Conclusion: AR882 produced marked reductions in sUA, with all patients achieving and maintaining levels below 6 mg/dL following multiple dosing of AR882. These data provide clear guidance for dose selection in future large phase 2 studies and support continued development of AR882 alone or in combination with XO inhibitors for treatment of gout.

Denosumab Did Not Improve Computerized Tomography Erosion Scores When Added to Intensive Urate-Lowering Therapy in Gout: Results from a Pilot Study

Angelo Gaffo[1], Kenneth Saag[2], Anthony Doyle[3], Joshua Melnick[4], Anne Horne[5], Jeffrey Foster[1], Amy Mudano[1], Stephanie Biggers[1], David Redden[1] and Nicola Dalbeth[6], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [3]University of Auckland, Grafton, Auckland, New Zealand, [4]University of Alabama at Birmingham (UAB), Vestavia Hills, AL, [5]The University of Auckland, Auckland, New Zealand, [6]University of Auckland, Auckland, New Zealand

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Bone erosion is a common complication of tophaceous gout. Disordered osteoclast activity has been implicated in the pathogenesis of gouty bone erosion. We sought to determine if the addition of denosumab

to intensive urate-lowering therapy (ULT) improves gouty bone erosion through targeting receptor activator of nuclear factor kappa-B ligand (RANKL).

Methods: Open-label, parallel-group pilot randomized controlled trial in which 20 participants with gout with at least one confirmed conventional radiographic foot bone erosion were assigned in a 1:1 allocation to receive denosumab (60 mg subcutaneous every 6 months) added to intensive ULT (serum urate ≤5 mg/dL or 300 μmol/L at the time of randomization and continued for the duration of the study) or intensive ULT alone. The primary outcome was the change in the foot computed tomography (CT) bone erosion score from baseline to 12 months. Erosion score was assessed by an experienced musculoskeletal radiologist blinded to study assignment. Secondary outcomes included change in serum c-terminal telopeptide (CTX), functional status by Health Assessment Questionnaire-II, physical and mental health by Short Form Health Survey 12 and pain scores by visual analogue scale (VAS).

Results: The mean age of all study participants was 65.0 (SD 12.4) years and 19/20 were men. Mean disease duration was 15 (SD 9.3) years, serum urate at randomization was 4.3 (0.6) mg/dL and the mean CT erosion score was 6.8

Table 2. Primary and Secondary Study Endpoints. Unless stated, data are shown as mean ± SD.

(SD 5.1). Baseline characteristics were balanced between the denosumab and active comparator groups (Table 1). There was no interval change in CT erosion score in either the denosumab or active comparator group after one year of follow-up (Table 2). Serum CTX declined markedly in the denosumab group compared with the active comparator group. Other secondary outcomes did not change between groups (Table 2). One patient developed atrial fibrillation (on denosumab) and another atrial flutter (on active comparator). There were no serious adverse events and no events led to study discontinuation.

Conclusion: In this one-year pilot study, denosumab did not offer additional benefit to intensive urate lowering therapy for gouty bone erosion.

Pre-Operative Opioid Usage Increases Length of Stay for Rheumatoid Arthritis Patients Undergoing Total Hip Arthroplasty and Total Knee Arthroplasty

Kyle Morse[1], Nicole Heinz[1], Jeremy Abolade[1], Joshua Wright-Chisem[1], Linda Russell[2], Meng Zhang[3], Serene Mirza[1], Dana Orange[4], Mark Figgie[5], Peter Sculco[2] and Susan Goodman[5], [1]Hospital for Special Surgery, New York, [2]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [3]Feinstein Institute, Northwell Health, New York, [4]Rockefeller University, New York, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Total Hip (THA) and total knee arthroplasty (TKA) are cost-effective procedures that improve the health-related quality of life for patients with advanced symptomatic joint damage, including patients with rheumatoid arthritis (RA). However, increasing utilization has led to marked increase in cost with inpatient costs representing the largest proportion of expenditures for TKA. For this reason, it is important for cost containment efforts to address length of stay (LOS). Preoperative opioid usage has been associated with increased LOS and postoperative complications in osteoarthritis (OA) patients. Patients with RA have a longer LOS after THA/TKA than OA patients, yet the factors contributing to LOS, including preoperative opioid use, have not been investigated.

Methods: We retrospectively reviewed data from a prospectively collected cohort of 252 RA patients undergoing either THA or TKA. Demographics, RA characteristics, medications, and disease activity were systematically collected pre-operatively. Disease activity was measured utilizing the DAS28 and CDAI, PROMs included HOOS/KOOS and MDHAQ, and ESR, CRP, and serologies were drawn pre-operatively. Baseline characteristics were summarized using descriptive statistics and compared using Chi-squared, Fisher's exact test, or two-sample t-test or Wilcoxon rank-sum test as appropriate. Linear Regression analysis was performed to explore the relationship between LOS

Table 1: Multivariate Analysis for Predictors of Length of Stay following Total Hip and Total Knee Arthroplasty in Patients with Rheumatoid Arthritis.

Multivariate variable	Level	Estimated model coefficient (standard error)	Percentage change in the original scale of length of stay with 1 unit increase of a continuous predictor, or a comparison of one category to the reference category for a categorical predictor * (95% CI)	p-value
Sex	Female vs. Male	0.18 (0.08)	19.72% (2.35%, 40.05%)	0.04
TKA	No vs. Yes	0.04 (0.07)	4.08% (-9.26%, 19.38%)	0.61
Type of Surgery	Hip vs. Knee	-0.22 (0.06)	-19.75% (-28.65%, -9.73%)	0.0002
Opioid	No vs. Yes	-0.20 (0.06)	-18.13% (-27.21%, -7.91%)	0.0007
Post-op Transfusion	No vs. Yes	-0.25 (0.09)	-22.11% (-34.71%, -7.10%)	0.006
Hemoglobin at baseline		0.03 (0.02)	-2.96% (-6.69%, 0.92%)	0.18
Das28_esr at baseline		0.07 (0.04)	7.25% (-0.84%, 16.00%)	0.053
CDAI at baseline		-0.003 (0.004)	-0.30% (-1.08%, 0.49%)	0.51

*Percentage change in the original scale of length of stay with 1 unit increase of a continuous predictor, or a comparison of one category to the reference category for a categorical predictor: (exponential (estimated model coefficient)-1)*100

(log-transformed) and predictors. The final multivariate model was constructed through backward selection among predictors that were found statistically significant ($p< 0.05$) in the univariate analysis.

Results: RA cases were predominantly women (83%), with median disease duration (14.1 +/-12 years), and moderate disease activity (mean DAS28= 3.7±1.3, CDAI=18.4±10.9). 240(95%) cases had LOS data available. 88 (37%) patients were taking opioids pre-operatively. The mean LOS was 3.4±1.5 days with those undergoing THA having a LOS of 3.1±1.6 and TKA with a LOS of 3.7±1.4. In the univariate analysis, post-operative transfusion (p=0.01), baseline DAS 28 (p=0.02), sex (p=0.001), BMI (p=0.03), Employment status (p=0.04), type of surgery ($p< 0.001$), opioid usage (p=0.001), duration of surgery (p=0.01), HOOS/KOOS baseline pain score (p=0.01), HOOS/KOOS baseline function score (p=0.003), duration of disease (0.03), baseline MD-HAQ (p=0.01), baseline ESR (p=0.03) were significantly associated with extended LOS. The multivariate analysis revealed several factors that impact LOS. LOS was decreased for patients who underwent THA (p=0.002), male gender (p=0.04), did not have a post-op transfusion (p=0.006) and did not take opioids pre-operatively (p=0.0007) (**Table 1**).

Conclusion: Patients who receive a post-operative transfusion, undergo knee surgery, women, and increased opioid usage were associated with increased length of stay. While gender and surgical type are non-modifiable risk factors, pre-operative optimization should focus on transfusion risk factors and pre-operative opioid reduction. We recommend that patients undergo pre-operative opioid cessation counseling, and multimodal pain management should be used peri-operatively to reduce opioid usage.

Effect of Physical Activity on Cartilage Degradation and Inflammation in Individuals with Lumbar Spinal Stenosis

Gustavo Almeida[1], Samannaaz Khoja[2], Lauren Terhorst[3], Gwendolyn Sowa[4], Sara Piva[2] and Michael Schneider[2], [1]Department of Physical Therapy, UT HEALTH SAN ANTONIO, San Antonio, TX, [2]Department of Physical Therapy, University of Pittsburgh, Pittsburgh, PA, [3]Department of Occupational Therapy, University of Pittsburgh, Pittsburgh, PA, [4]Department of Physical Medicine and Rehabilitation, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Guidelines recommend 150 minutes a week in moderate-intensity physical activity (MPA) to improve health in individuals with chronic disease such as those with lumbar spinal stenosis (LSS). LSS affects older adults' physical function and limits their mobility, which leads to reduced activity participation that might result in further disability. Because of the anatomical changes found in LSS and symptoms presented by patients, health professionals are hesitant in promoting MPA as they are fearful of worsening the condition. Therefore, it is imperative to understand whether MPA affects the concentration of plasma biomarkers in individuals with LSS. Our study aimed to determine the associations between MPA and concentration of plasma biomarkers (i.e., cartilage degeneration

Biomarkers	Concentration in pg/ml median (Q25, Q75)	Moderate Physical Activity (min/day)	
		Spearman's rho	p-value
IL-2 §	-3.00 (-15.00, 10.15)	-.18	.066
IL-1β §	-.35 (-14.65, 12.28)	-.15	.130
IL-5 §	-.50 (-14.60, 11.83)	**-.19**	**.049**
IL-6 §	-2.00 (-14.95, 14.05)	**-.24**	**.011**
IL-10 §	.50 (-16.50, 11.38)	**-.20**	**.037**
IL-12p70 §	.10 (-12.00, 8.45)	**-.20**	**.042**
IL-13 §	-.60 (-5.93, 8.00)	-.07	.464
IFN-γ §	-.60 (-12.78, 8.15)	**-.23**	**.016**
COMP ¶	-20.83 (-122.65, 86.35)	.03	.791
CTX-II ¶	6.55 (-201.31, 209.31)	-.16	.091
CS846 ¶	-73.21 (-303.97, 165.61)	**.26**	**.007**
TIMP-1 ¶	8441.13 (-42366.19, 44697.94)	**.22**	**.029**

Pg/ml: picogram per milliliter; Q25: quartile 25; Q75: quartile 75; min/day: minutes per day; IL: interleukin; IFN: interferon; COMP: Cartilage Oligomeric Matrix Protein; CTX-II: Carboxy-Terminal Telepeptides of Type II Collagen; CS846: aggrecan Chondroitin Sulfate 846 epitope; TIMP-1: Tissue Inhibitor of Metalloproteinase-1.

and inflammation) in individuals with LSS, and to also explore associations between changes in MPA and changes in concentration of biomarkers.

Methods: We performed a secondary analysis from a randomized trial that compared three non-surgical approaches to manage LSS. Participants with available blood samples and MPA measured at baseline and 2-month follow-up were included (N=109). Cartilage degradation was assessed by analyzing the concentration (volume expressed in pg/ml) of different biomarkers (COMP, CTX-II, CS864 and TIMP-1) using enzyme-linked immunosorbent assay kits specific to each biomarker. A panel of 8 inflammatory biomarkers (interleukin [IL]-1β, IL-2, IL-5, IL-6, IL-10, IL-12p70, IL-13 and IFN-γ) were assessed using a MILLIPLEX® MAP Human High Sensitivity T Cell Magnetic Bead Panel. Daily time (min/day) in MPA was assessed using the Sensewear Armband activity monitor for 7 days. Changes (i.e. follow-up minus baseline) in concentration of each biomarker and MPA were calculated. Associations between changes in concentration of biomarkers and in MPA were computed as Spearman's rho with an alpha of .05. Statistical analyses were performed using IBM SPSS Statistics 26 (IBM Corp, Armonk, NY, USA).

Results: Participants were 52% female, 72.9±7.5 years old, with a BMI of 29.7±5.8. They barely changed their time in MPA from baseline to 2-month follow-up (-4.4±30.8 min/day; median [Q25, Q75] = 0.0 [-8.5, 5.5] min/day). This change in MPA was inversely associated with changes in concentration of inflammatory biomarkers: IL-5 (rho=-.19; p=.049), IL-6 (rho=-.24; p=.011), IL-10 (rho=-20; p=.037), IL-12p70 (rho=-.20; p=.042), IFN-γ (rho=-.23; p=.016); and directly associated with changes in concentration of cartilage degradation biomarkers (pg/ml): CS864 (rho=.26; p=.007) and TIMP-1 (rho=.22; p=.029).

Conclusion: This exploratory analysis in individuals with LSS showed a trend indicating that increases in time spent in MPA may reduce inflammation, however, it may increase cartilage degradation. Promoting MPA in those with LSS may be challenging as few individuals engage in it and the benefit/risk ratio in terms of disease modulation needs further investigation.

Abstract Number: 0694

Relationships Among Adherence and Patient Outcomes in a Cognitive Behavioral Plus Physical Activity Intervention for Older Adults with Osteoarthritis and Hypertension

Xiaojun Shi[1], Elizabeth Schlenk[2] and Susan Sereika[1], [1]University of Pittsburgh School of Nursing, Pittsburgh, [2]University of Pittsburgh School of Nursing, Pittsburgh, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis of the knee (OAK) affects nearly 14 million older adults and more than half are diagnosed with hypertension (HTN). Cognitive behavior therapy (CBT) has demonstrated inconsistent effectiveness on OAK symptoms. The purpose of this secondary analysis was to examine if patient adherence to CBT influences its effectiveness for OAK outcomes (pain, function, stiffness, health-related quality of life [HRQoL], and fatigue) among people with comorbid HTN.

Methods: This longitudinal comparative study analyzed data from a randomized controlled trial of a CBT plus physical activity (Staying Active with Arthritis or STAR) intervention vs. a control intervention in older adults with OAK and HTN. Participants who completed at least one session of the STAR or control interventions were included (n=172). STAR intervention consisted of 15 sessions including six weekly face-to-face physical therapy (lower extremity exercise and walking) sessions and nine biweekly telephone sessions for support (mean adherence was 10.8±0.6). Patient adherence was derived by dichotomizing participants into adherers who completed 15 STAR sessions (n=37) and non-adherers who completed < 15 STAR sessions (n=51). Control intervention consisted of 15 telephone sessions on senior health topics (n=84). Pain, function, and stiffness were measured by WOMAC Osteoarthritis Index subscales, HRQoL was measured by Short Form-36v2 Physical Component Summary and Mental Component Summary, and fatigue was measured by Brief Fatigue Inventory at baseline, immediate post-intervention, and 6 months post-intervention. Linear mixed modeling controlling for baseline outcome value, time, significant demographics and medical factors (age, sex, race, marital status, education, employment status, duration of OAK and HTN, and number of comorbidities) were used to compare within-group and between-group differences in the outcomes.

Results: The sample was primarily female (n=126, 73.3%), non-Hispanic white (n=130, 75.6%), married/partnered (n=86, 50.0%), and not working/retired (n=86, 50.0%) with mean (±SD) age of 65.0±8.0 years. On average, the duration of OAK and HTN was 11.3±9.3 and 13.6±9.2 years, respectively, and the number of comorbidities was 8.4±3.6. Regardless of adherence group, STAR participants had significant improvement in pain, function, and stiffness from baseline to immediate post-intervention and 6 months post-intervention. Compared with adherers, controls reported significantly greater knee pain (b=0.69, p=0.035) and a trend for worse function (b=2.24, p=0.051), but the difference between non-adherers and controls was not significant. There was no significant difference between adherers and non-adherers in pain, function, stiffness, HRQoL, and fatigue.

Conclusion: Both adherers and non-adherers showed improved OAK-specific outcomes of pain, function, and stiffness, but not HRQoL and fatigue. There was no difference in OAK outcomes between adherers and non-adherers or between non-adherers and controls. Adherers had less knee pain and a trend for better function compared to

controls. Patient adherence to intervention sessions was a significant factor influencing the effectiveness of the intervention.

Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic back pain (CBP) is a common musculoskeletal complaint and a significant cause of disability (Weisman et al., 2013). A subset of CBP, chronic inflammatory back pain (CIBP) occurs in about one third of CBP patients in the NHANES 2009-2019 survey, especially in younger individuals (Weisman et al., 2013). For older individuals, there is little known about CIBP. Although older age is not an exclusion factor in many criteria for inflammatory back pain (IBP) (Weisman, 2012), it is generally thought IBP begins in patients less than 45 years old. Thus, we endeavored to review CIBP in individuals 50 years and older by i) a systematic literature review, ii) evaluating prevalence using National Health and Nutrition Examination (NHANES) data from the 2009-2010 survey, and iii) reporting clinical features of late onset ankylosing spondylitis (AS) from a longitudinal AS cohort.

Methods: The design of the present analysis was based on a systematic literature review using "chronic inflammatory back pain" and "chronic low back pain" as search terms to identify articles of interest between January 1, 2013,

Table 2. Characteristics of Late Onset AS from 1253 Patients in the PSOAS Cohort

and March 1, 2020. The search was restricted to articles about human subjects, in English, and including subjects >65 years of age. The data from the arthritis questionnaire in the 50-59 age group of the 2009-2010 NHANES were analyzed using the Berlin 7b criteria looking at prevalence of CIBP. Lastly, the clinical features of AS patients in the Prospective Study of Outcomes in AS (PSOAS)/Australo-Anglo-American Spondyloarthritis Cohorts (TASC) were examined comparing patients with age of onset less than 20 years old to those 50 years and older, using Chi-square test to look at significance.

Results: Using the search term "chronic inflammatory back pain," the literature search identified 1,203 articles. The second search using "chronic low back pain" identified 2,245 articles. Eighteen articles were included in the review that met search criteria for CIBP in the elderly. Fifteen articles were cross-sectional studies, one was case-control, one longitudinal, and one was a randomized trial (*Table 1*). In NHANES 2009-2010, 55 (2.9%) subjects otherwise met Berlin criteria for CIBP but that started over the age of 50 years (*Figure 1*). Of the 1,253 patients in the PSOAS cohort, 33 (2.6%) had disease onset ≥ 50 years old. There was markedly lower frequency of HLA-B27 and lower frequency of uveitis with late onset disease (*Table 2).*

Conclusion: In a systematic review of articles about CIBP, we found a wide range of studies on chronic back pain from different specialties: rheumatology, pain management, orthopedic surgery, neurosurgery, chiropractic, imaging, and general medicine. However, there was not one article addressing CIBP in the older population. Based on the NHANES data, if the age restriction is omitted, nearly 3% of the population has chronic inflammatory back pain commencing on or after the age of 50 years. Moreover, from the PSOAS/TASC data, one in 40 AS patients may have disease onset after age 50. These are unmet needs for this population group, for non-rheumatologists to identify at-risk patients and refer appropriately, and for rheumatologists to consider as an important clinical entity.

Femoral Cartilage Ultrasound Echo-Intensity Associates with Arthroscopic Cartilage Damage in People Following Anterior Cruciate Ligament Reconstruction

Matthew Harkey[1], Erin Little[2], Mikaela Thompson[3], Ming Zhang[4], Jeffrey Driban[4] and Matthew Salzler[3], [1]University of Massachusetts, Worcester, MA, [2]Tufts Medical Center, Cambridge, MA, [3]Tufts Medical Center, Boston, [4]Tufts Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Over one-third of people will develop knee osteoarthritis within 10 years of an anterior cruciate ligament (ACL) injury. Ultrasound may be used to monitor early pathological cartilage changes that occur after an ACL injury. However, it is unclear if a non-invasive quantitative ultrasound assessment correlates with arthroscopic

cartilage damage. The purpose of our study was to compare quantitative cartilage ultrasound metrics between people with and without arthroscopic cartilage damage following an ACL injury.

Methods: We recruited individuals between 18 and 35 years of age with a primary unilateral ACL injury at a pre-operative visit with an orthopaedic surgeon. Participants were excluded if they had a history of lower extremity surgery, injured either knee within the last 6 months (other than ACL injury), or previously been diagnosed with any form of arthritis. A knee ultrasound assessment occurred pre-operatively prior to an arthroscopy. With the knee in maximal knee flexion, a transverse suprapatellar ultrasound assessment was used to image the femoral cartilage in the individual's injured knee. One reader manually segmented the cartilage. Next, a custom program automatically divided the cartilage into standardized medial and lateral femoral condyle regions and calculated 3 measures (Figure): 1) mean cartilage thickness (cartilage cross-sectional area divided by the cartilage length), 2) echo-intensity mean (average grey-scale pixel value ranging from 0–255), and 3) echo-intensity heterogeneity (standard deviation of the pixel intensity within the region). During a clinical arthroscopy, an orthopaedic surgeon with a sub-specialty in sports medicine graded the medial and femoral condyle using the Outerbridge grading system and operationally defined cartilage status as: *normal cartilage*: Outerbridge = 0 or *cartilage damage*: Outerbridge ≥1 (i.e., Outerbridge 1 = cartilage

Table 2. Comparison of Femoral Cartilage Ultrasound Outcomes Between People With and Without Arthroscopic Cartilage Damage. SD = standard deviation; d = Cohen's d effect size; 95% CI = 95% confidence intervals. *statistically significant compared to people with arthroscopically normal cartilage; Bold text indicates statistically significant and large magnitude effect sizes between people with and without cartilage damage

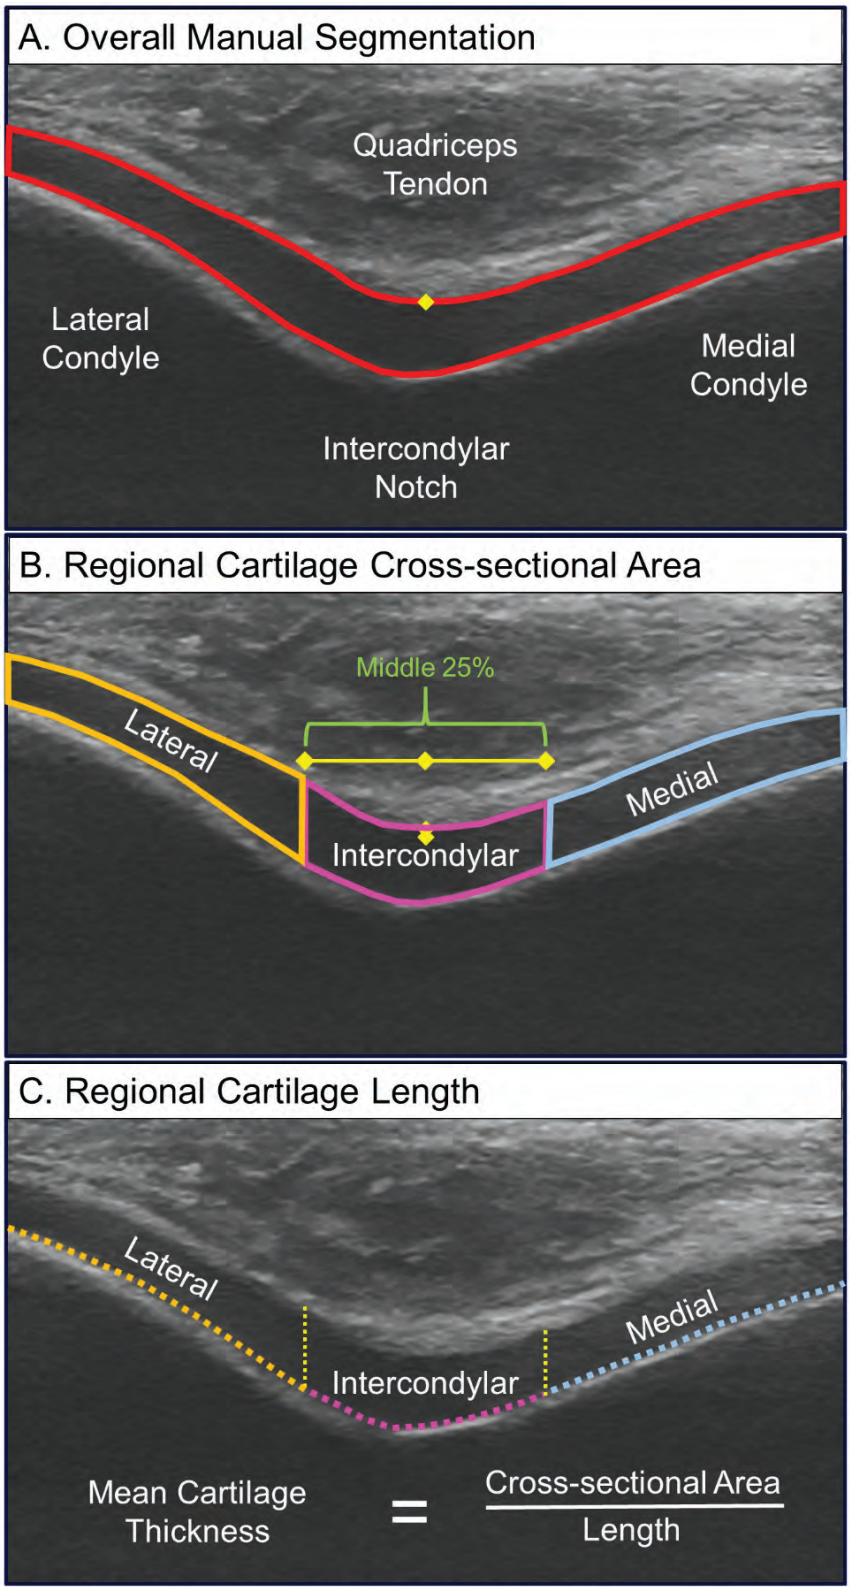

Figure Standardized Femoral Cartilage Segmentation. We used a custom program to take an overall cartilage manual segmentation (A), and use a standardized method to automatically separate the cartilage (B). This abstract focused on cartilage in the medial and lateral regions. The custom program calculated the mean cartilage thickness by dividing the regional cartilage cross-sectional area (B) by the regional cartilage length (C).

softening and swelling). We performed independent samples t-tests and used Cohen's *d* effect sizes to compare the quantitative ultrasound metrics between individuals with (n=12) and without (n=12) arthroscopic cartilage damage.

Results: The 24 participants were primarily male (n=16) and on average 24 ± 5 years old and 50 ± 52 days since ACL injury (Table 1). In the medial femoral condyle, echo-intensity mean and heterogeneity are greater in individuals with normal cartilage compared to those with cartilage damage (Table 2). In the lateral femoral condyle, there are no differences between cartilage ultrasound outcomes between individuals with and without arthroscopic cartilage damage.

Conclusion: Following ACL injury, an ultrasound assessment detects hypo-intense and less heterogeneous medial femoral cartilage in people with arthroscopically identified medial femoral cartilage damage. Future studies are needed to identify the prognostic importance of cartilage ultrasound echo-intensity characteristics, and validate these clinically-accessible metrics against more sophisticated markers of cartilage health.

Inferior Tendon Structure and Function Seen in Patients with Achilles Tendinopathy and Neovascularization of the Achilles Tendon

Brian Honick[1], Haraldur Sigurdsson[1] and Karin Silbernagel[1], [1]University of Delaware, Newark, DE

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In prior research, the incidence rate of neovascularization with Achilles tendinopathy ranged between 47-88% of cases. The purpose of this study was to identify the incidence rate of neovascularization in individuals with midportion Achilles tendinopathy, and to examine if there were differences in tendon structure, hopping performance, and symptom severity based on the presence or absence of neovessels.

Methods: Eighty-three participants (41 females) with a mean ± SD age of 48 ± 12 years, and BMI of 28 ± 5 with midportion Achilles tendinopathy were recruited. A standardized clinical examination confirmed the diagnosis of midportion Achilles tendinopathy. Tendon morphology was examined with diagnostic ultrasound to measure thickness and cross-sectional area (CSA) at the thickest free portion of the tendon. Power Doppler assessed whether neovessels were present within the tendon. Functional performance was measured with a single-leg hopping task and the plyometric quotient was used for analysis. The Victorian Institute of Sport Assessment-Achilles questionnaire (VISA-A) and Numeric Pain Rating Scale (NPRS) quantified the symptom severity. Participants with and without neovascularization were separated into groups. The differences between groups were assessed with independent t-tests.

Results: On the side with Achilles tendinopathy, neovascularization occurred in 28/83 (34%) of participants. The group with neovascularization, had a significantly greater degree of tendon thickness with a median (interquartile range [IQR]) of 0.3 (0.2-0.4) cm compared to 0.1 (0.1-0.2) cm in the group without neovascularization. The neovascularization group also had a greater CSA (mean ± SD 1.2 ± 0.4 cm^2) compared to those without neovascularization (mean ± SD 0.7 ± 0.3 cm^2). Those with neovascularization had worse jumping performance (plyometric quotient mean

± SD 0.3 ± 0.2) than those without neovascularization (mean ± SD 0.3=5 ± 0.1). There were no differences were observed in pain with hopping [present, mean ± SD3.7 ± 2.7; absent 2.7 ± 2.3)] or on the VISA-A [present, mean ± SD 48.1 (3.2); absent, 53.0 (2.5)].

Conclusion: Patients with Achilles tendinopathy and neovascularization had reduced jumping performance and worse tendon structure but similar symptom severity as those without neovascularization. Additional research is needed to understand the impact of neovascularization in response to treatment. Neovessels identified through power Doppler ultrasound may assist clinicians in diagnosing the stage of tendinopathy.

Baseline Factors Are Not Associated with Rehabilitation Dose over Six Months Among Adults with RA

Louise Thoma[1], Elizabeth Wellsandt[2], Kristin Wipfler[3] and Kaleb Michaud[2], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of Nebraska Medical Center, Omaha, NE, [3]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Functional limitation is common in adults with rheumatoid arthritis (RA). Rehabilitation services, like physical therapy (PT) and occupational therapy (OT), are effective in improving function; however little is known regarding rehabilitation utilization patterns in adults with RA. The purpose of this study was to evaluate the association of baseline factors (demographic and clinical characteristics) with rehabilitation dose (number of subsequent PT/OT visits) among adults with RA who received PT/OT services. We hypothesize that worse disease activity and functional status will associate with more PT/OT visits.

Methods: We used data from the FORWARD registry. Participants in the FORWARD registry completed questionnaires every six months regarding health care utilization and patient reported outcomes. The analytic sample includes adults with doctor-diagnosed RA who reported new PT/OT utilization after at least 1 year with no PT/OT utilization. We excluded those with total joint replacement or skilled nursing/inpatient rehab within one year prior to first report of PT/OT or during the first episode of care. The baseline factors of interest were extracted from the preceding study visit 6 months before the study visit with reported PT/OT utilization. These baseline factors included demographic and clinical characteristics: age, sex, body mass index, race, disease duration, disease activity (Patient Activity Scale), functional status (Health Assessment Questionnaire Disability Index), pain severity (Visual Analog Scale), and fatigue severity (Visual Analog Scale). The study outcome was rehabilitation dose (number of PT/OT visits) in the past 6 months. The number of PT/OT visits was self-reported as one of five categories: 1-2, 3-4, 5-6, 7-8, or >8 visits. We examined the association of the baseline factors with rehabilitation dose (more PT/OT visits) using logistic regression (proportional odds model), and mutually adjusted for the other baseline factors.

Results: In the FORWARD registry, 979 adults received rehabilitation after a minimum one-year period with no reported rehabilitation (Table 1). Worse functional status, greater disease severity, and higher pain severity were associated with a higher dose of rehabilitation in unadjusted models, however the associations were attenuated in adjusted mod-

Lumbar Spine Stenosis Treatment : Is Surgery Better Than Medical Treatment in Afro-Descendant Populations ?

Fabienne Louis-sidney[1], Serge Arfi[1], Moustapha Drame[1], Christophe Deligny[1], Philippe Cabre[1] and Michel de Bandt[1], [1]University Hospital Martinique, Fort de France, Martinique

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lumbar spinal stenosis (LSS) is a disabling condition, mostly prevalent in the aging population and associated with significant healthcare cost. Clinical presentation involving neurogenic claudication and low back pain results from congenital or degenerative narrowing of the spinal canal. Greater narrowing of the lumbar spinal canal has been described in African which contrasts with a lower incidence of the condition in this population. In clinical trials and meta-analysis of LSS treatment, the majority of the study populations are of Caucasian origin, accounting for 70% to 95% of the patients[1,2,3]. No difference between surgery, physiotherapy or epidural corticosteroid injection in LSS has been reported in those studies. To our knowledge, none has been performed in Afro-descendant populations (AD). We aim to assess efficacy of 3 different treatment approaches for lumbar spine stenosis in Martinique, a French Caribbean island with a high level of care in the region and an aging population mostly composed of AD.

Methods: Prospective cohort of 138 Afro-Caribbean patients with LSS, evaluated at 3 months from a first course of epidural corticosteroid injections in combination with standardized physiotherapy then assigned to 3 arms of treatment according to clinical evolution and wishes: rehabilitation (R: physiotherapy and oral medication), second course of epidural corticosteroid injections (ECI) or decompression surgery (DS). The primary endpoint was change in Oswestry Disability index (ODI) at 3 months (M3), M12, M18, M24. Secondary endpoints were change in leg pain and back pain measured by Visual Analog Scale (respectively L-VAS and B-VAS).

Results: Seventy-one patients were assigned to the R arm, 37 to the second ECI arm, 30 patients to the DS arm. All arms were comparable in age (62.3 +/- 13.1 years), sex (male/female ratio 0.75) and BMI with an average of 27.0 +/- 5.97 kg/m^2. ODI and L-VAS were significantly higher in the DS arm at baseline ($p< 0.01$). No difference in B-VAS was observed at baseline (Table1). A significantly higher decrease in ODI was observed in the DS arm at M3 and M12 (respectively $P< 0.001$ and $P< 0.01$). Results were not replicated at M18 and M24. A significantly higher decrease in L-VAS was observed in the DS arm at M3, M12, M18 (respectively $P< 0.01$, $P=0.011$, $P< 0.01$), not replicated at M24. No difference was observed between the 3 arms for B-VAS at no time (Table 2).

Conclusion: This is the first comparative treatment study in LSS performed in an AD population. We report a significant superiority of DS in evolution of ODI, a composite functional score, and L-VAS at M3 and M12. These results are very similar to those of major studies comparing surgical to non-surgical therapies for LSS in Caucasian cohorts[2,3]. If long terms (M24) favorable outcomes of L-VAS and ODI is not replicated in our study contrary to others, there is clearly a tendency in favor of surgery. Absence of statistical significance could be explained by important loss to follow up.

Lipoxin A4 Induces Lipid Class Switching and Inflammation Resolution at the Genomic Level in Human Osteoarthritis

Mandar Dave[1], Abul Islam[2], **Akshat Parekh**[3], Jay Patel[4], Arushi Chawla[5] and Ashok Amin[6], [1]Department of Rheumatology and Pathology, New York University Hospital for Joint Diseases, New York, [2]Department of Genetic Engineering and Biotechnology, University of Dhaka, Dhaka, Bangladesh, [3]Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, [4]Northeast Ohio Medical University, Rootstown, OH, [5]Gujarat Forensic Science University, Gujarat, India, [6]Department of Rheumatology and Pathology, New York University Hospital for Joint Diseases, New York, NY

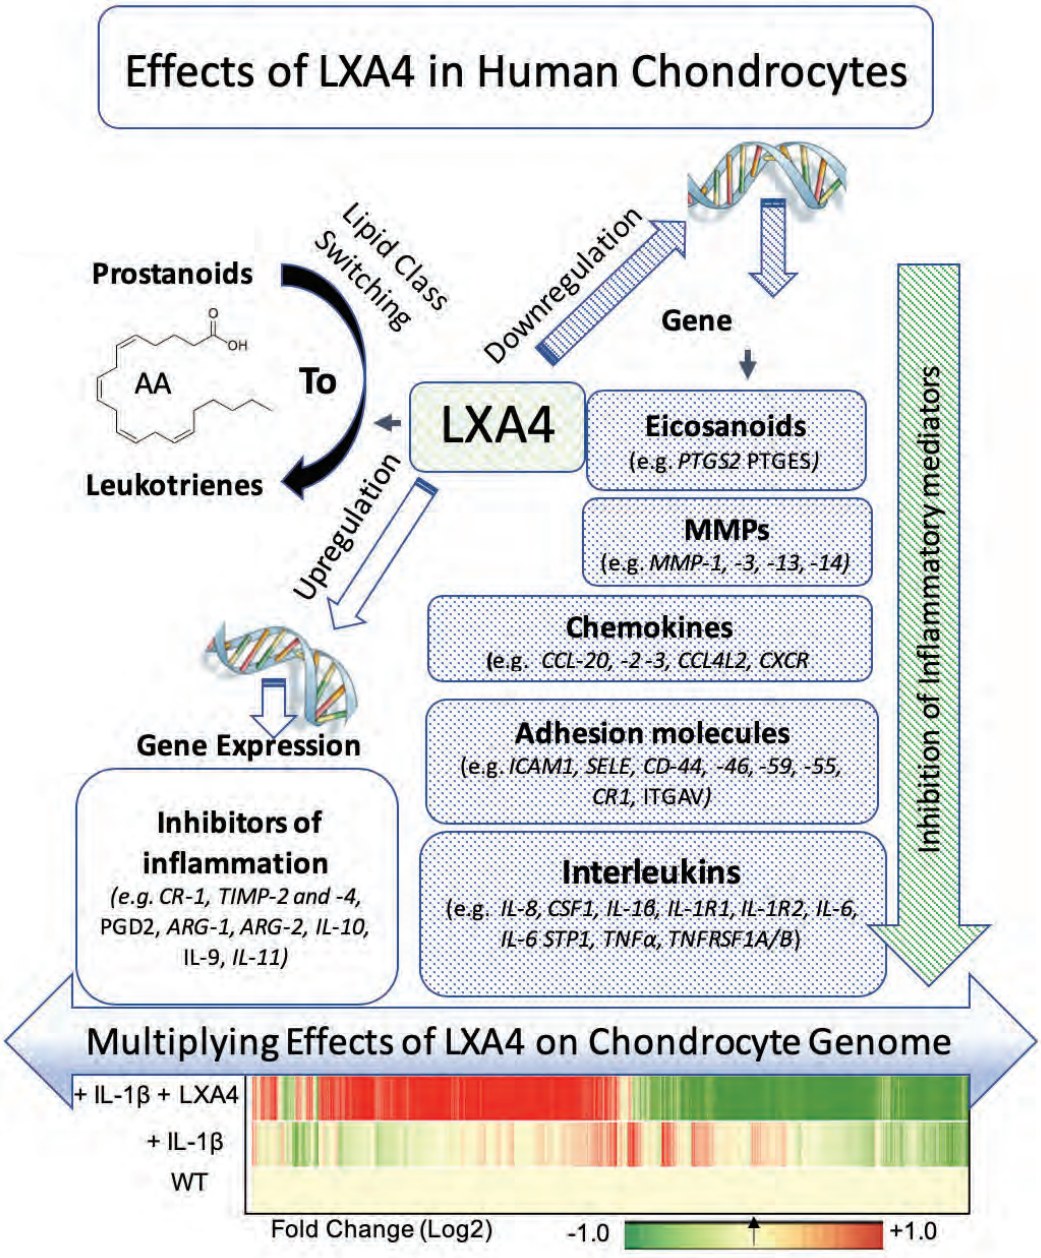
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Human OA-affected cartilage does not show the cardinal signs of inflammation (redness and swelling with heat and pain—*rubor et tumor cum calore et dolor*) because of its unique architecture (avascular, aneural and alymphatic) of the cartilage. However, there is an upregulation of inflammatory mediators at the molecular and biochemical levels [1]. We examined if the human OA-affected cartilage [a] induced innate anti-inflammatory mediators like Lipoxin A4 [LXA4] to counter and promote inflammation resolution in OA, [b] if so, what was the range and mechanism of action of LXA4 at the genomics level in human OA-affected chondrocytes.

Methods: Primary human OA-affected cartilage or chondrocytes were examined for spontaneous release of LXA4 [in *ex-vivo*] condition using liquid chromatography-tandem mass spectrometry and LXA4-specific ELISA. Furthermore, the effects of recombinant LXA4 [rLXA4] were validated in TNFα induced primary human neutrophils *in vitro*. The rLXA4 and then tested in spontaneous or IL-1β induced primary human OA-affected cartilage or human or bovine chondrocytes. Gene expression arrays and bioinformatic analysis examined the total genome. Inflammatory mediators were ELISA or RIA.

Results: LXA4 and 15-epi-LXA4 was spontaneously released [or augmented by IL-1β] in *ex-vivo* conditions in human OA-affected cartilage and chondrocytes. Exogenously added LXA4 (1nM) significantly [$p \leq 0.01$] inhibited 77% TNFα-induced PGE_2 production in human neutrophils. 1-100 nM of LXA4 significantly [$p \leq 0.01$] inhibited IL-1β induced nitric oxide (NO), and PGE_2, in human OA-affected cartilage, -chondrocytes or bovine chondrocytes. IL-1β and LXA4 exhibited an antagonistic pattern of gene expression in human chondrocytes. Specifically, LXA4 inhibited (basal and/or IL-1β-induced) gene expression of inflammatory mediators, their receptors and signaling apparatus [e.g., *IL-8, CSF1, IL-1β, IL-1R1, IL-1R2, IL-6, IL-6STP1, TNFα, TNFRSF1A/B, ICAM1, SELE, CD44, ITGAV, CCL-20, -2 -3, CCL4L2, CXCR- 5, -7, MMP-1, -3, -13, -14, CD-46, -55, -59, LTC4, LTB4, LTA4, PTGS2* and *PTGES*]. Furthermore, LXA4 upregulated the expression of inhibitors of inflammation such as *CR-1, TIMP-2 and -4, ARG-1, -2, IL-10,* and *IL-11*. Unlike IL-1β, LXA4 induced lipoxygenases [*ALOX5, ALOX5AP, ALOX15B*], phospholipases [*PLA2G1B, PLA2G7*], and PGD synthase of the eicosanoid pathway. LXA4 significantly dampened the cycloxygenase pathway and related prostaglandins.

Conclusion: Human OA-affected cartilage spontaneously releases LXA4 and 15-epi-LXA4. rLXA4 inhibits gene expression of [basal and IL-1β-induced] inflammatory mediators. Furthermore, LXA4 induced lipid class switching by shifting the regulation of cyclooxygenases towards the leukotriene pathway discretely from IL-1β. LXA4 exhibits multiple targets and mechanisms during anti-inflammatory, pro-resolving, and tissue repairing activity in human cartilage and chondrocytes.



The effects Lipoxin A4 in human chondrocytes in inducing lipid class switching from prostanoids to leukotrienes, downregulation of multiple inflammatory mediators, and upregulation of several inhibitors of inflammation. The effect of Lipoxin A4 on genomic expression in IL-1B-stimulated chondrocytes is depicted on a log2 fold change heat map exhibiting their antagonistic pattern of gene expression.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: MicroRNAs have been shown to contribute to osteoarthritis (OA) pathophysiology, yet little is known about the circulating miRNome in OA. The circulating miRNome (e.g. all microRNAs in blood plasma) may include promising biomarkers of disease given that microRNAs are relatively stable, easy to detect, and easy to quantify. Since there are currently no validated biomarkers for detecting early stages of OA, profiling the circulating miRNome in different stages of OA holds potential for biomarker discovery. Next generation sequencing is an advantageous approach for profiling microRNAs because it offers the sensitivity and specificity to detect novel and low abundance microRNAs that are potentially unique to disease stages. Therefore, we hypothesize that sequencing will identify unique signatures of circulating microRNAs in symptomatic patients with early radiographic knee OA as compared to late radiographic knee OA.

Methods: Early knee OA patients were defined based on radiographic Kellgren-Lawrence grades 0 and 1 (N=41), and late knee OA patients defined based on Kellgren-Lawrence grades 3 and 4 (N=50). All patients were symptomatic and showed clinical features of knee OA. Of note, patients with Kellgren-Lawrence grade 2 were excluded in an effort to clearly demarcate early from late stage OA. Plasma from each patient (N=91) was subjected to microRNA library preparation and sequencing on the Illumina NextSeq550 platform. Sequencing reads were aligned and counts were generated for both known microRNAs (documented in miRBase v22.1) and novel microRNAs (predicted using bioinformatic tools). Demographic, anthropometric, and clinical data collected for all patients were considered as covariates in statistical analyses. Further statistical, bioinformatics, and computational biology approaches were taken to refine and interpret the final list of microRNAs and their predicted gene targets.

Results: Sequencing data were first explored in an unbiased manner using principal component (PC) analysis. This revealed clear separation of samples according to OA stage, with late OA samples forming a distinct cluster from early OA samples (PC1 = 58.2%). Differential expression analysis identified 215 microRNAs at FDR < 0.01 in early OA versus late OA. Refining this list for microRNAs that were consistently increased or decreased across ≥ 85% of samples in the early OA group as compared to their median expression in the late OA group, we found 97 microRNAs. At a threshold of ≥ 95%, 7 microRNAs were identified, one of which was consistently found to be increased in 100% of early OA samples. Exploring novel microRNAs, 4 were found in ≥ 50% of early OA samples. Interestingly, gene target predictions showed several common targets between the 97 shortlisted microRNAs and the 4 novel microRNAs, including SMAD2 and associated TGF-beta signaling pathway.

Conclusion: Sequencing the circulating miRNome identified a unique signature of 11 microRNAs, which included 4 novel microRNAs, in patients with early knee OA. Future studies should be directed towards understanding the role, mechanisms, and utility of these microRNAs as OA biomarkers.

Distinct Murine Cartilage Microbial DNA Signatures Are Seen in High Fat Diet-Induced Obesity and Aging

Christopher Dunn[1], Cassandra Garman[2], Jake Martin[2], Vladislav Izda[2], Cassandra Velasco[2] and **Matlock Jeffries**[2], [1]University of Oklahoma Health Sciences Center, Oklahoma Cityq, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK

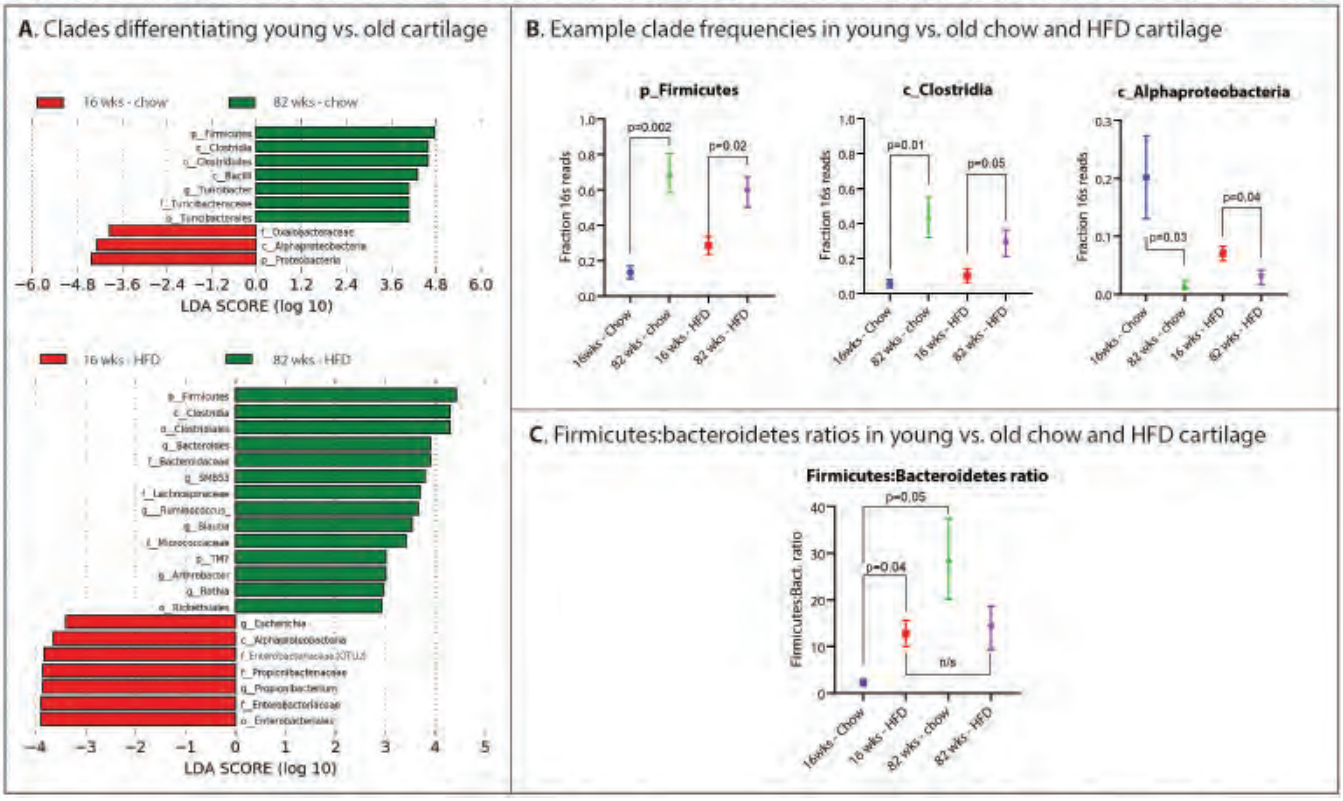
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The strongest nongenetic risk factors for primary knee OA are advanced age and obesity. We have previously shown a human cartilage microbial DNA signature associated with OA. In this study, we hypothesized that aging and obesity, known to cause gut microbiome shifts, would also produce shifts in cartilage microbial DNA patterns.

Methods: Young (8 week old, n=10) and old (74 week old, n=10) male C57BL/6J mice were divided into equal groups and randomly assigned to chow (NIH-31) or high fat (RD D12492, 60% kcal fat) diet for 8 weeks. Mice were sacrificed at 16 weeks and 82 weeks of age and knee cartilage collected using sterile technique, and DNA extracxted. The V3 and V4 regions of the bacterial rRNA gene were amplified and deep sequenced on an Illumina HiSeq. Operational taxonomic units (OTUs) were assigned in QIIME 1.9.1 using the Greengenes 13_8 97% representative reference set. Group composition differences were compared by Linear Discriminant Analysis Effect Size (LEfSe, LDA-effect sizes ≥ 2 or ≤ -2 were considered significant) following rarefaction.

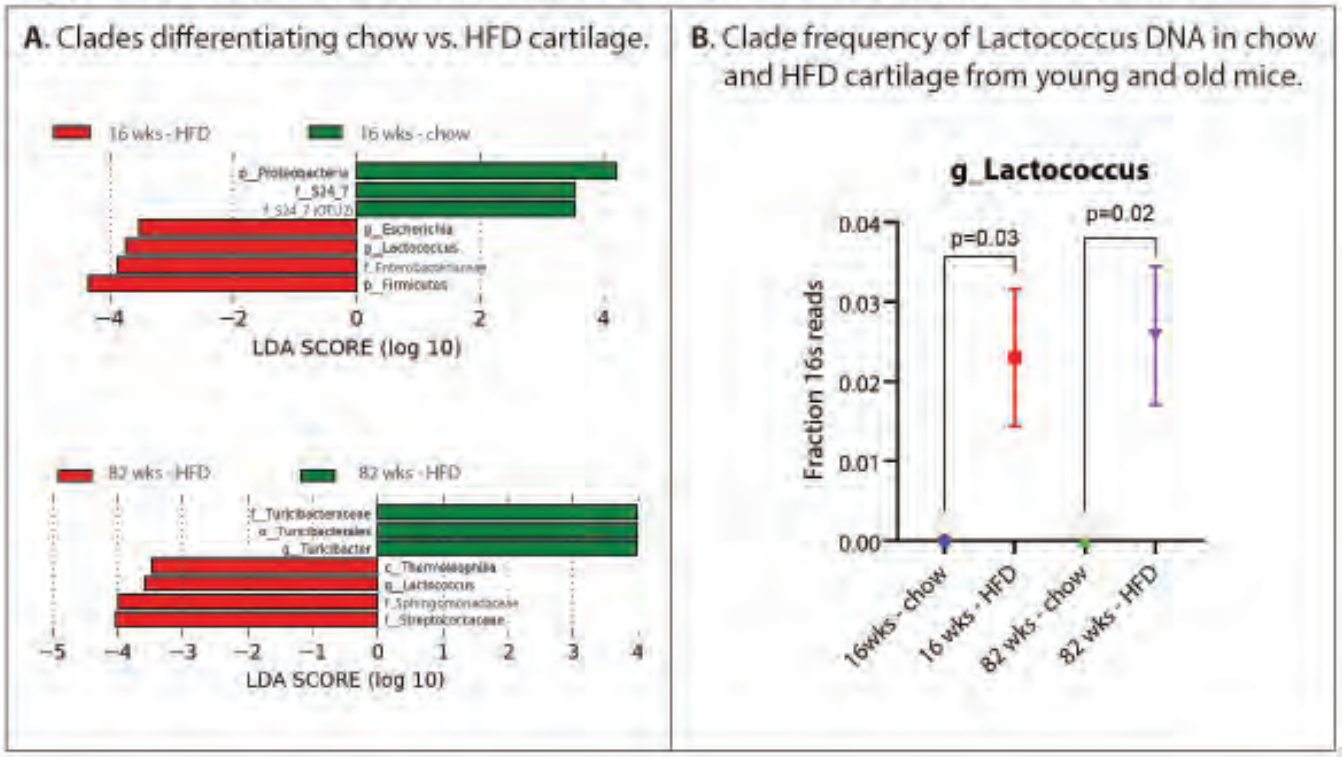
Results: In both HFD and chow animals, aging was associated with expansion of DNA from members of the phylum *Firmicutes* (LDA ES 4.8, p=0.009 for chow young vs. old, LDA ES 4.4, p=0.04 for HFD young vs. old, Figure 1A,B), specifically class *Clostridia* (LDA ES 4.6, p=0.009 for chow, LDA ES 4.3, p=0.03 for HFD, Figure 1A,B) , along with reductions in DNA from members of class *Alphaproteobacteria* with age (LDA ES 4.3, p=0.02 for chow, LDA ES 3.6, p=0.04 for HFD, Figure 1A,B). Comparing chow to HFD young mice, phylum *Proteobacteria* was expanded in chow (LDA ES 4.2, p=0.03) whereas members of phylum *Firmicutes* were expanded in HFD mice (LDA ES 4.3, p=0.02, Figure 2A), specifically including genus *Lactococcus* (LDA ES 3.7, p=0.005 Figure 2 A,B). Comparing chow to HFD old mice, chow were enriched in order *Turicibacterales* (LDA ES 4.0, p=0.02, Figure 2A), whereas HFD were enriched in class *Thermoleophilia* (LDA ES 3.5, p=0.02, Figure 2A) and genus *Lactococcus* (LDA ES 3.6, p=0.02, Figure 2A,B).

Figure 1: Comparison of microbial DNA clades in young vs. old cartilage from chow and HFD mice.



Microbial clades identified in cartilage of young and old mice fed chow or high-fat diet.

Figure 2: Comparison of microbial DNA clades in chow and HFD mice.



Comparison of microbial clades identified in cartilage of chow-fed and high-fat-diet-fed mice.

We also noted significant increases in the Firmicutes:Bacteroidetes ratio in both HFD and aging (chow young vs. old 2.3±0.7 vs. 29±9, p=0.05, young chow vs HFD 2.3±0.7 vs. 13±3, p=0.04) Figure 1C.

Conclusion: Cartilage microbial DNA patterns vary with nongenetic OA risk factors, including obesity and aging. Previous studies have shown increases in the Firmicutes:Bacteroidetes ratio in the gut microbiome associated with both obesity and aging, we identified a similar pattern within articular cartilage. Future studies should investigate the relationship between cartilage microbial DNA patterns and the gut microbiome, as well as localized innate immune activation driven by intraarticular microbial DNA.

Liraglutide as a Potential Intra-Articular Treatment for Cartilage Regeneration in Osteoarthritis: *In Vitro* and *In Vivo* Studies Supporting a Pro-Chondrogenic Effect

Francis Berenbaum[1], Coralie Meurot[2], Laure Sudre[3], Keren Bismuth[2], Revital Rattenbach[2], Patrice Denefle[2], Celine Martin[2] and Claire Jacques[3], [1]AP-HP, Hôpital Saint-Antoine, Service de Rhumatologie, Centre de Recherche Saint-Antoine, INSERM UMR_S 938,Sorbonne Université, Paris, 75012, France, Paris, France, [2]Campus Institut Pasteur Lille, 4P Pharma, Lille, France, [3]Inserm, UMR_S938, Hospital Saint-Antoine, Paris, France

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is an age-related joint disease affecting millions of individuals worldwide and associated with an extremely high burden largely attributable to disability. To date, there are only symptomatic treatments and no disease-modifying OA drugs (DMOADs) acting on both symptoms and structure are yet approved. Although OA is a disorder of the whole joint, progressive cartilage degeneration is considered as its hallmark. Indeed, differentiation and function of chondrocytes are impaired in OA, resulting in the breakdown of the cartilage matrix. Liraglutide is a Glucagon-Like-Peptide 1 Receptor (GLP-1R) agonist widely prescribed for the treatment of type 2 diabetes. We have previously shown that intra-articular (IA) liraglutide exerts anti-inflammatory and anti-degradative effects1. In this study, liraglutide was assessed for its pro-chondrogenic properties.

Methods: IA injection of liraglutide or vehicle was performed 2 days after injection of monoiodoacetate (MIA) or saline in mice. RTqPCR analyses of knee joint was performed 10 days following saline or MIA injection. The capacity of liraglutide (10-500nM) to induce chondrogenesis was evaluated using human mesenchymal stem cells (hMSCs) and mouse embryonic fibroblasts (MEFs) high-density micromass in-well culture systems. Safranin O and/or alcian blue staining was used to assess differentiation into chondrocytes. Exendin 9-39, a GLP-1R antagonist, was used to confirm target specificity. A commercial differentiation medium and bone morphogenetic protein 2 (BMP-2) were used as positive controls for hMSC and MEFs models, respectively.

Results: Col2a1 gene expression was significantly increased in total knee joints from MIA-induced mice treated with 30µg of liraglutide compared to vehicle (At Day 11, Liraglutide= 1.96±1.34, vs vehicle= 0.64±0.46, $p< 0.05$, fold change related to saline treatment). Moreover, there was a significant induction of Sox9 gene expression in MIA mice treated with 30µg and 20µg of liraglutide (Fold 2.46±1.84; 2.08±1.36, respectively, $p\leq0.05$) compared to vehi-

cle (0.92±0.67). Using hMSC, after 21 days of treatment, liraglutide but not vehicle induced their differentiation into chondrogenic 3D spheroids (Liraglutide 10nM= 5 alcian-blue positive spheroids out of 6 counted wells, $p< 0.05$; Liraglutide 100nM= 4/6, p=0.06, vs vehicle= 0/6). 5/6 alcian-blue positive spheroids were also observed for the positive control. Both Liraglutide or BMP-2 induced MEFs to differentiate into chondrocytes as revealed by cytologic analysis using alcian blue and safranin O staining. Spectroscopic quantification (in arbitrary unit, AU) of the Safranin O stain in MEFs after 21 days of chondrogenic differentiation indicated a significant increase of absorbance for liraglutide 500nM (2.90±0.03 AU, $p< 0.001$) and BMP-2 (3.17±0.06, $p< 0.001$) vs vehicle (1.99±0.34). The use of exendin 9-39 confirmed that the effect of liraglutide on chondrogenesis was GLP-1R dependent in both in vitro models.

Conclusion: Liraglutide promotes chondrocyte differentiation, which could facilitate cartilage regeneration in OA, and thus represents a potential DMOAD treatment for knee OA.

The Murine Ear Wound Cartilage Superhealer Trait, Mediated by the Gut Microbiome, Is Transgenerationally Heritable Following Cecal Transplantation

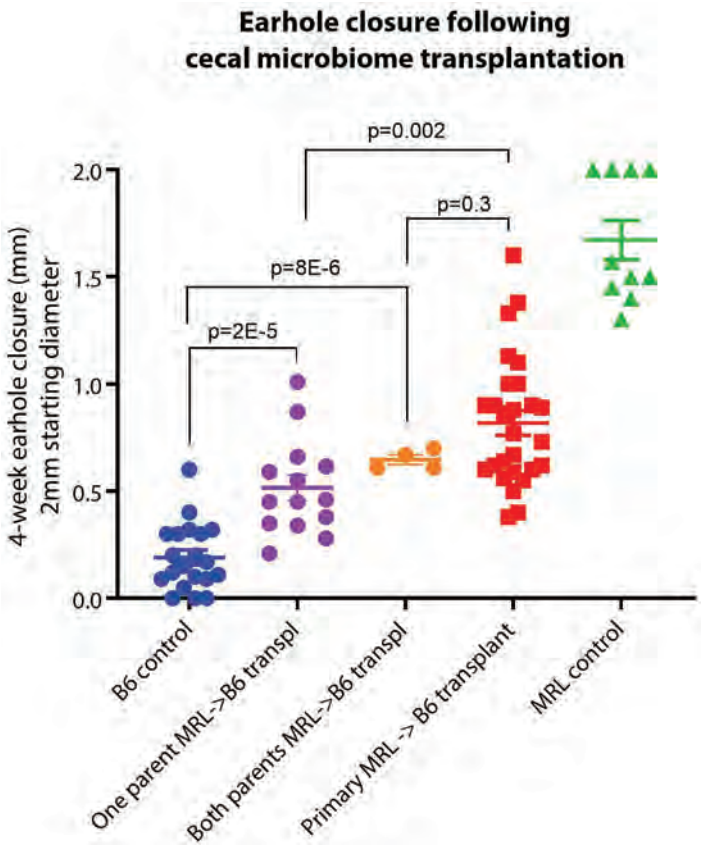
Christopher Dunn[1], Cassandra Garman[2], Cassandra Velasco[2], Vladislav Izda[2], Jake Martin[2] and **Matlock Jeffries**[2], [1]University of Oklahoma Health Sciences Center, Oklahoma City, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: MRL/MpJ mice are substantially protected from developing post-traumatic osteoarthritis (OA), a trait with strong correlation to the ability to heal ear wounds. We have previously shown that this ear wound healing trait is partially determined by the gut microbiome, and that gut microbial transplantation into non-healer mice can confer the healing phenotype. In this study, we sought to examine whether the earhole healing phenotype associated with microbiome transplantation can be transgenerationally inherited.

Methods: Three-week-old C57BL6/J mice were inoculated by oral gavage with diluted cecal contents from adult male MRL/MpJ mice, or with vehicle control. Mice were then segregated into breeding cages, including cages where both parents were transplanted and cages where only one parent was transplanted. Offspring of these breeding pairs (n=4 for 'both parents transplanted', n=14 for 'one parent transplanted') received a 2mm earhole punch at 6 weeks of age, and final hole size was measured 4 weeks later. Group differences were compared to previous data on earhole closure from B6 vehicle, MRL vehicle, and primary B6- >MRL transplant mice.

Results: First-generation offspring wherein both parents received microbiome transplantation healed well (mean earhole closure at 4 weeks, mm, 0.65±0.02, p=8E-6 vs. B6 vehicle control) and were statistically indistinguishable



Earhole closure in animals following microbiome transplant, and their progeny.

from primary transplant mice (p=0.3). First-generation offspring wherein one parent was transplanted and the other also healing compared to vehicle B6 mice (earhole closure 0.52±0.08, p=2E-5 vs. B6 vehicle control), but worse than primary transplanted mice (p=0.002), Figure 1. 16S profiling of cecal microbiomes in each of these groups is ongoing.

Conclusion: The ear wound healing phenotype seen following cecal microbiome transplantation from healer MRL mice into nonhealer B6 mice is present in first generation offspring of transplanted mice. Further work will focus on identifying the key microbial clades being inherited which correlate with this phenotype, and examining any differences in healing based on mouse sex. Future studies should examine whether first generation offspring of transplanted mice are also protected against post-traumatic osteoarthritis.

lncRNA H19 and Micro RNA 675-3p Are Altered by Visfatin During Osteogenesis

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Long non-coding (lnc-)RNAs are transcribed from DNA similar to mRNA. lncRNA are able to interact directly with DNA, RNA and proteins. Some lncRNAs contain micro (mi-)RNAs in their sequence. The miRNAs can be released by splicing leading to active miRNA molecules. lncRNA H19 includes two miRNAs 675-3p and -5p in its sequence. Adipose tissue derived adipokines are involved in inflammation processes as well as osteoarthritis (OA) development. The proinflammatory adipokine visfatin is able to alter osteogenic differentiation (OD) of pluripotent mesenchymal stem cells (MSCs). Visfatin reduces elastic fiber expression, increases matrix mineralization and proinflammatory factor production.

Methods: MSCs isolated from OA hip or knee bone (phMSCs) and commercially obtained healthy human hMSCs were differentiated towards osteoblasts stimulated with or without visfatin, resistin, leptin as well as TNF and Wnt/TGFβ1 pathway inhibitors. Supernatants were collected at days 2, 7, 9, 14 and 21 of OD, cell lysates at day 2, 7, 9, 14. Matrix mineralization assays were performed at day 21. lncRNA H19 and miRNA expression was evaluated by real-time PCR after miRNA and total RNA isolation. IL-6 was measured by ELISA.

Results: Visfatin increased matrix mineralization and IL-6 release (hMSC: p=0.03, phMSC: p=0.01) (1). lncRNA H19 was continuously upregulated in unstimulated controls during OD as well as with leptin or resistin. Stimulation with visfatin significantly decreased lncRNA H19 (d2 to d14 of OD, phMSC: p=0.01, h-MSC: p=0.04). TNF stimulation during OD did not lead to downregulation of H19 nor increased matrix mineralization. lncRNA H19 endogenous miRNA 675-5p was reduced in parallel with H19: increased during OD and downregulated by visfatin significantly (e.g. d14 p=0.02). However, H19 endogenous miRNA 675-3p was inversely regulated: downregulated during OD while visfatin attenuated this effect (e.g. d14 p=0.03). Altered Wnt-signaling or TGFβ1 pathway were not observed.

Conclusion: lncRNA H19 is upregulated during OD playing a regulatory role during osteogenesis. During OD, visfatin showed proinflammatory effects and increased matrix mineralization while reducing elastic fiber production. These effects were associated with a reduction of lncRNA H19, an effect not triggered by other adipokines or TNF. We demonstrated that the lncRNA H19 endogenous miRNA 675-5p was regulated in parallel to H19, whereas miRNA 675-3p was inversely regulated and increased continuously upon visfatin stimulation. These results indicate that miRNA 675-3p is released out of the lncRNA H19 sequence leading to H19 reduction representing an effector mechanism

of visfatin. We hypothesize that this is a restrictive process in which either microRNA 675-5p or -3p is liberated from H19 and, in this setting, of miRNA 675-3p.

Adenosine A2A Receptor Activation Reduces Markers of Chondrocyte Senescence and Cartilage Inflammation Associated with Osteoarthritis

Benjamin Friedman[1] and Bruce Cronstein[2], [1]NYU Rheumatology, New York, NY, [2]NYU Grossman School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis is an aging-associated disorder linked to dysfunctional metabolism, chronic inflammation, oxidative stress, and cellular senescence. Cellular senescence is associated with stable cell cycle arrest, resistance to apoptosis, and the senescence-associated secretory phenotype with NFkB activation and inflammation with upregulation of senescence markers p16, p21, and p53. Importantly, senescence causes chondrocyte dysfunction by disrupting local cartilage homeostasis and promoting ECM degradation.

Methods: TC28α2 human chondrocytes were treated with or without the A2AR agonist CGS21680 (CGS, 1μM). WB, IF, and RT-qPCR were employed to evaluate *in vitro* markers of senescence and inflammation. IHC staining was used to evaluate *in vivo* markers in mice with obesity-induced OA. A resazurin assay was used to measure cell viability.

Results: We demonstrated that the deacetylase Sirt1, which is known to enhance metabolism and reduce senescence, accumulates in the nucleus by WB within 30 minutes following A2AR stimulation *in vitro* (1.7±0.2 vs 1.0±0.2, p=0.021, n=3). This is supported by a decrease in the nuclear-to-cytoplasmic ratio of acetylated nuclear NFkB by IF (0.67±0.14 vs 1.0±0.2 , p=0.038, n=3, 20-30 cells per representative 40x HPF per experiment). We have previously shown that A2AR binding likely increases Sirt1 deacetylase activity on known target p53 because total cellular p53 and nuclear acetylated p53 were reduced. Interestingly, while full length p53 levels decrease with A2AR ligation, there was a concomitant increase in an anti-senescent, pro-longevity, stem-cell associated 35 kDa transcriptional splice variant d133p53 as assessed by western blot ratio of the isoform to full length p53 (3.0±0.8 vs 1.0±0.06, p=0.005, n=3-4). This increase was also clearly apparent by IF. Accordingly, TC28α2 chondrocyte viability was increased *in vitro* with A2AR activation by resazurin assay over 3 hours (1.15±0.08 vs. 1.0±0.08, p< 0.001, n=10). We evaluated p53-induced senescence *in vivo* by staining for target p21 in an obese mouse OA model. We observed a cytoplasmic shift in signal throughout the cartilage layers in mice treated with liposomal-CGS joint injections. Untreated mice had increased nuclear p21 most notable in the superficial cartilage layers. In concordance, preliminary *in vitro* experiments cells displayed a moderate A2AR-mediated reduction and cytoplasmic shift of p21 and p16 in TC28α2 chondrocytes.

Conclusion: These results indicate that A2AR binding decreases markers associated with chondrocyte senescence both *in vitro* and *in vivo* likely via activation of metabolic proteins Sirt1 and AMPK. Activation of A2AR demonstrates the integral link between healthy metabolism and organismal and cellular longevity and suggests that targeting me-

tabolism can also reduce aging/senescence. This highlights the importance of studying the obesity-induced OA model in addition to other key OA models. Lastly, to our knowledge, the d133p53 p53 variant has not been identified in cartilage or chondrocytes and hence could provide further explanation for the specific mechanism of A2AR-mediated cartilage homeostasis and also further the general understanding the effect of senescence in OA.

Contribution of NOTUM and Glypicans to the Development of Osteoarthritis

Arkaitz Mucientes[1], Eva Herranz[1], Pia Lois[2], Gloria Candelas[2], Lydia Abasolo[1], Luis Rodriguez-Rodriguez[1], Jose Ramon Lamas[1] and Benjamin Fernandez-Gutierrez[3], [1]IdISSC, Madrid, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Madrid, Spain, [3]Hospital Clínico San Carlos / IdISSC, Madrid, Madrid, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a degenerative disease characterized by altered homeostasis of joint cartilage and bone, the functionality of which relies on chondrocytes and osteoblasts, that leads to the formation of a defective extracellular matrix (ECM). The ECM plays an essential role in bone biology as it provides the structure of cartilage which serves as a template for bone formation. Collagen X, main component of the ECM, has been described by our group as down-regulated in OA. Our data also points to an important role of the Wnt pathway in OA. Furthermore, Wnt proteins have been reported to inhibit chondrogenesis, and the Wnt pathway and its modulators have gained attention. Glypicans (GPC1 to GPC6) and NOTUM have been identified as modulators of this pathway. Notably, due to its highly specific inhibition of the Wnt pathway, NOTUM has been proposed as a therapeutic target in conditions with a high activity of the Wnt pathway is involved, such as OA.

We hypothesize that modulators of the Wnt pathway are involved in the development of OA. The aim of this study is to evaluate the presence of Glypicans and NOTUM in the serum, and their gene expression on BM-MSCs of OA patients and healthy individuals in order to determine whether significant differences exist and could clarify their likely involvement in OA.

Methods: Peripheral blood samples were obtained from OA patients, according to the ACR criteria, during routine rheumatologist visits. Samples from healthy individuals were obtained from the local Blood Bank. In both cases, serum was obtained. BM-MSCs form OA patients and healthy donors were isolated and expanded.

Quantitative ELISA assays for GPC1-6 and NOTUM were carried out using commercial kits (GPC1, #E-EL-H1710, Elabscience; GPC2, #E-EL-H1711, Elabscience;GPC3, #E-EL-H1712, Elabscience;GPC4, #E-EL-H1713, Elabscience;GPC5, #ELH-GPC5, RayBiotech;GPC6, #CSB-EL009708HU, Cusabio;NOTUM, #EK3787, Sab Biotech).

Expression of *GPC1-6* was evaluated by RT-qPCR using gene-specific probes (Applied Biosystems; Assay ID: GPC1 Hs00892476_m1; GPC2 Hs00242584_m1; GPC3 Hs01018936_m1; GPC4 Hs00155059_m1; GPC5 Hs00270114_m1; GPC6 Hs00170677_m1).

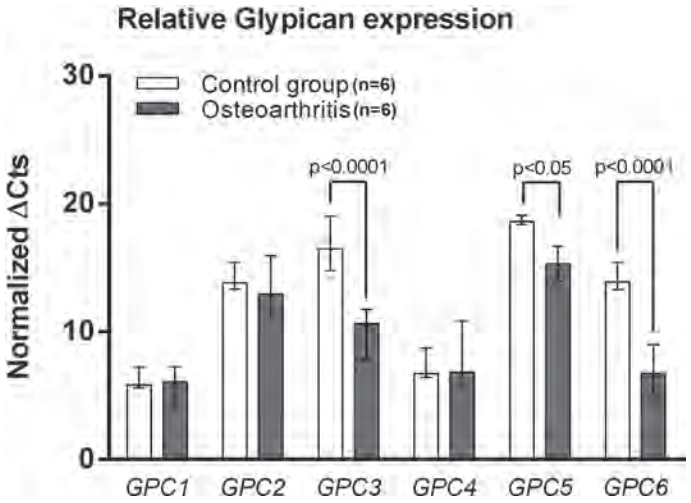

Figure 1. Glypican 1-6 gene expression on BM-MSCs form OA patients and healthy donors (ΔCts normalized to house-keeping genes β-actin and RNA18S5).

Protein concentration in serum and ΔCt for each gene was calculated using GraphPad Prism 7 software. Differences between samples were analysed with Mann-Withney U and multiple t-test. Significance level set was $p< 0.05$.

Results: A total of 40 OA patients and 40 healthy donors were included (Table 1).

Out of 7 proteins analyzed, only NOTUM showed a significant difference groups (Table 2): $Median_{OA}$=0.4451ng/mL, $Median_{CONTROL}$=0.8263ng/mL, p=0.0013.

Gene expression analysis showed a significant down-expression of 3 genes (Figure 1): GPC1, $Mean_{OA}$=5.74, $Mean_{CONTROL}$=6.48 , p=0.53; GPC2, $Mean_{OA}$=13.32, $Mean_{CONTROL}$=14.53 , p=0.34; **GPC3, $Mean_{OA}$=10.07, $Mean_{CONTROL}$=16.73 , p< 0.0001**; GPC4, $Mean_{OA}$=7.94, $Mean_{CONTROL}$=7.63 , p=0.79; **GPC5, $Mean_{OA}$=15.31, $Mean_{CONTROL}$=18.71 , p=0.042**; **GPC6, $Mean_{OA}$=6.94, $Mean_{CONTROL}$=14.17 , p< 0.0001**.

Conclusion: Our results suggest that low levels of *GPC3*, *GPC5*, *GPC6* and NOTUM may contribute to the development of OA. The lack of these inhibitors promotes the activation of the Wnt pathway, high activity of which has been related with OA.

Abstract Number: 0708

Differences in Treating Knee Osteoarthritis by Clinician Specialty

Denise Baldock[1] and Casey Zhang[2], [1]Ipsos MORI, London, England, United Kingdom, [2]Ipsos Insight, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Current treatment of knee osteoarthritis (OA) is focused primarily around pain relief offering sustained mobility and prioritizing symptom relief over disease progression potentially impacts treatment outcome in the longer term for patients. With candidate therapies being investigated to address disease progression, it is important to examine if and where differences exist, with the prescribing behavior of current treaters of knee OA.

Methods: A cross-sectional chart review survey was conducted in Q2 2019 among US rheumatologists (rheums), orthopedic surgeons (orthos), primary care physicians with a focus in sports medicine (SM PCPs), and pain specialists practicing across hospital and private practices. Recruited from a large access panel, physicians were screened for duration of practice in their specialty (3-50 years) and caseload (35 or more knee OA patients, at least 10 of which must be classified as moderate-severe). Participants were asked to complete a 3-part survey: (1) a doctor demographic questionnaire, (2) a perceptual questionnaire, assessing perception of available and upcoming OA therapies, and (3) patient charts for the next 5 knee OA patients seen following receipt of the survey, capturing demographics and treatment history. Data were analyzed using descriptive statistics.

Results: A total of 275 physicians were recruited, reporting on 1375 patients in total (Table 1). When focusing primarily on patients with moderate-severe knee OA, this represented 65% of patients for SM PCPs and orthos. Pain specialists and rheums by comparison, had a significantly larger caseload of moderate-severe patients, at 79% and 77% respectively.

When looking at the proportion of patients treated with prescription medication for their knee OA, pain specialists and rheums stated an average of 69% and 68% of their managed patients, while SM PCPs stated 66%. Orthos stated a significantly lower proportion of patients treated with prescription therapy, at 55%.

Looking at therapies across specialties, orthos state greater use of traditional NSAIDs to treat their knee OA patients compared to pain specialists and SM PCPs (53% vs 36% vs 44%), with a significant difference to the stated use of

	Rheumatologists	Orthopedic Surgeons	SM PCPs	Pain Specialists
Physicians	55	111	56	55
Patient charts	275	555	280	265

Table 1. Physician and patient sample size

Table 1. Physician and patient sample size

rheums (35%). Rheums on the other hand, state significantly greater use of opioids compared to orthos, 18% vs 12% for mild opioids and 8% vs 1% for strong opioids.

From commonly used imaging techniques, X-ray and Magnetic resonance imaging (MRI) were used in greater proportion over ultrasound or computed tomography (CT) scan and when considering evidence of radiographic progression from imaging, rheums reported a significantly lower proportion of patients demonstrating radiographic evidence of bone erosion, compared to all specialties researched- 36% compared to 65% reported by orthos, 65% by SM PCPs and 75% by pain specialists.

Conclusion: From the sample surveyed, knee OA patients may exhibit differing outcomes based on the management adopted by their presiding clinician. With candidate therapies offering alternatives to how we currently treat knee OA, understanding nuances between treaters may prove an important consideration, when examining treatment outcomes in the longer term.Table 1. Physician and patient sample size

Anatomical Distribution of Mrgprd-expressing Nonpeptidergic C-fibers in the Mouse Knee

Alia Obeidat[1], Rachel Miller[1] and Anne-Marie Malfait[1], [1]Rush University, CHICAGO, IL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The voltage-gated sodium channel, $Na_V1.8$, marks the majority of C-fiber nociceptors. We have used $Na_V1.8$ tdTomato reporter mice to describe the nociceptive innervation of the mouse knee (PMID: 31351964). We reported that 16 weeks after destabilization of medial meniscus (DMM), osteoarthritic (OA) joint damage is accompanied by extensive remodeling of nociceptors in the medial compartment of the knee, including increased $Na_V1.8$+ innervation in the medial synovium and within subchondral bone channels. Distinct functional classes of C-fibers have been identified, where it has been proposed that TRPV1+ C-fibers mediate heat sensitivity and C-fibers that express the G protein-coupled receptor (GPCR), Mrgprd, mediate behavioral sensitivity to mechanical stimuli. Their potential role in mechanosensation makes Mrgprd neurons an interesting subject in the context of OA pain, which is why we developed Mrgprd-EGFP reporter mice and investigated if they are present in the murine joint.

Methods: DMM surgery was performed in the right knee of 10-week old male C75BL/6 Mrgprd-EGFPf mice. Knees were harvested from 10-week old naïve mice (n=5), 26-week old naïve mice (n=3), and 16 weeks after DMM (n=3). Mice were perfused transcardially with paraformaldehyde. Knees were harvested, decalcified and cryo-sectioned. Twenty-µm thick coronal sections were collected throughout the joint. Sections were imaged using laser-scanning

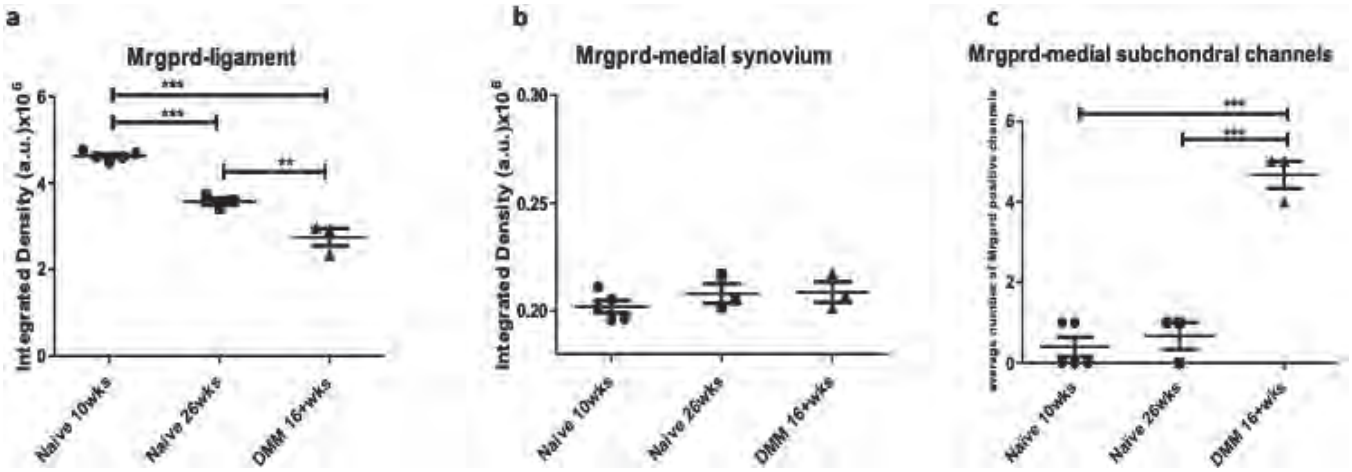

Figure 1. Quantification of MRGPRD+ signal in knees of 10- and 26-week old naïve mice and 16 weeks after DMM surgery, in (a) cruciate ligament insertions; (b) medial synovium; (c) within subchondral channels.** p<0.01 , *** p < 0.001; mean±SEM

confocal microscope (Olympus IX70) and the fluorescence signal was quantified using image J by an observer blinded to the groups.

Results: Mrgprd signal was present in the knee joint of 10-week old naïve mice, specifically at the insertions of the cruciate ligaments and in bone marrow cavities. By the age of 26 weeks, Mrgprd+ innervation decreased significantly in the cruciate ligament insertions (Fig 1a), which is similar to the age-related decline seen in the cruciate ligaments of $Na_V1.8$-tdTomato mice. No signal was observed in the medial synovium of young or old naïve mice (Fig 1b). Sixteen weeks after DMM, OA knees showed further decrease in the Mrgprd+ innervation of the cruciate ligament insertions, compared to 26-week old naïve knees (Fig 1a). In contrast to the increase in the medial synovial $Na_V1.8$+ innervation we previously observed in $Na_V1.8$-tdTomato mice, no change was observed in the Mrgprd+ innervation of the medial synovium after DMM (Fig 1b). Interestingly, Mrgprd signal was present in channel like structures in the subchondral bone of the medial femoral condyle and tibial plateau of the OA knee (Fig 1c), similar to findings in $Na_V1.8$-tdTomato mice.

Conclusion: The intra-articular Mrgprd innervation changed markedly with age and after DMM. The innervation pattern of this mechanosensitive subset was different than the pattern we observed for $Na_V1.8$, which marks all nociceptors. Sixteen weeks after DMM, at which point there is extensive joint damage, mechanosensitive Mrgprd nerve fibers were recruited in subchondral bone channels, but not in the synovium. In contrast, Mrgprd fibers declined significantly in cruciate ligament insertions with age and after DMM. The biological significance of these findings needs to be further explored

Early Start of Biological Treatment in Juvenile Idiopathic Arthritis: Does a Therapeutic Window Exist in Real Life?

Alina Lucica Boteanu[1], Andrea Briones-Figueroa[2], Laura Calvo-Sanz[2], África Andreu Suárez[2] and Antía García-Fernández[2], [1]PRINTO, Istituto Giannina Gaslini, Genova, Italy, [2]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Data about when is the best moment to start BT in Juvenile Idiopathic Arthritis (JIA) patients and the impact of this prompt initiation are scarce.Our aim is to analyze the response to BT of JIA patients according to the time when the BT was started.

Methods: A retrospective, descriptive study of JIA patients followed up in a referral hospital that started BT up to 24 months after diagnosis from 2000 to 2018. Disease activity was measured, at 2 years after diagnosis, according to Wallace criteria for remission for at least 6 months.

Results: 55 JIA patients that started BT up to 24 months from diagnosis were analyzed. 69,1% were girls. The median age at diagnosis was 8 years IQR(3-13) and the median age at the start of BT was 9 years IQR(3-13). Regarding JIA categories: 25,5% were Oligoarticular Persistent (OligP), 18,2% Systemic JIA (sJIA), 16,4% Entesitis related Arthritis (ERA), 12,7% Psoriatic Arthritis (APso) and Polyarticular RF- (PolyRF-), 5,5% Oligoarticular Extended (OligE) and Polyarticular RF+ (PolyRF+), 3,6% Undifferentiated (Und). 20% of patients had uveitis during followup.

Conventional DMARD (cDMARD) was indicated in 83,6% of patients (95,7% Methotrexate) at diagnosis [median 0 months IQR(0-2,3)]. At the end of followup only 30,9% of patients continued with cDMARDs. The main causes of discontinuation were: adverse events (46,7%), remission (36,7%). TNF inhibitors were prescribed in 81,8% of patients and 18,2% of patients received two BT during the study period. 54,5% of BT were indicated during the first 6 months from diagnosis, 27,3% from 7 to 12 months, 12,7% from 13 to 18 months, 5,5% from 19 to 24 months.

After 2 years from diagnosis, 78,2% of patients were on remission and 21,8% active. Among patients with active disease: 75% had arthritis, 16,7% had uveitis and 8,3% had both. There were no differences regarding disease activity among patients with uveitis and neither taking cDMARDs. Regarding JIA categories: 66,7% of OligE, 57,1% of PolyRF- and 57,1% of APso patients were active at 2 years from diagnosis when compared to the other categories (p=0.004).

Patients on remission at 24 months from diagnosis started sooner the BT than active patients [CI 95% (0,46-8,29) p=0,029]. The time when the BT was started was correlated to the activity at 2 years (K= 0,294 p=0,029). When the BT was prescribed after 7,5months from diagnosis it was correlated, in a COR curve, with a higher probability of active disease at 2 years (S=0,67 E=0,63). There was a correlation, among patients on remission at 2 years, between prompt start of BT and less time to reach remission (K= -0,345 p=0,024). Patients with active disease at 2 years, regardless of moment of BT initiation, required more BT during follow-up (p=0,002).

Conclusion: Prompt initiation of BT was correlated with a better outcome. JIA patients that started BT early after diagnosis had a higher probability of remission after 2 years. Starting BT after 7,5 months was correlated with a higher probability of active disease at 2 years. Active disease at 24 months was correlated with presistent active disease during follow-up

Alternative Dosing of Biologic Therapies Is Frequent Among Children with Juvenile Idiopathic Arthritis in the Childhood Arthritis and Rheumatology Research Alliance Registry

Colleen Correll[1], Peter Shrader[2], Anne Dennos[3], Thomas Phillips[2], Natalie Shiff[4], Ruud Verstegen[5] and Timothy Beukelman[6], [1]University of Minnesota, Minneapolis, MN, [2]Duke University, Durham, [3]Duke University, Durham, NC, [4]Florida, Gainesville, FL, [5]The Hospital for Sick Children, Toronto, ON, Canada, [6]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic agents are integral to the treatment of juvenile idiopathic arthritis (JIA) and associated uveitis. Pediatric rheumatologists may increase the dosage of biologics beyond the labeled ranges in order to achieve better disease control or decrease the dosage when the disease is well-controlled. Though alternative dosing of biologics in the treatment of JIA and uveitis is often discussed anecdotally, there have been few published studies. We used the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry to describe alternative dosing of biologics.

Methods: Patients with JIA enrolled in the CARRA Registry and ever treated with a biologic after enrollment were eligible for the study. We defined high-dose and low-dose as 40% higher or lower than the upper or lower limits of the labeled dose (standard dose), respectively, to exclude instances of minor dose variations due to changes in patients' body weight or rounding of doses for convenience. When a labeled dose was not available, we determined a standard dose using phase 3 clinical trials and published studies. We assessed the number of patients with use of low- and high-dose biologics (patients could be counted in more than one dose category). We also reported the subset patients who initiated treatment with a biologic for the first time following Registry enrollment and who initiated low-, standard- and high-dose.

Results: We assessed 5,352 patients treated with 6,740 different biologics following enrollment. At the patient-level, 1,080 (20%) patients ever received high-dose, and 434 (8%) patients ever received low-dose (Table 1). Commonly used biologics that had the highest proportion of patients ever receiving high-dose included infliximab (47%), adalimumab (21%), and anakinra (18%). Commonly prescribed biologics that had the highest proportion of patients ever receiving low-dose included tocilizumab (15%) and anakinra (13%). There were 951 new biologic users after Registry enrollment; 3% were prescribed low-dose, 87% standard-dose, and 11% high-dose.

Conclusion: More than 25% of patients with JIA treated with biologics received doses well outside the standard dose range, despite the fact that there are very little data on the safety and efficacy of such dosing. The vast majority of patients (87%) received standard-dose when initiating their first biologic; therefore, low-dose and high-dose use are generally the result of subsequent dose adjustments rather than disregard for standard dosing. TNF-inhibitors were commonly used at higher doses, especially the monoclonal antibodies that may be used to treat uveitis. Anakinra was commonly used at both high-dose and low-dose, and this may possibly result from variability in individual patient's responses to anakinra and the relative lack of published data and consensus on recommended dosing. Given the frequent use of low-dose and high-dose biologics in clinical practice, there is an urgent need to assess the relative safety and effectiveness of alternative biologic dosing strategies.

Table 1: Frequency of non-standard biologic dosing ever used in patients with JIA after enrollment in the CARRA

Biologic	N	Low dose	High dose
Any	5,352	434 (8.11%)	1,080 (20.18%)
Abatacept	351	12 (3.42%)	49 (13.96%)
Adalimumab	2,502	61 (2.44%)	521 (20.82%)
Anakinra	245	31 (12.65%)	45 (18.37%)
Canakinumab	230	9 (3.91%)	6 (2.61%)
Certolizumab	24	6 (25.00%)	7 (29.17%)
Etanercept	2,165	215 (9.93%)	215 (9.93%)
Golimumab	68	2 (2.94%)	8 (11.76%)
Infliximab	506	4 (0.79%)	236 (46.64%)
Rilonacept	6	0 (0.00%)	0 (0.00%)
Tocilizumab	643	96 (14.93%)	100 (15.55%)

CARRA = Childhood Arthritis and Rheumatology Research Alliance, JIA = juvenile idiopathic arthritis

* Please note that the two columns are not necessarily mutually exclusive. A patient with high-dose biologic therapy can later have a low-dose therapy and would be included in both categories.

	JADAS10	0 (0-3.4)	0 (0-2.8)	0 (0-0)	0 (0-0)

Background/Purpose: Limited data about the use of biosimilar are available in children with Juvenile Idiopathic Arthritis (JIA). To evaluate the long-term efficacy and safety of switching from the etanercept (ETA) and adalimumab (ADA) originators to their biosimilars, in children with JIA.

Methods: Medical charts of JIA children who switched from ETA or ADA originators to the biosimilars were retrospectively evaluated. Efficacy of anti-TNF therapy was evaluated at last follow-up during the originator therapy and at 3, 6 and 12 months following the switch to biosimilar, assessing number of inflamed joints, CRP, ESR, Juvenile Arthritis Disease Activity Score (JADAS 10), Visual Analog Scale (VAS) and Childhood Health Assessment Questionnaire (CHAQ). Occurrence of adverse event (AE) during treatment was evaluated. Continuous variables were reported as median value and interquartile range (IQR) and compared using the Wilcoxon test for paired data, and csquare analysis.

Results: 43 children (31 Female, median age at onset 65 months (IQR 31-125) received originator ETA (n=14) or ADA (n=29), as first-line anti-TNF treatment for refractory JIA. Due to healthcare politics, patients have been switched to the biosimilar: Benepali®(n=13), Erelzi® (n=1) for ETA; Imraldi® (n=24), Amgevita® (n=5) for ADA, after 40.5 months (IQR 19.1-73.8) duration of originator treatment. At time of switch, 10/14 patients on ETA and 19/29 on ADA were on complete disease remission. No significance difference of entered parameters has been found at 3, 6 and 12 months thereafter the switch. Nine patients discontinued biosimilars, due to disease remission (5), to family willing (2), to occurrence of burning at injection site (2, on Benepali). The number of patients who experienced an AE was not different in different frame follow-up when comparing exposure to the originator and that to biosimilar, respectively: during 0-3 months, 15/42 (35.7%) *vs* 7/37 (18.9%), c^2: 2.76; during 3-6 months, 16/40 (40.0%) *vs* 17/31 (54.8%), c^2: 1.54; during 6-12 months, 15/39 (38.5%) *vs* 11/24 (45.8%), c^2: 0.33 . Most frequent AEs were upper respiratory tract infections (31) and injection site reactions (7).

Conclusion: Data from this small, retrospective inception cohort, showed similar efficacy and safety of the originator and a type of ETA and ADA biosimilars in JIA.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept is a selective T-cell co-stimulation modulator approved for use in JIA. Efficacy and safety of abatacept in patients with JIA has been demonstrated previously in two Phase III studies.[1,2] The objective of this analysis was to provide data from a real-world setting for longitudinal effectiveness of IV and SC abatacept in patients with JIA.

Methods: By protocol, clinical sites in the Pediatric Rheumatology Collaborative Study Group and Paediatric Rheumatology International Trial Organization enrolled patients meeting the ILAR criteria for one of the categories of JIA[3] currently taking or starting IV or SC abatacept. Planned duration of follow-up (FU) is 10 years; data were collected up to March 31, 2018. Effectiveness was assessed at day of entry into registry (baseline [BL]), 3 and 6 months and 1, 2, 3, 4 and 5 years. Safety data were collected at each visit.

Results: Of the 438 patients enrolled, 435 were included in the analysis; 346/435 (80%) were female. At BL, 17 (4%) patients were aged 2–5 years, median age was 13.6 years, JIA disease duration was 4.4 years, abatacept treatment duration was 6.5 months and number of active joints was 1 (mean 2.7). JIA categories were systemic (2%), oligo (23%), polyarticular RF– (55%), polyarticular RF+ (10%), psoriatic (3%), enthesitis-related (3%) and undifferentiated (4%). Total abatacept exposure was 474.0 patient-years. At 1-year FU, patients had low Physician Global Disease Activity, low Juvenile Arthritis Multidimensional Assessment Report scores and improved joint assessments (**Table 1**). A higher percentage of patients achieved clinically inactive disease after 1 year of FU vs BL (32 vs 45; **Table 1**). This trend continued despite low numbers of patients with 4 and 5 years of FU. There were 5 serious infections reported (incidence rate [IR] 0.66 /100 patient-years of FU, 95% CI: 0.22, 1.55; IR 0.79/100 patient-years on treatment, 95% CI: 0.26, 1.84). There were 15 autoimmune events (9 new onset) in 14 patients (IR 1.98/100 patient-years of FU, 95% CI: 0.66, 4.65; IR 2.37/100 patient-years on treatment, 95% CI: 0.78, 5.52). No malignancies or tuberculosis were reported. There was 1 death (unrelated pre-existing cardiac problems).

Table 1. Assessment of disease activity and impact

Endpoint	BL (n=435)	3 months (n=348)	6 months (n=319)	1 year (n=296)	2 years (n=189)	3 years (n=75)	4 years (n=21)	5 years (n=3)

BL=baseline; HRQoL=health-related quality of life; JAMAR=Juvenile Arthritis Multidimensional Assessment Report.

Conclusion: In this real-world JIA cohort, abatacept was safe and well-tolerated with no new safety risks identified. This longitudinal analysis further supports the persistent effectiveness of abatacept in patients with JIA.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept, a selective T-cell co-stimulation modulator, has been demonstrated to be well tolerated and effective in JIA in 2 Phase III studies.[1,2] The ongoing Phase IV Pediatric Rheumatology Collaborative Study Group and Paediatric Rheumatology International Trial Organization (PRCSG/PRINTO) registry aims to provide monitoring data from a real-world setting regarding longitudinal effectiveness and safety of abatacept in JIA. Here we assess the effectiveness of abatacept in JIA categories in patients who enrolled ≤1 month after starting abatacept treatment.

Methods: Using a standardized protocol and data collection process, clinical sites enroll patients with JIA currently receiving/starting IV/SC abatacept and follow them for up to 10 years. Patients are assessed at baseline and at 3, 6, 9, 12, and 24 months. Disease-related quality of life and physical function were quantified using the Juvenile Arthritis Multidimensional Assessment Report scale.[3] Proportions of patients with JIA-ACR 30, 50, 70, and 90 level of responses were determined using validated definitions based on 5/6 JIA core set measures (CRP/ESR not included).[4] The clinical 10-joint Juvenile Arthritis Disease Activity Score (cJADAS10) used validated cut-offs for low disease (LD) and inactive disease (ID) activity.[5] Disease remission was defined as cJADAS10-validated ID for ≥6 months. As-observed analysis is presented.

Results: As of March 31, 2018, 115 patients were included. Of these, 93 (80.9%) were female, the baseline mean (median) age at enrollment was 12.8 (13.1) years, and disease duration was 60.0 (42.1) months. The JIA categories identified were: polyarticular RF–, 52 (45.2%); oligoarticular, 36 (31.3%); polyarticular RF+, 11 (9.6%); enthesitis-related arthritis (ERA), 9 (7.8%); psoriatic and undifferentiated, 3 (2.6%) each; systemic, 1 (< 1%) (**Table 1**; patient with systemic JIA excluded). The proportions of patients achieving JIA-ACR responses, cJADAS10 LD, cJADAS10 ID and cJADAS10 remission are shown in **Figure 1** (patient with systemic JIA excluded).

Conclusion: Abatacept treatment resulted in rapid, clinically important and sustained JIA-ACR responses in all JIA categories with polyarticular or oligoarticular disease course and few achieved cJADAS10 ID and cJADAS10 remis-

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Effectiveness of SC abatacept in patients with polyarticular-course JIA (pJIA) was shown in a 2-year, open-label Phase III international study (NCT01844518). Here we assess potential predictors of Juvenile Arthritis Disease Activity Score 27-CRP (JADAS27-CRP) minimal disease activity (MDA), inactive disease (ID) and remission.

Methods: Patients with pJIA aged 2–17 years received weight-tiered SC abatacept (10–< 25 kg: 50 mg; 25–< 50 kg: 87.5 mg; ≥50 kg: 125 mg) weekly for 4 months.[1] JIA-ACR30 responders at Month 4 could receive SC abatacept for another 20 months.[1] Potential predictors of response over 11 time points to Month 21 were determined with a multivariate logistic regression (MVR) analysis; Month 4, 13 and 21 data are presented. MVR variables assessed were baseline age, sex, race, weight, geographic region, CRP, MTX use, prior biologic use, number of active joints, number of joints with limitation of motion, physician's global assessment of disease activity, Childhood HAQ-DI (CHAQ-DI), parental assessment of well-being (PaGA) and JIA-ACR50 or JIA-ACR70 responses at Month 3. Variables were deemed significant if corresponding p values were < 0.05 at ≥6 of the 11 time points. Missing values were imputed as non-responders. Baseline continuous variable cut-offs (high/low) were determined by receiver-operator curve analysis. Outcomes analyzed included JADAS27-CRP MDA (≤3.8), ID (≤1) and remission (JADAS27-CRP ID for ≥6 months) rates. Odds ratios and 95% CIs were computed.

Table 1. ORs (95% CI) for variables potentially predictive of JADAS27-CRP MDA, ID or remission at Month 13[a]

	MDA		ID		Remission	
	Cut-off	OR (95% CI)	Cut-off	OR (95% CI)	Cut-off	OR (95% CI)

*Statistically significant (p<0.05).

[a]n=217; [b]Showing trend (p=0.05–0.1).

CHAQ-DI=Childhood HAQ-DI; ID=inactive disease; JADAS27-CRP=Juvenile Arthritis Disease Activity Score 27-CRP; MDA=minimal disease activity; OR=odds ratio; PaGA=parental global assessment.

Results: In all treated patients (N=219), median (range) baseline characteristics were: age 11.0 (2.0–17.0) years, CRP 0.2 (0.1–21.1) mg/dL, CHAQ-DI 1.0 (0.0–2.9) and PaGA 47.2 (0.0–95.8). Variables with the highest number of significant p values (≤0.05) were baseline CRP, CHAQ-DI, PaGA, and Month 3 JIA-ACR50 and JIA-ACR70. Baseline CRP, PaGA and CHAQ-DI were predictive of JADAS27-CRP MDA, ID and/or remission at multiple time points (Month 13: **Table 1**; Month 21: **Table 2**). JIA-ACR50 response at Month 3 was statistically significant at predicting achievement of JADAS27-CRP MDA at Month 13 (**Table 1**) and Month 21 (**Table 2**), and showed a statistical trend at Month 4 (data not shown). JIA-ACR50 response was statistically significant (p< 0.05) at five consecutive time points between Months 10 and 21.

Conclusion: Clinically important JIA-ACR50 response at Month 3 was predictive of the attainment of JADAS27-CRP MDA status at Month 13 and Month 21 in patients aged 2–17 years with pJIA treated with SC abatacept.

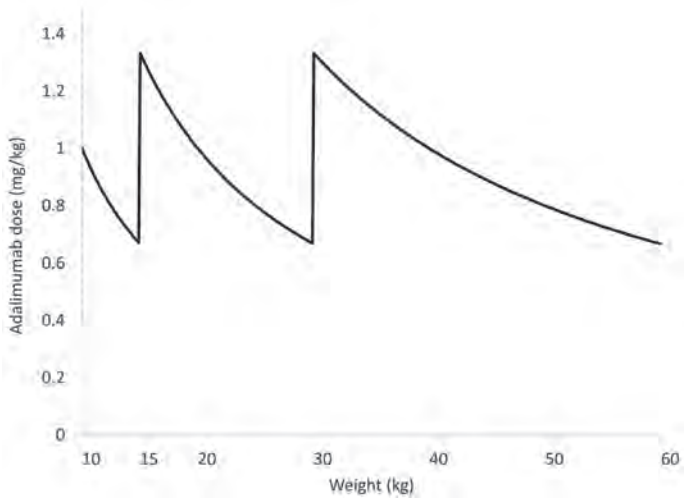
Variations in Adalimumab and Etanercept Dosing in Juvenile Idiopathic Arthritis and Their Effect on Treatment Outcome: A Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry Study

Ruud Verstegen[1], Peter Shrader[2], Stephen Balevic[3], Timothy Beukelman[4], Colleen Correll[5], Anne Dennos[6], Thomas Phillips[2] and Brian Feldman[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Duke University, Durham, [3]Duke University Medical Center, Durham, [4]University of Alabama at Birmingham, Birmingham, AL, [5]University of Minnesota, Minneapolis, MN, [6]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Different dosing strategies of adalimumab and etanercept have been used over the past decade in the treatment of juvenile idiopathic arthritis (JIA). With regards to adalimumab, dosing was initially 24 mg/m^2 body surface area (BSA) every other week (eow) but changed to fixed dosing by weight categories (10-15 kg: 10 mg eow; 15-30 kg: 20 mg eow; ≥30 kg: 40 mg eow), resulting in large variation in body weight-adjusted exposure (See



Recommended Adalimumab dose according to product monograph in mg/kg/every other week. Dosing categories: 10 mg (body weight 10-15 kg), 20 mg (body weight 15-30 kg) and 40 mg (body weight >30 kg) biweekly.

	Adalimumab (dose per 2 weeks)			Etanercept (dose per week)

BSA-adjusted dose (mg/m²)	30.45 (20.56)	31.80 (20.08)	0.65	27.07 (7.14)	25.61 (5.06)	0.19

Dose comparison between patients (all ages) who achieved the outcome of interest, and those who did not. BSA, body surface area. Numbers in bold represent the number of patients. Underlined results reached statistical significance ($p<0.05$).

Figure). For etanercept, the dosing recommendations remained 0.8 mg/kg per week, but the presence of single-dose prefilled syringes (25 or 50 mg) unintentionally promotes rounding of doses. These practices contribute to variable drug exposure in patients with JIA. In addition, metabolism of therapeutic proteins is increased in younger children especially in those aged < 6 years, which reduces drug exposure (i.e., serum drug concentrations). We hypothesize that a higher relative dose (mg/kg or mg/m^2) improves the treatment response of children with JIA who start adalimumab or etanercept.

Methods: This is a retrospective cohort study of CARRA Registry data, which contains prospectively collected data from children with rheumatic diseases. Patients aged < 18 years old were included in the analysis if they had a diagnosis of JIA (systemic JIA excluded), started adalimumab or etanercept after Registry enrollment as their first biologic DMARD, and had follow-up data available. The following outcomes were determined between 4-7 months after start of treatment: pediACR100, 90, 70, 50, 30, clinical juvenile arthritis disease activity score (cJADAS; clinically inactive disease: ≤ 1; low disease activity ≤ 2 for oligoarticular course, ≤ 3.8 for polyarticular course), as well as treatment continuation for > 6 months, as a surrogate marker for treatment efficacy. The weight- and BSA-adjusted dose (mg/

kg and mg/m^2, respectively) were compared using Student's t-tests (significance $p < 0.05$; no adjustment for multiple comparisons) between patients with and without the outcome and stratified by age group (< 6 years, 6-12 years, 12-18 years).

Results: This analysis included 406 and 296 patients treated with adalimumab and etanercept, respectively. Children < 6 years old attaining pediACR90/100 received higher adalimumab dosing (1.32 vs 1.06 mg/kg [p = 0.03] and 31.78 vs 25.42 mg/m^2 [p = 0.02]). For etanercept, children (all ages) who achieved cJADAS ≤ 1 received lower doses by BSA (24.79 vs 27.53 mg/m2, p=0.01; See Table). In the subgroup analysis, this was only true for 6-12 years (cJADAS ≤ 1: 22.98 vs 27.60 mg/m^2 [p = 0.007]; cJADAS ≤ 2: 21.80 vs 29.52 mg/m^2 [p = 0.003]). All other analyses did not show associations between dose and outcome variable.

Conclusion: This study provides some evidence that children younger than 6 years old have improved treatment response (pediACR90/100) when treated with a relatively higher dose of adalimumab, while lower etanercept dosing was associated with improved cJADAS outcome. As these analyses are unadjusted, further studies using a Bayesian approach with propensity score matching will follow to adjust for patient characteristics that may contribute to receiving a higher treatment dose (e.g., age, disease activity, uveitis, etc).

Predictors of Clinical Remission in Children with Extended Oligoarticular Arthritis, Enthesitis-related Arthritis, or Psoriatic Arthritis Treated with Etanercept in the CLIPPER Studies

Jelena Vojinovic[1], Vyacheslav Chasnyk[1], Joke Dehoorne[1], Violeta Panaviene[1], Jonathan Akikusa[2], Tadej Avcin[1], Jeffrey Chaitow[1], Bernard Lauwerys[1], Jordi Antón[1], Inmaculada Penades[1], Berit Flato[1], Alina Boteanu[3], Hans-Iko Huppertz[1], Juan Jaller[1], Daniela Graham[4], Cecilia Borlenghi[5], Bonnie Vlahos[6], Chuanbo Zang[6] and Nicolino Ruperto[2], [1]Paediatric Rheumatology International Trials Organisation (PRINTO), Genoa, Italy, [2]PRINTO, Istituto Giannina Gaslini, Genova, Italy, [3]Hospital Universitario Ramón y Cajal, Madrid, Spain, [4]Pfizer, Groton, PA, [5]Pfizer, New York, NY, [6]Pfizer, Collegeville, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: CLIPPER is an ongoing, 8-year, phase 3b, multicenter, open-label study of the safety and efficacy of etanercept in the treatment of juvenile idiopathic arthritis (JIA) categorized as extended oligoarticular arthritis (eoJIA), enthesitis-related arthritis (ERA), or psoriatic arthritis (PsA). The aim of this study was to identify predictors of sustained 6-month clinical remission on medication using long-term data from CLIPPER.

Methods: Previously reported baseline characteristics of the 127 children enrolled in CLIPPER (60 eoJIA [2–17 years], 38 ERA [12–17 years], and 29 PsA [12–17 years])[1] were analyzed post hoc as possible predictors of the attainment of clinical remission on medication (per the JIA ACR criteria or Juvenile Arthritis Disease Activity Score 71-joint [JADAS] criteria) sustained for 6 consecutive months using univariate logistic regression models and stepwise multivariate

Table. Predictors of sustained 6-month clinical remission on medication during the CLIPPER studies

Univariate analyses		
	Definition of remission	
	JIA ACR (N=127)	JADAS (N=127)
Patient characteristic	OR (95% CI)	OR (95% CI)
Age at onset (≤7.61 years vs older)	5.17 (2.31, 11.57)	1.93 (0.90, 4.14)
Patient/Parent Global Assessment score (≤2.5 vs >2.5)	2.67 (1.13, 6.28)	2.75 (1.13, 6.67)
JIA ACR IA at Week 12 (Yes vs No)	5.06 (1.51, 16.99)	4.64 (1.24, 17.38)
JADAS LDA at Week 12 (Yes vs No)	5.83 (2.60, 13.06)	7.06 (3.02, 16.51)
JADAS IA at Week 12 (Yes vs No)	7.00 (2.14, 22.89)	4.10 (1.26, 13.29)

Multivariate analyses	
Definition of remission and patient characteristic	OR (95% CI)
JIA ACR	
Age at onset (≤7.61 years vs older)	7.19 (2.71, 19.09)
JADAS LDA at Week 12 (Yes vs No)	6.29 (2.46, 16.06)
JADAS	
JADAS LDA at Week 12 (Yes vs No)	7.68 (3.08, 19.14)

CI: confidence interval; IA: inactive disease; LDA: low disease activity; OR: odds ratio.

models. Clinical response and disease activity status after 4, 8, and 12 weeks of treatment were also evaluated as predictors. Analyses were based on observed cases in CLIPPER and 6-year follow-up data from the CLIPPER2 extension.

Results: Univariate analyses showed that baseline Patient/Parent Global Assessment score, JIA ACR inactive disease (IA) at Week 12, JADAS low disease activity (LDA) at Week 12, and JADAS IA at Week 12 were associated with the attainment of 6-month remission according to both JIA ACR criteria and JADAS criteria (**Table**). Multivariate analyses showed that age at onset and JADAS LDA at Week 12 were predictors of 6-month remission according to JIA ACR criteria, whereas JADAS LDA at Week 12 was a predictor according to JADAS criteria.

Conclusion: JADAS LDA at Week 12 of etanercept treatment was a predictor of attaining sustained 6-month clinical remission on medication according to JIA ACR criteria and JADAS criteria during the CLIPPER studies. Younger age at onset was also a predictor according to JIA ACR criteria.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: to assess prevalence and disease features associated with obesity in juvenile idiopathic arthritis (JIA) and to evaluate the impact of obesity on the achievement of clinical inactive disease (CID) at six months from the start of treatment with tumor necrosis factor inhibitors (TNFi).

Methods: retrospective analysis of demographic, clinical and laboratory features and body mass index (BMI) collected at the start of TNFi treatment in patients with oligoarticular and rheumatoid factor (RF)-negative polyarticular JIA. Patients were divided into obese and non-obese; demographic, clinical and disease features were compared in the two groups. The distribution of obese, overweight, healthy-weight and underweight patients according to the achievement of CID at 6 months was investigated.

Results: 234 patients with JIA (39% RF-negative polyarthritis, 25% extended oligoarthritis, 36% persistent oligoarthritis) were enrolled in the study. Obesity (BMI $\geq 95^{th}$ percentile for age and gender) was present in 31 patients (13.2%). Obese patients compared to non-obese patients, had an older age at disease onset (p=0.020), lower frequency of antinuclear-antibody positivity (p=0.043), a higher number of active joints at baseline (p=0.0048) and higher C-reactive protein at baseline (p=0.043). Obese JIA patients achieved clinical inactive disease (CID) at 6 months with a lower frequency compared to non-obese patients (p=0.005). In multivariate regression analysis obesity at baseline was confirmed as an independent risk factor for non-achievement of CID at 6 months from starting TNFi (OR 2.42 [95% CI 1.04-5.61]; p=0.040).

Conclusion: obesity negatively affects response to TNFi in oligo- and RF-negative polyarticular JIA, independently from other disease-associated variables.

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immunogenicity and development of anti-drug antibodies have been associated with treatment failure and adverse events during biologic treatment. Anti-drug antibodies (ADAs) have been reported in 21% of Juvenile Idiopathic Arthritis patients treated with Adalimumab. However, their role in reducing adalimumab efficacy is still debated due to conflicting results. No study has been directed toward identification of neutralizing ADAs in paediatric rheumatic disorders.

Aim of our study was to detect ADAs, along with their clinical relevance, using a new theranostic peptide-base assay in a cohort of children with inflammatory chronic diseases on Adalimumab treatment.

Methods: ix candidate Adalimumab derived peptide antigens (HC-CDR1, HC CDR2, HC CDR3, LC CDR1, LC CDR 2, LC CDR3) have been developed and optimized to be tested. Their performance has been compared with commercial ELISA kit and a SPR-based optical assay (Biacore®). Assays have been performed in sera of a cohort of children receiving Adalimumab due to an inflammatory chronic disease. Mean age, disease duration, concomitant treatment with methotrexate (MTX), ANA positivity, disease activity parameters and scores at the time of ADA determination have been recorded. Chi-square, and Fisher exact test were used to compare data. Pearson's and Spearman's correlation tests were used to determine correlation coefficients for entered variables.

Results: Eighteen (14 F, median age 12.6, range 3.8-16, yrs) patients were enrolled: 16 affected by Juvenile Idiopathic Arthritis, 7 of whom complicated by JIA -associated chronic uveitis, and 2 patients affected by chronic idiopathic uveitis. Peptide assay revealed ADAs in 8 children, Biacore in 6, commercial Elisa in 5. Of note, we found total concordance among the 3 tests just in 2 patients. No significant correlation has been proven among the 3 ADA determinations. Biacore and ELISA determination showed significant concordance (r_s: 0.72, $p< 0.006$). The presence of HC CDR3 and LC CDR 3 resulted significantly correlated with disease activity (r_s: 0.57, $p< 0.05$), and, inversely, with disease remission on treatment (r_s= -0.523, $p< 0.05$). No patient experienced severe adverse events and no correlation with ADAs has been revealed.

Conclusion: In chronic rheumatic disorders, novel reliable methods are urgently required to guide clinical decision and support decisions about switching within or between drugs in refractory children. The 3 different methods, since based on different antigenic probes, detect different antibody populations. The present peptide-based assays might contribute to identify neutralizing ADAs in patients treated with Adalimumab. Further validation in larger cohort is required.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease of childhood. Intra-articular corticosteroids joint injection (IAJI) with Triamcinolone hexacetonide (TH) or triamcinolone acetonide (TA) is considered as the first-line therapy for oligoarticular JIA. Previous studies showed benefit of TH vs. TA; however TA is still used in most of Israeli pediatric rheumatology centers. Our unit has experience with both regimens and therefore we aimed to compare the efficacy and safety of TA versus TH for JIA patient.

Methods: Chart review of JIA patients who were randomly (based on drug availability) treated with TA or TH IAJI between 2010-2019 was conducted. Primary outcome for efficacy was defined as full recovery of arthritis one month after IAJI and recurrence of arthritis 3 months month after IAJI. Primary outcome for safety was defined as the occurrence of adverse events (AEs) one month after IAJI.

Results: Overall 292 joints of 102 JIA patients were treated (138 TA/154 TH joints). Complete recovery after one month was documented in 107 (69.6%) TA treated joints and 96 (69.5%) TH treated joints (P=0.232). However, rate of relapse after 3 months was significantly higher in TA treated joints [27 (20.1%) vs. 13 (8.8%); (P< 0.01)]. No AEs were documented except of minor scar at 2 joints injection sites.

Conclusion: Although arthritis recovery was similar (~70%) with both regimens, relapse rate was more than doubled in TA injected joints vs. TH. These findings are specifically important due to contemporary shortage of TH in the US market.

Validation of New Antirheumatic Drug Use as a Proxy for Increased JIA Disease Activity

Avinash Gabbeta[1], Evan Mulvihill[2], Timothy Beukelman[3], James Lewis[4], Carlos Rose[5], Brian Strom[6] and Daniel Horton[7], [1]St. Christopher's Hospital for Children, Philadelphia, PA, [2]Nemours A.I. duPont Hospital for Children, Wilmington, DE, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Pennsylvania, Philadelphia, PA, [5]Nemours A.I. duPont Hospital for Children, Wilmingon, DE, [6]Rutgers University, Newark, NJ, [7]Rutgers University, New Brunswick, NJ

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Administrative claims databases are valuable tools for studying treatment effects in large JIA populations but do not contain direct measures of disease activity, limiting conclusions about treatment effectiveness. We sought to validate a claim-based algorithm based on new medication use as a proxy for worsening JIA disease activity.

Methods: We queried clinical and prescription data in electronic medical records from 3 participating centers (2004-2019) for patients with JIA age < 21. We randomly selected a group of subjects who met a prespecified definition for new antirheumatic drug: 1) newly prescribed conventional or biologic DMARD ≥90 days after diagnosis and ≥90 days after starting the most recent DMARD; 2) DMARD re-initiation ≥180 days since the end of the most recent prescription; 3) systemic steroid prescribed ≥180 days since the most recent prescribed systemic steroid; or 4) intra-articular glucocorticoid injection (IAGC) ≥180 days after the most recent injection and after starting the most recently prescribed JIA drug. One eligible new antirheumatic drug event was randomly selected per subject. We excluded subjects for prior diagnoses of inflammatory bowel disease, immunodeficiency, and non-JIA systemic rheumatic disease (e.g., lupus). We estimated the positive predictive value (PPV) based on the proportion of subjects for whom new antirheumatic drug use was accompanied by documentation of increased disease activity within the prior 90 days. Increased disease activity was defined as: worsening joint symptoms (degree or extent of pain, stiffness, or swelling), new or recurrent joints with active arthritis on exam, new or worsening uveitis, new or recurrent symptoms or signs of systemic inflammation (e.g., fever, rash; systemic JIA only), or worsening disease activity per treating rheumatologist. We also examined the PPV of alternate definitions of new antirheumatic drug use.

Results: 87 subjects were included (Table 1). Of 66 subjects with use of a new conventional or biologic DMARD, 35 (53%) had taken a prior DMARD, and 9 (13.6%) were restarting the same DMARD that was previously stopped. Overall, among subjects who used a new antirheumatic drug, 75% (95% CI 65%, 83%) had evidence of worsening disease activity within the prior 3 months (Table 2). The PPV was lower for those starting a new DMARD (65%) than for those restarting a prior DMARD (89%), starting systemic steroids (91%), or receiving IAGC (93%). The PPV increased with longer durations of time since the last new medicine was prescribed and with longer times after diagnosis (Table 2). Reasons for new prescriptions in subjects without worsening disease activity were: inadequate response to prior treatment (86%), intolerance or side effects (23%), and patient/family preference (5%) (not mutually exclusive).

Table 1. Select characteristics of subjects sampled

	Total (n=87)
Age at diagnosis, median years (IQR)	7.2 (4.3, 12.9)
Female, n (%)	58 (67%)
Type of JIA, n (%)	
Oligoarticular	27 (31%)
Polyarticular, RF negative	28 (33%)
Polyarticular, RF positive	7 (8%)
Psoriatic	6 (7%)
Enthesitis related	7 (8%)
Systemic	7 (7%)
Undifferentiated	5 (6%)
Disease duration at index date, median years (IQR)	2.1 (0.9, 4.6)
Drug at index date[1], n (%)	
DMARD	66 (76%)
Conventional DMARD	35 (40%)
Biologic DMARD	33 (38%)
Systemic glucocorticoid	11 (13%)
Intra-articular glucocorticoid	14 (16%)

DMARD disease modifying antirheumatic drug, IQR interquartile range, RF rheumatoid factor 1 Some subjects were started on more than 1 drug at the index date

Table 2. Positive predictive value of definitions of new antirheumatic drug use as proxies for worsening JIA disease activity

	n with worse JIA / n total (%)
New antirheumatic drug use	65/87 (75%)
New DMARD (not restart)	37/57 (65%)
Restarted DMARD	8/9 (89%)
New systemic steroid	10/11 (91%)
New IAGC	13/14 (93%)
Type of new DMARD	
New conventional DMARD	17/27 (63%)
New biologic DMARD	21/31 (68%)
History of prior DMARD use	
New DMARD (not restart), no prior DMARD	19/27 (70%)
New DMARD (not restart), prior other DMARD	18/30 (60%)
Time since last new drug was first prescribed	
≥6 months since last new drug was first prescribed	39/49 (80%)
≥12 months since last new drug was first prescribed	32/35 (91%)
Time since JIA diagnosis	
≥6 months since JIA diagnosis	57/74 (77%)
≥12 months since JIA diagnosis	53/64 (83%)
≥24 months since JIA diagnosis	44/52 (85%)
JIA category	
Oligoarticular or RF negative polyarticular	43/55 (78%)
RF positive polyarticular	6/7 (86%)
Enthesitis related or psoriatic arthritis	9/13 (69%)
Systemic JIA	4/6 (67%)

DMARD disease modifying antirheumatic drug, IAGC intra-articular glucocorticoid injection, JIA juvenile idiopathic arthritis, RF rheumatoid factor

Conclusion: New prescriptions of antirheumatic drugs may serve as a reasonable proxy for worsening JIA disease activity in claims data. Restricting new use events to at least 6 months after the last newly prescribed drug or after JIA diagnosis may improve the likelihood that these events correspond to worsening disease activity.

Abstract Number: 0722

Evaluation of Flare Rate and Tapering Strategies in Juvenile Idiopathic Arthritis

Antía García-Fernández[1], Andrea Briones-Figueroa[1], Laura Calvo-Sanz[1], África Andreu Suárez[1] and Alina Lucica Boteanu[2], [1]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [2]PRINTO, Istituto Giannina Gaslini, Genova, Italy

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biological treatment (BT) has changed the perspectives of Juvenile Idiopathic Arthritis (JIA) patients, but it remains unclear when and how to taper or to withdraw treatment, neither the effect of treatment withdrawal after remission is achieved.

Our aim is to assess the course of the disease after tapering or stopping BT in a cohort of JIA patients. Tapering strategies and median time to flare were analyzed.

Methods: A retrospective, descriptive study was conducted in a cohort of JIA patients followed up in a Pediatric and Transition Unit of a referral hospital and who had received BT between 2000 and 2019. All JIA patients with at least one attempt of tapering were included. Remission was defined according to Wallace criteria.

Results: 131 JIA patients and 219 BT were reviewed. 198 deescalations in 108 (49,3%) BT in 95 (72,5%) JIA patients were included. 67,7% were female. The median age at diagnosis was 5 years [IQR (2-12)] and the median age at the beginning of tapering was 17 years [IQR (11,8-26)]. Patients were in remission a median of 9 months [IQR (6-17)]. Main BT tapered were: TNF inhibitors (76,3%), IL6 inhibitors (15,2%) and IL1 inhibitors (6,5%).Conventional DMARDs were administrated in combination with BT in 40,4% of the deescalations. Regarding JIA categories: 44 (22,2%) were Oligoarticular Persistent, 36 (18,2%) were Oligoarticular Extended, 32 (16,2%) were Systemic, 31 (15,7%) were Enthesitis related Arthritis, 19 (16,2%) were Psoriatic Arthritis, 16 (8,1%) were Polyarticular RF+, 16 (8,1%) were Polyarticular RF- and 5 (2,5%) were Undifferentiated. 8 (6,3%) patients were lost in follow-up.

171/198 (86,3%) cases started a deescalation. The most frequent tapering strategy was prolonged interval between applications (90,6%), combined strategy (5,8%) and lower dosage (3,5%). The median remaining dose administrated was 50% [IQR (50, 75)].

Twenty-seven (13,6%) cases withdrawn BT abruptly. The main causes of abrupt BT withdrawal were: remission (33,3%), pregnancy (29,6%).

Forty-five (26,3%) cases stopped BT after tapering. Median time to withdrawal was 11 months [IQR (6-22)]. The main causes of withdrawal after tapering were remission (66,7%), pregnancy (11,1%). There was no difference in remission rates after withdrawal among cases with previous tapering (PT) or abrupt discontinuation(AD) [Median PT 5 +-(1,1), median AD 7 +- (2,6), Log rank=0,946]. After 6 months of withdrawal 48,1% of AD cases and 56,1% of PT

Time, months	Cases on remission, n.%
6	101 (79,8)
12	86 (68,1)
24	60 (47,4)
Currently on remission	40 (31,8)

Table 1: Remission rates among cases tapered without withdrawal during follow-up. n=126.

cases had presented a flare. 10/72 (13,8%) cases are currently on remission without BT during follow-up, 9,7% without any treatment and 4,1% with cDMARDs.

BT was tapered without withdrawal in 126 (63,6%) cases. Remission rates during tapering are specified in table 1. 40 (20%) cases continue tapered without a flare after a median of 77 months [IQR (36,3-111,3)] of follow-up.

Conclusion: - There was no difference in remission rates among patients that discontinuated BT after tapering or after abrupt discontinuation. After 6 months of withdrawal 48,1% of cases that stopped abruptly and 56,1% of cases that stopped after tapering had presented a flare.

- Tapering without withdrawal is safe: 79,8% of cases at 6 months and 47,4% of cases at 24 months that tapered without withdrawal remained on sustained remission.

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with polyarticular JIA (pJIA) have a refractory disease course with increased risk for joint damage resulting in poor functional outcome and decreased quality of life. The highest risk is in patients who are younger at diagnosis. Therefore, it is important for patients to receive timely access to pediatric rheumatology for management. The objective of this study is to examine the association of social determinants of health (SDoH) on

Community Poverty Level ***						
> 20% population/ ZCTA	0.96	0.84-1.11	0.6	0.96	0.84-1.1	0.6

Table 2. Association of social determinants of health with time to first presentation to pediatric rheumatologist

ucation, and community poverty level. Demographics, approximate date of symptom onset, were queried. Five-digit zip-codes were used to extrapolate community poverty levels using 2014-2018 American Community Survey data. The Kaplan-Meier method was used to estimate rheumatology visit-free survival. The log-rank test was used to compare rheumatology visit-free survival between the SDoH. Cox proportional-hazards models were utilized to estimate hazard ratios for the outcome mentioned above, adjusted for age of diagnosis.

Results: 1684 patients fit criteria for this study. Demographics are listed in Table 1. Twenty percent of patients had missing time to first appointment. The median time from symptom onset to first pediatric rheumatology visit was 3 months (IQR: 1,6). Kaplan-Meier curves showing the probability of first rheumatology visit for time from symptom onset are shown in figure 1. Children with family reported income in the range of $25,000-49,999 were likely to have longer time to first appointment (unadjusted HR 0.76, CI 0.6-0.97, p = 0.025). These relationships remain consistent when additionally adjusted for age at diagnosis (table 2). Guardian's highest level of education, and community poverty level did not affect the time to first appointment.

Conclusion: Family reported income, guardian education, and community poverty did not impact time to first appointment. Children within the income bracket of $25,000-49,999 may have less access to subspecialists, transportation, or advocacy compared to other children. Ascertainment bias into the registry may skew the cohort to a wealthy and educated population. Recall bias on symptom onset is possible. Future directions for research include stratification of community poverty levels and evaluation of public vs private insurance on time to first appointment.

Abstract Number: 0724

Anxiety and Depressive Symptoms in Juvenile Idiopathic Arthritis (JIA) Correlate with Pain and Stress Using Patient-Reported Outcomes Measurement Information System (PROMIS®)

Danielle Fair[1], Judyann Olson[2], Jan Lemke[1], Stella Protopapas[3], Ke Yan[2] and Jian Zhang[2], [1]Children's Wisconsin, Milwaukee, WI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Riley Children's Hospital at Indiana University, Indianapolis, IN

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Children with chronic diseases have higher rates of mental health issues and less favorable outcomes than the general pediatric population. Children with JIA experience pain and limited mobility which may affect their mental health. Prior studies of mental health and the relationship to disease manifestations in JIA have had variable results, partly due to a lack of a standard assessment tool. PROMIS has recently been developed to help standardize and validate assessments on patient-reported outcomes. The aims of this study were to describe anxiety and depressive symptoms in children with JIA using PROMIS measures and to evaluate potential correlations with disease manifestations.

Methods: We conducted a two-center, cross-sectional study of JIA patients and their parents. JIA ILAR subtypes included: 36% oligoarticular (52% extended; 48% persistent), 32% polyarticular (81% RF –; 19% RF +), 7% systemic, 3.5% psoriatic, 3.5% enthesitis-related, and 18% undifferentiated (Table 1). Participants completed PROMIS measures on depression, anxiety, psychological stress experiences, and pain interference to assess psychosocial functioning, and the Childhood Health Assessment Questionnaire (CHAQ) to assess physical functioning. Disease activity was measured using the clinical juvenile arthritis disease activity score (cJADAS10). A general pediatric reference population served as the control group. The Pearson correlation and Kruskal-Wallis tests were used to determine the relationship between mental health PROMIS T-scores and disease manifestations.

Results: Eighty-five JIA patients completed the study; 75% female, 86% Caucasian, median age of 14 years, and median disease duration of 4.77 years (range 0.28-16.86 years). Patients had a median active joint count of 0 joints (range 0-11) and a median cJADAS10 score of 2 (range 0-23). The median CHAQ score was 0 (range 0-1.75) (Table 1). Using the cJADAS10, 58 patients (68%) had inactive or low disease activity. Mean PROMIS T-scores for depressive and anxiety symptoms were significantly lower in JIA patients compared to the general pediatric reference population ($p < 0.0001$). Nineteen patients (23%) had moderate to severe symptoms of anxiety and/or depression (Table 2). Age correlated with depressive symptoms ($r=0.38$; $p=0.0004$) but not anxiety ($r=0.21$; $p=0.056$). Depressive and anxiety symptoms correlated with pain ($r=0.64$ and $r=0.46$, respectively; $p < 0.0001$) and stress ($r=0.78$ and $r=0.74$, respectively; $p < 0.0001$), but not with JIA subtype, disease duration, physical function, or disease activity (Table 3).

Conclusion: Using PROMIS, approximately one-quarter of JIA patients reported moderate to severe symptoms of anxiety and depression. JIA patients in our study experienced less anxiety and depressive symptoms compared to the general pediatric reference population. Anxiety and depressive symptoms in JIA patients are associated with pain and stress, but they are not associated with other disease manifestations.

Abstract Number: 0725

A Data Science Evaluation of the Juvenile Arthritis Multidimensional Assessment Report (JAMAR) Questionnaire for Improving Management of JIA Patients

Humbert Quesada-Masachs[1], Michalis Faloutsos[2], Shomit Ghose[3], Sara Marsal[4], Consuelo Modesto[4] and Estefania Quesada-Masachs[5], [1]University of California Riverside, San Diego, [2]University of California Riverside, Riverside, [3]University of California Berkeley, San Francisco, [4]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [5]Hospital Universitari Vall d'Hebron, San Diego

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The Juvenile Arthritis Multidimensional Assessment Report (JAMAR) is a questionnaire developed to comprehensively assess Juvenile Idiopathic Arthritis (JIA) patients. Despite being translated into 54 languages, there is still limited literature about it. The length of the questionnaire could have been influencing its clinical practicality. The purpose of this study is to answer the following questions:

1. "Which are the most informative questions?";
2. "How well do the collected data correlate with other clinical variables?";
3. "Are there discrepancies between the perceptions of patients and parents?";

Methods: We included 71 children with JIA according to ILAR criteria, all of them receiving treatment and we followed them up for a year. JAMAR questionnaires were answered by both children and parents at baseline, 6 and 12 months. Also, a thorough clinical examination was performed in every visit: all the joints were clinically assessed for swelling, tenderness, and limited range of motion, and Juvenile Arthritis Disease Activity Score (JADAS), disease activity state, parents and patients assessment through Visual Analogue Scale (VAS), physician's VAS, Erythrocyte Sedimentation Rate (ESR) and C-reactive protein (CRP) were recorded. We applied state of the art machine learning methods in order to find the most relevant questions in JAMAR. Additionally, we utilized tensor decomposition to identify relevant patient clusters. Furthermore, we correlated these critical questions with clinical and biological parameters recorded. We have compared the discordance rate between patients vs parents responses in 5 of JAMAR parameters as previously reported (Vanoni F, et al. *Pediatr Rheumatol Online J*. 2016;14(1):2). We explored the relation between discordance and demographic and clinical variables.

Results: A total of 374 JAMAR questionnaires are analyzed with our Machine Learning algorithms. First, we identify a small group of questions as the most relevant for patients and parents. The identified questions exhibit better correlations with the JADAS scores than the non-relevant ones. Second, 96% of the pairs (child-parent) are discordant for at least one item, but the differences are small and VAS well being is the only score with a statistically significant difference ($P < 0.0001$). We observe a higher rate of activity in the patients exhibiting discordant evaluations with their parents. In addition, the observation patient-parent agreement in Juvenile Arthritis Functionality Scale (JAFS) is better than Pediatric Rheumatology Quality of Life Scale (PRQL).

Conclusion: In this study, we revisit the JAMAR questionnaire by applying modern data mining techniques in a longitudinal dataset. Our results suggest that a small number of questions in the JAMAR questionnaire provide significant information and correlate well with the JADAS scores. We argue that this reduced set of questions could make the data collection easier by trading off the number of questions for frequency and ease of self-reported data collection.

Table 2. Unadjusted and Age at Diagnosis Adjusted Odds Ratios for >60 minutes of morning stiffness at baseline

Background/Purpose: Joint stiffness as a sign of intra-articular inflammation may be an early presenting symptom of JIA. Studies following pain in chronic disease have shown that pediatric patients from lower socioeconomic brackets report less pain compared to severity matched disease in affluent patients, it is unknown if joint stiffness in JIA follows a similar trend. The objective of this study is to assess the relationship between social determinants of health (SDoH) and presence and duration of morning joint stiffness. Polyarticular JIA (pJIA) patients were studied as they are older cohort of patient more likely to accurately describe presence of stiffness.

Methods: We retrospectively analyzed Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry from July 2015 through February 2020. Inclusion criteria were USA residency and pJIA diagnosis with recorded >4 joints involved in first 6 months of disease; exclusion criteria were invalid zip code and additional diagnosis of systemic inflammatory or autoimmune disease. The primary outcomes of interest are presence and duration of morning stiffness. SDoH we studied were reported family income, highest level of completed guardian education, and community poverty level. Demographics, RF and anti-CCP status were included as covariates. Five-digit zip-codes were used to extrapolate community poverty levels using 2014-2018 American Community Survey data. Chi-square tests were utilized to assess the bivariate relationships between SDoH and study outcomes. We used logistic regression models to determine association of SDoH with duration of morning stiffness (>60min vs < 60min) and adjusted for age at diagnosis.

Results: 1684 patients were included in the study. Demographics and baseline disease severity are listed in table 1. On unadjusted analysis, guardian education (p=0.018), reported family income (p< 0.001), RF IgM status (p< 0.001), and anti-CCP IgG status (p< 0.001) were significantly associated with increased risk for presence and longer duration of morning stiffness, while community poverty level was not (p=0.6). Children who came from families with >$100,000 income were half as likely to report greater than 60 minutes of morning stiffness at baseline (OR 0.54, CI 0.31-0.97, p= 0.035). This was consistent after adjusting for age at diagnosis, CCP and RF status (table 2).

Conclusion: We found a significant inverse association between family income level and duration of morning stiffness. It is possible that this may be a reflection of increased reporting of stiffness in low income families. Further

studies to see association of SDoH on morning stiffness are warranted not only in pJIA but also in other forms of JIA to further understand these associations.

Hip Involvement Leads to Poor Outcome in Adulthood in Children with Enthesitis Related Arthritis (ERA) Category of Juvenile Idiopathic Arthritis (JIA)

Naveen R[1], Namita Mohindra[1], Neeraj Jain[1] and Amita Aggarwal[2], [1]Sanjay Gandhi Post graduate institute of medical sciences, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis related arthritis (ERA) is the commonest category of JIA seen in India and constitutes 30-40% of all JIA patients. There are many studies on long term outcomes in adult Spondyloarthritis but the data in children with ERA is scant. The available data is also mostly from developed countries. Thus, we studied outcome of ERA in adulthood in resource constrained setting where there is limited availability of anti-TNF agents.

Methods: Patients with ERA (ILAR classification) having >5 years of disease and above the age of 18 years were included in the study. Data on clinical features, Bath indices (BASMI, BASDAI, BASFI), health assessment questionnaire disability index (HAQ DI) was collected. CRP was measured by Nephelometry. X-ray pelvis including hips was obtained and compared with baseline X-ray available at first visit to our hospital for progression of radiological sacroiliitis and hip arthritis. The X-rays were assessed by two radiologists. In addition, fulfilment of adult criteria of Spondyloarthropathy (SpA), assessment of Spondylarthritis International Society (ASAS) and modified New York (NY)] were assessed.

Results: 73 patients (72 male) of median age 20 (18-23) years and median disease duration of 8 (5.5-11) years were recruited. There was delay in diagnosis of 4 (1.75-6) years. Nearly all (96%) had active disease (BASDAI >0) and median CRP was 2.1 (0.6-4.8) mg/dl. Three-fourth (75.3%) had functional disability (HAQ DI >0) and median BASFI was 1.95 (0.6-3.5). 67 patients fulfilled axial ASAS criteria, while 71 fulfilled peripheral SpA criteria.

Overall, 81% had radiological sacroiliitis and 37% had hip involvement. Nearly half (46.6%) of the patients had radiological progression in sacroiliitis and one-fourth (25%) had progression of hip arthritis over 3.5 (2.5-5.5) years. Patients with radiological sacroiliitis had higher CRP (2.5 vs 1 mg/dl) and more hip arthritis (37 vs 7%) than those without it.

Those with radiological hip arthritis had longer delay in diagnosis (6 vs 3 years) than those without it. They also had higher BASDAI, BASMI, BASFI and HAQ DI. Hip arthritis correlated with radiological sacroiliitis (r= 0.301). Fulfillment of modified NY criteria was seen more often in patients with hip arthritis (95% vs 63%; p< 0.002) (Table 1).

Table 1. Differences in baseline characteristics and outcomes between groups			
	Radiological hip arthritis (n=27)	**No radiological hip arthritis (n=46)**	**P**
Duration of disease in years median (IQR)	9 (7-11)	6.5 (5-10)	0.063
Age in years	21 (19-23)	19.5 (18-22.5)	0.137
Age of onset of disease (years)	13 (10-15)	14 (12-15)	0.198
Delay in diagnosis (years)	**6 (2-9)**	**3 (1-5)**	**0.011**
Duration between initial and latest X- ray pelvis (years)	3.5 (2-5.5)	3.5 (2.5-5.5)	0.377
School years lost (in years)	1 (0.26-2)	0.5 (0-2)	0.648
Clinical features n (%)			
Arthritis	27 (100)	42 (91.3)	0.115
Enthesitis	24 (88)	42 (91)	0.735
IBP	24 (88)	43 (93.9)	0.491
Sacroiliitis	18 (66)	25 (54)	0.302
Hip involvement	**17 (63)**	**6 (13)**	**0.000**
Tarsitis	18 (66)	25 (54)	0.335
Uveitis	4 (14)	9 (16)	0.609
Lab parameters			
Hemoglobin (g/dl)	12.1 (10.9-13)	12.4 (11.5-13.3)	0.391
ESR (mm/hr)	26 (17-50)	20 (14-39)	0.200
CRP (mg/dl)	**3 (2.1-6.1)**	**1.1 (0.2-4.23)**	**0.014**
Platelets ($x10^5$/dl)	2.3 (1.8-2.9)	2.2 (1.8-2.7)	0.391
HLA B27+ (%)	11/11 (100)	21/23 (91)	0.313
Outcome measures			
BASDAI	**5 (3.2-6.5)**	**2.6 (1.2-4.8)**	**0.002**
BASMI	**2 (1.6-4.6)**	**1.2 (0.7-1.8)**	**0.000**
BASFI	**3.4 (2.1-4.8)**	**1.3 (0.35-2.3)**	**0.000**
HAQ DI	**0.45 (0.2-0.75)**	**0.15 (0-0.35)**	**0.000**
BASDAI>0 (%)	27 (100)	43 (93)	0.175
HAQ DI >0 (%)	**25 (92)**	**30 (65.2)**	**0.009**
Radiological sacroiliitis (%)	**26 (96.3)**	**33 (71.7)**	**0.010**
Progression of Radiological Sacroiliitis (%)	13 (48)	21 (48)	0.995
Fulfilment of adult criteria			
ASAS criteria	26 (96)	45 (97)	0.699
Modified NY criteria	**25 (96)**	**29 (63)**	**0.002**
Treatment received			
NSAIDS alone	7 (25)	13 (28)	0.829
DMARDS+ NSAIDS	20 (74)	32 (69)	0.681

Conclusion: Most adults with ERA have active disease even after 8 years of disease Hip involvement is associated with poorer outcome.

Clinical Outcomes of Juvenile Arthritis in Adulthood: A Systematic Review

Lily Siok Hoon Lim[1], **Woo Jin Kim**[2], Yushi Wang[2] and Kaien Gu[3], [1]University of Manitoba, Children's Hospital of Manitoba, Winnipeg, MB, Canada, [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada, [3]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile arthritis (JA) is the most common pediatric rheumatic disease, with potentially permanent functional impacts on patients long after initial diagnosis. Little is known about adulthood outcomes. This systematic review aims to summarize clinical outcomes in adults with JA (age >16), identify gaps of knowledge and recommend future research directions.

Methods: MEDLINE and EMBASE searches were developed and conducted with an academic librarian. We focused on studies 2000-2017 for contemporary management outcomes. We excluded: non-English publications, studies evaluating the transition process, qualitative studies, obstetric outcomes, short reports/letters, case series. Mixed population studies were included if the mean/median age at assessment was >16 years. The Quality in Prognosis Studies (QUIPS) tool was used to assess risk-of-bias in 6 study domains: population, attrition, outcomes, prognostic factors, confounding, statistics. Each publication was assessed by 2 reviewers. Study data were extracted using a standard form.

Results: 56 of 12 243 papers were included in this study for analysis. The majority (52%) of studies were retrospective cohorts, and the most common study queries were disease (34.9%), functional status/psychosocial (22.2%), temporomandibular joint (11.1%), and uveitis (9.5%) outcomes. 13 publications (21%) were repeat publications of non- unique cohorts, with the majority of these using the same cohort from Norway. Moderate-high risks of bias were present especially in study confounding (95%), participation (81%) and attrition (82.1%) domains.

In disease outcomes, the most common reported were remission (36%), and use of DMARDs (71%). HAQ functional status was reported with a median score of 0.49, signifying mild disability. VAS pain scale had a median score of 6.51 cm. DMARDs and NSAIDs usage ever were reported with 42.8% and 63.3% respectively. Uveitis was reported in 22.9% patients. Out of 56 papers, 35 performed statistical multivariable modelling. Within each study topic there were no multivariable models of similar outcomes to allow for identification of consistent prognostic factors.

Conclusion: Only 2 (3.1%) truly longitudinal studies focused on the adult outcomes of JA patients. Although there have been many studies published on outcomes in JA adults, they have moderate-high risks of bias in crucial study domains that limited interpretation of results. Prognostic factors were non-reproducible and could not be summarized. Attention to selection of study population and accounting for attrition and confounding will improve quality of future studies. There should be a discussion among investigators to establish reporting of core outcomes in future adult JA studies to allow comparisons and facilitate future meta-analysis. In future studies we aim to categorize outcomes by duration of disease and start formulating a potential standard reporting format for future JIA research.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis is the most common extra-articular complication of juvenile Idiopathic arthritis (JIA). Due to its typical indolent and chronic course, children with this condition are at risk for ocular morbidity with a significant impact on their quality of life. The aim of this study is to describe demographic and clinical features, treatment approaches and outcome of a population of patients with JIA-associated uveitis.

Methods: Charts of patients with JIA-associated uveitis, followed in two tertiary Pediatric Rheumatology Centres were retrospectively reviewed with regard to clinical features, therapeutic choices and outcome

Results: Data from 162 JIA patients with uveitis were analysed (81.5% female), with a mean follow up of 8.9 years (SD ± 2.56). Mean age at JIA onset was 3.6 years (SD± 3.1) and the mean JIA duration at uveitis onset was 2.5 years (SD ± 4.3). Uveitis was diagnosed at JIA onset in 9.9% of patients. The most frequent JIA category was oligoarthritis (88.9%), which was persistent in 72.8% of cases, followed by RF- polyarthritis (9.3%). No systemic JIA was reported. Uveitis was predominantly anterior (96.9%), and reported bilateral in 65.4% of cases. In almost all patients (87.6%) antinuclear antibodies (ANA) were positive. Systemic medications were required in 134 (82.7 %) patients. Methotrexate and cyclosporine were used in 66.0% and 7.4% of cases, respectively, while 86 patients (53.1%) required biologic therapy, mainly adalimumab (34.6%), followed by infliximab (10.5%) and tocilizumab (3.7%). In 28.4% of cases more than 1 biologic was needed. Mean recurrence rate in our cohort was 1.3 per year (SD ±1.1). In 79 patients (49.8%) uveitis was complicated by ocular damage, which is summarized in Table 1. A best-corrected visual acuity (BCVA) ≤ 0.4 and ≤ 0.1 were observed in 14.2% and 10.5% of patients, respectively.

Table 1. Ocular damage in the cohort (total JIA patients with uveitis, n = 162)

	Number of patients with complication (%)
Synechiae	56 (34.6%)
Band keratopathy	32 (19.8%)
Cataract	29 (17.9%)
Glaucoma	9 (5.6%)
Cystoid macular edema	7 (4.3%)
Any surgery	28 (17.3%)
Cataract	24 (14.8%)
Synechiotomy	2 (1.2%)
Other (band keratopathy, glaucoma)	2 (1.2%)

Conclusion: Despite continue improvement in JIA therapeutic options, uveitis remains a complication with high morbidity. Clinical predictors and biomarkers are needed to identify patients at higher risk of unfavourable outcome. Careful monitoring and follow-up are crucial for timely detection of ocular inflammation and prevention of damage.

To Taper or Not to Taper in Juvenile Idiopathic Arthritis: Is There a Risk of Development of Uveitis Flares?

Maria Teran[1], Alina Lucica Boteanu[2], Carlos Guillen[1], Cristina Pijoan[1], Jose Quinones[1], Veronica Garcia[3], Ivan Del Bosque-Granero[3], Laura Calvo-Sanz[4] and Mónica Vázquez[4], [1]Hospital Ramon y Cajal, Madrid, Madrid, Spain, [2]PRINTO, Istituto Giannina Gaslini, Genova, Italy, [3]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Madrid, Spain, [4]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the association between the occurrence of uveitis flares in patients with Juvenile Idiopathic Arthritis (JIA) and the de-intensification of immunosuppressive treatment.

Methods: We conducted a retrospective longitudinal cohort study, including a single-centre consecutive cohort of patients diagnosed with oligoarticular JIA antinuclear antibody (ANA) positive, who had had at least one uveitis flare during their follow-up up to 19.5 years. Patiens with the same JIA category, ANA positive, with no history of uveitis flare were considered controls. Epidemiological data, age of first uveitis flare, number of previous episodes, treatments prescribed at the time of the flare and time since the last treatment modification were recorded. Treatment tapering was defined as a reduction in dose or increase in the inter-doses period, according to datasheet of the corresponding treatment. The relative risk (RR) for the development of uveitis flare and treatment tapering were determined by contingency tables.

Results: We included 68 patients of which 22 had had uveitis flares during their follow-up, and 46 controls. The mean age of patients at JIA diagnosis was3.56 ± 2.17 years. A total of 107 uveitis flares were recorded with an average of 4.54 ± 4.70 episodes per patient. The first uveitis flare was registered at an average age of 6.57 ± 5.79 years. Four patients (18.1%) had had only one episode. Among patients with more than one flare, the inter-flare period was 17.84 ± 21.8 months. Thirty flares (27%) were registered in patients without immunosuppressive treatment. Twenty patients (90%) required the initiation of biological therapy specific for uveitis. Adalimumab (ADA) was chosen in 19 (86.3%) patienst and avoided further uveitis flares in 15 (68%) cases. Treatment with Tocilizumab (TCZ) was used in 6 (27.7%) cases and avoided further uveitis flares in 5 (27.3%). Thirty-three episodes (33.1%) were registered in patients with Methotrexate (MTX) of which, 8 (7.5%) were receiving doses below datasheet (< 10mg/m2). Forty-four uveitis flares (41%) took place in patients on biological treatment, of which 27 were receiving ADA (25.3%), 2 (1.9%) TCZ and 15 (14%) other therapies. Thirty-seven flares (32.1%) took place in patients on tapered treatments and 11 (10.3%) after non scheduled withdrawal. In terms of risk of developing a new uveitis flare, tapering had a RR of 2.79 (CI 2.01-3.7; $P< 0.05$) while therapy withdrawal had a RR of 5.91 (CI 3.23-10.8; $P< 0.05$). MTX tapering had a RR of 12.5 (CI 6.4-24.5 $P< 0.05$). Patients with ADA had a RR of 0.88 (CI 0.4-1.6; $P=0.84$) of developing uveitis flares, with TCZ a RR

of 4,65 (CI 1.2-17.8; *P*< 0.05) and with other biological therapy (Etanercept, Infliximab, Abatacept) a RR of 3.56 (CI 2.05-6.2; *P*< 0.05).

Conclusion: Tapering immunosuppressive treatment in oligoarticular JIA ANA positive patients, increases the risk of developing uveitis flares.

Abstract Number: 0731

Comparing S100 Proteins and Cytokine Levels in Tears Based on Uveitis Activity Laterality in Children with JIA-associated Uveitis and Non-JIA-U

Jackeline Rodriguez-Smith[1], Virginia Miraldi Utz[2], Amy Cassedy[1], Sherry Thornton[1], Grant Schulert[3], Alyssa Sproles[4], Najima Mwase[1], Theresa Hennard[1], Mekibib Altaye[2], Alexei Grom[1] and Sheila Angeles-Han[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, [3]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Cincinnati Children's Hospital, Cincinnati

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The pathogenesis of pediatric uveitis remains unclear. Studies of biomarkers using aqueous humor (AqH) identified S100 proteins, cytokines, and chemokines as potential biomarkers of uveitis activity. AqH collection is invasive and less feasible. Tears may serve as a surrogate as the same biomarkers present in AqH were detected in tears of uveitis patients. We showed that S100A12, IL-8, and sICAM-1 levels differ based on uveitis activity in JIA-associated uveitis (JIA-U). We aim to determine if tear-based biomarkers differ in a patient's eyes based on uveitis activity by laterality and diagnoses.

Methods: Tears were collected by Schirmer strips from children ≥5 years old with diagnosis of bilateral uveitis. Uveitis activity was graded by SUN criteria. Anterior chamber (AC) cell grade < 0.5 was inactive. AC grades ≥0.5+ were active. S100A8, A9 and A12 were measured by ELISA, and IL-18, IL-8, IP-10, MCP-1, RANTES and sICAM-1 by Luminex assays. Biomarkers levels were assessed between paired eyes of a person by 1) unilateral activity (active eye and inactive contralateral eye), 2) bilateral activity (both active eyes), and 3) diagnosis (JIA-U vs non-JIA-U).

Results: Fifteen children contributed 34 tear samples (JIA-U n=8; idiopathic chronic anterior uveitis n=5; and idiopathic uveitis n=2). At time of tear collection, 53% had bilateral active uveitis (53% AC cell grade 0.5+). Treatment included topical (82%) and systemic therapy (76%) (Table 1). Stratifying by laterality, all biomarker levels were similar between the active uveitic eye and the inactive contralateral uveitic eye in those with unilateral active uveitis. In bilateral active uveitis, levels were also similar in both eyes except for S100A12 that was lower in the higher-grade uveitic eye (7979 pg/ML-/+SD 7835) compared to the lower-grade (25,727+/- 39,154; P=0.032). Stratifying by diagnosis, children with JIA-U relative to non-JIA-U group, primarily had unilateral active uveitis (78 vs 25%) with AC cell grade 0.5+ (100 vs 53%), greater use of systemic therapy (89 vs 63%) with similar use of topical steroids (83 vs 81%). Regardless of uveitis activity, biomarkers levels between both eyes of children with JIA-U were similar. In non-JIA-U, only S100A12 was higher in the lower-grade or inactive eye. All other biomarkers levels were similar. Comparing eyes

sICAM-1	20307.89 (12134.98)	5317.13 (4505.96)	0.0006

*<p=0.05; IL: interleukin; IP-10/CXCL10: interferon gamma-induced protein/chemokine (C-X-C motif) ligand; RANTES/CCL5: Regulated on activation, normal T expressed, and secreted/chemokine (C-C motif) ligand; sICAM-1: soluble intracellular adhesion molecule 1; MCP-1:monocyte chemoattractant protein.

Table 2. Tear biomarker levels between JIA-U and non-JIA-U

of children with JIA-U and non-JIA-U, the JIA-U group had significantly higher S100A12, IL-8, RANTES, and sICAM than non-JIA-U (Table 2).

Conclusion: Our results suggest that S100A12 levels may differ in the eyes of children with a history of bilateral uveitis who have bilateral active disease especially non-JIA-U. Although we expected a difference in biomarker levels of paired eyes of children with unilateral active uveitis, earlier damage to the blood-ocular barrier may allow crossing of biomarkers to the inactive uveitic eye. Use of topical steroids may also dampen the inflammatory response. Elevated S100A12, sICAM, and IL-8 in children with JIA-U compared to non-JIA-U supports the potential role of neutrophils in JIA-U. A limitation of our study is sample size. Further work is needed to clarify the impact of topical steroids on biomarkers levels and the role of S100A12, sICAM1, and IL-8 in uveitis activity.

Changing Evidence over Time: Updated Meta-analysis Regarding Anti-TNF Efficacy in Childhood Chronic Uveitis

Ilaria Maccora[1], Eleonora Fusco[2], Edoardo Marrani[3], AV Ramanan[4] and Gabriele Simonini[5], [1]Paediatric Rheumatology Unit, Anna Meyer Children's University Hospital, School of Human Health Science, Florence, Italy, Florence, Italy, [2]Rheumatology Unit, Anna Meyer Children's Hospital, School of Human Health Science, University of Florence, Florence, Italy, [3]University of Florence, Firenze, Italy, [4]Department of Paediatric Rheumatology, Bristol Royal Hospital for Children, Bristol, United Kingdom, [5]Rheumatology Unit, Meyer Children's University Hospital, Florence; NEUROFARBA Department, University of Florence, Italy, Florence, Italy

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To summarize evidence regarding efficacy of anti-tumour necrosis factor-α (anti-TNFα) in childhood autoimmune chronic uveitis (cACU), refractory to common disease modifying antirheumatic drugs (DMARDs).

Methods: An updated systematic search was conducted between November 2012 and January 2020. Studies investigating the efficacy of anti-TNFα therapy, in children ages < 16 years, as the first biologic treatment for cACU, refractory to topical and/or systemic steroid and at least one DMARD, were eligible for inclusion. The primary outcome measure was the improvement of intraocular inflammation according to Standardization of Uveitis Nomenclature Working Group criteria. A combined estimate of the proportion of children responding to etanercept (ETA), infliximab (INF), and adalimumab (ADA) was determined.

Results: We identified 1677 articles and 37 articles were eligible. Three were randomized clinical trials (RCTs), one on ETA and 2 on ADA, and were excluded from pooled analysis. From the observational studies, a total of 487 children were identified: 226 received ADA, 213 INF and 48 ETA. The proportion of responding children was 86% (95% CI 76–95%) for ADA, 68% (95% CI 50–85%) for INF, and 36% (95% CI 9–67%) for ETA. Pooled analysis showed clear

differences ($\chi2$= 32.2, p< 0.0001): ADA and INF were both significantly superior to ETA ($\chi2$ =26.8, p< 0.0001, and $\chi2$= 7.41, p< 0.006 respectively), ADA significantly superior to INF ($\chi2$= 13.4, p< 0.0002).

Conclusion: This metanalysis, consistent with recent RCT data, suggests the efficacy of ADA and INF in cACU treatment. However, ADA results superior to INF in this clinical setting.

Abstract Number: 0733

Practice Patterns for Tapering Medications in the Treatment of JIA-associated Uveitis

Ivan Foeldvari[1], Jens Klotsche[2], Sheila Angeles-Han[3], Jordi Anton[4], Gabriele Simonini[5], Nadine Groesch[2] and Jean Baer[6], [1]Head of the Hamburg Centre for Pediatric and Adolescence Rheumatology, Budapest, Hungary, [2]German Rheumatism Research Center, Berlin, Germany, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Sant Joan de Déu Hospital, Madrid, Spain, [5]Anna Meyer Children's Hospital, Firenze, Italy, [6]Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis associated uveitis (JIAU) is the most common extra-articular manifestation of JIA, and occurs in approximately 10% of affected children. Although there are effective medications to treat JIAU, guidelines and large studies that inform of tapering treatment after disease remission are lacking.

Methods: We surveyed vie email international pediatric rheumatologists: 1. Multinational Interdisciplinary Working Group for Uveitis in Childhood (MIWGUC), 2. Pediatric Rheumatologic Email-Listserve, 3. CARRA uveitis workgroup, and international ophthalmologic specialized in children with JIAU. Survey questions focused on the definition of remission, duration of remission prior to initiation of medication tapering, and method of tapering. Specific medications included methotrexate (MTX), adalimumab (ADA), infliximab (IFX), abatacept (ABA), and tocilizumab (TOC).

Results: Of 45 responses, 88% were from pediatric rheumatologists with a mean work experience of 18 years. The regional distribution was 31 form Europa, 9 from North-America, 3 from South-America and 2 from Asia. The responding colleagues managed a mean number of 43 JIAU patients. Remission on medication was defined as no cells in the anterior chamber (78%), followed by no need for eye drops (36%), and no uveitis flares (32%). Tapering practices were described for MTX monotherapy (100%) ADA (100%), IFX (80%), TOC (56% [25% s.c.]) and ABA (46% [30% s.c.]).

Standardized protocol for tapering exists in 32% of centers for MTX, in 26% for ADA, and 20% for IFX. The timepoint for tapering was after 6 months of remission on medication by 14% of respondents, 12 months for 38%, 24 months for 56% and 36 months for 12%.

MTX was tapered by dose in 42%, dose and interval in 40%, and interval in 15%. The lowest dose of MTX was 6mg/m2/week at the time of tapering and the longest mean interval 2.5 weeks (1 to 4 weeks). ADA was first tapered to

every 3 weeks by 76% of the responders and then to every 4 weeks by 49% before discontinuing. Fewer respondents used or tapered IFX, TOC or ABA. Around 65% tapered the interval and 20% tapered the dose and interval for ABA, 26% for TOC and 37% IFX

There were differences in the duration of tapering prior to discontinuation of specific medications. For ADA it was 6 months in 62%, 12 months in 36% ,and 24 months in 10%. For IFX it was 6 months in 27%, 12 months in 45%, and 24 months in 33%. For TOC it was 40% after 4 weeks, 87% after 6 weeks and 53% after 24 weeks. For ABA i.v. it was 30% after 8 weeks, and 90% after 12 weeks.

If combination therapy was used, 36% tapered the bDMARD first, 62% csDMARD first, and 12% both simultaneously.

Conclusion: This is the first survey to describe "real world" medication tapering and discontinuation practices of pediatric rheumatologists and ophthalmologists globally. Most physicians start to taper medication after 24 months of remission on medication and discontinue after the 6 to 12 months of tapering.

Abstract Number: 0734

Differences and Similarities Between down Syndrome-associated Arthritis and Juvenile Idiopathic Arthritis in the New Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry

Jordan Jones[1], Chelsey Smith[2], Daniel J Lovell[3] and Mara Becker[4], [1]Children's Mercy Kansas City, Kansas City, MO, [2]Children's Mercy Kansas City, Holden, MO, [3]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Duke University School of Medicine, Durham, NC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Down syndrome-associated arthritis (DA) is under-recognized with delay in diagnosis (1). The majority of those with DA present with polyarticular, rheumatoid factor (RF) and anti-nuclear antibody (ANA) negative disease, which is different compared to those with juvenile idiopathic arthritis (JIA). Therapy for JIA has been used to treat DA, but appear to be poorly tolerated, more toxic and less effective in patients with DA (1). The objective of this study was to characterize differences between those with DA and JIA, using the new Childhood Arthritis and Rheumatology Research Alliance Registry (nCARRA).

Methods: The nCARRA began prospectively collecting data on children with JIA in the United States and Canada in July 2015. Down syndrome (DS) is documented in the CARRA Registry as a coexisting condition. Between the dates of July 2015 and March 2019, patients with a diagnosis of JIA *and* DS were identified and matched (in a 1:5 ratio) on

Table 1. Demographics of patient with and without Down syndrome at baseline visit

Demographics and clinical variables	Down Syndrome (n = 36)	Without Down syndrome (n = 165)
Female, n (%)	24 (67)	116 (70)
Age at arthritis diagnosis, years (range)	6.9 (2 - 15)	7.7 (1 - 17)
Time to diagnosis*, months (range)	8.3 (0 - 49)	9.8 (0 – 112)
Arthritis subtype, n (%)

Clinical Juvenile Arthritis Disease Activity Score 10 (cJADAS10) ‡	6.1 (5.6)	7.2 (7.2)	0.91	4.4 (4.5)	2.6 (4.5)	**< 0.01**

* MD-global; 10-point Likert visual analog scale, 0 = clinically inactive disease

** Pt-global; 10-point Likert visual analog scale, 0 = very good

† CHAQ; eight domains, questionnaire scores averaged to obtain disability Index score (0 - 3), 0 = no disability

‡ cJADAS10; composite disease activity (0 - 30), sum of the MD-global (0-10 VAS), Pt-Global (0-10 VAS) and number of joints with active arthritis capped at a maximum of 10, ≤ 1.0 = inactive disease

age, sex, and JIA subtype to patients with a diagnosis of JIA and without DS. Collected data included demographics, disease characteristics, laboratory results, treatment exposure, and outcomes measures.

Results: Thirty-six patients were identified with DS and 165 patients without DS. Those with DS had a mean follow-up period of 4.5 years (SD 3.2), while those without had 4.7 years (SD 3.9). Most patients were female and had polyarticular, RF negative disease (Table 1.). The treatment approach at diagnosis for both groups were similar with no significant difference (p-value < 0.05) in initiation of disease modifying antirheumatic drug (DMARD)(44% for those with DS, and 32% for those without DS) or biologic therapy (17% those with DS, and 7% for those without DS). DMARD therapy was used in 78% of those with DS and 87% of those without DS. Methotrexate was the most used DMARD for both groups, but those with DA had more DMARD adverse events (93% versus 25%). Biologic therapy was used

in 75% of those with DS and 70% of those without DS, and biologic therapy ineffectiveness was much higher in those with DS (60% versus 17%). At entry into the nCARRA, there was no significant difference between joints with active arthritis, limited range-of-motion (ROM) or clinical juvenile arthritis disease activity score (cJADAS10), however, at last reported visit there was significant (p-value < 0.05) difference in almost all outcomes measures (Table 2.).

Conclusion: This study from a large multicenter registry reveals that children with DA have a similar presentation to children with JIA without DS, however, their disease course and disease burden is significantly worse. There is also more drug adverse events and higher rates of therapeutic ineffectiveness. This raises concern for possible physiologic reasons that place them at higher risk for resistant disease and treatment ineffectiveness. Collective work is needed to characterize DA, understand the pathophysiology, and understand clinical pharmacologic factors that will help identify the most effective and tolerated therapies to treat arthritis in children with Down syndrome.

Paediatric Sarcoidosis: Phenotype of a Retrospective Cohort of Biopsy-proven Patients

Kerstin Nott[1], Veronica Nott[2] and Sandrine Compeyrot-Lacassagne[1], [1]Great Ormond Street Hospital for Children, London, United Kingdom, [2]Imperial College, ANDOVER, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Paediatric sarcoidosis is a multisystemic inflammatory condition characterised by the formation of non-caseating granulomata that may lead to end-organ damage. Diagnosis is challenging as a compatible clinical-radiographic presentation with histopathologic confirmation is needed. Caution must be exercised to exclude granulomata of infectious aetiology as well as those seen in immunodeficiencies associated with immune dysregulation. Little is known about this rare disease's presentation and outcome in children. We report a retrospective cohort of children with biopsy-confirmed sarcoidosis, their treatment and the course of the disease.

Methods: Patients' notes were reviewed retrospectively, and multisystem involvement identified. We included patients with biopsies, performed or reviewed at our centre between 2010 and 2020, which were consistent with sarcoidosis and a compatible clinical phenotype.

Results: We identified 42 children with biopsy-proven sarcoidosis. Mean age at diagnosis was 9.4 years; male to female ratio 0.68. Twenty-seven of 42 patients were of Afro-Caribbean descent. Tissues biopsied included lymph node, skin, kidney, liver, lung, submandibular, lacrimal and salivary gland, eye, spleen, bone, brain and synovium.

28 patients had lymphadenopathy, 16 glandular involvement, 17 liver, 17 pancreas, 13 renal, 11 spleen, 27 skin, 14 lung involvement, 11 arthritis, 4 tenosynovitis, 3 hearing loss, 2 bone, 1 cerebral, and 25 eye involvement.

Remarkable laboratory findings included raised levels of serum calcium in 9, amylase in 16, lipase in 4 and ACE in 30 patients; 12 patients had abnormal renal function, 13 abnormal liver function; 13 patients were tested for NOD2 mutations, which were present in 5.

38 patients received treatment for sarcoidosis. Of those, 37 received steroids, 16 intravenous followed by oral steroids, 18 oral steroids only and 18 received steroid eye drops; 36 patients received disease-modifying antirheumatic drugs (DMARDs) including 26 methotrexate, 11 mycophenolate mofetil and 10 azathioprine; 4 patients received hydroxychloroquine, 5 cyclophosphamide; 10 received biologic therapy including anti-TNF, interleukin-1 and IL-6 blockade, JAK inhibitor and rituximab.

All patients had a good response to steroids, and most responded to methotrexate. The treatment of a subset of patients was escalated to include a biologic agent, owing to grumbling disease activity. Although most of the patients were able to wean off regular steroids, the majority remained on long-term DMARDs to maintain disease control.

Conclusion: Our study suggests that non-caseating granulomatous inflammation on biopsy, multiorgan involvement, response to steroids and chronic course are hallmarks of paediatric sarcoidosis. DMARDs, in particular methotrexate, were used with efficacy. When response was partial, addition of a biologic agent was beneficial, particularly in ocular disease. Additional organ involvement occurs over time when the disease is not fully controlled. However, no biomarkers are available to assess disease activity apart from ACE, which demonstrated low sensitivity. Prospective cohort studies are needed to define this rare paediatric disease.

Identification of Salient Resilience Domains Among Adolescents with Chronic Musculoskeletal Pain and Their Parents

Lauren Pianucci[1], Maitry Sonagra[2], Daneka Stryker[3] and **Sabrina Gmuca**[4], [1]Arcadia University, Philadelphia, [2]Children's Hospital of Philadelphia, Cherry Hill, NJ, [3]Drexel University College of Medicine, Philadelphia, PA, [4]Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: JIA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Adolescents with chronic musculoskeletal pain (CMP) and their parents have been found to have low to moderate levels of resilience and resilience levels are associated with symptom severity. However, the causal role of resilience in CMP has not yet been established. We aimed to identify resilience domains that differ among youth with high versus low levels of resilience, as well as their parents, in order to elucidate salient resilience domains relevant to symptom severity in adolescent CMP.

Methods: This was a cross-sectional study of patients aged 13-17 years diagnosed with CMP, and one of their parents, seen in a pediatric Rheumatology subspecialty pain clinic for an initial consultation between March and May 2018. A series of online questionnaires, including the Resilience Scale 14-item (RS-14), were administered to the patient-parent pairs within 12 weeks of the initial clinic visit. Questionnaires were complemented by data abstraction from the electronic medical record. The RS-14 was re-categorized into three resilience levels: low (14-73), average

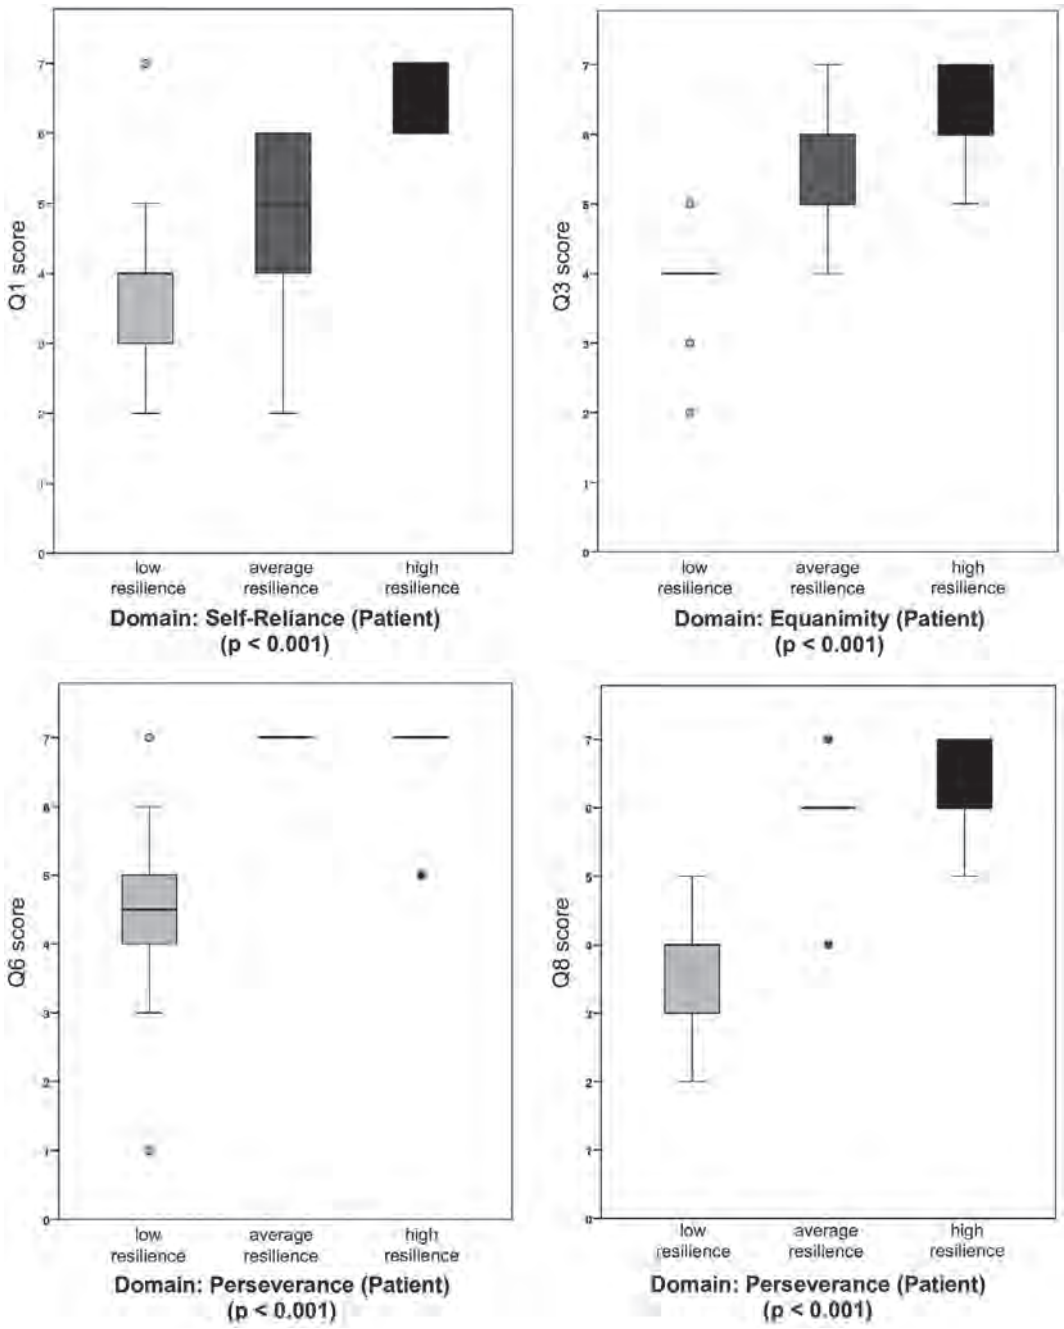

Figure 1. Box-plots of Scores in Salient Domains Identified on the RS-14 Stratified Across Levels of Resilience Among Patients. Legend. Patients with high resilience scored highest on RS-14 questions representing the salient domains of self-reliance, equanimity, and perseverance when compared to patients with low and average resilience.

(74-81), and high (82-98). Scores on each question of the RS-14 were summarized for each resilience level (low, average, and high). Differences in question scores and variables of interest between resilience groups were assessed with Kruskal-Wallis tests and Freeman Halton Fischer's exact tests, as appropriate.

Results: A total of 28 patient-parent pairs were included. The majority of patients (71.4%) and parents (92.9%) were female. Patient-parent pairs were predominantly non-Hispanic whites (75.0%) with most residing in a suburban area (60.7%). The median age of parents was 48 years (IQR 45-51) and the median age of patients was 15 years (IQR 14-16). Half of the patients had low resilience (n=14) and a little more than half (53%) of parents had high resilience (n=15). The questions with the most significant differences ($p < 0.001$) between resilience groups for patients were

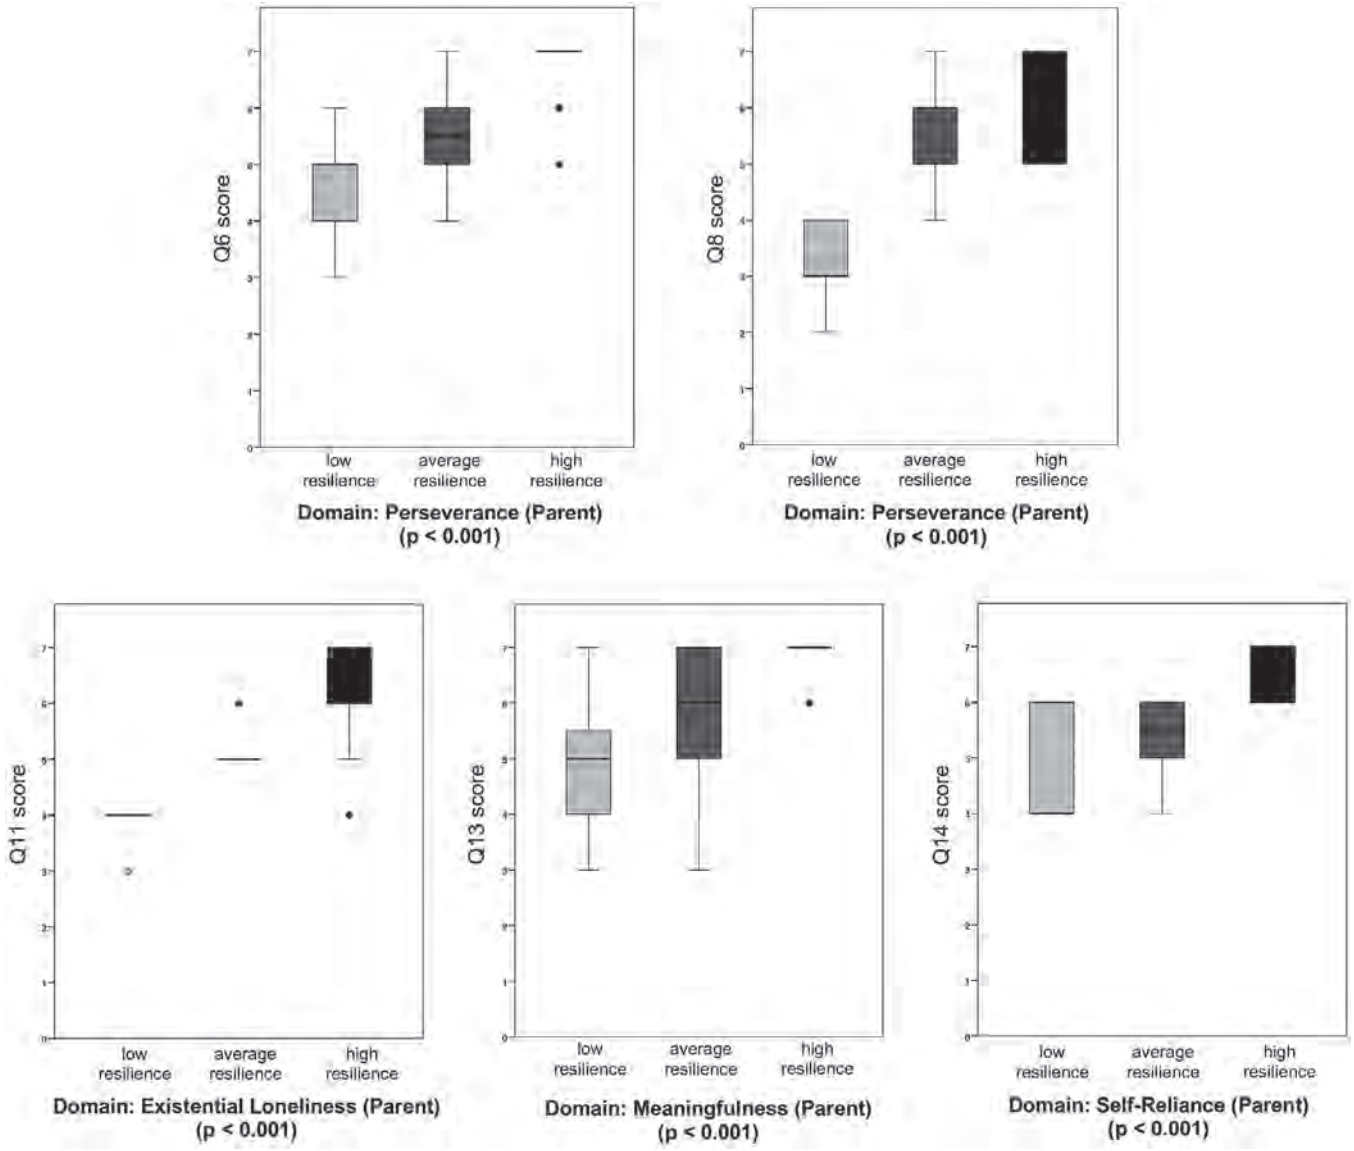

Figure 2. Box-plots of Scores in Salient Domains Identified on the RS-14 Stratified Across Levels of Resilience Among Parents. Legend. Parents with high resilience scored highest on RS-14 questions representing the salient domains of perseverance, existential loneliness, meaningfulness, and self-reliance when compared to parents with low and average resilience.

within the domains of equanimity, perseverance, and self-reliance (Figure 1). The questions with the most significant differences ($p < 0.001$) between resilience groups for parents were within the domains of existential aloneness, meaningfulness, perseverance, and self-reliance (Figure 2). Overall health-related quality of life (HRQoL) as defined by the PROMIS Pediatric Global Health 7 (PGH-7) score varied significantly across resilience levels for patients ($p < 0.01$) as did a history of suicidality ($p = 0.03$) (Table).

Conclusion: Domains of resilience most prominent among both youth with CMP and their parents included self-reliance and perseverance. Differences in patient-level resilience were associated with overall HRQoL and a history of suicidality. These findings lay the groundwork for future mixed methods research to better characterize and target these salient domains of resilience as they relate to adolescent CMP and guide novel treatment interventions.

Table. Differences in Clinical Characteristics by Patient Resilience Level

	all patients (n=28)	low resilience (n=14)	average resilience (n=5)	high resilience (n=9)	p-value
Clinical Characteristics, median (IQR) or n (%)					
Pain intensity (VAS [0-100])	61.5 (30.0-82.3)	64.0 (54.0-83.8)	80.0 (13.5-88.0)	31.0 (28.5-64.0)	0.44
Energy level (0-100)	55.0 (40.0-78.8)	50.0 (28.8-65.5)	43.6 (40.0-75.0)	75.0 (55.0-92.5)	0.06

"It'll Go Away. There's Nothing Wrong with you:" the Experience of Pain-Related Stigma Among Adolescents with Pain Amplification Syndrome

Emily Wakefield[1], William Zempsky[1], Rebecca Puhl[2] and Mark Litt[3], [1]Connecticut Children's/University of Connecticut School of Medicine, Hartford, CT, [2]Rudd Center for Food Policy & Obesity/University of Connecticut, Hartford, CT, [3]University of Connecticut School of Medicine, Farmington, CT

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: JIA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic pain in adolescence is a complex and significant medical condition, with a reported prevalence of 11-38%.[1] Pain amplification syndrome (PAS), which includes fibromyalgia, is a common chronic pain syndrome in adolescents characterized by allodynia without specific somatic injury or illness.[2] Physicians are often puzzled by pain reports that seem disproportionate to medical findings. As a result, the complaints of adolescents with chronic pain are often viewed with skepticism by others. This disbelief is a phenomenon referred to as pain-related stigma.[3] Pain-related stigma has not been studied in adolescents with chronic pain. Pain-related stigma may account for poor health outcomes in this population, such as depression,[4] anxiety,[5] problems in school[6] and social impairment.[7] In the current study, we sought to evaluate pain-related stigma in adolescents with PAS using focus group methodology.

Methods: Five focus groups of 3-5 adolescents with PAS (*N*=18), ages 12-17, were conducted to evaluate the impact of, and reaction to, pain-related stigma. Patients were recruited from an outpatient pediatric pain management clinic. Patients with a comorbid chronic medical condition, such as juvenile idiopathic arthritis, were excluded to reduce the bias of other disease-related stigma. Using a semi-structured interview, we asked questions targeting stigma in an open-ended manner. Focus group length ranged from 36-106 minutes with a total of 363 responses. Transcripts were validated for accuracy and coded independently by two raters (90.34% agreement) who identified pain-related themes using grounded theory.

Results: Findings suggest evidence of pain-related stigma among medical providers, school staff, peers and family members. Adolescents described sources of the pain-related stigma as the invisibility of pain and diagnostic uncertainty. Additionally, several incidents of peer bullying were also described secondary to respondent references to having chronic pain. There is evidence that adolescents with chronic pain attempt to conceal their symptoms from others to avoid negative social interactions, and that they internalize their pain-related stigma experiences.

Conclusion: Our findings indicate that adolescents with PAS experience pain-related stigma among medical providers, peers, school personnel and family members. Disbelief of pain symptoms may be critical in understanding disease-related burden and social disruptions in this population. There are several potential clinical implications of pain-related stigma among adolescents with chronic pain, including healthcare utilization, poor health outcomes and quality of healthcare.

Acknowledgments: This research is supported by the National Institute of Arthritis and Musculoskeletal and Skin Disease of the National Institutes of Health under award number 1K23AR073934-01A1 and the Goldfarb Pain and Palliative Medicine Fund.

Systemic Administration of Novel Hydroxyl Dendrimers to Target Inflammation in Arthritic Tissues

Jeffrey Cleland[1], Rishi Sharma[2], Minghao Sun[3], Santiago Appiani La Rosa[3] and **Rangaramanujam M. Kannan**[4], [1]Ashvattha Therapeutics, Inc, Redwood City, CA, [2]Ashvattha Therapeutics, Baltimore, MD, [3]Ashvattha Therapeutics, Inc, Baltimore, MD, [4]Johns Hopkins School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammation observed in arthritis and other autoimmune disorders is mediated primarily by pro-inflammatory reactive macrophages. Systemic administration of anti-inflammatory agents does not selectively target the affected tissue, or the reactive macrophages and often has significant side effects. Hydroxyl dendrimers have been observed to selectively target reactive macrophages and have been well tolerated in humans. Hydroxyl dendrimer-drug conjugates may provide a superior method for treating localized inflammation, from systemic administration.

Methods: The binding affinity of the dendrimer-alendronate conjugate (D-ALN) was evaluated against hydroxyapatite (HAP) using UV/Vis spectrophotometry. Lewis rats were immunized with an emulsion of type II bovine collagen in incomplete Freund's adjuvant intradermally on Day 1 and Day 7 to establish collagen-induced arthritis (CIA). Groups of CIA rats and naïve rats (N=5/group) were administered by IV on Day 19 either hydroxyl dendrimer labelled with Cy5 (D-Cy5), D-Cy5 conjugated with alendronate (ALN-D-Cy5), or vehicle control. On Day 21, animals were sacrificed for imaging of hind limbs, kidney and liver. Immunohistochemistry was also performed on hind limbs using CD68 (macrophages), CathK (osteoclasts) and DAPI.

Results: *In vitro*, D-ALN demonstrated strong binding affinity toward HAP with >85% of D-ALN bound to HAP in less than 10 minutes. Upon intravenous administration, more than 100-fold greater radiant intensity from Cy5 was noted in the paw and knee joint of the CIA rats compared to the naïve rats, indicating significant selective uptake of the D-Cy5 into the regions of inflammation. While a comparable radiant intensity was noted in the joints of CIA rats treated with D-Cy5 or ALN-D-Cy5, a two-fold greater radiant intensity was noted in the paws for CIA rats treated with D-Cy5. A single dose of ALN-D-Cy5 reduced paw volumes by in CIA rats ~10% after 2 days and clinical scores were comparable in all CIA groups.

Conclusion: Systemically administered hydroxyl dendrimer-drug conjugates localize to sites of inflammation in arthritic tissues. Alendronate, which binds bone, conjugated to the hydroxyl dendrimer appears to concentrate only in regions of the bone with potentially less uptake in reactive macrophages away from the bone. These results indicate the types of dendrimer constructs to utilize for drug conjugates to treat inflammation or bone metabolism. Efficacy studies are planned with dendrimer drug conjugates to evaluate modulators of bone resorption and inflammation.

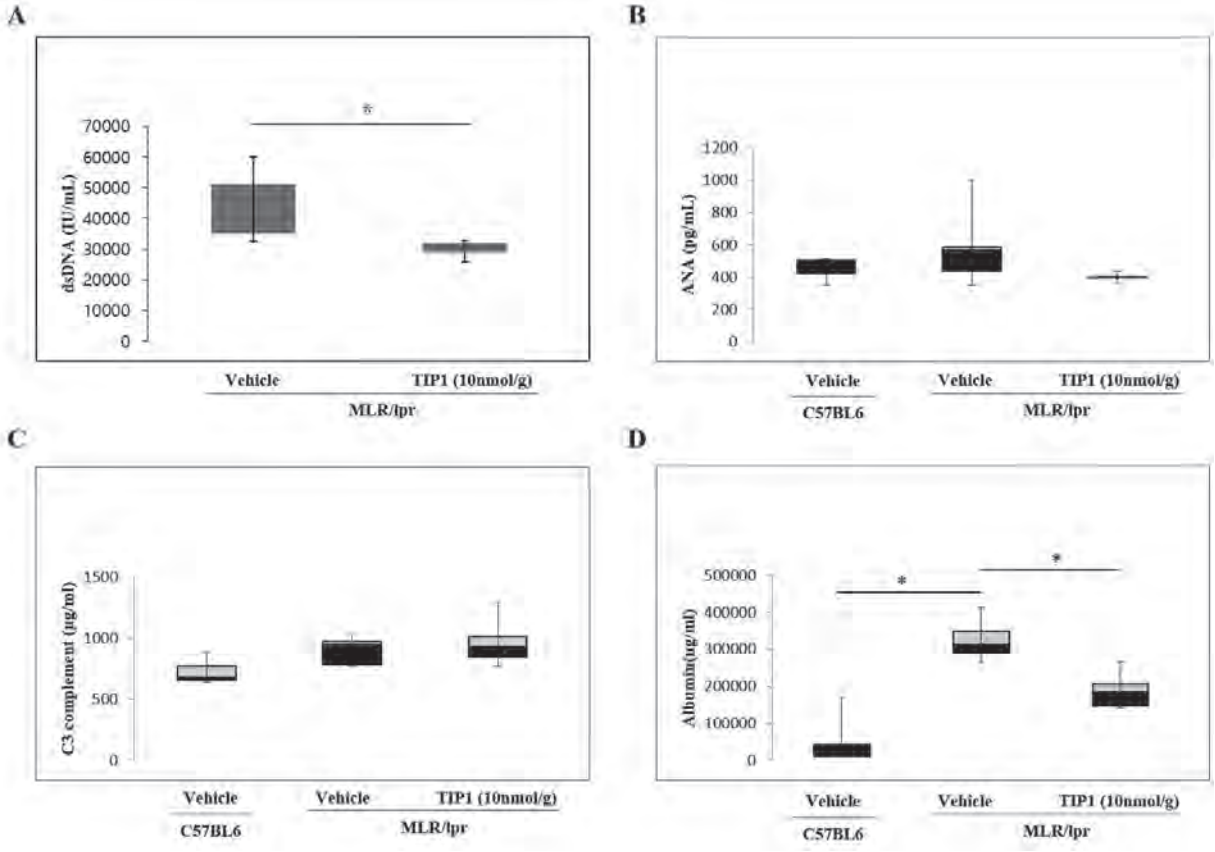
Toll-like Receptor Inhibitor Peptide Improves the Clinical, Immunologic, and Pathologic Manifestations of Systemic Lupus Erythematosus

Chang-Hee Suh[1], **Wook-Young Baek**[1], Ji-Won Kim[1], Yang-Seon Choi[2], Sung-Min Lee[1], In-Ok Son[1], Ki-Woong Jeon[1] and Sangdun Choi[2], [1]Ajou University School of Medicine, Suwon, Republic of Korea, [2]Ajou University, Suwon, Republic of Korea

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Fig. 1.



Background/Purpose: Toll-like receptors (TLRs) are a type of protein that plays a major role in the innate immune system. In recent years, several studies have shown that TLR-mediated pathways regulate in immune and inflammatory diseases. Also, dysregulated TLRs within the endosomal compartments such as TLR 7/9 trafficking can cause systemic lupus erythematosus (SLE). The TLR signaling pathways are fine-tuned by Toll/interleukin-1 receptor (TIR) domain-containing adapters, which leading to interferon (IFN)-α production. This study reports a Toll-like receptor inhibitor (TIP)1, that primarily suppresses TIR domain-containing adapters mediated downstream signaling in the animal model of lupus and patients with lupus.

Methods: MMRL/lpr mice were received an intraperitoneal injection of as a single daily dose, at a dose of 10 nmol/g/day for 4 weeks beginning at 14 weeks to 18 weeks of age. The concentration of cytokines in mice serum was measured by enzyme-linked immunosorbent assay (ELISA), and pathological analysis of kidney and spleen was analyzed by immunohistochemistry. In addition, protein expression levels of mouse major tissues and peripheral blood mononuclear cells (PBMC) of patients with SLE were analyzed by western blot.

Results: We examined the major organ size of the MRL/lpr mouse treated with TIP1. Kidney, spleen and lymph node of MRL/lpr mice were significantly increased in size but, after the administration of TIP1, the size of kidneys, spleen and lymph node were greatly reduced compared to vehicle treatment group. We next evaluated whether TIP1 can be useful for treatment of SLE in a murine model by assessing the ability of TIP1 to reduce circulating autoantibody levels, hallmarks of SLE. We performed ELISA for antinuclear antibody and anti-dsDNA antibody in serum collected from the treated lupus-prone mice. As a results, TIP1 significantly reduced the production of anti-dsDNA antibody and urine albumin (Fig 1). When assessed the expression of proteins involved in TLR 7/9 signaling in major tissues such as kidney, spleen and lymph nodes, most downstream proteins of the TLR 7/9/MyD88/IRF7 signaling pathway were reduced in the mice with TIP1 treatment compared to vehicle treatment. Furthermore, pathological analysis of mouse kidney tissue confirmed that TIP1 could improve the inflammation in MRL/lpr mice. In addition, the TIP1 treat-

ment reduced many downstream proteins in the TLR signaling such as Myeloid differentiation primary response 88 (MYD88), Interleukin-1 receptor-associated kinase (IRAK), Tumor necrosis factor receptor–associated factor (TRAF) and Interferon-alpha (IFN-α) in the PBMC of patients with SLE.

Conclusion: Our data suggest that TIP1 can be developed as a potential candidate for the treatment of SLE.

Card9 Promotes Th17-mediated Arthritis and Spondylitis via Control of Acute Pathogenic Neutrophil Responses in SKG Mice

Holly Rosenzweig[1], Emily Vance[1], Ellen Lee[1] and **Ruth Napier**[1], [1]Oregon Health & Science University and VA Portland Health Care System, Portland, OR

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Caspase recruitment domain-containing protein 9 (CARD9) is an intracellular signal transduction molecule that mediates antimicrobial responses following activation of C-type lectin receptors (ie. Dectin-1) by fungal ligands including β -glucans (zymosan). CARD9-deficient patients have defects in Th17 immunity and succumb to systemic candidiasis, and single nucleotide polymorphisms in *CARD9* have been associated with susceptibility to Th17-mediated autoimmune diseases including ankylosing spondylitis. However, how dysregulation of CARD9 may regulate autoimmunity remains unknown. Here we sought to investigate the role of CARD9 in arthritis and spondylitis (spinal inflammation) as modeled in SKG mice.

Methods: Arthritis was induced in SKG vs. Card9$^{-/-}$ SKG mice by intraperitoneal injection of 1.5mg β-glucan (zymosan) and evaluated clinically for 8 weeks, by near-infrared imaging, and histologically. CD4^{+} T cells from draining lymph nodes were stimulated *in vitro* with PMA/ionomycin and Th effector subsets were quantified by intracellular cytokine staining and flow cytometry. For lavage studies, peritoneal fluid collected 4h post-zymosan was analyzed for immune cellular composition by flow cytometry and ELISA. Neutrophils were depleted in SKG mice with anti-Ly6G (1A8) or isotype control (2A3) beginning 24h prior to zymosan and every 2 d for 5 d. For all studies, three independent experiments were performed (n=5-6 mice/genotype), and data analyzed using non-parametric statistics.

Results: In stark contrast to SKG mice that developed chronic arthritis and features of spondylitis by 8 weeks post zymosan, Card9$^{-/-}$SKG mice were completely protected from both diseases. Cell composition analysis of the ankle-draining lymph nodes at both 5 d and 8 wk post-zymosan revealed reduced numbers of neutrophils and effector Th17 responses in Card9$^{-/-}$SKG mice. CARD9 promoted acute (pre-arthritic) neutrophil responses in SKG mice as Card9$^{-/-}$SKG mice had reduced numbers of neutrophils, but not dendritic cells or macrophages, in lavage fluid as early as 4 h post-zymosan. Furthermore, neutrophils from Card9$^{-/-}$SKG lavage fluid had similar surface expression of Dectin-1 to neutrophils from SKG mice, yet had decreased activation status (retention of CD62L) and reduced degranulation of primary (CD63) and secondary (CD66b) granules. These data suggest that Card9 may function downstream of Dectin-1 ligation to promote activation and degranulation of neutrophils. Akin to Card9$^{-/-}$SKG mice,

neutrophil-deplete SKG mice had delayed onset of arthritis and decreased Th17 responses 5 d post-zymosan, supporting a pathogenic function for early neutrophil responses in induction of arthritis. Cumulatively, these data support an integral role for Card9 in regulation of early neutrophil responses that promote Th17 cells and induction of arthritis.

Conclusion: These data show a direct link between Card9 signaling and neutrophil-intrinsic induction of autoreactive Th17 responses in arthritis. Further investigation of how Card9 functions within neutrophils to drive autoimmunity may serve to unveil novel therapeutic avenues for human Th17-mediated diseases including ankylosing spondylitis.

Constitutive Inhibitor Kappa B (IκB) Kinase 2 (IKK2) Activation Induces an Inflammatory State in Fibroblast-Like Synoviocytes

Sergio Ramirez-Perez[1], Umesh Gangishetti[1], Kyle Jones[1] and Pallavi Bhattaram[2], [1]Department of Orthopaedics, Department of Cell Biology, Emory University School of Medicine, Atlanta, GA, [2]EMORY UNIVERSITY, Atlanta, GA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) are key players involved in the production of inflammatory mediators that trigger joint tissue damage in inflammatory arthritis (IA). The most important mechanism proposed for FLS activation is the NF-κB-dependent signalling pathway. Inhibitor kappa B (IκB) kinase 2 (IKK2) plays a critical role in the activation of NF-κB, resulting in transcription of several inflammation-associated genes. The aim of this research was the characterization of a constitutive IKK2 activation (IKK2ca) in FLS as a strategy to study tissue-specific inflammation in the joint.

Methods: In order to acquire new information regarding pathological pathways underlying IA, we develop an *R26Stop*^{FL}*ikk2ca-Prg4*^{CreERT2} mouse model, which expresses a constitutive active form of IKK2 restricted to Prg4-expressing cells in the joints. Cre-recombinase activation was induced by tamoxifen (TMX) intraperitoneal injection to 2-month old mice. Samples were collected after 4 weeks of TMX injection. Isolation of FLS was performed and NF-κB signalling pathway activation was analyzed by RT-qPCR and western blot. Additionally, flow cytometry was carried out to identify IKK2ca FLS population (Prg4 red cells). FLS at passages 2 to 4 were used for all experiments. R26-tdTomato-*Prg4*^{CreERT2} and TNF$^{tg/0}$rtTA$^{tg/0}$ FLS were taken as Wild type (WT) for RT-qPCR, western blot, and FACS analysis.

Results: Preliminary results showed high expression of IKK2 in IKK2ca FLS compared with WT FLS, as well as decreased expression of IκBα in the cytoplasm because of IKK2 constitutive activation. However, we did not observe differences in RelA nuclear expression between IKK2ca and WT FLS. In addition, we identify higher expression of *Il1b*, *Il6*, *Nanog*, and *Sox2* genes in IKK2ca than in WT FLS, which is consistent with the inflammatory state of IKK2ca FLS established in IA. Regarding FACS results, we identified a specific synovial sub-lining inflammatory population of IKK2ca-Prg4 CD14^{-} Thy1^{+} tdTomato^{+} FLS, which has reported as key player in IA.

Conclusion: Constitutive IKK2 activation in FLS induces an inflammatory phenotype characterized by increased expression of proinflammatory mediators, and represents an interesting strategy to study tissue-specific inflammation in the joint.

Effect of IA OnabotulinumtoxinA and Vanilloids on Substance P and Neurokinin 1 Receptor Expression in the Dorsal Root Ganglia of Mice with Monoarthritis

Hollis Krug[1], Nicole Blanshan[2], Christopher Dorman[2] and Sandra Frizelle[2], [1]Minneapolis VAHCS and University of Minnesota Medical School, Minneapolis, MN, [2]Minneapolis VAHCS, Minneapolis

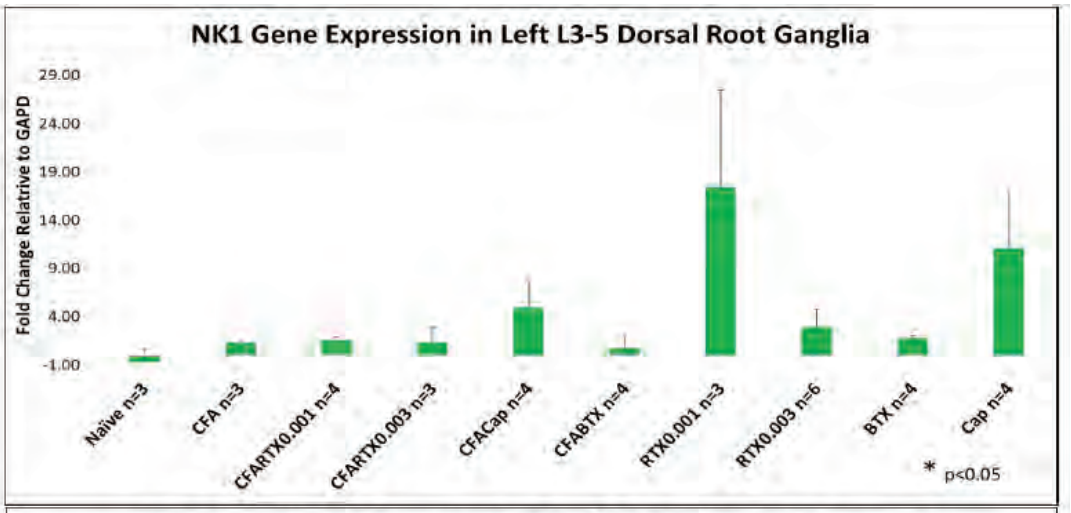
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

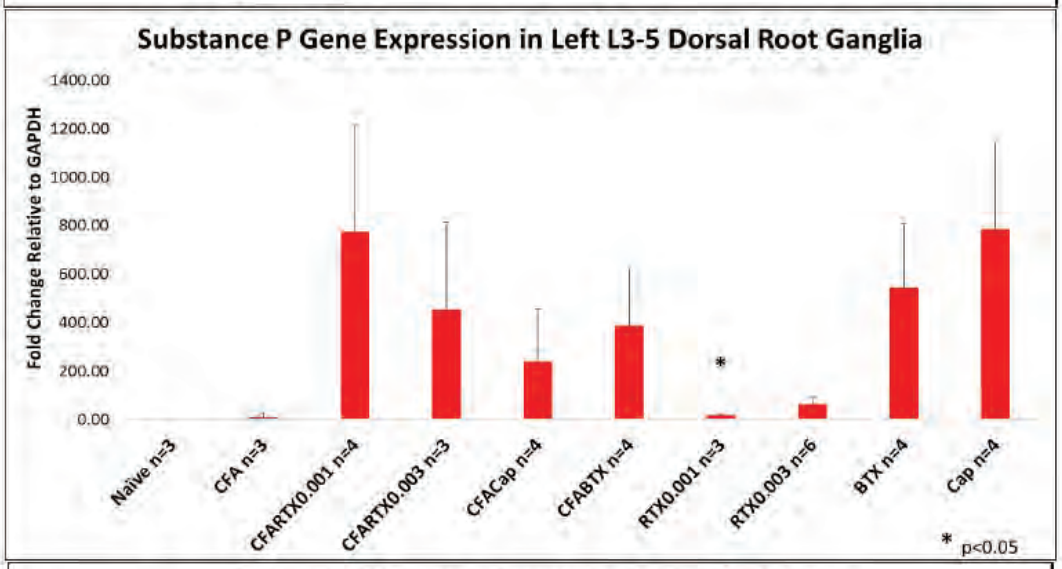
Background/Purpose: Neurotoxins are increasingly being proposed as analgesics for arthritis pain. Phase II and III clinical trials have shown efficacy but with potential toxicities such as rapidly progressive osteoarthritis that may be neurally mediated. We have shown efficacy of intra-articular (IA) onabotulinumtoxinA (BTX) and the vanilloids capsaicin (CAP) and resiniferatoxin (RTX) in monoarthritis in mice. To better understand the effect of these toxins on the sensory nervous system we examined their effect on the expression of substance P (SP) and neurokinin 1 receptor (NK1) in the dorsal root ganglion (DRG).

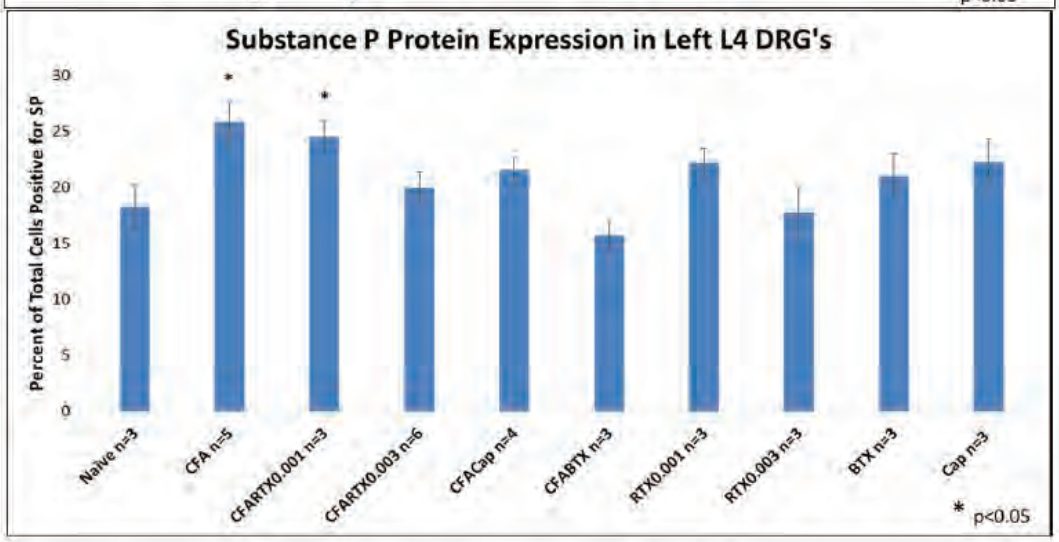
Methods: C57/Bl6 male mice received intra-articular (IA) Complete Freund's Adjuvant (CFA) to produce chronic inflammatory monoarthritis. IA therapies were given at appropriate intervals before examination and DRG harvest. Tissue samples were obtained after arthritis induction at 12 weeks of age from mouse dorsal root ganglia (DRG) and were subjected to immunohistochemistry and real-time reverse transcription polymerase chain reaction (RT-PCR). Neurotransmitter substance P (SP) protein expression was measured as percent of DRG neurons expressing SP. Both SP and receptor neurokinin-1 (NK1) gene expression were quantified using RT-PCR and expressed as a fold change relative to GAPDH values.

Results: CFA induction resulted in a significant increase in % SP protein expressing cells in DRG's but gene expression of SP and NK1 were not significantly changed from naïve. Neither vanilloids nor BTX had any effect on SP protein expression in nonarthritic animals. Only low dose RTX significantly increased SP gene expression in nonarthritic animals but had no effect onNK1 gene expression . High dose RTX, CAP and BTX all normalized % SP protein expressing cells in the DRG of arthritic animals but NK1 and SP gene expression was not significantly different from naïve. Interestingly, SP gene expression was more variable in all treated arthritic animals and in nonarthritic animals treated with BTX and CAP. NK1 gene expression in low dose RTX and CAP treated non arthritic animals was also more variable than in other groups. In general, BTX and CAP produced an increase in SP gene expression in nonarthritic animals but this was not significant.

Conclusion: Alterations in SP protein expression in the DRG of mice with chronic monoarthritis does not appear to be related to increased gene expression of either SP or NK1. Although the mechanism of action of BTX and vanilloids is hypothesized to be quite different, there does not appear to be a consistent effect of impaired neurotransmitter







release (BTX) or enhanced release (vanilloids) on SP or NK1 gene expression. Although numbers were small in this experiment, variability may be due to inherent differences in the animals' pain perception, pain behavior and response to therapy. Further studies to correlate pain behavior to SP and NK1 expression and to TRPV1 expression would be informative.

Substance P and NK 1 Receptor Gene and Protein Expression in the DRG of Mice with Inflammatory Monoarthritis: Effect of Neurotoxin Treatment.

Higher Baseline Fine-Specificity ACPAs Predict Greater Treatment Response with Abatacept + MTX versus MTX Monotherapy in Seropositive RA: A Post Hoc Analysis

William Robinson[1], Chun Wu[2], Sarah Hu[2], Sean Connolly[2] and Sumanta Mukherjee[2], [1]Stanford University School of Medicine, Stanford, CT, [2]Bristol-Myers Squibb Company, Princeton, NJ

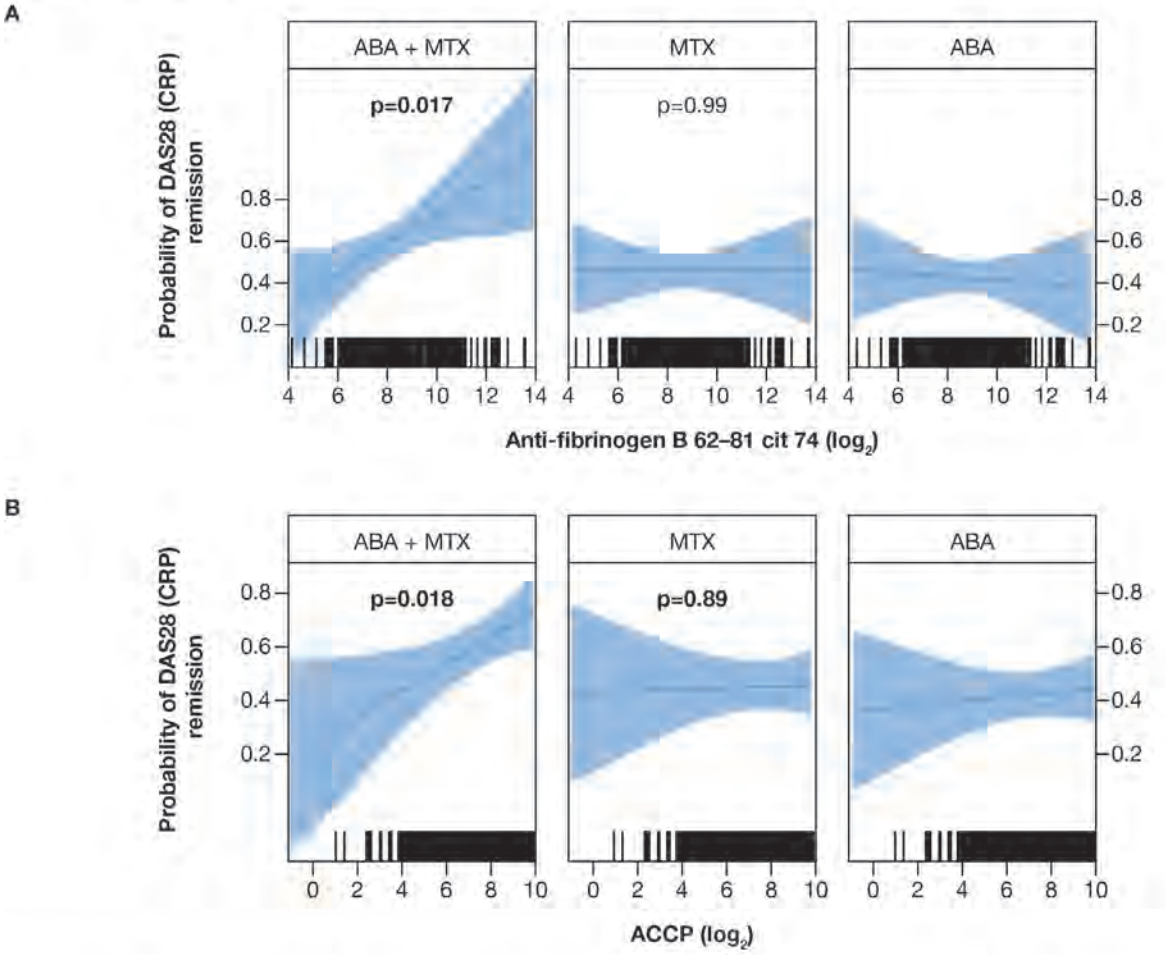
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: ACPAs are sensitive, highly specific markers of RA. Current tests cannot differentiate ACPA+ RA subtypes. Fine-specificity ACPAs (FS) can distinguish between ACPA+ RA subtypes to explore predictors of treatment (tmt) response. Higher vs lower baseline (BL) ACPA levels have been associated with improved response to abatacept (ABA).[1] In the Phase IIIb AVERT study, ABA + MTX was more effective than MTX in early RA: 61% vs 45% of patients (pts) achieved DAS28 (CRP) remission (< 2.6) at 12 mths.[2] We investigated FS as biomarkers to predict tmt response in pts with seropositive RA in AVERT.

Methods: Pts in AVERT (NCT01142726) were randomized to double-blind weekly SC ABA 125 mg + MTX, SC ABA 125 mg or MTX for 12 mths. In this *post hoc* analysis, predictive value of 29 BL FS and 10 non-citrullinated control antibodies (Ab) for efficacy measures (DAS28 [CRP], SDAI) was explored using logistic or linear regression models for remission rates (RR; SDAI remission ≤3.3) and change from BL (CfB) outcomes, respectively, with tmt arm, BL disease activity, age, sex, prior CS use, BL FS (continuous or categorized into tertiles [T; specific for each FS and control Ab]) and FS-by-tmt arm interaction as covariates. Linear mixed-effects model with repeated measures was used for time series analysis. Pairwise comparisons (unadjusted p values) between tmt arms were performed for DAS28 (CRP) and SDAI RR or adjusted mean CfB in each T. FS were analyzed with custom Bio-Plex™ bead-based autoantibody assay.[3]

Results: BL characteristics were comparable in overall (N=351) and target biomarker (n=340) populations and across tmt arms (not shown). Of 29 BL FS, 15 significantly correlated with anti-CCP Ab (ACCP; surrogate of ACPA). Of 29 FS or ACCP, higher BL anti-fibrinogen B 62–81 cit 74 (ABA + MTX p=0.017; MTX p=0.99) and ACCP (ABA + MTX p=0.018; MTX p=0.89) levels were significantly associated with higher probability of DAS28 (CRP) remission in pts who received ABA + MTX but not MTX (**Figure 1**); levels of non-citrullinated control anti-fibrinogen B 62–81 did not correlate with tmt response (p=0.324). For DAS28 (CRP) RR, tmt differences (ABA + MTX vs MTX) were greater in medium (T2) and high (T3) subgroups vs overall population: ACCP (T2; p≤0.01), 28%; anti-fibrinogen B 62-81 cit 74 (T3; p≤0.01), 32%; overall population, 16% (**Figure 2**). Tmt differences in adjusted mean DAS28 (CRP) CfB for ABA + MTX vs MTX and ABA vs MTX were greater in medium (T2; Mth 6) and high (T3; Mths 6, 12) vs low (T1) anti-fibrinogen B 62–81 cit 74 subgroups (**Figure 3**); similar findings were seen for SDAI. Anti-fibrinogen B 62–81 cit 74 (vs ACCP) better predicted DAS28 (CRP) CfB improvement with ABA + MTX vs MTX (not shown).

Figure 1. Probability of DAS28 (CRP) remission (<2.6) with ABA + MTX, MTX or ABA as predicted with A) anti-fibrinogen B 62–81 cit 74 and B) ACCP



The following FS and control antibodies were tested: B-actin 191–216 cit 196, biglycan 247–266 cit cyclic, clusterin 221–240 cit cyclic, clusterin 231–250 cit cyclic, collagen Type II 281–298 cit 290, collagen Type II 281–298, enolase 1A 5–21 cit, fibrinogen A 211–230 cit cyclic, fibrinogen A 27–43 cit, fibrinogen A 41–60 cit3 cyclic, fibrinogen A 563–583 cit 573, fibrinogen A 616–635 cit3 cyclic, fibrinogen B 246–267 cit, fibrinogen B 285–305 cit, fibrinogen B 285–305, fibrinogen B 36–52 cit, fibrinogen B 54–74 cit 60, fibrinogen B 54–74, fibrinogen B 62–81 cit 72, fibrinogen B 62–81, fibrinogen B 62–81 cit 74, fibrionectin cit 1035, filaggrin 48–65 cit2 cyclic, filaggrin 48–65 cyclic, H2A/a 1–20 cit cyclic, H2A/a 1–20 cyclic, H2A/a-2 1–20 cit, H2A/a-2 1–20, H2B/a 62–81 cit cyclic, H2B/a 62–81 cyclic, H4 33–48 cit39, tenascin C1, tenascin C5, vimentin 1–16 cit, vimentin 1–16, vimentin 265–278, vimentin 58–77 cit3 cyclic, vimentin 58–77 cyclic and ACCP BL levels.
ABA=abatacept; ACCP=anti-CCP antibody; FS=fine-specificity anti-citrullinated protein antibody.

Conclusion: BL FS predicted improved DAS28 (CRP), SDAI RR and CfB with abatacept + MTX vs MTX; higher BL T showed greater differentiation in tmt response with abatacept + MTX vs MTX. Anti-fibrinogen B 62–81 cit 74 (vs ACCP) better predicted DAS28 (CRP) improvement with abatacept + MTX vs MTX. These data support anti-fibrinogen B 62–81 cit 74 as a predictor of tmt response to abatacept.

Circulating Fibroblast Growth Factor-21 Levels in Rheumatoid Arthritis: Associations with Disease Characteristics, Body Composition, and Physical Functioning

Patrick Gould[1], Babette Zemel[2], Elena Taratuta[3] and Joshua Baker[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, [3]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) can lead to changes in body composition, including muscle loss and excess adiposity, which are in turn associated with physical disability. It is of interest to identify biomarkers that could help identify patients most at-risk for these changes. Fibroblast Growth Factor (FGF)-21, an adipokine associated with obesity, insulin resistance, and metabolic stress, is known to be elevated in patients with muscle stress conditions but has not been well-described in RA patients. In this study, we evaluated associations between FGF-21 and adverse changes in body composition and physical functioning in patients with RA, hypothesizing that levels of FGF-21 at baseline would be associated with worsening muscle deficits and physical functioning over time.

Methods: At baseline and follow-up, RA patients meeting 2010 ACR criteria, aged 18-70, completed whole-body Dual Energy Absorptiometry (DXA) and peripheral quantitative computed tomography (pQCT) to quantify lean mass, fat mass, visceral fat area, and muscle density. Dynamometry was used to measure strength at the hand and knee, and physical functioning was measured with the Health Assessment Questionnaire (HAQ) and the Short Physical Performance Battery (SPPB). Cytokines and inflammatory markers were measured at baseline, and serum FGF-21

was assessed using ELISA. Linear and logistic regression analyses assessed associations between FGF-21 levels, and body composition and physical functioning over 2-5 years of follow-up.

Results: 113 patients with RA were enrolled, and 84 (74%) returned for follow-up at a median (IQR) time of 2.7 years (2.30, 3.56). At baseline, higher FGF-21 levels were independently associated with older age, smoking, lack of methotrexate use, and greater adiposity (both total and visceral) (**Table 1**). The highest quartile of FGF-21 was associated with worse HAQ and SPPB scores, independent of other baseline characteristics (p=0.03 and p=0.01, respectively; data not shown). FGF-21 was not associated with common measures of RA activity or severity, including DAS28(CRP) and radiographic damage scores, but was associated with higher levels of specific inflammatory cytokines including TNF-RI, YKL-40, VEGF, and Resistin, before and after adjusting for visceral fat area (all p< 0.05, data not shown). Over time, higher baseline FGF-21 levels were numerically, but not statistically significantly, associated with greater worsening per year in muscle density and area z-scores [β=-0.056 (-0.12, 0.008), p=0.08; β=-0.049 (-0.10, 0.006), p=0.08], and the fourth FGF-21 quartile was associated with greater worsening in SPPB score [β=-0.57

Table 1. Associations Between FGF-21 Levels and Participant Demographics and RA Disease Characteristics at Baseline

	Univariate Model		**Multivariable Model**	
	β (95% CI)	p	β (95% CI)	p

Current Methotrexate	-0.35 (-0.74, 0.037)	0.08	-0.45 (-0.80, -0.10)	0.01
Current Biologic	0.016 (-0.36, 0.39)	0.93	--	--
Current Prednisone	0.052 (-0.32, 0.43)	0.79	--	--

β coefficients represent differences in FGF-21 level associated with changes in each respective measure. FMI Z-score, waist circumference, and visceral fat area are all highly collinear, and therefore only visceral fat area was included in multivariable model because it was the most correlated with FGF-21. All other variables that were moderately associated (p<0.2) with FGF-21 in a univariate model were initially tested in the multivariable model. Variables remaining moderately significant (p<0.10) in the multivariate model were included in the final model, along with basic demographic characteristics (age, gender).

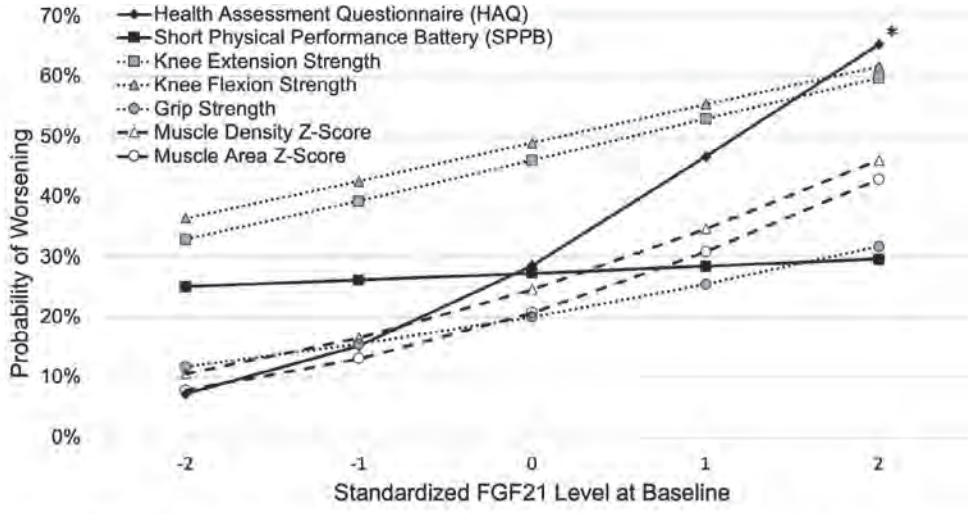
Table 1. Associations Between FGF-21 Levels and Participant Demographics and RA Disease Characteristics at Baseline

Table 2. Associations Between FGF-21 Values and RA Outcomes Over Time		
	Association with Rate of Change of Outcome	
	β (95% CI)	p
Muscle Density Z-Score		
FGF-21 (Continuous)	-0.056 (-0.12, 0.008)	0.08
FGF-21 in Top Quartile	-0.074 (-0.20, 0.056)	0.26
Muscle Area Z-Score		
FGF-21 (Continuous)	-0.049 (-0.10, 0.006)	0.08
FGF-21 in Top Quartile	-0.034 (-0.15, 0.081)	0.55
Grip Strength (kg)		
FGF-21 (Continuous)	0.10 (-0.62, 0.83)	0.77
FGF-21 in Top Quartile	-1.39 (-2.79, 0.014)	0.05
Health Assessment Questionnaire (HAQ)		
FGF-21 (Continuous)	0.025 (-0.015, 0.064)	0.22
FGF-21 in Top Quartile	0.034 (-0.045, 0.11)	0.29
Short Physical Performance Battery (SPPB)		
FGF-21 (Continuous)	-0.14 (-0.37, 0.088)	0.22
FGF-21 in Top Quartile	-0.57 (-1.04, -0.091)	0.02
All models include adjustments for age, gender, visceral fat area, current smoking, and methotrexate use (all at baseline). Models involving grip strength include an adjustment for height at baseline. β coefficients represent differences in the rate of change of each outcome associated with either a 1 SD higher FGF-21 level at baseline, or a FGF-21 value in the fourth quartile (as compared to the bottom three together).		

Table 2. Associations Between FGF-21 Values and RA Outcomes Over Time

(-1.04, -0.091), p=0.02] (**Table 2**). Higher FGF-21 (per SD) was also associated with a greater probability of clinically meaningful worsening of HAQ score [OR=2.37 (1.21, 4.64), p=0.01] (**Figure 1**).

Conclusion: FGF-21 levels were associated with obesity, physical functioning, and inflammatory mediators at baseline, and with worsening in muscle quality and physical functioning over time. These associations support the hypothesis that FGF-21 serves as a biomarker of metabolic stress that could predict greater functional declines in RA patients.



