LA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is a rare life-threatening disease characterized by immune-overstimulation and a hyperinflammatory response resulting in cytokine storm and multi-organ failure.[1]

	Age	Gender	Predisposing Condition	Immunosuppressive Treatment prior to Onset	Precipitating Factor	Treatment	Outcome
P1	53	F	Marginal cell lymphoma	Rituximab and bendamustine	Pyelonephritis and Pneumonia	HLH-94 Protocol, antibiotics	Deceased
P2	37	F	Juvenile idiopathic arthritis	Abatacept and azathioprine	EBV	Methylprednisolone 1000mg x 3 days	Resolution
P3	22	F	-	-	Streptococcal toxic shock syndrome	HLH-94 Protocol, IVIg, antibiotics	Deceased
P4	21	M	Crohn's disease	6-mercaptopurine	CMV	Methylprednisolone 1000mg x 3 days, antivirals, tocilizumab 4mg/kg	Resolution
P5	47	M	B-cell lymphoma, psoriasis and CVID	R-EPOCH, topical steroids, phototherapy	MRSA cellulitis	HLH-94 Protocol, antibiotics, antifungals	Deceased
P6	19	M	Adult onset Still's disease	Anakinra	EBV	Anakinra, methylprednisolone 1000mg x 3 days	Resolution
P7	30	F	Dermatomyositis	Prednisone	Pharyngitis with negative serology	Methylprednisolone 1000mg x 5 days IVIg 2g/kg over 5 days, cyclosporine 125mg, then rituximab	Resolution
P8	36	F	T cell lymphoproliferative disorder	Cyclophosphamide, vincristine, prednisone	T cell lymphoproliferative disorder	HLH-94 protocol then alemtuzumab	Recurrent HLH, then deceased
P9	43	M	NK cell leukemia	HLH-2004 Protocol	NK cell leukemia	HLH-94 Protocol	Deceased
P10	46	F	SLE, Kikuchi disease	Hydroxychloroquine	SLE flare	Methylprednisolone 1000mg x 3 days, IVIG 2g/kg over 5 days, then rituximab 375mg weekly x 4 weeks	Resolution
P11	18	F	-	-	Pyelonephritis	Antibiotics	Resolution
P12	25	M	-	-	Mycoplasma pneumonia	HLH-94 Protocol, antibiotics	Deceased
P13	33	F	NK cell lymphoma	Gemcitabine, cisplatin, dexamethasone	MAC pneumonia	HLH-94 protocol, antibiotics	Deceased
P14	60	M	S/P Liver transplant for alcoholic cirrhosis and HCV	Mycophenolate and tacrolimus	Invasive aspergillosis, pneumonia	HLH-94 protocol, antibiotics, antifungals	Deceased
P15	50	F	SLE	-	Possible autoimmune hepatitis	HLH-94 protocol, cyclophosphamide, IVIg	Deceased

Table 1. Therapeutic Approaches and Outcomes (1/2)

	Age	Gender	Predisposing Condition	Immunosuppressive Treatment Prior to Onset	Precipitating Factor	Treatment	Outcome
P16	70	F	T cell lymphoma, sarcoidosis	R-CHOP	EBV	Methylprednisolone 1000mg x 3 days then R-CHOP	Resolution
P17	35	M	-	-	Group G streptococcus Lemierre's disease	Antibiotics, surgery	Resolution
P18	62	M	Peripheral T-cell lymphoma of the thorax	EPOCH	-	HLH-94 protocol	Resolution
P19	29	M	-	-	EBV	HLH-94 protocol, ganciclovir	Resolution
P20	21	F	Systemic juvenile idiopathic arthritis	Methotrexate and tocilizumab	EBV	Methylprednisolone 1000mg x 3 days	Resolution
P21	65	F	Rheumatoid arthritis	Methotrexate, prednisone, etanercept	Large B cell lymphoma	HLH-94 protocol	Deceased
P22	38	F	SLE	Hydroxychloroquine	Influenza	Supportive therapy	Resolution
P23	56	M	Ulcerative colitis	Azathioprine and mesalamine	CMV	Ganciclovir	Resolution

P25	27	F	Adult onset Still's disease	Prednisone	-	HLH-94 protocol	Recurrence of HLH, invasive fungal infection
P26	24	F	Pituitary tumor s/p resection	-	CMV	Antiviral, antibiotics	Deceased
P27	55	M	-	-	HSV encephalitis, MSSA pneumonia	Acyclovir, antibiotics	Resolution
P28	33	M	SLE	Hydroxychloroquine, cyclophosphamide 1 year prior	MSSA bursitis	Antibiotics, methylprednisolone 1000mg x 3 days	Resolution
P29	51	M	Angioimmunoblastic T-cell lymphoma	-	Angioimmunoblastic T-cell lymphoma	HLH-94 protocol	Resolution

* R-CHOP = rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone; EPOCH = etoposide, vincristine, doxorubicin, and prednisone; EBV = Epstein Barr Virus; CMV = cytomegalovirus; SLE = systemic lupus erythematosus; HLH-94 protocol = dexamethasone daily (10 mg/m^2 for 2 weeks, 5 mg/m^2 for 2 weeks, 2.5 mg/m^2 for 2 weeks, 1.25 mg/m^2 for 1 week, and taper and discontinue during one week; then pulses every second week with 10 mg/m^2 for 3 days), etoposide 150 mg/m^2 IV, cyclosporine A aiming at trough levels of 200 µg/L, intrathecal methotrexate 12mg per dose if with progressive neurological symptoms [16]

Table 1. Therapeutic Approaches and Outcomes (2/2)

Secondary HLH usually occurs in adults in the setting of malignancy, infection, or a rheumatic condition. It is often triggered by an infection such as Epstein-Barr virus (EBV).[1] Secondary HLH occurring in patients with autoimmune diseases is referred to as macrophage activation syndrome (MAS). The approach to the management of secondary HLH can be confusing and problematic due to the rarity of the condition and the heterogeneity of treatment approaches for HLH. The aim of this study was to study the patients diagnosed with hemophagocytic lymphohistiocytosis at our center, and to compare their predisposing conditions, treatments, and outcomes.

Methods: We conducted a retrospective chart review of all patients over 18 years of age diagnosed with hemophagocytic lymphohistiocytosis at our center between 2013 and 2019. Patients who met HLH-2004 or H-score criteria were included in this study. The patients' presentations, management, and outcomes were analyzed.

Results: Twenty-nine patients with hemophagocytic lymphohistiocytosis met inclusion criteria. 7 patients had a malignancy, 11 had a rheumatic disease, 6 had an infection alone, 2 were transplant patients, and 3 had a combination of malignancy, rheumatic disease, and/or infection. Of all the patients treated with the HLH-94 protocol 73% (11/15) died, 13% (2/15) had recurrence of HLH, and 6% (1/15) developed an invasive fungal infection. The patients with underlying rheumatologic conditions received targeted personalized therapy with pulse steroids, tocilizumab, anakinra, IVIg, cyclosporin, rituximab and/or cyclophosphamide in addition to antiviral/antibiotic therapy. All of the patients treated with targeted therapy had resolution of HLH.

Conclusion: Our findings suggest that the rheumatologic patient population responds well to a targeted and more personalized therapeutic approach, and poorly to the standard HLH-94 protocol. It is unclear whether the poor outcomes found with the use of the HLH protocol are secondary to the protocol itself, or the aggressive nature of

malignancy-associated HLH. HLH is a rare life-threatening disease, and further studies are needed to develop more tailored therapeutic regimens.

Profile of Topical Diclofenac Sodium Gel 1% (Voltaren®) Users in a United States Longitudinal Electronic Health Records Database

Amy Kenneally[1], Frédérique Bariguian[2], Richard Petruschke[1], Arlene Tave[3], **Jess Edison**[4], Nicholas M. Sicignano[5] and Francis Barbone[1], [1]GSK Consumer Healthcare, Warren, NJ, [2]GSK Consumer Healthcare S.A., Nyon, Switzerland, [3]PharmaLex US Corporation, Fairfax, VA, [4]Walter Reed National Military Medical Center, Bethesda, [5]Health ResearchTx LLC., Prevose, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Diclofenac sodium gel 1% (DSG), a topical non-steroidal anti-inflammatory drug (NSAID), is effective for the relief of osteoarthritis (OA) pain in the elbows, wrists, hands, feet, ankles, and knees. Over-the-counter (OTC) NSAIDs, including DSG, carry label warnings for systemic side effects, such as gastrointestinal (GI), cardiovascular (CV), and hepatic events. However, in controlled clinical trials, DSG had similar rates of these adverse events as placebo, with only application-site reactions reported more frequently. This study was conducted to support the switch of DSG from a prescription to an OTC product in the USA (OTC approved February 2020) and to further evaluate DSG for NSAID-associated events of interest (EOIs) in a real-world setting.

Methods: This retrospective, longitudinal cohort study sourced data from the United States Department of Defense Military Health System (MHS) electronic health records database. The study period was 01Jan2007 to 31Dec2016. Individuals with ≥1 prescription for DSG dispensed between 01Jan2008 and 30June2016 (screening period) and ≥1 year of continuous enrollment/eligibility in the MHS prior to their first DSG prescription fill in the screening period (index date) were included. ICD-9-CM/ICD-10-CM diagnosis, ICD-9-CM/ICD-10-PCS procedure codes, and medications (as proxy) were used to identify specific EOIs (ie, GI, hepatic, or renal injury/disease, CV event/disease, incident or exacerbated hypertension, skin reactions, misuse/abuse, and death). These were assessed from the index date until earliest occurrence of last DSG treatment episode end date, disenrollment from MHS, death, or end of study (follow-up period).

Results: For 521,593 individuals with ≥1 DSG prescription fill who met study criteria, mean age was 57 years and 60% were female; the median duration of follow-up was 60 days. Overall, 79% of the study population had baseline diagnoses of musculoskeletal and/or connective tissue diseases, and 32% had a baseline diagnosis of OA (**Table 1**). Comorbidities included obesity, diabetes, smoking, alcohol use, and lupus (**Table 1**). At baseline, >50% of patients also had filled prescriptions for NSAIDs or opioids. Overall, 93% of the population had risk factors at baseline associated with ≥1 of the 7 study EOIs (excluding death; **Table 1**); baseline risk factors for GI, CV, hypertension, and hepatic events were 79%, 63%, 52%, and 49%, respectively. In presence of baseline risk factors, 26% of the population experienced ≥1 EOI during the study period; mean (SD) time from index date to first event was 244 (369) days. An average of 2.5 DSG prescription fills per patient was dispensed during the study period (**Table 2**).

Table 1. Baseline Medical History and Comorbid Conditions of Individuals With DSG Prescriptions in the MHS Database From January 1, 2008 – December 31, 2016

Table 2. Treatment Patterns Associated With DSG Use During the Study Period: Data From the MHS Database From January 1, 2008 – December 31, 2016

	N	%
All individuals	**521,593**	***100***
Number of DSG prescriptions dispensed		
Mean, SD	2.5	*3.6*
1 prescription	301,441	*57.8*
2 prescriptions	91,065	*17.5*
3+ prescriptions	129,087	*24.7*
Number of therapy periods		
Mean, SD	1.9	*1.8*
Median	1	
Maximum	31	
1 therapy period	329,238	*63.1*
2 therapy periods	95,738	*18.4*
3+ therapy periods	96,617	*18.5*

DSG, diclofenac sodium gel 1%; GI, gastrointestinal; MHS, Military Health System.

Conclusion: The >500,000 DSG users in this retrospective study were generally older, more likely to be female, and had baseline comorbidities and risk factors of interest. Over half had a history of NSAID or opioid use at baseline. This study found that few DSG users (< 15%) had any single EOI despite baseline comorbidities and risk for these events, and that the EOIs on average occurred after the last prescription fill when DSG was no longer being used.

8 Years Follow-Up of a Novel Autoinflammatory Disease: CD59 Malfunction Causes Hemolytic Anemia, Recurrent Guillain-Barre Syndrome, and Strokes in Pediatric Populations and Respond Well to Eculizumab and Pozelimab

Dror Mevorach[1] and Netanel Karbian[1], [1]Hadassah-University Hospital, Jerusalem, Yerushalayim, Israel

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2013 we have described the first patients with a novel autoinflammatory disease manifested in 4 children with recurrent Guillain-Barre syndrome and hemolytic anemia in infancy due to loss of function of CD59 (Nevo et al., Blood). Since then, additional 3 mutations were recognized and clinical course of 14 patients was

documented. Eculizumab was started in all patients and polezimab in one patient and clinical course was evaluated using clinical scores questionnaires and follow-up and laboratory evaluation.

Methods: The 4 mutations, p.Cys64Tyr, p.Asp24Val, p.Asp24Valfs*, and p.Ala16Alafs*, were identified in 14 individuals with CD59 malfunction. All 14 presented with recurrent Guillain-Barré syndrome or chronic inflammatory demyelinating polyneuropathy, recurrent strokes, and chronic hemolysis. The molecular consequences of the 4 mutations and their effects on CD59 expression, localization, glycosylation, degradation, secretion, and function was evaluated and treatment with eculizumab or pozelimab was established with a follow-up up to 7 years. All patients responded well to eculizumab. One patient developed hypersensitivity to eculizumab that was successfully switched to pozelimab with similar clinical and in vitro complement inhibition effect.

In this study we aimed to determine whether chronic hemolysis and cumulative doses of steroid and IV IgG were reduced, and neurological deficits compared to those observed before treatment, were ameliorated. Treatment response was evaluated every 4 weeks over 6-8 years and included examination with gross motor scoring ASIA and INCAT, laboratory examination, and SF-12 fulfillment. Neurological relapses and the cumulative dose of IVIG and/or corticosteroids before and after initiation of treatment were documented. RBCs and neutrophils were stained to evaluate C5b-9 deposition. ClinicalTrials.gov, NCT01579838.

Results: All patients responded well to eculizumab. One patient developed hypersensitivity to eculizumab that was successfully switched to pozelimab with similar clinical and in vitro complement inhibition effect.

A 7-8 years follow-up in 4 patients showed a dramatic and significant neurological amelioration in the upper limbs and trunk with a more modest amelioration in the lower limbs was observed and maintained in all patients. Corticosteroids and immunoglobulin treatment, which had been used extensively prior to eculizumab initiation, was completely stopped. No patient suffered a relapse during the treatment period despite infections, and there were no hospital admissions apart fro 2 admissions due to reduced drug administration and allergic reaction. Decreased deposition of C3bi and C5b-9 on RBCs and neutrophils was documented ($p < 0.0001$). The SF-12 health questionnaires indicated significant improvement ($p < 0.003$).

Conclusion: The autoinflammatory disease seen with CD59 congenital malfunction was well controlled by eculizumab and pozelimab

Comparison of Nation-wide Epidemical Study on 2009 and That on 2019 Revealed That Improvement of Disease Severity and Mortality Rate May Come from Progress of Proficient Management in Patients with Relapsing Polychondritis in Japan

Jun Shimizu[1], Yoshihisa Yamano[1], Kimito Kawahata[2] and Noboru Suzuki[1], [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: We conducted a retrospective survey study in 2009 and collected clinical data of 239 patients with relapsing polychondritis (RP). Using the survey data, we found a strong inverse relationship between ear and airway involvement, suggesting that the two major clinical symptoms of RP occurred in a mutually exclusive manner (Arthritis Rheumatol. 2018). When we divided the patients into three subgroups, namely patients with airway involvement (A subgroup, 20% of 239 patients), patients with ear involvement (E subgroup, 49%), and patients with both ear and airway involvement (B subgroup, 29%), patients in B subgroup had more progressive and longer disease course (Medicine. 2018). Actually, 59% patients presented with ear involvement at disease onset and a third of the patients were allocated into B subgroup (patients with both ear and airway involvement) with a high mortality rate (BMC Rheumatol. 2020). To confirm the issue, we conducted 2nd nationwide survey in 2019.

Methods: The survey questionnaire was sent to Japanese major medical facilities and outpatient clinics in 2019. In this study, we analyzed clinical data of 128 patients with RP of the 2nd survey and made comparison with those of 239 patients with RP of the 1st survey.

Results: In 2019 survey, patient age, disease duration, and male to female ratio were 60.7 ± 1.36 years (57.4 ± 1.07 years in the 1st survey conducted 2009), 8.26 ± 0.74 years (4.76 ± 0.33 years), and 1.13:1 (1.13:1), respectively. The disease duration in 2019 survey was significantly longer than those in 2009 survey ($p < 0.001$). Numbers of the involved organs per-patient basis of 2019 survey were 1.30 ± 0.06 organs at disease onset and 3.09 ± 0.13 organs at the last follow-up (8.26 years). In 2009 survey, numbers of the involved organs at onset were 1.13 ± 0.02 organs and increased to 3.13 ± 0.09 organs at the last (4.76 years). The comparison suggests that the disease progressed modestly taking more time in 2019 survey. The prognostic stages tended to improve (from 2.45 ± 0.07 to 2.21 ± 0.07, $p = 0.06$) and the mortality rate declined significantly (from 9.2% to 2.3%, $p = 0.01$) in the 2019 survey compared with 2009 survey. At the last follow-up, incidence of ear (79% versus 89%, $p = 0.02$) and joint involvement (39% vs. 57%, $p = 0.001$) was significantly higher in 2019 survey than that in 2009 survey. Incidence of airway (49% vs. 28%, $p = 0.001$) and CNS (12% vs. 4.7%, $p = 0.03$) involvement was significantly lower in 2019 survey than that in 2009 survey. Use of immunosuppressants (except steroids) was significantly frequent in 2019 survey (59.4 ± 4.36%) than that in 2009 survey (37.2 ± 3.13%, $p < 0.001$).

Conclusion: In patients with RP, incidence of airway involvement and their mortality rate declined significantly during the decade in Japan. We are hard to exclude a possibility that RP spontaneously became mild in the decade. Nonetheless, our second survey suggests important implications of current treatment and/or management of RP, including advances of medications.

Systemic Treatment in Behçet's Disease According to Clinical Phenotypes. Study of 111 Patients

David Martinez-Lopez[1], Lara Sanchez-Bilbao[2], Carmen Alvarez-Reguera[2], Alba Herrero Morant[2], Inigo Gonzalez-Mazon[3], José Luis Martín-Varillas[4], Guillermo Suarez-Amorin[2], Patricia Setien-Preciados[2], Cristina Mata-Arnaiz[5], Miguel Ángel González-Gay[6] and Ricardo Blanco[2], [1]Hospital Universitario Marques de Valdecilla, Santander (SPAIN), Spain, [2]Hospital Universitario Marques de Valdecilla, Santander, Spain, [3]Hospital Universitario Marques de Valdecilla, Bezana, Spain, [4]Hospital Sierrallana, Torrelavega, Spain, [5]Hospital de Laredo, Santander, Spain, [6]Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is a multisystemic vasculitis. Different clinical phenotypes can be distinguished. Systemic corticosteroids are the most used drugs in BD. Conventional and biological immunosuppressants (IS) may also be used. **Objectives**: To evaluate the systemic treatment of BD according to clinical domains

Methods: Study of all consecutive 111 patients diagnosed with definitive or possible BD by expert rheumatologists in a well-defined population of Northern Spain, between 1980 and 2019. Most of them met the International Criteria for BD (ICBD) Study of all consecutive 111 patients diagnosed with definitive or possible BD by expert rheumatologists in a well-defined population of Northern Spain, between 1980 and 2019. Most of them met the International Criteria for BD (ICBD).

Abbreviations: BT: Biologic Therapy; ADA: Adalimumab; IFX: Infliximab; ETN: Etanercept; TCZ: Tocilizumab

Results: We studied 111 patients (62 women/49 men), mean age at diagnosis 36.8±13.2 years. After a mean follow-up of 81.4±85 months, all patients required systemic treatment (TABLE 1-2). Biological therapy (n=28) was indicated by ocular manifestations (n=13; 46.4%) persistent, severe and refractory oral ulcers (n=10, 35.7%), neurological (n=2; 7.1%), musculoskeletal (n=2; 7.1%) or cutaneous involvement (1; 3.6%). Adalimumab and Infliximab were the biological therapy more frequently used.

Conclusion: Most patients with BD required oral corticosteroids and colchicine. Almost half required conventional IS. Up to a third required biologic therapy, especially by ocular involvement. Most patients had clinical improvement.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster III: Therapies

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: There is significant unmet need for new treatments to achieve disease control in dermatomyositis (DM), because of limited efficacy or toxicity of immunosuppressive agents or refractory disease.[1] Lenabasum is an oral, selective cannabinoid receptor type 2 (CB_2) agonist that resolves inflammation and attenuates fibrotic processes. In a Phase 2 DM trial (NCT02466243), lenabasum vs. placebo treatment was well tolerated and associated

Other[f]	26 (24%)

[a] Data blinded to treatment assignment and immunomodulating treatments include immunosuppressive therapies, hydroxychloroquine, and IVIG
[b] Diagnosed by Bohan and Peter criteria and/or ACR/EULAR criteria
[c] % of enzyme elevations > upper limit of normal [LDH (22.5%); CK (15.5%); AST (12.4%); aldolase (10.4%); ALT (8.5%)].
[d] Interstitial lung disease is defined as history of fibrosis on CXR, history of interstitial lung disease on CT scan of the lungs, or forced vital capacity (FVC), % predicted < 80% at baseline.
[e] Maximum daily dose of prednisone allowed is 20 mg or equivalent dose
[f] Other immunomodulators (e.g. rituximab, tacrolimus, cyclosporine)

with improvement in Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity score and other efficacy outcomes.[2] Efficacy and safety of lenabasum in DM is being tested in a global, randomized, double-blind, placebo-controlled Phase 3 trial (NCT03813160). Preliminary baseline demographics, disease characteristics, and immunomodulating treatments in the first 129 enrolled subjects are presented as blinded data. This is the largest interventional, placebo-controlled trial to date in DM.

Methods: 150 subjects will be enrolled in an ongoing trial with sites in North America, Europe, and Asia. Subjects are ≥ 18 years of age, with a diagnosis of DM by Bohan and Peter or ACR/EULAR criteria.[3,4] Stable doses of immunomodulating medications are allowed. Disease must be active by physician assessment with ≥ 1 of 3 criteria: 1. Physician global activity (MDGA) ≥ 3 cm [10 cm visual analogue scale (VAS)] and Manual Muscle Testing (MMT)-8 score ≤ 142 points (max 150); 2. Sum of MDGA, patient global activity (PtGA), and extramuscular global assessment (EMGA) VAS scores ≥ 10 cm (each 10 cm VAS scales); or 3. MDGA ≥ 3 cm and CDASI activity score > 14 (≥ moderate/severe skin activity).

Results: As of May 31, 2020, 129 subjects were dosed (**Table 1)**. Most subjects are female (79%), white (70%), and middle-aged. More have classic (85%) than clinically amyopathic DM (15%). Most (86%) have significant moderate/severe skin activity (CDASI > 14). Most (87%) have muscle weakness with mean MMT-8 ± SD, 135 ± 14, and 37% have ≥ 1 elevated muscle enzyme test. Physician-reported outcomes include EMGA VAS score = 5.4 ± 1.76 and MDGA VAS score = 5.5 ± 1.75. Patient-reported outcomes include Health Assessment Questionnaire-Disability Index (HAQ-DI) score = 0.83 ± 0.713, pain score on HAQ-DI = 34 ± 27, and PtGA VAS score = 5.1 ± 2.32. Glucocorticoids were used in 52% of subjects. Eighty-four percent were on ≥ 1 immunomodulating drug and 56% were on ≥2.

Conclusion: Baseline demographics of enrolled subjects are as expected (majority white, female, and middle-aged) and reflects the estimated proportion of classic to clinically amyopathic patients in the overall DM population (~5:1). Most subjects are concurrently receiving immunomodulatory drugs and have active, refractory disease with glucocorticoid use in half of subjects.

Clinically Important Improvement in Osteoarthritis Pain at Week 16 After Subcutaneous Administration of Tanezumab: Pooled Analysis from International Studies

Thomas Schnitzer[1], Francis Berenbaum[2], Philip G Conaghan[3], Robert Dworkin[4], Takaharu Yamabe[5], Isabelle Davignon[5], Stefan Wilhelm[6], Erika Dragon[7] and Lars Viktrup[6], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]AP-HP, Hôpital Saint-Antoine, Service de Rhumatologie, Centre de Recherche Saint-Antoine, INSERM UMR_S 938,Sorbonne Université, Paris, 75012, France, Paris, France, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and National Institute for Health Research Leeds Biomedical Research Centre, Leeds, United Kingdom, [4]University of Rochester School of Medicine and Dentistry, Rochester, NY, [5]Pfizer Inc, Groton, CT, [6]Eli Lilly and Company, Indianapolis, IN, [7]Pfizer Ltd, Budapest, Hungary

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoarthritis – Clinical Poster II

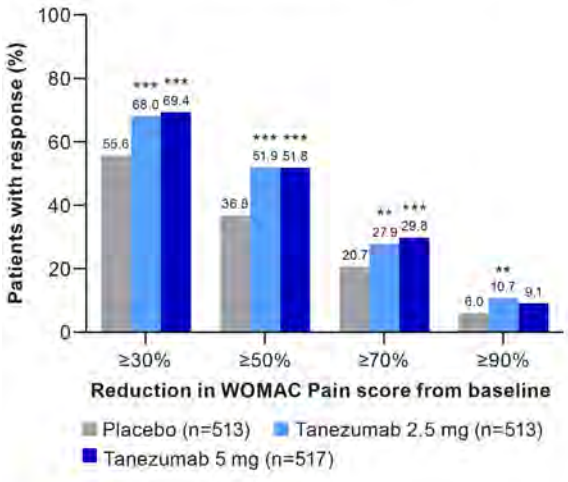
Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Tanezumab is under investigation for the treatment of moderate to severe OA pain. As part of the phase 3 OA program, two randomized, placebo-controlled studies were completed and the data reported separately. Both studies showed early and sustained pain relief, following subcutaneous administration of tanezumab, at the time of the respective primary endpoints. The objective of this pooled analysis of 2 studies was to evaluate the treatment response of tanezumab versus placebo as assessed by reductions in the WOMAC Pain subscale of ≥30%, ≥50%, ≥70% or ≥90% at Week 16. Reductions from baseline of ≥30% (moderate) or ≥50% (substantial) are often reported to be clinically important improvements.

Methods: Both phase 3 studies were randomized, double-blind, and placebo-controlled. Study 1, with primary endpoint at Week 24, enrolled patients from Europe or Japan (NCT02709486) who then received 3 doses of placebo, tanezumab 2.5 mg or tanezumab 5 mg (at baseline, Week 8 and Week 16). Study 2, with primary endpoint at Week 16, was a dose-titration study conducted in North America (NCT02697773) with three arms: placebo at baseline

Figure 1. Proportion of patients with ≥30%, ≥50%, ≥70% or ≥90% reduction from baseline in WOMAC Pain at Week 16



* $P \leq 0.05$; ** $P \leq 0.01$; *** $P \leq 0.001$ versus placebo
WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index

and Week 8, tanezumab 2.5 mg at baseline and Week 8, or tanezumab 2.5 mg at baseline and tanezumab 5 mg at Week 8. Data from this study's dose-titration group (tanezumab 2.5 mg to 5 mg at Week 8) were pooled with the study 1 tanezumab 5 mg group for analyses at Week 16. Eligibility criteria included OA diagnosis (hip or knee, ACR criteria, Kellgren-Lawrence grade ≥2); WOMAC Pain and Physical Function scores ≥5; Patient's Global Assessment of Osteoarthritis 'fair', 'poor' or 'very poor'; and a history of acetaminophen, nonsteroidal anti-inflammatory drugs, and tramadol/opioids being inadequate or unsuitable. The proportions of patients with ≥30%, ≥50%, ≥70% or ≥90% reduction from baseline at Week 16 in WOMAC Pain were estimated by logistic regression.

Results: A total of 1545 patients were evaluated. The index joint was the knee for 84.1% (1299/1545) of patients. Radiographic severity of the index joint was Kellgren-Lawrence grade 3 or 4 for 77.1% (1191/1545) of patients. Baseline WOMAC Pain scores were 6.9 ± 1.1 (mean ± standard deviation) in all three pooled groups. The proportion of patients achieving improvement from baseline in WOMAC Pain at Week 16 of ≥30% (55.6%, 68.0% and 69.4% in the placebo, tanezumab 2.5 mg and tanezumab 5 mg groups, respectively), ≥50% (36.8%, 51.9% and 51.8%, respectively), or ≥70% (20.7%, 27.9% and 29.8%, respectively) was significantly greater in both tanezumab treatment groups compared with the placebo group (all $P< 0.05$ versus placebo; Figure 1). The proportion of patients with ≥90% improvement was significantly greater in the tanezumab 2.5 mg group (10.7%; $P< 0.05$), but not in the tanezumab 5 mg group (9.1%), compared with the placebo group (6.0%).

Conclusion: The pooled analysis of these studies showed that at Week 16, a significantly higher proportion of patients achieved a clinically important improvement in pain when treated with tanezumab (both treatment groups) than placebo, with little difference between the tanezumab treatment groups. Funded by Pfizer and Lilly.

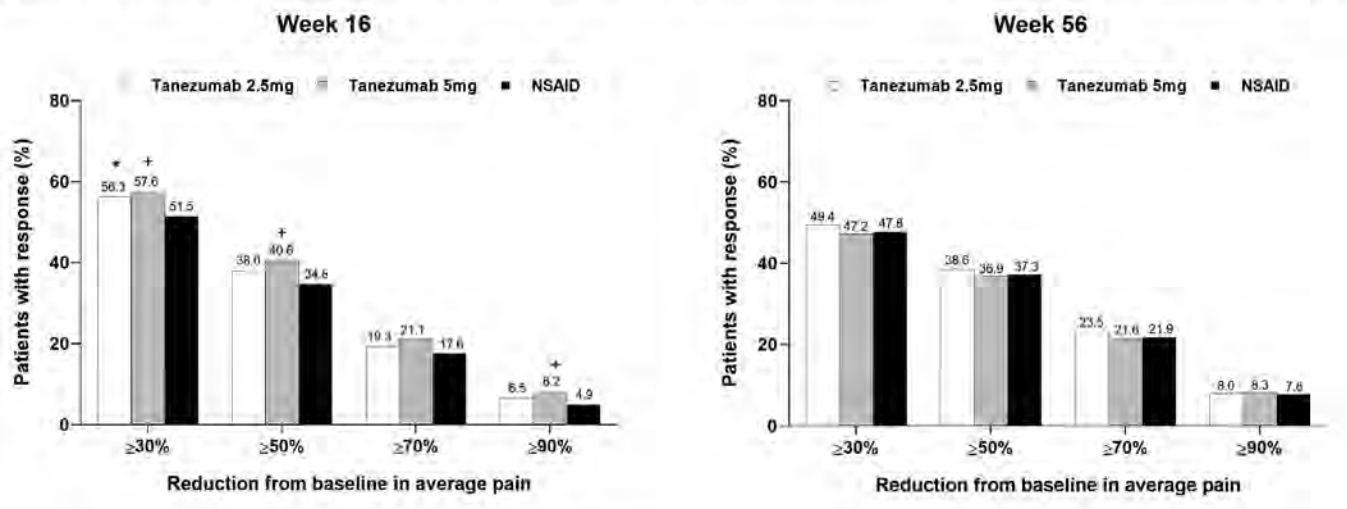
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Subcutaneous (SC) tanezumab, a monoclonal antibody that inhibits nerve growth factor, was investigated for the relief of signs and symptoms of moderate-severe OA in patients (pts) for whom use of other analgesics was ineffective or not appropriate in a randomized NSAID-controlled global long-term safety study (NCT02528188). The current analysis examines the effect of tanezumab versus NSAID on clinically important improvements in pts with OA.

Methods: Eligible pts had hip or knee OA based on ACR criteria with x-ray confirmation; baseline (BL) WOMAC Pain and Physical Function subscale scores of ≥5; BL Pt Global Assessment of OA (PGA-OA) of "fair", "poor", or "very poor"; history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance to tramadol or opioids, or unwilling to take opioids. Pts were on a qualifying, stable dose of NSAID before study entry. Pts received SC tanezumab (2.5 mg or 5 mg every 8 Wks) or oral NSAID (BID) over the 56-Wk treatment period. At Wk 16, pts who did not have the required efficacy response (≥15% reduction from BL in WOMAC Pain subscale score at Wk 2, 4, or 8, and ≥30% reduction from BL at Wk 16) were discontinued from study treatment and entered the safety follow-up period. The proportion of pts who had a reduction from BL of ≥30%, ≥50%, ≥70% or ≥90% in average weekly pain (electronic pain diary) was evaluated at Wks 16 and 56. Pt Acceptable Symptom State (PASS; the value beyond which pts consider themselves well) and Minimum Clinically Important Improvement (MCII; smallest change in measurement that signifies an important improvement in a pt's symptoms) were evaluated at Wks 16 and 56 using Tubach and colleagues' composite endpoints of improvement based on average pain, WOMAC Physical Function and PGA-OA (definitions provided in Figure 2).[1,2] Responders in average pain, PASS, and MCII are post-hoc analyses. Unadjusted p-values are presented.

Results: In total, 3,021 pts were randomized and 2,996 received at least 1 dose of blinded SC study drug and are included in the efficacy analyses. A total of 1,312 pts completed the treatment period (42–45% across treatment groups). BL pt characteristics were similar across treatment groups: mean age 60.3–61.2 years; female 63.6–66.5%; duration of index joint OA 7.9–8.1 years; index joint was knee 84.9–85.5%, and hip in 14.5–15.1%. The proportion of pts with reductions from BL in average pain was significantly greater for tanezumab (2.5 mg, ≥30% responders; 5 mg, ≥30%, ≥50%, and ≥90% responders) versus NSAID at Wk 16 and largely similar across treatment groups at Wk 56 for all categories of response (Figure 1). There were no significant differences in the proportion of pts achieving MCII and PASS between treatment groups at Wks 16 and 56 (Figure 2).

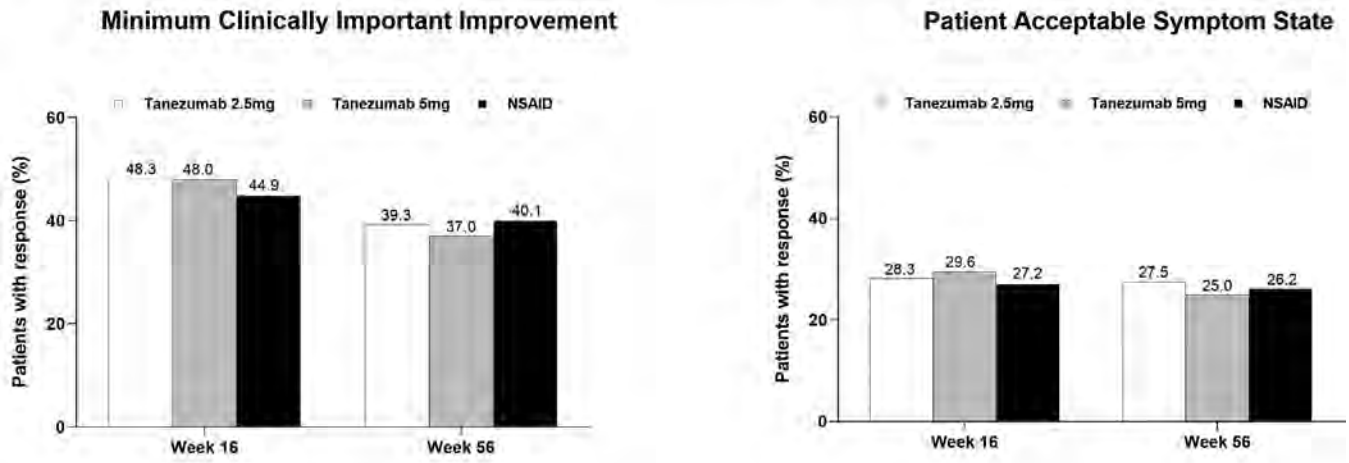
Figure 1 Treatment response: Proportion of patients with percent reduction from baseline in average pain (ITT, mixed BOCF/LOCF)



* Unadjusted $P \leq 0.05$ for tanezumab 2.5mg versus NSAID. + Unadjusted $P \leq 0.05$ for tanezumab 5mg versus NSAID.

BOCF, baseline observation carried forward; ITT, intent to treat; LOCF, last observation carried forward

Figure 2 Proportion of patients with clinically important improvement (ITT, mixed BOCF/LOCF)



BOCF, baseline observation carried forward; ITT, intent to treat; LOCF, last observation carried forward

Minimum Clinically Important Improvement = improvement from baseline in OA pain in index joint (knee ≥1.99, hip ≥1.53) and WOMAC Physical function (knee ≥0.91, hip ≥0.79) and PGA-OA in ≥1 category.

Patient Acceptable Symptom State: OA pain score for index joint (knee ≤3.23, hip ≤3.50) and WOMAC Physical Function (knee ≤3.10, hip ≤3.44) and PGA-OA of "good" or "very good".

Conclusion: The majority of tanezumab treated pts had a clinically important pain improvement (≥30%) at Wk 16, significantly more than with NSAID. The composite pain and function improvement and acceptable severity level after treatment was similar for tanezumab and NSAID.

er analgesics was ineffective or not appropriate in a randomized NSAID-controlled long-term global safety study (NCT02528188). The primary safety (joint safety over 80 weeks [Wk]) and coprimary efficacy endpoints (pain, function, and Pt Global Assessment of OA [PGA-OA] at Wk 16) were recently disclosed.[1,2] The current analysis examines

the time-course and longer term maintenance of treatment effect of tanezumab versus NSAID on pain and physical function through Wk 56.

Methods: Eligible pts had hip or knee OA based on ACR criteria with x-ray confirmation; baseline (BL) WOMAC Pain and Physical Function subscale scores of ≥5; BL PGA-OA of "fair", "poor", or "very poor"; history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance tramadol or opioids, or unwilling to take opioids. Pts were on a qualifying, stable dose of NSAID before study entry. Pts received SC tanezumab (2.5 mg or 5 mg every 8 Wks) or oral NSAID (BID) over the 56-Wk treatment period. At Wk 16, pts who did not have the required efficacy response (≥15% reduction from BL at Wk 2, 4, or 8, and ≥30% reduction from BL in WOMAC Pain at Wk 16) were discontinued from study treatment and entered the safety follow-up period. Pts were permitted to use rescue medication (≤3000 mg/day acetaminophen) up to 3 days/Wk up to Wk 16 and daily thereafter. Treatment effect through Wk 56 versus NSAID was evaluated by measuring change from BL in average index joint pain (electronic pain diary: daily from Day 1 to Wk 16, then weekly to end of study) and WOMAC Pain and Physical Function, and PGA-OA scores (Wk 2 through Wk 56 at clinic visits). Unadjusted p-values are presented.

Results: In total, 3,021 pts were randomized and 2,996 included in the efficacy analyses. A total of 1,312 pts completed the treatment period (42–45% across treatment groups). BL pt characteristics were similar across treatment groups: mean age 60.3–61.2 years; duration of index joint OA 7.9–8.1 years; index joint was the knee 84.9–85.5%; female 63.6–66.5%. Reductions from BL in average index joint pain scores were largely similar across treatment groups from BL to Wk 4 (Figure 1). From Wk 4 to Wk 20 reductions were significantly greater ($P \leq 0.05$) in both tanezumab groups versus NSAID. Changes from BL in WOMAC Pain, Physical Function and PGA-OA scores were largely similar across treatment groups but there were scattered significant improvements for pts receiving tanezumab versus NSAID at Wks 4, 8 and 16 (Figure 2). Changes in WOMAC Pain, Physical Function and PGA-OA scores across treatment groups were generally maintained up to Wk 56.

Conclusion: Pts with moderate-severe hip or knee OA treated with tanezumab or NSAID experienced an early improvement in pain and function that was maintained long-term.

Disclosures: Sponsored by Pfizer and Eli Lilly & Company.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Tanezumab is a monoclonal antibody against nerve growth factor being investigated for treatment of the signs and symptoms of osteoarthritis (OA). Subcutaneous tanezumab was efficacious, based on Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain, WOMAC Function, and Patient's Global Assessment of Osteoarthritis scores, in 2 recent Phase 3 studies, one in North America, and one in Europe and Japan in patients with moderate-to-severe OA of the knee or hip for whom standard of care treatment was not adequate. The current pooled analysis assessed the onset and maintenance of analgesic response to tanezumab in these patients, based on daily pain scores recorded in an electronic diary (e-diary).

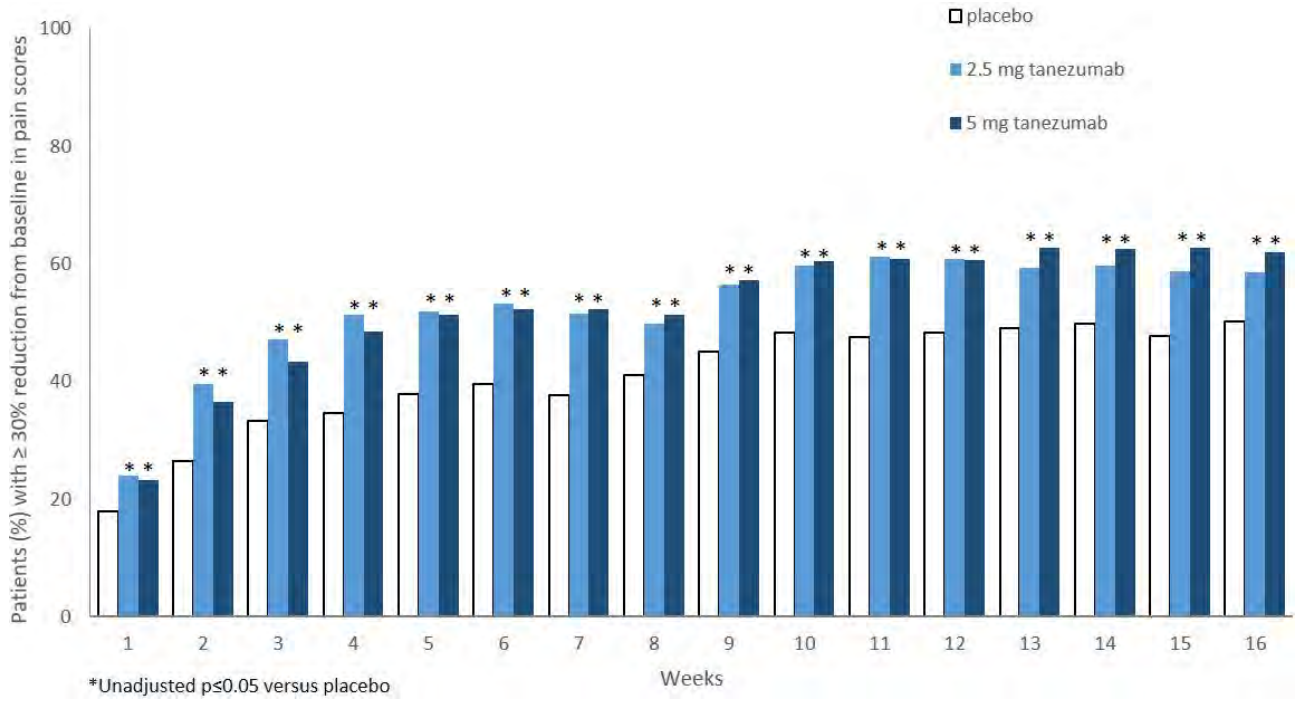

Figure 1. Proportion of patients with a ≥ 30% improvement in pain score

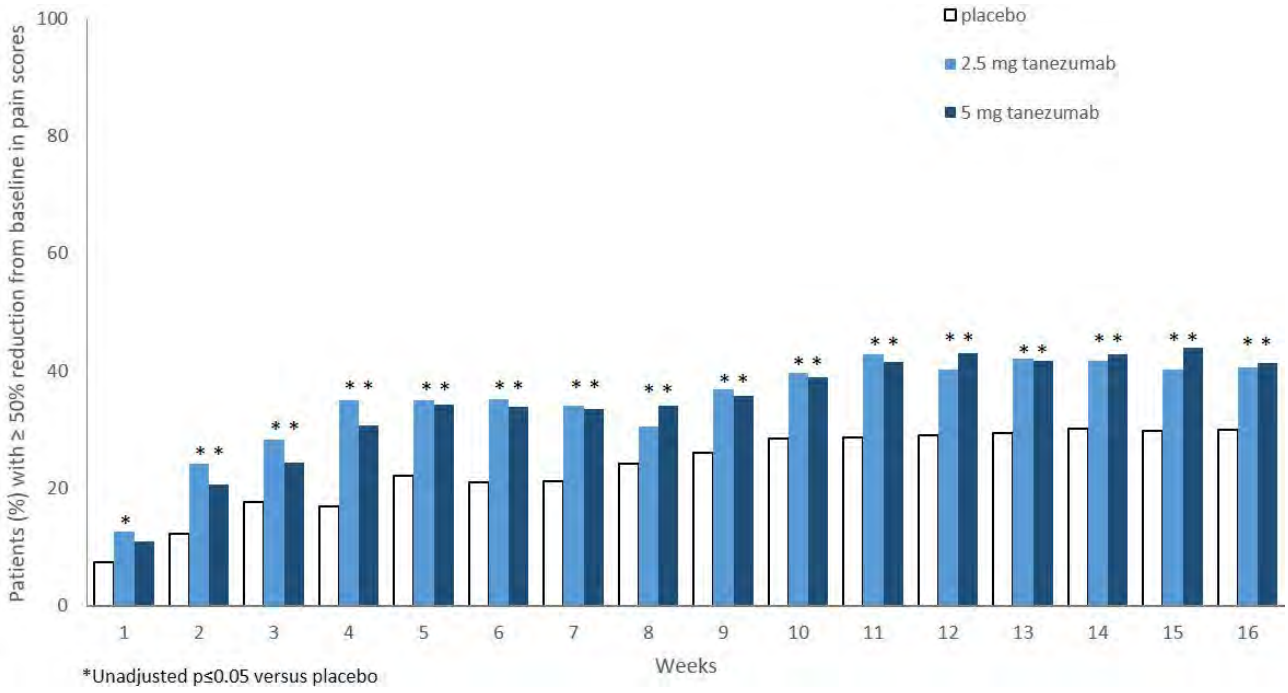

Figure 2. Proportion of patients with a ≥ 50% improvement in pain score

Methods: In study A4091056 (clinicaltrials.gov: NCT02697773), patients received 16-week treatment with placebo, tanezumab 2.5 mg (baseline and week 8), or tanezumab 2.5/5 mg (2.5 mg at baseline and 5 mg at week 8; included in the 5 mg group for the current pooled 16-week analysis). In study A4091057 (clinicaltrials.gov: NCT02709486), patients received placebo or tanezumab (2.5 mg or 5 mg) every 8 weeks for 24 weeks. Average pain over the past 24 hours was collected daily in the e-diary during the treatment period using an 11-point numeric rating scale (NRS; from 0 = no pain to 10 = worst possible pain). In the current analysis, the proportion of patients who achieved ≥30% or ≥50% decrease from baseline in NRS pain scores, based on weekly average of daily scores, were compared between placebo and tanezumab groups at each study week through week 16 using a logistic regression model. The median time to achieve ≥30% or ≥50% improvements in pain were compared between groups using a Kaplan-Meier analysis.

Results: Overall, 1545 patients were included in the analysis: placebo (n = 514), tanezumab 2.5 mg (n = 514), or tanezumab 5 mg (n = 517). Significant improvement over placebo was observed by Week 1 in both tanezumab groups for the ≥30% level. For the ≥50% level, significant improvement over placebo was observed by Week 1 for tanezumab 2.5 mg and by Week 2 for tanezumab 5 mg. These significant differences from placebo were maintained at all weeks up to Week 16 for both tanezumab groups at both response levels ($p < 0.05$ Figures 1 and 2). The time to achieve 30% and 50% response was significantly faster in the tanezumab groups than in the placebo group. The median (95% CI) time to onset of a ≥30% decrease in pain score from baseline was approximately 3 weeks for the tanezumab 2.5 mg group (range 3-4 weeks; $p < 0.0001$) and 4 weeks for 5 mg (range 3-5 weeks; $p=0.0002$) compared to 8 weeks for placebo (range 6-10 weeks; Table 1). The median time to onset of a ≥50% decrease in pain score from baseline was approximately 11 weeks in the tanezumab 2.5 mg and 5 mg groups (ranges 9-15 and 9-13 weeks, respectively; $p < 0.0001$). Not enough patients achieved a 50% response in the placebo group to calculate median time to onset (Table 1).

Conclusion: Tanezumab treatment resulted in significantly more patients reaching moderate (30%) or substantial (50%) improvements in pain compared with placebo as early as Week 1 and through Week 16. The median time to reach ≥30% and ≥50% improvement were 3-4 weeks and 11 weeks, respectively for tanezumab treated patients.

Group	Number (%) of patients achieving threshold[a]	Quartile 1[b] Time in weeks (95% CI)	Median[c] Time in weeks (95% CI)	p-value[e]
Placebo				
≥30%	328 (63.8%)	2 (2,3)	8 (6,10)	
≥50%	223 (43.4%)	5 (4,7)	Unable to calculate[d]	
Tanezumab 2.5 mg				
≥30%	377 (73.3%)	2 (1,2)	3 (3,4)	<0.0001
≥50%	281 (54.7%)	2 (2,3)	11 (9,15)	<0.0001
Tanezumab 5 mg				
≥30%	380 (73.5%)	2 (1,2)	4 (3,5)	0.0002
≥50%	291 (56.3%)	3 (2,4)	11 (9,13)	<0.0001

Table based on Kaplan Meier Analysis

[a] Total N was 514, 514, 517 for the placebo, tanezumab 2.5 mg and tanezumab 5 mg treatment groups, respectively. Percentages are based on overall proportion of responders through week 16.

[b] Quartile 1 reflects the time (in weeks) for 25% of patients to reach the response threshold

[c] Median reflects the time (in weeks) for 50% of patients to reach the response threshold.

[d] An insufficient number of patients achieved the ≥50% response threshold to perform median calculation.

[e] Versus placebo
Note: Q3 data is not presented as less than 75% of patients across treatment groups achieved the response thresholds of interest.

CI = Confidence interval.

Table 1. Time to ≥30% and ≥50% Improvement from Baseline in Pain Numeric Scale score

Radiographic Exclusionary Findings During Screening for Three Phase III Trials of Subcutaneous Tanezumab in Patients with Moderate to Severe Hip or Knee Osteoarthritis

Ali Guermazi[1], Frank Roemer[2], Andrew Kompel[1], Luis Diaz[3], Michel Crema[4], Mark Brown[5], Anne Hickman[5], Glenn Pixton[6], Lars Viktrup[7], Robert Fountaine[5], Aimee Burr[5], Sarah Sherlock[5] and Christine West[8], [1]Boston University School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, and Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany, [3]Boston Veteran Affairs Healthcare System, Boston, MA, [4]Boston University School of Medicine, Paris, France, [5]Pfizer Inc., Groton, CT, [6]Pfizer Inc., Morrisville, NC, [7]Eli Lilly and Company, Indianapolis, IN, [8]Pfizer Inc, Groton, CT

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Tanezumab is a nerve growth factor monoclonal antibody in development for osteoarthritis (OA). Following a clinical hold due to concerns around adverse joint events, the tanezumab clinical trial program implemented comprehensive radiographic eligibility criteria. We describe the frequencies of exclusionary radiographic findings during screening in three Phase III randomized studies of subcutaneous tanezumab.

