SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a multisystemic disease characterized by the formation of non-necrotizing granulomas. The most frequently affected organs are the lungs, skin and eyes. Systemic corticosteroids are the most used drugs in the treatment of this disease. Conventional and biological immunosuppressants may also be used.

Objectives: To evaluate the systemic treatment of sarcoidosis according to clinical domains.

Methods: Study of all consecutive patients diagnosed with sarcoidosis between 1/1/1999 and 1/1/2019 in a tertiary university hospital. The diagnosis was established following the ATS/ERS/WASOG criteria *(Eur Respir J. 1999;14(4):735-737):* compatible clinical and radiological presentation, evidence of non-caseifying granulomas and exclusion of other granulomatous diseases.

Results: We studied 377 patients (188 men/189 women), mean age at diagnosis of 46.0±14.8 years. After a mean follow-up of 13.0±9.3 years, 161 (42.7%) patients did not require treatment. The remaining 216 (57.3%) received oral glucocorticoids (206, 54.6%) with a maximum mean dose of 43.2±19.0 mg/day, conventional immunosuppressants (60, 16.2%), biological therapy (28, 7.4%) and/or endovenous methylprednisolone (15, 4.0%). Biological therapy was indicated by pulmonary (9, 32.1%), ocular (9, 32.1%), neurological (3, 10.7%), muskuloeskeletal (3, 10.7%), cutane-

BT: biologic therapy; IFX: infliximab; ADA: adalimumab; ETN:etanercept; GLM: golimumab; TCZ: tocilizumab; RTX: rituximab

ous (2, 7.1%), nephrological involvement (1, 3.6%); and Heerfordt's syndrome (1, 3.6%). Adalimumab and Infliximab were the biologics used more frequently (**Table 1-2**).

Conclusion: Compared to other studies, the high percentage of patients who required systemic treatment is remarkable. It also highlights the frequency of the use of biological drugs in more severe organ involvement (ocular and neurological), which is consistent with the trend in recent years.

Background/Purpose: Pharmacological management of cardiac sarcoidosis (CS) includes immunosuppressive therapy for active lesions, guideline-directed medical therapy for heart failure, and antiarrhythmics. Our goal was to observe the various clinical characteristics of CS patients, choice of treatment plans, and outcomes of therapy via analysis of standardized uptake values (SUV) and ejection fraction (EF) using pre- and post-treatment cardiac PET-CT.

Figure 1. Box Plot of SUV uptake values pre- and post-initiation of therapy

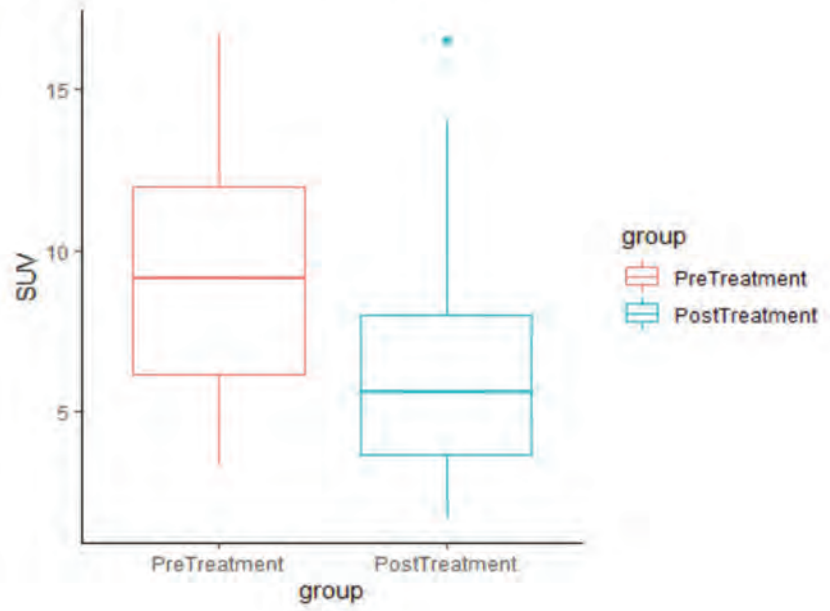

Figure 2. Sunburst plot of the sequence of medications used in cardiac sarcoidosis patients

Methods: The data was gathered by retrospective chart review of 31 patients treated at our institute with a diagnosis of CS (as defined by the Heart Rhythm Society diagnostic criteria). Patients having at least two PET scans spaced at least 6 months apart were included, and they had to be on a sTable treatment regimen for at least 6 months prior to their follow up PET-CT. Changes in medications were noted.

Results: Table 1 summarizes patient's baseline clinical characteristics, diagnostic workup, treatments and the changes in SUV and EF using pre- and post-treatment PET-CT. The average time between first PET-CT and therapy initiation was 4.3 months and the average time between therapy initiation and follow-up PET-CT was 14.5 months. The average SUV uptake before starting any therapy was 9.2 ± 3.64, which decreased to 5.98 ± 3.67 on follow-up assessment (Figure 1). The average difference between pre- and post-treatment SUV was -3.22 (SD=5.39, 95% CI: -5.23, -1.21) with paired t-test (p-value=0.002) suggesting improvement in mean SUV with therapy. The average difference between pre- and post-treatment ejection fraction was 0.13% (95%CI: -3.5%, 3.8%) with paired t-test (p=0.94) suggesting no difference.

MTX was used most commonly as initial therapy followed by AZA, HCQ, LEF and MMF. Many treatment combinations also used background therapy with prednisone. The most common biologic used was infliximab followed by adalimumab. A sunburst plot provides a representation of the sequence of medications use in this cohort of CS patients (Figure 2). Patients were divided into a MTX treatment group (n=16) where MTX formed the backbone of therapy with or without HCQ (n=2) or prednisone (n=10). A second group termed the 'Other treatment group' (OT group) was formed for analysis consisting of: AZA monotherapy (n=1), AZA in combination with prednisone (n=1), prednisone monotherapy (n=1) and MMF in combination with prednisone (n=2). The baseline SUV max was similar in the MTX and OT groups (9.2 vs 10.4) as was the EF (52% vs 46%). There was a difference in the interval between the baseline cardiac PET-CT and the initiation of medical therapy in the MTX group vs the OT group (4 months vs 0.5 months). The change in SUV max was slightly greater in the OT group when compared to the MTX group (-5.6 vs -3.5), though the change in EF was similar (-3% vs 2%).

Conclusion: We described the clinical characteristics and treatment patterns of 31 patients with CS. We did not observe a pronounced difference between the MTX and the OT group with respect to SUV patterns and EF before and after initiating therapy. Further large-scale prospective studies are required to identify the most effective treatment regimen in the management of CS.

Study of Ocular Sarcoidosis and Clusters of Clinical Associations in a Series of 383 Patients with Systemic Sarcoidosis from a Single Hospital

Inigo Gonzalez-Mazon[1], Carmen Alvarez-Reguera[2], Lara Sanchez-Bilbao[2], David Martinez-Lopez[3], Alba Herrero Morant[2], Jorge Javier Gaitan-Valdizan[4], Raul Fernandez-Ramon[2], Rosalia Demetrio-Pablo[2] and Ricardo Blanco[2], [1]Hospital Universitario Marques de Valdecilla, Bezana, Spain, [2]Hospital Universitario Marques de Valdecilla, Santander, Spain, [3]Hospital Universitario Marques de Valdecilla, Santander (SPAIN), Spain, [4]Hospital Universitario Marqués de Valdecilla, Santander, Spain

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

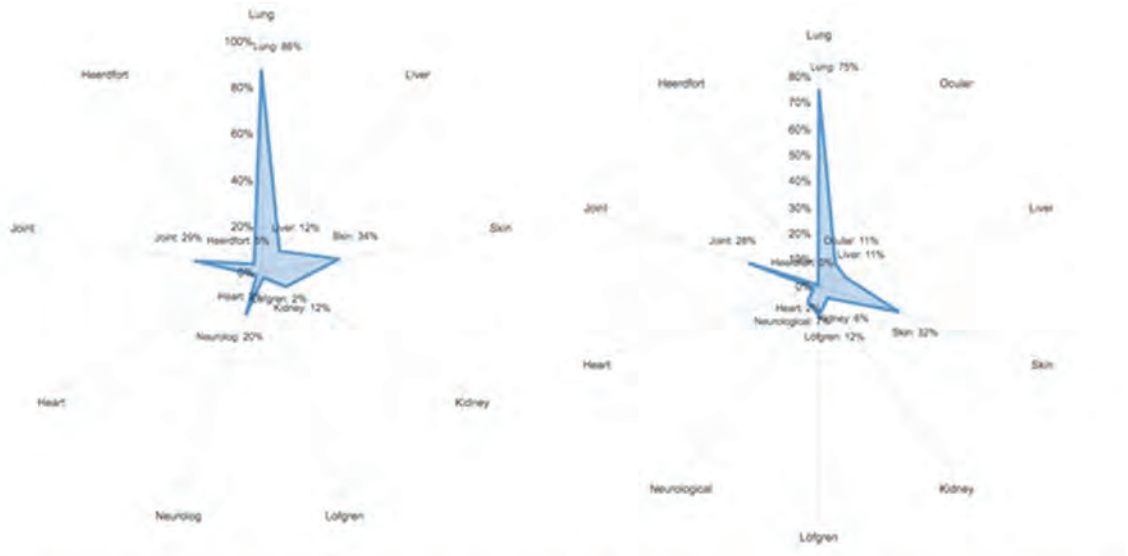

FIGURE: Comparison between distribution of organs affected in ocular sarcoidosis (left) and distribution of organs affected in general sarcoidosis (right).

Background/Purpose: Sarcoidosis is an inflammatory disease which can affect multiple organs. The most frequent affected organs are lungs, skin and eyes. Ocular involvement is a severe complication. The objective of this study was to assess the association of ocular sarcoidosis with other clinical domains.

Methods: Study of a large cohort of systemic sarcoidosis from a single tertiary university hospital. All consecutive patients were diagnosed with systemic sarcoidosis from January 1, 1999 to January 1, 2019 according the ATS/ERS/WASOG criteria.

Results: 41 (22 women/19 men) of 383 (10.7%) patients had ocular involvement, mean age 44.8±16 years. Lung was the most common affected organ associated with ocular sarcoidosis (n=36; 87.8%) followed by skin (n=14; 34.1%), joints (n=12; 29.3%) and neurological affection (n=8; 19.5%).

Ocular sarcoidosis presents a higher percentage of renal and neurological affection compared to organs affected in general sarcoidosis of our larger cohort (12% vs 6% and 19.5 vs 7%; respectively). In **Figure** is shown comparison between distribution of organs affected in ocular sarcoidosis.

Conclusion: The proportion of clinical domains affected in ocular sarcoidosis is mostly similar to global sarcoidosis, except the neurological (which almost is threefold) and renal (which doubles) affection. Hence, the importance of being aware of neurological and renal complications when ocular affection is present.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Background: The eye is a common and potential severe complication of sarcoidosis. Topical and systemic corticosteroids are the first-line treatment. Conventional and biological immunosuppressants are frequently needed.

Objectives: To assess the frequency, clinical and treatment of ocular involvement of sarcoidosis.

Methods: Study of a large cohort (n=383) of systemic sarcoidosis from a single university hospital. All consecutive patients diagnosed with sarcoidosis from January 1, 1999 to January 1, 2019 according the ATS/ERS/WASOG criteria *(Eur Respir J 1999;14:735–737)* were included.

Results: 41 (22 women/19 men) of 383 (10.7%) patients had ocular involvement, mean age 44.8±16 years. Uveitis (n=34; 82.9%) was the most common ocular manifestation, especially anterior uveitis (n=18; 52.9%). Ocular surface and eye orbit may also be affected **(Table 1)**.

In addition to topical and systemic corticosteroids, conventional (n=23; 56.1%) and biologic (n=14; 34.1%) immunosuppressive drugs were required. Adalimumab and Infliximab were the most used biologic treatments **(Table 2).**

Cystoid macular edema (CME) and Retinal Vasculitis was observed in both cases in 3 (7.3%) patients, 2 of them (66.7%) required biological treatment. Papilitis appeared in 7 (17.1%) cases, biological treatment was needed in 3 (42.9%) patients.

The most frequent sequels were cataract (n=9, 21.9%), intraocular hypertension (n=5; 12.2%) and pupil alterations (n=4; 9.7%). The average of the best corrected visual acuity was 0.6±0.3 at diagnosis and 0.7±0.3 after one year follow up.

Conclusion: Ocular involvement of sarcoidosis is a relative frequent and potential severe complication, especially if panuveitis is presented.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: African Americans [AA] and minorities in the lower socioeconomic strata of Chicago are disproportionately affected by pulmonary sarcoidosis, and regularly exposed to poorer air quality than Caucasians [C]. Histopathologically, sarcoidosis is characterized by granulomatous inflammation, and elevated serum angiotensin converting enzyme (sACE) are observed in about 75% of untreated patients with sarcoidosis, in part due to macrophage activation. Though the etiology remains unknown, exposure via antigen inhalation has been posited to evoke this inflammatory immune response. In this study, we examine the relationship between particulate matter air pollution and sarcoidosis inflammation and hypothesize that poor air quality indices are associated with sACE.

Methods: A cohort of female patients from the University of Illinois at Chicago lung disease registry residing in the Chicago area with sarcoidosis and documented sACE levels (2010-2015) was evaluated retrospectively. Demographic and clinical variables were abstracted from the medical record. ACE levels ≥ 50 U/L were considered elevated and inflammatory. Daily AQI measurements were obtained from the USA EPA database during a 6-month interval prior to ACE level measurement. Residential AQI levels were interpolated from the 5 nearest pollution monitors to a patient's residence by inverse distance weighting with a power of 2 (R-package "*phylin"*) and maximum average AQI levels at 10-day intervals were calculated. Demographic/clinical parameters were compared among AA and C groups and the risk of elevated sACE at the end of the 6-month interval was estimated by Cox proportional hazard ratio models (R-package "*survival"*).

Results: We identified 32 female patients (AA=21, C =11) in the study period. sACE levels between AA and C and baseline demographics were similar at the time of sACE measurement (*MWU-test p-val >0.05*). Evaluation of environmental factors, AQI and smoking history on ACE level, adjusted for time from sarcoidosis diagnosis, revealed a significant hazard reduction of elevated sACE levels by 2% for every unit increase in AQI in AA (*Figure 1A, Log-Rank p-val=0.002*). Contrastingly, in C, current or former smoking history, not AQI, was associated with reduced risk of elevated ACE levels (*Figure 1B, Log-Rank p-val=0.005*). At time of ACE level measurements, a trend of increased utilization of systemic immunosuppressive therapy was observed in AA (χ*2 p-val=0.053, odds ratio=5*).

Conclusion: A paradoxical association between inflammatory activity in sarcoidosis and environmental factors that may increase antigenic exposure was identified. It is possible that AA and C females show different phenotypes of sarcoidosis and respond distinctly to inhaled antigens. In AA females, a higher AQI was linked to lower ACE levels while in C, current or former smoking status was linked with lower ACE levels. Further studies are needed to expound underlying mechanisms of these associations; however, our data supports the idea that inhaled antigenic stimuli are directly related with sarcoidosis inflammatory activity and suggest that some antigens may downregulate granulomatous inflammation.

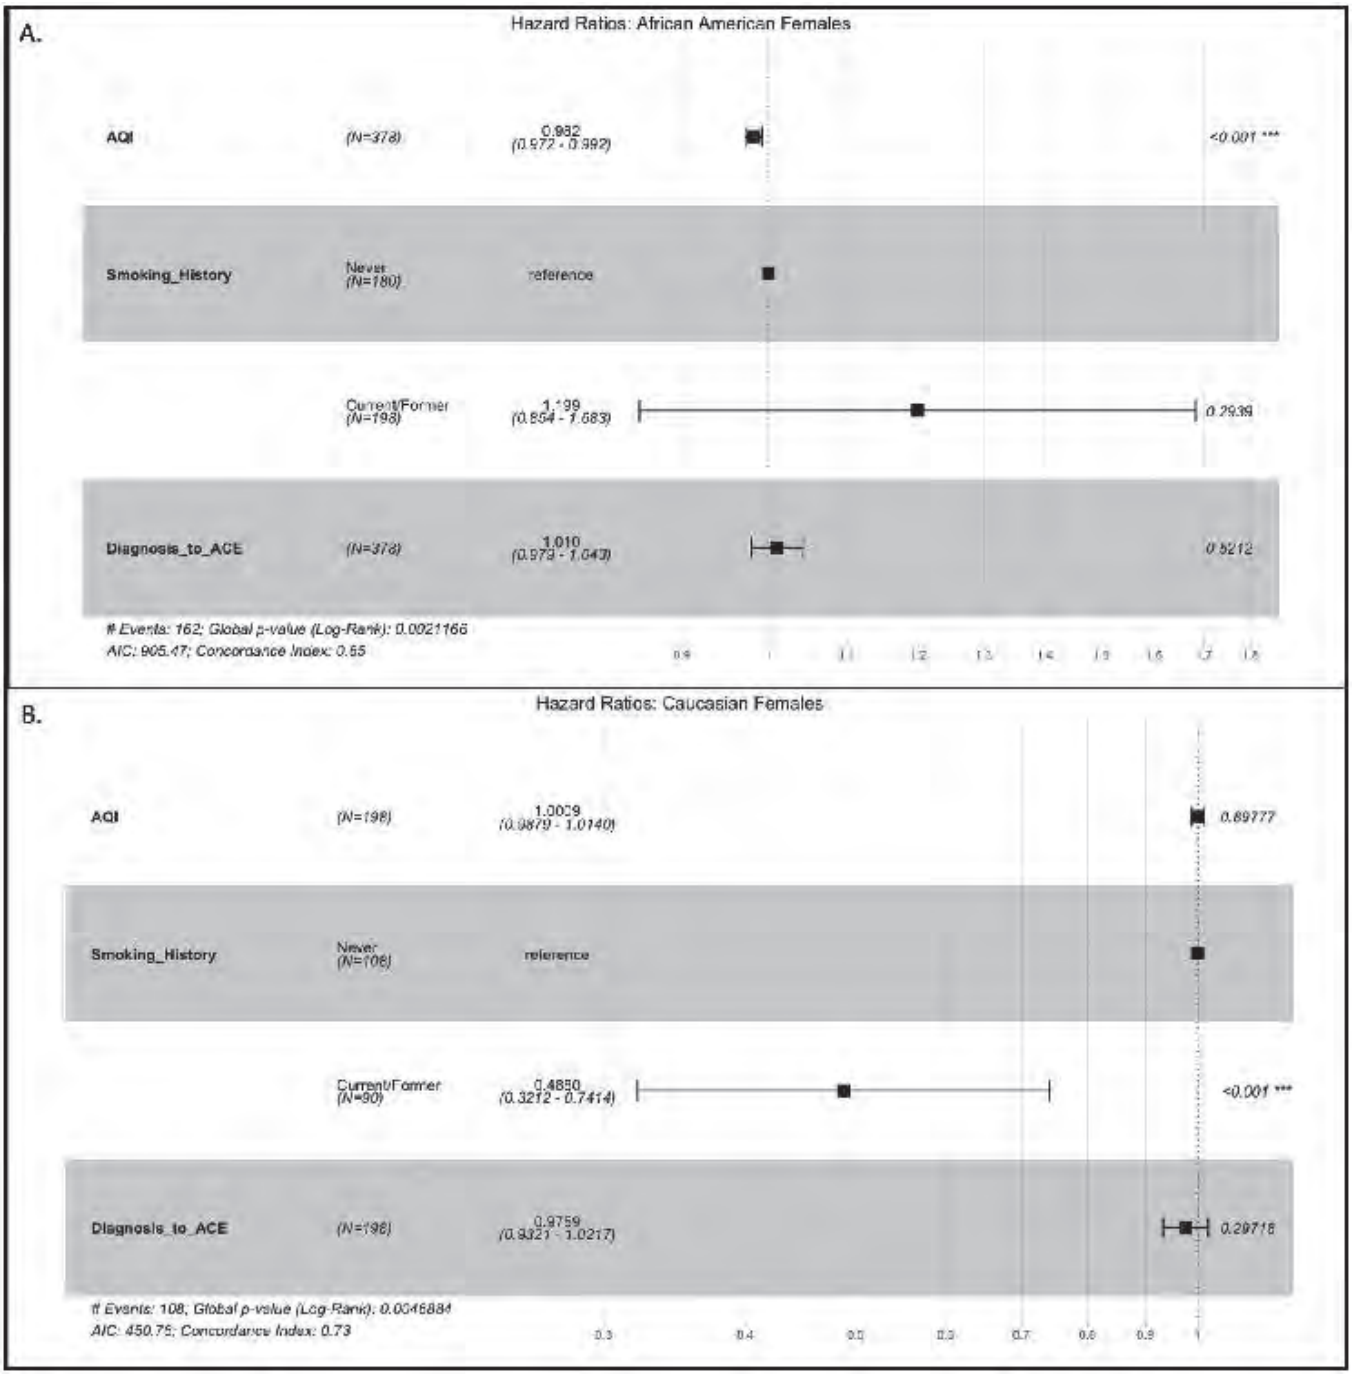

Figure 1. Forest plot demonstrating the Cox proportional hazard ratio and 95% confidence intervals associated with risk of angiotensin converting enzyme (ACE) levels over 50 U/L in (A) African American and (B) Caucasian females. In African American females, unit increments in air quality index (AQI) are associated with a 2% hazard reduction of elevated ACE levels at 6 months. In African Americans, smoking history and time from diagnosis of sarcoidosis (in years) to ACE level are not associated with increased ACE levels. Contrastingly, in Caucasian females, current or former smoking history is associated with a hazard reduction of 51% of elevated ACE levels. In Caucasians, AQI and time from years from diagnosis of sarcoidosis to ACE are not associated with ACE levels.

STAT1 and JAK2 Are the Most Appropriate Targets of JAK-inhibitor Therapy for Sarcoidosis: An In-silico Meta-nalysis

Marcia Friedman[1], Brian Le[2], Dongseok Choi[2] and James Rosenbaum[2], [1]Oregon Health and Science University, Portland, OR, [2]Oregon Health & Science University, Portland, OR

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Our group was the first to contend that STAT1 mediated genes were expressed in sarcoidosis. Since that time, several other groups have found similar results. In a direct extension of these data, JAK-inhibitors have shown benefit in treating sarcoidosis. There are now numerous JAK inhibitors approved to treat inflammatory and hematologic diseases, with varying specificity for JAK molecules. To design more robust clinical studies, we need to determine which JAK-inhibitors are most likely to work in sarcoidosis.

Methods: All publicly available gene expression microarray data from the Gene Ontology Omnibus (GEO) was queried. GEO was queried using the search terms “sarcoidosis” or “sarcoid”, and all human datasets which compared sarcoidosis to healthy controls were included. Microarray data were evaluated for differential expression using GEO2R, a limma based public access software. We analyzed the differential expression of the 4 JAK and 7 STAT genes in all sarcoidosis datasets to date. Significant differential expression was defined as a FC >1.5 or < -1.5, and an adjusted p-value or FDR p-value of < 0.05.

Microarray data were evaluated for differential expression using GEO2R, a limma based public access software available as part of the GEO database. For each dataset, sarcoidosis samples were compared to healthy controls. When sarcoid activity vs inactivity was reported (2 datasets), only active sarcoid samples were included. We analyzed the differential expression of the 4 JAK and 7 STAT genes in all sarcoidosis datasets to date. Significant differential expression was defined as a log2FC >0.585 or < -0.585 (corresponding to a FC >1.5 or < -1.5), and an adjusted p-value or FDR p-value of < 0.05.

Microarray data were evaluated for differential expression using GEO2R, a limma based public access software available as part of the GEO database. For each dataset, sarcoidosis samples were compared to healthy controls. When sarcoid activity vs inactivity was reported (2 datasets), only active sarcoid samples were included. Two analyses were planned. The first was an analysis of differential expression of the 4 JAK and 7 STAT genes. The second was a pathway-based analysis of all pathways known to signal through JAK-STAT. Pathways were evaluated using Gene Set Enrichment Analysis (GSEA).

Results: 12 datasets were included: 6 whole blood, 1 peripheral blood mononuclear cells, and 1 each of anterior orbit, lacrimal gland , bronchoalveolar lavage fluid, lung biopsy, and skin. STAT1 and JAK2 were the most commonly differentially expressed JAK-STAT genes. STAT1 was significantly differentially expressed in 85% of sarcoid datasets; the average FC was 2.6 compared to healthy controls. JAK2 was differentially expressed in 62% of datasets; the average FC was 1.7 compared to healthy controls.

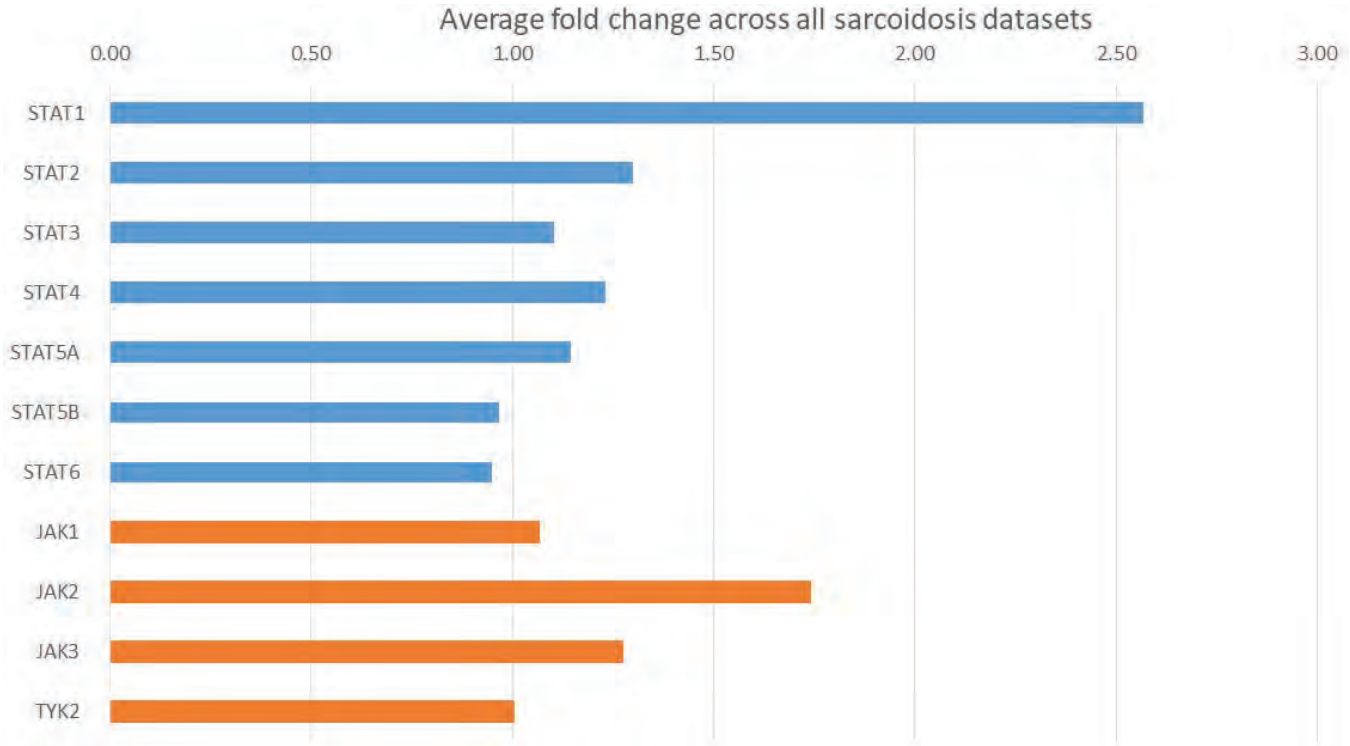

Figure 1. Average fold change of JAK-STAT genes across all sarcoidosis datasets.

Conclusion: This in-silico meta-analysis found that STAT1 and JAK2 are the most significantly expressed JAK-STAT genes in sarcoidosis tissues. We hypothesize that JAK-inhibitors targeting JAK2 are the most likely to be useful in sarcoidosis. Potential JAK inhibitor candidates for clinical trials include tofacitinib, ruxolitinib, baricitinib and peficitinib. We would not suggest trialing JAK1-specific inhibitors in sarcoidosis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

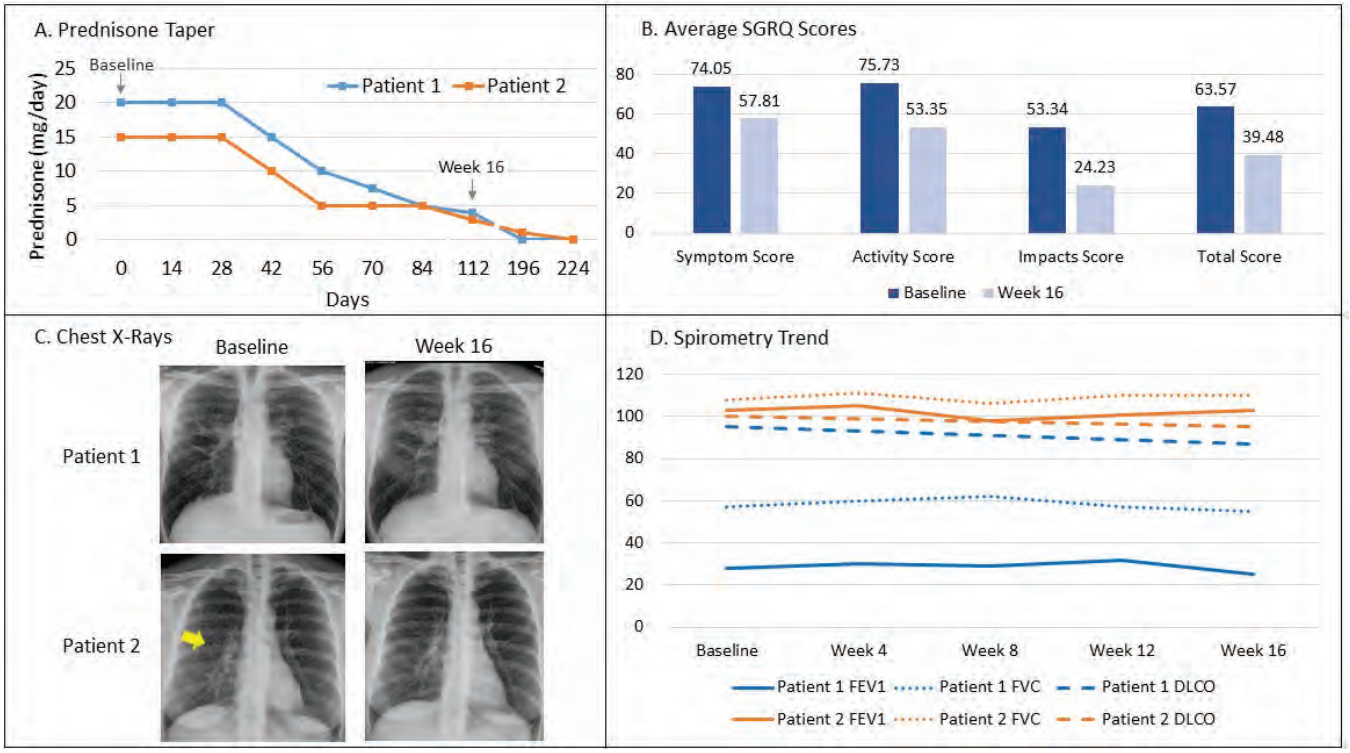

Figure 1. Changes in clinical data from baseline to week 16: A) Prednisone was tapered according to a specified protocol; there were no deviations from the planned taper. Both patients tapered prednisone to <5mg by week 16 and continued to taper during 1-year extension. B) Saint George Respiratory Questionnaire (SGRQ) scores all improved during the trial; a clinically significant difference for SGRQ is 4 units, thus all SGRQ changes were clinically significant. C) The chest x-ray for patient 1 remained sTable over 16 weeks, the chest x-ray for patient 2 showed improvement in mild bronchovascular nodularity (arrow indicates area of improved nodularity). D) Pulmonary function was sTable for both patients given established 10% between-test margin of variability for spirometry measurement.

Background/Purpose: Patients with pulmonary sarcoidosis often require prolonged corticosteroids to treat their disease. There are currently no FDA approved steroid-sparing therapies for sarcoidosis. We report here on the first two patients who have completed a prospective open-label study evaluating tofacitinib as a steroid-sparing therapy in pulmonary sarcoidosis.

Methods: Patients with pulmonary sarcoidosis who were unable to taper below 15-30mg/day of prednisone were invited to participate in this open-label proof of concept study. Patients were started on tofacitinib 5mg twice daily. After 4 weeks, prednisone was tapered according to a specified protocol. The primary endpoint was a ≥ 50% reduction in corticosteroids at week 16 with no worsening of respiratory symptoms by Saint George Respiratory Questionnaire (SGRQ) or pulmonary function; patients who met the primary endpoint were invited to enroll in a one-year extension study.

Results: The first two patients have completed this open-label study. By week 16 each had tapered to ≤ 5mg/day prednisone and thus met the primary endpoint. During the one-year extension study, both patients tapered fully off prednisone. There was no significant change in spirometry. Respiratory symptoms improved (average total SGRQ score change of -24.1 points). Chest imaging was sTable or mildly improved.

Conclusion: We report here the first two patients enrolled as part of an open-label prospective pilot study of tofacitinib as a steroid-sparing agent in pulmonary sarcoidosis. Both patients were able to taper steroids successfully with no disease worsening or significant adverse events. Tofacitinib is a promising therapy for pulmonary sarcoidosis.

Clinical Characteristics of Sarcoidosis in Asian Population: A 14-year Single Center Retrospective Cohort Study from Thailand

Athiwat Tripipitsiriwat[1], Chulaluk Komoltri[1], Ruchira Ruangchira-Urai[1] and **Patompong Ungprasert**[2], [1]Mahidol University, Bangkok, Thailand, [2]Cleveland Clinic, Cleveland, OH, Cleveland Heights, OH

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Data on clinical manifestations of Asians with sarcoidosis are still relatively limited and most of the previously published studies are from East Asia. This study aimed to examine the epidemiology and clinical characteristics of Thai patients with sarcoidosis, using databases of a tertiary care medical center.

	Mean or proportion (N = 89)
Intrathoracic disease	
Intrathoracic involvement	81 (91.0%)
-Stage I	43 (53.1%)
-Stage II	32 (39.5%)
-Stage III	5 (6.2%)
-Stage IV	1 (1.2%)
Pulmonary symptoms	34 (41.9%)
-Dyspnea	21 (25.9%)
-Cough	18 (22.2%)
-Chest pain	2 (2.5%)
Extrathoracic disease	
Uveitis	35 (39.3%)
Skin	24 (26.9%)
Joint	4 (4.5%)
Nervous system	3 (3.4%)
Kidney	3 (3.4%)
Parotid gland	3 (3.4%)
Liver	2 (2.2%)
Spleen	2 (2.2%)
Heart	2 (2.2%)
Bone	1 (1.1%)
Extrathoracic lymph node	18 (22.5%)
Hypercalcemia	9 out of 56 patients who had at least one calcium level checked (16.1%)
Biopsy (positive for non-caseous granuloma / number performed)	
Intrathoracic	53/68 (77.9%)
Skin	21/22 (95.5%)
Extrathoracic lymph node	8/8 (100.0%)
Parotid gland	1/1 (100.0%)
Kidney	1/1 (100.0%)
Treatment	
Oral prednisolone	46 (51.7%)
Methotrexate	16 (17.9%)
Azathioprine	8 (9.0%)
Chloroquine	3 (3.4%)
Leflunomide	1 (1.1%)
Sulfasalazine	1 (1.1%)
Inhaled corticosteroids	6 (6.7%)
Topical corticosteroids	28 (31.5%)

Table 1. Characteristics of patient with sarcoidosis in the current study

Methods: Potential cases of sarcoidosis were identified from two sources, the medical record-linkage system and the pathology database of Siriraj Hospital, Mahidol University in Bangkok, Thailand. Patients with ICD-10-CM codes for sarcoidosis were identified and retrieved from the medical record-linkage system from 2005 to 2018. Patients

with histopathology positive for non-caseating granuloma were identified and retrieved from the pathology database from the same time period. All potential cases underwent individual medical record review to confirm the diagnosis of sarcoidosis which required compatible clinical pictures supported by presence of non-caseating granuloma after exclusion of other granulomatous diseases. A standardized case record form was used to record demographics, clinical manifestations and treatment of confirmed sarcoidosis cases.

Results: From 2005 to 2018, 89 confirmed cases of sarcoidosis were identified. There was female predominance (80.9%) with mean age at diagnosis of 46.8 years (standard deviation [SD] 13.9 years) and mean follow-up time of 5.4 years (SD 4.5 years). The majority of patients with sarcoidosis in this cohort had intrathoracic disease (81 cases; 91.0%). About half of them had stage I pulmonary sarcoidosis (43 cases; 53.1%) followed by stage II (32 cases; 39.5%), III (5 cases; 6.2%) and IV (1 case; 1.2%). However, less than half of patients with intrathoracic disease were symptomatic (34 cases; 41.9%) with dyspnea and cough being the most common symptoms (25.9% and 22.2%, respectively). The yield of intrathoracic biopsy was fair that histopathology was positive for non-caseating granuloma in 53 of 68 patients (77.9%) who underwent biopsy.

Extrathoracic disease was common in this cohort that pulmonary sarcoidosis was accompanied by extrathoracic involvement in 53 patients (65.4%). Isolated extrathoracic disease was observed in 8 patients. Sarcoid uveitis was the most common extrathoracic disease (35 cases; 39.3%; 4 males and 31 females) followed by cutaneous sarcoidosis (24 cases; 26.9%). Calcium was tested in 56 patients and hypercalcemia was seen in 9 of them (16.1%). Biopsy of extrathoracic organs appeared to have a high sensitivity with 21 of 22 skin biopsies and all 8 extrathoracic lymph node biopsies showed evidence of non-caseating granuloma.

A total of 48 patients (53.9%) received at least one systemic treatment during the course of their illness. The most commonly prescribed systemic treatment was oral prednisolone (46 cases; 51.7%) followed by methotrexate (16 cases; 17.9%), azathioprine (8 cases; 9.0%) and chloroquine (3 cases; 3.4%) (**Table 1**).

Conclusion: The current study described clinical characteristics of sarcoidosis in an Asian population. The most prominent findings that are different from sarcoidosis in other ethnic groups included the high prevalence of uveitis and the marked female predominance.

Pharmaco-epidemiology of Non-infectious Ocular Inflammatory Disease in a Tertiary Academic Center

Sanjeev Patil[1], Justine Cheng[2], Lorraine Provencher[3] and Scott Vogelgesang[4], [1]University of Vermont Medical Center, Essex Junction, VT, [2]University of Iowa Hospitals and Clinics, Iowa City, IA, [3]Cincinnati Eye Institute, Cincinnati, OH, [4]University of Iowa Hospitals and Clinics, Iowa City, IA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

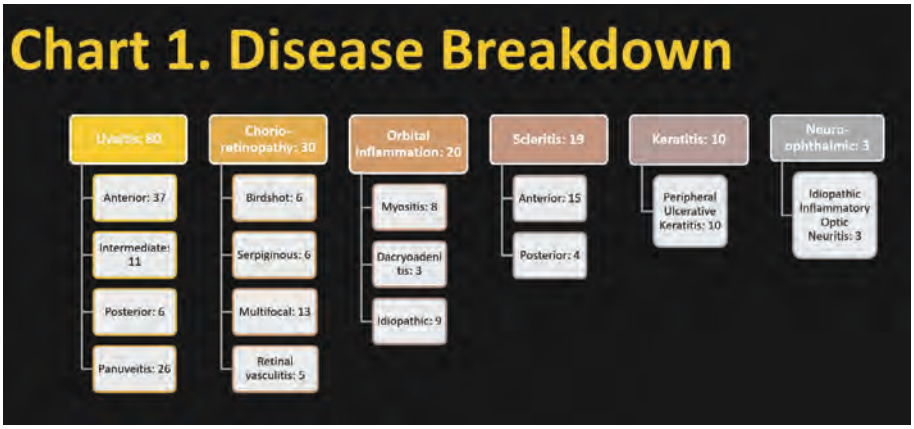
Background/Purpose: Non-Infectious Ocular inflammatory disease (OID) is a group of immune-mediated diseases involving the ocular surface, uveal tract, retina, optic nerve, and peri-orbital tissue. Patients are often referred to rheumatology for assistance with Disease-Modifying Anti-Rheumatic Drug (DMARD) therapy, when topical or systemic corticosteroids have not been completely effective. Real-world rheumatology practice of DMARD therapy selection to treat OID remains undescribed. We aim to describe the current DMARD prescribing practice at a tertiary academic center and identify effectiveness of these DMARDs.

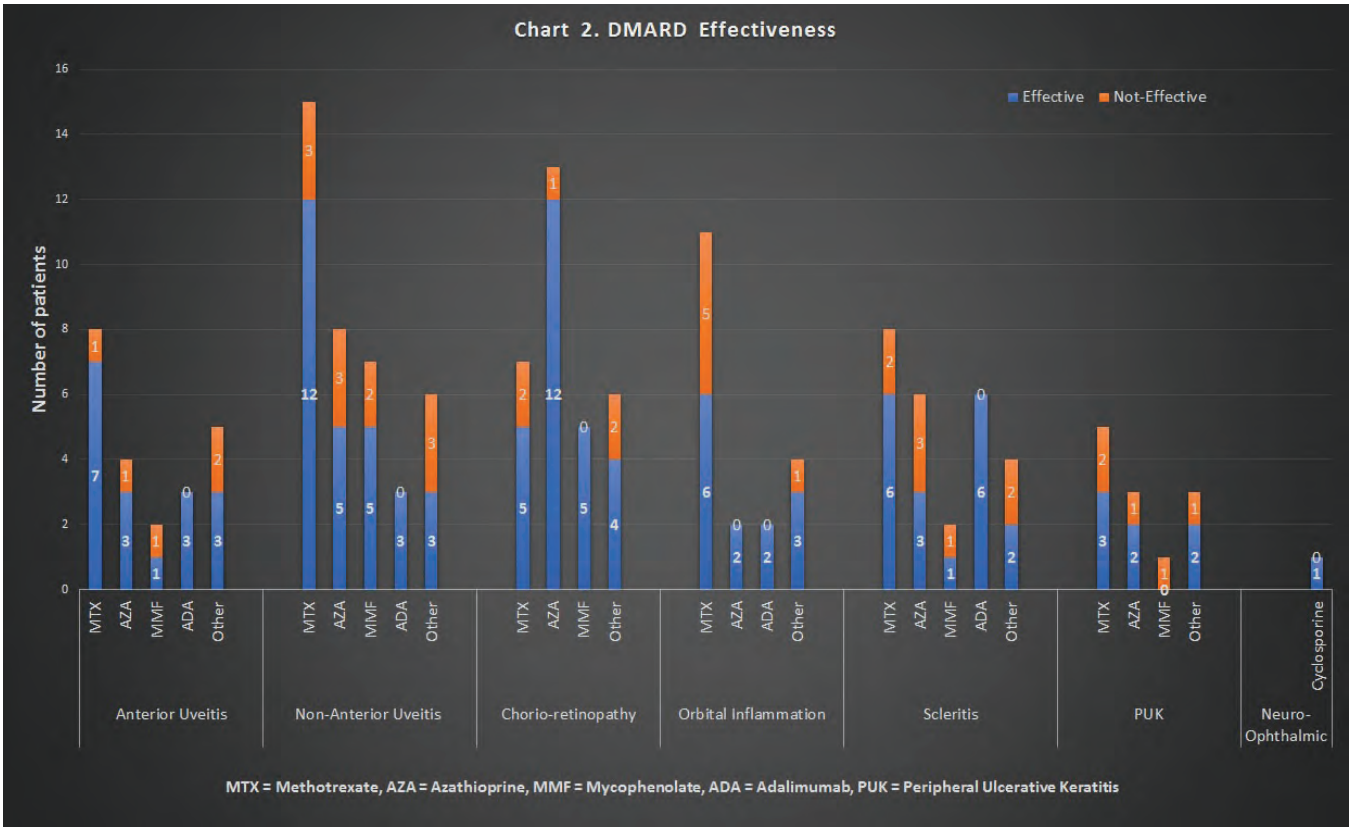
Methods: Retrospective descriptive cohort study of patients with OID treated at an academic tertiary center from 2000 to 2017. Inclusion criteria: age > 18 years, use of DMARDs, ≥ 2 visits with a rheumatologist, treatment with oral corticosteroid (≥10mg). Exclusion criteria: DMARD use for a systemic autoimmune disease and not particularly for OID.

DMARD effectiveness was defined as disease control, as determined by the ophthalmologist, and the ability to taper oral prednisone to ≤ 10mg. DMARD therapy was considered not effective when oral prednisone could not be tapered

Table 1. Patient characteristics

		Number of patients (N=162)	Percentage
Age	Median 42 years [IQR 29 - 56 years]		
Gender	Male	67	41.4%
	Female	95	58.6%
Race	African American	5	3.0%
	Asian	22	13.6%
	Caucasian	102	63.0%
	Hispanic	7	4.3%
	Native American	3	1.8%
	South Asian	2	1.2%
	Unspecified	19	11.7%
Smoking status	Ever smoker	76	47.0%
	Never smoker	77	47.5%
	Unknown	9	5.5%
Systemic Associations: 61 (37.2%)	Ankylosing spondylitis	13	7.9%
	RA	7	4.3%
	GPA	7	4.3%
	Sarcoidosis	7	4.3%
	Behcet's	5	3.0%
	JIA	4	2.4%
	Inflammatory arthritis	3	1.8%
	IBD (UC/Crohn's)	2	1.2%
	Multiple sclerosis	2	1.2%
	SLE	2	1.2%
	Psoriatic arthritis	2	1.2%
	Sjogren's	1	0.6%
	TINU	1	0.6%
	VKH	1	0.6%
	EGPA (Churg Strauss)	1	0.6%
	Relapsing polychondritis	1	0.6%
		Range	
Average Follow-up	7 years	0 to 18 years	





≤10mg due to active disease, active ocular disease as evaluated by the ophthalmologist despite the DMARD, or the need to discontinue the DMARD due to adverse effects.

Proportions were used to describe demographic characteristics, diagnoses, DMARDs prescription trends and effectiveness.

Results: A total of 369 patients were identified and 162 met the inclusion criteria. Median age was 42 years [Interquartile Range (IQR) 29 - 56 years]. The majority were Caucasian (63.0%) and female (58.6%). The most common OID was uveitis (49.4%), followed by chorioretinopathy (18.5%), orbital inflammation (12.3%), scleritis (11.7%), keratitis (6.2%), and neuro-ophthalmic (1.9%) (Chart 1).

With the exception of chorioretinopathy, methotrexate was the most common initial DMARD used in all forms of OID, ranging from 29% in chorioretinopathy to 63.2% in orbital inflammation. Mycophenolate followed by adalimumab were the most common subsequent DMARDs chosen. Other anti-TNF biologics were not used as often.

Chart 2 shows effectiveness of DMARDs in the different forms of OID. Methotrexate was found to be more effective in uveitis (around 80%), scleritis and chorioretinopathy, as compared to in orbital inflammation and keratitis. Adalimumab was found to be highly effective in uveitis, orbital inflammation and scleritis.

Conclusion: Our data suggests that the most common OID rheumatologists at our center treat is Uveitis, while most common DMARD used is methotrexate. Methotrexate and adalimumab were more commonly noted to be effective in treating some forms of OID.

Some of the limitations of our study are that this is a single institutional study, with small cohort when broken down into various subgroups of OID diagnoses, many patients lost to follow up which led to their exclusion, and lack of standardized practice patterns and steroid tapering schedule.

While there are RCTs on treatment of anterior uveitis, there is a need for multicenter RCTs for difficult to treat anterior uveitis and other OIDs.

Building LSU Uveitis Registry (BLUR) Study – a Review of an Academic Rheumatology Center's Experience and Approach to Uveitis

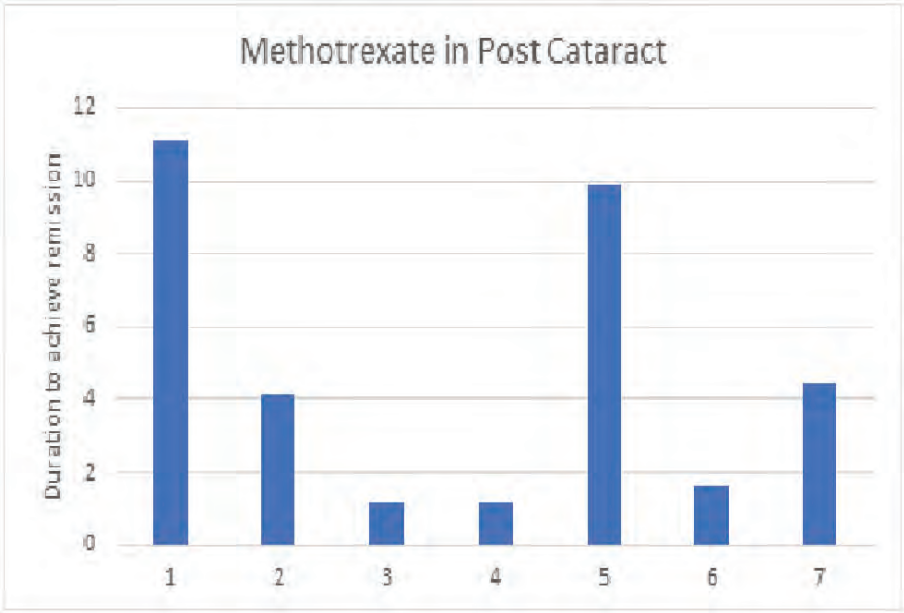
Anusha Vuppala[1], Kinza Muzzafar[1], Swathi Chalasani[1], Sibile Pardue[2], Samina Hayat[3] and Sarwat Umer[3], [1]LSUHSC Shreveport, Shreveport, LA, [2]LSUHSC Shreveport, Shreveport, [3]LSU Shreveport, Shreveport, LA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

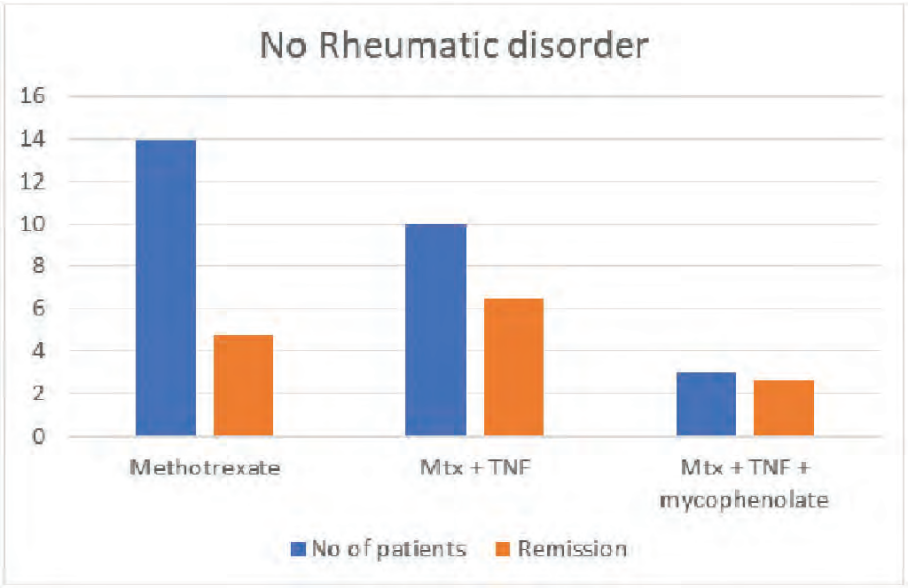
Background/Purpose: Uveitis is the most common ophthalmological finding seen by Rheumatologists. Ocular inflammation commonly presents as a manifestation of underlying rheumatic disorder. Local and systemic glucocorticoid therapies remain mainstay for initial therapy and various steroid sparing agents are being used to achieve disease stability. This study was performed in our Academic Center to identify the steroid sparing drugs with best efficacy to achieve remission in our patient population.

Methods: This is a retrospective analysis of 96 patients seen in our clinic with the diagnosis of Uveitis. Data analysis was done by student t test.

Results: Uveitis in our population is seen from ages 12 – 80 yrs with mean age of 51 yrs. 82% of our patients are African American and 17% are Caucasian. Patients with Sarcoidosis constituted about 23.9% and post cataract constituted 7%. The remaining 20% included RA, SLE, Scleroderma, JIA and ANCA vasculitis. 72% of our patients presented with Anterior uveitis, 14% with posterior uveitis and 10% with pan uveitis. Methotrexate was used most



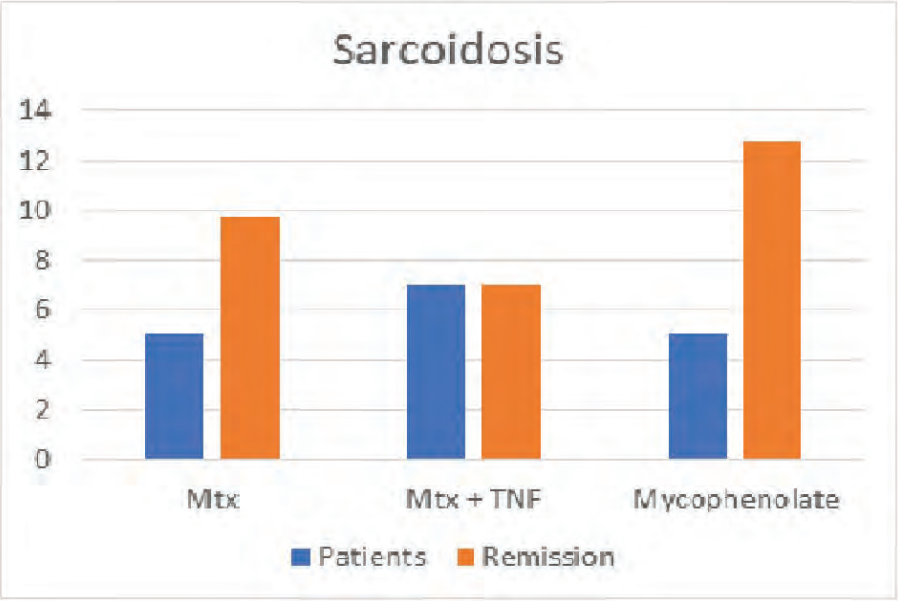
Methotrexate for remission induction in Post cataract patients



Medications for patients with no rheumatic disorder

frequently with 62% of our patient population. It was followed by TNF alpha inhibitors with frequency of 39%. 100% of our post cataract patients achieved remission just with methotrexate with mean remission duration of 4 months. Of the patients with no associated rheumatic disorder, methotrexate is associated with lowest duration to achieve remission – 4.8 months. Patients with Sarcoidosis achieved remission with methotrexate and TNF alpha inhibitors in mean of 7.8 months

Conclusion: Uveitis in our patients is associated with Sarcoidosis, post cataract and few patients with RA, Scleroderma, SLE, JIA, ANCA Vasculitis. 39% of our patients have no associated autoimmune disorder. Stability of disease was able to be achieved in 4 months with use of methotrexate in almost half of our population. 37% of patients required to be placed on combination methotrexate and TNF alpha inhibitors. Remission in these patients was achieved in 6.8



Medications for remission induction in sarcoid

months. Uveitis due to post cataract attained remission solely with the use of methotrexate. Whereas patient with Sarcoidosis responded well to combination of TNF alpha inhibitors and methotrexate rather than methotrexate alone. Mycophenolate was used in few patients with Sarcoidosis who were intolerant to methotrexate, thus confounding the duration for remission. Rituximab was added for refractory uveitis unresponsive to other therapies. Duration for remission with Rituximab appears shorter mainly due to low sample size. More studies are needed to further tailor the treatment regimen for Uveitis associated with various autoimmune rheumatic disorders.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

TABLE 1. General features and etiology, n (%)

Episcleritis (n=132): Simple / Nodular	115 (87.1%) / 17 (12.9%)
Scleritis (n=38): Diffuse anterior / Nodular anterior	23 (60.5%) / 15 (39.5%)
Complications	30 (17.7)
- Uveitis	10 (5.9)
- Keratitis	7 (4.6)
- Glaucoma	9 (3.9)
- Cataract	4 (2.6)
ETIOLOGY	
Idiopathic	**85 (50)**
Infectious	**11 (6.5)**
Herpes simplex virus / Varicella zoster virus	9 (5.3) / 2 (1.2)
IMID*	**74 (43.5)**
- Spondyloarthritis	19 (11.2)
- Crohn's disease	16 (9.4)
- Rheumatoid Arthritis	12 (7.1)
- Granulomatosis with polyangiits	7 (4.1)
- Relapsing polychondritis	6 (3.5)
- Systemic lupus	4 (2.4)
- Ulcerative colitis	3 (1.8)
- Psoriasis	2 (1.2)

***Behçet, Sarcoidosis, Leucocytoclastic vasculitis, Thyroiditis, Celiac disease, was observed 1 case of each.**

TABLE 2. Treatment, n (%)

Systemic	
- NSAIDs	119 (70)
- Prednisone	63 (37.1)
- Bolus MTP	6 (3.5)
Conventional immunosupressants	
- Methotrexate	39 (22.9)
- Azathioprine	16 (9.4)
- Salazopyrine	6 (3.5)
- Hydroxychloroquine	6 (3.5)
- Cyclophosphamide	3 (1.8)
- Mycophenolate mofetil	2 (1.2)
Biological agents	
- Infliximab	13 (7.7)
- Adalimumab	11 (6.5)
- Etanercept	3 (1.8)
- Golimumab	5 (2.9)
- Secukinumab	5 (2.9)
- Abatacept	2 (1.8)

Background/Purpose: Ocular scleral pathology (OSP) includes episcleritis and scleritis. Episcleritis is generally a benign disease with a self-limited course, while scleritis is a more severe ocular condition. Both may be associated

with immune-mediated inflammatory diseases (IMID).

In a wide series with OSP our aim was to assess the **a)** epidemiological and clinical features and **b)** relationship with IMID.

Methods: Study of all consecutive patients studied in a single Universitary Hospital during the last ten years with**: a)** episcleritis and **b)** scleritis diagnosed by clinical features and slit-lamp (Watson and Hayreh criteria).

Results: We studied 170 patients (101 women/ 69 men) / 340 affected eyes with OSP (episcleritis=132; scleritis=38); mean age at diagnosis 49.03±14.11 years.

OSP was unilateral in 138 (81.2%), recurrent in 70 (41.2%) and chronic in 21 (12.4%). Most of them were idiopathic (n=85, 50%) while associated IMID were 43.5% (**TABLE 1)**.

Topical treatment was used in all patients. In addition to systemic corticosteroids, conventional immunosuppressive and biological drugs were required in 52 cases (30.6%) and 20 (11.8%), respectively (**TABLE 2)**. The main indication for biological therapy was the presence of underlying IMID.

Conclusion: Scleral pathology is a relatively frequent entity and it is necessary to exclude an underlying systemic disease.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory bowel disease (IBD), which includes Crohn's disease (CD), and Ulcerative colitis (UC) are related to Spondyloarthritis (SpA). Ocular manifestations (OM) are well-stablished in SpA but not in IBD. It has been classically reported that whereas uveitis with SpA is predominantly anterior, unilateral, sudden, and limited; in IBD it is bilateral, posterior, insidious, and chronic *(Lyons & Rosenbaum JT. Arch Ophthalmol 1997; 115:61-4).*

TABLE.

	Uveitis (n= 23)	Epi/scleritis (n=19)	p

NASH, n (%)	4 (17.39)	6 (31.58)	p= 0.28

***p value < 0.05. SD:** standard deviation; **CD:** Crohn's disease; **UC:** ulcerative colitis; **NASH:** non-alcoholic steatohepatitis.

In a large unselected series of IBD, we study the OM and assess; **a)** epidemiological, clinical features, **b)** the relationship with extraintestinal manifestations

Methods: Study of all consecutive patients from a single University Hospital during the last 40 years with**: a)** IBD (CD and UC), and **b)** OM: uveitis and scleral pathology diagnosed by clinical features and slit-lamp.

Results: OM were present in 42 (2.9%) (25 women/17 men) (84 eyes) of 1442 IBD patients; OM included the uveitis group (UG) (n=23; 1.6%) and the scleral pathology group (SG) (n=19, 1.32%) (**TABLE)**.

The most common pattern in SG was episcleritis (n=16; 84.21%) and scleritis (n=3). In UG, uveitis was typically anterior (n=18; 78.3%), unilateral (n=19; 82.6%), sudden (n=19; 82.6%), and limited (n=12; 52.2%).

The comparative study between SG vs UG showed in UG a significant predominance of women and UC. Also, a non-significative higher frequency in Pyoderma gangrenosum, erythema nodosum and joint involvement was observed in UG.

After a mean follow-up of 15.2±9.97 years, extraintestinal manifestations were observed in 100% of patients, being articular forms (n=16; 38.10%) the most common type. In addition, joint/axial flare is more related to the presence of uveitis (p=0.038).

Conclusion: Both uveitis and episcleritis are equally frequent OM in IBD. Although uveitis is more infrequent in IBD than in SpA, it is also anterior, unilateral, sudden and limited in contrast with published data from selected series.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Optic Neuritis (ON) is an inflammation of the optic nerve. Its most common presentation is demyelinating typical ON. Atypical ON is rare, severe, non-demyelinating and can be isolated or associated to different diseases including autoimmune diseases. If it is not treated, it can lead to devastating visual results. Conventional treatment includes systemic corticosteroids and conventional immunosuppressants (CIS). Our aim was to assess the efficacy of biological therapy in atypical ON refractory to conventional treatment.

Methods: Open-label multicenter study including 19 patients diagnosed with atypical ON refractory to systemic corticosteroids and at least one CIS. The main outcomes assessed were Best Corrected Visual Acuity (BCVA) and optic nerve and ganglionar cells Optical Coherence Tomography (OCT). These outcome variables were recorded at baseline, 1 week, 2 weeks, 1 month, 3 months and 6 months and 1 year after biological therapy onset.

Results: We studied 19 patients (12 women/7 men); mean age of 34.8 ± 13.9 years. The underlying diseases were idiopathic (n=7), Behçet´s disease (n=5), systemic lupus erythematosus (n=2), neuromyelitis optica (n=3), sarcoidosis (n=1) and relapsing polychondritis (n=1) **(TABLE).** Before biological therapy and besides systemic corticosteroids, patients had received different CIS. Biological therapy was adalimumab (n=6), rituximab (n=6), infliximab (n=5) and tocilizumab (n=4). After biological therapy, an improvement in ocular parameters was observed: BCVA [0.7±0.3 to 0.8±0.3; p= 0.03], optic nerve OCT [123.2±58.3 to 190.5±175.4; p= 0.11], and ganglionar cells OCT [369.6±137.4

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a frequent complication of RA and is associated with increased morbidity and mortality.[1] Previous studies have shown variability in risk factors for RA-associated ILD (RA-ILD).[1,2] The objective of this analysis was to systematically evaluate the risk factors of RA-ILD in a real-world population of patients with RA.

Methods: Patient demographic and disease characteristics were retrospectively analyzed following data extraction from the Discus Analytics JointMan database, a large US electronic medical records-based dataset. Adults with an RA diagnosis (International Classification of Disease, Ninth Revision, Clinical Modification [ICD-9-CM] code: 714.0; ICD, Tenth Revision, CM [ICD-10-CM] codes: M05, M06) between January 1, 2009 and September 20, 2019, ≥1 visit after the initial visit date, no diagnosis code for ILD prior to RA diagnosis and no diagnosis code for drug-induced ILD at any time during the study period were included in the analysis. Patients with ILD were identified by ICD diagnosis

prior to or on date of initial RA diagnosis). RA characteristics were identified during and after the initial RA diagnosis and were controlled as time-varying covariates in the Cox model. Significance was set at $p< 0.05$.

Results: Of the 5817 patients included, 5612 had RA only and 205 had RA-ILD. Several baseline differences between patients with and without ILD were identified: a greater proportion of patients with RA-ILD vs RA only were older, male, of white race, had a history of chronic obstructive pulmonary disease (COPD) and had more severe and more active RA than did patients with RA only (**Table 1**).[3] Cox multivariate regression analysis showed older age (>65 years old) and a history of COPD at baseline to be risk factors for developing ILD (**Figure 1**). Additionally, several time-varying covariates (anti-CCP positivity, CRP >5 mg/L and a moderate-to-high CDAI score) were also shown to be predictive of developing ILD.

Conclusion: In this large, real-world analysis of patients with RA, several risk factors for RA-ILD were identified: age, COPD, anti-CCP+, CRP and CDAI score. Recognition of these risk factors may lead to improved identification and a tailored approach to treatment of RA-ILD.

Prospective Analysis of a Cohort of Patients with Interstitial Lung Disease Associated with Connective Tissue Disease and Their Response to Immunosuppression with Mycophenolate Mofetil and Rituximab

Yan Li[1], Hassan Baig[2], Carlos Rojas[2], Justin Stowell[2], Elizabeth Lesser[2], Shalmali Borkar[2], Andy Abril[1] and Isabel Mira-Avendano[1], [1]Mayo Clinic, Ponte Vedra Beach, FL, [2]Mayo Clinic, Jacksonville, FL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Connective tissue diseases (CTDs) are commonly identified causes for interstitial lung disease (ILD). Compared with idiopathic interstitial pneumonias, patients with CTD-ILD and interstitial pneumonia with autoimmune features (IPAF) are more likely to respond to immunosuppression with a better prognosis. We aim to investigate use of mycophenolate (MMF) and rituximab (RTX) in a mixed cohort of patients with CTD-ILD, prospectively followed up for one year in a single academic center.

Methods: Patients with CTD and ILD were identified based on electronic medical records from Mayo Clinic Jacksonville and Rochester campuses from 2009 - 2019. Chart review was conducted in 413 patients, with 138 confirmed cases of CTD-ILD or IPAF based on multidisciplinary evaluation. 91 were further excluded due to post transplant status, mild disease only on observation, treatment with agents other than MMF and RTX, or incomplete data. Eventually, 47 patients with CTD-ILD or IPAF, treated with MMF and / or RTX, were included. Demographics, pertinent clinical symptoms, pulmonary function test (PFT) and treatment were collected at baseline, 6-month and 12-month follow up.

MMF and RTX doses and treatment track were analyzed individually with improvement in PFT. Multivariable linear regression models were used to assess baseline and 6-month treatment doses of MMF and RTX, with changes in outcomes during 12-month follow-up. All models were adjusted for age, sex, and prednisone dose at corresponding follow-ups.

Results: Baseline characteristics of the 47 patients are summarized in Table 1. Forty (85%) patients were diagnosed with CTD-ILD, with 19 (40%) as Antisynthetase Syndrome, and 7 (15%) had IPAF. Six (13%) patients were on RTX only, 28 (60%) on MMF only, and the remaining 13 (28%) were on combined therapy with MMF and RTX or switched from MMF to RTX due to lack of response or intolerance to MMF.

PFT outcomes in association with medication dose are summarized in Table 2. Throughout the 12-month study period, forced vital capacity (FVC) and FVC% remained sTable with each treatment dose or track. Patients on higher doses of MMF were associated with an average increase of 1.34 (95% CI: 0.38, 2.29) units in diffusing capacity for carbon monoxide (DLCO) for every 1-gram increase in MMF, from baseline to 6-month (P=0.01), which stabilized from 6 to 12-month follow-up. Patients on RTX monotherapy had significantly worsening in DLCO by 7.21 (95% CI: 4.08, 10.33) units (P< 0.001) from baseline to 12-month.

Ten patients received MMF and RTX combined therapy during study period, with clinical features summarized in Table 3. Although pulmonary function was severely compromised at baseline, these patients acquired sustained improvement from baseline to 12-month. In all cases, prednisone was decreased to a maintenance average dose of 8 mg/day at 12-month follow up.

Table 2. Summary of treatment with PFT outcomes

Conclusion: Through the study period, patients with CTD-ILD or IPAF, treated with MMF, presented with stability of FVC and significant improvement in DLCO; while RTX monotherapy was associated with worsening DLCO. Combination of both medications was related with sustained improvement in PFT and gradual decrease in concurrent steroids doses.

Reduced Decline in Forced Vital Capacity in Patients with Progressive Fibrosing Autoimmune Disease-Related Interstitial Lung Diseases (ILDs) Treated with Nintedanib

Eric Matteson[1], Oliver Distler[2], Jörg HW Distler[3], Masataka Kuwana[4], Janet Pope[5], James Seibold[6], Alexandra James[7], Rozsa Schlenker-Herceg[8], Klaus Rohr[7] and Kevin Flaherty[9], [1]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, MN, [2]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Switzerland, Zurich, Switzerland, [3]University of Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany, [4]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Tokyo, Japan, [5]Department of Medicine, University of Western Ontario, St. Joseph's Health Centre, London, ON, Canada, [6]Scleroderma Research Consultants LLC, Aiken, South Carolina, USA, Aiken, SC, [7]Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany, Ingelheim am Rhein, Germany, [8]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, Connecticut, USA, Ridgefield, CT, [9]Division of Pulmonary and Critical Care Medicine, University of Michigan, Ann Arbor, Michigan, USA, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In the randomized placebo-controlled INBUILD trial in patients with chronic fibrosing ILDs with a progressive phenotype, nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks, with an adverse event profile characterized mainly by gastrointestinal events. We analyzed the effects of nintedanib on categorical changes in FVC in the subgroup of patients with autoimmune disease-related ILDs.

Methods: The INBUILD trial enrolled patients with a fibrosing ILD other than idiopathic pulmonary fibrosis, reticular abnormality with traction bronchiectasis (with or without honeycombing) of >10% extent on high-resolution computed tomography (HRCT), FVC ≥45% predicted, and DLco ≥30%–< 80% predicted. To be eligible to participate, patients had to meet protocol-specified criteria for progression of ILD within the 24 months before screening despite management as deemed appropriate in clinical practice. In the subgroup of patients with autoimmune disease-related ILDs, we analyzed absolute changes from baseline in FVC (mL) and FVC % predicted at week 52, and the proportions of patients with categorical declines in FVC % predicted at week 52 (analyzed using a worst observation carried forward approach).

Results: The subgroup with autoimmune disease-related ILDs comprised 170 patients (Table 1). At baseline, mean (SD) FVC was 69.6 (15.1) % predicted in the nintedanib group and 72.1 (14.6) % predicted in the placebo group. Mean (SE) absolute changes from baseline in FVC were -92.7 (29.1) mL in the nintedanib group and -185.7 (27.3) mL in the placebo group (difference 93.0 [95% CI 14.1, 172.0]). Mean (SE) absolute changes from baseline in FVC % predicted were -2.7 (0.9) in the nintedanib group and -6.0 (0.8) in the placebo group (difference 3.3 [95% CI 0.9, 5.6]). The proportions of patients with absolute and relative declines in FVC >5% predicted or >10% predicted at week 52 were numerically lower in the nintedanib group than in the placebo group (Table 2).

Conclusion: In patients with progressive fibrosing autoimmune disease-related ILDs, the proportions of patients with categorical declines in FVC % predicted supported an effect of nintedanib in slowing the progression of ILD.

Table 1. ILD diagnoses in patients with autoimmune disease-related ILDs in the INBUILD trial

	Nintedanib (n=82)	Placebo (n=88)
Rheumatoid arthritis-ILD	42 (51.2)	47 (53.4)
Systemic sclerosis-ILD	23 (28.0)	16 (18.2)
Mixed connective tissue disease-ILD	7 (8.5)	12 (13.6)
Other autoimmune disease-related ILDs*	10 (12.2)	13 (14.8)

Data are n(% of patients in that treatment group).

*Other autoimmune disease noted in the "Other fibrosing ILDs" category of the case report form, including Sjogren's disease-related ILD, interstitial pneumonia with autoimmune features (IPAF), and undifferentiated autoimmune disease-related ILD.

Table 2. Proportions of patients with categorical changes in FVC % predicted at week 52 in patients with autoimmune disease-related ILDs in the INBUILD trial

	Nintedanib (n=82)	Placebo (n=88)
Relative decline from baseline in FVC >5% predicted at week 52, n (%)	42 (51.2)	57 (64.8)
Odds ratio (95% CI)	0.56 (0.30, 1.04)	
Nominal p-value	0.07	
Relative decline from baseline in FVC >10% predicted at week 52, n (%)	32 (39.0)	44 (50.0)
Odds ratio (95% CI)	0.63 (0.34, 1.16)	
Nominal p-value	0.14	
Absolute decline from baseline in FVC >5% predicted at week 52, n (%)	35 (42.7)	51 (58.0)
Odds ratio (95% CI)	0.55 (0.30, 1.01)	
Nominal p-value	0.05	
Absolute decline from baseline in FVC >10% predicted at week 52, n (%)	25 (30.5)	37 (42.0)
Odds ratio (95% CI)	0.60 (0.32, 1.15)	
Nominal p-value	0.12	

Analyzed using a worst observation carried forward approach.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

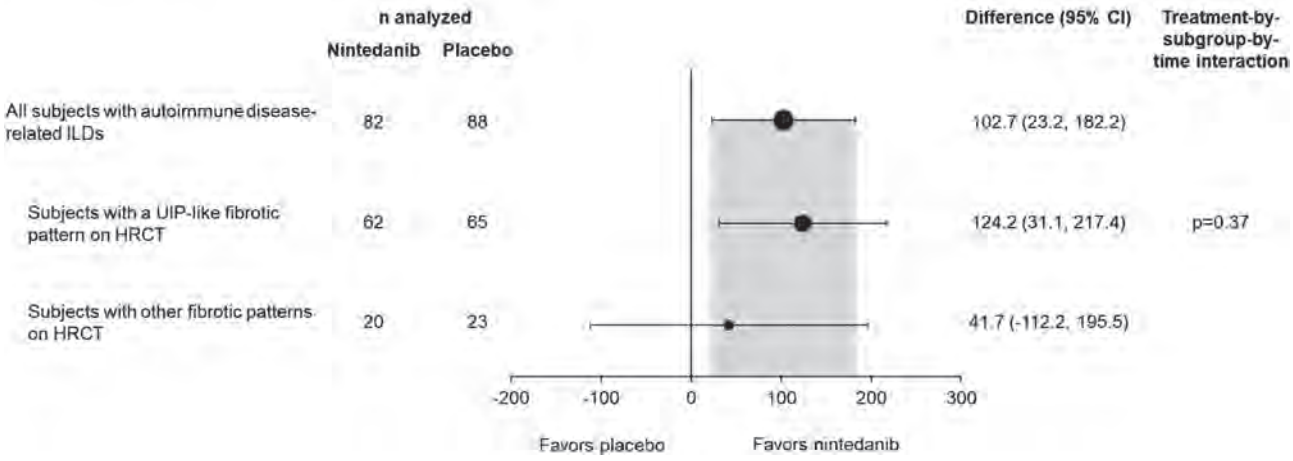
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In the INBUILD trial, nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks compared with placebo in patients with chronic fibrosing ILDs with a progressive phenotype. Several studies have suggested that a usual interstitial pneumonia (UIP) pattern on high-resolution computed tomography (HRCT) is associated with faster progression of ILD. We assessed the effect of nintedanib on FVC decline in patients with autoimmune disease-related ILDs in the INBUILD trial in subgroups by fibrotic pattern on HRCT at baseline.

Methods: The INBUILD trial enrolled patients with a fibrosing ILD other than idiopathic pulmonary fibrosis, reticular abnormality with traction bronchiectasis (with or without honeycombing) of >10% extent on HRCT, FVC ≥45%

Figure. Rate of decline in FVC (mL/year) over 52 weeks in subjects with autoimmune disease-related ILDs treated with nintedanib versus placebo in the INBUILD trial by fibrotic pattern on HRCT.



predicted, and DLco ≥30%–< 80% predicted. To be eligible to participate, patients had to meet protocol-specified criteria for progression of ILD within the 24 months before screening despite management as deemed appropriate in clinical practice. Patients were randomized to receive nintedanib or placebo, stratified by fibrotic pattern on HRCT (UIP-like fibrotic pattern or other fibrotic patterns) based on central review. In a post-hoc analysis, we analyzed the rate of decline in FVC over 52 weeks in patients with autoimmune disease-related ILDs in subgroups by UIP-like fibrotic pattern on HRCT and other fibrotic patterns on HRCT.

Results: The subgroup with autoimmune disease-related ILDs comprised 170 patients (89 rheumatoid arthritis-ILD, 39 systemic sclerosis-ILD, 19 mixed connective tissue disease-ILD, 23 other autoimmune disease-related ILDs), of whom 127 (74.7%) had a UIP-like fibrotic pattern on HRCT and 43 (25.3%) had other fibrotic patterns on HRCT. In the placebo group, the rate of decline in FVC over 52 weeks was similar in patients with a UIP-like fibrotic pattern on HRCT (n=65) and with other fibrotic patterns on HRCT (n=23) (-182.8 [SE 32.6] vs -168.1 [51.8] mL/year). The effect of nintedanib versus placebo on reducing the rate of decline in FVC was numerically greater in subjects with a UIP-like fibrotic pattern on HRCT than in those with other fibrotic patterns on HRCT (difference 124.2 mL/year [95% CI 31.1, 217.4] vs 41.7 mL/year [95% CI -112.2, 195.5]) but the interaction p-value did not indicate heterogeneity in the treatment effect between the subgroups by HRCT pattern (p=0.37) (Figure).

Conclusion: In patients with progressive fibrosing autoimmune disease-related ILDs in the INBUILD trial, nintedanib slowed the rate of FVC decline both in patients with a UIP-like fibrotic pattern on HRCT and in patients with other fibrotic patterns on HRCT, with a numerically greater effect in patients with a UIP-like fibrotic pattern on HRCT.

Sulfasalazine	1 (3.8)
Tacrolimus	1 (3.8)
I.V. immunoglobulins	1 (3.8)

AD: autoimmune disease; ILD: interstitial lung disease; IS: immunosuppressive; NSIP: nonspecific interstitial pneumonia; RTX: rituximab; SD: standard deviation; UIP: unusual interstitial pneumonia.

Table 1. Demographic and clinical characteristics of 26 AD-ILD patients included in this study.

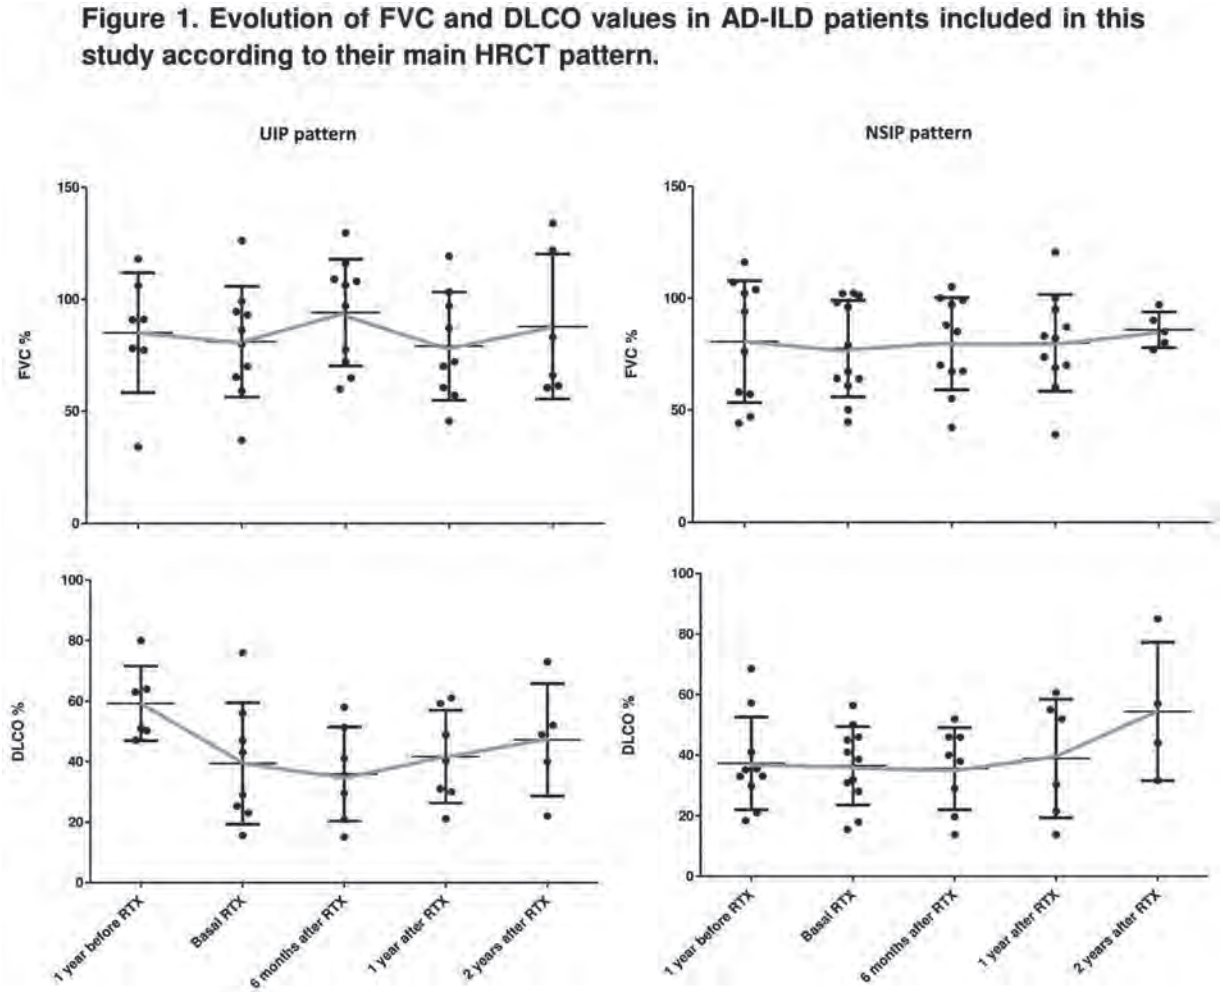

Figure 1. Evolution of FVC and DLCO values in AD-ILD patients included in this study according to their main HRCT pattern.

Background/Purpose: The presence of interstitial lung disease (ILD) in patients with autoimmune diseases (AD)s influences significantly on their morbidity and mortality [1]. Different treatment strategies have been proposed, including lung transplantation as the last alternative [2]. Corticosteroids, cyclophosphamide and mycophenolate mofetil are the most widely used conventional immunosuppressive drugs [3]. Rituximab (RTX), a chimeric (human/ murine) monoclonal antibody against the surface antigen CD20 expressed on pre-B and B lymphocytes, has shown efficacy in the treatment of patients with ILD associated with AD (AD-ILD), even as a rescue alternative in severe and refractory cases [4]. In the present study, we aimed to report our experience with RTX in the treatment of patients with AD-ILD.

Methods: We performed a retrospective study of patients assessed from May 2016 until March 2020 in a referral clinic of ILD and lung transplantation (Hospital Universitario Marqués de Valdecilla, Santander, Spain). Patients with a diagnosis of AD-ILD who received RTX were assessed. The main indications for RTX administration were the presence of a significant ILD in the setting of AD or the identification of an AD in the course of an established ILD. Clinical characteristics, radiological findings and pulmonary function tests (PFTs) were evaluated. PFTs were collected at baseline (RTX onset), at 6 months and annually until 2 years with RTX therapy.

Results: A total of 26 patients were included, with a mean age of 58.3 ± 11.1 years at ILD diagnosis. The most frequent ADs related to ILD were systemic sclerosis, idiopathic inflammatory myositis (including anti-synthetase syn-

drome) and rheumatoid arthritis. Non-specific interstitial pneumonia and usual interstitial pneumonia were the predominant radiological patterns. Demographic and clinical characteristics of the AD-ILD patients are shown in Table 1. A sustained improvement of PFTs was observed from the initiation of RTX, with a statistically significant increase of DLCO from basal to one year after RTX (mean + 4.2%, p = 0.024). Overall, no differences were found comparing PFT's outcomes according to the radiological pattern (Figure 1) or the specific type of AD.

Conclusion: RTX constitutes a good therapeutic option to preserve lung function in patients with AD-ILD, regardless of the radiological pattern or the underlying AD.

Abstract Number: 1051

Rituximab for Interstitial Pneumonia with Autoimmune Features at Two Academic Medical Centers

Kristin D'Silva[1], Iazsmin Bauer Ventura[2], Marcy Bolster[3], Flavia Castelino[4], Amita Sharma[1], Brent Little[1], Ayodeji Adegunsoye[2], Mary Strek[2], Sydney Montesi[1] and Hyon Choi[5], [1]Massachusetts General Hospital, Boston, MA, [2]University of Chicago, Chicago, IL, [3]Massachusetts General Hospital, Concord, MA, [4]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [5]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Many patients with interstitial lung disease (ILD) have autoimmune features without a distinct rheumatic disease and are thus designated as having interstitial pneumonia with autoimmune features (IPAF). Rituximab (RTX) may be effective in IPAF, but relevant data are scarce. We describe 50 patients with IPAF treated with RTX at 2 large academic medical centers.

Methods: Patients age ≥18 years meeting the 2015 IPAF classification criteria and treated with rituximab were identified at two large academic medical centers, Mass General Brigham (MGB) and University of Chicago Medicine (UCM). At MGB, patients were identified using an institution-wide data repository of patients seen from 2000-2018. At UCM, patients were identified from an ILD registry between 2006-2019. Patients were excluded if they received RTX for a classifiable autoimmune disease or malignancy or if they had < 1 year of follow-up available. Clinical improvement was defined as meeting all 4 clinical domains at 1 year after RTX initiation: improvement in clinician assessment, decreased oxygen requirement, no hospitalization, and survival. Only those subjects with PFTs within 3 months prior to or 1 month after RTX initiation and 6-18 months after RTX initiation were included in the PFT analysis. PFT improvement was defined as ≥10% increase in forced vital capacity (FVC).

Results: At MGB, 36 IPAF patients (mean age 61 years, 44% female) were treated with RTX, with an average of 2.4 ± 1.3 cycles of RTX and 1.7 ± 0.6 doses per cycle (**Table 1**). At one year, 18 (50%) were clinically improved, 12 (33%) were sTable, and 6 (17%) died from progressive respiratory failure (**Table 2**). Of 32 patients with PFTs available, the

*Other patterns include non-classifiable, desquamating interstitial pneumonia, hypersensitivity pneumonitis, and diffuse lung injury. No patients had usual interstitial pneumonia (UIP).

mean absolute change in FVC (% predicted) was +9.3% ± 16.4%. At UCM, 14 IPAF patients (mean age 53 years, 71% female) were treated with RTX with an average of 2.9 ± 2.1 cycles and 2.0 ± 0 doses per cycle. Compared to the MGB cohort, the UCM cohort was younger and had more females, Black/African American and Latinx patients, and baseline comorbidities. At the time of IPAF diagnosis, fewer patients at UCM required hospitalization for hypoxemia than at MGB (1 [7%] vs. 10 [28%]). In the UCM cohort at one year, 8 (57%) were improved, 2 (14%) were sTable, and 3 (21%) died from progressive respiratory failure. Of 12 patients with PFTs available, the mean absolute change in FVC (% predicted) was +1.3% ± 6.3%. By one year, 14 (39%) patients in the MGB cohort and 7 (50%) in the UCM cohort had tapered off glucocorticoids completely. Overall at both sites, 9 patients had infections and 2 had minor infusion reactions; only 2 discontinued therapy due to adverse events (infections) during 1 year of therapy.

Table 2. Outcomes at one year after treatment with rituximab in patients with interstitial pneumonia with autoimmune features (IPAF).

	Mass General Brigham (N = 32 with PFTs, 36 total)	University of Chicago (N = 12 with PFTs, 14 total)

Clinically stable, N (%)	12 (33)	2 (14)
Clinically worsened/died, N (%)	6 (17)	3 (21)
Absolute change in FVC (% predicted), mean % (SD)	+9.3 ± 16.4	+1.3 ± 6.3
Absolute change in DLCO (% predicted), mean % (SD)	+2.0 ± 13.5	+7.0 ± 8.8
FVC improved, N (%)†	15 (47)	7 (58)
FVC stable, N (%)	14 (44)	5 (42)
FVC worsened, N (%)	3 (9)	0
Tapered off corticosteroids completely, N (%)	14 (39)	7 (50)

All values are mean ± SD for continuous variables or number (percentage) for categorical variables. PFTs = pulmonary function tests; FVC = forced vital capacity; DLCO = diffusion capacity of carbon monoxide.
*Improvement defined as positive change in 4 out of 4 domains: clinician assessment, oxygen requirements, need for hospitalization, and survival.
†Improvement defined as ≥10% improvement in forced vital capacity. Stable defined as forced vital capacity within ±10% of prior measurement. Worsening defined as ≥10% decline in forced vital capacity.

Table 2. Outcomes at one year after treatment with rituximab in patients with interstitial pneumonia with autoimmune features (IPAF).

	Mass General Brigham (N = 32 with PFTs, 36 total)	University of Chicago (N = 12 with PFTs, 14 total)
Clinically improved, N (%)*	18 (50)	8 (57)
Clinically stable, N (%)	12 (33)	2 (14)
Clinically worsened/died, N (%)	6 (17)	3 (21)
Absolute change in FVC (% predicted), mean % (SD)	+9.3 ± 16.4	+1.3 ± 6.3
Absolute change in DLCO (% predicted), mean % (SD)	+2.0 ± 13.5	+7.0 ± 8.8
FVC improved, N (%)†	15 (47)	7 (58)
FVC stable, N (%)	14 (44)	5 (42)
FVC worsened, N (%)	3 (9)	0
Tapered off corticosteroids completely, N (%)	14 (39)	7 (50)

All values are mean ± SD for continuous variables or number (percentage) for categorical variables. PFTs = pulmonary function tests; FVC = forced vital capacity; DLCO = diffusion capacity of carbon monoxide.
*Improvement defined as positive change in 4 out of 4 domains: clinician assessment, oxygen requirements, need for hospitalization, and survival.
†Improvement defined as ≥10% improvement in forced vital capacity. Stable defined as forced vital capacity within ±10% of prior measurement. Worsening defined as ≥10% decline in forced vital capacity.

Conclusion: In 50 patients with IPAF treated with RTX at 2 large academic medical centers, most patients demonstrated improvement or stability at 1 year. These findings call for prospective studies, including randomized controlled trials, to further determine the risks, benefits, optimal timing, and cost effectiveness of RTX use in IPAF.

Abstract Number: 1052

Connective Tissue Disease-Related Interstitial Lung Disease in American Indian/Alaska Native People in Alaska

Joanna Marco[1] and Elizabeth Ferucci[2], [1]University of Washington, Seattle, WA, [2]Alaska Native Tribal Health Consortium, Anchorage, AK

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Many connective tissue diseases are known to cause interstitial lung disease (ILD). American Indian/Alaska Native (AI/AN) populations have higher prevalence and severity of a number of connective tissue diseases that can be associated with ILD, but no previous studies have examined the clinical characteristics of connective tissue disease-associated ILD (CTD-ILD) in AI/AN populations. We sought to describe the spectrum of CTD-ILD in the AI/AN population in Alaska.

Methods: Through this retrospective chart review conducted at the Alaska Native Medical Center, 45 AI/AN adults with a clinical diagnosis of CTD-ILD were identified. A detailed medical record abstraction was performed for each potential case. Clinical characteristics are reported, including demographics, underlying CTD, ILD subtypes, serologies, pulmonary function tests (PFTs) with changes over time, and medications prescribed.

Results: Underlying connective tissue disease diagnosis was heterogeneous in this population. Rheumatoid arthritis (RA) was the most common (n = 13), followed by systemic sclerosis (SSc, n = 12; limited cutaneous n = 7, diffuse cutaneous n = 5), and mixed connective tissue disease (MCTD, n = 9). The mean age at connective tissue disease diagnosis was 45 (standard deviation (SD) 15), and the mean age at ILD diagnosis was 52 (SD 14), for a mean time from CTD diagnosis to ILD diagnosis of 7 years. Most patients were diagnosed with usual interstitial pneumonia (UIP) by high resolution CT (HRCT) (60%). The baseline forced vital capacity (FVC) was 68 percent predicted, and fell by an average of 1.2 absolute percentage points per year. The baseline diffusing capacity of the lungs for carbon monoxide (DLCO) was 56 percent predicted and fell by an average of 5.1 absolute percentage points per year.

Conclusion: This study is the first to describe patterns of CTD-ILD in any AI/AN population. As in other populations, RA-ILD and SSc-ILD are common, but this population additionally had a high proportion of ILD associated with of MCTD. Understanding the clinical characteristics of CTD-ILD in this population may improve recognition and care of CTD-ILD in AI/AN people.

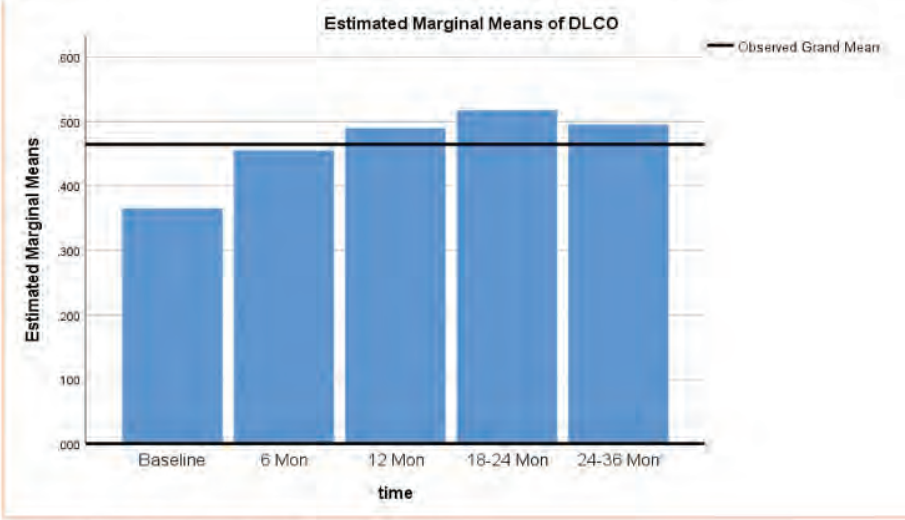
HRTC Changes from Baseline

Background/Purpose: Interstitial lung disease (ILD) is a fatal complication associated with connective tissue diseases (CTDs), often resulting in substantial morbidity and mortality. Despite numerous advances in immunosuppressive agents, there remains limited data on effective treatment for this challenging entity. This study aims to evaluate the efficacy of rituximab (RTX) in patients with CTD-ILD and determine factors correlated with outcomes at 6, 12, 24 and 36 months post-RTX.

Methods: We analyzed data for 47 patients with CTD-ILD, all of whom met ACR classification criteria for a specific CTD. ILD was confirmed by high-resolution CT chest (HRCT) and pulmonary function tests with forced vital capacity (FVC) and diffusion capacity of lung for carbon monoxide (DLCO). We compared HRCT chest findings, FVC and DLCO at time of diagnosis and at 6, 12, 24 and 36 months post-RTX. At diagnosis HRCT chest findings classified into 3 groups (mild, moderate and severe). At 6, 12, 24 and 36 months after RTX, using the same semi-quantitative scoring system, HRCT chest findings were ranked as worsening, sTable or improving.

Multiple patient characteristics (Table 1) were tested for their correlation with each outcome. For some variables, nonparametric statistical methods were used due to a small number of non-missing variables. The Spearman rank

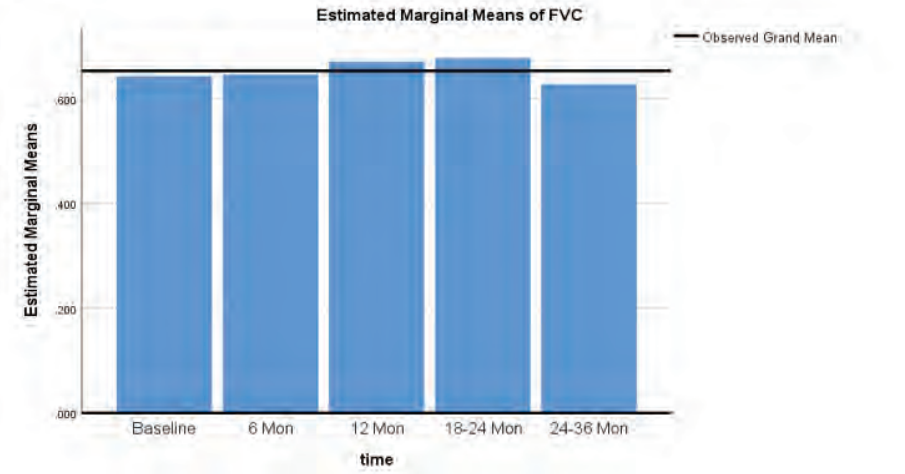
Figure 1A



No significant changes in DLCO over time: $p > 0.12$

No significant differences in DLCO values at any two time points: $p > 0.20$

Figure 1B



No significant changes in FVC over time: $p > 0.7$

No significant differences in FVC values at any two time points: $p > 0.34$

Figure 1A and 1B

correlation and Wilcoxon signed rank test were used to determine changes in FVC and DLCO at 6, 12, 24 and 36 months after RTX treatment.

Results

1. Majority of the patients were female and African American with median age of 60.
2. HRCT Chest findings after RTX showed either improvement or stability at 6, 12, 24 months, 3 cases showed worsening at 36 months, two of them missed one or two doses of Rituxan, and the 3rd cases was a longstanding ILD secondary to Scleroderma

(Table 2).

3. There was no statistical significance at p-value for changes in FVC and DLCO, however observed changes have shown improvement as evidenced by observed grand mean. The largest changes were observed for FVC and DLCO at 1 year and DLCO at 2 years after treatment (Figure 1A, Figure 1B).
4. CTD duration showed negative correlation with FVC change at 1 year post-RTX with estimated 1.1% decrease in FVC for every year increase in CTD. ILD duration showed negative correlation with DLCO change at 2 years post-RTX with estimated 3.9% decrease in DLCO for every year increase in ILD.

Conclusion: Based on this single center retrospective study, RTX appears to be an effective therapy for CTD-ILD. Our observations also suggest using RTX earlier in the disease course of CTD-ILD may have a greater long-term impact. RTX may help to fill an unmet therapeutic need for CTD-ILD but larger randomized clinical trials are needed

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Infliximab and adalimumab therapy has significantly improved the prognosis of patients with non-infectious refractory uveitis. However, there is not enough evidence for the use of other anti-TNFs such as Certolizumab Pegol (CZP). Our objective was to evaluate the efficacy and safety of CZP in uveitis due to Immune-Mediated Inflammatory Diseases (IMID).

Methods: Multicenter study of 39 patients with uveitis due to IMID refractory to glucocorticoids and conventional immunosuppressants. The efficacy of CZP was evaluated with the following ocular parameters: best corrected visual acuity (BCVA), anterior chamber cells, macular thickness and presence of retinal vasculitis. Efficacy of CZP was com-

	Baseline	1st week	1st Month	6th Month	1st year	2nd year
BCVA (mean±SD)	0.77±0.29	0.77±0.30*	0.82±0.29*	0.85±0.26*	0.86±0.27*	0.88±0.23*
Tyndall (median [IQR])	0 [0-2]	0 [0-2]	0 [0-1]*	0 [0-0]*	0 [0-0]*	0 [0-0]*
OCT (mean±SD)	355±61.5	-	284.1±40.4*	-	224.8±121.1*	-
Retinal Vasculitis (eyes affected, %)	2 (3.6)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)

*$p<0.05$

pared between baseline, 1st week, 1st and 6th month, and 1st and 2nd year. Statistical analysis was performed with STATISTICA (Statsoft Inc. Tulsa, Oklahoma, USA).

Results: 39 patients/56 affected eyes (18 men/21 women) with a mean age of 40.5±11.9 years were studied. IMIDs included were: spondyloarthritis (n=17), psoriatic arthritis (6), Crohn (3), juvenile idiopathic arthritis (JIA) (2), Behçet (2), reactive arthritis (2), rheumatoid arthritis (1), relapsing polychondritis (1), pars planitis (1), Birdshot (1) and idiopathic uveitis (3). Uveitis pattern was as follows: anterior (n=30), posterior (4), panuveitis (3) and intermediate (2).

Previous CZP, patients received: oral prednisone (n=18) methylprednisolone bolus (1), methotrexate (22), azathioprine (10), cyclosporine (4), leflunomide (2), mycophenolate mofetil (2) and cyclophosphamide (1). 77% of patients had received previous biological therapy, with a mean of 1.6±1.2 biological drugs per patient. Gestational desire was the reason for prescribing CZP in 8 patients. CZP was administered in monotherapy in 16 patients and in the remaining 23 patients combined with conventional immunosuppressants.

After a median follow-up of 24 [6-36] months, most of the ocular variables analysed showed a rapid and significantly sustained improvement (**Table**). CZP was discontinued in 11 patients for the following reasons: remission (n=1), insufficient response of ocular symptoms (n=1) and limited response of extraocular manifestations (n=9). No serious adverse effects were reported.

Conclusion: CZP seems to be effective and safe in patients with refractory uveitis due to IMID.

Myositis and Systemic Sclerosis Spectrum IPAF Patients Are More Likely to Respond Favorably to Immunosuppression

Erin Wilfong[1], Gabriel Schroeder[1], April Barnado[1], Steven Lord[1], Narender Annapureddy[1], Rosemarie Dudenhofer[1] and Leslie J. Crofford[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Sarcoidosis, Interstitial Lung Disease, & Inflammatory Eye Disease

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Classification criteria for interstitial pneumonia with autoimmune features (IPAF) were introduced in 2015 to identify interstitial lung disease (ILD) patients who might benefit from immunosuppression but do not meet classification criteria for a defined connective tissue disease. While many descriptions of IPAF have focused on radiographic and histologic distinctions (e.g. usual interstitial pneumonia v. non-specific interstitial pneumonia), fewer investigations probed whether various autoantibodies correlate with immunosuppression response. We hypothesized that IPAF patients with myositis and systemic sclerosis associated antibodies would have a greater improvement in % predicted forced vital capacity (FVC) and diffusing capacity of the lungs for carbon monoxide (DLCO) compared to other IPAF patients.

Methods: Patients meeting classification criteria for IPAF were enrolled in the longitudinal VUMC Myositis and Scleroderma Treatment Initiative Center Cohort (VUMC IRB 141415). Patients were enrolled from 9/17/2017-3/30/2019). Inclusion criteria included treatment with immunosuppression (e.g. azathioprine, mycophenolate mofetil, or rituximab), complete serologies (RF, CCP, immunofluorescent ANA, and extended myositis panel), and at least 6 months of physiologic follow-up data. Patients with an anti-synthetase antibody, Scl70, Pm/Scl70, or MDA5 antibody were classified as myositis/systemic sclerosis spectrum.

Results: Twenty-eight patients were identified from the MYSTIC cohort who met inclusion criteria. Demographics and pulmonary radiographic and physiologic features are shown in Table 1. There was no difference in age, female gender, or Caucasian race between IPAF and myositis/SSc spectrum patients. There was no difference in the severity of restriction between the groups at baseline, but myositis/SSc spectrum patients had a greater improvement in the % predicted FVC (7.5 ± 2.7% v. -1.7 ± 1.8%, p=0.006) after immunosuppression. At baseline, IPAF patients trended towards a worse % predicted DLCO than myositis SSc spectrum patients at baseline (33.9 ± 4.3 v. 43.5 ± 4.8 %, p=0.06). Myositis/SSc patients also trended towards greater improvement in the % predicted DLCO after immunosuppression (5.6 ± 4.0% v. -2.3 ± 2.2, p=0.13).

Table 1. Demographic and pulmonary characteristics of IPAF patients

	IPAF (n=17)	Myositis/SSc spectrum (n=11)	p value
Age (yrs)	56.0 ± 3.1	55.9 ± 3.1	0.82
Female Gender	10 (58.8%)	7 (63.6%)	1.00
Caucasian Race	12 (70.5%)	8 (72.3%)	1.00
Probable or definite UIP	2 (11.8%)	1 (9.0%)	1.00
Baseline % predicted FVC	59.1 ± 3.6	54.5 ± 7.0	0.17
% Change in FVC at 6 months	-1.7 ± 1.8	7.5 ± 2.7	0.006
Baseline % predicted DLCO	33.9 ± 4.3	43.5 ± 4.8	0.06
% Change in DLCO at 6 months	-2.3 ± 2.2	5.6 ± 4.0	0.13

Conclusion: In this single-center prospective longitudinal study, patients with myositis and SSc specific antibodies derived benefit from immunosuppression and should be immunosuppressed even if they do not meet classification criteria. These findings further highlight the importance of comprehensive serologies in the initial evaluation of ILD.

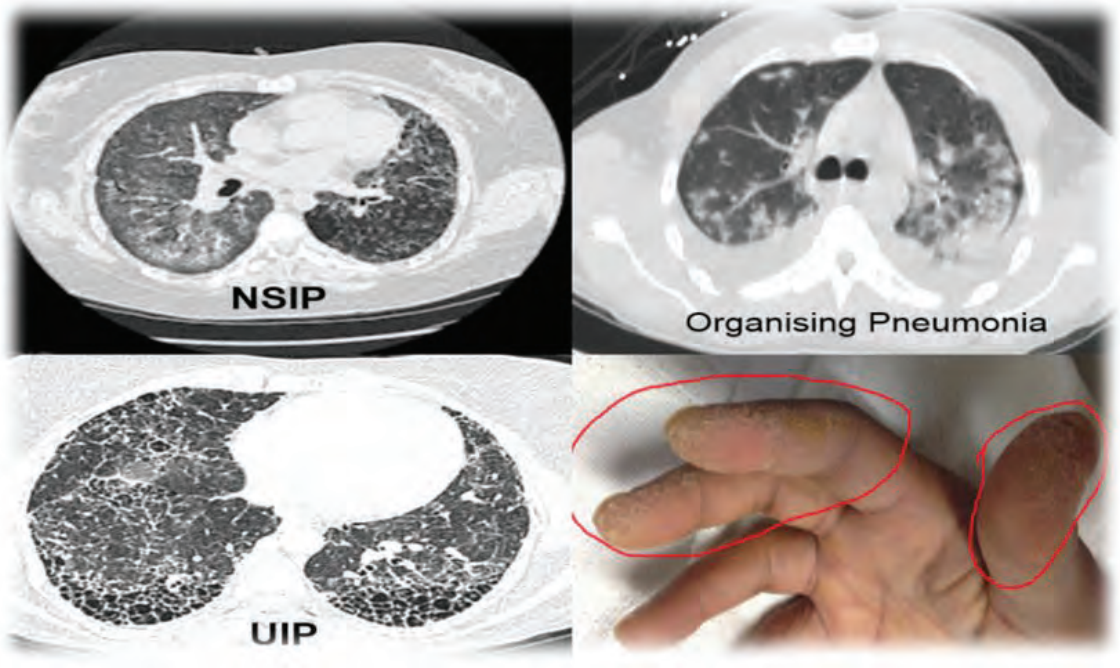
Descriptive Data Analysis of Patients with Anti Jo1 Syndrome (AJS) and Lung Involvement

Mohamed Alalwani[1], Bassam Alhaddad[2], Basem Zraik[3], Christopher O'Rourke[3], Ruchi Yadav[3], Ali Askari[1], Charles Malemud[1] and Soumya Chatterjee[4], [1]Case Western Reserve University / University Hospitals Cleveland Medical Center, Cleveland, OH, [2]MetroHealth Medical Center, Westlake, OH, [3]Cleveland Clinic, Cleveland, OH, [4]Cleveland Clinic, Richmond Heights, OH

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the patterns, severity and, prognostic parameters of interstitial lung disease (ILD) in Anti Jo1 Syndrome (AJS).

Methods: We identified 51 anti-Jo-1 patients with ILD between 2003 and 2012. Clinical and laboratory data were obtained along with PFTs and pattern/scoring of thoracic HRCT scans based on Ooi scoring system (inflammation and



ILD patterns and Mechanic's hands in AJS

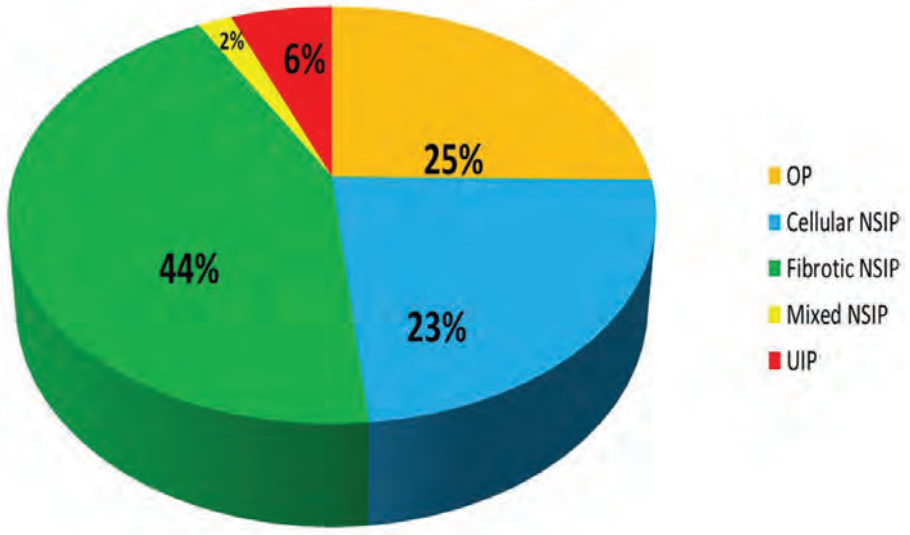
Table: Comparisons by Esophageal Disorder



Patterns of ILD in AJS at diagnosis

fibrosis indices) [1]. Progression of ILD was defined as follows: a decrease in DLCO and/or FVC (first to last reported) by >15%, an increase in fibrosis index or total HRCT score of ≥2, and death from respiratory failure.

Results: Of 51 patients; 20 were male and 15 had a diagnosis of dermatomyositis (DM). The median age at onset was 47 years, mean follow-up duration was 6.6 years; 3/15 (20%) presented with ILD prior to AJS diagnosis. Arthritis, mechanic's hands, Raynaud phenomenon and fever were reported in 88%, 37%, 31%, and 23% of DM patients, respectively. Four patients had cancer: lung (1), prostate and gallbladder (1) and lymphoma (2). At diagnosis 3 patients had upper respiratory pneumonia, 13 (25%) had organizing pneumonia (3 with non-specific interstitial pneumonia

(NSIP), with 5 developing NSIP later); 36 (70%) had NSIP: 22 fibrotic, 2 mixed and 12 cellular; 75% of cellular NSIP became fibrotic on subsequent imaging. Mean DLCO and FVC at diagnosis were 58.9% and 67%, respectively. The median initial inflammation and fibrosis indices at diagnosis were 5.6, 1.16 and at last follow-up 4.8, 2.1, respectively. Among 45 patients with available follow-up data; 17 had worsening ILD (39%) and 5 (11%) died of respiratory failure. A lower DLCO at diagnosis of DM was a predictor of disease progression [50 vs. 65% (p=0.0290)]. All upper respiratory pneumonia patients progressed during follow-up. Only 7 patients had a late diagnosis of ILD (≥3 years after onset of AJS). Of those, 5 (70%) had a DLCO ≤50% compared to a DLCO of 25% in those with early diagnosis. Sjögren's syndrome antibody (SSA) positivity was detected in 53% of patients; lower initial (53% vs. 62%) and last (56% vs. 67%) DLCO as well as higher fibrosis score at last follow-up [3.5 vs. 0.9 (p=0.089)] were observed in SSA negative group. These differences did not reach statistical significance. Interestingly; 6/7 patients who died were SSA negative. Nine patients who developed pulmonary hypertension had higher median disease duration (10 years) and CT score (12.5) and all of them had DLCO ≤50%. Esophageal disease other than dysphagia was detected in 43% [GERD (33%), abnormal manometry or gastric emptying (15%) and dilatation on chest CT (10%)]. Esophageal disease trended towards lower DLCO at diagnosis [53 vs. 62% (p=0.084)], higher fibrosis score [2.7 vs. 1.6 (p=0.089)] and higher %change of total CT score [1.1 vs. -0.7 (p=0.007)].