*p value <0.05. Models include adjustments for age, gender, visceral fat area, current smoking, and methotrexate use (all at baseline). Clinically meaningful worsening was defined as follows (or as patient death before visit):

- HAQ: increased by 0.2
- SPPB: decreased by 1
- Extension and flexion strength: decreased by 10%
- Grip strength: decreased by 6.5 kg
- Muscle density and muscle area z-score: decreased by 0.5

Figure 1. Probability of a Clinically Meaningful Negative Change in Selected RA Outcomes at Second Visit, by Baseline FGF-21 Z-Score

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sero-positive rheumatoid arthritis (RA) is a chronic autoimmune disease that without effective treatment, leads to joint damage and disability. Not all patients respond to currently available medications. Human mesenchymal stem cells (hMSCs) have the potential to be used therapeutically to attenuate immune-mediated diseases. To understand how to select hMSCs for RA therapy 1) hMSC culture medium was tested for the ability to suppress RA and healthy control allogeneic T-cells; 2) the degree of T-cell suppression was compared using hMSCs

from distinct donors; 3) preconditioning of hMSCs with cytokines was tuned for maximal suppressive effect and likely mediators of suppression measured.

Methods: CD4+ T-cells obtained from healthy controls (HC) and RA patients were stimulated for 4 days to proliferate. Medium used in suppression assays were:1) culture conditioned medium (CCM) in which hMSCs were preconditioned by a single cytokine; TNFα, IFNγ, IL-1β or a combination of the three cytokines (all-3) or 2) unconditioned control medium (UC) that was cultured like CCM but was not preconditioned with cytokines. T-cell proliferation was measured using eFluor670 vital dye and proliferation was measured using flow cytometry. IDO mRNA and protein were quantified by qRT-PCR and western blot, respectively. Statistical analyses were performed using two-tailed Student's t-test and one-way ANOVA was used for multiple comparison tests in GraphPad Prism 8.1.2.

Results: RA and HC CD4+ T-cell proliferation was suppressed by all-3-CCM compared to UC (76%±2 of UC $p< 0.0001$). IFNγ-CCM was also suppressive (43%±6 of UC $p< 0.001$). CCM containing all-3 cytokines suppressed HC CD4+ T-cell proliferation best (68%±9 $p< 0.05$) when hMSCs were preconditioned with cytokines for 48 hours compare to 24 hours (42%±8). CCM from different donors varied in potency of suppression in both RA and HC. Differences between individual hMSC donors were best detected using all-3-CCM and IFNγ-CCM. CD4+ T-cell suppression was positively correlated with increases in IDO mRNA and IDO protein in both RA and HC.

Conclusion: The data demonstrate that hMSC can be tuned using cytokines to maximally suppress HC and RA T-cells. IDO mediates hMSC effects on T-cells, but hMSC also secrete other molecules that contribute toT-cell suppression. Standardizing cell-based therapy using functional assays *ex vivo* should facilitate comparing potency of distinct cellular products across disease indications. The suppression assays described directly test an admixture of soluble mediators that arise from hMSC rather than just describing mRNA or protein levels. Whether hMSCs should be cytokine primed prior to therapeutic infusion, is of great interest and has implications for hMSC-therapy in RA.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

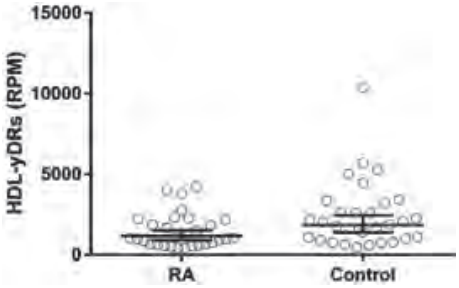

Figure 1. HDL-bound yRNA-derived sRNAs as a class are significantly reduced 36% among patients with RA compared to control subjects(P=0.03). Each dot represents an individual subject's total HDL-yDR reads per million. Bars indicate geometric mean and 95% confidence intervals.

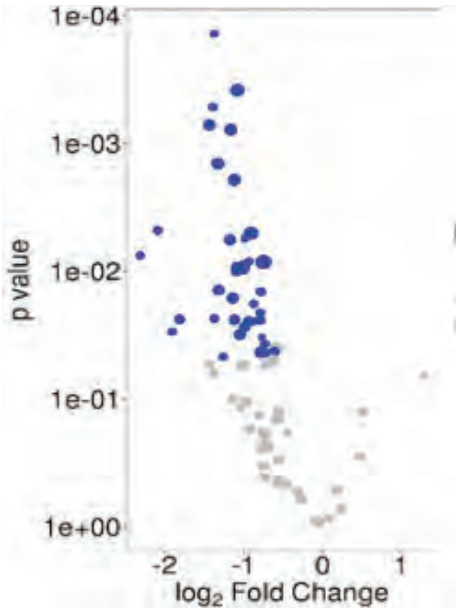

Figure 2. Volcano plot displaying difference in HDL-bound yDR sequences in RA versus control subjects. Blue dots indicate sequences which are reduced among RA patients.

Background/Purpose: Small RNAs (sRNAs), including microRNAs (miRNAs) and yRNA-derived sRNAs (yDRs), are important gene regulators and markers of disease. HDL, while known for its anti-atherogenic function, can traffic sRNAs between cells to alter gene expression and thus cellular function. Additionally, HDL interacts with cells of the immune system and synovial fibroblasts, making it an important sRNA carrier to examine in rheumatoid arthritis (RA). HDL carries yDRs, some of which are known to promote apoptosis. Apoptosis is impaired in RA, particularly in the synovial fibroblasts of RA patients. The purpose of this study was to determine if HDL-bound yDRs are altered in RA and if they are associated with disease measures.

Methods: HDL was purified from 30 patients with RA and 30 control subjects matched for age, race and sex subject plasma by density gradient centrifugation and fast protein liquid chromatography. Total RNA was extracted from the purified HDL. Next generation sequencing (NGS) was performed on sRNA libraries by Illumina NextSeq500. The TIGER pipeline was used to quantify yDRs. The yDRs were compared between RA and control subjects by DESeq2 with 5% false discovery rate multiple comparison adjustment by Benjamini-Hochberg method. Spearman correlation was used to determine relationship between sRNAs and disease measures.

Results: HDL-bound yDRs as a class were significantly reduced 36% among patients with RA compared to control subjects (p=0.03) (Figure 1). Eighteen yDR sequences were significantly reduced up to 5-fold among RA versus con-

trol subjects (Padj < 0.05) (Figure 2). Among these altered yDRs, 17 map to the 5' and 3' ends of RNY4 (Ro60-associated yRNA 4), with only minor sequence variation. Based on NGS the two most abundant sequences aligning to each end of RNY4 were significantly associated with swollen joint count (ydr-ccccccactgctaaatttgactggctt, Rho=0.39, p=0.04; and ydr-ggctggtccgatggtagtgggttatcagaact, Rho=0.40, p=0.03), but were not altered based on disease modifying antirheumatic drug use, seropositivity or erosive disease (all P >0.05).

Conclusion: HDL-bound yDRs are reduced in patients with RA and several yDRs are associated with swollen joint count. Further work will be necessary to validate these findings and to determine the functional role of these HDL-bound yDRs in RA.

Isotope-Labeling-LC-MS-based Metabolic Profiling of Multiple Serum Sample Sets for the Discovery of High-confidence Rheumatoid Arthritis Biomarkers

Xiaohang Wang[1], Wei Han[1], Liang Li[1], Stephanie Wichuk[2], Edna Hutchings[3], Rana Dadashova[3], Joel Paschke[3] and Walter Maksymowych[2], [1]Department of Chemistry, University of Alberta, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]CARE Arthritis, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of rheumatoid arthritis (RA) is hampered by suboptimal accuracy of currently available serological biomarkers. In this work, we applied a high-performance chemical isotope labeling (CIL) LC-MS technique for in-depth profiling of the amine/phenol-submetabolome in serum samples. To avoid false positives and obtain high-confidence biomarker candidates, we analyzed three independent sets of serum samples collected from RA patients and healthy controls to examine the common effects.

Methods: Serum samples were taken from 3 RA cohorts, which comprised 50, 49, and 131 RA patients, respectively. Within each cohort, there were sex/age-matched healthy controls: 50 in Cohort 1, 50 in Cohort 2, and 100 in Cohort 3. Amine/phenol-containing metabolites were labeled by ^{12}C-dansyl chloride to improve the LC-MS detection. For each cohort, a pooled sample was prepared and labeled by ^{13}C-dansyl group to serve as the reference sample for relative quantification. Individual samples and the pooled sample were mixed 1:1 and an LC-QTOF-MS platform analyzed the mixtures and output the intensity ratios of ^{12}C/^{13}C peak pairs.

Results: 1,149 amine/phenol-containing metabolites were commonly detected across the three sample sets. Among them, 134 were positively identified by our dansyl-labeling standard library, and 141 were matched to predicted retention times and mass values of dansyl-labeled human metabolites. Visualized by the partial least squares discriminant analysis (PLS-DA), the overall amine/phenol-submetabolome demonstrated clear and consistent differences between healthy controls and the RA groups, with cross-validation Q2 = 0.765, 0.745, 0.793, respectively. The selection of significant metabolites was conducted according to the fold change and false-discovery-rate-adjusted Welch's

t-test. Cohort 1 demonstrated 85 metabolites having higher and 89 with lower concentrations in the RA samples than the controls. The numbers of increased/decreased metabolites in Cohort 2 and 3 were 87/26 and 90/53, respectively. Importantly, there were 59 significantly discriminatory metabolites commonly found in the three data sets (49 increased and 9 decreased). We picked the top three with the highest univariate classification performance to form a biomarker panel. We implemented the linear support vector machine (SVM) to build the classifier and the receiver operating characteristic (ROC) analysis to measure the performance. The area-under-the-curve (AUC) values (95% confidence interval) were 1.000 (1.000-1.000), 0.992 (0.967-1.000) and 0.902 (0.858-0.945) for the three cohorts, respectively. The results revealed the importance of examining multiple sample sets and even in the worst case (Cohort 3), our biomarker candidates could differentiate RA at 82.5% sensitivity and 82.5% specificity. Particularly, in Cohort 3, there were 30 RA patients negative for anti-cyclic citrullinated peptide and rheumatoid factor, and our metabolite panel demonstrated consistently high performance for differentiating these specific subjects from healthy controls.

Conclusion: Metabolites showing significant and consistent changes associated with RA have been identified with high discriminative power.

Joint Space Narrowing Precedes Erosive Radiographic Damage in Patients with Rheumatoid Arthritis

Andreas Kerschbaumer[1], Gabriela Supp[2], Farideh Alasti[1], Josef Smolen[2] and Daniel Aletaha[1], [1]Division of Rheumatology, Department of Medicine III, Medical University of Vienna,, Vienna, Austria, [2]Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized through symmetric polyarthritis leading to joint destruction over time in many patients. Radiographic damage is an important outcome in RA clinical trials, most commonly assessed by conventional radiographs and quantified/reported by the modified total Sharp van der Heijde Score (mTSS). The mTSS is assessing erosive (ERO) changes as well as joint space narrowing (JSN; reflecting cartilage wasting) in the small joints of the hands and feet. While erosions are the hallmarks of RA, loss of cartilage has been reported to be highly relevant for functional limitations in RA. The sequence of occurrence of these events is not completely understood.

Methods: Radiographs of RA patients from a large prospective clinical routine cohort were scored using the mTSS by one experienced reader (G.S.) unaware of the aim of this project. Time-to-JSN and time-to-ERO was estimated using survival analyses utilizing the Kaplan-Meier estimator. In additional analyses, patients were stratified based on JSN and/or ERO damage at baseline. Further, potential predictors (demographics, csDMARD/bDMARD treatment/combination therapy) of time-to-ERO and time-to-JSN were evaluated using Cox-regression techniques. All statistical analyses were conducted using SAS v9.4 (Cary, New York, USA).

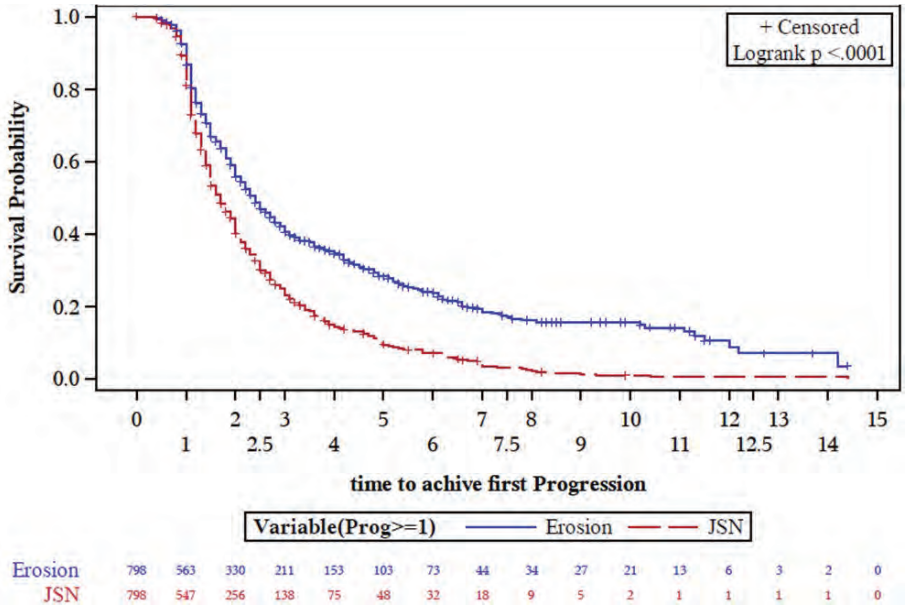

Figure 1. Kaplan-Meier analysis showing time to progression of radiographic progression. Curves represent time to first occurance of joint space narrowing (red) and erosive (blue) progression.

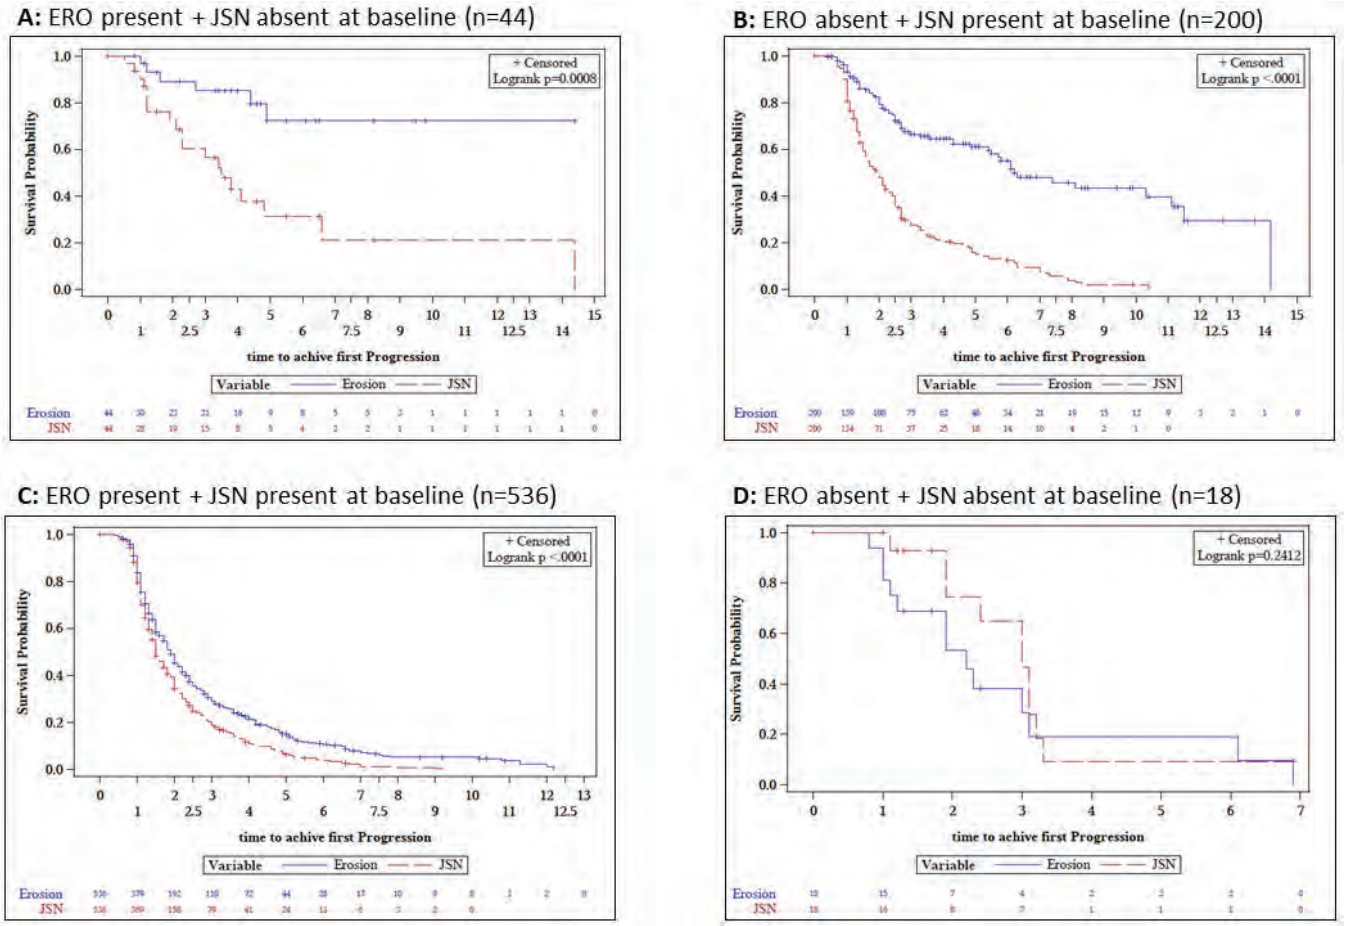

Figure 2. Time to progression of structural damage after stratification for baseline damage. A: Patients with erosions and absence of joint space narrowing; B: Patients with absence of erosions and presence of joint space narrowing; C: patients with presence of erosions and joint space narrowing; D: patients with erosions and absence of joint space narrowing.

Results: We assessed 798 patients longitudinally for radiographic progression. JSN occurred significantly earlier than erosions ($p < 0.001$, Figure 1). After stratification for baseline damage (Figure 2), these differences remained significant with a shorter time-to-JSN in patients without any baseline ERO or JSN (n=44, p=0.008), patients with JSN but no ERO at baseline (n=200, $p < 0.001$), and patients with baseline ERO and JSN (n=536, $p < 0.001$). Only in the small group of patients with isolated erosions (without JSN) at baseline there was no difference in time-to-progression of ERO vs. JSN (n=18, p=0.241). Overall, shorter time to progression of ERO was significantly predicted by positivity for rheumatoid factor or anti-citrullinated peptide antibodies (CCP; $p < 0.003$), as well as by erosions at baseline ($p < 0.001$) in Cox regression. In contrast, seropositivity for neither RF nor CCP was associated with shorter time to JSN progression (p=0.226); however, baseline concomitant JSN and ERO damage did show to be a significant predictor ($p < 0.001$).

Conclusion: We identified a significantly shorter time to progression of JSN compared to ERO in this longitudinal cohort of RA patients. JSN remains an important radiographic outcome, as it is strongly associated with impairment of physical function. This calls for a stronger focus on cartilage damage in RA, and a stronger consideration of JSN in routine evaluation of RA radiographs in clinical practice.

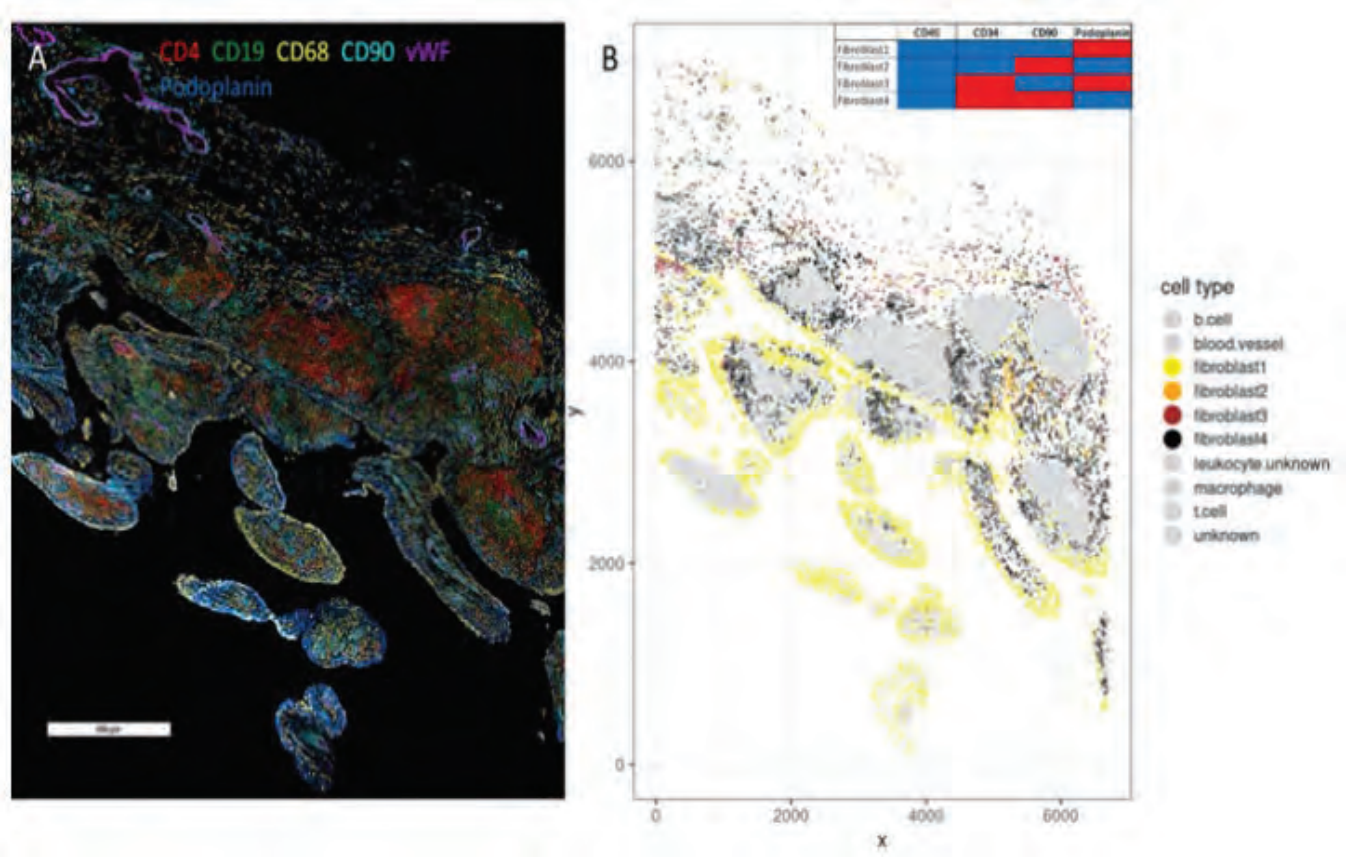
Locating Cellular Subsets in Rheumatoid Arthritis Synovium Using CO-Detection by IndEXing (CODEX)

Isabella Wulur[1], David Boyle[2], Lin Zhang[1], Andrea Martin[1], Robert Benschop[3] and **Gary Firestein**[4], [1]Eli Lilly, Indianapolis, IN, [2]UC San Diego, San Diego, CA, [3]Eli Lilly and Company, Indianapolis, IN, [4]University of California, San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To better understand site-of-disease mechanisms in arthritis, the phenotypes and organization of synovial cells and infiltrates are critical. Conventional histology-based approaches are limited in the number of proteins that can be detected and quantification can be difficult due to non-linear detection systems. Tissue disaggregation techniques have advantages for some techniques, but disrupt tissue organization, might not liberate all cell types with equal efficiency and can result in loss of cell surface markers. To address this, we applied a novel multiplex immunofluorescence imaging platform (CODEX) to synovial tissue obtained from patients with rheumatoid arthritis (RA) or osteoarthritis (OA).

Methods: CODEX was performed by simultaneously applying 20 different antibodies, each labeled with a unique tag, to a 6 μm frozen tissue section. This technique was followed by iterative marker imaging, data processing and single



Representative CODEX image of RA synovium with CD4 staining in red, CD19 in green, CD68 in yellow, CD90 in cyan, von Willebrand factor (vWF) in magenta and podoplanin in blue. B) Location of 4 distinct phenotypes of putative fibroblasts defined by combinations of podoplanin, CD90, and CD34 expression. Fibroblast type 1 (Fb1) cells are almost exclusively found in the intimal lining, whereas Fb2, Fb3 and Fb4 are all located in the sublining.

cell segmentation to generate high resolution images along with marker intensities of each cell. These were used to create a model of cell phenotype, quantification and spatial organization of all identified cell types.

Results: In our initial analysis of 20 markers, we identified the location of multiple subsets, including macrophages, B cells, T cells and mesenchymal cells (Fig 1A). Signals for individual subsets correlated with standard histology in leukocyte-rich and leukocyte-poor tissue sections. One example of how CODEX can identify phenotypically defined cells was fibroblasts, where 4 distinct phenotypes of putative fibroblasts (CD45-) were defined by combinations of podoplanin, CD90, and CD34 (Fig 1B). Type 1 cells (Fb1; podoplanin+ CD34-, CD90-) are almost exclusively found in the intimal lining, whereas Fb2 (CD90+, CD34-, podoplanin-), Fb3 (CD34+, podoplanin+, CD90-), and Fb4 (CD34+, CD90+, podoplanin-) are all located in the sublining. In our small test cohort (4 RA, 3 OA) we noted a nonsigificant numerical increase in total cells in leukocyte-rich RA vs. OA (4994 vs. 2469 average cells/mm2, respectively). The percentage of Fb4 cells was numerically higher in leukocyte-rich RA compared with OA (13.6% vs. 7.5%, respectively).

Conclusion: CODEX technology allows the accurate simultaneous spatial mapping of a multiple cellular phenotypes in situ as suggested here by the location of fibroblast subtypes. Future direction includes combining CODEX with transcriptomics to provide additional characterization of potential pathogenic cells in RA.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Hematoxylin and eosin (H&E) stained rheumatoid arthritis synovium are routinely used to assess inflammation [1]. In this work, we propose an automated approach using artificial intelligence (AI) to quantify all cell nuclei in whole slide H&E stained images. This approach provides quantitative information on the number and

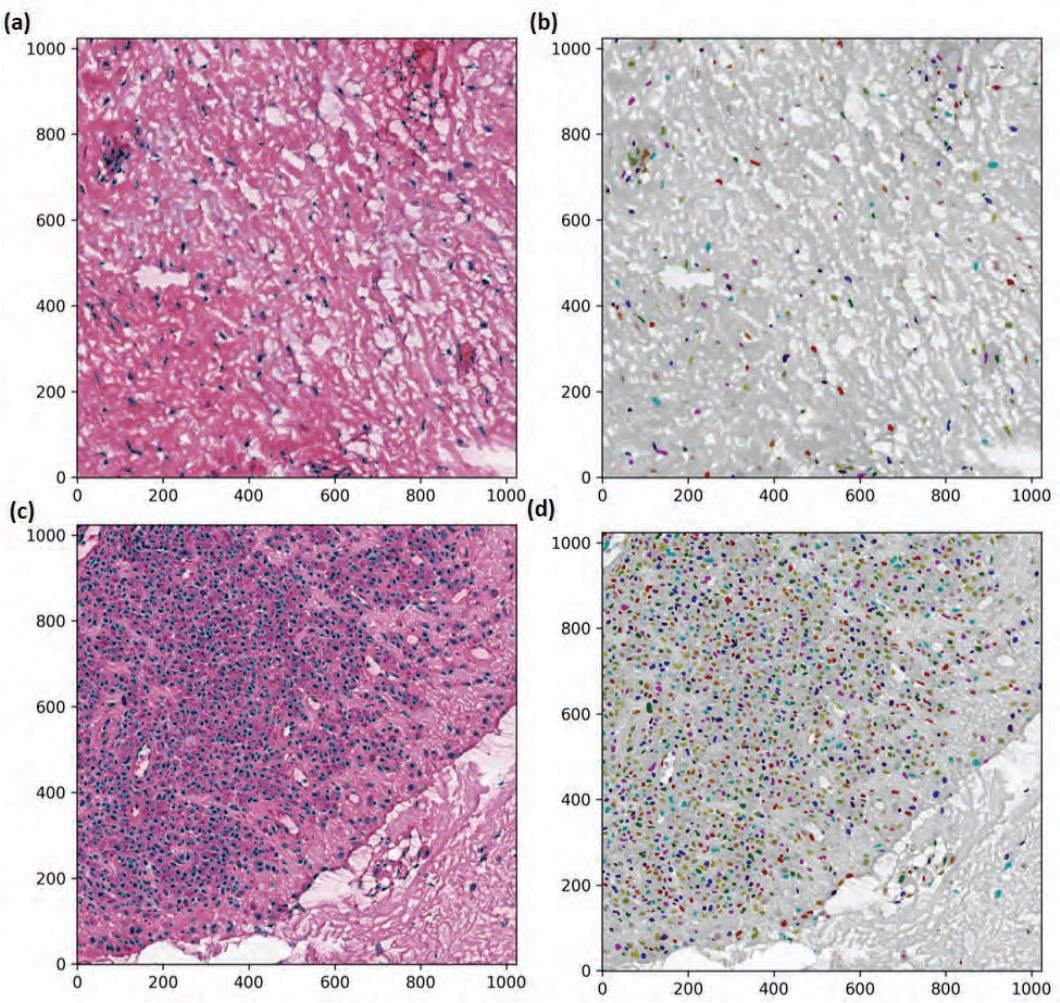

Figure 1. Nuclei identified using the proposed AI algorithm and visualized with boundaries and masks for tiles with mild (a-b) and band-like (c-d) lymphocytic inflammation.

	Class	n	Nuclei Count	Nuclei Density
RNA Subtype	Low	11	89,990 ± 56,555	303 ±114
	Mixed	13	69,360 ± 57,985	284 ± 116
	High	11	147,288 ± 56,820	417 ± 138
Lymphocytic Inflammation	0 (None)	39	65,106 ± 47,923	271 ± 111
	1 (Mild)	46	77,244 ± 52,852	285 ± 96
	2 (Moderate)	39	90,224 ± 64,876	310 ± 97
	3 (Marked)	33	140,118 ± 96,961	398 ± 142
	4 (Band-like)	9	202,084 ± 92,717	459 ± 185

Table 1. RA cohort description of nuclei count and density by RNA subtypes and pathologist lymphocytic inflammation scores.

density of nuclei in synovial images. Given nuclei density is generally increased in sites of inflammation, this approach can identify areas of interest for further evaluation [2].

Methods: The proposed AI algorithm was used to segment cell nuclei in H&E-stained images. First, we split the whole slide image into 1024x1024 tiles with a resolution of 50 µm. Each tile was then processed as follows: 1) separate stained components using color deconvolution, 2) binarize image using local adaptive thresholding, 3) split clustered nuclei using the watershed algorithm, and 4) remove false-positive detected nuclei using shape analysis. Finally, the total nuclei count normalized for area of tissue and the nuclei density were calculated. In total, 166 H&E stained images were analyzed, and corresponding synovial tissue samples were classified by pathologist score of lymphocytic inflammation (0-4). Of which, 35 samples were also classified by RNA sequencing gene expression

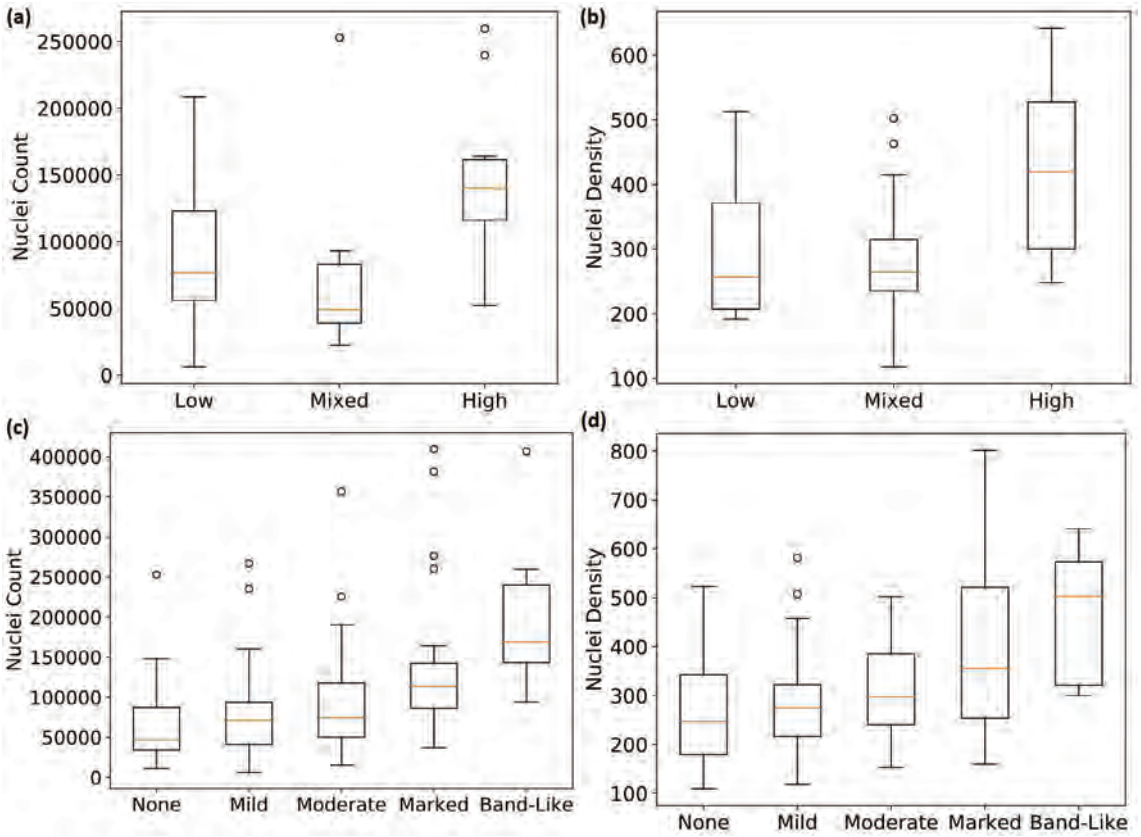

Figure 2. Boxplots to visualize distribution of nuclei count and density by RNA subtypes (low, mixed, and high inflammatory) (a-b) and lymphocytic inflammation scored by pathologist (c-d).

cluster (low, mixed, and high inflammatory gene expression) as previously described [1]. A one-way ANOVA test and post-hoc analysis using the Tukey's test corrected for multiple comparisons were conducted.

Results: Upon visual inspection, the algorithm identified majority of the nuclei in a tile, as seen in Figure 1. There was a statistically significant difference in the mean nuclei count and nuclei density between the gene expression subtypes ($p=0.01$, $p=0.03$) as well as pathologist scores of lymphocytic infiltration ($p< 0.01$, $p< 0.01$), as seen in Table 1 and Figure 2. The post-hoc analysis revealed that the mean normalized nuclei count and nuclei density was significantly different between the mixed and high-inflammatory subtypes ($p=0.01$, $p=0.03$) and between the lowest and highest lymphocyte pathologist scores ($p< 0.01$, $p< 0.01$).

Conclusion: Automated image quantification of H&E stained nuclei suggests that nuclei count and density are increased in synovial samples with high inflammatory gene expression and high pathology scores of synovial lymphocytic inflammation. Additional algorithm validation is needed to better understand its limitations. This approach provides a quantitative framework to score stained images and identify abnormal or inflamed areas. Future efforts will attempt to identify other histological features which might be clinically useful for assessing RA synovium.

Serum Interferon-Alpha Levels Could Help Identify a Subgroup of Rheumatoid Arthritis with Poorer Physical Function and Higher Physician Global Assessment

Yong Gil Hwang[1], Lei Zhu[2], Dongwen Wu[2] and Larry Moreland[3], [1]University of Pittsburgh Physicians, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Colorado, Colorado

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Our objective was to identify the clinical significance of serum interferon-alpha levels in patients with established rheumatoid arthritis (RA).

Methods: Serum samples and clinical data including demographic information, body mass index measured in kg/m^2, seropositivity, medications were obtained for 173 RA patients who were enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER). Patients who underwent clinical evaluations and completed three self-report questionnaires (PainDETECT, Patient-Reported Outcomes Measurement Information System (PROMIS) 29, Widespread Pain Index/Symptom Severity Scale) were included. Serum cytokines including interleukin (IL)-1 beta, IL-6, and interferon (IFN)-alpha were measured on serum samples using enzyme-linked immunosorbent assay.

Results: Among those patients (N=18) who had detectable IFN-alpha, there were significant differences observed for physician global assessment, physical function, depression, and abilities to participate in social roles, compared with patients who did not have IFN-alpha detected. (Table 1) Those who had detectable IFN-alpha had a poorer physical function and impaired abilities to participate in social roles. (Figure 1) Although there was no statistically significant difference, those who have detectable IFN-α tend to have a higher number of swollen joints, higher seropositivity, and higher pain interference. Interestingly, inflammatory cytokines such as IL-1 beta, IL-6, and C-reactive protein (CRP), pain levels, and RA disease activity scores such as disease activity score 28-CRP and clinical disease activity index were not different between the patients with detectable IFN-alpha and without. (Table 1)

Conclusion: This study highlights the potential roles of serum IFN alpha as a biomarker in identifying a distinct subgroup of patients among those who have similar RA disease activity scores.

Table 1. Comparison of clinical characteristics and serum cytokine levels by Interferon alpha status

Characteristics	Undetected (N=142)	Detected (N=18)	P value

Serum Proteomics Implicates Neutrophil Degranulation in Rheumatoid Arthritis Disease Activity

Liam O'Neil[1], Vidyanand Anaparti[1], Dana Wiens[1], Irene Smolik[1], Xiaobo Meng[1] and Hani El-Gabalawy[1], [1]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Though targeted therapeutics have improved outcomes in Rheumatoid Arthritis (RA) treatment, the understanding of the underlying biological mechanisms that mediate inflammatory arthritis in RA is incomplete. We aimed to use unsupervised proteomics to identify serum proteins and active mechanistic networks that are associated with disease activity in RA.

Methods: Using the SOMAscan (slow off-rate modified aptamer) array, we generated quantitative levels of 1307 proteins in serum samples from 68 RA patients. Differentially expressed proteins between patients with high disease activity (HDA, DAS28 > 3.2) relative to low disease activity (LDA) were determined using linear modeling and visualized with hierarchical clustering. Spearman correlation was used to determine the relationship between individual proteins and DAS28, a disease activity score widely use in RA. Correlation adjusted mean rank (CAMERA) competitive gene

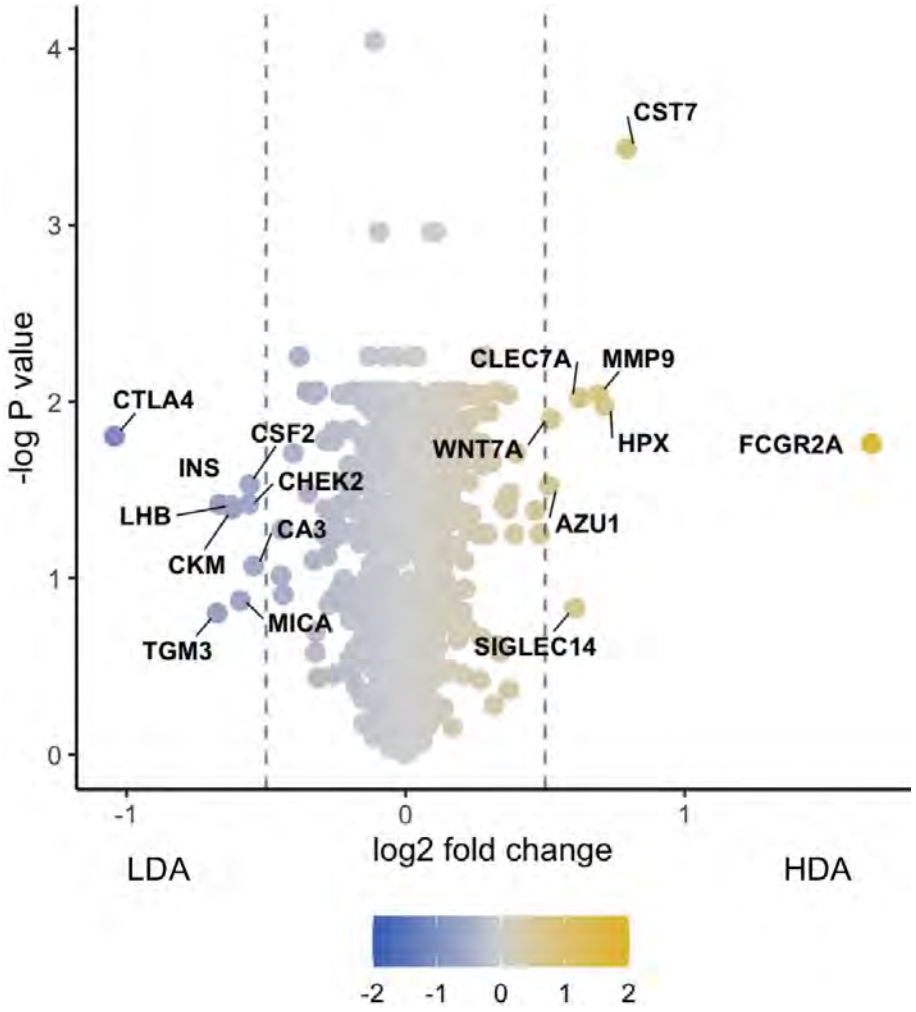

Figure 1. Volcano plot depicting fold differences between low disease activity RA patients (LDA) and high disease activity RA patients (HDA), coloured by magnitude of fold change.

set testing was performed to identify pathway enrichment while accounting for inter-gene correlation. Network analysis was then performed using Clusterprofiler and gene-concept network.

Results: 50% (n = 34) of the cohort were classified as HDA DAS28 (median 4.49 +/- 0.89) while 50% (n = 34) were LDA DAS28 (median 2.68, +/- 0.82). Principle components analysis based on expression of all proteins did not clearly separate HDA from LDA patients. *CST7 (*Fold Change (FC) = 6.2)) , *ELANE* (FC = 1.1), *S100A12* (FC = 1.9, $p < 0.001$) were all highly upregulated in HDA, while *CTLA4* (FC = 11.1) was the highest upregulated protein in LDA. Correlation between DAS28 and SERPINA3 ($R = 0.53$, $p = 2.4 \times 10^{-6}$) and S100A12 ($R = 0.46$, $p = 8.6 \times 10^{-5}$) were numerically higher than CRP (0.42, $p = 0.0003$). Gene-concept plotting linked *extracellular matrix disassembly*, *endopeptidase activity*, *platelet degranulation*, *and leukocyte migration/antimicrobial humoral response* with 19 upregulated proteins. Gene set enrichment identified *Immature Neutrophil* upregulation as one of the highest enriched gene networks in HDA ($p = 1.49 \times 10^{-4}$).

Conclusion: Our rich proteomic dataset provides a foundation for understanding of the underlying biological processes that underpin active RA. In particular, we identified proteins that implicate systemic neutrophil degranulation as a highly active process in RA, which may link systemic inflammation and tissue destruction in these individuals.

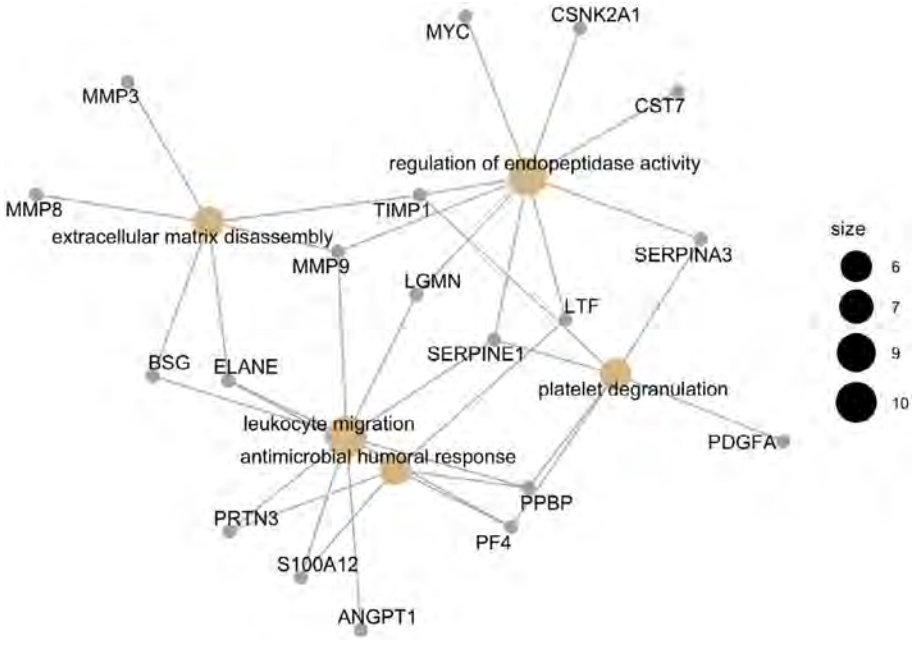

Figure 2. Gene network of protein interactions linked with GO biological processes using gene-concept plotting. Size of nodes are reflective of member inclusion. All protein members are upregulated in high disease activity relative to low disease activity.

Synovial Tissue Histopathology Findings in Early RA. Is It Useful? Analysis of the Belgian CAP48 Cohort

Stéphanie de Montjoye[1], Tatiana Sokolova[1], Emilie Sapart[1], Bernard Lauwerys[2], Stéphanie Dierckx[3], Christine Galant[4], Laurent Meric de Bellefon[1], Adrien Nzeusseu Toukap[5], Clément Triaille[6] and Patrick Durez[7], [1]Rheumatology, Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium, [2]Paediatric Rheumatology International Trials Organisation (PRINTO), Genoa, Italy, [3]Rheumatology, CHU Mont-Godinne, Mont Godinne, Belgium, [4]3Pathology, Cliniques universitaires Saint-Luc - Université Catholique de Louvain - Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium, Brussels, Belgium, [5]1Department of Rheumatology, Cliniques Universitaires Saint Luc, 2Institut de recherche expérimentale et clinique (IREC), Brussels, Belgium, [6]Rheumatology, Cliniques universitaires Saint-Luc - Université Catholique de Louvain - Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium, Brussels, Belgium, [7]Division of Rheumatology, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis is a heterogeneous disease with different clinical presentation and prognostic factors including the immune process in the synovium. The development of ultrasound-guided synovial biopsy will enable synovial tissue collection from small joints and will facilitate histopathological studies, thus improving the understanding of the immunopathology in early rheumatoid arthritis (ERA).

Table 1. Baseline characteristics of the cohort ; (*) P<0,05

The objectives of this ERA cohort are to compare the baseline clinical, biological and radiological characteristics and the clinical response on methotrexate (MTX) according to the histological "inflammatory pattern" of the synovial tissue.

Methods: 152 ERA patients fulfilling the ACR/EULAR 2010 criteria and naïve to DMARDs therapy were recruited from our Brussels Louvain ERA cohort. Synovial biopsies before treatment were obtained using an ultrasound guided needle biopsy (US-NB) of the small joints or miniarthroscopy of the knee. RA disease activity measures including DAS28-CRP were evaluated every 3 months on MTX treatment. Tissues were assessed for quality. Retrieved tissue was fixed, stained and paraffin embedded for blinded tissue pathotype description.

The pathotypes were divided in 2 groups according the absence or presence of *inflammatory infiltrates* (pauci-immune, score 0-1 *vs* inflammatory, score 1-6) and absence or presence of *synovial hyperplasia* (score >1).

Results: The average age of population is 48.3 years. 63.2% of the patients are women. 24.6% are smokers and 62.3% are positive for anti-citrullinated protein antibody (ACPA). Baseline characteristics of the cohort are summarized in Table 1. There was a significant predominant presence of ACPA+ (%) in the group without synovial hyperplasia. CRP levels were significantly higher in patients with the inflammatory pattern than those with the pauci-immune pattern. Synovial hyperplasia was also associated with these parameters.

A significantly higher rate of SJC was observed in the group with synovial hyperplasia compared to the group without hyperplasia.

Clinical response (DAS-44, SJC and CRP) was statistically better after 3 months of MTX treatment in patients with baseline inflammatory and hyperplasia pathotypes and CRP remained lower at 6 and 12 months compared to the pauci-immune group.

Conclusion: Synovial tissue analysis allows us to better define the spectrum of ERA. We have demonstrated a predominance of ACPA positive patients in pauci-immune synovial pathotypes. A better clinical response to MTX was observed in patients presenting inflammatory infiltrates or synovial hyperplasia. Further studies should validate a step change towards personalized medicine in daily clinical practice for disease stratification and treatment selection of ERA.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid factors (RFs) are RA-related autoantibodies like anti-cyclic citrullinated peptide antibodies, and are used for classifying and diagnosing RA. In addition, positivity and high titers in serum RFs are risk or prognostic factors of joint damage for both early and established RA patients. However, it remains unclear whether the changes in serum RF titers are correlated with progressions of joint damage in RA. The purpose of this study is to clarify whether continuous decreases in RF titers during treatment with biological or targeted synthetic DMARD (b/tsDMARD) were associated with radiographic remission in progression of RA joint damage.

Methods: 130 RA patients were enrolled, who filled RA criteria 2010, were treated with b/tsDMARD for more than 4 months, had serum RF titers above 45 IU/ml at starting therapy (month 0), and were followed up until month 12. Serum RF titers were measured at month 0, 4 and 12 after starting b/tsDMARD therapy, and continuous RF decreases were defined as not less than 10% decreases in RF titers during both month 0-4 and 4-12. RA disease activity was assessed by DAS28-ESR at month 0, 4 and 12, and time-integrated DAS28-ESR was calculated. Joint damage was assessed by modified total Sharp score (mTSS) at month 0 and 12, and radiographic remission was defined as yearly mTSS progression below 0.5. Their medical records were reviewed retrospectively. In case of withdrawal from b/tsDMARD therapy during month 4-12 due to some causes, data upon the discontinuation of b/tsDMARD was used as that at month 12 using the last observation carried forward method. Baseline demographic, disease- and RF-related variables were included in univariate and multivariate logistic regression analysis for identifying the factors related to radiographic remission.

Results: Subjects were 102 female, were median age 61.7 years with 4.8 years of disease duration, and were treated with abatacept (n=27), JAK inhibitors (n=9), tocilizumab (n=39) and TNF inhibitors (n=55) in addition to MTX (median dose; 8 mg/week). Serum RF titers decreased from 127 IU/ml (month 0, median) to 89.5 (month 4, $p=0.0022$) and 84.5 (month 12, $p=0.0115$). DAS28-ESR improved from 3.92 (month 0, median) to 2.65 (month 4, $p< 0.0001$) and 2.58 (month 12, $p< 0.0001$). 65 of 130 subjects achieved radiographic remission in mTSS at month 12. During b/tsDMARD therapy, 46 of 130 patients showed continuous decreases in serum RF titers (CD group), and 84 cases did not (non-CD group). Compared with non-CD patients, CD had younger age of RA onset ($p=0.0456$), higher ratio of anti-TNF therapy ($p=0.0170$), lower DAS28-ESR at month 12 ($p=0.0404$) and higher ratio of radiographic remission in mTSS

(p=0.0056). In multivariate analysis, continuous decreases in serum RF titers were associated with radiographic remission in mTTS (OR=3.7316; 95% CI:1.5427–9.5980) in addition to time-integrated DAS28-ESR.

Conclusion: Continuous decreases in serum RF titers were associated with radiographic remission of mTSS in RA patients treated with b/tsDMARD. The changes in serum RF titers may become a prognostic factor for joint damage in RA.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: ANA testing has been a well-established screening tool for autoimmune conditions such as SLE. Current practice for classification of RA does not include ANA positivity; however, ANA testing is performed in many patients who are ultimately diagnosed with RA. In the general population, ANA positivity is thought to be increasing in prevalence and has been associated with elevated rates of all-cause mortality and cardiovascular events (1-2). ANA positivity has also been studied in patients with RA who are taking TNF-α inhibitors who develop "lupus-like syndrome" (3). There is a gap in the understanding of the role a positive ANA has in the management of

RA. The aim of this study is to describe differences in the clinical course, treatment, and outcomes of patients with RA who are ANA positive as compared to those who are ANA negative.

Methods: The study design is a retrospective, population-based cohort study of 252 residents of a geographically-defined area who first fulfilled 1987 ACR criteria for RA in 1999-2014 assembled using the resources of the Rochester Epidemiology Project (REP). Data was collected on first documentation of joint swelling, RF or CCP antibody

testing, ANA level ≥1U by ELISA or IF titer of ≥1:80, and pharmacotherapies. Comparisons between groups were performed using chi-square and rank sum tests.

Results: Sixty-four percent of RA patients in the cohort were tested for ANA within ±90 days of RA criteria fulfillment. Patients tested for ANA were more likely to be younger and to be RF or CCP seropositive. In the 161 patients with ANA testing, 25% were ANA positive (Table 1). ANA positive patients were slightly younger, were less likely to be male and somewhat less likely to be current smokers (Table 2). In terms of diagnostics, there were no differences in RF/CCP or RA criteria met, though in patients with seropositivity, the time from joint swelling to fulfillment of RA criteria was increased for ANA positive patients. The length of time to first DMARD initiation in the ANA positive patients was also increased. ANA positive patients were more likely to receive HCQ over MTX as a first treatment (Table 3). ANA positive patients were less likely to receive biologic therapy, but this association did not reach statistical significance.

Conclusion: ANA positivity does not differ between seropositive and seronegative RA patients. However, there is a difference in the time to fulfillment of RA criteria, time to treatment with DMARD, as well as in choice of initial pharmacotherapy with more ANA positive patients receiving HCQ over MTX. These findings may indicate a difference in patient presentation or clinical perception of RA patients with ANA positivity. Further research is needed to better understand what drives the treatment rationale for ANA positive, RA patients and what implications that may have for their health outcomes.

Hospitalizations recorded within 6 months of the index date and within 24 months of the index date. Significant p values (<0.05) and standardized differences (>0.10) for the SE+ vs SE– patients are shown in bold.

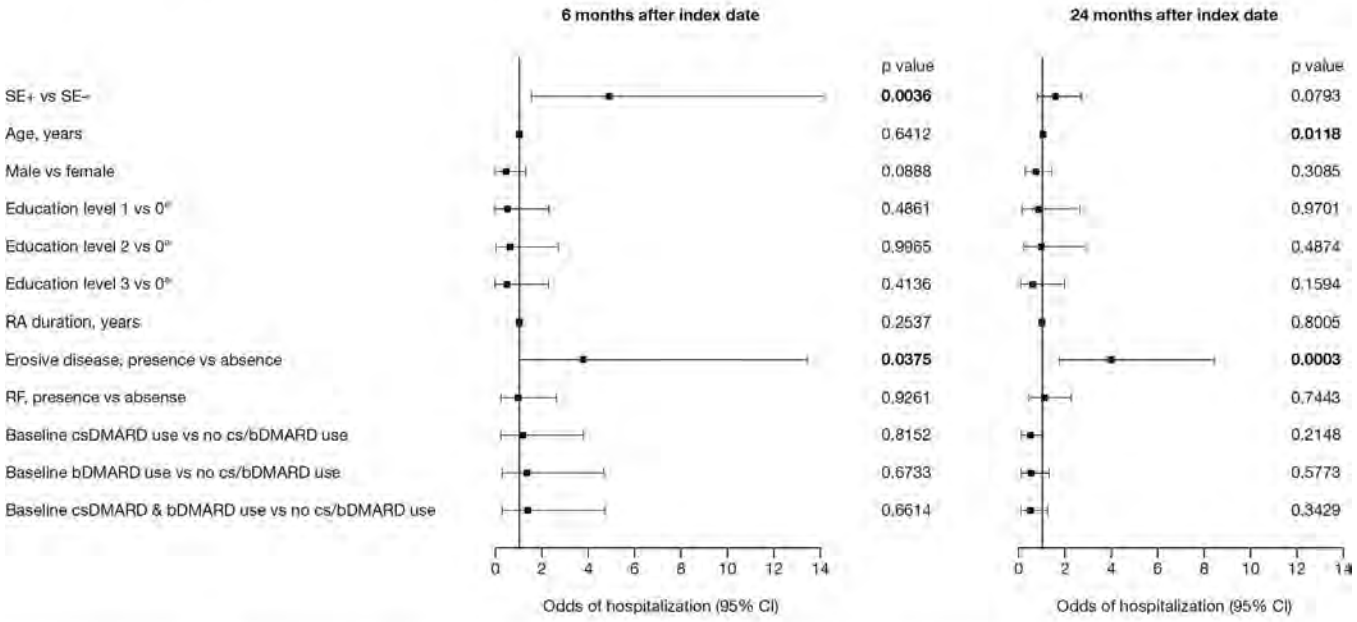
[a]Calculated using Chi squared tests.

[b]Common reasons include: gynecological surgery, colonoscopy, eye surgery, oral surgery, partial hysterectomy and gastric bypass.

CV=cardiovascular; SE=shared epitope

Methods: This was a retrospective analysis of patients (pts) enrolled in the Brigham and Women's Rheumatoid Arthritis Sequential Study (NCT01793103; BRASS) registry between March 2003 and June 2019. Pts with known ACPA and SE status were included. *HLA-DRB1* SE status (1 or 2 alleles [+], 0 alleles [–]) was determined by allele-specific polymerase chain reaction and DNA sequencing for most pts and by genome-wide association study-based imputation for the others. Pts were stratified by ACPA and SE status. Index date was the date of the baseline visit. Baseline demographics and disease characteristics, hospitalization rates (yes/no) and causes of hospitalization over 6 and 24

Figure 1. Odds of hospitalization at 6 and 24 months among ACPA+ patients



Total number of observations: 641 (6 and 24 months); number of observations used: 454 (6 months) and 491 (24 months). Significant p values are shown in bold.
[a]Education level: 0 (reference) – did not graduate high school, 1 – high school graduate, 2 – any college education, 3 – graduate education.
bDMARD=biologic DMARD; csDMARD=conventional synthetic DMARD; SE=shared epitope.

months were reported descriptively. Associations between SE status and hospitalization were examined using multivariable adjusted logistic regression models.

Results: Of 961 pts with known ACPA and SE status included in the analysis, 641 were ACPA+ and 620 were SE+ (466 [48%] were both ACPA+ and SE+). In ACPA+ pts, most baseline characteristics were similar between those who were SE+ and SE– (**Table 1**); SE+ vs SE– pts were more likely to receive conventional synthetic or biologic DMARDs. Among ACPA– pts, SE+ vs SE– pts had longer RA duration and were more likely to be RF+. Among ACPA+ pts 6 months after index date, the rate of hospitalization in SE+ pts was twice that for SE– pts (12.3% vs 5.3%; p=0.0156); joint replacement and cardiovascular (CV) conditions combined were more common causes of hospitalization in SE+ pts (50%) than SE– pts (25%; **Table 2**). Similarly, among ACPA+ pts 24 months after index date, the rate of hospitalization remained significantly higher for SE+ vs SE– pts (29% vs 21%; p=0.0487), with joint replacement and CV conditions combined being more common causes of hospitalization (SE+, 42% vs SE–, 26%; **Table 2**). No noTable differences were seen in ACPA– pts. Among ACPA+ pts, the adjusted risk of hospitalization was 4.84-fold higher in SE+ vs SE– pts at 6 months (p=0.0036) and 1.56-fold higher at 24 months (p=0.0793; **Figure 1**). Overall, joint replacement and CV conditions combined accounted for 46.0% and 24.0% of hospitalizations at 6 months in SE+ vs SE– pts and 39.9% and 29.2% of hospitalizations at 24 months, respectively.

Conclusion: In ACPA+ pts with established RA, being SE+ increased the risk of hospitalization over 6 months approximately 5-fold. The majority of the increased risk in hospitalization was accounted for by joint replacement and CV conditions, indicating the more rapidly progressive disease and greater co-morbidity burden associated with SE+ in this pt population.

Sunlight Exposure, Sun-protective Behaviour, and Anti-citrullinated Protein Antibody Positivity: A General Population-based Study in Quebec, Canada

Naizhuo Zhao[1], Audrey Smargiassi[2], Ines Colmegna[3], Marie Hudson[4], Marvin Fritzler[5] and Sasha Bernatsky[6], [1]McGill University, Montreal, Canada, [2]l'Université de Montréal, Montreal, Canada, [3]The Research Institute of the McGill University Health Centre, Montreal, Canada, [4]Division of Rheumatology, Jewish General Hospital, Montréal, QC, Canada, [5]Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [6]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sunlight exposure has been associated with lower rheumatoid arthritis (RA) risk, but to our knowledge, no one has ever studied sunlight exposure and anti-citrullinated protein antibodies (ACPA). Our objective was to examine associations between sunlight exposure and ACPA using general population data from Quebec, Canada.

Methods: A random sample of 7600 individuals (including 786 positive ACPA subjects and 201 self-reported rheumatoid arthritis, RA cases) from the CARTaGENE cohort was studied cross-sectionally. All subjects were nested in four census metropolitan areas, and mixed effects logistic regression models were used to calculate odds ratios (OR) and 95% confidence intervals (CIs) for ACPA positivity related to sunlight exposure, adjusting for sun-block use, industrial fine particulate matter ($PM_{2.5}$) exposures, smoking, age, sex, French Canadian ancestry, and family income. We also performed sensitivity analyses excluding subjects with RA, defining ACPA positivity by higher titers, and stratifying by age.

Results: The adjusted ORs and 95% CIs did not suggest conclusive associations between ACPA and sunlight exposure or sun-block use, but robust positive relationships were observed between industrial $PM_{2.5}$ emissions and ACPA (OR 1.19 per $\mu g/m^3$**,** 95% CI 1.03 – 1.36 in primary analyses).

Table 1. Adjusted odds ratios, OR (95% confidence intervals, CIs) for associations between sunlight exposures and ACPA positivity (>20 U/ml)

Variables		Overall	Excluding RA
Sunlight exposure for weekdays	<30 minutes	Reference	
	30 to 60 minutes	0.89 (0.70 – 1.12)	0.85 (0.67 – 1.07)
	1 to 2 hours	1.08 (0.83 – 1.41)	1.04 (0.79 – 1.36)
	2 to 3 hours	0.87 (0.62 – 1.21)	0.79 (0.56 – 1.12)
	3 to 4 hours	0.83 (0.53 – 1.31)	0.83 (0.53 – 1.31)
	>4 hours	0.80 (0.48 – 1.35)	0.76 (0.45 – 1.29)
Sunlight exposure for weekends	<30 minutes	Reference	
	30 to 60 minutes	1.03 (0.78 – 1.36)	1.04 (0.78 – 1.39)
	1 to 2 hours	0.85 (0.63 – 1.14)	0.85 (0.63 – 1.15)
	2 to 3 hours	1.01 (0.74 – 1.38)	1.04 (0.76 – 1.44)
	3 to 4 hours	0.99 (0.68 – 1.43)	1.03 (0.71 – 1.49)
	>4 hours	1.22 (0.82 – 1.82)	1.29 (0.86 – 1.93)
Sun-block use	Rarely	Reference	
	Sometimes	0.88 (0.70 – 1.12)	0.89 (0.70 – 1.12)
	Often	1.00 (0.83 – 1.21)	0.98 (0.81 – 1.19)
Industrial $PM_{2.5}$ exposure*		**1.19 (1.03 – 1.36)**	**1.19 (1.03 – 1.36)**
Age		1.01 (1.00 – 1.02)	1.01 (1.00 – 1.03)
Sex	Male	Reference	
	Female	1.01 (0.85 – 1.20)	0.98 (0.82 – 1.16)
Ancestry	French Canadian	Reference	
	Other	0.98 (0.83 – 1.17)	1.05 (0.88 – 1.25)
Smoking	Never	Reference	
	Occasional	0.96 (0.74 – 1.23)	0.93 (0.72 – 1.21)
	Daily	1.09 (0.85 – 1.42)	1.08 (0.83 – 1.41)
Annual income level (Canadian $)	<25,000	Reference	
	25,000 to 49,999	0.98 (0.72 – 1.33)	1.00 (0.72 – 1.37)
	50,000 to 74,999	0.99 (0.73 – 1.34)	1.03 (0.75 – 1.41)
	75,000 to 149,999	0.93 (0.69 – 1.25)	0.95 (0.70 – 1.30)
	≥150,000	1.02 (0.72 – 1.44)	1.07 (0.74 – 1.53)

*OR reported per increase in 1 µg/m3 – a value well above median levels.

Table 1. Adjusted odds ratios, OR (95% confidence intervals, CIs) for associations between sunlight exposures and ACPA positivity (>20 U/ml)

Conclusion: We did not see clear links between ACPA and sunlight exposure or sun-block use, but we did note positive associations with industrial $PM_{2.5}$. Future studies of sunlight and RA (or ACPA) should consider taking air pollution exposures into account.

Anti-citrullinated Protein Antibodies Are Associated with Functional Disability in Unaffected First-degree Relatives of Rheumatoid Arthritis Patients

Dana Wiens[1], Irene Smolik[1], Xiaobo Meng[1], Vidyanand Anaparti[1], Hani El-Gabalawy[1] and Liam O'Neil[1], [1]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The preclinical stage of Rheumatoid Arthritis (RA) is characterized by seropositivity for anti-citrullinated protein antibodies (ACPA). We (PubMed ID 30861615), and others, have shown that ACPA seropositivity is prevalent in the first-degree relatives (FDR) of RA patients. While ACPA is highly predictive of RA development in individuals who were selected by healthcare providers based on having joint symptoms such as arthralgia, the association between ACPA and self-reported symptoms in an unselected population of at-risk FDR has not been well studied. Because it has been proposed that the ACPA themselves may induce joint symptoms in the absence of joint inflammation, we sought to determine whether ACPA seropositivity is associated with self-reported symptoms and functional impairment in a large, unselected, cohort of at-risk Indigenous North American (INA) FDR of RA patients.

Methods: Baseline demographics, Health Assessment Questionnaire (HAQ), and arthritis symptom survey data were obtained from a cohort of 607 unaffected FDR of RA patients. ACPA were detected using commercial kits (CCP2 or CCP3.1) and the manufacturer's cut-off was used to define seropositivity. Associations between ACPA status and the self-report variables were analyzed by unsupervised univariate correlation, followed by logistic regression to identify variables that were independently associated with ACPA seropositivity.

Results: 51 (8.4%) individuals were ACPA positive at baseline. Because smoking was prevalent in the cohort (85.4%), we were not able to demonstrate a clear relationship with ACPA seropositivity. Although joint symptoms were common amongst FDR (53.6%), they were not associated with ACPA seropositivity. Mean HAQ scores were higher in ACPA positive individuals compared to ACPA negative (0.313 vs 0.197, $p = 0.14$), but this did not reach statistical significance. Unexpectedly, we found that compared to FDR from urban settings, FDR from rural communities were twice as likely to be ACPA seropositive (11.5% vs. 5.2%, $p < 0.001$). Logistic regression modelling showed that *Rural status* (odds ratio (OR) 3.2, 1.5 to 7.6), *Difficulty lifting a glass* (OR 4.3, 1.1 to 17.2), and *Difficulty walking on a flat surfaces* (OR 2.9, 1.1 to 7.6) were independently associated with ACPA seropositivity, after adjusting for age and sex.

Conclusion: Although we were unable to demonstrate a relationship between joint symptoms and ACPA seropositivity, functional disability is associated with ACPA, even in the absence of detectable joint inflammation. The discordance in ACPA seropositivity between rural and urban locations is intriguing and warrants further investigation.

Presence of Ultrasound Imaging Biomarkers Are Good Predictors of Arthritis Development in a Population at Risk for Rheumatoid Arthritis

Yogan Kisten[1], Alexandra Circiumaru[1], Malena Loberg-Haarhaus[2], Nancy Vivar[2], Aleksandra Antovic[3], Hamed Rezaei[2], Erik Af Klint[1], Aase Hensvold[1] and Anca Catrina[1], [1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden, [2]Rheumatology clinic, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden, [3]Center for Rheumatology, Academic Specialist Center, Stockholm Health Region, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US) imaging biomarkers in the context of Anti-Citrullinated Protein Antibody (ACPA) autoimmunity might play an important role in the very early detection of Rheumatoid Arthritis (RA).

Methods: Individuals with musculoskeletal complaints suspicious for rheumatic disease, and having a positive anti-CCP2 test were referred to the Rheumatology Unit. Sixty eight joint counts as well as hands, feet and any symptomatic joints by US examination were performed. US were scored for synovial hypertrophy (SH) and Doppler activity according to EULAR-OMERACT definitions. Individuals not having arthritis defined by clinical examination and ultrasound were included in the RISK RA prospective cohort. Finger and wrist tendons were examined for any signs of tenosynovitis, including evaluations between joints for bursitis. The associations of US biomarkers with arthritis development was tested (comparing proportions) using Chi-Squared or Fisher's exact tests.

Results: 288 individuals were included in the RISK RA study from year 2014 to October 2019 (79% female, 35% RF positive, median age 48 yrs: IQR: 36-58). Within a median of 38 months (IQR: 1-72) since recruitment, 28% (84/288) progressed to arthritis.

At any scan done prior to diagnosis (either inclusion or follow-up visits), two thirds (193/288) of all individuals lacked any signs of US changes with only 16% (31/193) of them developing arthritis. One third (95/288) of all individuals had at least one type of US change (tenosynovitis, synovial hypertrophy without Doppler and/or bursitis) and 56% (53/95) of them developed arthritis. A majority, 64% (61/95), of individuals with any US changes had only one type of US change.

Tenosynovitis was detected in 22% (64/288) of all individuals, more frequently in those developing arthritis (44%, 37/84) as compared to those not developing arthritis (13%, 27/204), $p< 0.0001$. The extensor-carpi-ulnaris wrist tendons were mostly affected. Synovial hypertrophy (grade 1 or 2) was detected in 11% (32/288) of all individuals, more frequently noted among those developing (21%,18/84) as compared to those not developing arthritis (7%,14/204), $p< 0.0001$. The MCP joints were mostly affected. Bursitis between MTP joints were detected in 9% (25/288) of all individuals, more frequently among those developing (13%, 11/84) as compared to those not developing arthritis (7%, 14/204), $p=0.09$.

Conclusion: Tenosynovitis, synovial hypertrophy and bursitis are useful ultrasound biomarkers for predicting arthritis development in a population at-risk for RA.

X-rays Bone Erosions Are Uncommon in Anti-CCP Positive Individuals At-risk of Rheumatoid Arthritis with Musculoskeletal Symptoms Without Clinical Synovitis, and Do Not Predict the Development of Inflammatory Arthritis

Andrea Di Matteo[1], Kulveer Mankia[1], Jacqueline L Nam[1], Edoardo Cipolletta[2], Leticia Garcia-Montoya[3], Laurence Duquenne[1], Emma Rowbotham[4] and Paul Emery[5], [1]University of Leeds and Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [2]Polytechnic University of Marche, Rheumatology Unit, Department of Clinical and Molecular Sciences, "Carlo Urbani" Hospital, Jesi (AN), Italy, [3]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom, [4]Department of Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: In individuals at-risk of RA, the identification of reliable biomarkers for the future development of clinical arthritis is of critical importance for risk-stratification and management of these individuals. Imaging, in particular US and MRI, has demonstrated the potential to predict the development and timing of RA in individuals at-risk, raising important implications on disease prevention studies.

To date, there is no consensus or guideline for the most appropriate investigations to perform in this population and clinicians would often request x-rays for the assessment of joint damage in at-risk individuals who present with hand and foot symptoms. To our knowledge, no previous study has evaluated the role of x-rays in this context.

The aims of this study were to investigate the prevalence and distribution of bone erosions (BE) in the x-rays of the hands and feet in CCP positive (CCP+) at-risk individuals, and their association with the development of inflammatory arthritis (IA).

Methods: Baseline x-rays of the hands and feet and a full US protocol were performed as part of the current study. X-rays BE were reported as standard by MSK radiologists and confirmed by subsequent reading by a second independent MSK radiologist, blinded to the clinical and US findings. The Simple Erosions Narrowing Score (SENS) was calculated for BE. The presence of US synovitis and BE was explored in the areas in which x-rays BE were reported. A subset of CCP+ individuals (n=73) had repeated x-rays at the time of progression. Subjects with ≥1 follow-up visit were included in the progression analysis (n=394).

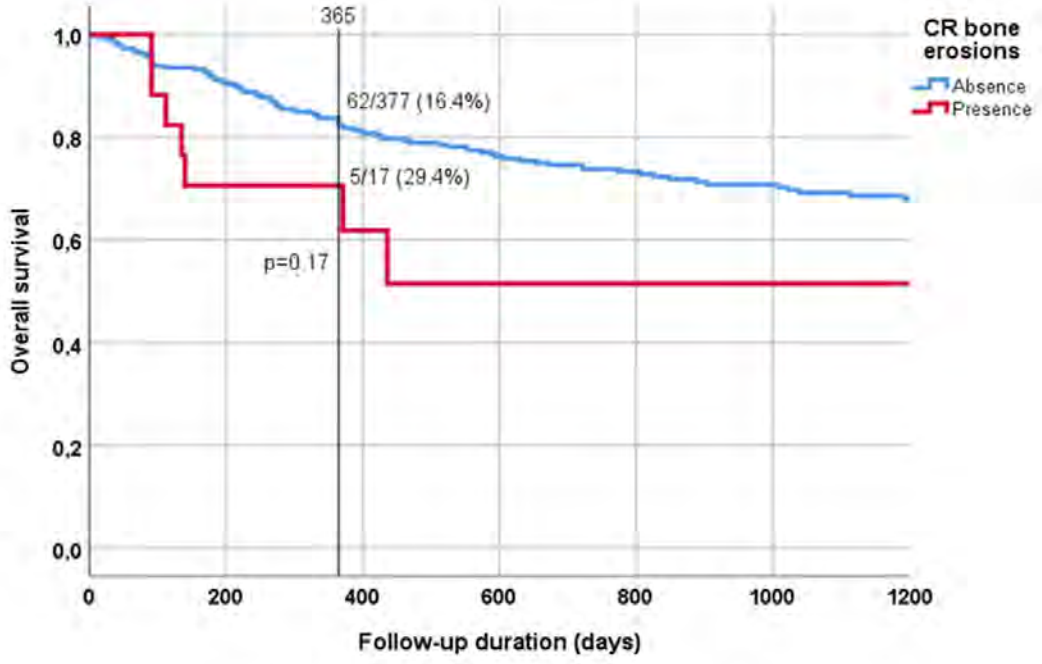
Results: The hands and feet x-rays of 418 CCP+ individuals were analysed. X-rays BE were found in 17 (4.1%), most frequently in the feet (64.7% individuals). The median SENS score was 2.0 (IQR: 1.0-2.0). Of the 17 CCP+ individuals with x-rays detected BE, 7 (41.2%) developed IA and 10 (58.8%) did not progress to IA. The clinical and imaging characteristics of the CCP+ individuals with x-rays BE detected are shown in Table 1.

Table 1. Clinical and imaging characteristics of the CCP+ at-risk individuals with x-rays bone erosions (n=17)

	Hands/wrists BE (x-rays)	Feet BE (x-rays)	SENS score	US synovitis	US BE	X-rays pattern (IA)	Hands/feet tenderness	Anti-CCP (high titre)	RF	Smoking exposure
Progressors (n=7)	42.9%	71.4%	2 (IQR 1-2)	42.9%	57.1%	71.4%	57.1%	100%	100%	71.4%
P value	*NS*	*NS*	*NS*	*NS*	*NS*	*NS*	*NS*	*NS*	***P<0.01***	*NS*
Non progressors (n=10)	60%	60%	2 (IQR 1-2.8)	40%	10%	50%	70%	90%	30%	50%

Legend. Ab: antibodies, BE: bone erosions, CCP: cyclic citrullinated peptide; EMS: early morning stiffness, IA: inflammatory arthritis, IQR: interquartile range; min: minutes, NS: not significant; RF: rheumatoid factor, SENS: Simple Erosions Narrowing Score, US: ultrasound.

Figure 1. Kaplan-Meier curves showing IA free survival time according to the presence/absence of x-rays bone erosions.



Legend. Percentages refer to the individuals progressing at 12 months follow-up (black line).

A total of 123/394 (31.2%) CCP+ at-risk individuals developed IA (median follow-up: 336 days; IQR: 167-748). Seven out of 17 (41.2%) individuals with x-rays detected BE, and 116/377 (30.8%) individuals without x-rays detected BE, developed IA (p=0.37) (Figure 1). New BE were found in only 4/73 (5.4%) CCP+ individuals on repeated x-rays at the time of progression.

Both in the univariable and multivariable analysis, CR detected BE were not predictive for the development of IA [OR: 1.60 (95%CI: 0.60-4.20) p=0.37 and OR: 1.00 (95%CI: 0.30-2.90) p=1.0, respectively], also when these analyses were carried out in individuals with BE in ≥ 3 joints and individuals with radiographic pattern indicating IA (according to the MSK radiologist's diagnosis). In individuals in which BE were detected by both x-rays and US, borderline results were observed in the univariable analysis [OR=9.08 (95%CI: 1.00-82.06) p=0.05].

Conclusion: In CCP+ individuals at-risk of RA, x-rays BE are uncommon and do not predict the development of clinical arthritis. Prevention studies should be able at least to prevent radiographic damage in CCP+ at-risk individuals.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In order to identify the individuals at risk of imminent progression to rheumatoid arthritis (RA), EULAR has established a definition of clinically suspect arthralgia (CSA). Individuals carrying autoantibodies e.g. anti-citrullinated protein antibodies (ACPA) and rheumatoid factors (RF) are at high risk of developing RA. Peptidyl arginine deaminases (PAD) are enzymes responsible for producing autoantigens by citrullination of proteins and, importantly, may themselves represent as an autoantigen. Similar to ACPA and RF, anti-PAD antibodies are detectable years before the disease onset. We aimed to determine the prevalence of anti-PAD autoantibodies and their coincidence with RF and ACPA in sera of the individuals at risk-of developing RA.

Methods: Our prospective study included 86 individuals at-risk of progression to RA defined as having arthralgia without arthritis and being either ACPA+ or meeting the clinical CSA definition. Antibodies against PAD3 and PAD4 were analyzed in serum using commercially available ELISA kit (MyBioSource).

Results: Of the 86 at-risk individuals, 65 were seropositive (RF+ and/or ACPA+) and 54 met the CSA definition (33 were seropositive) with median duration of arthralgia 12 months. Of all individuals, 30 (34.8%) were anti-PAD+ (spe-

cifically, 14% were anti-PAD3+ and 21% were anti-PAD4+). Of 21 individuals who were both RF+ and ACPA+, 57% were anti-PAD+. Thirty % of RF- and 26% of ACPA- individuals were anti-PAD+. Of 21 seronegative (RF- and ACPA-) individuals, 33% were anti-PAD+. A third of individuals who met the CSA definition were anti-PAD+, irrespective of RF and ACPA positivity, 33% of seropositive CSA individuals were also anti-PAD+.

Sixteen patients progressed to RA within a median of 7.5 months of follow up with median DAS28(CRP) 2.28. Of these, 14 were RF+ and/or ACPA+ and 9 were anti-PAD+. All RF, ACPA and anti-PAD autoantibodies were positive in 5 individuals, both seronegative individuals were also anti-PAD-.

Conclusion: A third of the at-risk individuals with arthralgia, originally assessed as seronegative, were carriers of anti-PAD autoantibodies, however, none of them was both anti-PAD3 and anti-PAD4 positive. Similarly, a third of seropositive at-risk individuals were anti-PAD positive. The predictive value of anti-PAD antibodies for future development of RA in the at-risk individuals with arthralgia needs to be investigated.

Anti-Protein-Arginine Deiminase (PAD) 1 IgG Is a Promising Novel Autoantigen in Rheumatoid Arthritis (RA) and Increases Diagnostic Performance in Combination with Anti-PAD4 IgG Using a Composite Biomarker Score

Marcos Lopez-Hoyos[1], Chelsea Bentow[2], Andy Ishii[2], Laura Martinez-Prat[3] and Michael Mahler[2], [1]Marques de Valdecilla University Hospital-IDIVAL, Santander, Spain, [2]Research and Development, Inova Diagnostics, San Diego, CA, [3]Research and Development, Inova Diagnostics, Barcelona, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Over the past years, novel biomarkers have been identified in the sera of rheumatoid arthritis (RA) patients, including autoantibodies to the protein-arginine deiminase (PAD) enzymes. These proteins are involved in the disease pathogenesis, and a total of five PAD family members (PAD1, 2, 3, 4 and 6) have been described in humans, of which PAD2, PAD3 and PAD4, and more recently PAD1, have been identified as autoantigenic targets. Nevertheless, fewer studies have explored the clinical value of anti-PAD1 antibodies. Especially anti-PAD4 antibodies have been shown to help in the diagnosis of RA. The objective of this study was to evaluate the presence of anti-PAD1 and anti-PAD4 IgG in the sera of RA patients and to investigate the utility of an anti-PAD1/PAD4 composite score.

Methods: Serum samples from RA patients (n=262) and controls (n=270) were used to evaluate the discriminatory power of antibodies targeting the individual PAD enzymes. All samples included in this study were tested for an-

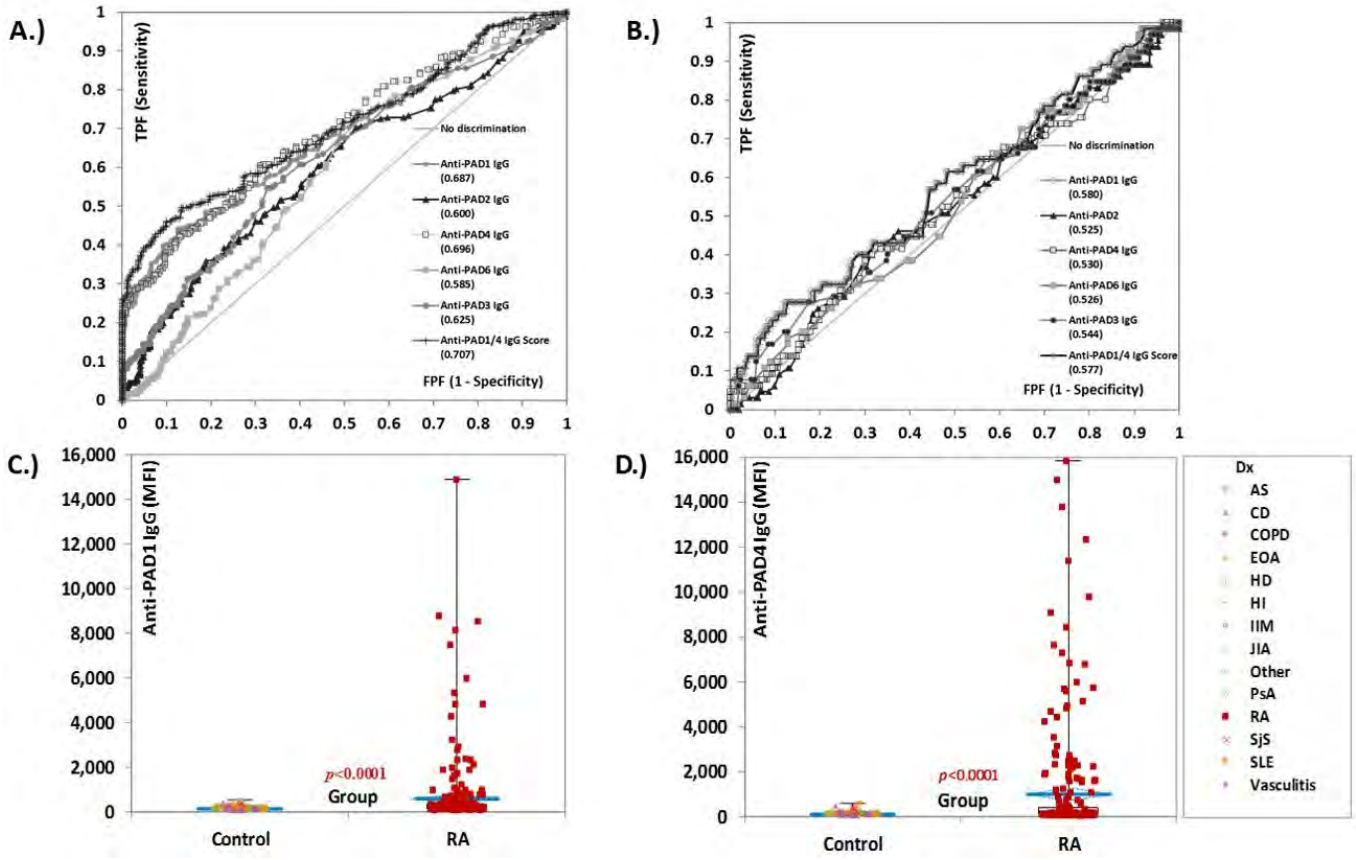

Figure 1. Diagnostic performance of individual antibodies to the protein-arginine deiminase (PAD) enzymes and of the anti-PAD1/4 IgG composite score. Receiver operating characteristic (ROC) analysis comparing the five individual anti-PAD antibodies and the anti-PAD1/4 composite score in their ability to discriminate between RA and controls in the total population (n=532) in panel A.), and in the ACPA negative individuals (n=321) in panel B.). Varying discrimination ability was observed, with anti-PAD1 and 4 showing the best diagnostic performance. The compositive PAD1/4 score shows improved discrimination between rheumatoid arthritis (RA) and controls. Area under the curve (AUC) values are shown for each of the anti-PAD antibodies. The pairwise comparison of the levels of anti-PAD1 and anti-PAD4 in patients with RA (n=262) vs controls (n= 270) are shown in C.). Panel D.) shows the same data for for anti-PAD4 IgG. Results are expressed in median fluorescence intensity (MFI). Abbreviations: AS: ankylosing spondylitis; CD: Chron's disease; CI: confidence interval; COPD: chronic obstructive pulmonary disease; EOA: erosive osteoarthritis; FPF: false positive fraction; HD: Hashimoto's disease; HI: healthy individuals; IIM: idiopathic inflammatory myopathies; JIA: juvenile idiopathic arthritis; MFI: median fluorescent intensity; PAD: protein-arginine deiminase; PsA: psoriatic arthritis; RA: Rheumatoid arthritis; SjS: Sjogren's syndrome; SLE: systemic lupus erythematosus; TPF: true positive fraction.

ti-PAD1, PAD2, PAD3, PAD4, and PAD6 IgG using the novel particle-based multi-analyte technology (PMAT, research use only, Inova Diagnostics, San Diego, USA). Anti-citrullinated protein antibodies (ACPA) IgG was also measured in these patients by QUANTA Lite CCP3 enzyme-linked immunoassay (ELISA, Inova Diagnostics, San Diego, US).

Results: Autoantibodies against all five PAD proteins were detected. Interestingly, anti-PAD1 were preferentially observed in patients with RA resulting in good discrimination between RA and controls from receiver operating characteristic (ROC) analysis (Figure 1). The area under the curve (AUC) for anti-PAD1 was comparable to the AUC obtained for anti-PAD4 antibodies, in both the total (AUC= 0.687, 95% CI 0.642-0.732 and AUC=0.696, 95% CI 0.652-0.740, respectively), and the ACPA negative population (AUC= 0.580, 95% CI .500-0.660 and AUC=0.530, 95% CI 0.450-0.610, respectively). Combining anti-PAD1 and anti-PAD4 in a composite score improved the discrimination between RA and controls substantially (Table 1). In addition, anti-PAD1 and anti-PAD4 were found in the ACPA negative RA group where anti-PAD1 had slightly higher positivity than anti-PAD4.

Table 1 Diagnostic performance characteristics of anti-PAD1 and anti-PAD4 antibodies individually and in a composite score. Abbreviations: ACPA= anti-citrullinated protein antibodies; LR= likelihood ratio; OR= odds ratio; PAD= protein-arginine deiminase.

Conclusion: Our study is one of the first to confirm PAD1 and PAD6 as autoantigenic targets in RA. Interestingly, anti-PAD1 antibodies were mostly found in patients with RA with high disease specificity and although a high degree of overlap with anti-PAD4 was observed, they were also observed in the absence of these anti-PAD antibodies. Anti-PAD1 antibodies hold promise to help to close the serological gap in RA and might be superior to anti-PAD4 in the ACPA negative population, but future studies are warranted to validate in larger populations. Moreover, the observation that anti-PAD1 and anti-PAD4 antibodies combined in a composite score increases the discrimination between RA and control has the potential to further improve the diagnosis of RA.

Plasmatic Proteome in Individuals with Arthralgia at Risk of Developing Rheumatoid Arthritis

Klára Prajzlerová[1], Nora Petrovská[1], Monika Gregová[1], Jiří Baloun[2], Petra Hánová[2], Karel Pavelka[1], Jiří Vencovský[1], Ladislav Šenolt[1] and Mária Filková[1], [1]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of antibodies against citrullinated proteins (ACPA) significantly increases the risk of developing rheumatoid arthritis (RA). EULAR characterised individuals with arthralgia suspicious for progression to RA based on their clinical features (clinically suspect arthralgia, CSA). We aimed to analyse proteins at different stages of RA development with special interest in the at-risk individuals with arthralgia.

Methods: Plasma samples were obtained from 28 at-risk individuals with arthralgia and no previous history of arthritis, who were either ACPA+ or met the CSA definition. Samples collected at baseline or at the time of manifestation of arthritis were analysed by tandem mass spectrometry (nLC-MS2) using Q-OT-qIT mass spectrometer (Thermo Scientific™) followed by MaxQuant software quantification and normalization. Data were analysed using Mann Whitney or Wilcoxon pairs tests and presented as median and interquartile range [IQR]. Protein interaction networks were analysed using STRING v11.0.

Table 1. List of differentially expressed proteins Table 1: List of differentially expressed proteins

Results: Out of 28 individuals with arthralgia (96% females), 13 were ACPA+ and 23 met the CSA definition (8 were ACPA+). Median age was 47 [15] years, median symptom duration 12 [17] months and CRP 3.18 [3.56] mg/L. Thirteen individuals developed RA (10 were ACPA+) within a median of 7 months of follow up with CRP 3.25 [13.10] mg/l and DAS28(CRP) score 4.39 [2.18].

Out of 393 identified proteins, 90 proteins were detected in all tested samples. In individuals who progressed to RA, 6 proteins were differentially expressed at baseline and the manifestation of arthritis (Table 1): complement factor B (CFB), complement C1q subcomponent subunit A (C1QA) and complement component C6 were significantly higher at the time of RA onset. Protein interaction network linked C1QA to C6 by CFB. Moreover, these proteins are involved in innate immune response and regulation of acute inflammatory response. Hemoglobin subunit beta (HBB) was significantly lower at the time of RA onset.

Nine proteins showed differential baseline expression between individuals with ongoing arthralgia (median follow up 12 months) and individuals who have developed RA (Table 1): fibrinogen alpha chain (FGA) was significantly higher in future RA patients while heparin cofactor 2 (SERPIND1), prothrombin (F2), apolipoprotein B-100 (APOB) and beta-2 glycoprotein 1 (APOH) were significantly lower compared to individuals with ongoing arthralgia. Protein interaction networks linked all these four proteins involved in metabolic processes.

Nine proteins were differentially expressed at baseline between ACPA+ and ACPA- individuals (Table 1).

Conclusion: Using proteome analysis we identified several differentially expressed proteins in the at-risk individuals with arthralgia during the progression to RA that were mostly involved in innate immune and acute inflammatory response. Their predictive value as prognostic biomarkers for future development of RA in the at-risk individuals with arthralgia needs to be confirmed in larger patient cohorts.

Abstract Number: 0764

Uncovering Novel Biomarkers for Rheumatoid Arthritis from Feature Selection and Machine Learning Approaches on Synovium and Blood Gene Expression Data

Dmitry Rychkov[1], Jessica Neely[1] and Marina Sirota[1], [1]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is an urgent need to develop objective biomarkers for early diagnosis and monitoring of disease activity in Rheumatoid arthritis (RA). Here we define a RA meta-profile using publicly available cross-tis-

sue gene expression data and apply machine learning to identify putative biomarkers, which we further validate on independent datasets.

Methods: We carried out a comprehensive search for publicly available microarray gene expression data at NCBI Gene Expression Omnibus database for whole blood and synovial tissues in RA and healthy controls. The raw data from 13 synovium datasets with 284 samples and 14 blood datasets with 1,885 samples were downloaded and processed. The datasets were merged and batch corrected separately for each tissue. We further developed a robust feature selection pipeline to identify genes dysregulated in both tissues and highly associated with RA. Within training sets for each tissue, two sets of selected differentially expressed genes were identified and overlapped followed by the condition of co-directionality. Each gene in the resulting set was evaluated on the testing sets using AUROC. The process was repeated 100 times. 2 synovium and 3 blood independent datasets were used to validate the feature selected (FS) genes. We used the averaged AUC 0.8 threshold for the final filtering to define the RAScore, composed of a geometric mean of the selected genes.

Results: The result of the feature selection pipeline was a set of 25 upregulated and 28 downregulated genes. To confirm the robustness of the feature selected genes, we trained a Random Forest machine learning model with this set of 53 genes and the set of 32 common differentially expressed genes and tested on the validation cohorts. The model with FS genes outperformed the model with common DE genes with AUC 0.89 ± 0.04 vs 0.86 ± 0.05. The FS genes were further validated and thresholded on the 5 independent datasets resulting in 10 upregulated genes, TNFAIP6, S100A8, TNFSF10, DRAM1, LY96, QPCT, KYNU, ENTPD1, CLIC1, ATP6V0E1, that are involved in innate immune system pathways, including neutrophil degranulation and apoptosis and expressed in granulocytes, dendritic cells, and macrophages; and 3 downregulated genes, HSP90AB1, NCL, CIRBP, involved in metabolic processes and T-cell receptor regulation of apoptosis and expressed in lymphoblasts.

To investigate the clinical utility of the FS genes, RAScore was composed and found to be highly correlated with DAS28 ($r = 0.33 \pm 0.03$, $p = 7e\text{-}9$) and able to distinguish RA and OA samples (t-test, $p = 2.3e\text{-}6$). However, it did not show any difference between RF-positive and RF-negative RA sub-phenotypes (t-test, $p = 0.9$) suggesting the generalizability of this score in clinical applications. The RAScore was also able to monitor the treatment effect among RA patients (t-test of treated vs untreated, $p = 2e\text{-}4$) and separate polyJIA from healthy individuals in 7 independent pediatric cohorts (t-test, $p = 2e\text{-}4$).

Conclusion: This novel list of biomarkers, identified through a robust feature selection procedure on public data and validated using multiple independent data sets, coupled with the RAScore may be useful in the early diagnosis and disease and treatment monitoring of RA.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite recent therapeutic advances, our ability to predict prognosis and therapeutic response in RA remains imprecise. This study examines for biomarkers predictive of outcome at one year following arthroscopy.

Methods: RA patients were prospectively recruited and underwent knee arthroscopy performed under local anaesthetic. Each patient underwent a careful systematic assessment of demographic, clinical, and serologic factors on the day of arthroscopy and were reviewed at 2 weeks, 3, 6 and 12 months post arthroscopy. Erosive disease was defined based on plain-film radiographs of hands and feet. Disease activity at one year was used to define treatment response into responders (moderate/good EULAR Response) and non-responders.

Clinical characteristics, synovial tissue cell profiles and immunohistochemistry were analysed for T Cells (CD3), B Cells (CD20, CD138), macrophages (CD68) and vascularity (Factor VIII) to establish predictors of treatment response. All areas of each biopsy section were examined and the sub-lining layer independently scored by 2 observers using a well-validated semiquantitative scoring method, ranging from 0 to 4 (0=no staining, 1=< 25%, 2=25–49%, 3=50–74%, and 4=75–100% staining). Factor 8 was scored by calculating the mean count of stained blood vessels per high-power field (at 20X magnification).

Results: Baseline features of the study participants are presented in Table 1. There were no significant differences in gender, age, disease duration, medications, erosive status, ESR, CRP or synovitis or vascularity at arthroscopy. Interestingly, rates of RF and ACPA positivity, tender and swollen joint counts, DAS28 and DAS28CRP were all higher amongst treatment responders. One year outcomes are shown in Table 2. Immunohistochemistry was a very poor

ACPA and Cholesterol Titers as Predictors of Good Clinical Response at One Year in an Argentine Cohort

Rodrigo Garcia Salinas[1], Alvaro Ruta[1], Santiago Ruta[1], Einer Sanchez Prado[1], Jessica Torres Chichande[1] and Sebastian Magri[1], [1]Hospital Italiano La Plata, La Plata, Argentina

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Biomarkers
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibody positivity, erosions, activity level, and functional capacity were classically defined as poor prognosis. Paradoxically, many of them also predict a good response to treatment. Objective: To estimate the proportion of patients achieving remission and low activity by CDAI and SDAI per year in a cohort of patients with RA. To assess the impact of basal ACPA titers and total cholesterol level on response to treatment.

Methods: An observational study, where patients older than 18 who entered the Reumacheck program were included, in the first visit it was carried out: laboratory (including ACPA and total cholesterol: CT), Rx, ultrasound, and interview where were collected sociodemographic data (age, sex, schooling, occupation, toxic habits), clinical data (time of evolution, comorbidities, family history) and CDAI, SDAI, HAQ; each evaluator did not know the data from the other studies and evaluations, ACPA levels were measured in titles and divided into quartiles (Q1: 0-5, Q2: 5-50, Q3:50 -200, Q4: > 200). Those who were diagnosed with RA one year underwent a new control (FR and ACPA) where the same laboratory, clinical and treatment data were collected, and CDAI and SDAI remission and low activity (LDA) were calculated. Statistical analysis: descriptive statistics, Chi2 test and Fisher's exact test were performed. T-test of student and Mann Whitney. Multiple logistic regression. ROC curve analysis to estimate cutoff values for cholesterol.

Results: Of the 183 patients diagnosed with RA between 2018-19, 83 performed a new check-up per year. The baseline characteristics are in Table 1. They achieved CDAI - SDAI remission at one year, CDAI-SDAI LDA (%): 21, 22.4, 55.3, 55 respectively. Reaching CDAI LDA (≤ 10) was associated at baseline to: ACPA (yes-no) 64.4% p 0.05 RR 2.5 (1.02-6.4), ACPA quartile 3-4 76.5% p 0.016 RR 3.3 (1.2-11.5), ACPA title 79.5 vs. 3.95 p 0.04, initiation of anti TNF

Table 1: Baseline RA patient characteristics (N: 83)

Symptom onset less 6 months (%)	22,7	Age (IQR)	57 (43-64)
Female (%)	83	Education time (years)(IQR)	12 (8,5-15)
RF + (%)	68,4	Disease duration (months) (IQR)	48 (12-84)
ACPA + (%)	59,2	Weight (DS)	76,4 (18,3)
Double-sero + (%)	54	FR title (IQR)	34,5 (11,8-132)
Seronegative (%)	26,3	ACPA title (IQR)	28 (0,5-184)
CRP + (%)	27,6	Cholesterol (IQR)	185 (163-223)
Comorbidities (%)	59,2	ESR (IQR)	25 (10,5-40,7)
Lung disease (%)	10,5	CRP (IQR)	3 (1-7)
DMARc started (%)	89,5	CDAI (DS)	14,4 (8,9)
Prednisone ≤ 10mg (%)	22,4	SDAI (DS)	15, (9,3)
Prednisone> 10mg (%)	4	DAS28 (DS)	3,88 (1,2)
Biological - DMARtd (%)	45	TBQ (%)	32

66% p 0.04 RR 2.6 (1.3-6), CT levels 185 vs 207 p 0.04, HAQ 0.5 vs 0.8 p 0.047 and swollen joints 1 (0-3) vs 2 (0-6) p 0.05. CDAI remission (≤ 2.8) was associated only with lower baseline total cholesterol levels: 170 (38) vs. 202 (47) p 0.025.

Reaching SDAI LDA (≤ 11) was associated at baseline to: ACPA (yes-no) 69% p 0.05 RR 2.5 (1.01-6.4), ACPA quartile 3-4 76% p 0.016 RR 3 , 3 (1,2-11), ACPA titer 80 vs 3.45 p 0.047, initiation of anti TNF 66.7% p 0.04 RR 2.6 (1.2-6), levels CT 184 vs 206 p 0.04, HAQ 0.5 vs 0.78 p 0.047 and swollen joints 1 (0-3) vs 2 (0-6) p 0.05. SDAI remission (≤ 3.3) was associated only with lower baseline total cholesterol levels: 168 (36) vs. 203 (47) p 0.025. Two logistic regression models were made, where the predictor variables, sex, age, dyslipidemia, use of statins and treatment were included: both for CDAI and SDAI LDA was independently associated with ACPA quartile 3-4 p 0.02 expB 3 and high cholesterol p 0.016 expB 0.21. In the ROC curve analysis, the best cut-off value was estimated for the baseline CT level predicted by CDAI LDA: AUC 0.67 (0.54-0.8): value 180 (S: 70% E: 50%) for both.

Conclusion: Patients with RA at one-year follow-up reached CDAI - SDAI remission, CDAI-SDAI LDA (%): 21, 22.4, 55.3, 55 respectively. High ACPA titers and low cholesterol levels were associated with achieving remission and LDA by these methods.

Anti-acetylated Protein Antibodies in Rheumatoid Arthritis (RA): Clues for the Starting Point of Autoantibody Responses in RA

Tineke van Wesemael[1], Nazike Salioska[2], Annemarie Dorjée[1], Thomas Huizinga[1], Annette van der Helm - van Mil[3], René Toes[1] and Diane van der Woude[1], [1]Leiden university medical center, Leiden, Netherlands, [2]leiden university medical center, Rotterdam, Netherlands, [3]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by autoantibodies such as rheumatoid factor (RF) and anti-modified protein autoantibodies (AMPAs) like anti-citrullinated protein antibodies (ACPA) and anti-carbamylated protein antibodies (anti-CarP). Recently, another AMPA: anti-acetylated protein antibodies (AAPA) have been found in RA patients [1]. The prevalence of AAPA antibodies and their isotypes have yet to be determined. Since isotype profiles reflect the breadth of an immune response, the prevalence of AAPA isotypes in arthritis patients with and without RA can help to understand the relevance of this autoantibody response in RA.

Objective: To describe the prevalence of AAPA isotypes in arthritis patients with and without RA.

Methods: In 650 RA patients fulfilling the 1987 RA criteria and 555 non-RA arthritis patients from the Leiden Early Arthritis Cohort, baseline serum samples were screened by ELISA for IgG, IgM and IgA to an acetylated- and control peptide that was based upon the CCP-2 backbone . The cutoff for positivity was based on 80 controls (mean + 2SD).

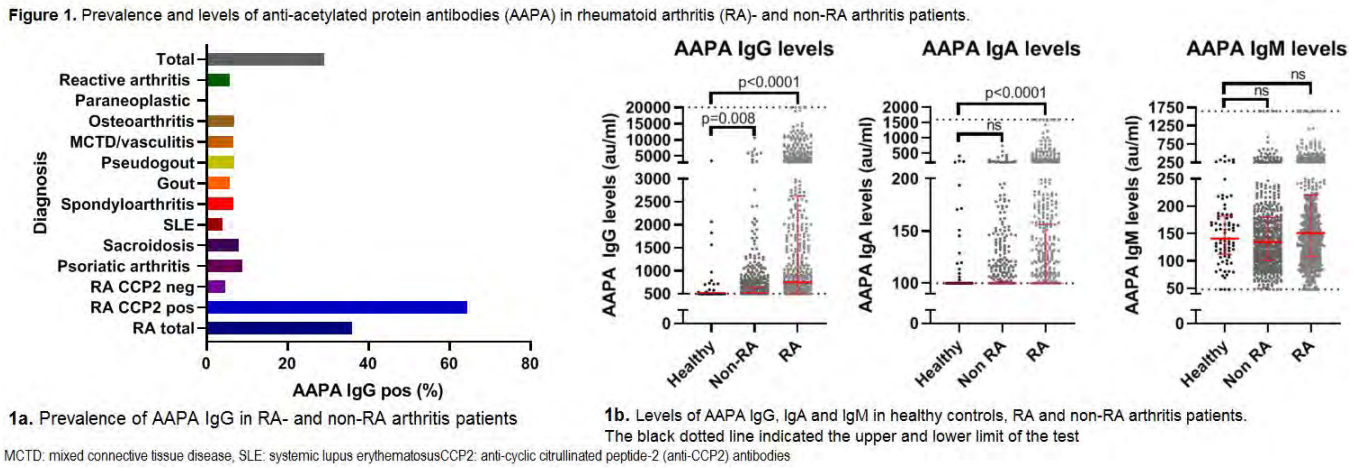

Figure 1. Prevalence and levels of anti-acetylated protein antibodies (AAPA) in rheumatoid arthritis (RA)- and non-RA arthritis patients. 1a. Prevalence of AAPA IgG in RA- and non-RA arthritis patients, 1b. Levels of AAPA IgG, IgA and IgM in healthy controls, RA and non-RA arthritis patients

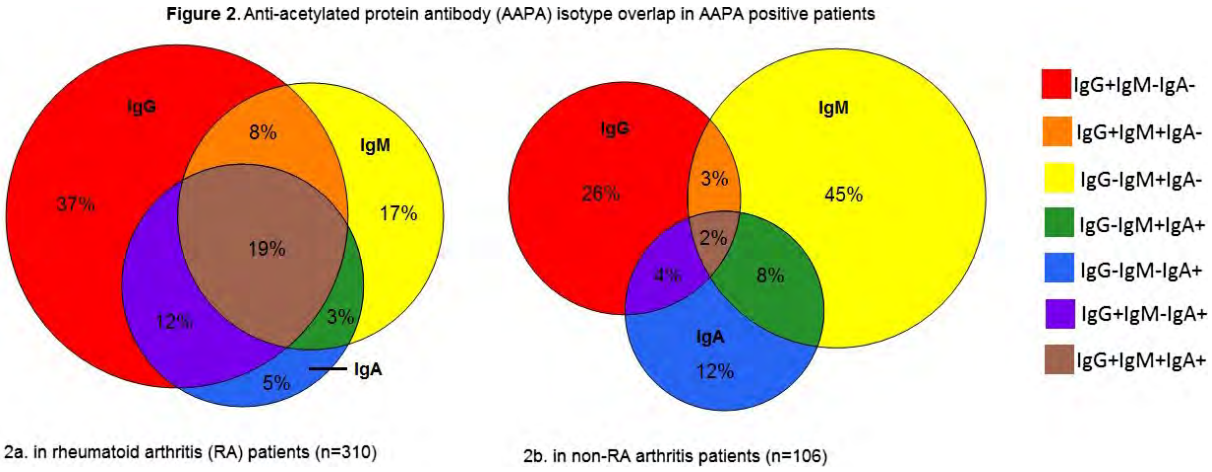

Figure 2. Anti-acetylated protein antibody (AAPA) isotype overlap in AAPA positive patients. 2a. in rheumatoid arthritis (RA) patients (n=310), b. in non-RA arthritis patients (n=106)

A sample was considered positive if it was above the cutoff and was 0.1 optical density higher on the acetylated peptide than on the control peptide.

Results: AAPA IgG was found in 36% of RA patients versus 6.7% of non-RA arthritis patients (Figure 1a). Within RA patients, AAPA IgG antibodies were mostly present in the ACPA-(CCP-2) positive group (64% in ACPA-positive, compared to 5% in ACPA-negative). Levels of AAPA IgG and IgA were higher in RA patients than in healthy controls and non-RA arthritis patients (Figure 1b), however, surprisingly, no difference in levels was found for IgM.

If isotypes profiles in AAPA- positive arthritis patients were compared, patients with RA were more often positive for two or more isotypes then patients without RA, and thus displayed considerably more overlap in AAPA isotypes compared to non-RA patients (Figure 2). Intriguingly, IgM AAPA was the most prevalent isotype in non-RA patients, versus IgG in RA patients.

Conclusion: AAPA are detected in a minority of RA patients, and mainly in the ACPA-positive subgroup. The predominance of IgM AAPA in non-RA arthritis patients and healthy controls suggests that healthy persons can develop AAPA IgM without the development of RA. These results also suggest that in healthy individuals, AAPA responses can occur, but do not mature past the IgM-stage, while in RA patients, the AAPA-response does mature and might form a "starting point" for development of other AMPA leading to the concurrent present of several AMPA in disease.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by the production of autoantibodies like rheumatoid factor and anti- citrullinated protein. $CD4^+$ follicular helper T cells (Tfh) play a critical role in immunity by supporting several events involved in antibody (Ab) production by B cells, including class-switch recombination, germinal center B cell differentiation, and affinity maturation. Remarkably, high levels of Tfh are associated with humoral autoimmunity. We aimed to evaluate the frequency of Tfh in RA patients under different treatment conditions and to characterize the Tfh according their ability to produce Interleukin (IL)-17 and Interferon (IFN)-γ, cytokines with opposite roles in Ab production.

Methods: One hundred subjects over 18 years diagnosed with RA according to ACR/EULAR 2010 criteria untreated and under different treatments were recruited. Twenty-seven of these patients were re-evaluated after 3 months of treatment and treatment response was determined according to EULAR response criteria. Forty-six healthy donors (HD) sex- and age-matched were recruited as controls (Table 1). Ex-vivo Tfh frequency was analyzed by flow cytometry (Figure 1a). Cryopreserved peripheral blood mononuclear cells were used to determine the frequency of IL-17- and IFN-γ-producing Tfh. GraphPad Prism version 7.00 software was used for statistical analysis and p values < 0.05 were considered significant.

Results: The frequency of total Tfh (tTfh: $CD3^+CD4^+CD45RA^-CXCR5^+CD25^{lo}CD127^{hi}$) and of $CCR7^{lo}PD1^{hi}$ Tfh, a subset with demonstrated increased ability to promote Ab response, were significantly increased in RA patients in comparison to HD (p=0.004, p=0.01, respectively) (Figure 1b). When the RA patients were segregated according to the presence of autoAbs, the increase in Tfh was limited to seropositive patients (p=0.04; p=0.03; respectively) (Figure 1c). The activated Tfh subset $CCR7^{lo}PD1^{hi}ICOS^+$ was also increased in RA patients (p=0.01) (Figure 1b) but not in

RA= Rheumatoid Arthritis; HD= Healthy Donors; pts=patients; DMARDs= Disease Modifying Anti-Rheumatic Drugs; TNF inh= Tumour Necrosis Factor inhibitors drugs; Tofa= tofacitinib; F/M= Female/Male; WBC= White Blood Cells; Hb=Hemoglobin; Plat= Platelets; ERS= Erythrocyte Sedimentation Rate; CRP= C-Reactive Protein; DAS28=Disease Activity Score in 28 joints; RF=Rheumatoid Factor (RV<1/20); anti-CCPhs= anti-cyclic citrullinated peptide high sensitive (RV<20U/mL).

Table 1

seropositive group of patients (p=0.13) (Figure 1c). Interestingly, RA patients showed a tendency to increase the percentage of Tfh IL-17^+IFN-γ^- (p=0.057) but no changes were observed in the frequency of IFN-γ^+IL-17^- producing Tfh (p=0.82) respect to HD. When analyzing the effect of treatment, we determined that only untreated patients showed increased frequency of tTfh compared to HD (p=0.03) (Figure 2a). *There were* no statistically *significant differences* in the percentage of tTfh in RA patients after 3 months of treatment (p=0.36), even in the group with good/moderate response (p=0.16) (Figure 2b). Noteworthy, a decrease in the percentage of TfhCCR7^{lo}PD1^{hi} subset (p=0.004) (Figure 2c) was observed after treatment.

Conclusion: The RA patients had increased frequencies of tTfh and the subsets TfhCCR7^{lo}PD1^{hi} and TfhCCR7^{lo}PD1^{hi}ICOS$^+$, with the better capacity to induce Ab responses. tTfh and the subset CCR7^{lo}PD1^{hi}, were increased only in patients with ongoing autoreactive humoral response, and treatments only decrease the subset CCR7^{lo}PD1^{hi}. Studies aimed to understand the dynamics of Tfh subsets may be of relevance to understand and treat pathologies with uncontrolled Ab-responses.

Does the Autoantibody-Response Mature Between Presentation with Arthralgia and Development of Rheumatoid Arthritis? – a Longitudinal Serological Study

Fenne Wouters[1], Ellis Niemantsverdriet[1], Nazike Salioska[1], Annemarie Dorjée[1], René Toes[1] and Annette van der Helm - van Mil[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Auto-antibodies in rheumatoid arthritis (RA) are often present years before disease onset but their mere presence does not seem enough to induce RA. Several nested-case control studies have shown that autoantibody-response maturation precedes disease onset, suggesting its role in disease triggering. At present, it is

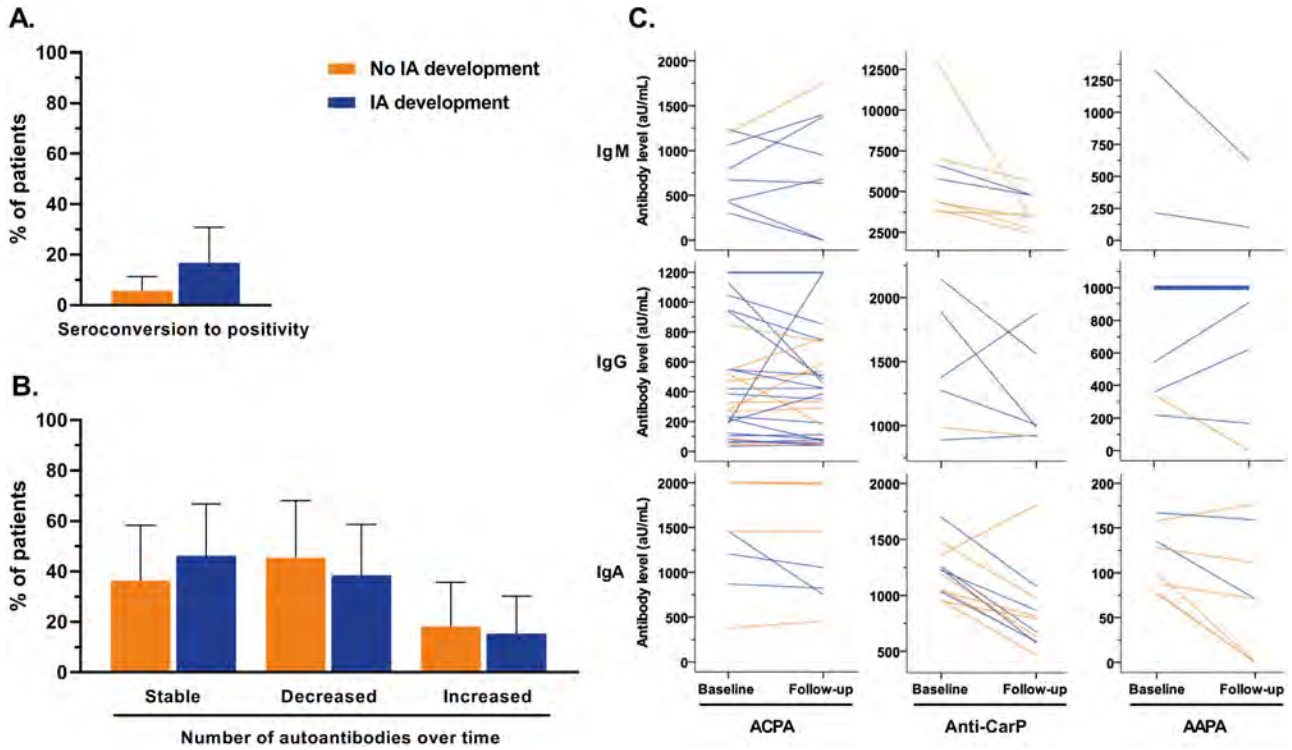

Figure 1 Changes in autoantibodies over time: A) percentage of patients with seroconversion to positive in patients negative for all autoantibodies at baseline (n=100), B) percentage of patients that has an increasing, decreasing or stable number of positive measurements over time in patients positive for ≥1 autoantibodies at baseline (n=48), C) autoantibody levels over time in patients positive for the respective autoantibody at baseline. IA: clinical inflammatory arthritis, ACPA: anti-citrullinated protein antibodies, anti-CarP: anti-carbamylated protein antibodies, AAPA: anti-acetylated protein antibodies

undetermined whether autoantibody-response maturation occurs in the symptomatic phase preceding clinical arthritis (i.e. clinically suspect arthralgia, CSA), or whether it only occurs earlier, in the asymptomatic phase. Likewise, if autoantibody-response maturation relates to disease-development, maturation is expected to be more pronounced in CSA-patients that progress to clinical arthritis compared to CSA-patients that do not. To better understand the relation between autoantibody-response maturation in time and RA-development, we performed a longitudinal study on autoantibody-response maturation in CSA-patients that did and did not progress to clinical inflammatory arthritis (IA).

Methods: In serum from 148 CSA-patients, we determined the presence and levels of anti-citrullinated, anti-carbamylated and anti-acetylated antibodies (ACPA, anti-CarP and AAPA), with three isotypes each (IgM, IgG and IgA), resulting in 9 autoantibody measurements per patient per time-point. In-house ELISA was used for all measurements. CSA-patients with paired samples at first presentation at the outpatient clinic and at IA-development (n=56) or else after 2-years (n=92) were selected. First, in patients negative for all measurements at baseline, we determined the frequency of conversion to seropositivity. Second, in patients with ≥1 positive autoantibody at baseline, we studied the frequency of autoantibody positivity over time. Finally, we determined changes in autoantibody levels in patients positive for the respective autoantibodies at baseline.

Results: In patients negative for all autoantibodies at baseline, 17% of patients that progressed to IA became positive, compared to 6% of ”non-progressors” (Figure 1A, p=0.12). In patients with ≥1 autoantibody at baseline progressing to IA, the median number of autoantibodies was 1.5 (IQR 1-3, max. 6) at baseline and 1.0 (IQR 1-4, max. 6) at IA-development (p=0.18). In CSA-patients with ≥1 autoantibody at baseline not progressing to IA, this was 1.0 (IQR 1-2, max. 4) at baseline and 1.0 (IQR 0-2, max. 5) after 2-years (p=0.07). As shown in Figure 1B; an increase in the

number of autoantibodies was infrequent (15% in progressors, 18% in non-progressors (p=1.00)). Levels of autoantibodies did not significantly change over time (p-values ranging 0.25-1.00) both in progressors and non-progressors (Figure 1C).

Conclusion: The presence and levels of IgM, IgG and IgA ACPA, anti-CarP and AAPA autoantibodies did not significantly increase over time in patients with CSA; this was similar for patients that did and did not develop clinical arthritis. These findings indicate that autoantibody-response maturation, as measured in this study, occurs in the vast majority of CSA-patients before presenting with symptoms and broadening of the autoantibody-response is not specific for progression from arthralgia to RA.

Abstract Number: 0770

Effect of Citrullination on the Processing and Presentation of Rheumatoid Arthritis Autoantigens

Ashley Curran[1], Jonathan Crawford[1] and Erika Darrah[1], [1]Division of Rheumatology, Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Citrullinated proteins are hallmark targets of the autoimmune response in rheumatoid arthritis (RA), but the mechanism by which immune tolerance is broken to these self-proteins is poorly understood. $CD4^+$ T cells are implicated as important drivers of the autoimmune response due to the high-affinity, class-switched nature of anti-citrullinated protein antibodies (ACPAs) present in the majority of RA patients and the prominent genetic contribution of certain HLA-DR alleles to RA susceptibility. However, the precise effect of citrullination on MHC class II antigen processing and presentation of autoantigens to $CD4^+$ T cells remains unknown. Here we aimed to examine the hypothesis that citrullination impacts the processing and presentation of RA autoantigens via destabilization of protein folding and modification of protease cleavage sites, altering the peptide repertoire presented by antigen-presenting cells (APCs).

Methods: Using fibrinogen as a model RA autoantigen, the native and citrullinated forms were digested *in vitro* by a cocktail of lysosomal cathepsins (cathepsins B, S, and H) for proteolytic mapping, or incubated with monocyte-derived dendritic cells (mo-DCs) in a natural antigen processing assay (NAPA). Peptides generated by digestion with the cathepsin cocktail or presented by HLA-DR molecules on mo-DCs were then isolated and identified by mass spectrometry.

Results: We found that the repertoire of peptides generated by each method was altered by citrullination. By proteolytic mapping, we detected both changes in the pattern of cathepsin cleavage and an increased number of peptides in the citrullinated samples. Utilizing NAPA, we observed the creation of newly presented peptides in the citrullinated samples in some cases, and loss of presented peptides in others (Fig. 1). Strikingly, all peptides whose presentation

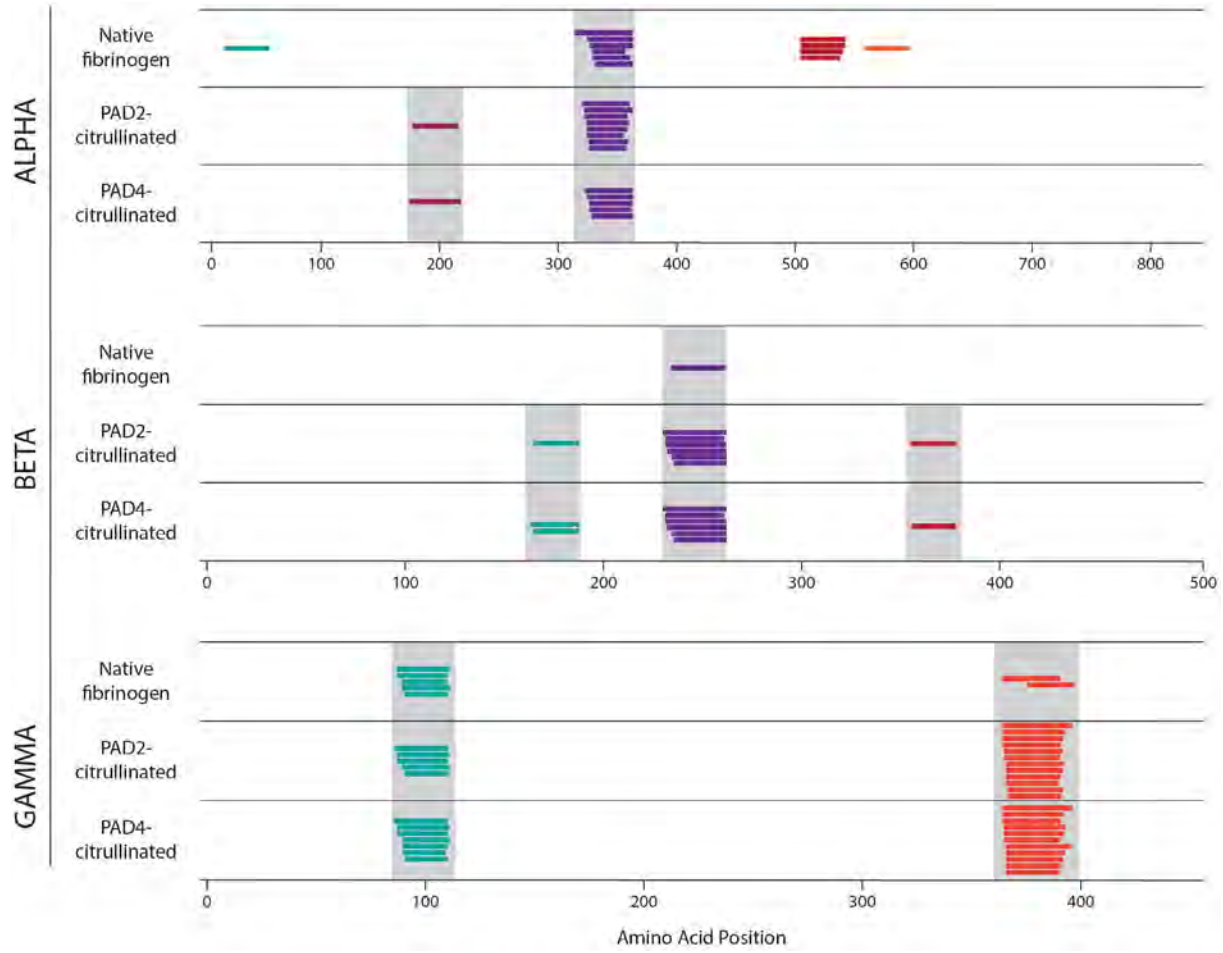

Figure 1. NAPA performed on healthy donor mo-DCs incubated with native, PAD2-citrullinated, and PAD4-citrullinated fibrinogen. Alpha, beta, and gamma chains of fibrinogen are shown separately. Each colored line represents a unique peptide. Nested peptides with a common core motif are shown in the same color within each chain. Grey bar denotes peptides with identical core motif between samples.

was destroyed by citrullination contained a citrullination site. Together these results suggest that both protease cleavage and selection of peptides by HLA-DR are impacted by citrullination.

Conclusion: Citrullination alters the peptide repertoire presented by APCs. Interestingly, no citrullinated peptides were identified by NAPA, suggesting that presentation of citrulline-containing peptides to T cells may not be the primary mechanism by which tolerance is broken to citrullinated antigens. Rather, citrullination-induced destabilization of protein folding and modification of protease cleavage sites, leading to the generation of a new peptide repertoire, could play a role in activating autoreactive T cells. This mechanism could thus drive the loss of immune tolerance to the citrullinated forms of RA autoantigens.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), autoimmunity towards citrullinated peptides driven the hypothesis, in which periodontal disease (PD) is strongly related to the pathogenesis. Given the genetic association, first degree relatives (FDR) of RA-patients are considered a high-risk population to develop RA. The objective is to assess the evolution of clinical disease activity and radiographic progression associated with PD in early RA (eRA) and FDR at one-year follow-up

Methods: Patients fulfilling 2010 ACR/EULAR classification criteria and disease duration less than 2 years, additionally, relatives of patients with RA having a first degree of consanguinity were included. The following parameters were assessed: disease activity (DAS-28, SDAI), radiographic assessment of hands/feet (SENS score) for eRA, joint count assessment, serological bio-markers and a clinical periodontal evaluation was performed. Data was collected at baseline and one-year follow-up. The statistical analyses were done using the chi-square test. Ethical committee approval was obtained

Results: In total 46 eRA-patients and 83 FDR-individuals were included. In eRA the mean age was (47.8 ± 11.7 years). The increasing disease activity by DAS-28 was associated with the presence of RF ($p = 0.020$), ACPA($p = 0.008$), tender joints ($p = 0.001$), swollen joints ($p = 0.016$) and SDAI ($p = 0.005$). In all patients increasing their disease activity, the presence of *P. gingivalis* bacteria in sub-gingival plaque was observed ($p = 0.016$). With regard to periodontal condition, the incremental disease activity was associated with the presence of periodontal pockets (4-5 mm) ($p = 0.018$) and the bleeding at probing ($p = 0.046$). The change in total SENS score was observed in 55 % of progressors, associated with the presence of ACPA ($p = 0.009$). Additionally, in 100% of eRA patients who had radiological progression, a diagnosis of PD was established ($p = 0.003$). Moreover, in those who had radiological progression, the average loss of tooth insertion increased more than three times, ($p = 0.001$) and more than 50% of the sites evaluated had insertion loss ≥3 mm ($p = 0.014$)

In the FDR group (76% women), the increasing number of swollen joints at one-year follow-up was associated with active smoking (p=0.050), overweight (p=0.026), obesity (p=0.003) and fewer teeth (p=0.041). The periodontal pockets were associated with an increase of 30% in CRP levels (p=0.05), and the number of erosions (hands/feet) were associated with higher ESR levels (p=0.004). The increase in foot radiographic score was associated with higher levels of CRP (p=0.039). Finally, 2 out of 83 FDR were diagnosed with RA at one year of follow-up, for an accumulated incidence of 2.4 in individuals having genetic-risk. These 2 individuals (women) has PD and were ACPA positive.

Conclusion: In patients with eRA, disease activity and radiographic progression were directly related to periodontal involvement and ACPA levels at one-year follow-up. In FDR individuals the swollen joints and positivity of acute-phase reactants were associated to overweight/obesity and periodontal parameters. The incidence of RA in FDR is significant in this population

Modification of THP-1 Cells with Malondialdehyde-Acetaldehyde Increases Cellular Calcium Load Rendering Cells Susceptible to Citrullination of Self-Proteins

Nozima Aripova[1], Michael Duryee[1], Xiarepati Tieliwaerdi[1], Xiaoting Jiang[1], Lynell Klassen[2], James O'Dell[1], Bryant England[1], Ted Mikuls[1] and Geoffrey Thiele[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Univerisity of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The post translational modification of self-proteins with malondialdehyde-acetaldehyde (MAA) has been shown to alter protein function and antibodies to MAA are increased in both ACPA positive and negative RA patients. Recently, we have shown that immunization of mice with MAA-modified proteins increases both ACPA and T-cell responses to MAA modified and citrullinated proteins. However, few if any, MAA modified and/or citrullinated proteins have been identified *in vivo*. One protein that is of interest and has been recently identified by our group is matrix Gla protein (MGP), one of the most powerful naturally occurring inhibitors of calcification. While much is known about this protein, there has been limited investigation examining whether this protein could be MAA-modified and/or citrullinated. Therefore, it was the purpose of this study was to evaluate whether MGP could be "naturally" modified with MAA and/or citrulline.

Methods: Human THP-1 monocytes were activated into macrophages with Phorbol 12-myristate 13-acetate (PMA). To evaluate whether MGP could be modified *in vitro*, THP-1 activated cells were incubated with 0.5mM MDA and 0.25mM AA (to form MAA modified proteins) ionomycin (a calcium ionophore) or media alone for 24 hours. Cell lysates were then assayed using a unique capture assay to confirm MGP could be MAA adducted and/or citrullinated. In separate experiments, activated THP-1 cells were incubated as above and then loaded with a Fluo-4 calcium indicator and observed for fluorescence at 488nm to evaluate intracellular calcium level efflux and retention.

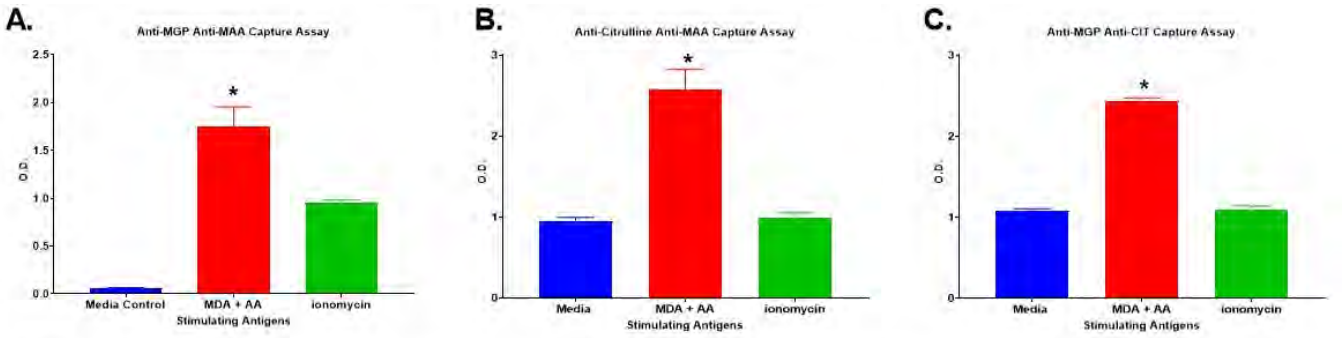

Figure 1. Identification of MAA/Citrulline and MGP on the Same Protein. Activated THP-1 cells were incubated in the presence of 0.5mM MDA and 0.25mM AA, media only, and ionomycin for 24 hours to induce MAA protein antigens. Cell lysates were assayed by ELISA capture assay for: (A) proteins both MAA adducted and Citrullinated *P<0.0001 significantly increased compared to ionomycin and media control (B) MGP MAA adducted *P<0.001 significantly increased compared to ionomycin and media control (C) MGP citrullined *P<0.0001 significantly increased compared to ionomycin and media control. N=5

Figure 1

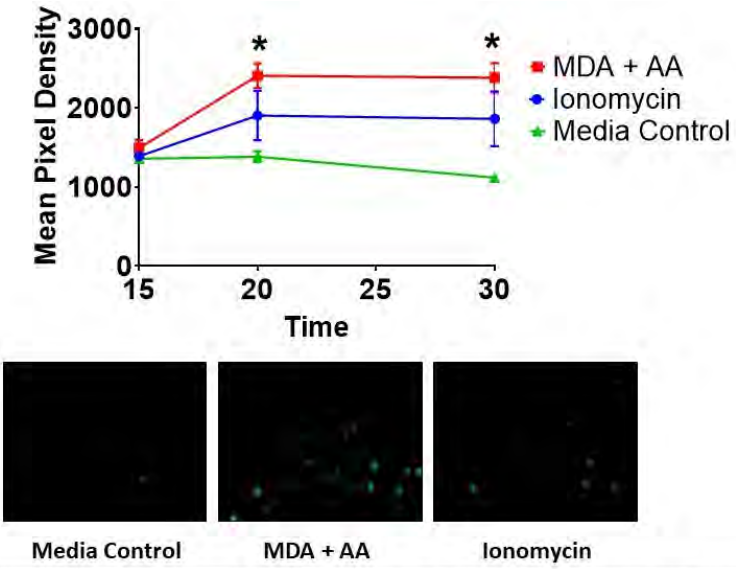

Figure 2. Increase Calcium Levels following MAA Stimulation. Activated THP-1 cells were incubated with media only, MDA + AA to create the MAA Antigen or ionomycin for 30 minutes. Cells were then loaded with a Fluo-4 and observed at 488nm for increased calcium levels. *P<0.01 significantly increased compared to the media control. N=5

Figure 2

Results: THP-1 cell lysates assayed, using the antigen capture ELISA, confirmed that MGP was both MAA-adducted and citrullinated when incubated with MDA and AA ($p < 0.0001$) as compared to ionomycin incubated and media controls (Figure 1). This was interesting as the cells were not exposed to peptidyl arginine deiminase (PAD) suggesting that citrullination was a secondary effect during the modification of cellular proteins MAA. In previous experiments, it has been shown that exogenously added MAA modified proteins decrease calcium efflux which may contribute to the activation of endogenous PAD and the citrullination of proteins. In this study, MDA and AA incubated THP-1 cells

showed significantly increased ($p< 0.01$) levels of intracellular calcium as compared to both the ionomycin and media controls (Figure 2), suggesting that calcium was indeed retained inside the cell.

Conclusion: Incubating THP-1 cells with the precursors (AA and MDA) of MAA modifies cellular proteins including MGP, which was also citrullinated in the absence of adding exogenous PAD. PAD activity is calcium dependent and we were able to show that these THP-1 macrophages incubated with AA and MDA, retained more calcium than those incubated with with appropriate controls. Mechanisms linking MAA formation to citrullination need to be identified, but it is possible that MGP function (binds calcium) is altered to help retain calcium and initiate this response. It is interesting to speculate that MGP is playing a role in the retention of calcium and the increased citrullination observed in these studies.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-carbamylated protein autoantibodies (anti-CarP Abs) of IgG and/or IgA isotype have potential diagnostic and prognostic value Carbamylated Fetal Calf Serum (FCS) is the substrate for the ELISA tests being currently developed (gold standard) for their detection. However, the precise target(s) of these Abs remained undetermined *in vivo*, even though some works suggest that carbamylated fibrinogen would be the most recognized protein by them, particularly the β chain. The objectives were (i) to identify the targets recognized by anti-CarP *in situ*, (ii) to determine whether these anti-CarP Abs recognizing one or several in situ targets have a cross-reactivity with ACPA and (iii) to evaluate their diagnostic and prognostic value in a well-documented cohort.

Methods: All the sera used are from the VeRA cohort of 310 early inflammatory rheumatic diseases (median inclusion at 4 months) including 185 RA (meeting ACR 2010 criteria). To identify new carbamylated targets *in situ*, we performed mass spectrometry on sera from RA patients. An epitopic mapping was performed on the γ-chain of the carbamylated fibrinogen (target identified in the previous step) using 15 27-mer peptides overlapping on 3 amino acids, carbamylated *in vitro* (i). Two immuno-dominant epitopes were identified. The specificity of these targets was asked by performing inhibition assays with the major antigens of the citrulline response (ii). An anti-CarP FCS IgG

ELISA test on the one hand and anti-CarP Fib IgG ELISA test on the other hand were developed. An analysis with clinical, biological (CRP) and radiological data (*van der Heijde* score) at inclusion, 6 months 2 years was performed to determine the diagnostic and prognostic value of these antibodies (iii).

Results: Using a label free proteomic approach, we have identified in RA sera the γ chain of fibrinogen as a potential new target epitope mapping of this chain led to the identification of 2 immuno-dominant epitopes (peptides 5 and 13). Inhibition tests by immunodominant epitopes targeted by ACPA revealed that only peptide 13 has a specific reactivity distinct from that of anti-citrullinated fibrinogen.

The prevalence of Anti-CarP-Fib in VeRA cohort, regardless the patient status (RA or not) is 37% at baseline, which is similar to that of anti-CarP-FCS. Anti-CarP-Fib IgG has diagnostic value since 10.9% of ACPA negative RA are immuno-positive for anti-CarP-Fib IgG at early stage of the disease.

In ACPA-negative patients, anti-CarP-Fib positivity is associated with more inflammatory (higher CRP levels) and erosive disease at baseline ($p< 0.05$). However, this autoantibody population is not associated with radiological progression, which remains strongly related to the presence of ACPA.

Conclusion: One of the primary antigen targeted by the anti-CarP response in RA is carbamylated fibrinogen, particularly 2 epitopes of the γ chain whose one of them does not overlap with the ACPA response. This specificity seems to be associated to a distinct clinical phenotype since anti-CarP-Fib IgG are linked to systemic inflammation, notably in the early stage of RA.

Nr4a1-high Arthritogenic T Cells from SKG Mice Are Associated with Markers of Recent and Chronic Antigen-stimulation and an Altered T Cell Receptor Repertoire

Judith Ashouri-Sinha[1], Elizabeth McCarthy[1], Steven Yu[2], Chun Jimmie Ye[1] and Arthur Weiss[1], [1]UNIVERSITY OF CALIFORNIA, SAN FRANCISCO, San Francisco, CA, [2]UNIVERSITY OF CALIFORNIA, SAN FRANCISCO, San Francsico, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: T cells can either be activated through their T cell receptor (TCR) in an antigen-specific manner, or in response to cytokines. Identification of antigen-reactive T cells in rheumatoid arthritis (RA) would allow us to investigate arthritogenic clones and elucidate early events in disease pathogenesis. We developed a model to identify and study such T cell responses in RA using a specific marker of TCR signaling—Nur77 (*Nr4a1*)—and identified antigen-reactive T cells in the SKG arthritis model and in RA synovial tissue. The immediate early gene *Nr4a1* (encoding the orphan nuclear hormone receptor Nur77) is upregulated in response to antigen, but notably is not induced by cytokine stimulation. Using a fluorescent reporter of Nur77 expression in SKG mice, we found that higher levels of Nur77-eGFP (GFP^{hi}) in SKG CD4 T cells were more arthritogenic and autoreactive and found an analogous

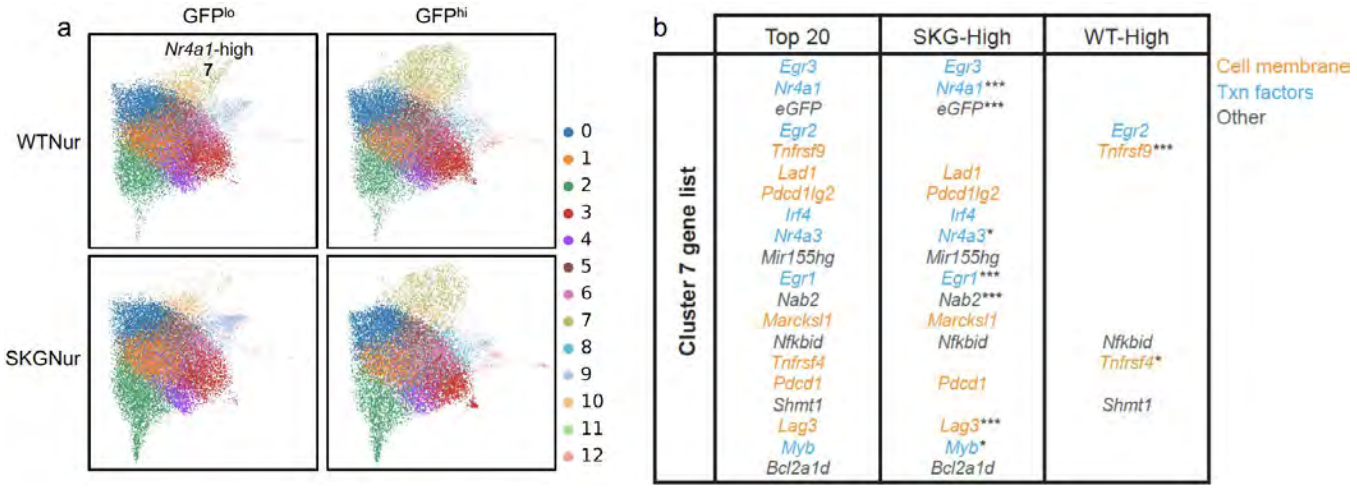

Figure 1. Nr4a1-high cluster 7 memory-like cells associated with markers of TCR signaling and enriched in SKG GFPhi CD4 T cells Transcriptional analysis of SKG and WT GFPhi and GFPlo CD4 naïve (CD4+CD25-CD62LhiCD44lo) T cells sorted based on Nur77-eGFP expression. Unbiased leiden clustering demonstrates high Nr4a1 expression in cluster 7, which is enriched with GFPhi T cells (a) and is associated with expression of immediate early genes and markers of anergy and exhaustion (b). DEG analysis by Wilcoxon rank-sum test P *< 0.05, **< 0.01, ***<0.001

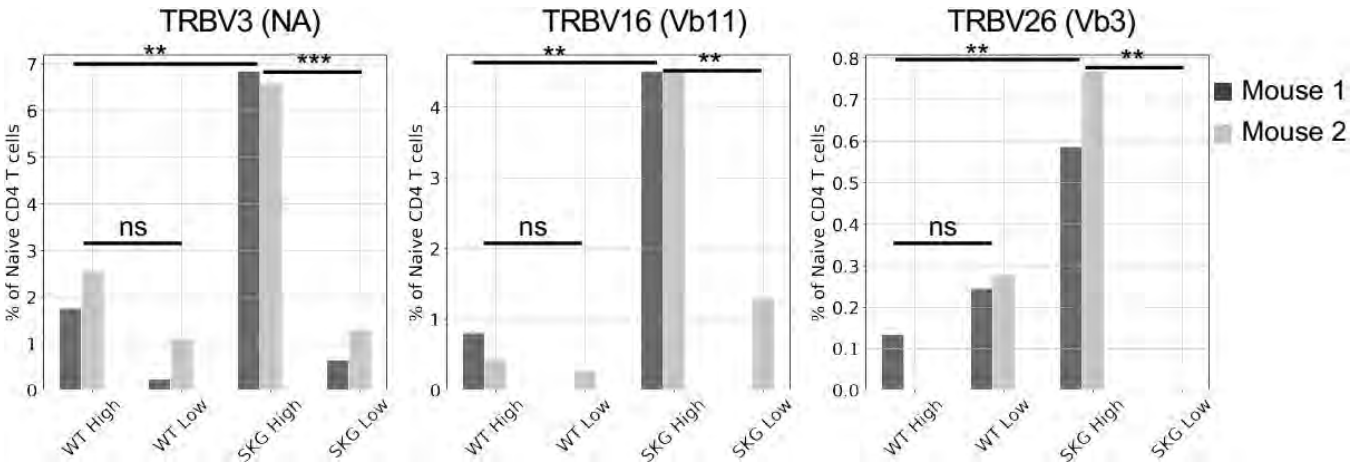

Figure 2. Altered SKG GFPhi TCR Vb repertoire. Bar graphs of TCR beta variable gene usage that are significantly enriched in SKG GFPhi T cells in cluster 7. Graph labels: TRBV gene name (TCR Vb protein name). Significance determined by one-way ANOVA followed by Tukey's HSD. NA – no named TCR Vb protein, ns: P > 0.05, **P < 0.01, ***P < 0.001

population in RA synovial tissue. Here, we set-out to examine the transcriptional program and TCR repertoire of the more antigen-experienced SKG GFP^{hi} T cells that may contribute to disease.

Methods: Paired single cell transcriptional and TCR repertoire analysis was performed on sorted naïve SKG and Balb/c (WT) CD4 T cells from 2 mice based on their Nur77-eGFP levels (GFP^{hi} and GFP^{lo}) using the 5' 10X single-cell platform. We examined our dataset for differentially expressed genes (DEG) and TCR variable genes enriched in the arthritogenic SKG GFP^{hi} T cells.

Results: After filtering, there were 99,074 cells with a mean of 12,384 cells per condition (min 9,979, max 14,899). Using leiden clustering of nearest neighbors, 12 heterogeneous cell clusters were identified from SKG and WT GF-

P^{hi} and GFP^{lo} naïve CD4 T cells. DEG analysis by Wilcoxon rank-sum test identifies a cluster marked by high *Nr4a1* expression (cluster 7). Cells in cluster 7 are associated with a memory-like phenotype, which is enriched in the SKG GFP^{hi} T cells (Fig 1). Within cluster 7 there are two highly variable gene (hvg) modules that correlate with either *Egr2* and *Egr3* (both immediate early gene transcription factors), or *Tnfrsf9* (4-1BB – the TCR inducible co-stimulatory receptor) expression using Spearman's correlation for all cells within cluster 7. The *Egr* module correlates with additional immediate early genes or markers of early T cell activation, whereas the *Tnfrsf9* module is associated with markers of chronic or prolonged TCR input. Furthermore, the SKG GFP^{hi} T cells in *Nr4a1*-high cluster 7 are associated with a biased TCR variable beta (Vb) repertoire. We find significantly higher expression of TCR Vb genes *TRBV3* ($P < 0.001$) , *TRBV16* ($P < 0.0049$), and *TRBV26* ($P < 0.001$) in SKG GFP^{hi} T cells compared to SKG GFP^{lo} and WT GFP^{hi} groups (Fig 2).

Conclusion: This scRNA and TCR sequencing dataset highlights the surprising heterogeneity found within naïve CD4 T cells and identifies a memory-like cluster marked by high *Nr4a1* expression with 2 hvg modules that likely segregate acute from chronic antigen-activated T cells. Moreover, the altered SKG GFP^{hi} TCR Vb repertoire may be an important contributor to their autoreactivity and arthritogenicity and suggests further peripheral repertoire pruning.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Although autoreactive CD4+ T cell and antibody responses against citrullinated antigens are known to contribute to loss of immune tolerance in rheumatoid arthritis (RA), identifying the immunodominant antigens remains an important priority. In this study, we focused on tenascin-C, an extracellular matrix protein with proinflammatory properties, based on our previous studies reporting the presence of autoantibodies targeting a citrullinated epitope in the fibrinogen-like globe of tenascin-C in patients with established RA and patients with early synovitis. Here, we extend these findings utilizing a systematic discovery approach to identify novel citrullinated tenascin C epitopes that elicit T and B cell responses in patients with RA.

Methods: An algorithm was used to predict HLA-DRB1*0401 restricted epitopes along the entire length of the tenascin-C monomer. Predicted epitopes were then tested for their ability to bind HLA-DRB1*0401 and to elicit a T cell response *in vitro*. Multiplex HLA class II tetramer staining combined with cell surface marker antibodies was used

to assess the frequency and phenotype of T cells specific for the immunogenic citrullinated-tenascin-C peptides in peripheral blood. Fluorospot assays were used to measure cytokines produced by synovial fluid mononuclear cells in response to citrullinated-tenascin-C peptides. Antibodies to citrullinated-tenascin-C peptides were detected in sera and synovial fluid using ELISAs and an extracellular matrix peptide microarray. The relationship between antibody seropositivity and clinical variables was modeled using logistic regression models with age and sex as co-variates. All RA subjects met the 2010 American College of Rheumatology criteria, and ACPA positivity was determined based on clinical testing for CCP.

Results: We identified five novel citrullinated-tenascin-C epitopes that were restricted by HLA-DRB1*0401. Notably, CD4 T cells specific for these epitopes were increased in the peripheral blood of patients with RA compared to healthy control subjects, and were present in synovial fluid. Furthermore, two of these citrullinated tenascin-C epitopes were also B cell epitopes that were recognized by antibodies in sera and synovial fluid from RA subjects. Strikingly, antibodies were present in 75% of the patients for one of these epitopes. Serum levels of these citrullinated-tenascin-C reactive antibodies were associated with rheumatoid factor, CCP seropositivity, the shared epitope, and smoking.

Conclusion: Taken together this work demonstrates the importance of citrullinated-tenascin C as an autoantigen in RA. Furthermore, our findings suggest that a unique set of epitopes recognized by both CD4 T cells and B cells have the potential to amplify autoimmunity and promote the development and progression of RA.

The Influence of Adipokine Profile and Periodontal Infection in Early Stages of Rheumatoid Arthritis and First-degree Relatives

Consuelo Romero-Sanchez[1], Juliette De Avila[2], Jeimmy Andrea Chaparro-Sanabria[3], Philipe Chalem Choueka[4], Juan Manuel Bello-Gualtero[5], Alejandro Ramos-Casallas[2], Lorena Chila-M[2] and Wilson Bautista-Molano[6], [1]Hospital Militar Central, Rheumatology and Immunology Department, Universidad Militar Nueva Granada / Clinical Immunology Group, Hospital Militar Central, School of Medicine, Universidad Militar Nueva Granada /Universidad El Bosque, Cellular and Molecular Immunology Group -InmuBo-, School of Dentistry, Bogotá D.C., Colombia, [2]Universidad El Bosque, Cellular and Molecular Immunology Group -InmuBo-, School of Dentistry, Bogotá D.C., Colombia, [3]Clinical Immunology Group, Hospital Militar Central, School of Medicine, Universidad Militar Nueva Granada, Bogotá D.C., Colombia, [4]Fundacion Instituto de Reumatología Fernando Chalem, Universidad El Rosario, Bogotá D.C., Colombia, [5]Hospital Militar Central, Rheumatology and Immunology Department, Universidad Militar Nueva Granada/ Clinical Immunology Group, Hospital Militar Central, School of Medicine, Universidad Militar Nueva Granada, Bogotá D.C., Colombia, [6]University Hospital Fundación Santa Fé de Bogotá and Universidad El Bosque, Bogotá, Colombia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Early RA (eRA) patients have a significant incidence of periodontal inflammation and overweight/obesity. A similar degree of disease activity, functional disability and health-related quality of life has been observed in comparison to established disease. Based on the evidence with regard to the relationship between obesity and periodontitis, these two conditions could be linked because of the production of adipokines. Therefore, the aim

of this study is to evaluate the association of adipokines with of rheumatologic parameters, body mass index (BMI) and periodontitis in eRA and first-degree relatives of RA (FDR).

Methods: A cross-sectional study was conducted including 62 eRA patients (fulfilling the 2020 ACR/EULAR criteria), 124 FDR (genetic risk for developing RA according to EULAR recommendations) and 186 healthy controls matched by age and gender for each group. A complete medical history and joint count was performed. Adiponectin, adipsin, resistin and vaspin levels measured using Luminex technology, IL6 and leptin were measured by ELISA and *Porphyromonas gingivalis* by qPCR. Serum markers such as RF, ACPA, ESR and CRP were evaluated. Disease activity and radiographic assessment were evaluated using DAS-28 CRP, DAS-28 ESR, SDAI, RAPID3 and SENS score (hands/feet). An association analysis was made to evaluate the relationship between adipokines levels, rheumatologic parameters and *P.gingivalis* using X2, Fisher's Exact or U Mann Whitney test. A logistic regression model was performed to confirm associations.

Results: In patients with eRA, 35.8% were ACPA plus *P. gingivalis positive*, whereas 57.9% had high levels of adipsin. In total, 53.8% had both *P. gingivalis* plus high leptin levels, and 37.7% had both *P. gingivalis plus* high adipsin levels. High disease activity (DAS28ESR >3.2) was observed in 63.6%. Patients ACPA plus *P. gingivalis positives*, had high leptin levels (68.4%), and high disease activity (DAS28ESR >3.2) (62.53%). The following associations were found: high leptin levels (OR, 8.22; 95% CI, 2.7–24.5; p = 0.001), high adipsin levels (OR, 3.06; 95% CI, 1.0–8.9; p = 0.041) and DAS-28 ESR >3.2 (OR, 2.59; 95% CI, 1.4–4.5; p = 0.001).

In the FDR group, the *P. gingivalis* presence was associated to lower levels of adipsin (p = 0.002), resistin (p = 0.001), adiponectin (p = 0.003) and a statistical tendency to high levels of leptin (p = 0.060). Tender joints were related to low levels of adipsin (p = 0.019), and high levels of resistin (p = 0.040) and leptin (p=0.040). High levels of leptin were associated with radiographic damage SENS in hands (p = 0.037), total SENS (p=0.026), narrowing joint space in feet (p=0.020) and ACPA positivity (p=0.038).

Conclusion: High levels of leptin and adipsin were associated with clinical disease activity in patients with early RA and periodontal infection, presented simultaneously. In the genetic risk group (FDR) the adipokine profile was associated with the presence of *P. gingivalis* and joint parameters. This factor may modulate the inflammatory environment and increase the risk of developing RA.

CLEC12A Expression as a Potential Predictor of Disease Activity in Early Rheumatoid Arthritis

Myriam Vaillancourt[1], Philippe Desaulniers[1], Guillaume Paré[1], Nathalie Pagé[1], Asmaa Lachaab[1], Anthony Kerever[1], Anne-Sophie Julien[1], Nathalie Amiable[1], Martin Pelletier[1], Philippe Tessier[1], Louis Bessette[2], Paul Fortin[3], Laetitia Michou[1] and **Maria Fernandes**[1], [1]Université Laval, Québec, QC, Canada, [2]Laval University, Quebec, Canada, [3]CHU de Quebec - Universite Laval, Quebec, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) develops as a result of the dysregulation of immune activating and inhibitory pathways. Several lines of evidence indicate that inhibitory receptors on circulating leukocytes are potential predictors of disease activity, seropositivity and/or inflammation markers. Although myeloid cells play an important role in the pathogenesis of RA, less is known about the correlation between the expression of their inhibitory receptors and clinical outcomes in RA compared to inhibitory receptors on lymphocytes. CLEC12A is a myeloid inhibitory receptor that negatively regulates neutrophil activation *in vitro* and whose polymorphisms have been associated with RA. Moreover, CLEC12A knock-out mice with collagen-induced arthritis exhibit enhanced joint inflammation and impaired resolution of joint injury indicative of a potential role for this inhibitory receptor in RA. The goal of this study was to determine whether CLEC12A is differentially expressed in circulating neutrophils and monocytes of human early RA (eRA) patients and if its expression correlates with clinical parameters and cytokine production.

Methods: Seventeen patients with early RA (eRA), symptom duration of >6 weeks but less than 15 months of symptoms, were recruited as part of the Systemic Autoimmune Rheumatic Disease biobank and database repository of the CHU de Québec-Université Laval. Clinical data and serum samples were obtained at the first visit (baseline), 3, 6, 12 and 18 months and a one-time control sample was obtained from healthy donors. Simple disease activity index (SDAI) was determined at each visit, and autoantibody levels at baseline and 12 months. CLEC12A receptor expression was determined on circulating neutrophils and monocytes by flow cytometry at baseline and 3, 6, 12 and 18 months follow-up. Serum cytokines were quantified at baseline. Group generalized estimating equations model, Student's *t* test and Spearman's correlations were performed to identify correlations between CLEC12A expression and clinical parameters.

Results: Cell-surface expression of CLEC12A is significantly higher on neutrophils of early rheumatoid arthritis patients at baseline compared to healthy donors ($p = 0.014$). Cross-sectional analyses indicate a negative correlation of CLEC12A expression at baseline with the SDAI at baseline ($r_s = -0.55$; $p = 0.032$). The same observation was observed at 3 months ($r_s = -0.65$; $p = 0.01$). CLEC12A expression at baseline was predictive of the SDAI score at 6 months ($r_s = -0.52$; $p = 0.046$) and correlated positively with eotaxin levels at baseline ($r_s = 0.71$; $p = 0.003$). Similar observations were made for monocytes. No correlations were identified between CLEC12A expression and autoantibodies.

Conclusion: Our observations provide further support to the recurring theme that the expression of inhibitory receptors on circulating leukocytes changes during disease and predictive of disease parameters. The correlations we observed in this discovery cohort between CLEC12A expression and disease activity as well as cytokines strongly suggests that CLEC12A modulates the immune response that drives the early stages of this autoimmune disease.

Session Title: RA – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Circulating autoantibodies, including anti-CCP and RF, develop years before physical manifestations of rheumatoid arthritis (RA), with several lines of evidence suggesting that these autoantibodies may be driven in part by microbial-mucosal interactions. We hypothesized that discrete bacterial strains in the gut may drive autoantibody generation, inducing a systemic breach of tolerance in the autoantibody positive preclinical RA period that leads to the future development of joint inflammation.

Methods: Human fecal samples were obtained from 16 healthy controls (HC), 12 at-risk individuals (AR) (serum anti-CCP+ in the absence of current or prior arthritis), and 13 individuals with early RA (< 1 year duration). Antibody-seq was performed by flow sorting bacteria endogenously coated with human IgA, followed by 16S rRNA sequencing. Plasmablasts (PB) were isolated from 4 additional AR individuals, defined by serum CCP+ (83%) and/or RF+ (83%), and from 2 individuals with early RA (CCP+). Subdomains of the antigen binding region from PB-produced antibodies were selected by sequence analysis for their origin in a dual IgA/IgG isotype family, cloned onto a mouse IgG2a framework and expressed as monoclonal antibodies (mAbs). 94 mAbs were chosen for further study based on recombinant antibody reactivity with synovial antigens. *Lachno(spiraceae)/Rumino(coccaceae)* strains were isolated from the feces of an AR subject. After culture in anaerobic media, 7 strains of interest were identified by 16S sequencing.

Results: The closely related families *Lachno*/*Rumino* were expanded in AR and RA compared to HC. This expansion was accompanied by increased IgA coating of *Lachno*/*Rumino* in AR when compared to family abundance. 62% of 94 PB-derived mAbs that bound synovial antigens also targeted intestinal bacteria, specifically *Lachno*/*Rumino*. Together these suggest altered mucosal responses to these families and cross-reactivity between *Lachno*/*Rumino* bacterial and host self-antigens in RA joints. To analyze phenotypic effects of these families, primary human bacterial strain isolates within *Lachno*/*Rumino* were verified as targeted by representative PB-derived mAbs. Germ-free DBA/1j mice were mono-colonized with *Lachno*/*Rumino* strain isolates, *Prevotella copri*, or culture media. Within 14 days arthritis, characterized by joint swelling and bone loss, was observed in mono-colonized mice receiving one *Lachno*/*Rumino* strain.

Conclusion: In a cohort of AR and RA individuals, we identified altered mucosal and systemic immunity to *Lachno*/*Rumino*. Germ-free mice mono-colonized with a strain derived from an AR individual developed arthritis. Although

the full mechanism has not been fully elucidated, the observed cross-recognition of *Lachno*/*Rumino* and joint derived antigens by AR and early RA PB-derived mAbs, and induction of joint inflammation by such bacteria in mono-colonized mice, suggests that bacterial antigens and/or arthritogenic factors derived from these families drive a breach in tolerance during human preclinical RA and contribute centrally to the development of arthritis and classified RA.

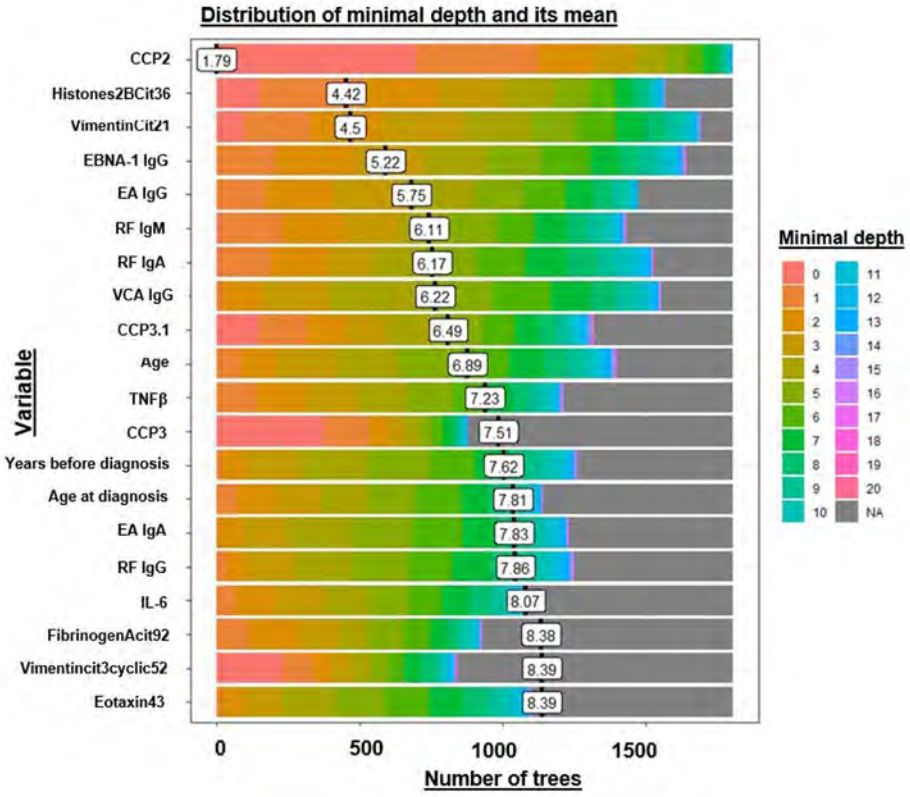
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Viral infections, including infection with Epstein-Barr virus (EBV), have been suggested as environmental risk factors for rheumatoid arthritis (RA). EBV infections are known to be nearly ubiquitous in adults, life long, and asymptomatic. EBV infection status has been determined using circulating levels of IgG antibodies to Epstein Barr viral capsid antigen (VCA), nuclear antigen 1 (EBNA-1), and early antigen (EA). Prior studies have shown that patients with established RA have altered immune responses to EBV; however, the presence and role(s) for this altered immune response has not been fully understood in the autoantibody positive early period before clinically apparent RA develops. We hypothesize that EBV infection, as evidenced by an altered anti-EBV antibody response in preclinical RA, can play an important role in driving the expansion of RA-related autoimmunity.

Methods: 83 subjects had a date of RA diagnosis established by chart review and stored serum samples available through the Department of Defense Serum Repository (DoDSR) that include the pre and post RA diagnosis period based on 1987 ACR criteria. Controls (n=83) were matched to RA cases based on age, race, sex, region, and timing of blood draw. Subjects' sera were tested for 5 anti-EBV antibodies (EBNA-1-IgG, VCA-IgG, EA-IgG, VCA-IgA, and EA-IgA), 7 RA-related autoantibodies (RF-neph, -IgA, -IgM, -IgG, CCP2, CCP.3, CCP3.1), 22 cytokine/chemokine markers, and 36 APCAs. Random forest classification modelling included pre-selected biomarkers based on bivariate association with RA case versus control outcome using Mann-Whitney test ($p< 0.20$). Mixed models were used to estimate the earliest time point when the case's least-squares mean estimate was significantly higher than the control estimate for each marker. The time when an RA subject's marker level was outside the upper 95% CI for their matched control was also identified. These times were compared across each maker using an analysis of variance



The distribution of minimal depth for the top 20 significant variables among the trees of the forest is shown in different colors for each value of minimal depth. The mean minimal depth for each variable is marked by a vertical black bar and labeled with the mean depth inside the box. The lower the mean minimal depth of a variable the more important the variable is in classification of RA cases and controls.

to identify the mean time that each case differed from their control and how the mean time of each antibody relates to the others in time.

Results: Random forest analysis identified anti-EBNA1 IgG, EA-IgA, EA-IgG, and VCA-IgG among the top 20 important RA-related preclinical markers based upon mean minimal depth in trees and gini decrease importance measures that classify RA cases from controls *(Figure 1)*. Results of serologic analyses showed that EBNA-1 IgG levels are significantly higher in RA cases, whereas EA-IgA and VCA-IgG levels are significantly higher overall and in the pre-diagnosis period *(Table 1)*. Mixed modeling analysis of anti-EBV antibody levels identified the earliest divergence of EA IgG, EBNA-1 IgG, and VCA IgG levels between cases and controls are at 8.3, 3.5, and 1.9 years prior to RA diagnosis respectively. The difference in the timing of these case/control mean biomarker level differences is significant between each antibody and each group.

Conclusion: Our study suggests that several anti-EBV antibody levels are significantly elevated in the preclinical time of RA. In addition, altered EBV antibody titers suggests that this virus may contribute to a specific endotype of preclinical RA.

Subsets of Synovial Fluid Derived Fibroblast-like Synoviocytes in Rheumatoid Arthritis

Kuninobu Wakabayashi[1], Takeo Isozaki[1], Shin Ohta[2] and Tsuyoshi Kasama[3], [1]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan, [2]Division of Respiratory Medicine and Allergology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan, [3]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Koutou-ku Tokyo, Japan

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLS) secrete inflammatory cytokines and chemokines, invade and degrade cartilage, and stimulate osteoclast that cause bone erosion. Recently, it is reported that the subsets of RA FLS in fresh human synovial tissues were characterized by the expression of podoplanin (PDPN), CD34, and THY1 (also known as CD90). Especially $PDPN^+CD34^-THY1^+$ FLS may be pathogenic since these cells secrete proinflammatory cytokines and are proliferative and invasive. Adherent cells with FLS appearance are observed when the cells in synovial fluid (SF) are cultured. The aim of this study is to investigate the subsets of SF-derived FLS in RA.

Methods: We collected the SFs aspirated from the knee joint of RA patients, who were not treated with DMARDs at the onset or at the flare. The SFs were centrifuged and the cell pellets were resuspended in RPMI-1640 medium supplemented with 10% FBS and 1% Pen-Strep. The attached cells were cultured until 80% confluent growth was observed, and these cells were harvested and passaged. The profile of cell surface markers expressed by SF-derived adherent cells were analyzed using flow cytometry. Flow cytometry was performed by triple staining with PDPN, CD34 and THY1. The data are reported as the mean ± SE.

Results: We got the synovial fluid from 17 patients with RA. The characteristics of the 8 patients, whose SF-derived adherent cells were able to be passaged, were long duration of arthralgia (102.1 ± 35.1 vs 11.0 ± 6.9 months, $p< 0.05$), lower levels of serum rheumatoid factor (30.9 ± 15.5 vs 152.0 ± 48.9 IU/mL, $p< 0.05$) and lower proportion of lymphocytes of white blood cells in SF (11.4 ± 3.2 vs 39.0 ± 10.6 %, $p< 0.05$). At the passage 0 (n=8), $PDPN^+$ cells were lower than $PDPN^-$ cells (35.6 ± 4.1 % and 64.4 ± 4.1 %, respectively, $p< 0.05$). The proportion of $CD34^-THY1^+$, $CD34^-THY1^-$, $CD34^+THY1^+$, and $CD34^+THY1^-$ in the $PDPN^+$ cells were 54.2 ± 10.8 %, 25.7 ± 12.2 %, 23.1 ± 9.2 %, and 2.2 ± 0.3 % respectively. Among the 3 patients whose cells were passaged up to P2, the rate of $PDPN^+$ cells were increased with every repeated the passage (P0: 28.8 ± 4.4 %, P1: 60.3 ± 7.7 %, P2: 71.4 ± 3.2 %). In addition, the rate of $CD34^+THY1^+$ cells in the $PDPN^+$ cells were increased (P0: 4.4 ± 1.7 %, P1: 16.9 ± 6.8 %, P2: 25.4 ± 6.0 %).

Conclusion: These data show that $PDPN^+$ SF-derived FLS have the subsets, and $CD34^-THY1^+$ cells would be major subsets. $PDPN^+$ SF-derived FLS, particularly $CD34^+THY1^+$ cells, are proliferative. Considering SF-derived FLS have the merit of easy accessibility, these cells could substitute for ST-derived FLS in studying the pathogenesis of RA.

Phenotypic and Functional Characterisation of Synovial Fluid-derived Fibroblast-like Synoviocytes in Rheumatoid Arthritis

Ditte Køster[1], Johanne Hovgaard Egedal[1], Malene Hvid[1], Martin Roelsgaard Jakobsen[1], Ulf Müller-Ladner[2], Bent Deleuran[1], Tue Wenzel Kragstrup[1], Elena Neumann[3] and **Morten Aagaard Nielsen**[1], [1]Aarhus University, Aarhus, Denmark, [2]Department of Rheumatology, Immunology, Osteology and Physical Medicine, Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, Bad Nauheim, Germany, [3]Department of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus Liebig University Giessen, Bad Nauheim, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) are central cellular components in persistent inflammatory joint diseases such as rheumatoid arthritis (RA). Pathological subsets of FLS have been identified from synovial tissue. However, the synovial tissue obtained from arthroplasty procedures is aquired at late disease stages and the cellular yield obtained from synovial tissue biopsies can be low. Challenging the establishment of human RA *in vivo* and *in vitro* models. FLS obtained from the synovial fluid (SF-FLS) are proposed as an alternative source of FLS, but a detailed phenotypical and functional characterization of FLS subsets from the synovial fluid has not been performed.

Methods: In the present study, paired peripheral blood mononuclear cells (PBMC) and SF-FLS from patients with RA were obtained (n=7). FLS were isolated from the synovial fluid by a strict trypsinization protocol and their cellular characteristics and functionality were evaluated at passage 4. Monocultures (SF-FLS) and autologous co-cultures (SF-FLS+PBMC) were established from five patients with RA and subsequently evaluated by flow cytometry, Western blotting and multiplex immunoassays. Human cartilage-sponges (n=3) with SF-FLS and without SF-FLS (n=3) were co-implanted subcutaneously in 15 SCID mice, mice with only cell-free human cartilage-sponges were used as controls (n=12). After 45 days, the implants were evaluated using stained sections to determine the SF-FLS invasion score based on perichondrocytic cartilage degradation. Data are expressed as median (25-75 percentile). P-values < 0.05 were considered statistically significant.

Results: The homogeneous subpopulations of FLS, isolated from the synovial fluid, were negative for CD34 and CD45 [98.9%, (97.5-99.7]) and positive for Thy-1 and PDPN [94.6%, (79.9-97.4]). Without stimulation, RA SF-FLS showed high and comparable levels of NFκB related pathway proteins and secreted multiple pro-inflammatory cytokines and chemokines dominated by IL-6 [2648 pg/mL, (1327-6116)] and MCP-1 [2458 pg/mL, (692-8719)]. SF-FLS increased their ICAM-1 and HLA-DR expression after encountering autologous PBMCs ($p< 0.01$), ($p< 0.05$). Further, SF-FLS and PBMC interacted synergistically in a co-culture model of RA and significantly increasing the secretion of several cytokines (IL-1β, IL-2, IL-6, ($p< 0.01$)) and a chemokine (MCP-1, ($p< 0.01$)). The invasion score of the human SF-FLS *in vivo* was at primary site, [1.6, (1.3-1.7)] and contralateral implantation site [1.5, (1.1-2.2)]. The invasion score of the human SF-FLS-containing implants both at primary and contralateral site were significantly higher compared with cartilage-sponges evaluated from SF-FLS-free control mice ($p< 0001$).

Conclusion: This phenotypical and functional characterization of SF-FLS, do not deviate from synovial tissue FLS and lay a foundation for establishing *in vivo* and *in vitro* FLS models. These FLS models will be beneficial in our understanding of the role of this cellular subset in arthritis and for characterization of drugs specifically targeting this pathological RA FLS subset.

Abstract Number: 0782

Epigenetic Regulation of Metabolic Transporters in Rheumatoid Arthritis Fibroblast-Like Synoviocytes

Brian Pedersen[1], Rizi Ai[1], Alyssa Torres[1], Wei Wang[1], Gary Firestein[2] and Monica Guma[3], [1]University of California San Diego, La Jolla, [2]University of California, San Diego, La Jolla, CA, [3]Division of Rheumatology, University of California San Diego, Department of Medicine, Autonomous University of Barcelona, La Jolla, CA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Epigenetic changes contribute to the pathogenesis of rheumatoid arthritis (RA) and a comprehensive epigenomic characterization of RA fibroblast-like synoviocytes (FLS) has recently been described. Nutrient transporters, with the SLC transporter families that contain 400 genes and 52 subfamilies among others, serve as 'metabolic gate' of cells by mediating the transport of a wide range of essential nutrients and metabolites such as glucose, amino acids, vitamins, neurotransmitters, and inorganic/metal ions. As previous studies indicate that metabolism is altered in RA FLS, we hypothesize that ChIP mark changes in nutrient transporters genes would correlate with differences in expression of these genes and would help to identify activated metabolic pathways.

Methods: ChIP-sequencing data, for six different ChIP marks (H3K4me1, H3K4me3, H3K9me3, H3K27ac, H3K27me3, H3K36me3), and DNA methylation from a publicly available data set from FLS derived from 11 RA patients and 11 OA patients were compared to identify regions with a difference in these histone modifications. Single nearest genes to regions of interest were then utilized for pathway analyses (REACTOME classification) to determine if particular cellular processes and pathways are associated with these chromatin changes. Pathways associated with nutrient transporters were enriched near ChIP mark changes commonly associated with active transcription (H3K4me1,

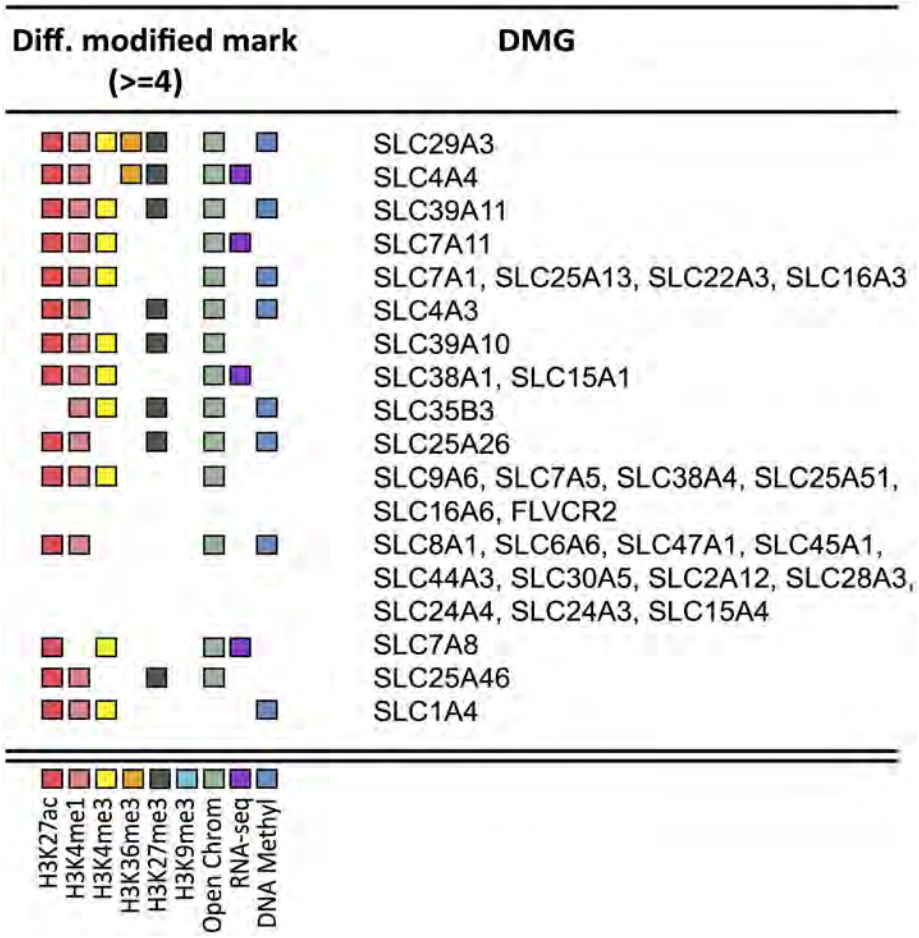

Figure 1. Shown the 34 differentially modified nutrient transport genes with differentiated modified marks.

H3K4me3, H3K27ac) with the use of the whole genome as a reference. To further elucidate these findings, single nearest genes associated with any ChIP mark change and transporters were utilized for a secondary pathway analysis. Changes in transcription of genes associated with the ChIP mark changes were assessed using RNA-sequencing data from the same cells. ATAC-Seq to study the open chromatin regions in FLS was also assessed.

Results: As per the unbiased pathway analysis, 21 pathways significantly associated with at least 3 either epigenetic marks, RNA-Seq or ATAC-Seq changes were associated with energy metabolism. "SLC-mediated transmembrane transport" was one of these pathways and associated with 4 changes. 34 different genes involved in nutrient transportation were associated with a change in at least 4 epigenetic marks (Figure 1). These genes were then used in a Reactome pathway analysis. Amino acids and oligopeptide SLC transporters (including SLC38A4, SLC38A1, SLC6A6, SLC7A8, SLC7A5, SLC7A11, SLC7A1, SLC1A4, SLC15A1, SLC15A4) was one of the top ranked pathways (adjusted p= 5.13e-13). Of note, most of these transporters are known to be glutamine transporters. Transporters for organic and metal ions were also heavily epigenetic regulated. Interestingly, ATAC-Seq analysis showed a significant enrichment of open chromatin regions near those genes.

Conclusion: This study of RA FLS demonstrates changes in epigenetic marks of genes related to nutrient transporters and suggests that metabolism is critical in RA pathogenesis and may be involved in the imprinted aggressive phenotype displayed by RA compared to OA FLS. Additionally, this dataset has the potential to identify RA-specific targets that can be used to develop novel therapeutic agents.

Abstract Number: 0783

Role of Glutamine Metabolism in Rheumatoid Arthritis Fibroblast-Like Synoviocyte Aggressive Phenotype

Alyssa Torres[1], Brian Pedersen[1], Gary Firestein[2], Elsa Sanchez-Lopez[1] and Monica Guma[3], [1]University of California San Diego, La Jolla, [2]University of California, San Diego, La Jolla, CA, [3]Division of Rheumatology, University of California San Diego, Department of Medicine, Autonomous University of Barcelona, La Jolla, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibroblast-like synoviocyte (FLS) activation is a key component of rheumatoid arthritis (RA) inflamed synovium. Their aggressive phenotype in RA contributes to initiation and perpetuation of destructive joint inflammation. Understanding changes in RA FLS metabolism is becoming a new focus of research in RA. We previously showed that the glutaminase gene, which encodes for the enzyme that generates glutamate from glutamine, is highly epigenetically regulated in RA FLS compared to osteoarthritis (OA) FLS. Here, we determined the importance of glutamine (gln) as an alternate carbon source to glucose for FLS and whether or not interference of this pathway can decrease the aggressive phenotype of FLS in RA.

Methods: Uptake of glutamine was determined by Glutamine/Glutamate-Glo kit by Promega. Dependence of glutamine by RA FLS was determined by functional assays, including invasion (matrigel assay), proliferation assays (EdU assay), and a migration assay (scratch assay), that were conducted using DMEM without glucose supplemented with

dialyzed fetal bovine serum. We then used increasing amounts of glutamine before and after PDGF stimulation in the presence or absence of glucose. RA FLS were also incubated with CB-839 (300nM), a glutaminase inhibitor.

Results: Glutamine/glutamate luminescence test displayed significant glutamine uptake in FLS starved of glucose after PDGF stimulation (3938±10425 vs 1165±371.8, p< 0.0001). Functional assays revealed that 6mM glutamine (FLS cultured in a media without glucose) is sufficient as an alternate source of energy to 6mM glucose (FLS cultured in media without gln) in proliferation (6mM gln 0.3±0.07 vs 6mM glucose 0.37±0.21; ns) and invasion (6mM gln 21.47±1.34 vs 6mM glucose 20.91±1.3; ns). In addition, the use of glutamine allows for an increase of invasion (0mM gln 12.87±3.316 vs 6mM 18.83±3.236; p< 0.002), proliferation (0mM gln 8.752±4.7 vs. 6mM gln 40.55±14.07; p< 0.02), and migration (0mM gln 219.8±49.88 vs 6mM gln 186.4±45.90; p=0.0002) in the absence of glucose. Of interest, OA FLS do not migrate more on 6mM glutamine compared to 0mM glutamine (0mM gln 216.1±46.35 vs 6mM gln 219.4±58.64; ns). Experiments with CB-839 showed significant decrease in invasion (vehicle 23.11±3.161 vs CB-839 14.46±2.036 p< 0.0001) and proliferation (vehicle 0.2548±0.03589 vs CB-839 0.1278±0.02861 p< 0.0001) of RA FLS under glucose depletion with varying amounts of glutamine compared with vehicle control.

Conclusion: RA FLS are able to utilize glutamine as an alternative carbon source in the absence of glucose, which mimics the starvation conditions within the joint. Glutaminase could potentially be a good target to reduce the aggressive phenotype of FLS in RA.

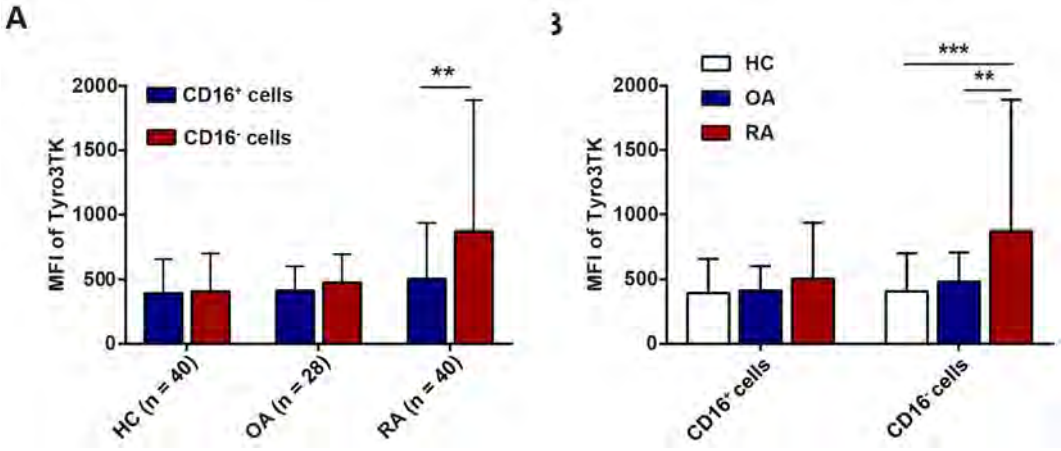
Upregulation of Tyro3TK on $CD14^+CD16^-$ Monocytes Promotes Osteoclast Formation in Rheumatoid Arthritis

Jimeng Xue[1], Liling Xu[1], Fanlei Hu[1] and Yin Su[2], [1]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing Key Laboratory for Rheumatism Mechanism and Immune Diagnosis (BZ0135), Beijing, China, Beijing, China (People's Republic), [2]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The study aimed to investigate the expression and clinical significance of Tyro3TK on $CD14^+CD16^+$ and $CD14^+CD16^-$ monocyte subsets and explore the effect of Tyro3TK on osteoclast formation in rheumatoid arthritis (RA).

Methods: Osteoclasts were induced by $CD14^+CD16^+$ and $CD14^+CD16^-$ monocyte subsets isolated from healthy control (HC) and RA in vitro, and evaluated by tartrate-resistant acid phosphatase (TRAP) staining. Then, the expression of Tyro3TK on $CD14^+CD16^+$ and $CD14^+CD16^-$ monocyte subsets were evaluated in peripheral blood of RA by flow cytometry, and the correlation between the expression of Tyro3TK on $CD14^+CD16^+$ and $CD14^+CD16^-$ monocyte subsets with RA patient clinical data were analyzed. At last, the role of Tyro3TK on $CD14^+CD16^-$ monocyte in RA patient osteoclastogenesis was further performed by osteoclast differentiation assay.



The expression of Tyro3TK on CD14+CD16- monocytes is increased in RA. (A) The expression of Tyro3TK on CD14+CD16+ and CD14+CD16- monocytes in HC (n = 40), OA (n = 28), and RA patients (n = 40, **P = 0.008) were analyzed, and presented as mean fluorescence intensity (MFI). (B) The expression of Tyro3TK on CD14+CD16+ monocytes and CD14+CD16- monocytes were compared between HC, OA, and RA patients (**P = 0.008, ***P < 0.001).

Results: The results revealed that $CD14^+CD16^-$ monocytes were the main source of osteoclasts. The expression of Tyro3TK on $CD14^+CD16^-$ monocytes was significantly upregulated in RA patients as compared with HC and osteoarthritis (OA) patients, which was positively correlated with the disease manifestations. Moreover, anti-Tyro3TK antibody could dose-dependently inhibited Gas6-mediated osteoclast differentiation in $CD14^+CD16^-$ monocytes.

Conclusion: These findings indicate that elevated Tyro3TK on $CD14^+CD16^-$ monocytes serves as a critical signal for osteoclast differentiation in RA, but its mechanism needs to be further studied.

Identification of Recruited CCR2+ Inflammatory Monocytes in a Mouse Model of RA-associated Lung Disease with Potential Role for resolvin-D1 in Reducing Monocyte Inflammatory Responses

Austin Barry[1], Geoffrey Thiele[1], Ted Mikuls[1], Michael Duryee[1], Amy Nelson[1], Rohit Gaurav[1], Bryant England[1] and Jill Poole[1], [1]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at an increased risk for comorbid chronic lung disease, with premature mortality. Therapies for RA-associated lung disease are limited. Organic dust extract (ODE)-induced airway inflammation model was previously combined with the collagen-induced arthritis (CIA) model to model RA-related lung disease. The combination of CIA+ODE resulted in increased arthritis severity and higher levels of an-

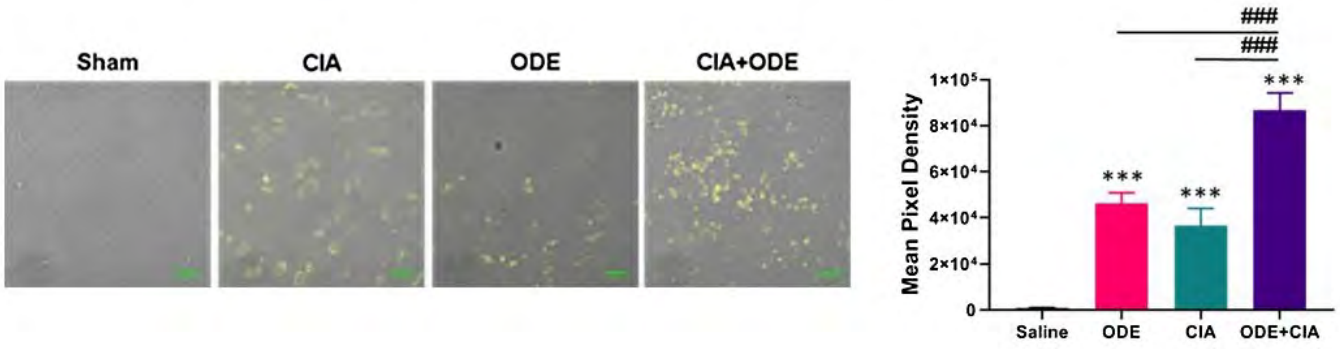

Figure 1. CCR2+ monocytes are increased with ODE and CIA treatment conditions in murine lungs. Representative image (1 of 5) of CCR2 expression (yellow) of lung tissue from each treatment group. Bar graph depicts mean with standard error bars of CCR2 staining (N=5). Statistical difference ***p<0.001 vs. saline/sham control and ###p<0.001 denoted by line between groups

ti-malondialdehyde-acetaldehyde (MAA) and anti-cyclic citrullinated (CIT) protein antibodies (vs. CIA or ODE alone). Co-exposure also promoted pro-fibrotic lung inflammatory features. $CCR2^+$ monocytes migrate to lung tissues under inflammatory conditions to influence inflammatory fibrotic consequences and may be a target for therapies. We aimed to determine whether $CCR2^+$ monocytes were recruited to the lungs in this mouse RA-lung disease model, and whether anti-inflammatory omega-3 fatty acid derivatives (DHA, resolvin-D1, and maresin-1) would reduce inflammatory responses *in vitro* from monocyte stimulation with ODE and/or autoreactive antigens.

Methods: Arthritis prone DBA/1J mice were assigned to 1 of 4 groups: Sham (saline injection/saline inhalation), CIA (CIA injection/saline inhalation), ODE (ODE inhalation/saline injection), or CIA+ODE treatment for 5 weeks as previously established. CCR2 expression was quantified using confocal microscopy in murine lung sections. In cell culture studies, human THP-1 monocytes were exposed to varying doses of: ODE, CIT peptides, and MAA-adducted protein, and the combination of ODE + autoantigens. In parallel experiments, cells were pre-treated for one hour with docosahexaenoic acid (DHA) or its metabolites (maresin-1 and resolvin-D1) before stimulation. TNF-α was quantitated in cell-free culture supernatant by ELISA.

Results: In animal studies, CCR2 expression was significantly increased in lung tissues of treated animals CIA+ODE >CIA >ODE vs. sham (Figure 1; N=5 mice/group). In monocyte studies, TNF-α levels were significantly increased following stimulation with ODE (mean ± SEM pg/ml; 1104.2 ± 91.7), MAA (167.8 ± 19.3), and CIT (75.7 ± 22.4) as compared to control (7.4 ± 4.0) (N=9; $p< 0.05$). No additive effects were demonstrated when agents were combined. Pretreatment with resolvin-D1 significantly reduced ODE-induced TNF-α at 4 hours (75% reduction) and reduced MAA (58%) and CIT (55%) stimulated TNF-α release at only 48 hours. Pretreatment with DHA or maresin-1 did not reduce ODE or autoantigen stimulated TNF-α release. No cytotoxicity was detected with respective treatments.

Conclusion: Arthritis induction promotes the recruitment of $CCR2^+$ monocytes to the lung and this response is augmented by airborne biohazard exposures to suggest that targeting recruited inflammatory monocytes may be a potential strategy. Reduction in TNF-α levels with resolvin-D1 pretreatment in monocytes strengthens the need of future *in vivo* studies to define whether specific dietary interventions focused on the omega-3 fatty acid resolvin-D1 might help in the prevention and/or treatment of RA-related lung disease..

Session Title: RA – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

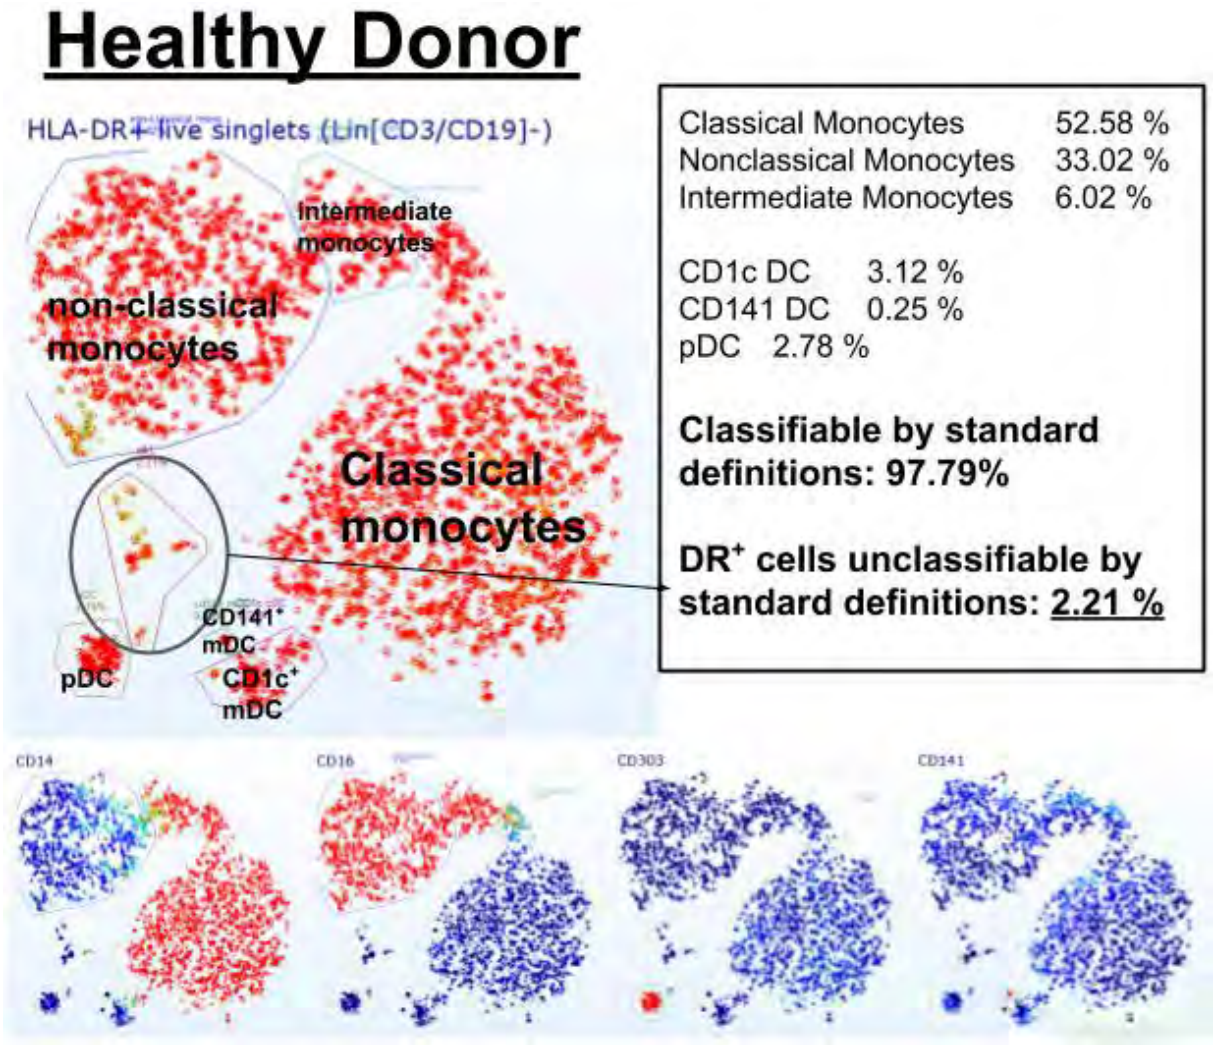

Figure 1. Example of t-distributed Stochastic Neighbor Embedding (t-SNE) guided manual annotation of high-dimensional flow cytometry data of a healthy blood donor. Non-lymphoid cells with antigen-presenting potential (DR positive, Lin negative) can be classified into established lineages in 97.79%. Bottom row shows color coded overlays of expression intensity (red positive, blue negative) of select monocyte and DC markers (CD14, CD16, CD303, CD141). Dimensions not shown: CCR2, XCR1, CD1c, CD11c, CD45RA, CD56, CD163, CD123, CD172a (SRPα)

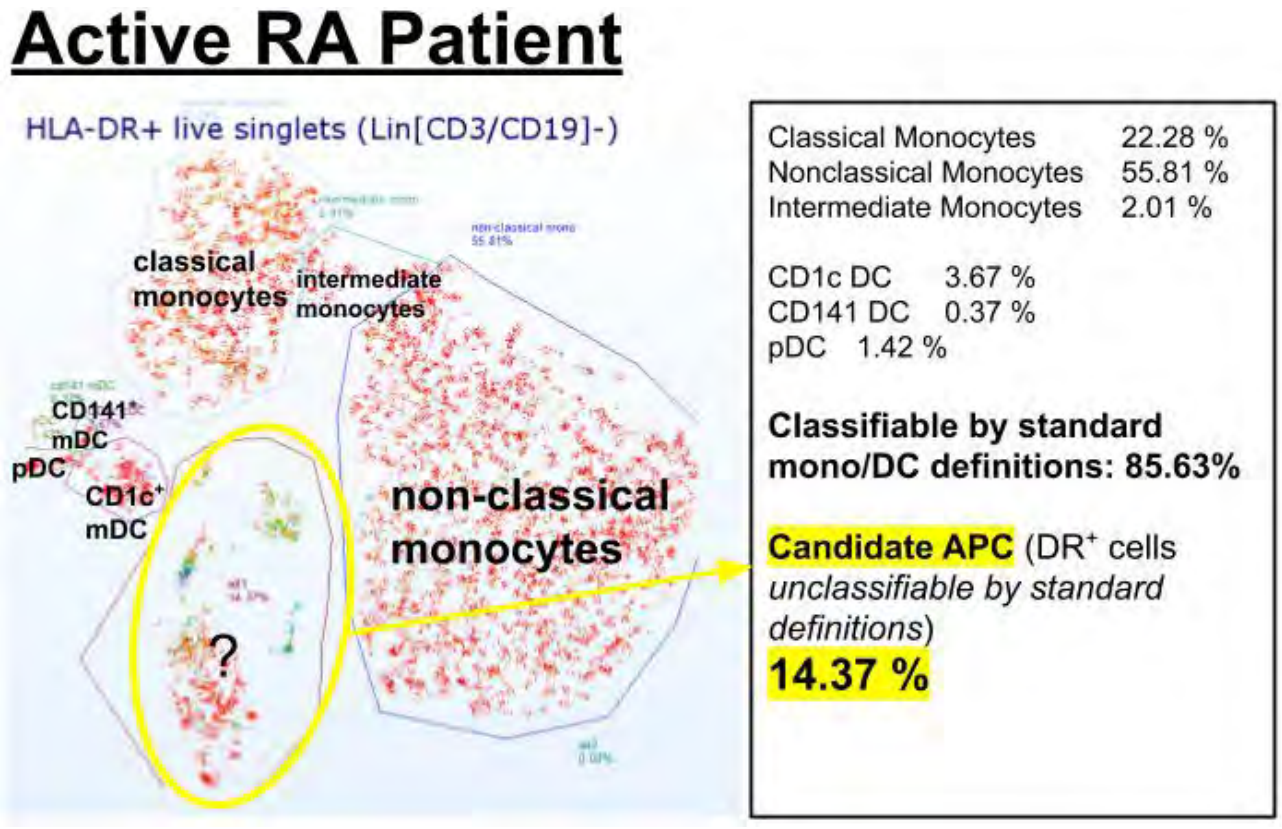

Figure 2. Example of t-SNE guided manual annotation of flow cytometry data of an active RA patient (CDAI 29), showing the emergence of 14.37% of phenotypes with antigen-presenting potential (HLA-DR positive) which are unclassifiable using standard definitions (candidate APC).

Background/Purpose: The presentation of MHC-peptide complexes to T lymphocytes via antigen-presenting cells (APC) is a crucial step in the initiation of immune responses. Dendritic cells (DC) are potent APC with remarkable plasticity that are classically divided into DC1 (141^+), DC2 ($1c^+$) and plasmacytoid (pDC) subsets. Decreases in these classic blood DC occur in patients suffering from autoimmune conditions including RA. We have previously reported that in RA, peripheral decreases of DC2 are strongly associated with clinical RA features including measures of cardiovascular disease (CVD), the main driver of RA related mortality. We reasoned that — given the importance of DC in immune activation — their apparent decrease might be more adequately explained by phenotypic alteration rather than 'true' disappearance. We hypothesized that this highly plastic compartment under inflammatory conditions might harbor alternative phenotypes that lack classic combinations of DC markers while retaining potential APC function (HLA-DR).

Methods: Patients with RA and SLE — two prototypical autoimmune rheumatic diseases (ARD) — and healthy donors (HD) underwent immunophenotyping; to capture the presumed candidate APC we first gated all viable HLA-DR^+ cells. By eliminating the lymphoid lineage ($CD3^-$,$CD19^-$) we created an HLA-DR^+Lin^- superset containing classic DCs, monocytes and candidate APC. We next classified HLA-DR^+Lin^- cells into established non-lymphoid APC [classic DC and Monocyte] by using a combination of t-distributed stochastic neighbor embedding (t-SNE) and manual annotation. HLA-DR^+Lin^- cells that did not meet established APC criteria we designate candidate APC. To screen for common characteristics across patients within this subset we performed Uniform Manifold Approximation and Projection (UMAP).

Results: Strikingly, candidate APC were higher in ARD (n=21) (7.3% vs. 3.9%; [median %DR+, Kruskall-Wallis tests), particularly SLE (11.8% vs 3.9%; p=0.01). UMAP of RA cAPC identified a dominant cluster of $CD45RA^+CD14^{lo}$ as a feature present across RA samples. $CD14^{int}CCR2^+$ cAPC represented a second major cluster. Confirming traditional

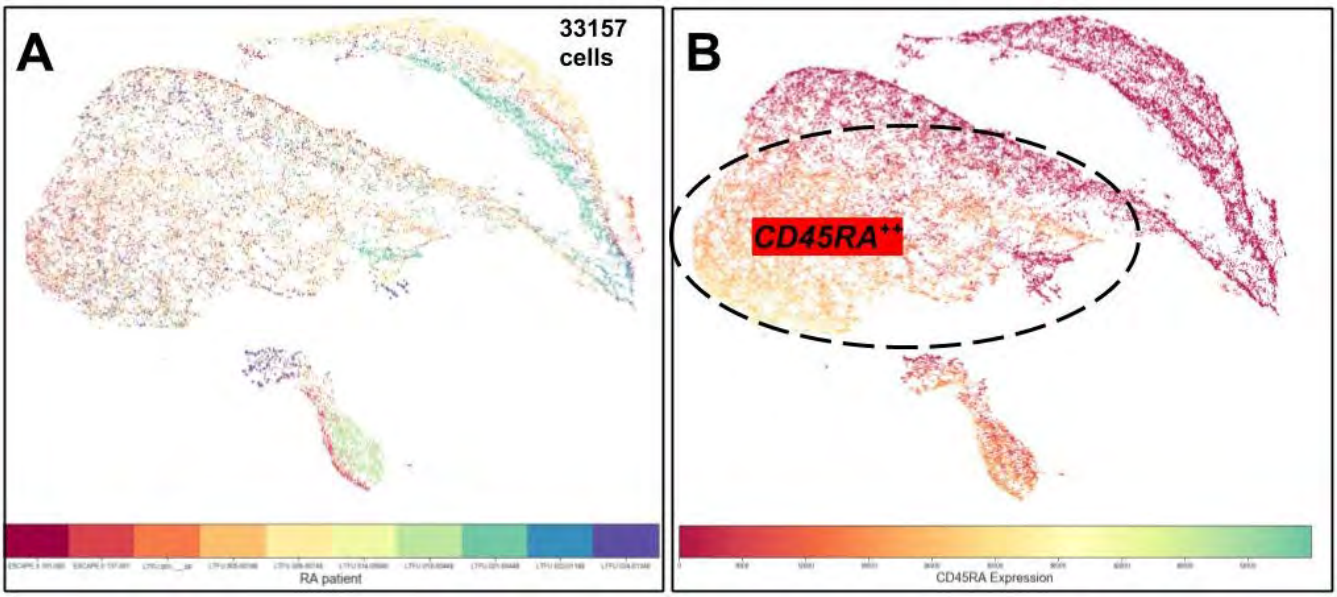

Figure 3. Uniform Manifold Approximation and Projection (UMAP) using 33157 candidate APC which were concatenated from 10 RA patients. A. Color coded by donor, showing three main clusters with cells derived from multiple donors. B. Same UMAP Heat-coded overlay showing expression of CD45RA in majority of the dominant cluster. Dimensions not shown: CD14, CD16, CD141, 303, CCR2, XCR1, CD1c, CD11c, CD45RA, CD56, CD163, CD123, CD172a (SRPα).

gating approaches, DC classical subsets were decreased in ARD when compared with HD (n=10): DC1 0.1% vs 0.4% (p=0.01), DC2 2.6% vs 5.3% (p=0.03) and pDC 1.5% vs 2.9% (p=0.03). Classical ($CD14^+CD16^-$) monocytes were not different (p=0.19) whereas intermediate monocytes ($CD14^+CD16^+$) were higher in RA than SLE and HD (13.2% vs. 8.9% vs. 6.2; p=0.01).

Conclusion: Using a combination of dimensionality reduction techniques on an unbiased $HLA\text{-}DR^+Lin^-$ APC superset we observed the appearance of $HLA\text{-}DR^+$ candidate APC. These cells do not conform to traditional APC gating definitions and were increased in ARDs relative to healthy controls. Their dominant cluster showed widespread expression of CD45RA suggesting, despite lack of CD1c expression, a developmental relationship with DC2. CD14/CCR2 co-expression was seen in three patients, supporting a relationship to monocyte-derived DC in these individuals. The novel subsets may be implicated in the pathophysiology of ARDs including RA associated cardiovascular disease, potentially via anomalous presentation of self-antigen to T lymphocytes..

MerTK Synovial Expression Correlates with Disease Activity and Treatment Response in Rheumatoid Arthritis Patients

Alessandra Nerviani[1], Marie-Astrid Boutet[1], Giulia Maria Ghirardi[2], Gloria Lliso-Ribera[2], Felice Rivellese[1], Myles Lewis[1], Michele Bombardieri[2], Frances Humby[2] and Costantino Pitzalis[2], [1]Centre for Experimental Medicine and Rheumatology, Queen Mary University of London, London, United Kingdom, [2]Queen Mary University of London, London, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite valuable improvements in long-term clinical outcomes, a significant portion of rheumatoid arthritis (RA) patients still do not adequately respond to available treatments, and early prognostic biomarkers of response are missing. Single-cell transcriptomic studies on RA synovial tissue (ST) revealed that MerTK is highly expressed in "anti-inflammatory" macrophages [1]. Moreover, synovial macrophages isolated from RA patients in remission show a typical CD206+/MerTK+ signature [2]. Finally, monocyte-derived macrophages from RA patients treated with TNF-inhibitors (TNF-i) up-regulate MerTK on their surface.

In this study, we aim at i) assessing the modulation of synovial tissue MerTK+ macrophages upon treatment with conventional synthetic (cs) disease-modifying anti-rheumatic drugs (DMARDs) and ii) evaluating the relationship between baseline MerTK synovial gene expression and future response to TNFi.

Methods: Patients with early (< 12 months) treatment-naïve RA (as per ACR/EULAR 2010 criteria) underwent a US-guided synovial biopsy of an inflamed peripheral joint at baseline and a second biopsy of the same joint six months after starting treatment with single or multiple csDMARDs. ST was collected and used for histology and RNA extraction. ST (n=15) was stained for CD68, MerTK and CD206 by immunofluorescence using a tyramide amplification signal system. The percentage of single- (MerTK+ or CD206+) and double-positive (CD206+MerTK+) CD68+ macrophages was quantified by digital image analysis (Image J). Gene expression analysis was performed on RNA sequences of 22 baseline ST-samples (treatment-naïve).

Results: Before treatment, the percentage of MerTK+CD206+ macrophages was significantly higher in RA patients with low (DAS28< 3.2) versus high (DAS28 >5.1) disease activity (24.5±20.1 versus 4.8±4.8, p< 0.05). No differences were detected in the relative number of MerTK+ or CD206+ or MerTK+CD206+ macrophages at baseline in relationship with the clinical response to csDMARDs at 6-months. Patients (n=5) achieving remission (DAS< 2.6) at 6-months significantly increased the number of MerTK+ macrophages from baseline in comparison with patients (n=5) who were still active post-treatment (23.6±23.8 to 55.5±15.4, p< 0.05 versus 18±15.6 to 30.4±11.17, p=ns). MerTK synovial gene expression at baseline (i.e., in newly diagnosed treatment-naïve RA patients) was significantly higher in patients who subsequently responded to TNFi (n=14, good/moderate EULAR) in comparison with those who did not respond (n=8) (p = 0.003).

Conclusion: Our whole-tissue expression data further corroborate the hypothesis that a selective expansion of the MerTK+ macrophage subset defines patients achieving remission. Moreover, the up-regulation of the MerTK gene at baseline in patients future responders to TNFi suggest that MerTK is involved in modulating synovial inflammatory responses and might be exploited as a therapeutic target in RA.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The mucosal microbiome contributes to disease pathogenesis via local and systemic interaction with the host. The hallmark of this interaction in the physiological condition is the varying ability of bacterial products to translocate into the circulation via mucosa. Thus, the blood microbiome is important to investigate microbial-host interactions and the effects on systemic immune perturbations. However, this effort has met with major challenges due to low microbial biomass and background artifacts.

Methods: In the current study, microbial 16S DNA sequencing was applied to analyze the plasma microbiome. We have developed a quality-filtering strategy to evaluate and exclude low levels of microbial sequences, potential contaminations, and artifacts from plasma microbial 16S DNA sequencing analyses. Furthermore, we have applied our technique in individuals with systemic lupus erythematosus (SLE) and corresponding healthy controls.

Results: We first analyzed the potential contamination sources from the collection of blood samples, microbial DNA extraction, to microbial DNA sequencing. Notably, the β-diversity of plasma microbial 16S rDNA was significantly

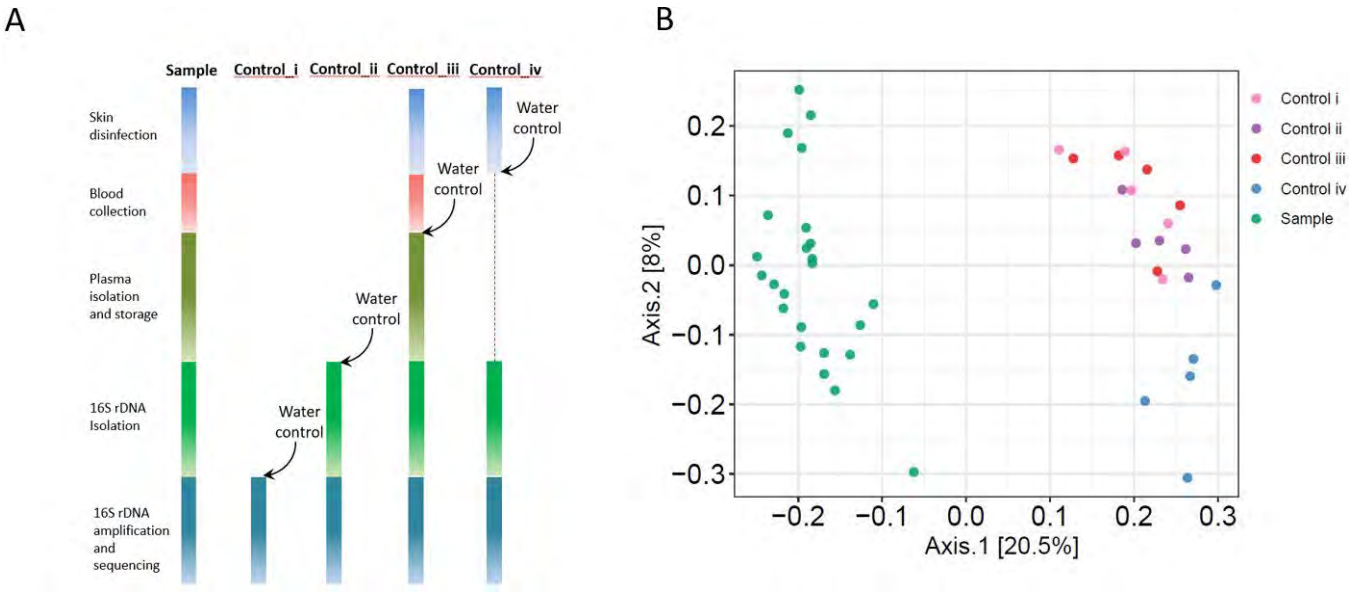

Figure 1. Overall 16S rDNA plasma microbiome analysis. (A) A workflow diagram is shown to collect blood samples and each control. (B) Principal coordinate analysis (PCoA) was conducted based on the unweighted UniFrac distance to determine the beta diversity of plasma microbial community among each controls and plasma samples.

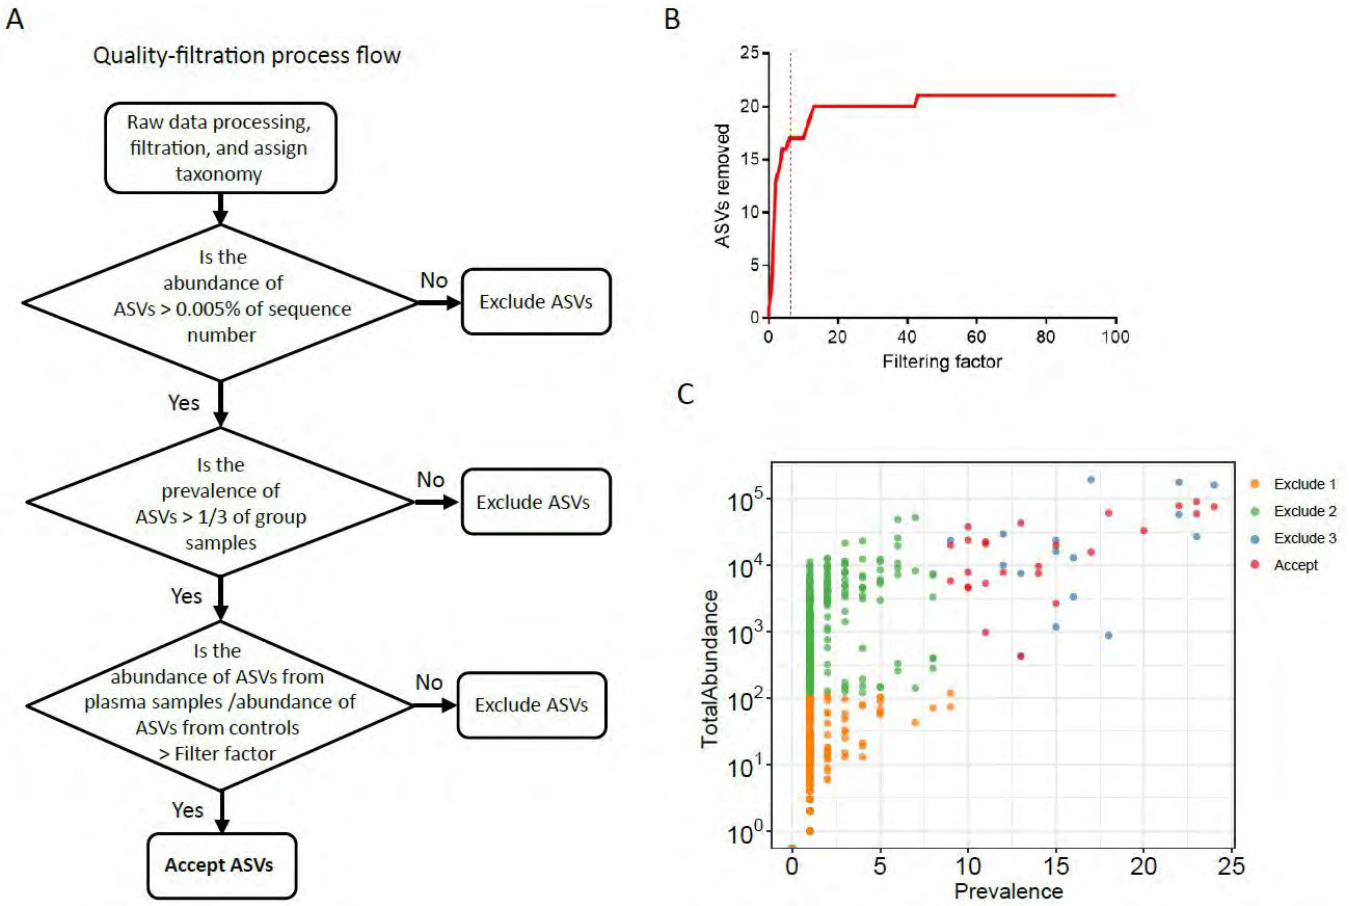

Figure 2. Strategies for removing background and potential artifacts from plasma microbiome. (A) A workflow diagram of user-defined quality-filtering strategy to exclude the background and artifacts. (B) The number of removed amplicon sequence variants ASVs with different filtering factors, we chose the filtering factor of 6 which showed the lowest number of removed ASVs during the plateau effect. (C) The abundance and prevalence of ASVs in each step of filtration. The "exclude 1" step is removing low abundance of ASVs across samples, in which a 0.005% minimum abundance threshold was applied. The "exclude 2" step is removing low prevalence of ASVs in each sample; we retained ASVs only if its prevalence was more than 1/3 across study groups. If the prevalence of ASVs was lower than 1/3 in both control and case groups, it would be removed, because it was not considered the representative disease associated ASVs. The "exclude 3" step is removing potential contaminants and artifacts using filtering factors.

different from those of the controls ($P < 0.001$, Multivariate Welch *t*-test, Figure 1). To identify the microbial amplicon sequence variants (ASVs) that are associated with disease pathogenesis, 97%-99% of total sequence data was removed using stringent quality-filtering strategy analyses; those removed ASVs were low levels of microbial sequences, contaminations, and artifacts (Figure 2). The specifically enriched pathobiont bacterial ASVs have been identified in plasmas from individuals with SLE but not from the control subjects (Nonparametric Mann-Whitney's *U* tests, Figure 3). The associations between these ASVs and plasma levels of SLE-related autoantibodies were demonstrated (Spearman correlation tests, $P < 0.05$, Figure 3).

Conclusion: The whole-genome sequencing technique has been applied to analyze the blood microbiome (Poore GD, et al, Nature, 2020); in this study, more than 90% of total sequence data was removed after decontamination analysis. In the current study, we present a quality-filtering strategy to identify abundant plasma microbial ASVs. This strategy can be used to discover translocated microbial DNAs that correlate with biological conditions. Our approach provides a cost-saving method for the diagnosis of subclinical microbial infection as well as for understanding the roles of microbiome-host interaction in disease pathogenesis.

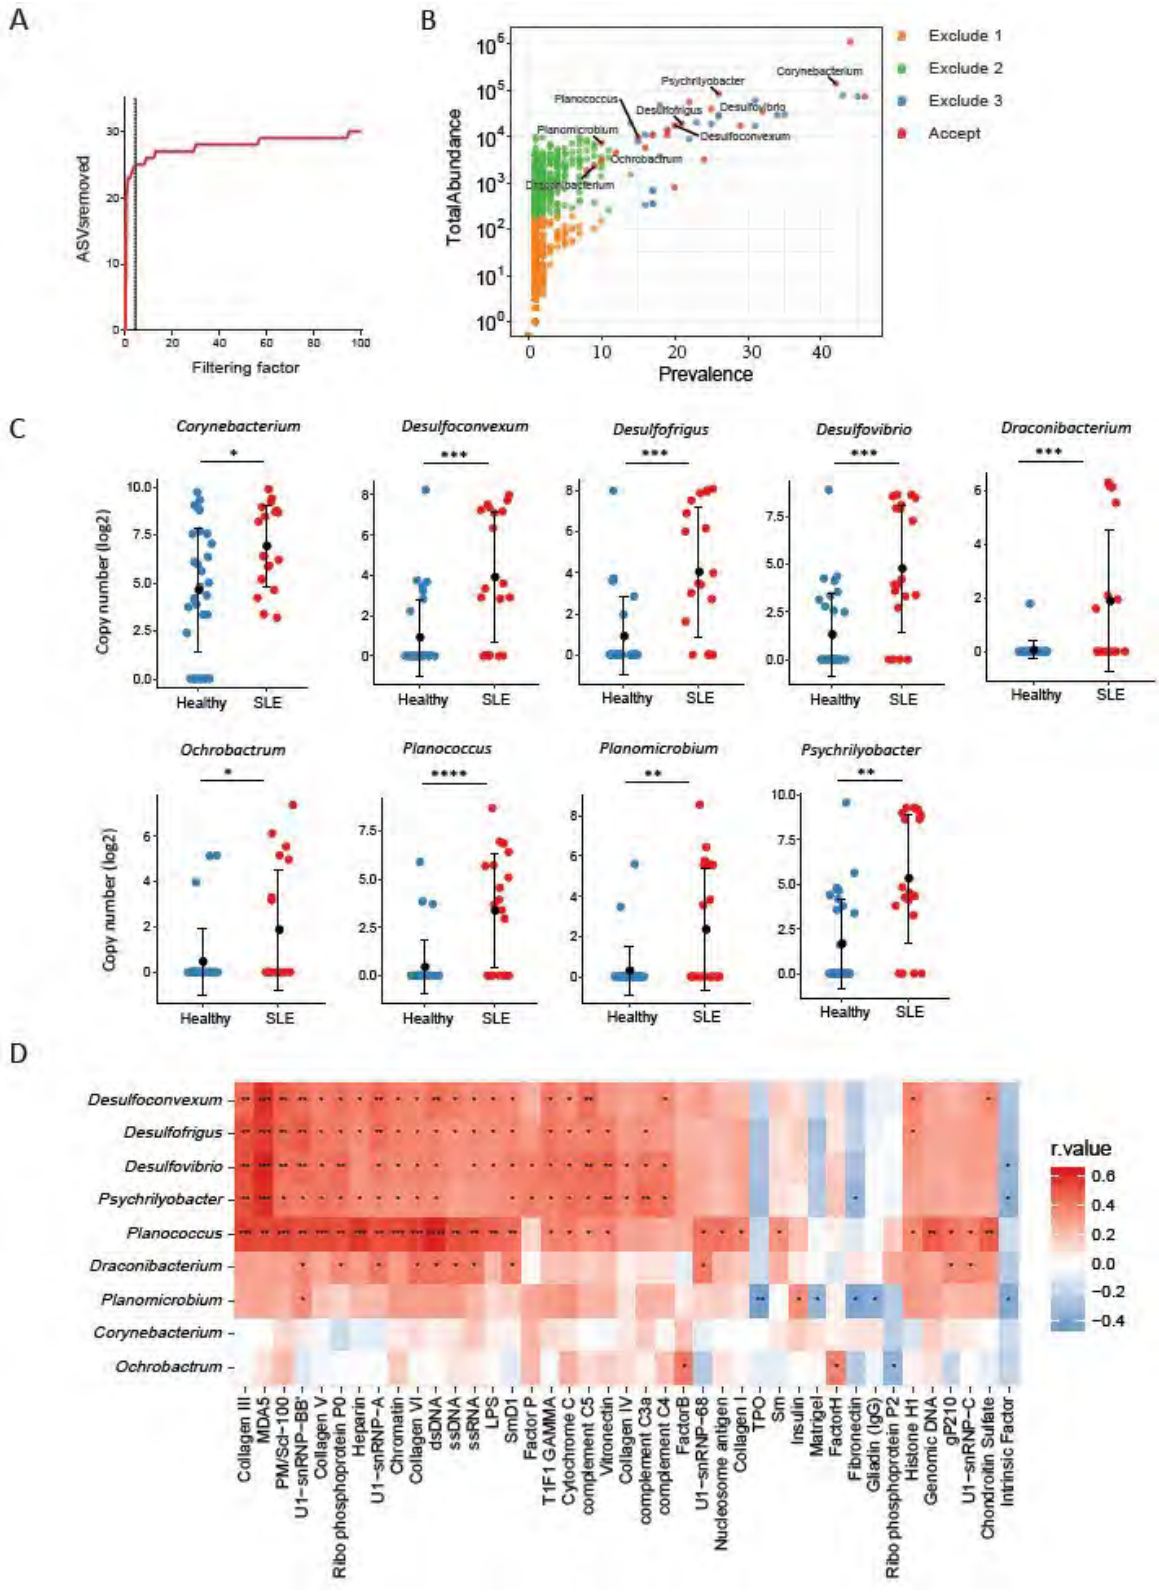

Figure 3. Plasma microbiome in female SLE patients and healthy female controls. (A) The number of removed ASVs with different filtering factor, we chose the filtering factor of 3 which showed the lowest number of removed ASVs during the plateau effect. (B) The abundance and prevalence of ASVs in each step of plasma microbiome filtration are shown, and the significantly different taxa in SLE patients compared with healthy controls are labeled in black (enriched in SLE patients). (C) The significantly different taxa in SLE patients compared with healthy controls. (D) Correlations between plasma levels of autoantibodies and differential plasma taxa levels in the two study groups. Correlation coefficient r values are indicated by color from red (directly correlations) to blue (inversely correlations); p-value significance is shown in the heatmap. Matrix Gla Protein (MGP) Modified with Malondialdehyde/Acetaldehyde Is Increased in Rheumatoid Arthritis and Cardiovascular Patients

Xiarepati Tieliwaerdi[1], Nozima Aripova[1], Michael Duryee[1], Xiaoting Jiang[1], Lynell Klassen[2], James O'Dell[1], Bryant England[1], Daniel Anderson[1], Ted Mikuls[1] and Geoffrey Thiele[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Univerisity of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased cardiovascular disease (CVD) burden, dramatically increasing the risk of mortality. Circulating antibodies to Malondialdehyde-Acetaldehyde (MAA) modified proteins have been found in patients with RA and CVD. MAA-modified protein adducts have also been identified in RA joint tissues, atherosclerotic lesions, and plaques. However, the proteins found in these tissues have been difficult to identify. Matrix gla protein (MGP) is a robust inhibitor of calcification, binds calcium, is a constituent of atherosclerotic lesions and is thought to play a pathogenic role in CVD. The purpose of this study to determine if MAA-modified MGP is present in both RA and CVD tissues.