Methods: NCT02697773[1] was a 40-week placebo-controlled study (16-week treatment). NCT02709486[2] was a 48-week placebo-controlled study (24-week treatment). NCT02528188[3,4] was an 80-week active-controlled (oral NSAID) study (56-week treatment). Bilateral shoulder, hip and knee screening radiographs were taken by trained imaging technologists and read by one of five central musculoskeletal radiology experts (central readers). Central readers were trained using a program-specific imaging atlas and underwent periodic re-calibration sessions.[5] Eligibility criteria for all studies included an OA diagnosis in the index hip or knee based on ACR criteria and a Kellgren Lawrence (KL) grade of ≥2 on radiograph as diagnosed by the central reader. Radiographic exclusion criteria included a KL grade of 0 or 1 in a non-index knee or hip with patient reported pain of ≥7 on a 0-10 numerical rating scale, without other exclusionary radiographic findings (discordant pain to X-ray), confounding joint or systemic conditions (severe malalignment of the knee, inflammatory joint disease etc.), presence of rapidly progressive OA type 2 (RPOA2), or potential risk factors for RPOA (such as osteonecrosis, subchondral insufficiency fracture, or atrophic OA; Figure 1) in any joint.

Results: In the three studies, conducted at >480 international sites, 23,079 patients were screened and 13,797 proceeded to radiography (producing 81,055 knee, hip or shoulder screening radiographs read by the central reader). Overall, 8024 patients (58.2%) were declared radiographically eligible. Among the 5773 (41.8%) patients declared

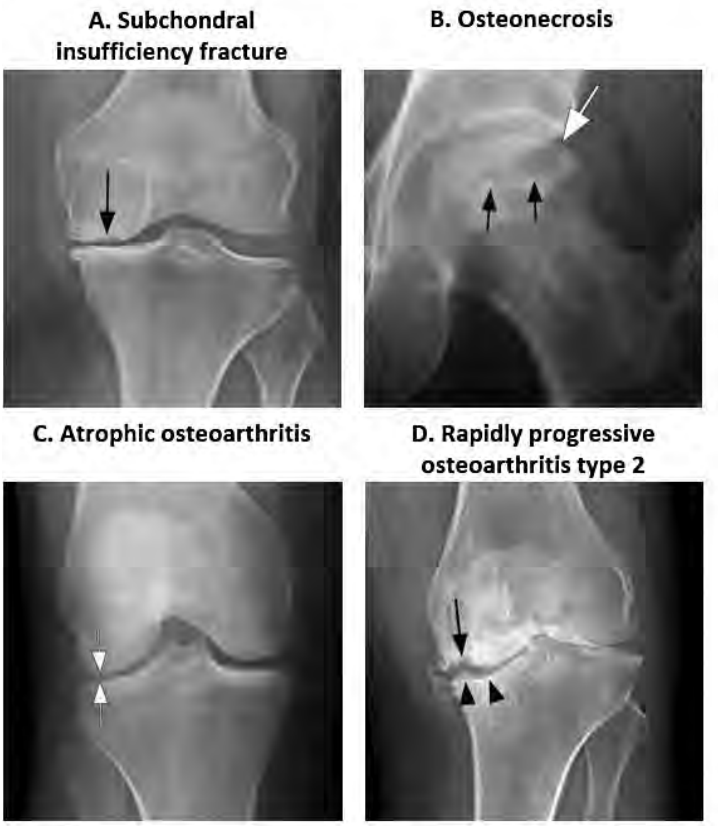
Table 1: Most common exclusionary radiographic findings from three Phase III trials of subcutaneous tanezumab.

	Knee radiographs (n = 26,597)		Hip radiographs (n = 26,938)		Shoulder radiographs (n = 27,520)	
Exclusionary radiologic finding	n radiographs (%)	Observed frequency during screening	n radiographs (%)	Observed frequency during screening	n radiographs (%)	Observed frequency during screening
Discordant pain to X-ray[a]	2508 (9.43 %)	~1 in 10 X-rays	2612 (9.70%)	~1 in 10 X-rays	N/A	N/A
Severe malalignment of the knee[b]	751 (2.82%)	~1 in 35 X-rays	N/A	N/A	N/A	N/A
Subchondral insufficiency fracture[c]	586 (2.20%)	~1 in 50 X-rays	61 (0.23%)	~1 in 500 X-rays	10 (0.04%)	~1 in 2500 X-rays
Atrophic/hypotrophic OA[d]	486 (1.83%)	~1 in 50 X-rays	105 (0.39%)	~1 in 250 X-rays	3 (0.01%)	~1 in 10,000 X-rays
Osteonecrosis[e]	119 (0.45%)	~1 in 250 X-rays	323 (1.20%)	~1 in 100 X-rays	82 (0.30%)	~1 in 325 X-rays
RPOA type 2[f]	18 (0.07%)	~1 in 1500 X-rays	110 (0.41%)	~1 in 250 X-rays	14 (0.05%)	~1 in 2000 X-rays

One or more exclusionary radiological finding may have been reported for each patient or from each radiograph. Exclusionary findings as defined in Roemer F., et al. Osteoarthritis Cartilage. 2015. 23(S1):S22–42. [a]Patient reported pain of ≥7 on a 0-10 numerical rating scale with a Kellgren Lawrence grade of 0 or 1 in a non-index hip or knee, without other exclusionary radiographic findings. [b]Cut-off of ≥10° varus or valgus on the anterior–posterior view. [c]Focal bone defect, or loss of sphericity of the articular surface and/or focal radiolucency in the subchondral trabecular bone, with or without adjacent cortical defect. [d]Joint space narrowing without relevant osteophyte formation and absence of erosions or other radiographic signs of inflammatory arthritis. [e]Focal circumscribed or extended region of infarcted bone. [f]Abnormal bone loss or destruction, including limited or total collapse of at least one subchondral surface that is not a feature of conventional advanced osteoarthritis. N/A, not applicable

Table 1. Most common exclusionary radiographic findings from three Phase III trials of subcutaneous tanezumab

Figure 1: Examples of exclusionary radiographic findings



A. Anteriorposterior radiograph of a left knee with definite medial joint space narrowing (i.e. Kellgren-Lawrence grade 3) at screening shows medial femoral subchondral collapse as the result of **subchondral insufficiency fracture (SIF)** with mild depression of the medial femoral surface. In addition, there is surrounding sclerosis.
B. Anteroposterior radiograph of a left hip shows femoral head **osteonecrosis** as geographic lucency of the femoral head demarcated by curve linear sclerosis (black arrows). In addition there is loss of femoral head sphericity with focal cortical collapse (white arrow).
C. Anteroposterior radiograph of a right knee shows definite joint space narrowing at the lateral tibio-femoral compartment (arrows) without osteophyte formation classifying this knee as **atrophic osteoarthritis**.
D. Deformity of the medial femoral (arrow) and tibial articular surface (arrowheads) is noted in this anteroposterior left knee radiograph representing **rapidly progressive osteoarthritis (RPOA) Type 2**. In addition there is articular surface collapse especially of the tibial plateau. Consequent varus deformity is observed.

Figure 1. Examples of exclusionary radiographic findings

ineligible, exclusionary radiographic findings were noted in 1 (4116 [29.8%]), 2 (1268 [9.2%]), 3 (279 [2.0%]), 4 (108 [0.8%]), or 6 joints (2 [0.01%]). The most common exclusionary radiographic finding in both knees and hips was discordant pain to X-ray (Table 1; ~1 in 10 screening X-rays), with other findings being much rarer (≤~1 in 35), particularly

in the hip (≤~1 in 100). Exclusionary radiographic findings were rare in the shoulder — the most common was osteonecrosis (~1 in 325, vs ~1 in 250 and 100 in the knee and hip, respectively).

Conclusion: Conclusion: The Phase III tanezumab trial program included comprehensive radiographic screening. The most common exclusionary finding in knees and hips was pain discordant to X-ray (~1 in 10 screening X-rays).

Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The level of placebo group response in clinical trials for chronic pain conditions is a concern for the development of novel analgesics[1]. Here, we investigate the placebo group responses over time in data from the clinical studies of tanezumab, a monoclonal antibody against nerve growth factor which is intended for the relief of signs and symptoms of moderate to severe osteoarthritis (OA) in adult patients for whom use of other analgesics is ineffective or not appropriate.

Methods: Tanezumab studies from 2008 to 2018 were included in these analyses. Those completed prior to 2015 utilized intravenous (IV) administration, while those conducted after 2015 used subcutaneous (SC) administration. We used data from IV and SC studies to create two cohorts to examine the change in placebo group responses over time. Data from 4 studies (NCT00733902, NCT00744471, NCT00830063 and NCT00863304), conducted between

Table 1. Treatment discontinuations: IV versus SC pooled data.

Patients n (%)	IV cohort (n=1814)			SC cohort (n=1545)		
	Placebo (n=744)	Tanezumab 2.5 mg (n=327)	Tanezumab 5 mg (n=743)	Placebo (n=514)	Tanezumab 2.5 mg (n=514)	Tanezumab 5 mg (n=517)
All reasons	329 (44.2)	87 (26.6)	180 (24.2)	84 (16.3)	49 (9.5)	53 (10.3)

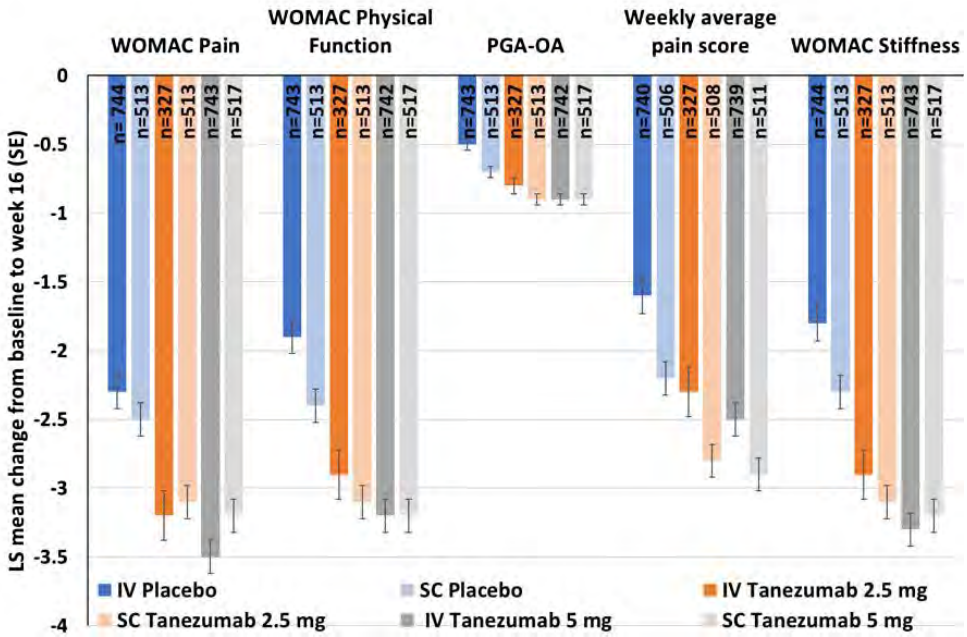
Death	1 (0.1)	0	0	0	0	2 (0.4)
Lost to follow-up	1 (0.1)	0	7 (0.9)	3 (0.6)	3 (0.6)	3 (0.6)
Study terminated by sponsor	2 (0.3)	0	3(0.4)	0	0	0
Withdrawal by subject	45 (6.0)	10 (3.1)	32 (4.3)	22 (4.3)	19 (3.7)	20 (3.9)
Insufficient clinical response	241 (32.4)	58 (17.7)	98(13.2)	31 (6.0)	8 (1.6)	7 (1.4)
Protocol violation	8 (1.1)	9 (2.8)	9 (1.2)	4 (0.8)	4 (0.8)	1 (0.2)
Other	6 (0.8)	1 (0.3)	6 (0.8)	12 (2.3)	7 (1.4)	13 (2.5)

The incidences of withdrawal by reason were determined through completion of the treatment period of each study. IV, intravenous; SC, subcutaneous

Figure 1. Change from baseline to week 16 in efficacy endpoints: IV versus SC pooled data.



A change from baseline <0 represents an improvement in all outcomes. IV, intravenous; LS, least squares; PGA-OA, patient global assessment of osteoarthritis; SC, subcutaneous; SE, standard error; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index

2008–2010, were pooled to create the IV cohort (n=1814). The SC cohort (n=1545) comprised data from 2 studies, conducted between 2016–2018 (NCT02697773 and NCT02709486). Although there were some differences in the patient populations in the IV and SC cohorts, all studies enrolled patients with a diagnosis of OA in the hip or knee, baseline Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain subscale scores of ≥5 in the index joint and Patient Global Assessment of OA (PGA-OA) of "fair", "poor" or "very poor". A WOMAC Physical Function score ≥5 at baseline was also required, with the exception of IV studies NCT00830063 and NCT00863304, which

required a score ≥4. Treatments were administered every 8 weeks for 16 ([IV: NCT00830063 and NCT00863304] [SC: NCT02697773]) or 24 weeks [IV: NCT00733902 and NCT00744471] [SC: NCT02709486]).

Results: The percentage of patients who discontinued from the SC cohort for any reason and particularly for insufficient clinical response was lower, compared with the IV cohort (**Table 1**). The change from baseline to week 16 in the efficacy endpoints of WOMAC Pain, WOMAC Physical Function, PGA-OA, weekly average pain score and WOMAC Stiffness revealed consistently greater placebo group improvements in the SC cohort, compared with the IV cohort (**Figure 1**).

Conclusion: These data showed an increased placebo group response in patients receiving SC administration in a later time period (2016-2018), compared with IV administration in an earlier time period (2008-2010) across the tanezumab development program. Further analyses will be presented to examine the factors that account for these differences, for example, changes in the route of administration, temporal trends in the patients enrolling in the trials or in the study sites and differences in clinical trial design. These analyses may help advance drug development by identifying critical factors that may increase placebo group responses and thereby limit the assay sensitivity of clinical trials to identify truly efficacious pain treatments.

These studies were sponsored by Pfizer and Lilly. Medical writing support was provided by Steven Moore, PhD, of Engage Scientific Solutions and was funded by Pfizer and Lilly.

Table 2. Clinical guideline recommendations on NSAID use by risk for NSAID-related AEs

creased risk for these AEs changes the risk-benefit profile of certain NSAIDs such that they are not recommended by clinical treatment guidelines. However, information for real-world NSAID use despite these recommendations is lacking. This study aimed to evaluate the use of prescription NSAIDs among patients with hip/knee OA for whom specific NSAID treatment is not recommended per clinical treatment guidelines.

Methods: This retrospective cohort study used the IBM MarketScan® claim database (July 2016–June 2019). Adult patients with a diagnosis of hip/knee OA between July 2017 and June 2018 (index date) were identified. If more than one diagnosis was available, one was randomly selected as the index date. Patients were required to have 1 year of continuous enrollment before the index date (baseline period) to establish their baseline risks (high, moderate, or

Table 3. 1-year rate* of NSAID use that was inconsistent with clinical guideline recommendations	
Baseline risk profile	**NSAID use inconsistent with clinical guideline recommendations, % (95% CI)**
Overall†	49.1 (48.7–49.4)
High GI risk and low CV risk	63.8 (63.0–64.5)
High GI risk and moderate CV risk	58.8 (57.7–59.7)
High GI risk and high CV risk, or high renal risk	61.0 (59.9–62.1)
Low-to-moderate GI risk and high CV risk	51.8 (51.0–52.7)
Low-to-moderate GI risk and moderate CV risk	33.2 (32.7–33.8)
*Based on 1-year cumulative incidence from the Kaplan–Meier survival analysis. †Patients with low-to-moderate GI risk and low CV risk were excluded from this analysis because the guidelines did not recommend against use of NSAIDs in this population (table 2). CI, confidence interval.	

Table 3. 1-year rate* of NSAID use that was inconsistent with clinical guideline recommendations

low) for NSAID-related GI, CV, and renal AEs, respectively (table 1), and were categorized into 6 risk profiles based on clinical guidelines (table 2). Patients were followed post-index to assess specific prescription NSAID use that was not recommended per the patient's risk profile, and Kaplan–Meier survival analyses were used to estimate 1-year cumulative incidence rates.

Results: Among 218,349 adults with hip/knee OA (mean age ± standard deviation, 60.8 ± 11.1 years; 61.9% female; 74.4%/25.6% commercial/Medicare), 65.9% (n=143,833) had no evidence of increased risk. Therefore, for these patients, there was no guideline recommendation against NSAID use (table 2). Among the remaining patients (n=74,516; 34.1%), the 1-year rate of NSAID use that was not consistent with guideline recommendations was 49.1% overall and ranged from 33.2%–63.8% for the different risk profiles (table 3). The subgroup of patients at high risk of NSAID-related GI AEs and at low risk of NSAID-related CV AEs (6.9% of the study population) had the highest 1-year rate of NSAID use that was not consistent with guideline recommendation (63.8%; table 3).

Conclusion: This study showed that in the real-world setting, over one-third of patients with hip/knee OA were found to have risk factors that could increase their risk for NSAID-related AEs. Approximately half of these patients had evidence of prescription NSAID use that was inconsistent with guideline recommendations, suggesting the lack of reliable pain medications for OA patients. These results emphasize the need to consider the risks associated with NSAIDs and to individualize OA management strategies to mitigate the risk of NSAID-related AEs. This study was limited by the lack of information on the use of over-the-counter NSAIDs and drugs that would decrease the risk of NSAID-related AEs, as well as by the inability to distinguish between short-term and long-term prescription NSAID use.

Abstract Number: 1647

An Oleuropein-based Dietary Supplement Improves Joint Function in Older People with High Knee Joint Pain

Marie-Noelle Horcajada[1], Maurice Beaumont[2], Nicolas Sauvageot[2], Madleen Saboundjian[1], Laure Poquet[1], Anne-Christine Hick[3], Berenice Costes[4] and **Yves Henrotin**[5], [1]Nestle Research, EPFL Innovation Park, Lausanne, Switzerland, [2]Nestle Research, Clinical Development Unit, Lausanne, Switzerland, [3]Artialis SA, Liège, Belgium, [4]Artialis SA, Liege, Belgium, [5]University of Liège, Liège, Belgium

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to investigate the effects of a 6-month intervention with an Olive Leaf Extract (OLE) standardized for oleuropein content on knee functionality and biomarkers of bone/cartilage metabolism and inflammation.

Methods: The study was a randomized, double-blind, placebo-controlled, multi-centric trial of 124 subjects with mild knee pain or mobility issues. Subjects were randomized equally to receive twice a day one capsule of either maltodextrin (control treatment, CT) or 125-mg OLE (Bonolive™, an Olive Leaf Extract containing 50 mg of Oleuropein) for 6 months. The co-primary endpoints were Knee injury and Osteoarthritis Outcome Score (KOOS) using a self-administered questionnaire and serum Coll2-1NO2 specific biomarker of cartilage degradation. The secondary endpoints were each of the five sub-scales of the KOOS questionnaire, Knee pain VAS score at rest and at walking, OARSI core set of performance-based tests and serum biomarkers (Coll2-1, MPO, CTX1, osteocalcin, PGE_2 and Vplex cytokines assay in serum) and concentration of Oleuropein's metabolites in urine.

Results: Primary (global KOOS score, biomarker Coll2-1 NO2) and secondary endpoints (the five subscales of the KOOS score) improved time dependently in both groups. OLE treatment showed significantly elevated urinary oleuropein metabolites (oleuropein aglycone, hydroxytyrosol, homovanillyl alcohol and isomer of homovanillyl alcohol), and was well tolerated without significant differences in number of subjects with adverse events. At 6 months, OLE group showed a higher global KOOS score compared to placebo (treatment difference = 3.73; 95% CI = [-4.08;11.54]; p = 0.34), without significant changes of inflammatory and cartilage remodeling biomarkers. Subgroup analyses demonstrated a large and significant treatment effect of OLE in subjects with high walking pain at baseline (14.4; 95% CI = [1.19;27.63], p=0.03). This was observed at 6 months for the global KOOS score and each different subscale and for pain at walking (-23.07;95% CI = [-41.8;-4.2];p=0.02). These treatment effects at 6 months were significant for KOOS score as well as for the subscales Pain and QoL and the pain at walking.

Conclusion: OLE was not effective on joint discomfort in people with low to moderate pain at baseline but significantly benefited subjects with high pain at treatment initiation. As oleuropein is well-tolerated, OLE can be used to relieve knee joint pain and enhance mobility in subjects with articular pain the most painful subjects.

Abstract Number: 1648

Comparison of Methotrexate and Glucosamine in Primary Knee Osteoarthritis with Inflammation

Biswadip Ghosh[1], Subhankar Haldar[2] and Meghna Saha[2], [1]IPGME&R, Kolkata, Kolkata, West Bengal, India, [2]IPGME&R, Kolkata, KOLKATA, India

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Many patients suffering from knee OA show swelling, warmth along with pain which are features of inflammation. There are no accepted pharmacological therapy for osteoarthritis that target inflammation though inflammation plays a crucial role in pain generation and progressive joint damage.

There are some evidence that Methotrexate may be useful in knee osteoarthritis. The latest ACR recommendation for OA is not in favour of MTX, but it seems they have more weight to the evidence in case of hand OA than knee OA. ACR recommendation found no evidence of usefulness of glucosamine also, another very commonly used drug for knee OA.

We decided to evaluate the effect of methotrexate in primary knee OA with inflammation in comparison with glucosamine as placebo.

Methods: Primary knee OA of both sex, aged 40-65 years, having swelling and pain of both knee joints for at least six months with radiographic OA and consent to study were recruited. Exclusion criteria consisted of KL grade 4, secondary OA, arthroscopy or intra articular injections in last three months, uncontrolled Diabetes, renal, hepatic diseases or gout.

Patients with signs of local inflammation i.e. pain swelling of whole knee and warmth were checked for ESR and CRP.

If there was increase in both in one occasion or either of them in two occasions 1 month apart (ESR >30mm/1st Hr and CRP >1.5 times of reference), they were placed in systemic Inflammatory group.

Others were placed in non-inflammatory group.

Blood was collected from all patients and healthy controls for testing of selected biomarkers.

Patients in the inflammatory group were stringently screened for Inflammatory arthritis by clinical examination, blood tests, Musculoskeletal ultrasound, X-ray..

MRI of knee was done in all patients of Inflammatory group.

Then, patients of inflammatory group were randomly allocated to receive Methotrexate (15-20 mg/week) or Glucosamine (placebo) and followed monthly for three months.

All patients were allowed to take paracetamol and tramadol on as needed basis. NSAIDs were given in the beginning for 7-10 days to improve compliance.

WOMAC (CRD Pune version) was measured at beginning and end of three months.

Results: Total 344 primary knee OA patients who fulfilled the inclusion and exclusion criteria, were examined from July 2016 to June 2019 in Department of Rheumatology, IPGME&R and SSKM Hospital, Kolkata.

249 patients had local inflammation (swelling of both knees). 172 patients of them had elevated ESR/CRP, both in one occasion or either of them in two occasions 1 month apart.

Table 1: Demography

	Non inflammatory group (N=77)	Inflammatory group (N=172)
Age	51.85±7.027	51.56±7.030
Sex	32:56	11:104
CRP	Normal	Raised
ESR	17.43±6.142	44.46±16.398
WOMAC	45.20±15.472	49.356±15.037

Demography

Parameter	Patient number	Pre-MTX	Post-MTX	P value
ESR	78	44±19	35±16	0.0007
CRP	78	Reactive	non-reactive	
WOMAC	78	52±14	38±17	P<0.0001

Patients suffering from primary knee OA with inflammation receiving MTX

Parameter	Patient number	Pre glucosamine	Post-glucosamine	P value
ESR	59	39±13	43±19	0.2947
CRP	59	Reactive	reactive	
WOMAC	59	47±16	43±19	0.1877

Patients suffering from primary knee OA with inflammation receiving Glucosamine

Table 2: Patients suffering from primary knee OA with inflammation receiving MTX

Table 3: Patients suffering from primary knee OA with inflammation receiving Glucosamine

Conclusion: We found significant improvement in WOMAC, ESR and CRP in patients suffering from primary knee OA with inflammation after three months of taking methotrexate while there was insignificant effect with glucosamine, used as placebo. Our study provides proof that oral Methotrexate may be an important intervention in primary knee osteoarthritis with inflammation.

Effect of Knee Aspiration and Intra-articular Corticosteroid Injection on Gait Biomechanics and Strength Impairment in Patients with Signs of Inflammation Due to Knee Osteoarthritis

Ryan Pinto[1], Trevor Birmingham[1], Holly Philpott[2], Dominique Arsenault[1], Codie Primeau[1] and Tom Appleton[3], [1]Western University, London, Canada, [2]Western University, London, ON, Canada, [3]The University of Western Ontario, LONDON, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial inflammation in knees with OA can be measured with musculoskeletal ultrasound (MSK US), is associated with increased pain and disease progression, and may adversely affect joint biomechanics. Knee effusion has been associated with quadriceps avoidance gait (decreased external knee flexion moment (KFM) during walking, altered quadriceps and hamstring activation) in patients with knee OA, however, the effect of treating knee inflammation on gait biomechanics and strength is unknown. The purposes of this study were to: 1) investigate the effects of treating knee inflammation on gait biomechanics, strength and patient-reported outcomes in patients with knee OA and inflammation, and 2) explore the associations between these measures.

Methods: 72 knees from 51 patients with knee OA and signs of moderate synovitis and effusion on MSK US underwent bilateral gait biomechanics, strength and US assessments, and completed knee-specific numeric rating scales (NRS) for pain and Knee Injury and Osteoarthritis Outcome Scores (KOOS) before and 3 weeks after receiving an US-guided knee aspiration and injection of 40 mg triamcinolone acetonide. Three-dimensional quantitative gait analysis was completed using a 12-camera motion capture system and floor-mounted force plate to calculate knee angles and moments, with the peak external KFM as the primary outcome. Knee extension and flexion strength (peak torque in Nm) was tested using an isokinetic dynamometer (90°/s). US assessments were performed using a linear 3-12 MHz probe. The suprapatellar recess was scanned in the long axis view (medial, lateral, midline) with the knee flexed to 20°. All US exams were graded using the OMERACT system for inflammatory features of knee OA. Paired T-tests were used to determine mean changes and 95% confidence intervals from pre to 3 weeks post injection for all measures. Mixed effects regression with robust sandwich estimators was then used to evaluate the associations between potential predictors and peak KFM during walking. Random intercepts and slopes were specified by patient ID, time and limb. Potential predictors included US regional score (0-9), effusion depth (mm), gait speed (m/s), NRS (0-10), and quadriceps strength (Nm). Only knees undergoing aspiration and injection were evaluated.

Results: Baseline demographic and clinical characteristics are presented in Table 1. US regional score, effusion depth and NRS pain decreased post injection (Table 2). The peak KFM during walking, quadriceps and hamstring

Table 3. Linear mixed effects model estimates

strength and KOOS subscales (symptoms, pain, daily living) increased post injection (Table 2). While controlling for time and limb, increases in gait speed and reductions in NRS pain were associated with greater peak KFM (Table 3).

Conclusion: Aspiration and corticosteroid injection improves signs of inflammation on MSK US, gait biomechanics associated with quadriceps avoidance gait, strength, and patient-reported measures of pain and function in patients

with knee OA. Greater gait speed and lesser knee pain were associated with less quadriceps avoidance gait. This suggests that local knee inflammation may contribute to abnormal gait biomechanics, however, further research is needed to understand the mechanism.

A Double-Blind Randomized Trial to Evaluate the Efficacy of Corticosteroid Injections for Osteoarthritis of the Knee Using Mobile Devices

Joshua Baker[1], Mitesh Patel[1], Tuhina Neogi[2], Keith Robinson[3], Alexis Ogdie[1] and Carla Scanzello[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Boston University School of Medicine, Boston, MA, [3]Corporal Michael J Crescenz VA Medical Center, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The value of intra-articular (IA) corticosteroid injections for osteoarthritis of the knee (KOA) has recently been called into question. Variability in clinical trial design has resulted in inconsistent results from clinical studies evaluating efficacy of this commonly performed procedure. We designed a pilot and feasibility double-blind trial to evaluate the benefit of IA corticosteroid injections with monitoring of response using mobile devices at 2-week intervals.

Methods: Participants with KOA, ages 40-80, who were either receiving or found to be a candidate for ia corticosteroid injection by their physician were eligible for enrollment. Participants received a Fitbit™ activity monitor and were signed up to an online platform (*Way To Health*). Participants were randomized after a 2-4 week run-in period to assess baseline physical activity. Participant could receive 40 mg methylprednisolone acetate plus 2 mL 1% lidocaine or 2 mL 1% lidocaine only in each affected knee. Participants were also randomized in a factorial design to receive social incentives to promote exercise (not shown here). Participants and study staff were blinded to treatment allocation and the research pharmacist prepared an opacified syringe to the physician at the time of the injection. Text messages were sent at 2-week intervals to remind participants to complete the Knee Injury and Osteoarthritis Outcome Score (KOOS). The Minimal Clinically Important Difference (MCID) for KOOS subscales ranges between 16 and 18. The primary outcome was the change in total KOOS from baseline. We compared change in KOOS across treatment groups incorporating all outcome measures over 12 weeks (2, 4, 6, 8, 10, and 12 weeks) using linear regression with generalized estimating equations. Sensitivity analyses were performed utilizing a last-observation-carried-forward (LOCF) approach.

Results: At the time of this interim analysis, 27 out of 32 planned participants (24 male) were randomized (Figure 1). Baseline characteristics are shown in Table 1. A total of 18 had completed all 12 weeks of follow-up. Participants that

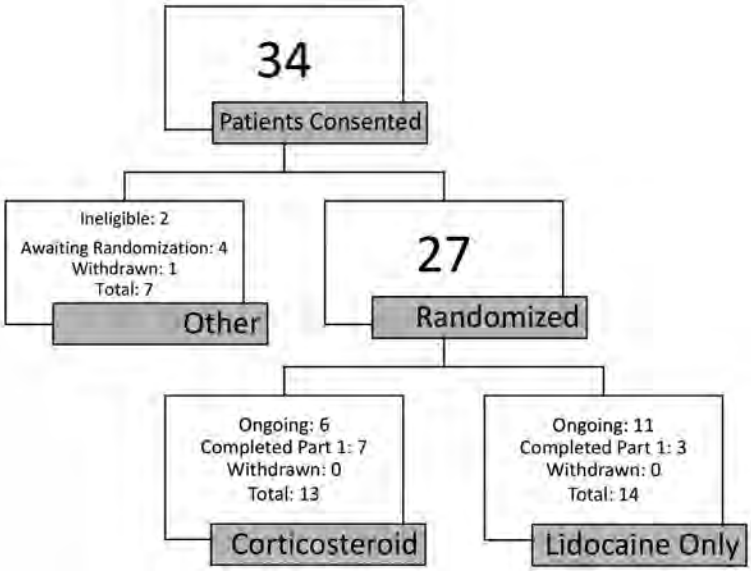

Figure 1. Consort Diagram. Corticosteroid Lidocaine Only N 13 14 Age 58.4 (2.0) 63.1 (2.1) Female, N (%) 2 (15%) 1 (7%) Black 9 (69%) 11 (79%) BMI 35.5 (1.8) 31.8 (1.5) Current Smoker 2 (15%) 2 (14%) K-L grade 3 (2, 4) 4 (3, 4) Baseline KOOS 38.8 (17.2) 44.0 (14.4) Prior Injections 13 (100%) 14 (100%)

received corticosteroids had significantly greater improvement in overall KOOS score [B: 10.2 (2.7, 17.7) p=0.007]. This pattern was observed for all KOOS sub-scales (Figure 2), and was most prominent between weeks 4 and 10 weeks of follow-up. Three adverse events were reported during the trial; none were considered related to the intervention. The effect was robust with imputation of missing values in sensitivity analyses using LOCF [B: 10.2 (2.8, 17.6) p=0.007]. In addition, among the 18 participants that had completed follow-up, the difference was significant at 12-weeks [B: 14.4 (0.58, 28.1) p=0.007]. The number needed to treat to achieve an improvement in pain at least as much as the MCID was 3.

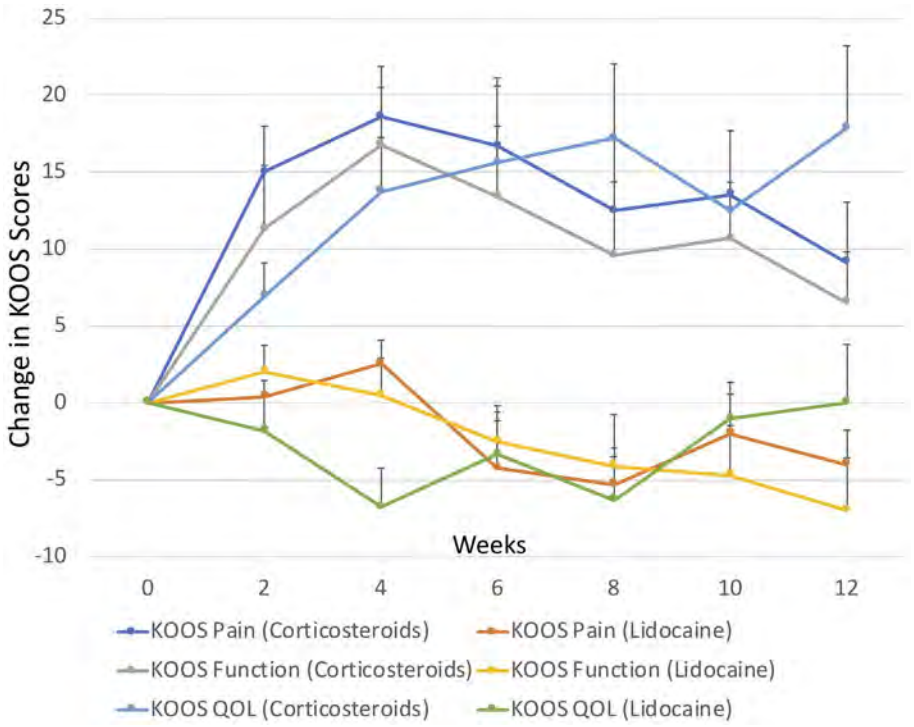

Figure 2. Mean change from baseline (SE) in KOOS scores (pain, function, and quality of life) over 12 weeks of follow-up by treatment arm.

	Corticosteroid	Lidocaine Only
N	13	14
Age	58.4 (2.0)	63.1 (2.1)
Female, N (%)	2 (15%)	1 (7%)
Black	9 (69%)	11 (79%)
BMI	35.5 (1.8)	31.8 (1.5)
Current Smoker	2 (15%)	2 (14%)
K-L grade	3 (2, 4)	4 (3, 4)
Baseline KOOS	38.8 (17.2)	44.0 (14.4)
Prior Injections	13 (100%)	14 (100%)
Exercise Incentive	6 (46%)	7 (50%)

Table 1. Patient characteristics at enrollment among participants receiving corticosteroids + lidocaine v. lidocaine only.

Conclusion: In this pilot double-blinded randomized trial, there was a significant benefit of ia corticosteroid injections compared to lidocaine. The intervention was beneficial in terms of pain, function, and quality of life and was clinically-important in magnitude, though the effects start to diminish by week 12. This study suggests that trials evaluating benefits of IA corticosteroid should consider the importance of short-term benefits.

Efficacy and Safety of Multiple Intra-articular Corticosteroid Injections for Osteoarthritis – a Systematic Review and Meta-analysis of Randomised Controlled Trials and Observational Studies

Shazeen Ayub[1], Jaspreet Kaur[1], Michelle Hui[2], Michelle Hall[1], Michael Doherty[3] and Weiya Zhang[1], [1]Academic Rheumatology, School of Medicine, University of Nottingham, UK, Nottingham, United Kingdom, [2]Royal Derby Hospital, Derby, UK, Derby, United Kingdom, [3]Academic Rheumatology, School of Medicine, University of Nottingham, UK, Nottingham, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis worldwide and is becoming more prevalent with the increasing age of the population. As Intra-articular Corticosteroids (IACS) in clinical practice are often given serially to improve patient symptoms, we undertook this systemic review to summarise literature for the two key clinically relevant questions- are multiple IACS injections effective for OA and are they safe?

Table 1 Characteristics of studies with efficacy data of multiple IACS

Author Year	Joint	Intervention					Comparator					Time points measured (weeks)
		Number patients	Name	Dose	Number of injections	Interval	Number patients	Name	Dose	Number injections	Interval	
Hyaluronic acid as comparator												
Bisicchia 2016	Knee	75	6-methyl-prednisolone acetate	40mg	2	Day 0 and week 1	75	Hyaluronic acid	Not stated	2	Day 0 and week 1	0, 6, 12, 26, 52
Bjornland 2007	TMJ	20	Betametasone sodium phosphate	Not stated	2	Day 0 and week 1	20	Hylan G-F20	0.7-1ml	2	Day 0 and week 1	0, 2, 4, 26
Davalillo 2015	Knee	91	Betametasonedipropionate 5mg+ Betametasone sodium phosphate 2mg	5mg +2mg	2	Day 0 and week 4	89	Hyaluronic acid 1%	Not stated	5	Day 0 and weekly thereafter	0, 13, 26, 39, 52
Monfort 2014	1st CMC	40	Betametasone disodium phosphate + Betametasone acetate	1.5mg + 1.5mg	3	Day 0, week 1, and week 2	48	Hyaluronic acid	5mg	3	Day 0, week 1 and week 2	0, 1, 2, 4, 12, 24
Normal saline as comparator												
McAlindon 2017	Knee	70	Triamcinolone	40mg	8	Day 0 and then every 12 weeks	70	0.9 % Normal saline	1ml	8	Day 0 and then every 12 weeks	0, 13, 26, 39, 52, 65, 78, 91, 104
Raynauld 2002	Knee	34	Triamcinolone acetonide	40mg	8	Day 0 and then every 12 weeks	34	0.9% Normal saline	1ml	8	Day 0 and then every 12 weeks	0, 13, 26, 39, 52, 65, 78, 91, 104

TMJ temporomandibular joint; CMC carpometacarpal joint

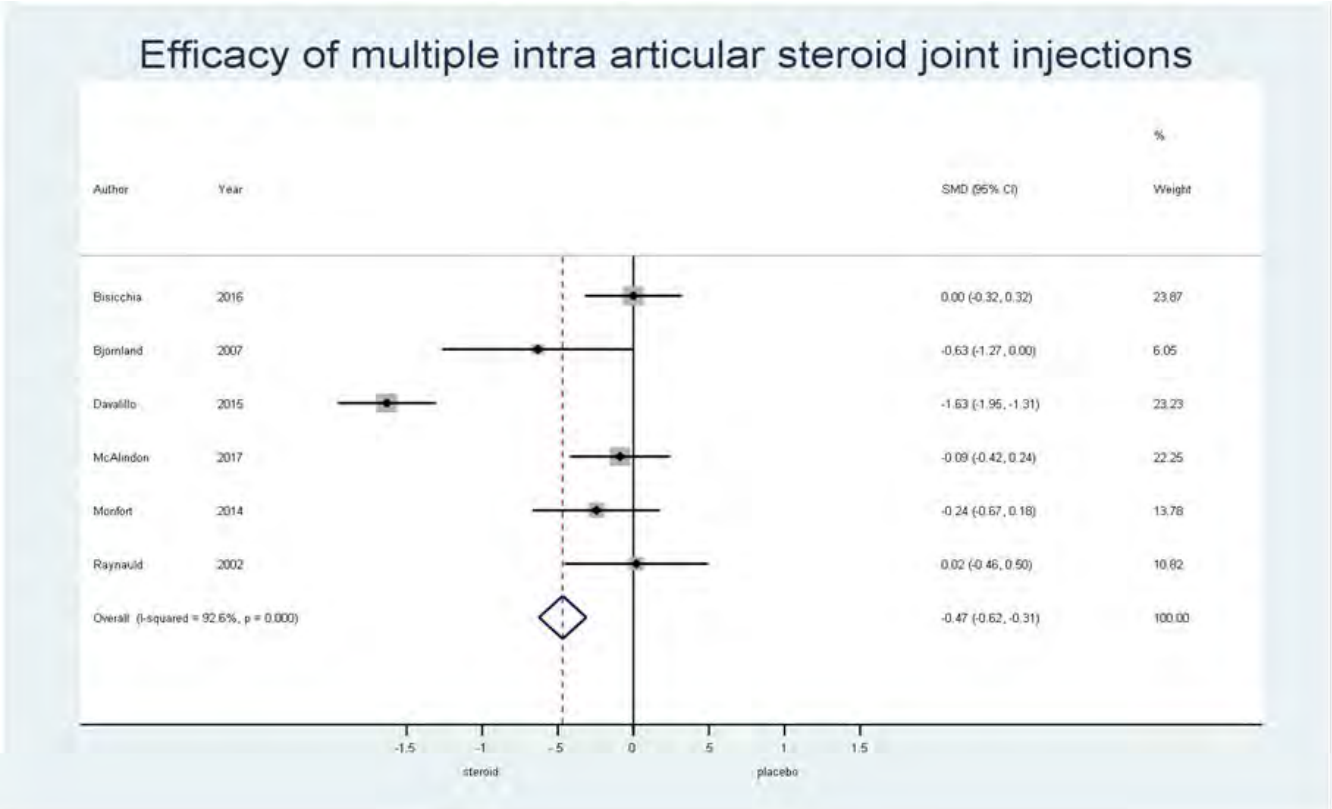

Figure 1. Forest plot of effects size for pain relief

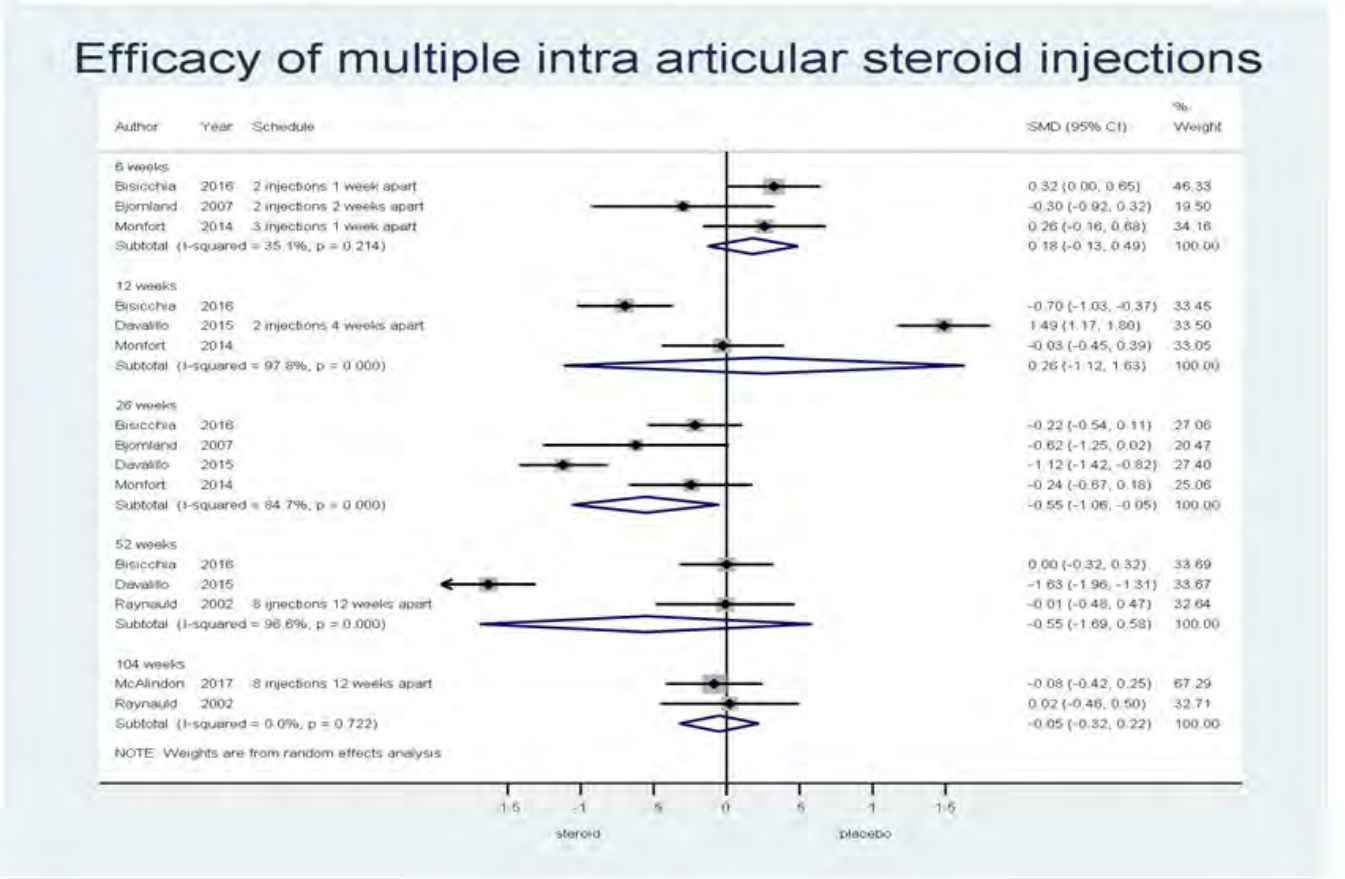

Figure 2. Forest plot of subgroup analysis of pain scores according to varying time points

Methods: Systematic literature searches was performed in January 2019 using the databases MEDLINE, EMBASE, AMED, Web of Science, PubMed, Cochrane Library, and Google Scholar. Relevant references were also explored. A structured search strategy was used for both efficacy and safety. Data extracted included study design characteristics, participant details, characteristics of IACS (including dosage, frequency and duration of treatment), comparator used and outcomes examined. Any discrepancies were resolved through discussion of papers by the reviewers.

Results: Six RCTs were included for efficacy assessment (Table 1). The use of multiple IACS appeared to be better than comparator (SMD for pain -0.47, 95% CI -0.62, -0.31). An I^2 statistic of 92.6% indicates a great deal of heterogeneity (figure 1). However one study stood out strongly in favour of IACS (SMD -1.63, 95% CI -1.95, -1.31). With a weighting of 23% this was further excluded as an outlier of results. This resulted in the overall change in VAS between IACS and comparator being not statistically different (SMD -0.12, 95% CI -0.29, 0.06), with improved heterogeneity (I^2 0.00%, p value 0.444).

Subgroup analysis by comparator showed no separation of regular IACS from placebo, though timing of pain assessments was questionable. Figure 2 shows the subgroup analysis according to varying time points at 6, 12, 26, 52 and 106 weeks. Apart from pain reduction on 26 months (SMD -0.55, 95%CI -1.06 to -0.05), no difference was observed between IACS and comparator.

Fourteen RCTs and two observational studies were assessed for the safety of multiple IACS. Minor local adverse events were similar in both groups. One RCT found that regular IACS every 3 months for 2 years caused greater cartilage loss compared to saline injection (-0.21mm vs 0.10mm). One cohort study found that multiple IACS injections

associated with worsening of joint space narrowing (HR 3.02, 95% CI 2.25-4.05) and increased risk of total joint replacement (HR 2.54, 95% CI 1.81- 3.57).

Conclusion: This systematic review included RCTs of regularly repeated IACS injections, using different steroid regimes and different joint sites, and with infrequent pain assessment predominantly undertaken just prior to each injection. This makes it difficult to come to any firm conclusion about the efficacy of multiple IACS injection however it would appear that multiple IACS injections overall are no better than placebo for OA pain. The preliminary finding of a detrimental effect on structural OA progression warrants further investigation. Efficacy and safety of multiple IACS reflecting recommended best practice has yet to be assessed.

Progression of Knee OA with Use of Intra-articular Corticosteroids (CS) vs Hyaluronic Acid (HA)

Justin Bucci[1], Xiaoyang Chen[1], James Torner[2], Michael Nevitt[3], Cora Lewis[4] and David Felson[5], [1]Boston University, Boston, MA, [2]University of Iowa, Iowa City, IA, [3]University of California, San Francisco, Orinda, CA, [4]University of Alabama Birmingham, Birmingham, AL, [5]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies have questioned whether CS injections (CSI), a popular treatment recommended by guidelines, hasten progression of knee OA. A recent cohort study suggested a three-fold higher risk for knee OA progression with CSI.

Table 1. Pre-injection Clinical and Radiographic Status

Variable	Single Reported CSI (n=523)	Single Reported HAI (n=126)	>1 Reported CSI (n=124)	>1 Reported HAI (n=19)
Age in years (mean)	66.8	65.7	66.5	65.7
% Women	69.4%	49.2%	66.1%	63.2%
BMI in kg/m2 (mean)	30.3	30.7	29.8	31.8
XJRS (mean) (0-3)	1.00	1.36	1.04	1.42
KL (mean) (0-4)	1.85	2.07	1.91	2.32

Table 1

Table 2. Annualized Difference in Rate of Radiographic Progression Between CSI and HAI*

Comparison	JSN (Δ grade/year)	KL (Δ grade/year)	JSW250 (OAI) (Δ mm/year)
Single Reported HAI vs CSI	0.023 (95% CI:-0.056-0.10, p=0.57)	0.047 (95% CI:-0.041-0.13, p=0.30)	-0.018 (95% CI:-0.16-0.12, p=0.80)
>1 Reported HAI vs CSI	-0.060 (95% CI: -0.20-0.071, p=0.35)	-0.061 (95% CI: -0.23-0.11, p=0.48)	0.033 (95% CI: -0.26-0.33, p=0.82)

*Reported in comparison to CSI, positive values reflect lower rates of progression for CSI and negative values higher rates for CSI. Analyses adjusted for age, sex, BMI, study of origin and baseline KL grade.