Conclusion: Lower DLCO at diagnosis was associated with progression of ILD. The lower DLCO observed in late onset ILD may suggest a silent disease and reemphasizes the role of screening for ILD in AJS. In contrast to previous studies; SSA co-positivity was not associated with an adverse outcome. Esophageal disease seemed to be prevalent in anti-Jo-1 patients with ILD and may predict worsening fibrosis. However, the association of malignancy with anti-Jo1 syndrome (AJS) was not significant.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The idiopathic inflammatory myopathies (IIMs) are strongly associated with the development of clinically detecTable cancer. Cancer screening has therefore been advocated in newly diagnosed IIM cases, however no study has investigated if this confers improved long term survival. This study aimed to investigate if a shorter time between IIM onset and cancer diagnosis is associated with improved long term survival.

		Whole cohort N = 248	Female cohort N = 169	Male cohort N = 79
Median follow up time / years (IQR)	Whole cohort	5.1 (1.7, 8.9)	5.0 (1.7, 8.5)	5.5 (1.5, 9.8)
	Alive	5.9 (2.8, 10.3)	5.6 (2.7, 10.2)	6.6 (3.0, 10.3)
	Deceased	2.3 (0.3, 6.1)	2.8 (0.4, 6.4)	1.2 (0.2, 3.8)
Median age at IIM onset / years (IQR)	Whole cohort	56.5 (46.2, 63.7)	56.2 (46.0, 63.6)	56.9 (47.9, 64.0)
	Alive	56.5 (46.0, 63.7)	58.7 (46.0, 63.9)	55.6 (46.8, 62.6)
	Deceased	56.4 (47.6, 63.4)	53.8 (47.2, 62.1)	61.4 (56.1, 67.8)
Median time between IIM onset and cancer diagnosis / years (IQR)	Whole cohort	4.6 (1.2, 10.5)	5.0 (1.3, 11.5)	4.1 (1.0, 9.0)
	Alive	4.5 (1.0, 10.2)	5.0 (1.1, 10.5)	4.1 (1.0, 9.4)
	Deceased	5.5 (1.5, 13.6)	5.5 (1.5, 15.5)	4.9 (1.2, 8.8)
Number of deaths in follow up period (%)		60 (24.2)	44 (26.0)	16 (20.3)
Median time between cancer diagnosis and death / years (IQR)		2.0 (0.3, 5.3)	2.4 (0.4, 5.6)	1.0 (0.2, 3.3)

IQR = inter-quartile range, IIM = idiopathic inflammatory myopathy

Table 1. Time to cancer diagnosis and death for the whole cohort, divided by gender

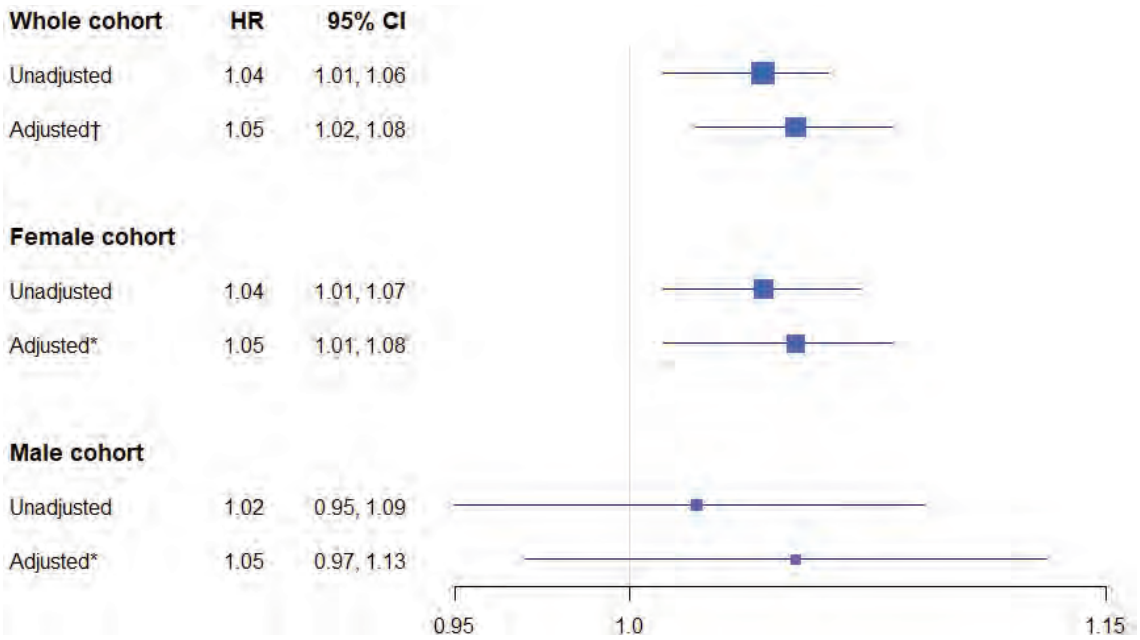

Figure 1. Modelling results of relationship between survival and time between IIM onset and cancer diagnosis, divided by gender.

HR = hazard ratio. CI = confidence interval.
† Hazard ratio for survival - adjusted for age and gender.
* Hazard ratio for survival - adjusted for age.

Methods: Adult IIM cases (dermatomyositis, polymyositis and anti-synthetase syndrome) were recruited from four separate cohort studies from the UK, France, Czechia and Hungary.

Only cases with cancer diagnosis following IIM onset were included in analysis (i.e. synchronous cancer cases were excluded). The time between IIM onset and cancer diagnosis was calculated for each case. Where death occurred, the time between cancer diagnosis and death was calculated and employed as follow up time. Where death did not occur, the time between cancer diagnosis and their follow up cut-off date was calculated. Cases were censored at the end of their follow up period if death did not occur. The relationship between survival at the end of follow up and

time between IIM onset and cancer diagnosis was quantified via calculation of hazard ratios using a Cox-proportional hazard model adjusted for age and gender.

Results: A total of 248 (68% female) verified IIM cases with a total of 1,601 person-years follow up (median 5.1 years [IQR 1.7, 8.9]) were included in the analysis (Table 1).

Sixty deaths occurred within the follow up period in the whole cohort. The median time between cancer diagnosis and death was 2 years (IQR 0.3, 5.3). The IIM to cancer diagnosis time was shorter for those that survived at the end of follow up, compared to those that died: 4.5 years (IQR 1.0, 10.2), 5.5 years (IQR 1.5, 13.6), respectively. Deaths in the male cohort occurred earlier after cancer diagnosis than in the female cohort: 1 year vs 2.4 years.

Cox-proportional hazard modelling indicated that a longer IIM onset to cancer diagnosis time was significantly associated with death for the whole cohort (HR 1.04 [95% CI 1.01, 1.06], p-value < 0.01) (Figure 1). This relationship persisted after adjustment for age and gender (HR 1.05 [95% CI 1.01, 1.08], p-value < 0.01). However, this relationship was observed in the female cohort only (HR 1.05 [95% CI 1.01, 1.08], p-value < 0.01) and not the male cohort (HR 1.05 [95% CI 0.97, 1.13], p-value 0.26).

Conclusion: This is the first study to identify that earlier cancer diagnosis after IIM onset is associated with improved long term survival in a large cohort, comprising UK, French, Czechia and Hungarian cases. However, this relationship was only significant for the female cohort. These findings indicate that cancer screening in newly diagnosed IIM cases may confer improved survival, especially in female cases.

Abstract Number: 1058

The Relationship of Different Muscle Enzymes in Adult Myositis Patients

Rohit Aggarwal[1] and **Tanya Chandra**[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Connecticut, HARTFORD, CT

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Muscle enzymes are a core set measure (CSM) in clinical trials. The 2016 ACR/EULAR myositis response criteria and the IMACS definition of improvement recommend using the most abnormal muscle enzyme at trial entry among the following five, creatine kinase (CK), aldolase, AST, ALT, and LDH. However, there is limited data on their relationship when assessed at the same time and which muscle enzyme should be followed as the CSM

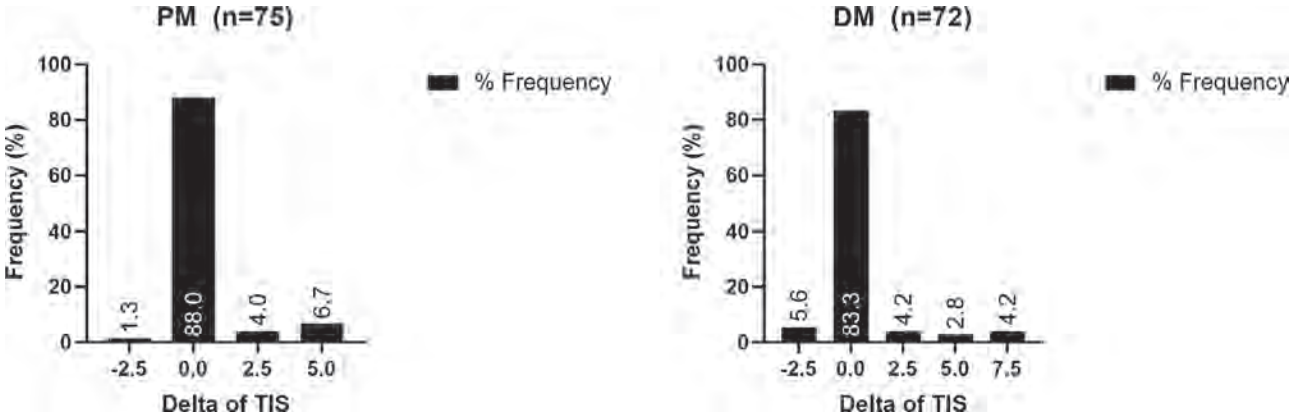

Figure 1. TIS change when CK is substituted for the most abnormal muscle enzyme in PM and DM subjects

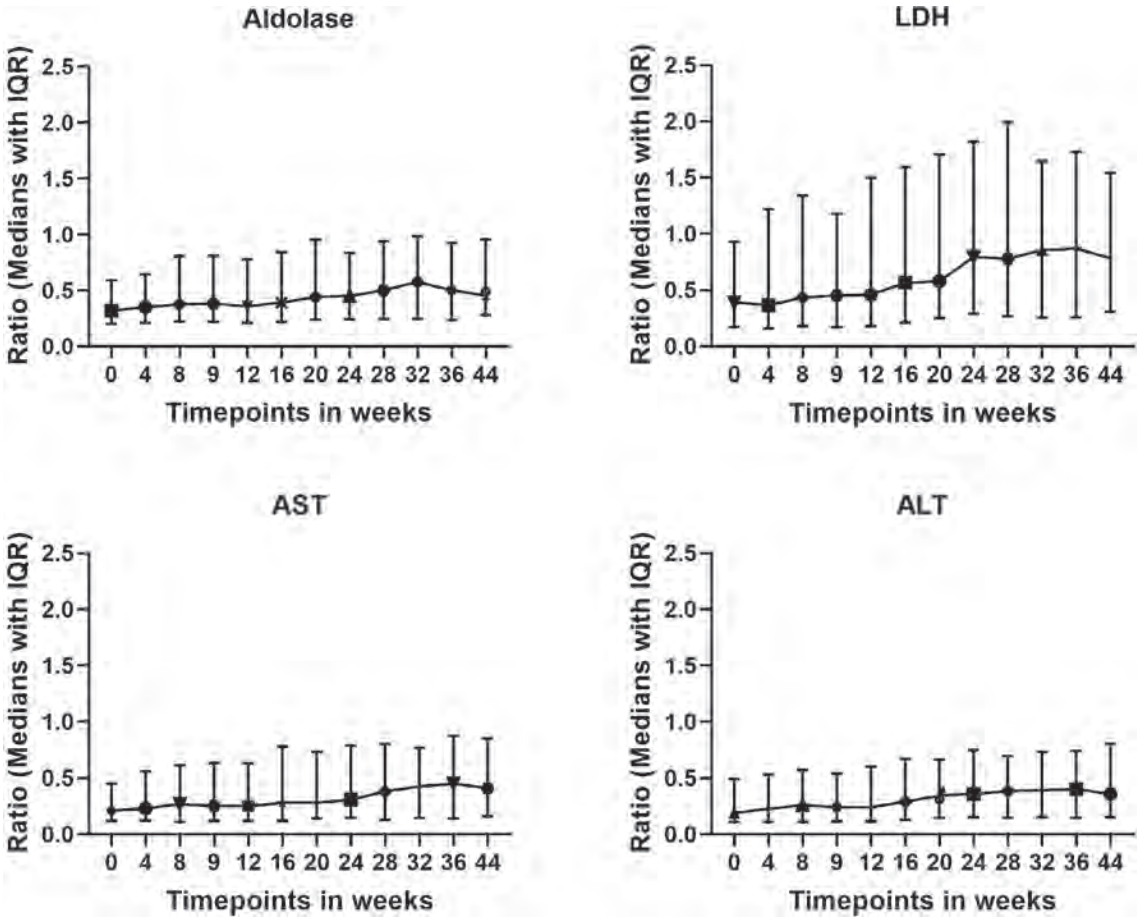

Figure 2. Ratios of the different muscle enzymes related to serum CK (all expressed as xULN)

in adult myositis clinical trials. We aimed to evaluate the relationship of the aforementioned muscle enzymes in the Rituximab in Myositis (RIM) trial.

Methods: All five muscle enzymes and their summary statistics were analyzed at baseline and longitudinally in 75 adult polymyositis (PM) and 72 adult dermatomyositis (DM) subjects enrolled in the RIM Trial. Their respective values

were incorporated into the published Total Improvement Score (TIS) of the 2016 ACR/EULAR Myositis Response Criteria at weeks 24 and 44. All muscle enzymes were reported as the times of upper limit of normal (xULN).

Results: At baseline, the CK was the most abnormal enzyme in adult PM and DM (81.3%, 55.6 %) followed by LDH (10.7%, 25%), aldolase (5.3%, 6.9%), AST (0%, 8.3 %) and ALT (2.7%, 4.2%). The CK was elevated in 86.7% of PM and 63.9 % of DM patients respectively, followed by LDH (89.3%, 62.5%), aldolase (68%, 51.4%), AST (65.3%, 45.8%) and ALT (65.3%, 47.2%). Similar results were seen across gender, race, age groups as well as different autoantibody subsets . Even when CK was not the most abnormal muscle enzyme in PM and DM (18.7%, 44.4%), the frequency of abnormal enzymes was: CK (5.3% PM, 9.7% DM), Aldolase (6.7% PM, 11.11%DM), LDH (12%PM, 16.7%DM), AST (4%PM, 6.9%), ALT (6.7%PM, 9.7%) and the CK levels were only marginally lower than the levels of the most abnormal enzyme. The median difference between the CK and most abnormal enzyme was only 0.03% at 24 weeks. Thus, when the CK was substituted as the most abnormal muscle enzyme in calculating the TIS, most (85.7%) adult myositis subjects (88% PM, 83.3% DM) had no change in the TIS at week 24. In the approximately 15% of subjects demonstrating a change in the TIS score, the mean (SD) change was quite small at 4.05 (1.8) for all subjects [3.89 (1.24) for PM and 4.17 (2.12) for DM (Figure 1)]. Only 1 adult PM patient had a change in the TIS score that translated to a shift from a 'minimal' clinical response to 'no' response. Similar results were observed at week 44.

The ratios between the different enzymes (expressed as xULN) across all the time points throughout the RIM Trial were relatively well preserved with median (IQR) ratios of CK with aldolase, LDH, AST, ALT of 0.41(0.12), 0.57 (0.35), 0.28 (0.15) and 0.32 (0.14) respectively (Figure 2).

Conclusion: The serum CK is most frequently elevated in adult PM and DM, followed by the LDH especially in DM, and can be used as the single muscle enzyme for published myositis response criteria without significant change in the outcome analysis. This is particularly important when other muscle enzyme levels may not be feasible for the determination of outcome given the adverse effect of many drugs. Muscle enzyme ratios are well-preserved over time, such that AST and ALT elevations outside of these ratios should prompt evaluation for other causes.

Anti-mitochondrial Autoantibodies Are Associated with Cardiomyopathy, Dysphagia, and Features of More Severe Disease in Adult-onset Myositis

Sara Sabbagh[1], Iago Pinal-Fernandez[2], Maria Casal-Dominguez[3], Jemima Albayda[4], Julie Paik[4], Frederick W. Miller[2], Lisa G. Rider[5], Andrew Mammen[3] and Lisa Christopher-Stine[4], [1]Medical College of Wisconsin, Fox Point, WI, [2]National Institutes of Health, Bethesda, MD, [3]NIH, Bethesda, MD, [4]Johns Hopkins University, Baltimore, MD, [5]Environmental Autoimmunity Group, Clinical Research Branch, NIEHS, NIH, Garrett Park, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: We examined the prevalence of anti-mitochondrial autoantibodies (AMA) in adult- and juvenile-onset myositis longitudinal cohorts and investigated phenotypic differences between myositis patients with or without AMA.

Methods: We screened sera from myositis patients who were classified as adult- or juvenile-onset dermatomyositis (DM, JDM), polymyositis (PM, JPM), inclusion body myositis (IBM), or amyopathic DM, including 619 adults and 371 children, compared to healthy controls (64 adults and 92 children), for AMA by ELISA. Clinical characteristics were compared between myositis patients with and without AMA.

Results: AMA were present in 5% of adult myositis patients (16 DM, 10 PM, 4 IBM, 1 amyopathic DM), 1% of juvenile myositis patients (3 JDM, 1 JPM), and 1% of adult and juvenile healthy control subjects. In patients with adult-onset myositis, AMA were associated with persistent muscle weakness (90% vs 62%, p=0.005), DM-specific rashes (60% vs 41%, p=0.04), Raynaud's phenomenon (43% vs 14%, p< 0.001), dysphagia (63% vs 36%, p=0.003), and cardiomyopathy (16% vs 5%, p=0.01). Adult myositis patients with AMA may have more severe or treatment refractory disease, as they more frequently received glucocorticoids (90% vs 67%, p=0.04), intravenous immunoglobulin (IVIG) (60% vs 29%, p=0.003), and overall received a higher total number of medications, including glucocorticoids, mycophenolate mofetil, methotrexate, IVIG, azathioprine, rituximab and cyclophosphamide, (2.8 vs 2.0, p=0.002) than those who were AMA negative. In juvenile myositis, children with AMA often had falling episodes (4/4) and dysphagia (3/4), but no other clinical features or medication usage were significantly associated with AMA.

Conclusion: AMA are present in 5% of adult myositis patients and associated with cardiomyopathy, dysphagia, persistent weakness, vasomotor instability, and additional therapy. The prevalence of AMA is not increased in patients with juvenile myositis compared to age-matched controls. These data suggest that the presence of AMA in adult myositis patients should prompt screening for cardiac and swallowing involvement.

B-cell-rich Inflammatory Myopathies in Adults: Striking Association with Connective Tissue Diseases

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis with significant B-cell infiltrates on muscle biopsy has scarcely been described in adults. Radke (2018) found B cells in adult dermatomyositis (DM) and stratified them as classic, B-cell-rich and follicle-like DM. In patients without DM, three neuropathology studies described myositis with significant B-cell infiltrates. De Bleeker (1996) reported 7 patients with biopsies showing nodules resembling lymph nodes, i.e. a B-cell-rich center surrounded by CD4+ T-cell-rich peripheral zone; noTable findings were cervical muscle weakness and the presence of a connective tissue disease (CTD). Pestronk (2006) described 9 patients with prominent perimysial and perivascular B-cell infiltrates, cervical muscle weakness and either myasthenia gravis or a CTD. Espitia-Thibault (2017) studied 4 patients with primary Sjögren syndrome (SS) and myositis; and found germinal centre-like structures composed predominantly of CD4+ T cells and B cells. The aim of the present study was to describe the clinicoserological findings of patients with B-cell-rich infiltrates on muscle biopsy, and no DM.

Methods: Muscle biopsies with significant B-cell infiltrates (≥ 30 CD20+ cells/aggregate) were identified from 2 neuropathology centers. All cases were reviewed in multidisciplinary meetings. Clinical, serological, pathological features and classification criteria for inclusion body myositis (IBM) were recorded. Patterns of muscle involvement were noted, including cervical, finger flexor and quadriceps weakness. The presence of a CTD and cancer within 3 years of myositis diagnosis was also recorded. Patients with a DM rash were excluded.

Results: Ten patients with myositis, no DM rash, and significant B-cell infiltrates on muscle biopsy were included. Nine were female; median age at myositis diagnosis was 66.5 years (range 51-85). Median CK level was 291 UI/L (range 98–4372). Two patients with normal strength, but myalgias (n=1) or cervical muscle edema (n=1), had imaging suggestive of myositis. All remaining patients had cervical muscle weakness (n=8), and 3 had objective oropharyngeal dysphagia. Quadriceps (n=6) and finger flexor (n=3) weakness was noted, and 4 patients met the Lloyd IBM classification criteria. Associated diseases included anti-CCP positive RA (n=3), systemic sclerosis (SSc) (n=3), primary SS (n=1), systemic lupus erythematosus (n=1) and lung cancer (n=1). Serologically, all patients but one were tested: none had myositis-specific autoantibodies (aAbs) and 2 patients with SSc had anti-Th/To (n=1) and anti-PM-Scl (n=1) aAbs. Anti-Ro52/TRIM21 (n=4), anti-SSA/Ro60(n=3), anti-SSB/La (n=2) were present. Anti-NT5c1A aAbs were present in 1 of 3 tested patients.

Conclusion: Myositis and significant B-cell infiltrates were associated, as in previous studies, with various CTDs, and not only with SS. Cervical weakness and features of IBM were frequent in this subset of patients. CD20 stains were listed as optional in the 205th European Neuromuscular Centre international workshop. Routine CD20 staining should be considered in patients with cervical muscle weakness and suspected myositis in the setting of an associated CTD.

Daily Myositis Symptom Changes Collected via a Smartphone-Based App Are Associated with Flare Occurrence - Providing Evidence of Potential Digital Biomarkers

Alexander Oldroyd[1], Belay Yimer[2], Max Little[3], William Dixon[2] and Hector Chinoy[4], [1]University of Manchester, Manchester, United Kingdom, [2]Centre for Epidemiology Versus Arthritis, University of Manchester, Manchester, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom, [4]The University of Manchester, Manchester, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The concept of idiopathic inflammatory myopathy (IIM) flare is widely used, although no consensus definition exists. Studies have demonstrated the feasibility and utility of using tailor-made smartphone apps to collect daily symptom patient-reported outcome measurements (PROMs). This methodology allows researchers to investigate relationships between events, such as a flare, with changes of daily symptoms. Delineation of patterns of symptom changes associated with flares may provide a preliminary patient definition of an IIM flare and identify "digital biomarker" candidates.

This study aimed to use daily smartphone app-collected data to:

	Variable	Flare occurrence	No flare occurrence	p-value†	Modelling results*		
					OR	95% CI	p-value
Mean symptom score 7 days prior to flare reporting (SD)	Participant global activity	39.0 (19.7)	30.8 (21.6)	<0.01	1.09	1.03, 1.15	<0.01
	Fatigue	43.1 (19.4)	35.2 (22.5)	<0.01	1.05	1.02, 1.09	<0.01
	Overall pain	36.1 (21.0)	26.4 (18.5)	<0.01	1.10	1.04, 1.16	<0.01
	Myalgia	34.5 (22.0)	23.5 (16.8)	<0.01	1.09	1.04, 1.15	<0.01
	Weakness	38.5 (20.0)	32.1 (24.1)	0.03	1.07	1.01, 1.13	0.02
Mean magnitude of day to day change 7 days prior to flare reporting (SD)	Participant global activity	9.3 (5.5)	7.6 (5.9)	0.03	1.07	1.01, 1.14	0.04
	Fatigue	11.7 (6.8)	10.8 (7.6)	0.33	1.01	1.01, 1.01	<0.01
	Overall pain	9.2 (6.4)	8.2 (5.8)	0.25	1.03	0.97, 1.10	0.33
	Myalgia	8.6 (6.2)	7.4 (5.6)	0.13	1.05	0.99, 1.13	0.12
	Weakness	10.1 (5.8)	7.8 (5.9)	<0.01	1.09	1.01, 1.16	0.02
Mean entropy 7 days prior to flare reporting (SD)	Participant global activity	7.5 (0.1)	7.5 (0.1)	0.36	8.60	0.12, 38.47	0.27
	Fatigue	7.5 (0.1)	7.5 (0.1)	0.52	4.25	0.13, 13.63	0.42
	Overall pain	7.5 (0.1)	7.5 (0.1)	0.38	4.95	0.15, 16.03	0.37
	Myalgia	7.5 (0.1)	7.5 (0.1)	0.44	7.58	0.11, 54.50	0.35
	Weakness	7.5 (0.1)	7.5 (0.1)	0.69	0.57	0.02, 14.65	0.74

† Variables were compared between flare and non-flare weeks using the independent 2 group t-test

* Odds ratio for flare occurrence - multi-level mixed effects logistic regression modelling, adjusted for age and gender

OR = odds ratio, CI = confidence interval, SD = standard deviation

Table 1. Summary and modelling results of daily symptom scores, day to day change and entropy, divided by flare occurrence

1. Characterise the pattern of patient-reported flares in an IIM cohort
2. Identify changes of daily symptoms associated with flares
3. Identify IIM flare digital biomarker candidate variables

Methods: Data was collected via the Myositis Physical Activity Device (MyoPAD) study. Recruited participants (UK adult participants with a verified IIM diagnosis) answered PROMs every day of the 91 day study period via an IIM-tailored smartphone-based app. Daily symptom PROMs addressed 1) global activity, 2) overall pain, 3) myalgia, 4) fatigue and 5) weakness (0-100 visual analogue scale). Every 7 days, participants were also asked whether or not they suffered a flare (present/absent) via the app. To illustrate the daily symptom and weekly flare reporting, Figure 1 shows a single participant's data over a 3 week period.

The following were calculated for each 7 day period prior to each flare question:

1. Mean score of each daily PROM
2. Mean magnitude of day-to-day change of each daily PROM (i.e. negative differences were multiplied by -1)
3. Entropy (measure of variability) of each daily PROM

Multi-level mixed effects logistic regression models tested the relationships between flare occurrence and each above calculated measurement. This was subsequently adjusted for age and gender.

Results: 21 participants (67% female) took part in the study. The median age of the cohort was 50 years (IQR 43, 56) and median disease duration 3 years (IQR 2, 5). Engagement was high - a total of 22880 PROMs, 88% of a potential total 25977, were entered. Participants reported experiencing flares on a median of 3 weeks (IQR 2, 5) per participant, out of a possible 13. A total of 81 (31%) flares were reported across the cohort from 261 answered flare questions (4% questions not answered).

Modelling revealed that a higher score of each daily symptom PROM was significantly associated with flare occurrence (Table 1 and Figure 2). Higher magnitude of day-to-day change of participant global activity, fatigue and weakness were also significantly associated with flare occurrence. Flare occurrence was not significantly associated with entropy of any daily symptom.

Conclusion: This study has characterised the frequency of flare occurrence in an IIM cohort - flares were reported to occur one week in four on average. This study has also delineated daily symptoms associated with patient-reported IIM flares - particularly global activity, fatigue and weakness. Smartphone app collected daily symptom data

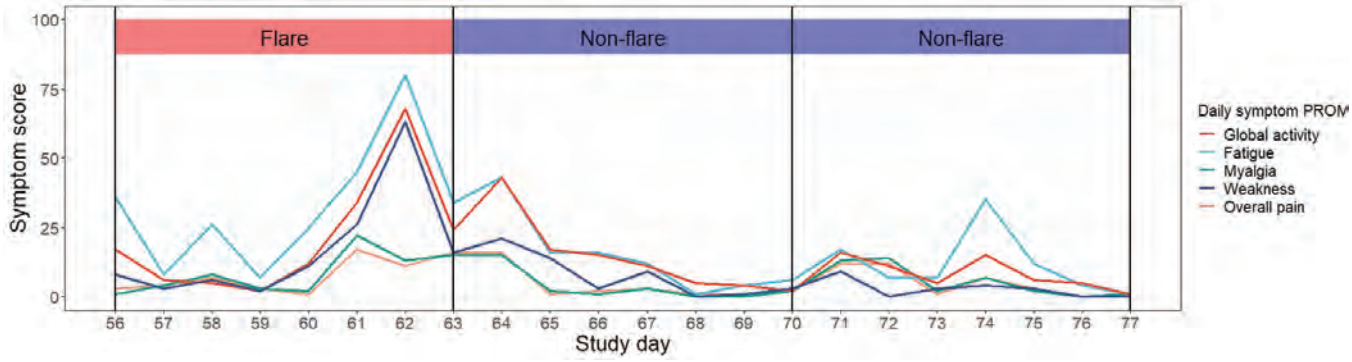

Figure 1. Three week extract (days 56 to 77 of 91 day study period) of single participant's daily symptom PROM scores and flare occurrence. PROM = patient reported outcome measurement

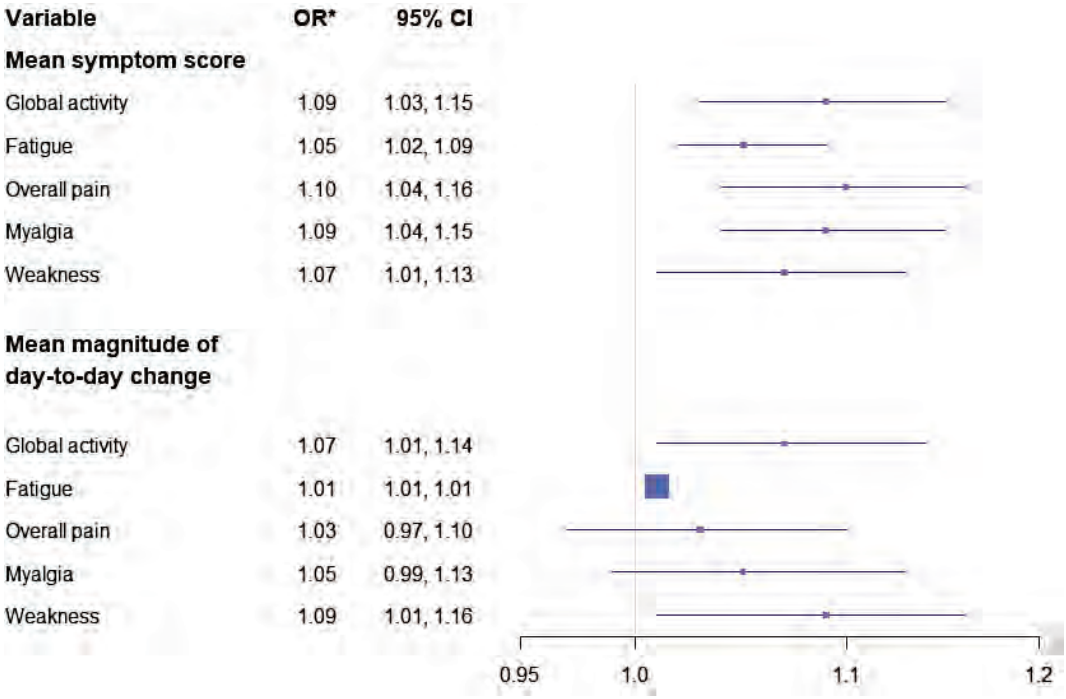

Figure 2. Modelling results of mean symptom score and magnitude of day-to-day change over 7 day period prior to flare occurrence.

may therefore provide digital biomarkers capable of predicting IIM flare occurrence and enable reactive treatment instigation.

OR = odds ratio, CI = confidence interval.
* Odds ratio for flare occurrence - multi-level mixed effects logistic regression modelling, adjusted for age and gender.

Dermatomyositis: A Dermatology-Rheumatology Clinic Retrospective Analysis

Burak Elkiran[1], Mahroo Tajalli[2], Terrence M. Vance[3], Abrar A. Qureshi[4] and Anthony M. Reginato[5], [1]Department of Medicine, Division of Rheumatology; Warren Alpert Medical School of Brown University, BOSTON, [2]Department of Dermatology, Warren Alpert Medical School of Brown University, PROVIDENCE, [3]Department of Epidemiology, Warren Alpert Medical School of Brown University, PROVIDENCE, [4]Department of Dermatology, Warren Alpert Medical School of Brown University, BOSTON, [5]Department of Medicine, Division of Rheumatology, Warren Alpert Medical School of Brown University, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

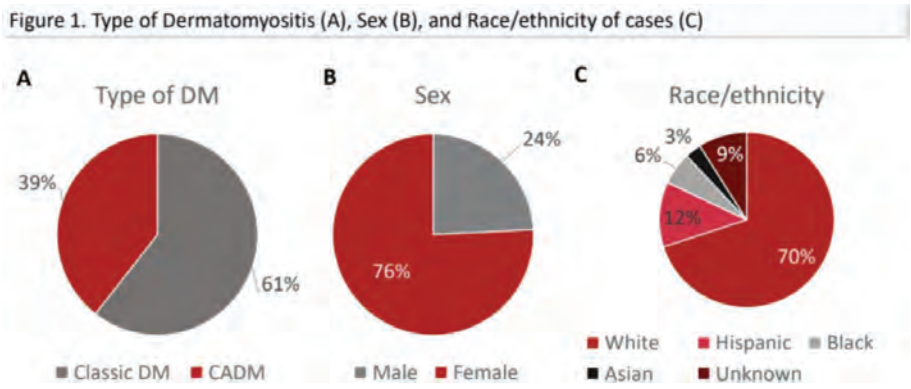

Figure 1. Type of Dermatomyositis (A), Sex (B), and Race/ethnicity of cases (C)

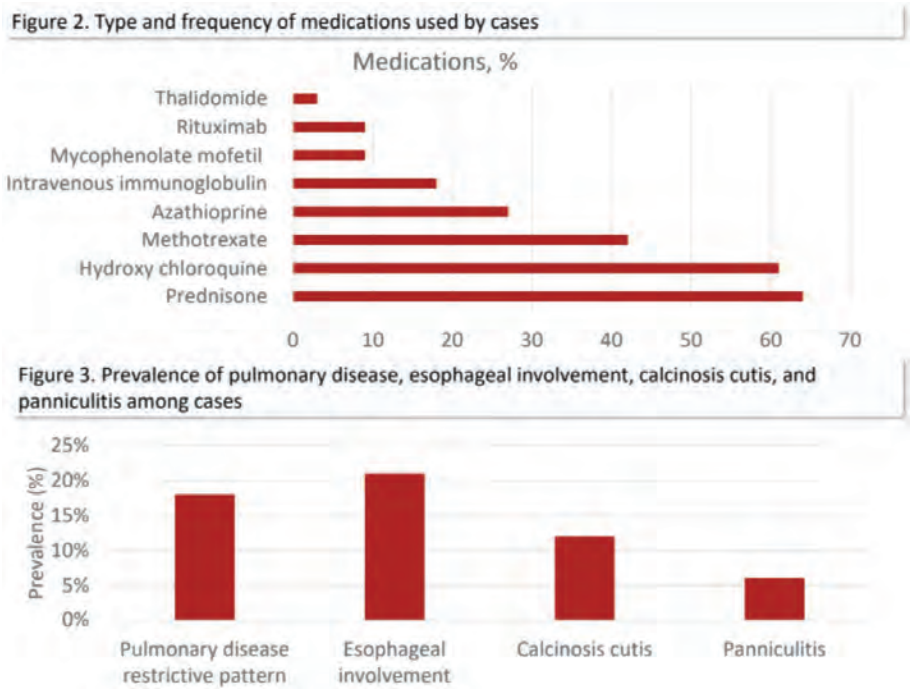

Figure 2. Type and frequency of medications used by cases Figure 3: Prevalence of pulmonary disease, esophageal involvement, calcinosis cutis, and panniculitis

Background/Purpose: Dermatomyositis (DM) can be categorized into two major subtypes: clinically amyopathic dermatomyositis (CADM) and classic dermatomyositis (CDM). In this study, we aimed to identify characteristics of the patients with DM evaluated at the combined Dermatology-Rheumatology clinic.

Methods: We used ICD-9/10 codes to identify patients with DM. Demographics, clinical features, laboratory values, type cancer diagnosis (if any) was obtained by electronic medical records. We used descriptive statistics to present characteristics of patients. The association between a variety of factors and risk of cancer was examined using logistic regression.

Results: 33 patients with DM were identified. 8 (24%) were male and 25 (76%) were female. The average age at diagnosis was 50 (SD:17). 61% had CDM, 39% had CADM. 70% White, 12% Hispanic, 6% Black, 3% Asian and 9% unknown (Figure 1). Medications used by patients for DM in order of frequency (n, %) include prednisone (21, 64 %), hydroxychloroquine (20, 61 %), methotrexate (14, 42%), azathioprine (9, 27%), intravenous immunoglobulin (6,

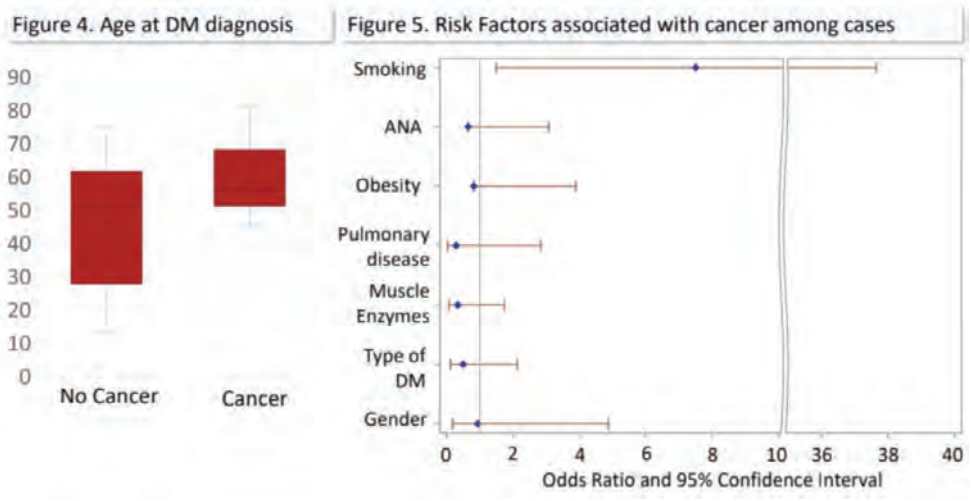

Figure 4. Age at DM diagnosis Figure 5: Risk Factors associated with cancer among cases

18%), mycophenolate mofetil (3, 9%), rituximab (3, 9%), and thalidomide (1, 3%) (Figure 2). Pulmonary disease with restrictive pattern 6 (18%), esophageal involvement 7 (21%), calcinosis cutis 4 (12%) and panniculitis were reported in 2 (6%) of the patients (Figure 3). Muscle enzymes were high in 20 (61%), normal in 9 (27%) and unknown in 4 (12%). Positive antinuclear antibodies were reported in 52%, majority with speckled pattern. One patient had juvenile DM. 36% (n=12) had a history of cancer, including breast 12%, prostate 6%, T-cell lymphoma, gastric lymphoma, non-small cell lung cancer, cervix, squamous cell carcinoma (SCC) of the tonsil and invasive skin SCC, each one 3%. Three cancer cases occurred within 1 year, 5 cases within 5 years and 4 cases more than 5 years before/after the diagnosis of DM. Average age at diagnosis for patients with cancer was 57 (SD: 12) and for patients without cancer was 45 (SD: 19) (Figure 4). We found no evidence of an association between gender, type of DM, enzyme level, pulmonary involvement, obesity, positive ANA and cancer. History of current or former smoking was strongly associated with increased risk of cancer (OR: 7.50, 95% CI: 1.49-37.66) (Figure 5).

Conclusion: Our results show a higher prevalence of cancer among DM patients compared to the general population. The average age at diagnosis of DM was higher in patients with cancer. We found no association between gender and cancer which is in contrast to previous studies that reported higher risk of malignancy in males compared to females. Smoking (ever versus never) was strongly associated with cancer. This can be explained by the synergistic effect of smoking in patients with DM. No association between pulmonary involvement and cancer was found. Limitations include small sample size and retrospective study design.

Spirulina Stimulates Inflammatory Cytokine Production Through the STING and TLR Pathways in Dermatomyositis in Vitro

Christina Bax[1], Yubin Li[1], Spandana Maddukuri[2], Adarsh Ravishankar[3], Jay Patel[3], Daisy Yan[1], Josef Symon Concha[1] and Victoria Werth[1], [1]University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Philadelphia, PA, [2]University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Montville, NJ, [3]University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Philadelphia

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Spirulina, a popular herbal supplement, stimulates the immune system, as determined by in vitro and in vivo studies. Our recent epidemiologic data suggest that Spirulina is associated with the onset or exacerbation of pre-existing autoimmune skin diseases, such as DM. The purpose of this study was to investigate the immunostimulatory effects of Spirulina and characterize the role of the Stimulator of interferon genes (STING) and Toll-like Receptor (TLR) pathways.

Methods: PBMCs were isolated from DM and normal controls and stimulated with increasing concentrations of pure Spirulina supernatant (0, 0.3, and 1 mg/ml). All DM patients met the EULAR/ACR definition of DM or amyopathic DM. PBMCs were also pre-treated for 1 hour with the following inhibitors: STING inhibitor, H-151; TLR4 inhibitor, TAK 242; TLR2 and TLR4 inhibitor, Sparstolonin B; and TBK1 inhibitor, MRT67307. Cells were incubated for 18 hours before supernatant was collected for ELISA.

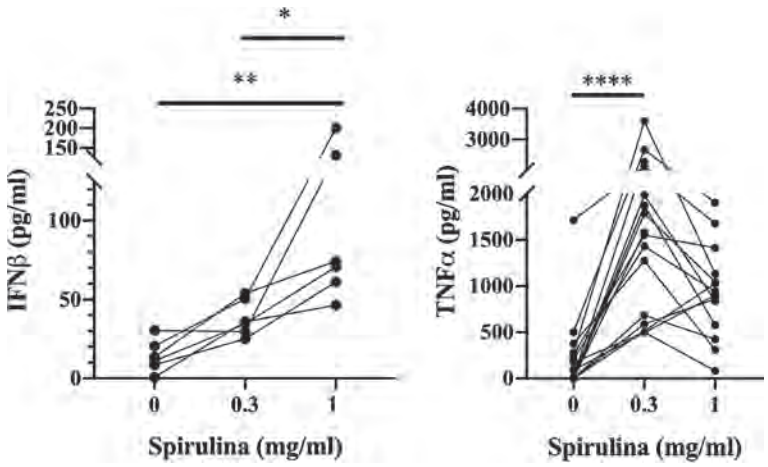

Figure 1. (a) DM PBMCs secreted mean (standard error of mean) IFN**β** of 14.18 (4.18), 38.26 (4.69), and 97.42 (23.76) pg/ml, at 0, 0.3, and 1 mg/ml Spirulina concentrations, respectively (n=6). (b) DM PBMCs secreted mean (standard error of mean) TNF**α** of 213.03 (101.08), 1718.94 (208.95), and 938.36 (134.72) pg/ml at 0, 0.3, and 1 mg/ml Spirulina concentrations, respectively (n=17). Bars show * p<0.05, ** p<0.01, **** p<0.0001. Line represents the median.

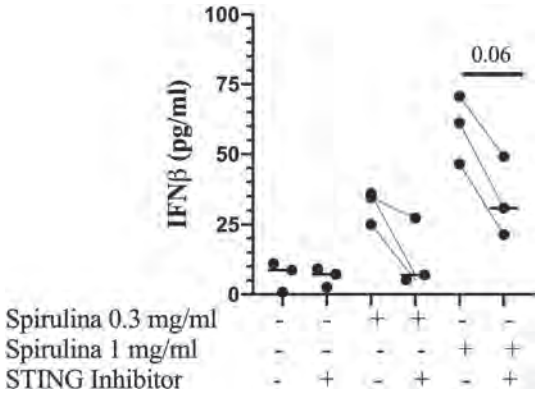

Figure 2. Effects of STING inhibitor versus sham on secretion of IFN**β** from unstimulated and Spirulina-stimulated PBMCs in "Good Responders." Line represents the median. (n=3)

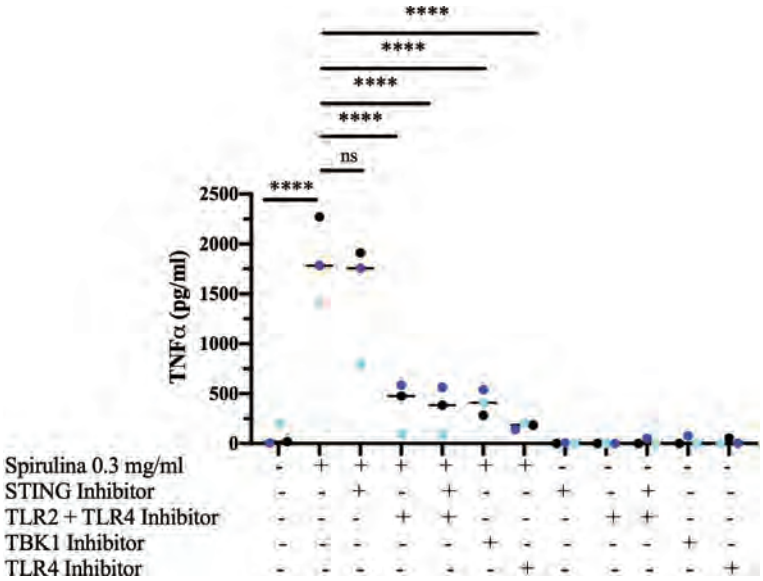

Figure 3. Effects of STING, TLR2 + TLR4, TLR2 + TLR4 + STING, TBK1, or TLR4 inhibition versus sham on secretion of TNF**α** from unstimulated and Spirulina-stimulated PBMCs (n=3). Bars show **** p<0.0001. Line represents the median.

Results: Spirulina dose-dependently increases PBMC production of IFNβ in DM patients (Figure 1a). Spirulina also increases PBMC production of TNFα, with peak levels when stimulated with 0.3 mg/ml Spirulina (Figure 1b).

In the presence of Spirulina, STING inhibitor suppressed secretion of IFNβ in all five DM patients. "Good Responders," defined as subjects with >20% decrease in cytokine levels with STING inhibitor and stimulation at both Spirulina concentrations had mean (standard error of mean) IFNβ levels of 33.78 (1.51) pg/ml pre-antagonist and 13.19 (7.11) post-antagonist when stimulated with Spirulina 0.3 mg/ml and IFNβ levels of 59.47 (7.04) pg/ml pre-antagonist and 33.81 (8.17) post-antagonist when stimulated with Spirulina 1 mg/ml (p=0.06) (Figure 2).

With Spirulina stimulation, STING inhibitor only suppressed secretion of TNFα in 6/15 subjects and these results were not statistically significant. A second experiment using 3 subjects further examined the effects of TLR2 and TLR4, TLR2 and TLR4 and STING, TBK1, or TLR4 inhibition on PBMC production of TNFα. In the presence of 0.3 mg/ml Spirulina stimulation, these four inhibitors significantly decreased TNFα levels (Figure 3) with TNFα decreasing from mean (standard error of mean) 1829 (243.47) pg/ml to 384.6 (149.27), 346.0 (138.11) 410.7 (73.43), and 175.7 (17.68) pg/ml when TLR2 and TLR4, TLR2 and TLR4 and STING, TBK1, or TLR4 inhibitors were added, respectively (n=3) (p< 0.0001). STING inhibition decreased TNFα production from 1829 pg/ml to 1488 pg/ml (n=3) (p=0.84).

Conclusion: Our preliminary results show that Spirulina increases production of key inflammatory cytokines TNFα and IFNβ. For TNFα production, Spirulina's immunostimulatory effects appear to be primarily mediated via the TLR4 pathway. Inhibition of TBK1, an important kinase in the innate immune system active in both the STING and NF-kappa B pathways, also significantly decreases TNFα production. For IFNβ production, Spirulina's immunostimulatory effects appear to be partially mediated by the STING pathway. Our findings provide a potential mechanism by which Spirulina use may lead to disease onset or flare in susceptible patients.

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The survival of motor neuron (SMN)/gemin proteins are components of a multifunctional protein complex that plays an essential role in RNA metabolism. SMN is present in Cajal bodies, i.e. nuclear structures that play an essential role in the assembly of small nuclear RNPs. Deletion or mutation of the SMN gene is associated with spinal muscular atrophy. Autoantibodies (aAbs) to SMN (anti-SMN) have not been thoroughly studied. Anti-SMN have been associated with scleromyositis (SM), originally in a cohort of 163 autoimmune myositis (AIM) (n=3, 1.8%) patients, and recently in a cohort of 20 seronegative SM (n=5, 25%). In another report, a single patient with anti-U1RNP and anti-SMN aAbs had a necrotizing autoimmune myopathy. The aim of this study was to evaluate the prevalence of anti-SMN aAbs in patients with anti-U1RNP+ AIM, and compare phenotypic differences in patients with and without anti-SMN aAbs.

Methods: All patients with a diagnosis of AIM associated with anti-U1RNP were identified from a clinically and serologically described retrospective cohort of 100 AIM patients. Sera were analyzed for anti-SMN by addressable laser bead immunoassay with results expressed as median fluorescence units (MFU) and positivity defined as 3 SD above the mean of normal and unrelated disease controls (>900 MFU), as previously validated by protein A-assisted immunoprecipitation. Clinical features were collected to assess the presence of ACR/EULAR and non ACR/EULAR features of systemic sclerosis (SSc), systemic lupus erythematosus (SLE) and Sjögren syndrome (SS).

Results: Of 9 AIM patients with anti-U1RNP+, 8 (88.9%) were females and median age at myositis diagnosis was 45 years old (range 24–61). At presentation, clinical features included Raynaud phenomenon (100% of patients), sclerodactyly (100%), lower esophageal dysmotility (88%), arthritis (78%) and proximal weakness (100%). Mean serum CK level was 2601 IU/L (range 329–6000). At myositis diagnosis, 88%, 22% and 22% of 9 patients fulfilled the ACR/EULAR criteria for SSc, SLE and SS, respectively. Five of 9 patients (55.6%) had anti-SMN aAbs (median 15952 MFU, range 4321–18848). These patients had a higher proportion of neck flexor weakness (60% vs 0%), bilateral trigeminal neuropathy (40% vs 25%), interstitial lung disease (40% vs 0%), acute lupus rash (80% vs 25%) and leucopenia

(80% vs 25%) compared to patients without anti-SMN aAbs. Strikingly, only patients with anti-SMN aAbs had SSc small-bowel involvement (n=4/5, 80% vs n=0/4, 0%, P=0.048 by Fisher's exact test) that included pneumatosis intestinalis (n=2/4), small intestine bacterial overgrowth (n=3/4) and pseudo-obstruction (n=4/4). One of these patients required parenteral nutrition whereas 3 others presented severe pseudo-obstruction necessitating hospitalization. At last follow-up (mean duration 12 years), 100%, 22% and 67% of 9 patients fulfilled the ACR/EULAR criteria for SSc, SLE and SS, respectively.

Conclusion: More than 50% of patients with anti-U1RNP+ AIM and SSc also have high titers of anti-SMN aAbs. The presence of anti-SMN aAbs may be predictive of severe SSc small bowel involvement compared to patients without anti-SMN aAbs.

Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of complementary and alternative medicine (CAM) is prevalent in dermatology. Certain CAMs, including Spirulina, Alfalfa, Chlorella, Echinacea, and Blue-Green Algae have been reported to incite an immune response or induce dermatomyositis (DM), cutaneous lupus erythematosus (CLE) or autoimmune blistering diseases (AIBD). Given these potential effects, there is a need to characterize CAM usage in patients.

Methods: We performed a retrospective chart review of prospectively-collected data at the University of Pennsylvania to characterize CAM usage among patients with DM, CLE, AIBD (including pemphigus vulgaris and bullous pemphigoid), and controls without autoimmune disease. Information gathered included demographic information, disease history, and CAM usage and duration (Spirulina, Chlorella, Alfalfa, Green Algae, Echinacea, or other). CAM use was elicited in a stepwise manner, starting with asking patients open-ended questions about CAM use, followed by handing a flyer that lists herbal supplements to aid with recall. Statistical analysis was performed using logistic regression to calculate odds ratios (OR), accounting for race and sex as covariates, at a significance level of 0.05.

Results: 372 patients were enrolled, including 158 DM (42.5%), 122 CLE (32.8%), 31 AIBD (8.3%), and 61 controls (16.4%). All cohorts were predominantly female and Caucasian. DM had the greatest proportion of Caucasians (81.6%), followed by controls (78.7%), AIBD (61.3%), and CLE (52.5%). CAM use was reported in 12.1% of all patients

Total # of patients	Any Herbal	Spirulina	Echinacea	Blue-Green Algae	Chlorella	Alfalfa
Dermatomyositis (n = 158)	31 (19.6)	23 (14.6)	4 (2.5)	4 (2.5)	12 (7.6)	3 (1.9)
Lupus (n = 122)	7 (5.7)	5 (4.1)	2 (1.6)	0 (0)	2 (1.6)	2 (1.6)
AIBD (n = 31)	2 (6.5)	0 (0)	1 (3.2)	2 (6.5)	1 (3.2)	0 (0)
Control (n = 61)	5 (8.2)	4 (6.6)	1 (1.6)	1 (1.6)	3 (4.9)	2 (3.3)
Total (n = 372)	44 (11.8)	32 (8.6)	8 (2.2)	7 (1.9)	18 (4.8)	7 (1.9)

Patient Demographics (%)

Cohort	Sex		Age at Visit	Race	
	Male	Female		Caucasian	Non-Caucasian
Dermatomyositis (n = 158)	20 (12.7)	138 (87.3)	56.3 ± 14.2	129 (81.6)	29 (18.4)
Lupus (n = 122)	20 (16.4)	102 (83.6)	51.5 ± 15.1	64 (52.5)	58 (47.5)
AIBD (n = 31)	9 (29.0)	22 (71)	66.0 ± 13.7	19 (61.3)	12 (38.7)
Control (n = 61)	15 (24.6)	42 (75.4)	51.4 ± 15.9	48 (78.7)	13 (21.3)
Total (n = 372)	64 (17.2)	304 (81.7)	54.7 ± 15.3	260 (69.9)	112 (30.1)

Herbal supplement use for each cohort (%)

Cohort Comparisons	Any Herbal		Spirulina	
	Odds Ratio (95% CI)	p-value	Odds Ratio (95% CI)	p-value
Dermatomyositis vs. Controls	2.37 (0.94, 7.30)	0.0919	2.34 (0.85, 8.29)	0.1345
Dermatomyositis vs. non-DM Autoimmune	3.47 (1.57, 8.33)	0.0032*	4.92 (1.87, 15.53)	0.0027*
Non-DM Autoimmune vs. Controls	0.82 (0.26, 2.86)	0.7477	0.56 (0.14, 2.39)	0.4084

Logistic regression comparison of herbal and spirulina use between cohorts

(19.6% of DM, 5.7% of CLE, 6.5% of AIBD, and 8.2% of controls). Spirulina was the most frequently-used herbal supplement for DM (14.6%), CLE (4.1%), and controls (5.7%), while blue-green algae was the most frequently-used CAM for AIBD (3.2%). Herbal use in DM was greater compared to controls (OR = 2.37, p = 0.0919), and compared to other autoimmune cohorts (OR = 3.47, p = 0.0032). Spirulina use was greater among DM patients compared to both controls (OR = 2.34, p = 0.1345) and to other autoimmune cohorts (OR = 4.92, p = 0.0027). Herbal and spirulina use were not significantly associated with non-DM autoimmune diseases compared to controls.

Conclusion: Our study demonstrates that CAM use, in particular spirulina, is greater among patients with DM. This association is statistically significant for DM compared to CLE or AIBD. This study demonstrates that the use of CAM is of concern among the patients with a history of DM. Patients with DM should be educated regarding the risk of onset or flare from using immunostimulatory CAM such as Spirulina.

Abstract Number: 1066

Prevalence of Cervical Dysplasia in Women with Antisynthetase Syndrome

Alexis Katz[1], Yuxuan Jin[1] and Soumya Chatterjee[2], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic, Richmond Heights, OH

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased risk of cervical dysplasia and cervical cancer have been reported in patients with systemic lupus erythematosus (SLE). However, the reason for this increased risk is not known but may be related to chronic inflammation or immunosuppressive medications. We hypothesize that patients with Antisynthetase Syndrome (ASS), which is also an inflammatory disease treated with immunosuppression, will have an increased risk of cervical abnormalities. There has not previously been a study evaluating the risk of cervical dysplasia or cervical cancer in ASS patients.

Methods: Clinical data were obtained by retrospective review of EMR at Cleveland Clinic (CC) from 2000-2020. Female patients, over the age of eighteen, diagnosed with ASS by a CC rheumatologist and with the presence of one of the ASS specific autoantibodies (Ab): Jo-1, PL-7, PL-12, EJ, or OJ, were selected. Patients with SLE diagnosed by a CC rheumatologist were age-matched to the ASS patient cohort. An age-matched control population without any known autoimmune rheumatic disease was obtained through the Medicine Institute Value-Based Care Research Registry. In addition to the above criteria, the patients were also required to have Pap smear data available in the EMR. Patients who carried concurrent diagnoses of ASS and SLE were excluded from the study.

Variables	Odds Ratio (95% CI)	P-value
Group:

Table 1. Multivariable Logistic Regression

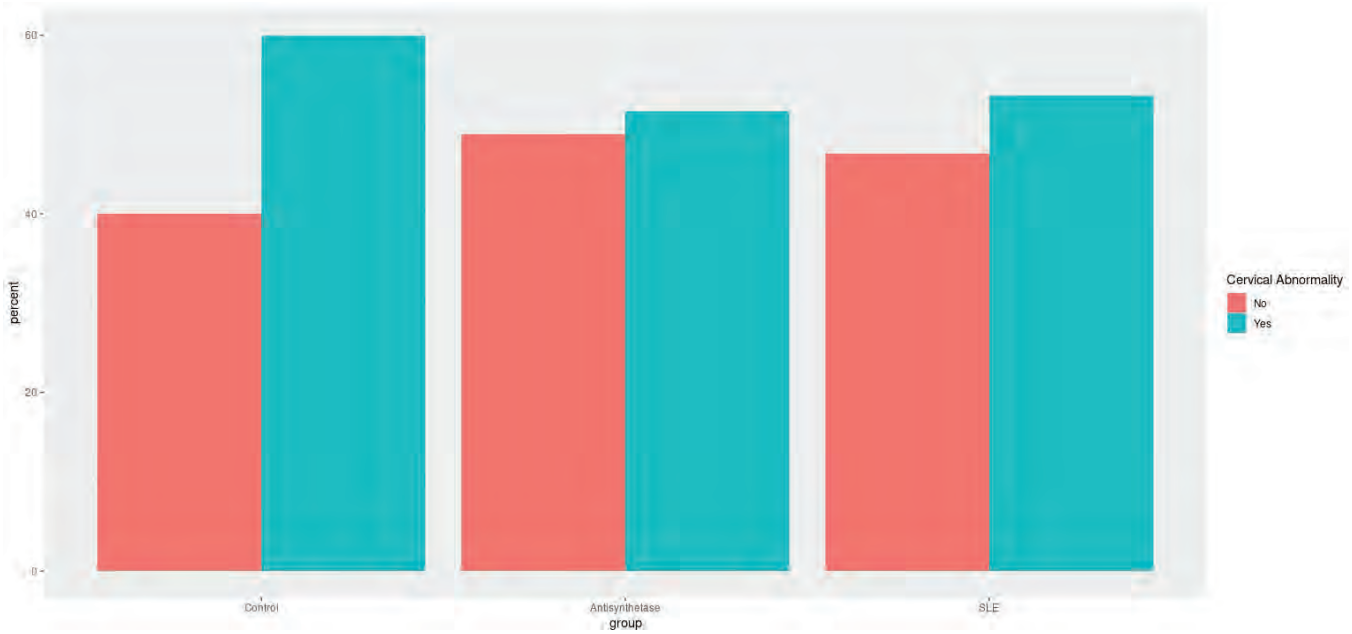

Figure 1. Comparison of the Presence of Cervical Abnormalities by Group

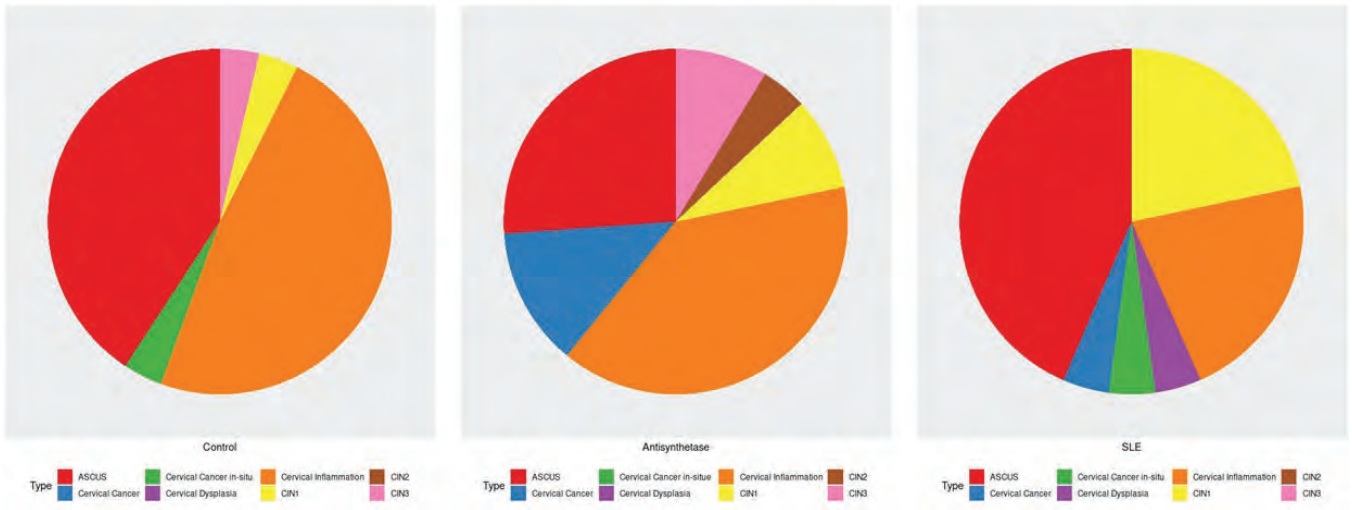

Figure 2. Comparison of Cervical Abnormality Type by Group

Results: A total of 135 patients were included in our analysis with 45 patients in each subgroup: ASS, SLE, or controls. The median age was 52 years. Cervical abnormalities, including cervical inflammation, cervical dysplasia, and cervical cancer, were compared between groups. More than half (53.3%) of all patients had some degree of cervical abnormality, most commonly cervical inflammation (27/74, 37%) and atypical squamous cells of undetermined significance (ASCUS) (27/74, 37%). There were no statistically significant differences in the presence of cervical abnormalities between the three groups. Cervical cancer was present in 6 patients. HPV infections were documented in 23% of patients (31/135), and even after multivariable analysis HPV remained a strong predictor of cervical abnormalities (p= < 0.001). There was also a trend towards use of oral contraceptive pills (OCPs) predicting cervical abnormalities, but this did not reach statistical significance once multivariable logistic regression was completed (p=0.054).

Conclusion: In our cohort, there was no statistically significant difference in the prevalence of cervical dysplasia and cervical cancer in the three groups. This is an interesting finding as numerous studies have reported an increased prevalence of cervical abnormalities in SLE patients, but this was not found in our cohort. The reason for this is unclear but may be related to the small number of ASS patients available for review. Additionally, there may be selection bias towards sicker patients who are more likely to be encouraged to have age-appropriate cancer screening. Our study was limited by being a single-center retrospective analysis of a relatively small cohort. Further studies, with larger sample sizes, maybe helpful to fully understand the underlying risk factors contributing to the prevalence of HPV, cervical dysplasia, and cervical cancer in SLE and ASS patients.

Anti-Viral Proinflammatory Phenotype in Circulating Monocytes from Patients with Anti-Melanoma Differentiation-Associated Gene 5 Antibody-Associated Interstitial Lung Disease

Takahisa Gono[1], Yuka Okazaki[1] and Masataka Kuwana[2], [1]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, [2]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-melanoma differentiation-associated gene 5 (MDA5) antibody is associated with interstitial lung disease (ILD), which often represents rapidly progressive course and fatal outcomes. Circulating levels of ferritin were remarkably increased in patients with anti-MDA5-associated ILD, especially in those with rapidly progressive ILD, suggesting involvement of monocyte/macrophage activation in the pathogenic process. However, stimuli that trigger activation of monocytes/macrophages in anti-MDA5-associated ILD still remain unknown. In this study, we investigated molecules and pathways involved in activated monocytes in circulation from patients with anti-MDA5-associated ILD, using microarray expression profiling combined with the integrated miRNA-mRNA association analysis.

Methods: We first examined comprehensive expression profiling of mRNA and miRNA by a microarray system using circulating $CD14^+$ monocytes from 3 untreated patients with anti-MDA5-associated ILD and 3 healthy controls (HCs). Then, integrated miRNA-mRNA association analysis was conducted to identify molecules related to disease pathways and their regulator effect networks using Ingenuity Pathway Analysis (IPA) system. The relevant gene expression levels were validated by real-time PCR using additional circulating monocyte samples obtained from 5 untreated patients with anti-MDA5-associated ILD, 5 patients with anti-aminoacyl tRNA synthetase (ARS)-associated ILD, and 5 HCs.

Results: Twenty-six significant matched pairs of differentially down-regulated miRNA and up-regulated mRNA were identified by IPA, and 6 relevant genes associated with disease pathways included IFIT2, IFIT3, MX1, IRF7, CCL2 and CLU. The major relevant genes of our dataset were type 1 interferon (IFN)-inducible genes. The regulator effect network analysis identified 5 predicted upstream regulators, including IFN-β, toll-like receptor (TLR) 3, TLR7, TLR9, and

SPI1. Anti-viral infection pathway was identified as the predicted downstream effect involved with those 6 relevant genes. The mRNA expressions levels of 6 genes associated with disease pathways were confirmed to be higher in patients with anti-MDA5-associated ILD than in those with anti-ARS-associated ILD or HCs, and were declined after immunosuppressive treatment in patients with anti-MDA5-associated ILD.

Conclusion: Anti-viral proinflammatory pathways are activated in circulating monocytes from patients with anti-MDA5-associated ILD, suggesting roles of viral infection in triggering this devastating condition.

Abstract Number: 1068

Efficacy of Early Initiation of Plasma Exchange Therapy for a Patient with Anti-MDA5 Autoantibody-Positive Dermatomyositis Developing Refractory Rapidly Progressive Interstitial Lung Disease

Noriko Sasaki[1], Akira Ishii[1], Keigo Shimura[1], Azusa Kojima[1], Mai Sugiyama[2], Yuto Izumi[1], Kazuki Hirano[1], Sho Sasaki[2], Takayoshi Kurabayashi[1], Yuji Hosono[2], Chiho Yamada[2] and Shinji Sato[2], [1]Tokai University School of Medicine, Isehara, Kanagawa, Japan, [2]Tokai University School of Medicine, Isehara, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM), and particularly the subtype clinically amyopathic DM (CADM), is often associated with fatal rapidly progressive interstitial lung disease (RP-ILD) when anti-melanoma differentiation-associated gene 5 (MDA5) antibody is present, especially in Eastern Asian populations. There is no evidence-based strategy for treating this disease, but intensive treatment with high-dose corticosteroid and multiple immunosuppressants may be effective. However, RP-ILD often fails to respond to such intensive treatment regimens, and still has a very poor prognosis. Here, we report the efficacy of early initiation of plasma exchange (PE) therapy in addition to high-dose corticosteroid and multiple immunosuppressants.

Methods: Retrospective study of DM patients who satisfied the ACR/EULAR classification criteria attending Tokai University Hospital between 2010 and 2019, screened for autoantibodies, and with RP-ILD diagnosed based on the clinical course of respiratory symptoms, function and computed tomography. A model combining 4 serum biomarkers (ferritin ≥ 500 ng/mL, CRP ≥1 mg/dL, KL-6 ≥1,000 U/mL and anti-MDA5 antibody positivity) was used for predicting poor prognosis. All patients received intensive immunosuppressive therapy (high-dose prednisolone (PSL) including methyl-PSL pulse therapy, calcineurin inhibitor and/or intermittent intravenous cyclophosphamide). In addition to this, one group of patients also underwent PE. Comparisons of treatment response and prognosis between the two groups were assessed using Fisher's exact test and paired or unpaired t-test.

Results: Fifteen DM/CADM patients with RP-ILD and at least 3 factors predicting poor prognosis were identified, 7 of whom had classic DM and 8 had CADM. Of these 15 patients, 11 (5 female, 6 male, mean age 57 ± 12 SD, range 38-75 years) received intensive immunosuppressive therapy (IS group) and 4 received PE therapy in addition to im-

munosuppressive therapy (PE group, 2 female, 2 male, mean age 56 ± 14 SD, range 40-70 years). PE therapy was started at the same time as immunosuppressive therapy in 3 of 4 these patients. Respiratory symptoms improved in all 4 patients receiving PE, who were still alive at the end of the study, whereas only 3 of 11 patients receiving immunosuppression alone survived (100% vs. 27%, P= 0.026). Three patients in the PE group and 3 of 11 in the IS group exhibited all 4 indicators of poor prognosis conferring the highest risk of death. Notably, of these 6 patients, all 3 in the PE group but none in the IS group survived. Serum ferritin levels were significantly reduced in the PE group (1459 ng/mL vs. 57 ng/mL, P= 0.043), with decreasing to within the normal range in all 4 patients. Moreover, the mean ferritin level in the PE group after remission was significantly lower than in the IS group (57 vs. 3450 ng/mL; P= 0.037).

Conclusion: PE therapy, especially its early initiation in addition to intensive immunosuppressive therapy, is effective in patients with DM and severe refractory RP-ILD.

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Scleromyositis (SM) is an emerging subgroup of autoimmune myositis associated with features of systemic sclerosis (SSc) and characterized by prominent vasculopathic features on ultrastructural evaluation of muscle capillaries. Yet, SM is also a frequent mimicker of immune-mediated necrotizing myopathy (IMNM) on muscle biopsy. Therefore, the aim of this study was to explore whether nailfold videocapillaroscopy (NVC) patterns in SM were distinct from IMNM.

Methods: A systematic review of NVCs from SM patients and IMNM controls was performed. In the absence of a gold standard or classification criteria, the clinical diagnosis of SM was based on expert opinion (consensus of ≥2 experts). Clinical, serological and pathological data were collected using a standardized protocol. NVC images were acquired using the DS MEDICA Videocap (200X magnification). Nailfolds of the 2nd, 3rd, 4th and 5th fingers of both

hands were photographed by two experienced physicians (GG and MK) and scored by one of them (GG). Microhemorrhages, giant capillaries, ectasias and ramified capillaries were scored using a standardized semi-quantitative scale (0 = no, 1 = ≤33%, 2 = 33–66%, and 3 = ≥66% abnormalities/linear mm). Capillary density was scored both semi-quantitatively (0 if ≥7, 1 if 4–6, or 2 if ≤3 capillaries/mm) and quantitatively (mean number of capillaries/mm). Patterns were classified as SSc-active, SSc-like, non-specific abnormalities or normal. Each NVC parameter and the different NVC patterns were compared between SM and IMNM.

Results: 20 SM cases and 5 IMNM comparators (4 anti-HMGCR positive, 1 anti-HMGCR/anti-SRP negative) were included. SM patients were predominantly females (80%), mean duration from myositis diagnosis to NVC was 2±17 months and vasculopathic features included: Raynaud in 18/20 (90%), history of digital ulcers in 4/20 (20%) and pulmonary arterial hypertension in 1/20 (5%) patient. Sixty-five percent of SM patients fulfilled the ACR/EULAR SSc criteria at myositis diagnosis. SSc features leading to the diagnosis of SM in the remaining 7 patients included: positive ANAs and/or SSc-associated autoantibodies (n=7/7, 100%), Raynaud (n=5/7, 71%), interstitial lung disease (n=5/7, 71%), sclerodactyly (n=1/7, 14%) and SSc calcinosis (n=1/7, 14%). Giant capillaries, ramified capillaries and ectasia were present in 65%, 75% and 80% of SM subjects (median scores 0.16; 0.24 and 0.63, all $p< 0.05$ by Wilcoxon-Mann Whitney U test), respectively, and none of the IMNM controls. Capillary density was lower than normal (7.0-11.0/mm) in SM (median 4.9/mm) and significantly lower compared to IMNM controls (median 8.5/mm, $p=0.012$ by Wilcoxon-Mann Whitney U test). Seventy percent of SM patients had an SSc-active or an SSc-like NVC pattern (35% each), 15% had non-specific abnormalities and 15% were normal. Using the European NeuroMuscular Center pathological criteria, 29% of the SM muscle biopsies were classified as IMNM and 100% of these patients had an abnormal NVC whereas all NVCs were normal in IMNM controls.

Conclusion: An abnormal NVC may serve as a clue to support the diagnosis of SM in anti-SRP or anti-HMGCR negative patients presenting with histologic features of IMNM.

Scleromyositis Is Associated with Distinct Muscle Vasculopathic Features

Océane Landon-Cardinal[1], Valérie Leclair[2], Yves Troyanov[3], Alain Meyer[4], Sabrina Hoa[1], Josiane Bourré-Tessier[1], Valérie Nadon[5], Julie Drouin[6], Jason Karamchandani[7], Erin O'Ferrall[8], Minoru Satoh[9], Marvin Fritzler[10], Jean-Luc Senécal[1], Marie Hudson[2] and Benjamin Ellezam[11], [1]Division of Rheumatology, Centre hospitalier de l'Université de Montréal, Montréal, QC, Canada, [2]Division of Rheumatology, Jewish General Hospital, Montréal, QC, Canada, [3]Division of Rheumatology, Hôpital du Sacré-Coeur, Montréal, QC, Canada, [4]Service de rhumatologie et Centre de références des maladies autoimmunes rares, Hôpitaux universitaires de Strasbourg, Strasbourg, Alsace, France, [5]Division of Rheumatology, Hôpital Notre-Dame, Montreal, Québec, Canada, Montréal, QC, Canada, [6]Division of Rheumatology, Centre hospitalier régional de Trois-Rivières, Trois-Rivières, QC, Canada, [7]Department of Pathology, Montreal Neurological Institute and Hospital, Montreal, QC, Canada, [8]Department of Neurology and Neurosurgery, Montreal Neurological Institute and Hospital, Montreal, QC, Canada, [9]Department of Clinical Nursing, University of Occupational and Environmental Health, Kitakyushu, Japan, [10]Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [11]Division of Pathology, Centre hospitalier universitaire Sainte-Justine, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleromyositis (SM) is an emerging subgroup of autoimmune myositis (AIM) associated with features of systemic sclerosis (SSc). Muscle biopsy studies are sparse and have suggested that SM is heterogeneous. Whether there is a distinct pathological signature remains uncertain. SSc is associated with a prominent vasculopathy. The aim of this study was to explore whether a distinct vasculopathic pattern is associated with SM as compared to other AIM.

Methods: A systematic review of SM muscle biopsies and AIM controls was performed by 2 reviewers. In the absence of gold standard, SM clinical diagnosis was based on expert opinion (consensus of ≥2 experts). Reviewers were blinded to the clinical diagnosis/serological status and used a pre-specified protocol including all stains recommended by the ENMC for the pathological diagnosis of AIM, and collagen IV immunofluorescence for endomysial capillary abnormalities (dropout and/or mural thickening and/or luminal dilation). Examination of capillaries was also done by electron microscopy (EM) for the presence of marked basement membrane (BM) reduplication (≥5 layers) and endothelial abnormalities.

Results: 31 SM cases and 18 AIM controls (4 dermatomyositis, 5 immune-mediated necrotizing myopathies (IMNM, all anti-HMGCR+), 5 inclusion body myositis (IBM), and 4 antisynthetase syndrome) were included. SM patients were predominantly females (86%) and mean age at muscle biopsy was 55.6±13.1 years. Myopathic features at presentation were: proximal weakness in 86% of patients and mean CK elevation of 1596±1510 IU/L. 71% of patients fulfilled the ACR/EULAR SSc criteria at myositis diagnosis. SSc features leading to the diagnosis of SM in the remaining 8 patients included: Raynaud phenomenon (n=7), positive ANAs and/or SSc-associated autoantibodies (n=7), interstitial lung disease (n=5), SSc nailfold capillaroscopy (n=3), sclerodactyly (n=1) and puffy fingers (n=1). Capillary BM reduplication was observed in 68% (n=21) of SM muscle biopsies compared to 11% of AIM controls (mildly observed in 2 IBM) ($p < 0.001$). Marked capillary BM reduplication was only observed in SM biopsies (55%, n=17). Of the SM patients without BM reduplication, all but one presented capillary abnormalities on immunofluorescence and/or endothelial abnormalities on EM. Using the ENMC pathological criteria for AIM, our SM cases would have been most frequently classified as IMNM (32%) or non-specific myositis (32%). In the subset of SM cases with an IMNM-like phenotype, marked BM reduplication and/or other ultrastructural capillary abnormalities were observed in all SM cases and none of the IMNM controls. No cases of dermatomyositis showed marked BM reduplication.

Conclusion: SM is associated with endomysial capillary BM reduplication, a distinct ultrastructural vasculopathic feature compared to other AIM. SM is a frequent mimicker of IMNM on muscle biopsy and should be ruled out by ultrastructural examination of capillaries in patients negative for anti-SRP or anti-HMGCR autoantibodies. The identification of marked BM reduplication may improve early identification of SM, especially in those presenting without SSc skin involvement.

Characteristics of Anti-Transcription Intermediary Factor 1-gamma Autoantibody Positive Dermatomyositis Patients in Singapore

Choon Guan Chua[1], Jia Zhen Low[1] and Mona Manghani[1], [1]Tan Tock Seng Hospital, Singapore, Singapore

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-transcription intermediary factor 1-gamma autoantibody (anti-TIF-1y Ab) associated dermatomyositis (DM) is strongly associated with the occurrence of malignancies. Patients may develop cancers prior to, concurrent with, or at a period after the diagnosis of DM. Close surveillance for cancer has been advocated for this group to allow early detection and cure of the underlying malignancy. The objective of this study was to determine the clinical profile and outcomes of anti-TIF-1y positive DM patients in Singapore.

Methods: A chart review was undertaken of 79 DM patients with positive myositis specific antibodies diagnosed between January 2015 and July 2019 at a major tertiary hospital in Singapore. All patients included fulfilled the Bohan/

Table : Demographics and clinical characteristics of anti-TIF1- γ Ab-positive and negative DM groups

	Total Cohort N=79	Anti-TIF1-γ Ab positive N=33	Anti-TIF1- γ Ab negative N=46
Female, n (%)	51 (64.6%)	23 (69.7%)	28 (60.9%)
Smokers, n (%)	10 (12.7%)	5 (15.2%)	5 (10.9%)
Age of DM onset, years, median (range)	58 (7-96)	61 (29-96)	56 (7-76)
Patients with cancer, total, n (%)	23 (29.1%)	19 (57.6%)	4 (8.7%)
Sequence of DM and cancer diagnosis, patients with cancer			
DM diagnosed first, subsequent cancer, n (%)	7 (30.4%)	5 (26.4%)	2 (50%)
Cancer diagnosed first, subsequent DM, n (%)	7 (30.4%)	7 (36.8%)	0 (0.0%)
Cancer and DM diagnosed at same time, n (%)	9 (39.2%)	7 (36.8%)	2 (50%)
Time from DM to cancer onset, months, median (range)	4 (1-22)	4 (1-22)	3 (2-4)
Time from cancer to DM onset, months, median (range)	12 (288-6)	12 (288-6)	n/a
Patient outcomes, with cancer			
Died, n (%)	8 (34.8%)	7 (36.8%)	1 (25.0%)
Improved and stable, n (%)	14 (60.9%)	11 (57.9%)	3 (75.0%)
Relapse, n (%)	1 (4.3%)	1 (5.3%)	0 (0.0%)
Sites of cancer			
Nasopharyngeal (NPC), n (%)	7 (30.4%)	6 (31.6%)	1 (25.0%)
Breast, n (%)	5 (21.7%)	4 (21.1%)	1 (25.0%)
Bowel (intestine), n (%)	3 (13.0%)	3 (15.8%)	0 (0.0%)
Lung, n (%)	2 (8.7%)	2 (10.5%)	0 (0.0%)
Cervical/Ovarian, n (%)	1 (4.3%)	1 (5.3%)	0 (0.0%)
Lymphoma, n (%)	1 (4.3%)	1 (5.3%)	0 (0.0%)
Thyroid, n (%)	1 (4.3%)	1 (5.3%)	0 (0.0%)
Kidney, n (%)	1 (4.3%)	1 (5.3%)	0 (0.0%)
Prostate, n (%)	1 (4.3%)	0 (0.0%)	1 (25.0%)

Peter criteria for probable/ definite DM and had International Myositis Classification Criteria scores of at least 55% consistent with probable idiopathic inflammatory DM.

Results: Of the 79 patients diagnosed with DM, 33 were found to be anti-TIF-1y Ab positive. In the anti-TIF-1y Ab positive group, 69.7% were female, 15.2% were smokers, and the median age of DM diagnosis was 61 years. A higher proportion of the anti-TIF-1y Ab positive group (57.6%) developed cancer compared to the anti-TIF-1y Ab negative group (8.7%).

The median time interval to diagnosis of malignancy in the cancer associated anti-TIF-1y Ab positive DM group was 12 months prior to or 12 months following the onset of DM. In the cancer associated anti-TIF-1y Ab positive group, DM was diagnosed before cancer in 26.3 % of patients, cancer before DM in 36.8 % and both cancer and DM diagnosed at the same time in 36.8 %. In those anti-TIF-1y Ab negative DM patients that developed cancer, the cancer was either diagnosed prior or concurrently with DM.

Nasopharyngeal carcinoma (NPC) was the commonest cancer (31.6%) in the anti-TIF-1y Ab positive DM group, followed by breast (21.1%), bowel (15.8%), lung (10.5%), cervical/ovarian (5.3%), lymphoma (5.3%), thyroid (5.3%), and kidney (5.3%). Of these patients 35% died, 60% improved and remained sTable, and 5% sustained a relapse. Of those anti-TIF-1y Ab positive NPC, 66.6% presented with advanced stage (Stage III or more) and all had undifferentiated histology.

Conclusion: Our results show the strong association of anti-TIF-1y Ab DM and increased risk of malignancy, particularly nasopharyngeal cancer in our Singaporean population. The cancer associated anti-TIF-1y Ab DM patients developed cancer within a year prior to or following the onset of DM and had a worse prognosis than the anti-TIF-1y Ab negative group. The clinical profile revealed in this review will be useful in guiding the targeted cancer surveillance needed for this group of patients to reduce morbidity and mortality.

SFQ28: Sexual Function Questionnaire – 28, subscale pain: 2 (worst)-15 (best)	12.5 (10.0-15.0)	15.0 (13.0-15.0)	p=0.011
SFQ28: Sexual Function Questionnaire – 28, subscale enjoyment: 6 (worst)-30 (best)	19.0 (14.5-23.5)	23.0 (19.0-25.0)	p=0.023

Table. Sexual function and pelvic floor function in women with IIM and healthy controls

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of rare diseases characterized by chronic muscle inflammation and multiple organ involvement. These serious clinical manifestations can be associated with significant impairment of quality of life including sexual life. The aim of this study was to assess sexual functioning in female IIM patients compared to age-/sex-matched healthy controls (HC) and to determine the association between sexual health impairment and physical and psychological aspects of the disease.

Methods: In total, 62 women (45 currently have a partner) with IIM [mean age: 53.1, disease duration: 5.2 years, dermatomyositis (DM, 29)/ polymyositis (PM, 27)/ necrotizing myopathy (IMNM, 5)/ inclusion body myositis (IBM, 1)], who fulfilled the Bohan/Peter 1975 criteria for DM/PM, or ENMC criteria for IMNM or IBM, and 62 healthy controls (HC) (51 currently have a partner, mean age: 53.1) without rheumatic diseases filled in 11 well-established and validated questionnaires assessing sexual function (FSFI, SFQ28, BISF-W), quality of sexual life (SQoL-F), pelvic floor function (PFIQ-7, PISQ-12), fatigue [Fatigue impact scale (FIS)], physical activity [Human activity profile (HAP)], depression [Beck's depression inventory II (BDI-II)], quality of life [36-item Short form survey (SF-36)], and disability [Health assessment questionnaire (HAQ)]. A routine laboratory testing was performed. Data are presented as median (IQR).

Results: Patients with IIMs reported significantly greater prevalence and severity of sexual dysfunction (FSFI, BISF-W, SFQ28, SQoL-F) and pelvic floor dysfunction (PISQ-12) compared to HC (Table). When we analyzed only sexually active patients compared to sexually active HC, the difference between patients and HC remained significant (Table). The prevalence of sexual dysfunction in patients with IIM according to the FSFI cut-off score was 59%. Worse scores in IIM patients were associated with greater muscle weakness of m. gluteus maximus [MMT8: FSFI (r=0.289, p=0.035), PFIQ-7 (r=-0.407, p=0.003)], m. gluteus medius [MMT8: PFIQ-7 (r=-0.381, p=0.005)], greater fatigue [FIF: FSFI arousal subscale (r=-0.343, p=0.007), SQoL-F (r=-0.412, p=0.003)], severer depression [BDI-II: SQoL-F (r=-

0.459, p=0.0007)], increased disability and deteriorated quality of life [HAQ: FSFI (r=-0.436, p=0.005); SF-36 D1: BISF-W (0.449, p=0.0005), SF-36 D5: SQoL-F (0.428, p=0.002], and worse ability to perform physical activities [HAP: FSFI (r=0.403, p=0.001), SQoL-F (r=0.368, p=0.007)]. We did not observe any associations with disease duration, current prednisone dose, or serum levels of muscle enzymes. Furthermore, no significant differences between DM and PM were found.

Conclusion: Women with IIM reported significantly impaired sexual function and pelvic floor function compared to healthy females with identical age. The prevalence of sexual dysfunction in IIM patients was 59%. Worse scores in IIM were associated with muscle weakness, decreased physical activity, greater fatigue, severer depression, increased disability and deteriorated quality of life.

Anti Melanoma Differentiation-associated Protein Gene 5 Antibody Titer Monitoring Is a Useful Indicator for Early Detection of Recurrence in Rapidly Progressive Interstitial Lung Disease Associated with Dermatomyositis

Yuji Hosono[1], Azusa Kojima[2], Keigo Shimura[2], Akira Ishii[2], Yuto Izumi[2], Kazuki Hirano[2], Sho Sasaki[2], Takayoshi Kurabayashi[2], Noriko Sasaki[2], Chiho Yamada[2] and Shinji Sato[2], [1]Tokai University School of Medicine, Kanagawa, Japan, [2]Tokai University School of Medicine, Isehara, Kanagawa, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti melanoma differentiation-associated gene 5 (MDA5) antibody (Ab) positive dermatomyositis (DM) often complicates rapidly progressive interstitial lung disease (RP-ILD), which shows fatal prognosis at early phase from the onset in spite of intensive immunosuppressive therapies. Although relapse of RP-ILD after remission with initial treatment is relatively rare in this condition, its long-term clinical course still remains unclear. Therefore, we investigated clinical characteristics and possible indicators for early detection of recurrence in patients with anti-MDA5 Ab positive DM and RP-ILD.

Methods: Adult Japanese DM patients who were treated at Tokai University Hospital from 2012 to 2019 were screened. Anti-MDA5 Ab was identified by immunoprecipitation with [35S] methionine-labeled HeLa cells, and anti-MDA5 Ab titers were measured using anti-MDA5 enzyme-linked immunoabsorbent assay. Patients who showed the exacerbation of RP-ILD and/or DM symptom after stabilized for more than a year were considered as recurrence.

Clinical and immunological features were retrospectively collected. Statistical analyses were performed using the Fisher's exact test.

Results: Thirty patients were diagnosed as DM with anti-MDA5 Ab. All had ILD and required hospitalization for intensive treatment. Seventeen of 30 (57%) achieved an improvement in respiratory function in response to their initial treatment and were discharged from the hospital. During their disease courses in outpatient care, 3 (18%) of 17 patients experienced recurrence and required re-hospitalization. Among 3 relapsed cases, 2 (67%) showed exacerbation of RP-ILD and remaining 1 (33%) revealed muscle weakness. Although all 3 relapsed patients showed anti-MDA5 Ab titer elevation at the time of relapse, no increase in the titer was seen in 14 non-relapsed patients (100% vs. 0%, P=0.002) Interestingly, marked increase of anti-MDA5 Ab titers preceded appearance of recurrent symptoms in all relapsed cases, whereas ferritin levels were within normal range at the recurrence (38-120 ng/dl) and gradually increased after readmission.

Conclusion: These results suggest that continuous measurement of anti-MDA5 Ab titer as well as careful observation of physical and imaging findings is crucial for monitoring disease activity and early detection of relapse in patients with anti-MDA5 Ab positive DM.

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Scleromyositis (SM) is an emerging subgroup of autoimmune myositis associated with features of systemic sclerosis (SSc). There is a paucity of data on scleromyositis associated with head drop and/or bent spine. The aim of this study was therefore to describe the clinical and serological features of scleromyositis patients presenting with head drop and/or bent spine as the dominant myopathic feature.

Table 1. Comparison of scleromyositis subjects based on the presence and the absence of dropped head and/or bent spine

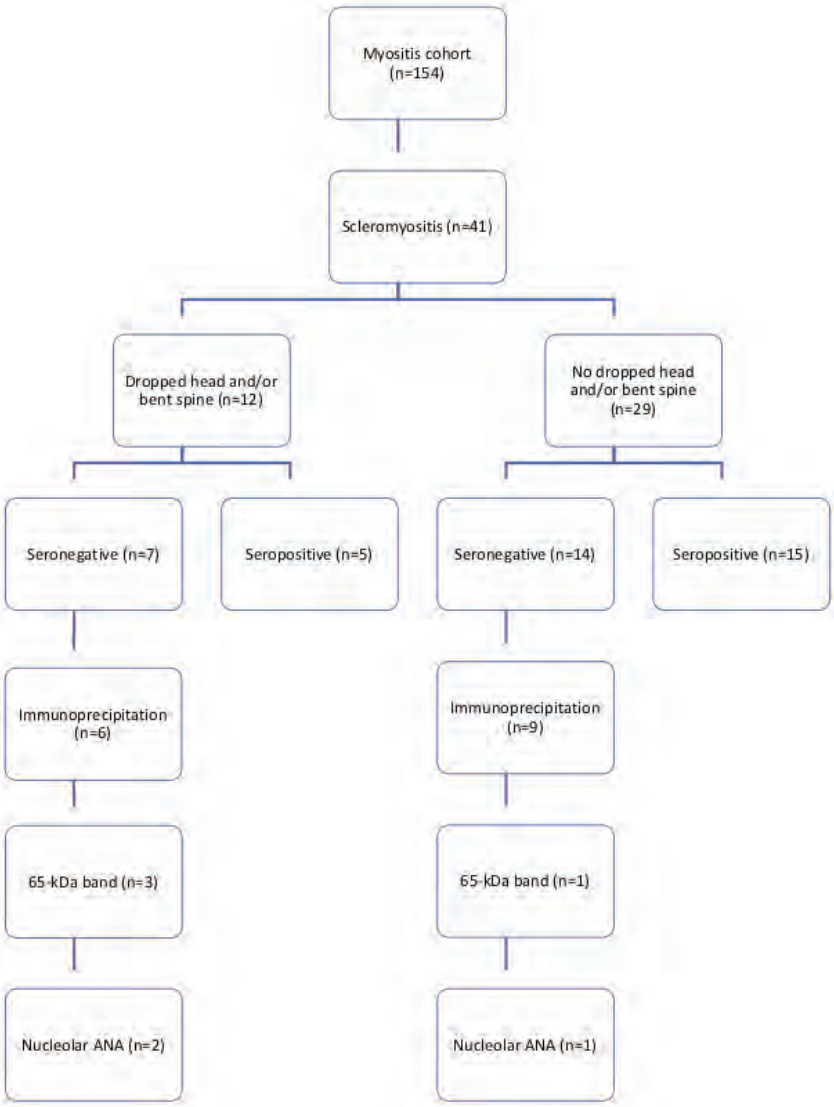
	Dropped head and/or bent spine (n = 12)	**No** dropped head and/or bent spine **(n = 29)**
Female n,%	11 (92)	22 (76)
Age at diagnosis mean, range	55 (38-79)	55 (20-81)
Autoantibody profiles		
Centromere	0	1 (3)
Topoisomerase	0	0
RNA polymerase III	2 (17)	2 (7)
Th/To	1 (8)	0
Fibrillarin	0	2 (7)
PM/Scl	2 (17)	7 (24)
Ku	0	0
U1-ribonucleoprotein (RNP)	0	4 (14)
Ro52	2 (17)	7 (24)
Skin thickening		
Diffuse	5 (42)	9 (31)
Limited	5 (42)	8 (28)
Sine	2 (17)	12 (41)
Raynaud	9 (75)	26 (90)
Pitting scars	1/10 (10)	4/27 (15)
Digital ulcers	1/11 (9)	6/28 (21)
Telangiectasias	8 (67)	9 (31)
Abnormal nailfold capillaroscopy	5/5	18/23 (78)
Calcinosis	1 (8)	3 (10)
Muscle weakness		
Proximal weakness	11 (92)	24 (83)
Distal weakness	8 (67)	14/28 (50)
Diaphragmatic weakness	1 (8)	1 (3)
Dysphagia	4 (33)	13 (45)
Classic dermatomyositis rash	2 (17)	7 (24)
Mechanics' hands	0	1 (3)
Elevated creatine kinase	8 (67)	26 (90)
Peak creatine kinase median, range	283 (84-1488)	877 (48-5075)
Myopathic electromyography	9/10 (90)	23/25 (92)
Arthritis	2 (17)	9 (31)
Interstitial lung disease on HRCT	1 (8)	16 (55)
Pulmonary hypertension*	0	1 (3)
Trigeminal neuropathy	1 (8)	2 (7)

Abbreviations: HRCT, high resolution computed tomography; PM/Scl, antibodies to polymyositis/scleroderma exosome antigen; Th/To, mitochondrial RNA processing (MRP) complex (note LIA detects only anti-hPOP1).

* Right heart catheterization was available for 7 patients of which one had pulmonary arterial hypertension. The rest of the cohort was screened by cardiac echocardiography and none had signs of pulmonary hypertension.

Methods: All patients with a diagnosis of SM were identified from a research cohort of 154 autoimmune myositis patients. In the absence of a gold standard, the clinical diagnosis of SM was based on expert opinion (consensus of ≥2 experts). SM patients were grouped according to the presence or absence of dropped head and/or bent spine. Clinical and serological data were collected and stored using a standardized protocol. Sera from patients with no known SSc-specific (anti-centromere (ACA), -topoisomerase I (Scl-70) (ATA), RNA polymerase III (RNApol), -Th/To, -fibrillarin) or SSc-associated (anti-PM/Scl), -Ku, -U1RNP) were tested by immunoprecipitation (IP) of ^{35}S-methionine-labeled cell extracts. Descriptive statistics were used to summarize the data.

Figure1. Flowchart



Results: Forty-one SM subjects were identified (Table 1). The majority were female (80%) and mean age at diagnosis was 55 years (range: 20-81). Most of the SM subjects had Raynaud's phenomenon (85%) and all had abnormal nailfold videocapillaroscopies. Although the majority had proximal weakness (85%), more than 50% also had distal weakness. Head drop and/or bent spine was the dominant myopathic feature in 12 (29%) SM patients. In those with head drop and/or bent spine compared to those without, SSc skin involvement was more common (84% vs 59%), interstitial lung disease (ILD) was less frequent (8% vs 55%), and peak creatine kinase level was lower (median 283 IU/L (range: 84-1488) vs 877 IU/L (range: 48-5075)). Only 5 of 12 patients (42%) with dropped head and/or bent spine had SSc-specific or -associated antibodies, including -RNApol III (n=2), Th/To (n=1) and PM/Scl (n=2). Among patients without known antibodies, IP was performed in 15 subjects: 6 of 7 subjects with and 9 of 14 subjects without dropped head and/or bent spine (Figure 1). Among these 15 patients, a 65- kiloDalton (kDa) band was identified in 3 subjects with, and 1 subject without, dropped head and/or bent spine. Three of the four patients with a 65-kDa band had a nucleolar pattern on HEp-2 indirect immunofluorescence staining. The subjects with a 65-kDa band had limited

skin disease (3/4) and dysphagia (3/4) but no ILD or arthritis. The subject with a 65-kDa band without dropped head and/or bent spine had a nucleolar IIF and predominantly distal weakness.

Conclusion: Dropped head and/or bent spine was a dominant myopathic feature in a third of our scleromyositis patients. An autoantibody recognizing a 65-kDa protein represents a novel autoantibody associated with scleromyositis presenting with dropped head and/or bent spine. Further studies to identify the 65-kDa autoantibody target are underway.

Diagnostic Utility of Myositis Antibodies in HyperCKemia: A University Affiliated Single Center Retrospective Study

Sandeepkumar Gupta[1], Debendra Pattanaik[2], Tulio Bertorini[2] and Amado Afreire[3], [1]Medical College Of Georgia at Augusta University Medical Center, Augusta, GA, [2]University of Tennessee Health Science Center, Memphis, TN, [3]University of Tennessee Health Science Cente, Memphis, TN

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis specific and associated autoantibodies are now being used more frequently in the diagnosis of idiopathic inflammatory myositis. However there is a no study looking at the utility of antibody testing in subjects presenting with HyperCKemia during routine clinical practice. We aimed to determine the usefulness of antibody testing in subjects with both symptomatic and asymptomatic hyperCKemia referred to a university affiliated practice.

Methods: This was a retrospective chart review of electronic health records of subjects in whom antibody testing was performed between January 2013 till December 2018. The autoantibody testing were performed using myomarker panel 3® (Anti-Jo-1 Ab, Anti-Mi-2 Ab, Anti-PL-12 Ab, Anti-PL-7 Ab, Anti-EJ Ab, Anti-OJ Ab, Anti-SRP Ab, Anti-Ku Ab, Anti-U2 RNP, Anti-PM/Scl-100 Ab, Anti-MDA5 Ab, Anti-NXP2 Ab, Anti-TIF-1γ Ab, Anti-SSA 52 kD IgG Ab, Anti-U1 RNP Ab, Anti-Fibrillarin U3 RNP Ab), [RDL Reference Laboratory, Los Angeles, CA], Anti-cN-1A (NT5c1A)and Anti-HMGCR Ab IgG . Baseline demographics, reason for referral, presenting symptoms, muscle enzymes (CPK, Aldolase, ALT, AST), autoantibody results, electromyography and nerve conduction studies (EMG & NCS), muscle biopsies and final clinical diagnosis were extracted from the records.

Only HyperCKemia with and without symptoms were considered for the study. We used Stat view version 5.01 (SAS Institute Inc. Cary, NC) for analysis

Results: There were 138 subjects for whom antibody testing were performed. 47 subjects met our inclusion criteria. 9 subjects were excluded from final analysis as their final diagnosis was not classified. 38 subjects included in final analysis. Baseline demographics, presenting symptoms and muscle enzyme levels are presented in Table 1. Results

Table 1. Baseline Characteristics of study population(N = 47)

Age (Mean ± SD)	58 ± 12 years
Gender (%)	
Male	32 (68%)
Female	15 (32%)
Ethnicity (%)	
Caucasian	22 (47%)
African American	20 (43%)
Other	5 (2%)
Asymptomatic hyperCKemia	12(26%)
*Symptomatic w/o weakness	18(38%)
*Symptomatic w/ weakness	15 (32%)
CPK (Mean ± SD)	1147 ± 1245 (24-204 U/L)
AST (Mean ± SD)	44 ±23 (0-40 IU/L)
ALT (Mean ± SD)	47 ± 45(0-44 IU/L)
Aldolase (Mean ± SD)	9.5 (<8 U/L)

Symptomatic = Myalgia, muscle cramps, decrease exercise tolerance, unsteady gait, paresthesia, muscle stiffness.

Table 1. Baseline Characteristics of study population(N = 47)

of EMG & NCS, myositis antibody and final clinical diagnosis details are presented in Table 2. The relationship between CPK, final diagnosis and myositis antibodies are shown in Figure 1. Subjects with moderate elevation of CPK and positive antibody are more likely to have polymyositis. Subjects with mild elevation of CPK and positive antibody are more likely to have inclusion body myositis. Negative antibody subjects are more likely to be diagnosed with idiopathic hyperCKemia and metabolic myopathy.

Antibody positive was statistically associated with polymyositis, inclusion body myositis with a chi square of 25.94 with p value 0.002 with 9 degree of freedom.

Antibody positivity was statistically associated with inflammatory myositis on muscle biopsy with a chi square of 16.37 p value 0.01 with 6 degree of freedom.

Metabolic myopathy will likely have negative myositis antibody test.

Conclusion: Subjects presenting with asymptomatic or symptomatic hyperCKemia and having positive antibody, are more likely to have positive muscle biopsy and final diagnosis of inflammatory myositis. Therefore, performing initial antibody testing in such cases would help clinicians in pursuing these cases with EMG & muscle biopsy.

Table 2. Muscle biopsy, EMG & NCS, Myositis antibody and Final clinical diagnosis

Muscle biopsy (N=29)	
Normal biopsy	1 (3 %)
Neurogenic atrophy	6 (21%)
necrotizing myopathy without inflammation	1(3%)
Inclusion body myositis	5 (17%)
Metabolic myopathy	4 (14%)
Polymyositis	5 (17%)
Non diagnostic	7 (24%)
Electromyography/Nerve conduction study (N=38)	
Brief polyphasic motor units	17 (44%)
Myopathy	9 (24%)
Myositis antibody positive (N=47)	**12 (26%)**
Anti-cN-1A (NT5c1A) IBM (N=15)	4 (27%)
Anti-HMGCR Ab IgG (N=19)	1 (5%)
Anti-Jo-1 Ab (N=42)	2 (5%)
Anti-Ku Ab(N=42)	1(2%)
Anti-TIF-1γ Ab(N=42)	1(2%)
Anti-SSA 52 kD IgG Ab(N=42)	4(10%)
Anti-PM/Scl-100 Ab(N=42)	2(5%)
Anti-U1 RNP Ab(N=42)	2(5%)
Anti-U2 RNP(N=42)	1(2%)
Final Clinical Diagnosis (N =47)	
Idiopathic HyperCKemia	16 (34%)
Polymyositis	7 (15%)
Inclusion body myositis	4 (9%)
Metabolic myopathy	4 (9%)
Not classified	9 (19%)
Others*	7 (15%)

(*IgM Monoclonal gammopathy of unknown significance, chronic inflammatory demyelinating polyneuropathy, Rhabdomyolysis, HIV infection/Highly active antiretroviral therapy (HAART) related, Movement disorder/amyotrophic lateral sclerosis)

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Synthetase Syndrome (ASyS) is a rare systemic autoimmune disease defined by a combination of pulmonary, muscle, joint, and skin manifestations and the presence of antibodies (Aab) targeting a tRNA t-synthetase. The anti-Jo1 (Histidyl-t-RNA-synthetase) antibody is the most commonly found and can be quantified

by Luminex® technology. The aim of this study was therefore to evaluate the value of indirect quantification by LUMINEX® technology of anti-Jo1 Aab as a prognostic factor and biomarker of activity.

Methods: We conduct a retrospective, bi-centric study beetween the Pitié Salpêtrière Hospitals and Reims University Hospital Centre. ASyS diagnostic was defined by the presence of at least 2 clinical manifestations associated with this Aab.

Severity was defined by the need for mechanical intubation-ventilation, hypoxemia < 60 mmHg PaO2, the presence of proven cardiac injury, severe muscle injury with bed confinement, diaphragmatic injury, or the presence of swallowing difficulties. Activity assessment was rated using the tools recommended by IMACS and ACR/EULAR and was represented on a numerical scale summarizing the practitioner's overall assessment. Quantification of Anti-Jo1 Aab was performed using a Luminex® approach (Euroline Myositis Profile 3: Euroimmun).

Results: Among the 99 patients followed for SAS, 27 were excluded for lack of information. Patients from sub-Saharan Africa and the Caribbean were more represented in the group with a complication at diagnosis (23% vs. 9%, p=0.04). The anti-Jo1 Aab titer (209 [176.8-257.3] vs 128 [89.5-169]; p< 0.001), as well as the CK level (3350 [1486-15000] vs 1078 [246-4125] p< 0.05) were higher in the severe event group. For the 37 patients whose titer was available at diagnosis, one or more controls were available for 24 patients. The median titre of Jo1 antibody was higher at diagnosis compared to the corresponding assay at the time of clinical remission (171.5 [113.3-232.3] vs 137 [90-160.3] p=0.02). The maximum anti-Jo1 antibody titer was significantly higher in the patient with severe event than the no severe event group (229.5 [182-272.3] vs 149.5 [118.8-184.3] p< 0.001). The ROC curve produced had an area under the curve of 0.81 IC95(0.71-0.91) p< 0.001. A value of anti-Jo1 Ac > 186 had a sensitivity of 74% and a specificity of 79% to predict the risk of a serious event.

Of the 33 patients with a titer > 186, 70% had a serious event in follow-up, of which 50%, the vast majority, occurred within the first 30 days of follow-up. Conversely, only 21% of patients with a titer < 186 had an event during follow-up.

Conclusion: Indirect quantification of Ac anti-Jo1 by fluorescence intensity using the Luminex technology was correlated with the occurrence of serious events in the monitoring of ASyS. It was a reliable, reproducible and automated technique that could be used to assist in patient follow-up and treatment monitoring. The validation of these results on independent cohorts is nevertheless necessary.

Glucagon-like Peptide-1 Receptor Agonist Suppresses Muscle Inflammation and Muscle Fiber Death, and Ameliorates Muscle Weakness in Experimental Polymyositis

Mari Kamiya[1], Seon Uk Kim[2], Jeong Yeon Kim[3], Shinsuke Yasuda[4], Eun Young Lee[5] and Fumitaka Mizoguchi[1], [1]Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (TMDU), Tokyo, Japan, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Jongno-gu, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, [4]Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (TMDU), Tokyo, Tokyo, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GC) are the cornerstone of the treatment for polymyositis (PM). However, the treatment with GC causes GC-induced myopathy, which further deteriorates the muscle weakness. Therefore, new therapeutic strategy that not only suppresses muscle inflammation but also improves muscle strength is needed. Glucagon-like peptide-1 receptor (GLP-1R) agonists, which have been developed as an anti-diabetic therapy, have pleiotropic actions including anti-inflammatory effects, suppression of muscle wasting, and inhibition of cell death. We hypothesized that GLP-1R agonists have beneficial effects on PM to recover muscle strength and to suppress muscle inflammation. The aim of this study is to examine the effect of a GLP-1R agonist on in vitro and in vivo models of PM.

Methods: Muscle specimens of PM patients and C protein-induced myositis (CIM), a murine model of polymyositis, were examined with immunohistological staining for the expression of GLP-1R. The effect of PF1801 (ImmunoForge, Seaul, South Korea), a GLP-1R agonist, on CIM was examined in monotherapy (5 mg/kg body weight (BW)/day) or in combination with prednisolone (PSL, 20 mg/kg BW/day). The levels of HMGB1, TNF-α and IL-6 in the serum and the muscle were measured by ELISA. C2C12-derived myotubes were treated with FAS ligand (FASLG) to induce the myotube death. The effect of PF1801 on the myotube death was examined.

Results: Histological analysis of muscle specimens of PM patients and CIM revealed that GLP-1R was expressed on the plasma membrane of muscle fibers. The expression level of GLP-1R on the muscle fibers was high in the area where inflammatory infiltrates were observed. The treatment of CIM with PSL ameliorated CIM histologically in the levels of inflammatory infiltrate and the necrotic area, but did not ameliorate the muscle weakness nor muscle weight loss. The treatment with PF1801 in monotherapy (PF) or in combination with PSL (PF+PSL) suppressed CIM-induced muscle weakness (grip strength, mean ± SD ($\times 10^3$ g/kg BW); PF 12.2 ± 1.0 ($p< 0.0001$), PF+PSL 12.7 ± 1.7 ($p< 0.0001$), Vehicle 8.4 ± 1.0) and the muscle weight loss (wet weight of quadriceps, mean ± SD (mg/g BW); PF 6.35 ± 0.72 ($p< 0.01$), PF+PSL 7.02 ± 0.42 ($p< 0.001$), Vehicle 5.16 ± 0.80) as well as the severity of histological myositis (histological score, median (interquartile range); PF 0.0 (0.0 to 0.5) ($p< 0.05$), PF+PSL 0.0 (0.0 to 0.0) ($p< 0.001$), Vehicle 1.9 (1.3 to 3.3)). The levels of HMGB1, TNF-α and IL-6 in the serum and the muscle were lower in PF1801-treated CIM mice than the mice treated with the vehicle control. In vitro, PF1801 inhibited FASLG-induced myotube death.

Conclusion: GLP-1R agonist could be a novel therapy to recover muscle weakness and to suppress muscle inflammation in PM.