Methods: Joint tissues from 3 RA and 3 OA controls, along with 3 aortic lesions and 3 plaques obtained from patients with cardiovascular disease (CVD), were stained by immunohistochemistry (IHC) for the presence of MAA and MGP using zenon labeled 405 and 568 antibodies, respectively. Human vascular smooth muscle cells (VSMC) were

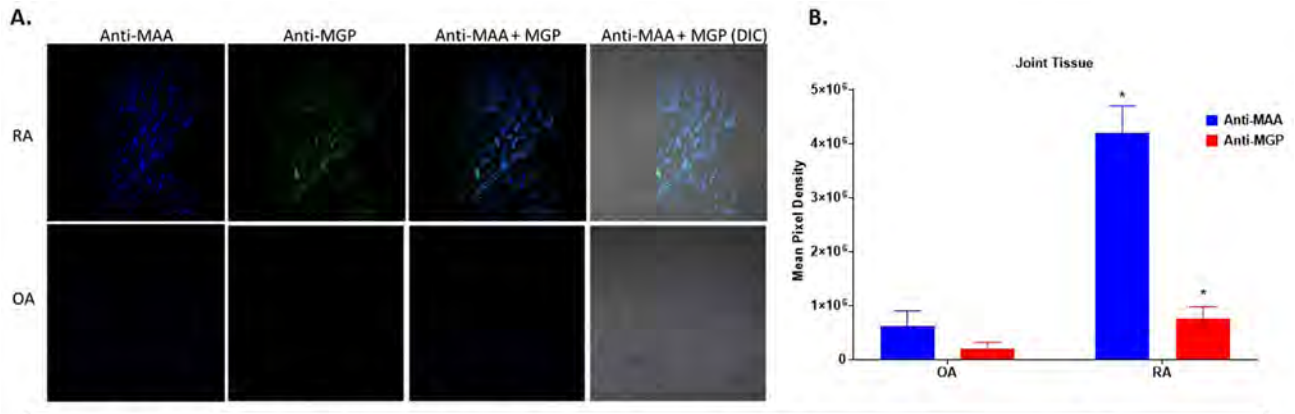

Figure 1. Anti-MAA and Anti-MGP Staining in Joint Tissue from OA and RA Patients. Joint tissue from OA and RA patients was IHC stained for the presence of MAA and MGP antigens. Detection of antibodies was done using a Ziess 710 confocal microscope and images analyzed using Image J. MAA antigens were significantly present in the RA joint tissue ($p<0.0001$) compared to the OA controls. MGP antigen were significantly present in the RA joint tissue ($p<0.05$) compared to the OA controls. Image J Coloc2 software revealed R^2 value of 0.71 when comparing MAA to MGP for colocalization. (A) Raw confocal images from OA and RA joint tissues. (B) Mean pixel density of calculated images. N=6

Figure 1

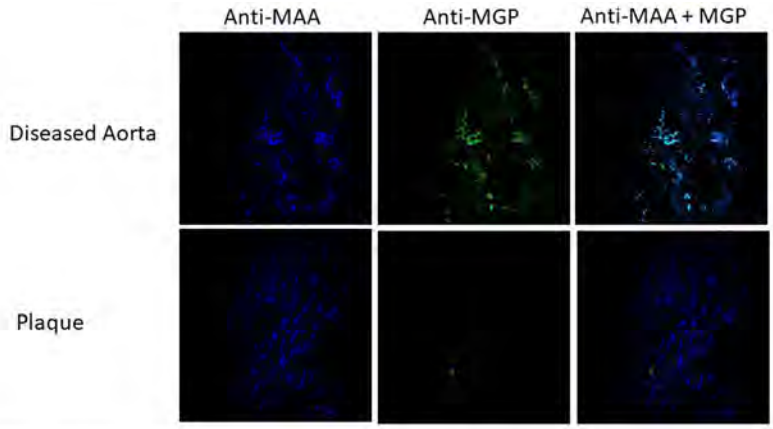

Figure 2. Anti-MAA and Anti-MGP Staining in Diseased Aorta and Plaque from Cardiovascular Patients. Aortic and plaque tissue from CVD patients was IHC stained for the presence of MAA and MGP antigens. Detection of antibodies was done using a Ziess 710 confocal microscope and images analyzed using Image J. MAA and MGP antigens were increased in all tissues. Image J Coloc2 software revealed R^2 value of 0.53 for diseased aorta and 0.45 for plaque when comparing MAA to MGP for colocalization. Representative images of 3 separate tissues.

Figure 2

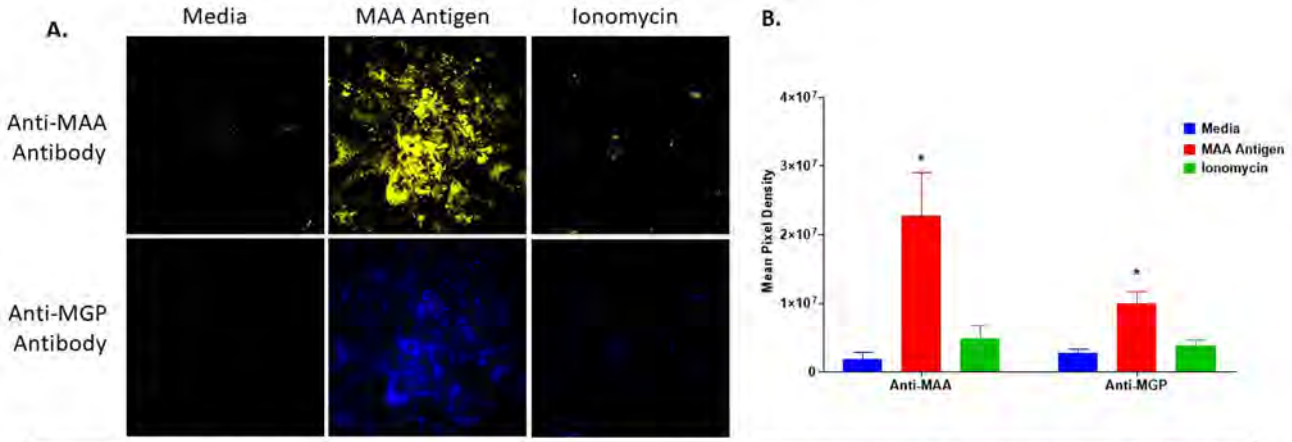

Figure 3. Anti-MAA and Anti-MGP Staining in Vascular Smooth Muscle Cells Stimulated with Acetaldehyde (AA) and Malondialdehyde (MDA). Vascular smooth muscle cells (VSMC) were incubated in the presence of 0.5mM MDA and 0.25mM AA, media only, and ionomycin for 24 hours to induce MAA protein antigens. Cells were washed and IHC stained for the presence of MAA and MGP antigens. Detection of antibodies was done using a Ziess 710 confocal microscope and images analyzed using Image J. MAA antigens were significantly present in the VSMC incubated with AA and MDA ($p<0.0001$) compared to controls. MGP antigen was significantly present in the VSMC incubated with AA and MDA ($p<0.01$) compared to controls. Image J Coloc2 software revealed R^2 value of 0.93 when comparing MAA to MGP for colocalization. (A) Raw confocal images from VSMC. (B) Mean pixel density of calculated images. N=8.

Figure 3

incubated in the presence media, ionomycin, or MAA precursors, malondialdehyde (MDA; 0.5mM) and 0.25mM acetaldehyde (AA; 0.25mM), for 24 hours, fixed and stained for MGP and MAA using specific antibodies. A Ziess 710 confocal microscope was used to determine antibody reactivity and images analyzed using Image J for mean pixel density to quantitate the amount antibody present in tissue sections. For colocalization, Image J Coloc2 plug in was used to generate a correlation coefficient as means of quantifying the magnitude of overlapping colors.

Results: MAA expression was significantly increased in RA joint tissues ($p < 0.0001$) compared to joint tissues of OA controls. Likewise, MGP was expressed significantly more ($p < 0.05$) in RA joint tissues vs. OA controls (Figure 1). Co-localization of ($r = 0.71$) was present between MGP and MAA in the RA tissues. Although less than that seen in RA joint tissues, MGP was also co-localized with MAA in aortic lesions and plaques ($r = 0.53$; $r = 0.45$ Figure 2). Human VSMC incubated with MAA precursors demonstrated increased ($p < 0.0001$) expression of both MAA antigen and MGP ($p < 0.01$) compared to media or ionomycin controls (Figure 3) with evidence of strong MAA/MGP co-localization ($r = 0.93$).

Conclusion: Previous studies have shown that MAA-modified antigen characterizes diseased tissues in both RA and CVD. To date, however, identification of the precise proteins are MAA-modified in these lesions is unknown. Findings from this study suggest that MGP, a calcium binding protein, is present in diseased tissues in both RA and CVD and appears to be MAA adducted. Indeed, findings using human tissues were confirmed with *in vitro* experiments identifying MGP as a target for MAA modification. As MAA modification has been shown to alter the biologic function of other proteins, it is possible that MAA adduction could similarly alter MGP function, increasing calcium binding, causing tissue calcification, or impacting other calcium-dependent pathways. The presence of this unique protein modified with MAA in both RA and CVD tissue could be a potential link between the two diseases providing a mechanism as to why patients with RA experience a higher comorbidity with CVD.

Background/Purpose: Rheumatoid arthritis (RA) is a complex autoimmune disease whose etiology remains largely unknown. Vitamin D has been widely studied due to its association with numerous autoimmune diseases such as systemic lupus erythematous, multiple sclerosis, and type 1 diabetes. Genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) that are associated with levels of 25-hydoxyvitamin D3 ($25(OH)D_3$) (Jiang et al). We hypothesize that a polygenetic risk score (PRS) comprised of alleles from SNPs associated with in-

creasing levels of serum 25(OH)D_3 will be inversely associated with the presence of RA autoantibodies (aAbs) among at-risk first-degree relatives (FDRs) of RA subjects.

Methods: The FDR study population was derived from the prospective Study of the Etiologies of Rheumatoid Arthritis (SERA). We tested the following RA-related aAbs; anti-CCP2, anti-CCP3.1, RF-neph, RF IgA, RF IgM, and RF IgG. We selected 189 non-Hispanic white (NHW) FDRs that tested positive for any aAb (aAb+) and compared them to 181 NHW FDRs that tested negative for all autoantibodies (aAb-). FDRs were genotyped using the Illumina MEGA^{EX} BeadChip per Illumina protocols. Five SNPs associated with serum 25(OH)D_3 levels were analyzed individually as well as in a PRS: rs4588 (GC), rs12785878 (NADSYN1), rs10741657 (CYP2R1), rs6538691 (AMDHD1), and rs8018720 (SEC23A). A proxy SNP (R^2=1.0) was chosen if the GWAS identified SNP was not typed on the MEGAchip. The PRS was calculated by summing the number of copies of the allele associated with increasing serum 25(OH)D_3 and ranged from 0 to 10. The PRS was also analyzed as a dichotomous variable (high PRS ≥5 v. low PRS < 5). In a subset of the cohort on whom we had previously measured 25(OH)D_3 (N=28), we tested whether the PRS was associated with

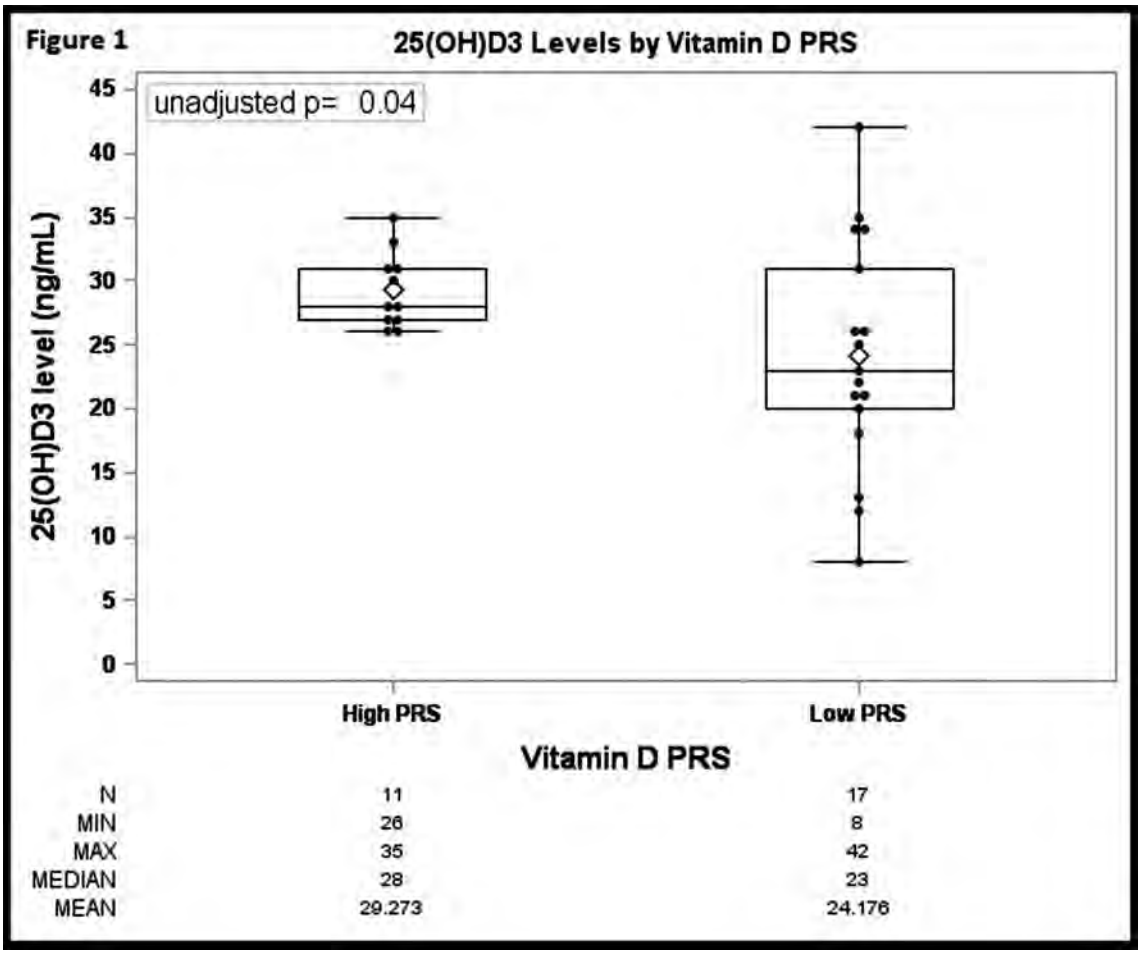

Figure 1. Comparison of mean 25(OH)D3 serum levels by high and low PRS. Subjects with a high vitamin D PRS (≥5 alleles associated with increasing 25(OH)D3 levels) had significantly higher levels of serum 25(OH)D3 (p=0.04).

25(OH)D_3 levels. Logistic regression models were used to test the association between each individual SNP and the PRS variables with the aAb+ outcome. We tested the additive interaction between the SNPs or PRS and vitamin D supplement use.

Results: The aAb+ subjects were significantly older and more likely to be male compared to the aAb- subjects (Table 1). High PRS was associated with higher levels of 25(OH)D_3 compared to low PRS (unadjusted p=0.04 and adjusted for season of blood draw p=0.08, Figure 1). We observed a significant inverse association between the SEC23A SNP rs8018720 and RA aAb+. In addition, both PRS variables were inversely associated with RA aAb+ (Table 2). There was no evidence of an additive interaction between SNPs and vitamin D supplement use.

Conclusion: A higher vitamin D PRS (reflecting higher 25(OH)D_3 levels) was inversely associated with RA aAb+. This finding indicates that genes associated with vitamin D regulation may play a protective role in the development of RA aAbs. In particular, the SEC23A SNP may be of interest for future investigation since it was the only vitamin D related SNP individually associated with the aAb+ outcome.

Peficitinib Inhibits Angiogenesis via Suppression of VEGF Production in Rheumatoid Arthritis Fibroblast-like Synoviocytes

Yuzo Ikari[1], Takeo Isozaki[1], Kuninobu Wakabayashi[1] and Tsuyoshi Kasama[2], [1]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan, [2]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Koutou-ku Tokyo, Japan

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Peficitinib is a novel Janus kinase (JAK) inhibitor developed for the treatment of rheumatoid arthritis (RA). Peficitinib has approved in 2019 in Japan, but elucidation of its mechanism of action in RA involving the inflammatory process is still inadequate. So far, we clarified JAK1, JAK2 and JAK3 were expressed in RA synovial tissue and fibroblast-like synoviocytes (FLS), and peficitiib suppress the activation of JAK-STAT pathway on RA FLS. In this study, we examined the role of peficitinib in RA angiogenesis.

Methods: To examine the functional analysis of peficitinib, we performed a proliferation and chemotaxis assays with FLS using THP-1 (human acute monocyte leukemia cell line) and peripheral blood mononuclear cells (PBMC). RA FLS supernatant was obtained from RA FLS-conditioned medium stimulated with IL-6 (100 ng/ml) and IL-6R (100 ng/ml) with or without adding peficitinib (5 μM). RA FLS were stimulated with IL-6 and IL-6R after treated peficitinib for 24 h. Next, to evaluate the effects of peficitinib on RA angiogenesis, we performed in vitro Matrigel tube formation assays using human umbilical vein endothelial cells (HUVECs). Finally, we investigated whether peficitinib suppresses the secretion of FLS inflammatory mediator using ELISA kit. The amounts of VEGF, RANTES/CCL5, MCP-1/CCL2, MMP-3, fractalkine/CX3CL1, ENA78/CXCL5 and IL-8 in IL-6 and IL-6R stimulated peficitinib treated RA FLS conditioned medium were determined.

Results: We found peficitinib treated RA FLS conditioned medium reduced THP-1 migration compared to nontreated RA FLS conditioned medium (number of THP-1 cells migrated ± SEM; 42 ± 3 and 66 ± 6 cells migrated, respectively, $p< 0.05$). Peficitinib treated RA FLS conditioned medium also reduced PBMC migration compared to nontreated RA FLS conditioned medium (number of PBMC migrated ± SEM; 36 ± 5 and 63 ± 9 cells migrated, respectively, $p< 0.05$). In addition, peficitinib treated RA FLS showed a 14 ± 2 % decrease in proliferation of RA FLS compared with nontreated RA FLS. In addition, peficitinib treated RA FLS condition medium decreased HUVEC tube formation compared to nontreated RA FLS condition medium (number of endothelial cell tubes formed ± SEM; 9 ± 1 and 13 ± 1, respectively, $p< 0.05$). Finally, we found peficitinib suppress the secretion of inflammatory mediators in RA FLS. VEGF and MCP-1/CCL2 in RA FLS supernatant was suppressed in peficitinib compared to nontreated (mean ± SEM; VEGF: 77.1 ± 69.5 and 110.4 ± 81.0 pg/ml, MCP-1/CCL2 160.1 ± 65.6 and 846.0 ± 107.1 pg/ml, respectively, $p< 0.05$).

Conclusion: We demonstrated that peficitinib is involved in the suppression of FLS proliferation, and inhibits the chemotaxis of THP1 and PBMC through inhibition of MCP-1/CCL2. Furthermore, peficitinib suppressed RA angiogenesis through inhibition of VEGF.

LY294002 Improves the Collagen-induced Arthritis by Inducing Neutrophil Apoptosis

Xuechan Huang[1], Tianwang Li[1], Shuyang Chen[1], Zhixiang Huang[1] and Junming Chen[1], [1]Department of Rheumatology and Immunology, Guangdong Second Provincial General Hospital, Guangdong, China (People's Republic)

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophils play a central role in host defense, but they also play important effectors on acute and chronic inflammation. Neutrophil apoptosis is essential for the resolution of inflammation. Previous studies have shown that delayed apoptosis of neutrophils correlate with the pathogenesis of rheumatoid arthritis (RA). This study aimed to investigate the effects of LY294002, the PI3K inhibitor, on neutrophil apoptosis in RA patients and collagen-induced arthritis (CIA) in mice.

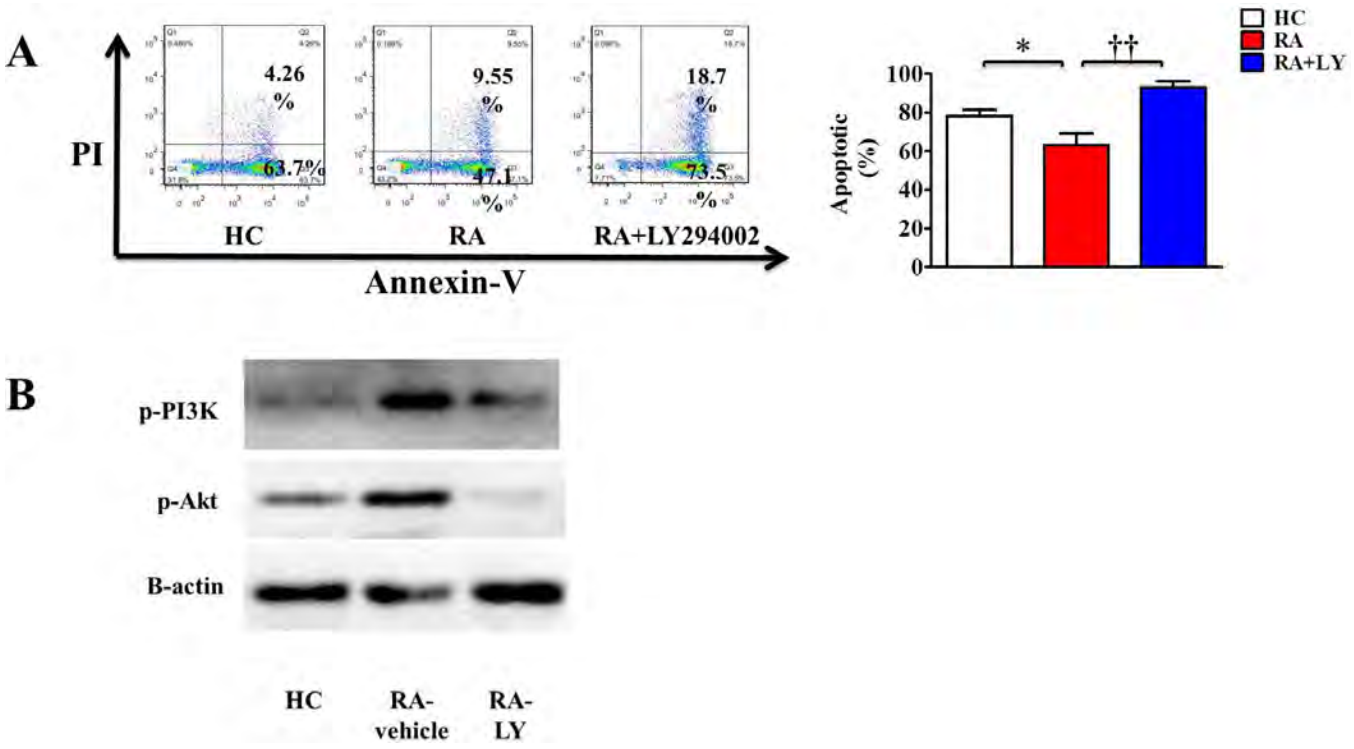

Figure1 (A) Apoptosis rate of neutrophils in peripheral blood of healthy controls (HC) or rheumatoid arthritis (RA) patients.(B) The expression of p-PI3K and p-Akt in HC and RA. *HC compare with RA **p < 0.01 † LY294002(LY) treatment group compare with untreated group † † p < 0.01

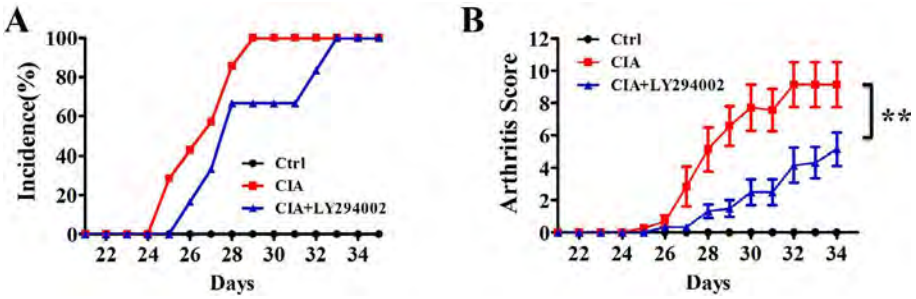

Figure 2. LY294002 treatment delayed the onset(A), reduced the severity (B)of arthritis in CIA mice.*CIA+LY294002 compare with CIA **p < 0.01

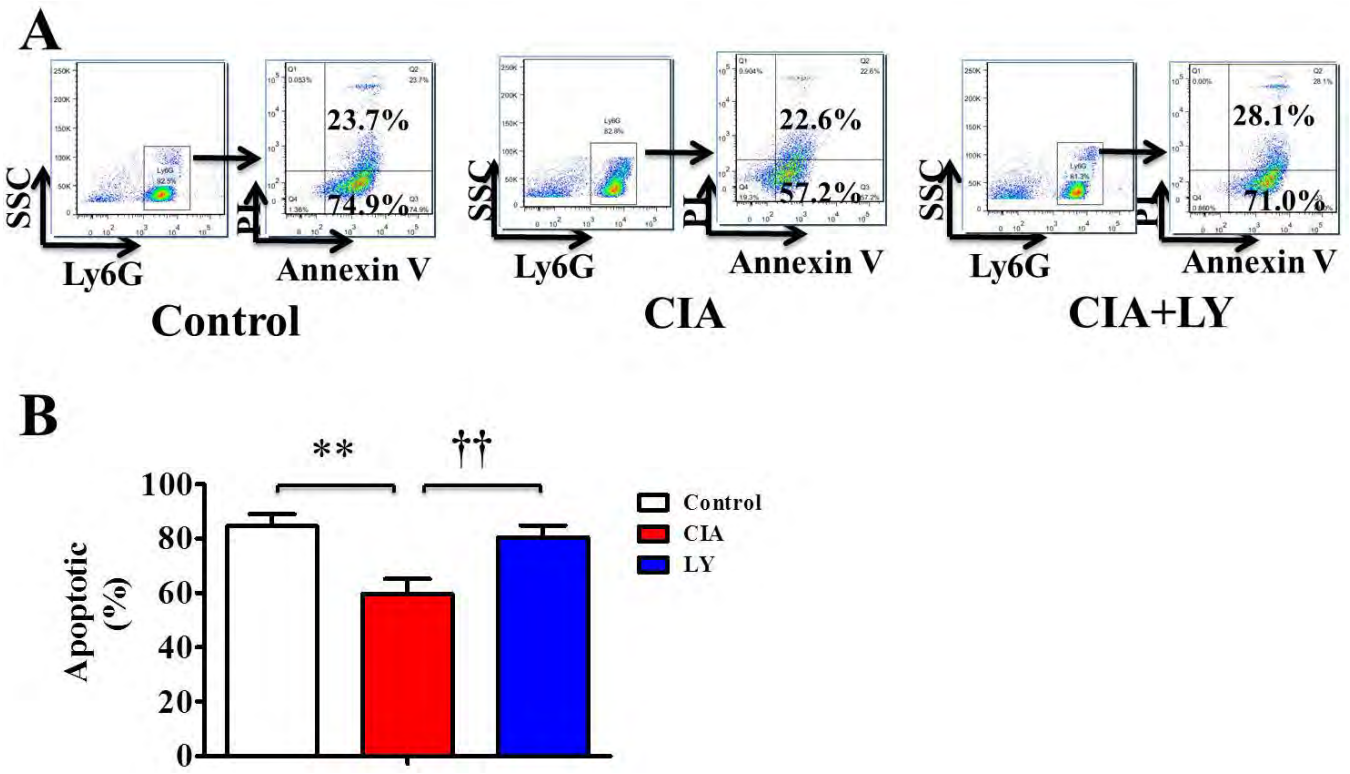

Figure 3 Apoptosis rate of neutrophils in peripheral blood of Collagen-Induced Arthritis(CIA) mice. *Control compare with CIA **p < 0.01 † LY294002(LY) treatment group compare with untreated group † † p < 0.01

Methods: The peripheral blood from untreated RA patients (n=25) and healthy volunteers (HC) (n=15) were isolated the neutrophils by density gradient centrifugation and cultured with or without LY294002(LY) in vitro for 18 h. The rate of neutrophils apoptosis were analyzed by flow cytometry and the intracellular protein of PI3K-Akt pathway in neutrophils were measured by Western blot. CIA mice were treated with vehicle or LY294002, and then analyzed the effect of LY294002 on arthritis as well as the apoptosis rate of neutrophils from peripheral blood of CIA mice.

Results: The peripheral blood neutrophils apoptosis delayed in RA patients as compared with neutrophils from HC**.** LY294002 could significantly promote neutrophils apoptosis in peripheral blood from RA patients **(Figure1 A)**. The expression of phosphorylation PI3K(p-PI3K), p-Akt were increased in RA patients and LY294002 inhibited the expression of p-Akt **(Figure1 B)**. Moreover, LY294002 treatment delayed the onset, reduced the severity of arthritis in CIA

mice **(Figure2)**.The peripheral blood neutrophils apoptosis delayed in CIA mice as compared with the control group, and LY294002 treatment facilitated the neutrophil apoptosis **(Figure3)**.

Conclusion: This data suggested that delayed apoptosis of neutrophils played an important role in the development of RA, therefore, inhibition of PI3K pathway to facilitate neutrophil apoptosis are possible approaches to reduce inflammatory arthritis which might open new doors to future clinical treatment of RA.

Topological Laser Capture Microscopy (LCM)-RNAseq to Map the Rheumatoid Arthritis (RA) Synovial Transcriptome

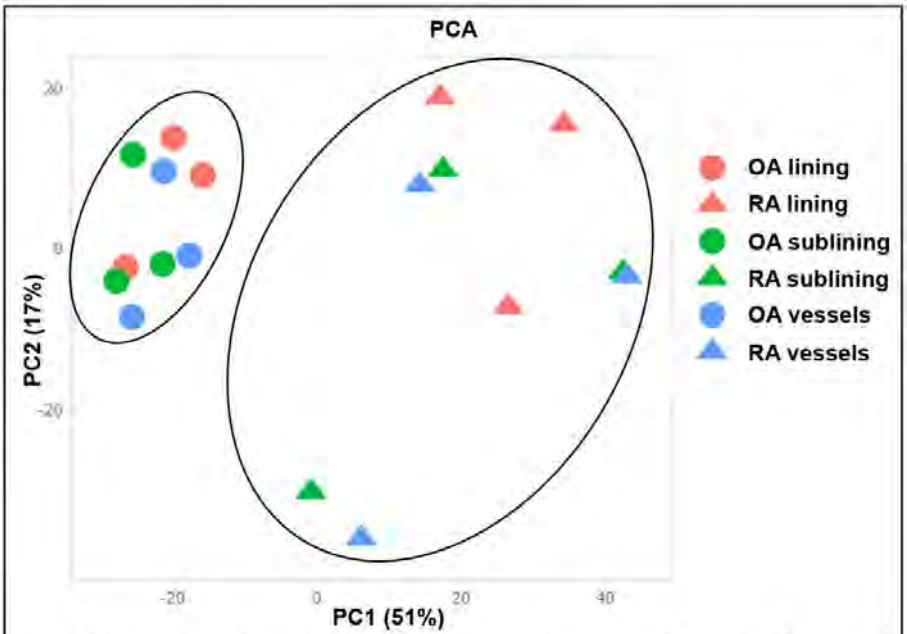
Benjamin Van Espen[1], Andrew Wilson[1], Gregory Seumois[2], Narayanan Perumal[3], Robert Benschop[4], Gary Firestein[5], Nunzio Bottini[5] and **Stephanie Stanford**[1], [1]University of California, San Diego, La Jolla, [2]La Jolla Institute for Immunology, La Jolla, [3]Eli Lilly, Indianapolis, [4]Eli Lilly and Company, Indianapolis, IN, [5]University of California, San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding pathogenic processes in the diseased tissue in rheumatoid arthritis (RA) is a critical step to defining disease pathogenesis and identifying novel therapeutic targets. However, the use of enzymatically dispersed cells can lead to changes in the gene transcription and bias due to cell death. Therefore, we established laser capture microscopy followed by RNAseq (LCM-RNAseq) to study the regional transcriptome.

Methods: Synovial tissue was captured by LCM after H&E staining from lining, sublining, and blood vessels from 3 RA and 3 osteoarthritis (OA) patients. RNA was extracted and subjected to RNAseq. Principal component analysis (PCA) by disease state was performed on the top 500 most variable genes among the sample set. Analysis of differentially expressed genes (DEGs) between disease state was performed using the Bioconductor DESeq2 package. DEGs had adjusted p-values of < 0.05 and log2 fold change >1 or < -1. Pathway analysis on the unique DEGs for each substructure was performed using the Canonical Pathways function in Ingenuity Pathway Analysis (IPA) platform. The significance of the pathways was calculated using a right-tailed Fisher's exact test and adjusted using the Benjamini-Hochberg method.

Results: PCA revealed striking separation between RA and OA transcriptomes (see Figure), indicating that the transcriptomes could be readily distinguished. Pairwise comparisons of synovial lining, sublining and blood vessels between RA and OA revealed substantial differences in transcriptional patterns between each region. Pathway analysis of DEGs unique to each substructure revealed that each region displayed distinct phenotypic abnormalities in RA. For example, RA synovial lining was marked by anomalies of innate immunity, including Role of Pattern Recognition Receptors in Recognition of Bacteria and Virus ($p< 0.001$) and LPS/IL-1 Mediated Inhibition of RXR Function ($p< 0.01$) pathways. Intriguingly, RA sublining abnormalities were primarily in metabolic pathways involving fatty acid regulation, such as Fatty Acid Activation ($p< 0.01$) and Mitochondrial L-carnitine Shuttle Pathway ($p< 0.01$). RA synovial vessels displayed evidence of alterations in pathways indicative of dysregulated angiogenesis, including Melatonin Signaling ($p< 0.0001$) and Apelin Cardiomyocyte Signaling ($p< 0.001$).



Principal component analysis (PCA) of transcriptomes of RA and OA synovial substructures. PCA was performed using the prcomp function in R statistical software on the top 500 most variable genes among the entire sample set. Proportion of variability explained for PC1 and PC2 is shown in parentheses.

Conclusion: Through use of LCM, we established a method for RNAseq-quality extraction of RNA and showed large differences between RA and OA synovial substructures that are difficult to detect using single cell analysis. This technology can supplement disaggregation techniques to provide key information on in situ gene expression profiles and identify disease and substructure-specific targets for RA.

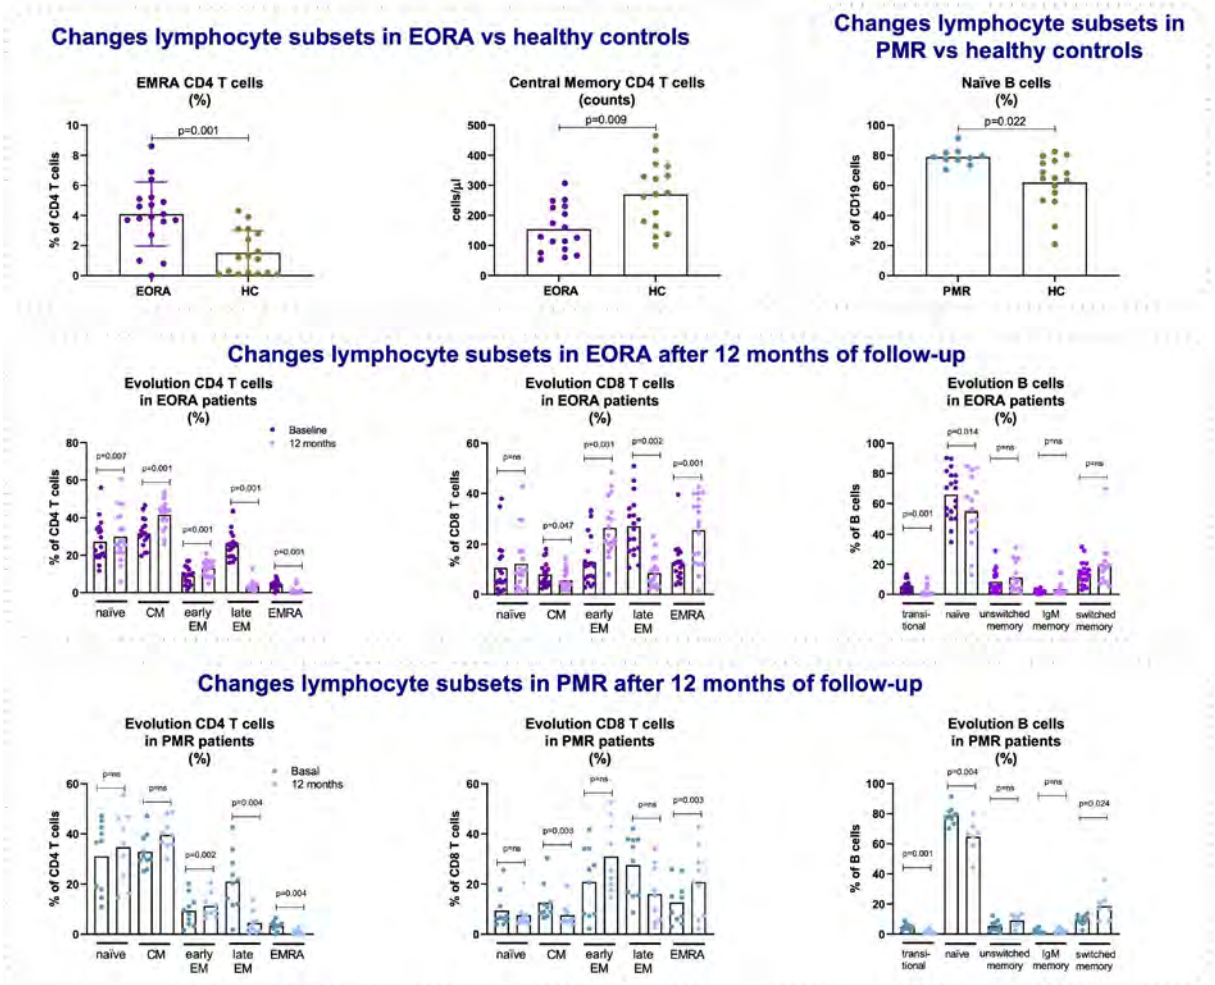
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple lymphocyte subsets like T and B cells have been connected to joint infiltration and inflammation in rheumatoid arthritis (RA). Identification of leucocyte subsets that are dysregulated in arthritis development could provide insight into the aetiology of RA. Elderly-onset RA, EORA, which is defined as rheumatoid arthritis (RA) starting at > 60 years of age, has received less attention than young-onset RA. Polymyalgia rheumatica (PMR) is another common rheumatic disease in the elderly. This study aimed to investigate the composition of the peripheral blood component. We hypothesize that by defining lymphocyte subsets we might be able to define elements of inflammation pathobiology in this population.

Methods: ARTIEL (Arthritis in the Elderly) is a collection cohort with newly diagnosed arthritis in patients older than 60 years, with blood samples collected at baseline (pre-treatment) and 12 months after treatment, along with physician and patient outcome measures through 12 months. They are compared with randomly control individuals of the same age and gender. A thorough clinical examination was conducted. Patients completed a health assessment questionnaire (HAQ). Disease activity score (DAS)28CRP was calculated. Absolute numbers of lymphocyte subsets in whole EDTA blood were determined with complete blood counts and flow cytometry fluorescent labelled antibodies for T and B cell subsets. Data processing and statistical analysis were performed in SPSS.

Results: 29 patients (average: 75.15, standard deviation (SD) 6.80) and 18 controls (C; average: 75.39, SD, 6.04) were analyzed. Of these, 19 were diagnosed with RA and 10 with PMR. At the start of the study, patients had a mean DAS28CRP of 5.72 (SD, 1.05), mean HAQ was 1.64 (SD, 0.73). In addition, 84% of the patients reported scapular



pain, and 56% of the patients reported pelvic pain at baseline. Several lymphocyte subsets were different between populations. In patients with EORA, significant increase in percentage and numbers of CD4+ effector subset (EMRA; defined as $CD3^+CD4^+CD45RA^+CCR7^-CD27^-$) and significantly decrease in numbers of CD4+ central memory (CM; defined as $CD3^+CD4^+CD45RA^-CCR7^+CD27^+$). In patients with PMR, a trend towards different B cell subsets were observed with an increase in percentage of naïve B cells ($CD19^+CD27^-IgM^+IgD^+$) was observed compared to HC and a significant increase in percentage and numbers of CD8 + CM ($CD3^+CD8^+CD45RA^+CCR7^-CD27^-$). Longitudinal analysis showed that several B and T cell subsets were significantly different at 12 months in both EORA and PMR patients (see Figure) suggesting an effect of therapy in the lymphocyte subsets.

Conclusion: This study revealed that patients with EORA and PMR demonstrate a change in cellular immune parameters apparent in the periphery. More studies are needed to show whether these subsets before and after treatment might be related to clinical and therapeutic outcomes in these populations.

Abstract Number: 0795

Minimum Clinically Important Improvement in Patients with Rheumatoid Arthritis Associates with Gut Microbiome

Vinod Gupta[1], Kevin Cunningham[2], Benjamin Hur[1], John Davis[1] and Jaeyun Sung[1], [1]Mayo Clinic, Rochester, MN, [2]University of Minnesota, Minneapolis, MN

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Within the past decade, there have been several major discoveries in cross-sectional gut microbiome studies suggesting that dysbiosis of the gut microbiota is a key hallmark in Rheumatoid arthritis (RA). However, the association of gut microbiome with improvement in disease activity in RA patients remains unknown. In this study, we aimed to investigate the association of minimum clinically important improvement (MCII) in RA disease activity with gut microbiome of RA patients. In addition, we generated a machine-learning model, incorporating gut microbiome and clinical data, that could predict the course of RA irrespective of the treatment strategy.

Methods: Illumina based DNA shotgun sequencing was performed on 72 stool samples, which were collected at two time-points, from 36 RA patients. Disease activity and gut microbiomes were assessed in order to investigate the association of gut microbiome with MCII (i.e., CDAI change of at least 1 for low (CDAI less than 10); of 6 for moderate (CDAI 10–22); and of at least 12 for high (CDAI greater than 22) disease activity) in RA disease activity. Machine-learning models based on XGBoost were also generated based on gut microbiome composition and clinical data at baseline to predict the future disease activity in RA patients.

Results: We found that distributions of gut microbiome profiles were significantly different in patients of $MCII^+$ (i.e., patients who show improvement in disease activity) and $MCII^-$ groups (i.e., patients who did not show improvement). At baseline, Fisher's alpha diversity and species richness were significantly higher (**Fig.1b**), and five microbial taxa, including Negativicutes, Selenomonadales, Prevotellaceae, Coprococcus, and *Ruminococcus sp.*, were significantly

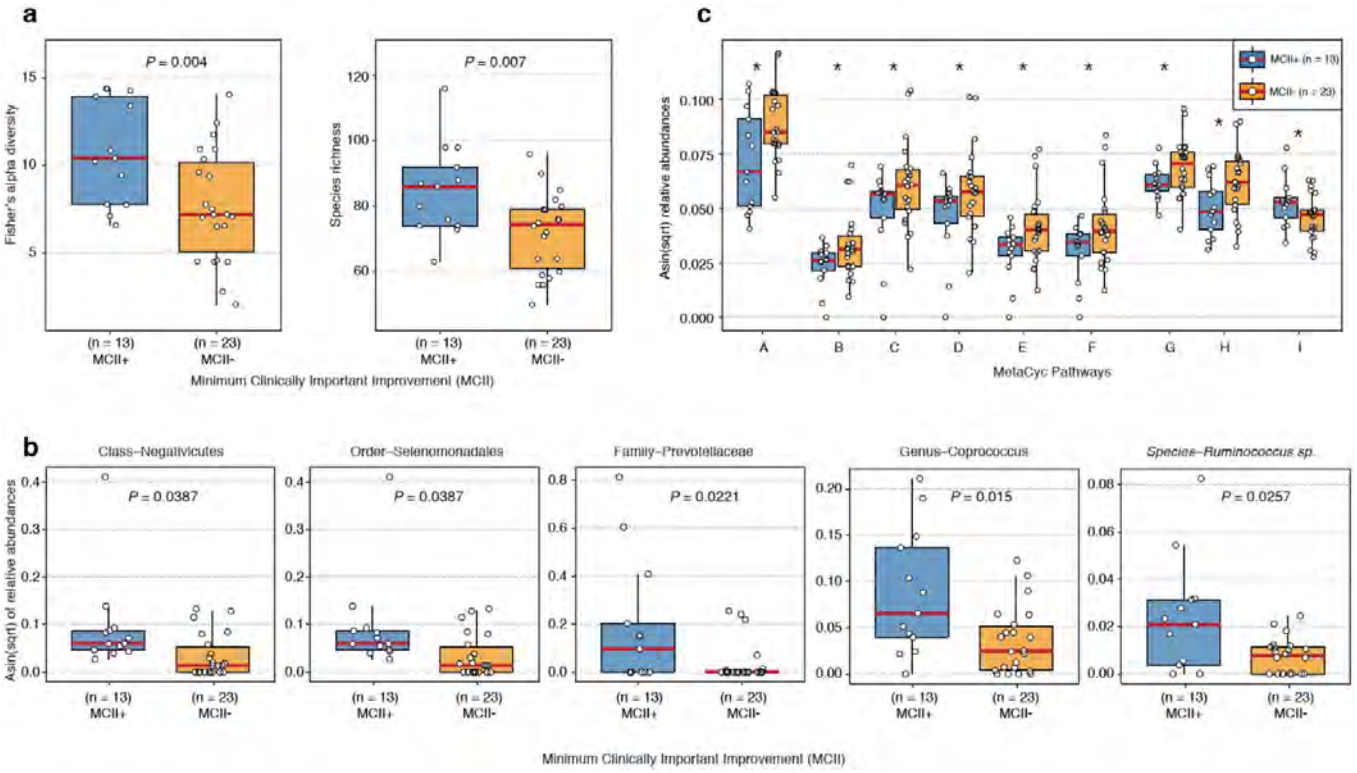

Figure 1. Significant differences in gut microbiomes of baseline stool samples between MCII+ and MCII- groups. (a) Higher distributions of Fisher's alpha diversity and species richness were observed in baseline stool samples of patients of MCII+ group than in those of MCII- group. (b) Five taxa, Ruminococcus sp, Coprococcus, Prevotellaceae, Prevotellaceae, and Negativicutes, were significantly more abundant in baseline stool samples of patients of MCII+ group than those of MCII- group. (c) MetaCyc pathways that were significantly differentiated between MCII+ and MCII- groups in baseline stool samples. P-values shown above the box plots were found using multiple linear regression models on arcsine square-root transformed relative abundances of microbial taxa and MetaCyc pathways, while adjusting for age group (middle age: age < 64 years; and old age: age >= 64 years), sex, smoking status and use of csDMARDs (conventional synthetic Disease-Modifying Antirheumatic Drugs). *, P < 0.05; ns, not significant. Pathway codes: A, L-ornithine de novo biosynthesis; B, L-ornithine biosynthesis; C, L-arginine biosynthesis IV; D, L-arginine biosynthesis I; E, L-arginine biosynthesis III; F, L-arginine biosynthesis II; G, L-rhamnose degradation I; H, CMP-3-deoxy-D-manno-octulosonate biosynthesis I; I, tetrapyrrole biosynthesis I.

more abundant among patients of $MCII^{+}$ group than those of $MCII^{-}$ group (**Fig.1b**). Biochemical pathway-level analysis of baseline stool metagenomes suggested that eight MetaCyc pathways, including ornithine biosynthesis, arginine biosynthesis, and rhamnose degradation were significantly decreased in RA patients of $MCII^{-}$ group (**Fig.1c**). For the machine-learning model, the Pearson correlation coefficient between predicted and actual disease activity score (CDAI) at follow-up visits was 0.77 ($P = 2.9 \times 10^{-12}$), which shows that our machine-learning model, incorporating gut microbiome and clinical data, is very effective in forecasting the disease activity in RA patients.

Conclusion: Our findings confirm the association of gut microbiome with MCII in disease activity in RA patients, and highlights the importance of gut microbiome in predicting the course of RA irrespective of the treatment strategy.

Development of a Tool to Assess Synovial Tissue Infiltrates and Derive Histological Pathotype in Inflammatory Arthritis: Relationship to Clinical and Ultrasound Variables

Hayley Carr[1], Ilfita Sahbudin[1], Mark Maybury[1], Bernard Dyke[2], Jason Turner[3], Nicola Gullick[4], Karim Raza[5], Dagmar Scheel-Toellner[1] and Andrew Filer[1], [1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom, [2]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, England, United Kingdom, [3]Rheumatology Research Group, Institute for Inflammation and Ageing, College of Medical and Dental Sciences, University of Birmingham, Queen Elizabeth Hospital, Birmingham, United Kingdom, [4]University Hospitals Coventry & Warwickshire, Coventry, United Kingdom, [5]Sandwell and West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence suggests that histological pathotypes are linked to pathogenic mechanisms in inflammatory arthritis and may be useful as biomarkers of outcome. The frequently used Krenn score was developed and validated to distinguish inflammatory from non-inflammatory synovitis using longstanding disease and does not distinguish the degree of histological organisation from the degree of infiltrate. We therefore developed discrete semi-quantitative indices of infiltrate density and aggregate size from which a simple pathotype grade could be derived in H&E stained tissue and examined their relationship with clinical and ultrasound variables in baseline synovial tissue biopsies from the BEACON early arthritis inception cohort.

Methods: Synovial tissue biopsies were obtained at baseline from unselected treatment naïve patients presenting to the Birmingham BEACON cohort with at least one clinically swollen joint. Final diagnosis was assigned after 18 months. 71 samples were analysed: RA (46), PsA (7), unclassified arthritis (8), and other inflammatory arthritis (10). Ultrasound (US) greyscale (GS) hypertrophy and Power Doppler (PD) were graded in joints prior to biopsy. 4 point semi-quantitative scales (0-3) were developed for discrete variables of cellular infiltrate density and aggregate size and number, with written definitions and an extensive image atlas. The BEACON density and aggregate scores were then used to create a summary pathotype: lymphoid (≥ grade 1 aggregates); diffuse (immune infiltrate in absence of aggregates); pauci-immune (absence of immune infiltrate). Following iterative assessments for face and construct

	US GS	US PD	CRP	DAS28-CRP	MD global
Krenn lining layer module	0.27 (0.026)	-0.061 (0.62)	0.087 (0.47)	0.18 (0.14)	0.051 (0.67)
Krenn infiltrate module	**0.34* (0.0052)**	0.15 (0.23)	**0.37* (0.0023)**	**0.33* (0.0056)**	**0.40* (0.0009)**
BEACON density	**0.39* (0.0008)**	0.22 (0.068)	**0.45* (0.0001)**	0.22 (0.066)	**0.35* (0.0025)**
BEACON aggregates	**0.31* (0.01)**	**0.28* (0.02)**	0.22 (0.07)	0.12 (0.32)	0.19 (0.10)

Table 1. Spearman rank correlations of Krenn lining layer and infiltrate modules, BEACON density and aggregate scores with ultrasound and clinical variables. Spearman r (p value) *Significant after Benjamini Hochberg correction

validity, 3 independent scorers blindly graded 10 representative H&E sections using the atlas and the Krenn lining layer and infiltrate modules.

Results: Reliability of the BEACON scoring system was good (mean BEACON density ICC=0.69, BEACON aggregate Kappa=0.69, pathotype Kappa=0.72).

The BEACON density and aggregate scores correlated moderately with the Krenn lining layer module (r=0.48, p< 0.001 and r=0.43, p=< 0.001 respectively) and highly with the Krenn infiltrate module (r=0.92, p< 0.001; r=0.76, p< 0.001).

Table 1 shows correlation analysis for Krenn lining layer and infiltrate modules, BEACON density and aggregate scores vs US and clinical variables (CRP, DAS28-CRP, MD global score). The Krenn infiltrate module and BEACON density correlated with US GS, CRP, and MD global assessment; BEACON aggregate score correlated with US PD and GS. The Krenn infiltrate module alone correlated with DAS28-CRP. There were no correlations with the Krenn lining layer module.

There was a greater proportion of higher US GS grades in lymphoid than diffuse and pauci-immune pathotypes (X^2(4, N=70)=11.18, p=0.025).

Conclusion: The BEACON scores and derived pathotype showed good inter-observer reliability and correlated significantly with US and clinical variables. Derived histological pathotype was also associated with US GS hypertrophy. This suggests that these variables have utility in describing infiltrate extent and complexity in early arthritis samples.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Janus Kinase (JAK) inhibitors have shown long term benefit in patients with active RA with inadequate response to conventional or biologic DMARDs (1). Due to a lack of head-to-head comparison trials, the relative efficacy and safety of JAK inhibitors remains unclear. Consequently, previous network meta-analysis had assessed the relative efficacy and safety of JAK inhibitors but were restricted to studies with adalimumab (2).

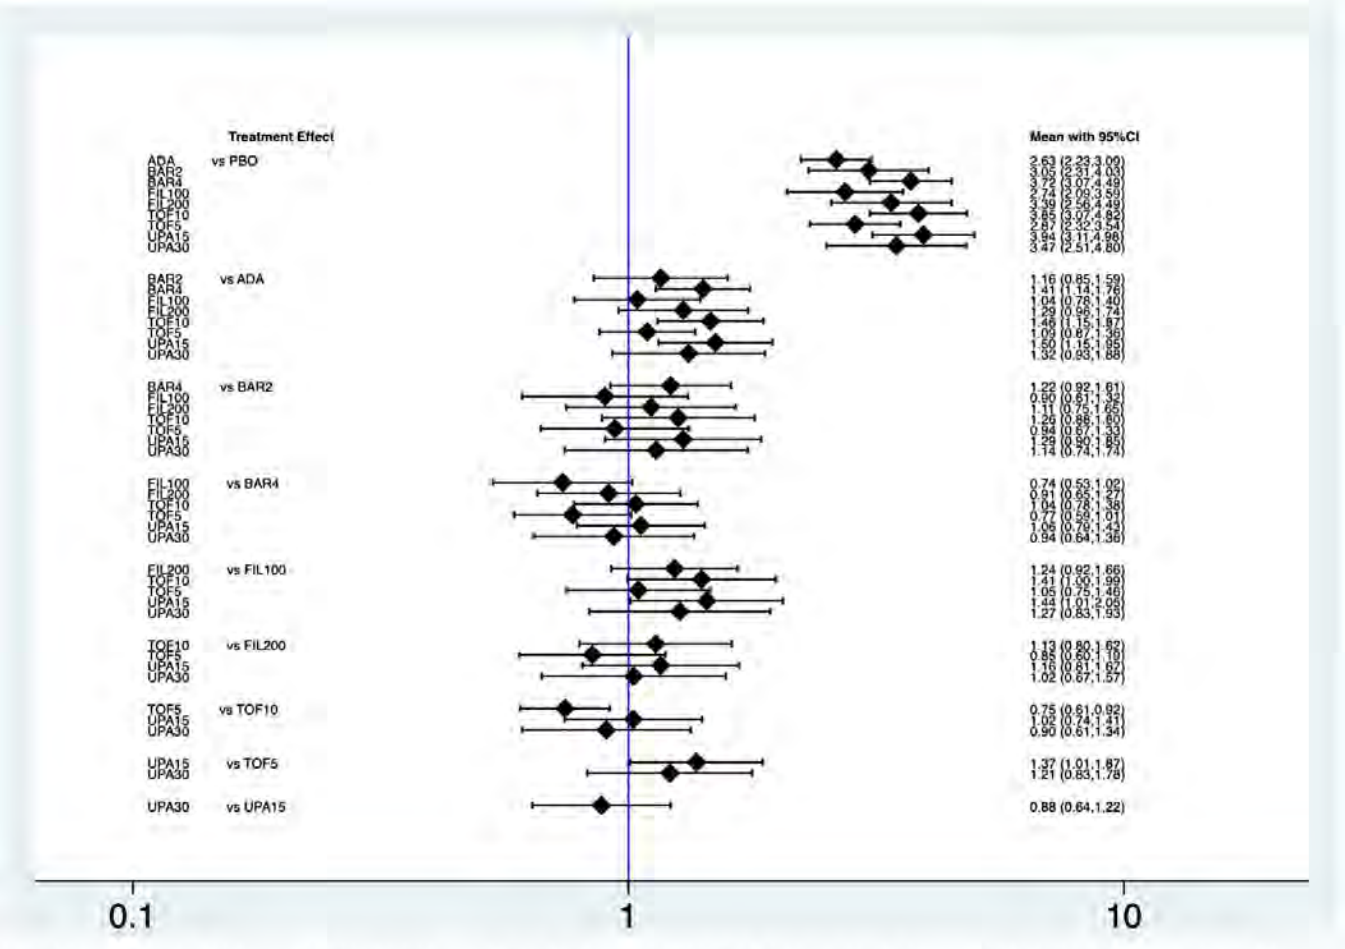

Figure 1. Predictive interval plot for active RA network for the ten-intervention analysis for ACR20.

The purpose of this study was to investigate the relative efficacy and safety of tofacitinib, baricitinib, filgotinib and upadacitinib in patients with active RA with inadequate response to conventional or biologic DMARDs.

Methods: Bayesian random-effects network meta-analysis was performed to combine the direct and indirect evidence from randomized controlled trials (RCTs) reporting efficacy and safety outcomes of tofacitinib + MTX, baricitinib + MTX, filgotinib + MTX and upadacitinib + MTX in patients with active RA despite treatment with conventional or biologic DMARDs.

Results: Twenty RCTs including 13.178 patients met the inclusion criteria. There were 45 pairwise comparisons including 18 direct comparisons of 10 interventions. The American College of Rheumatology 20% (ACR20) response rate was significantly higher for all the intervention groups other than placebo (Figure 1). The ranking probability based on the surface under the cumulative ranking curve (SUCRA) indicated that upadacitinib 15mg + MTX (SUCRA = 0.9), tofacitinib 10mg + MTX (SUCRA = 0.8). and baricitinib 4mg + MTX (SUCRA = 0.8) had the highest probability of being the best treatment in terms of the ACR20 response rate. This was followed by upadacitinib 30mg + MTX (SUCRA = 0.6), filgotinib 200mg + MTX (SUCRA = 0.6), baricitinib 2 mg + MTX (SUCRA 0.4), tofacitinib 5mg + MTX (SUCRA = 0.3), filgotinib 100mg + MTX (SUCRA = 0.3), adalimumab + MTX (SUCRA = 0.2) and placebo + MTX (SU-

ACR20	Intervention	HZ

Drugs are reported in order of ACR20 ranking according to SUCRAs. Comparisons should be read from left to right. The efficacy (ACR20) and safety (herpes zoster infection) estimate is located at the intersection of the column-defining treatment and the row-defining treatment. Significant results are in bold and underlined.

Table 1. Network league of estimated effects of ACR20 and herpes zoster infection.

CRA = 0). The SUCRAs for the ACR50 indicated that upadacitinib 30mg + MTX (SUCRA = 0.9) and upadacitinib 15mg (SUCRA =0.8) had the highest probability of being the best treatment. Safety based on number of severe adverse events did not differ significantly among the ten interventions within 12 weeks suggesting comparable safety among the different regimens and the placebo. However, it was observed an increased risk of herpes zoster infection in the group of tofacitinib 10mg + MTX (odds ratio (OR) 8.27, 95% credible interval (CrI) 1.56 – 43.7) and baricitinib 4mg + MTX (OR 2.36, 95% CrI 1.1 – 5.1) in comparison with placebo group (Table 1).

Conclusion: In patients with active RA with inadequate response to conventional or biologic DMARDs the JAK inhibitors are an effective and safe alternate therapy. The two with the best relative efficacy were upadacitinib 15mg/30mg and baricitinib 4 mg. In terms of serious infectious events, there was an increase of herpes zoster infections with tofacitinib 10mg and baricitinib 4mg.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the long-term safety, immunogenicity (IG), and efficacy of the adalimumab (ADL) biosimilar, PF-06410293 (ADL-PF), in patients (pts) with moderate to severe active RA who continued ADL-PF treatment throughout 78 weeks (wks) or who switched from reference ADL sourced from the European Union (ADL-EU) to ADL-PF at wk 26 or wk 52 in a randomized, double-blind, comparative clinical trial (NCT02480153). This report includes results from wks 52-92 (including 16-wk follow-up [FU]).

Methods: Eligible pts met 2010 ACR/EULAR RA diagnosis criteria for ≥4 months, had an inadequate response to MTX, and had received ≤2 doses of 1 lymphocyte-depleting or non-ADL biologic. Pts stratified by geographic regions were initially randomized (1:1) in treatment period 1 (TP1) to ADL-PF or ADL-EU (40 mg subcutaneously every other wk), both with MTX (10–25 mg/wk). The primary endpoint was ≥20% clinical improvement of ACR criteria (ACR20) at wk 12. Secondary efficacy endpoints included ACR20 other than at wk 12, DAS28; 4 components based on high-sensitivity CRP (DAS28-4[CRP]), and other measures of clinical response or remission. At wk 26 (start of TP2), pts receiving ADL-EU were blindly re-randomized (1:1) to remain on ADL-EU or transition to ADL-PF for 26 wks. At wk 52 (start of TP3), all pts received open-label treatment with ADL-PF for 26 wks; 3 groups (gps) were evaluated corresponding to the treatment sequence during the study: biosimilar; wk 26 switch; wk 52 switch.

Results: Of the randomized TP1 pts (N=597), 552 pts entered TP2. At wk 52, all pts remaining on ADL-EU were switched to ADL-PF; 507 pts continued to participate in TP3. The majority of TP3 pts were female (78.1%) and White (86.6%). ACR20 response rates and DAS28-4(CRP) scores were sustained and comparable across gps (**Table**). ADL-PF was generally well tolerated, with a comparable safety profile across gps. Incidence of treatment-emergent adverse events (AEs) during TP3 and FU was 42.6% (biosimilar), 37.0% (wk 26 switch), and 50.8% (wk 52 switch); 3 (0.6%) pts overall (all in the wk 52 switch gp) reported treatment-related serious AEs. There was 1 death (wk 52 switch gp). Pre-dose (TP3) anti-drug antibody (ADA) prevalence at wk 52 was 41.5%, 42.5%, and 48.3% for the biosimilar, wk 26, and wk 52 switch gps, respectively. The incidences of pts with a first positive ADA result during TP3 or FU, among pts who were ADA negative on entry to TP3, were 8.9%, 6.3%, and 8.3% for the biosimilar, wk 26, and wk 52 switch gps, respectively; overall, incidences of pts with ADAs in TP3 and FU were comparable among gps (46.1%, 46.5%, and 54.2%, respectively).

Efficacy Endpoints by Visit (TP3 ITT Population)			
Group[a]	Biosimilar[b] (N = 259)	Week 26 switch[c] (N = 127)	Week 52 switch[d] (N = 121)
ACR20 Response, n (%)			
Week 52	229 (88.4)	112 (88.2)	106 (87.6)
Week 78	216 (83.4)	109 (85.8)	102 (84.3)
DAS28-4(CRP) Score, Mean (SD)			
Week 52	3.0 (1.15)	2.8 (1.14)	3.2 (1.26)
Week 78	2.7 (1.12)	2.6 (1.16)	3.0 (1.33)

[a]Treatment sequence TP1/TP2/TP3; [b]ADL-PF/ADL-PF/ADL-PF; [c]ADL-EU/ADL-PF/ADL-PF; [d]ADL-EU/ADL-EU/ADL-PF.

Abbreviations: ADL-EU, reference adalimumab sourced from the European Union; ADL-PF, PF-06410293; DAS28-4(CRP), Disease Activity Score-28; 4 components based on high-sensitivity C-reactive protein; ITT, intent-to-treat; N, number of patients in the TP3 ITT population; SD, standard deviation; TP, treatment period.

Conclusion: Results from TP3 and FU (wks 52–92) are consistent with earlier findings from this study, demonstrating no clinically meaningful differences in safety, IG, and efficacy between treatment gps, independent of a single treatment switch from ADL-EU to ADL-PF at wk 26 or wk 52.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Medication non-adherence in rheumatoid arthritis (RA) is associated with disease flares, increased disability and increased costs. Electronic Monitoring Feedback (EMF) to improve adherence has shown promising effects in various chronic diseases, however, it has never been studied in RA nor with biological DMARDs. This study aims to assess the effectiveness of EMF on medication adherence in RA patients starting with or switching to a new bDMARD.

	12 months		
	Feedback	Control	p
DAS28-ESR (SD)	2.71 (1.3)	2.63 (1.5)	0.801
ΔDAS28-ESR (baseline to 12 months)	-1.63 (1.2)	-1.14 (1.3)	0.105
ΔDAS28-ESR (baseline to average of month 3, 6, 9, 12)	-1.16 (1.2)	-0.990 (1.1)	0.325
Proportion with LDA (DAS28<3.2) at 3 months, %	60	68	0.307
Proportion with LDA (DAS28<3.2) at 6 months, %	42	51	0.260

	10, other	6, other	

Table 1. results for both groups. Means and number of patients are presented, unless otherwise stated. CQR Zk- score combined with DAS score was available for 64 patients.

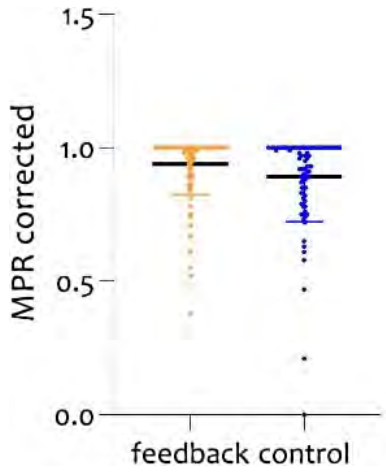

Figure 1. MPR for both groups. Scores >1 were truncated to 1.0.

Methods: In this RCT, RA patients starting a (new) bDMARD were 1:1 assigned to the intervention or control group and followed for 1 year. The intervention group received a special needle container which was equipped with a Medication Event Monitoring System (MEMS) cap registering patient's adherence to subcutaneous medication injections. During the intervention, adherence score was read out every 3 months with MEMS, on which motivational interviewing feedback based on patient's medication adherence was given. Furthermore, reasons for non-adherence were explored and counselled. The control group received usual care. At the start and after 12 months, Compliance Questionnaire in Rheumatology (CQR), Beliefs about Medicines Questionnaire (BMQ) and Health Assessment Questionnaire (HAQ) were obtained. The feedback group also received BMQ and HAQ at months 3, 6 and 9. Effectiveness of EMF on adherence was assessed with the validated discriminant CQR-Z score for taking compliance ≤80% and medication possession ratio (MPR, total day's supply in period divided by total period, truncated to 1.0). Patients taking >80% of their medication were considered adherent. Effectiveness of EMF on DAS28-ESR and side effects was also assessed.

Results: 207 consecutive patients were included,105 in feedback group and 102 control (mean age 52 years, 74% female, 88% Caucasian ethnicity, 5.3 years since diagnosis of RA, 51 used a bDMARD before). At baselins there were no differences with respect to the DAS28 and HAQ (intervention 3.95 vs control 3.74 and 1.15 vs 0.98 respectively) in both groups. Most patients started with etanercept (95) or adalimumab (91).

The percentage of CQR adherent patients increased for both groups from 68.5 and 63.1 (baseline) to 75.6 and 81.7 (12 months) for intervention and controls respectively (no difference between groups at baseline and 12 months, p=0.534 and p=0.446.

MPR was 0.95 in the feedback group and 0.92 in the control group (p=0.048, Figure 1), corrected for returned defect syringes and medical indicated postponing

Correct dosing measured by MEMS decreased slightly from 92.6% (after 3 months) to 90.5% (after 12 months).

Methotrexate, prednisolone and other csDMARD use throughout the study was similar for both groups and BMQ and HAQ scores remained nearly equal.

Side effects such as infections did not differ between groups (47% and 57% of the patients reported any side effect, p=0.142).

Conclusion: Taking compliance and correct dosing were relatively high in RA patients starting with or switching to a biological DMARD, as measured with MPR, CQR and MEMS. Since high rates were found in the control group too, probably because of a ceiling and a placebo effect, EMF did not increase adherence. Presumably the effect of EMF should be targeted to non-adherent patients.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: CT-P17 (100 mg/mL) is the first proposed biosimilar of the high concentration and citrate-free formulation of reference adalimumab. The purpose of this study was to compare the efficacy and safety of CT-P17 with reference adalimumab in patients with active moderate-to-severe RA up to Week 52.

Methods: Patients with active moderate-to-severe RA despite methotrexate treatment were randomly assigned to receive 40 mg of CT-P17 or reference adalimumab every 2 weeks up to Week 24. Prior to dosing at Week 26, patients in the reference adalimumab group were re-randomized either to continue receiving reference adalimumab or to switch to CT-P17 until end of study. All patients initially randomized to CT-P17 continued CT-P17. The primary endpoint was ACR20 response rate at Week 24. Secondary measures of efficacy, pharmacokinetics (PK) and safety, including immunogenicity, were also evaluated.

Table 1. Efficacy Results at Week 24 (ITT population)

	CT-P17 N=324	Reference Adalimumab N=324
ACR20, n (%)	268 (82.7)	268 (82.7)
ACR50, n (%)	195 (60.2)	206 (63.6)
ACR70, n (%)	132 (40.7)	144 (44.4)
DAS28-CRP, change from baseline, mean (SD)	-2.7 (1.19)	-2.7 (1.21)
CDAI remission, %	82 (25.3)	86 (26.5)
SDAI remission, %	86 (26.5)	93 (28.7)
EULAR (good) response, %	208 (64.2)	208 (64.2)

Abbreviations: CDAI, clinical disease activity index; ITT, intent-to-treat; SD, standard deviation; SDAI, simplified disease activity index.

Figure 1. ACR20 Response Rates (ITT population)

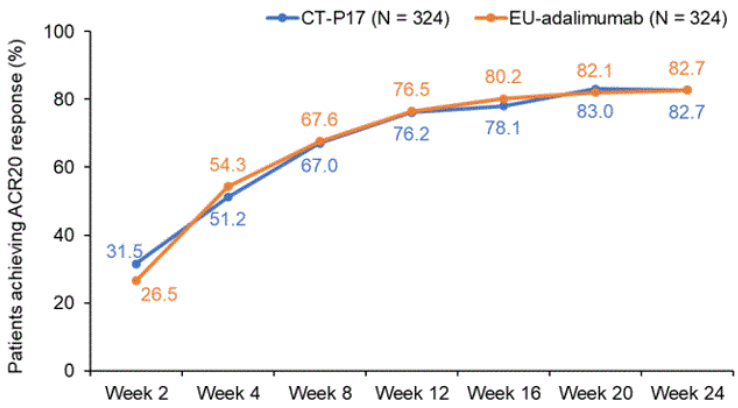

Table 2. Overview of TEAEs up to Week 24 (Safety population)

Patients, n (%)	CT-P17 N=324	Reference Adalimumab N=324
≥1 TEAE	169 (52.2)	184 (56.8)
≥1 TESAE	10 (3.1)	16 (4.9)
≥1 TEAE leading to study drug discontinuation	5 (1.5)	8 (2.5)
≥1 TEAE classified as hypersensitivity/allergic reactions	2 (0.6)	4 (1.2)
≥1 TEAE classified as injection site reactions	16 (4.9)	22 (6.8)
≥1 TEAE classified as infection	97 (29.9)	103 (31.8)
≥1 TEAE classified as malignancy	1 (0.3)	0

Abbreviation: TEAE, treatment-emergent adverse event; TESAE, treatment-emergent serious adverse event.

Results: 648 patients initiated treatment (324 patients in each arm). Baseline characteristics were similar between groups.

The ACR20 response rate at Week 24 was 82.7% (268/324) and 82.7% (268/324) for CT-P17 and reference adalimumab and the confidence intervals of the treatment difference (95% CI: -5.94 to 5.94, 90% CI: -4.98 to 4.98) were entirely within the equivalence margins agreed upon with EMA (±15%) and FDA (-12% to +15%). Secondary efficacy endpoints were also similar between groups (Table 1).

In terms of PK, geometric mean trough serum concentration was slightly higher in CT-P17; 5.3 μg/mL in CT-P17 vs. 4.3 μg/mL in reference adalimumab at Week 24 (p=0.0501).

Overall, 353 (CT-P17: 169 [52.2%] vs. reference adalimumab: 184 [56.8%]) patients experienced at least 1 treatment-emergent adverse event (TEAE). The most common TEAEs were injection site reactions (16 [4.9%] vs. 22 [6.8%]). 26 patients experienced at least 1 treatment-emergent serious adverse event (TESAE). Similar proportions of patients in both groups experienced at least 1 TEAE that was classified as hypersensitivity/allergic reactions and infections (Table 2). One malignancy (breast cancer; unrelated) was reported in a patient receiving CT-P17.

The proportion of patients who had anti-drug antibodies (ADAs) at Week 24 (209 [32.3%]), was slightly lower for CT-P17 (93 [28.7%]) than for reference adalimumab (116 [35.8%]) (p=0.0643). Of these, 83 (25.6%) receiving CT-P17 and 103 (31.8%) receiving reference adalimumab also had neutralizing ADAs.

Conclusion: Over 24 weeks, CT-P17 has equivalent efficacy to reference adalimumab, with ACR20 response rates of 82.7% for each, and similar additional secondary efficacy endpoints. Considering the ACR20 response rate of 64.0% - 82.5% [1-4] reported in previous studies of low concentration (50 mg/mL) adalimumab biosimilar, further investigation is needed to ascertain the factors associated with the slightly higher response rate in this study.

CT-P17 was well tolerated with a safety profile comparable to that of reference adalimumab.

Data are mean (SD), unless otherwise stated.

[a]Standardized difference >0.1.

ABA=abatacept; mHAQ=modified HAQ; PS=propensity score; TNFi=TNF inhibitor; VAS=visual analog scale.

Background/Purpose: The *HLA-DRB1* shared epitope (SE) is associated with joint destruction in ACPA+ patients (pts) with RA.[1] In the Early AMPLE trial, among ACPA+ pts with early RA, efficacy responses with abatacept (ABA) but not adalimumab were numerically higher in pts who were SE+ vs SE–.[2] This real-world analysis compared the mean change (Δ) from baseline to the 6-mth follow-up visit in CDAI score among ACPA+/SE+ pts treated with ABA or TNF inhibitors (TNFi).

Methods: Using data from CERTAIN (Comparative Effectiveness Registry to study Therapies for Arthritis and Inflammatory CoNditions; NCT01625650)[3], this study included pts with RA who initiated ABA or a TNFi, were CCP3+ (>20 U/mL), SE+ (presence of SE on *HLA-DRB1* allele) and had moderate or high CDAI score (>10) at initiation and 6-mth follow-up (+/– 3 mths). The primary outcome was mean Δ in CDAI score over 6 mths; secondary outcomes included achievement of remission (CDAI ≤2.8) and low disease activity (CDAI ≤10) and mean Δ in pain, fatigue and pt global assessment. Analyses were conducted using both propensity score (PS)-trimmed and -matched populations. PS was calculated within each line of therapy. The PS-trimmed cohort included pts with scores overlapping both

Table 2. Clinical outcomes in the overall PS-trimmed and -matched populations

Outcomes	PS-trimmed analysis[a]			PS-matched analysis		
	ABA (n=170)	TNF (n=157)	p value[b]	ABA (n=111)	TNF (n=111)	p value[b]

Patient global assessment, VAS 0–100 mm[c]	−14.5 (2.1)	−10.9 (2.2)	0.220	−16.4 (2.3)	−12.7 (2.3)	0.265
Achievement of LDA[d]	1.8 (0.5, 5.9)	Ref	0.358	1.6 (0.4, 6.6)	Ref	0.553
Achievement of remission[d]	1.4 (0.6, 3.5)	Ref	0.471	1.6 (0.6, 4.3)	Ref	0.371
Drug retention						
Patients who remained on drug at 6-mth visit, n (%)	117 (68.8)	101 (64.3)	0.389	79 (71.2)	73 (65.8)	0.386

[a]The PS-trimmed cohort included pts with scores overlapping both populations.

[b]p values for primary and secondary outcomes were from the adjusted mixed-effects models. Drug retention was assessed using the chi-square test.

[c]Mean (standard error) change from baseline to 6 mths.

[d]OR (95% CI) for difference between treatments at 6-mth visit.

ABA=abatacept; LDA=low disease activity; OR=odds ratio; PS=propensity score; ref=reference; VAS=visual analog scale.

populations. After PS trimming, TNFi initiators were PS matched 1:1 to ABA initiators within each line of therapy. A sensitivity analysis was conducted in biologic-experienced pts only. Mixed-effects models were used for primary and secondary outcomes and included baseline characteristics that remained unbalanced (standardized difference [sDiff] >0.1) between treatment groups.

Results: In the overall PS-trimmed cohort (ABA, n=170; TNFi, n=157), baseline characteristics that were imbalanced (sDiff >0.1) between treatments included sex, RF+, physician and pt global assessments, pain, fatigue and prior biologic use (**Table 1**). Baseline characteristics in the overall PS-matched cohort (ABA, n=111; TNFi, n=111) were generally well balanced. Similar trends for imbalances in baseline characteristics were seen in biologic-experienced cohorts. In the overall population for both the PS-trimmed and -matched cohorts, there were numerically greater improvements in mean Δ in CDAI and nearly all secondary efficacy outcomes between ABA and TNFi (**Table 2**). There was no significant difference in the percentage of pts who remained on study medication at 6 mths. Similar trends for efficacy outcomes were seen for biologic-experienced pts; statistical significance was reached for mean Δ in CDAI in the PS-trimmed cohort (**Table 3**).

Conclusion: There was a consistent numerical improvement in efficacy outcomes with abatacept over TNFi in pts with long-standing RA who were SE+ and ACPA+ over 6 mths in all four study cohorts. After adjusting for covariates that remained imbalanced between groups in the biologic-experienced PS-trimmed cohort, the improvement in CDAI with abatacept vs TNFi was significant. Additional studies to explore these findings in a larger population would be of interest.

Table 3. Clinical outcomes in the biologic-experienced PS-trimmed and -matched populations

Outcomes	PS-trimmed analysis[a]			PS-matched analysis

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: There are several conventional synthetic, targeted synthetic and biological disease-modifying anti-rheumatic medications (DMARDs) approved for the treatment of rheumatoid arthritis (RA) in Japan. Little is known regarding the characteristics of patients treated by these DMARD classes and their respective effectiveness in a real-world cohort of patients in Japan.

Methods: We identified RA patients in the Corrona RA Japan Registry who initiated a DMARD (methotrexate [MTX], TNFi, nonTNFi, tofacitinib) between March 1, 2016 to December 31, 2019 with enrollment capping for some drug classes. We characterized the four drug groups in terms of sociodemographics, comorbidities, disease characteristics, medications (current and prior), disease activity, and patient-reported outcomes (PROs). Drug effectiveness in each of the drug groups was assessed for all initiators with baseline and 6-month follow-up (FU) visits available by change in Clinical Disease Activity Index (CDAI) and PROs (pain, fatigue, patient global assessment, and J-HAQ), as well as the achievement of minimal clinically important difference (MCID) in CDAI and modified ACR20/50/70s in the six months following medication initiation.

Determining the Minimally Important Difference in the Clinical Disease Activity Index for Improvement and Worsening in Early Rheumatoid Arthritis Patients. *Arthritis Care & Research*. 2015;67(10):1345; ¥Patients who did not remain on drug had either switched to another medication or were not being treated.

Table 2. Unadjusted Effectiveness Outcomes (Baseline to 6-month follow-up) by Drug Group

Results: There were 1293 patients in the registry with 275 MTX, 331 TNFi, 525 nonTNFi, and 162 tofacitinib initiators that had both baseline and 6-month FU visits available. Mean disease duration was 2.4, 7.2, 9.8, and 11.8 years, respectively, in the MTX, TNFi, nonTNFi, and tofacitinib groups. Almost all MTX initiators (99.3%) were biological naïve. Among TNFi initiators, 76.7%, 16.9%, 3.6%, and 2.7% received their drug as their 1st, 2nd, 3rd, and 4th biological/Janus Kinase inhibitor (JAKi), respectively. For patients in the nonTNFi group, it was 62.7% 21.3%, 9.3%, and 6.7%, respectively. Among tofacitinib initiators, 26.5% of patients received the drug as their 1st, 35.2% as their 2nd, 21.0% as their 3rd, and 17.3% as their 4th biological/JAKi. At initiation, mean disease activity, as measured by CDAI, was 19.0, 22.6, 21.9, and 23.1 for the MTX, TNFi, nonTNFi, and tofacitinib patients, respectively (Table 1).

At the 6-month FU visit following initiation, mean change in CDAI was -9.9, -11.6, -11.8 and -12.4 in the MTX, TNFi, nonTNFi, and tofacitinib initiators, respectively. Additionally, the majority of the patients (61.0%, 62.6%, 67.1%, and 66.7% for the MTX, TNFi, nonTNFi, and tofacitinib initiators, respectively) reached MCID in CDAI. Almost half of all initiators achieved ACR20 responses (46.9%, 42.6%, 48.2%, and 45.1% of the MTX, TNFi, nonTNFi, and tofacitinib initiators, respectively). Approximately 80% or more initiators remained on the drug until their 6-month FU visit (79.6%, 82.8%, 85.1%, and 85.2% for MTX, TNFi, nonTNFi, and tofacitinib, respectively) (Table 2).

Conclusion: There were distinct patient profiles for those initiating each of the four drug classes in Japan. Overall, the majority of patients receiving MTX, TNFi, nonTNFi, and tofacitinib all had good responses. This positive patient response to DMARDS in a Japanese population adds to the growing scientific literature for those seeking to understand real-world outcomes.

Real-World DMARD Experience and Outcomes for Rheumatoid Arthritis Patients in Japan: Safety

Mitsumasa Kishimoto[1], Yoshiya Tanaka[2], Leslie Harrold[3], Alina Onofrei[3], Christine Barr[4], Ekta Agarwal[5], Jose L Rivas[6], Naonobu Sugiyama[7], Jeffrey Greenberg[8] and Hisashi Yamanaka[9], [1]Department of Nephrology and Rheumatology, Kyorin University School of Medicine, Yokohama, Japan, [2]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Corrona, LLC, Waltham, MA, [4]Corrona, LLC, Albany, NY, [5]Pfizer, Inc., Princeton Jct, NJ, [6]Pfizer SLU, Madrid, Spain, [7]Pfizer Japan Inc, Tokyo, Japan, [8]Corrona, LLC and NYU School of Medicine, Waltham, MA, [9]Sanno Medical Center, Tokyo, Japan, Tokyo, Japan

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is limited information on the real-world safety of disease-modifying anti-rheumatic drugs (DMARDs) approved for treating rheumatoid arthritis (RA) in Japan. Using a Japanese RA registry, rates of serious adverse events among initiators of methotrexate (MTX), TNFi, nonTNFi, and tofacitinib were calculated.

Methods: We identified RA patients (pts) in the Corrona RA Japan Registry who initiated a DMARD between 03/01/2016 to 12/31/2019 and had at least one follow-up (FU) visit or had an adverse event before the first FU visit. If pts switched to another drug in the same drug class, they remained in the original drug group. Each initiation was considered so pts could be in ≥ 1 drug group. Adverse events of interest were cardiovascular disease (CVD), serious infections, Herpes Zoster [(HZ) serious and non-serious], and malignancy, excluding non-melanoma skin cancer (NMSC). The incidence of adverse events was calculated. For all events except malignancy, person-time at risk was estimated from time of drug initiation until the occurrence of the first event or 90 days after discontinuation. For risk of malignancies, the risk window for any therapy included all person-time in the designated period (time since starting therapy) and extended until the end of data collection. Incidence rates (IR), expressed as number of first events per 100 person-years (PY), were calculated with 95% confidence intervals (CI) assuming a Poisson distribution.

Results: There were 1,546 pts with first-time use of MTX, TNFi, nonTNFi, or tofacitinib who had at least one FU visit or had an adverse event before the first FU visit. Drug groups included 296 MTX, 491 TNFi, 560 nonTNFi, and 199 tofacitinib initiators. History of prior CVD, serious infection, HZ, and malignancy ranged from 8-14%, 9-15%, 10-14%, and 6-16%, respectively (Table 1).

The average PY of FU time was 2.0, 1.6, 1.5, and 1.4 PY for MTX, TNFi, nonTNFi, and tofacitinib initiators, respectively (Table 2). The IR for serious infections was (IR=6.47, 95% CI, 4.70-8.68) for nonTNFi, (3.86, 1.77-7.33) for tofacitin-

[a]Excluding those who initiated methotrexate (MTX) with other biologicals (TNFi or nonTNFi) or Janus Kinase inhibitor (JAKi); [b]Number of non-missing observations; [c]Prior CVD includes hypertension requiring hospitalization, cardiac revascularization procedure (CABG, stent, angioplasty), ventricular arrhythmia, cardiac arrest, myocardial infarction, acute coronary syndrome, unstable angina, CHF requiring hospitalization, stroke, transient ischemic attack, other cardiovascular event, deep vein thrombosis, peripheral arterial thromboembolic event, urgent peripheral arterial revascularization, peripheral ischemia or gangrene (necrosis) and pulmonary embolism; [d]For example, if a patient was in the tofacitinib group and had used MTX, etanercept, and abatacept prior to tofacitinib, the patient would be listed as having MTX, TNFi, and nonTNFi.

Table 1. Baseline Characteristics of the Safety Cohort

	Years of follow-up in Corrona		
Drug group	**Total**	**Mean**	**Median**
MTX*	598.5	2.0	2.1
TNFi	796.0	1.6	1.6
nonTNFi	838.5	1.5	1.5
Tofacitinib	285.3	1.4	1.4

* Excluding those who initiated MTX with other biologics (TNFi or nonTNFi) or JAKi.

Table 2. Follow-up Time for Each Drug Group

ib, (3.46, 2.17-5.24) for TNFi, and (2.16, 1.04-3.97) for the MTX groups. The tofacitinib group had the highest IR for HZ (9.31, 5.76-14.23) and nonTNFi (2.02, 1.11-3.40), TNFi (0.93, 0.34-2.03), and the MTX (0.86, 0.23-2.20) groups were lower. All the HZ events were non-serious (e.g., did not require hospitalization or intravenous antivirals). Total CVD was (0.43, 0.05-1.54), (0.77, 0.25-1.80), (1.57, 0.79-2.82), and (1.27, 0.26-3.72 in the MTX, TNFi, nonTNFi, and the tofacitinib groups, respectively. For malignancy excluding NMSC, the IRs were (1.65, 0.88-2.82) in TNFi, (1.52,0.70-2.89) in MTX, (1.20, 0.58-2.21) in nonTNFi, and (0.35, 0.01-1.96) in the tofacitinib groups (Table 3).

Conclusion: There were similar rates of serious infection, CVD, and malignancy adverse events among pts initiating MTX, TNFi, nonTNFi, and tofacitinib. Yet, the rate of HZ, due to non-serious events, was greater in those initiating tofacitinib, which is consistent with what is known from Japanese tofacitinib clinical trial data.

Total Counts of Events of Interest	MTX		TNFi Initiators		nonTNFi Initiators		Tofacitinib Initiators	
	N/PYR	Rate (95% CI)	N/PYR	Rate (95% CI)	N/PYR	Rate (95% CI)	N/PYR	Rate (95% CI)
CVD[a]	2/469.46	0.43 (0.05-1.54)	5/647.66	0.77 (0.25-1.8)	11/698.79	1.57 (0.79-2.82)	3/235.42	1.27 (0.26-3.72)
Serious Infections[b]	10/462.98	2.16 (1.04-3.97)	22/635.82	3.46 (2.17-5.24)	44/680.14	6.47 (4.70-8.68)	9/232.96	3.86 (1.77-7.33)
Herpes Zoster[c]	4/465.45	0.86 (0.23-2.2)	6/644.5	0.93 (0.34-2.03)	14/691.8	2.02 (1.11-3.4)	21/225.58	9.31 (5.76-14.23)
Cancer excluding NMSC[d]	9/591.36	1.52 (0.7-2.89)	13/787.32	1.65 (0.88-2.82)	10/830.37	1.20 (0.58-2.21)	1/284.78	0.35 (0.01-1.96)

[a]CVD includes hypertension requiring hospitalization, cardiac revascularization procedure (CABG, stent, angioplasty), ventricular arrhythmia, cardiac arrest, myocardial infarction, acute coronary syndrome, unstable angina, CHF requiring hospitalization, stroke, transient ischemic attack, other cardiovascular event, deep vein thrombosis, peripheral arterial thromboembolic event, urgent peripheral arterial revascularization, peripheral ischemia or gangrene (necrosis) and pulmonary embolism; [b]Serious infections includes pneumonia, sepsis, joint/bursa, cellulitis/skin, sinusitis, diverticulitis, bronchitis, gastroenteritis, meningitis/encephalitis, urinary tract infection, upper respiratory infection, tuberculosis and other infections meeting serious adverse event criteria (resulting in hospitalization (new or prolonged) death, disability, congenital anomaly, was immediately life-threatening or otherwise deemed serious in the opinion of the investigator), and/or requiring treatment with an IV antibiotic; [c]Herpes zoster includes both serious and non-serious herpes zoster; [d]Cancer excluding non-melanoma skin cancer

Table 3. Crude Incidence Rates (number of first events/100 PY) for MTX group, TNFi Initiators, nonTNFi Initiators, and Tofacitinib Initiators

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Data on biological survival, stratified for discontinuation reasons, and predictors that influence survival time have not been explored extensively. Therefore, we aim to explore real-world first and second-line biological survival and determine its influenceability in rheumatoid arthritis (RA) patients.

Methods: Data from the local pharmacy database and patient records of a university hospital in the Netherlands were used. RA patients who started a biological between 2000-2020 were included. Data on age, anti-citrullinated protein

	RA patients, n=318
Demographic	
• Age at diagnosis, mean (sd)	40.9 (16)
• Gender, female, n (%)	264 (83)
• BMI, mean (sd)	26.9 (6.3)
Disease characteristics	
• ACPA positive, n (%)	224 (70)
• RF positive, n (%)	226 (71)
• Erosive disease, n (%)	141 (44)
Medication	
• Time to first biological, years, median (IQR)	3.6 (1-7)
• First-line biologicals	
o Etanercept, n (%)	142 (45)
o Adalimumab, n (%)	90 (28)
o Certolizumab Pegol, n (%)	59 (19)
o Infliximab, n (%)	15 (5)
o Golimumab, n (%)	5 (2)
o Anakinra, n (%)	3 (1)
• csDMARDs used with first-line biological	
o MTX, n (%)	66 (21)
o MTX + SASP and/or HCQ , n (%)	147 (46)
o Other csDMARDs (SASP, HCQ, LEF), n (%)	53 (17)
o No combination therapy, n (%)	52 (16)

ACPA: anti-citrillunated protein antibody, BMI: body mass index, csDMARD: conventional synthetic disease modifying anti-rheumatic drug, HCQ: hydroxychloroquine, IQR: inter quartile range, LEF: leflunomide, MTX: methotrexate, RF: rheumatoid factor, SASP: sulfasalazine, sd: standard deviation

Table 1 Characteristics of patient population

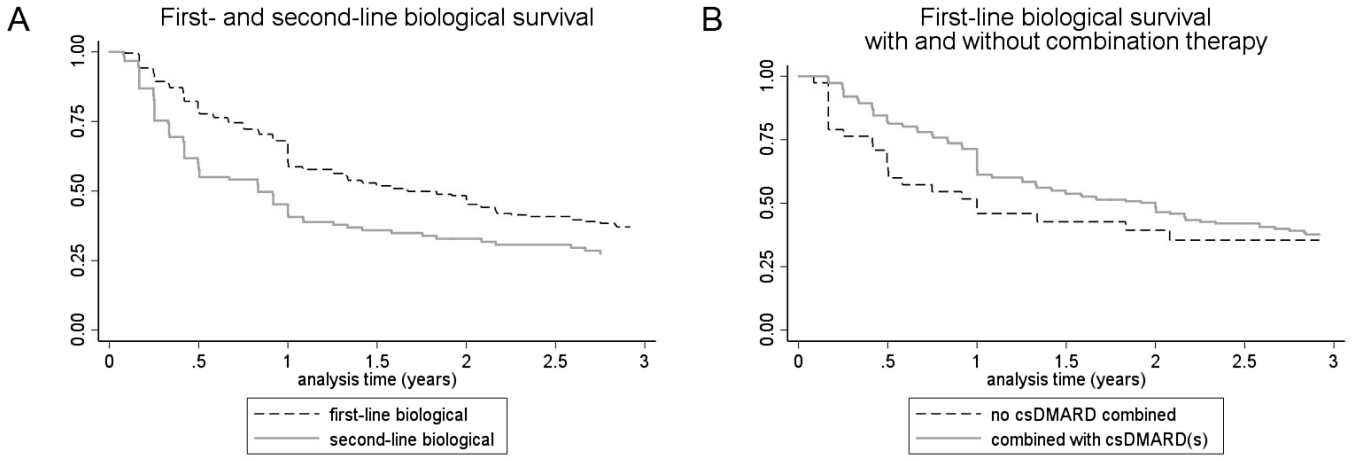

Figure 1 Kaplan Meier curves for biological survival. (A) Biological survival of first- and second-line biological in rheumatoid arthritis patients. (B) Biological survival with and without combination therapy with a csDMARD.

antibody (ACPA) and rheumatoid factor (RF)-status, presence of erosions, gender, body mass index, time to first biological, biological survival time, use of csDMARDs and discontinuation reasons were collected.

Results: Of the included 318 patients, 39 (12%) started their first biological within 6 months after diagnosis. Median time between diagnosis and first biological prescription was 3.6 years (95% confidence interval (CI) 1.0-7.2). 50%

of patients started their first biological after 2013. Median survival time of the first- and second-line biological was respectively 1.7 years (95%CI 1.3-2.2) and 0.8 years (95%CI 0.5-1.0)(p=0.0001)(Figure 1A). Discontinuation reasons for the first-line biological were ineffectiveness (47%), adverse events (17%), remission (16%), pregnancy (30%), or patient preference (10%)(Table 1). Multivariable Cox regression analyses, performed on the population that discontinued due to inefficacy or adverse events, showed that use of csDMARDs (HR=1.32, p< 0.001) positively influenced biological survival (Figure 1B) RF positivity on the other hand (HR=0.82, p=0.03) negatively influenced biological survival. Biological survival in ACPA positive patients was longer compared to ACPA negative patients taking in to account discontinuation due to remission (HR=1.43, p=0.023). This indicates that ACPA positive patients were less likely to discontinue their biological due to remission. Second-line TNF-inhibitor survival did not differ between patients with a primary, < 6 months, and secondary, ≥6 months, non-response on the first-line TNF-inhibitor (HR=1.28, p=0.34).

Conclusion: Biological survival diminishes with the number of biologicals used. Biological survival is prolonged if patients use concomitant csDMARDs, and is shortened when patients are RF positive. ACPA positivity lowers the chance to discontinue biologicals due to remission.

The PROPER Study: Results of the First Interim Analysis of a Pan-EU Real-World Study of SB5 Biosimilar Following Transition from Reference Adalimumab in Patients with Rheumatoid Arthritis, Axial Spondyloarthritis or Psoriatic Arthritis

Ulf Müller-Ladner[1], Karl Gaffney[2], Deepak Jadon[3], Ulrich Freudensprung[4] and Janet Addison[5], [1]Department of Rheumatology, Immunology, Osteology and Physical Medicine, Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, Bad Nauheim, Germany, [2]Norfolk and Norwich University Hospital NHS Foundation Trust, Norfolk, United Kingdom, [3]Cambridge University Hospitals NHSFT, Cambridge, United Kingdom, [4]Biogen International GmbH, Baar, Switzerland, [5]Biogen Idec, Maidenhead, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: SB5, an adalimumab biosimilar received EU marketing authorisation in August 2017, based on the totality of evidence from pre-clinical and clinical Phase I and III studies that demonstrated bioequivalence, similar efficacy, and comparable safety and immunogenicity to reference adalimumab (ADL). There are few published data on the transition from reference ADL to SB5 outside the controlled, randomised, clinical trial setting. This study aims to evaluate candidate predictors of persistence on SB5 in EU patients across multiple indications.

Methods: This ongoing observational study will enrol approximately 1200 subjects with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) or psoriatic arthritis (PsA), ulcerative colitis or Crohn's disease who initiated SB5 as part of routine clinical practice following a minimum of 16 weeks' treatment with reference ADL, at clinics in Belgium, Germany, Ireland, Italy, Spain and the UK. Data are captured from clinic records retrospectively for the 24 weeks prior to transition, and prospectively and/or retrospectively for 48 weeks following transition. The primary objective is to

Table 1: Patient baseline characteristics

evaluate candidate predictors of persistence; primary outcome measures include baseline clinical characteristics, disease activity scores and clinical management over time. This interim analysis provides an overview of baseline characteristics, and disease scores and dose regimen up to 24 weeks post-initiation of SB5 in subjects with RA, axSpA or PsA enrolled at 16 specialist sites (11 in Germany, 5 in UK), followed up to the data extract date of 1st May 2020.

Results: Of the 256 patients included in this interim analysis 85 with RA and 23 with PsA were enrolled in Germany, and 86 with axSpA and 62 with PsA in U.K.

Conclusion: This interim analysis provides an early insight into a contemporary cohort of EU patients with established RA, axSpA and PsA, switched from reference to biosimilar ADL in clinical practice. The majority of patients had sTable disease at transition, with no meaningful difference seen in disease score by Week 24 post-transition, while 75% or more of each cohort transitioned to the same dose regimen of SB5 as received for reference ADL prior to transition, and the majority of patients continued the same SB5 regimen to Week 24. With ongoing enrolment and longer follow-up, the study will provide pertinent information about clinical outcomes of transition from reference to biosimilar ADL in real-world practice and in indications not investigated in controlled studies.

Abstract Number: 0806

Identification and Adjustment for Factors Associated with Clinical Response in Rheumatoid Arthritis Clinical Trials to Improve Comparisons of Treatment Efficacy

Anthony Cordisco[1] and Joshua Baker[1], [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Numerous clinical trials have been published in rheumatoid arthritis (RA), but comparing efficacies of disease-modifying anti-rheumatic drugs (DMARDs) is complicated by a lack of head-to-head studies and because study populations are heterogeneous. We aimed to identify and adjust for patient/trial characteristics associated with clinical response to enable fairer comparisons between different drugs/drug classes, e.g. abatacept (co-stimulation modulator) vs. adalimumab (TNFi).

Methods: We reviewed 565 DMARD clinical trial papers using the following criteria: studies had to be randomized, controlled, Phase III trials published after 1995 reporting ACR20/50/70 with follow-up ≥ 6 months. 73 met criteria. We explored associations between 33 patient/trial characteristics and ACR response. We constructed models incorporating these factors to compute predicted ACR response rates for each trial arm and their residual differences from actual response rates. Some factors associated with response weren't reported in every study, so ACR20, 50, and 70 each required constructing multiple models to allow for different numbers of independent variables. The model used for a given trial arm was selected based on the information available (algorithm for ACR50 shown in Fig. 1).

Results: Based on linear regressions, multiple patient/trial characteristics were associated with ACR response, including age, calendar year of publication, DAS28-CRP, disease duration, and prior MTX/biologic use (Table 1). Trials with patients having greater disease duration at enrollment had lower response rates. Similarly, previous therapy

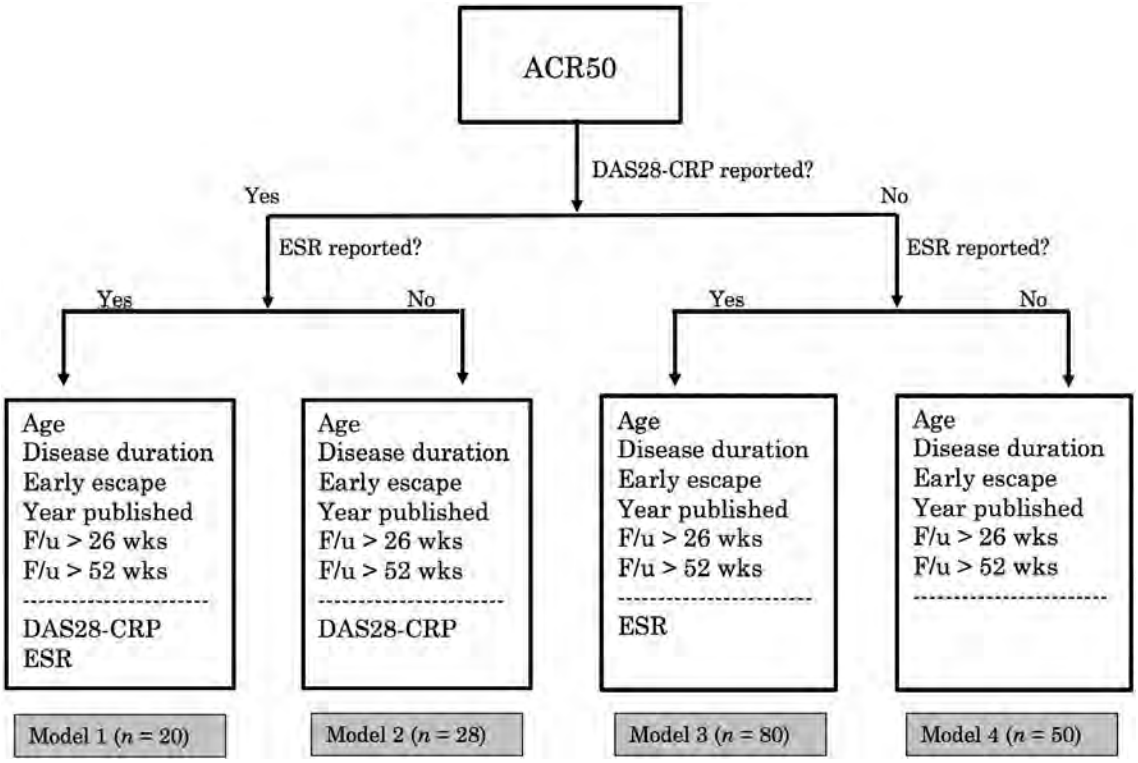

Figure 1: Choosing among four models for predicting an ACR50 score. Here n denotes the number of treatment arms for which a given model applied. Variables above the dashed line were reported in every treatment arm and are included in every model. Those below the line were not reported in some treatment arms. Calculating ACR50 scores for such arms required models not taking those variables as inputs.

failure (MTX or biologics) was associated with poorer response in trials. Conversely, trials with patients having higher baseline disease activity as characterized by DAS28-CRP (but not by DAS28-ESR) had higher response rates. Sex, white race, swollen/tender joint counts, and RF serostatus weren't associated with response. Several variables were associated with ACR70 response only, including steroid usage, anti-CCP serostatus, and ESR.

Before adjusting for the model predictions, ACR response rates were higher for abatacept compared to TNFi (both with MTX). The differences in average ACR20, 50, and 70 response rates, respectively, were 10.6 (p = 0.063), 13.3 (p = 0.018), and 15.3 (p = 0.005) percentage points, in favor of abatacept (Fig. 2). After adjustment, the differences were smaller and non-significant: 6.7 (p = 0.214), 3.9 (p = 0.421), and 6.6 (p = 0.087) points. These findings are more comparable to those reported in a direct head-to-head study by Schiff et. al. in 2014—between-group differences of -0.4, -1.9, and 1.8 points, respectively.

Conclusion: We identified factors associated with ACR response in RA clinical trials, awareness of which may inform interpretation of therapy response rates. Adjusting for them could enable more appropriate efficacy comparisons across therapies studied in different settings. In the case of abatacept vs. TNFi, adjustment via the predictive models we developed yielded results more similar to results of an existing head-to-head trial. These models may be useful for comparing other drugs/drug classes, particularly when no head-to-head trial exists.

Table 1. Simple linear regression coefficients from modeling ACR response rates as functions of patient/trial characteristics. N represents the number of observations for a given association, i.e. how many treatment arms contained both the independent and dependent variables of interest. Statistically significant associations are bolded with * = $p < 0.05$, ** = $p < 0.01$, and *** = $p < 0.001$.

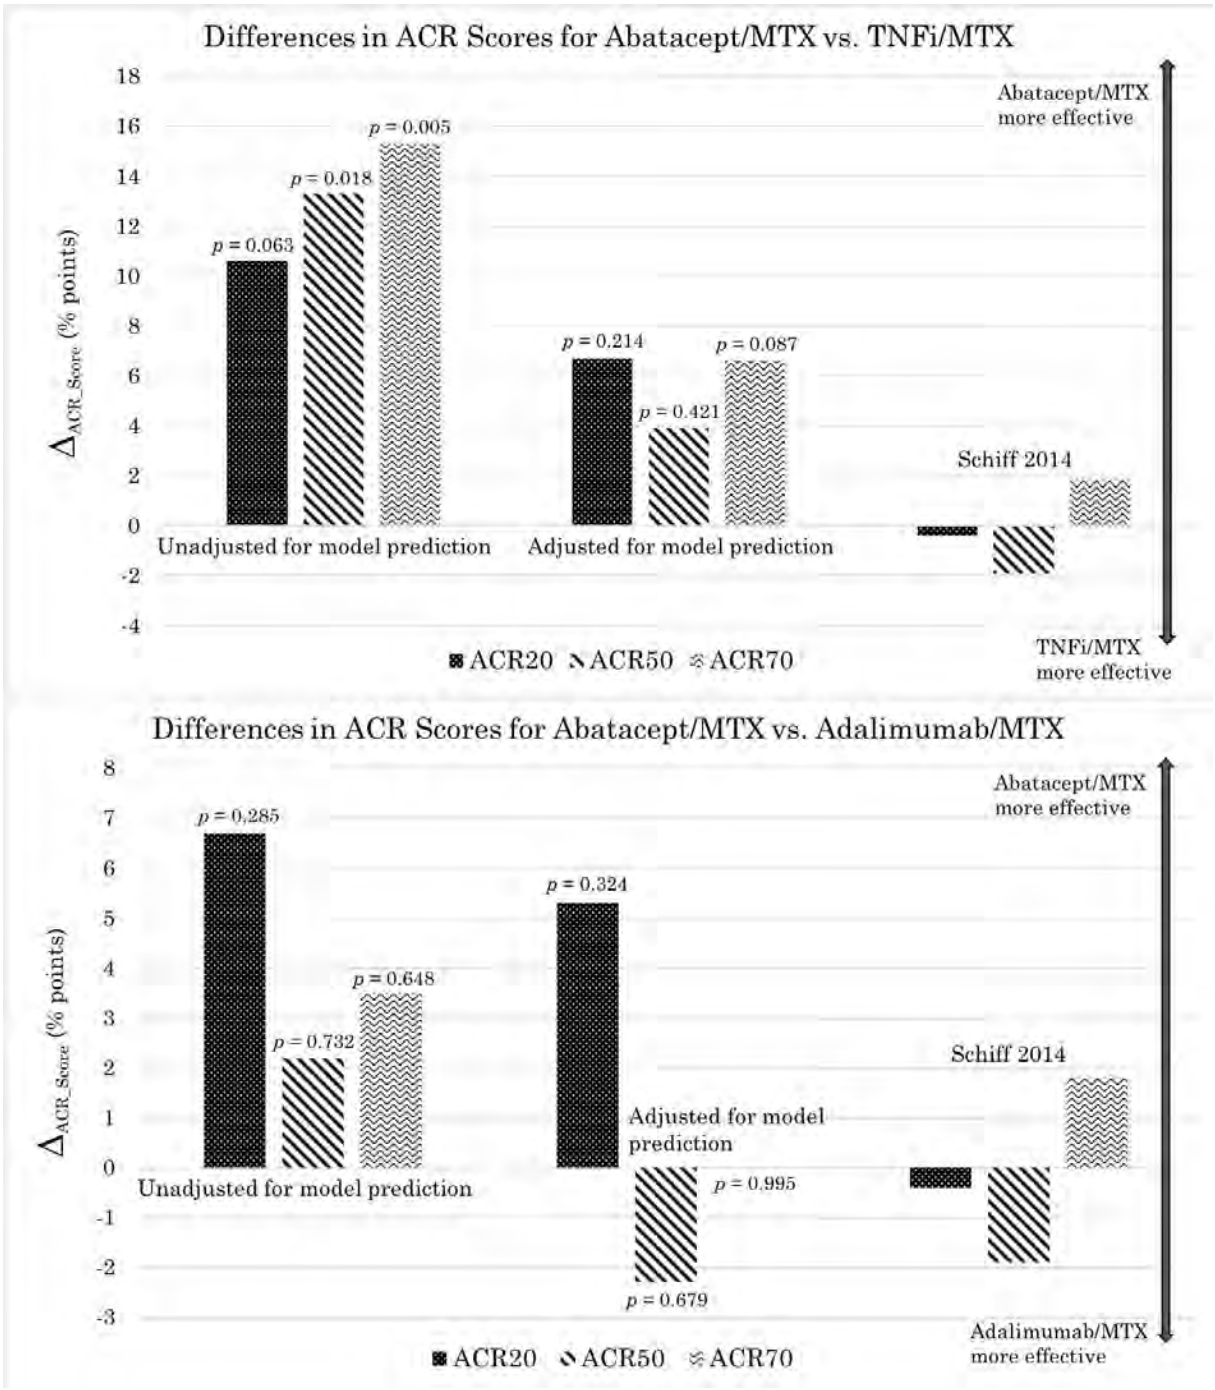

Figure 2. Differences in ACR response rates for abatacept vs. TNFi (comparison based on drug class) and abatacept vs. adalimumab (comparison based on drug)—all combined with MTX—unadjusted and adjusted for predictive models. Here ACR response rates for TNFi or adalimumab have been subtracted from those for abatacept, thus the positive vertical axis corresponds to superior efficacy for abatacept.

Safety of Biologic & Targeted Therapies Among Elderly Patients with Rheumatoid Arthritis: A Systematic Review and Meta-analysis

Akhil Sood[1], Soham Al Snih[1], Vijaya Murthy[2], Emilio Gonzalez[1] and Mukaila Raji[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Medical Branch, League City, TX

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent developments in biologic and targeted therapy have led to better control of disease activity and improved quality of life in patients with rheumatoid arthritis (RA). Many patients with RA are living longer, adding to the growing elderly population. A critical appraisal of extant data from studies on safety of these immunomodulatory therapies in the elderly can inform decision-making by patients and their physicians. We thus conducted a systematic review and meta-analysis of research studies on safety of biologics and targeted therapy in patients aged >60 years with RA.

Methods: We systematically searched Pubmed/Medline and Scopus from January 1, 1999 to June 1, 2020 to identify eligible studies that examined the safety of biologic & targeted therapies in older patients with rheumatoid arthritis. Included studies provided information on patients who received biologic (anti-TNF, IL-1, IL-6, B cell, or T cell) or targeted therapy (Janus kinase inhibitor), patients older than 60 years and a control population (younger users on biologics). Information on overall pooled rates of infections and malignancy was extracted from the studies. Meta-analysis was performed using RevMan software.

Results: We identified 823 studies; of these, 16 were included in the final analysis (12 observational studies and 4 randomized clinical trials) that comprised 8992 older users on biologics and 25,564 younger users of biologics. The pooled prevalence of infections in older and younger users of biologics was 11% and 7%, respectively, yielding a

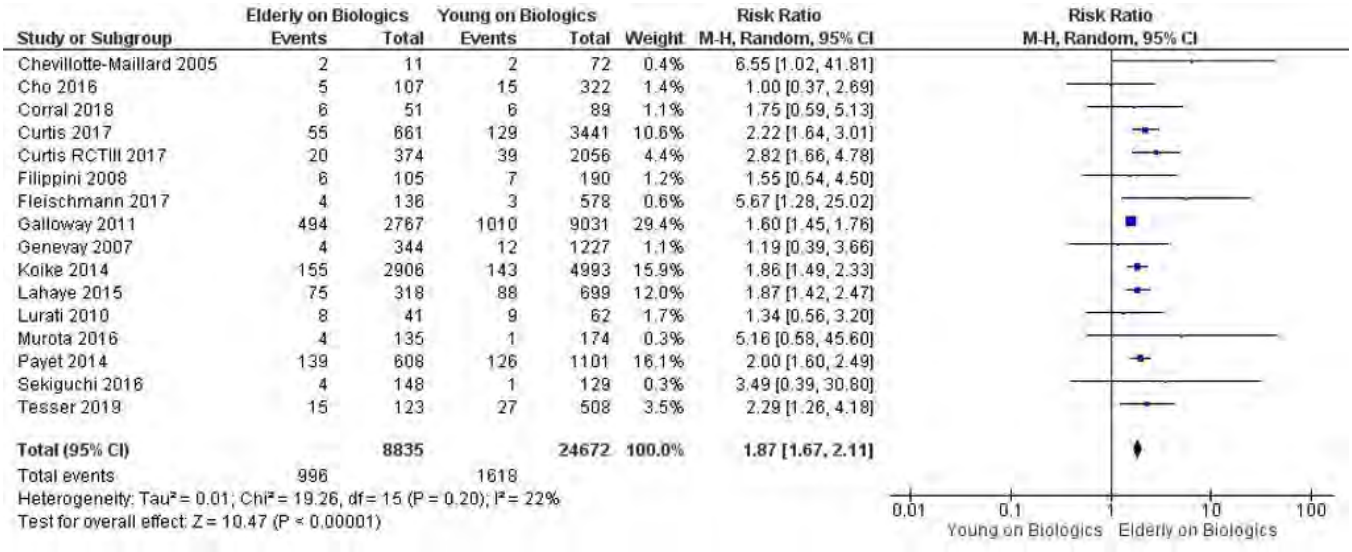

Figure 1. Forest plot on risk of infection among older patients (>60 years) on biologics compared to younger patients on biologics

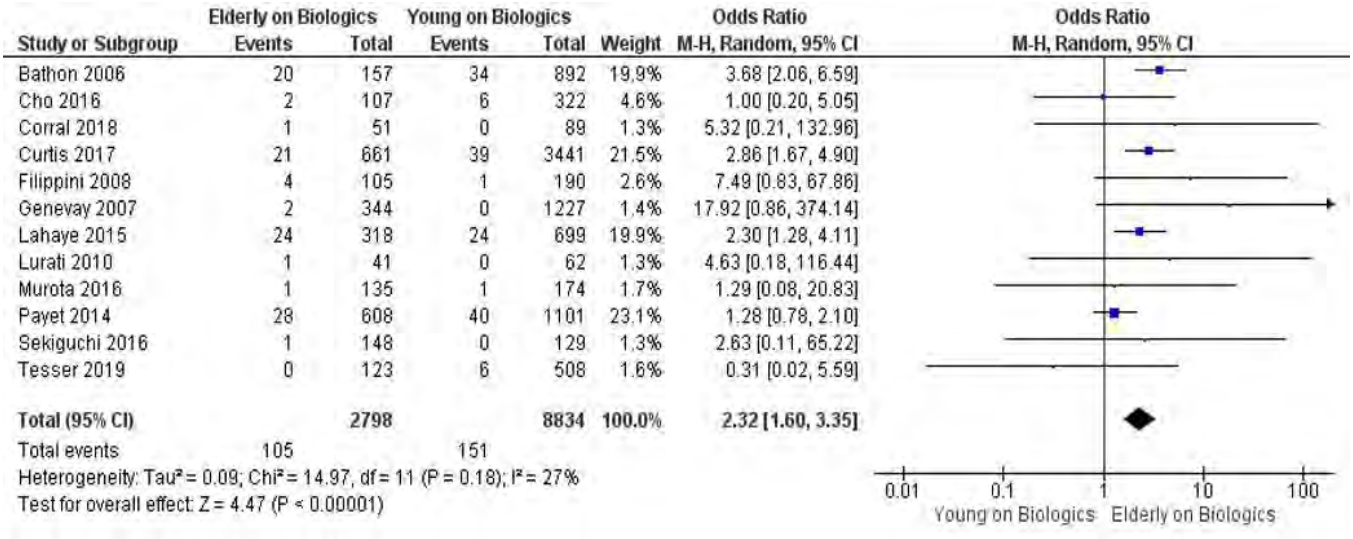

Figure 2. Forest plot on risk of malignancy among older patients (> 60 years) on biologics compared to younger patients on biologics

pooled random effects odds ratio of 1.87 (95% CI, 1.67–2.11). Older age was associated with a significant increase in risk of malignancy (OR, 2.32; 95% CI, 1.60–3.35) compared to younger users on biologics. The majority of the eligible studies were conducted in White population.

Conclusion: In a systematic review and meta-analysis, older patients with RA on immunomodulatory therapies were at significantly increased risk of infection and malignancy compared to younger patients on these treatments. Additional studies involving more racially and ethnically diverse cohorts are necessary to broaden our understanding of safety profile of biologics in different populations of older patients with RA. Furthermore, studies which include elderly patients on non-biologics as comparison would be necessary to better assess safety of biologics within elderly population.

Time to Discontinuation of Tofacitinib and TNF Inhibitors in Rheumatoid Arthritis Patients with and Without Methotrexate: Real World Results from a Rheumatoid Arthritis Cohort

Mohammad Movahedi[1], Angela Cesta[2], Xiuying Li[3], Edward C Keystone[4] and Claire Bombardier[5], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, Toronto, Canada, [4]Mount Sinai Hospital, Toronto, ON, Canada, [5]Institute for Work and Health, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment and is prescribed alone or with methotrexate (MTX). TOFA can be used as an alternative to biologic disease mod-

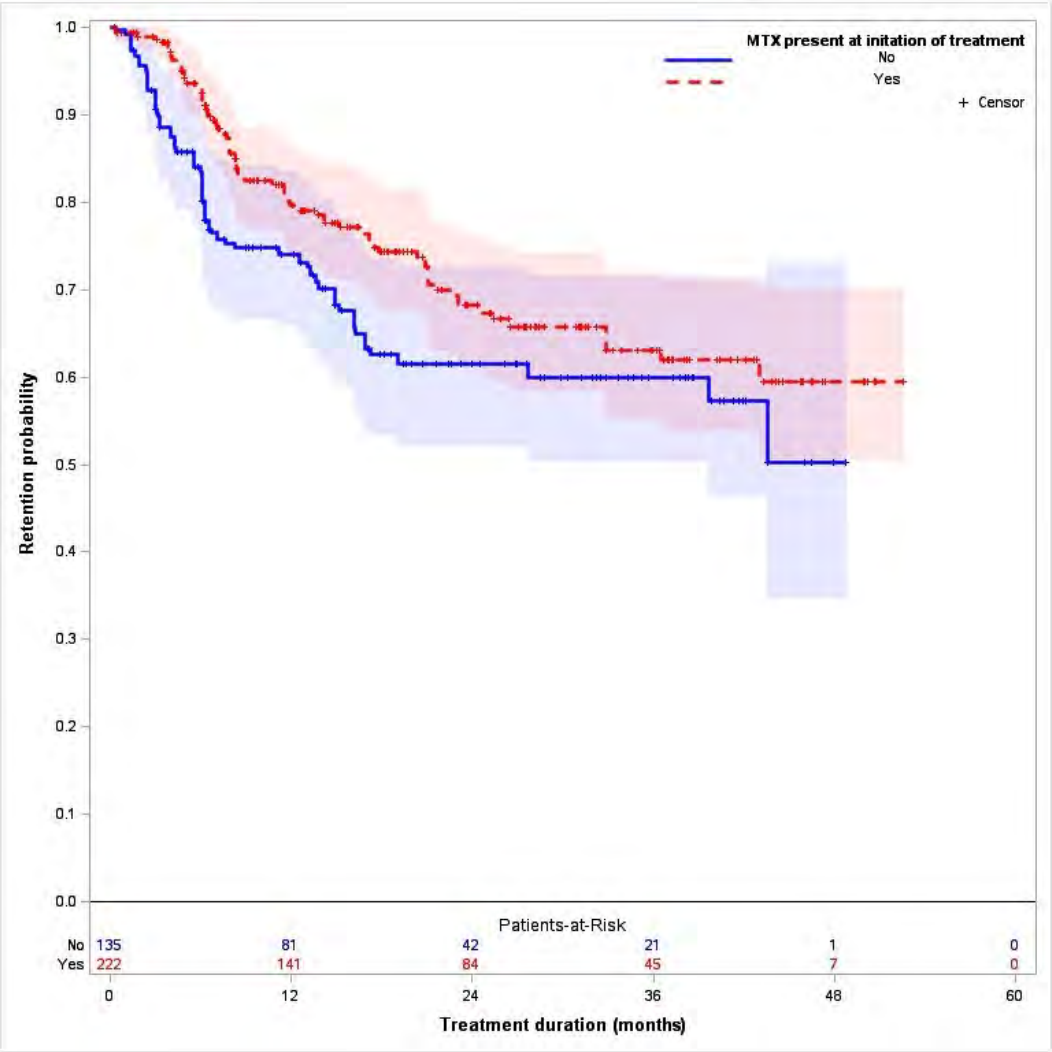

Figure 1. Drug discontinuation TNFi and TOFA; with and without MTX A. TNFi

ifying antirheumatic drugs (bDMARDs) including tumor necrosis factor inhibitors (TNFi). We aimed to evaluate the discontinuation rate of this drug, with and without concurrent MTX in comparison with TNFi, in patients with RA in the Ontario Best Practices Research Initiative (OBRI).

Methods: RA patients enrolled in the OBRI initiating their TOFA or TNFi (adalimumab, certolizumab, etancercept, golimumab, and infliximab) between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2018 were included. Time to discontinuation (due to any reason) were assessed using Kaplan-Meier survival (adjusted for propensity score using inverse probability of treatment weight) to compare patients with and without MTX use at initiation of TOFA or TNFi. We used multiple imputation (N=20) to deal with missing data for covaraites at treatment initiation.

Results: A total of 565 patients initiated TOFA (n=208) or TNFi (n=357). Of those, 106 (51%) and 222 (62%) were treated with MTX in the TOFA and TNFi group, respectively. There was no significant difference for sociodemographic , comorbidity, and disease profile between MTX groups in TOFA users. In TNFi users, compared with no MTX group, patients with MTX were significantly less likely to be women (77.9% vs. 88.9%) and to have prior bDMARDs use (24.3% vs. 42.4%).

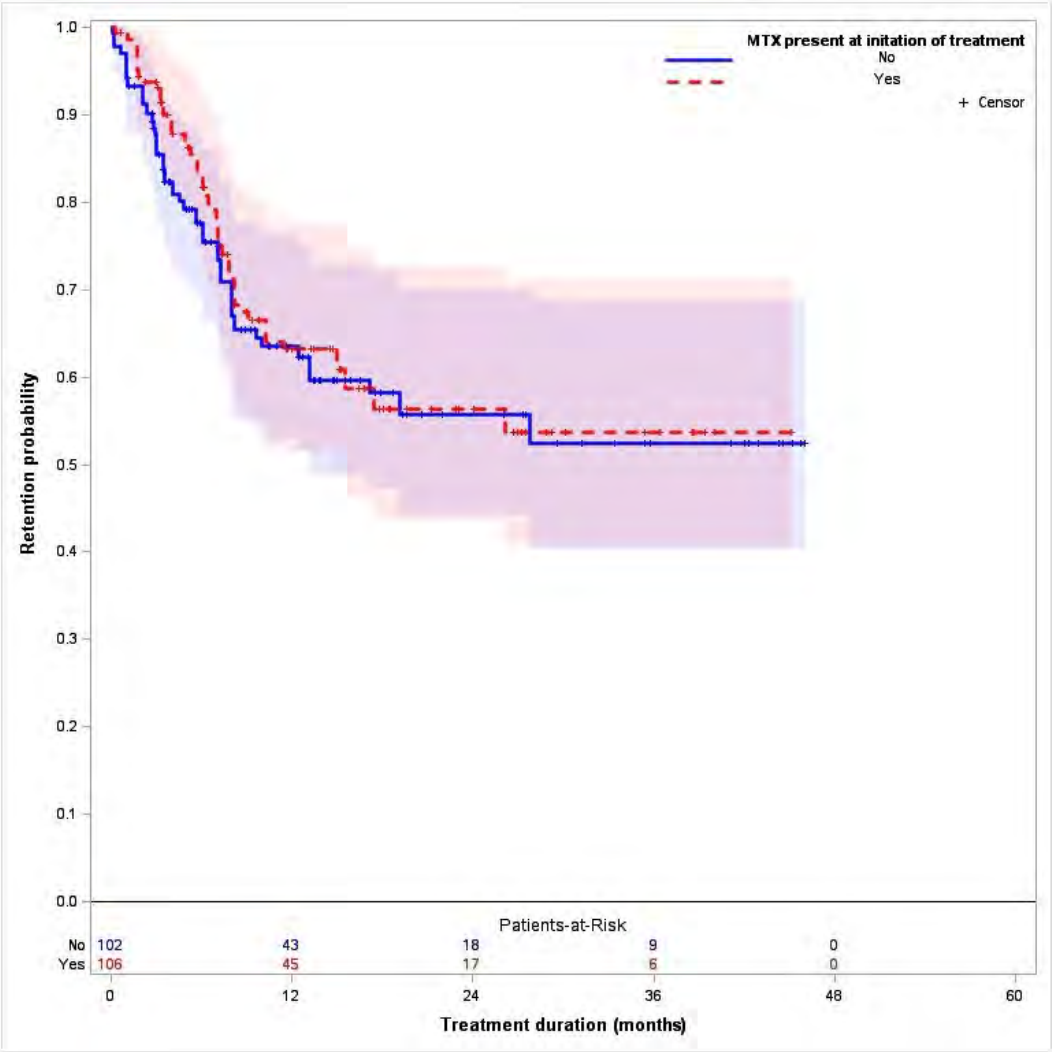

Figure 1. Drug discontinuation TNFi and TOFA; with and without MTX B. TOFA

Over a mean of 17.3 month follow-up, discontinuation was reported in 75 (36%) and 103 (29%) of all TOFA and TNFi patients, respectively. After adjusting for propensity score, patients treated with TNFi and MTX remained on treatment longer than those treated without MTX (Logrank p=0.002) (Figure 1A) while there was no significant difference in TOFA discontinuation in patients with and without MTX (Logrank p=0.31) (Figure 1B).

Conclusion: In this real world data study, we found that TOFA retention is similar in patients with and without MTX, while patients treated with TNFi and MTX remained on treatment longer than those treated without MTX. Merging data with other RA registries in Canada is proposed to increase study power and to provide more robust results.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is a Phase 4, prospective, noninterventional, observational, multicenter (88 sites), 3-year US study providing real-world assessment of intravenous golimumab (GLM) and infliximab (IFX) in patients with rheumatoid arthritis. Treatment decisions, including prescribed dose and dosing interval, are made by the treating rheumatologists. This analysis of 52-week results from AWARE explored patterns of dose escalation among IFX patients and compared changes in Clinical Disease Activity Index (CDAI), comparing IFX and GLM.

Table. Change from Baseline in CDAI Among Bionaïve Patients at Month 6 and Month 12 for GLM, Dose-Escalated IFX, and Non-Dose Escalated IFX – Comparison of Change in CDAI of Imputed Propensity Balanced vs. Observed Completer Analyses

CDAI=clinical disease activity index, DE=dose escalation, GLM=IV golimumab, IFX=infliximab, IPTW=Inverse probability of treatment weighted, SD=standard deviation.
Change from baseline in CDAI is based on imputed data using Last Observation Carried Forward for missing data and/or treatment failure rules. Mean changes in CDAI were controlled for baseline values using inverse probability of treatment weighted (IPTW) propensity score. DE (observed completer analysis) = Any patient with at least one normalized prescribed dose > baseline dose and the first dose escalation date was at least 30 days prior to CDAI collection date at Month 12.

Methods: AWARE enrolled patients initiating GLM or IFX treatment. Prescribed dose was recorded at the time of infusion. IFX patients had dose-escalation when ≥1 normalized prescribed dose exceeded the baseline dose. Normalized prescribed dose = ([prescribed dose] x [scheduled time interval] / [actual time interval]). CDAI was determined at baseline and Months 3, 6, and 12. See Table for statistical methods.

Results: Baseline demographics were generally similar between 685 GLM and 585 IFX patients (including 425 dose-escalated IFX patients), although mean ± SD disease duration was 9.20 ± 9.97 years for GLM and 6.87 ± 9.28 years for dose-escalated IFX patients. Among bionaïve and non-bionaïve GLM patients with an imputed CDAI measure, the mean prescribed dose was 2.0 mg/kg from infusion 1 through 9. The mean normalized prescribed dose among bionaïve dose-escalated IFX patients with CDAI data as 3.25 mg/kg and increased at each infusion through infusion 9 (5.14 mg/kg). The mean normalized prescribed dose among non-bionaïve dose-escalated IFX patients with CDAI data was 3.29 mg/kg and increased at each infusion through infusion 9 (5.48 mg/kg). Based on the definition of normalized dose, 75.9% of all IFX patients were dose-escalated (72.4% of bionaïve IFX and 78.7% of non-bionaïve IFX patients). The percent of bionaïve IFX patients prescribed at least 1 dose ≥8 mg/kg increased with each infusion through infusion 12. At the 10^{th} and 12^{th} infusions, respectively, 15.1% (39/258) and 19.1% (36/188) of IFX patients had received at least 1 IFX dose ≥8 mg/kg. Mean changes from baseline in CDAI for GLM, dose-escalated IFX, and non-dose-escalated IFX patients at Months 6 and 12 are shown in the Table.

Conclusion: The majority of IFX patients were dose-escalated, evident in the increasing mean normalized dose and the proportion of patients prescribed at least 1 IFX dose ≥8 mg/kg. The mean changes from baseline in CDAI scores were similar between GLM patients and dose-escalated IFX patients, although numerically lower for non-dose-escalated IFX patients.

Table 1. Baseline demographics

Background/Purpose: Biologic therapies are widely used and greatly improve outcomes in RA and PsA. Yet, our ability to predict long-term remission and persistence remains limited. This study explores predictors of remission and persistence in patients 12 years after commencing biologic therapy.

Methods: RA (ACR criteria) and PsA (CASPAR criteria) patients were prospectively enrolled into a specific biologic clinic. Outcomes at the beginning of biologic therapy, at one year and at 12 years were reviewed. Predictors of biologic persistence and remission by EULAR criteria (DAS28-CRP < 2.6) were identified with univariate and multivariate analysis.

Results: RA patients tended to be older, predominantly female and have more severe disease at baseline (Table 1). When looking at disease activity, both groups showed significant clinical improvement (Table 2). DAS28-CRP remission was 91.3% in PsA and 60.6% in RA patients at 12 years (Figure 1). PsA patients had significantly better outcomes than RA patients, despite lower levels of methotrexate use. Multivariate analysis showed 12-year initial biologic persistence [OR 4.98 (95% CI 1.83-13.56)] and male gender [OR 4.48 (95% CI 1.25-16.01)] were predictors of remission. When looking for predictors of long-term persistence, one-year persistence [OR 4.28 (1.28-14.38)] and one-year low disease activity [OR 3.90 (95% CI 1.05-14.53)] were most predictive.

Conclusion: This is the first study to show better long term (12 year) outcomes with biologic therapy in PsA compared to RA. Persistence with initial biologic agent was high and predicted outcome. Persistence and low disease activity at one year predicted long term biologic persistence. Interestingly, PsA patients had higher levels of employment, educational attainment, alcohol use and long term remission rates.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

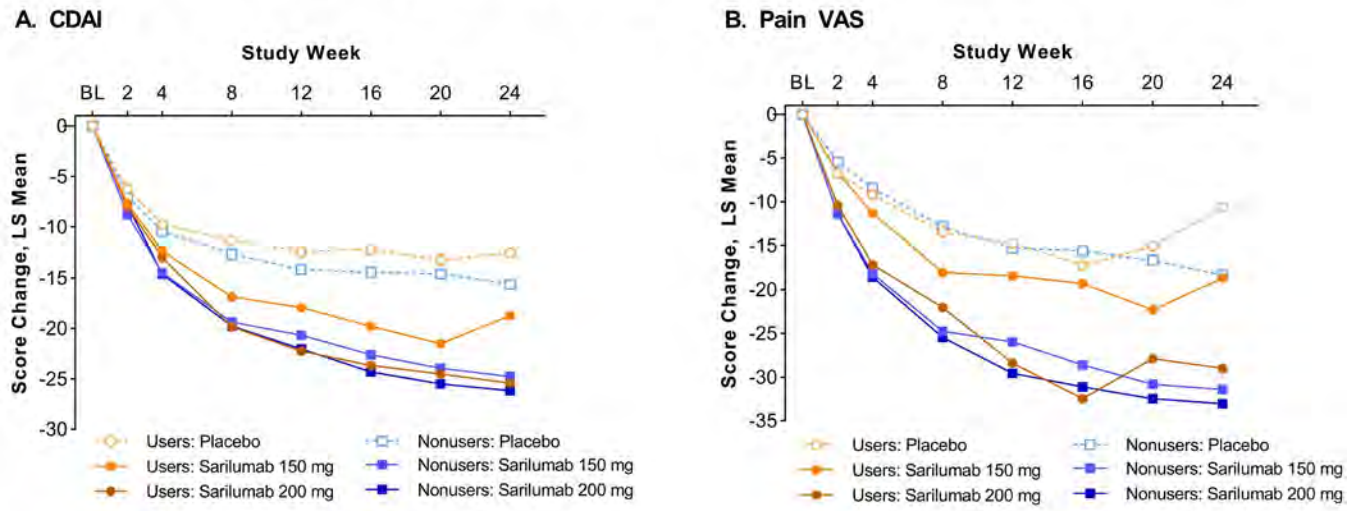
Session Time: 9:00AM–11:00AM

Background/Purpose: Prescription opioids are routinely used in patients with RA. However, use of opioids should be minimized to prevent abuse and addiction. Chronic opioid use doubled from 2002 to 2015 among patients with RA, with severe pain being a strong predictor of use (Lee YC, et al. *Arthritis Rheumatol.* 2019;71:670-677). This post hoc analysis investigated the association between the effect of treatment with sarilumab, an IL-6 receptor antagonist, and opioid use in patients with RA using clinical trial data.

Methods: Data were collected from placebo-controlled, randomized controlled trials (RCTs) MOBILITY (NCT01061736) and TARGET (NCT01709578) (pooled analysis), and from the adalimumab-controlled RCT MONARCH (NCT02332590). Patients received sarilumab (doses of 150 mg or 200 mg) or placebo once every 2 weeks (q2w) in MOBILITY and TARGET, and sarilumab 200 mg or adalimumab 40 mg q2w in MONARCH. Patients could then enroll in the open-label extension (OLE) studies wherein they received sarilumab 200 mg q2w. Change in concomitant medications, including opioids, was not permitted in the RCTs, but was permitted in the OLEs. Outcomes included evaluation of baseline characteristics associated with higher opioid use, efficacy in both RCTs and OLEs based on opioid use, and the rate of opioid discontinuation in OLEs. Data were analyzed using descriptive statistics and logistic regression.

Results: At baseline, 13% (234/1743) of patients in MOBILITY and TARGET, and 10% (38/369) of patients in MONARCH used opioids. Baseline characteristics were consistent among patients with higher opioid use across all trials. Compared with opioid nonusers, opioid users across all trials had higher mean BMI (MOBILITY-TARGET: 32 vs 28 kg/m^2; MONARCH: 30 vs 27 kg/m^2), longer mean disease duration (MOBILITY-TARGET: 12 vs 10 years; MONARCH: 9 vs 7 years), and higher mean Clinical Disease Activity Index score (MOBILITY-TARGET: 46 vs 41; MONARCH: 46 vs 43). In MOBILITY and TARGET, in both opioid users and nonusers, the reduction in disease activity and pain was numerically greater in sarilumab-treated patients versus placebo, but opioid users treated with sarilumab 200 mg showed

Figure 1. Score changes in CDAI (A) and pain VAS (B) in opioid users and nonusers in the RCTs MOBILITYand TARGET (pooled analysis)



CDAI=Clinical Disease Activity Index; RCT=randomized controlled trial; VAS=visual analog scale.

Figure 1

Figure 2: Prevalence of opioid use in the MOBILITY and TARGET OLE studies (pooled analysis, N=1353, ITT)

Figure 3

greater improvements than those treated with 150 mg (Figure 1). In MONARCH, sarilumab 200 mg was numerically superior to adalimumab 40 mg in reducing both disease activity and pain, regardless of opioid use. After 4 to 6 years of treatment with sarilumab 200 mg in the OLE, efficacy was maintained in patients who were treated with sarilumab in the RCTs, and improved among patients treated with placebo in the RCTs, with those treated with placebo during the RCTs achieving approximately the same level of disease activity as those treated with sarilumab (data not shown). In MOBILITY-TARGET, the proportion of patients using opioids decreased from 10% at OLE baseline to 4% by Year 6 (Figure 2); in MONARCH, the proportion of opioid users decreased from 11% at OLE baseline to 0 at Year 4 (Figure 3).

Conclusion: In this post hoc analysis of long-term data in patients with RA, the efficacy of sarilumab was maintained in both opioid users and nonusers. In addition, the use of opioids decreased over time in patients treated with sarilumab.

Real-World Utilization of Infliximab (IFX) and Its Biosimilars in Patients (Pts) with Rheumatoid Arthritis (RA) Since the First Biosimilar Approval in the US

Simon Helfgott[1], Janna Radtchenko[2], Nehad Soloman[3], Kent Kwas Huston[4], Jasvinder Singh[5] and Colin Edgerton[6], [1]BWH- HMS, Boston, MA, [2]Trio Health, Louisville, CO, [3]Arizona Arthritis & Rheumatology Associates, P.C., Peoria, AZ, [4]Kansas City Physician Partners, Kansas City, MO, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Articularis Healthcare, Summerville, SC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologics have revolutionized the treatment of autoimmune diseases, though costs and payer restrictions have limited who are treated and when these agents are used. Potentially lower cost biosimilars have been developed and FDA-approved, although only 2 TNF inhibitors have been made available to pts. Here, we describe utilization and characteristics of pts receiving IFX and its biosimilars in US community rheumatology practices.

Methods: Electronic medical records data from the American Rheumatology Network (ARN) - Trio Health Rheumatology registry was used for the study. The ARN is a physician-led and owned organization with over 200 practicing rheumatologists that supports some of the largest independent practices in the US. Pts with RA diagnosis who initiat-

Infliximab group	0.883			
Infliximab-abda vs infliximab	0.952	1.02	0.54	1.91
Infliximab-dyyb vs infliximab	0.620	1.11	0.74	1.65
Number of prior regimens	0.101	0.93	0.86	1.01
Duration of current therapy (months)	**0.001**	1.04	1.01	1.06

Table 2. Logistic regression results: outcome remission/low disease activity at 6 months since regimen initiation

ed or switched to IFX or biosimilars since December 2016 were selected for analysis. Differences between treatment groups were assessed using t-test for continuous variables and chi-square test for categorical variables. Logistic regression model was used to evaluate outcome remission/low disease activity at 6 mo accounting for demographic and treatment characteristics. Time to treatment discontinuation was assessed using Kaplan-Meier method.

Results: 3156 pts met study criteria; 1972 (62%) were on IFX (775 [39%] as monotherapy) and 1184 (38%) received biosimilars (306 [26%] as monotherapy). Of pts on biosimilars, 350 (30%) switched between different biosimilars or IFX and were removed from the analysis. The remaining 834 pts were treated with infliximab-dyyb (574 [69%]) or infliximab-abda (260 [31%]).

There were no differences by age and gender between IFX and each biosimilar group [Table 1]. Compared to pts on biosimilars, pts receiving IFX had longer follow-up, fewer prior DMARD or biologic regimens, and longer duration of treatment with IFX. Pts on biosimilars were less likely to be commercially insured and more likely to be on Medicaid compared to IFX. IFX pts were more likely to be in remission/low disease activity at treatment initiation and at 6 mo since treatment initiation compared to pts on biosimilars; there were no differences between biosimilar groups. IFX pts had smaller improvement from baseline (BSL) to 6-mo CDAI compared to pts on biosimilars.

Accounting for age, payer, regimen, steroid use, duration of therapy, number of prior regimens, and BSL disease activity status, variables significantly impacting the outcome were BSL disease activity, regimen duration, and use of steroids but not choice of a biologic [Table 2].

Median time to treatment discontinuation was not statistically different among groups [Figure 1].

Conclusion: Among RA pts treated with IFX and its biosimilars there were differences in demographic and BSL clinical characteristics. IFX was used earlier in the treatment journey than biosimilars with higher proportion of pts in remission at BSL and last observation. Time to treatment discontinuation was similar among groups. After accounting

for other pt and treatment characteristics, regimen choice (use of a particular biosimilar vs IFX) was not significantly associated with treatment success at 6 mo since regimen initiation.

Abstract Number: 0813

Treatment Outcomes in Patients with Seropositive versus Seronegative Rheumatoid Arthritis in Czech Registry ATTRA Treated with JAK Inhibitors

Karel Pavelka[1] and Zlatuše Křístková[2], [1]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Biostatistics and Analyses, Ltd., Brno, Czech Republic

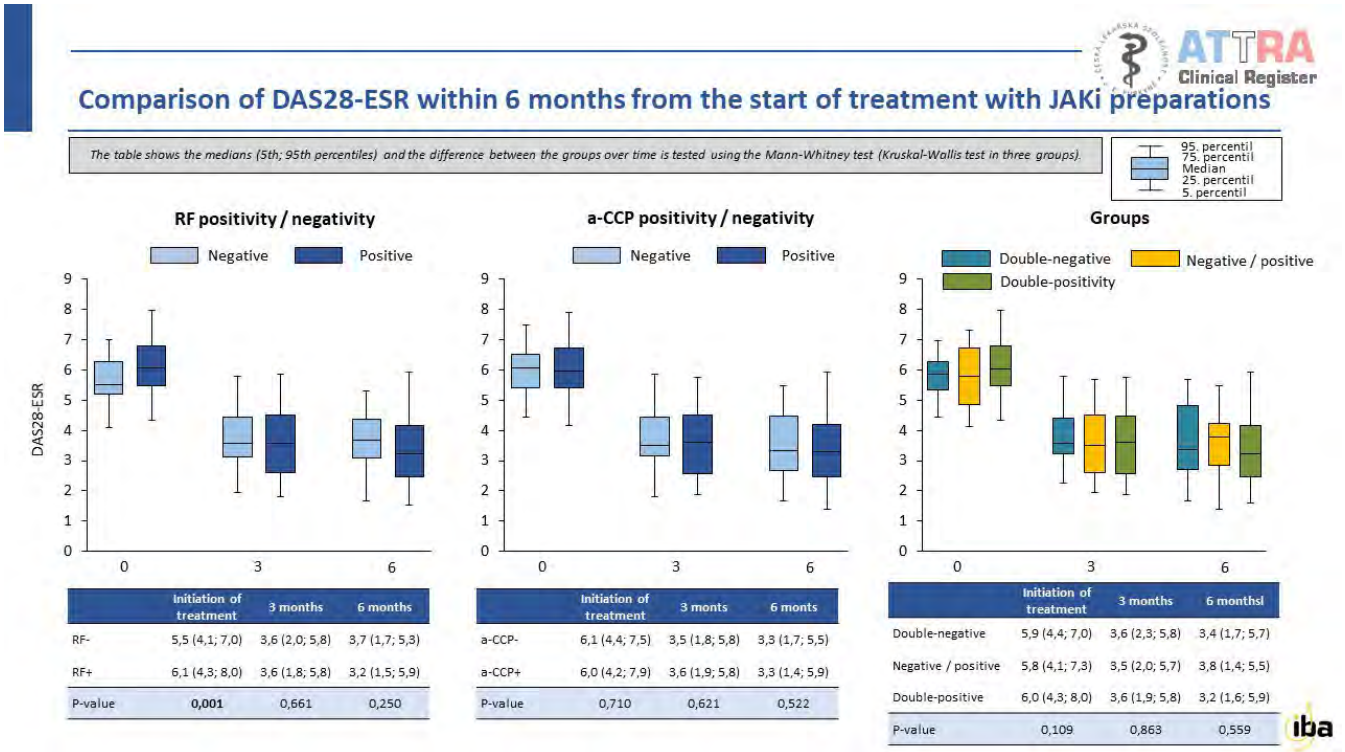
SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM



Background/Purpose: Seropositivity / seronegativity in RA may have influence on response to bDMARDs or tsDMARDs. There is incomplete knowledge of differences in efficacy of JAK inhibitors in different subgroups of patients in real clinical practice. We aimed to compare treatment response between seropositive and seronegative RA patients in the Czech National Registry ATTRA.

Methods: We included patients with moderate to severe RA, who failed in the past MTX or bDMARDs. Primary outcome measure was change(Δ) in DAS28 btw start of therapy and 6 months. Secondary outcomes measures were ΔSDAI and survival on therapy.

Results: We have included 263 patients treated with JAK inhibitors (130 tofacitinib, 133 baricitinib). Mean age at baseline was 55 ± 10 years, disease duration 13 ± 9 years, mean CRP in seropositive group was 25 mg/l and seronegative 21 mg/l ($p = 0,012$), mean DAS 28 ESR was 6.0 in seropositive and 5.6 in seronegative groups ($p < 0.001$). About 60 % patients have concomitant steroids. Concomitant treatment with MTX had 39 % in seronegative and 57 % in seropositive group ($p = 0.028$).

DAS 28 improved in both groups significantly. There were no differences between patients with double positivity (RF, anti CCP), single positivity or double negativity (Figure 1). There were no significant changes in SDAI as well. Adherence to therapy was very good, with no differences in seropositive and seronegative groups (68 % vs. 72 %).

Tolerance on therapy was good with no new signals and no differences between seropositive and seronegative groups.

Conclusion: There were no differences in efficacy of JAK inhibitors between seropositive and seronegative patients in Czech National Registry ATTRA. Double seropositive patients had more severe disease at baseline.

"I Want to Switch Back": Real-world Experience of Switching Intravenous Abatacept and Tocilizumab to Subcutaneous Injection During the COVID-19 Pandemic

Rishi Gupta[1], Muhammad Shipa[2], Su-Ann Yeoh[2], Pauline Buck[1] and Michael Ehrenstein[2], [1]University College London Hospital, London, United Kingdom, [2]University College London, LONDON, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: During the COVID-19 pandemic, rapid guidelines by the National Institute for Health and Care Excellence (NICE) in the United Kingdom[1] recommended consideration of switching from intravenous (IV) treat-

ment to subcutaneous (SQ) form to minimise the risk of exposure. The aim of this study is to assess patient-reported outcomes of those who have been switched to SQ form from IV abatacept (ABT) and tocilizumab (TCZ).

Methods: We analysed RA patients at a large rheumatology centre fulfilling the 2010 ACR/EULAR classification criteria who were switched from IV to SQ ABT and TCZ. Patients who have not responded to the SQ form in the past were not switched. We compared Multi-Dimensional Health Assessment Questionnaire (MD-HAQ) scores immediately before and 3 months after the IV to SQ switch. RAPID3 was calculated using three components of MD-HAQ (functional status, pain, and global health). Patients were also asked whether they would prefer their current SQ regimen to continue or whether they would like to revert to IV. Reasons for patient preference to revert to IV were also captured.

Results: 32 patients were switched from IV to SQ [14 (43.7%) ABT and 18 (56.3%) TCZ]. Of the 32 patients who switched, 29 responded to our questionnaires. The majority of patients were in DAS28-ESR clinical remission or low disease activity prior to the switch (mean DAS28-ESR 3.00 for ABT, 2.15 for TCZ).

Unexpectedly, 77% (10/13) in the ABT group and 88% (14/16) in the TCZ group, expressed a preference to return to their IV regimen **(Fig. 1).** In the ABT group, patient preference to revert to IV was primarily due to worsening symptoms of joint pain/stiffness since the switch to SQ (symptom recurrence described in the last 2 days of weekly injection) **(Table 1)**. This, in turn, is associated with a negative impact on function, represented by the statistically significant increase in MD-HAQ functional status score from 3.662 to 4.408 (p= 0.042), with higher values reflecting negative

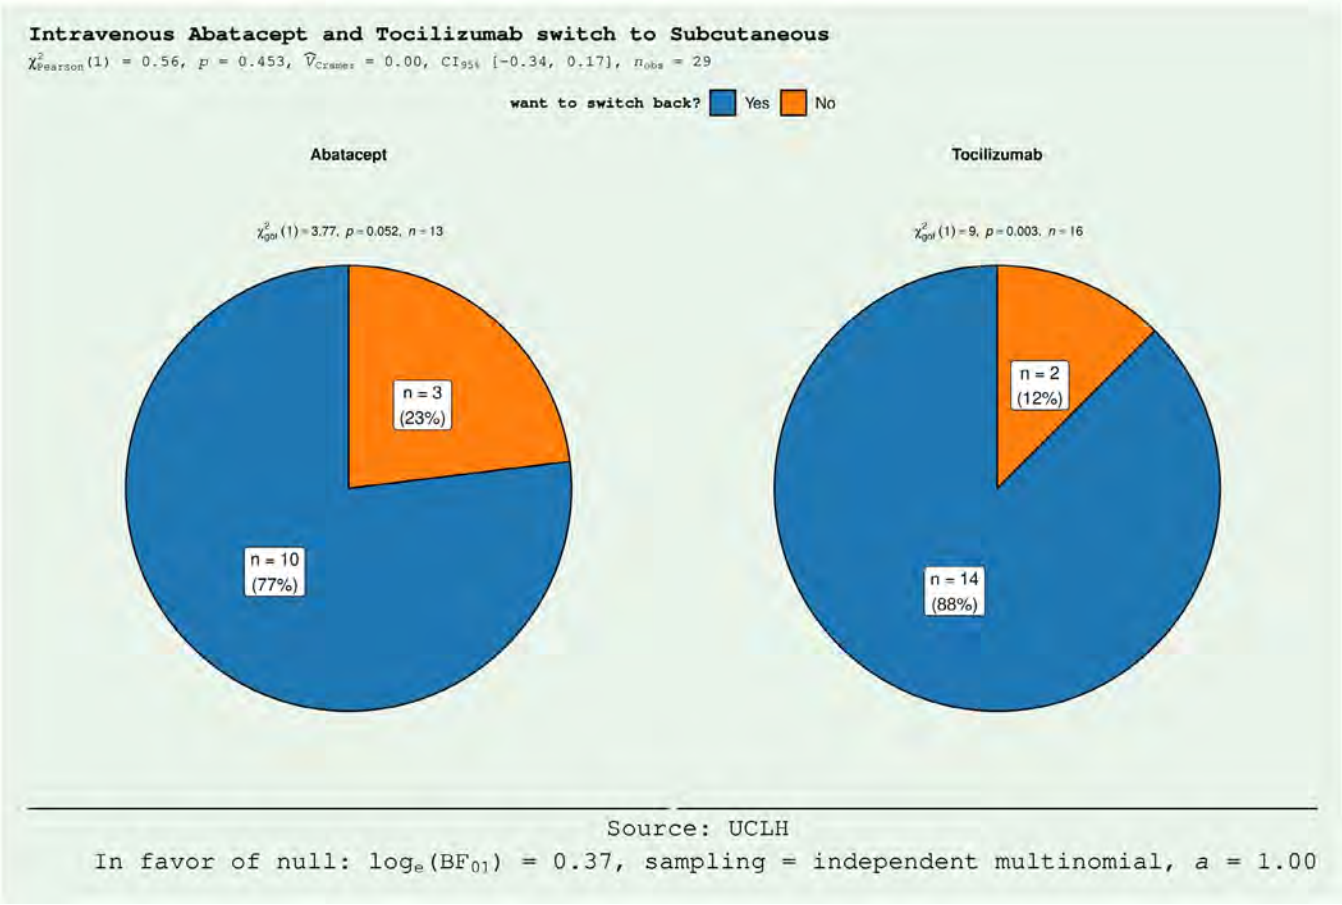

Figure 1. The majority of the patients in the abatacept (ABT) and tocilizumab (TCZ) groups preferred to switch back from subcutaneous (SQ) to intravenous (IV) form. In ABT group, 10/13 wanted to switch back (χ2 3.77, p = 0.052). In the TCZ group, 14/16 would like to switch (χ2 9, p = 0.003).

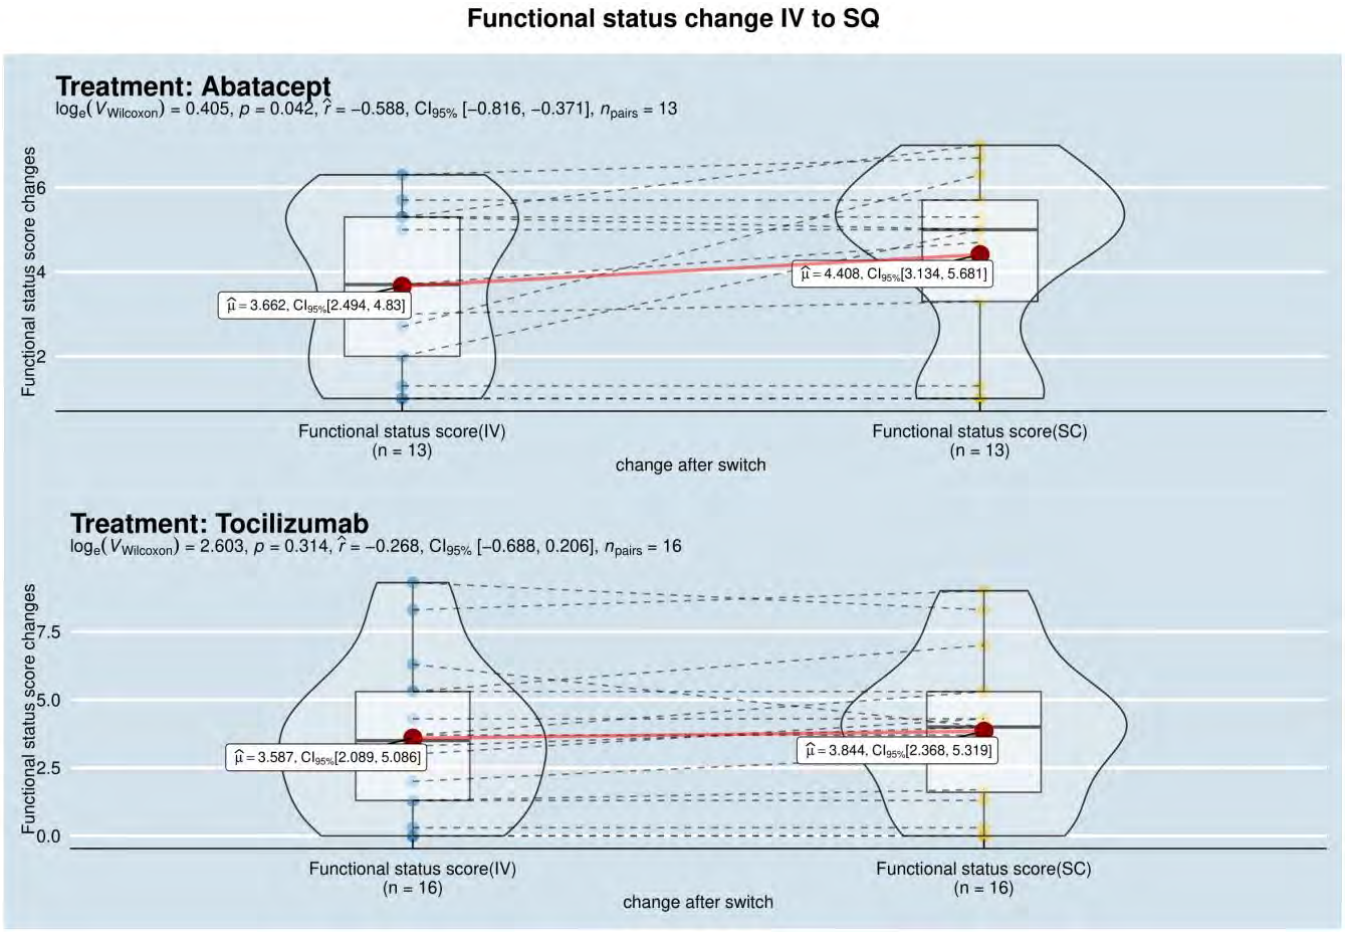

Figure 2. Switching Abatacept (ABT) to subcutaneous (SQ) form, resulted increase in mean score to 4.408 from 3.66 (p = 0.042).

Reason for wanting to switch back from SQ to IV	Abatacept (N = 10), n (%)	Tocilizumab (N = 14), n (%)	p value
Worsening symptoms	6 (60%)	7 (50%)	0.69
Preferred monthly administration over weekly	1 (10%)	2 (14%)	1.00
Preferred seeing healthcare professional in hospital	2 (20%)	5 (36%)	0.65
Preferred not to self-administer own medication	1 (10%)	0 (0%)	0.41

Table 1. Reasons for wanting to switch back from SQ to IV.

patient experiences **(Fig. 2)**. We did not find any significant differences in the other 2 components of MD-HAQ and RAPID3.

In the TCZ group however, although the majority expressed a preference to revert to IV, no statistically significant differences were noted in MD-HAQ and RAPID3. 50% (7/14) preferred to revert to IV due to worsening of symptoms,

whilst 35.7% (5/14) requested to revert to IV as they preferred the face-to-face interaction with a healthcare professional.

Conclusion: This was a small study but nevertheless indicates that the vast majority of RA patients who switched from IV to SQ ABT and TCZ expressed a preference to switch back. For ABT, this decision was associated with worsening of their functional status whereas for TCZ, although we did not find any statistical significant difference in MD-HAQ and RAPID3, the most commonly reported reasons for request to revert to IV were either worsening of symptoms or the benefit of interaction with a healthcare professional with the IV route of administration. These results suggest that IV and SQ formulations should not be considered as equivalent medications for RA.

Initial Pharmaceutical Management in a National Cohort of Elderly-Onset Rheumatoid Arthritis Patients

Deepan Dalal[1], Tingting Zhang[2], Hiren Varma[2] and Theresa Shireman[2], [1]Brown University, East Providence, RI, [2]Brown University, Providence, RI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate is the preferred initial drug for treatment of rheumatoid arthritis (RA) per American College of Rheumatology guidelines (2015). People with elderly-onset RA, classified as onset of disease after 60-65 years of age, are frequently undertreated with biologic disease modifying agents (bDMARDs) farther along the course of disease. However, little is known is about the initial management of RA in older patients. Using Medicare data, we examine the pattern in initial drug therapy in elderly onset RA patients.

Methods: We used Medicare claims from the years 2012 - 2016 to identify older adults (>65 years) with RA defined on the basis of a single ICD9/ICD10 claim in hospital claims, two or more ICD9/ICD10 claims in outpatient claims (7 days apart but within 365 days), or single ICD9/ICD10 claim in outpatient claim plus a prescription or outpatient claim for a disease modifying agents (DMARDs). Study subjects were enrolled in Medicare fee-for-service for at least 12 months prior to case ascertainment. We excluded patients with any prior RA claim or DMARD claims in the prior 12 months to establish an incident RA cohort. Measures included baseline demographics and comorbidities, initial DMARDs used after diagnosis of RA along with their initial average daily dose prescribed and average steroids dose used in the first 90 days after first diagnosis.

Results: We identified 99,491 incident cases of RA (see Table 1 for baseline characteristics). The average time from first claim for RA to the first prescription of DMARD was 28.6 days. Conventional DMARDs (cDMARD) were used as an initial drug in 13.9% patients as compared to bDMARDs in 0.3% patients; 45.9% of patients received steroids within the first 3 months. Of all patients starting a cDMARD, hydroxychloroquine (41.04%) and methotrexate (35.72%)

Table 2 Initial DMARD therapy amongst elderly onset RA patients

were the most common initial cDMARDs. Methotrexate initiation declined with increasing age (36.2% in 65-69-year age group v. 30.77% in >85-year age group). As the age of onset increased, doses of hydroxychloroquine, methotrexate, leflunomide and steroids decreased. Adalimumab and infliximab were the most prescribed bDMARDs.

Conclusion: In a national of elderly-onset RA patients, hydroxychloroquine instead of methotrexate was the preferred initial cDMARD, which could lead to inadequate control of disease. Further, with increasing age, the doses of cDMARDs prescribed reduced which could further contribute to reduced control of early disease.

Treat-to-target Strategy in Patients with Rheumatoid Arthritis in Daily Clinical Practice -still Underused, but Superior to Routine Care: A Propensity Score Matched Analysis from the ATTRA Registry

Jakub Závada[1] and Lucie Nekvindova[2], [1]Revmatologický ústav, Praha 2, Czech Republic, [2]Institute of Biostatistics and Analyses, Ltd., Brno, Czech Republic

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target (T2T) is a widely accepted management strategy for RA. It recommends attaining a goal of at least low disease activity (LDA) within 6 months, otherwise the current therapy should be modified. We assessed the compliance with and effectiveness of the T2T principles in real clinical practice using data in the Czech biologics register ATTRA. The ATTRA registry captures more than 95% of patients with RA treated with bDMARDs/tsDMARDs (or Targeted Therapies, TTs) in the Czech Republic (CZ). In CZ, TTs is reimbursed for RA if DAS28 >5.1 despite therapy with csDMARDs. We aimed to investigate whether switching the first-line targeted drug in pts not reaching LDA within the 6 months since baseline leads to a higher probability of meeting LDA at 12-month visit.

Table 1. Comparison of parameters related to disease activity, quality of life and concomitant therapy between C3 and C4 cohort at the 6-month and 12-month visit (before PS matching)

Methods: We included all adult RA patients starting first-line TT from 1 January 2012 to 31 January 2017 with at least one-year follow-up (FUP), and available DAS28-ESR at baseline, 6- and 12-month visits. We created four mutually exclusive cohorts C1-4 based on 1) switching (and its timing) to another TT within the first year, and 2) reaching LDA (DAS28-ESR ≤ 3.2) at 6-month visit (Fig). The primary outcome was the comparison of odds for reaching LDA at the 12-month visit between patients switching and not switching TT after not reaching LDA at 6 months. Before using logistic regression to estimate the odds ratio, we employed the propensity score (PS) to match patients and make them comparable in characteristics related to disease activity and quality of life at the 6-month visit.

Results: 1275 patients were eligible for the analysis. 62 patients switched within the first 1-5 months of the treatment before evaluating treatment response at the 6-month visit (C1). 598 patients reached LDA within six months of therapy (C2), 124 patients did not reach LDA at 6-month visit and switched to another therapy (C3), and 491 patients continued with the same treatment despite not reaching LDA at the 6-month visit (C4). Clinical cahracteristics of cohorts C3 and C4 at 6 and 12 months are shown in Table 1.75 patients from cohort C3 and 75 patients belonging to a cohort C4 were matched using the PS (Table 2). After PS matching, patients following T2T principle (C3) showed 2.8 (95% CI 1.4–5.8; p=0.005) times increased likelihood of achieving LDA at 12-month visit compared to patients not following T2T strategy (C4).

Conclusion: In daily clinical practice, application of T2T strategy is underused. Switching to another TT after not reaching LDA within the first six months leads to a higher probability of achieving LDA in RA patients at the 12-month visit.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: JAK inhibitors (JAKi) are targeted synthetic DMARDs (tsDMARDs) with a different mode of action (MOA) to conventional synthetic and biologic DMARDs (cs and bDMARDs). In Australia the cost of b/tsDMARDs for treatment of RA is subsidized if the patient has high levels of clinical/laboratory disease activity and has not responded to a pre-specified combination of csDMARDs, including methotrexate. Once eligible for subsidy the clinician can prescribe the b/tsDMARD deemed most clinically appropriate until the desired level of disease control has been reached. The aim of this analysis was to determine the patterns of use and reasons for initiation and discontinuation of JAKi in real-world practice in Australia.

Methods: Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record at the time of the consultation. Data from RA patients 18 years and older who commenced a b/tsDMARD between Jan-2007 and Mar-2020 were included in the analysis. The software program Tableau® was used to display data on medication initiation and cessation dates, and reasons for starting and stopping b/tsDMARDs, which is recorded at the time of the decision.

Results: At Mar 2020, there were 47,455 patients with RA in the data set; 27% prescribed b/tsDMARDs. Of patients on treatment at Mar 2020, 51% were receiving a TNF inhibitor (TNFi) and 23% a JAK inhibitor (JAKi), with the remainder receiving tocilizumab, abatacept or rituximab. Of patients who commenced their treatment after JAKi's become available in Sept 2015, 45% were treated with a TNFi, and 32% were treated with a JAKi. Tofacitinib (TOF) has been the most prescribed b/tsDMARD since Sept 2015 with 21% of all initiations; however, since baricitinib (BARI) became available in Sept 2018, it has taken over as the preferred JAKi with 23% of new initiations compared to 14% for TOF. From Sept 2018-Mar 2020 etanercept and adalimumab were the most commonly prescribed first line agents, followed by BARI then TOF; however, BARI was the most prescribed agent in lines 2-6+. The main clinician-listed reason for choice of TOF was MOA in 58%, efficacy compared with alternatives in 21%, mode of administration in 11%, efficacy as monotherapy in 7%, and safety in 1%. BARI was chosen for MOA in 28%, efficacy compared with alternatives in 42%, mode of administration in 19%, efficacy as monotherapy in 8%, and safety in 1%. The main reasons for stopping TOF were lack of efficacy (34%), better alternative (25%), and adverse reaction (14%); those for BARI were lack of efficacy (35%), adverse reaction (25%), and better alternative (12%). Patient non-adherence was listed in 1% and 2% of cessations for TOF and BARI, respectively. 49% of patients discontinuing a JAKi in first line switched to a TNFi in second line, and 34% switched to another JAKi, citing lack of efficacy, adverse reaction, and better alternative as the reason for switching.

Conclusion: There has been significant and sustained uptake of JAKi for the management of RA in Australia. MOA and perceived efficacy rate much higher than mode of administration for clinicians when selecting a JAKi. Clinical outcomes and persistence following JAKi cycling requires further investigation.

Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Different jakinibs have shown efficacy in rheumatoid arthritis (RA) but in an important proportion of patients, insufficient response leads to therapy withdrawal. The different jakinibs show variable selectivity for the four Jak isoforms (Jak1,2,3 y Tyk2) but there are no clinical trials analyzing the response to a jakinib after the suspension of another jakinib and therefore, observational data may be useful in this regard. The aim of this study is to describe efficacy and safety of the second jakinib in patients with suspension of the first due to failure or side effects.

Methods: Spanish observational multicentric study. Data were retrospectively obtained from medical records of 31 patients with RA sequentially treated with baricitinib or tofacitinib in any order.

Results: We identified 31 patients with RA, median age 62 years (IQR 51-67), 80.6% female (Table 1). Rheumatoid factor and anti-CCP was positive in 80.6% and 71% of the patients . Most of the patients (87%) had received previously treatment with bDMARD, median number of previous bDMARDs 4 (IQR 2-5). Half of the patients received Tofacitinib first, and the other half Baricitinib as the first Jakinib. Median survival for the first Jakinib was 5 months (IQR 3-8) and the reason for withdrawal was inefficacy in 19 cases (61.3%) and adverse effects in 12 (38.7%). Median DAS28CPR in the beginning of the second jakinib was 5.3 (IQR 5-5.9), 9 patients were treated in monotherapy and 26 used glucocorticoids.

9 patients discontinued the second Jakinib, in all of them the reason was inefficacy. The treatment suspension rate was similar among patients discontinuing the first Jakinib for inefficacy (5/19, 26.3%) or for adverse effects (3/12; 25%). Median follow-up of patients who didn't discontinue the second Jakinib was 19.5 (IQR 12-24) months. Disease activity data along this follow-up are depicted in Figure 1 and 2.

*Data are offered as median (IQR)

Table 1. Characteristics of 31 patients with RA treated sequentially with two jakinibs

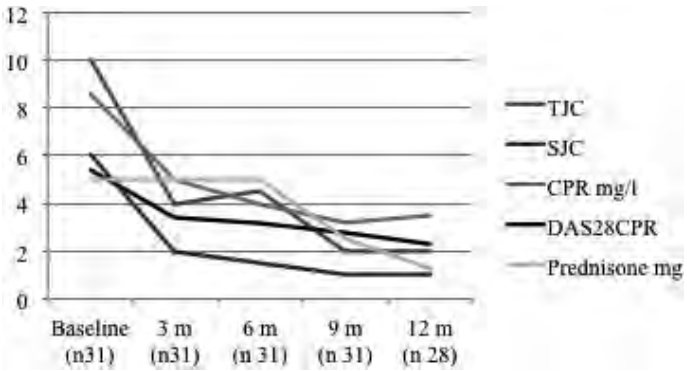

Figure 1. Second jakinib treatment results during the follow-up period (median).

Conclusion: Our data show that therapy with a second jakinib is a safe and efficacious option after discontinuation of the first jakinib due to either inefficacy or side effects. The response rate to the second jakinib is similar in patients with inefficacy or side effects which suggests that failure to the first does not reduce the chance of response to the second.

The Adherence Patterns Among Patients Using Infliximab Bio-originator and Biosimilar

Joseph Alanaeme[1], Sujith Sarvesh[1], Jeffrey R Curtis[2] and **Huifeng Yun**[2], [1]University of Alabama at Birmingham, BIrmingham, AL, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Infliximab (INF) biosimilar was approved for multiple indications in U.S. in 2016. Although clinical trials have demonstrated that switching from infliximab bio-originator to its biosimilar is safe with no significant loss of efficacy, there are limited real-world data comparing their utilization and adherence patterns. Thus, we evaluated medication adherence among INF biosimilar users and compared them to INF bio-originator users using national administrative data, 2014-2018.

Methods: We established 4 cohorts among patients who had at least one administration or pharmacy claim for INF bio-originator or biosimilar in 2017 Truven Marketscan data, including INF biosimilar naïve users, INF biosimilar prevalent users, INF bio-originator naïve users, and INF bio-originator prevalent users. We evaluate the prior use of INF and other biologics using all available data in 2014-2017 prior to the first INF administration in 2017 (index date).The INF naïve users were defined as no prior use of INF bio-originator or INF biosimilar, whereas prevalent users had any prior use of bio-originator INF but no prior INF biosimilar use. Eligible patients were ≥18 years of age, continuously enrolled with full coverage from 2014 and through follow up. Follow-up started on the index date and ended on the earliest date of death, loss of coverage, or 12/31/2018. For patients who had at least 12 or 18 months of follow-up time, we calculated their proportion of days covered (PDC) at 12 or 18 months. Ongoing analyses are adjusting for important patient characteristics that differ across cohorts.

Table. Proportion of days covered calculated at months of 12 and 18 during following up

Cohorts	12 Months Follow-Up Adherence (365 days)			18 Months Follow-Up Adherence (548 days)		
Inflectra (N = 319)	**<50%**	**50 – 80%**	**>80%**	**<50%**	**50 – 80%**	**>80%**
Naïve Inflectra without Past use of Infliximab (N = 96)	27 (40.30)	11 (16.42)	29 (43.28)	9 (39.13)	3 (13.04)	11 (47.83)
Naïve Inflectra with Past use of Infliximab (N = 223)	61 (41.50)	19 (12.93)	67 (45.58)	28 (50.00)	8 (14.29)	20 (35.71)
Infliximab (N = 13, 119)	**< 50%**	**50 – 80%**	**>80%**	**< 50%**	**50 – 80%**	**>80%**
Naïve Infliximab without Past use of Inflectra (N = 2,149)	485 (30.72)	276 (17.48)	818 (51.80)	350 (42.42)	135 (16.36)	340 (41.21)
Prevalent Infliximab Users (N = 10, 970)	1,069 (13.46)	1,082 (13.62)	5,793 (72.92)	1,262 (17.06)	1,381 (18.67)	4,754 (64.27)

Results: We identified 96 INF biosimilar naïve users, 223 INF biosimilar prevalent users, 2,149 INF bio-originator naïve users, and 10,970 INF bio-originator prevalent users. The proportion of other biologic use prior to index date and demographic characteristics are similar across different cohorts with mean age of 45 and 60% females. Among patients who had >=12m of follow-up, 43% INF biosimilar naive users, 41.5% INF biosimilar prevalent users, 52% INF bio-originator naïve users and 73% INF bio-originator prevalent users continued to be adherent (>80%) at 12 months. Among patients who had >=18m of follow-up, 48%, 36%, 41%, and 64% user continued to be adherent at 18 months respectively (Table).

Conclusion: The adherence patterns were similar among INF biosimilar naïve, INF biosimilar prevalent, and INF bio-originator naïve users. We found the INF bio-originator prevalent users had the highest adherence within 12 or 18 months of follow-up. However, further studies with large sample size are needed to evaluate the adherence of INF biosimilar users.

High Remission Rates in RA – Real Life Data from Bariticinib

Sara Bayat[1], Koray Tascilar[2], Arnd Kleyer[2], David Simon[2], Axel Hueber[3] and Georg Schett[4], [1]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany, [2]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Bayern, Germany, [3]Section Rheumatology, Sozialstiftung Bamberg, Bamberg, Germany, [4]Friedrich-Alexander-Universität Erlangen- Nuremberg, Erlangen, Germany

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent developments of targeted treatments such as targeted synthetic DMARDs (tsDMARDs) increase the chances of a sustained low disease activity (LDA) or remission state for patients suffering rheumatoid arthritis (RA). tsDMARDs such as baricitinib, an oral inhibitor of the Janus Kinases (JAK1/JAK2) was recently approved for the treatment of RA with an inadequate response to conventional (cDMARD) and biological (bDMARD) therapy (1, 2).

Aim of this study is to analyze the effect of baricitinb on disease activity (DAS28, LDA) in patients with RA in real life, to analyze drug persistance and associate these effects with various baseline characteristics.

Methods: All RA patients were seen in our outpatient clinic. If a patient was switched to a baricitinib due to medical reasons, these patients were included in our prospective, observational study which started in April 2017. Clinical scores (SJC/TJC 76/78), composite scores (DAS28), PROs (HAQ-DI; RAID; FACIT), safety parameters (not reported in this abstract) as well as laboratory biomarkers were collected at each visit every three months. Linear mixed effects models for repeated measurements were used to analyze the time course of disease activity, patient reported outcomes and laboratory results. We estimated the probabilities of continued baricitinib treatment and the probabilities of LDA and remission by DAS-28 as well as Boolean remission up to one year using survival analysis and explored

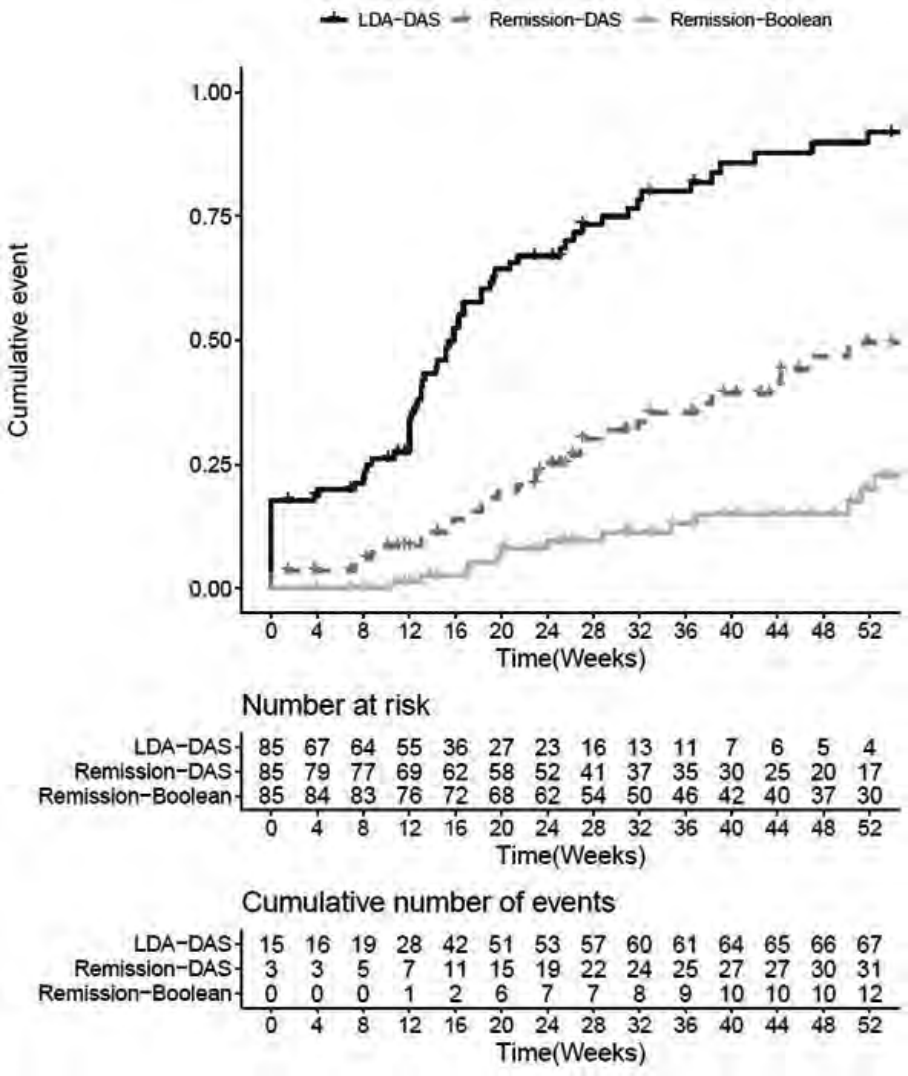

Figure-1. Cumulative probability of low disease activity or remission under treatment with baricitinib.

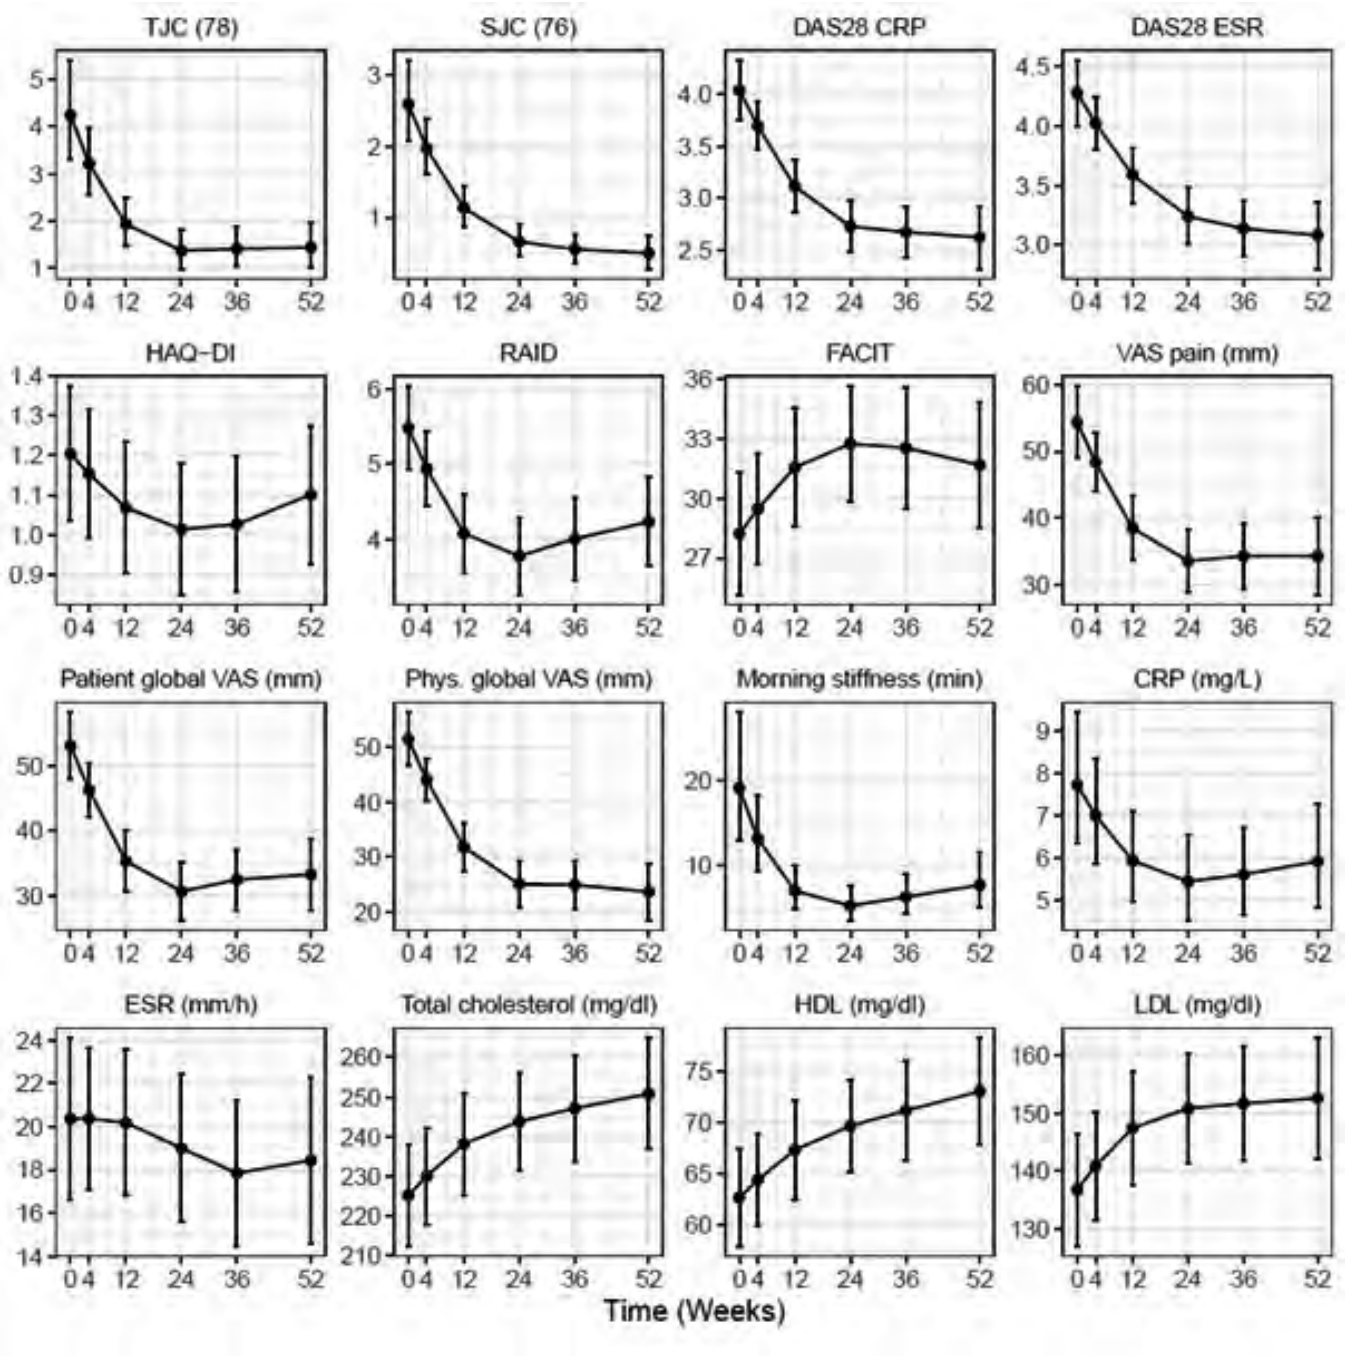

Figure-2. Course of disease activity measures, patient reported outcome measures, acute phase response and cholesterol levels over treatment course in baricitinib users.

their association with disease characteristics using multivariable Cox regression. All patients gave informed consent. The study is approved by the local ethics.

Results: 95 patients were included and 85 analyzed with available follow-up data until November 2019. Demographics are shown in Table 1. Mean follow-up duration after starting baricitinib was 49.3 (28.9) weeks. 51 patients (60%) were on monotherapy. Baricitinib survival (95%CI) was 82% (73% to 91%) at one year. Cumulative number (%probability, 95%CI) of patients that attained DAS-28 LDA at least once up to one year was 67 (92%, 80% to 97%) and the number of patients attaining DAS-28 and Boolean remission were 31 (50%, 34% to 61%) and 12(20%, 9% to

	2	19 (22.4)
	3	8 (9.4)
	4	8 (9.4)
	5	6 (7.1)

30%) respectively. Median time to DAS-28 LDA was 16 weeks (Figure-1). Cox regression analyses did not show any sufficiently precise association of remission or LDA with age, gender, seropositivity, disease duration, concomitant DMARD use and number of previous bDMARDs. Increasing number of previous bDMARDs was associated with poor baricitinib survival (HR=1.5, 95%CI 1.1 to 2.2) while this association was not robust to adjustment for baseline disease activity. Favorable changes were observed in tender and swollen joint counts, pain-VAS, patient and physician disease assessment scores, RAID, FACIT and the acute phase Response.

Conclusion: In this prospective observational study, we observed high rates of LDA and DAS-28 remission and significant improvements in disease activity and patient reported outcome measurements over time.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

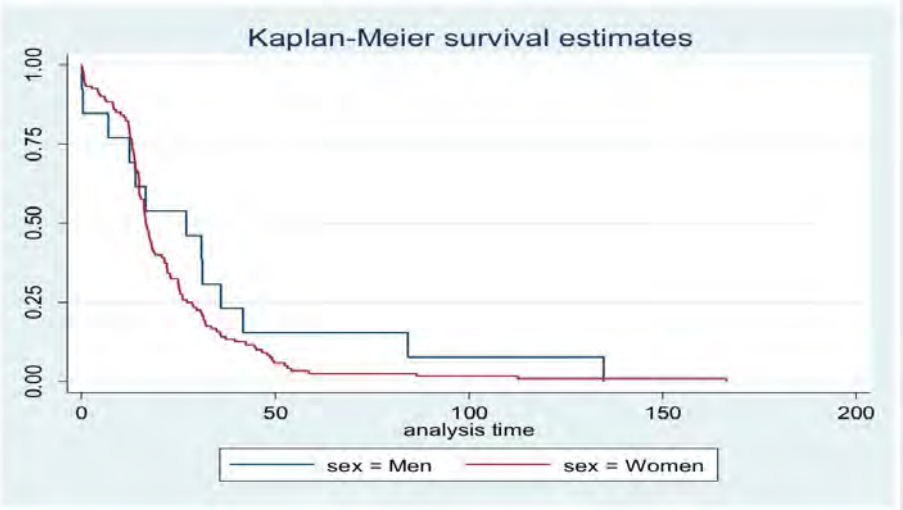
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most common autoimmune disease and is more frequent and severe in women than in men. Symptom severity, disease progression, response to therapy and overall survival differ between males and females with AR.

Determine if drug discontinuation of biologic DMARDs (bDMARDs) differs by gender in patients with rheumatoid arthritis in the Mexican Adverse Events Registry (BIOBADAMEX).

Methods: BIOBADAMEX is a Mexican ongoing cohort of patients using bDMARDs since 2016. In this analysis we included all patients with diagnosis of RA with at least two assessments. Survival on bDMARDs was estimated using Kaplan-Meier analysis. Predictors of discontinuation, including gender were investigated by Cox regression analyses. This analysis did not show a sex role on discontinuation of bDMARDs in Mexican RA patients, however we found high DAS28 had a protective role. Further longitudinal analyses will be performed including more patients to assess retention rate of bDMARDs and identify predictive variables of discontinuation.

Results: Among 727 RA patients in the cohort, 134 patients had at least two assessments, from which 121 (90%) were women. At baseline, patients had a median (IQR) disease duration of 11 (5-18) months and 55.2 (45-61) years old of age, with a median DAS28 of 5.2 (4-6). Conventional DMARDS were used by 116 (87%) patients and 53 (40%) used corticosteroids. Comorbidities were present in 66 (50%). The most common bDMARDs received at baseline were tocilizumab 31 (23%), abatacept 29(22%), adalimumab 22 (16%) and certolizumab 20 (15%). At the time of analysis, the median bDMARDs treatment duration was 17 (13-29) months, 59 (44%) had discontinued treatment, 24 for inefficacy, 17 for adverse events and 18 for other reasons. Fig shows discontinuation rate curves by sex. Cox proportional-hazards demonstrated that high DAS28 >5.1 (HR 0.5, 95% CI 0.4-0.9, p=0.01) had a protective role on bDMARD discontinuation that remained in the multivariable analysis (p=0.02), while no significant differences were found regarding female sex (HR 1.4, 95% CI 0.8-2.5, p=0.26), use of corticosteroids (HR 1.3, 95% CI 0.9-1.8, p=0.20), comorbidities (HR 1.0, 95% 0.7-1.5, p=0.82) or other factors, such as age, obesity, tobacco smoking or use of conventional DMARDs.



Discontinuation rate curves by sex

Baseline characteristics	Women 120 (90%)	Men 14 (10%)	Univariable [a]
Age, median (IQR)	55.4 (45.3 – 61.4)	51.5 (45.7 – 64.4)	0.08
Disease duration, median (IQR)	11.5 (4.8 – 17.8)	8.4 (5.2 – 12.7)	0.48
DAS 28, median (IQR)	5.1 (3.78 – 5.9)	5.2 (4.4 – 5.9)	0.04
Body Mass Index, median (IQR)	27.8 (25.4 – 30.8)	28.9 (25.3 – 29.8)	0.00
Smoking, n(%)	10 (8.5)	3 (25)	0.06
Use of DMARD, n(%):	104 (86.7)	13 (92.9)	0.5
Use of steroids, n(%):	47 (39.2)	6 (42.8)	0.7
Use of previous biologic, n(%):	117 (97.5)	14 (100)	0.5
Any comorbidities, n(%):	61 (50.8)	6 (42.9)	0.5
[a] Chi^2test or Kwallis			

Baseline Characteristics

Conclusion: This analysis did not show a sex role on discontinuation of bDMARDs in Mexican RA patients, however we found high DAS28 had a protective role. Further longitudinal analyses will be performed including more patients to assess retention rate of bDMARDs and identify predictive variables of discontinuation.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: COMPANION-B was a prospective real-world observational study designed to provide evidence on the effectiveness of SB4, a biosimilar of ETN compared to ETN originator in rheumatoid arthritis (RA) pa-

Table 1 RA Disease Activity at Baseline (Mean, Standard Deviation)

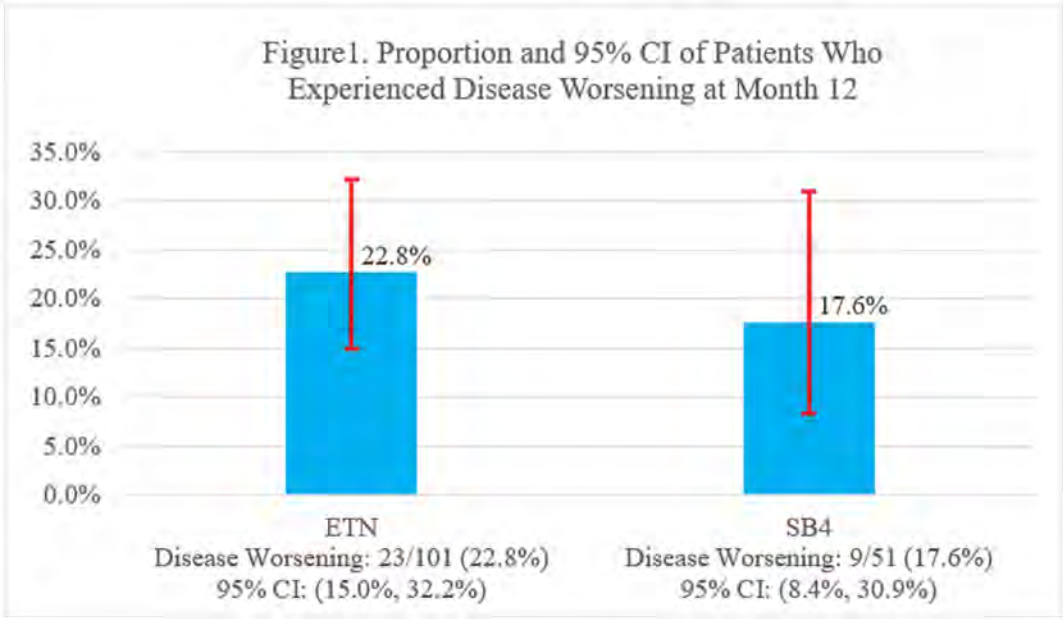
	SB4 (N=51)	ETN (N=101)
Erythrocyte Sedimentation Rate (mm/hr)	11.3 (10.2)	14.5 (13.1)
DAS28-ESR	2.0 (0.7)	2.1 (0.8)
Clinical Disease Activity Index	3.6 (2.7)	3.4 (2.9)
HAQ-DI Score	0.7 (0.7)	0.6 (0.7)
Tender Joint Count	0.5 (1.3)	0.8 (1.7)
Swollen Joint Count	0.4 (1.0)	0.5 (1.3)
Patient Global Assessment	22.3 (19.7)	15.3 (14.5)
Physician's Global Assessment	5.7 (7.9)	6.3 (7.5)

RA Disease Activity at Baseline (Mean, Standard Deviation)

Table 2 RA Disease Activity at 12 Months (Mean, Standard Deviation)

	SB4 (N=51)	ETN (N=101)
Erythrocyte Sedimentation Rate (mm/hr)	13.5 (11.5)	17.1 (14.9)
DAS28-ESR	2.1 (1.0)	2.6 (1.2)
Clinical Disease Activity Index	3.71 (3.7)	5.8 (6.9)
HAQ-DI Score	0.7 (0.8)	0.7 (0.7)
Tender Joint Count	0.6 (2.1)	1.3 (2.8)
Swollen Joint Count	0.1 (0.3)	1.0 (1.8)
Patient Global Assessment	24.8 (25.5)	25.3 (22.2)
Physician's Global Assessment	5.0 (7.1)	10.8 (16.8)

RA Disease Activity at 12 Months (Mean, Standard Deviation)



Proportion and 95% CI of Patients Who Experienced Disease Worsening at Month 12

tients in routine care. The goal was to evaluate whether sTable RA patients with low disease activity or in remission who elected to transition to SB4 had a similar rate of disease worsening over 12 months vs. patients who continued with ETN. Due to insufficient enrollment, the decision was made to conduct only descriptive analyses. Disease worsening (study endpoint) was defined as a composite of occurrence of anyone of the following: 1) A DAS28-ESR increase of ≥1.2 from baseline and minimum score of ≥3.2; 2) increase dose/frequency of treatment due to disease worsening; 3) discontinuation of SB4 or ETN due to disease worsening.

Methods: The study was conducted in 14 sites in Canada and 5 sites in Australia. Patients were ≥18 years old, diagnosed with RA by 2010 American College of Rheumatology (ACR) criteria, with treatment with ETN as their first or second biologic for at least 6 months. Patients needed to have sTable disease defined by DAS28-ESR < 3.2 at enrollment with no evidence of flare within the previous 3 months. Use of background disease modifying antirheumatic drugs (DMARDs) was allowed if patients had taken the same combination for ≥12 weeks and the same dose and frequency of each DMARD for the last 6 weeks.

Results: Of the 163 patients enrolled, 109 patients elected to continue to receive ETN and 54 patients transitioned to SB4. Mean (SD) age was 60.4 (12.7) for ETN and 61.1 (13.6) for SB4. 71.3% of ETN and 66.7% of SB4 patients were female. Approximately 90% of both groups were Caucasian. The mean (SD) duration of RA was 17.2 (10.4) and 18.6 (10.8) years for ETN and SB4 respectively. Approximately half of both groups used concomitant methotrexate. Baseline RA Disease Activity (Table 1) was similar for the two groups.

83.5% of ETN patients and 75.9% of SB4 patients completed the study. The majority of patients (94.1% in ETN group and 84.3% in SB4 group) received ≥36 weeks of study treatment.

RA disease activity at Month 12 was similar between groups (Table 2). Occurrence of adverse events was low and similar between groups.

The primary study endpoint of proportion of disease worsening at Month 12 is 17.6% (95% CI [8.4%, 30.9%]) for SB4 and 22.8% (95% CI [15.5%, 32.2%]) for ETN (Figure 1).

Conclusion: The biosimilar SB4 was shown to have similar efficacy over 12 months compared to originator ETN in this prospective observational study in well-controlled RA patients with sTable disease in a real-world setting. There did not seem to be evidence of a nocebo effect as there was no difference in worsening between groups. This study adds to the accumulating evidence that transitioning patients from originator ETN to biosimilar SB4 offers effective treatment in people willing to switch to a biosimilar and may allow for a reduction in costs.

Abstract Number: 0823

Identifying Physician-Perceived Barriers to a Pragmatic Treatment Trial in Rheumatoid Arthritis

Haiyan Qu[1], Shamly Austin[2] and **Jasvinder Singh**[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Gateway Health Plan®, Pittsburgh, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this qualitative research was to identify physician-perceived patient and clinic barriers to patient recruitment in a RA pragmatic trial of anti-TNF biologic vs. non-TNF biologic/Janus-Kinase inhibitor initiation after an inadequate response to methotrexate (MTX-IR).

Methods: Semi-structured telephone interviews were conducted with 26 rheumatologists in March 2019. An exploratory thematic analysis approach was used to analyze the interview data.

Results: Physician perceived patient barriers to the implementation of a RA pragmatic trial.

Two main themes were coded, consistent with the research questions identified and included patient barriers, and clinic barriers (**Figure 1).** This theme covers three sub-themes: 1) patients' personal barriers, 2) patients' treatment-related factors, and 3) trial-related factors (e.g., patient recruitment, side effects, mode of use, etc.). Patients' personal factors, the largest sub-theme, included insurance status, language barriers, and travel-related factors. Insurance status and plan was the biggest factor thought to influence patients' medication affordability and thus, trial participation. Seventeen out of 26 (65%) physicians mentioned health insurance as one of the top three patient barriers. The second sub-theme was treatment-related factors, including patients' medical condition and complexity,

Figure 1: Patient Barriers and Clinic Barriers

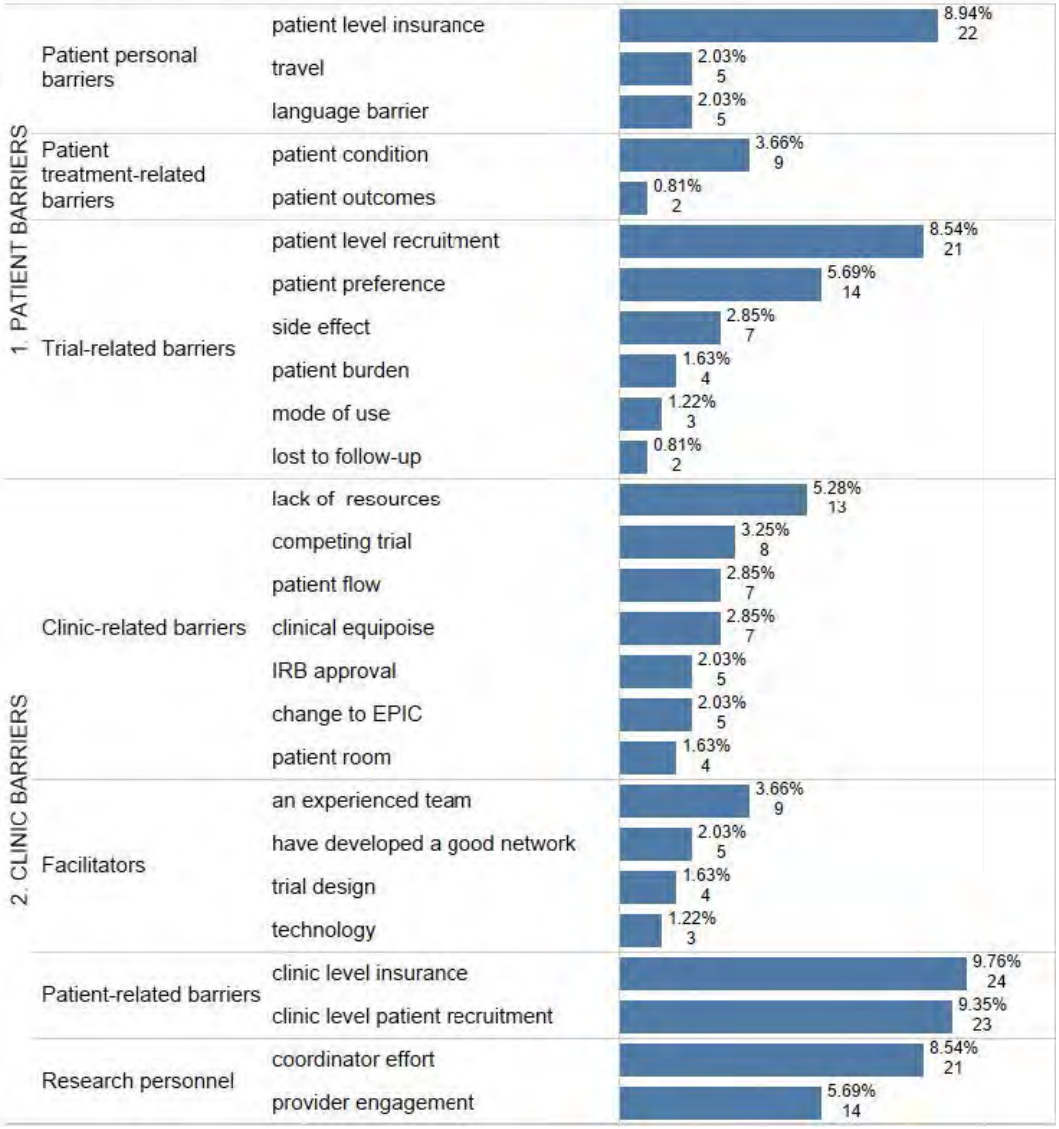

Figure 1. Patient Barriers and Clinic Barriers

comorbidities, treatment, and patient outcomes. The third large sub-theme was trial-related factors, and included patient recruitment, preferences, burden, and side effects (Figure 1).

Physicians perceived clinic barriers interfered with the pragmatic trial enrollment from the clinic or the healthcare system perspective. This theme covered four sub-themes (Figure 1): 1) clinic-related factors, 2) patient-related factors, 3) research personnel, and 4) facilitators (positive factors of the clinic). The clinic-related factors include patient/clinic flow, lack of resources (e.g., patient room, infrastructure, and time), ethics committee approval, competing trial/studies, clinical equipoise, and recent changes to a new health care record system (e.g., EPIC). Among all patient-related factors, insurance was considered as the key clinic barrier by 12 (46%) participants, including 7 participants who thought that insurance was a barrier for both clinic and patients. Research personnel was the third sub-theme under clinic barrier theme, including coordinator efforts and provider engagement.

Conclusion: Our results from the inductive thematic analysis will help researchers understand the key patient and clinic/system factors/barriers that may influence pragmatic RA trial implementation. The themes suggest there are

factors that can be modified (e.g., coordinator effort needed, effective patient recruitment during clinic visits, provider engagement) and challenges to overcome (patient insurance status, busy clinic flow, and space issues including limited number of patient rooms). In summary, these themes provide a basis for our and other research teams to develop clinic-centered and patient-centered strategies to implement a pragmatic RA trial.

Abstract Number: 0824

The Comparative Effectiveness of Abatacept versus Tofacitinib After 6 Months of Treatment in Patients with RA Who Were Anti-citrullinated Protein Antibody Positive at Baseline: Results from a US National Observational Study

Leslie Harrold[1], Keith Wittstock[2], Sheila Kelly[2], Xue Han[2], Ying Shan[1], Page Moore[1], Lin Guo[1] and Vadim Khaychuk[2], [1]Corrona, LLC, Waltham, MA, [2]Bristol-Myers Squibb Company, Princeton, NJ

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous data from the Corrona RA registry, conducted in a US clinical practice setting, demonstrated that patients (pts) with RA who were ACPA+ had a greater clinical response to abatacept than ACPA– pts, a relationship not observed with TNF inhibitors or tofacitinib.[1,2] This comparative study evaluated the effectiveness of abatacept vs tofacitinib in pts with RA (ACR 1987 criteria) who were ACPA+.

Methods: Pts from the Corrona RA registry who were aged ≥18 years and were anti-CCP+ (≥20 U/mL) before starting treatment, initiated abatacept or tofacitinib from Dec 2012 onwards, had 6-month follow-up data (including CDAI score at initiation and 6 months) and were not in remission at index date were included. Pts were frequency matched 1:1 based on the number of prior biologics (0, 1, ≥2) before 1:1 propensity score matching (PSM) based on: duration of RA, education, number of prior biologics, time on therapy, baseline CDAI, current smoker, history of malignancy and BMI. Primary (mean change in CDAI score) and secondary outcomes 6 months after index date were compared using mixed-effects models. Variables that remained unbalanced after PSM were used as covariates in adjusted multivariable models, including age, sex, race, work status, BMI, systolic blood pressure, history of non-TNF inhibitor biologic (b)DMARD use, history of cardiovascular (CV) disease, baseline CDAI and modified HAQ score. Standardized difference >0.1 indicates a meaningful difference between treatments.

Results: Following PSM, most baseline characteristics for the 276 pt pairs included in the abatacept and tofacitinib groups were well balanced with a standardized difference ≤0.1 (**Table 1**). Compared with those initiating tofacitinib, fewer pts initiating abatacept had received prior treatment with non-TNF bDMARDs, were on monotherapy or had CV disease or chronic obstructive pulmonary disorder, and more had a dose of prednisone >7.5 mg/day (**Table 1**). In the adjusted analyses, there was not a significant difference in mean change from baseline in CDAI score at 6 months in pts initiating treatment with abatacept vs tofacitinib (p=0.400; **Table 2**). Among pts stratified by prior b/targeted syn-

thetic (ts)DMARD use, those who were b/tsDMARD-naïve at baseline had a numerically greater mean change in CDAI at 6 months in the abatacept vs tofacitinib group, although this difference was not statistically significant (p=0.170; **Table 2**). There were no significant differences between abatacept and tofacitinib for any of the secondary outcomes,

Table 1. Demographics and baseline characteristics of anti-CCP+ patients initiating treatment with abatacept or tofacitinib after propensity score matching

	Anti-CCP+ abatacept initiators (n=276)	Anti-CCP+ tofacitinib initiators (n=276)	Standardized difference

mACR70[e]	0.05 (0.04, 0.06)	0.05 (0.04, 0.06)	0.803

[a]Outcomes adjusted for: age, sex, race, work status, BMI, systolic blood pressure, history of non-TNF inhibitor biologic DMARD use, history of CV disease, baseline CDAI and modified HAQ score.
[b]For the difference between the anti-CCP+ patients initiating abatacept and tofacitinib according to the primary outcome.
[c]CDAI ≤10 among those with moderate or high disease activity.
[d]CDAI ≤2.8 among those with low disease activity or higher.
[e]mACR was based on 2 out of 4 measures (not using ESR or CRP).
b/tsDMARD=biologic/targeted synthetic DMARD; CV=cardiovascular; mACR=modified ACR criteria.

although improvements in mean change in pain and fatigue at 6 months were numerically greater in pts receiving abatacept vs tofacitinib (**Figure 1**).

Conclusion: In adjusted analyses, ACPA+ pts with RA treated with abatacept vs those treated with tofacitinib did not have statistically significant differences in reduction of disease activity and pt-reported outcomes. Additional studies to explore these findings in a larger population would be of interest.

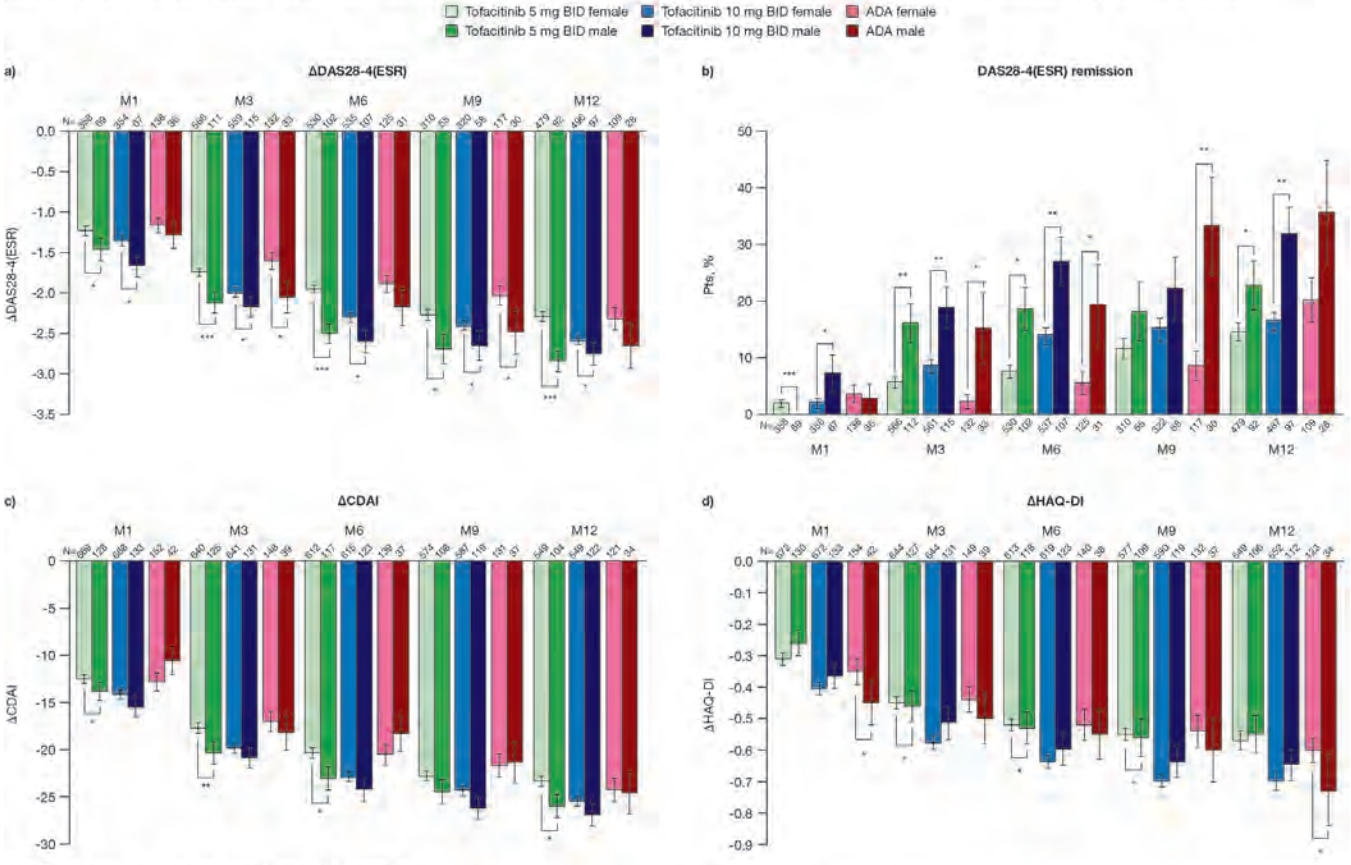
*Includes all randomized and treated pts from ORAL Scan (NCT00847613), ORAL Standard (NCT00853385), and ORAL Sync (NCT00856544) Pts from ORAL Standard who were found to be non-compliant with study procedures were excluded; Placebo data not presented; Binary endpoints were assessed using logistic regression at each visit
ACR 20/50/70, improvement in American College of Rheumatology criteria of 20/50/70%; ADA, adalimumab; BID, twice daily; M, Month; N, number of patients assessed at each visit; pts, patients

Background/Purpose: Differences in efficacy outcomes favoring male vs female patients (pts) with RA have been reported with csDMARDs[1] and TNF inhibitors;[2] results with JAK inhibitors are less clear.[3] Here, we assess the impact of sex on efficacy, safety, and persistence in clinical trials of tofacitinib in RA.

Methods: Efficacy and safety were assessed using data from pooled Phase (P)3 RCTs of pts with RA and an inadequate response to MTX (NCT00847613; NCT00853385) or ≥1 DMARD (NCT00856544) who received tofacitinib 5 or 10 mg BID, adalimumab (ADA) 40 mg Q2W, or placebo (PBO; advancing to tofacitinib at Month [M]3/6) + csDMARDs. Persistence was assessed in pts receiving tofacitinib 5 or 10 mg BID ± csDMARDs using data pooled from two LTE trials (NCT00661661; NCT00413699). Efficacy outcomes (to M12): ACR20/50/70 responses, changes (Δ) from baseline (BL) in DAS28-4(ESR), CDAI, CRP, and HAQ-DI, and DAS28-4(ESR) remission (< 2.6). Safety outcomes (to M24) for tofacitinib and ADA: adverse events (AEs), serious AEs (SAEs), severe AEs, discontinuations due to AEs, and AEs of special interest (AESIs). Kaplan-Meier persistence analysis estimated 2- and 5-year drug survival rates with tofacitinib.

Results: 2,265 pts were included from the P3 RCTs. Demographics and BL characteristics were comparable across sexes and treatments. Tofacitinib or ADA vs PBO generally led to significantly higher ACR20/50/70 responses in both sexes through M6 (data not shown). Up to M12, ACR20/50/70 responses were broadly comparable across active treatments and between sexes, with significant differences favoring males observed at some timepoints (Figure 1). Statistically significant differences favoring males vs females were observed in ΔDAS28-4(ESR) and DAS28-4(ESR) remission rates at most timepoints across treatment groups (Figure 2a,b). Differences in ΔCDAI, ΔCRP (data not shown), and ΔHAQ-DI tended to favor males (except ΔHAQ-DI with tofacitinib 10 mg BID, which was numerically greater in females) (Figure 2c,d). Rates of AEs, SAEs, severe AEs, and discontinuations due to AEs were slightly high-

Figure 2. a) Change from baseline in DAS28-4(ESR), b) DAS28-4(ESR) remission rates, c) change from baseline in CDAI, and d) change from baseline in HAQ-DI up to M12, stratified by sex and treatment group[a]



*p<0.05, **p<0.001, ***p<0.0001 for comparisons of female vs male

[a]Includes all randomized and treated pts from ORAL Scan (NCT00847613), ORAL Standard (NCT00853385), and ORAL Sync (NCT00856544) Pts from ORAL Standard who were found to be non-compliant with study procedures were excluded; Placebo data not presented; Binary endpoints were compared using logistic regression at each visit; Continuous endpoints were compared using a longitudinal mixed-effects linear regression model

Δ, change from baseline; ADA, adalimumab; BID, twice daily; CDAI, Clinical Disease Activity Index; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; M, Month; N, number of patients assessed at each visit; pts, patients

er in females vs males with tofacitinib 5 mg BID (Table 1a); with tofacitinib 10 mg BID and ADA, this trend was generally reversed. AESIs were comparable between sexes with tofacitinib and ADA, although event numbers were low and results should be interpreted with caution. 2- and 5-year tofacitinib survival rates were mostly similar between sexes, with some numerical, non-significant differences favoring females (Table 1b).

Conclusion: In this post hoc analysis, efficacy outcomes with tofacitinib and ADA were generally higher in males and comparable in females vs previously reported mixed population response rates for advanced therapies.[4,5] Safety findings did not reveal a consistent pattern between sexes. Tofacitinib persistence was similar between sexes.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: In the 56-week (wk) induction period (IP) of the Phase IIIb Assessing Very Early RA Treatment (AVERT)-2 trial (NCT02504268), a greater proportion of patients (pts) achieved SDAI remission (≤3.3) with SC abatacept (ABA) 125 mg once weekly (QW) + MTX vs ABA placebo (PBO) + MTX.[1] Of pts who achieved sustained SDAI remission in the IP and completed a subsequent 48-wk de-escalation (DE) period, ~50% had maintained remission at DE Wk 48.[2] However, whether pts were in sustained remission throughout the DE period is not known. This analysis evaluated pt flow during the DE period.

Methods: Pts who met the inclusion criteria (age ≥18 years [yrs]; RA diagnosis [ACR/EULAR 2010 criteria]; RA duration ≤6 months; SDAI >11; ACPA+; elevated CRP >3 mg/L or ESR ≥28 mm/h; TJC ≥3 and SJC ≥3; DMARD naïve) were enrolled in the 56-wk IP of AVERT-2 and received 1 yr of blinded treatment with ABA QW + MTX or ABA PBO + MTX. Pts who completed induction with ABA + MTX and had sustained SDAI remission (≤3.3 at both Wks 40 and 52 of the 56-wk IP) entered the DE phase and were re-randomized 1:1:1 to ABA QW + MTX for 48 wks (ABA continuation), ABA every other wk (EOW) + MTX for 24 wks then ABA PBO + MTX for 24 wks (DE/withdrawal), or ABA QW + MTX PBO for 48 wks (ABA monotherapy). Pts in sustained SDAI remission on ABA PBO + MTX during the IP were not re-randomized and continued the same blinded treatment in the DE phase (MTX monotherapy). MTX and oral CS doses were maintained in the DE period. Proportion of pts in each SDAI disease activity category (remission, low, moderate, high) was assessed over time (intent-to-treat analysis). Flow of disease activity to DE Wk 48, among re-randomized patients, was plotted using Sankey diagrams.

Results: The proportion of pts with high disease activity at IP baseline, by DE treatment arm, ranged from 72% to 76% for ABA + MTX-treated pts (DE re-randomization). Among pts who had achieved sustained SDAI remission in the IP, at the start of the DE period, 147 ABA + MTX-treated pts were re-randomized to ABA continuation (n=50), DE/withdrawal (n=50) or ABA monotherapy (n=47), and 37 pts assigned MTX monotherapy during the IP continued

Figure 1. Proportion of patients per SDAI disease activity category over time: abatacept continuation arm (n=50)

	Baseline	DE Week 0	DE Week 8	DE Week 24	DE Week 40	DE Week 48
Unknown[a]	0	3 (6.0)	2 (4.0)	5 (10.0)	6 (12.0)	5 (10.0)
High disease activity (SDAI 26.1–86)	38 (76.0)	0	0	0	0	0
Moderate disease activity (SDAI 11–26)	12 (24.0)	0	0	0	1 (2.0)	0
Low disease activity (SDAI 3.4–11)	0	11 (22.0)	9 (18.0)	6 (12.0)	5 (10.0)	8 (16.0)
Remission (SDAI ≤3.3)	0	36 (72.0)	39 (78.0)	39 (78.0)	38 (76.0)	37 (74.0)

[a]For patients who did not have data available at all time points, the status was recorded as unknown.
DE=de-escalation; QW=once weekly.

treatment in the DE period. During the DE period, fewer changes in disease activity were seen with ABA continuation versus DE/withdrawal or ABA monotherapy. The proportions of patients in SDAI remission were: ABA continuation: 72% at Wk 0, 74% at Wk 48 (**Figure 1**); ABA DE/withdrawal: 88% at Wk 0, 74% at Wk 24 for ABA EOW + MTX and 48% at Wk 48 after ABA withdrawal (**Figure 2**); ABA monotherapy: 77% at Wk 0, 57% at Wk 48 (**Figure 3**).

Conclusion: Fewer changes in disease activity were observed when IP treatment was maintained during the DE period. Most pts with high disease activity at IP baseline who achieved SDAI remission sustained remission during the DE period, suggesting that DE is possible once sustained remission has been achieved. Continued treatment with abatacept QW + MTX provided the best outcome.

Figure 2. Proportion of patients per SDAI disease activity category over time: DE/withdrawal arm (n=50)

	Baseline	DE Week 0	DE Week 8	DE Week 24	DE Week 40	DE Week 48
Unknown[a]	0	3 (6.0)	2 (4.0)	4 (8.0)	6 (12.0)	11 (22.0)
High disease activity (SDAI 26.1–86)	38 (76.0)	0	0	0	2 (4.0)	0
Moderate disease activity (SDAI 11–26)	12 (24.0)	1 (2.0)	4 (8.0)	2 (4.0)	4 (8.0)	7 (14.0)
Low disease activity (SDAI 3.4–11)	0	2 (4.0)	7 (14.0)	7 (14.0)	13 (26.0)	8 (16.0)
Remission (SDAI ≤3.3)	0	44 (88.0)	37 (74.0)	37 (74.0)	25 (50.0)	24 (48.0)

Patients received abatacept EOW + MTX from DE Week 0 to DE Week 24 and then abatacept PBO + MTX from DE Week 24 to DE Week 48.
[a]For patients who did not have data available at all time points, the status was recorded as unknown.
DE=de-escalation; EOW=every other week; PBO=placebo.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarilumab, an IL-6 receptor inhibitor, and upadacitinib, a Janus kinase (JAK) 1 inhibitor, are both approved for the treatment of patients with moderately to severely active RA. In the absence of head-to-head trials, it has been suggested that treatments can be indirectly compared using the matching-adjusted indirect comparison (MAIC) method, in which patient-level data from one trial can be weighted for preselected patient characteristics to match against aggregated data from a comparator trial. Here, we report an MAIC comparison of sarilumab and upadacitinib outcomes using data from 2 phase 3 trials in patients with RA who were refractive to previous treatment with biologic DMARDs, including TNF inhibitors.

Methods: TARGET (NCT01709578) and SELECT-BEYOND (NCT02706847) were randomized, placebo-controlled trials, and included adults with active RA who had received synthetic DMARDs and had an inadequate response or intolerance to ≥1 biologic DMARD. Patient-level data of participants from TARGET treated with subcutaneous placebo or sarilumab (200 mg once every 2 weeks), and aggregated data of patients from SELECT-BEYOND treated with placebo or oral upadacitinib (15 mg/day) were analyzed. Baseline characteristics with noTable differences between the 2 trials that were potential treatment effect modifiers were identified. They included age, tender joint count (TJC) of 68 counts, swollen joint count (SJC) of 68 counts, and CRP concentration. Individual patients from the TARGET trial were assigned weights such that weighted mean baseline characteristics of the treatment effect modifiers matched those from SELECT-BEYOND. Treatment effects for the adjusted TARGET population at Week 12 were compared with published aggregate data from SELECT-BEYOND. Endpoints evaluated included the proportions of patients achieving ACR20, ACR50, ACR70, DAS28-CRP < 3.2 (low disease activity), and DAS28-CRP < 2.6 (remission).

Results: The analysis included 365 patients from TARGET (sarilumab, n=184; placebo, n=181) and 333 patients from SELECT-BEYOND (upadacitinib, n=164; placebo, n=169). After weighting, the 2 trials were matched for the treatment effect modifiers, which resulted in the decline of the effective sample size of TARGET population to 185 (sarilumab, n=89; placebo, n=96) (Table). After MAIC, the odds of achieving various clinical outcomes versus placebo were similar for sarilumab and upadacitinib for all evaluated clinical outcomes (all nominal p >0.05; Figure). A nonadjusted analysis yielded similar results (data not shown).