Table 2

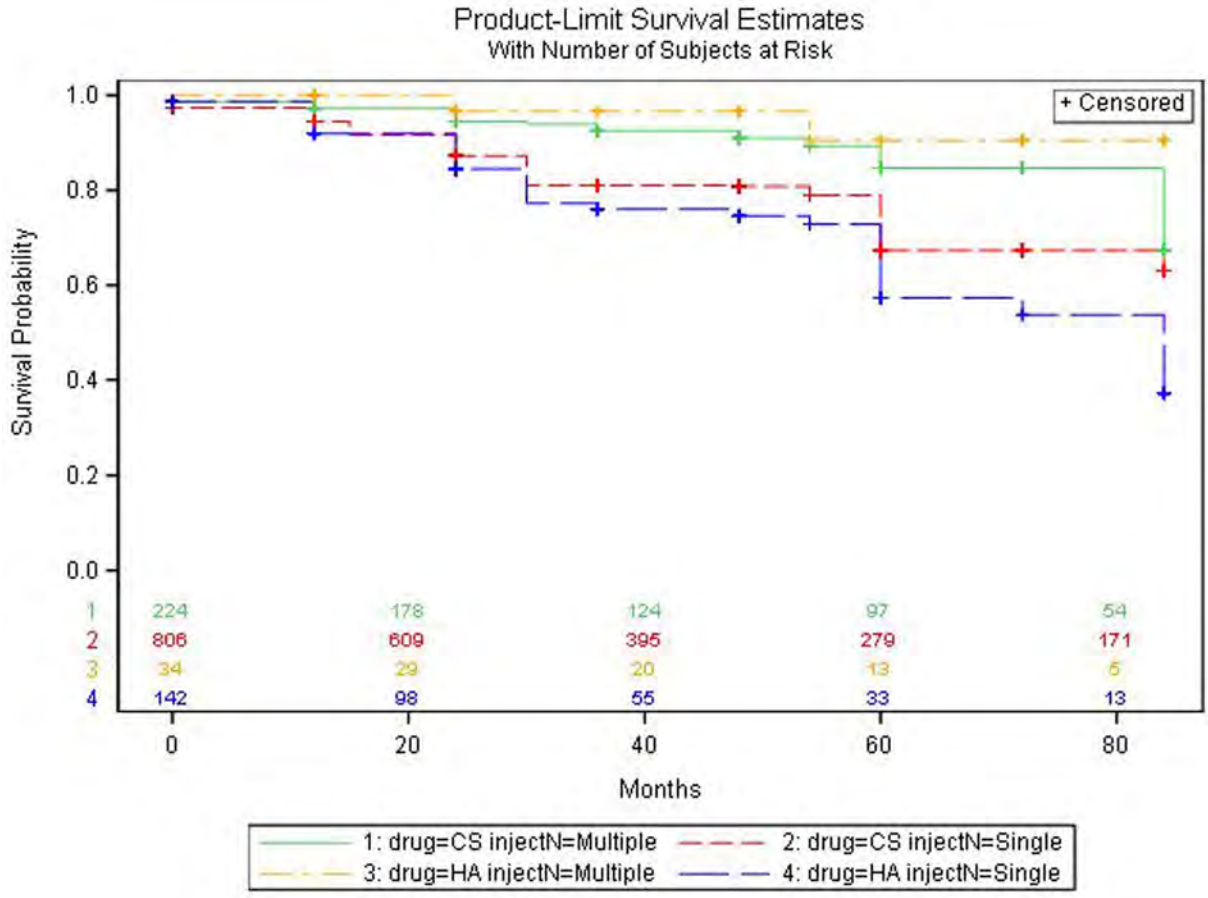

Figure 1

A limitation of such studies is CSI recipients have more advanced knee OA, which is itself a risk factor for OA progression, making it impossible, despite statistical adjustments, to compare those undergoing CSI to those who do not report injections. Patients receiving HA injections (HAI) are a natural comparator to those receiving CSI, as HAI has not been associated with cartilage loss. The purpose of this study was to assess whether CSI was associated with increased rates on knee OA progression in comparison to HAI.

Methods: We used 2 cohort studies of knee OA, MOST and OAI, to look at rates of x-ray progression and total knee replacement (TKR) among CSI or HAI recipients. OAI and MOST visits were performed every 12 and 30 months, respectively, and included knee x-rays and questions about HAI or CSI in the preceding 6 months. The studies use similar acquisition and reading protocols. Kellgren and Lawrence grades (KL) (0-4), joint space narrowing (JSN) (0-3) were scored for both studies and in OAI, medial joint space (JWS250) was measured.

For analysis of x-ray progression, we excluded knees with baseline KL 4, CSI or HAI reported at first visit, and recipients of HAI and CSI. We compared x-rays from the visit before first reported injection to x-rays at the visit after the last injection. TKR without post-injection x-ray was assigned KL grade 4 and JSN 3 at visit at which TKR was first present. Annualized deterioration rates were calculated for KL, JSN and JWS250. Using multivariable linear regression, we examined deterioration rates for reports of injections at single and multiple exams adjusting for age, sex, BMI, study, and baseline KL grade. For TKR survival analysis, we added subjects who reported injections at baseline visits. TKR events were censored after 7 years from first reported injection.

Results: 792 knees were analyzed, of which 647 reported CSI use and 145 reported HAI use. 124 reported CSI and 19 reported HAI at >1 visit. For additional characteristics, see table 1.

Unadjusted analysis for time to TKR is shown in figure 1. The rate of TKR was greater among those with single exam reports of HAI than of CSI (p=.04) but not different for those reporting at multiple exams, although numbers were small. Multivariable analysis showed similar rates of radiographic progression between CSI and HAI among subjects reporting injections at single or multiple exams (table 2).

Conclusion: CSI for knee OA was not associated with higher rate of radiographic progression or progression to TKR than HAI. The risk of disease progression attributed to CSI in earlier studies may reflect the presence of more severe OA in those undergoing injections.

Urban teaching	2,573,263 (46.7)	135,051 (49.1)	

Note:

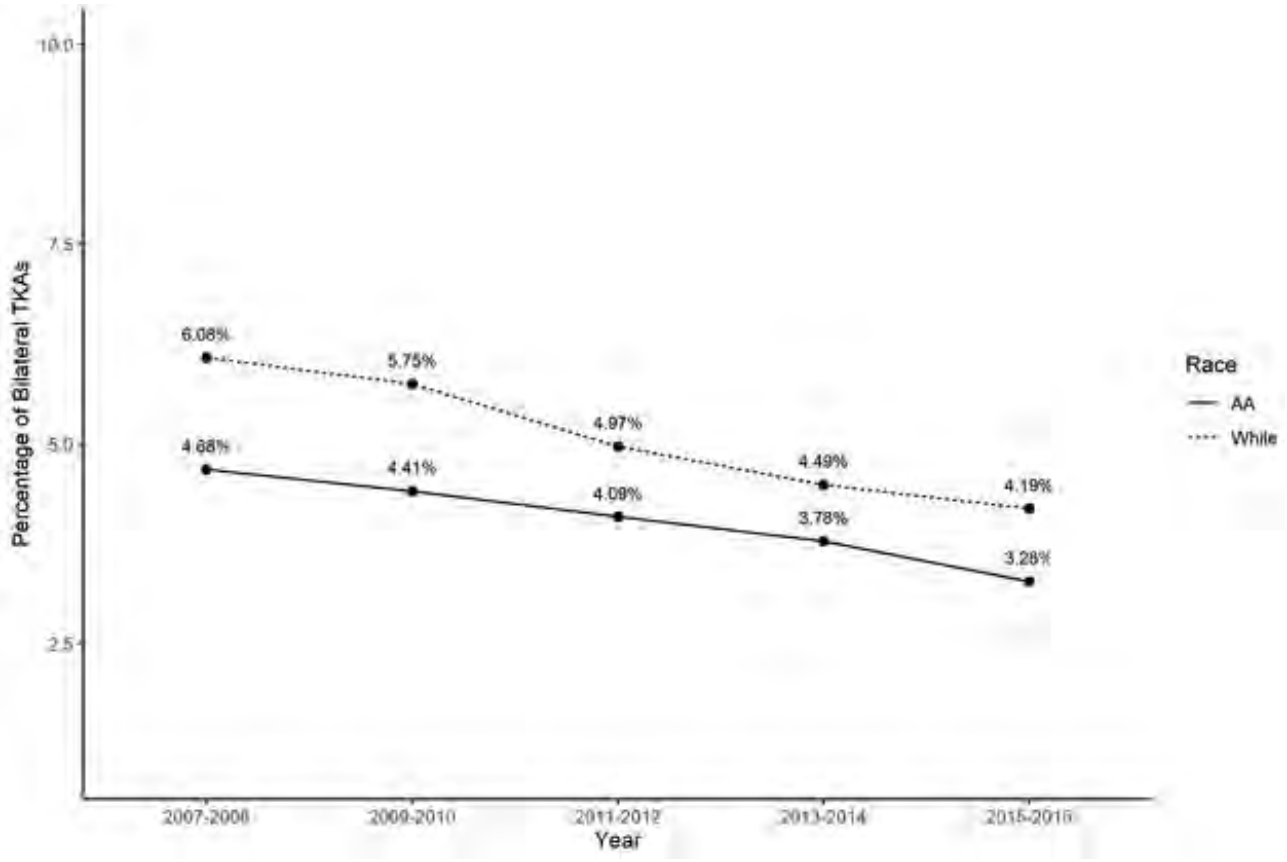
All values were estimated using sampling weights and hospital clusters.

[a]P-values are calculated based on the Rao-Scott chi-square test for all categorical variables and 2-sample independent t-test for continuous variables. Significance levels: * = p<0.05, ** = p<0.01, *** = p<0.001.

[b]Clinical comorbidities were identified based on coding algorithms developed by Quan and colleagues (enhanced Elixhauser version), using either ICD-9-CM or ICD-10 codes, as appropriate. The Elixhauser co-morbidity index score is calculated based on the cumulative number of comorbidity conditions.

Weighted frequencies and percentages of demographic characteristics among unilateral TKA vs. bilateral TKA.

Methods: In this retrospective analysis, we sought to examine BTKA vs UTKA utilization and in-hospital complications comparing AAs and Whites. Using the National Inpatient Sample (NIS)- Healthcare Cost and Utilization Project (HCUP) database (2007-2016), we computed differences in temporal trends in utilization and major in-hospital com-

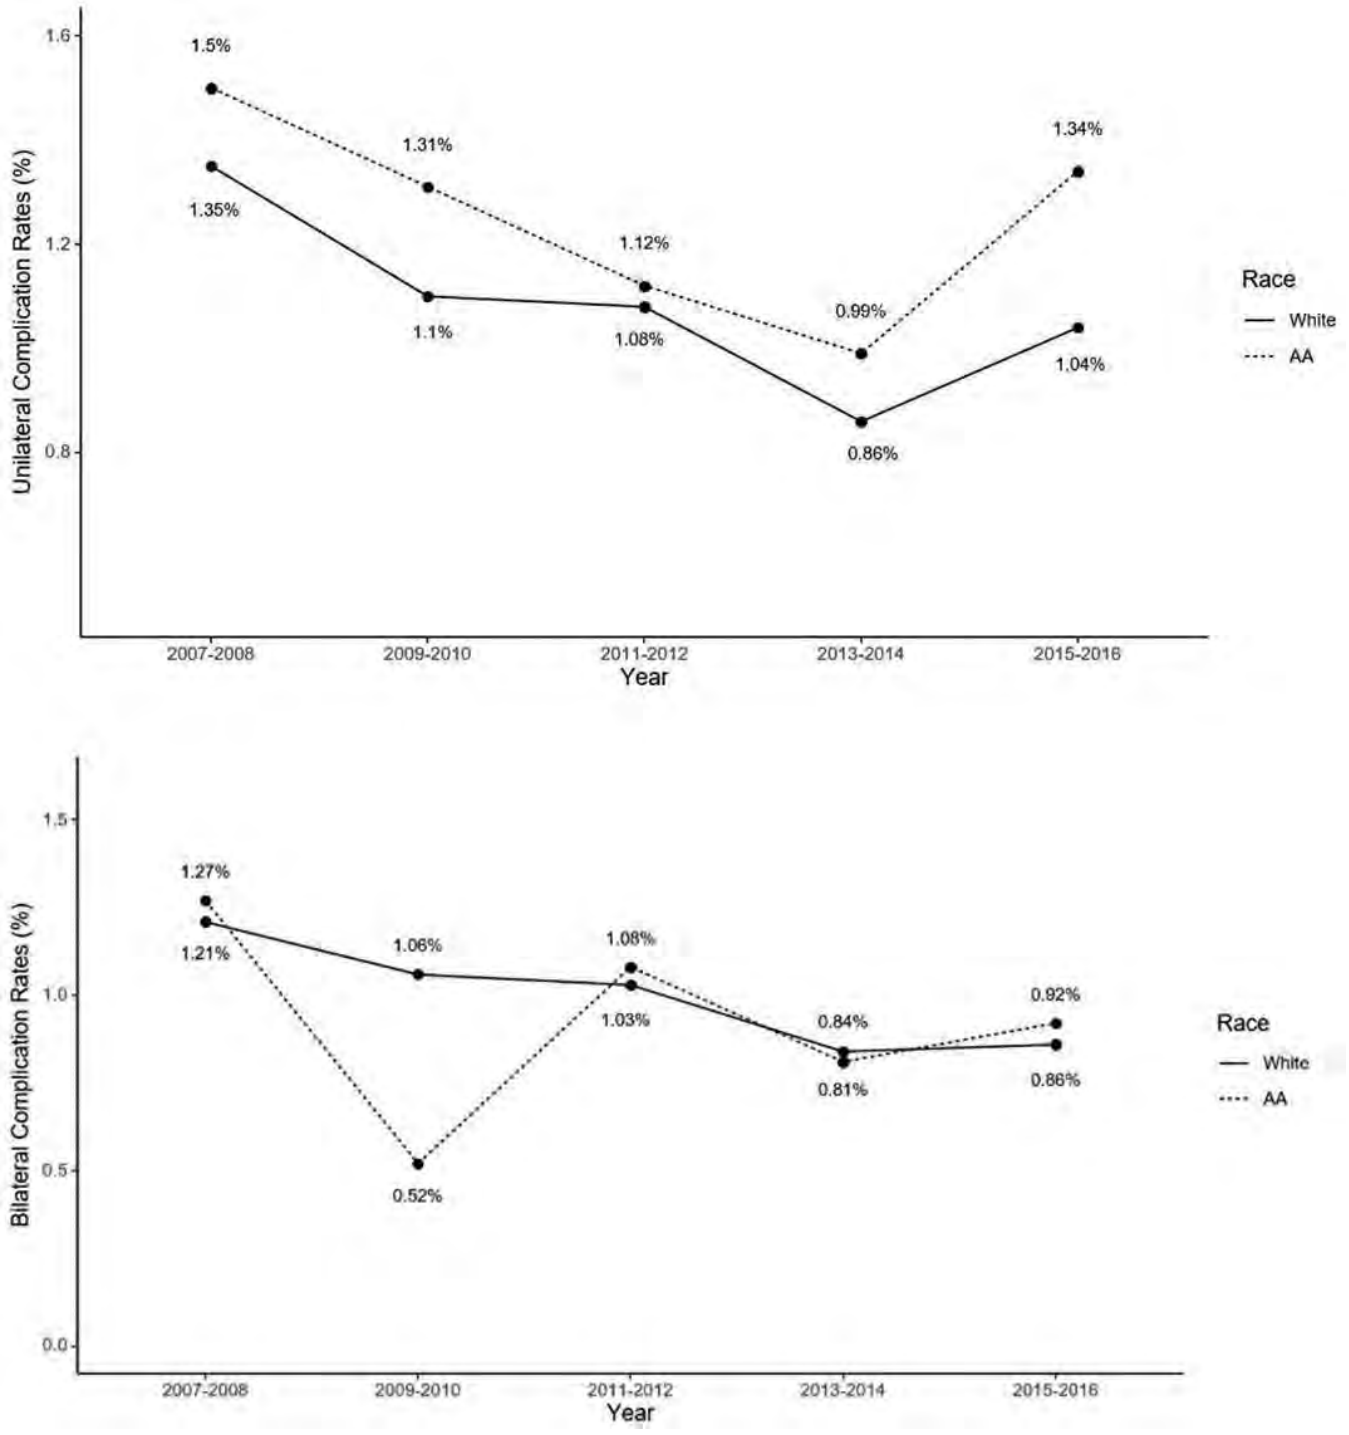


Utilization of Bilateral Total Knee Arthroplasty (TKA) amongst all TKAs stratified between Whites and African Americans.

plication rates of BTKA vs UTKA comparing AAs and Whites. All patients ≥ 50 years who underwent elective primary TKA were included. We performed multivariable logistic regression models to assess racial differences in trends adjusting for individual (age, sex, Elixhauser comorbidity index, and morbid obesity), hospital level (hospital volume, bed size, region and teaching status) and community level (median household income) variables. Discharge weights were used to enable nationwide estimates. We used multiple imputation procedures to impute values for 12% missing race information.

Results: An estimated 276,194 BTKA and 5,528,429 UTKA were performed in US. The proportion of BTKA amongst all TKAs declined from 5.53% in 2007-08 to 4.03% in 2015-16. AAs were significantly less likely to undergo BTKA compared to Whites throughout the study period (4.68% in AAs vs 6.08% in Whites in 2007-08, whereas 3.28% AAs vs 4.19% Whites in 2015-16, trend $P < 0.001$). In-hospital complication rates for UTKA were higher in AAs compared to Whites throughout the study period (1.35% Whites vs 1.50% AAs, 2007-08, 1.00% Whites vs 1.35% AAs in 2015-16, trend $P < .0001$). However, for BTKA, the in-hospital complication rates varied between Whites and AA throughout the study period (1.21% Whites vs 1.27% AAs, 2007-08; 1.03% Whites vs. 1.08% AAs, 2011-12; 0.86% Whites and 0.92% AAs, 2015-16, trend $P = 0.09$).

Conclusion: In this nationwide sample of patients from 2007-2016 who underwent total knee arthroplasty, the utilization rate of BKTA was higher in Whites compared to AAs. On the other hand, while AAs have consistently higher in-hospital complication rates in UTKA over the time period, this pattern was not consistent for BTKA.



Unilateral and Bilateral Total knee Arthroplasty in-hospital Complications in Whites and African Americans

Abstract Number: 1654

The Relationship Between Patient-Reported Readiness for Total Knee Arthroplasty and the Likelihood of a Good Outcome at One Year

Gillian Hawker[1], Barbara Conner-Spady[2], Eric Bohm[3], Michael Dunbar[4], Allyson Jones[5], Bheeshma Ravi[1], Tom Noseworthy[2], Linda Woodhouse[6], Peter Faris[7], Donald Dick[8], James Powell[2], Paulose Paul[5] and Deborah Marshall[2], [1]University of Toronto, Toronto, ON, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]Concordia Hip & Knee Institute, University of Manitoba, Winnipeg, MB, Canada, [4]Dalhousie University, Halifax, NS, Canada, [5]University of Alberta, Edmonton, AB, Canada, [6]Curtin University, Perth, Western Australia, Australia, [7]Alberta Health Services, Calgary, ON, Canada, [8]Alberta Bone and Joint Health Institute, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In prior qualitative research, we found that patients with knee osteoarthritis (OA) equated appropriateness for total knee arthroplasty (TKA) with candidacy for the procedure. Pain intensity, the ability to cope with the pain and how the pain affected quality of life were seen as important factors determining surgical candidacy. The importance of psychological readiness and a positive attitude, were additionally perceived as critical to achievement of a good TKA outcome. The current study examined the relationship between patients' pre-operative psychological readiness for TKA and surgical outcome at one year.

Methods: This prospective cohort study recruited knee OA patients aged 30+ years referred for TKA at two hip/knee surgery centers in Alberta, Canada. All participants met ACR criteria for knee OA. Those who received primary, unilateral TKA completed questionnaires pre-TKA to assess TKA readiness (Patient Acceptable Symptom State – knee symptoms acceptable/unacceptable; Perceived Arthritis Coping Efficacy; General Self-Efficacy; definite willingness to undergo TKA - yes/no) and covariates (age, sex, WOMAC pain, Knee injury and Osteoarthritis Outcome Score Physical Function [KOOS-PS], Patient Health Questionnaire depression scale, BMI, comorbidities), and one year post-TKA to assess TKA outcome. A good TKA outcome was defined as improved knee symptoms (OARSI-OMERACT responder criteria) AND overall satisfaction with TKA results (yes/no). Using multivariable logistic regression, we examined the relationship of our exposures to a good TKA outcome, before and after controlling for covariates.

Results: Of 1,272 TKA recipients assessed at one year, 1,030 without complications and with data for the primary outcome were included (mean age 66.9 years [SD 8.8]; 58.5% female). 79.3% achieved a good TKA outcome. In multivariable analysis, controlling for covariates, unacceptable knee symptoms and definite willingness to undergo TKA were associated with higher odds of a good TKA outcome (adjusted ORs 1.55, 95% CI, 1.06 - 2.71, and 1.70, 95% CI 1.09 - 2.66, respectively).

Conclusion: Among OA TKA recipients, greater psychological readiness for TKA was associated with higher odds of a good TKA outcome. Incorporation of patient readiness in TKA decision-making may enhance patient outcomes and appropriate use of TKA.

Pain Reduction Post Total Knee Replacement in Opioid Users and Non-users

Lindsey MacFarlane[1], Yinzhu Jin[1], Yvonne Lee[2], Joyce Lii[3], Jeffrey Katz[4], Patricia Franklin[5] and Seoyoung Kim[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Brigham and Women's Hospital, Boston, [4]Harvard Medical School / The Orthopaedic and Arthritis Center for Outcomes Research (OrACORe) at Brigham and Women's Hospital, Boston, MA, [5]Northwestern University, Chicago

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: End-stage knee osteoarthritis (OA) is often managed with opioids and total knee replacement (TKR). Studies ascertaining opioid use via record review are conflicting as to whether opioid users experience similar pain reduction post TKR compared to non-users. We used claims data to identify opioid prescriptions and analyzed pain response after TKR among naïve, intermittent and continuous opioid users.

Methods: We used Medicare claims data (Parts A/B/D 2010-2014) linked to data from the FORCE-TJR, a research cohort of U.S. patients receiving total joint replacement who completed the Knee Injury and Osteoarthritis Outcome Score (KOOS) at baseline and follow-up. Included patients were ≥ 65 years old, received TKR, and had continuous enrollment in Medicare for the 360 days prior to TKR. We assessed for opioid dispensation in each of the 12 months leading up to TKR. We categorized pre-baseline opioid use as follows, naïve: patients with no opioid prescription, intermittent: those with opioid prescription ≥1 and < 12 months, continuous: patients with a prescription in all 12 months. KOOS Pain (0-100, 100 best) was measured at baseline and at 6 and 12-months post-TKR. We compared post-TKR KOOS Pain at 6 and 12 months among the opioid use groups. We then developed linear regression models to ascertain the association between opioid use and KOOS Pain at 12-months follow up and change in KOOS Pain from baseline to 12-months. For patients not providing 12-month KOOS scores, 6-month data were used. We considered the following covariates baseline KOOS Pain, age, sex, race, body mass index, mental component summary (MCS), comorbidity index, medication use (NSAIDs, COX-2 inhibitors, gabapentin and pregabalin), and indicators of widespread pain- back pain, non-operative knee pain, and neuropathic pain.

Results: We included 799 patients; 372 were opioid naïve, 385 intermittent users and 42 continuous users. Mean age was 72-73 years and 69-76% were female. Continuous (44±20 p=0.04) and intermittent (47±17 p=0.03) users reported worse KOOS Pain at baseline compared to opioid naïve (50±16) patients. Continuous and intermittent users had more comorbidities and reported greater pain in the back and other knee (Table 1). There were no statistically significant differences in KOOS Pain between opioid users and non-users at 6 and 12-month follow-up (Figure 1). Unadjusted KOOS Pain at 12mo follow up and change in KOOS Pain was similar across the opioid use categories with 85 (Δ=35) for naïve patients, 86 (Δ=38) for intermittent users and 82 (Δ=38) for continuous users. Adjusting for baseline KOOS Pain, and further for demographics, MCS, comorbidity index, medication use and indicators of widespread pain attenuated the difference in both KOOS Pain and change in KOOS Pain across the opioid use categories (Table 2). The differences among the opioid use groups in both the unadjusted and adjusted models are small (effect size < 0.26) and unlikely to be clinically meaningful.

Table 1: Baseline characteristics by opioid use category			
	Opioid Use		
	Naïve (n=372)	Intermittent (n=385)	Continuous (n=42)
Age, years, mean (SD)	74 (6)	73 (6)*	72 (7)*
BMI, kg/m^2, mean (SD)	30 (5)	30 (6)	31 (6)
SF-36 Mental component summary, mean (SD)	55 (11)	52 (12)*	51 (14)*
Combined co-morbidity index, mean (SD)	0.8 (2)	1 (2)*	2 (3)*
KOOS Pain index knee, mean (SD)	50 (16)	47 (17)*	44 (20)*
Gender			
Female, n (%)	255 (69)	270 (70)	32 (76)
Race			
% White, n (%)	350 (94)	354 (92)	31 (74)*
% Black or Other, n (%)	22 (6)	31 (8)	11 (26)*
Neuropathic pain, n (%)	75 (20)	120 (31)*	14 (33)
Backpain, n, (%)			
None/mild	292 (79)	245 (64)*	24 (57)*
Moderate/severe	75 (20)	136 (35)*	17 (41)*
Non-operative knee pain, n (%)			
None/mild	306 (82)	297 (77)	26 (62)*
Moderate/severe	36 (10)	62 (16)*	13 (31)*
Medication usage, n (%)			
Antidepressants/ benzodiazepines	85 (23)	164 (43)*	23 (55)*
NSAID/coxib	148 (40)	206 (54)*	22 (52)
Gabapentin/pregabalin	20 (5)	64 (17)*	18 (43)*
BMI; body mass index MME; morphine milligram equivalent KOOS; Knee injury and osteoarthritis score NSAID; non-steroidal anti-inflammatory drugs COXIB- COX-2 inhibitor * $p<0.05$ for opioid user group compared to opioid naïve			

Table 1

Conclusion: Opioid users, whether intermittent or continuous, achieved similar improvement in knee pain post TKR as opioid naïve patients. This suggests that baseline opioid use alone does not predict which patients will have symptomatic benefit from TKR.

Table 2: Least Squared Means (95% CI) for KOOS Pain post-total knee replacement			
KOOS Pain at 12-months follow up			
	Unadjusted	Model 1[a]	Model 2[b]
Baseline opioid use			
Naïve	85 (83, 87)	85 (83, 86)	80 (69, 92)
Intermittent	86 (84, 87)	86 (85, 88)	83 (72, 94)
Continuous	82 (77, 87)	83 (78, 88)	82 (70, 93)
Change in KOOS Pain from baseline to 12-months			
	Unadjusted	Model 1[a]	Model 2b
Baseline opioid use			
Naïve	35 (33, 37)	36 (35, 38)	32 (20, 43)
Intermittent	38 (36, 40)	38 (36, 39)	35 (24, 46)
Continuous	38 (32, 44)	35 (30, 39)	33 (21, 45)

KOOS: Knee Injury and Osteoarthritis Outcome Score

a. Model 1- adjusted for baseline KOOS Pain

b. Model 2- Model 1 + adjusted for age, sex, race, mental component summary score, comorbidity index, medications (non-steroidal anti-inflammatory drugs, coxibs, gabapentin, pregabalin), baseline contralateral knee pain, back pain, neuropathic pain

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: High body mass index (BMI, kg/m^2) is a modifiable risk factor that has been associated with the development and progression of osteoarthritis (OA) and knee pain. While total knee arthroplasty (TKA) is the gold standard for the treatment of end stage OA, morbidly obese patients (BMI≥40kg/m^2) are often required to lose weight prior to TKA due to increased surgical risk and a higher rate of complications. While conservative weight-loss often fails to help these patients, bariatric surgery can be an alternative option. Here we present interim data from the trial

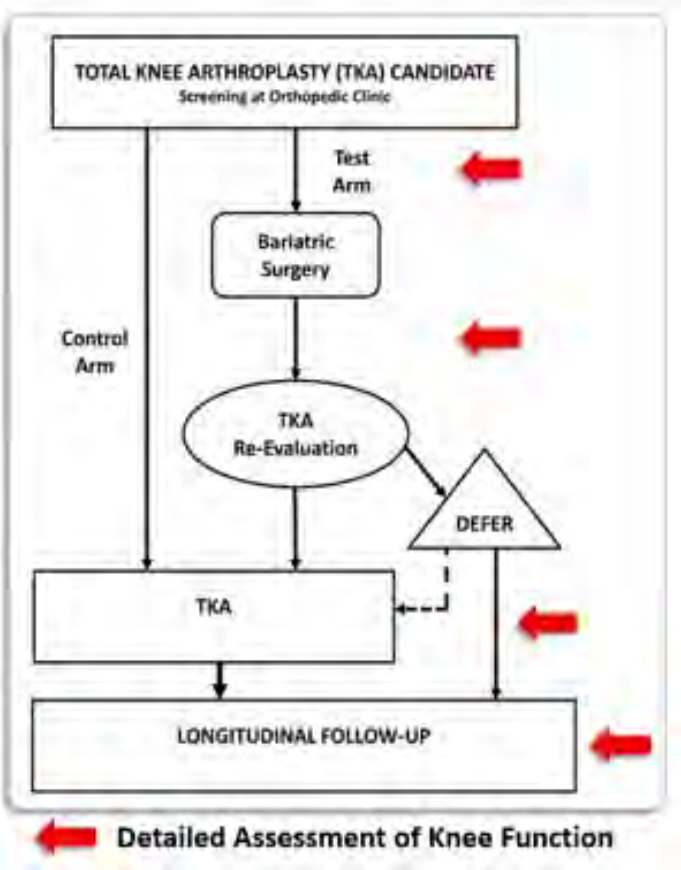

Figure 1. Study flowchart

entitled "Surgical Weight-loss to Improve Functional Status Trajectories following arthroplasty for painful knee osteoarthritis**".** This current multi-center, prospective study compares pain and functional outcomes in patients receiving bariatric surgery prior to TKA versus obese patients who go straight to TKA.

Methods: Patients with BMI ≥40 kg/m^2 and painful knee osteoarthritis who met the indications for TKA were recruited at four hospital centers. Patients with a BMI >35 kg/m^2 were also recruited if they had a qualifying comorbid condition including obstructive sleep apnea, diabetes, hypertension or hyperlipidemia. Patients were assigned to either the bariatric (BAR) or TKA arm based on surgical choice (goal n=150 for each arm), with all bariatric patients having anatomy-altering sleeve gastrectomy or gastric bypass. At baseline and several time points after surgery **(Figure 1)**, we documented height, weight, the Knee injury and Osteoarthritis Outcome Score (KOOS), visual analog pain (VAS) scales, and the Western Ontario and McMaster Universities Arthritis Index (WOMAC), and had patients perform functional assessments (Timed-Up and Go, 30-second Chair Stand and 40-meter fast paced walk test). We targeted minimum detectable change (MDC) in outcomes for the VAS for knee pain (33% reduction), Timed Up and Go (decrease by 2 seconds), 30-second Chair Stand (increase by 2 reps), 40-meter fast paced walk (increase by 0.16 m/s), WOMAC score (16% reduction), and the KOOS pain score (10-point improvement). Using a logistic regression to adjust for age and baseline BMI, we compared the percentage of patients in the two arms who achieved an MDC for the various outcomes.

Results: To date, 25 BAR and 28 TKA patients have completed their follow-up visits through at least 6 months. Although there was a similar sex distribution, the bariatric group was younger (52 vs 60 years old, p=0.0023) with a higher baseline BMI (47.0 vs 41.6 p=0.0006). Most bariatric patients achieved comparable improvement to the TKA cohort with regards to the benchmarks of the 30-second Chair Stand (TKA 54% vs BAR 33%, p=0.156), KOOS pain score (TKA 91% vs BAR 67%, p=0.130), the Visual Analog Pain Scale (TKA 50% vs BAR 39%, p=0.466), Timed Up and Go test (TKA 43% vs BAR 22%, p=0.141) and the 40-meter fast paced walk (TKA 61% vs BAR 35%, p=0.073). The TKA cohort had a greater percent with a MDC for the WOMAC (TKA 88% vs BAR 54%, p=0.030).

Conclusion: In morbidly obese patients who are eligible for TKA, bariatric surgery may result in modest improvements in knee outcomes and may eventually delay the need for a TKA.

Do Comorbidities Limit Improvement in Pain and Physical Function After Total Knee Arthroplasty in Patients with Knee Osteoarthritis?

Lauren King[1], Esther Waugh[1], Allyson Jones[2], Deborah Marshall[3] and Gillian Hawker[4], [1]University of Toronto, Toronto, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]University of Calgary, Calgary, AB, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with knee osteoarthritis (OA) are increasingly living with multiple comorbid conditions. The presence of comorbidities has been associated with having worse OA symptoms but few studies have assessed their impact on response to OA treatment. We assessed the impact if any of comorbidities on improvement in pain and physical function (patient-reported and performance-based) in recipients of total knee arthroplasty (TKA) for knee OA.

Methods: In the BEST Knee prospective cohort study, patients with knee OA underwent assessment one month prior and 12 months after TKA at two tertiary referral centres in Alberta Canada. Standardized questionnaires assessed sociodemographics social support smoking status self-reported comorbidities and patient-reported outcomes (WOMAC pain, KOOS physical function short-form). Using multivariable generalized-estimating-equation extension of linear regression accounting for potential clustering by surgeon and adjusting for potential confounders we assessed the impact of specific comorbid conditions a priori hypothesized to impact pain and function and total number of conditions reflective of total comorbidity burden separately on change in patient-reported knee pain and physical function at 12 months after TKA. In an exploratory analysis in a subset of patients for whom six-minute walk test (6MWT) a performance-based measure of functional exercise capacity was performed one month prior and 12 months after TKA we assessed the impact of specific and total number of comorbid conditions on change in walking distance.

Results: 1027 participants were included (Table 1) 278 for the 6MWT subset. Mean age was 67 years (SD 8.87) 60% were female 59.3% had a BMI ≥ 30 kg/m2 and 85% reported at least one comorbidity. Individuals with higher number of comorbidities had worse pre-TKA scores for pain physical function and walking distance. At follow-up

QIC, quasi-information criteria; WOMAC, Western Ontario and McMaster Universities Arthritis Index; KOOS, knee osteoarthritis outcome score physical function short-form; 6MWT, six-minute walk test

*Models adjusted for age, sex, education, smoking status, and social support, as well as clustering by surgeon

** Other painful disorder defined as: fibromyalgia, migraines and/or neurological disease

*** Depressed mood defined as PHQ-8 score ≥10

**** Total number of conditions include 12 conditions assessed (did not include obesity or total number of troublesome joints, but included kidney disease, liver disease and hypertension that were not included as specific conditions)

mean changes in pain function and walking distance were similar for those with and without comorbidities (Table 1). In regression analysis back pain (ß=3.3, 95% CI: 0.6 to 6.1) and cancer (ß=8.4, 95% CI 1.8 to 15.0) were associated with less improvement in patient-reported physical function while depressed mood and a higher total number of conditions were associated with greater improvement in both pain and function. No specific conditions were associated with less improvement in pain. Improvement in walking distance after TKA as measured by the 6MWT was unrelated to specific and total number of conditions (Table 2).

Conclusion: For individuals with knee OA most comorbid conditions do not limit improvement in pain physical function and walking distance (6MWT) after TKA. Understanding response to OA treatment in individuals with comorbidities is important for individualized patient counselling. For patients living with comorbidities these findings are important as improvement in long-term OA outcomes may facilitate better engagement in self-management such as physical activity for their other conditions.

Abstract Number: 1658

Mediation of the Association Between Obesity and Osteoarthritis by Blood Pressure, Arterial Stiffness, and Subclinical Atherosclerosis

Marieke Loef[1], Rob van der Geest[1], Hildo Lamb[1], Renée de Mutsert[1], Frits Rosendaal[1] and Margreet Kloppenburg[1], [1]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity-related metabolic dysregulation may lead to atherosclerotic vascular changes. It has been hypothesized that a compromised blood flow may cause detrimental changes to the subchondral bone and decrease nutrient supply to the cartilage. To which extent atherosclerosis may explain the association between obesity and osteoarthritis has not been investigated. Therefore, we aimed to investigate the role of blood pressure, arterial stiffness (pulse wave velocity (PWV)) and subclinical atherosclerosis (carotid intima-media thickness (IMT), popliteal vessel wall thickness (VWT)) as mediators of the association of obesity with hand and knee osteoarthritis.

Methods: We used cross-sectional data from the population-based NEO study, excluding participants with concomitant rheumatic diseases (n = 323) and missing physical examination (n = 14), resulting in 6,334 participants. Clinical hand and knee osteoarthritis were defined by the ACR classification criteria. Eight percent of the participants satisfied the ACR classification criteria for hand osteoarthritis, and 10% of participants was classified with clinical knee osteoarthritis. Structural knee osteoarthritis was assessed on MRI in a subpopulation (n = 1,285). Popliteal VWT was assessed on MRI (n = 1,095), using VesselMASS for semi-automated detection of the vessel wall boundaries. Aortic PWV was estimated on abdominal velocity-encoded MRI (n = 2,580). Carotid IMT was assessed by ultrasonography in all participants. Blood pressure was corrected for the use of antihypertensive medication (systolic +15 mmHg, diastolic +10 mmHg). Continuous variables were standardized (mean 0, standard deviation 1). Associations between BMI and osteoarthritis were assessed with logistic regression analyses, adjusted for age, sex and education. Subsequently, possible mediators were added to the model. The assumptions for mediation according to the Baron and Kenny framework were assessed, and if fulfilled the percentage mediation was calculated.

Results: The population consisted of 55% women, with a mean age of 56 years and BMI of 26 kg/m2. Clinical hand osteoarthritis was present in 8%, clinical knee osteoarthritis in 10% and structural knee osteoarthritis in 12% of participants. Mean blood pressure was 134/85 mmHg. Mean carotid IMT was 0.62 mm, popliteal VWT was 0.53 mm, and PWV was 6.56 m/s (table 1). BMI was positively associated with all osteoarthritis outcomes. Carotid IMT partially mediated the association of BMI with clinical hand osteoarthritis (10.6 (6.2; 30.5)%) and structural knee osteoarthri-

Table 1. Characteristics of the weighted NEO study population

	Overall n = 6,334
General patient characteristics	
Age (year)	56 (6)
Sex (% women)	55
Education (% high)	46
Body mass index (kg/m²)	26 (4)
History of cardiovascular disease (%)	6
Lipid lowering medication (% users)	11
Antihypertensive medication (% users)	23
Exposure variables	
Systolic blood pressure (mmHg)*	134 (19)
Diastolic blood pressure (mmHg)*	85 (12)
Hypertension† (%)	62
Carotid intima-media thickness (mm)	0.62 (0.09)
Popliteal artery vessel wall thickness (mm)^	0.53 (0.05)
Pulse wave velocity (m/s)^	6.56 (1.30)
Osteoarthritis phenotypes	
Clinical hand OA (%)	8
Clinical knee OA (%)	10
Structural knee OA (%)~	12

Results are based on analyses weighted towards the BMI distribution of the general population (n=6,334). ^Popliteal VWT (n=1,095) and PWV (n=2,382) measurements are performed in MRI subpopulations. ~Percentage of participants who underwent knee MRI (n=1,285). Numbers represent mean (SD) unless otherwise specified. Blood pressure was adjusted for antihypertensive medication use when applicable (systolic +15 mmHg, diastolic +10 mmHg). †Defined as a systolic pressure ≥130 mmHg or diastolic pressure ≥85 mmHg or antihypertensive mediation use.

tis (3.1 (1.9; 7.3)%). Diastolic blood pressure (2.1 (1.6; 3.0)%) limitedly mediated the association between BMI and clinical knee osteoarthritis. PWV and popliteal VWT did not mediate the association between BMI and osteoarthritis.

Conclusion: Blood pressure and carotid IMT limitedly mediated the association of BMI with hand and knee osteoarthritis, suggesting that such mediation is questionable in the middle-aged population.

Synergistic Effect of Quadriceps Weakness and Obesity in Women at Risk of Knee Osteoarthritis

Jose Rubio[1], David Felson[2], Xiaoyang Chen[3], Kathy Bacon[4], Neil Segal[5], Michael Nevitt[6], Cora Lewis[7], Tuhina Neogi[2] and Devyani Misra[8], [1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, MA, [4]Boston University School of Medicine, Boston, [5]University of Kansas Medical Center, Kansas City, [6]University of California San Fransisco, Orinda, CA, [7]University of Alabama Birmingham, Birmingham, AL, [8]Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Quadriceps weakness is associated with an increased risk of incident symptomatic and radiographic knee osteoarthritis (OA), particularly in women. Stronger quadriceps muscles may confer a protective effect by acting as shock absorbers and joint stabilizers, especially if excess load across the joint is conferred by obesity, one of the strongest known risk factors for knee OA. Compared to men, women are more likely to have weaker quadriceps muscles leading to joint instability and articular damage. Thus, we investigated whether increased loading with obesity works synergistically with quadriceps weakness to increase the risk of developing knee OA, and whether this effect differs in men versus women.

Methods: We included participants from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of adults with or at risk for knee OA. Isokinetic quadriceps strength from baseline was categorized into sex-specific tertiles, with quadriceps weakness defined as being in the lowest tertile (yes/no). Obesity (yes/no) was defined as body mass index ≥30kg/m^2 at baseline. Our outcomes at 60-month follow-up were incident **radiographic OA** (ROA) (KL-grade ≥2) and **symptomatic OA (SOA)** (radiographic OA with frequent knee pain in the same knee), among those without ROA and SOA, respectively at baseline. To determine the synergistic effect of quadriceps weakness and obesity on the risk of knee OA, we performed knee based, sex-stratified log-binomial regression models, calculating beta coefficients to estimate the risk differences, adjusting for pertinent confounders.

Results: At baseline, mean age was 61yrs, 58% women, mean BMI 29.4 kg/m2. By 60 month follow up, 305 out of 1870 knees (16.31%) developed incident ROA and 492 of 2816 knees (17.47%) SOA. Obese women had 22% more risk of incident ROA than nonobese women. Although quadriceps weakness did not affect the risk difference for incident ROA, there was a trend towards obese women's risk being 34% more for developing ROA with concomitant quadriceps weakness than those without obesity and quadriceps weakness (*p = 0.10 interaction of weakness and obesity*). Obese women had a 24% higher incidence of SOA than nonobese women. Quadriceps weakness itself did not affect SOA risk (< 1% risk difference) in women but obese women's risk with quadriceps weakness had a 43% higher risk of SOA incidence than nonobese and non-weak women (p= 0.0004 *interaction of weakness and obesity*). In men, neither obesity, quadriceps weakness nor their combination had significant effect on risk of either ROA or SOA. See Table.

Conclusion: We found the presence of obesity with quadriceps weakness to have a synergistic effect on higher risk of radiographic and symptomatic knee OA in women, but did not find any significant effect of obesity, quadriceps weakness, or the combination of the two on the risk of these outcomes in men.

Table: Cumulative incident risk difference in radiographic and symptomatic OA risk by quadriceps weakness, obesity, and interaction of both, stratified by sex

	ROA*	P value	SOA**	P value
# Knees (%)	305/1870 (16.31%)		492/2816 (17.47%)

Abstract Number: 1660

Sleep Disturbance and Pain Severity and Multi-site Pain: A Prospective 10.7-year Follow-up Study

Feng Pan[1], Jing Tian[1], Flavia Cicuttini[2] and Graeme Jones[1], [1]University of Tasmania Menzies Institute for Medical Research, Hobart, Tasmania, Australia, [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Sleep disturbance is often comorbid with chronic pain disorders, with emerging evidence suggesting a stronger effect of sleep disturbance on pain than vice versa; however, few studies have evaluated the long-term effect of sleep disturbance on pain. This study sought to examine the association of sleep disturbance with knee pain severity and number of painful sites (NPS) and investigate whether persistent sleep disturbance increases the risk of persistent pain.

Methods: 1,099 community-dwelling older adults (age: mean±SD, 63±7.5 years; 51% female) were recruited and followed-up at 2.6, 5.1 and 10.7-year later. Data on demographics, body mass index, physical activity, comorbidities were collected. At each time-point, sleep disturbance, knee pain severity and NPS were assessed by using questionnaires. Radiographic knee osteoarthritis (ROA) was measured using x-ray. Multi-site pain (MSP) was defined as NPS ≥2. Persistent pain was defined as having knee pain or MSP at all time-points. Multivariable mixed-effects models and log-binomial regression were applied for the analyses.

Results: Sleep disturbance was associated with greater knee pain severity (β 0.91, 95%CI 0.70-1.11) and higher risk of having more NPS [(Relative risk (RR) 1.10, 95%CI 1.07-1.14] in a dose-response manner in multivariable analyse with adjustment for age, sex, body mass index, physical activity, comorbidities, pain medications, ever smoking, emotional problems, employment, and education level. Persistent sleep disturbance was associated with a greater risk of persistent knee pain (RR 1.90, 1.26-2.87) and MSP (RR 1.29, 1.07-1.56). In participants with ROA, results were similar apart from the link between sleep disturbance and persistent pain.

pain.

Conclusion: Sleep disturbance was independently associated with greater pain severity and significantly increases risk for MSP with a long-term effect of sleep on pain in general and ROA population, suggesting beneficial effects of treating sleep problems on long-term pain control.

Systematic Review and Meta-Analysis of the Prevalence of Neuropathic-Like Pain and Pain Sensitisation in People with Knee and Hip Osteoarthritis

Luigi Zolio[1], Kai Ying Lim[2], Mabel Yan[1], Mahnuma Estee[3], Sultana Monira Hussain[4], Flavia Cicuttini[4] and Anita Wluka[5], [1]Alfred Health, Melbourne, Australia, [2]Monash University, Kuala Lumpur, Malaysia, [3]Monash University, Melbourne, Australia, [4]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia, [5]Monash University, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain in osteoarthritis (OA) may be nociceptive or neuropathic-like in nature. In knee OA, pain severity is known to be poorly correlated with joint damage. Identifying a patient's pain profile may guide the provision of specific therapy. We sought to determine the prevalence of neuropathic-like pain (NP) and pain sensitisation (PS) as defined by self-report questionnaires in people with knee and hip OA.

Methods: MEDLINE, EMBASE, CINAHL were systematically searched in duplicate (1990-April 2020) for full text articles presenting the prevalence of NP and PS in knee and hip OA using self-report questionnaires, with ≥30 participants, age ≥18 years. Data were extracted into a prespecified form in duplicate. Risk of bias was assessed using the National Institute of Health Quality Assessment Tool for Observational Cohort and Cross Sectional Studies. Meta-analysis was performed using RevMan, using a random effects model. Heterogeneity between studies and subgroups was assessed using Cochran's Q and I^2 statistics.

Results: From 2706 non-duplicated references, 39 studies were included (2011-2020), from Europe (n=17), Asia (n=14), North America (n=4), Oceania (n=3) and Africa (n=1). Thirty-six studies reported on knee pain and 6 on hip pain. Study populations were recruited from hospital outpatients (n= 21), presurgical candidates (n=10), trials (n=5) and community (n=3). NP was defined using the following self-report questionnaire tools: PainDETECT (PDQ, n=30 studies), Douleur Neuropathique 4 (DN4, n=5), Self-Report Leeds Assessment of Neuropathic Symptoms and Signs (S-LANSS, n=2). PS was defined by Central Sensitisation Index (CSI, n=6) and Fibromyalgia Survey Questionnaire (FSQ n=1).

For knee OA, the prevalence of possible NP, defined by PDQ score ≥13 was 40% (95% CI 32-48%, p< 0.00001, I^2=97%). The prevalence of probable NP, defined by PDQ score ≥19 was 20% (95% CI 15-24%, p< 0.00001, I^2=94%). Using PDQ, there were no significant differences in prevalence between study population subgroups, for possible or probable NP (I^2 = 0%). The prevalence of NP using S-LANSS was 32% (95% CI 26-38%, I^2=0%, p=0.43), and using DN4 was 41% (95% CI 24-59%, p< 0.001, I^2=97%). The prevalence of PS using CSI was 36% (95% CI 12-59%, p< 0.001, I^2=95%).

For hip OA, the prevalence of possible NP (PDQ score ≥13) was 28% (95% CI 10-45%, p< 0.001, I^2=92%). The prevalence of probable NP (PDQ score ≥19) was 9% (95% CI 6-13%, I^2=0%, p< 0.00001). Using PDQ, the overall prevalence of possible NP was similar across multiple study population sources (I^2 = 0%).The prevalence of NP using DN4 was 22% in 1 study. One study used FSQ to assess PS but did not report prevalence.

Conclusion: Using self-report questionnaire tools, NP was determined to be more prevalent in knee than hip OA. Further study is required into the prevalence of PS in knee and hip OA and differences between tools. The prevalence of NP in knee and hip OA were similar for each joint across study population sources. This suggests that NP pain is unrelated to OA severity. NP may be used to phenotype patients, enabling targeted analgesic and non-pharmacological therapy in OA and potential improvement to quality of life.

OR, 95% CI presented for all models. All models adjusted for age, sex, BMI, catastrophizing, depressive symptoms, and widespread pain.
*Weightbearing includes walking up- and downstairs, walking on a flat surface, and standing. Non-weight-bearing includes pain while sitting and while in bed.
Abbreviations: QST, quantitative sensory testing; PPT, pain pressure thresholds; TS, temporal summation; CPM, conditioned pain modulation. TS is presented as a continous measure.

Table 1. Results for the multivariable analyses of the association between QST measures and individual or grouped WOMAC pain questions (n=5479 knees)

pain with non-weight-bearing that often occurs. Pain sensitization, reflecting altered pain processing, may contribute to pain at rest or while sleeping. The aim of this study was to determine the extent to which pain with different degrees of weight-bearing were associated with objective measures of pain sensitization.

Methods: Participants from the Multicenter Osteoarthritis (MOST) study, a longitudinal prospective cohort of older adults with or at risk of knee OA, were included in this cross-sectional analysis. Mechanical pressure pain threshold (PPT) at the wrist and patellae were assessed with a handheld algometer, and categorized into sex-specific tertiles. Lower PPTs indicate greater sensitization. Weighted mechanical punctate probes were used to assess temporal summation (TS) at the wrist, an indicator of central sensitization, with a train of 10 stimuli at 1 Hz; increase in pain by the end of the train indicates TS. Adequacy of conditioned pain modulation (CPM) was determined by assessing PPT at the wrist (test stimulus, PPT1) with forearm ischemia as the conditioning stimulus, followed by PPT reassessment (PPT2). Adequate CPM (pain inhibition) was operationalized as PPT2:PPT1 >1. Individual WOMAC pain questions were dichotomized as having at least moderate pain on each question, and categorized into weight-bearing pain (stairs, standing, walking) vs. non-weight-bearing pain (sitting, nocturnal), based on having moderate or greater pain on at least one question. We evaluated the relation of each QST measure to WOMAC pain questions or categories using logistic regression, adjusting for age, sex, body mass index (BMI), catastrophizing, depressive symptoms, and widespread pain.

Results: 2749 subjects were included (mean age 64±11, 57% female, mean BMI 29.5±5.7 kg/m^2). Higher patellar PPT was significantly associated with lower odds of reporting at least moderate pain for each WOMAC pain question (**Table 1**), with similar magnitudes of association for weight-bearing and non-weight-bearing pain. Higher wrist PPT was significantly associated with weight-bearing activities, while TS was only significantly associated with stair climbing; neither were significant associated with non-weightbearing pain. Adequate CPM was not significantly associated with either weight-bearing or non-weight-bearing.

Conclusion: Greater peripheral sensitization, as assessed by patellar PPT, was associated with having moderate pain with both weight-bearing and non-weight-bearing activities. Wrist PPT and TS, reflecting central sensitization, were significantly associated with weight-bearing but not non-weight-bearing pain. CPM, a marker of descending pain modulation, was not significantly associated with either category of pain. Our findings may challenge the hypothesis that non-weight-bearing pain may reflect greater pain sensitization than pain while weight-bearing. The contribution of other pain mechanisms, including inflammation, should be further explored.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Walking for exercise is recommended for knee osteoarthritis (OA) management though benefits have not been demonstrated in epidemiologic studies. We aimed to assess the relationship between walking for exercise and symptom or structure progression in those with knee OA.

Methods: This was a nested cohort study within the Osteoarthritis Initiative (OAI) of those ≥ 50 years old with radiographic OA (ROA) at baseline. A modified version of the Historical Physical Activity Survey Instrument was used to assess walking for exercise during ages ≥ 50 years old, dichotomously and with 4 levels of walking, including the referent group, those who did not walk for exercise. At baseline and 48-month visits, participants were assessed for frequent knee pain and Kellgren-Lawrence (KL) grade and medial joint space narrowing (JSN) on posterior-anterior semi-flexed knee radiographs. ROA was defined as KL ≥ 2. Outcomes were: 1) *New knee pain* - frequent knee pain absent at baseline but present at 48 months (only including those without frequent knee pain at baseline), 2) *KL worsening* - increase in KL grade, 3) *Medial JSN worsening* - increase in medial JSN score, and 4) *Improved knee pain* - frequent knee pain present at baseline but absent at 48 months (only including those with frequent knee pain at baseline). Participants with knee arthroplasty between baseline and 48 months were classified as having new knee pain and KL and Medial JSN worsening. Assessed on long limb films, the Hip-Knee-Ankle angles defined static alignment: 1) varus: ≤ -2°, 2) valgus: ≥ +2°, 3) neutral: between -2° and +2°. Including only ROA knees, we performed logistic regression using generalized estimating equations to account for correlation between knees, adjusting for age, sex, and baseline KL grade. Analyses were stratified by static alignment.