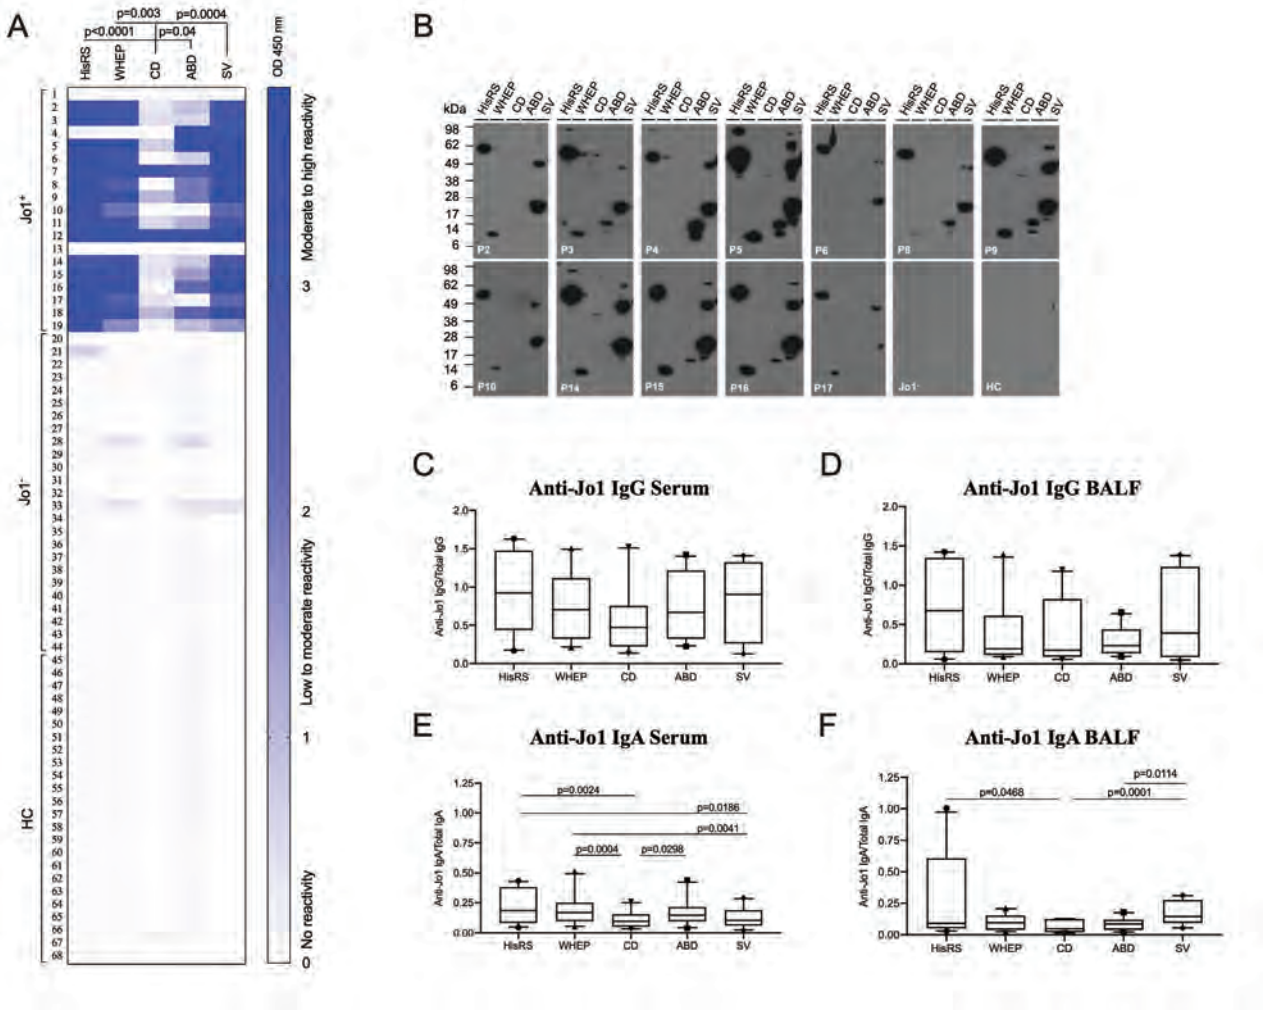
SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM



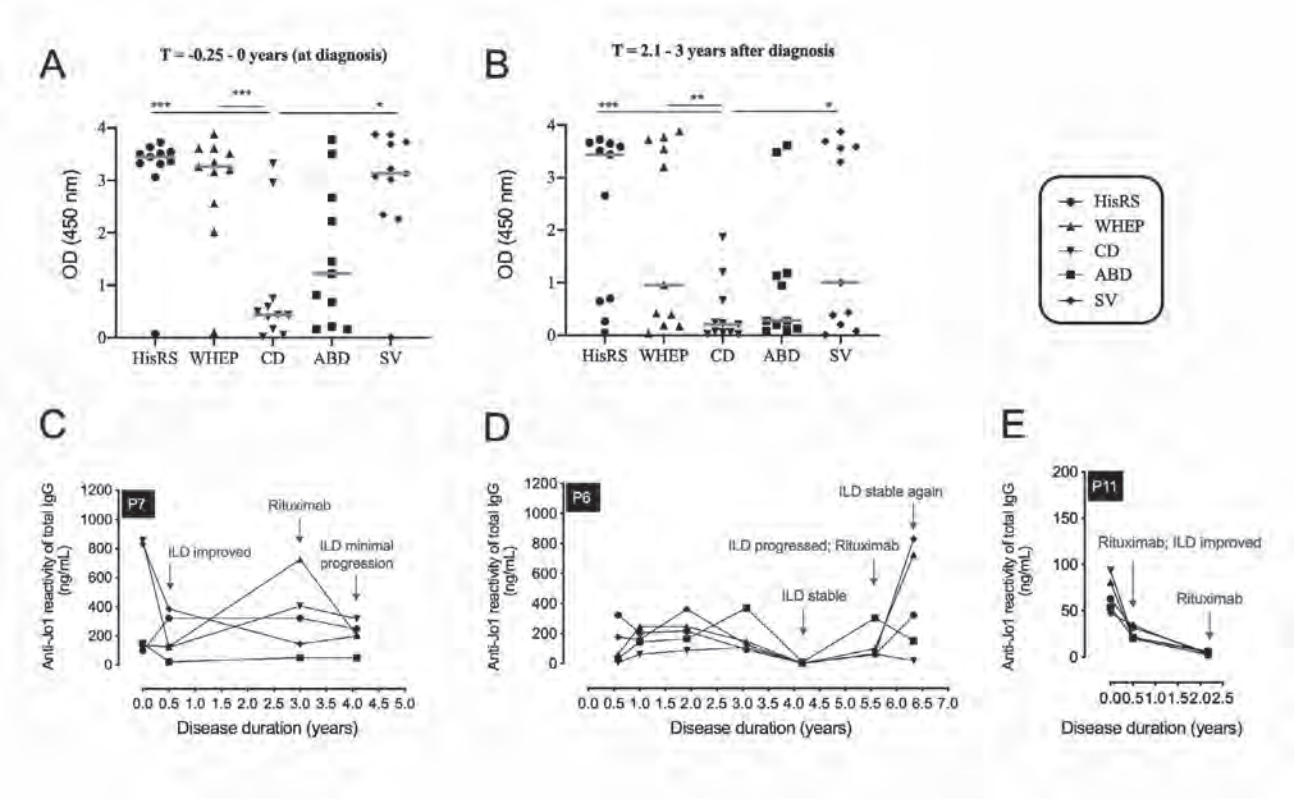
Background/Purpose: To address the reactivity and affinity against histidyl-transfer RNA synthetase (HisRS) autoantigen of anti-Jo1 autoantibodies from serum and bronchoalveolar lavage fluid (BALF) and associations with clinical data in patients with idiopathic inflammatory myopathies/anti-synthetase syndrome (IIM/ASS).

Methods: Samples and clinical data were obtained from: i) 25 anti-Jo1^{+} (19 sera and 6 BALF/matching sera at diagnosis, 16/19 sera at follow-up); ii) 29 anti-Jo1^{-} (25 sera and 4 BALF/matching sera at diagnosis) patients; iii) 24 age/gender matched healthy controls. Reactivity towards HisRS full-length (HisRS-FL), two HisRS domains, and two HisRS splice variants (WHEP and SV) was tested. Anti-Jo1 IgG reactivity was evaluated by ELISA and western blot in IgG purified from serum by affinity chromatography. In paired serum-BALF, anti-Jo1 IgG and IgA reactivity was analyzed by ELISA. Autoantibodies affinity was measured by surface plasmon resonance. Correlations between autoantibody reactivity and clinical data were evaluated.

Results: Anti-Jo1 IgG from serum and BALF bound HisRS-FL, WHEP and SV with high reactivity, already at diagnosis and recognized both conformation-dependent and -independent HisRS epitopes (Figure 1). Levels of autoantibodies (against HisRS-FL, -domains and -splice variants) generally decreased over time (Figure 2). Individuals with interstitial lung disease, arthritis and less skin involvement presented higher autoantibody levels against HisRS-FL (Figure 3). IgG with anti-WHEP reactivity in BALF correlated with poor pulmonary function. Anti-HisRS-FL IgG displayed high affinity early in the disease.

Conclusion: High levels and high affinity of anti-Jo1 autoantibodies towards HisRS early in disease in sera and BALF support the hypothesis that autoimmunity against HisRS is most likely initiated before IIM/ASS diagnosis.

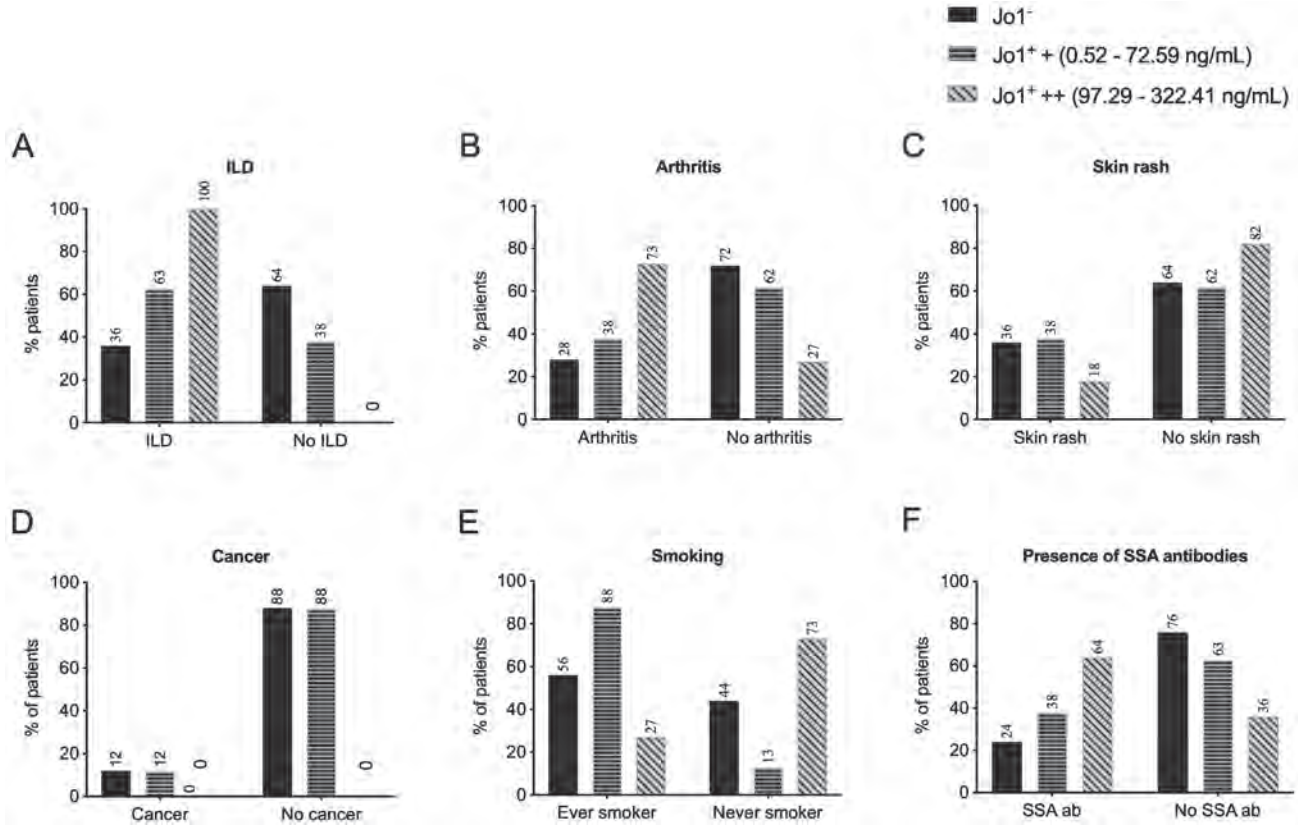
Serum and BALF-derived anti-Jo1 autoantibodies display high reactivity against HisRS variants/domains already at IIM/ASS diagnosis. (A) The reactivity towards HisRS-FL, WHEP, CD, ABD, and SV as conformational epitopes was



measured by ELISA in IgG purified from serum of 19 anti-Jo1+, 25 anti-Jo1-, and 24 healthy controls (HC). Higher reactivity corresponds to stronger blue color. (B) Anti-Jo1 reactivity against linear HisRS antigens was addressed by WB in IgG purified from serum of 12 anti-Jo1+, 1 anti-Jo1-, and 1 HC. Stronger band intensity denotes higher anti-Jo1 reactivity. Some patients also showed an additional band, correspondent to HisRS dimer. (C-D-E-F) Anti-Jo1 IgG and IgA reactivity in BALF and paired serum was measured by ELISA in 6 anti-Jo1+. Autoantibody levels were normalized to total values of IgG and IgA (Y-axis). Kruskal-Wallis (A) and Friedman's tests (C-D-E-F) corrected for multiple comparisons by Dunn's test was applied. $P<0.05$ was assumed as significantly different.

Reactivity of anti-Jo1 autoantibodies towards HisRS variants decreases over time but remains high against HisRS-FL. (A-B) Reactivity against HisRS-FL, -splice variants (WHEP and SV), and -domains (CD and ABD) displayed by total IgG purified from the first available anti-Jo1+ sera close to diagnosis (T = -0.25 – 0 years) and 2.1 – 3 years after diagnosis. (C-D-E) Anti-Jo1 reactivity of 3 anti-Jo1+ patients (P7, P6, P11) displayed by total IgG purified from sera collected longitudinally. Y-axis represents anti-Jo1 antibody levels against HisRS, measured in the total IgG isolated from anti-Jo1+ IIM/ASS sera. X-axis represents disease duration in years. Dark grey sentences provide information on rituximab introduction and/or follow-up on interstitial lung disease/arthritis. Concentration (ng/mL) of anti-Jo1 antibodies was calculated based on a standard curve derived from anti-Jo1 IgG isolated from a sera pool of 38 anti-Jo1+ IIM/ASS individuals. Total anti-Jo1+ IgG from different patients present distinct binding capacity to HisRS proteins (note the different scale which goes from 100, 200, 400 up to 1200 ng/mL). The letter P (Patient) followed by a number in each graph represents an anti-Jo1+ IIM/ASS individual.

IIM/ASS patients diagnosed with ILD and arthritis and less skin involvement harbor more reactive anti-Jo1 autoantibodies. (A-B-C-D-E-F) Percentage of IIM/ASS patients distributed according to anti-HisRS full-length (HisRS-FL) reactivity levels, clinical diagnosis and clinical manifestations. The anti-HisRS-FL reactivity displayed was measured in total anti-Jo1+ IgG purified from serum. Numbers on top of the bars represent the percentage of patients in the group. Jo1-, anti-Jo1 IIM/ASS negative patients; Jo1+ +, anti-Jo1 IIM/ASS positive patients with low to moderate



reactivity (0.52 – 72.59 ng/mL); Jo1+ ++, anti-Jo1 IIM/ASS positive patients with moderate to high HisRS reactivity (97.29 – 322.41 ng/mL). IIM, idiopathic inflammatory myopathies. ILD, interstitial lung disease; ASS, anti-synthetase syndrome.

Sex Differences in Antibody Profile, Phenotype, and Treatment Response in a Racially Diverse Population with Idiopathic Inflammatory Myopathies

Ana Valle[1], Jammie Law[2], Katherine Mullins[3] and Shereen Mahmood[4], [1]Albert Einstein College of Medicine, New York, NY, [2]Montefiore Medical Center, Bronx, NY, [3]Montefiore Medical Center, BROOKLYN, NY, [4]Albert Einstein College of Medicine / Montefiore Medical Center, Wantagh, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: It is established that autoimmune diseases are more common in females than males. Large scale idiopathic inflammatory myopathy (IIM) registries have shown a similar pattern of female predominance. However, inflammatory myopathies have a wide variability of clinical manifestations and it remains unclear if differences in prevalence leads to different phenotypes and thus, a different medication response, between males and females. We aim to compare differences in antibody profile, organ involvement, frequency of comorbidities, and treatment response between male and female patients with IIM.

Methods: A registry was created of Montefiore Medical Center patients that met 2017 EULAR/ACR classification criteria for IIM. Demographics, IIM subtype, clinical manifestations, comorbidities, and treatment history were documented. Interstitial lung disease (ILD) presence, progression, and severity were determined by CT and pulmonary function tests. Medication failure was defined by rheumatologist, discontinuation due to adverse effects, or medication change within 3 months. Medication control was defined by documented clinical improvement. Statistical analyses included Chi-square and Fisher's Exact test.

Results: The cohort consisted of 152 patients, of which 114 (75%) were women and 38 (25%) were men. 25% of cohort was of Latin ethnicity and races represented included African American (53%), Caucasian (34%), Asian (4%), and American Indian (2%).

The distribution of myositis exhibited was predominantly female, as expected, except IBM was more prevalent in males (27% vs 7%, p=0.008). Antibody profiles revealed men had increased frequency of NXP2 (21% vs 2%, p= 0.0443) while the rest of antibodies were similarly distributed between the sexes.

	Control	21/35 (60%)	6/18 (33%)	0.20
HCQ	Failure	12/44 (27%)	4/5 (80%)	0.034
	Control	32/44 (73%)	1/5 (20%)	0.034
Steroids	<2 years, <20 mg	35 (31%)	0 (0%)	0.0006
	<2 years, >20 mg	32 (28%)	9(24%)	0.65
	>2 years, <20 mg	36 (32%)	16 (42%)	0.34
	>2 years, >20 mg	4 (3%)	7 (18%)	0.003
	Never	6% (6%)	6 (16%)	0.08

Table 2. Differences in medication response and steroid exposure between males and females with IIM.

There were no significant sex differences in frequencies of DM skin manifestations, except the holster sign was not documented in men. Prevalence, severity, and progression of ILD were similar (Table 1). The frequency of neoplasms, HTN, HLD, and GERD were evenly distributed. However, 17 (19%) females patients had osteoporosis while only 1 (3%) male patient was had osteoporosis (p= 0.039). 29% of women had a single secondary autoimmune condition in comparison to 10% of men (p value = 0.0279).

Comparison of treatments revealed patients, regardless of sex, had less disease control with AZA and MTX, yet MMF and Rituximab had increase rates of control (Table 2). Men achieved less disease control with HCQ in comparison to women (p value =0.034). 35 (31%) of women had limited, low dose exposure to steroids while 0 (0%) of men were exposed to similar length and dosing of steroids (p value =0.0006). Yet, 18% of men had increased exposure to chronic, high dose steroids in comparison to 3% of women (p value= 0.003).

Conclusion: Although antibody profiles and clinical presentations between the sexes were similar, men had less disease control with MTX and were exposed to increased dose and length of steroid treatment. Women had shorter time and smaller dose exposure to steroids, yet steroid damage was still evident. This retrospective chart review was limited by small sample sizes but differing medication responses and prescriber patterns between sexes in IIM warrants further investigation.

Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of diseases characterized by muscle inflammation and internal organ involvement. The Bohan & Peter (B&P) criteria (1) have been widely used for both, diagnostic and classification criteria for IIM, up until recently, when newer classification criteria were developed by the European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) (2). These criteria are based on data from children and adults with different ethnicities from Europe, America and Asia, but the original study did not include patients from Latin America. We sought to determine the performance of the 2017 EULAR/ACR classification criteria for IIM in a cohort of Chilean patients in Latin America.

Methods: We performed a retrospective study of all patients from a tertiary referral medical center in Chile from 2014 to 2019 who had an associated ICD-10 code of M33 (dermatomyositis (DM)/polymyositis(PM)), M60.9 (myositis), and G72.4 (inflammatory myopathy). Demographic data, clinical and serological features were collected from medical records according to a pre-defined protocol in REDCap.(3) Patients were classified according to B&P criteria and 2017 EULAR/ACR classification criteria for IIM. Sensitivity, specificity, and Cohen's Kappa coefficient of agreement (κ) were calculated to assess the performance of the 2017 EULAR/ACR classification criteria when compared to B&P criteria.

Results: 150 patients were included in the study. Our cohort was 77% female, mean age was 43.2±22.6 years, 61% presented with heliotrope rash, 53% with Gottron papules, 61% with proximal muscle weakness, 64% patients had elevated CK (mean CK 3386±9391 U/L), 60% had positive ANA, 5% had a positive Jo-1 antibody. 42 patients had myositis-associated antibodies (MAA) and 37 patients had at least one myositis-specific antibody (ASM). Muscle biopsy was available in 58 patients, electromyography was available in 76 patients, and was suggestive of myositis in 38 patients. 139 patients met B&P criteria; 34 (24.5%) were classifiable as PM (12 patients definite, 9 probable, 13 possible) and 105 (75.5%) as DM (30 definite, 48 probable, 27 possible). 134 patients (89.3%) met EULAR/ACR criteria; 105 (78.4%) patients were classifiable as definite IIM, 27 (20.2%) patients as probable IIM, and 2 (1.5%) as possible. Subclassification of IIM was as follows: 22 (16.4%) patients were classified as juvenile DM, 51 (38%) as adult DM, 32 (23.9%) as amyopathic DM, 28 (21%) as PM, and 1 (0.75%) as inclusion body myositis. Sensitivity of EULAR/ACR criteria to detect IIM was 0.92, and specificity was 0.53 when compared to B&P criteria. Kappa coefficient of agreement was weak between the two classification criteria (0.39, SD 0.15-0.64). Sensitivity and specificity of

	Patients (N)	Sensitivity	Specificity
IIM	134	0.92	0.53
Dermatomyositis	105	0.92	0.82
Polymyositis	27	0.85	0.90

IIM= Idiopathic inflammatory myopathy

Table 1. Sensitivity and specificity of 2017 ACR/EULAR criteria for IIM

ACR/EULAR criteria to diagnose DM was 0.92 and 0.82, respectively. Sensitivity of ACR/EULAR criteria for PM was 0.85 and specificity was 0.9 (Table 1).

Conclusion: The current most accepted classification criteria for IIM have good sensitivity but low specificity in a Latin American cohort of patients. The new EULAR/ACR criteria performed well in this cohort to classify DM and PM correctly.

Mental component summary, mean (SD)	42 (15)	5

Legend: HAQ, Health Assessment Questionnaire; IQR, interquartile range; FACIT, Functional Assessment of Chronic Illness Therapy; PHQ-9, Patient Health Questionnaire; SD, standard deviation; VAS, visual analog scale.

Background/Purpose: Patient-reported outcomes (PROs) are increasingly used in rheumatology. Such outcomes are under-reported in autoimmune inflammatory myopathies (AIM) especially in incident cohorts. The objective of this study was to explore physical function, fatigue, depressive symptoms, sleep quality and health-related quality of life (HRQoL) in early AIM, and the effect of disease activity on those domains.

Methods: Cross-sectional study of adult AIM subjects with disease duration of ≤2 years enrolled in a multicenter research cohort. Standardized clinical histories, medical examinations, and self-administered questionnaires were collected at baseline visit. Physical functioning was assessed using the Health Assessment Questionnaire (HAQ; scores from 0 (no disability) to 3 (severe disability)). Fatigue was measured using the Functional Assessment of Chronic Illness Therapy (FACIT; scores from 0-52, lower scores representing more fatigue). Depressive symptoms were assessed using the Patient Health Questionnaire (PHQ-9; scores from 0-27, higher scores representing worse symptoms). The PROMIS Short Form v1.0 – Fatigue 8a and the Medical Outcomes Trust Short Form-36 (SF-36) were used to assess sleep quality and HRQoL, respectively. Both are norm based, with mean scores of 50 and standard deviations (SD) of 10 (PROMIS, higher scores representing worse sleep quality; SF-36, lower scores representing worse HRQoL). Disease activity was measured by the recruiting physician using a numerical rating scale ranging from 0 (no activity) to 10 (maximum severity). Multivariate linear regression models were generated to determine the association between disease activity and PROs.

Results: The study included 72 AIM subjects (71% female, mean age 53 years, mean disease duration 0.8 years) with dermatomyositis (49%), overlap myositis (47%) and immune-mediated necrotizing myopathies (4%) (Table 1). Half of the subjects had interstitial lung disease, 29% dysphagia and 19% arthritis. Baseline median (IQR) disease activity was 3 (2-5).

PRO results are presented in Table 2. Median (IQR) HAQ score was 1 (0.3-1.6) indicating moderate disability. Median (IQR) FACIT scores was 28 (19-40). Mean (SD) PROMIS score was 57 (10), indicating substantially worse sleep quality compared with the general population. Median (IQR) PHQ-9 score was 10 (6-16). The mean (SD) SF-36 physical and mental component summary scores were 1.5 SD (35 (11)) and almost 1 SD (42 (15)) below that of the general population, respectively. Multivariate linear regression analyses (Table 3) showed a statistically significant association between disease activity and worse physical functioning measured with the HAQ (β 0.17, 95%CI 0.09, 0.26), more

Table 3. Multivariate linear regression showing the effect of selected clinical variables on patient-reported outcomes in early disease

	Estimate (β)	95% CI	p-value
Physical disability (HAQ, median)			
Age	-0.0008	-0.01, 0.01	0.90
Female	0.33	-0.08, 0.73	0.12
Disease activity	0.17	0.09, 0.26	<0.001
Fatigue (FACIT, median)			
Age	0.18	-0.02, 0.39	0.08
Female	-1.98	-8.31, 4.35	0.53
Disease activity	-2.41	-3.81, -1.01	0.001
Sleep quality (PROMIS, mean t-score)			
Age	-0.12	-0.30, 0.05	0.15
Female	2.80	-2.49, 8.10	0.29
Disease activity	0.91	-0.24, 2.06	0.12
Depression (PHQ-9, median)			
Age	0.03	-0.11, 0.17	0.70
Female	2.60	-1.63, 6.78	0.23
Disease activity	-0.03	-0.95, 0.89	0.95
HRQoL – physical component (PCS, mean)			
Age	0.11	-0.09, 0.30	0.27
Female	-2.85	-8.62, 2.92	0.33
Disease activity	-1.77	-3.05, -0.48	0.008
HRQoL – mental component (MCS, mean)			
Age	0.22	-0.03, 0.48	0.08
Female	-3.60	-11.2, 4.01	0.35
Disease activity	-1.42	-3.11, 0.28	0.10

Legend: HAQ, Health Assessment Questionnaire; FACIT, Functional Assessment of Chronic Illness Therapy; PHQ-9, Patient Health Questionnaire, HRQoL, health-related quality of life; PCS, physical component summary; MCS, mental component summary; CI, confidence interval.

fatigue measured with the FACIT (β -2.41, 95%CI -3.81, -1.01) and impaired physical HRQoL measured with the SF-36 PCS (β -1.77, 95%CI -3.05, -0.48).

Conclusion: Early AIM subjects feel and function poorly. Impairments in PROs for which standards exist, in particular function, sleep quality and HRQoL, are large, in some cases exceeding 1 SD. There is a need to standardize fatigue and depressive measures to better understand those results. Further research into correlates of and trajectories in PROs in AIM are urgently needed.

Abstract Number: 1082

The Presence of Anti-Jo1, anti-PL7, And/or anti-MDA5 Antibodies in Idiopathic Inflammatory Myopathy Confers an Increased Risk of a Significant Restrictive Pulmonary Defect

Dmitriy Cherny[1] and Carrie Richardson[1], [1]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A subset of patients with idiopathic inflammatory myopathy develop significant restrictive lung disease, although risk factors for this are poorly defined. Autoantibodies may be important in defining risk. The primary purpose of this study is to identify clinical and serologic risk factors for development of significant restrictive pulmonary defects on pulmonary function testing in patients with idiopathic inflammatory myopathy.

Methods: We conducted a retrospective chart review of patients with diagnoses of dermatomyositis, polymyositis, and/or anti-synthetase syndrome with at least one pulmonary function test seen at Rush University Medical Center between January 1, 2010, and October 6th, 2019. We used ICD-9 and ICD-10 codes to identify study patients and confirmed the diagnoses via chart review. We extracted baseline demographic data, relevant disease features, smoking history, serologic data (hemoglobin, muscle enzymes, autoantibody profiles), chest CT reports, and pulmonary function data from the medical record. We compared patients with forced vital capacity (FVC) % predicted < 70 at any time during their clinical course to patients with FVC % predicted ≥ 70, using this cut point to define a significant restrictive defect. We used two-tailed Student's T-tests to compare continuous variables and Chi square tests (or Fisher's exact tests) for categorical variables. We used the exploratory analyses to select factors to include in a multivariable logistic regression to model the outcome of FVC% predicted < 70.

Table 2. Univariate and Multivariable Regression of Factors Predictive of FVC ever <70%

	Univariate Regression[1]		Multivariable Regression[2]	
Factor	OR (95% CI)	p-value	OR (95% CI)	p-value
Female sex	1.33 (0.48-3.67)	0.578	5.73 (0.68-8.64)	0.110
Age at first symptom, y	1.00 (1.00-1.00)	0.465	1.00 (0.99-1.01)	0.921
Disease duration since first symptom, y	0.95 (0.88-1.03)	0.204	0.88 (0.76-1.01)	0.075
Baseline CK	1.00 (1.00-1.00)	0.080	1.00 (1.00-1.00)	0.178
Ever smoker	1.00 (0.38-2.64)	1.00	0.48 (0.06-3.77)	0.487
Presence of: Jo1, MDA5, or PL7 antibodies	7.15 (1.93-26.5)	0.003	18.49 (2.13-160.76)	0.008

Abbreviation: CK = creatine kinase

1. Logistic regression was used with each individual factor as the predictor and FVC status as the outcome.
2. Significant factors were included in a multivariable logistic regression model as the predictors of FVC status.

Univariate and Multivariable Regression of Factors Predictive of FVC Ever <70%

Results: Eighty-eight patients met the inclusion/exclusion criteria. Of these, 50/88 (56.8%) patients had FVC% predicted ≥ 70 and 38/88 (43.2%) patients had FVC% predicted < 70. Patients' ages ranged from 28.0 to 56.7 years, 48/85 (56.5%) were African-American, and 45/88 (51.1%) had a primary diagnosis of dermatomyositis. Patients with FVC% predicted < 70 had a greater mean CK (4264.3 units/L vs. 1461.0 units/L; p= 0.0412) and were more likely to be positive for anti-Jo1 (4/35 [32.4%] vs. 4/35 [11.4%]; p=0.044), anti-MDA5 (7/17 [41.2%] vs. 3/19 [15.8%]; p=0.139), and anti-PL7 (4/17 [23.5%] vs. 1/20 [5.0%]; p= 0.159) antibodies. Multivariable logistic regression demonstrated that the presence of anti-Jo-1, anti-MDA5, and/or anti-PL-7 antibodies was independently associated with a significant restrictive pulmonary defect (OR 18.49 95% CI 2.13-160.76; p = 0.008).

Conclusion: The presence of anti-PL-7, anti-Jo1, and/or anti-MDA5 antibodies was associated with a nearly 19-fold increased risk of significant restrictive pulmonary defect in this cohort of patients with dermatomyositis and polymyositis. Patients with a significant restrictive defect had greater mean CK levels, but CK level was not an independent risk factor for a significant restrictive defect in multivariable analyses. Future studies should be conducted to validate these findings in an external cohort and to differentiate between restrictive pathology due to ILD and restrictive pathology due to muscle weakness.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by skeletal muscle and organ involvement and chronic course. Systemic inflammation, limited mobility, and glucocorticoid treatment can have a negative impact on intermediate metabolic pathways, especially on lipid metabolism. The aim of this study was to assess the differences in the lipid profile of IIM patients and healthy controls (HC) and the association with disease-specific features.

Methods: 133 patients with IIM (106 females; mean age 60.3; disease duration 2.2 years; DM 47 / PM 41 / IMNM 45) and 133 age-/sex-matched HC (106 females, mean age 60.2) without rheumatic diseases were included. Patients with DM and PM fulfilled the Bohan/Peter criteria for PM/DM and patients with IMNM fulfilled the ENMC criteria.

Table 1

Table 1: Baseline characteristics					
	IIM (n = 133)	DM (n = 47)	PM (n = 41)	IMNM (n = 45)	HC (n = 133)
Gender, n (%): female / male	106 (80) / 27 (20)	37 (79) / 10 (21)	34 (83) / 7 (17)	34 (76) / 11 (24)	106 (80) / 27 (20)

Table 1. Baseline characteristics

Levels of selected parameters of lipid metabolism were measured in sera drawn after 8 hours of fasting by routine analytic methods. In IIM patients, disease activity, and damage were evaluated by MITAX and MDI, muscle involvement by manual muscle testing (MMT-8), and comorbidities of interest and current treatment were recorded. Data are presented as median (IQR).

AI: BMI	0.209	0.021

Acronyms: TC, total cholesterol; TG, triglycerides; LDL-C, low-density lipoprotein; Apo-B, apolipoprotein B; non-HDL-C, non-high-density lipoprotein (TC minus measured HDL-C); HDL-C, high-density lipoprotein; Apo-A, apolipoprotein A; AI, atherogenic index of plasma = log(TG/ HDL-C); LD, lactate dehydrogenase; PED, current prednisolone equivalent dose; CK, creatine kinase; BMI, body mass index; MMT-8, manual muscle testing-8; CRP, C-reactive protein

Table 3. Correlation of lipid profile parameters and disease-specific features in all IIM patients (n=133)

Results: Several differences in disease activity, the dose of glucocorticoids, prevalence of comorbidities, and serum lipid levels were observed among the three subtypes of IIM (Table 1). Lipid profile parameters, especially levels of negative cardiovascular predictive markers such as TC, TG, LDL-C, Apo-B, and the atherogenic index, were significantly higher compared to healthy controls. The most significant changes were observed in the IMNM group (compared to the corresponding age-/sex-matched HC) (Table 2). Levels of TC, TG, LDL-C, apo-B and nonHDL negatively correlated with disease duration, but positively with laboratory markers of disease activity and the current prednisolone equivalent dose. Higher levels of HDL-C were associated with decreased levels of CRP, which is in line with the negative correlation of apo-A levels with CRP, CK, and myoglobin (Table 3).

Conclusion: We have observed significant alterations in serum lipid parameters in our IIM patients compared to healthy age-/sex-matched individuals. Differences were also found among the three subtypes of IIM. These alterations were associated with laboratory parameters of disease activity and the current dose of corticosteroids. **Acknowledgement:** Supported by AZV NV18-01-00161A, MHCR-00023728, SVV-260373, and GAUK-312218.

Consumer-based Activity Trackers in Evaluation of Physical Function in Myositis Patients

Didem Saygin[1], Bonny Rockette-Wagner[2], Chester Oddis[3], Diane Koontz[1], Siamak Moghadam-Kia[1] and Rohit Aggarwal[2], [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Department of Medicine, Division of Rheumatology, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies are systemic inflammatory conditions characterized by muscle weakness and reduced muscle endurance that limit activities of daily living. Daily step count is an accepted metric of physical activity used in many population studies. Wearable technologies enable tracking of daily step counts longitudinally. The Actigraph is an FDA-approved triaxial accelerometer and tracks step count with high accuracy. It is used for research and not commercially available. Fitbit also measures step counts and is the most widely used consumer-based activity tracker with nearly 30 million users and many studies have validated Fitbit step counts compared to accelerometers. Given the need for objective measures of physical activity in myositis patients and broad availability of Fitbit, we assessed the reliability, validity and responsiveness of Fitbit in evaluating physical function in myositis patients and compared the accuracy of Fitbit step counts to the Actigraph.

Methods: This was a prospective longitudinal observational study with 3-visits at 0, 3-, and 6-months in polymyositis (PM), dermatomyositis (DM), necrotizing myopathy (NM) or anti-synthetase syndrome (AS) subjects. Six myositis core set measures [manual muscle testing (MMT), physician global disease activity (MD-GDA), patient global disease activity (PT-GDA), extra-muscular global disease activity (EM-GDA), HAQ-DI and creatine kinase (CK)], three functional measures [six-minute walk (6MWD), timed up-and-go (TUG) and sit-to-stand tests (STS)] and SF-36 physical function-10 (PF10) were collected at each visit. Total improvement score (TIS) was used as a measure of clinical response. Patients used a waist-worn Fitbit One and ActiGraph T3X-BT concurrently for 7 days/month for 6 consecutive months with a "valid day" defined as requiring ≥1500 steps.

Results: Twenty-four (10 DM, 8 PM/NM and 6 AS without myositis) patients (17 females/7 males; 91% Caucasian) were enrolled. Test-retest reliability of daily step count was strong in patients who had 1-month follow-up (r:0.84, ICC 0.89). Daily step count showed moderate-strong correlations with MD-GDA, PT-GDA, HAQ-DI, SF-36 PF10 and all

	Average daily step count

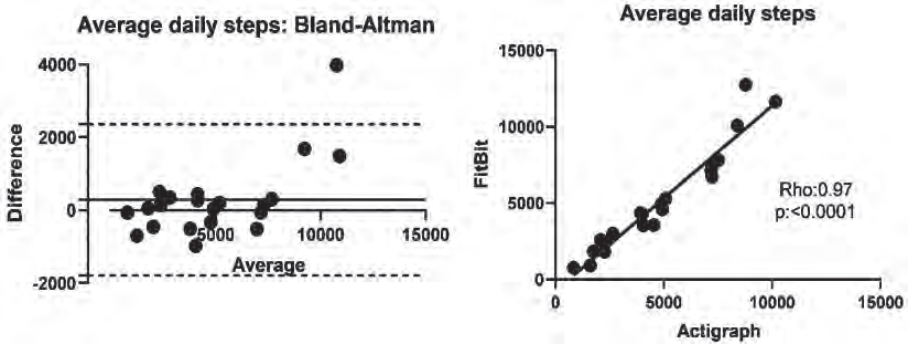
Correlations of Fitbit average daily steps and demographics, myositis outcome measures, and task-oriented functional tests.



Agreement (Bland-Altman plot) and correlation (scatter plot) between FitBit and Actigraph measured average daily steps in patients wearing both devices at the same time for the same duration.

three functional tests supporting convergent validity (Table 1). Patients with inactive muscle disease had 49% higher daily step count than patients with active myositis. Fitbit and Actigraph demonstrated excellent agreement and strong correlation (Rho:0.97, ICC 0.96; Figure 1). Fitbit overestimated the daily step count in two-thirds of the patients with a median of 6.8% (3.8-14.6). The absolute change in daily steps at 6 months correlated moderately-strongly with absolute changes in MD-GDA, TIS and 6MWD.

Conclusion: Fitbit measured daily step counts are a reliable and valid measure of physical activity in a cohort of myositis patients. Daily step counts measured by Fitbit and Actigraph are in strong agreement with a slight overestimation by Fitbit. This pilot data suggests that Fitbit daily step counts have a potential to be used in clinical practice and trials to monitor physical activity in myositis patients, but larger studies are needed for further validation.

Table 1. Correlation of pain by VAS with myositis disease activity, functional and patient-reported outcomes at baseline and longitudinal change at 6 months.

Background/Purpose: Pain in myositis is poorly studied and multifactorial relating to muscle weakness, arthritis, myofasciitis, fibromyalgia or other co-morbidities. We sought to prospectively evaluate patient-reported pain, cross-sectionally and longitudinally in association with the collection of myositis core set measures of disease activity, patient reported and functional measures.

Methods: In a prospective, longitudinal observational study, we enrolled 50 myositis patients [dermatomyositis (DM), polymyositis (PM), necrotizing myositis (NM), and anti-synthetase syndrome (AS)] from February 2016 to April 2018. Patients with fibromyalgia and severe arthritis (except from myositis) were excluded. All subjects had a baseline and 6-month visit, where all myositis core set measures (CSM) [muscle enzymes, manual muscle testing (MMT-9), patient and physician (MD) global disease activity, extra-muscular disease activity and HAQ-DI], functional measures [Timed up and go (TUS), Sit to Stand (STS), 6 Minute Walk Distance (6-MWD)] and patient-reported outcomes [PROMIS-physical function (PF) and SF-36] were evaluated. Further, a standard 10 cm visual analogue scale(VAS) for pain and fatigue were recorded at both visits. A score between 0-3 was considered mild, >3-7 moderate, and >7-10 as severe pain. The phenotypic and disease activity measures of the cohort were correlated with pain (Spearman) at baseline visit. Longitudinal changes in pain at 6 months were correlated with the CSM and the functional and patient-reported outcomes. The change in pain was also evaluated if it improves with the published 2016 ACR/EULAR myositis response criteria graded as no, minimal, moderate or major improvement and the MD and patient global assessment of change. Strength of correlation was defined as weak (0.1-0.29), moderate (0.3-0.49) or strong (≥0.5).

Results: Twenty-four patients had DM, 9 NM, 6 PM and 11 AS with a mean age, 51.6 (±14.9) with 60% (n=30) females. The mean (SD) of pain was 2.7 (2.6), with 55.1% having mild pain, 40.8 % moderate pain and 4.08% severe pain at baseline. There was no significant difference in pain by disease subsets (DM vs. non-DM), autoantibody status, age at diagnosis or enrollment, or BMI. Pain was associated with having muscle weakness (MMT), disease duration and showed trends for association with active disease (as per MD) and female gender. At baseline, pain showed a strong correlation with fatigue, patient-reported disease activity, HAQ-DI, PROMIS PF, SF36 and aldolase and a moderate correlation with muscle weakness (MMT), MD global disease activity and 6MWD. Longitudinal analyses suggested that changes in pain showed a moderate to strong correlation with MD global disease activity, patient-reported disease activity, fatigue, SF36 and functional measures (TUG and STS). Pain improved significantly

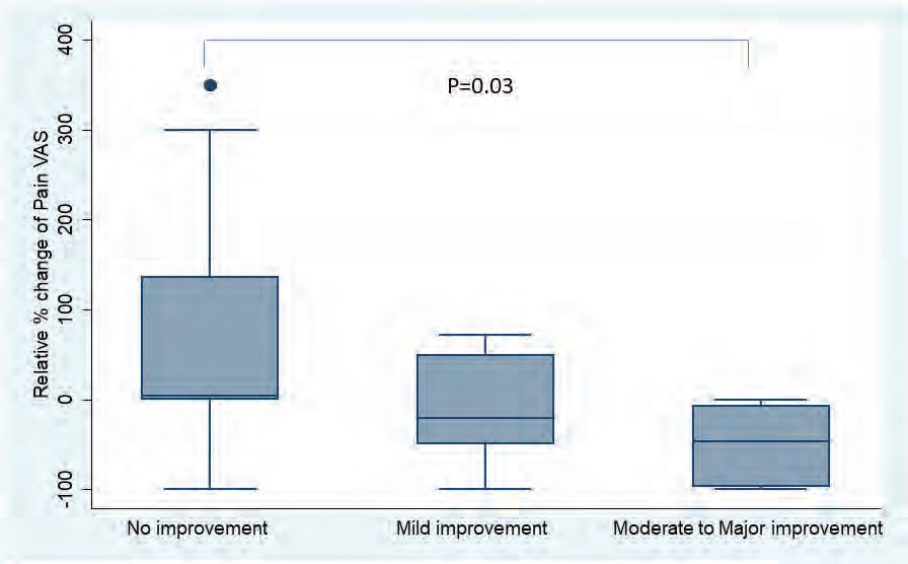

Figure 1. Relative percent change in VAS pain scores related to the ACR-EULAR myositis response criteria.

in patients with a moderate to major improvement, and similar non-significant trends were seen for the physician and patient reported change.

Conclusion: Pain in myositis is typically of mild to moderate severity and is moderately associated with the CSM and improves over time particularly in subjects demonstrating a moderate to major clinical response in published outcome metrics.

Abstract Number: 1086

The Diagnostic Value and Clinical Significance of Myositis-Specific Antibodies in Patients Suspected to Have Autoimmune Myopathies and/or Autoimmune Rheumatic Diseases

Sarah El Chami[1], Christopher Williams[1], Ghaith Noaiseh[1], Amrita Bath[1] and Duaa Jabari[1], [1]The University of Kansas Health System, Kansas city, KS

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis-specific antibodies (MSA) are thought to be highly specific in patients with idiopathic inflammatory myopathies.[1] However, in clinical practice these antibodies are frequently found in the absence of autoimmune myopathy which may lead at times to unnecessary interventions and treatments. We sought to determine the frequency of final clinical diagnoses, including autoimmune myopathy, in patients tested positive for one or more MSA.

Methods: We conducted a retrospective chart review on patients with documentation of MSA testing from November 1, 2007 to December 31, 2019 in our academic center.

Data extracted included clinical variables (myalgias, muscle weakness, interstitial lung disease (ILD) and history of malignancy within 3 years of positive antibody test) and laboratory tests including anti-nuclear antibodies and creatine kinase. Electromyographic testing and skeletal muscle biopsy studies were reviewed. Patients with a neuromuscular or autoimmune rheumatologic diagnosis were identified. A neuromuscular specialist determined the presence or absence of an autoimmune myopathy based on CK level, weakness, EMG and muscle biopsy findings when available. Frequency of associated clinical diagnoses in patients with positive MSA were calculated. In addition, we reviewed the frequency of certain clinical diagnoses specifically with anti-synthetase antibodies.

Results: We identified 47 subjects with positive MSA. Thirty-three (70%) were females. Thirty-four (72%) were Caucasian. Only 16 out of 47 subjects (34%) with positive MSA had an autoimmune myopathy. Among subjects with positive MSA but no autoimmune myopathy (n=31), 26 (83.8%) had ILD and/or a rheumatologic diagnosis and 5 (16.1%) had neither. In patients with autoimmune myopathy (n=16), there was an overlap with ILD and/or rheumatologic diagnosis in 5 patients (31.25%). Of all subjects with positive MSA (n=47), 31 (65.9%) had a rheumatologic diagnosis

Positive myositis specific antibody	Number of patients (n = 47)
With autoimmune myopathy n= 16	
Autoimmune myopathy alone	11 (68.75)
Autoimmune myopathy + ILD	2 (12.5%)
Autoimmune myopathy + Rheumatologic diagnosis	1 (6.25%)
Autoimmune myopathy + both ILD and rheumatologic diagnosis	2 (12.5%)
Without autoimmune myopathy n= 31	
ILD alone	5 (16.1%)
Rheumatologic diagnosis alone	7 (22.5%)
Both ILD and Rheumatologic diagnosis	14 (45.1%)
Patient with no ILD or rheumatologic diagnosis	5 (16.1%)

Positive myositis-specific antibodies in comparison to clinical diagnoses

and/or ILD. Five (10.6%) did not have a rheumatologic diagnosis, autoimmune myopathy or ILD. Anti-synthetase antibodies were found in 19 subjects. These antibodies were associated with autoimmune myopathy in 7 subjects (36.8%). Anti-synthetase syndrome was diagnosed in only 5 (26.3%) with positive anti-synthetase antibodies while a rheumatologic diagnosis was present in 12 (63.1%). Among patients with positive anti-synthetase antibodies and autoimmune myopathy (n=7), perimysial pathology on muscle biopsy was found in 4 (57.1%).

Conclusion: Despite the reported specificity of MSA for the diagnosis of autoimmune myopathy, we observed that most MSA positive subjects in our cohort did not have this diagnosis. We also found that rheumatologic diagnoses and ILD were frequently found in patients with positive MSA with or without autoimmune myopathy. Similarly, anti-synthetase antibodies did not necessarily indicate the presence of anti-synthetase syndrome or autoimmune myopathy.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is an acquired inflammatory myopathy characterized by chronic skin inflammation. The pathogenesis of DM is still unclear. Extracellular vesicles (EVs) are lipid bilayer membrane vesicles existing in various bodily fluids and implicated in the pathogenesis of autoimmune diseases. As type I interferons, specifically IFN-b, are uniquely elevated in DM, and Stimulator of interferon genes (STING) works as a critical sensor and adaptor in type I IFN signaling, we hypothesized that EVs derived from DM patients' plasma might trigger STING-mediated proinflammatory effects.

Methods: DM patients were recruited in the dermatology clinic at University of Pennsylvania. Peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll gradient. EVs derived from plasma were isolated via ultracentrifugation. The supernatant was harvested for ELISA and the lysed cells were collected for Western blot after HC-derived PBMCs were stimulated by EVs.

Results: Here we found that DM patients' plasma derived EVs triggered cytokine release (IFNb: (30.24±0.65) vs control (2.683±0.35); TNFα: (1451±98.40) vs control (16.75±1.407); IL6: (945.0±57.40) vs control (0.0±0.0)pg/mL; n=6) with STING phosphorylation. Inhibition of STING significantly attenuated DM patients' plasma-derived EVs-triggered cytokine production (IFNb: (21.58±2.22) vs (28.34±1.73); TNFα: (434.8±94.50) vs (919.1±133.0); IL6: (611.5±54.22) vs (844.2±73.60)pg/mL; n=6) via suppressing STING and its down-stream signal TBK1, IRF3, and NFκB phosphorylation. Besides, TBK1 inhibitors Amlexanox and MRT67307 also suppressed DM patients' plasma derived EVs-induced IFNb release by inhibiting TBK1 phosphorylation. To further explore whether STING signaling pathway activation and the proinflammatory effects were caused by EVs-captured dsDNA, EVs were pretreated with Triton X-100 and DNase I to digest DNA. Triton X-100 and DNase pretreatment decreased EVs-triggered cytokine release (IFNb: (4.113±2.08) vs (28.94±5.473); TNFα: (19.00±19.00) vs (1361±293.6); IL6: (210.7±103.6) vs (1020±43.86)pg/mL; n=3-6) and STING activation. To specifically digest dsDNA, EVs were also pretreated with dsDNase. Triton X-100 and dsDNase pretreatment also decreased EVs-triggered cytokine release (IFNb: (1.893±1.893) vs (28.94±5.473); TNFα: (290.3±57.03) vs (1361±293.6); IL6: (617.6±127.4) vs (1020±43.86)pg/mL; n=3-6) and STING activation..

Conclusion: EVs derived from plasma trigger STING-mediated proinflammatory effects in DM. The STING signaling pathway is activated during EVs triggering of proinflammatory effects and was at least partially mediated by dsDNA captured by EVs. Targeting STING pathway might provide insight into a potential therapeutic approach for DM.

Recruitment Rates of Virtual Remote Research (Tele-Research) in Myositis

Siamak Moghadam-Kia[1], Chester Oddis[2], Swamy Venturupalli[3], Shalini Mahajan[4], Daphne Scaramangas Plumley[5], Dana Ascherman[6], Nicole Neiman[7], Faith Onelangsy[7], Diane Koontz[1], Kim Goldby-Reffner[7], Sedin Dzanco[7], Lei Zhu[6] and Rohit Aggarwal[6], [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]Department of Medicine, Division of Rheumatology, University of Pittsburgh, Pittsburgh, PA, [3]Cedars Sinai Medical Center, Los Angeles, [4]Attune Health, Los Angeles, [5]Attune Health, Los Angeles, CA, [6]University of Pittsburgh, Pittsburgh, PA, [7]UPMC, Pittsburgh

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a paucity of randomized, controlled clinical trials in myositis. Subject enrollment and retention in clinical trials for this rare, heterogeneous disease has always been a major challenge. There is an urgent need for innovative recruitment and clinical trial strategies including a virtual and remote approach. Our aim was to compare the effectiveness of recruitment, enrollment and retention of a traditional center-based cohort (CBC) to a novel remote tele-research cohort (TRC) using state-of-the-art tele-medicine, wearable devices and mobile app.

Methods: The TRC was recruited remotely across the U.S. using a mobile app/website while the CBC was derived from two myositis centers in a prospective observational myositis study. Subjects in both cohorts were followed concurrently and longitudinally for 6 months using the same protocol including inclusion criteria, study visits and data collection. However, the TRC and CBC had 2 different recruitment methodologies: online/social media recruitment in the TRC with the help of myositis patient support organizations (The Myositis Association, Myositis Support & Understanding) vs. traditional clinic-based recruitment in the CBC which included directly approaching myositis clinic patients or traditional advertisement to local/regional subspecialists. Study visits included a baseline and 6-month physician evaluation conducted through telemedicine in the TRC with monthly patient-driven data collection through a mobile app/website. Conversely, the CBC utilized conventional in person clinic visits and monthly data collection on

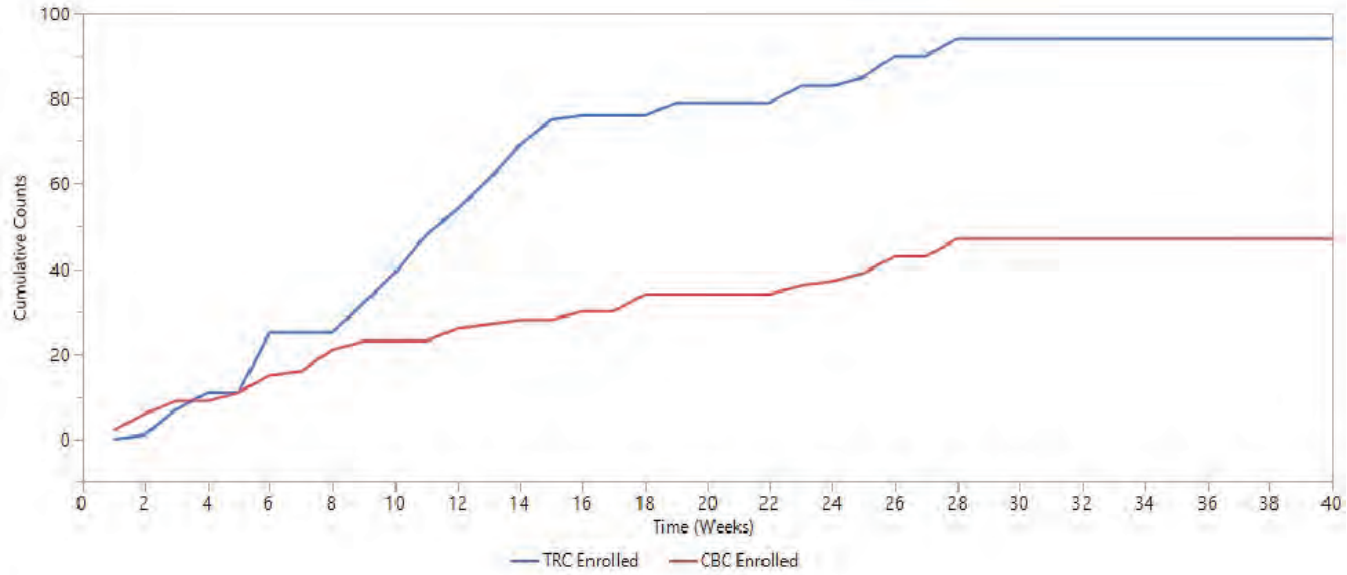
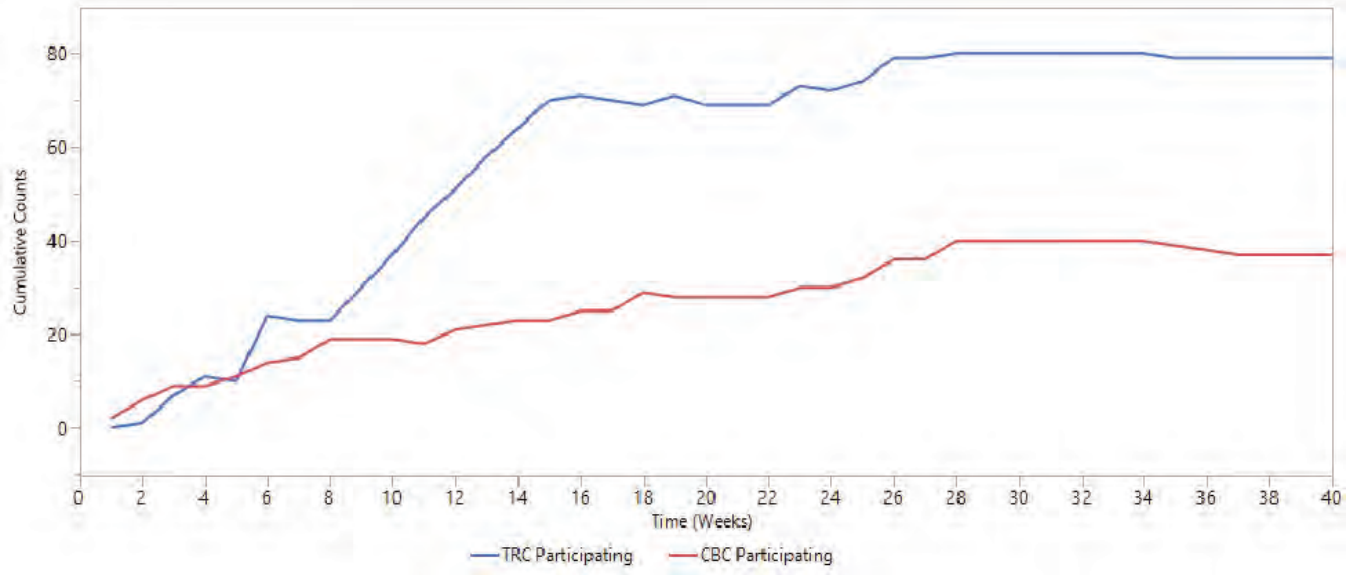
C.



D.



(A) Pre-screening, (B) screen, (C) enrollment, and (D) active participation rates in the TRC vs. CBC

paper forms or Tablets. The rates and success of prescreening, screening, enrollment and retention were compared between 2 parallel cohorts with competitive enrollment using time to event, t-test and Chi-square analysis.

Results: The TRC enrolled 94 subjects compared to only 47 in the CBC during the recruitment period of 40 weeks. Demographics and disease in both cohorts were similar (Table 1). In the TRC, 700 subjects completed prescreening on the app or website, and 626 (81%) met preliminary eligibility. In comparison, 205 patients were approached for prescreening in the CBC but only 60 agreed to undergo prescreening of which 56 (93.3%) met preliminary eligibility. During the enrollment process, 120 TRC participants were screened by physician review of medical records lead-

Demographics and Disease subsets	Tele-Research Cohort (TRC)	Center Based Cohort (CBC)
Gender (Female %)	76%	70%
Race (Caucasians %)	87%	79%
Age range	25-78	25-80
Mean (SD) age	54.5 (13.9)	56.9 (12.5)
Disease subset		
Dermatomyositis	52.3%	53.8%
Polymyositis	39.8%	35.8%
Necrotizing Myopathy	7.9%	10.3%

Table 1. Demographics and disease subsets in both tele-research cohort (TRC) and center based cohort (CBC).

ing to 94 (78%) being enrolled, while only 54 CBC subjects underwent screening and 47 (87%) were enrolled. The cumulative number and rate of prescreening, screening and enrollment was faster and 2-3 folds higher in the TRC compared to CBC over the same recruitment period (Figure 1). Prescreen to preliminary eligibility as well as screen failure rates were similar in both cohorts. Retention rates were similar in both cohorts, with only 14 (15%) drop outs in the TRC vs. 7 (15%) in the CBC.

Conclusion: Recruitment and enrollment for a virtual TRC was far superior to a traditional center-based approach, with similar screen failure and retention rates in this observational study. Further, the TRC recruitment techniques using social media and online approaches for a virtual TRC were surprisingly efficient and should be considered for rare diseases such as myositis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have reduced physical activity and frequently complain of fatigue. Exercise reduces fatigue in patients with SLE; however, the mechanism of the exercise-induced reduction in fatigue is unknown. Exercise also improves muscle quality, particularly by reducing intermuscular adipose tissue (IMAT). To date, no study has evaluated the presence of IMAT in patients with SLE. Thus,

Table 1.

Participant Characteristics

Parameter	Controls	SLE	p-value
Age	35 (26, 58)	38 (31, 54)	0.78
Sex (Female), N (%)	24 (85.7)	20 (87)	0.61
Race (African American), N (%)	6 (21.4)	5 (21.7)	0.52
BMI	22.7 (22.4, 23.8)	26.2 (22.9, 31.7)	0.16
Creatinine	0.74 (0.65, 0.81)	0.79 (0.63, 0.93)	0.99
History of hypertension, N (%)	2 (7.1)	8 (34.8)	0.02
History of diabetes, N (%)	0 (0)	1 (2)	0.45

BMI, body mass index; PR, patient-reported

Table 1

in this study, we hypothesize that IMAT is increased in patients with SLE, and it is associated with patient-reported physical activity and fatigue.

Methods: In a cross-sectional study, we evaluated 51 participants (23 patients with SLE and 28 controls). IMAT was evaluated in the calf muscles using sequential T1-weighted and Dixon magnetic resonance images (MRI). Patient-reported physical activity and fatigue were evaluated using visual analog scales.

Results: Patients with SLE and controls were similar in terms of age, sex, race, body mass index (BMI), and renal function (Table 1). Corticosteroid and antihypertensive medication use was higher in patients with SLE than in controls. IMAT accumulation, expressed as the ratio of IMAT area to total muscle size, was significantly higher in patients with SLE than in controls (7.92%, 4.51-13.39%, *vs.* 2.65%, 1.15-4.61%, median, IQR, p< 0.001, Figure 1). These differences between the groups remained significant after adjustment for age, race, and BMI. Corticosteroid use may affect the accumulation of IMAT, however, in patients with SLE IMAT accumulation did not differ significantly among corticosteroid users and non users p=0.48. Patient-reported fatigue and physical activity were higher and lower, respectively, in patients with SLE than in controls (Table 1). IMAT was positively correlated with patient-reported fatigue (rho=0.52, p< 0.001) and inversely correlated with patient-reported walking distance (rho=-0.60, p< 0.001). Physical

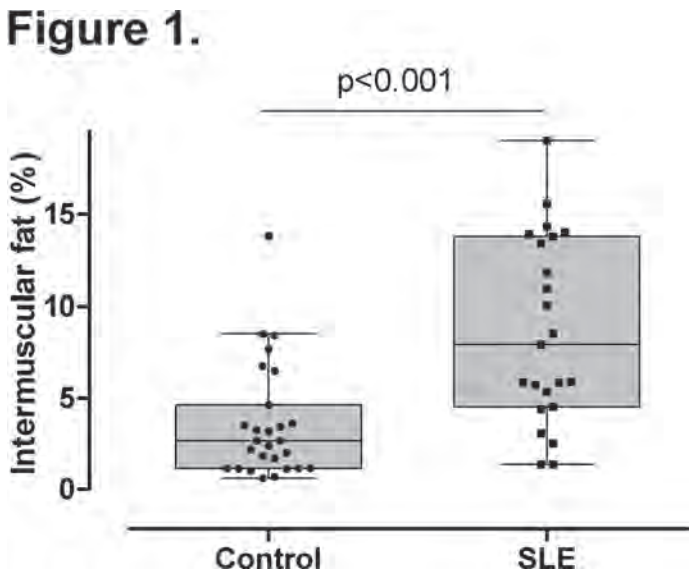

Figure 1

activity may affect IMAT accumulation, however, the difference in IMAT between controls and patients with SLE remains significant after adjusting for the reported physical activity (p=0.015).

Conclusion: Patients with SLE have greater IMAT accumulation than controls. Increased IMAT is associated with greater fatigue and lower physical activity. Future studies should evaluate the effectiveness of interventions that improve muscle quality to alleviate fatigue in patients with SLE.

Abstract Number: 1090

Abnormal HDL Antioxidant Function Is Associated with Longitudinal Change in Lung Physiology in Dermatomyositis/Polymyositis Associated Lung Disease

Sangmee Bae[1], Jennifer Wang[1], Ani Shahbazian[2] and Christina Charles-Schoeman[2], [1]University of California Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of death in patients with dermatomyositis (DM) and polymyositis (PM). We previously reported abnormal anti-oxidant function of HDL in DM/PM patients with ILD, which was associated with higher levels of oxidized fatty acids in HDL and worse lung function. The current project aimed to evaluate the predictive value of baseline HDL antioxidant function for change in lung physiology on longitudinal follow-up in DM/PM patients.

Methods: To determine the anti-oxidant capacity of HDL, the change in fluorescence intensity as a result of the oxidation of 2',7'-dichlorodihydrofluorescein diacetate to 2',7'-dichlorofluorescein in incubations with a standard LDL in the absence or presence of the patient HDL was assessed and the HDL inflammatory index (HII) calculated (*Arthritis Rheum 60(10):2870-9,2009*). Change in forced vital capacity (Δ FVC) at the follow-up visit was calculated as the difference between most recent and baseline FVC divided by baseline FVC. Linear regression models of baseline DM/PM clinical characteristics with ΔFVC as the outcomewere constructed in the total DM/PM group and in patients only with DM/PM-ILD; all models were adjusted for time between baseline and follow-up FVC assessment. Multivariate linear regression analysis examining an association of HII with ΔFVC included other clinical variables that were significantly associated with ΔFVC in univariate analysis.

Results: A total of 45 DM/PM patients with baseline HII assessments and follow-up FVC measurements were included in the study (Table 1). Mean (SD) follow up time between PFTs was 37(31) months. In univariate analysis, a higher baseline HII consistent with worse antioxidant function of HDL was associated with improvement in FVC over the follow-up period. In addition, baseline higher daily prednisone dose, fewer steroid sparing agents, the absence of mycophenolate use, and lower FVC and TLC were associated with greater improvement in FVC (Table 1). Higher baseline HII remained significantly associated with greater ΔFVC over time after multivariate adjustment.

TLC was not included as it was colinear with FVC, Mycophenolate use was not included as it was colinear with # of steroid sparing agents

Conclusion: Abnormal antioxidant function of HDL is associated with changes in lung physiology over time. We hypothesize that a higher baseline HII may identify patients with active, reversible lung disease that may be more likely to improve with treatment over time. Further studies are needed to determine the consequences of abnormal antioxidant function of HDL to the progression of DM/PM associated lung disease.

Abstract Number: 1091

A Computer-Aided Diagnostic System for Quantitative Scoring of Extent of Interstitial Lung Disease (ILD) in Dermatomyositis/Polymyositis Associated ILD

Sangmee Bae[1], Andrea Oh[2], Grace Kim[3], Jonathan Goldin[3] and Christina Charles-Schoeman[4], [1]University of California Los Angeles, Los Angeles, CA, [2]National Jewish Health, Denver, CO, [3]University of California, Los Angeles, Los Angeles, [4]University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) occurs in up to 80% of patients with dermatomyositis (DM) and polymyositis (PM), and is a leading cause of morbidity and mortality (Lung. 2016;194(5):733-737). The current study validates the use of a computer aided diagnostic system to quantitatively score ILD on high-resolution computed tomography (HRCT) scans (Clin Exp Rheumatol 2010;28, S26-35) in a cohort of DM/PM patients. The predictive value of the baseline quantitative ILD score on change in lung function at follow-up is also examined.

Methods: HRCT images were retrospectively analyzed from DM/PM patients in our longitudinal myositis cohort who had thin-section, full inspiration images available for review. The QILD is the sum of all abnormally classified scores, which include quantitative scores for reticulations/fibrosis (QLF) and ground glass opacity (QGG). Quantitative ILD scores (QGG, QLF, QILD) were assessed for whole lung, and for zone of maximum involvement. Linear regression models were constructed in patients with DM/PM associated ILD, as well as in total DM/PM patients with QILD scores to evaluate the association between baseline variables including QILD scores and the relative change in forced vital capacity (FVC) at the follow-up visit. Change in FVC was calculated as the difference between most recent and baseline FVC divided by baseline FVC. Mean (SD) follow-up time between PFTs was 37(31) months.

Results: A total of 72 DM/PM patients with baseline and follow-up HRCT scans were included in the analysis. Quantitative ILD scores showed predominance of ground glass rather than fibrosis with most of the involvement in lower lung zones, consistent with nonspecific interstitial pneumonia (NSIP) pattern. The quantitative ILD scores (QGG, QLF, QILD) demonstrated good concordance with lung physiology (FVC, TLC and DLCO) (correlation coefficient between -0.41 to -0.70, $p < 0.001$ for all). When analyzed by myositis autoantibody subgroups, patients with antisynthetase and anti-MDA5 antibodies had the highest fibrosis score (QLF) and total ILD score (QILD) (Table 1).

Linear regression models demonstrated that higher baseline quantitative ILD scores were associated with greater improvement in FVC at follow-up (Table 2). These relationships remained strong after multivariate adjustment of oth-

Baseline FVC	-	-	-	-	-	-	**-0.70**	**0.001**
R^2	0.33		0.48		0.41		0.43	

er baseline variables including baseline daily prednisone dose and number of steroid sparing agents (Table 3). The predictive value of QLF, QILD models assessed by R^2 was comparable to the model using baseline FVC, suggesting quantitative ILD scores may be used as a quantitative outcome measure for DM/PM-ILD severity.

Conclusion: Quantitative ILD scores can provide an objective quantitative tool for assessing ILD severity in DM/PM-ILD and are associated with clinically meaningful longitudinal outcomes.

NMR-Based Serum Metabolomics, Is It Different in Clinico-Serological Clusters of Idiopathic Inflammatory Myositis?

Naveen R[1], Anupam Guleria[2], Dinesh Kumar[2], Umesh Kumar[2], Anamika Anuja[1], Vikas Agarwal[3] and Latika Gupta[4], [1]Sanjay Gandhi Post graduate institute of medical sciences, Lucknow, Uttar Pradesh, India, [2]Centre of Biomedical Research, Sanjay Gandhi post graduate institute of medical sciences, Lucknow, Uttar Pradesh, India, [3]Sanjay Gandhi Post Graduate Institute of Medical Sciences, LUCKNOW, India, [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myositis (IIM) are rare and heterogenous. Myositis specific antibodies (MSA) show mutual exclusivity and identify specific clinical phenotypes[1]. Most biomarker studies are limited by the number of patients of individual phenotypes. Since serum metabolomics can distinguish active from inactive myositis[2,3], we determined if the serum metabolomic profile is distinctive in clinical and antibody-based phenotypes.

Methods: Sera (n=116) from IIM (ACR-EULAR criteria, 34 years (23.5 - 50.5 IQR), M/F 28:88] were compared with healthy controls [n=18, age= 44 (35-50) years, M/F-8:10]. Clinical phenotypes were defined as previously described[4] and antibody by presence of MSA and MAAs. In addition, those with 3 of 5 ASSD features were labelled as clinical ASSD for analysis.

Metabolic profiles were obtained at 800 MHZ NMR spectrometer and compared using multivariate partial least-squares discriminant analysis (PLS-DA). The discriminatory metabolites were identified based on variable importance in projection (VIP) statistics and further evaluated for statistical significance (p-value < 0.05). Metaboanalyst® was used for analysis.

Results: Serum metabolites were no different based on clinical diagnosis (Figure 1a) or in those with ILD, arthritis, bulbar weakness, amyopathic presentation and skin rashes (Gottron's, heliotrope, mechanic's hands, cutaneous ulcers and photosensitivity,) than individuals without these (Figure 1b-e). IIM with a clinical ASSD without ARS was similar to ARS group (Figure 1f). Metabolome clusters defined by distinct MSAs also exhibited significant overlap (Figure 2a-e). The presence and absence of MAA (Figure 2f) and ANA (Figure 2b) were not discriminative in the metabolome.

Conclusion: Serum metabolome does not reflect change with clinico-serologic phenotype in IIM, suggesting distinctive value as biomarker of disease activity uninfluenced by heterogeneity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sporadic inclusion body myositis (sIBM) is clinically characterised by marked progressive muscle weakness and impaired physical function. Physical training has become an area of interest with the aim of mitigating or circumventing the progressive decline in functional capacity, as immunosuppressive medication has shown little effect in sIBM patients. Low-load blood flow restricted (BFR) exercise has been shown to upregulate skeletal muscle stem cells (satellite cells) and evoke gains in myofiber cross sectional area. In addition, satellite cells appear to play an important role supporting myofiber hypertrophy through myonuclei addition and myofiber regeneration.

Consequently, the present study aimed to investigate the effect of BFR strength training on satellite cell content, myofiber hypertrophy and myogenic signalling markers in lower limb skeletal muscle of sIBM patients.

Methods: Muscle biopsies from a previous randomised control trial (NCT02317094) in sIBM patients performing 12-weeks of low-load blood flow restricted exercise were used. 11 patients (age: 67.5 + 6.5, months from diagnosis: 57.8 + 87.7) were included from the exercise group (BFRE) and 10 patients (age: 69.2 + 4.6, months from diagnosis: 46.6 + 27.2) from the control group (CON). Muscle biopsies were obtained from either the m. tibialis anterior or the m. vastus lateralis and were stained for Pax7, CD31, SIX1, KI67 and DAPI, which were visualized by using three-color immunofluorescence microscopy. Visiopharm-based image analysis quantification was used for assessing the amount of Pax7, CD31, SIX1, KI67 and DAPI positive cells. Myofiber cross sectional area was assessed in a separate analysis. A linear mixed model was used for the statistical analysis.

Results: Satellite cells ($Pax7^+$) including newly proliferated satellite cells ($Ki67^+/Pax7^+$) remained unaltered following the intervention period in both BFRE and CON. Likewise, total myonuclei content ($SIX1^+DAPI^+$) and capillaries ($CD31^+$) did not change in BFRE or CON. A group (intervention) by time interaction was observed in type 2 fibre cross-sectional area (CSA) ($p=0.04$). Notably, type 1 fibres demonstrated a larger CSA than type 2 fibres both pre and post intervention and irrespective of group ($p\leq0.05$).

Conclusion: 12 weeks of low-load blood flow restricted exercise training did not upregulate satellite cells, myogenic markers nor increase myofiber area in the present group of sIBM patients. These findings suggest that satellite cell function and myogenic capacity are impaired in long-term sIBM.

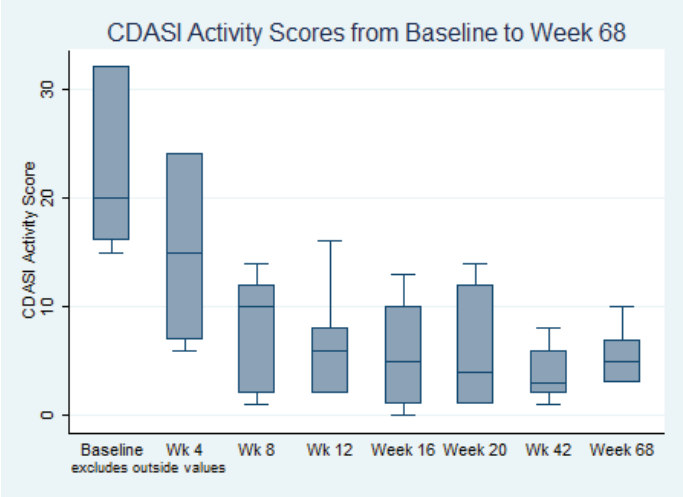
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM



CDASI Activity Scores from Baseline to Week 68

Background/Purpose: Tofacitinib is a pan-JAK inhibitor that demonstrated safety and efficacy in a 12 week open label trial of 10 subjects with refractory dermatomyositis (NCT03002649). Long term disease activity and safety is unknown in subjects receiving tofacitinib.

Methods: To provide long-term safety and efficacy data in dermatomyositis subjects in the study, subjects who completed up to week 12 were eligible to receive tofacitinib XR 11mg daily in a long term study extension. Safety and efficacy using the validated ACR/EULAR Myositis Response Criteria, as measured by the Total Improvement Score (TIS) and Cutaneous Dermatomyositis Activity and Severity Index (CDASI) was assessed every 4 weeks until 20 weeks. Following this, subjects remained on drug and returned for a 42 week and 68 week visit.

Results: 7 of 10 (70%) of patients entered the long term extension of the study drug. There were no serious adverse events to date. 6 of 7 (86%) continued to meet the IMACS DOI at 68 weeks. The median Total Improvement Score (TIS) was 37.5 [30, 37.5] at 42 weeks, and 25 [22.5, 37.5] at 68 weeks. There continued to be a statistically significant change in mean CDASI when compared to baseline at all time points during the extension period. The mean baseline CDASI was 25.4 ± 15 which dropped to 3.85 ± 2.41 (p=0.008) by week 42, and 5.43 ± 2.51 by week 68 (p=0.01). Two subjects required additional immunosuppression with low dose methotrexate during the long term extension period. No patients required any high dose steroid therapy or admission to the hospital for a flare.

Conclusion: Tofacitinib continues to be safe and well tolerated in the long term open label extension of the study. There were no serious adverse events or study discontinuation related to tofacitinib. These data support further investigation of JAK inhibitors in dermatomyositis in a randomized placebo controlled study.

Avascular Necrosis in the Hopkins Myositis Cohort: A Single Center Experience

Khalil Bourji[1], Christopher Mecoli[2], Julie Paik[3], Jemima Albayda[3], Eleni Tiniakou[3], William Kelly[3], Thomas E Lloyd[3], Andrew Mammen[4] and Lisa Christopher-Stine[3], [1]Wayne State University/Henry Ford Hospital, Dearborn, MI, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess the prevalence of avascular necrosis (AVN) in a large cohort of patients with idiopathic inflammatory myopathies (IIM) and define the major associated risk factors.

Methods: We retrospectively reviewed the electronic medical records of all patients with a definitive diagnosis of IIM in our cohort, querying for keywords ("avascular necrosis", "AVN", "osteonecrosis"). Pertinent demographic, clinical (including major risk factors for AVN), serologic and imaging data were collected. A matched group of patients without AVN was then selected for comparison (matched for sex, age at IIM diagnosis ± 2 years, and duration of IIM ± 1 year).

Table 1. Demographic and clinical characteristics of patients with AVN and myositis

		Myositis with AVN
Number of patients		53
Gender	Men	16 (30)
	Women	37 (70)

Table 3. Multivariate logistic regression analysis models, predictors of developing AVN in myositis population

	Variable	OR	95% CI [min-max]	P value
Model 1	History of Cancer, yes	0.47	[0.09-2.33]	0.3
	History of Hyperlipidemia, yes	2.55	[0.66-9.86]	0.1
	History of HIV, yes	2.20	[0.16-30.0]	0.5
	History of Alcohol abuse, yes	**3.98**	[1.31-12.0]	**0.01**
	History of tobacco abuse, yes	0.51	[0.19-1.37]	0.1
	History of Steroid use, yes	1.88	[0.46-7.55]	0.3
Model 2	History of Alcohol abuse, yes	2.81	[0.92-8.56]	0.06
	ANA, positive	**0.22**	[0.08-0.58]	**<0.01**
	Anti-Jo1, positive	0.42	[0.12-1.44]	0.1

Abbreviations: **OR** odds ratio, **CI** confidence interval. **Model 1** included the following variables (history of Cancer, history of hyperlipidemia, history of HIV, history of tobacco use, history of alcohol use, history of steroid use). **Model 2** included the following variables (history of alcohol use, ANA positivity, Anti-Jo1 positivity).

Results: A total of 1680 patients were diagnosed with IIM between 2003 and 2017. Fifty-three patients developed AVN, with a global prevalence of 3.1% (53/1680). Musculoskeletal magnetic resonance imaging (MSK MRI) was available for 1085 patients and AVN was present in 48 patients, with a relative prevalence of 4.4% (48/1085). The majority of patients were Caucasian females (57%) with a mean age at diagnosis of 44.5□12.4 years. 59% had dermatomyositis (DM), 28% had polymyositis (PM). The median time from diagnosis of IIM to diagnosis of AVN was 46 months. Only 18 % were symptomatic. Hip joint was involved in 77%, Knee joint in 16% and Shoulder joint in 7%. A history of alcohol use was the only risk factor that was statistically associated with AVN (36% vs 13%; OR=3.98, CI [1.31-12.0], p=0.01). Corticosteroid use was not associated with an increased risk of AVN.

Conclusion: Although mostly asymptomatic, the global prevalence of AVN in IIM was 3.1% but the prevalence on MSK MRI was 4.4% and alcohol use was the only risk factor for AVN development.

Assessing Interstitial Lung Disease in a Racially Diverse Population with Idiopathic Inflammatory Myositis

Jammie Law[1], Ana Valle[2], Katherine Mullins[3] and Shereen Mahmood[4], [1]Montefiore Medical Center, Bronx, NY, [2]Albert Einstein College of Medicine, New York, NY, [3]Montefiore Medical Center, BROOKLYN, NY, [4]Albert Einstein College of Medicine / Montefiore Medical Center, Wantagh, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common extra-muscular manifestation of Idiopathic Inflammatory Myositis (IIM) and increases risk of mortality. Prior studies and registries have focused on either smaller cohorts or predominantly Caucasian/European populations. Our aim was to better characterize the clinical disease manifestations of ILD in racially diverse population of IIM patients in the Bronx, NY, particularly to describe the associated phenotypes and antibody profiles, clinical skin manifestations, and autoimmune co-morbidities.

Methods: Montefiore Medical Center patients that met 2017 EULAR/ACR classification criteria for IIM were included. The presence of ILD, as well as the radiographic pattern, severity, and progression were determined using available pulmonary function testing and CT of the chest. Statistical analyses included Chi-Square test and Fisher's test.

Results: There were 152 myositis patients in this cohort, of which 62 patients had evidence of ILD (41%). Among the 62 patients with ILD, 71% were women and 29% were men. Patients with ILD were 44% Latin ethnicity and consisted of 56% Black, 24% White, 3% American Indian, 3% Asian (Table 1). Patients with ILD were radiographically classified as follows: 18 (29%) with ground glass opacities without specific pattern, 6 (10%) with usual interstitial pneumonia (UIP), 21 (34%) with nonspecific interstitial pneumonia (NSIP), and 17 (27%) with other patterns of ILD (Table 2).

		ILD (N=62)	No ILD (N=90)	P-value

	Non-Progressive (%)	35/62 (56)

Table 2. Incidence of ILD subtypes in IIM patients

Among patients with ILD, 22 (35%) had PM, 38 (61%) had DM with 7 of those patients having CADM, 2 (3%) had IBM, and 1 (2%) patient had necrotizing (statin-induced) myopathy. Of the PM/DM patients, 14 (23%) qualified as having anti-synthetase syndrome and 13 (21%) had MCTD, UCTD, or an overlap syndrome, both of which had higher ILD prevalences (p=0.0002 and p=0.0001). There was no statistical associated between IBM and ILD (p value = 0.01) but there were 2 cases of IBM with ILD. Patients with ILD had higher prevalence of Jo-1 and SSA antibodies (p=0.002, p=0.003). Dermatomyositis patients with Mi-2 antibody had no prevalence of ILD in this cohort (p=0.03) (Table 3). Majority of these findings are similar to larger, predominant Caucasian studies of IIM.

While IIM patients with ILD showed varying skin manifestations, there were no particular skin manifestations that were significantly more prevalent in patients with ILD in this racially diverse cohort. Patients with ILD also had a higher prevalence of one or more autoimmune comorbidities (p=0.01). Conversely, patients without ILD had higher prevalence of no autoimmune co-morbidities (p=0.04).

		ILD (N=62)	No ILD (N=90)	P-Value

Table 3. Antibody profiles, clinical manifestations, and autoimmune co-morbidities in IIM Patients with ILD

Conclusion: ILD in this racially diverse population with IIM is a significant manifestation of disease that presents heterogeneously. This study serves to confirm that certain myositis phenotypes, associated antibody profiles, and autoimmune comorbidities are associated with ILD, even in a racially diverse urban population. Limitations include

a small sample size of antibody profiles for study. Future direction will include further stratifying patients with ILD in this diverse population by radiographic patterns to assess if response to medications is similar to more homogenous cohorts.

Immunophenotypic Characterization of Myeloid Derived Supressor Cells (MDSCs) and Their Relationship to the Clinical Characteristics of Patients with Inflammatory Myopathies

Hector Culebro[1], Jose Torres-Ruiz[2], Fabiola Cassiano Quezada[1] and Alfredo Perez Fragoso[1], [1]INCMNSZ, MEXICO, Mexico, [2]NIAMS, National Institute of Health, Bethesda

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Myeloid derived suppressor cells (MDSCs) including their granulocyte (Gr-MDSCs) and monocyte (Mo-MDSCs) subtypes constitute a cellular subset with potent immune regulatory capacity. An augmented proportion of MDSCs has been described in patients with cancer, infections and autoimmune diseases, nevertheless the presence of MDSCs in Idiopathic inflammatory myopathies (IIM) has not been explored. The aim of this study is to evaluate the proportion of myeloid derived suppressor cells and their relationship with clinical characteristics of patients with IIM.

Methods: Twenty-two adult patients with the diagnosis of IIM according to the ACR/EULAR criteria and active disease were recruited. The disease activity, damage accrual and disability were evaluated with the myositis disease activity assessment tool (MDAAT), the manual muscle test 8 (MMT8), the myositis damage index (MDI) and the health assessment questionnaire (HAQ). MDSCs were measured by flow cytometry in the peripheral blood mononuclear cell (PBMC) fraction after separation of blood with density gradients. Gr-MDSCs were defined as those $CD33^{dim}$, $CD11b^{+}$, $CD66b^{+}$, $HLA\text{-}DR^{-}$. Gr-MDSCs were classified as mature if they expressed CD16 ($CD16^{+}$) and immature if they were $CD16^{-}$. Mo-MDSCs were defined as those $CD33^{+}$, $HLA\text{-}DR^{-}$ and $CD14^{+}$. Also, the proportion and expression of arginase 1^{+} and $PDL1^{+}$ in MDSCs was evaluated by their mean fluorescence intensity. The proportion of MDSCs and their expression of arginase 1 and PDL1 was compared with 14 healthy donors. Quantitative variables were expressed as medians and interquartile range (IQR). The difference between independent medians was assessed with the Mann-Whitney U test and the correlation between variables was evaluated with the Spearman Rho.

Results: Twelve patients with IIM were women (54.5%). The median of age was 40 (26-42.5) years and patients had a time since diagnosis of 6 (4.5-9.75) months. The most frequent diagnosis was dermatomyositis (72.7%) and most patients had positive anti-Ro52 (36.4%), anti-MDA5 and anti-Mi2 (18.2% each) antibodies. At the time of evaluation 68.2% of patients were taking prednisone, 31.8% methotrexate, 9.1% azathioprine, 18.2% mycophenolate mofetil and 31.8% hydroxychloroquine. Sixteen patients (76.2%) had cutaneous manifestations, 47.6% had dysphagia and 23.8% had interstitial lung disease. Five healthy donors were women (35.7%). The median of age was 27.5 (25-33) years. There was not a statistically significant difference in the age and gender of the study groups.

Table 1. Proportion of MDSCs and their expression of arginase 1 and PDL1 in IIM patients and healthy donors.

Variable	IIM N=22 Median (IQR)	Healthy donor N=14 Median (IQR)	P
% of Gr-MDSCs	0.73 (0.21-2.15)	0.037 (0.009-0.17)	<0.0001
% of immature Gr-MDSCs	89 (33-97.1)	28.3 (15.8-37)	0.003
% of mature Gr-MDSCs	10.2 (2.95-67.00)	71.7 (63.00-84.20)	0.003
% of Arg1+ Gr-MDSCs	0.62 (0.24-4.27)	0.007 (0.000-0.060)	0.016
Mean fluorescence intensity of Arg1 in Gr-MDSCs	4743 (2515-7618)	1556 (955-2593)	0.005
% of PDL1+ Gr-MDSCs	0.29 (0.07-0.67)	0.01 (0.0005-0.044)	0.022
Mean fluorescence intensity of PDL1+ in Gr-MDSCs	3517 (1669-3971)	1627 (1450-1797)	0.05
% of Mo-MDSCs	1.11 (0.07-2.93)	0.11 (0.01-2.99)	0.23
% of Arg1+ Mo-MDSCs	0.84 (0.15-1.38)	0.14 (0.003-0.47)	0.16
Mean fluorescence intensity of Arg1 in Mo-MDSCs	3507 (3339-5483)	1967 (1540-2849)	0.028
%of PDL1+ Mo-MDSCs	0.8 (0.13-2)	0.002 (0.000-0.031)	0.006
Mean fluorescence intensity of PDL1+ in Mo-MDSCs	2169 (1882-12857)	4445 (2216-6295)	0.89

Table 1. Proportion of MDSCs and their expression of arginase 1 and PDL1 in IIM patients and healthy donors.

As shown in Table 1, the proportion of MDSCs and their expression of arginase 1 and PDL1 was higher in patients with IIM, except for the proportion of Mo-MDSCs. The proportion of immature Gr-MDSCs was correlated with the cutaneous damage (Rho=0.486, P=0.048). There was not a relationship between immunosuppressive therapy and MDSCs.

Conclusion: Patients with IIM have a higher proportion of Gr-MDSCs with an immature phenotype and a higher expression of arginase 1 and PDL1+. Further studies are required to evaluate their suppressor capacity and their relationship with other clinical features including the presence of neoplasia.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Muscle Biology, Myositis & Myopathies Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: To define the prevalence and clinical phenotype of anti-cortactin autoantibodies in adult and juvenile myositis.

Methods: In this longitudinal cohort study, anti-cortactin autoantibody tiers were assessed by ELISA in 670 adults and 343 juvenile myositis patients as well as 202 adult and 90 juvenile healthy controls. The prevalence of anti-cortactin autoantibodies was compared among groups. The clinical features of patients with and without anti-cortactin autoantibodies were also compared.

Results: The prevalence of anti-cortactin autoantibodies was not different between all adult myositis patients compared to adult healthy controls (11% vs. 8%; p=0.2). However, compared to adult healthy controls, anti-cortactin autoantibodies were more common in adult dermatomyositis (DM) patients (15%, p=0.005), particularly those with co-existing anti-Mi2 (24%, p=0.03) or anti-NXP2 (23%, p=0.04) autoantibodies. In adult myositis, anti-cortactin was associated with DM-skin involvement (62% vs. 38%, p=0.03), dysphagia (36% vs. 17%, p=0.02) and co-existing anti-Ro52 (47% vs. 26%, p=0.001) or anti-NT5C1a autoantibodies (59% vs. 33%, p=0.001). Moreover, the titers of anti-cortactin antibodies were higher in patients with interstitial lung disease (0.15 vs. 0.12 arbitrary units, p=0.03). The prevalence of anti-cortactin autoantibodies was no different in juvenile myositis (2%) or any juvenile myositis subgroup compared to juvenile healthy controls (4%). Nonetheless, juvenile myositis patients with these autoantibodies had a higher prevalence of mechanic's hands (25% vs. 7%; p=0.03), a higher number of hospitalizations (2.9 vs. 1.3, p=0.04) and lower peak CK values (368 vs. 818 IU/L, p=0.02).

Conclusion: The prevalence of anti-cortactin autoantibodies is only increased in adult DM patients with co-existing anti-Mi2 or anti-NXP2 autoantibodies. In adults, anti-cortactin autoantibodies are associated with dysphagia and interstitial lung disease.

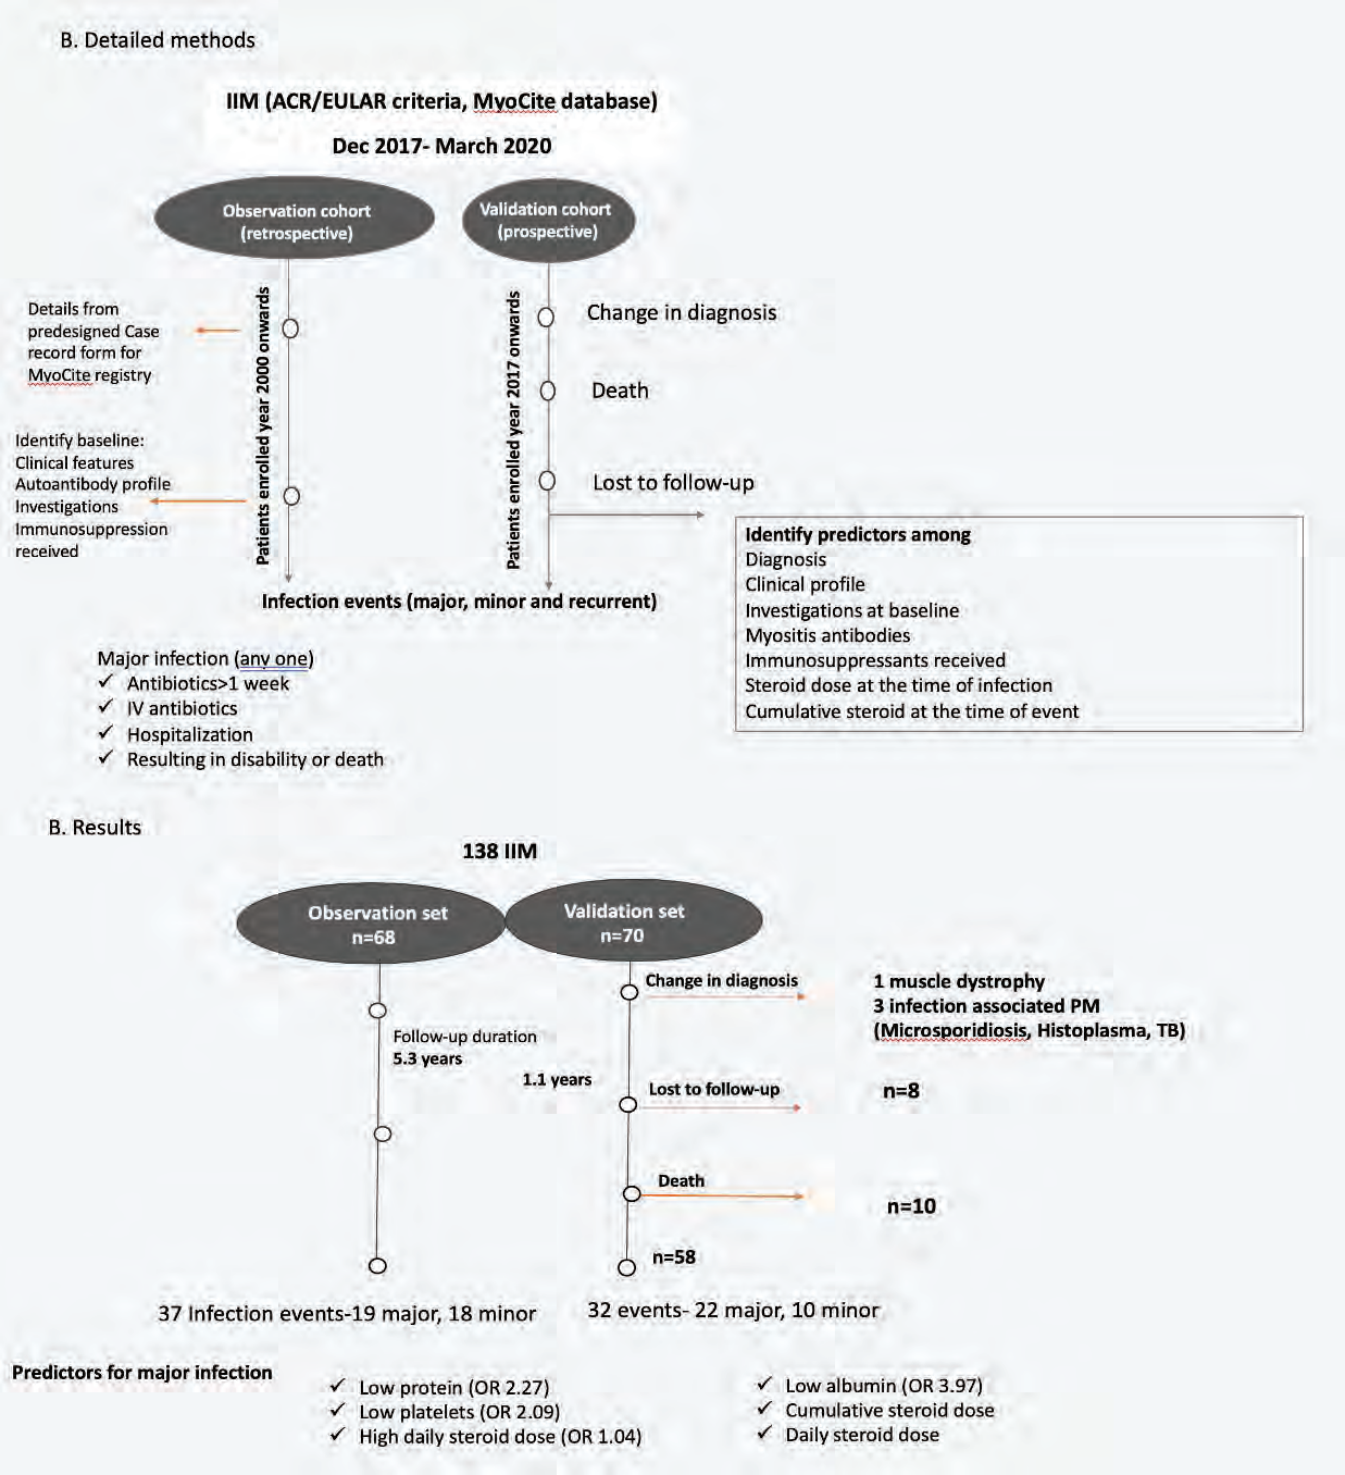
High Burden of Infections in Indian Patients with Idiopathic Inflammatory Myopathy: Validation of Observations from the MyoCite Dataset

Rudrarpan Chatterjee[1], Pankti Mehta[2], Vikas Agarwal[1] and Latika Gupta[2], [1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, lucknow, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Muscle Biology, Myositis & Myopathies Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Infections are a major cause of morbidity and mortality in idiopathic inflammatory myopathy (IIM), more so in India.[1-3] The objective of this study was to characterize the profile and predictors of infections in IIM.



Methods: Details of IIM from the MyoCite database (Dec 2017- March 2020) were retrieved and characterised as the observation cohort.[4-6] The patients enrolled at inception during this period were followed up as the validation cohort to confirm findings from the observation cohort. Definitions and statistical analysis are detailed in Figure 1A. Descriptive data is expressed as median/mean (IQR/SD). Multivariate analysis was done using logistic regression. Missing values imputed using predictive means modelling. Statistical analysis was carried out on Rstudio version 1.2.5033.

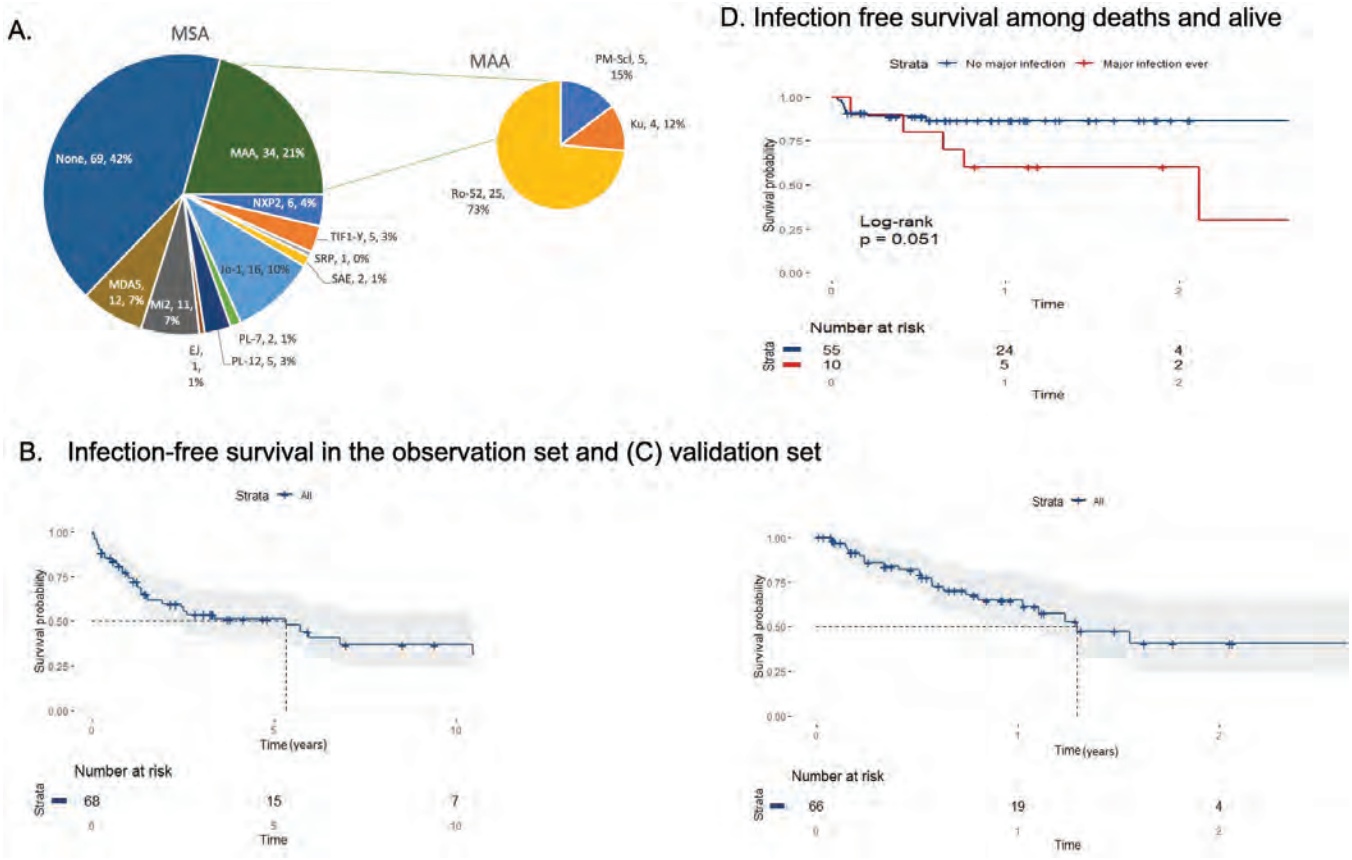


Table 1. Profile of infections in the observational and validation cohorts.

	Observational cohort (n=68)		Validation cohort (n=66)	
All infections	Influenza like illness	8	Influenza like illness	5
	Mucocutaneous	7	Mucocutaneous	
	Herpes zoster	4	Herpes zoster	8
	Pneumonia	6	Pneumonia	1
	Tuberculosis	11	Tuberculosis	4
	Gastrointestinal	2	Gastrointestinal	2
	Urinary tract infection	1	Urinary tract infection	4
			Dengue haemorrhagic fever	1
				1
Major infections	Tuberculosis		Pulmonary tuberculosis	2
	Pulmonary	6	Pneumonia	
	Tuberculous brain abscess	1	*Klebsiella*	2
	Cutaneous	1	*Streptococcus*	2
	Gastrointestinal	1	Cause undetermined	2
	Osteomyelitis	1	Sepsis	
	Pleural effusion	1	Mucocutaneous (MRSA)	1
	Pneumonia			1
	Streptococcus	1		
	Citrobacter	1		
	Cytomegalovirus	3		
	Cause undetermined	1		
	Urinary tract infection (E.Coli)	1		
	Pelvic inflammatory disease	1		

Results: A total 138 individuals (59 DM, 23 PM, 15 JDM, 34 OM, 3 CAM) were enrolled. Of these, 68 were in the retrospective observation cohort with median age 32 (25.5-42.4. F:M 4.2:1), and 66 prospectively enrolled at inception formed the validation cohort with median age 37 (21-47.7, F:M 3.7:1). Myositis antibodies are detailed in Figure 2 A.

Observation cohort.

Over a mean follow up of 64 months, 37 patients had infections (Table 1), of which 19 (51.3%) were major. 11 (29%) had recurrent infections. Tuberculosis was the most common infection (29% of all infections; 57% of major infections), with 45% being extra-pulmonary. On multivariate logistic regression low protein (OR 2.27), low platelets (OR 2.09) and high daily steroid dose (OR 1.04) were predictors of major infections, with a model accuracy of 79%. Median infection free survival was 64.9 months (Figure 2B).

Validation cohort.

Over a mean follow up of 13.6 months, 4 patients were reclassified as non-IIM, of which 3 had atypical infections of the muscle tissue. Among those with IIM, 22 developed had infections, of which 10(45.4%) were major. Four (18%) had recurrent infections. Median infection free survival was 22.7 months. Mots common infection was community acquired pneumonia. On multivariate logistic regression, low albumin (OR 3.97) was a predictor of major infections, with a model accuracy of 90%.

There were 10 deaths, 1 of them as a direct result of infection. Any major infection in the disease course was associated with overall deaths (p=0.013, Figure 2D).

Conclusion: Infections are common and predispose to mortality in Indian patients with IIM. Tuberculosis is the leading case of infections in North India with a higher incidence of extrapulmonary forms, in early as well as established disease.

The Hand Osteoarthritis Registry of New York University: Impacts of Gender and Obesity

Fernando Bomfim[1], Shannon Chen[2], Stephen Zak[3], Taylor Jazrawi[2], Vivienne Qie[3], Benjamin Plotz[2] and Jonathan Samuels[4], [1]New York University, Department of Medicine, Division of Rheumatology, Millburn, NJ, [2]NYU Langone Health, New York, [3]NYU Langone Health, New York, NY, [4]NYU Langone, Rye Brook, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hand osteoarthritis (HOA) data is often obtained from large knee OA cohorts. Targeted HOA cohorts in Europe have shed light on this disease, but the etiologies and pathophysiology remain less defined than other sites of OA. Some studies suggest a metabolic role of adiposity in OA (beyond mechanical load), as evidenced by prevalent HOA in obese patients, while other reports link hormonal status to HOA pain. Our dedicated cohort of HOA patients aims to study factors that contribute to its prevalence and severity.

Methods: From 2016 to 2020, we enrolled patients with interphalangeal (IP) OA, regardless of 1st carpometacarpal (CMC) involvement. Patients with rheumatoid arthritis, psoriatic arthritis or lupus were excluded. Demographic and relevant history data were collected. Participants completed adapted versions of the Michigan Hand Outcomes

MHQ: Michigan Hand Outcomes Questionnaire (0=no pain, 100 = worst pain); QuickDASH: Disabilities of the Arm, Shoulder and Hand Score (0= no disability, 100 = worst disability)

*indicates significant results for alpha set to 0.05

† indicates a post-hoc LSD subgroup ANOVA revealed significant differences in pain (p=0.046) between healthy weight (<25 kg/m^2) and obese (>30 kg/m^2) subjects at alpha set to 0.05

‡ indicates a post-hoc LSD subgroup ANOVA revealed significant differences in disability (p=0.020) between healthy weight (<25 kg/m^2) and obese (>30 kg/m^2) subjects at alpha set to 0.05

Table 1. Covariates affecting hand osteoarthritis symptoms.

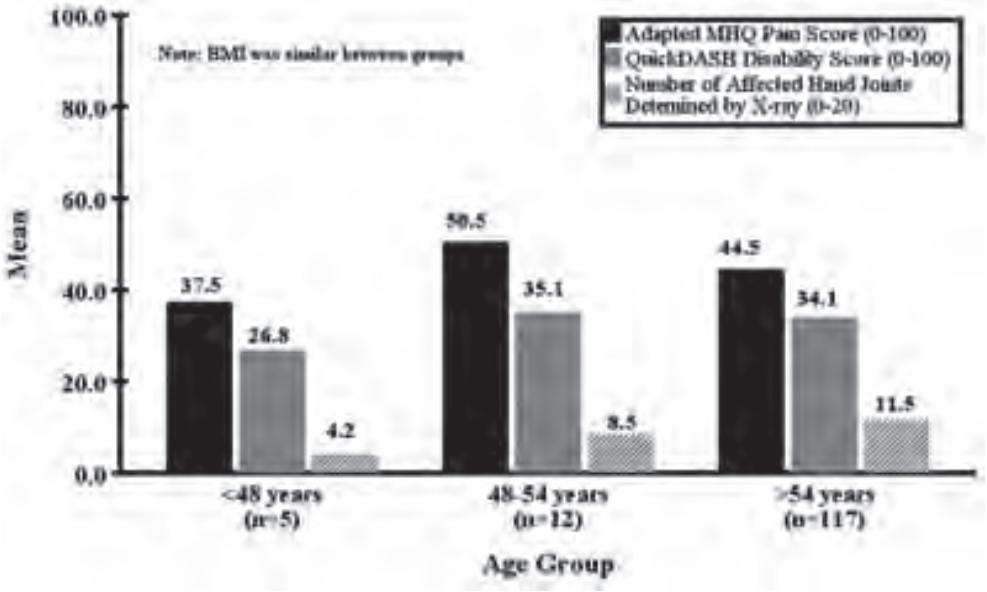

Figure 1. Women ages 48-54 demonstrated more severe hand OA pain and disability.

(MHQ) and QuickDASH Outcome questionnaires to assess pain, stiffness, and function. The semi-quantitative scores were aggregated and normalized to a 0-100 scale. Hand x-rays, if available, were scored in binary fashion for joint narrowing, osteophytes, and central erosions in all 20 joints (18 IPs, 2 1st CMCs). Blood and urine were banked for future assays.

Results: We screened 337 patients and found 170 to be eligible and willing to enroll. The present cohort is 80.0% Caucasian and 78.8% female with an average age of 66.3±9.5 years (range 42-90) and BMI of 26.2±5.0 kg/m^2 (range 16.4-42.1). Bilateral hand x-rays, available for 149 patients, involved 10.5±5.1 joints with OA on average, with 102 (68.4%) having concurrent IP and CMC OA. Radiographs revealed central erosive changes in ≥1 joint in 36.5% of patients, with this subset also reporting a higher number of affected joints (12.5 vs. 9.1, p=< 0.001). Patients with BMI > 30 kg/m^2 had significantly more hand pain (p=0.022) and stiffness (p=0.047) by the adapted MHQ, and more disability (p=0.025) by the QuickDASH, compared to those with BMI < 25 despite similar ages and joint burden by x-ray (**Table 1**). Patients reporting OA in additional sites also reported more hand pain (p=0.018) and more disability (p=0.003), though this signal could be confounded by this subgroup's advanced age (67.7 vs. 62.3 years, p=0.01). Women reported significantly more pain (p=0.035), disability (p=0.004), and a higher average number of joints affected (p=0.02) than men with similar ages and BMI. A small subgroup of likely perimenopausal women (ages 48-54) reported more pain and disability than their older counterparts, despite a lower mean BMI and fewer hand joints affected by OA. (**Figure. 1**). Our analyses did not reveal any association between hand symptoms and tobacco use, comorbidities, or prior hand trauma.

Conclusion: We have established the only registry and biorepository in North America focused on hand OA, which could enhance progress made by existing cohorts. HOA pain and disability independently associated with adiposity, and was more severe in women. We postulate that hormonal influences during the perimenopausal state may increase HOA symptoms during those years. As we run assays on stored biospecimens, we anticipate the HONEY cohort will further our understanding of HOA etiologies and pathophysiology while facilitating future clinical trials.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Beyond classical effect on vegetative functions, the activation of the vagus nerve inhibits inflammation and reduces the pain signal. Vagus nerve stimulation (VNS) can be performed using transcutaneous VNS (tVNS) of the ascendant auricular branch of the VN that selectively innervates the cutaneous zone of cymba conchae

Figure 1. tVNS device kit.

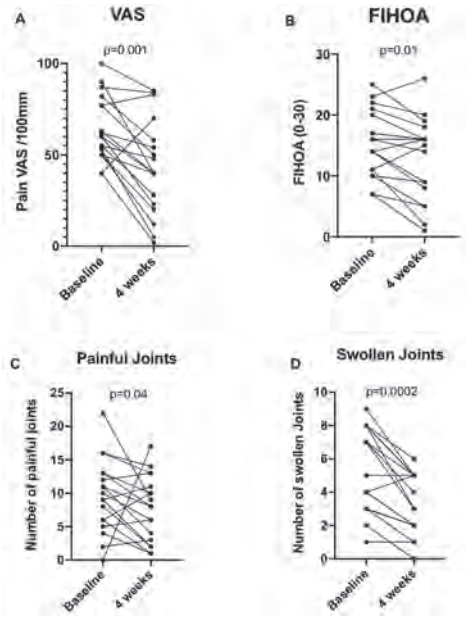

Figure 2. Effect of tVNS on EHOA symptoms. Evolution of (A) VAS hand pain on a 0-100mm scale, (B) function evaluated by FIHOA, (C) number of painful joints (0-30), (D) number of swollen joints (0-30) of the EHOA for each of the eighteen patients. Paired, non-parametric Wilcoxon t-test was used.

(1). Erosive hand osteoarthritis (EHOA) is the most severe HOA subtype characterized by a higher level of pain, a higher inflammation and functional disability than its non-erosive counterpart. The aim of this open-label pilot study was to determine the tolerance and the short-term efficacy of tVNS on EHOA symptoms (NCT03919279).

Methods: Symptomatic EHOA patients, defined by at least one erosive joint (phase E or R of the Verbruggen phase score) with a pain VAS ≥40/100mm and ≥ 1 interphalangeal swollen joint were included. The tVNS was performed using an auricular electrode applied one hour/day on the left ear, connected to a TENS device for 4 weeks (**Figure** 1). The TENS was set up at 25Hz frequency and 50 microseconds pulse width while the intensity was gradually increased to 15mA or below in case of ear discomfort on the stimulation zone (tingling, dysesthesia). Clinical efficacy was evaluated by hand pain VAS on a 0-100mm scale, the functional FIHOA score, the number of tender and swollen joints. Changes in EHOA symptoms between baseline and 4 weeks were evaluated using a Wilcoxon t-test. The proportion of patients that reached the Patient AccepTable Symptom State (PASS), defined by a VAS£40mm, and the minimum clinically important improvement (MCII), defined by an absolute decreased of 15mm or a relative improvement of 20% of their hand pain VAS, were calculated. Tolerance was also reported.

Results: Twenty patients were included but the analysis was performed on eighteen patients (median age 69 years-old [IQR 66.7;73.2], 83% women), two patients being lost to follow-up after the first session. At baseline, hand pain VAS was 60mm [50;78.2] and FIHOA score 15 [10.7;20.2], median number of tender and swollen joints was 9.5 [5.7;13] and 4.5 [3;8] respectively .After 4 weeks, tVNS significantly reduced pain, with a median decrease of 23.5mm

[7.7;37.2], p=0.001 and FIHOA by 2 points [0.75;5.2], p=0.01. Ten of the 18 patients (55%; CI95%: 0.33-0.75) reached the PASS and 13 the MCII (72%; CI95%: 0.49-0.87) (**Figure 2**). tVNS also induced a decrease of 3 [1;5.2] painful joints and 2 [1;3] swollen joints/patient. No serious adverse events were reported. One patient stopped tVNS because of an auricular discomfort.