Table. Baseline characteristics from TARGET and SELECT-BEYOND before and after matching, mean ± SD				
	TARGET		SELECT-BEYOND	
Before matching				
	Sarilumab n=184	Placebo n=181	Upadacitinib n=164	Placebo n=169

DAS28-CRP=disease activity score with CRP; MAIC=matching-adjusted indirect comparison

Figure 1

Conclusion: In this MAIC analysis of patients from the TARGET and SELECT-BEYOND trials matched for several key baseline characteristics, efficacy of sarilumab was statistically similar to upadacitinib when comparing ACR20/50/70 and DAS28-CRP low disease activity/remission outcomes in patients with active RA who had an inadequate response to biologic DMARDs. Prospective head-to-head comparisons are needed to confirm these findings.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

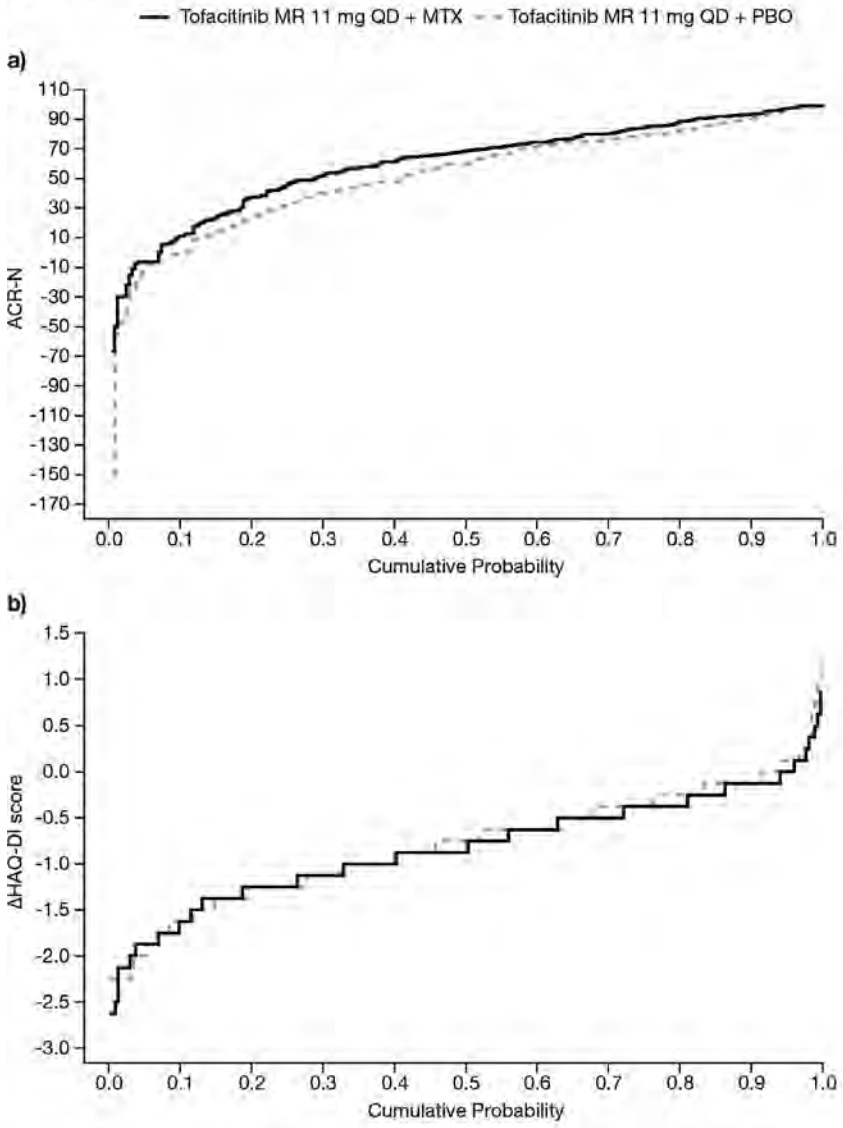
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: ORAL Shift (NCT02831855) was a 48-week Phase 3b/4 study, which demonstrated sustained efficacy/safety of tofacitinib modified release 11 mg once daily (QD) following MTX withdrawal, that was non-inferior to continued use of tofacitinib + MTX, in patients (pts) with moderate to severe RA who achieved low disease activity (LDA) with tofacitinib + MTX at Week (W)24.[1] This post hoc analysis of data from ORAL Shift assessed the differences and similarities in clinical/functional responses in pts receiving tofacitinib ± MTX.

Methods: Clinical efficacy endpoints included ACR-N (minimum percentage change from baseline [Δ] at W48 achieved by each pt in three efficacy measures), ΔDisease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28-4[ESR]), and DAS28-4(ESR)-defined clinical remission/LDA and moderate/high disease activity (defined as DAS28-4[ESR] ≤ 3.2 and > 3.2, respectively). Functional efficacy endpoints included ΔHAQ-Disability Index (HAQ-DI) score and clinically relevant functional progression (CRFP) status at W48, defined as failure to achieve an improvement in HAQ-DI score ≥ minimum clinically important difference (MCID; defined as ≥ 0.22 decrease from baseline in HAQ-DI). Consequently, CRFP was defined as < 0.22 decrease, no change, or increase from baseline in HAQ-DI at W48. Cumulative probability plots of ACR-N and HAQ-DI at W48 were used to evaluate tofacitinib ± MTX efficacy. Descriptive statistics were produced for all efficacy endpoints; median of mean CRP values from > baseline–W24 and > W24–W48 were assessed by response subgroups.

Figure 1. Cumulative probability plot at W48 for a) ACR-N; b) ΔHAQ-DI score



In ORAL Shift (NCT02831855), pts received open-label tofacitinib + MTX to W24; Pts who achieved CDAI-defined LDA at W24 were randomized to receive tofacitinib + MTX or tofacitinib + PBO until W48. Endpoints were assessed using the full analysis set (defined as all pts receiving ≥1 dose of study drug with ≥1 value post-baseline), with no imputation for missing values

Δ, change from baseline; ACR-N, American College of Rheumatology response, where N represents the minimum amount of improvement expressed by each pt in % ΔTJC28, % ΔSJC28, and the median of % Δ in PtGA, PGA, Pain, HAQ-DI, and CRP; CDAI, CDAI, clinical disease activity index; CRP, C-reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDA, low disease activity; MR, modified release; MTX, methotrexate; PBO, placebo; PGA, Physician Global Assessment; pt, patient; PtGA, Patient Global Assessment; SJC28, swollen joint count in 28 joints; TJC28, tender joint count in 28 joints; W, week

Results: The analysis included 266 and 264 pts receiving tofacitinib + MTX and tofacitinib + placebo (PBO), respectively, from W24–W48. Cumulative probability plots and descriptive statistics suggested that overall ACR-N responses and mean ACR-N at W48 were numerically greater in pts receiving tofacitinib + MTX vs tofacitinib + PBO (Figure 1a, Table 1); ΔHAQ-DI at W48 was generally similar between groups (Figure 1b; Table 1). ΔDAS28-4(ESR) was numerically greater in pts receiving tofacitinib + MTX vs tofacitinib + PBO (Table 1). A lower proportion of pts receiving tofacitinib + MTX vs tofacitinib + PBO had CRFP; CRFP rates were numerically lower in pts with remission/LDA vs moderate/high disease activity (Table 1). Median of mean CRP over time was generally numerically lower in pts with CRFP vs non-CRFP in pts with DAS28-4(ESR)-defined remission/LDA vs moderate/high disease activity, and in pts receiving tofacitinib + PBO vs tofacitinib + MTX, irrespective of CRFP or DAS28-4(ESR) disease status (Table 2).

Table 1. ACR-N, ΔHAQ-DI, and ΔDAS28-4(ESR) scores at W48, and proportion of pts with HAQ-DI CRFP by DAS28-4(ESR) disease status, at W48

	Tofacitinib 11 mg QD + MTX (N=266)	Tofacitinib 11 mg QD + PBO (N=264)
ACR-N, mean (95% CI)	60.8 (56.8, 64.9)	53.1 (48.5, 57.7)
ΔHAQ-DI, mean (95% CI)	-0.71 (-0.78, -0.63)	-0.67 (-0.75, -0.59)
ΔDAS28-4(ESR) score, mean (95% CI)	-2.95 (-3.12, -2.79)	-2.68 (-2.84, -2.52)
HAQ-DI CRFP, n/N1 (%), *[95% CI]*	46/246 (18.7) *[14.0, 24.1]*	56/238 (23.5) *[18.3, 29.4]*
DAS28-4(ESR) remission/LDA	16/132 (12.1) *[7.1, 18.9]*	20/119 (16.8) *[10.6, 24.8]*
DAS28-4(ESR) moderate/high disease activity	28/107 (26.2) *[18.2, 35.6]*	36/117 (30.8) *[22.6, 40.0]*

In ORAL Shift (NCT02831855), pts received open-label tofacitinib + MTX to W24; Pts who achieved CDAI-defined LDA at W24 were randomized to receive tofacitinib + MTX or tofacitinib + PBO until W48; CRFP was defined as failure to achieve an improvement in HAQ-DI score ≥MCID at W48, with MCID defined as ≥0.22 decrease from baseline in HAQ-DI; consequently, CRFP was defined as <0.22 decrease, no change, or increase from baseline in HAQ-DI score at W48; DAS28-4(ESR) remission/LDA and moderate/high disease activity were defined as DAS28-4(ESR)≤3.2 and DAS28-4(ESR)>3.2, respectively

Δ, change from baseline; ACR-N, American College of Rheumatology response, where N represents the minimum amount of improvement expressed by each pt in % ΔTJC28, % ΔSJC28, and the median of % Δ in PtGA, PGA, Pain, HAQ-DI & CRP; CDAI, CDAI, clinical disease activity index; CI, confidence intervals; CRFP, clinically relevant functional progression; CRP, C-reactive protein; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDA, low disease activity; MCID, minimum clinically important difference; MTX, methotrexate; n, number of pts meeting assessment criteria at W48; N, total number of pts included in the analysis, the number of pts assessed for each endpoint may be fewer than N; N1, number of pts with non-missing data for HAQ-DI CRFP status and DAS28-4(ESR) disease status at W48; PBO, placebo; PGA, Physician Global Assessment; pt, patient; PtGA, Patient Global Assessment; QD, once daily; SJC28, swollen joint count in 28 joints; TJC28, tender joint count in 28 joints; W, week

Table 2. Median of mean CRP[a] up to W48 by HAQ-DI CRFP status, and by DAS28-4(ESR) disease status

	Tofacitinib 11 mg QD + MTX	Tofacitinib 11 mg QD + PBO
HAQ-DI CRFP	(n=45)	(n=56)
Mean CRP, median (IQR)		
>Baseline–W24	2.84 (1.15–7.30)	1.45 (0.77–4.42)
>W24–W48[b]	2.30 (0.82–4.75)	2.28 (0.53–7.28)
HAQ-DI non-CRFP (HAQ-DI score ≥MCID)	(n=195)	(n=176)
Mean CRP, median (IQR)		
>Baseline –W24	2.81 (1.09–6.19)	2.26 (0.98–4.63)
>W24–W48[c]	2.91 (1.19–5.84)	2.47 (1.13–5.53)
DAS28-4(ESR) remission/LDA	(n=126)	(n=115)
Mean CRP, median (IQR)		
>Baseline –W24	2.48 (1.05–4.95)	1.70 (0.89–4.14)
>W24–W48[d]	2.46 (1.07–4.76)	1.95 (0.81–3.82)
DAS28-4(ESR) moderate/high disease activity	(n=107)	(n=115)
Mean CRP, median (IQR)		
>Baseline –W24	3.56 (1.17–7.13)	2.60 (0.87–5.16)
>W24–W48	3.58 (1.36–8.33)	2.68 (1.34–8.23)

[a]Mean CRP was calculated as the average CRP value during each time period (>baseline–W24 or >W24–W48); [b]At >W24–W48, n=46 for tofacitinib 11 mg QD + MTX; [c]At >W24–W48, n=178 for tofacitinib 11 mg QD + PBO; [d]At >W24–W48, n=127 and n=117 for tofacitinib 11 mg QD + MTX and tofacitinib 11 mg QD + PBO, respectively. In ORAL Shift (NCT02831855), pts received tofacitinib + MTX to W24; Pts who achieved CDAI-defined LDA at W24 were randomized to receive tofacitinib + MTX or tofacitinib + PBO until W48; CRFP was defined as failure to achieve an improvement in HAQ-DI score ≥MCID at W48, with MCID defined as ≥0.22 decrease from baseline in HAQ-DI; consequently, CRFP was defined as <0.22 decrease, no change, or increase from baseline in HAQ-DI score at W48; DAS28-4(ESR) remission/LDA and moderate/high disease activity were defined as DAS28-4(ESR)≤3.2 and DAS28-4(ESR)>3.2, respectively

CDAI, CDAI, clinical disease activity index; CRFP, clinically relevant functional progression; CRP, C-reactive protein; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; IQR, interquartile range; LDA, low disease activity; MCID, minimum clinically important difference; MTX, methotrexate; n, number of pts included in the analysis; PBO, placebo; QD, once daily; pt, patient; W, week

Conclusion: Although clinical and functional responses were generally similar between treatment groups overall, numerical improvements were observed in some efficacy endpoints with tofacitinib + MTX, compared with tofacitinib + PBO. A numerically higher rate of CRFP may be associated with higher DAS28-4(ESR) disease activity. Changes in CRP up to W48 may not trend with CRFP status.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Little is known regarding differences in DMARD utilization across countries. A better understanding is needed to contextualize findings from different countries.[1] Using the same type of registry and design approach, our study describes baseline characteristics and clinical measures among rheumatoid arthritis (RA) patients who initiated a disease-modifying anti-rheumatic drug (DMARD) in Japan and the US.

Methods: We identified RA patients in the Corrona RA Japan (RA-J) and Corrona RA US (RA-US) Registries who initiated a DMARD (methotrexate, TNF, nonTNF, Janus kinase inhibitor (JAKi)) between 01/March/2016 to 31/January/2020. We compared cohorts overall and by drug group for sociodemographics, disease characteristics, comorbidities, patient-reported outcome measures (PROMs), and medications (current and prior). Of note, 2nd, 3rd, and 4th DMARDs were initiated later in RA-J in terms of disease duration. Descriptive statistics were provided; t-tests were

used for continuous variables, chi-squared tests for categorical or dichotomous variables, and Fisher's exact tests for categorical/dichotomous variables with a category size smaller than five.

CVD: Includes cardiac arrest, myocardial infarction, acute coronary syndrome, unstable angina, coronary artery disease, ventricular arrhythmia, congestive heart failure, cardiac revascularization procedure, other cardiovascular event, stroke, transient ischemic attack, deep vein thrombosis, peripheral arterial disease, pulmonary embolism, carotid artery disease; CDAI, Clinical Disease Activity Index; MTX: methotrexate; csDMARDs: conventional synthetic DMARD; JAKi: Janus Kinase inhibitor; *: Two-sample t-tests are used for continuous variables, chi-squared independence tests for categorical or dichotomous variables; Fisher's exact tests are used for categorical/dichotomous variables with category size smaller than 5; **: Excluding non-melanoma skin cancer; NA: Test was not conducted because of no variation across subgroups.

Table 2. Baseline characteristics of RA Japan and RA US, by drug class

Results: Baseline data were available for 1996 RA-J and 6846 RA-US drug initiators. Overall, the two cohorts differed in most of the variables except that both groups were 79% female. At baseline, RA-J vs RA-US had a shorter mean duration of RA disease (8.1 yrs vs 10.4 yrs), higher percentage of history of serious infections (12% vs 9%), higher level of disease activity (CDAI: 22.5 vs 18.8), swollen joint count (6.2 vs 4.6), and physician global assessment (45.5 vs 31.7), but a lower percentage of history of cardiovascular disease (11% vs 14%) (Table 1).

When RA-J vs RA-US were stratified by drug class, the pattern of the differences between the two cohorts was mostly consistent with the overall analysis, except that the RA-J MTX initiators had a lower level of CDAI (19.1 vs 21.2) and prednisone use (17% vs 37%) than RA-US MTX initiators, while among the other groups (TNFi, nonTNFi, and JAKi) the pattern was reverse for CDAI or not present for prednisone use (Table 2).

Disease activity, PROMs, and current medication use was different between the two cohorts by line of therapy. Among RA-J vs RA-US, mean pain scores were higher (52.9 vs 45.9) in the 3rd line of therapy, and mean CDAI scores were higher [(21.8 vs 17.7), (22.3 vs 16.1), (25.1 vs 19.8)] and more prednisone use occurred [(30% vs 26%), (33% vs 26%), (37% vs 33%)] in the 2nd, 3rd, and 4th lines of therapy, respectively. A greater percentage of RA-J vs RA-US used nonTNFi in the 1st (12% vs 3%), 2nd (41% vs 10%), and 3rd line (40% vs 22%) of therapy. By contrast in RA-J vs

Line of Therapy: number of disease-modifying anti-rheumatic drug (DMARD): 1st line: no prior use of any DMARD at time of initiation; 2nd line: prior use of at least one csDMARD and no prior use of any biologic/JAKi; 3rd line: prior use of at least one csDMARD and/or prior use of 1 biologic/JAKi; 4th line+: prior use of at least one csDMARD and/or prior use of 2+ biologics/JAKi; CVD: includes cardiac arrest, myocardial infarction, acute coronary syndrome, unstable angina, coronary artery disease, ventricular arrhythmia, congestive heart failure, cardiac revascularization procedure, other cardiovascular event, stroke, transient ischemic attack, deep vein thrombosis, peripheral arterial disease, pulmonary embolism, carotid artery disease; CDAI, Clinical Disease Activity Index; MTX: methotrexate; csDMARDs: conventional synthetic DMARD; JAKi: Janus Kinase inhibitor; [a]: Two-sample t-tests are used for continuous variables, chi-squared independence tests for categorical or dichotomous variables; Fisher's exact tests are used for categorical/dichotomous variables with category size smaller than 5; [**]: Excluding non-melanoma skin cancer; NA: Test was not conducted because of no variation across subgroups.

Table 3. Baseline characteristics of RA Japan and RA US drug initiators, stratified by line of therapy

RA-US, TNFi use was lower in the 1st (4% vs 8%), 2nd (40% vs. 63%), 3rd (32% vs 60%) and 4th line (23% vs 36%) of therapy.

Conclusion: Patients in RA Japan and RA US Registries differed in many aspects of demographics, comorbidity histories, clinical measures, and the utilization of DMARDs. Understanding cross-cultural differences in RA management is essential when interpreting results of studies from different countries.

Abstract Number: 0830

Discontinuation Rate of Tofacitinib Is Similar When Compared to TNF Inhibitors in Rheumatoid Arthritis Patients: Real World Results from a Rheumatoid Arthritis Cohort

Mohammad Movahedi[1], Angela Cesta[2], Xiuying Li[3], Edward C Keystone[4] and Claire Bombardier[5], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, Toronto, Canada, [4]Mount Sinai Hospital, Toronto, ON, Canada, [5]Institute for Work and Health, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment and is prescribed alone or with methotrexate (MTX). TOFA can be used as an alternative to biologic disease modifying antirheumatic drugs (bDMARDs) including tumor necrosis factor inhibitors (TNFi). We aimed to evaluate the discontinuation rate of TNFi compared to TOFA, in patients with RA in the Ontario Best Practices Research Initiative (OBRI).

Methods: RA patients enrolled in the OBRI initiating their TOFA or TNFi (adalimumab, certolizumab, etancercept, golimumab, and infliximab) between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Time to discontinuation were assessed using adjusted Kaplan-Meier (KM) survival and Cox regression models. To deal with confounding by indication, we estimated propensity scores for selected covariates with a standard difference greater than 0.1. We then adjusted models by applying stratification and inverse probability of treatment weight (IPTW) methods to compare discontinuation of TNFi versus TOFA. Multiple imputation (N=20) was used to deal with missing data for covaraites at treatment initiation.

Results: A total of 721 patients initiated TNFi (n=417) or TOFA (n=304) with mean (SD) disease duration of 8.9 (9.0) and 13.6 (9.6) years, respectively. In the TNFi group 82% were female and mean age (SD) at treatment initation was 57.0 (13) years. In the TOFA group, 85% were female and mean (SD) age at treatment initation was 60.7 (11) years. The TNFi group was less likely to have prior biologic use (22%) compared with the TOFA group (66%). At treatment initiation, the mean (SD) 28-swollen joint counts was siginificantly lower in the TNFi group [4.8 (4.0)] compared to the TOFA group [5.7 (4.4)]. Physical function measured by HAQ-DI was also significantly lower in TNFi compared to the TOFA group (1.1 vs.1.3).

Over a mean of 20.3 month follow-up, discontinuation was reported in 134 (32.1%) and 108 (35.5%) of all TNFi and TOFA patients, respectively. After adjusting for propensity score across 20 imputated datasets, there was no significant difference in discontinuation between treatment groups (adjusted HRs: 0.80, 95% CI: 0.60-1.05; p=0.11). The

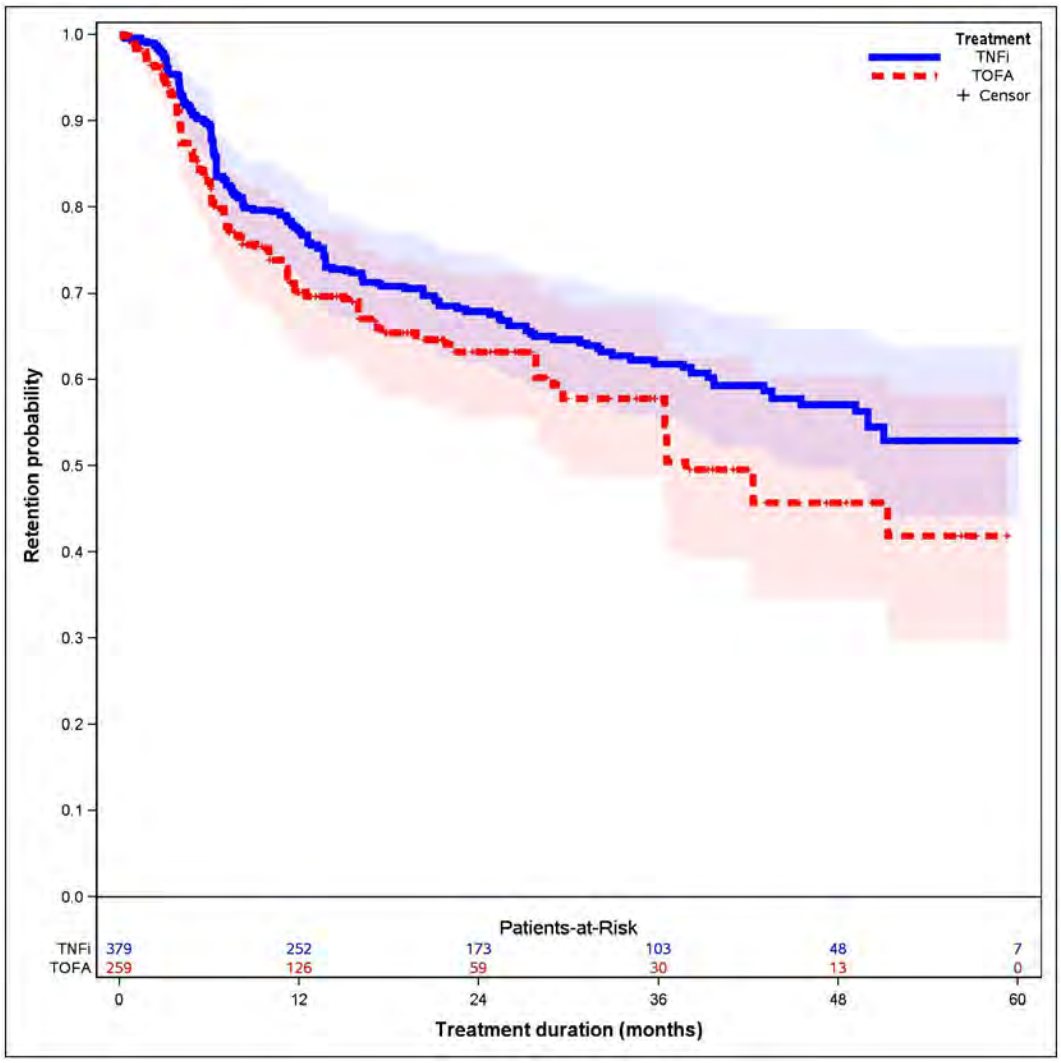

Figure 1. IPTW adjusted KM survival curves comparing discontinuation rates in patients treated with TNFi and TOFA.

results were similar for two propensity adjustment methods. Figure 1 shows IPTW adjusted KM survival curves comparing discontinuation rates in patients treated with TNFi and TOFA.

Conclusion: In this real world data study, we found that TNFi and TOFA retention is similar in patients with RA. Merging data with other RA registries in Canada is proposed to increase study power and to provide more robust results.

Sociodemographic, Disease, and Medication Profile of RA Patients Under 65 Years Compared with 65 Years or Older at Registry Enrollment: Real World Results from a Rheumatoid Arthritis Cohort

Mohammad Movahedi[1], Angela Cesta[2], Xiuying Li[3] and Claire Bombardier[4], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, Toronto, Canada, [4]Institute for Work and Health, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Age is an important factor that can affect disease course, physical function and treat to target strategy for patients with rheumatoid arthritis (RA). We aimed to describe sociodemographic, disease and medication profile of patients with RA in the Ontario Best Practices Research Initiative (OBRI) by their assigned age group at time of their enrollment.

Methods: RA patients enrolled in the OBRI between 1st Jan 2008 and 31st Dec 2019 were included. Patients were allocated into two age groups, under 65 years and 65 years or older. Descriptive cross sectional analysis was used to compare sociodemographic characteristics (gender, ethnicity, spoken language, education, health insurance, and smoking status), disease activity [28 tender and swollen joint count (28SJC and 28TJC), physician global assessment (PhGA), clinical disease activity index (CDAI)], patient report outcomes (PROs) including patient global assessment (PtGA), fatigue score, global pain, and HAQ-DI, and medication profile (prior use of csDMARDs, prior use of bDMARDs, using new bDMARDs or csDMARDs) between the two age groups at enrollment. We calculated the standardized difference as the difference in means or proportions divided by the standard error. A significant difference between the two groups was defined as an absolute value greater than 0.10.

Results: A total of 3,734 patients were included; 2562 (68.5%) were under 65 yeras old and 1172 (31.5%) were 65 years or older.

Sociodemographic profile: Patients under 65 years were significantly more likely to be female (79.7 vs. 73.5%), non-caucasian (14.4 vs. 7.4%), current smokers (18.8 vs 9.3%) and have post-secondary education (62.6 vs. 44.6%), and more likely to have private health insurance (75 vs. 49%) and report English as their spoken language (7.0 vs 9.8%).

Disease activity and PROs profile: Patients under 65 years were significantly more likely to be antiCCP positive (63.0 vs. 57.5%), report higher PtGA (mean: 4.8 vs. 4.5), higher global pain (mean 4.8 vs. 4.4), higher fatigue score (mean 5.0 vs. 4.6), and lower HAQ-DI (mean 1.1 vs. 1.2). No other significant differences were found between the two age groups.

In terms of presence of comorbidities, patients under 65 years had significantly lower proportions of hypertension, cardiovascular disease, diabetes mellitus, lung disease, gastrointestinal disease and malignancy. However, interestingly this group of patients had a higher proportion of depression (17.8% vs 13.3%).

Medication profile: At enrollment, patients under 65 years were significantly more likely to have used prior bDMARDs (31.4 vs.26.1%), and were more likely to be starting a new bDMARD (17.1 vs. 12.8%), or csDMARDs (38.6 vs. 35.6%). No difference in prior use of csDMARDs was found between the two groups.

Conclusion: In this real world data descriptive study, we found that disease activity measures were similar in patients under 65 years compared to those 65 years or older. However, sociodemographics, PROs , comorbidities, and medication profiles were different between two groups. These differences should be taken into account for any clinical decision toward outcome improvement in patients.

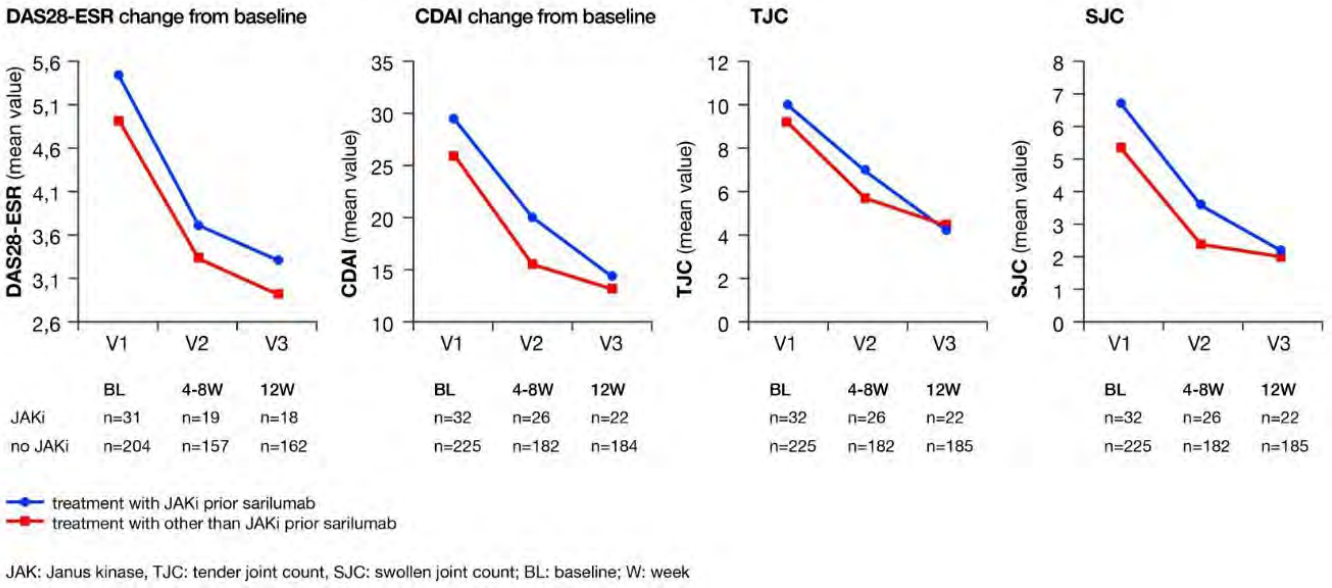
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Blockade of IL-6 signaling by sarilumab has been demonstrated to be an effective treatment approach for RA. Due to strict inclusion and exclusion criteria, randomized controlled trials may not represent the heterogeneous RA patient population encountered in regular care. Here we investigated the safety and effectiveness of sarilumab in the treatment of RA in regular care in Germany.

Methods: The prospective, observational, single-arm, 24-month PROSARA study (SARILL08661) is currently under way in Germany at 79 sites, aiming to include up to 750 patients with RA treated with sarilumab. Patients are selected at physician discretion and treated according to label. Study objectives include documentation of safety and various effectiveness outcomes. This interim analysis included patients with data available up to 12 weeks. All analyses are descriptive only.

Results: To date 348 patients were included in the study, 304 had baseline data, and 265 also had postbaseline data. The mean age was 59 years (range, 24–83 years); 76% (232/304) were women. Mean disease duration was 10 years; 81% (242/300) of patients had comorbidities. At baseline, 32% (86/265) of patients were biologic- and targeted synthetic DMARD (tsDMARD)-naive. Prior treatments with biologic or tsDMARDs included TNF inhibitors (TNFi; 56% [149/265]), non-TNFi biologics (29% [77/265]), and Janus kinase inhibitors (JAKi, 17% [46/265]). At baseline,

Figure 1. Effectiveness of sarilumab in patients switched from JAKi vs. patients switched from other DMARDs.



JAK: Janus kinase, TJC: tender joint count, SJC: swollen joint count; BL: baseline; W: week

Figure 1

49% (149/304) received sarilumab as monotherapy and 29% (88/304) in combination with conventional DMARDs; combination treatment status was not specified for 22% (67/304) of patients. After 12 weeks of sarilumab treatment, the mean ± SD DAS28-ESR score decreased from 5.0 ± 1.5 to 3.0 ± 1.4 and Clinical Disease Activity Index (CDAI) from 26.7 ± 13.8 to 13.6 ± 11.4. DAS28-ESR remission and low disease activity (LDA) were achieved in 43% (77/180) and 59% (107/180) of patients, respectively; 14% (28/206) and 49% (101/206) reached CDAI remission and LDA. At Week 12, 9% (19/201) of patients had Boolean remission. HAQ-disability index improved from 1.3 at baseline to 1.1 at Week 12 (n=195). Mean CDAI improvement at Week 12 was similar for autoantibody (RF or anticitrullinated protein antibody)-positive and -negative patients (–12.5 vs –15.4, respectively). Patients switching from JAKi to sarilumab (n=32) had longer disease duration than patients who switched from another compound. Of note, similar efficacy was observed between patients who switched from JAKi to sarilumab and those who switched from other DMARDs; disease activity measures (DAS28, CDAI, tender joint count, and swollen joint count) and global assessments improved consistently (Figure 1). Safety was consistent with the anticipated profile of IL-6 receptor inhibition and no new safety signals were observed. Adverse events (AEs) and serious AEs were reported in 34% and 6% of patients, respectively.

Conclusion: Sarilumab administered in regular care was associated with rapid and clinically meaningful improvements in a general RA population, including patients switching from JAKi. The safety profile was consistent with data reported from controlled clinical trials.

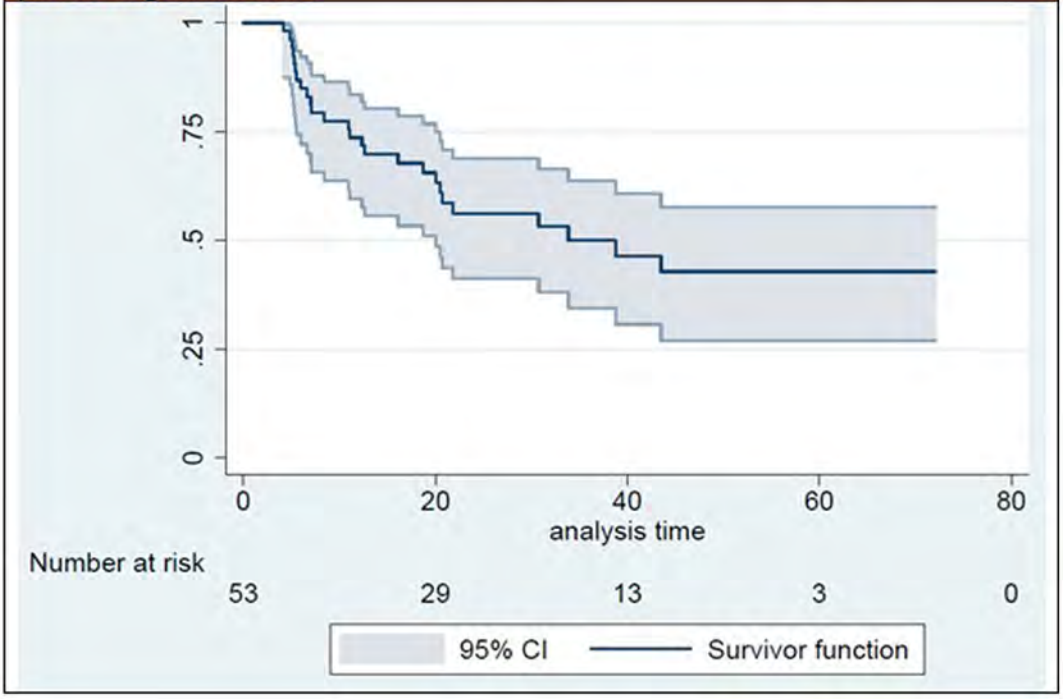
Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The emergence of biological disease modifying drugs (bDMARD) has allowed a targeted approach to rheumatoid arthritis (RA) (“treat-to-treat” strategy). Once sustained remission is achieved, optimized treatment of bDMARD (OT) is considered: using drugs at lower doses than indicated in data sheets. Studies show that 33-64.2% of patients on OT lose remission in the first 6 months. Still, it is a feasible practice in selected patients and so, it is of interest to study the situation of optimized patients to improve our practice. Our objectives were to describe

Image 1: Kaplan-Meier survival estimate of optimized treatment of biological DMARDs in patients diagnosed with RA.



Time is expressed in months.

Table 1: Characteristics of the sample (N = 53)	
Female	40 (75.47%)
Age at diagnosis (years)	49.54 (11.68)

demographic, clinical, analytical and therapeutic characteristics of RA patients on OT in our hospital. Secondly, to study the survival of OT and to compare patients with survival longer or shorter to one year.

Methods: We did a retrospective review of the medical records of RA patients who began bDMARD OT [Abatacept (ABA), anti-TNF drugs and Tocilizumab (TCZ)] between January 2014 and December 2018. We defined the end of OT as the restart of the usual dose. Continuous variables are described with mean and standard deviation (SD) and qualitative variables are shown in absolute value and percentage. We divided the sample into patients with OT survival greater than or equal to one year and patients with OT survival less than one year, after which the characteristics of both populations were compared. Categorical variables were analyzed using Pearsons chi^2 and quantitative variables using Student's t-test. Survival analysis was performed using a Kaplan-Meier estimator.

Results: We identified 234 RA patients on bDMARD at our hospital, of which 53 (22.6%) had been optimized between January 2014 and December 2018: 39 (73.6%) with anti-TNF, 7 (13.2) with ABA and 7 (13.2%) with TCZ. Their characteristics are shown in Table 1. It is worth mentioning the rate of monotherapy (43.3%) and the low number of bDMARD prior to optimization (median 0.71, SD 0.97). The median survival of OT was 33.8 months (Image 1) and thirty-nine patients (73.6%) maintained OT for at least one year (95% confidence interval, 0.59 to 0.83). When comparing patients with survival greater/equal versus shorter to one year (Table 2), the only variable showing significant differences was

Table 2: Comparison according to OT survival time			
	OT survival <1 year (N=14)	OT survival ≥1 year (N=39)	p Value
Female	12 (85.71%)	28 (71.79%)	0.299
Age at diagnosis (years)	50.25 (SD 11.87)	49.33 (SD 11.77)	0.815
ACPA positive	10 (71.43)	27 (69.23%)	0.918

Extra-articular disease	5 (35.71%)	6 (15.79)	0.108
Erosions	7 (50%)	28 (84.85%)	0.012
Months from debut to 1st csDMARD	34.67 (SD 55.25)	14.09 (SD 22.41)	0.0701
Months from Opt bDMARD start to OT	49.8 (SD 36.32)	40.78 (SD 34.62)	0.414
Months from debut to remission	31.38 (SD 20.61)	41.45 (SD 33.1)	0.3526
Months from remission to optimization	20.75 (SD 23.02)	24.72 (SD 22.50)	0.587
Monotherapy at optimization	6 (42.86%)	17 (43.59)	0.962
bDMARD* previous to OT	0.64 (SD 0.93)	0.74 (SD 0.99)	0.742
DAS28 at diagnosis	4.84 (SD 1.69)	4.89 (SD 1.12)	0.922
DAS28 at beginning -1st csDMARD	4.31 (SD 1.77)	4.73 (SD 1.54)	0.517
DAS28 at beginning -1st bDMARD	4.64 (SD 1.07)	5.1 (SD 0.18)	0.2001
DAS28 at beginning -Opt bDMARD	4.56 (SD 1.49)	4.72 (SD 1.06)	0.701
DAS28 Optimization	2.06 (SD 0.69)	1.82 (SD 0.64)	0.241

the presence of erosions at beginning of OT (28 patients in the >1 year group vs 7 in the < 1 year group; p=0.012). Although the difference is not significant (p = 0.07), patients with a survival of less than one year have more time between the debut and the beginning of the first conventional synthetic DMARD (csDMARD).

Conclusion: Two limitations should be noted: the sample size and the lack of a homogeneous optimization schedule among rheumatologists. More studies are needed to define the characteristics of patients who can safely benefit from OT.

Session Title: RA – Treatments Poster II: Comparative Effectiveness, Biosimilars, Adherence & the Real World

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with RA who have received multiple biologics or targeted therapies over time tend to have more refractory and more severe disease, which may lead to worse clinical response to treatment. We examined characteristics of sarilumab-treated patients with RA in order to evaluate the hypothesis that disease severity was greater in those who received sarilumab shortly after its Food and Drug Administration (FDA) approval (May 2017) than in subsequent time periods.

Methods: Patients with RA who initiated sarilumab treatment from May 2017 to June 2019 were identified in the American College of Rheumatology's Rheumatology Informatics System for Effectiveness (RISE) registry. They were

Table 1

divided into 3 cohorts based on time since FDA approval, with the overall period divided into tertiles rounded to the nearest calendar quarter (Cohort 1: May 2017 to March 2018; Cohort 2: April 2018 to December 2018; Cohort 3: January 2019 to June 2019). Patient characteristics reflecting demographics, RA-related features, and comorbidities (measured based on prescriptions, using the RxRisk score) were evaluated using all available data prior to sarilumab initiation. Between-cohort comparisons were made using chi-square test for categorical variables and a nonparametric test for continuous variables.

Results: A total of 2039 patients, treated by 585 rheumatologists, initiated sarilumab treatment in the period May 2017–June 2019 (Figure). Cohort comparison showed relative similarity over the 3 time periods in terms of patients' age, sex, race, and most clinical characteristics (Table). However, patients receiving sarilumab shortly after FDA ap-

proval (Cohort 1) had more ambulatory visits, a greater number of previously used non-TNF inhibitor (TNFi) biologics (particularly tocilizumab), a higher comorbidity burden, and were more likely to be current users of glucocorticoids or opioids than patients in Cohorts 2 and 3. Ongoing work is evaluating comparative response to therapy in the 3 cohorts.

Conclusion: We observed modest evidence for channeling of patients with greater RA severity and greater prior exposure to non-TNFi biologics to a newly introduced biologic, although disease activity at time of initiation was comparable over the 3 time periods. For real-world evidence generation, considerations should include cohort effects related to the timing of new drug approval in order to make valid inferences resulting from comparative effectiveness research.

Pathogenic Effect of Chronic Stress-induced interleukin-12/23p40 on Neuropsychiatric System in Lupus-prone Mouse

Nobuya Abe[1], Kenji Oku[1], Yuichiro Fujieda[1], Nobuhiko Takahashi[2], Kohei Karino[1], Michihito Kono[1], Masaru Kato[1], Yuki Tanaka[3], Rie Hasebe[4], Olga Amengual[1], Miwako Yamasaki[5], Masahiko Watanabe[5], Masaaki Murakami[3] and Tatsuya Atsumi[6], [1]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [2]Division of Molecular Psychoimmunology, Institute for Genetic Medicine, Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [3]Division of Molecular Psychoimmunology, Institute for Genetic Medicine, Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [4]Biomedical Animal Research Laboratory, Institute for Genetic Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [5]Department of Anatomy, Faculty of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [6]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine, Hokkaido University, Sapparo, Hokkaido, Japan

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Neuropsychiatric system is one of the major organs affected in systemic lupus erythematosus (SLE). However, the pathogenesis of neuropsychiatric SLE (NPSLE) has not been fully established due to a variety of pathogenic pathways including thrombosis, autoantibodies, cytokines, and microglial activation leading to neuronal damage. Physiopsychological stress affects immune responses, putatively being a risk factor for the development of autoimmune diseases. Therefore, we have hypothesized an impact of physiopsychological stress on the pathogenesis of NPSLE, and analyzed stress-induced neuropsychiatric impairment in a murine model of lupus with the aim of establishing a novel therapeutic approach for NPSLE.

Methods: We placed chronic sleep disturbance (SD) stress for 2 weeks on 6-8-week-aged female MRL/lpr lupus prone mice and MRL/MpJ control mice using SD cage (Melquest, Japan). Open field (OF) test and elevated plus maze (EPM) test were used to assess anxiety-like behavior. We performed immunohistochemistry to evaluate neuronal and microglial activation, and Golgi-Cox staining to assess dendric morphological changes of neurons. Gene expression was comprehensively analyzed using RNA sequencing, and enzyme-linked immunoassay was used to evaluate in-

terested protein level in cerebrospinal fluids (CSF) of the mice and of human including healthy controls and NPSLE patients.

Results: SD-subjected MRL/lpr exhibited less anxiety-like behavior than their counterparts in OF and EPM test, while control mice showed more anxiety when stressed. Stress activates ventral tegmental area, projecting medial prefrontal cortex (mPFC) and nucleus accumbens (NAcc). In the mPFC, SD-subjected MRL/lpr demonstrated significant numbers of phospho-cFos positive activated neuronal cells whereas both SD-subjected MRL/lpr and control mice contains higher number of such than SD-free mice in NAcc. Differential gene expressions of mPFC analyzed via RNA sequencing revealed that Il12b expression level was prominent in SD-subjected MRL/lpr. Il12b is reportedly expressed in microglia. We found that SD-subjected MRL/lpr had the highest numbers of activated microglia regarding the morphology and CD68 aggregation. The CSF level of interleukin (IL)-12/23p40 encoded by Il12b was the highest in SD-subjected MRL/lpr. Furthermore, NPSLE patients also showed higher CSF IL-12/23p40 levels than healthy controls and SLE patients without neuropsychiatric symptoms. In Golgi-Cox staining, the increased numbers of dendric spines in mPFC pyramidal neurons were observed only in SD-subjected MRL/lpr.

Conclusion: Physiopsychological stress induced abnormal behavior, microglial activation and elevated level of IL-12/23p40 in lupus model mice. Moreover, IL-12/23p40 in CSF was increased in NPSLE patients, possibly associated with the development of NPSLE. Our data indicates that IL-12/23p40 is a potential therapeutic target for NPSLE.

SH3BP2 Deficiency Ameliorates Murine Systemic Lupus Erythematosus

Tomoyuki Mukai[1], Kyoko Kawahara[1], Masanori Iseki[2], Akiko Nagasu[1], Hajime Nagasu[3], Takahiko Akagi[1], Shoko Tsuji[1], Yasuyoshi Ueki[4], Katsuhiko Ishihara[2], Naoki Kashihara[3] and Yoshitaka Morita[1], [1]Department of Rheumatology, Kawasaki Medical School, Kurashiki, Okayama, Japan, [2]Department of Immunology and Molecular Genetics, Kawasaki Medical School, Kurashiki, Okayama, Japan, [3]Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan, [4]Department of Biomedical Sciences and Comprehensive Care, Indiana University School of Dentistry, Indianapolis, IN

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The adaptor protein, Src homology 3 domain-binding protein 2 (SH3BP2), is widely expressed in immune cells, such as myeloid cells, B cells, and T cells. It controls intracellular signaling pathways such as Syk and Src. The present study was undertaken to investigate the role of SH3BP2 in a murine systemic lupus erythematosus model and to explore differential phenotypes in immune cell sub-populations isolated from SH3BP2-deficient mice.

Methods: For the lupus model, we used *Fas*^{lpr} mice (C57BL/6 background). Clinical and immunological phenotypes were compared between *Fas*^{lpr} and SH3BP2-deficient *Fas*^{lpr} mice. Splenomegaly and renal involvement were assessed in 35-week-old mice. Serum levels of anti-dsDNA antibody and rheumatoid factor were determined using ELISA. Lymphocyte subsets in spleen and lymph nodes were analyzed by flow cytometry. To examine the role of SH3BP2 in specific cells, B cell-specific SH3BP2-deficient lupus mice were generated and analyzed; differentiation of bone marrow-derived dendritic cell and activation of T cells and macrophages were determined in vitro.

Results: SH3BP2 deficiency significantly reduced lupus-like phenotypes, such as splenomegaly, renal involvement, elevated serum dsDNA antibody and rheumatoid factor, and increased splenic $B220^{+}CD4^{-}CD8^{-}$ T cells. Notably, SH3BP2 deficiency in B cells did not rescue the lupus-like phenotypes. Interestingly, SH3BP2 deficiency suppressed the differentiation of dendritic cells but it did not affect the functions of T cells and macrophages in vitro.

Conclusion: SH3BP2 deficiency ameliorated clinical and immunological manifestations in lupus-prone mice, possibly via targeting dendritic cells differentiation. Modulating SH3BP2 expression could thus provide a novel therapeutic approach to autoimmune diseases.

Deletion of miR-223 Exacerbates Lupus Nephritis by Targeting S1pr1 in *Fas*$^{lpr/lpr}$ Mice

Sumie Hiramatsu Asano[1], Tomoyuki Mukai[2], Yoshitaka Morita[3] and Jun Wada[4], [1]Kawasaki Medical School/Department of Rheumatology, Kurashiki city, Japan, [2]Kawasaki Medical School, Kurashiki-shi, Okayama, Japan, [3]Kawasaki Medical School/Department of Rheumatology, Kurashiki, Okayama, Japan, [4]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences., Okayama city, Japan

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify new candidate genes regulated by micro RNAs (miRNAs) and involved in the pathogenesis of systemic lupus erythematosus (SLE), we integrated miRNA and messenger RNA (mRNA) expression profiling data in $CD4^{+}$ splenic T cells derived from lupus-prone MRL/MpJ-*Fas*^{lpr} /J (MRL/lpr) mice and C57BL6/J (B6) mice. The reduction of sphingosine-1-phosphate receptor 1 (*S1pr1*) and upregulation of miR-223-3p in the splenic T cells in MRL/lpr was identified and we investigated the role of *S1pr1* as a predicted target of miR-223 (Mir223) in SLE.

Methods: L transduction particles containing luciferase reporter and *S1pr1*-3'UTR region was infected into human umbilical vein endothelial cells (HUVECs) for luciferase miRNA target screening. Luciferase reporter assay following co-transfection of lentiviral particles containing reporter vector with miR-223-3p mimic or nontargeting miRNA into HUVECs was performed. To further confirm that *S1pr1* is a target of miR-223-3p, miR-223-3p mimic or nontargeting miRNA was transfected into EL4 mouse T cell lines by lipofection. The transfection efficacy of miR-223-3p was con-

firmed by quantitative PCR (qPCR). The endogenous *S1pr1* mRNA and protein levels were detected by qPCR and Western blot analysis. To explore the involvement of miR-223-3p in SLE pathogenesis, we generated and analyzed *Mir223* knockout lupus-prone B6.MRL-*Fas*^{lpr} mice (*Mir223*$^{-/-}$*Fas*$^{lpr/lpr}$) until 44 weeks of age. The total IgG and titer of anti-ds-DNA antibodies in serum were measured by ELISA. Histopathological grading of glomerular, renal vascular and tubulointerstitial lesions were performed and the glomerular immune complex deposition was assessed by C3 and IgG staining. To clarify the cell types which infiltrates in glomerular lesion, immunofluorescence staining with CD4, CD8 and S1PR1 antibodies was performed. The cell population including apoptotic cells and S1PR1 positive cells in the lymph nodes and spleen were analyzed by flow cytometry. We also investigated the expression levels of *S1pr1* mRNA and miR-223-3p in circulating CD4$^+$ T cells isolated from SLE patients and healthy subjects.

Results: Transfection of HUVEC with mimic miR-223-3p significantly suppressed a luciferase-reporter containing the *S1pr1*-3'UTR. The mRNA levels of *S1pr1* was significantly decreased after miR-223-3p overexpression. *Mir223* deficiency increased the production of serum IgG2b and the proportion of CD3$^+$ T cells, CD3$^+$CD4$^-$CD8$^-$ T cells, CD19$^+$ B cells, CD19$^-$CD138$^+$ cells (Plasma cells), CD3$^+$S1PR1$^+$ T cells and CD3$^+$CD4$^+$S1PR1$^+$ T cells in spleen and the proportion of early apoptotic cells in CD4$^+$ and CD8$^+$ T cells in lymph nodes. Lupus nephritis in *Mir223* knockout mice was exacerbated accompanied with glomerulonephritis with infiltration of CD4$^+$S1PR1$^+$ T cells in glomerulus. *S1pr1* mRNA was significantly decreased in CD4$^+$ T cells from the patients with SLE. miR-223-3p tended to upregulate in lupus patients than healthy control. There was significant correlation between miR-223-3p and serum IgM titer.

Conclusion: Deletion of *Mir223* exacerbated the lupus phenotypes associated with increasing *S1pr1* expression in CD4$^+$T cells and their enhanced infiltration in inflamed kidney tissues.

T Cell–Specific CaMKIV Deficiency Protects Mice from Imiquimod-induced Glomerulonephritis

Milena Vukelic[1], Masataka Umeda[1], Andrew Ferretti[2], Rhea Bhargava[1], Nobuya Yoshida[1] and George Tsokos[3], [1]Beth Israel Deaconess Medical Center Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center Harvard Medical School, Boston, [3]Division of Rheumatology & Clinical Immunology/Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by autoantibody production, immune complex deposition and multisystem involvement. Calcium/calmodulin-dependent protein kinase type IV (CaMK4) is serine-threonine kinase overexpressed in SLE CD4 T cells. Global CaMK4 deficiency or inhibition with a small drug in MRL/lpr mice resulted in prolonged survival, significant suppression of proteinuria, severity of glomerulonephritis and autoantibody production. Here, we hypothesized that targeted T cell specific deletion of CaMK4 will protect mice from the development of systemic autoimmune disease induced by application of imiquimod, a toll-like receptor agonist.

Methods: We generated T cell specific CaMK4 conditionally deficient mice on C57BL/6 background by using *Cre-loxP* system. Mice harboring loxP sites of *Camk4* gene (*Camk4* $^{flox/flox}$) were crossed with Cre transgenic mice driven by distal *Lck* promoter. Female mice were genotyped and 12 weeks old *Lck-Cre* positive and negative *Camk4* $^{flox/flox}$ littermates were used for the experiment. Mice were treated with imiquimod applied to the ears 3 times weekly for 8 weeks. Serum, urine, kidneys and other organs were collected for the analysis. Levels of dsDNA were measured by ELISA. Proteinuria was assessed by measuring albumin to creatinine ratio. Kidney sections were scored for damage in a blinded manner by using the renal activity index. T- test was used for statistical analysis and data are expressed as mean±SEM.

Results: *Lck-Cre+ Camk4* $^{flox/flox}$ mice had normal development and lifespan. We had 4 *Lck-Cre Camk4* $^{flox/flox}$ negative and positive mice per group. After 8 weeks of imiquimod treatment elevated levels of autoantibodies to double-stranded DNA were similar between the groups (*Lck-Cre +/ Camk4* $^{flox/flox}$:18.68±1.72 vs. *Lck-Cre -/ Camk4* $^{flox/flox}$ 21.73± 3.34 IU /ml). Spleen sizes were similar between the groups. Excitingly, proteinuria was significantly decreased in *Lck-Cre +/ Camk4* $^{flox/flox}$ mice compared to *Lck-Cre* negative (871.94±227.24 vs. 1437.9±275.56 mg/gr; p= 0.0023). Histopathologic examination of the kidneys showed that T cell specific CaMK4 deficiency in *LcK-Cre* positive animals significantly decreased infiltration in the kidney parenchima.

Conclusion: We have generated evidence that specific deletion of CaMKIV in T cells ameliorates severity of glomerulonephritis after the administration of the TLR7 agonist without affecting the production of antibodies to dsDNA. Our data support the development targeted delivery of a CaMK4 inhibitors to T cells for the treatment of patients with SLE.

Single-Cell Transcriptomics of Mouse and Human Lupus Nephritis Identifies Conserved Myeloid Populations Across Species

Paul Hoover[1], Michael Peters[2], David Lieb[3], Rakesh Mishra[4], Nir Hacohen[2] and Anne Davidson[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Broad Institute, Boston, [3]Broad Institute, Boston, MA, [4]Feinstein Institute, Manhasset, NY, [5]Northwell Health, New York

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: We recently identified novel immune cell states in the kidneys of lupus nephritis patients (Arazi et al, Nature Immunology 2019). To determine the similarities with lupus mouse models, we compared human immune cell transcriptomes to those from Sle1.Yaa and NZBW mouse kidneys. We focused on macrophages and DCs since intrarenal myeloid abundance may drive tissue damage in lupus patients.

Methods: We collected myeloid cells from dissociated kidneys from pre- and post-nephritic Sle1.Yaa and NZBW mice (3-4 mice per group). Using 10x Genomics we performed single cell transcriptomic profiling and analyzed droplets that contained >500 genes and UMIs after doublet removal. To identify intrarenal mouse immune cells equivalent to those in humans, we leveraged immune cell transcriptomes collected from the kidneys of lupus patients in AMP

Phase 1 to generate state-specific gene signatures from each human myeloid cell cluster composed of: (i) the top 10 to 40 most highly and ubiquitously differentially expressed (DE) genes, (ii) the top 4-10 DE transcription factors, or (iii) modules of co-varying genes from non-negative matrix factorization. After clustering mouse myeloid cells (Seurat v3.0), we calculated the average of the scaled expression for each human signature across mouse clusters to identify those most similar to human. We also calculated the Pearson correlation coefficient between human and mouse clusters using homologous genes with identical names between species.

Results: We mapped gene signatures from the human myeloid states: 'inflammatory' macrophages (CM0) that likely enter from blood and transition to 'phagocytic' (CM1) and 'reparative' (CM4) states; resident macrophages (CM2); dendritic cells (CM3). We identified the human CM0 signature in clusters from NZBW (and weakly in Sle1.Yaa) post-nephritic pro-inflammatory macrophage/DC clusters that infiltrate from blood, similar to CM0 cells in humans. The human CM1 signature mapped to clusters in both mouse models that resembled DCs and that were enriched for transendothelial migration. We identified in both models the CM4 signature in pre- and post-nephritic mouse clusters that resembled resident macrophages and were enriched for antigen presentation and lysosomal processing. Like humans, the post-nephritic CM4 mouse equivalent cluster exclusively expressed Ccl8, a leukocyte chemoattractant and activator, and Gas6, a mediator of apoptotic cell clearance and was skewed towards an alternative phenotype. Finally, we mapped the human CM3 signature to mouse CD103+ DCs and identified gene programs shared with humans for immunoregulation and antigen presentation.

Conclusion: From the kidneys of Sle1.Yaa and NZBW mice we identified human myeloid gene signatures: 'inflammatory' macrophages (CM0), 'phagocytic' (CM1), 'reparative' (CM4) states; dendritic cells (CM3); we did not find the human resident macrophage (CM2) signature. We identified putative functions shared between mouse and human clusters including antigen presentation, phagocytosis, Ccl8 expression. These analyses indicate that we may be able to study in mice some of the myeloid subsets and genes that are highly relevant to human disease.

Amelioration of Immune Complex-Mediated Glomerulonephritis via CD6 Modulation

Samantha Chalmers[1], Sayra Garcia[1], Leal Herlitz[2], Jeanette Ampudia[3], Cherie Ng[4], Stephen Connelly[3] and Chaim Putterman[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Cleveland Clinic, Cleveland, OH, [3]Equillium, Inc, San Diego, CA, [4]Equillium, Inc, La Jolla, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: CD6 is a co-stimulatory receptor, predominantly expressed on T cells, that binds to activated leukocyte cell adhesion molecule (ALCAM), a ligand expressed on antigen-presenting cells and various epithelial and endothelial tissues. T cells are important contributors to the pathogenesis of SLE, especially in the development of kidney disease (lupus nephritis, LN). The CD6-ALCAM pathway plays an integral role in T cell activation, differentiation, proliferation, and trafficking, and increased levels of CD6 are associated with pathogenic T cell responses.

Thus, the CD6-ALCAM pathway is a potential contributor to disease pathogenesis and presents itself as a potential therapeutic target.

Methods: Nephrotoxic serum nephritis (NTN) is a validated, short-term model of LN. Disease was induced in two separate cohorts of female 129/svJ mice, both aged to 10 weeks. Mice were immunized with rabbit IgG and complete Freund's adjuvant on day 0, followed by passive transfer of pre-formed rabbit anti-mouse glomerular antibodies intravenously (i.e. nephrotoxic serum) given on day 5, causing an antibody-mediated nephritis similar in pathology to LN. One group of mice was treated 3x per week with anti-CD6 monoclonal antibody (10D12) (60ug/dose, n=23), while control mice were treated with either vehicle control (n=23) or isotype control (cohort 2 only, n=12). Healthy mice (immunized with rabbit IgG, but not given nephrotoxic serum) were also included as a control (n=12). We monitored the progress of kidney disease to assess the effect of the anti-CD6 treatment on both cohorts, and completed flow cytometry, RT-PCR, immunofluorescent staining, and multiplexed gene expression analysis to assess the effect of treatment on kidney disease development.

Results: Mice treated with anti-CD6 displayed decreased levels of proteinuria as measured by uristix and albumin:creatine ratios compared to vehicle control ($p < 0.0001$, $p < 0.0001$, respectively) and isotype control treated mice ($p < 0.05$, $p < 0.0001$, respectively). Blood urea nitrogen (BUN) levels were also significantly improved when comparing anti-CD6 to vehicle control treated mice ($p < 0.05$). Anti-CD6 treatment ameliorated glomerular histopathology, and had a near significant improvement in tubular histology. Flow cytometric analysis of kidney tissue indicated decreased numbers of activated T cells (CD4+CD25+CD69+, $p < 0.01$) as well as decreased inflammatory macrophages ($p < 0.05$). Finally, we performed a PCR array to assess expression of a number of inflammatory genes. When comparing anti-CD6 treated mice to both the vehicle and isotype control groups, 13 genes were significantly decreased in both comparisons, including *C3, CCL1, CCL2, CCL5, CCL7, CCL20, CSF1, CXCL3, CXCL2, CD14, CD40, CXCL5,* and *IL1rn*.

Conclusion: Anti-CD6 treatment is beneficial in ameliorating the nephritis associated with nephrotoxic antibody administration, an inducible model of lupus nephritis. These results suggest a promising therapeutic option that is more selective than the immunosuppressive therapies currently offered.

CD6 Modulation Ameliorates Kidney and Skin Disease in a Spontaneous Murine Lupus Model

Samantha Chalmers[1], Sayra Garcia[1], Rajalakshmy Ayilam Ramachandran[2], Chandra Mohan[2], Leal Herlitz[3], Dalena Chu[4], Jeanette Ampudia[4], Cherie Ng[5], Stephen Connelly[4] and Chaim Putterman[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Houston, Houston, TX, [3]Cleveland Clinic, Cleveland, OH, [4]Equillium, Inc, San Diego, CA, [5]Equillium, Inc, La Jolla, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: T cells are an important contributor to the pathogenesis of SLE and lupus nephritis, and thus present themselves as interesting therapeutic targets. CD6 is a co-stimulatory receptor, predominantly expressed on T cells, that binds to activated leukocyte cell adhesion molecule (ALCAM), a ligand expressed on antigen-presenting cells and various epithelial and endothelial tissues. The CD6-ALCAM pathway plays an integral role in modulating T cell activation and trafficking, and could potentially be targeted within the context of SLE and LN as a therapeutic avenue. In this study, we assessed the expression of CD6 and ALCAM within the context of a murine model of SLE, and then targeted this signaling axis to determine its role in the pathogenesis of disease.

Methods: The MRL/lpr mouse is a spontaneous murine model of SLE, which exhibits systemic autoimmunity, nephritis, and skin disease. In an initial experiment, kidneys from 6-month old MRL/lpr and B6 mice were analyzed for the presence of both ALCAM and CD6. Following the initial experiment, two separate cohorts of female MRL/lpr mice were aged to 9-10 weeks of age, at which point treatment was begun with either anti-CD6 monoclonal antibody (60 ug/dose, intraperitoneally twice per week), isotype control (60 ug/dose, twice per week), or cyclophosphamide (25 mg/kg, once per week). We also included a no treatment group, and a group of MRL/MpJ mice, a congenic control strain. Baseline levels of anti-DNA antibodies, weight, and proteinuria in the MRL/lpr groups were similar. Mice were monitored weekly for proteinuria, lymph node swelling, and macroscopic skin lesions.

Results: At 6 months, when disease is advanced, analysis of ALCAM and CD6 expression by both flow cytometry and immunofluorescence revealed increased levels of ALCAM in renal myeloid cell populations and within the glomeruli and tubules, and increased expression of CD6 on renal T cell subsets, in MRL/lpr compared to B6 healthy control mice. Subsequently, we blocked this signaling axis in MRL/lpr mice using a monoclonal antibody against CD6. Anti-CD6 treatment significantly improved proteinuria levels as measured by uristix and albumin:creatine ratios compared to isotype control treated mice. Blood urea nitrogen levels were also significantly improved ($p< 0.05$), and survival of anti-CD6 treated mice was significantly better than isotype control mice ($p=0.05$). Histology of renal tissue revealed an improvement with anti-CD6 treatment and immunofluorescence staining showed decreased accumulation of renal T cells and myeloid cells. Flow cytometry confirmed decreased renal infiltration T cells and myeloid cells, specifically activated and memory CD4+ T cells and memory CD8+ T cells. Interestingly, anti-CD6 treatment also decreased lymph node size and improved macroscopic skin lesions. The results were confirmed in two separate cohorts.

Conclusion: In a spontaneous model of SLE, anti-CD6 treatment ameliorated pathology in multiple end organs, namely the kidney and skin. Overall, these results indicate that targeting CD6-ALCAM interactions may have promising therapeutic potential within the context of different end organ pathologies of SLE.

mTOR Signaling Pathway Blockade and Rab4 Expression Affects Metabolism of Lupus T Cells

Tamas Faludi[1], Nick Huang[1], Manuel Duarte[1], Joshua Lewis[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pro-inflammatory T-cell development underlies the pathogenesis of systemic lupus erythematosus (SLE). Activation of the mechanistic target of rapamycin (mTOR) plays a central role in T-cell lineage specification both under physiological conditions and during inflammation in SLE. Persistent mitochondrial hyperpolarization (MHP) and the accumulation of mitochondria underlie mTOR activation which serves as a biomarker of pathogenesis and target for treatment in SLE (Nat Rev Rheumatol 2016; 12: 169-82). HRES-1/Rab4, a small GTPase enzyme regulating endosomal trafficking, is overexpressed in lupus T cells and triggers the accumulation of mitochondrial mass and the activation of mTOR. Therefore, understanding metabolic consequences of HRES-1/Rab4 overexpression is expected to shed light on the mechanisms of proinflammatory T cell lineage development in SLE.

Methods: To study the effects of Rab4A expression and mTOR pathway activity in T cells, a site-specific Cre/Lox recombinase system was used to knock down Rab4A expression in lupus-prone triple congenic SLE 1.2.3 mice. The mice were treated with 3 mg/kg intraperitoneal rapamycin three times weekly or solvent control or 10 g/l N-acetylcysteine (NAC) in the drinking water for 14 weeks starting at 27 weeks of age. The metabolic flux was characterized by feeding ^{13}C-sTable isotope labeled nutrients, such as glucose or glutamine, to cells in culture and subsequently measuring isotope labeled metabolites using liquid chromatography-mass spectrometry (LC-MS) after the preparation of cell extracts.

Results: Activation of Rab4A in triple congenic SLE 1.2.3 (B6.TC/ Rab4A^{Q72L}) mice carrying constitutively active Rab4A^{Q72L} alleles had earlier and more severe onset of glomerulonephritis (GN), ANA production and proteinuria than parental lupus-prone controls (B6.TC). In turn, deletion of Rab4A in T cells blocked GN, ANA production and proteinuria. Rapamycin and NAC reduced disease activity in B6.TC/ Rab4A^{Q72L} mice. Rapamycin decreased metabolic flux in CD8+ T cells from ^{13}C -labeled glutamine into mitochondrial tricarboxylic cycle metabolites, such as alfa-ketoglutarate (38% decrease, p=0.005), citrate (37% decrease, p=0.0018) and malate (20% decrease, p=0.025). NAC increased the metabolic flux derived from ^{13}C-labeled glutamine in CD8+ T cells into alfa-ketoglutarate (66% increase, p=0.046), citrate (53% increase, p=0.048) and malate (51% increase, p=0.032). T cell-specific deletion of Rab4A increased ^{13}C-labeled glucose flux into the non-oxidative pentose phosphate pathway (PPP) metabolite, sedoheptulose-7-phosphate (180% increase, p=0.002) and glycolysis intermediates glucose-6-phosphate/fructose-6-phosphate (61% increase, p=0.034) in CD4+ T cells. Rab4A deletion increased glutathione concentration in CD4+ T cells (101% increase, P=0.014).

Conclusion: mTOR pathway blockade and Rab4A inactivation may provide therapeutic targets for correcting pro-inflammatory metabolic dysfunction of T cells in SLE.

Rab4A Activation Predisposes to Hepatitis in Spontaneous and Pristane-Induced Mouse Models of Systemic Lupus Erythematosus

Nick Huang[1], **Akshay Patel**[1], Zachary Oaks[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: HRES-1/Rab4 or Rab4A, a GTPase responsible for mitochondrial oxidative stress[1] and activation of the mechanistic target of rapamycin[2], is overexpressed in T cells of systemic lupus erythematosus (SLE) patients[3] and livers of lupus-prone mice[4]. Therefore, we investigated the impact of Rab4A on hepatitis in spontaneous and pristane-induced mouse models of SLE.

Methods: C57Bl/6J wild-type (B6) mice, strains expressing constitutively active Rab4A ($Rab4A^{Q72L}$) in all cells, and strains lacking Rab4A in T cells ($Rab4A^{CD4\text{-}KO}$) were injected intraperitoneally (ip) with pristane (500µL/20g body weight). $Rab4A^{Q72L}$ and $Rab4A^{CD4\text{-}KO}$ mice were generated on both B6 and lupus prone *SLE1.2.3 B6*-triple congenic backgrounds (B6.TC). Rapamycin was administered to 27-week-old B6.TC mice (ip) 3 times weekly at a concentration of 3 µg/g for 14 weeks. The number of inflammatory cells, inflammatory foci, cells/foci, and vasculitic lesions were used to measure inflammation normalized to surface area within mouse livers. Vasculitis was scored as earlier

Table summary of liver disease in the following genotypes: Female SLE1.2.3. mice (20-40 weeks of age) with differential Rab4A expression (Wild Type, Q72L, CD4KO).

described[5]. Student's t-test was used to test significance; 2-tailed p values < 0.05 were considered significant for hypothesis testing

Results: Following pristane injection, B6/Rab4A^{CD4-KO} mice had fewer inflammatory foci/mm^2 (0.32±0.10 vs 1.62±0.45; p=0.042) and vasculitic lesions (0.22±0.02 vs 1.60±0.46; p=0.033) than WT controls. The average vasculitis score was decreased in B6 Rab4A^{CD4-KO} animals (2±0.324) compared to B6 (3.1±0.11; p=0.0016) and B6 Rab4A^{Q72L} controls (2.9±0.18; p=0.014). Female lupus prone B6.TC mice had more inflammatory foci/mm^2 (3.04±0.2) than B6 controls (0.93±0.15; p=0.0052). Male B6.TC mice did not show differences in liver inflammation relative to B6 controls. Rapamycin reduced the number of inflammatory and vasculitic foci irrespective of genetically enforced changes in expression of Rab4A. Among female B6.TC mice, 30-50 weeks of age, rapamycin-treated B6.TC Rab4A^{CD4-KO} had fewer inflammatory cells/mm^2 (0.41±0.039) compared to rapamycin-treated B6.TC mice (19.10±6.14; p=0.038) and rapamycin-treated B6.TC Rab4A^{Q72L} mice (4.52±1.21; p=0.020). Vehicle treated B6.TC Rab4A^{CD4-KO} also had less severe vasculitis (1.58±0.16) compared to vehicle treated B6.TC Rab4A^{Q72L} (2.67±0.56; p=0.014). Vehicle treated B6.TC Rab4A^{Q72L} had more severe vasculitis (2.67±0.56) compared to vehicle treated B6.TC mice (1.75±0.14; p=0.047). Among 20-40-week-old females, B6 Rab4A^{CD4-KO} mice had fewer inflammatory foci/mm^2 (8.36±2.66) compared to B6 Rab4A^{Q72L} mice (29.56±7.87; p=0.043). B6.TC/Rab4A^{Q72L} mice had moderately increased vasculitis severity (2.019±0.10) compared to B6.TC mice (1.82±0.094; p=0.151). By contrast, vasculitis was reduced in B6.TC/Rab4A^{CD4-KO} mice (1.71±0.075) relative to B6.TC/Rab4A^{Q72L} mice (2.02±0.10; p=0.0428).

Conclusion: Activation of Rab4A predisposes while its T cell-specific deletion protects against inflammation and vasculitis in the livers of mice with spontaneous or pristane-induced SLE. mTOR blockade with rapamycin reduced hepatitis in lupus prone mice.

Rab4A Regulates Glomerulonephritis and Tryptophan Metabolism in Sle1.2.3. Lupus-prone Mice via Recycling of CD98

Brandon Wyman[1], Nick Huang[1], Zhiwei Lai[1], Mark Haas[2], Manuel Duarte[1], Joshua Lewis[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY, [2]Cedars-Sinai, Los Angeles, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

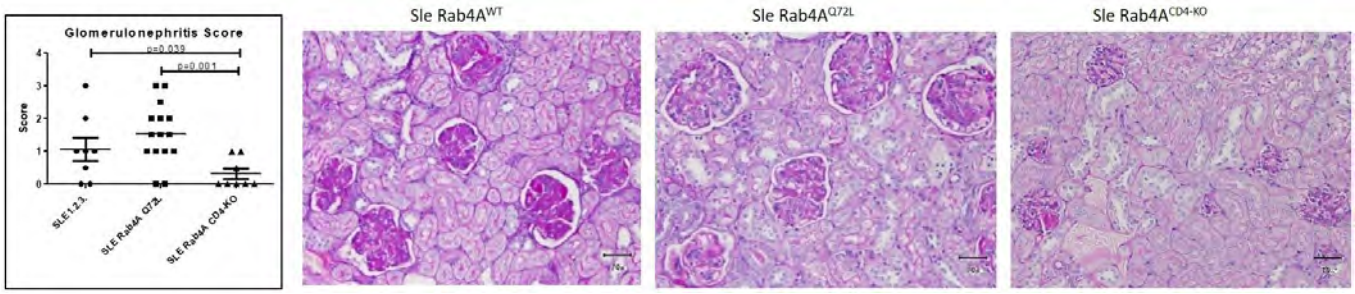

Figure 1. Glomerulonephritis scoring. Kidney sections from Sle Rab4AWT, Sle Rab4AQ72L, and Sle Rab4ACD4-KO mice were scored blind on a 0-4 scale. Left, scores of n=31 mice. Right, representative sections in Sle Rab4AWT, Sle Rab4AQ72L, and Sle Rab4ACD4-KO mice.

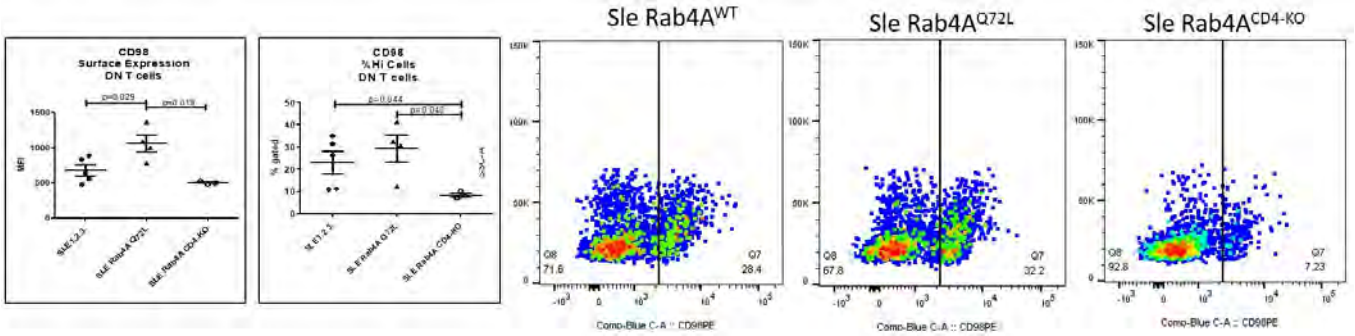

Figure 2. CD98 surface expression in CD4+ T cells and DN T cells. Surface expression was measured by flow cytometry. Left, mean fluorescent intensity and prevalence of CD98hi cells. Right, representative dotplots showing CD98 expression in DN T cells in Sle Rab4AWT, Sle Rab4AQ72L, and Sle Rab4ACD4-KO mice.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with an incompletely understood etiology. Previous work has identified Rab4A, a small GTPase responsible for endosomal recycling, to be a potential pathogenic driver of disease [Caza, et al. *Ann Rheum Dis.* 2014], which involves activation of mTOR that is responsive to accumulation of kynurenine. Here, we investigated whether Rab4A activity controls kynurenine metabolism through regulating surface expression of CD98 via recycling.

Methods: Using the wild-type parental line Sle1.2.3. (Sle Rab4a^{WT}), constitutively active (Sle Rab4A^{Q72L}), or T-cell deleted Rab4A (Sle Rab4A$^{CD4\text{-}KO}$) were generated using a Lox-Cre system. Splenocytes were harvested from the spleens of mice (n=12) and analyzed by flow cytometry using antibodies against CD3, CD4, CD8, CD19 and tryptophan/kynurenine transporter, CD98. Metabolomic data was acquired using a Q-Exactive Hybrid Quadrupole-Orbitrap Mass Spectrometer (ThermoFisher). CD4+ T cells were isolated using a positive selection kit (ThermoFisher), then stimulated for 72hrs with anti-CD3 and anti-CD28 antibodies. The metabolomic profile of Sle Rab4^{Q72L} (n=4) and SLERab-4$^{CD4\text{-}KO}$ (n=4) were compared using Metaboanalyst 3.0. Disease progression was assessed by glomerulonephritis (GN) scoring [1]. Statistical analysis was carried with ANOVA and Student's t-test using GraphPad.

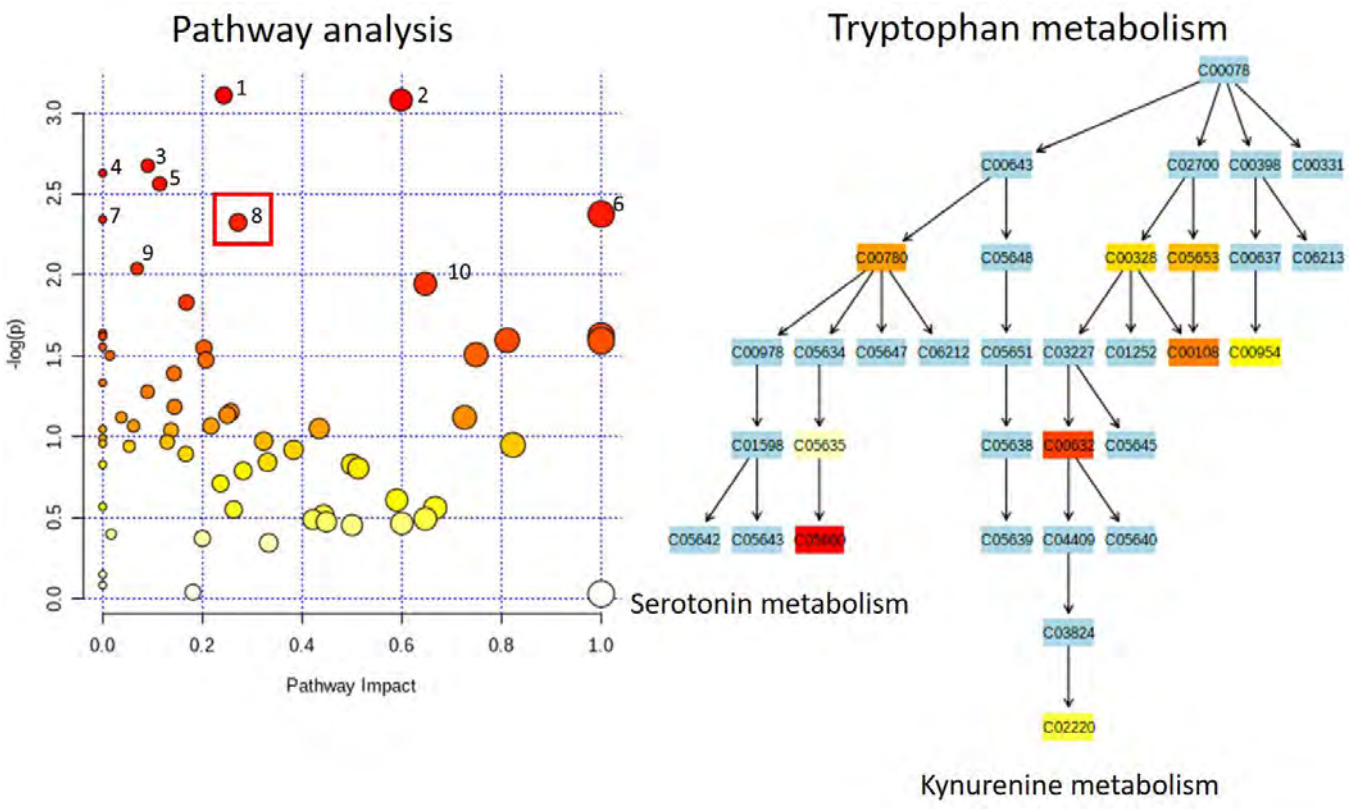

Figure 3. Metabolomic profile of Sle Rab4AQ72L vs. Sle Rab4ACD4-KO mice. CD4+ T cells were measured by mass spectrometry and analyzed by Metaboanalyst to identify discriminating pathways. Left, pathway analysis showing pathways significantly altered between Sle Rab4AQ72L and Sle Rab4ACD4-KO mice (Pathway 8 = Tryptophan). Right, metabolites measured in the tryptophan pathway that are accumulated in Sle Rab4AQ72L mice (increased discrimination colored as yellow -> red).

Results: Mean GN score was significantly reduced in Sle Rab4a$^{CD4\text{-}KO}$ (0.3) compared to Sle Rab4A^{WT} (1.1, p=0.039) and Sle Rab4A^{Q72L} mice (1.5, p=0.001). In pathogenic CD3+CD4-CD8- double-negative (DN) T cells, CD98 expression was significantly increased in Sle Rab4A^{Q72L} compared to Sle Rab4a^{WT} (p=0.029) and Sle Rab4A$^{CD4\text{-}KO}$ mice (p=0.019) (Figure 2). This trend was also seen in CD4+ T cells without reaching significance (Figure 2). CD98^{hi} cells were depleted in Sle Rab4A$^{CD4\text{-}KO}$ compared to Sle Rab4A^{WT} (p=0.044) and Sle Rab4A^{Q72L} mice (p=0.040). The tryptophan metabolomic pathway was measured by mass spectrometry to determine downstream effects of CD98 recycling by Rab4A. In Sle Rab4A^{Q72L} mice, accumulation of several tryptophan metabolites, including kynurenine, anthranilate, and serotonin was seen compared to Sle Rab4A$^{CD4\text{-}KO}$ mice (Figure 3). A global impact on tryptophan metabolism was supported by pathway analysis effectively discriminating between Sle Rab4A^{Q72L} and Sle Rab4A$^{CD4\text{-}KO}$ mice.

Conclusion: Rab4A activity controls the onset and severity of GN Sle1.2.3. lupus-prone mice. Constitutively active Rab4A has increased glomerulonephritis, while deleting Rab4A in T cells ameliorates disease activity. Activation of Rab4A promotes the expression the CD98 and the accumulation of kynurenine and other tryptophan metabolites, suggesting that Rab4A-dependent tryptophan and kynurenine uptake may control mTOR activation seen in human subjects with SLE.

Hematopoietic Specific Deficiency of Rho Kinase Attenuates Neutrophil NETosis and UVB-induced Skin Inflammation

Minghui Li[1], Xing Lyu[1], Yubin Li[2], James Liao[3], Victoria Werth[4] and **Ming-Lin Liu**[1], [1]University of Pennsylvania, philadelphia, [2]University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Philadelphia, PA, [3]University of Chicago, Chicago, [4]University of Pennsylvania and Corporal Michael J. Crescenz Veterans Administration Hospital, Philadelphia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophils are the most abundant leukocytes and the first to be recruited to the site of photodamage after ultraviolet B (UVB) exposure. We have shown that UVB induces neutrophil recruitment to the inflamed skin with NET formation and exhibition of NET-associated proinflammatory cytokines. Nuclear envelope rupture is a prerequisite for nuclear DNA release and NET formation. In our latest publication, we have identified that nuclear translocation of PKCα and its mediated lamin B phosphorylation is responsible for nuclear envelope rupture and NETosis. We have shown that application of Rho Kinase (ROCK) inhibitor HA1077 attenuates actin assembly and PKCα nuclear translocation, as well as NETosis in vitro. In our previous work, we found that intraperitoneal application of HA1077 alleviates NETosis in vivo and NET-associated proinflammatory cytokines in skin of the UVB-irradiated C57/BL6 wildtype (WT) mice.

Methods: In the current study, to further investigate the causal role of ROCK in NET formation and UVB-induced skin inflammation, we have generated CD45.1 mice with hematopoietic specific ROCK1 deficiency by bone marrow transplantation (BMT) of hematopoietic stem cells (HSCs) from ROCK1 deficient mice, and following by UVB exposure (150 mJ/cm^2, 5 consecutive days). Then we have examined IFNγ, TNFα, IL-17A expression and exhibition with NETs in skin of the UVB-irradiated skin. We also detected NET formation and cytokine release with NETs in platelet-activating factor (PAF) stimulated neutrophils from different groups of mice.

Results: In results, we found that NET formation in vitro triggered by PAF was significantly decreased in neutrophils isolated from ROCK1 deficient mice as compared to those from WT mice. Most importantly, NET formation and NET-associated IFNγ, TNFα, IL-17A were significantly attenuated in skin of UVB-irradiated CD45.1 BMT mice with ROCK1 deficiency as compared to those transplanted with HSCs from WT mice. To address what we saw in vivo, we conducted ex vivo experiment in which exhibition of neutrophil NET-associated IFNγ, TNFα, IL-17A were reduced in PAF-treated neutrophils from ROCK1 deficient mice as compared to those from WT mice.

Conclusion: In conclusion, using mice with hematopoietic specific ROCK1 deficiency, we demonstrated the role of ROCK1 in neutrophil NET formation and NET-associated proinflammatory cytokine display in UVB-induced skin inflammation. In addition, our study provide insight into a potential therapeutic strategy of targeting on ROCK as a novel potential target treatment of neutrophil NET-associated diseases and UVB-induced skin inflammation and the relevant diseases.

MHC Class I Epitopes Derived from Autoantibody Variable Regions, Conjugated to Synthetic Oligodeoxynuleotides, Induce Cytotoxic T Cells That Deplete Autoreactive B Cells and Ameliorate Murine Lupus

Ram Singh[1], [1]UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: B cell depletion or modulation is emerging as a major treatment modality for autoimmune diseases. However, the current treatments to accomplish this non-specifically target pathogenic as well as normal B cells. We previously demonstrated that the heavy chain variable regions of anti-DNA antibodies contain epitopes that can bind MHC class I molecules. Vaccination of lupus-prone mice with plasmid DNA vectors carrying minigenes that encode such epitopes induced CD8+ cytotoxic T lymphocytes (CTL) that killed anti-DNA antibody-producing B cells, reduced serum anti-DNA antibody levels, retarded the development of nephritis, and improved survival (Fan G and Singh RR, J Exp Med 2002). Treatment with peptides alone did not induce such CD8+ T-cells, as we and others have reported impaired CD8+ regulatory and CTL responses in mice and humans (Singh RR, et al, J Immunol 2002; Stohl W, et al, Lupus 1999). Here, we asked if we could overcome such impairment using synthetic oligodeoxynuleotides containing unmethylated cytidine-phosphate-guanosine dinucletides (CpG-ODN) that can enhance innate and adaptive immunity, and whether autoantibody V region epitopes delivered as conjugates with CpG-ODN elicit CTLs that will selectively ablate autoreactive B cells and ameliorate autoimmune disease.

Methods: We compared cytokine responses to CpG-ODN in normal and lupus-prone BWF1 mice, screened and verified BWF1-derived anti-dsDNA antibody VH regions for MHC class I binding epitopes, constructed conjugates of these epitopes with CpG-ODN or a control ODN, immunized BWF1 mice with these conjugates, and assessed CTL responses against anti-dsDNA hybridoma B cells and B cells from nephritic BWF1 mice. We then treated BWF1 mice with selected conjugates and monitored animals for serum anti-dsDNA antibody levels, proteinuria, and survival.

Results: CpG-ODN-induced cytokine responses were lower in BWF1 mice as compared to MHC-matched healthy control animals. BWF1 mice also elicited weak CD8+ T cell responses to immunization with synthetic peptides representing MHC class I binding epitopes from anti-dsDNA VH regions. Immunization with CpG-ODN conjugated to MHC class I-binding, anti-DNA Ab V_H-derived epitopes corrected this impairment in peptide-specific CTL responses in BWF1 mice. Treatment with these conjugates induced strong peptide-specific CTL responses that killed anti-dsDNA hybridoma B cells that carry these epitopes and B cells from diseased lupus-prone mice but not B cells from normal mice, reduced anti-DNA Ab production, retarded the development of lupus nephritis, and improved survival.

Conclusion: CpG-peptides conjugates can be used to elicit a robust CTL response in lupus mice. Immunization with these conjugates carrying autoantibody VH region epitopes can be used to selectively ablate autoreactive B cells. These observations have important implications for developing selective B cell depletion treatments.

Impact of Hydroxychloroquine Treatment on Immunologic Markers in SLE Depends on Ethnicity

Laurence Magder[1], Daniel Goldman[2] and Michelle Petri[2], [1]University of Maryland, Baltimore, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Timonium, MD

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients with certain immunological markers (i.e., anti-DNA, low complement) are at higher risk of lupus nephritis and those with antiphospholipid antibodies are at higher risk of thrombosis. We explored whether treatment with hydroxychloroquine has an impact on these markers.

Methods: We analyzed data gathered prospectively from quarterly clinic visits from a large American SLE cohort.

Patients visits were classified as "on HCQ" if they reported taking HCQ at that visit and at the previous visit. Patient visits were classified as "off HCQ" if they reported not taking HCQ at that visit and at the previous visit. For a recent subset of visits of patients on HCQ, blood levels of HCQ were also measured.

Table 1: Impact of treatment with HCQ on the odds of being positive for immunologic markers

Clinical marker	All Patients		Number of patients informative about biomarker
	Odds Ratio (95% CI)	P-value	
Confirmed Lupus Anticoagulant	0.58 (0.45, 0.74)	<0.0001	145
antidsDNA	0.81 (0.72, 0.90)	0.0002	356
Low complement	0.72 (0.65, 0.80)	<0.0001	387
aCL IGG>20	0.45 (0.35, 0.58)	<0.0001	123
aCL IGG >40	0.25 (0.16, 0.37)	<0.0001	58
aCL IGM>20	0.42 (0.32, 0.54)	<0.0001	114
aCL IGM >40	0.43 (0.29, 0.65)	<0.0001	55

Table 2: Impact of treatment with HCQ on the odds of being positive for immunologic markers, by race

Clinical marker	Caucasian Americans			African Americans			P-value comparing Caucasians to African Americans
	Odds Ratio (95% CI)	P-value	Number of patients informative about biomarker	Odds Ratio (95% CI)	P-value	Number of patients informative about biomarker	
Confirmed Lupus Anticoagulant	0.31[1] (0.22, 0.45)	<0.0001	66	1.04[1] (0.71, 1.52)	0.82	70	<0.0001

Confirmed Lupus Anticoagulant	0.76 (0.41, 1.38)	0.36	0.92 (0.47, 1.79)	0.80	0.87 (0.69, 0.42)	0.72	141
antidsDNA	1.05 (0.66, 1.67)	0.85	0.85 (0.52, 1.40)	0.53	0.71 (0.42, 1.22)	0.22	224
Low complement	0.86 (0.61, 1.21)	0.38	0.81 (0.56, 1.17)	0.26	0.71 (0.48, 1.05)	0.08	339
aCL IGG >20	0.46 (0.23, 0.94)	0.034	0.41 (0.18, 0.92)	0.031	0.26 (0.11, 0.64)	0.0035	76
aCL IGG>40	0.43 0.09, 2.00)	0.37	0.61 0.12, 3.21)	0.38	1.18 (0.21, 6.70)	0.40	19
aCL IGM >20	0.89 (0.43, 1.87)	0.76	1.02 (0.46, 2.29)	0.96	0.91 (0.37, 2.23)	0.83	84
aCL IGM>40	0.87 (0.24, 3.22)	0.84	0.95 (0.22, 4.11)	0.94	1.20 (0.25, 5.68)	0.82	28

Serum markers studied included Lupus Anticoagulant (dRVVT, mixing plus confirmatory test), anti-DNA (measured by Crithida), low complement, and anticardiolipin (aCL) IgG and IgM which were considered positive if the titer was greater than 20 or 40.

For each patient, visits on and off HCQ were compared with respect to the rates of immunologic marker positivity. These comparisons were summarized across “informative” patients using conditional logistic regression controlling for age. “Informative” patients were those who sometimes but not always were on HCQ, and sometimes, but not always, were positive for an immunologic marker.

Results: Table 1 shows the overall results of our analyses. While on HCQ, the odds of being positive were significantly reduced for each test. Table 2 shows the same results, stratified by race. There were striking differences between Caucasian and African Americans. Notably, HCQ was associated with a 62% reduction in the odds of lupus anticoagulant among Caucasian Americans, but no association was observed among African Americans. Table 3 shows the relationship between blood concentration of HCQ and immunologic markers among those on HCQ. This analysis (based on a smaller subset with less power) generally showed that those with concentration exceeding 100 ng/ml had lower odds of being positive, but the protective effect was most striking for aCL IgG >20.

Conclusion: These findings suggest that the benefit of HCQ may be mediated by its effects on antiphospholipid antibodies, complement and anti-dsDNA. These findings also highlight the differences between Caucasian Americans and African Americans with respect to these effects of HCQ.

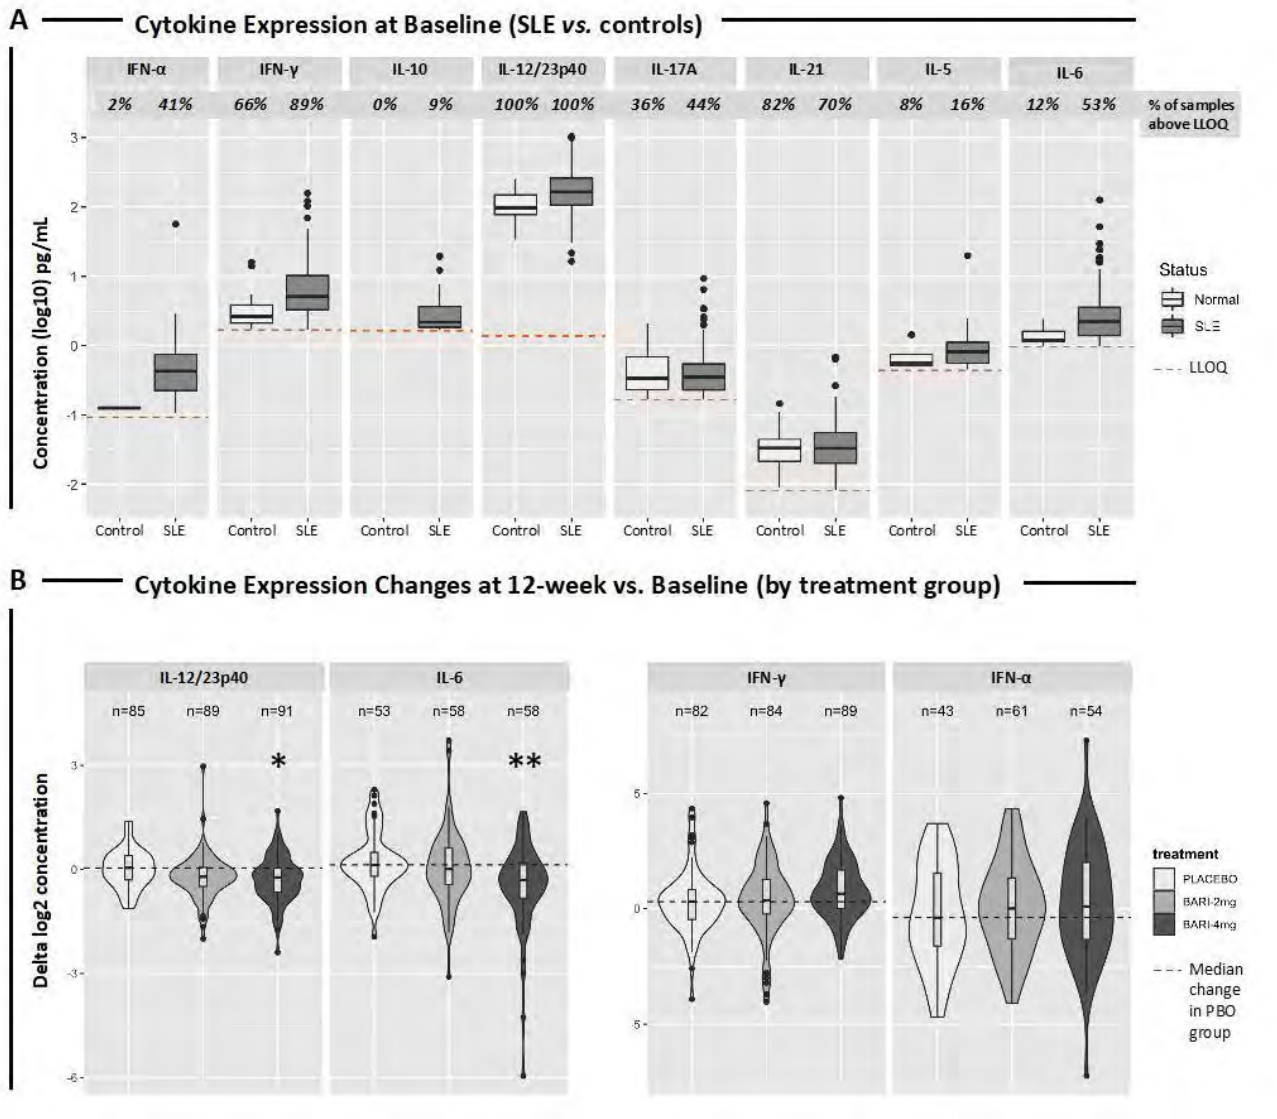
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Given the unmet clinical needs in systemic lupus erythematosus (SLE), including poor disease control and drug toxicities, new therapies are needed. In a phase 2, randomized, placebo-controlled, double-blind study (JAHH), once-daily baricitinib (bari) resulted in significant clinical improvement in patients (pts) with active SLE versus (vs.) placebo (PBO). Bari inhibits Janus Kinase (JAK)1 and JAK2 signaling, and in turn may affect signal transducer and activator of transcription (STAT)1, STAT2 and STAT4 pathways. Therefore, bari has the potential to simultaneously impact several pro-inflammatory immune cytokines implicated in the pathogenesis of SLE, including interferon (IFN)-α, IFN-γ, interleukin (IL)-6, IL-12, and IL-23. The objectives of the current study were: 1) to examine baseline serum cytokines in the JAHH phase 2 clinical trial for correlations with clinical or immunologic assessments; 2) to determine if changes in serum cytokine levels were associated with bari treatment.

Methods: Pts enrolled in the JAHH phase 2 trial received daily treatment with PBO, bari 2 mg, or bari 4 mg through Week 24. Serum samples were collected at baseline (Week [Wk] 0), Wk 12, and Wk 24) from SLE pts (n=270) and 50

Figure 1



*p = 0.015; **p = 0.001; Bari=baricitinib; IFN=interferon; IL=interleukin; LLOQ=lower limit of quantification; PBO=placebo; SLE=systemic lupus erythematosus.

sex- and age-matched controls. Samples were analyzed for: IL-2, IL-3, IL-5, IL-6, IL-10, IL-17A, IL-21, IL-12/23p40, IL-12p70, granulocyte-macrophage colony-stimulating factor (GM-CSF), IFN-α and IFN-γ using ultrasensitive quantitative assays. IFN gene signature, autoantibodies, complement component 3 and 4 (C3 and C4) were measured as previously described.[1]

Results: At Wk 0, serum IL-17A, IL-12/23p40, IL-6, IFN-γ and IFN-α were readily detectable. IL-12/23p40 was detectable in 100% of pts vs. 100% of controls, IFN-γ in 89% of pts vs. 66% of controls, IL-6 in 53% of pts vs. 12% of controls and IFN-α in 41% of pts vs. 2% of controls; detection of serum IL-2, GM-CSF, IL-5, IL-10 and IL-17A was variable (Figure 1). At baseline (Wk 0), IL-12/23p40 was positively correlated with SLE disease activity index and IFN gene signature, and negatively correlated with serum C4. IL-6 was positively correlated with joint swelling, joint tenderness, IFN-γ and C3. Serum IFN-α was positively correlated with serum IFN-γ, antibodies to Smith and ribonucleoprotein antigens (anti-Sm and anti-RNP), and the IFN gene signature (Figure 2). Treatment with bari 4 mg (Figure

1B) significantly decreased serum IL12/23p40 and IL-6 cytokine levels at Wk 12 ($p< 0.05$) but not serum IFN-α or IFN-γ levels (Figure 1B).

Conclusion: Bari 4 mg treatment was associated with statistically significant decrease of serum IL-12/23p40 and IL-6 at Week 12 which continued through Week 24. Serum IFN-α or IFN-γ were not reduced with bari treatment. Thus, bari 4 mg simultaneously impacted multiple pro-inflammatory cytokines implicated in the pathogenesis of SLE.

Abstract Number: 0849

Herpes Zoster Events with Anifrolumab in Patients with Active SLE: An Integrated Analysis of Phase 2 and Phase 3 Trials

Joan Merrill[1], Kenneth Kalunian[2], Richard Furie[3], Kevin Winthrop[4], Patricia Primakov[5], Lilia Pineda[6], Gabriel Abreu[7] and Raj Tummala[6], [1]Oklahoma Medical Research Foundation, Oklahoma City, [2]School of Health Sciences, University of California, La Jolla, [3]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [4]Oregon Health & Science University, Portland, OR, [5]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD, [6]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, [7]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In the phase 2 MUSE and phase 3 TULIP-1 and TULIP-2 trials, treatment with anifrolumab, a monoclonal antibody to the type I interferon receptor, was associated with clinical benefit in patients (pts) with SLE.[1–3] In all 3 trials, herpes zoster (HZ) was observed more frequently with anifrolumab vs placebo. We conducted an integrated analysis to characterize the frequency and nature of HZ events with anifrolumab across the MUSE and TULIP trials.

Methods: MUSE, TULIP-1, and TULIP-2 were randomized, double-blind, 52-wk trials that evaluated anifrolumab 300 mg (IV Q4W for 48 wks) or placebo in pts with moderately to severely active SLE despite SOC.[1–3] MUSE also included a 1000-mg treatment arm, and TULIP-1 included a 150-mg treatment arm; these pts were analyzed separately. We assessed HZ AE incidence, severity, intensity, discontinuation, and time to onset.

Results: In pooled data from MUSE, TULIP-1, and TULIP-2, 459 pts received ≥1 dose of anifrolumab 300 mg and 466 received ≥1 dose of placebo. In addition, 93 pts received anifrolumab 150 mg in TULIP-1 and 105 received 1000 mg in MUSE. HZ occurred in 5.4% (n=5), 6.1% (n=28), and 8.6% (n=9) of pts in the anifrolumab 150-mg, 300-mg, and 1000-mg groups, respectively, and in 1.3% (n=6) of the pooled placebo group (**Table 1**). Forty-four pts had HZ AEs that were mild or moderate, and 4 had events that were severe (anifrolumab 300 mg, n=2; 1000 mg, n=2). Three pts had serious AEs of HZ (anifrolumab 300 mg, n=2; 1000 mg, n=1). Of the 48 pts with HZ AEs, all but 4 continued in the study and all AEs leading to discontinuation were nonserious and moderate (anifrolumab 150 mg, n=1; 300 mg, n=2;

Anifrolumab 300 mg vs placebo	Placebo (n=466)		Anifrolumab 300 mg (n=459)		Difference (anifrolumab 300 mg vs placebo)	
	n (%)	EAIR (per 100 PY)	n (%)	EAIR (per 100 PY)	EAIR (per 100 PY) risk difference (95% CI)	Adjusted difference in cumulative percentage (95% CI)

Any HZ AE by maximum reported intensity						
Mild	1 (0.2)	0.3	9 (2.0)	2.2		
Moderate	5 (1.1)	1.2	17 (3.7)	4.1		
Severe	0	0	2 (0.4)	0.5		
Anifrolumab 150 mg vs placebo and anifrolumab 1000 mg vs placebo	Placebo (n=184), n (%)	Anifrolumab 150 mg (n=93), n (%)	EAIR (per 100 PY) risk difference (anifrolumab 150 mg vs placebo) (95% CI)	Placebo (n=101), n (%)	Anifrolumab 1000 mg (n=105), n (%)	EAIR (per 100 PY) risk difference (anifrolumab 1000 mg vs placebo) (95% CI)
Any HZ AE	3 (1.6)	5 (5.4)		1 (1.0)	9 (8.6)	
Any HZ AE with outcome of death	0	0	0	0	0	0
Any HZ SAE	0	0	0	0	1 (1.0)	1.1 (–3.3, 5.9)
Any HZ DAE	0	1 (1.1)	1.2 (–1.1, 6.5)	0	1 (1.0)	1.1 (–3.3, 5.9)
Any HZ AE by maximum reported intensity						
Mild	0	1 (1.1)		1 (1.0)	1 (1.0)	
Moderate	3 (1.6)	4 (4.3)		0	6 (5.7)	
Severe	0	0		0	2 (1.9)	

AE, adverse event; DAE, adverse event leading to discontinuation of investigational product; EAIR, exposure-adjusted incidence rate; PY, patient-years; SAE, serious adverse event.
EAIR was reported per 100 PY and defined as the number of patients with the specific event divided by the total exposure time in years and then multiplied by 100. The exposure time was defined as the time from the date of first administration of investigational product to the date of first event, death, end of treatment plus 28 days, or end of study, whatever came first.

Table 1. Herpes Zoster Events During Treatment With Anifrolumab 300 mg vs Placebo in Pooled MUSE, TULIP-1, and TULIP-2 Data, 150 mg vs Placebo in TULIP-1, and 1000 mg vs Placebo in MUSE

1000 mg, n=1). In pooled data available from TULIP-1 and -2, all HZ AEs with anifrolumab 300 mg were cutaneous (21 localized, unilateral; 2 disseminated, unilateral); all 5 HZ AEs with placebo were localized cutaneous. HZ resolved in all cases in MUSE and TULIP; all pts in the anifrolumab group and 4 of 6 pts in the placebo group received antiviral treatment. Using pooled TULIP data, no pattern of HZ event frequency was identified in protocol-defined subgroups. Pts using immunosuppressants (IS; n=349) had a difference in the rate of HZ between anifrolumab vs placebo groups of 8.1% (CI 2.6, 13.7) and those without IS use (n=376) had a difference of 2.2% (CI –1.8, 6.2) (**Figure 1**). Time to first onset of HZ was marginally shorter in the anifrolumab 300-mg vs placebo group (**Figure 2**).

Conclusion: In MUSE and TULIP trials, there appears to be an increased risk of HZ with anifrolumab vs placebo. HZ event characteristics, including duration and severity, were comparable between treatment groups, and most HZ events were mild to moderate, cutaneous, and resolved without discontinuation of study drug.

Subgroup		Placebo n/N (%)	Anifrolumab 300 mg n/N (%)	Treatment difference (95% CI)	Treatment difference (95% CI)

Abstract Number: 0850

What Does It Mean to Be a BICLA (BILAG-Based Composite Lupus Assessment) Responder? Post Hoc Analysis of the Phase 3 TULIP-1 and TULIP-2 Trials

Richard Furie[1], Eric Morand[2], Ian Bruce[3], David Isenberg[4], Ronald van Vollenhoven[5], Gabriel Abreu[6], Lilia Pineda[7] and Raj Tummala[7], [1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, [2]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, [3]Centre for Epidemiology Versus Arthritis, The University of Manchester and NIHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [4]Centre for Rheumatology, University College London and Department of Rheumatology, University College Hospital, London, United Kingdom, [5]Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands, [6]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [7]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: SLE – Treatment Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Assessment	BICLA responders[a] at Week 52 (n=318)	BICLA nonresponders[a] at Week 52 (n=501)
Change in SLEDAI-2K from baseline to Week 52		
n	308	352
Mean (SD)	–7.4 (3.64)	–4.2 (4.28)
Change in PGA from baseline to Week 52		
n	309	354
Mean (SD)	–1.28 (0.538)	–0.72 (0.643)
Change in OCS dosage (mg/day) from baseline to Week 52		
n	318	379
Mean (SD)	–5.41 (6.841)	–1.67 (8.081)
OCS AUC (mg) at Week 52		
n	318	501
Mean (SD)	2159.2 (1661.39)	3140.8 (3081.19)
Sustained OCS dosage reduction at Week 52 in patients with OCS ≥10 mg/day at baseline		
≥10 mg/day at baseline, n	165	258
Responders,[a,b] n (%)	130 (79.2)	50 (19.1)
95% CI response rate	72.9, 85.5	14.2, 24.0
Reduction in CLASI activity score (≥50%) at Week 52 in patients with CLASI activity ≥10 at baseline		
≥10 at baseline, n	103	128
Responders,[a,c] n (%)	95 (92.0)	31 (23.2)
95% CI response rate	85.9, 98.1	15.8, 30.6
Change in joint counts from baseline to Week 52		
n	309	355
Tender, mean (SD)	–8.1 (6.81)	–5.3 (7.56)
Swollen, mean (SD)	–5.9 (4.94)	–4.4 (5.51)
Active, mean (SD)	–5.7 (4.96)	–4.4 (5.41)

AUC, area under the curve; BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment; CI, confidence interval; CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; IFNGS, interferon gene signature; OCS, oral corticosteroid; PGA, Physician's Global Assessment; SD, standard deviation. [a]Responder/nonresponder rates are calculated using a stratified Cochran–Mantel–Haenszel approach, with stratification factors SLEDAI-2K score at screening, Day 1 OCS dosage, and IFNGS status at screening. Patients who prematurely discontinued study drug or received restricted medications were classified as nonresponders; [b]Sustained OCS dosage reduction was defined as OCS dosage ≤7.5 mg/day achieved by Week 40 and sustained through Week 52; [c]CLASI activity score response was defined as ≥50% reduction of CLASI activity score from baseline to Week 52 for patients with CLASI activity ≥10 at baseline.

Table 1. SLE Assessments in BICLA Responders vs Nonresponders in Pooled Data From the Phase 3 TULIP-1 and TULIP-2 Trials

Background/Purpose: BICLA is a validated composite global measure of SLE disease activity that incorporates BILAG, an instrument that distinguishes between partial and complete improvement. BICLA was an endpoint in the phase 3 TULIP-1 and TULIP-2 trials of anifrolumab.[1,2] This study investigated the relationships between BICLA response and SLE clinical and laboratory assessments in TULIP-1 and -2, irrespective of treatment assignment.

Methods: This was a post hoc analysis of pooled data from the 52-week (wk), double-blind TULIP-1 and -2 trials. Patients with moderately to severely active SLE, despite standard of care, were randomized to receive anifrolumab (150 or 300 mg IV Q4W) or placebo for 48 wks. BICLA responses were defined by the following: reduction of all baseline BILAG-2004 A and B domain scores to B/C/D and C/D, respectively, and no worsening in any organ system; no worsening of SLEDAI-2K score; and no worsening ≥0.3 points in Physician's Global Assessment (range 0–3).[3] Attempts to taper oral corticosteroids (OCS) to ≤7.5 mg/day between Wks 8 and 40 were required for patients receiving OCS

Biomarker change from baseline to Week 52	BICLA responders[a] at Week 52 (n=318)	BICLA nonresponders[a] at Week 52 (n=501)
C3[b]		
n	121	127
Mean, g/L (SD)	0.101 (0.1762)	0.078 (0.1889)
C4[b]		
n	70	79
Mean, g/L (SD)	0.016 (0.0284)	0.022 (0.0412)
Anti-dsDNA antibodies[b]		
n	132	147
Mean, U/mL (SD)	−46.1 (335.69)	15.8 (450.92)

BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment; IFNGS, interferon gene signature; OCS, oral corticosteroid; SD, standard deviation.
[a]Responder/nonresponder rates are calculated using a stratified Cochran–Mantel–Haenszel approach, with stratification factors SLEDAI-2K score at screening, Day 1 OCS dosage, and IFNGS test status at screening. Patients who prematurely discontinued study drug or received restricted medications were classified as nonresponders; [b]Only patients with baseline positive anti-dsDNA and abnormal complement level are included.

Table 2. Change in Biomarker Levels From Baseline to Week 52 in BICLA Responders vs Nonresponders in Pooled Data From the TULIP Trials

PRO improvement from baseline to Week 52	BICLA responders[a] at Week 52 (n=318)	BICLA nonresponders[a] at Week 52 (n=501)
FACIT-F		
n	318	501
Responders,[a,b] n (%)	176 (55.6)	79 (15.7)
95% CI response rate	50.2, 61.1	12.4, 19.0
SF-36 PCS		
n	318	501
Responders,[a,c] n (%)	183 (57.9)	65 (12.8)
95% CI response rate	52.5, 63.3	9.7, 15.8

BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment; IFNGS, interferon gene signature; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; OCS, oral corticosteroid; PCS, physical component summary; PRO, patient-reported outcome; SF-36, Short Form 36 Health Survey.
[a]Responder/nonresponder rates are calculated using a stratified Cochran–Mantel–Haenszel approach, with stratification factors SLEDAI-2K score at screening, Day 1 OCS dosage, and IFNGS test status at screening. Patients who prematurely discontinued study drug or received restricted medications were classified as nonresponders; [b]A response in FACIT-F is defined as an improvement from baseline to Week 52 >3 points; [c]A response in SF-36 is defined as an increase from baseline to Week 52 >3.4 in the PCS domain.

Table 3 Improvement in Patient-Reported Outcome Assessments From Baseline to Week 52 in BICLA Responders vs Nonresponders in Pooled Data From the TULIP Trials

≥10 mg/day at baseline. Sustained OCS dosage reduction was defined as OCS dosage ≤7.5 mg/day achieved by Wk 40 and sustained through Wk 52.

Results: Baseline characteristics were generally similar between BICLA responders (n=318) and nonresponders (n=501). Overall, improved outcomes were observed in BICLA responders vs nonresponders, including numerically greater improvements in SLEDAI-2K (–7.4 [SD: 3.64] vs –4.2 [SD: 4.28]) from baseline to Wk 52 (**Table 1**). Greater mean daily OCS dosage reduction was observed in BICLA responders vs nonresponders (–5.41 [SD: 6.84] vs –1.67 [SD: 8.08] mg/day) from baseline to Wk 52, and sustained OCS dosage reduction was achieved by more BICLA responders vs nonresponders (79.2% vs 19.1%). A ≥50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index activity (CLASI-A) score, for patients with baseline score ≥10, was achieved by more BICLA responders vs nonresponders (92.0% vs 23.2%) at Wk 52. Greater reductions of mean anti-dsDNA antibody levels were observed in BICLA responders vs nonresponders (–46.1 [SD: 335.69] vs 15.8 [SD: 450.92] U/mL) from baseline to Wk 52; numeric improvements were also observed for complement C3 (**Table 2**). More patients who were BICLA responders vs nonresponders reported improved patient-reported outcomes, with greater improvements in the Func-

tional Assessment of Chronic Illness Therapy-Fatigue of >3 points (55.6% vs 15.7%) and the Short Form 36 Health Survey physical component summary of >3.4 (57.9% vs 12.8%) (**Table 3**).

Conclusion: BICLA response was associated with clinical benefit in multiple SLE measures, including SLEDAI-2K, CLASI-A, OCS dosage reduction, and patient-reported outcomes. These data uphold the value of BICLA as an endpoint in SLE trials and also expand its benefit to translating trial data to metrics that are clinically meaningful in everyday practice.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

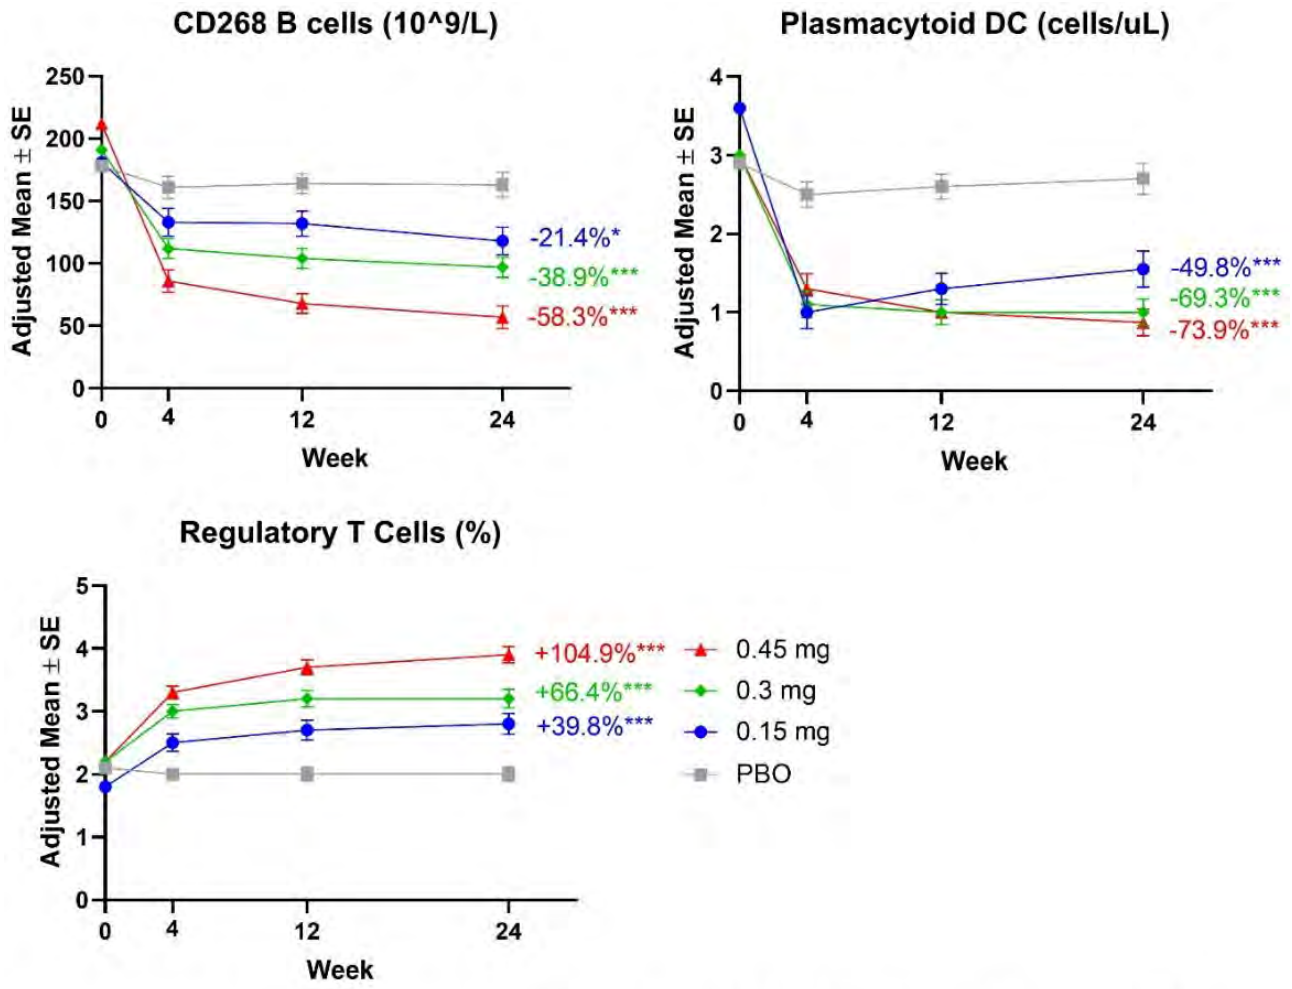

Figure 1. Pharmacodynamic changes in CD268 B cells, plasmacytoid dendritic cells, and regulatory T cells during iberdomide treatment. Values shown are the treatment comparison vs. placebo of adjusted means percent change from baseline (*p≤0.05, **p≤0.01,***p≤0.001).

Background/Purpose: Iberdomide is a high-affinity cereblon ligand that promotes ubiquitination and proteasomal degradation of Ikaros (*IKZF1*) and Aiolos (*IKZF3*), transcription factors linked to the genetic risk for systemic lupus erythematosus (SLE). Ikaros is required for development of B cells and plasmacytoid dendritic cells (pDC) and represses IL-2 transcription. Aiolos is a B-cell modulator and required for maturation of plasma cells. The pharmacokinetics, pharmacodynamics (PD), efficacy, and safety of oral iberdomide were evaluated in a phase 2b study in subjects with active autoantibody-positive SLE (NCT03161483).

Methods: Adult SLE patients (N=288) with a ≥6-month history of SLE and SLE Disease Activity Index (SLEDAI 2K) ≥6 were randomized to placebo (n=83) or iberdomide 0.15 mg QD (n=42), 0.3 mg QD (n=82), or 0.45 mg QD (n=81). Clinical response was determined by the SLE Responder Index 4 (SRI-4) at week 24 for all patients and within prespecified biomarker-enriched subsets based on expression of Ikaros, Aiolos, the Type 1 IFN signature (*IFI27, IFI44, IFI44L, RSAD2*), and other gene modules measured from fingerstick blood collected at baseline (Modular Immune Profile Test, DxTerity Diagnostics, Inc.). PD changes in whole blood leukocytes were measured by flow cytometry (Covance), T regulatory cells (Tregs) by epigenetic assay (EpiontisID, Epiontis GmbH), and plasma cytokines by ul-

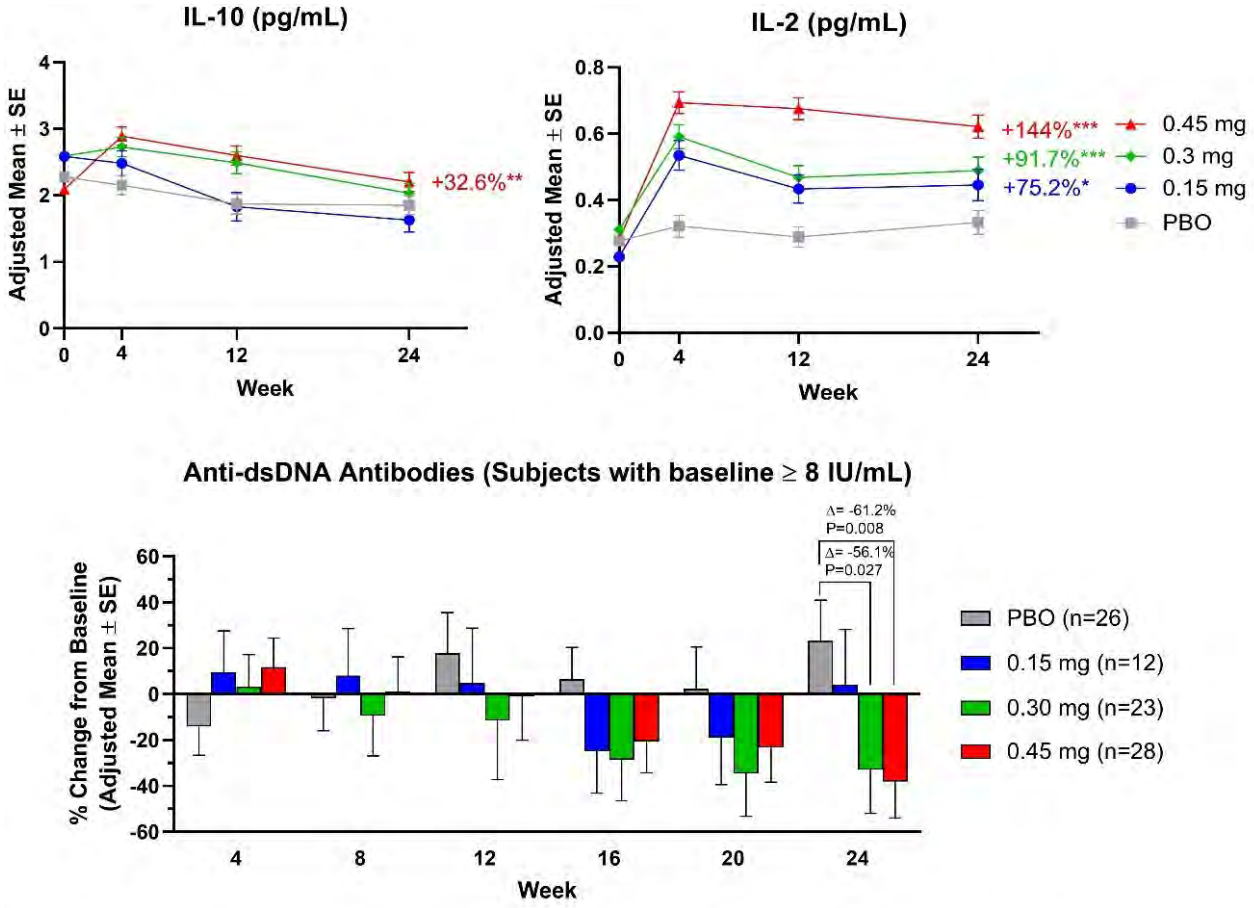

Figure 2. Pharmacodynamic changes in plasma IL-10, IL-2, and anti-dsDNA autoantibodies during iberdomide treatment. Values shown are the treatment comparison vs. placebo of adjusted means percent change from baseline (*p≤0.05, **p≤0.01,***p≤0.001).

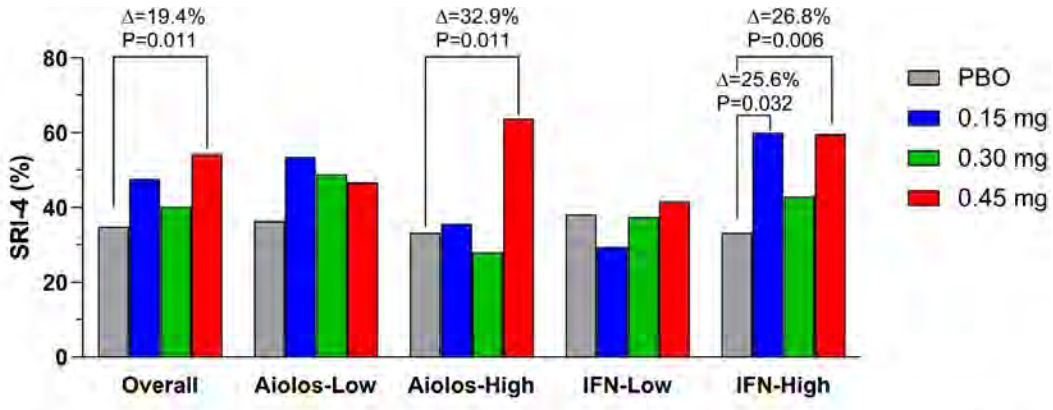

Figure 3. Week 24 SRI-4 clinical response rates in patient subsets defined by Aiolos and Type 1 IFN gene signature status at baseline. Aiolos = IKZF3; Type 1 IFN gene signature= *IFI27, IFI44, IFI44L, RSAD2;* Δ=treatment effect (stratified difference vs. placebo).

tra-sensitive cytokine assays (Erenna, EMD Millipore). PD data were reported as treatment differences from placebo in adjusted mean percent changes from baseline.

Results: Iberdomide pharmacokinetics were linear, with highest mean exposure observed at 0.45 mg. Iberdomide modulated leukocytes and cytokines in a dose-dependent manner, with significant changes at week 24 in the iberdomide 0.45 mg group compared with placebo, including decreased numbers of B cells, including those expressing CD268 (TNFRSF13C) (–58.3%; $P< 0.001$); decreased pDCs (–73.9%; $P< 0.001$); and increased Tregs (+104.9%; $P< 0.001$) (**Figure 1**). At week 24 compared with placebo, iberdomide 0.45 mg increased IL-10 (+32.6%; $P=0.005$) and IL-2 levels (+144.1%; $P< 0.001$) and decreased anti-double stranded (ds) DNA antibodies in patients with ≥8 IU/mL at baseline (–61.2%; $P=0.008$) (**Figure 2**). Iberdomide also decreased expression of the Type 1 IFN gene module. Iberdomide 0.45 mg caused a significant SRI-4 treatment effect versus placebo among patients within the baseline Aiolos-High subset (32.9%; $P=0.011$) and baseline Type 1 IFN-High subset (26.8%; $P=0.006$) (**Figure 3**).

Conclusion: Iberdomide significantly reduced activity of the Type 1 IFN and B cell/plasma cell pathways, including pDCs and Type 1 IFN-inducible genes as well as total B cells and those expressing TNFRSF13C, and anti-dsDNA antibody levels. Increases in Tregs, IL-2, and IL-10 suggest a broad rebalance of immune regulation. Clinical efficacy was noted in the entire cohort receiving 0.45 mg and was greater within the subsets with high expression of Aiolos or the Type 1 IFN gene signature at baseline. If validated, these PD effects may help refine future patient selection and dosing strategies for optimal use of iberdomide in SLE.

Antimalarials	69 (58.5%)	67 (56.8%)	0.789
ACEIs/ARBs	50 (42.4%)	48 (40.7%)	0.782

Categorical variables are presented as n (%), continuous as mean±standard deviation

*Defined as BP≥130/90mmHg

**All patients received the Euro-lupus cyclophosphamide protocol (6 intravenous bi-weekly pulses of 500mg each)

SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000; SDI: Systemic Lupus International Collaborating Clinics/Damage Index; ACEIs: angiotensin converting enzyme inhibitors; ARBs: angiotensin receptor blockers

Background/Purpose: The existing guidelines for remission induction in lupus nephritis (LN) from both the ACR and the EULAR recommend initial prednisone doses of 0.5-1mg/kg/day. However, recent observational studies reported non-inferior outcomes with significantly lower doses. The aim of this study was to compare the complete renal response rates in LN patients treated initially with £30mg/day or ³40mg/day of prednisone.

Methods: Patients with new-onset LN and standard immunosuppressive treatment with azathioprine or mycophenolate mofetil in standard doses or cyclophosphamide (Euro-lupus protocol) were included and followed for at least 12 months. Subjects were divided into low-to-medium (£30mg/day) and high prednisone groups (³40mg/day) and propensity score-matched based on global and renal disease activity. Complete renal response was defined as pro-

Table 2. Rates of complete renal remission at 12 months for different patient subgroups

	Low-to-medium prednisone (≤30mg/day, n=118)	High dose prednisone (≥40mg/day, n=118)	*p*
Complete remission* (n=236)	45 (38.1%)	68 (57.6%)	**0.003**
Complete and partial remission** (n=236)	64 (57.1%)	76 (66.7%)	0.061
Remission induction with AZA (n=66)	17/33 (51.5%)	19/33 (57.6%)	0.617
Remission induction with MMF or CYC (n=52)	11/26 (42.3%)	18/26 (69.2%)	0.052
Proliferative LN (classes III, IV) (n=66)	12/33 (36.4%)	19/33 (57.6%)	0.127
Non-proliferative LN (classes II, V) (n=26)	2/13 (15.4%)	9/13 (69.2%)	**0.02**
Sub-nephrotic proteinuria (n=86)	19/43 (44.2%)	26/43 (60.5%)	0.144
Treatment initiation before 2003*** (n=40)	10/20 (50%)	12/20 (60%)	0.527
Treatment initiation after 2003*** (n=102)	17/51 (33.3%)	32/51 (62.8%)	**0.004**

AZA: azathioprine, MMF: mycophenolate mofetil, CYC: cyclophosphamide

*Complete remission: proteinuria<0.5g/day and serum creatinine <120% of the baseline value

**Partial remission: proteinuria <50% and serum creatinine <120% of the baseline values

***After 2003, major changes were implemented in the management of LN in the UTLC with more frequent use of MMF and ACEIs/ARBs

teinuria < 0.5g/day and no worsening in renal function (serum creatinine £120% from baseline). Glucocorticoid-related damage was also assessed.

Results: Two hundred and thirty-six patients (118 in each group) were included. Baseline characteristics were well-balanced between groups except Black patients' predominance in the high prednisone group (25.4% vs. 15.3%, p=0.04) and higher frequency of LN class V in the low dose group (35.6% vs. 22.9%, p=0.036), Table 1. Median prednisone doses were 45mg/day and 20mg/day for the high and low-to-medium dose groups respectively. Complete renal response rates at 12 months in the main groups and certain subgroups of patients are shown in Table 2. Complete remission rates were also higher at two [75% vs. 40.3%, p=0.0002] and three years [67.2% vs. 51.7%, p=0.144] after LN diagnosis. Patients in the high dose group received less cumulative glucocorticoids during the 2nd and 3rd year after LN diagnosis and did not accrue more glucocorticoid-related damage, Table 3.

Conclusion: Higher initial prednisone doses (median 45mg/day) achieved significantly better rates of complete renal response at 12 and 24 months in new-onset LN. Findings were similar in different patient subgroups. These patients received less cumulative glucocorticoids in the 2nd and 3rd year and did not accrue more glucocorticoid-related damage. Our findings suggest that the treatment of LN with initially high doses of prednisone leads to improved rates of renal response that, in turn, allows for faster glucocorticoid tapering compared to patients who were treated with lower doses.

Table 3. Yearly cumulative glucocorticoid dose and glucocorticoid related damage accrual over time			
	Low-to-medium prednisone (≤30mg/day)	High dose prednisone (≥40mg/day)	p
At 12 months:	**N=118**	**N=118**	
Cumulative prednisone dose (g)	6.9 ± 3.0	8.9 ± 3.5	0.014
Prednisone dose at 12 months:	16.0 ± 12.4	13.4 ± 9.3	0.101
Cataract (new)	3 (2.5%)	0 (0%)	0.081
Osteoporosis (new)	0 (0%)	1 (0.8%)	0.316

Gradual Glucocorticoid Withdrawal Is Safe in Clinically Quiescent Systemic Lupus Erythematosus

Konstantinos Tselios[1], Dafna Gladman[2], Jiandong Su[3] and Murray Urowitz[1], [1]University Health Network, University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients are usually treated with glucocorticoids even during periods of clinically quiescent disease. A recent study showed that abrupt glucocorticoid withdrawal was associated with increased likelihood of flare in the next 12 months. The aim of the present study was to assess clinical flare rates and damage accrual in patients who tapered glucocorticoids gradually.

Methods: Lupus patients with two consecutive years of clinically quiescent disease were retrieved from our long-term longitudinal cohort. Individuals who maintained a low prednisone dose (5mg/day) comprised the maintenance group whereas patients who tapered prednisone within these two years comprised the withdrawal group. All individuals were followed for two years after discontinuation. Outcomes included clinical flares (any increase in clinical SLEDAI-2K, any increase $^{3}4$ and any increase in clinical SLEDAI-2K plus escalation in systemic therapy (glucocorticoids and/or antimalarials and/or immunosuppressives) as well as damage accrual. A Cox proportional regression analysis was performed for the identification of predictors for clinical flare.

Results: Of 270 eligible patients, 156 maintained low dose prednisone and 114 discontinued gradually (62 within 12 months and 52 in 12-24 months). Demographic, clinical, serological and therapeutic characteristics are shown in Table 1. Patients in the withdrawal group developed significantly less flares by any applied definition at 24 months compared to the maintenance group, Table 2. Flare rates at 12 months were similarly better for withdrawal patients, although insignificantly. Regarding damage, less withdrawal patients accrued new damage at 24 months, Table 2. Further analysis of the slow (within 12-24 months) and fast (within 12 months) withdrawal patients demonstrated that the former group achieved better outcomes both for clinical flares and damage accrual, although insignificantly. Regarding predictors of flares, immunosuppressive therapy at baseline was associated with decreased likelihood of new flare [HR=0.64, 95%CI=0.435-0.943, p=0.024].

Conclusion: Gradual glucocorticoid withdrawal was associated with significantly less clinical flares at 24 months. Damage accrual was significantly less in the withdrawal patients. Immunosuppressive therapy at baseline was protective against new flares. Gradual glucocorticoid withdrawal is safe in clinically quiescent SLE.

Table 1. Demographic, clinical, serological and therapeutic characteristics of the patients at baseline

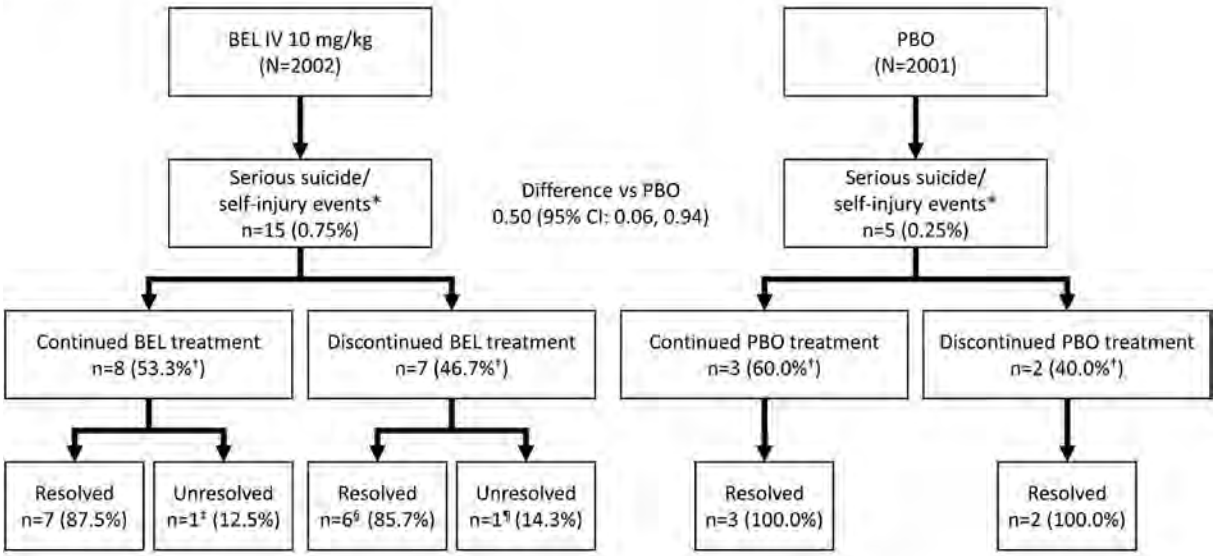
BEL, belimumab; C-SSRS, Columbia-Suicide Severity Rating Scale; IV, intravenous; PBO, placebo; PMH, prior medical history

Background/Purpose: Intravenous (IV) belimumab (BEL) is approved in patients ≥5 years of age with active systemic lupus erythematosus (SLE). Results of the BASE study (the largest SLE clinical study to date: n=4003), demonstrated similar rates of on-treatment all-cause mortality, infection and malignancy adverse events of special interest (AESI) between BEL and placebo (PBO). However, infrequent but higher incidences of other AESI including serious psychiatric events, fatal infections and hypersensitivity reactions occurred with BEL than PBO.[1] This analysis provides a *post hoc* descriptive summary of the disposition of patients who reported on-treatment serious suicide/self-injury events.

Methods: BASE (GSK Study BEL115467; NCT01705977) randomized adults with SLE (1:1) to receive BEL 10 mg/kg IV or PBO, plus standard SLE therapy, administered on Weeks 0, 2, 4, then monthly until Week 48. Rates of mortality and other pre-specified AESI, including serious psychiatric events and suicidality by Columbia-Suicide Severity Rating Scale (C-SSRS), were assessed on-treatment. The following were summarized *post hoc* for on-treatment serious

Figure. BASE study psychiatric events summary



*On-treatment serious suicidal ideation/behavior and self-injury events per GSK adjudication; †Percentages calculated from patients with serious suicide/self-injury events in each treatment group; ‡Lost to follow up; §One patient considered resolved with sequelae; ¶Withdrew from the study upon experiencing an event of major depression and considered recovering/resolving at follow-up.
BASE, Belimumab Assessment of Safety in SLE; BEL, belimumab; CI, confidence interval; IV, intravenous; PBO, placebo

suicide/self-injury events: time to onset, prior medical history (PMH), treatment completion and study completion, whether investigational product (IP) was taken after these events occurred, time to recovery, the C-SSRS score profile and outcome.

Results: There were 20 on-treatment serious suicidal/self-injury events (per sponsor adjudication), reported in 20 patients: 15 (0.75%) BEL and 5 (0.25%) PBO (*post hoc* difference vs PBO [95% confidence interval] 0.50 [0.06, 0.94]: **Figure**). All patients who experienced an event were female (aged 18–66 years, weight 40.5–99.3 kg, and mainly white [n=9] or black/African American [n=6]); 8/20 patients had a PMH of psychiatric disorder (**Table**). The median time to onset of the event was 205 days for BEL and 204 days for PBO. Approximately half (8/15) of the BEL patients and 3/5 PBO patients continued IP after these events occurred. The median time to recovery (number of days from onset to documented resolution) was shorter in those who did versus did not receive further IP, respectively, and lower in the BEL group vs the PBO group overall (**Table**). For the BEL and PBO groups who received further IP after the event, the C-SSRS score generally fell to 0 after the event (**Table**) and did not rebound, indicating resolution without further suicidal ideation and/or behavior during the study. Overall, 18/20 events were considered resolved and 0 patients experienced a recurrent event (**Figure**). No suicide-related deaths were reported.

Conclusion: An imbalance was observed with higher on-treatment serious suicidal ideation/behavior and self-injury events with BEL than PBO. These results are consistent with previously published data. The median time to onset of these events was similar between BEL and PBO, with the majority resolving with no sequelae, regardless of whether IP was discontinued or not. Overall the benefit:risk profile of belimumab remains positive.

Treatment of SLE with or Without Nephritis with the Immunoproteasome Inhibitor KZR-616: Updated Results of the MISSION Study

Richard Furie[1], Samir Parikh[2], Kenneth Harvey[3], Christopher Kirk[4], Darrin Bomba[4] and MK Farmer[5], [1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [2]The Ohio State University, Columbus, OH, [3]Kezar Life Sciences, South San Francisco, CA, [4]Kezar Life Sciences, Inc, San Francisco, CA, [5]Kezar, Raleigh, NC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoproteasome inhibition has demonstrated meaningful therapeutic potential in preclinical models of systemic lupus erythematosus (SLE) and lupus nephritis (LN). KZR-616 is a first-in-class selective immunoproteasome inhibitor, which has been shown to have a favorable safety and tolerability profile in early clinical trials. Across 2 healthy volunteer studies, 100 subjects received KZR-616, up to 75 mg subcutaneously (SC), with target levels of immunoproteasome inhibition achieved with doses ≥30 mg. Here we report updated safety, tolerability and exploratory efficacy data from the Phase 1b portion of MISSION (KZR-616-002; NCT: NCT03393013) in which patients with active SLE or LN were treated with KZR-616.

Methods: SLE patients (per Systemic Lupus International Collaboration Criteria [SLICC] Classification Criteria) with SLEDAI ≥4 despite sTable background therapy were enrolled in this open-label dose-escalation study and received KZR-616 at doses of 45 mg (Cohort 1), 60 mg (Cohort 2), 60 mg following a step-up dose (Cohorts 2a, 2b, 2c), or 75 mg (Cohort 3) SC weekly through Week 13 (W13) with 12 weeks of follow-up. Safety, tolerability, PK and PD and early efficacy measures were collected.

Results: Through Cohort 2c, 41 patients with SLE, including 2 patients with active, biopsy-proven proliferative LN, have enrolled in the MISSION Phase 1b study. The majority of TEAEs have been mild or moderate with transient injection-site reactions as the most common TEAE. Improved tolerability was seen with a dose step-up strategy, use of the lyophilized formulation, subsequent doses, and use of pre-medications. To date, no patients have discontinued from later cohorts. All measures of disease activity (SLEDAI, Cutaneous Lupus Erythematosus Disease Area and Severity Index [CLASI], Tender and Swollen Joint Counts using 28 joints, Physician Global Assessment [PhGA], Patient Global Assessment [PtGA], and Patient Assessment of Pain [PtP]) improved from Baseline to W13 and were maintained or improved during the follow-up period compared to baseline. KZR-616 administration resulted in improvements in multiple serologic markers of disease activity as well as reduced expression of inflammatory gene expression modules. Both patients with active proliferative LN showed greater than 50% reductions in urine protein:creatinine ratios (UPCR) from baseline.

Conclusion: KZR-616 demonstrated a favorable safety and tolerability profile at target doses of 45 and 60 mg weekly for 13 weeks. Step-up dosing, use of the lyophilized formulation, subsequent doses, and use of select pre-medications increased tolerability. KZR-616 demonstrated early signals of efficacy as evidenced by improvement in multiple

disease activity and serologic markers, including reduction in proteinuria in 2 of 2 patients with LN. Weekly administration of 75 mg is currently being evaluated in Cohort 3, and a Phase 2 study of KZR-616 in active proliferative LN is open for enrollment.

Association between HCQ levels and renal insufficiency

Background/Purpose: Hydroxychloroquine (HCQ) dosing is reduced in those with renal insufficiency according to guidelines (Marmor MF, et al. Ophthalmology 2016;123:1386–94) as it is partially cleared by the kidneys. Some studies have found that HCQ use might protect against end stage renal disease. We explored these issues using HCQ blood levels.

Methods: Hydroxychloroquine blood levels were measured by liquid chromatography-tandem mass spectrometry as described by Füzéry et al (Clin Chim Acta 2013;421:79–84). Renal insufficiency was defined as GFR < 50% or creatinine > 1.5 mg/mL. At least one HCQ blood level was measured at a clinic visit in 1,066 patients. Excluding patients with prior renal insufficiency (275) and missing information (6), there were 785 patients eligible for analysis, contributing 34,046 person months. There were 71 incident renal insufficiency events after the first HCQ blood level measurement. For this analysis, a dataset with one record for each month of follow up for each person were constructed. Patients were followed from first measure of HCQ blood levels to their first incident renal insufficiency or their last recorded visit with HCQ blood levels. To calculate the rate of renal insufficiency in each demographic or clinical subgroup, the number of renal insufficiency events was divided by the number of person months at risk and then converted to rates per 1,000 person years. Pooled logistic regression was used to assess the relationship between HCQ blood levels and rates of renal insufficiency.

Results: All patients met revised ACR or SLICC classification criteria and were 93.2% female, 41% African-American, and 47.8% Caucasian. Table 1 shows the association between patient characteristics and the rate of renal insufficiency. The categories of HCQ blood levels (mean or most recent) were divided into tertiles, each containing a third

of the person-years, to see if there were any trends of HCQ blood levels in incident renal insufficiency. Table 2 shows the association between HCQ blood levels tertiles and the rate of renal insufficiency. The rate of renal insufficiency increased with HCQ blood levels. Next, the HCQ blood levels were modeled as continuous variables (Table 3). There were significant associations between HCQ blood levels and incident renal insufficiency. The associations persisted after adjustment of covariates.

Conclusion: HCQ blood levels clearly rose in those with renal insufficiency, whether we looked at the most recent level before renal insufficiency or the mean of all prior HCQ blood levels. Disappointingly, HCQ blood levels at the mid or high tertile did not reduce later renal insufficiency. Thus, our data do not support that HCQ would reduce end stage renal disease. Renal insufficiency was associated with higher HCQ blood levels, likely due to reduced HCQ renal clearance, justifying the recommendation to reduce dose in those with chronic kidney disease.

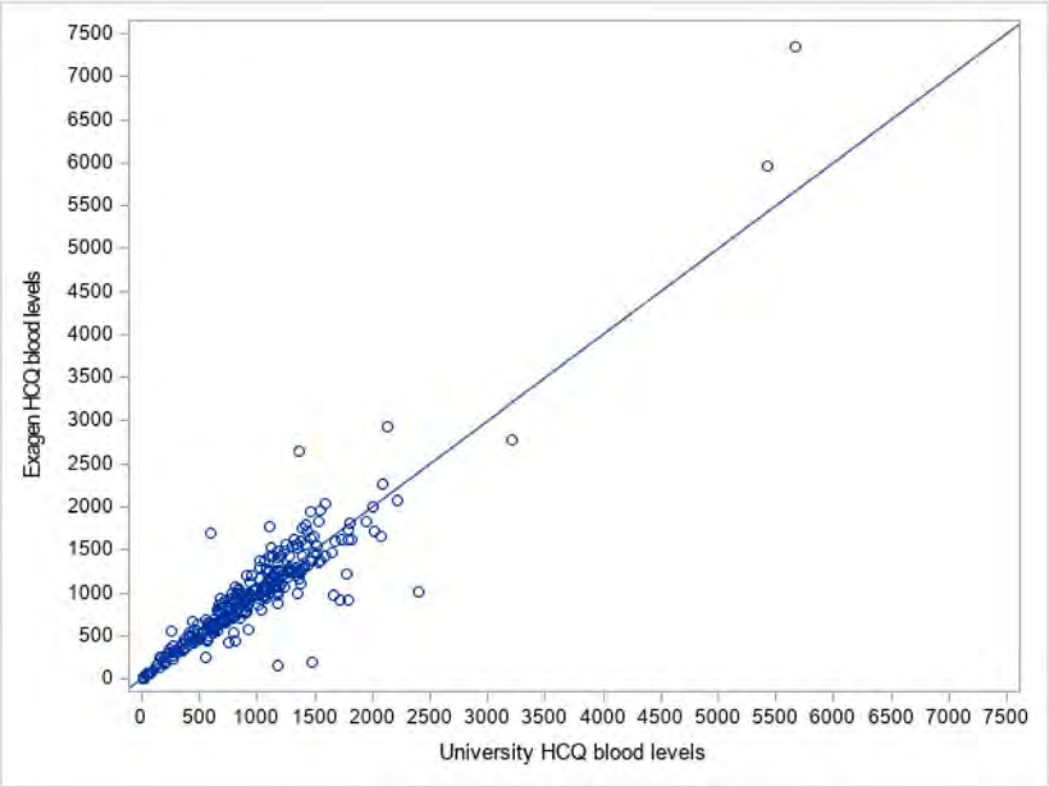
Agreement of Hydroxychloroquine Blood Levels Between a University and Commercial Laboratory

Michelle Petri[1], Jessica Li[2], Kelley Brady[3], John Conklin[4], Tyler O'Malley[5] and Thierry Dervieux[6], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Exagen Diagnostics, San Diego, CA, [4]Exagen Inc., Vista, CA, [5]Exagen, Inc, San Diego, CA, [6]Prometheus Biosciences, Inc. (former employee of Exagen Diagnostics), Irvine, CA

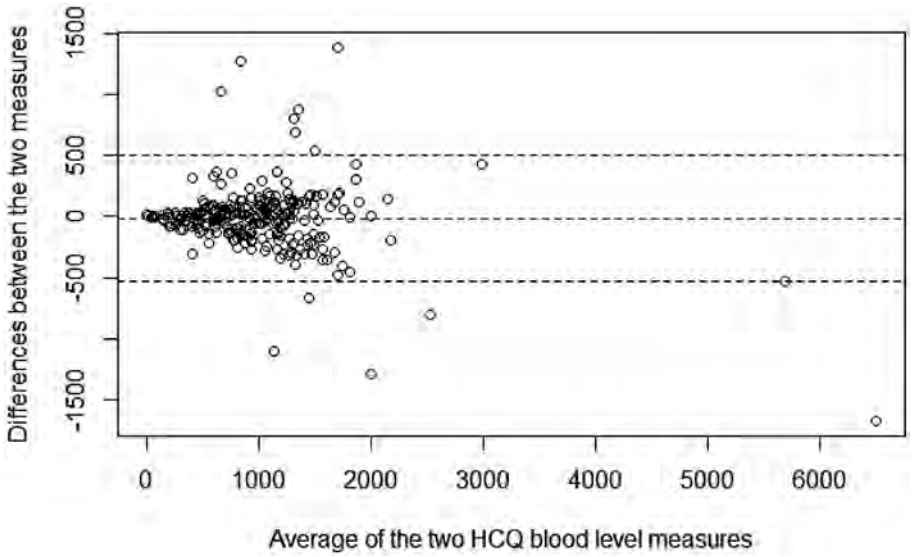
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Therapeutic blood monitoring is not yet an accepted practice in rheumatology. Although hydroxychloroquine (HCQ) blood level monitoring has been utilized in limited pharmacokinetic studies for some time, evidence for the utility of HCQ therapeutic blood monitoring in clinical practice has accumulated in recent years. Blood levels, rather than plasma levels, accurately reflect exposure and measure adherence over the last month. HCQ blood levels predict retinopathy (Arthritis Rheumatol 2020;72:448–53) but also predict benefit, such as prevention of thrombosis (Abstract OP0160, European e-Congress of Rheumatology 2020, June 3-7). We compared HCQ blood levels from the same visit done at two laboratories to ascertain agreement.

Methods: All patients met revised ACR or SLICC classification criteria for SLE. Of the 114 patients included, 15 patients had 1 visit, 27 2 visits, 71 3 visits, and 1 patient 4 visits for a total of 286 visits. Patients were 85% female, 37% African American, and 51% Caucasian. HCQ blood levels were measured using the method of Füzéry et al. (Clin Chim Acta 2013;421:79–84) with a coefficient of variation < 3%, and at Exagen Diagnostics using liquid chromatography coupled to mass spectrometry (AVISE® HCQ). The Bland-Altman plot was generated using R package *BlandAltmanLe*. Intra-class correlation coefficient (ICC) was calculated using *irr* package in R version 3.6.1. Deming regression was performed using mcr package in R. Confidence bounds (95%) were calculated with the bootstrap method.

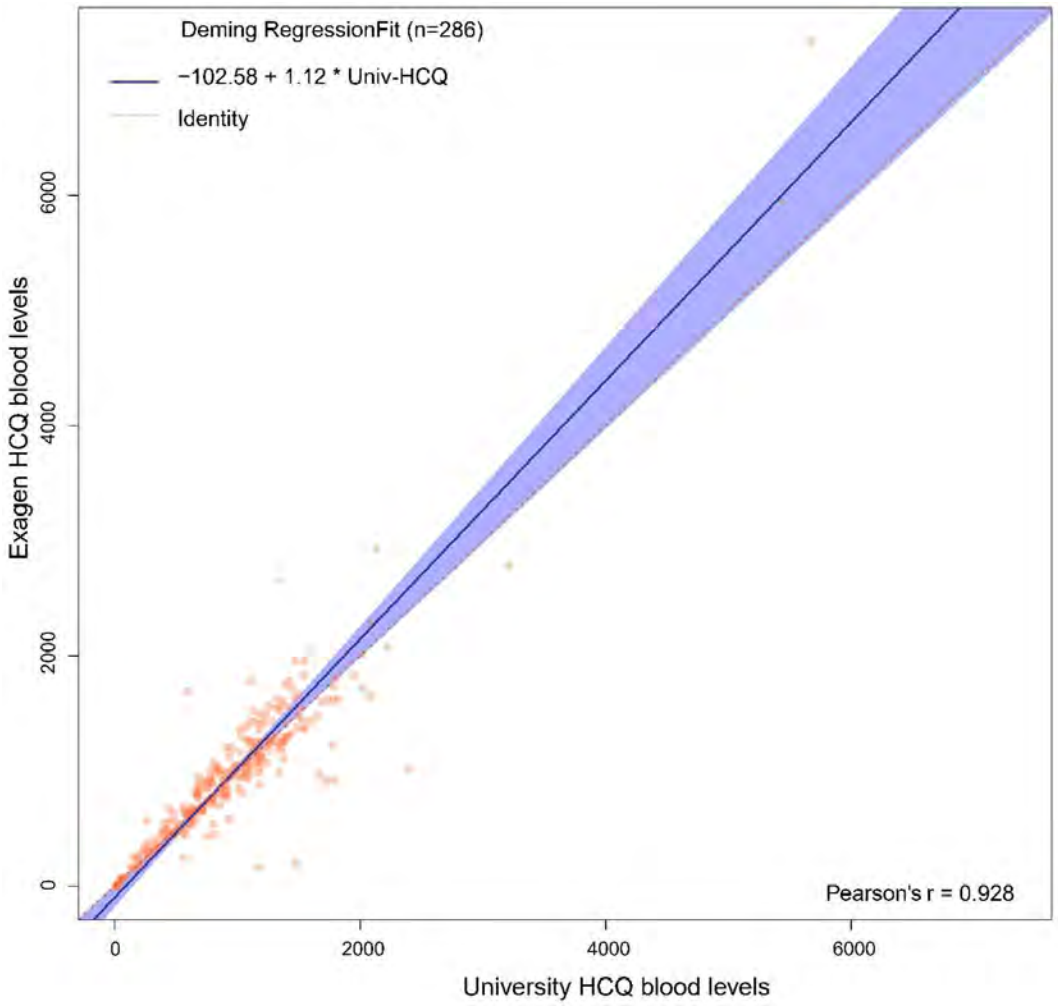


Deming Regression Plot Looking at Systematic Differences Between the Two Hydroxychloroquine Blood Level Measurement Methods



Bland-Altman Plot Showing Differences Between the Two Measures of Hydroxychloroquine Blood Level

Results: Figure 1 shows the comparison of the University HCQ blood levels to the commercial HCQ blood levels. The Bland Altman plot showed the difference between the two measures of HCQ blood level of each patient against the average of the two measures (Figure 2). The mean difference between the two methods was -13.9, 95% limits



Comparison of the University Hydroxychloroquine Blood Levels to the Exagen Hydroxychloroquine Blood Levels

of agreement were (-529.3, 501.5), and 4.2% (n=12) data points fell outside of the confidence limits. Intra-class correlation coefficient was used to calculate an estimate of the overall agreement between the two measurements. The ICC was 0.923 (0.904, 0.938). Deming regression was used to look at systematic differences between the two HCQ blood level measurement methods (Figure 3). The slope of best fit was 1.12 with 95% confidence limits of (0.99, 1.22).

Conclusion: There is excellent agreement between a university and commercial laboratory in measuring HCQ blood levels. Clinicians can be confident in the reliability of the hydroxychloroquine blood level. This should increase acceptance and utilization. Hydroxychloroquine blood levels have proven there is a “therapeutic window” to maintain benefit and still reduce risk of retinopathy.

Leflunomide: A Safe and Effective Alternative in Systemic Lupus Erythematosus

Irene Carrión-Barberà[1], Tarek Carlos Salman Monte[1], Luciano Polino[1], Miguel Mejía[1], Manel Ciria[1], Carolina Pérez-García[1], Eva Rodríguez[1] and Jordi Monfort[1], [1]Hospital del Mar, Barcelona, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Leflunomide (LEF) is a DMARD commonly used safely and effectively in rheumatoid arthritis. The experience with LEF in SLE is mainly based on what has been reported in cases or case series [1], with only one clinical trial evaluating its efficacy in extrarenal manifestations [2].

The purpose of our study is to assess the efficacy and safety of LEF in the treatment of SLE patients as well as to investigate if there are any clinical characteristics that correlate with a better response to treatment and, thus, identify the subgroup of patients that would benefit most from it.

Methods: Retrospective observational study. Medical records of all patients diagnosed with SLE (1997 ACR criteria) were reviewed and those who had received LEF were selected. Patients were evaluated for safety and efficacy after 4.9±3.2 months of therapy. Demographic and clinical data were collected. Variables were analyzed using SPSS 25 (IBM®) by descriptive statistics and cross-tabs if qualitative, the comparison of means by the Student's t-test and correlations by Pearson's correlation coefficient.

Results: Thirty-five patients were included, with a mean age of 52.2±14.7 years and 15.1±13 years since SLE diagnosis. The indication for LEF was arthritis in 34 patients (94.7%), relapsing polychondritis in 1 (2.9%). Age at LEF initiation was 48.3±14.7 years. The dose started was 20mg/day in 20 patients (57.1%), 10mg/day in 13 (37.1%). Seventeen patients (48.7%) went into joint remission after the initiation of LEF, and glucocorticoids (GC) could be withdrawn in 7 (20%). In 7 patients (20%) LEF was withdrawn before the first efficacy evaluation. The different adverse effects, as well as the demographic and clinical data of the patients are detailed in Table 1. We did not find any serious adverse effect or any case of subcutaneous lupus attributed to LEF. Our patients SLE baseline activity was mild–moderate: SLEDAI 6.3±3.1, normal average C3 and C4. Pre-LEF, 10 patients had positive DNA, 7 low C3, and 6 low C4. Failed treatments before LEF and treatments received concomitantly are detailed in Figure 1. In Figure 2, a statistically significant pre- and post-LEF decrease in physician global assessment (PGA), SLEDAI and ESR was observed, a non-significant one in dsDNA and GC values, as well as a non-significant increase in C3 and C4.

No correlation was found between the maximum dose of GC ever used, as an indicator of disease severity, and a better response in any parameters (ESR, CPR, PGA, dsDNA, C3, C4) pre- and post-LEF, or with going or not into joint remission. Neither was found a correlation between achieving remission or not, and the different demographic, clinical or treatment characteristics of patients, which does not allow to discern which subgroup of patients would benefit most from LEF treatment.

Nowadays, 15 patiens continue taking LEF (42.8%), with a mean treatment time of 4.4±3.9 years.

Variables	Number of patients (%)
Sex	
Women	31 (88.6%)
Men	4 (11.4%)
Race	
Caucasians	27 (77.1%)
Hispanics	4 (11.4%)
African-American	1 (2.9%)
Asians	2 (5.7%)
Maghrebi	1 (2.9%)
Reason for LEF withdrawal	
Digestive intolerance	2 (5.7%)
Hypertension	2 (5.7%)
Transient leuko/neutropenia	1 (2.9%)
Transient high liver enzymes	1 (2.9%)
Ineffective	3 (8.6%)
Other active manifestations	3 (8.6%)
Other side effects	6 (17.1%)
dsDNA +	22 (62.9%)
Anti–Ro60 +	12 (34.3%)
Anti–Ro52 +	9 (25.7%)
Anti–Sm +	8 (22.9%)
APS antibodies	10 (28.6%)
RF +	5 (14.3%)
ACPA +	3 (8.6%)
Lupus nephritis	7 (20.0%)
Other autoimmune systemic diseases	15 (42.8%)
Sjögren's syndrome	8 (22.85%)
Rheumatoid arthritis	4 (11.4%)
Antiphospholipid syndrome	3 (8.6%)
Relapsing polychondritis	1 (2.9%)

Table 1. Demographic and clinical characteristics of the 35 included patients.

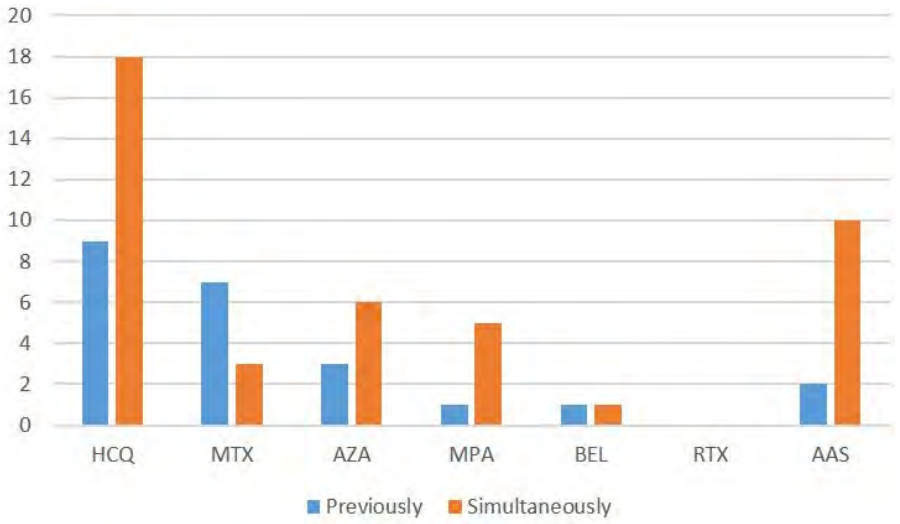

Figure 1. Previous and concomitant treatments to LEF. A treatment is reported as "previously" if it was stopped before LEF was started and "simultaneously" if it was started or maintained at the same time as LEF. HCQ: hydroxychloroquine; MTX: methotrex-ate; AZA: azathioprine; MPA: mycophenolic acid; BEL: belimumab; RTX: rituximab; AAS: acetylsalicylic acid.

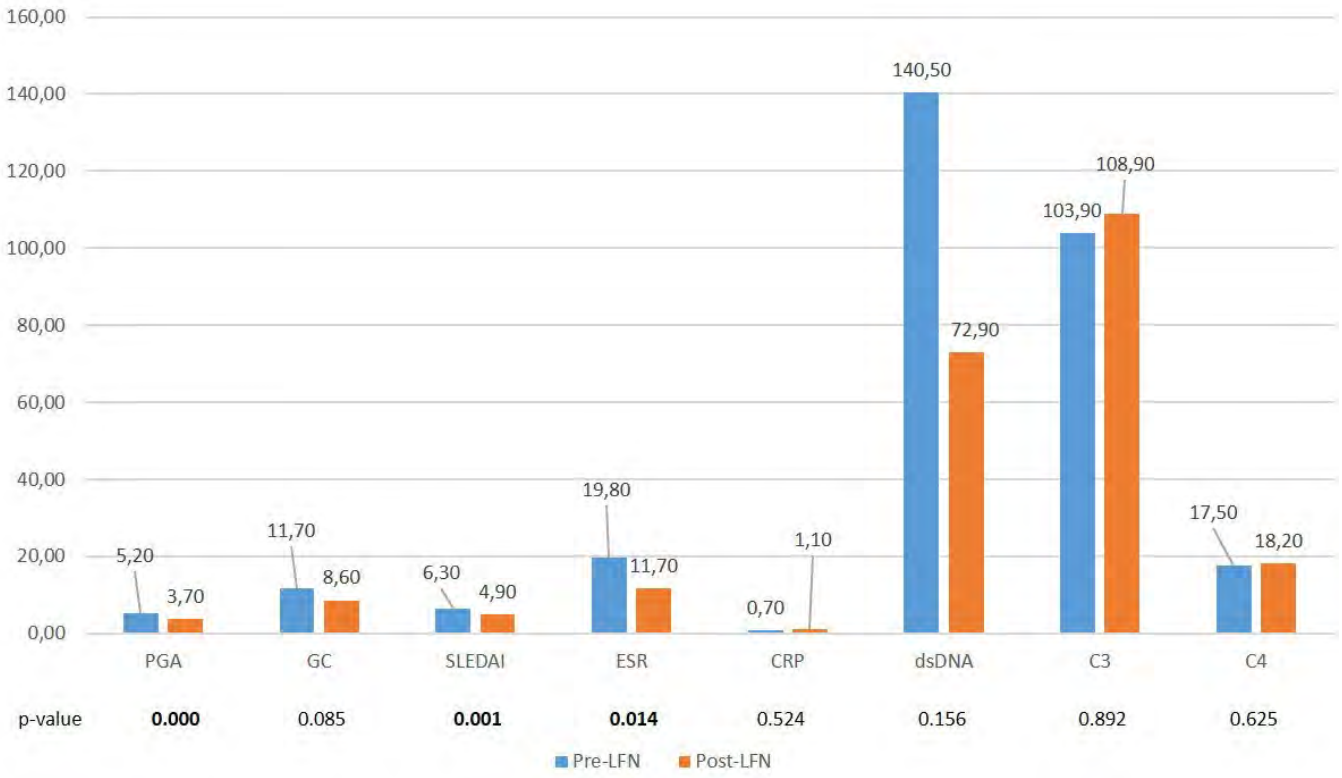

Figure 2. Value changes in different parameters before and after LEF. PGA: physician global assessment, GC: glucocorticoids, SLEDAI: Systemic Lupus Erythematosus Disease Activity Index; ESR: erythrocyte sedimentation rate; CRP: C-Reactive Protein; dsDNA: double-stranded DNA; C3: complement C3; C4; complement C4.

Conclusion: Treatment with LEF in SLE seems to be an effective and safe option, particularly for joint symptoms, with significant improvement observed in PGA, SLEDAI and ESR, as well as a 48.6% of joint remission after its onset.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Incomplete B-cell and plasmablast depletion, as measured using highly sensitive flow cytometry (HSFC), is associated with lower response rates following rituximab in SLE [1]. Enhanced B-cell depletion with the type II anti-CD20 monoclonal antibody obinutuzumab resulted in increased renal responses in proliferative lupus nephritis (LN) in the NOBILITY trial (NCT02550652) and will be further evaluated in the Phase 3 REGENCY trial (NCT04221477). The objective of this analysis was to measure peripheral B-cells, B-cell subsets (naïve, memory and plasmablast) and B-cell activating factor (BAFF) levels and to assess associations between B-cell depletion and renal response in LN patients in a clinical trial of obinutuzumab.

Methods: 126 patients with active Class III/IV LN were randomized to obinutuzumab or placebo infusions in combination with mycophenolate and glucocorticoids. Peripheral B-cells were measured using a HSFC method with a lower limit of quantitation of 0.441 cells/μL. Serum levels of BAFF were evaluated using ELISA. Sustained depletion was defined by total B-cells below the limit of detection at both weeks 24 and 52. Renal response definitions from Phase 2 NOBILITY and Phase 3 REGENCY trials were used.

Results: Obinutuzumab resulted in rapid depletion of total B-cells, memory and naïve B-cells, and plasmablasts from peripheral blood, with 88% of obinutuzumab patients depleted to < 0.441 total B-cells/μL at week 2 (Figure). Mean serum BAFF increased from 4,585 pg/mL at baseline to 14,601 pg/mL at week 52 in the obinutuzumab group. Sustained B-cell depletion was achieved in 32/52 (62%) of patients with complete data and was associated with a higher renal response rate at week 76 (Table), although patients who achieved sustained depletion also had lower baseline proteinuria and serum creatinine.

Conclusion: Obinutuzumab, a type II anti-CD20 mAb, mediated rapid, complete and sustained depletion of peripheral B-cells and plasmablasts and large increases in serum BAFF. Similar to previous reports, sustained B-cell depletion was associated with increased renal response though there may have been confounding factors. REGENCY is being conducted to further evaluate the therapeutic hypothesis with obinutuzumab in LN.

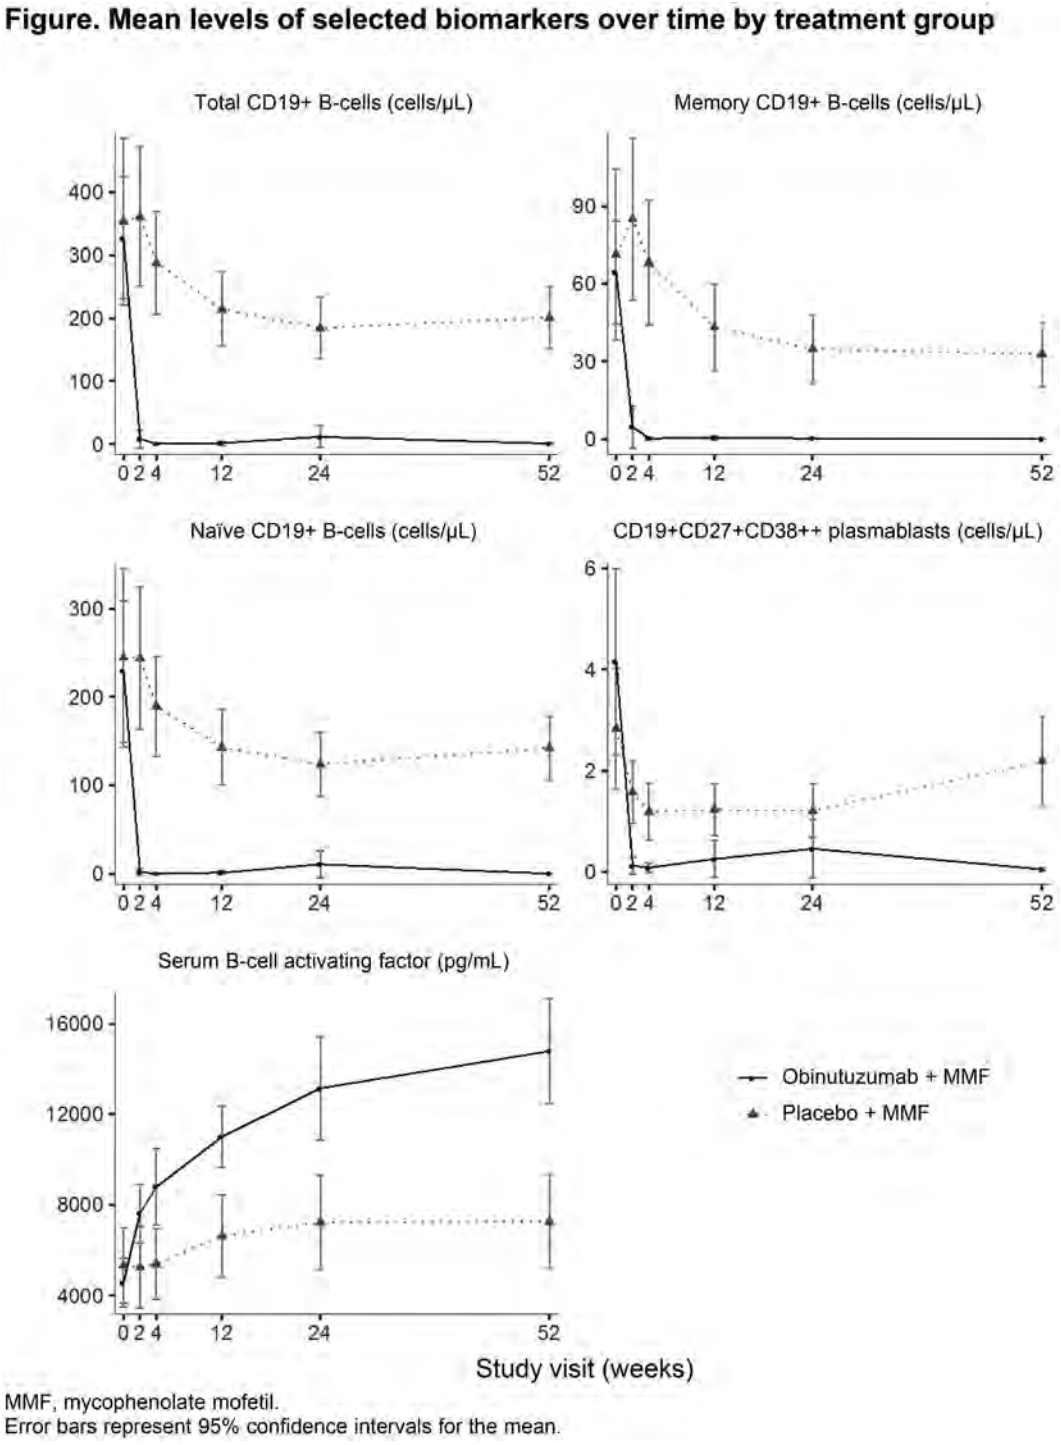

Figure. Mean levels of selected biomarkers over time by treatment group.

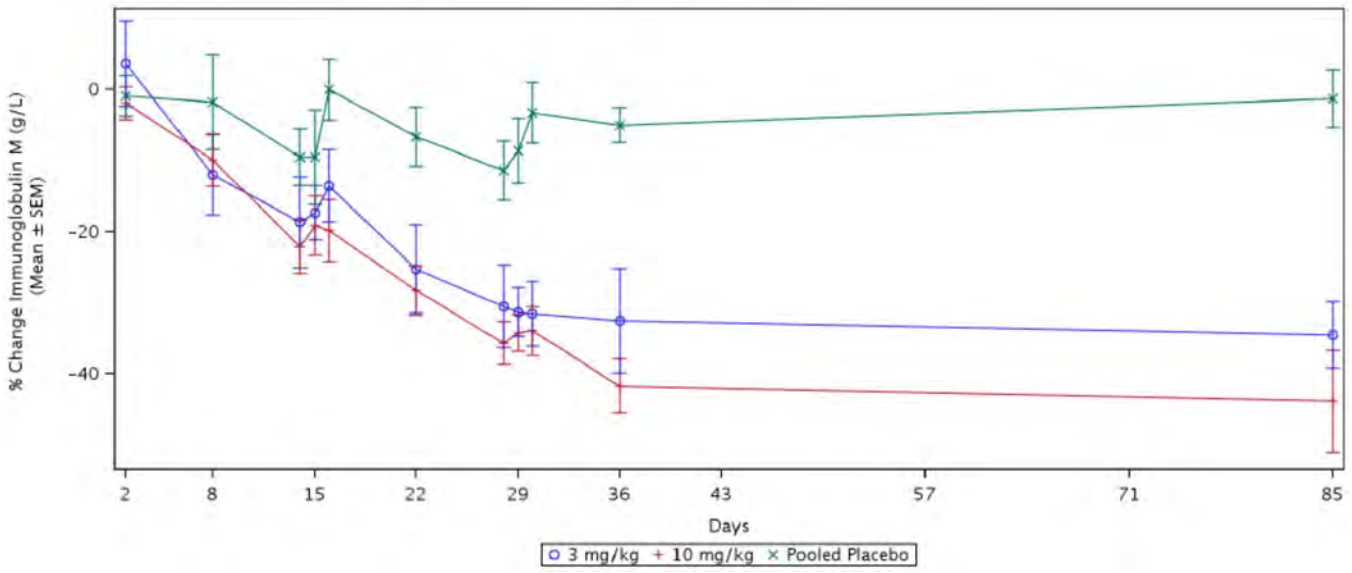
*n=5

Background/Purpose: B-cell targeted therapeutics have proven efficacious in the treatment of autoimmune disorders. A desired improvement in efficacy and safety necessitate the development of alternate, fast acting and non-depleting B cell modulators. PRV-3279 (previously MGD010) a bispecific molecule, exploits the inhibitory function of the SLE-associated checkpoint molecule, CD32B, (FcγRIIb) via its simultaneous co-ligation with the BCR component, CD79B. Initial single-dose Phase 1 trials in healthy subjects demonstrated PRV-3279 was well tolerated and modulated B cells without depletion. PREVAIL (PRV-3279 EVAluation In Lupus) 1, a multiple ascending dose study in healthy subjects, was performed to further characterize the safety, PK and PD of PRV-3279 upon repeat administration. In vitro studies on B cells from SLE subjects were also performed to support transition into the planned Phase 2a PREVAIL 2 study in SLE.

Methods: This was a double-blind, placebo-controlled MAD study in healthy volunteers. Subjects (n=8 per group) were randomly assigned to two cohorts to receive an IV administration of 3 bi-weekly infusions of 3 or 10 mg/kg PRV-3279, or placebo (6:2). Safety, PK, binding of PRV-3279 to total and B cell sub-sets, peripheral lymphocyte counts, and determination of serum immunoglobulin levels were assessed for 12 weeks. Additionally, CD32B and CD79B

Figure 1: Effect of PRV-3279 on Circulating IgM Levels



levels on purified B cells from SLE subjects and the effect of PRV-3279 on SLE B cell proliferation was determined, compared with healthy controls.

Results: PRV-3279 was well-tolerated, with no serious adverse events **(Table 1).** Pharmacokinetic **(Table 2)** and pharmacodynamic parameters were dose-dependent with extensive binding to both naïve and memory B cells, and a mean sustained binding of >90% available B cells observed at 10 mg/kg. An extended pharmacodynamic effect was demonstrated by a sustained and maximum mean reduction of 44% in circulating IgM levels at 10 mg/kg, at the final sampling at Week 12 **(Figure 1).** PRV-3279 did not deplete B cells, although there was a mean transient decrease of up to 47% after each infusion, returning to baseline at the next measurement (+1 week). In vitro, expression of CD32B and CD79B on SLE patient B cells was similar to healthy controls, and PRV-3279 inhibition of SLE B cell proliferation (mean 63% reduction) was not significantly different to those from healthy controls.

Conclusion: PRV-3279 was well tolerated after repeat administration with no B cell depletion and dose-dependent PK and PD. Consistent with its mechanism of action, sustained IgM reduction was observed. In vitro studies demonstrated equivalent effects of PRV-3279 on B cells from SLE subjects. These data support further development of PRV-3279 in SLE and other autoimmune disorders**.**

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: SLE – Treatment Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) has been used for decades to treat systemic lupus erythematosus (SLE) and is associated with decreased lupus flares and damage. However, despite reports of an impact on TLR pathways, its mechanism of action remains controversial.

Methods: Whole blood from healthy controls (n=8) and SLE patients taking (n=9) or not taking HCQ (n=9) were stimulated for 15 minutes or 24 hours with either Toll-like receptor (TLR) (for TLR4, TLR7/8 or TLR9), interferon-α (IFNα), T cell (phytohemagglutinin and ionomycin), or cell signaling inducers (phorbol myristate acetate and ionomycin). Cell culture supernatants and phospho-proteins were analyzed. Cytokine levels from patient plasma and culture supernatants were assessed by 37-plex xMAP assays and ELISAs. Alterations in phospho-signaling proteins were assessed by mass cytometry. To determine alterations in phospho-signaling pathways, whole blood from healthy controls were stimulated with IFNα or TLR7/8 or TLR9 agonists with or without HCQ.

Results: We found no differences in plasma IFNα levels of patients taking HCQ versus those not taking it, nor was there altered IFNα production following TLR stimulation. In SLE, persistent activation of T cell, TLR7/8, and TLR9 signaling leads to exhaustion of these pathways. Compared to controls, we confirmed reduced phosphorylation of multiple signaling proteins and reduced cytokines in patients on or off HCQ after stimulation by TLR agonists (Figure 1A and 1B). However, cytokine production following T cell or TLR stimulation was less impaired in patients on HCQ with an increased fold change in IL-10 ($p=0.003$), IFNg ($p=0.011$), IL-18 ($p=0.016$), CXCL13 ($p=0.009$), IL-6 ($p=0.046$), IL-1α ($p=0.036$) and other cytokines that approached healthy controls. The only cytokines that did not exhibit improved production in those on HCQ were IFNα and TNFα following TLR stimulation, where fold change was reduced in all SLE patients compared to healthy controls ($p< 0.01$). In control samples treated with HCQ in vitro, TLR9 induced signaling of p-p38 ($p=0.046$) and pIκBα ($p=0.047$) was reduced in plasmacytoid and myeloid dendritic cells. In SLE samples (where exhaustion of the TLR9 signaling pathway occurs) (Figure 1A and 1B), HCQ use was not associated with any further reduction or rescue of TLR9 signaling. However, IFNα signaling was diminished within the MAPK pathway ($p=0.004$) in SLE patients taking HCQ (Figure 1C), consistent with impeded Type I IFN signaling.

Conclusion: SLE is characterized by diminished cytokine production after prolonged T Cell and TLR stimulation. Once this occurs, HCQ has no observable impact on circulating or TLR-stimulated whole blood IFNα levels. However, rescue of some T Cell and TLR-driven cytokine production, and decreased signaling in the IFNα-induced MAPK pathway occurs in patients on HCQ. This suggests that TLR9 pathway exhaustion circumvents some, but not all, therapeutic activity of HCQ on Type I interferon-mediated pathology.

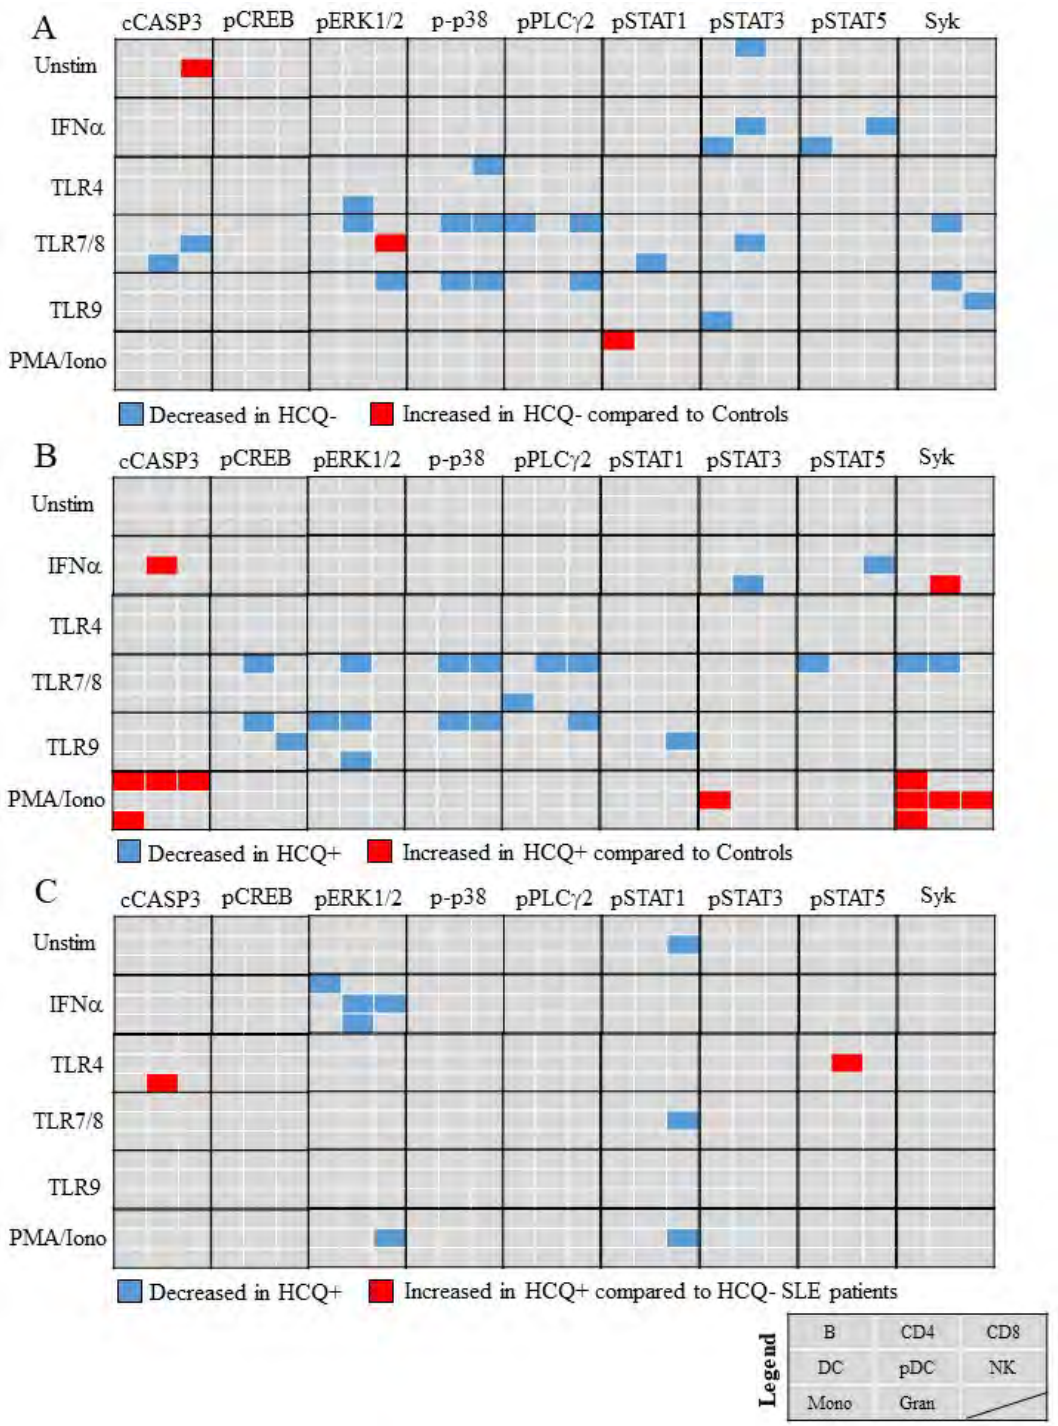

Figure 1. IFN-alpha signaling is diminished in SLE patients taking HCQ. Whole blood from either HCQ+ (SLE patients taking HCQ) or HCQ- SLE patients (SLE patients not taking HCQ) or healthy controls were stimulated for 15 minutes with either no stimuli, IFN-alpha, PMA and ionomycin, or TLR4, TLR7/8, or TLR9 agonists. The median 95th percentile was used to calculate the fold change of (A) HCQ- over controls (B) HCQ+ over controls or (C) HCQ+ over HCQ- in 8 cell populations (B cells, CD4+ T cells, CD8+ T cells, dendritic cells (DCs), plasmacytoid DCs (pDCs), natural killer (NK) cells, monocytes (mono) and granulocytes (gran). Significant increases or decreases in phophorylation following stimulation in a particular signaling molecule are noted by a blue box (decrease) or a red box (increase). The location of the box coincides with significant differences found in a specific cell population (refer to legend). $p<0.05$

Voclosporin Does Not Decrease Mycophenolic Acid Concentrations in Patients with SLE

Teun van Gelder[1], Robert Huizinga[2], Neil Solomons[2] and Laura Lisk[3], [1]Leiden University Medical Centre, Leiden, Zuid-Holland, Netherlands, [2]Aurinia Pharmaceuticals, Victoria, BC, Canada, [3]Aurinia Pharmaceuticals Inc., Victoria, BC, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Voclosporin (VCS) is a novel calcineurin inhibitor, structurally similar to cyclosporine A (CsA). In a Phase 3 clinical trial in patients with active lupus nephritis (AURORA 1), patients treated with VCS in combination with MMF, achieved renal response rates of 40.8% vs. 22.5% for the control arm (OR 2.65; $p < 0.001$). Drug-drug interactions have been demonstrated between CsA and MMF, where CsA interferes with MPA recirculation resulting in up to 50% lower exposure to mycophenolic acid (MPA), the active metabolite of MMF. While VCS did not demonstrate a negative impact on MPA levels in transplantation, the primary objective of this study was to investigate the effect of VCS on MPA levels in subjects with systemic lupus erythematosus (SLE), with or without lupus nephritis.

Methods: Twenty-five subjects with Systemic Lupus Erythematosus, treated with MMF at an oral dose of 1 g BID for at least 28 days prior to screening were enrolled and continued at the same dose throughout the study. Voclosporin was administered at a dose of 23.7 mg BID for seven consecutive days, starting in the evening of Day 1 and ending with the morning dose on Day 7. Blood samples for PK analysis of MPA and mycophenolic acid glucuronide (MPAG) were were collected at pre-am. doses and 0.25, 0.5, 0.75, 1, 1.25, 1.5, 1.75, 2, 3, 4, 5, 6, 8, 10, and 12 hours post-a.m. doses after the morning dose of both drugs on Day 1 and 7. Analyses were performed using Phoenix™ WinNonlin® (Version 6.3)

Results: MPA exposure parameters were similar in the absence and presence of VCS (Cmax: 16.5 µg/mL [Day 1] vs. 15.8 µg/mL [Day 7], AUC0-12: 39.1 µg.h/mL [Day 1] vs. 40.8 µg.h/mL [Day 7]). The median time to Tmax was similar on both days, with comparable ranges of individual values. MPAG exposure showed a small increase in the presence of VCS (12% for Cmax and 27% for AUC0-12). Voclosporin exposure was consistent with previous studies. Administration of VCS with MMF over 7 days was well tolerated

Conclusion: There is no clinically meaningful interaction between voclosporin and MMF. As changes in exposure to MPA may affect its efficacy and safety, these data confirm that VCS and MMF can be given concomitantly without the need to adjust MMF dose

Residual Treatment Burden, Desired Improvement, and Prioritized Treatment Goals in Systemic Lupus Erythematosus (SLE): Results from the SLE-UPDATE (Understanding Preferences, Disease Activity and Treatment Expectations) Survey in the United States

Diane Kamen[1], Julie Birt[2], Monica Hadi[3], Nashmel Sargalo[3], Ella Brookes[3], Paul Swinburn[3], Leslie Hanrahan[4], Karin Tse[5], Natalia Bello[6], Kirstin Griffing[2], Maria Silk[2], Laure Delbecque[7] and Anca Askanase[8], [1]Medical University of South Carolina, Charleston, SC, [2]Eli Lilly and Company, Indianapolis, IN, [3]Evidera, London, United Kingdom, [4]Carra Group, Milwaukee, WI, [5]Lupus Foundation of America, DC, WA, [6]Eli Lilly and Company, Indianapolis, [7]Eli Lilly and Company, Brussels, Belgium, [8]Columbia University College of Physicians & Surgeons, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Literature describes a fairly high degree of satisfaction with SLE therapies, despite patients reporting high rates of adverse event (1-2). The objectives of this study were to understand patient satisfaction with their treatment, patient reported treatment burden, desired improvements with therapies, and treatment goal priorities.

Methods: A cross-sectional, non-interventional, online survey was developed based on literature review and expert clinician input. Participants were identified through patient panels and included English-speaking patients ≥18 years old from the United States who self-reported a SLE diagnosis by a physician. For each class of medications used for the treatment of SLE (e.g. anti-malarials (AM), corticosteroids (CS), immunosuppressants (IS), or biologics, patients indicated their level of satisfaction on a 5-point scale ranging from completely satisfied to very unsatisfied, how burdensome each medication was on a 4-point scale (very burdensome to not at all burdensome), reasons it was considered burdensome, and side effects experienced in the past 3 months. Additionally, patients were asked about their desired improvements with treatment and what they considered to be the most important treatment goals. Descriptive data are presented by means (standard deviation [SD]) for continuous measures, and frequency (n, %) for nominal or ordinal measures.

Results: Patients (n=500) were mostly female (75%), Caucasian (76%), with a mean age of 42.6 [12.7] years and mean disease duration of 11.1 [10.6] years. Patient reported current SLE medications included: AM 42%, CS 33%, IS 33%, and biologics 19%. Across medications patients were taking at the time of the survey, 16-38% indicated they were 'completely satisfied', and 41-56% indicated they were 'somewhat satisfied' (Table 1). CS had the highest percentage of 'neutral or not satisfied' responses (35%), while biologics had the largest percentage of 'satisfied' patients (86-94%). However, biologics had the highest percentage of patients rating their medication as 'somewhat' or 'very burdensome' (62-67%). "Reasons for burden" varied by medication, with the most common reported burden being short or long-term side effects, or inconvenient administration. The most common desired improvements to current lupus therapy were keeping lupus disease activity very low (66%), reduction in all symptoms (64%), and reduction in flares (61%). Highest priority lupus treatment goals included reduction in fatigue, pain, and flares. Lower ranked goals were the reduction in use of CS or IS. Over 60% of patients said their physicians did not ask about their most important treatment goals. When they did ask, over 75% of patients felt their goals matched their physician, 16% did not.

Table 1 Patient Reported Treatment Satisfaction, Burden, and Most Common Side Effects

	Corticosteroids (n= 231)	Immunosuppressants (n=163)	Belimumab (n=57)	Rituximab (n=16)	Antimalarials (n=211)
Satisfaction n (%) • Completely satisfied • Somewhat satisfied • Not satisfied*	 36 (15.6%) 115 (49.8%) 80 (34.7%)	 30 (18.4%) 85 (52.1%) 48 (29.4%)	 22 (35.1%) 23 (50.9%) 12 (14.1%)	 6 (37.5%) 9 (56.3%) 1 (6.3%)	 66 (31.3%) 86 (40.8%) 59 (28.0%)
Burden of taking n (%) • Very burdensome • Somewhat burdensome • Only a little burdensome • Not at all burdensome • Unsure	 41 (17.7%) 71 (30.7%) 49 (21.2%) 65 (28.1%) 5 (2.2%)	 27 (16.6%) 53 (32.5%) 34 (20.9%) 45 (27.6%) 4 (2.5%)	 11 (19.3%) 27 (47.4%) 10 (17.5%) 9 (15.8%) n/a	 4 (25.0%) 6 (37.5%) 5 (31.3%) 1 (6.3%) n/a	 12 (5.7%) 32 (15.2%) 52 (24.6%) 108 (51.2%) 7 (3.3%)
Reason for Burden n (%)	• Risk of long-term problems (eg. cataract, osteoporosis): 117 (50.6%) • Experienced side effects: 105 (45.5%) • Have to take pills daily: 104 (45.0%)	• Experienced side effects: 75 (46%) • Risk of organ damage: 60 (36.8%) • Routine lab monitoring: 56 (34.4%) • Have to take pills daily: 55 (33.7%)	• Inconvenience of infusion visits: 24 (42.1%) • Did not start working fast enough: 16 (28.1%) • Experienced side effects: 12 (21.1%)	• Inconvenience of infusion visits: 6 (68.8%) • Routine lab monitoring: 6 (37.5%) • Cost: 5 (31.3%)	• Have to take pills daily: 105 (49.8%) • Routine monitoring for possible eye problems: 94 (44.5%) • Experienced side effects: 49 (23.2%)
Most common side effects n (%)	• Chubby face or cheeks (moon face): 98 (42.4%) • Weight Gain: 97 (42.0%) • Muscle weakness: 75 (32.5%) • Insomnia/sleep difficulty: 72 (31.2%)	• Stomach problems: 77 (47.2%) • Hair loss: 58 (35.6%) • Infections: 40 (24.5%) • Skin or nail changes: 36 (22.1%)	• Depression: 15 (26.3%) • Redness, tenderness, itching at injection site: 15 (26.3%) • Nausea: 12 (21.1%)	• Nausea: 7 (43.8%) • Infections: 5 (31.3%) • Diarrhea: 2 (12.5%)	• Stomach problems: 71 (33.6%) • Headache: 54 (25.6%) • Insomnia/vivid dreams: 51 (24.2%) • Dizziness: 39 (18.5%) • Mood changes: 39 (18.5%)

*Includes: Neither satisfied nor dissatisfied; Somewhat unsatisfied; Very unsatisfied

Conclusion: Patients report relatively high rates of satisfaction with current therapies, despite identifying high levels of treatment burden. From the patient perspective, reduction in fatigue, pain, and flares are the most important treatment goals.

Effect of Cumulative Hydroxychloroquine Dose on Prevention of Damage Progression in Patients with Systemic Lupus Erythematosus

Lisa Zhu[1], Manpreet Singh[2], Caroline Siegel[3], Lori Sahakian[2], Jennifer Grossman[4] and Maureen McMahon[5], [1]University of California, Los Angeles, Van Nuys, CA, [2]University of California, Los Angeles, Los Angeles, CA, [3]Hospital for Special Surgery, New York, NY, [4]University of California, Los Angeles, Sherman Oaks, CA, [5]University of California Los Angeles, Los Angeles, CA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: SLE – Treatment Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Table 1. Correlation between Lifetime Yearly HCQ Dose and SDI

	Correlation	p-value
Baseline	-0.22	p<0.0001
3 Years	-0.18	p=0.008
5 Years	-0.22	p=0.0001

Table 2. Relationship Between Lifetime Yearly HCQ Dose and Disease Damage

	Lifetime Yearly Average HCQ Dose (grams, mean ± SD)		p-value
	SDI = 0	SDI ≥ 1	
Baseline	104.3 ± 52.6 (n=96)	80.9 ± 54.4 (n=146)	p=0.001
3 years	106.2 ± 50.3 (n=69)	81.9 ± 55.5 (n=152)	p=0.006
5 years	113.9 ± 46.9 (n=152)	80.9 ± 54.4 (n=69)	p=0.001

HCQ = hydroxychloroquine; SD = standard deviation; SDI = SLICC/ACR damage index.
Note HCQ 200 mg/day is equivalent to 73 grams/year, HCQ 300 mg/day is equivalent to 110 grams/year, HCQ 400 mg/day is equivalent to 146 grams/year.

Background/Purpose: Hydroxychloroquine (HCQ) has demonstrated a wide array of beneficial effects in patients with systemic lupus erythematosus (SLE), with regard to disease activity, flare rates, organ damage, survival, thrombosis, lipid profile, diabetes mellitus and bone metabolism. Most of the existing data assesses HCQ use as a dichotomous variable at a single time point in a patient's disease process. We looked at lifetime cumulative HCQ doses in a cohort of SLE patients to gain a more comprehensive view of the relationship between HCQ use and damage accrual. It is important to better characterize the benefits and risks of prolonged HCQ use given ongoing concerns about antimalarial-induced retinal toxicity, which is a common reason for HCQ discontinuation.

Table 3. Relationship Between Lifetime Yearly HCQ Dose and Cardiovascular Events

	Lifetime Yearly Average HCQ Dose (grams, mean ± SD)		p-value
	Had Event	No Event	
Any CVE	69.7 ± 54.5 (n=50)	92.5 ± 55.9 (n=194)	p=0.02
Cardiac Event	46.2 ± 48.8 (n=15)	90.6 ± 55.8 (n=229)	p=0.003
Stroke/TIA	67.2 ± 54.6 (n=29)	90.6 ± 56.1 (n=215)	p=0.04

HCQ = hydroxychloroquine; SD = standard deviation; CVE = cardiovascular event; TIA = transient ischemic attack.

Methods: We studied a prospective cohort of 244 adult patients who met the 1997 American College of Rheumatology (ACR) classification criteria for SLE. Patients received care at a university medical center and were followed over at least 10 years. The cumulative HCQ dose from time of enrollment to last known follow-up was calculated for each patient via retrospective chart review. This value was then divided by the number of years since their SLE diagnosis to give a lifetime yearly average HCQ dose. Quinacrine use was accounted for by using a conversation of 300 mg HCQ for every 100 mg quinacrine. Disease damage was assessed using SLICC/ACR Damage Index (SDI) scores at baseline, 3 years, and 5 years after enrollment. We also recorded the incidence of cardiovascular events (CVE), defined as coronary artery disease, myocardial infarction, ischemic stroke, transient ischemic attack (TIA), or peripheral artery disease. Chi-squared test was used for dichotomous variables and Student's t-test for continuous variables. Spearman's test was used to examine correlations between two continuous variables.

Results: The cohort was composed of 99% females, and the mean age of all patients was 40.7 years. There was a statistically significant negative correlation between lifetime yearly average HCQ dose and SDI at baseline, 3 years, and 5 years (Table 1). At all of these time points, patients who had an SDI of zero had a higher lifetime yearly average HCQ dose compared to patients who had an SDI of 1 or greater. These differences were all statistically significant (Table 2). Thirty-six of the 244 patients (18.8%) had at least one CVE during follow-up. Patients who did not have a CVE had a higher lifetime yearly average HCQ dose compared to patients who did have a CVE. The same pattern was seen when looking at cardiac events and ischemic stroke/TIA individually. These differences were all statistically significant (Table 3).

Conclusion: We found an inverse correlation between lifetime yearly HCQ dose and damage accrual in our cohort of patients with SLE. This was seen with regard to overall damage accrual as represented by the SDI, and specifically with cardiovascular damage as represented by CVE incidence. These findings reaffirm existing data on the benefits of HCQ use in SLE, and provide stronger support for the continuous use of HCQ at appropriate dosages over the course of disease unless clearly contraindicated.

Abstract Number: 0865

Efficacy and Safety of Evobrutinib (M2951) in Adult Patients with Systemic Lupus Erythematosus Who Received Standard of Care Therapy: A Phase II, Randomized, Double-blind, Placebo-controlled Dose Ranging Study

Daniel J Wallace[1], Thomas Dörner[2], David Pisetsky[3], F Jorge Sanchez-Guerrero[4], Amy Kao[5], Dana Parsons-Rich[5], Anand Patel[6], Yulia Zima[5], Claire Le Bolay[7], Karthinathan Thangavelu[6] and Maria Dall'Era[8], [1]Cedars-Sinai Medical Center, Beverly Hills, CA, [2]DRFZ and Charité University Hospitals, Berlin, Germany, [3]Duke University Medical Center, Durham, NC, [4]University Health Network/Sinai Health system, Toronto, ON, Canada, [5]EMD Serono (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA, [6]EMD Serono (a business of Merck KGaA, Darmstadt, Germany), Billerica, [7]Merck KGaA, Darmstadt, Germany, [8]Division of Rheumatology, University of California, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Bruton's tyrosine kinase (BTK) is involved in signalling pathways known to be important to the pathogenesis of systemic lupus erythematosus (SLE). Evobrutinib is a highly-selective, oral BTK inhibitor. This global Phase IIb randomized, double-blind, placebo-controlled study evaluated the efficacy, dose response and safety of evobrutinib compared to placebo in adult patients with active autoantibody-positive SLE who received standard of care (SoC) therapy.

Methods: Patients diagnosed with SLE by the SLICC or ACR classification criteria ≥6 months before screening, who had a SLEDAI-2K total score ≥6 at screening, were autoantibody-positive, and on sTable SLE SoC background therapy; were randomized 1:1:1:1 to oral evobrutinib 25 mg once-daily (QD), 75 mg QD, or 50 mg twice-daily (BID), or placebo. Active or severe central nervous system manifestations were exclusionary. The two primary endpoints were the SLE-Responder Index (SRI)-4 at Week 52 in all patients and the SRI-6 response at Week 52 in the subgroup of patients with High Disease Activity (defined as SLEDAI-2K total score ≥10 at screening). Primary safety endpoints included the incidence and severity of treatment-emergent adverse events (TEAEs), and key secondary endpoints were SRI-4 response in the serologically active subgroup, defined as patients with positive anti-dsDNA antibodies and/or low complement levels at screening, and time to first new severe (BILAG A) flare during treatment.

Results: A total of 469 patients were randomized for the study's primary analysis. Age at baseline was 40.7 years ±12.3 (mean ±SD) and 95% were female. Baseline disease characteristics were generally balanced across treatment groups. Median disease duration ranged from 51.6 to 69.2 months across treatment groups. Neither primary endpoints, SRI-4 response at Week 52 or SRI-6 response in patients with High Disease Activity, were met (Table). There was no clinically meaningful treatment difference for SRI-4 response in the serologically active subpopulation (Table). No treatment effect was observed for time to first severe flare. Serious adverse events were infrequently reported in all groups, 8.5% in placebo versus 9.4% in the evobrutinib groups combined. Infections and infestations were the most common treatment-emergent adverse event (TEAE), 42.7% for placebo versus 58.0% for evobrutinib groups combined. Overall, there was no dose effect in TEAEs or SAEs.

Table: Efficacy Results

Endpoints	Placebo N=114	Evobrutinib 25 mg QD N=115	Evobrutinib 75 mg QD N=116	Evobrutinib 50 mg BID N=114
SRI-4 Response Rate in mITT, n (%)	52 (45.6)	64 (55.7)	60 (51.7)	55 (48.2)
Absolute treatment difference of response rate vs Placebo, %		10.0	6.1	2.6
Odds-ratios [95% CI]		1.55 [0.91, 2.64]	1.29 [0.76, 2.18]	1.13 [0.67, 1.93]
P-value before adjustment for multiplicity		0.0522	0.1741	0.3209
	Placebo N=56	**Evobrutinib 25 mg QD N=54**	**Evobrutinib 75 mg QD N=65**	**Evobrutinib 50 mg BID N=55**
SRI-6 Response Rate at Week 52 in HDA, n (%)	22 (39.3)	27 (50.0)	30 (46.2)	24 (43.6)
Absolute treatment difference of response rate vs Placebo, %		10.7	6.9	4.4
Odds-ratios [95% CI]		1.50 [0.69, 3.24]	1.42 [0.68, 2.97]	1.27 [0.59, 2.75]
P-value before adjustment for multiplicity		0.1510	0.1780	0.2731
	Placebo N=59	**Evobrutinib 25 mg QD N=65**	**Evobrutinib 75 mg QD N=60**	**Evobrutinib 50 mg BID N=63**
SRI-4 Response Rate at Week 52 in serologically active patients, n (%)	28 (47.5)	38 (58.5)	29 (48.3)	34 (54.0)
Absolute treatment difference of response rate vs Placebo, %		11.0	0.9	6.5
Odds-ratios [95% CI]		1.52 [0.74, 3.15]	1.03 [0.49, 2.13]	1.35 [0.65, 2.81]
P-value before adjustment for multiplicity		0.1279	0.4729	0.2094
	Placebo N=114	**Evobrutinib 25 mg QD N=115**	**Evobrutinib 75 mg QD N=116**	**Evobrutinib 50 mg BID N=114**
Time to first severe BILAG A flare – mITT Hazard ratios [95% CI]		1.17 [0.57, 2.40]	0.69 [0.31, 1.52]	0.90 [0.42, 1.97]
P-value before adjustment for multiplicity		0.7034	0.5462	0.5462

mITT: modified intent-to-treat; HDA: high disease activity; SRI: SLE-responder index

Conclusion: This Phase IIb dose-ranging study in SLE showed no treatment effect of evobrutinib versus placebo at any dose. Evobrutinib was well tolerated across the overall and high disease activity subgroup populations, and there was no dose effect observed for any adverse events. These results, combined with the negative results of the fenebrutinib SLE study, suggest that BTK inhibition is not an effective therapeutic intervention for patients with SLE.

Identifying an SLE Patient Cluster with Greater Treatment Effect: Immune Cell Deconvolution of Gene Expression in Two Atacicept Phase II Studies

Joan Merrill[1], Matthew Studham[2], Eric Morand[3], Aida Aydemir[2], Cristina Vazquez Mateo[2], Alex Rolfe[2], Amy Kao[2] and Robert Townsend[2], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]EMD Serono (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA, [3]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Atacicept, a dual inhibitor of the B lymphocyte stimulator and a proliferation-inducing ligand (APRIL), has been associated with a reduction of flares in the Phase II/III APRIL-SLE study (NCT00624338) and disease improvement in a subset of patients (pts) with baseline high disease activity (HDA; SLEDAI-2K ≥10) in the Phase IIb ADDRESS II study (NCT01972568). Using immune cell deconvolution of gene expression data, we previously distinguished two pt clusters in the APRIL-SLE study characterized by different rates of flare in the placebo (PBO) group [1]. We proposed an analysis of ADDRESS II to confirm the differential treatment effect observed using baseline gene expression in the APRIL-SLE study.

Methods: In a prior study of APRIL-SLE samples, a cell deconvolution algorithm [2] was used to assess 17 immune cell subsets in gene expression data from mRNA extracted from whole blood at baseline (N=105). Unsupervised clustering revealed five clusters of pts (P1–P5). In two clusters (P1,3), PBO-treated pts, when compared with atacicept-treated pts, had few new BILAG A or B flares. In the other three clusters (P2,4,5), PBO-treated pts had high flare rates. The P2,4,5 subset includes pts with high plasmablasts, high B cells and low neutrophils, or high activated natural killer cells and high activated dendritic cells. Using the cellular modules that defined these clusters, we developed an algorithm to distinguish P1,3 from P2,4,5 and applied it to the ADDRESS II mITT and HDA populations with gene expression data at baseline. Treatment arms in the two resulting subsets were compared using SLE Responder Index (SRI)-4, SRI-6, BILAG-based Combined Lupus Assessment (BICLA), and low disease activity (SLEDAI-2K ≤2).

Results: In ADDRESS II, 179 pts (58.5%) of the mITT and 93 pts (59%) of the HDA subpopulation had RNAseq expression data; their clinical response rates were similar to the overall mITT and HDA populations. The algorithm assigned 93 mITT pts (52%) to the P1,3 subset and 86 (48%) to the P2,4,5 subset. For HDA pts, 35 (38%) were assigned to P1,3 and 58 (62%) to P2,4,5. The P2,4,5 subset was confirmed to have lower PBO response rates and higher treatment difference for atacicept compared to the P1,3 subset as measured by SRI-4, SRI-6, and BICLA in both mITT and HDA populations. (Table 1).

Conclusion: This exploratory analysis of the ADDRESS II trial demonstrated greater treatment effect of atacicept in a subset of pts identified by an algorithm derived from unsupervised clustering of whole blood gene expression in a

Hydroxychloroquine Use Predicts Significantly Higher Patient and Graft Survival in Post-Renal Transplant Lupus Nephritis Patients

Shivani Garg[1], Tripti Singh[1], Sarah Panzer[2] and Christie Bartels[3], [1]UW Madison, Madison, WI, [2]UW-Madison, Madison, [3]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a pivotal therapy for lupus nephritis (LN) as it contributes to 65% lower mortality and 84% lower renal damage compared to HCQ non-users. End-stage renal disease (ESRD) due to LN is a leading cause of renal transplantation and almost 30% of patients suffer from LN recurrence after renal transplant. Yet, the impact of post-transplant HCQ use on LN recurrence, and patient and graft survival has not been elucidated. Therefore, this study aims to examine the role of post-transplant HCQ use on LN recurrence, and patient and renal graft survival. We also examined other predictors of post-transplant patient and graft survival. *We hypothesized that post-transplant HCQ use will predict lower LN recurrence, and better patient and graft survival.*

Methods: Using a comprehensive transplant database, we identified all patients with ESRD due to LN who underwent renal transplant between 1994-2016 at an academic center. Data, including patient, lupus, and transplant characteristics, were extracted from this database. Post-transplant medication HCQ use and biopsy confirmed LN recurrence were abstracted. Primary outcomes were all-cause mortality and graft failure, defined as re-transplant or dialysis. Cox proportional hazards models were used to examine predictors of patient and graft survival. Fisher test was used to examine association between LN recurrence and HCQ use.

Results: Overall, we identified 205 patients undergoing renal transplant for ESRD due to LN. The mean age of 43 years, 78% were white female, and only 34% of the patients were on HCQ after transplant. The post-transplant LN recurrence rate was 14%, with 52% of recurrences occurring in HCQ non-users (p 0.09).

Patient Survival: We identified 47 deaths (23%) during 11-year post-transplant follow up, with 79% of deaths occurring in HCQ non-users. Stratified survival analysis by HCQ use highlighted significantly lower mortality in HCQ users compared to non-users (10/47 vs. 37/47, $p < 0.0001$) (Figure 1). We found that HCQ use predicted 40% lower mortality compared to non-users and a trend was noted on multivariable analysis (*HR 0.6, CI 0.3-1.2, p 0.1*; Table 1). Post-transplant graft failure predicted 51-fold higher mortality risk in our cohort (*HR 51, CI 7-77, p 0.0001*) (Table 1). Age ≥ 45 years predicted 4-fold higher mortality (*HR 3.5, CI 1.8-6.6*), and non-white race predicted 2-fold higher mortality (*HR 2.3, CI 1.1-4.7*).

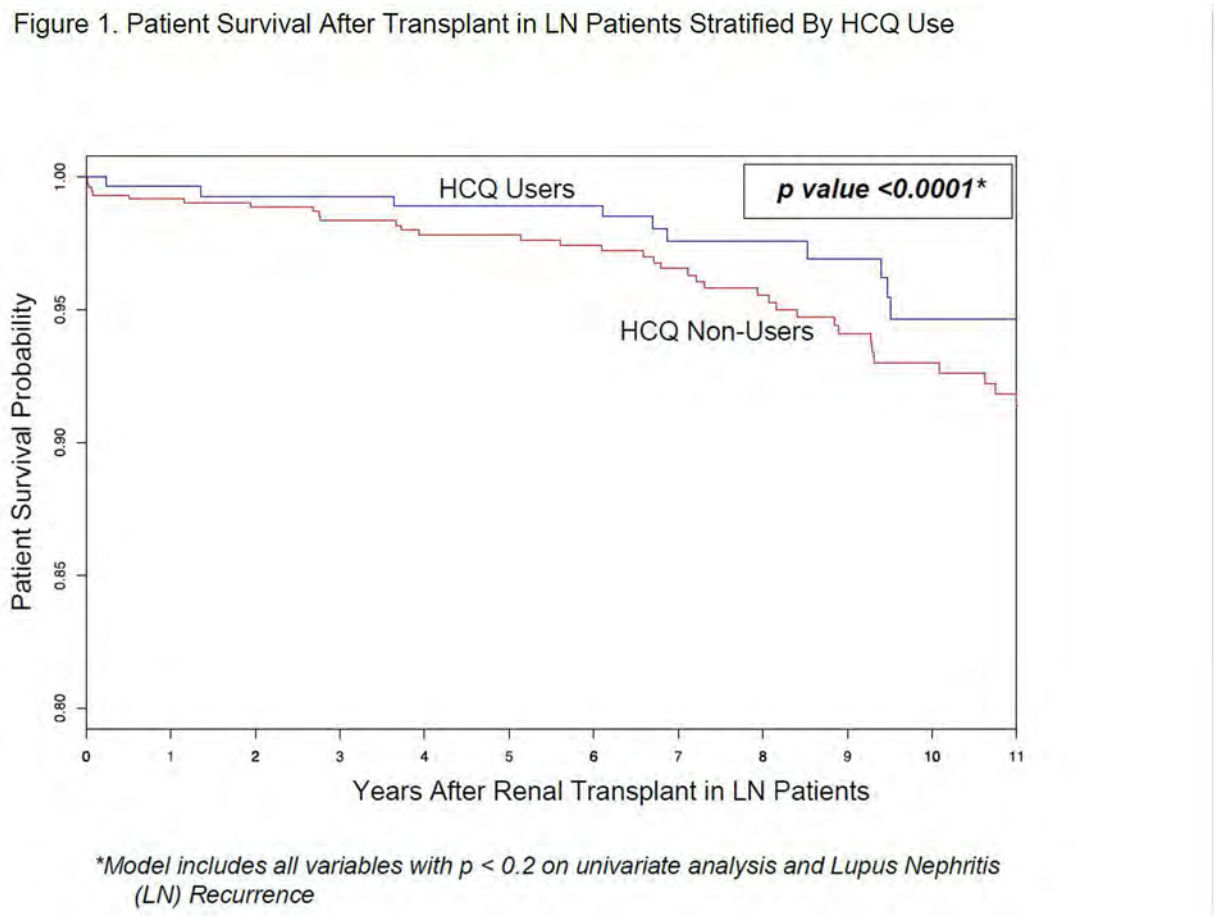

Figure 1. Patient Survival After Transplant in LN Patients Stratified By HCQ Use

Graft Failure: We identified 99 graft failures (48%) during post-transplant follow up. Stratified graft survival analysis revealed significantly lower graft failure in post-transplant HCQ users compared to non-users (29/99 vs 70/99, $p < 0.0001$) (Figure 2). Multivariable analysis showed post-transplant LN recurrence predicted 2-fold higher graft failure risk *(HR 1.7, CI 1.02-3, p 0.04; data not shown)*.

Conclusion: HCQ use predicted higher post-transplant LN patient and renal graft survival. LN recurrence was a strong predictor of graft failure, and renal graft failure predicted 51-fold higher post-transplant mortality. Future efforts should prospectively examine the impact on post-transplant HCQ use on graft and patient outcomes.

Table 1. Cox Proportional Hazards Model to Predict Post-Transplant Survival

Variable	HR (95% CI)	p value
Age at Tx ≥45 years	**3.5 (1.8-6.6)**	**<0.0001**
Non-White Race	**2.3 (1.1-4.7)**	**0.03**
Female	1.2 (0.6-2.3)	0.6
Post-Tx Graft Rejection	**51 (7-77)**	**0.0001**
Live Donor	1.1 (0.5-2.3)	0.8
Pre-Tx HD Duration, 1 year Increments	1.1 (0.98-1.2)	0.09*
Post-Tx LN Recurrence	0.5 (0.2-1.1)	0.08*
HCQ Use	0.61 (0.3-1.2)	0.1*

*Model includes all variables with p < 0.2 on univariate analysis and Lupus Nephritis Recurrence; HCQ Hydroxychloroquine; HD Hemodialysis; LN Lupus Nephritis; Tx Transplant; *indicates a trend; significant p <0.05 are shown in bold*

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In general, renal elimination is minimal for therapeutic proteins with a molecular weight more than 69 KDa. However, in patients with proteinuria, there is impaired filtration or insufficiency of absorption of serum protein in the kidney. Proteinuria is commonly seen in a variety of kidney diseases involvement, including lupus ne-

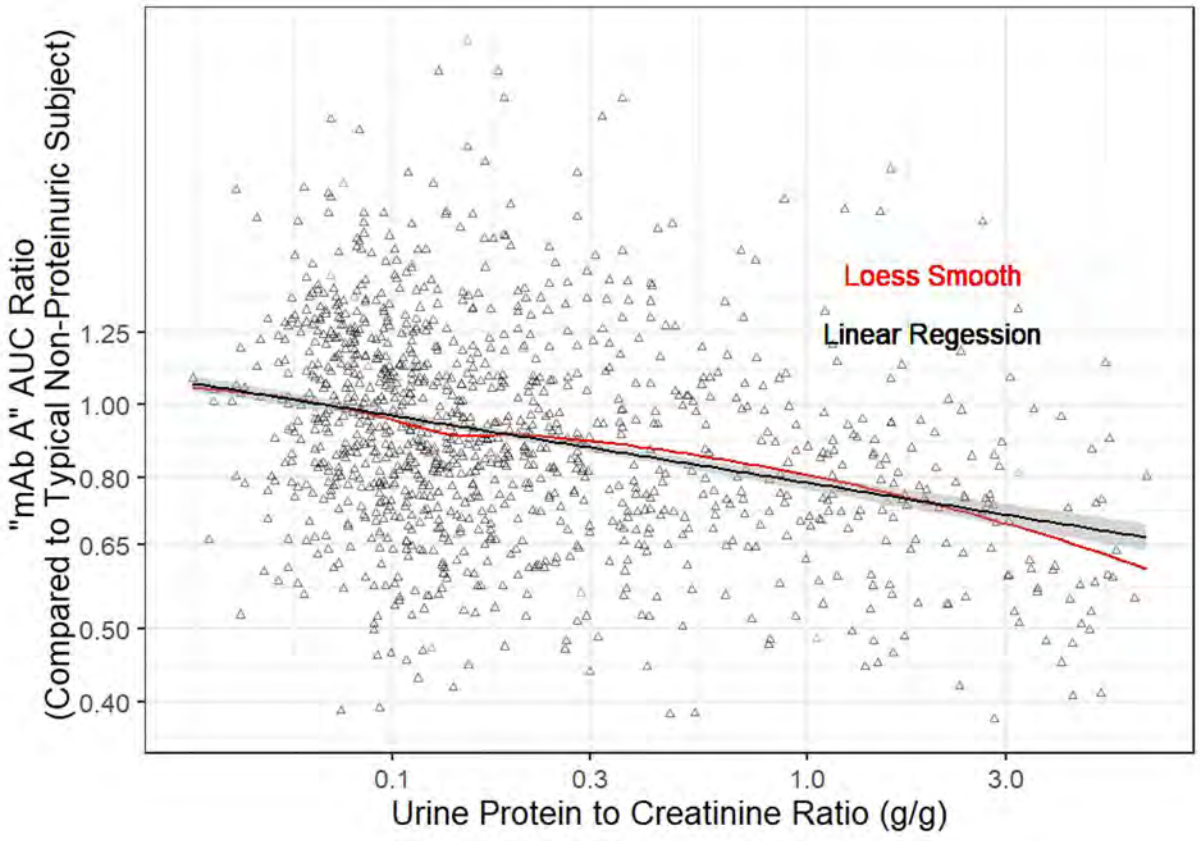

Figure 1. The relationship between baseline urine UPCR and mAb A exposure (AUC) in SLE patients. The black line represents linear regression, and the red line represents Loess smooth fitting.

phritis (LN), nephrotic syndromes, diabetic nephropathy, etc. In these cases, along with the endogenous serum protein, the therapeutic protein such as monoclonal antibody (mAb) is also detected in urine. Additional renal clearance of mAb may lead to a clinically important reduction in serum drug concentration.

Methods: We evaluated longitudinal pharmacokinetic and spot urine protein data for three monoclonal antibodies: mAb A in systemic lupus erythematosus (SLE), mAb B in ANCA-associated vasculitis (AAV), and mAb C in sickle cell disease (SCD). Two studies (in AAV and SCD) collected qualitative urine protein (i.e. dipstick) values, and two studies in SLE collected quantitative urine protein information (i.e., total Urine Protein to Creatinine Ratio, UPCR). The relationship between drug exposure and quantitative UPCR was assessed by fitting a linear model on log-transformed and normalized variables. The assumption of linearity was assessed using a loess-smoothed overlay.

Results: For the SLE studies (mAb A), the median baseline of UPCR (g/g) was 0.144 (IQR: 0.092 – 0.355), and 216 subjects had greater than 500 mg/g (n=1128). In the SCD study (mAb C), a majority of subjects (100/150) had negative protein dipstick readings at baseline, and 50/150 had detectable urine protein. In the AAV study (mAb B), 25/64 had negative protein dipstick readings, and 39/64 were positive for trace to 4+ protein dipstick values.