Results: Of 1203 participants, 73% walked for exercise. New knee pain was less common in those who walked (OR 0.6; 95%CI 0.4 – 0.8) (see Table). In varus knees, results were similar but also less KL (OR 0.7; 95%CI 0.5 - 1.0) and medial JSN progression (OR 0.7; 95%CI 0.5 – 0.9) was observed (See Table). Neutral and valgus analyses had insufficient numbers to calculate ORs; however in neutral knees, those who walked had more improved knee pain (47% v 39%) but no structural benefits. In valgus knees, those who walked for exercise had modestly more new knee pain (33% v. 29%), KL progression (20% v. 15%) and medial JSN worsening (9% v. 5%).

Conclusion: Walking may be disease modifying for knee OA. In individuals ≥ 50 years old with knee OA, walking for exercise was associated with less development of frequent knee pain. There may be differential effects of walking based on static alignment. In varus knees, walking was also associated with less structural progression. These findings support that walking for exercise should be encouraged for most people with knee OA. A clinical trial to confirm these findings is warranted.

Walking Energetics, Fatigue, and Physical Activity in People with Knee Osteoarthritis

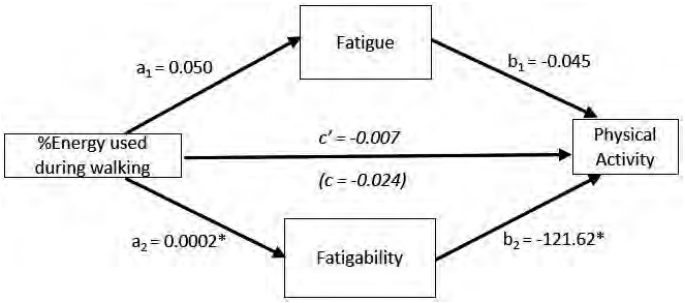
Kharma Foucher[1], Burcu Aydemir[1] and Chun-Hao Huang[1], [1]University of Illinois at Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is associated with limitations in physical activity (PA) for many reasons which are not fully understood. While pain can be associated with reduced PA, other biomechanical and psychological factors can also be limiting. Walking energetics, specifically the amount of energy used for walking relative to total energy capacity, has been proposed as a mechanism by which PA is reduced in older adults. Fatigue is a common symptom of OA and has been linked to reduced PA in this group. Fatigability is a separate but related construct that may also be associated with PA in people with OA. These factors have not been previously investigated together. The purpose of this study was to evaluate the association of walking energetics, fatigue, and fatigability on PA in people

Table 1. Associations between UCLA activity scores and predictor variables.

	% Energy used for walking	VO_2cost	Fatigue Score	Fatigability Score	KOOS pain score
Spearman's Rho	-0.379	-0.517	-0.585	-0.573	0.569
p value	0.042	0.004	< 0.001	0.001	0.001



Fatigability mediates the association between percent energy used for walking and physical activity.

with knee OA. We hypothesized that people who use an increased amount of energy for walking, experience more fatigue, or are more fatigable are less active.

Methods: We tested our hypothesis in 29 people with knee OA (age 58 ± 9 years, 10 M/19 F, BMI 33.5 ± 5.8 kg/m^2). We assessed PA by self-report using the UCLA activity score. We used a six-minute walk test to measure VO_2max, then used a portable oxygen exchange system to measure percent energy used during walking (100 * VO_2rate/VO_2max) and VO_2cost at preferred speeds. We used the KOOS pain subscale to characterize pain. We used the PROMIS Fatigue survey and a treadmill-based fatigability test to assess overall fatigue and performance-related fatigability. We used Spearman correlations and regression analysis to test our hypotheses.

Results: UCLA scores ranged from 2, indicating "mostly inactive", to 10, indicating "regularly participate in impact sports" (mean 5 ± 2). Percent energy used during walking, VO_2cost, fatigue, and fatigability were all associated with lower PA (Table 1). These associations persisted when controlling for pain. Together, pain, percent energy used for walking or VO_2cost, fatigue and fatigability predicted 57.7 to 58.4% of the variance in UCLA scores ($p < 0.001$). Fatigability mediated the association between percent energy used for walking and PA (Figure 1). There was no evidence that fatigue or fatigability mediated the association between VO_2cost and PA.

Conclusion: Walking energetic factors are important predictors of PA in knee OA even after controlling for pain. The effect of walking energetics on PA may work through its impact on fatigability. Walking energetics may be a useful target to promote PA in people with OA and may have beneficial effects on fatigue as well. The effect of biomechanical interventions for knee OA on walking energetics should be considered to avoid potential adverse effects on PA.

Sociodemographic and Clinical Predictors of Childhood-Onset SLE Disease Activity in the Childhood Arthritis and Rheumatology Research Alliance Registry

Emily Smitherman[1], Rouba Chahine[1], Timothy Beukelman[1], Andrea Knight[2], AKM Rahman[1], Mary Beth Son[3], Jeffrey R Curtis[4] and Aimee Hersh[5], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Division of Rheumatology, The Hospital for Sick Children and Department of Paediatrics, University of Toronto, Toronto, ON, Canada, [3]Boston Children's Hospital, Boston, MA, [4]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [5]University of Utah and Primary Children's Hospital, Salt Lake City

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with childhood-onset systemic lupus erythematosus (cSLE) are at high risk for early morbidity and mortality, but predictors of moderate/high cSLE disease activity have not been well-studied. Our objective was to determine sociodemographic and clinical predictors for moderate/high disease activity scores in a cohort of North American cSLE patients. Our hypothesis was minority race/ethnicity, lower household income, lower parental education, and non-private insurance status would be associated with moderate/high disease activity at follow-up.

Table 1. Sociodemographic and Clinical Predictors of Disease Activity at Most Recent Follow-up Visit				
	Total Cohort (n=423)	SLEDAI-2K ≤ 4 (n=310)	SLEDAI-2K > 4 (n=113)	p-value

Table 1. Sociodemographic and Clinical Predictors of Disease Activity at Most Recent Follow-up Visit

Methods: The Childhood Arthritis and Rheumatic Disease Research Alliance (CARRA) Registry enrolls patients with cSLE from >65 North American pediatric rheumatology centers. We performed a cross-sectional analysis of CARRA Registry data collected prospectively from March 2017 to December 2019. Patients with cSLE or probable cSLE with at least two study visits at least 6 months apart were included. Disease activity at most recent follow-up visit was measured using **Systemic Lupus Erythematosus Disease Activity Index 2000 (**SLEDAI-2K, range 0-105) and dichotomized as low disease activity, SLEDAI-2K ≤ 4, or moderate/high disease activity, SLEDAI-2K > 4. Chi-square and two-sample Student *t* tests were performed to compare sociodemographic and clinical characteristics between patients with low vs. moderate/high disease activity at most recent follow-up. Multivariable logistic regression was conducted to determine predictors for SLEDAI-2K > 4 at most recent follow-up.

Results: There were 423 eligible patients with cSLE (Table 1). The mean ± SD time from diagnosis to most recent follow-up was 27.1 ± 22.2 months. The cohort was 85% female, 27% Black, 25% White, 24% Hispanic, and 17% Asian with a mean ± SD age at diagnosis of 13.8 ± 2.9 years. Lupus nephritis was present in 41% and neuropsychiatric

Table 2. Multivariable-Adjusted Odds Ratios for SLEDAI > 4

Symptom onset to diagnosis	0.992 (0.970-1.014)	0.4603
Diagnosis to enrollment	1.009 (0.968-1.051)	0.6779
Diagnosis to follow-up visit	0.997 (0.961-1.033)	0.8558
SLEDAI-2K at enrollment	1.044 (1.003-1.086)	0.0333
PGA at enrollment	1.161 (1.029-1.310)	0.0153

Table 2. Multivariable-Adjusted Odds Ratios for SLEDAI > 4

lupus in 28%. At the most recent visit, the range of SLEDAI-2K scores was 0-25, and 27% of patients had SLEDAI-2K > 4. Results of univariate analyses showed there were not statistically significant differences in sociodemographic variables between patients with low vs. moderate/high disease activity (Table 1). However, patients with moderate/high disease activity at most recent follow-up had statistically higher number of ACR and SLICC criteria, SLEDAI-2K at enrollment, and physician global assessment (PGA) at enrollment and shorter time from diagnosis to enrollment (Table 1). Using multivariable logistic regression adjusted for disease duration, SLEDAI-2K at enrollment (OR=1.04, 95% CI=1.003–1.086) and PGA at enrollment (OR=1.16, 95% CI=1.029–1.310) remained independently associated with moderate/high disease activity.

Conclusion: This analysis demonstrates a substantial proportion of patients with cSLE in the CARRA Registry have moderate/high disease activity at most recent follow-up. Disease activity at registry enrollment, measured by SLEDAI-2K and PGA, was the only predictor of moderate/high disease activity. Interestingly, sociodemographic charac-

teristics did not predict moderate/high disease activity. Improved understanding of modifiers of cSLE disease activity is needed for the development of targeted interventions to improve outcomes.

Elucidating Research Priorities in Childhood-Onset Systemic Lupus Erythematosus: A Qualitative Study

Laura Cannon[1], Anne Skelley-Caliendo[2], Aimee Hersh[3] and Andrea Knight[4], [1]Duke University, Durham, NC, [2]Northwestern University, Chicago, IL, [3]University of Utah and Primary Children's Hospital, Salt Lake City, [4]Division of Rheumatology, The Hospital for Sick Children and Department of Paediatrics, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: An estimated 15 to 20% of patients with systemic lupus erythematosus (SLE) have childhood-onset SLE (cSLE). Given the early onset of cSLE, patients often experience significant burden due to cSLE disease, comorbidities and immunosuppressive treatment. There is a pressing need for high quality, comprehensive research efforts to define the natural history, best treatments, access to care and disparities in care for cSLE patients. Building on a previously published survey study of clinicians caring for cSLE patients to describe research priorities in cSLE, the primary objective of this study was to conduct expert interviews to define a cSLE research agenda.

Methods: Individuals with identified expertise in cSLE were recruited worldwide using a purposive sampling technique including providers from several disciplines: pediatric rheumatology, pediatric nephrology, dermatology, psychiatry, medicine/pediatrics, and adolescent medicine. Experts participated in open-ended, semi-structured qualitative interviews. Interviews were designed to elicit expert perspectives on research priorities, optimal research approaches, and factors that facilitate and hinder advancing cSLE research. Interviews were digitally recorded, transcribed, and de-identified for qualitative analysis. 30 interviews were conducted between January and May 2020. Analysis for underlying themes of cSLE expert perspectives was performed using a constant comparative approach in which summaries and themes of each expert's interview transcript informed the presence or absence of themes in subsequent cases (iteration). Two researchers conducted the analysis. To establish a consistent identification of themes, the first third of transcripts were analyzed by both researchers. The remaining transcripts were summarized by one researcher followed by a review from the second researcher to look for any missed additional elements.

Results: Several notable themes emerged from analysis of the interview data, supported by illustrative quotes (Table). A salient priority identified among interviewees was the importance of better (and more targeted) treatment for cSLE. Two major barriers to the development of new therapies were lack of pediatric clinical drug trials and need for biomarker research. Interviewees also identified individual investigator barriers to performing cSLE research, including obtaining funding to conduct projects, and having adequate time to conduct research. Last, collaboration was

cSLE Research Priority and/or Barrier	Quote
Need for new medications and targeted therapies	"And I think right now we're finding drugs that might work in a small subset of people and then throwing them at the whole group of lupus at large and often not seeing results which is really not surprising. So really molecularly genetically immunophenotyping our patients and then finding subsets, identifying potential targets for discovery or potential targets for tailoring appropriate therapy. That's what I see is the biggest gap." "…we know that we have certain drugs for treatment for lupus, but we don't know some of the differences in different populations. So is the Hispanic population that's in Texas and California, do they react the same way to medications as maybe our African-American group that is here in [State 1] or in [State 2]? And then…Caucasian males tend to have really severe lupus nephritis when they actually get lupus, which is rare, but why is that?"
Need for more pediatric clinical trials	"So better alignment of the pharmaceutical companies' motivations and needs with the FDA's perspective as to physicians and with the clinicians' desires and patients' desires in terms of the drugs, is important" "So, I would say that inclusion of children in clinical trials of emerging therapies for lupus is of the utmost importance, so that they can have access to newly developed therapies very early on in their life cycle."
Need for biomarker research and better understanding of disease biomarkers	"[I] think that making sure that tissue was included in [a registry] as well – so not just blood and urine, but also kidney tissue from kidney biopsies and skin tissue from – some punch biopsies and if we can get joint tissue from – or joint fluid or anything like that – I think that those sorts of things are big, huge investments." "But if you asked me to prioritize, I would say biomarkers, looking at precision-based treatments based on pathophysiology's, and then sorting through clinical phenotypes so that when we think through therapy, we're comparing the right groups and we're thinking about the right outcomes… It's not a single cell disease that we can study and think about in clean way. I think that's why, in some ways, any biomarker analysis has to start with a cohesive homogenous clinical phenotype of patients. And so, trying to stratify out what the buckets we should be looking at to do that work becomes really complicated when this is 5, or 10, or 15 diseases and not one."
Need for more funding resources for investigators and dedicated protected time to conduct research	"And I feel like, as physicians, our time gets sort of fractionated into these teeny little pieces like three days a week we're in clinic all day. And then, those days you're basically like a shift worker. You have absolutely no time. And then the other days you get pulled into meetings, things appear on your calendar. There's almost no space to think and write and be creative. And, without that, I don't think we can move this work forward." "And then another barrier is that…we have a very worrisome shortage of people doing basic and translational investigation in pediatric rheumatology. And we don't have the manpower within our workforce to do this – because there are so few pediatric rheumatologists, most of them with the exception of a few big centers are required to do a large burden of clinical care. And it's really tough then to, A, find the people to do it who have the time to do it and, B, have the mentors who can teach the next generation to do it and I think that's a huge problem that we need to address."
Need for collaboration between centers	"I think we need to come up with better ways to fund and to reward involvement in collaborative research…for example – if people are calling in once a month to be on a workgroup to design a research study, no one's getting reimbursed for that time. And so…if we want to have the CARRA registry succeed, we need to be able to reimburse the PIs and the sites for what they're doing to enroll those patients and to get all those patients' data shared." "And as much as we can, we try to work together with other sites. You know, one site chosen as the where the principle investigator is, and then multiple other sites contributing patients, or samples, or whatever it is depending on the study. I think that's really the key in this disease, in a rare disease. In any rare disease collaboration is the key for research."

Table: Illustrative quotes from cSLE providers discussing research priorities and barriers to advancement of research for cSLE.

identified as a necessity within the cSLE research community, recognizing The Childhood Arthritis and Rheumatology Research Alliance (CARRA) as a powerful tool for multi-center collaboration in cSLE research.

Conclusion: cSLE expert interviewees identified the need for improved targeted therapies through pediatric clinical drug trials and biomarker research as well as collaboration between researchers and centers as research priorities. Funding and protected time for research are major individual barriers to involvement in cSLE research.

Development of Autoimmune Diseases and HLA Associations in Children with Neonatal Lupus and Their Unaffected Siblings

Amit Saxena[1], Aaron Garza Romero[2], Daniel Gratch[3], Peter Izmirly[4], Hannah Ainsworth[5], Miranda Marion[5], Carl Langefeld[6], Robert Clancy[7] and Jill Buyon[8], [1]NYU School of Medicine, New York, [2]Gonzaba Medical Group, San Antonio, [3]NYU Langone Health, New York, [4]Department of Medicine, New York University School of Medicine, New York, NY, [5]Wake Forest School of Medicine, Winston-Salem, [6]Wake Forest School of Medicine, Winston Salem, NC, [7]New York University School of Medicine, New York, NY, [8]Department of Medicine, NYU School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Neonatal Lupus (NL) is a model of passively acquired autoimmunity conferred by exposure to maternal anti-Ro antibodies with major manifestations being congenital heart block (CHB) and/or cutaneous disease. This study was initiated to address the development of de novo autoimmunity in these children and identify associated clinical and genetic risk factors.

Methods: In a retrospective cohort study of enrollees in the Research Registry for Neonatal Lupus (RRNL), 511 children exposed to anti-Ro in utero responded to a follow up questionnaire focused on symptoms of autoimmunity. Self-reported diseases were confirmed via medical record review. Bivariate analyses were performed with potential risk factors for the development of autoimmune disease (AD) and included the NL status per se, a disease severity score based on mortality risk factors, and maternal AD (inclusive of lupus, Sjogren's syndrome, psoriasis, rheumatoid arthritis, or thyroid disease). A subset of 99 CHB, 9 cutaneous, and 55 unaffected anti-Ro exposed RRNL individuals were genotyped at Class II HLA DRB1 and DQB1 four-digit alleles, which were assigned by imputation (HIBAG) or sequencing. Generalized estimating equations (logit link, exchangeable correlation) were used to test for associations between HLA alleles and the development of AD.

Results: Of the respondents, 182 offspring had CHB, 95 had cutaneous only NL and 234 were siblings without NL. Females comprised 53% and 80% were Caucasian. The mean age was 14.2±9.7; 4% age 0-2 years, 48% 2-13 years, and 47% > 13 years. An AD developed in 38 offspring (20 CHB, 7 cutaneous NL, 11 non-NL siblings; Table 1). The most prevalent AD was thyroid disease. The development of an AD was significantly associated with presence of CHB vs. cutaneous only or non-NL siblings (11% vs. 5%, p=0.033). The maternal health status did not influence the development of an AD in the child (7% mothers with AD vs. 6% asymptomatic mothers, p=0.67). Mean NL severity score was higher in offspring with AD (3.8±4.8 vs. 2.2±4.0, p= 0.031). Other markers of fetal CHB disease severity were associated with subsequent AD development, including in-utero exposure to fluorinated steroids (15% vs. 6%, p=0.088) and beta agonists such as terbutaline (23% vs. 9%, p=0.043). In the study of 163 RRNL cases with HLA data (20 with AD, 143 without), HLA DRB1*03:01 (OR 3.4, CI 1.46-7.90, p=0.0045), DQA1*05:01 (OR 3.39, CI 1.16-9.92, p=0.0262), and DQB1*02:01 (OR 4.28, CI 1.73-10.62, p=0.0017) were associated with increased risk of AD (of

note, these loci are in high linkage disequilibrium). In contrast, these alleles were not significantly associated with development of CHB (99 CHB vs. 64 without).

Conclusion: The development of an autoimmune disease was more common in anti-Ro exposed children with CHB, greater NL severity, and MHC Class II haplotypes. These factors may relate to an inherent susceptibility to inflammation and fibrosis, occuring in utero and later in life.

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Neonatal Lupus Erythematosus (NLE) is an acquired autoimmune disorder associated with the transplacental passage of maternal anti-Ro and/or anti-La antibodies. Previous studies have suggested that children born to anti-Ro/La antibody positive mothers with a rheumatic disease, might be at greater risk of developing autoimmune and non-autoimmune diseases, as children or young adults. The aim of this study was to determine the prevalence of autoimmune and non-autoimmune diseases in children born to anti-Ro/La positive mothers.

Methods: We conducted a cohort study of infants seen in the NLE clinic at SickKids Hospital between 1987-2019. Infants born to anti-Ro/La antibody positive mothers in the Greater Toronto Area were referred to the NLE clinic. Surveys were sent to those children discharged from the NLE clinic and consented to this study. We invited parents of patients ≥ 1y and < 18 years of age, and patients >18 y of age to complete a follow-up questionnaire via RED-Cap survey link. The survey included questions about autoimmune diseases such as rheumatic diseases (arthritis, connective tissue disease, vasculitis) and non-rheumatic diseases (psoriasis, thyroid disease, inflammatory bowel disease, type I diabetes), and non-autoimmune diseases such as allergic (seasonal allergies, anaphylaxis, asthma, eczema, urticaria), neurodevelopmental (autism, attention deficit hyperactivity disorder, global developmental delay), and neuropsychiatric diagnoses (anxiety, depression, tics, seizures, obsessive-compulsive disorder). NLE manifestations and maternal disease status during pregnancy were obtained from a dedicated database prospectively collected. Descriptive statistics were used for demographic characteristics and clinical features of NLE. Prevalence of autoimmune and non-autoimmune diseases were compared using Fisher's exact test.

Results: We sent 354 surveys with a completion rate of 61% (n=217). Eight patients were excluded due to unconfirmed antibody status during pregnancy. We included 209 children born to 166 unique mothers. Median age at questionnaire completion was 6 years (IQR: 3,11), 50% female (**Table 1)**. Forty-seven percent (n=96) of the children had NLE, and 67% (n=141) of the children were born to a woman with a rheumatic disease diagnosis during pregnancy. In our cohort, allergic diseases were the most frequent reported at 28% (n=59) and only 6 patients (3%) had developed

autoimmune diseases. There was no difference in the prevalence of reported diseases/conditions between children born to a mother with or without rheumatic disease (**Table 2)**.

Conclusion: In our multiethnic population of children born to women with positive anti-Ro and/or anti-La antibodies, there was no significant difference in the prevalence of autoimmune and non-autoimmune diseases between children with and without NLE manifestations, or born to women with and without a rheumatic disease during pregnancy. This is one of the largest cohort studies investigating long-term outcomes in this population. Continued recruitment of older participants will improve our ability to detect diseases with onset in young adulthood.

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Genome wide association studies (GWAS) have identified >90 SNPs associated with systemic lupus erythematosus (SLE) risk. However, there may be additional loci impacting the age of diagnosis. The purpose of this study is to identify genetic variants for age of SLE diagnosis.

Methods: Our cohort included patients with childhood-onset SLE (cSLE) diagnosed < 18 years of age, and adult-onset SLE (aSLE), who met ACR and/or SLICC classification criteria for SLE. All patients were followed at tertiary care centers: Toronto Western Hospital, Hospital for Sick Children (Toronto), University of Manitoba (Winnipeg), Lurie Children's Hospital of Chicago, St. Joseph's Health Centre (London, ON), and Hospital for Special Surgery (New York). We censored patients with age at diagnosis ≥ 70 years. Patients were genotyped on the Illumina Multiethnic Array (MEGA), and ungenotyped SNPs were imputed using the Haplotype Reference Consortium (HRC) reference. We restricted to SNPs with a minor allele frequency (MAF) ≥ 0.01 and imputation quality ≥ 0.8. Ancestry was genetically inferred from principal components (PCs) and ADMIXTURE calculated in reference to 1000 Genome Project (1KGP). Non-HLA, additive SLE weighted genetic risk scores (GRSs) were computed using published SLE GWAS log-odds ratio weights. Single-variant genome-wide linear regression of age of SLE diagnosis was performed with GENESIS. Multivariate models were adjusted for sex, aSLE/cSLE status, indicator for center, 5 PCs and SLE non-HLA GRS. We

Table 1. Age at systemic lupus erythematosus diagnosis, overall and stratified by sex and ancestry

also completed a genome-wide test of cSLE risk (vs. aSLE) using a logistic regression model adjusted for the same covariates.

Results: Our cohort included 1093 patients, 88% female. 36% were of European ancestry, 23% East Asian and 18% Admixed. The median age at diagnosis was 17.1y (IQR 13.6, 30.8) (Table 1). We included 8.9M SNPs in GWAS. The most significant SNP associated with age at SLE diagnosis in the linear model was on chr11, rs138239231 (Beta 10.0y, SE 1.85y, $P=5.73x10^{-8}$, MAF 0.01) upstream of *DHCR7* and *NADSYN1*. *DHCR7* encodes an enzyme involved in cholesterol metabolism, and *NADSYN1* encodes a coenzyme involved in metabolic redox reactions and cell signalling. The second locus on chr14 (rs144180822: Beta 5.7y, SE 1.15y, $P=7.15x10^{-7}$, MAF 0.03) is intronic to *NUBPL*, a gene encoding an iron/sulfur protein involved in the assembly of a mitochondrial inner membrane enzyme. In the logistic model, the most significant SNPs were on chr1, rs12024309 upstream to anti-sense RNA *SMG7-AS1* (OR 0.5, [95% CI: 0.4, 0.7], $P=1.16x10^{-6}$, MAF 0.39); chr4, rs10001705 upstream to *HS3ST1,* involved in the biosynthesis of anticoagulant heparin sulfate (OR 3, [95% CI:1.9, 4.6], $P=1.31x10^{-6}$, MAF 0.11); on chr17, rs116981214, intronic to *MRPL45P2*, a mitochondrial ribosomal protein (OR 4.7, [95% CI: 2.5, 8.7], $P=1.46x10^{-6}$, MAF 0.05). None of these loci reached genome-wide significance ($P< 5x10^{-8}$).

Conclusion: In our multiethnic cSLE and aSLE cohort, GWAS did not identify a genome-wide significant SNP association with the age at diagnosis or cSLE risk. We identified 2 loci near genome-wide significance for age at SLE diagnosis, and 3 near genome-wide significance for cSLE risk. We plan to expand our analyses including more patients.

Low Copy Number of Long C4 Genes Is a Genetic Risk Factor for Childhood Onset SLE (cSLE) but Is Associated with Higher Age of Disease Onset

Fatima Barbar-Smiley[1], Danlei Zhou[2], Joanne Drew[2], Bi Zhou[2], Cagri Yildirim-Toruner[2], Vidya Sivaraman[3], Wael Jarjour[4], Stacy Ardoin[2] and Chack-Yung Yu[5], [1]Nationwide Children's Hospital/The Ohio State University, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Nationwide Children's Hospital, Bexley, OH, [4]The Ohio State University, Columbus, OH, [5]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypocomplementemia is a marked feature of systemic lupus erythematosus (SLE), which may be a result of consumption initiated by immune complexes between self-nuclear antigens and autoantibodies. Lower copy number of C4 genes is cited as a risk factor for SLE. Located in the MHC class III region on chromosome 6, there are two versions of C4 genes: the long gene and the short gene. This variation is triggered by the integration of an endogenous retrovirus HERV-K(C4) into intron 9 of the long genes. The role that long and short C4 genes plays in SLE pathogenesis remains unclear. This is especially important for childhood onset SLE (cSLE), as childhood-onset SLE conveys worse disease outcomes when compared to adult onset SLE. To help further understand the role of C4 genetic variants in the immune pathogenesis of cSLE, we performed a cross-sectional case-control study of 37 patients with cSLE (mean age: 19.08±3.22 yo; 81.1% female) and 40 healthy children (mean age: 19.30±3.75 yo; 75% female).

Methods: EDTA-Blood samples were obtained after informed consent and assent. Blood differentials for all samples were measured using a Sysmex automated hematology analyzer. Plasma protein concentrations of complement C4 and C3 were assayed by radial immunodiffusions (Binding Sites, UK); polymorphisms of C4 proteins for C4A and C4B allotypes were determined by immunofixation; gene copy numbers of total C4, C4A, C4B, long C4 genes and short C4 genes were elucidated by multiple genomic Southern blot analyses. Binary analyses of categorical data were performed by Chi^2 analyses. Continuous data between groups were compared by Student's t-test or analyzed by linear regression. Because of small sample size, our pilot analysis is focused on Caucasian patients (N=21) and Caucasian healthy controls (N=31).

Results: We observed significantly lower lymphocyte counts (1.81±0.87 $x10^3$ /ml vs 2.51±0.75x $x10^3$ /ml, p=0.0004) and complement C4 plasma protein concentrations (19.8±7.7 mg/dL vs 25.4±7.4 mg/dL; p=0.002), plus lower C4 protein yield per copy of C4 genes (5.63±1.84 mg/dL vs 6.59±1.79 mg/dL; p=0.025) in cSLE patients than in controls. The mean protein levels for complement C3 were similar between patients and controls (126.4 vs 133.0, p=0.25). Genetically, the copy number of long C4 genes was significantly lower among cSLE patients (2.30±1.081) than controls (2.903±0.944; p=0.04). Subjects with only one or two copies of long C4 genes had an odds ratio of 6.36 (95% CI: 1.83-22.1) on genetic risk of cSLE (p=0.0023). The age of onset or diagnosis among patients with cSLE was inversely correlated with copy number of long C4 genes (R^2=0.38, p=0.0036), a phenomenon that remains true when patients with other racial groups were included in the analyses (R^2=0.23, p=0.0032).

Conclusion: Diversities of complement C4 genes and variation in levels of plasma C4 proteins are both a cause and an effect of cSLE. Intriguingly, the inverse relation of copy number long C4 genes with age of onset was an unex-

pected finding and its clinical implications, though, is yet to be explored. A larger study sample will help us better understand the potential role that long C4 gene plays in SLE pathogenesis and its implications on lupus disease activity or clinical outcomes.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Among children diagnosed with systemic lupus erythematosus (SLE), there exists monogenic forms of SLE, where rare variants in a single gene lead to disease. The aim of this study was to calculate the burden of rare variants in monogenic SLE genes, in children suspected of monogenic SLE or lupus-like disease.

Methods: From the Hospital for Sick Children (SickKids) Lupus clinic, we identified patients suspected of monogenic SLE due to young-onset disease (< 11y), one or more affected first-degree relatives, and/or history of consanguinity. We completed paired end whole genome sequencing (WGS) using an Illumina HiSeq X platform (n=69) or paired end whole exome sequencing (WES) with an Illumina HiSeq 2500 platform (n=3). Variant calling was performed with GATK and HAS, and functional annotation with ANNOVAR. We prioritized rare exonic variants (MAF< 1%) based on predicted functional impact (frameshift, nonsynonymous and stop-gain) and 36 monogenic lupus genes. Chi-squared tests identified a subset of variants with an increased burden in monogenic SLE cases compared to relevant ethnic controls (Bonferroni correction p< 8.9E-4). Polyphen, SIFT and CADD scores (≥30) predicted damaging and/or deleterious variants.

Participants also underwent genotyping on the Illumina multiethnic MEGA or GSA array. Ancestry was genetically inferred using principal component and ADMIXTURE, or by self-report (Canada census ethnicity categories). Additive non-HLA and HLA SLE genetic risk scores (GRSs) were calculated using common risk single nucleotide polymorphisms. We tested the relationship between GRSs and the number of rare monogenic SLE variants with functional impact using Spearman correlation (r_s) coefficients.

Chr	Position	Gene	Referent Allele	Alternative Allele	cSLE MAF	Referent MAF (1)	p value (2)
1	22965784	*C1QA*	C	T	0.014	0	6.53E-12
1	22974076	*C1QC*	G	A	0.007	1.20E-4	3.01E-4
3	58191226 (3)	*DNASE1L3*	ATG	A	0.028	0	4.23E-35
3	58183689	*DNASE1L3*	G	C	0.014	3.18E-5	3.97E-37
6	31996484 (3)	*C4B*	T	C	0.014	4.20E-4	6.61E-9
12	7187985	*C1R*	C	T	0.007	8.43E-5	1.53E-5
19	12774178	*MAN2B1*	T	C	0.007	0	5.11E-9

Table. Frequency of predicted deleterious monogenic SLE variants in monogenic SLE cases compared to referent populations. (1) MAF reported for relevant referent population in gnomAD v2.1.1. (2) Chi-squared tests used to compare cSLE and referent variant frequencies. (3) Variant found in more than one monogenic cSLE patient.

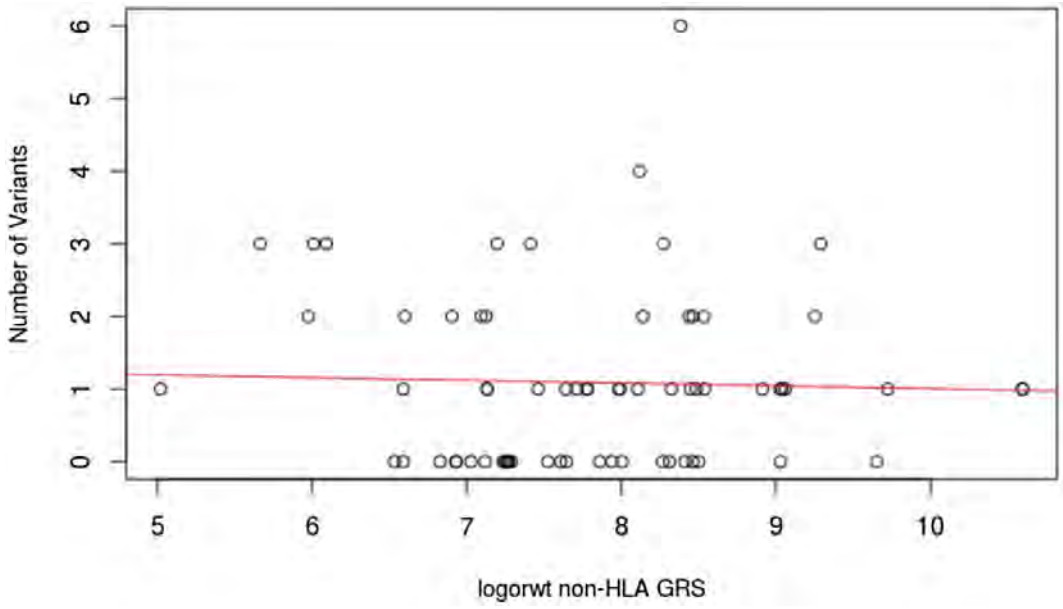

Figure. Correlation between non-HLA GRS and rare monogenic SLE variants with functional impact*. *Data of 68 patients with non-HLA GRS and WGS data.

Results: The cohort included 72 suspected monogenic SLE patients, 65 with SLE and 7 with lupus-like disease (79% females), with a median age of diagnosis of 8 years (IQR=7,10). The majority of patients were admixed (33%) or European (29%). WGS analysis showed 1032 rare variants in monogenic SLE genes, with a median of 17 variants/gene (IQR= 10,32) and 14 variants/person (IQR=11,17). We identified 56 exonic variants with predicted functional impact, of which 18 variants in 24 patients had a significantly higher frequency in monogenic SLE cases compared to referent populations. We found 7 variants predicted to be disease-causing in 9 SLE patients, in genes: *C1QA, C1QC, C1R, C4B, DNASE1L3* and *MAN2B1* (Table).

In 68 individuals with calculated GRSs, we did not observe a correlation between the burden of rare monogenic SLE variants with functional impact and SLE HLA GRS (r_s= 0.11, p=0.65) or non-HLA GRS (r_s= 0.04, p=0.78) (Figure).

Conclusion: In our cohort of suspected monogenic SLE patients, WES/WGS identified a likely causal genetic variant in 13% of patients. We did not detect a significant correlation between the number of rare monogenic SLE variants with functional impact and non-HLA or HLA GRS. Studies with larger cohort sizes are needed to validate our findings.

Renal Activity Index for Lupus Nephritis Distinguishes Active Renal Disease Among Childhood Systemic Lupus Erythematosus Patients

Najla Aljaberi[1], Arjun Mathur[2], Steffy Jose[3], Theresa Hennard[4], Angela Merritt[1], Qing Ma[5], James Rose[5], Rashmi Sahay[6], Chunyan Liu[6], Scott Wenderfer[7] and Hermine I Brunner[8], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, [3]Renal Section, Baylor College of Medicine and Texas Children's Hospital, Houston, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Divison of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, [6]Division of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, [7]Renal Section, Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [8]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Renal involvement in childhood-onset systemic lupus erythematosus (cSLE) is a major cause of morbidity and mortality. Current tools to identify lupus nephritis (LN) fall short compared to renal biopsy. The renal activity index in lupus (RAIL) was developed using 6 urinary biomarkers to reflect disease activity(1).

Purpose: To test the usefulness of the RAIL in the clinical setting to identify children with active LN.

Methods: Urine samples were collected cross-sectionally from cSLE patients at the time of active LN or routine clinic visit. Patients were classified into active LN, inactive LN or non-LN SLE based on results of a renal biopsy and/or absence of LN determined by routine urinalysis. The following urine biomarkers are included in the RAIL score (neutrophil gelatinase-associated lipocalin, ceruloplasmin, monocyte chemoattractant protein-1, adiponectin, hemopexin, kidney injury molecule-1, urinary protein and creatinine). Analysis was done by Enzyme-linked immunosorbent assay (ELISA) and nephelometry. RAIL scores were calculated per the defined algorithm. The accuracy of the RAIL score was compared between groups.

Results: Among 117 cSLE patients, 37 had active LN, 30 had inactive LN and 50 had no LN. Clinical characteristics and distribution of RAIL scores are outlined in Table 1. RAIL scores of inactive LN and no-LN group largely overlapped so they were combined in one group (Group 2) and compared to active LN (Group 1). The RAIL score was significantly higher in Group 1 vs Group 2 (median 0.7 vs -1.1 respectively, $p< 0.0001$). The RAIL score diagnostic accuracy was assessed in a multivariable regression model. Adjusting for patient's age and extra-renal SLE activity index (SLEDAI) score, the RAIL score was associated with odds ratio of 2.16 (95%CI 1.4-3.3, $p=0.001$) for active LN vs. inactive LN and non-LN SLE. A receiver operating curve for a RAIL cut-off score of 0.35 produced an area under the curve of 0.9

Table 1. Clinical characteristics and distribution of RAIL scores among Group 1 (active LN) and Group 2 (inactive LN + non-LN SLE) patients.

	Group 1 N = 37	Group 2 N = 80	*p*-value
Age (y)	15 (13-17)	18 (16-21)	<0.0001
NIH-AI[¥]	9 (4-13)	0 (0-0)	<0.0001
NIH-CI[¥]	1 (0-2.75)	0 (0-0)	0.12
Extra-renal SLEDAI	9 (6-13)	2 (0-4)	<.0001
GFR	91 (60-129)	108 (98-126)	0.05
Urinary creatinine	92 (61-191)	134 (73-183)	0.32
Urinary protein	254 (98-404)	21 (11-50)	<.0001
Urinary microalbumin	254 (189-316)	15 (9-43)	<.0001
RAIL Score	0.7 (-0.1-1.6)	-1.1 (-2.5-0.3)	<.0001

Values represent median (interquantile range).

[¥] Includes only active (N=24) and inactive LN (N=4) patients with renal biopsies within 30 days of urine collection.

Table 1. Clinical characteristics and distribution of RAIL scores among Group 1 (active LN) and Group 2 (inactive LN + non-LN SLE) patients.

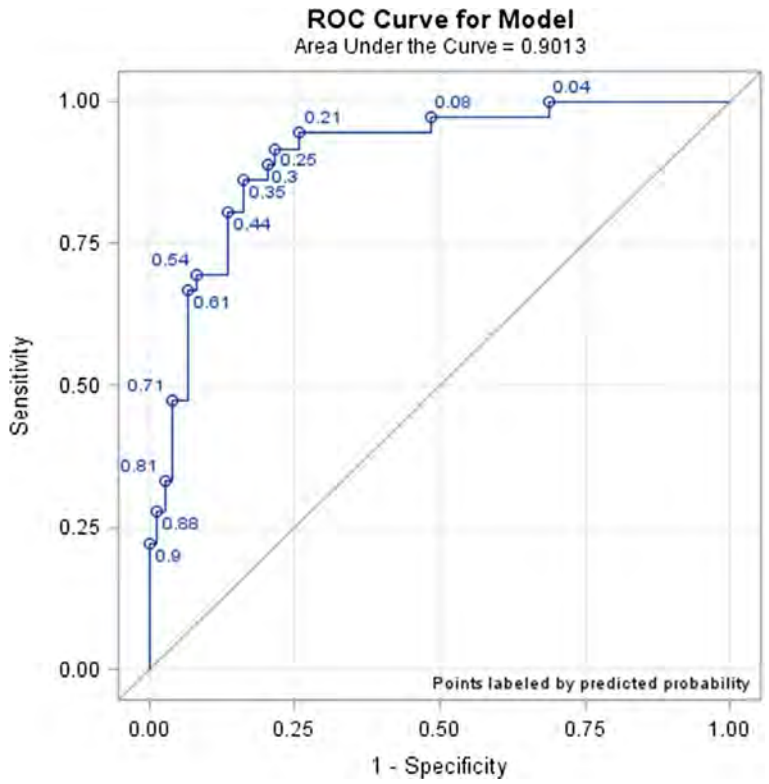

Figure 1. Receiver Operating Curve (ROC) for the RAIL score in differentiating active LN (Group 1) from Inactive LN & non-LN SLE (Group 2).

(sensitivity 86%, specificity 84%) for active LN. A RAIL score < 0.35 had a negative likelihood ratio of 0.17. Further adjustment for urinary protein and creatinine did not significantly influence the results.

Conclusion: The RAIL score is highly accurate in distinguishing active LN identified by renal biopsy, from inactive LN and non-LN SLE. A score of 0.35 identifies cSLE patients who very likely have active LN.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a well-established and life-threatening manifestation of systemic lupus erythematosus (SLE) that is more common in children than adults. The demographics of childhood-onset SLE (cSLE) and management of disease have changed over time, prompting the need to update outcomes. The purpose of this study is to use the Childhood Arthritis and Rheumatology Research Alliance (CARRA) prospective registry to validate historical principles about LN in a contemporary, real-world cohort.

Methods: Through literature review of LN studies in cSLE patients from 1992 to 2012, the following principles were identified:

- 20%-75% of cSLE patients will develop LN
- LN develops within 1 year of diagnosis in 82% of cSLE patients; 92% develop LN within 2 years of diagnosis
- Membranous (ISN/RPS class V) LN more often presents with nephrotic-range proteinuria than does proliferative LN (class III or IV)
- Short-term renal outcomes are worse in Black vs non-Black patients
- Short-term renal outcomes are worse in patients who present with eGFR < 60mL/min/1.73 m2 and/or moderate proteinuria (urine protein: creatinine ratio (UPC) > 1 mg/mg)
- Rituximab is used as a steroid-sparing agent for induction in proliferative LN

The CARRA registry was queried to determine the rates of LN in cSLE, time from diagnosis to LN, presentation at LN onset, short-term renal outcomes, and instances of rituximab as induction therapy. The eGFR (calculated by the modified Schwartz equation) was separated into 3 stages of chronic kidney disease (CKD) for analysis: 1: >60ml/min/1.73 m^2, 2: 30-60ml/min/1.73 m^2, and 3: < 30ml/min1.73 m^2. Occurrences of end-stage renal disease (ESRD),

Table 1. Class of LN at LN diagnosis

LN Class	*N*	*Percentage*
III/IV	138	73.0%
III/IV + V	22	11.6%
V only	29	15.3%

Table 2. GFR State at diagnosis and follow-up

Initial GFR (mL/1.73m²/min)	*N(%)*	*CKD 1/2 at follow up, N(%)*	*CKD 3 at follow up, N(%)*	*CKD 4/5 at follow up, N(%)*
>60	167 (71%)	121 (96.0%)	3 (2.4%)	2 (1.6%)
30-60	11 (5%)	7 (87.5%)	1 (12.5%)	0 (0.0%)
<30	2 (1%)	0 (0.0%)	1 (100%)	0 (0.0%)
Unknown	54 (23%)			

transplant, and dialysis were recorded. We compared eGFR change over time in Black vs non-Black subjects. This study was exempt from Institutional Board Review.

Results: Of the 675 cSLE patients in the CARRA registry, 235 (35%) had documented LN. Of those, 74% were diagnosed with LN within 1 year and 87% within 2 years of cSLE diagnosis. Table 1 describes the LN classes. eGFR decline was more common in Black cSLE patients than non-Black patients (p=0.04). Changes in eGFR over time are described in Table 2. Three patients were documented as being on dialysis. Nine were reported to have ESRD. No renal transplants were reported. Of those with LN, 24.3% were treated with rituximab with no statistically significant difference by LN class, sex, or age.

Conclusion: In the CARRA registry, 35% have LN, in range of prior literature estimates. Of those that have LN, 74% developed it within the first year of their lupus diagnosis, slightly lower than prior reports of 82%. Black race remains associated with worse short-term renal outcomes. In short-term follow up, most eGFR remained unchanged or improved and ESRD was rare. A study limitation is the inception cohort is 2 years old and some data were unavailable. Efforts are underway to study long-term outcomes in the CARRA registry to better inform on contemporary rates and outcomes of LN in cSLE.

Pediatric and Adolescent One Year Protocol Kidney Biopsies Should Be Performed, Even in Patients with Complete Remission of Their Lupus Nephritis

Peter Yorgin[1], Suhas Radhakrishna[1], Caitlin Carter[1], Johanna Chang[1], Katayoon Shayan[1], Lieuko Nguyen[1], Peter Chiraseveenuprapund[1] and Robert Sheets[2], [1]UCSD/Rady Children's Hospital, San Diego, CA, [2]University of California San Diego, San Diego, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The value of one-year protocol kidney biopsies in children who have proliferative lupus nephritis (LN) is unclear, particularly in patients who meet CARRA criteria for a complete renal response.

Methods: Subjects < 18 yrs of age, who met ACR systemic lupus erythematosus (SLE) classification criteria with initial kidney biopsy (KBx) proven proliferative LN at Rady Children's Hospital San Diego (RCHSD) between 1/1/2010 – 12/31/2019 and a pre-planned one year protocol KBx (0.75-1.25 years), were selected for this study. Kidney biopsies were read by RCHSD Pathologists. CARRA criteria for complete response (CR), partial remission (PR) and flare (F) were assessed at the time of protocol KBx. Patients were allocated into either CR or non-complete response (PR and F) groups (NCR) for analysis. UCSD/RCHSD IRB 200870X

Results: Of the 19 patients who had a one year protocol KBx, there were 11 CR (58%) and 8 NCR study subjects. There were no statistically significant differences between CR and NCR patients at initial KBx. Induction therapy was different between the two groups, with CR subjects more likely to receive intravenous cyclophosphamide (CTX). Patients with CR had significantly improved ISN/RPS class and lower NIH activity and chronicity scores on follow up biopsy compared to the NCR group. There was no statistically significant worsening in CR NIH chronicity scores. All SLEDAI scores in CR group at the time of protocol KBx were 4 or less, but 2 NCR patients also had SLEDAI scores of 4. All but one patient in the NCR group had a change (n=4) or increase in maintenance immunosuppression (n=3) after their KBx. Five CR subjects had no change in immunosuppression; while 6 (55%) had a decrease in immunosuppression. CR patients with immunosuppression reduction were more likely to have a decrease of ≥5 in NIH activity scores. There was one perinephric hemorrhage out of 38 KBx (2.6%) that necessitated an overnight hospital stay.

Conclusion: One year protocol KBx were beneficial in most patients with proliferative LN because the KBx provided histopathologic data to support a change in immunosuppression. Subjects meeting the CARRA criteria for complete renal response (CR) at had significantly better one year protocol KBx outcomes with greater ISN/RPS class improvement, and lower NIH activity and chronicity scores. Unexpectedly, two CR patients had KBx that no longer met the criteria for ISN/RPS class 1. CTX induction therapy of proliferative LN may have been a factor leading to better outcomes. While it is not unexpected that immunosuppression was changed or increased in nearly all NCR patients, the improved KBx results in CR subjects created a decision tree, where physicians either: 1) continued the effective

	Baseline		p-value	At protocol biopsy		p-value

immunosuppression, or 2) decreased immunosuppression. One year protocol KBx were associated with a low risk of serious adverse events. Study limitations include: a single center, non-randomized cohort, physician-directed protocol KBx selection and grouping of partial remission and flare groups into the NCR group. A prospective randomized trial would be able to determine if decreasing immunosuppression at one year for CR subjects would yield acceptable outcomes, as assessed by a two year protocol KBx.

Microstructural Damage Is Associated with Age at Disease-onset and Cognitive Impairment in Systemic Lupus Erythematosus

Paulo Julio[1], Renan Frittoli[1], Aline Lapa[1], Thais Caldeira[1], Leticia Rittner[1], Fernando Cendes[1], Roberto Marini[1], Paula Fernandes[1], Lilian Costallat[1] and **Simone Appenzeller**[1], [1]UNICAMP, Campinas, Brazil

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare corpus callosum (CC) volume and diffusion tensor imaging in systemic lupus erythematosus according to age of disease-onset.

Methods: We selected 75 patients with childhood-onset (c)SLE [mean age of 24.6 years (SD 4.6) and disease duration of 11.6 years (SD 4.8)] and two control groups: 1. Matched by disease duration, consisting of 51 patients with adult-onset (a)SLE [mean age of 32.4 (SD 3.2)] and disease duration of 11.5 years (SD 4.2)] and 2. Matched by age consisting of 77 healthy controls (HC) [mean age of 28 years (DP 3.6)]. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Cognitive impairment were screened with Montreal Cognitive Assessment (MoCA), mood and anxiety disorders were determined through Beck Inventory. SLE patients were further assessed for disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current and cumulative drug exposures. All subjects underwent MRI examination with a Philips 3T scanner. Sagittal T1-weighted images were used for CC segmentation using FreeSurfer. Diffusion Weighted Images (DWI) were analyzed in FSL tool and scalar maps of the Fractional Anisotropy (FA), Mean Diffusivity (MD), Axial Diffusivity (AD) and Radial Diffusivity (RD) were calculated. The CC was parcellated based on DTI. Using the scalar maps we obtained the average and standard deviation of FA, MD, AD and RD for the segmented CC and each parcel. P values < 0.05 were considered statistically significant.

Results: We observed similar CC volume in cSLE [mean volume = 6410.19mm^3 (SD 2026.85)] when compared to aSLE [mean volume = 6658.61mm3 (SD = 2121.50)]; p=0.465] and HC [mean volume=7216.40mm3 (DP 1991.61)]; p=0.175]. When CC was divided into different portions, we observed significant smaller volumes in the mid-anterior region, the central portion, the mid-posterior portion ($p^<0.001$) in cSLE and HC. No significant difference was observed between CC parcels in cSLE and aSLE and between aSLE and HC. We observed that FA values were significantly lower cSLE (0.63603; SD±0.0665) when compared with the aSLE (0.677624 SD ± 0.08920; p=0.002) and HC (0.699624;SD±0.07920; p=0.001). Increased MD (0.00096,SD±0.00014), RD (0.00057, SD±0.00015) and AD (0.0017, SD± 0.00014) were observed in cSLE when compared to aSLE [(MD:0.00096, SD ± 0.00014; p = 0.002); (RD:0.00048, SD ± 0.00019; p = 0.002); (AD:0.0016, SD±0.00011; p=0.024)] and HC [(MD:0.00116, SD±0.00024; p< 0.001); (RD:0.00052, SD± 0.00023; p< 0.001); (AD:0.0020, SD±0.00018; p=0.014)]. MoCA scores were significantly lower in cSLE [20.82(SD±4.6)] when compared to aSLE [23.27(SD±4.4); p=0.005] and HC [26.52(SD±2.6); p< 0.001]. No significant differences between BDI and BAI scores were observed (p >0.05). When comparing MoCA scores with diffusion parameters we observed a correlation with FA (r=0.65; p=0.03), MD (r=0.7; p=0.03) and RD (r=0.647; p=0.04).

Conclusion: We observed more frequently microstructural changes in the corpus callosum in adults with cSLE when compared to aSLE with similar disease duration and HC. Microstructural changes can explain worse neurocognitive outcome in cSLE.