Conclusion: This first proof-of-concept trial indicated that targeting the vagus nerve using tVNS stimulation may decrease joint inflammation and clinical symptoms in painful EHOA without major safety concern. A randomized controlled study versus sham stimulation is now necessary to confirm these results.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate whether neuropathic pain is present in patients with inflammatory hand OA, to investigate characteristics of those patients and the impact of neuropathic pain on quality of life (QoL), and whether neuropathic pain is influenced by anti-inflammatory treatment.

Methods: Data from a randomized, double-blind, placebo-controlled trial in which 92 patients with hand OA fulfilling ACR criteria were treated with prednisolone, has been analysed. Patients had signs of synovial inflammation, a VAS finger pain of ≥30 and showed flaring ≥20 upon NSAID washout. The primary endpoint of this trial was VAS finger pain (0-100) at week 6.

Neuropathic pain was measured at baseline and after treatment by the painDETECT questionnaire, consisting of questions on pain quality, pain intensity over time and radiating pain. Total score: -1 to 38. Scores< 12 unlikely, scores 13-18 undetermined, scores >18 likely neuropathic pain. QoL was measured with physical component scale (PCS) of Short-Form 36 (SF36; 0-100), comorbidities with the Self-administered Comorbidities Questionnaire (SCQ; 0-45);

Table 1. Multivariate Multinomial logistic regression with painDETECT categories as dependent variable

		PainDETECT		
Variables	All N=91 (100%)	Score <13 N=48 (53%) Reference group	Score 13-18 N=28 (31%)	Score >18 N=15 (16%)
Age	64 (9)	1	0.91 (0.83 to 0.98)*	0.97 (0.90 to 1.08)
Female sex	72 (79%)	1	3.20 (0.78 to 13.13)	9.50 (0.81 to 111.7)
BMI	27 (24 to 29)	1	1.06 (0.94 to 1.19)	0.96 (0.83 to 1.12)
SCQ score	2 (1 to 5)	1	1.13 (0.96 to 1.35)	1.30 (1.05 to 1.60)*
VAS finger pain	53.8 (2.1)	1	1.01 (0.99 to 1.04)	1.03 (0.99 to 1.07)
KL sumscore	37 (16)	1	0.99 (0.95 to 1.04)	0.94 (0.89 to 1.00)*

Table 1. Data are mean (SD), number (%) or median (IQR) in the first column. Data are relative risk ratios (95% Confidence Interval) in the second through fourth column. * Indicates a $p<0.05$. SCQ = Self-administered comorbidities questionnaire. BMI = body mass index. VAS = visual analog scale. KL= Kellgren-Lawrence.

Figure 1

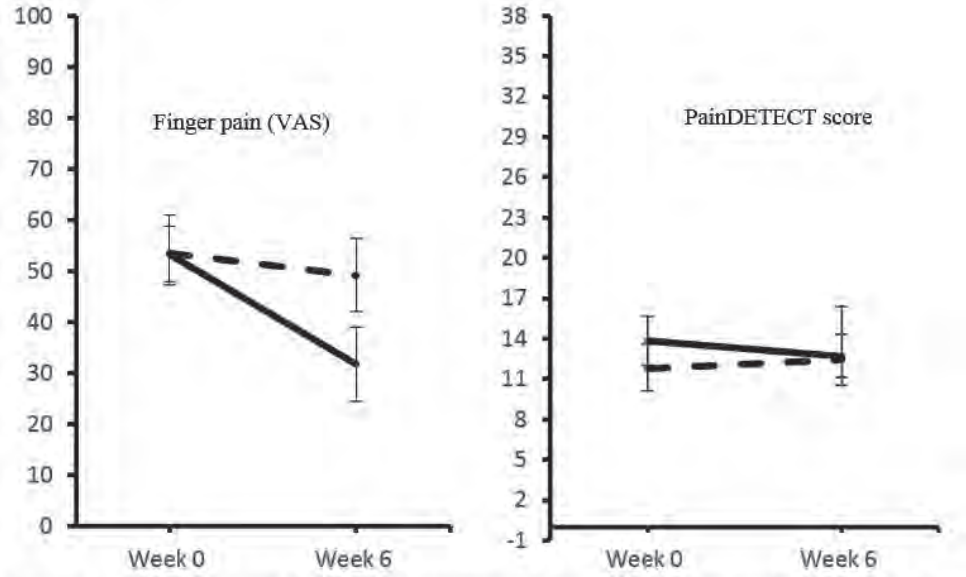

Figure 1. Mean pain at week 0 and week 6, per treatment arm, for VAS finger pain and PainDETECT. Placebo shown in dashed line, prednisolone 10 mg daily in solid line. Whiskers indicate 95% CI.

radiographic severity with Kellgren-Lawrence (KL) sumscore (0-120). OMERACT-OARSI responder criteria were used to determine response on prednisolone.

Association of patient characteristics with neuropathic pain was analysed with multivariate multinominal logistic regression with painDETECT categories as dependent variable. Association of neuropathic pain with QoL was analysed with multivariate linear regression, adjusted for age, sex, BMI, VAS finger pain, SCQ score and KL sumscore, with PCS as dependent variable. Response of neuropathic pain to prednisolone was analysed with generalised estimating equations. Association of neuropathic pain at baseline with response to treatment were analysed using chi-squared tests.

Results: 91 Patients had complete painDETECT data at baseline (mean 12.8 (SD 5.9)). Of these, 53% had no neuropathic pain, 31% were undetermined and 16% had neuropathic pain. Higher painDETECT scores at baseline were associated with lower age, female sex, less radiographic damage and more comorbidities in multivariate analysis (Table 1).

Patients with likely neuropathic pain had a lower QoL (PCS -6.5 (95%CI -10.4 to -2.6), than those without (painDETECT < 13). Neuropathic pain did not change during the trial in both treatment groups, and there was no difference in painDETECT scores between the groups (between group difference mean -1.7 (95%CI -3.9 to 0.4)). VAS pain improved more in the prednisolone group than in the placebo group (between group difference mean -16.5 (95%CI -26.1 to -6.9)) (Figure 1). In this study we could not show an association between the presence of neuropathic pain at baseline and OMERACT-OARSI response to treatment (data not shown).

Conclusion: Patients with inflammatory hand OA and additional neuropathic pain are more often female and have more comorbidities, and report a lower QoL, than those without. Neuropathic pain seems unresponsive to anti-inflammatory therapy. Clinicians should be aware of the presence of neuropathic pain in their patients as these findings might implicate that this kind of pain should be specifically targeted.

Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Proximal and distal inter-phalangeal (PIP, DIP) and thumb base joints are the most common sites affected in hand osteoarthritis (HOA), while involvement of metacarpo-phalangeal (MCP) joints is considered as uncommon and rather related to chondrocalcinosis, haemochromatosis or chronic inflammatory arthritis. The aim of this study was to assess the prevalence of radiographic MCP OA in a large cohort of HOA patients and to determine the factors associated with radiographic MCP OA.

Table. Univariate and multivariate analysis. * Systematic adjustment on age, sex, BMI and family history of osteoarthritis

Methods: Using the data from DIGital Cohort Osteoarthritis Design (NCT01831570), a French hospital-based observational cohort including patients of >35 years-old with symptomatic HOA, we evaluated the prevalence of radiographic MCP HOA defined by at least two MCP joints with a Kellgren Lawrence (KL) score ≥ 2. This cohort includes patients who have symptomatic HOA according to one of the following definitions: i) symptomatic HOA fulfilling American College of Rheumatology (ACR) criteria on at least 2 joints among proximal or distal interphalangeal (PIP/DIP) joints or first IP joint with KL ^{3} 2, or ii) symptomatic thumb base OA with KL ^{3} 2. Patients with chondrocalcinosis or other inflammatory rheumatic diseases (such as psoriatic arthritis or rheumatoid arthritis) were not included. We

compared the prevalence of MCP HOA between dominant and non-dominant hands (McNemar test). Associations between radiographic MCP OA and patients characteristics (general and HOA characteristics) were studied using logistic regression. Adjustment was made on age, gender, Body mass index (BMI) and family history of HOA and factors selected in unadjusted analysis ($p \leq 0.20$). Odds ratios and their 95% confidence intervals were reported.

Results: 425 patients were included of whom 45.6% had erosive HOA. Radiographic MCP OA was present in 138 patients (32.5%), and 139 (32.8%) patients had at least one painful MCP on pressure. Only two patients (0.5%) had an erosive MCP joint. MCP OA patients had a mean±SD age of 69.2±6.9 years-old, a BMI of 25±4.2kg/m2, 119 patients (86.2%) were women and 89 (66.9%) had a family history of HOA. MCP OA was more frequent at the dominant hand (40.6% vs 34.7%, p=0.01) and predominated at the 1st and 2nd MCP joints.

In multivariate analysis, radiographic MCP OA was associated with older age (OR 1.05; CI95% [1.01-1.10] for each year), manual occupations (OR 3.74, CI95% [1.21-11.54]), the presence of scapho-trapezial OA (OR 2.18, CI95% [1.27-3.72]) and with a higher number of radiographic PIP OA joints (OR 14.29, CI 95% [6.46-31.64]) (**Table**). No association with obesity or metabolic syndrome (ATPIII criteria), HOA symptoms (pain, stiffness, or function), hyperferritinemia or elevated transferrin saturation coefficient were found.

Conclusion: In this hospital-based HOA cohort, radiographic MCP OA was frequent (32.5%) and associated with structure rather than symptom severity. Our results strongly suggest that the involvement of MCP joints in HOA is predominantly related to mechanical rather than systemic factors.

Abstract Number: 1104

The Disability Associated with Hand Osteoarthritis Is Substantial in a Cohort of Post-menopausal Women : The QUALYOR Study

Maxime Auroux[1], Blandine Merle[2], Eric Lespessailles[3] and Roland Chapurlat[1], [1]Hospices Civils de Lyon, Lyon Cedex 03, Rhone-Alpes, France, [2]INSERM UMR 1033, Université de Lyon, Lyon Cedex 03, Rhone-Alpes, France, [3]Regional Hospital and University of Orleans, Orléans, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a highly prevalent disease, affecting more than 400 millions individuals around the world. Hand osteoarthritis (HOA) is the most frequent form of OA. The prevalence is variable depending on the definition used and the population studied. It has been suggested in a few studies that disability may be comparable to that seen in rheumatoid arthritis (RA). As HOA is more frequent than RA, the burden of disease is greater. The aim of this study was to systematically assess the disability associated with HOA, along with its correlates, in a cohort of post-menopausal women, the QUALYOR study (QUalité Osseuse Lyon Orléans).

Methods: At the 72 months follow-up visit of the study, we performed, radiographs using a High-resolution direct digital X-ray device (BMA®, D3A Medical Imaging), clinical examination assessing pain, nodes and deformations, grip

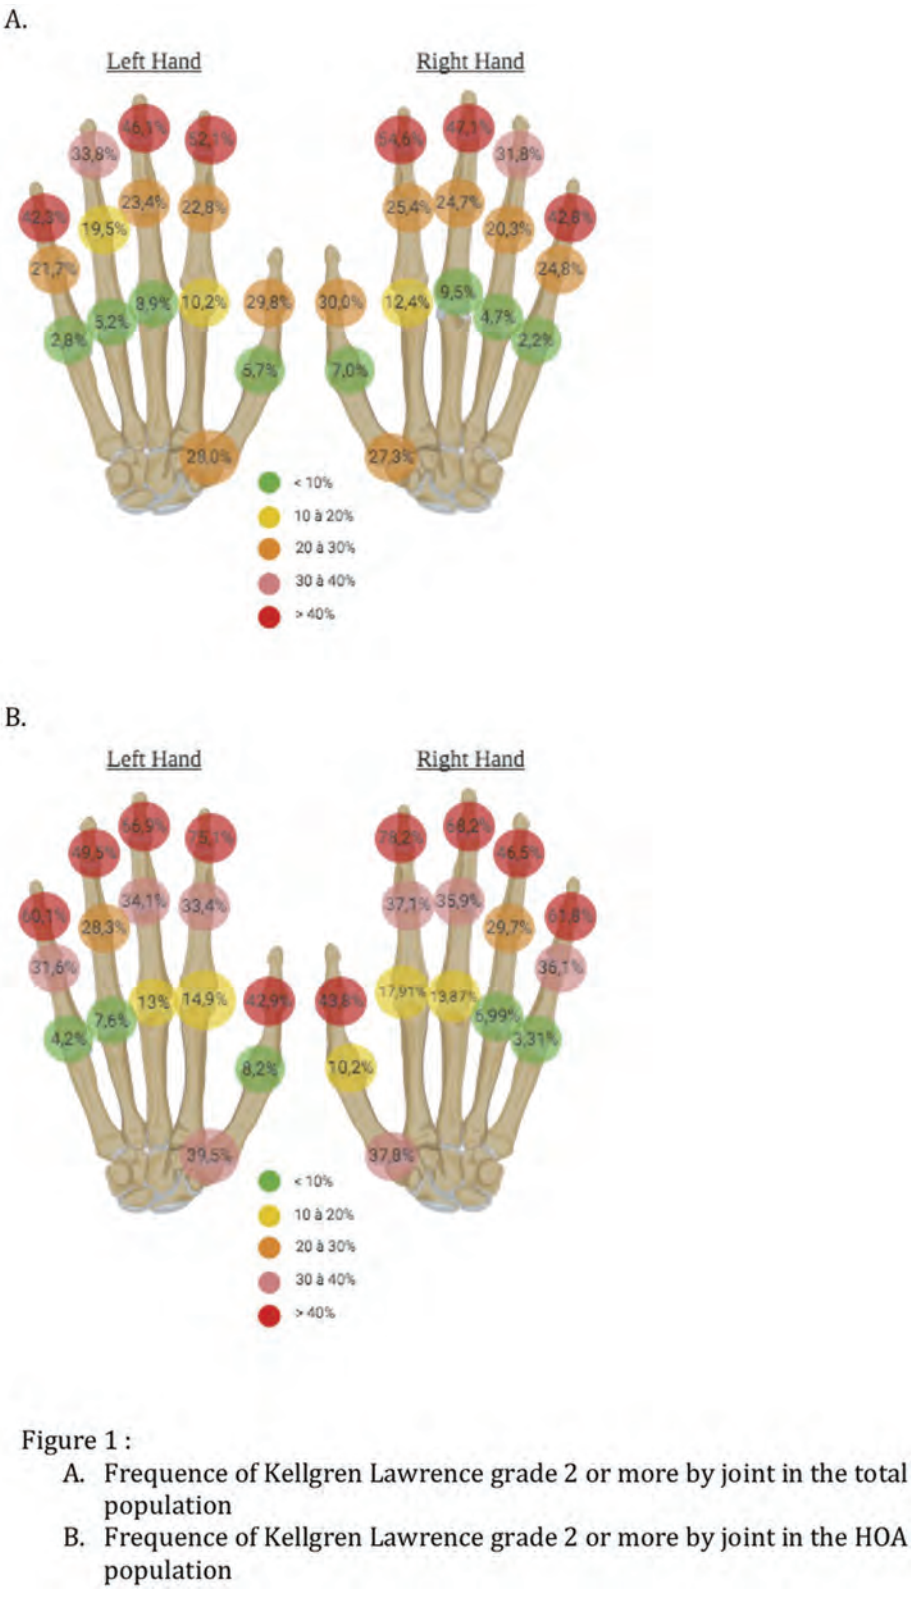

Figure 1 :

A. Frequence of Kellgren Lawrence grade 2 or more by joint in the total population
B. Frequence of Kellgren Lawrence grade 2 or more by joint in the HOA population

Figure 1

strength, AUSCAN and COCHIN questionnaires and a bone densitometry (DXA Hologic Discovery A). At baseline, a HRpQCT (XtremeCT, Scanco Medical), a DXA and a blood sample to assess bone turnover markers (CTX, PINP) were performed. Radiographic hand OA (RHOA) was defined as at least 2 over 30 articulations grading 2 or more using the

Kellgren Lawrence score. Moderate to severe symptomatic HOA was defined as radiographic hand OA and AUSCAN total score > 43/100 (threshold previously identified as the level of non accepTable disability in HOA(1)). T-tests were used to compare continuous variables, Spearman correlations were performed to explore the association of these parameters with HOA and a multivariate analysis including age using logistic regression models was made.

Results: We included 1189 patients, aged at least 55. The mean age was 71.7 years. Inter-reader reliability was good (ICC = 0.86) and intra-reader reliability was excellent (ICC = 0.97). RHOA was rare before age 60. Among 1189 women, 815 (68.5%) had RHOA. They were older than those without RHOA and grip strength was significantly lower in this group. No significant difference was noted on bone microarchitecture, bone turnover markers and clinical characteristics especially BMI. Figure 1 presents RHOA prevalence by joint in the total population and in the RHOA population. Of note, 194 patients with RHOA had erosions on radiographs (23.8%). 86 patients over 815 (10.5%) had moderate to severe symptomatic HOA. BMI at the time of osteoarthritis evaluation was significantly higher in this group. Grip strength was significantly lower in those with symptomatic RHOA. No significant difference was seen in bone microarchitecture, bone mineral density and bone turnover markers in RHOA.

Conclusion: In our cohort of post-menopausal women aged at least 55, 68.5% had RHOA and 10.5% of them had a moderate to severe HOA related disability. BMI was associated with symptomatic RHOA.

Abstract Number: 1105

RANK-L Activity: Understanding the Pathogenesis of Erosive Osteoarthritis

Kalyna Jakibchuk[1], Javier Rangel-Moreno[1], Bethany Marston[2], Jennifer Anolik[1] and Allen Anandarajah[1], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester Medical Center, Rochester

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Erosive osteoarthritis (EOA) is characterized by osteoarthritic findings with central erosions and collapse of the interphalangeal joint subchondral bone plate. A number of studies indicate that there is an inflammatory component but the pathophysiology of the erosions is not known. Receptor activator of nuclear factor kappa-B ligand (RANK-L) is involved in the erosive process of inflammatory arthritides and we hypothesized that it would be involved in the erosive process of EOA. We therefore compared the RANK-L levels in histological specimens of EOA with non-erosive hand OA specimens and compared the bone mineral densities (BMDs) of a cohort of EOA patients with those of OA patients.

	OA (n=60)		EOA (n=20)		Significance
	Mean	SD	Mean	SD	P value
RANK-L$^+$ Area (microns^2)	1102.32	606.91	3773.24	2372.35	p<0.0001

Table 1. RANK-L signal area per 200x field of synovial tissue

	OA		EOA	
	Fields (n)	Mean number of cells	Fields (n)	Mean number of cells
Reader 1	61	1.80	30	5.4
Reader 2 (1st pass)	61	1.64	30	5.07
Reader 2 (2nd pass)	61	1.61	30	4.8

Table 2. RANK-L+ cells counted per 200x field of synovial tissue

Methods: This was a single center retrospective, observational study. Histological tissue from EOA (n=8) and hand OA (n=15) patients who underwent surgery between 2005 and 2015 were retrieved and stained with an antibody to RANK-L. The diagnosis of EOA was defined by OA based on American College of Rheumatology (ACR) clinical criteria with erosions in at least two interphalangeal joints, as well as a negative rheumatoid factor, anti-citrullinated antibody, and anti-nuclear antigen without personal or family history of psoriatic arthritis or crystal-induced arthritis.

RANK-L$^+$ cells were counted in two to five random 200x fields and RANK-L area was measured in 200X pictures with Image J NIH software. Morphometric analysis was performed in a blinded fashion by two independent evaluators.

A retrospective chart review, of diagnostic codes for EOA and OA from 7/1/2009-7/1/2019 was conducted. EOA diagnosis was confirmed either by radiologic evidence of characteristic erosions in at least two interphalangeal joints or diagnosis by a rheumatologist. Patients with crystalline arthritis, rheumatoid arthritis, psoriasis, and psoriatic arthritis

	OA (n=50)	EOA (n=23)
Median T-score [a]	-1.35	-1.5
Median BMD (g/cm^2) [a]	0.85	0.79
Median Height (in.)	63.1	64
Median Weight (lbs.)	148	142
Median Age	67	63
Sex	45 F (90%), 5 M (10%)	22 F (95.65%), 1 M (4%)
Race	46 C (92%), 3 B (6%), 1 H (2%)	21 C (91.30%), 2 B (8.70%)
Patients on osteoporotic meds [b]	9 (18%)	3 (13.04%)
Smoking status	29 non (58%), 18 former (36%), 2 current (4%), 1 unknown (2%)	10 non (43.48%), 10 former (43.48%), 2 current (8.70%), 1 unknown (former or current) (4.34%)

F = female, M = male, C= caucasian, B = black, H = hispanic

Table 3. DEXA measurements with group demographics

diagnoses as well as those with a family history of psoriasis were excluded. Dual energy x-ray absorptiometry (DEXA) scans for 23 EOA and 50 randomly selected OA patients from the University of Rochester Medical Center were reviewed. Data on age, sex, race, smoking history, height, weight, and osteoporotic medication use was collected. Patients on high doses of steroids were excluded.

Results: There was a significantly larger area of RANK-L staining found with Image J NIH software area calculations for EOA (3773.24 ± 2372.35 microns^2, p< 0.0001) compared to OA (1102.32 ± 606.91 microns^2, p< 0.0001) (Table 1). There was also a higher number of RANK-L$^+$ cells in the EOA samples compared to the OA samples (Table 2).

DEXA comparison between OA and EOA patients showed a lower median BMD and T-score in the EOA group (0.79 g/cm^2, -1.5) compared with the OA group (0.85 g/cm^2, -1.35). Demographics between these groups were also compared and were relatively unremarkable (Table 3).

Conclusion: Our study demonstrated that EOA patients had higher levels of RANK-L in synovial tissue and were with lower BMD scores than patients with OA. We therefore propose that RANK-L activity promotes the osteoclastic driven erosive changes in EOA and also results in systemic bone loss.

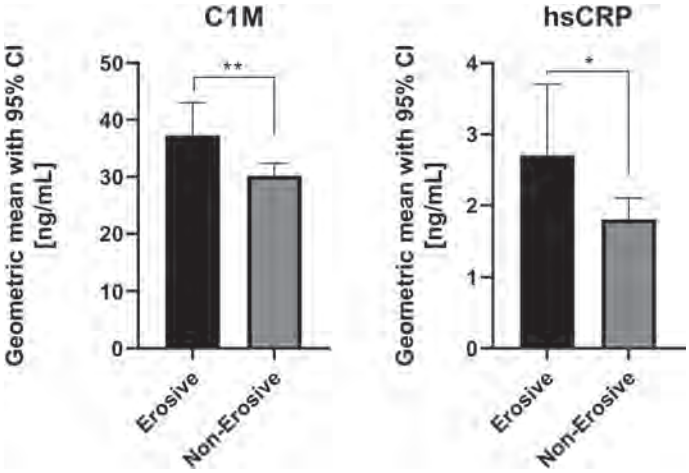
MMP Mediated Type I Collagen Degradation Is Associated with Erosive Hand Osteoarthritis in a Hospital-based Observational Cohort – the NOR-HAND Study

Christian Thudium[1], Neha Sharma[2], Marthe Gløersen[3], Peder Frederiksen[2], Anne C. Bay-Jensen[1] and **Ida Haugen**[3], [1]Nordic Bioscience, Herlev, Denmark, [2]Nordic Bioscience, Herlev, [3]Diakonhjemmet Hospital, Oslo, Norway

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hand osteoarthritis (OA) is a common degenerative joint disease affecting mainly the interphalangeal and first carpometacarpal joints. The disease manifests as inflammation and deterioration of joint structure leading to pain, loss of function, and reduced quality of life. Hand OA presents as different subtypes, where the erosive type is considered a more severe phenotype with more pronounced symptoms, more inflammation and a faster disease progression. The erosive suptype is associatedwith the development of joint erosions followed by characteristic repair and remodeling of the joint plate. Type I collagen turnover, measured by MMP generated type I collagen neo-epitope C1M in serum have previously been associated with synovial inflammation, disease activity and structural progression in rheumatoid arthritis (RA). The aim of this study was to investigate the association between erosive hand OA and systemic levels of C1M.

Methods: Serum was collected from 291 hand OA patients in the Nor-Hand study, a hospital based cohort study exploring the validity of imaging modalities and disease processes in hand OA. C1M, a measure of MMP mediated type I collagen tissue degradation and the acute phase reactant hsCRP reflecting inflammation was measured at baseline.



Bilateral hand radiographs were evaluated by an experienced reader (IKH)(n=287). Erosive hand OA was defined as at least one distal or proximal interphalangeal joint with erosions (defined as E or R stage according to the Verbruggen Veys anatomical phase scoring system). Logistic regression was used to model the odds of having erosive hand OA as function of C1M. C1M was log transformed before entering the model(s). Similar analysis was performed for hsCRP as comparison. All analyses were corrected for age, sex, BMI, and grey scale synovitis of the knee (0-3 scale) or hip (capsule thickness in millimeters) measured by ultrasound.

Results: The greater part of patients were women (n=256, 89%) with a mean (SD) age of 60.8 (6.2) years. 58 (20 %) patients were identified with erosive hand OA. These patients had higher levels of both C1M and hsCRP than patients with non-erosive disease (Table). A 10% increase in C1M was associated with an increase in the odds of having erosion by 1.069 (95% CI 1.016 – 1.126). The estimated odds ratio was similar after adjustment for clinical and demographic covariates (OR = 1.072; 95% CI 1,014 – 1.134). In comparison, a 10% increase in hsCRP was associated with an increase in odds by 1.027 (95% CI 1.016-1.051). The association remained after adjustment for covariates (OR=1.031; 95%CI 1.004-1.059).

Conclusion: MMP driven turnover of type I collagen measured by C1M, is associated with the presence of erosive hand OA, which is considered a more inflammatory phenotype. These findings suggest that systemic C1M levels may reflect specific pathological joint tissue alterations, and may be a potential biomarker in hand OA studies. Future studies are needed to explore the associations with synovitis and the sensitivity to change.

IL1RN Polymorphism Predicts Weight Loss, Inflammatory Biomarker Changes and Knee Osteoarthritis Pain Relief After Bariatric Surgery

Jonathan Samuels[1], Fernando Bomfim[2], Mukundan Attur[3], Christine Ren-Fielding[4], Manish Parikh[5], Renata La Rocca-Vieira[6] and Steven B. Abramson[7], [1]NYU Langone, Rye Brook, NY, [2]New York University, Department of Medicine, Division of Rheumatology, Millburn, NJ, [3]NYU Langone Health, New York, NY, [4]NYU Langone Health, New YOrk, [5]Bellevue Hospital, New York, NY, [6]NYU, New YOrk, [7]New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Symptomatic knee osteoarthritis (SKOA) patients with obesity who undergo bariatric surgery experience knee pain relief, though the reduced mechanical load explains only part of the improvement. A reduction in inflammatory biomarkers from adipose tissue may also impact pain. We previously identified an *IL1RN* haplotype (TTG; rs419598, rs315952, and rs9005) that associates with OA severity and inflammatory markers. We aimed to determine whether TTG distinguishes patients who lose more weight and have more significant decreases in inflammation with greater knee OA pain relief.

Methods: From 2013-2019 we enrolled patients ≥30 years old with BMI ≥30 kg/m^2 and painful knee OA who planned surgical (sleeve gastrectomy, gastric bypass, or laparoscopic band) or medical weight loss (MWL) at Bellevue Hospital or NYU Langone Health. Patients with lupus, rheumatoid arthritis, or psoriatic arthritis were excluded. Weight-bearing knee x-rays assessed OA severity to confirm a Kellgren-Lawrence grade of at least 1 (scale 0-4). Participants completed the Knee Injury and Osteoarthritis Outcomes (KOOS) questionnaire and provided blood at baseline and 1, 3, 6, and 12 months. Patients were genotyped to determine whether they carried 1 or 2 copies of the TTG haplotype (TTG-1/2) or none (TTG-0). Sleeve was the most common weight loss intervention, therefore our analysis is focused on this surgical subset to minimize variable effects on weight and biomarkers.

Results: We enrolled 113 patients (95 F, 18 M) with painful knee OA prior to their weight loss intervention. The mean age, BMI, and KOOS pain at baseline were 50.3 ± 12.0 years, 44.8 ± 8.9 kg/m^2, and 48.4 ± 18.2 (0-100, with 100 = no pain). Of 113 patients, 48 underwent sleeve, 20 bypass, 9 laparoscopic banding, 12 did not have the surgery, and 24 pursued medical weight loss. The 77 who completed surgery had a mean % excess weight loss (%EWL) of 51.7 after 6 months, with significant decreases in hsCRP (4.4 mg/L) and leptin (32.8 ng/dL), and mean KOOS pain improvement of 22.4 (MCID= 16.7). The corresponding changes for patients who tried various MWL regimens were modest at best. We obtained the *IL1RN* haplotype for 45 of the 48 sleeve patients, and found 34 (70.8%) carried the TTG-1 or TTG-

	Baseline	1 Month	3 Month	6 Month	
	mean (n)	mean (n)	mean (n)	mean (n)	p-value
% excess weight loss					
TTG-0 (n=11)	N/A	33.3 (9)	53.5 (7)	70.0 (7)	**0.005***
TTG-1/2 (n=34)	N/A	24.3 (26)	42.1 (26)	53.8 (24)	
KOOS Pain					
TTG-0 (n=11)	52.3 (11)	79.9 (9)	79.4 (7)	82.5 (7)	**0.021***
TTG-1/2 (n=34)	46.3 (34)	65.2 (26)	75.6 (26)	77.4 (24)	
hsCRP (mg/L)					
TTG-0 (n=11)	6.2 (10)	2.3 (5)	2.1 (6)	1.9 (6)	0.36
TTG-1/2 (n=34)	7.8 (34)	6.1 (18)	5.1 (25)	4.9 (21)	
Leptin (ng/mL)					
TTG-0 (n=11)	105.3 (10)	36.8 (8)	17.5 (6)	16.5 (6)	**0.006***
TTG-1/2 (n=34)	94.7 (33)	46.8 (23)	38.6 (25)	31.6 (19)	

Table 1

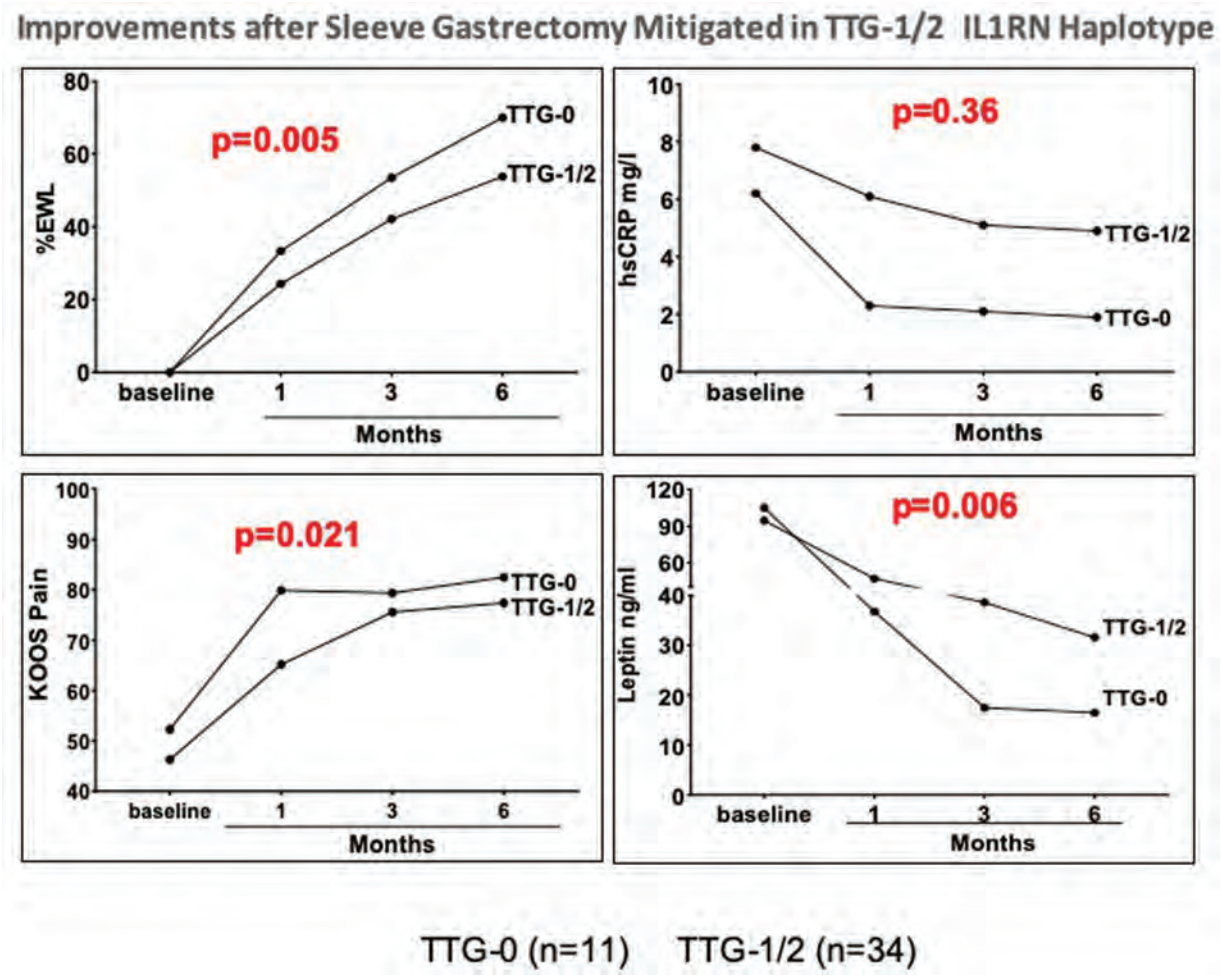

Figure 1

2 haplotype while 11 were TTG-0 (with similar baseline age, BMI, and KOOS for the two groups). At each follow-up time point through 6 months (Figure 1), TTG-1/2 patients had more difficulty losing weight than the TTG-0 group ($p< 0.005$ by ANOVA), with corresponding smaller reductions in *hs*CRP ($p=0.36$) and leptin ($p=0.006$). TTG-1/2 carriers also reported less KOOS pain relief relative to the TTG-0 group ($p=0.021$), markedly at 1 and 3 months with some improvement later (Table 1). All of these findings held true when only plotting data only from the 23 patients (18 TTG-1/2, 5 TTG-0) who completed each of the followup visits.

Conclusion: SKOA patients with obesity achieve marked excess weight loss, reductions in inflammatory mediators, and knee pain relief with bariatric surgery. The subset of patients with the TTG-0 *IL1RN* haplotype demonstrated more significant and/or rapid improvement in each of these outcomes, suggesting a potential predictor of which OA patients will have a more successful response to bariatric surgery.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: To identify if biochemical markers s-Coll2-1, a peptide of type collagen and its nitrated from, s-Coll2-1NO2 are associated to knee osteoarthritis (OA), focusing on pain, function as well as structural features assessed by MRI and to assess their ability at predicting knee OA worsening.

Methods: 116 subjects with knee OA were followed during one year with pain, function and MRI evaluation (PRODIGE study, NCT02070224). Type II collagen-specific biomarker Coll2-1 and its nitrated form Coll2-1NO2 were directly measured in serum using immunoassays at baseline and after three, six and twelve months follow-up.

Results: S-Coll2-1 was significantly correlated with bursitis (r=0.29, P< 0.01), bone attrition (r=0.25, P=0.01), cysts (r=0.24, P=0.02) and cartilage (r=0.23, P=0.03) WORMS sub-scores for the whole joint as well as with the medial femorotibial joint sum score (r=0.26, P=0.01) and medial femorotibial joint cartilage (r=0.23, P=0.02). s-Coll2-1NO2 was correlated with WORMS total score (r=0.23, P=0.02), WORMS scores in the patellofemoral (r=0.23, P=0.02) and medial femorotibial compartments (r=0.21, P=0.03) and with osteophytes scores (r=0.27, P< 0.01). Baseline s-Coll2-1NO2 was higher in subjects with a pain worsening (426.4 pg/mL [278.04-566.95]) as compared to non-progressors (306.84 [200.37-427.84]) over one year (AUC=0.655, P=0.015).

Conclusion: Cartilage biomarkers s-Coll2-1 and s-Coll2-1NO2 are associated to several knee OA features quantified with WORMS scoring system on MRI. Serum values of Coll2-1NO2 are also associated to a worsening of target knee pain over one year. Coll2-1 and Coll2-1NO2, in association with other structural features, pain and function, could help at identifying OA phenotypes and patients at risk of OA worsening.

Pain in Women with Knee and/or Hip Osteoarthritis Is Related to Systemic Inflammation and to Adipose Tissue Dysfunction and Distribution: A Cross-sectional Metabolic Biomarkers Cohort Study

Jeremie Sellam[1], Anne-Christine Rat[2], Soraya Fellahi[3], Jean-Philippe Bastard[4], Willy NGUEYON SIME[5], Hang Korng EA[6], Pascal Richette[7], Jacqueline Capeau[8], Francis Guillemin[9] and Francis Berenbaum[1], [1]AP-HP, Hôpital Saint-Antoine, Service de Rhumatologie, Centre de Recherche Saint-Antoine, INSERM UMR_S 938,Sorbonne Université, Paris, 75012, France, Paris, France, [2]Universite de Caen Normandie and Université de Lorraine, EA 4360, Caen, France, [3]AP-HP INSERM, Paris, France, [4]INSERM AP-HP UPEC, Paris, France, [5]Universite de Lorraine, INSERM, CIC, Nancy, France, [6]Universite de Paris, AP-HP, INSERM, paris, France, [7]Department of Rheumatology, Lariboisière Hospital, Paris, France, [8]INSERM Sorbonne Universite, Paris, France, [9]Universite de Lorraine CIC INSERM, Nancy, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Beyond the link between metabolic diseases and osteoarthritis (OA) risk, some studies have suggested an association between metabolic syndrome or visceral obesity and OA-related pain (1,2). Here, we investigated whether biomarkers of adipose tissue dysfunction and distribution could be associated with OA-related pain.

Methods: We cross-sectionally analyzed patients with knee and/or hip OA at inclusion in the 863 patients included in the national multicentric KHOALA cohort (NCT00481338). We used visual analogic scale (VAS) for pain, the Western Ontario and McMaster Universities Arthritis Index (WOMAC) and Osteoarthritis Knee and Hip Quality of Life (OAKHQOL) pain subscores. For WOMAC and VAS pain, higher scores reflects more symptoms, while it is the opposite for OAKHQOL.

At inclusion, we measured in the serum ultra-sensitive C reactive protein (usCRP), leptin and total adiponectin for calculation of leptin:adiponectin ratio (LAR), a marker of adipose tissue dysfunction associated with truncal obesity, high-molecular-weight adiponectin, visfatin and apolipoproteins (apoA1, apoB100). Univariate and multivariate analyses using stepwise linear regression models were performed to search for correlation between pain assessments and these biomarkers, with adjustment on age and Kellgren-Lawrence score and with stratification by sex since gender interacts with pain intensityand with adipokines level.

Results: In 596 women with hip and/or knee OA, multivariate analyses indicated that higher pain intensity was associated with higher LAR (VAS pain: b=0.48; p=0.0001, OAKHQOL pain: b=-0.45; p=0.0002, WOMAC pain: b=0.29; p=0.002) in the whole group. Analyzing knee and hip OA populations separately, these correlations were found for both joints in multivariate analyses (knee OA: VAS pain b = 0.52 p = 0.0001; OAKHQOL pain: b = -0.48 p = 0.0002; WOMAC pain b = 0.28 p = 0.006; hip OA: VAS pain b = 0.64 p = 0.03; OAKHQOL pain: b = -0.55 p = 0.04). Pain intensity correlated also with usCRP level (VAS pain: b= 0.27; p=0.02, OAKHQOL pain: b =-0.31; p=0.01) and Kellgren-Lawrence score. Serum visfatin, high-molecular-weight adiponectin, Apo A1 and Apo B100 levels were not related to pain level, whatever the score used. In 267 men, no correlation between biomarkers and pain was found.

Conclusion: Serum LAR and usCRP level are associated with pain level, independently of radiographic structural severity in women with hip and/or knee OA, emphasizing the role of adipose tissue dysfunction, truncal fat repartition and meta-inflammation in pain experience in this population.

measures of function or muscle strength in patients with knee OA. Understanding the relationship between imaging features of knee OA and functional limitations, may help guide treatment algorithms and assessment of disease burden. The aim of this study was to assess the association of US-synovitis with performance-based measures of function and muscle strength in patients with knee OA.

Methods: Patients diagnosed with clinical knee OA based on the American College of Rheumatology (ACR) criteria were included in this cross-sectional analysis. Patients completed the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire (0-100; lower scores indicate more pain) and a series of performance-based measures of function including the chair-sit-stand test, 40-meter walk test, 6-minute walk test, and quadriceps and hamstring strength (knee extension and flexion peak torque assessed using isokinetic dynamometry). Musculoskeletal-US was used to measure synovitis in the suprapatellar region (0-3; None-Severe). Radiographs were used to obtain Kellgren-Lawrence (KL) grades of OA severity. We fitted a series of multivariate linear regression models to evaluate the association between synovitis (predictor of interest) and performance-based measures of function (outcome), adjusting for age, sex, body mass index (BMI), KL grade, and KOOS Pain. Model outcome measures were 1) 40-meter walk test 2) 6-minute walk test 3) chair-sit-stand test, 4) extension (quadriceps strength), and 5) flexion (hamstring strength). Robust sandwich estimators were used. We reported results as unstandardized β coefficients with 95% confidence intervals (CIs), and robust standard errors. We evaluated for confounding and completed mediation analyses using PROCESS macro v3.5. Mediation results are reported as indirect effect estimates, standard error, and 95% CIs.

Results: Analyses included 183 patients (Table1). Greater synovitis was associated with decreased time for the 40-meter walk test, and increased quadriceps and hamstrings muscle strength, only when adjusting for age, sex, BMI, KL grade, and KOOS Pain (Table 2). Mediation analyses (Figure 1) for each model show that the effect of synovitis (0 vs 3) on performance-based functional outcomes and muscle strength is mediated by KOOS Pain. Indirect effects for 40-meter walk (3.30; SE:1.50; 95%CI: 0.86-6.75), chair-sit-stand (-1.08; SE:0.41; 95%CI: -19.6- -0.36), 6-minute walk test (-29.61; SE: 10.59; 95%CI: -52.67- -10.50), and extension (-5.97; SE: 2.98; 95%CI: -12.43- -0.80) indicate significant mediation.

Conclusion: Important factors such as pain, age, sex, and body size are known to be related to function in knee OA. We demonstrated that US-synovitis is another important factor that should be considered. Moreover, our findings suggest that a complex relationship exists between knee synovitis and physical function that is mediated by pain.

Intra-Articular Mineralization on Knee CT Increases Risk of Knee Pain: The Multicenter Osteoarthritis Study

Tuhina Neogi[1], John Lynch[2], Mohamed Jarraya[3], David Felson[1], Na Wang[1], James Torner[4], Cora Lewis[5], Michael Nevitt[6] and Ali Guermazi[1], [1]Boston University School of Medicine, Boston, MA, [2]UCSF, San Francisco, CA, [3]Boston University School of Medicine, Boston, [4]University of Iowa, Iowa City, IA, [5]University of Alabama Birmingham, Birmingham, AL, [6]University of California, San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Intra-articular (i.a.) calcium crystal deposition is common in knee osteoarthritis (OA). Low-grade inflammation related to crystals may contribute to knee pain, including pain fluctuation. Chondrocalcinosis has been measured primarily on radiographs to date, which have low sensitivity. We used CT to identify i.a. mineralization to overcome this limitation, and used longitudinal data to examine the relation of i.a. mineralization to the development of knee pain.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of people with or at risk of knee OA. The 12th-year visit was the baseline for this analysis as this was the first study visit at which CTs were obtained, and a new cohort was recruited (age 45-69) who had KL ≤2 in both knees, and either no knee pain or if they had knee pain, it could not be severe, constant pain. All participants had pain questionnaires, knee radiographs, and bilateral knee CTs at baseline, and assessed for pain outcomes every 8 months x3. A musculoskeletal radiologist scored multiplanar CT images (axial native images with coronal and sagittal 2D reformats)

Location/Extent of Intra-articular Mineralization	Odds Ratio (95% CI)		
	Incident Frequent Knee Pain	Incident Frequent Intermittent or Constant Pain	WOMAC Pain Worsening
Any mineralization in the knee	1.18 (0.76, 1.83)	1.37 (0.86, 2.18)	1.36 (0.98, 1.90)
Any cartilage mineralization	1.44 (0.88, 2.36)	**1.72 (1.04, 2.84)**	**1.48 (1.03, 2.14)**
Any meniscal mineralization	1.37 (0.89, 2.11)	1.55 (0.94, 2.56)	1.27 (0.88, 1.83)
Mineralization in >5 regions vs. 0 regions	**1.95 (1.12, 3.40)**	**1.97 (1.06, 3.66)**	1.54 (0.99, 2.40)

Relation of Intra-Articular Mineralization to Risk of Developing Knee Pain or Knee Pain Worsening Over Two Years

using the Boston University Calcium Knee Score (BUCKS). Mineralization in each of WORMS-defined subregions of cartilage and menisci was scored on a 0-3 scale. Ligament and joint capsule mineralization were scored as present or absent. We examined presence of any i.a. mineralization, any cartilage mineralization, and any meniscal mineralization to the risk of development of: frequent knee pain (FKP) among those free of FKP at baseline, development of more frequent intermittent knee pain (indicated as at least "often") or constant pain among those with no constant pain or only infrequent intermittent pain (occurring no more than "sometimes" based on the ICOAP) at baseline, and WOMAC worsening of ≥2/20 (MCID) over 2 years. We carried out knee-specific analyses using logistic regression with GEE and adjusting for age, sex, BMI, race, and KL grade.

Results: A total of 2090 participants were included (mean age 61, mean BMI 28.8, 57% female). Overall, 10.2% of knees had i.a. mineralization, 7.3% had any cartilage, and 8.2% had meniscal mineralization. Presence of i.a. mineralization in a greater number of regions was associated with risk of developing FKP (OR 1.95, 95% CI 1.12-3.40), more frequent intermittent or constant pain (OR 1.97 (95% CI 1.06-3.66), and a trend towards more severe pain (OR 1.54, 95% CI 0.99-2.40) (**Table**). In addition, cartilage mineralization was significantly associated with developing more frequent intermittent and constant pain as well as developing more severe knee pain, while the association of meniscal mineralization with these pain outcomes did not reach statistical significance, though there were trends towards increased risk.

Conclusion: Intra-articular mineralization was associated with risk of developing knee pain and worsening pain over two years. This first report of CT-based i.a. mineralization on risk of knee pain highlights the important role crystals play in the knee pain experience. These findings implicate crystal deposition in changing pain patterns over time in knee OA, and point to need for research at therapy directed towards crystal disease in OA.

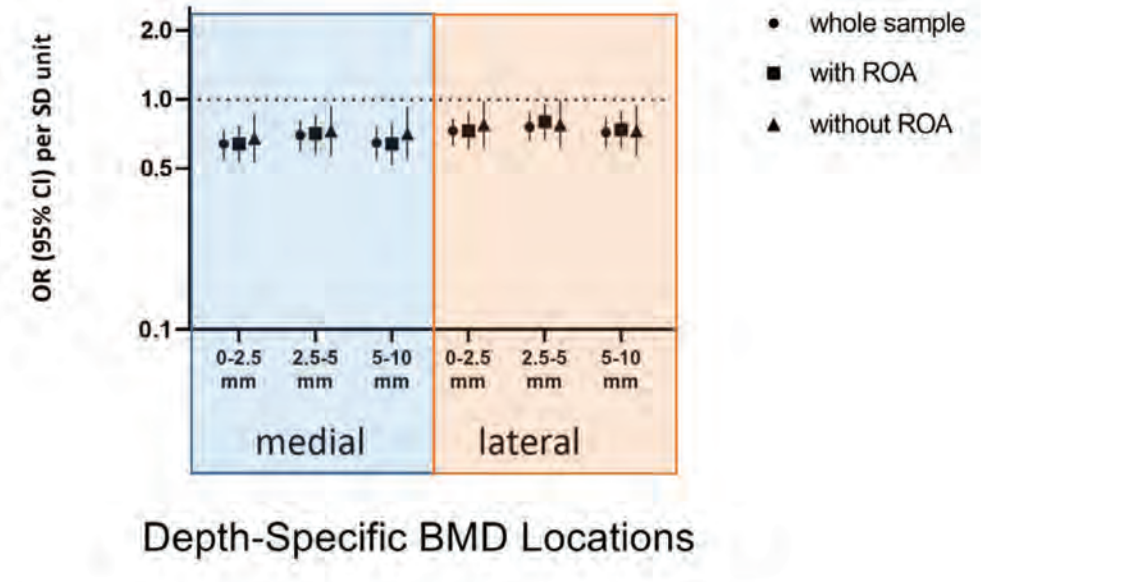
Relationship of Depth-Specific Subchondral Bone Mineral Density and Pain in Knee Osteoarthritis: The Multicenter Osteoarthritis Study

Jean Liew[1], JD Johnston[2], Na Wang[3], John Lynch[4], Cora Lewis[5], James Torner[6] and Tuhina Neogi[3], [1]University of Washington, Seattle, WA, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]Boston University School of Medicine, Boston, MA, [4]UCSF, San Francisco, CA, [5]University of Alabama Birmingham, Birmingham, AL, [6]University of Iowa, Iowa City, IA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: OA has traditionally been considered a disease of cartilage but early OA changes in subchondral bone may precede cartilage abnormalities. Altered subchondral bone mineral density (BMD) is thought to lead to cartilage pathology through abnormal force transfer. This in turn may contribute to pain in OA. It is unclear whether BMD increases or decreases with OA, and/or what effect these changes may have on pain. CT topographic mapping of subchondral density (CT-TOMASD) is a 3D imaging tool that precisely measures subchondral cortical and trabec-

Figure 1. Relation of subchondral tibial BMD to knee pain, by compartment and depth, with stratification by ROA status



All models adjusted for age, sex, and BMI. Adjusted ORs are reported for a SD-unit difference in subchondral BMD.

Abbreviations: BMD, bone mineral density; BMI, body mass index; OR, odds ratio; ROA, radiographic osteoarthritis; SD, standard deviation

Figure 1.

ular BMD in relation to depth from the subchondral surface. The aim of this study was to evaluate compartment- and depth-specific subchondral BMD in relation to knee pain.

Methods: Participants from the Multicenter Osteoarthritis (MOST) study, a NIH-funded longitudinal prospective cohort of older adults with or at risk of knee OA, who had knee CTs and knee pain assessed were included in this cross-sectional analysis. Knee pain was measured as the mean pain in the past 30 days, scored on a visual analog scale (VAS) (range 0-100), and dichotomized at 40/100. CT-TOMASD was used to assess tibial subchondral BMD at depths of 0-2.5 mm, 2.5-5.0 mm, and 5-10 mm relative to the subchondral surface. Regional analyses of each medial and lateral plateau, at each depth were performed to calculate average BMD. We evaluated the relation of subchondral BMD to presence of knee pain using logistic regression with generalized estimating equations to account for 2 knees within individuals, for each compartment and depth in separate models, and adjusted for age, sex, and body mass index (BMI). We additionally adjusted for, and stratified by, radiographic OA (ROA) status in separate models.

Results: 2082 subjects were included (mean age 61.1±9.7, 56.5% female, mean BMI 28.8±5.2 kg/m^2). The odds of having a VAS knee pain of ≥40/100 was significantly lower for a SD-unit increase in average subchondral BMD, after adjustment for age, sex, and BMI. This association was seen in both medial and lateral compartments though more marked within the medial compartment. The magnitude of association did not differ for increasing depths beneath the subchondral surface. Analyses adjusting for, or stratifying by, ROA status did not differ substantially from the main results.

Conclusion: Lower subchondral tibial BMD measures were associated with higher knee pain scores in individuals with or at risk for knee OA. There were no clear differences noted with increasing depths beneath the subchondral surface that would support differential depth-specific contributions from subchondral BMD involved in the pathogenesis of pain in knee OA. These findings may reflect the stage of OA at which there may be high bone remodeling in response to abnormal joint loading, impact or injury, and may be worth exploring as a more timely stage of intervening for targeting OA-related pain. Further studies using CT-TOMASD will evaluate the association of these subchondral BMD measures, including effects of stress-shielding, and structural changes seen on MRI.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: It is unknown whether early changes in the menisci (e.g., intrameniscal signal alterations) have long-term consequences. We conducted a study to assess the prognostic potential of intrameniscal signal alterations with incident destabilizing meniscal tears (radial or complex tears or macerated menisci) or accelerated knee osteoarthritis (KOA).

Methods: We used existing magnetic resonance (MR)-based data from a sex-matched nested case-control study of 3 groups from the Osteoarthritis Initiative without radiographic KOA at baseline (Kellgren-Lawrence [KL] < 2): 1) accelerated KOA: developed KL 3 or 4 within 48 months; 2) typical KOA: increased in KL grade within 48 months (excluding accelerated KOA); 3) no KOA: no change in KL grade within 48 months. From the original groups (n = 375), we included people with intact medial and lateral menisci at baseline (n = 226) and 48-month meniscal data (n = 221). Two readers read annual intermediate-weighted MR sequences with and without fat-suppression from baseline to the 48-month visit using a modified version of the International Society of Arthroscopy, Knee Surgery, and Orthopaedic Sports Medicine meniscal tear classification. The readers assessed 3 regions (anterior, body, posterior) of the medial and lateral menisci. Baseline meniscal status was operationally defined: 1) normal (intact with no signal intensity abnormalities) and 2) intrameniscal signal alteration (intrameniscal increased signal on a fluid-sensitive sequence that does not extend to an articular surface). We defined an incident destabilizing meniscal tear as the emergence of a radial (including root tears) or complex tear or maceration. Our readers had good inter-reader agreement (medial meniscal interobserver kappa = 0.90; lateral meniscal kappa = 0.63). We used 2 logistic regression models to assess

Table. The Presence of Baseline Intrameniscal Signal Alterations Predicts Future Destabilizing Meniscal Tears and Incident Accelerated Knee Osteoarthritis (KOA)				
Outcome	**Predictor**	**Outcome Presence**		
		Absent	**Present**	**Odds Ratio (95% CI)**
Incident Medial Destabilizing Meniscal Tear	No medial intrameniscal signal alterations	122 (91%)	12 (9%)	Reference
	Medial intrameniscal signal alterations	67 (77%)	20 (23%)	3.03 (1.40 to 6.59)
Incident accelerated KOA (reference= typical KOA)	No medial or lateral intrameniscal signal alterations	34 (71%)	14 (29%)	Reference
	Medial or lateral intrameniscal signal alterations	31 (40%)	47 (60%)	3.68 (1.71 to 7.95)
Note. 95% CI = 95% confidence interval				

1) whether the presence of medial intrameniscal signal alteration (predictor) was associated with an incident medial destabilizing meniscal tear versus no incident medial destabilizing meniscal tear (reference group), and 2) if the presence of intrameniscal alterations in either meniscus predicted incident accelerated versus typical KOA (reference group) over the next 4 years.

Results: We analyzed 221 knees with intact medial and lateral menisci at baseline. Overall, the study sample was mostly female (68%), with an average age of 58 (8) years, and an average body mass index of 28.1 (4.8) kg/m^2. The presence of medial intrameniscal signal alterations was strongly associated with incident medial destabilizing meniscal tears (odds ratio = 3.0 [95% CI = 1.4 to 6.6]; Table). Though numbers were small, 8 out of 9 incident lateral destabilizing meniscal tears had lateral intrameniscal signal alterations at baseline. The presence of baseline intrameniscal signal alteration in a knee strongly predicted the onset of accelerated versus typical KOA (odds ratio = 3.7 [95% CI = 1.7 to 8.0]; Table).

Conclusion: Intrameniscal signal alterations on intermediate-weighted fat-suppressed images may be clinically meaningful as they relate to future outcomes. Intrameniscal signal alterations may be a potential therapeutic target and warrant further study.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: MRI has identified joint tissues affected during knee OA development, though the relative importance of structures in the pathogenic process is unknown. Our objective was to estimate relative contributions of structural abnormalities to risk of incident radiographic knee OA (iRKOA), with assessment of longitudinal MRI during 10 year follow-up.

Methods: We conducted a case-cohort study with 10 year follow-up. The parent cohort included 2,987 Osteoarthritis Initiative participants with at least one knee at risk of developing iRKOA (i.e., Kellgren-Lawrence [KL] 0 or 1 at baseline). Within the parent cohort, participants who developed iRKOA (cases, n=844) and a random sample of the parent cohort (subcohort, n=868) were identified for MRI readings, a total of 1,455 participants (Figure 1). If a participant had two knees at risk, we selected the first knee to develop iRKOA or otherwise selected a knee at random (one knee per person).

Participants underwent bilateral posteroanterior fixed-flexion weight-bearing x-ray at baseline and annually through year 4, and then every two years until year 10; x-rays were centrally read for KL grade. 3T MRI was acquired at clinic visits up to year 8; longitudinal structural abnormalities in knees identified as cases and/or in the subcohort were graded using the MRI Osteoarthritis Knee Score (MOAKS).

We fit Cox models for time to iRKOA, with subcohort controls weighted inversely proportional to the sampling fraction; longitudinal structural features were included as time-varying predictors, lagged from the visit prior to each x-ray to establish temporality. We fit feature-specific models for bone marrow lesions (BML), cartilage damage, and meniscal damage with maximum scores in each compartment (i.e., medial tibiofemoral [TF], lateral TF, patellofemoral

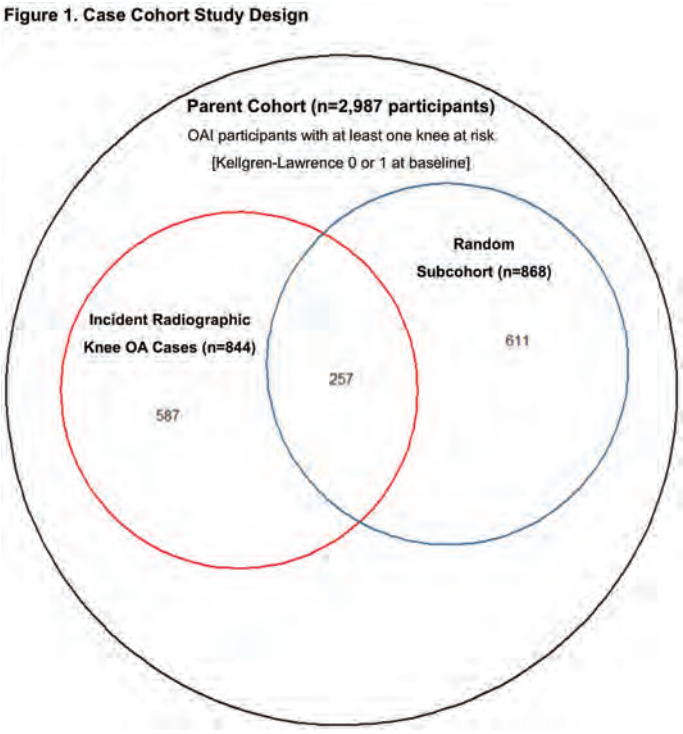

Figure 1.

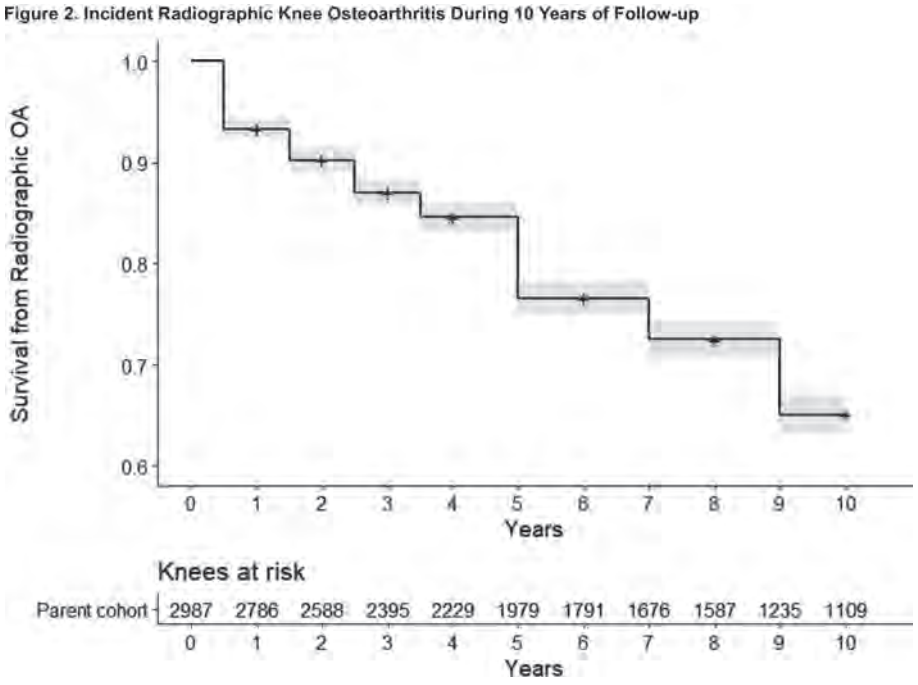

Figure 2.

[PF]), as well as an inflammation model for whole-knee effusion-synovitis (ES) and Hoffa-synovitis (HS). We also fit a full model with all features.

Results: Time to iRKOA is shown in Figure 2. The subcohort reflected the parent cohort, with a mean age of 60 years (SD 9), 55% female, 84% white and 14% African American, and predominately overweight (40%) or obese (32%).

In feature-specific models, all structural abnormalities were associated with iRKOA, and in nearly every compartment. The magnitude of association for specific abnormalities attenuated in the full model that included all features, though medium/large ES and PF cartilage damage of >10% surface area with >10% full-thickness or >75% surface area was associated with at least a two-fold increase in risk of iRKOA (based on lower bounds of the 95%CIs). Small ES, large medial TF BMLs, and PFJ cartilage damage of 10-75% surface area with any full-thickness, and lateral meniscus maceration were estimated to increase risk by at least 50% (Table 1).

Conclusion: While all structural abnormalities were associated with iRKOA in at least one compartment, our findings suggest that ES, PF cartilage damage, large medial TF BMLs, and lateral meniscus maceration are particularly indicative of increased risk of iRKOA. Varied structural abnormalities associated with knee OA development suggests heterogenous disease pathology that may require custom multifaceted treatment approaches.

Table 1. MRI-detected abnormalities and Incident Radiographic Knee Osteoarthritis

MRI-detected abnormalities			Time points	HR (95%CI)* (feature-specific models)	Wald X^2 p-value*	HR (95%CI)** (full model with all features)	Wald X^2 p-value**

The Relation of MRI-Based Cartilage Lesions to Knee Replacement and Knee Pain Severity in Osteoarthritis: The Multicenter Osteoarthritis Study

Tuhina Neogi[1], David Felson[1], Kathy Bacon[2], James Torner[3], Cora Lewis[4], Michael Nevitt[5] and S. Reza Jafarzadeh[1], [1]Boston University School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, [3]University of Iowa, Iowa City, IA, [4]University of Alabama Birmingham, Birmingham, AL, [5]University of California, San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, the FDA has indicated that data supporting imaging biomarkers of relevance to clinically important outcomes, such as knee replacement (KR) may be considered as an endpoint for OA RCTs, including MRI-based cartilage evaluations. We therefore evaluated the relation of MRI-based cartilage lesions to knee replacement and knee pain severity, short-term change in cartilage lesions, which is of relevance for drug development programs so that insights can be gained regarding likelihood of clinically important outcomes after a shorter term RCT based on a surrogate.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of persons with or at risk of knee OA. All participants had knee MRIs and WOMAC pain obtained at baseline, 30-, 60-, and 84-months. Cartilage lesions were scored from 1.0 T knee MRIs using WORMS. To replicate eligibility for trials, we excluded knees with KL=4 or malalignment >5 degrees. We evaluated the relation of baseline and 2.5-year changes in cartilage lesions to subsequent risk of KR and WOMAC knee pain severity over 7 years. Baseline cartilage lesions were analyzed as: 1) maximal score across all subregions (0-6); 2) sum of scores across all subregions (0-84). Change over 2.5 years were analyzed as: 1) change in sum of scores; 2) proportion of subregions with worsening lesions. We evaluated the sample as a whole, as well as limited to those with JSN=2 (~ JSW=1.5-3.5mm), a group demonstrating more responsiveness in recent RCTs, and to those with WOMAC pain 8-18 (out of 20), a typical pain range for entry into RCTs. For the relation of cartilage lesions to KR, we used a mixed-effects Cox proportional hazards model with a random-intercept for subjects. For WOMAC pain, we used linear mixed-effects model with a random-intercept for subjects and a nested random-intercept for knees within subjects. For analyses of change in cartilage score from baseline to 2.5 years later, we evaluated outcomes occurring at time-points after 2.5 years.

Results: Overall, 1755 subjects (2554 knees) met inclusion criteria (mean age 62, 64% female, 86.5% White, mean WOMAC pain 2.7). 113 knees underwent KR overall (4.4%); of knees that were JSN=2 at baseline, 19.8% (41/258)

Knee Replacement		**Worst cartilage score across all subregions at baseline**		
		Whole Sample (N=2554)	Among JSN=2 (N=258)	Among WOMAC pain 8-18/20 (N=244)
	% with event	4.4%	19.8%	10.2%
	Hazard Ratio* (95% CI) (per unit increase** in score)	**1.71 (1.38, 2.12)**	**1.78 (1.04, 3.04)**	**3.17 (1.33, 7.53)**
		Change in sum of WORMS cartilage score across all subregions over 2.5 years

	Beta Coefficient* (95% CI) (per unit increase** in sum)	**0.08 (0.04, 0.11)**	0.07 (-0.10, 0.23)	-0.04 (-0.15, 0.07)

*adjusted for age, sex, BMI, race, education, employment status, insurance status, maximum joint-space narrowing grade, alignment

**each unit increase in score for worst cartilage score (0-6) is not the same as the increment for each increase in sum for change in sum of WORMS cartilage score (-17 to +26.5)

Relation of Baseline & 2.5-year Change in Cartilage Morphology to Risk of Knee Replacement and to Knee Pain Severity

underwent KR and of knees with WOMAC 8-18 at baseline, 10.2% (25/244) underwent KR. Overall, both severity and extent of baseline cartilage lesions as well as change in cartilage lesions over 2.5 years were significantly associated with risk of KR (**Table**). In contrast, while cartilage lesions were significantly associated with WOMAC pain severity, the relationship was weak (**Table**).

Conclusion: These findings support the clinical relevance of cartilage lesions to the clinically important endpoint of KR. Relatively short-term changes in cartilage lesions over 2.5 years may be potentially useful as a prognostic marker for later clinical endpoints such as KR. However, the magnitude may not be sufficient for validation as an imaging

biomarker. In contrast, cartilage lesions were not strongly associated with WOMAC pain, potentially partly reflecting the uncertainty in utility of WOMAC pain to detect long-term change in pain over several years.

Magnetic Resonance Imaging Structural Changes Correlated with Knee Extension: Data from the Osteoarthritis Initiative

T Mark Campbell[1], Guy Trudel[2] and Dennis McGonagle[3], [1]Elisabeth Bruyère Hospital, Ottawa, ON, Canada, [2]The Ottawa Hospital, Ottawa, ON, Canada, [3]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Knee OA is often accompanied by loss of passive extension, termed a flexion contracture (FC), resulting in worse clinical outcomes. To our knowledge, MRI-based studies examining OA-related changes associated with knee FC have not been performed. Our objective was to study associations between knee FC and MRI-based OA-related structural changes. We hypothesized: 1) knee FC would be associated with cartilage lesions and bone marrow lesions (BMLs) in the patellofemoral (PF) joint, as well as osteophytes and meniscal alterations, and 2) normal knee extension would have high negative predictability for PF cartilage lesions and BMLs. We tested our hypotheses using data from the Osteoarthritis Initiative (OAI).

Methods: The OAI (NCT00080171, ethics approval #10-00532) is a National Institutes of Health (NIH)-funded, multi-center, prospective cohort study focusing on knee OA. For this study, 596 knees with knee extension data from the Foundation for the NIH nested case-control study were included. Knee extension was measured with a goniometer using a method with high inter-rater reliability. Inability to extend the knee to 0° constituted a FC.

Enrolment 3-Tesla MRI images were scored with the MRI Osteoarthritis knee score (MOAKS) system with assessors blinded to participant ID. Structural changes (cartilage lesions, BMLs, osteophytes, meniscal alterations, effusion, synovitis) within MOAKS-based regions of the knee that could biomechanically obstruct extension were analyzed (Figure 1A). Multivariable linear regression models evaluated for effect size of MRI outcomes on knee extension. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated based on presence or absence of FC. Area under the curve (AUC) was calculated using knee extension as a continuous variable for all participants and those without radiographic OA [Kellgren-Lawrence (KL) scores 0-1] or knee hyperextension.

Results: Of 596 participants, 72 (12.1%) had KL scores 0-1 (3.9% FC, 8.2% no FC). Knee alignment was overall 0.3±3.7° valgus. Higher lateral femoral cartilage scores (indicating greater size and depth of cartilage lesions on the femoral side of the lateral PF joint) and BML number scores were associated with lost knee extension (Table 1). Higher osteophyte scores in multiple regions correlated with lost knee extension (Table 1). Worse meniscal score in the medial meniscal body and posterior horn and a worse effusion score correlated with lost knee extension (Table 1). A representative image of a knee with FC is shown in Figure 1B.

Table 1. Multivariable linear regression showing effect size of OA-related structural changes on knee extension loss

Structural feature	Beta	95% C.I.	p-value
Cartilage morphology			
Femur lateral anterior	0.709	0.399-1.019	<0.001
BML Number			
Femur lateral anterior	0.666	0.211-1.122	<0.001
Osteophytes			
Femur medial anterior	0.649	0.533-0.765	<0.001
Femur lateral anterior	1.145	1.044-1.245	<0.001
Tibia medial	0.883	0.755-1.011	<0.001
Tibia lateral	1.031	0.901-1.160	<0.001
Patella superior	0.634	0.528-0.741	<0.001
Patella inferior	0.814	0.687-0.942	<0.001
Patella medial	0.608	0.481-0.736	<0.001
Patella lateral	0.598	0.486-0.709	<0.001
Meniscus			
MM morphology - body	0.164	0.007-0.321	0.040
MM morphology – posterior horn	0.400	0.229-0.570	<0.001
Whole Joint effusion	0.711	0.324-1.098	<0.001

Linear regression model adjusting for age, BMI, gender, KL grade, knee laterality, knee alignment, WOMAC pain.
C.I.: confidence interval; MM: medial meniscus.

Table 2. Sensitivity, specificity, positive and negative predictive values of knee extension loss for the detection of an anterior lateral cartilage and BML number

	All participants	KL 0-1, no hypertextension
	Value (%) [95% C.I.]	Value (%) [95% C.I.]
Presence of cartilage lesion		
Sensitivity	43.1 [36.7-49.6]	54.5 [26.5-80.6]
Specificity	72.5 [67.8-76.9]	55.3 [39.5-70.3]
PPV	48.7 [41.8-55.7]	26.1 [11.3-45.9]
NPV	67.8 [63.1-72.2]	80.8 [63.1-92.6]
Presence of BML		
Sensitivity	41.5% [34.3-49.0]	83.3 [44.6-99.0]
Specificity	69.9 [65.4-74.1]	58.1 [43.2-72.1]
PPV	35.7 [29.2-42.5]	21.7 [8.4-41.0]
NPV	74.8 [70.4-78.9]	96.2 [84.1-99.8]

BML: bone marrow lesion; C.I.: confidence interval; NPV: negative predictive value; PPV: positive predictive value.

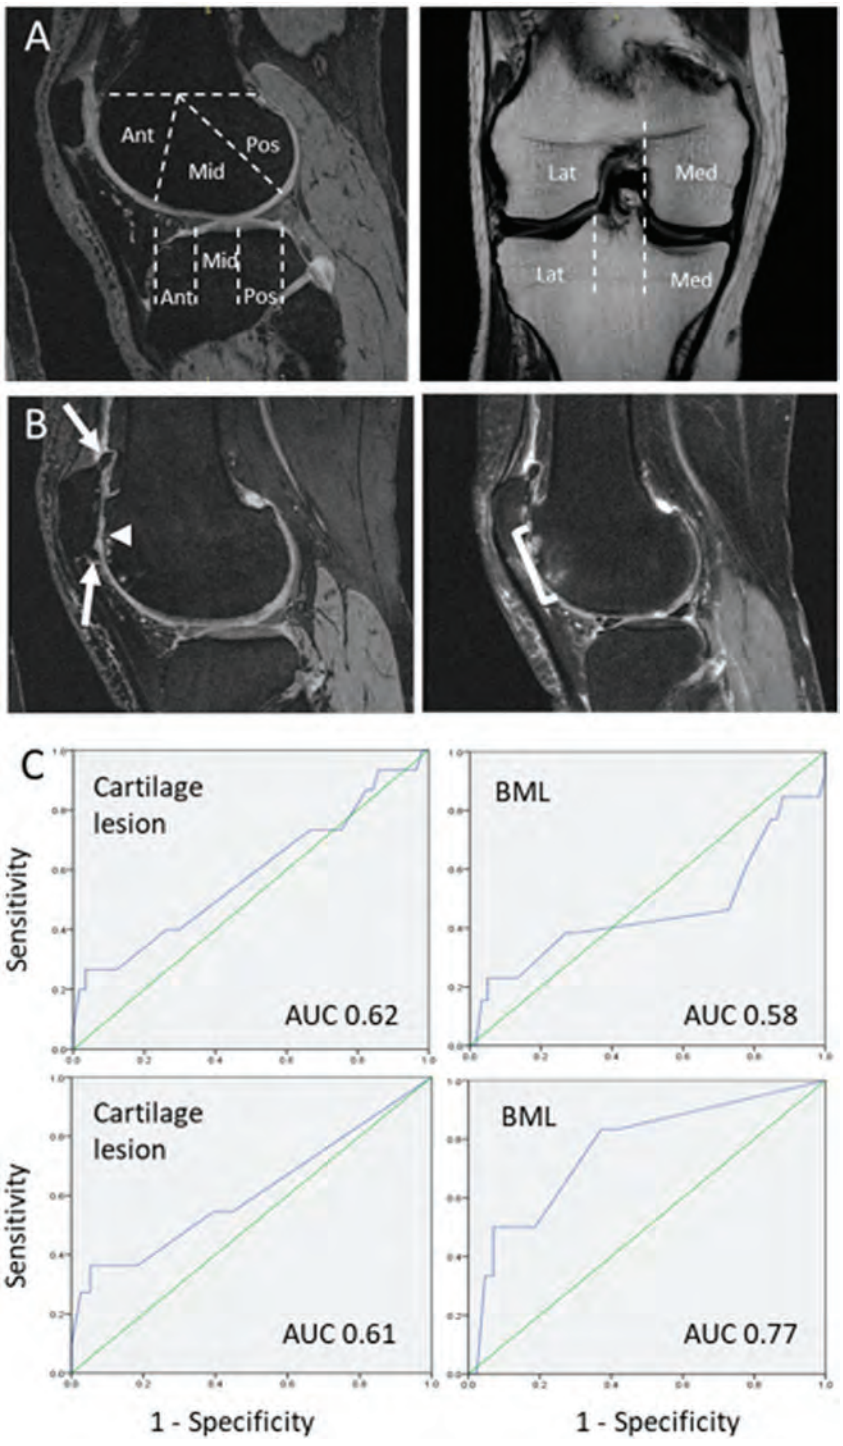

Figure 1. Structural changes associated with knee extension loss. (A) Left: Regional knee division of the MRI Osteoarthritis Knee Scoring system. Cartilage and bone marrow lesions were evaluated in the patellar, anterior (ant) and middle (mid) femoral, and anterior tibial regions where they could limit knee extension via pain inhibition. Osteophytes were evaluated in the patellar, anterior and middle femoral and anterior tibial regions where they could mechanically limit knee extension. Meniscal lesions were evaluated in all regions, as any "locking" from meniscal tears could limit knee extension. Right: Corresponding coronal sections where medial and lateral regions were investigated. (B) MRI of a participant with knee flexion contracture Left: Dual echo steady state sequence showing thinner articular cartilage in the antero-lateral femur making up the femoral side of the patellofemoral joint (arrowhead) and patellar osteophytes (arrows). Right: T2-weighted image with bracket showing large BML in the antero-lateral femur. (C) Receiver-operator curves for the presence of cartilage lesion (left) and bone marrow lesion (BML, right). Top: All participants KL 0-1 (n=596). Bottom: KL 0-1, excluding knees with hyperextension (n=49). Ant: anterior; AUC: Area under the curve; Med: medial; Lat: lateral; Mid: middle; Pos: posterior.

Sensitivity, specificity, PPV and NPV for presence/absence of knee FC are summarized in Table 2. For those with KL score 0-1 without hyperextension AUC was 0.77 (95% C.I. 0.55-0.98; Figure 1C).

Conclusion: Knee extension loss was associated with widespread degenerative changes, including those not visible on knee x-ray, and appears to be linked to global severity of disease. Precisely measuring knee extension may help predict knee OA progression, obviating the need for MRI and reducing health care costs. Longitudinal studies evaluating knee extension as a biomarker for MRI-related structural changes are needed.

Prediction Model for Progression to Different Find-Grained MRI-Based Osteoarthritis Severity States: The Vancouver Longitudinal Study of Early Knee Osteoarthritis (VALSEKO)

Jolanda Cibere[1], Ali Guermazi[2], Savvas Nicolaou[3], Jacek Kopec[4], John Esdaile[5], Hubert Wong[6], Joel Singer[6], Anona Thorne[6] and Eric Sayre[7], [1]Arthritis Research Canada, University of British Columbia, Vancouver, BC, Canada, [2]Boston University School of Medicine, Boston, MA, [3]University of British Columbia, Vancouver, BC, Canada, [4]University of British Columbia, Arthritis Research Canada, Richmond, BC, Canada, [5]Arthritis Research Canada, Vancouver, BC, Canada, [6]University of British Columbia, Vancouver, Canada, [7]Arthritis Research Canada, Richmond, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To develop a novel, fine-grained MRI osteoarthritis (OA) severity score, based on cartilage, osteophytes and meniscus (OA-COM) scores and to predict the progression to different OA severity states using OA-COM scores as the outcome and clinical variables as predictors in a population-based 7-year longitudinal cohort study.

Methods: A population-based cohort, age 40-79, was assessed at baseline, 3- and 7-year follow-up using clinical assessments, x-ray and MRI. MRI OA severity score was based on the sum of scores for cartilage, osteophytes and menisci, measured semi-quantitatively at 6, 8 and 6 sites, respectively, using 0-3 grading for cartilage and osteophytes and 0-2 grading for menisci, for a total score ranging from 0-54, where 0 = no MRI OA and 54 = severe MRI OA. In order to anchor the OA-COM score at interpreTable points representing different levels of disease severity, we fit logistic regression models using baseline OA-COM score to predict each baseline Kellgren Lawrence (KL) grade in a subset of data including only KL grades at or one point below the predicted grade. For each model, we produced ROC curves and for each cut point we computed sensitivity, specificity, positive and negative predictive values and sum of squares (SS) of those statistics. The optimal threshold for OA-COM scores in predicting a given KL grade was selected using the cut points with the highest SS, adjusted to attain equal spacing between cut points. To predict progression to different OA severity states, we developed logistic regression models for progression at or above the given OA-COM score cut point from baseline to 7-year follow-up, using the subset of data of patients who could progress; that is, with OA-COM score below the given cut point at baseline. Predictors in multivariable models were selected using forward selection based on best AIC at each step. In order to obtain results that were population-representative, sample weights were used for all analyses.

OA-COM cut-point	Predictor variable	OR (95% CI)	AUC (95% CI)
12	Age (per 10 years) BMI Female Effusion	1.34 (0.57, 3.13) 1.19 (1.00, 1.41) 6.82 (1.40, 33.3) 8.74 (0.62, 123.5)	0.793 (0.658, 0.929)
18	Age (per 10 years) BMI Female Effusion	1.13 (0.61, 2.07) 1.11 (0.99, 1.25) 2.11 (0.75, 5.94) 8.43 (2.20, 32.38)	0.719 (0.602, 0.837)
24	Age (per 10 years) BMI Crepitus (fine) Crepitus (coarse) Malalignment Effusion	1.82 (0.99, 3.35) 1.03 (0.89, 1.19) 0.94 (0.24, 3.64) 3.63 (0.80, 16.35) 4.68 (1.08, 20.25) 3.56 (0.99, 12.86)	0.823 (0.730, 0.916)
30	Age (per 10 years) BMI Female Crepitus (fine) Crepitus (coarse)	1.77 (0.99, 3.17) 1.07 (0.92, 1.23) 0.51 (0.17, 1.54) 4.55 (0.77, 26.86) 6.48 (0.94, 44.50)	0.768 (0.660, 0.876)

Logistic regression analysis to predict progression to OA-COM states, using cut-points 12, 18, 24 and 30 as outcomes.

Results: Of 122 subjects, at baseline, 39.6% had radiographic OA (KL grade ≥2), mean age 55.5, female sex 55.7%. OA-COM score cut points were 12, 18, 24 and 30 for KL grades 1 to 4, respectively. Clinical predictor variables and odds ratios for each OA-COM cut point are shown in the Table 1. BMI was predictive of progression to all OA-COM scores over 7 years. Effusion was a strong predictor for progression to an OA-COM score of 12, 18 and 24, while malalignment and coarse crepitus predicted progression to higher OA-COM scores of 24 and 30.

Conclusion: We have developed a novel MRI OA severity score, the OA-COM score, using cartilage, osteophytes and menisci. OA-COM scores of 12, 18, 24 and 30 represent an MRI score that is equivalent to KL grades 1 to 4, while offering fine-grain differentiation of OA states between KL grades. In prediction modeling, we found that effusion, malalignment and crepitus, as well as age, sex and BMI, were predictive of progression to different states of OA severity over 7 years in this population-based cohort.

Bone Marrow Lesion Scores in Patients with Knee Osteoarthritis Undergoing Tibial Osteotomy: Reliability and Concurrent Validity of the Knee Inflammation MRI Scoring System (KIMRISS)

Jenna Schulz[1], Trevor Birmingham[1], Walter Maksymowych[2], Robert G Lambert[3], Stephany Pritchett[4], Frank Beier[1], J. Robert Giffin[5] and Tom Appleton[6], [1]Western University, London, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]University of Alberta and CARE Arthritis, Edmonton, AB, Canada, [4]London Health Sciences Centre, London, Canada, [5]Western University and London Health Sciences Centre, London, Canada, [6]The University of Western Ontario, LONDON, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Bone marrow lesions (BMLs) commonly occur in knee osteoarthritis (OA) and are associated with increased risk of cartilage damage and pain. The Knee Inflammation MRI Scoring System (KIMRISS) is a semi-quantitative (score range 0-500) grading tool designed to evaluate features of inflammation in patients with knee OA. Therefore, we assessed 1) inter-rater reliability of KIMRISS BML scores between expert readers and a trainee reader before and 1-year BML scores before and 1-year after medial opening wedge HTO and 2) concurrent validity of semi-quantitative (KIMRISS) and quantitative (manual segmentation) measures of BMLs at baseline.

Methods: Thirty-four patients with varus alignment and medial compartment knee OA undergoing unilateral HTO were included. 3-Tesla MRIs were acquired of both knees pre and 1-year post HTO, after surgical removal of hardware. Femoral BML scores in the medial and lateral compartments were assessed on images blinded to limb and time by masking evidence of surgery. Three raters independently scored the same 136 scans (two limbs at two time points

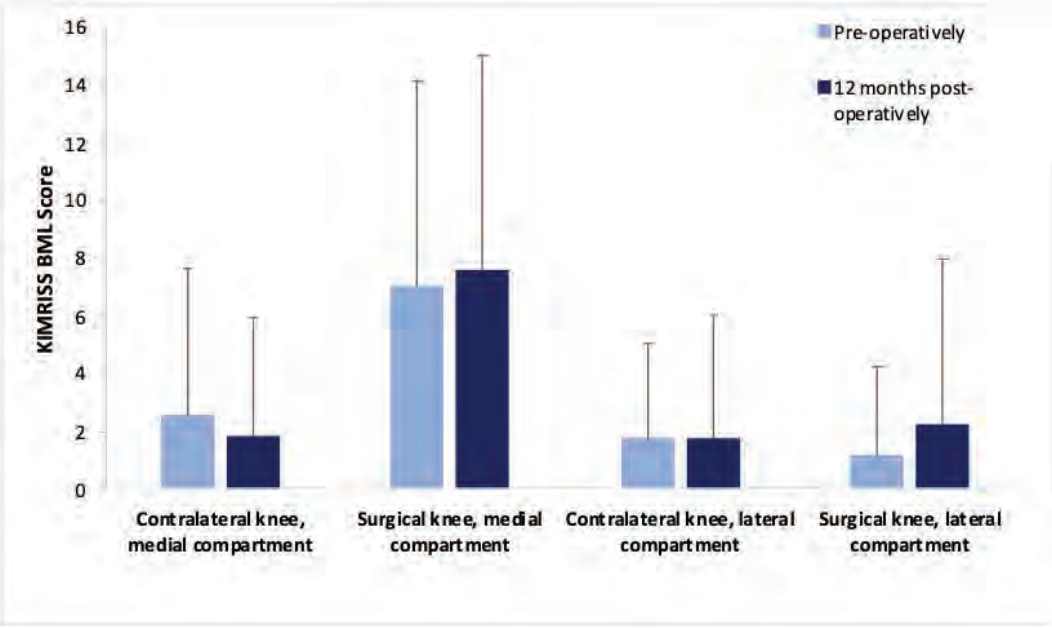

Figure 1. Means and standard deviations for KIMRISS femoral BML scores in the medial and lateral compartments for surgical and contralateral knees.

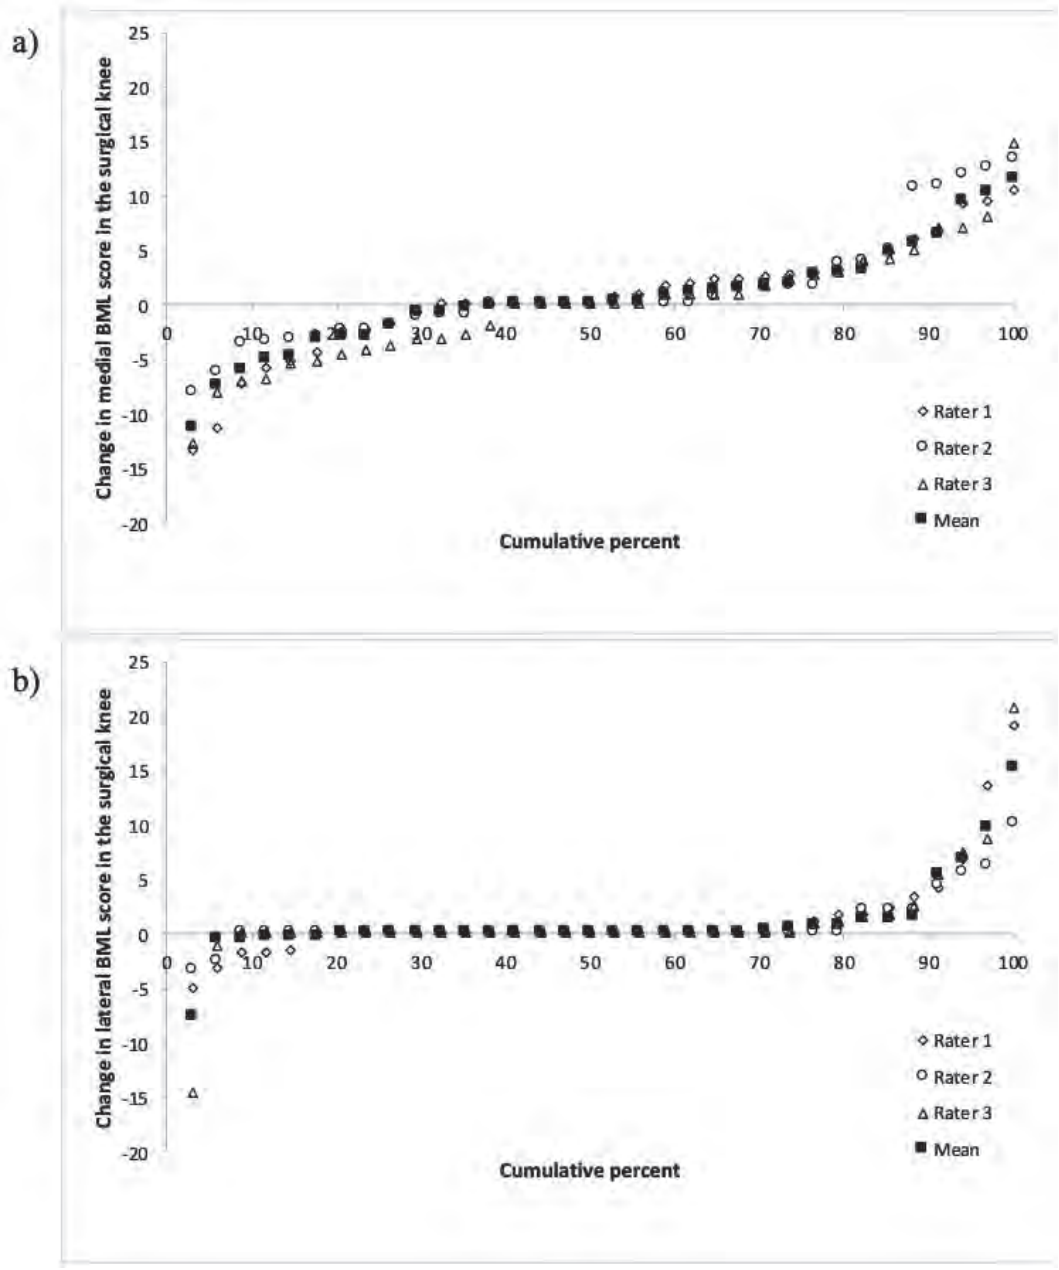

Figure 2. Change after surgery in the femoral BML score in both the medial (a) and lateral (b) compartments of the surgical knee for all three raters individually, as well as the average.

for each patient) using the KIMRISS. Additionally, one rater manually segmented femoral BMLs. Reliability of BML change scores in the medial and lateral compartment of the surgical limb were evaluated by calculating intraclass correlation coefficients (ICC) and Bland-Altman plots with 80% Limits of Agreement (LoA). Correlations between KIMRISS and manual segmentation values on the pre-operative surgical limb were evaluated using Pearson's correlation coefficients (r).

Results: Descriptive statistics for KIMRISS scores are reported in Figure 1. The mean change in the surgical limb (± SD) was 0.54 ± 4.78 in the medial compartment and 1.00 ± 3.62 in the lateral compartment. Changes following surgery varied considerably but were detected by all three raters (Figure 2). When combining all three raters, the ICC

a) Medial compartment		c) Medial compartment	
Rater pair	**ICC (95% CI)**	**Rater pair**	**80% LoA**
1 vs 2	0.77 (0.59, 0.89)	1 vs 2	-4.68, 7.51
1 vs 3	0.76 (0.57, 0.87)	1 vs 3	-5.07, 6.55
2 vs 3	0.69 (0.45, 0.83)	2 vs 3	-5.03, 7.13
Combined	0.74 (0.59, 0.85)	Combined	-3.57, 5.44
b) Lateral compartment		**d) Lateral compartment**	
Rater pair	**ICC (95% CI)**	**Rater pair**	**80% LoA**
1 vs 2	0.68 (0.45, 0.83)	1 vs 2	-3.31, 5.89
1 vs 3	0.83 (0.68, 0.91)	1 vs 3	-4.92, 7.70
2 vs 3	0.56 (0.28, 0.76)	2 vs 3	-3.75, 5.96
Combined	0.71 (0.55, 0.83)	Combined	-1.57, 3.47

Table 1. Intraclass correlations (95% Confidence Intervals) (a,b) and 80% Limits of Agreement (c,d) for change in BML scores in the surgical knee in the medial and lateral compartments. Rater 1 = trainee, raters 2-3 = experts (one MSK radiologist and one rheumatologist).

(95% confidence interval) was 0.74 (0.59, 0.85) for the medial compartment and 0.71 (0.55, 0.83) for the lateral compartment. Paired rater ICCs ranged from 0.56-0.83. The 80% LoA was -3.57 to 5.44 for the medial compartment and -1.57 to 3.47 for the lateral compartment (Table 1). Paired rater LoA ranged from -5.07 to 7.70. Semi-quantitative and quantitative BML measures were positively correlated for the medial (r=0.54) and the lateral (r=0.39) compartments.

Conclusion: The KIMRISS can reliably detect small differences between femoral BML scores after HTO and can be learned by a trainee reader both efficiently and effectively. The KIMRISS BML scores are moderately correlated with scores from manual segmentation. These findings support the inter-rater reliability, concurrent validity and feasibility of KIMRISS compartment-specific BML scoring

Association of Primary Insurance Status on Bilateral Knee Arthroplasty Utilization and Complications: A United States Nationwide Analysis

Bella Mehta[1], Kaylee Ho[2], Jennifer Bido[3], Stavros Memtsoudis[3], Michael Parks[4], Linda Russell[5], Susan Goodman[1] and Said Ibrahim[6], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]Weill Cornell Medicine, New York, [3]Hospital for Special Surgery, New York, [4]Hospital for Special Surgery, Weill Cornell Medicine, New York, [5]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [6]Weill Cornell Medicine, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with end-stage bilateral knee osteoarthritis, treatment options include either a staged total knee arthroplasty (TKA) procedure, often with a few months in between surgeries, or a simultaneous bilateral TKA (BTKA) procedure during the same anesthetic session. The choice in treatment strategy largely depends on patient and surgeon preferences, and guidelines vary per institution. Our objective was to assess if variations in utilization and in-hospital complications in BTKA are associated with primary insurance.

Methods: Using the National Inpatient Sample (NIS)- Healthcare Cost and Utilization Project (HCUP) database (2007-2016) we sought to examine BTKA utilization and in-hospital complications comparing those with Medicare/Medicaid (CMS) vs those with private insurance (Pvt) in a retrospective analysis. All patients ≥ 50 years who underwent elective primary TKA were included. We computed differences in temporal trends in proportional utilization and in-hospital complications after BTKA comparing those with CMS vs Pvt insurance. Next, we performed multivariable logistic regression models to assess insurance differences in temporal trends adjusting for individual (age, sex, Elixhauser comorbidity index, and morbid obesity), hospital level (hospital volume, bed size, region and teaching status) and community level (median household income) variables. Discharge weights were used for nationwide estimates.

Results: An estimated 132,400 (49.5%) CMS patients and 135,046 (50.5%) privately insured patients underwent BTKA from 2007-2016. (Table 1) Amongst UTKA patients, 62.7% had CMS insurance and 37.3% had Pvt. While in both UTKA and BTKA, patients with private insurance were more likely to be younger and had a higher proportion of females. In univariate analysis, hospital mortality, length of stay and complications were significantly higher in those with CMS compared to private insurance ($p < 0.001$). After adjusting for covariates, CMS was associated with higher odds of in-hospital BTKA and UTKA complications compared to Pvt (Bilateral aOR: 1.10, 95% CI: 1.05–1.15, P = < 0.0001; Unilateral aOR: 1.32, 95% CI: 1.10–1.59, P = 0.003). BTKA in-hospital complications remained higher in CMS group throughout the study period (1.23% in Pvt vs 1.36% in CMS in 2007-08, whereas 0.54% in Pvt vs 1.14% in CMS in 2015-16), though the trend difference was not statistically significant (Figure 1). Proportional utilization of BTKA amongst private insurance was higher than CMS throughout the study period even after adjusting for covariates (7.18% in Pvt vs 4.59% in CMS in 2007-08, whereas 5.63% in Pvt vs 3.13% in CMS in 2015-16, P < .0001) (Figure 2).

Conclusion: In this nationwide study of BTKA patients from 2007 to 2016, we found that the utilization of BTKA is higher in those who are privately insured compared to those who have Medicare/Medicare insurance. Further privately insured patients have lower in-hospital complication rates compared to those with government insurance. There can be many factors explaining these findings such as working status and patient preference which may play a role in BTKA decisions and thus further research in this area need to be done to understand these differences.

A Comparison of Opioid-Related Outcomes Among Commercially-Insured Osteoarthritis Patients Treated with Tramadol vs. Non-Tramadol Opioids

Stuart Silverman[1], James Rice[2], Alan White[2], Catherine Fernan[2], Michael Somma[2], Craig Beck[3], Rebecca Robinson[4] and Patricia Schepman[5], [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Analysis Group, Boston, MA, [3]Pfizer, London, [4]Eli Lilly and Company, Indanapolis, IN, [5]Pfizer, New York City, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2019, the American College of Rheumatology conditionally recommended tramadol for patients with hip and knee osteoarthritis (OA). While tramadol is known to be less prone to opioid use disorders, little is known about the degree to which the magnitude of these disorders differ among patients receiving tramadol relative to other non-tramadol opioids, and also the degree to which other opioid-related outcomes are lower among those receiving tramadol. The goal of this research is to compare the clinical burden of commercially-insured patients diagnosed with OA of the hip and/or knee among patients initiated on treatment with tramadol relative to those receiving non-tramadol opioids, using a large, national database in recent years.

Methods: The Optum Healthcare Solutions, Inc. data (1/2012-3/2017) were used to identify patients ≥18 years old with ≥2 diagnoses of hip and/or knee OA, and ≥90 days supply of tramadol or non-tramadol opioids during the three-year period from first prescription (*index date*) after their first OA diagnosis. Patients were required to be continuously-enrolled during the six months before (baseline) and 36 months after (follow-up) the index date. Selected clinical outcomes including rates of opioid use disorders, opioid dependence medications, constipation, fatigue, nausea, falls, and fractures. Patients in each cohort were matched 1:1 using a propensity score model accounting for baseline characteristics that included demographics, underlying comorbid conditions, medical resource use, and direct medical costs prior to initiation of treatment.

Results: Data for 14,491 patients were analyzed: 4,048 (28%) were initiated on tramadol, and 10,443 (72%) were initiated on non-tramadol opioids. After matching, 4,048 patients in each cohort were analyzed. Tramadol patients had elevated risk of opioid use disorders (1.2% of patients with opioid use disorder diagnoses), however risk of opioid use disorders was almost 3-fold higher in the non-tramadol cohort (4.2%) ($p< 0.01$). Consistent with those findings, rates of methadone and buprenorphine were also elevated in the non-tramadol cohort relative to the non-tramadol cohort (1.9% vs. 0.5% ($p< 0.01$); 3.2% vs. 1.4% ($p< 0.01$) respectively). Rates of other opioid-related outcomes were also lower, although quantitatively similar among the tramadol cohort vs. non-tramadol cohort, with rates of falls of 7.9% and 9.2% ($p=0.03$); fractures of 15.6% and 17.9% ($p< 0.01$); nausea of 17.4% and 20.0% ($p< 0.01$); fatigue of 33.5% and 37.1% ($p< 0.01$); and constipation of 12.9% and 15.0% ($p< 0.01$), respectively. Total 3-year healthcare costs of the tramadol cohort were lower than the non-tramadol cohort ($54,122 vs. $60,303 ($p< 0.01$), or avg. annual costs of $18,040 vs. $20,101).

Conclusion: This study reinforces that rates of opioid use disorders among OA patients initiated on tramadol are lower than those initiated on non-tramadol opioids; other negative events commonly associated with opioid treatment are lower but quantitatively similar among patients receiving tramadol and non-tramadol opioids.

Session Date: Sunday, November 8, 2020

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) had profound impacts on societal and patient-centered outcomes, including disability. As the first step to leverage the rich resource of the Million Veterans Program (MVP) to examine genetic variants for OA in a large, ethnically diverse cohort, we implemented to characterize OA using data collected from the electronic health record (EHR).

Methods: OA cases and controls were identified using ICD9 and ICD10 codes, using data from 1990-2019. For OA case identification, lists of codes were provided for a general OA category and overlapping lists for specific subtypes of OA (Hip, Knee, Spine, Hand, Finger, and Thumb). Inclusion and exclusion lists were adapted from Zengini et al. 2018 (PMC5896734). Exclusion criteria for controls included a wide range of non-OA arthropathies. We further identified a list of codes for traumatic and post-traumatic arthropathy by examining ICD9 and ICD10 code descriptions for the string 'trauma' and identifying those denoting traumatic or post-traumatic arthropathy. To further increase specificity, a Veteran OA case was defined as having at least two ICD codes within an OA category at least 30 days

Prevalence of OA at each site by ancestry and key biological variables

apart, within the general OA category and/or within a subtype (e.g. Spine). Controls were identified as participants who were not OA cases and who had no codes in the exclusions list.

Results: A total of 121,229 Veterans of European, 29,225 Veterans of African, 10,613 Veterans of Hispanic and 1,399 Veterans of Asian descent had complete phenotypic and genotypic data for analyses. Using the above inclusion and exclusion criteria, the frequency of OA was 47% among Veterans of Europen descent, 58.1% among Veterans of African descent, 52.8% among Veterans of Hispanic descent and 33.1% among Veterans of Asian descent.

We found differences in prevalence of OA at various sites by sex, age and obesity (BMI >=30 kg/m^2) within different ancestaries (**Table 1**).

Conclusion: Overall OA burden was higher in non-Caucasian Veterans, except in Asian descent, where it was lower. OA prevalence by joint varied by biological factors.

Osteoarthritis in a Large Integrated Health System Population: 18-Year Retrospective Review

Jove Graham[1], Tonia Novosat[1], Haiyan Sun[1], Brian Piper[2], Joseph Boscarino[1], Melissa Kern[1], Vanessa Duboski[3], Eric Wright[3], Patricia Schepman[4], Rebecca Robinson[5], Edward Casey[6], Craig Beck[7] and Jerry Hall[8], [1]Geisinger, Danville, [2]Geisinger, Scranton, [3]Geisinger, Forty Fort, [4]Pfizer, New York City, NY, [5]Eli Lilly and Company, Indianapolis, [6]Pfizer, New York, [7]Pfizer, London, [8]Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a mechanically and immunologically mediated common disease with a complex pathogenesis. Despite epidemiologic studies proving increasing age, obesity and female gender as risk factors, many individuals are unable to manage OA symptoms and optimal treatment strategies at a population health level remain a challenge. Our aim was to determine prevalence, incidence and characteristics of OA patients over an 18-year timeframe to provide insight into what treatments and preventative strategies would maximize impact.

Methods: This was a retrospective descriptive study reviewing electronic health records and billing data at Geisinger, an integrated health system in central and northeastern Pennsylvania serving over 500,000 patients per year. Patients were included if they had at least two outpatient encounters at age 18 or greater and defined as having OA after having at least one diagnosis code for OA (ICD-9: 715.*, ICD-10 M15-19) on a problem list or encounter diagnosis or had an OA-related procedure (hip or knee replacement, arthroscopy or injection). Patients with total knee replacement (TKR) were also examined separately as a subset. For each year from 2001-2018, we calculated OA prevalence

	Patients with OA (n=271,126)	Patients with OA and total knee replacement (n=10,788)
Age at first visit, in years, N (%)		
<45	109,754 (40.5%)	1,013 (9.4%)
45-65	100,469 (37.1%)	5,681 (52.7%)
65-79	49,384 (18.2%)	3,668 (34.0%)
80+	11,519 (4.3%)	426 (4.0%)
Sex, N (%)		
Males	113,013 (41.7%)	4,308 (39.9%)
Females	158,086 (58.3%)	6,480 (60.1%)
Not documented	7 (<0.1%)	0 (0%)
Body mass index, in kg/m^3, N (% with measure available)		
<30	123,964 (51.7%)	2,669 (29.4%)
30-35	64,066 (26.7%)	3,140 (34.6%)
>35	51,680 (21.6%)	3,271 (36.0%)
Patients with medication at any time, N (%)		
Acetaminophen	170,384 (62.8%)	9,668 (89.6%)
Duloxetine	15,348 (5.7%)	897 (8.3%)
Homeopathic medication	3,346 (1.2%)	333 (3.1%)
Injectable OA medication	2,786 (1.0%)	316 (2.9%)
Oral NSAID or Continuous NSAID	162,288 (59.9%)	8,446 (78.3%)
Opioid (non-tramadol)	221,201 (81.6%)	10,316 (95.6%)
Salicylates	31,284 (11.5%)	4,472 (41.5%)
Topical OA medication	25,066 (9.3%)	1,669 (15.5%)
Tramadol	95,957 (35.4%)	8,006 (74.2%)
Patients with comorbidities at any time, N (%)		
Chronic pulmonary disease	56,522 (20.9%)	2,349 (21.8%)
Diabetes without complications	52,565 (19.4%)	3,142 (29.1%)
Any tumor	37,870 (14.0%)	1,267 (11.7%)
Hypertension	114,020 (42.1%)	6.983 (64.7%)
Chronic kidney disease	35,630 (13.1%)	2,520 (23.4%)
Gastroesophageal reflux disease	57,999 (21.4%)	3,045 (28.2%)
Depression	45,739 (16.9%)	1,904 (17.7%)
Anxiety disorders	53,50 (19.8%)	1,905 (17.7%)

Demographics, Medications, and Comorbidities Table

(percent of patients seen with OA) and incidence (percent of patients newly diagnosed with OA that year). We also examined baseline demographics, OA-related prescription medication use, and comorbidities at any time during the study period.

Results: We identified 271,126 patients with encounters in the health system and evidence of OA, representing 32% of the total patient population in 2018. Yearly incidence remained steady over the past 10 years at between 4 and 5 newly diagnosed per 100 and was similar between males and females. The cohort remained steady at approximately 60% female, and consistent with the geographic region, was 98% Caucasian and non-Hispanic. The largest segment of the OA population was in the range of 45 to 64 years old at first encounter, but the youngest age segment (18-45 years old) increased from 20% to 25% of the OA population over the study period. Over half (54%) of OA patients had a BMI over 30 and this percentage increased by 7% since 2001. Non-tramadol opioids were the most commonly prescribed pain medications, followed by acetaminophen (prescription or over-the-counter) and oral non-steroidal anti-inflammatory drugs. Depression and anxiety disorders were diagnosed in 17% and 20% of the OA population, respectively, 20% reported chronic obstructive pulmonary disease, and 46% reported current or past tobacco smok-

ing. Approximately 4% of patients underwent TKR; this subgroup was more likely to use prescription pain medication and had higher rates of several chronic diseases including congestive heart failure, hypertension and chronic kidney disease.

Conclusion: Osteoarthritis affected a large, increasing segment of a large health system population, with higher rates among females and the proportion of younger individuals increasing over time. The treatment of these patients may have been further complicated by comorbidities including obesity, depression, anxiety and multiple chronic disease states.

Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Knee osteoarthritis (OA) affects 32.5 million US adults and is typically treated by primary care physicians, rheumatologists (RH), orthopedists (OS), sports medicine (SM) physicians, and pain specialists (PS). Treatment is multimodal and comprises conservative and pharmacological therapies, intra-articular injections, and

Table 1: Demographics

	Total *N=854*	Orthopedist (OS) *n=352*	Rheumatologist (RH) *n=250*	Sports Medicine (SM) *n=152*	Pain Specialist (PS) *n=100*

Opioid; n=173 (20%)	3.2 years	32% (55)	51% (n=28) safety concerns 18% (n=10) unknown 36% (n=20) side effects 16% (n=9) lack of efficacy
Prescription antidepressant; n=89 (10%)	3.0 years	25% (22)	36% (n=8) lack of efficacy 36% (n=8) unknown 18% (n=4) side effects
Injectables	**Duration (mean)**		
Intra-articular corticosteroid; n=512 (60%)	1.4 years	82.4% (422)	17% (n=73) lack of efficacy 48% (n=201) unknown 14% (n=59) cost of medication 12% (n=50) worsening of symptoms
Single-injection hyaluronic acid; n=187 (22%)	2.0 years	52.4% (98)	61% (n=60) lack of efficacy 10% (n=10) unknown 22% (n=22) worsening of symptoms 12% (n=12) residual symptoms 9% (n=9) cost

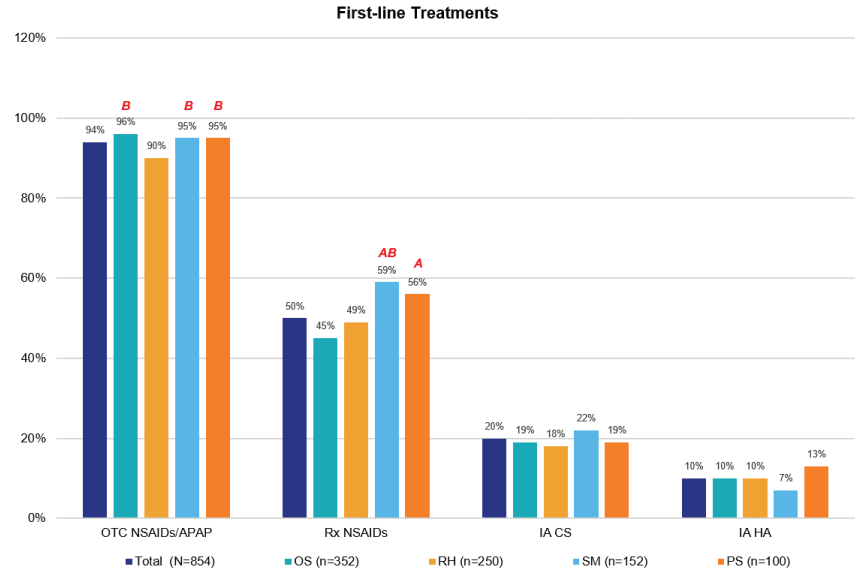
†Reasons for discontinuation are not mutually exclusive.

surgery. Guidelines provide recommendations in idealized settings, but little documentation exists in real world settings; hence, we aimed to assess patient characteristics and treatment patterns across 4 specialties.

Methods: This project was exempt from IRB review and HIPAA consent. Physicians with >2 years in practice and >10 knee OA patients per week were interviewed about their 2 most recent knee OA patients. Interviews (structured questions and answers) assessed demographics, referrals, comorbidities, time to treatment, and lines of therapy. As this study was designed to assess effect modifications, a confidence level of 90% was used.

Results: Patient demographics are shown in Table 1. Participating physicians included 125 RH, 176 OS, 76 SM, and 50 PS. Overall, 854 patients were included in the chart review. Patients were mean age 65 years, mean BMI 30.7, and 51% were female. First-line treatments are shown in Figure 1. Mean time between symptom onset and diagnosis was 3.4 years. Over 90% of patients used over-the-counter (OTC) nonsteroidal anti-inflammatory drugs (NSAIDs) and acetaminophen (APAP), with lowest use in RH patients. IA corticosteroids (CS) were used in ~20% of patients and hyaluronic acid (HA) in ~10% of patients, with similar use across specialties. Reasons for therapy discontinuation (DC) included lack of efficacy, AE/safety, and formulary/cost (Table 2). DC for lack of efficacy was 61% for single-injection HA. AE/safety concerns were reasons for DC of prescription (Rx) NSAIDs and opioids. Second-line treatments included CS >OTC Rx NSAIDs/APAP >HA. Third-line treatments were HA >CS >OTC Rx NSAIDs/APAP.

Figure 1: First-line treatments



Key: Statistical significance, *P*<0.1; A: versus orthopedist, B: versus rheumatologist, C: versus sports medicine physician, D: versus pain specialist

Mean BMI was significantly higher in SM (33) and PS (32) patients compared with OS (30) and RH (30) patients. There were significantly more female RH patients (56%) than OS patients (47%). PS patients had significantly higher current unemployment (73%) due to an inability to perform function (15%) than patients treated by other specialties. RH, SM, and PS patients had significantly more comorbidities than OS patients. Overall, mean pain (NRS 0–10) was 5.6 and KL grade was 3. PS patients had significantly higher pain scores (6.5) than patients treated by other specialties. Limitations included selection bias, confounding, small N, and missing data.