A statistically persuasive negative correlation between quantitative urine protein with total drug exposure was identified for mAb A in lupus patients ($p < 0.00001$).

The relationship between baseline urine UPCR and drug exposure was well-described by a linear model with logarithmic transformations. This model suggests, on average, a patient with 0.5 g/g UPCR would be expected to have 84% of the exposure (95% CI – 82-86%) of a subject with spot protein of 0.1 g/g or less. Likewise, a subject with 5 g/g would be expected to have 68% (95% CI: 64-73%) of the exposure of a subject with 0.1 g/g or less. Additionally,

preliminary analyses suggest that the pre-dose trough concentration (a key covariate determining adequate dosing interval) may be more affected than overall exposure.

In contrast, no relationship was observed between qualitative urine protein and drug clearance for mAb B in AAV or mAb C in SCD. This may be due to the nature of the disease or the underlying pathophysiology of the kidney involvement, the degree of proteinuria, or other factors.

Conclusion: Overall, different types and severity of proteinuria may have different impact on the clearance of therapeutic proteins. The clinical impact of these observations remains to be determined. These findings may warrant the assessment, during drug development, of the impact of proteinuria on efficacy, safety, or the need for dosing adjustment for biological proteins.

Session Title: SLE – Treatment Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the beneficial effects of hydroxychloroquine (HCQ) in systemic lupus erythematosus (SLE), retinal toxicity is a concern. Factors associated with retinal toxicity have been studied among long-term HCQ

Table 1. Uni and multivariable Cox regression for retinal toxicity in HCQ-exposed SLE patients

Characteristics*	HR (95% CI)	aHR (95% CI)
Male sex	2.18 (0.47, 10.1)	1.73 (0.36, 8.36)
Race/ethnicity		
Caucasian	Reference	-
Black	1.21 (0.25, 5.92)	2.16 (0.37, 12.60)
Others	0.44 (0.09, 2.13)	0.58 (0.11, 2.97)
Age at SLE diagnosis in years	**1.05 (1.01, 1.09)**	1.05 (1.00, 1.09)
HCQ daily dose >5mg/Kg	1.16 (0.35, 3.80)	1.55 (0.46, 5.19)
Overweight (Body mass index≥25)	1.64 (0.44, 6.06)	2.50 (0.54, 11.51)
Smoker	1.23 (0.26, 5.69)	1.26 (0.27, 5.94)

*At baseline, except for age.

Table 1. Uni and multivariable Cox regression for retinal toxicity in HCQ-exposed SLE patients

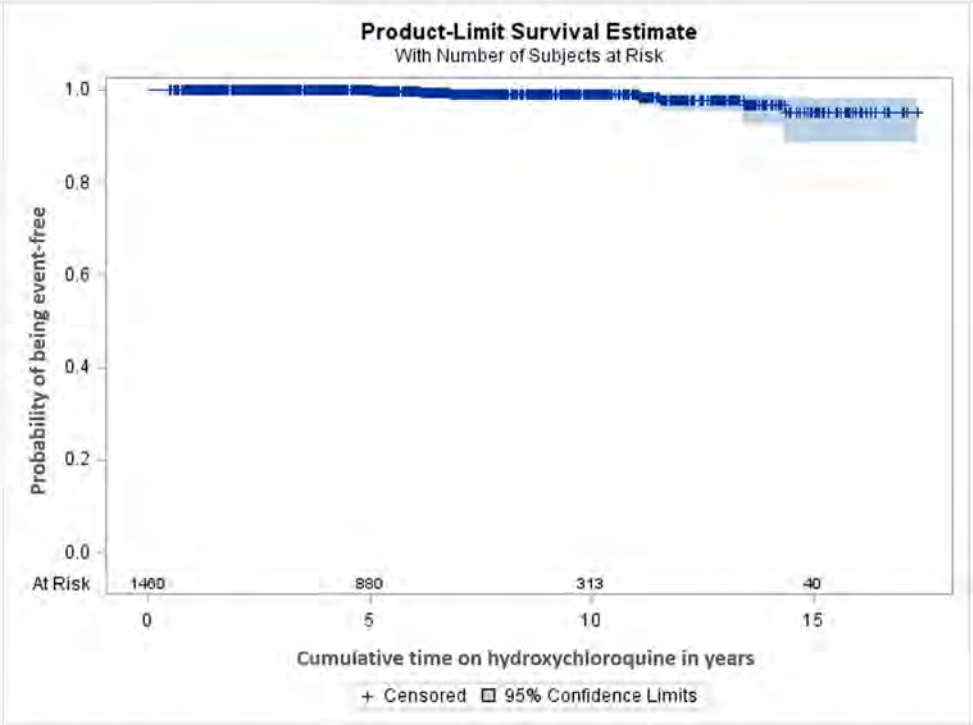

Figure 1. Kaplan-Meier curve for cumulative probability of retinal toxicity. The shaded areas represent pointwise 95% confidence intervals.

Figure 1. Kaplan-Meier curve for cumulative probability of retinal toxicity. The shaded areas represent pointwise 95% confidence intervals.

users but have not been described for incident SLE patients. We evaluated the incidence of HCQ-related retinal toxicity in a large, international, inception cohort of SLE patients, and assessed factors potentially associated with this event.

Methods: We analyzed prospective data from the Systemic Lupus International Collaborating Clinics (SLICC) cohort, that includes SLE patients from 33 sites in Europe, Asia, and North America, enrolled within 15 months of diagnosis.

Using annual study visits between 1999-2019, we followed patients from first visit on HCQ (time zero/baseline) up to the time of retinal toxicity documentation (outcome) or death, loss to follow-up, or censoring at end of study interval. Retinal toxicity was identified based on the SLICC/ACR damage index item for retinal damage and cases were confirmed with chart review. Multivariable Cox regression was used to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for baseline factors potentially associated with retinal toxicity (i.e., sex, race/ethnicity, age at SLE onset, HCQ daily dose/kg, body mass index, and smoking). We also plotted a Kaplan-Meier curve for probability of retinal toxicity related to total duration of HCQ therapy.

Results: A total of 1460 patients (89% female, 52% Caucasian) were included. Mean SLE duration at time zero (HCQ initiation) was 2.4 (standard deviation, SD 2.2) years and patients remained on HCQ an average of 6.4 (SD 4.2) years. Retinal toxicity was confirmed for 11 patients (incidence 1.0 per 1000 person-years) at a mean of 8.8 (SD 4.0) years. Our hazards regression model (Table 1) identified non-significant trends for greater risk in men, black patients, those receiving more than 5 mg per kg at baseline, overweight patients and smokers. In the Kaplan-Meier curve (Figure 1), the crude probability of retinal toxicity was less than 1% until 10 years of cumulative HCQ use, but increased around 1% each year after that, reaching 5% after 14 years.

Conclusion: In recent-onset SLE patients receiving HCQ, the probability of retinal toxicity increases after 10 years of cumulative use. There were non-significant trends for greater risk in men, black patients, those receiving more than 5 mg per kg at baseline, overweight patients and smokers. More sophisticated analyses with time-dependent variables are under way.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk of premature atherosclerosis and thrombosis. Hydroxychloroquine (HCQ) is widely used in the treatment of SLE and has been considered of benefit for overall vascular health albeit studies to address this benefit at the cellular level have been limited. Accordingly, this study was initiated to investigate the relationship between HCQ use and dose with platelet activity, the platelet transcriptome, and vascular functional readouts.

Methods: Patients fulfilling ACR or SLICC criteria for SLE were consecutively recruited for platelet evaluation with the only exclusion being on nonsteroidal anti-inflammatory medications, aspirin or anticoagulants. At enrollment, blood was collected for hematology analysis using the Sysmex XN-1000 analyzer, platelet aggregation via the Helena AggRAM™ system, and platelet RNA isolation and storage. Microvascular function was assessed via sublingual sidestream darkfield imaging. Brachial artery reactivity testing was used to evaluate large vessel function. Stored platelet RNA was isolated and analyzed by RNA sequencing (Illumina HiSeq4000 Sequencing).

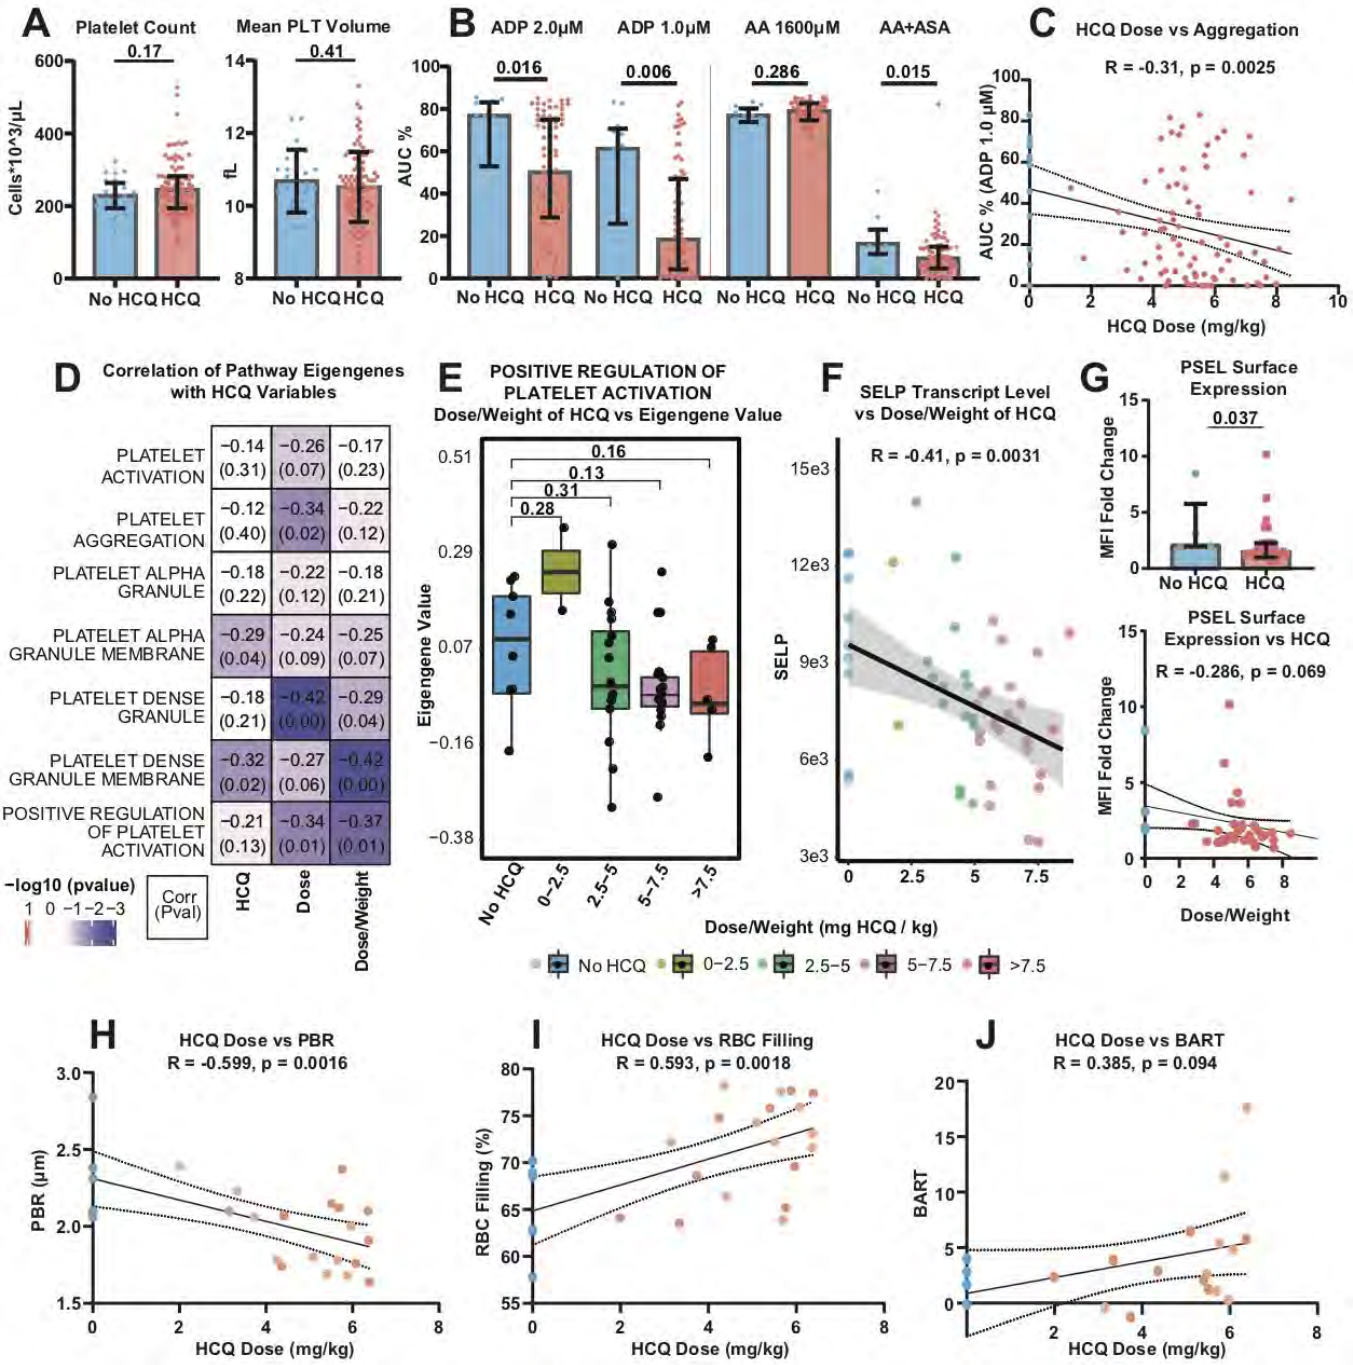

Figure 1. Associations between HCQ use and dose and platelet function, transcriptomics, and vascular function. Comparison of HCQ and non-HCQ groups of SLE subjects examining (A) platelet count and size. (B) Aggregation in response to ADP and AA with and without in vitro aspirin. (C) Pearson correlations of daily HCQ dosing and aggregation in response to 1µM ADP. (D) Heatmap depicting the correlation and p value between the sample eigengene values associated with platelet pathways and HCQ use, dose, and dose adjusted for weight. (E) Boxplots showing the eigengene values for the GO term Positive Regulation of Platelet Activation across different binned ranges of HCQ dose/weight. (F) Scatterplot showing the normalized transcript level of SELP compared against HCQ dose/weight for each patient. (G) Comparison of p-selectin surface expression fold change in subjects on and off HCQ as measured by flow cytometry and a Pearson correlation of HCQ dose and p-selectin fold change. Platelet activity and p-selectin surface expression comparisons made using the Mann-Whitney rank-sum test show median and IQR; for platelet aggregation the HCQ group ranged from 71 to 81 subjects and non-HCQ group ranged from 13 to 15 depending on the measure. For p-selectin, HCQ N=36, No HCQ N=5. Pearson correlations of daily HCQ dosing and PBR (H), RBC Filling (I), and BART (J) were also examined, shown here with 95% CI bands.

Results: Among 132 SLE subjects, 108 were on HCQ. Mean age was 39.9 ± 13.0 and 97% were female. Lupus disease activity at the time of blood draw assessed by the SELENA-SLEDAI activity index was 3.44 (range 0-20). Demographics and SLE disease activity did not differ between those on versus off HCQ (**Table 1**). Platelet count and size were not different between groups (**Figure 1A**). Platelet aggregation in response to submaximal ADP at multiple concentrations was lower in participants on HCQ (**Figure 1B**). Consistently, there was an inverse relationship between HCQ dosing and platelet aggregation in response to ADP (2uM: R=-0.213, P=0.037; 1uM: R=-0.310, P=0.0025; 0.4uM: R=-0.376, P=0.00018; **Figure 1C**). Since no subjects were on aspirin (or any other antiplatelet therapy at enrollment), aggregation in response to arachidonic acid (AA) was robust and similar between groups. However, after incubating platelets with aspirin (3mM) *in vitro*, platelet aggregation in response to AA was lower in the HCQ group compared to non-HCQ group (P=0.035, **Figure 1B**). To investigate the potential mechanisms of HCQ induced lower platelet aggregation, we evaluated platelet RNA sequencing in 49 subjects (8 no HCQ, 41 on HCQ). Positive regulation of pathways related to platelet activation (and in particular, P-selectin expression) was inversely related to HCQ, especially with higher doses (**Figure 1E**). In terms of vascular function, subjects on HCQ had improved microvascular function as noted by an increased proportion of sublingual capillaries filled with RBCs (P=0.011) and smaller perfused boundary region (PBR, P=0.010). HCQ dosing correlated with PBR (R=-0.599, P=0.002, **Figure 1H**) and RBC Filling (R=-0.592, P=0.002, **Figure 1I**). BART also trended positively with HCQ dose (R=0.385, P=0.094; **Figure 1J**).

Conclusion: These findings suggest that HCQ may provide benefit for vascular health in SLE as supported by ex vivo experiments demonstrating decreased platelet aggregation and downregulation of platelet functional pathways as well as improved vascular readouts.

Abstract Number: 0871

Hydroxychloroquine Dose Reduction and SLE Flares

April Jorge[1], Gary Ho[2], Michael Wu[2], Karen Costenbader[3] and Hyon Choi[4], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: 2016 ophthalmology guidelines recommend using hydroxychloroquine (HCQ) dosages < 5mg/kg/day, which is lower than the traditional 400mg/day for the majority of SLE patients. However, it is unknown whether lower dosages retain efficacy for controlling SLE disease activity. The aim of this study was to determine trends of HCQ dose reduction among SLE patients and identify a potential association with the risk of lupus flares.

Methods: We identified a cohort of patients with SLE from our academic medical center using a previously validated electronic health record SLE phenotype algorithm (PPV 92%) (Jorge A et al. *Semin Arthritis Rheum* 2019) and included patients who met 1997 ACR classification criteria and who had at least two visits in our academic rheumatology practice since 1/1/2016. We excluded patients who did not use HCQ at any time after that date. We obtained

Characteristics at Baseline Visit	Overall	Underwent HCQ Dose Reduction	Remained on 400mg/day	p values
N	216	30	111	
Age (y), mean (SD)	46.2 (15.9)	46.7 (14.7)	44.4 (13.7)	0.42

Other/unknown, n (%)	50 (23.0)	8 (26.7)	23 (20.7)	0.58
Body Weight (kg), mean (SD)	75.5 (18.9)	71.7 (17.9)	81.7 (18.4)	<0.01
Body Weight under 80 kg, n (%)	127 (63.4)	22 (73.3)	57 (51.4)	<0.01
SLE Disease Duration (y), median	9.5	11.2	8	0.09
SLE Manifestations, n (%)				
Malar Rash	52 (24)	8 (26.7)	30 (27.0)	0.98
Discoid Rash	17 (7.8)	6 (20)	7 (6.3)	0.05
Arthritis	175 (80.6)	26 (86.7)	98 (88.3)	0.95
Nephritis	42 (19.4)	3 (10.0)	23 (20.7)	0.28

Table 1. Baseline Characteristics of SLE Patients According to Time-Varying Hydroxychloroquine Dose

	Before Dose Reduction			After Dose Reduction			
HCQ Dose-Reduction	Person-time (Y)	Flares (N)	Flare Rate	Person-time (Y)	Flares (N)	Flare Rate	Rate Ratio (95% CI)
Reduction to 200mg	21.3	3	0.14	23.1	7	0.30	2.08 (0.71-6.08)
Reduction to 300mg	15.5	2	0.13	12.3	3	0.24	1.89 (0.32-11.3)

Table 2. Hydroxychloroquine Dose-Reduction and the Incidence of SLE Flares

demographics, anthropometrics, medication use, SLE disease history, and SLE manifestations and disease activity assessed at each rheumatology visit. HCQ dose was assessed as a time-varying exposure, in mg/day as 400, 200, or between 200-400 (typically 300). We identified all dose change events. The primary outcomes were combined mild, moderate, and severe SLE flares defined by the revised SELENA-SLEDAI flare index (rSSFI). The secondary outcome was severe rSSFI flares alone. We determined the rates of SLE flares overall, prior to HCQ dose changes, and following HCQ dose reduction and calculated SLE flare incidence rate ratios.

Results: 216 patients met the inclusion criteria, with a mean 2.6 years of follow up since 2016. Patients were on average 46.2 years of age and were 90.3% female (**Table 1**). A total of 111 patients (51.4%) were treated with a HCQ dose of 400mg/day without a dose change, whereas 33 patients (15.3%) received 200mg/day and 12 (5.6%) received 300mg/day without a dose change during the study period. 30 patients (13.9%) initially received 400mg/day and underwent HCQ dose reduction (n=18 to 200mg/day, n=12 to 300mg/day). A higher proportion of patients who underwent dose reduction had body weight under 80kg (thus 400mg of HCQ would exceed 5mg/kg), but the dose also exceeded 5mg/kg for 51.7% of patients who remained on 400mg/day throughout study follow up. The overall rSSFI flare rates were 0.39 total flares per person-year (PY) and 0.06 severe flares per PY. For patients who received 400mg/day throughout study follow up, the overall flare rate and severe flare rate were 0.48 per PY and 0.08 per PY, respectively. Among patients who underwent HCQ dose reduction, overall SLE flare rates were 0.14 per PY prior to HCQ dose reduction from 400mg to 200mg/day and 0.30 per PY following dose reduction to 200mg. The SLE flare

rates were 0.13 per PY prior to HCQ dose reduction from 400mg to 300mg/day and 0.24 per PY following dose reduction to 300mg (**Table 2**).

Conclusion: In recent years, a minority of patients with SLE underwent HCQ dose reduction. Of those who did, we found a numerically higher incidence of SLE flares following HCQ dose reduction. This finding should be replicated in a larger cohort to clarify a potential loss of benefits associated with lowering the treatment dose.

Usage of Corticosteroids and Hospitalisation Duration in Adult Patients with Systemic Lupus Erythematosus (SLE) in Latvia

Ilze Vinkalna[1], Inita Bulina[2], Natalija Vellere[2], Kristine Ivanova[2], Pauls Rubins[2], Renate Diura[2], Santa Mikena[2], Julija Zepa[2] and Daina Andersone[2], [1]Pauls Stradins Clinical University Hospital, Rīga, Latvia, [2]Pauls Stradins Clinical University Hospital, Riga

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the factors influencing hospitalisation duration, re – hospitalisation (more than 1 hospitalisation during the study period), frequency of the usage of corticosteroids (CS) and its correlation with SLEDAI, SLICC/ACR DI of systemic lupus erythematosus (SLE) patients.

Methods: A retrospective study performed from 01 January 2018 till 31 December 2019 analysed the data of 80 SLE patients, including hospitalisation episodes, in Pauls Stradins Clinical University Hospital.

Results: 70 (87.5 %) patients were females and 10 (12.5%) males. 44 (55 %) patients were admitted to the hospital due to SLE flare and 5 (6.3%) patients due to a new onset of SLE. The mean duration of hospitalisation was 6.8 days (SD 4,9). CS (the mean dosage of prednisolone was 12.6 mg (SD 16.1)) was used in 54 (67.5%) patients before hospitalisation. The proportion of re-hospitalised patients was higher among CS users in comparison with CS non-users (61.1% (n = 33) vs. 26.9% (n=7), p = 0.004). CS users were hospitalised due to infection in 9.3% vs. 0.0% in non-users. An overall infection rate as the reason of hospitalisation was increased in 24.4% CS users vs. 3.8% non-users, p< 0.05. The dose of CS correlated with SLICC/ACR DI (r=0.363, p=0.001), but did not correlate with SLEDAI (r=-0.192, p=0.089). Duration of hospitalisation was longer in case of infection (11.4 vs. 5.9 days, p = 0.000), serositis (9.4 vs. 6.2 days, p = 0.018), fever (8.9 vs. 4.7 days, p = 0.004) and neurolupus (7.4 vs. 3.4 days, p = 0.008). Hospitalisation duration had correlation with ESR (r = 0.284, p = 0.012), CRP (r = 0.323, p = 0.003), SLEDAI (r = 0.237, p =0.034), total count of leukocytes (r = -0.317, p = 0.004), and neutrophils (r = -0.287, p = 0.01).

Conclusion: The most common cause of hospitalisation in SLE patients was a flare. More than half of SLE patients in long-term treament received CS with higher rate of hospitalisation and re-hospitalisation within a year due to infection.

Impact of Skin Involvement on Disease Burden Among Patients with Psoriatic Arthritis: Data from the Corrona Psoriatic Arthritis/Spondyloarthritis Registry

Philip Mease[1], Robert McLean[2], Taylor Blachley[2], Laura Anatale-Tardiff[3], Christopher Saffore[4], Charlie Lovan[5] and Alexis Ogdie[6], [1]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA, [2]Corrona, LLC, Waltham, MA, [3]Corrona, LLC, Waltham, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie Inc., North Chicago, [6]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: When deciding to start patients with PsA on biologic therapy, rheumatologists may focus on skin involvement in addition to joint symptoms. The purpose of this study is to investigate the clinical significance of skin involvement in patients with PsA newly initiating an advanced therapy.

Methods: This was a descriptive analysis of adult patients (≥18 years) with PsA enrolled in the Corrona PsA/SpA Registry between March 2013 and March 2020. Patients were included if they initiated an advanced therapy (i.e.,

Table 1. Demographics and Comorbidities of Patients With PsA at Initiation of Advanced Therapy

Characteristic	Body Surface Area (BSA) Category				*P* value[a]
	Overall N=574	Mild BSA ≥0% and ≤3% N=354 (62%)	Moderate BSA >3% and ≤10% N=144 (25%)	Severe BSA >10% N=76 (13%)

[a]Except where indicated otherwise, values are mean ± SD. [b]*P* value from two-sample t-tests or Wilcoxon rank sum tests. [c]Measured using a 100-point scale. [d]Measured only in patients reporting morning stiffness. ASAS HI, Assessment of SpondyloArthritis international Society Health Index; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BSA, body surface area; CDAI, Clinical Disease Activity Index; DAPSA, Disease Activity Index in Psoriatic Arthritis; HAQ-DI, Health Assessment Questionnaire-Disability Index; PASDAS, Psoriatic Arthritis Disease Activity Score; PtGA, Patient Global Assessment; PsO, psoriasis; SPARCC, Spondyloarthritis Research Consortium of Canada; VAS, visual analog scale; WPAI, Work Productivity and Activity Impairment.

biologic or targeted synthetic disease-modifying antirheumatic drug) at enrollment, had a body surface area (BSA) measurement, and had no prior history of advanced therapy at initiation. Baseline demographics, clinical characteristics, treatment history, disease activity measures, and patient-reported outcome measures were stratified by BSA categories of mild (BSA ≥0 and ≤3%), moderate (BSA >3% and ≤10%), and severe (BSA >10%). Continuous measures were reported using means and standard deviation; means for BSA groups were compared using two-sample t-tests or Wilcoxon rank sum tests. Categorical measures were reported as frequencies and percentages; frequencies in BSA groups were compared using chi-square or Fisher exact tests.

Results: A total of 574 eligible initiators included 354 (61.7%), 144 (25.1%), and 76 (13.2%) with mild, moderate, and severe skin involvement, respectively. Across BSA groups, mean age was 51.0–53.2 years and 48.7–58.1% were female (**Table 1**). TNF inhibitors were the most commonly initiated biologic (77.1–79.0%). Overall, BSA groups were very similar across baseline demographics and comorbidities. Across BSA groups, mean baseline scores were generally similar ($P>0.05$) for musculoskeletal PsA domains (tender/swollen joint, dactylitis, enthesitis counts, and axial involvement), disease activity measures (Clinical Disease Activity Index, Disease Activity in Psoriatic Arthritis, and Psoriatic Arthritis Disease Activity Score), and patient-reported outcomes of pain, Health Assessment Questionnaire-Disability Index, the Assessment of SpondyloArthritis international Society Health Index, and impairment of work productivity and ability to perform daily activities (**Table 2**). BSA groups also did not differ significantly on prior or current therapy at baseline (**Table 3**).

Conclusion: The majority of patients with PsA who initiated an advanced therapy had mild to moderate skin involvement. Moreover, baseline demographics, disease activity in musculoskeletal PsA domains, and patient-reported outcomes were comparable across mild to severe skin involvement. Although rheumatologists' treatment decisions can

Table 3. Treatment History of Patients With PsA at Initiation of Advanced Therapy

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SHR-1314 is a humanized monoclonal immunoglobulin (IgG1/κ isotype) targeting human interleukin-17A (IL-17A). Preliminary data from phase I study has shown that single dose of SHR-1314 from 8 mg to 240 mg was safe and well-tolerated in healthy subjects (data on file, Hengrui). Here, we report the interim results of a Phase II study (NCT03463187) assessing the efficacy and safety of SHR-1314 in subjects with moderate-to-severe plaque psoriasis after 12-weeks treatment.

Methods: This phase II study was conducted in 20 centers in China, Australia, and the US. Eligible subjects with moderate-to-severe chronic plaque psoriasis were randomized 1:1:1:1:1 into one of five groups to receive SHR-1314 (40 mg, 80 mg, 160 mg, or 240 mg) or placebo subcutaneously at week 0, 4, 8, and 12, followed by unblinding. The date of data cutoff for the present analyses was Dec 18, 2019, although subjects on SHR-1314 received two more drug administration on Week 16 and 20 respectively afterwards. The primary endpoint was the percentage of subjects who achieve at least 75% improvement in the psoriasis area and severity index score (PASI 75) at week 12.

Table 1. Baseline Demographics and Clinical Characteristics.

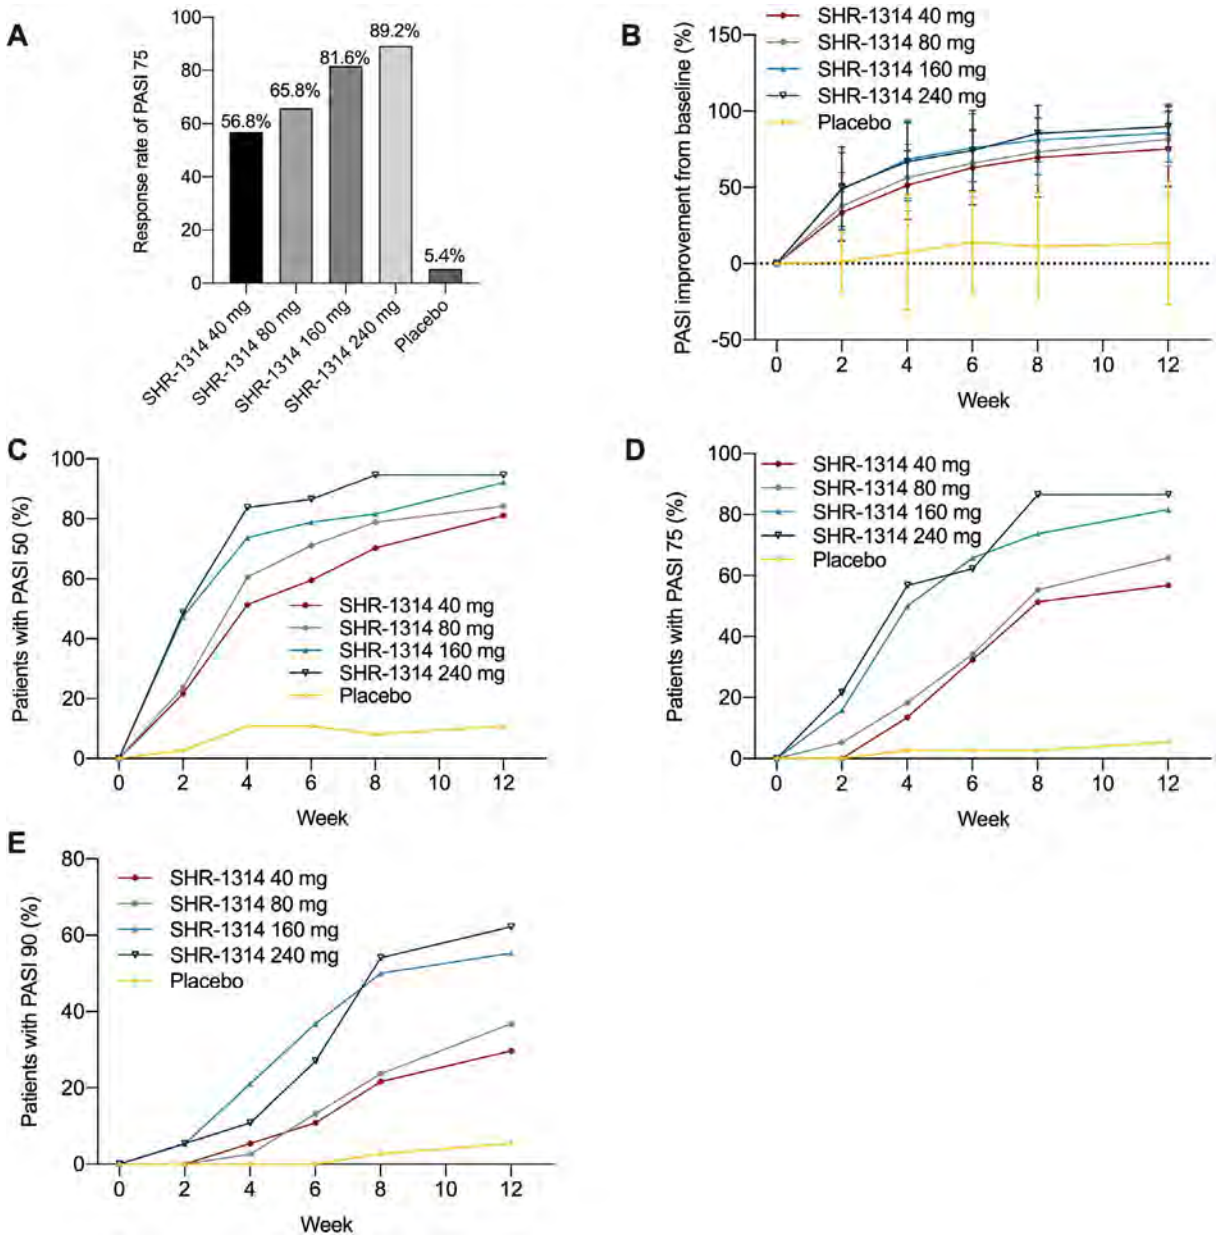

Figure 1. Changes from baseline in PASI score and response rates of PASI 50, PASI 75, and PASI 90. (A) Proportion of PASI 75 responders at week 12. Missing values are handled by LOCF (last observation carried forward). (B) Mean of percent change from baseline in PASI score. (C) Response rate of PASI 50 through Week 12. Missing values are handled by NCF (non-completers considered failure). (D) Response rate of PASI 75 through Week 12. Missing values are handled by NCF. (E) Response rate of PASI 90 through Week 12. Missing values are handled by NCF.

Results: 187 were randomized to receive SHR-1314 at a dose of 40 mg (37 subjects), 80 mg (38 subjects), 160 mg (38 subjects), or 240 mg (37 subjects), or placebo (37 subjects). Baseline demographic and disease characteristics were similar among treatment groups (Table 1). There were significantly greater proportions of PASI 75 responders in all SHR-1314 groups (40, 80, 160, 240 mg: 56.8%, 65.8%, 81.6%, 89.2%; $p< 0.001$ [calculated by Chi-square test] for every SHR-1314 group) compared to placebo (5.4%) at week 12 (Figure 1A). In comparison with placebo, greater improvements over time were observed for subjects with SHR-1314 in percent change from baseline in PASI score (Figure 1B), proportion of subjects with at least 50%, 75%, or 90% improvement from baseline in PASI (PASI 50, PASI 75, or PASI 90, Figure 1C-E), and proportion of subjects achieving physician global assessment (PGA, Figure 2) response of 0 or 1. Treatment-emergent adverse events (TEAEs) were reported in 107 (71.3%) of the 150 subjects with SHR-1314 and 24 (64.9%) of 37 subjects with placebo. The most frequent TEAEs included upper respiratory

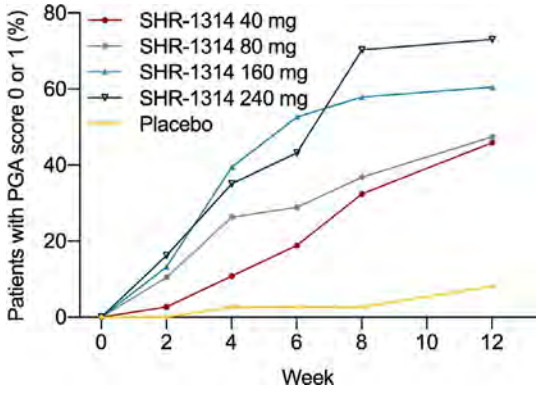

Figure 2. PGA 0 or 1 response rate through Week 12. Missing values are handled by NCF.

tract infection (SHR-1314, 13.3%; placebo, 16.2%) and hyperuricaemia (SHR-1314, 7.3%; placebo, 5.4%). Sixty-five (43.3%) subjects with SHR-1314 and 11 (29.7%) subjects with placebo had treatment-related TEAEs. Most of TEAEs were mild or moderate. Serious TEAEs occurred in one (0.7%) subject with SHR-1314 and two (5.4%) with placebo, none were considered as treatment-related. One (0.7%) subject with SHR-1314 and one (2.7%) with placebo discontinued treatment due to TEAEs. No deaths were reported.

Conclusion: SHR-1314 showed superior efficacy compared to placebo in all groups in subjects with moderate-to-severe plaque psoriasis. 240 mg dosing led to numerically higher PASI 75 responders by week 12 than other doses. SHR-1314 was well-tolerated in the present trial.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab, a fully human monoclonal antibody that neutralizes interleukin-17A, has shown long-term efficacy and tolerability in patients with psoriatic arthritis (PsA) in FUTURE 2. Tender joint count (TJC) and swollen joint count (SJC) scores measure synovitis, a key assessment of disease activity. TJC and SJC scores are components of composite measures used to assess joint response to treatment. It is known that response

[a]SEC 150 mg arm includes 42 patients who were uptitrated to SEC 300 mg from Week 128.

[b]PBO–SEC 150 mg arm includes 19 patients who were uptitrated to SEC 300 mg from Week 128. Data are reported as observed.

N=number of randomized patients; n=number of patients with evaluation.

IR, inadequate response; MTX, methotrexate; PBO, placebo; PsA, psoriatic arthritis; SC, subcutaneous; SD, standard deviation; SEC, secukinumab; SJC, swollen joint count; TJC, tender joint count; TNFi, tumor necrosis factor inhibitor.

Table 2. 78 TJC and 76 SJC results at Weeks 24 and 260

4, and every 4 weeks thereafter. Patients receiving placebo were re-randomized to secukinumab 300 or 150 mg at Week 16 (non-responders) or 24 (responders). Secukinumab dose could be escalated from 150 to 300 mg or from 75 to 150 or 300 mg starting at Week 128 and maintained thereafter, if active signs of disease were observed based on physician's assessment. ACR20 response and changes in 78 TJC/76 SJC are reported over 5 years (2 years of core study and 3-year extension) for secukinumab 300 and 150 mg (approved PsA doses) in key subgroups: TNFi-naive, TNFi-IR, and with/without concomitant MTX.

Results: Baseline characteristics were similar across treatment arms (Table 1). At baseline, 33.0%, 37.0%, and 35.7% of patients were TNFi-IR, and 44.0%, 44.0%, and 51.0% were using concomitant MTX in the secukinumab 300, 150 mg, and placebo arms, respectively. The primary endpoint, ACR20 response at Week 24, has been reported previously (McInnes, 2015). In subgroup analyses of the secukinumab 300 and 150 mg arms, 79.6% and 77.1% of TNFi-naive patients achieved an ACR20 response versus 56.3% and 66.7% of TNFi-IR patients at Week 260. At the same timepoint, 62.5% and 73.5% of patients with concomitant MTX use achieved an ACR20 response versus

84.8% and 75.0% of patients without concomitant MTX use in the secukinumab 300 and 150 mg arms, respectively. At Week 260, mean change from baseline in adjusted 78 TJC/76 SJC scores for TNFi-naive and TNFi-IR patients was –13.1/–9.5 and –12.0/–8.9 for secukinumab 300 mg, and –15.3/–8.8 and –14.4/–7.9 for secukinumab 150 mg, respectively (Table 2). At Week 260, mean change from baseline in adjusted 78 TJC/76 SJC scores for patients with and without concomitant MTX was –11.2/–8.9 and –14.4/–9.7 for secukinumab 300 mg, and –14.7/–9.5 and –15.4/–7.5 for secukinumab 150 mg, respectively.

Conclusion: Analysis of 78 TJC and 76 SJC scores demonstrated that treatment with secukinumab provided improvements in synovitis at Week 24, which were sustained over 5 years, irrespective of TNFi history and concomitant MTX use.

Abstract Number: 0876

Gender Differences in Baseline Clinical Characteristics Among Patients with Ankylosing Spondylitis and Non-radiographic Axial Spondyloarthritis: Data from 3 Randomized Ixekizumab Controlled Trials

Marina Magrey[1], Kurt de Vlam[2], Rebecca Bolce[3], Soyi Liu-Leage[4], Danting Zhu[4], Theresa Hunter[3], David Sandoval[3] and Irene van der Horst-Bruinsma[5], [1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]Department of Rheumatology, University of Leuven, Belgium, Leuven, Belgium, [3]Eli Lilly and Company, Indianapolis, [4]Eli Lilly and Company, Indianapolis, IN, [5]Department of Rheumatology, Amsterdam UMC, location VU University Medical Centre, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE), an anti-interleukin-17A monoclonal antibody, has demonstrated superior efficacy to placebo in the treatment of patients with axial spondyloarthritis (axSpA) (Dougados M et al., Ann Rheum Dis, 2020; Deodhar A et al., Lancet, 2020). Previous studies have shown that the clinical presentation of women and men with ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) may differ and influence treatment response (van der Horst-Bruinsma IE et al., Ann Rheum, 2019; Rusman T et al., Curr Rheumatol Rep, 2018). This analysis explored gender differences in baseline clinical characteristics among patients with AS and nr-axSpA using data from 3 randomized IXE controlled trials.

Methods: Baseline data for patients with AS before IXE treatment were integrated from COAST-V (biologic-naïve; NCT02696785) and COAST-W (prior tumor necrosis factor inhibitor inadequate response; NCT02696798). Baseline data for patients with nr-axSpA before IXE treatment from COAST-X (biologic-naïve; NCT02757352) were analyzed separately. Assessment of SpondyloArthritis International Society (ASAS) criteria was used to classify radiographic axSpA and nr-axSpA. The patients meeting the ASAS criteria for radiographic axSpA also fulfilled modified New York criteria for AS. Descriptive statistics were used to evaluate demographics and baseline clinical characteristics stratified by gender.

BASFI score, mean (SD)	6.8 (1.8)	7.0 (2.0)	6.2 (1.8)	6.7 (2.1)
SF-36 PCS score, mean (SD)	30.9 (8.3)	28.9 (8.2)	33.1 (7.7)	32.1 (7.2)
SF36 MCS score, mean (SD)	47.2 (12.7)	44.4 (12.2)	48.5 (11.3)	46.4 (13.2)

a DMARDs included methotrexate, sulfasalazine, and hydroxychloroquine. Abbreviations: AS, ankylosing spondylitis; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI; Bath Ankylosing Spondylitis Functional Index; BMI, body mass index; CRP, C-reactive protein; DMARD, disease-modifying antirheumatic drug; HLA-B27, human leukocyte antigen B27; nr-axSpA, non-radiographic axial spondyloarthritis; NRS, numeric rating scale; Q, question; SD, standard deviation; SF-36 MCS: Medical Outcomes Study 36-Item Short Form Health Survey Mental Component Score; SF-36 PCS: Medical Outcomes Study 36-Item Short Form Health Survey Physical Component Score

Results: Women were older at disease onset (AS: mean 30.1 [standard deviation 10.1]) vs. 26.5 [8.7] years; nr-axSpA: mean 32.0 [10.7] vs. 27.9 [7.7] years) and had a longer symptom duration (AS: mean 17.8 [12.2] vs. 16.7 [10.5] years; nr-axSpA: 12.3 [11.3] vs. 9.5 [9.2] years) than men. High disease activity, as measured by mean total Bath AS Disease

Activity Index (BASDAI) score, was reported for both women (AS: 7.4 [1.5]; nr-axSpA: 7.4 [1.4]) and men (AS: 7.1 [1.4]; nr-axSpA: 6.9 [1.4]). Women scored higher than men on 5 of the 6 BASDAI questions, indicating that women reported more fatigue, spinal pain, peripheral joint symptoms, discomfort and tenderness, and morning stiffness. Women also reported more spinal pain at night vs. men (AS: 7.8 [1.7] vs. 7.4 [1.5]; nr-axSpA: 7.6 [1.8] vs. 7.0 [1.8]). Anterior uveitis was more common among men than women with AS (23.8% vs. 17.9%) and more common among women than men with nr-axSpA (15.2% vs. 7.1%). The prevalence of human leukocyte antigen B27 (HLA-B27) was higher among men vs. women (AS: 86.9% vs. 79.5%; nr-axSpA: 76.3% vs. 70.7%). C-reactive protein levels were higher in men compared to women with AS (17.4 [25.5] vs. 11.2 [12.8]) but similar in patients with nr-axSpA (men: 12.1 [17.4] vs. women: 12.3 [18.5]).

Conclusion: Baseline clinical characteristics differed between genders in both patients with AS and nr-axSpA. Women were older at disease onset, experienced longer symptom duration, had more peripheral joint symptoms, and had a lower prevalence of HLA-B27 than men.

Improvements in Global Functioning and Health-related Quality of Life and Their Association with Disease Activity and Functional Improvement in Patients with Active Ankylosing Spondylitis Treated with Upadacitinib

Uta Kiltz[1], Joachim Sieper[2], Atul Deodhar[3], Patrick Zueger[4], In-Ho Song[4], Naijun Chen[4] and Désirée van der Heijde[5], [1]Rheumazentrum Ruhrgebiet, Herne, and Ruhr-University Bochum, Herne, Germany, [2]Charité Universitätsmedizin Berlin, Berlin, Germany, [3]Oregon Health & Science University, Portland, OR, [4]AbbVie Inc., North Chicago, IL, [5]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

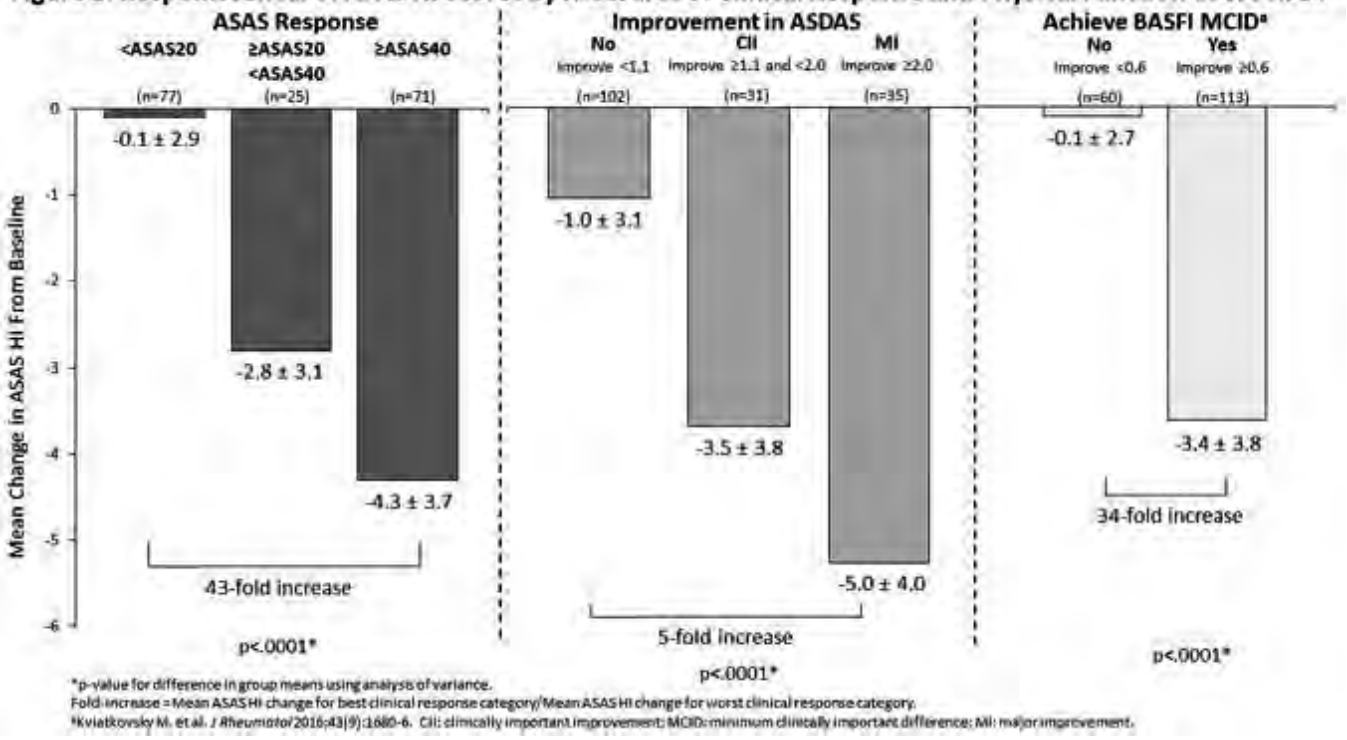
Background/Purpose: Upadacitinib (UPA) has been shown to be effective and well tolerated in patients with active ankylosing spondylitis (AS) [1]. However, improvements in global functioning and health-related quality of life (HRQoL) in patients treated with UPA, and their relationship with established clinical response measures have not been fully characterized. We evaluate the effect of UPA on the Assessment of SpondyloArthritis international Society Health Index (ASAS HI) and Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire and to quantify incremental improvements in ASAS HI and ASQoL response in patients achieving established AS disease activity and physical function improvements at week 14.

Table. ASAS HI and ASQoL Outcomes at Week 14

Outcome	ASAS HI		ASQoL	
	UPA (n=93)	PBO (n=94)	UPA (n=93)	PBO (n=94)
LSM change from baseline	-2.8[a]	-1.4	-4.2[a]	-2.7
Achievement of MCID (≥3-point improvement)[c], n/N (%)	38/85 (44.7)[b]	24/89 (27.0)	51/83 (61.4)[b]	37/86 (43.0)
ASAS HI good health state (ASAS HI score ≤5)[d], n/N (%)	33/74 (44.6)[b]	15/71 (21.1)	NA	NA

[a]p<0.05 vs PBO based on mixed-effects model for repeated measures
[b]p<0.05 vs PBO based on Cochran-Mantel-Haenszel test with non-responder imputation
[c]In patients with ASAS HI/ASQoL score ≥3 at baseline
[d]In patients with ASAS HI >5 at baseline
LSM, least squares mean; NA, not applicable

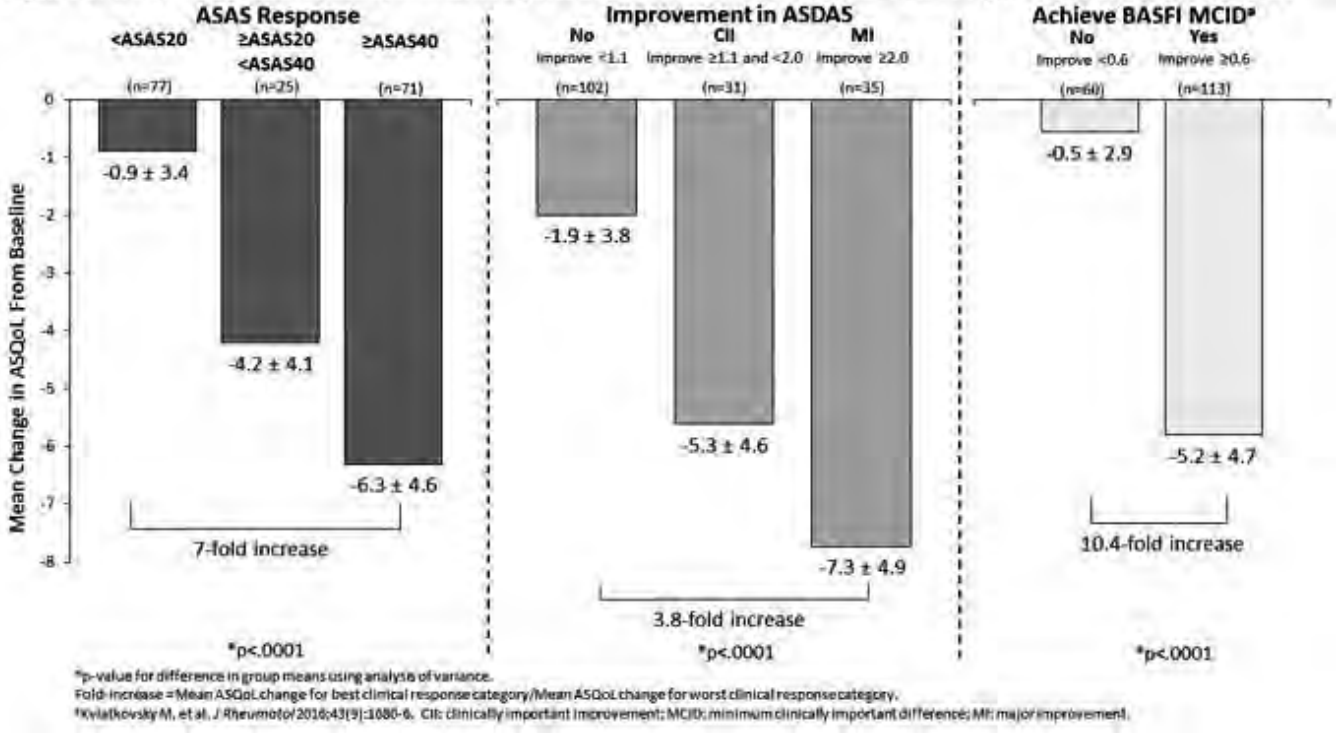
Figure 1. Responsiveness of ASAS HI Scores by Measures of Clinical Response and Physical Function at Week 14



*p-value for difference in group means using analysis of variance.
Fold-increase = Mean ASAS HI change for best clinical response category/Mean ASAS HI change for worst clinical response category.
[a]Kviatkovsky M. et al. *J Rheumatol* 2016;43(9):1680-6. CII: clinically important improvement; MCID: minimum clinically important difference; MI: major improvement.

Methods: This was a post-hoc analysis of the SELECT-AXIS 1 trial [1]. Patients were randomized to either UPA 15 mg once daily or placebo (PBO) for 14 weeks. Mean change in ASAS HI and ASQoL from baseline (BL) to weeks 4, 8 and 14 for UPA and PBO were calculated and UPA vs PBO responses were compared. Achievement of changes in ASAS HI and ASQoL above the minimum clinically important difference (MCID ≥3-point improvement for both measures) and ASAS HI 'good health state' (ASAS HI score ≤5) at week 14 were determined. Changes from BL in ASAS HI and ASQoL were assessed within the combined UPA and PBO group reaching established improvement thresholds across AS clinical response measures at week 14, including ASAS response criteria, ASDAS improvement criteria, and BASFI MCID. Mean ASAS HI and ASQoL changes across groups within each clinical measure and magnitude of ASAS HI and ASQoL change between responders and non-responders were compared.

Figure 2. Responsiveness of ASQoL Scores by Measures of Clinical Response and Physical Function at Week 14



*p-value for difference in group means using analysis of variance.
Fold-increase = Mean ASQoL change for best clinical response category/Mean ASQoL change for worst clinical response category.
[a]Kvien TK, et al. J Rheumatol 2016;43(9):1680-6. CII: clinically important improvement; MCID: minimum clinically important difference; MI: major improvement.

Results: UPA treatment resulted in significant improvement from BL in ASAS HI and ASQoL at week 14 with more patients achieving a MCID and ASAS HI good health state vs PBO (Table). Significant improvements were observed earlier for ASAS HI than for ASQoL, starting at Week 4. At week 14, achievement of clinical improvement thresholds was associated with increasing improvements in both ASAS HI and ASQoL scores (Figures 1 and 2). The magnitude of improvement between the best and worst clinical response categories was greater for ASAS HI than ASQoL: 43-fold vs 7-fold for ASAS response, 5-fold vs 3.8-fold for ASDAS improvement, and 34-fold vs 10.4-fold for BASFI MCID achievement.

Conclusion: UPA treatment in patients with active AS resulted in significant and clinically meaningful improvements compared with PBO in global functioning and HRQoL as measured by ASAS HI and ASQoL, with both measures showing discriminatory ability. Earlier UPA vs PBO response and greater magnitude of change across known clinical response groups suggests that ASAS HI may demonstrate greater responsiveness and ability to capture improvements in AS disease activity and physical function achieved with treatment and translate them to a patient-centric measure.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Absolute lymphocyte count (ALC) is a parameter that represents the number of lymphocytes (B, T, and NK cells) in the blood, and lymphopenia often accompanies rheumatologic disease. Lymphopenia, even in those without rheumatologic disease, has been associated with worse survival due to cardiovascular disease (CVD), especially when accompanied by other pro-inflammatory surrogates, including increased red cell distribution width (RDW). The connection between rheumatic disease and increased risk of atherosclerotic disease has been established, but there is lack of data on ALC levels in patients with psoriatic arthritis. We sought to test the hypothesis that alterations in immunohematologic abnormalities in the setting of psoriatic arthritis may in part reflect traditional cardiovascular risk factors, but are also driven by inflammation.

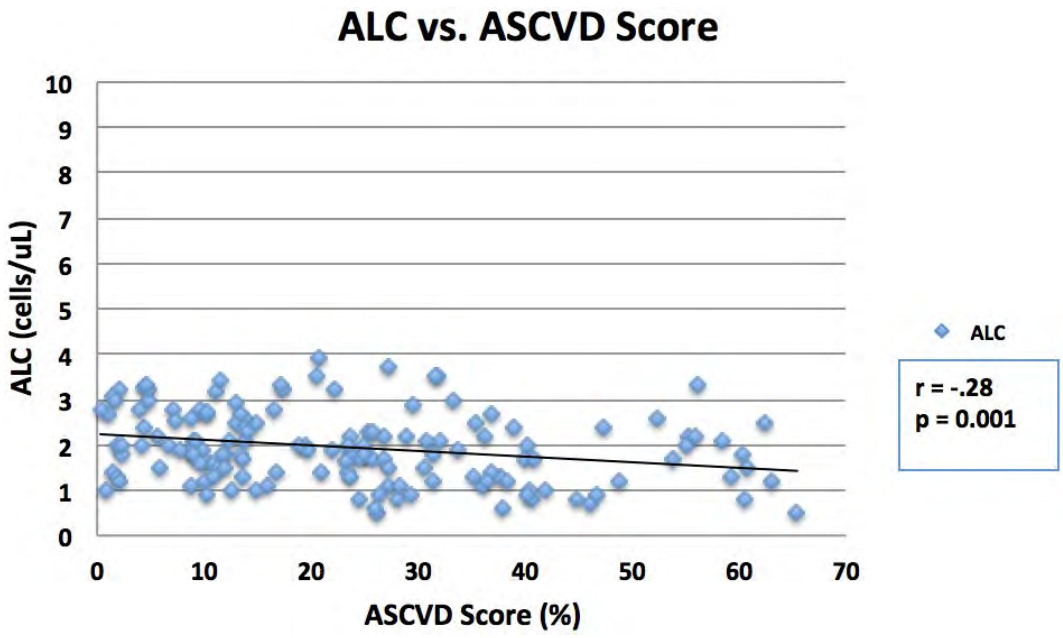

Figure 1 There was a negative, statistically significant, correlation between ALC and ASCVD risk score. As ASCVD score increased, ALC value decreased.

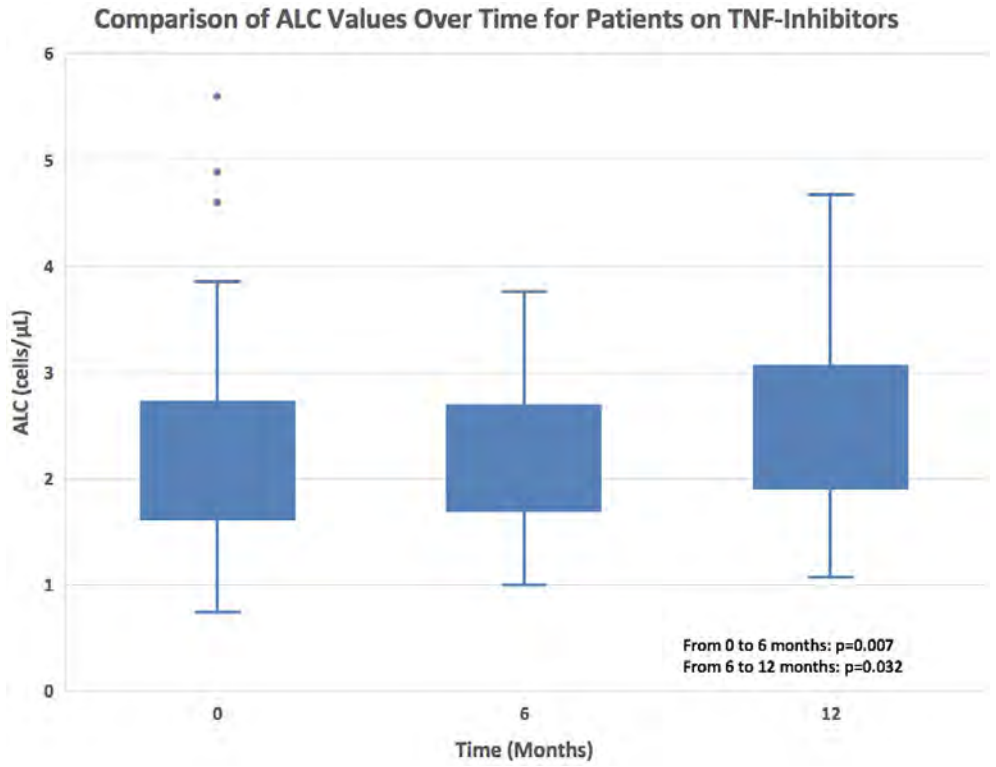

Figure 2. Patients on TNF-inhibitor therapy exhibited a statistically significant increase in ALC over the course of 12 months.

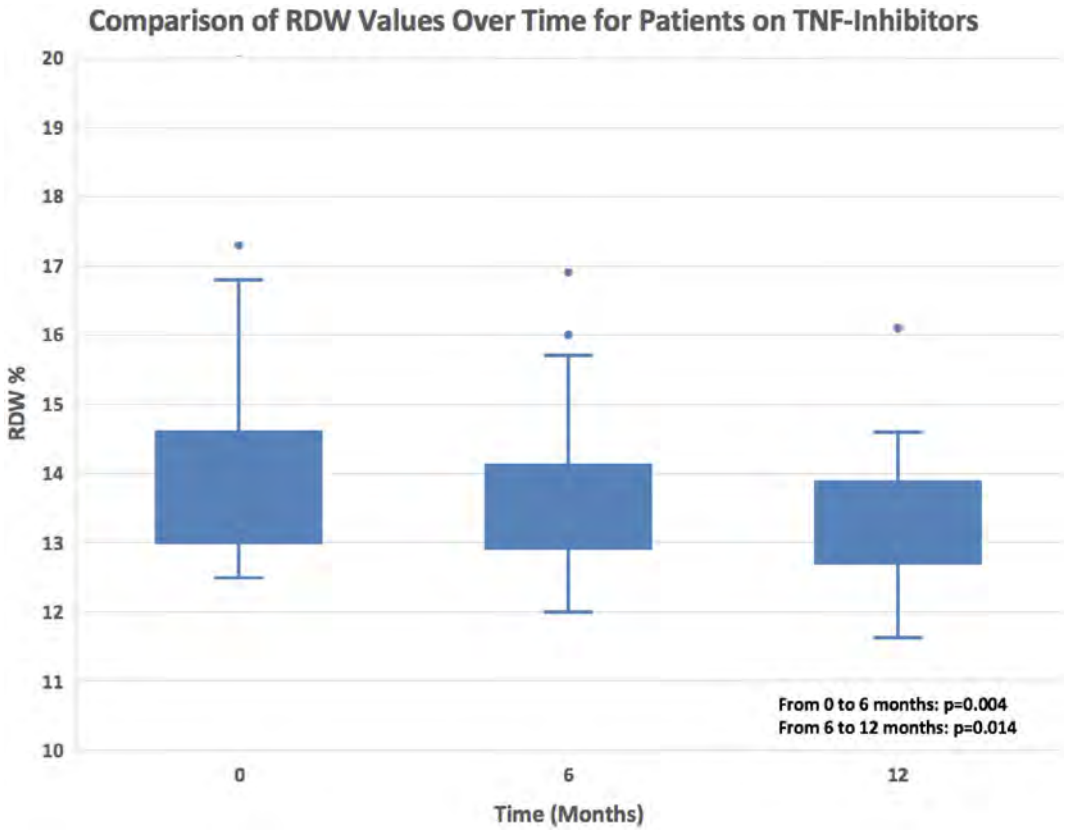

Figure 3. Patients on TNF-inhibitor therapy exhibited a statistically significant decline in RDW over the course of 12 months.

Methods: We performed a retrospective chart review study examining the relationship between ALC, RDW, and traditional atherosclerotic cardiovascular disease (ASCVD) risk in a cohort (n=170) of patients with psoriatic arthritis at the Louis Stokes Cleveland VA Medical Center. All patients had an ICD-10 diagnosis of psoriatic arthritis and either a rheumatologist confirmed diagnosis of psoriatic arthritis or met CASPAR criteria. ASCVD risk was quantified using the pooled cohort equation risk model (based on age, gender, race, presence of hypertension or diabetes, lipid profile, and smoking status). We examined patient treatment history and recorded laboratory values in relation to treatment to understand the effect of immunomodulation on these parameters. The Wilcoxon signed-rank test was used for statistical analysis.

Results: ALC was negatively correlated with ASCVD score (r=-0.28, p=0.001) (Figure 1). Positive correlations were observed between ASCVD score and RDW (r= 0.339, p=0.01), ASCVD score and ESR (r=0.20, p=.02), and negative correlations were observed between ASCVD score and albumin (r=-.20, p=.01), and ASCVD score and hemoglobin (r=-.22, p=.009). When evaluating parameters over the course of therapy, those who were started on TNF-inhibitor therapy (n=60) had an increase in ALC between time 0 and 6 months (p = 0.007), and this was maintained at twelve months (p = 0.032) (Figure 2). Patients on TNF-inhibitor therapy also experienced a decline in RDW at 6 months (p = 0.004) and at 12 months (p = 0.014) (Figure 3).

Conclusion: Our data shows that abnormal lymphocyte levels and RDW are associated with traditional cardiovascular risk factors but also tend to revert with anti-TNF therapy. Thus, correlates of immunohematologic dysfunction relevant to CVD risk may be dynamic and modified by reducing inflammation, at least in psoriatic arthritis. Future studies to define whether trajectories of ALC or RDW can improve cardiovascular disease risk stratification both in psoriatic arthritis and in the general population are warranted.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target (T2T) management strategies in inflammatory rheumatic diseases aim to prevent damage and improve overall functioning and health by treating patients towards a predefined target reflecting inactive disease/low disease activity (ID/LDA). An international task force recommended to apply this strategy also in patients with SpA (1). T2T requires regular monitoring of disease activity. Currently, it is unknown what the uptake of these recommendations is in clinical practice. The objective of this study is to evaluate the extent to which T2T is applied in daily practice in patients with axial SpA (axSpA).

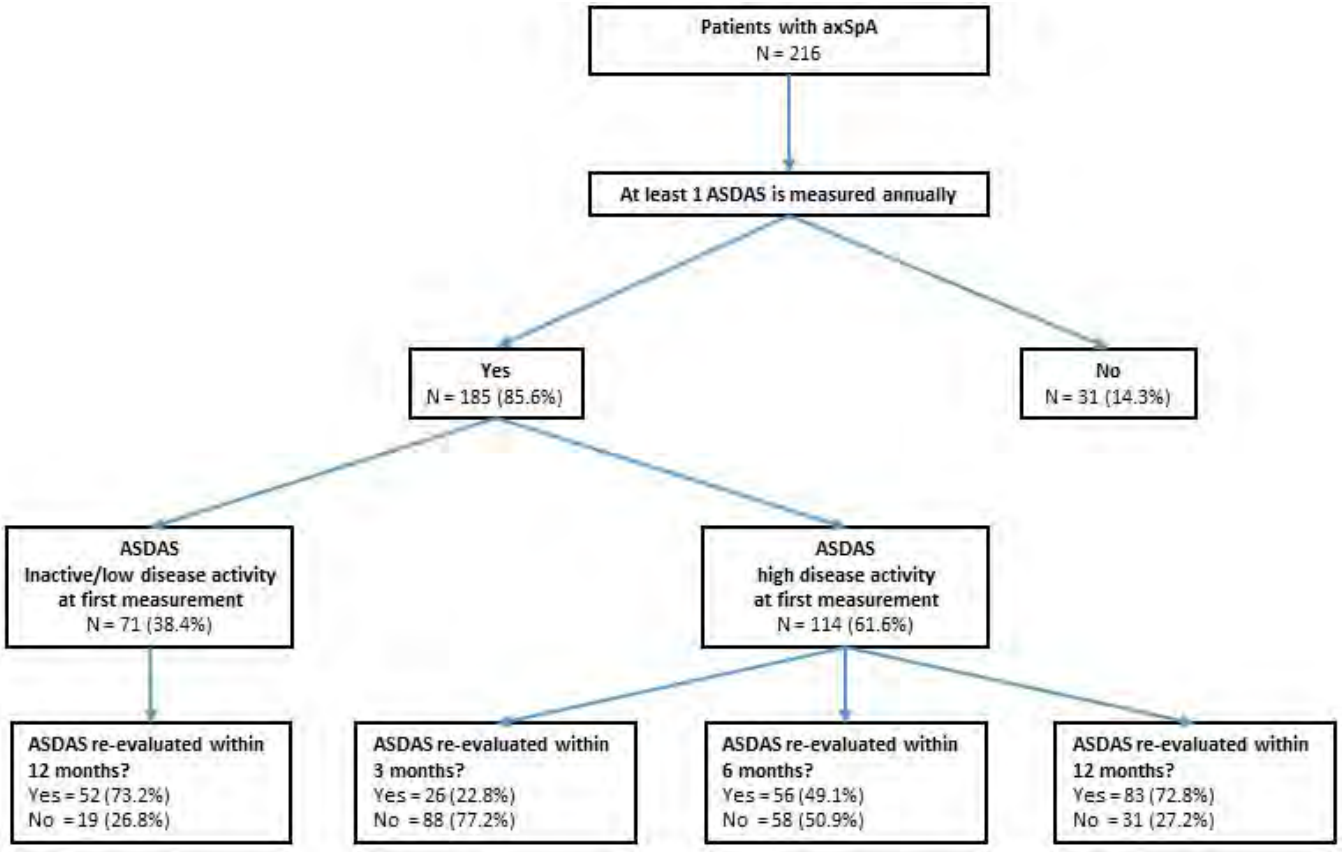

Figure 1 Flowchart of patients with axSpA and measurements of ASDAS within the study period in SpA-Net

Methods: Data were used from three rheumatology centers participating in a quality registry for SpA in the Netherlands (SpA-Net) in which patient and physician relevant outcomes are collected electronically in daily practice (2). Patients were selected if diagnosed with axSpA before July 2017, enrolled in SpA-Net before 2018 and had ≥1 patient or physician reported outcome measure available throughout 2018 (January to December). The extent to which the T2T recommendations were followed was evaluated through four endpoints: First, in which proportion of patients disease activity was measured with ≥1 Ankylosing Spondylitis Disease Activity Score (ASDAS) annually. Second, in which proportion of patients with ≥1 measurement the target of ASDAS< 2.1 was achieved. Third, in which proportion of patients with high disease activity (=ASDAS≥2.1) the ASDAS was re-evaluated within 3, 6 or 12 months, and in patients with ID/LDA (=ASDAS< 2.1) within 6 or 12 months. Fourth, in which proportion of patients pharmacological treatment for SpA was adapted within 6 weeks after obtaining ASDAS≥2.1. The clinical characteristics of patients with high disease activity in whom treatment was adapted or not adapted were compared.

Results: In 185 out of 216 patients (86%) disease activity was measured with ≥1 annual ASDAS and in 71 out of these 185 (38%) patients the target was achieved at the first measurement. In patients with high disease activity, the score was re-evaluated within 3, 6 or 12 months in 26, 56 and 83 out of 114 patients (23%, 49% and 73%, respectively, Figure 1). The proportion of patients in whom disease activity was re-evaluated within 12 months was the same in patients with ID/LDA and with high disease activity (73% and 73%, respectively). In 24 out of 114 (21%) patients with high disease activity at first measurement, treatment was adapted (Figure 2). In this group, the ASDAS and physician global assessment were significantly higher compared to patients in whom treatment was not adapted (3.3 (SD 0.7) versus 3.0 (SD 0.6), p-value< 0.05 and 3.4 (SD 2.1) versus 1.6 (SD 1.1), p-value< 0.01, respectively, Table 1).

Conclusion: Most patients with axSpA had ≥1 annual ASDAS recorded, but the target of ID/LDA was achieved in only one third of the patients at the first measurement. Subsequently, the scores do not seem to be used explicitly, as in

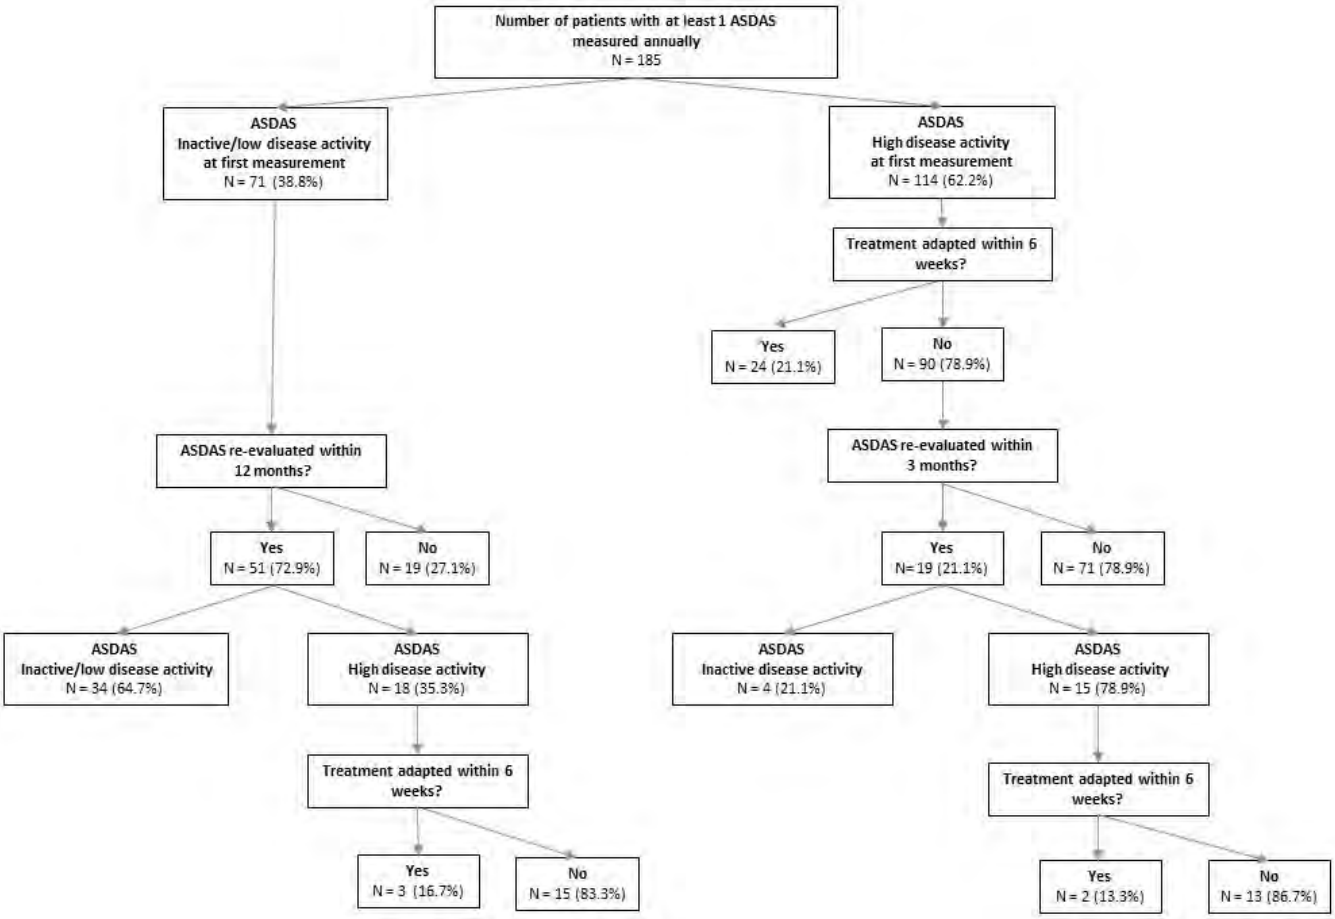

Figure 2. Flowchart of patients, re-evaluation and treatment adaptations based on ASDAS scores

patients with high disease activity re-evaluation of disease activity within recommended time periods and treatment adaptions occur only in a small proportion of patients. We conclude that T2T is applied only to a limited extent in clinical practice in patients with axSpA.

	ASDAS ≥2.1		
Patient and disease characteristics	**No adapted treatment** n = 88	**Adapted treatment** n = 26	**p-value**

Table 2. BASFI and SF-36 responses in all patients, patients with remission of peripheral enthesitis (SPARCC=0) or patients with no remission of peripheral enthesitis (SPARCC>0) at Week 16

Background/Purpose: Axial SpA (axSpA) is a chronic inflammatory disease affecting the spine and sacroiliac (SI) joints and has two subtypes that represent the spectrum of disease: radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA). The distinction between the two is defined by the presence or absence of radiographic changes at the SI joints. Both subtypes may have extra-articular manifestations such as peripheral enthesitis, increasing the disease burden and decreasing quality of life (QoL). Ixekizumab is a high-affinity monoclonal antibody that selectively targets IL-17A. It has shown efficacy in clinical trials for r- and nr-axSpA as well as psoriasis and PsA. This *post-hoc* analysis explores the efficacy of ixekizumab in improving enthesitis, overall disease activity and QoL in patients with r-axSpA, who are biologic DMARD-naïve (COAST-V) or previously exposed to TNF inhibitors (COAST-W), or patients with nr-axSpA (COAST-X).

Methods: Patients with enthesitis at baseline from three Phase 3, randomized, double-blind, placebo (PBO)-controlled studies [COAST-V (NCT02696785), COAST-W (NCT02696798), and COAST-X (NCT02757352)] examining the efficacy and safety of ixekizumab in patients with r-axSpA or nr-axSpA. Ixekizumab (80 mg) or PBO were given SC every 2 (Q2W) or 4 (Q4W) weeks during a double-blind 16-week treatment period, with a starting dose of 80 mg or 160 mg at Week 0. Here, we explore the efficacy of ixekizumab at week 16 in resolving peripheral enthesitis in patients as assessed by Spondyloarthritis Research Consortium of Canada (SPARCC). We also compare the % patients achieving Assessment of Spondyloarthritis International Society 40 (ASAS40), Ankylosing Spondylitis Disease Activity Score (ASDAS) < 2.1 and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), change from baseline (CFB) in BASFI and 36-Item Short Form Health Survey (SF36-PCS) in patients achieving and not achieving

SPARCC=0. Missing data were imputed using non-responder imputation for categorical data and modified baseline observation carried forward for continuous data.

Results: 543 Patients had enthesitis at baseline. In patients with r-axSpA, 48.6% and 67.6% achieved resolution of peripheral enthesitis (SPARCC=0) at week 16 in the IXE80Q4W and IXE80Q2W groups, respectively, compared to only 22.9% in the PBO group. For the patients with nr-axSpA, resolution of peripheral enthesitis at week 16 was observed in 52.2% and 57.7% in the IXE80Q4W and IXE80Q2W groups, respectively, while enthesitis resolved in 31.3% of PBO patients. The % of patients achieving ASDAS < 2.1 and BASDAI50 were also greater for the IXE80Q4W and IXE80Q2W groups vs PBO for both r-axSpA and nr-axSpA (Table 2). Patients with enthesitis resolution with ixekizumab showed improvements in BASFI and SF36-PCS compared to PBO for both r-axSpA and nr-axSpA (Table 3). Improvements were also seen in patients with SPARCC >0 at week 16.

Conclusion: Ixekizumab is effective in resolving enthesitis and improvements in overall disease activity and QoL in patients with r-axSpA and nr-axSpA.

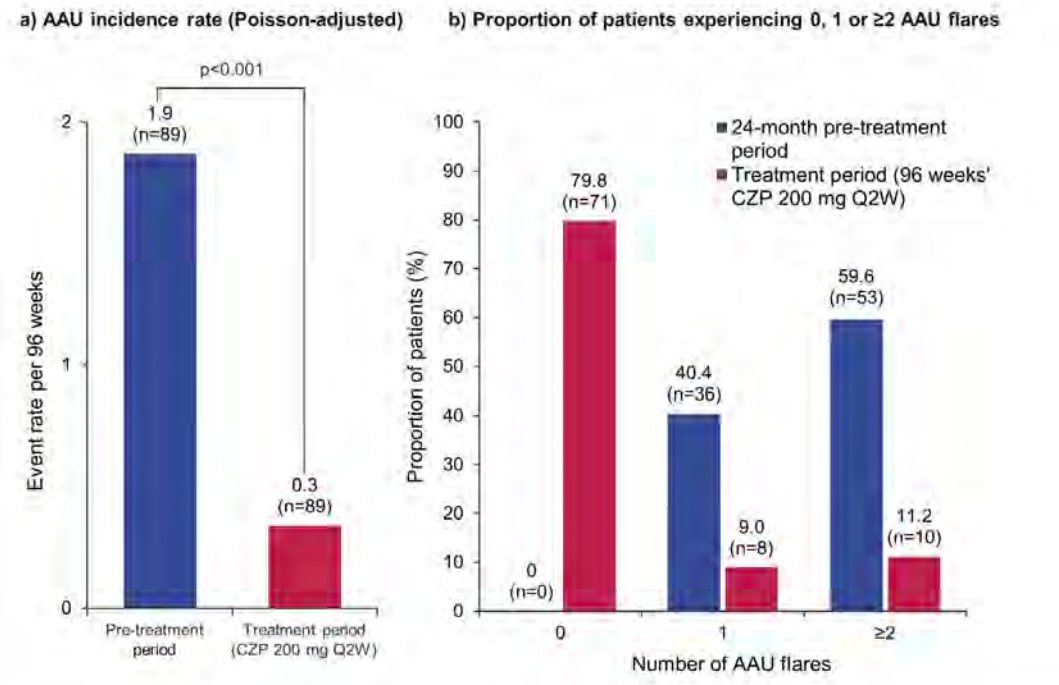
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Acute anterior uveitis (AAU) is the most common extra-articular manifestation in axial spondyloarthritis (axSpA), affecting up to 40% of patients and causing significant burden.[1] Previous studies have shown that tumor necrosis factor inhibitors (TNFi) can reduce the incidence of AAU flares in patients with radiographic axSpA (ankylosing spondylitis),[2-4] but few have focused on patients across the full axSpA spectrum. We report 2-year outcomes from the phase 4, open-label C-VIEW study (NCT03020992), which investigated the impact of certolizumab pegol (CZP) treatment on AAU in patients with active axSpA and a recent history of AAU.

Figure 1: Summary of AAU flares (observed data)



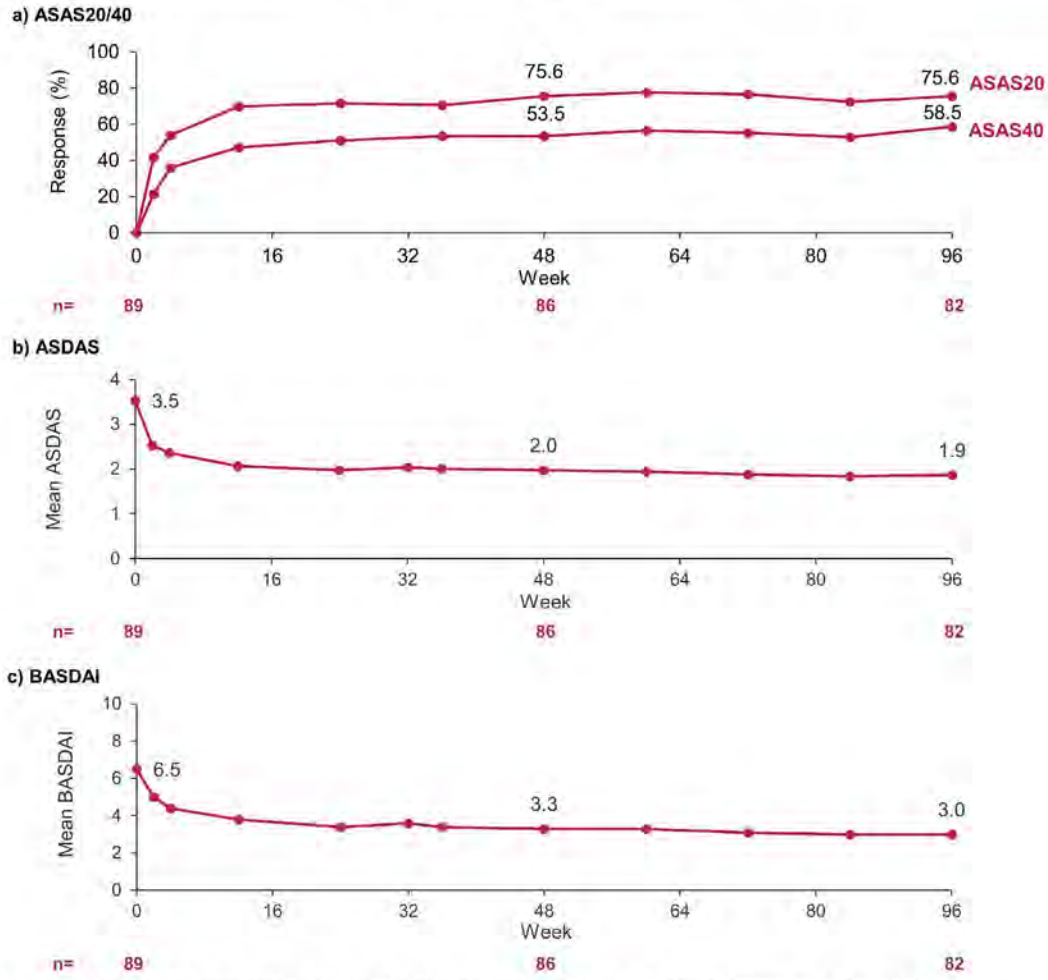
Treatment period: after start of study medication until Week 96 or discontinuation visit. Pre-treatment period: 24 months prior to treatment start. Flares on the same eye are combined and counted as one flare if the time interval between two subsequent flares is <3 months (90 days). Patients received CZP 400 mg at Weeks 0/2/4, then 200 mg Q2W through 96 weeks. a) Poisson regression analysis, with period (pre-/post-baseline) and axSpA disease duration as covariates and adjusting for the length of time in the pre- and post-baseline periods. AAU: acute anterior uveitis; CZP: certolizumab pegol; Q2W: every 2 weeks.

Methods: C-VIEW prospectively investigated patients with active axSpA who were HLA-B27 positive and had recurrent AAU, with a history of ≥1 AAU flare in the year prior to baseline (additional study criteria and study design are described elsewhere[5]). The primary efficacy variable was the incidence of AAU flares during 96 weeks of CZP treatment versus the 2-year pre-baseline period. AAU incidence was evaluated using Poisson regression adjusted for duration of time in each period, with period (pre- and post-baseline) and axSpA disease duration as covariates. Secondary efficacy variables were Assessment of SpondyloArthritis international Society 20%/40% (ASAS20/40) response rates, as well as mean Ankylosing Spondylitis Disease Activity Score (ASDAS) and mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) to Week 96.

Results: Of 115 enrolled patients, 89 initiated CZP treatment; 83 completed Week 96. The primary analysis revealed an 82% reduction in the incidence of AAU flares during CZP treatment compared with pre-baseline (**Figure 1**; rate ratio [95% CI]: 0.18 [0.12, 0.28], p< 0.001). The percentage of patients experiencing ≥1 and ≥2 AAU flares reduced from 100% and 59.6% pre-baseline to 20.2% and 11.2% during treatment. There were also improvements in axSpA disease activity (**Figure 2**): by Week 96, 75.6% and 58.5% of patients had achieved ASAS20 and ASAS40 responses, respectively. ASDAS and BASDAI also improved substantially over the 96-week treatment period. No new safety signal was identified, compared to previous reports.[5]

Conclusion: These data support the use of CZP for the treatment of patients with axSpA and a history of recurrent AAU. During 96 weeks' CZP treatment, there was a significant reduction of 82% in the AAU flare rate compared to pre-baseline. There were also substantial improvements in patients' axSpA disease activity.

Figure 2: Changes in axSpA disease activity to Week 96 (observed data)



Patients received CZP 400 mg at Weeks 0/2/4, then 200 mg Q2W through 96 weeks. ASAS20/40: Assessment of SpondyloArthritis international Society 20%/40% response; ASDAS: Ankylosing Spondylitis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CZP: certolizumab pegol; Q2W: every 2 weeks.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is a key feature of all types of spondyloarthritis (SpA) that substantially contributes to the overall burden of disease. Inhibition of the key effector cytokines of enthesitis, IL-17, IL-23, and TNF, has proved effective in resolution of PsA and axial (ax)SpA.[1] Secukinumab (SEC) is a fully human monoclonal antibody that directly inhibits IL-17A and significantly reduces entheseal inflammation in patients (pts) with PsA.[2] The clinical efficacy and safety outcomes from the ACHILLES trial in a heterogeneous SpA population (PsA and axSpA pts) with enthesitis at the Achilles tendon treated with SEC are presented.

Methods: ACHILLES study included pts (≥18 years) with a diagnosis of active PsA (CASPAR criteria and ≥1 TJC and SJC) or axSpA (ASAS axSpA criteria and total BASDAI ≥4) and MRI-positive heel enthesitis (according to the investigator's judgement) refractory to standard treatment. Pts were randomized to receive s.c. SEC 150 mg, 300 mg or placebo (PBO) at baseline, Weeks (Wks) 1, 2, 3 and 4, followed by once every 4 wks. At Wk 24, pts on PBO were switched to SEC 150 or 300 mg. The primary endpoint was the proportion of pts achieving resolution of Achilles tendon enthesitis at the affected foot (assessed by the respective subcomponent of Leeds Enthesitis Index, LEI) with SEC vs PBO at Wk 24. Assessments at Wks 24 and 52 included LEI, heel pain (by NRS [0-10]), physician's and pt's heel enthesopathy activity and global assessment of disease activities (by VAS [0–100]), and quality of life (QoL, SF-36 v2). Analysis comparing treatments with respect to the primary efficacy variable used a logistic regression model and continuous variables were analyzed using an Analysis of covariance model. Missing values were handled using mixed-effects model repeated measures and last observation carry forward method.

Results: A total of 204 pts (128 PsA, 76 axSpA) were included (SEC, N=102; PBO, N=102; **Table 1**). A numerically higher percentage of SEC-treated pts, though not statistically significant vs PBO, reported resolution of Achilles tendon enthesitis at the affected foot (42.2% vs 31.4%) and in LEI (33.3% vs 23.5%) at Wk 24 (**Table 2**); statistically significant LEI improvement was achieved in PsA pts treated with SEC vs PBO (35.9% vs 18.8%, p=0.025). Pts with a BMI < 30 kg/m^2 improved considerably with SEC vs PBO (49.2% vs 24.6%). Heel pain significantly improved in SEC-treated pts vs PBO (**Table 2**). Significant improvements in physician and pt reported heel enthesopathy activity along with physician and pt global assessment of disease activity were observed in SEC-treated pts vs PBO. SEC

Variables Mean (SD) unless otherwise specified	SEC 150 or 300 mg s.c. N=102	Placebo N=102

Table 1. Demographics and Baseline Characteristics

provided sustained improvements in all efficacy endpoints through Wk 52. The safety profile of SEC was consistent with previous studies.

Conclusion: Although SEC was not significantly superior to PBO in the resolution of Achilles tendon enthesitis as assessed by the LEI subcomponent at the affected foot, it significantly improved the burden of heel enthesitis, global disease activity, and QoL in pts with active SpA refractory to standard treatment.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease-modifying anti-rheumatic drugs (bDMARDs) have demonstrated large clinical improvements in patients with non-radiographic axial spondyloarthritis (nr-axSpA), with patients naïve to bDMARDs experiencing substantial benefits; additional treatments are also becoming available. The aim of this network meta-analysis (NMA) was to compare efficacy of various bDMARDs in bDMARD-naïve adult patients with nr-axSpA.

Methods: A systematic literature review (SLR) identified randomized controlled trials (RCTs) published on bDMARDs in adult patients with axSpA who failed at least one non-steroidal anti-inflammatory drug. RAPID-axSpA (NCT01087762) and C-axSpAnd (NCT02552212) clinical study reports informed clinical efficacy of certolizumab pegol (CZP). After evaluation of the evidence, trials assessing the efficacy of bDMARDs in initially bDMARD-naïve nr-axSpA populations/subpopulations were analyzed. Fixed-effects Bayesian NMAs were conducted to compare treatments of interest; fixed-effects models were employed due to limited data. At 12–16 and 52 weeks, the Assessment of SpondyloArthritis international Society 40% response (ASAS40) was evaluated with odds ratios (ORs) and 95% credible intervals (CrIs).

Results: The SLR identified 10 trials evaluating nr-axSpA patients, of which seven were considered comparable for the NMA. Trials primarily evaluated bDMARD-naïve patients, while others reported data for bDMARD-naïve subgroups. Identified bDMARDs included adalimumab (ADA), CZP, etanercept (ETN), golimumab (GOL), ixekizumab (IXE), and secukinumab (SEC), encompassing tumor necrosis factor inhibitors (TNFi) and anti-interleukin (anti-IL) agents. From these trials, RAPID-axSpA (CZP), ABILITY-1 (ADA), EMBARK (ETN), and GO-AHEAD (GOL) reported

Table: NMA results for CZP vs other bDMARDs in bDMARD-naïve Patients

Comparison	ASAS40 OR (95% CrI)	
	12–16 weeks	52 weeks
CZP pooled vs ADA 40 mg	2.14 [0.87, 5.18]	NA
CZP pooled vs ETN 50 mg	2.75 [1.17, 6.37]	NA
CZP pooled vs GOL 50 mg	1.60 [0.71, 3.55]	NA
CZP pooled vs SEC 150 mg	4.07 [2.13, 7.95]	2.94 [1.45, 5.92]
CZP pooled vs IXE 80 mg Q2W	2.45 [1.06, 5.54]	2.35 [0.96, 5.75]
CZP pooled vs IXE 80 mg Q4W	3.01 [1.30, 6.83]	2.50 [1.01, 6.09]

CZP pooled includes both 200 mg Q2W and 400 mg Q4W. SEC 150 mg includes regimens with and without loading dose. ADA: adalimumab; ASAS40: Assessment of SpondyloArthritis international Society 40% response; bDMARD: biologic disease-modifying anti-rheumatic drug; CrI: credible interval; CZP: certolizumab pegol; ETN: etanercept; GOL: golimumab; IXE: ixekizumab; NA: not applicable; OR: odds ratio; Q2W: every two weeks; Q4W: every four weeks; SEC: secukinumab

data only at 12–16 weeks; C-axSpAnd (CZP), PREVENT (SEC), and COAST-X (IXE) reported data at both 12–16 and 52 weeks. At 12–16 weeks (**Table**), CZP demonstrated the greatest odds of ASAS40 compared with SEC (OR [95% CrI]: 4.07 [2.13, 7.95]), with significantly greater odds of response vs ETN or IXE every two weeks (Q2W), and IXE every four weeks (Q4W). Treatment advantage for CZP vs ADA and GOL in ASAS40, while numerically greater, did not reach statistical significance. At 52 weeks (**Table**), CZP demonstrated significantly greater odds of ASAS40 response compared to SEC (2.94 [1.45, 5.92]) and IXE Q4W (2.50 [1.01, 6.09]); advantages for CZP compared to IXE Q2W for ASAS40 did not reach statistical significance. Exploration of statistical heterogeneity was limited by the fact that only one study per treatment was identified for all treatments but CZP.

Conclusion: In bDMARD-naïve patients with nr-axSpA, CZP showed increased odds of an ASAS40 response vs most bDMARDS investigated at 12–16 weeks, and vs anti-IL agents investigated at 52 weeks.

Comparison of Disease Control Thresholds in Psoriatic Arthritis: Results from the Corrona Psoriatic Arthritis/Spondyloarthritis Registry

Philip Mease[1], Robert McLean[2], Taylor Blachley[2], Laura Anatale-Tardiff[3], Christopher Saffore[4], Patrick Zueger[4] and Alexis Ogdie[5], [1]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA, [2]Corrona, LLC, Waltham, MA, [3]Corrona, LLC, Waltham, [4]AbbVie Inc., North Chicago, IL, [5]University of Pennsylvania, Philadelphia, PA

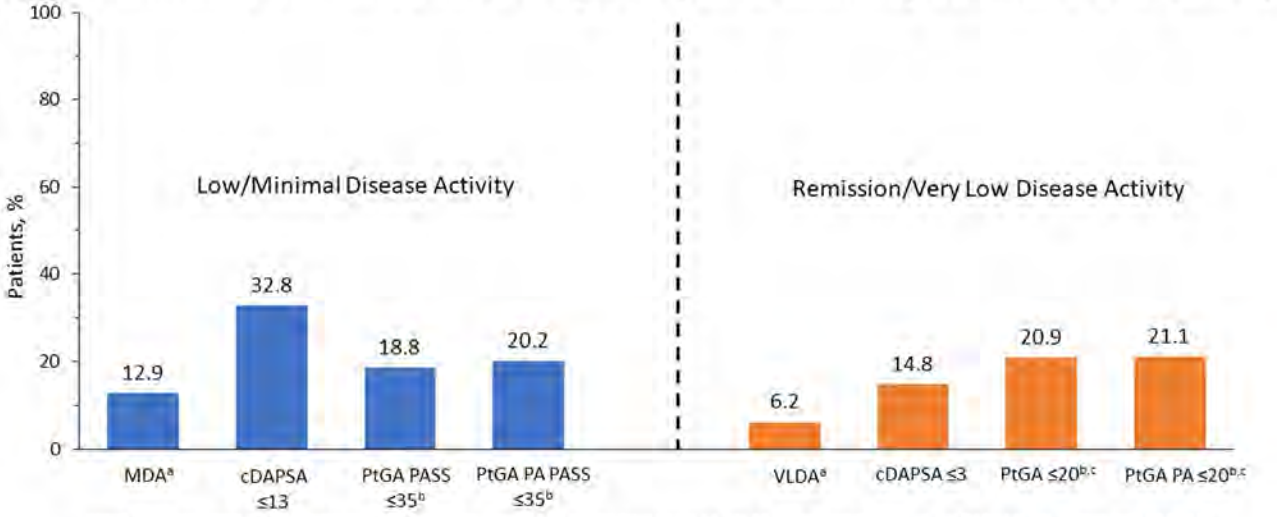
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is no single accepted measure of low/minimal disease activity (LDA/MDA) for patients with PsA; thus, describing the characteristics of real-world patients meeting different criteria will provide insight as to the most appropriate criteria for assessing disease control. The aim of this study was to identify and characterize patients with PsA who met LDA/MDA and remission/very low disease activity (VLDA) criteria by multiple measures of PsA disease severity.

Methods: This was a cohort study of patients (≥18 years) who enrolled in the Corrona PsA/SpA Registry between March 2013 and March 2020. Patients who received a biologic DMARD or Janus kinase inhibitor at enrollment, had a 6-month follow-up visit, and were not in a state of LDA/MDA at baseline were included. Percentages of patients who achieved LDA/MDA, remission/VLDA, and Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA) thresholds at 6-month follow-up were identified. We also examined the patient accepTable symptom state (PASS) for Patient Global Assessment (PtGA) and PtGA of Psoriasis and Arthritis (PtGA PA) using published cutoffs and examined how these exploratory thresholds compared with MDA, VLDA, and cDAPSA thresholds at 6 months. Clinical characteristics were assessed in patients who met disease thresholds at 6 months. Continuous measures were reported as means and standard deviations and categorical measures as frequencies and percentages.

Results: A total of 287 and 569 patients were eligible for the LDA/MDA and remission/VLDA analyses, respectively. Most patients were taking a TNF inhibitor at baseline. The proportion of patients who achieved LDA/MDA at 6 months differed across the LDA/MDA measures (**Figure 1**). MDA had the lowest rate (12.9%) of achievement vs cDAPSA

Figure 1. Achievement of Various Low Disease Activity and Very Low Disease Activity Measures at 6-Month Follow-up



[a]MDA was achieved if 5 of the following 7 criteria were met: (1) 68 tender joint count ≤1, (2) 66 swollen joint count ≤1, (3) BSA ≤3%, (4) patient pain VAS ≤15, (5) PtGA PA VAS ≤20, (6) HAQ-DI ≤0.5, (7) SPARCC enthesitis count ≤1. VLDA was achieved if all 7 of the preceding criteria were met. [b]Measured on a 0–100 numeric scale. [c]There is no established cut-off point for 'very low symptom state' for PtGA PASS or PtGA PA PASS; thus, these cut-off points are considered exploratory. There are more patients in the Remission/VLDA group than in the MDA/LDA group (569 vs 287), so the percentage of patients achieving more stringent conditions appears artificially greater than those achieving less stringent conditions. BSA, body surface area; cDAPSA, Clinical Disease Activity Index for Psoriatic Arthritis; HAQ-DI, Health Assessment Questionnaire-Disability Index; MDA, minimal disease activity; PASS, patient acceptable symptom state; PtGA, Patient Global Assessment; PtGA PA, Patient Global Assessment of Psoriasis and Arthritis; SPARCC, Spondyloarthritis Research Consortium of Canada; VAS, visual analog scale; VLDA, very low disease activity.

Table 1. Disease Activity and Patient-Reported Outcomes in Patients Achieving Various Low Disease Activity/Very Low Disease Activity Measures at 6-Month Follow-up

Low Disease Activity	**MDA[a] N=37**	**cDAPSA ≤13 N=94**	**PtGA PASS ≤35[b] N=54**	**PtGA PA PASS ≤35[b] N=58**
Tender joint count (68), mean ± SD	0.6 ± 1.8	0.8 ± 1.4	3.7 ± 7.2	3.3 ± 6.6

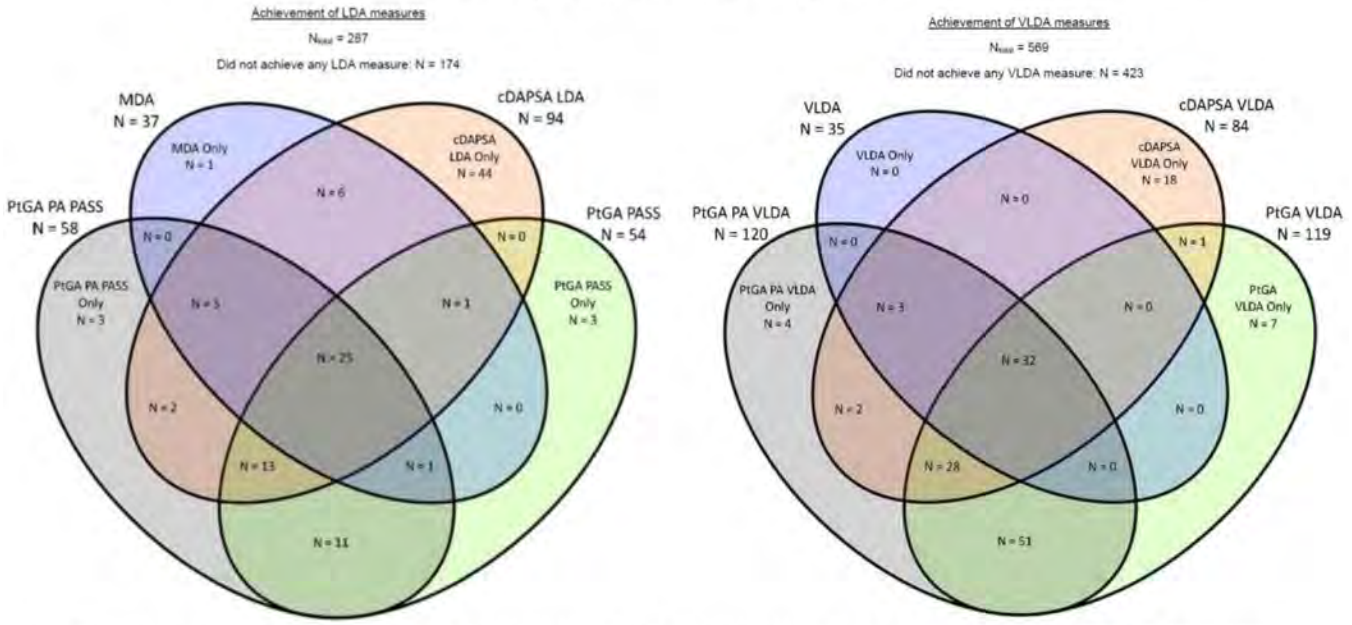
BSA (%), mean ± SD	0.6 ± 0.7	1.6 ± 2.5	2.2 ± 5.3	2.3 ± 8.1

[a]MDA was achieved if 5 of the following 7 criteria were met: (1) 68 tender joint count ≤1, (2) 66 swollen joint count ≤1, (3) body surface area (BSA) ≤3%, (4) patient pain VAS ≤15, (5) PtGA PA VAS ≤20, (6) HAQ-DI ≤0.5, (7) SPARCC enthesitis count ≤1. VLDA was achieved if all 7 of the preceding criteria were met. [b]Measured on a 0–100 numeric scale. [c]There is no established cutoff point for 'very low symptom state' for PtGA or PtGA PA; thus, these cutoff points are considered exploratory. BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BSA, body surface area; cDAPSA, Clinical Disease Activity Index for Psoriatic Arthritis; HAQ-DI, Health Assessment Questionnaire-Disability Index; LEI, Leeds Enthesitis Index; MDA, minimal disease activity; PASDAS, Psoriatic Arthritis Disease Activity Score; PASS, patient acceptable symptom state; PtGA, Patient Global Assessment of Arthritis; PtGA PA, Patient Global Assessment of Psoriasis and Arthritis; SD, standard deviation; SPARCC, Spondyloarthritis Research Consortium of Canada; VAS, visual analog scale; VLDA, very low disease activity.

Figure 2. Venn Diagrams Showing Achievement of Low Disease Activity/Minimal Disease Activity and Remission/Very Low Disease Activity Measures



cDAPSA, Clinical Disease Activity Index for Psoriatic Arthritis; LDA, low disease activity; MDA, minimal disease activity; PASS, patient acceptable symptom state; PtGA, Patient Global Assessment; PtGA PA, Patient Global Assessment of Psoriasis and Arthritis; VLDA, very low disease activity.

(32.8%) which had the highest rate. At 6 months, patients who achieved MDA reported less pain, lower tender joint, dactylitis, and enthesitis counts, less axial symptoms, and better physical function than those who met the cDAPSA, PtGA PASS, and PtGA PA PASS thresholds for LDA (**Table 1**). Percentages of patients who achieved remission/VLDA differed across remission/VLDA measures. VLDA had the lowest rate (6.2%) of achievement vs PtGA PA (21.1%) which had the highest rate at 6-month follow-up. Patients achieving VLDA reported less pain and axial involvement, and better physical function than patients achieving less stringent remission/VLDA thresholds for cDAPSA, PtGA PASS, and PtGA PA PASS (**Table 1**). Relationships among and between measures of PsA disease severity are illustrated in **Figure 2**.

Conclusion: MDA and VLDA were the most stringent disease activity measures of the respective criteria in patients with PsA and resulted in overall lower disease activity in all of the domains compared with patients who met cDAPSA, PtGA PASS, and PtGA PA PASS thresholds. Rheumatologists should be encouraged to use MDA and/or VLDA to assess disease control in their patients with PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is strongly associated with the genetic marker HLA-B27. In patients with AS, negative HLA-B27 status is a predictor of worse response to tumor necrosis factor inhibitors.[1] Approximately 80%-90% of Caucasian patients with AS express HLA-B27 compared with < 8% of the Caucasian pop-

Figure 1. Percentage of Patients With AS Achieving ASAS Responses at Week 16 (nonresponder imputation)

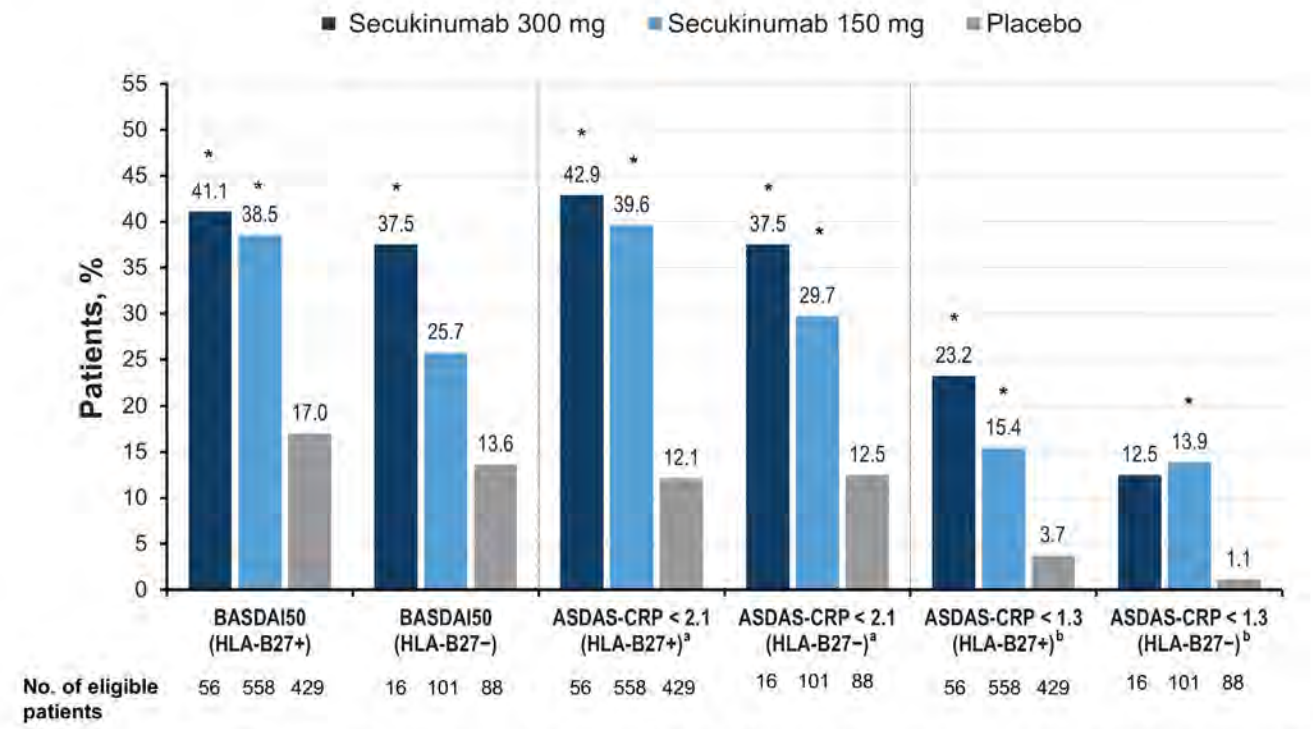
Logistic regression analysis used treatment and TNF-α inhibitor status as factors and baseline weight as a covariate.
* $P < .05$ compared with placebo.
[a] 20% improvement in ≥ 5 ASAS domains.
[b] Score of ≤ 2 in the patient global, pain, function, and inflammation domains.

Figure 2. Percentage of Patients With AS Achieving BASDAI50 and ASDAS-CRP Responses at Week 16 (nonresponder imputation)



AS, ankylosing spondylitis; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CRP, C-reactive protein; TNF-α, tumor necrosis factor α.
Logistic regression analysis used treatment and TNF-α inhibitor status as factors and baseline weight as a covariate.
* $P < .05$ compared with placebo.
[a] All patients had ASDAS-CRP of > 2.1 at baseline.
[b] All patients had ASDAS-CRP of > 1.3 at baseline.

ulation; these trends are similar in Chinese patients. The objective of this study is to analyze the impact of HLA-B27 status on clinical outcomes at Week 16 in a racially diverse population of patients with AS treated with secukinumab vs placebo.

Methods: Patients with AS were pooled from the MEASURE 1-5 studies (NCT01358175, NCT01649375, NCT02008916, NCT02159053, and NCT02896127) and stratified by HLA-B27 status. All trials included patients who received secukinumab 150 mg every 4 weeks with or without an initial loading dose (10 mg/kg IV at Weeks 0, 2, and 4 or 150 mg SC at Weeks 0, 1, 2, and 3) or placebo control. MEASURE 3 included patients receiving secukinumab 300 mg every 4 weeks following the initial IV loading dose. A large proportion of patients enrolled in MEASURE 5 were from China. Efficacy at Week 16 was determined by the proportion of patients reporting 20% improvement in Assessment of SpondyloArthritis international Society (ASAS20), ASAS40, ASAS5/6, ASAS partial remission, 50% improvement in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), and Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS-CRP) of < 2.1 or < 1.3. All outcomes were compared within HLA-B27 strata for secukinumab vs placebo using logistic regression at Week 16 with nonresponder imputation for missing data. All analyses were for hypothesis generation, without adjustment for multiple comparisons.

Results: Of 1248 patients included in this pooled analysis, 1043 (83.6%) were HLA-B27+ and 205 (16.4%) were HLA-B27−. Compared with HLA-B27− patients, HLA-B27+ patients were younger (38.6 vs 45.0 years) and more frequently male (77.1% vs 48.8%). Regardless of HLA-B27 status, patients receiving any dose of secukinumab were significantly more likely to report ASAS40, ASAS5/6, ASAS partial remission (**Figure 1**) and ASDAS-CRP of < 2.1 (**Fig-**

ure 2) than those receiving placebo ($P < .05$ for all comparisons). HLA-B27+ patients receiving any dose of secukinumab were also significantly more likely to report ASAS20, BASDAI50, and ASDAS-CRP responses vs those receiving placebo ($P < .05$) (**Figures 1 and 2**), although HLA-B27– patients experienced at least numerical improvements vs placebo in these measures. Among HLA-B27– patients, only those receiving secukinumab 300 mg were significantly more likely to report BASDAI50 response vs those receiving placebo, and only patients receiving secukinumab 150 mg were significantly more likely to have ASDAS-CRP of < 1.3 vs placebo ($P < .05$ for all comparisons) (**Figure 2**).

Conclusion: In a large pooled population of patients with AS including patients from China, secukinumab was effective regardless of HLA-B27 status, although HLA-B27+ patients experienced increased therapeutic benefit compared with HLA-B27– patients.

Chu[5] and Denis Poddubnyy[6], [1]Oregon Health & Science University, Portland, OR, [2]Cabrini Medical Center, Monash University, Malvern, Victoria, Australia, [3]AbbVie Inc., North Chicago, IL, [4]AbbVie Inc., Baar, Switzerland, [5]AbbVie, North Chicago, IL, [6]Charité – Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

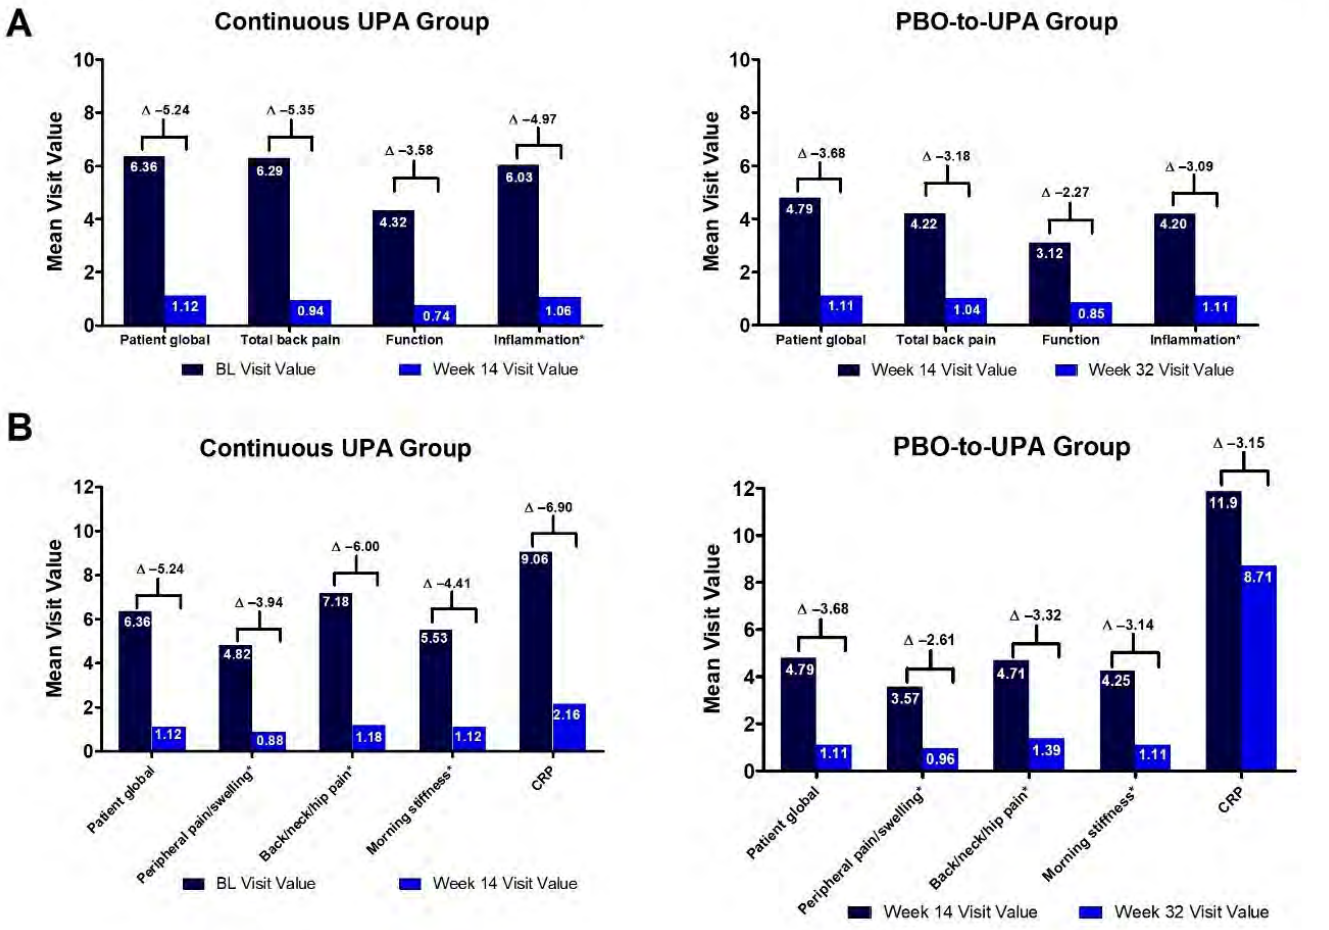
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Assessment of SpondyloArthritis international Society (ASAS) response criteria and AS Disease Activity Score (ASDAS) are both commonly used, rigorous composite indices consisting of components with relevance to patients. Clinically meaningful thresholds for these measures have been defined to reflect partial remission (PR), inactive disease (ID), and low disease activity (LDA). The objective of this analysis was to study the association of ASAS PR and ordinal ASDAS disease categories (including ASDAS ID, which is the most stringent category of this composite score) in upadacitinib (UPA)-treated patients with AS.

Figure. Core ASAS (A) and ASDAS (B) Components Among Patients Who Achieved ASAS PR



*Inflammation based on mean of BASDAI question 5 and 6; peripheral pain/swelling based on BASDAI question 3; Back/neck/hip pain based on BASDAI question 2; duration of morning stiffness based on BASDAI question 6.
ASAS, Assessment of SpondyloArthritis international Society response criteria; ASDAS, AS Disease Activity Score; PBO, placebo; PR, partial remission; UPA, upadacitinib.

Figure

Methods: In the SELECT-AXIS 1 (NCT03178487) study, biologic DMARD naïve-patients (pts; ≥18 y) with active AS and intolerance/contraindication or inadequate response to ≥2 NSAIDs were randomized 1:1 to UPA 15 mg once daily (QD) or placebo (PBO).[1] At wk 14, pts entered an open-label extension (OLE) of UPA 15 mg QD; pts randomized to PBO were switched to UPA. This post hoc analysis assessed the responsiveness of individual ASAS and ASDAS core components among pts who achieved ASAS PR. The association of ASAS PR with achievement of ASDAS ID (ASDAS < 1.3), ASDAS LDA (ASDAS < 2.1 but ≥1.3) or ASDAS high disease activity (HDA)/very HDA (VHDA) (ASDAS ≥2.1 for HDA/VHDA) was also assessed by measures including Youden index, distance to perfect point, and sensitivity/specificity equality. These evaluations were performed in pts randomized to UPA from baseline (BL; continuous UPA, assessed at wk 14) and those who were randomized to PBO and switched to UPA upon entry in the OLE (PBO to UPA; re-baselined at wk 14 and assessed at wk 32, representing 18 wks of UPA exposure).

Results: At wk 14, for the continuous UPA group, 16 pts (19%) achieved ASAS PR. At wk 32, following 18 wks of UPA exposure for the PBO-to-UPA group, 28 pts (33%) achieved ASAS PR. Among both groups (continuous UPA

Table. Association Between ASAS PR and ASDAS Clinical Thresholds (ID/LDA/HDA or VHDA)

	ASDAS ID (<1.3)	ASDAS LDA (1.3 to <2.1)	ASDAS HDA or VHDA (≥2.1)
Continuous UPA Group	n=15	n=31	n=39
ASAS PR Responders (n=16)	11	5	0
ASAS PR Non-responders (n=69)	4	26	39
PBO-to-UPA Group	n=25	n=35	n=25
ASAS PR Responders (n=28)	16	8	4
ASAS PR Non-responders (n=57)	9	27	21

P<0.001 for association of ASAS PR with the ordered ASDAS categories of ID-LDA-HDA, for both Continuous UPA Group and PBO-to-UPA Group.
P value calculated from Cochran-Armitage trend test for association of ordinal categories.
ASAS, Assessment of SpondyloArthritis international Society response criteria; ASDAS, AS Disease Activity Score; HDA, high disease activity; ID, inactive disease; LDA, low disease activity; PBO, placebo; PR, partial remission; UPA, upadacitinib; VHDA, very high disease activity.

Table

and PBO-to-UPA), improvements were seen across all core components (**Figure**). Of the 44 total pts who achieved ASAS PR, 91% achieved either ASDAS ID or LDA. The majority of patients who achieved ASAS PR achieved ASDAS ID in the continuous UPA and PBO-to-UPA groups: 11/16 (69%) and 16/28 (57%), respectively. For the continuous UPA group, the remaining 5 pts who achieved ASAS PR also achieved ASDAS LDA (**Table**). ASAS PR was associated with ASDAS categories in the following manner: the highest rate of ASAS PR was achieved for ASDAS ID followed by ASDAS LDA followed by ASDAS HDA/VHDA. The cutoff of 1.3 (the upper threshold for ASDAS ID) was a better discrimination threshold for ASAS PR than the cutoff of 2.1 (the upper threshold for ASDAS LDA).

Conclusion: Nineteen percent of pts receiving UPA from BL achieved ASAS PR after 14 wks of treatment, with similar results seen in pts who were originally randomized to PBO and switched to UPA at wk 14. A consistent improvement was seen across all core components of ASAS among those who achieved ASAS PR with UPA treatment. The achievement of ASAS PR was most closely associated with the achievement of ASDAS ID, providing further clarity on the reduction of disease activity in AS pts treated with UPA.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) treatments include steroids, antimalarials, immunosuppressants and/or biologics, though the use of biologics has been reported as minimal in claim-based studies examining real-world treatment patterns between 2006 to 2016. Here, we examine choice of treatments in the last three years within community rheumatology practices to understand current use of biologics. In addition, we examine persistence to belimumab, the most commonly used biologic for SLE, and association with different treatment and patient characteristics.

Figure 1: Percentage of patient starts by drug class

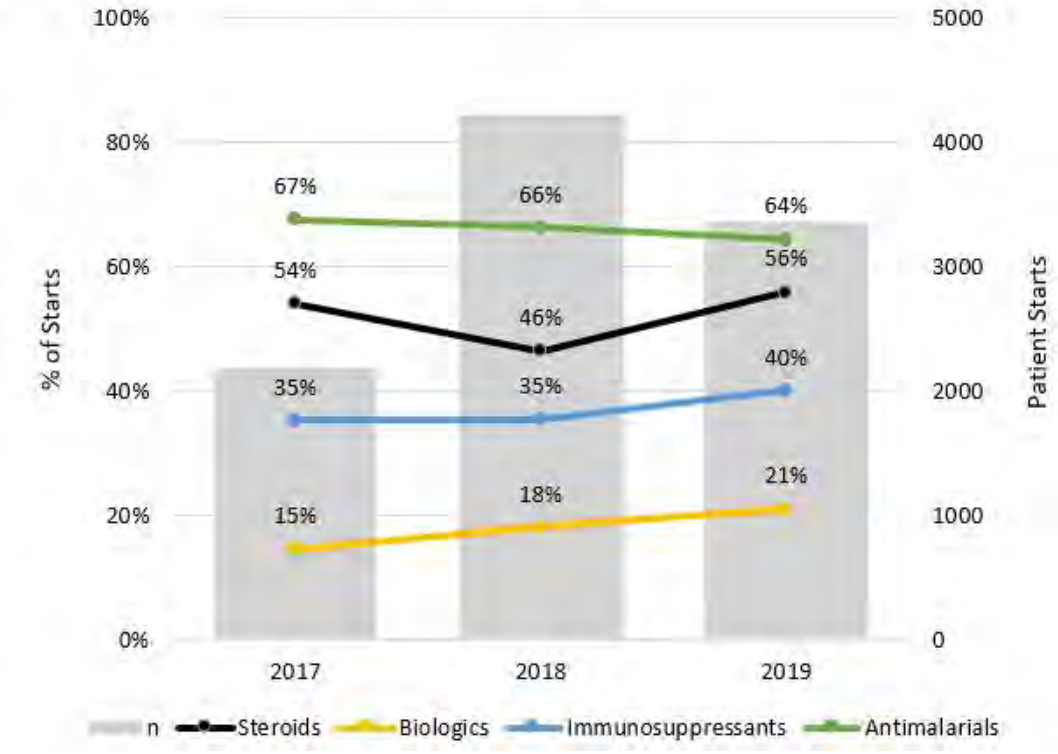

Figure 1. Percentage of patient starts by drug class

Methods: The ARN-TRIO Rheumatology registry contains EMR (fielded and open text), lab, procedure, infusion, medical claims, and specialty pharmacy data generated in care of >75,000 patients by ARN, a network of independent practices with >200 rheumatologists across the US. Data for adult (18+) patients with SLE who initiated or switched to a new treatment (starts) from Jan 2017 to May 2020 were included in this study. Comparisons between groups were made using t-test for continuous variables and chi-square or Fischer's exact tests for categorical variables. Time to events analyses were conducted by Kaplan-Meier and subsequent log-rank test.

Results: A total of 5,797 SLE patients started 10,913 distinct treatments in the observation window. Comparing starts by drug class between 2017 to 2019 indicated annualized growth rates of 20% for biologics, 7% for immunosuppressants, 2% for steroids, and -2% for antimalarials, with significant differences ($p< 0.050$) between 2019 and 2017 start percentages for all drug classes except steroids. [FIGURE 1] To compare populations receiving different drug classes, patients were classified into biologic or non-biologic groups based on initial treatment (index). [TABLE 1] At index, 91% (5,272) received non-biologic therapy; 67% (3,884) received antimalarials, 36% (2,098) steroids, and 22% (1,287) immunosuppressants. Patients treated with biologic therapies at index mostly received belimumab (66%, 347/525); rituximab was used for 11% (60/525) of patients. Compared to the non-biologic group, the biologics group differed in use of other drug classes and payer, but not in age, gender, or race. For patients receiving belimumab, the mean time to discontinuation was 838 days (25th percentile = 620 days, median not reached). Time to belimumab discontinuation differed by concomitant use of steroids, antimalarials, or immunosuppressants and these individual

*overlapping subsets within the "not on biologics" group

Table 1 Patient Characteristics at index

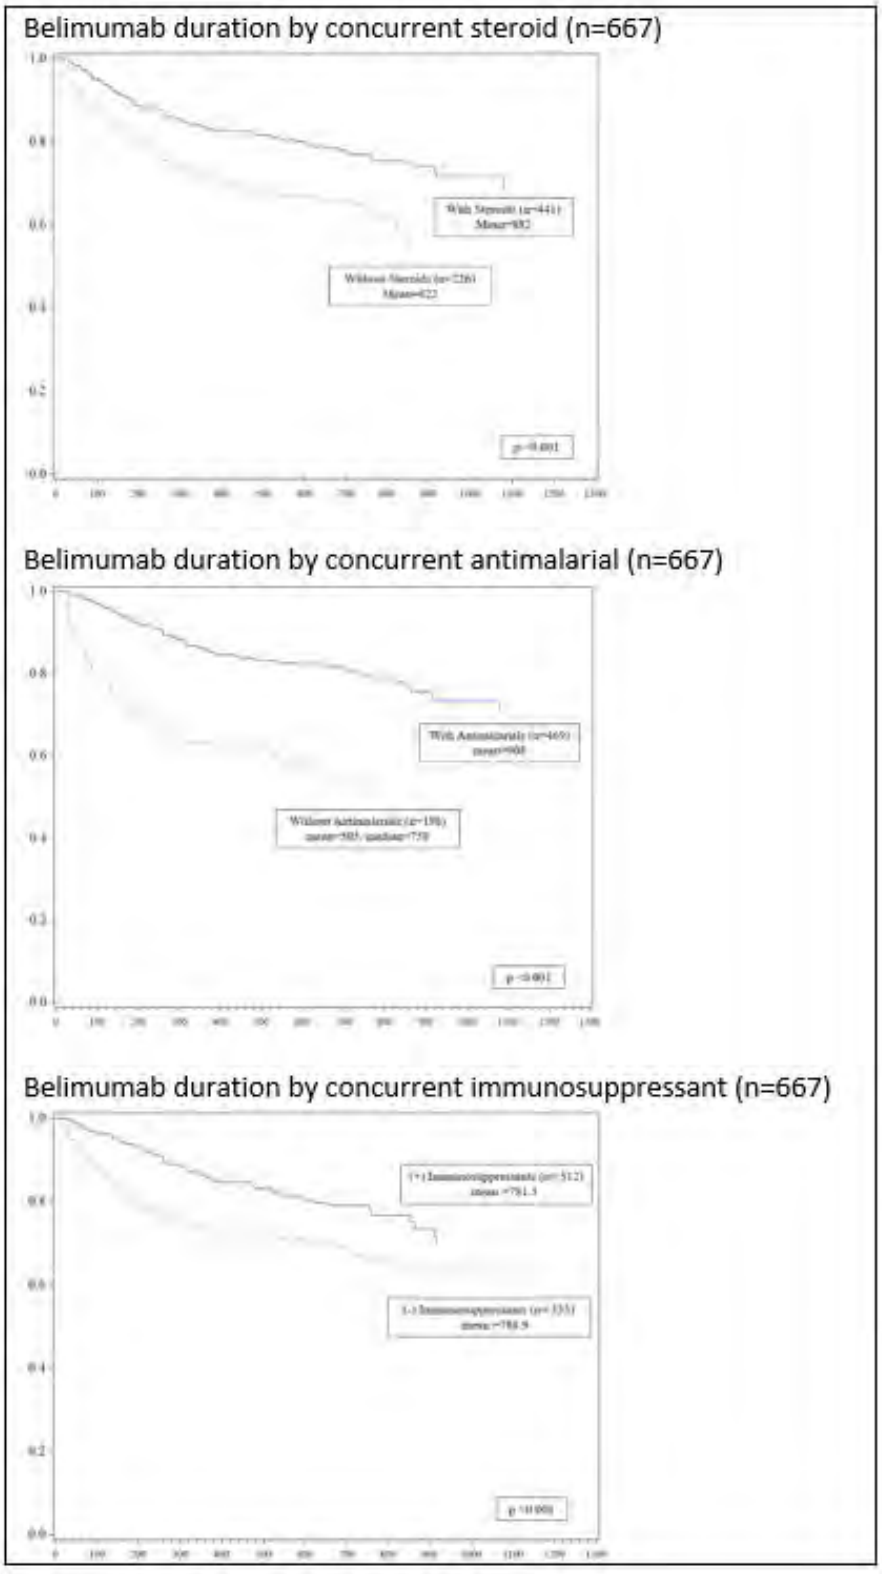

Figure 2. Days to belimumab discontinuation by concurrent drug class

associations persisted regardless of the presence of other drug classes. [FIGURE 2] Time to belimumab discontinuation was not associated with age, gender, race, or payer.

Conclusion: The use of biologics has increased considerably since 2017 though these agents are still limited to a fifth of treatment starts. Aside from a slight but significantly higher percentage with commercial coverage, the group initiating biologics was similar to the non-biologic group for patient characteristics. For patients that received belimumab, persistence on therapy was considerable and increased in populations receiving concomitant steroids, antimalarials, or immunosuppressants.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), a novel anti-IL-23 monoclonal antibody specific to the IL-23p19-subunit, is approved to treat psoriasis. Through week (W) 24 of the Phase 3, double-blind, placebo (PBO)-controlled DISCOVER-1 trial in patients (pts) with active psoriatic arthritis (PsA), significantly more pts receiving GUS 100 mg every 4 weeks (Q4W) or every 8 weeks (Q8W) vs PBO achieved ACR20 response. 31% of pts previously received 1-2 TNFα inhibitors (TNFi), and ACR20 response patterns through W24 were comparable in TNFi-naïve vs. experienced pts.[1] Here we assess GUS efficacy and safety through 1-year by prior TNFi use.

Methods: Adults with active PsA (≥3 swollen+≥3 tender joints; CRP ≥0.3mg/dL) despite standard therapies were eligible. Pts were randomized 1:1:1, stratified by W0 DMARD use [Y/N] and prior TNFi use (Y/N), to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W through W48; or PBO and then GUS 100 mg Q4W from W24-W48 (PBO→Q4W).

Table. Summary of Prior TNFi Exposure and Clinical Response by Prior TNFi Exposure Through Week 52 of DISCOVER-1 (Missing Data Imputed as Nonresponse).

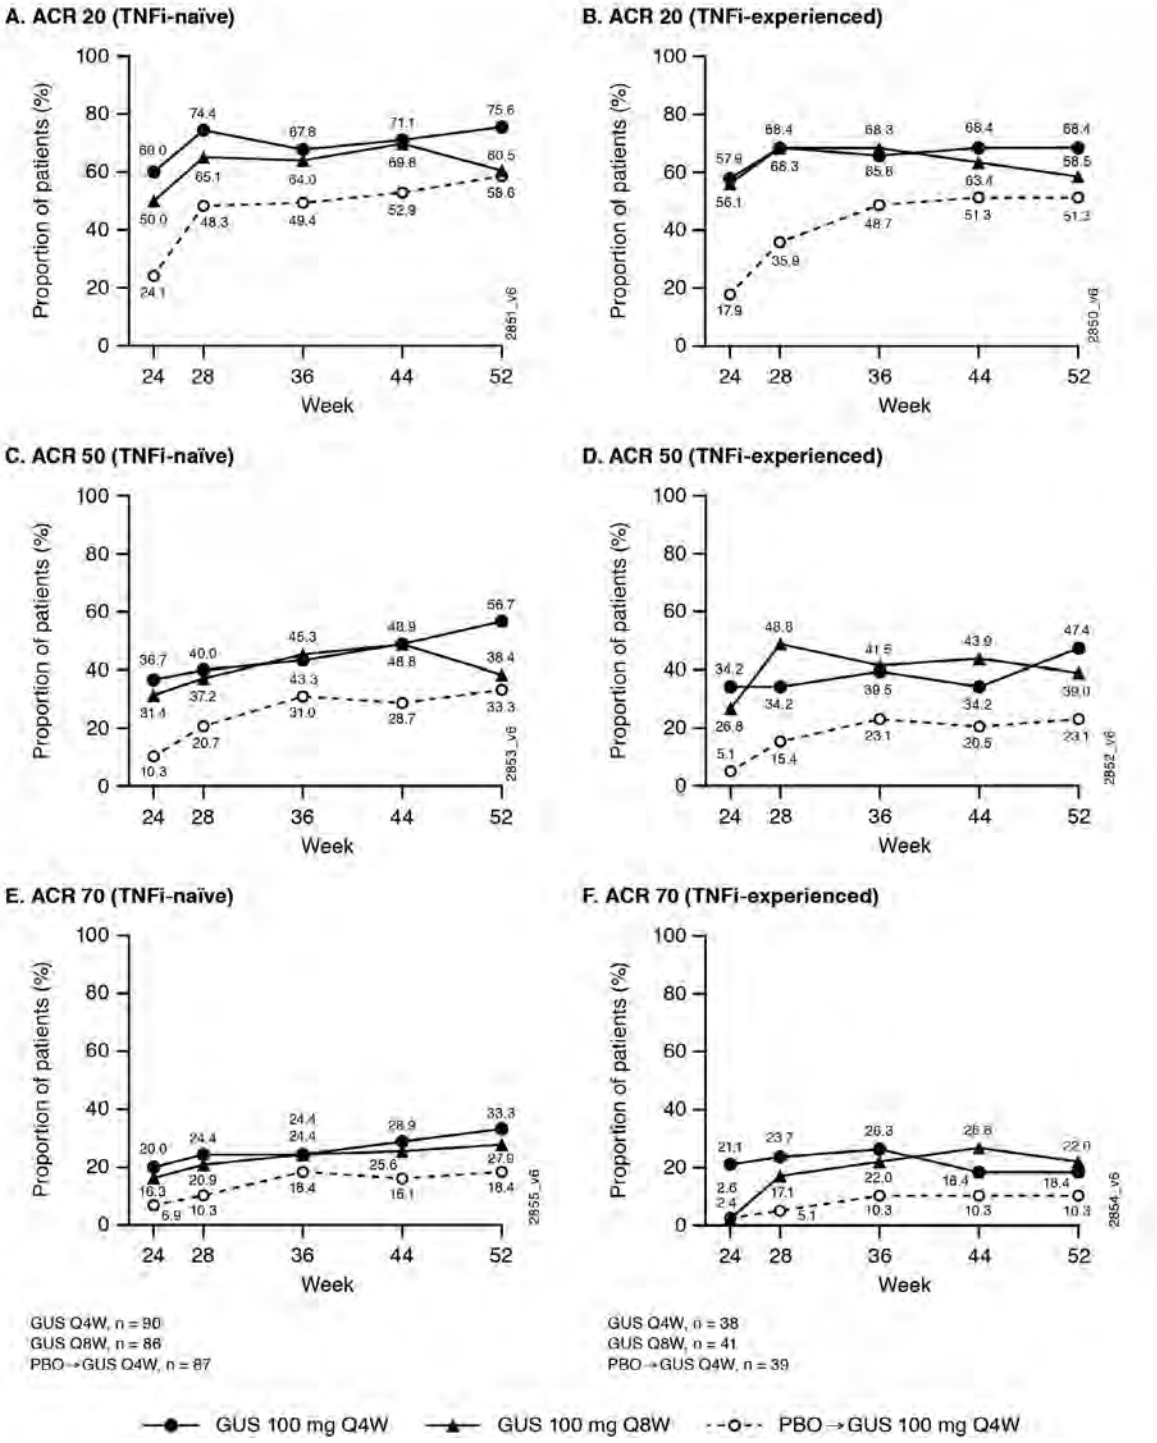
MDA	10 (26.3)	11 (28.9)	7 (17.1)	9 (22.0)	1 (2.6)	5 (12.8)

Data are n (%) unless otherwise noted.

Effects of GUS on joint (ACR20/50/70), skin (Investigator's Global Assessment response [IGA=0/1 + ≥2-grade reduction from W0], IGA=0, and Psoriasis Area Severity Index [PASI] 75/90/100 responses, all in pts with ≥3% BSA psoriasis and IGA ≥2 at W0), physical function (HAQ-disability index [HAQ-DI] ≥0.35 improvement in pts with HAQ-DI ≥0.35 at W0), and composite disease state (minimal disease activity [MDA]) were assessed through W52 using non-responder imputation (NRI) for missing data and summarized by prior TNFi use. Adverse events (AEs) through study completion (W60) were summarized by prior TNFi use.

Results: Of 381 treated PsA pts, 362 continued at W24, and 347 completed treatment through W48. 65% of pts were receiving DMARDs at W0; 31% previously received TNFi (**Table**). In both TNFi-naïve and experienced pts, proportions of GUS-treated pts achieving ACR20/50/70 and HAQ-DI ≥0.35 improvement were maintained from W24-W52 (**Fig**). Consistent joint response patterns were seen even in the smaller number of pts who discontinued (d/c) prior TNFi use due to inadequate response, e.g., Q4W and Q8W W52 response rates were 82% (14/17) and 60% (9/15) for ACR20 and 47% (8/17) and 40% (6/15) for ACR50. Robust skin response (IGA/PASI) rates were also maintained at W52 in both TNFi exposure subgroups. Most joint and skin response rates continued to increase over time through W52 regardless of prior TNFi use (**Table, Fig**). Through W60 in GUS-treated TNFi-naïve (n=258) and experienced (n=111) pts, 62% and 64%, respectively, reported ≥1 AE, 3% and 6% had serious AEs, 0.4% and 3% had serious infections, 3% and 2% had AEs lead to treatment d/c, and 7%/7% and 4%/3% had increased ALT/AST levels.

Figure 1. Proportions of randomized and treated patients achieving ACR20, ACR50, and ACR70 responses (NRI) from W24–W52 by prior TNFi use. Among 87 TNF-naïve and 39 TNFi-experienced patients randomized to receive PBO, 82 and 32, respectively, crossed over to GUS Q4W at W24 (after the W24 response assessments); the remaining pts (5 TNFi-naïve, 7 TNFi-experienced), who received PBO only and discontinued from the study, were included as nonresponders over time through W52.



Conclusion: Through 1 year, GUS 100 mg Q4W and Q8W provided robust and sustained improvements in joint symptoms and physical function in both TNFi-naïve and TNFi-experienced pts with active PsA. Meaningful improvements in skin psoriasis and composite disease state were observed, and GUS appeared to be well tolerated in PsA pts, regardless of prior TNFi status.

Figure 2. Proportions of randomized and treated patients with ≥3% BSA psoriasis and IGA ≥2 at Wk0 achieving IGA (IGA 0/1 + ≥2-grade decrease from W0 IGA), PASI90, and PASI100 responses (NRI) from W24–W52 by prior TNFi use. Among 52 TNFi-naive and 26 TNFi-experienced patients randomized to receive PBO, 47 and 21, respectively, crossed over to GUS Q4W at W24 (after the W24 response assessments); the remaining pts (5 in each TNFi subgroup), who received PBO only and discontinued from the study, were included as nonresponders over time at W52.

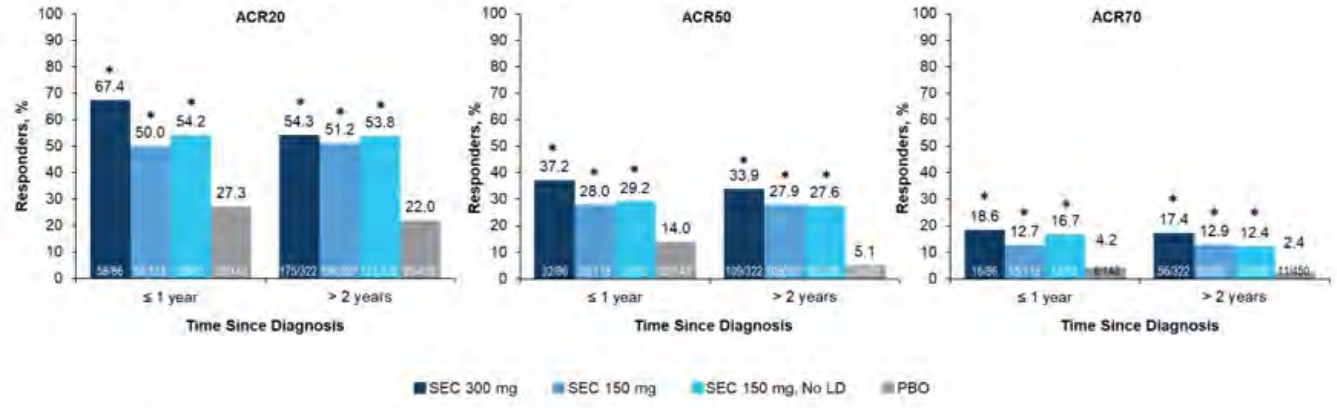
Figure 1. ACR Response at Week 16 by Treatment and Time Since Diagnosis



* *P* < .05 vs placebo. LD, loading dose; PBO, placebo; SEC, secukinumab

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) can progress quickly and lead to irreversible damage within 2 years of initial assessment if not treated.[1] Secukinumab (SEC), a selective interleukin 17A inhibitor, demonstrated rapid and sustained improvement in the signs and symptoms of PsA in the phase 3 FUTURE 1-5 studies; the mean time since PsA diagnosis (TSD) was 6 to 7 years in these studies.[2-6] To better understand the effect of earlier treatment in patients (pts) with PsA, we evaluated SEC treatment in pts with a TSD of ≤ 1 year or > 2 years.

Methods: Data from pts enrolled in FUTURE 2 (NCT01752634), 3 (NCT01989468), 4 (NCT02294227), and 5 (NCT02404350) were pooled and included in this hypothesis-generating analysis (N = 1803). Pts received SEC 300 or 150 mg with subcutaneous loading dose (LD), 150 mg without LD, or placebo (PBO). Pts were classified into 2 groups according to TSD: ≤ 1 year or > 2 years. Response to treatment was assessed using multiple outcome measures, including ACR20/50/70, PASI75/90/100, and additional disease activity and quality of life (QOL) measures at week 16. Responses were calculated using nonresponder imputation. No adjustment was made for multiple comparisons.

Results: Overall, 419 pts (23.2%) had a TSD ≤ 1 year; 1384 (76.8%) had a TSD > 2 years. At baseline, most pt characteristics were comparable between the 2 TSD groups (**Table 1**). Dactylitis and prior treatment with TNF inhibitors were more common in pts with a TSD > 2 years at baseline; the mean tender joint count (TJC) was also higher in these pts. At week 16, ACR20/50/70 response rates were higher with SEC than with PBO, regardless of TSD (**Figure 1**). SEC 300 mg was associated with higher ACR response rates than SEC 150 mg. In general, ACR response rates were slightly numerically higher in pts with a TSD ≤ 1 year, especially in those treated with SEC 300 mg. SEC also led to higher response rates in other efficacy outcomes compared with PBO, including resolution of enthesitis and dactylitis and improvement of skin and nail psoriasis (**Table 2**). In SEC-treated pts, the proportion of pts with swollen joint count = 0, TJC = 0, CRP ≤ 10 mg/L, and improved SF-36 mental component score were numerically higher in pts with a TSD ≤ 1 year vs those with a TSD > 2 years. Common adverse events in SEC-treated pts (TSD ≤ 1 year/ > 2 years) were nasopharyngitis (8.3%/6.1%), headache (6.2%/3.6%), and upper respiratory tract infection (5.1%/4.7%). Inflammatory bowel disease was reported in 4 pts (SEC, n = 3; PBO, n = 1), all in pts with a TSD > 2 years. Major adverse cardiovascular events occurred in 2 pts (SEC 300 mg, TSD > 2 years). No tuberculosis events were reported.

Conclusion: SEC treatment led to improvement in clinical outcomes and QOL measures in pts with PsA regardless of TSD. Pts with a TSD of ≤ 1 year had higher clinical response rates in some outcome measures, suggesting that earlier treatment may lead to better outcomes in pts with PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Common symptoms of axial spondyloarthritis (axSpA) include fatigue, spinal pain, stiffness, and sleep problems, which can impair health-related quality of life. Ixekizumab (IXE) treatment shows efficacy in active non-radiographic axSpA (nr-axSpA).[1] The objective of this study was to assess fatigue, spinal pain, stiffness, and sleep with IXE treatment versus placebo in patients (pts) with active nr-axSpA up to 16 and 52 weeks.

Table: Least squares mean (standard error) change from baseline-ITT population (mixed-effect model of repeated measures)

Measure	Timepoint	PBO N=105	IXE Q4W N=96	IXE Q2W N=102
Spinal pain[a]	Week 16	-1.45 (0.244)	-2.35 (0.248)*	-2.59 (0.244)†
	Week 52	-2.29 (0.350)	-2.92 (0.305)	-3.32 (0.304)*

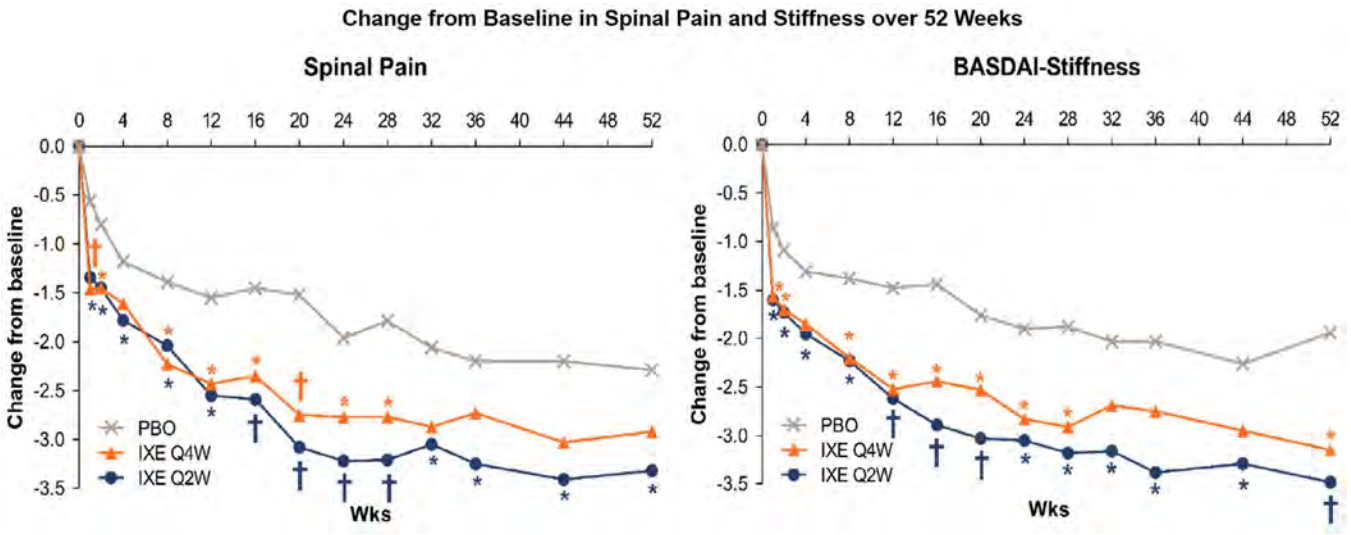
	Week 52	-1.81 (0.378)	-2.77 (0.320)	-3.30 (0.321)*

*P<.05 vs PBO; †P≤.001 vs PBO. ITT population: all randomized pts. Pts needing rescue treatment after Week 16 per investigator could switch to open-label IXE Q2W; observations at visits thereafter not included in analyses. Baseline values similar across treatments. Numerical improvements in BASDAI-fatigue not significant vs PBO. [a]Scored 0 (no pain) to 10 (most severe pain) on NRS [b]Mean score BASDAI questions 5 (intensity) and 6 (duration) [c]Scored 1–10 on NRS [d]Scored 0 (no fatigue) to 10 (as bad as you can imagine) [e]Jenkins Sleep Evaluation Questionnaire scored 0 to 20: each of 4 items scored 0 (0 days) to 5 (22–30 days) [f]Scored 0 (not active) to 10 (very active) on NRS BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; BL=baseline; ITT=intent-to-treat IXE=Ixekizumab; N=number of pts in ITT population; NRS=numeric rating scale; PBO=placebo; pt=patient; Q2W=every 2 weeks; Q4W=every 4 weeks; vs=versus; wk=week.



*P<.05 vs PBO; †P≤.001 vs PBO. Significant differences between placebo and IXE Q4W and IXE Q2W are shown by orange and blue symbols, respectively. Changes from BL (Least squares mean) up to Wk 52 were analysed using MMRM analysis in the ITT population, which included all randomized pts. BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; BL=baseline; ITT=intent-to-treat IXE=Ixekizumab; MMRM=mixed-effects model of repeated measures; PBO=placebo; pt=patient; Q2W=every 2 weeks; Q4W=every 4 weeks; vs=versus; wk=week

Methods: In COAST-X, pts with active nr-axSpA were randomized to 52 weeks of double-blind IXE 80 mg once every 4 weeks (Q4W) or every 2 weeks (Q2W), or placebo. Data were collected from baseline to Week 52.

Results: At Week 16, IXE Q4W significantly improved fatigue, spinal pain, and stiffness, and IXE Q2W improved spinal pain, spinal pain at night, and stiffness vs placebo (Table). At Week 52, IXE Q4W significantly improved stiffness, and IXE Q2W improved spinal pain, spinal pain at night, and stiffness vs placebo. Numeric improvements in sleep were not significant vs placebo. Week 1, and up to Week 16, IXE Q4W and Q2W significantly reduced spinal pain and stiffness vs PBO; stiffness was significantly reduced vs placebo up to Week 52 (Figure).

Conclusion: IXE Q4W and/or Q2W significantly improved spinal pain, spinal pain at night, and stiffness vs placebo at 16 and 52 weeks in pts with nr-axSpA. IXE Q4W also improved fatigue at 16 weeks in these pts. Numerical improvements in sleep were not significant vs placebo.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), a fully human monoclonal antibody, selectively binds and blocks IL-23. VOYAGE 1 and VOYAGE 2 are two ongoing Phase 3, randomized, double-blind, placebo (PBO)/active comparator-controlled clinical trials of GUS in patients with moderate-to-severe psoriasis (PsO). This post-hoc analysis reported pooled results through 4 years among a subgroup of moderate-to-severe PsO patients with self-reported PsA at baseline.

Methods: 1829 patients were randomized to GUS 100 mg at Weeks 0, 4, and 12, then every 8 weeks (q8wk); PBO at Weeks 0, 4, and 12, GUS at Weeks 16 and 20 then q8wk; or adalimumab (ADA) 80 mg at Week 0, 40 mg at Week 1, then 40 mg q2wk until Week 47 (VOYAGE 1) or Week 23 (VOYAGE 2). In VOYAGE 1, all patients received open-label GUS 100 mg q8wk during Weeks 52-204. VOYAGE 2 incorporated a randomized withdrawal study design, followed by open-label GUS during Weeks 76-204. Pooled subgroup analyses using the combined GUS group were conducted based on self-reported PsA status at baseline. Efficacy based on Investigator Global Assessment (IGA) score and Psoriasis Area and Severity Index (PASI) response was assessed using prespecified treatment failure rules (nonresponder status for all time points after discontinuing due to lack of efficacy, worsening of PsO, or use of a prohibited treatment).

Results: For pooled VOYAGE 1 and VOYAGE 2 patients (N=1721), combined GUS and ADA→GUS response rates at Weeks 100, 156, and 204 were: PASI 90 80.6%, 80.0%, and 80.4%; PASI 100 50.1%, 49.9%, and 52.2%; IGA 0/1 83.6%, 83.3%, and 81.7%; and IGA 0 54.3%, 52.9%, and 53.9, respectively. In the pooled subgroup analysis of patients with and without PsA, response rates were similar across the Week 100, Week 156, and Week 204 evaluations (Table). Rates of adverse events through Week 204 were comparable for patients with PsA vs those without PsA at baseline.

Table: Pooled Guselkumab Response Rates

	Without PsA at Baseline			With PsA at Baseline		
	Wk 100	**Wk 156**	**Wk 204**	**Wk 100**	**Wk 156**	**Wk 204**
	N=1301	N=1239	N=1191	N=289	N=276	N=264
PASI 90	1049 (80.6%)	1001 (80.8%)	964 (80.9%)	233 (80.6%)	211 (76.4%)	206 (78.0%)
PASI 100	648 (49.8%)	631 (50.9%)	635 (53.3%)	149 (51.6%)	125 (45.3%)	125 (47.3%)
	N=1300	N=1235	N=1189	N=288	N=276	N=264
IGA 0/1	1086 (83.5%)	1042 (84.4%)	979 (82.3%)	241 (83.7%)	217 (78.6%)	208 (78.8%)
IGA 0	702 (54.0%)	664 (53.8%)	649 (54.6%)	160 (55.6%)	135 (48.9%)	134 (50.8%)

IGA, Investigator Global Assessment; PASI, Psoriasis Area and Severity Index; Wk, week

Table. Pooled Guselkumab Response Rates

Conclusion: Among GUS-treated patients with moderate-to-severe PsO with and without self-reported PsA at baseline, sTable, durable, and high levels of skin responses, as well as comparable safety outcomes, through 4 years were observed.

Abstract Number: 0892

Long-Term Safety Profile of Ixekizumab Treatment in Patients with Axial Spondyloarthritis

Sergio Schwartzman[1], David Sandoval[2], Andris Kronbergs[2], Jeffrey Lisse[3], Himanshu Patel[3], Wen Xu[3], Soyi Liu-Leage[3], Marina Magrey[4], Helena Marzo-Ortega[5] and Denis Poddubnyy[6], [1]Weill Cornell Medical College, New York, NY, [2]Eli Lilly and Company, Indianapolis, [3]Eli Lilly and Company, Indianapolis, IN, [4]Case Western Reserve University School of Medicine, Cleveland, OH, [5]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom, [6]Charité – Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab, a high-affinity monoclonal antibody that selectively targets interleukin-17A, has demonstrated efficacy in the treatment of the axial spondyloarthritis (axSpA) spectrum (ankylosing spondylitis and non-radiographic axSpA) in patients who are naive to biologic treatments and in those with an inadequate response or intolerance to a tumor necrosis factor (TNF) inhibitor. The objective of this study was to report the long-term safety profile for ixekizumab in patients with axSpA, using integrated safety data from the COAST clinical trial program.

Methods: Safety data from 3 clinical studies and long-term extensions were integrated. Study populations were composed of patients naïve to biological disease-modifying rheumatic disease treatment (bDMARD-naïve) or TNF-experienced, including patients who had intolerance to bDMARDs. The integrated safety population included all patients with axSpA who received ≥1 dose of ixekizumab. Incidence rates (IR) per 100 person-years with 95% confidence interval (CI) and the number of patients were reported. Adverse event (AE) terms were derived from MedDRA (v221.0).

Results: The integrated safety population consisted of 932 patients with a total of 1849 person-years. Among 932 patients with ≥1 TEAE, 775 (IR 41.9, 95% CI 39.1–45.0) TEAEs were reported, of which 95 (IR 5.1, 95% CI 4.2–6.3) were severe (Table). Nasopharyngitis (IR 8.8, 95% CI 7.5–10.2) and upper respiratory infections (IR 6.0, 95% CI 5.0–7.2) were the most commonly reported TEAEs. A total of 90 (IR 4.9, 95% CI 4.0–6.0) SAEs occurred, and 62 AEs led to treatment discontinuation (IR 3.4, 95% CI 2.6–4.3). Injection site reactions occurred in 155 patients (IR 8.4, 95% CI 7.2–9.8). The IR of SAEs declined from year 1 (IR 6.3, 95% CI 4.9–8.3) through 2 years of follow up (IR 4.5, 95% CI 2.8–7.3), as did discontinuations due to AEs (year 1: IR 5.1, 95% CI 3.7–6.8; year ≥2: IR 1.9, 95% CI 0.9–3.9). Allergic reactions/hypersensitivity occurred in 86 patients and decreased slightly from year 1 (IR 6.6, 95% CI 5.1–8.5) through year 3 (IR 3.5, 95% CI 2.0–6.0). The IR of neutropenia (grade 1 or worse) was 8.4 (95% CI 7.2–9.9, and candidiasis (invasive and oral) was 1.4 (95% CI 1.0–2.1). A total of 20 serious infections, 17 reports of adjudicated inflammatory bowel disease, and 1 incidence of potential (unconfirmed) anaphylaxis occurred. No tuberculosis was reported (Table).

Conclusion: This integrated safety analysis demonstrates the overall safety profile of ixekizumab for treatment of axSpA, shows no new signals, and is consistent with that previously reported in previous studies including psoriasis and psoriatic arthritis indications.

Table. Integrated Safety Outcomes

	Pooled Ixekizumab (N=932) n (IR[a])	95% CI
Total patient years	1849.0	
TEAEs[b]	775 (41.9)	39.1 – 45.0
Nasopharyngitis	162 (8.8)	7.5 – 10.2
Upper respiratory tract infection	111 (6.0)	5.0 – 7.2
SAEs[b]	90 (4.9)	4.0 – 6.0
Discontinuations due to AEs	62 (3.4)	2.6 – 4.3
Deaths[c]	3 (0.2)	0.1 – 0.5
Major adverse cardiac events	4 (0.2)	0.1 – 0.6
Infections	511 (27.6)	25.3 – 30.1
Candida[d]	26 (1.4)	1.0 – 2.1
Serious infections	20 (1.1)	0.7 – 1.7
Opportunistic infections[e]	17 (0.9)	0.6 – 1.5
Injection site reactions	155 (8.4)	7.2 – 9.8
Iridocyclitis	52 (2.8)	2.1 – 3.7
Depression	19 (1.0)	0.7 – 1.6
Inflammatory bowel disease[f]	17 (0.9)	0.6 – 1.5
Ulcerative colitis	10 (0.5)	0.3 – 1.0
Crohn's disease	7 (0.4)	0.2 – 0.8

AE=adverse event; CI=confidence interval; IR=incidence rate; SAE=serious adverse event; TEAE=treatment-emergent adverse event

[a]Incidence rate per 100 patient-years

[b]Deaths due to suicide (1), sepsis (1), and general disorders (1)

[c]Patients with ≥1 event

[d]Candida infections included oral Candida, oral candidiasis, oral fungal infection, esophageal candidiasis, fungal esophagitis, genital Candida, and skin Candida

[e]Opportunistic infections included oral candidiasis, hepatitis B reactivation, herpes simplex (invasive), and herpes zoster

[f]Confirmed by adjudication

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

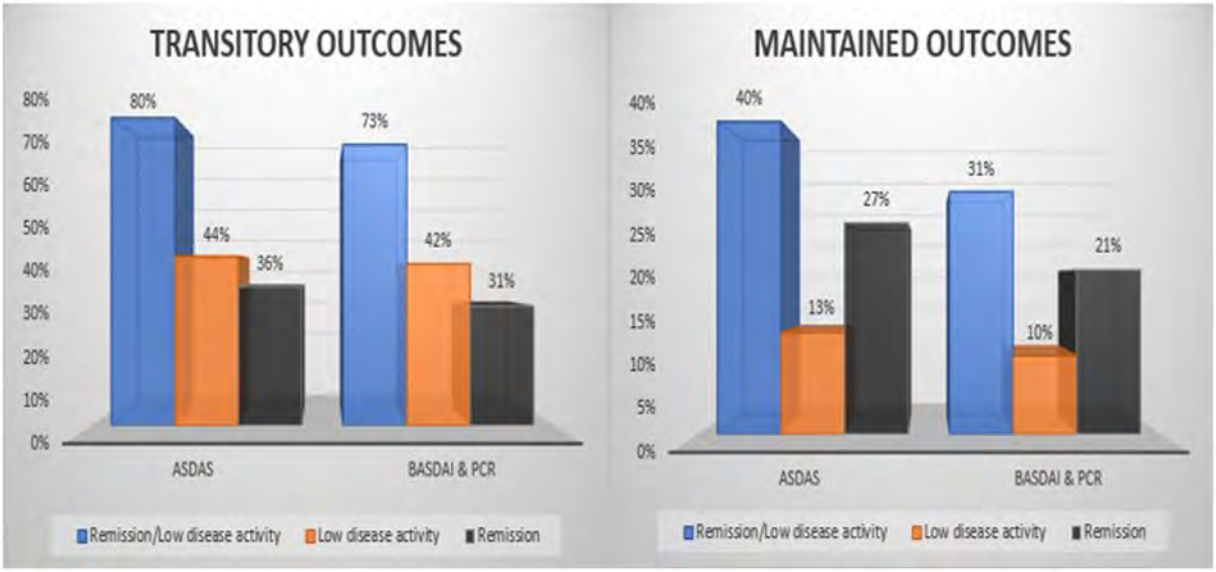
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: to analyze the frequency of patients with axSpA achieving maintained remission (R) or low disease activity (LDA) after receiving biological therapy. Secondary objectives included: i) to assess if the activity index used influences the frequency of maintained R/LDA, ii) analyze the prognostic factors for achieving maintained R/LDA.

Methods: an observational, longitudinal study of a prospective cohort (SpA-Paz) including all patients with axSpA who initiated biological treatment between the years 2003-2017. Demographic, clinical and analytical data were collected at the beginning of treatment and clinical disease activity measured by BASDAI&CRP and ASDAS every 6 months for at least 2 years. Maintained R was defined as (BASDAI < 2 & normal CRP and / or ASDAS < 1.3) and maintained LDA (BASDAI < 4 & normal CRP and / or ASDAS < 2.1) on at least 3 consecutive visits. Statistical analysis: i) measures of central tendency and dispersion for quantitative variables and frequencies for qualitative variables; ii) univariate and multivariate analysis of binomial logistic regression model and calculation of OR and 95% CI.



Graphics

Results: Out of 186 patients with axSpA who initiated their first biological therapy during the study period, 63% were men with a mean age of 54 ± 14.1 years. 75.3% of the patients had radiographic axSpA and 74.7% were HLA-B27 positive. Other baseline characteristics are shown in *Table 1*. Overall, 80% of the patients achieved ASDAS R/LDA (R36%/LDA44%) in at least one of the visits after 2 years of follow-up, but only 40% (R27%/LDA13%) of the patients fulfilled the maintained ASDAS R/LDA state. On the other hand, 73% of patients were classified as BASDAI&CRP R/LDA (R31%/LDA42%) in at least one of the visits, but only 31% (R21%/LDA10%) of the patients obtained the maintained BASDAI&CRP R/LDA state. In the multivariate analysis, we observed an independent statistically significant association with male sex (OR=3.19; 95% CI=1.46-6.99), being younger at the beginning of the biological treatment (OR= 0.97; 95% CI=0.95-0.99) and the use of methotrexate (OR=3.07; 95% CI =1.39-6.78) in patients who achieved maintained BASDAI&CRP R/LDA and with male sex (OR=4.01; 95% CI=1.83-8.77), younger age at the beginning of the biological therapy (OR=0.96; 95% CI=0.94-0.99) and B27 positive (OR=4.30; 95% CI=1.68-11.01) in patients who achieved maintained ASDAS R/LDA.

Conclusion: Although most patients with axSpA who initiate biological therapy achieve the recommended therapeutic goal in the first two years of biological treatment, the percentage of patients who manage to maintain the R/LDA status is limited. In our study, maintained R was more frequent than maintained LDA, being somewhat higher when measured by ASDAS. This fact may suggest that patients who achieve maintained R have a greater inhibition of their inflammatory activity and, therefore, it remains in time. Male sex and younger age at the beginning of the biological therapy were the main baseline predictors for achieving maintained R /LDA.

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Neihulizumab is a novel immune checkpoint agonistic antibody that binds to human CD162 (PSGL-1), thereby preferentially inducing apoptosis in late stage activated T cells. It is being tested in putative T-cell mediated inflammatory diseases including ulcerative colitis and graft versus host disease. To assess the efficacy and safety of Neihulizumab in patients with active psoriatic arthritis (PsA) in an open-label 24-week Phase II POC study.

Table 1. Demographic and Baseline Characteristics

Female, n (%)	12 (60%)
Age (years), median (min, max)	55.5 (42, 72)
BMI (kg/m^2), median (min, max)	33.06 (24.50, 42.50)
Race, n (%)	
White	18 (90%)
African American	0
American Indian or Alaska native	0
Asian	0
Others	2 (10%)
Duration of psoriatic arthritis (years), median (min, max)	4.5 (0.7, 30)
Duration of psoriasis (years), median (min, max)	25 (1.9, 47)
Methotrexate current use, n (%)	11 (55%)
Prior exposure to biologics, n (%)	10 (50%)
Disease-related assessment-Baseline values, median (min, max)	
Swollen joint count (SJC)	16.5 (3, 57)
Tender joint count (TJC)	31.5 (5, 65)
Patient's assessment of Pain (VAS)	63.5 (18, 96)
Patient's global assessment of disease activity (VAS)	55.0 (10, 96)
Physician's global assessment of disease activity (VAS)	64.5 (38, 87)
HAQ-DI	1.4375 (0.25, 2.125)
C-reactive protein (mg/L)	0.608 (0.021, 4.346)
DAS28 (CRP), median (min, max)	5.588 (3.249, 7.585)
Static physician's global assessment (sPGA), n (%)	
Clear	0
Almost clear	2 (12.5%)
Mild	7 (43.8%)
Moderate	7 (43.8%)
Severe	0
Target Lesion Psoriasis Severity Score (TLPSS), median (min, max)	5.5 (2, 9)

Methods: Twenty (20) patients with active PsA fulfilling Classification Criteria for Psoriatic Arthritis (CASPAR) were treated with 3 weekly doses plus 4 bi-weekly doses of 9 mg/kg IV Neihulizumab with follow-up at weeks 12, 16, 20, and 24. The primary endpoint was the proportion of patients achieving an ACR 20 response at Week 12. Safety was assessed throughout the study period.

Results: Twenty patients (20) were enrolled. The majority of the patients were female (12/20, 60.0%) and white (18/20, 90.0%). The median age was 55.5(42-72) years. The median duration of psoriatic arthritis was 4.5 (0.7-30) years. The median duration of psoriasis was 25 (1.9-47) years. Forty (40.0) % (8/20) of patients achieved ACR20 responder

Table 2. Summary of Efficacy Results at Week 12 and Week 24

Primary Endpoint	Week 12	Week 24*
ACR 20 (%)	40%	25%
Secondary Endpoints	Week 12	Week 24

status at Week 12 in ITT population by Non-Responder Imputation. At week 12 the ACR50 and 70 response rates were 30%, and 10%, respectively. Analysis by DAS28(CRP) showed concordant result. Durability of ACR20/50/70 was maintained through week 24 for at least 50% of responders after the last treatment at Week 10. Neihulizumab treatment was well tolerated with no deaths, no serious AEs, and no severe AEs observed. The most frequent TEAEs overall (including the treatment period and follow-up period) were urinary tract infection (15.0%), psoriatic arthropathy (15.0%), headache (10.0%), sinus congestion (10.0%), and hematoma (10.0%).

Conclusion: Overall treatment of Neihulizumab was well tolerated in this study. Improvement was seen in efficacy parameters, suggesting there may be clinical utility with this novel agent for the treatment of psoriatic arthritis. Controlled studies are indicated

active PsA.[1,2] Dactylitis & enthesitis, key PsA clinical manifestations, can be difficult to treat and may portend more significant disease burden.[3,4] This study assessed 1) changes in symptoms over time and 2) relationships between improvements in dactylitis or enthesitis and other PsA domains in pts with dactylitis or enthesitis at baseline.

Methods: Adults with active PsA despite standard therapies were eligible for D1 & D2. Approx. 30% of D1 pts previously received 1-2 TNF inhibitors; D2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100mg Q4W; GUS 100mg at W0, W4, Q8W; or PBO. Independent assessors evaluated dactylitis (total score: 0-60) & enthesitis (Leeds Enthesitis Index [LEI]; total score 0-6). Dactylitis and enthesitis findings through W24 were prespecified to be pooled across D1 & D2. P-values are unadjusted. We assessed changes in dactylitis and LEI scores over time (ANCOVA); associations between dactylitis or enthesitis resolution and ACR/PASI responses at W24 (Chi-square); and correlations between dactylitis or LEI and HAQ-DI/SF-36 change scores at W24 (Spearman's correlation). AEs through W24 were reported.[1,2]

Results: At W0, 42% of pooled D1+D2 pts had dactylitis; 65% had enthesitis. GUS improved dactylitis and LEI scores vs PBO at W8, W16, W24. GUS vs PBO differences were significant for dactylitis changes at W16 & W24 and LEI changes at W8 (Q4W only), W16 & W24; no dose response was observed (Fig). Rates of dactylitis or enthesitis

resolution by W24 were consistently significantly (p< 0.001) associated with ACR20/50/70 and PASI75/90 response (Table). In GUS-treated pts at W24, significant correlations were observed between dactylitis change scores and PASI (p< 0.001 Q4W; p=0.006 Q8W) and SF-36 MCS (p=0.038 Q4W; p=0.003 Q8W) changes, and between LEI and HAQ-DI change scores (p< 0.001 Q4W; p=0.005 Q8W). No consistent correlations/associations were observed between dactylitis or LEI scores and other clinical outcomes.

Conclusion: In PsA pts with dactylitis or enthesitis at W0, GUS improved dactylitis or LEI scores vs PBO by W8; treatment differences were significant at W16 & W24. Resolution of dactylitis or enthesitis was significantly associated with clinically meaningful improvements in PsA joint & skin symptoms. Improved dactylitis scores correlated with improved skin symptoms and mental health; improved LEI scores correlated with improved physical function.

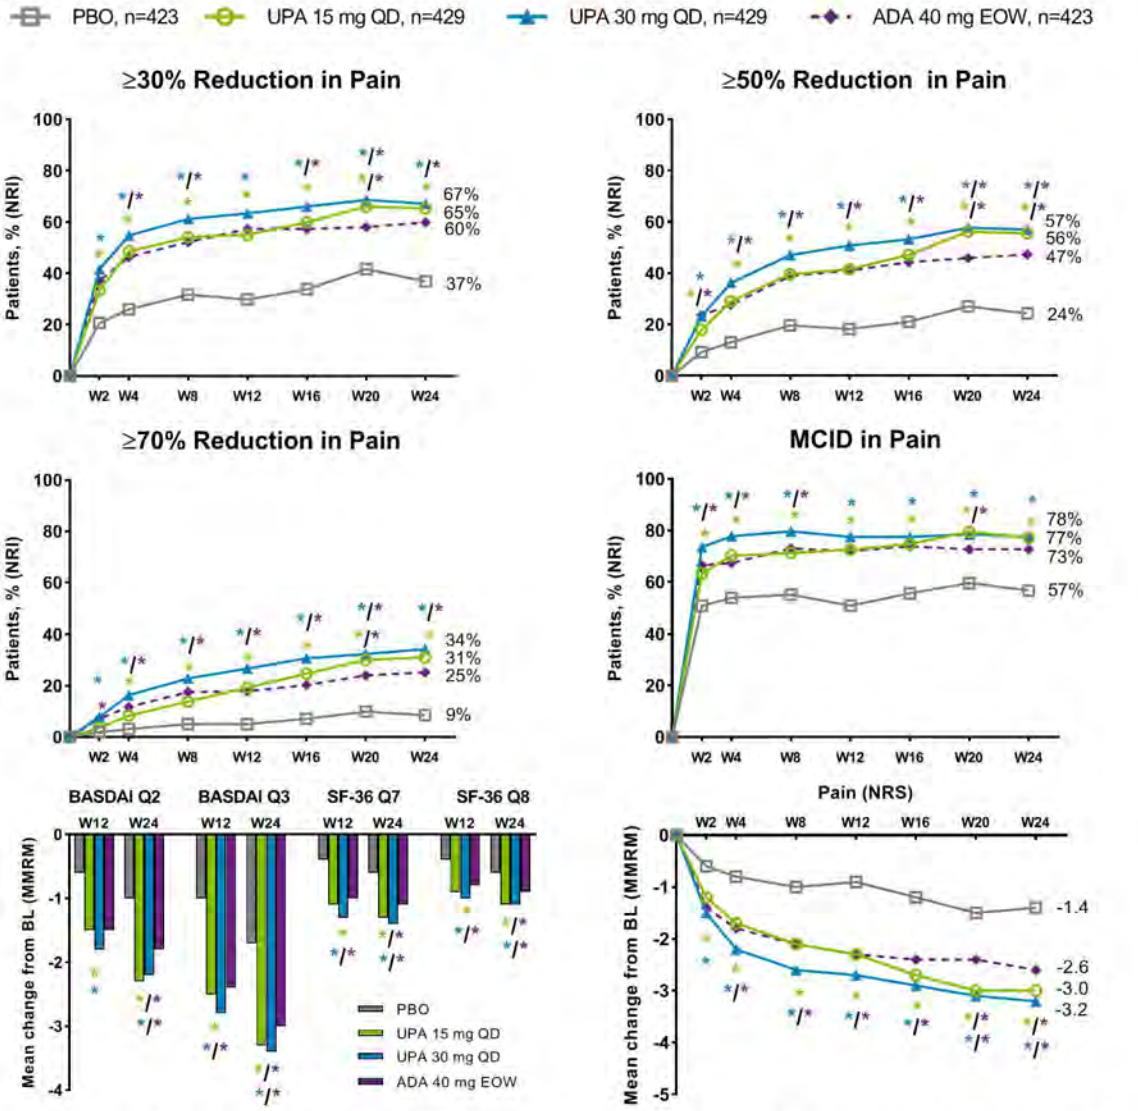
Figure 1. PGA of Pain and BASDAI and SF-36 Pain Assessments in SELECT- PsA 1 Over 24 Weeks



ADA, adalimumab; MCID, minimal clinically important difference; MMRM, mixed-effects model for repeated measurements; NRI, non-responder imputation; NRS, numeric rating scale; PBO, placebo; PGA, patient's global assessment; SF-36, 36-item Short Form; UPA, upadacitinib.
All pain assessments evaluated in overall study population. N's for NRI analysis; nominal *P* value for a binary endpoint was constructed using the Cochran-Mantel-Haenszel test adjusting for the main stratification factor of current DMARD use (yes/no). In the MMRM, the within-subject dependence was modelled by an unstructured variance-covariance matrix. The fixed effects included the continuous baseline measurement, and treatment, visit, treatment-by-visit interaction and the stratification factor of current DMARD use (yes/no) as fixed factors
Blue asterisks: UPA 30 mg vs PBO; green asterisks: UPA 15 mg vs PBO; purple asterisks: UPA vs ADA. *Statistically significant at 0.05 level.

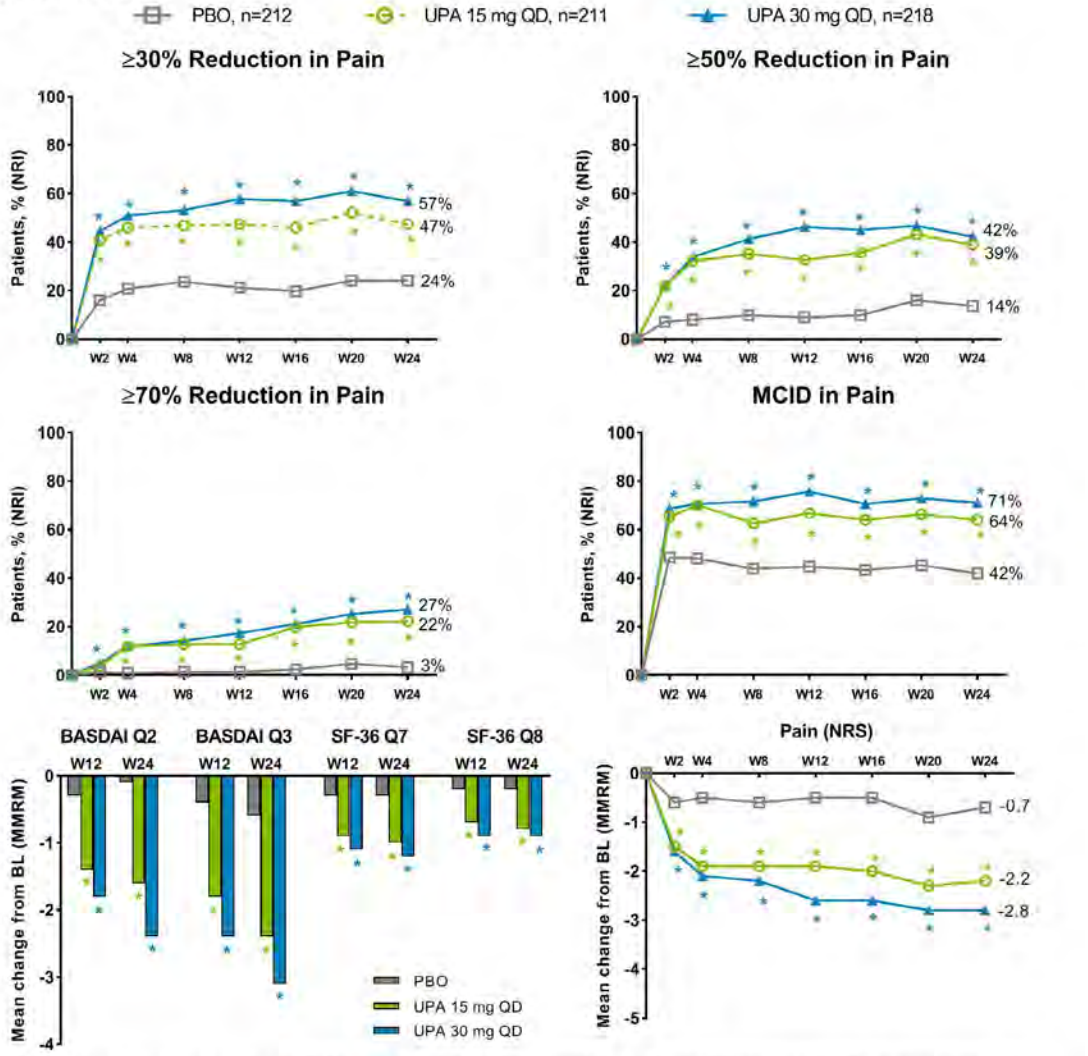
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a dominant symptom of psoriatic arthritis (PsA), and pain reduction is a priority for patients (pts) that is often assessed in clinical trials. Upadacitinib (UPA), a Janus kinase (JAK) inhibitor engineered for increased selectivity for JAK1 over JAK2, JAK3, and tyrosine kinase2, has demonstrated safety and efficacy in pts

Figure 2. PGA of Pain and BASDAI and SF-36 Pain Assessments in SELECT-PsA 2 Over 24 Weeks



MCID, minimal clinically important difference; MMRM, mixed-effects model for repeated measurements; NRI, non-responder imputation; NRS, numeric rating scale; PBO, placebo; PGA, patient's global assessment; SF-36, 36-item Short Form; UPA, upadacitinib.
All pain assessments evaluated in overall study population. N's for NRI analysis; nominal *P* value for a binary endpoint was constructed using the Cochran-Mantel-Haenszel test adjusting for the main stratification factor of current DMARD use (yes/no). In the MMRM, the within-subject dependence was modelled by an unstructured variance-covariance matrix. The fixed effects included the continuous baseline measurement, and treatment, visit, treatment-by-visit interaction and the stratification factor of current DMARD use (yes/no) as fixed factors.

Figure 2

with active PsA in the SELECT-PsA 1 and 2 studies.[1,2] The objective of this analysis was to compare the efficacy of UPA vs placebo (PBO) and adalimumab (ADA) on pain using different assessments through 24 weeks (wks).

Methods: The SELECT-PsA program enrolled adult pts with active PsA with prior inadequate response (IR) or intolerance to ≥1 non-biologic DMARD (SELECT-PsA 1; NCT03104400) or prior IR or intolerance to ≥1 biologic DMARD (SELECT-PsA 2; NCT03104374). Concomitant background therapy with ≤2 non-biologic DMARDs was allowed but not required. Pts were randomized to UPA 15 mg or UPA 30 mg once daily (QD) or PBO (both studies), or ADA 40 mg every other week (EOW; SELECT-PsA 1 only). Pain was assessed as proportion of pts achieving ≥30%, ≥50%, or ≥70% reduction from baseline (BL) in Pt's global assessment (PGA) of pain numeric rating scale (NRS) score (0–10), proportion of pts achieving minimal clinically important difference (MCID) in pain (defined as ≥1 point reduction or 15% reduction from BL on a 0–10 NRS)[3,4] and change from baseline in pain NRS (0–10) at all time points. In addition,

change from BL in BASDAI questions 2 (spinal pain) and 3 (joint pain/swelling) and 36-Item Short Form Survey (SF-36) questions 7 (bodily pain) and 8 (pain interference) at weeks 12 and 24 were assessed. Non-responder imputation was used for binary endpoints and mixed-effects model for repeated measurements for continuous endpoints. The statistical significance defined as $P< 0.05$ was exploratory in nature.

Results: In both studies, a significantly higher proportion of pts receiving UPA 15 mg QD and UPA 30 mg QD vs PBO achieved improvements in most pain endpoints as early as wk 2, and improvements were generally either sustained or increased through wk 24 (nominal $P<0.05$; **Figure 1** and **2**). A significant improvement with UPA vs PBO was also observed for change from BL in PGA of pain NRS scores over time, as well as in BASDAI spinal pain and joint pain/swelling and SF-36 bodily pain and pain interference at weeks 12 and 24 (**Figure 1** and **2**). In SELECT-PsA 1 significantly higher proportions of pts receiving UPA 30 mg QD vs ADA 40 mg EOW achieved improvements in most pain assessments as early as wk 2 which were sustained through wk 24; improvements in several assessments were also significantly greater with UPA 15 mg QD vs ADA 40 mg EOW at wk 24 (nominal $P < 0.05$; **Figure 1**).

Conclusion: In pts with active PsA who had inadequate response to non-biologic or biologic DMARDs, a greater proportion of pts treated with UPA vs PBO achieved rapid, significant, and clinically meaningful reductions in pain across multiple pain assessments. The reductions in pain were sustained over 24 wks.

SESSION INFORMATION

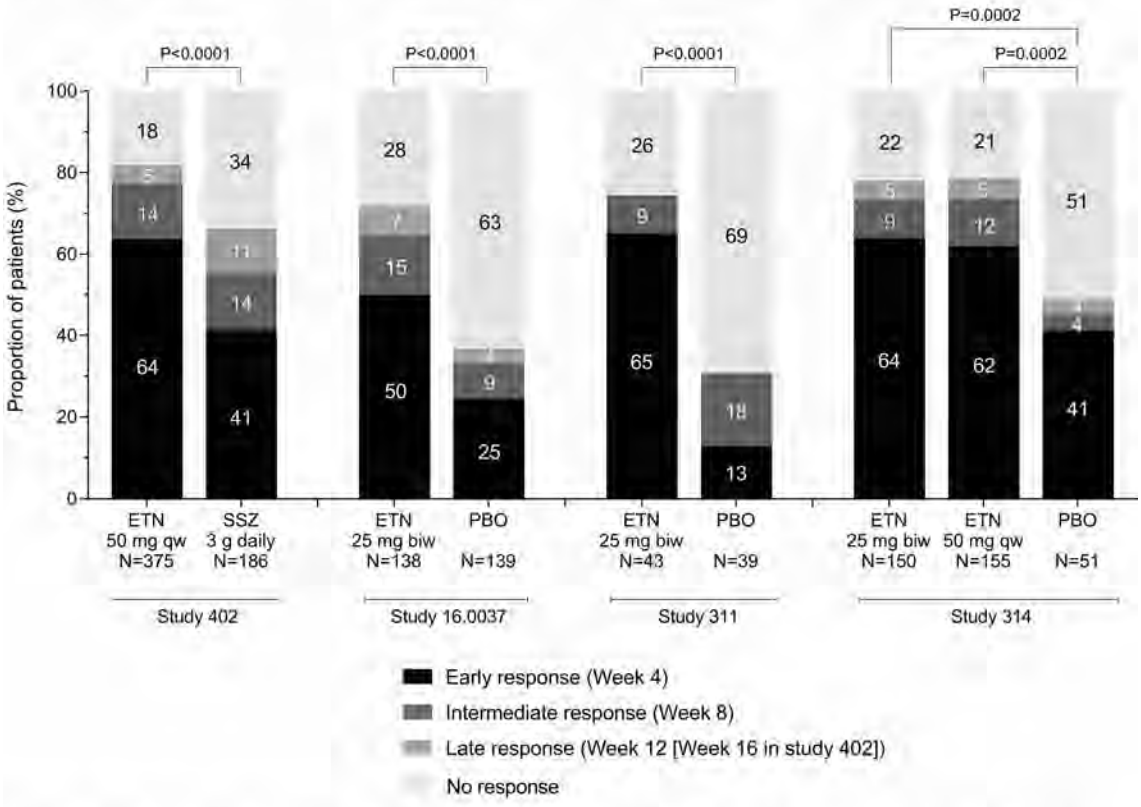
Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Figure 1. Proportions of patients achieving an early, intermediate, or late ASAS20 response



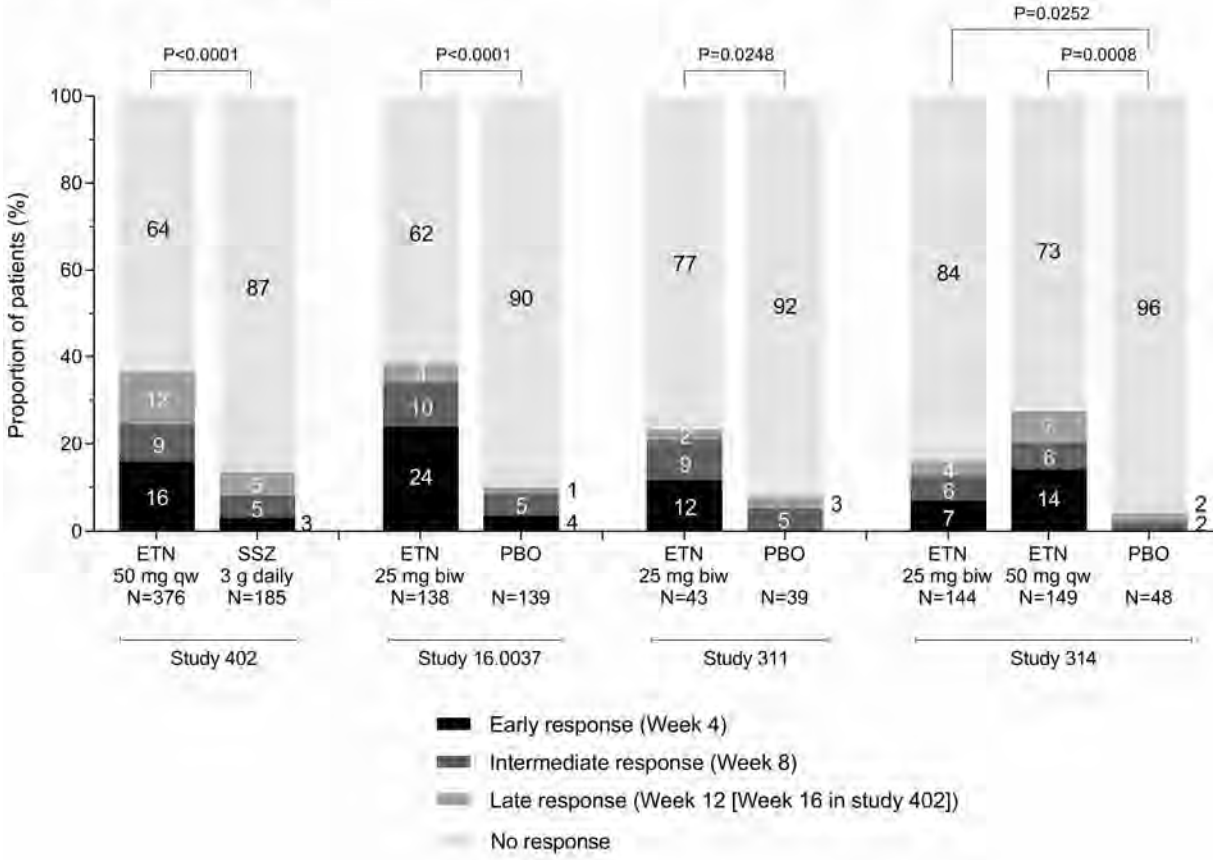
N.B. In all 4 studies, patients could receive optional background therapy with stable doses of NSAIDs and/or hydroxychloroquine, sulfasalazine, or methotrexate (sulfasalazine was not permitted in Study 402 and no NSAIDs were used in Study 16.0037)

ASAS20: Assessment in SpondyloArthritis International Society 20; biw: twice weekly; ETN: etanercept; NSAID: non-steroidal anti-inflammatory drug; PBO: placebo; qw: once weekly; SSZ: sulfasalazine.

Background/Purpose: Treatment with etanercept (ETN) is effective and well tolerated in patients with axial spondyloarthritis (AS), but the time frames within which patients tend to achieve clinical responses have not been well characterized. The aim of this post hoc analysis was to compare the temporal achievement of initial Assessment in SpondyloArthritis International Society 20 (ASAS20) response or initial inactive disease (ID) status in patients randomized to the ETN or control arms of clinical trials.

Methods: Data from 4 multicenter, double-blind, randomized, placebo- or sulfasalazine-controlled trials evaluating the safety and efficacy of ETN in patients with AS were included: Study 402 (phase 4, N=566; NCT00247962), Study 16.0037 (phase 3, N=277; NCT00356356), Study 311 (phase 3, N=84; NCT00421915), and Study 314 (phase 3, N=350; NCT00418548). The proportion of patients achieving ASAS20 response was the primary endpoint in all 4 studies and each study involved patients receiving ≥12 weeks of ETN treatment. In all 4 studies, patients could receive optional background therapy with sTable doses of NSAIDs and/or DMARDs. Analyses were based on observed cases, with the first incidence of each patient achieving an ASAS20 response or ID status (Ankylosing Spondylitis Disease Activity Score with C-reactive protein [ASDAS-CRP] < 1.3) categorized as early, intermediate, or late depending on whether it occurred at Week 4, Week 8, or Week 12 (Week 16 for Study 402), respectively. Patients not achieving ASAS20 response or ID status by Week 12/Week 16 were categorized as “no response”. Proportions of patients achieving early, intermediate, late, or no response in the different treatment arms within each study were compared using Cochran–Mantel–Haenszel tests without adjustment for multiplicity.

Figure 2. Proportions of patients achieving an early, intermediate, or late inactive disease status (ASDAS-CRP <1.3)



N.B. In all 4 studies, patients could receive optional background therapy with stable doses of NSAIDs and/or hydroxychloroquine, sulfasalazine, or methotrexate (sulfasalazine was not permitted in Study 402 and no NSAIDs were used in Study 16.0037)

ASDAS-CRP: Ankylosing Spondylitis Disease Activity Score with C-reactive protein; biw: twice weekly; NSAID: non-steroidal anti-inflammatory drug; ETN: etanercept; PBO: placebo; qw: once weekly; SSZ: sulfasalazine.

Results: Overall, analyses of ASAS20 response and ID status included data from 1276 and 1261 patients, respectively. Within each of the 4 studies, the proportion of patients who achieved either early ASAS20 response (**Figure 1**) or early ID status (**Figure 2**) was significantly greater in the ETN arm compared with the control arm. Across the 4 studies, 50–65% of patients in the ETN arms and 13–41% of patients in the control arms had an early ASAS20 response, with smaller proportions achieving intermediate or late ASAS20 responses. For the analysis of ID status, 7–24% of patients in the ETN arms and ≤4% of patients in the control arms achieved early ID status across the 4 studies, with similar proportions achieving intermediate or late ID status.

Conclusion: The proportion of patients with no response to treatment was smaller in the ETN arms than the control arms throughout all 4 studies analyzed, with the superior clinical response to ETN predominantly driven by significantly greater proportions of the ETN-treated patients achieving an early ASAS20 response or early ID status. The achievement of ASAS20 response showed a different temporal pattern to the achievement of ID status. The majority of ASAS20 responses were categorized as early whereas similar proportions achieved ID status categorized as early, intermediate, or late.

Inadequate Response Among Psoriatic Arthritis Patients Prescribed Advanced Therapy in a Real-world US Commercially Insured Population

Julie Birt[1], **Michael Grabner**[2], Keith Isenberg[3], Theresa Hunter[4], Chia-Chen Teng[2], Mingyang Shan[1], Jeffrey Lisse[1], Jianmin Wu[1], Kirstin Griffing[1] and Jeffrey R Curtis[5], [1]Eli Lilly and Company, Indianapolis, IN, [2]Healthcore, Inc, Wilmington, DE, [3]Anthem, Inc, Indianapolis, IN, [4]Eli Lilly and Company, Indianapolis, [5]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this analysis was to assess the frequency of inadequate response (IR) over 1 year associated with advanced therapy (AT) initiation among psoriatic arthritis (PsA) patients in the US using a claims-based algorithm that was originally developed and validated for rheumatoid arthritis[1]. Baseline factors associated with IR to AT were also analyzed.

Methods: This was a retrospective cohort study using claims data from the HealthCore Integrated Research Database®. Adult patients with PsA who initiated an AT (TNFi: adalimumab, certolizumab, etanercept, golimumab, infliximab; non-TNFi biologic: abatacept, ixekizumab, secukinumab, ustekinumab; other: apremilast, tofacitinib) from 7/1/2016 to 8/31/2018 and had continuous enrollment ≥6 months before and ≥12 months after index date (date of first biologic claim) were included. The index AT was defined as the first AT prescribed during the study time period. Patients were identified as having IR to their index AT if during the 12 months after index date (defined as date of first AT claim) they had one or more of the following: low adherence (defined as proportion of days covered (PDC)< 80%), switched/added a new AT, added a new conventional synthetic immunomodulator (e.g. methotrexate), increased dose/frequency of AT, had >1 glucocorticoid injection/infusion, addition or dose increase of oral glucocorticoids, used a new topical treatment, actinotherapy, or retinoids, or used a new pain medication. Baseline characteristics were compared between responders and IRs using Chi-squared tests for categorical variables and t-tests for continuous variables. A multivariable logistic regression model was constructed to identify baseline characteristics associated with IR to index AT.

Results: A total of 1,433 PsA patients were included in this analysis. Mean age was 49 years, 47% were male, 67% initiated a TNFi, 22% initiated other ATs, and 11% initiated a non-TNFi biologic (Table 1). Over the 1-year follow-up period, 77% of PsA patients had IR to their index AT: 63% of patients had low adherence, 21% switched/added a new AT, 9% added a new conventional synthetic immunomodulator, 3% had a dose/frequency increase of their index AT, 11% had >1 glucocorticoid injection/infusion, 7% had an addition/dose increase of oral glucocorticoids, 3% used a new topical treatment, actinotherapy or retinoids, and 12% used a new pain medication (Table 2). Inadequate responders were more likely to be female (odds ratio (OR)=1.37; p=0.017), have anxiety or depression (OR=1.80; p=0.002), and have a higher baseline Quan-Charlson Comorbidity Index (QCI) score (OR=1.21; p=0.036); while patients with baseline use of methotrexate were more likely to be responders (OR=0.72; p=0.015) (Table 3). Prior exposure to TNFi was associated with a 2.14-fold greater odds of non-response (p=0.003).

Table 1. Demographic and Baseline Characteristics of PsA Patients at Advanced Therapy Index Date

	PsA Patients N=1,433	Responders N=336	Inadequate Responders N=1,097	p-value

[1]HMO=health management organization; [2]PPO=preferred provider organization; [3]CDHP=consumer-driven health plan; [4]Commercial plan is reference group on index date; [5]Based on US census regions; [6]6-months prior to index date; * denotes n < 10, which was blinded for privacy

Conclusion: Over 75% of PsA patients had an IR to their index AT 1 year after initiation, mostly driven by low adherence and switching to or adding on a new treatment. Health plan claims data appears useful to classify inadequate responders in PsA, and additional research should be done to further validate this claims-based algorithm in a clinical setting.

Table 2. Criteria Classifying PsA Patients as Inadequate Responders 1-year from initiation of an Advanced Therapy

	All PsA Patients N=1,433	TNFi Biologic N=963	Non-TNFi Biologic N=151	Other Advanced Therapy N=319
Inadequate Response (IR) n (%)	1,097 (76.6%)	732 (76.0%)	115 (76.2%)	250 (78.4%)
Criteria for IR, n (%)				
Low adherence to index advanced therapy (PDC[1]<80%)	904 (63.1%)	602 (62.5%)	83 (55.0%)	219 (68.7%)

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: SKIPPAIN (NCT03136861) is the first randomized controlled study involving a biological disease modifying antirheumatic drug, with spinal pain as the primary endpoint as early as Week (Wk) 8 in a broad population of patients (pts) with axial spondyloarthritis (axSpA; ankylosing spondylitis [AS] and non-radiographic [nr]-axSpA). Clinical studies in axSpA routinely use composite measures of disease activity to assess treatment effect, despite pain being the most troubling symptom for pts[1–2]. Here we present the 24-wk results from the SKIPPAIN study that evaluated the efficacy and safety of secukinumab (SEC) in reducing spinal pain and disease activity following a step-up dosing approach.

Methods: SKIPPAIN was a 24-wk, randomized, double-blind, multicenter, placebo (PBO)-controlled phase 3b study. Pts (aged ≥18 years) diagnosed with active disease defined by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score ≥4 and average spinal pain numerical rating scale (NRS) score >4 at baseline and inadequate response to ≥2 NSAIDs ≥4 wks were enrolled. Pts were randomized (3:1) to receive subcutaneous SEC 150 mg or PBO wkly followed by every 4 wks (q4w) starting at Wk 4. At Wk 8, PBO pts were re-randomized to SEC 150 or 300 mg q4w up to Wk 24. Pts originally randomized to SEC 150 mg, were further classified as responders (spinal pain NRS score < 4) or non-responders (spinal pain NRS score ≥4) at Wk 8. Responders were re-assigned to continue double-blind treatment with 150 mg q4w up to Wk 24 (Arm A1). Non-responders were re-randomized to receive double-blind treatment with either 150 (Arm A2) or a step-up dose of 300 mg (Arm A3) q4w up to Wk 24. Primary endpoint was the proportion of pts achieving an average spinal pain score < 4 on a 0–10 NRS with SEC vs PBO at Wk 8. Change in spinal pain NRS and Ankylosing Spondylitis Disease Activity Score using C-reactive protein (ASDAS-CRP) scores at Wk 24 were exploratory endpoints.

Results: A total of 380 axSpA pts (269 [70.8%] AS and 111 [29.2%] nr-axSpA) were randomized to SEC 150 mg (N=285) or placebo (N=95). Primary endpoint of the study was met (proportion of spinal pain NRS (average) score responders: 32% vs 20% with an odds ratio [95% CI] of 1.9 [1.1, 3.3] favoring SEC vs PBO; $P < 0.05$). At Wk 24, further reductions in spinal pain were observed across treatment groups especially in those initially randomized to

Table. Spinal pain and ASDAS-CRP scores at Wks 8 and 24

placebo and switched to active drug at Wk 8. Pronounced improvements were also observed in other disease activity measurements such as ASDAS-CRP score (**Table** and **Figure**). Of note, a numerically higher proportion of pts achieved ASDAS low disease activity at Wk 24 after SEC dose escalation at Wk 8 (Arm A3) as compared to those who remained on the same dose (Arm A2). No new or unexpected safety signals were reported.

Conclusion: Conclusion: SEC provided rapid, significant improvement in spinal pain and led to low disease activity in pts with axSpA. SEC dose escalation might be beneficial for pts not responding fully to the starting dose.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The efficacy of ixekizumab (IXE), a selective interleukin-17A antagonist, was assessed in patients (pts) with axial SpA (axSpA) in three Phase 3, randomized, double-blind, placebo (PBO)-controlled trials, COAST-V, COAST-W and COAST-X. The BASDAI is frequently used by clinicians to measure disease activity and response to treatment in pts with axSpA, and when considering starting biologic DMARD therapy[1,2]. We present BASDAI and quality of life (QoL) outcomes at 16 weeks from the COAST trials.

Methods: COAST-V (NCT02696785) and COAST-W (NCT02696798) assessed pts with radiographic axSpA, and COAST-X (NCT02757352) assessed pts with non-radiographic axSpA. All pts fulfilled Assessment of Spondyloarthritis International Society (ASAS) classification criteria for axSpA. Pts were either biologic-naive (COAST-V, COAST-X) or TNFα inhibitor-experienced (COAST-W) and were randomized to IXE (80 or 160 mg at week 0 then 80 mg every 2 or 4 weeks [Q2W, Q4W]) or PBO or adalimumab (ADA, 40 mg Q2W; COAST-V only). Treatment response at week 16 was assessed by the proportion of patients achieving BASDAI< 4, 50% reduction from baseline in BASDAI (BASDAI50), and a clinically meaningful change from baseline in BASDAI of at least 2 units (ΔBASDAI≥2)[1,2]. Categorical variables were analyzed by logistic regression with non-responder imputation (NRI) for missing data. QoL was assessed by change from baseline in Short Form (SF)-36 Physical Component Summary (PCS) scores according to BASDAI< 4 response status at week 16; missing data were imputed using modified baseline observation carried forward (mBOCF).

Results: In total, 341 pts from COAST-V, 316 from COAST-W, and 303 from COAST-X were included in this analysis. At week 16, a greater proportion of pts treated with IXE achieved BASDAI< 4, BASDAI50, and ΔBASDAI≥2 (Figure 1) compared to PBO across all three trials, and the difference was statistically significant for the majority of endpoints. Furthermore, pts achieving BASDAI< 4 showed greater improvements in SF-36 PCS scores (Figure 2).

Conclusion: In the COAST trials, IXE delivered clinically meaningful improvements in pts with axSpA after 16 weeks of treatment. Low disease activity (BASDAI< 4) was achieved with IXE regardless of axSpA type (radiographic or non-radiographic) or prior use of TNFα inhibitors. Achieving BASDAI< 4 was associated with greater improvements in physical QoL.

Proinflammatory Neutrophil Function Is Modulated During Secukinumab Therapy in Psoriatic Arthritis Without Compromising Host Defence

Robert Moots[1], Andy Cross[2], Helen Wright[2], Steven Edwards[2], Nicola Goodson[3], Jenny Hawkes[3], Ayren Mediana[1] and Helen Frankland[1], [1]Liverpool University Hospitals, Liverpool, United Kingdom, [2]University of Liverpool, Liverpool, United Kingdom, [3]University of Liverpool, Liverpool

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab is a monoclonal antibody that neutralises IL-17A, which plays a key role in the IL-23/17A axis underlying the pathophysiology of psoriatic arthritis (PsA). In this disease, Th17 cells produce IL-17A to trigger the release of chemoattractants such as CXCL8 and CCL20, leading to the infiltration of other immune cells including neutrophils. Activated neutrophils can themselves generate numerous chemokines and cytokines that can amplify and sustain inflammation. Therapeutic targeting of IL-17 with biologics such as secukinumab in PsA may

block this inflammatory cycle, but such inhibition should not have deleterious effects on other aspects of immunity associated with host defence.

This study measured changes in the functions of circulating neutrophils in PsA patients pre-therapy, compared to age- and sex-matched healthy controls, and determined if these functions changed in PsA patients prior to and during secukinumab therapy.

Methods: Neutrophils were isolated from venous blood of 20 PsA patients due to start secukinumab and 10 healthy controls. Key neutrophil functions such as: reactive oxygen species (ROS) production; phagocytosis; apoptosis (+/- TNF and GM-CSF); receptor expression and chemotaxis, were measured at baseline and 12 weeks. Changes in gene expression pre- and 12-weeks post-therapy (n=5 PsA) were measured by RNAseq, and pre-treatment PsA neutrophil transcriptomes were also compared to healthy controls.

Results: There were no significant differences in ROS production, phagocytosis or chemotaxis in PsA patients at baseline (compared to healthy controls) or during therapy. RNA-seq analysis revealed many genes with altered expression between PsA neutrophils at baseline and healthy controls. For example, up-stream cytokines predicted to be regulating neutrophil gene expression in PsA included CSF2 (G-CSF), CD40LG, oncostatin M, interferons-a and -g, and TNFa. Ingenuity analysis revealed that signalling pathways associated with IL-8 signalling, toll-like receptor signalling and apoptosis signalling were among those significantly down-regulated by secukinumab. Of note, none of the patients treated with secukinumab contracted Covid-19.

Conclusion: Selective up- and down-regulation of neutrophil transcription was observed in PsA neutrophils compared to healthy controls, and in PSA neutrophils post treatment with secukinumab. However, while these changes may alter the pro-inflammatory function of neutrophils in PsA in response to IL-17A blockade, they did not adversely affect the ability of these neutrophils to carry out their role in host defence against infections.

Impact of Dose Escalation of Secukinumab in Patients with Psoriatic Arthritis in Real-World Setting

Maria Martin-Lopez[1], Beatriz Joven[2] and Jose Luis Pablos[1], [1]Hospital 12 de Octubre, Madrid, Spain, [2]Hospital Universitario 12 de Octubre, Madrid, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC) has provided efficacy in clinical trials in patients with psoriatic arthritis (PsA). In PsA patients, a gain in response has been suggested by dose escalation from 150 to 300 mg in the open phase of the FUTURE study[1]. We analyze the usefulness of dose escalation of SEC from 150 to 300 in patients with non-responding PsA to 150 mg in real-world setting.

TABLE 1. Characteristics of the PsA patients according to the SEC dose

	SEC150 (n=58)	SEC300 (n=12)	SEC150-300 (n=28)
n previous biological therapy			
0	24 (41%)	2 (17%)	11 (39%)
1	16 (28%)	1 (8%)	7 (25%)
2	8(14%)	3 (25%)	2 (7%)
3 or more	10 (17%)	6 (50%)	8 (29%)
Survival of SEC (years)	1,3±1	1,6±1,3	1,6±0,9
n SEC discontinuation	24 (41%)	8 (67%)	13 (46%)
Causes of SEC discontinuation			
Primary failure	9 (37%)	2 (25%)	-
Secondary failure	10 (42%)	5 (63%)	13 (100%)
Adverse events	4 (17%)	-	-
Allergy to latex	1 (4%)	-	-
Remission	-	1 (12%)	-

SEC: secukinumab. n: number. PsA: psoriatic arthritis

Methods: Unicentric observational, longitudinal, retrospective study conducted in a tertiary hospital between January 2016 and December 2019. Patients with PsA (CASPAR criteria) receiving at least one dose of SEC were included. Medical records were reviewed to collect demographic and clinical data related to PsA (including activity assessment and treatment).

Descriptive statistics and a comparative analysis of the efficacy of SEC by the Student *t* test in the different dose groups and by the ANOVA test to compare the response between the three dose groups were performed.

Results: 98 PsA patients treated with SEC, of which 69 (70%) female, were included. Mean age was 54 y.o (SD12) and average duration of the disease was 9 (SD 7) years. Three groups were performed according to the dose received, SEC150, SEC300 and SEC150-300 (non-responders after SEC150 onset increasing to 300 mg). *Characteristics are detailed on Table 1.* The SEC150 group includes 58 (59%) patients, SEC300 12 (12%) and SEC150-300 28 (29%) patients.

In the SEC150-300 group, 54% of the patients maintains SEC after responding to the dose increase. The average time of dose increase to 300 mg was 9 (SD6) months in this group.

At 6 months of SEC therapy, a significant decrease in CRP, ASDAS-CRP and DAPSA values was observed in the three treatment groups *(Table 2).* However, when comparing the difference of means obtained during follow-up (ΔCRP, ΔASDAS-CRP and ΔDAPSA) between the 3 dose groups, no significant differences were found (p=0.76 for CRP, p=0.86 for ASDAS-CRP and p=0.35 for DAPSA).

TABLE 2. Disease activity assessment at 6 months of SEC therapy

	Baseline	6 months after SEC	Mean difference	*p* value
CRP_{300} (mg/L)	9±8,3	4,7±3,7	-4,3 (IC95% -8,9 a 0,2)	p=0,06
CRP_{150} (mg/L)	7,3±9,1	4,0±4,7	-2,9 (IC95% -4,7 a -1,3)	p=0,0009
$CRP_{150\text{-}300}$ (mg/L)	9,9±11	6,0±7,4	-3,9 (IC95% -6,9 a -8,5)	p=0,0142
ASDAS-CRP_{300}	2,3±0,7	1,6±0,6	-0,6 (IC95% -0,9 a -0,3)	p=0,0014
ASDAS-CRP_{150}	2,3±0,6	1,6±0,7	-0,7 (IC95% -0,8 a -0,5)	p<0,0001
ASDAS-$CRP_{150\text{-}300}$	2,2±0,6	1,6±0,7	-0,6 (IC95% -0,8 a -0,4)	p<0,0001
$DAPSA_{300}$	33,7±19,3	16,9±10,6	-16,8 (IC95% -29,6 a -3,9)	p=0,01
$DAPSA_{150}$	27,4±11,4	15,4±10,4	-11 (IC95% -14,4 a -7,6)	p<0,0001
$DAPSA_{150\text{-}300}$	28±9,9	15,8±8,7	-12,2 (IC95% -15,3 a -9,1)	p<0,0001

CRP_{300}: C-reactive protein in patients with SCK 300 mg, CRP_{150}: in patients with SCK 150, $CRP_{150\text{-}300}$: in patients with dose escalation from 150 to 300 (same for ASDAS-CRP and DAPSA), SEC: secukinumab

Conclusion: There are no significant differences in the response evaluated by CRP, ASDAS-CRP and DAPSA between the dose of 150 and 300 mg of SEC. However, both doses of treatment provided efficacy in clinical practice with significant reduction of activity parameters.

In patients with non-responding PsA to SEC150 mg and prior failure to TNFi, increasing the dose to 300 mg could be an effective option.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In Australia the cost of biologic/targeted synthetic DMARDs (b/tsDMARDs) for treatment of PsA is subsidized if the patient has documented high levels of clinical/laboratory disease activity and has not responded to a pre-specified combination of conventional synthetic DMARDs, including methotrexate. Once eligible for subsidy the clinician can then prescribe the b/tsDMARD deemed most clinically appropriate until the desired level of disease control is reached, with the available options being adalimumab, etanercept, certolizumab pegol, golimumab, infliximab, secukinumab, ixekizumab, ustekinumab and tofacitinib. The aim of this analysis was to determine the patterns of use and reasons for initiation and discontinuation of b/tsDMARDs for PsA in real-world rheumatology practice in Australia.

Methods: Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record at the time of the consultation[1] by 110 rheumatologists in Australia. Prescribing data for patients >18 years with PsA treated with a b/tsDMARD between Jan 2007-Mar 2020 was included in the analysis. The software program Tableau® was used to display data on medication initiation and cessation dates, and reasons for starting and stopping b/tsDMARDs, which is recorded at the time of the decision.

Results: At Mar 2020, there were 13,767 PsA patients in the dataset, with 35% (4,854) prescribed b/ts DMARDs. 67% of patients were receiving a TNF inhibitor (TNFi), 22% an IL-17 inhibitor (IL-17i), 7% a JAK inhibitor (JAKi) and 4% an IL-12/IL-23 inhibitor. In the prior 12 months (April 2019-Mar 2020) TNFi was the preferred 1st line treatment (66%) with adalimumab taking 31% of all initiations, followed by secukinumab and golimumab (16% of initiations each). Secukinumab was the most prescribed bDMARD in 2nd line (23%) followed by tofacitinib (21%), and tofacitinib was the most prescribed 3rd line agent (31%) followed by secukinumab (20%). Mode of action (MOA) was selected as the most common reason for choosing a drug (48%), followed by efficacy compared to alternatives (34%) and efficacy as monotherapy (11%). Mode of administration was considered the driver for 17% of tofacitinib initiations compared to 5% overall. The main reasons for stopping treatment were lack of efficacy (40%), better alternative (25%) and adverse reaction (12%). 42% of patients who switched from a TNFi in 1st line received a TNFi in 2nd line, 33% switched to an IL-17i, and 23% switched to a JAKi. 43% of patients that switched from an IL-17i switched to a TNFi, 33% switched to a JAKi, and 24% switched to an alternative IL-17i.

Conclusion: Clinicians appraise different characteristics of each drug when choosing interventions for their patients. MOA is rated highly which is reflected in the rapid uptake of IL-17i and JAKi in early lines of therapy for patients with PsA. Clinical outcomes following in-class switching versus switching to an agent with a different MOA requires further investigation.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFis) are effective treatments for radiographic axial spondyloarthritis (r-axSpA), but may be less effective in patients (pts) without elevated C-reactive protein (CRP). This study evaluated the efficacy of ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A, in pts with r-axSpA at 52 weeks (wks) with nonelevated (≤5 mg/L) and elevated (>5 mg/L) baseline (BL) CRP. Week 16 Assessment of Spondyloarthritis International Society 40% response rate (ASAS40) results comparing IXE to placebo (PBO) stratified by CRP are published.[1]

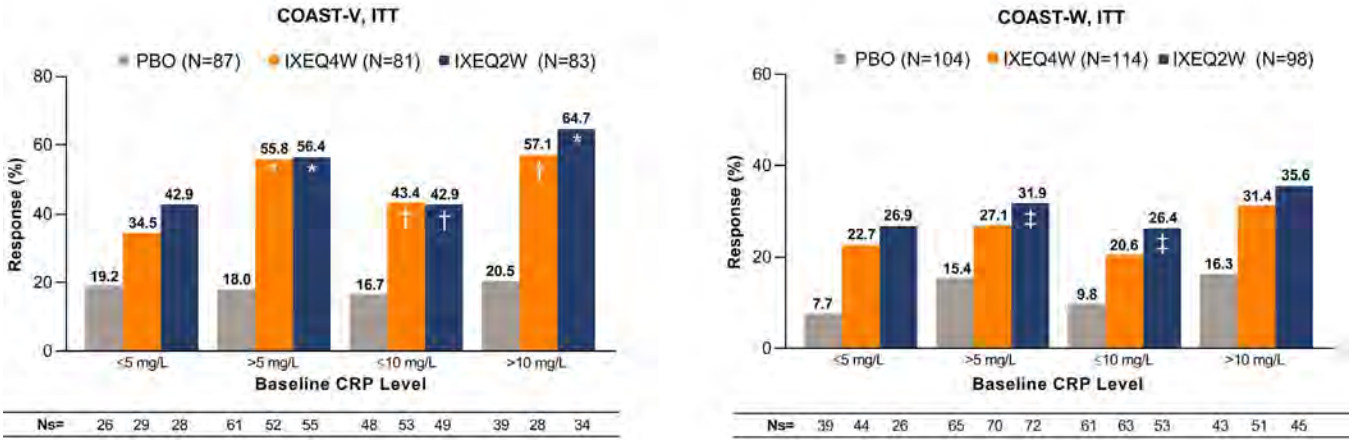
Methods: COAST-V (NCT02696785) and COAST-W (NCT02696798) were phase 3, multicenter, randomized, double-blind, PBO-controlled trials investigating efficacy of 80-mg IXE every 4 wks and every 2 wks in pts who met ASAS criteria for r-axSpA, had radiographic sacroiliitis according to mNY criteria, and were biological disease-modifying antirheumatic drug (bDMARDs)-naïve (COAST-V) or TNFi-experienced (COAST-W). Data from 157 COAST-V pts and 188 COAST-W pts treated with IXE from Wk 0 to Wk 52 were analyzed. Patients were stratified based on nonelevated (≤5 mg/L) vs elevated (>5 mg/L) BL CRP. Additional analysis was done with BL CRP ≤10.0 mg/L vs >10.0 mg/L. Efficacy was assessed by ASAS40, ≥50% improvement in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), and change in Short Form 36 physical component summary (SF-36 PCS) score. Missing data were imputed by non-responder imputation for binary measures and modified BL observation carried forward for continuous measure. Week 16 data are presented for comparison.[1]

Results: Of pts treated with IXE through Wk 52, 34.4% had CRP ≤5.0 mg/L, 65.6% had CRP >5.0 mg/L, 61.8% had CRP ≤10.0 mg/L, and 38.2% had CRP >10.0 mg/L at BL in COAST-V and 33.0% had CRP ≤5.0 mg/L, 67.0% had CRP >5.0 mg/L, 55.9% had CRP ≤10.0 mg/L, and 44.1% had CRP >10.0 mg/L at BL in COAST-W.

At Wk 16, the proportion of pts achieving ASAS40 in COAST-V was numerically higher with IXE in the ≤5 mg/L group and significantly higher with IXE in the >5 mg/L group vs PBO, as previously shown [1], and was significantly higher with IXE in the ≤10 mg/L and >10 mg/L groups vs PBO (Fig. 1). Results were similar in COAST-W and significant in the >5 mg/L and ≤10 mg/L groups vs PBO (Fig. 1).

At Wk 52, greater than 45% of COAST-V pts and greater than 35% of COAST-W pts treated with IXE achieved an ASAS40 response, greater than 40% of COAST-V pts and greater than 25% of COAST-W pts treated with IXE

Figure 1. COAST-V and COAST-W ASAS40 Response at Week 16, NRI[a]



a. Week 16 data for the CRP ≤5 mg/L and >5 mg/L groups were previously published in a COAST V/COAST-W integrated dataset.[1] *p<0.001, †p<0.01, ‡p<0.05 vs PBO, ASAS40=Assessment of Spondyloarthritis International Society 40% response rate; CRP=C-reactive protein; ITT=intent-to-treat; IXE=ixekizumab; N=number of patients in the treatment group; Ns=number of patients in each subgroup; NRI=non-responder imputation; PBO=placebo; Q2W=every 2 weeks; Q4W=every 4 weeks.

achieved a BASDAI50 response, and change from baseline in SF-36 PCS score in pts treated with IXE was greater than 5 points in both studies regardless of the BL CRP cutoffs evaluated (Figs. 2 and 3).

Conclusion: A higher proportion of ASAS40 responders was observed in IXE treated arms versus PBO among bDMARD-naïve and TNFi-experienced pts with r-axSpA when the CRP cutoff of 10 mg/L was evaluated, and the responses were consistent through Wk 52. Furthermore, similar proportions of pts achieved BASDAI50 and SF-36 responses within each patient population regardless of the BL CRP cutoff evaluated.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Apremilast (APR) is associated with comparable ACR response rates in DMARD-naive vs DMARD-experienced patients (pts) with PsA (Wells AF, et al. *Rheumatology*. 2018;57:1253-63; Kavanaugh A, et al. *Arthritis Res Ther.* 2019;21:118). A question that remains is if DMARD-naive pts treated with APR have greater chances of achieving treatment targets than DMARD-experienced pts. cDAPSA is a commonly used treatment target. We assessed the predictive value of baseline (BL) clinical disease status on achieving long-term cDAPSA treatment

Probability of Achieving cDAPSA Treatment Targets at Week 52 by Baseline cDAPSA Category

cDAPSA Categories at Baseline*	HDA	Mod	LDA	REM	LDA/REM
LDA	0.0%	0.0%	50.0%	50.0%	100.0%
Mod	9.1%	29.2%	39.8%	21.9%	61.7%
HDA	27.1%	44.7%	24.3%	3.9%	28.2%

cDAPSA Categories at Week 52

- Subjects achieving treatment targets
- Subjects with ≥1 disease activity category improvement
- Subjects with no change in disease activity category
- Subjects with ≥1 disease activity category worsening

*Subjects randomized to APR 30 mg twice daily with cDAPSA scores available at baseline (n = 175). Percentage represents the proportion of subjects in each cDAPSA category at baseline (from left to right, HDA, Mod, LDA, and REM at Week 52 = 100%). Multiple imputation. REM, cDAPSA ≤4; LDA, cDAPSA >4 to ≤13; Mod, cDAPSA >13 to ≤27; HDA, cDAPSA >27. Mod = moderate disease activity.

targets at Week 52 among DMARD-naive subjects in PALACE 4; compared these findings vs those recently reported from PALACE 1-3 in subjects with prior exposure to DMARDs; and provided further evidence that at a group level, achievement of cDAPSA disease targets with APR is associated with no or mild articular and extra-articular disease activity by Week 52.