Neuropsychiatric Involvement in Juvenile-onset Systemic Lupus Erythematosus (JSLE): Data from the UK JSLE Cohort Study

Teresa Giani[1], Eve Smith[2], Rolando Cimaz[3], Michael Beresford[4] and Christian Hedrich[2], [1]AOU Meyer, Florence, Italy, [2]University of Liverpool, Liverpool, United Kingdom, [3]ASST Gaetano Pini-CTO Institute and Università degli Studi di Milano, Milan, Italy, Milan, Italy, [4]Department of Women's & Children's Health, Institute of Life Course and Medical Sciences, University of Liverpool, Liverpool, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile-onset systemic lupus erythematosus (JSLE) is a rare autoimmune/inflammatory disease, accounting for up to 20% of SLE cases. Though clinically similar to adult-onset disease, it frequently follows a more severe course. Neuropsychiatric (NP) involvement in JSLE can be aggressive and significantly affect patients' quality of life as well as disease outcomes.

The aim of this study was to describe the demographic characteristics, clinical and laboratory features of NP involvement in JSLE.

Methods: We analyzed data from JSLE patients enrolled in the UK JSLE Cohort Study between August 2006 and June 2019. Demographic (age, gender, ethnicity, family history), clinical (1997 ACR classification criteria, disease activity BILAG, SLICC, and damage index SLICC-SDI) and laboratory (ESR, CRP, CBC with diff, ANA, anti-ENA, anti-dsDNA, aCL, lipid profile, renal function, C3, C4, Ig levels, thyroid function, UA) data collected at disease onset and at last visit were analyzed.

Results: A total of 428 JSLE patients were included, with a female:male ratio of 5.4:1. The median age at diagnosis was 12.2 years (range: 0-17). A majority of JSLE patients were Caucasian (51.4%), followed by patients of South Asian (23.3%), Black African/Caribbean (16.7%), and East Asian (6.5%) descent. Patients with headaches as the only NP symptom were excluded here, because of the low specificity of this feature.

Overall, one quarter of JSLE patients (107/428, 25%) showed NP features; in 48.5% of these cases, NP symptoms were the presenting manifestation. The median age at disease onset and ethnic composition did not differ between sub-cohorts with vs without NP involvement. Most frequently recorded NP manifestations included cognitive impairment (n=45, 42%), seizures (n=21, 20%), psychotic features (n=11, 10%), peripheral nerve involvement (n=9, 8%), cerebral vasculitis (n=10, 9%), and ischaemic stroke (n=7, 6%). Headache was an accompanying manifestation in 74% of all NP-JSLE patients.

While no differences were recorded in autoantibody patterns and immune cell counts, lower platelet counts (< 100.000/mmc) were found in patients with NP involvement (p=0.02). Children with NP involvement showed both a higher number of ACR criteria (mean 4.9 *vs* 4.6, p=0.07) and higher SLICC scores (0.3 *vs* 0.2, p=0.029) at disease onset.

As compared to JSLE patients without neurological involvement, at diagnosis, patients with NP-JSLE exhibited higher disease activity (pBILAG) in the constitutional (p< 0.01) and ophthalmologic (p< 0.05) domains. At last visit, NP-JSLE patients had an increased number of ACR criteria (mean 6 vs 5.5; p< 0.001) and more damage (SLICC) (mean 1.2 vs 0.4; p< 0.001). Comparing JSLE patients with primary NP involvement to individuals who developed NP symptoms later, patients with early NP involvement exhibited more damage (SLICC) at diagnosis (mean 0.63 vs 0.05; p< 0.01) and last visit (mean 1.7 vs 0.7; p< 0.01).

Conclusion: Approximately 25% of JSLE patients enrolled in the UK JSLE Cohort Study have NP involvement. Patients with NP involvement exhibit higher disease activity and more disease-associated damage when compared to patients without NP involvement.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

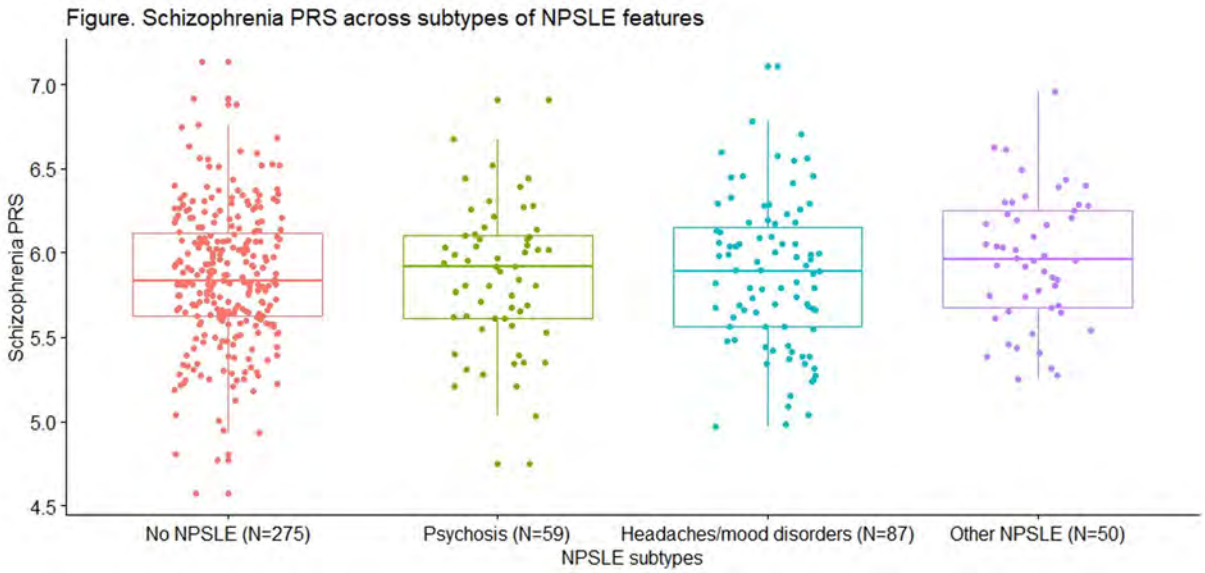
Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Prior studies indicate that schizophrenia and systemic lupus erythematosus (SLE) share genetic risk loci. Despite overlapping phenotypic features such as psychosis, little is known of the link between genetic susceptibility for schizophrenia and neuropsychiatric SLE (NPSLE). We aimed to examine the association between a polygenic risk score (PRS) for schizophrenia and NPSLE as well as NPSLE feature subtypes in childhood-onset SLE (cSLE) patients.

Methods: Study participants from the cSLE Lupus Clinic at the Hospital for Sick Children, met ≥ 4 of the ACR and/or SLICC SLE classification criteria. Patients were genotyped on the multiethnic Illumina MEGA array. Un-genotyped single nucleotide polymorphisms (SNPs) were imputed. Principal components (PCs) were calculated using the 1000 Genomes Project (1KGP) and the Haplotype Reference Consortium as referents and ancestry was genetically inferred. We calculated an additive schizophrenia risk-weighted PRS using genome-wide significant SNPs ($P< 5x10^{-8}$) from the largest published schizophrenia GWAS to date. The following SNPs were excluded: insertion/deletions, sex chromosomes, MHC region, minor allele frequency < 5%, imputation quality < 0.8 and SNPs within 500kb of and in $r^2 \geq 0.1$ with more significant markers. Demographic and clinical data were extracted from the Lupus database. NPSLE events were defined using ACR case definitions. We defined two outcomes compared to absence of NPSLE features: 1) any NPSLE features and 2) subtypes of NPSLE features: psychosis, headaches and/or mood disorders, other NPSLE. NPSLE features were independently validated by two pediatric rheumatologists. We tested the association of the schizophrenia PRS and NPSLE using logistic and multinomial regressions, adjusted for sex, age at SLE diagnosis, follow-up duration, the first five PCs, the presence of antiphospholipid antibodies, and non-HLA SLE PRS.

Results: Our cohort included 471 participants with cSLE. Median age at SLE diagnosis was 13.8 years (IQR,11.3-15.6), 82% were female and 31% were European. In total, 42% of all participants had ≥1 NPSLE feature: 59 (13%) had psychosis, 87 (18%) had headaches and/or mood disorders and 50 (11%) had other NPSLE features. Median follow-up was 5.0 years (IQR,3.2-7.8). The GWAS PRS included 83 SNPs. A higher schizophrenia PRS was not significantly associated with having any NPSLE features versus having no NPSLE features (OR=1.18, 95%CI 0.73-



NPSLE, neuropsychiatric systemic lupus erythematosus; PRS, polygenic risk scores.

1.94, p=0.49). A higher schizophrenia PRS was not significantly associated with having psychosis (OR=0.92, 95%CI 0.44-1.94, p=0.84), headaches and/or mood disorders (OR=1.05, 95%CI 0.56-1.98, p=0.88) or other NPSLE features (OR=1.96, 95%CI 0.86-4.46, p=0.11) compared to having no NPSLE features (Figure).

Conclusion: We did not observe a statistically significant association between PRS for schizophrenia and NPSLE features in cSLE. We found a trend toward significance with higher schizophrenia PRS being associated with a higher odds of non-psychosis NPSLE features, which warrants further validation. Next steps include creating a PRS adding SNPs moderately associated with schizophrenia and testing the association with NPSLE.

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Renal involvement is reported in up to 80% of juvenile systemic lupus erithematosus (JSLE) and its among the most severe manifestations in these population. Antimalarials are one of the cornerstones of lupus treatment with beneficial effects in maintenance of disease remission. In fact, low hydroxychloroquine (HCQ) blood levels are predictors of flare in adult lupus patients. The aim of this study is to determine the HCQ cut-off levels which

Table 1 – Baseline characteristics of 60 stable juvenile lupus nephritis (LN) patients with and without disease flares during six months of follow-up

* Ratio of the number of medication doses taken and the number of doses prescribed during the time between first study visit and the refill date of the medication.

predicts flare and to assess the adherence pattern by overall blood HCQ concentration in juvenile lupus nephritis (LN) patients.

Methods: Juvenile LN patients under the prescribed HCQ 2016-American Academy Ophtalmology (AAO) recommended dose for at least six months were prospectively followed. Participants were evaluated at baseline (BL) and 6-months for clinical, laboratorial data and HCQ blood levels (high-performance liquid chromatography-tandem mass spectrometry). Disease flare was defined as increase ≥3 in SLEDAI-2K and/or increase in immunosuppressive/ glucocorticoid.

Results: Sixty JSLE patients, 80% female, mean age of 16.6 ± 3.13 years and mean disease duration of 5.5 ± 3.65 years were included. Nineteen patients (32%) evolved with disease activity after 5.8 (1.6 – 9.8) months. Participants with flare presented a lower BL median HCQ blood level compared to stable patients [557.5 (53.5 – 2137.8) ng/ml vs. 1061.9 (53.5 – 2137.8) ng/ml, p=0.009]. There were no differences in demographic data, disease parameters and concomitant treatment in both groups. A ROC curve analysis demonstrated a BL blood HCQ cut-off level of 573.45 ng/ml as predictor of disease reactivation, with an OR=3.75 (95%CI 1.19-11.76, p=0.023) for flare (Table 1). Flare frequencies were lower in patients with adequate BL HCQ blood levels (> 573 ng/ml) compared to those with inadequate levels (≤ 573 ng/ml) (21% vs. 50%, p=0.042). A prospective 6-months blood HCQ monitoring was performed in 54 patients, demonstrating an overall stable pattern from baseline to the final evaluation in McNemar's analysis (p=0.359) with most patients (57%) presenting fluctuating/ persistently low levels (≤573 ng/ml). Among those with persistently inadequate HCQ pattern (n=12) half activated disease during this period. The higher frequency of flares in patients with persistently low HCQ levels vs. persistently adequate (50% vs. 26%, p=0.260) or vs. fluctuating levels (50% vs. 26%, p=0.255) did not reach statistical significance.

Conclusion: In conclusion, we demonstrated for the first time that HCQ blood cut-off level of 573 ng/ml predicts 6-months flare in juvenile lupus nephritis patients under prescribed HCQ 2016-AAO dose. We further observed that most of these patients have compliance issues reinforcing the need for a close surveillance particularly in those with levels below the defined cut-off. (Clinicaltrials.gov number #NCT03122431).

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Corticosteroids (CS) remain the mainstay of therapy for childhood-onset systemic lupus erythematosus (cSLE). However, widely accepted strategies for oral (PO) or intravenous (IV) CS dosing are lacking. We aimed to 1) develop a standardized CS dosing regimen (SSR) and 2) achieve consensus for this SSR among pediatric rheumatology and nephrology physicians treating cSLE, including lupus nephritis (LN).

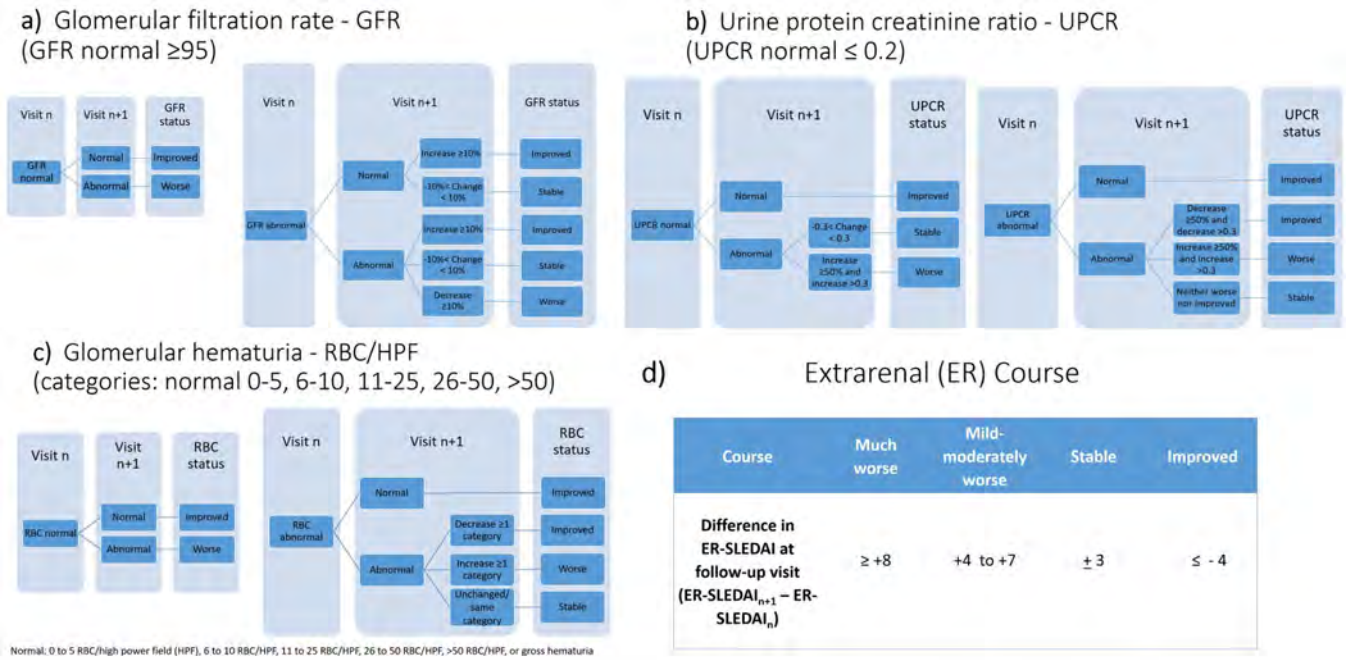

Figure 1. Consensus definitions for assessing changes in lupus nephritis response variables (LN-RVs) and extrarenal (ER) disease activity between clinical encounters

INITIAL 4 WEEKS OF INDUCTION THERAPY		
PO CS		**IV CS**
Patients≥50 kg	Prednisone* 60 mg/day divided in up to 4 doses	Up to 3 doses (30 mg/kg; max 1 gram of methylprednisolone)
Patients<50 kg	Prednisone 1.5 mg/kg/day	
Median–lowest PO CS dose at week 4**	40 mg/day - 30 mg/day	
WEEKS 5 – 26 OF INDUCTION THERAPY (based on LN and extrarenal trends since last visit)		
LN course *(assumption stable extrarenal)*	*Much worse*	Increase PO CS to 50-60 mg/day; Re-assess in 1-3 weeks; if response is (a) *Satisfactory→ No IV CS; (b) Non-satisfactory→ IV pulses + PO CS* Possible change of immunosuppressive drug
	Mild-moderately worse	Increase PO CS by about 30% (if dose < 40 mg; max 60 mg)
	Active stable	Stable PO CS dose (if dose < 40 mg; else: slow decrease)
	Improved active or PRR[1]	Slow decrease of PO CS dose
	CRR[2]	More pronounced decrease of PO CS dose
Extrarenal course *(assumption stable LN)*	*Much worse*	Increase PO CS dose; Re-assess in 1-3 weeks; if response is (a) *Satisfactory→ No IV CS; (b) Non-satisfactory → IV pulses + PO CS* Possible change of immunosuppressive drug
	Mild-moderately worse	Increase PO CS by 20% for doses < 40 mg; otherwise stable PO CS dose
	Active stable or improved active	Stable PO CS dose
	Inactive[3]	Decrease PO CS dose
Median–lowest PO CS dose at week 26	12.5 - 10 mg/day	
BEYOND 26 WEEKS POST KIDNEY BIOPSY - MAINTENANCE THERAPY		
LN course *(assumption stable extrarenal)*	*Flare[4] after PRR/CRR*	Prednisone ≥ 40 mg, irrespective of extrarenal course Re-assess in 1-3 weeks; if response is (a) *Satisfactory→ No IV CS; (b) Non-satisfactory→ IV pulses + PO CS*
	Worse after PRR/CRR	Increase PO CS dose FIRST
	PRR stable	Slow decrease of the CS dose
	Inactive/CRR or PRR improved	More pronounced decrease of the CS dose
Extrarenal course *(assumption at least sustained PRR)*	*Much worse*	Increase PO CS dose by 30-50% (max 60 mg); Re-assess in 1-3 weeks; if response is (a) *Satisfactory → No IV CS; (b) Non-satisfactory → IV pulses + PO CS* Possible change of immunosuppressive drug
	Mild-moderately worse	Increase PO CS dose by 25% for doses < 40 mg; otherwise stable PO CS dose
	Stable/Improved/Inactive	Decrease PO CS dose

*Or CS equivalent dose; **For patients ≥ 50 kg
[1]PRR (Partial renal remission): >50% improvement of ≥2 lupus nephritis response variables (LN-RVs) PLUS remaining LN-RV is NOT worse.
[2]CRR (Complete renal remission): All LN-RVs are NORMAL.
[3]Inactive extrarenal (ER) disease activity: ER-SLEDAI$_{n+1}$ (at follow up visit) ≤ +2
[4]LN flare defined by at least 1 of the LN-RV changes being persistently present on ≥2 subsequent time points ≥1week apart. LN-RV changes are defined as a) newly abnormal GFR, b) abnormal GFR that decreased by >10%, c) persistent increase of UPCR to ≥0.5, after CRR, d) persistent doubling of UPCR with values ≥1.0, after PRR, or e) newly active or worsening glomerular hematuria.

Table 1. Corticosteroid (CS) use provided by the standardized CS dosing regimen (SSR)

Methods: Consensus formation techniques were used. A Delphi questionnaire was completed to select relevant covariates influencing CS dosing in LN (Step 1). Retrospective data from 147 children with proliferative LN at 8 major cSLE treatment sites in North America were used to generate Patient Profiles (PP) describing cSLE course at 2 subsequent visits (Step 2). PP were sent to 142 physicians experienced in cSLE to rate the course of LN and extrarenal

disease and propose PO and IV CS dose adjustments (Step 3). Using PP data for which consensus was achieved, an SSR was developed (Step 4) and refined based on responses from another questionnaire and a focus group of experienced physicians (Step 5). Then, the SSR was validated (Step 6) using a second subset of PP describing disease course for up to 6 months since the time of initial kidney biopsy. Consensus was defined as agreement by majority (>50%) of PP ratings (Step 3, Step 6).

Results: In Steps 1 and 3, 103 physicians answered Delphi questions and rated 353 PP (response rate: 73%). In Step 6, 18 physicians (mean 13.4 years of experience) were asked to review 33 PP each resulting in 564 PP ratings, of which 437 (77.5%) and 460 (81.6%) yielded consensus on PO and IV CS dosing respectively. PO and IV CS dosing depends on the patient's weight, the course of extrarenal activity, measured by the extrarenal SLEDAI score (Figure 1d), and the course of LN, described by changes/status of 3 LN response variables (LN-RVs, Figure 1a-c). The SSR reflects dosing customs agreed upon by physicians. Table 1 summarizes the SSR with focus on 2 disease courses (1:stable extrarenal/various LN; 2:stable LN/various extrarenal), with permutations of extrarenal disease course (much worse, mild-moderately worse, active stable/improved, inactive) and LN course (flare, mild-moderately worse, active stable/improved/partial or complete renal remission). Doses of PO CS ≥ 40 mg are guided by LN course except in major extrarenal flares with potential organ damage. IV CS are used for worsening disease courses that fail to respond to PO CS of ≥ 40 mg up to 4 weeks (Table 1). Small decreases of PO CS occur even with stable LN or extrarenal activity. Complete renal remission allows more pronounced reduction of PO CS. Beyond 6 months post kidney biopsy (maintenance therapy), CS dosing is informed by the renal response during induction therapy, the course of LN, and extrarenal activity (Table 1).

Conclusion: The proposed standardized CS dosing regimen for LN in cSLE may be useful for clinical care and regulation of background CS use during clinical trials of new medications for cSLE.

Abstract Number: 1680

Lupus Anticoagulant as a Predictor of Adverse Outcomes in Children with Venous Thromboembolism

Elizabeth Sloan[1] and Ayesha Zia[1], [1]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of antiphospholipid antibodies, including lupus anticoagulant (LA), is a risk factor for development of venous thromboembolism (VTE) in children. The impact of transient LA positivity on clinical outcomes of VTE are unknown. We investigated (1) the association of clinical outcomes with LA positivity at VTE di-

Characteristics	Lupus anticoagulant positive (N=28)	Lupus anticoagulant negative (N=50)	p-value
Age (years)	11±5.9	10.4±6.7	0.6838
Male	17 (60.7%)	26 (52%)	0.4579
Race			
White	22 (78.6%)	31 (62%)	0.1325
Non-white	6 (21.4%)	19 (38%)	
BMI z-scores (WHO)	1.66±1.44	0.71±1.51	0.0081
Inherited thrombophilia	4 (14.3%)	10 (20.4%)	0.5028
Primary VTE type			0.5433
Extremity	12 (42.9%)	25 (50%)	
Non-extremity	6 (21.4%)	13 (26%)	
Pulmonary Embolus	10 (35.7%)	12 (24%)	
Diagnosis labs			
D-dimer (ng/mL)	4988±5065	3666±5095	0.2873
Factor VIII (%)	232±66	207±74	0.1615
CRP (mg/L)	101±76	64±73	0.1642

Table 1. Demographic Characteristics

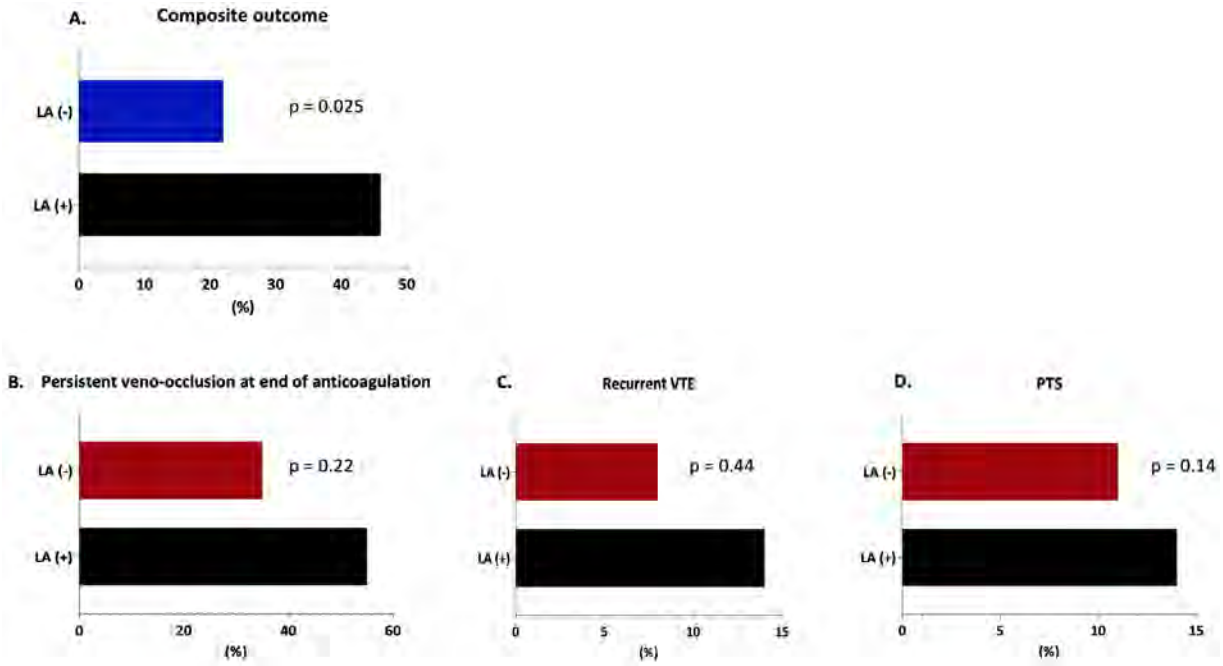

Figure 1. Impact of LA positivity on the development of clinical outcomes

agnosis in the acute and chronic VTE phases and (2) the impact of LA at VTE diagnosis with fibrinolysis in the acute and chronic VTE phases.

Methods: We utilized a nested case-control study design to identify pediatric cases (VTE patients with positive LA at VTE diagnosis) and controls (VTE patients without LA at VTE diagnosis) nested within an ongoing prospective cohort

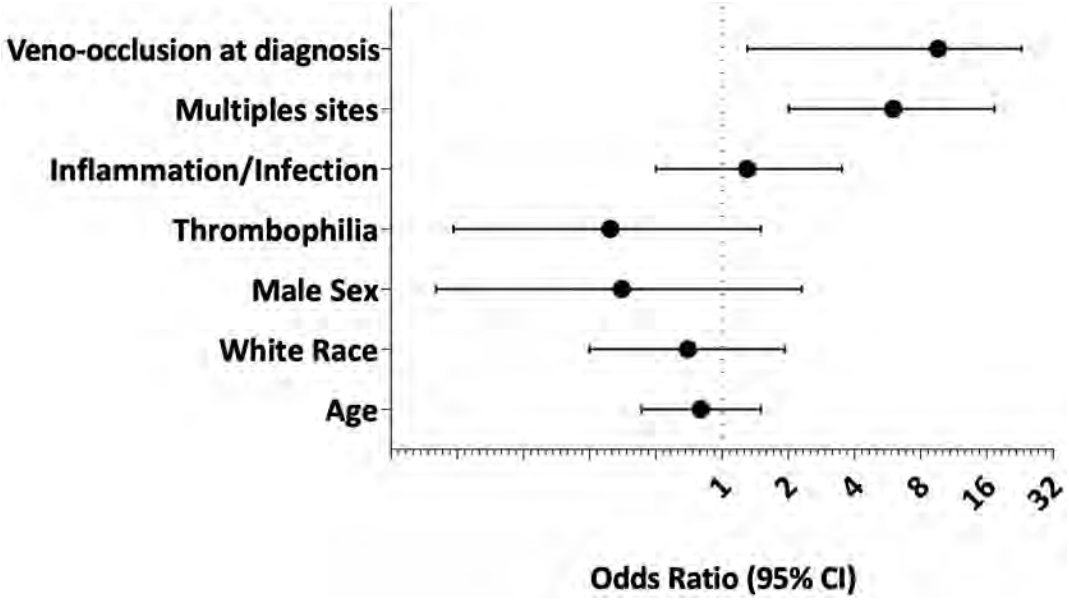

Figure 2. Predictors of composite clinical outcomes in LA positive patients

study. Patients without a known lupus anticoagulant status within 4 weeks of VTE were excluded. We assessed participants for a composite clinical outcome of persistent veno-occlusion, recurrent VTE, or post-thrombotic syndrome (PTS) at 12 months post-diagnosis and a translational outcome of fibrinolysis capacity using a modified thromboelastography at 3- and 12-months post-diagnosis. We examined demographic and clinical characteristics between the cases and controls by univariate analysis and constructed a multivariable logistic regression model to identify predictors of our outcomes in LA positive patients.

Results: We identified 50 controls and 28 cases in our cohort. Baseline characteristics between both groups were similar with the exception of a higher BMI in the LA positive group (*Table 1*). Children with LA positivity at VTE diagnosis were more likely to present with thrombosis at multiple sites (46% vs. 18%, p=0.0074) and more likely to develop the composite clinical outcome (46% vs. 22% p=0.025) despite LA resolution at follow-up (*Figure 1*). In children with transient LA positivity, complete veno-occlusion and multi-site involvement at VTE diagnosis predicted the composite clinical outcomes at 12 months post-diagnosis. (*Figure 2)*. No difference in fibrinolysis was observed at 3 months, but LA positive children were hypofibrinolytic at 12 months; this was not associated with BMI.

Conclusion: We present the first evidence that hypercoagulability induced by transient LA is prognostic in pediatric VTE. Children with LA positivity, even if transient, represent a unique subset of patients with adverse VTE outcomes in the acute and chronic VTE phases independent of inherited thrombophilia, inflammatory and infectious states. Larger studies are needed to validate our findings and to investigate if LA positive children require higher intensity of anticoagulation or upfront thrombolysis in the acute VTE phase to prevent adverse outcomes in the chronic phase.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Familial Hemophagocytic lymphohistiocytosis (fHLH) is an autosomal recessive, hyper-inflammatory, life-threatening disease. Macrophage activation syndrome (MAS) is also known as secondary HLH due to the clinical and biological similarities. MAS is increasingly recognized as a complication of systemic lupus erythematosus (SLE). This study compares the frequency of HLH genetic variants in childhood-onset SLE (cSLE) patients with and without MAS.

Methods: Our retrospective cohort was drawn from the Lupus Clinic at SickKids Hospital (Toronto) from 1987-2018. All participants met ACR, and/or SLICC SLE classification criteria. MAS diagnosis was based on expert physician diagnosis. The non-MAS cSLE comparator group was comprised of patients suspected monogenic SLE with whole genome sequencing (WGS). The non-MAS patients had young age of diagnosis (< 11y), consanguineous parents or multiple SLE affected first-degree relatives. Patients with MAS had paired-end whole exome sequencing (WES) by Illumina HiSeq 2500 platform (read depth 70-118X). Patients without MAS had paired-end WGS by Illumina HiSeq X platform (read depth 37-40X). Variant calling was completed with GATK and HAS and functionally annotated with ANNOVAR at The Centre for Applied Genomics (TCAG) in SickKids (annotation pipeline, v26.2, v.26.5). We restricted analyses to exonic regions in the following 16 HLH-genes (*AP3B1, BLOC1S6, CD27, GATA2, ITK, LYST, MAGT1, NLRC4, PRF1, RAB27A, SH2D1A, SLC7A7, STX11, STXBP2, UNC13D, XIAP*). Missense variants with MAF < 0.05 were prioritized. Ancestry was genetically inferred from multiethnic genotyping arrays (Illumina MEGA or GSA) using the ADMIXTURE software and the 1000 Genomes Project as reference. Otherwise, we used self-reported ethnicity according to Canada census categories. Demographic and baseline characteristics were extracted from the Lupus dataset, and analyzed using summary statistics. Medians and interquartile ranges (IQR) were calculated for non-normally distributed data and P-values were derived using two-tailed Fischer exact test.

Results: Our cohort consisted of 19 patients with MAS and 64 without MAS. The age of cSLE diagnosis was younger in the non-MAS cohort but the ethnicity distributions were no different between the two cohorts (Table). Eleven (58%) MAS and 39 (61%) non-MAS patients had exonic HLH variants; 6 (32%) MAS and 30 (47%) non-MAS had missense

		cSLE_MAS (n= 19)	cSLE_no MAS (n= 62)	P*
Sex: Female [n (%)]		16 (84)	53 (83)	1.00
Ancestry: [n (%)]^				
	European	2 (11)	19 (31)	0.13
	East Asian	6 (32)	7 (11)	0.07
	South Asian	4 (21)	5 (8.1)	0.20
	African	2 (11)	7 (11)	1.00
	Amerindian	0	5 (8.1)	0.59
	Mixed	5 (26)	19 (31)	0.78
Median age of SLE diagnosis, yrs (IQR)		12 (8.6, 14.7)	8.6 (7, 10)	
Patients with HLH variants [n (%)]				
	Exonic	11 (58)	39 (61)	0.79
	Missense	6 (32)	30 (47)	0.29

^ Inferred Ancestry – used the 2M MEGA array genotyped-data to identify ethnicity; for those who did not have MEGA array, self-reported Ethnicity was used.

* Fischer exact test was used -- https://www.graphpad.com/quickcalcs/contingency1/; P<0.05 is statistically significant

Table. Demographic and HLH variant comparison of cSLE patients with and without MAS

HLH variants. All these HLH variants were heterozygotes. There was no statistically significant difference in the number of HLH variants (exonic or missense) between MAS and non-MAS cohorts.

Conclusion: We did not observe a difference in the number of HLH exonic or missense variants in cSLE patients with MAS compared to those without MAS. Although this is the largest study of HLH variants in cSLE to date, our sample size had limited power to detect significant differences in rare variants which may have included variants associated with HLH. The non-MAS comparator cohort was likely enriched with rare pathogenic variants based on selection criteria for WGS. Future sequencing studies in larger cohorts of MAS and non-MAS cSLE patients are required to validate our findings.

Goal-Setting Improves Transition Readiness in Adolescents with Juvenile Idiopathic Arthritis and Systemic Lupus Erythematosus

Teresa Semalulu[1], Karen Beattie[1], Jeanine McColl[1], Arzoo Alam[2], Steffy Thomas[2], Julie Herrington[3], Jan Willem Gorter[2], Tania Cellucci[2], Stephanie Garner[1], Liane Heale[2], Mark Matsos[1] and Michelle Batthish[4], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster University, Hamilton, Canada, [3]ACPAC - University of Toronto, Hamilton, ON, Canada, [4]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The transition from pediatric to adult rheumatology care is associated with increased morbidity, mortality and loss to follow-up. This is largely due to a dramatic change in expectations as patients move from a family-centred, multidisciplinary pediatric care model to adult care models, which require independence and active engagement by the patient. Thus, adolescents must acquire sufficient self-management skills in order to successfully navigate the adult health care system independently. Comprehensive transition programs must recognize the variability in transition preparedness among similarly-aged individuals and allow for individualized intervention accordingly. The objective of our study was to assess the impact of goal-setting on changes in transition-readiness among adolescents with JIA and jSLE.

Methods: Patients (age 14-19) with JIA and jSLE were recruited from pediatric and young adult rheumatology transition clinics at a single academic institution. To assess transition readiness, each participant completed the TRANSITION-Q questionnaire. This self-administered, validated, 14-item questionnaire (max score = 100) is used to assess healthcare self-management skills as a proxy for preparedness for transition from pediatric to adult care. Participants completed the TRANSITION-Q at the time of consent and at all subsequent follow-up visits thereafter. Time between visits was at the physicians' discretion. Upon completion of the TRANSITION-Q at each appointment, goals were established with multidisciplinary care members in areas identified as needing improvement based on the participants' responses. Descriptive statistics were summarized for patient characteristics at baseline and for TRANSITION-Q scores at each time point.

Baseline Characteristics

	Mean (SD) or n (%)	Range
Age (years)	16.7 (1.0)	14-19
Female	27 (19)	-
JIA **cSLE**	30 (81) 7 (16)	-
Age at diagnosis (years)	12.6 (3.9)	2-18
Disease duration (years)	4.1 (3.9)	0-14

Baseline Characteristics

TRANSITION-Q Scores

TRANSITION-Q Scores

Results: Among 37 respondents, 10 were male and 23 were female (mean (SD) age 16.7 (1.0) years); n=30 JIA (81%), n=7 jSLE (19%). Thirty-two participants were seen twice (mean (SD) follow-up time 6.4 (2.5) months),14 were seen 3 times (mean (SD) time from first to second follow-up 3.4 (1.7) months) and 2 were seen 4 times (mean(SD) time from second to third follow-up 2.8 (2.0) months). Mean (SD) TRANSITION-Q scores at baseline and 3 follow-ups were 60.8 (14.8), 67.5 (11.5), 73.0 (9.4), and 76.0 (8.5), respectively.

Conclusion: We observed increases in TRANSITION-Q scores over time in this cohort. Goal setting and using a validated tool to track self-management skills may be particularly beneficial as self-management skills appeared to improve over time among our patient population.

Ready or Not? Measuring Readiness for Transition to Adult Care in Adolescents with JIA & jSLE

Jeanine McColl[1], Teresa Semalulu[1], Arzoo Alam[2], Steffy Thomas[2], Julie Herrington[3], Jan Willem Gorter[2], Tania Cellucci[2], Stephanie Garner[2], Liane Heale[2], Mark Matsos[2], Karen Beattie[1] and Michelle Batthish[4], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster University, Hamilton, Canada, [3]The Canadian Arthritis Society, Hamilton, Canada, [4]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Transitioning from pediatric to adult care represents a particularly vulnerable period among patients with JIA and jSLE. The shift to adult care is often unsuccessful, with patients being lost to follow-up or non-adherent to medications. Transition programs must support adolescents in acquiring and improving skills necessary to manage their own disease. Measuring patients' current level of transition readiness is the first step in identifying areas for improvement in self-management skills and the transition process itself. Our objectives were to 1) examine variability in transition readiness using the Transition-Q in adolescents with JIA and jSLE; 2) determine the association between age and Transition-Q scores; and 3) identify areas that may be the biggest challenges to these adolescents.

Methods: Over a one-year period, patients 14-20 years of age with JIA or jSLE were recruited from transition and young adult clinics at a single academic institution. Participants completed the Transition-Q, a validated 14-item

	Mean (SD) or n (%)	Range
Age (years)	16.4 (1.3)	14-20
Female	48 (45)	-
Diagnosis JIA jSLE	 61 (87.1) 9 (12.9)	-
Age at diagnosis (years)	11.7 (4.6)	1-17
Disease duration (years)	4.6 (4.5)	0-16
Transition-Q score[2]	59.7 (14.9)	31-100

Table 1 Baseline Characteristics (n=70)

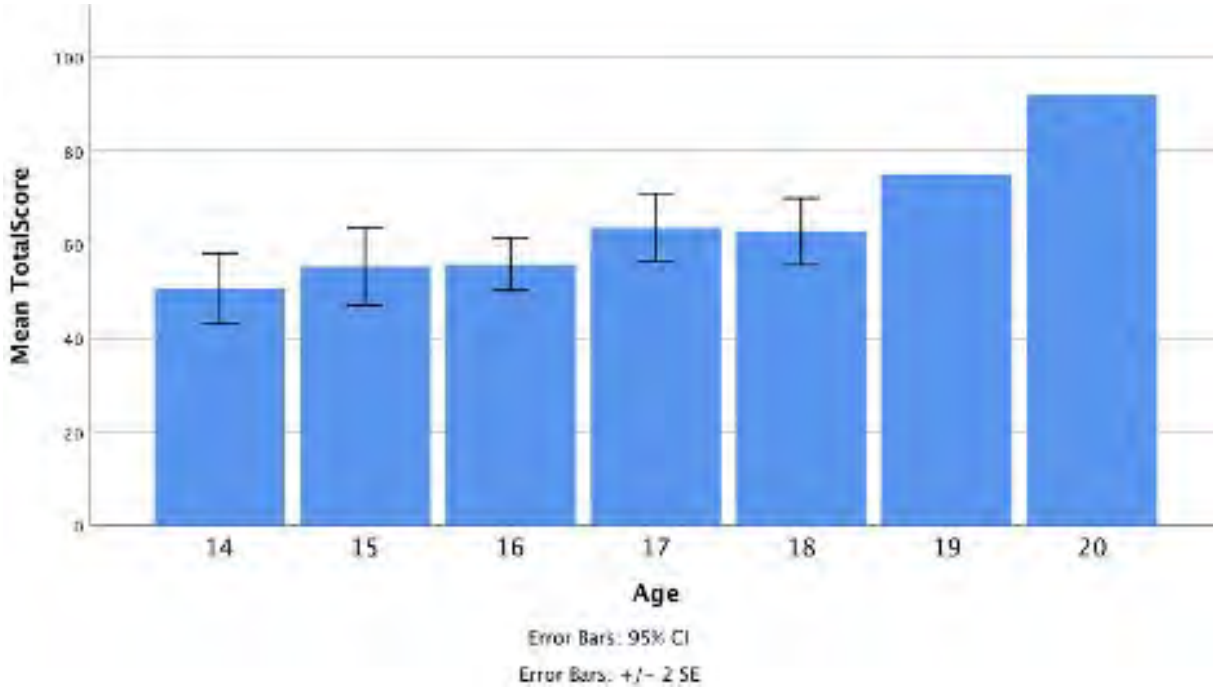

Figure 1 Mean Total Transition-Q Scores by Age

questionnaire which assesses healthcare self-management skills as a proxy for readiness to transition to adult care. Adolescents respond "never," "sometimes," or "always" to each question. Total scores range from 0-100; higher scores indicate greater transition readiness. Descriptive statistics summarized patient characteristics and Transition-Q scores. Differences in Transition-Q scores between sexes and diseases were explored using independent t-tests. Regression analyses determined the association between Transition-Q scores and age, controlling for sex and disease duration. Frequencies of responses to each question were determined.

Results: Of 70 participants (mean (SD) age 16.4 (1.3) years, 68.6% female), 61 had JIA and 9 had jSLE (Table 1). The mean (SD) Transition-Q score was 59.8 (14.9). Females had significantly higher mean total Transition-Q scores (62.3 (14.5)) compared to males (54.5 (14.9), p=0.043). The mean (SD) total Transition-Q score was 58.7 (15.2) amongst those with JIA and 67.9 (11.1) amongst those with jSLE (p= 0.105). Transition-Q scores significantly increased with age after accounting for sex and disease duration (standardized β=0.380, p=0.001) (Table 1). Most patients responded "never" to "I travel on my own to a doctor's appointment" (82.9%), "I see the doctor or nurse on my own during an appointment" (60.0%), "I drop off or pick up prescriptions when I need medicine" (58.6%) and "I book my own doctor's appointments" (58.6%).

Conclusion: This is the first study to use the Transition-Q to measure transition readiness in adolescent rheumatology patients. Transition readiness varied between and within age groups yet increased with age. Compared to males, females had higher total Transition-Q scores reflecting higher self-management skills. There was no difference in total Transition-Q scores between individuals with JIA compared to jSLE. Future work will examine the trajectory of changes in Transition-Q scores within patients over time, including after they transition to adult care. We will explore strategies to improve self-management skills and, subsequently, Transition-Q scores.

Increase in Emergency Department Visits and Hospitalizations, Decrease in Outpatient Visits Following Transition to Adult Rheumatologic Care

Paul Jensen[1], **Jessica Greco**[2], Kenneth Jackson[3] and Stacy Ardoin[4], [1]Intermountain Healthcare, St. George, UT, [2]Ohio State University/Nationwide Children's Hospital, Columbus, OH, [3]Ohio State University Medical Center, Columbus, OH, [4]Nationwide Children's Hospital, Columbus, OH

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Many children with rheumatic disease have active disease as adults, and health care gaps often occur in the transition from pediatric to adult care. We evaluated health care utilization during the adult to pediatric transition.

Methods: This IRB-approved, retrospective study evaluated individuals with rheumatic disease transferring from a pediatric to an adult health system (1/1/2006 -12/31/2016). Subjects age ≥ 8 yrs by 1/1/2010 with ≥ 1 visit before age 20 y, ≥ 2 visits with same rheumatology-related ICD-9 and 10 diagnostic codes (RDC), initial visit with RDC in the children's health system , ≥1 visit with RDC in adult system, and ≥ 1 rheumatology specialty provider visit were included. Pre-transition period was defined as time between first and last rheumatology visits in the children's health system. Transition period was time from last pediatric rheumatology visit to second adult rheumatology visit, and post-transition period was time between second and last adult rheumatology visits. Gender, self-reported race/ethnicity, medication (disease modifying anti-rheumatic drugs or biologic) use, diagnosis and household income [estimated by post-transition zip code using US Census Bureau American Community Survey (2014-2018)] were analyzed. Mixed effects binomial modeling of the dichotomous variable of ≥ 1 emergency department (ED) visit or hospitalization was performed examining variables denoted in Table 1. Poisson modeling of the continuous outcomes of number of rheumatology and non-rheumatology office visits was performed including predictors in Table 1 except period duration.

Variable	Pre-transition (122)	Transition (122)	Post-transition (93)
Male (n, %)	26 (21.3)	26 (21.3)	19 (20.4)
Non-white race (n, %)	32 (26.2)	32 (26.2)	26 (28.0)
Inflammatory arthritis* (n, %)	81 (66.4)	83 (68.0)	60 (64.5)
Lupus* (n, %)	36 (29.5)	37 (30.3)	31 (33.3)
Other autoimmune* (n, %)	20 (16.4)	22 (18.0)	18 (19.4)
Vasculitis* (n, %)	7 (5.7)	7 (5.7)	6 (6.50)
DMARD use (n, %)	73 (59.8)	91 (74.6)	72 (77.4)
Biologic/small molecule (n, %)	56 (45.9)	63 (51.6)	45 (48.4)
≥ 1 ED visit or hospitalization (n, %)	46 (37.7)	103 (84.4)	82 (88.2)
No. of rheumatology office visits (median, interquartile range)	22 (11-37)	1 (1-1)	3 (1-8)
No. of non-rheumatology office visits (median, interquartile range)	14.5 (3-36)	1 (0-2)	3 (1-7)
Duration of period (days, interquartile range)	1339.5 (805-1855)	190 (90.5-366.5)	567 (204-1044)

Table 2: Variables Associated with Emergency Department Visits and Hospitalizations During Transition to Adult Rheumatologic Care

Variable	Odds Ratio (95% CI)	P-value
Transition period	17.53 (7.85-39.19)	< 0.001
Post-transition period	19.62 (8.83-43.58)	< 0.001
Duration of period	1.00 (1.00-1.00)	0.136
Median household income*	0.99 (0.98-0.99)	0.026
Inflammatory arthritis diagnosis	1.44 (0.48-4.36)	0.514
Vasculitis diagnosis	7.22 (1.29-40.53)	0.025
Lupus diagnosis	2.80 (0.96-8.17)	0.060
Other autoimmune diagnosis	0.83 (0.35-1.99)	0.676

Table 3: Variables Associated with Outpatient Office Visits During Transition to Adult Rheumatologic Care

Variable	Coefficient (95% CI)	P-value
Rheumatology office visits		
Transition period	-0.78 (-0.99, -0.56)	< 0.001
Post-transition period	-1.20 (-1.56, -0.84)	< 0.001
Non-white race	0.37 (0.12, 0.62)	0.003
Non-rheumatology office visits		
Transition period	-0.71 (-1.11, -0.30)	0.001
Post-transition period	-0.65 (-0.99, -0.31)	< 0.001
Non-white race	0.64 (0.20, 1.08)	0.005

Results: 122 subjects met inclusion criteria for analysis. Of these, 93 (76%) reached post-transition period; 96 (79%) were female and were 32 (26%) non-white. Median household income was $67,872 (IQR $46,013 - $81,813). Patient characteristics during the transition periods are summarized in Table 1. Median transition time was 190 days (IQR 90.5 - 366.5). As noted in Table 2, risk of ≥ 1 ED visit or hospitalization significantly increased during transition period (OR 17.5; 95% CI 7.8 - 39.2), post-transition period (OR 19.6; 95% CI 8.8 - 43.6) and with diagnosis of vasculitis (OR 7.2; 95% CI 1.3 - 40.5). As shown in Table 3, the number of rheumatology and non-rheumatology office visits, corrected for period duration and other co-variates, decreased during transition and post-transition periods and was lower in non-white subjects.

Conclusion: In this retrospective analysis of health care transition over a 10 yr period between large pediatric and adult medical facilities, the rate of transition to adult care was 76%, higher than in most reported studies, and the median time between last pediatric and second adult rheumatology visits was ≥ 6 months. ED use and hospitalization significantly increased in the transition and post-transition periods and in individuals with vasculitis. Both rheumatology and non-rheumatology office visits decreased in the transition and post-transition periods. Non-white individuals had fewer office visits. These results suggest that efforts to increase post-transition outpatient care have the potential to reduce ED visits and hospitalizations.

Impact of the COVID-19 Pandemic Among Children with Rheumatic Diseases from Around the Globe

Jonathan Hausmann[1], Kevin Kennedy[2], Salman Surangiwala[3], Maggie Larche[4], Karen Durrant[5], Rashmi Sinha[6] and Emily Sirotich[4], [1]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Cambridge, MA, [2]McMaster University, Hamilton, Canada, [3]Queen's School of Medicine, Kingston, Canada, [4]McMaster University, Hamilton, ON, Canada, [5]Autoinflammatory Alliance, San Francisco, CA, [6]SJIA Foundation, Cincinnati

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Children with rheumatic diseases face unknown risks in the setting of the COVID-19 pandemic. These children are often immunosuppressed due to their underlying disease or the medications used to treat them. It is unknown whether children with rheumatic diseases are at increased risk of SARS CoV-2 infection or of developing serious disease complications should they become infected. We report on the pediatric data from the COVID-19 Global Rheumatology Alliance (C19-GRA) Patient Experience Survey.

Methods: The C19-GRA launched an international Patient Experience Survey for adults and parents of children with rheumatic disease, with or without COVID-19 infection. The survey was distributed online through patient support organizations and on social media. Parents completed the data on behalf of their children, including their child's rheumatic disease diagnosis, medications, disease activity (as measured by a visual analog scale from 0-10, where 0=very good and 10=very poor), whether or not they developed COVID-19, and COVID-19 disease outcomes. Parents also completed the PROMIS Parent Proxy Scale v1.0 – Global Health 7. We report on data for children less than 18 years of age from April 3-May 8, 2020.

Results: A total of 427 children are included in the analyses. Their demographics and clinical characteristics are shown in Table 1. Most respondents resided in the Americas (64.9%) and were white (73.3%), female (63.0%), and between the ages of 5-14 (64.9%). The majority of patients had juvenile idiopathic arthritis, and most were taking conventional synthetic DMARDs (csDMARDs) and/or biologic DMARDs (bDMARDs). The median disease activity score was 3 (IQR 1-6). The median T-score of the PROMIS Global Health measure was 43.9. Within this group, only 5 children (1.2%) were diagnosed with COVID-19, and none required hospitalization. Their COVID-19 disease experience is shown in Table 2.

Conclusion: In this international survey of children with rheumatic diseases, only a handful of children developed COVID-19, all of whom had benign outcomes. Similar to otherwise healthy children, those with rheumatic disease do not seem to be at greater risk of developing COVID-19 or of COVID-19-related complications, even while taking immunosuppressive medications. Limitations of this study include a convenience sample of parents engaged in social media, which may not be representative of the pediatric rheumatology population. Data were self-reported and could not be verified. Future studies should assess the long-term effect of COVID-19 infection in patients with rheumatic disease, as well as assess the rates of complications such as Multisystem Inflammatory Syndrome in Children (MIS-C).

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: At the end of April 2020, national and international Pediatrics scientific societies diffused an alert about a rise in the number of pediatric severe, inflammatory syndrome, coronavirus 2 (SARS-CoV-2) related, resembling Kawasaki disease (KD).