Conclusion: PS see more patients with pain syndromes and higher BMIs. RH see more patients with rheumatoid conditions. OS patients used significantly more OTC NSAIDs/APAP than RH patients and were less likely than SM and PS patients to use Rx NSAIDs. Lack of efficacy drove most therapy changes. Of HA patients, 61% discontinued due to lack of efficacy. These data suggested that treatment patterns for knee OA were similar across physician types, and new therapies can provide additional options to currently available treatments that may have efficacy or safety concerns.

Abstract Number: 1124

Improving Documentation Rates of Non-Pharmacologic Therapies for Knee Osteoarthritis

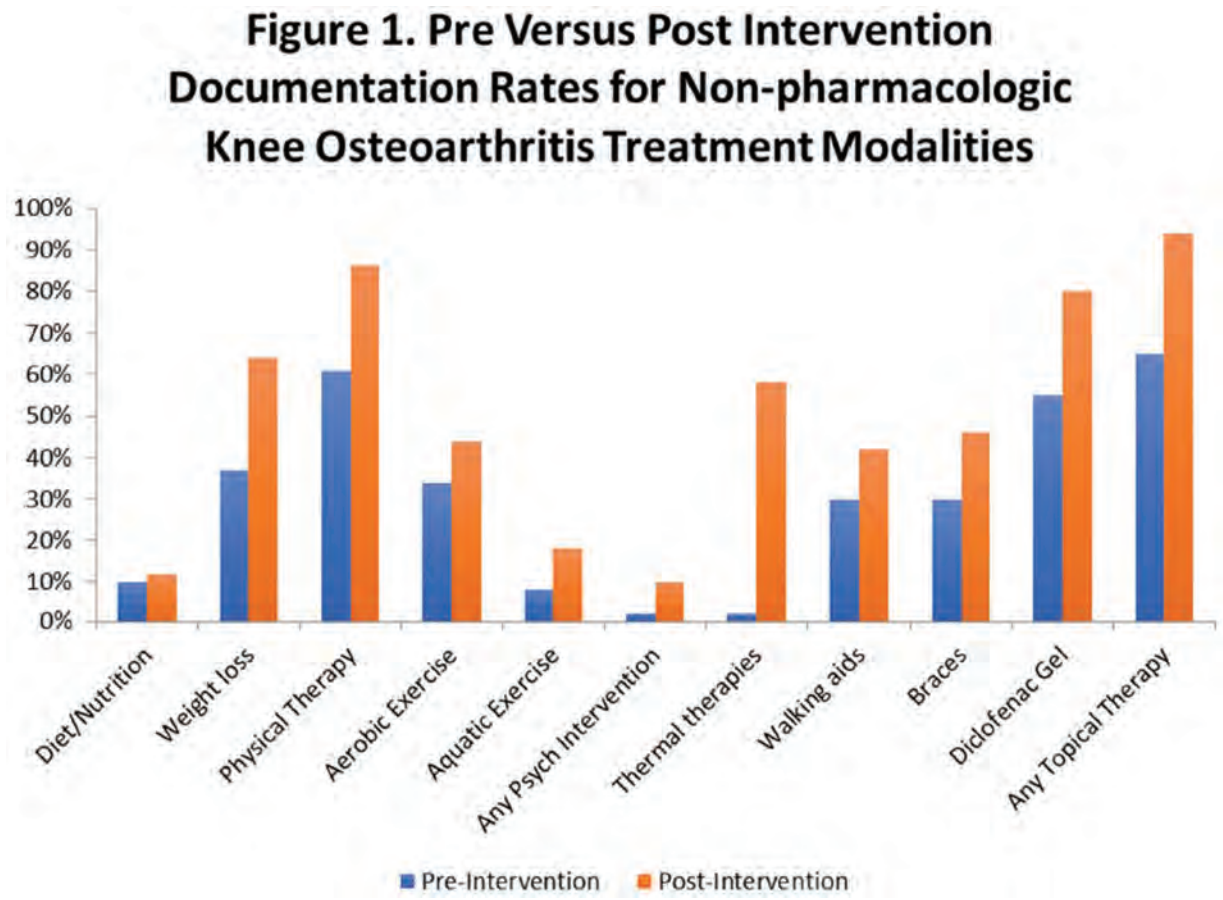
Megan Milne[1], Travis Welsh[1] and Una Makris[2], [1]University of Texas Southwestern, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal (MSK) pain is the leading cause of disability in older adults. Specifically, knee osteoarthritis (OA) accounts for a large burden of MSK disability worldwide. A multi-modal approach is necessary to treat this common disease. Current guidelines recommend a combination of pharmacologic and non-pharmacologic treatments. A multi-phase quality improvement project was conducted at the Dallas VAMC Rheumatology clinic to improve documentation of non-pharmacologic therapies offered to older veterans with knee OA. The VA is an ideal location to conduct a quality improvement project to enhance MSK pain care as many of the guideline-concordant referrals are readily available, accessible and integrated into the care for Veterans.

Methods: Fifty charts from a VA rheumatology clinic were reviewed for documentation of non-pharmacologic knee OA therapies during outpatient office visits in May 2018. Then, a new note template dedicated to MSK pain management was developed and implemented in August 2019. The Assessment and Plan utilized pre-written management options for specific non-pharmacologic modalities: aerobic exercise, aquatic exercise, weight loss, nutrition counseling, physical therapy referral, use of assistive devices, Yoga/Tai Chi, thermal therapies, and psychological interventions. The pre-written plans permitted editing by the note author. Next, a rheumatology grand rounds presentation emphasized the importance of non-pharmacologic interventions for knee OA to both trainees and faculty. A post-intervention chart review was conducted on a subsequent 50 charts in November 2019.

Results: The majority of patients were men aged 65 years or older. All patients had a documented history of knee OA in a rheumatology clinic note. Therapies with the most improvement in documentation rates were: thermal therapies (2% to 58%), use of topical therapies (66% to 94%), weight loss (36% to 64%), physical therapy (60% to 86%), and



Pre-intervention versus post-intervention rates of documentation for non-pharmacologic knee osteoarthritis treatment modalities

exercise regimens (42% to 62%) (Figure 1). Psychological therapies were the least documented therapy and had the lowest rate of improvement (2% to 8%) as seen in Figure 1.

Conclusion: A dedicated MSK pain template note and departmental presentation on OA management improved documentation rates of non-pharmacologic therapies for knee OA. Further improvement is needed, as important modalities, specifically mental health interventions, remain under-utilized. Documentation is important for continuity of care for this clinic. Many medical trainees rotate through the clinic, and a patient is unlikely to have the same provider on subsequent visits, making the note a vital tool of care continuity. Future providers now have access to all prior treatment strategies and the current treatment plan in one well-organized location –the clinic note. The next step in this quality improvement project is to assess if increasing documentation rates of non-pharmacologic modalities is associated with increased referral rates for these interventions, followed by an increased use of non-pharmacologic therapies by patients, and ultimately improved patient outcomes.

Patient Reported Impact of Lupus on Quality of Life

Beth Schneider[1], [1]MyHealthTeams, San Francisco, CA

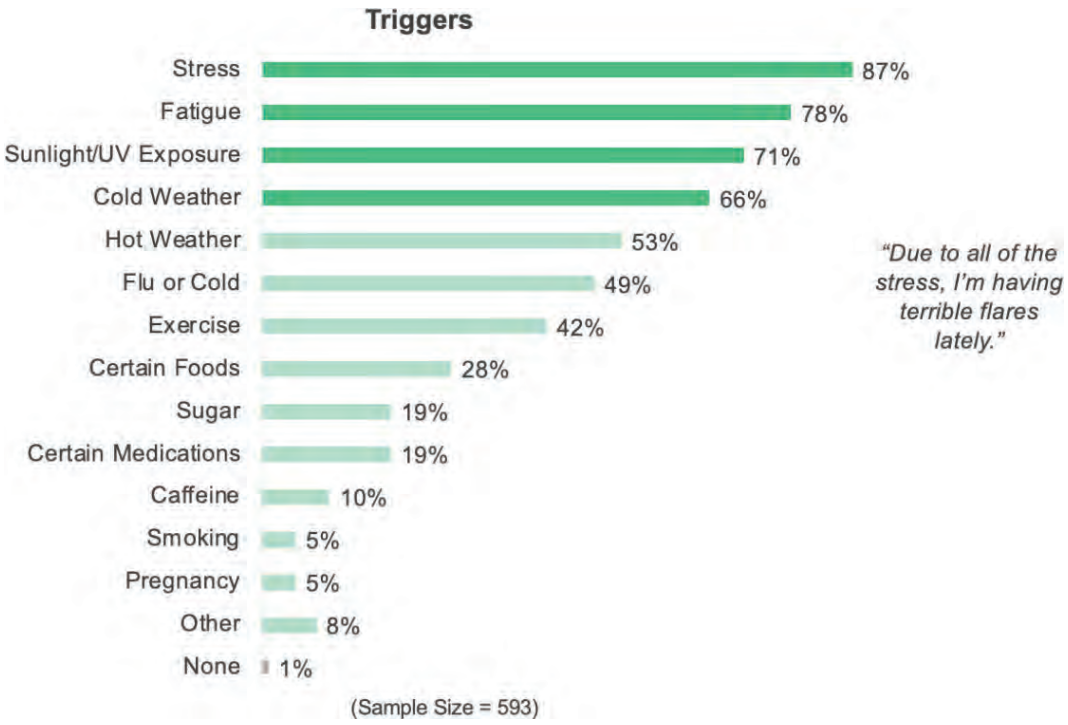
SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Research was undertaken to better understand how people living with lupus describe its sum total impact on their lives including work, challenges with relationships and its toll on mental health.

Methods: In January 2020 an email invitation to an online survey was sent to US members of MyLupusTeam, a social network of over 171,000 members. In total, 593 members completed the 21-question survey regarding experiences with lupus and impact of the disease on everyday life.

Results: The far-reaching impact on quality of life was evident in that most reported that they found it hard to exercise (85%) and do everyday chores (83%). They also felt that lupus interferes with social life (77%) and disrupts education/work (71%). The emotional toll of lupus manifested in anxiety (72%), depression (70%), feeling isolated/alone (66%) and ensuing challenges in sleeping (79%). Patients reported that the biggest triggers exacerbating lupus symptoms were stress (87%), fatigue (78%), UV exposure (71%) and cold weather (66%). Top two symptoms reported were joint pain/swelling (93%) and fatigue (92%) and these symptoms were considered to be the biggest obstacles to managing lupus (82% pain and 76% fatigue). While lupus patients had a good understanding of potential lupus symptoms they might experience (75%) and potential triggers (68%), they were less clear on types of medications (58%), exercises (54%) and foods to eat/avoid (48%). The sum total impact of lupus is that only 49% reported that they are able to lead a full life.

Conclusion: Understanding the physical, emotional and quality of life impact of lupus, can help rheumatologists provide a more holistic approach to treating lupus patients. Importantly, by addressing the mental health aspects of lupus, HCPs can help create better health outcomes, including treatment adherence and effective self-care regimens.



Triggers That Worsen Lupus Symptoms

A Mobile Mindfulness Meditation Program May Improve Health-Related Quality of Life for Patients with Rheumatic Disease, a Pilot Study

Dana DiRenzo[1], Carly Hunt[2], Erica Sibinga[2], Neda Gould[2], Ami Shah[3], Susan Bartlett[4] and Clifton Bingham III[1], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, [3]Johns Hopkins University School of Medicine, Ellicott City, MD, [4]McGill University, Montreal, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Mindfulness Based Interventions (MBIs) are well-established self-management programs shown to be beneficial for pain, depression, and anxiety that focus on learning how to respond to bodily sensations and emotions through guided meditative practices. However, due to time constraints, scheduling, and physical limitations, we found it difficult for patients to attend in-person MBIs; we therefore implemented a mobile MBI, using the commercially available smartphone application, Calm©.

Methods: Established patients with rheumatic disease in our Rheumatology Division at a tertiary referral center were eligible for inclusion. Participants were asked to engage in the app for a minimum of 5 minutes/day for 30 days, provide baseline clinical and demographic information, and complete baseline and 30-day questionnaires pertaining to health-related quality of life (HRQL). Questionnaires included the Patient Reported Outcome Measurement Information System (PROMIS) (v2.0) 4a short forms (physical function, social participation, fatigue, sleep disturbance, pain interference), computer adaptive tests (CATS) (v1.0) for anxiety, depression, self-efficacy for managing emotions, and for managing symptoms and the NIH Toolbox Perceived Stress FF v2.0. Demographics, clinical characteristics, and

Table 1. Baseline patient characteristics comparing those who completed the full program compared to those lost to follow up.

mean T-scores were compared between groups using t-tests or chi-square. A sensitivity analysis was performed for participants who fully completed the program.

Results: 40 participants consented, 35 participants completed baseline questionnaires, 17 participants completed post survey questionnaires and used Calm, 17 participants completed baseline questionnaires but were lost to follow up, and 1 participant completed both surveys but did not use Calm. Participants had a mean age (SD) of 50 years (13), were mostly female (91%), white (74%), well-educated (66% with a college degree or greater) and working full time (56%). Most participants had inflammatory arthritis (60%); patients with lupus (17%), Sjogren's syndrome (9%), and scleroderma (14%) were also included. Compared to non-completers, full completers had similar demographics and use of medications that could potentially impact mood. However, full completers had higher patient

HRQL Domain	Day 0	Day 30	Mean Difference	p-value
Fatigue T-Score (SD) *	62.9 (9.7)	55.4 (8.3)	7.6	**0.017**
Sleep Disturbance T-Score (SD) *	56.3 (8.8)	52.8 (5.3)	3.5	0.15
Pain Interference T-Score (SD) *	60.0 (5.0)	57.3 (7.4)	2.7	0.21
Anxiety T-Score (SD) **	62.1 (8.8)	57.9 (8.1)	4.2	0.14
Depression T-Score (SD) **	56.6 (8.4)	54.6 (9.2)	2.0	0.50
Self-Efficacy, Emotions T-Score (SD) **	42.1 (8.7)	45.3 (6.9)	-3.2	0.23
Self-Efficacy, Symptoms T-Score (SD) **	40.3 (5.7)	43.9 (7.1)	-3.6	0.10
Perceived Stress T-Score (SD) ***	63.1 (12.5)	55.4 (10.7)	7.7	0.055
Pain VAS, mean (SD)	61 (18)	51 (21)	10.0	0.14
PGA, mean (SD)	59 (28)	52 (27)	7.0	0.47

Table 2. HRQL domains pre/post 30-day mobile, mindfulness meditation trial for participants who completed pre/post questionnaires (n=18). * Derived from PROMIS 4a form extracted from Global-29 collection of surveys; **CATs, ***NIH Fixed Form.

global assessment of disease activity (PGA) scores, more pain (VAS), higher perceived stress, and more anxiety at baseline (Table 1). Full completers meditated on average for 302 minutes (SD 254; n=15). For completers, significant improvements were noted in fatigue by course end with trends for improvement in perceived stress, anxiety, sleep disturbance, and self-efficacy (Table 2).

Conclusion: Results from a pilot study on use of a 30-day smartphone mindfulness meditation application for patients with rheumatic disease revealed that this is a feasible and accepTable non-pharmacologic modality to target HRQL. Participants with higher baseline stress, anxiety, pain, and PGA scores were more likely to complete the mobile MBI program. Among completers, preliminary results showed improvements in fatigue and perceived stress. More rigorous study on mindfulness application use and barriers, as well as potential effect on HRQL, is needed.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Over 33 percent of American adults have low health literacy, which limits their ability to understand basic health information and make healthcare decisions. A component of health literacy is health numeracy (quantitative skills). Low health literacy has been associated with negative psychological and patient reported outcomes in other disease states including lower self-efficacy, reduced quality of life, and higher rates of depression.

Table 1: Demographic Differences between Patients with Low/Adequate Health Literacy and Numeracy

	Health Literacy by BHLS		
	Adequate	Low (Limited)	p-value
	n=148	n=24	
Demographics			
Age [Mean (SD)]	43.2 (13.4)	44.2 (17.2)	0.8
Female	140 (95%)	22 (92%)	0.6
African American (n=169)	90 (62%)	16 (65%)	0.8
College Graduate (n=165)	86 (60%)	9 (43%)	0.2
Income <$50,000 (n=159)	74 (54%)	15 (71%)	0.2
Medicaid Insurance (n=164)	64 (45%)	13 (62%)	0.2
Disability (n=158)	42 (31%)	11 (52%)	0.08
	Numeracy by SNS3		
	Adequate	Low (Limited)	p-value
	n=88	n=82	
Demographics			
Age [Mean (SD)]	43.5 (14.1)	43.0 (13.7)	0.8

African American (n=167)	47 (54%)	56 (70%)	0.04*
College Graduate (n=163)	58 (68%)	36 (46%)	0.007*
Income <$50,000 (n=158)	38 (46%)	50 (66%)	0.02*
Medicaid Insurance (n=162)	32 (38%)	43 (55%)	0.04*
Disability (n=156)	21 (26%)	31 (42%)	0.04*

*$p \leq 0.05$

However, the relationship between health literacy and psychological outcomes has not been evaluated in SLE. The objective of this study was to assess the relationship of health literacy with psychological and patient-reported outcomes in SLE.

Methods: SLE patients meeting SLICC criteria were recruited from an academic university clinic from March 2019 through January 2020. Self-reported health literacy and numeracy were assessed using the Basic Health Literacy Screen (BHLS) and the 3-item Subjective Numeracy Scale (SNS-3). Low health literacy was defined as BHLS < 12 and low numeracy as SNS3 ≤ 14. Patients completed assessments for depression (Patient Health Questionnaire, PHQ9), fibromyalgia severity score (FSS), and self-reported cognitive dysfunction. Additionally, PROMIS Short-Forms for General Self-Efficacy and for Managing Treatments and Medications were obtained. We evaluated relationships between health literacy, self-efficacy and psychological covariates using descriptive statistics. Fisher's exact testing was performed for categorical measures and two-sample t-tests were performed for continuous measures.

Results: The study included 172 patients with SLE with average age 41 years, 94% female, and 61% African American. Mean clinical SLEDAI was 3.17. We found 14% of patients had low health literacy, while 45% of patients had low numeracy.

Health Literacy:

There were no differences in demographics or patient-reported outcomes between patients with low versus adequate health literacy (**Tables 1-2**).

Table 2: Association of Health Literacy with Patient-Reported Psychological Outcomes and Self-Efficacy

	Health Literacy by BHLS		
	Adequate	Low (Limited)	p-value
	n=148	n=24	
Psychosocial			
PHQ-9 Depression (n=156)	20 (15%)	5 (24%)	0.3
Cognitive Dysfunction	84 (57%)	14 (58%)	1.0
Fibromyalgia Severity Score	7.4 (5.7)	7.6 (5.3)	0.9
Self-Efficacy	n=115	n=20	
PROMIS Self-Efficacy General (n=87)	53.1 (10.2)	54.8 (10.6)	0.7
PROMIS Self-Efficacy for Managing Chronic Conditions (Manage Meds/Treatments) (n=87)	50.3 (8.6)	48.6 (7.6)	0.6

	Numeracy by SNS3		
	Adequate	Low (Limited)	p-value
	n=88	n=82	
Psychosocial			
PHQ-9 Depression (n=154)	5 (6%)	20 (27%)	0.0004*
Cognitive Dysfunction	43 (49%)	54 (66%)	0.03*
Fibromyalgia Severity Score	6.3 (5.0)	8.6 (6.1)	0.01*
Self-Efficacy	n=68	n=65	
PROMIS Self-Efficacy General (n=87)	55.3 (8.0)	50.6 (11.9)	0.04*
PROMIS Self-Efficacy for Managing Chronic Conditions (Manage Meds/Treatments) (n=87)	51.7 (7.9)	48.2 (8.9)	0.06

*$p \leq 0.05$

Numeracy:

Patients with lower numeracy were more likely to be African American, less likely to be a college graduate, more likely to have income < $50,000 annually, and more likely to be on Medicaid insurance or disability (**Table 1**). Those with lower numeracy were more likely to have depression, higher fibromyalgia severity scores, and cognitive dysfunction (**Table 2**). Additionally, patients with lower numeracy had worse self-efficacy by PROMIS Self-Efficacy (50.6 vs 55.3, p=0.04).

Conclusion: Lower numeracy was associated with higher rates of depression, higher fibromyalgia severity, lower self-efficacy and lower socioeconomic status factors. This data suggests numeracy may be an important factor to consider in patient counseling, particularly patients with concomitant depression or other psychiatric comorbidities. Future studies should evaluate the role of health literacy with other lupus outcomes.

The Diagnosis of Systemic Sclerosis as a Traumatic Experience: Patients' Reactions to the Diagnostic Process

Fennell Patricia[1], Lee Shapiro[2], Nancy Dorr[3], Roberta Lukasiewicz[4], Frank Houser[5] and Madison Taylor[6], [1]Albany Health Management Associates, Steffens Scleroderma Foundation, Albany, NY, [2]Albany Medical College, Stillwater, NY, [3]The College of Saint Rose, Albany, NY, [4]Steffens Scleroderma Foundation, Albany, NY, [5]The College of Saint Rose, Nassau, NY, [6]The College of Saint Rose, Mississauga, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Both the process of being diagnosed with a chronic illness and the illness itself can be a traumatizing experience (1). The current study examined the diagnosis of a chronic illness, systemic sclerosis (SSc), as a potentially traumatic experience. We examined SSc patients' perceptions of the process of getting diagnosed and their reactions to this diagnosis. Our research question was, "What do patients report experiencing regarding the process of being diagnosed with SSc?"

Methods: Patients with SSc were approached to participate by their rheumatologist (specializing in SSc) during an office visit. Sixty-four patients completed the study (42% diffuse, 45% limited, 13% unknown type of SSc). All patients included met ACR-Eular criteria for diagnosis of SSc. Most respondents were female (85%), white (95%), and had an average age of 61 years.

Patients completed open-ended questions (e.g., what prompted you to first go to the doctor, what occurred through the time you were diagnosed with SSc, how did you react to the diagnosis). Two researchers independently categorized responses. Discrepancies were resolved by discussion. Additionally, one researcher retrieved demographic and disease information from patients' records.

Reaction to SSc Diagnosis	Percent of Patients Reported Reaction
Fear (all types)	78%
Fear of future	48%
Fear of dying	30%
Fear of falling apart	11%
Fear, unspecified	31%
Upset (previously) about not having a diagnosis	20%
Concerned due to disease progression in others	17%
Grief or anticipatory grief	14%
Sad	13%
Questioning ability to cope	11%
Shock	11%

Table 1. Reactions to Being Diagnosed With SSc and Percent of Patients Who Reported Each Reaction

Results: Seventeen percent of the sample received a potentially traumatic message from a health professional during the diagnostic process. For example, one patient reported learning there was no treatment for SSc and it would continue to get worse, one reported being told she was dying (before SSc was diagnosed), and another reported physicians involved in the diagnostic process were dismissive of independent and seemingly unrelated symptoms.

As can be seen in Table 1, fear was the most common patient reaction, especially fear of the future and fear of dying. Other reactions were feeling upset about not having a diagnosis (before SSc was diagnosed), feeling concern because of the disease progression they witnessed in others, feeling anticipatory grief, feeling sad or shock, and questioning their ability to cope.

Conclusion: Diagnosing and treating chronic illness can be a difficult process for both patients and practitioners (1). Consistent with past research, reactions to the diagnostic process showed patients did not self-label their reactions as depression (2). In the current study, few patients even reported sadness; fear was the overwhelmingly common reaction.

The current data emphasize the importance of physicians attending to the way information regarding SSc is conveyed to patients. Although a majority did not report receiving traumatic messages from a health care professional during the diagnostic process, over 1 in 6 patients did. Given the diagnostic process for SSc can be lengthy, patients may be feeling distressed for years. Health providers working with SSc patients should address patients' emotions and the causes of them (e.g., internet, statement by health provider) and know that their conversations with patients can make a difference.

Abstract Number: 1129

Discordance in Patient and Physician Assessment of Disease Activity in Relapsing Polychondritis

Emily Rose[1], Marcela Ferrada[1], Kaitlin Quinn[2], Wendy Goodspeed[1], Laurent Arnaud[3] and Peter C. Grayson[4], [1]Systemic Autoimmunity Branch, Vasculitis Translational Research Program, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Washington, DC, [3]Department of rheumatology, University Hospitals of Strasbourg and French National Reference Center for Rare Auto-immune diseases, Strasbourg, Alsace, France, [4]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare chronic disabling inflammatory condition primarily affecting cartilage tissue. Self-reported patient outcome measures, which have not been evaluated in RP, are necessary to understand how RP disease manifestations affects patients. The objective of this study was to compare patient and physician assessment of disease activity in a cohort of patients with RP to determine the need for multimodal response criteria in RP.

Methods: Adult patients who fulfilled diagnostic criteria for RP were recruited into a prospective, observational cohort. Patients underwent a standardized comprehensive evaluation at six-month interval visits that included a clinical evaluation by rheumatology and otolaryngology, laboratory studies, audiology, and chest imaging. From this information, physicians rated the Physician Global Assessment (PhGA) on a scale of 0 to 10. Patients simultaneously completed four patient-reported outcome questionnaires: Patient Global Assessment (PtGA), SF-36 Health Survey, Brief Illness Perception Questionnaire (BIPQ), and Multidimensional Fatigue Inventory (MFI). The intraclass correlation coefficient (ICC) (2, 1) was calculated to determine the agreement between physicians and patients. Patient – Physician discordance was defined as a difference (PtGA-PhGA). Visit characteristics were compared between the positive discordant group and the concordant group using Mann Whitney or Fisher's exact test. Response to treatment was analyzed in all patients who had at least two study visits.

Results: A total of 154 visits from 76 patients were analyzed. The median PhGA was 3 (interquartile range 2-3) and median PtGA was 5 (interquartile range 4-7). The ICC was low (0.14; 95% confidence interval -0.06 to 0.334, *p=0.10)*. PtGA and PhGA were concordant in 66 visits (42.6%). In a total of 84 visits (54.2%), patients scored disease activity 3 or more points higher than physicians (positive discordance), whereas in only 4 visits (2.6%) PtGA was 3 or more points less than PhGA (negative discordance). Compared to visits with concordance, visits with positive discordance were associated significantly with worse scores on the MFI, BIPQ, SF 36 Physical component score (PCS), and SF 25 Mental component score (MCS). There were no differences in demographics, medication use, clinical symptoms, or objective measures of airway inflammation between the concordant and positively discordant groups. Treatment was increased over 52 visit intervals in 36 patients. Whereas PhGA scores significantly improved in response to increased treatment from a median 3 (interquartile range 2-4) to 2 (interquartile range 2-3) (P< 0.01), there was no significant change in PtGA. (Figure 1)

Conclusion: Patients with RP typically self-report higher disease activity than their physician counterparts and do not necessarily perceive similar improvement in response to treatment. Discordance is possibly due to the psychological

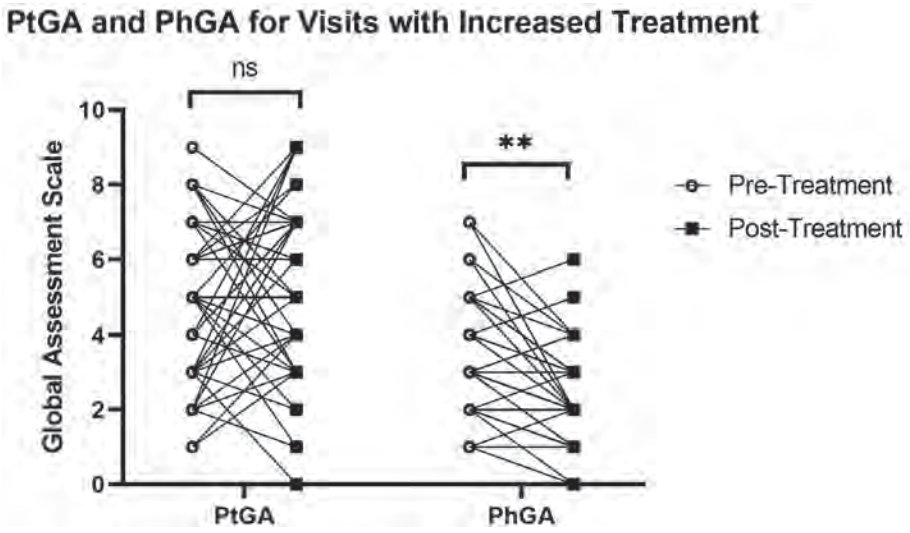

Figure 1. Increased treatment improves disease activity from physician (median change PhGA=-1 , IQR= -2-0) but not patient perspective (median change PtGA=0 , IQR= -1-1)

burden of illness experienced by patients. Future disease activity assessment instruments in RP should consider the utilization of composite response criteria that incorporate patient-reported outcome measures.

Table 2. Illustrative quotes

Theme	Illustrative quotes
Knowledge of biobanking and data-linkage	
	"One of the things I have not given any thought to" (60s female)
	"It's personalised medicine and I think that's the future. And that's right. And so again, the more the data is linked to our specific profile, the more personalized medicine can grow." (40s female)
	"I just have a vision of a huge big fridge with loads of test tubes in it" (70s female) "storing biological material… keeping like a safe of someone's biological material.. keeping like a database but a physical database.. (30s female)
Perceived barriers	
Privacy protection	"It's a bit like the whole having my health record, isn't it?...But do you ever get that a biobank like that sort of information could get into the wrong hands and then adversely affect you." (60s female)
	"you need good data governance. But I think that that good data, data governance should be openness to all kinds of researchers to do all kinds of things with the data and how it's linked to me in my personal records. Yeah, there's a little bit more risk there, but I'm also willing for that to happen as an ongoing flow of information. I'm willing to take that risk." (40s female)
	"I think those are things that we really do need to consider because there's all this discussion about, you know, lack of privacy and the impact it could have on things like health insurance, super and work, employment. So I think it is important…some sort of guarantee that would be necessary." (60s female)
Data-sharing	
Fears of data being used for secondary purposes	"Abused" (70s male)
	"Unless you're going to make cyborgs' out of them?" (70s female)
	"I guess the only thing which is, which I'd be concerned about is if someone decides to take some and then clone me, but hopefully that won't happen." (40s male)
	"Those kinds of things where they can just look you up and be like, you're not fit to drive anymore even though you're perfectly able.." (20s female)
Fears of data being manipulated	"we can manipulate the samples right" (60s male)
	"I would like to figure it out that there are some preventive methods … to… prevent any undue influence.. on the data and how it's used to come up with certain specific results..." (60s male)
Cost and funding	
Time consuming	"It probably sounds terrible, but just the time factor involved… I am very interested. But if it's going to take out a huge chunk of my time, I just don't have it because of what's going on in my life at the moment. And the other thing is you know, blood tests and things like that, stool samples, et cetera, they're all very easy. If it was anything more, which would take like a few hours, then I'd have to really consider how would I make that fit in" (40s female)
Frequency of samples	"But if someone was to turn around and say for the next 12 months, you need to give me a stool sample every two weeks, I think I'd be like, no, not interested. If it was once every six months, depends on the consistency. And then again, same with the needle side of things. Once a month. Yes. Once every two, three days, no." (20s female)
Funding	"Funding is shocking." (70s female)
Fear of discomfort	"Nothing too invasive." (20s female)
	"Would patients go through any pain when they're giving these samples."(30s female)
Perceived benefits	
Personal benefit	"What you really want is your condition to be improved." (60s female)
Helping science or society	"that could impact me personally. But I also think that it's you know contributing to the collective is really important …especially now that statistics can do so much calculation so quickly with stuff like all of the different genes in our gut. That's not something we could have parsed before, but now we can. And we need more data to get the best results." (40s female)
	I think it's the way we improve the health of the human race…I think the faster the better and you know, let the machine learning out on the data. Let's see what happens. (40s female)
	"A: Well, I think any research is tremendously important because I don't think it's going to go away. And future generations they, what can you say, you just hope that something's going to turn up. To make their lives easier? "(70s female) "B: I think it's very important. I've got my son, my nephew, who are looking very much, they are seeing rheumatologists already." (60s female)
Giving back	"I got really excellent medical care and that was given to me by this hospital and by a researcher here. And you know, that's something that I can give back." (40s female)
Attitudes towards participation	
General support	"No ! don't have any concerns. I came here with two hands up with bells on." (70s male)
Concerns about privacy do not influence willingness to participate	"I know a lot of people are very picky about things, such as privacy, but I think people are generally overly protective over that kind of stuff…unless you know, unless you've done something illegal (40s male)
	"I'm trusting that the data governance" (40s female)
	"When it comes to health and medicine, it doesn't worry me no." (20s male)
Positive relationship with healthcare providers	"I know this organization, I trust this organization." (60s female)
	"I got really excellent medical care and that was given to me by this hospital and by a researcher here" (40s female)
COVID19 and timing of participation	"So if the covid19 thing didn't exist, what sort of timeframe were you're looking at to sort of get the ball rolling?" (40s female)

Table 2. Illustrative quotes for the identified themes

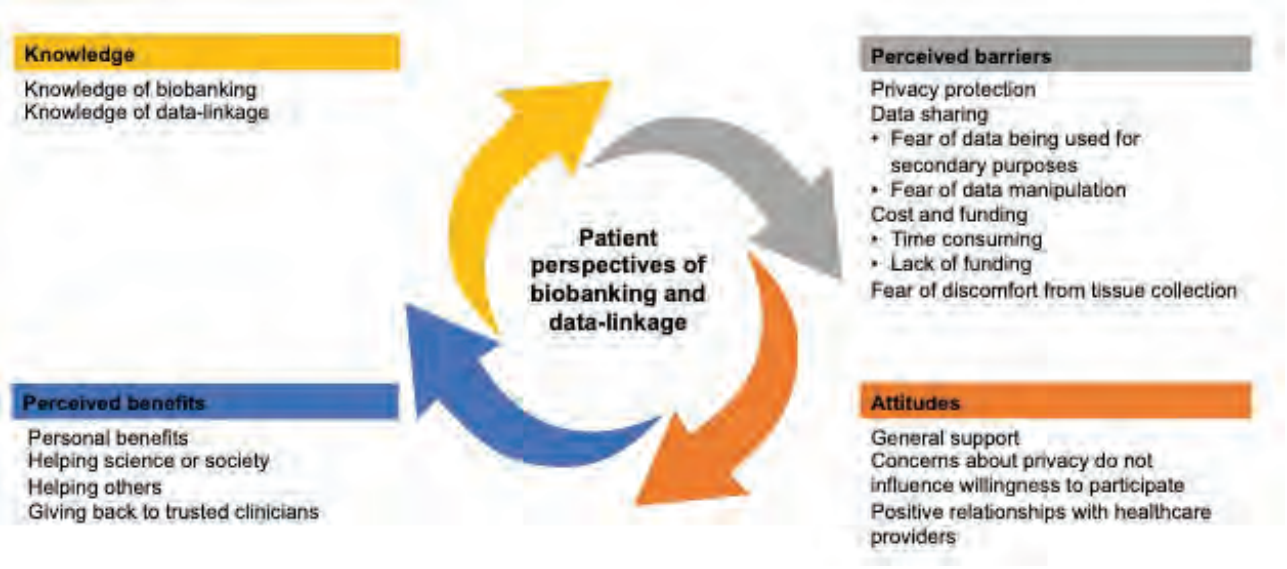

Figure 1. Thematic schema Our participants had varied knowledge of biobanking and data-linkage. Although there were many perceived barriers, as illustrated in the schema, participants' attitudes towards participations were generally supportive and we hypothesise this is likely due to the perceived benefits of helping themselves, their families, society and giving back to their clinicians.

stool samples from patients will be necessary for identifying biomarkers which may play critical roles in predicting, managing and preventing arthritis and autoimmune conditions.

Biobanking refers to the collection, storage and distribution of human biospecimens and linked health data for research. Engagement with patients and the public is required for the success of biobanking endeavours.

To our knowledge there are no qualitative studies investigating the attitudes of patients with rheumatic conditions towards biobanking and data-linkage. This is of importance for us as we, like a growing number of countries globally, develop a national biobank for rheumatic conditions in Australia. Our aim is to explore participants' knowledge, attitudes, perspectives and beliefs regarding the process of biobanking and data-linkage to national health statistics in the context of their illness.

Methods: This qualitative study was conducted between October 2019 and April 2020. Ethics approval was granted by Northern Sydney Local Health District Ethics Committee (2019/ETH11659). Adult patients with rheumatic conditions were invited to participate in focus groups or semi-structured phone interviews. Patients were recruited via rheumatology clinics from a tertiary hospital in Sydney, Australia.

Focus groups and semi-structured interviews were moderated according to a question guide which was informed by current literature. Recruitment ceased when no new themes emerged.

The collection, analysis and interpretation of data was an iterative process using grounded theory underpinned by the health belief model. Data was entered into computerised data management program (NVivo 12) where further refinement occurred.

Results: There were fifteen participants, their characteristics are summarised in Table 1, nine of fifteen were women, the mean age was 55.7years (range 27 – 76), majority of patients had rheumatoid arthritis (11/15) and the average disease duration was 15.1years (range 0.33 – 62 years). Four main themes arose including knowledge of biobanking

and data-linkage, perceived barriers, perceived benefits and attitudes towards biobanking. Table 2 shows illustrative quotes from the interviews and Figure 1 provides a diagrammatic representation of the identified themes.

Conclusion: Knowledge of biobanking varied significantly amongst Australian patients with rheumatic conditions. Although there were many perceived risks to participation, the majority of participants in this study were willing to accept these risks and engage with biobanking research. We hypothesise that this willingness to participate was influenced by the relevance of the biobank's objective to their own condition, perceived benefits in helping themselves, their families, future generations and their trusted clinicians. This study should inform patient information and frequently asked questions when developing recruitment strategies for rheumatic disease biobanks.

Abstract Number: 1131

Patient Perspective of Helpfulness of Lupus Medications: A Qualitative Study of Medication Use Within the Type 1 and 2 SLE Model

Mithu Maheswaranathan[1], Kevin McKenna[2], Amy Corneli[2], David Pisetsky[3], Megan Clowse[4] and Amanda Eudy[1], [1]Duke University, Durham, NC, [2]Duke University, Durham, [3]Duke University Medical Center, Durham, NC, [4]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication management in systemic lupus erythematosus (SLE) is particularly complex given the clinical heterogeneity of symptoms and a wide range of medications used. We developed a conceptual model that characterizes symptoms and corresponding medications into two categories: Type 1 medications are used for Type 1 SLE symptoms or inflammatory manifestations (such as arthritis, nephritis, rashes) while Type 2 medications are used for Type 2 SLE symptoms of fatigue, myalgia, anxiety/depression and cognitive dysfunction. Type 1 medications included antimalarials, oral immunosuppressants, biologics and steroids. Type 2 medications included pain medications, muscle relaxants, sleep medications, and antidepressants. We conducted a qualitative descriptive study to assess perceived helpfulness (benefits and drawbacks) of Type 1 and Type 2 medications and describe disease experiences in patients with SLE.

Methods: We conducted semi-structured qualitative interviews among purposefully selected adult patients meeting SLICC criteria for SLE from an academic medical center. We asked patients to describe the helpfulness of medications, including whether they believed their symptoms had improved. All interviews were audio-recorded and transcribed, and we used applied thematic analysis to analyze the data.

Results: We interviewed 37 patients (12 with Type 1 SLE, 12 with Type 2 SLE, and 13 with Mixed SLE); 73% were age ≤55 years, 84% had disease duration ≥5 years, 49% were black or African American, and 35% had a history of nephritis.

Medication Helpfulness: The majority of patients endorsed benefit from at least one Type 1 or Type 2 medication. More patients reported at least one Type 2 medication as not helpful (n=24) compared to those reporting at least one Type 1 medication as not helpful (n=18).

Table 1: Themes Observed and Selected Quotes, by Medication Class

	Medication Class	Themes	Selected Patient Quotes
TYPE 1 Medications	**ANTIMALARIAL** • hydroxychloroquine	• mild or delayed benefit, often minimal improvement of symptoms • uncertainty regarding helpfulness or indication	*"Like, if I were taking it, it would probably be a 1 on the side of the pain, but like if I weren't taking it, it would be like a 2 or a 3." [**HCQ**]*
	ORAL IMMUNOSUPPRESSANTS • azathioprine • methotrexate • mycophenolate	• varying degrees of helpfulness • no change in symptoms observed • uncertainty regarding helpfulness	*"They don't change them or improve them [symptoms]... I just don't see where any of it is doing anything"*
		• uncertainty regarding indication	*"That's the hard part. I really can't tell you. Besides it helped my lupus." [**methotrexate**]*
		• medication concerns re pill burden or medication management • side effects often limiting benefit	*"The one thing I do not like... is that the pills are humongous, and you have to take six a day... That can be difficult" [**mycophenolate mofetil**]*
	BIOLOGICS/ IV INFUSION • belimumab • Rituximab • cyclophosphamide • IVIg	• varying degrees of helpfulness (more dramatic benefit noted)	*"I nicknamed that one my Super Woman drug" [**cyclophosphamide**]*
		• initially felt worse followed by a delayed response	*"I felt sicker... I was constantly nauseous... I actually felt worse on Benlysta than I felt before. Now that I've been on it about a year, I do notice a difference... my joint pain has improved. [**belimumab**]*
		• more certainty re helpfulness or indication	
	STEROIDS • oral prednisone • intramuscular • intravenous (methylprednisolone)	• majority noted helpfulness (rapid improvement or dramatic benefit) • no uncertainty regarding the helpfulness or indication • concerns regarding long-term side effects	*It's one of those love-hate relationships... because you know it works and I think that's a lot of the issue as far as a lot of the lupus medications that we don't see it. We can't tell. [**prednisone**]*
TYPE 2 Medications	**NERVE and PAIN MEDICATIONS** • gabapentin, pregabalin • opioids, Tramadol • topiramate	• helpful but often with associated side effects influencing adherence • no change or improvement in symptoms in some patients	*"Thank God for Gabapentin. Gabapentin is a wonder drug... like if miss a dose or something, you can tell right away. It comes right back – that tingling feeling"*
	MUSCLE RELAXANTS • cyclobenzaprine • tizanidine	• helpful with improved symptoms (muscle pain and insomnia) • side effects (drowsiness) noted, sometimes influenced adherence	*"It does help with pain... But at the same time, it also makes me really drowsy so it's not something I can take and...work." [**cyclobenzaprine**]*
	SLEEP MEDICATIONS • melatonin • zolpidem, eszopiclone • trazodone	• helpful in some patients, although side effects (psychological or cognitive) sometimes precluded use	*"It will definitely mellow you out. It will definitely make you tired... I found it a lot more mentally and cognitively dampering" [**trazodone**]*
	ANTI-DEPRESSANTS • SSRI medications • SNRI medications • TCA (amitriptyline) • benzodiazepines	• helped with depression and anxiety symptoms in a subset • some with no benefit or psychological SE limiting use	*"It did suppress some of those feelings of sadness, and loneliness... but I wasn't myself. It wasn't my personality. It was augmenting the happiness that really wasn't there" [**alprazolam**]*

Unable to Assess Helpfulness: More patients were unable to assess the helpfulness of Type 1 medications (~50%, n=19) compared to Type 2 medications (~20%, n=7). Inability to determine helpfulness was often due to no change in symptoms or uncertainty of symptoms the medication was supposed to improve.

We categorized participant experiences with Type 1 and Type 2 medications by class of medication thematically (Table 1). For example, patients viewed hydroxychloroquine as minimally beneficial compared to the dramatic improvements they noted on biologics and IV infusions. Patients also had less certainty regarding the helpfulness and indication for antimalarials and oral immunosuppressants compared to biologics, steroids, and Type 2 medications.

Conclusion: For both Type 1 and 2 medications, the vast majority of patients reported at least some benefit in helping symptoms. However, substantially more patients were unable to assess the helpfulness of Type 1 medications compared to Type 2, most often due to uncertainty regarding helpfulness or lack of awareness of indication. These findings suggest physician/patient discussion about specific indications for which medications are prescribed and potential side effects may increase patient understanding and expectations regarding medication use.

Abstract Number: 1132

Reliability of Virtual Sources of Education for Patients with Vasculitis

Patil Injean[1], Kathleena D'Anna[2], Lorena Salto[3] and Mehrnaz Hojjati[3], [1]Loma Linda University Medical Center, Redlands, CA, [2]Loma Linda University Medical Center, Moreno Valley, CA, [3]Loma Linda University, Loma Linda

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Vasculitides are defined as inflammation of the vessel wall of different organ systems with reactive damage of mural structures. Patient education in understanding the pathophysiology of the disease and its treatments can be challenging and affects medication compliance and disease outcomes. YouTube (YT) is one of the most popular websites with visual representations of healthcare topics recorded by a diverse group of people including patients, healthcare providers, organizations, universities, etc. There have been multiple studies done investigating the quality and reliability of information available on multiple diseases on YT. However, investigation of videos pertaining to vasculitis education is not known. Our objective was to review the quality of videos on vasculitis education and compare them to the popularity of each video.

Methods: A search was performed on YT using the term "vasculitis education." A total of 30 videos were reviewed. Duration of the video, number of viewers, time since video, likes, and dislikes were recorded. The video power index (VPI) and view ratio (VR) were used to determine video popularity. The DISCERN instrument, a questionnaire developed for judgement of the quality of consumer health information, was used to determine quality and reliability of each video. We further collapsed the DISCERN summated score into two categories, Excellent (EQ) or Good (GQ) Quality (51-80) and Fair (FQ) or Poor Quality (PQ) (7-50) according to the standard score ranges. The Mann-Whitney U test was done to determine video quality categories resulted in differences in the VR and VPI outcomes. Fisher's Exact test was done to determine if there were proportional differences in video quality based on publisher. We set alpha equal to 0.05 for statistical significance.

Results: A total of 30 videos were analyzed. The individuals who recorded these videos included 23 physicians, 4 allied health professionals, 1 commercial company, and 2 patients. On average, duration of each video was 14:25. The average time since upload was 40 months. The average DISCERN score was 52 (SD 13). Out of the 30 videos, the DISCERN score showed 8 EQ videos (63-80), 8 GQ (51-62), 9 FQ (39-50), 5 PQ(27-38 points), and no videos were very poor quality (16-26 points). According to the DISCERN quality labels, videos that were either EQ or GQ (n=16), had an average VR of 373.9 ± 607.2 and an average VPI score of 359.8 ± 595.3. Videos that were either FQ or PQ in quality (n=14), had an average VR of 1588.9 ± 2081.9 and average VPI score of 1550.8 ± 2077.9. These mean ranking differences were statistically significant for VR and VPI (p= 0.04 and p= 0.03, respectively). Most videos were published by physicians (77%). Of those videos, 65% were rated as EQ or GQ. Of the videos published by others (n=7), only 1 (14%) was rated as EQ or GQ and this proportional difference was statistically significant (p= 0.03).

Conclusion: Videos that were rated as Fair or Poor in quality tended to be more popular on YT compared to the videos that were rated as EQ or GQ. In addition, physician recorded videos had better quality. Further larger scale studies are required to determine the utility of YT as an educational tool for patients with vasculitis.

Abstract Number: 1133

Patient Perceptions of Diagnosis, Tests, Treatments, Adherence and the Impact on Their Disease Understanding and Participation in Research Studies

Viviana Marzaioli[1], Mary Canavan[1], Siobhan Wade[2], Alexander Fraser[3], Sinead Harney[4], Alex Donnelly[5], Arthritis Ireland Charity[6], Douglas Veale[7] and Ursula Fearon[1], [1]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland, [2]Molecular Rheumatology, Trinity College Dublin, Dublin, Ireland, [3]University College Limerick, Limerick, Limerick, Ireland, [4]University College Cork, Cork, Ireland, [5]Patient Advocate Arthritis Ireland, Dublin, Ireland, [6]Arthritis Ireland, Dublin, Ireland, [7]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The diagnosis and treatment of inflammatory arthritis has been transformed largely by the development of drugs that target specific molecules of the immune system. However, these changes have increased the complexity of the mechanisms of disease, its treatment and patients understanding. Patient education is needed in this area to facilitate decision making.

Methods: An online anonymous survey of 27 questions addressed patient understanding of their diagnosis, diagnostic tests performed at outpatient clinics, their treatments and how they worked. Questions also addressed adherence and disease flare, issues of heredity and pregnancy, and patient involvement in research.

Results: The survey was completed by 1,873 patients, 1607 had an inflammatory arthritis RA (62.29%), SpA (41.88%) and JIA (2.92%). Respondents were predominantly female (83.77%). Most patients understood the difference between inflammatory arthritis and osteoarthritis (68.12% vs 31.88%), and 76.48% were concerned it was hereditary. Patients were asked to indicate their understanding of diagnostics tests performed at out-patient clinics (Scale 1-10; 1=don't understand at all, 10=understand very clearly). For all diagnostic tests < 25% of patients had an understanding of what was measured and the implication for disease, including ESR, CRP, RF, anti-CCP, VAS and Das28. Significantly, 72% understood how specific medications treat inflammatory arthritis, while 27.97% had no understanding. Adherence was strong with >87% vs 12% adhering to their medication. Of those stopping medication, without the advice of their doctor, the main reasons were 'feeling better', 'don't think it works' and 'side effects', however 68.43% of these patients also reported disease flare following cessation of medication. Patients of childbearing age (31%) worried that inflammatory arthritis reduced their chances of getting pregnant, and 79% believed arthritis medications are not safe to take during pregnancy. Finally, only 9% of patients had ever been asked to participate in a research study by their doctor.

Conclusion: This patient awareness survey demonstrates that patients have an understanding of their diagnosis, but little understanding of the diagnostic tests performed, their implication for disease progression and response. Furthermore patients concerns regarding heredity and pregnancy need to be addressed more thoroughly. Patients reported significant medication adherence, with those non-adherent experiencing flares. Finally, very few patients had been asked to participate in a research study.

Prevalence of Frailty and Associated Factors in a National Observational Cohort of Rheumatic Diseases

Katherine Wysham[1], Joshua Baker[2], Kristin Wipfler[3], Sarah Lieber[4], Sebastian Sattui[4], Patricia Katz[5] and Kaleb Michaud[6], [1]VA Puget Sound/University of Washington, Seattle, WA, [2]University of Pennsylvania, Philadelphia, PA, [3]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [4]Hospital for Special Surgery, New York, NY, [5]University of California, San Francisco, Novato, CA, [6]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty is associated with poor health outcomes in the general population, and recent studies have highlighted its importance in rheumatic musculoskeletal diseases (RMDs). Prior studies have found associations between frailty and low bone mineral density and fractures in RA and mortality in SLE and OA. These studies used performance or comorbidity-based measures of frailty which may not be feasible to collect in routine clinical care. Self-reported measures of frailty are validated in the general population but have not been widely studied in RMDs. We aimed to describe the prevalence of self-reported frailty across RMDs and to determine factors associated with frailty in a large observational cohort.

Methods: Data were from participants in FORWARD, The National Databank for Rheumatic Diseases, an observational longitudinal US-cohort registry with biannual patient questionnaires since 1998. The most recent wave of questionnaires, released in January 2020, included a 5-item validated patient-reported frailty index[1]. Participants were asked to report levels of fatigue, ability to walk several blocks, ability to climb ten stairs, weight loss, and presence of 11 comorbidities. Those meeting ≥3 of 5 criteria were categorized as frail. This analysis included all responses collected as of June 5, 2020. Multivariable logistic regression analysis was performed to identify factors independently associated with frailty.

Results: 1423 responses were included in this analysis, 63% with RA, 15% with OA, 7% with SLE, 4% with FM and 11% with other/unknown RMDs. Those categorized as frail (N=420, 30%) were older, had longer disease duration, greater pain, and were more likely to be obese (Table 1). The frail group reported a higher frequency of prednisone use in the last year as compared to the non-frail group (26% vs. 16%) but reported similar ever and never use of prednisone. The frail group reported more historical fractures than those who were not frail. SLE had the highest proportion of frailty (39%) despite being the youngest group (61±12 years). The top three factors contributing to frailty scores were inability to walk several blocks, inability to climb 10 stairs, and [3]5/11 comorbidities (Table 1). In the multivariable model, age, disease duration, pain scale, prednisone use within the last year, and prior fracture were associated with elevated odds ratios of frailty (ORs 1.04, 1.01, 1.23, 1.58 and 2.02 respectively, all $p< 0.05$) (Table 2). Within RMDs, using OA as the reference group, SLE was associated with 2.39-fold greater odds of frailty ($p=0.008$). Using normal weight as the referent, overweight and obesity were also associated with a greater odds of frailty (ORs 2.02 and 4.99, $p< 0.0001$).

Table 1- Cohort characteristics as a whole and by frailty status determined by a five question, patient-reported index. Frailty index range 0-5 and frailty defined as ≥3/5 criteria. Reported as N (%) or mean (SD).

	Overall (N=1423)	Not Frail (N=1003, 70%)	Frail (N=420, 30%)
Age (years)	65.4 (11.3)	64.6 (11.5)	67.4 (10.4)
Female	1230 (86.5%)	857 (85.9%)	373 (88.8%)
White Race	1292 (90.8%)	918 (91.5%)	374 (89.0%)
Disease Duration (years)	23.7 (12.3)	22.8 (12.0)	25.9 (12.8)
Primary Diagnosis			
-Osteoarthritis	213 (15.0%)	147 (14.7%)	66 (15.7%)
-RA	901 (63.3%)	643 (64.1%)	258 (61.4%)
-SLE	92 (6.5%)	56 (5.6%)	36 (8.6%)
-Fibromyalgia	63 (4.4%)	40 (4.0%)	23 (5.5%)
-Other or missing[a]	154 (10.8%)	117 (11.7%)	37 (8.8%)
Pain Scale[b]	3.26 (2.59)	2.79 (2.43)	4.42 (2.62)
Body Mass Index[c]			
-Underweight	22 (1.6%)	18 (1.8%)	4 (1.0%)
-Normal	447 (31.4%)	378 (37.7%)	69 (16.4%)
-Overweight	419 (29.4%)	308 (30.7%)	111 (26.4%)
-Obese	535 (37.6%)	299 (29.8%)	236 (56.2%)
Prior Fracture	426 (29.9%)	246 (24.5%)	180 (42.9%)
Prednisone Use			
-Never	786 (55.2%)	587 (58.5%)	199 (47.4%)
-Ever (not last year)	371 (26.1%)	258 (25.7%)	113 (26.9%)
-Within the last year	266 (18.7%)	158 (15.8%)	108 (25.7%)
Frailty Categories[d]			
-Fatigue	818 (57.4%)	579 (57.7%)	238 (56.7%)
-Stair Climb	464 (32.6%)	131 (13.1%)	333 (79.3%)
-Walking	632 (44.4%)	249 (24.9%)	383 (91.2%)
-Illnesses	534 (37.5%)	244 (24.3%)	290 (69.1%)
-Weight Loss	233 (16.4%)	92 (9.2%)	141 (33.6%)

-RA: rheumatoid arthritis; SLE: systemic lupus erythematosus.
[a]-Other category comprised of >20 primary rheumatic disorders other autoimmune and musculoskeletal syndromes or those missing a primary diagnosis.
[b]-Pain by visual analog scale. Range 0 (no pain at all) to 10 (worst pain imaginable).
[c]-Based on World Health Organization Body Mass Index categories: Underweight (<18.5 kg/m^2), Normal (18.5-24.9 kg/m^2), Overweight (25-29.9 kg/m^2) and Obese (>30 kg/m^2).
[d]-FRAIL scale frailty categories: self-reported fatigue, inability to climb 10 stairs, inability to walk several blocks, ≥5/11 comorbidities, ≥5% weight loss in the last year. Morley JE et al. *J Nutr Health Aging*. 2012; 16(7):601–608.
-Missing >5% data: Disease Duration (N=242) and Primary Diagnosis (N=110).

Conclusion: Self-reported frailty was prevalent in a third of participants with RMDs, with the highest rate in those with SLE despite that group having the lowest age. SLE, prior fracture, prednisone use within the last year, and obesity had the greatest odds of frailty in the multivariable model. Future longitudinal analyses to determine factors associated with incident frailty and its sequelae are needed in this high-risk population.

Abstract Number: 1135

Barriers to Influenza Vaccination in Patients at a Tertiary Care Rheumatology Clinic

Audra Horomanski[1], Gabriela Triant[1], Kathleen Kolstad[1], Melissa Dymock[2] and Janice Lin[1], [1]Division of Immunology & Rheumatology, Stanford University School of Medicine, Palo Alto, CA, [2]Department of Technology and Digital Solutions, Stanford University School of Medicine, Palo Alto, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatologic conditions are at high risk of hospitalization, ICU admission, and death related to influenza infection due to their underlying diseases and associated treatments. The influenza vaccination rate for the Stanford Rheumatology Clinic during the 2019/2020 influenza season was 61%, leaving a significant number of patients without this protection. We sought to investigate the personal and environmental factors that prevented patients from receiving the influenza vaccine.

Methods: During each clinic visit, patients were asked if they received, plan to receive, or decline the influenza vaccination. At the end of the influenza season, the demographics of patients who received and did not receive the influenza vaccine were compared. Those who did not have a confirmed vaccination in the electronic medical record (EMR) were contacted by secure message or phone and asked open-ended questions regarding their reasoning for not receiving the influenza vaccine in the past year. These responses were recorded and categorized, allowing for multiple responses if given.

Results: Demographic analysis found that patients aged 18-29 were less likely to be vaccinated compared to those aged 50-64 (p=0.018) and those aged 65-79 (p=0.014). No significant difference in vaccination status was found based on sex, race, or health insurance provider (Table 1). Five hundred and ninety two (592) patients without a recorded vaccine at the end of the influenza season were contacted to date and 368 responded (Figure 1). Of those who "Planned To", 50.3% reported being vaccinated, although this had not been captured in the EMR. The most common barriers cited by this group were lack of time (25.2%) and access (19.4%). In the "Decline" group, patients

Other	18 (2.6%)	14 (2.4%)		32 (2.5%)

Table 1. Demographics of patients who were vaccinated for influenza during the 2019/2020 influenza season compared to those who remained unvaccinated.

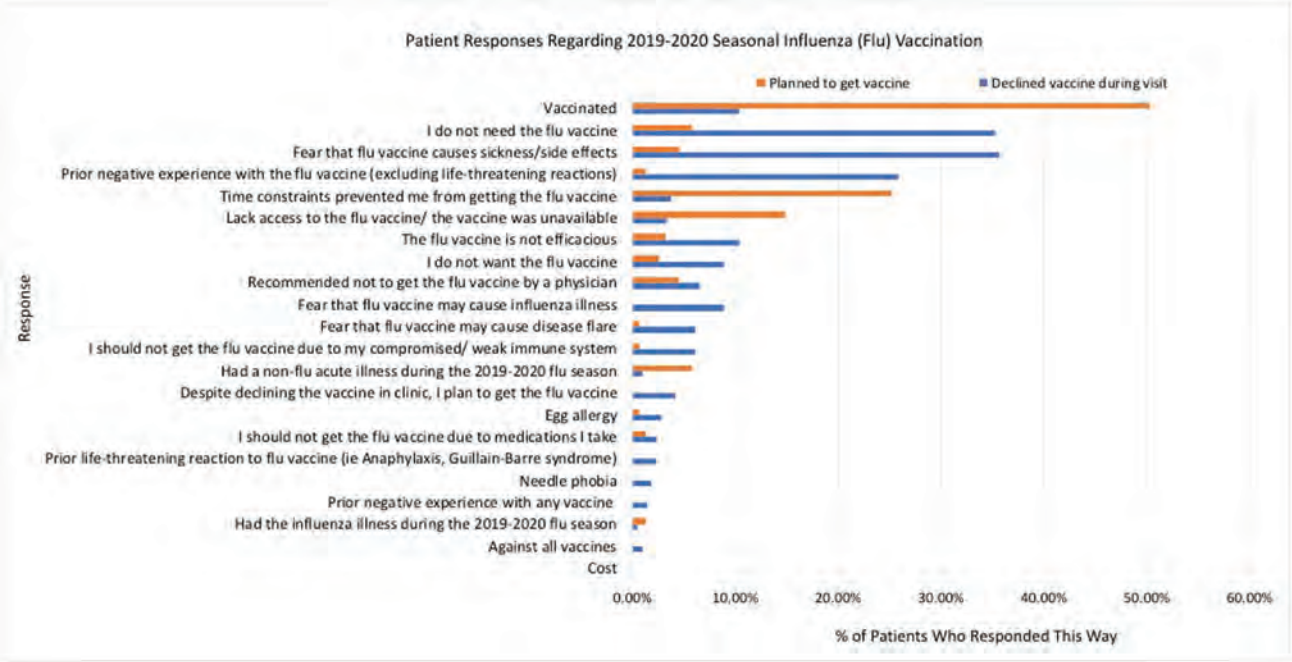

Figure 1. Patient reasons for not obtaining the influenza vaccination during the 2019/2020 influenza season separated into groups of patients who initially planned to get vaccinated (orange, n=155) and declined vaccination (blue, n=213).

reported fear of getting sick or side effects (35.6%), belief that they did not need the vaccine (35.2%), and prior negative influenza vaccine experience (25.8%) as reasons for not pursuing vaccination. Only a small proportion reported concerns related to their rheumatologic disease such as prompting a flare (6.1%), a weakened immune system (6.1%), and medication concerns (2.3%). No patient reported cost as a significant barrier.

Conclusion: In patients who desired influenza vaccination, time and vaccine availability were significant barriers. Fear of adverse reaction and prior negative experiences with the influenza vaccine were the primary reasons for active avoidance, although a significant percentage generally did not feel it was necessary. The results of this project can be used for targeted patient education to help improve vaccination rates in the future.

Abstract Number: 1136

Survey of Medical Cannabis Use in Lupus and Scleroderma

Wassim Karkache[1] and Catherine Ivory[2], [1]University of Ottawa, Ottawa, ON, Canada, [2]University of Ottawa Faculty of Medicine, Rheumatology, Ottawa, ON, CANADA, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the lack of research regarding medical cannabis, marijuana and its by-products have gained popularity over the last decades. A 2019 Statistics Canada report revealed that approximately 16% of Cana-

dians used marijuana in the last year. A Canadian study also revealed that 80% of rheumatologist participants were questioned by their patients weekly regarding medical marijuana; and in a similar study, 75% of participants were not comforTable prescribing medical marijuana. Despite being a common and debilitating feature in rheumatic diseases, there is little attention given to the study of medical options for the management of pain. The effects, both positive or negative of medical marijuana in patients suffering from lupus or scleroderma, is still unclear. We conducted a survey amongst patient diagnosed with lupus or scleroderma to evaluate their beliefs, concerns and personal experience if any with medical cannabis.

Methods: Patients with diagnosed lupus or scleroderma were recruited from the Ottawa Hospital division of Rheumatology. Consent was implied with completion of the survey and answers remained anonymous. Inclusion criteria: age >18, diagnosis of systemic lupus or scleroderma and able to complete survey in English or French. Data analysis of the results of the survey are qualitative.

Results: On preliminary results, 20% of participants are actively using medical cannabis, primarily in the form of CBD oil or inhaled. In those patients taking medical cannabis, they reported no significant side effects. Of those not using cannabis, 49% of participants considered using it, and 62% would like further discussion with their rheumatologist regarding pros and cons of medical cannabis. Among our participants, the most common reasons for use of medical cannabis were insomnia, anxiety, and pain. The majority (97%) were aware that there can be side effects, and this was often the reason for wanting more information. The main elements important to the discussion was trust in their treating physician, having a non-judgemental approach, the degree of uncontrolled pain/symptoms and need for alternatives as well as receiving reliable information.

Conclusion: Our survey results suggest that a proportion of our patients have already tried medical cannabis, and most have an interest in the use of cannabis to help with symptoms not relieved by standard therapies to date. We need to be prepared to better guide our patients with respect to medical cannabis. These results will highlight common reasons/indications for medical cannabis use in this patient population. This study will ultimately assist with broadening patient perspective on medical cannabis, its impact on our patients and guide us in elaborating new strategies when discussing medical cannabis.

Access to Digital Health in an Urban Rheumatology Population

Bruce Youm[1] and Aruni Jayatilleke[2], [1]University of the Pacific, Arthur A. Dugoni School of Dentistry, San Jose, CA, [2]Section of Rheumatology, Lewis Katz School of Medicine at Temple University, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Advances in treatment of rheumatologic diseases have increased emphasis on physician and patient use of health information technologies (HIT). While studies indicate that e-health platforms can improve rheumatology outcomes, patients with rheumatologic disease are at risk for being caught on the wrong side of the digital divide. However, despite this potential disconnect, few studies have examined barriers to e-communication and preferences in rheumatology.

Table 1. Demographic of patient survey respondents.

Characteristic	Mean (SD) or n (%)		
	Clinic Population	Clinic Low SES	Clinic Non-Low SES
Age in years, mean (SD)	53 (14)	57 (13)	47 (14)
Male, n (%)	31 (19%)	12 (24%)	9 (35%)
Female, n (%)	129 (81%)	38 (76%)	17 (65%)
Household income in US Dollars, n (%)			
<$20,000	50 (31%)	50 (100%)	0 (0%)
$20,000—49,999	43 (27%)	0 (0%)	0 (0%)
$50,000—100,000	18 (11%)	0 (0%)	18 (69%)
>$100,000	8 (5%)	0 (0%)	8 (31%)
I don't know or I don't want to answer	29 (18%)	0 (0%)	0 (0%)
Highest Education Completed, n (%)			
Some High School	33 (21%)	15 (30%)	0 (0%)
Completed High School	72 (45%)	25 (50%)	7 (27%)
Completed college or graduate school	53 (33%)	10 (20%)	19 (73%)

Methods: We investigated preferences regarding e-communications in an urban rheumatology clinic using a patient survey to quantify HIT access, identify barriers to HIT access, and evaluate HIT preferences. We used a cross-sectional survey design to study patients from our rheumatology clinic (n=160, 81% female, 19% male, average age 53, SD 14 years).

Results: Demographic characteristics are shown in Table 1. The high percentage of female respondents is in accordance with the institutional analysis of all patients visiting the Drexel Rheumatology Clinic for the duration of the study (82% female and 18% male, average age 54 years old with SD of 14, n=687).

Patients reported their preferred method of contacting physicians as being the phone (74%) followed by email (29%), online patient portal (17%), mail (11%), and other, such as in person (3%) (Table 2). The general population of rheumatology patients does not use patient portals. Specifically, only 21% of survey participants reported using Drexel's online patient portal, FollowMyHealth, while 14% reported using external electronic patient portals.

A large percentage of patients reported believing that it is very important or absolutely necessary to contact physicians electronically (40%) (Table 3). Respondents reported their main preferred method of internet access as being a mobile device (64%) followed by home computer (44%), Tablet (23%), outside computer (8%).

Cross-tabulation analyses indicate that the rate of internet access for an urban rheumatology clinic is similar to that of the general population. Within the clinic, higher SES demographic is significantly associated with higher internet access ($\chi 21$, N=76=28.27, P< 0.01), utilization of internet for health purposes ($\chi 21$, N=76=7.82, P< 0.01), use of smartphones ($\chi 21$, N=76=8.55, P< 0.005) and laptops ($\chi 21$, N=76=3.85, P< 0.05) for HIT access, and rating of the importance of contacting physicians electronically ($\chi 21$, N=76=4.45, P< 0.05).

Conclusion: Our institutional experience confirms that the rheumatology clinic population faces a digital divide. As expected, individuals of low SES in comparison to higher SES exhibit differences in access to, use of, and perception of HIT. We also note a low adoption rate of e-health platforms, suggesting that despite the development and promo-

Table 2. Patient consumption behavior for health information technology.

Patient Consumption Behavior for HIT	n (%)
Contacting physicians outside appointments	
Talk on the phone (landline, regular cell phone, or smart phone)	118 (74%)
Email	46 (29%)
Online patient communication portal	27 (17%)
Through the mail	17 (11%)
Other	5 (3%)
Utilization of patient portal access	
Uses the Drexel online patient portal usage (Follow my Health)	34 (21%)
Unfamiliarity with this particular patient portal	14 (9%)
Uses other electronic patient portals outside of Drexel	23 (14%)
Unfamiliarity with patient portals	9 (6%)
Internet access at home via mobile device or personal computer or laptop	129 (81%)
Utilization of electronic devices at least once a week	
Smartphone with internet access	120 (75%)
Traditional mobile device without internet access	32 (20%)
Landline phone	50 (31%)
Desktop Computer	41 (26%)
Laptop Computer	57 (36%)
Tablet	50 (31%)
Frequency of internet access for health purposes	
At least few times a week	33 (21%)
A few times a month	26 (16%)
Once a month	10 (6%)
Once every few months	29 (18%)
None	60 (38%)

tion e-communication, mobile health applications, and tele-health technologies, further effort is required to improve access to and comfort with HIT for rheumatology patients. Physician and patient education, intervention programs, and technology improvements should be explored to narrow this observed digital divide for rheumatology patients, inclusive of and tailored for low SES patient populations.

Table 3. Patient preferences for health information technology.

Patient Preference Categories for HIT	n (%)
Preference for contacting physicians electronically	
Very important or absolutely necessary	64 (40%)
Somewhat important but necessary	55 (34%)
Not important at all or don't care	39 (24%)
Preferred method of internet access	
Home Computer	71 (44%)
Outside Computer	13 (8%)
Mobile Device	102 (64%)
Tablet	37 (23%)
I don't go on to the internet regularly	27 (17%)
Importance of reviewing test results online	
Very important or absolutely necessary	79 (49%)
Somewhat important, but not necessary	47 (29%)
Not important at all or don't care	28 (18%)
Importance of learning more about health or tracking health online	
Very interested	60 (38%)
Somewhat interested	49 (31%)
Not very interested	18 (11%)
Not interested at all	32 (20%)

Estimation of Clinically Important Differences in Patient-Reported Outcomes Measurement Information System (PROMIS) Measures in Juvenile Myositis

Madison Wolfe[1], Amanda Robinson[2], Jin-Shei Lai[3], Theresa Coles[4], Elizabeth Gray[3], Rowland Chang[3], David Cella[3] and **Kaveh Ardalan**[5], [1]Creighton University School of Medicine, Omaha, NE, [2]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Duke University, Durham, [5]Duke University Medical Center, Durham, NC

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile myositis (JM) causes weakness, rashes, pain, and fatigue, thereby impacting health-related quality of life (HRQoL). Patient-Reported Outcomes Measurement Information System (PROMIS®) measures have undergone initial validation in JM, but clinical interpretability is limited. Estimates of clinically important differences (CIDs) have not yet been determined for PROMIS measures in JM. This study estimates CIDs of PROMIS fixed short forms in JM.

Table 1. Descriptive Statistics	
Diagnosis	n (%) / median (IQR)
Juvenile Dermatomyositis	71 (94.7)
Juvenile Polymyositis	1 (1.3)
Mixed Connective Tissue Disease	1 (1.3)
Overlap Syndrome	1 (1.3)
Autoimmune Necrotizing Myopathy	1 (1.3)
Female Gender	59 (78.7)
Race (White)	59 (78.7)

Treatment	78.6 (60.0, 100.0)
Worry	100.0 (79.2, 100.0)
Communication	91.7 (66.7, 100.0)

Table 1. Descriptive Statistics

Methods: JM patients (5-17 yo) and their parents were recruited at routine clinic visits. Clinical/demographic data were collected. Patients (8-17 yo) and parents (5-17 yo) completed PROMIS pediatric fixed short forms for Anxiety, Depressive Symptoms, Mobility, Upper Extremity Function, Fatigue, and Pain Interference domains. Distribution-based estimates (i.e. 0.5 standard deviation) of CIDs were calculated. Cross-sectional and longitudinal anchor-based estimation of CIDs was performed. Longitudinal anchor-based CID estimates (i.e. change in PROMIS score associated with change in anchor variable) were calculated for patient-parent dyads with data collected at 2

Table 2. Cross-Sectional Anchor-Based Clinically Important Differences (CIDs)

Child Report

PROMIS Measure	# CID Estimates	CID Range (min-max)	Effect Size (min-max)
Anxiety	6	6.2 - 12.1	0.53 - 1.0
Depression	7	7.1 - 12.6	0.67 - 1.2
Fatigue	7	5.9 - 17.6	0.49 - 1.4
Mobility	9	5.5 - 11.7	0.72-1.5
Pain Interference	6	7.6 - 16.0	0.73-1.5
Upper Extremity Function	1	12.5*	1.8*

Parent Report

PROMIS Measure	# CID Estimates	CID Range (min-max)	Effect Size (min-max)
Anxiety	7	5.8 - 14.0	0.46 - 1.1
Depression	7	5.7 - 12.4	0.54 - 1.2
Fatigue	14	3.9 - 17.3	0.32 - 1.4
Mobility	12	4.7 - 13.9	0.50 - 1.5
Pain Interference	7	5.9 - 13.8	0.53 - 1.2
Upper Extremity Function	11	5.9 - 14.8	0.6 - 1.5

*A single value, rather than a range, is provided if there is only one CID estimate for a given PROMIS measure.

Table 2. Cross-Sectional Anchor-Based Clinically Important Differences (CIDs)

Table 3. Longitudinal Anchor-Based Clinically Important Differences (CIDs)

*Child Report**

PROMIS Measure	# CID Estimates	CID Range (min-max)	Effect Size (min-max)
Anxiety	1	8.3**	0.73**
Depression	1	4.9**	0.49**
Fatigue	5	7.2 - 16.0	0.51 - 1.1
Mobility	5	6.1 - 14.3	0.57 - 1.33
Pain Interference	1	9.3**	1.0**

Parent Report

PROMIS Measure	# CID Estimates	CID Range (min-max)	Effect Size (min-max)
Anxiety	3	5.9 - 11.5	0.59 - 1.2
Depression	4	5.5 - 11.3	0.64 - 1.3
Fatigue	12	4.0 - 17.3	0.31 - 1.3
Mobility	13	4.6 - 12.4	0.45 - 1.2
Pain Interference	5	8.4 - 11.2	0.74 - 0.98
Upper Extremity Function	10	5.7 - 13.1	0.53 - 1.2

*Upper Extremity Function (child report) did not have any eligible longitudinal CID estimates.

**A single value, rather than a range, is provided if there is only one CID estimate for a given PROMIS measure.

Table 3. Longitudinal Anchor-Based Clinically Important Differences (CIDs)

study visits. Anchor variables collected at study visits included: Physician's Global Assessment of Disease Activity (PGA), muscle enzymes, Disease Activity Score Muscle and Skin Domains (MDAS, SDAS), Childhood Myositis Assessment Scale (CMAS), PedsQL Generic Core Scales (PedsQL-GC) and PedsQL Rheumatology Modules (PedsQL-RM). Anchor variables were grouped into clinically distinct categories based on published score cutoffs. Criteria for reporting anchor-based CID estimates included: 1) Spearman's correlation ≥0.3; 2) n ≥5 per clinically distinct anchor variable category; 3) effect size (i.e. Cohen's D) > 0.2. Differences in mean PROMIS scores across adjacent clinically distinct anchor variable categories were reported as CID estimates. Mean standard error of measurement (SEM) for each PROMIS domain served as the lower bound for CID estimates.

Results: Seventy-five patient-parent dyads enrolled, with descriptive data in Table 1. Mean SEM for PROMIS child report and parent report were respectively: Anxiety (4.7; 3.9), Depressive Symptoms (4.7; 4.5), Fatigue (4.6; 3.5), Mobility (5.3; 4.6), Pain Interference (4.4; 3.9), Upper Extremity Function (6.5; 5.7). Distribution-based PROMIS CID estimates ranged 3.4-6.1 and 4.7-6.3 for child report and parent report respectively. Cross-sectional anchor-based CID estimates are shown in Table 2. Longitudinal anchor-based CID estimates are presented in Table 3.

Conclusion: Our CID estimates enhance interpretability of PROMIS measures in JM by linking differences in PROMIS measures with relevant clinical and patient-reported anchors. CIDs can support the design and power calculations for future studies (e.g. clinical trials). Future multicenter studies should enhance precision and generalizability of CID estimates and assess differences in CIDs by disease status (e.g. high vs low disease activity).

Abstract Number: 1139

Primary Non-adherence in Patients with Systemic Lupus Erythematosus

Ankoor Shah[1], Megan Clowse[2], Daniel Wojdyla[1] and Amanda Eudy[1], [1]Duke University, Durham, NC, [2]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 50% of patients with systemic lupus erythematosus (SLE) are nonadherent to their medications, which increases the risk of renal failure and death (1). SLE is a particularly challenging disease because it primarily affects young, black women who are less likely to be insured, potentially making adherence more of a challenge. While some factors like depression, polypharmacy, low socioeconomic status, and education level may contribute to nonadherence, factors that can reliably predict nonadherence have not been thoroughly identified. We evaluated the rates of primary nonadherence (defined as patient not filling a medication at the pharmacy) in our population of patients with SLE. We also evaluated demographics and other variables that may be associated with primary nonadherence

1. Feldman CH Arth and Rheum 2016 68(6): 1323-6

Methods: Prescription fill data and medication orders were extracted from the electronic medical record (EMR) between 1/1/2018 and 12/31/2018 for 181 patients who were enrolled in an SLE or pregnancy-rheumatology registries. Prescription fill data is automatically entered into the EMR through a vendor (Surescripts) that pulls this information from pharmacies and prescription benefit managers. Specifically, we evaluated 5 medications for adherence: hydroxychloroquine, methotrexate, azathioprine, mycophenolate mofetil and belimumab. We compared prescription fill data to medication orders during this time period and measured the percentage of medications that were filled within 30 days of a medication order or expected refill. We also calculated the medication possession ratio (MPR) during this time frame. We designated a patient as adherent if they had an MPR of Finally, we evaluated several demographic and patient variables that may serve as predictors of non-adherence.

Characteristic	
Gender (Female)	174 (96.1%)
Age, median (quartiles)	36 (29 – 47)
Race	
Caucasian/White	56 (31.1)
Black or African American	105 (58.3)
Other	19 (10.6)
Missing	1
Hispanic	10 / 181 (5.5)
Education	
High school graduate/GED or less	18 (10.6%)
Some college but no degree	56 (33.1%)
College graduate and some graduate education	63 (37.3%)
Graduate education	32 (18.9%)
Missing	12
Income	
Up to $15,000	29 (18.6%)
$15,001 - $50,000	52 (33.3%)
$50,001 - $100,000	38 (24.4%)
$100,001 or more	37 (23.7%)

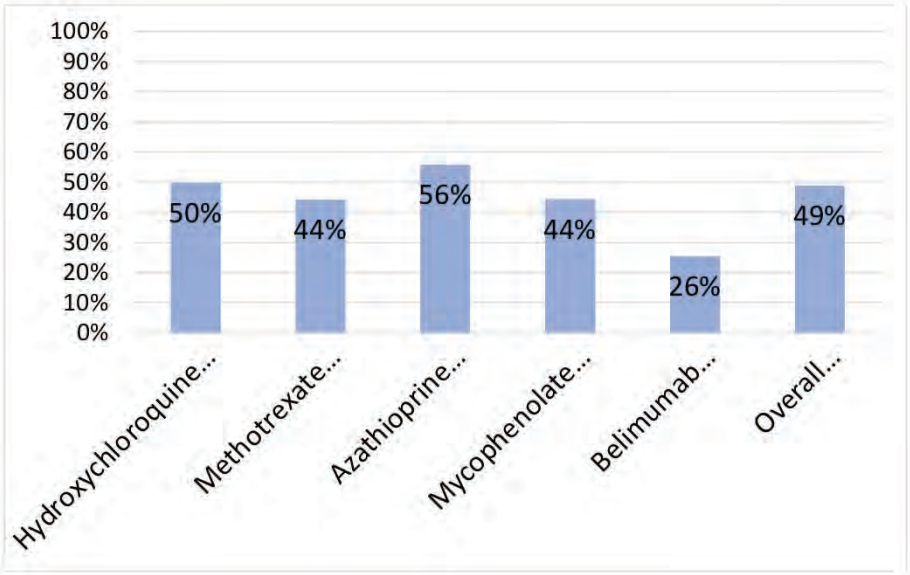
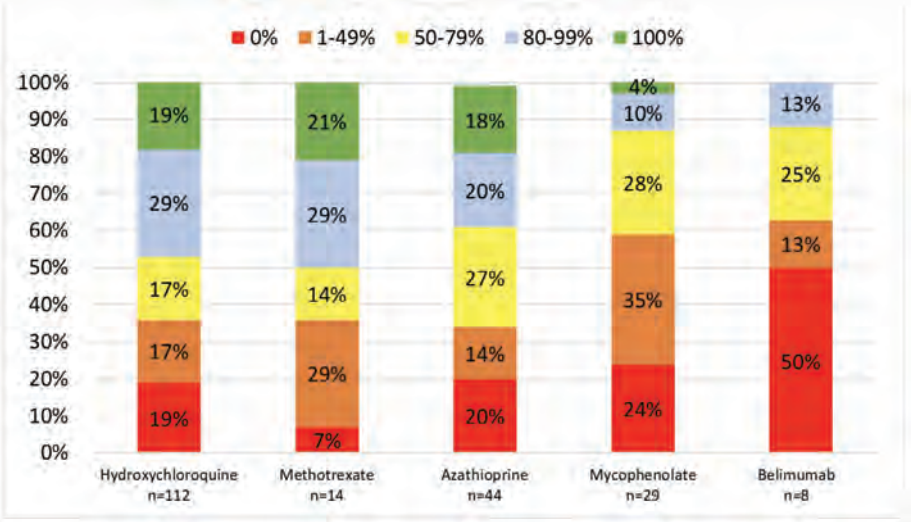
Maternal Autoimmune Disease Research Alliance	17 (9.4%)

Characteristics of patients entered into analysis

Results: Study population characteristics are presented in Table 1. At total of 181 patients were evaluated. 49% of prescription orders were filled within 30 days (Figure 1). Azathioprine was filled most often (56%) while belimumab the least (26%). Only 40-50% of patients had an MPR of at least 80% to hydroxychloroquine, azathioprine and meth-



Medication fills within 30 days of order



Medication possession ratio

otrexate. Less than 15% had an MPR of 80% to mycophenolate mofetil and belimumab. When evaluating predictors of non-adherence only age (less than 30 years old) was a significant predictor of non-adherence to all prescribed medications. Additionally, Caucasian patients had greater adherence to all medications compared to those identified as “Black” or “other”. Gender, level of education, income, insurance type and marital status were not significant predictors.

Conclusion: By using a methodology that allows for data supplied by Surescripts to be easily and directly extracTable from an EMR, we were able to identify that nearly 50% of patients were non-adherent in terms of filling prescriptions at a pharmacy, particularly for mycophenolate mofetil and belimumab. This correlates with other studies of adherence (both primary and secondary) using different methodology. Specifically, younger, non-white patients may be at the largest risk for primary non-adherence and may serve as a target population for intervention.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Social isolation during SARS-CoV-2/COVID-19 pandemic has undermined follow-up of patients with rheumatic diseases. These patients face a critical dilemma between the risk of exposure as a vulnerable population and the need of medical attention. During previous pandemics, factors associated with differential behaviors have been identified, including lack of knowledge and perception of risk. Knowledge, attitudes, and behaviors studies are used to investigate patterns of community reactions to a disease. The aim of this study was to explore the knowledge, attitudes, and behaviors of patients with rheumatic diseases in Latin America during the COVID-19 pandemic.

Methods: We performed a cross-sectional observational study by means of a digital anonymous survey (RedCap®). We included patients over 18 years old from Spanish-speaking PANLAR countries with at least one rheumatic disease (self-reported). We retrieved demographics, comorbidities, rheumatic disease treatment, adherence and self-reported activity prior and during the pandemic, COVID-19 basic knowledge, diagnosis and risk perception, information sources, adherence to precaution measures, impact on daily living, attitudes and behaviors regarding telehealth. We calculated median and interquartile range for quantitative variables and frequencies and percentages for qualitative variables.

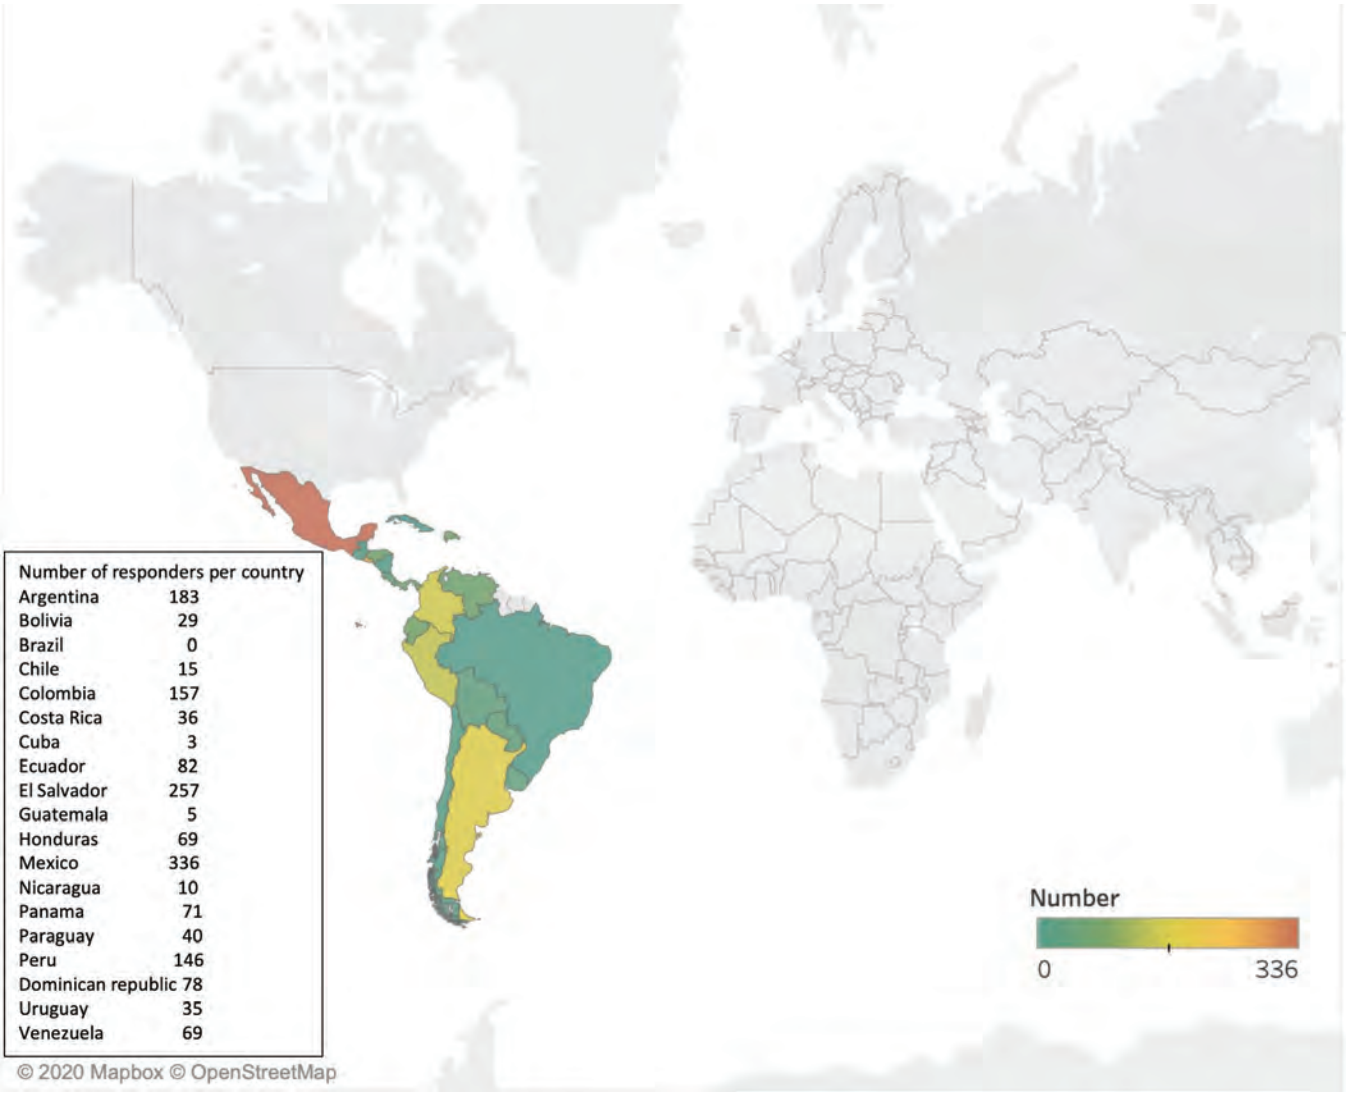

Figure 1. Number of patients filling the survey per country

Results: Our interim results include 1621 patients from 19 countries. The median age is 46 (37-56), most of them are women (92.4%). The most frequent rheumatic diseases were RA (54%) and SLE (26%). Self-reported disease activity increased during the pandemic (35% [8-60] vs 50% [13.5-70]). Twenty-seven (1.7%) responders were diagnosed with COVID-19. Twenty-three percent suspended at least 1 antirheumatic drug, particularly due to unavailability in pharmacies (34.7%); antimalarials were suspended by 22.2% of patients, mainly for the same reason (60.5%). Almost half reported that their follow-up appointments were cancelled and only 29% were offered an alternative. Twelve percent received telehealth, mainly via telephone (58%) and video call (34%), with a median satisfaction of 90% (62.5-100). Although 84% of responders consider telehealth as a valid strategy during the pandemic, this proportion reduces to 53.9% as a hypothetical alternative after the pandemic. An adequate knowledge on COVID-19 was found in 46%. The most frequent sources of information were television and social networks. Most patients reported a disruption in daily living due to social restrictions. Most responders reported an adequate adherence to general precautions.

Conclusion: Patients with rheumatic diseases in Latin America were negatively affected by the SARS-CoV2/COVID-19 pandemic. An increase in self-reported disease activity, a reduction in medication adherence and hurdles for medical follow-up were reported. Telehealth is perceived as a valid alternative to in-person consults during the pan-

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

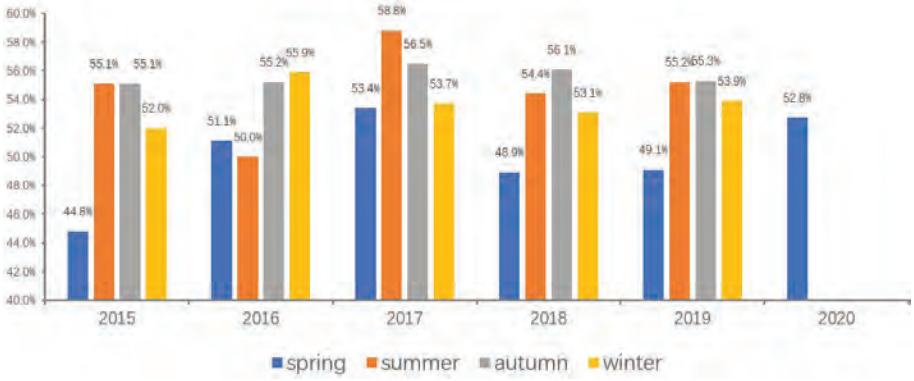
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target (T2T), achieving a DAS28 below 3.2 is the main management strategy for RA. The Chinese New Year is a long holiday started in Jan. or Feb. based on the lunar calendar. Few clinics were available and most of the patients could returned to their hometown for over a month. The Chinese New Year of 2020 initiated at the end of January, which was overlapped with the quarantine of the COVID-19 epidemic. The whole country was locked down till late of April.

The purpose of this study was to evaluate T2T status of RA patients under double hits by long holiday and COVID-19 lockdown via the Smart System of Disease Management (SSDM).

Figure 1. T2T model of RA patients(monthly) 2015-2019 and 2020

Figure 2. The T2T rate of every season



Methods: SSDM is an interactive mobile disease management tool, including two application systems (APPs) for both doctors and patients. From Jun. 2014 to Jun. 2020, more than 180,000 patients with rheumatic diseases were trained to use SSDM. After executing DAS28 assessment, inputting treatment regiments and lab test records by patients themselves, all data can be synchronized automatically to the authorized physicians' tool. The doctors can practice online consultation and continue or adjust treatment regiments based on patients' profile.

Data were extracted from SSDM cloud to develop data analysis model by python software based on data mining since January 2015 to June 10, 2020, and monthly distribution models of the T2T rate were structured. Changes in SSDM online services such as consultation and refilling/adjusting medicines before and during the outbreak were evaluated. Calculations of the monthly average T2T from 2015 to 2019 in spring season, and comparations with the rate of the T2T rate in 2020 were performed.

Results: From June 2014 to June 2019, 56,546 adult RA patients (mean age was 51.35±14.13 years, and median disease duration was 45.97 months) performed self-assessment of DAS28 totally for 127,316 times via SSDM. The T2T rates were the lowest in the year during consecutive 3 months after Chinese New Year eve throughout 2015-2019. In 2020, the country was locked down on January 23, the New Year Eve. Compared with 2019, the T2T rates of RA patients increased significantly by 11.3%, 15.8%, 12.0% and 10.4% from January to April 2020, and was also significantly higher than monthly average rate in same period of 2016-2019. ($p < 0.01$) Fig 1.

During the COVID-19 epidemic, the interactions between doctors and patients via SSDM was increased significantly. SSDM data in holiday-epidemic season showed 628 rheumatologists from 277 hospitals provided 9,924 consultations for 6,041 RA patients. And 407 rheumatologists in 192 hospitals conducted 3,493 refilling/adjusting medications for 2,233 patients. Compared with 2019, the number of consultations has increased by 2.85 times, and the number of medication refill/adjustment had increased by 4.29 times.

Conclusion: The T2T rate of RA patients was lowest in every past Chinese New Year season. During the COVID-19 epidemic, the trend of decline at T2T rates were reversed by strengthen SSDM's online consultation and continued medication services. Through active interactions between rheumatologists and patients via SSDM, the outcomes were improved and the double hits of Chinese New Year-Epidemic turned out to be a happy accident for Chinese RA patients.

Implementation of an Evidence-based Transition Clinic in a Pediatric Rheumatology Academic Institution

Rebecca Overbury[1], Tracy Frech[2], John Bohnsack[3], CJ Inman[1], Sara Stern[1], Karen James[1], Erin Treemarcki[4] and Aimee Hersh[4], [1]University of Utah and Primary Children's Hospital, Salt Lake City, UT, [2]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT, [3]University of Utah and Primary Children's Hospital, Cincinnati, OH, [4]University of Utah and Primary Children's Hospital, Salt Lake City

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Transition from pediatric to adult rheumatology care is more likely to be successful if a transition program is in place. Previously successful interventions to improve transition outcomes have included integrating an adult subspecialist in the pediatric clinic setting. We hypothesize that we will improve transition outcomes by implementing a transition clinic which includes an adult rheumatologist providing care within a pediatric rheumatology clinic.

Methods: We initiated a weekly transition clinic in November 2018 called ACCORD (Adult Center for Childhood Onset Rheumatic Disease). This clinic is staffed by 1 adult rheumatologist (board certified in internal medicine and pediatrics), 2 pediatric nurses, and 2 research coordinators. Patients can be seen if they are ≥ 16 years old with known rheumatic disease or suspicion for rheumatic disease. All patients (and legal guardians) receive education and monitoring of transition readiness. We provide transition readiness education and feedback in 6 discrete modules adapted from Got Transition $_{Tm}$ (Table 1). All patients (and legal guardians) complete patient reported outcome measures (PRO's). We maximize continuity of care in several ways: our adult rheumatologist meets pediatric patients who anticipate transfer to the transition clinic, she manages all transition clinic visits and education, and when possible she migrates care to our institution's associated adult rheumatology clinic. Demographics, PRO's, transition readiness measures, and clinical outcomes are collected in a prospective longitudinal registry.

Results: 35 patients have now participated in our transition clinic and been enrolled in our registry (Table 2). 9 patients (25.7%) thus far have decided, with the adult rheumatologist, to attempt to transition to an adult provider. 1 of the 9 transitioned to a provider other than the adult rheumatologist. 8 of the 9 transitioned to the adult clinic of the adult rheumatologist. Of the 9, all have had at least one follow up appointment with their new adult provider. 5 of the 9 (55.6%) had gaps of ≤ 4 months between their last pediatric rheumatology clinic visit and their first adult rheumatology clinic visit. The longest gap between visits was 8 months. Of the 4 in whom subsequent follow up appointments have been indicated with their adult rheumatologist, all 4 have successfully kept these appointments on time. 1 of 35 (2.9%) has been lost to follow up (gap > 3 months past scheduled/recommended visit without subsequent successful contact).

Conclusion: Our unique transition clinic is in its early stages of development. However, this research shows that our interventions including a dedicated transition education and planning in the clinical setting as well as the integration of a Med/Peds trained adult rheumatologist can improve the chance of a successful clinical transition from pediatric to adult sub-specialty care.

Abstract Number: 1143

The Influence of YouTube on Spreading Awareness and Patient Education Regarding Systemic Lupus Erythematosus

Priyatha Garlapati[1], Jasmeen Uppal[1], Sarwat Umer[2] and Samina Hayat[2], [1]LSU Shreveport, Shreveport, [2]LSU Shreveport, Shreveport, LA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A large global survey released by the World Lupus Federation showed that the awareness of SLE is low and many individuals have never heard of the disease. Amongst the patients diagnosed with SLE, most of the patients were noted to have poor insight. Therefore, it is essential to have good patient education in order to improve the overall outcomes. Most of the patients with SLE are young and are known to use the internet as a source of information to learn about their disease. As of May 2020, YouTube is the most popular website with monthly traffic of 1.62 billion in the world. YouTube being the most popular website, we have analyzed the source, content, quality, and association between several variables of the videos.

Methods: We searched YouTube using the keywords Systemic Lupus Erythematosus. The resulting search feed of the top 100 videos was arranged in descending order of the number of views which was then analyzed. We included

Global Quality Score :
1.Definition (1 point):
Systemic lupus erythematosus (SLE) is a chronic autoimmune disease of unknown cause that can affect virtually any organ of the body
2.Etiology (2 points; 1 point for 1-3, 2 points for >4)
Autoimmune, Genetic, Environmental, Drugs, Hormonal, Infectious
3.Symptoms (3 points; 1 point for 1- 3 systems, 2 points for 4-6 systems, 3 points for >7 systems)
Constitutional symptoms, Dermatological and Mucosal, Musculoskeletal, Renal, Pulmonary, Neurologic symptom, Hematological, Gastrointestinal involvement, Gynecological involvement.
4.Diagnosis: (3 points;1 point for each of the following)
Signs and symptoms, Appropriate laboratory workup, Imaging, Histopathology
5.Disease complications(2 points; 1 point for each)
Medication toxicity, Related to disease process
6.Prognosis (Max 1 point)
Survival rate with and without treatment
7.Preventative interventions (Max 2 points, 1 point for 1-2, 2 points for >3)
Photoprotection, Lifestyle- diet, exercise, smoking cessation, Compliance with medications
8.Treatment (Max 3 points, 1 p, point for 1-2, 2 points for 3-4, 3 points for >4)
NSAIDs, Corticosteroids, DMARDS - Nonbiologic and Biologic, IVIG, Plasmapheresis.
Scoring system: Total: 17 points

Figure 3. Video source and number of views, likes, and dislikes.

videos that are less than 30 minutes in length and only in the English language. These following variables and their combinations thereof were analyzed:-

1. Content of the video: Patient experience, Advertisement, Patient education, and Medical professional education
2. Source of the video: Professional Societies, Health care providers, Patients, and Media
3. Duration
4. The number of views likes and dislikes
5. Quality of patient education videos

The quality of these videos was rated using a Global Quality Score system(Figure 1) which is derived from the following- definition, etiology, signs and symptoms, diagnosis, prognosis, complications, and treatment measures. This scoring system has a minimum of 0 points and a maximum of 17 points. This statistical data were analyzed using the SAS system.

Results: The top 100 viewed videos were classified based on the content of the video. Medical professional education contributed to 46 videos(46%), whereas 29 videos (29%) were related to patient education and 20 videos (20%) were based on personal experience and 5% on advertisements. Of the 29 patient education videos analyzed 22 videos defined Systemic Lupus Erythematosus,11 videos out of 29 discussed etiology, 4 videos of 29 discussed the signs and symptoms, 5 videos of 29 discussed prognosis, 6 videos of 29 discussed the complications of the disease, 8 videos of 29 discussed treatment modalities and 3 videos of 29 discussed preventative measures. The results of the Global Scoring System is further analyzed in Figure 2. Further analysis regarding the association of the video source and Number of views, likes, and dislikes was made. Of all the video sources, media (tv shows, news, social media received the most number of views, likes, and dislikes. (Figure 3)

Conclusion: Based on the information obtained, these videos are very popular but a poor source of educating people regarding the disease. There is a clear need to increase the understanding and awareness of systemic lupus erythematosus and highlight the prognosis, treatment options, and preventative measures. Healthcare providers should emphasize the impact lupus has on people living with lupus and provide more insight into the disease and spread education materials and videos. We should also advise the patients to obtain information from reputed sources.

Abstract Number: 1144

Concerns and Behaviors of Patients with Common Autoimmune Rheumatic Diseases in the United States Early in the COVID-19 Pandemic

Michael George[1], Shilpa Venkatachalam[2], Shubhasree Banerjee[1], Joshua Baker[1], Peter Merkel[1], David Curtis[3], Kelly Gavigan[4], Maria (Maio) Danila[5], Jeffrey R Curtis[6] and William Nowell[7], [1]University of Pennsylvania, Philadelphia, PA, [2]Global Healthy Living Foundation, Upper Nyack, [3]Global Healthy Living Foundation, New York City, [4]Global Healthy Living Foundation, Upper Nyack, NY, [5]University of Alabama at Birmingham (UAB), Birmingham, AL, [6]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [7]Global Healthy Living Foundation, New York City, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with autoimmune rheumatic diseases may be particularly concerned about COVID-19. We aimed to assess concerns and associated health behaviors of patients with autoimmune rheumatic diseases during the COVID-19 pandemic and evaluate geographic differences within the United States.

Methods: Members of the ArthritisPower research registry and CreakyJoints patient community were invited to complete a baseline survey online with plans for follow-up surveys every 2 weeks for 8 weeks and then at 6 and 12 months. Reponses to the baseline surveys in adults from the United States with self-reported physician diagnoses of rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), and systemic lupus erythematosus (SLE) were analyzed. Differences in patient concerns, avoidance of office visits and testing, use of telehealth, and interruptions in medications were assessed, comparing patients with different autoimmune conditions, immunosuppression use, and residing in different geographies, using zip code-based measures of income, education, rural residence, and COVID-19 activity. Patient concerns (5-point Likert scale) were compared with Kruskal-Wallis tests and other outcomes with univariate logistic regression.

Results: Among 1517 participants (925 RA, 299 PsA, 185 AS, 108 SLE) the mean age was 55.1, 88.3% were female, and 89.5% white (Table 1). 243 participants (13.9%) reported a respiratory illness but were not diagnosed with COVID-19, 47.9% of whom wanted to be tested but were not. 11 patients reported a physician diagnosis of COVID-19. Participants reported substantial concerns about COVID-19 and that their autoimmune disease affected these concerns, with greater concerns among those on biologics/Janus kinase inhibitors (JAKi) (both $p < 0.01$) (Figure 1). There were no significant differences in concern geographically (census bureau divisions) or in urban versus rural areas. Use of telemedicine (29.5%) and avoidance of doctor's office visits (56.6%), laboratory testing (42.3%), and other testing (36.0%) were more common in participants from urban areas and counties with more COVID-19 cases per capita (Table 2). Among participants on DMARDs who did not report a respiratory illness or COVID-19 diagnosis, 14.9% stopped one of their medications, more commonly those receiving biologics and with greater COVID-19 concerns (Table 2). Most medication interruptions (78.7%) were not recommended by a physician. Patients who reported that telemedicine was not available were more likely to stop medications (25.4% versus 13.1%, $p < 0.01$).

Conclusion: In the early months of the COVID-19 pandemic, patients with RA, PsA, AS, and SLE frequently avoided office visits and laboratory testing. Patient behavior was associated more with urban status and geographic variation

Table 1: Participant demographic and clinical characteristics

	No reported respiratory illness	Reported a respiratory illness but not COVID-19	Reported a physician diagnosis of COVID-19
Sample size, N	1,295	211	11
Age (years)	55.4 +/- 11.8	53.5 +/- 11.9	46.9 +/- 8.8
Female	1,140 (88.0%)	191 (90.5%)	9 (81.8%)
Caucasian	1,169 (90.3%)	179 (84.8%)	10 (90.9%)
Hispanic	60 (4.6%)	15 (7.1%)	0 (0.0%)

Implementation of Web-Based Patient-Reported Outcome Measures (PROMs) in SLE Clinical Care: A Multi-Center Prospective Cohort Study

Shanthini Kasturi[1], Lori Lyn Price[1], David Curtis[2], William Nowell[3], Norma Terrin[1], Jane Salmon[4], Lisa Mandl[4] and Timothy McAlindon[1], [1]Tufts Medical Center, Boston, MA, [2]Global Healthy Living Foundation, New York City, [3]Global Healthy Living Foundation, New York City, NY, [4]Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcome measures (PROMs) are powerful tools which can highlight the patient experience of illness. Although PROMs are standard metrics in SLE clinical research, they are not routinely integrated in clinical care. Individuals with SLE are enthusiastic about the potential of PROMs to facilitate patient-centered care, but little is known about the utility and burden of implementing PROMs in SLE clinical encounters. The aim of this study was to assess the feasibility and impact of implementing web-based PROMs in the routine clinical care of outpatients with SLE.

Methods: Outpatients fulfilling 1997 ACR SLE classification criteria were enrolled in this longitudinal cohort study at two academic medical centers. Subjects completed PROMIS computerized adaptive tests at enrollment and prior to two consecutive routinely scheduled rheumatology visits using the ArthritisPower research registry mobile or web-based application. Score reports were shared with patients and providers before the visits. Patients and rheumatologists completed post-visit surveys evaluating the utility of PROMs in the clinical encounters.

Table 1. Characteristics of Participants

Patient Characteristics (n = 105)	**Value**
Age, median [25th, 75th percentiles] years	39 [32, 51]
Disease duration, median [25th, 75th percentiles] years	8 [4, 15]
Sex, n (%)	
Male	3 (2.9)
Female	102 (97.1)
Race, n (%)	
White	47 (44.8)
Black or African-American	25 (23.8)
Asian	16 (15.2)
More than one	9 (8.6)
Not Reported	8 (7.6)
Ethnicity, n (%)	
Hispanic or Latino	20 (19)
Insurance, n (%)	
Medicaid	25 (23.8)
Medicare	14 (13.3)
Commercial/private	64 (61.0)
None	2 (1.9)
Baseline SELENA-SLEDAI, mean [SD]	3.8 [3.8]
Baseline SLICC-ACR Damage Index, mean [SD]	1.1 [1.8]
Provider Characteristics (n = 16)	**Value**
Years in practice, median [25th, 75th percentiles]	5.5 [1.75, 15.75]
SLE patients seen/week, median [25th, 75th percentiles]	3.5 [3, 5]

SELENA-SLEDAI = Safety of Estrogens in Lupus Erythematosus National Assessment-Systemic Lupus Erythematosus Disease Activity Index
SD = Standard deviation
SLICC-ACR Damage Index = Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index

Table 1. Characteristics of Participants

Table 2. Post-Visit Survey Results (n = 159 visits)

Question	"Yes" Patient Responses (n = 157)	"Yes" Physician Responses (n = 159)
Did you review PROM scores?	**73%** (95% CI 66, 80)	**92%** (95% CI 86, 96)
Were PROMs discussed during the visit?	**60%** (95% CI 52, 68)	**65%** (95% CI 57, 72)
Were PROMs useful?	**91%** (95% CI 85, 95)	**83%** (95% CI 76, 89)
Did PROMs help communication?	**86%** (95% CI 80, 91)	**72%** (95% CI 64, 79)
Did PROMs identify issues for discussion?	**44%** (95% CI 36, 52)	**36%** (95% CI 28, 44)
Did PROMs impact treatment plan/management?	**43%** (95% CI 35, 51)	**51%** (95% CI 43, 59)

PROM = Patient-reported outcome measure
CI = Confidence interval

Table 2. Benefits, Challenges, and Ideal Use of Patient-Reported Outcome Measures in Clinical Care

PROMs in 159 of 184 eligible encounters (86%, 95% CI 81 – 91) prior to study suspension due to the COVID-19 pandemic. Following baseline surveys, PROMs were completed for 90% (95% CI 82 – 95) of visit 1's and 82% (95% CI 72 – 90) of visit 2's. Nearly all PROMs (93%) were completed remotely. Patients and rheumatologists found that PROMs were useful (91% and 83% of encounters respectively) and improved communication (86% and 72%) (Table 2). Rheumatologists reported that PROMs impacted patient management in 51% of visits, primarily by guiding conversations (84%), but also by influencing medication changes (15%) and prompting referrals (10%). There was no statistically significant difference in visit length before (mean=19.5 minutes) and after (mean=20.4 minutes) implementation of PROMs (p=0.52).

Conclusion: The remote capture and subsequent integration of PROMs into clinical care was feasible in this diverse cohort of SLE outpatients. PROMs were useful to both patients and rheumatologists, promoting patient-centered care primarily by facilitating communication. The implementation of PROMs was not significantly associated with an increase in length of visits.

Pilot Study of an Internet-Based Pain Coping Skills Training Program for Patients with Systemic Lupus Erythematosus

Kelli Allen[1], Tyler Beuchamp[2], Rebecca Cleveland[3], Kimberlea Grimm[1], David Hu[1], Katie Huffman[1], Frances Keefe[4], Julie Norfleet[1], Christine Rini[5], Andres Santana[1], Shruti Saxena Beem[6] and Saira Sheikh[7], [1]University of North Carolina at Chapel Hill, Chapel HIll, NC, [2]Medical College of Georgia, Augusta, GA, [3]University of North Carolina, Chapel Hill, NC, [4]Duke University Medical Center, Durham, NC, [5]Northwestern University, Chicago, IL, [6]University of North Carolina at Chapel Hill, Chapel Hill, [7]University of North Carolina Thurston Arthritis Research Center, Chapel Hill

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) have increased symptoms of fatigue, chronic pain, depression and anxiety, which are associated with negative impacts on quality of life. Interventions that enhance the use and effectiveness of coping strategies may lead to better physical and psychological outcomes among patients with SLE. Pain coping skills training (PCST) programs have been shown to improve outcomes among patients with other rheumatic conditions, but there have been no trials of PCST among patients with SLE. This study was a preliminary assessment of the feasibility and efficacy of painTRAINER (formerly PainCOACH), an automated, internet-based PCST program, among patients with SLE.

Methods: Participants were 60 individuals with a diagnosis of SLE, identified from electronic medical records of one health care system. Participants were randomly assigned with equal allocation to painTRAINER or a wait list control group. PainTRAINER involves 8 modules; participants were instructed to complete one module weekly, along with practice activities for each cognitive or behavioral coping skill. Outcomes were assessed at baseline and 9-week follow-up, including the Pain Catastrophizing Scale, PROMIS Subscales (Pain Interference, Physical Function, Sleep Disturbance, Anxiety, Depression, Fatigue and Participation), and the LupusPRO quality of life questionnaire. Baseline characteristics and changes in outcomes from baseline to follow up (mean, standard deviation and Cohen's d effect sizes) were computed for painTRAINER and wait-list control groups.

Results: Participant characteristics are shown in Table 1. Among those randomized to the painTRAINER group, 53% accessed the program ("painTRAINER users"). Most of those who did not access the program stated that they did not receive instructions via email. Table 2 shows changes in study outcomes for the wait list and painTRAINER groups, as well as participants randomized to painTRAINER who did access the program. PainTRAINER users had a small decrease in Pain Catastrophizing (the tendency to ruminate about pain and feel helpless in dealing with it), while participants in the other groups had increases in scores. Participants in the painTRAINER group had greater improvement in PROMIS Pain Interference than the wait list group, with painTRAINER users having the greatest improvement. PainTRAINER users also had more favorable responses than the other groups with respect to PROMIS sleep disturbance, fatigue, and the LuposPRO Health-Related Quality of Life Score.