Methods: This post hoc analysis included subjects assigned to APR 30 mg BID at BL who had available cDAPSA data at BL. We calculated the probabilities of shifting across different cDAPSA categories (remission [REM]: ≤4; low disease activity [LDA]: >4 to ≤13; moderate disease activity [Mod]: >13 to ≤27; high disease activity [HDA]: >27 [Machado PM. *Ann Rheum Dis*. 2016;75:787-790]) from BL to Week 52. Mean values of articular and non-articular variables (PASI, SJC/TJC, MASES, dactylitis) from BL to Week 52 were assessed by cDAPSA category achieved at Week 52 to determine the association between achievement of targets and control of articular and non-articular manifestations. Results from the current analyses were compared with the previously reported results from PALACE 1-3.

Results: A total of 175 subjects receiving APR were included; at BL, 66.3% were in HDA, 31.4% in Mod, and 2.3% were in LDA. Overall, subjects who achieved treatment targets (LDA or REM) by Week 52 had lower levels of disease activity at BL, as shown by a lower number of swollen and tender joints and lower presence of enthesitis and dactylitis. Higher prevalence of psoriasis-involved body surface area ≥3% at BL was observed. Subjects in Mod at BL were estimated to be more than twice as likely to achieve REM or LDA at Week 52 vs subjects in HDA at BL; for subjects in LDA at BL, the estimated probability of achieving cDAPSA treatment targets was 100% (Figure). PALACE 4 subjects with LDA and Mod at BL exhibited higher estimated probabilities of achieving treatment targets (100.0% and 61.7%, respectively) than those observed in the DMARD-experienced population of PALACE 1-3 (71.1% and 46.9%). Subjects in PALACE 4 who achieved REM or LDA by Week 52 showed no or mild articular and extra-articular disease activity by Week 52, similar to what was observed in the PALACE 1-3 population (Mease PJ, et al. *Arthritis Care Res.* 2020 Jan 7. Epub).

Conclusion: DMARD-naive subjects in PALACE 4 who had LDA or Mod at BL had the highest likelihood of achieving treatment targets (cDAPSA REM or LDA) by Week 52 with continued APR treatment. Results from the current probability analyses revealed higher probability rates than those observed in the DMARD-experienced PALACE 1-3 population; control of articular and extra-articular manifestations was observed in the DMARD-naive and DMARD-experienced populations.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with psoriatic arthritis (PsA) require effective treatment across all symptoms. Bimekizumab (BKZ) is a humanized IgG1 monoclonal antibody which selectively neutralizes interleukin (IL)-17A and IL-17F. During BE ACTIVE (NCT02969525), a phase 2b dose-ranging study in pts with PsA, BKZ demonstrated improved peripheral joint, skin, and extra-articular outcomes over 48 weeks (wks).[1] The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)[2] is a validated instrument for evaluating disease activity and symptoms in pts with axial spondyloarthritis. We use the BASDAI to assess the effect of BKZ treatment on fatigue and pain in pts with PsA.

Methods: In this randomized controlled trial, pts received BKZ or placebo (PBO).[1] This post hoc analysis focuses on BASDAI over 48 wks. BASDAI data were collected prospectively from all pts as an efficacy variable. We report BASDAI50 (a 50% improvement on baseline [BL] BASDAI score), and mean change from BL (CfB) in BASDAI question scores (higher scores denote worse symptoms), for all BASDAI questions, with a focus on Question 1 (Q1; fatigue) and Question 2 (Q2; neck/hip/back pain). We also report the percentage (%) of pts who had a CfB in BASDAI Q1 or Q2 scores of ≥2 points.[3,4] Observed data are reported for the Full Analysis Set (FAS) in pt subsets with a baseline (BL) BASDAI score of ≥4, and ≥4 for all individual questions. Treatment-emergent adverse event (TEAE) rates are reported per 100 pt-years (PY) for the Safety Set (SS; pts who received ≥1 dose BKZ).

Results: 206 pts were randomized at BL (42 to PBO every 4 weeks [Q4W], 41 to each BKZ Q4W arm: 16 mg, 160 mg, 160 mg+320 mg loading dose [LD] and 320 mg). 152 pts had BASDAI ≥4 at BL (**Table**). 93 of these pts were in the 160–320 mg pool. Their mean (SD) BASDAI at BL was 6.20 (±1.42), and the BASDAI50 response rate was 43% (9%

Table: Mean change from baseline in BASDAI individual question scores at Week 12

[a] Patients on bimekizumab 160 mg, 160 mg LD or 320 mg. Dosing frequency was every 4 weeks. Patients in the 160 mg LD arm received a 320 mg dose at baseline and then 160 mg every 4 weeks from Week 4. BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BL: baseline; FAS: Full Analysis Set; LD: loading dose; OC: observed case; PBO: placebo.

for PBO), and 56% at Wk 12 and Wk 48, respectively. 84 pts in the 160–320 mg pool scored ≥4 for BASDAI Q1 (mean at BL: 6.19 [±1.59]; Wk 48: 3.58 [±2.67], a mean CfB of –2.59). 87 pts in this BKZ pool scored ≥4 for BASDAI Q2 at BL (mean 6.47 [±1.66]; Wk 48: 3.49 [±2.56], a mean CfB of –2.99). Across all 160–320 mg doses, clear improvements in BASDAI Q1 and Q2 scores were seen by Wk 12, continuing to Wk 48. This was also shown for pts with BASDAI Q1 and Q2 scores ≥4 at BL (**Figures 1 and 2**).

For pts in the 160–320 mg pool with a BASDAI Q1 or Q2 score ≥4 at BL, 58–66% and 63–68% had a ≥2-point reduction in their Q1 and Q2 scores, respectively, across Wks 12, 24, and 48. For the same pts on PBO, 26% and 43% had a ≥2-point reduction in their Q1 and Q2 scores at Wk 12, respectively. TEAEs were reported in 74% of BKZ-treated pts (exposure-adjusted event rate [EAER]: 294/100 PY). Serious TEAEs were reported for 3.9% (EAER: 4.52/100 PY).

Conclusion: In this exploratory analysis, BKZ treatment was associated with improvements in BASDAI total and single question scores related to fatigue and neck, back and hip pain in pts with PsA.

Table 1. Overview of safety with FIL 200 mg QD at Week 52 and Week 100 of the EQUATOR2 OLE. *Defined as Grade ≥3. †Excludes deaths. AE, adverse event; FIL, filgotinib; OLE, open-label extension; PYE, patient-years of exposure; QD, once daily; RTI, respiratory tract infection; TEAE, treatment-emergent adverse event

Background/Purpose: EQUATOR (NCT03101670) was a randomized, 16-week, Phase 2, multicenter, double-blind, placebo (PBO)-controlled trial of filgotinib (FIL) in patients with active PsA (Mease P, et al. *Lancet* 2018;392:2367–77) . In EQUATOR, FIL was well tolerated and was efficacious vs PBO for the primary endpoint of Week 16 ACR20 response. Patients completing EQUATOR could join an ongoing 304-week OLE (EQUATOR2; NCT03320876). We report the findings of an interim analysis of EQUATOR2 at Week 100. Primary and secondary objectives were to assess safety/tolerability and efficacy, respectively.

Methods: In EQUATOR, patients with active moderate-to-severe PsA (≥5 swollen joints and ≥5 tender joints, fulfilling Classification for PsA [CASPAR] criteria) were randomized 1:1 to receive oral FIL 200 mg or PBO once daily (QD) for 16 weeks. At Week 16, patients could continue into the OLE, receiving FIL 200 mg QD. For this interim analysis, patients were followed for efficacy until the last patient completed their Week 100 visit; safety data were collected up to April 8, 2020. Efficacy measures included minimal disease activity (MDA; meeting 5/7 MDA criteria), MDA/very low disease activity (VLDA; meeting 7/7 MDA criteria), Psoriatic Arthritis Disease Activity Score (PASDAS) low disease activity (score ≤3.2) and VLDA (score ≤1.9), ACR20/50/70, and Psoriasis Area and Severity Index (PASI) 75/90/100. The number and proportion of patients achieving each endpoint were calculated using observed case (OC) and non-re-

	n/N (%)
MDA*	41/131 (31.3)
MDA VLDA†	13/131 (9.9)
PASDAS LDA‡	57/131 (43.5)
PASDAS VLDA§	23/131 (17.6)
ACR20	79/131 (60.3)
ACR50	57/131 (43.5)
ACR70	38/131 (29.0)
PASI 75¶	32/82 (39.0)
PASI 90¶	20/82 (24.4)
PASI 100¶	11/82 (13.4)

Table 2. Responders at Week 100 of the OLE (NRI). *Defined as meeting 5 out of 7 of the MDA criteria. †Defined as meeting 7 out of 7 of the MDA criteria. ‡Defined as a PASDAS score of ≤3.2. §Defined as a PASDAS score of ≤1.9. ¶PASI was only measured in patients with ≥3% of their body surface area affected by psoriasis. ACR, American College Rheumatology; LDA, low disease activity; MDA, minimal disease activity; NRI, non-responder imputation; OLE, open-label extension; PASDAS, Psoriatic Arthritis Disease Activity Score; PASI, Psoriasis Area and Severity Index; VLDA, very low disease activity

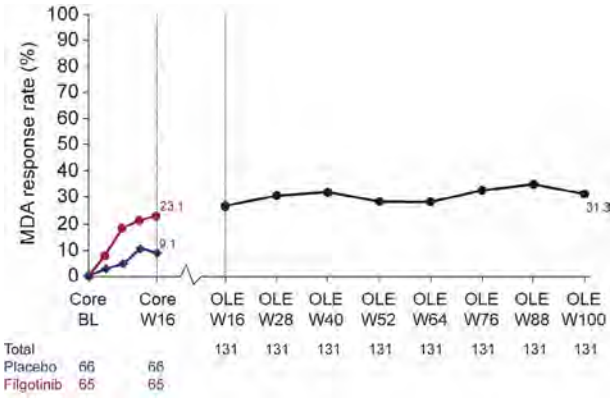

Figure 1. MDA response rate over time (NRI). BL, baseline; MDA, minimal disease activity; NRI, non-responder imputation; OLE, open-label extension; W, Week

sponder imputation (NRI) approaches. Adverse events (AEs) per 100 patient-years of exposure (from first exposure to FIL) are summarized.

Results: Of 131 randomized patients, 124 (95%) completed EQUATOR and 122 (93%) were enrolled in the OLE, of whom 104 patients (85%) remained in the study at Week 100. Safety and tolerability were similar at Week 100 to a previous analysis conducted at Week 52 (**Table 1**). No unexpected safety issues were identified. By Week 100, 1 death (bilateral pneumonia, leading to toxic shock with multi-organ failure) and 1 adjudicated major adverse cardiac event had occurred (both prior to Week 52). Five additional serious treatment-emergent AEs occurred from Week 52 to 100, including 1 serious infection (COVID-19). No deep vein thromboses or pulmonary embolisms occurred up to Week 100. Efficacy was sustained at Week 100 (**Table 2**). The response rate at Week 100 for all patients (regardless of original randomization to PBO or FIL) was 31.3% for MDA (NRI; 42.3% for OC; **Figure**), and 60.3%/43.5%/29.0% for ACR20/50/70 (NRI; 81.4%/58.8%/39.2% for OC). Of 15 patients originally randomized to FIL who were MDA responders at Week 16, 73.3% also had an MDA response at Week 100 (NRI). Sustained responses were observed at ≥3 consecutive visits (each of which was 12 weeks apart) for MDA in 34.4% of patients (NRI).

Conclusion: This interim analysis of long-term extension data from the PsA EQUATOR2 study found FIL 200 mg QD to be generally well tolerated up to Week 100 with a safety profile comparable to that seen up to Week 52. Response rates at Week 100 to FIL 200 mg QD were sTable and comparable to those reported at Week 52. In most patients who were MDA responders at Week 16, responses were also seen at Week 100.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), a human monoclonal antibody targeting the IL-23p19-subunit, has shown consistent efficacy in psoriasis pts regardless of body weight/body mass index (BMI).[1] GUS has also shown efficacy across joint and skin endpoints at Week 24 (W24) of the Phase 3 DISCOVER-1[2] and DISCOVER-2 PsA[3] trials. We assessed GUS efficacy at W24 across baseline demographic and disease characteristics subgroups by pooling data across the 2 trials.

Figure 1. ACR50 Response at Week 24 by Select Baseline Characteristics: Pooled Results of DISCOVER-1 and DISCOVER-2

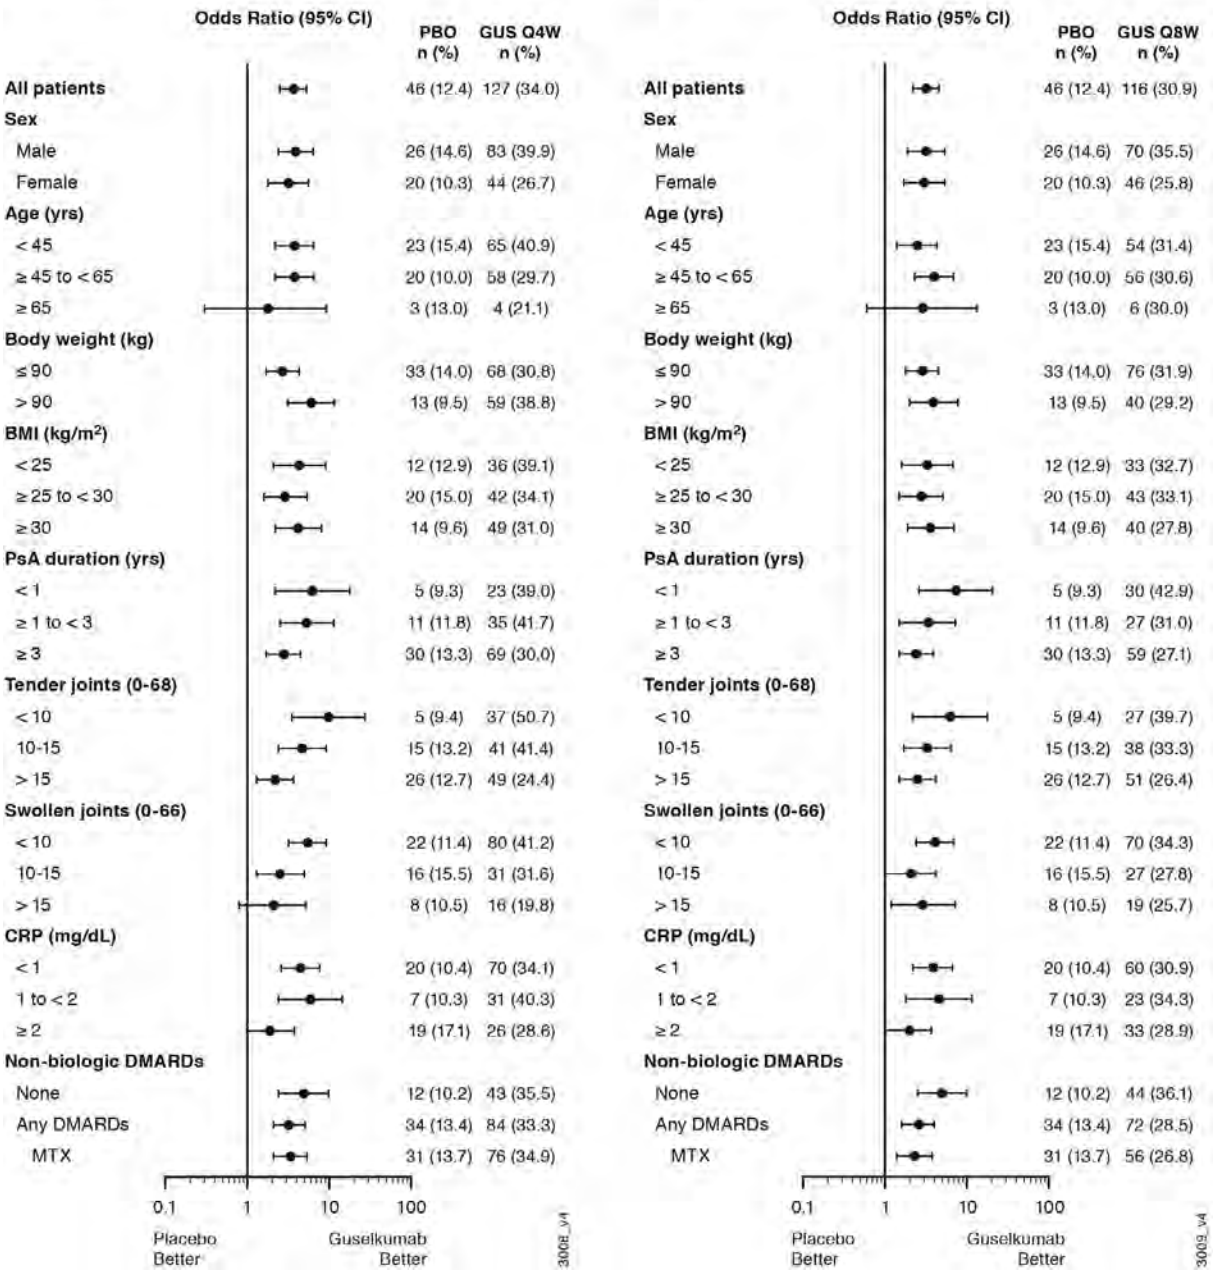

Figure 2. IGA 0/1 Response at Week 24 by Select Baseline Characteristics: Pooled DISCOVER-1 and DISCOVER-2 Patients with ≥3% BSA psoriasis and IGA ≥2 at W0

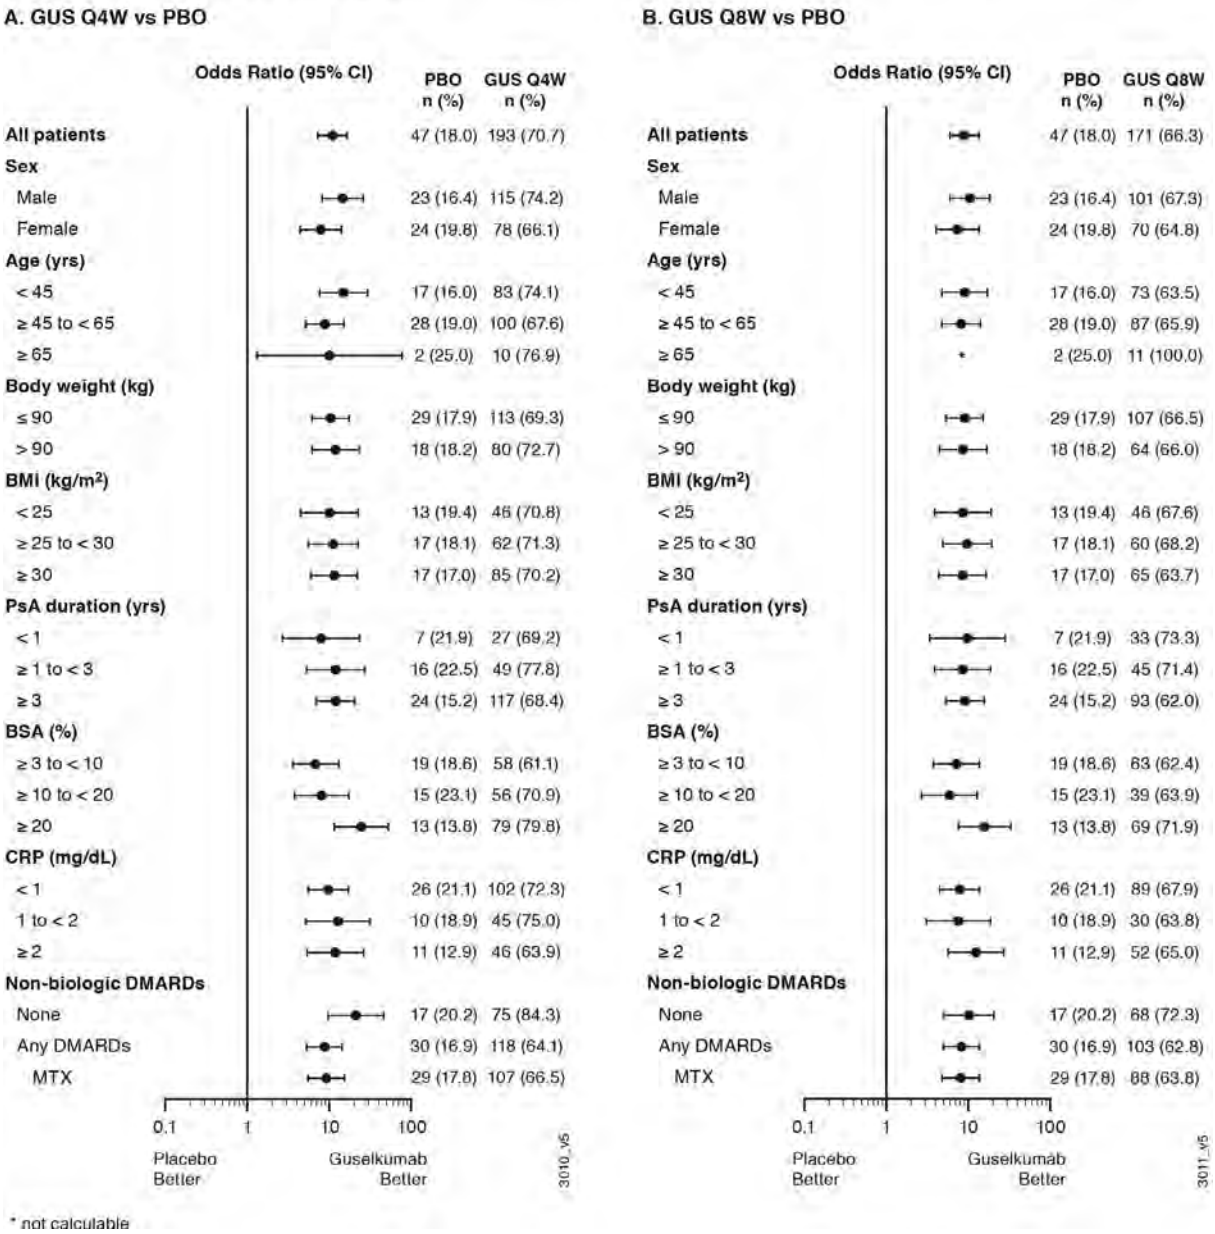

Methods: Adults with active PsA despite standard therapies were enrolled in DISCOVER-1 (≥3 swollen & ≥3 tender joints; CRP ≥0.3 mg/dL) and DISCOVER-2 (≥5 swollen & ≥5 tender joints; CRP ≥0.6 mg/dL). 31% of DISCOVER-1 pts had received 1-2 prior TNF inhibitors; DISCOVER-2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (Q8W); or placebo (PBO). GUS effects on joint (ACR50) and skin (Investigator's Global Assessment [IGA=0/1 + ≥2-grade reduction from W0] in pts with ≥3% body surface area [BSA] psoriasis and IGA ≥2 at W0) responses were evaluated by pt sex, age, body weight, BMI, PsA duration, tender/swollen joint counts (ACR50 only), % BSA (IGA 0/1 only), CRP, and non-biologic (nb) DMARD/methotrexate (MTX) use at W0. Missing data were imputed as nonresponse. Logistic regression compared GUS vs PBO; odds ratios (ORs) and 95% confidence intervals (CIs) are shown on a logarithmic scale.

Results: Baseline characteristics of randomized and treated pts in DISCOVER-1 (N=381) and DISCOVER-2 (N=739) were generally well-balanced across groups.[1,2] On average, the 1120 pooled pts were 47 yrs and 85 kg at W0; 52%

were male; 96% were white. At W24, 34% (127/373) and 31% (116/375), respectively, of pooled GUS Q4W- and Q8W-treated pts achieved ACR50 vs 12% (46/372) for PBO; respective ORs (95% CIs) were 3.7 (2, 5) and 3.2 (2, 5). In subgroups with sufficient sample size, the benefit of GUS Q4W and Q8W over PBO in substantially improving joint signs and symptoms was seen regardless of sex (ORs 3–4), age (2–4), body weight/BMI (3–6), PsA duration (2–7), swollen/tender joint count (2–10), CRP (2–6), or nbDMARD/MTX use (2–5) at baseline. In pooled pts with ≥3% BSA psoriasis and IGA ≥2 at W0, 71% (193/273) and 66% (171/258), respectively, of GUS Q4W- and Q8W-treated pts, vs 18% (47/261) for PBO, had an IGA 0/1 response at W24; respective ORs (95% CIs) were 11 (7, 16) and 9 (6, 14). The benefit of GUS in achieving clear or almost clear skin was seen regardless of sex (ORs 7-15), age (8-15), body weight/BMI (9-12), PsA duration (8-12), % BSA (7-25), CRP (8-13), or nbDMARD/MTX use (8–21) at baseline. Note that small sample sizes in several pt subgroups (eg, pts >65 years, swollen joint count >15) limit their data interpretation. Consistent results were seen for other joint (ACR20/70), skin (PASI90/100), and soft tissue (enthesitis) outcomes.

Conclusion: Conclusions: The benefits of guselkumab 100 mg Q4W and Q8W in substantially improving signs and symptoms of active PsA appeared to be consistent irrespective of the baseline characteristics assessed.

Session Date: Saturday, November 7, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent EULAR recommendations propose that treatment of psoriatic arthritis (PsA) should seek remission (REM) or alternatively low disease activity (LDA) by regular disease activity assessments using composite indices targeting one or several key manifestations in PsA.[1,2] The EXCEED study compared secukinumab (SEC) and adalimumab (ADA) monotherapy in patients with active PsA with inadequate response/intolerance to csDMARDs. We present a *post hoc* analysis of patients who achieved LDA and/or REM at Week 24 and 52 with their respective levels of residual disease activity (RDA) in the core components of the various composite indices.

Methods: Head-to-head, phase-3b, randomized, double-blind trial: biologic naïve active PsA patients were randomized to receive SEC 300 mg subcutaneous at baseline, Week 1-4, and then every 4wks (q4w) until Week 48 or ADA 40 mg subcutaneous at baseline and then q2w until Week 50. The primary and key secondary endpoints at Week 52 were previously reported.[3] LDA and REM were assessed using MDA, VLDA, DAPSA REM/LDA and PASDAS REM/LDA. The proportions of RDA were established for clinical domains of PsA (articular, enthesitis, and psoriasis), HAQ, VAS pain, patient global assessment (PtGA) and Physician's global assessment (PhGA) of disease activity. The composite indices were analyzed using logistic regression and missing data was handled using multiple imputation. RDA levels are presented in patients who achieved either LDA and/or REM.

Results: A similar proportion of patients receiving SEC and ADA achieved LDA and REM at Week 24. Further increase from Week 24 in LDA/REM was observed in both treatment groups through Week 52. VLDA was achieved by a lower proportion of patients than PASDAS LDA+REM/REM and DAPSA LDA+REM/REM at Week 24 and 52 (Table 1). The proportion of patients achieving VLDA, PASDAS REM and DAPSA REM in the treatment groups at Week 24 had low RDA (10%-19%) across core components except for PhGA and PASI ≤1 (Table 2). At least 66%, 59% and 49% of the patients achieving MDA, PASDAS LDA+REM and DAPSA LDA+REM, respectively, across both treatment groups had no RDA at Week 24 suggesting that MDA was the most stringent composite index. Further decrease in RDA was observed among patients who achieved either REM or LDA at Week 52 across all composite indices in both treatment groups (Table 2 and 3).

Conclusion: A comparable proportion of patients achieved LDA and/or REM at Week 24 across the two treatment groups with further improvements in response/targets at Week 52. Patients who achieved VLDA or MDA tended to

Outcomes, data is presented as % response unless specified otherwise	Week 24			Week 52		
	SEC 300 mg (N=426)	ADA 40 mg (N=427)	P value*	SEC 300 mg (N=426)	ADA 40 mg (N=427)	P value*
MDA	34.5	33.0	0.7084	43.4	37.9	0.1141
VLDA	10.3	11.2	0.6579	18.1	16.9	0.6755
PASDAS based REM	10.7	11.8	0.5553	21.9	18.0	0·1708

Abstract Number: 0910

Effect of Filgotinib on the Complete Resolution of Enthesitis in Psoriatic Arthritis (PsA) Patients: 52-week Results from EQUATOR2

Philip Mease[1], Laura Coates[2], Filip Van den Bosch[3], Philip Helliwell[4], Dafna Gladman[5], Leen Gilles[6], Lien Gheyle[6], Mona Trivedi[7], Muhsen Alani[8] and Robin Besuyen[9], [1]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA, [2]University of Oxford, Oxford, United Kingdom, [3]Ghent University Hospital, Ghent, Belgium, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [5]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [6]Galapagos NV, Mechelen, Belgium, [7]Gilead Sciences, Inc., Foster City, CA, [8]Gilead Sciences, Inc. and University of Washington, Foster City, CA, [9]Galapagos BV, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: EQUATOR (NCT03101670) was a 16-week, Phase 2, double-blind, randomized placebo-controlled trial of filgotinib for PsA. At Week 16, placebo-treated patients could switch to filgotinib and those on filgotinib could continue treatment for up to an additional 304 weeks in an open-label extension (OLE) study (EQUATOR2; NCT03320876). This prespecified analysis at Week 52 of the OLE assessed the effect of filgotinib on clinical enthesitis after 52 weeks of treatment in the OLE.

Methods: In EQUATOR, patients with active moderate-to-severe PsA (≥5 swollen joints and ≥5 tender joints, fulfilling Classification for PsA [CASPAR] criteria) were randomized 1:1 to receive oral filgotinib 200 mg or placebo once daily (QD) for 16 weeks. At Week 16, patients could continue into the OLE, receiving filgotinib 200 mg QD. The effects on Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index and Leeds Enthesitis Index (LEI) resolution were assessed in patients with core baseline enthesitis (SPARCC or LEI >0) up to and including Week 52 of EQUATOR2 (≤68 weeks in total), using observed case (OC) and non-responder imputation (NRI) analyses.

	Responder at OLE Week 52 n/N (%)					
	NRI			Observed cases		
	Filgotinib → filgotinib	Placebo → filgotinib	Total	Filgotinib → filgotinib	Placebo → filgotinib	Total
LEI resolution						
Core Week 16 responder	13/17 (76.5)	8/11 (72.7)	21/28 (75.0)	13/15 (86.7)	8/10 (80.0)	21/25 (84.0)
Core Week 16 non-responder	10/13 (76.9)	20/32 (62.5)	30/45 (66.7)	10/12 (83.3)	20/27 (74.1)	30/39 (76.9)
SPARCC Enthesitis Index resolution						
Core Week 16 responder	10/13 (76.9)	8/11 (72.7)	18/24 (75.0)	10/11 (90.9)	8/10 (80.0)	18/21 (85.7)
Core Week 16 non-responder	17/21 (81.0)	20/36 (55.6)	37/57 (64.9)	17/20 (85.0)	20/31 (64.5)	37/51 (72.5)

Table. Number of patients who achieved or maintained their LEI and SPARCC resolution of enthesitis at OLE Week 52. Only subjects with enthesitis (LEI >0 or SPARCC Enthesitis Index >0) at core baseline were considered. LEI, Leeds Enthesitis Index; NRI, non-responder imputation; OLE, open-label extension; SPARCC, Spondyloarthritis Research Consortium of Canada

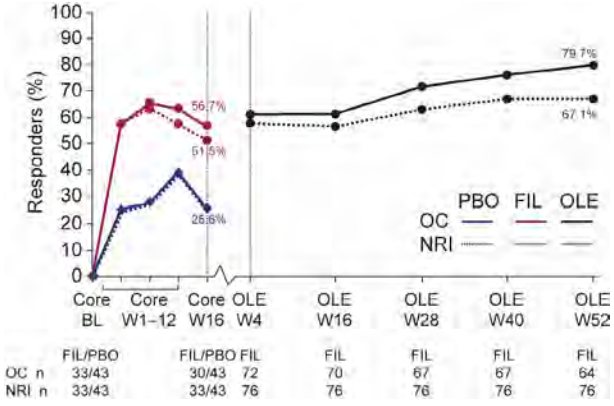

Figure 1. Proportion of LEI responders over time. BL, baseline; FIL, filgotinib; LEI, Leeds Enthesitis Index; NRI, non-responder imputation; OC, observed cases; OLE, open-label extension; PBO, placebo; W, week. Note: The percentage of responders in the placebo group up to core Week 16 was the same in the OC and NRI analyses

Results: In EQUATOR, 131 patients were randomized, of which 76 and 85 had LEI >0 and SPARCC >0 at baseline, respectively. At OLE Week 52, 79.7% and 67.1% of all patients with LEI >0 at baseline (regardless of treatment in the core 16-week trial) achieved LEI resolution (i.e. LEI=0) in the OC and NRI analyses, respectively (Figure 1), and 76.4% and 64.7% of those with SPARCC >0 at baseline, achieved SPARCC Enthesitis Index resolution (i.e. SPARCC=0) in the OC and NRI analyses, respectively (Figure 2). Comparing patients originally assigned filgotinib versus placebo, the proportion of patients with clinical resolution at Week 16 of the core EQUATOR trial was 51.5% and 25.6%, respectively, for LEI, and 35.1% and 22.9%, respectively, for SPARCC (NRI analysis; Figures 1 and 2). At OLE Week 52, the proportion of patients with clinical resolution had increased in both the filgotinib and placebo groups from core

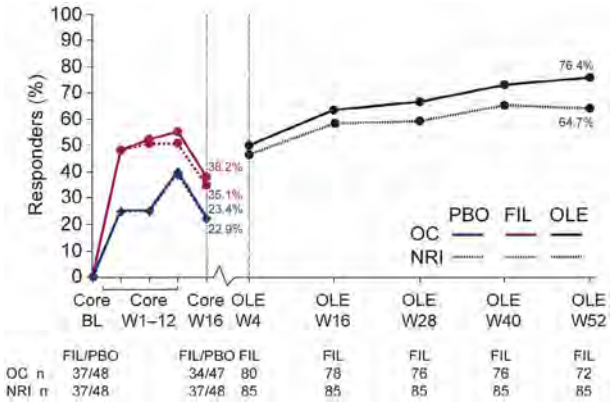

Figure 2. Proportion of SPARCC responders over time. BL, baseline; FIL, filgotinib; NRI, non-responder imputation; OC, observed cases; OLE, open-label extension; PBO, placebo; SPARCC, Spondyloarthritis Research Consortium of Canada; W, week

Week 16 (Figures 1 and 2). Of filgotinib-treated patients who achieved clinical resolution of enthesitis (LEI or SPARCC) at core Week 16 of EQUATOR, 76.5% (13 out of 17) and 76.9% (10 out of 13) also achieved responses at Week 52 of the OLE for LEI and SPARCC, respectively, in the NRI analysis (Table). Of filgotinib-treated patients who did not achieve clinical resolution of enthesitis (LEI or SPARCC) at core Week 16, 76.9% (10 out of 13) and 81.0% (17 out of 21) had responded by Week 52 for LEI and SPARCC, respectively, in the NRI analysis (Table).

Conclusion: Data from this 52-week OLE interim analysis suggest that further improvement in enthesitis can be expected with filgotinib 200 mg QD beyond 16 weeks of treatment in patients with pre-existing enthesitis. The majority of patients were able to maintain and/or achieve clinical resolution of enthesitis by Week 52. These findings should be confirmed in the further extension of this trial and in future Phase 3 trials.

Abstract Number: 0911

Impact of Filgotinib on Structural Lesions in the Sacroiliac Joints at 12 Weeks in Patients with Active Ankylosing Spondylitis: Correlation with Clinical Endpoints

Walter Maksymowych[1], Mikkel Østergaard[2], Robert Landewé[3], William Barchuk[4], Ke Liu[4], Chantal Tasset[5], Leen Gilles[5], Thijs Hendrikx[6], Robin Besuyen[6] and Xenofon Baraliakos[7], [1]University of Alberta, Edmonton, AB, Canada, [2]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [3]Amsterdam University Medical Center & Zuyderland Hospital, Amsterdam, Netherlands, [4]Gilead Sciences, Inc., Foster City, CA, [5]Galapagos NV, Mechelen, Belgium, [6]Galapagos BV, Leiden, Netherlands, [7]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In the Phase 2 TORTUGA trial (NCT03117270), the oral, selective Janus kinase 1 inhibitor filgotinib reduced inflammation in patients with active ankylosing spondylitis (AS), as measured by Spondyloarthritis Research Consortium of Canada (SPARCC) MRI scores (van der Heijde D, et al. *Lancet* 2018;392:2378–87). In this post hoc analysis, we compared the effects of filgotinib on MRI measures of structural change in the sacroiliac joint (SIJ) with effects on clinical parameters.

Methods: TORTUGA was a randomized trial of 116 patients with active AS (as per modified New York classification criteria, with sacroiliiitis confirmed by central reading) treated with filgotinib 200 mg (n=58) or placebo (n=58) once daily for 12 weeks. MRI scans at baseline and Week 12 (or early discontinuation) were re-evaluated post hoc in a blinded fashion by 2 experts to determine SPARCC SIJ Structural Scores (SSS); erosion, backfill, ankylosis, and fat lesion scores. Observed changes from baseline in the SPARCC SSS measures were evaluated using analysis of covariance with factors for treatment, baseline value, and randomization stratification. Least squares mean changes from baseline and between-group differences with 95% confidence intervals were calculated; p values were nominal. Data were then compared with clinical outcomes. Pearson correlations to assess intra-subject relationships were determined for changes in structural lesions from baseline to Week 12 versus changes in C-reactive protein, Ankylosing Spondylitis Disease Activity Score, Bath Ankylosing Spondylitis Disease Activity Index, Bath Ankylosing Spondylitis Functional Index, and SPARCC MRI SIJ and spine inflammation scores.

Results: Evaluable MRI scans (baseline and Week 12) were obtained from 87 patients (48 filgotinib, 39 placebo). At baseline, there were no noTable differences in MRI structural lesions (erosion, backfill, ankylosis, or fat lesion scores) between filgotinib and placebo (**Table 1**). From baseline to Week 12, erosion scores decreased with filgotinib and

Score	Mean (SD) baseline score	LSM change from baseline (95% CI) at Week 12	LSM group difference at Week 12 (95% CI)
Erosion			
Filgotinib	3.38 (5.34)	−0.46 (−1.31, 0.40)	−1.01 (−1.87, −0.16) p=0.02
Placebo	2.62 (3.76)	0.56 (−0.31, 1.42)	
Backfill			
Filgotinib	1.02 (1.99)	0.76 (0.07, 1.45)	1.02 (0.32, 1.72)
Placebo	1.35 (2.59)	−0.26 (−0.97, 0.45)	p=0.005
Ankylosis			
Filgotinib	9.58 (8.15)	0.14 (−0.02, 0.30)	0.06 (−0.10, 0.22)
Placebo	9.83 (8.45)	0.08 (−0.08, 0.25)	p=0.46
Fat lesions			
Filgotinib	4.19 (6.06)	0.37 (−0.23, 0.97)	0.43 (−0.18, 1.03)
Placebo	4.35 (5.44)	−0.06 (−0.67, 0.56)	p=0.17

Table 1. SPARCC SIJ SSS. CI, confidence interval; LSM, least squares mean; SD, standard deviation; SIJ, sacroiliac joint; SPARCC, Spondyloarthritis Research Consortium of Canada; SSS, SIJ structural scores

	Placebo (n=39)	–0.06349	0.7010	–0.06885	0.6770	–0.06645	0.6878	–0.02965	0.8578

Table 2. Pearson correlations between change from baseline to Week 12 in clinical and MRI inflammation endpoints and MRI structural lesions. ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; CRP, C-reactive protein; MRI, magnetic resonance imaging; R, Pearson correlation; SIJ, sacroiliac joint; SPARCC, Spondyloarthritis Research Consortium of Canada

increased with placebo (p=0.02 for between-group difference; **Table 1**). Backfill scores increased with filgotinib but not placebo (p=0.005). There were no significant between-group differences in the change from baseline to Week 12 for ankylosis (p=0.46) or fat lesions (p=0.17) (**Table 1**). At Week 12, changes in erosion scores were positively correlated with changes in SPARCC MRI SIJ inflammation scores (filgotinib: r=0.35921, p=0.0132; placebo: r=0.56043, p=0.0002; **Table 2**), indicating that changes in inflammation and structural scores occur together in the same individual. A negative correlation was observed for backfill (filgotinib: r=–0.41479, p=0.0037; placebo: r=–0.37483, p=0.0187; **Table 2**). All observed correlations were moderate. Overall, significant correlations with erosion and backfill scores were not observed for other clinical endpoints, or for any clinical endpoint with ankylosis or fat lesion scores (**Table 2**).

Conclusion: In the 12-week TORTUGA trial, filgotinib was associated with a decrease in SIJ inflammation compared with placebo—as assessed by MRI—that correlated with a decrease in SIJ erosions and an increase in backfill.

Effectiveness of DETECT Algorithm in Japanese Systemic Sclerosis Patients with Old or New Hemodynamic Definition of Pulmonary Arterial Hypertension

Takanori Ito[1], Takehiro Nakai[2], Genki Kidoguchi[2], Sho Fukui[2], Hiroki Ozawa[2], Satoshi Kawaai[2], Yukihiko Ikeda[2], Hisanori Shimizu[2], Yasuhiro Suyama[3], Atsushi Nomura[2], Hiromichi Tamaki[1], Kenichi Yamaguchi[2] and Masato Okada[1], [1]St. Luke's International Hospital, Tokyo, Japan, [2]St. Luke's International Hospital, Chuo-ku, Tokyo, Japan, [3]JR Tokyo General Hospital, Tokyo, Japan

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

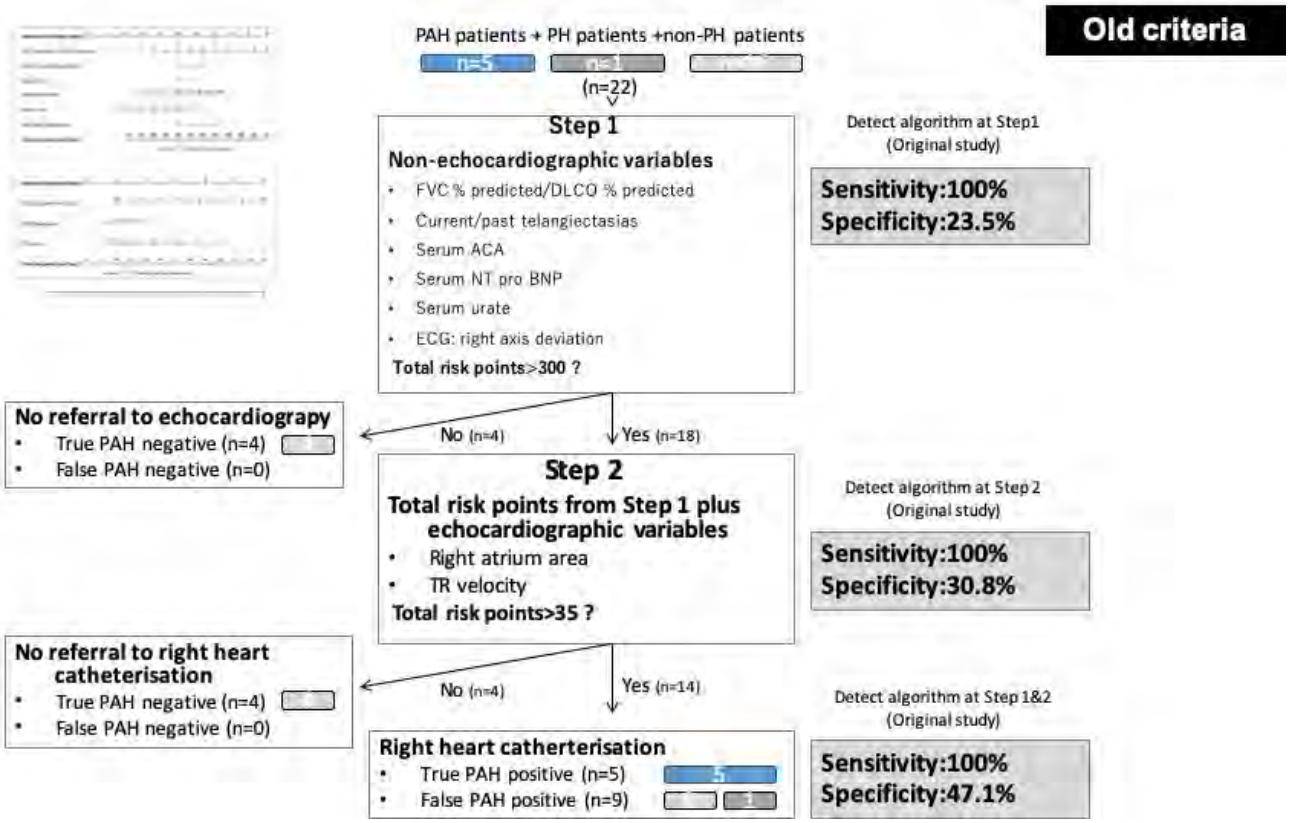
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

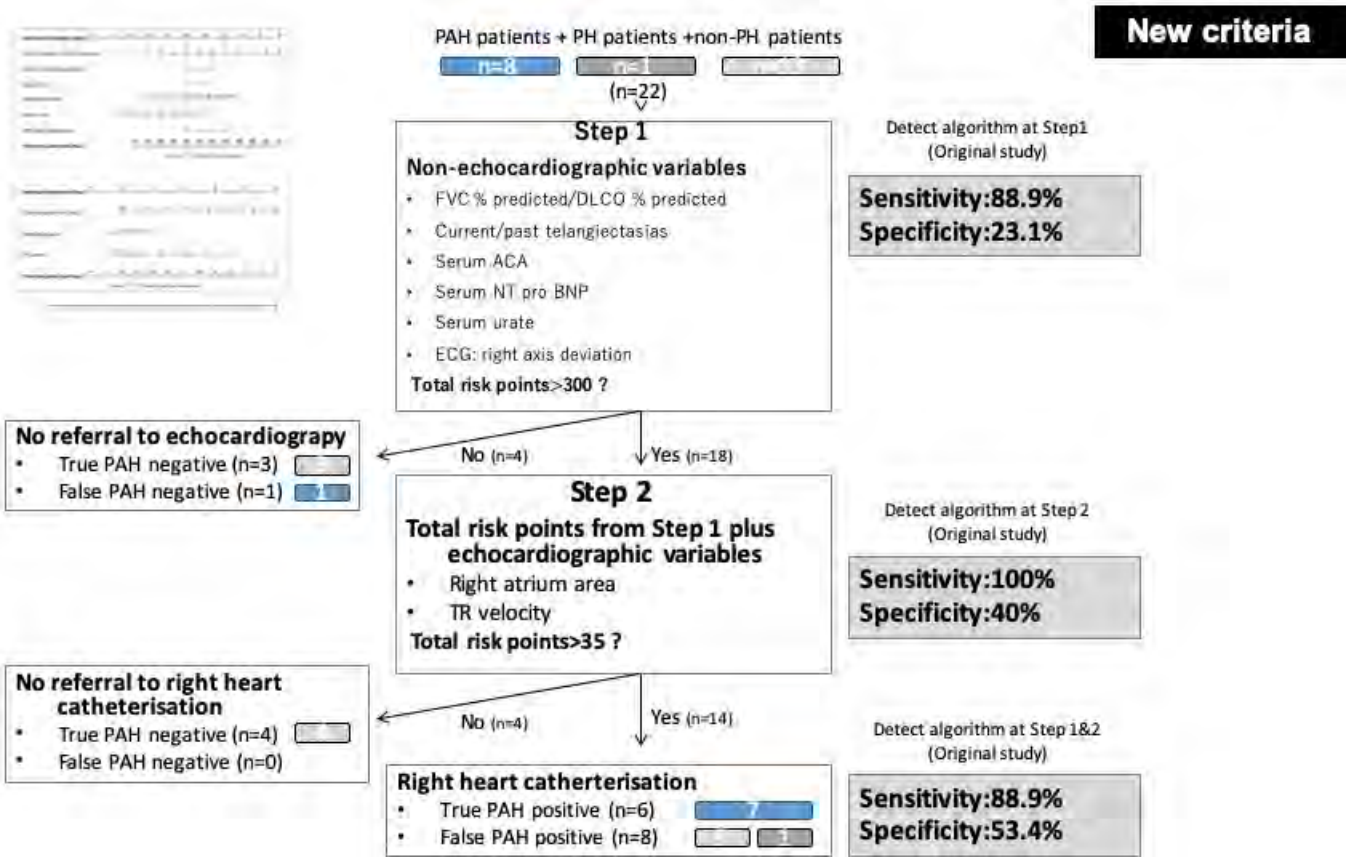
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis-associated pulmonary arterial hypertension (SSc-PAH) has been known as a life-threatening manifestation in SSc. Earlier detection and subsequent interventions are important to improve the prognosis. DETECT algorithm was established in 2013, however Japanese patients were not included in the original study. The objective of this study was to verify the effectiveness of this algorithm in Japanese with old and new hemodynamic definition of PAH.

Methods: In this retrospective, single-center study, patients with SSc who fulfilled American College of Rheumatology criteria and underwent right heart catheterization (RHC) for the diagnosis of PAH from 2004 to 2019 were included.





We analyzed their results of DETECT algorithm in old and new hemodynamic definition of PAH (Mean pulmonary pressure (mPAP) ≧25 mmHg in old definition and >20 mmHg in new definition, with mean pulmonary capillary wedge pressure ≦15 mmHg).

Results: Twenty-two patients were analyzed in this study. The mean age of enrolled patients was 59 years. The female patients were 73% and limited cutaneous SSc patients were 68%. Five and eight patients were diagnosed as PAH with old and new definition respectively. Overall sensitivity and specificity of DETECT algorithm to PAH in old criteria was 100% and 47.1% (Figure 1). On the other hand, 88.9% and 53.4% in new definition (Figure 2).

Conclusion: The DETECT algorithm was confirmed to be very sensitive and safely used in Japanese patients with SSc as a screening before RHC to minimize missed diagnosis of PAH. However, the algorithm should be used with caution, considering sensitivity was slightly lower with new PAH criteria.

Session Date: Saturday, November 7, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac involvement, including electrocardiogram (ECG) abnormalities, is associated with worse prognosis in systemic sclerosis (SSc). We studied the incidence, risk factors and outcomes of conduction and rhythm disorders in a population-based cohort of patients with SSc and non-SSc comparators from the same geographic area.

Methods: A previously identified incident cohort of SSc patients (1980-2016) in a well-defined geographic area was compared to a randomly selected 2:1 cohort of age- and sex-matched non-SSc subjects from the same population base. Demographics, disease characteristics, cardiovascular risk factors and laboratory tests were abstracted by manual record review. ECGs and Holter ECGs were reviewed to determine the occurrence of any conduction or rhythm abnormalities. The need for cardiac interventions was also abstracted.

Results: 78 incident SSc cases and 156 non-SSc comparators were identified [age 56 years± 15.7, 91% female]. Prevalence of any conduction disorders before SSc diagnosis compared to non-SSc comparators was 15% vs. 7% (p=0.06), and any rhythm disorder was 18% vs. 13% (p=0.33). During a median follow up of 10.5 years in patients with SSc and 13.0 years in non-SSc comparators, conduction disorders developed in 25 SSc patients with a cumulative incidence (ci) of 20.5% (95% CI: 12.4-34.1%) compared to 28 non-SSc patients with ci of 10.4% (95% CI: 6.2-

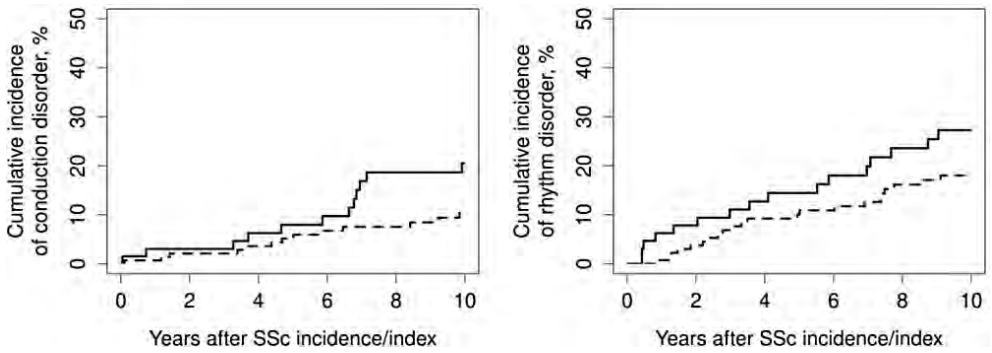

Figure 1. Cumulative incidence of any conduction or any rhythm disorder in systemic sclerosis (SSc) (solid line) vs non-SSc comparators (dashed line).

Outcome	Prior to incidence/index in SSc / non-SSc	After incidence/index in SSc / non-SSc	Cumulative incidence at 10 years for SSc patients (95% CI)*	Cumulative incidence at 10 years for non- SSc subjects (95% CI)*	Hazard ratio (95% CI)**
Surveillance					
Any Holter	6 / 7	18 / 30	19.7 (12.0 , 32.1)	12.0 (7.4 , 19.3)	1.78 (0.98 , 3.25)
Any ECG	42 / 65	30 / 30	57.0 (42.7 , 76.0)	27.6 (19.2 , 39.5)	4.86 (2.81 , 8.40)
Disorders					
Any conduction disorder	12 / 11	25 / 28	20.5 (12.4 , 34.1)	10.4 (6.2 , 17.4)	2.57 (1.48 , 4.45)
Any rhythm disorder	14 / 20	27 / 43	27.3 (17.9 , 41.6)	18.0 (12.3 , 26.4)	1.62 (1.00 , 2.64)
Outcomes					
Cardioversion	2 / 0	3 / 5	2.9 (0.7 , 11.5)	1.3 (0.3 , 5.3)	1.52 (0.35 , 6.47)
Ablation	0 / 0	2 / 2	1.3 (0.2 , 9.0)	0.7 (0.1 , 4.8)	2.13 (0.29 , 5.44)
Pacemaker	0 / 0	4 / 6	4.1 (1.4 , 12.5)	2.1 (0.7 , 6.4)	1.53 (0.42 , 5.60)
CRT	0 / 0	1 / 0	0.0	0.0	--
Defibrillator	0 / 0	4 / 1	4.1 (1.4 , 12.5)	0.0	17.56 (1.44, 214.37)

*Cumulative incidence is adjusted for the competing risk of death.
**adjusted for age, sex and calendar year of SSc/index date
Abbreviation: SSc=Systemic Sclerosis, CI=Confidence Interval, CRT= Cardiac resynchronization therapy

Table 1. Cumulative incidence of conduction and rhythm disorders in 78 patients with systemic sclerosis (SSc) compared with 156 non-SSc comparators

17.4%) (HR: 2.57; 95% CI: 1.48-4.45), while rhythm disorders developed in 27 SSc patients with ci of 27.3% (95% CI: 17.9-41.6%) vs 43 non-SSc patients with ci of 18.0% (95% CI: 12.3-26.4%) (HR: 1.62; 95% CI: 1.00-2.64). (**Figure 1**)

Conduction disorders in patients with SSc during follow up included: 1st-degree atrioventricular block (AVB) (n=12), 2nd-degree AVB (n=1), 3rd-degree AVB (n=1), right bundle branch block (n=10), left bundle branch block (n=4), bifascicular block (n=6), and prolonged-QT (n=13). Rhythm disorders included: atrial fibrillation (n=10), atrial flutter (n=4), supraventricular tachycardia (n=4), ventricular tachycardia (n=1), and premature ventricular contractions (n=16).

ECG, Holter ECG, and cardiac interventions are presented in **Table 1**. Pulmonary hypertension (PHT) was the only significant risk factor identified for development of both conduction and rhythm disorders, while current smoking was a significant risk factor for development of rhythm disorders only (**Table 2**). Conduction and rhythm disorders were associated with increased mortality among patients with SSc (HR=7.60, 95% CI: 3.49-16.55 and HR=4.87, 95% CI: 2.28-10.42, respectively, after adjusting for age, sex and calendar year of diagnosis).

Conclusion: Patients with SSc have a significantly higher prevalence of conduction disorders at disease onset than non-SSc comparators. During the course of their disease, their risk of developing conduction disorders is 2.6-fold, and risk of rhythm disorders is 1.6-fold increased, compared to non-SSc subjects. Our study findings warrant increased vigilance and screening for ECG abnormalities in patients with SSc who have PHT. Underlying mechanisms for this association require further elucidation.

Serious Infections in People with Systemic Sclerosis: A National U.S. Study

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To study incidence, time-trends and outcomes of serious infections in systemic sclerosis (SSc).

Methods: We used the 1998-2016 U.S. National Inpatient Sample data. We examined the epidemiology, time-trends and outcomes of five serious infections (opportunistic infections (OI), skin and soft tissue infections (SSTI), urinary tract infection (UTI), pneumonia, and sepsis/bacteremia) in hospitalized people with SSc. We performed multivariable-adjusted logistic regression analyses to analyze independent association of factors with healthcare utilization (hospital charges, length of hospital stay, discharge to non-home setting), and in-hospital mortality.

Results: There were 49,904,955 hospitalizations with serious infections in people without SSc and 61,615 in those with SSc. The average age of patients with SSc with a serious infection was 61.4 years (median of 61.7 years; **Table 1**), similar to all SSc hospitalizations.

Compared to patients admitted with serious infection without SSc, people with SSc were younger (median age, 65 vs. 62 years), and were more likely to be female (52% vs. 84%), or have Deyo-Charlson score of 2 or more (42% vs. 64%; **Table 1**).

During 1998-2016, the most common serious infections in SSc were pneumonia (45%), sepsis (32%), SSTI (19%), UTI (3%) and OI (3%). In 2013-14, sepsis surpassed pneumonia as the most common serious infection; by 2015-16, sepsis was 1.8-times more common than pneumonia (**Figure 1**). Over the study period, hospital charges increased, while length of hospital stay and in-hospital mortality decreased, overall and for each serious infection.

Multivariable-adjusted analyses showed that sepsis, age ≥80 years and Deyo-Charlson score ≥2 were associated with significantly higher odds of healthcare utilization and in-hospital mortality; and Medicare or Medicaid insurance payer, Northeast location, urban teaching or non-teaching hospital, and medium or large hospital bed size with significantly higher odds of healthcare utilization (**Table 2**).

Conclusion: Outcomes in people with SSc hospitalized with serious infections have improved over time, except higher hospital charges. Identification of factors associated with higher healthcare utilization and in-hospital mortality allows for developing interventions to further improve these outcomes.

Clinical Bedside Tools to Assess Systemic Sclerosis Vasculopathy: Can Digital Thermal Monitoring and Sublingual Microscopy Identify Patients with Current or past Digital Ulcers?

Tracy Frech[1], Zhining Ou[2], Julie Thomas[2] and Angela Presson[2], [1]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sublingual microscopy is reported as a useful tool for vasculopathy assessment in SSc. Digital thermal monitoring (DTM) correlates with flow-mediated dilatation, and may identify patients at risk for digital ulcer (DU). The purpose of this analysis was to assess sublingual microscopy and DTM in SSc patients with and without digital ulcers in order to determine the utility of these clinical tools for end-stage vasculopathy assessment.

Methods: Consented SSc registry patients that presented for routine clinical care and had both DTM and sublingual microscopy on the same day were included in this cross-sectional analysis. Measurements were performed in a quiet room at a controlled ambient temperature. DTM records a temperature rebound in the fingertip after blood pressure cuff occlusion, and is provided as a single, automated vascular reactivity index (VRI) value. Sublingual microscopy provides an automated measure of microvascular perfusion (longitudinal red blood cell fraction, RBC fract) and glycocalyx penetrability (perfused barrier region, PBR). We summarized demographics and clinical outcomes of interest using median, interquartile range (IQR) and range for skew continuous variables; we reported counts and percentages for categorical variables. Exact Wilcoxon rank sum test and Fisher's exact test were used to compare variable between DU groups. We evaluated the pairwise association between VRI, RBCfract and PBR in a monotonic relationship using Spearman's rank correlation in the DU subset. We reported the correlation coefficients (r-s) and their 95% confidence intervals (CIs). We also reported the asymptotic p-values. Statistical significance was assessed at the 0.05 level.

Results: Of the 90 patients that met inclusion criteria, 29 had digitals pits and/or active DU and 61 never had a DU (Table 1). These patients were 76% female, 83% white, 11% current smoker, and 87% SSc-specific autoantibody positive. At the time of assessment, 91% were on vasodilators for Raynaud's phenomenon. The only significant clinical feature associated with the presence of DU was modified Rodnan skin score (p=0.003). The VRI captured by DTM was lower in patients with DU (p=0.01). The sublingual microscopy RBCfract and PBR were monotonic associated ($p < 0.001$) with monotone decreasing with the higher RBCfract the lower PBR (r¬s=-0.71, 95% CI: -0.86, -0.47). VRI was not associated with RBCfract or PBR (p=0.24 or 0.55, respectively) in the small group DU patients (Table 2).

Conclusion: DTM, which captures damage as a vasculopathy feature, is a potentially useful tool for assessing DU risk in the SSc population. In this cross-sectional analysis, sublingual microscopy measurements of perfusion and

Validating Autoantibody Associations and Clinical Impact of Severe Gastrointestinal Involvement in Systemic Sclerosis

Fiza Ahmed[1], Svetlana Nihtyanova[1], Stamatia Chatzinikolaou[2], Voon Ong[1], Charles Murray[2] and Christopher Denton[3], [1]Centre for Rheumatology, Royal Free Campus, UCL Division of Medicine, UK, London, United Kingdom, [2]Department of Gastroenterology, Royal Free London Foundation Trust, UK, London, United Kingdom, [3]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic sclerosis (SSc) frequently experience gastrointestinal (GI) symptoms, ranging from mild to debilitating in severity. Better prediction of those most at risk of developing severe GI disease would be helpful for clinical trials and practice.

Previously, we identified demographic factors and serological markers associated with certain gastrointestinal symptoms, in a cohort (n=214) of consecutive SSc patients. Here, we have validated and extended our work in a second independent cohort.

Methods: SSc patients attending our centre between December 2019 and March 2020 completed the UCLA SCTC GIT 2.0 questionnaire, encompassing various domains of SSc-associated GI disease (reflux, distension/bloating, diarrhoea, soilage, constipation, social functioning and emotional wellbeing). Higher domain scores correspond with greater GI disease severity (domain scores range from 0 to 3). Analysis of associations was undertaken using appropriate non-parametric tests. Subgroups on basis of antibodies included ACA, ATA, ARA, U3RNP, nRNP, PmScl and other antibodies. Double autoantibodies were present in 10 subjects and those were classified into the group of the more SSc-specific antibody.

Results: 314 patients completed UCLA GIT 2.0. Mean (SD) age was 55.2 (14.5) and 85.7% were female. The mean number of years since SSc onset was 12.9 (10.0). Limited cutaneous SSc was present in 66.6%, and disease overlap syndromes were present in 25.4%. The most common autoantibody was anti-centromere (ACA, 28.0%), followed by anti-topoisomerase (ATA, 24.2%), anti-RNA polymerase III (ARA, 9.9%), Ro (8.9%), anti-PMScl (6.1%) and anti-nRNP (5.7%). The mean (SD) total GIT score was 0.70 (0.58) and 56.4% patients reported moderate-severe symptoms (Table 1). There was a positive correlation between total GIT score and patient visual analogue scale (VAS) self-reported GI disease burden (Spearman's Rho = 0.68, $p < 0.0001$). There was no association between GI symptoms and disease subset or duration. Gender was only associated with emotional wellbeing, which was more severely affected in

	No/mild symptoms (<0.5)	Moderate symptoms (0.5-1.0)	Severe symptoms (>1.0)
Total GI score	137 (43.6)	93 (29.6)	84 (26.8)
Reflux	141 (44.9)	80 (25.5)	93 (29.6)
Distension/bloating	78 (24.8)	86 (27.4)	150 (47.8)
Faecal soilage	202 (64.3)	62 (19.7)	50 (15.9)
Diarrhoea	158 (50.3)	68 (21.7)	88 (28.0)
Constipation	173 (55.1)	81 (25.8)	60 (19.1)
Social functioning	190 (60.5)	71 (22.6)	53 (16.9)
Emotional wellbeing	181 (57.6)	58 (18.5)	75 (23.9)

Table 1. Distribution of severity of GI symptoms in SSc cohort (n=314), based on total GI score and individual domain scores for patients fully completing the UCLA SCTC GIT 2.0 questionnaire. Total GI score excludes constipation score. Total score and individual domain score frequencies are represented as n (%).

Table 2. Comparison between autoantibody subgroups in terms of GIT symptoms. Comparisons were undertaken using the Kruskal-Wallis test. Cells represent mean/median, Q2-Q3

p-value		0.0054	0.0153	0.0602	0.5591	0.0463	0.0092	0.0821	0.0001

Table 2. Comparison between autoantibody subgroups in terms of GIT symptoms. Comparisons were undertaken using the Kruskal-Wallis test. Cells represent mean/median, Q2-Q3.

females compared to males (score 0.68 v 0.42, p=0.0339). There were significant differences between the antibody subgroups in terms of GI symptoms (Table 2). Of the SSc-specific antibodies, ARA and ACA appeared to convey increased risk overall and throughout the domains, demonstrating the highest scores. Mean/median total GIT scores and scores for reflux, distension/bloating, constipation, social functioning and emotional wellbeing were highest among ARA+, while scores for diarrhoea and faecal soilage were highest among ACA+ subjects. On the other hand, anti-PmScl+ patients had the lowest scores in most domains, including total GIT 2.0 score.

Conclusion: We have validated our previous results in a second SSc cohort. Higher GIT scores were associated with significantly worse self-reported impact on quality of life. In addition, in this cohort, ARA and ACA positivity appeared to be associated with more severe GI disease. Future studies should explore whether ANA reactivity may identify cases at risk of severe GI manifestations.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

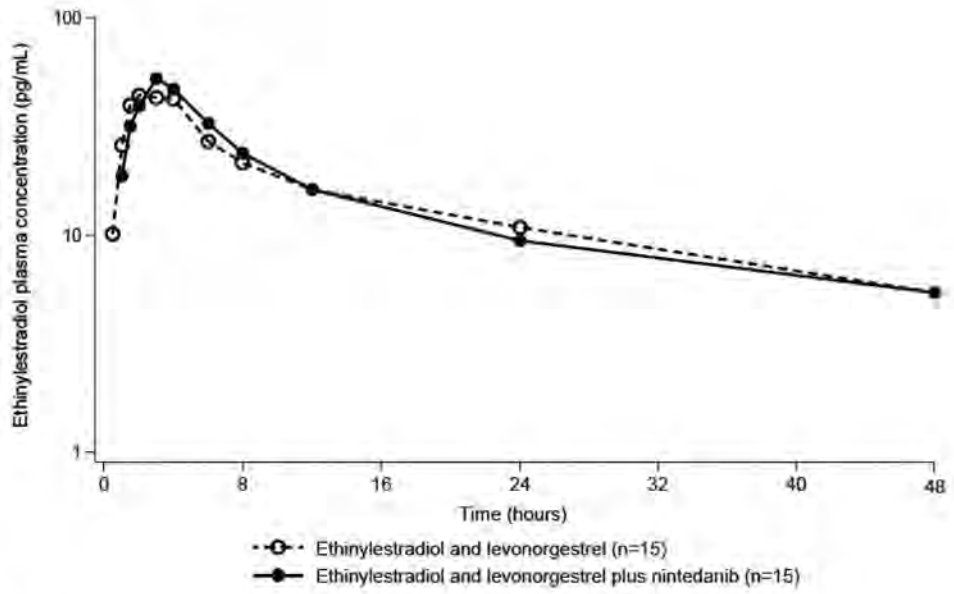
Background/Purpose: Nintedanib is a tyrosine kinase inhibitor that has been approved for the treatment of SSc-ILD. As nintedanib may cause fetal harm, patients taking nintedanib should avoid pregnancy. The combination of ethinylestradiol and levonorgestrel is a commonly used oral contraceptive. We investigated the pharmacokinetics (PK) of the combination of ethinylestradiol and levonorgestrel alone and with nintedanib at steady-state in female patients with SSc-ILD.

Methods: We conducted an open-label, two-period, fixed-sequence, drug–drug interaction study (NCT03675581). Female patients aged ≥18 years, with SSc (based on 2013 ACR/EULAR criteria) and ≥10% extent of fibrotic ILD on a high-resolution computed tomography (HRCT) scan were eligible to participate. In Period 1, patients received a single Tablet containing 30 μg ethinylestradiol and 150 μg levonorgestrel (reference treatment) ≥3 days before the first administration of nintedanib in Period 2. In Period 2, patients received a second Tablet containing 30 μg ethinylestradiol and 150 μg levonorgestrel after continuous intake of nintedanib 150 mg bid for ≥10 consecutive days (test treatment). The primary PK endpoints were the areas under the concentration–time curve of ethinylestradiol and levonorgestrel in plasma over the time interval from 0 to the last quantifiable data point (AUC_{0-tz}) and the maximum measured concentrations of ethinylestradiol and levonorgestrel in plasma (C_{max}). The areas under the concentration–time curve of ethinylestradiol and levonorgestrel in plasma over the time interval from 0 extrapolated to infinity ($AUC_{0-\infty}$) were secondary PK endpoints. The relative exposure to ethinylestradiol and levonorgestrel when administered alone versus in combination with nintedanib was assessed using an ANOVA model.

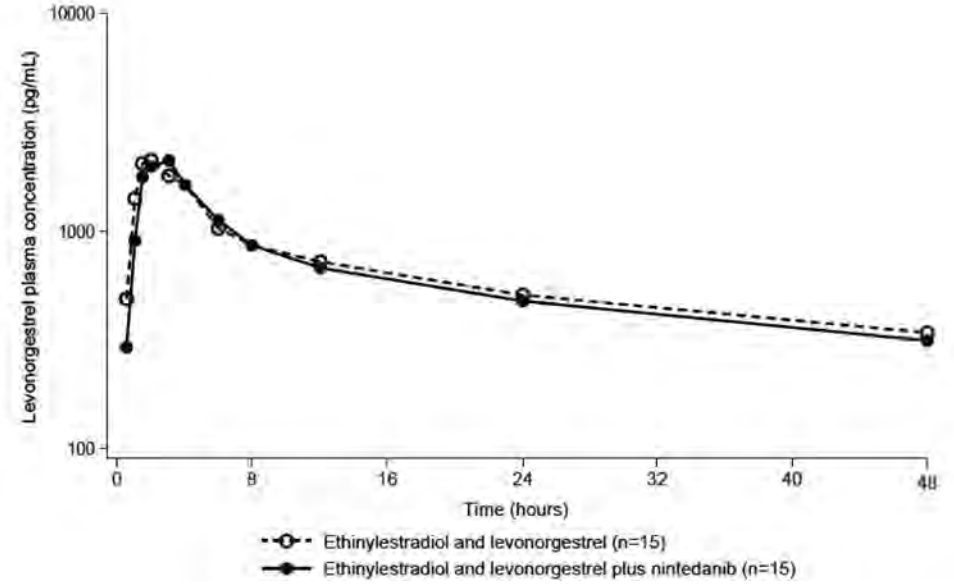
Results: PK data were analyzed from 15 treated patients. Plasma concentration–time profiles of ethinylestradiol and levonorgestrel were similar after administration alone or after administration of nintedanib 150 mg bid for ≥10

Figure. Geometric mean plasma concentration–time profiles on a semi-logarithmic scale of a) ethinylestradiol and b) levonorgestrel after a single oral administration of ethinylestradiol and levonorgestrel alone (Period 1) or after a single oral administration of ethinylestradiol and levonorgestrel after multiple oral administrations of nintedanib 150 mg bid for ≥10 days (Period 2).

a)



b)



consecutive days (Figure). Total exposure to ethinylestradiol ($AUC_{0\text{-}tz}$ and $AUC_{0\text{-}\infty}$) was similar when ethinylestradiol and levonorgestrel were administered alone or after multiple administrations of nintedanib and peak exposure to ethinylestradiol (C_{max}) slightly increased (by approximately 16%) after multiple administrations of nintedanib (Table).

Table. Adjusted gMean comparisons of exposure to ethinylestradiol and levonorgestrel after single oral administration alone (Period 1) and after multiple oral administrations of nintedanib 150 mg bid for ≥10 days (Period 2)

Parameter	Adjusted gMean (gSE)		Adjusted gMean ratio, % (90% confidence interval)
	Ethinylestradiol and levonorgestrel with nintedanib (n=15)	Ethinylestradiol and levonorgestrel alone (n=15)	
Ethinylestradiol			
AUC_{0-tz}, [pg·h/mL]	618.3 (1.2)	610.0 (1.2)	101.4 (92.8, 110.7)
C_{max}, [pg/mL]	63.9 (1.1)	54.8 (1.1)	116.7 (107.6, 126.5)
$AUC_{0-\infty}$, [pg·h/mL]	759.0 (1.1)	749.7 (1.1)	101.2 (94.0, 109.1)
Levonorgestrel			
AUC_{0-tz}, [pg·h/mL]	31872.5 (1.2)	33062.7 (1.2)	96.4 (91.5, 101.6)
C_{max}, [pg/mL]	3152.4 (1.1)	3124.5 (1.1)	100.9 (89.9, 113.2)
$AUC_{0-\infty}$, [pg·h/mL]	49605.4 (1.2)	56311.7 (1.2)	88.1 (80.0, 97.0)

No differences in total or peak exposure to levonorgestrel (AUC_{0-tz} or C_{max}) were observed when ethinylestradiol and levonorgestrel were administered alone or after multiple administrations of nintedanib (Table).

Conclusion: PK results indicate that there is no relevant effect of nintedanib 150 mg bid on the plasma exposure to ethinylestradiol and levonorgestrel in female patients with SSc-ILD.

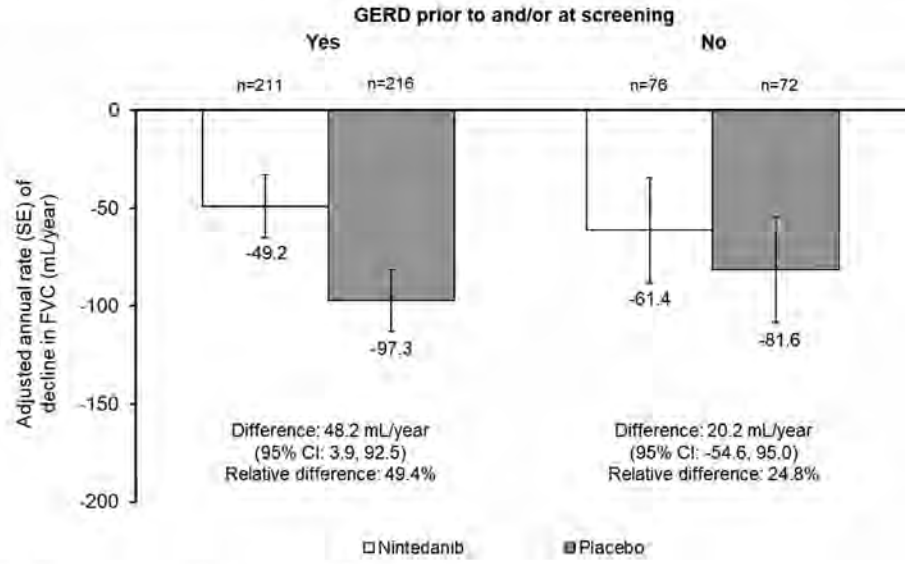
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Gastroesophageal reflux disease (GERD) is a common comorbidity in patients with SSc-ILD and may be associated with progression of SSc-ILD. In the SENSCIS trial in patients with SSc-ILD, nintedanib

Figure. Annual rate of decline in FVC (mL/year) over 52 weeks in the SENSCIS trial in subgroups by presence of GERD prior to and/or at screening.



Treatment-by-time-by-subgroup interaction p=0.53

Table. Most frequent adverse events in the SENSCIS trial in subgroups by presence of GERD prior to and/or at screening.

	With GERD prior to and/or at screening		Without GERD prior to and/or at screening	
	Nintedanib (n=212)	Placebo (n=216)	Nintedanib (n=76)	Placebo (n=72)
Any adverse event	208 (98.1)	208 (96.3)	75 (98.7)	68 (94.4)
Most frequent adverse events*				
Diarrhea	163 (76.9)	74 (34.3)	55 (72.4)	17 (23.6)
Nausea	64 (30.2)	31 (14.4)	27 (35.5)	8 (11.1)
Vomiting	55 (25.9)	25 (11.6)	16 (21.1)	5 (6.9)
Skin ulcers	41 (19.3)	35 (16.2)	12 (15.8)	15 (20.8)
Cough	29 (13.7)	45 (20.8)	5 (6.6)	7 (9.7)
Nasopharyngitis	23 (10.8)	36 (16.7)	13 (17.1)	13 (18.1)
Upper respiratory tract infection	25 (11.8)	27 (12.5)	8 (10.5)	8 (11.1)
Abdominal pain	27 (12.7)	15 (6.9)	6 (7.9)	6 (8.3)
Fatigue	24 (11.3)	17 (7.9)	7 (9.2)	3 (4.2)
Weight decreased	28 (13.2)	10 (4.6)	6 (7.9)	2 (2.8)

Adverse events were reported irrespective of causality and coded using preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA). Data are n (%) of patients with ≥1 such event, reported over 52 weeks (or until 28 days after last trial drug intake in patients who discontinued trial drug before week 52). *Adverse events reported in >10% of patients in either treatment group in either subgroup.

reduced the rate of decline in forced vital capacity (FVC) over 52 weeks by 44% versus placebo, with an adverse event profile characterized mainly by gastrointestinal events. We investigated the efficacy and safety of nintedanib in subgroups by presence of GERD at baseline.

Methods: In the SENSCIS trial, patients with SSc-ILD with first non-Raynaud symptom ≤7 years before screening, extent of fibrotic ILD ≥10% on HRCT and FVC ≥40% predicted were randomized to receive nintedanib or placebo until the last patient had reached week 52 but for ≤100 weeks. In post-hoc analyses, we analysed the annual rate of decline in FVC (mL/year) over 52 weeks and adverse events in subgroups by presence of GERD prior to and/or at screening. GERD was defined as present if it was noted as a present or past comorbidity on the SSc-related medical history page of the case report form.

Results: Of 576 patients who received ≥1 dose of trial medication, 74.3% had GERD prior to and/or at screening. At baseline, in patients with and without GERD, respectively, mean (SD) FVC was 2532 (787) and 2405 (744) mL and 72.3 (16.7) and 73.1 (16.7) % predicted; 88.8% and 52.0% of patients were taking anti-acid therapy. In the placebo group, the adjusted annual rate of FVC decline was numerically more pronounced in patients with than without GERD (-97.3 vs -81.6 mL/year). The effect of nintedanib versus placebo on reducing the rate of FVC decline (mL/year) was numerically more pronounced in patients with than without GERD (difference: 48.2 [95% CI: 3.9, 92.5] vs 20.2 [-54.6, 95.0]), but the exploratory interaction p-value did not indicate heterogeneity in the treatment effect of nintedanib between these subgroups (p=0.53) (Figure). The most frequent adverse event reported in all the subgroups was diarrhea (Table). In the nintedanib and placebo groups, respectively, the proportions of patients who had adverse events leading to treatment discontinuation were 14.6% and 9.7% in patients with GERD and 19.7% and 5.6% in patients without GERD.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, nintedanib slowed the rate of FVC decline versus placebo both in patients with and without GERD. The adverse event profile of nintedanib was similar in patients with and without GERD.

FVC= forced vital capacity, DLCO= diffusing capacity for carbon monoxide, pred=predicted, LVEF= left ventricular ejection fraction, GI=gastro-intestinal

Table 1. Baseline characteristics of the included patients

with other rheumatic diseases, health-related quality of life (HRQoL) is significantly more affected in SSc. How disease specific determinants influence HRQoL over time has not been described thus far.

We aim 1) to evaluate if and how HRQoL changes over time, and 2) to assess how different SSc domains contribute to variations in HRQoL measured over time.

Methods: All SSc patients of the Leiden Combined Care in SSc cohort who fulfilled the ACR/EULAR 2013 criteria for SSc and had at least two visits were included. HRQoL was annually assessed using the EuroQol (EQ5D) and the 36-Item Short Form Health Survey (SF36): mental component score (MCS), and physical component score (PCS). Longitudinal data on clinical characteristics including organ involvement, organ progression and functional assessments were collected. Firstly, we evaluated the mean scores of the EQ5D, MCS and PCS over time and compared these between disease progressors and non-progressors. Secondly, linear mixed-effect regression models were applied to assess changes in HRQoL during the observation time, to control for repeated measurements, and to identify predictive factors. Separate models with the primary outcomes EQ5D, MCS and PCS were applied, first with the independent variables of organ involvement and second with the independent variables of the functional assessments, all adjusted for confounders.

Results: Four-hundred-ninety-two SSc patients were included, with a median follow-up duration of 3.4 years (range 2-6). Over time, both the MCS and PCS worsened with respectively 1.32 points and 1.30 points per year ($p < 0.001$

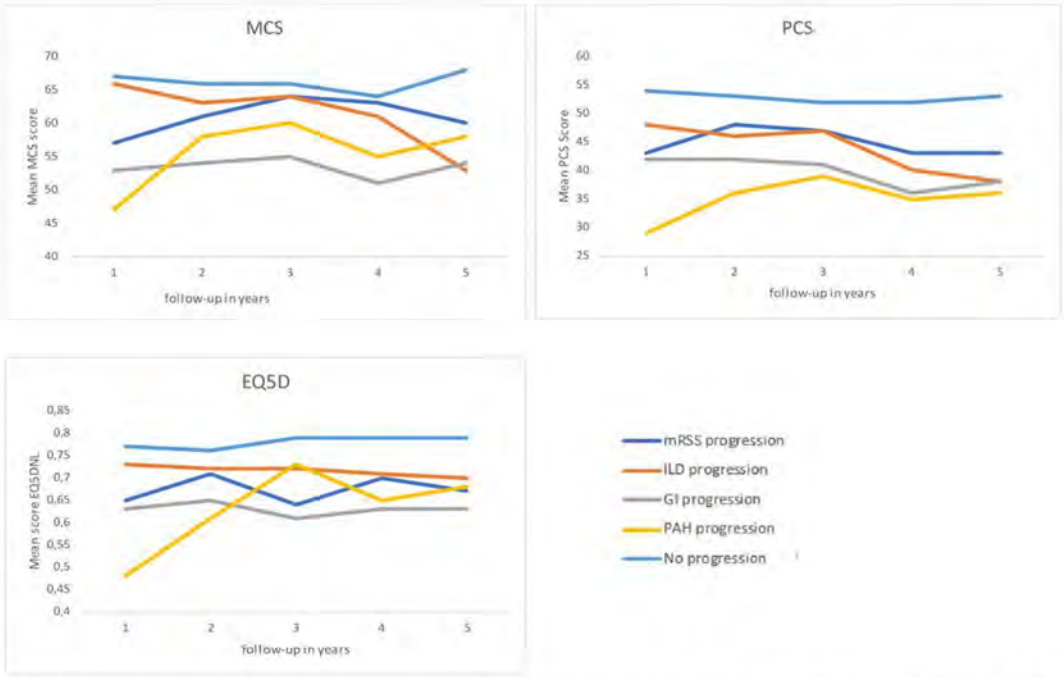

Figure 1. Mean scores of the MCS, PCS and EQ5D for progressors versus never progressors over the follow-up period. Patients who never show progression show higher scores on the PCS, MCS and EQ5D indicating better HRQoL.

Figure 1. Mean scores of the MCS, PCS and EQ5D for progressors versus never progressors over the follow-up period. Patients who never show progression show higher scores on the PCS, MCS and EQ5D indicating better HRQoL.

scale 0-100), while the EQ5D showed slight improvement (0.01 points per year, on a scale of -0.57-1, $p< 0.001$). Progression of organ involvement was numerically associated with lower HRQoL scores, indicating a worse HRQol in progressors (Figure 1). The results of the linear mixed model showed that over time the clinical characteristics with the highest impact on deterioration of HRQoL were: digital ulcers (DU) (on the PCS β-3.36), modified Rodnan Skin Score (mRSS) > 15 (PCS β -3.8 and EQ5D β -0.06), Raynaud VAS (on the MCS β-0.10, PCS β-0.12 and EQ5D β-0.002), and severe gastro-intestinal involvement (GI) (EQ5D β-0.05). A worse score on any of the functional assessments, including the six-minute walking test (MCS β 0.007, PCS β 0.009), mouth opening distance (MCS β 0.03, PCS β 0.02) fingertip-to palm distance (MCS β -0.07, PCS β -0.05) and grip strength (MCS β 0.05, PCS β 0.03) was associated with deterioration in HRQoL over time as measured by SF36 ($p< 0.001$).

Conclusion: Over time, HRQoL in patients with SSc slightly worsens and is mainly determined by skin problems including DU, Raynaud and mRSS, and by GI affection. More severe functional impairments also contribute to worsening in HRQoL over time, while impact of ILD seems smaller. These observations underline the heterogeneous nature of SSc and can contribute to interpretation of changes in HRQoL reported in clinical trials.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) disease course can range from mild, to very severe with progressive organ involvement within months. Guidelines for follow-up are mainly based on expert consensus, and advocate annual assessment. So far, no data driven guidelines exist that describe tailormade systematic assessments for individual patients in line with individual disease course.

Baseline characteristics

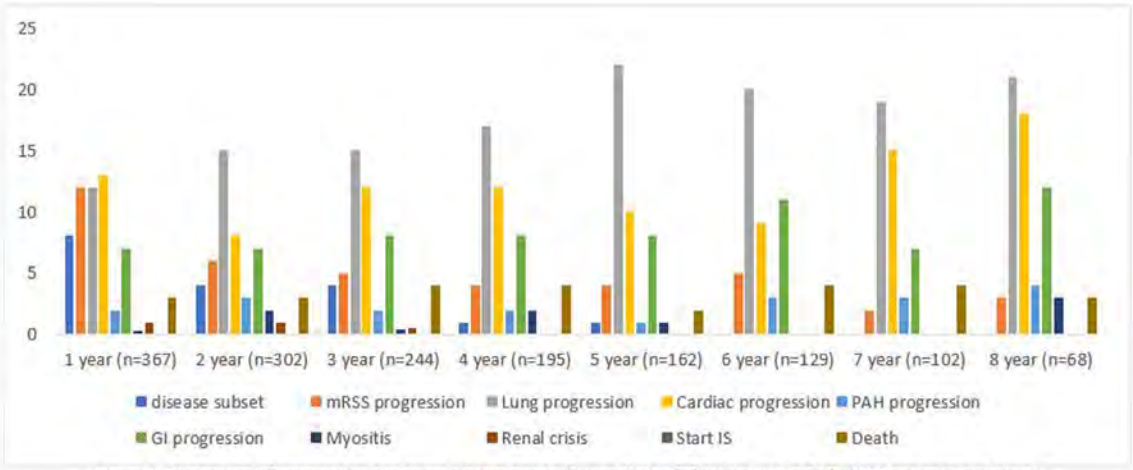

Figure 1. Percentage of progression per organ system per each year during follow-up. We included 492 patients, not every patient had annual complete assessments. Therefore, the n. at visit 1 is not equal to 492.

Figure 1. Percentage of progression per organ system per each year during follow-up. We included 492 patients, not every patient had annual complete assessments. Therefore, the n. at visit 1 is not equal to 492.

In this study we aim to develop a tailormade model to guide annual assessment in individual SSc patients. To address this we 1) determined disease progression in all SSc patients participating in the prospective Leiden SSc cohort with ≥ two visits and 2) applied machine learning to predict progression in patients with complete data available at ≥ 3 time points to determine the outcome.

Methods: Disease progression, evaluated in all SSc patients, was defined per organ system: skin (based on modified Rodnan Skin Score (mRSS) and disease subset), lung (interstitial lung disease and pulmonary function test), myocardial (ejection fraction, arrhythmias, cardiac events), gastro-intestinal (GI) (GAVE, weight loss AND anemia), pulmonary arterial hypertension (PAH), renal crisis, and myositis. The primary endpoint in the prediction model was defined as progression in ≥ 1 organ system, and/or start of immunosuppression (IS) or death between the two most recent visits. To identify patients at risk, we used a machine learning approach known as elastic net regularization using 90 independent patient variables (100% complete) to predict progression. The patients with complete data available at 3 time points were randomly divided over a training (75%) and test (25%) set in order to perform internal validation of the final model. By expert assessment of the test characteristics, including swarm plots of the probability scores, cut-offs were identified for low, intermediate and high risk for disease progression.

Results: In 492 SSc patients (range of follow-up 2-10 years), disease progression during total follow-up was observed in 52% after median 4 years (range 1-8), including myocardial progression in 29%, lung progression in 23%, skin progression in 16%, and death in 12%. Complete data of ≥3 visits were available in n=248. The primary endpoint, i.e. progression at most recent visit, occurred in 24% (median follow-up duration 5 years (range 3-10)). Identified predictors included: previous IS treatment, previous GI or heart progression, previous cardiac event (heart attack, pacemaker), PAH, mRSS, creatinine kinase and diffusing capacity for carbon monoxide. Performance of the model in the test set showed a ROC AUC of 0.66. With the aim to optimize negative predictive value (NPV) cut-offs of probability scores were determined: low risk for disease progression (< 0.197, NPV 1.0; 29% of patients), intermediate risk (0.197-0.223, NPV 0.82; 27%) and high risk (> 0.223, NPV 0.78; 44%).

Conclusion: Our data confirm the severe nature of SSc with cumulative progression in 52%. Although precise risk stratification for the individual patient is difficult, a machine learning approach enabled us to classify 29% of patients as 'low risk'. In this group annual assessment programs might be less extensive.

Session Date: Saturday, November 7, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The Hospital Anxiety and Depression Scale (HADS) is a screening tool used in patients with different medical conditions. However, its validity, reliability and responsiveness to change in systemic sclerosis (SSc) patients have not been evaluated yet.

Our objectives were to evaluate the feasibility, validity, reliability, and responsiveness of the Hospital Anxiety and Depression Scale (HADS) and to analyse its model structure in patients with systemic sclerosis (SSc).

Methods: In this study, 307 systemic sclerosis patients were included, of these, 90 participated in the responsiveness analysis. Psychometric properties were tested in analogy to the Outcome Measures in Rheumatology (OMERACT) filter and an exploratory and confirmatory factor analysis was performed to examine the structure of HADS.

Results: The HADS showed adequate feasibility, validity, reliability, and responsiveness to clinically relevant worsening of the disease (Table 1). For our population of SSc patients, the HADS model with two sub-scales, HADS-A and HADS-D, and a general scale HADS-S, measuring anxiety, depression, and distress, respectively, was most appropriate (Figure 1). The rates of anxiety, depression, mixed anxiety-depressive disorder (MADD) and distress identified by HADS in our cohort were 32.7%, 26.1%, 18.6%, and 49.7%, respectively (Figure 2).

Conclusion: The psychometric properties of the HADS make it useful for screening in SSc, where anxiety, depression, MADD, and distress represent a significant burden to patients.Table 1: HADS assessed by OMERACT filter criteria

Cancer in Systemic Sclerosis: Analysis of Antibodies Against Components of the Th/To Complex

Christopher Mecoli[1], Brittany Adler[2], Qingyuan Yang[2], Laura Hummers[3], Antony Rosen[2], Livia Casciola-Rosen[4] and Ami Shah[5], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Univerisity, Ellicott City, MD, [4]Johns Hopkins University, Johns Hopkins University, MD, [5]Johns Hopkins University School of Medicine, Ellicott City, MD

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study is to describe four of the most common autoantibodies against components of the Th/To complex: hPOP1, RPP25, RPP30, and RPP40. We report their prevalence and clinical characteristics in a systemic sclerosis (SSc) population, and determine whether these specificities associate with cancer.

Methods: A case control study was performed utilizing data from the Johns Hopkins Scleroderma Center Cohort. A total of 804 adult patients with SSc were included; 401 SSc patients with no history of cancer after at least 5 years of disease were compared to 403 SSc patients who ever had a history of cancer. Antibodies against hPOP1, RPP25, RPP30, and RPP40 were assayed by immunoprecipitation of ^{35}S-methionine-labeled proteins generated by in vitro transcription/translation. Demographic and clinical characteristics were compared between groups.

Results: 67/804 (8.3%) of patients had antibodies against any component of the Th/To complex. Patients with antibodies to any component were significantly more likely to have limited cutaneous disease, less likely to have tendon friction rubs, and more likely to have findings consistent with interstitial lung disease or pulmonary hypertension. Patients with antibodies against hPOP1, RPP25, RPP30, and/or RPP40 were significantly less likely to develop cancer within 2 years of SSc-onset (0% vs 11%, p=0.016).

Conclusion: The majority of SSc patients produce autoantibodies to multiple components of the Th/To complex, and have a clinical phenotype characterized by limited cutaneous disease and pulmonary involvement. Our findings show that the presence of any Th/To autoantibody may have a protective effect against contemporaneous cancer.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Different criteria aiding the diagnosis of Raynaud's phenomenon (RP) have been proposed. Wigley's "RP criteria 2002", defined RP by history of cold sensitivity, accompanied by pallor and/or cyanosis, and a 3-item questionnaire[1]. International Consensus Criteria proposed criteria ("RP criteria 2014") take a three-step conditional approach (i.e. a screening question, assessment of colour changes and a disease score calculation[2]. As the latter criteria seem more stringent for RP, we aimed to compare the agreement between the two criteria sets and their correlation with nailfold capillaroscopy (NFC) findings and results of immunoserological tests.

Methods: This cross-sectional study was performed between January 2018 and December 2019 at our secondary/tertiary rheumatology centre. Both RP criteria questionnaires were applied by the rheumatologist to all patients and the same day the NFC was done. The agreement between the criteria was determined by the Cohen κ-test. The

Table 1. Comparison between Raynaud's phenomenon criteria

Characteristic	RP Criteria 2014*	RP Criteria 2002*
ANA ≥1:160	0.130 (0.045 – 0.213) p=0.003	0.004 (-0.082 – 0.089) p=0.931
Scleroderma specific Ab$	0.155 (0.069 – 0.237) p <0.001	0.039 (-0.047 – 0.5) p=0.374
ANA ≥1:160 or any Ab against ENA	0.115 (0.029 – 0.199) P=0.009	0.019 (-0.067 – 0.105) P=0.662
Pathologic NFC#	0.135 (0.053 – 0.215) p=0.001	0.163 (0.082 – 0.243) p <0.001
NFC scleroderma pattern	0.175 (0.094 – 0.254) p <0.001	0.098 (0.016 – 0.179) p=0.020
NFC nonspecific pattern	< 0.001 (-0.082 – 0.083) p=0.991	0.094 (0.011 – 0.175) p=0.026

Legend: * Pearson correlation coefficient (95%CI) and p value; ANA antinuclear antibody; Ab antibody; ENA extractable nuclear antigen; $ ACmA or anti-Scl70; # any type of pathological result; NFC nailfold capillaroscopy;

Legend: * Pearson correlation coefficient (95%CI) and p value; ANA antinuclear antibody; Ab antibody; ENA extractable nuclear antigen; $ ACmA or anti-Scl70; # any type of pathological result; NFC nailfold capillaroscopy;

correlation between the two criteria sets, NFC and immunoserological tests (antinuclear antibodies and scleroderma specific antibodies) was calculated with the Pearson correlation test.

Results: We included 565 consecutive patients referred for NFC (84.1% female, median age (IQR) 51.1 (40.1–61.6) years). "RP criteria 2002" and "RP criteria 2014" were fulfilled in 485/565 (85.8%) and 248/565 (43.9%) patients, respectively. The κ-coefficient of agreement between the criteria was 0.22 (95% CI 0.11-0.26). Table 1 shows the correlations between RP criteria and results of NFC and immunoserology.

Conclusion: We found a low level of agreement between the two criteria sets. "RP criteria 2014" correlated better than "RP criteria 2002" with scleroderma specific immunoserology and the scleroderma pattern at NFC, albeit the correlation was low for both criteria.

Towards Systemic Sclerosis Rehabilitation via Videogames

Marica Doveri[1], Marco Trombini[2], Federica Ferraro[3], Rossana Galli[1], Anna Laura Bargeri[4], Simone Rando[1], SIlvana Dellepiane[2] and Gerolamo Bianchi[1], [1]Hospital La colletta Arenzano(Genoa), Arenzano, Liguria, Italy, [2]Department of Electrical, Electronics and Telecommunication Engineering and Naval Architecture (DITEN), University of Genoa, GENOVA, Liguria, Italy, [3]Department of Electrical, Electronics and Telecommunication Engineering and Naval Architecture (DITEN), University of Genoa, Ponsacco, Liguria, Italy, [4]Hospital La colletta Arenzano(Genoa), Arenzano, Italy

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The excessive production and accumulation of collagen in systemic sclerosis (SSc) leads to the gradual loss of mobility which affects the quality of life of patients [Parisi, S., et al. 2017]. Hand disabilities in SSc are frequent and contribute to the manifestation of several diseases e.g. reduced mobility, dexterity, and grip strength. Recognizing such symptoms is essential, however no definitive medical treatment is yet available [Young, A., et al. 2016]. The rehabilitation is crucial, and it involves a multidisciplinary team, and aims at improving hand mobility, functionality, and strength [Parisi, S., et al. 2017].

Repetitive movements, typically involved in rehabilitative exercises, can be executed as videogame goal to keep the patient's engagement high. Several studies which make use of videogames can be found in literature, however, very few, and with a limited number of games, refer to the SSc [Eusterwiemann, E., et al. 2019].

The aim of this study was to compare the use of videogames in the assessment phase, in order to address the coherence between the outcome from the digital support, and the standard ones.

Methods: ReMoVES is a telerehabilitation system which provides a support for recovery through videogames, carried out via Leap Motion [Morando, M., et al. 2018].

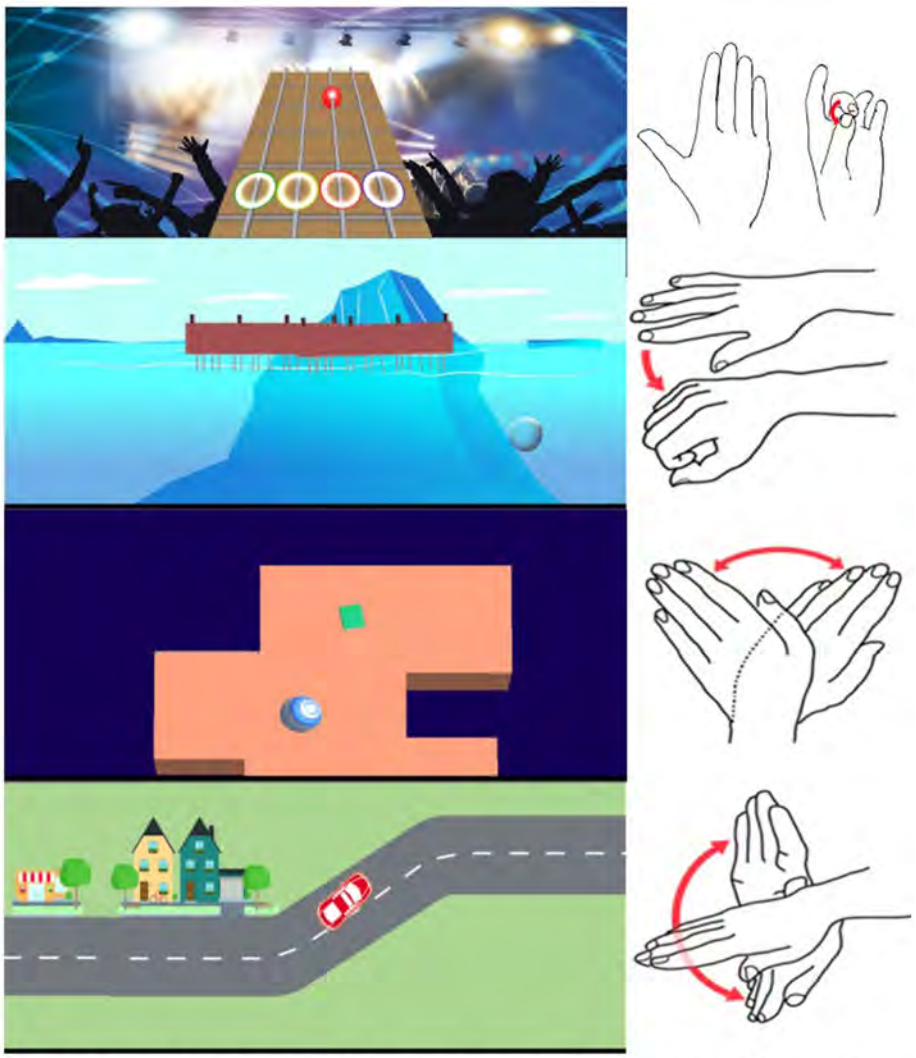

Figure 1: screenshot captured during activity and corresponding thumb opposition, finger flexion-extension, radial-ulnar deviation, and wrist flexion-extension movements respectively.

Four games for hand and wrist movements stimulation were analyzed. They enable the practicing of movements that are typically impaired for SSc patients, i.e. thumb opposition, finger flexion-extension, radial-ulnar deviation, and wrist flexion-extension (Figure 1).

The first purpose was to distinguish patients and control group, based on the ReMoVES feedback. For each activity, the available population is specified in Table 1. The Kruskal-Wallis test was used to this purpose. Then, the correlation between the outcomes deriving from ReMoVES and the score from items 3,6, and 8 from the HAMIS test [Del Rosso, A., et al. 2010], was studied on a population of 12 patients with SSc.

Results: The resulting p-values from the test ($p = 0.0001$ for thumb opposition, $p = 0.0019$ for finger flexion-extension, $p = 0.0028$ for radial-ulnar deviation, and $p = 0.0011$ for wrist flexion-extension) confirmed that the features from ReMoVES are significantly different between patients and control group. Also, the correlation coefficient considering the ReMoVES outcomes and the HAMIS questions proved the coherence between the standard and digital assess-

Activity	Group
Thumb opposition	Patients: 19
	Control: 16
Finger flexion-extension	Patients: 19
	Control: 16
Radial-ulnar deviation	Patients: 18
	Control: 15
Wrist flexion-extension	Patients: 18
	Control: 14

Table 1: Number of participants for each activity.

ment. Such values are: 0.756 for thumb opposition and item 3, 0.767 for finger flexion-extension and item 6, 0.764 for wrist flexion-extension and item 8, 0.788 for radial-ulnar deviation and item 3, and 0.754 for wrist flexion-extension and item 6

Conclusion: Physicians involved in the treatment of SSc need to consider rehabilitation, and skilled physiotherapists and occupational therapists also play a crucial role in evaluating and treating SSc patients. Movements that are typically impaired for SSc patients are stimulated by ReMoVES videogames, which help to entice patients in practicing the rehabilitation activity. The feedback from ReMoVES on the population who participated to the trial is reliable and coherent with the standard outcomes

Early Hydroxychloroquine Use May Reduce Risk for SSc-Associated Pulmonary Hypertension

Alexandra Boucher[1], Yongseok Park[2], Shannon Zalewski[3], Maureen Laffoon[2], Thomas Medsger[4], Robert Lafyatis[2] and Robyn Domsic[5], [1]University of Pittsburgh, Camp Hill, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Washington University Barnes Jewish Hospital, Saint Louis, MO, [4]University of Pittsburgh School of Medicine, Verona, PA, [5]University of Pittsburgh School of Medicine, Pittsburgh, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients are at high risk for pulmonary hypertension (PH), a leading cause of death in this population. Chloroquine is a pulmonary vasodilator shown to attenuate hypoxia-induced PH in mouse models (1). In culture with pulmonary arterial smooth muscle cells (PASMC), chloroquine increases BMPR-II protein expression and inhibits proliferation of PASMC via inhibition of autophagy (2). Our objective was to evaluate whether treatment with hydroxychloroquine (HCQ) was associated with a lower rate or longer time to onset of PH in SSc patients.

Methods: We performed a survival analysis using a prospective, observational SSc cohort from a US SSc Center. We identified SSc patients seen for an initial visit between 1990 and 2015. Individuals exposed to HCQ for a minimum

Table 1. Baseline Characteristics

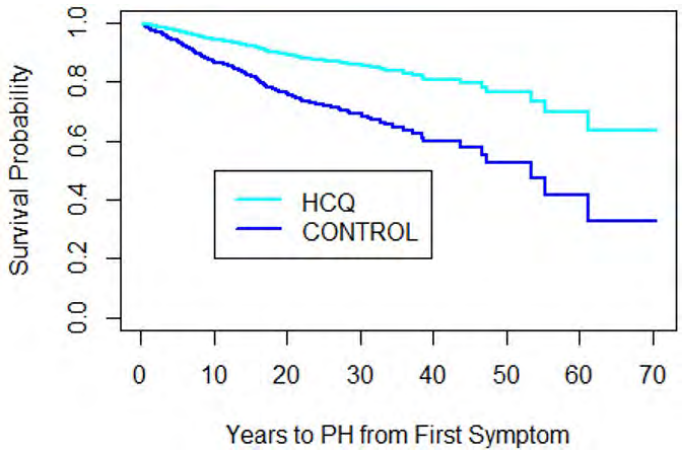

Figure 1. Kaplan-Meier curve of pulmonary hypertension survival probability in SSc patients exposed with HCQ during the first 18 months of disease and SSc patients who were not exposed to HCQ. p=0.04

of 90 days were in the treatment group and all others were controls. Additional chart review and use of electronic medical record coding was performed to confirm HCQ exposure dates and PH evaluations. Descriptive analysis plus Cox Proportional-Hazards modeling with time-dependent covariates to account for duration of HCQ exposure was performed. We analyzed all HCQ exposure, with separate analysis for early (< 18 months of disease) HCQ use.

Results: Eligible were 228 with HCQ exposure and 977 controls; 21 had missing onset of HCQ use, symptoms, or PH diagnosis and were excluded from analysis. Baseline characteristics for the 208 cases and 976 controls are shown in Table 1. HCQ-treated patients were younger, more often female and non-Caucasian. HCQ patients had a higher rate of limited cutaneous disease with more joint involvement at baseline, but lower rates of pulmonary fibrosis, PH and renal crisis. HCQ patients had significantly higher frequencies of anti-centromere (ACA) and anti-U1RNP antibodies, both of which are recognized to be associated with increased risk of PH.

In time to event analysis of the entire group, there was no difference in development of PH between those treated with HCQ, and those not. However, when we evaluated those treated early in their disease, defined as within 18 months of their initial SSc symptom (approximately 25% of HCQ-exposed patients), the time to development of PH was slower (p=0.04), as shown in Figure 1.

Conclusion: Patients with SSc treated with HCQ are younger, more frequently female and more often have limited SSc, joint symptoms and ACA and U1-RNP antibody positivity. Although limited SSc and these antibodies are linked to higher rates of PH, our findings suggest that when HCQ is initiated early in disease (< 18 months) there is a reduced rate of progression to PH. This is in keeping with the plausible biologic actions of HCQ on preventing PH. This early stage of SSc may represent a critical period for therapeutic intervention with HCQ.

Risk Factors for Fractures and Osteoporosis Among Patients with Systemic Sclerosis in a United States Cohort

Sina Famenini[1], Jamie Perin[2], Kristin Wipfler[3], Kaleb Michaud[4] and Zsuzsanna McMahan[5], [1]Johns Hopkins School of Medicine, Baltimore, MD, [2]JHUSPH, Baltimore, [3]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [4]University of Nebraska Medical Center, Omaha, NE, [5]Johns Hopkins University, Baltimore

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is associated with several risk factors for osteoporosis and fractures due to malabsorption or malnutrition, physical disability, chronic inflammation, and use of corticosteroid therapy. However, the risks for osteoporosis and fracture in SSc patients in the United States not well-defined. The aim of this study was to examine the relationship between risk factors (e.g. medication use, clinical characteristics of SSc) and the incidence of fractures and osteoporosis (OP) in SSc patients in a large U.S. cohort.

Methods: Patients from 1998 to 2019 in FORWARD, National Databank for Rheumatic Diseases, were screened. Patients with SSc and respective 5:1 age- and gender-matched patients with osteoarthritis (OA) from the same database were included as controls. The primary endpoint was the occurrence of a physician-confirmed diagnosis of OP or an osteoporotic fracture. Single and multivariate Cox proportional hazard models were used to investigate the risk factors for fractures or OP in the SSc and OA cohorts. Models were constructed using stepwise and purposeful selection methods.

Results: The study included 922 patients, 154 with SSc and 768 with OA. For 5046 patient-years (median (IQR) 4.16 (6.2)) of follow-up, 90 patients had either a fracture or incident OP. Univariate analysis (Table 2) showed a significant fracture/OP risk (HR (95% CI)) increase for women (HR 2.49 (1.09 – 5.71)), with being underweight (HR 4.57 (1.56 – 13.4)), higher rheumatic disease comorbidity index (HR 1.10 (1.07 – 1.39)), higher Health Assessment Questionnaire Disability Index (HAQ) (HR 1.60 (1.16 – 2.20)), proton pump inhibitor (PPI) use (HR 1.62 (1.05 – 2.47)), SSRI use (HR 1.91 (1.15 – 3.18)), and OP medication use (HR 2.08 (1.10 – 3.94).

The adjusted model (Table 3) of the combined cohort showed a significant increase in fracture/OP risk with PPI use (HR 1.58 (1.01 – 2.49)), higher HAQ score (HR 1.48 (1.00 – 2.50)), and with being underweight (HR 5.37 (1.69 – 17.0)). However, in the subgroup analysis of SSc patients, PPI use was associated with lower risk (HR 0.81 (0.29 – 2.29)), with the lower risk being significant for those with the highest cumulative omeprazole-equivalent PPI exposure (HR 0.15 (0.03 – 0.85).

Conclusion: Our findings suggest that several risk factors are associated with a higher risk of fractures in SSc. Functional status of SSc and OA patients, as measured by HAQ, is a particularly strong indicator of future fracture/OP risk. Thus, interventions aimed at improving patients' functional status may lead to improved clinical outcomes. Furthermore, while PPIs are often associated with a higher risk of fractures/OP, our findings suggest that such risks may vary across different disease types. Further investigations are necessary to further characterize these relationships.

Care Gap in Patients with Systemic Sclerosis with CXR Findings Suggestive of Fibrosis

Sandeep Dhillon[1], Jessica Kapralik[2], Curtis Sobchak[3], Nader Khalidi[4], Martin Kolb[5], Nathan Hambly[2], Gerard Cox[2], Karen Beattie[4] and Maggie Larche[4], [1]McMaster University, Burlington, ON, Canada, [2]McMaster University, Hamilton, [3]McMaster University, St. Catharines, ON, Canada, [4]McMaster University, Hamilton, ON, Canada, [5]McMaster University and Firestone Institute for Respiratory Health, St Joseph's Healthcare, Hamliton, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lung involvement, including interstitial lung disease (ILD), is the leading cause of death in patients with systemic sclerosis (SSc). High resolution CT (HRCT) is the gold standard for diagnosing SSc-ILD as chest x-rays (CXR) are poorly sensitive for documenting the presence and extent of disease. As such, a CXR suggestive of ILD should warrant the completion of HRCT chest for further characterization. We explored a national patient registry of SSc patients to determine the proportion of patients who receive an HRCT after a CXR suggestive of fibrosis.

Methods: Longitudinal clinical data from patients in the registry collected and contributed by SSc experts between 2004-2018 was reviewed. We included patients at least 18 years of age, with a diagnosis of SSc, and with at least one CXR indicating fibrosis. We excluded patients who had previously known ILD or an abnormal HRCT prior to their first abnormal CXR. Of these patients, we determined the proportion of patients who underwent an HRCT within a year of CXR findings. Using SPSS, descriptive statistics characterized the population and analyses (Pearson's chi-square and T-tests) determined whether there were differences in patient characteristics between those who did and did not receive an HRCT.

Results: Of 1698 SSc patients, we identified 223 who had a positive CXR with no previous abnormal HRCT; Mean (SD) age was 56.6 (12.2) years, 83.9% were female, and 38.1% of patients had diffuse systemic sclerosis. Average FVC and DLCO were 90.4% (SD 18.2%) and 68.8% (SD 23.1%) of predicted, respectively. Only 21.5% (48/223) underwent an HRCT within 12 months following their abnormal CXR. There were no significant group differences in age, sex, smoking history, co-morbidities, subset of disease, autoantibody profile, symptoms, or skin score between those who did and did not undergo an HRCT. Of the patients who had a HRCT, 83.3% had ≥1 abnormality reported.

Conclusion: A large proportion of SSc patients in this study whose CXR suggested fibrosis did not have a HRCT ordered within 1 year of the CXR, suggesting a care gap. A major limitation of this study is that we are unable to account for under-reporting of HRCTs as it may not be available at the time of CSRG data submission; we will examine for this by completing a comprehensive chart review of a smaller cohort of CSRG patients. Other next steps include exploring if HRCT ordering practices evolved over time and how this impacted the proportion of patients who did not undergo HRCT.

Systemic Sclerosis Progression and Pregnancy: A Hopeful Message from the Canadian Scleroderma Registry Database

Siobhan Deshauer[1], Mats Junek[2], Maggie Larche[3] and Karen Beattie[3], [1]McMaster University, Hamilton, Canada, [2]McMaster University, Hamilton, [3]McMaster University, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is limited guidance for women with systemic sclerosis (SSc) in making decisions about pregnancy and informing them about their disease post-partum. Peripartum maternal and fetal complications have been reported, yet little is known about disease activity *after* pregnancy. We explored the trajectory of disease activity in women who experienced a pregnancy after scleroderma diagnosis and compared it with women who were nulliparous (NP).

Methods: We conducted a retrospective cohort study using data from a national SSc database. We identified two groups of women: those who were NP and those who experienced ≥ one pregnancy after their diagnosis (PAD) of scleroderma. Women with pre-pregnancy cardiac, lung or renal disease were excluded. Of these patients, 97% met ACR classification criteria. Descriptive statistics at the time of entry into the CSRG for each group are shown in Table 1. T-tests compared differences between groups. We used generalized estimating equations to test for the effect of pregnancy on the following outcomes over 8 years: force vital capacity, diffusing capacity of the lungs for carbon monoxide, right ventricular systolic pressure, glomerular filtration rate, antibody-status, active digital ulcers, physician global assessment of activity and physician global assessment of severity. We controlled for age, smoking and time since SSc diagnosis.

Descriptive Table: Nulliparous vs. Pregnancy After a SSc Diagnosis			
	Nulliparous n=152	Pregnancy After Diagnosis n=45	p value
Age, years (mean, SD)	48.42 ± 13.56	44.49 ± 8.04	0.066
Age of Diagnosis, years (mean, SD)	38.77 ± 14.22	22.6 ± 6.79	<0.001
Duration of disease, years (mean, SD)	9.65 ± 8.94	21.89 (9.62)	<0.001
Smoker (n, %)	74 (49.33)	17 (37.78)	0.173
Meets ACR Criteria (n, %)	149 (98)	43 (96)	0.355
Limited SSc (n, %)	94 (61.8)	30 (66.7)	0.556
Diffuse SSc (n, %)	58 (38.2)	15 (33.3)	0.610
Arthritis present (n, %)	41 (28)	22 (49)	0.009
Myositis present (n, %)	17 (11)	7 (16)	0.440
Overlap present (n, %)	31 (20)	7 (16)	0.455
MCTD present (n, %)	8 (5)	3 (7)	0.7262
Raynaud's present (n, %)	150 (99)	44 (98)	0.663
Ulcers present (n, %)	73 (48)	29 (64)	0.053
Scleroderma renal crisis (n, %)	2 (1)	2 (4)	0.194
History of malignancy (n, %)	10 (7)	2 (4)	0.593
CRP, mg/L (mean, SD)	3.65 (1.05-6.2)	2 (1.7-1)	0.375
ESR, mm/hr (mean, SD)	17.5 (8.5-34)	9.5 (4.5-26)	0.311
Centromere + (n, %)	51 (41)	14 (35)	0.514
Topoisomerase + (n, %)	23 (18)	5 (13)	0.387
RNA pol III + (n, %)	16 (13)	1 (3)	0.062
eGFR, mL/min/1.73m^2 (mean, SD)	155.37 ± 48.6	156.98 ± 53.64	0.858
DLCO, mL/min/mmHg (mean, SD)	74.86 ± 22.58	75.88 ± 20.77	0.823
FVC, % predicted (mean, SD)	90.23 ± 19.12	91 ± 18.75	0.837
FEV1/FVC (mean, SD)	79.67 ± 9.9	78.8 ± 8.55	0.658
RVSP, mmHg (mean, SD)	34.47 ± 15.05	31.47 ± 7.03	0.426

Results: At entry into CSRG there were 153 women in the NP group and 45 in the PAD group. After 6 years, n=48 in NP and n=21 in PAD decreased to 18 and 9 patients after 9 years, respectively. Prevalence of anti-topoisomerase positivity was 18.3% in NP and 12.5% in PAD. Differences in baseline characteristics included age of diagnosis (NP 38.8 years, SD 14; PAD 22.6, SD 6.8; p< 0.001), duration of disease (NP 9.6 years, SD 8.9; PAD 21.9, SD 9.6; p< 0.001) and inflammatory arthritis reported by rheumatologists (NP 41, 28%; PAD 22, 49%, p=0.009). Arthritis was not assessed over time.

There were no statistical differences between groups in the change of force vital capacity, diffusing capacity of the lungs for carbon monoxide, right ventricular systolic pressure, glomerular filtration rate, antibody-status, active digital ulcers, physician global assessment of activity and physician global assessment of severity over time.

Conclusion: This retrospective cohort study demonstrated that having ≥1 pregnancy after a diagnosis of systemic sclerosis did not appear to significantly impact renal, respiratory or global function outcomes over 10 years of follow-up. Study limitations include a small cohort size, retrospective data, unknown infertility rates and attrition. While our study offers a hopeful longer-term message for patients with SSc who are planning a pregnancy, physicians and patients should remain vigilant for potential post-partum complications.

The Effect of Mycophenolate Mofetil on Pulmonary Function Tests in Patients with Systemic Sclerosis-associated Interstitial Lung Disease, and the Difference Between the African Americans versus Non-African Americans

Afroditi Boulougoura[1], Shannon Lance[2], Duncan Moore[3], Haijun Wang[4], Julio Huapaya[5] and Virginia Steen[3], [1]Department of Internal Medicine, Medstar Georgetown University Hospital, Washington, DC, USA., Washington, DC, [2]Department of Internal Medicine, Medstar Georgetown University Hospital, Washington, DC, USA., Washington, [3]Division of Rheumatology, Department of Medicine, MedStar Georgetown University Hospital, Washington, DC, [4]MedStar Health Research Institute, Washington, DC, USA, Washington, [5]Department of Critical Care Medicine, National Institutes of Health, Bethesda, MD, USA., Bethesda

SESSION INFORMATION

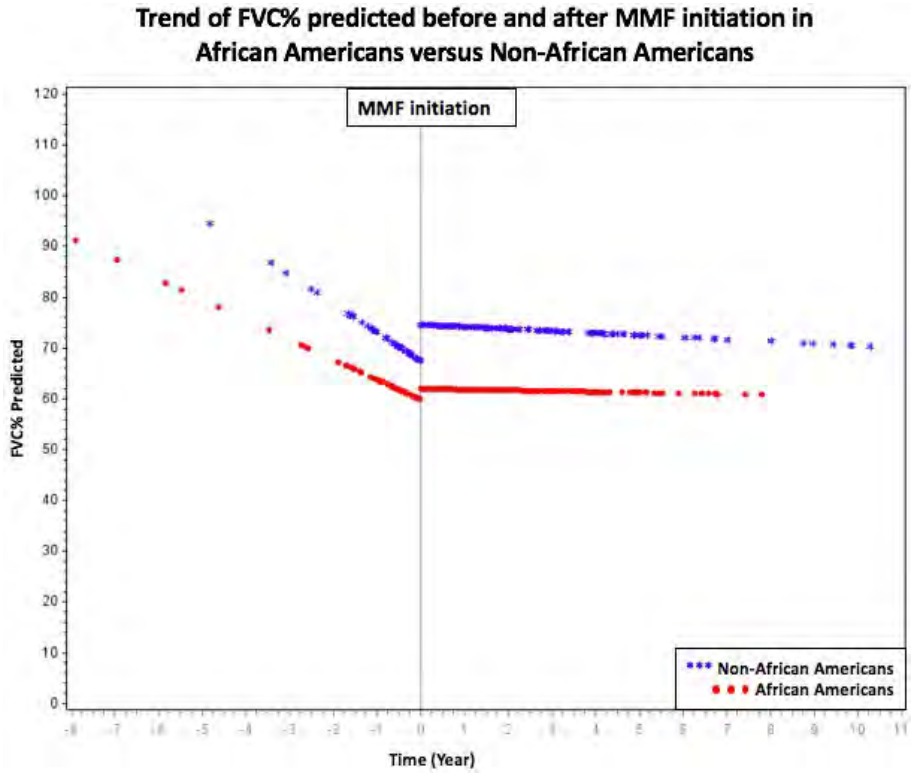
Session Date: Saturday, November 7, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma-related interstitial lung disease (SSc-ILD) is a pulmonary fibrosing disorder characterized by systemic inflammation and progressive scarring of the lungs that leads to respiratory failure. Previous studies have shown that mycophenolate mofetil (MMF) can be beneficial in SSc-ILD. The majority of studies characterizing patients with ILD and evaluating survival have been conducted in populations with a Caucasian predominance. The objectives of the current study were to explore the role of MMF in the treatment of SSc-ILD, and examine whether racial differences influence response to treatment, specifically between African Americans (AAs) and Non-African Americans (Non-AAs).



Baseline Characteristics	African-American (N=38)	Non-African (N=30)	P- value
Age at first PFTs, median (IQR) years	44 (13.5)	46 (15.1)	0.3192
Female sex -N (%)	35 (92.1)	23 (76.6)	0.0853
Disease duration at first PFTs, median (IQR) years	2.9 (1.4-5.8)	1.3 (0.8-4.6)	0.0725
Disease duration at MMF initiation, median (IQR) years	3.6 (2.0-9.0)	2.3 (1.1-5.5)	0.0647
Scleroderma type -N (%)			
Diffuse	23 (60.5)	19 (63.3)	0.8164
Limited	15 (39.5)	11 (36.7)	0.8164
Pulmonary Function Test mean ± SD			
FVC (% of predicted)	59.8 (2.3)	67.7 (2.7)	0.0228
TLC (% of predicted)	59.5 (2.5)	74.5 (2.9)	0.0001
DLCO (% of predicted)	43.6 (2.8)	56.8703 (3.3)	0.0025
Antinuclear antibodies, N (%)	34/37 (91.9%)	26/27 (96.3%)	0.4801
Anti-centromere	0/22 (0.0%)	0/24 (0.0%)	-
Anti-Scl-70	10/33 (30.3%)	13/28 (46.4%)	0.2016
Anti- RNA polymerase III	1/15 (6.7%)	5/21 (23.8%)	0.1835
Anti-U1 RNP	3/19 (15.8%)	1/21 (4.8%)	0.2569
Isolated nucleolar	10/31 (32.3%)	5/22 (22.7%)	0.4575
Other ANA	1/38 (2.6%)	4/30 (13.3%)	0.3481
Anti-SSA autoantibodies, N (%)	12/27 (44.4%)	4/21 (19.0%)	0.0527
Anti-SSB autoantibodies, N (%)	2/25 (8.0%)	1/21 (4.8%)	0.6662

Methods: We conducted a retrospective study of patients with SSc-ILD that were seen at our institution since 2008, treated with MMF (target dose 1500 mg bid) and had documented PFTs at least once prior to MMF initiation. PFTs at 6, 12, 18, 24, 36, 48 months after initiation of MMF were also documented. Baseline characteristics as well as PFTs were compared using t-test. A regression analysis was used to compare the trend of FVC% predicted, TLC% predicted and DLCO% predicted before and after MMF treatment, as well as to compare AAs and Non-AAs.

Results: Sixty-eight patients were included of which 38 (55.8%) were AAs. The median age in AAs and Non-AAs was 44 (IQR 13.5) and 46 (IQR 15.1), respectively (Table 1). The AA group had a higher female percentage, slightly but not significantly longer disease duration at first PFTs and no significant difference in anti-nuclear antibodies subtypes compared to Non-AA group. Prior to MMF initiation, the average FVC% predicted was 63.2 (± 1.9) for the entire cohort, with AAs having a statistically significant lower baseline than non-AAs (59.8 ± 2.3 vs. 67.7 ± 2.7, p=0.02). The trend change in FVC% predicted pre- and post- treatment was significant in both groups (+3.8 (SE 1.0), p=0.0002 in

AAs and +5.2 (SE 1.1), p < .0001 in non-AAs) with significant stabilization of FVC% predicted after initiation of MMF (Figure 1). The difference in the trend change between the AA and non-AA group was not statistically significant. There was no significant trend change in TLC% predicted and DLCO% predicted, although the AA group showed an insignificant decrease in both values post- MMF compared to non-AA that showed an increase (p >0.05).

Conclusion: MMF can significantly slow the decrease in FVC% predicted in patients with SSc-ILD in both AAs and non-AAs. The main difference in our population was the significantly lower FVC in our AA patients at the start of MMF. It is critical to identify patients with ILD as early as possible to initiate treatment and prevent further deterioration. This is particularly true in AAs.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic, multisystem, connective tissue disorder characterized by fibrosis of the skin and internal organ involvement. These serious clinical manifestations can be associated with significant impairment of quality of life including sexual life. The aim of this study was to assess sexual functioning in female SSc patients compared to age-/sex-matched healthy controls (HC) and to determine the association between sexual health impairment and physical and psychological aspects of the disease.

Methods: In total, 90 women (70 currently have a partner) with SSc (mean age: 49.1, disease duration: 6.1 years, lcSSc/dcSSc: 62/28, mRSS: 9.3, ESSG activity index: 2.1), who fulfilled the ACR/EULAR 2013 criteria, and 90 healthy controls (82 currently have a partner, mean age: 49.1) without rheumatic diseases filled in 12 well-established and validated questionnaires assessing sexual function [Female sexual function index (FSFI), Sexual function questionnaire (SFQ28), Brief index of sexual function for women (BISF-W)], quality of sexual life [Sexual quality of life questionnaire – female (SQoL-F)], pelvic floor function [Pelvic floor impact questionnaire–short form 7 (PFIQ-7), Pelvic organ prolapse/urinary incontinence sexual questionnaire–short form (PISQ-12)], fatigue [Fatigue impact scale (FIS)], physical activity [Human activity profile (HAP)], depression [Beck's depression inventory II (BDI-II)], quality of life [36-item Short form survey (SF-36)] and disability [Health assessment questionnaire (HAQ), Scleroderma health assessment questionnaire (SHAQ)]. Routine laboratory testing was performed. Data are presented as median (IQR).

Questionnaire: score range (meaning)	SSc (n=90)	HC (n=90)	p-value

Table 1. Sexual function and pelvic floor function in women with SSc and healthy controls

Results: Patients with SSc reported significantly greater prevalence and severity of sexual dysfunction (FSFI, BISF-W, SFQ28 – in all subscales as well as total scores), worse sexual quality of life (SQoL-F) and pelvic floor dysfunction (PISQ-12, PFIQ-7) compared to HC (Table 1). When we analyzed only sexually active patients compared to sexually active HC, the difference between patients and HC remained significant (Table 1). The prevalence of sexual dysfunction in patients with SSc according to the FSFI cut-off score was 77%. Worse scores in SSc patients were associated with disease duration, disease activity, increased inflammation, greater fatigue, severer depression, increased disability, deteriorated quality of life, and worse ability to perform physical activities (Table 2). We did not observe any associations with the current prednisone dose or skin score. Furthermore, no significant differences between lcSSc and dcSSc were found.

Conclusion: Women with SSc reported significantly impaired sexual function and pelvic floor function compared to healthy females with identical age. The prevalence of sexual dysfunction in SSc patients was 77%. Worse scores in SSc were associated with disease duration, disease activity, increased inflammation, severer disability, physical inactivity, fatigue, depression, and decreased quality of life.

Oropharyngeal Dysfunction in Patients with Systemic Sclerosis - Results of a Monocentric Clinical Study

Philipp Klemm[1], Mirjam Wirths[2], Ole Hudowenz[2], Ulrike Hoffmann[3], Ulf Müller-Ladner[2] and Uwe Lange[2], [1]Department of Rheumatology, Immunology, Osteology and Physical Medicine, Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, Bad Nauheim, Hessen, Germany, [2]Department of Rheumatology, Immunology, Osteology and Physical Medicine, Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, Bad Nauheim, Germany, [3]Practice for Speech Therapy Ulrike Hoffmann, Friedberg, Germany

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Nearly 98% of patients with systemic sclerosis (SSc) are suffering from gastrointestinal involvement (Schmeiser et al. 2012). While in everyday clinical practice screening for reflux and gastrointestinal dysmo-

Testing method	**Type of oropharyngeal dysfunction**		**n**
subjective (anamnesis)			43/55 (78%)
	reflux		29 (67%)
	voice disorder		7 (16%)
	dysphagia		31 (72%)
objective (logopedic examination)			26/26 (100%)
	speech disorder		1 (4%)
	voice disorder		12 (46%)
	breathing disorder		19 (73%)
	dysphagia		15 (58%)
	restriction of oropharyngeal musculature		25 (96 %)
		palate	11 (44 %)
		tongue	19 (76%)
		mimic musculature	13 (52%)

Frequency und type of oropharyngeal dysfunction

	subjectively experiencing oropharyngeal Dysfunction (n=43)	subjectively not experiencing oropharyngeal dysfunction (n=12)	p-values (x^2-test)
dcSSc	9	2	0,86
lcSSc	31	8	0,86
disease duration < 60 months	14	8	0,04
disease duration > 60 months	28	4	0,04
mRSS < 4	15	5	0,66
mRSS >4	28	7	0,66

Influencing factors

tility is part of the routine procedure and evidence-based treatment options exist (Mercado et al. 2005; Boeckxstaens et al. 2002), screening for oropharyngeal dysfunction is rarely done nor adequately treated. In 2012, a study of the German Network of Systemic Scleroderma (DNSS) showed, that about 78% of patients reported hoarseness and/

or chronic cough. As oropharyngeal dysfunction (e.g. voice dysfunction, dysphagia) can significantly affect quality-of-life and lead to social stigmatization, we initiated a study (DRKS00020776) to address this problem.

Methods: We examined patients with systemic sclerosis using a self-constructed questionnaire and a standardized logopedic examination for signs and symptoms of oropharyngeal dysfunction (e.g., speech disorder, voice disorder, reflux, dysphagia), restrictions of the oropharyngeal musculature (palate, tongue, mimic musculature) and breathing disorders. If any of these were positive, oropharyngeal dysfunction was diagnosed. Furthermore, we analysed, if these findings were associated with specific disease characteristics.

Results: Of 55 patients with SSc fulfilling the inclusion criteria, 55 patients agreed to screening for oropharyngeal dysfunction (medical history and physical examination).

43 out of 55 (78%) SSc patients described at least one symptom of oropharyngeal dysfunction: dysphagia (72%), reflux (67%) and/or voice disorder (16%). In physical examination, 43 out of 55 (78%) patients showed also an oropharyngeal dysfunction.

Neither the subtyp of SSc (d/lcSSc) nor the extent of skin fibrosis (mRSS) were significantly associated with the manifestation of oropharyngeal dysfunction. In contrast, a statistically significant relationship between duration of illness and the manifestation of oropharyngeal dysfunction could be found.

26 out 55 patients received an additional logopedic examination. Of these, 26 out of 26 patients (100%) showed to have at least one type of oropharyngeal dysfunction (Table 1). Most striking was the altered function (limitation) of oropharyngeal musculature in 25 out of 26 (96%) cases.

Conclusion: Although it is known that nearly all patients with SSc have an involvement of at least one part of the gastrointestinal tract, examination for oropharyngeal dysfunction is rarely done. The data of our study indicate, that independently of the subtype of SSc, this complication is more frequent than expected, increases with the duration of the disease and should therefore be implemented in the standard routine diagnostics for SSc.

Table 2. Follow-Up After First Visit

have shown separate associations between skeletal muscle with cardiac and GI involvement. Our objective was to further evaluate the relationship between skeletal muscle involvement and severe or end-stage cardiac and GI involvement in systemic sclerosis (SSc).

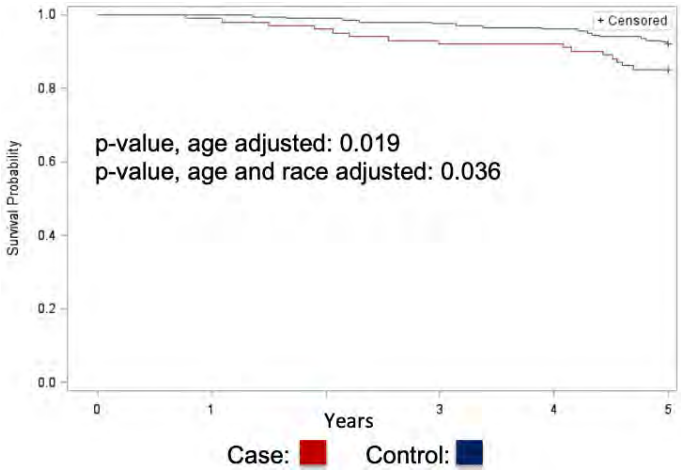

Figure 1. 5-year Survival from First SSc Symptom Onset

Methods: We used an observational SSc cohort from a US Scleroderma Center to perform a case-control study. We included patients seen for an initial visit between 2000-2015 with 2 or more follow up visits at least 4 months apart and continued follow up through at least 3 years after first SSc visit or death. Skeletal muscle cases were identified as those with objective proximal muscle weakness and either CPK level 2 times upper limit of normal, EMG findings of myositis or myopathy, or positive muscle biopsy. Controls included patients that did not meet case identification criteria over a 3-year period. Controls were matched 2:1 with cases and were the next two consecutive SSc initial visits. Disease severity was assessed using the Medsger Severity Scale. Statistical analysis was performed using SAS 9.4 (Cary, NC).

Results: 101 muscle cases and 202 controls were identified. Baseline demographics are shown in Table 1. Cases were significantly younger ($p=0.01$), more frequently non-Caucasian ($p< 0.001$), and had a higher frequency of both diffuse skin disease ($p=0.02$) and joint contractures ($p< 0.001$). As expected, autoantibody profiles were different between cases and controls, with cases having higher frequencies of antibodies associated with myopathy (Table 1): anti-U1RNP, PMScl, Ku, RUV-BL1/2, and U3-RNP antibodies. 23% of cases vs 14% of controls ($p=0.07$) had severe or end-stage GI muscle disease and 18% of cases vs. 13% of controls ($p=0.30$) had severe or end-stage cardiac muscle disease. Cases and controls were treated differently with cases significantly more frequently treated with methotrexate (49% vs 13%, $p< 0.0001$) and prednisone (83% vs 48%, $p< 0.0001$) (Table 2). Overall, cases had a better 5-year survival from first SSc symptom onset when adjusted for age and race (Fig 1).

Conclusion: Severe and end-stage GI and cardiac disease occur at higher frequencies in patients with myopathy, although not statistically significant. Patients with myopathy have a lower rate of 5-year survival. Although the overall frequency of severe and end-stage GI or cardiac disease is low at < 20%, given the poor prognosis of severe GI tract and cardiac involvement, SSc patients with skeletal muscle disease should be followed carefully for these serious complications.

Abstract Number: 0933

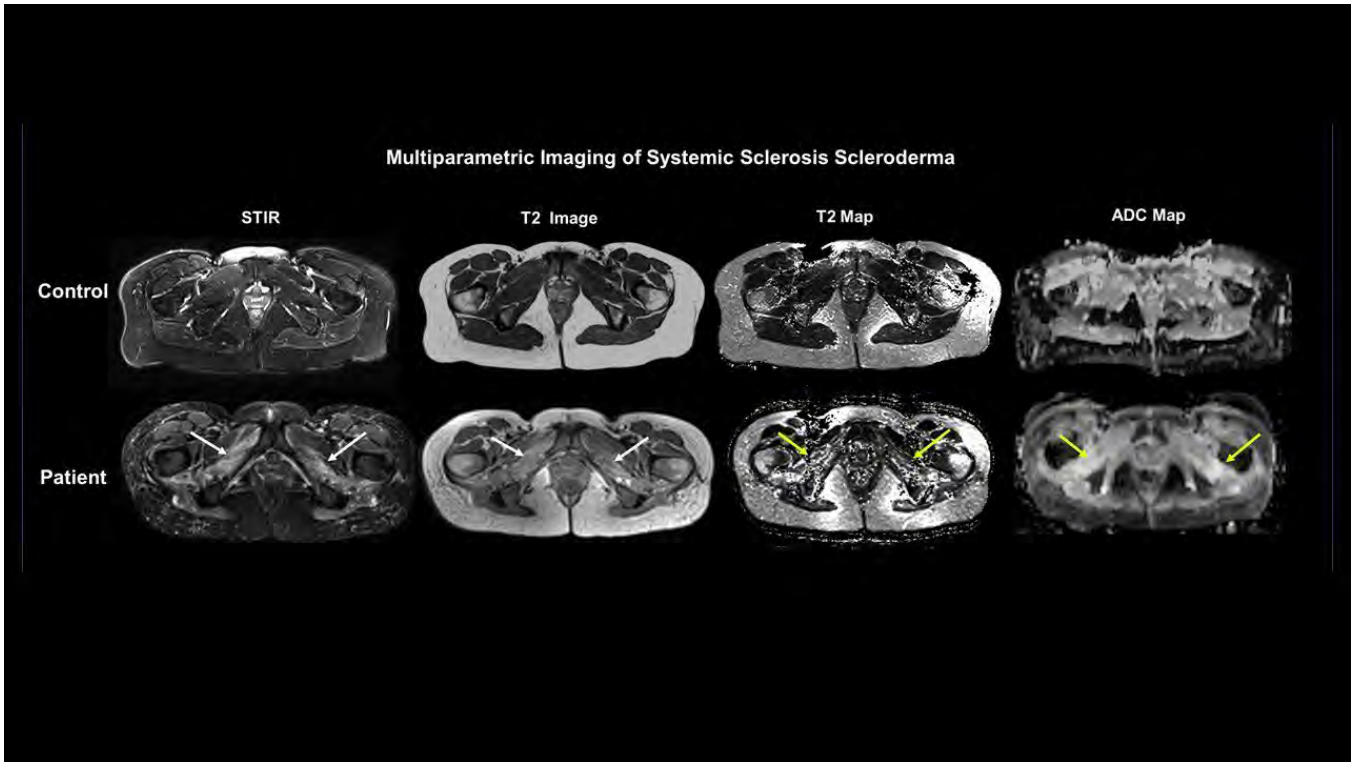
Advanced Multiparametric Magnetic Resonance Imaging of Muscle for Detection and Quantification of Muscle Disease in Systemic Sclerosis

Julie Paik[1], Fredrick Wigley[2], Laura Fayad[3], Laura Hummers[4] and Michael Jacobs[1], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Joh, Baltimore, MD, [4]Johns Hopkins Univerisity, Ellicott City, MD

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Skeletal myopathy in systemic sclerosis (SSc) is underappreciated yet an important manifestation of SSc. While it has been reported that there are distinct histopathologic subsets of myopathy, Multiparametric muscle magnetic resonance imaging (mpMRI) patterns are unknown and the degree of involvement is yet quantified. In order to determine whether unique mpMRI muscle tissue signatures exist in SSc associated myopathy, we implemented advanced mpMRI muscle techniques in the evaluation of SSc in patients with muscle weakness.

Methods: SSc patients were identified as having a skeletal myopathy as defined by proximal weakness and at least one abnormal diagnostic test such as muscle enzymes, EMG, MRI or muscle biopsy. Eligible SSc patients with a myopathy and age matched healthy controls were prospectively recruited. The mpMRI protocol consisted of anatomical and advanced functional sequences that included T_1- and T_2-weighted, T_2 mapping, STIR, Dixon, and diffusion weighted images(DWI) and Apparent Diffusion Coefficient of Water (ADC) maps for detection and quantification the



Representative cases of Multiparametric muscle MRI in a control and SSc patient

burden of muscle involvement in SSc associated myopathy. MpMRI between muscle groups in each cohort were tested using a paired t-test and significance was set at $p< 0.05$.

Results: There were a total of 10 patients, seven who met the 2013 ACR/EULAR criteria for systemic sclerosis and three healthy controls, who underwent the research mpMRI. Six of seven (86%) had diffuse cutaneous SSc. Four of the 7 patients had prior muscle biopsies and demonstrated muscle heterogeneity ranging from a fibrosing myopathy (n=1), necrotizing myopathy (n=2), and dermatomyositis (n=1). Five of the seven were on at least 1 immunosuppressant and/or IVIG for the treatment of myopathy. Mean creatine kinase was 152 ± 111 within 3 months of the mpMRI. There were significant differences between abnormal and normal obturator muscle groups (external and internal) using mpMRI T_2 map values (p=0.02). (Internal Right Side:130±28 versus 87±16 msec and Left Side:138±23 versus 91±16 msec), (External Right Side:157±26 versus 87±16 msec and Left Side:155±26 versus 100±33 msec). Similarly, the ADC values were significantly different in these muscle groups. Figure 1 depicts a representative case where the white arrows show the increased signal intensity in the obturators on the STIR, T_2 maps and ADC maps in a patient compared to a normal control.

Conclusion: In this preliminary study of SSc patients with skeletal myopathy, we demonstrated that by using advanced mpMRI, techniques, the obturator muscles of the pelvis were preferentially affected by SSc compared to healthy controls. Advanced muscle mpMRI could be a useful non-invasive imaging biomarker for muscle disease in SSc associated myopathy that provides new quantifiable metrics.

Abstract Number: 0934

Warfarin Use and Risk of Knee and Hip Replacements

Priyanka Ballal[1], Christine Peloquin[1], Cindy Boer[2] and Tuhina Neogi[1], [1]Boston University School of Medicine, Boston, MA, [2]Erasmus Medical Center, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Plenary Session II
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Vitamin K is an essential co-factor in the post-translational gamma-carboxylation of glutamic acid to form gamma-carboxy-glutamic acid (Gla) residues. This confers functionality to vitamin K-dependent proteins including those in bone and cartilage that play an important role in regulating mineralization. Low vitamin K can lead to under-carboxylation of Gla proteins and thus their dysfunction. Vitamin K deficiency has been associated with OA, and a randomized trial of vitamin K supplementation demonstrated trends towards less OA progression. Studies to date have not evaluated whether vitamin K antagonism with warfarin can be detrimental to OA. We therefore evaluated the relation of warfarin to risk of knee and hip replacements as a reflection of end-stage OA.

Methods: We conducted a nested case-control study using The Health Improvement Network, a general practitioner (GP)-based electronic medical records database from the UK that is representative of the general population. To minimize confounding by indication, we limited our study sample to adults (aged 40-89) with atrial fibrillation, as this diagnosis warrants therapy with anticoagulation. Additionally, we compared warfarin, a vitamin K antagonist, with

	Cases	Controls
Subjects (n)	913	3652
Warfarin use	592 (64.9%)	2057 (56.3%)
Direct oral anticoagulant (DOAC) use	321 (35.1%)	1595 (43.6.%)
Odds Ratio (95% CI), matched for age & gender	1.58 (1.33, 1.87)	
Adjusted* Odds Ratio (95% CI), matched for age & gender	1.57 (1.30, 1.89)	
*adjusted for BMI, factors influencing choice of anticoagulant (CKD 4/5, ESRD, kidney transplant, severe liver disease, mitral stenosis or prosthetic valve, previous intracranial hemorrhage, GI bleed and frequent falls), comorbidities (cancer, congestive heart failure, COPD, dementia, diabetes, hyperlipidemia, hypertension, ischemic heart disease, renal disease, stroke, venous thromboembolism/pulmonary embolus), medications (anti-hypertensives, insulin, oral anti-diabetic drugs, lipid-lowering drugs, NSAIDs, acetaminophen), general practitioner visits, hospitalizations		

Table. Relation of Warfarin versus DOAC use to Risk of Knee or Hip Replacement

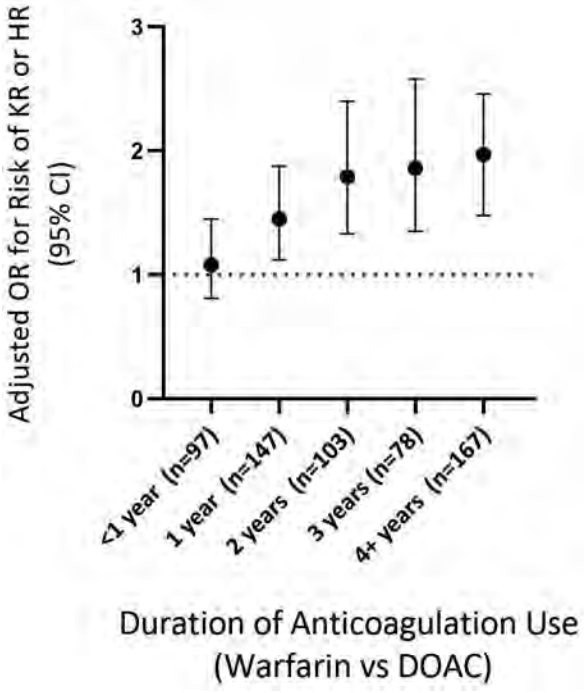

Figure. Relation of Duration of Anti coagulation use (warfarin vs. DOAC) to Risk of KR or HR

direct oral anticoagulants (DOAC), which are not vitamin K antagonists. Because DOACs were first marketed in the UK in 2008, we limited our study to those who had been enrolled for ≥1 year with a GP between 2009 and 2018. We excluded individuals with knee or hip replacement (KR/HR) prior to 2014, severe co-morbidities that would limit surgery, those with warfarin or DOAC use within 1 year prior to our study period, and those who used both drugs during study period. We identified cases as those with KR or HR between 2014-2018, with surgery date being the index date for cases. Each case was matched with up to 4 controls by age and gender. We defined warfarin and DOAC use as having ≥1 prescription after study entry and within 1 year prior to the index date. We assessed the relation of warfarin compared with DOAC use to risk of KR or HR using conditional logistic regression, adjusting for potential confounders.

Results: We identified 913 subjects with KR or HR (cases) who were age and gender-matched 4:1 with 3652 controls (mean age 74, 46% female). Of the 913 cases, 64.9% were warfarin users while 35.1% were DOAC users; in contrast, of the 3652 controls, 56.3% were warfarin users while 43.6% were DOAC users. With adjustment for potential

confounders, warfarin users had 1.57 times higher odds of KR or HR than DOAC users (Adjusted OR 1.57, 95% CI (1.30-1.89)) (Table). When matched by practice ID to account for practice variation, we found a slightly diminished but significant association (Adjusted OR 1.25, 95% CI (1.03-1.52)). There was increasing risk of KR or HR with duration of warfarin vs. DOAC exposure (Figure).

Conclusion: Warfarin use, a vitamin K antagonist, was associated with significantly greater risk of KR or HR (an indicator for end-stage knee OA) than DOAC use, with risk increasing with duration of use. These data add further support to the importance of adequate vitamin K and its dependent proteins in limiting progression of OA and raises the consideration of using DOACs over warfarin when indicated in those with or at risk of OA.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Plenary Session II
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Type I interferons (IFN-I), inflammatory mediators principally produced by plasmacytoid dendritic cells (pDCs), components of the innate immune system, have been implicated in the pathogenesis of SLE.[1-3] BIIB059 is a humanized IgG1 mAb that binds blood dendritic cell antigen 2 (BDCA2), a pDC-specific receptor, which upon ligation and internalization results in inhibition of the production of IFN-I and other inflammatory cytokines.[4] Administration of BIIB059 in a phase 1 SLE study (NCT02106897) resulted in decreased expression of IFN-response genes in the skin and peripheral blood; reductions of myxovirus resistance protein 1, an IFN-modulated protein, in the skin; reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity (CLASI-A) scores; and was associated with an accepTable safety profile.[5] LILAC (NCT02847598) is a 2-part, phase 2 study that evaluated the efficacy and safety of BIIB059 in participants with SLE in part A, presented here, and participants with cutaneous lupus erythematosus in part B.

Methods: Enrollment was open to adults fulfilling 4 of 11 1997 revised ACR classification criteria, with ≥4 tender and ≥4 swollen joints (28-joint assessment), active skin disease defined by SLEDAI-2K, and positive ANA and/or elevated anti-dsDNA antibodies. Oral CS doses could not exceed 20 mg/day of prednisone (or equivalent), and mandatory CS tapering was initiated 4 weeks after the first dose of investigational therapy. Concomitant SLE therapy had to be initiated ≥12 weeks and remain sTable ≥4 weeks before randomization and throughout the study. Participants were randomized to BIIB059 450 mg or placebo administered subcutaneously every 4 weeks for 20 weeks (additional dose at week 2). The primary endpoint was the change in total active joint count (sum of tender and swollen joints) from baseline to week 24. Secondary endpoints compared the proportions of participants with 50% improvement from

baseline in CLASI-A score and the proportions of participants who achieved an SRI-4 response at week 24. Safety was assessed.

Results: Of 56 and 64 participants dosed in the placebo and 450 mg BIIB059 groups, respectively, 89.3% and 90.6% completed treatment. The study met its primary endpoint: At week 24, there was a significant difference in least squares mean absolute changes (SE) from baseline in the total active joint count between placebo (-11.6 [1.3]) vs BIIB059 450 mg (-15.0 [1.2], p=0.037). There was a 26-percentage point difference (95% CI: 9.46, 43.24, p=0.003) in the SRI-4 response rate between the BIIB059 450 mg vs placebo group at week 24 (Table 1). Although there was a higher CLASI-50 response rate in the BIIB059 group vs placebo, statistical significance was not attained. The percentages of participants in the placebo and pooled BIIB059 groups that experienced any adverse event were 67.9% and 59.2%, respectively (Table 2).

Table 1. Efficacy endpoints at week 24.

Endpoint	Placebo	BIIB059 450 mg
Primary[a]		
Absolute change from baseline in total active joints[b,c]	n = 46	n = 56
LS mean (SE)	-11.6 (1.3)	-15.0 (1.2)
LS mean diff (95% CI)		-3.4 (-6.7, -0.2)
p value		0.037
Secondary[d]		
CLASI-50 response rate[e]	n = 38	n = 39
LS mean (SE)	49.10 (9.63)	69.10 (8.83)
LS mean diff (95% CI)		20.00 (-1.34, 41.34)
p value		0.064
SRI-4 response rate	n = 56	n = 64
LS mean (SE)	30.42 (7.38)	56.77 (7.36)
LS mean diff (95% CI)		26.35 (9.46, 43.24)
p value		0.003

[a]Post-treatment-failure data were imputed using worse of baseline values or values from the last visit before treatment failure. Data after treatment discontinuation were censored. [b]Total active joints=sum of tender joints and swollen joints (28-joint assessment; maximum score=56). [c]Data from participants enrolled under protocol version 1 were only included in this analysis if they had at least 4 tender joints and 4 swollen joints (28-joint assessment). [d]Participants who failed/discontinued treatment were classified as nonresponders at visits post-treatment failure/discontinuation. Participants who completed treatment but had a missing score at a primary timepoint were classified as nonresponders for that timepoint. [e]Data from participants enrolled under protocol version 2 were only included in this analysis if baseline CLASI-A was ≥8.
CLASI-A = Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity; CLASI-50 = at least 50% improvement from baseline in CLASI-A score; LS mean diff = least squares mean difference from placebo; SRI-4 = SLE Responder Index-4 defined as: reduction from baseline of ≥4 points in the Systemic Lupus Erythematosus Disease Activity Index score 2000, no new British Isles Lupus Activity Group 2004 (BILAG-2004) A domain score or more than 1 new B domain score, no worsening (<10%) from baseline in physician global assessment, and no violations of protocol-specified medication rules.

Table 2. Numbers and percentages of participants with adverse events according to group in LILAC part A.

Event	Placebo (n = 56)	Pooled BIIB059[a] (n = 76)
Any event, n (%)	38 (67.9)	45 (59.2)
Severity, n (%)

Urine Proteomics and Single Cell Transcriptomics Identify IL-16 as a Biomarker for Lupus Nephritis

Andrea Fava[1], Jill Buyon[2], Chandra Mohan[3], Ting Zhang[3], H. SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Plenary Session II
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Treatment of lupus nephritis relies on renal histopathological features. However, renal biopsies do not capture patient-specific active biological pathways. Urine proteomic biomarkers could revolutionize the diagnosis and management of lupus nephritis by predicting active intrarenal biological pathways and can be noninvasively monitored over time.

Methods: One thousand proteins were quantified (RayBiotech) in a total of 112 longitudinal urine samples from 30 SLE patients with active lupus nephritis and 7 healthy controls (HC). The proteins and molecular pathways detected in the urine proteome at the time of biopsy were then analyzed with respect to lupus nephritis class, response to treatment after 1 year, histopathological features (activity and chronicity indeces), and trajectory over time (baseline and week 12, 26, and 52). The intrarenal expression of candidate biomarkers was evaluated using single cell transcriptomics of renal biopsies from patients with active lupus nephritis.

Results: There were 237 proteins (FDR < 10%) enriched in the urine of patients with lupus nephritis reflecting several molecular pathways involving chemotaxis, extracellular matrix remodeling, and activation of neutrophils and platelets. Hierarchical clustering using urine proteomics segregated SLE patients into 2 groups, with 80% of complete responders clustering together. This finding could not be similarly reproduced using standard features including baseline proteinuria, creatinine, histologic activity or chronicity scores, or class, indicating unique informative features of urine proteomics (**Fig. 1**). Patients

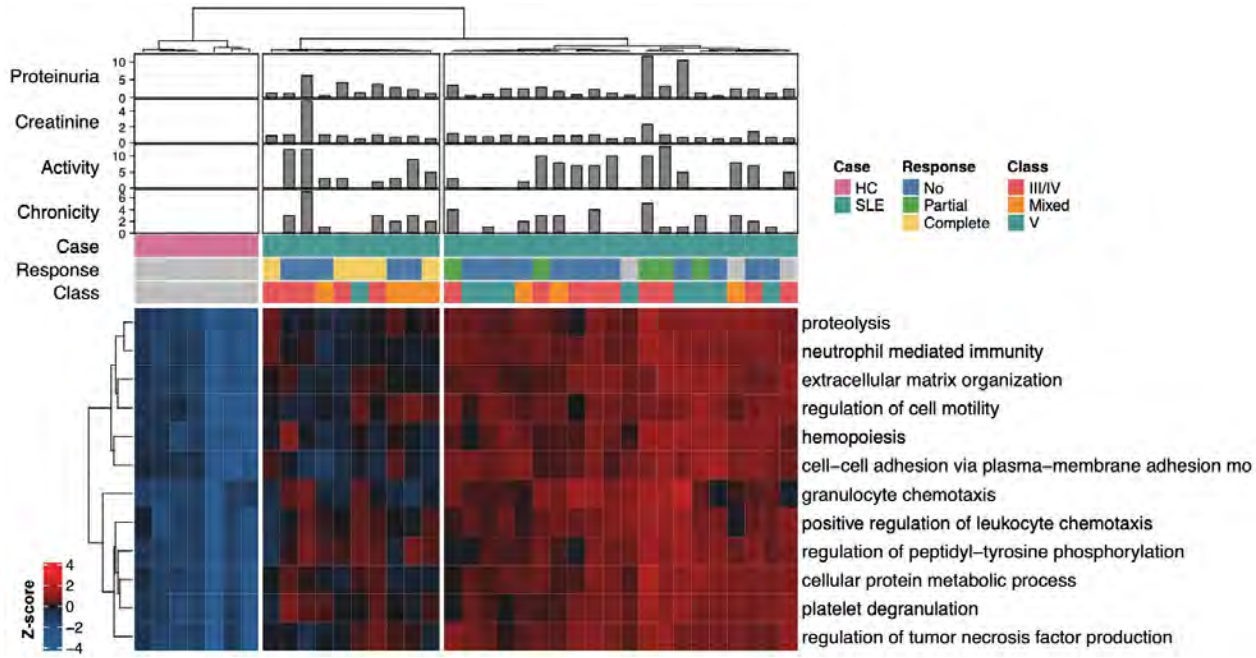

Figure 1. Concentration of enriched proteomic pathways in lupus neprhitis urine. The relative concentration of the 12 non overlapping pathways (GO Biological Process) enriched in the urine of lupus nephritis (LN) patients is reported in this heatmap. Colors represent row-normalized Z-scores. Unsupervised hierarchical clustering identified the healthy controls and two clusters of LN patients. The LN cluster on the left showed overall lower concentration of proteins in the 12 pathways and included 4/5 of complete responders. Figure 1. with proliferative lupus nephritis (class III or IV) had stronger activation of chemotaxis pathways. IL-16 was the urinary protein most significantly increased in proliferative disease compared to membranous (FC 6, p=0.002) (**Fig. 2A**). Assessment of urine proteins that correlated with histologic activity kidney highlighted IL-16 as the single most strongly correlated protein with histologic activity (r=0.69, $p=9.5 \cdot 10^{-5}$; **Fig. 2B**). IL-16 concentration was independent of the amount of proteinuria and progressively diminished over time in patients who were responding to immunosuppression (**Fig. 2C**). Single cell RNA sequencing revealed significant intrarenal expression of IL16 by all infiltrating immune cells and highlighted IL16 as the second most expressed cytokine in lupus nephritis kidneys out of a compendium of 236 cytokines (**Fig. 3A-B**).

Conclusion: Urine proteomics can noninvasively identify active and biologically relevant pathways in lupus nephritis. Integrated urine proteomics and renal single cell transcriptomics revealed that IL-16, a CD4 ligand with chemotactic

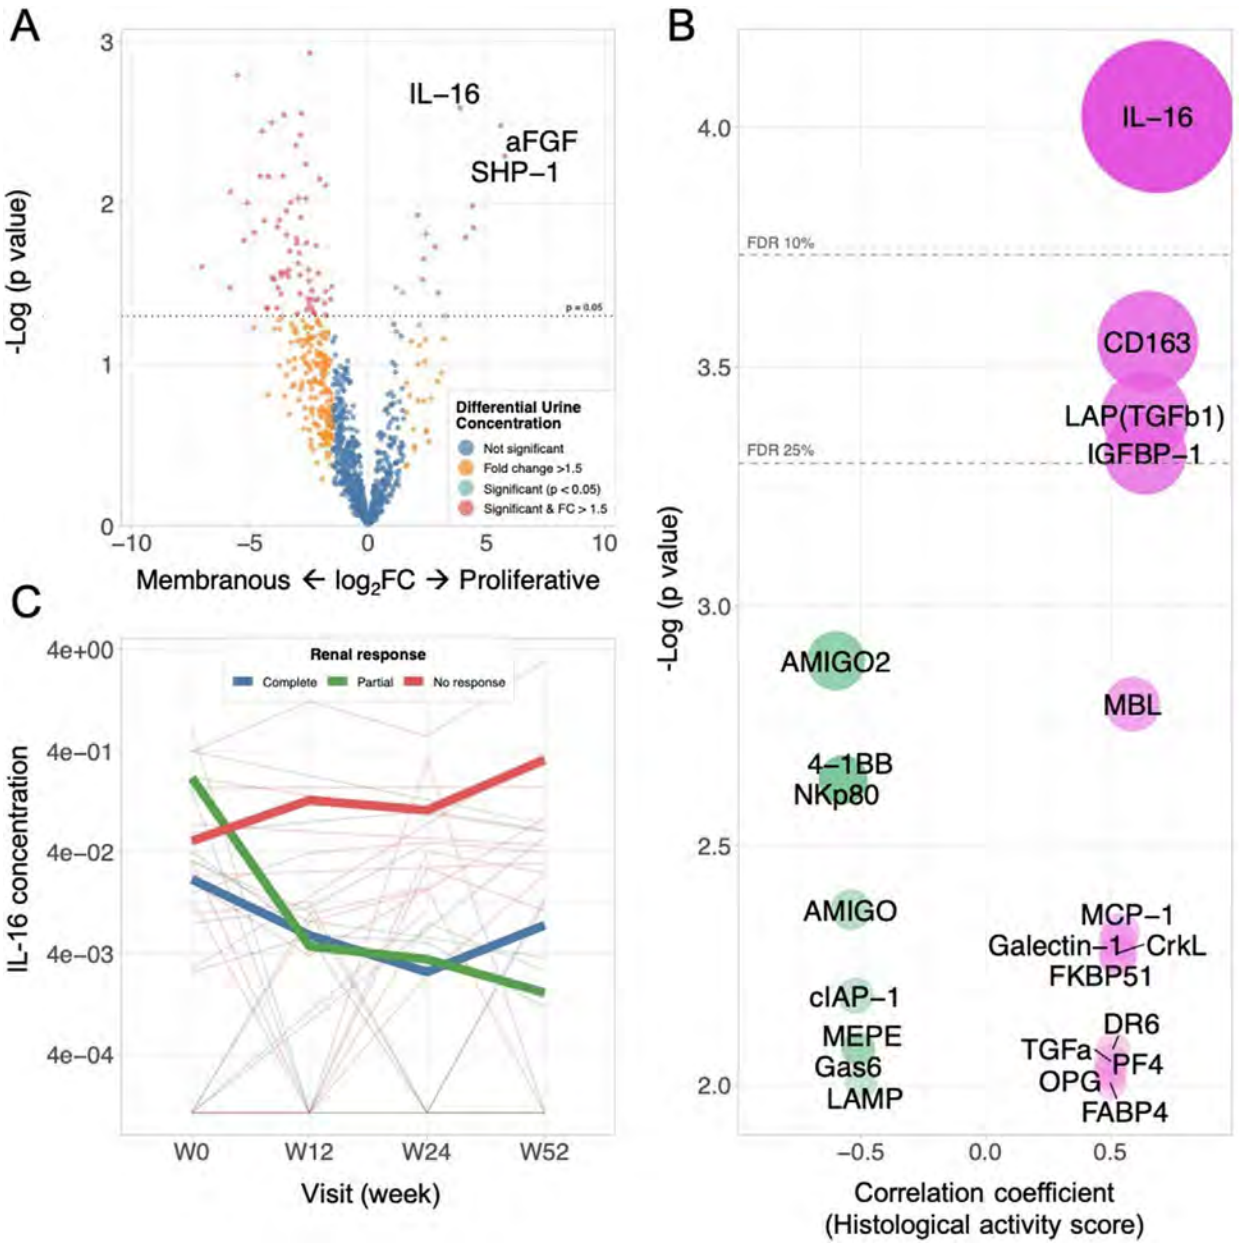

Figure 2. Urinary IL-16 is correlated with renal histological activity and response to treatment. (A) Volcano plot comparing the concentration of 1000 urinary proteins in proliferative vs pure membranous lupus nephritis. (B) Top 20 Pearson's correlations of urinary proteins with renal histological NIH activity index. IL-16 was the only protein with a false discovery rate (FDR) < 10%. Circle areas represent a combination of the absolute correlation coefficient and p value. (C) Longitudinal trends of urinary IL-16 at baseline, week 12, 24 and 52. Thick lines represent the mean concentration according to the response status at week 52.

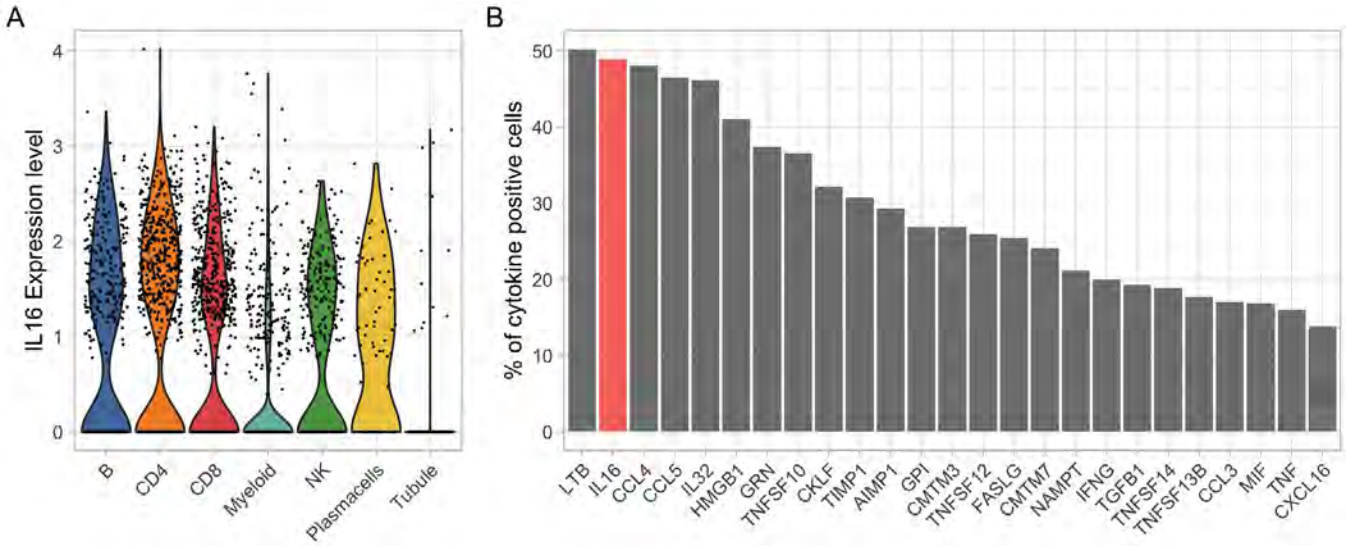

Figure 3. Intrarenal expression of IL16 based on single cell RNA sequencing of lupus nephritis kidney biopsies. (A) Violin plots showing IL16 expression by all kidney infiltrating immune cells. (B) Percentage of cytokine positive cells across all kidney infiltrating immune cells. The bar plot shows the top 25 cytokines out of a comprehensive list of 236 obtained from the "Cytokine Registry" (Immport) and the Gene Ontology database.

and proinflammatory functions, was one of the most expressed cytokine in lupus nephritis. As a urine proteomic biomarker, IL-16 may predict renal histological activity and could be monitored over time to assess response to immunosuppression. Urinary IL-16 is independent of proteinuria thus potentially providing actionable clinical information that is not captured by currently used biomarkers. Further studies are ongoing to validate these findings.

MACE – Major Adverse Cardiac Event, MI – myocardial infarction, TIA – transient ischemic attack
* Hazard ratios for "MI and ischemic heart disease" included angina pectoris, coronary thrombosis, post-myocardial infarction syndrome, and chronic ischemic heart disease. Separate hazard ratios were calculated for acute myocardial infarction but could only be reported between 0-1yr (KD: 7 (0.2%) *vs.* non-exposed: 43 (0.01%), HR 15.88 [7.15-35.31]), due to low event numbers at other time periods.
† NR: not reported as ≤ 5 individuals in one or both groups

Table 1. Incidence and risk of cardiovascular events, comparing KD vs. non-exposed children at 0-1yr, 1-5yr, 5-10yr and >10yr follow-up

Background/Purpose: Kawasaki disease (KD) is a common childhood vasculitis associated with coronary artery aneurysms (CAA). Based on our recent work, the incidence of KD has significantly increased in Ontario over the past two decades. However, the risk of long-term cardiovascular events in children without large CAA remains unknown. Our objectives were to: 1) determine the risk and timing of long-term cardiovascular events (diagnoses and procedures) among KD survivors; and 2) determine the risk of all-cause mortality.

Methods: We identified all children (0-18yr) surviving hospitalization with a KD diagnosis in Ontario between 1995-2018, through validated algorithms using population health administrative databases. We included only the first eligible hospitalization and excluded children previously diagnosed with KD and non-residents. KD cases were matched to 100 non-exposed controls by age, sex and index year. Follow-up continued until death or March 2019 (maximum 24 years). We determined incidence rates (per 1000 person-years (py)) and unadjusted hazard ratios (HR) for cardiovascular events, major adverse cardiac events (MACE; cardiovascular death, myocardial infarction (MI) or stroke composite) and all-cause mortality, comparing KD and non-exposed cohorts during the following time periods: 0-1yr, 1-5yr, 5-10yr and >10yr.

Results: Among 4,597 KD survivors, 746 (16.2%) experienced cardiovascular events, 79 (1.7%) MACE and 9 (0.2%) died during median 11.1-year follow-up (Table 1). The most frequent cardiovascular events among KD survivors were ischemic heart disease (231 children, 4.6 events/1000py), arrhythmias (229, 4.5/1000py), hypertension (159, 3.1/1000py) and peripheral vascular disease (107, 2.1/1000py). KD survivors were at increased risk of cardiovascular events and MACE *vs.* non-exposed children between 0-1yr, 1-5yr and 5-10yr, and cardiovascular events at >10yr

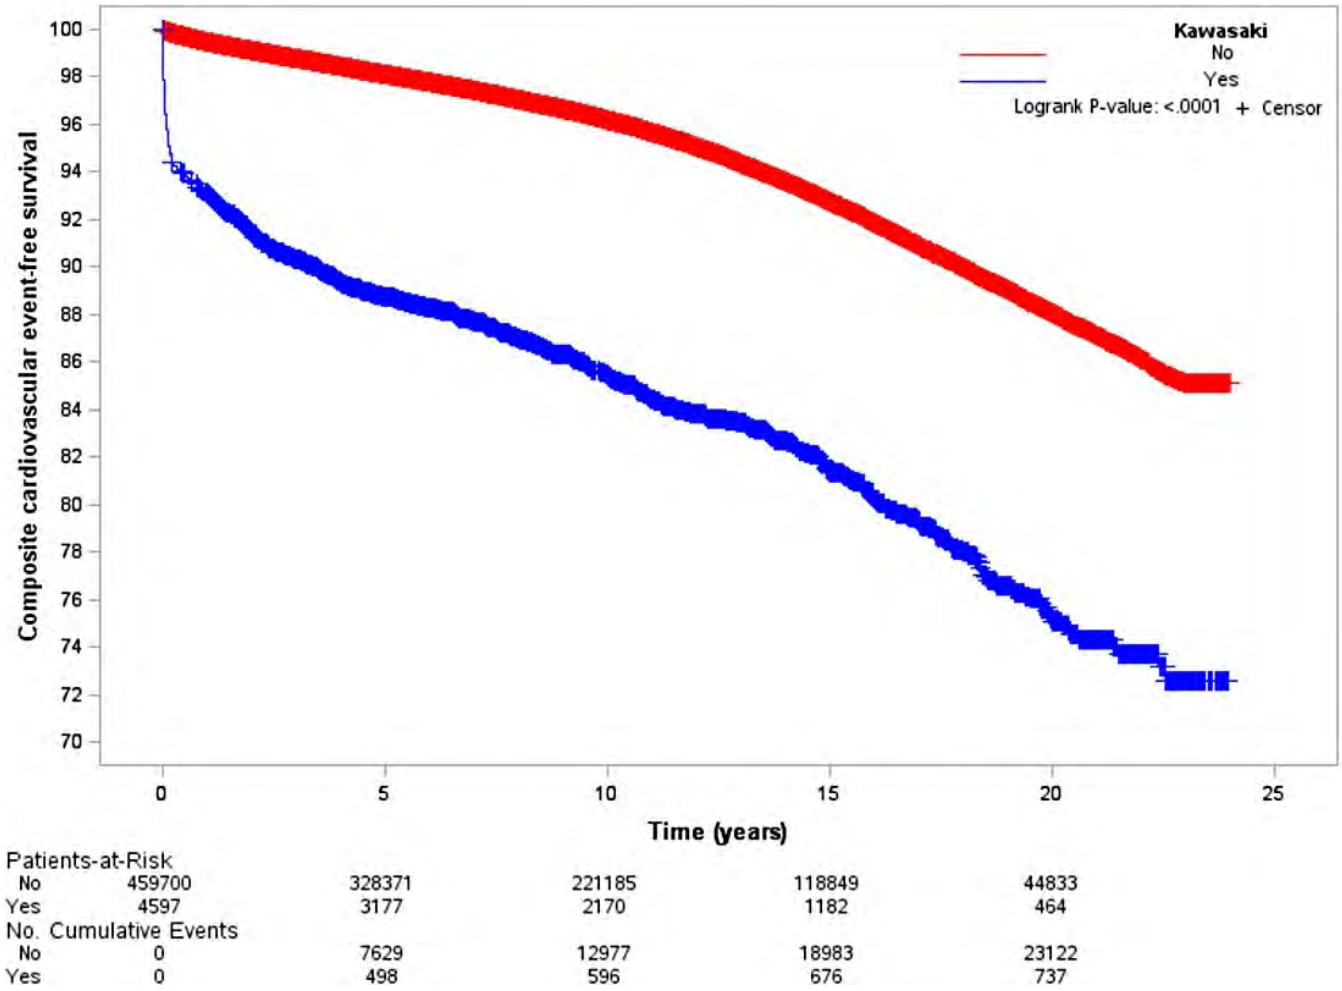

Figure 1. Composite cardiovascular event-free survival among KD survivors vs. non-exposed children

follow-up (Table 1). KD survivors experienced cardiovascular events sooner than non-exposed children (Figure 1; Kaplan-Meier curve, log-rank p< 0.0001). Their risk of cardiovascular events was highest in the first year post-discharge (HR 14.13 [12.57-15.89]). KD survivors were at increased risk of undergoing percutaneous coronary intervention or coronary artery bypass grafting throughout follow-up (KD: 12 (0.3%) *vs.* non-exposed: 63 (0.01%), HR 14.68 [7.73-27.88]). KD survivors were at lower risk of mortality throughout follow-up (KD: 9 (0.2%) *vs.* non-exposed: 2,012 (0.4%), HR 0.42 [0.22-0.81]).

Conclusion: Children diagnosed with KD remain at increased risk of cardiovascular events for >10 years after index hospitalization. Despite the prevalence of cardiovascular disease, they have a lower risk of long-term mortality. Our findings highlight the need for cardiovascular disease surveillance and risk reduction strategies among KD survivors.

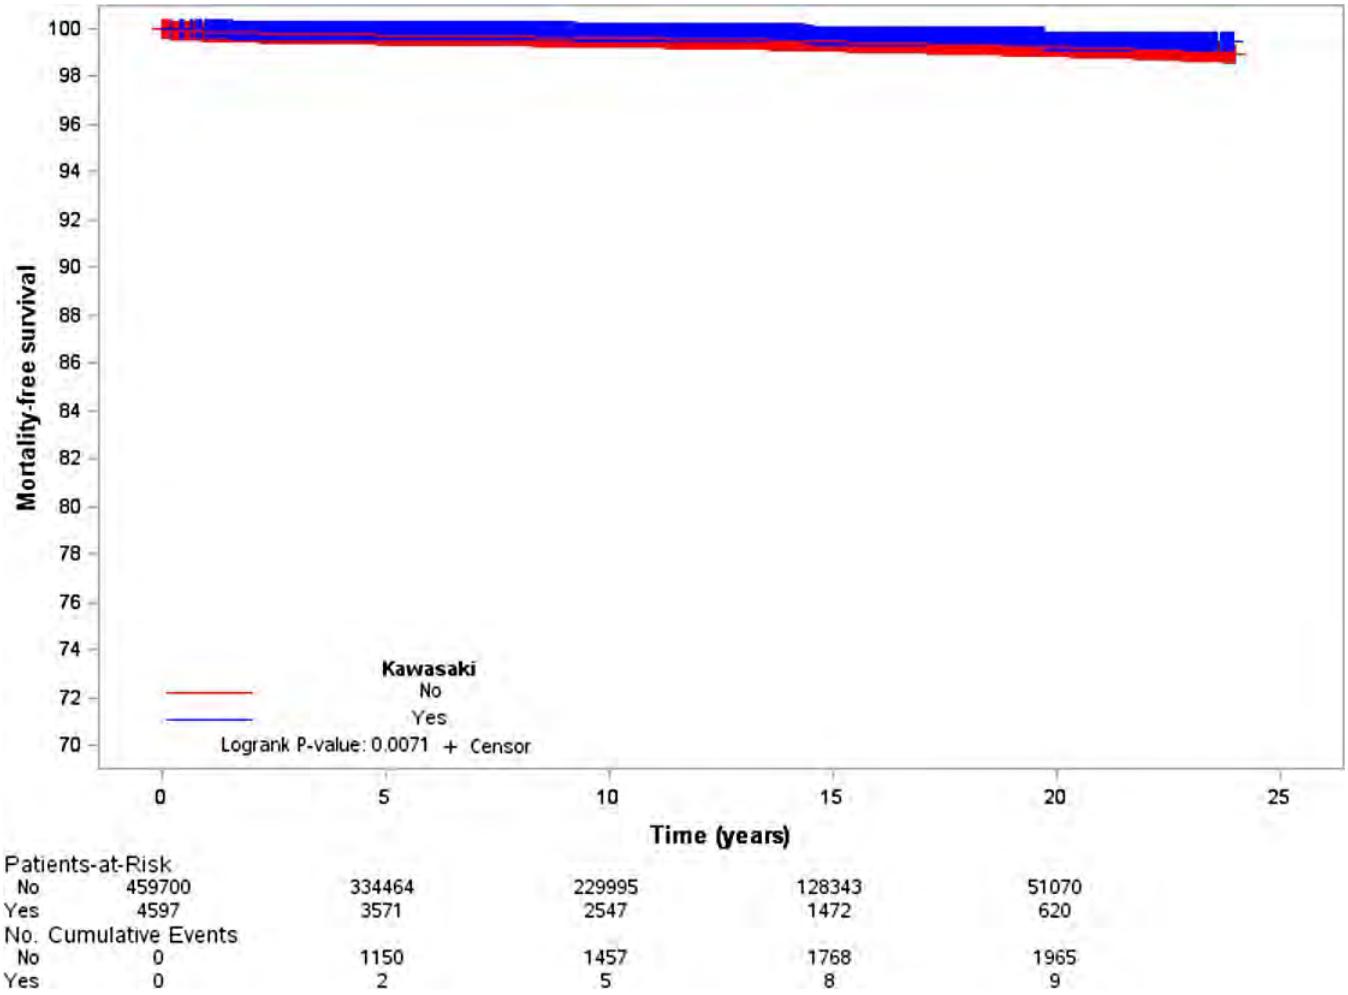

Figure 2. Patient survival among KD survivors vs. non-exposed children

Session Date: Saturday, November 7, 2020

Session Title: Plenary Session II

Session Type: Plenary Session

Session Time: 11:30AM–1:00PM

Background/Purpose: The role of complement in the aPL related pathology has been widely studied in animal models. aPL can induce fetal loss in experimental animals but mice deficient in specific complement components (C4, C3, C5) appear somehow protected. In addition, in pregnant mice injected with aPL, antibody deposition has been found at decidual level causing focal necrosis, apoptosis and neutrophil infiltrates and supporting aPL pathogenetic potential. Instead, human studies did find hypocomplementemia associated to pregnancy complications in patients with obstetric APS. These results, however, are not unanimously confirmed and some studies only show increased levels of complement activation products (i.e. Bb) and not decreased levels of C3 and C4. This can be obviously due to methodological problems, challenging also because of the physiological alteration of complement profile during pregnancy. Recently low levels of C3 and/or C4 in early pregnancy and before pregnancy were found to significantly predict pregnancy complications and loss in a large cohort of primary APS. Therefore, we have thought that it would be interesting to investigate if the simple detection of low C3 and/or C4 could be considered a risk factor for adverse pregnancy outcome in obstetric APS and aPL carriers.

Methods: We performed a multicentric study (487 pregnancies from 10 Italian Rheumatology Centers were included) and collected retrospectively data on pregnancies in women with primary APS (n=293) and aPL carriers with persis-

Table 1. Relationship between gestational outcome, maternal pregnancy complications and preconceptional complement levels

	All pregnancies		p	Triple aPL positivity		p	One or double aPL positivity		p
Gestational outcome	**Low C3/C4 (n=97)**	**Normal C3/C4 (n=134)**		**Low C3/C4 (n=32)**	**Normal C3/C4 (n=16)**		**Low C3/C4 (n=65)**	**Normal C3/C4 (n=118)**	
Term live birth (≥37w)	55 (60%)	88 (70%)	ns	16 (50%)	10 (63%)	ns	15 (23%)	20 (17%)	ns
Preterm live birth (<37w)	18 (20%)	25 (20%)	ns	7 (22%)	6 (37%)	ns	11 (17%)	19 (16%)	ns
Pregnancy losses (abortion and miscarriages)	18 (20%)	10 (8%)	0.01	9 (28%)	0 (0%)	0.04	39 (60%)	79 (67%)	ns

Legend: PE, preeclampsia; DVT, deep vein thrombosis.

tent antibody positivity (n=194). Serum C3 and C4 levels were evaluated by nephelometry; hypocomplementemia was defined by local laboratory reference values. Statistical analysis was performed using GraphPad.

Results: Preconceptional complement levels and gestational outcome were available for 96 (49%) aPL carriers pregnancies and 135 (46%) APS pregnancies. In patients with low preconceptional C3 and/or C4, a significantly higher prevalence of pregnancy losses was observed.(p=0.01). A subgroup analysis considered patients with triple aPL positivity. In this subgroup of high risk patients preconceptional low C3 and/or C4 levels were found associated with increased rate of pregnancy loss (p=0.04). On the other hand, in women with single or double aPL positivity, adverse pregnancy outcome was not found related to preconceptional complement levels (Table 1). To note, all pregnancy losses in the subgroup of triple aPL positivity were treated with low dose aspirin and low molecular weight heparin from the pregnancy test positivity. No relationship was found between low preconceptional complement levels and maternal complications (pre-eclampsia, eclampsia, deep vein thrombosis, thrombocytopenia).

Conclusion: Our findings confirm that decreased complement levels before pregnancy are associated with increased risk of adverse outcome in women with aPL, with or without APS. Even in the group of triple aPL positivity, considered *per se* at high risk, the presence of low C3 and/or C4 seems to predict a worse prognosis. Complement levels are cheap and easy to measure, therefore, they could represent a useful aid to identify patients with aPL at increased risk of pregnancy loss.

Abstract Number: 0939

Maintenance of Remission After Withdrawal of Etanercept or Methotrexate in Patients with Rheumatoid Arthritis in Sustained Remission on Combination Therapy: Results from a Randomized, Double-blind, Controlled Trial

Jeffrey R Curtis[1], Paul Emery[2], Elaine Karis[3], Boulos Haraoui[4], Vivian Bykerk[5], Priscilla Yen[3], Gregory Kricorian[6] and James Chung[3], [1]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds, United Kingdom, [3]Amgen, Inc., Thousand Oaks, CA, [4]Rheumatology Institute of Montréal, Montreal, Canada, [5]Hospital for Special Surgery, New York, NY, [6]Amgen Inc., Thousand Oaks, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Plenary Session II
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Rheumatoid arthritis (RA) patients (pts) in remission on combination therapy (Combo) of methotrexate (MTX)+etanercept (ETN) face ongoing medication burden and long-term safety/tolerability concerns related to continuing therapies. Reducing therapy has been studied, but whether pts could discontinue either MTX or ETN and maintain remission on monotherapy (mono) has not been rigorously tested. This study compared withdrawing either MTX or ETN on remission maintenance in RA pts who had been in sustained, stringent remission while on Combo.

Methods: The Study of ETN And MTX in RA (SEAM-RA) enrolled adult RA pts on ETN 50 mg/week + MTX 10-25 mg/week who met ACR/EULAR remission criteria (Simplified Disease Activity Index [SDAI] score ≤3.3) in a 24-week, open-label period. After 24 weeks, pts remaining in remission entered a 48-week, double-blind period and were randomized to: (1) withdrawal of ETN (MTX mono); (2) withdrawal of MTX (ETN mono); or (3) continue Combo. Pts with disease-worsening (DW; defined as SDAI >11 at any time or SDAI >3.3 and ≤11 on 2 consecutive visits ≥2 weeks apart or on ≥3 separate visits) received Combo rescue therapy (Combo arm continued Combo therapy) and were considered non-responders. Endpoints included proportion of pts in SDAI remission without DW at week 48 in the ETN mono vs MTX mono arms (primary) and in the Combo vs MTX mono arms (secondary). Other secondary endpoints included time to DW and time to recapture SDAI remission in pts needing rescue therapy. For the primary endpoint, non-responder imputation was used for missing data. The P-value for the primary endpoint was estimated from the Chi-squared test. For secondary endpoints, P-values were not adjusted.

Results: Of 371 pts enrolled in the 24-week, open-label period, 253 (68.2%) remained in remission and were randomized to the double-blind period (101 MTX mono, 101 ETN mono, and 51 Combo). Baseline values were similar across treatment arms: mean (SD) age 55.6 (12.2) years, RA duration 10.3 (7.8) years, MTX dose 16.3 (4.7) mg/week, and SDAI score of 1.3 (1.2). At week 48, SDAI remission was maintained by significantly more pts on ETN mono vs MTX mono (49.5% vs 28.7%; P=0.004) and by more pts on Combo vs MTX mono (52.9% vs 28.7%; P=0.006). Time to DW was shorter with MTX mono compared with ETN mono or Combo (P< 0.001 for both comparisons; Fig. 1). In

Figure 1. Kaplan-Meier Curves of Time to Disease-Worsening (Primary Analysis Set)

	MTX Mono (N = 101)	ETN Mono (N = 101)	Combo (N = 51)
Days to Disease-Worsening, Median (95% CI)	198 (96, 263)	NE (253, NE) P<0.001*	NE (336, NE) P<0.001*

*P-values are nominal and compare the ETN-containing arms with the MTX mono arm using a log-rank test. One patient in the MTX arm discontinued at study day 0, and was thus no longer at risk and was censored.
CI, confidence interval; Combo, combination; ETN, etanercept; mono, monotherapy; MTX, methotrexate; NE, not estimable.

Figure 1. Kaplan-Meier Curves of Time to Disease-Worsening (Primary Analysis Set)

pts with DW treated with Combo rescue therapy, the cumulative percentage who recaptured SDAI remission by end of study was 71%, 75%, and 80% in the MTX mono, ETN mono, and Combo arms, respectively. Time to recapture SDAI remission after initiating rescue therapy was similar in all 3 treatment arms. No new safety signals were reported.

Conclusion: In pts in remission on Combo who then withdrew either MTX or ETN, this study showed that ETN mono was superior to MTX mono in maintaining remission. Similar proportions of pts maintained remission with ETN mono as with Combo. The majority of pts who received rescue therapy recaptured remission. For pts and physicians seeking to reduce treatment burden, these data inform decision-making on therapy withdrawal in well-controlled RA pts.

Abstract Number: 0940

In Patients with Inflammatory Arthritides Central Pain Sensitization Is Strictly Associated with Functional Disability

Giovanni Adami[1], Angelo Fassio[1], Elisabetta Gerratana[2], Alessandro Giollo[1], Camilla Benini[1], Luca Idolazzi[1], Elisabetta Vantaggiato[1], Davide Gatti[1] and Maurizio Rossini[1], [1]Rheumatology Unit, University of Verona, Verona, Italy, [2]Rheumatology Unit, University of Messina, Messina, Italy

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Long-term nociceptive pain, as in inflammatory arthritides, can cause Central Sensitization (CS) to pain. CS Inventory (CSI) is a validated screening instrument for clinicians to help identifying patients with CS. We sought to investigate the association between CSI score and clinical, demographic and ultrasonographic parameters of patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA)

Methods: We conducted a cross-sectional analysis on patients with an established diagnosis of RA or polyarticular PsA. Disease activity was measured with SDAI and DAS28-CRP in RA patients and with DAPSA in PsA patients. The presence and severity of synovitis was also measured with the overall ultrasound (US) 7-joints score and its components (gray-scale ultrasound [GSUS], power-Doppler ultrasound [PDUS] and erosions). CSI questionnaire was analyzed either as a continuous variable or as positiveegative (threshold 40 points) or divided in four categories, i.e., subclinical (≤29), mild (30-39), moderate (40-49), severe/extreme (≥50). Exclusion criteria included: diagnosis of PsA with enthesitis predominant and/or spondylitis subtypes.

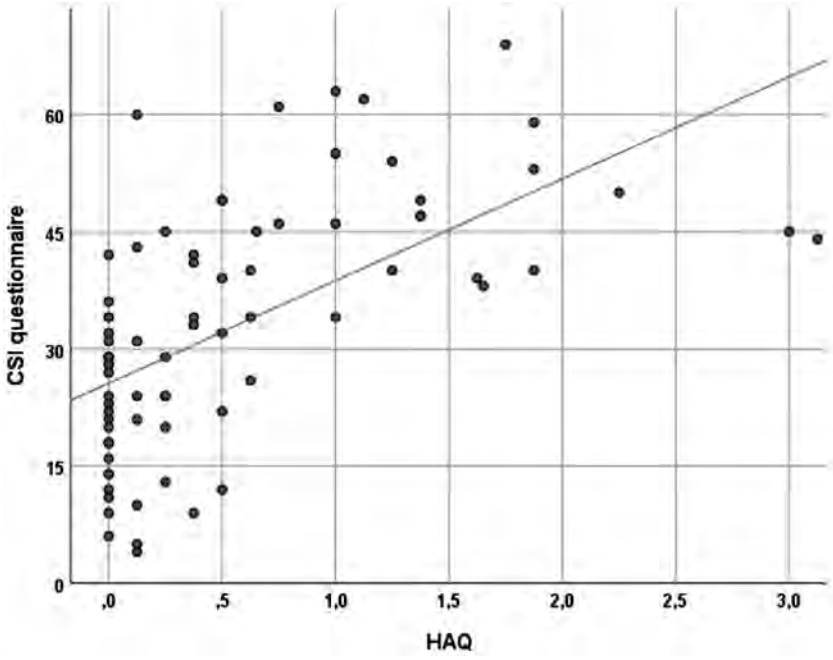

Figure 1. Relationship between HAQ and CSI questionnaire score in patients with inflammatory arthritides. R2 0.361, p <0.0001

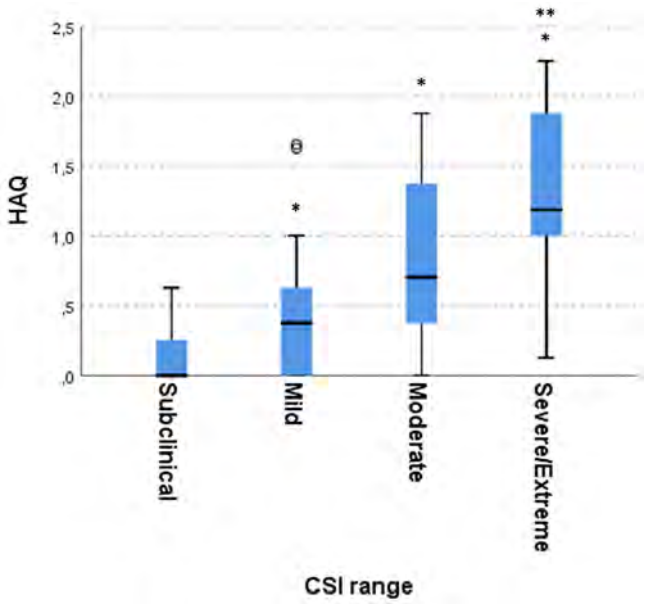

Figure 2. Median HAQ at different CSI questionnaire score ranges

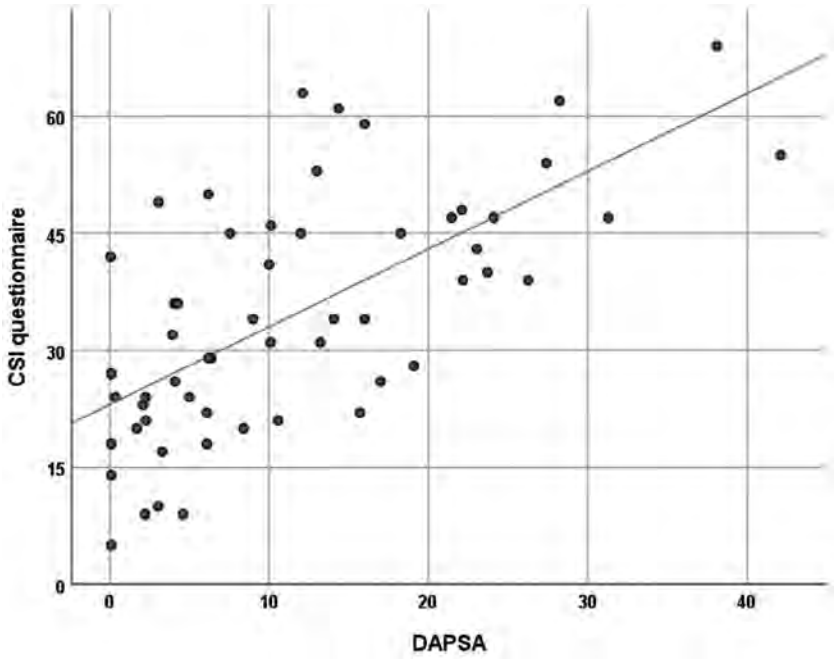

Figure 3. Relationship between DAPSA and CSI questionnaire score in patients with psoriatic arthritis. R2 0.436, p <0.0001

Results: A multiple linear regression analysis was performed to predict CSI score based on clinical and demographic characteristics (age, sex, BMI, disease duration, tender and swollen joints, CRP, 7-joints US score and fibromyalgia diagnosis), including HAQ. HAQ was the only significant predictor of the CSI score (Figure 1 and 2). CSI score increased of 15.3 points for each point of HAQ (95% CI 7.4-23.3, $p < 0.0001$). In PsA patients, but not in RA patients, disease activity was strongly correlated with CSI score (Figure 3).

Overall, we did not find any correlation between 7-joints US score and CSI score. We found a significant association between 7-joints US score (and its components) and disease duration (year to diagnosis r 0.53, $p < 0.0001$), interestingly, only the erosion score correlated significantly with the time from symptoms onset to the diagnosis (0.28, $p < 0.01$). In subgroups analyses, in patients with RA, 7-joints US overall score was positively associated with disease duration (years to onset of symptoms r 0.77, $p < 0.0001$). We found a strong relationship between 7-joints overall, PDUS scores and disease activity scores of RA (r 0.50 p 0.006 for SDAI and PDUS). In PsA patients, we found no association between 7-joints US overall, GSUS, PDUS or erosion score and DAPSA.

Conclusion: In summary, central sensitization assessed with CSI questionnaire was significantly associated with functional disability measured with HAQ independently from age, sex, BMI, concomitant fibromyalgia diagnosis and other clinical parameters (CRP, time to disease onset, tender and swollen joint count). SDAI and DAS28-CRP were significantly associated with ultrasonographic parameters of synovial inflammation.

Abstract Number: 0941

MDHAQ/RAPID3 (multidimensional Health Assessment Questionnaire/ routine Assessment of Patient Index Data) Levels Are Elevated in Rheumatology Patients Who Meet 2011 Fibromyalgia (FM) or MDHAQ/FAST3 (fibromyalgia Assessment Screening Tool) Criteria

Juan Schmukler[1], Tengfei Li[2], Kyle Schroeder[3] and Theodore Pincus[3], [1]Mount Sinai Hospital Chicago, IL, Chicag, IL, [2]Georgetown University, Washigton, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: RAPID3 (routine assessment of patient index data) on an MDHAQ (multiple multidimensional health assessment questionnaire) was developed initially to assess patients with rheumatoid arthritis (RA) according to agreement with the DAS28 (disease activity score 28).[1] Routine completion of self-report MDHAQ/RAPID3 by patients with all diagnoses prior to seeing the physician was found to be the most effective strategy for MDHAQ completion by all RA patients in routine care.[2] This led to recognition that RAPID3 was clinically informative to describe clinical status and change in patients with all rheumatic diagnoses,[3] such as evidence of a similar disease burden in osteoarthritis (OA) and RA patients.[4] Another index of MDHAQ scores, FAST3 (fibromyalgia assessment screening tool 3) has been developed to screen for fibromyalgia (FM) on the same MDHAQ that includes RAPID3, with agreement of about 80% with formal 2011 revised FM criteria.[5] We examined RAPID3 levels in patients seen in routine care at one academic site, including all patients and those with OA, RA, systemic lupus erythematosus (SLE), and other diagnoses, in subsets of patients who were FM positive or negative

Methods: All patients with all diagnoses seen at one academic rheumatology site complete an MDHAQ at all visits. The MDHAQ includes 0-10 scores for physical function (FN), pain (PN), patient global assessment (PATGL), fatigue (FT), 0-54 self-report rheumatoid arthritis disease activity index (RADAI) painful joint count, and 0-60 symptom checklist (SX). MDHAQ/RAPID3 (0-30) =FN+PN+PATGL; RAPID3 severity categories include high >12, moderate=6.1-12,

RAPID3 scores according to primary diagnosis by physicians and by FM 2011 and FAST3-P criteria

Primary diagnosis according to physician	Total N (%)	N (%) Diagnosed by physician as having FM	Median RAPID3 (IR) in all patients with this primary diagnosis	Analyses according to FM 2011 fibromyalgia Criteria			Analyses according to FAST3-P fibromyalgia criteria		
				# (%) Positive by these criteria	Median (IR) RAPID3 in FM positive patients	Median (IR) RAPID3 in FM negative patients	# (%) Positive by these criteria	Median (IR) RAPID3 in FM positive patients	Median (IR) RAPID3 in FM negative patients
Total	569 (100%)	121 (21.3%)	12.5 (5.8, 17.7)	146 (25.7%)	19.0 (15.8, 22.5)	9.3 (4.3, 15.3)	188 (33.0%)	19.1 (16.3, 22.5)	8.0 (3.7, 13.2)

P value		<0.0001*	<0.0001#	<0.0001*	0.560#	0.0001#	<0.0001*	0.445#	0.0001#

Differences between FM positive and FM negative patients were p<0.001 for 2011 and FAST3-P criteria for all diagnoses

* P-values calculated from Chi-squared test for the comparisons of percentages between different primary diagnoses.

P-values calculated from Kruskal-Wallis test for the comparisons of distributions between different primary diagnoses.

low=3.1-6 and remission≤3. MDHAQ/FAST3-P is a 0-3 cumulative index to screen for FM: 1 point each for PN≥6, RADAI≥16, and SX≥16 (2/3=FM). The 2011 FM criteria are based on 2 questionnaires, somatic symptom scale and widespread pain index, compiled into a polysymptomatic distress scale. RAPID3 scores were classified by severity categories in all patients and in subsets with OA, RA, SLE or other diagnoses, according to positive or negative 2011 FM criteria or MDHAQ FAST3-P FM criteria. Statistical analyses: Chi-square test for comparisons of percentages and Kruskal-Wallis test for RAPID3 distributions between diagnoses

Results: Median RAPID3 was 12.5 (high severity) in all patients, but only 9.3 (moderate severity) in 423 patients (74.3%) who did not meet 2011 FM criteria and 8.7 (moderate severity) in 406 patients (71.4%) who did not meet FAST3-P FM criteria (Table). By contrast, median RAPID3 was 19.0 (high severity) in 146 patients (25.7%) who met 2011 FM criteria and 19.8 in 163 patients (28.9%) who met FAST3-P FM criteria (Table). Similar patterns were seen in patients with OA, RA or SLE or other diagnoses (Table)

Conclusion: Patients who have comorbid FM have substantially elevated scores for RAPID3. Results of treatment in rheumatology clinical trials and clinical care may be underestimated by inclusion of patients with FM; routine FAST3-P screening for FM might be desirable.

Use of Medical Cannabis by Patients with Fibromyalgia: A Prospective Cross-sectional Study

Mary-Ann Fitzcharles[1], Emmanouil Rampakakis[2], Yoram Shir[1], John Sampalis[2], Martin Cohen[1], Michael Starr[1] and Winfried Häuser[3], [1]McGill University, montreal, Canada, [2]JSS Medical Research, St-Laurent, QC, Canada, [3]Technische Universität München, Munich, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Treatment strategies for chronic widespread pain (CWP)/fibromyalgia (FM) are imperfect with only a modest effect from medications. Due to the many symptoms experienced by patient, including pain, sleep disturbance and often mental health complaints, an agent that could address multiple symptoms would be ideal. Cannabinoids may have potential to fill this gap. In the setting of recreational legalization of cannabis in Canada, patients now have easier access and may be self-medicating with cannabis. We have examined the prevalence and characteristics of use in FM patients.

Methods: During a two-month period (April-May 2019), consecutive patients attending an academic, community-based rheumatology clinic staffed by 3 rheumatologists participated in an onsite survey comprising 2 questionnaires: 1) demographic and disease information completed by the rheumatologist, 2) patient anonymous questionnaire of health status, cannabis use (recreational and/or medicinal) and characteristics of use.

Results: In a cohort of 1000 rheumatology attendees (73% females; mean age 64 ± 14 yrs), 117 (11.7%) were diagnosed with FM. Medical cannabis (MC) had ever been used by 12.6% (95% CI: 10.7%-14.8%) of the whole cohort, with half continuing use for mostly pain relief. Of the 117 FM patients, 28 (24%) had ever used medical cannabis (95% CI: 16.5%-32.7%), with 16 (57%) continuing use. Users vs. non users were more likely to be younger, 53 vs.58 yrs (p=0.072) and unemployed or disabled 39% vs. 17% (p=0.019), and used more medication types for symptom control (p=0.013), but symptom severity parameters did not differ between groups Table 1. Users were more likely to be past and current cigarette smokers, and previous or current recreational cannabis users. Some comorbid rheumatic condition was present in 82 (70.1%), with 35 (30%) diagnosed with an inflammatory condition. Almost half of patients with FM comorbid with ankylosing spondylitis had used medical cannabis. Symptom relief (VAS, 1-10) was 7.0 ±2.3.

Table 1. Demographic and Disease Related Information for FM Patients

		All patients (n=117)	Never medical cannabis users (n=89)	Ever medical cannabis users (n=28)	p-value

Table 1. Demographic and Disease Related information for fibromyalgia patients (part 1)

Conclusion: FM patients, including those with comorbid rheumatic conditions, have commonly used medical cannabis, with more than half continuing use. Although symptom severity parameters were similar for users vs. nonusers, symptom relief was reported to be moderately good. Cigarette smoking and recreational cannabis use may play a facilitatory role in medical cannabis use in FM. Adjunctive medical cannabis may be a treatment consideration for patients with CWP, either as a unique diagnosis of FM or comorbid with inflammatory arthritis.

Session Title: Fibromyalgia & Other Clinical Pain Syndromes

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Fibromyalgia (FM) is a widely recognized and commonly diagnosed disorder that has also been the subject of thousands of research studies. There is no gold standard definition of FM, but well-vetted diagnostic criteria exist. The extent to which these criteria are used for diagnosis by community physicians is uncertain. In 3 large epidemiologic studies, we compared physician diagnosis with diagnosis by published criteria to determine the

Diagnostic category	N	Prevalence	Sens	Specificity	Kappa	Phi	PSD
		(%)	(%)	(%)			Mean (SD)
	Criteria comparisons in research clinical studies						
FM 2016 criteria vs.	4,348	21.4 (20.2, 22,7)		—	—		20.9 (5.5)
London 6 criteria	4,348	26.3 (25.0,27.6)	91.4	91.5	.765	.772	18.9 (6.4)
AAPT criteria	4,348	30.1 (28.7,31.5)	95.6	87.7	.726	.745	16.4 (6.2)
London 4 criteria	4,348	39.1 (37.7,40.6)	98.9	77.2	.586	.640	16.5 (7.0)
	Physician diagnosis in community epidemiologic studies						
FM 2016 criteria vs.	3,276	5.5 (4.8,6.3)					18.4 (4.4)
Primary care practice MDs	3,276	6.1 (5.2,6.9)	35.4	95.6	.296	.297	12.4 (6.9)
FM 2016 criteria vs.	2,531	3.4 (2.7,4.3)					17.7 (3.9)
German population MD Dx	2,531	1.1 (0.6,1.5)	17.3	99.3	.235	.261	11.3 (7.4)
FM 2011 criteria vs.	8,486	2.7 (2.7,2.8)					16.1 (2.9)
US Population MD Dx	8,486	1.8 (1.4, 2.1)	25.7	98.5	.248	.248	9.58 (5.8)

FM 2016 = 2016 revised FM diagnostic criteria; AAPT = AAPT FM diagnostic criteria; London 4 = London 4 quadrant pain FM criteria; London 6 = London 4 + Fatigue score moderate of greater.

Table 1. Characteristics and agreement according to FM diagnostic methods.

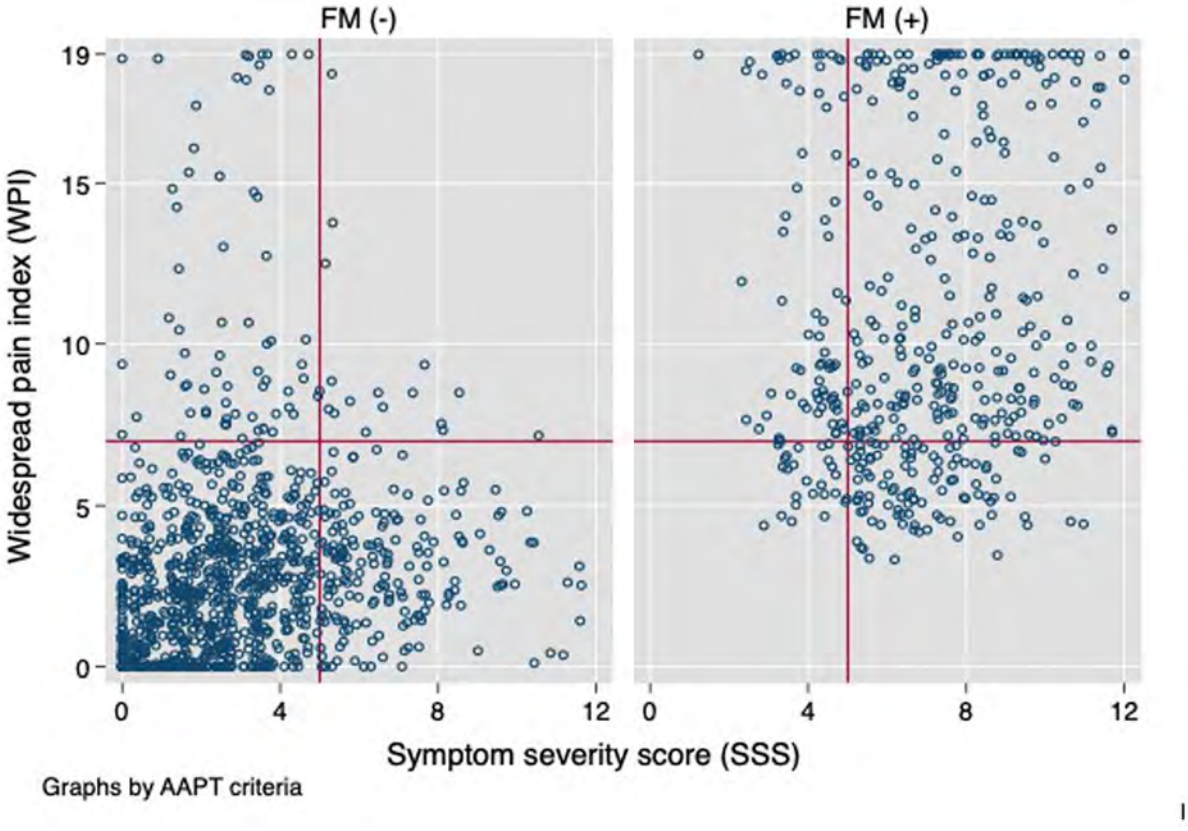

Figure 1. Plot of symptom severity score (SSS) against widespread pain index (WPI) according to AAPT criteria status. Horizontal line at 7 is level of WPI required by FM 2016 criteria. A small amount of random noise is added to each observation so that observations are seen more clearly. Vertical line at 5 is level required by FM 2016 criteria.

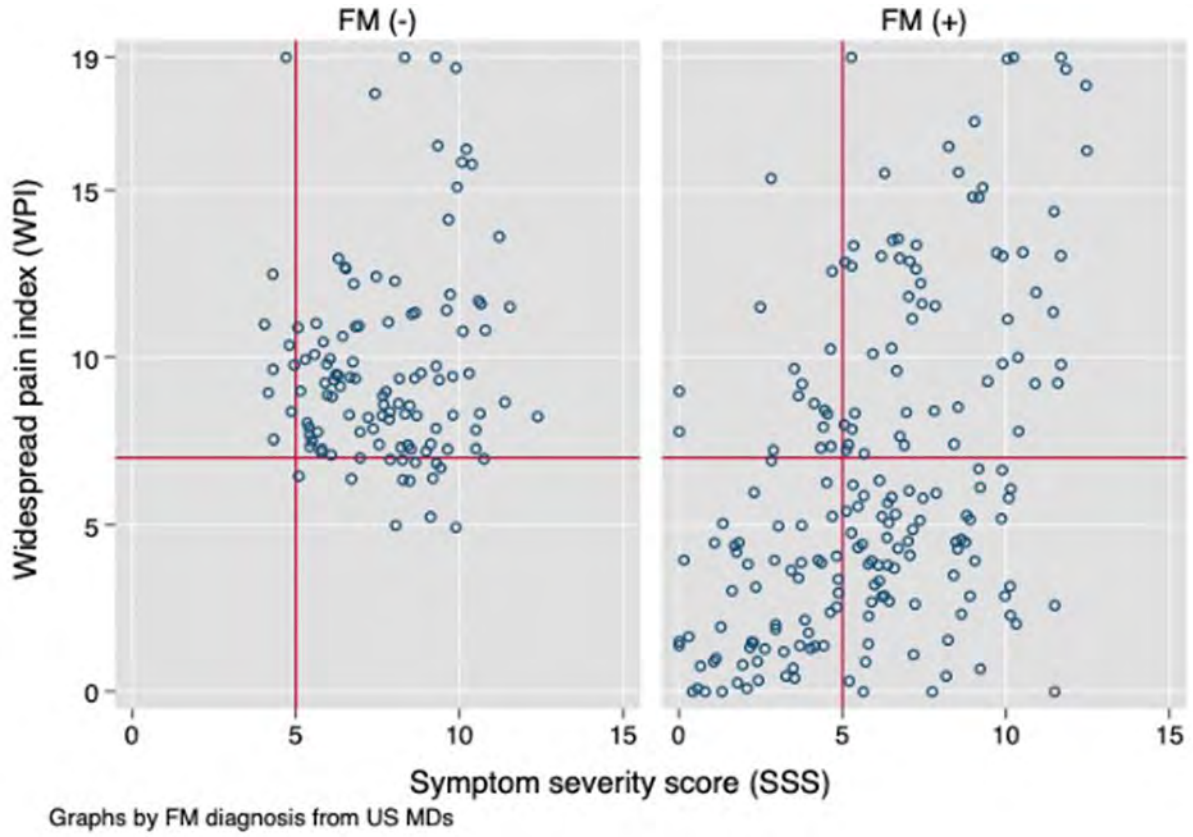

Figure 2. Plot of symptom severity score (SSS) against widespread pain index (WPI) according to reported US primary care physician diagnosis. Horizontal line at 7 is level of WPI required by FM 2016 criteria. Vertical line at 5 is level required by FM 2016 criteria. A small amount of random noise is added to each observation so that observations are seen more clearly. Data include only patients who are FM positive by FM2016 or ad hoc US primary care physician criteria.

level of agreement between criteria and physician diagnosis. We also compared different research criteria in clinical settings to obtain estimates of agreement among competing FM criteria

Methods: We compared 4 sets of published FM diagnostic criteria: The 2016 modification of ACR 2010 criteria (FM 2016), ACTTION-APS Pain Taxonomy criteria (AAPT), London widespread pain criteria (LFESSQ 4), and London widespread pain plus fatigue abnormality (LFESSQ 6) in 4,348 patients using Forward, the National Data Bank for Rheumatic Diseases (NDB) as to agreement with FM 2016. We then compared reported physician (MD) diagnosis of FM with FM 2016 criteria in 3,276 consecutive primary care patients (PC), 2531 persons in a German general population survey (GPS), and 8486 in the US National Health Interview Survey (NHIS). We used Cohen's kappa and the Phi coefficient as measures of agreement, and the polysymptomatic distress (PSD) scale as a measure of FM symptom severity.

Results: As shown in Table 1, FM 2016, LFESSQ 6 and AAPT criteria tapped into similar concepts, yielding kappa and phi coefficients of .726-.752, prevalence values between 21.4-30.1%, and PSD scores between 16.4-20.9. Figure 1 shows increased cases meeting AAPT criteria compared with FM 2016. None of the physician criteria adequately agreed with FM 2016 criteria (all kappa and phi statistics < .300). As shown in Figure 2, many patients who were MD diagnosis positive clearly failed FM 2016 criteria, and many MD classification negative subjects satisfied FM 2016 criteria. The lower the kappa and phi values the less severe were values of PSD (9.6-12.4) among MD diagnosed patients.

Conclusion: Diagnosis by formal criteria had conceptually adequate agreement overall, but at the patient level 34% of positive diagnoses disagreed between FM 2016 and AAPT. Physician diagnosis and formal criteria are in poor agreement. As shown in Figure 2, this is not merely failure to diagnose, but represents incorrect classification. There is not "one" FM. Diagnoses based on physician diagnoses (not formal criteria), such as in hospital and insurance company registries have limited validity and reliability, and kappa and phi values so low as to render diagnosis almost meaningless. FM is a symptom severity-based diagnosis, but until FM care and research rely primarily on reliable continuous severity scales, FM will remain an uncertain diagnosis. Some of the disagreement between MD diagnosis and FM criteria may represent changes in severity over time that are not captured in our data, but also raise the question of the nature of the FM diagnosis.

Obstructive Sleep Apnea in Fibromyalgia Patients: A Meta-analysis

Nouran Eshak[1], Wasawat Vutthikraivit[1], Asmaa Beltagy[2] and John Pixley[3], [1]Texas Tech Health Science Center, Lubbock, TX, [2]Faculty of Medicine, Alexandria University, alexandria, egypt, Egypt, [3]Texas Tech University HSC, Lubbock, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Fibromyalgia is a chronic pain disorder prevalent in about 3% of the population, mostly in females. A common complaint is non-restorative sleep. Obstructive sleep apnea (OSA), the most common sleep related breathing disorder, has an estimated prevalence of 10-15% in females. It is characterized by upper airway collapse during sleep leading to apnea and hypopnea with poor fragmented sleep. Several studies have reported a positive correlation between chronic pain syndromes and sleep disorders. The link between OSA and pain syndromes is still unknown. It has been hypothesized that hyperalgesia occurs because of fragmented sleep and hypoxemia that enhance sensitivity to pain, promote inflammation, and increase spontaneous pain. Our study aimed to determine the incidence and prevalence of OSA in FM patients.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane from inception to May 2020. Included studies were published observational studies (cohort or case-control) that investigated the incidence of OSA comparing patients with and without FM. We also included studies that reported the prevalence of OSA in FM. Data from each study were combined using the random-effects, generic inverse variance method of DerSimonian and Laird to calculate odd ratio and 95% confidence intervals.

Results: Fifteen studies from 1989 to 2020 were included in this meta-analysis involved ten studies reported prevalence and five case-control studies reported the incidence of OSA in FM patients. Pooled prevalence of OSA was 38.5 per 100 FM patients [95% confidence interval (CI): 24.4-52.6]. Incidence of OSA was significantly higher in patients with FM compared to without FM (pooled odd ratio = 3.51, 95% CI: 1.36-9.05, p = 0.008, I^2=71.3%) (Figure1). There was no publication bias observed in Funnel plot as well as no small-study effect observed in Egger's test (p-value = 0.921)

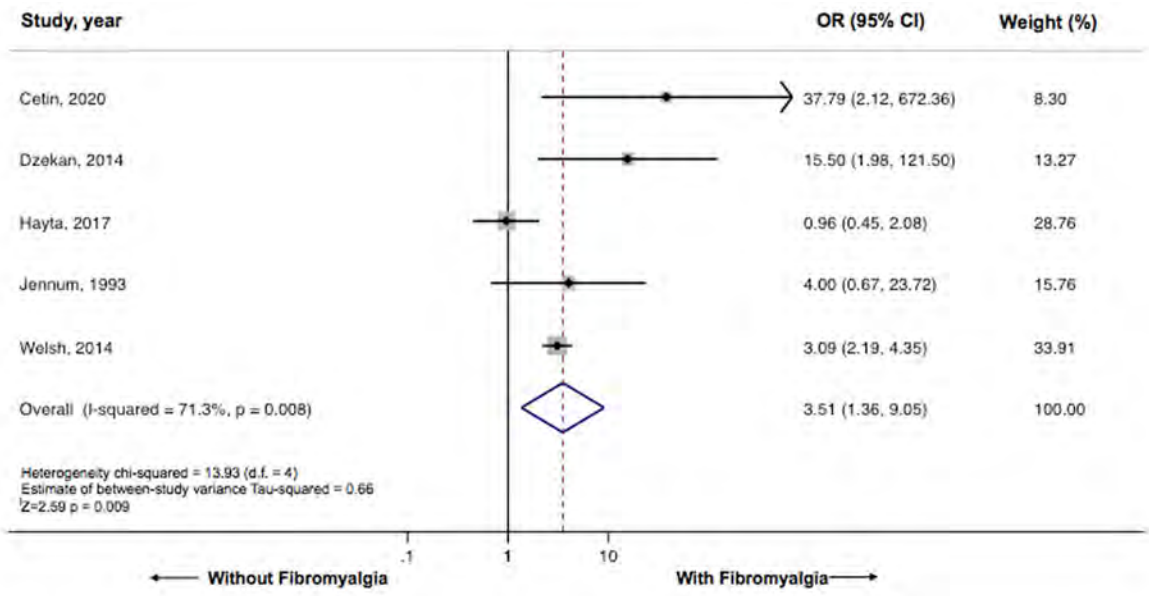

Figure 1. Forest plot demonstrating the association between Fibromyalgia and the Incidence of Obstructive Sleep Apnea

Conclusion: Our study demonstrated that there was a higher incidence and prevalence of OSA among FM patients. Polysomnography should be a standard diagnostic tool in the assessment of FM to unmask underlying treaTable conditions that may contribute to the symptoms. As yet, there is no evidence that the treatment of OSA would lead to amelioration of chronic pain in FM. Further studies are needed to examine whether the treatment of the commonly detected OSA will have a beneficial effect on fibromyalgia symptoms.

Neutrophils Mediate Kidney Inflammation Following Acute Skin Exposure to UV Light

Sladjana Skopelja-Gardner[1], Joyce Tai[2], Xizhang Sun[2], Lena Tanaka[2], James Kuchenbecker[2], Tomas Mustelin[1] and Keith Elkon[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Innate Immunity
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Sensitivity to ultraviolet (UV) light affects up to 80% of SLE patients and can exacerbate systemic disease flares, including lupus nephritis (LN). Our findings that neutrophils are the dominant skin infiltrating immune cell after exposure to UV light together with the recent discovery that neutrophil gene signature is the strongest predictor of active SLE prompted the hypothesis that *neutrophils are a key pathogenic link between UV-induced inflammation in the skin and kidney injury in SLE*.

Methods: Mice (C57BL/6J, 3-4mo) were exposed to one dose of UVB (500mJ/cm2). Individual mice were euthanized on 1, 2, or 6 days after UV and perfused with saline; non-irradiated matched mice were used as controls. Immune cells from the skin, bone marrow, blood, lung, and kidney were profiled by flow cytometry (FC). Gene expression was evaluated by QPCR, plasma protein concentration by Legendplex Inflammatory Panel, and proteinuria by Bradford assay. Immunofluorescence staining of fixed kidney tissue was performed. PhotoactivaTable (UBC-PA-GFP) mice were used to photoconvert skin infiltrating neutrophils to GFP+ cells and track them systemically by FC.

Results: Following acute skin exposure to UV light, neutrophils migrate not only to the skin, but also to the kidney, where we observed a 10-fold increase in neutrophil numbers, mainly localized to the tubulointerstitium. Neutralization of IL-17A, which increased 10-100-fold in circulation after exposure to UV light (6-24 hr), inhibited neutrophil migration to the kidney. Relevant to SLE pathogenesis, neutrophil infiltration into the kidney was accompanied by renal inflammatory and injury processes: increased expression of adhesion molecules VCAM-1 and E-Selectin, inflammatory proteins IL1β, s100A8/9, and s100A6, tubular injury markers Ngal and Kim1, as well as elevated urine protein levels. Kidney infiltrating neutrophils produced reactive oxygen species (ROS) and inhibition of neutrophil mobilization by G-CSF neutralization resulted in significant reductions in the expression of adhesion molecules, inflammatory cytokines, and kidney injury markers. Using a mouse model with photoactivaTable immune cells, we observed that a subset of neutrophils found in the kidney had transited through UV light-exposed skin, expressing the pro-inflammatory phenotypes of aged (CXCR4^{hi}) or reverse-transmigrating (ICAM1^{hi}CXCR1^{lo}) cells. We identified elevated levels of CXCR4^{hi} and ICAM1^{hi}CXCR1^{lo} neutrophils in SLE patients particularly within the low-density granulocytes (LDG).

Conclusion: Our study provides several novel findings that could help explain how exposure to sunlight impacts the kidney: i) skin exposure to UV light triggers IL17-A-dependent neutrophil migration to the kidney, accompanied by renal inflammatory and injury responses, ii) neutrophils are directly implicated in subclinical kidney injury as neutralization of G-CSF abrogated renal inflammation and injury, iii) a subset of activated neutrophils has migrated to the kidney via reverse transmigration and is found in SLE patients, suggesting a pathogenic role for these neutrophil populations in lupus.

ENPP1 Regulates UV Light Triggered Type I Interferon Response in the Skin

Sladjana Skopelja-Gardner[1], Joyce Tai[2], Xizhang Sun[2] and Keith Elkon[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Innate Immunity
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients have a prominent type I interferon (IFN-I) signature in both the lesional and non-lesional skin. We recently showed that exposure to ultraviolet (UV) light triggers cutaneous IFN-I response, in a cGAS-dependent manner. The discovery that ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1) hydrolyzes cGAMP, second messenger of the cGAS-STING DNA sensing pathway, in tumor

immune responses prompted the *question whether ENPP1 regulates UV light stimulated IFN-I signature in the skin.* Since ENPP1 expression has been association with melanogenesis, we also investigated the role of skin pigmentation in IFN-I response and its link with ENPP1 expression.

Methods: Mice (C57BL/6J, *cGAS*-/-, and B6(Cg)-*Tyr*$^{c-2J}$/J Albino, 3mo) were exposed to one dose of UVB light (500mJ/cm^2). Skin biopsies (6mm) were obtained prior to and on days 1 and 2 after UV and tissue digested with DNAse I and Liberase TM, from UV exposed and unexposed skin (< 0.5cm from exposed area) in some experiments. ENPP1 protein expression in non-immune (CD45-) and immune cells (CD45+) was determined by flow cytometry and gene expression by qPCR. Mice were treated intradermally with ENPP1 inhibitor (STF-1084, 0.1mM) or vehicle and expression of interferon stimulated genes (ISG) determined 16hr later by qPCR.