Methods: The Pediatric Rheumatology Tuscany Network worked out the COV-ASAKI survey to track children who received a KD diagnosis in during COVID-19 pandemic in a region hosting 593.606 people aged less than 18 years. We retrospectively collected demographics, clinical and imaging findings, treatment and outcome of KD children between February 1st to April 30th, 2020 and compared the number of cases in the 2020 index trimester with the same trimesters of the previous 5 years and overall with the total number in the last 5 years.

	Age Weight Comorbidities	Clinical presentation	Pharmacological treatment	Imaging results	Laboratory results	SARS COV-2 tests	Hospital length of stay	Outcome
Patient 1 (Female, Caucasian)	3 years, 15 Kg No comorbidities	5 days fever (T> 38°C), rash, palm-plantar edema, conjunctivitis, cheilitis, lymphadenopathy, irritability, arthralgia	IVIG, aspirin and iv. antibiotics	Normal abdominal US and echocardiography	WBC 14,380 cells/mm^3, ESR 53 mm/h, CRP 12.5 mg/dL, ALT 238 UI/l	Nasopharyngeal swab: negative Serological test: negative	8 days	Complete recovery
Patient 2 (Male, Caucasian)	4 years, 15 Kg, No comorbidities	6 days fever (T> 38°C), rash, conjunctivitis, cheilitis, lymphadenopathy, irritability, vomiting	IVIG, aspirin and iv. antibiotics	Normal abdominal US and echocardiography	WBC 25,570 cells/mm3, PLT 528,000 cells/mm3, ESR 120 mm/h, CRP 16.4 mg/dL, fibrinogen 937 mg/dL	Not performed	7 days	Complete recovery
Patient 3 (Male, Caucasian)	4 years, 17 Kg, No comorbidities	9 days fever (T> 38°C), rash, palm-plantar edema cheilitis, lymphadenopathy, irritability, myalgia	IVIG, aspirin and iv. antibiotics	Normal echocardiography	WBC 11,550 cells/mm^3, ESR 63 mm/h, CRP 10 mg/dL, ferritin 116 ng/mL	Nasopharyngeal swab: negative Serological test: negative	8 days	Complete recovery
Patient 4 (Female, Caucasian)	2 years, 11 Kg, Congenital hypothyroidism	5 days fever (T> 38°C), rash, conjunctivitis, cheilitis, dyspnea, irritability	IVIG, aspirin and iv. antibiotics	Normal echocardiography, reactive lymphadenopathy at neck US, pneumonitis at chest US	WBC 3,470 cells/mm^3, L 711 cells/mm^3, ESR 4 mm/h, CRP 2.1 mg/dL	Not performed	16 days	Complete recovery
Patient 5 (Female, Caucasian)	2 years, 11 Kg, No comorbidities	5 days fever (T> 38°C), rash, conjunctivitis, cheilitis, lymphadenopathy, irritability	Methylprednisolone, IVIG, aspirin and iv. antibiotics	Normal abdominal US and echocardiography, pneumonitis at chest XR	WBC 9,360 cells/mm^3, PLT 277,000 cells/mm3, Hb 8,3 g/dL, ESR 76 mm/h, CRP 4.61 mg/dL, ferritin 866 ng/dL, triglycerides 419 mg/dL, albumin 1.98 g/dL	Nasopharyngeal swab: negative Serological test: negative	15 days	Complete recovery
Patient 6 (Female, Asiatic)	2 years, 12 Kg, No comorbidities	5 days fever (T> 38°C), febrile seizures, rash, conjunctivitis, cheilitis, palm-plantar edema lymphadenopathy, arthritis	IVIG, aspirin and iv. antibiotics	Normal echocardiography, pneumonitis at chest XR, hydrops of the gallbladder at abdominal US	WBC 12,600 cells/mm^3, ESR 59 mm/h, CRP 26.02 mg/dL, ALT 485 UI/L, AST 536 UI/L, fibrinogen 924 mg/dL, ferritin 227 ng/mL	Nasopharyngeal swab: negative Serological test: negative	11 days	Complete recovery
Patient 7 (Male, Caucasian)	1.5 years, 10.4 kg, No comorbidities	5 days fever (T> 38°C), rash, conjunctivitis, cheilitis	IVIG, aspirin and iv. antibiotics	Normal echocardiography	WBC 17,280 cells/mm^3, ESR 31 mm/h, Hb 9.8 g/dL CRP 5.96 mg/dL	Not performed	10 days	Complete recovery
Patient 8 (Female, Caucasian)	4 years, 15.5 Kg, No comorbidities	5 days fever (T> 38°C), rash, conjunctivitis, cheilitis lymphadenopathy	IVIG and aspirin	Normal echocardiography, hydrops of the gallbladder at abdominal US	WBC 19,900 cells/mm^3, ESR 120 mm/h, CRP 25.72 mg/dL, fibrinogen 620 mg/dL, ferritin 183 ng/mL	Nasopharyngeal swab: negative Serological test: not performed	9 days	Complete recovery

Abbreviations: IVIG =Intravenous immunoglobulins, iv.=intravenous, US=ultrasonography, XR=radiography, MRI: magnetic resonance, WBC=white blood cells count, PLT=platelets, L= lymphocytes, Hb= hemoglobin, ESR=erythrocyte sedimentation rate, CRP=C-reactive protein, ALT= alanine aminotransferase, AST= aspartate aminotransferase, PT=prothrombin time

Table1. Demographics, clinical findings, imaging findings, treatment, and outcome of Kawasaki syndrome patients

Results: 8 children were diagnosed as KD, with an incidence rate of 2.6/ month. 1 child presented an incomplete KD. 7 were Caucasian and 1 Asiatic, without any underlying disease. 6 recovered after one course of intravenous immunoglobulins (IVIG), no specific intensive support was required. 1 patient needed two IVIG courses, a young girl developed an incipient macrophage activation syndrome (MAS) responsive to a single steroid pulse. The SARS-CoV-2 on nasopharyngeal swab, available in 6/8 children, was negative. 4 KD children, sampled for antibodies after recovery, resulted negative. No coronary involvement was reported. From February 1st and April 30th, 1992 nasopharyngeal swabs have been performed to the Tuscan children admitted to the hospitals: 85/1992 (4.3%) resulted positive for SARS CoV-2. 50 serological tests have been performed with 7 positive results. Considering the previous 5 years, 165 children were diagnosed with KD (incidence 2.7 per month). 59 were incomplete forms; 3 developed MAS and 1 experienced Kawasaki disease shock syndrome (KDSS). 38 showed coronary involvement , 11 received steroid pulses and additional 3 biologic therapy. No statistically significant difference in the incidence/month was found (RR 1.09, 95% CI 0.52-2.04, p=0.76), neither limiting the analysis to the 45 KD children diagnosed during the same corresponding 3-months of the last 5 years: 3 vs 2.6 (RR 1, 95% CI 0.46-1.98, p=0.96). Chi square analysis with Fisher's exact test correction failed to detect significant differences among the principal outcomes of KD children observed during the COVID-19 time and in the last 5 years: incomplete KD 59 *vs* 1, c^2=1.82; KDSS 1 *vs* 0, c^2=0.04; MAS: 3 *vs* 1, c^2=3.85; coronary involvement 38 *vs* 0, c^2=2.36. The same results have been detected adjusting the analysis for the 45 cases during the corresponding trimesters of the last 5 years (p=n.s, Fisher's exact test).

Conclusion: In Tuscany, during the COVID-19 pandemic, almost all KD patients, showed a mild disease course and completely recovered without complications. The long-lasting collaboration and the well-structured communication of our pediatric network provided a prompt intervention in new KD cases during COVID-19 pandemic and allowed a comparison between 2020 KD cluster and the previous ones, A comparison between our data and the results seen worldwide will be helpful to define the multifaceted nature of the pediatric COVID-19 and its potential relationship with the KD.

Abstract Number: 1687

Kawasaki Disease Shock Syndrome in the Intensive Care Unit: A Single Center Cohort

Monica Bray[1], Jennifer Rammel[2], Andrea Ramirez[1], Kristen Sexson[1], Fong Lam[1], Eyal Muscal[3] and Marietta DeGuzman[3], [1]Baylor College of Medicine, Houston, TX, [2]University of Florida Health Jacksonville, Jacksonville, FL, [3]Baylor College of Medicine, Houston

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Kawasaki disease (KD), a well described vasculitis of childhood, is the leading cause of acquired heart disease in developed countries. Kawasaki disease shock syndrome (KDSS) has been described in a limited number of small single center cohorts and case reports but its incidence and prognosis are poorly understood. Here we aim to add to the existing body of knowledge by describing patients with the diagnoses of KD and shock at our institution.

Methods: With IRB approval, the electronic medical record was used to retrospectively identify a total of 9286 PICU admissions between March 2012 and February 2016, 269 of whom had rheumatology consult. Of those 269, 30 patients (11 %) had KD and 27 (90%) had the specific diagnosis of KDSS. Five patients were excluded whose hypotension was documented after IVIG initiation and seven patients were excluded who did not have documented evidence of shock. The diagnosis of shock was confirmed by the combination of clinical concern requiring PICU admission and objective evidence, defined by hypotension for age or laboratory evidence of impaired perfusion (lactate > 2.0 mmol/L or mixed venous sat < 70%). The 18 remaining patients' charts were reviewed for the features presented in tables and results.

Results: The patients described in our cohort were predominantly African American (39%) and Hispanic (44%) and mostly male (61%) (table 1). The median age was 3.9 years and the median duration of fever was 8 days (table 2). Laboratory values are provided in table 3. Eight (44%) patients required inotropic support for their shock with one requiring extracorporal membrane oxygenation (ECMO). The shock was mostly distributive in nature with only one patient presenting with isolated cardiogenic shock with pulmonary edema. Fifteen patients (83%) received pulse dose steroids, 11 (61%) received daily steroids and 3 (17%) received no steroids. Steroids were given an average of 2 days after the first IVIG. Five patients (28%) received a second IVIG. Two patients received infliximab after fever resolution. On initial echocardiograms, six patients (33%) had systolic dysfunction and two (11%) had coronary dilation with z-score > 2.5. On the 6-8 week echocardiogram, three (17%) had coronary dilation with z-score > 2.5 but this had resolved by recent follow-up in all but one patient (6%). The prevalence of shock in KD was 1 in 27 patients, while prevalence of KDSS in the PICU was 1 in 550 admissions.

Conclusion: All of our KDSS patients had good coronary outcomes except one patient who required ECMO. Our coronary outcomes at last echo were better than previously published data and the majority of our patients received steroids. However, there were 3 patients who received no steroids and also had good coronary outcomes. The steroids were not typically given immediately as distinguishing KDSS from sepsis without blood cultures can be

Feature	Proportion (Positive/Total)
Diagnostic Criteria	12/18 Complete, 5/18 Incomplete, 1/18 Echo
Sex	11/18 Male
Ethnicity	8/18 Hispanic, 7/18 African American, 4/18 Asian
Systolic dysfunction	6/18 patients with evidence of systolic dysfunction
Hemodynamic Shock Features	9/18 Hypotension, 1/18 Pulmonary edema
Biochemical Shock Features (Lactate > 2 mmol/L or Mixed venous sat < 70%)	14/15 Low mixed venous sat, 5/14 elevated lactate
Inotropic support	8/18
Received pulse steroids	15/18
Received daily steroids	11/18
Fevered through first IVIG	5/18
Fevered through second IVIG	1/5
Received infliximab	2/18
First echo coronary changes	2/18 with coronary dilation with Z score > 2.5 on first echo
Aneurysm at 6-8 week echo	3/18 with aneurysm
Aneurysm at last echo	1/18 with persistent aneurysm

Table 1. Patient Characteristics, Shock Features, Coronary Outcome

Feature	Mean	Median	Range
Age (years)	4.3	3.9	0.4 - 14.2
Day of Illness of First IVIG	7.3	6	4 - 20
Fever Duration (days)	9.6	8	4 - 33
Admission Duration (days)	10.8	7.5	3 - 45
Day of First IVMP after IVIG	1	2	0 - 9
Number of IVMP pulses	2.9	3	0 - 8
Duration of oral steroids (days)	30	38	0 - 72
Duration of follow–up (years)	2.4	2.2	0.1 - 6.2

Table 2. Patient Age and Therapy

challenging. The true utility of steroids is limited by the small cohort size and variety of dosing regimens. KDSS is an uncommon diagnosis in the PICU and it is important for the intensivist to consider this diagnosis in patients presenting with shock.

Lab (normal values)	Total Patients Measured	Mean	Median	Range
Initial CRP (< 1.0 mg/dL)	18	22	23.9	4.6 - 41.8
Maximum CRP (< 1.0 mg/dL)	18	23.2	24.3	4.6 - 41.8
Initial ESR (<= 20 mm/hr)	16	57.7	58	13 - 99
Initial Platelets (150 – 450 x 10^3/µL)	18	280	310	67 - 485
Minimum Platelets (150 – 450 x 10^3/µL)	18	186	154	37 - 416

Long-term Hearing Loss, Anxiety and Neurodevelopmental Outcomes Following Kawasaki Disease: A Population-based Cohort Study

Cal Robinson[1], Francis Lao[2], Rahul Chanchlani[1], Anastasia Gayowsky[3], Sandeep Brar[4], Elizabeth Darling[5], Catherine Demers[5], Tapas Mondal[1], Rulan Parekh[6], Hsien Seow[5] and Michelle Batthish[1], [1]McMaster Children's Hospital, Hamilton, ON, Canada, [2]Michael G. DeGroote School of Medicine, McMaster University, Hamilton, ON, Canada, [3]ICES McMaster, Hamilton, ON, Canada, [4]University of California, San Fransisco, [5]McMaster University, Hamilton, ON, Canada, [6]University of Toronto, Toronto, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The incidence of Kawasaki disease (KD) is increasing in Ontario. Cardiovascular sequelae following KD are well-described. However, there are limited and conflicting non-cardiovascular outcome data among KD survivors. Our objectives were to determine the incidence and risk of hearing loss, anxiety, developmental disorders, intellectual disabilities and attention-deficit/hyperactivity disorder (ADHD) among KD survivors *vs.* non-exposed children.

Methods: We included all Ontario children (≤18yr) surviving hospitalization with a KD diagnosis between 1995-2018, through validated algorithms using population-based health administrative databases. We excluded children with a prior KD diagnosis, non-residents, and those with incomplete records. KD cases were matched with 100 non-exposed children by age, sex and index admission year. Follow-up continued until death or March 2019. We calculated the prevalence, incidence (per 1000 person-years (py)) and unadjusted hazard ratios (HR) for each outcome between 0-1yr, 1-5yr, 5-10yr and >10yr.

Results: Among 4,597 KD survivors and 459,700 non-exposed children (median 11.1yr follow-up), KD survivors had more hearing loss: 364 cases (7.9%) *vs.* 31,442 (6.8%); anxiety disorders: 1,213 (26.4%) *vs.* 99,965 (21.8%); developmental disorders: 398 (8.7%) *vs.* 28,211 (6.1%); intellectual disabilities: 52 (1.1%) *vs.* 2,931 (0.6%); and ADHD: 21 (0.5%) *vs.* 1,214 (0.3%). Compared to non-exposed children, KD survivors were at increased risk of hearing loss between 0-1yr (HR 1.25 [95%CI 1.00-1.54]); anxiety disorders between 0-1yr (HR 1.75 [1.46-2.10]), 1-5yr (HR 1.12 [1.00-1.27]) and 5-10yr (HR 1.12 [1.00-1.25]); developmental disorders between 0-1yr (HR 1.66 [1.42-1.93]) and 1-5yr

Outcome	KD survivors (N=4597)		Non-exposed (N=459,700)		0-1 years		1-5 years		5-10 years		> 10 years	
	n (%)	Incidence (/1000py)	n (%)	Incidence (/1000py)	HR	95% CI	HR	95% CI	HR	95% CI	HR	95% CI
Hearing loss †	364 (7.9)	7.45	31,442 (6.8)	6.92	1.25	1.00 - 1.54	1.00	0.86 - 1.16	1.17	0.93 - 1.48	1.22	0.89 - 1.68

* NR: not reported as ≤ 5 individuals
Abbreviations: py – person-years, ADHD – Attention-deficit/hyperactivity disorder
† Hearing loss includes sensorineural hearing loss, conductive hearing loss, hearing aid insertion or adjustment
‡ Anxiety disorders includes generalized anxiety, phobias, panic disorder, obsessive-compulsive disorder, adjustment disorders, conversion disorders and somatoform disorders
§ Developmental disorders includes speech and language disorders, specific learning disorders, developmental coordination disorder, autism spectrum disorder and disintegrative disorders

Table 1. Incidence and risk of hearing loss, anxiety and neurodevelopmental disorders, comparing KD vs. non-exposed children at 0-1yr, 1-5yr, 5-10yr and >10yr follow-up

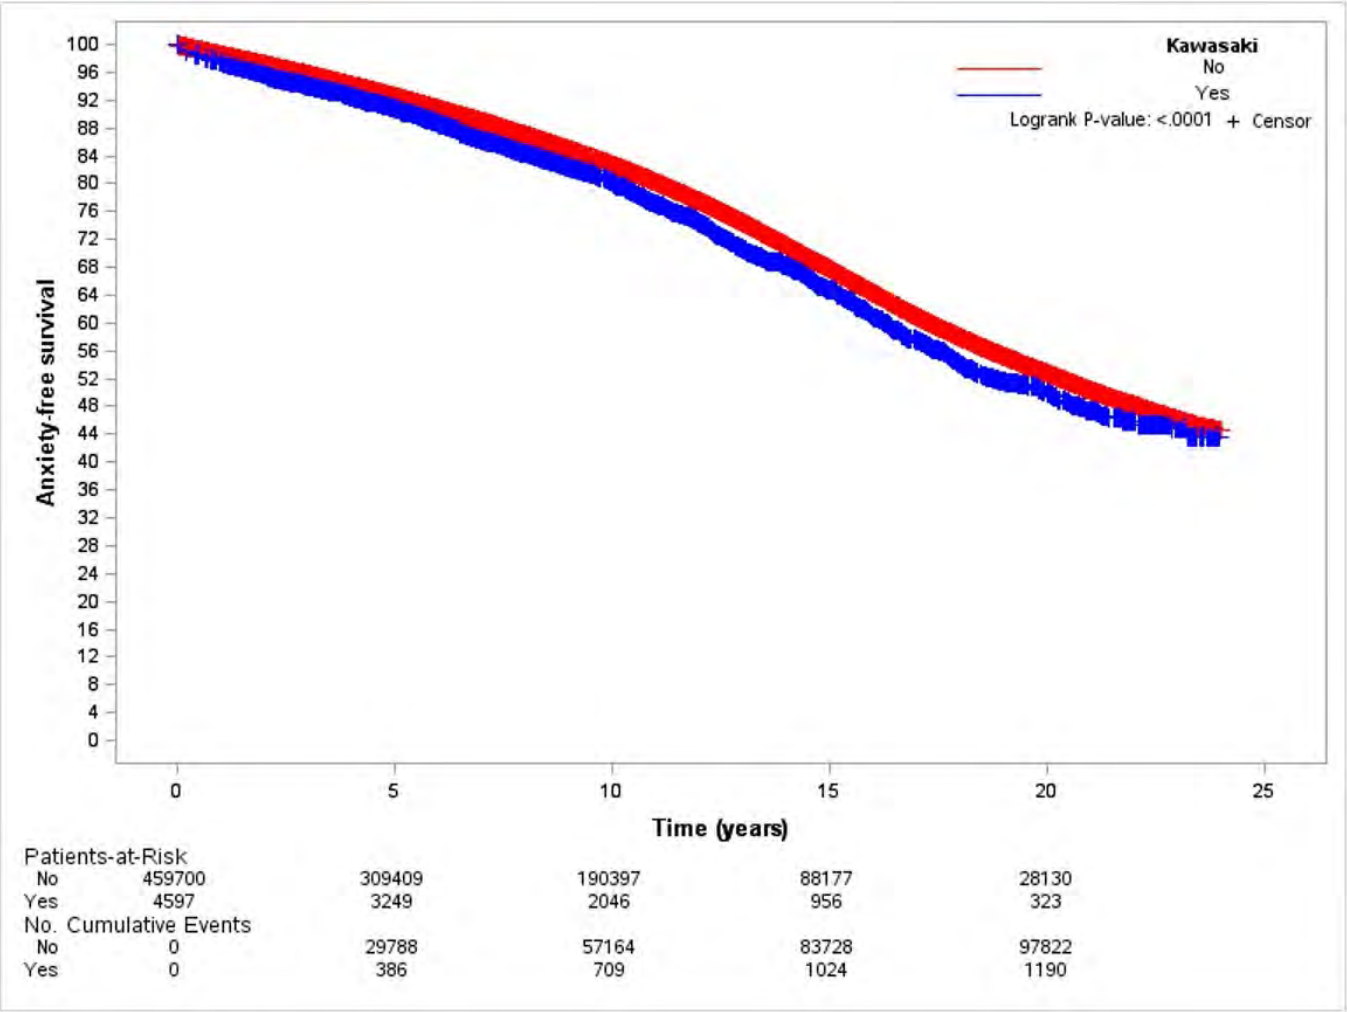

Figure 1. Anxiety disorder-free survival among KD survivors vs. non-exposed children

(HR 1.24 [1.06-1.46]); intellectual disabilities between 1-5yr (HR 1.64 [1.07-2.53]) and >10yr (HR 2.55 [1.47-4.43]); and ADHD >10yr after index hospitalization (HR 1.97 [1.11-3.48]).

Conclusion: KD survivors are at increased risks of adverse neurodevelopmental outcomes, which may impair their academic and social functioning. This justifies enhanced developmental and audiological surveillance of KD survivors.

Unexpectedly High Incidence of Kawasaki Disease in a Well-Characterized Population in Atlantic Canada

Abdulrahman Alkanhal[1], Joseph Saunders[2], Fajer Altammar[3], Adam Huber[4], Andrew Lynk[2], Alison MacLeod[5], Oliva Ortiz-Alvarez[6], Meighan Adams[2], Suzanne Ramsey[7], Elizabeth Stringer[8], Andrew Warren[2] and Bianca Lang[9], [1]University of Alberta, Edmonton, AB, Canada, [2]Dalhousie University, Halifax, Canada, [3]Mcmaster University, Hamilton, Canada, [4]Dalhousie University, Halifax, NS, Canada, [5]Annapolis Valley Health, Kentville, Canada, [6]St Martha's Regional Hospital, Antigonish, Canada, [7]IWK Health Centre, Dalhousie University, Halifax, NS, Canada, [8]IWK Health Centre, Halifax, NS, Canada, [9]Dalhousie University - Halifax, Halifax, NS, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Kawasaki Disease (KD), a systemic vasculitis of unknown etiology, is now the leading cause of acquired heart disease in children in North America. Its reported incidence varies widely around the world. A recent pan-Canadian study utilizing hospital discharge data reported an unexpectedly high incidence of KD in Atlantic Canada. The primary goal of this study was to validate the finding of a high incidence of KD in an Atlantic Canadian province and review factors contributing to the frequency in our population.

Methods: Our study was a retrospective review of all patients less than 16 years of age from the province of Nova Scotia (NS) diagnosed with KD between July 2007 and June 2018. All children with KD in NS undergo echocardiography evaluated in one central location. We used the cardiology and discharge databases of the pediatric tertiary care center, and the provincial Medical Examiner database to identify patients with KD. Clinical information was collected by health record review using a standardized form following local ethics approval. The 2011 Canadian census population data were used to calculate incidence rates and determine the proportion of the population of Asian descent.

Results: Out of the 309 possible KD cases that we identified, 220 residents of the province were diagnosed with KD during the study period. Exclusions are shown in Figure 1. Patients were included if they were treated for KD with IVIG (87%) or, if untreated, the physician diagnosed KD and obtained echo follow-up (13%). Cases where the physician subsequently doubted the diagnosis of KD were recorded. The annual incidence was 29.6, 13.9 and 1.6 per 100,000 children < 5 years, 5 to less than 10 years and 10 to less than 15 years, respectively (recurrence rate 1.8%). The male to female ratio was 1.3:1; the median age was 3.6 years (range 18 days-14.6 years). 61.4% and 23.2% met American Heart Association criteria for complete and incomplete KD, respectively. All patients diagnosed in the acute phase received IVIG; 12% of patients were refractory to the initial IVIG dose; 8% of treated patients received steroid and or biologic therapy. 14 (6%) developed a coronary artery aneurysm (CAA) during the disease course. One death from cardiac arrest occurred in a child with a large CAA with thrombosis. The proportion of our population of Asian descent was 1.25%.

Conclusion: We have confirmed a high incidence of KD in the specified Atlantic province. Other features of KD (age, sex, recurrence rate, IVIG resistance and CAA) are similar to previous studies. The incidence is higher than that reported in Europe and the United States (4.5-15 and 19 per 100,000 children < 5 years, respectively), similar to Canadian provinces with significantly higher proportions of the population of Asian descent (20-26 per 100,000 children < 5 years), and among the highest reported outside of Asia. Local population ethnicity does not explain our findings. Our comprehensive method to capture KD patients may have contributed to the detection of the higher than expect-

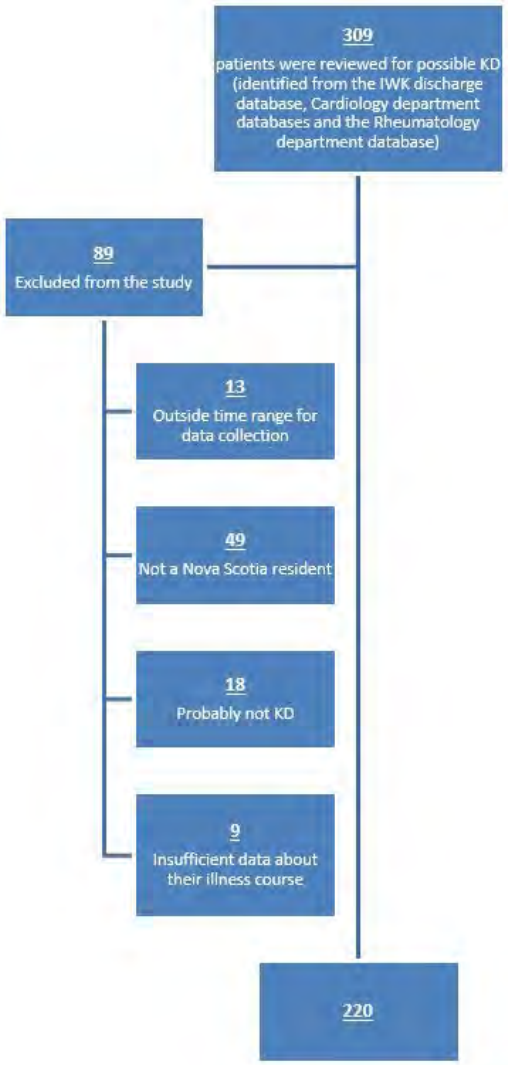

Figure 1: Reasons for exclusion of cases of possible of KD identified through the review of the cardiology and discharge databases.

ed incidence, raising the possibility that the incidence of KD has been underestimated in other populations. The role of environmental and genetic factors also deserves further study.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Henoch-Schönlein purpura nephritis (HSPN) is the main and almost the only cause of morbidity and mortality among children suffering from this most common vasculitis in childhood. Several classifications are used in the analysis of renal biopsies in HSPN, but it is unknown which one has the strongest association with the severity and outcome. The aim of the study was to compare the four most commonly used histological classifications for HSPN to determinate which one is the best predictor of disease outcome and to establish which variables of each histological classification have the strongest association with unfavorable outcomes.

Methods: The cross-sectional study included 69 patients with HSPN (diagnosed by EULAR/PRES/PRINTO criteria) and available renal biopsy specimens for analysis using 4 histological classifications for HSPN (the International Study of Kidney Disease in Children (ISKDC) classification, the Oxford classification, the Haas histologic classification of IgA nephropathy and the modified semi-quantitative classification (SQC), developed by Koskela *et al.*). The clinical outcome was defined through 4 categories, graded according to the modified classification of Counahan (physical examination, hematuria, proteinuria, urine albumin-to-creatinine ratio, hypertension and eGFR). The linear relationships between outcome and histological classifications were analysed using ordinal regressions using the first-order of polynomial orthogonal contrasts.

Results: The SQC classification proved to be the best, reducing the deviation (of the model-predicted outcome value from the observed value) by 9.5% (X^2_1=13,89, p < 0,001), followed by the Oxford classification with a deviation reduction of 8.0% (X^2_1=11,76, p = 0,001), then the ISKDC classification with a decrease in deviation of 3.3% (X^2_1=4,89, p = 0,027), and the worst was the Haas classification with a decrease in deviation of 2.1% (X^2_1=3,06, p = 0,080). Analysis of individual variables of Oxford and SQC classifications showed that with increasing values in the variables of interstitial fibrosis (t_{66} = 3,23, p = 0,002), tubular atrophy (t_{66} = 2,94, p = 0,005) and tubular dilatation (t_{66} = 2,40, p = 0,019) in the SQC classification, and endocapillary hypercellularity (t_{66} = 3,14, p = 0,003) and crescents (t_{66} = 2,07, p = 0,043) in the Oxford classification the outcome worsens.

Conclusion: The pilot study showed that the SQC classification, developed by Koskela *et al.*, has the strongest association with the severity and outcome of HSPN, followed by the Oxford classification, while other classifications are less related to the outcome of the disease. Although crescents on renal biopsy were considered the most important outcome indicators, this pilot study suggests that tubulointerstitial changes could be even more important as predictors of poor outcome. Histological changes in the interstitium and renal tubules of HSPN patients should be further explored in order to have an even better predictive value in terms of disease outcomes and to be incorporated into existing or new classifications, on the basis of which guidelines for the treatment of patients would be developed.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: IgA vasculitis (IgAV) is the most common childhood vasculitis, which etiology seems to be related to the combination of genetic as well as environmental factors. The application of geostatistical analyses in medicine was mostly focused on the analysis of infectious diseases spreading showing the significance of spatiotemporal trends in diseases spreading. Unfortunately, there is only a small amount of research on the application of geostatistical analyses on rheumatic diseases. The aim of this research was to investigate whether geospatial analytical tools can be applied in characterizing the spatial distribution of rheumatic diseases, especially IgAV.

Methods: A retrospective database was created containing the data from patients diagnosed with IgAV in five tertiary hospitals in Croatia, over a ten years period between 2009 and 2019. The average annual incidence of IgAV based on the population census data from 2011. Descriptive choropleth maps were created to observe the spatial distributions of raw and Bayesian adjusted incidence data. Three geospatial methods: spatial-empirical Bayesian smoothing, local

spatial autocorrelations assessed with Moran's I, and local identifiers of spatial autocorrelations (LISA) were applied to make inferences about the spatial incidence distribution of IgaV.

Results: 596 patients, of which 52.52% male, and 47.48% females, were included in the study with a median age of 6.42 (4.42 – 8.84). The estimated average annual incidence was 7.47 with a 95% confidence interval between 6.88 and 8.98 per 100 000 children. The raw data showed the highest number of cases in the cities with a higher population count. However, spatial empirical Bayes smoothed average annual incidenes were clustered similarly around these areas. Three statistically significant clusters were found: two in the Mediterranean, and one in the continental part of Croatia. The obtained Morran's I autocorrelation coefficient was 0.493, which showed significant positive spatial autocorrelation of IgAV. LISA analysis further identified those areas as statistically significant higher incidence clusters with an estimated average annual incidence above 13 per 100 000 children.

Conclusion: This study shows that IgAV exhibits spatial clustering features. While applying modern analytical methods on pediatric IgAV, this research shows the potential application of geostatistical analysis in identifying clusters in noncommunicable diseases that were previously not known. Further research is needed to investigate the importance and relationship of temporal trends in spatial clustering.

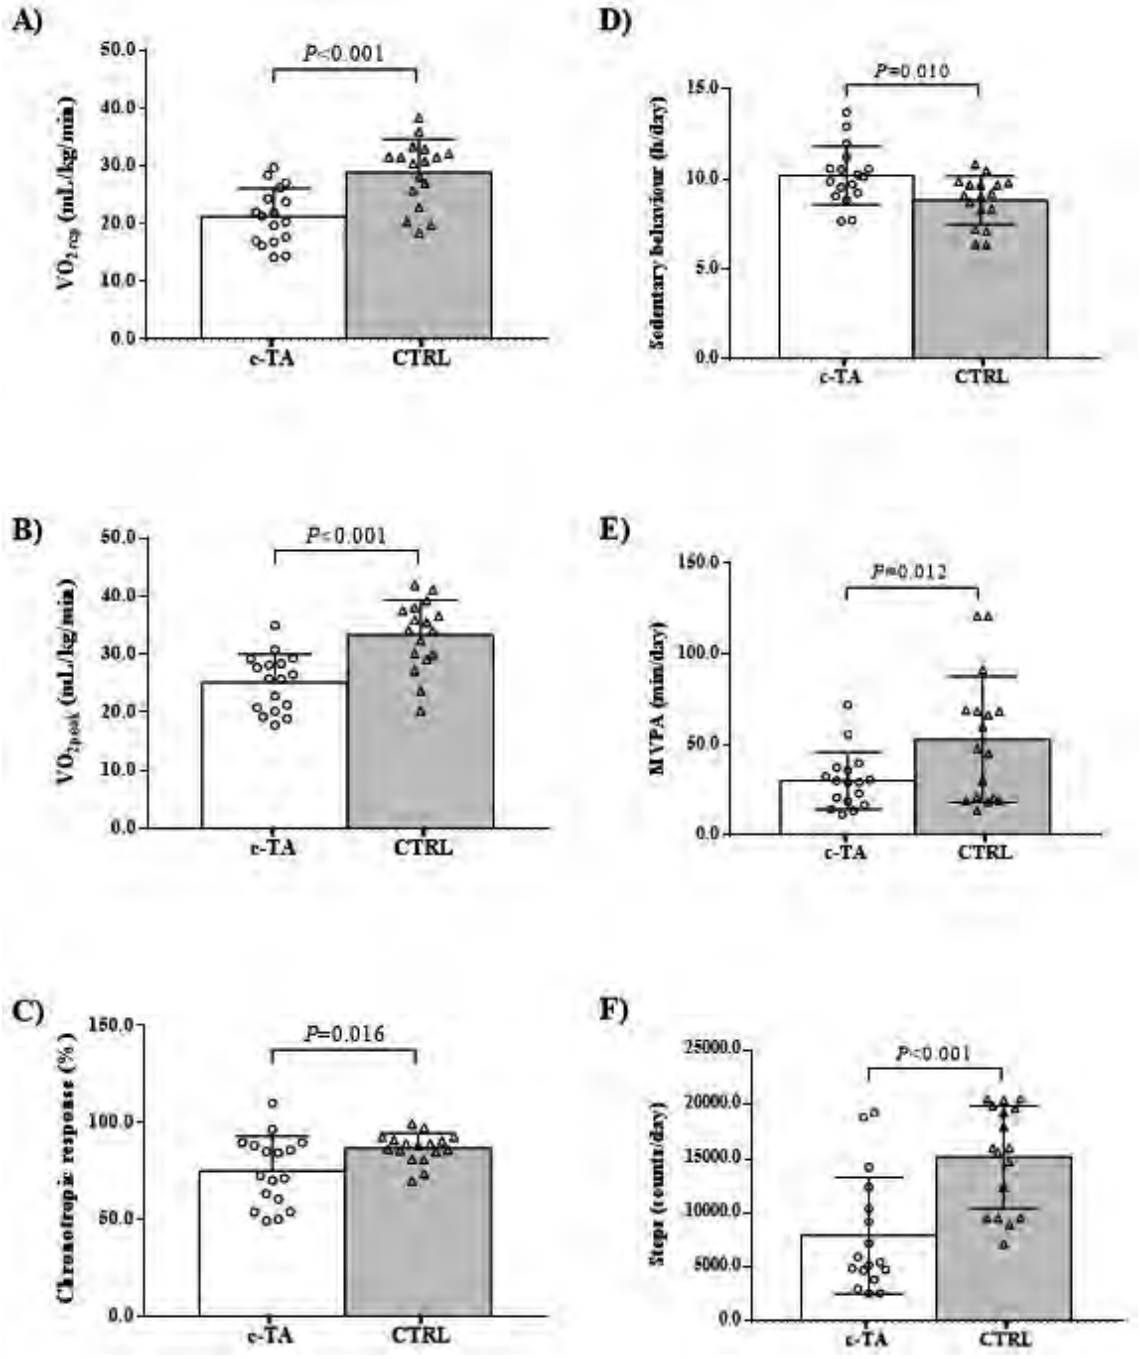
Poor Physical Activity Levels and Cardiorespiratory Fitness Among Patients with Childhood-Onset Takayasu Arteritis in Remission

Camilla Astley[1], Saulo Gil[2], Gleice Clemente[3], Maria Teresa Terreri[4], Lucia Campos[5], Nadia Aikawa[5], Ana Lucia de-Sá Pinto[2], Rosa Pereira[5], Hamilton Roschel[2] and Bruno Gualano[2], [1]University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [2]University of Sao Paulo, Sao paulo, Brazil, [3]Federal University of Sao Paulo, Sao Paulo, Brazil, [4]Federal University of São Paulo, São Paulo, Brazil, [5]Hospital das Clínicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Sao Paulo, Brazil

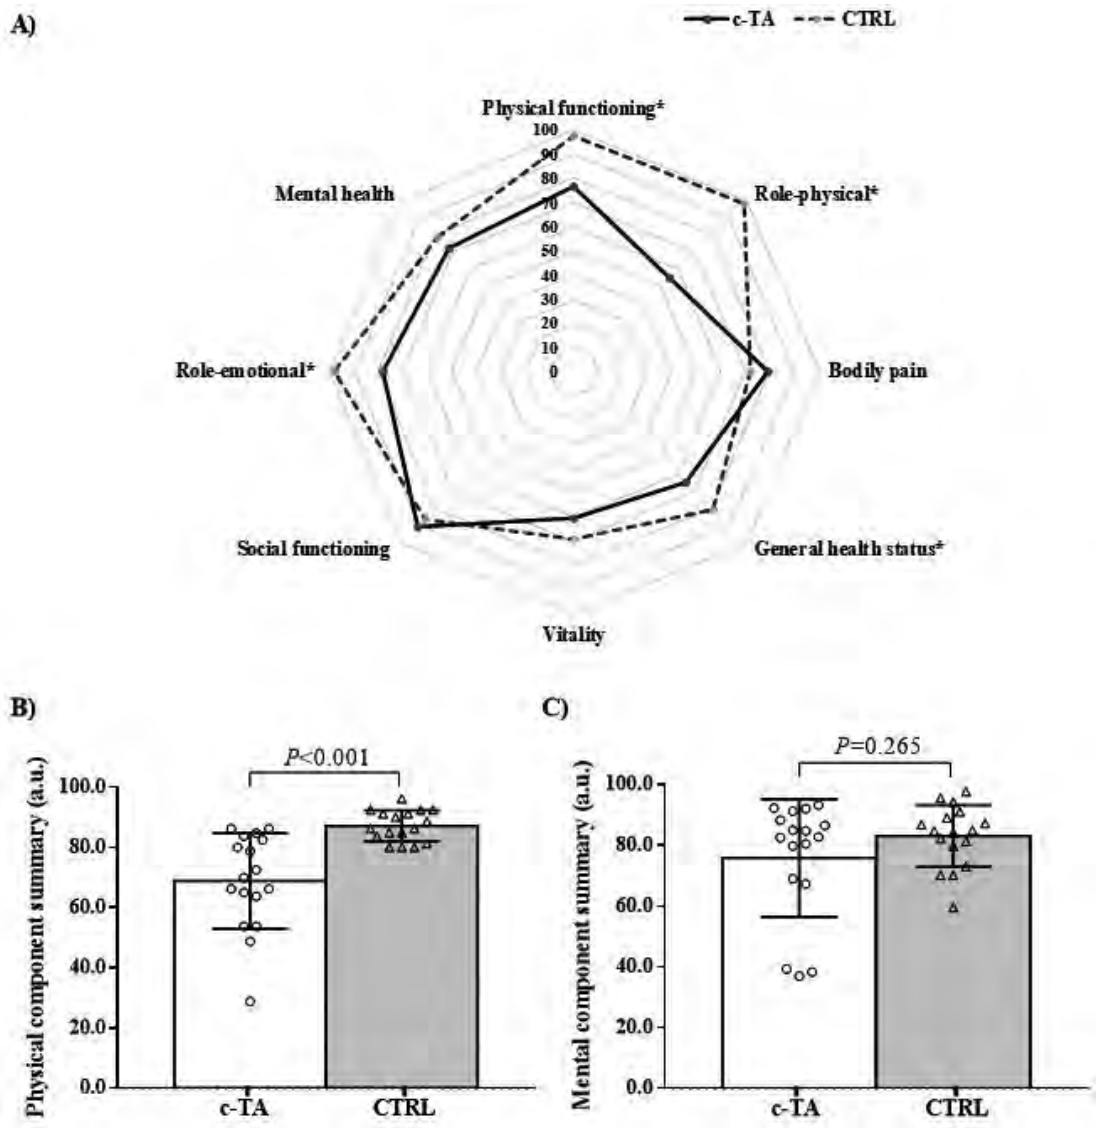
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset Takayasu Arteritis (c-TA) is a rare, granulomatous, chronic large-vessel vasculitis that involves mostly the aorta and its major branches with a high mortality rate (~35%) related to cardiovascular diseases, such as arterial occlusions and stenosis, ischemia or aneurysm formations. Due to the putative limitations imposed by the disease, the cardiovascular involvement, and other indirect factors (e.g., superprotection by parents and health practitioners, low self-efficacy and, social isolation), one could speculate that c-TA patients could also experience low physical activity levels and decreased aerobic conditioning. Therefore, assessing physical activity and cardiorespiratory fitness levels along with health-related quality of life (HRQL) and various traditional and non-traditional risk factors related to physical activity and physical capacity among c-TA patients *vs.* healthy controls remains clinically relevant for clinical practitioners.



Cardiorespiratory fitness and objectively-measured physical activity in patients with childhood-onset Takayasu Arteritis (c-TA) and healthy controls (CTRL). Panel A) Respiratory compensation point (VO2rcp); Panel B) Peak oxygen uptake (VO2peak); Panel C) chronotropic response; Panel D) Sedentary behavior; Panel E) Moderate-to-vigorous physical activity (MVPA); Panel F) Steps per day.

Methods: We recruited c-TA patients with non-active disease (n=17) from three rheumatological centers in Sao Paulo. An age- and sex-matched healthy controls (n=17) were also enrolled in the study. We assessed physical activity levels (Actigraph GT3X accelerometers), aerobic capacity (a maximum graded exercise test on a treadmill), systemic inflammation (IFN-γ, IL-10, IL-12p70, IL-1ra, IL-1β, IL-6, TNF-α, VEGF and PDGF), cardiometabolic markers, dis-



Healthy-related quality of life in patients with childhood-onset Takayasu Arteritis (c-TA) and healthy controls (CTRL). Panel A) Short Form-36 health survey domains between-group; B) Physical health domain; Panel C) Mental health domain.

ease-related parameters (Indian Takayasu Arteritis Clinical Activity Score; ITAS2010 and Pediatric Vasculitis Activity Score; PVAS), and HRQL (short-form health survey with 36 questions).

Results: The summary results from this study can be found in Figure 1. c-TA patients showed greater time spent in sedentary behavior (P=0.010), and lower moderate-to-vigorous physical activity (P>0.001) and lower step counts per day (P>0.001). VO_{2rpc} (P< 0.001), VO_{2peak} (P< 0.001) and chronotropic response (P=0.016) were significantly lower in c-TA patients. c-TA patients had worse HRQL in physical domain (P< 0.001). In the SF-36 subscales, functional capacity, physical appearance, and general health status were reduced in patients in comparison with CTRL (all P< 0.05). Inflammatory and angiogenesis markers did not differ between groups. However, c-TA patients displayed worse insulin sensitivity, based on insulin fasting (P=0.050), HOMA-IR (P=0.033) and lower HDL cholesterol levels (P=0.017) *vs.* CTRL (data not shown).

Conclusion: c-TA patients exhibited reduced physical activity levels and aerobic capacity, worse cardiometabolic risk factors and HRQL parameter compared with healthy peers. Physical inactivity and aerobic deconditioning emerge as potentially novel risk factors for c-TA. The role of physical activity interventions in preventing poor outcomes and improving HRQL in c-TA remains to be explored.

Background/Purpose: Rituximab is standard therapy for autoimmune brain disease (ABD) including autoimmune encephalitis (AE) and Neuromyelitis Optica Spectrum Disease (NMOSD). Recommendations for continuing concurrent intravenous immunoglobulin (IVIG) during rituximab treatment in patients with ABD vary. Mechanisms of rituximab B cell depletion include antibody-dependent cell-mediated and complement mediated cytotoxicity. In contrast,

Patients Escalated to Next Line Therapy	8 (16%)
Patients Discontinuing Rituximab Remission/Lack of Active Disease Lack of Response Other Reasons	24 (49%) 14 (29%) 6 (12%) 4 (8%)

IVIG's immunomodulation includes attenuation of many of these same mechanisms. Despite the frequent use of IVIG as adjunct therapy, there is little data on how concomitant use may affect B-cell depletion and efficacy.

The objective of this study was to determine if concurrent treatment of rituximab with IVIG altered B-cell depletion and time to repopulation in pediatric patients with ABD. We also assessed rates of hypogammaglobinemia (hypogam), duration of continuous maintenance therapy, and reasons for discontinuation of therapy.

Methods: We conducted a retrospective chart review of 58 patients who received rituximab for ABD. All patients met criteria for probable autoimmune encephalitis defined by a multidisciplinary team including a pediatric neurologist, rheumatologist and psychiatrist or NMOSD per established criteria. 49 patients met our inclusion criteria: follow-up for $\geq$1 year, standard rituximab induction, and CD19/CD20 counts recorded post-treatment.

We calculated time from most recent rituximab dosing to CD19/CD20 repopulation (defined as CD19 or CD20 $\geq$0.2%) and noted if IVIG was given within 4 weeks. We evaluated duration of rituximab therapy, concurrent IVIG, B cell repopulation, frequency of hypogam and serious infections. We noted the longest consecutive period of maintenance therapy for each patient. Dosing intervals for maintenance therapy varied from every 3 to 12 months, reflecting evolving recommendations for optimal dosing and early repopulation. Rationale for discontinuation was determined through chart review.

Results: 161 doses of rituximab were given in 49 patients, with 125 given concurrently with IVIG and 36 without. There was no statistical difference in B-cell repopulation in concomitant treatment compared to rituximab alone, in mean time to repopulation, or percent requiring escalation to next line therapy, as noted in Table 1.

We observed hypogam in only 8 of our patients (16% of study population). All patients with serious infection had prompt recovery with replacement dose IVIG and antibiotics. Hypogam was noted on average 12.2 months after last rituximab and 18.5 months after last IVIG.

33 patients (67%) received prolonged treatment (>1 year), of which 14 were on maintenance therapy 13-24 months and 19 on therapy for over 24 months. Of note, NMO patients in our practice continue rituximab chronically given high rates of relapse, even in clinical remission. 35% of patients continued rituximab at the completion of this study, 29% ended therapy for remission, 16% escalated to a different DMARD and 12% failed to respond with no escalation.

Conclusion: There was no difference in rates or time to B cell repletion in patients treated with rituximab alone vs concurrent IVIG treatment. Rates of hypogammaglobinemia were low in our cohort.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: *Pneumocystis jirovecii* pneumonia (PJP) is associated with significant morbidity and mortality in adult myositis patients; however, few studies have examined PJP in juvenile myositis (JIIM). The purpose of this study was to determine risk factors and clinical phenotypes associated with PJP in JIIM.

Methods: An electronic REDCap questionnaire regarding myositis features, disease course, medications, and PJP infection characteristics was completed by treating physicians for 13 JIIM patients who developed PJP (PJP[+]) from the United States and Canada. Myositis features and medications were compared to 147 JIIM patients without PJP (PJP[-]) from similar geographic regions who enrolled in National Institutes of Health natural history studies.

Results: The median age at PJP diagnosis was 6.1 years (IQR 2.6-10.5). PJP occurred shortly after myositis diagnosis in the majority of patients, with a median time from JIIM diagnosis to PJP diagnosis of 2.3 months (IQR 1.7-7). At PJP diagnosis, overall JIIM disease severity was rated as moderate or severe in 10/13 patients. PJP[+] patients were more often of Asian ancestry than PJP[-] patients (OR 8.7; 95% CI 1.3-57.9). Anti-MDA5 autoantibodies (OR 12.5; 95% CI 3.0-52.4), digital infarcts (OR 43.8; 95% CI 4.2-460.2), skin ulcerations (OR 12.0; 95% CI 3.5-41.2), and interstitial lung disease (ILD) (OR 10.6; 95% CI 2.1-53.9) were more frequent in PJP[+] than PJP[-] patients. Before PJP diagnosis, patients more frequently received pulse steroids (OR 3.8; 95% CI 1.2-12.4), rituximab (OR 52; 95% CI 5.2-515.4), and a greater number of immunosuppressive therapies, including corticosteroids, immunosuppressive drugs, and/or rituximab (OR 2.4; 95% CI 1.3-4.5) compared to PJP[-] patients; daily corticosteroid dose, however, did not differ between PJP[+] and PJP[-] patients. Seven PJP[+] patients were admitted to the intensive care unit, and four patients died due to PJP or its complications.

Conclusion: We identified that PJP more often affects JIIM patients early in their disease course, when patients have more severe manifestations requiring more intensive therapy. Importantly, we also identified anti-MDA5 autoantibodies, digital infarcts, skin ulcerations, and ILD as risk factors for developing PJP infection in JIIM. Thus, prophylaxis should be strongly considered in JIIM patients, especially those early in the disease course with these clinical features, and those who have received IVMP and multiple immunosuppressive therapies, particularly rituximab.

Anti-Melanoma Differentiation Associated Protein 5 (MDA5) Positive Juvenile Dermatomyositis: Focus on the Lung

David Moreno McNeill[1], Miriah Gillispie-Taylor[2], Kevin Baszis[3], Edouard Sayad[1], Manuel Silva Carmona[1] and Tiphanie Vogel[1], [1]Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [2]Baylor College of Medicine, Houston, [3]Washington Univ School of Medicine, St Louis, MO

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical Poster III: SLE, Vasculitis, & JDM
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: A subset of juvenile dermatomyositis (JDM), clinically amyopathic dermatomyositis (CADM), is uncommon and mainly described in adults. CADM is classically characterized by skin ulcerations, minimal muscle involvement, and interstitial lung disease (ILD). Anti-MDA5 antibodies are associated with CADM and ILD. A subset of anti-MDA5 patients have rapidly progressive ILD (RP-ILD), that is typically fatal. Limited data exists on pulmonary manifestations of these presentations in pediatric patients. We aimed to describe pulmonary manifestations, as well as outcomes, in a cohort of patients with pediatric anti-MDA5-associated lung disease.

Methods: A retrospective chart review was completed on patients < 18 years of age at presentation with the diagnosis of JDM, ILD and positive anti-MDA5 antibodies.