Table 1. Participant Characteristics

	Wait List (N=30)	painTRAINER (N=30)
Mean Age (SD)	47 (12)	51 (14)
% Female	93%	97%
% Caucasian	37%	33%
% With Some College Education	87%	77%
% Married / Living with Partner	50%	40%
% With "Adequate" Income	83%	70%
% Working	37%	23%

Table 1

Table 2. Mean Changes (SD), Follow-up minus Baseline, and Effect Sizes Compared to Wait List					
	Wait List (N=30)	painTRAINER (N=30)		painTRAINER Users (N=16)	
	Mean (SD) Change	Mean (SD) Change	Effect Size	Mean (SD) Change	Effect Size
Pain Catastrophizing†	3.6 (6.5)	2.3 (9.6)	-0.16	-0.4 (8.8)	-0.53
PROMIS Pain Interference†	-1.7 (790)	-2.6 (6.6)	-0.12	-4.2 (6.4)	-0.33
PROMIS Physical Function*	-0.6 (7.0)	-3.8 (4.1)	-0.56	-3.8 (4.4)	-0.51
PROMIS Participation*	0.5 (6.8)	0.7 (6.5)	0.03	1.0 (7.4)	0.08

Development of a Digital Toolkit to Improve Quality of Life of Patients with Systemic Lupus Erythematosus: A Pilot Study

Jerik Leung[1], Ashish Shrestha[1], Jennifer Ra[2], Laura Brennan[3], Alfred Kim[4] and Elizabeth Baker[1], [1]Saint Louis University, College for Public Health and Social Justice, St. Louis, [2]Washington University School of Medicine, Lake Forest, CA, [3]Transtria, St. Louis, [4]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Miscellaneous Rheumatic Diseases

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals living with systemic lupus erythematosus (SLE) face a number of challenges in managing their condition. Initial interviews and community forums with SLE patients suggested that unpredictability and variability of symptoms contribute to the erosion of formal and informal social support and highlighted the need for information and skills to adapt to symptom fluctuations. Patients suggested that digital tools may be particularly well suited to addressing these unmet needs because symptom unpredictability reduces the ability to reliably attend in-person interventions. The purpose of this project was to use patient-centered outcomes research (PCOR) and community-based participatory research (CBPR) principles of practice to engage stakeholders including SLE patients, patient advocacy organizations, and providers to prioritize unmet needs and to develop resources to address those needs.

Methods: Initial recommendations for content priorities and methods of delivery were developed through a series of stakeholder meetings (patients, health care providers, representatives from community-based organizations) and a mixed-methods survey of SLE patients evaluating internet usage and access. A clickable prototype of the digital toolkit was then developed incorporating priority content areas. Alpha (individuals with no affiliation with SLE clinic) and beta (patients and family members, health care providers, clinical staff) usability assessments of the clickable prototype were conducted through semi-structured interviews.

Results: Content areas identified as priorities included: nutrition, improving communication (family/friends and health care providers), physical activity, and self-management. Respondents provided a number of suggestions based on their review of our toolkit and experiences with existing SLE resources. Respondents emphasized the benefits of digital access to this content (website, smartphone application). Given the variability of SLE experiences, respondents desired the ability to regularly visit the platform, to receive tailored messages which would guide them to relevant information, and to conduct open searches of the material. Key suggestions for improving the platform included a sign-in for users to track activity, a live chat with SLE experts, a variety of static and dynamic virtual tools, and an ability to connect with other SLE patients.

Conclusion: Individuals living with SLE have dynamic needs that change over time. Digital platforms were identified by stakeholders as a viable way to respond to these dynamic needs since they can be easily accessed and tailored to individuals. Community-based/patient-centered approaches ensure that the perspectives of those who are affected most by a problem are included in intervention design.

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a rare, complex auto-inflammatory disease with significant morbidity including fever, rash, serositis and articular problems. With the availability of interleukin-1 (IL-1) and IL-6 inhibitor treatment, morbidity has significantly reduced and the (long term) outcome for sJIA patients has improved over the last decade. However, differences in access to care and differences in treatment strategies between countries in and outside of Europe remain a concern.

The Single Hub and Access point for paediatric Rheumatology in Europe (SHARE) consortium aimed to develop best practices for paediatric rheumatic diseases in order to decrease differences in care between European countries. Here, we present the final results of the literature review and a series of consensus meetings on defining overarching, diagnostic and therapeutic recommendations for diagnosis and treatment of systemic JIA.

Methods: The SHARE methodology concerning consensus-based principles and guidelines has been previously published, including the use of the EULAR standardized operating procedure for developing best practice recommendations(1). As per these guidelines, a methodologist provided supervision during the process and consensus meetings.

A systematic literature search of the Medline, Embase and Cochrane databases was performed in June 2013 and this was updated in November 2019. Results were used to develop and support recommendations on diagnosis, treatment and complications of systemic JIA. These recommendations were pre-tested in an online survey to a task-force of expert paediatric rheumatologists to assess potential agreement and enable rewording. The participating experts convened in 3 consensus meetings (Genua 2014, Barcelona 2015 and Utrecht 2020) to develop the best practices.

Table 1	Principles for systemic juvenile idiopathic arthritis (sJIA)		
Overarching principles	**L**	**S**	**A (%)**
Systemic JIA is a systemic auto-inflammatory disease.	1B	B	96
Systemic JIA and Adult Onset Still's Disease (AOSD) represent a single disease entity with different age at onset.	5	D	100
In patients with suspicion of MAS, even without fulfilling the EULAR/ACR/PRINTO 2016 MAS classification criteria, MAS specific treatment should not be delayed.	3	B	100
Treating physicians should be aware of the rare risk of sJIA patients developing associated interstitial lung disease (sJIA-ILD).	4	C	100
Diagnostic principles			
Important differential diagnoses for sJIA include: infections, malignancies, vasculitides and other auto-inflammatory syndromes. If suspected, these diagnoses should be actively excluded by appropriate diagnostic procedures upon indication.	3-4	C	96
Arthritis can be an important feature but may not be present at the early stage of the disease.	3	C	91
Although several diagnostic biomarkers have been shown to be promising in case control and cohort studies, so far no single biomarker has been validated to help diagnosing sJIA with sufficient specificity and sensitivity.	2B-4	C-D	100
Treatment principles			
High-dose glucocorticoids are effective in sJIA, but their use is limited by glucocorticoid toxicity. Therefore their use and duration should be minimized where possible.	2B	B	100
IL-1 blocking agents (both anakinra and canakinumab) are an effective treatment option in glucocorticoid resistant or glucocorticoid dependent sJIA.	1	A	91
Anakinra is an effective treatment option early in the disease course of sJIA, including in glucocorticoid naïve patients.	3	C	96
Tocilizumab, an IL-6 blocking agent, is an effective treatment option in glucocorticoid resistant or glucocorticoid dependent sJIA.	1	A	96
Tocilizumab may prevent radiological damage of the joints in sJIA.	3	C	91
Methotrexate can be of some benefit in the treatment of arthritis in sJIA, but has no proven benefit in the treatment of systemic features.	1B	A	86
Overall, TNF blockade is of less benefit for the treatment of sJIA compared to IL-1 or IL-6 blockade, but may be useful for the treatment of some patients with persistent arthritis.	2	B	100
So far, no evidence-based recommendations can be made on how and when to stop biologicals for sJIA.	4	D	100

Making use of the Nominal Group Technique, recommendations were proposed, discussed and voted on. Recommendations that reached ≥80% were accepted in this guideline.

Results: The 2-step systematic literature review finally included 98 papers on sJIA. Quality and grade of evidence was assessed and a categorized overview was used as backbone and reference during the consensus meeting. In total, 15 recommendations were developed and accepted in the final consensus meeting: 4 overarching principles, 3 diagnostic recommendations and 8 recommendations on treatment of sJIA and its complications. Recommendations are presented with accompanying level of evidence (LoE), strength of recommendation (SoR) and percentage of agreement (PoA). In addition, adherence to the 2018 EULAR Treat-to-Target principles on JIA was confirmed by the expert panel.

Conclusion: These SHARE best practices on sJIA are based on the best available evidence and expert opinion, and provide recommendations for the diagnosis and treatment of patients with sJIA, aiming to improve the outcome for all sJIA patients in Europe and beyond.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophage Activation Syndrome (MAS) is a severe, life-threatening, complication of Systemic Juvenile Idiopathic Arthritis (sJIA) with a significant mortality. A score that identify sJIA patients with high risk to develop MAS would be useful in clinical practice.

Table 1. Laboratory parameters and cut-off used to create the MAS risk score in sJIA patients.

Laboratory parameters	Cut-off	Score
Ferritin (ng/ml)	>750	3.5
LDH (UI/L)	>540	2.5
AST (UI/l)	>30	2
Triglycerides (mg/dl)	>100	1.5

Table 2. Sensitivity, Specificity, Positive predictive value and Negative predictive value in the construction and validation cohorts.

	Construction cohort	Validation cohort
Sensitivity (Se)	96.4	81.3
Specificity (Sp)	80.5	60.0
Positive predictive value (PPV)	77.1	39.4
Negative predictive value (NPV)	97.1	90.9

Methods: We evaluated whether routine laboratory parameters at disease onset may predict the development of MAS in patients with sJIA and we defined a risk score of MAS using these parameters. Then, we validated the score in a second population. Laboratory parameters of disease activity and severity were retrospectively evaluated in 99 sJIA patients referred to Bambino Gesù Hospital in the last 10 years with at least 2 years of follow-up. Laboratory parameters were evaluated during active sJIA, without MAS, at disease onset or disease flare, immediately before treatment for sJIA was started or modified. Patients were divided in two groups: sJIA patients without MAS in the 2 years of follow-up and sJIA patients with at least one MAS episode. To create the MAS risk score, laboratory parameters with a statistically significant difference between the 2 groups were selected.

Results: Thirty patients, that fulfilled the 2016 classification criteria for MAS [1] at time of sampling, were excluded from the analysis. Therefore, we analysed laboratory parameters of 69 sJIA patients, 41 without MAS in the follow-up and 28 with at least one episode of MAS. Levels of ferritin, AST, LDH and triglycerides were significantly higher in patients with MAS during follow-up compared to those without. Their respective cut-off were computed by means of ROC curve analysis. A regression coefficient-based scoring system was used to assign weights to the risk index and the optimal score cut-off was defined by ROC curve analysis (Table 1). A MAS risk score ≥5 identified 27 out of 28 sJIA patients with MAS during the follow-up and 8 out of 41 sJIA patients without MAS. Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of the score are detailed in Table 2. In order to validate the MAS risk score on a different population, we applied the score on 132 sJIA patients from other pediatric rheumatology centers, 100 without history of MAS and 32 with at least one episode of MAS. Se, Sp, PPV and NPV of the score are reported in Table 2.

Conclusion: In conclusion we developed a MAS risk score based on routine laboratory parameters, available worldwide, that can help clinicians to identify early in the disease course sJIA patients with high risk to develop MAS.

Traditional Laboratory Parameters and New Biomarkers in Macrophage Activation Syndrome and Secondary Hemophagocytic Lymphohistiocytosis

Arianna De Matteis[1], Denise Pires Marafon[1], Ivan Caiello[1], Manuela Pardeo[1], Giulia Marucci[1], Emanuela Sacco[1], Giusi Prencipe[1], Fabrizio De Benedetti[2] and **Claudia Bracaglia**[1], [1]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, Italy, [2]Division of Rheumatology, Laboratory of Immuno-Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, Italy

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

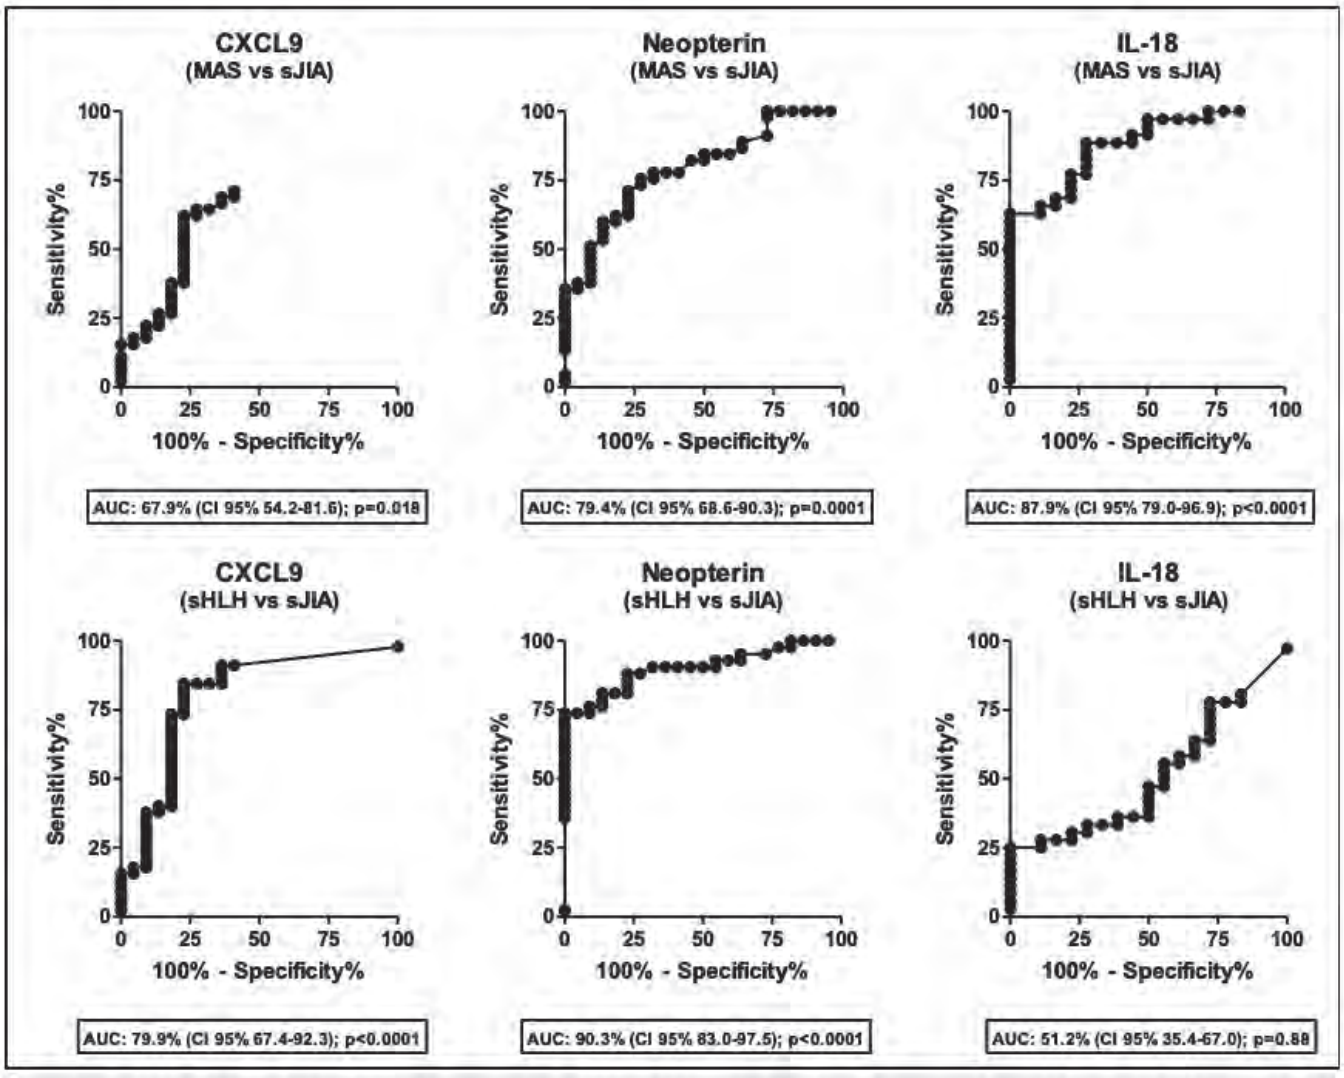
Background/Purpose: Macrophage Activation Syndrome (MAS) and secondary Hemophagocytic Lymphohistiocytosis (sHLH) are hyperinflammatory conditions caused by a cytokine storm, in which IFNγ plays a pivotal role. In this study we aimed to evaluate clinical characteristics of sHLH, MAS and systemic Juvenile Idiopathic Arthritis (sJIA) patients at disease onset. We compared laboratory parameters of hyperinflammation (platelet count, ferritin, AST, triglycerides, fibrinogen) and IFNγ related biomarkers in samples collected in three different time points: active disease (T0), 7-10 days from starting therapy (T1) and in clinical inactive disease (from 1 to 3 months from onset) (T2).

Methods: Routine laboratory parameters of disease activity and severity were collected from a cohort of 82 patients with sHLH (38), MAS in the context of sJIA (26), and sJIA (18) at T0, T1 and T2. Serum levels of the IFNγ related biomarkers (CXCL9, CXCL10, neopterin and IL-18) were measured at each time points by ELISA.

Results: A total of 306 samples were collected. Fever was present in the majority of patients (95%), while splenomegaly was more frequently in MAS (65%) and sHLH (63%) compared to sJIA (17%). Laboratory characteristics at T0 are detailed in Table 1. Using the 2016 classification criteria for MAS [1], we found that platelet count is a specific parameter, any patient with sJIA had a value < $181x10^9$/liter; while ferritin is a sensitive one, 94% of patients with MAS had ferritin > 684 mg/ml. CXCL9, CXCL10 and neopterin levels in T0 were significantly higher in MAS and in sHLH compared to sJIA, while IL-18 was significantly higher only in MAS group (Table 2). The ROC curves performed for each biomarker in MAS showed a statistically significant AUCs ($p< 0.05$). In sHLH the AUCs was significant for CXCL9, CXCL10 and Neopterin ($p< 0.0001$), while for IL-18 was not ($p= 0.9$) (Figure 1). In MAS CXCL9 and neopterin were significantly correlated to laboratory parameters of hyperinflammation as well as IL-18, except for ferritin. In sHLH only neopterin was significantly correlated to platelet count and triglycerides. CXCL9, CXCL10, neopterin and IL-18 levels progressively lowered at T1 and normalized in T2. CXCL9 decreased faster compared to neopterin, with a similar trend of laboratory parameters.

Conclusion: Our results confirme that platelet counts and ferritin have and high specificity and sensitivity, respectively, to diagnose MAS in the context of sJIA. Moreover, our results confirmed that IFNγ related biomarkers are significantly high in patients with MAS and sHLH and could be useful for diagnosis in addition to traditional laboratory

Figure 1. ROC curve of IFNγ related biomarkers at T0 in patients with MAS and sHLH.



parameters. CXCL9 seems to be more related to active disease, while neopterin seems to be more useful to follow the disease course. As already known, IL-18 is a specific biomarker for MAS.

Implementation and Initial Experience with a Screening Protocol for Inflammatory Hyperferritinemia

Michael Zhang[1], Corinne Schneider[2], Vinh Dang[2] and Scott Canna[3], [1]Children's Hospital UPMC, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, [3]University of PIttsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) and hemophagocytic lymphohistiocytosis (HLH) epitomize a diverse and deadly group of inflammatory hyperferritinemic syndromes. Early biomarkers distinguishing these syndromes, especially those indicating specific treatments, are lacking.

Methods: .Between 6/2017 to 6/2019, we instituted a hyperferritinemic alert system for serum ferritin >1000ng/mL (Figure 1). Positive alerts were screened via real-time chart review and categorized into inflammatory hyperferritinemia, hemoglobinopathy (e.g. sickle cell disease), malignancy, post-transplant (solid organ and hematopoietic), and miscellaneous. The earliest available leftover serum samples from inflammatory hyperferritinemia alerts were set aside by and frozen in our clinical laboratory. Such patients were contacted for enrollment into an ongoing natural history protocol, and samples from patients able to be (or previously) enrolled were collected and tested. Longitudinal samples were obtained when possible focusing on changes in clinical status. Subsequently, we divided the inflammatory hyperferritinemia patients into infectious, rheumatic (all of whom were systemic JIA, or SJIA, during this period), or immune dysregulation. We extracted laboratory elements of MAS/HLH from enrolled patients' electronic medical record (AST, CRP, platelets) and measured IL-18, IL-18 binding protein (IL-18BP), and CXCL9 on stored samples. All procedures were approved by the University of Pittsburgh Institutional Review Board (STUDY20010099).

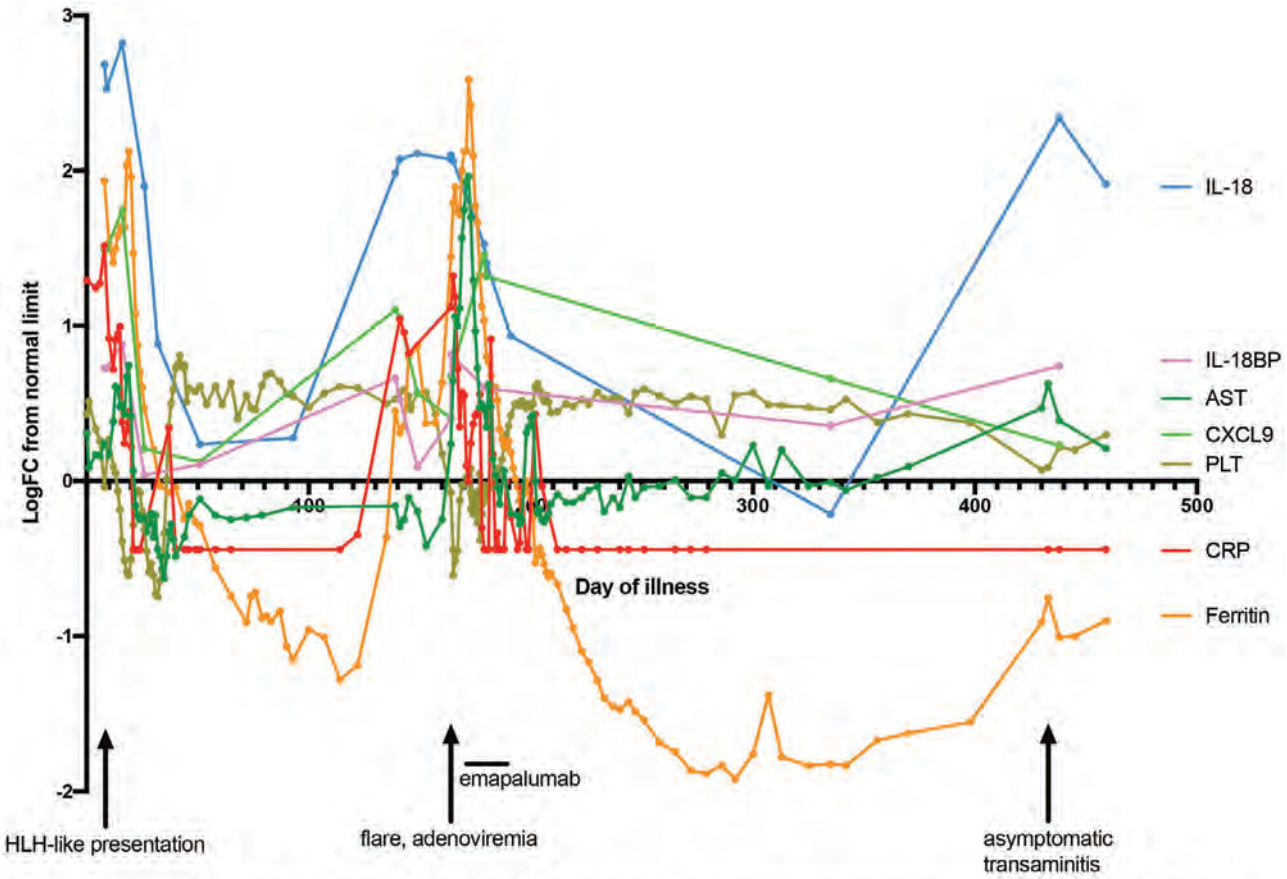

Figure 3: Course of a patient with mixed MAS/HLH picture. LogFC=Log10 Fold Change from normal limit: AST/55, Ferritin/300, PLT=Platelets/150, CRP/0.8, IL-18/540, IL-18BP/5000, CXCL9/1000.

Results: We screened 931 alerts from 180 unique patients. Inflammatory hyperferritinemia was adjudicated as the cause of 40.3% of screened ferritin levels from 30.5% of distinct patients. Maximum ferritin levels were higher in patients with inflammatory hyperferritinemia compared to hemoglobinopathies, malignancies, post-transplant, and miscellaneous diseases. Among the inflammatory hyperferritinemia group, the highest AST levels were observed in patients with "immune dysregulation", whereas maximum CRP levels were higher in infectious and SJIA-associated hyperinflammatory states. Platelets were less-consistently depressed in SJIA-associated hyperferritinemia. Consistent with previous findings, highly elevated IL-18 was uniquely observed in samples from patients with SJIA/MAS, whereas this group showed slightly less IL-18BP and CXCL9 elevation (Figure 2). Longitudinal analysis showed that IL-18 correlated with active or "smoldering" MAS activity (Figure 3).

Conclusion: Prospective screening based on hyperferritinemia is a feasible way to identify patients and collect early samples. Extremely elevated serum IL-18 was consistently observed in patients with SJIA, and improved pathophysiologic understanding in patients with unclear diagnoses (e.g. Figure 3). This protocol would be amenable to lower triggering thresholds and expanded biomarker screening to further optimize identification, diagnosis, and treatment of MAS/HLH and related diseases.

IL-18: A Biomarker That Reflects Disease Activity, Could It Be the Next Disease Activity Measure in Systemic Juvenile Idiopathic Arthritis?

Shima Yasin[1], Thuy Do[2], Sanjeev Dhakal[2], Elizabeth Baker[2], Alexei Grom[3] and Grant Schulert[4], [1]Cincinnati Children's Hospital Medical Center, Liberty twp, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

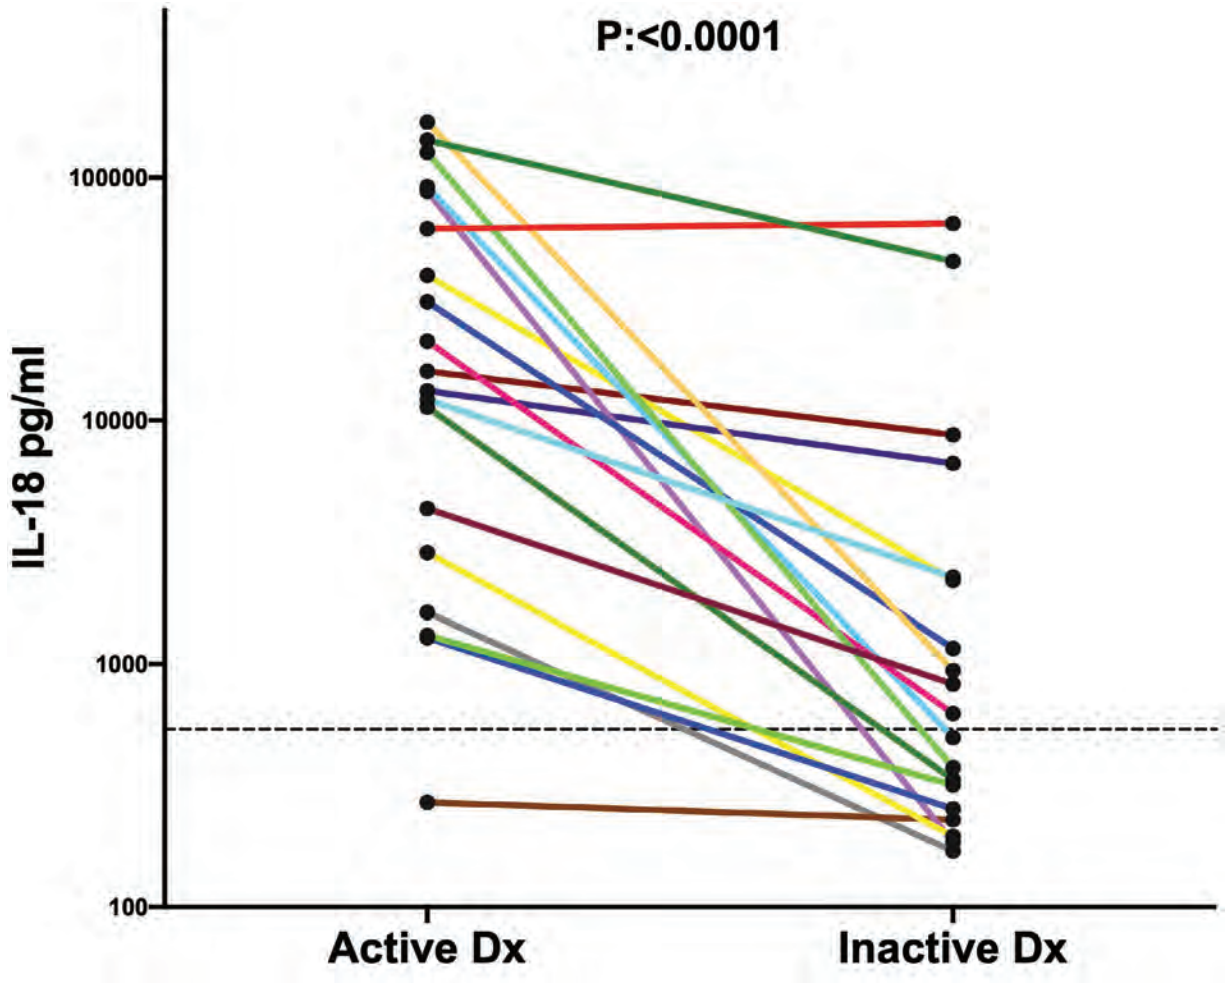

Figure 1: Total IL-18 levels for each individual patient at active disease and inactive disease status and different time points. Each line represents an individual patient. Horizontal dotted line represents upper limit of normal of total IL-18 (540 pg/ml).

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a childhood arthritis with prominent innate immune activity. Disease presentation and flares could largely mimic infections with fever being a prominent feature. sJIA is associated with production of inflammatory cytokines including IL-18. IL-18 plays a key role in the pathogenies, with high levels in patients with active disease. To date, there are no specific reliable biomarkers for disease activity in sJIA. IL-18 may be a useful biomarker for diagnosis and more importantly monitoring disease activity and flares. Our objective is to quantify change in serum IL-18 levels in response to change in clinical disease activity in patients with sJIA.

Methods: This is a prospective longitudinal study. Serial serum levels of total IL-18 (pg/ml), CXCL9, and S100 proteins were obtained from 30 sJIA patients aged 1-19 at time of sampling. Clinical data was abstracted from medical records. Levels were compared within and between individual patients with regards to clinical and laboratory features. This study was approved by CCHMC Institutional Review Board, and informed consent was obtained.

Results: IL-18 was significantly higher in active disease (median 13279 pg/ml (IQR: 2496-61638), N=35) in comparison to clinically inactive disease (CID) (median 810 (326.5-4471), N=25). The median difference (12469 pg/ml) was statistically significant ($p < 0.0001$). IL-18 correlated with S100 A8/9 ($r=0.49$, $p=0.0008$) and CXCL9 ($r=0.55$, $p=0.0004$) regardless of clinical disease activity.

IL-18 was significantly different between patients with CID, active disease due to arthritis only, active disease due to systemic features only or active disease due to both ($p< 0.0001$). Post-hoc analysis showed that there is no difference between CID and active disease due to arthritis only ($p >0.999$). The difference was significant between those with systemic features only or systemic features combined with arthritis compared to CID ($p=0.0012$ and 0.0002, respectively). Also, IL-18 correlated strongly with systemic manifestation score of systemic JADAS ($r=0.67$, $p< 0.0001$).

19 patients had paired samples captured at both CID and active disease status, while 8 had samples at only active disease and 3 only at CID. Median time difference between samples for each patient was 10.5 months. Comparing paired samples, median difference in IL-18 was not significant (455.5 pg/ml, $p=0.855$). Interestingly however, median decline in IL-18 between paired samples of patients changing status from active to inactive approached 90% (median decrease 9963 pg/ml, $p< 0.0001$). The difference was minimal (343 pg/ml) and not significant with no status change ($p=0.7002$). For paired samples with changing disease status, IL-18 performed well with AUC of 84% ($p=0.0002$).

Conclusion: Capturing within individual changes, IL-18 drops significantly with disease control and decreased clinical disease activity, but change is minimal for those with unchanged activity. IL-18 is significantly higher in patients with systemically active disease. This report raises optimism about the use of IL-18 as a biomarker of disease activity change and to guide initiation, continuation, escalation and cessation of therapy.

Trends in Timing of Biologic Use for Treatment of Systemic Juvenile Idiopathic Arthritis in the CARRA Registry

Ginger Janow[1], Timothy Beukelman[2], Yukiko Kimura[3], Rayfel Schneider[4], Shalini Mohan[5], Gail Rodich[6] and Mary Beth Son[7], [1]Joseph M. Sanzari Children's Hospital at Hackensack Meridian Health, Hackensack, NJ, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Hackensack Meridian School of Medicine, Hackensack, NJ, [4]University of Toronto, The Hospital for Sick Children, Toronto, Canada, [5]Genentech, Inc., South San Francisco, CA, [6]Genentech, Mill Valley, CA, [7]Boston Children's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment of systemic juvenile idiopathic arthritis (SJIA) has changed dramatically over the past decade, associated with overall improvement in functional outcomes. There may be an early "window of opportunity" where biologic therapies provide maximal benefit while decreasing morbidity associated with glucocorticoids (GC). The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry has enrolled more than 10,000 patients with pediatric rheumatic diseases. Our aim was to (1) assess temporal trends in the timing of non-biologic and biologic medication use in the first year after diagnosis of SJIA with an emphasis on early initiation of biologics, and (2) determine if demographic factors impact timing of biologic introduction.

Methods: Patients with SJIA enrolled in the CARRA registry between 2015 and 2018 were included. Medication information was collected retrospectively for all patients at enrollment in the Registry and prospectively after enrollment. Patients with missing month of diagnosis or medication start date were excluded. Medications were grouped by mechanism of action, and temporal trends in medication class usage were assessed using frequencies. Timing of initiation of IL-1 inhibition (IL-1i) and IL-6 inhibition (IL-6i) were assessed by year of diagnosis. Patients were grouped into one of three categories: (1) initiated IL-1i or IL-6i in first 91 days, (2) initiated on day 92-364, and (3) no use in first year. Sub-analysis was performed looking at the timing of IL-1/6i initiation (0-3, 3-6, 6-12 months after diagnosis) was analyzed to determine if demographic factors contribute to timing of medication start.

Results: 561 patients were included in the analysis. There was an upward trend in IL-1/6i usage during the first year of treatment over time (Figure 1), with a concurrent decline in tumor necrosis factor inhibitor (TNFi) use. Nearly half of patients (46%) were treated with IL1/6i in the first 3 months and 59.4% were treated with IL-1/6i in the first year. Initiation of IL-1i and IL-6i in the first 91 days following diagnosis appears to have increased over time (Figure 2). No significant differences were found in timing of introduction of IL-1/6i based on age, sex, race, or median time from symptom onset to diagnosis. Timing of IL-1/6i introduction did not affect frequency of DMARD use in the first 12 months (Table 1).

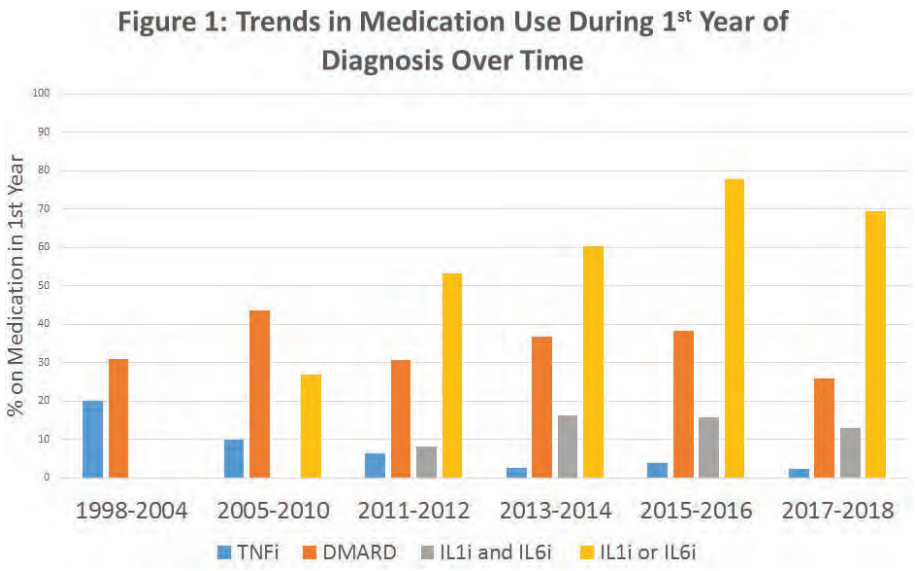

Fig 2: Timing of IL1i or IL6i initiation from 1998-2018

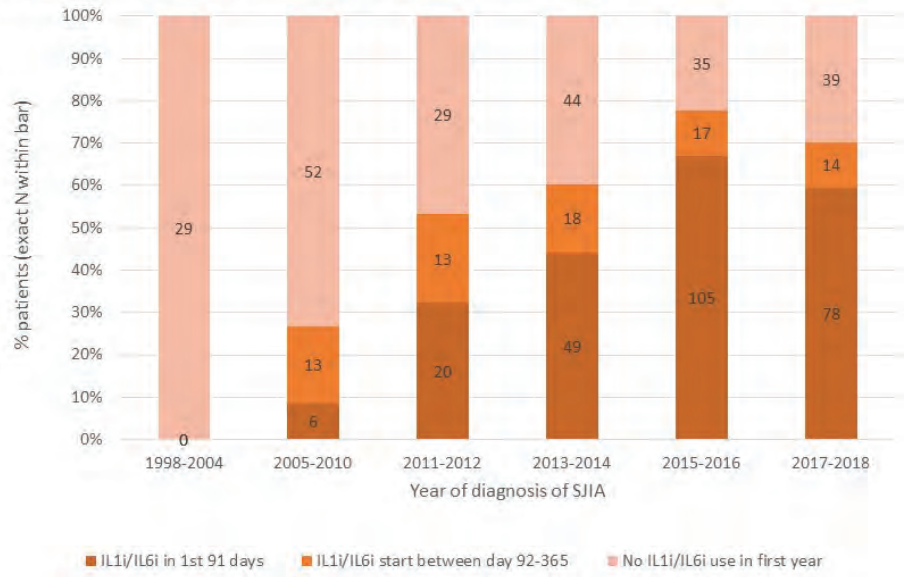

Table 1: Demographics by timing of IL-1 Inhibition or IL-6 Inhibition

	Entire Cohort	First IL-1 or IL-6 inhibition within 91 days after diagnosis	First IL-1 or IL-6 inhibition between 92-183 days after diagnosis	First IL-1 or IL-6 inhibition between 184-365 days after diagnosis	No IL-1 or IL-6 inhibition in first 365 days after diagnosis	p-value
N	561	258	36	39	228	
Sex (% female)	245 (43.7)	115 (44.6)	16 (44.4)	18 (46.2)	96 (42.1)	0.94
Age at diagnosis (median [IQR])	5.9 (4.26)	6.38 (4.5)	5.28 (4.6)	4.8 (4.1)	5.6 (3.9)	0.05
Race						
-White	379 (70.8)	187 (72.5)	26 (72.2)	27 (69.2)	157 (68.9)	0.84
-Black	79 (14.1)	34 (13.2)	4 (11.1)	5 (12.8)	36 (15.8)	0.79
-Hispanic	60 (10.7)	31 (12.0)	2 (5.6)	3 (7.7)	24 (10.5)	0.61
Average (SD) time from symptom onset to diagnosis (mean [SD])	117.5 (293.9)	83.1 (134.1)	130.5 (264.6)	127.5 (185.7)	152.6 (416)	0.08
Median (IQR) time from symptom onset to diagnosis	45 (22, 95.5)	37 (21, 83)	62.5 (26.8, 116.8)	48 (28.5, 132.5)	49.5 (21, 105.3)	0.09
Use of non-biologic DMARD in first 12 months	194 (34.6)	87 (33.7)	16 (44.4)	16 (41.0)	75 (32.9)	0.5

Conclusion: In SJIA patients in the CARRA Registry enrolled over a 3-year period, there has been an increase in IL-1/6i usage. Of those prescribed IL-1/6i, the majority began treatment in the first three months of disease. This does not appear to vary by age of diagnosis, time from symptom onset to diagnosis, race/ethnicity, or methotrexate use. Our data suggests that there may be an increase in "early" use of IL-1i and IL-6i, possibly due to increasing provider comfort, experience, and availability, as well as the perceived potential for a "window of opportunity" in treatment and desire to decrease GC use in these patients. Whether these changes result in improved disease outcomes requires further study.

Distinct Gene Signature Predicts Strong Clinical Responses to Canakinumab in Children with Systemic Juvenile Idiopathic Arthritis

Emely Verweyen[1], Alex Pickering[2], Alexei Grom[3] and Grant Schulert[4], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Harvard Medical School, Boston, MA, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Canakinumab is a human anti-IL1β blocking agent that effectively neutralizes IL1β mediated signaling and is used to treat diseases such as systemic juvenile idiopathic arthritis (sJIA). To date there is no predictive analysis that can identify patients that respond to canakinumab or those that do not respond, requiring alternative treatments. Here, we investigate and characterize a potentially predictive gene signature for treatment response to canakinumab in sJIA patients.

Methods: Whole blood gene expression of healthy controls and patients with sJIA during baseline (day 0, before treatment) and day 3 after treatment onset was previously measured by Affymetrix DNA microarrays [GEO:GSE80060]. Strong responders were based on the JIA American College of Rheumatology (aACR) response criteria and defined as >90, while non-responders were defined as < 30. A random effects model with patient identity as the random variable was used for differential expression analysis.

Results: We identified a distinct gene expression signature in patients with strong clinical response to canakinumab treatment vs non-responders. This signature was characterized by a severely dysregulated gene profile at baseline, and the degree of clinical response (ACR 90/100 vs 50/70 vs 30/0) correlated with upregulation of this signature. The gene profile of responders was mediated by significant (adj. P-val ≤0.05) upregulation of neutrophil and IL1β related genes, as well as Toll-like-receptor and inflammasome associated genes. In line with this, GO pathway analysis top upregulated pathway was ficolin-1-rich granule membrane (P-val 5.74E-13), representing neutrophil activation. Interestingly, while there was no direct upregulation of IL-6 or of IFNγ, SOCS3 was upregulated. Upon treatment initiation, early changes by day 3 in the gene expression profile of the responders were highlighted by significantly decreased expression of these above noted genes and pathways. Interestingly, CD163, a marker for polarization of haemophagocytic macrophages that is upregulated in sJIA-MAS (Macrophage activation syndrome) and sJIA-LD

(lung disease), was among the genes upregulated in non-responders, and was not affected by treatment, suggesting IL-1-independent gene pathways in these patients.

Conclusion: Here, we identify several genes and gene pathways whose expression levels distinguish high clinical responders to IL-1 blockade from non-responders before treatment onset. Further study is needed to assess this potentially valuable tool aiding treatment decisions in sJIA.

Table 3. Overall MAS events and by history of MAS.

Methods: Data from patients with sJIA according to the ILAR classification criteria, treated with anakinra and enrolled in the Pharmachild registry before 30 September 2018 were analyzed (EUPAS28378). The study endpoints were: the occurrence of non-serious adverse events of at least moderate severity (AEs), serious AEs (SAEs), and events of special interest (ESI) including macrophage activation syndrome (MAS) according to MedDRA version 21.1; the duration of anakinra treatment and the reasons for discontinuation. All endpoints were analyzed overall and stratified by 6 months time windows.

Results: 306 patients were enrolled with both genders equally represented (Table 1). Almost half of the patients (n=146; 46%) were continuously treated with anakinra for at least 12 months, 34.0% for at least 18 months and 28.1% for at least 24 months. A total of 201 AEs was reported during a total of 509.3 patient years (py) of treatment with an overall incidence rate (IR) of 39.5 (95% CI 30.8-50.6) per 100 py , mostly represented by infections (52 events, 25.9%; IR 10.2/100 py). 56 SAEs were reported (IR 11.0/100 py; 95% CI 7.9-15.2), whereof 13 infections (23.2%; IR 2.6/100 py), and 11 MAS episodes (19.6%; IR 2.2/100 py).The proportion of patients experiencing AEs was highest during the first 6 months of treatment and did gradually decrease over time (Table 2). Ten patients (3.3%) had a history of MAS before anakinra start, 9 of these patients did not experience any new MAS episode after anakinra start. 8 patients developed MAS several months after anakinra discontinuation (Table 3). Discontinuation of treatment occurred at least once in 233 patients (76%), more often during the first 6 months, then decreasing over time, and was overall secondary to inefficacy (43%), remission (31%) or AEs and intolerance (15.0%). No deaths occurred during anakinra treatment while 3 deaths occurred after anakinra discontinuation (5 months, 3 years, and 5 years after discontinuation, respectively). No malignancies were reported neither during treatment with anakinra nor after discontinuation .

Conclusion: The results of the present study confirm the long-term safety profile of anakinra in sJIA patients without any new safety findings. Long-term treatment with anakinra in sJIA patients was well tolerated, with a decreasing overall incidence rate of AEs over time.

Comparison of Immunological Biomarkers and Lung Histology in Patients with Elevated IL18 - Pulmonary Alveolar Proteinosis and Recurrent Macrophage Activation Syndrome (IL-18PAP-MAS) and Other Inflammatory Lung Diseases

Alhanouf Alsaleem[1], Adriana de Jesus[2], Sofia Torreggiani[3], Chyi-Chia Lee[4], Les Folio[5], Huy Do[6], Andrew Oler[7], Caroline Kim[3], Stewart Levine[8], Anthony Suffredini[9], Cem Gabay[10], Joseph Fontana[11], Scott Canna[12] and Raphaela Goldbach-Mansky[13], [1]Division of Pediatric Rheumatology, Department of pediatrics, King Faisal specialist hospital and research center, Riyadh, Saudi Arabia, RiYADH, Saudi Arabia, [2]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Silver Spring, MD, [3]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, MD, [4]Pathology Department/NCI/NIH, Bethesda, MD, [5]Radiology and Imaging Services/NIH, Bethesda, MD, [6]Radiology and Imaging Sciences, Bethesda, MD, [7]Bioinformatics and Computational Biosciences Branch/NIAID/NIH, Bethesda, MD, [8]Laboratory of Asthma and Lung Inflammation, Division of Intramural Research, NHLBI, NIH,, Bethesda, MD, [9]Critical Care Medicine Department, Clinical Center, NIH, Bethesda, MD, [10]University Hospitals of Geneva, Geneva, Switzerland, [11]NHLBI/NIH, Bethesda, MD, [12]University of PIttsburgh, Pittsburgh, PA, [13]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Potomac, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, pulmonary alveolar proteinosis (PAP) and recurrent macrophage activation syndrome (MAS) have been reported in rare patients (pts) with systemic juvenile idiopathic arthritis (SJIA) like disease. The pathomechanisms of lung disease remain elusive. We aimed to characterize genetic and immunological biomarkers IL-18PAP-MAS pts. We sought to understand pathophysiology by comparison of blood and lung biopsy markers to other inflammatory diseases.

Methods: Eight patients with IL-18PAP-MAS were enrolled in an IRB approved protocol (NCT02974595). Serum (n=8), whole blood RNA (n=8) bronchoalveolar lavage (BAL, n=2) samples and lung biopsies (n=3) from IL-18PAP-MAS pts were compared to samples from pts with NLRC4-MAS (n=4), Interferon (IFN) mediated diseases (n=10), including pts with STING associated vasculopathy with onset in infancy (SAVI, n=7), neonatal onset multisystem inflammatory disease (NOMID, n=4), sarcoidosis (n=10) and healthy controls (HC, n=3). Cytokines were measured by Luminex assay in serum and BAL, *CXCL9* and *CXCL10* transcript levels were quantified by Nanostring. Lung biopsies were scored for inflammatory features, including cell infiltrate, lymphoid aggregates, type 2 pneumocyte hyperplasia and cholesterol crystals and damage (emphysema, consolidation, vascular damage, fibrosis, neovascularization, thrombosis). Radiographs were scored by one radiologist.

Results: Of 8 pts with IL-18PAP-MAS and nail clubbing, 2 pts (25%) met the ILAR SJIA criteria. All patients had high elevation of serum IL-18 levels similar to patients with NLRC4-MAS. *CXCL9* and *CXCL9*/*CXCL10* ratio (IFN gamma response markers) were higher in IL-18PAP-MAS compared to interferonopathy and controls (Fig.1A). BAL fluid from IL-18PAP-MAS pts had higher expression of IL-18 and free IL-18, which were solely detected in IL18 PAP-MAS in contrast to SAVI and sarcoidosis (Fig.1B). Histologic features showed innate immune cells including high expression of neutrophils, histiocytes and alveolar macrophages with fewer lymphocytes and B cell infiltrates compared to SAVI, and low numbers of parenchymal and peribronchial lymphoid aggregates (Fig.2A). Cholesterol clefts and mucous plugging were cardinal features in IL18 PAP-MAS (Fig.2B). Distinctive radiological features suggestive of active in-

Figure 1

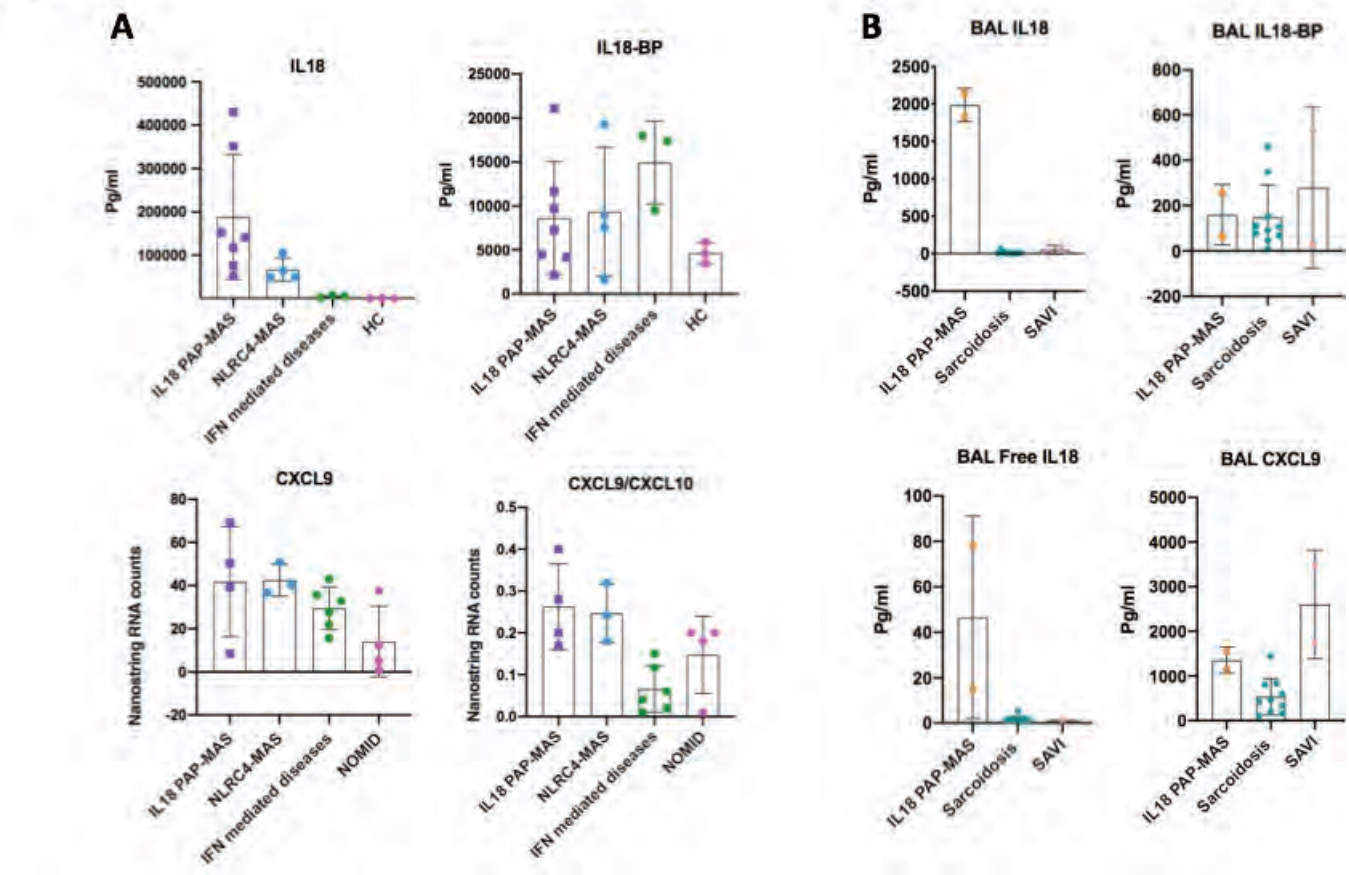

Figure 1. Assessment of total IL18, IL18-BP, CXCL9 and CXCL9/CXCL10 ratio (Higher ratio likely indicate IFN gamma response). A. Serum (upper panel) and whole blood RNA (lower panel) and B. BAL (bronchoalveolar lavage).

flammation included consolidation most prominent in the lower lobes, intralobular septal thickening, and pulmonary nodules, with higher inflammatory vs damage scores in contrast to SAVI (Fig. 3A, B).

Conclusion: IL-18PAP-MAS/SJIA like lung disease is a recently characterized, not yet genetically defined clinical syndrome. Histological pulmonary features of IL18 PAP-MAS differ from lung manifestations of SAVI and sarcoidosis, which includes recruitment of innate immune cells, predominantly neutrophils and alveolar macrophages. BAL fluid shows high expression of total and free IL-18 compartmentalized in the BAL of IL-18 PAP-MAS but not in SAVI and sarcoidosis pts suggesting a role of free IL-18 in the distinct pathogenesis of PAP in IL-18PAP-MAS.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with NOMID have systemic inflammation and organ damage such as sensorineural hearing loss, hydrocephalus, optic nerve atrophy and growth plate defects. IL-1 blocking agents are approved for the treatment of NOMID[1,2]. This study is reporting the long-term health and socioeconomic outcomes in NOMID patients on treatment.

Methods: We followed 41 NOMID patients (Female n=24, White n=27), median age 21 years (range 9-57) who were treated with IL-1 blockade (anakinra n=35, canakinumab n=6) for the median of 15 years (range 7-18). All were enrolled in an IRB-approved natural history protocol. Disease remission, organ damage, incidence of medical and psychological diagnoses and socioeconomic status were evaluated.

Results: Sustained remission and normalization of inflammatory markers was achieved in 38 pts (93%) with continued dose adjustment for weight and temporary dose increase during stress. 1 patient is non-compliant, 1 has recurrent uveitis and 1 has aseptic meningitis. 23 pts required at least 5 mg/kg of anakinra (or equivalent canakinumab) to achieve remission (56%). In 11 pts anakinra was switched to canakinumab, 6 switched back to anakinra because of worsened headache (55%)[2]. Bone age and mineral density normalized in all children on treatment. 20 pts (49%) have moderate to severe hearing loss, from those 16 use hearing aids, 2 have cochlear implants. 7 pts (17%) are legally blind and 5 (12%) are wheelchair bound . All but 2 pts attended school, 14 out of the remaining 39 (36%) required individualized education plans; speech therapy is the most common service received. 10 pts (24%) have neurocognitive delay, 8 (20%) have anxiety or mood disorders and 1 has schizophrenia. 16 out of 22 adults (72%) hold a high school diploma or college degree. 10 (45%) are either full time students or have a job. 10 pts (24%) are obese, 8 (20%) have hypertension, dyslipidemia or both. 12 pts (30%) developed skin abscess, cellulitis, or pustular acne on treatment. A 57 years old man developed a Hurtle cell thyroid dysplasia, a 44 years old woman was diagnosed with EBV negative large diffuse B-cell lymphoma of the liver and completed chemotherapy.

Conclusion: IL-1 inhibition provides sustained efficacy in the treatment of NOMID with the requirement for dose adjustment based on weight and intermittent dose escalation during stress or infections. Hearing loss is the leading cause of disability. Most can walk without assistive devices but challenges with mobility are not uncommon. Skin infections are common on treatment. Headache with or without low grade CSF leukocytosis was the most common reason for switching from canakinumab to anakinra. Anakinra allowed normalization of growth and bone health, but obesity and hypertension in adults were similar to reports in the general population. No obvious malignancy signals were detected; however, long term follow-up in a larger cohort of the entire CAPS spectrum are needed to estimate the effect on the development of hematologic and solid malignancies.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: STING-Associated Vasculopathy with Onset in Infancy (SAVI) is an autoinflammatory interferonopathy caused by gain-of-function mutations in *STING1*, characterized by peripheral vasculopathy and interstitial lung disease. Our aim is to describe the clinical and immunological manifestations of SAVI.

Methods: Clinical information on 33 patients with SAVI, based on NIH evaluation (n=15) or on records and samples provided by collaborators (n=18), were retrospectively reviewed. Patients were enrolled in an IRB-approved natural history protocol. The IFN score was calculated as previously described [1]. Features of lung inflammation and damage on Computed Tomography (CT) were scored by a single radiologist (LF). Severe lung disease was defined as presence of at least one characteristic: lung fibrosis, respiratory insufficiency, pulmonary hypertension, or digital clubbing associated with interstitial lung disease on chest CT.

Results: 13/33 (39.4%) patients were female. SAVI was sporadic in 73% and familial in 27%. Heterozygous mutations were disease-causing in 81.8%, however, a p.R281W mutation, present in 6 patients from 4 families, required homozygosity (additive gain-of-function). The p.N154S and p.V155M mutations were most common (27.3% and 24.2% respectively, see Table 1). Disease symptoms presented in the first year of life (75%), with rash (18/31), respira-

Table 2. Clinical and laboratory features in 33 patients with SAVI

Clinical features	n (%)	Laboratory features	n (%)	Outcomes and complications	n (%)
Cutaneous manifestations	29/32 (90.6%)	Elevated inflammatory markers	26/31 (83.9%)	Premature death	7/33 (21.2%)
Vasculopathy	22/31 (71.0%)	Anemia	22/28 (78.6%)	Lung fibrosis	15/27 (55.5%)
Lung disease	28/33 (84.9%) (severe disease in 22/33 (66.7%)	Thrombocytosis	16/24 (66.7%)	Respiratory insufficiency	11/31 (35.5%)
Failure to thrive	25/33 (75.8%)	Lymphopenia	12/25 (48%)	Pulmonary hypertension	4/30 (13.3%)
Fever	22/29 (75.9%)	Elevated IgG	20/28 (71.4%)	Nasal septum perforation	7/31 (22.6%)
Clubbing	12/24 (50%)	Elevated IgA	16/26 (61.5%)	Amputations	7/32 (21.9%)
Arthralgia/arthritis	12/31 (38.7%)	Autoantibodies	28/31 (90.3%)	Osteoporotic fractures	4/16 (25%)
Myositis	5/32 (15.6%)				
Basal ganglia calcifications	2/12 (16.7%)	Elevated IFN Score	17/17 (100%)*	Short stature	16/27 (59.3%)

* In 4 patients the IFN score was positive only inPBMCs

tory symptoms (13/31) and fever (11/31). Table 2 lists clinical and laboratory features in SAVI. The p.N154S mutation is associated with vasculopathy (p=0.03); patients with the p.V155M mutation tend to have more severe lung disease (p=0.2). Median age at last evaluation was 12 years (range 0.4-54.1). 7 patients died at a mean age of 7 years (range 0.4-15); due to respiratory failure n=4, multiorgan failure n=1, sepsis n=1, unknown n=1. In 4/17 the IFN score was negative in whole blood, but positive in PBMCs. Patients failed a mean of 2.1 DMARDs or biologics, 76.6% received steroids. 25 patients were treated with a JAK-inhibitor (baricitinib n=14, tofacitinib n=7, ruxolitinib n=7), for an average of 2.1 years (range 0-5.7). Skin ulcers improved in 10/10, but recurred. Over an average of 2.6 years (range 1.1-3.9), on chest CT, features of inflammation improved in 6/7, with sTable/improved damage in 6/7.

Conclusion: SAVI is a severe early-onset interferonopathy, that can lead to amputations, respiratory insufficiency and premature death. SAVI is sporadic in 73%. Most pathogenic *STING1* mutations are heterozygous, except for

p.R281W, which is disease-causing in homozygosity. With the absence of peripheral disease in 9.4%, SAVI should be suspected in any patient with interstitial lung disease even in the absence of vasculopathy. The p.N154S mutation is associated with vasculopathy, and the p.V155M with more severe lung disease. Rarely, the IFN score can be negative in whole blood and positive in PBMCs. Treatment with JAK inhibitors halted progression of lung damage over an average of 2.3 years, but only partially controlled peripheral vasculopathy and did not normalize the IFN score.

Novel *STING1* Mutations Including in the Transmembrane Linker Region Cause STING-associated Vasculopathy with Onset in Infancy (SAVI)

Bin Lin[1], **Dana Kahle**[1], Adriana Almeida de Jesus[1], Sofia Torreggiani[2], Jacob Mitchell[2], Alexander Aue[1], Zheng Ji[3], Tengchuan Jin[3] and Raphaela Goldbach-Mansky[4], [1]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, [2]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, MD, [3]University of Science and Technology of China, Hefei, China (People's Republic), [4]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Potomac, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: STING-associated vasculopathy with onset in infancy (SAVI) is an autoinflammatory disease caused by gain-of-function (GOF) mutations in *STING1*/*TMEM173* that encodes stimulator of interferon genes, STING, a key mediator in the cytosolic DNA sensing pathway that drives the synthesis of type-I interferons. We report 3 novel SAVI-causing mutations that all lead to STING auto-activation in heterozygosity; 2 mutations occurred de novo and are located in the connector loop domain of STING, and one SAVI-causing mutation was present in 3 affected family members (autosomal-dominant transmission by mother) and is located in the transmembrane linker region.

Methods: All patients were clinically evaluated and studied under an institutional review board (IRB) approved protocol (NCT02974595). To investigate the autoactivating potential of these novel mutations, mutant STING constructs with the respective mutations were transfected into HEK293T cells. *IFNB1* reporter activation was measured, and interferon-response gene signatures were measured from whole blood and peripheral blood mononuclear cells (PBMC) RNA samples from patients and their family members.

Results: We identified 3 novel SAVI-causing mutations, p.G158A, or p.F153V occurred de novo and p.H72N was present in 3 symptomatic family members. All patients developed disease in childhood (age at onset 2 months-4 years) and experienced peripheral vasculopathy with chilblains in 4 and erythematous-purple discoloration of the extremities and nasal septal perforation in one; mild lung disease was present only in two patients (p.H72N and p.G158A). None of the patients received chronic steroid treatment or DMARDs, 3 were treated with baricitinib. In an *IFNB1* luciferase reporter assay all 3 mutant STING constructs were auto-activating in the absence of cGAMP ligand consistent with previously reported SAVI-causing GOF mutations. Additional mutations of H72 into K, R, D, L, Q, or F, all lead to loss-of-function or partial loss-of-function, indicating the importance of H72 in maintaining the STING structure. Structural modeling reveals that H72 lies in the "arm" restraining the ligand-binding domain, and the H72N mutation partly relieves this restrain and allows the ligand-biding domain to rotate, thus leading to auto-activation. The other 6 mutations on the H72 residue may strongly destabilize this supporting arm and lead to an ill-structured STING dimer, which results in loss-of-function. In contrast to previously reported SAVI patients, patients with the H72N and G158A mutations had a normal interferon scores in the whole blood RNA samples but were positive in PBMC samples.

Conclusion: We identified 3 novel SAVI-causing variants, that all confer a GOF in an *IFNB1* luciferase reporter assay. Two mutations, p.F153V and p.G158A, in the connector loop were predicted to be activating by a recent STING Cryo-EM structural model. The H72N is the first mutation in the transmembrane linker region, thus revealing a novel important region that controls STING activation. The absence of an elevated interferon signature in whole blood but presence in PBMCs needs further investigation, but points to the need to evaluate PBMCs in some patients.

Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare bone lesion evolution and bone lesion distribution patterns identified by whole body magnetic resonance imaging (WB-MRI) by treatment intensity in patients with chronic recurrent multifocal osteomyelitis (CRMO).

Methods: We performed an IRB-approved observational study of previously collected data from a large longitudinal CRMO cohort at the University of Iowa. We extracted detailed demographic, clinical, treatment and imaging data in patients with biopsy-proven CRMO who have undergone ≥2 serial WB-MRIs between 2014-2019. WB-MRIs were reviewed by two pediatric radiologists with expertise in imaging of CRMO. Bone lesions were characterized for anatomic location and lesion evolution on serial scans; specifically, we identified the total number of unique lesions on

NSAID: non-steroidal anti-inflammatory drug, DMARD: disease-modifying antirheumatic drug, SD: standard deviation, GC: glucocorticoid.

initial and follow-up scans, as well as fully resolved lesions at the final scan. We stratified our CRMO cohort into four treatment groups based on a hierarchical therapy approach reflective of clinical practice at our institution. We defined the active treatment groups at the time of the initial WB-MRI scan. The four groups were: non-steroidal anti-inflammatory (NSAID) group (defined as active NSAID use only); synthetic disease-modifying antirheumatic drug (DMARD) group (defined as active sDMARD ± NSAID); biological DMARD group (defined as active bDMARD ± sDMARD ± NSAID); and bisphosphonate group (defined as active bisphosphonate use ± bDMARD ± sDMARD ± NSAID). Descriptive statistics were used to compare the 4 treatment intensity groups.

Results: The findings of our study are summarized in Tables 1 and 2. In our CRMO cohort (n=51), the majority of patients belonged to the bisphosphonate group (n=28), followed by NSAID (n=10), bDMARD (n=8) and sDMARD (n=5) groups respectively (Table 1). Mean age, sex distribution and mean follow-up time were overall similar across groups, except for younger age and higher proportion of females in the sDMARD group. Prior systemic glucocorticoid use was similar, except less frequent in the NSAID group. Patients in the bisphosphonate group had the highest total and mean (per patient) number of bone lesions identified on WB-MRI (Table 1). Additionally, the mean number of bone lesions per patient was ~4x higher on initial and ~8x higher on follow-up imaging in the bisphosphonate group compared to the three non-bisphosphonate groups. The bone lesion distribution pattern in the bisphosphonate group most frequently involved the lower extremity (LE), spine and pelvis; this group had the highest spine burden compared

Table 2. Comparison of Bone Lesion Distribution by Treatment Intensity in Chronic Recurrent Multifocal Osteomyelitis

	Bisphosphonate group	NSAID group	Biologic DMARD group	Synthetic DMARD group
Unique Bone Lesions (total), n	505	51	55	30
Spine, n (%)	177 (35)	3 (5.9)	1 (1.8)	3 (10)
Mandible, n (%)	1 (0.2)	0 (0)	0 (0)	0 (0)
Medial clavicle, n (%)	9 (1.8)	3 (5.9)	0 (0)	0 (0)
UE, n (%)	19 (3.8)	2 (3.9)	20 (36.4)	0 (0)
LE, n (%)	259 (51.3)	41 (80.4)	28 (50.9)	25 (83.3)
Anterior chest, n (%)	8 (1.6)	0 (0)	0 (0)	0 (0)
Pelvis, n (%)	27 (5.3)	2 (3.9)	6 (10.9)	2 (6.7)
Ribs, n (%)	5 (1)	0 (0)	0 (0)	0 (0)

NSAID: non-steroidal anti-inflammatory drug, DMARD: disease-modifying antirheumatic drug, UE: upper extremity, LE: lower extremity.

to other groups (Table 2). Peripheral (upper extremity and LE), medial clavicular and pelvic bone lesions, without spine involvement, were a common pattern observed in the NSAID, bDMARD and sDMARD groups. The proportion of resolved bone lesions on follow-up imaging was highest in the bisphosphonate group, followed by bDMARD group.

Conclusion: Treatment-stratified bone lesion evolution and distribution patterns reflect the severity of CRMO and current management strategies. Further study to elucidate differential treatment effects on individual bone lesions is needed to individualize therapeutic approaches in patients with severe CRMO.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Radiological imaging is integral to the diagnosis of chronic nonbacterial osteomyelitis (CNO) and has been included as a central component in suggested diagnostic criteria [1,2]. Objectives of this study were: 1) to determine imaging modalities and features deemed important by radiologists in the diagnostic workup of suspected CNO cases; 2) to generate input from radiologists regarding monitoring of patients with CNO.

Methods: Population targeted were active attending radiologist physician members of the Society of Skeletal Radiology email list serve. The survey was administered online through RedCap. Descriptive statistics were conducted with continuous variables reported as medians/means and categorical variables as frequencies/percentages.

Results: A total of 66 respondents (5%) consented and completed the survey. The majority were pediatric radiologists, subspecializing in musculoskeletal radiology, with >10 years of experience (Table 1). Radiologists consider CNO in the radiological imaging interpretation differential diagnosis an average of 10 cases per year. 79% and 45% of respondents reported high confidence in identifying imaging features of CNO on whole body MRI (WBMRI) and localized MRI, respectively. The level of confidence drops to 24% and 19% when interpreting X-rays (XRs) and

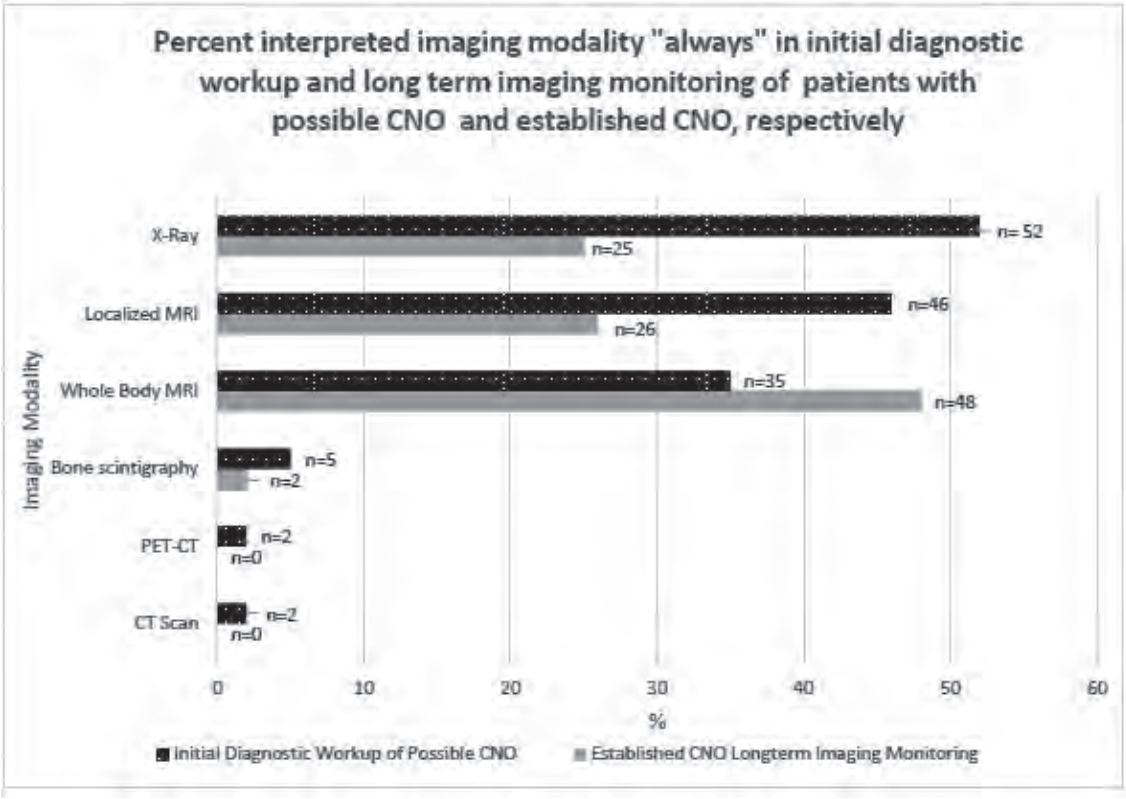
Percent reporting high confidence in identifying CNO imaging features, by imaging modality

bone scintigraphy, respectively (Figure 1). Among all imaging modalities interpreted "always" in the initial diagnostic workup of potential cases of CNO, XRs (52%) were most commonly interpreted, followed by localized MRI (46%) and WBMRI (35%), which suggested the sequence of utilization of these three imaging modalities in new cases. In estab-



Percent interpreted imaging modality "always" initial diagnostic workup and longterm imaging monitoring of patients with possible CNO and established CNO, respectively

lished cases of CNO, wherein WBMRI was the most frequently interpreted (48%), followed by localized MRI (26%) and XRs (25%) (Figure 2). Most common imaging features that led respondents to suggest a bone biopsy included disorganized bone formation (64%/56%), moth-eaten appearance (61%/56%), and lytic lesions (50%/44%) on XRs/CTs, respectively as well as the presence of soft tissue mass/swelling(68%/44%) and MRI signal hyperintensity of bone marrow at unifocal site (24%). A majority of respondents preferred a combination of short tau inverse recovery (STIR), T1 and diffusion weighted imaging (DWI) sequences in the MRI images of potential CNO cases. 46% of respondents reported using an established WBMRI protocol at their institutions.

Conclusion: WBMRI is considered the most useful imaging modality for initial diagnosis and monitoring of CNO by radiologists. Certain morphological features including disorganized bone structure, moth-eaten appearance, lytic lesions, soft tissue mass/swelling and unifocal signal hyperintensity of bone marrow may result in increased chance of bone biopsy to exclude differential diagnoses. Findings from this survey will promote discussion within a focused group to develop imaging guidelines for the diagnostic workup and disease monitoring in CNO and contribute to earlier diagnosis and individualized care.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO)/chronic recurrent multifocal osteomyelitis (CRMO) predominantly affects children and young adults. Classification criteria are not available and diagnostic criteria that have been suggested have not been validated. We previously identified candidate items for the development of classification criteria.

Methods: We aimed to refine candidate items for pediatric classification criteria for CNO by comparing clinical, laboratory and imaging features of CNO against mimicking conditions. International multicentre collection of clinical and investigational features of cases with CNO or mimicker diseases with at least 12 months follow-up was conducted through a REDCap online database. Prevalence ratios of each collected item between CNO and mimickers were calculated. A p value of <.05 was considered significant.

Results: 450 cases were collected from 20 centers in 7 countries and 4 continents. Cases were filtered based on indicated confidence levels of diagnosis for CNO or mimickers using a cut-off of +/- 2 (moderately confident). 264 (59%) CNO cases and 145 (32%) mimicker controls were used for analysis. 41 (9%) cases were excluded. Key findings are summarized in Table 1.

When compared to mimicker diagnoses, CNO patients were predominantly female, more frequently exhibited intermittent versus continued pain (especially of neck, back and upper torso), but less commonly had fever. Clavicular swelling was more common in CNO, while active arthritis was less common as compared to controls. CNO patients more frequently had whole body imaging (usually whole-body MRI). Symmetric patterns of bone lesions were more common in CNO. CNO frequently involved the thoracic spine, clavicle, sternum/manubrium, pelvic bones, bilateral femur, bilateral tibia, unilateral fibula, and foot bones. Imaging features that are concerning for infection or malignancy (including cortical bone disruption, disorganized bone formation, mass structure, marrow infiltrate, abscess or geographic appearance) were less common in CNO. Lastly, complete and sustained response to antibiotic treatment was less frequent in CNO patients.

Conclusion: Using a case-based approach, key features of CNO were identified to support the development of classification criteria. Next steps will include expert panel discussions and a 1000Minds exercise.

Predictors of Colchicine Response in Patients with Undefined Systemic Autoinflammatory Diseases

Mariana Correia Marques[1], Edwin Anderson[1], Kathryn Williams[2], Jonathan Hausmann[3] and Fatma Dedeoglu[4], [1]Boston Children`s Hospital, Department of Pediatrics, Harvard Medical School, Boston, MA, [2]Biostatistics and Research Design Center ICCTR Boston Children`s Hospital, Boston, MA, [3]Boston Children's Hospital, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, [4]Boston Children's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic autoinflammatory diseases (SAIDs) result from dysregulation of the innate immune system. Many patients with SAIDs have specific mutations that lead to the release of inflammatory cytokines that can be targeted with anti-inflammatory drugs or cytokine blockers. However, up to half of the patients with SAIDs do not have symptoms or mutations indicative of a specific SAID and are diagnosed with undefined (uSAIDs). Little is known about therapeutic options for these patients. The goal of this single-center study was to evaluate predictors of colchicine response among patients with uSAIDs in an American cohort.

Methods: We conducted a retrospective chart review of patients with clinical diagnoses of uSAIDs who tolerated colchicine for at least 3 months, followed at a large pediatric rheumatology clinic. "Complete colchicine response" was defined as having a complete resolution of the episodes and not requiring additional therapy for the treatment of flares (e.g. NSAIDs, acetaminophen, prednisone, tonsillectomy). "Partial colchicine response" was defined as a decrease in the frequency, severity, or length of episodes, without complete resolution of symptoms or the requirement of additional therapy to achieve full response. "No colchicine response" was defined as no change in the clinical and laboratory features in response to colchicine. For statistical analyses, "partial" and "no colchicine response" were combined into a single category.

Table 1. Patient characteristics

	Partial and non-colchicine responders n= 42	Complete colchicine responders n= 33	P-value
Age of onset in months - median (IQR)	18 (9-72)	35 (13-63)	0.469
Duration of fever (days)	4.5 (3-6)	4 (3.5-7)	0.845
interval between flares (days)	30 (21-49)	30 (22-37.5)	0.708
Female Sex	30 (71%)	16 (48%)	**0.043***
Family history of recurrent fevers	11 (26%)	9 (27%)	1.0
Genetic test sent	36 (86%)	23 (70%)	0.154
Heterozygous MEFV mutation (n=59)	7/36 (19%)	6/23 (26%)	0.748
Regular interval between episodes n= 57	10 (29%)	11 (48%)	0.175
Region of ancestry			
America	15 (36%)	10 (30%)	0.806
Europe	32 (76%)	22 (67%)	0.440
Eastern Mediterranean	0 (0%)	7 (21%)	**0.002***
South-East Asia	0 (0%)	0 (0%)	N/A
Western Pacific	3 (7%)	3 (9%)	1.0
Africa	1 (2%)	1 (3%)	1.0

Table 2. Clinical features

	Partial and non-colchicine responders n= 42	Complete colchicine responders n= 33	P value
Oral ulcers	19 (45%)	7 (21%)	**0.049***
Genital ulcers	3 (7%)	0 (0%)	0.251
Oral herpetic-like lesions	1 (2%)	5 (15%)	0.081
Maculo-papular rash	6 (14%)	7 (21%)	0.543
Urticarial rash	4 (10%)	4 (12%)	0.725
Thoracic pain	0 (0%)	3 (9%)	0.080
Vomiting	7 (17%)	13 (39%)	**0.036***
Abdominal pain	17 (40%)	16 (48%)	0.640
Myalgia	13 (31%)	10 (30%)	1.0
Arthralgia	16 (38%)	10 (30%)	0.626
Lymphadenopathy	10 (24%)	10 (30%)	0.603

Results: Of the 75 patients identified, 33 (44%) were complete colchicine responders, 35 (47%) were partial responders, and seven patients (9%) did not respond. Patient characteristics are shown in Table 1 and clinical features of disease flares are in Table 2. Eastern Mediterranean ancestry and the presence of vomiting were predictive of a complete colchicine response, whereas oral ulcers and female sex were associated with partial or no colchicine response.

Conclusion: Many patients with uSAIDs had a complete response to colhicine. Confirming results of our previous preliminary study (1), the presence of oral ulcers remained as a predictor of partial response and vomiting was a predictor of complete response. Unlike a similar study conducted in a European cohort (2), short episode duration, and the regular interval between episodes were not associated with good response to colchicine in this American cohort. Limitations of this study include its retrospective nature and potential physician selection bias of patients to start on cochineal. Prospective studies would help better identify patients who could benefit the most from this therapy.

All Patients	n=471	194|277	302|32|34|16|87	21.7 (16.8)	16 (0-87)	18/471 3.8%

[1]Ethnicity Ratio = White|Black|Hispanic, Latino|Asian|Unknown, Other, Mixed

[2]No single gene defect was detected in patients with IL-18PAP-MAS.

[3]Clinical diagnoses include: juvenile dermatomyositis (JDM, n=30), pustular psoriasis (n=19), chronic recurrent multifocal osteomyelitis (CRMO, n=16), adult-onset Still's disease (AOSD, n=14), others (n=5)

Table 1. Demographic Features of Patients Enrolled in an Autoinflammatory Disease Natural History Protocol

AIDs. We aim to identify the frequency of genetically defined diagnoses, demographic information and mortality rates in patients enrolled in TADS Natural History Protocol.

Methods: All patients were consented to an IRB-approved natural history protocol (NCT02974595) and underwent a standard procedure of clinical and laboratory evaluation. For genetic investigation, most patients had Sanger sequencing, whole exome (WES) or genome sequencing (WGS) performed. Patients with IFN-mediated diseases had whole blood interferon scores performed to assess disease-associated flare status. Patient information was compiled into a clinical database that includes variables such as demographic features, diagnosis, clinical manifestations, disease outcome and gene affected.

Results: Since 2003, 471 patients have been enrolled in the AID natural history protocol. Genetic diagnoses were assigned to 197/471 (41.8%). The cohort consists of 194 males (41.1%), 277 females (58.8%). Demographics and outcomes of genetic diagnoses with more than 3 confirmed patients are depicted in Table 1. These included patients with CANDLE (n=17), SAVI (n=24), DIRA (n=9), NOMID (n=60), IL-18 pulmonary alveolar proteinosis and macrophage activation syndrome (IL-18PAP-MAS, n=8), Aicardi-Goutières syndrome (AGS, n=7), NEMO-deleted exon 5 autoinflammatory syndrome (NEMO-NDAS, n=10), and SAMD9L-associated autoinflammatory disease (SAMD9L-SAAD, n=6). Among patients with undifferentiated AID and genetic diagnoses with less than 3 confirmed cases (Other genetic diagnosis)(Table 1), we have identified two patients with LYN-kinase associated AID, two with dysferlin associated AID, one patient with Majeed syndrome and another with CARD14-mediated psoriasis (CAMPS). We have also identified 5 patients with monogenic forms of MAS, including 3 patients with NLRC4-MAS and 2 with CDC42-AID. Interestingly, 7 patients had 2 genetic diagnoses, including one patient with NEMO-NDAS and LRBA-deficiency. Diseases showing the highest mortality in our cohort were SAMD9L-SAAD (33.3%), SAVI (21%), IL-18PAP-MAS (20%), and CANDLE (11.8%).

Conclusion: A comprehensive characterization of an AID cohort revealed a variety of monogenic AIDs in 42% of the patients. Future studies to assess response to treatment, end organ damage and disease progression are needed.

Funding for this study was provided in part by the Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health.

Abstract Number: 1165

Validation of Healthcare Claims Algorithms for Identification of Herpes Zoster Among Children with Autoimmune/Autoinflammatory Disease

Beth Rutstein[1], Sabrina Gmuca[2], Jeffrey S. Gerber[2] and Alexis Ogdie[3], [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes zoster (HZ) is a known serious infectious complication in children with autoimmune/autoinflammatory disease and potentially exacerbated by immunomodulatory medications. Information on HZ burden is especially pertinent as JAK-STAT inhibitors have been recently FDA approved for use in children and are known to reactive latent VZV infection. However, our knowledge of HZ prevalence among children is limited. Because of its relative rarity, validating the diagnosis of HZ in healthcare claims and electronic medical record (EMR) databases is a critical first step. This study aimed to evaluate the validity of International Classification of Diseases, 10th Revision, (ICD-10) code-based algorithms for identification of HZ.

Methods: We identified all patients with ICD-10 for HZ (B02.xx) as their primary or secondary diagnosis in the EMR of a large, integrated pediatric healthcare network including 31 primary care practices, 4 urgent care centers, 19

Table 1. Demographics and Clinical Characteristics of Subjects with HZ ICD-10 code (B02). All ICD-10 codes corresponding to HZ infection (B02.xx) were used for inclusion into cohort. Rash defined as pruritic and/or painful dermatomal rash documented by treating physician. Antiviral prescription defined as prescription for any oral and/or IV antiviral treatment, including IV acyclovir, oral acyclovir, and valacyclovir.

	Definitive HZ	*Possible HZ*	*False HZ*
Number	47	18	7
Female, N (%)	20 (43%)	8 (44%)	4 (57%)
Age Mean at diagnosis (SD)	12.2 (6.3)	11.9 (7.12)	8.9 (5.1)
Positive VZV PCR, N (%)	16 (34%)	1 (6%)	0 (0%)
Dermatomal Rash, N (%)	46 (98%)	11 (61%)	4 (57%)
Antiviral Rx, N (%)	40 (85%)	7 (39%)	5 (71%)
Inpatient treatment, N (%)	10 (21.3%)	0 (0%)	0 (0%)
Immunomodulatory Rx, N (%)	9 (12.8%)	0 (0%)	0 (0%)
Chronic disease, N (%)	14 (29.8%)	1 (5.6%)	2 (28.6%)
*Autoimmune/autoinflammatory**	6 (12.8%)	1 (5.6%)	1 (14.3%)

*Genetic/congenital****	2 (4.3%)	0 (0%)	1 (14.3%)

Abbreviations: VZV = Varicella Zoster Virus, HZ = Herpes Zoster; Rx = prescription, Heme/onc = hematologic/oncologic
*Autoimmune/autoinflammatory group included the following diagnoses: multiple sclerosis (1), autoimmune thyroiditis (1), systemic lupus erythematosus (2), inflammatory bowel disease (2), Type 1 diabetes mellitus (1), HIV (1)
**Heme/onc group included the following diagnoses: solid tumors (3), leukemia (2), aplastic anemia (1)
***Genetic/congenital group included the following diagnoses: Xp22 deletion/MIDAS syndrome (1), spina bifida (1), congenital cranial vascular abnormalities (1)

Table 2. Alternative Algorithms for Defining HZ Infection

	Total	Definitive	Possible	Definitive only* PPV % (95% CI)	Combined** PPV % (95% CI)
One ICD-10 Code	72	47	18	65.3 (53.4-75.5)	90.3 (80.8 – 95.4)
ICD-10 + Rash	61	46	11	75.4 (62.9-84.8)	93.4 (83.5 – 97.6)
ICD-10 + Antiviral Rx	52	40	7	76.9 (63.3-86.6)	90.4 (78.5 – 96.0)
ICD-10 + Rash + Antiviral Rx	46	39	4	84.8 (70.9-92.7)	93.5 (81.2 – 97.9)

Abbreviations: HZ = Herpes Zoster; Rx = prescription
*PPVs calculated using only those with definitive/confirmed HZ diagnosis
**PPVs calculated using those with both definitive/confirmed and possible HZ diagnosis

subspecialty divisions, and a 600-bed tertiary care hospital from January 2010 – March 2019. Both ambulatory and inpatient databases were queried. Electronic charts were reviewed to adjudicate diagnostic code-based algorithms for true HZ infection. Positive predictive values (PPVs) for confirmed HZ as well as those with confirmed or possible HZ were calculated for each algorithm.

Results: A total of 72 unique individuals were identified as having at least one physician-entered ICD-10 corresponding to HZ (B02). The PPV for a single ICD-10 code was 90.3% (95% CI 80.8-95.4) for definitive and/or possible cases of HZ and 65.3% (95% CI 53.4-75.5%) for definitive cases alone. Adding a prescription for an antiviral did not improve the PPV (90.4%; 78.5-96.0), while adding documentation of pruritic and/or painful dermatomal rash increased the PPV to 93.4 (95% CI 83.5-97.6). The combination of diagnostic code, antiviral prescription and documentation of rash had the highest PPV of 93.5% (95% CI 81.2-97.3) but with substantial loss in sample size. Seventeen of the 72 patients identified (23.6%) had underlying chronic conditions (excluding asthma) requiring frequent follow-up with a sub-specialist. Eight patients (11.1%) had autoimmune/autoinflammatory diagnoses, 6 (8.3%) had oncologic/hematologic diagnoses requiring systemic therapy and 3 (4.2%) had genetic/congenital disease. Out of the 47 cases of definitive HZ, 10 (21.3%) required inpatient hospitalization for IV antiviral therapy, 7 (70%) of which had underlying chronic disease and 5 (50%) of which were on systemic immunomodulatory therapy. Seven out of the 17 patients (41.7%) with chronic disease required inpatient admission for HZ treatment, and 5 of these 7 (71.4%) were on systemic immunomodulatory therapy.

Conclusion: HZ can be identified with a high PPV in electronic medical records of children. There were modest improvements in PPV with the addition of characteristic rash. These findings can be employed in pharmacoepidemiologic research to better understand risk factors for HZ infection, which is especially important as new immunomodulatory medications come to market.

Abstract Number: 1166

Use of Rituximab to Treat COPA Syndrome: A Multi-Institutional Cohort

Leigh Stubbs[1], Isabella Osuna[2], Tarin Bigley[3], Michal Cidon[4], Kristen Mengwasser[5], Simon Helfgott[6], Marietta DeGuzman[7], Manuel Silva-Carmona[8] and Tiphanie Vogel[9], [1]Baylor College of Medicine, Houston, TX, [2]Department of Pediatrics, Division of Rheumatology, Baylor College of Medicine and Texas Children's Hospital, Houston, Texas, USA, Houston, TX, [3]Washington University in St. Louis, Saint Louis, MO, [4]CHLA, Los Angeles, CA, [5]Department of Medicine, Division of Rheumatology, Immunology, and Allergy, Harvard Medical School and Brigham and Women's Hospital, Boston, Massachusetts, USA, Boston, MA, [6]BWH- HMS, Boston, MA, [7]Baylor College of Medicine, Houston, [8]Department of Pediatrics, Division of Pulmonology Medicine, Baylor College of Medicine and Texas Children's Hospital, Houston, Texas, USA, Houston, TX, [9]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Coatomer protein complex subunit α (COPA) syndrome is a rare genetic multisystem autoimmune disorder inherited in an autosomal dominant manner. Onset typically occurs in childhood, including pulmonary, musculoskeletal, and renal manifestations. Pulmonary features include cough, dyspnea, and life-threatening diffuse alveolar hemorrhage. Lung involvement is a key negative prognostic factor. Musculoskeletal and renal manifestations

can include arthralgias, polyarticular arthritis, and glomerulonephritis. Patients are usually diagnosed with other rheumatologic conditions prior to the discovery of COPA syndrome and are often treatment refractory. Therefore, it remains unclear which immunomodulating drugs are the most beneficial for these patients. We report the demographics, clinical findings, prior medications, and current outcomes for COPA syndrome patients treated with rituximab, including 3 patients not previously reported.

Methods: A retrospective chart review was performed for 11 COPA syndrome patients who were treated with rituximab.

Results: The mean age of symptom onset was 8 years (range 0.5-18). The mean current age is 25 years (range 4-55), with a mean of 16 years (range 2-54) since illness onset. There was a female majority (55%), and patients were white non-Hispanic (55%), white Hispanic (27%), and black (18%). Diagnoses given prior to the discovery of COPA syndrome included mixed connective tissue disease, juvenile idiopathic arthritis, ANCA-associated vasculitis, rheumatoid arthritis, and idiopathic pulmonary hemosiderosis. Patients predominantly carried the p.R233H mutation (82%). The majority of patients presented with pulmonary symptoms (55%), but some presented with arthritis (27%), renal (9%), and neurologic (9%) manifestations. All patients had interstitial lung disease by chest CT. Other features included pulmonary hemorrhage (27%), arthritis (55%), and renal disease (36%). Laboratory results revealed elevated ESR (82%) and the presence of ANA (82%), ANCA (73%), RF (82%), and ACPA (50%). Prior to rituximab, the majority of patients (55%) failed 5 or more immunomodulatory drugs (mean: 4.5, range 1-9), and 3 patients (27%) were on oxygen therapy at rest. Patients had been treated with corticosteroids (100%), hydroxychloroquine (82%), methotrexate (45%), TNF-inhibitors (45%), azathioprine (36%), mycophenolate mofetil (36%), cyclophosphamide (27%), sulfasalazine (27%), tofacitinib (9%), and anti-IL-6R (9%). At last follow-up after rituximab (mean 2 years, range 1-5), no patients were on oxygen at rest. Chest CT results remained sTable or showed improvement of nodules and ground glass opacities. The majority of patients (90%) reported symptomatic respiratory improvement; one patient had an arthritis flare. No patients have required listing for lung or renal transplants. These COPA patients tolerated rituximab without serious adverse events, specifically there were no infectious complications.

Conclusion: The COPA syndrome patients in our cohort had symptomatic improvement, sTable or improving chest CT results, and decreased oxygen requirements after rituximab. Rituximab is a potentially promising therapy for patients with COPA syndrome.

Abstract Number: 1167

Capturing the Range of Disease Involvement in Localized Scleroderma: The Total Morbidity Score

Suzanne Li[1], Aashka Patel[1], Elena Pope[2], Thomas Mason[3], Vidya Sivaraman[4], Fatma Dedeoglu[5], Kathryn Torok[6], Katie Stewart[7], Gloria Higgins[8], C. Egla Rabinovich[9], Robert Fuhlbrigge[10], Maria Ibarra[11], Sandy Hong[12], Polly Ferguson[13], Mara Becker[14], Brian Feldman[15], Ronald Laxer[15] and CARRA Investigators[16], [1]Hackensack University Medical Center, Hackensack, [2]Hospital For Sick Kids, Toronto, ON, Canada, [3]Mayo Clinic, Rochester, MN, [4]Nationwide Children's Hospital, Bexley, OH, [5]Boston Children's Hospital, Boston, MA, [6]University of Pittsburgh, Pittsburgh, PA, [7]UT Southwestern, Dallas, TX, [8]Nationwide Childrens Hospital/ The Ohio State University, Columbus, OH, [9]Duke University Hospital, Durham, NC, [10]University of Colorado, Denver, CO, [11]Children's Mercy Kansas City, Kansas City, MO, [12]University of Iowa Stead Family Children's Hospital, Iowa City, IA, [13]University of Iowa Carver College of Medicine, Iowa City, IA, [14]Duke University School of Medicine, Durham, NC, [15]The Hospital for Sick Children, Toronto, ON, Canada, [16]CARRA, Durham

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Localized scleroderma (LS) is a chronic inflammatory and fibrosing disease that causes both cutaneous and extracutaneous (EC) damage. EC involvement (ECI) is common in juvenile LS (jLS), and includes joints, bones, eye, and nervous system. A measure that captures the full spectrum of morbidity would improve disease assessment. The CARRA LS group generated a measure, the Total Morbidity score (TMS), for this purpose. We report on its performance in a prospective cohort of jLS patients beginning methotrexate (MTX) treatment.

Methods: The TMS specifies that items should only be scored if considered related to LS, not to treatment or other factor. TMS items were generated based upon literature review and expert group discussion. A modular design was used, with modules of cutaneous features (i.e., dyspigmentation, subcutaneous atrophy) and extent, musculoskeletal (MSK, i.e., arthritis, myositis), growth difference of body (i.e., limb girth or length difference), head/neuro (i.e., facial hemiatrophy, brain involvement), other organ (i.e., vasculopathy). The weighting of scored items was determined by surveys, 1000Minds software, and iterative cycles of testing and discussion.

We evaluated the TMS in a prospective cohort of jLS patients followed for 12 months after starting MTX treatment (jLS consensus treatment plan pilot study). Clinical assessments included skin scores, physician global assessment of disease damage (PGA-D), and ECI scoring. Data was analyzed by descriptive statistics, Wilcoxon sign rank test, Spearman's rho. p values < 0.05 were considered to be significant.

Results: Fourty-eight patients had TMS scores at baseline, 43 at 12 months. There were 33 females, 44 Caucasian, median age of LS onset 9.6 years, median disease duration 12.5 months. The most common LS subtype was linear scleroderma. Baseline median TMS was 7, range 0-40. Patients with ECI had higher scores than those without ($p < 0.001$, Table 1), and there was a trend towards higher scores in patients with disease duration > 2 years ($p = 0.086$,

	# Patients	Median score (IQR)	Scoring Range	P value
All patients	48	7 (4, 13)	0-40	
EC involvement	34	10.5 (6, 15)	3-40	<0.001
No-EC involvement	14	4 (2.5, 6)	0-10	
Disease duration ≤ 2 years	30	6.5 (5, 10)	0-20	0.086
Disease duration > 2 years	18	11.5 (4.3, 15.8)	2-40	
Linear scleroderma	28	9 (6, 15)	0-20	NS
Non-linear subtypes	20	6.5 (4, 10.5)	2-40	
Mixed morphea	10	10.5 (9.3, 12.8)	5-40	NS
Non-mixed subtype	38	6.5 (4, 13.3)	0-20	

Table 1. Total Morbidity Scores at the Baseline Visit of 48 jLS patients beginning methotrexate-based treatment. The number of patient in each category, their median TMS, and the range of scores is shown. P-values were calculated by t-test, $p < 0.05$ considered to be significant. EC: extracutaneous; IQR: interquartile range; jLS: juvenile localized scleroderma.

Table 1). Higher scores were seen in linear scleroderma and mixed morphea subtype patients, but these differences were not significant (Table 1).

The most commonly scored TMS module was Cutaneous, followed by MSK, Growth differences, and Head/Neuro modules, which were each scored in >30% of patients at baseline (Figure 1). From 0 to 12 months, scores changed in 31 patients (72%), with change most often occurring in the Cutaneous and MSK modules (Figure 2). Patients with

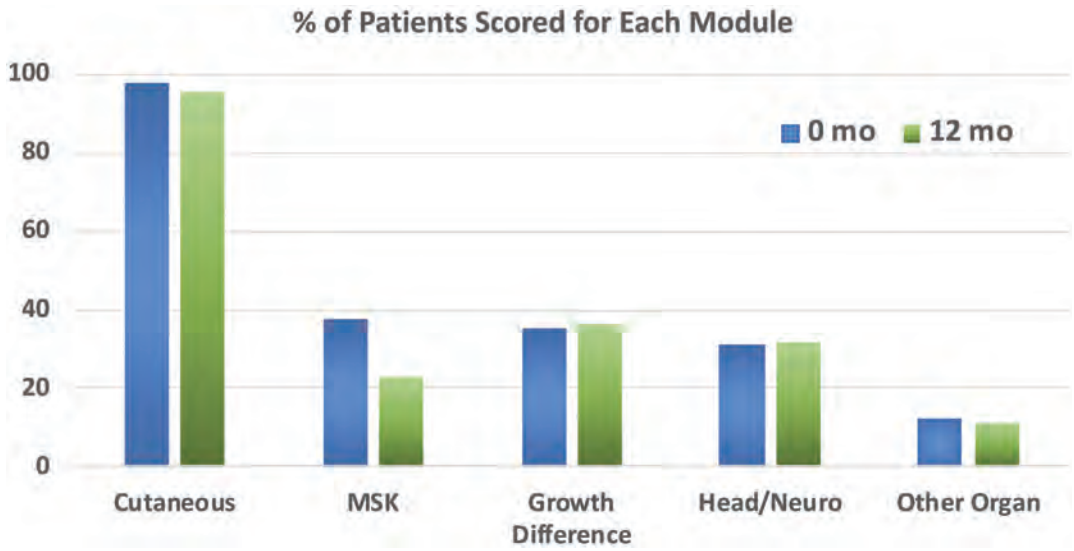

Figure 1. Percent of patients that were scored for each of the modules of the Total Morbidity Score at start of treatment (0 months) and after 12 months of methotrexate treatment. 48 jLS patients were assessed at 0 months, 43 at 12 months. Cutaneous refers to skin features (dyspigmentation, dermal atrophy, and skin thickening), subcutaneous tissue atrophy, and extent of these features in affected anatomic sites. Musculoskeletal (MSK) includes arthritis, joint contractures, myositis, fasciitis. Growth difference includes girth hemiatrophy, limb length differences, and breast, trunk, or buttock hemiatrophy. Head/Neuro includes hair loss, facial disFigurement, seizures, peripheral neuropathy, brain imagining abnormalities, and ocular or oral involvement. Other organ includes gastroesophageal reflux, Raynauds phenomenon, and other miscellaneous morbidities.

	Cut Features	Cut extent	MSK	Growth diff	Head & Neuro	Other Morbidity
Score Changed	12	5	13	3	5	1
Score Decreased	9	4	9	1	4	0
Score Increased	3	1	4	2	1	1

Figure 2. Change in TMS modules from 0 to 12 months. JLS patients were followed for 12 months after beginning methotrexate treatment. The columns show the percent of patients that had a change in their score of each TMS module from 0 to 12 months. 31 patients had a change in their TMS score, and 12 had sTable scores. Cut. Extent (cutaneous extent) refers to estimate of surface area of involvement of skin and subcutaneous damage features in each affected anatomic site. Growth diff = growth difference module.

linear scleroderma had a decrease in TMS scores from 0 (9, IQR 6-15) to 12 months (6, IQR 5-12, p =0.028). Good correlation was found between TMS and PGA-D at 0 and 12 months (rho = 0.778, p < 0.001; 0.756, p < 0.001, respectively), higher than that found for the localized scleroderma skin damage index (0.629 at 0 months, 0.713 at 12 months).

Conclusion: The Total Morbidity Score was developed to capture the range of, and quantify, LS morbidity. Scores were found to reflect a range of damage levels and morbidities in jLS patients, and vary over time. The TMS showed good correlation with PGA-D. Our findings suggest the TMS could aid tracking of clinical status and response. More study is needed to further assess its performance.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile localized scleroderma (jLS) is a chronic inflammatory and fibrosing disease. Treatment is directed towards controlling disease activity to minimize risk for functional impairment and severe damage. To work towards identifying optimal therapy, sensitive disease measures are needed to allow for comparative effectiveness studies.

A prior study identified several lesion features specific to and/or tracking with disease activity. These features were used to generate a new skin activity measure, LS Cutaneous Activity Measure (LSCAM), by LS Childhood Arthritis and Rheumatology Research Alliance (CARRA) group. We report its performance in two prospective cohorts.

Methods: The LSCAM was modelled after the modified Localized Scleroderma Scoring Index (mLoSSI). Both measures score and sum disease extension, erythema, and skin thickening across affected sites; mLoSSI weighs extension more. LSCAM also scores violaceous color, tactile warmth, and waxy white/yellow, weighing variables equally.

	W Round 1	W Round 2	Intra-rater	Average score
LSCAM	0.594	0.661	0.730	2.21
mLoSSI	0.5401	0.670	0.678	1.12
PGA-A	0.645	0.667	0.724	19.1
LSCAM variables				
-Erythema	0.437	0.536	0.626	0.87
-Violaceous/Blue	0.473	0.431	0.710	0.10
-Waxy/white/yellow	0.398	0.502	0.754	0.30
-Lesion Warmth	0.257	0.288	0.448	0.13
-Skin Thickening	0.494	0.460	0.620	0.46

Table 1. Reliability of Localized Scleroderma Cutaneous Activity Measure scoring from one day meeting. Thirteen jLS patient volunteers were evaluated two times in a one day meeting by 14 raters: 13 pediatric rheumatologists, 1 pediatric dermatologist. Patients were evaluated in a different random order by each rater in the two rounds. A maximum of two anatomic sites were evaluated per patient, with these sites identified in advance by one of the investigators (K. Torok). PGA-A was scored from 0-100. The average score of each measure and feature is shown; Erythema and skin thickening were scored from 0-3, other variables were scored from 0-1. For inter-rater reliability, Kendall's coefficient of concordance (W) were calculated. For Intra-rater reliability, Spearman's correlation were calculated for each rater. All reliability values shown were found significant, p <0.0001. LSCAM: Localized scleroderma cutaneous activity measure = disease extension + erythema + skin thickening + violaceous color + waxy white or yellow + tactile warmth. mLoSSI: modified localized scleroderma severity index= 3*disease extension + erythema + skin thickening. PGA-A = Physician global assessment of disease activity

	LSCAM	mLoSSI
Convergent validity: comparison to PGA-A		
-1 day meeting	0.951[1]	0.7765[1]
-12 month CTP pilot study	0.7487[1]	0.7268[1]
Divergent validity: comparison to PGA-D		
-1 day meeting	-0.137	-0.0261
-12 month CTP pilot study	0.4326[1]	0.3495[1]

Table 2. Construct validity of Localized Scleroderma Cutaneous Activity Measure. LSCAM and mLoSSI scores were analyzed in comparison to PGA-A for convergent validity, and to PGA-D for divergent validity in the two prospective jLS cohorts: 13 patient volunteers in a one day meeting, and 44 jLS patients initiating methotrexate treatment in the jLS CTP pilot study. Spearman's rho correlation coefficients are shown. 1p < 0.001. CTP: consensus treatment plan; LSCAM: Localized scleroderma cutaneous activity measure; jLS: juvenile localized scleroderma; mLoSSI: modified localized scleroderma severity index; PGA-A = Physician global assessment of disease activity; PGA-D = Physician global assessment of disease damage

Reliaibity of LSCAM scoring was evaluated in a 1-day meeting where, following a training session, 14 physicians scored 13 jLS patient volunteers twice. Each scorer was given a photo scoring atlas to aid scoring standardization.

Construct validity was determined by comparison to Physician Global Assessment of disease activity (PGA-A) and disease damage (PGA-D) in two cohorts: The patient volunteers as described, and a cohort of jLS patients followed for 12 months on methotrexate treatment (consensus treatment plan (CTP) pilot study). We calculated Kendall's coefficient of concordance to assess inter-rater reliability, and Spearman's rho to assess intra-rater reliability and validity. Levels of 0.2 to < 0.4 were considered poor, 0.4 to < 0.6 moderate, 0.6 to 0.8 good, >0.8 excellent.

Results: A moderate to good level of inter-rater reliability of scoring of LSCAM and mLoSSI was found in both rounds at the meeting (Table 1). A good level of intra-rater reliabiilty of scoring was found for LSCAM, mLoSSI, and PGA-A.

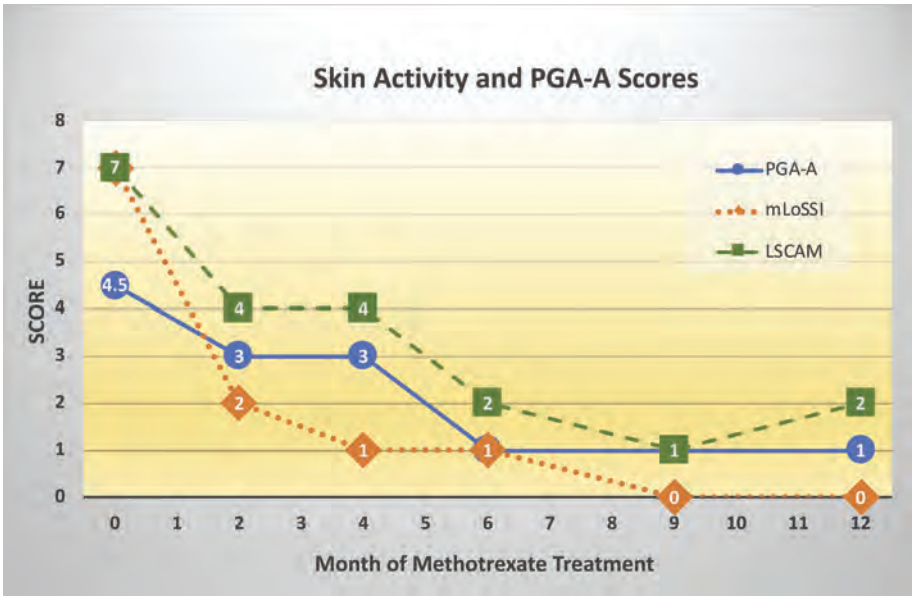

Figure 1. Change in scores for Skin Activity measures and PGA-A over 12 months of methotrexate treatment (jLS CTP Pilot study). Fourty-four jLS patients were monitored for 12 months after initiating methotrexate treatment (one of three methotrexate-based consensus treatment plans). The median LSCAM, mLoSSI, and PGA-A scores at each visit is shown. CTP: consensus treatment plan; LSCAM: Localized scleroderma cutaneous activity measure; mLoSSI: modified localized scleroderma severity index; PGA-A: physician global assessment of disease activity.

Among the individual variables, all except waxy white or yellow and tactile warmth had moderate reliability in both rounds (Table 1). Intra-rater was higher than inter-rater reliabiity (Table 1).

Excellent convergent construct validity was found between LSCAM and PGA-A, and good between mLoSSI and PGA-A in the 1-day meeting (Table 2). Good construct validity was found for LSCAM and mLoSSI in the CTP Pilot (Table 2). Divergent construct validity with PGA-D was shown between LSCAM and mLoSSI in the meeting, but not in the CTP Pilot (LSCAM 0.433, mLoSSI 0.350, Table 2). Scores for LSCAM, mLoSSI, and PGA-A decreased over time in the CTP study, with LSCAM appearing to more closely mirror changes in PGA-A score than mLoSSI (Figure 1).

Conclusion: LSCAM is a reliable and valid measure for assessing cutaneous activity in jLS. The level of inter- and intra-rater reliability of LSCAM was similar to greater than mLoSSI. A similar to higher level of convergent construct validity with PGA-A was found for LSCAM compared to mLoSSI, with LSCAM appearing to track better with PGA-A scores in the 12 month study. Our findings suggest the LSCAM will aid monitoring of LS activity, and facilitate conducting comparative treatment studies.

Three-Dimensional Analysis of Facial Asymmetry in Craniofacial Scleroderma

Daniel Glaser[1], Christopher Liu[2] and Kathryn Torok[3], [1]UPMC Children's Hospital of Pittsburgh, Piitsburgh, PA, [2]Children's Hospital of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Localized scleroderma (LS) is a rare, progressive autoimmune disease of the skin and underlying connective tissue that can result in devastating functional impairment and cosmetic damage in children. Approximately 25% of patients with pediatric-onset LS have the craniofacial (Cf-LS) subtype, with scalp and face involvement known as *en coup de sabre* or Parry Romberg Syndrome. Standardized cutaneous evaluations may be limited for monitoring craniofacial lesions due to deeper tissue involvement. Advanced stereophotogrammetrical imagers create high-resolution 3D craniofacial models that can be manipulated and analyzed to identify degree and location of facial asymmetry, such as seen in Cf-LS. Normative measurements of asymmetry have been suggested. (*Taylor HO, et al. Quantitative facial asymmetry: using three-dimensional photogrammetry to measure baseline facial surface symmetry. J Craniofac Surg. 2014;25(1):124-128*)

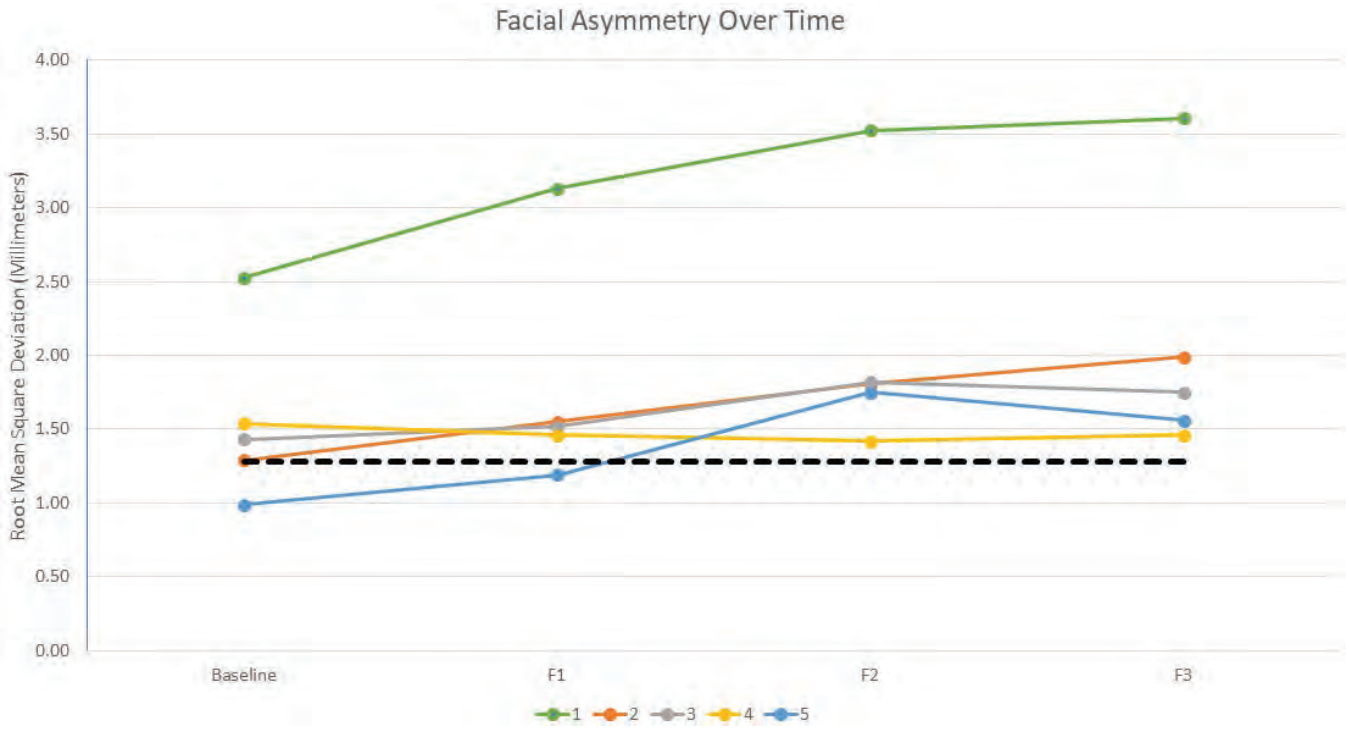

Figure 1. Longitudinal facial asymmetry root mean square deviation (RMSD) values. Baseline and four follow up time points are denoted. The dashed line represents the upper limit of normal RMSD values (1.28mm), defined as 2 standard deviations (0.24mm) above the normative mean (0.80mm) per Taylor et al 2014.