Results: Exposure to a single dose of UV light triggers ISG expression in both the UV-exposed (6hr and 24hr) and non-UV exposed skin (24hr) in B6 mice. This spreading of the IFN-I response 24hr after UV exposure was significantly lower in cGAS-deficient mice. Dermal inhibition of ENPP1, extracellular enzyme that hydrolyzes cGAMP, significantly augmented skin ISG expression after UV light exposure in B6 mice. Interestingly, we observed that ENPP1 expression, found on both CD45- and CD45+ skin cells, was markedly increased in albino CD45- but not B6 mouse skin cells after UV exposure (~60% vs. 5% positive, respectively). This differential ENPP1 response was accompanied by significantly lower ISG expression in albino compared to B6 skin, on day 1 after UV exposure. Dermal inhibition of extracellular ENPP1 in albino mice significantly increased the ISG expression in response to UV light.

Conclusion: Acute skin exposure to UV light triggers spreading of ISG expression in non-UV exposed skin, suggesting that UV light contributes to the IFN-I signature observed in non-lesional skin in SLE. The cGAS requirement for ISG spreading and augmented IFN-I response following ENPP1 inhibition, indicate that extracellular cGAMP amplifies skin ISG induction following UV exposure. The reduced ISG expression in albino compared to B6 mice is likely explained by UV induced ENPP1 expression which reduces extracellular cGAMP. Overall, these findings suggest a role for skin pigmentation in the IFN-I response to UV light that is linked to ENPP1 mediated regulation.

STING Gain-of-Function in Radio-resistant Cells Supports a Lymphocyte Dependent Auto-inflammatory Lung Disease

Kevin Gao[1], Mona Motwani[1], Ann Marshak-Rothstein[2] and Katherine Fitzgerald[1], [1]University of Massachusetts medical school, worcester, MA, [2]University of Massachusetts medical school, Newton, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Innate Immunity
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: cGAS-STING is a cytosolic dsDNA sensing pathway whose regulation is vital to immune homeostasis. Pediatric patients with constitutively active STING mutations develop an autoinflammatory syndrome known as STING Associated Vasculopathy with onset in Infancy (SAVI) and suffer from treatment resistant lung fibrosis. Interestingly, SAVI patients develop immune abnormalities including lymphopenia concomitant with hyperactivation, and lung biopsies from SAVI patients show lymphocyte predominant immune aggregates which strongly

resemble bronchus associated lymphoid tissues (BALT), suggesting a role for lymphocytes in SAVI lung disease. We have genetically engineered a mouse model of SAVI (STING V154M or VM mice) that recapitulates the development of lymphocyte rich BALTs in the lung as early as 6 weeks of age and develops progressive fibrotic disease by 16 weeks. Here, we test our hypothesis that lymphocytes are required for inflammatory lung disease in SAVI mice and use radiation-chimera mice to investigate the mechanism of lymphocyte activation.

Methods: To test the requirement of lymphocytes in SAVI disease, we bred VM Rag1$^{-/-}$ and VM TCR$\beta^{-/-}$ and treated VM mice with αCD20 antibodies. We also generated chimeric mice to test if immune abnormalities were due to hematopoietic or radioresistant cell intrinsic STING Gain-of-Function (GOF) by transferring donor VM bone marrow (BM) into irradiated WT mice or vice versa. We then assessed autoinflammatory disease by body weight, spleen weight, lung histopathology, and performed flow cytometric profiling of central, peripheral, and tissue resident immune cells.

Results: We found that although lymphocytes were required for SAVI inflammatory disease, ablation of only $\alpha\beta$ T cells or B cells failed to rescue disease. These results support the notion that T and B cells could independently contribute to SAVI lung disease. Moreover, we found that VM splenic $\alpha\beta$ T and B cells depended on each other for maximal hyperactivation, suggesting a potential synergistic interaction as well.

Using chimeric mice, we found that BM intrinsic STING GOF was insufficient for lymphocyte activation, and instead, lymphocyte hyperactivation was dependent on STING GOF in radioresistant recipient cells, as donor WT splenic T cells transferred into a VM host developed hyperactivation that phenocopied VM mice. Finally, we found that radio-resistant cell STING GOF was sufficient to perpetuate a progressive SAVI inflammatory lung fibrosis.

Conclusion: Together, these findings suggest that STING GOF in radioresistant cells organizes and activates a profibrotic inflammatory lymphocyte response in the lung. We are currently investigating candidate radioresistant cell populations as initiators of this process including lung epithelium, which is known to robustly express STING, as well as mechanisms by which lymphocytes drive SAVI lung pathology. These findings are clinically relevant for SAVI patients, as well as more broadly for patients suffering from interstitial lung disease associated with rheumatic disease and suggest that lymphocyte depleting therapies may mitigate further lung injury and worsening of fibrosis.

Abstract Number: 0948

Mass Cytometry Reveals Activation Heterogeneity of Circulating Neutrophils in Systemic Lupus Erythematosus

Ricardo Grieshaber-Bouyer[1], Joshua Keegan[2], Peter Nigrovic[3], James Lederer[4] and Deepak Rao[2], [1]Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany; Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, Heidelberg, Germany, [2]Brigham and Women's Hospital, Boston, MA, [3]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston, [4]BWH Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Innate Immunity
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Neutrophils are important effector cells in systemic immune-mediated diseases. Neutrophil phenotypes vary depending on their age, maturity, activation state, and local environment; however, differences among neutrophils across different inflammatory conditions are poorly understood.

Methods: We analyzed mass cytometry data on blood neutrophils generated in the Accelerating Medicines Partnership RA/SLE Network, which included > 65 million neutrophils from 10 healthy controls, 13 patients with rheumatoid arthritis and 24 patients with biopsy-confirmed lupus nephritis. Neutrophil phenotypes were assessed by dimensional reduction and visualization with UMAP, and subclusters were partitioned by FlowSOM clustering and ConsensusClusterPlus metaclustering.

Results: Using unsupervised dimensionality reduction, we observed that neutrophils clustered by surface phenotype rather than by disease. Comparison of expression levels of surface proteins on neutrophils revealed a significant increase in the expression of Lysosomal-associated membrane protein 1 (LAMP1; CD107a) on neutrophils from SLE patients compared to controls (p=0.022). LAMP-1 expression largely segregated to a subcluster of neutrophils by UMAP visualization, suggesting an increase in a subset of neutrophils with recent de-granulation in SLE patients. SLE patients showed a range of expression of LAMP-1 on neutrophils, and LAMP-1 expression did not correlate with frequencies of PD-1hi CXCR5- T peripheral helper (Tph) cells, PD-1hi CXCR5+ T follicular helper (Tfh) cells, or CD11c+ B cells, which are highly expanded lymphocyte populations in lupus nephritis patients. Hierarchical clustering based solely on neutrophil protein expression distinguished two subgroups of SLE patients. Patients in the SLE1 group had an expanded population of LAMP1+ degranulated neutrophils, and this group also had higher chronicity scores in kidney biopsies. In contrast, patients in SLE2 group displayed an increased frequency of C5aR+ CXCR1+ neutrophils and had higher dsDNA titers and a higher SLEDAI composite score. These two subgroups did not differ in frequencies of Tph cells, Tfh cells, CD11c+ B cells, again suggesting that the neutrophil phenotypes may be independent of activated T/B cell pathways.

Conclusion: This work highlights an altered neutrophil phenotype in patients with lupus nephritis, in particular in a subset of patients associated with increased LAMP-1 expression. Neutrophil surface phenotypes may reveal a unique axis of immune activation in SLE patients.

Abstract Number: 0949

SLAMF7 Engagement Drives Monocyte Super-Activation in Acute and Chronic Inflammation

Daimon Simmons[1], Hung Nguyen[2], Emma Gomez-Rivas[3], YunJu Jeong[4], William Apruzzese[5], Edy Kim[6] and Michael Brenner[7], [1]Department of Pathology, Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology, Brigham and Women's Hospital,, Boston, MA, [3]Division of Rheumatology, Brigham and Women's Hospital, Boston, MA, [4]Division of Pulmonary and Critical Care, Brigham and Women's Hospital, Boston, MA, [5]., Boston, [6]Brigham and Women's Hospital, Division of Pulmonary and Critical Care Medicine, Boston, MA, [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Innate Immunity
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

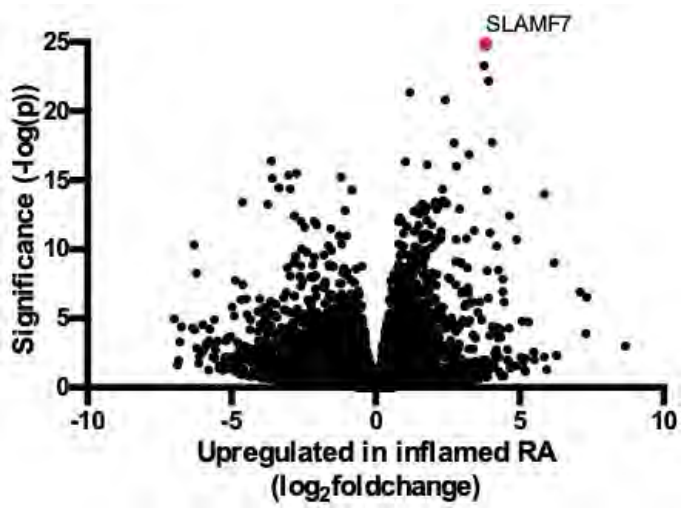

Figure 1. Upregulation of SLAMF7 in inflamed synovial tissues. Differentially expressed genes in synovial monocytes from patients with inflamed RA (n=11) compared to OA (n=10) from AMP Phase 1 bulk RNA-sequencing are shown, with SLAMF7 labeled in red.

Background/Purpose: Monocytes orchestrate immune responses that protect against microbes but can also drive pathological inflammation and autoimmune disease. Monocytes are thought to be activated primarily by cytokines or by microbial molecules, but they express a broad array of receptors allowing them to integrate responses from the environment. We hypothesize that monocytes may be activated by a first, or primary signal, and that a second, booster stimulus can then drive a pathological super-activated state. To address this hypothesis, we analyzed high dimensional transcriptomic data for monocytes from diseased human tissue to identify receptors that might serve as super-activators of these cells, and identified SLAMF7, a receptor that regulates leukocyte activation.

Methods: We analyzed bulk RNA-sequencing (RNA-seq) data from Phase I of the Accelerating Medicines Partnership to identify genes upregulated in monocytes from rheumatoid arthritis synovial tissue compared to osteoarthritis synovial tissue. We used flow cytometry to quantify this receptor on monocytes and sorted monocytes with high versus low SLAMF7 expression for RNA-seq. We used an activating antibody or recombinant SLAMF7 protein to stimulate monocytes *in vitro* and performed ELISA to measured cytokine release and quantitative real-time PCR to quantify gene expression. We also collected RNA-seq data from monocytes after stimulation and identified upregulated genes as the "SLAMF7 Activation Signature." We than analyzed publicly available single cell RNA-seq data from individuals with RA, Crohn's disease and COVID-19 lung infection with the "SLAMF7 Activation Signature."

Results: Through differential gene expression analysis we identified SLAMF7 as a receptor that is profoundly upregulated in monocytes from inflamed synovial tissues (Fig 1). We identified an interferon signature in SLAMF7-high monocytes, and additional *in vitro* stimulation experiments implicated IFN-γ as a key regulator of SLAMF7 expression. Engaging SLAMF7 with an antibody or recombinant protein on monocytes drove profound production of inflammatory cytokines TNF-α, IL-6, and IL-1β, and chemokines CCL3, CXCL1, and CXCL8. We performed transcriptome-wide analysis on these stimulated monocytes to generate a "SLAMF7 Activation Signature". We observed a striking overlap between our experimental signature and the transcriptional signature identified in infiltrating monocytes from RA synovial tissue, bronchoalveolar lavage cells of patients with COVID-19, as well as from ileal tissue of patients with Crohn's disease.

Conclusion: SLAMF7 is a receptor that is massively upregulated on monocytes from inflamed tissues. IFN-γ drives monocytes to express high levels of SLAMF7 but does not drive complete monocyte activation on its own. A second booster activation signal through engagement of SLAMF7 then triggers profound super-activation, resulting in monocyte production of high levels of inflammatory effector molecules. We implicate this pathway as a major contributor

to pathologic inflammation in human diseases. Therapies targeting different steps in monocyte super-activation could have potential for treating diverse human diseases.

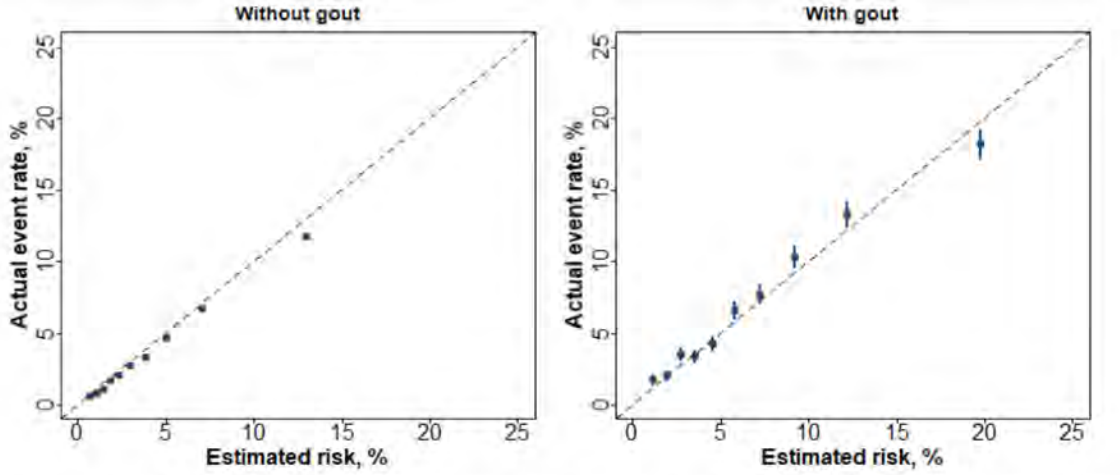
Table. Participant characteristics (n = 441,723). Data are shown n (%), except age in years.



X-axis represents the 5-year estimated risk of CVD events at the time of risk assessment (enrolment into the PREDICT study) and Y-axis represents the actual CVD event rate after 5 years obtained from linked national ICD-coded hospitalisations and mortality databases. The estimated risk of a CVD event in the next 5 years is adjusted for age, sex, ethnicity, NZ deprivation quintile, smoking history, family history of premature CVD, atrial fibrillation, diabetes, mean systolic blood pressure, mean total cholesterol/HDL cholesterol ratio, BMI and baseline dispensing of blood pressure lowering, lipid lowering and antithrombotic medications.

Figure. Estimated versus actual CVD event rate in people with and without gout.

assessed the performance of these equations in people with gout and recalibrated the primary prevention equation to improve the prediction of CVD events in people with this condition.

Methods: The PREDICT study recruits people in primary care when general practitioners in New Zealand use PREDICT software to routinely assess their patients' risk profile for CVD, which are prospectively linked to national ICD-coded hospitalisation and mortality databases. The study population included men and women (ages 30-74 years) who had no prior CVD, renal disease or congestive heart failure. A validated national health data definition of gout was used to identify those with gout: discharge diagnosis of gout (ICD-9 274, ICD-10 M10) from a public hospital admission or dispensed gout specific medications (Winnard, Rheumatology 2012). Baseline estimates of 5-year CVD risk (of cardiovascular death, non-fatal myocardial infarction, stroke, or other vascular event) were calculated using sex-specific PREDICT-1° risk scores and initially assessed via the slope between estimated and observed risk on the calibration plot ("slope"). Gout was added as a binary predictor to the recalibrated risk models.

Results: From January 1, 2007 to December 31, 2018, 441,723 people (56% men) had a PREDICT-1° risk assessment (**Table**). Of these, 23,229 met the definition of gout (3325 females and 19,904 males). In the whole cohort, 14,693 (3.3%) people had a first CVD event within 5 years of risk assessment. Of these, 1505 occurred in people with gout (6.5% event rate) and 13,188 occurred in people without gout (3.2% event rate). The risk scores underestimated the risk of CVD events in people with gout compared with people without gout (slope = 0.88) (**Figure**). This was more pronounced in women with gout (slope = 0.77) compared with men (slope = 0.96). Adding gout to the recalibrated risk estimates demonstrated that gout was independently associated with an increased risk of CVD events (adj. HR (95% CI) = 1.24 (1.08-1.42) for women; 1.21 (1.14-1.28) for men).

Conclusion: Current cardiovascular risk prediction equations underestimate the risk of CVD in people with gout. Despite adjustment for known CVD risk factors, gout independently increased the hazard ratio for CVD events.

Abstract Number: 0951

The Comparative Effect of Exposure to Various Risk Factors on the Risk of Hyperuricaemia: Diet Has a Weak Causal Effect

Ruth Topless[1], Tanya Major[1], Jose Florez[2], Joel Hirschhorn[3], Murray Cadzow[1], Nicola Dalbeth[4], Lisa Stamp[5], Phillip Wilcox[1], Richard Reynolds[6], Joanne Cole[2] and **Tony Merriman**[1], [1]University of Otago, Dunedin, New Zealand, [2]Massachusetts General Hospital, Boston, [3]Harvard Medical School, Boston, [4]University of Auckland, Auckland, New Zealand, [5]University of Otago Christchurch, Christchurch, New Zealand, [6]University of Alabama Birmingham, Birmingham

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Metabolic & Crystal Arthropathies

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Prevention of hyperuricaemia (HU) is critical to the prevention of gout. Therefore, understanding the causal relationships and relative contributions of various risk factors to HU is important. Inherited genetic variants have a significant causal role. However, the relative importance of other exposures and questions of causality are still unresolved. Here we use attribuTable fraction to compare the relative contribution of genetic, dietary, urate-lowering therapy (ULT) use and other exposures to HU. We also use Mendelian randomization to evaluate whether diet has a causal role in determining serum urate levels.

Methods: Four sample sets, three from the general population (n = 419,060) and one of gout patients (n = 6,781), were derived from the Database of Genotypes and Phenotypes (Cohort 1) and the UK Biobank resources (Cohorts 2, 3, and Gout). These sample sets were comprised from individuals of European ancestry with measured serum urate levels and dietary, clinical, and genome-wide genotype information available. Dichotomised exposures to diet, the *SLC2A9 rs12498742* risk variant, BMI, alcohol, diuretic treatment, sex and age were used to calculate adjusted population and average attribuTable fractions for HU (≥0.42 mmol/L in men and women). Exposure to urate-lowering therapy was also assessed in the gout-only cohort. Two sample Mendelian randomization using the UK Biobank cohort was conducted to test for a causal role of dietary habits in determining serum urate levels, using as instruments genetic variants previously reported as associated with dietary patterns (Cole et al. *Nat Comm* 2020;11:1467).

Results: Adherence to dietary recommendations, achieving BMI (< 25 kg/m^2), and absence of the *SLC2A9 rs12498742* urate-raising allele produced population attribuTable fractions for HU of 20 to 24%, 59 to 69%, and 57 to 64%, and average attribuTable fraction estimates of 6 to 7%, 24 to 26%, and 22 to 24%, respectively in the three non-gout cohorts (Table). In the gout cohort, diet, BMI, *SLC2A9 rs12498742,* and urate-lowering treatment population attribuTable fractions for hyperuricaemia were 12%, 47%, 47%, and 62%, and average attribuTable fractions for hyperuricaemia were 3%, 14%, 14%, and 33%, respectively (Table). In the gout cohort ULT explained 34% of variance in serum urate levels, ≥10-fold higher than the other exposures tested. Mendelian randomization (Figure) demonstrated weak causal effects of two dairy-related dietary habits, margarine consumption and dried fruit consumption on serum urate levels (e.g. preferentially drinking skim milk increased urate, β = 0.050 mmol/L, $P = 3.78 \times 10^{-8}$), which were all mediated by BMI, losing significance ($P \geq 0.06$) in multivariate models assessing the BMI-independent effect of diet on urate.

Conclusion: The attribuTable fraction and Mendelian randomization data emphasise the minor role of diet in determining serum urate levels and HU. In gout the use of urate-lowering therapy was the dominant attribuTable fraction tested for serum urate level, with a population attribuTable fraction approximately 6-fold greater and an average attribuTable fraction approximately 10-fold greater than following healthy-eating guidelines.

Table Estimated population and average attributable fractions (PAF / AAF)

Table 1. Patient demographics for treatment arms of pegloticase with MMF and pegloticase with placebo

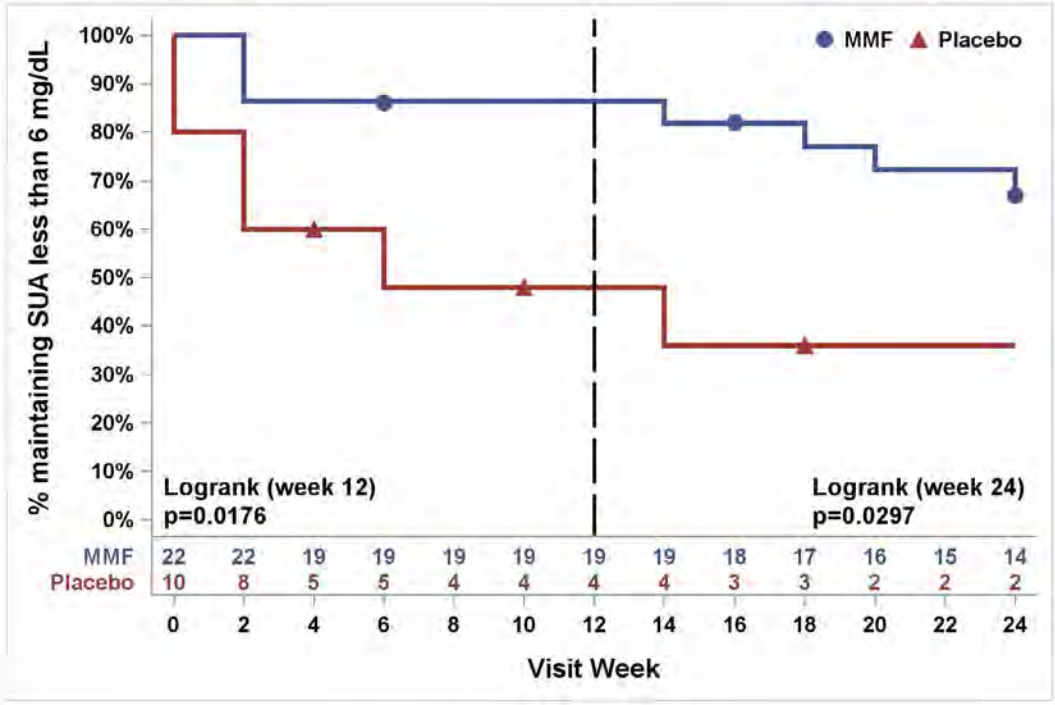

Figure 1. Percentage of subjects maintaining SUA less than 6 mg/dL in MMF/pegloticase vs PBO/pegloticase arms over 24 Weeks (Kaplan-Meier Estimates)

Background/Purpose: Pegloticase, a recombinant, pegylated uricase, is used for treatment of gout in patients who fail oral urate lowering therapy (ULT). Despite successful reduction of urate levels and flares, its use is limited due to immunogenicity leading to infusion reactions.[1] Co-administration of an immunomodulatory agent may mitigate this loss of efficacy and concern for drug-related toxicity.

Methods: Patients from 5 rheumatology practices were recruited over 18 months, and randomized (3:1) by site to either to mycophenolate mofetil (MMF) 1 gram twice a day or placebo (PBO) with a run-in of 2 weeks (wks) prior to intravenous pegloticase at 8 mg every 2 wks (12 infusions). MMF or PBO was given for the first 12 wks. Inclusion criteria were: a) patients ≥ 18 years of age who met 2015 ACR/EULAR gout classification criteria and b) chronic refractory gout defined as symptoms inadequately controlled with ULT or contraindication to ULT. Endpoints included: a) proportion of subjects achieving and maintaining a serum urate (sUA) ≤ 6 mg/dL at 12 wks (primary), b) assess 6-month durability of immune modulation after discontinuation of MMF at 12 wks (secondary), and c) adverse events (AE). Analyses were conducted using SAS (Cary, NC) Version 9.4 with Fisher's exact test for binary outcomes and Wilcoxon two-sample test for continuous outcomes. Kaplan-Meier estimates and log-rank test were performed to compare survival curves between groups. Hypothesis tests were two-tailed and p-value (p) < 0.05 indicated statistical significance.

Results: Of 42 subjects screened, 35 were randomized, and 32 who received at least one dose of pegloticase were included in modified intention to treat analyses (Table 1- demographics). 19 of 22 (86%) in the MMF arm achieved the primary outcome at 12 wks of sUA ≤ 6mg/dL, compared to 4 of 10 (40%) in placebo, p-value 0.01. At wk 24, sUA response was sustained in 68% of MMF arm vs. 30% in placebo. Estimated rates of AEs per month was similar between groups -MMF (0.3) and placebo (0.4). The MMF arm had higher AEs compared to placebo: musculoskeletal (36% vs. 10%), respiratory (18% vs. 0%), and infections (9% vs. 0%). The placebo arm had a greater percentage of infusion reactions (30% vs. 0%). Figure 1 demonstrates that the percentage of subjects maintaining a sUA < 6 mg/dL at 12 wks was significantly higher (p=0.02) in the MMF arm, and a significant difference (p=0.03) at 24 wks indicating sustained benefit from MMF.

Conclusion: Short-term concomitant use of MMF with pegloticase was generally well tolerated in our proof of concept study. It was associated with a statistically significant and clinically meaningful impact on the proportion of subjects achieving and maintaining a sUA ≤6 mg/dL at 24 weeks. To our knowledge, this is the first randomized controlled trial to demonstrate prolonged efficacy of pegloticase with co-administrations of an immunomodulatory agent.

Long-term Xanthine Oxidase Inhibitor Treat to Target Urate Lowering Therapy Coordinately Re-wires the Mononuclear Leukocyte Mitochondrial and Inflammatory Proteome in Gout

Jacob Wozniak[1], Ru Bryan[2], David Gonzalez[3] and Robert Terkeltaub[4], [1]UC San Diego, San Diego, CA, [2]UCSD, San Diego, CA, [3]UC San Diego, San Diego, CO, [4]VA Medical Center/UC San Diego, San Diego, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: In gout, long-term xanthine oxidase inhibitor treat to target urate lowering therapy (XOIT2T) markedly reduces flares and synovitis, despite delayed resolution of tissue crystal deposits. XOI drugs inhibit oxidative stress and the NLRP3 inflammasome in cultured leukocytes, but XOI effects on immune cells *in vivo* are poorly understood. To better define mechanisms and markers of long-term XOIT2T effects on gouty inflammation *in vivo* we curated PBMCs in a sub-cohort (n=32) of allopurinol vs. febuxostat comparative effectiveness trial CSP594 “STOP GOUT”.

Methods: All subjects reported recurrent acute flare activity and poorly controlled serum urate (>6.8 mg/dL) at enrollment. Serum cytokine quantification used mesoscale discovery immunoassay. PBMCs were analyzed by multiplexed, quantitative proteomics. Significantly altered proteins (via *p*-value and fold-change; pi score > 0.6) were subject to K-means clustering, then pathway and network analyses.

Results: At study endpoint (EP: 48 weeks XOIT2T), serum urate dropped by >30% to reach normouricemia, and gout flares dropped by ~50% from baseline (BL)($P < 0.05$ for both). Two subgroups of patients were clearly separable by BL serum IL-8, though indistinguishable by age, comorbidities, and gout flare rates. One subgroup had elevated IL8 at BL that fell until EP (“IL8+” group); the other subgroup had consistently low IL8 (“IL8-” group). To probe for differential responses to XOIT2T, we stratified samples into the 2 subgroups. At study EP, we saw broad PBMC

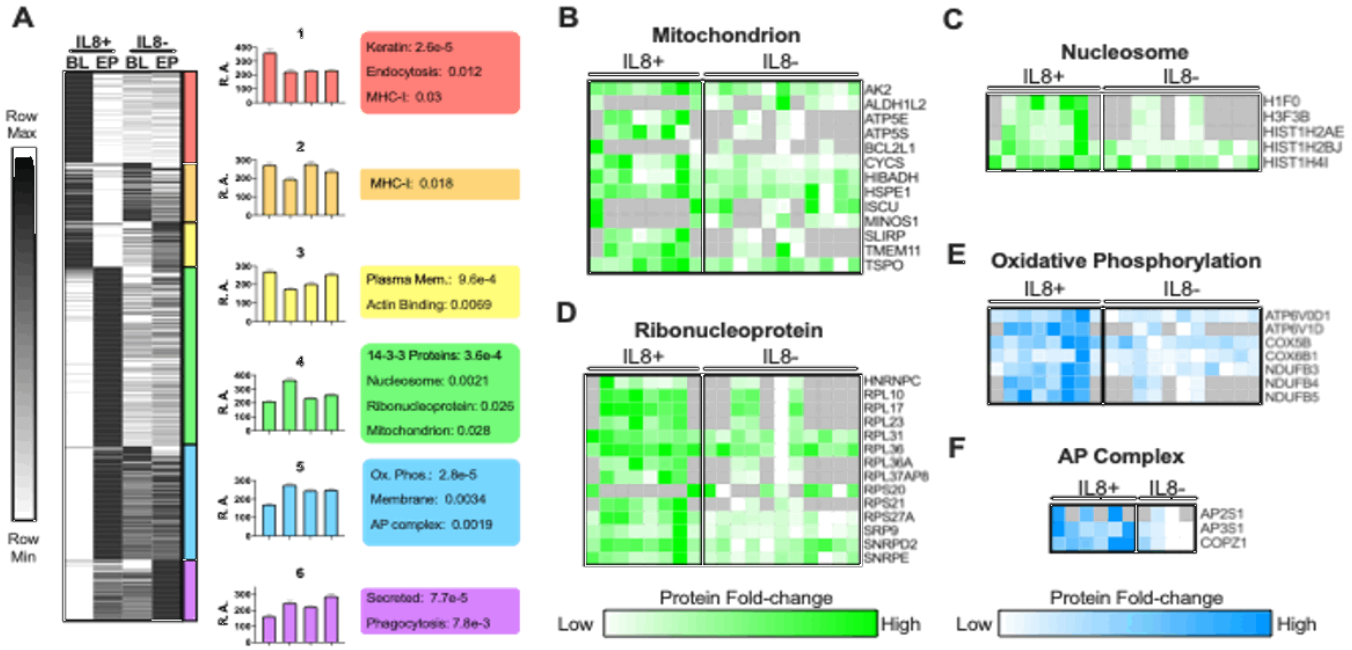

Figure 1. Overview of PBMC Proteomic Response to XOIT2T. (A) K-means clustered heatmap of significantly altered proteins (pi score > 0.6) in response to XOIT2T. Clusters are colored and matched with their respective average profiles and gene ontology analyses. Heatmaps of mitochondrion protein (B), nucleosome protein (C) and ribonucleoprotein (D) fold-changes from cluster 4. Heatmaps of oxidative phosphorylation (E) and AP complex protein (F) fold-changes from cluster 5.

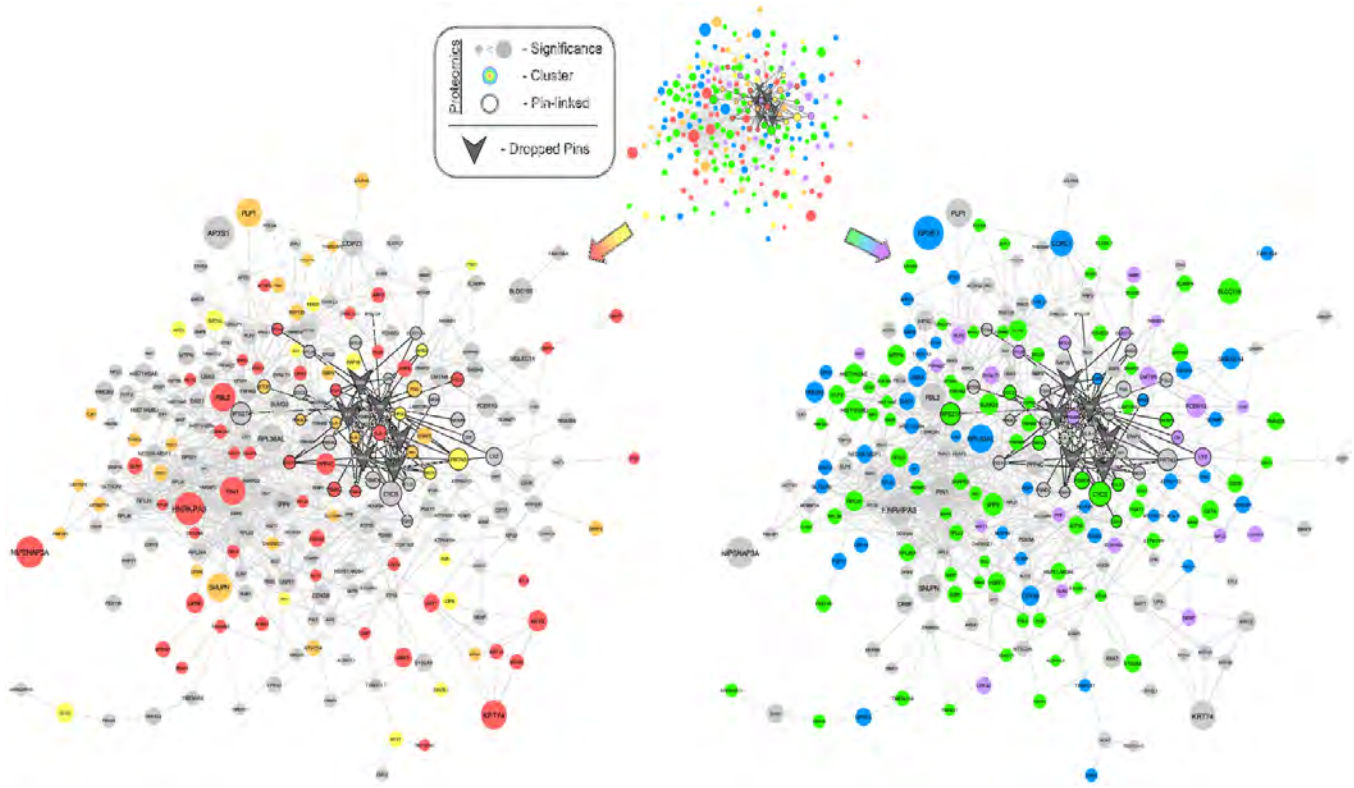

Figure 2. Linkage of Known Gout Mediators to PBMC Proteome Changes Induced by XOIT2T. STRING-db protein association network of significantly altered proteins (pi score > 0.6) and known gout mediators (TNF, IL6, IL1B, IL17A, CXCL8 and CSF2). Proteomic nodes are sized by average significance (ie. pi score) across stratified groups, colored according to K-means clusters in Fig 1 and have black border if directly linked to pin-dropped gout mediators.

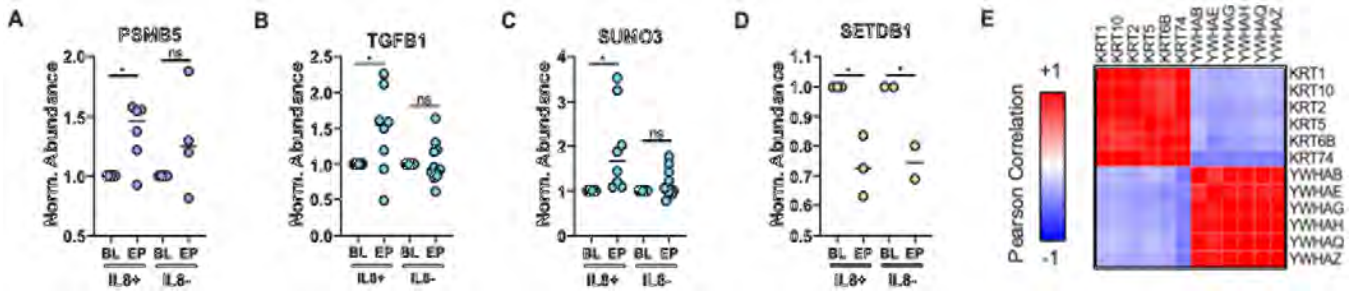

Figure 3. Specific PBMC Proteins of Interest Altered by XOIT2T. Expression of PSMB5 (A), TGFB1 (B), SUMO3 (C) and SETDB1 (D) across all groups normalized to patient BL (*pi score > 0.6; points are colored according to their K-means clusters in Fig 1). (E) Correlation matrix of keratin and 14-3-3 proteins significantly altered by XOIT2T.

proteome changes, with many prominent in the IL8+ subgroup. Specifically, we found increased mitochondrial and oxidative phosphorylation proteins, as well as nucleosome, ribonucleoprotein, and AP protein coat complexes (**Fig 1**). To assess how the proteome changes related to known gout pathways, we "pin-dropped" known central gout signaling molecules into a protein association network derived from the proteomic data (**Fig 2**). From this analysis, we defined a core XOIT2T response linked to known gout mediators (**Fig 2** - black outline), that included increased M2 macrophage markers (TGFB1, PSMB5) and NLRP3 inflammasome inhibition (SUMO3) (**Fig 3**). Differential keratin and 14-3-3 protein expression suggested that XOIT2T alters IL8+ subgroup gout monocytes to limit both a keratinocyte-like subset linked to MMP1 tissue remodeling, and hypermigratory, pro-atherogenic monocytes physiologically suppressed by 14-3-3zeta. However, XOIT2T, which promoted early gout flares, significantly reduced SETDB1, a xanthine oxidase expression regulating histone modifier that also blunts TLR4 inflammatory signaling.

Conclusion: Serum cytokine immunoassays merged with leukocyte quantitative proteomics identified novel markers and mechanisms for gouty arthritis altered by long term flare-reducing XOIT2T. Prior to XOIT2T, gout patients were stratifiable into high and low serum IL8 subgroups. XOIT2T reduced the anti-inflammatory histone H3 modifier SETDB1, a novel potential contributor to early gout flares. However, overall, and especially in IL8+ patients, XOIT2T re-wired the PBMC proteome, promoting mitochondrial function and manifold inflammation resolving mechanisms.

Dual-energy CT Predicts Mortality in Gout Patients: A 3-year Follow-up Cohort Study

Anne Marty-Ané[1], Laurène Norberciak[2], Jean--Francois Budzik[3] and **Tristan Pascart**[2], [1]GHICL, Lille, France, [2]GHICL, Lomme, France, [3]University of Lille, Lille, France

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Cardiovascular events, chronic kidney disease and increased mortality are common in gout patients but what links them remains unclear. Tophaceous gout in particular is associated with higher mortality which raised the potential causal role of the monosodium urate (MSU) crystal burden. The volume of MSU crystal depo-

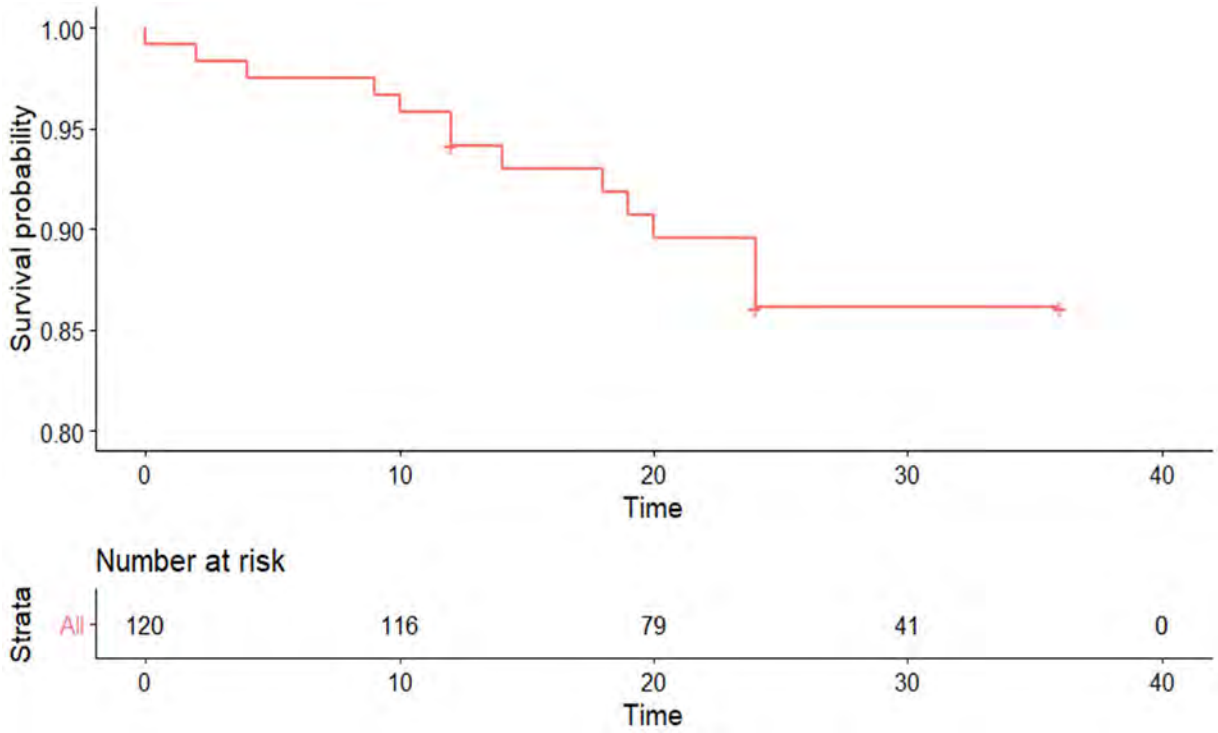

Figure 1. Kaplan-Meyer survival curve.

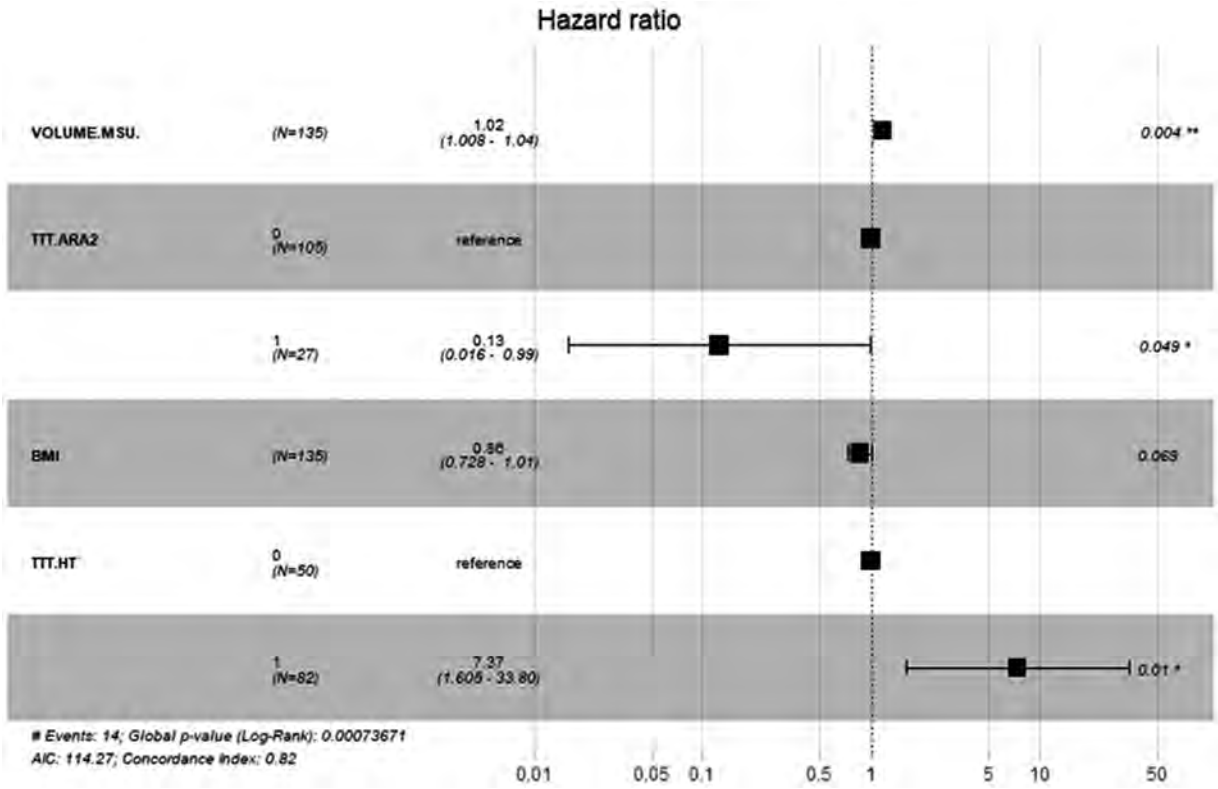

Figure 2. Cox Hazard ratios of factors predictive of short-term mortality in gout patients (within 36 months).

sition in soft tissues measured with dual-energy computed tomography (DECT) is cross-sectionally associated to cardiovascular diseases. The objective of this study was to determine if the initial volume of MSU crystal deposition measured with DECT is predictive of the mortality risk and development of cardiovascular and kidney diseases.

Methods: From April 2016 to May 2019, we prospectively enrolled in the CRYSTALILLE inception cohort of gout patients to undergo baseline DECT scans of both knees and ankles/feet.

Data including disease history and treatment, existing comorbidities, serum urate levels, estimated glomerular filtration rate (eGFR), and volume of MSU crystal deposition measured with DECT at the ankles/feet and knees were assessed at baseline. Data on the onset of major cardiovascular events (MACEs) and mortality, serum urate and eGFR were collected for months 12, 24 and 36. Baseline factors associated with evolution of the eGFR (±5 points of change was considered significant) were studied at months 12, 24 and 36, as well as those associated with MACEs and mortality.

Results: A total of 135 patients were enrolled, they were aged 66 years (±14) years and had a disease duration of 11 years (±10). Patients had baseline serum urate levels of 7.4 mg/dL (±2.2), 62% were naïve of urate lowering therapy and 36% had tophaceous gout. At baseline, 25% of patients had diabetes mellitus, 19% had a history of myocardial infarction, 11% of stroke, and 9% of transient cerebral ischemia.

Follow-up data was available for 123 patients at month 12, 86 at month 24 and 44 at month 36. All-cause mortality was 12% (n=14) during follow-up (Figure 1). In univariate analysis, patients that were deceased during follow-up had a median initial volume of MSU crystal deposition at the knees and feet of 0.4cm^3 [0.2 ; 2.9] and those who survived had a baseline volume of 0.2 cm^3 [0 ; 0.9] (p=0.045). In the multivariate cox model, factors influencing the risk of all-cause mortality were the volume of MSU crystals measured with DECT (HR 1.02 (1.008-1.04) for each additional cm^3), taking with renin-angiotensin inhibitors (HR 0.13 (0.016-0.99)) and taking any anti-hypertensive drugs (HR 7.37 (1.605-33.80)) (Figure 2).

The average serum urate level at months 12 was 5.6 mg/dL (±1.7), 5.9 mg/dL (±2.2) at month 24 and 5.8mg/L (±2.0) at month 36. Overall, at months 12, 24 and 36, 16%, 15% and 21% respectively of patients had improved their eGFR while 36%, 34% and 31% had degraded their eGFR compared to baseline. Neither reaching serum urate levels below 6.0mg/dL nor the initial volume of MSU crystal deposition measured with DECT were predictive of eGFR evolution. A total of 6 (5%) patients presented non-fatal MACE, which was too few to identify predictive factors.

Conclusion: The volume of MSU crystal deposition at the knees and ankles/feet is an independent predictor of short-term mortality in gout patients.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Muscle Biology, Myositis & Myopathies

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

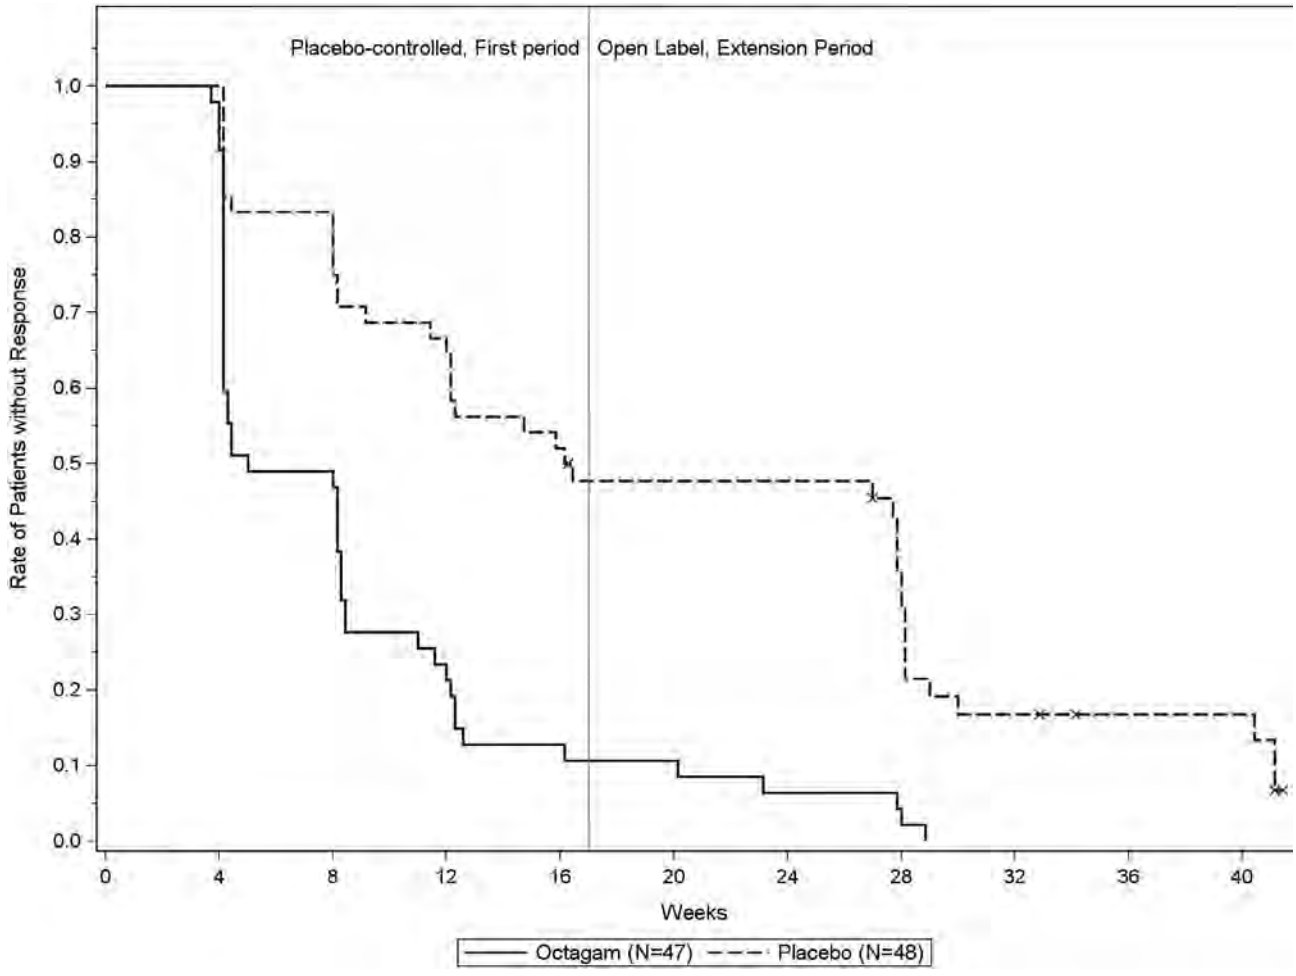

Figure 1. Time to Response (at Least Minimal Improvement; TIS ≥ 20) in both treatment arms

Background/Purpose: Dermatomyositis (DM) is a rare chronic systemic autoimmune disease with characteristic skin rash and progressive proximal muscle weakness. Intravenous immunoglobulin (IVIg) has long been used as adjuvant treatment for DM, but evidence from large randomized clinical trials supporting the efficacy and safety of IVIg in DM is limited.

The ProDERM study aimed to evaluate the efficacy and safety/tolerability of IVIg in DM patients in a double-blind, randomized, placebo-controlled, international multi-centre, phase III clinical trial.

Methods: The trial consisted of 2 periods of 16 and 24 weeks each. In the 1st double-blind, placebo-controlled period, adult patients with definite or probable DM (according to Bohan and Peter criteria) were randomized 1:1 to either high dose IVIg (2g/kg every 4 weeks) or placebo. To be included, subjects must have active disease with a manual muscle testing-8 (MMT-8) score < 142/150. Patients were switched to the alternate treatment arm if they showed clinical worsening (defined according to Oddis *et al*, 2013 - with slight adaptation) between week 8 and week 16. After week 16, all patients on placebo and patients without clinical worsening while on IVIg treatment entered the open label extension period, receiving 2 g/kg IVIg infusions every 4 weeks for 24 weeks. Primary endpoint was the proportion of responders in the IVIg vs. placebo arm at week 16, where response was defined per 2016 ACR/EULAR Myositis response criteria of at least minimal improvement [Total Improvement Score (TIS) ≥ 20 points)] and without clinical worsening at 2 consecutive visits up to week 16.

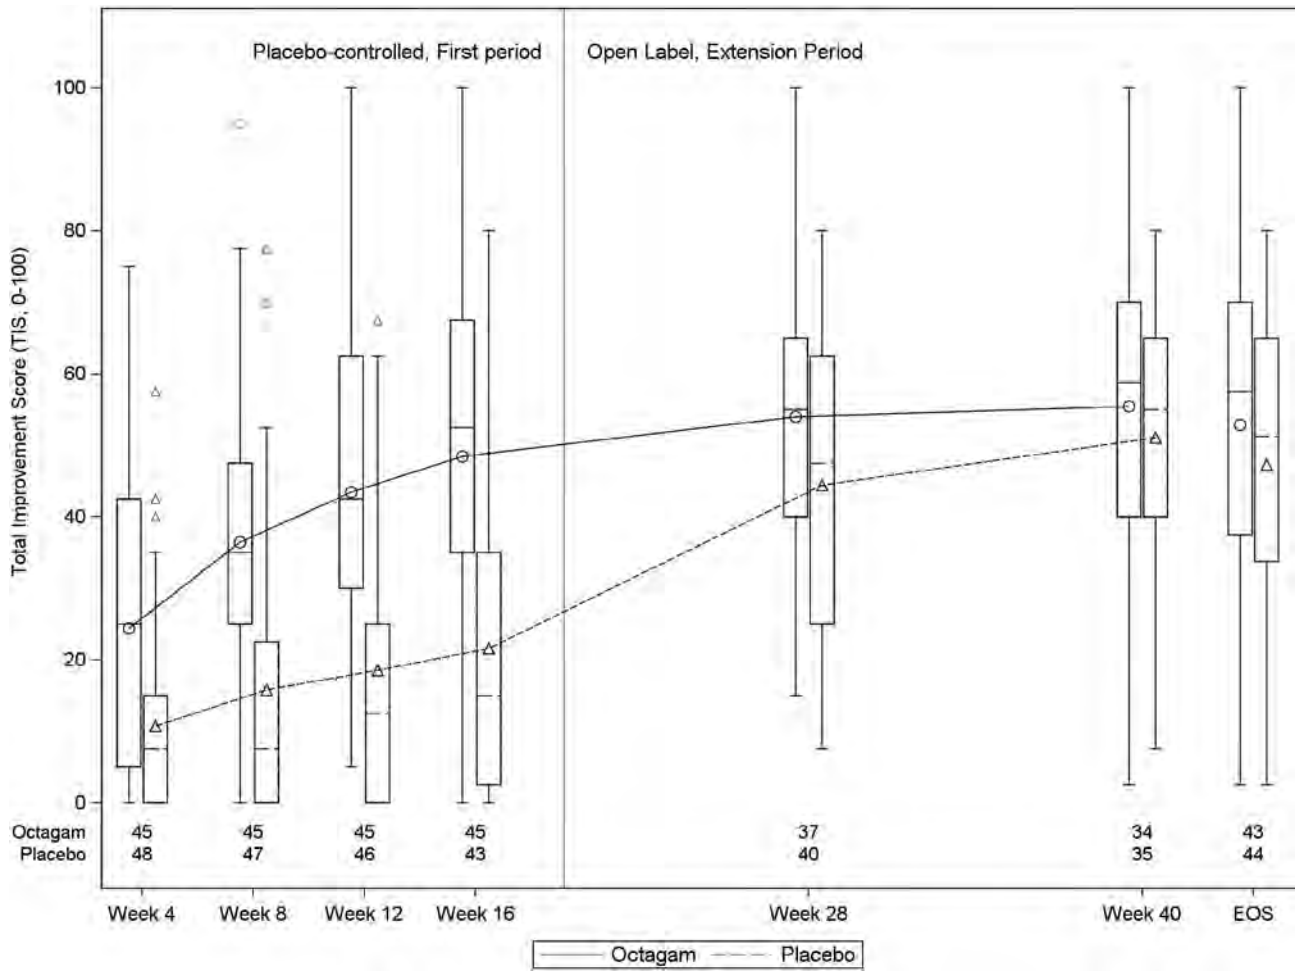

Figure 2. Mean Total Improvement Score (TIS) from week 4 to 40, among the two treatment arms

Results: A total of 95 adult DM patients (mean age: 53 years; 75% females; 92% Caucasian) were enrolled, with 47 and 48 randomized to IVIg and placebo, respectively. Baseline clinical characteristics were balanced between the 2 arms. At week 16, the proportion of responders was significantly higher in the IVIg group (37/47; 78.7%) as compared to the placebo group (21/48; 43.8%; p-value 0.0008) thus meeting the primary endpoint. Only 3 patients worsened in placebo group and none in IVIg group at or before 16 weeks. During the first period time to response was significantly shorter with IVIg (median of 35 days vs. 115 days for placebo; Fig 1).

The difference in response rate was even more marked for at least moderate improvement (TIS $\geq$ 40): 68.1% in the IVIg arm as compared to 22.9% in the placebo arm ($p < 0.0001$).

The mean TIS (SD) was significantly higher in IVIg group [48.4 (24.4)] than in placebo arm [21.6 (20.2)] at week 16 (Fig 2).

The proportion of responders as well as mean TIS at the end of the open-label extension period (week 16 to week 40) was similar in both treatment groups, showing that patients randomized to placebo in the first period improved after switching to IVIg in the extension period (Fig 1,2). Other secondary end points [e.g. MMT-8 and Cutaneous DM Disease Activity Area and Severity index (CDASI)], were also met, further supporting efficacy of IVIg.

The safety and tolerability profile of IVIg was consistent with previously reported safety outcomes.

Conclusion: This is the first large international phase III randomized, placebo-controlled trial demonstrating the efficacy and safety of IVIg as a treatment for patients with DM.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Muscle Biology, Myositis & Myopathies
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Skin lesions in dermatomyositis (DM) patients are common, frequently refractory, and have prognostic significance. Histologically, DM lesions appear similar to cutaneous lupus erythematosus (CLE) lesions and frequently cannot be differentiated. We thus undertook to examine the transcriptional profile of DM biopsies and compared them to CLE lesions in order to identify unique features.

Methods: For the inquiry cohort, 43 skin biopsies from 36 unique DM patients were identified within the University of Michigan Pathology Database. Comparative cases of 43 subacute cutaneous lupus erythematosus (SCLE) and 47 discoid lupus erythematosus (DLE) biopsies were similarly acquired. RNA was isolated and expression analysis was completed through the University of Michigan Advanced Genomics core using Affymetrix Human Gene ST 2.1 array plates for transcriptional analysis. Following normalization, 5-fold cross-validation was used to train random forest classifiers for genes that are only up-regulated in the control vs DM comparison microarray but not in the control vs CLE comparison (restricted to genes with $p > 0.5$ and $\log_2 FC < |\log_2 1.5|$). A secondary validation cohort was analyzed by real-time quantitative PCR and two additional patients underwent single-cell RNA sequencing. Protein expression was confirmed by immunohistochemistry.

Results: Type I interferon (IFN) signaling, including upregulation of IFN kappa, was a common pathway in both DM and CLE, but CLE also exhibited other inflammatory pathways. Importantly, DM lesions could be distinguished from CLE by a five-gene biomarker panel that included upregulation of *IL18*. Using single-cell RNA-sequencing, we further identified keratinocytes and monocyte/macrophages as the source of increased IL-18 in DM skin.

Conclusion: The novel molecular signature identified in this study has significant clinical implications for differentiating DM from CLE lesions, and we have highlighted the potential role for IL-18 in the pathophysiology of DM skin disease. Further work should examine the potential for anti-IL-18 directed therapies to treat DM skin lesions.

Mitochondrial ROS as a Regulator of Calcinosis in Juvenile Dermatomyositis

Bhargavi Duvvuri[1], Lauren Pachman[2], Richard Moore[1], Stephen Doty[3] and Christian Lood[1], [1]University of Washington, Seattle, WA, [2]Department of Pediatrics, Northwestern University Feinberg School of Medicine; The Ann and Robert H. SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Muscle Biology, Myositis & Myopathies
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Calcinosis, the accumulation of calcium crystals in soft tissues, is often a locus of infection and a debilitating manifestation of chronic juvenile dermatomyositis (JDM), contributing to long-term disability and sometimes death. Mechanistic understanding of calcinosis in JDM remains poorly understood, thus impeding therapeutic strategies. Our prior findings that the presence of calcified mitochondria and their remnants in degenerated muscle fibers and blood of JDM associated with calcinosis suggested that mitochondrial calcification plays a central role in JDM calcinosis. In this study, we hypothesized that the pathophysiological process in chronic active JDM contributes to mitochondrial activation and impairment, leading to mitochondrial calcification and extrusion.

Methods: To facilitate mitochondrial calcification, human skeletal muscle cells (RH30 cell line) were incubated in calcium phosphate (Ca-P) solution in the absence or presence of $CoCl_2$ (100 μM) or recombinant interferon-α (IFN-α) to mimic hypoxia and inflammation, respectively. Calcification in cells was assessed using Osteoimage, a stain for hydroxyapatite calcium salt crystals, by flow cytometry and microscopy. The extrusion of calcified mitochondria was determined by fluorescence microscopy. Mitochondrial damage was analyzed by flow cytometric analysis of mitochondrial ROS (mtROS) using fluorescent stain MitoSOX. Inflammation in RH30 cells in response to calcification was quantified by RT-PCR and ELISA.

Results: Hypoxia-mimetic $CoCl_2$ augmented Ca-P media-induced calcification in RH30 cells (% of osteoimage+ cells, 86.85 vs. 52.25; MFI 66929 vs. 12649, $p< 0.05$). Hypoxia caused mitochondrial formation of ROS, a process deemed essential for calcification as mitoTEMPO, a mitochondrial ROS scavenger, completely abrogated mitochondrial calcification. Fluorescent microscopy revealed an extrusion of calcified mitochondria in extracellular vesicles, resembling calcinosis. Muscle cells undergoing mitochondrial calcification demonstrated inflammation characterized by increased expression of interferon-induced genes and secretion of IL-6 in cellular supernatants. Finally, we hypothesized that IFN-α, one of the pathogenic factors of JDM found in muscle tissue, would promote mitochondrial calcification. Accordingly, we found a dose-dependent increase in the calcification of RH30 cells cultured in the Ca-P medium supplemented with IFN-α ($p< 0.05$).

Conclusion: Mitochondrial ROS is a chief regulator of mitochondrial calcification and extrusion in *in vitro* systems, promoting inflammation in muscle cells. Calcinosis associated with JDM is dystrophic, which, by definition, occurs in injured tissues despite the presence of normal systemic levels of calcium and phosphate. Hence, pathologic calcification in JDM does not regress in response to therapy of calcium depletion suggesting a role of local mechanisms in calcium dyshomeostasis. Our findings suggest that therapeutic agents targeting mtROS may prevent mitochondrial impairment and subsequent mitochondrial calcification/extrusion in skeletal muscle cells reducing calcinosis.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Muscle Biology, Myositis & Myopathies
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: To assess the efficacy and tolerability of tocilizumab (anti-IL-6R, TCZ), in a multi-center, randomized, double blind, placebo-controlled trial in refractory adult dermatomyositis (DM) and polymyositis (PM) patients.

Methods: Adult patients with refractory DM and PM were enrolled in a phase IIb double blind; placebo-controlled, clinical trial randomized 1:1 for active drug:placebo for 6 months, with a targeted enrollment of 40 subjects. Inclusion criteria included: (a) probable or definite PM or DM (modified Bohan and Peter criteria), (b) either a classic DM rash, a myositis associated autoAb *or* a PM diagnosis vetted by adjudication, (c) refractory myositis defined by glucocorticoid (GC) failure, or GC/at least one other immunosuppressive failure and (d) active disease defined by at least 3 of 6 abnormal myositis core set measures (CSM) including an MMT< 136/150 or if MMT >136 then the 3 abnormal CSM plus a cutaneous VAS ≥ 3/10 cm. Subjects were randomized to receive either 6 doses of TCZ (8 mg/kg IV) or placebo every 4 weeks for 24 weeks. The primary endpoint compared the Total Improvement Score (TIS; 2016 ACR/EULAR Criteria) between both arms at weeks 4-24, using a GEE model including treatment, diagnosis and time. Secondary outcomes included time to meeting minimal improvement, changes in CSM, steroid-sparing effect, proportion of patients meeting minimal, moderate and major improvement, and safety/tolerability outcomes between both treatment arms.

Results: 36 subjects (23DM, 13PM) were randomized (18 in each arm) and analyzed using intention to treat. All but 4 (2 TCZ/2 placebo) completed 24 weeks of treatment. There was no significant difference (p=0.86) in the TIS (primary outcome) over 24 weeks between TCZ and placebo in the entire cohort or by subgroup (DM alone). There was no significant difference in the mean TIS score over 4-24 weeks between the two arms [mean (SD) all visits: TIS 26.4 (16.75) vs. 29.3 (16.76)] (Figure 1). However, the mean TIS improved significantly (p=0.02) from baseline to the last study visit in both arms. The proportion of patients meeting no, minimal, moderate and major improvement at last study visit, were similar (p=0.22) in both arms [TCZ: 8 (44.4%), 3 (16.7%), 4 (22.2%), and 3 (16.7%); placebo: 5 (27.7%), 5 (27.7%), 6 (33.3%) and 2 (11.1%), (Figure 2)]. The secondary endpoints of time to minimal improvement, CSM change, and steroid-sparing effect were not significantly different between treatment arms. The adverse/serious adverse events (AE/SAE) were not significantly different between both arms [TCZ: 14 events (44.4 % of pts) vs. 9 events (33.3% of pts)]. TCZ was well tolerated and only 4 patients stopped treatment early due to disease worsening (n=3) or SAE (n=1).

Conclusion: TCZ treatment did not meet the primary or secondary efficacy outcomes in refractory DM and PM in this 24-week phase IIb study. TCZ was safe and well tolerated.

Altered Gut Microbiome in Dermatomyositis

Sangmee Bae[1], Tien Dong[2], Venu Lagishetty[3], William Katzka[4], Jonathan Jacobs[3] and Christina Charles-Schoeman[5], [1]University of California Los Angeles, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, [3]University of California, Los Angeles, Los Angeles, [4]UCLA, Los Angeles, [5]University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Muscle Biology, Myositis & Myopathies
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Dermatomyositis (DM) is an autoimmune myopathy associated with marked microvascular dysfunction and high morbidity and mortality. The gut microbiome has been implicated in the pathogenesis of both vascular and autoimmune disease, however, no studies to date have evaluated whether the gut microbiome is altered in patients with dermatomyositis.

Methods: Fecal samples from DM patients and healthy controls underwent 16S rRNA gene sequencing by Illumina MiSeq. Amplicon sequence variants were identified using DADA2 and the SILVA 132 database. Microbial composition was compared between DM and control groups (beta diversity analysis) using the robust Aitchison distance metric and permutational multivariate analysis of variance controlled for significant differences between groups such as antibiotic use. Alpha diversity was measured by the Shannon Index (reflecting species richness and evenness in each sample) and was compared between groups using analysis of variance. Microbiome diversity and composition were also examined in association with several clinical variables including myositis-specific autoantibodies (MSA). Differentially abundant microbial taxa associated with clinical characteristics were identified using DESeq2.

Results: A total of 36 DM patients and 26 healthy controls (Table 1) were analyzed. Compared with controls, DM patients exhibited a trend towards lower microbial alpha diversity based on the Shannon index (p= 0.08). Higher disease damage (measured by physician global visual analogue scales) in DM patients was significantly correlated with lower microbial diversity (Figure 1-d). When DM patients were analyzed by MSA subgroups (ILD-associated MSA: antisynthetase ab,anti-MDA5 ab, n=12; Cancer-associated: anti-NXP2 ab, anti-TIF1gamma ab, n=13) and compared with controls, there were significant differences in their microbial composition (Figure 2-a). This was also associated with significantly reduced Shannon index in the ILD-associated MSA group compared to controls (Figure 2-b). Differential abundance testing demonstrated that several amplicon sequence variants within the *Firmicutes*, *Actinobacteria*and *Bacteroidetes* phyla were found in greater abundance in ILD-associated and cancer-associated MSA patients compared to controls (Figure 2-d).

Conclusion: DM patients with ILD-associated MSAs have an altered gut microbiome including significantly decreased microbial diversity. Further studies are warranted to determine whether these abnormalities contribute to disease pathogenesis including microvascular damage.

*p<0.05 in DM vs controls

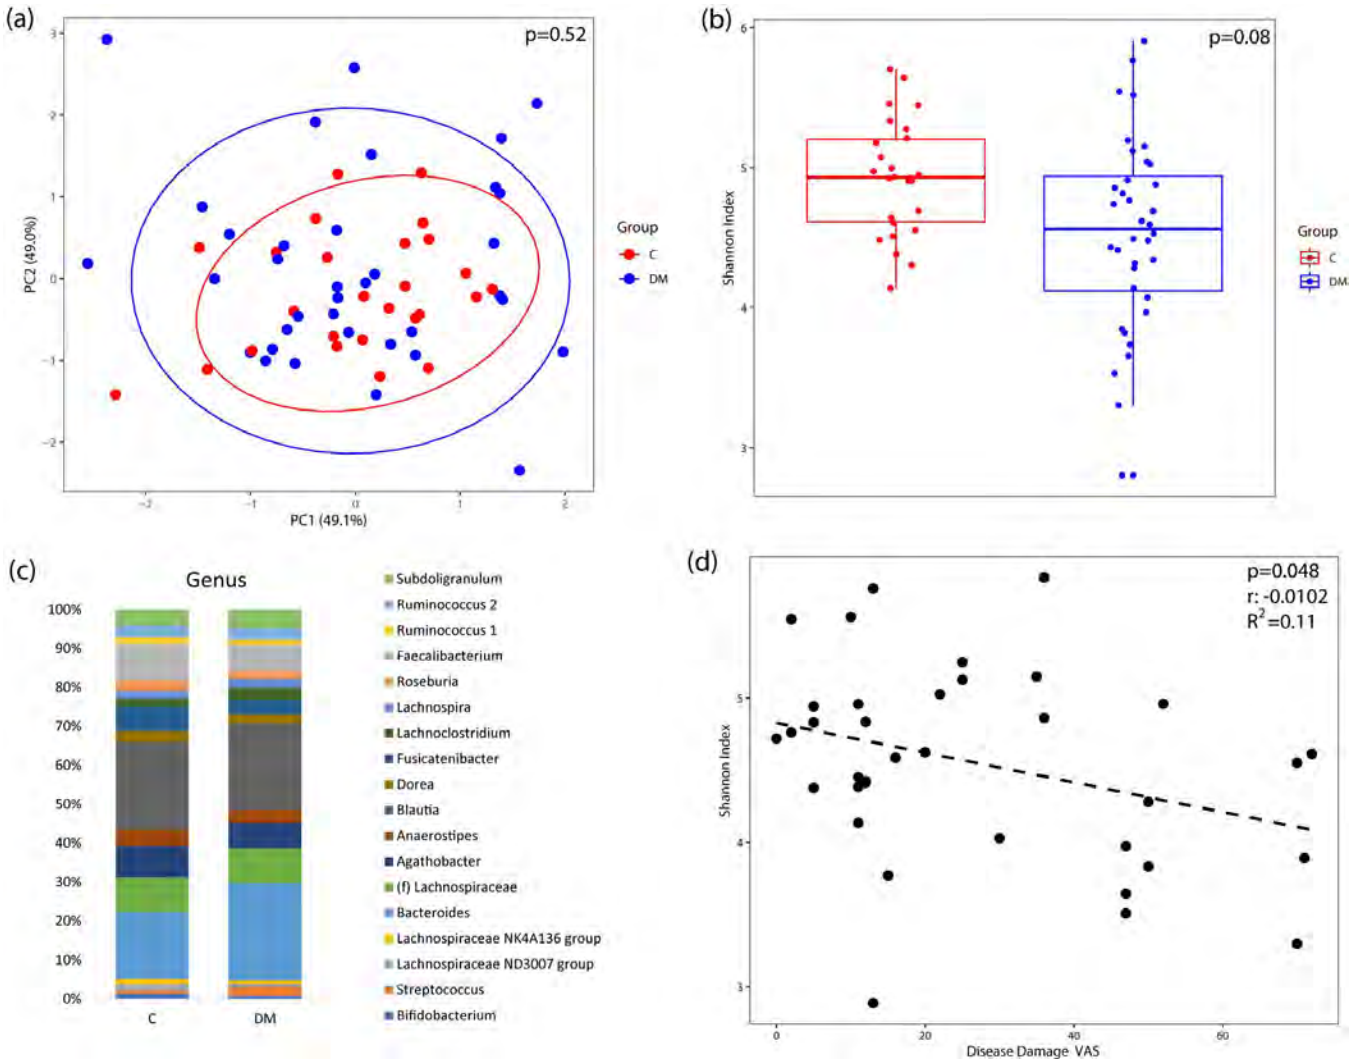

Figure 1. Microbiome diversity in DM patients (n=36) compared to healthy controls (n=26). (a) Comparing the overall microbial composition in DM and healthy control samples by principal components analysis plot using a robust Aitchison distance matrix. Each dot represents a sample from a DM patient (blue) or a healthy control (red). Ellipse represents the 95% confidence interval for each group. (b) Species evenness and richness in DM vs controls by Shannon index adjusted for significant differences in antibiotic use. p value = 0.08 (c) Taxa summary plots between DM and control with only those genera with a relative abundance of ≥ 1%. No genus was differentially abundant in DM compared to controls. (d) Higher disease damage score by visual analog scale in DM patients was significantly correlated with lower evenness and diversity of microbial species.

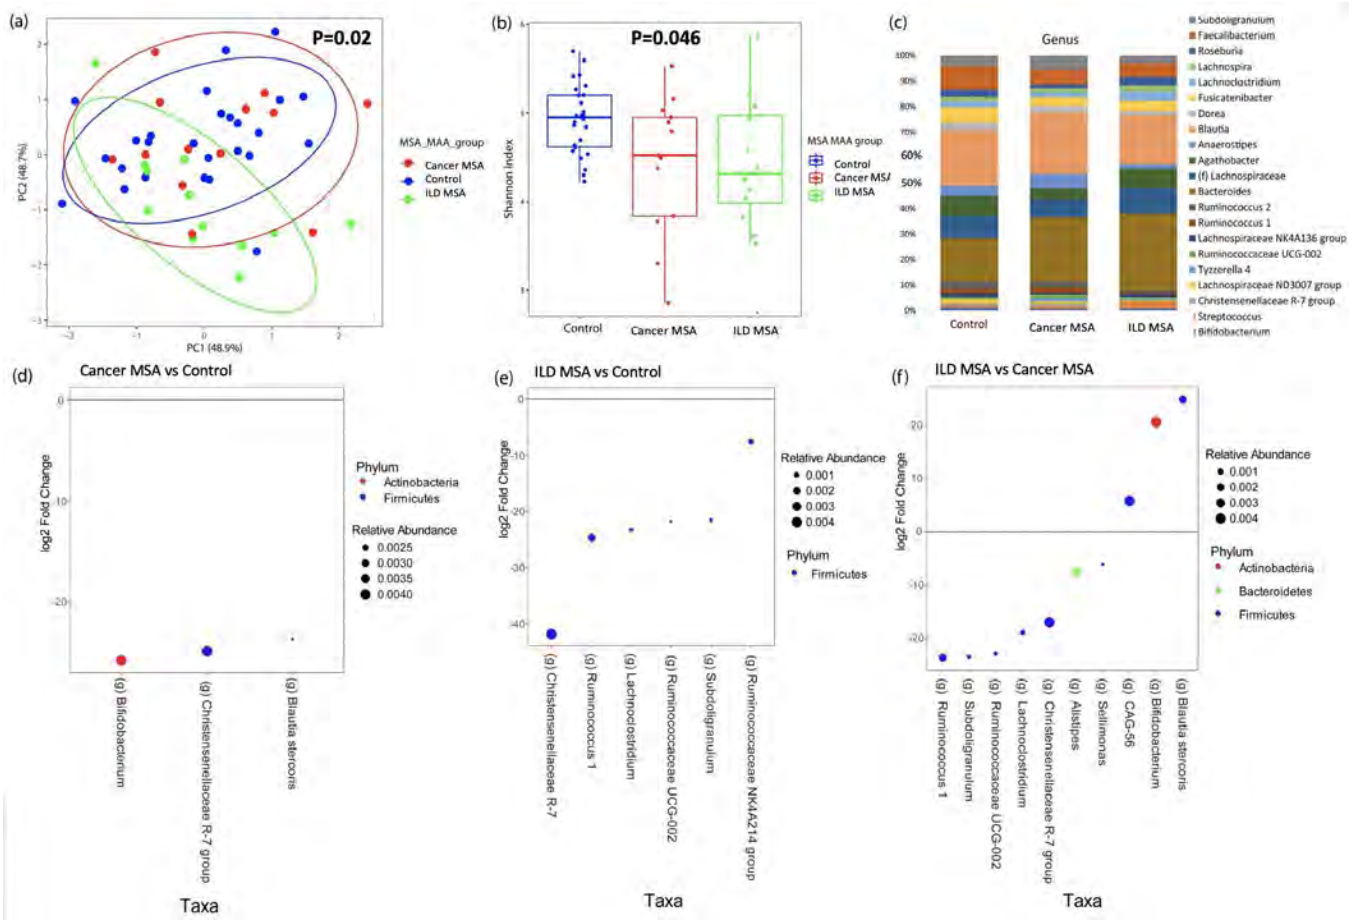

Figure 2. Microbiome diversity in DM patients by MSA subgroups (ILD associated MSA n=12, Cancer associated MSA n=13) compared to healthy controls (n=26). (a) Significant differences in the overall microbial composition between MSA/MAA subgroups of DM and controls. Each dot represents a sample from a DM patient with ILD associated MSA (green), DM patient with cancer associated MSA (red) or healthy control (blue). Ellipse represents the 95% confidence interval for each group. (b) Decreased species evenness and richness in MSA/MAA subgroups of DM compared to controls. (c) Taxonomic summary plots by MSA subgroups, only showing those genera with a relative abundance ≥ 1%. Differential abundance testing at the amplicon sequence variant level between (d) cancer associated MSA patients vs control, (e) ILD associated MSA patients vs control, and (f) ILD associated MSA patients vs Cancer associated MSA patients.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Orthopedics, Low Back Pain, & Rehabilitation

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Infection can trigger coagulation pathways and increase the risk of thrombosis. However, the impact of infection on postoperative venous thromboembolism (VTE) risk is poorly defined. The aim of this study was to assess the 90-day risk of VTE following total knee replacement (TKR) revision by indication for revision to estimate the impact of infection on postoperative VTE risk.

Table 2. VTE within 90 days of aseptic, septic and fracture-related TKR revision

Methods: We used New York Statewide Planning and Research Cooperative System data to identify all New York

Table 3: Risk of VTE within 90 days of septic and fracture TKR revision in comparison to aseptic TKR revision: results of multivariable logistic regression analysis

	Odds ratio (95% confidence interval)	P value
Septic TKR revision	2.01 (1.72-2.36)	<.001
Fracture TKR revision	2.61 (1.9-3.58)	<.001

VTE = venous thromboembolism; TKR = total knee replacement

Table 3. Risk of VTE within 90 days of septic and fracture TKR revision in comparison to aseptic TKR revision: results of multivariable logistic regression analysis

State residents undergoing TKR revision from 1998 to 2014. Only the first revision was included for patients undergoing multiple revisions. ICD-9-CM codes were used to identify patient comorbidities and classify indication for TKR revision as aseptic, septic or fracture. The primary outcome was any diagnosis code for VTE (pulmonary embolism and/or deep vein thrombosis) recorded for the revision surgery and/or subsequent admissions within 90 days. A multivariable logistic regression analysis adjusting for demographics and comorbidities was performed to estimate the risk of VTE after septic vs aseptic revision TKR, and of fracture-related revision vs. aseptic revision.

Results: This study included 25,441 TKR revision surgeries, 17,563 (69%) of them aseptic, 7075 (28%) septic and 803 (3%) for fracture. Mean (SD) age was 66 (12) years, 15,592 (61%) were female, 3198 (12%) were black, 1192 (5%) were smokers and 4222 (17%) were obese (**Table 1**). A total of 719 (2.8%) patients experienced VTE within 90 days of revision TKR, 387 (1.5%) during the index admission. The 90-day incidence of VTE was 2.1% after aseptic revision, 4.3% after septic revision and 5.9% after revision for fracture (**Table 2**). The 90-day incidence of pulmonary embolism was 0.7% after aseptic revision, 1.0% after septic revision and 1.9% after revision for fracture. The adjusted odds ratio (OR) for VTE relative to aseptic revision was 2.01 (95% CI 1.72-2.36) for septic TKR revision and 2.61 (95% CI 1.9-3.58) for fracture-related TKR revision (**Table 3**). Prior history of VTE was also a risk factor for post revision VTE (OR 2.01, 95% CI 1.48-2.71, p< 0.001).

Conclusion: The risk of VTE after septic TKR revision is double that after aseptic TKR revision. Although fractures account for a small percentage of TKR revisions, the risk of VTE is 2.6-fold higher after those procedures. VTE prophylaxis guidelines should distinguish between the indications for TKR revision, and potent/fast acting VTE prophylaxis should be strongly considered in those with infection or fracture.

Development of a Pain Sensitivity Index to Examine the Transition from Intermittent to Constant Pain in Knee Osteoarthritis: The Multicenter Osteoarthritis Study

Kosaku Aoyagi[1], Lisa Carlesso[2], S. Reza Jafarzadeh[1], Michael LaValley[3], Na Wang[1], Laura Frey Law[4], Beth Lewis[5], Michael Nevitt[6] and Tuhina Neogi[1], [1]Boston University School of Medicine, Boston, MA, [2]McMaster University, Hamilton, ON, Canada, [3]Boston University School of Public Health, Boston, MA, [4]University of Iowa, Iowa City, IA, [5]University of Alabama at Birmingham, Birmingham, [6]University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Orthopedics, Low Back Pain, & Rehabilitation

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Alterations in nociceptive signaling, such as pain sensitization, which is an abnormal ascending pain facilitation, and/or inadequate descending pain modulation, are thought to be underlying mechanisms contributing to the transition from intermittent to constant pain in knee osteoarthritis (OA). Studies to date have primarily focused on individual measures of pain sensitivity, which can be assessed by quantitative sensory testing (QST). Whether combining pain sensitivity measures may provide better insights into the transition from intermittent to persistent pain than individual QST measures is not known. We therefore sought to develop a composite pain sensitivity index (PSI) based on QST measures that incorporates multiple aspects of nociceptive alterations and evaluated its relation to development of constant pain in knee OA.

Methods: We included subjects from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort study of persons with or at risk of knee OA. We assessed Intermittent and Constant Osteoarthritis Pain (ICOAP) at baseline and two years later, and the following QST measures at baseline: i) pressure pain thresholds (PPT) at the wrist and patellae assessed with an algometer as the point at which pressure changed to slight pain; ii) temporal summation (TS) at the wrist using weighted probes; and iii) conditioned pain modulation (CPM) using PPT at the wrist as the test stimulus pre- and post-conditioning stimulus (forearm ischemia); CPM was computed as the post-PPT: pre-PPT ratio. Each QST measure was standardized and rescaled to 0-100 score, and then the PSI was created by taking the average of the summed scores of the four measures with equal weights, leading to PSI on a 0-100 scale. A lower PSI score represents greater pain sensitivity. Among participants at baseline who had intermittent pain of at

	Development of Constant Pain
Per 10-unit increase	*Odds ratio (95% CI)*
Pain Sensitivity Index	**0.67 (0.49, 0.92)**
PPT, wrist	0.81 (0.67, 0.99)
PPT, patella	0.84 (0.73, 0.97)
TS, wrist	1.00 (0.77, 1.30)
CPM	0.80 (0.44, 1.48)
Analyses were adjusted for age, sex, race, body mass index (BMI), widespread pain, sleep, depressive symptoms, pain catastrophizing, and use of opioids. QST: quantitative sensory testing, PPT: pressure pain threshold, TS: temporal summation, CPM: conditioned pain modulation,	

Table. Relation of PSI Score vs. Individual QST to Developing of Constant Pain Over Two-year Period

least ‘mild’ severity occurring ‘sometimes’, we examined the relation of the PSI to the development of knee-specific constant pain by ICOAP two years later using logistic regression with GEE, adjusting for potential confounders. We repeated analyses for individual QST measures that were also standardized and rescaled to 0-100.

Results: 2737 participants (3031 knees) were included (mean age 64 ± 10, 58% female, mean BMI 29.4 ± 5.7). Over a two-year period, 6.7% developed constant pain. Each 10-unit increase in PSI score (signifying less pain sensitivity) was significantly associated with 33% lower odds of developing constant pain over 2 years (**Table**). In contrast, the magnitude of association for each individual QST measures was either smaller than that of the PSI score, or not associated with developing constant pain (**Table**).

Conclusion: The PSI score was associated with developing constant pain, whereas the individual QST measures had either smaller or null associations. This PSI score highlights the potential clinical relevance of multiple coexisting nociceptive signaling alterations to the pain experience in knee OA, and supports the importance of performing a global assessment of pain sensitization to capture the overall status of the nociceptive system.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Lumbar radicular pain is the most common chronic neuropathic pain syndrome. Antidepressants are highly recommended for neuropathic pain, but there is no evidence for their efficacy.

The aim of this double-blind, randomised, placebo-controlled trial is to determine whether clomipramine (an antidepressant) is more effective than placebo in reducing pain in individuals with resistant chronic lumbar radicular pain.

Methods: A double-blind, randomized, clinical trial. Sixty-two patients with resistant chronic lumbar radicular pain were included. (The sample size was calculated on the assumption that clomipramine would reduce the incidence of lumbar radicular pain of 35%, compared with placebo, with a two-sided test, an alpha level of 0.05, and a power of 85%). Patients were randomly allocated to receive either Clomipramine by slow intravenous infusion for 10 days in a hospital setting with progressively increasing doses, 25 mg on the first day, 50 mg on the second day and 75 mg on the third day until the tenth day, or placebo (500 ml of physiological serum a day). For both groups, paracetamol

is added intravenously at a dose of 3g per day for ten days, Parecoxib for 3 days and ten sessions of lumbar spine rehabilitation including analgesic massage, muscle strengthening and joint maintenance. At the exit, clomipramine was relayed with 25 mg per day orally until the 90th day for clomipramine group, and paracetamol was authorized in both groups, in case of severe pain. The primary outcome was pain intensity, measured at baseline, 5th day, 10th day and 90th day using VAS pain (10 mm). Secondary outcome included DN4-questionnaire, lumbar radicular discomfort (VAS 10 mm), pain-free perimeter of walking (min), disability assessed using the Roland Morris Disability questionnaire and severity of mood symptoms assessed using the Hospital Anxiety and Depression scale (HAD), measured on days 0, 5, 10 and 90.

Results: 31 patients were assigned to the clomipramine group and 31 to the placebo group. There were no differences between the groups in baseline characteristics. Treatment by clomipramine had a significantly greater reduction in pain, discomfort and DN4 from the 5thday compared to the placebo (3,83 ± 1,63 vs 5,38 ± 1,11, p< 0.0001, 3,90 ± 1,85 vs 5,35 ± 1,45, p= 0.001, 1,87 ± 1,68 vs 3,09 ± 1,49, p= 0.004 respectively) with significant differences maintained until 90th day. There was a statistically significant improvement in pain-free walking distance and disability for the clomipramine group from the 10th day compared to placebo (38 ± 27,04 vs 24,35 ± 17,25, p = 0.02 and 7,61 ± 4,96 vs 11,70 ± 4,51, p=0.001, respectively) and that maintained until 90th day. However, there was no statistically significant differences in HAD between the 2 groups.

Conclusion: This double-blind, randomized, clinical trial shows that clomipramine is quickly effective and maintained over time in the management of resistant chronic lumbar radicular pain. It can therefore be part of the therapeutic arsenal in this sense.

Chronic Obstructive Pulmonary Disease Associated with Prolonged Opiate Use, Increased Short-Term Complications and the Need for Revision Surgery Following Total Knee Arthroplasty

Jillian Glasser[1], Nicholas Lemme[2], Daniel Yang[2], Edward Testa[2], Alan Daniels[3] and Valentin Antoci[3], [1]University Orthopedics Inc, East Providence, RI, [2]Warren Alpert School of Medicine, Providence, RI, [3]Warren Alpert School of Medicine, East Providence, RI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Chronic obstructive pulmonary disease (COPD) is a condition which causes a substantial burden to patients, physicians, and the healthcare system at large. Medical comorbidities are commonly associated with adverse health outcomes in the postoperative period. Here, we present a large database review of patients undergoing total knee arthroplasty (TKA) to determine the effect of COPD on patient outcomes.

Methods: The PearlDiver database was queried for all patients who underwent TKA between 2007 and the first quarter of 2017. Medical complications, surgical complications, 30-day readmission rates, revision rates, and opioid utilization were assessed at various intervals following TKA.

Results: 46,769 TKA patients with COPD and 120,177 TKA patients without COPD were studied. TKA patients with COPD experienced increased risk of 30-day readmission (40.8% vs. 32.2%, p< 0.0001), 30-day total medical complications (10.2% vs. 7.0%, p< 0.0001), prosthesis explanation at 6 months (0.4% vs. 0.2, p=0.0130), 1 year (0.6% vs. 0.3%, p=0.0005), and 2 years (0.8% vs. 0.5%, p=0.0003), as well as an increased rate of revision (p< 0.0046) compared to TKA patients without COPD. Opioid utilization of TKA patients with COPD was greater than that of TKA patients without COPD at 3,16 and 12 months.

Conclusion: Patients with COPD have an increased risk for medical and surgical complications, readmission, and prolonged opioid use following TKA. Patients undergoing TKA with a history of COPD represent a high-risk patient population, and it is prudent to ensure that such patients are fully optimized in the perioperative period to reduce complications and minimize health-care costs.

Is Meniscal Status in the Anterior Cruciate Ligament Injured Knee Associated with Change in Bone Surface Area? An Exploratory Analysis of Data from the KANON Trial

Barbara Snoeker[1], Aleksandra Turkiewicz[1], Mike Bowes[2], Frank Roemer[3], Stefan Lohmander[1], Richard Frobell[1] and **Martin Englund**[1], [1]Lund University, Lund, Sweden, [2]Imorphics Ltd, Manchester, United Kingdom, [3]Boston University School of Medicine, Boston, MA, and Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Bone shape changes, which may be an important feature of osteoarthritis (OA) development, have been observed to occur early in the knee after anterior cruciate ligament (ACL) injury. The association between co-existing meniscal damage and bone shape changes is unclear. To gain new knowledge of early joint changes post-trauma, we studied the association between meniscal status in the ACL-injured knee and differences in bone surface area.

Methods: We used data from the KANON trial including 121 young ACL-injured adults. We obtained baseline and 2-year follow up knee MRIs read by one musculoskeletal radiologist. Our outcome was bone surface area at 2 years (mean mm^2, log-transformed) in 4 regions (femur, tibia, patella, and trochlea femur) in the medial and lateral compartment. We used data as reported by Bowes et al, who determined bone surfaces of the different areas and their limits with the use of active appearance models, a form of statistical shape model.[1] We defined meniscal damage based on Anterior Cruciate Ligament Osteoarthritis Score (ACLOAS).(Table 1) Meniscal damage was defined as both *present at baseline* and *newly developed*. *Newly developed* meniscal damage includes incident *or* worsening, i.e. pre-existing tears that expanded to another segment, or to extrusion or incident loss of meniscus substance.(Table 1) We used

Table 1. ACLOAS grading system

Type of meniscal damage	*ACLOAS grade*
Normal meniscus with absence of tear, maceration and hypointense signal	0
Intrameniscal hyperintensity not extending to meniscal surface	1
Horizontal tear	2
Radial and vertical tear	3
Bucket-handle tear, displaced tear (including root tears) and complex tears	4
Meniscal repair	5
Partial meniscectomy and partial maceration	6
Progressive partial maceration or re-partial meniscectomy (i.e., loss of morphological substance of the meniscus) as compared to the previous visit	7
Complete maceration or resection	8
Meniscal body extrusion <50%	na
Meniscal body extrusion >50%	na

Meniscal damage was defined as meniscal tear (ACLOAS grade 2 to 4), partial or complete maceration or resection (ACLOAS grade 6 to 8) or meniscal bod extrusion >50%. No tear (0), meniscal extrusion <50%, intrameniscal signal (ACLOAS grade 1) or status post meniscal repair (ACLOAS grade 5) were classified as no meniscal damage. *Worsening of meniscal damage* was defined in a knee with pre-existing meniscal damage in at least one segment as incident meniscal damage in a new segment or new tear, maceration/resection or extrusion >50% in the same segment.

Table 2 Baseline characteristics

	Baseline meniscal damage			Developed (incident/worsening) meniscal damage			Full cohort (N=121)
	MM (N=14)	LM (N=19)	No damage (N=88)	MM (N=24)	LM (N=26)	No damage (N=72)	
Sex, male (N,%)	11 (79)	16 (84)	62 (71)	19 (79)	21 (81)	51 (71)	89 (81)
Age, years (median, range)	25 (20-32)	23 (19-35)	27 (18 – 36)	27 (18 – 35)	25 (18 – 35)	25 (18 – 36)	25 (18 – 36)
BMI, kg/m^2 (median, range)*	23.0 (20.2 – 34.0)	24.8 (21.8 – 39.9)	23.5 (19.4 – 30.8)	24.1 (19.6 – 34.0)	24.2 (21.4 – 39.9)	23.3 (19.4 – 30.8)	23.6 (19.4 – 39.9)

BMI= body mass index, MM=medial meniscus, LM=lateral meniscus, MF=medial femur, LF=lateral femur, TrFMed=medial trochlea femur, TrFLat=lateral trochlea femur, MT=medial tibia, LT=lateral tibia, MP=medial patella, LP=lateral patella. *Baseline meniscal damage* includes every person with a meniscal tear at baseline, irrespective of their meniscal status after two years; *Developed meniscal damage* includes every person that has an incident or progressed meniscal tear after two years of follow-up. Because persons could have both medial and lateral meniscal tears at baseline or developed, the same person could have been included for both medial as well as lateral meniscal tear.
* N=119, because of two missing BMIs at baseline

multilevel linear regression adjusted for baseline bone area, age, sex, body mass index, treatment arm (i.e. early and optional delayed ACL reconstruction), and location. We compared bone area changes in subjects with meniscal damage at baseline or newly developed to those without meniscal damage. We present results as percentage (%) difference in bone area between the groups with 95% confidence intervals (CI).

Results: We included 121 subjects (median age 25 (18-36) years, 81% men). Due to missing MRI information, 109 subjects were analyzed. Baseline bone area in mean mm^2 were similar in those with and without meniscal damage for all four regions (Table 2). In the whole cohort, the bone surface area increased on average by ~2% over 2 years, with ~1% higher increase for *both* subjects with ipsicompartmental meniscal damage at baseline and with newly developed meniscal damage compared to those without meniscal damage during the 2-year follow-up (Figure 1).

Conclusion: In the ACL-injured knee, persons with baseline or newly developed meniscal damage had ~1% increased bone area in the affected compartment compared to persons without such meniscal damage. The clinical relevance of early bone shape changes for future structural and clinical outcomes needs further exploration.

Figure 1 Difference (%) in bone surface area at 2 years of four bone areas in the ACL injured knee between persons with meniscal damage in the same compartment compared to persons without meniscal damage in the same compartment either at baseline or newly developed

Repetitive Inhalant Lipopolysaccharide Exposure in the Setting of Arthritis Induction Potentiates Pro-Fibrotic Inflammatory Lung Disease in Mice

Madison Wolfe[1], Ted Mikuls[1], Geoffrey Thiele[1], Amy Nelson[1], Michael Duryee[1], Rohit Gaurav[1], Bryant England[1], Debra Romberger[1] and Jill Poole[1], [1]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Rheumatoid arthritis (RA) is associated with several lung diseases. Various airborne exposures have been implicated as RA disease risk factors including cigarette smoke and exposures related to pollution, farming, and construction among others. These exposures have also been linked to inflammatory lung disease in RA. A mouse model combining the agriculture organic dust extract-induced airway inflammatory model with collagen induced arthritis (CIA) led to increases in arthritis, autoimmunity, and pro-fibrotic inflammatory lung consequences. Agriculture exposures are complex with lipopolysaccharide (LPS) representing a major component; LPS exposure is

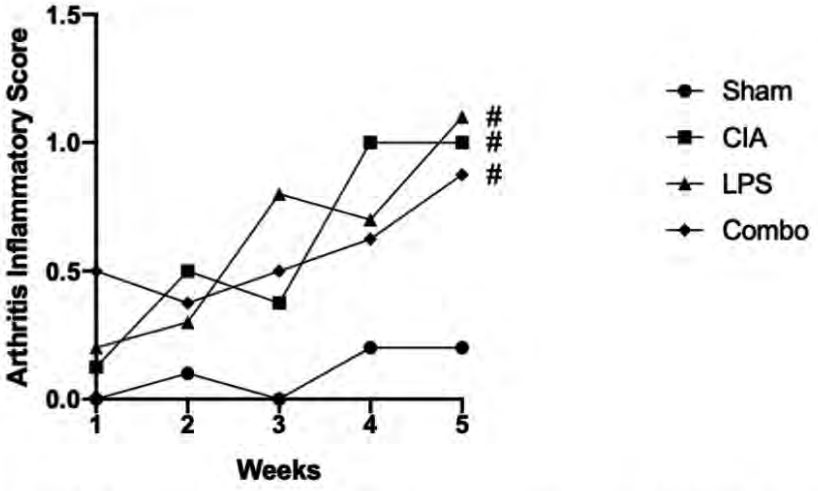

Figure 1. Arthritis inflammatory scores in hind paws increased following repetitive inhalant LPS (100 ng/day) exposure, arthritis induction (CIA), and combination CIA+LPS exposure. There was no difference among CIA, LPS, and combination CIA+LPS. Statistical significance denoted as #p<0.05 vs sham.

commonly found in other pollutant settings. It has been established that systemic LPS potentiates RA joint disease, but it is not known whether repetitive inhalation exposure to a biologically relevant airborne concentration of LPS modulates the RA-lung inflammatory axis.

Methods: DBA1/J male mice (n=5/group) were assigned to either: sham (saline injection/ saline inhalation), CIA (CIA/ saline inhalation), LPS (saline injection/ LPS 100 ng inhalation), or CIA+LPS for 5 weeks. Hind paws were observed weekly and given an arthritis inflammatory score of 0-4 based upon swelling and redness of the hind paws. Bronchoalveolar lavage fluid (BALF) and lung tissues were collected for cell enumeration, flow cytometry and ELISA.

Results: The arthritis inflammatory scores (mean±SEM) for CIA (1.0±0), LPS (1.1±0.24) and CIA+LPS (0.9±0.13) were significantly increased compared to sham (0.2±0.12) (**Figure 1**). **Table 1** depicts lung experimental outcomes. There was profound potentiation in BALF total lung cells ($p< 0.0001$) including neutrophils, macrophages, and lymphocytes in CIA+LPS versus other exposure groups. There was increased lung activated macrophages ($CD11c^{hi}CD11b^{hi}$), neutrophils ($Ly6C^{+}Ly6G^{+}$), monocytes ($CD11c^{-}CD11b^{hi}$) and recruited monocyte/macrophages ($CD11c^{int}CD11b^{+}$) with CIA+LPS exposure. The pro-inflammatory cytokine TNF-α ($p< 0.001$) and neutrophil chemokine (CXCL2) ($p< 0.0001$) were increased in LPS alone, but not LPS+CIA. In contrast, levels of fibronectin and the alarmin IL-33 were increased in the lung homogenates of CIA+LPS versus all other exposure groups. In addition, BALF complement (C5a) and fibronectin were increased in LPS and CIA+LPS and potentiated with combined treatments. As compared to sham, lung IL-33 was increased in LPS alone ($p< 0.01$) and lung fibronectin was increased in CIA alone ($p< 0.05$).

Conclusion: Repetitive LPS inhalation in the setting of arthritis induction induced striking lung inflammatory consequences. This was marked by reduction in classic pro-inflammatory mediators and augmentation of wound repair fibronectin, alarmin IL-33, and C5a with increased recruitment of activated macrophages, recruited/transitional monocyte-macrophages, and monocytes to potentially signify the transition toward pro-fibrotic consequences. These findings would suggest that patients with RA may be more susceptible to developing interstitial lung disease following occupational and environmental exposures enriched in LPS and that interventions to reduce airborne biohazard exposures could be important.

Decoupling Inflammation and Bone Loss in Rheumatoid Arthritis via Schnurri-3

Zheni Stavre[1], JungMin Kim[2], Jae-Hyuck Shim[2] and Ellen Gravallese[3], [1]University of Massachusetts Medical School-Rheumatology Division, Worcester, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: RA – Animal Models

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that leads to local and systemic bone loss. TNF is a key mediator of bone loss, not only through promotion of osteoclastogenesis, but also through inhibition of osteoblast function. Schnurri3 (*Shn3*) is a large, intracellular zinc-finger adaptor protein and is a suppressor of osteoblast activity, as *Shn3*-deficient mice show a significant increase in bone mass due to augmentation of bone formation. We questioned whether targeting SHN3 in bone cells has therapeutic potential in RA-induced bone loss.

Methods: To investigate the effect of *Shn3* global deletion on bone loss in arthritis, *Shn3*-deficient mice were crossed with SKG mice, a model of IL-17A and TNF-driven RA. SKG or *Shn3*-deficient-SKG mice were injected intraperitoneally with curdlan to synchronize arthritis onset. Mice were scored weekly for peripheral joint inflammation and sacrificed after 7 weeks of inflammation. Micro-computed tomography was used to evaluate joint erosions (ankles) and systemic bone loss (femurs). Histologic sections were scored for inflammation and bone erosion. To test the effect of deletion of *Shn3* in osteoblast precursor cells in the setting of TNF overexpression, $Shn3^{Prx1}$ mice were crossed with TNF-transgenic (TNF-tg) mice. Ankles and femurs were analyzed for inflammation and bone parameters as above. To further determine the effect of *Shn3*-deficient osteoblasts on bone in RA, the serum transfer arthritis (STA) model was employed in $Shn3^{Prx1}$ mice sacrificed at peak inflammation. Mice were again similarly analyzed for inflammation and bone parameters.

Human bone marrow stromal cells (BMSCs) were infected with lentivirus (vector alone (control), SHN3 overexpression, control-shRNA, or SHN3 knockdown) and cultured under osteogenic conditions in the absence or presence of TNF plus IL-17A for 14 days. Mineralization activity was measured by alizarin red staining. Mouse COBs isolated from P5 WT and *Shn3*-deficient pups were cultured in the absence or presence of TNF plus IL-17A and mineralization was measured.

Results: Significant protection from joint erosion and systemic bone loss was noted in *Shn3*-deficient SKG and $Shn3^{Prx1}$;TNF-tg mice, despite similar and ongoing inflammation. In STA, *Shn3*-deficient osteoblasts were present at sites of erosion at the bone-pannus interface where typically few mature osteoblasts are present, indicating that *Shn3*-deficient osteoblasts continue to differentiate and populate eroded bone surfaces despite the presence of inflammation. In parallel with this observation, *Shn3*-deficiency in BMSCs and osteoblasts blocked the inhibitory activity of TNF/IL-17 for differentiation in vitro.

Conclusion: SHN3 acts downstream of and potentiates the negative effects on osteoblasts of TNF/IL-17A. Its inhibition allows for continued bone formation despite the presence of inflammation. Therefore, targeting this pathway provides a potential therapeutic strategy for RA-induced bone loss.

Absence of Thy1 Associated with Severe Bone Loss in the TNF-transgenic (TNF-Tg) Mice Arthritis Model

Ananta Paine[1], Maria de la Luz Garcia-Hernandez[2], Marc Nuzzo[3], Stacey Duemmel[3], Benjamin Korman[1] and Christopher Ritchlin[1], [1]Department of Medicine, University of Rochester Medical Center, Rochester, NY, [2]Department of Medicine, University of Rochester Medical Center, West Henrietta, NY, [3]Department of Medicine, University of Rochester Medical Center, Rochester

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Thy1 (CD90) is a glycosylated, glycophosphatidylinositol (GPI)-anchored membrane protein noted to be expressed on many cells including T lymphocytes, stem cells, osteoblasts and fibroblasts. Thy1 is also abundantly expressed by mesenchymal stem cells (MSCs) and we previously demonstrated that it is required for osteoblast differentiation and bone homeostasis. The goal of this study was to examine if knockout of the membrane protein Thy1 (CD90), is associated with increased pathologic bone resorption in a murine model of inflammatory arthritis.

Methods: We performed real-time PCR (RT-PCR) to compare Thy1 mRNA expression levels in mouse bone marrow cells and monocyte-derived dendritic cells (mDCs) of TNF overexpressing (TNF-Tg) and wild type (WT) mice and murine embryonic fibroblasts (MEFs) from (WT) mice. Subsequently, we also investigated the impact of the Thy1 deletion in TNF-Tg (Tg3647) mice, a murine model of inflammatory arthritis. To study the effect of Thy1 depletion on bone erosion, we analyzed bone loss by performing micro-computed tomography (micro-CT) analysis of the long bones, and ankle joints of Thy1$^{-/-}$TNF-Tg, TNF-Tg, Thy1$^{-/-}$ and WT mice.

Results: In vitro assays revealed a significant decrease in Thy1 expression (40% - 65%) in primary bone marrow cells and mDCs of the TNF-Tg mice compared to the WT mice (Figure 1). Thy 1 mRNA levels decreased by more than 25% in murine embryonic fibroblasts following exposure to TNF for 24 hours. Most importantly, micro-CT analysis of the long bone and ankle joints revealed a significant increase in bone loss in the Thy1$^{-/-}$TNF-Tg mice, compared to the TNF-Tg or Thy1$^{-/-}$ mice (Figure 2). In particular, a significant reduction in bone parameters were observed in Thy1$^{-/-}$ TNF-Tg mice compared to the TNF-Tg, Thy1$^{-/-}$ or WT mice. Significant differences were noted in BV/TV (0.003 ± 0.02 in Thy1$^{-/-}$TNF-Tg vs 0.024± 0.01 in TNF-Tg, $p < 0.01$, for tibia), trabecular number (1.57 ± 0.2 in Thy1$^{-/-}$TNF-Tg vs 2.4 ± 0.1 in TNF-Tg, $p < 0.005$, for tibia), and trabecular thickness (0.026 ± 0.002 in Thy1$^{-/-}$TNF-Tg vs 0.032 ± 0.01 in TNF-Tg, $p < 0.01$, for tibia). Similar bone loss was not noted in WT or Thy1 KO mice.

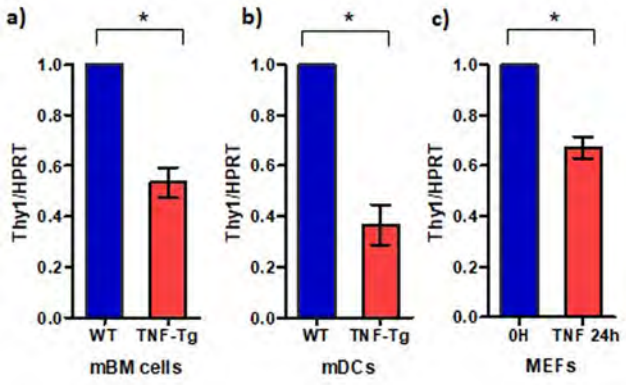

Figure 1. TNF exposure downregulates Thy1 expression in RA SFs, MEFs, BM cells, and mDCs a) Thy1 expression level in SFs from RA patients incubated with or without TNF for 12 hours (microarray data: GSE13837, fold change, n=3); b) MEFs were incubated with or without 5 ng/ml human TNF for 24 hours and thereafter Thy1 expression levels were compared using qPCR (n=3); c) Thy1 expression levels in freshly harvested bone marrow cells from 6 months old male WT and TNF-Tg mice (n=4); d) Thy1 mRNA expression levels in the monocyte-derived DCs of 4-month-old female WT and TNF-Tg mice (n=4). For qPCR data, HPRT1 was used as the housekeeping gene.

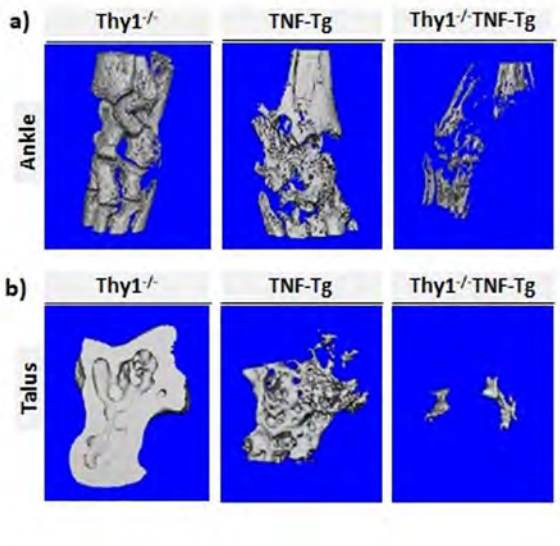

Figure 2. Increased bone loss in Thy1 KO TNF-Tg mice. Long bones from normal diet fed 8 months old male Thy1-/-, TNF-Tg, and Thy1-/-TNF-Tg mice were analyzed with micro-CT to compare changes in bone architecture and structural parameters. Representative micro-CT images of the ankle (a), and talus (b) presented.

Conclusion: We find Thy1 expression significantly decreased in MSCs and myeloid cells following exposure to TNF. Absence of Thy1 was associated with enhanced pathologic bone resorption in murine model of arthritis. Thus, TNF-mediated downregulation of Thy 1 may serve as an important mechanistic link between inflammation and progressive bone loss in inflammatory arthritis.

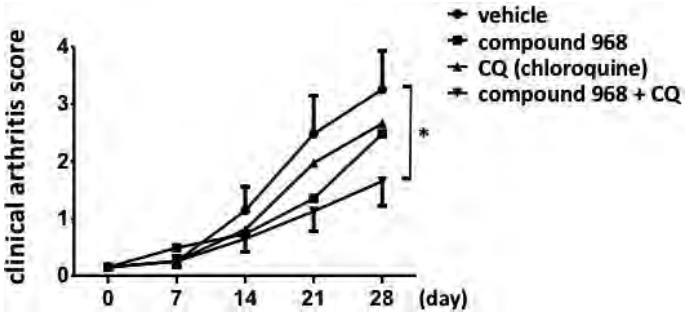
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Immunometabolism is now recognaized to be crucial in the pathogenesis of rheumatoid arthritis (RA). We have recently shown that the expression of glutaminase 1 (GLS1), a key enzyme in glutaminolysis,



Combination of C968 and CQ significantly attenuated the degree of arthritis in SKG mice.

is upregulated in fibroblast-like synoviocytes from RA patients (RA-FLS) and that GLS1 inhibition suppresses RA-FLS proliferation (1). However, glutaminolysis has been known to suppress autophagy by activating mTORC1 or counteracting ROS production (2). Given the possibility of autophagy upregulation following glutamiolysis inhibition, therapies targeting both autophagy and glutaminolysis may be more effective in suppressing cell growth of RA-FLS, yet the relation between glutaminolysis and autophagy in RA-FLS has not been investigated. Here we examined the effects of inhibiting both glutaminolysis and autophagy on RA-FLS and autoimmune arthritis in SKG mice.

Methods: GLS1 inhibitor, compound 968 (C968), was used to suppress glutaminolysis, and Chloroquine (CQ) was used to inhibit autophagy. To detect autophagy, the expression of ATG5 and LC3B was measured by real-time PCR and the production of LC3-II was analyzed by Western blotting. The formation of autophagic vacuoles was identified by immunfluorescense. Cell growth was evaluated by BrdU assay. Apoptosis was analyzed by flow cytometry staining with Annexin V-FITC and PI. C968 and CQ were administered subcutaneously to Zymosan A-injected SKG mice.

Results: C968 upregulated the expression of ATG5 and LC3B, and increased the protein level of LC3-II in RA-FLS. C968 also facilitated autophagosome formation. These results suggested that inhibition of glutaminolysis promoted autophagy in RA-FLS. The combined treatment with C968 and CQ significantly suppressed cell proliferation of RA-FLS more strongly than did C968 or CQ alone. In addition, C968 combined with CQ increased the apoptosis rate, whereas either C968 or CQ alone did not. Furthermore, combination of C968 and CQ significantly attenuated the degree of arthritis in SKG mice, while C968 or CQ monotherapy did not (Figure).

Conclusion: The GLS1 inhibitor C968 promotes autophagy in RA-FLS. C968 in combination with CQ reduces proliferation and enhances apoptosis in RA-FLS, and ameliorates the arthritis in SKG mice. Suppressing C968-induced autophagy may be a promising therapy for arthritis.

Investigating Murine Joint-Draining Lymphatics: Lineage Tracing and Single Cell RNA Sequencing Reveal Evidence That Popliteal Lymphatic Muscle Cells and Their Progenitors Represent Distinct Cell Types Divergent from Striated and Vascular Muscle Cells

H. Mark Kenney[1], Richard Bell[2], Elysia Masters[1], Lianping Xing[1], Christopher Ritchlin[3] and Edward Schwarz[1], [1]University of Rochester Medical Center, Rochester, [2]Hospital for Special Surgery, New York, [3]Department of Medicine, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Animal Models
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Previous studies demonstrated that tumor necrosis factor transgenic (TNF-Tg) mice with inflammatory arthritis have damaged lymphatic muscle cells (LMCs) and eventual loss of popliteal lymphatic vessel (PLV) contractions associated with severe joint disease.[1] Anti-TNF therapy in flaring TNF-Tg mice recovers these PLV-LMCs and PLV contractions concomitant with amelioration of arthritis.[1] As this regenerative process is critical for resumption of joint function, knowledge regarding PLV-LMC progenitor origins and physiology is needed. Surprisingly, LMCs express an enigmatic actin profile with co-existing striated and smooth muscle actin isoforms,[2] which is incompatible with the differentiation of known muscle progenitors. To determine PLV-LMC origin, we tested the hypothesis that PLV-LMCs are derived from previously characterized striated or vascular smooth muscle cell (VSMC) progenitors via lineage tracing studies in mice. We also utilized these lineage tracing models to specifically isolate PLV-LMCs and VSMCs for comparative single cell RNA sequencing (scRNAseq) transcriptomic analysis.

1. Bouta et al. 2018. *Nature Reviews Rheumatology*. 14(2):94-106.

2. Muthuchamy et al. 2003. *The FASEB Journal*. 17(8):920-922.

Methods: Constitutive Cre and tamoxifen-inducible CreER models were crossed into Ai9^{tdTomato} reporter lines for lineage tracing of PLV-LMCs during neonatal development. Induction of the CreER was achieved with 0.1 mg/g of tamoxifen administered intraperitoneal on postnatal days 10 – 13 (P10 – 13). All cohorts were sacrificed at both P21 and/or after 6-weeks. Pax7^{Cre} and MyoD^{iCre} animals were used to study striated muscle cell origin, while Prrx1$^{Cre/CreER}$ and NG2$^{Cre/CreER}$ mice were used to trace VSMC progenitors by tdTomato (tdT) expression visualized by ex vivo whole mount immunofluorescent microscopy of PLVs. The NG2^{Cre};tdT model was also utilized for fluorescence activated cell sorting (FACS) of tdT^{+} PLV-LMCs and VSMCs with downstream scRNAseq analysis on a 10X genomics platform.

Genes: Pax7 = Paired Box Protein 7; MyoD = Myogenic Differentiation Protein 1; Prrx1 = Paired Related Homeobox 1; Neural Glial Antigen 2 = NG2

Results: We demonstrate that PLV-LMCs originate from Pax7^{-}/MyoD^{-}/Prrx1^{+}/NG2^{+} progenitors prior to P10, and from previously unknown Pax7^{-}/MyoD^{-}/Prrx1^{+}/NG2^{-} progenitors during development after P10 **(Figure 1)**. In addition, our preliminary scRNAseq results suggest that mature PLV-LMCs are transcriptionally distinct muscle cells **(Figure 2)**.

Conclusion: This is the first study to describe the unique origin of PLV-LMC progenitors and to assess the distinct characterization of mature PLV-LMCs using a scRNAseq approach. Our analysis suggests that PLV-LMCs do not derive from striated muscle progenitors with Pax7- and MyoD-negativity. In addition, PLV-LMCs appear to originate from similar Prrx1^{+}/NG2^{+} progenitors to VSMCs, but derive from distinct Prrx1^{+}/NG2^{-} progenitors prior to P10 to become transcriptionally unique muscle cells. Thus, future work elucidating the PLV-LMC lineage, and defining specific markers of PLV-LMCs, will catalyze the development of LMC targeted therapies for diseases with lymphatic involvement, such as inflammatory arthritis.

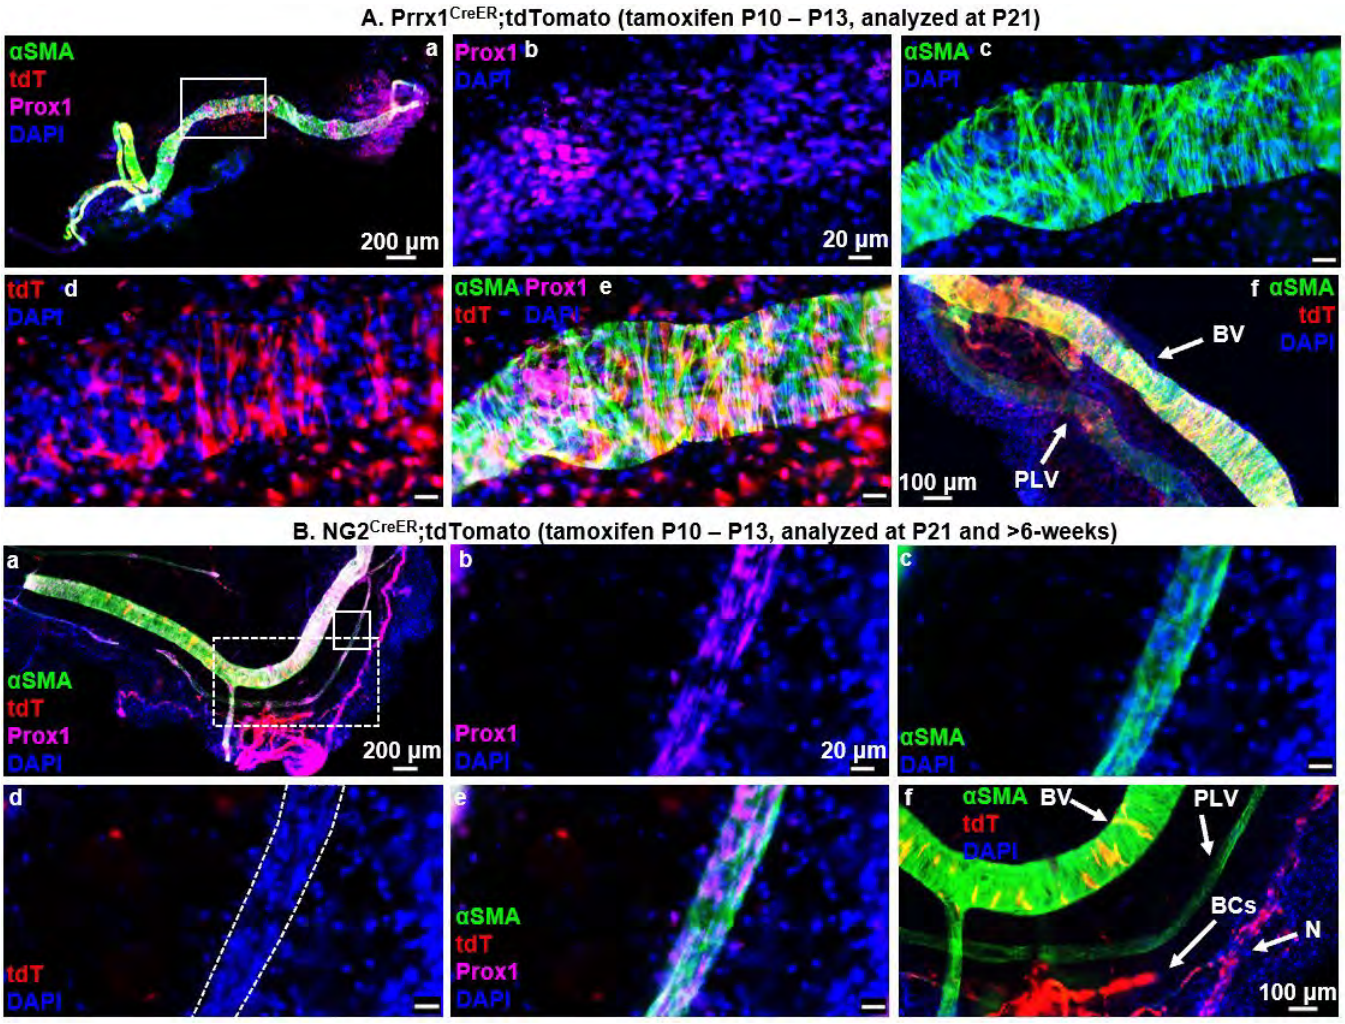

Figure 1. LMCs derive from a unique Prrx1+ and NG2- progenitor cell incorporated onto PLVs between P10 and P21. Multicolor fluorescent microscopy was performed on whole mount immunostained PLVs and adjacent blood vessels (BVs) from tamoxifen-inducible Prrx1CreER (n = 6, P21 depicted), and NG2CreER (n = 5, P90 depicted) reporter mice as described in Fig. 1. Representative low-magnification overlay images of all channels show the PLVs with a highlighted region of interest (white boxes) (A.a, B.a). High-magnification images of the region of interest show Prox1 immunostain of LECs (A.b, B.b), αSMA immunostain of LMCs (A.c, B.c), Cre-driven tdT expression (A.d,.d), overlay of all channels (A.e, B.e), and positive control BV VSMCs (A.f, B.f), blood capillary (BC) pericytes, and peripheral nerves (N) all directly adjacent to PLVs (B.f). Lineage tracing of Prrx1CreER (A.a-f) mice demonstrates tdT expression in PLVs (A.d) that colocalizes with αSMA+ LMCs (A.e) along with successful Cre-recombination with tdT expression in positive control VSMCs, as expected (A.f). NG2CreER (B.a-f) shows absent tdT expression in PLVs (no red staining in outlined PLV) (B.d) with successful tamoxifen induced NG2-driven Cre-recombination depicted by tdT expression in BV VSMCs, BC pericytes, and peripheral nerves (N), as expected (B.f). Note the few yellow VSMCs on the BV, which indicates that these cells were added to the fully formed BV after tamoxifen treatment.

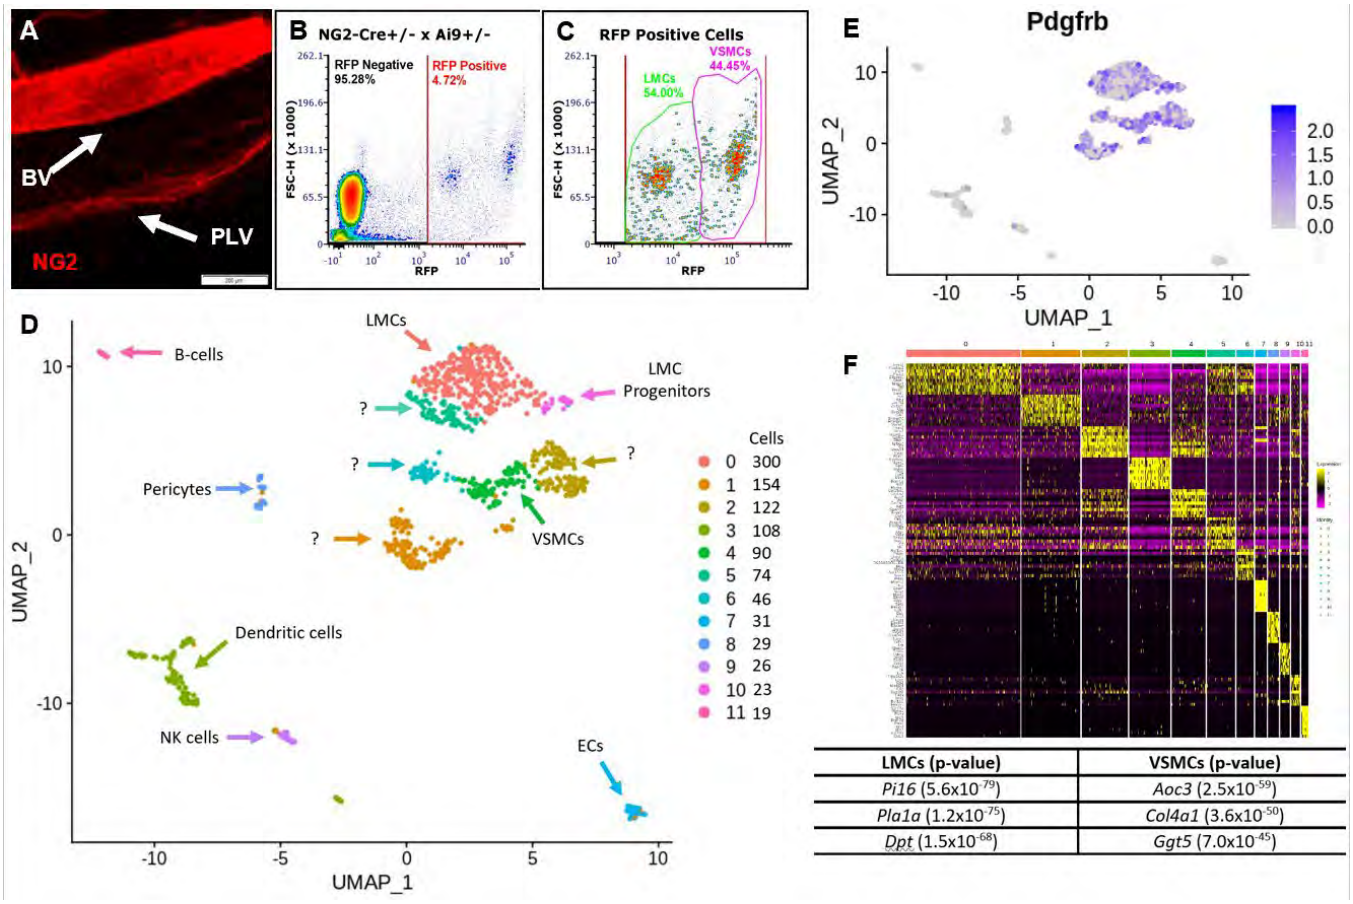

Figure 2. FACS and scRNAseq of tdT+ PLVs and BVs identifies LMC and VSMC populations. Whole mount fluorescent microscopy of PLVs and adjacent BV from NG2-Cre+/- x Ai9+/- mice revealed that both LMCs and VSMCs are RFP+, but VSMCs are much brighter than LMCs (MFI = 63.83 +/- 5.43 vs. 22.28 +/- 5.45 in arbitrary units; p<0.05 n=5 vessels) (A). A single cell suspension was prepared by pooling the lateral saphenous vein and both adjacent PLVs from both hindlegs of 3 NG2-Cre+/- x Ai9+/- mice. The cells were analyzed by FACS with ~6,000 RFP+ events/animal (B), and revealed two distinct populations based on RFP signal intensity (C), presumed to be LMCs and VSMCs based on the whole mount studies. The tdT+ sample contained 1,504 viable cells and was analyzed using scRNAseq (93,099 reads of 2,142 genes/cell with 97.2% barcode validity). UMAP was used to embed the data into 2D space and an sNN clustering algorithm resolved 12 clusters (Clusters 0-11 with cells/cluster, right; Seurat, R). Clusters were annotated using Mouse Gene Atlas, KEGG, Wiki Pathways & GO Biological Process (D). High levels of Pdgfrb expression are seen in the clusters annotated as LMCs and VSMCs validating their identification as mesenchymal muscle cells (E). A heatmap showing the ten most differentially regulated genes between each cluster identified unique muscle-defining genes between LMCs and VSMCs (F).

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Altered eicosanoids have been linked to rheumatoid arthritis (RA), suggesting an enhanced metabolization. Eicosanoid metabolism forms a complex network, involving different pathways and mediators, including oxylipins, which are known to modulate inflammation. However, the role of oxylipins in RA is still to be elucidated. This study aims to characterize oxylipins networks during the earliest phases of RA and evaluate their associations with clinical features.

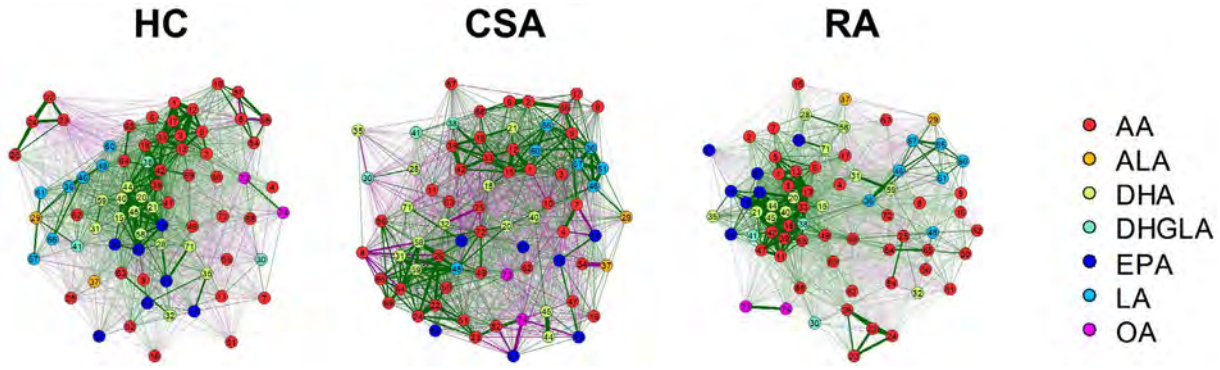

Figure 1. Network analyses based on the concentration of oxylipins in the different study groups. Each node corresponds to a single oxylipin, numbered as per the Figure legend list. Node colours represent the fatty acid precursor as follows: red (AA), green (DHA), dark blue (EPA), light blue (LA), turquoise (DHGLA), orange (ALA) (orange), magenta (OA). The lines between nodes illustrate the strength (width) and type (green: positive, red: negative) of the correlations between each pair of oxylipins. The relative position of the nodes parallels its degree of correlation that is, nodes more closely correlated locate closer to each other.

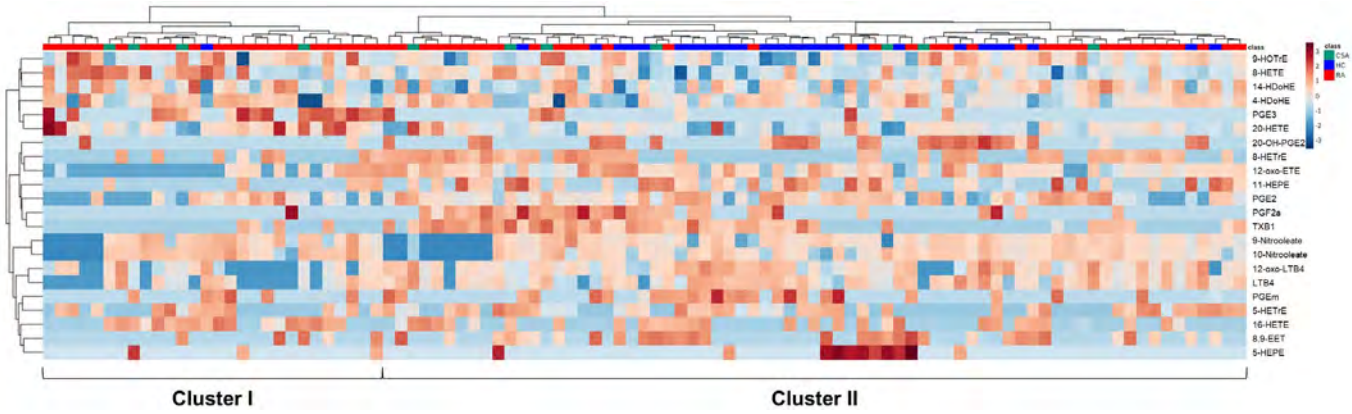

Figure 2. Heatmap and cluster analysis based on oxylipins that best separate the groups. Tiles were coloured based on concentrations, red and blue indicating high and low levels respectively, as indicated in the legend (top right). Upper bar indicates group classes (HC: blue, CSA: green, RA: red). Heatmap allowed the identification of two clusters (bottom).

Figure 3. Clinical features of RA patients based on oxylipins clusters. Variables were expressed as median (interquartile range) or n(%), unless otherwise stated. Differences were assessed by Mann-Withney or chi-square tests (or Fisher exact test, when appropriate), according to the distribution of the variables.

Methods: 60 early RA patients (2010 ACR/EULAR criteria), 11 clinically suspect arthralgia (CSA) individuals and 28 control subjects (HC) were recruited. Serum samples were collected at onset, and treatment-naïve patients (n=50) were prospectively followed-up upon csDMARD treatment.

Results: 75 oxylipins, mostly derived from arachidonic, eicosapentanoic and linoleic acids, were identified by LC-MS/MS. Differences in serum levels of 14 oxylipins across HC, CSA and RA were found, exhibiting different trajectories. Network analyses revealed strong differences in the association among oxylipins, with a clear grouping in RA and a fuzzy network with high degree and closeness found in CSA (Figure 1). PLS-DA did not provide a neat separation of groups, but cluster analysis based on oxylipins with VIP scores >1 (n=22) allowed the identification of two clusters. Cluster usage differed among groups (p=0.003) (Figure 2), and showed associations with disease severity and low rates of remission at 6 and 12 months in treatment-naïve RA (Figure 3). Pathway enrichment analyses revealed different precursors and pathways highlighting the relevance of AA and LOX pathway in CSA and RA, respectively.

Conclusion: oxylipins networks differ across stages during earliest phases of RA. Oxylipins can inform on pathways with clinical relevance for disease progression, clinical heterogeneity and treatment response.

Single-cell Profiling of Synovial Stromal Cells Reveals an Angiocrine Endothelium in Rheumatoid Arthritis

Kevin Wei[1], Ilya Korsunsky[2], Jennifer Marshall[3], Gerald Watts[4], Triin Major[3], Zhu Zhu[4], Yuhong Li[5], Christopher Buckley[6], Soumya Raychaudhuri[7] and Michael Brenner[1], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Rheumatology Research Group, Institute for Inflammation and Ageing, College of Medical and Dental Sciences, University of Birmingham, Queen Elizabeth Hospital, Birmingham, United Kingdom, [4]Brigam and Women's Hospital, Boston, [5]Brigham and Women's Hospital, Boston, [6]University of Birmingham, Birmingham, United Kingdom, [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Vascular endothelial cells that provide the structure for blood vessels have traditionally been perceived as passive, structural units that provide blood flow. We recently discovered that a key step in synovial sublining fibroblast expansion in rheumatoid arthritis (RA) is driven by endothelial-derived Notch signaling and that Notch3 blockade attenuates arthritis pathology. This observation suggests that synovial endothelial cells, rather than being passive conduits of blood flow, and orchestrate tissue remodeling through secretion of paracrine growth factors, or angiocrine factors. The goal of this study is 1) to define heterogeneity of synovial endothelial cells and 2) to identify novel angiocrine factors involved in the RA pathogenesis.

Methods: Synovial tissues were obtained from RA or osteoarthritis (OA) patients. For scRNAseq analysis, CD45- stromal cells from were subjected to droplet-based scRNAseq (10X Genomics). For bulk RNA-seq analysis of synovial endothelial cells, disaggregated synovial endothelial cells (CD45- PDPN- CD31+ CD146+) from were FACS-sorted and subjected to SMART-seq2. Confocal microscopy imaging analysis were performed to visualize protein expression of endothelial cell subset-specific markers.

Results: Synovial endothelial cell heterogeneity. We identified arterial (*PODXL*+ *NOTCH4*+), venous/capillary (*DARC*+ *CD74*+), and lymphatic (*LYVE1*+) endothelial cells as the major endothelial cell types in synovia. We identified distinct effector modules in venous/capillary and arterial endothelial cells. Whereas venous/capillary endothelial cells are characterized by high expression of genes encoding HLA class II molecules (*CD74*, *HLA-DRA*), arterial endothelial cells are the dominant cellular source of growth factors (*IGF2*, *PDGFB*) and morphogens (*DLL4*, *JAG1*).

Expansion of arterial endothelium in RA synovia. To define transcriptomic changes in RA synovial endothelial cells, we performed deep RNA-seq analysis of CD31+ CD146+ endothelial cells from RA and OA synovia. Differential gene expression analysis revealed striking upregulation of genes involved in cell adhesion (*ICAM2*, *MCAM*) and leukocyte recruitment (*CXCL12*). Interestingly, many endothelial genes upregulated in RA map to the arterial as opposed to

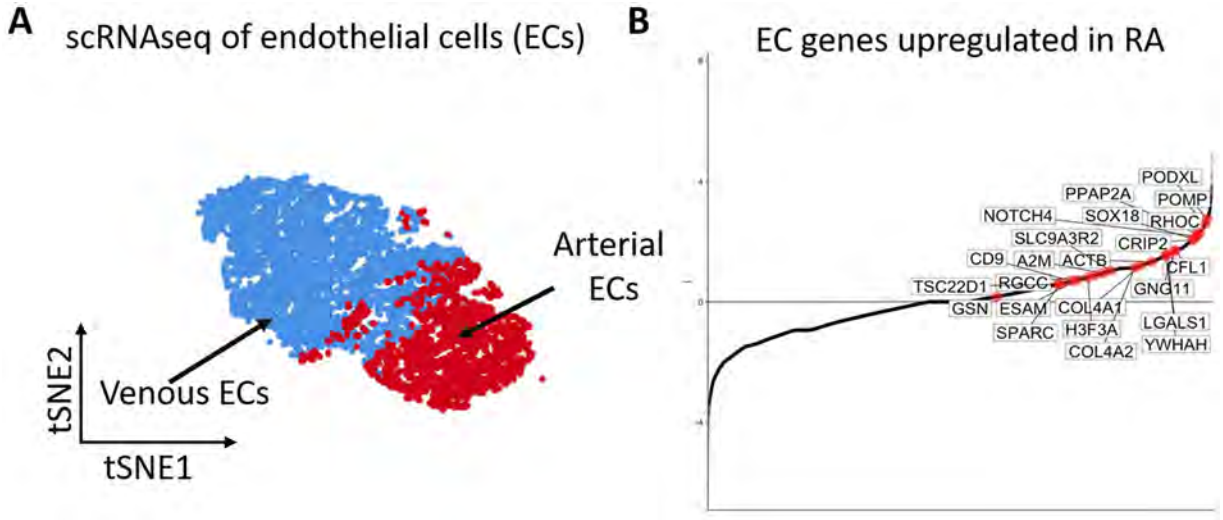

Figure 1. ScRNAseq analysis of synovial endothelial cells. A. Venous (blue) and arterial (red) endothelial cells projected in tsNE space. B. Endothelial genes upregulated in RA synovia.

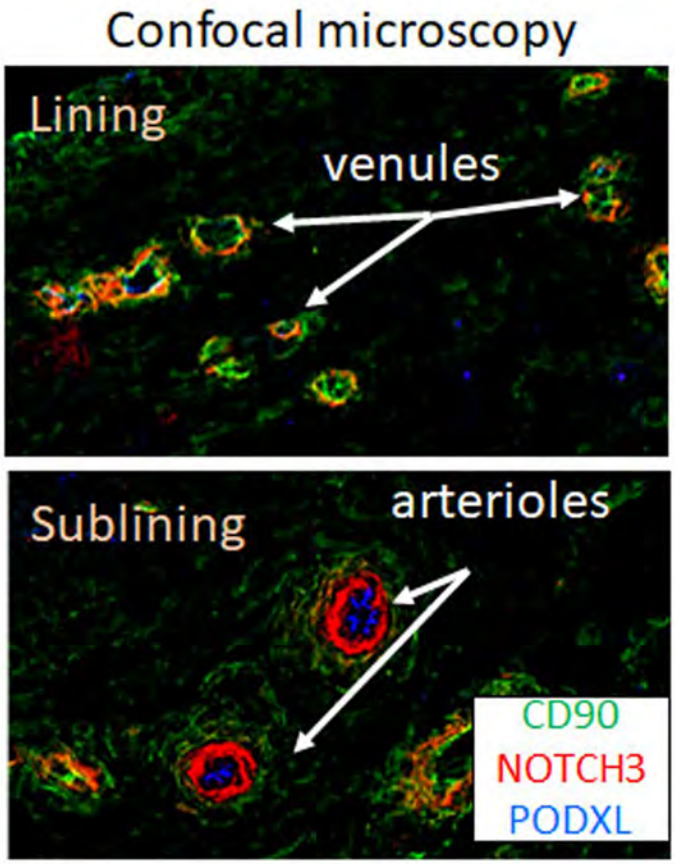

Figure 2. Representative confocal microscopy image of RA synovia endothelium network showing venules near lining and PODXL1+ arterioles in the subliing. Note Notch3 (red)+ cells near arterioles.

venous endothelial cell clusters in our scRNAseq analysis, including *NOTCH4* and *PODXL*, suggesting relative arterialization of endothelial cells in RA synovia (Fig. 1).

Arterial endothelium as the source of Notch gradient in synovial sublining. Using *PODXL* as a marker for arterial endothelial cells, we found PODXL+ endothelial cells are located deep in the synovial sublining. Spatial analysis revealed signification correlation between PODXL+ arterial endothelium and NOTCH3+ fibroblasts, suggesting arterial endothelium is the dominant source of Notch gradient driving sublining expansion in RA (Fig 2).

Conclusion: Single cell profiling of synovial endothelial cells revealed previously underappreciated transcriptomic heterogeneity that reflect distinct lineages and functional states. In RA, synovial endothelium transition towards an arterial state characterized by expression of angiocrine factors that contribute to arthritis pathology.

Mapping Oligoclonally Expanded T Cells Within the Peripheral and Synovial Immune Landscape of Untreated ACPA+ Rheumatoid Arthritis Patients at the Single Cell Level

Pascale Wehr[1], Hendrik Nel[1], Chenhao Zhou[2], Ahmed Mehdi[2], Angelika Christ[3], Helen Weedon[4], Mihir Wechalekar[5] and Ranjeny Thomas[6], [1]University of Queensland Diamantina Institute, Brisbane, Queensland, Australia, [2]University of Queensland Diamantina Institute, Brisbane, Australia, [3]University of Queensland Institute for Molecular Bioscience, Brisbane, Australia, [4]Flinders Medical Centre, Adelaide, Australia, [5]Flinders Medical Centre, Adelaide, South Australia, Australia, [6]University of Queensland Diamantina Institute and Rheumatology Department, Princess Alexandra Hospital, Brisbane – Australia., Brisbane, Australia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Clonal T cell expansions – some large – have been identified in the peripheral blood (PB) and in synovial tissue (ST) of multiple joints from recently-diagnosed rheumatoid arthritis (RA) patients. As the degree of ST clonal dominance decreased with longer disease duration, new-onset RA presents the ideal opportunity to study the transcriptome and TCRα/β of individual clonotypes. This can be achieved using single-cell RNA-sequencing, which already identified novel T cell subsets in longstanding RA. To elucidate the TCR usage and transcriptome of oligoclonally expanded T cells in the PB and ST compartments in newly-diagnosed RA, we combined TCR repertoire, clonality and transcriptomic analysis of individual ST and paired PB mononuclear cells (PBMC) in untreated HLA-DRB1*0401$^+$ ACPA$^+$ RA patients.

Methods: PBMC and whole cryopreserved ST samples were collected from 4 treatment-naïve RA patients undergoing arthroscopic synovial biopsy. CD45$^+$ leukocytes from cryopreserved PBMC, and CD45$^+$ leukocytes and CD45$^-$ fibroblasts isolated from paired disaggregated ST, by fluorescence-activated cell sorting, were sequenced using 5' RNA/TCR single-cell 10x Genomics kits. Single-cell transcriptomic analysis, using the Seurat package in R, reconstructed the compartment-specific composition of PB and ST.

Results: Myeloid cells were expanded in the ST relative to PB. Myeloid and NK cell expansion was related to arthroscopic synovitis severity. NK and B cell clusters were proportionately smaller among ST than PB leukocytes. Transcriptomics identified 10 unique $CD3^+TCR^+$ populations in PB and ST, including cytotoxic, helper and regulatory T cells. In PB, the most expanded clonotypes were $CD8^+$ and $CD4^+$ cytotoxic T cells. ST expanded clonotypes included $CD8^+$ and $CD4^+$ T cells expressing cytotoxic and multiple cytokine genes, $CD4^+$*ICOS*$^+$ T cells with evidence of IL-6 signalling, and $CD4^+$*GATA3*$^+$ tissue-resident T cells. Shared ST and PB T cell clonotypes were predominantly cytotoxic polyfunctional $CD8^+$ T cells. A proportion of PB cytotoxic clonotypes matched known EBV and CMV-reactive clones, and a proportion of shared PB/ST cytotoxic clonotypes matched CMV-reactive clones.

Conclusion: Similar T cell clusters were identified in ST and PB. Transcriptomes of non-cytotoxic expanded $CD4^+$ T cell clonotypes in the ST of untreated patients suggest B cell interaction and help. The most expanded clonotypes in circulation include T cells with cytotoxic and proinflammatory capability, including known viral-specific clones, some of which reach and expand in RA ST. Antigen derived and presented from persistent viruses may expand responsive clones to be bystander drivers of synovial inflammation.

Novel Network Tool Highlights Key Features Associated with Disease Pathotypes and Response to Treatment in Early Rheumatoid Arthritis

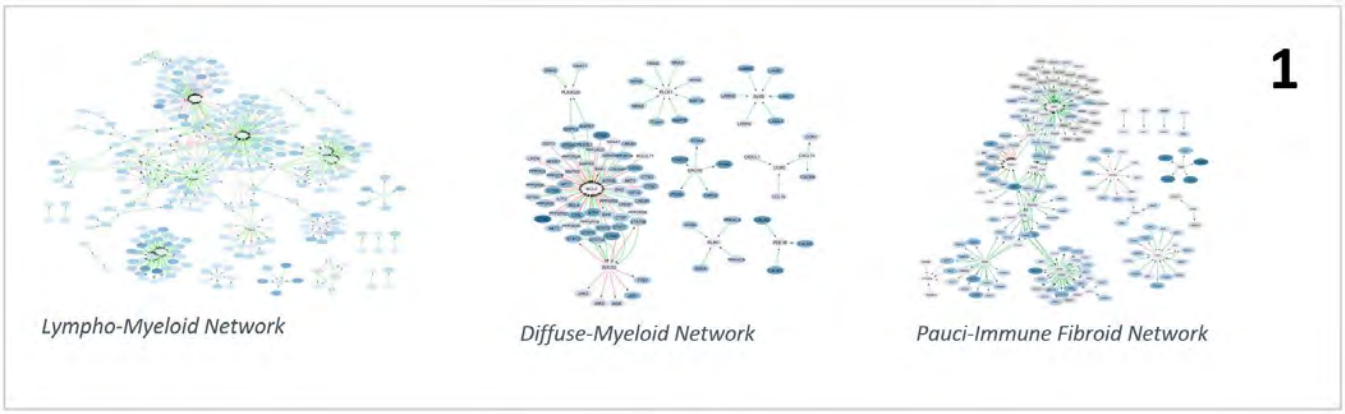
Elisabetta Sciacca[1], Anna Surace[2], Myles Lewis[1], Salvatore Alaimo[3], Vito Latora[4], Felice Rivellese[1], Alfredo Pulvirenti[3], Alfredo Ferro[3] and Costantino Pitzalis[5], [1]Centre for Experimental Medicine and Rheumatology, Queen Mary University of London, London, United Kingdom, [2]Centre for Experimental Medicine and Rheumatology, Queen Mary University of London, Liverpool, United Kingdom, [3]Bioinformatics Unit, Dept of Clinical and Experimental Medicine, University of Catania, Catania, Sicilia, Italy, [4]School of Mathematical Sciences Queen Mary, University of London, London, United Kingdom, [5]Queen Mary University of London, London, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Biomedical research uses many statistical/bioinformatics tools to find genes or proteins differentially expressed between patient group of interest. However, biological elements are related to one another in a complex network. Understanding those networks is vital to give results meaning in a disease context.

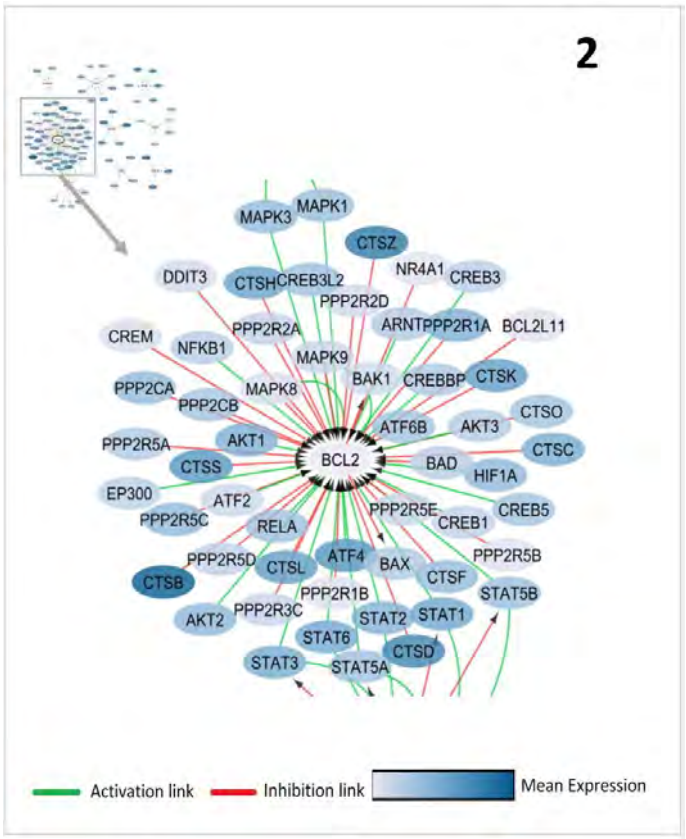
Treatment-naïve early rheumatoid arthritis (RA) patients have been described to have different histological pathotypes (lympho-myeloid, diffuse-myeloid, pauci-immune fibroid), with corresponding molecular signatures, associated with response to conventional synthetic Disease-Modifying Anti-Rheumatic Drugs (csDMARDs) [Lewis et al. 2019, Cell reports]. Purpose of this study was to use a novel pathway analysis approach to determine which gene networks are specifically activated in patients with different pathotypes or different response to csDMARDs.

Methods: We analysed RNA-Sequencing of 90 patients with early treatment-naïve RA fulfilling the 2010 ACR/EULAR Criteria recruited into the Pathobiology of Early Arthritis Cohort (PEAC). A detailed network of biological interactions



Pathotypes networks overview showing different number of nodes, edges and topology across the three groups.

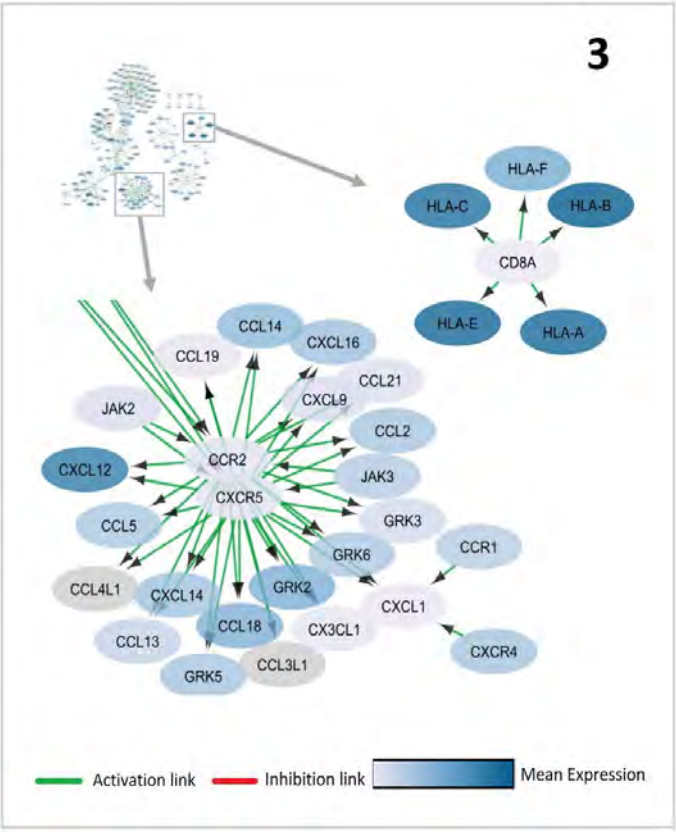
was built starting from the KEGG pathway repository and enriched with miRNA interactions from miRTarBase and



Cell survival genes in patients responding to Disease-modifying anti-rheumatic drug (DMARD) treatment.

miRecords. Interactions between transcription factors (TFs) and miRNAs were added from TransmiR.

For each category, the most active links between genes, protein, metabolites and miRNA were selected based on their RNA-Sequencing expression values. Links redundantly active in two or more categories were removed. The resulting subnetworks show interactions that are active in the selected category only.



Chemokine and T cell cluster genes activated in patients not responding to DMARD treatment.

Results: The interactions networks found for the three pathotypes showed a gene level confirmation of the above taxonomy. The lympho-myeloid pathotype network (373 activator links, 96 inhibitor links) is characterized by lymphocyte activation with NFKB and mTOR signalling and recruitment via chemokines (for example CCL5, CCL2 and CCL19). We found IL3R signalling and cell survival networks to be central in the diffuse-myeloid pathotype (20 activator links, 5 inhibitor links), while in a pauci-immune fibroid environment (430 activator links, 99 inhibitor links) remodelling of the extracellular matrix and vasculature was prominent (Fig. 1).

On one hand, patients who had a good EULAR response to csDMARDs showed cell survival networks with MAP kinase and STAT signalling around BCL2 (Fig. 2). On the other hand, non-response was linked to T cell genes and lymphocyte attraction via chemokine signalling (Fig.3).

Conclusion: Our novel approach of investigating gene networks leads to a deeper understanding of differences in disease pathotypes and response to treatment. Allowing greater insight into underlying mechanisms, it will facilitate more targeted treatment.

Session Date: Saturday, November 7, 2020

Session Title: RA – Etiology & Pathogenesis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Ectopic lymphoid structures (ELS) have been observed in synovial tissue of rheumatoid arthritis (RA) patients but their functional relevance in the disease remains unclear. Additionally, little is known about B cell activation pathways during ectopic lymphoid neogenesis (ELN). In this study, we utilized single cell RNA sequencing coupled with B cell repertoire sequencing to characterize B cell subsets that may play a role in ELN in RA synovial tissue and support local B cell activation and development of autoreactive plasma cells.

Methods: Synovial tissue was selected based on the presence of lymphocytic infiltrates by histology (n=4 RA patients). Tissue was disaggregated using protocols established by the Accelerating Medicines Partnership (AMP) consortium. scRNA-seq was performed on sorted tissue B cells using the 10x genomic platform with poly-A selected, 5' initiated expression and V(D)J libraries generated from each single cell. Transcriptomic clusters were compared using supervised classification techniques to AMP phase I RA synovial B cells (n=10), SLE kidney B cells, and blood B cells. Combined single cell repertoire/RNA sequencing from an additional 13 RA synovial samples and 10 matched blood B cells are currently under analysis in AMP phase II. In vitro studies were conducted for elucidation of signals promoting in situ B cell activation, with NR4A detected by qPCR and flow cytometry.

Results: Using single cell RNA sequencing analysis, we identified a unique B cell subset in the RA synovium characterized by high expression of NR4A1-3, a family of orphan nuclear receptors (NUR77, NURR1, and NOR1) that are induced by acute and chronic antigen stimulation in lymphocytes and function as ligand-independent transcription factors. The $NR4A^+$ B cell cluster showed evidence of somatic hypermutation (SHM) and class-switched recombination based on repertoire analysis. The rate of SHM was positively correlated with NR4A1 and NR4A2 gene expression and inversely correlated with IGHD gene expression. Gene Set Enrichment Analysis revealed that the $NR4A^+$ cluster has a transcriptomic profile between naïve and germinal center (GC) B cells sorted from tonsil and differentially expressed genes characteristic of GC centrocytes including CD83 and GPR183. In SLE kidney, and peripheral blood B cells, $NR4A^+$ B cells were reduced to 0.7% and 1.5% abundance, respectively, compared to >40% abundance in synovial tissue from AMP phase I and the 10X platform ($p< 0.001$ under logistic mixed models). NRA4 was upregulated at both the RNA and protein level upon activation through the B cell receptor in vitro. NR4A1 protein was expressed spontaneously in RA tissue B cells by flow cytometric and histologic analysis.

Conclusion: Our data suggest a dynamic progression of B cell activation in RA synovial ectopic lymphoid structures, with NR4A a potential read-out of chronic antigen activation and local adaptive immune responses.

Gasdermin D Modulates Murine Lupus and Its Associated Organ Damage

Xinghao Wang[1], Luz Blanco[2], Carmelo Carmona-Rivera[3], Shuichiro Nakabo[3], Hege Pedersen[4], Zu-Xi Yu[5] and Mariana Kaplan[3], [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Canton, MI, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Centreville, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, [5]National Heart, Lung, and Blood Institute Pathology Core, Bethesda

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Gasdermin D (GSDMD) is the key executioner of the inflammatory cell death mechanism pyroptosis. Recent reports have also implicated GSDMD in other mechanisms of cell death, including apoptosis, necroptosis, and NETosis. Given the role of dysregulated cell death in autoimmune syndromes such as systemic lupus erythematosus (SLE), we hypothesized that GSDMD would play a pathogenic role by promoting inflammatory cell death leading to increased generation of nuclear autoantigens and autoantibodies.

Methods: Methods: The imiquimod-induced model of SLE was tested in Gsdmd-/- and wild-type C57BL/6 (WT) mice. At euthanasia, mice were examined for serum autoantibodies, renal function, immune complex deposition, organ inflammation, immune dysregulation and type I Interferon responses. A pristane-induced lung injury model in Gsdmd-/- and WT C57BL/6 was used to further confirm pulmonary phenotype. Regulation of various mechanisms of cell death was investigated in the mice.

Results: Unexpectedly, Gsdmd-/- mice developed enhanced mortality, more severe renal and pulmonary inflammation, and exacerbated autoantibody production in response to TLR-7 agonists. Pulmonary involvement was also more severe in the short-term pristane model in the absence of GSDMD. Lack of GSDMD was associated with increased levels of circulating nuclear autoantigens, tissue immune complex deposition, significant expansion of myeloid cell subsets, and enhanced B cell activation and differentiation. In the absence of GSDMD, enhanced autoantigen generation was associated with increased local induction of cell death in vivo.

Conclusion: GSDMD negatively regulates autoantigen generation and immune dysregulation in response to tissue injury, and may play previously unappreciated protective roles in systemic autoimmunity.

Kidney-infiltrating T Cells in Murine Lupus Nephritis Exhibit Transcriptional Heterogeneity and Oligoclonal Expansion

Shuchi Smita[1], Minjung Kim[1], Maria Chikina[1], Mark Shlomchik[1] and **Jeremy Tilstra**[1], [1]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Lupus nephritis (LN) is a hallmark of SLE, affecting 50-60% of patients within 10 years of diagnosis. Current treatments for LN have suboptimal response rates and considerable side effects. T cells comprise the majority of infiltrating cells in LN kidney biopsies and contribute to end-organ damage in both SLE patients and murine models. Paradoxically, our recent work showed that kidney-infiltrating T cells (KITs) in murine LN exhibit classic features of T cell exhaustion, including expression of inhibitory receptors, suppressed cytokine production, reduced proliferation and altered metabolism. What remains unknown is whether KITs are a heterogenous or homogenous population. Additionally, prior work suggests that KITs are oligoclonal; however, these studies were completed using low resolution methods only assessing β-chain sequences of the T cell receptor (TCR). Thus, in this study using high throughput single cell RNAseq (scRNAseq) and TCR sequencing, we aim to more definitely define KITs in murine lupus nephritis.

Methods: To explore whether there is heterogeneity amongst KITS we performed scRNAseq using the 10X Genomics platform on flow-sorted kidney and splenic CD4 and CD8 T cells from lupus (MRL/lpr) prone mice. We completed two different comparisons in this study: the first comparing splenic T cells and KITs from MRL/lpr mice, with B6 splenocytes used as naïve controls. In the second study we evaluated KITs from 5 MRL/lpr mice using 5' libraries to obtain traditional scRNAseq transcripts along with TCR sequences, and cite-seq for PD-1 and Tim3 expression to better evaluate the exhausted T cell population. In all we obtained reads from nearly 30,000 individual cells.

Results: Despite KITs exhibiting a homogenous functional phenotype in our prior work, we found that there is significant heterogeneity in the transcriptional profile of KITs. CD8 KITs were mainly defined by four subgroups: activated (T_{EM}), exhausted (T_{EX}), tissue resident (T_{RM}), and a transitional group. Interestingly, all of these populations were transcriptionally distinct from splenic T cells. Similarly, CD4 KITs exhibited significant heterogeneity. One specific population of CD4 KITs may represent cytotoxic CD4 T cells defined by granzyme and perforin expression. Similar to the CD8 KITs, the CD4 KITs expressed more exhaustion related genes than did their splenic or naïve CD4 counterparts. Pseudotime trajectory analysis suggested that kidney infiltrating cells and specifically T_{EX} KITs could represent a terminal differentiation state. TCR sequencing analysis confirmed that there is an oligoclonal population of KITs, with single clones representing up to 10% of the CD4 or CD8 T cell compartment in a single mouse. Notably, these clones were more often associated with transcriptional clusters associated with T_{EX}.

Conclusion: These findings will improve our understanding of T cell function in lupus nephritis. We have uncovered that the KIT population is heterogenous, but also oligoclonal in nature. Furthermore, since clonal T cells are associated with an T_{EX} transcriptional profile, this supports the hypothesis that chronic antigen exposure and immune activation in the kidney drives T cell exhaustion.

Expanded T Peripheral Helper Cells and Increased Pathologic B Cell Lung Infiltration in Pristane-induced Murine Lupus in the Absence of BCL6+ Tfh Cells

Runci Wang[1], Pui Lee[2], Peter Nigrovic[3] and Deepak Rao[1], [1]Brigham and Women's Hospital, Boston, MA, [2]1. Boston Children's Hospital;2.Brigham and Women's Hospital;3.Harvard Medical School, Newton, MA, [3]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: PD-1^{hi} CXCR5^{-} T peripheral helper (Tph) cells are highly expanded in RA and SLE patients. Like T follicular helper (Tfh) cells, human Tph cells express high levels of ICOS and MAF and secrete IL-21 to facilitate B cell function. While Tfh cells depend on CXCR5 to home to follicles, Tph cells frequently express chemokine receptors that enable migration to inflamed sites. Whether Tph cells expand in murine autoimmunity models, and what the role of Tph cells is in vivo remains unknown. Further, whether Bcl6, a master regulator for Tfh cells, is necessary for Tph cells has not been established. We investigated these questions in pristane-induced lupus.

Methods: We evaluated the cellular and molecular features of Tph cells in the tissues of pristane-treated mice. C57bl6 or CD4^{cre}Bcl6$^{fl/fl}$ mice were injected with 0.4-0.5 ml pristane intraperitoneally once and harvested 2 weeks or >2 months later with age-matched controls. Tissues were processed for flow cytometry and histology.

Results: In pristane-treated mice, PD-1^{hi} CXCR5^{-} CD4^{+} T cells accumulated first in peritoneal fluid and spleen, and later in lung and peritoneal granulomas. These cells in the periphery expressed high levels of ICOS and Maf and produced IL-21, with an intermediate level of Bcl6. While lacking CXCR5, ~40% of PD-1^{hi} CXCR5^{-} T cells in pristane-treated mice expressed CXCR6 across multiple tissues. These results demonstrate that PD-1^{hi} CXCR5^{-} CD4^{+} T cells in this model closely resemble human Tph cells (Fig.1).

Accompanying Tph expansion, B cell responses were seen in pristane-treated mice. In spleen, frequencies of extrafollicular B cells, CD138^{+} plasmablasts, CD11c^{+}CD21^{-} age-associated B cells (ABC), and CD73^{+}IgD^{-} class-switched memory B cells increased, while the proportion of CD23^{hi}CD21^{+} follicular B cells decreased. The frequencies of plasmablasts, ABCs, and memory B cells also increased in lungs (Fig.2). Immunofluorescence microscopy revealed lymphoid aggregates within lungs of pristane-treated mice, which contained clusters of Tph cells and B cells.

To determine the role of Bcl6-dependent Tfh cells in this B cell response, we compared pristane-induced lupus in mice with conditional loss of Bcl6 in CD4^{+} T cells (CD4-Bcl6 KO) and littermate controls (WT). As expected, CD4-Bcl6 KO mice had reduced CXCR5^{+} Tfh cells, and also showed less expansion of extrafollicular, memory and CD138^{+} B cells in spleen, indicating a critical role for Tfh cells in B cell activation in spleen. In contrast, pristane-treated CD4-Bcl6 KO mice had increased frequencies of Tph cells, memory B cells and plasmablasts in lungs, suggesting that Tph accumulation and B cell responses within lungs can occur independently of Bcl6^{+} Tfh cells in pristane-induced lupus.

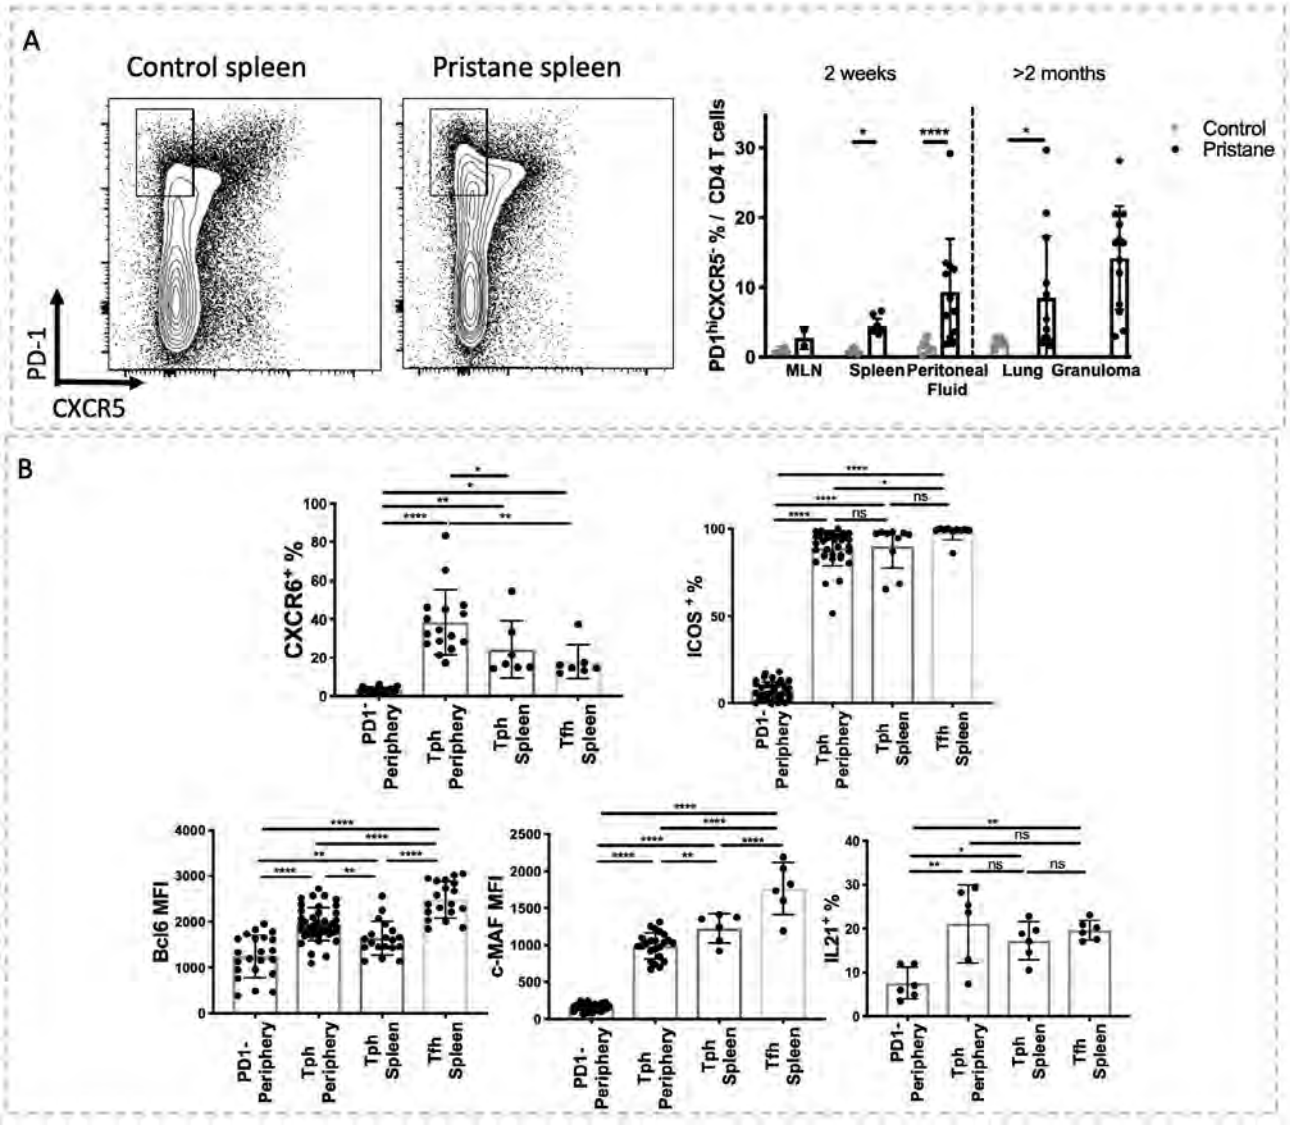

Figure 1. Expanded PD-1hiCXCR5- CD4 Tph cells in murine lupus expressed factors associated with B cell help, including ICOS, Maf and IL-21. A). PD-1hiCXCR5-CD4 T cells expanded in peritoneal fluid and spleen at 2 weeks and were found in lung and granuloma after 2 months in pristane-treated lupus mice (Mann-Whitney test, n= 5 - 13); B). CXCR6 was more frequency expressed on Tph cells in peripheral tissues (PF, lung, and granuloma) than in spleen Tph/Tfh cells and peripheral PD-1- cells; Tph and Tfh cells expressed comparable levels of ICOS, both significantly higher than PD-1-CXCR5- DN cells; Bcl6 and c-Maf were highly expressed by spleen Tfh cells, intermediately expressed by Tph cells in spleen and peripheral tissue, greater than peripheral DN cells; PD-1-, PD1hiCXCR5- Tph, PD1hiCXCR5+ Tfh cells were sorted from pristane-treated mice and stimulated in vitro; Tph and Tfh expressed higher IL-21 than PD1- cells; ordinary ANOVA. Mean±SD shown, , *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

Conclusion: Tph cells are expanded in spleen, target tissues, and ectopic lymphoid structures in pristane-treated mice. Murine Tph cells express molecules involved in B cell activation and migratory receptors distinct from Tfh cells. In the absence of Bcl6 and Tfh cells, pristane-induced lupus mice developed increased Tph cells and B cell activation in lung. These results provide the first in vivo evidence of a role for Tph cells in peripheral B cell responses in autoimmunity.

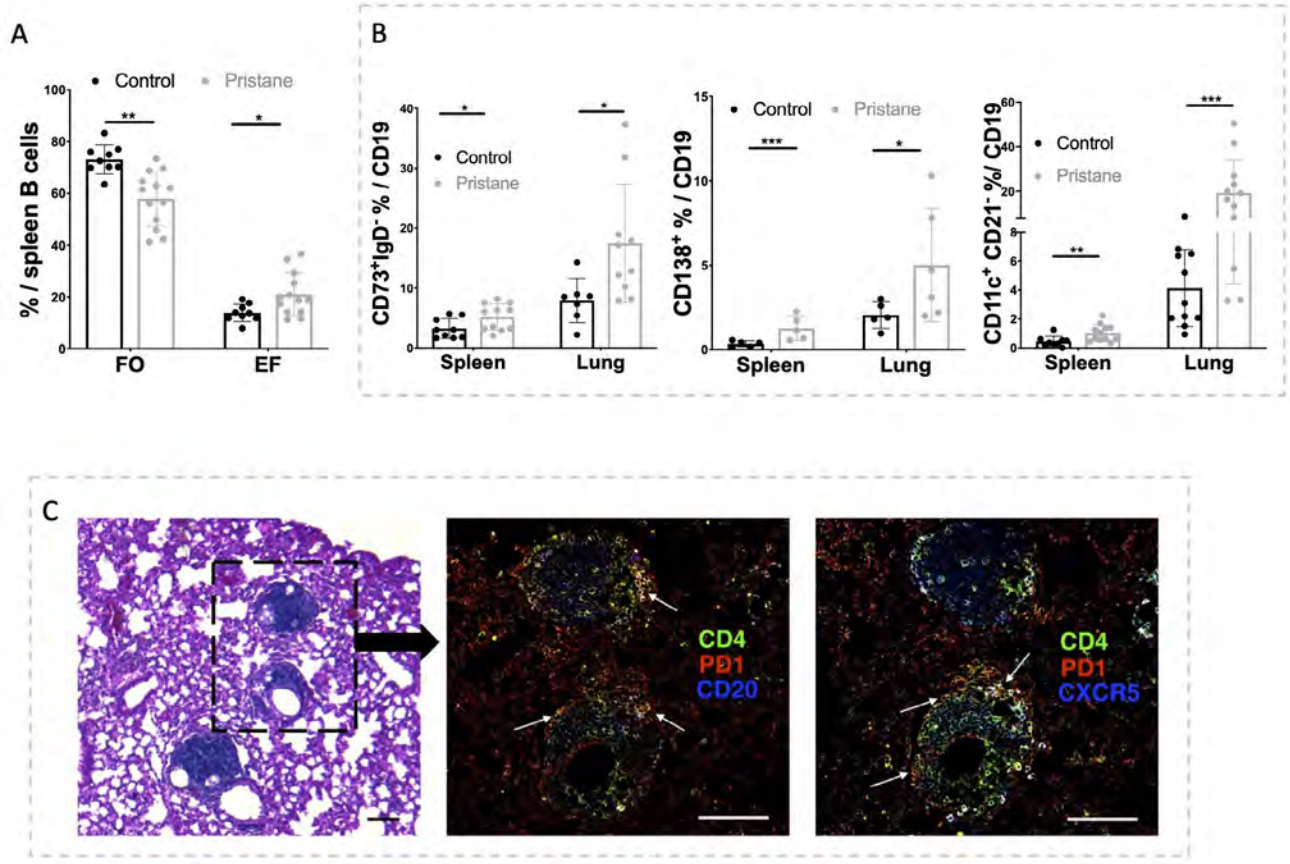

Figure 2. Pathologic B cells expanded in spleen, target organs, and ectopic lymphoid structures in pristane-treated mice. A) Increased extrafollicular B cells (mostly CD23loCD21hi marginal zone B cells) and decreased CD23hiCD21+ follicular B cells were found in the spleen of pristane-treated mice (n=9-13). B) CD11c+CD21- ABCs and CD73+IgD- class-switched memory B cells increased in PF and lung (n=6-12). CD138+ plasmablasts increased in spleen and lung (n=5-6). C) Immunofluorescence images of ectopic lymphoid aggregates in the lung of pristane-treated mice. Mean±SD shown, Mann-Whitney test, *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

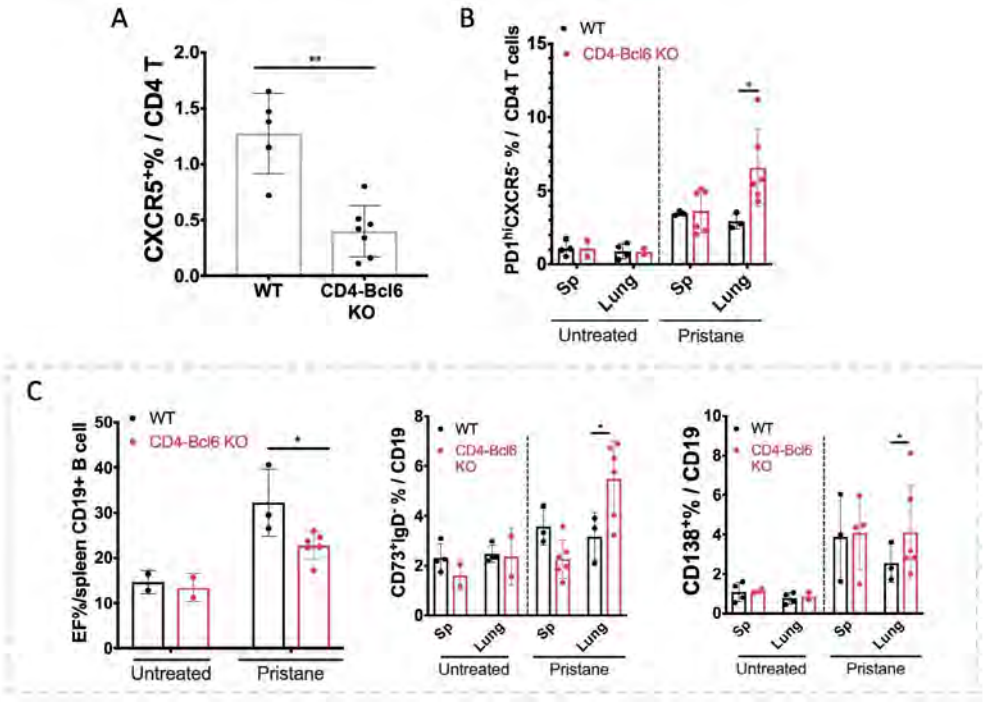

Figure 3. Pristane-treated CD4-Bcl6 KO mice had preferential expansion of Tph in the periphery with pathological B cell changes in the lung. A) Pristane-treated CD4-Bcl6 KO had decreased CXCR5+ CD4 cells compared to littermate controls; B) CD4-Bcl6 KO mice showed increased Tph expansion in lung (6% in CD4-Bcl6 KO and 3% in control) than littermate controls, with comparable Tph frequency in spleen. C) CD4-Bcl6 KO showed less expansion of extrafollicular B cells, class-switched memory B cells and CD138+ B cells in the spleen, while these populations were expanded in the lung compared to WT (n=2-6). Mean±SD shown, Mann-Whitney test, *p<0.05, **p<0.01.

Abstract Number: 0978

Border-associated Macrophages Drive Recruitment of Immune Cells into the Choroid Plexus in Mice with Neuropsychiatric Lupus

Erica Moore[1] and Chaim Putterman[1], [1]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Neuropsychiatric manifestations are observed in 20-40% of systemic lupus erythematosus patients, including cognitive deficits and affective behaviors such as anxiety and depression. Neuropsychiatric lupus (NPSLE) involves complex mechanisms that are not yet completely understood. Inflammatory mediators such as cytokines and brain-specific autoantibodies, together with compromised brain barriers including the blood brain barrier and the blood-cerebrospinal fluid barrier (formed by the choroid plexus) as the site of entry of these mediators, are thought to play an important pathogenic role. Furthermore, a leukocytic infiltration into the brain is observed in

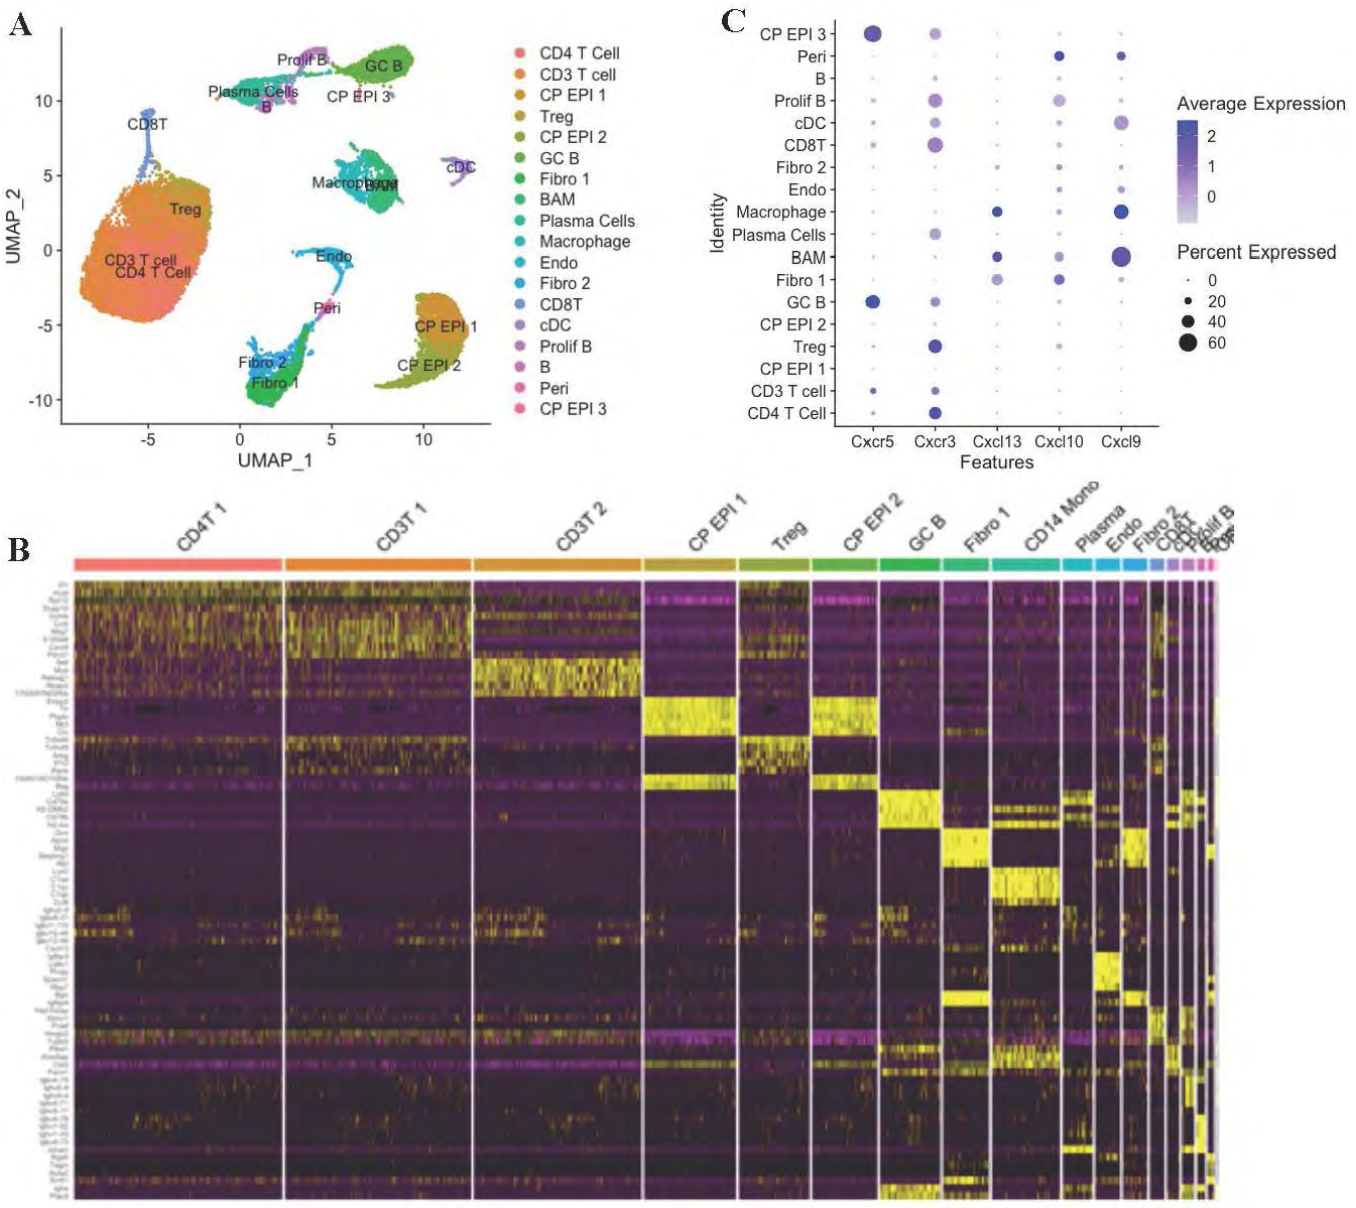

Figure 1. A) Uniformed Manifold Approximation and Projection of three 17 week old MRL/lpr choroid plexuses. B) Heatmap of top 5 significant markers in each cluster. C) Dot plot demonstrating both percentage and average expression of recruiting chemokine and cognate receptor expression. CP EPI = choroid plexus epithelial cells, Treg = T regulatory cells, GC B = germinal center B cells, Fibro = stromal fibroblast-like cells, BAM = border-associated macrophages, Endo = endothelial cells, cDC = circulating dendritic cells, Prolif B = proliferating B cells, Peri = pericytes.

both mouse NPSLE models and in some human NPSLE patients, and the resolution of this infiltration with treatment correlates with improved neuropsychiatric manifestations. Additional characterization of the choroid plexus and its cellular infiltrate was undertaken to better understand the potential contributions of B cells, T cells, and the choroid plexus to NPSLE.

Methods: The choroid plexus from 17-week old MRL/lpr mice (n=3) was excised and digested with 0.5% trypsin-EDTA. The single cell suspension was stained and subsequently sorted for live cells. Single cell immune profiling was performed with the 10X Genomics platform and the reads were sequenced with Illumina High-Seq instrument. The

transcripts were aligned using reference genome, mm10, using the CellRanger pipeline (10X Genomics). The Seurat R package and the 10X Genomics Loupe Browser were used for analysis.

Results: MRL/lpr choroid plexuses clustered into 18 unique cell clusters as depicted in Figure 1A. Preliminary characterization revealed four T cell clusters and multiple B cell subsets including germinal center B and plasma cells. Furthermore, the top 5 significant markers for each cluster is depicted by a heatmap in Figure 1B. Previous bulk RNA-sequencing revealed the upregulation of a number of germinal center-associated genes in the MRL/lpr choroid plexus including chemokines such as Cxcl9, Cxcl10, Cxcl11, and Cxcl13. We found that border-associated macrophages (BAM) and the additional macrophage cluster were the predominant sources of recruiting chemokines, particularly Cxcl9. Correspondingly, immune cells infiltrating the choroid plexus including T cells, B cells, and myeloid cells expressed the cognate receptors, Cxcr3 and Cxcr5. Further profiling of the T and B cells revealed the top BCR and TCR clones in the plasma cell and T cell clusters. The top BCR clones formed IgG2c and IgA antibodies and ranged between 15.3% to 41.1% of all B cells present in the libraries.

Conclusion: The extensive immune infiltration observed in the choroid plexus of neuropsychiatric lupus mice are potential contributors in the pathogenesis of NPSLE. Preliminary analysis reveals that border-associated macrophages contribute to the recruitment of immune cells into the choroid plexus by secreting CxCl9. Understanding the heterogeneity of brain resident and infiltrating immune cells and their transcriptomes may help identify potential therapeutic targets in NPSLE.

Abstract Number: 0979

The Identification of Shared and Unique Myeloid Cell States in Pre- and Post-nephritic Lupus Mouse Models, Sle.Yaa1 and NZBW

Paul Hoover[1], Michael Peters[2], David Lieb[3], Heather Geiger[4], Rakesh Mishra[5], Nir Hacohen[2] and Anne Davidson[6], [1]Brigham and Women's Hospital, Boston, MA, [2]Broad Institute, Boston, [3]Broad Institute, Boston, MA, [4]New York Genome Center, New York, NY, [5]Feinstein Institute, Manhasset, NY, [6]Northwell Health, New York

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Animal Models
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Poor renal prognosis in lupus nephritis (LN) is associated with an abundance of renal macrophages and dendritic cells (DCs) but the role of these cells is not well understood. Because mouse models provide a system for studying the immune response in LN, we characterized the transcriptomes of myeloid cells during pre- and post-nephritic disease in Sle.Yaa1 mice that have an extra copy of TLR7 and NZB/W mice in which an activated adaptive immune system drives disease.

Methods: We sorted PBMCs and dissociated renal cells from pre- and post-nephritic Sle.Yaa1 and NZB/W mice (3-4 per group) using (i) CD45 beads/antibodies to isolate all immune cells or (ii) CD11b/CD11c to enrich for myeloid cells. We performed single cell transcriptomic profiling using 10x genomics and analyzed droplets that contained >500 genes and UMIs after doublet removal. We performed coarse and fine clustering and differential expression

(DE) (Seurat v3.0); gene set enrichment; trajectory (analysis Monocle v2.0 and Velcyto); and integration (Harmony). We identified residential vs. infiltrating cells by co-clustering intrarenal with blood data and by using published residential and infiltration gene signatures. We further identified macrophage and DCs subsets by scoring clusters using gene signatures generated from bulk RNASeq of intrarenal myeloid cells sorted by CD11b/CD11c and F4/80 expression.

Results: Several myeloid clusters were identified using data from >5000 cells from each mouse strain. Several novel subclusters of macrophages and DCs were identified in nephritic mice. Macrophages from pre- and post-nephritic mice clustered separately. Trajectory analysis of these cells indicated the acquisition of activation and inflammatory genes in nephritic mice including IL1b, AP1 (Fos and Jun), chemokines, cytoskeleton remodeling genes and polarization towards an alternative phenotype. Loss of Mmp13 and increased Mmp12 expression further suggests acquisition of a profibrotic phenotype. Fcrl5, Fcrg4 patrolling monocytes were found only in nephritic Sle.Yaa1 mice, confirming their expansion in TLR7 overexpressing models. Putative cluster functions were based on the top DE genes and gene set enrichment: macrophages had characteristics of resident cells and were enriched for phagocytosis, lysosomal function and antigen processing/presentation whereas DCs were enriched for transendothelial migration, chemokine signaling and cell adhesion genes, all characteristics of infiltrating cells. pDCs were enriched in genes in the glycolysis pathway whereas CD103 DCs were highly enriched for genes involved in oxidative phosphorylation.

Conclusion: Resident macrophages are the major myeloid subpopulation in pre-nephritic kidneys in both models and acquire an activated and profibrotic phenotype during nephritis. Post-nephritic kidneys from both models contained novel subclusters of expanded residential and infiltrating macrophages and DCs. Only Sle.Yaa1 kidneys contained patrolling monocytes. These analyses generate new hypotheses about the development of tissue damage in lupus kidney disease and can be used to identify molecular features shared with myeloid cells from human lupus kidneys for targeted follow-up studies.

Hospitalized Infections in Lupus: A Nationwide Study of Types of Infections, Time-trends, Healthcare Utilization and In-Hospital Mortality

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes I: Morbidity
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: To examine the time-trends in hospitalized infections in lupus and the factors associated with healthcare utilization and in-hospital mortality.

Methods: We used the U.S. National Inpatient Sample data from 1998-2016 to examine the epidemiology, time-trends and outcomes of five, common hospitalized infections in people with lupus, namely, pneumonia, sepsis/bacteremia, urinary tract infection (UTI), skin and soft tissue infections (SSTI) and opportunistic infections (OI). Time-trends were compared using the Cochran Armitage test. Multivariable-adjusted logistic regression models examined

Table 2. Multivariable-adjusted correlates of healthcare utilization and mortality for hospitalized infections in lupus

infection, and lowest income quartile for 30% . The lowest income quartile accounted for a third of all lupus and lupus with primary infection hospitalizations.

Hospitalization for any of these 5 infections (composite) increased from 10.7% of all lupus hospitalizations in 1998-2000 to 15.6% in 2015-16 (10,748 vs. 15,645 per 100,000). The corresponding rate of composite infection in the general NIS population increased from 5.8% in 1998-2000 to 10.2% in 2015-16 (5,836 vs. 10,171 per 100,000).

The hospitalization rate /100,000 claims in 1998-2000 versus 2015-2016 (and increase) were as follows: OI, 1.13 vs. 1.61 (1.2-fold); SSTI, 4.78 versus 12.2 (2.5-fold); UTI, 1.94 versus 6.12 (3.2-fold); pneumonia, 15.09 vs. 17.05

Figure 1. Time-trends in the rates of various infections in people with lupus with varying denominator of total NIS claims (A) or total lupus claims (B)

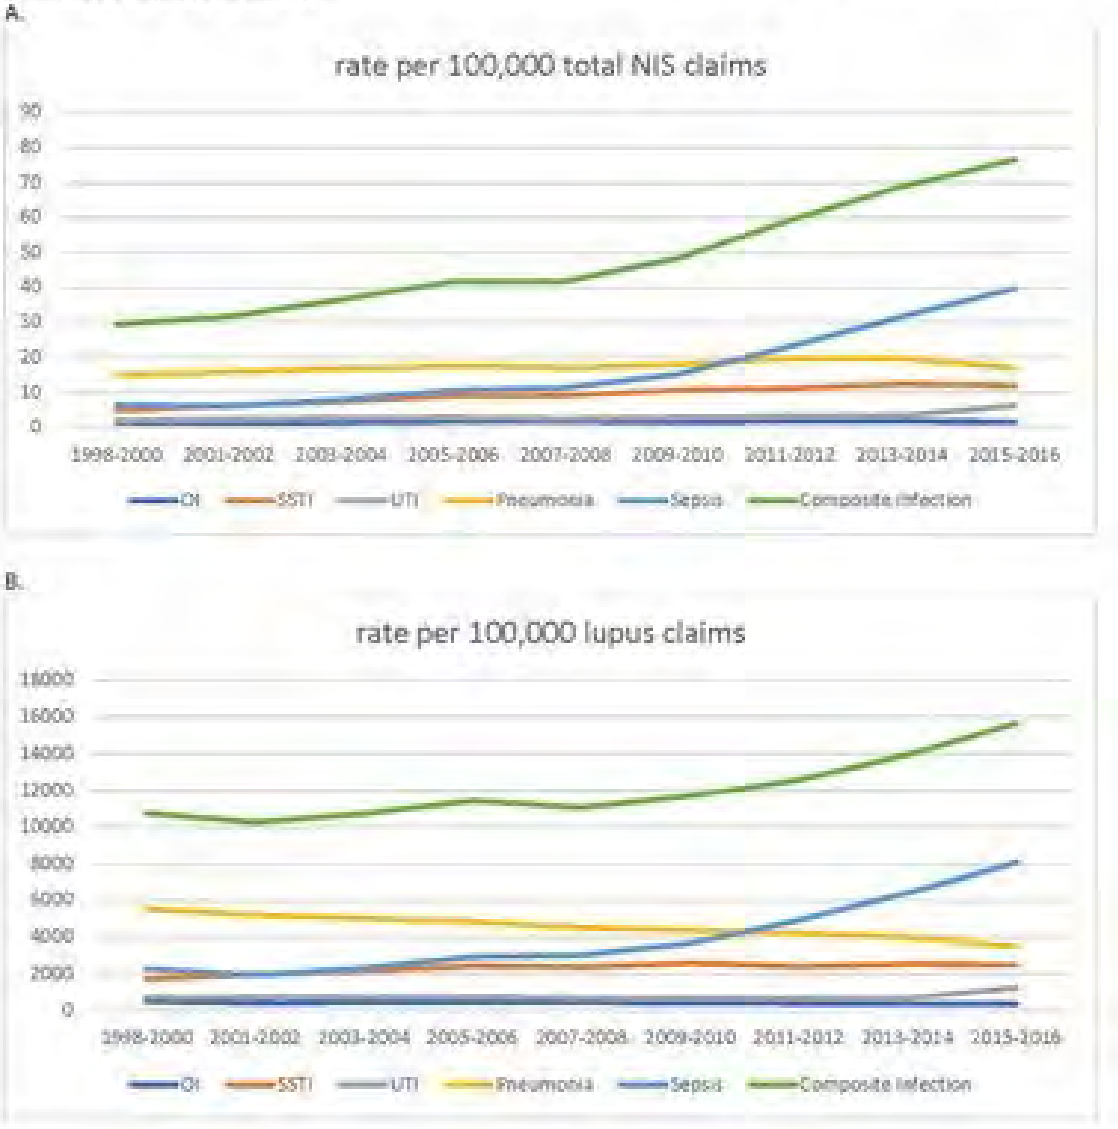

Figure legend
Infection rates are per 100,000 NIS claims (A) and per 100,000 lupus claims (B). The y-axis scales are different for the two panels. The x-axis shows study time-periods from 1998 to 2016

Figure 1. title. Time-trends in the rates of various infections in people with lupus with varying denominator of total National Inpatient Sample claims (A) or total lupus claims (B) Figure 1 legend Infection rates are per 100,000 NIS claims (A) and per 100,000 lupus claims (B). The y-axis scales are different for the two panels. The x-axis shows study time-periods from 1998 to 2016

(1.1-fold); and sepsis, 6.31 vs. 39.64 (6.3-fold; **Figure 1**). In 2011-12, sepsis surpassed pneumonia as the most common hospitalized infection in people with lupus. In multivariable-adjusted models, sepsis diagnosis, older age, Deyo-Charlson score ≥2, Medicare or Medicaid insurance, and urban hospital location were significantly associated with increased odds of in-hospital mortality and all healthcare utilization outcomes; and the black race was significantly associated with increased odds of healthcare utilization (**Table 2**).

Conclusion: Our study found increasing rates of hospitalized infections in lupus over time, and the surpassing of pneumonia by sepsis as the most common infection. We identified risk factors associated with poorer healthcare utilization outcomes and in-hospital mortality. These findings can inform patients, providers and policy-makers regarding lupus infection burden and lead to interventions/pathways to improve outcomes.

Mortality Among Minority Populations with Systemic Lupus Erythematosus, Including Asian and Hispanic Status: The California Lupus Surveillance Project, 2007-2017

Milena Gianfrancesco[1], Maria Dall'Era[2], Louise Murphy[3], Charles Helmick[3], Jing Li[1], Stephanie Rush[1], Laura Trupin[1] and Jinoos Yazdany[4], [1]University of California, San Francisco, San Francisco, CA, [2]Division of Rheumatology, University of California, San Francisco, CA, [3]Centers for Disease Control and Prevention, Atlanta, GA, [4]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes I: Morbidity
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease with manifestations that vary widely in severity. Contemporary data indicate that minority populations are at higher risk of developing SLE and have more severe outcomes. However, population-based estimates of mortality by race and ethnicity are lacking, particularly for Asians and Hispanics.

Methods: The California Lupus Surveillance Project identified potential SLE cases using community rheumatology and nephrology clinics, community hospitals, and integrated healthcare systems among individuals who were residents of San Francisco County, CA during January 1, 2007 – December 31, 2009. SLE cases were defined as using American College of Rheumatology Classification Criteria (≥4 of the 11 revised criteria as defined in 1982 and updated in 1997) or two alternative definitions: SLE diagnosed by the patient's treating rheumatologist plus 3 ACR criteria; or lupus-related kidney disease (World Health Organization class II-VI lupus nephritis upon biopsy or documented record of SLE diagnosis and dialysis or renal transplantation). Cases were matched to the 2007-2017 National Death Index (NDI) data to measure SLE mortality by age, sex, race and ethnicity. Multivariable risk ratios estimated the association between race and Hispanic/Latino ethnicity with mortality, adjusting for age, sex and years since diagnosis. Standardized mortality ratios (SMRs) estimated observed versus expected deaths by age group, sex, race and Hispanic/Latino ethnicity.

Results: Of the 812 SLE cases analyzed, 90% were female; 38% were white, 20% black, 36% Asian, and 5% mixed/other race; and 17% were Hispanic/Latino. 135 deaths (16.6%) were identified. Mean age at diagnosis among all SLE cases was 34.9 (±15.9) years, and mean age at death was 62.0 (±15.8) years. Mortality increased with older age; among racial/ethnic groups, blacks had the highest percent mortality (25.0%) and a significantly increased risk of mortality after adjusting for age group, sex, ethnicity and disease duration (Table 1). There were no differences in mortality by sex or Hispanic/Latino ethnicity. On average, black individuals died 6.8 years earlier than whites; individuals of Hispanic/Latino ethnicity died 9.5 years earlier than non-Hispanic/Latinos.

Overall, SMRs were three times higher among SLE cases than in the general population of San Francisco County (Table 2). SMRs for those with SLE were four times higher for females, Asians and Hispanic/Latinos, three times higher for males, and two times higher for whites and blacks compared with their non-SLE counterparts. Among females, SMRs were exceptionally high for Asians (4.1) and Hispanic/Latinas (5.8).

Table 1. Factors associated with mortality among cases of systemic lupus erythematosus (SLE) from 2007-2017 – California Lupus Surveillance Project†

Table 2. Standardized mortality ratios* for cases of systemic lupus erythematosus (SLE) from 2007-2017, age-standardized†, by sex, race§, and Hispanic/Latino ethnicity¶ – California Lupus Surveillance Project

Characteristic	Standardized mortality ratio (95% CI)
Overall	3.0 (2.5, 3.5)
Sex	
Female	3.8 (3.1, 4.5)
Male	2.9 (1.7, 4.7)
Race	
White	2.3 (1.6, 3.0)
Black	2.0 (1.4, 2.7)
Asian	3.8 (2.7, 5.0)
Ethnicity	
Hispanic/Latino	3.9 (2.4, 6.1)
Race for females**	
White females	2.9 (2.1, 3.9)
Black females	2.5 (1.8, 3.4)
Asian females	4.1 (2.9, 5.7)
Ethnicity for females**	
Hispanic/Latina females	5.8 (3.5, 9.2)

Conclusion: These findings provide the first population-based estimates of mortality among Asians and Hispanic/Latinos with SLE and suggest that public health programs and clinical practices targeting the health and maintenance of low disease activity within these populations are needed to reduce mortality.

Disclaimer: The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention.

CI = Confidence Interval * Population estimates by age group, sex, race, and ethnicity for San Francisco County from 2007-2017 were obtained from the CDC Wonder database (https://wonder.cdc.gov): Centers for Disease Control and Prevention, National Center for Health Statistics. Underlying Cause of Death 1999-2018 on CDC WONDER Online Database, released in 2020. Data are from the Multiple Cause of Death Files, 1999-2018, as compiled from data provided by the 57 vital statistics jurisdictions through the Vital Statistics Cooperative Program. Accessed at http://wonder.cdc.gov/ucd-icd10.html on Mar 21, 2020 6:24:20 PM † Risk ratios estimated using a multivariable Poisson model that modeled sex, age category, race (white, black, Asian, other), ethnicity (non-Hispanic/Latino, Hispanic/Latino) simultaneously, adjusting for years since diagnosis. A total of 104 cases were excluded from the multivariable model: 19 cases were missing race information, including two who died, and 85 cases were missing Hispanic/Latino ethnicity status, including four who died. § Hispanic/Latino ethnicity is considered a distinct concept from race, therefore it was collected and reported separately from race.

CI = Confidence Interval * The standardized mortality ratio is a ratio between the observed number of deaths in those with SLE and the number of deaths expected, based on age groups defined in the CDC Wonder Database. Sex, race and Hispanic/Latino ethnicity specific rates in San Francisco County were used, depending on the particular characteristic examined. CIs are calculated for each estimated SMR by assuming a Poisson process. †Age in 2008 was used for adjustment. §Forty-one cases were excluded from race-specific analyses, including four who died: 22 cases had missing race information and 19 cases identified as a race other than white, black or Asian, for which estimates are not available through the CDC Wonder Database. ¶Eighty-five cases who were missing Hispanic/Latino ethnicity status, including four who died, were excluded from ethnicity-specific estimates. ** For female-specific race and ethnicity analyses, crude rates for age group < 15 years were not provided by the CDC Wonder Database or were unreliable and therefore not included in calculations; there was insufficient sample size to generate specific race/ethnic estimates for men.

RSID = Rapid Stain Identification; CHR = Chromosome; BP = Base Pair; CI = Confidence Interval; MAF = Minor Allele Frequency

Background/Purpose: Genetics have been shown to contribute to risk of avascular necrosis (AVN), a debilitating complication of systemic lupus erythematosus (SLE). Our aim was to identify genetic risk loci for AVN in people with childhood-onset (cSLE) and adult-onset SLE (aSLE).

Methods: The study consisted of patients with SLE from two tertiary care centres. Participants all met ≥4 of the ACR/SLICC classification criteria for SLE. All participants had prospectively collected clinical data and were genotyped on the Illumina multiethnic array. Ungenotyped SNPs were imputed and ancestry was inferred using principal components (PCs) (1000 Genomes Project reference). The outcome was defined as symptomatic AVN confirmed by imaging (radiograph, CT, bone scan and/or MRI). GWAS of AVN using both time-to-event analysis and logistic regression were conducted with follow-up truncated at 20 years. Models were adjusted for sex, age of SLE diagnosis, cSLE vs. aSLE, PCs, lupus nephritis status, exposure to high dose glucocorticoids, and time from SLE diagnosis to first clinic appointment. High dose glucocorticoids were defined as ≥40 mg/day or ≥2 mg/kg body weight per day (for pediatrics) for at least 30 days. A genome-wide significance threshold ($p< 5x10^{-8}$) was used to indicate statistical significance.

Results: The cohort included 940 individuals with SLE (56% cSLE). The median age of SLE diagnosis was 16.9 years (IQR=15.8) and 87% were female. 71 patients (8%) had imaging-confirmed AVN. Among AVN cases, 82% met the definition for high-dose glucocorticoid exposure compared to 46% of non-AVN patients. In the multivariate time-to-event GWAS, 11 SNPs met the genome-wide significance threshold. The hazard ratios for these significant SNPs ranged from 3.0 (95%CI: 2.4, 4.0) to 26.1 (95% CI: 8.6, 79.5) (Table). These SNPs represented 6 independent loci predictive of earlier AVNinkage disequilibrium < 0.8), with minor allele frequencies (MAF) from 1-18%. Of these SNPs, 3 were linked with genes: *WIPF1*, *TMEM74*, and *LOC105375976*. No SNPs met genome-wide significance in multivariate logistic GWAS with AVN.

Conclusion: Six independent SNPs were found to be significantly associated with decreased time to AVN, in children and adults with SLE. All variants were rare (MAF< 0.05) with the exception of rs34118383 (Chr2), an intronic variant of

the *WIPF1* gene (MAF=0.18). *WIPF1* encodes a protein essential in the formation of podosomes, actin-rich adhesive structures which are necessary for osteoclast-mediated bone resorption. *TMEM74* is involved in the induction of autophagy, a form of programmed cell death, which is necessary for osteoblast and osteoclast homeostasis. These SNPs have not been previously associated with AVN-risk in SLE or non-SLE populations. Future studies are required to replicate these findings in independent cohorts.

Outcomes Following Antimalarial Withdrawal in Patients with Quiescent Systemic Lupus Erythematosus

Danae Papachristos[1], Dafna Gladman[2], Jiandong Su[3] and Murray Urowitz[4], [1]University Health Network, Toronto, ON, Canada, [2]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [4]University Health Network, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes I: Morbidity
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Antimalarial medications (AMs) are central to the management of SLE, affording numerous clinical benefits including the reduction of disease flare. However, little is known about the effects of AM withdrawal in patients who have achieved prolonged disease quiescence. We aimed to investigate the rate of flare in lupus patients who withdrew their AM after achieving clinical remission for at least one year, compared to those who continued therapy. Furthermore, we aimed to compare flare rates in cases who tapered AM versus abruptly withdrew.

Methods: Using the University Lupus Clinic long-term observational cohort study database, we identified 1573 lupus patients ever treated with AM. Cases were defined as those who achieved clinical remission for at least one year then ceased their AM (n = 165). Index date was defined as the date of complete AM cessation. Controls were defined as patients who achieved clinical remission for at least one year and continued AM. Controls were matched according to the duration of antimalarial therapy before the start of clinical remission and the duration of therapy from remission date to case index date (Figure 1). All patients were required to have at least two years of follow up. Of 96 cases with adequate follow up, 88 were successfully matched to one control and 85 to a second control, resulting in a near 1:2 match. In total, there were 88 cases and 173 controls.

Results: Patient characteristics for cases (withdrew AM) and controls (continued AM) are presented in Table 1. Disease flare occurred in 61.4% of cases compared to 45.1% of controls (p = 0.002, Figure 2). The most common types of flare were skin and musculoskeletal flares. Reasons for AM withdrawal included self-cessation (feeling well, pregnancy, medication concerns), toxicity (retinal, mucocutaneous, cardiac), disease quiescence or other reasons such as side effects requiring investigation. Retinal toxicity as defined by the SLICC damage index occurred in 1.9% of patients. Over half of patients who withdrew AM later restarted it, typically due to disease flare. Following recommencement for flare, most patients (88%) recaptured control or improved, while 12% had further flares. Regarding

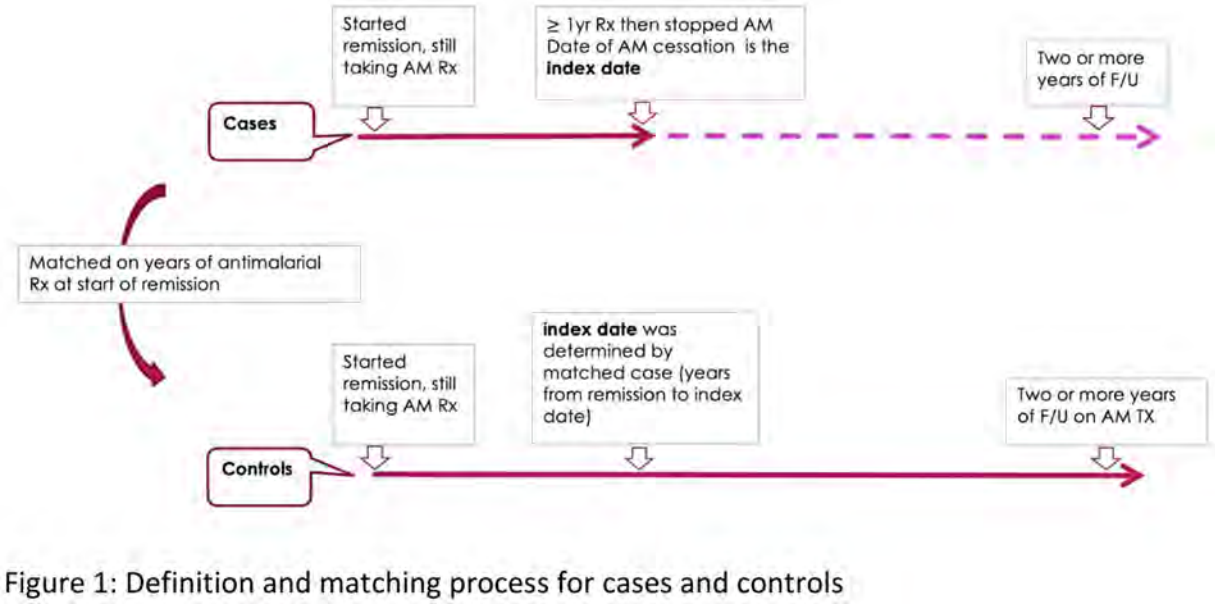

Figure 1. Definition and matching process for cases and controls

patients who withdrew AM, 42% tapered and 58% ceased abruptly (Table 1). The median duration (months) spent on AM from one year after clinical remission to cessation was expectedly longer in the taper group (29.2 months) compared to the abrupt withdrawal group (11.2 months). Patients who tapered had significantly fewer flares (45.9%), similar to the rate for controls (45.1%), when compared to those who withdrew abruptly (72.6%; $p = 0.01$, Figure 2). Additionally, fewer patients in the taper group restarted AM following cessation (37.8%) compared to the abrupt withdrawal group (62.7%; $p = 0.02$).

Conclusion: Antimalarial medications aid in preventing disease flare even in patients who have achieved prolonged clinical remission. For those who withdraw therapy, tapering results in lower rates of disease flare, similar to those seen in patients who continue AMs. Hence, except in the setting of toxicity, cessation of antimalarial therapy in patients with prolonged disease quiescence is feasible using a slow taper.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes I: Morbidity
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Disparities have been reported during the coronavirus disease (COVID-19) outbreak. Systemic lupus erythematosus (SLE) patients represent a unique group that is affected by clinical, treatment, demographic, and socioeconomic (SES) risk factors for severe COVID-19 disease. The Neighborhood Deprivation Index has been associated with non-communicable disease as well as communicable disease outcomes. We conducted this study to identify neighborhood SES factors influencing SLE COVID-19 outcomes.

Methods: Patients with SLE and COVID-19 (confirmed by RT-PCR testing), were identified through a longitudinal survey of an established NYU lupus cohort, query of NYU Langone Health and Bellevue Hospitals systems and referrals from rheumatologists at those institutions. All patients were age 18 or older and met SLE classification criteria or carried a clinical diagnosis of SLE. Baseline characteristics along with zip code neighborhood data including COVID-19 case rates and neighborhood characteristics were obtained using the Hopkins COVID database and the American Community Surveys (ACS 2014-2018) respectively. A principal component analysis was performed to identify contributory neighborhood characteristics. Then a logistic regression analysis identified predictors of testing positive for COVID-19 and COVID-19 hospitalization.

Results: A total of 59 SLE patients (41+ and 18-) were tested for COVID-19 by RT-PCR. The patients were predominantly female, aged 46±16, and racially/ethnically diverse. Roughly 140 neighborhood data points were recorded and categorized as follows: population density, race and ethnicity, household type, household size, education level, employment type and status, income and poverty, transportation method, and insurance status. COVID-19 positive patients tended to live in neighborhoods with more single parent households, households with >4 residents, higher unemployment rate, higher high school dropout rate, more public transit use, and more employment in retail, construction, and personal care services. These variables were directly proportional to principal component 1 (PC1) and accounted for 88% of the variance in neighborhood characteristics. A logistic regression model identified that PC1 (OR= 1.3; 95% CI: 1.0-1.8) and taking immune suppressants (IS) (taking vs not taking OR= 2.1; 95% CI: 1.5 to 23.3) independently correlated with having a positive COVID-19 test when controlling for hydroxychloroquine (HCQ), glucocorticoids (GC), and previous lupus nephritis (LN). Only PC1 independently correlated with COVID-19 hospitalization (OR= 1.4; 95% CI: 1.1-1.9) upon controlling for taking IS, HCQ, GCs, and LN. PC1 associated with African American (AA) or Hispanic patient race/ethnicity (OR= 1.6, 95% CI: 1.2-2.2).

SLE Patients	COVID-19 + (N = 41)	COVID-19- (N = 18)	P-value*
Age	47.0 ± 17.2	45.8 ±12.4	0.78
Gender			0.25
Female	38 (93%)	18 (100%)	
Male	3 (7%)	0 (0%)	
Race			0.48
African American	14 (34.2%)	4 (22.2%)	
White	18 (44%)	8 (44.4%)	
Asian	3 (7.3%)	2 (11.1%)	
Hispanic Ethnicity	15 (37%)	5 (28%)	0.5
SLE Risk Factors			
History of LN	14 (34%)	3 (17%)	0.18
Medications			
Hydroxychloroquine	32 (78.0%)	14 (78.0%)	0.98
Systemic steroids	20 (49%)	5 (28%)	0.25
Immunosuppressants‡	24 (59%)	4 (22%)	0.01

Values are expressed as % (N) for categorical variables and mean ± standard deviation (SD) or median (interquartile range [IQR]) for continuous variables. Categorical variables compared using Fisher's exact test; continuous variables compared using the two-sample T-test or Mann Whitney U Test. Immunosuppressants include non-biologic agents (azathioprine, cyclophosphamide, mycophenolate mofetil, mycophenolic acid, sirolimus, tacrolimus) and biologic agents (anakinra, abatacept, belimumab, rituximab, tocilizumab).

Conclusion: In addition to SLE disease, neighborhood characteristics and SES are important risk factors both for contracting COVID-19 and developing severe disease. Neighborhood deprivation may mediate the reported relationship between AA and Hispanic race/ethnicity and COVID-19. Given that a plurality of SLE patients are of AA and/or Hispanic backgrounds, care teams must formulate strategies to address socioeconomic stress in our patients.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: SLE – Treatment

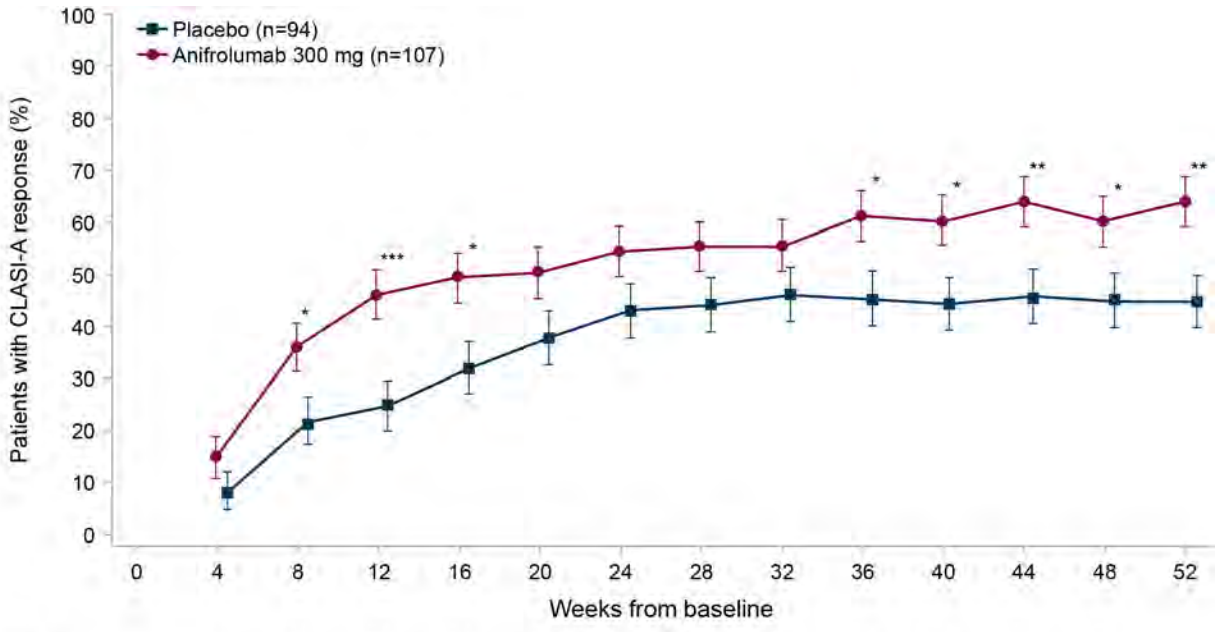
Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Up to 85% of patients with SLE experience skin disease.[1] The Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) is a validated index to measure skin disease severity; activity scores (CLASI-A) range from 0 (mild) to 70 (severe) and include measures for erythema, scale/hypertrophy, mucous membrane lesions, recent hair loss, and nonscarring alopecia. In the phase 3 TULIP-1 and -2 trials of patients with SLE, a greater proportion of patients with CLASI-A ≥10 at baseline achieved ≥50% CLASI-A reduction at Week 12 with anifrolumab compared with placebo.[2,3] We further evaluated the effect of anifrolumab on skin-specific SLE disease activity using data pooled from TULIP-1 and -2.

Methods: TULIP-1 and -2 were 52-week, randomized, double-blind, placebo-controlled trials that evaluated the efficacy and safety of anifrolumab (300 mg IV every 4 weeks for 48 weeks) in patients with moderately to severely active SLE despite standard-of-care treatment. TULIP-1 and -2 were analyzed separately using restricted medication rules per the TULIP-2 protocol, and data from both trials were pooled. We compared skin responses over time in patients receiving anifrolumab vs placebo. A CLASI-A response was defined as ≥50% reduction of CLASI-A from baseline for patients with CLASI-A ≥10. Baseline CLASI-A >0 as well as ≥75% reduction were also evaluated. Time to CLASI-A response sustained to Week 52 was evaluated using a Cox proportional hazards model.

Results: In total, 360 patients received anifrolumab and 366 received placebo. At baseline, 95.9% (696/726) of patients had CLASI-A >0, and 27.7% (201/726) had CLASI-A ≥10 (balanced between groups). In the subgroup of patients with baseline CLASI-A ≥10, CLASI-A response (≥50% reduction) was achieved by Week 12 in 46.0% (49/107) of patients receiving anifrolumab vs 24.9% (24/94) receiving placebo (difference 21.0; 95% CI 8.1%, 34.0%; nominal $P< 0.001$) (**Figure 1**). Separation between treatment groups was observed as early as Week 8 (difference 14.3; 95%



CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; CLASI-A, CLASI activity score; n, number of patients in analysis; OCS, oral corticosteroids.
Points are estimates and bars are standard errors. A response is defined as ≥50% reduction in CLASI-A from baseline for patients with baseline CLASI-A ≥10. Responder rates are calculated using a stratified Cochran–Mantel–Haenszel approach, with stratification factors SLEDAI-2K score at screening, Day 1 OCS dosage, type I IFN gene signature test result at screening, and study (TULIP-1 and TULIP-2).
Nominal *P*-values are presented,**P*<0.05; ***P*<0.01; ****P*<0.001.

Figure 1. Percentage of Patients With CLASI-A ≥10 at Baseline Achieving ≥50% Reduction in CLASI-A From Baseline Over Time in Pooled Data From the TULIP-1 and TULIP-2 Trials

CI 1.8%, 26.9%; nominal *P*< 0.02) (**Figure 1**). Time to CLASI-A response sustained to Week 52 favored anifrolumab in TULIP-1 (hazard ratio [HR] 1.91; 95% CI 1.14, 3.27) and TULIP-2 (HR 1.55; 95% CI 0.87, 2.85) (**Figure 2**). Of the subgroup of patients with baseline CLASI-A >0, a greater number of patients achieved a CLASI-A response (≥50% reduction) by Week 12 in the anifrolumab vs placebo groups in both TULIP-1 and -2 (nominal *P*< 0.05) (**Figure 3**); similar effects were observed in the subgroup of patients with baseline CLASI-A ≥10 in both TULIP-1 and -2 (nominal *P*< 0.05) (**Figure 3**).

Conclusion: Anifrolumab treatment was associated with rapid and durable improvements in skin-specific SLE disease activity, as assessed by CLASI-A, in subgroups of patients with mild to severe baseline cutaneous disease activity. These findings support the potential of anifrolumab to reduce skin disease activity in patients with moderately to severely active SLE.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: No approved targeted therapies have been developed for cutaneous lupus erythematosus (CLE), a disfiguring autoimmune disease that severely impairs quality of life.[1] BIIB059 is a humanized monoclonal antibody that binds blood dendritic cell antigen 2 (BDCA2), a receptor uniquely expressed on plasmacytoid dendritic cells, leading to BDCA2 internalization and subsequent inhibition of inflammatory mediator production, most notably type I IFNs.[2] LILAC (NCT02847598) was a 2-part, phase 2 study investigating the efficacy and safety of BIIB059. Part A enrolled SLE participants. Part B, presented here, is the largest interventional study to date in CLE participants.