Results: 10 patients were identified: 60% male, 70% White, 30% Black, 40% Hispanic. The mean age at symptom onset was 9.6±6.8 years, at diagnosis it was 10±6.8 years. The systems affected at initial presentation were integumentary (100%), musculoskeletal (90%) and respiratory (60%). 40% presented without respiratory symptoms, but were subsequently found to have lung disease. Skin manifestations included nonspecific erythema (70%), Gottron's papules (60%), ulcerations (50%) and heliotrope rash (40%). Musculoskeletal symptoms included arthritis (80%), mild weakness (60%), and muscular tenderness (50%). Mean creatine kinase was 92.7±69.3 units/L.

Respiratory symptoms at presentation included shortness of breath (67%), cough (67%), chest pain (33%), and wheezing (17%). Four patients required respiratory support; 1 nasal cannula, 1 high frequency oscillatory ventilation and 2 extracorporeal membrane oxygenation (ECMO). All patients had abnormal chest CT; findings included consolidation(s) (60%), pneumomediastinum (50%), ground glass opacities (50%), and nodules (30%). 8 patients had pulmonary function testing showing a diffusion defect in 75% and a restrictive pattern in 25%. At last follow-up (range 6 months-5 years), diffusion defects (60%) and dyspnea on exertion (30%) were still noted. All 3 patients with RP-ILD were toddlers at presentation (16, 21, and 25 months). 2 of the 3, both those requiring ECMO, died due to respiratory failure and diffuse alveolar damage refractory to extensive immunomodulatory therapy. The surviving patient with RP-ILD required mechanical ventilation for 14 months, but is now well off all therapies for 4 years. Treatment ranged: more than 1 patient was treated with corticosteroids (100%), hydroxychloroquine (70%), IVIG (50%), methotrexate (50%), rituximab (40%), azathioprine (40%), plasma exchange (30%), NSAIDs (10%), mycophenolate mofetil (10%), and cyclophosphamide (10%).

Conclusion: The pediatric presentation of anti-MDA5-associated CADM is similar to the adult disease, patients had skin ulcerations and lung disease, but minimal muscle involvement. Pneumomediastinum was common. RP-ILD was fatal in 2 of 3 cases. There is a need for further studies on this variant of JDM, specifically treatment options and investigations of younger patients who seem to be at higher risk of severe disease.

Abstract Number: 1696

Measuring Quality Improvement from CME Participants: Results from the RAPID® CME Initiative

Stephen Bender[1], Michael Weinblatt[2] and Daniel Duch[1], [1]FACTORx, Cherry Hill, NJ, [2]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Medical claims data have been used since 2008 to measure the implementation of the diagnostic and referral strategies resulting from participation in RAPID® CME activities. Since its inception, over 69,782 clinicians have completed at least one RAPID® CME activity. We have reported statistically significant improvements in the participants' diagnostic and referral performance (Bender S, et al. *CE Measure*, 2016;10:10-15). While measuring diagnostic and referral patterns is critical to the success of the initiative, the claims database is limited in its ability to provide objective measures in other areas that the RAPID® curriculum addresses. Therefore, an electronic

medical record analysis was used to determine the curriculum's effectiveness in improving clinician's performance of quality measures associated with rheumatoid arthritis (RA): smoking cessation counseling, cardiovascular (CV) risk, tuberculosis (TB) testing, influenza and other vaccination strategies.

Methods: A retrospective medical record review of recruited providers' patients was conducted for 23 primary care providers (PCP) meeting the study's inclusion criteria. To be included in the study, CME participants needed to be a primary care provider currently managing RA patients interested in improving the quality of the care of their RA patients. In order to assess effectiveness of CME on the use of quality measures and patient care, a two-part chart review (pre/post) was conducted with same data compared from random samples of providers' patients. The target population was defined as all patients, who received a diagnosis of RA, that were being treated by participants of the CME activities. Baseline reviews of 202 random charts from 23 PCPs were examined and compared on follow up with 198 charts from 21 of the same providers who also had participated in baseline chart examination. Patient inclusion criteria included: RA patients >18 years of age; RA ICD–10 codes present; and patients should be seen at least once/year. The quality measures were: Care plan; preventive care and screening; Pneumonia Vaccination Status for Older Adults; Pain Assessment and Follow-Up; falls plan of care; TB screening; tobacco use screening; screening for high blood pressure and follow-up documented; TB Prevention for pso, PsA and RA Patients on a Biological Immune Response Modifier.

Results: Statistically significant improvements were observed for five of the nine quality measures. Measures reaching statistical significance included: Care plan (9.39% Pre/24.29% Post/P-value < 0.0001); preventive care and screening (24.83% Pre/30.14% Post/P-value 0.0422); Pain Assessment and Follow-Up (3.66% Pre/6.59% Post/P-value 0.0096); high blood pressure screening and follow-up (86.1% Pre/94.9% Post/P-value < 0.0001); TB Prevention for pso, PsA and RA Patients on a Biological Immune Response Modifier (1.41% Pre/5.33% Post/P-value 0.0126).

Conclusion: A CME initiative improved clinical performance of learners that will lead to improved care and outcomes for RA patients. While limited in its ability to reach a large number of clinicians, use of electronic medical record data is a useful tool for assessing performance change.

Immune Related Adverse Events from Checkpoint Inhibitor Therapy: Survey of Hospitalists' Awareness and Experiences

Cassandra Calabrese[1], Alexa Meara[2] and Varalakshmi Janamanchi[1], [1]Cleveland Clinic, Cleveland, OH, [2]Ohio State University Wexner School of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

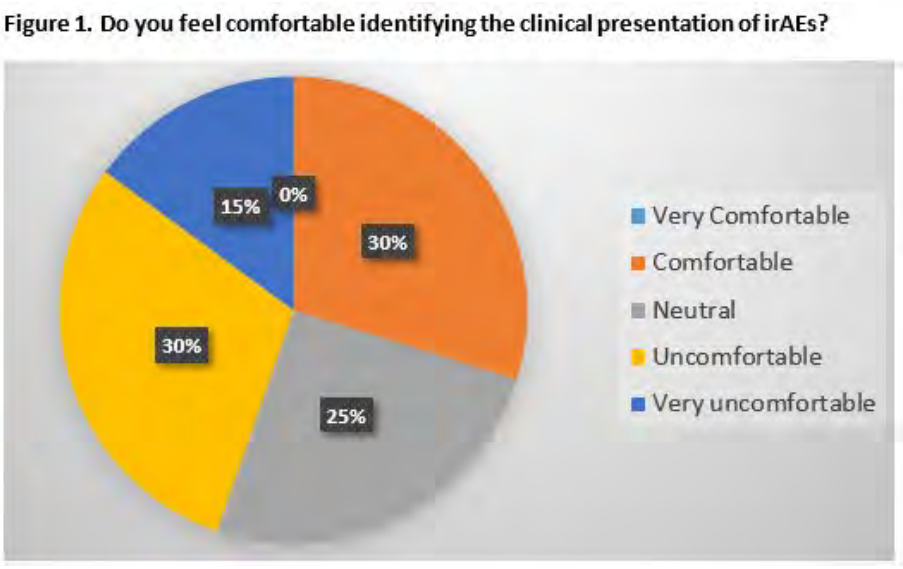

Figure 1. Do you feel comfortable identifying the clinical presentation of irAEs?

Background/Purpose: The introduction of immunologic checkpoint inhibitor therapy (ICI) has caused a paradigm shift in the world of cancer treatment. Their use, however, is attended by a slew of untoward, off-target effects that appear to be autoimmune and/or autoinflammatory in origin called immune related adverse events (irAEs), which pose diagnostic and management challenges. With the increasing use ICI for a growing number of indications, more health care providers are encountering patients with irAEs in outpatient clinic, the emergency room and the hospital wards. While education on irAEs amongst non-oncologists has improved on some fronts[1], we believe there still remain large knowledge gaps. We developed a survey to assess awareness and experience with ICI and irAEs amongst hospitalists

Methods: An online survey was generated using SurveyPlanet and distributed via e-mail to the population of hospitalists at the Cleveland Clinic Main Campus and The Ohio State Wexner School of Medicine. The survey questions aimed to assess hospitalists' awareness surrounding ICI and irAEs including whether they had encountered these

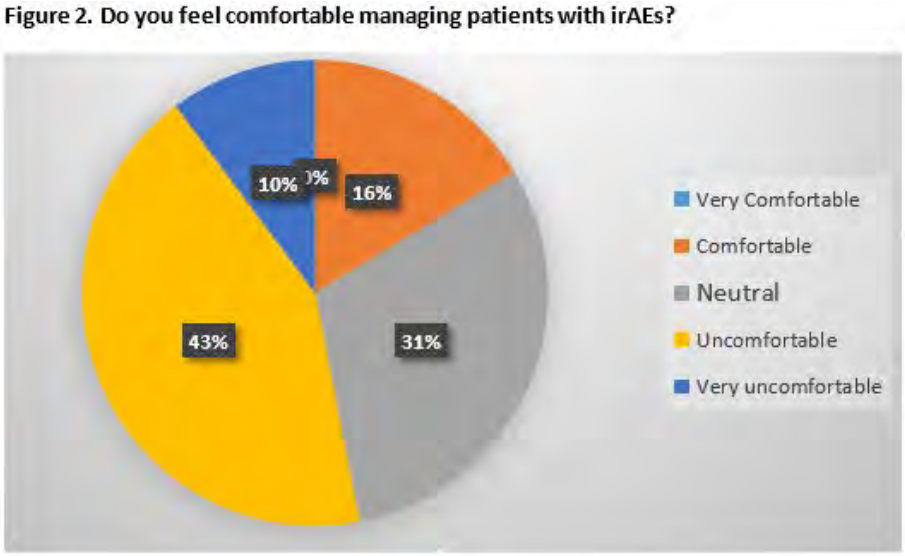

Figure 2. Do you feel comfortable managing patients with irAEs?

patients in the hospital, what types of irAEs were encountered, and comfort level with identifying and managing irAEs. A data use agreement between Cleveland Clinic and The Ohio State Wexner Medical Center was completed.

Results: The survey was sent to 90 hospitalists at the Cleveland Clinic and 92 hospitalists at The Ohio State Wexner School of Medicine with a response rate of 49/182 (27%). The majority of responders (61.2%) were between the ages of 30-40, and 28.6% were aged 40-50. Most were aware of ICIs and irAEs. 24/49 (49%) had encountered an irAE in the hospital, most often involving the gastrointestinal tract, lung or skin. Only about a third felt comfortable identifying the clinical presentation of irAEs (29.8%) and even fewer felt comfortable managing (16.3%) irAEs (Figures 1 and 2). Most expressed desire for more resources to learn about diagnosis and treatment of irAEs, with preferred tools being online learning modules (23/44), grand rounds (16/44), webcast (4/44) and other (3/44).

Conclusion: irAEs represent a new area of medicine that requires multidisciplinary collaboration for optimal management. New educational resources will be required for all medical professionals encountering these patients, including hospitalists.

Polyarthritis Workup in Primary Care Setting : How Are We Doing?

Ruhani Desai[1], Cassandra Calabrese[2], Neel Patel[3] and Jessica Donato[4], [1]Cleveland Clinic Foundation, DeLand, FL, [2]Cleveland Clinic, Cleveland, OH, [3]Case Western Reserve University, Cleveland, OH, [4]Cleveland Clinic Foundation, Cleveland

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Joint pain is a common presenting complaint in Primary Care with around 54.4 million adults diagnosed with some form of arthritis per 2013 CDC survey. Polyarthritis is defined as joint symptoms involving >/= 5 joints. It includes inflammatory and non-inflammatory arthritis. Rheumatoid arthritis (RA) is a primary consideration of inflammatory polyarthritis. Per the current American College of Rheumatology (ACR) classification criteria, the work up of inflammatory polyarthritis should include CBC, ESR, Rheumatoid Factor (RF), anti-cyclic citrullinated peptide antibody (anti-CCP), if RA is suspected. The specificity of anti-CCP underlies the rationale for checking RF and anti-CCP concurrently. We aim to understand the current practices of Polyarthritis work up in primary care physicians. (PCPs)

Methods: A cross-sectional survey was created via Redcap and administered to PCPs - Staff and Resident, across the Cleveland Clinic Enterprise in November 2019. It enquired about physician demographics, practice characteristics, knowledge and physician-reported ordering practices related to patients presenting with polyarthritis. We reviewed data from our electronic medical record (Epic) through the use of slicer-dicer, in order to identify patients with

Level of Training	PGY-1 PGY-2 PGY-3	33% 27% 20 41%
Number of patients with polyarthritis seen in last 6 months	Zero 1 to 5 6 to 10 11 to 20 >20	31% 53% 8% 4% 4%

*STJ = Stephanie Tubbs Jones (largest community site in East Cleveland)

Table 1. Physician Survey Respondent Demographics . @STJ = Stephanie Tubbs Jones

ICD-10 codes for Polyarthritis seen in the primary care setting between 9-2018 and 9-2019 and associated orders placed by providers. Statistical analysis was completed using descriptive statistics and Fisher's exact test of independence to find relationships between.

Results: The survey was sent to 325 physicians with a 28% response rate; the demographics of the 92 survey respondents are described in Table 1. Slicer-dicer data from EPIC showed RF was ordered 30% more than anti-CCP. Self-reported survey reveals similar discordance with 32% of respondents reported they would order both an RF and anti-CCP, and 33% would order only an RF. Both staff and residents report being unfamiliar with the guideline-based workup of polyarthritis (Table 2). Most respondents reported ordering an ESR and CRP (83% and 79%, respective-

Table 2: Physician-reported experience, attitudes and knowledge related to polyarthritis management in the ambulatory setting.

Survey Question	All respondents (N=92, % yes responses)	Staff Physicians (N=43, % yes responses)	Resident Physicians (N=49, % yes responses)
Do you evaluate patients with polyarthritis in your practice?	79%	95%	65%
Are you comfortable evaluating patients with polyarthritis?	62%	91%	37%
Are you familiar with guidelines for workup of polyarthritis?	18%	4%	35%
Do you have any difficulty finding orders for work up of polyarthritis?	37%	19%	53%

Table 2. Physician-reported experience, attitudes and knowledge related to polyarthritis management in the ambulatory setting.

Table 3: Physician-reported ordering practices for the workup of polyarthritis at the initial visit.

	All respondents (N=92)	Staff Physicians (N=43)	Resident Physicians (N=49)
CBC	25%	28%	22%
CBC with Diff	59%	58%	59%
Renal Functional Panel	11%	5%	16%
Complete Metabolic Panel	71%	88%	55%
ESR	83%	91%	76%
CRP	79%	84%	76%
RF	64%	74%	55%
Anti-CCP	39%	51%	29%
No lab Test	6%	0%	8%
RF and CCP ordering practices			
RF and Anti-CCP	31%	42%	22%
Only RF	33%	33%	33%
Only Anti-CCP	8%	9%	6%
No RF or CCP	28%	16%	39%

Table 3. Physician-reported ordering practices for the workup of polyarthritis at the initial visit.

ly), with 64% of respondents selected RF and 39% selected anti-CCP in the initial work-up of polyarthritis (Table 3). There was a statistically significant association between physician-reported evidence-based ordering of both an RF and anti-CCP with respondents being staff physicians ($P \leq 0.001$) and self-reported knowledge of guidelines ($P \leq 0.001$).

Conclusion: Physician-reported and observational EMR data suggest that the workup of polyarthritis in the primary care setting, as it relates to the ordering of RF and anti-CCP antibodies, is frequently incongruent with ACR recommendations. Guideline-discordant ordering practices are more common with residents and in those who report lacking knowledge of the guidelines. This suggests that physician experience and knowledge are the most likely underlying drivers of guideline-based workups of polyarthritis in the primary care clinic. We plan to address this issue by building an order set into our EMR that will provide decision support to promote workups of polyarthritis congruent with the ACR recommendations, thereby improving knowledge and practice.

Abstract Number: 1699

Training Residents to 'Choose Wisely' When Testing for Antinuclear Antibodies

Iman Qaiser[1], Tracy Koehler[1] and Richard Martin[2], [1]Mercy Health Saint Mary's, Grand Rapids, MI, [2]Michigan State University College of Human Medicine, Grand Rapids, MI

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

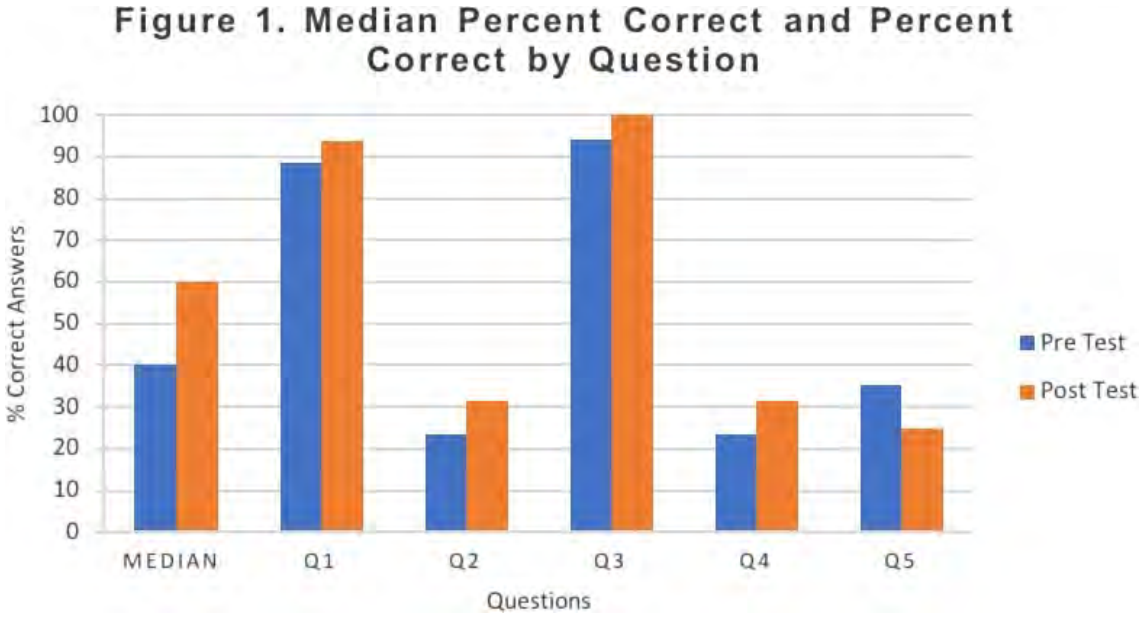

Figure 1. Median Percent Correct and Percent Correct by Questions

Background/Purpose: In many hospitals residents are the first providers to evaluate new patients. Consequently, residents often initiate the work-up of newly admitted patients. Multiple studies have shown that anti-nuclear antibody (ANA) testing is overutilized in both inpatient and outpatient settings [1,2]. Inappropriate ordering and misinterpretation of this test can lead to a subsequent cascade of unnecessary investigation which may lead to iatrogenic harm and waste resources. ABIM/ACR "*Choosing Wisely"* recommendations include: **Don't test ANA sub-serologies without a positive ANA and clinical suspicion of immune-mediated disease.**

Thus, it is vital that residents receive training about appropriate ANA testing. The aim of this study was to assess the effectiveness of an educational intervention on the appropriateness of ordering ANA testing in a community-based internal medicine program.

Methods: A 30-minute evidence-based presentation on ANA testing was developed and delivered to residents, medical students and faculty attending the weekly Internal Medicine (IM) resident didactics. Topics covered included:

1. ACR's "Choosing Wisely" recommendations for ANA testing
2. Clinical scenarios with discussions of appropriateness of ordering ANA in different patient cases
3. Methods used for ANA testing
4. Operating characteristics of ANA including: sensitivity, specificity and positive predictive value.
5. Interpretation of titers, patterns and specific ANA antibodies.

Five patient case scenarios evaluating each of the covered knowledge domains were created for use as a pre/post-test measure. These were administered as a pre and post-intervention test to all attendees. To assure the content validity of the presentation, the presentation and questionnaire were reviewed, edited and approved by the IM Residency Education Director (a hospitalist), an IM residency core faculty (a primary care physician), a Scholarly Activity support person and a board-certified rheumatologist. To assess the quality of test questions we conducted item analysis [3].

Results: Thirteen residents, three medical students and one faculty member participated. The median percentage of correct answers for the pre and post-tests were 40% and 60%, respectively (Figure 1). The number of correct

answers increased in 4 of 5 questions and decreased in the 5th question. The mean item difficulty index was 0.529 (range 0.235 – 0.941) and mean discrimination index was 0.305 (range 0.235-.353). All were above the 0.20 threshold which is considered satisfactory.

Conclusion: Residents should be educated regarding the ACR Choosing Wisely recommendations. The intervention overall showed improved knowledge scores on post-tests. Revision of test questions may provide better discrimination of knowledge gains.

Curricular Implementation of the Rheumatic Disease Patient Expert Program: The Students' Perspective

Eleni Sophocleous[1], Andri Phoka[2] and Konstantinos Parperis[3], [1]University of Cyprus Medical school, Nicosia, Cyprus, [2]Cyprus League Against Rheumatism, Nicosia, Cyprus, [3]University of Cyprus Medical School, Nicosia, Nicosia, Cyprus

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Medical education can be enriched by embracing patient involvement so that students can learn about rheumatic diseases (RMD) from patient experts. Patient experts have developed an expertise in their chronic disease by living with it, acquiring knowledge from courses and being empowered with the skills, needed to play an active role in teaching other patients and healthcare providers. In order to enhance students' knowledge about rheumatic diseases , improve their listening and communication skills, the Cyprus League Against Rheumatism in collaboration with University of Cyprus Medical School initiated a pilot, novel interactive educational activity. The objective of this study is to obtain feedback from the students about the program in order to assess the impact on the students' education and evaluate its integration in the school's curriculum

Methods: During the internal medicine rotation in year 4, the medical students had the opportunity to participate in a 2-hour session with a trained rheumatic disease patient expert. Each group comprised of 5 students, one attending rheumatologist and one patient expert. Through the session, the students had the opportunity to listen to the patient's journey, learn about symptoms and emotions, and were able to share thoughts and ask questions. The patient expert also demonstrated the hand musculoskeletal exam and students had the opportunity to practice with the patient and receive feedback. At the end of the academic year, an online survey was sent to 88 students by email and they

Question:	Strongly agree/agree response, number (%)
Were you satisfied with the introduction provided by the expert patient?	52 (91,2%)
Did you have enough contact/communication with the expert patient?	54 (93,1%)
Was the patient expert active in your teaching?	55 (93,2%)
Did the patient expert engage all students in relevant, meaningful learning?	53 (89,8%)
Was the expert patient committed to the program?	54 (91,5%)
Were you satisfied with the presentation of the hand and wrist anatomy by the expert patient?	39 (66,1%)
Were you satisfied with the demonstration of hand and wrist examination by the expert patient?	49 (83,1%)
Did you learn about assistive devices and aids for patients with rheumatic diseases?	45 (76,2%)
Did you learn about Rheumatic disorders from the patients' perspective?	54 (91,6%)
Did you learn about any possible stigma or stereotypes that may exist about rheumatic disorders?	49 (83,1%)
Do you feel that you improved your communication skills?	41 (69,5%)
Did you learn about the effect that patient autonomy has on the illness progression and management?	55 (93,2%)
Did the patient expert program help you grow as a professional?	45 (76,3%)
Was the learning environment safe and supportive?	56 (94,9%)
Did you have the opportunity to ask questions about the expert patient?	57 (96,6%)
Would you recommend the patient expert program to other students?	53 (89,8%)
Do you feel the patient expert program should be part of the medical school curriculum?	53 (89,8%)

Table. Patient expert program questionnaire results

were asked to fill out a 19-item question evaluation using a Likert-scale response and a free text comments section to assess the program.

Results: The voluntary response rate was 59 (67%) and 38(64,4%) were females. Overall, most of the participants had a favorable experience with the program (strongly agree/agree response on the Likert scale response), as shown in the Table. Fifty-four (93.1%) were satisfied with the communication they had with the patient, 55 (93.2%) felt the patient was active in their teaching, and engage them in meaningful learning, 53(89.8%).

Lower satisfaction was reported in the improvement of communication skills (n=41, 69%) and the hand and wrist anatomy presentation (n=39, 66%), however, 49(83%) of students were satisfied with the hand and wrist examination. Forty-five (76.3%) believe that the program helped them grow as professionals. The vast majority, 53(89%) of the students would recommend the program to their fellow students and they strongly believe that it should be a part of the medical school's curriculum (n=53, 89%).

Conclusion: The patient expert program is a novel educational activity that has a positive impact on medical students' education including enhanced communication skills, and professional growth. The students would recom-

mend it to their peers and they also believe it should be integrated into the school's curriculum. The program's implementation will raise awareness for RMD, might attract more students in the field of rheumatology, and promote the patient-centered care approach.

Development and Validity Evidence for a Tool to Assess the Performance of Shoulder Injections

Andrea Ramirez-Gomez[1], Amber Deptola[1], Colin Diffie[2], John Metzler[1], Peter McDonnell[1], Nathan Olafsen[1] and Lisa Zickuhr[3], [1]Washington University School of Medicine, St. Louis, MO, [2]Washington University, Saint Louis, MO, [3]Washington University/B-JH/SLCH Consortium, St. Louis, MO

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Shoulder pain is common. Subacromial bursa and intra-articular glucocorticoid injections can provide pain relief while avoiding the risks associated with systemic therapies. The American Board of Internal Medicine recommends internists achieve competence in arthrocenteses, but medicine residents at our institution report little practice doing them. Furthermore, validated assessment methods for these procedures are not published, making it difficult to decide when trainees achieve competence. We aim to develop and gather validity evidence for a tool that assesses the performance of shoulder injections.

Methods: A multi-disciplinary team of internists, physiatrists, and rheumatologists created a checklist and global rating score to assess the performance of shoulder injections. We used a modified Delphi to reach consensus on what to include as checklist items and assigned points to each one, weighing key maneuvers more heavily. We taught medicine interns the procedure on simulation models and observed them performing subacromial bursa injections for impingement syndrome during objective structured clinical examinations (OSCE). We graded their performances against our checklist, our global rating score, and a modified version of the Global Rating Scale for the Evaluation of Technical Skills in the Operating Room (GRSETSOR) that excluded items unique to surgery. Two graders evaluated 30% of the OSCEs. We totaled our checklist and global rating scale scores to compare with total GRSETSOR scores with Pearson's correlation coefficient in Excel. We calculated the intraclass correlation coefficient (ICC) to measure inter-rater reliability with SPSS (2019, Chicago, IL); 13 dual-graded OSCEs were needed to measure an ICC of 0.7 with 95% confidence.

Results: A global rating score and ten items related to pre-procedural, procedural, and post-procedural shoulder injection tasks met consensus for inclusion in our checklist. Checklist items totaled 28 possible points, and the global rating score ranged from one to nine points, set with behavioral anchors. 45 interns participated in our study, consenting to let us use their OSCE scores to calculate psychometrics. Out of the 45 participants, 19 had two raters evaluate their OSCE performances simultaneously. Our checklist and global rating score totals correlated well with the modified GRSETSOR scores ($r=0.71$, r^2 0.50, $p < 0.0001$, figure 1). ICC measured 0.835 (95% confidence interval 0.58-0.94) on evaluations with two raters.

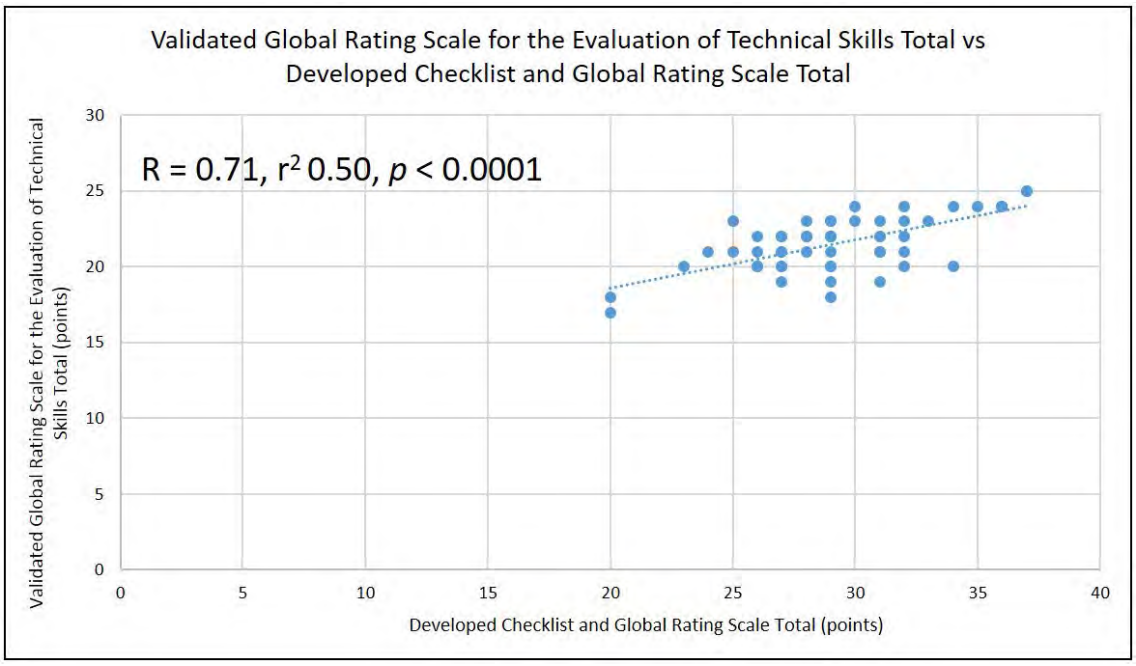

Figure 1. Correlation of validated Global Rating Scale for the Evaluation of Technical Skills in the Operating Room scores with total scores from our developed Checklist and Global Rating Score for Shoulder Injections. Pearson's correlation coefficient (r), R-squared (r2), and p value were calculated and demonstrate positive correlation between the two measures.

Conclusion: We developed a tool that assesses the performance of shoulder injections with strong supporting validity evidence. Our use of a multi-disciplinary team and modified Delphi method enhances content validity, while strong correlation of total scores with the modified GRSETSOR and high inter-rater reliability indicate relational and internal structure validity, respectively. This tool can be used to assess simulated performance of shoulder injections; further study is needed to measure its utility in clinical settings.

RA-Related Knowledge and Skills of Rheumatology Fellows Among 20 US Academic Institutions

Sandeep Agarwal[1], Rebecca Manno[2], Kristina Fajardo[3], Laura Simone[3], Jeff Carter[3] and Tamar Sapir[3], [1]Baylor College of Medicine, Houston, TX, [2]Johns Hopkins University School of Medicine, St. Thomas, Virgin Islands, U.S., U.S. Virgin Islands, [3]PRIME Education, LLC, Fort Lauderdale, FL

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Figure 1. Participants' Top Challenges in Managing Moderate to Severe RA

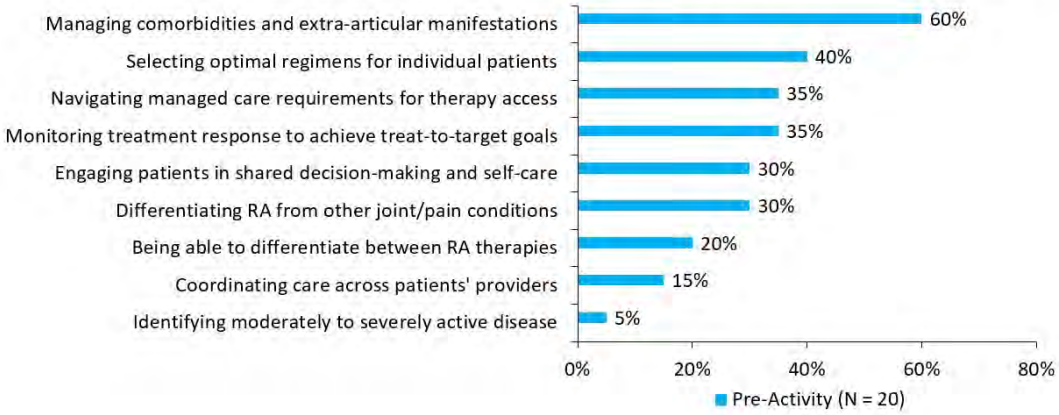

Figure 2. Participants' Confidence in Various Aspects of RA Management

Proportion of Rheumatology Residents/Fellows Who Rated High or Very High Confidence on a 5-point Likert Scale

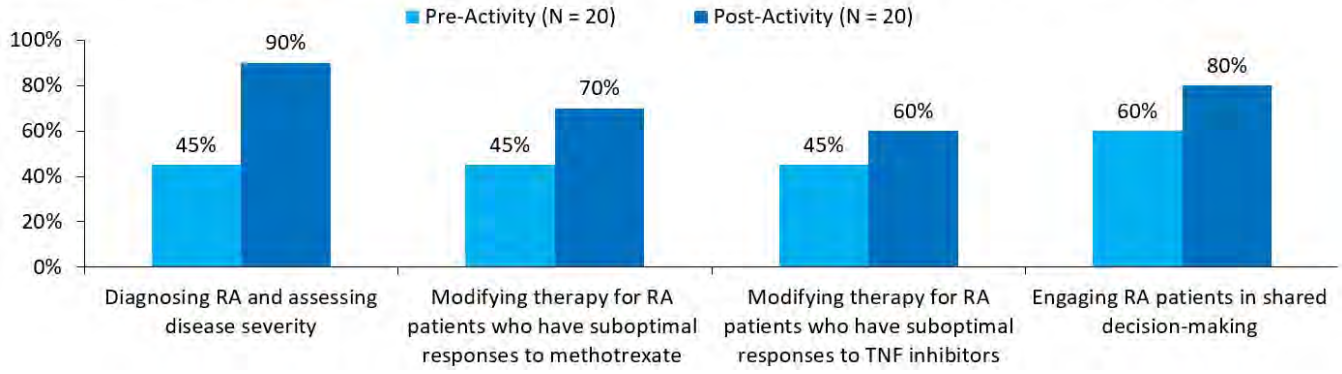

Figure 3. Participants' Confidence in Prescribing or Managing RA Therapies

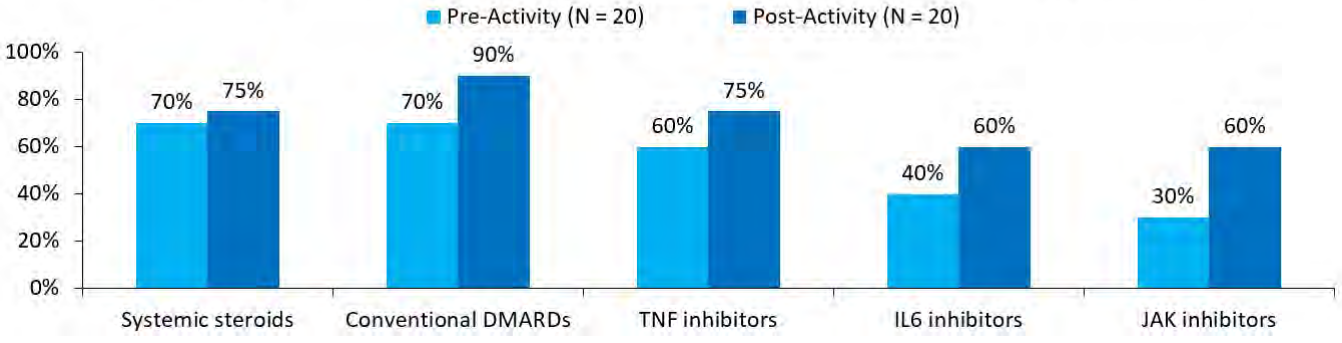
Proportion of Rheumatology Residents/Fellows Who Rated High or Very High Confidence on a 5-point Likert Scale



Background/Purpose: As the rheumatology workforce experiences an alarming shortage, it is critical that rheumatology fellows receive advanced training experiences to reinforce their commitment to rheumatology patient care and to strengthen their knowledge, competency, and skills in evidence-based management for common conditions like rheumatoid arthritis (RA). As part of a continuing medical education (CME) program in RA, we conducted a survey study in which rheumatology fellows rated their training in RA care.

Methods: On October 5, 2019, rheumatology residents and fellows from 20 US-based academic institutions were selected by their program directors to attend a 1-day educational workshop in RA. Three RA experts designed and led the interactive presentations, case-based discussions, and Q&A sessions. Pre-program surveys included items for trainees to assess and rate their challenges, confidence, and experience in various aspects of RA care. Post-program surveys included items assessing the impact of the education in these domains.

Results: Surveys were completed by 20 rheumatology residents and fellows (10% PGY2, 15% PGY3, and 75% fellows); 70% were female and had a median age of 31 years old. Participants indicated their main challenges in RA care are managing comorbidities and extra-articular manifestations (60%); selecting optimal regimens for individual patients (40%); navigating managed care requirements (35%); and monitoring treatment response to achieve treat-to-target goals (35%; Figure 1). Methods used by the participants to assess RA disease activity included joint examination (95%), clinical judgement (90%), laboratory tests (80%), validated disease severity scores (75%), and patient-reported outcomes (40%).

Before the education, low proportions of participants reported high confidence in performing various aspects of RA care, including diagnosing RA and assessing disease severity (45% with high or very high confidence), modifying therapy for patients with inadequate response to methotrexate (45%) or TNF inhibitors (45%), and engaging patients in shared decision-making (60%; Figure 2). After the education, participants reported increased confidence in these domains. In a separate question, 70% of participants reported high or very high confidence in prescribing or managing patients who are on systemic steroids and conventional synthetic DMARDs (Figure 3); lower proportions of participants reported high or very high confidence in prescribing or managing patients on TNF, IL-6, and JAK inhibitors (60%, 40%, and 30% respectively). These proportions also increased in post-program survey.

Lastly, the survey assessed participants' perspectives on strategies for addressing the shortage of rheumatologists in the US. Most participants (55%) indicated that creating collaborative models with primary care would have the largest impact on addressing patient needs in the immediate future.

Conclusion: Educational gaps exist among rheumatology residents and fellows in their confidence, perspectives, and experience in RA patient care. These findings can help develop additional education opportunities for fellows that help close these gaps.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Professional Education Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: While increasing numbers of women are choosing rheumatology, they remain underrepresented in academic medicine, particularly in senior leadership roles. The reasons for this are multifactorial but increased visibility of women leaders as role models has been proposed as one of the solutions. National and international academic congresses could promote gender equity among speakers.

In recent American College of Rheumatology (ACR) Annual Meeting, 42.8% of speakers and moderators were women in 2017, versus 47.0% in 2018 (1) and 49.1% in 2019 (personal communication). Such data were not available in Europe. The purpose of this study, within the remit of the EULAR Gender Equity Taskforce (2), was to describe the proportion of women invited as moderators or speakers to the European League Against Rheumatism (EULAR) Annual Congresses and National Congresses in Europe.

Methods: Using published congress materials, we determined the proportions of women included in the congresses as either moderators or invited speakers, for EULAR (2015-2019) and 2019 national congresses in France, Germany, Italy, Spain and UK. Individual speakers could be counted multiple times, if they had multiple roles within each congress. For EULAR congresses, we further categorized by Clinical/Science, Health Professionals in Rheumatology (HPR) and People with Arthritis and Rheumatism (PARE) sessions.

Results: The proportion of combined women speakers and moderators at EULAR between 2015 and 2019 varied from 39.7 to 43.2% with no obvious trend over time (Fig 1). Proportions of women moderators and invited speakers were similar. There were much greater proportions of female speakers in the HPR and PARE sessions (over 50% consistently) but these sessions represent < 30% of the EULAR congress invitations (Fig 1). Representation of women at national meetings in France and Germany appeared lower than that in Spain, the UK and at EULAR (Fig 2).

Conclusion: Women account for approximately 40% or less of invited moderators and speakers at the European congresses reviewed, whilst many national congresses are lower. A comparison with the available historical data on women moderators at EULAR in 2003 (16%) and in 2004 (19%) indicates formidable change over the last 15 years (3). Yet, our data does not show an improvement in gender equity in recent years at EULAR congresses, as was seen for the ACR meetings. The establishment of the EULAR Task Force on Gender Equity in Academic Rheumatology signals the commitment of EULAR to accelerate the pace of change in Europe.

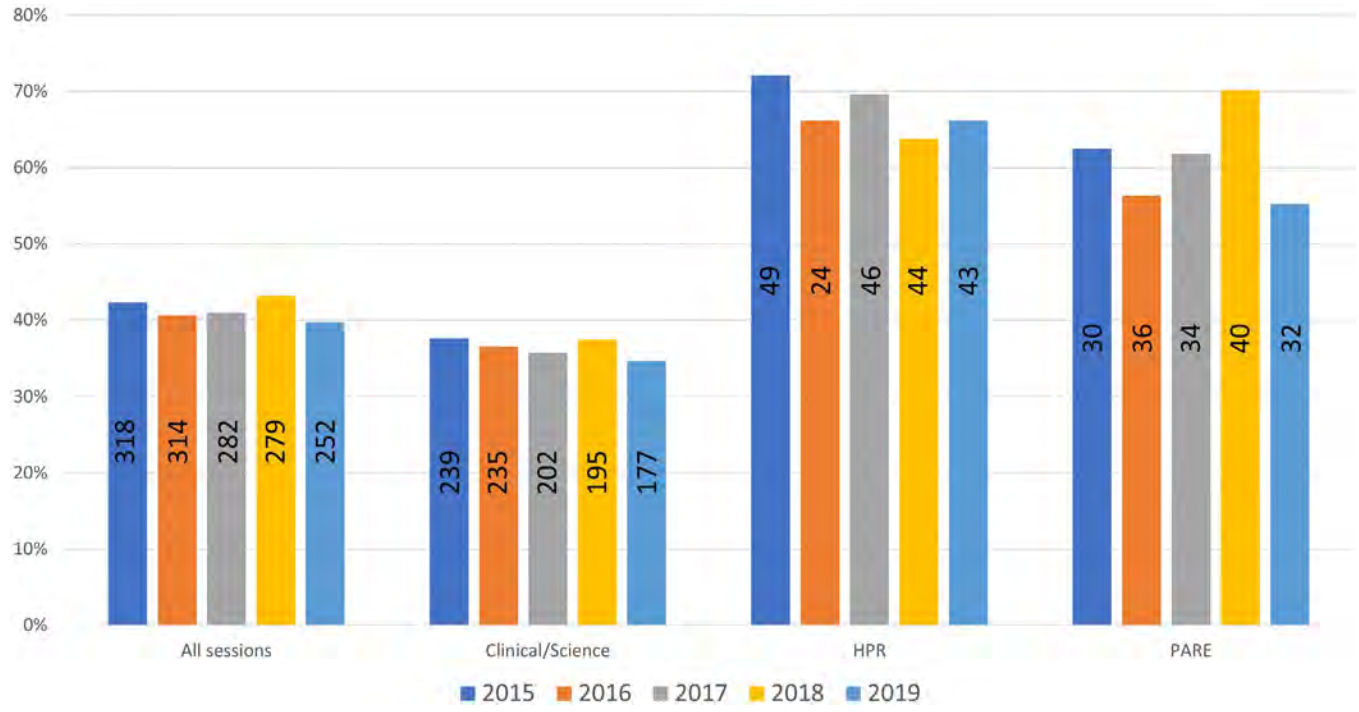

Figure 1. Proportion of women invited to participate in EULAR sessions, by type of session

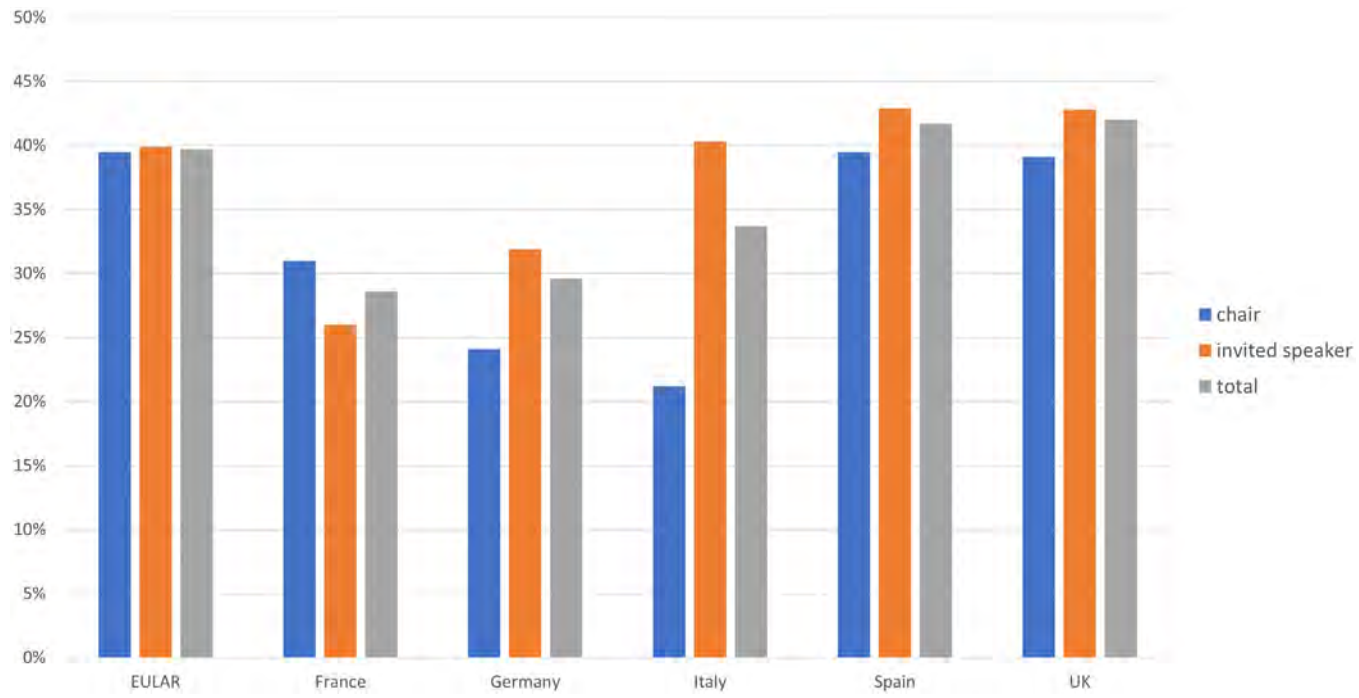

Figure 2. Proportion of women invited as chairs and Invited Speakers at EULAR and National Congresses in Europe in 2019

Identifying Primary Care Clinician Knowledge Gaps and Needs in Rheumatologic Care for Rural Veterans

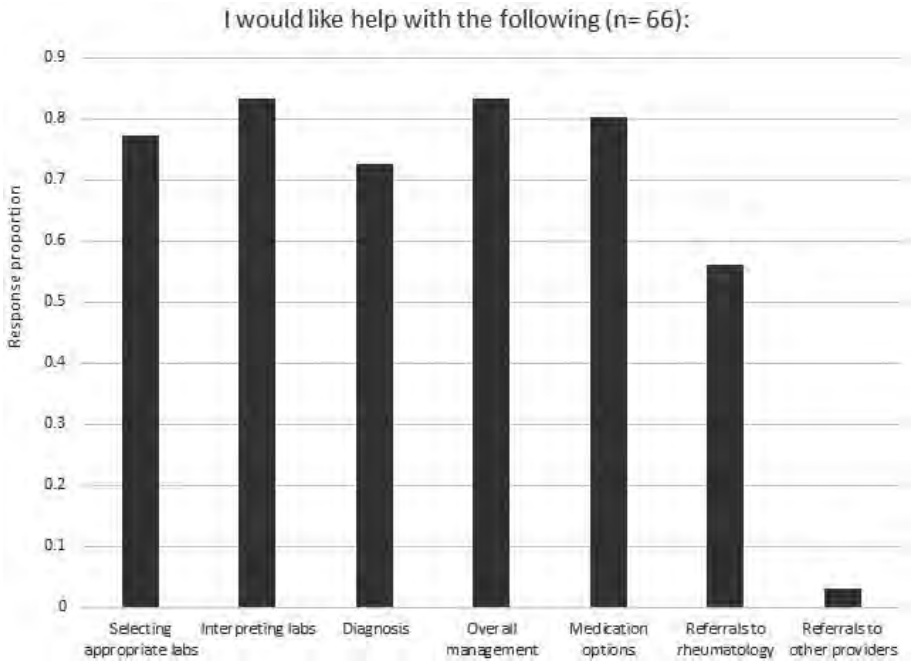
Rachel Matsumoto[1], Julie Kahler[1], Jacob Dougherty[1], Mary Bach[2] and Jennifer Barton[3], [1]VA Portland Health Care System, Portland, OR, [2]VA Puget Sound Health Care System, Seattle, WA, [3]VAPORHCS/OHSU, Portland, OR

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: One in 3 U.S. Veterans live with arthritis, the number one cause of disability. Despite this high prevalence, much needed care may be limited or delayed due to far distance to the nearest specialist, or even lack of specialists. There is an anticipated shortage of rheumatologists in the next 5 years in the Veterans Administration (VA). To overcome these barriers, VA adapted the Extension for Community Health Care Outcomes (ECHO) model for specialists to share expertise with primary care clinicians. Rheumatology VA-ECHO aims to improve care quality and access to care for Veterans who may not have access to a rheumatologist. Our objective was to identify gaps in knowledge and support for primary care clinicians serving rural Veterans in order to effectively expand the newly established Rheumatology VA-ECHO.

Methods: Two VA rheumatologists and a clinical psychologist developed a survey to assess primary care clinician confidence in diagnosing and caring for patients with select rheumatologic conditions. Additionally, the survey asked about clinician knowledge of, experiences with, and barriers to attending rheumatology-specific VA-ECHO sessions. Primary care clinicians in the Pacific Northwest who care for at least 50 rural Veterans were eligible to participate. A total of 313 clinicians were sent a REDCap survey invitation. Responses were collected for a period of 2 weeks. Data were analyzed using descriptive statistics.

Results: A total of 69 survey responses were collected (22% response rate). Respondents had a mean age of 52 (SD= 10.5), predominantly identified as female (60%), were physicians (43%) or nurse practitioners (43%), and had been serving rural Veterans for more than 5 years (65%). Most clinicians reported feeling somewhat comfortable taking a history (58%), performing a physical exam (60%), ordering labs (53%), interpreting labs (39%), and managing follow-up care (37%) for patients with rheumatologic conditions. Clinician confidence level in diagnosing and managing rheumatologic diseases varied based on disease (Table 1). Clinicians reported being very confident in diagnosing (77%) and managing (72%) osteoarthritis which contrasted with most clinicians reported no confidence in diagnosing (54%) and managing (56%) systemic sclerosis. While more than half of the sample had heard of VA-ECHO (64%), n (88%) had never attended a VA-ECHO session and 97% reported not knowing where to find past sessions. Despite this, 72% of respondents felt that they would benefit from additional rheumatology educational resources (Figure 1).



Proportion of respondents (y-axis) who reported they would like help with the following tasks (x-axis): selecting appropriate labs, interpreting labs, diagnosis, overall management, medication options, referrals to rheumatology or other providers.

Conclusion: Primary care clinicians caring for rural or highly rural Veterans agree that they would benefit from additional rheumatology specialty support and education around diagnosing and managing rheumatologic diseases. Despite this, few clinicians surveyed reported ever attending a Rheumatology VA-ECHO session, and even fewer knew how to locate an archived session. In order to continue to provide high quality rheumatologic care to rural Veteran populations, health systems should consider implementing organizational supports that draw awareness to and encourage use of resources such as Rheumatology VA-ECHO.

internal medicine residents after receiving a single in-person demonstration by a rheumatologist versus a virtual PowerPoint presentation for learning the musculoskeletal exam.