Table 1 Demographics (n=5)

Our goal was to longitudinally assess patients with Cf-LS to determine the course of facial asymmetry over time. We hypothesize that patients with Cf-LS have facial asymmetry beyond normative data which is maintained that can reliably be detected and tracked longitudinally via computerized stereophotogrammetrical measurements.

Methods: Patients (N=5) with craniofacial scleroderma (*en coup de sabre* and/or Parry Romberg Syndrome) were retrospectively identified in the National Registry for Childhood Onset Scleroderma (NRCOS). Demographic data, medication use, and standardized cutaneous outcomes were extracted from the NRCOS database. This data was paired with clinical 3D facial maps collected via Canfield VECTRA M3 or 3dMD.head.t imaging systems. Image surfaces were analyzed in Vectra Analysis Module. Trimmed and registered images were divided along the plane of maximal symmetry utilizing VAM automated alignment. The hemi-face was then reflected about this plane to superimpose the affected and unaffected sides. Root mean square deviation (RMSD) in millimeters was calculated for each reflection as the main outcome measure. Descriptive statistics were applied.

Results: Patients were followed for a mean of 28.6 months (Table 1). Body-mass index (BMI) was relatively sTable across the follow up period. All patients received systemic immunomodulation during the follow-up period. Stand-

Table 2 Individual longitudinal Root Mean Square Difference values

3	PRS+ECDS	1.43*	1.52&	1.82&	1.75&
4	ECDS	1.54&	1.46*	1.42*	1.46*
5	ECDS	0.99	1.19	1.75&	1.56&

#Normative mean RMSD = 0.80mm, standard deviation = 0.24mm per *Taylor et al. 2014*

* ≥2 SDs above the normative mean

& ≥ 3 SDs above the normative mean

PRS, Parry Romberg Syndrome; *ECDS*, en coup de sabre

Table 2 Individual longitudinal root mean square difference values

ardized cutaneous activity measurements decreased at follow up, though damage measures were unchanged (Table 1). At baseline, 4/5 patients had facial asymmetry RMSD exceeding 2 standard deviations (SD) of normal and 2/5 exceeded 3 SDs. All patients had facial asymmetry RMSD >2SD at the end of the follow-up period (28 months), and 4/5 exceeded 3 SDs. Asymmetry increased in 80% (4/5) compared to baseline (Table 2, Figure 1).

Conclusion: Facial asymmetry in patients with craniofacial scleroderma is reliably detecTable by 3D stereophotogrammetry. Asymmetry generally worsens over time. BMI and age-related skeletal growth do not appear to influence asymmetry. Conventional cutaneous scoring may fail to detect relevant changes in damage the lead to progressive asymmetry.

Exploring the Use of Von Willebrand Factor as a Disease Biomarker in a Cohort of Patients with Juvenile Scleroderma: A Pilot Study

Natalia Vasquez-Canizares[1], Beamon Agarwal[2], Tamar Rubinstein[3], Dawn Wahezi[1] and Morayma Reyes-Gil[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]GenomeRxUS LLC, Clifton Heights, PA, [3]Albert Einstein College of Medicine / Montefiore Medical Center, White Plains, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Scleroderma (JScl) is a heterogenous disease characterized by autoimmunity, vasculopathy, and fibrosis. Morbidity and mortality remain high in part due to the continuing limited understanding of disease pathogenesis, and in part due to the lack of validated biomarkers. Von Willebrand Factor (VWF) is a multimeric glycoprotein synthesized in endothelial cells (ECs) with high prothrombotic properties. In Scl, VWF has emerged as a potential biomarker based on evidence indicating that EC injury might be central to the pathogenesis. Cross-sectional studies in adults with Scl indicate: 1) levels of VWF antigen (Ag) in plasma are found elevated compared to healthy controls, 2) baseline levels can predict death and future development of pulmonary hypertension, and 3) presence of high-molecular weight multimers (HMWM), being the most active forms of VWF, may contribute to the significant microangiopathy. Longitudinal studies exploring the role of VWF as a disease biomarker in Scl are lacking and there

is limited understanding of its use in patients with childhood-onset disease. We aim to describe trajectories of VWF Ag levels over time in patients with JScI and its association with disease type. We also investigate for predictors of persistently elevated levels of VWF Ag, and for the presence of HMWM

Methods: Data of children ages < 18 years, fulfilling the 2007 Pediatric Rheumatology Provisional Classification Criteria for Juvenile Systemic Sclerosis (JSSc) and the Padua Criteria for Juvenile Localized Scleroderma (JLS) were reviewed between 2009-2020. Trends in VWF Ag levels were explored using time series plot. Cross-sectional and longitudinal analysis using linear and logistic regression models with GEE were performed to look for: 1) association of VWF Ag levels with disease type, and 2) independent predictors of persistently elevated levels of VWF Ag defined as a value of >150% in ≥75% of the visits. Leftover samples kept frozen for quality control studies were extracted for VWF multimeric analysis to study the presence of HMWM, and for the Ristocetin Cofactor assay to assess VWF activity [expressed as VWF Activity (Act): VWF Ag ratio]

Results: Twenty-four patients with JScI (50% jSSc, 50% JLS) were studied (Table 1). A negative trend in VWF Ag levels with different patterns in JSSc vs. JLS patients was seen (Figure 1). No statistically significant association was found between VWF Ag levels and disease type. Disease severity was an independent predictor of VWF Ag levels

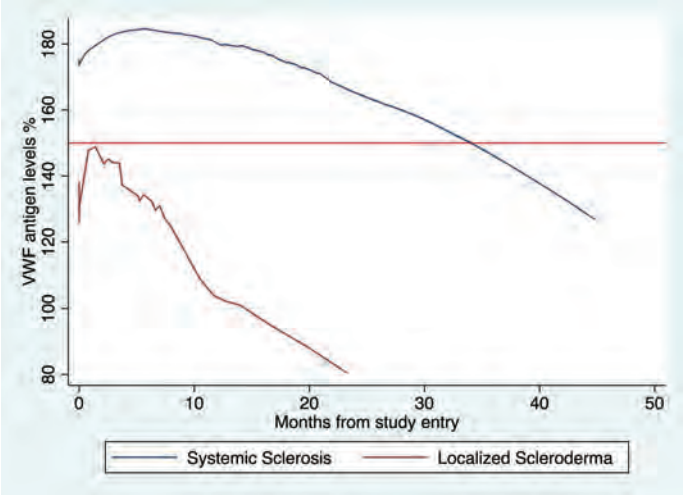

Figure 1. Lowess smoothed time series plot of Von Willebrand Factor antigen levels versus time by disease type. The normal upper cutoff value of VWF is represented by the horizontal red line (=150%). There is a negative trend of VWF antigen levels over time in both groups. Patients with systemic sclerosis have higher and more chronically elevated levels of VWF antigen compared to those with localized scleroderma. VWF=Von Willebrand Factor.

when adjusting for disease type (52.6% ± 23.7%, p=0.03). Skin ulcers (OR 0.25, p=0.01), exposure to DMARDs (OR 0.27, p=0.008), and Non-Hispanic ethnicity (OR 4.0, p=0.04) are independent predictors of persistently elevated levels of VWF Ag. In 8/15 samples (53%), HMWM of VWF were found elevated while median VWF Act: VWF Ag ratio was decreased [0.44 (IQR 0.21; 0.55)]

Conclusion: Consistent with literature in adults, in patients with childhood-onset disease: 1) elevated levels of VWF Ag are found in plasma, 2) higher levels of VWF Ag predict disease severity, and 3) a high proportion of individuals have circulating levels of HMWM of VWF. Larger prospective studies are needed to further characterize VWF and its potential use as a disease biomarker in JScl

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) has a prevalence in around 3 in a million children. Pulmonary involvement occurs in approximately 40 % in the international juvenile systemic scleroderma cohort (JSScC). Traditionally in jSSc, pulmonary function testing (PFT) with FVC and DLCO are used for screening and computed tomography (HRCT) was more reserved for those with abnormal PFTs. More recently, it has become apparent that PFTs might not be sensitive enough for detecting interstitial lung disease (ILD) in children.

Methods: JSScC database was queried for available patients with recorded PFT parameters and HRCT performed to determine sensitivity of PFTs detecting disease process.

Results: Of 129 patients in the jSScC, 67 patients had both CT imaging and an FVC reading from PFTs for direct comparison. DLCO readings were also captured but not in as many patients with tandem HRCT (n =55 DCLO and HRCT scan). Therefore, initial analyses focused on the sensitivity, specificity and accuracy of the FVC value from the PFTs to capture the diagnosis of interstitial lung disease as determined by HRCT.

Overall, 49% of the patients had ILD determined by HRCT, with 60% of patients having normal FVC (>80%) with positive HRCT findings, and 24% of patients having normal DLCO (> 80%) with positive HRCT findings. Fourteen percent (n = 3/21) of patients with both FVC and DLCO values within the normal range had a positive HRCT finding.

Conclusion: The sensitivity of the FVC in the JSScC cohort in detecting ILD was only 39%. Relying on PFTs alone for screening for ILD in juvenile systemic sclerosis would have missed the detection of ILD in almost 2/3 of the cohort, supporting the use of HRCT for detection of ILD. The cut off utilized, of less than 80% of predicted FVC or DLCO could be too low to exclude beginning ILD.

Cardiovascular involvement as a clue for diagnosis of Juvenile Systemic Sclerosis *sine scleroderma*

Gloria Lanzoni[1], Giorgia Martini[1], Alessandra Meneghel[1], Fabio Vittadello[2], Biagio Castaldi[1], Elisabetta Zanatta[3] and Francesco Zulian[1], [1]Department of Woman's and Child's Health, University of Padova, Padua, Italy, [2]Centro Studi Statistici Explora, Padua, Italy, [3]Department of Medicine-DIMED, University of Padova, Padua, Italy

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Systemic Sclerosis (JSSc) is a rare condition in childhood and its variety with no skin involvement, systemic sclerosis *sine scleroderma* (JSSSS) is anecdotal as only two cases have been reported to date[1,2]. We describe a series of four patients from our Center and compare these six patients with a cohort of patients with standard JSSc.

Methods: Unselected consecutive patients with Juvenile Systemic Sclerosis (JSSc), diagnosed according with the PRES/EULAR/ACR criteria[3] were retrospectively evaluated. For every patient, we collected demographic, clinical and laboratory data, autoantibody profile and treatment. The following clinical-instrumental parameters were considered: skin involvement by the mRodnan Skin Score, Raynaud's phenomenon (RP), chest x-ray, high-resolution computed tomography (HRCT), diffusing capacity for carbon monoxide (DLCO), forced vital capacity (FVC), musculoskeletal involvement, esophageal scintiscan or 24-hour pH-metry, and malabsorption test. Cardiac investigations included

at rest electrocardiography (EKG), cEcho and cMRI. Patients without skin involvement at onset were compared with those with standard JSSc. The association between categorical variables has been investigated with Fisher's exact test. Student T test or Mann Whitnet U test was used to compare numerical variables between the two groups, as appropriate.

Results: Among 47 patients with JSSc, 4 (8.5%) presented with systemic sclerosis *sine scleroderma (JSSSS).* The clinical features of these four patients and of other two, reported in the literature[1,2], were compared with a group of 30 JSSc patients with complete clinical data available. All JSSSS patients, 3 male and 3 female, had cardiovascular involvement as presenting feature, 3 primary myocarditis, 3 secondary to pulmonary arterial hypertension (PAH) and two (33.3%) died after a brief disease course. ANA was positive in all except one reported in 1993[2]. Scleroderma specific antibodies were present in Patient 4/5 tested patients (2 anti-topoisomerase, 1 anti-centromere, 1 anti-RNA polymerase I and III). Altered EKG and cMRI were present in all tested patients; cEcho parameter ejection fraction (EF) was reduced in 4/6 patients. The comparison between the two cohort of patients, JSSSS and JSSc, revealed a significant higher cardiac involvement in JSSSS (100% vs 16.7%, $p< 0.0001$), higher prevalence of EKG, cEcho and MRI abnormalities ($p< 0.001$). All the other clinical and laboratory parameters, including age at onset, sex and delay in diagnosis, were not significantly different in the two groups.

Conclusion: To the best of our knowledge, this is the first case series of patients JSSSS. Cardiovascular involvement represents the most important clinical feature of this subtype and still carries a very high morbidity and mortality rate[4]. Our experience, although in a small cohort, confirms the crucial role of complete rheumatologic work-up in pediatric patients with isolated myocardiopathy or PAH.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile systemic scleroderma (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. Longitudinal prospective follow up data of patients with jSSc is rare. In the international juvenile systemic scleroderma cohort (jSScC) patients are followed with a standardized assessment prospectively.

Methods: Patients diagnosed according the ACR 2013 criteria for systemic sclerosis were included, if they developed the first non-Raynaud symptom before the age of 16 and were under the age of 18 at the time of inclusion. Patients were followed prospectively every 6 months with a standardized assessment.

Results: 39 patients in the JSScC had 36 months follow up. 80% had a diffuse subtype. 95% of the patients were Caucasian origin and 80% female. Mean disease duration at time of inclusion was 3.5 years. Mean age onset of Raynaud's was 8.8 years and mean age of onset at the first non-Raynaud´s was 9.5 years. The MRSS dropped from the time point of the inclusion into the cohort from 13.9 to 11.8 after 36 months. Pattern of organ involvement did not show any significant change, beside the increase of the nailfold capillary changes from 49% to 73% (p=0.037). No renal crisis occurred. No mortality was observed.

They were positive significant changes in the patient related outcomes assessed on a VAS scale of 0 to 100. The physician global disease activity decreased from 40.0 to 22.1 ($p < 0.001$).

Patients global disease activity decreased from 43.3 to 20.4 and patients global disease damage from 45.0 to 21.7 ($p< 0.001$).

Conclusion: After 36 months follow up, we could observe a significant improvement of patient related outcomes and only one significant change in organ pattern involvement. In a mostly diffuse subset patient population this is a very promising result regarding outcome.

HEADSS and Shoulders, Knees and Toes: Improving Sexual Orientation and Gender Identity Screening in the Pediatric Rheumatology Clinic

Nayimisha Balmuri[1], Jacob Spitznagle[1], Alexa Adams[1], Karen Onel[2], Sarah Taber[1] and Nancy Pan[1], [1]Hospital for Special Surgery, new york, NY, [2]Pediatric Rheumatology, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Adolescence is an especially vulnerable time when many rheumatologic conditions first present for diagnosis and management. Adolescence brings unique challenges including those relating to body image, schooling, complexities of interpersonal relationships, compliance with medications, and independence with healthcare needs. Within this population, LGBTQ spectrum adolescents are a population with known health disparities and psychosocial stressors. It is of the utmost importance that providers for adolescent patients conduct appropriate

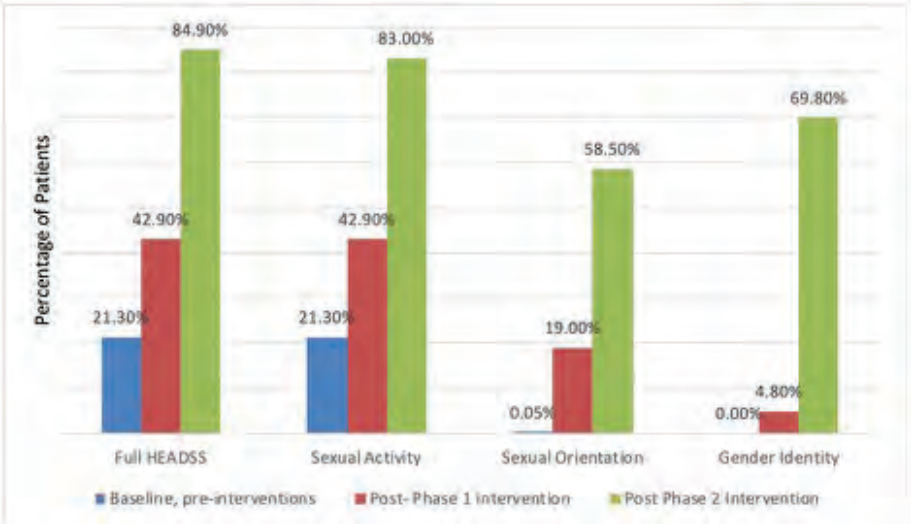

Figure 1. Comparison of Documentation Status Pre- and Post- Phase 1 and 2 Intervention

	Pre-Intervention	Post Phase 1 Intervention	P Value	Post Phase 2 Intervention	P Value
Full HEADSS	16/75 (21.3%)	18/42 (42.9%)	0.0194	45/53 (84.9%)	0.0001, <0.0001
Sexual Activity	16/75 (21.3%)	18/42 (42.9%)	0.0194	45/53 (84.9%)	0.0001, <0.0001
Sexual Orientation	4/75 (0.05%)	8/42 (42.9%)	0.0266	31/53 (58.5%)	0.0001, <0.0001
Gender Identity	0/75 (0%)	2/42 (4.8%)	0.1269	37/53 (69.8%)	0.0001, <0.0001

Table 1. Documentation Status Pre- and Post- Phase 1 and 2 of Intervention

psychosocial screenings to better identify these patients and address their unique healthcare needs. The HEADSS assessment (home, education/employment, activities, drugs, sexuality, suicide/depression) is a validated tool developed to provide a comprehensive psychosocial assessment of adolescent patients. Sexual orientation and gender identity (SOGI) screening can be incorporated within the HEADSS framework. We conducted a quality improvement (QI) project aimed to increase provider screening and appropriate documentation of SOGI data for adolescent patients seen for initial evaluation in pediatric rheumatology clinics at an academic medical center.

Methods: This QI initiative consisted of two phases: 1) a short lecture illustrating the components of the HEADSS assessment, highlighting the importance of SOGI screening, and discussing strategies to incorporate them into routine clinic visits and 2) an electronic note template to be utilized for HEADSS/SOGI documentation. Charts of all patients age 12 and older seen for initial evaluation in pediatric rheumatology clinic were reviewed during a two month window prior to interventions and one month after Phases 1 and 2 for documentation of a full HEADSS assessment, sexual activity and health assessment, sexual orientation, and gender identity. Documentation of HEADSS assessment and SOGI information prior to and after each phase were compared using Fisher's exact test. For all statistical analyses a two-tailed p-value < 0.05 was considered significant.

Results: Chart review included 75 patients pre- intervention for assessment of baseline information, 42 patients post-phase 1 intervention, and 53 patients post- phase 2 intervention (Table 1). There was a statistically significant increase in assessment of all measures in the period immediately following the interventions. The phase 2 intervention not only showed a statistically significant increase from the phase 1 intervention but also from baseline.

Conclusion: Provider education and introduction of an electronic note template greatly enhanced screening and documentation of SOGI data for adolescent patients seen in pediatric rheumatology clinics at an academic medical center. Further studies are needed to assess whether these findings are sustainable and reproducible between other centers.

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Mental health problems are common and often untreated in youth with rheumatologic disease, yet their relationship with disease features is poorly understood. We engaged patients and parents on the research team to identify cross-cutting disease factors impacting mental health in this population.

Methods: An anonymous cross-sectional online survey examined mental health experiences of patients with juvenile arthritis, juvenile dermatomyositis, or systemic lupus erythematous. Youth ages 14-24 years and parents of youth 8-24 years were eligible. The survey was developed with patient and parent advisors, the Childhood Arthritis & Rheumatology Research Alliance (CARRA), and the Patients, Advocates, and Rheumatology Teams Network for Research and Service (PARTNERS). Participants were recruited through the Arthritis Foundation, Lupus Foundation of America, and Cure JM Foundation. Primary outcome was the presence of any clinician or self-diagnosed mental health problem. Exposures of interest included several cross-cutting disease factors: disease duration, active disease status, current steroid medication, history of disease flare following remission, and appearance-altering comorbidities (psoriasis, stretch marks, alopecia, skin ulceration, visible scarring). We used logistic regression models to examine

Table 1. Demographic and disease characteristics of youth with rheumatologic disease

Demographic or Disease Characteristic	All Respondents (n=447)	Any self-reported mental health problem (n=293)	No mental health problem (n=154)	*p*
Age group				
8-17 years	303 (68%)	191 (65%)	112 (73%)	.105
18-24 years	144 (32%)	102 (35%)	42 (27%)

the association between any clinician or self-diagnosed mental health problems and disease factors for the combined youth/parent sample, and for youth and parents separately. Secondarily, we examined results by mental health problem (depression, anxiety, self-harm/suicidal ideation). Alpha values < .05 were considered significant.

Results: See Table 1 for sample characteristics. 447 respondents included 123 youth and 324 parents; they were not required to be dyads. Combining youth and parent responses, 210 had juvenile arthritis, 173 had juvenile dermatomyositis, and 64 had systemic lupus erythematosus. Those with and without mental health problems were comparable on many demographic and disease factors, although patients with appearance altering comorbidities were more

Table 2. Estimates for regression models predicting clinician or self-diagnosed mental health problems

Outcome	Predictor	Odds Ratio, 95% CI *Youth & Parents* n=447	*Parents only* n=386	*Youth only* n=123

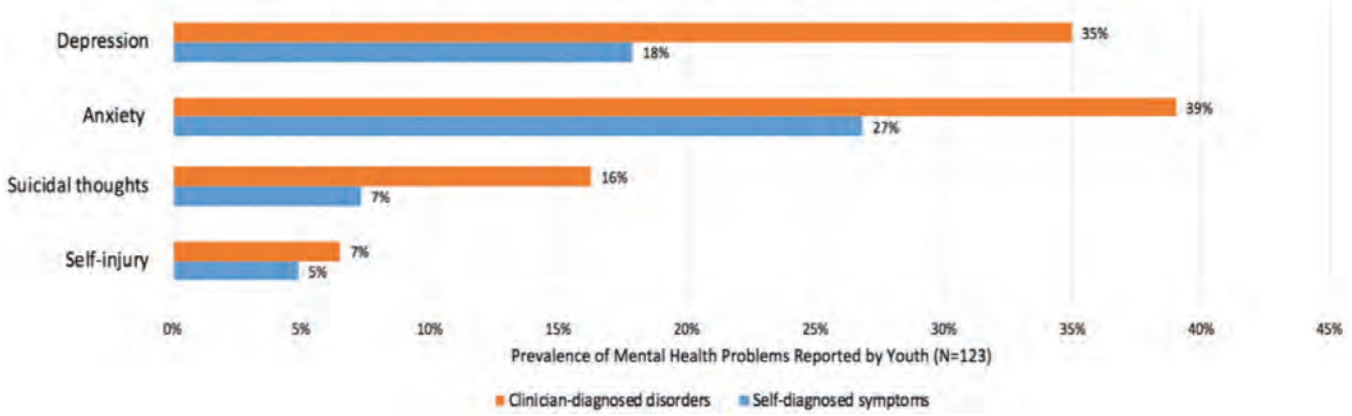
	Flare following remission	**2.46** [1.28, 4.71]**	2.28 [.91, 5.71]	2.02 [.74, 5.52]
	Appearance altering comorbidities	1.11 [.67, 1.86]	1.29 [.66, 2.51]	.89 [.37, 2.11]
	Gender	1.63 [.93, 2.86]	1.04 [.50, 2.14]	N/A[1]

*$p<.05$
**$p<.01$
[1]Gender was omitted from the model as all youth who endorsed reported suicidal ideation or self-harm were female

likely to report mental health problems. Rates of clinician and self-diagnosed depression, anxiety, suicidal thoughts, and self-harm are shown in Figure 1.

Adjusted logistic regression models (Table 2) indicate that having appearance altering comorbidities predicted the presence of a mental health problem in the combined youth/parent sample and in the parent-only sample. In the combined sample, appearance altering comorbidities also predicted depression and anxiety problems, whereas history of flare following remission predicted reported suicidal ideation or self-harm. Within the youth responses, reported depression trended to be more likely among those taking steroids ($p=.053$).

Figure 1. Prevalence of Mental Health Problems for Youth with Rheumatologic Disease



Conclusion: Certain cross-cutting rheumatologic disease factors such as appearance-altering comorbidities are predictive of mental health problems such as depression or anxiety. These findings are helpful for identifying targets for mental health screening in youth with rheumatologic disease, and should be addressed in screening recommendati ons.

Abstract Number: 1176

Identifying Targets to Improve the Assessment of Psychosocial Risk Factors in Adolescent Patients: Perspectives from Pediatric Rheumatology Fellows in the United States and Canada

Jacob Spitznagle[1], Nayimisha Balmuri[1], Alexa Adams[1], Karen Onel[2], Sarah Taber[1] and Nancy Pan[1], [1]Hospital for Special Surgery, New York, NY, [2]Pediatric Rheumatology, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Adolescent patients cared for in the pediatric rheumatology clinic balance challenges related to psychosocial stressors and physical growth with the complexities of living with a chronic medical condition. Due to the interplay between these factors, it is important that all providers for adolescent patients conduct appropriate psychosocial screenings to better identify at risk patients and address their unique healthcare needs. The HEADSS assessment (home, education/employment, activities, drugs, sexuality, suicide/depression) is a validated tool that provides a framework to comprehensively screen for psychosocial risk factors. The objective of this study was to identify targets to improve psychosocial screening of adolescent patients presenting to the pediatric rheumatology clinic by assessing current practice patterns and perceived barriers to screening by pediatric rheumatology fellows.

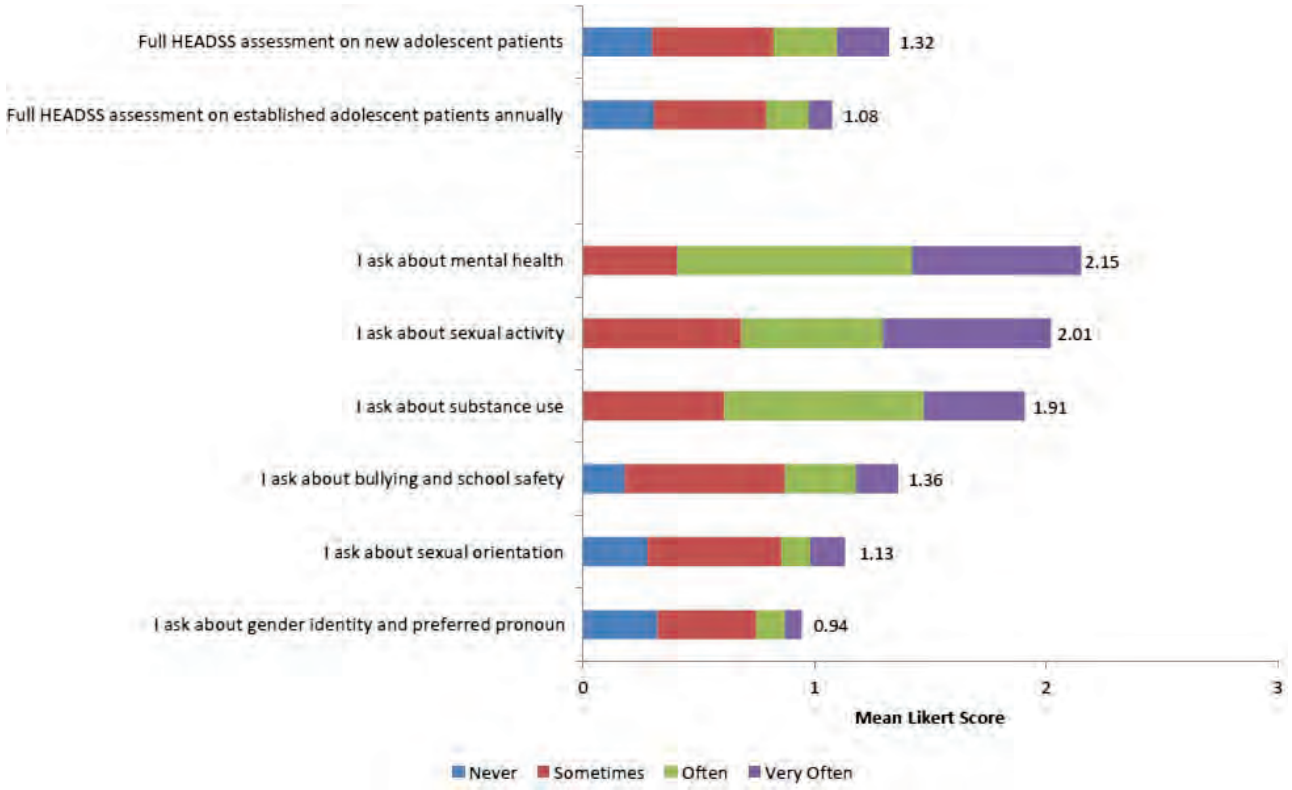

Figure 1. Frequency of pediatric rheumatology fellows performing a full HEADSS assessment and individual components of the HEADSS assessment on adolescent patients. Components of the HEADSS assessment are ranked by mean Likert score for frequency (range 0-3), as well as the proportion of responses for each frequency rating (0 = never, 1 = sometimes, 2 = often, 3 = very often).

Methods: This is a descriptive survey-based study sent to active fellow-in-training members of the Childhood Arthritis and Rheumatology Research Alliance (CARRA). Responders completed a secure web-based survey using REDCap (Research Electronic Data Capture) to assess current practices, beliefs, and barriers regarding the utilization of the HEADSS assessment.

Results: Of the 99 eligible CARRA fellow members, 57 responded (58%) and 53 completed the survey in its entirety. All but two responders are currently training in the United States, and the majority (81%) reported practicing in an urban setting. Sixty-one percent agreed or strongly agreed that a full comprehensive HEADSS assessment should be completed on all adolescent patients seen in the pediatric rheumatology clinic; however, only 38% reported often conducting a full HEADSS assessment on new adolescent patients, and 26% often conducted a full HEADSS assessment on established adolescent patients annually. Frequencies of conducting individual components of the HEADSS assessment are summarized in Figure 1. Of these, sexual orientation and gender identity (SOGI) data were cited as being the least frequently collected information. Barriers to screening are summarized and ranked in Figure 2. The most commonly cited barriers to screening were lack of time and providers not knowing what to do with positive screens. Fifty-seven percent of responders cited interest in receiving additional training in application of the HEADSS assessment. Sixty-five percent cited interest in receiving additional training in collecting SOGI information.

Conclusion: Pediatric rheumatology fellows perceive the importance of assessing psychosocial risk factors in adolescent rheumatology patients but have difficulty completing a full assessment due to lack of time and uncertainty of what to do with a positive screen. In particular, fellows are least likely to ask patients about SOGI information. Potential strategies to overcome barriers include enhanced adolescent and LGBTQ health-related training for pediatric

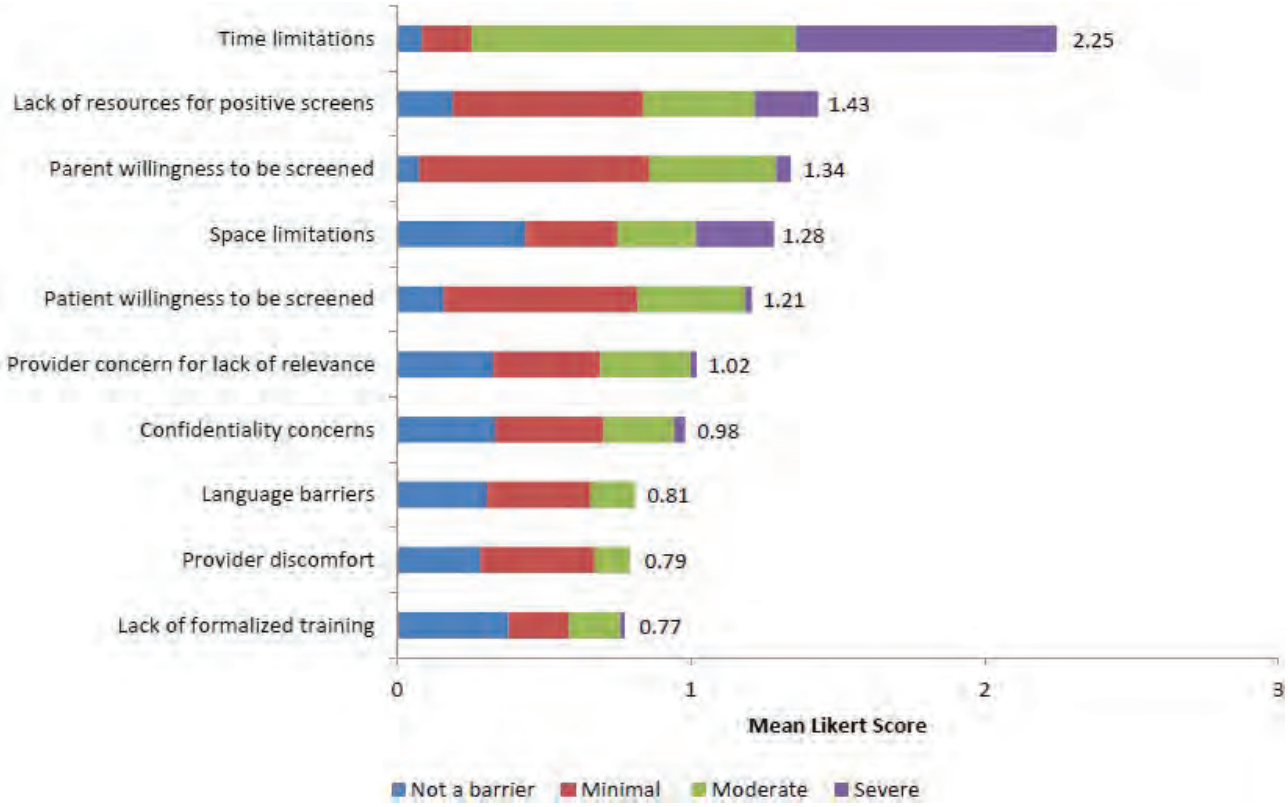

Figure 2. Barriers to performing a HEADSS assessment and collecting SOGI data as perceived by pediatric rheumatology fellows. Perceived barriers are ranked by mean Likert score for degree of perceived barrier (range 0-3), as well as the proportion of responses for each degree of perceived barrier rating (0 = not a barrier, 1 = minimal barrier, 2 = moderate barrier, 3 = severe barrier).

rheumatologists, standardized screening practices, and integration of multidisciplinary teams to develop an algorithm for referral services for positive screens.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Pediatric Rheumatology – Clinical Poster II: Systemic JIA, Autoinflammatory, & Scleroderma

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric rheumatic diseases (PRD) are a heterogeneous group of disorders. PRD patients and their caregivers face a number of challenges, these include the consequences of the PRD in patients and the impact on multiple dimensions of the caregiver's daily life. Our group developed and validated the CAREGIVERS questionnaire to measure the impact on caregivers of children with PRD.

The objective of this study was to measure the economic, psychological and social impact that PRD has on the caregivers of Mexican children and the factors associated with these impacts.

Methods: This is a cross-sectional study in which primary caregivers were prospectively included between April and November 2019 in four public hospitals of specialized care. Descriptive statistics used used to the sociodemographic characteristics of the participants and the patients' clinics, a univariate analysis was performed with the interview

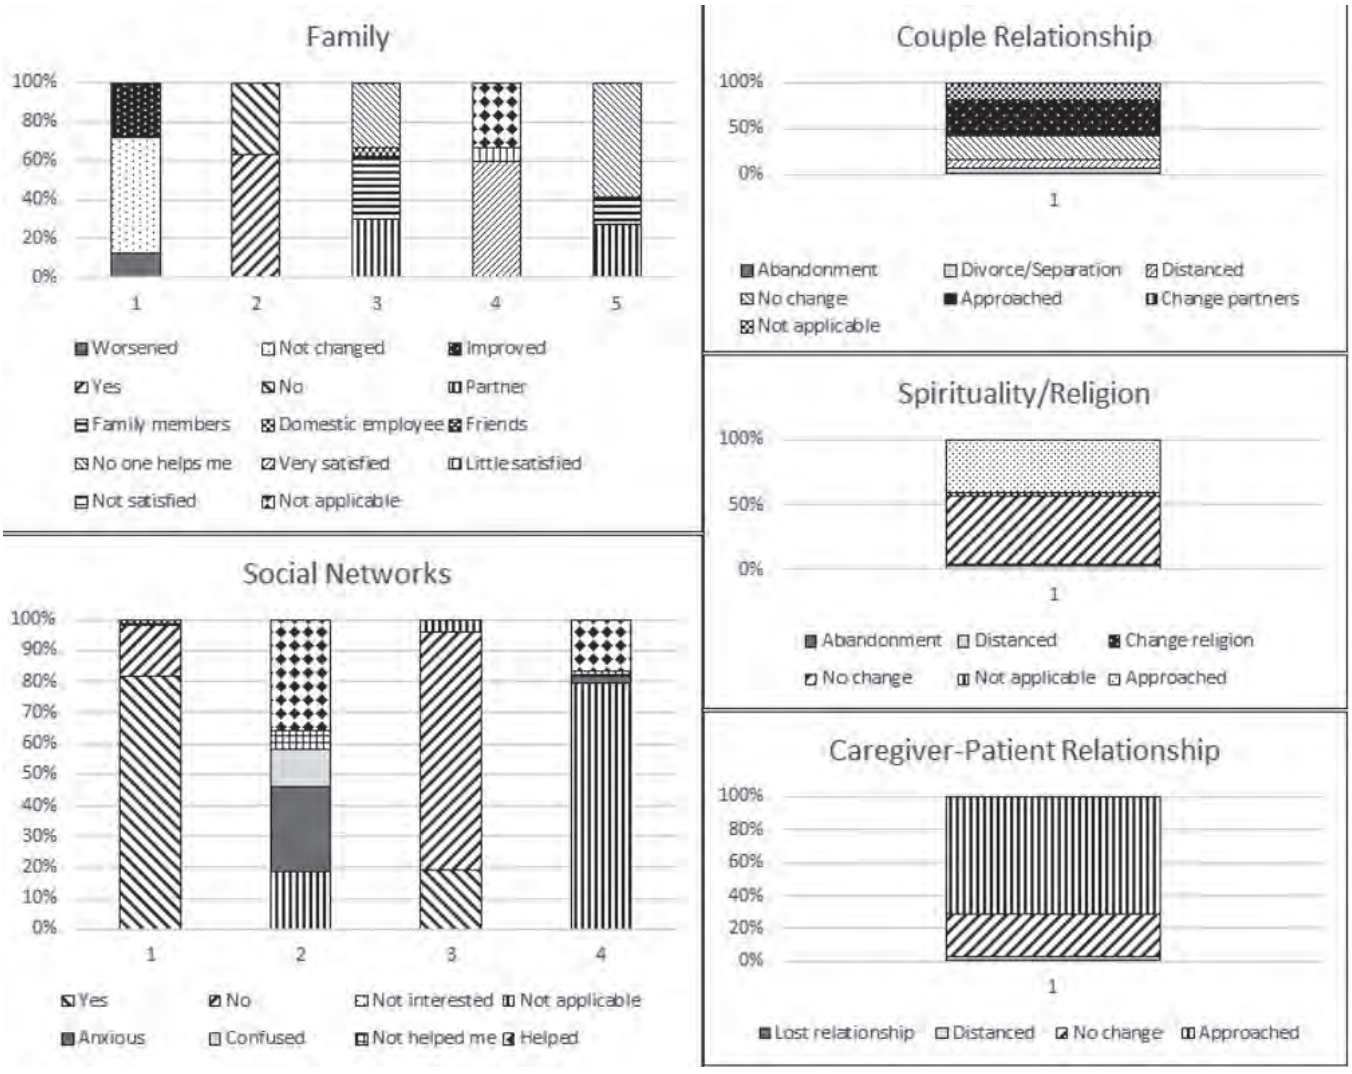

Figure.1 Socio-economic impact in caregivers

responses of the CAREGIVERS questionnaire and the sociodemographic, clinical, and health system variables using the Chi square, Mann-Whitney U, and Kruskal-Wallis tests ($p < 0.05$).

Results: 200 participants were included, women (84.5%) with median age of 38 years; 54.5% cared for patients with JIA, 14% with JDM and 31.5% with JSLE. Most of the caregivers felt concern (42.5%) when learning about the diagnosis, which then was modified by tranquility (44%) when the current feeling was questioned; however, 40 expressed sadness when sharing the patient's PRD (20%) and 39 do not like to do so (19.5%).The main cause of concern is pain (41.5%), followed by difficulty in movement (28.5%) and covering the costs of treatment (25%). Social impact: In 99 caregivers (49.5%), the use of their time changed a lot upon learning the PRD. Social life varied according to the PRD, in JSLE it had a significant change (39.6%), but it did not change in JIA (44%) and it slightly changed in JDM (53.5%, $p < 0.01$).Financial impact: the family financial situation worsened upon diagnosis of the patient in most cases (JIA 63 [57.8%], JSLE 19 [69.8%] and JDM 44 [67.8%], $p = 0.27$). Almost two thirds had had to borrow money, more frequently in JSLE (48 [76.1%] vs JIA 62 [56.8%] and JDM 19 [67.8%], $p = 0.03$); 63 stopped buying medicines due to lack of money (31.5%) and 86 received additional financial support for the treatment (43%).The emotional impact increased in caregivers of male patients. Social dimension showed significant differences regarding PRD, healthcare system, time to reach the center, presence of disability, active disease, cutaneous and systemic manifestations and treatment.

Conclusion: This study highlights a series of lessons learned and the most important is the need to improve opportunities for support, especially regarding financial support, for caregivers of patients with PRD. The study has shown that social status can be devastating in the impact that PRD can have on families. We feel confident that, although all the participants are Mexican, the findings can be generalized to populations with similar characteristics in other regions

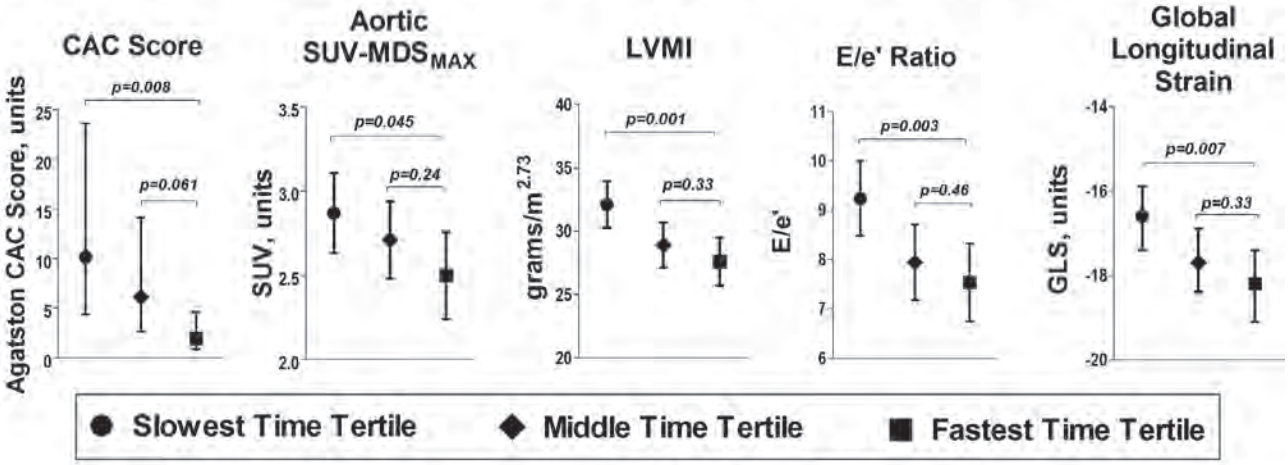
Associations of Walking Endurance and Speed with Multiple Measures of Subclinical Cardiovascular Disease in Rheumatoid Arthritis

Genna Braverman[1], Sabahat Bokhari[2], Kazato Ito[3], Joan Bathon[2] and Jon Giles[4], [1]NY Presbyterian - Columbia University Irving Medical Center, New York, NY, [2]Columbia University, Vagelos College of Physicians and Surgeons, New York, NY, [3]Division of Cardiology, Columbia University Vagelos College of Physicians and Surgeons, New York, NY, [4]Columbia University, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The 400 meter timed walk test has been studied as a simple summary measure of fitness that is predictive of mobility limitation and incident cardiovascular disease (CVD) events in older individuals. However, it has not been studied in the context of CVD in RA, a disease associated with physical disability, a heightened risk of atherosclerosis and myocardial dysfunction.

Figure. Association of 400m Walk Completion Time with Coronary Calcium, Arterial Inflammation, and Myocardial Structure and Function



Means and 95% CIs shown. CAC=coronary artery calcium; SUV=standardized uptake variable; MDS=most diseases segment; LVMI=left ventricular mass index; GLS=global longitudinal strain

Methods: RA participants in a study of subclinical CVD underwent cardiac computed tomography (CT) for assessment of coronary artery calcification (CAC), 18-flourodeoxyglucose (FDG) positron emission tomography (PET) CT for assessment of aortic FDG uptake (a measure of atherosclerotic plaque inflammation) and myocardial FDG uptake (a measure of myocarditis), stressed N-13 ammonia PET for assessment of coronary microvascular dysfunction (CMD) and 3D echocardiography for assessment of left ventricular structure and function. Patients also underwent the 400m timed walk test. Generalized linear models were used to model walking endurance (i.e. total walking time) and walking speed with CVD outcomes, adjusting for potential confounders. We explored whether self-reported disability—as captured by the Health Assessment Questionnaire (HAQ)—recreated the same associations as the walk test.

Results: A total of 119 RA patients were studied [mean age=54 ± 13 years; 82% female; 74% seropositive for RF or anti-CCP; median RA duration=7 years; median DAS28-CRP=3.9]. Among these, 103 (87%) completed the walk test. Nine (8%) started but could not complete the walk, and 7 (6%) did not initiate the test. Among completers, those in the slowest time tertile were significantly older, had higher BMIs and more traditional CVD risk factors. RA duration, DAS28-CRP, tender joint count, CRP and HAQ scores were significantly higher in the slower tertile compared with the faster, but DMARD treatment did not differ. Slower completion time was associated with significantly higher CAC, aortic FDG uptake, left ventricular mass index and echocardiographic measures consistent with diastolic dysfunction (i.e. higher E/e' ratio) (Figure). Although ejection fraction did not differ according to walk time, global longitudinal strain was worst in the slower group (Figure). Neither walk time nor walk speed was associated with myocardial FDG uptake or CMD. Modeling HAQ for walk time and walk speed did not recreate the associations. However, modeling potential confounders eliminated the associations of walk time and walk speed with all of the CVD outcomes except walk time with aortic FDG uptake, which remained significantly associated with slower walk time after adjustment for relevant confounders.

Conclusion: Although not independently associated with all CVD outcomes, walking endurance and speed is a potential summary measure of CVD risk that is a composite of multiple traditional and inflammatory risk factors for atherosclerosis and myocardial dysfunction in RA.

Association of 400m Walk Completion Time with Coronary Calcium, Arterial Inflammation, and Myocardial Structure and Function

---

Table 2. Rheumatoid Arthritis disease characteristics among patients included.

Background/Purpose: To assess the Cardiovascular Risk (CV) in Rheumatoid Arthritis (RA) patients using carotid ultasonography additionally to the traditional CV risk factors.

Methods: A single center cross-sectional case control study was performed. Inclusion criteria were adult patients who fulfilled the ACR/EULAR 2010 RA criteria (cases) and matched healthy adults in terms of age, sex and CV risk factors (controls). Population over 75 years old, patients with established CV disease and/or chronic kidney disease (from III Stage) were excluded. Controls with other inflammatory diseases, pregnant women or any malignancy were also excluded. This study was performed from July-2019 to January-2020.

CV risk assessment included risk factors collection such as serum biomarkers (glucose, total cholesterol, HDL cholesterol, LDL cholesterol, Triglycerides, Creatinine, Glomerular filtrate [CKD-EPI], uric acid, C reactive protein [CRP], Erythrocyte Sedimentation Rate [ESR]), Body Mass Index, life style habits, family history of early CV disease.

The US evaluator was blinded to the case/control condition and evaluated the carotid artery by using B-mode imaging of the arterial wall, color doppler flow analysis, presence of plaques, plaque number and measured the intima-media thickness in both right and left carotid.

Characteristic	RA cases n=200	Healthy controls n=111
Blood test		
Fasting plasma glucose –mg/dL	92.14 (14.98)	93.31 (15.22)
Estimated glomerular filtration rate	84.36 (17.49)	89.41 (15.37)
Uric acid – mg/dL	4.46 (1.2)	4.82 (1.33)
Total cholesterol –mg/dL	197.88 (37.17)	194.77 (35.79)
cLDL –mg/dL	108.79 (34.48)	114.44 (30.93)
cHDL –mg/dL	63.72 (15.66)	56.99 (15.1)
CT/cHDL	3.28 (0.97)	3.77 (1.05)
Tryglicerides –mg/dL	119.56 (63.83)	121.58 (75.08)
CRP –mg/dL	5.46 (8.5)	2.31 (2.32)
ESR –mm/h	20.75 (16.58)	11.25 (7.42)
25-hydroxyvitamin D –ng/mL	31.1 (11.78)	26.26 (9.87)
Ultrasound findings		
Right carotid cIMT	0.78 (0.15)	0.62 (0.11)
Left carotid cIMT	0.77 (0.14)	0.64 (0.12)
Plaques	101 (50.5%)	32 (28.83%)
Bilateral	64 (32%)	11 (9.91%)
Right carotid	17 (8.5%)	7 (6.31%)
Left carotid	20 (10%)	14 (12.61%)

Table 3. Blood test and Ultrasound Results in patients and controls.

Statistical analysis was performed with R software (3.6.1 version) and included a multivariate variance analysis (Manova) and a negative binomial regression adjusted by confounding factors.

Results: Overall, a total of 200 cases and 111 healthy controls were included in the study. Demographical and clinical variables were comparable between cases and controls and are shown in Table 1. In both groups a relationship between age, BMI and high blood pressure was detected (p< 0.001). RA disease characteristics are displayed in Table 2.

US study revealed a higher IMT in both right and left carotid arteries with greater presence of plaques in patients than in controls (CI 95% [1.542; 3.436], p< 0.001). Plaques were found in both carotid arteries in the 32% of cases and 9.91% of controls. The longer duration of RA was related to a higher presence of carotid plaques (95% [1.015; 1.056], p< 0.001). The age was also related to plaque development (CI 95% [1.051; 1.094], p< 0.001) as seen with high blood pressure (CI 95% [1.124; 2.27], p=0.012). Female sex protected against carotid plaques presence (CI 95% [0.367; 0.856], p=0-009). US and blood test results are shown in Table 3.

Conclusion: RA leads to a higher intima-media thickness and this is related to the disease duration. Traditional risk factor may explain only partially the global CV risk in RA. These findings might support that RA acts as an independent cardiovascular risk factor.

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: A novel score for predicting 3-year risk for CVD events in RA patients combines age, four traditional CVD risk factors (diabetes, hypertension, smoking, history of high-risk CVD event), a personalized assessment of RA-related inflammation based on the multi-biomarker disease activity (MBDA) score and, individually, 3 of its 12 biomarkers, TNF-R1, MMP-3 and leptin (log-transformed). This score was developed and internally validated using patient data from the Medicare database. The purpose of this analysis was to externally validate the MBDA-based CVD risk prediction score in a younger cohort from the Symphony claims database.

Methods: A cohort of patients ≥18 years old with RA diagnosis from a rheumatologist and evidence of an RA-specific treatment, excluding patients with malignancy, past myocardial infarction (MI) or stroke, was created by a third party (Symphony) by matching medical and pharmaceutical claims and linking them to MBDA scores from a database of tests done for routine care. Medicare patients were excluded to avoid overlap with the internal validation cohort. Only the first MBDA test was used for each patient. The study endpoint was time from MBDA testing to first CVD event within a 3-year time horizon. CVD event was defined as MI or stroke, based on ICD-9 or ICD-10 diagnosis codes in hospital claims. Analyses focused on relative risk, not absolute risk, because CVD event data in Symphony may be incomplete. A univariate Cox proportional hazards regression model was fit with the MBDA-based CVD risk score as the sole predictor of time to CVD event to obtain a hazard ratio (HR) estimate (95% CI) and p-values from a likelihood ratio test (LRT). Sensitivity analyses determined HR for patient subgroups, with p-values determined for the interaction between subgroups and the MBDA-based CVD risk score. Using a multivariate Cox proportional hazard regres-

Variable	Median (IQR) or N (%)
Total patients	48,868
Age, years	54 (46-60)
Sex, male	8,940 (18.3%)
Diabetes	7,974 (16.3%)
Hypertension	19,132 (39.2%)
History of high-risk CVD event	6,713 (13.7%)
Smoking	7,487 (15.3%)
CRP, mg/L	4.1 (1.4-11.5)
Leptin, ng/mL	24.3 (10.6-47.1)
MMP-3, ng/mL	21.1 (14.3-36.2)
TNF-RI, ng/mL	1.4 (1.1-1.7)
MBDA score	40 (31-48)
MBDA-based CVD risk score	3.3 (2.8-3.8)

Table 1. Cohort characteristics of RA patients with linked biomarker data and at risk for CVD events.

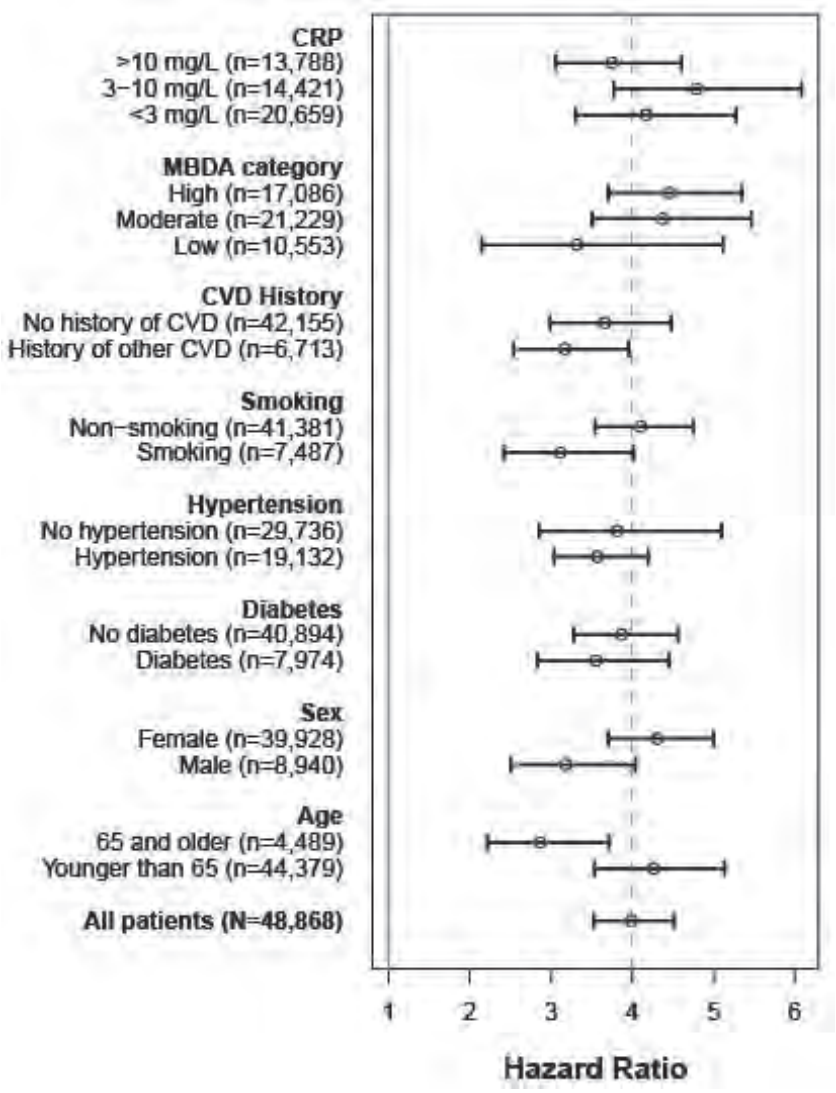

Figure 1. Hazard ratios for CVD event over 3 years in the external validation dataset (N=48,868). Vertical dashed line indicates the hazard ratio for all patients.

sion model, the MBDA-based CVD risk score was compared to a simpler model that included only age, sex, diabetes, hypertension, history of other CVD, smoking and CRP (log-transformed) for ability to predict time to a CVD event.

Results: 48,868 patients with 337 CVD events met eligibility criteria and had linked biomarker data. Mean age was 54.4 years. 81.7% were female (Table 1). Mean follow-up was 24.4 months. The MBDA-based CVD risk score (mean 3.3, IQR 2.8–3.8) was highly significant in univariate analysis, with HR = 3.99 (95% CI: 3.52-4.51, $p = 4.4\times10^{-95}$); i.e., for every 1-unit increase in risk score, the CVD event rate in this cohort was ~4 times as high. Similar results were seen in the subset of 44,379 patients < 65 years old, with HR=4.26 (95% CI: 3.53-5.14, $p = 1.2\times10^{-47}$). In sensitivity analyses, after adjusting for multiple comparisons, there were no significant differences between HR of complementary subgroups (Figure 1). The MBDA-based CVD risk score added significant prognostic information to a simpler, clinical model (HR=2.28 [95% CI: 1.69-3.08, $p = 1.6\times10^{-7}$] after accounting for all other factors).

Conclusion: The MBDA-based CVD risk prediction score has been externally validated in a cohort that is younger than and independent of the Medicare cohort used previously for test development and internal validation.

Gains in Cardiovascular Risk Knowledge Through Web Based Educational Intervention for Rheumatoid Arthritis Patients

Meenakshi Jolly[1], Courtney O'Brien[1], Aman Kugasia[2], Anna Gorfin[3], Lauren Klebek[3], Joshlean Fair[3] and Joel Block[1], [1]Rush University, Chicago, IL, [2]Arthritis Clinic of Cypress and Katy, PA, Katy, TX, [3]Rush University, Chicago

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) is a leading cause of mortality in rheumatoid arthritis (RA). Ischemic heart disease in RA is often silent and precedes myocardial infarction. Patients' understanding of conventional and RA-specific CVD risks is pivotal to improving CVD mortality in RA. We describe the results evaluating the effectiveness of a web based educational intervention (EI) for RA patients towards improving their CVD risk knowledge.

Methods: 296 consenting RA patients were enrolled through Rush University Rheumatology clinic. All patients completed demographics, Heart Disease Knowledge Questionnaire (HDKQ) and Heart Disease Fact Questionnaire-RA (HDFQ-RA)) at baseline; a higher score on the HDKQ & HDFQ indicates a higher level of knowledge. HDFQ-RA also includes RA specific CVD risk knowledge questions. An educational video was developed specifically for RA patients with emphasis on RA specific CVD risks. Patients in the EI arm (n=150) watched the 28-minute video, followed immediately by HDKQ and HDFQ-RA. All patients (EI and non EI) completed HDKQ and HDFQ-RA at a follow-up visit 3-4 months later. Medical chart reviews were completed for RA and CVD pertinent data. Correct response ratios (CRR) were obtained for both questionnaires. General linear model (GLM) analyses for repeated measure were used to compare within person changes with time and intervention status (EI or non EI) in CVD risk knowledge. Effect sizes (ES) for improvements were calculated.

Results: Mean age was 56.5±13.9 years, and 86% were women. 42% were Caucasians, and 40% were African American. There were no differences in EI or non EI group by age, gender, race, education, smoking, hypertension, dyslipidemia, diabetes, body mass index, disease activity or current use of steroids.

Mean (SD) CRR for HDKQ and HDFA-RA for 296 patients at baseline were 0.59 (0.18) and 0.76 (0.17) respectively. Summary scores for HDKQ and HDFA-RA at baseline, post intervention and 3 month follow up stratified by the study intervention group are shown in Table 1. Patients in the EI arm had significantly higher CRR on HDKQ than those in the non EI at baseline (p 0.007). Improvements in HDKQ were observed at 3 months in both EI (ES 0.35) and non EI (0.25) groups. Only within person changes in HDKQ were observed as significant on GLM. Large improvements were seen in the EI group on HDFQ-RA immediately post EI (ES 0.64), and the improvement in CVD risk knowledge was retained at 3 months post EI follow up (ES 0.48). There were no significant improvements noted in HDFQ-RA in non

Table 1: Correct Response Ratio for CVD risk Knowledge and Effect size as a function of time and intervention status

		Baseline		Post-Intervention				3 month

Table 1

Figure 1: Improvement in CVD Knowledge in RA through web based intervention

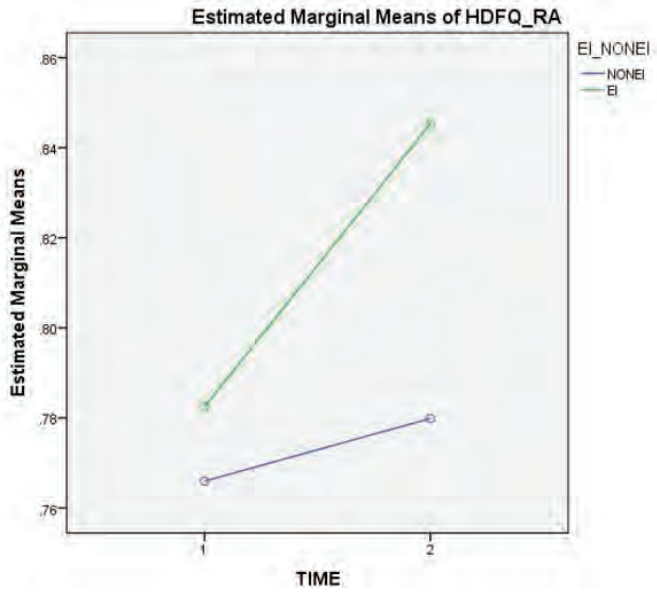

Figure 1

EI group patients at 3 months (ES 0.09). GLM showed both within (time) and between person changes (EI or non EI) to be significant with HDFQ-RA (Figure 1).

Conclusion: Large improvements in CVD risk knowledge (HDFA-RA) were observed among the patients who watched the educational intervention that specifically focused on RA related CVD risks, and the benefits were retained at 3 months. As expected, some improvements in CVD risk knowledge (HDKQ) were observed with time in both groups, as participation in the study and completion of the CVD risk questionnaires alone may have primed the participant's interest in the topic.

Increased Prevalence of Carotid Atherosclerosis in Postmenopausal Women with Rheumatoid Arthritis: A Case Control Study

Dionicio Ángel Galarza-Delgado[1], José Ramón Azpiri López[2], Iris Jazmín Colunga Pedraza[3], **Mayra Alejandra Reyes Soto**[3], Alejandra Pérez Villar[3], Itzel Corina Zárate Salinas[2], Paola Fernanda Frausto Lerma[3] and Salvador Lugo Pérez[2], [1]Rheumatology Service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Nuevo Leon, Mexico, [2]Cardiology Service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Mexico, [3]Rheumatology service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Mexico

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the primary cause of mortality in women in developed countries. CVD risk rises with age, yet for women there is a rapid increase in CVD that occurs after the onset of menopause (1). There has been found that there is four to five times atherosclerosis compared to premenopausal women. Adding to traditional CVD risk, subjects with rheumatoid arthritis (RA) have an increased CVD morbimortality because of the inflammatory disorder (2). To detect the burden of CVD, carotid ultrasound has been promoted to identify preclinical atherosclerosis.

Objectives: To determine the prevalence of carotid atherosclerosis and *carotid* intima-media thickness (cIMT) in postmenopausal patients with RA and compare them to matched controls.

Methods: Observational, cross-sectional study. RA patients aged 40 to 75 years that fulfilled 2010 ACR/EULAR criteria with post menopause and matched controls (without RA) were included. Patients with history of previous atherosclerotic CVD, women who undergone menopause due to hysterectomy or cessation of periods other than by a natural cause, women on hormone replacement therapy and having irregular menses were excluded. Clinical history and carotid ultrasound were performed by an expert radiologist. Increased cIMT was defined as ≥0.9 mm and carotid plaque as a focal narrowing ≥0.5 mm of the surrounding lumen. Descriptive analysis was done with frequencies (%), median (q25-q75). Comparisons with Chi-square and Mann Whitney-U test. Binary regression analysis was used to test association an increased cIMT with cardiovascular risk factors and RA diagnosis.

GRAPHIC 1. BASELINE CHARACTERISTICS

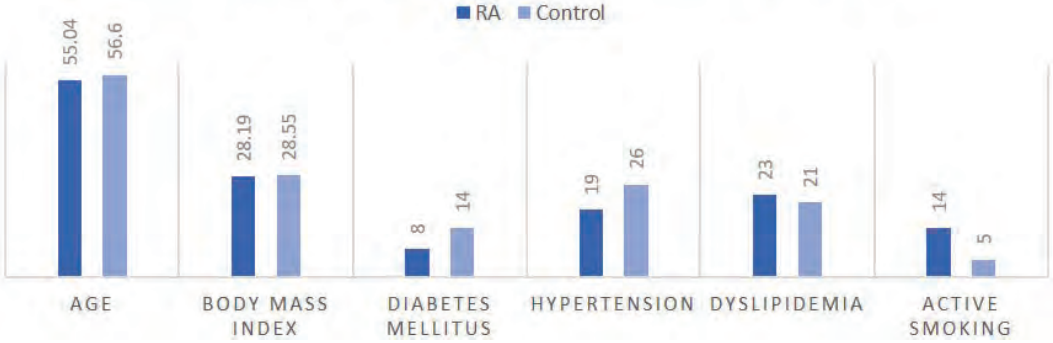

Table 2. Carotid ultrasound findings	RA (N= 70)	Controls (N=69)	p
Any plaque, n (%)	24 (34.3)	17 (24.6)	NS
Right CP, n (%)	19 (27.9)	8 (11.6)	0.01
Left CP, n (%)	17 (25)	13 (18.8)	NS
Any cIMT ≥0.9 mm, n (%)	38 (54.3)	19 (27.5)	0.001
Right carotid cIMT ≥0.9 mm, n (%)	25 (35.7)	10 (14.7	<0.001
Left carotid cIMT ≥0.9 mm, n (%)	31 (44.3)	15 (21.7)	<0.001
CP characteristics:			
Homogeneous n (%)	2 (2.8)	3 (4.3)	NS
Heterogeneous, n (%)	20 (28.6)	16 (23.2)	NS
CP:carotid plaque			

Results: A total of 139 women with established menopause were included. Median of disease duration of RA patients 10.32 (4.5-15.3). Baseline characteristics (Graphic 1). Right carotid atherosclerosis prevalence was found more than twice (19% vs 8%, p=0.01) and an increased cIMT was found higher in postmenopausal RA patients (right 25% vs 10%, p=< 0.001; left 31% vs 15%, p=< 0.001) compared to controls (Table 2). Binary regression showed that the odds of having RA increases three times the risk of having ≥0.9 mm CIMT when adjusted to age, hypertension, dyslipidemia, and active smoking OR 3.0, 95% CI (1.41-6.36) (p=0.004).

Conclusion: Despite the increase in cardiovascular risk in postmenopausal women compared to the general population, women with RA have a higher risk compared to healthy women. Carrying out cardiovascular prevention and management in patients with RA is essential, especially in those who are in a stage of post-menopause.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Heart failure (HF) is a major cause of mortality in rheumatoid arthritis (RA) and is broadly categorized into two subtypes, each with distinct pathophysiology: HF with preserved ejection fraction (HFpEF) and HF with reduced EF (HFrEF). Studies of HF subtypes in RA are limited as the EF data are typically embedded in narrative notes. Natural language processing (NLP) has allowed for efficient extraction of EF data from the electronic health

Table 1. Clinical characteristics of RA patients with HF compared those without evidence of HF. Demographics assessed at RA index date; RA-specific factors assessed between RA index date and end of follow-up; traditional HF factors assessed prior to RA index date.

Clinical characteristics	HF (n=1,007)	No HF (n=7,628)
Age (years, mean, sd)	66.22 (11.92)	54.73 (14.39)

records (EHR) facilitating studies of HF subtypes. The objective of this study was to examine the association between clinical risk factors for incident HF as well as the two subtypes, HFpEF and HFrEF, among RA patients.

Methods: Utilizing a validated EHR-based RA cohort (n=16,248), we identified patients with HF using a published approach (PPV=90%) and extracted EF using NLP from cardiac imaging reports. The RA index date was defined as the first occurrence of RA ICD-9, 10, or NLP code. The HF incident date was the date of the first HF ICD code. patients with HF were classified into HFrEF (EF< 40%) or HFpEF (EF >50%) using the EF value closest to the HF incident date. We excluded patients with < 1-year of EHR data, and those with HF prior to the RA index date. Follow-up started at the RA index date and continued through incident HF or a censoring event (death or last known visit date). Demographics were assessed at the RA index date; known comorbidities associated with HF from the general population were assessed from EHR entry to RA index date; and RA-specific factors were assessed from the RA index date until HF diagnosis or censoring; erythrocyte sedimentation rate (ESR), the most common inflammatory marker avail-

* Only variables with significant associations shown. Multivariable logistic regression model adjusted for age, sex, race, RA serostatus, ESR, methotrexate, TNFi, other bDMARD and nbDMARD, corticosteroid, peripheral vascular disease, diabetes, hypertension, valvular disease, CAD, atrial fibrillation, dyslipidemia, chronic kidney disease, stroke, and Charlson's comorbidity index.
CAD, coronary artery disease; DMARD, disease-modifying anti-rheumatic drug (nbDMARD: non-biologic DMARD, bDMARD: biologic DMARD); EF, ejection fraction; HF, heart failure; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction; RA, rheumatoid arthritis; TNFi, tumor necrosis factor alpha inhibitor.

Table 2. Clinical factors associated with incident (a) HF, (b) HFpEF, and (c) HFrEF vs. no HF (reference) among RA patients.

able was averaged from RA index date to either HF event or time of censoring. We tested the association between RA-specific factors with overall HF, HFpEF, and HFrEF using logistic regression adjusting for potential confounders.

Results: We studied 8635 RA patients of which 1007 (11.7%) developed HF during 9.3 (SD 6.5) years follow-up. In this RA cohort, patients with HF were older, more likely to be male, Caucasian, and had more comorbidities compared to those without HF (Table 1).

Higher levels of ESR was associated with a higher overall HF risk and across both subtypes compared to RA patients without HF, while MTX use was associated with a reduced risk in all HF patients, and in HFpEF and HFrEF (Table 2). TNFi and nbDMARD use was associated with a reduced risk of HFpEF but not HFrEF, after adjusting for potential confounders. Comorbidities more strongly associated with HFpEF and not HFrEF included valvular disease, hypertension, and diabetes, consistent with studies from the general population.

Conclusion: In this large cohort of RA patients, we observed differences in risk factors associated with incident HFpEF compared to HFrEF. While TNFi use is not recommended for patients with moderate to severe HF, these data suggest that TNFi's may have a different effect for risk of HF depending on the subtype. Future studies with more detailed drug data are needed to closely examine DMARD use and risk of HFpEF vs HFrEF in RA.

Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) patients are at nearly 50% increased risk of heart failure (HF) compared to non-RA patients, despite adjusting for the presence of coronary artery disease, suggesting that RA associated inflammation is an independent contributor to HF. Higher prevalence of diastolic dysfunction as well as significantly higher rate of change in key diastolic parameters (mitral A wave velocity, mitral E/A, and Left Atrial Volume Index (LAVI)) were demonstrated in RA patients without clinical HF vs. controls. While significant associations between baseline patient reported RA characteristics and adverse changes in diastolic parameters have been demonstrated, an association between RA disease activity against baseline and/or change in diastolic function has not yet been elucidated.

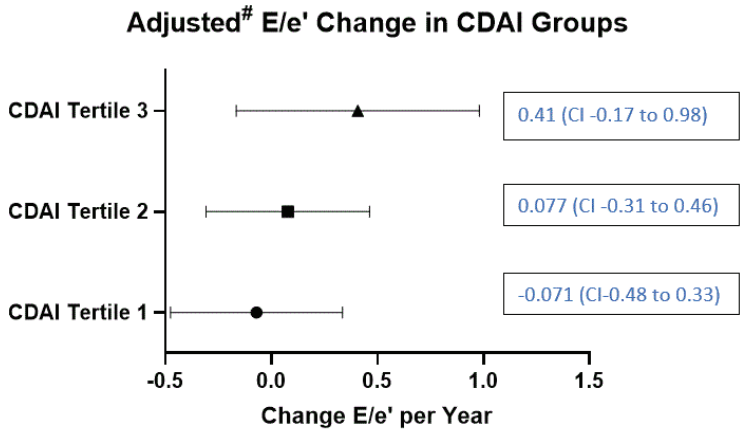
Methods: RA patients (N=163) without clinical cardiovascular disease were enrolled and followed over a 3-to 6-year time period. At baseline, patients underwent echocardiography and assessment of cardiovascular and RA associated disease risk factors. A subset (n=60) underwent repeat echocardiography on a subsequent visit 3-6 years later. Diastolic function was assessed according to 2015 guidelines. Annualized rate of change for each chosen diastolic outcome variable (E/e', E/A, tricuspid regurgitation (TR) velocity, LAVI, Deceleration Time (DT) of E wave) was calculated. Multivariable regression models were used to adjust for biologically plausible confounders identified from univariate regressions.

Table 1. Longitudinal Change in Diastolic Parameters

*Diastolic Parameters	Mean Annualized Rate of Change (SD)	P value
Δ E/e'	0.12 (0.81)	P=0.38#
Δ Septal e' Wave Velocity	-0.11 (0.46)	**P=0.05#**
Δ Lateral e' Wave Velocity	-0.22 (0.47)	**P=0.001##**
Δ E/A	-0.02 (0.07)	**P=0.03##**
Δ E Wave Velocity	-1.05 (3.91)	**P=0.01##**
Δ A Wave Velocity	0.34 (3.67)	P=0.60##
Δ Peak TR Velocity	0.07 (0.24)	P=0.63##
Δ Deceleration Time of E Wave	2.56 (20.22)	P=0.14##
Δ LAVI	0.09 (1.73)	P=0.82#

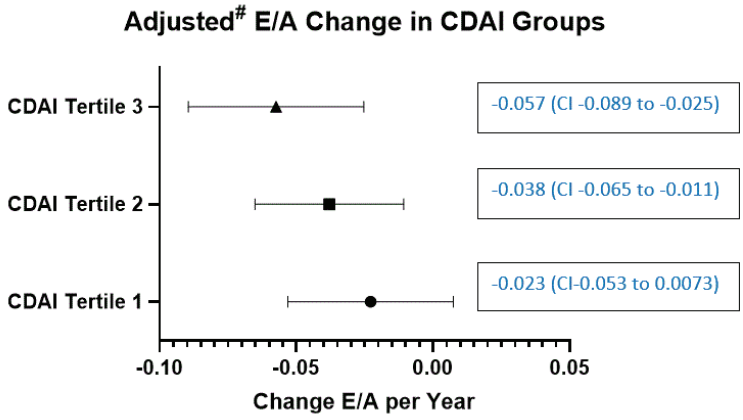
paired t-test; ## Wilcoxon signed rank test

Figure 1A.



#Adjusted for Age, Gender, BMI, SBP, MFR, and Prednisone Use

Figure 1B



#Adjusted for Gender, BMI, Race, LDL, CCP, HCQ use

Results: At least one abnormal diastolic parameter was observed in 59% of the cohort at baseline, and in 69% at follow-up. Significant decline in E velocity (*p=0.01*), lateral and septal e' velocity (*p=0.001 and p=0.05*, respectively) and E/A (*p=0.03*) were observed (*Table 1*). After adjustment for confounders, baseline E/e' was 0.363 units *higher* per square root Clinical Disease Activity Index (CDAI) (*p=0.002*) and 0.539 units *higher* per unit of DAS28CRP (*p=0.005*). Additionally, E/e' *increased* by 0.174 units/year per square root CDAI (*p=0.026)* in adjusted models. As CDAI increased in tertile, greater *increase* in E/e' per year was observed (*See Figure 1A*). Moreover, E/A *decreased* by 0.014 units/year per square root CDAI (*p=0.029*) in a final adjusted model. As CDAI increased in tertile, greater *decline* in E/A per year was observed (*See Figure 1B*).

Conclusion: We report significant adverse changes over time in 2 key diastolic parameters (increasing E/e' and decreasing E/A) in association with higher baseline disease activity, while adjusting for a number of potential confounders. Whether DMARD treatment and subsequent reduction of disease activity impacts baseline and follow up left ventricular structure and function in RA should be elaborated further in prospective/controlled studies.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: A novel risk prediction score combines serum biomarkers from the multi-biomarker disease activity (MBDA) test with clinical information to predict 3-year risk for a cardiovascular disease (CVD) event in RA patients. The CVD risk prediction score was developed and internally validated in a cohort of patients from the Medicare database. We have now examined the performance of the score in subgroups of patients of interest to practicing rheumatologists.

Methods: A cohort of RA patients age ≥40 with ≥1 RA diagnosis from a rheumatologist, without history of malignancy, past myocardial infarction (MI) or stroke was created by linking Medicare administrative data (2006-2016) to MBDA test results obtained during routine care. The cohort was randomly split 2:1 for training/internal validation. The composite CV outcome was MI, stroke or CV death occurring within 3 years. Candidate predictors for inclusion in model training were selected from traditional CV risk factors, RA-related factors and the MBDA score and its 12 biomarkers (log-transformed). Training was conducted using backward elimination. The final risk score algorithm included: age, diabetes, hypertension, smoking, prior history of CV disease, adjusted MBDA score, TNF-R1, MMP-3

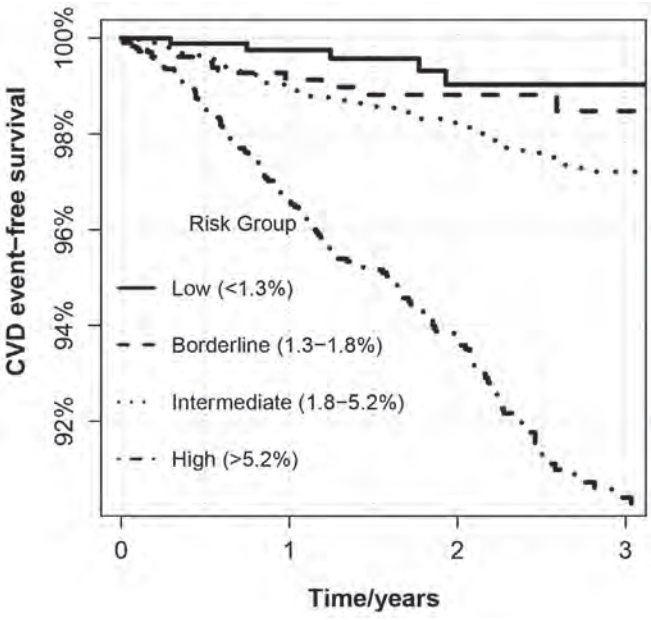

Figure 1. Kaplan-Meier plot for CVD event occurrence by the risk category predicted with the MBDA-based CVD risk score model, validation data (N=10,275)

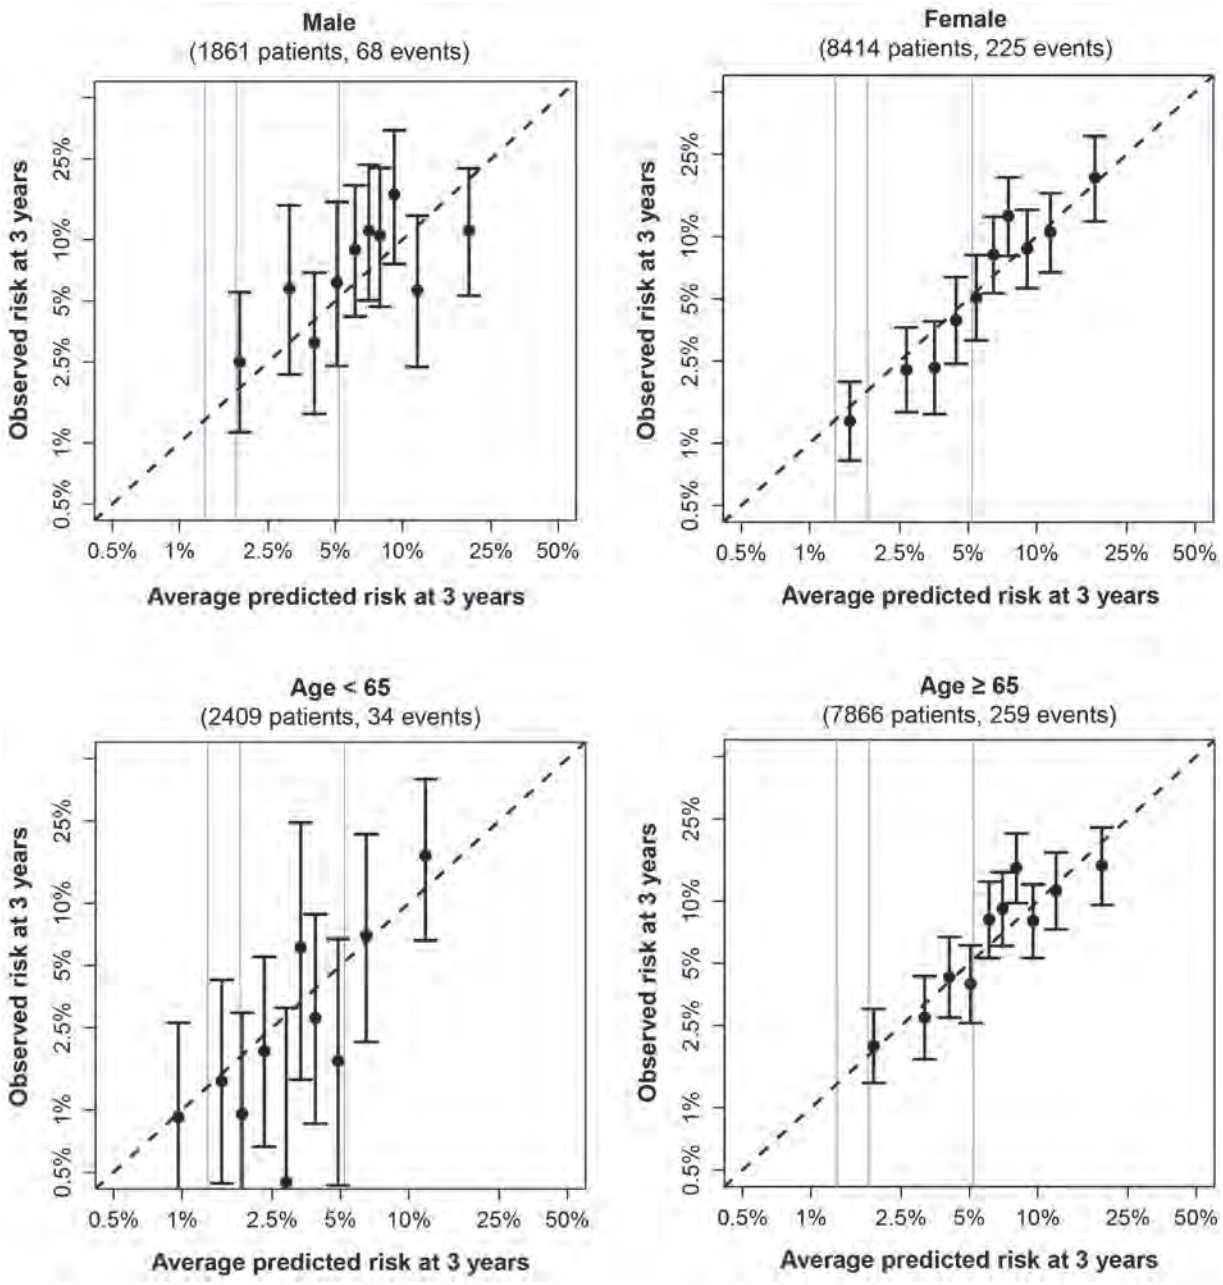

Figure 2. Goodness-of-fit Plots for Demographic Subgroups

and leptin. In the internal validation dataset this MBDA-based CV risk score was evaluated by: 1) Kaplan-Meier (KM) curves of observed event rates over time for patients grouped by the test into the low, borderline, intermediate or high categories of predicted risk and 2) goodness-of-fit plots showing the relationship between observed event rates and predicted risk for patients grouped by CV event-based deciles (based on Kaplan-Meier estimates with 95% CI).

Results: 30,751 RA patients were linked to MBDA test results and eligible for analysis. Mean (SD) age was 68.7 (9.5) years (23.4% < 65 years); 82% were women; mean MBDA score was 41 (14). Comorbidities were frequent (diabetes 39%, hypertension 78%, smoking 24%, history of high-risk CV condition 37%). RA-related features included use of glucocorticoids by 58%, methotrexate 60%, TNFi 33% and other biologics 16%. Median (IQR) 3-year CV risk predicted by the test was 3.4% (2.1%, 5.6%). Based on extrapolation to 10-year risk, 19.6% of patients would be

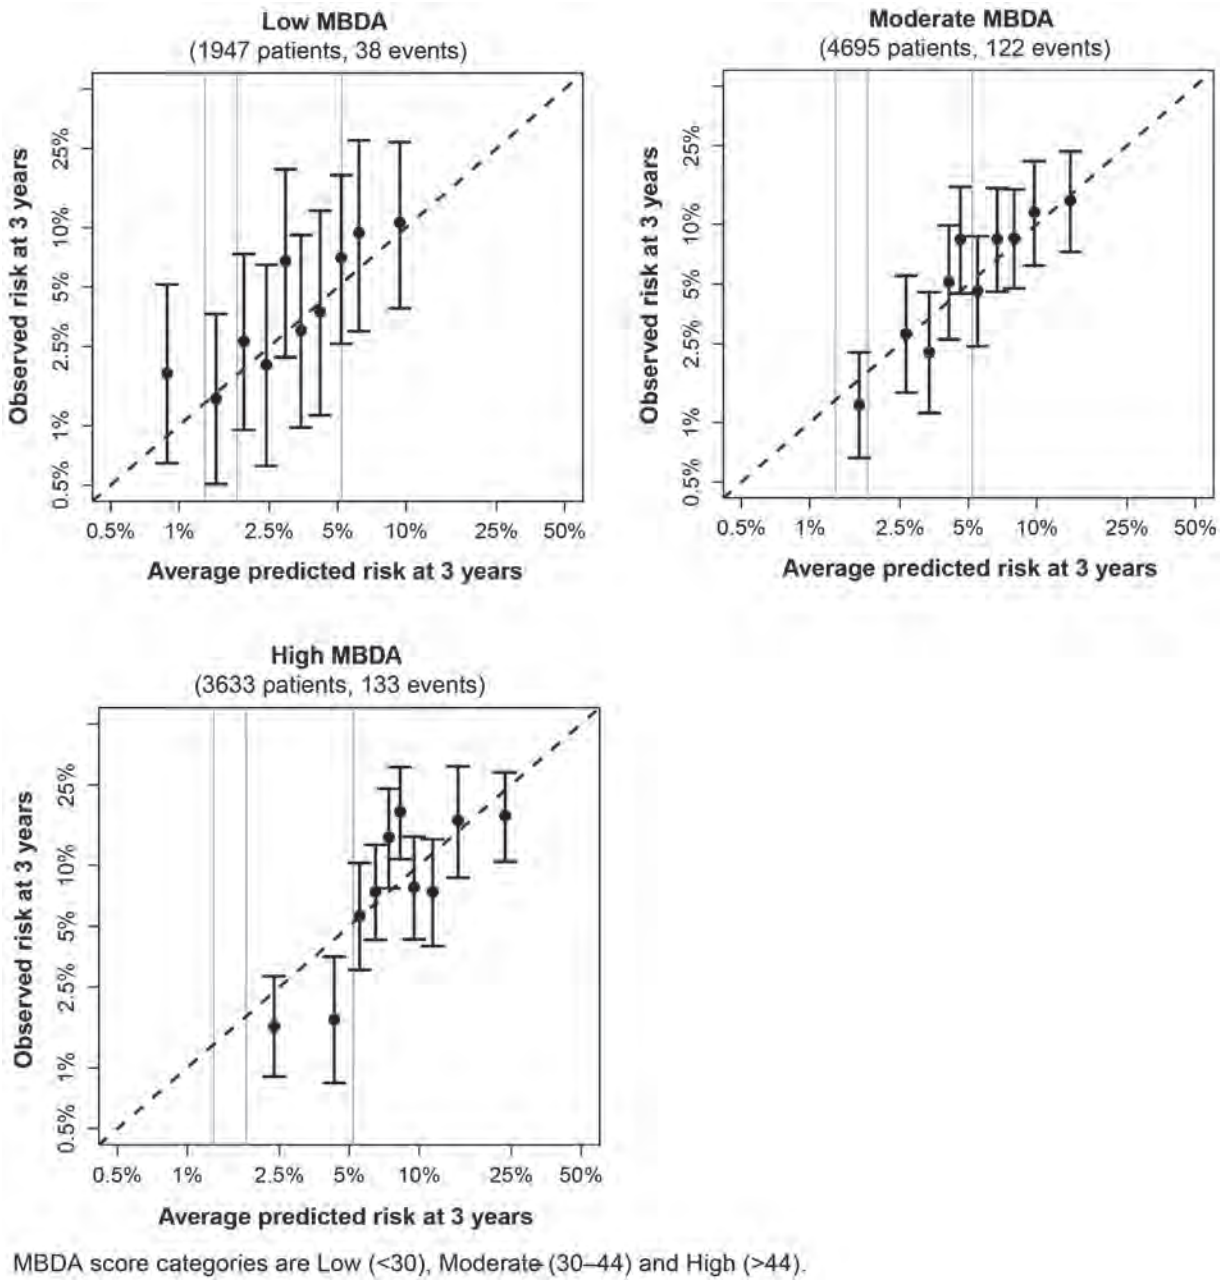

Figure 3. Goodness-of-fit Plots for Disease Activity Subgroups, based on Category of MBDA Score

considered low/borderline, 52.2% intermediate, and 28.2% high risk per ACC/AHA 2018 guidelines. In the validation dataset, CVD event rates increased the most over time for patients assigned by the test to categories of greatest CVD risk (Figure 1). The relationship between predicted CVD risk and observed CVD events demonstrated a good fit in the validation dataset, both overall and among patients grouped by sex, age, diabetes, prior CVD history, statin use, initiation of change of a biologic/targeted therapy and category of MBDA score (Figures 2 and 3).

Conclusion: The MBDA-based CVD risk prediction score, which combines biomarker and clinical variables, discriminated 3-year risk for a CVD event in RA patients. Predicted risk had good fit relative to observed CVD event rates, both overall and in several patient subgroups, including males/females, diabetics, statin users and patients with different levels of disease activity based on the MBDA score.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Peripheral blood red cell distribution width (RDW) and absolute lymphocyte count (ALC) are associated with aging, cardiovascular disease (CVD), and mortality in the general population, and in rheumatoid arthritis (RA) with disease activity. Little is known whether RDW or ALC are associated with specific parameters of inflammation or mortality in the setting of RA. We evaluated relationships between RDW, ALC, CVD, mortality, and plasma markers of systemic inflammation in persons with RA.

Methods: In a retrospective cohort of RA patients treated with methotrexate (MTX) since 2006 at a single VA Rheumatology Clinic with complete blood count lab results available prior to or during treatment (n = 499), we evaluated RDW and ALC prior to and over the course of MTX therapy, with and without the addition of TNF blocker. We further examined the associations between pre-treatment lab values and subsequent mortality. In a subset of these patients (n=64), and in non-RA general medicine clinic controls (n=37) we evaluated relationships between plasma levels of soluble tumor necrosis factor receptor II (sTNF RII), C-reactive protein (CRP), interleukin-6 (IL-6), soluble cluster of differentiation 14 (sCD14), sCD163, Pentraxin 3 (PTX3), Mac-2 binding protein (Mac2BP), and Monocyte Chemoattractant Protein-1 (MCP-1) by ELISA, and RDW and ALC.

Results: High RDW and Low ALC prior to treatment were both associated with increased mortality (log-rank test $p< 0.001$ for RDW > 14; $p=0.018$ for ALC < 1.2). Patients with both low ALC and high RDW had higher mortality than patients with neither or either alone ($p< 0.001$). After adjusting for age and co-morbidities, high RDW remained signif-

icantly associated with mortality (Cox regression model p< 0.001). In the sub-cohort sCD14, sCD163, TNFRII, IL-6, and MCP-1 plasma levels were higher in participants with RA than controls, and RDW levels correlated with PTX3 and MCP-1 levels, while ALC levels negatively correlated with RDW, sCD14, TNF RII, and sCD163 levels. Given these associations between levels of inflammatory markers, ALC and RDW, we evaluated the effect of in vivo MTX and TNF blocker therapy on RDW and ALC levels using longitudinal modelling adjusting for correlated results within patient. We observed MTX to result in increased RDW and lower ALC levels (pre-treatment vs. MTX, p< 0.01 for each), and this was partially reversed by the addition of TNF blocker therapy (MTX vs. MTX + TNFa, p< 0.01 for each).

Conclusion: These findings are consistent with a model wherein inflammatory pathways associated with RA alter erythropoiesis (reflected by RDW) and drive lymphopenia (before and/or after starting DMARD therapy) in association with specific biomarkers of monocyte/macrophage activity. Partial reversal with TNF blockade implies mechanistic/causal linkages. Together, these data suggest immunohematologic dysfunction in the context of RA identifies a poor prognosis, but may be reversible with TNF inhibition.

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has been shown to be associated with increased risk of cardiovascular disease (CVD) and mortality. Red cell distribution width (RDW) represents the variability of red blood cell size. RDW correlates with CVD in the general population as well as in those with spondyloarthritis including psoriatic arthritis. RDW also correlates with RA disease activity as measured by acute phase reactants. We explored the relationship between RDW, CVD and the composite of traditional cardiovascular risk factors, the Atherosclerotic Cardiovascular Disease (ASCVD) risk score, in patients with seropositive RA.

Methods: A retrospective chart review study was conducted at the Cleveland VA Medical Center. Medical records were reviewed for RA ICD10 diagnosis in 2017 in patients being treated with MTX monotherapy for seropositive RA (rheumatoid factor (RF) and/or cyclic citrullinated peptide antibody positive (CCP)). Charts were reviewed for de-

Table 1 lists the clinical characteristics of the 95 patients at the start of therapy and at the last available time point.

mographic information, concomitant diagnoses of diabetes, hypertension, CVD diagnosis and ASCVD risk factors as calculated by the ASCVD 10-Year Risk Score. RDW, C-Reactive Protein (CRP), hemoglobin, platelet count, and albumin were collected prior to the start of MTX, 6 and 12 months into therapy, and at the last time point available. ASCVD Risk Score was calculated both prior to treatment with MTX and at the last available time point. When calculating ASCVD Risk Score, if age or lipid levels were above or below the limitations of the calculator, either the upper or lower limit values were used, respectively. Correlations were analyzed by Spearman's and differences among groups by Mann-Whitney U (spss v24).

Results: Clinical characteristics of the 95 patients at the start of therapy and at the last available time point are shown in Table 1.

Prior to therapy with MTX: RDW positively correlated with CRP ($r=0.3$, $p=0.007$) and negatively correlated with albumin ($r= -0.4$, $p< 0.0001$), and hemoglobin ($r= -0.4$, $p< 0.0001$), but did not correlate with the ASCVD 10-Year Risk Score ($r=0.2$, $p=0.07$) or CVD at any time point ($p=0.6$).

Table 2: Treatment at the Last Available Time Point	
Treatment	**n**
MTX monotherapy	23
MTX + conventional DMARD (hydroxychloroquine, leflunomide, sulfasalazine)	22
MTX + biologic +/- conventional DMARD	7
Conventional or biologic DMARD, without MTX	27
No TX with DMARD	16
Total	**95**

Table 2 depicts the RA therapy of patients at the last available time point.

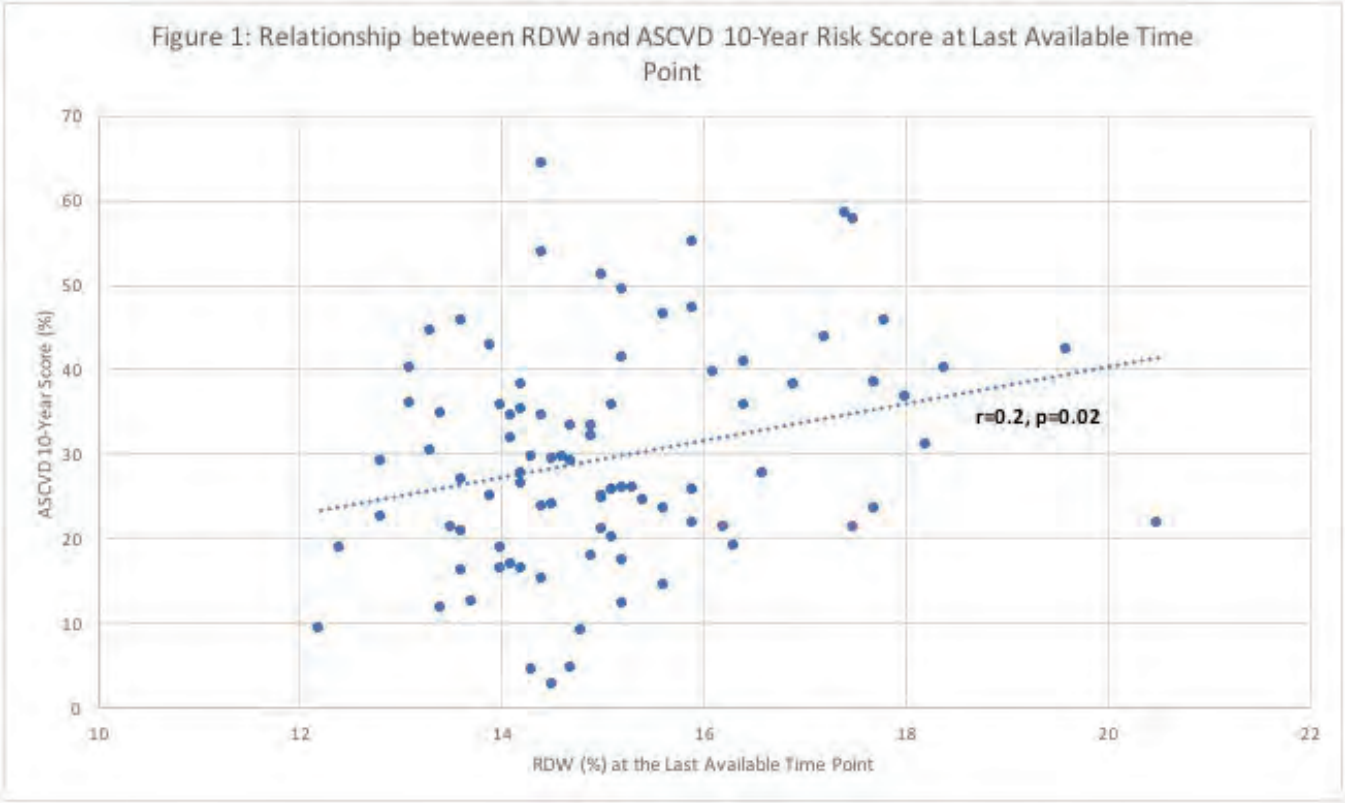

Figure 1 illustrates the linear relationship between RDW and ASCVD 10-Year Risk Score (r=0.2, p=0.02) at the last available time point.

At the last available time point: RA therapy at this time point is shown in Table 2. RA patients with CVD diagnosis had a higher ASCVD Risk Score (p=0.02). Positive correlations were found between RDW and age (r=0.3, p=0.002), and RDW and ASCVD 10-Year Risk Score (r=0.2, p=0.02) (Figure 1). Those RA patients diagnosed with CVD had higher RDW levels at the last endpoint (p=0.01) compared to RA patients without known CVD.

Conclusion: RDW correlates with ASCVD risk score and CVD in other arthropathies. Here we extend this observation to seropositive RA patients during the first year after the introduction of MTX. RDW prior to initiation of MTX associated with parameters of inflammation, including higher CRP, and lower albumin, but not ASCVD risk score or CVD, perhaps making it limited for pre-screening for CVD at the pre-treatment time point. However, at the last available time point post introduction of therapy, RDW correlated with ASCVD Risk Score and was associated with CVD. Fur-

ther study of RDW as a biomarker of CVD in seropositive RA is warranted to help identify those patients who need more CVD risk abatement.

Serum Anti-malondialdehyde-acetaldehyde IgA Antibody Concentration Improves Prediction of Coronary Atherosclerosis Beyond Traditional Risk Factors in Patients with Rheumatoid Arthritis

Hannah Lomzenski[1], Geoffrey Thiele[2], Michael Duryee[2], Sheau-Chiann Chen[1], Fei Ye[1], Ted Mikuls[2], C. Michael Stein[1] and Michelle Ormseth[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased cardiovascular disease (CVD) independent of traditional risk factors. Oxidative stress is increased in patients with RA and may contribute to CVD. Malondialdehyde-acetaldehyde (MAA) protein adducts are highly immunogenic products of oxidative stress; and anti-MAA antibodies are detecTable in human serum. The aim of this study was to examine the relationship between anti-malondialdehyde-acetaldehyde (MAA) antibody concentrations and CVD risk factors in patients with RA and determine their utility as a predictive biomarker for coronary atherosclerosis.

Methods: In this cross-sectional study, serum concentrations of anti-MAA antibody isotypes (IgA, IgG, and IgM) were measured in 166 patients with RA by ELISA. The relationship between serum anti-MAA antibody concentrations and cardiometabolic measures in RA patients were examined by Spearman correlation. The predictive accuracy of anti-MAA antibodies for presence of any coronary artery calcium (CAC) and high CAC (≥300 Agatston units or ≥75th percentile) were examined by calculating the c-statistic with bootstrapping for internal validation of each fitted logistic regression model.

Results: Serum IgA anti-MAA antibody concentration was modestly associated with increased CAC (Rho=0.18, P=0.02), insulin resistance (Rho=0.18, P=0.03), and decreased high-density lipoprotein (HDL) particle number (Rho=-0.20, P=0.01). Serum IgG and IgM anti-MAA antibodies were not associated with increased CAC. The addition of anti-MAA IgA antibody concentration as an interaction term with ACC/AHA 10-year risk score improved the c-statistic from 0.83 to 0.85 for prediction of presence of CAC and improved the c-statistic from 0.72 to 0.75 for prediction of high CAC.

Conclusion: Anti-MAA IgA concentration is significantly associated with several non-traditional cardiovascular risk factors in patients with RA. Anti-MAA IgA concentration may aid in prediction of elevated atherosclerotic cardiovascular disease and risk stratification when added to standard measures of cardiovascular risk.

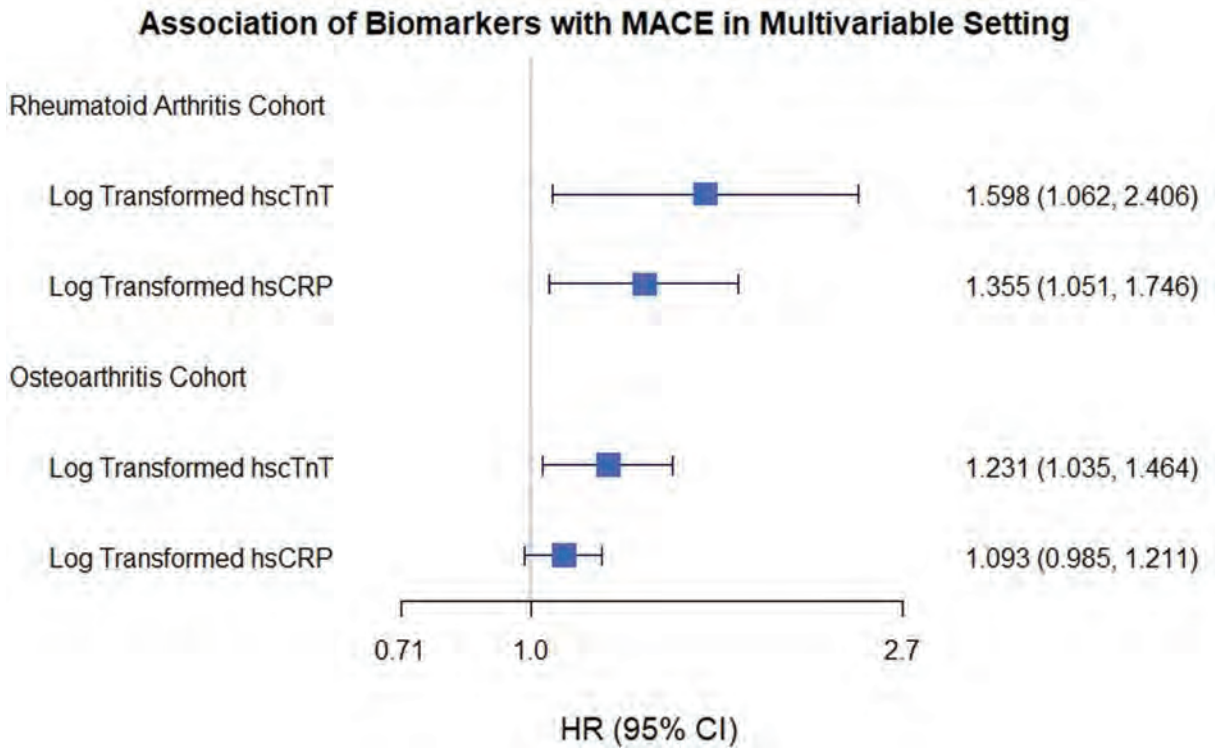
Serum High-sensitive Cardiac Troponin at Baseline Predict Cardiovascular Events in Rheumatoid Arthritis and Osteoarthritis

M. Elaine Husni[1], Daniel H Solomon[2], Mingyuan Shao[3], Katherine Wolski[3], Steven Nissen[3], Stanley Hazen[4] and WH Wilson Tang[4], [1]Cleveland Clinic, Cleveland, OH, [2]Brigham and Women's Hospital, Boston, MA, [3]Cleveland Clinic Foundation, Cleveland, OH, [4]Cleveland Clinic Foundation, Cleveland

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), excess mortality and inflammation has been attributed to cardiovascular (CV) diseases. High-sensitivity cardiac troponins (hscTnT) allow measurement of cardiac troponin concentrations below conventional levels of detection, and can be used to assess the severity of subclinical myocardial damage. Meanwhile, high-sensitivity C-reactive protein has traditionally been applied for CV risk stratification. We evaluated the prognostic relevance of hscTnT and hsCRP in RA and osteoarthritis (OA) patients enrolled in the PRECISION biomarker sub-study.



Methods: The PRECISION trial was a randomized, controlled non-inferiority clinical trial conducted worldwide involving patients who had RA or OA and with increased CV risk. We measured hscTnT (Roche Gen 5 STAT) and hsCRP (Roche) in a subset of 636 RA and 6,269 OA patients who participated in a biomarker sub-study. The primary CV outcome was major adverse cardiac events (MACE) which is defined as CV death, non-fatal myocardial infarction or non-fatal stroke, re-vascularization, hospitalization for unsTable angina or transient ischemic attack) with at least 18 months of follow-up. Multivariable Cox proportional hazards models were developed with age, gender and baseline status of the following: CAD, diabetes, hypertension, and smoking status as covariates.

Results: In the study cohort, mean age was 63.6±9.4 years, 58% were female, 80% Caucasian, and 32.7% were aCCP positive in the RA cohort. In the total cohort, 17.8% had known coronary artery disease, 36.5% diabetes, and 80% hypertension. The median baseline hscTnT was 6.3ng/L (IQR 3.6, 10.3) and was similar between the cohorts: 5.6ng/L [IQR 3.0, 9.1] in RA and 6.4ng/L [IQR 3.6, 10.3] in OA. We observed that baseline hscTnT was a significant predictor of MACE during follow-up in the RA cohort (HR 1.60, 95%CI 1.06, 2.41), as well as in the OA cohort (HR 1.23, 95%CI 1.04, 1.46, see Figure). In contrast, there was weaker association between baseline hsCRP levels and MACE in RA (HR 1.36, 95% CI 1.05, 1.75) and no significant association in OA (HR 1.09, 95% CI 0.99, 1.21).

Conclusion: In our study cohort, baseline hscTnT was independently associated with major adverse cardiovascular events in both RA and OA. There was a stronger association for both hsCRP and hscTnT in the RA cohort compared to the OA cohort. Further prospective studies addressing the predictive role of hscTnT for CVD events in patients with OA and RA can help expand preventative treatment strategies.

Sex Differences in Cardiovascular Disease Prevention in Patients with Rheumatoid Arthritis: World-wide Data from the SURF-RA

Elena Myasoedova[1], Cynthia Crowson[2], Joseph Sexton[3], Silvia Rollefstad[3] and Anne Grete Semb[4], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Preventive Cardio-Rheuma clinic, Dept Rheum, Diakonhjemmet Hospital, Oslo, Norway, Oslo, Norway

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with 2-fold increase in risk of cardiovascular (CV) disease. Extensive evidence from the general population suggests that control of CV risk factors helps in reducing CV morbidity and mortality. However, CV risk factor screening and management has been suboptimal both in the general population and in patients with RA. We aimed to establish whether there is a difference in CV risk factor screening and control of CV risk factors in RA by sex globally, and whether RA characteristics affect the likelihood of CV screening in women and men.

Table 1. Cardiovascular risk factor measures overall and by sex in patients with RA

Characteristic	Overall	Women	Men	P value[X]
Lipid panel available, n (%)*	9553 (66)	7055 (66)	2444 (67)	0.33
- Total cholesterol <174 mg/dL, n (%)**	3012 (32)	1980 (29)	1015 (42)	<0.0001
- LDL-C < 100 mg/dL, n (%)	3229 (36)	2308 (34)	903 (39)	<0.0001

* adjusted for age, sex, country and ethnicity
Abbreviations: 95%CI=95% Confidence Interval; HbA1C= Hemoglobin A1C; RF=rheumatoid factor; ACPA=anti-citrullinated protein antibodies; DAS28-CRP=disease activity score with 28 joint count and C-reactive protein (CRP)

Methods: The SUrvey of cardiovascular disease Risk Factor management in Rheumatoid Arthritis (SURF-RA) is an international clinical audit. The data were collected from rheumatology and cardiology clinics in Western and Eastern Europe, North and Latin America and Asia, using a one-page collection sheet. Information on demographics, CV risk factors (i.e. smoking, body mass index [BMI], physical activity, lipid panel, hemoglobin A1c [HbA1c], blood pressure [BP] measurements) and RA disease characteristics (i.e. serologic status, C-reactive protein [CRP], Disease activity score using 28 joints and CRP [DAS28-CRP]) was collected. Lipid panel and HbA1c were required within 1 year of clinic visit. CV Health Index Score was calculated as a sum of controlled CV risk factors out of the following six: smoking, BMI, physical activity, BP, low density lipoprotein cholesterol (LDL-C) and HbA1c. Normal levels were defined as follows: total cholesterol < 4.5 mmol/L (< 174 mg/dL), LDL-C < 2.5 mmol/L (< 100 mg/dL), BP< 140/90 mm/Hg, HbA1c < 7.0%, BMI < 25.0 kg/m^2.