Methods: To be eligible for enrollment, adults with histologically confirmed CLE must have had active CLE defined as a Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity (CLASI-A) score ≥8 despite prior use of or documented intolerance to topical CS and/or antimalarials and ≥1 lesion diagnostic of subacute CLE (CLASI-A erythema score ≥2) and/or chronic CLE (CLASI-A erythema score ≥2 and CLASI-Damage scarring score ≥1); all with or without systemic manifestations. Concomitant CLE/SLE therapy was allowed if doses were initiated ≥12 weeks and kept sTable ≥4 weeks prior to randomization and throughout the treatment period; systemic CS doses could not exceed 15 mg/day of prednisone (or equivalent). BIIB059 (50, 150, 450 mg) or placebo was subcutaneously administered once every 4 weeks, with an additional dose at week 2, for 12 weeks. The primary endpoint was a multiple comparison procedure–modeling test of dose response in % change in CLASI-A score from baseline to week 16. Secondary endpoints included proportion of participants with a 50% improvement in CLASI-A score (CLASI-50 response rate) and ≥7-point reduction in CLASI-A score from baseline over time. Safety was assessed throughout the study.

Results: Of 33, 26, 25, and 48 participants dosed in the placebo and BIIB059 50, 150, and 450 mg groups, respectively, 93.9%, 88.5%, 96.0%, and 87.5% completed treatment. The study met its primary endpoint, demonstrating a dose response (p=0.0005) and statistically significant differences in least squares mean % changes (SE) in CLASI-A score between the placebo vs. BIIB059-treated participants (Table 1). Meaningful clinical improvements in secondary skin-related efficacy endpoints were observed in the BIIB059 groups. AEs and serious AEs (SAEs) for the placebo and pooled BIIB059 groups occurred in 66.7% vs. 71.7% and 9.1% vs. 7.1%, respectively (Table 2). Three (3.0%)

Table 1. Primary and secondary cutaneous efficacy endpoints at week 16.

Endpoint	Placebo n = 33	BIIB059 50 mg n = 26	BIIB059 150 mg n = 25	BIIB059 450 mg n = 48
Primary[a]				
% change in CLASI-A from baseline, LS mean (SE)	-14.49 (6.43)	-38.78 (7.51)	-47.91 (7.47)	-42.48 (5.50)
LS mean diff (95% CI)		-24.29 (-43.70, -4.88)	-33.42 (-52.71, -14.12)	-27.99 (-44.55, -11.42)
p value		0.015	<0.001	0.001
Secondary[b]				
CLASI-50 response rate, LS mean (SE)	25.64 (7.55)	41.44 (9.88)	46.83 (10.47)	48.91 (8.06)
LS mean diff (95% CI)		15.80 (-7.21, 38.80)	21.19 (-2.79, 45.17)	23.28 (2.93, 43.62)

LS mean diff (95% CI)		10.08 (-13.00, 33.17)	22.76 (-1.45, 46.98)	17.33 (-6.23, 40.89)
p value		0.366	0.053	0.046

[a]Post-treatment-failure data were imputed using worse of baseline values or values from the last visit before treatment failure. Data after treatment discontinuation were censored. [b]Participants who failed/discontinued treatment were classified as nonresponders at visits post treatment failure/discontinuation. Participants who completed treatment but had a missing score at a primary timepoint were classified as nonresponders for that timepoint. Week 16 response data for participants who completed treatment up to week 12 under protocol version 1 but who could not reconsent to protocol version 2 were derived based on imputed continuous response.
CLASI-A = Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity; CLASI-50 = at least 50% improvement from baseline in CLASI-A score.

Table 2. Numbers and percentages of participants with adverse events according to group in LILAC part B.

Event	Placebo (n = 33)	BIIB059 50 mg (n = 26)	BIIB059 150 mg (n = 25)	BIIB059 450 mg (n = 48)	Pooled BIIB059 (n = 99)
Any event, n (%)	22 (66.7)	18 (69.2)	15 (60.0)	38 (79.2)	71 (71.7)
Severity, n (%)					
Mild	12 (36.4)	7 (26.9)	7 (28.0)	21 (43.8)	35 (35.4)
Moderate	6 (18.2)	11 (42.3)	7 (28.0)	14 (29.2)	32 (32.3)
Severe	4 (12.1)	0	1 (4.0)	3 (6.3)	4 (4.0)
Related event, n (%)[a]	7 (21.2)	11 (42.3)	5 (20.0)	18 (37.5)	34 (34.3)
Serious event, n (%)	3 (9.1)	1 (3.8)	3 (12.0)	3 (6.3)	7 (7.1)
Related serious event[a], n (%)	1 (3.0)	0	1 (4.0)	1 (2.1)	2 (2.0)
Event led to drug withdrawal, n (%)	0	3 (11.5)	1 (4.0)	4 (8.3)	8 (8.1)
Event led to study withdrawal, n (%)	0	0	0	1 (2.1)	1 (1.0)
Deaths, n (%)	0	0	0	0	0

[a]As determined by the investigator.

BIIB059 participants and no placebo participants had AEs of hypersensitivity. Herpes zoster meningitis was observed in 1 participant (BIIB059 50 mg) after study completion.

Conclusion: BIIB059 significantly reduced disease activity in CLE with an accepTable safety profile. Further development of BIIB059 for the treatment of CLE is warranted.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Iberdomide is a high-affinity cereblon ligand that promotes ubiquitination and proteasomal degradation of Ikaros (*IKZF1)* and Aiolos (*IKZF3*), transcription factors linked to the genetic risk for systemic lupus erythematosus (SLE). Efficacy, safety, pharmacodynamics (PD), and pharmacokinetics (PK) of iberdomide were evaluated in a phase 2b study in patients (pts) with active SLE (NCT03161483).

Methods: Adults (N=288) with autoantibody-positive SLE by ACR criteria and with SLEDAI 2K score ≥6 were randomized (2:2:1:2) to oral iberdomide (0.45, 0.3, 0.15 mg) or placebo (PBO) daily for 24 wks, on standard background medications. Pts on PBO were re-randomized to iberdomide 0.3 and 0.45 mg at wk 24. Pts were stratified by SLEDAI 2K score (≥10/< 10) and oral corticosteroid (OCS) dose (≥10/< 10 mg/d; max OCS = 20 mg/d prednisone or equivalent). OCS tapering was permitted from wk 8-16. Study duration was 52 wks, and the primary endpoint was

0.45 mg QD (N=81)	7/81 (9)	20/81 (25)	29/81 (36)	38/81 (47)	39/81 (48)	44/81 (54)

SLE Responder Index (SRI-4) response at wk 24. Efficacy analyses were based on the intent-to-treat population that included all pts who were randomized and received ≥1 dose of investigational product. Pts with missing data and treatment failures were imputed as nonresponders.

Results: Baseline demographic and disease characteristics were balanced between groups (**Table 1**). The primary endpoint at wk 24 was met: 54.3% of pts in iberdomide 0.45-mg group achieved SRI-4 response vs 34.9% in PBO group (stratified difference-19.4%; *P*=0.011). Notably greater SRI-4 responses, vs PBO, were seen starting at wk 16, especially in iberdomide 0.45- and 0.15-mg groups (**Figure**). Several secondary endpoints were also met. In those with SLEDAI 2K score ≥10, a greater proportion receiving iberdomide 0.45 mg also achieved SRI-4 response at wk 24 (66% vs 39%, nominal *P*=0.016). SRI-4 response in the prespecified biomarker-defined subset of baseline Aiolos-High was 64% vs 33% (*P*=0.011) and in pts who were Type 1 IFN-High was 60% vs 33% (*P*=0.006). At wk 24, iberdomide 0.45 mg was superior to PBO for CLASI-50 response in patients with subacute (92% vs 53%, *P*=0.035) and chronic cutaneous lupus (62% vs 28%, *P*=0.029), but not in the overall population. Other endpoints are shown in **Table 2**. Rates of AEs were 77% vs 65% for iberdomide all doses vs PBO; SAEs (6% vs 8%), severe AEs (4% vs 6%), serious infections (1%, both groups) and AEs leading to discontinuation (8% vs 7%) were comparable. The most common AEs with iberdomide (all doses vs PBO) were urinary tract infection (11%, 4%), upper respiratory tract infection (10%, 5%), neutropenia (8%, 2%), influenza (6%, 4%), nasopharyngitis (5%, 1%), and diarrhea (4%, 0%). Rates of neutropenia and infections were dose-dependent. Neutropenia was mostly grade (gr) 1 and 2 (gr 3, 6%; gr 4, 0.5%) and was reversible, not related to infection risk, and rarely led to discontinuation (2%). Neither systemic opportunistic infections nor tuberculosis occurred. There were 2 thromboembolic events observed with iberdomide and 2 with PBO.

Conclusion: Iberdomide showed significant efficacy in the treatment of active SLE and was generally well tolerated. Enhanced effects were observed in 2 biomarker-defined populations (Aiolos-High, Type 1 IFN-High), providing a rationale for this novel mechanism in SLE.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: NOBILITY demonstrated improved renal responses and complete B-cell depletion with the humanized type II anti-CD20 monoclonal antibody obinutuzumab (OBI) compared with placebo (PBO) through 18 months in patients with proliferative lupus nephritis (LN) when added to standard of care therapies [1]. Two-year results from NOBILITY are reported here.

Methods: Patients with class III/IV LN received mycophenolate and steroids and were randomized to blinded OBI or PBO infusions on weeks 0, 2, 24, and 26. The primary endpoint was complete renal response (CRR) at week 52. Patients were followed through week 104. Secondary endpoints included overall renal response (ORR) and modified CRR (mCRR). The prespecified alpha level was 0.2 and analyses after week 52 were exploratory.

Results: 125 patients were randomized and received blinded infusions; 102 patients (82%) completed 104 weeks of follow up. CRR was greater with OBI than PBO at week 52 (35% vs. 23%, $P = 0.115$), week 76 (40% vs. 18%, $P = 0.007$), and week 104 (41% vs 23%, $P = 0.026$; Table). At week 104, OBI patients had greater improvement in eGFR, UPCR, anti-dsDNA, C3, and C4. Fewer OBI patients required initiation of a new rescue therapy through week 104 (OBI 6, PBO 12). Peripheral B-cells were detected in 92% of OBI patients at week 104. Serious adverse events (OBI 25% vs. PBO 30%), serious infections (8% vs. 18%) and deaths (1 vs. 4) were not increased with OBI.

Conclusion: NOBILITY demonstrated a sustained benefit of OBI through week 104, approximately 18 months after the final OBI infusion. The OBI dosing regimen was associated with a return of peripheral B-cells by week 104. There were no unexpected safety findings. OBI use in LN will be further evaluated in the Phase 3 REGENCY trial.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: SLE – Treatment
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Mycophenolate Mofetil (MMF) is standard of care therapy for long term treatment of lupus nephritis and other manifestations of SLE. However, it is associated with adverse effects, pregnancy risks, increased cost, and requirement for routine laboratory monitoring. This randomized, unblinded, study compared the risk of SLE flare in subjects with quiescent disease who withdrew from long-term MMF therapy compared to those continuing maintenance MMF over 60 weeks.

Methods: Adults with quiescent SLE (clinical SLEDAI/cSLEDAI ≤4) on long term MMF therapy (≥ 2 years for nephritis; ≥ 1 year for non-nephritis) were randomized 1:1 to receive unblinded MMF at the baseline dose for 60 weeks (maintenance arm, MA) or to a 12-week structured taper off of MMF (withdrawal arm, WA). All subjects were taking sTable doses of hydroxychloroquine; prednisone ≤ 10 mg daily was permitted. Primary endpoint was the difference between arms in the rate of clinically significant disease reactivation (CSDR) by 60 weeks. CSDR was defined as any SELENA-SLEDAI flare and increased immunosuppression (prolonged corticosteroids, resumption or increased dose of MMF, or addition of other immunosuppressives). Rates of BILAG A and B flares, all SLEDAI flares and adverse events were assessed through 60 weeks. Event rates and time to flare were compared using Kaplan-Meier curves.

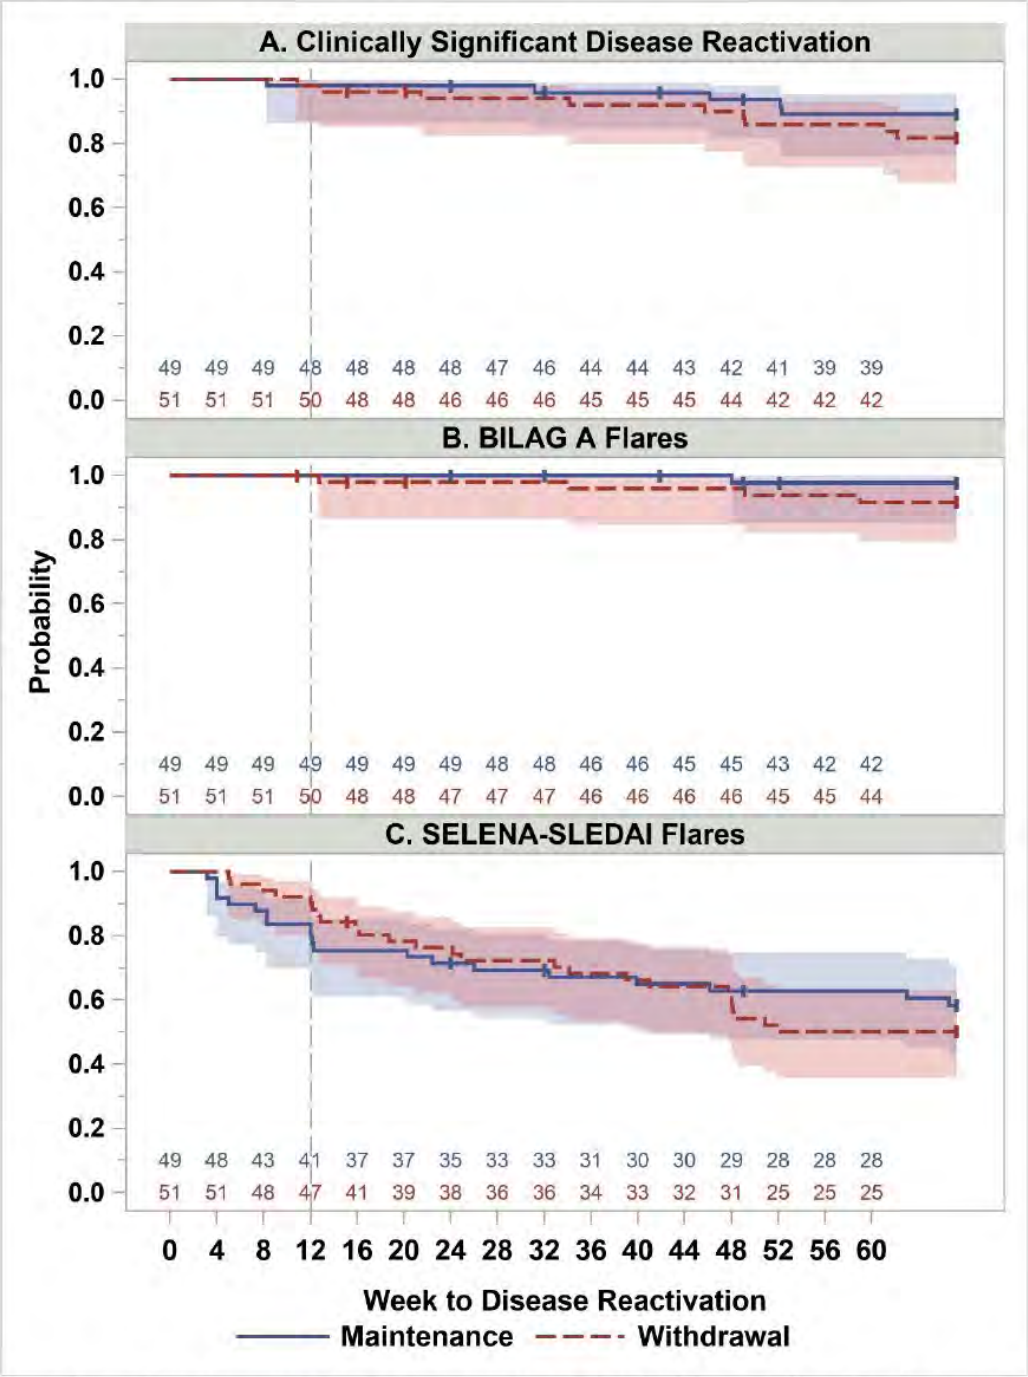
Results: 102 participants were randomized: 50 MA and 52 WA. One subject in each arm was ineligible and 10 subjects terminated early (7 MA, 3 WA). 84% subjects were female, with a mean of 13 years of SLE and 6.6 years of MMF therapy. 76% had a history of lupus nephritis, and mean baseline SLEDAI was 2.2. Five subjects (10%) in the MA experienced a CSDR compared to nine (18%) in the WA with a mean time to CSDR of 38 weeks (median 46 weeks) in both arms. Kaplan Meier estimate of risk difference was 0.07 (95% CI -0.07-0.21). BILAG A disease developed in one subject in the MA (pancreatitis) compared to four in the WA (cranial neuropathy, panniculitis, two renal flares). Kaplan-Meier curves overlapped for CSDR, BILAG A flares, and all SELENA-SLEDAI flares (Figure 1).

Table 1: Baseline and Demographic Characteristics

	Maintenance arm	Withdrawal arm	Total
Randomized	50	52	102
Female, n (%)	39 (78)	47 (90)	86 (84)
White, n (%)	25 (50)	19 (37)	44 (43)
Black, n (%)	19 (38)	22 (42)	41 (40)
Hispanic/Latino, n (%)	10 (20)	12 (23)	22 (22)
Age, Years, mean (SD)	42.4 (12.9)	41.6 (12.5)	42.0 (12.6)
Disease Duration, Years, mean (SD)	13.6 (8.2)	12.2 (7.9)	12.9 (8.0)
H/O Lupus Nephritis, n (%)	40 (80)	38 (73)	78 (76.5)
On Baseline Steroids, n (%)	18 (36)	23 (44)	41 (40)
Prednisone Dose, mg, mean (SD)	4.8 (2.7)	3.3 (1.7)	4.0 (2.3)
MMF Duration, Years, mean (SD)	6.8 (4.3)	6.4 (4.3)	6.6 (4.3)
Baseline MMF Dose, mg, mean	1,612	1,668	1,640
SELENA-SLEDAI, mean (SD)	2.4 (1.76)	1.9 (1.76)	2.2 (1.77)
Positive DsDNA, n (%)	35 (70)	27 (52)	62 (61)
Low C3[1], n (%)	14 (28)	9 (17)	23 (23)
Low C4[1], n (%)	6 (12)	5 (10)	11 (11)

[1]Low C3 and C4 were defined as complement levels below the lower limit of normal.

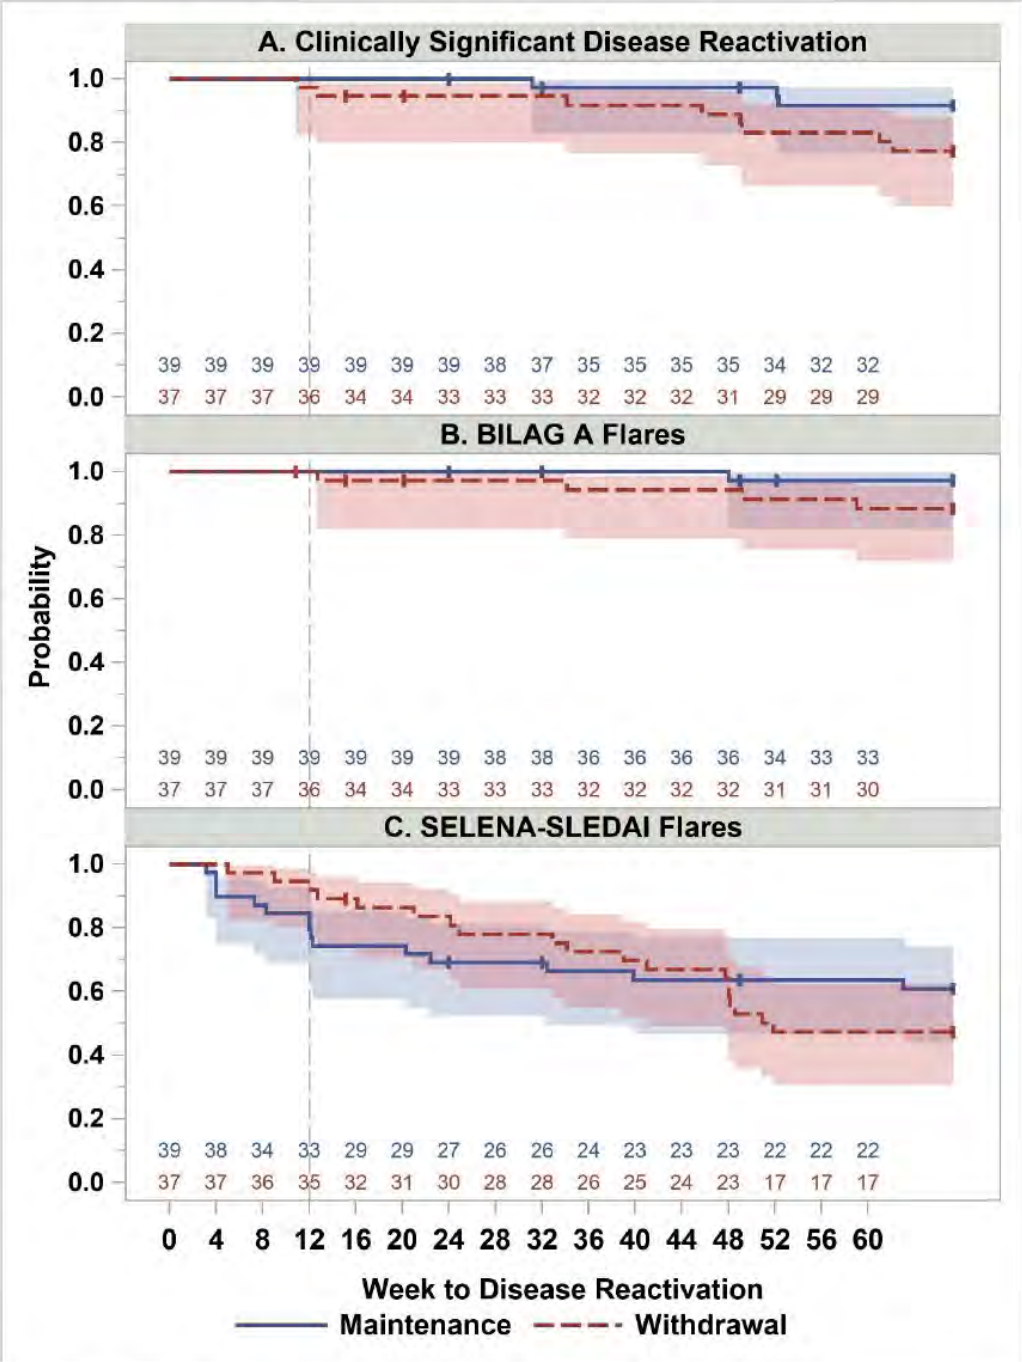
Figure 1: Kaplan-Meier Estimates of A: Clinically Significant Diseases Reactivation, B: BILAG A Flares, C: all SELENA-SLEDAI Flares in the ITT Population



Clinically significant disease reactivation requires a SELENA-SLEDAI defined mild/moderate or severe flare along with increased immunosuppressive therapy on a sustained basis.
The number of subjects at risk in each arm is shown along the bottom of the x-axis, and the vertical dashed line represents the end of the 12 week taper in the withdrawal arm.

In the participants with history of renal disease (76/100 eligible for analysis), demographics were similar to the entire cohort. Three subjects (7.7%) met CSDR criteria in the MA compared to 8 (22%) in the WA. Kaplan-Meier estimate of risk difference between groups was 0.14 (95% CI -0.02-0.31). BILAG A disease occurred in one in the MA compared to four in the WA. Mean time to CSDR was 45 weeks in the MA compared to 41 weeks in WA. BILAG A disease

Figure 2: Kaplan-Meier Estimates of A: Clinically Significant Diseases Reactivation, B: BILAG A Flares, C: all SELENA-SLEDAI Flares in the ITT Lupus Nephritis population.



Clinically significant disease reactivation requires a SELENA-SLEDAI defined mild/moderate or severe flare along with increased immunosuppressive therapy on a sustained basis.
The number of subjects at risk in each arm is shown along the bottom of the x-axis, and the vertical dashed line represents the end of the 12 week taper in the withdrawal arm.

occurred in one in the MA compared to four in the WA. BILAG A flares and all SELENA-SLEDAI flare Kaplan-Meier curves overlapped between arms. (Figure 2).

Adverse events were similar between groups with Grade 2+ infections occurring more commonly in the MA (63 vs. 49).

Conclusion: In this cohort of subjects with quiescent SLE on long-term MMF therapy, few serious flares occurred in the maintenance or withdrawal groups. Flare rates overlapped between groups, and time to flare was similar. The majority of quiescent SLE patients, including those with a history of lupus nephritis, can safely withdraw long-term MMF therapy.

Interferon Lambda Promotes Human Plasma Cell Differentiation in Lupus and Healthy Donors

Jennifer Barnas[1], Jennifer Albrecht[1] and Jennifer Anolik[1], [1]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by antinuclear autoantibodies produced by plasma cells. Type I interferon (IFN) are cytokines which promote plasma cell development and are important to lupus pathogenesis. Type III IFN (IFN lambda, IFN-λ) are more recently discovered and not as well-studied with unclear roles in human lupus pathogenesis and the immune system. Because type III IFN utilize a unique receptor from type I IFN, they are not targeted by type I IFN blocking therapies. We have previously shown an expansion of IgD- CD27- CD24- CD21- (DN2) B cells within lupus disease activity. This compartment contains age/autoimmunity-associated B cells (ABC) defined as either CD11c+ T-bet+ or CD11c+CD21-, which are poised for plasma cell differentiation. SLE is associated with an IFN gene signature in many cell types historically attributed to IFN-α. In epithelial cells, IFN-λ generates the same gene transcription profile as IFN-α. Since IFN-α and IFN-λ might induce a similar transcription program in B cells and IFN-α enhances plasma cell formation, we hypothesize that IFN-λ drives plasma cell differentiation.

Methods: Human peripheral blood B cells from healthy donors or SLE patients meeting 1997 ACR classification criteria were isolated for culture and phenotyping by flow cytometry. Dose response to IFN-λ in terms of RNA expression of interferon stimulated genes (ISG) at 4 hours was measured by RT-qPCR via the $2^{\Delta\Delta CT}$ method. B cells were also stimulated with TLR7/8 agonist R848 in the presence of BAFF and IL-21 +/- IFN-λ for flow cytometric analysis on day 7. IgG and IgM levels in culture supernatants at 7 days were quantitated by ELISA.

Results: DN2, T-bet+, and CD11c+CD21- peripheral blood B cells positively correlated with IFN-λ1 serum levels in SLE patients (n=26). IFN-λ1 directly induced IFIT1, IRF7, ISG15 expression at 4 hours *in vitro* confirming IFN-λ receptor functionality in human B cells. A dose response relationship between these ISG and IFN-λ stimulation was observed. When IFN-λ was included with R848 stimulation, CD27+ CD38+ plasmablast percentage increased amongst healthy (n=10, p = 0.002) and lupus B cell (n = 6, p= 0.2) cultures. In TLR7 activated lupus B cells, a higher IgG:IgM ratio was observed compared to cultures from age, sex, and race matched healthy donors. In TLR7 activated healthy

B cell culture supernatants with IFN-λ included, IgM was significantly increased at day 7 (n=8, p=0.02), but not IgG level.

Conclusion: IFN-λ1 stimulation of human B cells induces a gene signature historically attributed to type I IFN. IFN-λ significantly enhances the differentiation of plasmablasts and IgM levels in TLR7-activated B cell cultures from healthy donors with a lesser effect observed among lupus B cells, which may already have been exposed to interferon *in vivo*. IFN-λ could provide explanation for poor clinical response of subsets of patients to type I interferon blockade given type III interferon utilize a different receptor. Studies are ongoing to determine if IFN-λ1 has differential effects on B cell and plasma cell subsets in lupus versus healthy donors.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) often has a progressive and debilitating course, with significant impact on the patient's quality of life. Despite the long-known association with autoantibodies, knowledge of the role of B cells and their potential direct contribution to RA pathogenesis remains elusive.

Characterization of B cell subpopulations in the periphery and synovial tissue.

Identification of chemokine receptors responsible for the synovial accumulation of B cells.

Characterization of B cell function and metabolism under the hypoxic conditions of the RA joint.

Methods: Synovial tissue biopsies from RA patients were obtained through key-hole arthroscopy followed by single cell flow cytometric analysis of B cell subpopulations and chemokine receptor expression. SPICE analysis was performed for the chemokine receptor expression of synovial B cells and B cell invasion assays. Functional characterization of sorted RA B cells, cultured *in vitro* under hypoxia, simulating the inflamed joint environment. Characterization of B cell metabolism and transcriptional regulation of pSTAT3 by flow cytometry. Notably, novel, non-invasive Fluorescent Lifetime Imaging Microscopy (FLIM) assay for the characterisation of the metabolic status of sorted RA patient PD-1 B cells coupled with RNAseq analysis was performed.

Results: Extensive flow-cytometric characterisation and SPICE algorithm analyses of single-cell synovial tissue from RA-patients revealed the accumulation of switched and double negative memory PD-1 expressing B cells at the site of inflammation. Accumulation of memory B cells is mediated by CXCR3, evident by the observed increase in CXCR3 expressing synovial B cells compared to the periphery, differential regulation by key synovial cytokines, and restricted B cell invasion demonstrated in response to CXCR3 blockade. Notably, under 3% O_2 hypoxic conditions that mimic the joint-microenvironment, RA B cells maintain marked expression of MMP-9,-TNF and IL-6, with PD-1^+ B-cells demonstrating higher expression of CXCR3, CD80, CD86, IL-1β and GMCSF than their PD-1^- counterparts. Following functional analysis and flow cell sorting of RA PD-1^+ vs PD-1^- B-cells, we demonstrate using RNAseq and novel FLIM visualisation of cellular NADH, a significant shift in metabolism of RA PD-1^+ B-cells towards glycolysis, associated with an increased transcriptional signature of key cytokines and chemokines that are strongly implicated in RA pathogenesis.

Conclusion: Highly polyfunctional pro-inflammatory T cell responses pre-date disease onset as demonstrated by the accumulation of polyfunctional T cells in the synovial tissue of pre-RA arthralgia subjects. These data highlight a key early pathogenic role for T cell plasticity and specific synovial T cell clusters including, DP T cells in RA.

Impact of Selective Inhibitors of Nuclear Export on SLE Plasma Cells Is Modulated by the BM Microenvironment

Neha Nandedkar-Kulkarni[1], Nida Meednu[2], Jennifer Albrecht[2], Jennifer Barnas[2], Douglas Widman[3] and Jennifer Anolik[2], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical center, Rochester, NY, [3]Karyopharm Therapeutics, Newton, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematous (SLE) is a complex autoimmune disorder with heterogeneous disease presentation and a multi-pronged pathogenesis. Although autoreactive plasma cells play a key role in SLE, they are still elusive targets. Selective inhibitors of nuclear export (SINE) were recently approved by the FDA for treatment of refractory multiple myeloma (selinexor). Our lab has demonstrated that SINE abrogate lupus nephritis and significantly reduce autoreactive plasma cells in lupus prone NZBW/F1 mice. Here we investigated the impact of SINE on *In vitro* survival and antibody secretion of human plasma cells (PC) and how these classic PC functions are modulated by the bone marrow (BM) microenvironment.

Methods: Peripheral blood mononuclear cells (PBMCs) and bone marrow mononuclear cells (BMMCs) from healthy (n = 4) and SLE donors (n = 4), cultured in the presence of mesenchymal stromal cell secretome, were treated with KPT-335 for different periods of time. Number of antibody secreting cells (ASC) and PC survival were assessed by IgG ELISPOT and annexin V-propidium iodide flow based apoptosis assay, respectively. $CD19^+CD27^{hi}CD38^{hi}$ blood plasmablasts, $CD19^+CD27^{hi}CD38^{hi}CD138^+$ BM mature PCs and $CD19^-CD27^{hi}CD38^{hi}CD138^+$ BM long-lived PCs were sorted for transcriptomic analysis (controls: n = 7 and SLE: n = 9).

Results: Blood ASC were significantly reduced (IC50= 0.1uM) compared to BM ASC (IC50 = 10uM) after short-term *ex vivo* treatment with KPT-335 (24 hours). In long-term cultures (120 hours), there was a greater impact on BM PCs (IC50=0.1uM). We also examined the capacity of SINEs to induce apoptosis in different PC subsets. Blood plasmablasts from both healthy and SLE donors were reduced by 30-70% after SINE treatment for 48 hours. Of note, SINE treatment did not affect BM mature and long-lived PC. In transcriptomic analysis, BM PCs showed up-regulation of NFkB signaling and extra-cellular matrix receptor interactions (gene pathway analysis), and experienced down-regulation of cell cycle signaling pathways, compared to blood PC. Mature and long-lived PC in lupus BM had a prominent interferon (IFN) signature compared to controls. We are currently investigating the impact of type I IFN on PC survival and function.

Conclusion: SINEs represent a novel treatment approach for SLE. These results support the hypothesis that the effect of SINEs on PC depends upon the dose and duration of treatment, and is modulated by BM microenvironmental signals that orchestrate PC survival.

N-linked Glycosylation of the Immunoglobulin Variable Domain Affects Antigen Binding and Autoreactive B Cell Activation

Theresa Kissel[1], Changrong Ge[2], Lise Hafkenscheid[1], Linda Slot[1], Marco Cavallari[3], Joanneke Kwekkeboom[4], Manfred Wuhrer[1], Thomas Huizinga[1], Hans Scherer[1], Michael Reth[3], Rikard Holmdahl[2] and René Toes[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Karolinska Institutet, Solna, Sweden, [3]University Freiburg, Freiburg, Germany, [4]Leiden Univeristy Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-citrullinated protein antibodies, the hallmarking autoantibodies in Rheumatoid Arthritis (RA), are characterized by *N*-linked glycans in the variable domain (V-domain). The occurrence of these glycans results from the selective introduction of *N*-glycosylation sites during somatic hypermutation and their presence is predictive for the transition from pre-disease autoimmunity towards RA. We have now determined the biological implication of V-domain glycans on antigen-binding and B-cell activation.

Methods: ACPA crystal structures, including the starting monosaccharides of the V-domain glycans, were generated. These crystal structures were used as a basic framework and the complete glycan structure modelled onto the V-domain. Fab crystal structures with modelled V-domain glycans were subsequently used for molecular dynamics simulations. Antigen binding assays using monoclonal ACPA IgG including V-domain glycans and their non-glycosylated counterparts were performed. Further, we generated human Ramos B cells lines including V-domain glycosylated and non-glycosylated mIgG B cell receptors and identified their activation upon stimulation.

Results: Autoantibody crystal structures show that V-domain glycans are positioned in the vicinity of the binding-pocket and dynamic modelling shows their potential to interact with antigen-binding, which is confirmed by bind-

ing assays. Noteworthy, human Ramos B cells carrying V-domain glycosylated B cell receptors undergo increased signalling after stimulation compared to their non-glycosylated counterparts.

Conclusion: Our data indicate that autoreactive B cells in RA are selected for the presence of V-domain glycans that convey a signalling advantage, potentially explaining the outgrowth of autoreactive B cells and the increase of autoantibody levels towards disease-onset. These findings are relevant for the understanding of how autoreactive B cells escape immune checkpoints in humans and indicate that the introduction of V-domain glycans enables B cells to breach tolerance in the prominent autoimmune disease RA.

Does Tofacitinib Impact B Cell Functions?

Guillaume Decarriere[1], Julie Mielle[2], Bernard Combe[3], Jacques Morel[1], Rachel Audo[2] and Claire Daien[1], [1]Rheumatology department, CHU Montpellier and University of Montpellier, Montpellier, France, [2]Institut de génétique moléculaire de Montpellier (IGMM), Montpellier, France, [3]University of Montpellier, Montpellier, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib (tofa) inhibits cytokine signaling mediated by JAK1 JAK3 pathways leading therefore to a decrease in Th17 and an increase of Treg cells. The effect of tofa on B cell profile has been poorly explored. We aimed at studying the *in vitro* effect of tofa on B cell cytokine production (pro and anti-inflammatory) and plasmablast differentiation in the context of JAK-dependent and independent stimuli. The *in vivo* effect of tofa on B cell cytokine production was also assessed in mice.

Methods: Isolated B cells were cultured *in vitro* for 4 to 8 days in absence or presence of tofa and with JAK-dependent (CD40L, IL-2 and IL-21) or JAK-independent (CpG, a TLR9 ligand) stimuli. Cytokine production was assessed by flow cytometry and ELISA. Plasmablasts were defined as $CD19^{+}CD27^{+}CD38^{+}$ cells. p-STAT-3 was quantified by western blot at 30,120 and 240 minutes. IL-6, IL-10 and IFN-γ neutralizing antibodies were added in some experiments. *In vivo*, mice were treated with tofa or placebo for 8 days and B cells were analyzed in inguinal lymph nodes and peritoneal fluid.

Results: In presence of JAK-dependent IL-2/IL-21 stimuli, tofa (1 μM) decreased the levels of IL-6 (2.7%[1.0-7.6] vs 8.9%[7.1-18.1], n=7, p=0.01 for tofa and control respectively), IFN-γ, IL-10 (0.8%[0.5-1.4] vs 2.6%[0.7-3.3], p=0.04), IL-35 (Mean Fluorescence Intensity [MFI] =89.5[56.1-99.6] vs 163[125-239], p=0.01) produced by B cells.

In presence of the JAK-independent stimulation CpG, tofa also decreased IL-6 (30.2%[20.4-48.2] vs 35.5%[27.3-59.0], n=9, p=0.05), IFN-γ, IL-10 (1.9%[0.6-2.5] vs 2.5%[0.9-5.1], p=0.02) and IL-35 (MFI: 129.4[85.2-354.6] vs 177.7[132.5-566.8], p=0.001) in B cells. Whereas IL-2/IL-21 induced a phosphorylation of STAT3 at 30 min, CpG induced a delayed activation of JAK/STAT pathway, suggesting that cytokines produced in response to CpG have an autocrine effect with a secondary activation of JAK/STAT pathway which can be blocked by tofa. To confirm this

hypothesis, we cultured CpG activated B cells in the presence of cytokine-neutralizing antibodies and found that anti-IL-10 antibodies decreased the effect of CpG on IL-6 and IL-10 secretion and that tofa had then a decreased effect on those cytokines. In addition, tofa inhibited the plasmablasts differentiation in IL-2/IL-21 conditions (0.09%[0.05-0.17] vs 2.4%[1.4-3.3], n=6, p=0.03), but not with CpG (3.27%[0.57-4.97] vs 3.94%[0.73-8.41], p=0.15). *In vivo*, tofa decreased the frequency of IL-35 secreting B cells (0.8%[0.42-0.97] vs 1.6%[0.7-2.4, p=0.05] in peritoneal fluid but not IL-10 and TGF-β.

Conclusion: In addition to blocking cytokine pathways, tofa had a cellular impact on B cells, modifying their ability to produce pro- and anti-inflammatory cytokines both in JAK dependent and independent conditions. In JAK independent conditions, this effect of tofa was at least partly explained by the inhibition of an autocrine loop. Moreover, tofa decreased the differentiation of B cells into plasmablasts under conditions mimicking an interaction with T cells but not with TLR activation only, suggesting that tofa might have a lower impact on T-independent humoral immunity. We are currently evaluating the impact of tofa on B cells in tofa-treated rheumatoid arthritis patients.

Jo-1-Binding B Cells Undergo Limited Class-Switching but Are Biased Towards Autoreactive-Prone and Memory B Cell Subsets in Anti-histidyl-tRNA Synthetase Syndrome

Jennifer Young-Glazer[1], Alberto Cisneros[2], Erin Wilfong[1], Scott Smith[1], Leslie J. Crofford[1] and Rachel Bonami[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbit University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are systemic autoimmune diseases traditionally classified as dermatomyositis or polymyositis, but these disorders are increasingly defined by the presence of specific autoantibodies. Anti-Jo-1 autoantibodies recognize histidyl tRNA synthetase and are found in a subset of these patients, but anti-Jo-1 B cells have not been previously characterized. To target these antigen-presenting cells in anti-histidyl-tRNA synthetase syndrome (HARS), we must first understand how they expand in the repertoire. In this study, we aimed to characterize Jo-1-binding B cells in HARS.

Methods: We enrolled 10 patients diagnosed with HARS, 4 patients with non-Jo-1 IIM, and 8 age and sex-matched healthy controls. We performed flow cytometry to phenotype peripheral blood mononuclear cells (PBMCs) and define the B cell subsets in which Jo-1-binding B cells reside. We polyclonally stimulated PBMCs from HARS subjects to drive *in vitro* B cell differentiation into antibody-secreting cells, and phenotypically compared Jo-1-binding versus non-Jo-1 binding B cells from the same subjects.

Results: On average, 65% of Jo-1-binding B cells were IgM+ (not class-switched). Compared to other B cells from the same donor, anti-Jo-1 B cells contained a higher percentage of autoimmune-prone $CD21^{lo}$ cells, increased

$CD38^{+}CD27^{+}$ memory cells, but fewer $CD38^{hi}CD24^{-}$ plasmablasts. Consistent with phenotypic data, anti-Jo-1 B cells were less likely to differentiate into $CD38^{hi}24^{-}$ plasmablasts following *in vitro* stimulation.

Conclusion: Jo-1-binding B cells were identified in the peripheral blood of all HARS patients assessed, suggesting they can be tracked as biomarkers to assess whether experimental therapies limit their expansion and activation. These data suggest complex B cell biology exists beyond class-switched cells that differentiate to secrete anti-Jo-1 autoantibody, and provide an important advance towards defining antigen-specific B cells and developing novel B cell-directed therapies for HARS patients.

Bacteria-Derived Indole Drives Autoimmune Arthritis by Altering B Cell Glycosylation of Autoantibodies

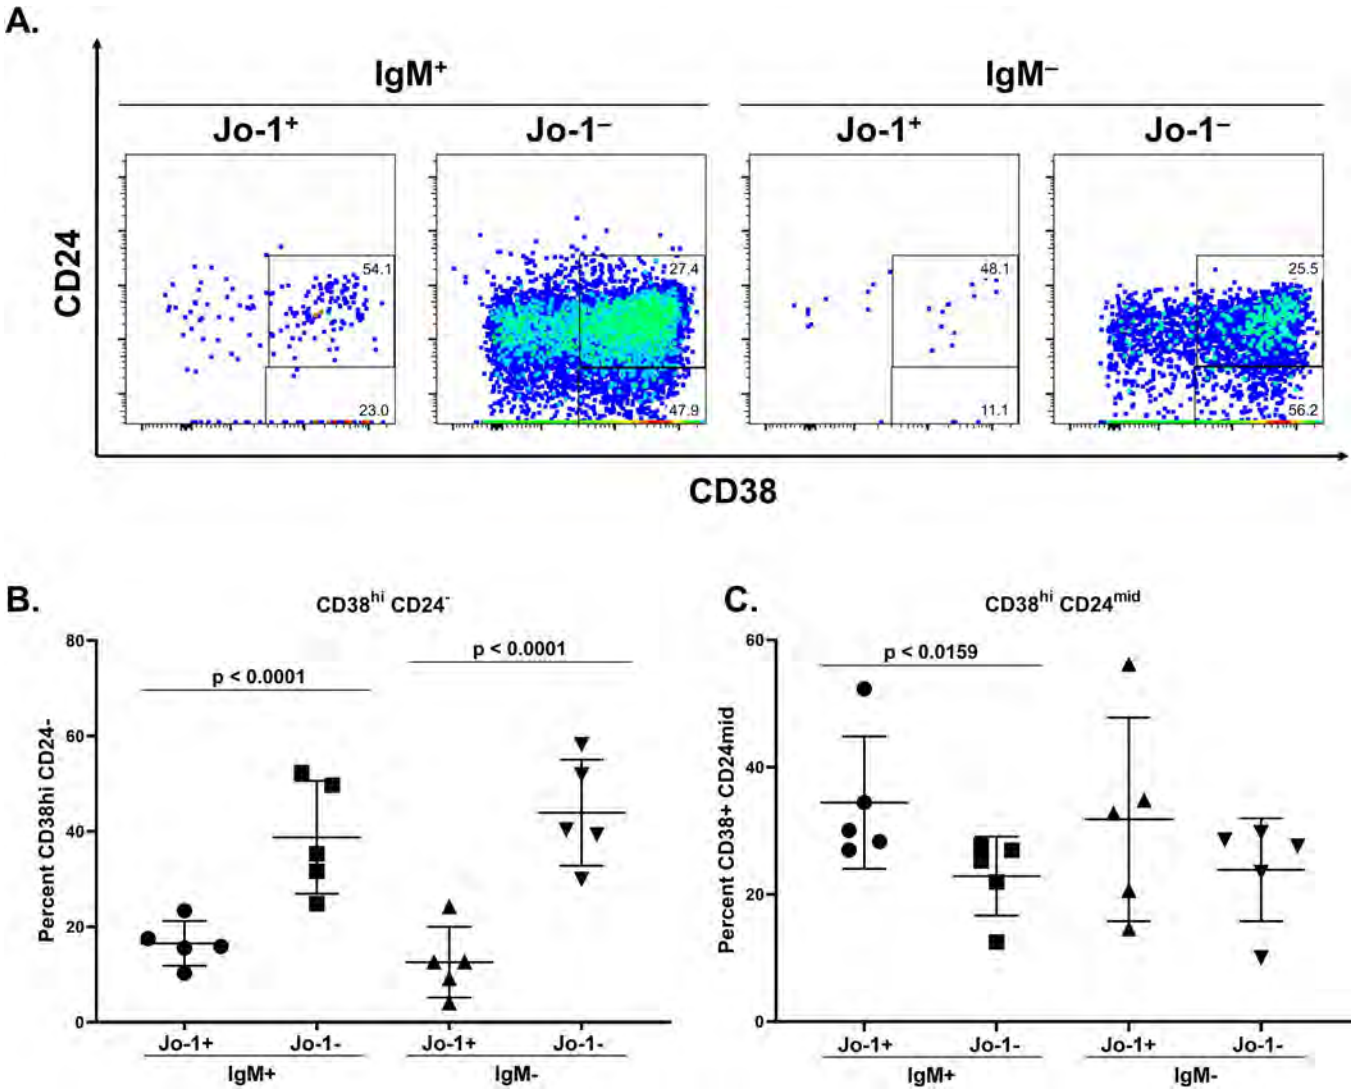
Brandon Trent[1], Meagan Chriswell[2], Widian Jubair[3] and Kristine Kuhn[1], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]UC Denver SOM, Denver, CO, [3]University of Colorado Denver, Denver, CO

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Dysbiosis of gut bacterial communities in rheumatoid arthritis (RA) is a noted phenomenon in both murine models and human patients; however, the mechanisms from dysbiosis that promote RA pathogenesis remain unclear. Our lab previously demonstrated that administration of antibiotics to deplete the microbiota late in the course of murine collagen-induced arthritis (CIA) significantly ameliorated disease and correlated with changes in total antibody glycosylation patterns, known to occur in RA patients and affect complement fixation and FC receptor engagement. We hypothesized that the microbiota mediated antibody glycosylation via production of bacteria-specific metabolites.

Methods: Methods: CIA was induced by immunization of male 6-8 week-old DBA/1 mice with bovine type II collagen emulsified in complete Freund's adjuvant on days 0 and 21. To understand the mechanisms by which late micriobiota depletion would significantly decrease CIA, we analyzed concentrations of cecal metabolites by LC-MS during CIA and after antibiotic treatment (1 mg/ml each ampicillin, neomycin, metronidazole and 0.5 mg/ml vancomycin). 10 mM indole or vehicle was then added to the drinking water containing antibiotics. Arthritis was evaluated based on a score of 0 (no swelling) to 4 (ankylosis) for each paw and summed for the mouse. Assessment of cell populations was performed by flow cytometry. Splenic B cells were evaluated *ex vivo* after stimulation with LPS (5μg/mL) and/or anti-IgM (10μg/mL) and total RNA was collected and analyzed via qRT-PCR.

Results: Results: Metabolomic profiling demonstrated a significant increase in bacteria-produced indole, a byproduct of tryptophan metabolism, in mice with CIA compared to unimmunized controls and those with CIA treated with antibiotics. Interestingly, administration of indole after antibiotic treatment resulted in a partial restoration of a CIA phenotype. Indole administration also resulted in increased T follicular helper cell (Tfh) and B cell populations in the Peyer's patches and mesenteric lymph nodes in mice, but not the spleen. Furthermore, *ex vivo* stimulation of murine



A lower frequency of Jo-1-binding B cells acquire a plasmablast phenotype following stimulation in vitro compared to non-Jo-1-binding B cells from the same IIM patients. PBMCs from n=5 HARS patients with active disease were polyclonally stimulated as in Methods. Cultured cells from 40-60 wells per patient were harvested on day 6 and stained for flow cytometry analysis. A) CD24 and CD38 expression is shown in representative flow plots derived from a single well of stimulated PBMCs. Comparison of relative frequencies for B) CD38 hi CD24 - B lymphocytes or C) CD38 + CD24 mid B lymphocytes between Jo-1 specific and Jo- 1 non-specific populations. Significant differences between IgM + Jo-1 + and IgM + Jo-1 – or IgM – Jo- 1 + and IgM – Jo-1 – populations as calculated using Mann-Whitney U test are indicated. The data are represented as the mean for each population within a given stimulation, the bars indicate the mean ± SD.

splenic B cells with indole induced gene expression of the B4Galt and Fut8 genes, transferases critical in antibody glycosylation.

Conclusion: Conclusions: Our results suggest that gut dysbiosis due to RA results in bacterial production of indole, which promotes RA pathogenesis via activation of B cell populations and altered antibody glycosylation patterns. Precise understanding of which indole metabolites are involved and how they engage cellular receptors will help elucidate the role of intestinal dysbiosis in RA development.

Table 1. Study Participant Characteristics

	Healthy Controls (n=8)	Non-Jo-1 IIM * (n=4)	Stable Jo-1+ Disease ** (n=5)	Active Jo-1 Disease *** (n=5)
Age (years)	48.2 (42.1 - 52.0)	58.2 (50.9 - 63.2)	57.1 (43.4 - 57.4)	53.8 (46.2 - 56.1)

Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's syndrome (SS) is a rheumatic autoimmune disease characterized by focal lymphocytic infiltrates in the lacrimal and salivary glands, severe dry mouth and eyes, pain and debilitation. Diagnosis requires autoantibodies to ubiquitous Ro antigens or a lip biopsy positive for focal lymphocytic infiltrates. Here we used human proteome arrays to identify novel antibodies in plasma from Ro antibody positive and Ro antibody negative SS patients compared with healthy controls.

Methods: Anti-Ro positive (n=15) and anti-Ro negative (n=15) cases meeting 2016 ACR/EULAR classification criteria for SS were age, race, and sex matched with each other and healthy controls (n=15). Plasma IgG binding to human proteome arrays containing >19,500 recombinant human proteins representing >80% of the human proteome

(HuProt v3.2 arrays, CDI Laboratories) was assessed. Data were normalized by the Robust Linear Model using the PAA Bioconductor Package in R and log intensity values for each protein generated. Thresholds of mean + 3SD were established using the controls. Antigens bound by IgG in at least 4 cases compared to controls were considered significant ($p< 0.05$, one-tailed Fisher's exact test).

Results: IgG from Ro positive SS cases significantly bound 42 proteins, including the canonical SS antigens Ro60, Ro52, and La, with an average of 15 specificities per individual. IgG from Ro negative SS cases significantly bound 24 proteins compared to controls, with an average of 7 specificities per individual. Of the antigens identified, 8 were shared in both the Ro positive and Ro negative groups. Binding to at least one of these 8 proteins identified 93% of the Ro positive cases and 87% of the Ro negative cases.

Conclusion: A set of 8 novel antigens were bound by plasma IgG in both Ro positive and Ro negative cases. These antigens may be useful for diagnosing SS without a lip biopsy.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumour necrosis factor (TNF) induced signaling events are important in lymphoid organ development and function, both in health and in immune-mediated inflammatory diseases such as arthritis. Important receptors involved in this process include TNF receptors (R) I and II that exert distinct functions. Mice overexpressing transmembrane (tm)TNF develop various features of chronic inflammation, including arthritis, that are mediated via TNFRI and/or TNFRII. In this study we investigated the contribution of TNFRI and TNFRII in spleen and peripheral lymph node (PLN) morphology in transgenic mice overexpressing tmTNF (tmTNF-tg).

Methods: Spleen and PLN were collected from wild type (wt) and heterozygous tmTNF-tg mice, with were either on a normal or TNFRI or TNFRII deficient background. Spleens were stained by immunofluorescence for B and T cell markers, imaged by confocal microscopy and analyzed using FIJI software. PLN were used for whole mount tissue staining for B and T cell markers, cleared, 3D imaged by light sheet microscopy and analyzed using Imaris software.

Results: TmTNF-tg mice exhibited an altered spleen morphology characterized by smaller follicles (tmTNF-tg 69.73 ± 72.25 μm^2; wt 139.3 ± 71.36 μm^2), and a reduced proportion of follicle T cell area (tmTNF-tg 15.22 ± 9.69%; wt 26.60

± 10.46%). Spleen morphology of TNFRI$^{-/-}$ and TNFRII$^{-/-}$ mice was similar to wt mice. TmTNF-tg x TNFRI$^{-/-}$ exhibited a normal spleen architecture (follicle size: 239.2 ± 250.5 μm^2; T cell area: 29.92 ± 11.46%). In contrast, spleen follicles of tmTNF-tg x TNFRII$^{-/-}$ mice had T cell areas (17.31 ± 8.88%) comparable to tmTNF-tg mice. PLNs of tmTNF-tg mice were increased in size (tmTNF-tg 3.74 ± 1.31 mm^3; wt 2.41 ± 0.60 mm^3), also in combination with deficiency of TNFRI (3.98 ± 2.07 mm^3) or TNFRII (4.01 ± 1.96 mm^3). TmTNF-tg PLNs had an increase in absolute B cell volume (tmTNF-tg 0.86 ± 0.33 mm^3; wt 0.51 ± 0.07 mm^3), but no change in B cell area as proportion of total PLN volume. The increased B cell volume was critically dependent on TNFRII. Interestingly, TNFRI deficiency caused profound alterations B cell area morphology that appeared as one peripheral layer of B cells covering a central T cell area rather than properly developed follicles.

Conclusion: This study demonstrates that overexpression of tmTNF leads to an aberrant spleen architecture, characterized by smaller follicles and reduced central T cell areas, which is critically dependent on TNFRI. In addition, overexpression of tmTNF results in enlarged PLN and increased total B cell volume, which is dependent on TNFRII, whereas TNFRI is more important in the proper organization of B cell follicles. Overall, this study employing different state-of-the-art (3D) imaging techniques highlights the importance of tmTNF-TNFR-induced signaling events in secondary lymphoid organ morphology and function, and reveals distinct roles for TNFRI and II. Advancing our knowledge in this field might provide a better understanding of the pathophysiology of TNF-associated diseases such as arthritis, which may be important to develop new or improved treatment strategies.

CXCL13 Is a Key Driver for Migration and Differentiation of Regulatory B Cells

Claire Rempenault[1], Julie Mielle[2], Kristina Schreiber[1], Pierre Corbeau[3], Jacques Morel[4], Claire Daien[4] and Rachel Audo[2], [1]Rheumatology, Montpellier, France, [2]Institut de génétique moléculaire de Montpellier (IGMM), Montpellier, France, [3]immunology, Nimes, France, [4]Rheumatology department, CHU Montpellier and University of Montpellier, Montpellier, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Human regulatory B cells still need to be characterized. Given the absence of phenotypical definition, a functional definition based on their ability to secrete IL-10 is often used (corresponding to B10$^+$ cells). Chemokine receptors (CKR) profiles are useful to characterize some populations of T cells but have never been explored among B10$^+$ cells. Moreover, very little is known about B10$^+$ cell migration. Chemokines (CK) have also been implicated in the differentiation of naïve T cells towards regulatory T cells. Therefore, the aims of our study were to characterize the profile of CKR on B10$^+$ cells and also to investigate CK implicated in their migration and differentiation both in control (CTL) and in rheumatoid arthritis (RA) patients.

Methods: B cells were isolated with Rosette Sep Human B cells enrichment followed by Ficoll separation. B cells were activated 24 hours with CpG and CD40L to generate B10$^+$ cells. For RNA sequencing and migration assay, B10$^+$ and IL-10^{neg} B cells (B10^{neg}) cells were then sorted using IL-10 secretion assay. IL-10 secretion from B cells was assessed by FACS and ELISA. For migration assay, ability to migrate in response to CCL21, CCL22, CXCL11, CXCL12

or CXCL13 or synovial fluid (SF) from RA or osteoarthritis (OA), were evaluated by migration assay in 5μM Transwell chambers and expressed as fold increase compare to basal migration towards control media.

Results: Transcriptomic analysis was done on $B10^{+}$ and $B10^{neg}$ from 5 CTL and 4 RA patients. 335 genes were found differentially regulated (DEG) in control $B10^{+}$ cells compared to $B10^{neg}$ in CTL and 188 in RA patients. Of note, only 159 DEG were shared by both groups, while 29 were specific to RA. Gene ontology classification of DEG revealed that genes from CKs pathways were highly enriched in $B10^{+}$ from CTL and to a lesser extend in $B10^{+}$ from RA patients. Among all CK tested, only CXCL13, attracted significantly more $B10^{+}$ than $B10^{neg}$ from CTL (12.4 ± 10.0-fold increased migration of B10+ vs 6.0 ± 3.4-fold increased migration of B10neg, n=21). This was also true in RA patients (18.7 ± 22.8-fold increased migration for $B10^{+}$ vs 6.4 ± 5.3-fold increased migration for $B10^{neg}$, n=13). SF from RA induced a significant migration of $B10^{+}$ cells in CTL (9.6 ± 12.0-fold increased migration, $p< 0.0001$, n=22) and RA patients (7.1 ± 9.7-fold increased migration, p=0.0002, n=13), higher than those induced by SF from OA. CXCL13 was significantly higher in SF from RA than in SF from OA (685.5 ± 135.1 pg/mL vs 122.8 ± 186.7 pg/mL, p=0.03). Importantly, $B10^{+}$ migration towards SF was significantly correlated with the levels of CXCL13 in these SF in CTL (r=0.62, p=0.007, n=17) and with a trend in RA patients (r=0.45, p=0.07, n=17). Lastly, CXCL13 was also found to increase IL-10 secretion in B cells stimulated with CpG in CTL (1.4 ± 0.3-fold increase, $p< 0.0001$, n=20) and in RA patients (1.2 ± 0.2-fold increase, p=0.01, n=13).

Conclusion: We showed that CXCL13 is a key driver for migration and differentiation of $B10^{+}$ cells in CTL and in RA patients.

Abstract Number: 1000

Passive Smoking Throughout the Life Course and the Risk of Incident Rheumatoid Arthritis in Adulthood Among Women

Kazuki Yoshida[1], Jiaqi Wang[2], Susan Malspeis[3], Bing Lu[4], Lauren C. Prisco[3], Lily Martin[3], Julia Ford[2], Karen Costenbader[5], Elizabeth Karlson[2] and Jeffrey Sparks[6], [1]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, [4]Brigham and Women's Hospital and Harvard Medical School, Newton, MA, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [6]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Personal cigarette smoking has been strongly associated with the risk for developing seropositive RA. Previous studies concerning passive smoking conflict; some suggested that childhood passive smoking confers RA risk but not all. No studies have investigated passive smoking throughout the life course and the risk of RA, while also accounting for the possible mediation of personal smoking.

Methods: We conducted a cohort study utilizing the Nurses' Health Study II, an ongoing prospective cohort of female registered nurses. Biennial questionnaires collected information on items such as sociodemographics, anthropomet-

rics, dietary intake, and health conditions. Incident RA and date of diagnosis were determined by medical record review (all meeting 1987 ACR or 2010 ACR/EULAR classification criteria). Serostatus for RA was determined by positive result for RF or anti-CCP protein antibody in medical records. Three passive smoking exposures spanning the life course were assessed: maternal smoking during pregnancy (In utero exposure), parental smoking at home during childhood, and years spent living with a smoker since age 18. Covariates included early life (e.g., parental education, parental occupation, birthweight) and time-updated adult (e.g., personal smoking pack-years, dietary intake, BMI, menopause) factors. Parental smoking behavior could have influenced participants' uptake of late adolescent and adult smoking, making the latter a possible mediator between early life passive smoking and adult-onset RA. We examined the association between each passive smoking exposure and incident RA risk using Cox regression models.

† Additionally adjusted for adult personal smoking pack-years (confounder in this analysis).

Table 3. Hazard ratios for rheumatoid arthritis, overall and by serologic phenotype, according to years lived with a smoker since age 18 (n=90,923).

Results: Among 90,923 women (mean age at baseline 34 years), we identified 532 incident RA cases (352 seropositive; 180 seronegative) during 2,340,436 person-years of follow-up (mean 25 years/participant). In the sample, 25% had in utero exposure to maternal smoking during pregnancy; 64% reported childhood home exposure to parental smoking; and 44% reported living with a smoker as an adult (35% with ≤20 years, 9% with 20+ years). Maternal smoking during pregnancy was associated with incident RA after confounding adjustment (HR 1.25 [95% CI 1.03, 1.52]). This finding was stronger for seropositive RA (HR 1.34 [1.06, 1.70]). Childhood parental smoking was associated with seropositive incident RA after adjusting for confounders including maternal smoking during pregnancy (HR 1.41 [1.08, 1.83]). This association was present even after adjusting for a potential mediator, adult personal smoking (HR 1.34 [1.03, 1.75]). After adjustment for confounders including personal smoking, there was no association of adult passive smoking with RA (20+ years lived smoker: HR 1.02 [0.74, 1.40] vs. none).

Conclusion: In this analysis spanning the life course, early life passive smoking exposures were associated with incident seropositive RA in adulthood. Childhood parental smoking was associated with incident seropositive RA even after adjustment for adult personal smoking, suggesting an important influence of early-life inhalant exposures on adult-onset RA. The possible association of adult passive smoking with RA was completely explained by confounders including personal smoking.

Abstract Number: 1001

Risk of Malignant Melanoma and Nonmelanoma Skin Cancer in Rheumatoid Arthritis Patients Initiating Methotrexate versus Hydroxychloroquine

Hemin Lee[1], Sarah Chen[2], Nileesa Gautam[2], Seanna Vine[1], Mengdong He[2], Rishi Desai[2], Michael Weinblatt[1], Robert Glynn[2] and Seoyoung Kim[2], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous randomized clinical trials and observational studies have signaled an increased risk of skin cancer in rheumatoid arthritis (RA) patients treated with immunosuppressants such as methotrexate (MTX). The objective of this study was to compare the incidence rates of malignant melanoma and nonmelanoma skin cancer (NMSC) in RA patients initiating MTX versus hydroxychloroquine (HCQ) using real-world data.

Methods: Using Medicare claims data (Parts A/B/D 2006-2017), we conducted a cohort study of RA patients who were 65 years or older and initiators of MTX or HCQ as their first DMARD. Cohort entry date was the date of the first dispensing for either MTX or HCQ. At least 365 days of continuous enrollment in Medicare parts A, B, and D was required. We excluded patients who used any disease-modifying antirheumatic drugs (DMARDs), chloroquine, other immunosuppressants, or had a history of malignancy including skin cancer, immunosuppression, psoriatic arthritis, or systemic lupus erythematosus. The primary outcome was a composite of malignant melanoma and NMSC. Malignant melanoma was defined based on a validated algorithm requiring two International Classification of Diseases (ICD) 9 or 10 diagnosis codes separated by 1-60 days (PPV 83%). NMSC was also defined based on a validated algorithm using one ICD 9 or 10 diagnosis code followed by a NMSC-related procedural code occurring within 60 days (PPV 84%). Secondary outcomes were components of the primary outcome: malignant melanoma, NMSC, basal cell carcinoma (BCC), and squamous cell carcinoma (SCC). To control for confounding, we conducted one-to-one propensity score (PS) matching using more than 60 covariates assessed during a 365-day baseline period. We calculated the incidence rates (IRs), hazard ratios (HRs), and corresponding 95% confidence intervals (CIs) for each outcome.

Results: A total of 24,611 PS-matched pairs of MTX and HCQ initiators were identified. The mean (SD) age was 73.8 (6.6) years and 78% were female. Patient demographics, dermatologic conditions, comorbidities, medication use, and healthcare utilization were well-balanced between the two treatment groups at baseline (**Table 1**). During a total person-years of 52,836, we observed 693 (MTX) and 612 (HCQ) cases of malignant melanoma or NMSC. The IR per 1,000 person-year for the primary outcome was 24.57 (MTX) versus 24.85 (HCQ), and the HR comparing MTX with HCQ was 0.97 (95%CI 0.87-1.09). For secondary outcomes, MTX was associated with an elevated risk of BCC (HR 1.32, 95%CI 1.08-1.60) but a decreased risk of SCC (HR 0.77, 95%CI 0.61-0.97) compared with HCQ (**Table 2**).

Conclusion: In this large cohort of older RA patients initiating MTX or HCQ as their first DMARD, we found no difference in the risk of skin cancer including malignant melanoma and NMSC. However, for individual subsets of NMSC, the risk of BCC was higher in the MTX group compared with HCQ initiators while the risk of SCC was lower.

Table 1. Selected Baseline Characteristics of MTX and HCQ Initiators in the 1:1 Propensity Score Matched Cohort

Characteristics	MTX (N = 24, 611)	HCQ (N = 24, 611)	Standardized difference
Demographics			
Age in years, mean (SD)	73.78 (6.57)	73.80 (6.54)	0.003

Prostate Cancer Risk Is Not Increased in Rheumatoid Arthritis After Accounting for Retention in a Health Care System

Kaitlyn Brittan[1], Punyasha Roul[1], Joshua Baker[2], Yangyuna Yang[1], Brian Sauer[3], Namrata Singh[4], Harlan Sayles[1], Grant Cannon[5], Ted Mikuls[1] and Bryant England[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Utah, Omaha, NE, [4]University of Washington, Bellevue, WA, [5]Salt Lake City VA Medical Center and University of Utah, Salt Lake City

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) may have up to a 15% increased risk of prostate cancer per a recent meta-analysis (Simon et al. *Arthritis Research & Therapy,* 2015). Previously, we found similar rates of prostate cancer in U.S. Veterans with RA as in individuals from the general population via indirect standardization using the Surveillance, Epidemiology, and End Results (SEER) Program (Brittan et al, Abstract #943, 2018). Recognizing the potential for bias based on the referent population and differences in cancer surveillance, we compared the risk of prostate cancer among RA and non-RA patients in the Veterans Health Administration (VHA; direct standardization).

Methods: We performed a retrospective, matched cohort study in the VHA from 2000 to 2018. We identified male patients with RA using a validated administrative algorithm and matched them to male patients without RA (no RA diagnostic codes or DMARDs) on age and enrollment year (up to 1:5). RA and non-RA patients with prior prostate cancer or prostatectomy were excluded. Prostate cancer and prostate cancer death were identified from the VA oncology domain within the Corporate Data Warehouse and the National Death Index. Multivariable Cox models compared prostate cancer risk after adjusting for race, smoking status, body mass index, Agent Orange exposure, Rheumatic Disease Comorbidity Index score, prostate-specific antigen testing, and health care utilization. Subjects were clustered by the matched RA/non-RA groups. Recognizing the potential for greater retention in the healthcare system and premature mortality among RA patients to influence results, we tested additional models censoring for a gap of >365 days between VA visits and censoring the matched patients at the time of death (in cases unrelated to prostate cancer) in RA patients.

Results: We included 56,514 Veterans with RA and 227,343 Veterans without RA. Mean (SD) age was 64 (11) years and the majority (74% RA, 88% non-RA) were Caucasian. There were 6,550 incident prostate cancers during 2,337,104 patient-years of follow-up. Prostate cancer incidence rates (per 1,000 patient-years) were 3.5 (95% CI 3.3-3.7) in RA and 2.7 (95% CI 2.6-2.7) in non-RA. There was a 28% increased risk of prostate cancer in RA (Model A; Table) that was attenuated to 15% after multivariable adjustment (Model B). Accounting for premature mortality in RA from other causes did not meaningfully affect results (Model C). However, after censoring for a gap of >365 days between VA visits, RA was not significantly associated with prostate cancer risk (Model D: HR 1.07; 95% CI 0.98-1.18; p=0.13). Several sensitivity analyses produced results consistent with the primary results.

Table. Risk of Prostate Cancer in U.S. Veterans with (n=56,514) and without (n=227,343) RA

Model	Hazard Ratio RA vs non-RA	95% Confidence Interval	P value
A. Unadjusted	1.28	(1.20, 1.36)	<0.001
B. Adjusted*	1.14	(1.07, 1.22)	<0.001
C. Adjusted* + Censor matched patients for RA death	1.15	(1.07, 1.23)	<0.001
D. Adjusted* + Censor for gap >365 days between VHA visits	1.07	(0.98, 1.18)	0.13
All models matched RA and non-RA for age and VA enrollment year *Adjusted for race, smoking status; Agent Orange exposure; number of outpatient visits; PSA testing; body mass index; Rheumatic Disease Comorbidity Index score			

Conclusion: Using direct standardization and accounting for relevant confounders and causes of potential bias, we did not find RA to be associated with an increased risk of prostate cancer. These findings highlight the importance of accounting for healthcare system retention when studying cancer risk in rheumatic diseases to prevent detection bias.

Abstract Number: 1003

Long-term Weight Changes and Risk of Rheumatoid Arthritis Among Women in a Prospective Cohort: A Marginal Structural Model Approach

Nathalie Marchand[1], Jeffrey Sparks[2], Kazuki Yoshida[3], Susan Malspeis[4], Xuehong Zhang[5], Karen Costenbader[6], Elizabeth Karlson[1] and Bing Lu[7], [1]Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [4]Brigham and Women's Hospital, Boston, [5]Brigham and Women's Hospital and Channing Division of Network Medicine, Boston, MA, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [7]Brigham and Women's Hospital and Harvard Medical School, Newton, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of rheumatoid arthritis (RA) has been shown to be elevated among overweight and obese women in several studies, but whether weight gain or weight loss are associated with RA risk has been studied less. To address time-dependent confounding and allow for a causal interpretation of the data, we used Marginal Structural Models (MSM) to examine the effect of long-term weight changes on the risk of RA in women using data from the Nurses' Health Study (NHS) II.

Methods: The NHS II prospective cohort study started in 1989 (baseline). We followed up 114,946 women aged from 25 to 42 years and without RA at baseline until 2017 (up to 28 years). We obtained information on lifestyle and health using validated biennial questionnaires. We investigated two time-varying exposures: weight changes from

*Adjusted for previous questionnaire cycle weight change, baseline weight, age (years, continuous), smoking (never smoker, 12 months breastfeeding), menopausal status and hormone use (pre-menopausal, post-menopausal with never use, current use and past use), census tract median family income (quartiles), physical activity (0–2.9, 3–8.9, 9–17.9, ≥18 METs/week), alcohol intake (0-<5, 5-<15, ≥15 grams/day).

study baseline) and weight changes from age 18. After calculating weight changes every two years, these continuous variables were then divided into 5 categories: 1) weight loss of < -2 kilograms (kg); 2) weight sTable -2 to < 2 kg

(reference); 3) weight gain of 5 to < 10; 4) weight gain of 10 to < 20; and 5) weight gain of 20+ kg. We used MSMs with inverse-probability-of-censoring and exposure weights that allowed us to create stabilized weights incorporating previous questionnaire cycle weight change, as well as baseline and time-varying covariates. These included baseline weight, age, smoking, parity and breastfeeding status, menopausal status and hormone use, census tract median family income, physical activity, and alcohol intake. Such an approach created a pseudo-population in which the final analyses were performed by pooled logistic regression to approximately calculate risk ratios (RR) and 95% confidence intervals (CI) for the effect of long-term weight gain on the risk of RA in women. Analyses were stratified by serostatus, as risk factors and disease prognosis and severity may differ between these two types of RA.

Results: Over 2,583,266 person-years, we identified 541 women who developed RA. Women who gained 2 kg or more over the study period were at a significantly increased risk of RA. Compared to sTable weight, weight gain from baseline of 2 to < 10, 10 to < 20 and 20+ kg was associated with an increased risk of all RA (RR = 1.87, 95% CI 1.29-2.73; 3.08 95% CI 2.03-4.65; 3.48, 95% CI 2.13-5.68, respectively) (**Table 1**). Weight loss (< -2 kg) was also associated with increased RA risk (RR=2.00, 95% CI 1.22- 3.27) (**Table 1**). Furthermore, weight gain was significantly associated with an increased risk of both seropositive and seronegative RA. Consistently, weight gain of 10 to < 20 and 20 kg or more from age 18 years was associated with an increased risk of RA (RR = 2.12, 95% CI 1.38-3.27; 2.40, 95% CI 1.55-3.71, respectively) (**Table 2**).

Conclusion: Long-term weight gain was associated with an increased risk of RA in women. Maintenance of healthy weight may be a potential strategy for the delay or prevention of developing RA.

Abstract Number: 1004

The Incidence, Mortality, and Economic Burden of Potentially PrevenTable Infections in Rheumatoid Arthritis Patients

Soumyasri Kambhatla[1], Estefania Gauto-Mariotti[2] and Augustine Manadan[3], [1]John H Stroger Hospital of Cook County, Riverside, IL, [2]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: *Streptococcus pneumoniae*, Herpes zoster, and influenza infections are common and potentially prevenTable causes of morbidity and mortality. Vaccinations have been shown to reduce infection rates. Unfortunately, some patients are not offered or refuse these vaccinations. Additionally, younger patients are not eligible for pneumococcal and zoster vaccines based on the current age recommendations. In this, study we aimed to determine incidence, mortality, and national costs of hospital admissions for *Streptococcus pneumoniae (Strep pneumo)*, Herpes Zoster, and influenza infections in patients with rheumatoid arthritis (RA).

Methods: Data were abstracted from the National Inpatient Sample (NIS) Database. This database is the largest collection of inpatient admission data in the USA. It is a nationally representative sample of 20% of hospitalizations from

Table 1

	Influenza	*Strep pneumo*	Zoster
# of Hospitalizations	1,120	785	640
Mean age (yrs)	68	66	70
Female (%)	76%	71%	84%
Mean LOS	4.85 days	7 days	5.6 days
Aggregate LOS	10,725 days	5,020 days	3,610 days
Mortality	2.7% (30/1,120)	8.3% (65/785)	2.3% (15/640)
Mean Hospital Charges	$46,087	$67,001	$42,909
Aggregate Hospital Charges	$50,696,057	$52,595,942	$26,818,325

approximately 1000 hospitals. The numbers in the databases are weighted to optimize national estimates. The NIS was searched for hospitalizations in 2016 containing ICD-10 RA codes M05 and M06 as the principal or secondary diagnosis. We further limited the RA cohort to hospitalizations with a principal discharge diagnosis of *Strep pneumo* infection (ICD 10 codes J13, M00.1x, A40.3, B95.3, or G00.1), Herpes Zoster (ICD-10 codes B02), and influenza (ICD 10 codes J09 or J10). The total number of discharges, age, race, length of stay (LOS), mortality and total hospital charges were recorded.

Results: Adult RA patients had 564,835 hospitalizations in 2016. Among the RA patients, there were 1,120 hospitalizations for influenza, 640 hospitalizations for zoster, and 785 hospitalizations for *Strep pneumo* (Table 1).

Of the RA patients hospitalized for influenza, mean age was 68 years, 76% were female, the mean LOS was 4.85 days, aggregate LOS 10,725 days, 2.7% (30/1,120) had in hospital mortality, the mean hospital charges were $46,087 and aggregate hospital charges were $50,696,057.

Of the RA patients hospitalized for zoster, mean age was 70 years, 84% were female, the mean LOS was 5.6 days, aggregate LOS 3,610 days, 2.3% (15/640) had in hospital mortality, the mean hospital charges were $42.909. and aggregate hospital charges were $26,818,325.

Of the RA patients hospitalized for *Strep pneumo* infections, the mean age was 66 years, 71% were female, the mean LOS was 7 days, aggregate LOS 5,020 days, 8.3% (65/785) had in hospital mortality, the mean hospital charges were $67,001, and the aggregate hospital charges were $52,595,942. These numbers do not account for outpatient or emergency department visits. Additionally, hospital charges are known to be higher than allowed or real charges.

Conclusion: Our analysis shows influenza, zoster, and *Strep pneumo* infections constituted only 0.5% of RA hospitalizations but in-hospital mortality was high. Additionally, the economic burden of these infections was large with aggregate national hospital charges totaling over $130 million and an aggregate LOS of 19,355 days. Universal vaccinations programs in RA patients should be studied to reduce hospitalizations, cost, morbidity, and mortality.

Risk of Non-vertebral Fractures Among Rheumatoid Arthritis Patients Treated with Biologic or Targeted-Synthetic DMARDs: A Multi-Database Comparative Safety Study

Ajinkya Pawar[1], Rishi Desai[1], Mengdong He[1], Lily Bessette[1] and **Seoyoung Kim**[2], [1]Brigham and Women's hospital, Boston, [2]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) increases risk of osteoporosis and fractures. However, limited head-to-head comparative data exists on the risk of non-vertebral osteoporotic fractures (NVFs) among biologic (b) or targeted-synthetic (ts) disease-modifying antirheumatic drugs (b/tsDMARDs). The primary objective of this study was to compare the incidence rate of NVFs in RA patients initiating one of the 9 b/tsDMARDs: abatacept (ABA), adalimumab (ADA), certolizumab (CER), etanercept (ETA), golimumab (GOL), infliximab (INF), rituximab (RIT), tocilizumab (TCZ) or tofacitinib (TOF).

Methods: We analyzed 3 U.S. healthcare claims databases [Optum (2008-03/19), Medicare and MarketScan (2008-17)]. RA patients aged≥18 years who newly started b/tsDMARDs without any use in the prior year were identified. Patients with previous fracture or malignancy were excluded. ADA was the most frequently used drug and selected as a common reference. The primary outcome was a composite endpoint of incident NVFs that included hip, humerus, pelvis and wrist fracture requiring intervention (except pelvis). Secondary outcomes were specific subtypes of fractures. We adjusted for >70 potential confounders including demographics, comorbidities, osteoporotic diagnosis and medication use, prior DMARD use, other medications, and healthcare utilization in each database through propensity score (PS)-based inverse probability treatment weighting. For the as-treated analysis, follow-up time started the day after cohort entry until the first occurrence of: outcome, treatment discontinuation, switching to other b/tsDMARD, nursing home admission, death, disenrollment, or the end of study period. For each drug-comparison, weighted Cox proportional hazards models estimated the hazard ratios (HRs) with 95% CIs, and provided pooled estimates after data source level stratification. Secondary analyses were conducted in patients switching from a tumor necrosis factor inhibitor to a b/tsDMARD.

Results: A total of 134,693 b/tsDMARD initiators were identified across 3 databases, of which 26% were ADA initiators. Mean age was 72 years in Medicare, 54 in Optum and 52 in MarketScan. During the 365-day baseline period, 39-65% patients used methotrexate, 64-71% used corticosteroids, and 13-30% had osteoporosis. After PS-weighting, majority of the covariates were well balanced. The average follow-up time (days) ranged from 384 (Optum) to 490 (Medicare). A total of 1,234 NVF events occurred (incidence rate/1,000 person-years: 7.8). The adjusted HRs showed similar risk of composite NVFs in all b/tsDMARD exposures compared to ADA: ABA (HR 1.04, 95% CI 0.82-1.30), CER (1.08, 0.79-1.49), ETA (1.11, 0.88-1.39), GOL (0.90, 0.59-1.39), INF (1.04, 0.84-1.28), RIT (1.07, 0.74-1.55), TCZ

Table. Risk of non-vertebral fractures associated with initiating b/tsDMARDs vs. adalimumab: a propensity score–based inverse probability treatment weighting (IPTW) as-treated analysis

	Exposures								Common reference
	Abatacept (n= 13,753)	Certolizumab (n= 7,864)	Etanercept (n= 34,661)	Golimumab (n= 6,836)	Infliximab (n= 21,408)	Rituximab (n= 7,195)	Tocilizumab (n= 3,499)	Tofacitinib (n= 4,172)	Adalimumab (n= 35,305)
Outcome	Weighted Hazard Ratio (95%CI)								
Primary									
Composite non-vertebral fracture	1.04 (0.82-1.30)	1.08 (0.79-1.49)	1.11 (0.88-1.39)	0.90 (0.59-1.39)	1.04 (0.84-1.28)	1.07 (0.74-1.55)	1.22 (0.69-2.13)	1.07 (0.70-1.65)	ref
Secondary									
Hip fracture	0.96 (0.65-1.41)	1.00 (0.61-1.65)	1.27 (0.85-1.89)	1.47 (0.78-2.78)	1.20 (0.84-1.70)	1.31 (0.71-2.39)	1.05 (0.35-3.10)	1.02 (0.48-2.17)	ref
Humerus fracture	1.60 (0.95-2.70)	1.59 (0.81-3.11)	1.54 (0.94-2.52)	0.73 (0.31-1.71)	1.27 (0.79-2.03)	1.04 (0.49-2.21)	2.03 (0.78-5.31)	1.09 (0.51-2.31)	ref
Pelvis fracture	0.85 (0.39-1.86)	0.59 (0.12-2.76)	0.78 (0.30-2.04)	0.08 (0.01-0.67)	0.71 (0.33-1.52)	0.47 (0.15-1.47)	0.21 (0.03-1.64)	1.58 (0.38-6.52)	ref
Wrist fracture	0.93 (0.65-1.33)	1.05 (0.62-1.78)	0.84 (0.61-1.16)	0.55 (0.33-0.92)	0.89 (0.64-1.24)	1.01 (0.56-1.82)	1.84 (0.77-4.38)	0.95 (0.47-1.93)	ref

Notes: 1. For the primary as-treated analysis, follow-up time started the day after cohort entry and ended on the first occurrence of: outcome, treatment discontinuation, switching to other b/tsDMARD, nursing home admission, death, disenrollment, or the end of study period.
2. Hazard ratios (HR) from the 3 PS-weighted cohorts were combined using weighted Cox models stratified by the data source.

(1.22, 0.69-2.13) and TOF (1.07, 0.70-1.65). Consistent findings were observed in the secondary analyses (not shown) and subtypes of NVFs (Table).

Conclusion: This large multi-database cohort study of RA patients found no differences in the risk of composite endpoint of NVFs or specific NVFs after starting ABA, CER, ETA, GOL, INF, RIT, TCZ or TOF versus starting ADA as their first or second b/tsDMARD therapy.

Post-menopausal Rheumatoid Arthritis Is Inversely Associated with Lifetime High Level of Estrogen Exposure in the French E3N Cohort

Carine Salliot[1], Yann Nguyen[2], Amandine Gelot[3], Xavier Mariette[4], Marie-Christine Boutron-Ruault[3] and Raphaèle Seror[5], [1]CHR orleans, Orleans, France, [2]1Department of Internal Medicine, Hôpital Beaujon, APHP Nord, Université de Paris, Clichy, Clichy, France, [3]Institut Gustave Roussy, Villejuif, France, [4]Paris-Sud University, Rueil-Malmaison, France, [5]Rheumatology Department, Bicetre Hospital, APHP, France, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The involvement of female hormones in the pathogenesis of Rheumatoid Arthritis (RA) is supported by numerous observations: a female predominance, an increased incidence in the post-partum, and around the age of menopause. In the literature, findings on the association between reproductive and hormonal factors, taken individually, and RA are conflicting. Our objectives were to assess the relationships between lifetime durations/level of female hormonal exposures and the risk of RA.

Methods: E3N is an ongoing French prospective cohort of 98,995 women since 1990 aged 40-65 years at enrolment. Validation of RA cases among the cohort has been previously published [Nguyen *et al.* BMJ Open 2019]. Lifetime female hormonal exposures were defined as follows:
-Reproductive span (in years) = duration from menarche to menopause
-Total ovulatory years (in years, time-dependent) = Reproductive span – (number of full-term pregnancies x 0.75 + number of miscarriages x 0.25 + total duration of breast feeding + total duration of oral contraception)
-Lifetime hormonal exposure (in years, time-dependent) = Reproductive span + total duration of menopausal hormonal therapy
-Composite Estrogen Score (CES, range = 0–5, time-dependent), calculated by point assignment for early menarche (≤10 years), high parity (>3 pregnancies), history of hysterectomy, use of hormone therapy (oral contraception and/or menopausal hormonal therapy, ever) and late menopause (≥53 years).

Hazard ratios (HRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using Cox proportional hazards regression models with age as the time scale.

Table: Hazard ratios (95% confidence intervals) for rheumatoid arthritis (RA) among 78,391 postmenopausal women by composite oestrogen score (CES) for 2 adjusted models (with stratification for year of birth)

		RA	Non-cases	HRs (95%CI), *p-value*	
				Age adjusted Model	Multi-adjusted Model
CES (0-5)					
	0	36	4173	1.03 (0.8–1.4)	1.04 (0.8–1.4)
	1	345	42,132	1	1
	2	225	26,719	1.02 (0.8–1.2)	1.01 (0.8–1.2)
	3	29	4428	0.70 (0.4–1.0), *p*=0.0705	**0.64 (0.4–0.9), *p*=0.0475**
	4	2	300	1.0 (0.2–3.9)	0.91 (0.2–3.7)
	5	0	2	-	-
Estrogen exposure levels					
	Low [CES =0–1]	381	46,305	1	1
	Moderate [CES=2]	225	26,719	1.01 (0.8–1.2), *p= 0.8631*	1.0 (0.8–1.2), *p=0.9921*
	High [CES=3–5]	21	4730	0.70 (0.4–1.0), *p=0.0738*	**0.65 (0.4–0.9), *p=0.0477***

HRs (95% CI): Hazard ratios (95% Confidence Intervals).
Multi-adjusted Model: adjustment for age, smoking (past/current/never), passive smoking during childhood (ever/never), educational level (<high-school, up to 2 years of University, ≥3 years of university), Body Mass Index (<18.5; 18.5–25; 25–30; >30kg/m²), duration of premenopausal progestogen (0;]0–24]; >24 months), age at the first pregnancy (<22, [22–27[, ≥27 years) and type of menopause (natural/artificial).

Models were adjusted for age (age-adjusted model) and additionally for smoking, passive smoking during childhood, educational level, body mass index , duration of premenopausal progestogen, age at the first pregnancy and type of menopause (multi-adjusted model).

Results: A total of 637 incident RA cases occurred among 78,391 post-menopausal women with a total of 1,864,915 women-years from baseline.

Reproductive span, total ovulatory years and lifetime hormonal exposure were not significantly associated with incident RA in postmenopausal women in age adjusted models (*p for trend*=0.2479, *p for trend*=0.4343, *p for trend*=0.9216 , respectively).

In multivariable-adjusted Cox regression models, high level of estrogen exposure (CES=3-5) was inversely associated with the risk of RA in post-menopausal women: HR=0.65 (95%CI 0.4–0.9), *p*=0.04, taking low level (CES=0-1) as reference (Table).

Interestingly, in a recent publication, high level of CES was associated with a reduced risk of primary Sjögren, but not cumulative menstrual cycling (reproductive span minus time to pregnant) [McCoy *et al.* Arthritis Care Res 2019]. RA and primary Sjögren share a marked female predominance with a peak onset around menopause and the participation of B lymphocytes in this physiopathology.

Conclusion: In E3N cohort, a high CES which reflects lifetime exposure to estrogen was associated with a decreased risk of RA in postmenopausal women.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

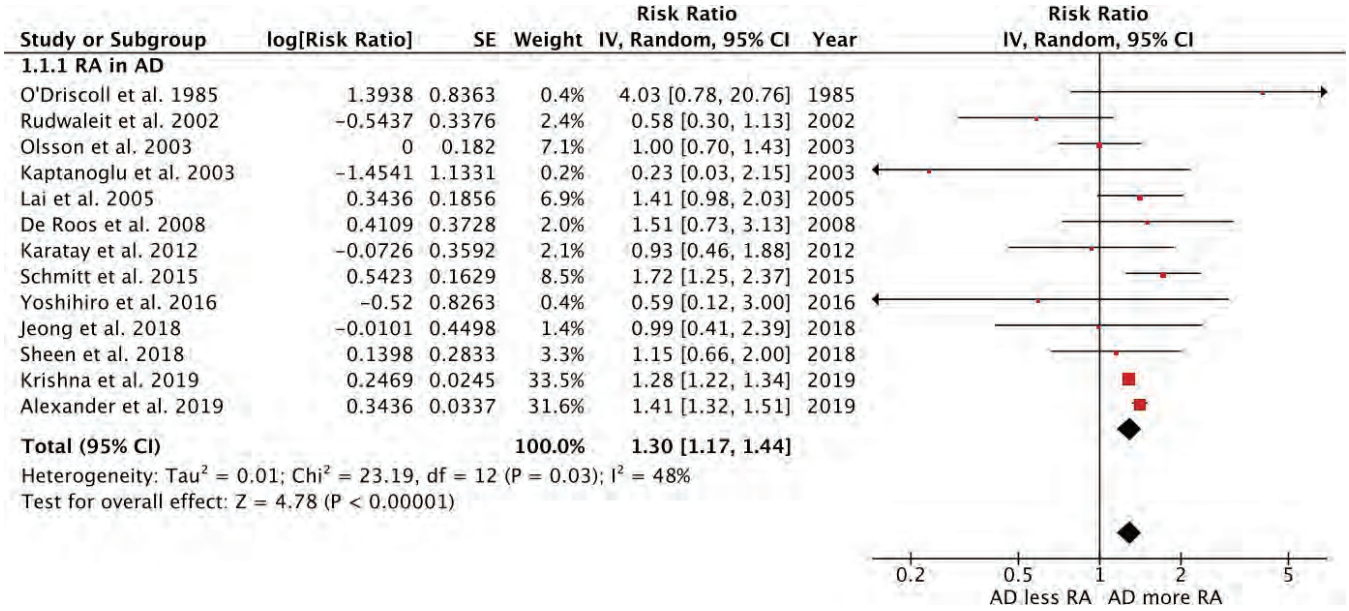
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent observational studies have suggested that patients with atopic dermatitis (AD) may have a higher risk of several non IgE-mediated inflammatory disorders, such as inflammatory bowel disease, systemic lupus erythematosus and Sjogren syndrome. The association between AD and rheumatoid arthritis (RA) is also described although results from previously published studies are conflicting. The current study aimed to combine all available data to investigate whether patients with AD had a higher risk of developing RA using systematic review and meta-analysis technique.

Methods: Systematic review was conducted using Medline and EMBASE database up to November 2019 using search strategy that comprised of terms for "atopic dermatitis" and "rheumatoid arthritis". Eligible cohort study must consist of one cohort of patients with AD and another cohort of comparators without AD. Then, the study must follow participants in both groups for incident RA and must report relative risk (RR), incidence rate ratio (IRR), hazard risk ratio (HR) or standardized incidence ratio (SIR) with 95% confidence intervals (CIs), comparing the incidence of RA between the groups. Eligible case-control study must recruit cases with RA and controls without RA. Then, the study must explore the prior history of AD of both groups and report odds ratio (OR) with 95% CIs comparing the prevalence of prior history of AD between the groups. Point estimates with standard errors were retrieved from each study and were combined together using the generic inverse variance method.



Results: The electronic search identified 21,824 records from the two databases. After two rounds of review, a total of 13 studies (four cohort studies and nine case-control studies) met the eligibility criteria and were included into the meta-analysis. The meta-analysis found that patients with AD had a significantly higher risk of incident RA than individuals without AD with the pooled RR of 1.30 (95% CI 1.17 to 1.44; I^2 48%).

Conclusion: The current systematic review and meta-analysis found a significantly higher risk of incident RA among patients with AD.

Forest plot of the meta-analysis of risk of incident rheumatoid arthritis in atopic dermatitis patients

Assessing Improved Risk Prediction of Seropositive Rheumatoid Arthritis by Environmental, Genetic, and Preclinical Plasma Metabolite Factors

Karen Costenbader[1], Jeffrey Sparks[2], Elizabeth Karlson[3], Kazuki Yoshida[4], Jing Cui[5], Susan Malspeis[6] and **Lilia Bouzit**[7], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [5]Brigham Women's Hospital, Boston, MA, [6]Brigham and Women's Hospital, Boston, [7]Harvard Chan School of Public Health, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent research has advanced the understanding of associations between environmental, genetic, and metabolic factors and rheumatoid arthritis (RA), introducing potential to improve risk prediction. A novel weighted genetic risk scored (wGRS) was generated from 90 non-*HLA* RA-associated risk alleles and five RA-associated amino acid positions of *HLA-DRB1* haplotypes. Additionally, several preclinical plasma metabolites were recently associated with seropositive RA. This study investigated whether the addition of variables representing the wGRS and preclinical metabolite levels increased the performance of seropositive RA risk prediction models compared to previously validated models in the Nurses' Health Studies (NHS).

Methods: This nested case-control study involved individuals with drawn plasma samples from the NHS prior to RA diagnosis or matched date for controls. Incident seropositive RA cases, based on the ACR 1987 criteria and ACR/EULAR 2010 criteria, were matched to two controls on age, blood collection features, and menstrual patterns at time of blood draw. Environmental variables, including age, smoking, alcohol use, socioeconomic status, region, reproductive factors, and BMI, were measured at the questionnaire cycle preceding the blood draw, corresponding to pre-diagnosis exposures. Four models were generated using logistic regression: a) base model with environmental factors (E), b) environmental and genetic and gene-environment interaction factors (E +G+GEI), c) environmental and pre-diagnosis metabolite factors (E+M), and d) all factors (E+G+GEI+M). Matching factors were included in the models to adjust for selection bias due to the matched case-control design. Model fit was assessed using Nagelkerke's R^2 and the Hosmer-Lemeshow test. The area under the receiver operating characteristic curve (AUC) was measured

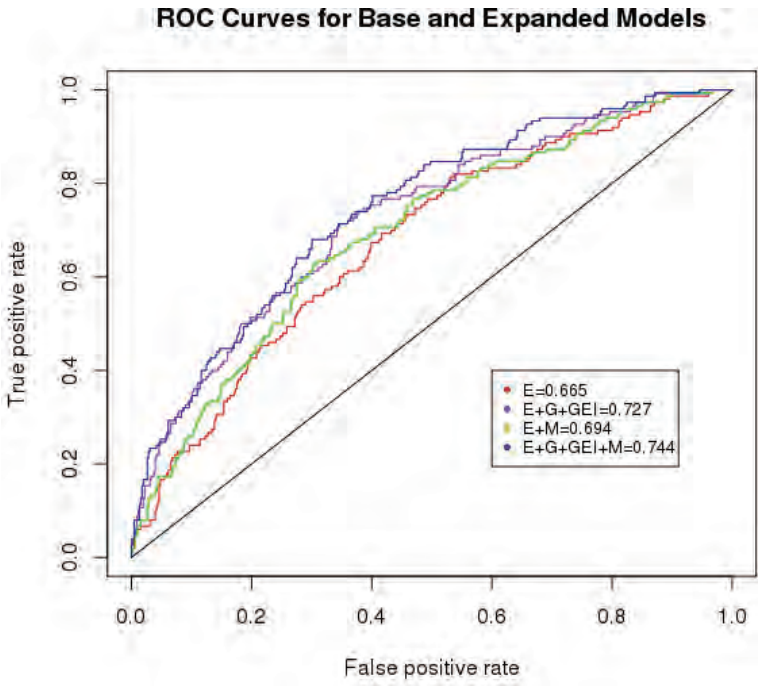
Table 1. Characteristics of Seropositive RA NHS* Sample Participants		
	Cases	Controls
N	150	456
Years prior to RA diagnosis or matched date (mean (SD))	10.09 (5.90)	10.04 (5.51)
Age at blood draw (mean (SD))◊	51.23 (7.79)	51.84 (7.81)
Post-menopausal hormone use (%)◊	61 (40.7)	190 (41.7)
Smoking in pack-years (mean (SD))	12.83 (15.97)	9.44 (16.07)
BMI (mean (SD))	26.01 (5.19)	25.04 (4.53)
Parity/breastfeeding (%)		
Nulliparous/Parous <1 month	62 (41.4)	191 (41.9)
Parous/1-11 months	62 (41.4)	146 (32)
Parous/12+ months	26 (17.3)	119 (26.1)
Cumulative alcohol use (mean (SD))	4.50 (6.12)	5.66 (8.90)
Region (%)		
West	67 (44.7)	184 (40.4)
Midwest	14 (9.3)	62 (13.6)
Mid-Atlantic	18 (12.0)	62 (13.6)
New England	28 (18.7)	81 (17.8)
Southeast	23 (15.3)	61 (13.4)
Irregular menses (%)	22 (14.7)	48 (10.5)
Menstruation before age 12 years (%)	26 (17.3)	105 (23.0)
Husband's education up to high school/vocational (%)	39 (26.0)	98 (21.5)
Median income quantile (%)		
1 – low income	31 (20.7)	80 (17.5)
2	26 (17.3)	94 (20.6)
3	38 (25.3)	86 (18.9)
4	29 (19.3)	98 (21.5)
5 – high income	26 (17.3)	98 (21.5)

*NHS=Nurses' Health Studies ◊Matching factors

to compare performance of expanded vs. base model. Models were internally validated using a bootstrapped estimate of optimism of the AUC. This measure of overfitting is based on the average difference between the predictive ability of the model built using the original sample, and the predictive ability of the models built using each bootstrap sample.

Results: 150 seropositive RA cases and 456 controls were included in the study. The E model yielded an AUC of 0.665 (95% CI 0.616, 0.714). The E model yielded an AUC of 0.665 (95% CI: 0.616, 0.714). The expanded model including genetic factors presented a strong improvement in discrimination; producing AUCs of 0.727 (95% CI: 0.676-0.770) in E+G+GEI model. The E+M model including preclinical metabolite factors produced a modest improvement in discrimination (AUC 0.694, 95% CI: 0.640, 0.736). The full E+G+GEI+M model yielded the highest AUC of 0.744 (95% CI: 0.697, 0.788). Optimism corrected models yielded an AUC of 0.596 for the E model, 0.666 for E+G+GEI, 0.606 for E+M, and 0.672 for E+G+GEI+M.

Conclusion: The addition of the wGRS and HLA haplotype-smoking interaction improve discrimination of the RA risk prediction model compared to models without genetic factors. However, recently reported preclinical metabolite levels do not appear to significantly contribute to prediction.



E: environmental- age, smoking pack-years, cumulative alcohol use, husband's education, income quintile, parity/ breastfeeding, early menses, menstrual irregularity, menopausal status, region, BMI.
E+G+GEI: environmental and genetic- all environmental variables, 90 SNP wGRS, HLA Haplotype GRS, HLA Haplotype GRS*Smoking.
E+M: environmental and metabolite1- all environmental variables, C5 carnitine, 4-acetamidobutanoate, C5:1 carnitine, 3-dehydroxycarnitine, C7 carnitine, N-acetylputrescine, 3-oxooctadecanoate, C3 carnitine, C16:1 CE, C35:0 PE.
E+G+GEI+M: environmental, genetic, metabolite- all variables.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

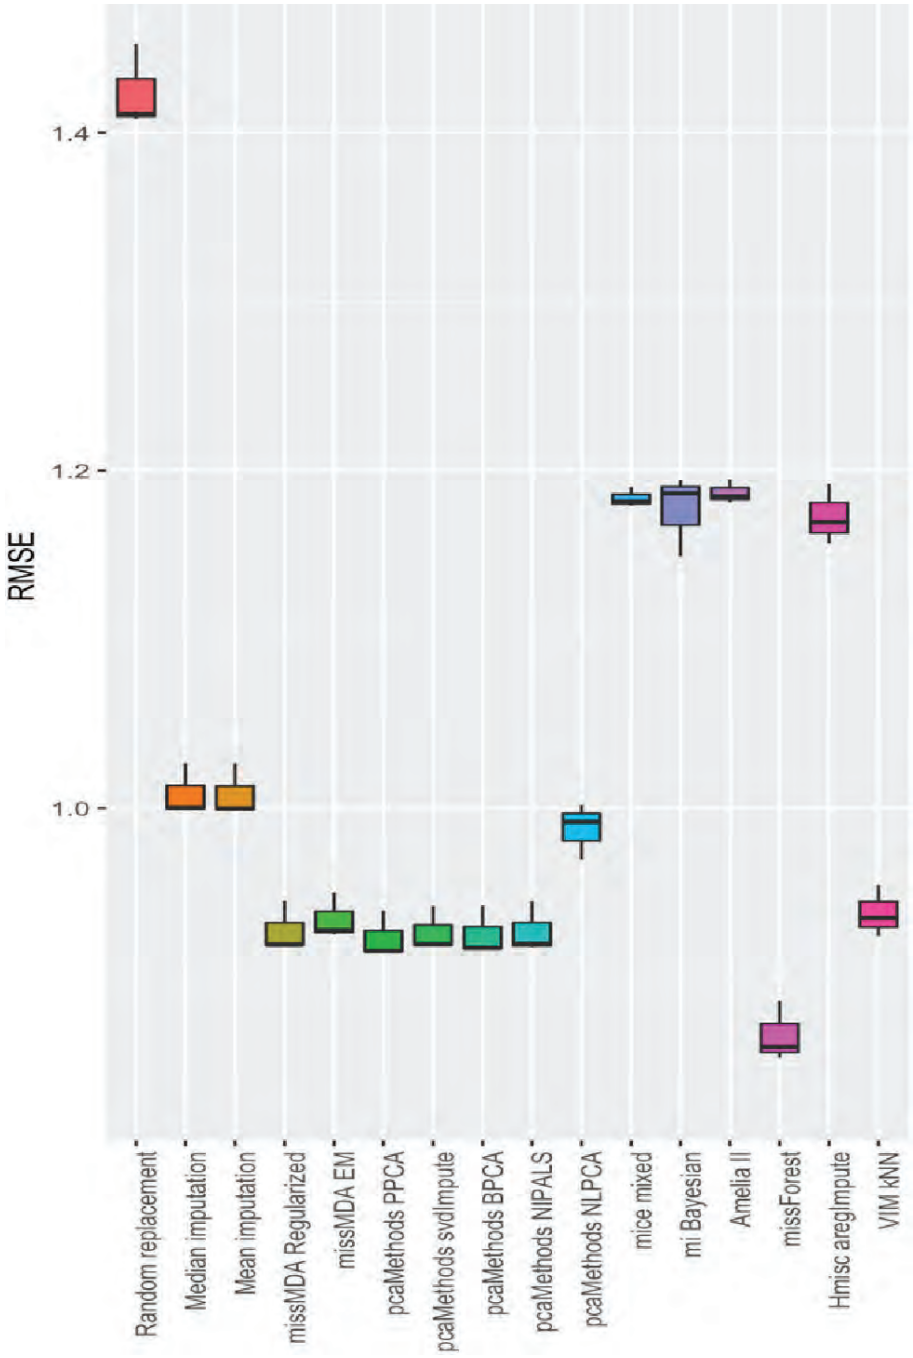
Session Time: 9:00AM–11:00AM

Background/Purpose: Missing data in clinical epidemiological researches violate the intention to treat principle, reduce statistical power and can induce bias if they are related to patient's response to treatment. In multiple imputation (MI), covariates are included in the imputation equation to predict the values of missing data. The purpose of this study is to find the best approach to estimate and impute the missing values in Kuwait Registry for Rheumatic Diseases (KRRD) patients data.

Methods: A number of methods were implemented for dealing with missing data. These included *Multivariate imputation by chained equations* (MICE), *K-Nearest Neighbors* (KNN), *Bayesian Principal Component Analysis* (BPCA), *EM with Bootstrapping* (Amelia II), *Sequential Random Forest* (MissForest) and mean imputation. Choosing the best imputation method was judged by the minimum scores of *Root Mean Square Error* (RMSE), *Mean Absolute Error* (MAE) and *Kolmogorov–Smirnov D test statistic* (KS) between the imputed datapoints and the original datapoints that were subsequently sat to missing.

Results: A total of 1,685 rheumatoid arthritis (RA) patients and 10,613 hospital visits were included in the registry. Among them, we found a number of variables that had missing values exceeding 5% of the total values. These included duration of RA (13.0%), smoking history (26.3%), rheumatoid factor (7.93%), anti-citrullinated peptide antibodies (20.5%), anti-nuclear antibodies (20.4%), sicca symptoms (19.2%), family history of a rheumatic disease (28.5%), steroid therapy (5.94%), ESR (5.16%), CRP (22.9%) and SDAI (38.0%), The results showed that among the methods used, MissForest gave the highest level of accuracy to estimate the missing values. It had the least imputation errors for both continuous and categorical variables at each frequency of missingness and it had the smallest prediction differences when the models used imputed laboratory values. In both data sets, MICE had the second least imputation errors and prediction differences, followed by KNN and mean imputation.

Conclusion: MissForest is a highly accurate method of imputation for missing data in KRRD and outperforms other common imputation techniques in terms of imputation error and maintenance of predictive ability with imputed values in clinical predictive models. This approach can be used in registries to improve the accuracy of data, including the ones for rheumatoid arthritis patients.



Root mean square error (RMSE) of various missing data imputation methods, showing that MissForest method has the lowest error to predict the missing information in KRRD data

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Compared with the general population, patients with RA are at an increased risk of infection and certain malignancies, which may be increased further with the use of DMARDs.[1,2] The abatacept global post-marketing epidemiology program included observational studies based on disease registries and healthcare claims databases. Reports from the core post-marketing epidemiology program on pre-specified outcomes associated with abatacept compared with other DMARD treatments in routine clinical practice showed no increase in the risk of infections requiring hospitalization or overall malignancies.[3,4] The aim of this supplemental post-marketing abatacept only study was to evaluate the incidence of infections and pre-specified malignancies in patients from several countries with RA who were treated with abatacept.

Methods: Data were analyzed from seven RA registries: Anti-TNF Therapy in Rheumatoid Arthritis (ATTRA, Czech Republic), Danish Database for Biologic Therapies (DANBIO), National Registry of Biological Treatment in Finland (ROB-FIN), Swiss Clinical Quality Management (SCQM), Orencia and Rheumatoid Arthritis (ORA, France), The Italian Group for the Study of Early Arthritis (GISEA) and Spanish Registry of Adverse Events of Biological Therapies in Rheumatic Diseases (BIOBADASER). The first day of abatacept treatment was considered the index date and exposure was measured in patient-years (p-y). Incidence rates (IRs) with 95% CIs were calculated for each pre-specified outcome.

Results: Patients treated with abatacept (>5000) were mostly female (78–85%), with a mean age ranging from 52–58 years. Baseline characteristics were largely consistent across the registries, except for longer disease duration in the ORA registry (mean [SD]: 20.4 [9.5] years; range across other registries: 8.1–13.3 years). In abatacept-treated patients, IRs for hospitalized infections across the registries varied, ranging from 0.4 to 10 per 100 p-y (**Table 1**). The IR for overall malignancies in abatacept-treated patients was low and ranged from 0.3 to 1.9 per 100 p-y (**Table 2**).

Table 1. Incidence rates per 100 p-y (95% CI), number of events and p-y of exposure for infections

	ATTRA (n=335)	DANBIO (n=1213)	ROB-FIN (n=362)	ORA[a] (n=1024)	GISEA (n=433)	BIOBADASER (n=350)	SCQM[b] (n=959/974)	Reference range[c,1,2]

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an orally applied Janus kinase inhibitor, which is approved for rheumatoid arthritis (RA) treatment in the USA since 2012, so that 'real world data' are already available there for many years. The prospective study ESCALATE-RA is the first non-interventional study with tofacitinib in Germany (ClinicalTrials.gov; NCT03387423). The first patient was enrolled in November 2017, the year of tofacitinib EMA-approval.

Methods: This 5-year study will enroll about 1500 patients at 200 centers in Germany. Adult patients eligible for tofacitinib therapy are documented in a standardized manner from the first tofacitinib intake for 24 months. According to standard clinical practice, patient documentation is expected quarterly and includes data on demographics, effectiveness, adverse events (AEs), and patient-reported outcomes. The present interim analysis (cut-off date January 31st, 2020) describes the patients in two subgroups (tofacitinib treatment without concomitant methotrexate treatment (mono-group); tofacitinib in combination with methotrexate (combi-group)), who reached the visit M12 after 12 months of treatment. In this non-interventional study, all analyses were based on observed data as reported by the site investigators with no imputation for missing data. Since this is an ongoing study, small changes in numbers may occur after the final data quality checks.

Results: In the M12-population (n=548), the mean age was 59 years, the majority of patients were female, had moderate to severe RA at baseline (BL), and were seropositive. 300 patients (54.7%) were treated with a bDMARD

Table 1. Demographics and Clinical Data at Baseline (M12-population)

	Monotherapy at M12 (N=332)[a]	Combination Therapy at M12 (N=216)[b]
Mean Age in years (SD)	60.04 (12.88)	57.93 (11.22)
	n/n_{tot} (%)	n/n_{tot} (%)
Gender		
Female	271/332 (81.6%)	148/216 (68.5%)
Smoking status		
Non-smoker	188/326 (57.7%)	119/205 (58.0%)
Prognostic factors		
Moderate to severe RA	314/332 (94.6%)	209/216 (96.8%)
ACPA positive	167/331 (50.5%)	118/216 (54.6%)
Rheumatoid factor positive	190/332 (57.2%)	141/216 (65.3%)
bDMARD premedication (prior tofacitinib treatment)	176/332 (53.0%)	124/216 (57.4%)
RA co-medication		
Glucocorticoids	212/332 (63.9%)	158/216 (73.1%)
Methotrexate	43/332 (13.0%)	182/216 (84.3%)

ACPA, Anti-citrullinated protein antibodies; bDMARD, biologic disease-modifying antirheumatic drug; M12, visit after 12 months of treatment; N, Number of patients with M12 visit; n_{tot}, Number of patients with available data; RA, rheumatoid arthritis; SD, standard deviation

[a] Includes 44 patients who switched from combination therapy to monotherapy.

[b] Includes 33 patients who switched from monotherapy to combination therapy.

Table 2. Treatment Escalation, Disease Activity, Functional Ability, Health-related Quality of Life and Safety (M12-population)

	Monotherapy at M12 (N=332)[a]	Combination Therapy at M12 (N=216)[b]
Mean Time to 1st Treatment Escalation	301 days	289 days
Treatment persistence after 1 year	0.72 (95% CI: 0.67; 0.76)	0.64 (95% CI: 0.57; 0.70)
Disease Activity		
DAS28-4 (ESR)		
BL Mean (SD), (n_{tot})	4.76 (1.34), (174)	4.61 (1.11), (119)
M12 Mean (SD), (n_{tot})	2.96 (1.13), (182)	3.04 (1.26), (115)
Mean change BL to M12 (SD), (n_{tot})	-1.71 (1.50), (150)	-1.63 (1.40), (97)
DAS28-4 (CRP)		
BL Mean (SD), (n_{tot})	4.37 (1.24), (181)	4.27 (1.03), (119)
M12 Mean (SD), (n_{tot})	2.54 (1.00), (185)	2.74 (1.10), (108)
Mean change BL to M12 (SD), (n_{tot})	-1.80 (1.45), (160)	-1.61 (1.40), (96)
Functional Ability		
Morning Stiffness [min]		
BL Mean (SD), (n_{tot})	75.21 (75.49), (189)	59.96 (54.06), (125)
M12 Mean (SD), (n_{tot})	42.50 (35.08), (119)	41.83 (41.85), (75)
Mean change BL to M12 (SD), (n_{tot})	-45.36 (152.06), (106)	-18.88 (50.32), (67)
Functional Ability Questionnaire Hannover (FFbH)		
BL Mean (SD), (n_{tot})	60.91 (23.04), (228)	65.12 (21.36), (155)
M12 Mean (SD), (n_{tot})	68.16 (23.71), (218)	75.50 (21.65), (128)
Mean change BL to M12 (SD), (n_{tot})	8.61 (16.27), (217)	5.24 (14.13), (127)
FFbH Remission Rate (FFbH >83%)

Safety (Patients)		
with tofacitinib related AE	127/332 (38.3%)	92/216 (42.6%)
discontinued study due to AE	0/332 (0.0%)	1/216 (0.5%)
discontinued study drug due to AE but continued study	78/332 (23.5%)	70/216 (32.4%)
with dose reduced or temporary discontinuation due to AE	49/332 (14.8%)	25/216 (11.6%)

AE, adverse event; BL, baseline; CI, confidence interval; CRP, C-reactive protein; DAS28-4, disease activity score in 28 joints based on 4 variables; ESR, erythrocyte sedimentation rate; FACIT, Functional Assessment of Chronic Illness Therapy; FFbH, Functional Ability Questionnaire Hannover; M12, visit after 12 months of treatment; N, Number of patients with M12 visit; n_{tot}, Number of patients with available data; SD, standard deviation

[a] Includes 44 patients who switched from combination therapy to monotherapy.
[b] Includes 33 patients who switched from monotherapy to combination therapy.

immediately prior to enrollment. 332 patients were in the mono-group and 216 patients in the combi-group at M12 (Table 1).

Average time to first treatment escalation was 301 days for patients with monotherapy and 289 days for patients with combination therapy. The treatment persistence after 1 year was 72% (mono-group) and 64% (combi-group) respectively. A considerable reduction of disease activity and morning stiffness was observed in both groups over time while functional ability according to FFbH (Functional Ability Questionnaire Hannover) and self-reported quality of life increased in both groups. The mean change from BL of disease activity and morning stiffness as well as functional ability was greater in mono-group compared to combi-group. Furthermore, patients in mono-group showed a greater improvement in self-reported quality of life than patients in combi-group. However, functional remission was achieved by more patients in the combi-group (44.5%) than in the mono-group (33.0%). An AE (adverse event) related to tofacitinib occurred in 38.3% of mono-group and 42.6% of combi-group (Table 2).

Conclusion: This interim analysis shows a good effectiveness profile and an increased quality of life with tofacitinib therapy. There were no unexpected AEs observed.

Abstract Number: 1012

The Global Prevalence of Rheumatoid Arthritis: A Meta-Analysis

Khalid Almutairi[1], Johannes Nossent[1], David Preen[1], Helen Keen[1] and Charles Inderjeeth[1], [1]The University of Western Australia, Perth, Western Australia, Australia

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the global population prevalence of rheumatoid arthritis (RA) based on published studies and assess factors that influence RA prevalence estimates.

Methods: Four electronic databases were searched (ProQuest, MEDLINE, Web of Science, and EMBASE) for publications that reporting prevalence estimates of RA from 1980 and 2019. A random-effect meta-analysis model was used to produce the pooled prevalence estimates. The potential between-study heterogeneity was identified using sensitivity analysis, sub-group and meta-regression analyses.

Results: A total of 67 studies were included in the meta-analysis, containing 742,246 RA patients and 211,592,925 healthy controls. The global RA prevalence estimate was 0.46% (95% confidence interval (CI): 0.39-0.54; I^2=99.9%) with a 95% prediction interval (0.06–1.27). The RA point-prevalence was 0.45% (95% CI: 0.38- 0.53%) between 1986 and 2014, while the pooled period-prevalence was 0.46% (95% CI: 0.36% and 0.57%) from 1955 to 2015. The highest RA pooled prevalence (0.69%; 95% CI: 0.47–0.95) was derived from linked data sources studies. Based on meta-regression, the factors that explain the studies' heterogeneity of RA prevalence, including geographical location, the risk bias assessment of studies and sample size.

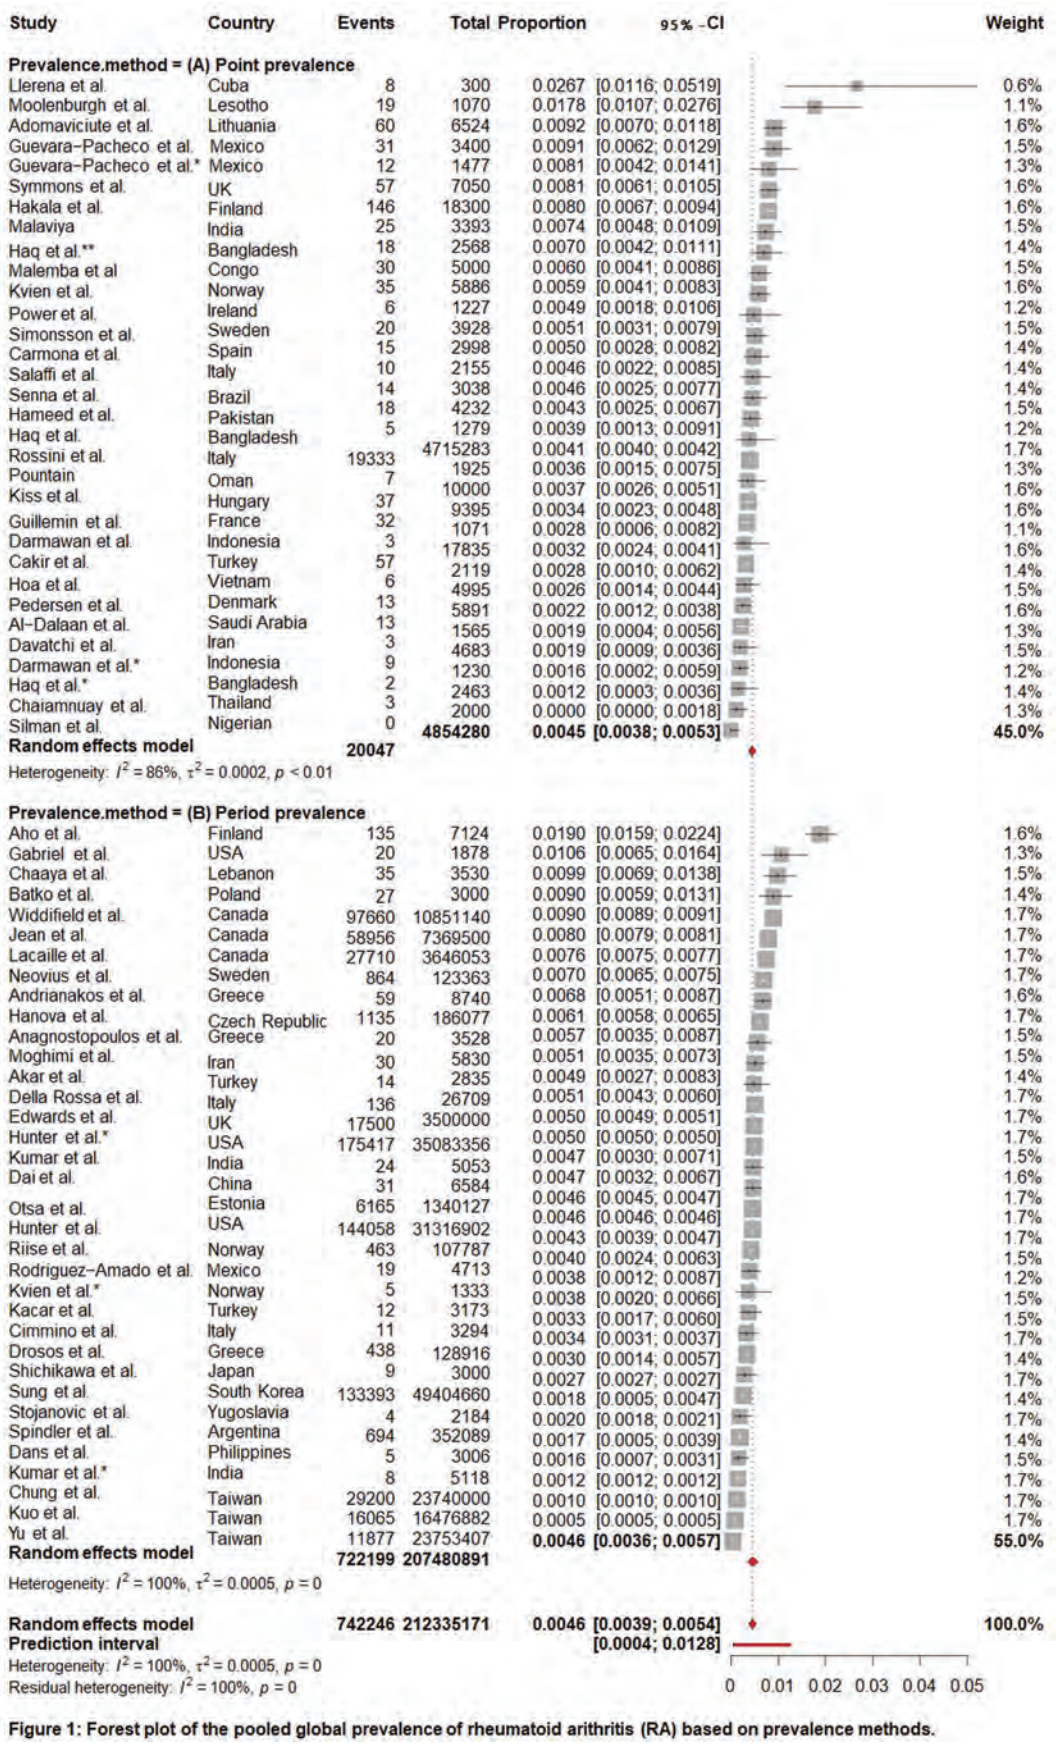

Figure 1. Forest plot of the pooled global prevalence of Rheumatoid Arthritis (RA) based on prevalence methods.

Table 1: The 95% prediction intervals for future RA prevalence estimates of different sub-groups category.

Sub-groups category	n	Lower predication interval	Upper predication interval
Geographical location			
North America	10	0.29%	1.29%
Europe	26	0.38%	0.73%
Asia	26	0.05%	0.73%
Africa	3	*	*
South America	2	*	*
RA classification criteria			
Clinical diagnosis by a doctor	19	0.17%	1.15%
Revised ARA criteria 1987	37	0.17%	0.73%
Modified ARA criteria 1987	7	0.18%	0.71%

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: It is estimated that over 120,000 individuals currently have rheumatoid arthritis (RA) in Canada, yet a comprehensive study summarizing the epidemiology of RA burden in the country is lacking. We used data from the Global Burden of Diseases, Injuries, and Risk Factors (GBD) Study 2017 to evaluate the level, and trends over time, of disease burden indicators prevalence, mortality, years of life lost (YLLs), years lived with disability (YLDs), and disability adjusted life years (DALYs) for RA in Canada by age, sex, and socio-demographic index (SDI), from 1990 to 2017.

Methods: We obtained publicly available data from GBD Study 2017 from the Institute for Health Metrics and Evaluation interactive visualization tool (http://vizhub.healthdata.org/gbd-compare). Estimates were calculated as non-age standardized and age standardized rates per 100,000 population. GBD estimated mortality and prevalence rates based on published literature, survey data, patient records, and health insurance claims. YLLs measure years lost due to premature death calculated as the number of deaths multiplied by the standard life expectancy at each age. YLDs measure the amount of time in a year an individual lives with a short- or long-term health condition, calculated by multiplying RA prevalence with disability weights for that condition, for each age, sex, and year. DALYs was calculated as the sum of YLLs and YLDs for each age group, sex, and year. SDI combines income per capita, average educational attainment, and fertility rates. Canadian DALYs were compared to DALYs of countries with similar SDI

Indicator	Standardization	ALL (Female & Male)			FEMALE			MALE		
		YEAR		Change	YEAR		Change	YEAR		Change
		1990	2017		1990	2017		1990	2017	
Prevalence	Non age standardized	170.3	352.2	107%	241.5	494.7	105%	97.1	205.1	111%
	Age standardized	144.7	223.7	55%	195.5	308.4	58%	87.6	133.1	52%
Mortality	Non age standardized	0.7	0.9	26%	1.0	1.2	21%	0.4	0.5	38%
	Age standardized	0.6	0.4	-22%	0.7	0.5	-23%	0.4	0.3	-18%
YLLs	Non age standardized	12.4	13.0	5%	17.4	17.0	-3%	7.3	8.9	22%
	Age standardized	10.0	7.1	-29%	12.8	8.8	-31%	6.6	5.2	-21%
YLDs	Non age standardized	22.5	46.0	105%	31.7	64.4	103%	13.0	26.9	108%
	Age standardized	19.1	29.5	54%	25.8	40.7	57%	11.7	17.7	51%
DALYs	Non age standardized	34.9	59.0	41%	49.2	81.4	66%	20.2	35.8	77%
	Age standardized	29.2	36.7	20%	38.6	49.4	28%	18.3	22.9	25%

Table 1. Time Trends for Non Age Standardized and Age Standardized RA Burden of Disease Indicators per 100,000, Canada, 1990-2017

values. All extracted data was analysed by DisMod-MR 2.1, a Bayesian meta-regression tool. All Canadian estimates were compared to global estimates.

Results: Time trends were evaluated over the study period 1990-2017. In Canada, the prevalence rate of RA increased by 55%, mortality rate decreased by 22%, YLL rate decreased by 29%, YLD rate increased by 54%, and DALY rate increased by 26%, all age-standardized. The age-standardized prevalence, mortality, YLL, YLD and DALY rates were higher in females. The Canadian prevalence rate increased at a greater rate than the global prevalence rate. The Canadian age-standardized mortality and YLL rates significantly declined after the year 2002. The global age-standardized mortality and YLLs rates declined at a slower rate than Canada. The DALY rate peaked at 70-74 and 75-78 age groups for both females and males. In 2017, YLDs contributed to 81% of the proportion of DALYs. Canada had lower age-standardized DALYs than countries of similar SDI. A weak association was found between age-standardized DALYs and SDI.

Conclusion: RA is a major public health challenge. The age-standardized prevalence, YLDs, and DALYs are increasing while mortality and YLLs are decreasing. Canada fairs better than other high SDI countries with regards to national RA burden. Early identification and management of RA is crucial to reducing the overall burden of RA in Canada, especially in women, who experience a higher burden of disease. Greater availability of data from multiple provincial RA databases would increase the accuracy and generalizability of our estimates for Canada.

Abstract Number: 1014

Disease Modifying Anti-rheumatic Drugs, Biologics and Corticosteroid Use in Older Patients with Rheumatoid Arthritis over 20 Years

John Hanly[1] and Lynn Lethbridge[2], [1]Dalhousie University, Halifax, NS, Canada, [2]Dalhousie University, Halifax, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The objective of the current study was to examine the change in prescribing patterns for older adults with RA over a 20 year period using a validated health administrative database. Specifically we wished to determine if the anticipated changes in prescribing over 2 decades had occurred in the broader population of RA patients and, in particular, if the use of corticosteroids fell over this time.

Methods: This was a secondary analysis of health administrative data using a previously validated dataset and case definition for RA. Cases were matched 1:4 by age and sex to controls within a population of approximately 1 million inhabitants with access to universal health care. Longitudinal data for incident and prevalent RA cases were studied between 1997 and 2017. Statistical analyses included descriptive statistics and linear regression.

Results: There were 8240 RA cases (all ≥ 65 years) with a mean (SD) age 72.2 (7.5) years and 70.6% were female. Over 20 years, annual utilization of coxibs in prevalent RA cases fell with a concomitant increase in disease modifying anti-rheumatic drugs (DMARDs) and biologics. Over the same period corticosteroid use was largely unchanged. Ap-

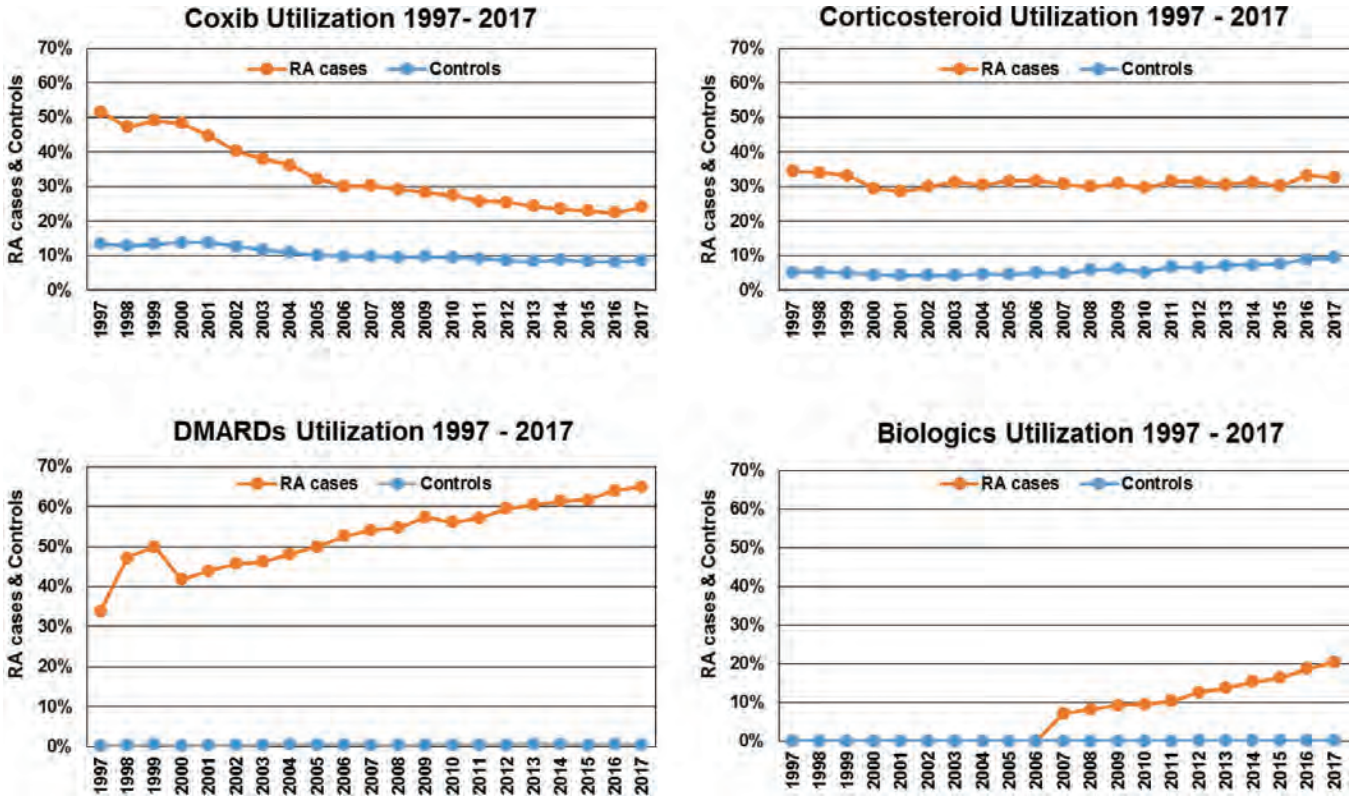

Figure 1. Annual utilization of coxibs, corticosteroids, disease modifying anti-rheumatic drugs (DMARDs) and biologics over 20 years as indicated by the proportion of RA cases and controls who received one or more prescriptions per year.

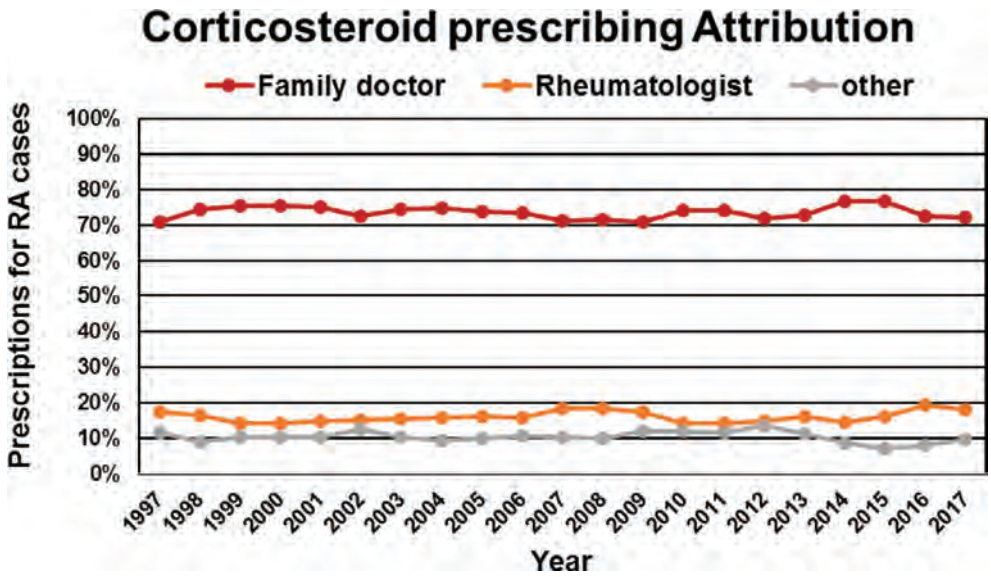

Figure 2. The annual proportion of total corticosteroid prescriptions for RA cases provided by family physicians and non-family physicians over 20 years.

proximately one third of patients had at least one annual prescription for corticosteroid, most frequently prednisone. The mean annual dose showed a modest reduction and the duration of utilization in each year shortened. Rheumatologists prescribed corticosteroids less frequently and in lower doses than other physician groups. For incident RA cases there was a significant fall in annual prescribed dose of prednisone by rheumatologists over time.

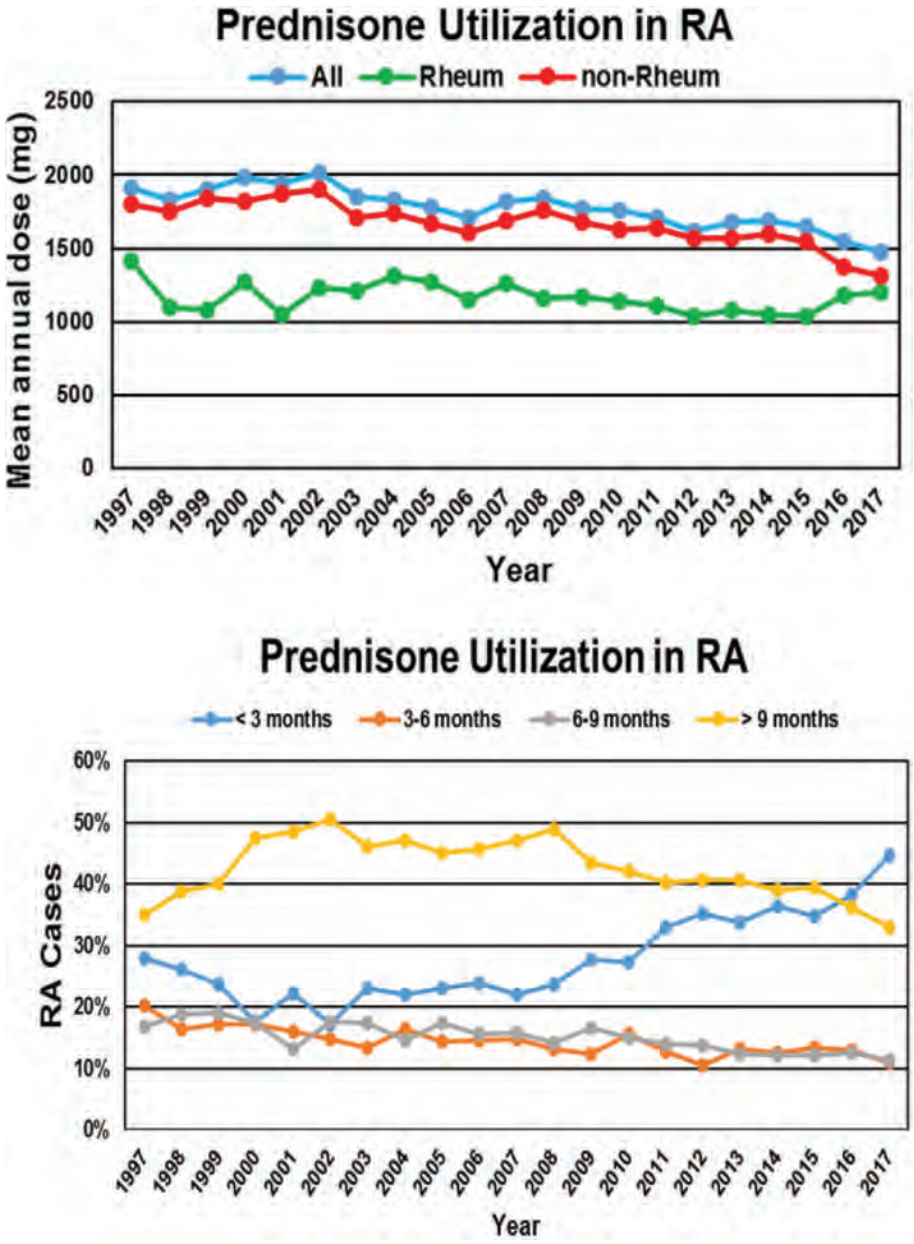

Figure 3. The change in annual utilization of prednisone in RA cases over 20 years. Top panel: change in mean annual dose of prednisone in RA cases and the attribution of prescriptions to rheumatologists (Rheum) and other physician groups (non-Rheum). Some patients received prescriptions from both rheumatologists and other physicians in the same year. Bottom panel: change in the annual duration of exposure to prednisone in RA cases as assessed by one or more prescriptions in each 3 month interval.

Conclusion: In older adults with RA the utilization of DMARDs and biologics has increased over the past 20 years. However, the use of corticosteroids has persisted. Renewed efforts are required to minimize their use in the long-term pharmacological management of RA.

The Prevalence and Risk Factors for Liver Fibrosis Among Rheumatoid Arthritis (RA) Patients on Disease-Modifying Anti-rheumatic Drugs (DMARDs)

Chou Luan Tan[1], Boon Han Ng[2], Noor Shahrazat Ahmad[2], Shahrul Aiman Soelar[2], Muhammad Zulhilmi Asyraf Jazlan[2], Mohd Ammar Dzakirin Md Mansor[2], Mohd Azri Mohd Suan[2], Kuang Kiat Kiew[2], Zalwani Zainuddin[2], Muhammad Radzi Abu Hassan[2] and Chong Hong Lim[2], [1]Hospital Sultanah Bahiyah, Kementerian Kesihatan Malaysia, Alor Setar, Kedah, Malaysia, [2]Hospital Sultanah Bahiyah, Alor Setar, Kedah, Malaysia

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Majority of DMARDs, including methotrexate (MTX), leflunomide (LEF) and sulfasalazine (SSZ) are believed to be hepatotoxic, causing liver fibrosis. However, the clinical findings were inconsistent. An ultrasound(US)-based transient elastography (TE) and shear-wave elastography (SWE) has become a promising tool in detecting liver fibrosis and fatty liver. Our study aims to determine the risk factors of liver fibrosis and fatty liver among RA patients on DMARDs.

Methods: Our cross-sectional cohort study recruited adult RA patients, who fulfilled ACR 1987 or EULAR-ACR 2010 classification criteria, from the rheumatology clinic at Sultanah Bahiyah Hospital, Malaysia. Liver fibrosis and fatty liver score were detected using US TE/SWE. Patient's demographic, disease activity (DAS28 score) and relevant blood parameter were recorded. Data were analysed using Spearman correlation, One-way Anova and Kruskal-Wallis Test.

Results: A total of 43 patients were recruited; the majority were female 38 (88%). The mean age of patients was 51.6± 10.5 years. The cumulative dose of each DMARDs: MTX 1572.5mg (IQR 762.5-2490.0), SSZ 1330g (IQR 685- 2607), LEF 19621± 19719 mg and HCQ of 193.5g (IQR 66.3- 283.6). Our study showed a positive correlation between triglyceride level and SWE (r_s= 0.476, p= 0.002), negative correlation of high-density lipoprotein and SWE (r_s= -0.474, p= 0.002). Whereas there was a negative correlation between albumin level and TE (r_s= -0.312, p= 0.044). High BMI was associated with an increased fatty liver score (r_s= 0.372, p= 0.033). Interestingly, our study demonstrated a negative correlation between the cumulative dose of HCQ and the fatty liver score (r_s= -0.782, p= 0.004). There were no significant differences between monotherapy and combination therapy on the fatty liver score (F(3,37)= 0.892, p= 0.454), SWE (H(3)= 3.687, p= 0.297) and TE (H(3)= 0.693, p= 0.875).

Conclusion: Our study demonstrated that DMARDs were generally safe with low risk of liver fibrosis. Dyslipidemia and obesity should be optimized in order to the reduce risk of liver fibrosis. Hydroxychloroquine administration may be a protective factor against fatty liver.

Abstract Number: 1016

Annual Cardiac or Orthopedic Procedure Volume in Gout versus Rheumatoid Arthritis: A National Time-trends Study

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The hospitalization rate for gout has been increasing in recent years with a reduction in people with RA. To our knowledge, there are no studies of time-trends in U.S. national estimates of cardiac versus orthopedic procedures in people with gout compared to RA. Our study objective was to compare time-trends in cardiac versus orthopedic procedures in people with gout versus RA. We hypothesized that (1) RA would be associated with higher annual volume and rates of both procedures at the beginning and the end of our study period, but the gout-RA gap will narrow over time, (2) increase in the annual volume of orthopedic procedures will be higher than cardiac procedures in both, and (3) increase in their annual volume in gout or RA will outpace that in the general U.S. population.

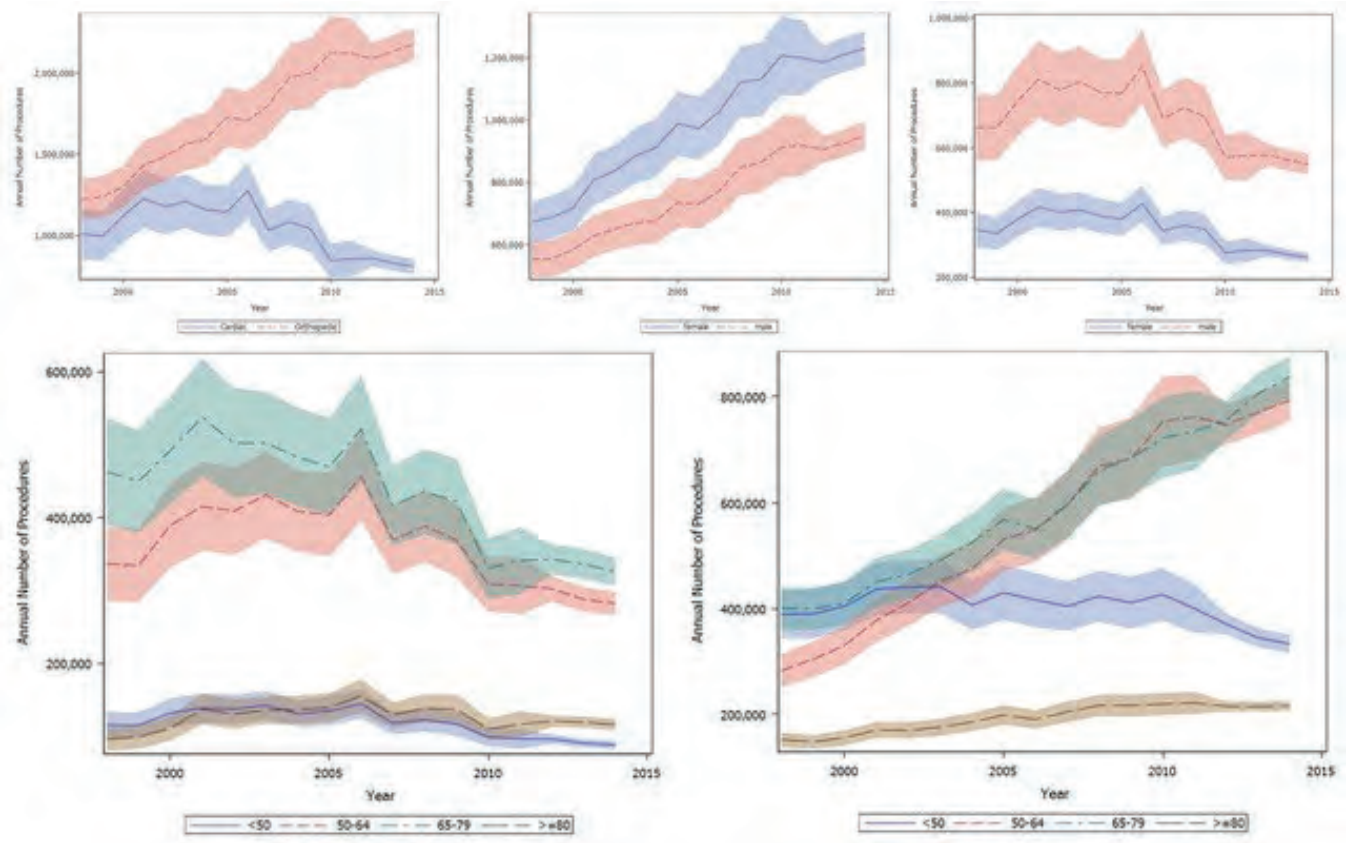

Figure 1. Time-trends in cardiac and orthopedic procedures in the U.S. general population during the study period 1998-2014 showing the overall trend (A), cardiac procedures by sex (B), orthopedic procedures by sex (C), cardiac procedures by age groups (D) and orthopedic procedures by age groups (E) Figure 1 legend: X-axis represents the study year and Y-axis shows the number of annual procedures. Estimates over time are shown with the line and the shaded area represents the upper and lower 95% confidence intervals. The Y-axis scales differs between panels.

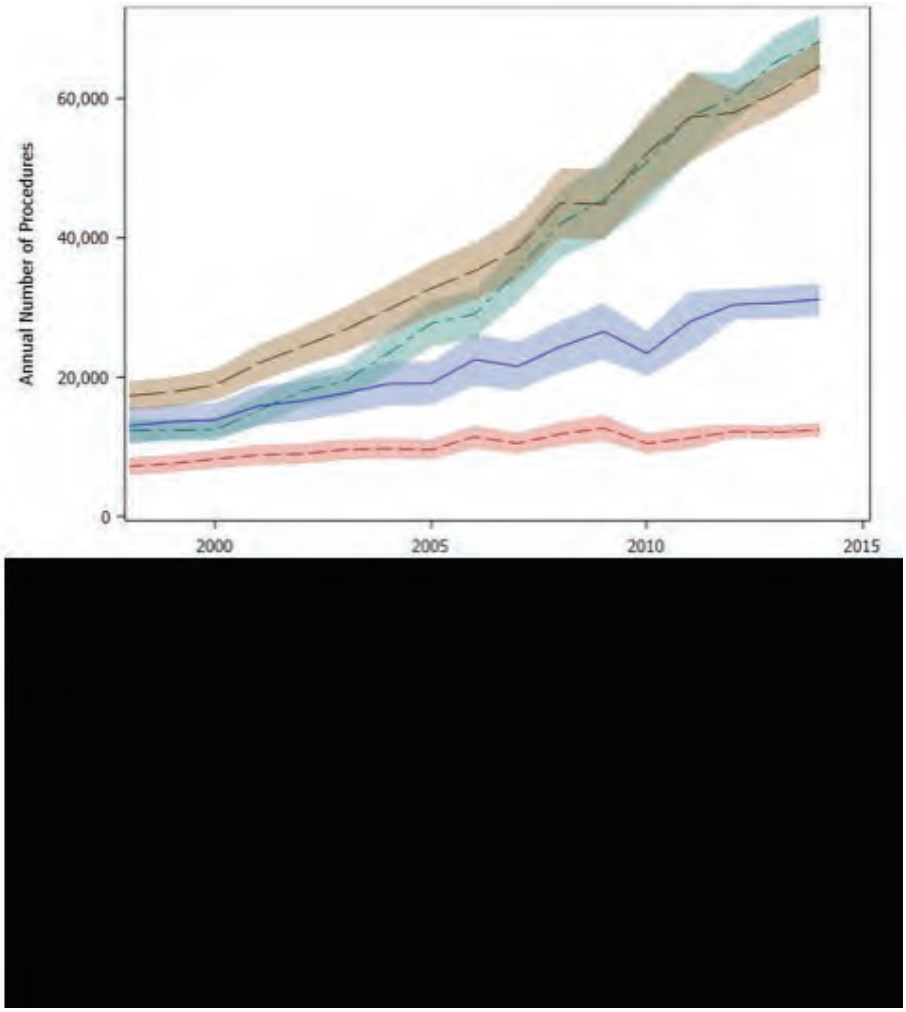

Figure 2. Time-trends in cardiac and orthopedic procedures from 1998-2014 in people with gout or rheumatoid arthritis (RA) during the study period showing the overall trends Figure 2 legend: X-axis represents the study year and Y-axis shows the number of annual procedures. Estimates over time are shown with the line and the shaded area represents the upper and lower 95% confidence intervals. The Y-axis scales differs between panels.

Methods: We examined the frequency of 7 common cardiac and orthopedic procedures in hospitalized people with gout or RA (or the general population) using the 1998-2014 U.S. National Inpatient Sample (NIS). Poisson regression evaluated the statistical significance of the differences in frequencies in 1998 versus 2014, between gout and RA, and within each cohort.

Results: The rate of cardiac procedures per 100,000 NIS claims decreased from 2,977 in 1998 to 2,292 in 2014; the rate of orthopedic procedures increased from 3,609 in 1998 to 6,160 in 2014 in the U.S. general population (**Figure 1**).

Both in-hospital cardiac and orthopedic procedures increased in gout and RA with time, in contrast to declining numbers in the general U.S. population; orthopedic procedures became more common than cardiac procedures in gout and RA. The corresponding increase in in-hospital cardiac and orthopedic procedure rates per 100,000 NIS claims in two populations were as follows: (1) gout, 2.3 (36.6 to 82.8) and 5.1-fold (34.2 to 174.6); and (2) RA, 1.6 (20.1 to 33.1) and 2.4-fold (70.2 to 170.8), respectively (**Figure 2**). In RA, the cardiac-orthopedic procedure volume difference was significant in 1998 and 2014. We noted no significant difference between cardiac versus orthopedic procedures in 1998 in gout, but the difference was significant in 2014. Cardiac procedures were significantly higher in gout versus RA in 1998 (59% higher) and 2014 (92% higher; **Figure 2**).

Table 1. Rate per 100,000 NIS population hospitalization for cardiac or orthopedic procedures or all hospitalizations in people with a concomitant diagnosis of gout or rheumatoid arthritis (RA) from 1998 to 2014

	Cardiac Procedure hospitalizations	Orthopedic Procedure hospitalizations	Cardiac Procedure hospitalizations	Orthopedic Procedure hospitalizations	Any hospitalization	Any hospitalization
	Gout- Primary or secondary	Gout- Primary or secondary	RA- Primary or secondary	RA- Primary or secondary	Gout- Primary or secondary	RA- Primary or secondary
1998	36.6	34.2	20.1	70.2	749.9	763.5
1999	37.4	34.1	21.1	68.4	775.9	791.0
2000	37.6	33.2	22.5	69.4	769.9	800.8
2001	42.3	39.2	23.4	75.3	825.6	834.9
2002	43.4	46.0	23.6	80.9	933.1	863.0
2003	45.8	48.6	24.9	82.5	991.4	889.1
2004	48.5	58.0	24.9	89.6	1071.6	920.3
2005	48.2	67.9	24.4	94.7	1137.7	961.5
2006	56.5	70.7	29.0	98.3	1253.7	1003.2
2007	53.5	85.1	26.3	104.6	1369.5	1034.9
2008	60.7	101.6	29.4	119.6	1556.9	1150.0
2009	66.3	110.5	31.9	118.2	1725.2	1215.3
2010	58.7	124.0	26.7	134.9	1906.3	1279.0
2011	70.8	141.1	28.9	147.3	2221.1	1433.9
2012	77.8	149.5	31.7	150.8	2280.7	1431.1
2013	80.8	166.2	31.7	160.8	2362.4	1471.9
2014	82.8	174.6	33.1	170.8	2416.6	1515.4
Trends were similar for RA or gout as primary diagnosis for cardiac and orthopedic procedure hospitalizations, where estimable						

Table 1. Rate per 100,000 NIS population hospitalization for cardiac or orthopedic procedures or all hospitalizations in people with a concomitant diagnosis of gout or rheumatoid arthritis (RA) from 1998 to 2014

The orthopedic procedures in gout were significantly lower than RA in 1998 (33% lower), but were significantly higher than RA in 2014 (5% higher; **Figure 2**). Of all hospitalizations with cardiac/orthopedic procedures, the proportion of people with each as primary or secondary diagnosis increased from 1998 to 2014: (1) in-hospital cardiac procedures: 1.2% to 3.6% with gout; 0.7% to 1.4% with RA; and (2) in-hospital orthopedic procedures: 0.9% to 2.8% with gout; 1.9% to 2.8% with RA

Conclusion: Cardiac and orthopedic procedures increased in gout and RA 1998-2014 versus decline in the general population. Cardiac procedure volumes and rates were higher in gout versus RA in 1998 and 2014. Increasing in-hospital cardiac procedures in gout and RA contrasting with declining rates in the general U.S. population indicated that early diagnosis of gout and RA, and management of systemic inflammation are needed. Orthopedic procedures were more in 1998, but fewer in 2014 in RA versus gout.

Racial and Ethnic Disparities in the Risk of Preterm Birth Among Women with Systemic Lupus Erythematosus or Rheumatoid Arthritis with Varying Reference Groups

Lena Sabih[1], Jennifer Strouse[1], Gretchen Bandoli[2], Rebecca Baer[3], Laura Jelliffe-Pawlowski[3], Christina Chambers[2], Namrata Singh[4] and Kelli Ryckman[5], [1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]University of California San Diego, La Jolla, CA, [3]University of California San Francisco, San Francisco, [4]University of Washington, Bellevue, WA, [5]University of Iowa, Iowa City

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are independently associated with preterm birth (PTB). Black women have higher risk of both ARD and PTB; however, few studies have examined race/ethnic disparities in PTB risk among women with SLE or RA. In a large multiethnic cohort of women, we examined race/ethnic disparities in PTB risk stratified by ARD type (SLE or RA) as well as the interaction between race/ethnicity and ARD type.

Methods: Birth records linked to hospital discharge data of singleton births in California from 2007 to 2012 were leveraged for a retrospective cohort study including women at least 18 years old diagnosed with either SLE or RA identified by the international classification of diseases (ICD), ninth revision. 222 women with both SLE and RA were excluded from analysis. Race/ethnicity (Asian, Black, Hispanic, and White) was abstracted from the birth certificate. The relative risk of PTB (< 37 weeks versus ≥37 weeks gestation) was compared among race/ethnicity and stratified by ARD type (RA or SLE). Results were adjusted for relevant covariates including maternal age, pre-pregnancy body mass index (BMI), insurance, education, country of origin, parity and smoking using Poisson regression with the log link function. In the model we examined all possible combinations of comparisons by race and ethnicity by altering the referent group in the model. Additionally, we identified differences in the racial/ethnic disparities in PTB risk between RA and SLE by including an interaction term to the model between race/ethnicity and ARD (RA versus SLE).

Results: A total of 2,309 with RA and 2,874 women with SLE were included in the analysis. In women with SLE, Black, Hispanic, and Asian women were ~1.3 to 1.5 times more likely to have PTB compared to White women (Table 1). Black, Hispanic, and Asian women with SLE did not significantly differ from each other in PTB risk. Black women with RA were ~1.6 to 2.4 times more likely to have PTB compared to either Asian, Hispanic, or White women. Asian, Hispanic, and White women with RA did not significantly differ from each other in PTB risk. When examining the interaction between race and ARD (RA versus SLE) the Black-White PTB risk disparity in women with RA was 1.5 times higher compared to the Black-White PTB risk disparity in women with SLE (Table 1). The Black-Hispanic PTB risk disparity in women with RA was 2.1 times higher compared to the Black-Hispanic PTB risk disparity in women with SLE. The Black-Asian PTB risk disparity in women with RA was 1.5 times higher compared to the Black-Asian PTB risk disparity in women with SLE, but this did not quite reach statistical significance ($p< 0.05$).

Conclusion: Our findings in this large multiethnic cohort of women are consistent with prior work demonstrating that race/ethnicity is associated with increased relative risk of PTB but indicate that some disparities differ between RA and SLE. Black-White, Black-Hispanic, and Black-Asian disparities in PTB risk were greater in women with RA

Table 1: Association of race with preterm birth stratified by ARD diagnosis.

Comparison	Model	Preterm (<37 vs. ≥37)		Interaction
		RA	SLE	RA vs. SLE
Black vs. White	Unadjusted	**2.22 (1.61, 3.05)**	**1.47 (1.16, 1.85)**	**1.51 (1.02, 2.25)**

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-Target(T2T) is the main therapeutic strategy for patients with RA and SLE. There has been no report on comparation of seasonal variations on T2T rates in patients with RA and SLE.

Smart System of Disease Management (SSDM) is a smart phone-based mobile disease management tool, equipped with two apps, one for doctors and one for patients. After training by health care professionals, rheumatic patients will download and use SSDM for DAS28 or SLEDAI-2000 self-assessment, and upload clinical data (including disease activity, medication status and laboratory test results) to SSDM cloud, meanwhile the data will be synchronized to authorized physicians. Based on the clinical data submitted by the patient, the doctor can respond to the patient's request of consultation and refill the medication.

The purpose of this study was to outline and compare the effect of seasonal variations in the T2T rates through analysis of self-reported disease activity data in patients with RA and SLE from the SSDM system.

Methods: Seasons were designed as following: Spring is from March to May, summer from June to August, autumn from September to November, and winter from December to February.

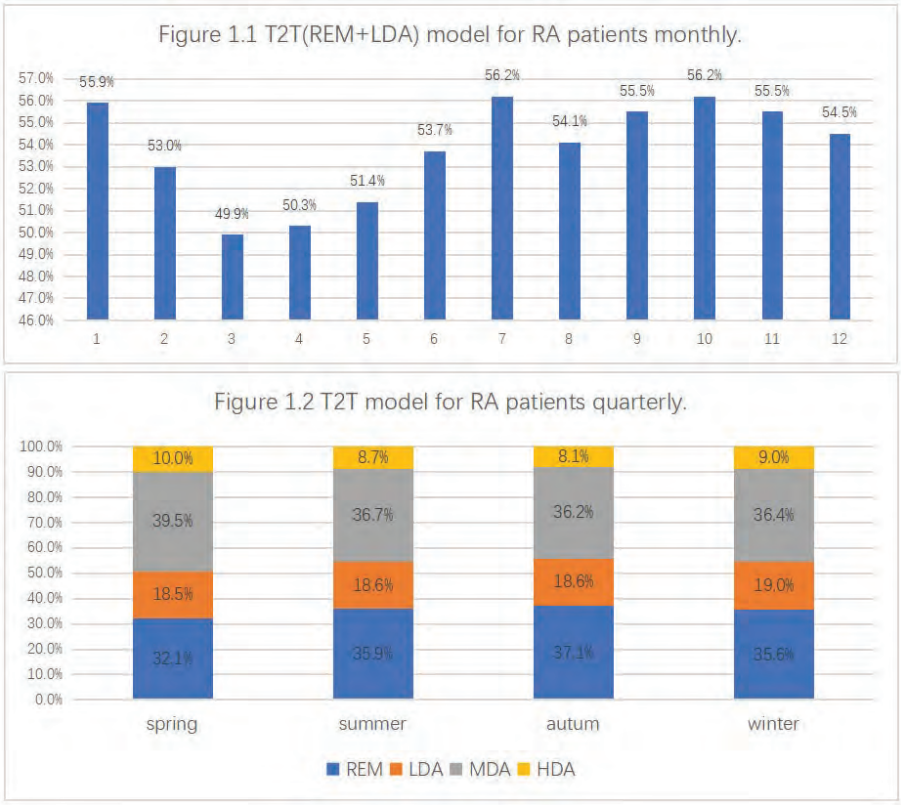

Figure 1. T2T model for RA patients (1.1 monthly;1.2 Quarterly)

DAS28 and SLEDAI-2000 data from each individual patient was extracted from cloud, and then pooled for analysis according to seasonal definition. DAS28≤3.2 and SLEDAI-2000≤4 are considered to be the criteria for achieving "T2T" for patients with RA and SLE, respectively.

Results: Between June 2014 and June 2020, 1,944 doctors from 632 hospitals in China joined the study, and 127,316 DAS28 assessments were conducted by 56,546 (male 10,260, female 46,286) RA patients (mean age 51.35 ±14.13 years, median course of disease 45.97 months), and 42,593 SLEDAI-2000 assessments were conducted by 19,629 (male 1,419, female 18,210) SLE patients (mean age 37.45 ±12.34 years, median course of disease 48.73 months)

The T2T rate of RA patients in spring is the lowest among four seasons in consecutive 5 years (mean rate of T2T is 50.5%, with 49.9% in March, 50.3% in April, and51.4% in May), while the average T2T rate in summer, autumn, and winter is 54.6%, 55.7%, and 54.5% respectively, with a U-shaped distribution from January to July. There is no significant difference in the overall distribution for SLE T2T rates among the four seasons. The T2T rates in spring, summer, autumn and winter were 55.8%, 55.5% ,56.7% and 57.3% respectively. However, there were two significant monthly drops on T2T rates in March (53.6%) and August (53.9%).

Conclusion: To our knowledge, this is the first study of outlining and comparing seasonal variation of T2T rates in patients with RA and SLE. Self-reported clinical data in SSDM for consecutive 5 years showed that RA patients have the lowest T2T rate in the spring season, which corelated with super long holiday of Chinese New Year, while SLE patients have the lowest T2T rate in March and August, which matched with holiday and strong UV light irradiation, respectively.

Outdoor Air Pollution and Systemic Lupus Erythematosus

George Stojan[1], Anton Kvit[2], Frank Curriero[2] and Michelle Petri[3], [1]Johns Hopkins University, BALTIMORE, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, [3]Johns Hopkins University School of Medicine, Baltimore

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding the role of environmental exposures in the development of SLE and their association with SLE activity may help identify modifiable risk factors and potential etiological mechanisms. We hypoth-

esized that changes in coarse particulate matter (PM10, < 10 micrometers in size), sulfur dioxide, carbon monoxide, lead, and nitrogen dioxide are predictive of organ specific flares in lupus.

Methods: 1628 patients who fulfill 4 of the 11 ACR or SLICC classification criteria for SLE were included in the analysis. The data ranged from 1999 to 2017. Maximum distance between visits was 110 days with 1-month time aggregation units. Disease activity was expressed as Physician Global Estimate (PGA), taken at every patient visit. A flare was defined as a PGA score increase of 1 point or more compared to the previous visit. Environmental and atmospheric data was obtained from the EPA, including PM10, sulfur dioxide, carbon monoxide, lead, and nitrogen dioxide. The average values of each factor 10 days prior to patient visit was calculated. Univariate and multivariate models were built in order to study the association of these variables with lupus disease activity. The models were adjusted for age, sex, income, county racial distribution, rural vs. urban patient residence, distance to highways, distance to airports, PM2.5, PM10, sulfur dioxide, carbon monoxide, lead, and nitrogen dioxide concentrations, temperature, humidity, barometric pressure, ozone concentration, and residual wind. Univariate and stepwise multivariate logistic regression was used to identify significant determinants associated with lupus flares. Regression was performed for each organ flare outcome. Regression inference was based on generalized estimating equations (GEE) to account for the time repeated outcomes.

Results: Increases in sulfur dioxide concentration were directly associated with rash ($p< 0.01$), joints ($p< 0.001$), and neurologic flares ($p< 0.001$), and inversely associated with renal flares ($p< 0.001$) in multivariate analyses. Lead concentration was directly associated with neurologic ($p< 0.001$) and pulmonary flares ($p< 0.001$), and indirectly associated with serositis ($p< 0.001$) and renal flares ($p< 0.001$) in multivariate analysis. Nitrogen dioxide was directly associated with rash ($p< 0.001$), joints ($p< 0.001$), serositis ($p< 0.001$), hematologic ($p< 0.001$), pulmonary ($p< 0.001$), and renal flares ($p< 0.001$) in multivariate analysis. PM10 and carbon monoxide had no significant associations in multivariate analysis.

Conclusion: There is a strong association between changes in nitrogen dioxide, sulfur dioxide, and lead concentrations 10 days prior to patient visit and organ specific lupus activity at the visit. Nitrogen dioxide is the only pollutant with a general association with all organ specific lupus flares.

*Skin-related quality of life (QoL) domains: Emotions (e.g., depression, embarrassment, anger), Functioning (e.g. sleep, social, work), Symptoms (itching, burning, bleeding) were measured with Skindex-29; Skindex-29 subscale scores range 0-100; a higher score indicates worse QoL). † Includes retirees, students and homemakers. Boldface values indicate a statistically significant association. Abbreviations: b= unstandardized beta (slope of the line between the independent and the dependent variable); CI=confidence interval

Table

Background/Purpose: Chronic stress may trigger or exacerbate physiologic pathways that worsen individual health and wellbeing. Stress is associated with the development and progression of skin conditions; however, little is known about its role in the quality of life (QoL) of people with cutaneous lupus erythematosus (CLE). African American (AA)

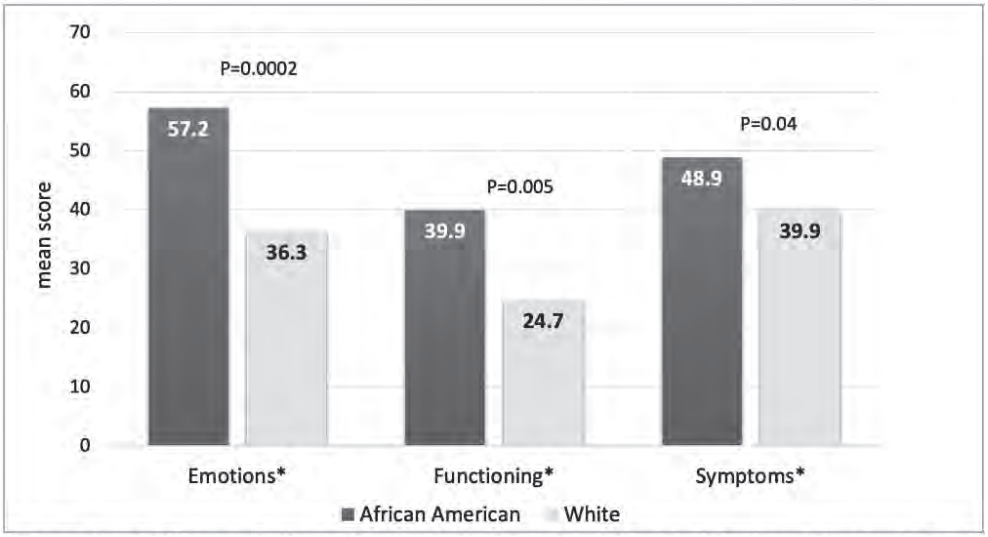

Figure. Racial Differences of Three Quality of Life Skin-related Domains (Emotions, Functioning and Symptoms) among Patients with Cutaneous Lupus Erythematosus. *Skin-related quality of life (QoL) Emotions (e.g., depression, embarrassment, anger), Functioning (e.g. sleep, social, work), and Symptoms (itching, burning, bleeding) were measured with Skindex-29; scores range 0-100; a higher score indicates worse QoL.

Figure

patients with CLE are more likely to be exposed to psychosocial stressors and may have worse QoL than whites. We examined racial differences in three skin-related QoL domains and explored the relationship between QoL, psychosocial stress, and race in patients with CLE.

Methods: We conducted a cross-sectional assessment among AA and white patients with a dermatologist-validated diagnosis of chronic or subacute CLE consented into the Georgians Organized Against Lupus (GOAL) study, a population-based cohort of individuals with lupus in the Southeastern U.S. The Skindex-29, a 5-point Likert scale was used to assess three skin-related QoL domains (emotions [e.g. depression, embarrassment, anger], functioning [e.g. sleep, social, work] and symptoms [e.g. itching, burning, bleeding]), with a higher score (range 0-100) indicating worse QoL of the domain being measured. Psychosocial stress was measured using validated patient-reported tools for disease-related stigma (PROMIS Stigma Short Form) and stress (Cohen self-perceived stress scale). For each skin-related QoL domain, three iterative multiple regression models were built to examine 1) stigma and stress, 2) these relationships controlling for demographic factors, and 3) with the addition of 2 disease-related factors.

Results: We examined 238 patients with CLE (chronic CLE (n=229); subacute CLE (n=9)), of whom 139 (58.4%) lacked systemic manifestations, and 99 (41.6%) had an associated diagnosis of systhemic lupus erythematosus (SLE). The large majority were females (n=208, 87.4%) and AAs (201, 84.5%). Mean age and disease duration were 48.5 and 11.6 years, respectively. AAs had significantly worse QoL (emotions, functioning and symptom scores) compared with whites **(Figure)**. Multivariable models revealed that both stigma and stress were independently associated with worse QoL in each domain, with little attenuation after controlling for race, other demographics, disease duration, and diagnosis of SLE **(Table).** AA race and unemployment were additional significant characteristics in the final two models for the emotions domain; for functioning lower education was significant after adjustment.

Conclusion: Our findings underscore significant racial disparities in three major domains of skin-related QoL among people with chronic or subacute CLE. We also highlighted a substantial role of stigma and stress on skin-related emotions, functioning and symptoms in this population. After controlling for multiple factors, skin-related emotions remained substantially worse in AAs, suggesting more susceptibility to psychological stress than whites. Our findings

suggest that interventions aimed at reducing stigma and managing stress may be helpful in improving the QoL of individuals with CLE and may ultimately contribute to reduced racial disparities in this population.

Abstract Number: 1021

Organ Damage in Systemic Lupus Erythematosus Is AttribuTable More to Comorbidity (Hypertension) and Less to Socioeconomic Status

Romy Kallas[1], Jessica Li[2], Daniel Goldman[3] and Michelle Petri[3], [1]Johns Hopkins Medical Institution, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Timonium, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple variables are known to contribute to development of organ damage in SLE patients, including prednisone use and ethnicity. The aim of this study was to evaluate the attribuTable risk due to comorbidities (hypertension, obesity, smoking), and socioeconomic factors on the total SLICC/ACR Damage Index (DI) and its sub-items in a large longitudinal prospective SLE cohort.

Methods: We analyzed data from a longitudinal cohort of 2,436 SLE patients who met the revised ACR or SLICC classification criteria (43% African-American, 57% Caucasian and 92% female). The SLICC/ACR DI was calculated based on organ damage that occurred after the diagnosis with SLE until the last visit. The outcome variable was the total damage score and that of each organ system at the last available cohort visit. We calculated the population attribuTable risk (PAR) for the total and each organ damage. Person month files since SLE diagnosis were created. At each month, variables were created to identify if patients had damage accrual. We analyzed the data using pooled logistic regression where the outcome was binary for each organ (accrual of damage). To account for the fact that some patients could contribute multiple damage events in the analysis, the GEE approach was used in fitting the model. Each model was adjusted for sex and age at the person month. Regression coefficients from the model were then used to calculate PAR.

Results: The mean total SLICC/ACR DI was 1.9 (SD=2.3). Hypertension was the strongest contributor to damage accrual, after adjusting for age and sex (Table 1 and 2). Hypertension was responsible for 30% of total damage: 70% of renal damage and 40% of cardiovascular damage was attributed to hypertension. The importance of hypertension was true regardless of ethnicity. Obesity was a strong contributor to neuro-psychiatric (23%) and renal (15.4) damage in Caucasians. It played a less important role in African-American patients, contributing only 3% and 0.8% to neuro-psychiatric and renal damage, respectively. Obesity was protective against skin damage in both African-Americans and Caucasians. Smoking contributed mostly to cardiovascular (13%) and skin (32%) damage. (Table 1). Only about 10% of any organ damage was accounted for by socioeconomic status. The 3 socioeconomic measures, education, low income, and insurance, contributed equally to total damage in patients with SLE. Socioeconomic status played a greater role in skin (28.3%) and peripheral vascular damage (21.5%), compared to damage in the other organ systems (Table 2).

Table 1: Population attributable risk estimates for hypertension, obesity, and smoking of each organ damage accrual in all patients, African-American, and Caucasian patients, adjusting for sex and age at the person month in each model

Skin	28.3	25.6	18.5	29.2	12.4	26.7	25.6	19.6	19.7
Other	3.2	7.1	-0.2	10.5	28.8	2.3	4.8	11.6	-0.3

Abbreviations:
PAR=population attributable risk

Conclusion: Of the three comorbidities, hypertension had the highest PAR for total, renal and cardiovascular damage, regardless of ethnicity. Obesity had a protective effect for skin damage. The three measures of socioeconomic status were less important than hypertension. Low income appeared to attribute more PAR than education or type of insurance. The Eight Americas Study found that ethnicity, rather than socioeconomic status, explained the ethnic differences in mortality. Our study suggests that ethnicity and hypertension are the most important contributors to organ damage (the strongest predictor of mortality).

Abstract Number: 1022

Declining In-hospital Mortality Gap in Lupus Compared to Non-lupus Hospitalizations: A National Study

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus is a serious, multi-system autoimmune disease that affects young people. Mortality is increased by over 2-3 fold compared to the general population. Time-trends showed a reduction in mortality in a multicentric lupus cohort from 1970 to 2001 and in a U.S. population-based lupus cohort from 1950 to 1992. In contrast, in a study using the U.S. National center for Health Statistics and National Inpatient Sample (NIS) data, in-hospital mortality was 2.9% and it increased from 1978 to 1998. Given these contradictory time-trends and the lack of contemporary data in lupus, an updated study of mortality are needed. Our objective was to assess the time-trends in in-hospital mortality rates in people with lupus hospitalized in the U.S. from 1998 to 2014, and compare it to people without lupus.

Methods: We included discharges from the Healthcare Cost and Utilization Project (HCUP) National Inpatient Sample (NIS) for 1998 through 2014, the last year of the use of the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM). The NIS is a 20% stratified sample of hospital discharges which is designed for creating national estimates.

We identified primary lupus hospitalizations based on the presence of an ICD-9-CM code of 710.0x in the primary position; this diagnostic code approach has a sensitivity of 98% and specificity of 72%.

We calculated the unadjusted in-hospital mortality rates per 1,000 hospitalizations for people with versus without primary lupus hospitalizations, with the respective denominators. Rates were adjusted by age, grouped in quintiles (< 20, 20-39, 40-59, 60-79, >79) then by age and sex. We analyzed for time-trends in rates over time using Cochran Armitage test, weighted by the number of hospitalizations in each year.

Results: The 241,130 primary lupus hospitalizations in 1998-2014 included predominantly black (34.3%), young (45% were 20-39 years; mean age, 36 years) and female (86.9%) patients. Deyo-Charlson comorbidity score was ≥2 for 47%, approximately 1/3rd were receiving Medicaid and 1.5% died during the index hospitalization (**Table 1**).

Unadjusted mortality in primary lupus hospitalizations decreased by 45.2% from 17.9 in 1998 to 9.5 per 1,000 in 2014, versus a 25.9% reduction in non-lupus (28.1 to 21.2 per 1,000; **Figure 1**). Age and sex-adjusted mortality gap by lupus also decreased: primary lupus hospitalization, 17.6 per 1,000 claims in 1998 to 13.8 in 2014 (21.5% reduction), versus 15.1 per 1,000 claims in 1998 to 13.2 in 2014 in non-lupus (12.5% reduction; **Figure 1**; **Table 2**). This caused the line of mortality rates for those with primary lupus hospitalization to overlap with that of the rest of the population. The number of primary lupus hospitalizations remained fairly constant at 12-15,000 per year 1998-2014

2013	21.1	12.3	12.8	13.0	15.8	19.6
2014	21.2	12.7	13.2	9.5	12.4	13.8
% reduction - 1998 to 2014	24.3%	12.1%	12.5%	45.2%	28.4%	21.5%

Table 2. Comparison of Mortality rates per 1,000 hospitalized people between lupus vs. non-lupus: unadjusted based on the NIS sample; age- and age- and sex-adjusted rates based on the NIS sample and the census data

(i.e., 0.04% of all NIS claims), and the rate per 100,000 NIS claims was 40.3 in 1998-2000 versus 34.9 in 2013-2014; the annual rates of total NIS hospitalizations were also sTable 1998-2014.

The lupus to non-lupus mortality rate ratio was 1.17 in 1998 and 1.04 in 2014.

Conclusion: The reduction in in-hospital mortality in people with lupus exceeded than in non-lupus, including age- and sex-adjusted. The improved in-hospital mortality in lupus is encouraging.

Epidemiology and Sociodemographic Distribution of Upper Gastrointestinal Bleeding Among Medicaid Beneficiaries with Systemic Lupus Erythematosus

Chang Xu[1], Molly Perencevich[2], Seoyoung Kim[2], Karen Costenbader[3] and Candace Feldman[1], [1]Brigham and Women's Hospital, Boston, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) have multiple risk factors for upper gastrointestinal bleeding (UGIB), including heightened susceptibility to infection and glucocorticoid, NSAID and anticoagulant use. We aimed to examine the epidemiology and sociodemographic distribution of UGIB in a population-based SLE cohort enrolled in Medicaid, the largest U.S. insurance for low income individuals.

Methods: Using Medicaid claims data from 47 states (2000-2006) and from 29 states (2007-2010), we identified individuals 18-65 years with SLE (≥3 ICD-9 codes of 710.0 ≥30 days apart), with ≥12 months of continuous enrollment (baseline period) prior to the third SLE code (index date). Our outcome was UGIB (ED visit or hospitalization discharge diagnosis codes beginning the day following the index date). We assessed demographic factors, medication use, and comorbidities during the 12-month baseline period prior to and including the index date and determined the incidence rates (IR, 95% CI) of UGIB overall and by sociodemographics, medications and comorbidities. We used Cox regression models to compare risk (HR, 95% CI) of first UGIB by these factors. We age, sex and index date-matched SLE patients to the general Medicaid population (1:4, 2007-2010) and compared the HRs of UGIB adjusted

Table 1: Incidence rates and adjusted hazard ratios of UGIB among Medicaid beneficiaries with SLE, 2000-2010

*Multivariable Cox regression model adjusted for age, sex, race/ethnicity, region, index year, medication use (including glucocorticoids, NSAIDs, aspirin, anticoagulation, PPI/H2 blocker, SSRIs, opioids, hydroxychloroquine, and immunosuppressives), and presence of comorbidities (cardiovascular disease, cerebrovascular disease, chronic pain, diabetes mellitus, depression, GERD, gastritis/duodenitis, prior UGIB, Peptic ulcer disease/H.pylori infection, hepatitis, renal disease, venous thromboembolism, and alcohol use disorder).

**Asian and American Indian/Alaska Native race/ethnicity and UGIB history results are not shown according to CMS regulations to suppress cell sizes <11.

for sociodemographic factors, medications and comorbidities. In sensitivity analyses we excluded individuals with UGIB during the baseline period.

Results: Among 49,489 Medicaid beneficiaries with SLE, the mean (SD) age was 42.2 (11.7) years, 93% were female, 40% black, 38% white, 15% Hispanic, and 39% were from the South. The mean (SD) follow-up was 3.4 (3) years. There were 378 ED visits or hospitalizations for UGIB (IR 2.23/1000 person-years) (**Table 1**). In adjusted models, the risk of UGIB was higher among blacks compared to whites (HR 1.43, 95% CI 1.12-1.81), and in the South compared to the Northeast (HR 1.58, 95% CI 1.16-2.14). Baseline UGIB, cerebrovascular disease, gastritis/duodenitis, peptic ulcer disease/H.pylori infection, renal disease, alcohol use disorder, and glucocorticoid use were associated with higher risk, while hydroxychloroquine was associated with lower risk (HR 0.69, 95% CI 0.55-0.86). Proton pump inhibitors (PPIs) and H2 blockers were not associated with lower UGIB risk (HR 0.95, 95% CI 0.75-1.19). In medication and comorbidity-adjusted age and sex matched analyses (2007-2010), individuals with SLE had 4.28 times higher risk of UGIB (95% CI 2.39-7.68) compared to the general Medicaid population. After excluding patients with UGIB at baseline, IRs and risk factors were similar.

Conclusion: Among Medicaid beneficiaries, individuals with SLE had >4 times higher risk of UGIB compared to the general population. Black race, residence in the South, related comorbidities and glucocorticoid use were associated with higher risk. Baseline hydroxychloroquine use was associated with reduced risk of UGIB, perhaps a marker of higher quality care, while PPIs and H2 blockers were not, likely because they were prescribed to higher risk individuals. Further studies are needed to understand the efficacy of prevention strategies given this significant burden of UGIB among individuals with SLE.

Time Trends in the Incidence of Systemic Lupus Erythematosus: A 40-Year Study

Ali Duarte-Garcia[1], Mehmet Hocaoglu[2], Shirley-Ann Osei-Onomah[3], Jesse Dabit[1], Rachel Giblon[1] and Cynthia Crowson[4], [1]Mayo Clinic, Rochester, MN, [2]University of Maryland Medical Center Midtown Campus, Baltimore, MD, [3]Mayo Clinic, Rochester, [4]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Changes over time in the incidence of Systemic Lupus Erythematosus (SLE) remain uncertain. It is unclear if the variations in established SLE risk factors, such as the decline in smoking over time or the trend towards use of low-dose oral contraceptives, has had an impact in SLE incidence. We aimed to investigate secular trends in the incidence of SLE in adults from 1976-2018.

Methods: Using established population-based research infrastructure that links the medical records of all the individuals in a geographically well-defined population, we identified all the incident SLE cases from 1976-2018 using diagnostic codes for cutaneous and systemic lupus and the following laboratory measures: anti-nuclear antibodies, anti-double

*Age-adjusted to the US White 2010 population
**Age- and sex- adjusted to the US White 2010 population

Table 2. Incidence rates of systemic lupus erythematosus from 1976-2018

stranded DNA, anti-Sm, anti-cardiolipin, anti-beta 2 glycoprotein 1 antibodies, complement, coombs and lupus anticoagulant. After an extensive medical record review, cases were classified based on the 1982 or 1997 American College of Rheumatology classification criteria, and we considered the date of meeting classification as the incidence date. Incidence rates were age- and/or sex-adjusted to the estimated 2010 white population of the US. To compute 95% confidence intervals for incidence rates, it was assumed that the number of incident cases followed a Poisson distribution.

Results: We identified 152 incident SLE cases between the years 1976 and 2018. As detailed in Table 1, the mean age was 46.3 years (SD16.4), 84% were female. The racial distribution was 5% Black, 12% Asian, 82% Caucasian while 5% were Hispanic.

The overall SLE incidence was 3.9 (95%CI: 3.2, 4.5) per 100,000. The incidence rate in females was 6.2 (95%CI: 5.1, 7.3) while in males was 1.6 (95%CI: 0.9, 2.2) per 100,000. Age- and sex- specific incidence peaked at 40-49 years for females. In males there was an upward trend in the incidence after age 50. There was an increase over the years in the proportion of incident SLE cases in minorities.

The incidence of SLE increased 29% from 3.5 (95%CI: 2.1, 4.9) in 1976-1988 to 4.5 (95%CI: 3.3, 5.7) in 2009-2018 per 100,000 (Table 2). This increase in incidence was more pronounced in males with an increase of 0.9 to 2 per 100,000. The incidence of SLE seemed to have a 10-year cyclical pattern (Figure 1).

Conclusion: Our 40-year population-based study suggests that the SLE incidence in adults had an overall 29% increase and has doubled in males over the last four decades. SLE has a cyclical pattern similar to other autoimmune diseases. It's unclear if the increase in incidence is due to improvement in awareness and detection of SLE, changes in the racial make-up of the population, changes in lupus-related risk factors or a combination thereof.

Prevalence Estimates for Systemic Lupus Erythematosus over Four Decades

Ali Duarte-Garcia[1], Mehmet Hocaoglu[2], Shirley-Ann Osei-Onomah[3], Jesse Dabit[1], Sara J. Achenbach[3] and Cynthia Crowson[4], [1]Mayo Clinic, Rochester, MN, [2]University of Maryland Medical Center Midtown Campus, Baltimore, MD, [3]Mayo Clinic, Rochester, [4]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Prevalence estimates of disease are important for public health planning. The available prevalence estimates of systemic lupus erythematosus (SLE) do not account for changes in exposures or survival that may contribute to prevalence changes over time. We aimed to estimate the prevalence of SLE over four decades.

Methods: Using established population-based research infrastructure that links the medical records of all the individuals in a geographically well-defined population, we identified all the prevalent SLE cases from 1976 through 2018 using diagnostic codes for cutaneous and systemic lupus and the following laboratory measures: anti-nuclear antibodies, anti-double stranded DNA, anti-Sm, anti-cardiolipin, anti-beta 2 glycoprotein 1antibodies, complement levels, coombs and lupus anticoagulant. Given that patients may migrate to our region after the diagnosis of SLE and might had longstanding disease, we classified prevalent cases if the treating rheumatologist or nephrologist had a statement confirming SLE diagnosis in the medical record.

We estimated point prevalence for January 1 of the years 1985, 1995, 2005 and 2015. Only individuals who were residents of our region for at least a year were included in the analysis.

Table 1. Prevalence Cohorts of Lupus on January 1
Patients can be in multiple cohorts

	1985 (N=46)	1995 (N=63)	2005 (N=92)	2015 (N=131)
Age (yrs) on prevalence date, mean (SD)	47.3 (17.6)	47.1 (17.2)	48.6 (16.2)	54.6 (15.7)
Female sex	42 (91%)	58 (92%)	82 (89%)	109 (83%)
Race

Years from SLE clinical dx to prevalence date, mean (SD)	9.6 (8.2)	11.6 (9.1)	12.4 (11.1)	15.1 (11.9)

Table 1. Prevalence Cohorts of Lupus Demographic Characteristics

Table 2 Prevalence rates of systemic lupus erythematosus over four decades

	Female		Male		Total	
Date (D/M/Y)	**N**	**Rate* per 100,000 (95%CI)**	**N**	**Rate* per 100,000 (95%CI)**	**N**	**Rate** per 100,000 (95%CI)**
1-1-1985	42	100.6 (68.0-133.2)	4	7.3 (0-14.8)	46	55.2 (38.1-72.4)
1-1-1995	58	109.8 (79.9-139.7)	5	10.9 (1.1-20.8)	63	61.4 (45.3-77.5)
1-1-2005	82	121.4 (94.5-148.3)	10	17.3 (6.1-28.6)	92	70.3 (55.5-85.1)
1-1-2015	109	144.9 (117.5-172.3)	22	33.6 (19.5-47.7)	131	90.8 (75.1-106.4)

*Age-adjusted to the US White 2010 population
**Age- and sex- adjusted to the US White 2010 population

Table 2. Prevalence rates of systemic lupus erythematosus over four decades

Prevalence rates were age- and/or sex-adjusted to the estimated 2010 white population of the US. To compute 95% confidence intervals for prevalence rates, it was assumed that the number of prevalent cases followed a Poisson distribution.

Results: We identified 46 prevalent cases in 1985, 63 in 1995, 92 in 2005 and 131 in 2015. As detailed in Table 1 the mean age of prevalent cases over four decades increased from 47.3 years in 1985 to 54.6 years in 2015. Race was reported consistently from 1995 onwards, the proportion of whites decreased from 95% to 82% while the proportion of males increased from 9% to 17%.

Overall, from 1985 to 2015 the prevalence increased by 64%; 55.2 per 100,000 in 1985 to 90.8 per 100,000 in 2015. In females the prevalence increased by 44% from 100.6 to 144.9 per 100,000, while in males it increased 360% from 7.3 to 33.6 per 100,000 (Table 2).

Conclusion: Results from the study show a dramatic increase in prevalence of SLE in the last four decades. These trends likely reflect improvements in survival. The biggest gains have been on the male SLE patients. It is unclear if other factors, such as an increase in SLE incidence or changes in the racial composition of the population are influencing these epidemiologic changes.

Abstract Number: 1026

The Incidence, Mortality, and Economic Burden of Potentially PrevenTable Infections in Systemic Lupus Erythematosus Patients

Estefania Gauto-Mariotti[1], Soumyasri Kambhatla[2] and Augustine Manadan[3], [1]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [2]John H Stroger Hospital of Cook County, Riverside, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: *Streptococcus pneumoniae*, Herpes zoster, and influenza infections are common and potentially prevenTable causes of morbidity and mortality. Vaccinations have been shown to reduce infection rates. Unfortunately, some patients are not offered or refuse these vaccinations. Additionally, younger patients are not eligible for pneumococcal and zoster vaccines based on the current age recommendations. In this, study we aimed to determine incidence, mortality, and national costs of hospital admissions for *Streptococcus pneumoniae (Strep pneumo)*, Herpes Zoster, and influenza infections in patients with systemic lupus erythematosus (SLE).

Methods: Data were abstracted from the National Inpatient Sample (NIS) Database. This database is the largest collection of inpatient admission data in the USA. It is a nationally representative sample of 20% of hospitalizations from approximately 1000 hospitals. The numbers in the databases are weighted to optimize national estimates. The NIS was searched for hospitalizations in 2016 containing ICD-10 SLE codes (M32, M32.1, M32.10, M32.11, M32.12, M32.13, M32.14, M32.15, M32.19, M32.8, and M32.9) as the principal or secondary diagnosis. We further limited the SLE cohort to hospitalizations with a principal discharge diagnosis of *Strep pneumo* infection (ICD-10 codes J13, M00.1x, A40.3, B95.3, or G00.1), Herpes Zoster (ICD 10 codes B02), and influenza (ICD 10 codes J09 or J10). The total number of discharges, age, race, length of stay (LOS), mortality and total hospital charges were recorded.

Results: Adult SLE patients had 173,765 hospitalizations in 2016. Among the SLE patients, there were 340 hospitalizations for influenza, 260 hospitalizations for zoster, and 315 hospitalizations for *Streptococcus pneumoniae* (see Table 1).

Of the SLE patients hospitalized for influenza, mean age was 56 years, 87% were female, the mean LOS was 3.6 days, aggregate LOS 1,230 days, 3% (10/340) had in hospital mortality, the mean hospital charges were $32,265 and aggregate hospital charges were $10,647,531.

Of the SLE patients hospitalized for zoster, mean age was 47 years, 77% were female, the mean LOS was 7 days, aggregate LOS 1,820 days, 0% (0/260) had in hospital mortality, the mean hospital charges were $53,988. and aggregate hospital charges were $ 14,036,866.

Of the SLE patients hospitalized for *Strep pneumo* infections, the mean age was 49 years, 87% were female, the mean LOS was 7.3 days, aggregate LOS 2,315 days, 9.5% (30/315) had in hospital mortality, the mean hospital charges were $ 87,893, and the aggregate hospital charges were $27,246,719. These numbers do not account for

Table 1

	Influenza	*Strep pneumo*	Zoster
# of Hospitalizations	340	315	260
Mean age (yrs)	56	49	47
Female (%)	87%	87%	77%
Mean LOS	3.6 days	7.3 days	7 days
Aggregate LOS	1,230 days	2,315 days	1,820 days
Mortality	3% (10/340)	9.5% (30/315)	0%
Mean Hospital Charges	$32,265	$87,893	$53,988
Aggregate Hospital Charges	$10,647,531	$27,246,719	$14,036,866

outpatient or emergency department visits. Additionally, hospital charges are known to be higher than allowed or real charges.

Conclusion: Our analysis shows influenza, zoster, and *Strep pneumo* infections constituted only 0.5% of SLE hospitalizations but in-hospital mortality was high. Additionally, the economic burden of these infections was large with aggregate national hospital charges totaling over $51,931,116 and an aggregate LOS of 5,365 days. Universal vaccinations programs in SLE patients should be studied to reduce hospitalizations, cost, morbidity, and mortality.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

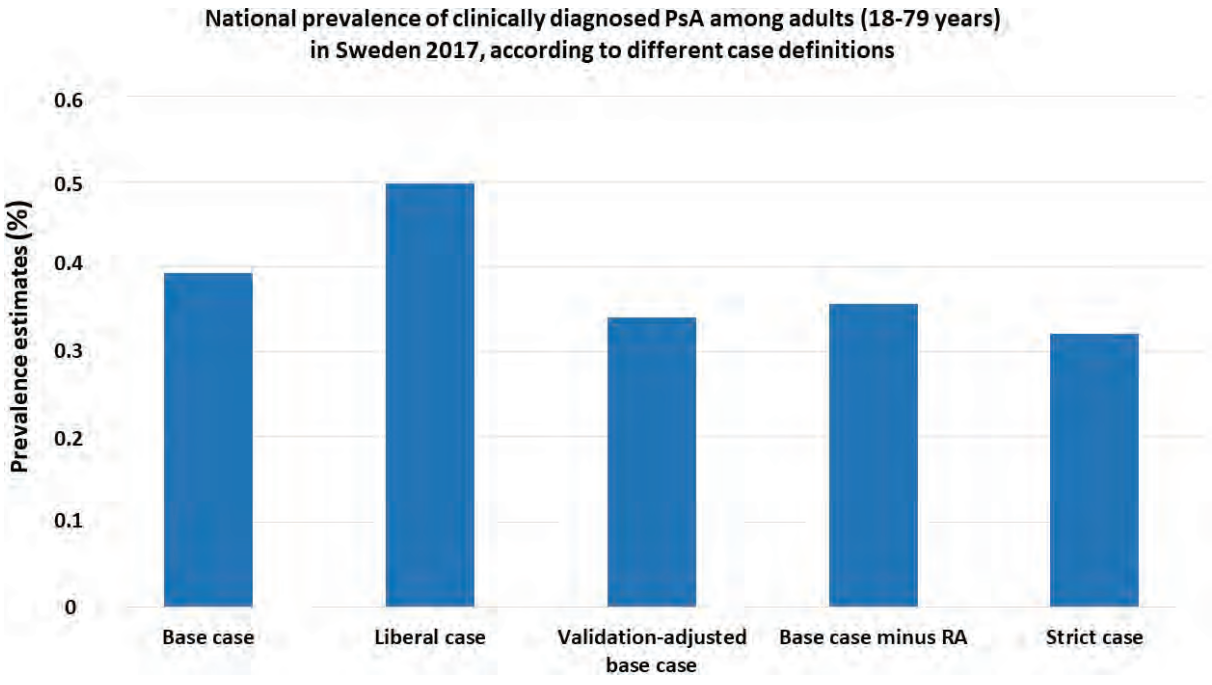
Session Type: Poster Session C

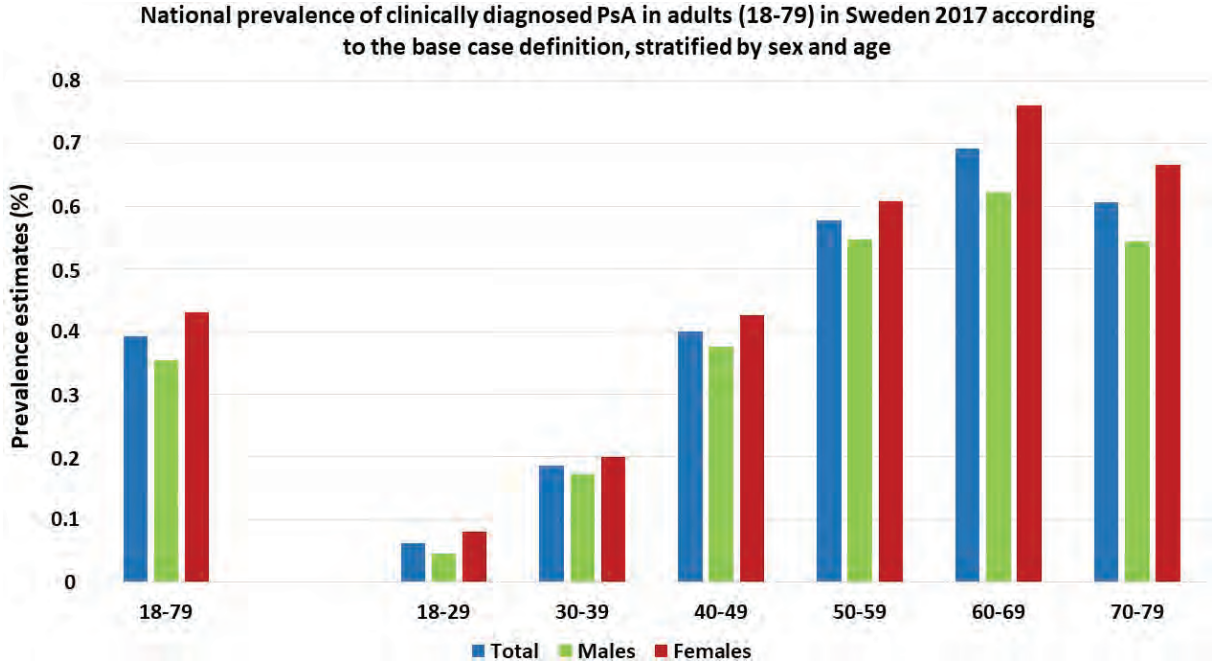
Session Time: 9:00AM–11:00AM

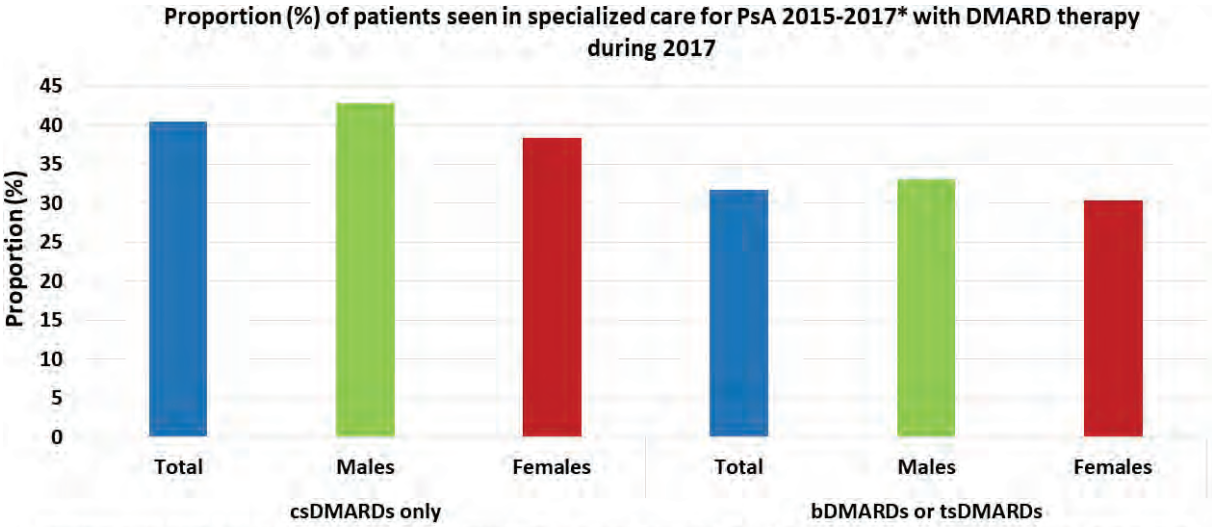
Background/Purpose: Reported prevalence estimates of psoriatic arthritis (PsA) vary considerably, with few nationwide Figures. This study aimed to estimate the prevalence of PsA among adults (18-79 years (y)) in Sweden 2017, overall, stratified by sex/age/education, and with contemporary need of specialized care, respectively. In the latter group, the proportion treated with disease-modifying anti-rheumatic drugs (DMARDs) was also assessed.

Methods: All individuals, 18-79y, alive and residing in Sweden on December 31, 2017, who had been seen in specialized care for clinically diagnosed PsA 1964-2017 were identified from 2 separate, overlapping sources: 1) individuals with ≥1 registered ICD diagnosis of PsA from out-/inpatient visits in the Swedish National Patient Register (NPR); 2) individuals registered with PsA in the Swedish Rheumatology Quality Register (SRQ). Data on the total Swedish population 2017, demographics, education (for individuals ≥30y), and treatments were retrieved from other registers. The base case (BC) PsA definition for prevalence estimation was ≥1 main ICD diagnosis of PsA (ICD-8:696.00; ICD-9:696A; ICD-10:L40.5/M07.0-M07.3) from a department of rheumatology or internal medicine (IM) in NPR, or a PsA diagnosis in SRQ. Sensitivity analysis definitions were: A) Liberal: ≥1 main or secondary ICD diagnosis of PsA from any department in NPR, or a PsA diagnosis in SRQ; B) As BC, but reducing the number of cases in line with a prior validation of the BC definition in which 86% of 400 cases fulfilled PsA classification criteria; C) As BC, but excluding cases with ≥1 main ICD diagnosis of rheumatoid arthritis from rheumatology or IM in NPR; D) Strict: ≥2 ICD diagnoses of PsA in NPR, of which ≥1 as main diagnosis from rheumatology or IM. Furthermore, the prevalence of PsA with contemporary need of specialized care was estimated by restricting the BC definition to 2015-2017 (≥1 main ICD diagnosis of PsA from rheumatology or IM in NPR or ≥1 visit in SRQ 2015-2017), and the proportion of this population with DMARD therapy in 2017 was assessed.

Results: A total of 29 359 cases, 18-79y, alive and residing in Sweden on December 31, 2017, with clinically diagnosed PsA according to the BC definition were identified, resulting in a national, prevalence of PsA in the adult (18-79y) population of 0.39%. Corresponding sensitivity analysis estimates ranged from 0.32-0.50%, with a validation-adjusted BC prevalence of 0.34% (**Figure 1**). Irrespective of age group, the PsA prevalence was numerically higher among females (**Figure 2**). Higher education was associated with numerically lower PsA prevalence (>12y education: 0.38%; 10-12y:0.58%; ≤9y:0.54%, in adults ≥30y; BC PsA definition). The prevalence of PsA seen in







*Defined as ≥1 main ICD diagnosis of PsA from rheumatology or internal medicine in NPR or ≥1 visit in SRQ 2015-2017; constituting 62% of all prevalent PsA patients according to the base case definition.
csDMARDs: Sulfasalazine, Leflunomide, Ciclosporine, Azathioprine, Methotrexate, Sodium aurothiomalate, Auranofin, Chloroquine, Hydroxychloroquine
bDMARDs: Adalimumab, Certolizumab pegol, Etanercept, Golimumab, Infliximab, Abatacept, Secukinumab, Ustekinumab
tsDMARDs: Apremilast.

specialized care 2015-2017 was estimated at 0.24%. In this population, 32% received biologic or targeted synthetic DMARDs, and 41% conventional synthetic DMARDs only, during 2017 (**Figure 3**).

Conclusion: The national prevalence of clinically diagnosed PsA in the adult (18-79y) Swedish population in 2017 was estimated at around 0.35% (0.32-0.39% across most definitions). Among the 62% of these patients who were seen in specialized care for PsA during the last 3 years of our study period, almost 3/4 received DMARD therapy in 2017.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: DESIR is the French cohort of patients with symptoms suggestive of early axial Spondyloarthritis (axSpA). Our objective was to enrich this cohort with claims and hospitalization data from the French national healthcare database (Système National des Données de Santé, SNDS) in order to provide opportunities to answer new research questions related to care consumption, the occurrence of health outcomes and costs and enhance data completeness.

Methods: We carried out a probabilistic linkage of the DESIR cohort database (N=703) and the SNDS (N= 387,463 individuals, sharing the same sex, birth month and year with DESIR patients). DESIR is a cohort of 708 individuals aged 18 to 60 years, included from 2007 to 2010 in 25 centers in France, of whom 703 were not opposed to this linkage. The probabilistic linkage was performed with the Fellegi and Sunter method, using 29 variables collected between baseline and the 24th month of follow-up. Matching variables included area of residence, attending physician, sacroiliac radiographs and MRI dates, blood test dates and treatment by a Disease Modifying Anti-Rheumatic Drug. We calculated for each DESIR-SNDS potential pair of patients a matching score that summed the matching probabilities calculated across all selected variables. Distributions of the highest matching scores for each DESIR patient and for other matching scores were displayed graphically and a cutoff was chosen visually. Pairs with highest matching score for each individual were matched if they exceed this cutoff. To assess the quality of the linkage we compared individuals' characteristics between matched and unmatched individuals. P values were computed with T.test, Chi-square test, Wilcoxon test or Fisher exact test.

Table 1. Characteristics of matched and unmatched individuals

N(%) mean ± SD N= 703	Unmatched N=109 (15,5)	Matched N=594 (84,5)	P-value
Age	31,1 ± 8,32	34,2 ± 8,61	0,0005 †
Men	46 (12,2)	330 (87,8)	0,0137§
BASDAI (/100)	44,6 ± 19,4	44,7 ± 20,1	0,9495*
BASFI (/ 100)	28,7 ± 22,0	30,7 ± 22,9	0,4359*
HLA-B27 positivity	74 (18,2)	333 (81,8)	0,0296§
MRI sacroiliac joint inflammation (ASAS criteria)	39 (16,7)	195 (83,3)	0,4896§
Radiographic sacroiliitis (mNY criteria)	18 (16,2)	93 (83,8)	0,7554§
Loss of follow up by year 5	32 (15,9)	169 (84,1)	0,9384§
Exit from study due to other diagnosis by year 5	2 (8)	23 (92)	0,4044**
TNF treatment by year 5	38 (14,8)	218 (85,2)	0,7962§

P value are computed with T.test (†), Chi-square test (§), Wilcoxon test (*) or Fisher exact test (**)

Results: A total of 594 (84%) were matched. They were, on average, 3 years older than unmatched individuals, were more likely men, and less likely to be HLA-B27 positive. No significant difference was observed between matched and unmatched on baseline clinical or radiographic characteristics: BASDAI and BASFI scores, MRI sacroiliac joint inflammation (ASAS criteria) neither among anti-TNF treatment during the first 5 years of follow-up. Finally, rate of loss to follow up by year 5 were similar in both groups while rate of exit from the DESIR cohort due to other diagnosis than axSpA was slightly higher but not significantly so, among matched vs. unmatched.

Conclusion: It was possible to perform a matching for 84% of patients. No difference was observed on clinical or radiographic characteristics nor treatment between matched and unmatched individuals, thus this cohort issued from the linkage can be used to study outcomes among patients with symptoms suggestive of early axSpA. A possible bias related to both male, older and HLA-B27 positivity over-representation should be discussed in any future study using this linked cohort. In a next step, a deterministic linkage will be performed using a unique individual identifier to validate this linkage and capture remaining unmatched individuals.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The ChinaAS is a nationwide, multicenter registry of patients with axial spondyloarthritis (SpA) in China to facilitate research in epidemiology, pathogenesis, diagnosis and treatment of Chinese patients with axial SpA. The objective of this study is to describe the clinical manifestation of patients registered between July 11th, 2018 and July 10th, 2019, and compare the characteristics of patients who fulfill ASAS criteria and patients who fulfill modified New York criteria for ankylosing spondylitis (AS).

Methods: Patients with a clinical diagnosis of AS or axial SpA were enrolled into the registry from 31 provinces in China. Demographics, clinical manifestations, HLA-B27 status, acute phase reactants, pelvis imagings, patient reported outcomes, medication use, and comorbidities were collected at baseline. Patients, who were enrolled between July 11th,2018 and July 10th, 2019, and fulfilled either ASAS axial SpA criteria or modified New York criteria for AS, were included in the study. Disease duration was defined as the difference between age of diagnosis and age of onset. Early axial SpA was defined as disease duration of less than 3 years. Descriptive statistics were used to described clinical characteristics of enrolled patients.

Results: A total of 3806 patients were included in the current analysis, including 3545 patients who fulfill modified New York criteria for AS, 3241 patients who fulfill ASAS criteria for axial SpA, and 3116 patients who fulfill ASAS criteria for axial SpA imaging arm. Mean age at enrollment was 33 years, 73% were male, about 80% were HLA-B27 positive, and median disease duration was 4 years (Table 1). Among these patients, 2384 patients had complete set of HLA-B27, baseline pelvis radiograph or CT, and baseline pelvis MRI. Nineteen hundred and forty two patients had radiographic axial SpA, with 98% also fulfilled AS criteria (Figure 1). In patients with early SpA (N = 924), majority (N=861, 93.2%) had sacroiliitis on pelvis radiograph or CT, 37 patients (4.0%) had sacroiliitis on MRI but not on pelvis radiograph or CT, and 26 patients (2.8%) were in the clinical arm without sacroiliitis on imaging studies.

Conclusion: In the ChinaAS registry, 3806 axial SpA patients were enrolled from July 11th, 2018 and July 10th, 2019. Majority of patients (98%) with radiographic axial SpA also fulfilled modified New York criteria for AS. In early axial SpA patients, more than 90% of them had a sacroiliitis on pelvis radiograph or CT.

Pain Medication Use Among Ankylosing Spondylitis and Psoriatic Arthritis Patients Before and After Initiation of Biologic Therapy

Theresa Hunter[1], Chi Nguyen[2], Julie Birt[3], Joseph Smith[2], Mingyang Shan[3], **Hiangkiat Tan**[2], Jeffrey Lisse[3] and Keith Isenberg[4], [1]Eli Lilly and Company, Indianapolis, [2]Healthcore, Inc, Wilmington, DE, [3]Eli Lilly and Company, Indianapolis, IN, [4]Anthem, Inc, Indianapolis, IN

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a common symptom among ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients and can be debilitating, making pain management an integral part of caring for these patients. The purpose of this analysis was to describe pain medication utilization of patients with AS and PsA over 12-months before and after initiation of a biologic.

Methods: This is a retrospective observational cohort study using administrative claims from the HealthCore Integrated Research Database (HIRD®). Patients newly diagnosed with AS or PsA who initiated a biologic from 1/1/2014 to 7/31/2017 were included. Medications that could be used for pain were assessed 12-months prior and 12-months after biologic initiation. Demographics, baseline clinical characteristics, and pain medication use were described using descriptive statistics. Frequencies and percentages were provided for categorical variables and means, standard deviations, and medians were presented for continuous measures. The differences in pain medication use were assessed using McNemar's Test for categorical variables or Wilcoxon signed-rank test for continuous variables as appropriate for comparing before and after biologic initiation.

Results: 188 AS patients and 921 PsA patients were included in this analysis. AS patients had a mean age of 41.6 years, 55.3% were male, and the mean time from diagnosis to biologic initiation was 4.0 months. PsA patients had a mean age of 48.0 years, 49.3% were male, and the mean time from diagnosis to biologic initiation was 6.6 months. Prior to biologic initiation, 68.1% of AS patients were prescribed NSAIDs, 56.4% glucocorticoids, 42.6% opioids, and 41.0% neuromodulators. Similarly, prior to biologic initiation, 51.1% of PsA patients were receiving NSAIDs, 57.4% glucocorticoids, 38.1% opioids, 38.9% neuromodulators, and 4.3% topical pain medication. Twelve months after biologic initiation, use of NSAIDs (AS: 68.1% vs. 51.1%; PsA: 51.1% vs. 42.5%) and glucocorticoids (AS: 56.4% vs. 41.5%; PsA: 57.4% vs. 46.9%) and opioids (AS: 42.6% vs. 36.2%; PsA: 38.1% vs. 33.8%) significantly decreased among AS and PsA patients. Use of neuromodulators did not significantly change from the 12-months prior to the 12-months after biologic initiation among AS (41.0% vs. 40.4%) and PsA (38.9% vs. 39.8%) patients.

Conclusion: Use of pain medications such as NSAIDs, glucocorticoids, opioids, and neuromodulators are common among AS and PsA patients. Though rates of NSAIDs and glucocorticoids decreased after the initiation of biologics, over 40% of AS and PsA patients were still receiving these medications 12-months after initiation of a biologic. In addition, over 30% of AS and PsA patients were still receiving opioids 12-months after initiation of a biologic. The results suggest that AS and PsA patients still require pain medication even after initiating biologics.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a systemic condition estimated to affect 0.05%-0.25% of the United States (US)[1] population. With approval of ixekizumab (a selectively binding IL-17 inhibitor biologic) for treatment of PsA, there is need to understand its treatment patterns in the real world. The current study aimed to describe adherence, persistence, discontinuation, switching, and dosing among patients with PsA newly initiating ixekizumab (IXE).

Methods: The IBM MarketScan administrative claims databases were used to select adults (≥18 years) initiating IXE between 1/1/2016- 7/31/2019 for this retrospective study (earliest IXE claim = index). Eligible patients had ≥1 PsA diagnosis (ICD-9 696.0x or ICD-10 L40.50-L4.059) during the 12 months preceding index and remained continuously enrolled for 12 months following (follow-up period) index. Adherence (measured by proportion of days covered [PDC]) to IXE, persistence on IXE (< 60 day gap with sensitivity analysis using a < 45 and < 90 day gap), discontinuation of IXE (≥90 day gap), and switching (discontinuation of IXE followed by a claim of a different biologic or targeted synthetic disease-modifying anti-rheumatic drug [tsDMARD] with ≥30 as monotherapy) patterns were reported over the

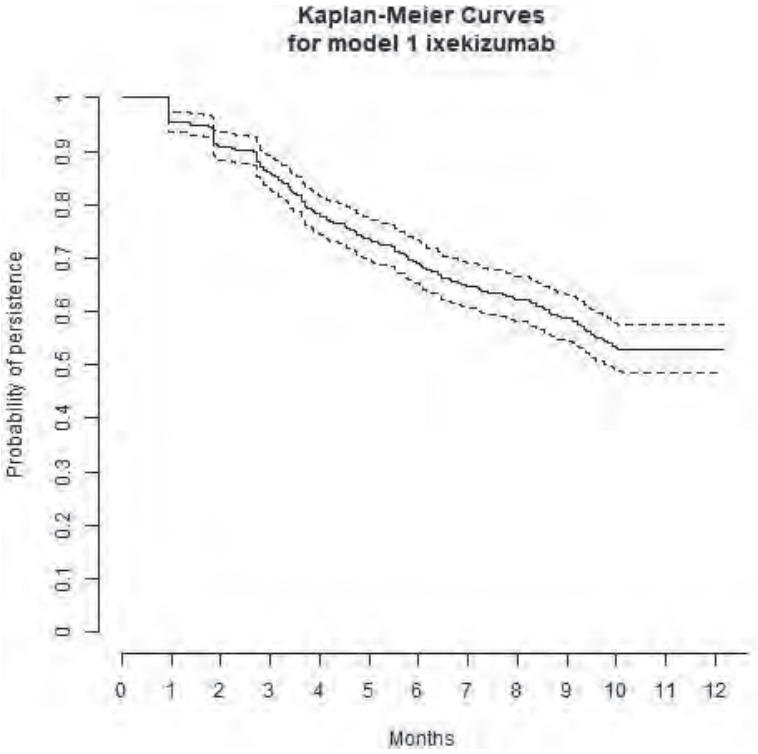

Figure 1. Time to Non-Persistence (60-day gap)

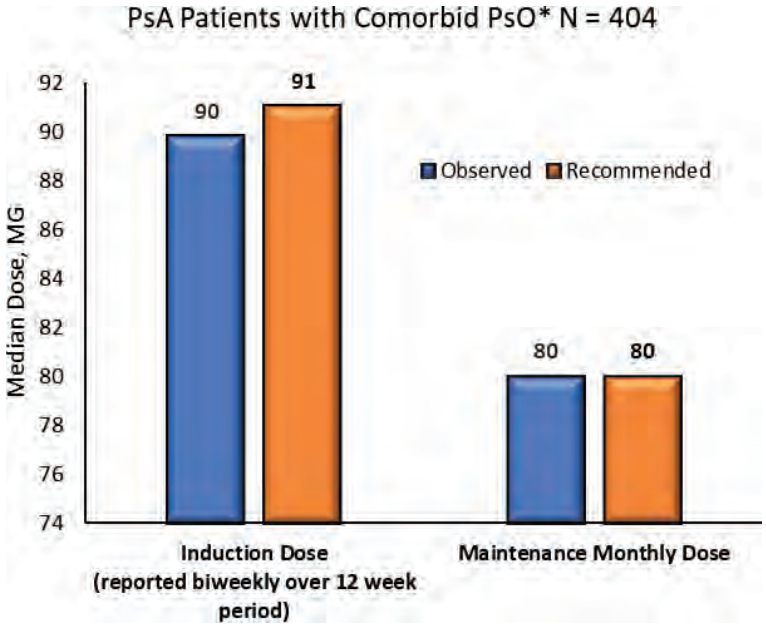

Figure 2a. IXE Dose* Observed in Real World Setting versus Recommended (based on prescribing information for FDA approved dose) Over 12 Months Following Initiation *For patients with comorbid PsO, dose was measured during an induction period of 12 weeks and then during maintenance starting at week 14 and continuing until discontinuation or end of the 12-month follow-up period. Recommended dose based on prescribing information for the FDA approved dose was defined as 160mg at week zero followed by 80mg at weeks 2,4,5,8,10 and 12 (which was equivalent to a dose of 91mg biweekly over the entire induction period).

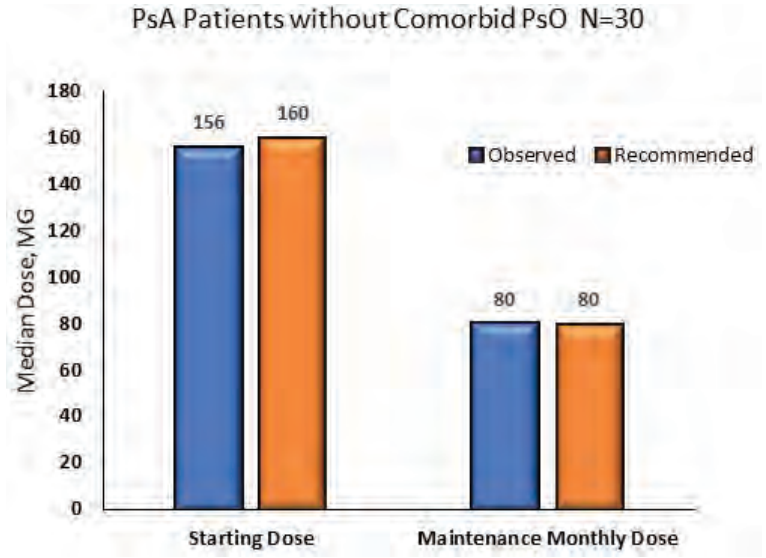

Figure 2b. IXE Dose* Observed in Real World Setting versus Recommended (based on prescribing information for FDA approved dose) Over 12 Months Following Initiation

12-month follow-up period. IXE dose (calculated by multiplying the drug strength by the quantity and dividing by the days of supply for each claim) was reported during the starting/induction and maintenance phase for patients eligible for dosing calculations with and without comorbid psoriasis (PSO).

Results: There were 496 PsA patients initiating IXE eligible for analysis. Mean age was 51.1 (SD 9.8) years, 50.4% were female, and 93.4% had comorbid PsO. Most patients (91.9%) were biologic or tsDMARD experienced, and the

average number of different biologic or tsDMARDs prior to starting IXE was 1.4 (SD 0.06). The most common drugs used prior to IXE were secukinumab, adalimumab, and ustekinumab (34.9%, 28.8%, and 21.4% respectively). Over the 12-month follow-up, 52.8% (using < 60-day gap) remained persistent (47.0% using < 45 day gap and 61.3% using < 90 day gap) on IXE (average of 262 days [SD 123] of persistence; Figure 1). Of all 496 IXE patients, 38.7% discontinued (≥90 day gap), 13.5% had no other treatment, 4.6% restarted IXE, and 20.6% switched to a new biologic/tsDMARD within the 12-month follow-up period.

Adherence to IXE prior to discontinuation was high (mean PDC 0.85 [SD 0.12]) with 70.6% of patients identified as highly adherent (i.e. PDC ≥0.80) to therapy. Dose values during the starting/induction and maintenance periods were consistent with prescribing information for patients with and without comorbid PsO (Figure 2).

Conclusion: Results from this real-world analysis suggest that among PsA patients treated with ixekizumab, 91.9% had previously experienced inefficacy or intolerance to different biologics including other IL-17A and tsDMARD. 52.8% remained persistent and 20.6% switched to a new agent over 12 months of follow-up. Dosing is consistent with prescribing recommendations for patients with and without comorbid PsO.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Epidemiology & Public Health Poster III: Inflammatory Rheumatic Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis has a reported prevalence ranging from 3.2 to 9.1 cases per 100,000 individuals, but little is known of geographic variations. The aim of this study is to observe the prevalence of AAV in a rural based health system using updated ACR/EULAR Diagnostic and Classification Criteria for Primary Systemic Vasculitis (DCVAS). The study also provides geographic mapping of cases to investigate potential environmental factors.

Methods: We reviewed patients with potential AAV through use of EHR from 1/1/2003-6/30/2018 with ICD 9/10 codes consistent with AAV, granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), or eosinophilic granulomatosis with polyangiitis (EGPA). We conducted a manual chart review of cases that satisfy ACR/EULAR DCVAS. Each case was independently confirmed by a rheumatologist, pulmonologist and nephrologist. The de-

Figure 1: Overall ANCA Vasculitis Prevalence and Patient Demographics

5-Year Point Prevalence	Geisinger Patients	Confirmed ANCA Patients	Prevalence Per 100,000	95% CI
ANCA 2018 Prevalence	465,588	54	11.60	(8.40, 14.80)
Age, mean (S.D.)	50.7 (19.1)	60.8 (16.5)		
Female, n (%)	256,138 (55.0%)	27 (50.0%)		
American Indian or Alaska Native, n (%)	718 (0.2%)	0 (0.0%)		
Asian, n (%)	5320 (1.1%)	0 (0.0%)		
Black or African American, n (%)	18,270 (3.9%)	1 (1.9%)		
Native Hawaiian or Other Pacific Islander, n (%)	2410 (0.5%)	0 (0.0%)		
White, n (%)	437,379 (93.9%)	52 (96.3%)		
Unknown, n (%)	1491 (0.3%)	1 (1.9%)		

nominator for a 5-year point prevalence estimate was calculated by identifying patients > 18 years old with a PCP encounter between 1/1/2003-6/30/2018 who had at least one outpatient encounter between 1/1/2014-12/31/2018. The numerator was calculated by identifying AAV cases within the denominator population. The prevalence estimate was calculated using a simple binomial proportion and the simple asymptotic continuity corrected 95% confidence interval. Prevalence estimates for GPA, MPA, and EGPA were calculated using similar methods as for overall AAV prevalence. Because of the rarity, the 95% confidence interval for the EGPA is reported using a Clopper-Pearson exact method. Statistical analysis was completed using SAS 9.4. All confirmed cases of AAV were plotted along a map to evaluate geographic distribution.

Results: Out of 2983 cases screened by ICD codes, 108 cases satisfied DCVAS. For prevalence criteria, there were 54 confirmed cases out of a denominator population of 458,588. The prevalence estimate for AAV is 11.6/ 100,000 (95% CI: 8.4, 14.8). The total population mean age was 50.7, 55.0% were female and 93.9% were Caucasian. Among the 54 AAV patients, the mean age was 60.8, 50.0% were female, and 96.3% were Caucasian. There were 38 patients with GPA, 13 with MPA, and 3 with EGPA. Prevalence estimates and demographic characteristics are shown in Figure 1 and Figure 2. The prevalence estimates for AAV and GPA is observed to be above the reported national average range. Our geographic mapping shows correlation of cases in counties deemed as Coal Region, following along a major interstate, a regional river, and primary medical service area (Figure 3).

Conclusion: Our prevalence estimates for AAV and GPA is observed to be higher than average, but MPA and EGPA has insufficient U.S. epidemiology to compare. Our health system captures a large region of predominantly Caucasian patients in a rural population so it is of interest to compare to national averages. Mapping suggests a correlation of AAV cases in Coal Region counties and along a major river, suggesting a possible environmental factor. We hope to explore potential environmental-gene interactions and compare epidemiology with an urban system in the future

Figure 2: Prevalence of GPA, MPA and EGPA and Patient Demographics

5-Year Point Prevalence	Geisinger Patients	Confirmed ANCA Patients	Prevalence Per 100,000	95% CI