Methods: We compared two cohorts with one group receiving an in-person demonstration of a complete musculoskeletal exam by a board certified rheumatologist, while the second group received a virtual PowerPoint presentation with diagrams and explanations by the same rheumatologist. Each group received a pretest and posttest evaluating comfort level with assessing range of motion/palpation of joints, detecting synovitis, maneuvers used by rheumatologists as well as interest in rheumatology and satisfaction level. Residents used a ranking system on a scale of 1 through 5, with 1 being the least and 5 being the most comfortable or satisfied. Within each cohort, the pretest and posttest were compared using the Wilcoxon Matched Paired Signed Rank Test and the Wilcoxon rank sum (Mann Whitney) test was used for comparison between cohorts.

Results: Twenty four internal medicine residents ranging from postgraduate year (PGY) 1 to 3 completed the study. When comparing the pretest and posttest within each group, there was improvement in comfort level in most joint exams and maneuvers. Notably, while the in-person group showed an increase in comfort level with the Empty-can test, Phalen/Tinel's test and hand range of motion/palpation on their posttests, the PowerPoint group did not have statistical improvement.

The pretests between groups did not have many significant differences indicating comparable baseline comfort levels with musculoskeletal exam. When comparing posttests, the in-person group had a greater increase in comfort level

with most range of motion/palpation joint examinations and maneuvers (Table 1). It was particularly helpful to have in-person demonstration for the Modified Schober's, Occiput Wall, and Patrick/FABER tests. Between groups, we did not detect statistical difference in posttest comfort levels for hands and feet range of motion/palpation, detecting synovitis in hands and knees, Hawkins-Kennedy test, and Empty Can test. The learners did not report increase in rheumatology interest after both sessions. The in-person group had increased pretest interest which could potentially introduce selection bias into the study.

Limitations included the small sample size, low interest in rheumatology, and PowerPoint presentation given virtually due to COVID-19 pandemic. Strengths include the comparable groups and both teaching sessions were given by the same rheumatologist.

Conclusion: We found the in-person demonstration of musculoskeletal exam by a rheumatologist was more effective than a virtual PowerPoint presentation for learning most joint exams and musculoskeletal maneuvers among internal medicine residents. More studies are needed to further investigate the most effective teaching modalities for musculoskeletal learning and interest in rheumatology.

Abstract Number: 1706

Advanced Integrated Science Courses: A Novel Approach to Medical Student Science Education

Eli Miloslavsky[1], Henrike Besche[2] and John Flanagan[2], [1]Massachusetts General Hospital, Harvard Medical School,, Boston, MA, [2]Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Scientific research is at the core of evidence-based medicine, and is transforming medical care at an increasingly rapid pace. The ability of students to engage with science as life-long learners is an important goal of undergraduate medical education and critical for practicing rheumatologists. However, there has been a trend towards shortening pre-clinical science curricula and less than 25% of medical schools incorporate science education in the clerkship years and beyond. We developed and evaluated the Advanced Integrated Science Courses (AISCs), a novel approach to teaching science in the post core-clerkship phase of the new *Pathways* curriculum at Harvard Medical School.

Methods: Following a 14 month pre-clinical curriculum that teaches foundational science concepts, the AISCs in contrast focus on frontier research and how it influences medical care. Students choose from a menu of basic, translational and population science courses in order to personalize the experience and align it with their anticipated career path (Table 1). Courses such as Immunology, Medications and Evidence as well as Health Systems Science are particularly relevant to rheumatology.

The AISCs aim to develop students' ability to engage with science by focusing on teaching four generalizable skills: 1) find and critically evaluate research information, 2) communicate science to peers or patients, 3) evaluate how

Table 1 – AISCs by year first offered

2018	Added 2019	Planned additions in 2020 and 2021

	2018 Mean (SD)	2019 Mean (SD)
Overall satisfaction	1.80 (0.97)	1.49 (0.82)
Improved ability to find and critically evaluate research information	1.73 (0.94)	1.53 (0.77)
Improved my ability to communicate scientific information	1.75 (0.94)	1.45 (0.67)
Improved ability to evaluate influence of new research on patient care	1.64 (0.82)	1.47 (0.77)
Improved my ability to formulate questions suitable for investigation	1.78 (0.95)	1.51 (0.68)
Engaged me to apply critical thinking to solve problems	1.68 (1.11)	1.51 (0.91)
Clinical experiences contributed to my learning	1.75 (1.06)	1.68 (1.03)

* 1-5 scale with 1 being the highest rating and 5 the lowest

Student course ratings

research influences patient care, and 4) formulate questions and ideas for research and innovation. In addition to common learning objectives, the AISCs have common elements such as an experiential component to explore the bi-directional relationship between science and medicine, allocated time for self-directed learning, reliance on active learning techniques, required projects to facilitate student inquiry and a shared student evaluation method. The focus of the curriculum is on gaining skills rather than memorizing content.

Results: Over the first two years of the *Pathways* curriculum, of the 351 students enrolled in an AISC, 301 completed the course evaluation (86% response rate). Overall students rated the AISCs highly, 1.80 in 2018 and 1.49 in 2019 on a 1-5 scale with 1 being the highest score (Table 2). Most students felt that the AISCs improved their ability to accomplish each of the four course objectives. Free-text responses demonstrated that students valued the generalizable skills gained in the AISCs, exposure to cutting edge research, integration of clinical experiences, and the opportunity to interact with experts in the field as particular strengths of the curriculum.

Conclusion: We describe a novel spiral science curriculum with AISCs designed to engage students in the dialogue between medicine and frontier research, at a developmentally appropriate stage following the core clerkships. The focus of the curriculum on a common skill set to engage productively with frontier science, rather than content delivery, was a key factor in facilitating the development of a unified curriculum across multiple disciplines. Personalization and experiential learning components enabled the curriculum to be well received by the students and successfully engaged science faculty in undergraduate medical education.

Abstract Number: 1707

Development and Delivery of Continuing Education Interventions Promoting Shared Decision Making in Rheumatoid Arthritis

Richard Martin[1], Marianna Shershneva[2] and Lily Zurkovsky[3], [1]Michigan State University College of Human Medicine, Grand Rapids, MI, [2]Senior Administrative Program Specialist, Office of Continuing Professional Development University of Wisconsin School of Medicine and Public Health, Madison, WI, [3]Forefront Collaborative, Carmel, IN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: A core CMS policy goal is to improve patient experience by encouraging patient-centered care and shared decision making (SDM). However, SDM techniques are underutilized in rheumatology practice[1]. We created two continuing medical education (CME) activities that present ACR guidelines, treat-to-target (T2T) concepts, and SDM as vehicles to increase the equity of the provision of healthcare[2] for rheumatoid arthritis (RA).

Methods: A live workshop (LW) and an online course (OC) were designed to explain ACR RA guidelines, treat-to-target concepts as well as to demonstrate and practice using SDM with the goal of aligning treatment with patient goals. In interviews with four rheumatologists, we identified three 'swimming lanes' in the RA patient experience of choosing DMARDs. This led to the development of Option Table Patient Decision Aids (PtDAs) presenting three common choice sets for a patient considering starting their 1st, 2nd or 3rd DMARD. PtDAs provide specific probabilities about outcomes to structure clinical discussion with patients and their deliberation after the visit. See figure 1.

Nearly half of the 90-minute workshop for rheumatology providers was focused on teaching SDM. Learners listened to a skill-oriented explanation of SDM as a multi-step interviewing procedure based on observable domains[3]. They then viewed a demonstration of SDM by a faculty and a patient-actor. A PtDA was used to support the clinical encounter by providing facts about options and structuring comparison of attributes of the DMARDs in the choice set being considered. Finally, learners practiced a new SDM encounter supported by a PtDA in pairs followed by debriefing.

A 75-minute online activity was developed based on the recorded workshop and disseminated on myCME.com to a broad audience of rheumatology providers and other clinicians.

Results: There were 54 participants in the LW and 1337 in the OC. After the interventions, 92% and 93% believed they could effectively engage in T2T-SDM, 78% and 93% believed the PtDA enhanced their learning of SDM. Comparing pre-post knowledge assessment, both groups (LW 56 to 82% and OC 57 to 99%) increased their ability to recognize patient statements consistent with being engaged in SDM. 59% of LW and 43% of OC intended to make changes in their practice as a result of participation

Conclusion: Both LW and OC reinforced positive attitudes towards learning about T2T and SDM. Modeling and active practice of SDM using a PtDA influenced beliefs, knowledge, and intentions to change practice related to SDM.

Option Table Decision Aid: For a Patient With Rheumatoid Arthritis Considering Starting Their Third DMARD

	RECOMMENDED OPTIONS				
Medication options	**Infused anti-TNF (ie, infliximab)**	**T-cell modulator (ie, abatacept)**	**B-cell depletion (ie, rituximab)**	**Anti-IL-6 (ie, tocilizumab)**	**JAK inhibitor (ie, tofacitinib or baricitinib*)**
Year of FDA approval	1999-2009	2005	2006	2008	2012, 2018*
How taken	Infusion	Injection or infusion	Infusion	Injection or infusion	Pill
Frequency	Every 4-8 weeks	Injection weekly or infusion monthly	At weeks 0 and 2, then every 6 months	Injection every 1-2 weeks or infusion monthly	Once daily
Benefits					
Power to suppress arthritis (ACR 20)	60 of 100 will improve	68 of 100 will improve	52 of 100 will improve	59 of 100 will improve	56 of 100 will improve
Power to slow joint damage (0-4+)	4+	4+	4+	4+	4+
Harms					
Risk of serious infection (event/100 patient years of use)	6 in 100	3 in 100	5 in 100	6 in 100	3 in 100
Other risks and side effects	Infusion reaction, immune reaction, skin cancer	Worsening COPD	Infusion reaction, immune reaction, rare infection (PML)	↑ liver test, ↑ lipids, ↓ blood counts, immune reaction	↑ liver test, ↑ lipids, ↓ blood counts, diverticulitis, blood clots*
Special population considerations	Caution with pregnancy; TB reactivation, fungus, or virus infection; worsening heart failure	Avoid pregnancy; avoid in hepatitis B; TB reactivation, fungus, or virus infection	Avoid pregnancy; avoid in hepatitis B; TB reactivation, fungus, or virus infection	Avoid pregnancy; TB reactivation, fungus, or virus infection; diverticulitis; BCP less effective	Avoid pregnancy; TB reactivation, fungus, or virus infection; caution in kidney disease
Practical Issues					
Safety monitoring plan (ACR guidelines)	Pretreatment: CXR, hepatitis B and C, TB test; labs every 6 months; yearly TB test	Pretreatment: CXR, hepatitis B and C, TB test; labs every 6 months; yearly TB test	Pretreatment: CXR, hepatitis B and C, TB test; labs every 6 months; yearly TB test	Pretreatment: CXR, hepatitis B and C, TB test; labs every 1-3 months; yearly TB test	Pretreatment: CXR, hepatitis B and C, TB test; labs every 3 months; yearly TB test
What is my monthly cost? (dependent on health plan)					

DMARD=disease modifying anti-rheumatic drug. ACR=American College of Rheumatology. COPD=chronic obstructive pulmonary disease. PML=progressive multifocal leukoencephalopathy. BCP=birth control pills. TB=tuberculosis. CXR=chest x-ray.

Itching to Learn: Infusion Reactions Curriculum for Medicine Trainees

Anastasiya Bagrova[1], Lena Eder[1] and Lisa Criscione-Schreiber[2], [1]Department of Medicine, Duke University Medical Center, Durham, NC, [2]Division of Rheumatology and Clinical Immunology, Department of Medicine, Duke University Medical Center, Durham, NC

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Comfort level with managing acute infusion reactions	Pre-curriculum	Post-curriculum
Extremely comfortable	0.00%	60.71%
Somewhat comfortable	38.89%	35.71%
Somewhat uncomfortable	61.1%	3.57%
Extremely uncomfortable	0.00%	0.00%

Table 1. Comfort level with managing acute infusion reactions before and after exposure to the infusion reactions curriculum

Confidence in managing acute infusion reactions	Pre-curriculum	Post-curriculum
Extremely confident	0.00%	67.86%
Somewhat confident	50.00%	32.14%
Somewhat not confident	34.38%	0.00%
Not at all confident	15.63%	0.00%

Table 2. Confidence in managing acute infusion reactions before and after exposure to the infusion reactions curriculum

Background/Purpose: Despite frequent use of infusion therapies, previous studies have demonstrated that trainees are poorly knowledgeable in managing infusion reactions, resulting in patient safety concerns. There are no easily implementable curricula addressing this barrier. The goal of this project was to refine, implement, and evaluate a concise and exportable curriculum on infusion reactions management for rheumatology fellows.

Methods: Fellows from 6 training programs completed an online pre-curriculum survey. Participants were emailed a link to a 9-minute educational video describing the pathophysiology and management of infusion reactions with a focus on anaphylaxis. The following week, fellows managed a simulated infusion reaction in a telephone conversation with "an infusion nurse." Two examiners scored simulation performance on a standardized form, then provided immediate feedback. A post-curriculum survey assessed changes in self-reported confidence and comfort managing acute infusion reactions.

Results: *Pre-curriculum*. Learning about infusion reactions was deemed "extremely" or "somewhat useful" by 92% (30/32). While 72% of respondents indicated no prior formal training on identification or management of infusion reactions, 54% had been directly involved in managing an acute infusion reaction; 87% of those were involved in more than one. Of fellows who had managed infusion reactions, 61.1% reported feeling "somewhat uncomfortable" doing it (Table 1). Exactly one half of the participants were "somewhat not confident" or "not at all confident" in doing so (Table 2).

Simulation. Fellows generally performed well, especially on the topics directly addressed in the video. However, learners across institutions missed similar expected tasks of infusion reaction management, such as activating EMS, ordering oxygen, notifying family, and adding the medication to the allergy list.

Post-curriculum. After completing the curriculum, 96% (27/28) of respondents reported feeling "extremely comfortable" or "somewhat comfortable" managing infusion reactions. All participants reported feeling either "extremely confident" or "somewhat confident" in their ability to manage these reactions. Fellows provided overwhelming positive feedback after the simulation.

Conclusion: This short curriculum successfully addressed a knowledge gap in management of acute infusion reactions in rheumatology fellows. Fellows agreed that the curriculum was needed. Respondents across institutions missed performing similar tasks on the infusion reaction simulation. Completing the curriculum increased participants' comfort and confidence in their ability to manage infusion reactions. Ongoing improvements are focused on creating a fully online interactive curriculum including an updated simulation script, a high-fidelity simulation exercise with real-time feedback, and expanding the curriculum to medicine residents and other subspecialty fellows.

Abstract Number: 1709

Teaching Clinical Application of Bayesian Reasoning in Rheumatology to Internal Medicine Residents and Medical Students

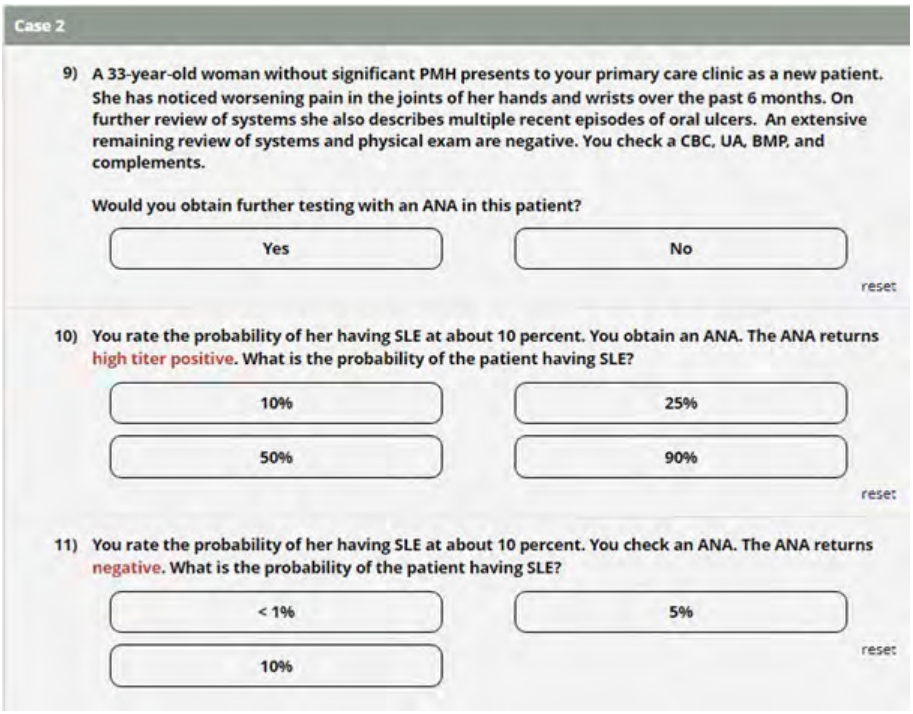
Joshua Gavin[1], Kristen Fadel[1], Yashswee KC[2], Evan Dombrosky[3], Sandra Johnson[4], Huzaefah Syed[5], Beth Rubinstein[6], Stamatina Danielides[6] and Abhishek Nandan[7], [1]Virginia Commonwealth University School of Medicine, Richmond, [2]Virginia Commonwealth University School of Medicine, Henrico, VA, [3]Virginia Commonwealth University School of Medicine, Glen Allen, VA, [4]Virginia Commonwealth University Health Systems, Richmond, [5]VCU Health, Richmond, VA, [6]Virginia Commonwealth University School of Medicine, Richmond, VA, [7]VCUHS and VA Medical Center- Richmond, VA, Richmond, VA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence-based medicine (EBM) is becoming an increasingly important skill in the clinical application of diagnostic reasoning. Didactic lectures focusing on EBM concepts are a common tool to teach trainees the skills to accurately assess and apply scientific information into clinical practice. However, this instruction format has not been demonstrated to be optimal for retention and application of knowledge. Other methods for learning statistics and critical appraisal certainly exist and include modules, self-directed programs, and problem-based learning.

We sought to create a brief module with the inclusion of adult learning theories to optimize delivery of knowledge of EBM concepts to residents and medical students and to assess the yield of the learners. Our purpose was to assess whether the use of this module would: 1) Increase learner comfort in the clinical application of likelihood ratios and 2) Improve appropriate application of rheumatologic testing at our center with this intervention.

Methods: The study was conducted at Virginia Commonwealth University School of Medicine (VCU SOM). We developed a short PowerPoint-slide based module with pre and post-test focused on application of Bayesian reasoning. Internal medicine residents and medical students on their rheumatology rotations were asked to complete our module. The pre-test was done immediately prior to the module and the post-test immediately following completion of the module. The test included 14 case-based questions evaluating application of Bayesian reasoning. An example



Example of the Survey Questions

of a typical case-based application question is included in Figure 1. Data was collected and stored on a secure cloud-based program, then analyzed using the student's t-test.

Results: A total of 12 trainees completed the pilot module with the pre-test and post-test. Five of the trainees were internal medicine residents and seven trainees were medical students. Baseline mean pre-test scores were 66.6% correct and the mean post-test score was 79.8%. Pre-test scores (P-Value = 0.0701) and post-test scores (P-Value = 0.0809) were not significantly different when comparing internal medicine residents to medical student. Completion of the EBM module led to significant improvement from pre- to post-test scores with a mean improvement of 13.20% (P-Value = 0.0147) as well as an improvement in comfort level of 21 points overall on a 1-100 scale (P-Value = 0.0082.

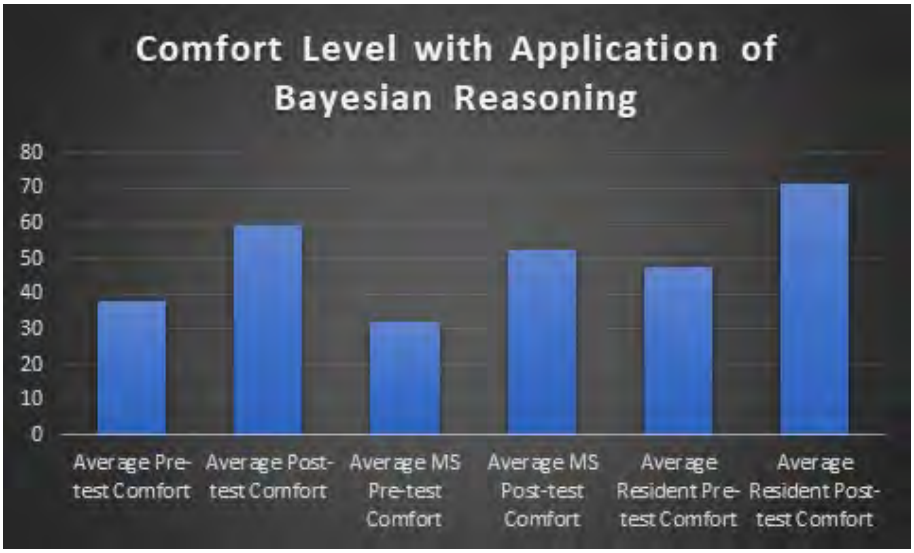


Figure 2. Comfort Levels from 0-100

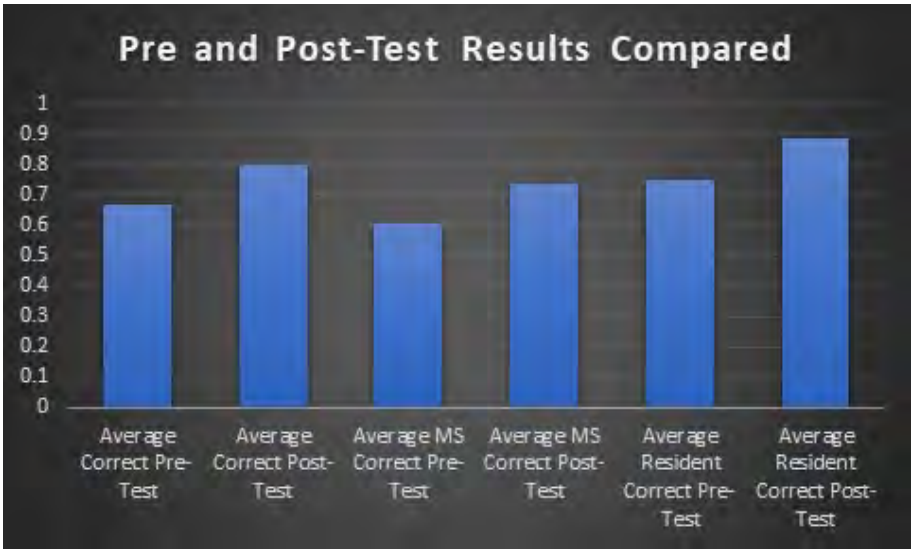

Figure 3

Conclusion: Our pilot study suggests that integrating rheumatology-oriented EBM didactics within internal medicine residency curriculum and internal medicine rotation of medical students results in immediate improvement and comfort with application of EBM concepts. The growing complexity of diagnostic testing in medicine and especially rheumatology highlights the importance of applying approachable and pragmatic methodology to appropriately utilize these tools. Re-testing after 12 months to evaluate durability of knowledge is a logical next step. We plan to continue to encourage trainee participation in our module. The module serves as a portion of the larger virtual curriculum that we are building at the VCU SOM for didactics in rheumatology.

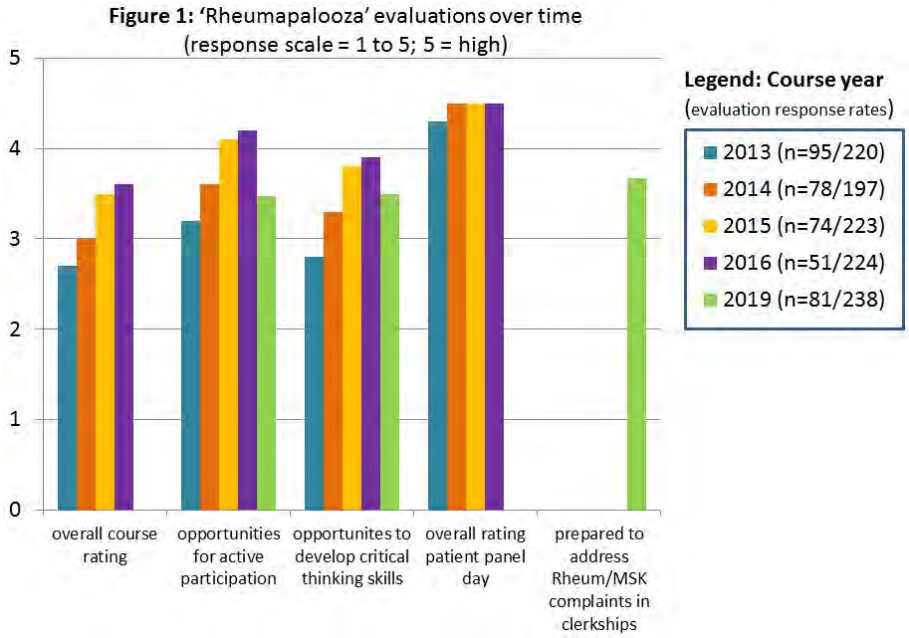
Abstract Number: 1710

Remote Rheumapalooza: Reboot of a Foundational Rheumatology Curriculum for Pre-Clinical Medical Students in the Era of Virtual Learning

Kristen Hayward[1], Meghan Kiefer[2] and Helen Emery[3], [1]Seattle Children's Hospital, Seattle, WA, [2]University of Washington School of Medicine, Seattle, WA, [3]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The original Rheumapalooza course was a required, independent 12 hour curriculum for pre-clinical medical students in the UWSOM from 2010 - 2016[1,2]. In 2015, the UWSOM implemented a new organ-based, flipped-classroom curriculum for entering students. Pre-clinical coursework was condensed from 24 to 18 months. In the new 'Foundations' curriculum students are divided between 6 regional campuses across five states (WA, WY, AK, MT, ID) for instruction. Site autonomy in delivery methods is encouraged, however course objectives,



Rheumapalooza Course Evaluations Over Time

learning opportunities and assessments must be uniform. These changes presented new educational challenges for the delivery of rheumatology content.

Methods: Rheumatology components are now taught throughout disparate courses including immunology and musculoskeletal blocks. After Foundations, preclinical students enter a 3 month distance learning course to prepare for the USMLE Step exam and to transition to required clerkships. A 5 session day of basic rheumatology content was developed as part of the final week and implemented in 2018. 'Remote Rheumapalooza' was adapted from previous course content: Introduction to Medical Decision Making, Developing Approach to Musculoskeletal Complaints, MSK radiology, Case Based Rheumatology and Rheumatology Patient Panel. Sessions were offered in a webinar format via ZOOM to allow synchronous student participation across the region. Attendance was on a 'selective' basis; students were required to attend a minimum number of hours during the week. Session evaluations were required to claim credit for participation and allowed tracking of virtual attendance. Based on positive feedback, 'Remote Rheumapalooza' was offered again in winter 2019. In March 2020, the COVID-19 pandemic led to closure of all UW campuses and recorded sessions from 2019 were re-utilized for distance learning.

Results: Student attendance at one or more Rheumatology sessions in 2019 was relatively high (range: 67-146/238). Individual sessions were rated 'useful and practical' (mean rating: 4.3-4.6; 1-5 Likert Scale). Comparison to parallel evaluation questions from the historical course indicated comparable ratings, with perhaps a loss in 'opportunities for active participation' (Figure1). Qualitative feedback highlighted the importance of hearing the patients' stories and observing how physicians interacted with patients. Some students requested more general musculoskeletal review and less detailed rheumatology content.

Conclusion: Implementation of a 5 hour webinar format 'Remote Rheumapalooza' was associated with high student attendance and comparable student ratings to the prior in-person course. Replication of the 'tour' of patient panel physical findings was most challenging from an educational design standpoint, however, students still found value in hearing patients' stories via webinar. This work has important ramifications given increasing reliance on distance

learning. Additional work is needed to enhance active participation in virtual sessions and to evaluate retention of concepts during clerkships.

Abstract Number: 1711

Musculoskeletal Sarcoidosis Learning Module for Internal Medicine Trainees: Developing a Rheumatology Curriculum

Kristen Fadel[1], Evan Dombrosky[2], Huzaefah Syed[3], Joshua Gavin[1], Abhishek Nandan[4], Stamatina Danielides[5], Beth Rubinstein[6], Yashswee KC[7] and Sandra Johnson[8], [1]Virginia Commonwealth University School of Medicine, Richmond, [2]Virginia Commonwealth University School of Medicine, Glen Allen, VA, [3]VCU Health, Richmond, VA, [4]VCUHS and VA Medical Center- Richmond, VA, Richmond, VA, [5]Virginia Commonwealth University School of Medicine, Richmond, VA, [6]Virginia Commonwealth University, Richmond, VA, [7]Virginia Commonwealth University School of Medicine, Henrico, VA, [8]Virginia Commonwealth University Health Systems, Richmond

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a systemic, multi-organ disease frequently overlooked in the development of a differential diagnosis. Although typically considered a pulmonary disease, management decisions often fall to the Rheumatologist especially in the context of sarcoid-related arthritis or the initiation of immunosuppressive therapy. We sought to create an interactive module to train internal medicine residents and medical students in the diagnosis and management ofmusculoskeletal sarcoidosis. This module is a part of a larger module-based Rheumatology curriculum undergoing development at Virginia Commonwealth University School of Medicine (VCU SOM). Our goal is to assess whether this module improves internal medicine trainee's understanding of musculoskeletal sarcoidosis.

Methods: This study was internally conducted at VCUSOM. We developed a module with a pre- and post-test focused on the varying presentations of musculoskeletal sarcoidosis. The module was based on a clinical case presentation to allow trainees to demonstrate their ability to obtain a thorough history and physical exam, order appropriate labs and imaging, create an appropriate differential diagnosis for musculoskeletal sarcoidosis, and reach an accurate final diagnosis. The module progresses to cover treatment options and reviews the different subtypes of musculoskeletal sarcoidosis, ultimately covering joint, muscular, and osseous sarcoid presentations. Internal medicine residents and medical students were asked to complete our module. The pre-test was done immediately prior to the module and the post-test immediately following completion of the module. The test included eight questions evaluating knowledge of the varying clinical presentations, features, and treatment of musculoskeletal sarcoidosis. The questions are included in Figure 1. Data was collected and stored on a secure cloud-based program, REDCap, and then analyzed using the students' t-test.

Figure 1. Pre- and post-test questionnaire.

#	Question	Answer Choices
1	What is the most common musculoskeletal manifestation of sarcoidosis?	- Chronic sarcoid arthritis - Heerfordt's syndrome - Lofgren's syndrome - Jaccoud's arthropathy - Sarcoid monoarthritis
2	Which manifestation of sarcoidosis does not require a biopsy?	- Lofgren's syndrome - Jaccoud's arthropathy - Sarcoid monoarthritis
3	What is typically seen histopathologically in sarcoidosis?	- Caseating granulomas - Non-caseating granulomas
4	What is the triad of Lofgren's syndrome? (Select 3)	- Arthritis - Hypercalcemia - Hilar lymphadenopathy - Erythema nodosum - Elevated 1,25(OH)2 Vitamin D - Elevated ESR
5	Which muscle groups are typically involved in sarcoid myopathy?	- Proximal - Distal
6	Which bones are most commonly affected in osseous sarcoid?	- Axial - Peripheral (hands) - Peripheral (knees)
7	What other diagnosis is considered in the differential for osseous sarcoid?	- Free text
8	Which immunosuppressant can be used in the treatment of sarcoidosis?	- Calcineurin inhibitors - DMARDs - Interleukin inhibitors

DMARDs = Disease modifying anti-rheumatic drugs

Figure 1. Pre- and post-test questionnaire.

Results: The module was tested by nine medical students and one fellow at VCU SOM. We observed a significant difference between the percentage correct for the pre- and post-tests (Figure 2), from an average of 46.25% to 90% (P-Value = < 0.001). Feedback was consistently positive and the comments are summarized in Figure 3.

Figure 2. Results of pre- and post-tests.

ID	Pre-test Percent Correct (%)	Post-test Percent Correct (%)
1	62.5	100
2	25	100
3	25	87.5
4	37.5	87.5
5	25	87.5
6	25	75
7	50	87.5
8	87.5	100
9	62.5	87.5
10	62.5	87.5
Average	46.25	90

Figure 2. Results of pre- and post-tests.

Figure 3. Summary of student feedback.

Summary of Student Feedback
"Great module. I liked the slides saying what you would rule out and the reasons for ruling them out. I would love some prognostic information… it would be nice to get some insight on mortality and morbidity so we know how to frame the disease when talking to patients."
"I thought the module was really great overall. I love the "ruling out" step. So many modules I do have the "what differential to consider?", but not so much the "how do you rule these things out?" logic."
"I think the presentation is great! The information is certainly all there, might be good to include a few more relevant pictures of imaging findings."
"All information was very concise and straight forward. Would consider including any associated conditions or specific pearls to pay attention to in the clinic about how to manage these patients (like what struggles they encounter or challenges to caring for them). Overall, very clear and great!"

Figure 3. Summary of student feedback.

Conclusion: Our pilot study suggests that integrating a sarcoidosis module within the internal medicine residency curriculum and the pre-clinical medical student curriculum may result in improved knowledge and recognition of musculoskeletal sarcoidosis. We plan to continue to recruit medical trainees to participate in our module, which serves as a portion of the larger virtual curriculum that we are building at the VCU SOM for didactics in rheumatology. We hope in future studies to evaluate a larger sample size and evaluate trainees for long term retention of knowledge gained through this module.

Abstract Number: 1712

Implementation of a Musculoskeletal Ultrasound (MSUS) Curriculum in an Academic Rheumatology Fellowship Within an Integrated Health System: A Four-Year Experience

David Bulbin[1], Brian Oppermann[2], Jonida Cote[3], David Pugliese[4] and Alfred Denio[5], [1]Geisinger Health System, Danville, PA, [2]Geisinger Medical Center, State College, PA, [3]Geisinger Medical Center, Danvile, PA, [4]Geisinger Health System, Wilkes Barre, PA, [5]Geisinger Medical Center, Danvill, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Professional Education Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal Ultrasound has become a significant training tool in rheumatology fellowships. A recent survey showed 94% of rheumatology fellowships have implemented a teaching program for US with 41% having implemented a curriculum. The ACR developed a teaching curriculum as a model for programs in 2019, updating the core curriculum from 2015. Our institution started MSUS training in 2012 as part of our training programs career tracks, which include medical education, quality improvement and osteoporosis management. This was revamped in 2016. We report the implementation of our MSUS curriculum.

Methods: MSUS training involves a two-year curriculum. The first year introduces the basics of ultrasound (US) and the second year is tailored to those pursuing MSUS as part of their career path. The curriculum was designed from the blueprint for RhMSUS certification and milestones were created for skills necessary to master MSUS (Table 1).

The first year focuses on developing basic US skills concentrating on understanding how to use and maintain equipment, learning basic anatomy based on 2017 EULAR guidelines and USSONAR US protocols for US scanning and acquiring studies. Fellows participate in monthly US clinics and didactic sessions with teaching based on a scanned area of interest. There are 8 hours of clinic and 6 hours of didactics monthly.

Table 1. Milestone requirements for 1st year MSUS ultrasound curriculum

MSUS COMPETENCY/ GOALS	Medical Knowledge	Patient Care	Practice-Based Learning	Systems Based Practice	Interpersonal & Communication Skills	Professionalism
First Year – PGY4	1. Learning the basic anatomy to recognize normal structures on ultrasound examinations 2. Recognize the abnormalities consistent with specific pathology and the definition of those pathologies as dictated by the literature. 3. Select the most appropriate transducer, based on patient and examination factors, in order to obtain optimal images. 4. Hands-on training sessions and didactics to improve technical skills	1. Educate the patient by explaining the role of and alternatives to the ultrasound examination in order to establish consent. 2. Understand specific reason for ordering laboratory tests and cost of laboratory tests used in pediatric rheumatology cases. 3. Demonstrate competency and sterile technique in joint aspiration in children.	1. Recognize when ultrasound would assist in establishing a diagnosis by analyzing clinical information and diagnostic testing in order to identify appropriate patients. 2 State the indication for the ultrasound study in order to document the reason for the examination. 3. Maintain a clinical portfolio of Ultrasound studies performed	1. Modify the environment by adjusting ambient lighting and temperature in order to optimize the ultrasound examination. 2. Position the patient and the ultrasound machine appropriately in order to allow safe and comfortable performance of the examination and to obtain high quality diagnostic images.	1. Label all images and clips using appropriate sonographic terminology in order to identify the examined structures. 2. Save images and clips using a system that is reliable and that permits retrieval in order to provide for documentation and report generation 3. Clearly discuss risks, benefits and procedures in children and parents of children with rheumatic diseases.	1. Recognize clinical scenarios where ultrasound use is inappropriate, not indicated, or outside the scope of the practitioner's expertise in order to optimize patient management and maintain the credibility and integrity of ultrasound in the field of rheumatology 2. Maintain equipment in good working order by conducting regular inspections and making necessary repairs in order to ensure acquisition of reliable images. 3. Clean the transducer with a disinfectant after each examination in order to prevent the transmission of infection. 4. Demonstrate integrity in reporting clinical findings of your ultrasounds

Table 2. Milestone requirements for second year MSUS ultrasound curriculum

MSUS COMPETENCY/ GOALS	Medical Knowledge	Patient Care	Practice-Based Learning	Systems Based Practice	Interpersonal & Communication Skills	Professionalism
Second Year – PGY5	1. Exhibit mastery of the ultrasound anatomy to recognize normal structures 2. Continue to improve skills at recognizing pathology in musculoskeletal ultrasound 3. Adjust B-mode settings by applying knowledge of sonographic principles for individual probes and body regions in order to obtain optimal images 4. Adjust Doppler settings by applying knowledge of sonographic principles for individual probes and body regions in order to obtain optimal images. 5. Lead didactic and hands on training session with the ultrasound machine	1. Determine if ultrasound guidance is likely to improve the outcome of a planned procedure by reviewing findings of the examination in order to maximize the probability of effective treatment. 2. Develop a differential diagnosis of findings on imaging studies.	1. Determine the appropriateness of ultrasound guidance of an intervention by incorporating best available evidence in order to optimize patient management. 2. Use aseptic technique as it applies to ultrasound-guided procedures in order to minimize the risk of infection. 3. Identify patient conditions where ultrasound can evaluate treatment response and disease progression, based on the best available evidence, in order to optimize patient management and education	1. Correlate ultrasound findings with the physical examination, available laboratory tests, and other imaging modalities in order to integrate diagnostic testing into a comprehensive management plan. 2. Refer patients for further evaluation when the practitioner is unable to answer the clinical question using the ultrasound examination in order to optimize care.	1. Report the technical components and quality of the examination when appropriate in order to clarify the context of examination. 2. Report ultrasound findings and conclusions using sonographic terminology in order to document findings clearly and guide further care. 3. Be able to maintain a sound relationship with patients over the course of the fellow's fellowship.	1. Store the ultrasound report and images in a secure, retrievable, and reliable manner in order to ensure ongoing coordination and quality of care. 2. Demonstrate respect for all patients regardless of race, gender and socioeconomic background.

The second year is a MSUS track year tailored to advanced US training. Fellows have three months of US through the academic year with focus on enhancing US skills while improving recognition of pathology. There is an increased focus in procedural US training with opportunities to perform US guided arthrocentesis and injection. Fellows apply to participate in the USSONAR course in the second year. Those who are unable to participate in USSONAR will

attend an US course that meets requirement for certification. There are 8 hours of clinic and 6 hours of didactics in addition to rotations and assignments for the 2nd years.

The goal of our curriculum and training course is to progress rheumatology fellows into certified ultrasonographers. Fellows are expected to sit for RhMSUS certification prior to completion of their fellowship. This curriculum allows fellows to meet required ACR pathways for RhMSUS certification.

Results: Over 4 years, 8 rheumatology fellows have participated in the MSUS program within our fellowship. Of those fellows, 6/8 have participated in the USSONAR training program in addition to their fellowship training, 5/6 fellows completed USSONAR certification. Seven fellows have completed RhMSUS certification with the eighth soon to take the exam, 7/7 fellows passed their certification exam. Of the fellows who have graduated, 4/6 have consistently utilized MSUS in clinical practice.

Conclusion: Our institution has successfully implemented a robust MSUS curriculum utilizing EULAR guidelines and USSONAR US protocols. We have been able to train rheumatology fellows to be competent musculoskeletal ultrasonographers and become RhMSUS certified prior to graduation. New opportunities include providing fellows with handheld US devices to enhance training. This will be a pilot program starting in the 2020-21 academic year.

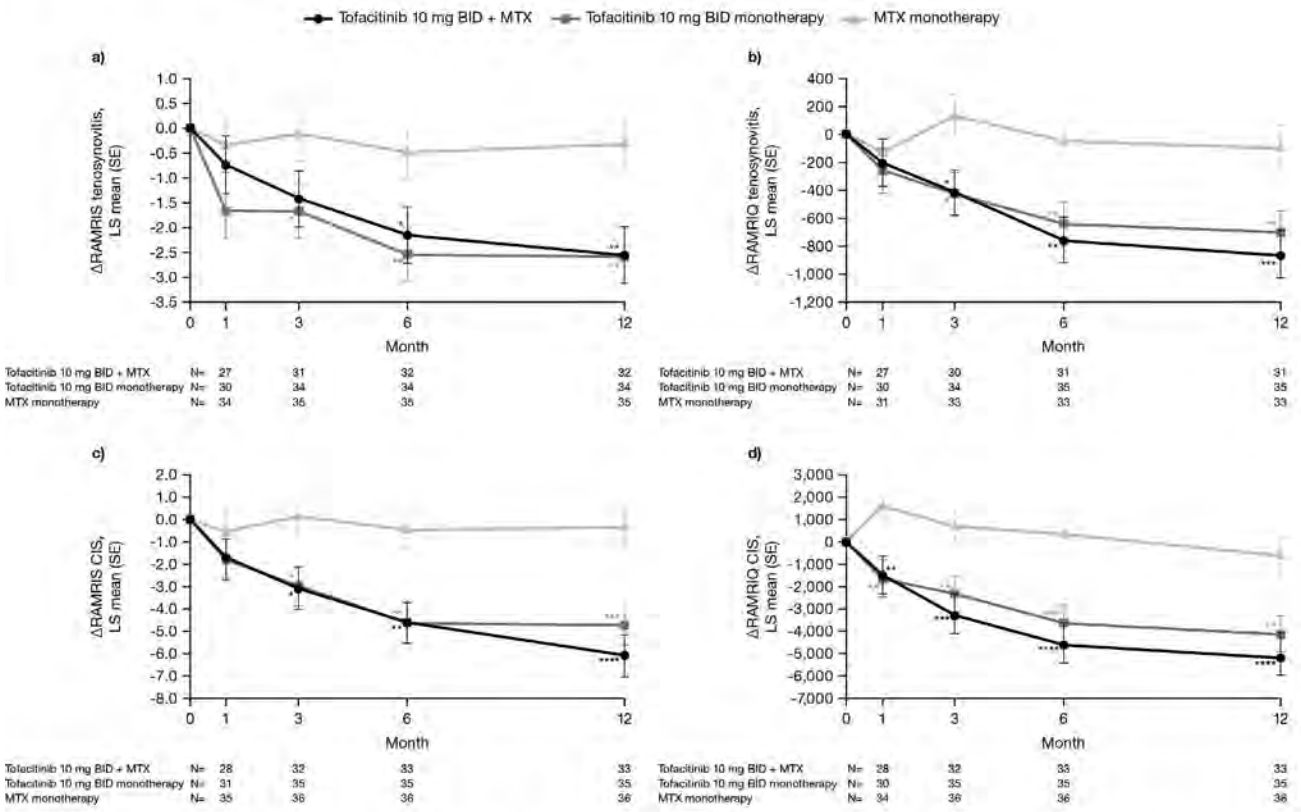
Exploring Novel Tenosynovitis and Combined Inflammation Imaging Outcomes: Results from a Randomized Controlled Trial in Early Rheumatoid Arthritis

Philip G Conaghan[1], Mikkel Østergaard[2], Orrin Troum[3], Zhiyong Xie[4], Alan Brett[5], Mark Snyder[6], Abbas Ebrahim[6], Douglass S Chapman[7], Gosford A Sawyerr[8] and John Andrews[6], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and National Institute for Health Research Leeds Biomedical Research Centre, Leeds, United Kingdom, [2]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [3]Division of Rheumatology, University of Southern California Keck School of Medicine, Santa Monica, CA, [4]Pfizer Inc, Groton, CT, [5]Imorphics Ltd, Manchester, United Kingdom, [6]Pfizer Inc, Collegeville, PA, [7]Pfizer Inc, New York, NY, [8]Syneos Health, -

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: MRI trial outcomes have largely focused on synovitis, bone marrow edema (BME), and erosions. Tenosynovitis is a common manifestation of RA, but is relatively understudied; a combined inflammation score (CIS) that sums the 3 inflammatory markers (synovitis, BME, and tenosynovitis) may be a highly responsive outcome measure. We have previously demonstrated the responsiveness of the OMERACT RA MRI scoring system (RAMRIS) and a machine-learning derived automated tool (RAMRIQ) in a randomized trial of tofacitinib and MTX in MTX-naïve patients (pts) with early RA.[1] This post hoc analysis evaluated the effects of tofacitinib ± MTX on MRI tenosynovitis and CIS in pts with early RA using semiquantitative and quantitative MRI outcomes.

Figure. a) ΔRAMRIS tenosynovitis, b) ΔRAMRIQ tenosynovitis, c) ΔRAMRIS CIS, and d) ΔRAMRIQ CIS at Months 1, 3, 6, and 12 (FAS)



*p<0.05, **p<0.01, ***p<0.001, ****p<0.0001 for comparisons of tofacitinib ± MTX vs MTX monotherapy, assessed using a mixed-effect model for repeated measures; missing values were imputed by LOCF; tenosynovitis and CIS were assessed using combined data from MCP and wrist joints; CIS was calculated by the sum of synovitis, BME, and tenosynovitis values
Δ, change from baseline; BID, twice daily; BME, bone marrow edema; CIS, combined inflammation score; FAS, full analysis set; LOCF, last observation carried forward; LS, least squares; MCP, metacarpophalangeal; MRI, magnetic resonance imaging; MTX, methotrexate; N, number of patients with values at baseline and the timepoint of interest; RA, rheumatoid arthritis; RAMRIQ, automated quantitative RA MRI assessment system, automated RAMRIS; RAMRIS, RA MRI scoring system; SE, standard error

Table. Correlations between a) BL RAMRIS and BL RAMRIQ tenosynovitis and CIS vs BL DAS28-4(CRP) (N=109) and b) ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at Month 12 vs ΔDAS28-4(CRP) at Month 12 (N=73), using pooled data across all three treatment arms[a]

a)

All treatment arms[a]	BL RAMRIS tenosynovitis		BL RAMRIS CIS		BL RAMRIQ tenosynovitis		BL RAMRIQ CIS	
	Correlation	p value	Correlation	p value	Correlation	p value	Correlation	p value
BL DAS28-4(CRP)	0.366	0.0001	0.399	<0.0001	0.205	0.037	0.180	0.062

b)

All treatment arms[a]	ΔRAMRIS tenosynovitis		ΔRAMRIS CIS		ΔRAMRIQ tenosynovitis		ΔRAMRIQ CIS	
	Correlation	p value	Correlation	p value	Correlation	p value	Correlation	p value
ΔDAS28-4(CRP)	0.531	<0.0001	0.554	<0.0001	0.543	<0.0001	0.564	<0.0001

[a]For this analysis, data were pooled across all three treatment arms (tofacitinib 10 mg BID + MTX, tofacitinib 10 mg BID monotherapy, MTX monotherapy)
Spearman's rank correlation coefficients and p values were calculated for the correlation of BL RAMRIS and BL RAMRIQ tenosynovitis and CIS vs BL DAS28-4(CRP) and ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at Month 12 vs ΔDAS28-4(CRP) at Month 12; tenosynovitis and CIS were assessed using combined data from MCP and wrist joints; CIS was calculated by the sum of synovitis, BME, and tenosynovitis values
Δ, change from baseline; BID, twice daily; BL, baseline; BME, bone marrow edema; CIS, combined inflammation score; DAS28-4(CRP), Disease Activity Score in 28 joints, C-reactive protein; MCP, metacarpophalangeal; MRI, magnetic resonance imaging; MTX, methotrexate; N, number of patients with values at baseline and timepoint of interest; RA, rheumatoid arthritis; RAMRIQ, automated quantitative RA MRI assessment system, automated RAMRIS; RAMRIS, RA MRI scoring system

Methods: Study A3921068 (NCT01164579) was a 1-year, exploratory, Phase 2, randomized controlled trial comparing tofacitinib 10 mg twice daily (BID) ± MTX, and MTX monotherapy, in MTX-naïve pts with early, active RA.[1] MRI of unilateral wrist and MCP joints was performed at screening/baseline (BL) and Months (M)1, 3, 6, and 12. MRI tenosynovitis and CIS were assessed using RAMRIS and RAMRIQ. Changes from BL (Δ) in RAMRIS and RAMRIQ tenosynovitis and CIS were evaluated at M1, 3, 6, and 12. Data were assessed using a mixed-effect model for repeated measures, with treatment arms as factors and BL values as covariates. Using data pooled across all treatment arms, Spearman's rank correlation coefficients were calculated for associations between BL RAMRIS and BL RAMRIQ tenosynovitis and CIS vs BL DAS28-4(C-reactive protein [CRP]) and between ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at M12 vs ΔDAS28-4(CRP) at M12.

Results: In total, 109 pts were randomized and treated (mean RA duration 0.7 years). ΔRAMRIS and ΔRAMRIQ tenosynovitis (Figure a,b) and ΔRAMRIS and ΔRAMRIQ CIS (Figure c,d) were generally significantly greater at M3, 6, and 12 in pts receiving tofacitinib ± MTX vs MTX alone, with significant improvements also seen at M1 for ΔRAMRIQ CIS. Compared with RAMRIS, RAMRIQ outcomes were generally more responsive to treatment with tofacitinib ± MTX. Significant correlations were seen between BL RAMRIS and BL RAMRIQ tenosynovitis and BL RAMRIS CIS vs BL DAS28-4(CRP), while significant correlations were also observed between ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at M12 vs ΔDAS28-4(CRP) at M12 (Table). In general, stronger correlations were seen between BL DAS28-4(CRP) and BL RAMRIS parameters vs BL RAMRIQ parameters, whereas correlations were similar between ΔDAS28-4(CRP) at M12 and ΔRAMRIS and ΔRAMRIQ parameters at M12.

Conclusion: Responsiveness of RAMRIS and RAMRIQ tenosynovitis and CIS was demonstrated with significant improvements through M12 in pts receiving tofacitinib 10 mg BID ± MTX vs MTX alone. Construct validity for RAMRIS and RAMRIQ tenosynovitis and CIS was evident from correlations with DAS28-4(CRP). Further work is required to validate these novel imaging biomarkers in terms of relative responsiveness and prediction for later structural progression.

Abstract Number: 1714

Disease Activity Trajectories for Early and Established Rheumatoid Arthritis: Real World Results from a Rheumatoid Arthritis Cohort

Mohammad Movahedi[1], Angela Cesta[2], Xiuying Li[3] and **Claire Bombardier**[4], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, Toronto, Canada, [4]Institute for Work and Health, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Description of disease activity status in patients with rheumatoid arthritis (RA) at fixed points in time modelled as continuous (e.g. number of swollen joints counts), dichotomous variable (e.g. remission or low disease status using composite measures) do not reflect the patient's disease course in chronic and relapsing RA. We proposed to describe the longitudinal disease activity trajectories for patients with early and established RA over two years' follow-up in routine clinical care.