Results: A total of 14,503 patients with RA from 53 centers in 19 countries were included in the study: mean age 60 years, 75% female, 57% rheumatoid factor (RF) positive, 54% positive for antibody to cyclic citrullinated peptide (ACPA), mean DAS28-CRP 3.0. Information on CV risk factor measures by sex is shown in Table 1. No difference was observed in frequency of assessment of lipid measures, BP or HbA1c. Men were more likely to have normal total cholesterol ($p< 0.0001$) and LDL-C than women ($p< 0.0001$). In contrast, women were more likely to have normal BP ($p< 0.0001$) and normal HbA1c ($p=0.02$) than men. Women had overall better CV Health Index Score than men ($p< 0.0001$). Table 2 shows associations of risk factor assessment in patients with RA, adjusting for age, sex, country and ethnicity. Longer RA disease duration, positivity for RF and ACPA, higher DAS28-CRP were associated with higher likelihood of lipid and BP testing, particularly in women, but did not appear to affect the odds of HbA1c assessment.

Conclusion: Women with RA are more likely to have normal BP and HbA1c, resulting in better overall control of CV risk factors, as assessed by CV Health Index Score than men. Patients with RF and/or ACPA, longer RA duration (particularly women), as well as men and women with higher DAS28-CRP are more likely to have lipid panel and BP assessments, suggesting physician awareness of adverse CV risk profile in RA.

Specificity for Inflammatory Pathways Associated with Coronary Microvascular Dysfunction in Rheumatoid Arthritis

Brittany Weber[1], Zeling He[1], Sicong Huang[1], Daniel H. Solomon[2], Elena Massarotti[1], Charlotte Golnik[1], Thany Seyok[1], Seth Brownmiller[1], Laurel Martell[1], Leann Barrett[1], Courtney Bibbo[1], Marcy Bolster[3], Marcelo DiCarli[1] and Katherine Liao[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Concord, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Coronary microvascular disease (CMD) is associated with increased mortality in RA independent of traditional cardiovascular (CV) risk factors. Inflammation likely plays an important role the pathogenesis of RA. Studies suggest that higher RA clinical disease activity index (CDAI) is associated with a higher degree of CMD. However, it is not known whether specific inflammatory pathways implicated in RA, including interleukin 6 (IL-6), tumor necrosis factor alpha (TNFα), and interleukin 1 beta (IL-1β), play a stronger role than others in the pathogenesis of CMD in RA. The objective of this study was to identify the associations between inflammatory cytokines and CMD in RA.

Methods: We used baseline data from the first 53 subjects enrolled in the Lipids, Inflammation, and CV Risk (LiiRA, ClinicalTrials.gov: NCT02714881) study. LiiRA enrolls RA patients, age >35, immediately prior to TNF inhibitor initiation. Exclusion criteria include known cardiovascular disease, statin use, prednisone dose >10mg, or biologic DMARD (bDMARD) use in the past 6 months. All subjects underwent a stress myocardial perfusion PET scan (cardiac PET). The cardiac PET quantifies myocardial blood flow at rest and during maximal hyperemia in response to a coronary vasodilator. Coronary flow reserve (CFR) is the ratio of myocardial blood flow during maximal hyperemia over that at rest. A lower CFR in the absence of obstructive coronary artery disease (CAD) is indicative of CMD.

Table 1. Baseline clinical characteristics of LiiRA subjects

Clinical characteristics	All, n= 53
Age, years mean (SD)	54.9 (11.1)
Female (%)	83.0
RA disease duration, years mean (SD)	9.1 (9)
Seropositive (%)	70
CDAI*, mean (SD)	22.2 (13.6)
Low (%)	22.6
Moderate (%)	34.0
High (%)	43.4
ESR mm/h, mean (SD)	29.3 (44)
Baseline RA treatment (%)	
Methotrexate	67.9
Sulfasalazine	1.9
Hydroxychloroquine	22.6
Leflunomide	13.2
No DMARD	17.0
Prednisone (%)	37.7
Prednisone, mean dose (SD)	8.7 (6.8)
Comorbidities (%)	
Hypertension	26.4
Coronary artery disease	0
Diabetes mellitus	0
BMI, mean (SD)	29.4 (6.7)
Family history of CVD (%)	60.4
Ever smoker (%)	43.4
Abnormal stress test, n (%)	3 (5.8)

CDAI=clinical disease activity index, CVD=cardiovascular disease, BMI=body mass index
*CDAI, remission=0-2.8; low activity=2.9-10.0; moderate activity 10.1-22.0; high activity 22.1-76.0

Demographics, RA clinical factors, serum inflammatory markers, and CDAI were collected. Inflammatory markers included high-sensitivity C-reactive protein (hsCRP), IL-6, soluble TNF receptor 2 (sTNFr2), and IL-1β. We tested the association between inflammatory markers and CFR using the Spearman correlation.

Results: The mean age of subjects in LiiRA was 55 years, 83% were female, 70% seropositive, with a mean RA disease duration of 9.1 years (Table 1); per the study protocol, none of the subjects were on a bDMARD. Baseline

Table 2: Correlation between inflammatory markers and coronary flow reserve (CFR)

Inflammatory marker	CFR	
	r	p-value
IL-6	-0.4	0.006
sTNFR2	-0.34	0.02
IL-1β	-0.1	0.5
hsCRP	-0.2	0.2

CFR=coronary flow reserve, IL-6=interleukin 6, sTNFR2=soluble tumor necrosis factor receptor 2, IL-1β= interleukin 1 beta, hsCRP=high sensitivity C reactive protein

cardiac risk factors were uncommon; no patients had diabetes and 26 % had hypertension. IL-6 and sTNFR2 were correlated with a lower CFR. However, no significant associations were observed between IL-1β and hsCRP (Table 2).

Conclusion: Among RA patients with no history of overt CAD and low prevalence of CV risk factors, the severity of CMD was correlated with IL-6 and sTNFR2 but not IL-1β or hsCRP, a general measure of inflammation. These findings provide potential insight into the mechanisms by which inflammation mediates microvascular dysfunction.

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

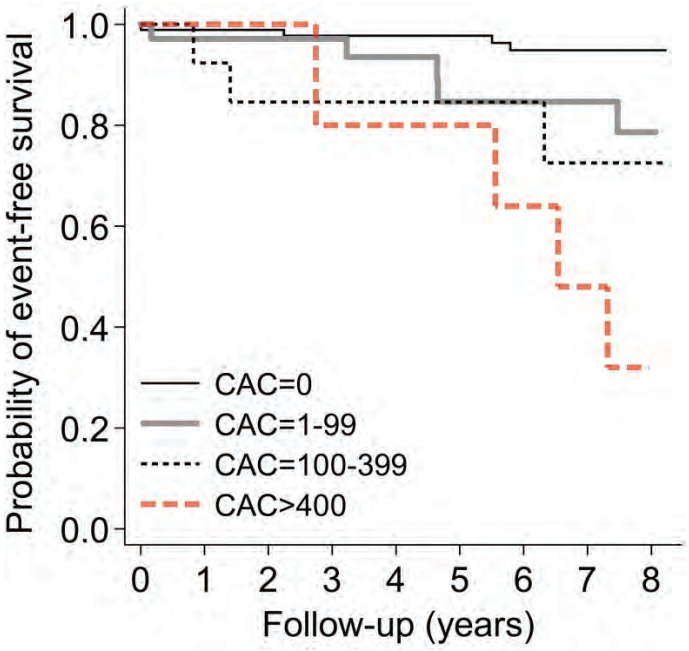

Figure 1. Increasing CAC scores associated with higher cardiovascular event risk in RA

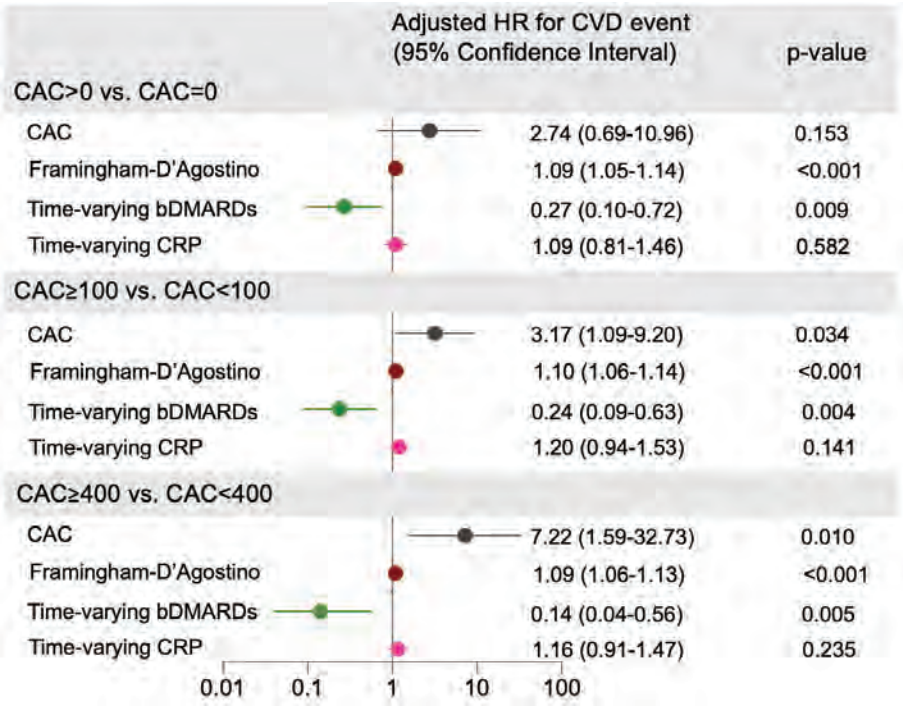

Figure 2. Impact of different CAC thresholds on cardiovascular event risk in RA

Background/Purpose: Large, multicenter studies established the strong prognostic value of coronary artery calcium (CAC) scoring in asymptomatic individuals. Increasing CAC score is an independent predictor of worsening cardiovascular disease event risk in general patients. The prognostic significance of higher CAC score strata in the long-term cardiovascular risk in rheumatoid arthritis (RA) is unknown. We sought to evaluate the long-term cardiovascular event risk across CAC strata in a prospective, single center cohort of established RA patients without symptoms or prior diagnosis of cardiovascular disease

Methods: One hundred-fifty patients underwent computed tomography angiography for coronary atherosclerosis evaluation. CAC score was measured according to Agatston. Cardiovascular disease (CVD) events were prospectively recorded, including cardiac death, myocardial infarction, unsTable angina, revascularization, stroke, claudication, and heart failure hospitalization over 6.0±2.4 years of follow-up. Unadjusted, robust Cox proportional hazards regression models evaluated CVD event risk across higher CAC strata (CAC = 1-99, CAC = 100-399 and CAC ≥ 400) compared to CAC = 0. Additional multivariable robust Cox regression models with time-varying covariates evaluated the impact of log transformed CAC or different CAC thresholds (CAC > 0 vs. CAC = 0, CAC ≥ 100 vs. CAC < 100 and CAC ≥ 400 vs. CAC < 400) on future CVD events. Models were controlled for Framingham-D'Agostino clinical risk score, time-varying current bDMARD use and time-varying CRP.

Results: Sixteen patients incurred 19 events, for a total of 2.1 (95% CI 1.3-3.3) events/100 patient-years. Increasing risk for cardiovascular events was observed across ascending CAC strata; HR 3.87 (95%CI 1.03-14.48), 6.31 (95%CI 1.38-28.91) and 16.98 (95%CI 4.50-64.10) for CAC = 1-99, CAC = 100-399 and CAC ≥ 400 respectively compared to CAC = 0 (Figure 1). In fully adjusted models, CAC score associated with future event risk independently of Framingham D'Agostino score, time-varying bDMARD use and time-varying CRP (HR 1.31 [95%CI 1.04-1.66]). CAC thresholds ≥ 100 (vs. < 100) and CAC ≥ 400 (vs. < 400) in fully adjusted models similarly constituted independent predictors of long-term cardiovascular events (Figure 2).

Conclusion: Increasing CAC scores are strong, independent predictors of long-term cardiovascular events in RA patients without symptoms or prior diagnosis of cardiovascular disease.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: To identify specific molecular profiles associated to the enhanced cardiovascular (CV)-risk present in Rheumatoid Arthritis (RA) patients and their modulation by biologic disease modifying anti-rheumatic drugs (b-DMARDs).

Methods: Two hundred and eleven RA patients and 52 healthy donors (HD) were recruited to the study. Serum inflammatory and oxidative stress biomolecules and Netosis-derived products were quantified, and miRNnomes were identified using next-generation sequencing miRNA assay. The CV-risk score was calculated following EULAR recommendations. To evaluate the contribution of molecular profiles to the CV-risk, unsupervised clustering analyses were developed.

In parallel cohorts of 45 and 27 RA patients, respectively, the in vivo effects of biologic drugs [anti-TNFalpha (TNFi) and anti-CD20 (CD20i) inhibitors] were evaluated before and after 6 months of therapy.

Results: A number of circulating biomolecules related to inflammation, NETosis, and oxidative stress were coordinately altered in the serum of RA patients and closely related to the activity of the disease. Besides, more than a hundred circulating miRNAs were found altered in RA patients and linked with the biomolecules found altered.

Unsupervised clustering analyses differentiated 2 clusters representing different molecular profile groups. Clinically, each cluster was characterized by: 1) RA patients with high CV-risk Score (7.01±8.4), medium disease score (DAS28: 3,37±1,4), and positivity for ACPAS and RF near 50%. 2) RA patients with low CV-risk Score (1.6±3.2), medium-high disease score (DAS28: 4.5±1.5) and positivity for ACPAS and RF around 75%. Interestingly, patients belonging to each cluster displayed a distinctive molecular profile in terms of inflammatory molecules deregulated, so that cluster 1 expressed higher levels of cytokines and chemokines related to cell proliferation, chemotaxis and angiogenesis (i.e. IFNg, IL5, IL6, IL10, IL15, VEGF, MCP1, and eotaxin), while in cluster 2 these molecules were reduced and predominated a different set of cytokines (IL1RA, IL1b, IL2, IL7, IL8, IL12, IL13, IL17, FGFb, MIP1b, TNFa). Hence, a different signature of miRNAs regulating these proteins was altered, so that in cluster 1 miR-106a-5p, miR-199a-5p and miR-148b-3p were reduced and miR-346, miR-299-3p, miR-6816 were elevated in relation to cluster 2. Likewise, NETosis derived products and oxidative stress molecules were increased in cluster 2 in comparison with cluster I. I*n vivo* treatments with TNFi and CD20i reduced disease activity and induced the re-establishment of normal levels in these altered biomolecules in an inhibitor-dependent manner.

Conclusion: 1. Extensive molecular profiling of serum in RA patients might help to define precise CV-risk profiles in RA patients. 2. Specific mediators of autoimmunity, inflammation, oxidative damage and Netosis, along with the miRNAs modulating their expression, coordinately determine a higher CV-risk score in RA patients. 3. Biological drugs, such as TNFi and CD20i re-establish normal levels of these circulating biomolecules, thus reducing the CV risk in RA patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is an extra-articular manifestation of rheumatoid arthritis (RA) detected in 20 to 60% of patients with RA on high-resolution computed-tomography (HRCT) chest scan and is clinically significant in near 10%. Despite a high morbi-mortality, a definite strategy for ILD screening in patients with RA remains to be determinate and the identification of markers predictive of the occurrence of ILD is needed. To date, numerous biomarkers have been reported to be associated with ILD among patients with RA but most of them requires validation in a prospective cohort. Recently, in a large international genetic association case-control study, the rs35705950 *MUC5B*promoter variant was identified as the major RA-ILD risk factor. The ESPOIR cohort included patients aged 18 to 70 years who had a definitive or probable diagnosis of RA and included a prospective follow-up. Consequently, we investigated in the ESPOIR cohort, whether the rs35705950 *MUC5B*promoter variant would improve risk stratification at baseline for ILD detection after 13 years of RA duration.

Methods: In this cross-sectional study of the French ESPOIR cohort, an ILD detection by chest HRCT scan was systematically proposed for every patient after 13 year of RA duration. Chest HRCT scans were centrally reviewed by an experienced radiologist and classified according to the presence, the extension and the pattern of ILD. All included patients were genotyped for rs35705950 *MUC5B*promoter variant. Baseline clinical and biological data were collect-

Variable		Odds ratio	p
MUC5Bd	GG	Reference

Baseline predictors of ILD occurence at 13 years of RA duration

ed. A logistic model was used to identify baseline predictors for the occurrence of ILD on HRCT scans. Confidence intervals were estimated using sampling methods.

Results: Among the 170 patients who were investigated with an HRCT scan (133 women (78.2%), mean RA duration 13.7 ±1.1 years), ILD was detected in 31 patients (18.2%). ILD extension was >10% in 9 patients (5.3%), fibrotic ILD was detected in 16 patients (9.4%). Two additional patients from the ESPOIR cohort that previously died from ILD were included in the analysis. Among European Caucasian patients, *MUC5B*rs35705950 minor allele frequency (MAF) was 26.5% in the RA-ILD population compared to 8.9% in the RA-noILD population (OR=6.0 $CI_{95\%}$(2.0-17.6)). After logistic regression, baseline predictors for ILD were male sex (OR=2.6 $CI_{95\%}$(1.0-6.6)), age at RA onset > 49 y/o (OR=5.2 $CI_{95\%}$(2.0-15.1)), number of swollen joints > 9 (OR=2.9 $CI_{95\%}$(1.2-7.2)), migrating arthritis vs persistent arthritis (OR=3.4 $CI_{95\%}$(1.4-8.7)) and *MUC5B*rs35705950 T risk allele (OR=3.8 $CI_{95\%}$(1.5-10.1)). The logistic model using could predict RA-ILD occurrence after 13 years of RA duration with an AUC=0.80 $CI_{95\%}$(0.72-0.90).

Conclusion: In RA patients, altogether with baseline clinical data, *MUC5B*rs35705950 genotyping could help to improve risk stratification for ILD occurrence at 13 years of RA duration.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) associated interstitial lung disease (ILD) and idiopathic pulmonary fibrosis (IPF) sharephenotypic and genotypic similarities. Recently, in a large international genetic association case-control study, the IPF major risk factor, *MUC5B*rs35705950 promoter variant was found to be associated with RA-ILD. Regarding IPF, *MUC5B*rs35705950 T risk allele has been associated with better prognosis. However, the impact of *MUC5B*rs35705950 on RA-ILD prognosis remains to be determined. Our objective was to explore the influence of *MUC5B*rs35705950 on pulmonary function tests (PFTs) evolution in patients with RA-ILD.

Methods: Patients with RA-ILD were included from France, USA, Mexico, Greece andtheNetherlands in this observationalinternational study. Patients were genotyped for *MUC5B*rs35705950 and PFTs data were collected. Longitudinal data up to a 10-year follow-up were considered and analyzed using mixed regression models. We defined a significant deterioration of pulmonary function as an absolute decrease of at least 10% in FVC (expressed in percent

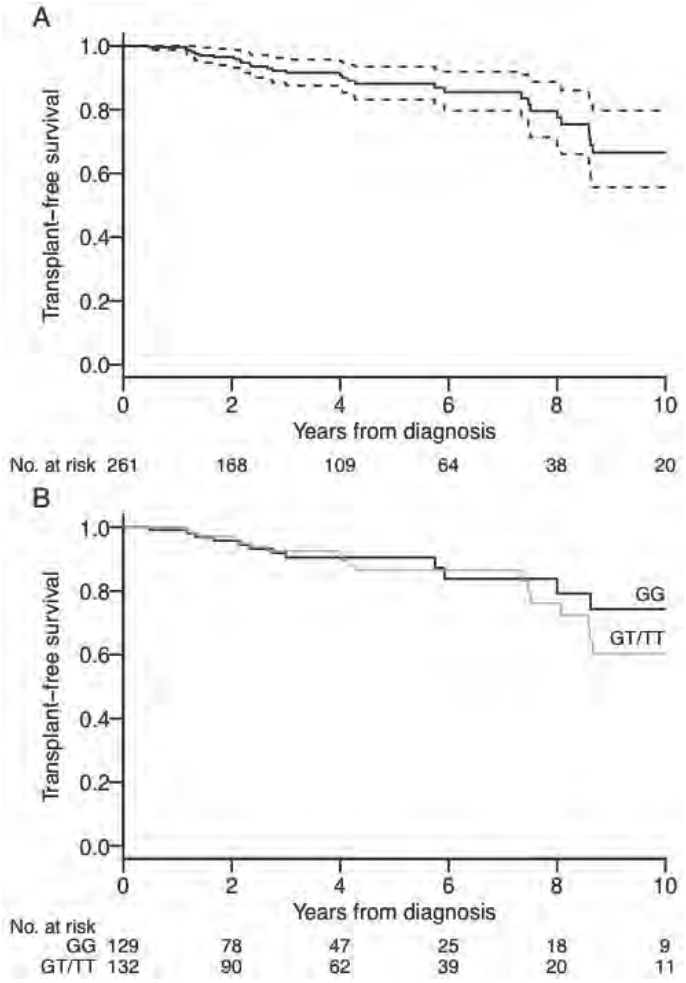

Figure 1. Transplant-free survival of all patients (A) and according to MUC5B rs35705950 polymorphism (B).

of the predicted value) or a relative decrease in FVC of at least 10%, at two years from baseline. Individuals who underwent lung transplantation or who died before 2 years from baseline were considered as experiencing a significant decrease of pulmonary function.

Results: Out of 321 registered patients, 261 could be included in the study: 139 women (53.3%), median age at RA-ILD diagnosis 65 y/o (IQR 57 – 71), 151 ever smokers (59.2%), 128 definite or possible usual interstitial pneumonia (UIP) (53.4%), 74 non-specific interstitial pneumonia (NSIP) (30.8%). Baseline median forced vital capacity (FVC) was 78.2% predicted (IQR 64.2 – 100.7) and Baseline diffusing capacity for carbon monoxide (DLCO) was 56.0% predicted (IQR 46.5 – 72.0). *MUC5B*rs35705950 minor allele frequency was 27.20%. Median follow-up was 3.5 years. Overall, there was a slight trend to decrease of 0.8% per year ($CI_{95\%}$ 0.3 – 1.4). Additionally, an important inter-patient variability of FVC was found at baseline as well as during follow-up. DLOC shows a significant decrease of 1.8% per year on average ($CI_{95\%}$ 1.2 – 2.3). A significant deterioration of PFTs at 2 years was observed for 33 of 256 evaluable patients. No baseline characteristics was associated with a significant deterioration of PFTs at 2 years, including the HRCT UIP pattern (OR=0.7; $CI_{95\%}$ 0.3 – 1.6). *MUC5B*rs35705950 T risk allele was not associated with a better or worse deterioration of PFTs (OR=0.7; $CI_{95\%}$ 0.2 – 2.2). No difference was found between *MUC5B*rs35705950 T risk allele carriers and non-carriers for transplant free survival (Figure 1.).

Conclusion: In this international multiethnicobservational study, PFTs from patients with RA-ILD were relatively sTable over time and*MUC5B*rs35705950 T risk allele was not associated with a better or a worse evolution of PFTs.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Extra-articular manifestations of rheumatoid arthritis (RA), such as nodules and interstitial lung disease (ILD), portend poor outcomes and are more common in men than in women. Whether differences in the risk of RA-ILD between men and women are related to biologic sex or to other known risk factors such as cigarette smoking or increased RA disease activity, which might differ by sex, is unknown. The purpose of this cross-sectional study was to evaluate sex differences in the prevalence of extra-articular manifestations in RA, accounting for known factors that might confound these associations.

Methods: Participants were enrollees in a multicenter, longitudinal observational cohort of US Veterans with RA. A total of 2,691 participants were studied. Baseline demographic, clinical, and treatment variables were collected and compared between men and women using either Student's t-tests or chi-square tests. Participants were categorized by the presence or absence of subcutaneous nodules, chronic lung disease (ILD or chronic obstructive pulmonary disease [COPD] vs. ILD alone) and ILD. Chronic lung diseases were determined from diagnostic codes recorded by treating rheumatologists at enrollment. Associations of sex (male vs. female) with each extra-articular manifestation was assessed using separate multivariable logistic regression models. Covariates included; Model 1: age; Model 2: age, race, body mass index (BMI); Model 3: age, race, BMI, measures of disease activity and RA treatments; Model 4: all aforementioned covariates and HLA-DRB1 shared epitope status, smoking history, and anti-citrullinated protein antibody (ACPA) status.

Results: Baseline characteristics of men and women with RA are shown in (**Table 1)**. Compared to women with RA, men were older, more likely to be Caucasian, smokers, and had greater disease activity, higher autoantibody concentrations and more comorbidity. Men more often had nodules (28% vs. 19%, p = 0.001), COPD (17% vs. 10%, p

* RAPID-3: Routine Assessment of Patient Index Data; MD-HAQ: Multidimensional Health Assessment Questionnaire; RDCI: rheumatic disease comorbidity index; ILD: interstitial lung disease; COPD: chronic obstructive pulmonary disease; HLA-SE: human leukocyte antigen shared epitope; RF: rheumatoid factor; ACPA: anti-citrullinated peptide antibodies

= 0.004) and ILD (4.7% vs. 1.0%, p = 0.002). In hierarchical regression models, these sex differences all remained following adjustment for age (**Table 2, Model 1**). With progressive adjustments (**Table 2, Models 2 to 4**), associations between sex and nodules or chronic lung disease were attenuated and no longer significant. In contrast, associations of male sex with ILD alone remained following progressive adjustments. Results were unchanged in more parsimonious models including only age, smoking, disease activity and ACPA positivity as covariates (data not shown).

Conclusion: The association between subcutaneous nodules and chronic lung disease with male sex in RA is confounded by other factors, rather than representing true differences arising from biologic sex. In contrast, associations of biologic sex with RA-ILD persist even after adjustment for multiple confounders, including cigarette smoking, RA disease activity and/or severity, and treatments. Our findings suggest that real sex differences drive the marked differences observed in RA-ILD prevalence in men compared to women. Further exploration into mechanisms underpinning the predisposition to RA-ILD among men is needed as this could inform future preventive and/or treatment strategies.

Table 2: Associations of biologic sex (male vs. female) with extra-articular disease manifestations (nodules, chronic lung disease, or ILD)

	Odds Ratio and 95% Confidence Intervals Male vs. Female Sex

Biomarkers for Rheumatoid Arthritis-Associated Interstitial Lung Disease: A Systematic Review

Dawson Shaver[1], Daniel Van Kalsbeek[1], Ariadne Ebel[1], Daniel Hershberger[1], Cynthia Schmidt[1], Jill Poole[1], Geoffrey Thiele[1], Dana Ascherman[2], Ted Mikuls[1] and Bryant England[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: RA-associated interstitial lung disease (RA-ILD) is among the most frequent and severe extra-articular manifestations of RA, contributing significantly to the excess mortality among RA patients. Optimal methods to identify RA-ILD and prognosticate its disease course are lacking. Peripheral biomarkers capable of performing these roles would be of great utility in the management of RA-ILD. To summarize this evidence, we performed a systematic review of peripheral biomarkers for the identification and prognosis of RA-ILD.

Methods: We performed a systematic review of published manuscripts investigating peripheral biomarkers in RA-ILD (PROSPERO registration number CRD42019137143) following PRISMA guidelines. We searched MEDLINE, EMBASE, the Cochrane Library, and Scopus from inception to 12/10/2019. We included primary studies evaluating pe-

ripheral biomarker(s) for the identification or prognostication of RA-ILD. We excluded those in non-English language, studies with < 20 RA-ILD patients, published reports prior to 1990 (given advancements in imaging for RA-ILD), and those not reporting results for RA-ILD specifically (e.g. grouped with CTD-ILD). We extracted study characteristics (including study design, method of biomarker measurement), patient characteristics (including demographics, smoking status, RA disease severity, and method of ILD ascertainment), and performance of peripheral biomarkers for identifying RA-ILD (vs. RA without ILD; or vs. other lung diseases) and predicting prognosis. We assessed the quality of studies using modified Quality Assessment of Diagnostic Accuracy Studies-2 (QUADAS-2) and Quality in Prognostic Studies (QUIPS) tools.

Results: Our search identified 1,189 studies, and 43 remained after applying inclusion and exclusion criteria. Study designs were primarily cross-sectional and included patients from the U.S., Japan, and China. Patient characteristics and sample sizes were highly variable across studies. Methods of ILD ascertainment were similar across most studies, typically incorporating imaging criteria (primarily CT) with or without clinical criteria. A total of 71 peripheral biomarkers were identified, with the majority being measured in serum. Peripheral biomarkers associated with the presence of RA-ILD included autoantibodies, lung epithelial/surfactant proteins, tumor markers, cytokines and

Table. Peripheral biomarkers associated with the presence of RA-ILD

Biomarker category	RA-ILD vs. RA without ILD	RA-ILD vs. other lung diseases
Autoantibodies	Anti-aminoacyl-tRNA synthetase antibodies (anti-threonyl tRNA synthetase [anti-PL7] antibody, anti-alanyl-tRNA synthetase [anti-PL-12] antibody), **Anti-citrullinated protein antibodies (anti-citrullinated alpha enolase antibodies***, Anti-citrullinated-heat shock protein 90, **Anti-CCP 1*/2***/3), Anti-IL-1a, **Anti-malondialdehyde acetaldehyde antibodies**, **Anti-peptidyl-arginine deiminase antibodies (Anti-PAD 2**, **Anti-PAD 3/4XR)**, **Rheumatoid factor***	Anti-citrullinated-heat shock protein 90, **Anti-malondialdehyde acetaldehyde antibodies**
Lung epithelial / surfactant proteins	**Krebs von den Lungen-6*, Surfactant protein-D***	Krebs von den Lungen-6*, Surfactant protein-D
Tumor markers	Cancer Antigen (CA) 15-3*, CA 19-9*, **CA 125***

Growth factors	**Fibroblast growth factor 2**, **FMS-related tyrosine kinase 3 ligand**, **granulocyte-macrophage colony-stimulating factor**, **transforming growth factor α**, **vascular endothelial growth factor**	
Extracellular matrix proteins	Lysyl oxidase-like 2, **matrix metalloproteinase (MMP)-1**, **MMP-2**, MMP-3, **MMP-7***, **MMP-9**, **MMP-10**	
Genetic markers	HLA haplotypes: DQB1*04, DQB1*06, **DR2 (*15:01**, ***15:02** and *16:02)*, DR4 (*04:01, *04:03, *04:04, *04:05, *04:06, *04:07, *04:10)*, DRB1*14:06, DRB1*16:02-DQB1*05:02, MUC5b promoter variant rs35705950, microRNA (hsa-miR-7-5p, has-miR-214-5-p), **shared epitope****	**DR2 (*15:01**, ***15:02 only)**, MUC5b promoter variant rs35705950
Other	**25-OH Vitamin D**, C-reactive protein*, erythrocyte sedimentation rate*, gamma-glutamyl transferase, globulin, lactate dehydrogenase, Lysine, **Wnt5a**	leukocyte telomere length, erythrocyte sedimentation rate

Bolded biomarkers were associated with RA-ILD in multivariable adjusted analyses
Underlined biomarkers were negatively associated with RA-ILD
* Biomarkers associated with RA-ILD in ≥ 2 studies
** Biomarker positively and negatively associated with RA-ILD

chemokines, growth factors, extracellular matrix proteins, genetic markers, and other biomarkers (**Table**). The risk of bias pertaining to patient selection, biomarker testing, reference standard assessment, and flow and timing was generally low or unclear. Several studies were determined to have a moderate to high risk of bias related to the statistical analyses due to lack of adjustment for confounding variables. Only 1 study focused on RA-ILD prognostication.

Conclusion: Several peripheral biomarkers have been found to be associated with the presence of RA-ILD, while few have been evaluated for their role in the prognostication of RA-ILD. Further investigation and clinical validation is needed before these candidate biomarkers can be employed in the care of RA and RA-ILD patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the known excess mortality of rheumatoid arthritis-associated interstitial lung disease (RA-ILD), its association with certain lifestyle factors such as obesity and future prediction have not yet been determined. We aimed to investigate the association between novel lifestyle factors on risk of incident RA-ILD, to define the threshold at which smoking increases risk of RA-ILD, and to calculate the degree to which known clinical risk factors predict RA-ILD.

Methods: This nested case-control study was performed within a prospective RA registry. All participants had RA confirmed by a rheumatologist using ACR/EULAR criteria. Three radiologists/pulmonologists determined incident RA-ILD status based on research review of clinically-obtained chest computed tomography (CT) scans. Controls had RA and no patient/physician report or billing codes for ILD. Index date was the first CT with RA-ILD or matched date. We matched each incident RA-ILD case to three controls on age, sex, RA duration, rheumatoid factor positivity, and time from exposure assessment to index date. Exposures were assessed at the earliest study visit prior to RA-ILD and included education, body mass index (BMI), smoking pack-years, anti-CCP positivity, race, hand bone erosions, rheumatoid nodules, CRP, DAS28-CRP, functional status (multi-dimensional HAQ [MDHAQ]), disease-modifying anti-rheumatic drug use, and glucocorticoid use. Conditional logistic regression models for each exposure determined

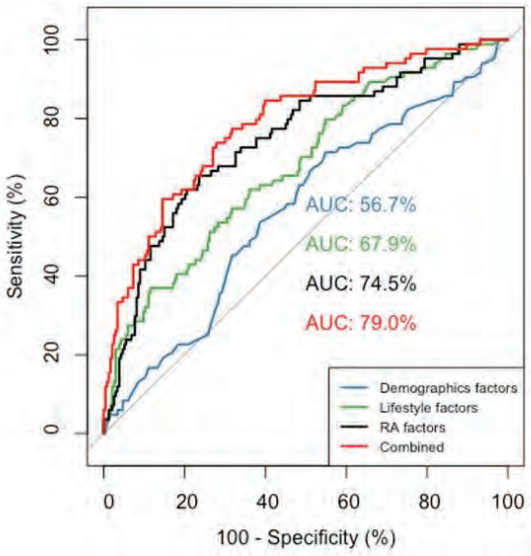
odds ratios (OR) for RA-ILD, adjusting for matching factors, anti-CCP, race, education, BMI, and smoking pack-years. Area under the receiver operating characteristic curves (AUROC) were calculated based on lifestyle and clinical exposures.

Results: We identified 84 confirmed incident RA-ILD cases and 243 matched controls. RA-ILD cases had a mean age of 67 (standard deviation 10), and 77% were female. Mean time from exposure assessment to RA-ILD onset was 1.5

Figure 1. Receiver operating characteristic curve for incident RA-ILD risk among the 84 RA-ILD cases and 243 RA non-ILD controls using demographic, lifestyle, and RA clinical risk factors



years. After adjustment, obesity, high-positive CRP (≥10 mg/L), and poor functional status (MDHAQ ≥1) were each associated with increased risk of RA-ILD (Table 1). Smoking pack-year history greater than 30 was associated with a six-fold increased risk of RA-ILD compared to nonsmokers; less than 30 pack-years were not associated with RA-IOLD risk. Together, lifestyle and clinical risk factors for RA-ILD had an AUROC of 0.79 (95% CI 0.73-0.85) (Figure 1).

Conclusion: This study identified obesity, high-positive CRP, poor functional status, and a smoking threshold of 30 pack-years as novel predictors of RA-ILD. The overall ability to predict RA-ILD based on lifestyle and clinical factors was modest. Future studies should investigate whether smoking cessation and weight loss may delay or prevent RA-ILD. Additional factors such as biomarkers may improve prediction of RA-ILD among patients with RA.

Demographic factors: age, sex, race, education Lifestyle factors: BMI, smoking pack-years RA factors: RA duration, RF status, anti-CCP status, hand bone erosions, rheumatoid nodules, biologic DMARD use, methotrexate use, glucocorticoid use, disease activity (DAS28-CRP), functional status (MDHAQ).

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a frequent extra-articular manifestation of rheumatoid arthritis (RA). It is associated with a high morbi-mortality. However, the exact prevalence of clinical and subclinical RA-ILD is still unknown as it largely varies between studies, depending on the screening tool and the temporality of the screening. Using a systematic detection by high-resolution computed-tomography (HRCT) chest scan, subclinical ILD has been reported in 20 to 60% of patients with RA. Our objective was to estimate the prevalence of clinical and subclinical ILD in the ESPOIR cohort after 13 years of RA duration.

Methods: In this cross-sectional study of the ESPOIR cohort, a HRCT chest scan was systematically proposed to the patients after a mean RA duration of 13 years. The ESPOIR cohort included patients aged 18 to 70 years who had a definitive or probable diagnosis of RA and included a prospective follow-up. HRCT scans were centrally reviewed by an expert radiologist. ILD presence, extension and characteristics were assessed using the current recommendations for ILD assessment (Raghu *et al*, Am J Respir Crit Care Med, 2011). To note, 2 patients had previously died from clinical ILD and were not included in this analysis.

Results: Within the ESPOIR Cohort, 493 patients had a 10 or more years of follow-up. 175 patients were assessed by HRCT scan. 170 patients (133 women (78.2%), mean age (61.1 ±10.3 y/o), mean RA duration (13.7 ±1.1 years)) had an interpreTable HRCT scans and were included in the analysis. Among them, chest HRCT scan identified subclinical ILD in 31 patients (18.2%): 19 women (61.3%), mean age 67.9 ±8.7 y/o, mean age at RA onset 54.3 ±8.6 y/o. Seventeen patients (54.9%) had a smoking history. Subclinical ILD with a HRCT extension of < 5%, 5-10% and >10% was observed in: 7 (4.1%), 15 (8.8%) and 9 patients (5.3%), respectively. Among the 9 patients with a HRCT extent >10%, 4 had a definite or probable usual interstitial pneumonia pattern, 3 patients had a non-specific interstitial pneumonia pattern and 2 had indeterminate patterns.

Conclusion: In the French ESPOIR Cohort, the prevalence of subclinical ILD after a mean RA duration of 13 years was 18.2%, illustrating that the occurrence of ILD is not a rare event.

Serum Anti-PAD4 and Anti-PAD3/4XR Antibodies in Rheumatoid Arthritis Associated-Interstitial Lung Disease Are Associated with Better Lung Function

Tim Wilson[1], Joshua Solomon[2], Jeffrey Swigris[2], Erika Darrah[3] and M Kristen Demoruelle[1], [1]University of Colorado, Denver, CO, [2]National Jewish Health, Denver, CO, [3]Division of Rheumatology, Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Cardiopulmonary Aspects

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) associated-interstitial lung disease (ILD) affects approximately 10% of RA patients. It is a leading cause of morbidity and mortality, which is more severe in the fibrotic subtype RA-usual interstitial pneumonia (RA-UIP). Serum antibodies to peptidylarginine deiminase type 4 (anti-PAD4), particularly a subset that cross-react with PAD3 (PAD3/4XR), have been associated with imaging evidence of ILD. However, whether anti-PAD4 and anti-PAD3/4XR antibodies are associated with a particular phenotype of RA-ILD is unknown. Importantly, idiopathic pulmonary fibrosis (IPF) shares similar risk factors and clinical features with RA-ILD, and a recently published study by our group found that anti-cyclic citrullinated peptide (anti-CCP) antibodies were present in 25% of IPF patients. As such, in this study, we sought to identify the specificity and lung disease characteristics of anti-PAD4 and anti-PAD3/4XR antibodies in RA-ILD and IPF.

Methods: Our cohort included 48 patients with RA-ILD (confirmed by chest imaging and assessment of a pulmonologist specializing in ILD) and 32 patients with IPF (meeting 2018 diagnostic criteria) who had stored serum in the National Jewish Health Biobank. Forty-six patients with RA-ILD and 28 with IPF performed pulmonary function tests within 3 months of serum collection. Subgroups of RA-ILD were defined by imaging pattern on high-resolution chest computed tomography (HRCT) scan (nonspecific interstitial pneumonia, RA-NSIP; usual interstitial pneumonia, RA-UIP) as determined via consensus reads by a trained radiologist and pulmonologist. Serum was tested for anti-CCP (CCP3.1 IgG/IgA, Inova) and rheumatoid factor (RF-IgA and IgM) by ELISA. Serum anti-PAD4 and anti-PAD3/4XR antibodies were quantified using immunoprecipitation of radiolabeled target protein and gel electrophoresis. Clinical characteristics, measures of lung function (% predicted forced vital capacity, FVC; % predicted diffusion capacity

Clinical data was missing for: Ever smoking for 1 PAD4-, 1 PAD3/4XR-; PY for 1 PAD4+, 3 PAD4-, 4 PAD3/4XR-; FVC % for 2 PAD4-, 2 PAD3/4XR-; DLCO % 4 PAD4-, 4 PAD3/4XR-.

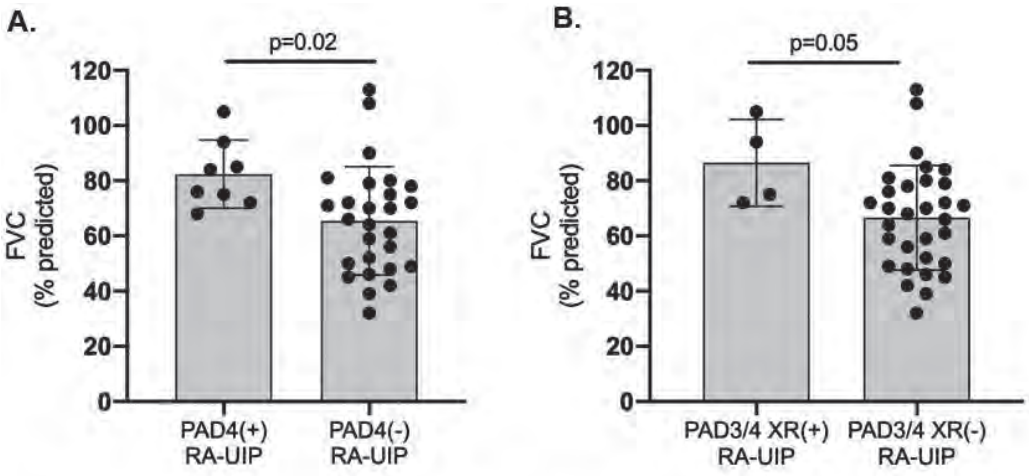

Figure 1. Forced vital capacity (FVC) in anti-PAD4+ and anti-PAD3/4XR+ RA-UIP. Mean FVC (% predicted) +/- SD in individuals with RA-UIP when stratified by anti-PAD4 status (panel A, n=8 anti-PAD4+, n=27 anti-PAD4-) and anti-PAD3/4XR (panel B, n=4 anti-PAD3/4XR+, n=31 anti-PAD3/4XR-) positivity. P-values based on independent samples t-test.

carbon monoxide, DLCO) and prevalence of serum antibodies were compared using Chi-square and t-tests as appropriate.

Results: Compared to IPF, subjects with RA-ILD were younger and more often female, but there were no differences in smoking history or baseline lung function (Table 1). Anti-PAD4 and anti-PAD3/4XR antibodies were present in 9/48 (19%) and 5/48 (10%) subjects with RA-ILD, respectively, and no subjects with IPF (Table 1). Within the RA-ILD group, anti-PAD4 antibodies were associated with better lung function. In particular, within RA-UIP subjects, the % predicted FVC was higher in anti-PAD4(+) and anti-PAD3/4XR(+) RA-UIP subjects (Table 2 and Figure 1).

Conclusion: We demonstrate that serum anti-PAD4 and anti-PAD3/4XR antibodies are highly specific for RA-ILD and associated with better lung function in RA-UIP patients. Because patients with RA-UIP can often have a worse

prognosis compared to RA-NSIP patients, the identification of a biomarker that is associated with better lung function could provide new insights into RA-ILD pathogenesis and may identify a new prognostic biomarker for RA-ILD, although future longitudinal studies are needed.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: RA patients (pts) often suffer substantial pain despite ongoing treatment (tx) and regard pain control as a top tx goal. Filgotinib (FIL)—a potent, oral Janus kinase-1 selective inhibitor—was efficacious and generally well tolerated in the FINCH phase 3 RA clinical trial program.[1,2] A post hoc analysis of FINCH studies was conducted to assess the impact of FIL on pain.

Methods: All pts met 2010 ACR/EULAR criteria for RA. In FINCH 3 (F3), MTX-naïve RA pts received FIL 200 mg + MTX, FIL 100 mg + MTX, FIL 200 mg monotherapy, or MTX monotherapy for up to 52 weeks (W). Pts in FINCH 1 (F1) had active RA and inadequate response to MTX (MTX-IR) and received FIL 200 mg, FIL 100 mg, adalimumab (ADA) 40 mg, or placebo (PBO) on a background of MTX for up to 52W; at W24, PBO pts were rerandomized to FIL 200 or 100 mg. In FINCH 2 (F2), pts receiving conventional synthetic (cs)DMARDs who had an inadequate response or intolerance to biologic DMARD (bDMARD-IR) received FIL 200 mg, 100 mg, or PBO on a background dose of csDMARD(s) for up to 24W.

Each study was analyzed separately. Pt-reported pain was assessed on a visual analog scale (VAS). Proportions of pts achieving thresholds of 30% (defined as "moderate clinically important differences") and 50% ("substantial improvements")[3] reduction from baseline were analyzed, as were exploratory thresholds of 70% and 90%, and residual VAS pain scores of ≤10/20/40 mm out of 100 mm. P-values were calculated from the logistic regression with tx groups and stratification factors in the model. Comparisons were not adjusted for multiplicity; nominal P values are presented and should be interpreted as exploratory.

Results: Median duration of RA since diagnosis was 0.3–0.4 years (y) in F3, 4.8–5.8y in F1, and 9.8–10.3y in F2. Baseline pain was high among all arms (mean VAS scores of 64–68 mm across studies). Pain improved across pt populations from MTX-naïve to bDMARD-IR during tx. At W2, the percent of pts with pain reduction ≥30%, ≥50%,

Table 1. Achievement of pain ≥30%/50%/70%/90% reduction and residual pain score <10/20/40 mm

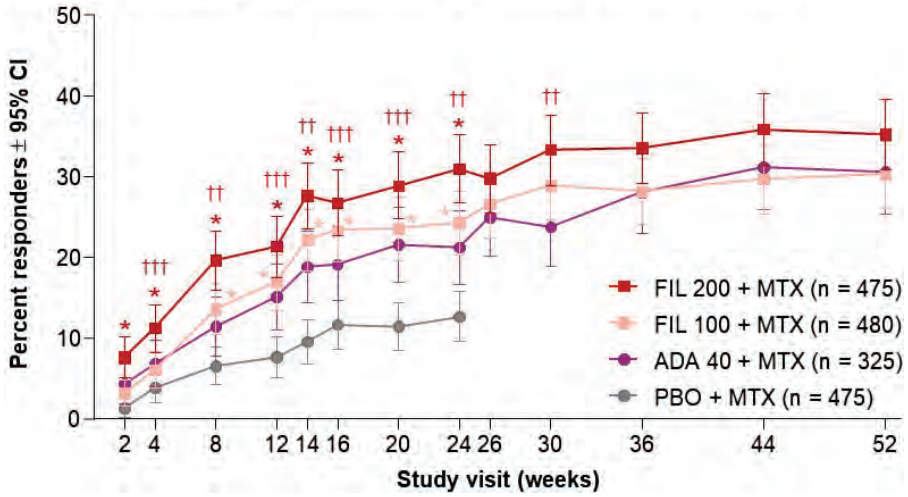
***Nominal P <0.05 for FIL arm vs PBO, **nominal P <0.01 for FIL arm vs PBO, *nominal P <0.001 for FIL arm vs PBO; †††nominal P <0.05 for FIL arm vs ADA or MTX, ††nominal P <0.01 for FIL arm vs ADA or MTX, †nominal P <0.001 for FIL arm vs ADA or MTX. P-values were calculated from the logistic regression with treatment groups and stratification factors in the model. Pts with missing outcomes were set as nonresponders for binary response measurements. —, not measured at this time point because in FINCH 1, pts receiving PBO were rerandomized 1:1 to FIL 200 or 100 mg at week 24, and, in FINCH 2, the study period ended at 24 weeks. ADA, adalimumab; csDMARD, conventional synthetic DMARD; FIL, filgotinib; PBO, placebo; pts, patients.

and residual pain ≤40 mm was significantly greater for all FIL arms compared with PBO (F1/F2) or MTX (F3) (nominal P < 0.05; **Table 1**). Pain was reduced by ≥90% by W52 in approximately 25% of pts in F1/F3 (**Table 1**). Except for pts receiving FIL 100 mg in the ≥30% reduction analysis, significantly more bDMARD-IR pts receiving FIL had pain reduction at W24 compared with PBO in all analyses (F2; nominal P < 0.05; **Table 1**). FIL + MTX significantly reduced pain in MTX-naïve pts vs MTX monotherapy (F3; nominal P < 0.05 for FIL 200 for all measures and time points and for FIL 100 for several measures and time points; **Table 1**). Overall, more pts with MTX-IR (F1) receiving FIL had greater pain reduction and lower residual pain vs pts receiving ADA, with significant differences noted for FIL 200 (but not FIL 100) for some measures at W2–W30 (nominal P < 0.05; **Table 1**; **Fig 1**; **Fig 2**).

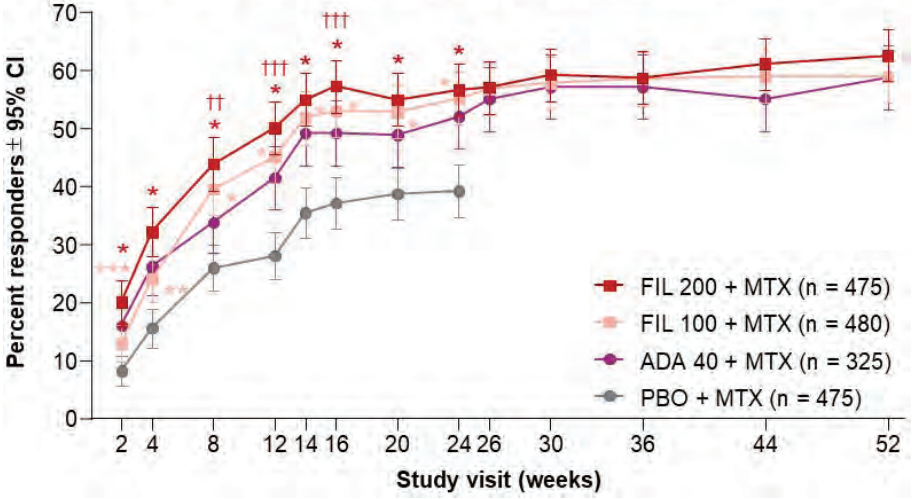
Conclusion: FIL 200 and 100 mg provided rapid, clinically meaningful pain relief among a broad spectrum of RA pts and across several measures. The degree of improvement was substantial for many pts; ≥40% of pts in all studies had a ≥50% reduction in pain.

Figure 1. Percent of patients with residual pain score of ≤10 mm in FINCH 1



Pts receiving PBO were rerandomized 1:1 to FIL 200 or 100 mg at week 24. P-values for FIL vs PBO were assessed for weeks 2—24; P-values for FIL vs ADA were assessed for all visits. *Nominal P <0.001 for FIL 200 or FIL 100 vs PBO; †††nominal P <0.05 for FIL 200 vs ADA, ††nominal P <0.01 for FIL 200 vs ADA. P-values were calculated from the logistic regression with treatment groups and stratification factors in the model. Pts with missing outcomes were set as nonresponders for binary response measurements. ADA, adalimumab; CI, confidence interval; FIL, filgotinib; PBO, placebo; pts, patients.

Figure 2. Percent of patients who achieved a ≥50% reduction of pain in FINCH 1



Pts receiving PBO were rerandomized 1:1 to FIL 200 or 100 mg at week 24. P-values for FIL vs PBO were assessed for weeks 2–24; P-values for FIL vs ADA were assessed for all visits. ***Nominal P <0.05 for FIL 100 vs PBO, **nominal P <0.01 for FIL 100 vs PBO, *nominal P <0.001 for FIL 200 or FIL 100 vs PBO; †††nominal P <0.05 for FIL 200 vs ADA, ††nominal P <0.01 for FIL 200 vs ADA. P-values were calculated from the logistic regression with treatment groups and stratification factors in the model. Pts with missing outcomes were set as nonresponders for binary response measurements. ADA, adalimumab; CI, confidence interval; FIL, filgotinib; PBO, placebo; pts, patients.

Abstract Number: 1202

Cannabis Use Assessment and Its Impact on Pain in Rheumatic Diseases: A Systematic Review and Meta-analysis

Manon Guillouard[1], Nicolas Authier[1], Bruno Pereira[1], Martin Soubrier[1] and **Sylvain Mathieu**[1], [1]CHU Gabriel Montpied, Clermont-Ferrand, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite classic analgesic or effective treatments in rheumatic diseases, such as synthetic Disease Modifying Anti-Rheumatic Drugs in rheumatoid arthritis (RA), patients remain in pain and often turn to non-prescribed pharmacological alternatives, such as cannabis self-therapeutic use. However, this medical use of cannabis has not been thoroughly studied.

Methods: We searched PubMed to find reports of interest published since 24 January 2020. The following search terms were used: "(cannabis OR cannabinol OR cannabinoids) and (rheumatoid OR osteoarthritis OR ankylosing OR arthritis OR arthralgia OR pain OR spondylitis)". The incidence of cannabis consumption was calculated by metaproportion. Differences between cannabis users and non-users were expressed as standardized mean differences using the inverse-variance method. We also assessed the effects of cannabis on pain.

Results: A total of 2,807 citations were obtained from the initial search. After reading the title, abstract, and full text, we obtained 13 eligible studies, plus 7 found searching abstract databases, for a total of 13,134 patients with rheumatic diseases. Cannabis consumption. In the 12 studies on rheumatic diseases, a total of 2,666 patients reported cannabis consumption in a sample of 9,665 patients (incidence 40.3% [95%CI 26.2,55.2]), and 16% [95%CI 4.8,32.1] specified that they were currently taking cannabis. Cannabis use was higher in the three fibromyalgia studies (56.3%

[95%CI 0.26,0.84], n=510) compared to five articles concerning RA or lupus (33.6% [95% CI 0.16,0.54], n=7,061). Effects of cannabis on pain over time. Cannabis consumption was associated with a decrease in pain intensity (VAS pain at baseline 8.2±2.9 vs. 5.6±3.5 mm over time; pooled effect size -1.75 [95%CI -2.75,-0.76]). Tolerance was good with mild or moderate side effects. Patients reported red eyes (7 to 90%), dry mouth (7 to 27%), hunger feeling (1 to 15%), sore thorat (10%), nausea (1 to 5%), somnolence (2 to 3%), hyperactivity (1 to 5%) or mood deflection (7%). Comparison of cannabis users and non-users. Cannabis users were younger (58.2±11.1 vs. 63.4±11.9 years; p< 0.001), more often smokers (OR 3.37 [95%CI 1.91,5.92]) or unemployed (OR 2.25 [95%CI 1.09,4.65]), and had higher pain intensity (4.9±2.4 vs. 4.1±2.5 mm; p< 0.001) than non-users. A significant relationship was found, with a three-fold risk of cannabis use among alcohol drinkers (148/304 (48.7%) vs. 382/1581 (24.2%); OR 3.12 [95% CI 2.41,4.04]). The proportion of cannabis users was significantly lower in female patients (OR 0.52 [95% CI 0.28,0.96], p=0.04).

Conclusion: Nearly 20% of patients suffering from rheumatic diseases actively consume cannabis, with an improvement in pain. The issue of cannabis use in the management of these patients should be addressed during medical consultation, essentially with cannabis-based standardized pharmaceutical products.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A prior post hoc analysis of tofacitinib clinical trial data reported improvements in RA outcomes with tofacitinib vs placebo (PBO) through Month (M)6, regardless of baseline (BL) BMI.[1] This post hoc analysis assessed change from BL (Δ) in BMI, and disease activity by BL BMI status, in patients (pts) with moderate/severe RA receiving tofacitinib through M12.

Methods: Data were pooled from Phase 3 and 3b/4 studies of pts who were MTX-naïve (NCT01039688), or inadequate responders to conventional synthetic (cs) or biologic DMARDs (NCT00960440; NCT00847613; NCT00814307; NCT00856544; NCT00853385; NCT02187055; NCT02831855). Pts received ≥ 1 dose of tofacitinib 5 or 10 mg twice daily (BID), or 11 mg once daily (QD), alone or with background csDMARDs, or PBO. Least squares (LS) mean ΔBMI (linear mixed model repeated measures; observed cases) was summarized for all treatment groups at M3/6/12 (M3/6 only for tofacitinib 11 mg QD and PBO). Other assessments at M3/6/12 included ΔBMI +/- BL concomitant glucocor-

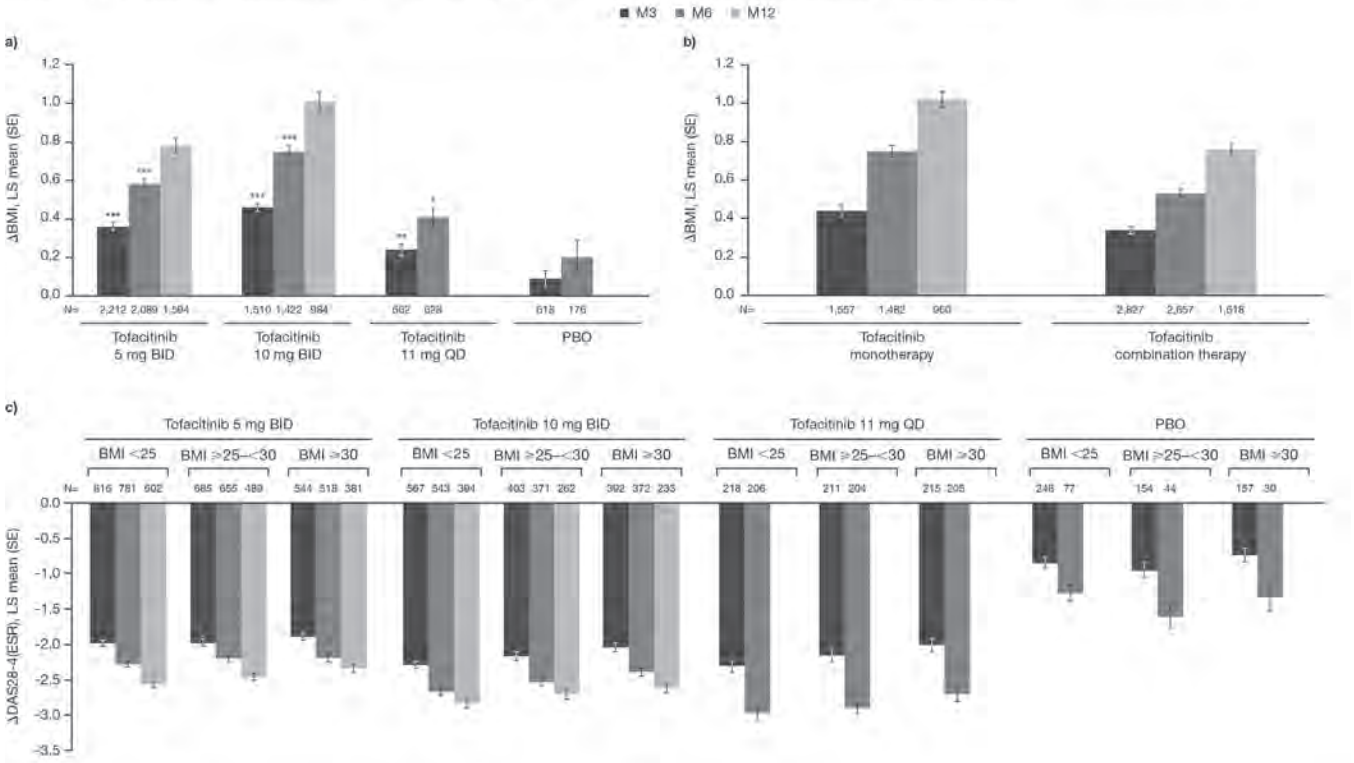
bDMARD, biologic DMARD; BID, twice daily; BMI, body mass index; csDMARD, conventional synthetic DMARD; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; DMARD, disease-modifying antirheumatic drug; MTX, methotrexate; N, number of patients in the analysis; n, number of patients in each category; PBO, placebo; QD, once daily; RA, rheumatoid arthritis; SD, standard deviation; TNFi, tumor necrosis factor inhibitor

ticoids (GC) or antidepressants (descriptive statistics only), LS mean ΔDAS28-4(ESR), stratified by BL BMI status (< 25, ≥ 25 – < 30, ≥ 30), and correlations between LS mean ΔBMI and ΔDAS28-4(ESR).

Results: In total, 2,349, 1,611, 694, and 681 pts received tofacitinib 5 mg BID, 10 mg BID, 11 mg QD, or PBO, respectively. Demographics and baseline characteristics were generally similar across treatment groups, except in pts receiving tofacitinib 11 mg QD, where some differences were observed in gender, race, and concomitant GC use (Table 1). At M3/6, LS mean BMI significantly increased from BL with all tofacitinib doses vs PBO (all $p< 0.05$); ΔBMI was greatest with 10 mg BID, and lowest with 11 mg QD (Figure 1a). LS mean ΔBMI was greater in pts receiving tofacitinib as monotherapy vs combination therapy at M3/6/12 (Figure 1b). ΔBMI was generally similar in pts receiving treatment +/- concomitant GCs or antidepressants (data not shown). Improvements in DAS28-4(ESR) scores were observed in each BL BMI status group at M3/6/12, and were greatest with all tofacitinib doses vs PBO. LS mean ΔDAS28-4(ESR) was generally numerically highest for pts with BMI < 25 and numerically lowest for pts with BMI > 30, for all tofacitinib doses. LS mean ΔDAS28-4(ESR) was also generally greatest with tofacitinib 10 mg BID and 11 mg QD vs 5 mg BID across BL BMI status groups (Figure 1c). Across treatment groups, model-adjusted associations between ΔDAS28-4(ESR) scores and ΔBMI were weak (correlation coefficients all < 0.3; Table 2).

Conclusion: ΔBMI was greater with tofacitinib (all doses) vs PBO at M3/6, and with tofacitinib monotherapy vs combination therapy at M3/6/12. Improvements in DAS28-4(ESR) were seen across all BL BMI status groups. BMI increases with tofacitinib were only weakly associated with DAS28-4(ESR) improvements. The relationship between disease activity and ΔBMI requires further investigation.

Figure 1. a) ΔBMI in patients with RA receiving tofacitinib 5 or 10 mg BID, tofacitinib 11 mg QD or placebo;[a] b) ΔBMI in patients with RA receiving tofacitinib monotherapy or tofacitinib in combination with csDMARDs;[b] c) ΔDAS28-4(ESR) in patients with RA, stratified by BL BMI status[c]



[a]Statistical analyses were performed for comparisons of ΔBMI in patients receiving tofacitinib vs PBO up to M6 only; [b]Descriptive statistics only.
*p<0.05, **p<0.01, ***p<0.001. LS means were calculated using longitudinal linear MMRM (observed cases), with treatment, visit, treatment*visit, BL BMI (panels A and B) or BL DAS28-4(ESR) (panel C), age, gender, race, and RA duration included in the model. For patients receiving tofacitinib 11 mg QD in ORAL Shift (NCT02831855), only data up to M6 were included: Patients who advanced from PBO to tofacitinib at the end of the PBO-controlled period were excluded from the analysis post-advancement
Δ, change from baseline; BID, twice daily; BL, baseline; BMI, body mass index; csDMARDs, conventiona synthetic DMARDs; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; DMARD, disease-modifying antirheumatic drug; LS, least squares; M, month; MMRM, mixed model repeated measures; N, number of patients in the analysis at each time point; PBO, placebo; QD, once daily; RA, rheumatoid arthritis; SE, standard error

Table 2. Correlations between LS mean ΔDAS28-4(ESR) and ΔBMI through M12

Correlation between ΔDAS28-4(ESR) and ΔBMI

	Tofacitinib 5 mg BID		Tofacitinib 10 mg BID		Tofacitinib 11 mg QD		PBO	
	N	Correlation coefficient	N	Correlation coefficient	N	Correlation coefficient	N	Correlation coefficient
M3	2,021	0.1169	1,348	0.1240	641	0.0907	554	0.0783
M6	1,918	0.1305	1,270	0.1397	611	0.0438	150	0.1556
M12	1,455	0.1213	874	0.1826	---	---	---	---

Slopes for associations between ΔBMI and ΔDAS28-4(ESR) were significantly different from 0 at M3/6/12 with tofacitinib 5 and 10 mg BID (all p<0.05); Correlations between ΔBMI and ΔDAS28-4(ESR) were analyzed by a general linear model method, with BL age, race, gender, and RA duration included in the model. For patients receiving tofacitinib 11 mg QD in ORAL Shift (NCT02831855), only data up to M6 were included; Patients who advanced from PBO to tofacitinib at the end of the PBO-controlled period were excluded from the analysis post-advancement
Δ, change from baseline; BID, twice daily; BL, baseline; BMI, body mass index; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; LS, least squares; M, month; N, number of patients in the analysis at each time point; PBO, placebo; QD, once daily; RA, rheumatoid arthritis

Use of Multi-Biomarker Disease Activity Scores to Assess Biosimilarity in a Phase 3 Randomized Controlled Trial Comparing Biosimilar Infliximab-qbtx (PF-06438179/GP1111) with EU-Sourced Reference Infliximab in Patients with Active RA

Jonathan Kay[1], Daniel Alvarez[2], Muhammad Iftikharur Rehman[3], Min Zhang[4] and Noriko Iikuni[5], [1]University of Massachusetts Medical School, Worcester, MA, [2]Pfizer, Collegeville, PA, [3]Pfizer, Andover, MA, [4]Pfizer, La Jolla, CA, [5]Pfizer, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

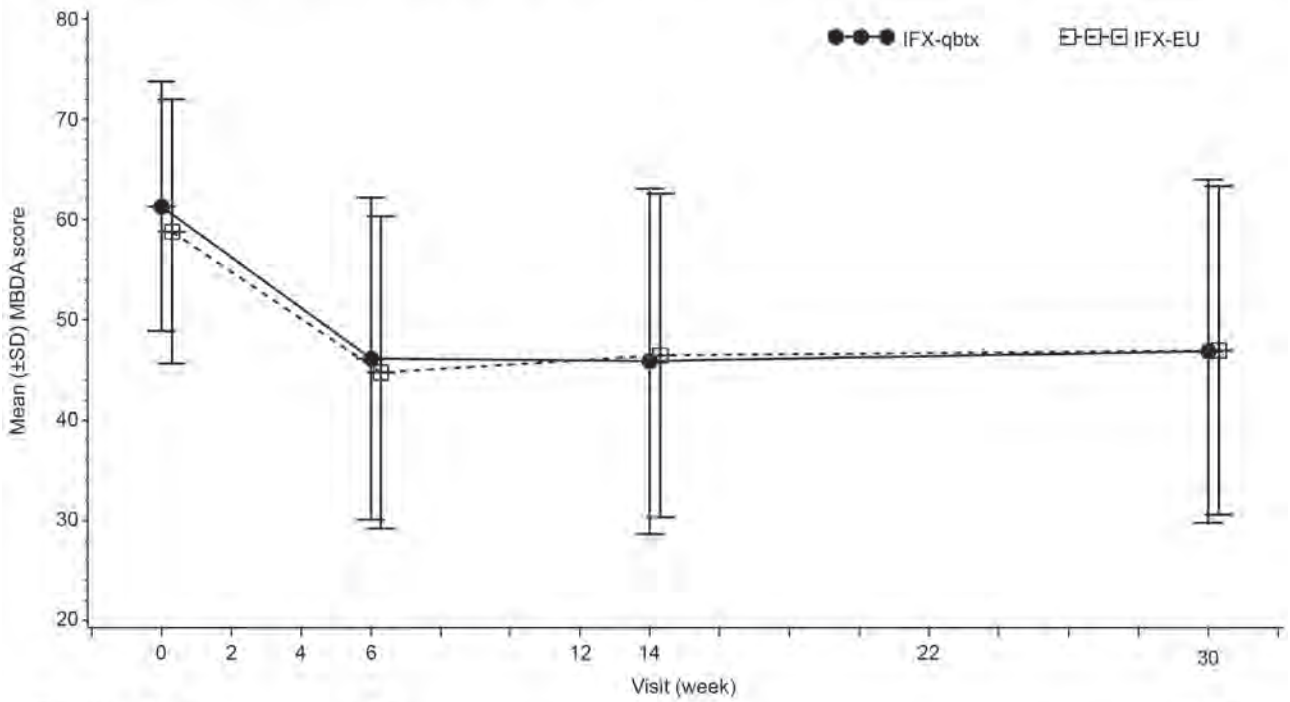
Background/Purpose: The multi-biomarker disease activity (MBDA; Vectra® DA, Myriad Genetics, Inc.) score is calculated from concentrations of 12 serum proteins to assess disease activity (DA) of patients with RA (Centola et al. PLoS One 2013;8(4):e60635). In a phase 3 randomized controlled trial (RCT), efficacy of the infliximab (IFX) biosimilar IFX-qbtx (PF-06438179/GP1111) was equivalent to that of reference IFX sourced from the European Union (IFX-EU; Janssen Biologics B.V., Leiden, The Netherlands) in patients with active, moderate to severe RA (Cohen et al. *Arthritis Res Ther* 2018;20(1):155). In this exploratory analysis, we compared MBDA scores between treatment groups in this RCT to determine the utility of this approach as an assessment of biosimilarity.

Methods: All 650 patients in the study met the 2010 ACR/EULAR classification criteria for RA and had disease duration of ≥4 months. Patients were randomized 1:1 to IFX-qbtx or IFX-EU (3 mg/kg intravenous at weeks 0, 2, 6, and then every 8 weeks), both given with MTX (10-25 mg/week). Mean values of MBDA scores (low: 1 to < 30; moderate: 30 to ≤44; high: >44–100) were calculated at baseline (BL), and at weeks 6, 14, 30, 54, and 78 by combining the concentrations of 12 serum biomarkers using the Vectra® DA algorithm. Mean MBDA scores were compared between treatment groups. Results are reported from treatment period 1 (weeks 0–30). Analyses were performed using the intent-to-treat (ITT) population, without imputation for missing data, and data were summarized using descriptive statistics.

Results: At baseline (BL), mean (± standard deviation [SD]) MBDA scores for IFX-qbtx (n=236) and IFX-EU (n=248) were 61.3 (±12.5) and 58.8 (13.2), respectively. Mean MBDA scores were comparable between IFX-qbtx and IFX-EU at all measured time points through week 30 (**Figure**). Similar proportions in the IFX-qbtx (66.0%) and IFX-EU (66.9%) groups had high (>44) MBDA scores at BL; the proportions of patients with high MBDA scores decreased to 42.3% and 40.2%, respectively, at week 30. Mean MBDA scores decreased by 15.2 and 14.1 from BL to week 6 in the IFX-qbtx and IFX-EU groups, respectively, and remained sTable between weeks 6 and 30. Changes in the concentrations of individual biomarkers over time were generally similar between treatment groups. Changes from BL in MBDA scores correlated positively with changes from BL in high-sensitivity CRP (hs-CRP) results (**Table**).

Conclusion: This RCT of IFX-qbtx and IFX-EU comparing efficacy of a biosimilar and its reference product is the first study that incorporated MBDA score as an assessment of biosimilarity. Changes in MBDA scores over time were similar between IFX-qbtx and IFX-EU groups. Use of an MBDA score based on serum biomarker levels provides a sensitive assessment of biosimilarity that is independent of DA measures, which require physical examination of the patient or subjective patient global assessment.

Figure. Mean MBDA score over time up to week 30 in patients with RA treated with IFX-qbtx or IFX-EU (ITT population)[a]



[a] Baseline was defined as the measurement taken at the week 0 visit. For post-baseline visits, patients with both baseline and post-baseline data at each visit were counted.

Table. Correlations between MBDA scores and hs-CRP (ITT population)[a]

	Pearson's correlation coefficient (r)	
MBDA score vs hs-CRP	**IFX-qbtx**	**IFX-EU**
Baseline	0.742	0.812
Change from baseline to week 6	0.798	0.814
Change from baseline to week 14	0.782	0.802
Change from baseline to week 30	0.814	0.820

[a] Baseline was defined as the measurement taken at the week 0 visit.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) have been associated with cardiovascular (CV) disease. The treatment of arthritis by tumour necrosis factor α (TNF-α) inhibitors may decrease the serum concentrations of vascular biomarkers. We determined circulating levels of oxidized LDL (oxLDL)/β2 glycoprotein I (β2GPI) complexes, antibodies to 60 kDa heat shock protein (anti-Hsp60), soluble urokinase plasminogen activator receptor (suPAR) and Brain type natriuretic peptide (BNP) fragment in sera of RA and AS patients undergoing anti-TNF treatment.

Methods: Fifty-three RA/AS patients were treated with etanercept (ETN) or certolizumab pegol (CZP) for one year. Circulating oxLDL/β2GPI complex (AtherOx®), anti-Hsp60 IgG and BNP_{8-29} fragment levels were assessed by ELISA. suPAR levels were determined by suPARnostic® Quick Triage test. Flow-mediated vasodilation (FMD), carotid intima-media thickness (IMT) and arterial pulse-wave velocity (PWV) were determined by ultrasound.

Results: One-year anti-TNF treatment significantly decreased oxLDL/β2GPI levels, as well as suPAR levels in patients with "critically" high suPAR levels at baseline. In RA, BNP levels were higher in seropositive vs seronegative patients. Serum levels of these vascular biomarkers variably correlated with lipids, ACPA, RF and CRP. IMT positively correlated with BNP, PWV with suPAR and anti-Hsp60, while FMD inversely associated with anti-Hsp60. In RM-ANOVA analysis, disease activity supported the effects of anti-TNF treatment on 12-month changes in oxLDL/β2GPI. IMT supported the effects of therapy on changes of anti-Hsp60 and suPAR.

Conclusion: These biomarkers may be involved in the pathogenesis of atherosclerosis underlying RA/AS. TNF inhibition variably affect the serum levels of oxLDL/β2GPI, suPAR and BNP.

Abstract Number: 1206

Associations of Vascular and Bone Status in Anti-TNF-treated Rheumatoid Arthritis and Ankylosing Spondylitis Patients

Anita Pusztai[1], Attila Hamar[2], Monika Czókolyová[2], Katalin Gulyás[2], Ágnes Horváth[2], Edit Végh[2], Zsófia Pethő[2], Szilvia Szamosi[2], Emese Balogh[2], Nóra Bodnár[2], Ágnes Szentpétery[3], Harjit Bhattoa[2], György Kerekes[2], Balázs Juhász[2], Éva Szekanecz[2], Katalin Hodosi[2], Andrea Domján[2], Sándor Szántó[2], Hennie Raterman[4], Willem Lems[5], **Zoltán Szekanecz**[2] and Gabriella Szűcs[2], [1]University of Debrecen Faculty of Medicine, Department of Rheumatology, Debrecen, Hungary, [2]University of Debrecen, Debrecen, Hungary, [3]Uppsala University Hospital, Uppsala, Sweden, [4]Northwest Clinics, Alkmaar, Netherlands, [5]Amsterdam Rheumatology and Immunology Centre, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular (CV) disease and osteoporosis (OP) have become increasing challenges in the ageing population, even more in patients with inflammatory rheumatic diseases, such as rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Both diseases have been associated with generalized and localized bone loss, accelerated atherosclerosis, increased CV morbidity and mortality.

Bone and vascular biomarkers and parameters along with the effect of one-year anti-TNF therapy on these markers were assessed in order to determine correlations between vascular pathophysiology and bone metabolism in RA and AS.

Methods: Fifty-three patients including 36 RA patients treated with etanercept (ETN) or certolizumab pegol (CZP) and 17 AS patients treated with ETN were included in a 12-month follow-up study. Bone and vascular markers were assessed by ELISA. Bone density was measured by DXA and quantitative CT (QCT). Flow-mediated vasodilation (FMD), common carotid intima-media thickness (IMT) and pulse-wave velocity (PWV) were assessed by ultrasound. Data on the effects of vascular markers on bone and bone effects on vasculature had undergone statistical analysis.

Results: We found a great number of correlations between vascular and bone surrogate markers. Both univariable and multivariable analyses suggested that osteoprotegerin (OPG) may positively determine FMD, parathyroid hormone (PTH) may be a determinant of PWV and sclerostin (SOST) may influence IMT at different time points. QCT total and trabecular BMD inversely correlated with IMT and IMT was also inversely associated with QCT total BMD. Baseline vitamin D3 (VITD3) inversely affected PWV. Some biomarkers at baseline also significantly determined other parameters at later time points. Moreover, one-year biologic treatment combined with baseline levels of different bone biomarkers may predict changes of IMT upon therapy. According to the multivariate analyses, systemic inflammation (C-reactive protein) or disease activity, as well as their change between baseline and 12 months may significantly influence the interrelationship between certain bone and vascular biomarkers.

Conclusion: In our study of anti-TNF treated RA and AS patients, vascular and bone parameters showed numerous correlations. Some bone markers may predict vascular status after one-year treatment and vice versa. Systemic inflammation and arthritic disease activity may influence the associations between bone and vascular biomarkers.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the analysis of PLANETRA, a Phase III randomized controlled trial (RCT), no significant association was found between body mass index (BMI) and clinical responses in rheumatoid arthritis (RA) patients using weight-based intravenous (IV) infliximab (3 mg/kg every 8 weeks)[1,2]. Since the subcutaneous (SC) formulation of CT-P13 which was approved from EMA after demonstrating non-inferiority compared to CT-P13 IV is a fixed-dose of 120 mg biweekly, it is meaningful to evaluate the impact of BMI on the clinical response of CT-P13 SC[3,4]. This study is to investigate the impact of BMI on clinical responses of CT-P13 SC 120 mg in Part 2 of Phase I/III RCT in active RA patients throughout the 1-year treatment period.

Methods: A total of 165 patients who received at least one full dose of CT-P13 SC (after IV infusions at Weeks 0 and 2 in the IV dose-loading phase) before Week 30 and who had at least one efficacy evaluation result after Week 6 or thereafter were included in this analysis. Patients were categorized into the three groups; under/normal weight (< 25kg/m^2), overweight (≥25kg/m^2, < 30kg/m^2), and obesity (≥30kg/m^2) based on the WHO BMI classification. Baseline characteristics, mean change from baseline in disease activity by DAS28 (CRP), remission (DAS28 [CRP]≤2.6) and low disease activity (LDA; 2.6< DAS28 [CRP]≤3.2), duration (week) of LDA, EULAR response, and ACR response were evaluated among the three BMI groups.

Results: In the under/normal weight (n=63), overweight (n=61), and obesity (n=41) groups, the mean±SD of age (years) (48.7±14.00, 51.5±10.93, 53.8±10.62) and the mean±SD of RA duration (years) (6.4±6.00, 8.2±9.27, 5.4±4.72) were comparable. At baseline, the rates of high disease activity (90.5%, 90.2%, 87.8%; DAS28 [CRP] >5.1) were similar among the groups. All other baselines and disease characteristics including gender, race, and other disease activity were also comparable among the groups. The rate of remission or LDA (Figure 1), the mean change from baseline of DAS28 (CRP) (-3.3, -3.1, -3.3 at Week 54), duration of LDA up to Week 54 (26.2, 29.2, 27.9 weeks), and the good or moderate EULAR responder rates (84.1%, 80.3%, 90.2% at Week 54) were all comparable among the groups and there were no statistically significant differences (p-value >0.05). The ACR responder rates were also comparable among the groups except for the ACR70 at Weeks 2 and 6 which were obtained following 2 IV infusions in the IV dose-loading phase. The absolute value of Pearson correlation coefficient was below 0.06 between BMI at baseline

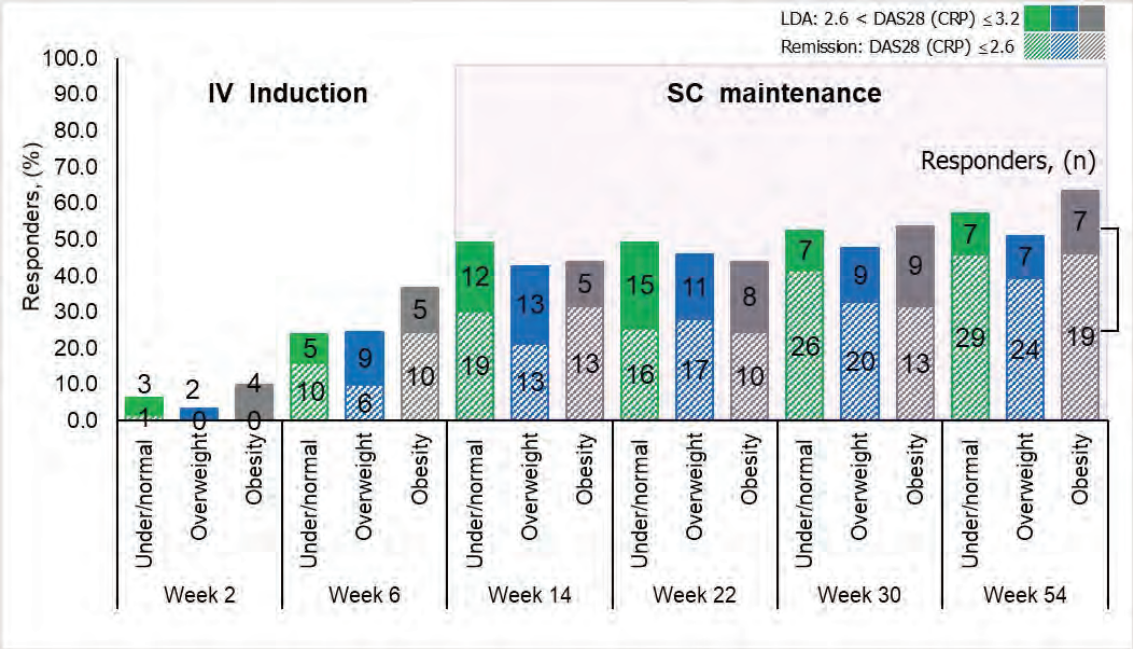

Figure 1. Remission or LDA Based on DAS28 (CRP)

and mean change from baseline in DAS28 (CRP) during the CT-P13 SC treatment from Weeks 14 to 54, indicating that correlation between two measurements was weak and was not statistically significant (p-value >0.05) (Figure 2).

Conclusion: These results showed that there was no impact of BMI on the clinical responses of CT-P13 SC 120 mg biweekly in RA patients. Therefore, CT-P13 SC 120 mg is considered to be a valid therapeutic option regardless of BMI.

Session Type: Poster Session C

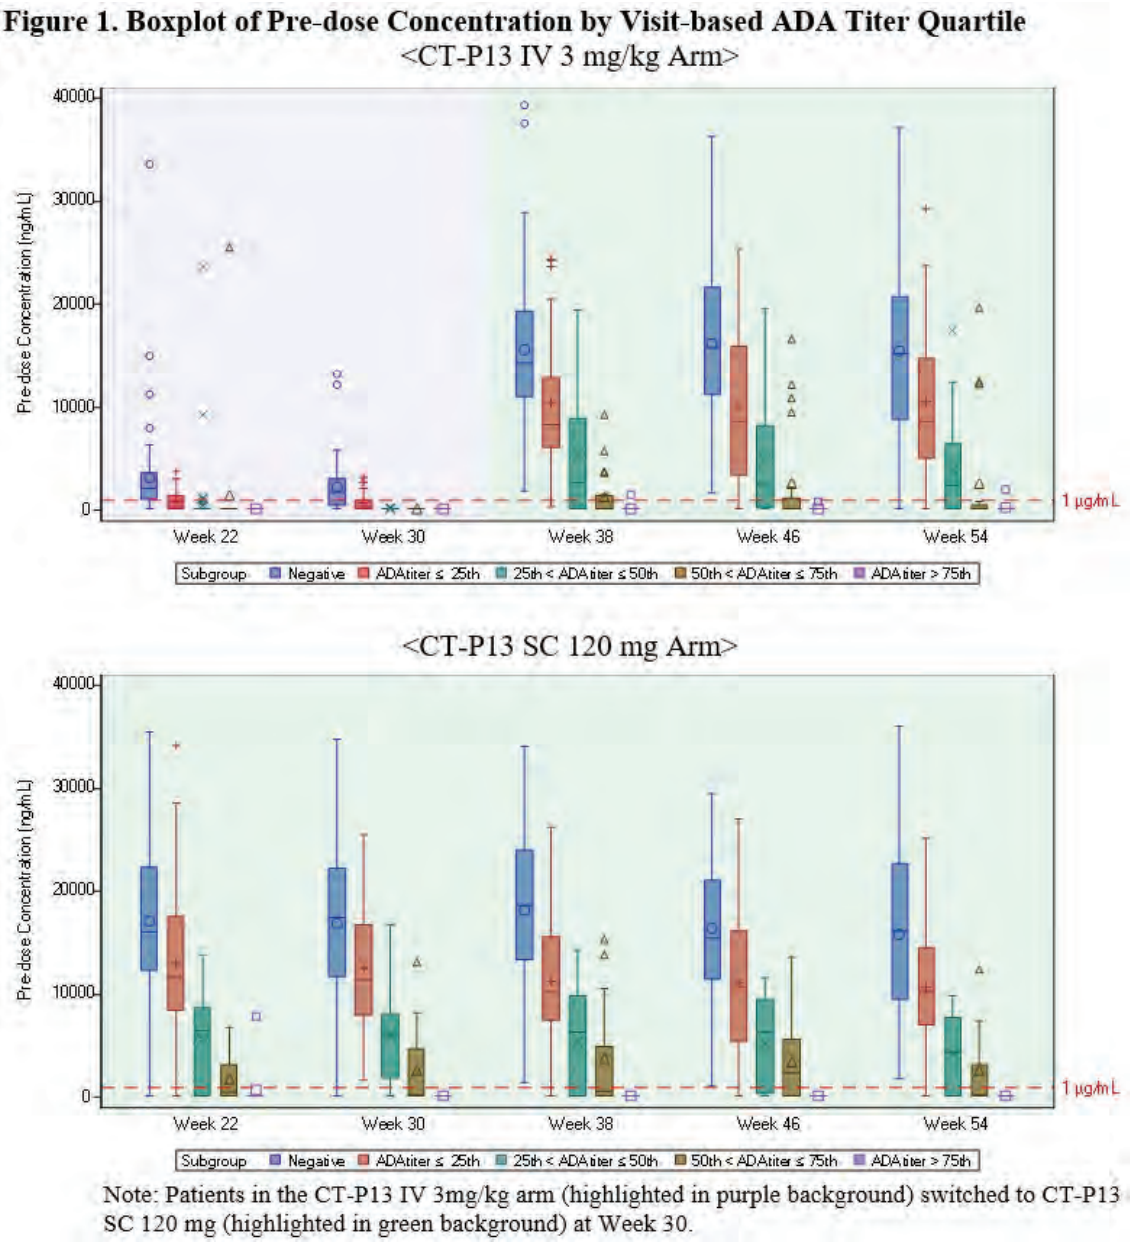
Session Time: 9:00AM–11:00AM

Background/Purpose: Novel subcutaneous infliximab (CT-P13 SC) was developed to augment the flexibility in the therapeutic use of infliximab and non-inferiority (NI) of CT-P13 SC versus CT-P13 intravenous (IV) was demonstrated for efficacy in patients with rheumatoid arthritis (RA)[1]. CT-P13 SC 120 mg biweekly showed relatively high therapeutic trough levels during the treatment period, which consistently helps in maintaining efficacy over time. Since immunogenicity has clinical importance in patients using anti-TNF alpha agents and there is a general presumption that SC route is more immunogenic than IV route, this needs careful assessment. In this report, immunogenicity assessment of CT-P13 SC with further impact analysis was performed on the pivotal data set[1] to determine whether there was any correlation between the magnitude of anti-drug antibody (ADA) positivity and clinical outcomes in RA patients or not.

Methods: The immune response against CT-P13 in human serum was detected using an electrochemiluminescence (ECL) platform with an Affinity Capture Elution (ACE) step. An ADA ECL ACE assay showed the ability to detect ADA at low levels in all samples regardless of residual drug in serum (25 ng/mL ADA in the presence of 80 μg/mL of CT-P13 in RA patient serum). To investigate the impact of ADA titer on PK, efficacy, and safety, key clinical parameters were assessed by visit-based ADA titer quartile. All patients who had 'Positive' ADA status result at each visit were included in the analysis and categorized into 4 groups using the 25th, 50th, 75th percentiles of ADA titer result, respectively.

Results: The 4 subgroups categorized by quartiles at each visit from week 22 to week 54 were: 1st (ADA titer ≤ 3), 2nd (3 < ADA titer ≤ 9), 3rd (9 < ADA titer ≤ 27) and 4th (27 < ADA titer). There was a trend for pre-dose concentration to decrease as ADA titer increases for both CT-P13 SC and CT-P13 IV arms as expected (Figure 1). Patients in the 1st and 2nd subgroup maintained a sufficient therapeutic drug concentration level. Figure 2 shows the correlation between ADA titer and efficacy outcomes where the change from baseline of DAS28 (CRP) and the proportion of patients achieving ACR20 were lower in the 3rd and 4th subgroup than 1st and 2nd subgroup. The ADA impact was especially apparent in the 4th subgroup where the mean pre-dose concentration of the patients was below the therapeutic drug concentration level (1 μg/mL), which led to worse efficacy outcomes in both IV and SC arms than other subgroups. Nevertheless, no impact of ADA on the safety profile in both arms was observed. A neutralizing antibody (NAb) method with enhanced drug tolerance but limited performance was also developed and clinical consequences of NAb titer in terms of PK, efficacy, and safety were not different from the results with ADA.

Figure 1. Boxplot of Pre-dose Concentration by Visit-based ADA Titer Quartile



Note: Patients in the CT-P13 IV 3mg/kg arm (highlighted in purple background) switched to CT-P13 SC 120 mg (highlighted in green background) at Week 30.

Conclusion: The analysis of both ADA positivity and titer is clinically meaningful in the prediction of PK profile and clinical response. CT-P13 SC administration did not result in a greater incidence of ADA compared to the CT-P13 IV and there were no clinical differences depending on the formulation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

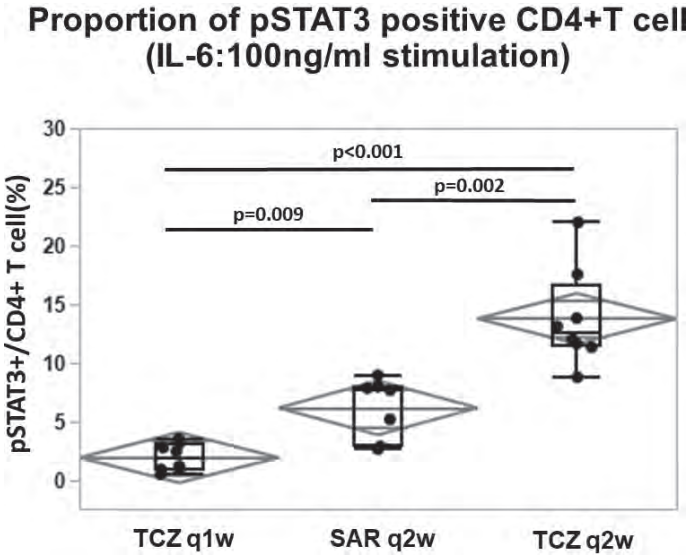
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin-6 (IL-6) is a key cytokine in the pathogenesis of rheumatoid arthritis (RA). Tocilizumab (TCZ) and Sarilumab (SAR) are monoclonal antibodies that bind to membrane and soluble forms of human IL-6 receptor, efficiently inhibiting IL-6/STAT3 signaling. Our group had previously reported the bioassay for measuring the strength of IL-6/STAT3 signal inhibition by TCZ (Arthritis Research & Therapy 2017.19:231). In this study, we measured phosphorylated STAT3 (pSTAT3) in RA patients treated with subcutaneous (s.c) administration of TCZ and SAR, in order to assess the difference in the strength of IL-6/STAT3 signal inhibition among both medications.

Methods: RA patients who achieved low disease activity (CDAI< =10) by treatment with weekly or biweekly administration of 162 mg s.c of TCZ (TCZ q1w, n = 8, and TCZ q2w group, n = 8), and those with 200 mg s.c of SAR biweekly (SAR q2w group, n = 7) were collected. Whole blood samples from each group were stimulated with each concentration of recombinant human (rh) IL-6 (0, 0.1, 1, 10, 100 ng/ml). The proportion of pSTAT3 positive CD4+ T cells was measured by phosflow cytometric analysis.



Proportion of pSTAT3 positive CD4+T cell

Clinical Characteristics

	A) TCZ q1w (N = 8)	B) SAR q2w (N = 7)	C) TCZ q2w (N =8)	A) VS B), p	B) VS C), p	A) VS C), p

Descriptive values are expressed as median (Q1-Q3)

Clinical Characteristics

Results: The clinical characteristics of each group were not different in each group (Table1). Proportion of pSTAT3 positive CD4+ T cells stimulated by 100ng/ml of rhIL-6 showed significant difference in each group (median 1.8 [0.9-3.0]% vs 7.7 [2.9-8.0]% vs 12.5 [11.4-16.6]% in TCZ q1w, SAR q2w, TCZ q2w group, respectively, $p < 0.05$ for all comparisons)(Figure 1).

Conclusion: The strength of IL-6/STAT3 signal inhibition by SAR 200mg q2w showed significantly higher level than that of TCZ s.c q2w but lower than TCZ s.c q1w. The result of this study might be useful in considering the adjustment of the strength of IL-6 blockade treatment in each RA patient.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: AWARE (Comparative & Pragmatic Study of Golimumab [GLM] Intravenous [IV] vs Infliximab [IFX] in RA) is a Phase 4 study designed to provide a real-world assessment of GLM IV and IFX in pts with RA. Patients (pts) with rheumatoid arthritis (RA) experience significant symptoms (eg, pain and fatigue) and impact on physical function. Using the Patient Reported Outcomes Measurement Information System (PROMIS), a validated disease agnostic set of health assessment instruments,[1] we assessed outcomes related to social, mental, and physical well-being through the 8th infusion (≈1 year of treatment).

Methods: AWARE is a prospective, noninterventional, multicenter (88 sites), observational study in the United States (US). A total of 1270 RA pts were enrolled when initiating treatment with GLM or IFX. The 52 Week Analysis Set reported here included pts with ≥1-year treatment or those discontinued for any reason and, while enrolled, completed PROMIS-29 or PROMIS short form (SF) questionnaires. The PROMIS instruments were administered at baseline and prior to infusions 2, 5, and 8. PROMIS-29 consists of 7 domains (Depression, Anxiety, Physical Function, Pain Interference, Fatigue, Sleep Disturbance, and Social Participation) and a pain intensity 0-10 visual analogue scale. The PROMIS SFs Fatigue 7a and Pain Interference 6b were also completed. The raw score of each domain was converted into a standardized T-score with a mean of 50 (general population mean) and a standard deviation (SD) of 10. All PROMIS T-scores are based on observed data without any imputation rules applied. Higher PROMIS scores represent more of the domain concept being measured.

Results: At baseline, treatment groups were balanced based on demographics and medical characteristics. The majority of pts were white (87.0% GLM, 86.2% IFX) and female (83.4% GLM, 82.4% IFX). Mean ages were 58.5 ±12.96 years for GLM and 59.6 ±13.24 years for IFX. Overall, 35.3% GLM and 42.9% IFX pts were bionaïve. The proportion of GLM and IFX pts with prior exposure to 1 or 2 biologics was similar; however, 20.1% GLM pts vs 10.8% IFX pts had exposure to ≥3 biologics. Methotrexate use was similar between GLM (76.4%) and IFX pts (75.0%). Based on mean PROMIS T-scores at baseline (Table), Fatigue, Pain Interference, and Physical Function domains assessed by PROMIS in RA pts indicate that these assessments were worse than those of the general US population. Among all PROMIS domains, mean Depression T-scores were closest compared with the general population (51.9 GLM, 52.5 IFX). Through the 8th infusion, GLM- and IFX-treated pts achieved meaningful improvement based on mean changes from baseline in all PROMIS-29 domains and respective SFs. The percentage of GLM or IFX pts with improvements of ≥3, ≥5, or ≥10 units change in T-scores increased from infusion 2 through infusion 8.

Table. Mean (SD) Change from Baseline PROMIS-29 Domain and Short Form T-Scores: 52 Week Analysis Set			
	GLM	IFX	Least square mean difference (95% CI)*
Anxiety (4-item)	N=674	N=570	
Baseline	53.4 (10.13)	54.6 (10.53)	
Change from baseline at infusion 5	N=435	N=397	-0.41 (-1.40, 0.58)
	-2.0 (7.98)	-2.9 (8.41)	
Change from baseline at infusion 8	N=223	N=286	-0.29 (-1.54, 0.97)

Depression (4-item)	N=674	N=574	
Baseline	51.9 (9.83)	52.5 (10.21)	
Change from baseline at infusion 5	N=434	N=399	0.54 (-0.39, 1.47)
	-1.8 (7.51)	-1.5 (7.98)	
Change from baseline at infusion 8	N=225	N=287	0.49 (-0.72, 1.70)
	-2.1 (7.56)	-2.3 (7.89)	
Fatigue (4-item)	N=671	N=574	
Baseline	58.4 (9.91)	59.4 (9.99)	
Change from baseline at infusion 5	N=435	N=393	-0.26 (-1.24, 0.71)
	-2.0 (7.81)	-2.6 (7.88)	
Change from baseline at infusion 8	N=225	N=281	0.69 (-0.64, 2.03)
	-3.4 (8.72)	-3.1 (7.77)	
Short form Fatigue 7a	N=681	N=576	
Baseline	59.1 (8.51)	59.7 (8.25)	
Change from baseline at infusion 5	N=441	N=400	0.60 (-0.20, 1.40)
	-2.6 (6.74)	-2.4 (6.11)	
Change from baseline at infusion 8	N=228	N=287	1.01 (-0.11, 2.14)
	-3.2 (7.40)	-2.4 (6.35)	
Pain interference (4-item)	N=679	N=574	
Baseline	63.0 (7.56)	63.9 (7.80)	
Change from baseline at infusion 5	N=440	N=398	0.83 (-0.05, 1.71)
	-3.4 (7.02)	-3.1 (6.95)	
Change from baseline at infusion 8	N=227	N=284	1.84 (0.55, 3.13)
	-4.2 (8.23)	-3.1 (7.77)	
Short form Pain interference 6b	N=680	N=576	
Baseline	61.9 (7.45)	62.8 (7.54)	
Change from baseline at infusion 5	N=441	N=400	0.43 (-0.40, 1.26)
	-3.4 (6.66)	-3.3 (6.31)	
Change from baseline at infusion 8	N=228	N=287	1.31 (0.15, 2.48)
	-3.8 (7.88)	-3.2 (6.67)	
Physical function (4-item)	N=678	N=571	
Baseline	38.2 (6.79)	38.0 (6.90)	
Change from baseline at infusion 5	N=435	N=396	-0.31 (-1.01, 0.39)
	1.8 (5.26)	1.8 (5.37)	
Change from baseline at infusion 8	N=224	N=283	-0.76 (-1.73, 0.21)
	2.2 (5.64)	1.9 (5.85)	
Sleep disturbance (4-item)	N=671	N=569	
Baseline	54.6 (8.72)	N=55.5 (8.61)	
Change from baseline at infusion 5	N=428	N=395	-0.04 (-0.95, 0.88)
	-1.7 (7.69)	-2.0 (7.26)	
Change from baseline at infusion 8	N=221	N=281	0.23 (-0.96, 1.42)
	-1.4 (7.45)	-1.7 (7.61)	
Social participation (4-item)	N=673	N=574	
Baseline	43.7 (8.40)	42.9 (8.77)	
Change from baseline at infusion 5	N=437	N=396	-0.27 (-1.15, 0.61)
	2.5 (7.40)	2.5 (6.64)	
Change from baseline at infusion 8	N=225	N=283	-0.10 (-1.36, 1.16)
	3.2 (8.15)	3.4 (7.48)	

*The least square mean difference and confidence interval (CI) are based on analysis of covariance controlling for baseline PROMIS score using inverse probability of treatment weighted propensity score.

Conclusion: RA pts treated with GLM or IFX achieved comparable improvements across social, mental, and physical well-being PROMIS measures. PROMIS-29 was able to detect change to subsequent anti-tumor necrosis factor-α therapies.

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) is an oral Janus kinase (JAK) inhibitor engineered to have greater selectivity for JAK1 vs JAK2, JAK3, and tyrosine kinase 2, and is approved for the treatment of RA. Across 2 double-blind, placebo (PBO)-controlled Phase 3 studies of UPA in patients with RA, after an initial increase through Week 8, lipid levels remained sTable up to Week 24.[1,2] Previous studies of JAK or IL-6 receptor inhibitors have reported a negative correlation between changes in lipid levels and RA disease activity.[3,4] The aim of this analysis was to determine the relationship between changes in lipid levels and disease activity outcomes in patients with RA treated with UPA.

Methods: Patients with RA and an inadequate response to conventional synthetic/biologic DMARDs (cs/bDMARD-IR) from SELECT-NEXT/SELECT-BEYOND, respectively, were randomized to receive UPA 15 mg once daily (QD), UPA 30 mg QD, or PBO for 12 weeks followed by an extension of up to 5 years; patients randomized to PBO switched to UPA 15 or 30 mg after 12 weeks. Spearman correlations of maximum changes from baseline (BL) through Week 12 in fasting-state lipid levels (low- and high-density lipoprotein cholesterol [LDL-C; HDL-C], and total cholesterol [TC]) with clinical disease activity outcomes measured by change from BL in Clinical Disease Activity Index (CDAI), DAS of 28 joints using CRP (DAS28[CRP]), tender/swollen joint count in 28 joints (TJC28/SJC28), and pain by visual analog scale (VAS) at Weeks 12 and 24, were determined. Spearman correlations of maximum changes from BL in lipid levels and CRP through Week 12 were also determined.

TC	−0.132* (n=304)	−0.169** (n=301)	−0.045 (n=301)	−0.095 (n=294)	−0.208*** (n=275)

*p<0.05, **p<0.01, ***p<0.001. BL, baseline; CDAI, Clinical Disease Activity Index; DAS28(CRP), DAS of 28 joints using CRP; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; PBO, placebo; QD, once daily; SJC28, swollen joint count in 28 joints; TC, total cholesterol; TJC28, total joint count in 28 joints; UPA, upadacitinib; VAS, visual analog scale

Results: Available fasting samples from 1,160 pooled patients (UPA 15 mg, n=386; UPA 30 mg, n=384; PBO, n=390) were included. Modest, but statistically significant, negative correlations were observed between maximum changes from BL in TC through Week 12 and change from BL in CDAI, DAS28(CRP), SJC28, and pain (VAS) at Week 12 with UPA 15 or 30 mg (**Table 1**); similar trends were observed at Week 24. Significant correlations between changes in LDL-C and HDL-C and disease activity outcomes were also observed, but were not consistent across UPA doses and time points. No significant correlations were noted between changes in lipid levels and disease activity outcomes in the PBO group. Statistically significant weak negative relationships were observed between maximum changes from BL in lipid levels and CRP levels through Week 12 with UPA 15 mg (HDL-C and TC) or UPA 30 mg (LDL-C and TC) (**Table 2**).

Conclusion: In this large pooled data set of patients receiving UPA, increases in lipid levels showed modest, but statistically significant, correlations with improvement in clinical disease activity outcomes in patients with cs/bD-

Whole Blood Transcriptional Changes Following Selective Inhibition of Janus Kinase 1 (JAK1) by Filgotinib in MTX-Naïve Adults with Moderately-to-Severely Active Rheumatoid Arthritis (RA)

Peter Taylor[1], Bryan Downie[2], Emon Elboudwarej[2], Sam Kim[2], Angie Hertz[2], Amer Mirza[2], Jeff Siegel[3], Rachael Hawtin[2] and Jinfeng Liu[2], [1]Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Gilead Sciences, Inc., Foster City, [3]Gilead Sciences, Inc., Foster City, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL), a selective, oral JAK1 inhibitor, has shown efficacy and safety in phase 3 studies in adults with moderately-to-severely active RA. Previously, we described molecular response to FIL in large-scale RNA sequencing studies of gene expression in other RA populations[1-3].We conducted a similar study in methotrexate (MTX)-naïve RA patients (pts) (FINCH3; ClinicalTrials.gov NCT02886728) to identify gene transcripts and biological pathways associated with RA and altered in response to FIL.

Methods: MTX-naïve RA pts received sTable dose of MTX+placebo (PBO+MTX), FIL 200mg alone (FIL 200mg), FIL 100mg+MTX, or FIL 200mg+MTX. Whole blood samples were collected using PAXgene tubes at baseline (BL), weeks 4, 12, and 24. RNA was extracted and sequenced on Illumina HiSeq 2500 platform following globin RNA depletion. Correlations between BL gene expression and disease measurements were performed using Spearman's rank partial correlation to account for covariates. Differentially expressed genes (DEGs) were identified using voom-limma. Biological pathway analyses were performed on Molecular Signature Database v6.1 using single sample gene set enrichment analysis with focus on immune signaling pathways from Kyoto Encyclopedia of Genes and Genomes (KEGG). A false-discovery rate of 5% was applied.

Results: Differential gene expression analyses comparing BL samples with after-treatment samples showed rapid onset of transcriptional changes in FIL pts. Fewer DEGs were observed in PBO+MTX patients with peak number at week 24, an observation consistent with MTX clinical response kinetics.[4] Up to 3x as many significant DEGs were observed in FIL 200mg+MTX compared to FIL 100mg+MTX arm, a finding consistent with superior clinical efficacy of FIL 200mg. As with other FIL clinical trial RNA-seq studies and consistent with the selective MoA of FIL, JAK-STAT pathway-induced genes *SOCS2* and *CISH* were significantly downregulated across FIL arms and timepoints, but not PBO+MTX. RA disease activity-associated genes[2-3] *FAM20A* and *METTL7B* were significantly reduced at all timepoints in FIL pts, but only at week 24 in PBO+MTX. While no significant changes in KEGG immune signaling pathways were observed in PBO+MTX arm, a dose-dependent effect on pathway modulation was observed in FIL arms, including reductions in JAK-STAT, toll-like receptor, chemokine, and RIG-I like receptor signaling.

Conclusion: More rapid and sustained changes of transcriptional activity in whole blood transcriptional profile of RA pts after FIL treatment were found compared to PBO+MTX. Dose dependent changes were observed in FIL-treated pts, most notably in KEGG JAK-STAT signaling pathway. These observations confirm an inhibition of JAK-STAT signaling by FIL and are consistent with observed clinical efficacy of FIL in these pts.

Discrepancy Between the Multi-biomarker Disease Activity Score and Clinical Disease Activity Scores in a 2-Part, Multicenter Study of Repository Corticotropin Injection (Acthar® Gel) for Patients with Persistently Active Rheumatoid Arthritis

Roy Fleischmann[1], Jingyu Liu[2], Julie Zhu[2], Oscar Segurado[3] and Daniel Furst*[4], [1]Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX, [2]Mallinckrodt Pharmaceuticals, Bedminster, NJ, [3]SSI Strategy, San Jose, CA, [4]Department of Medicine, Division of Rheumatology, University of California at Los Angeles, Los Angeles, California, USA, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Assessment of disease activity in RA with validated measures, such as the Disease Activity Score with 28 joint count and erythrocyte sedimentation rate (DAS28-ESR) and the Clinical Disease Activity Index (CDAI), is useful in evaluating therapeutic efficacy and guiding treatment. The multi-biomarker disease activity (MBDA) score was developed to provide an objective laboratory assessment of disease activity. We assessed DAS28-ESR, CDAI, and MBDA scores in a multicenter, placebo-controlled, randomized, phase 4 withdrawal study of repository corticotropin injection (RCI, Mallinckrodt Pharmaceuticals), a naturally sourced complex mixture of adrenocorticotropic hormone analogs and other pituitary peptides, in patients with persistently active RA despite treatment with sTable low-dose glucocorticoids and 1 or 2 nonbiologic and/or biologic disease-modifying antirheumatic drugs (ClinicalTrials.gov ID: NCT02919761).

Methods: Patients received 80 U of RCI subcutaneously (SC) twice weekly during a 12-week open-label period; those who achieved low disease activity (LDA; DAS28-ESR < 3.2) were randomly assigned to receive 80 U of RCI or placebo SC twice weekly during a 12-week double-blind period. Disease activity was assessed using the DAS28-ESR, CDAI, and MBDA at baseline (BL), week (W) 12, and W24; changes were evaluated via *t* tests. Correlations for the total MBDA score and its individual components with both DAS28-ESR and CDAI scores at BL, W12, and W24 were assessed via Pearson correlation coefficients for subgroups with/without LDA at W12 or W24. Analyses used the modified intent-to-treat population, defined as patients who received ≥1 dose of study drug and contributed any efficacy data.

Results: RCI therapy was associated with clinically meaningful improvements in disease activity; mean decreases exceeded the minimal clinically important difference thresholds for the DAS28-ESR and CDAI, but not the minimally important difference for the MBDA (**Table 1**). Statistically significant correlations between MBDA and DAS28-ESR scores were seen at BL and W12 in patients with and without LDA at W12, but low correlation coefficients suggested weak relationships (**Table 2**). Low correlation coefficients (most nonsignificant) also suggested weak relationships between MBDA and CDAI scores (**Table 2**). Among individual MBDA components, some significant correlations were

Table 1. Change from BL in DAS28-ESR, CDAI, and MBDA scores at W12 and W24 (mITT population)

Assessment	Part 1: Open-label RCI (N=259)		Part 2: Double-blind						MCID/MID (absolute difference)

LDA was defined as DAS28-ESR <3.2 across all analyses.

P values are from Pearson correlation coefficient test.

Abbreviations: BL, baseline; CDAI, Clinical Disease Activity Index; DAS28-ESR, Disease Activity Score with 28 joint count and erythrocyte sedimentation rate; LDA, low disease activity; MBDA, multi-biomarker disease activity; RCI, repository corticotropin injection; W, week.

noted with both the DAS28-ESR and CDAI scores at BL, W12, and W24; low correlation coefficients suggested weak relationships (data not shown).

Conclusion: In this study of RCI therapy in patients with persistently active RA, clinical disease activity scores were weakly correlated with MBDA total and individual component scores. Similar results have been seen with 3 other agents with different mechanisms of action.[1,2] These findings support the 2019 ACR recommendations against use of MBDA as a preferred measure for disease activity in RA.[3]

Association Between Changes in C-reactive Protein at Week 12 and Patient-Reported Outcomes at Week 24 with Sarilumab Therapy Across Three Pivotal Phase 3 Studies

John Tesser[1], Grace Wright[2], Vibeke Strand[3], Jeffrey Kaine[4], Karina Maslova[5], Gregory St John[6], Kerri Ford[5], Amy Praestgaard[5] and Ernest Choy[7], [1]Arizona Arthritis & Rheumatology Associates, Phoenix, AZ, [2]Association of Women in Rheumatology, New York, NY, [3]Division of Immunology/Rheumatology, Stanford University, Palo Alto, CA, [4]Independent Rheumatology Consultant, Sapphire, NC, [5]Sanofi, Cambridge, MA, [6]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [7]CREATE Centre, Cardiff University, Cardiff, Wales, United Kingdom

SESSION INFORMATION

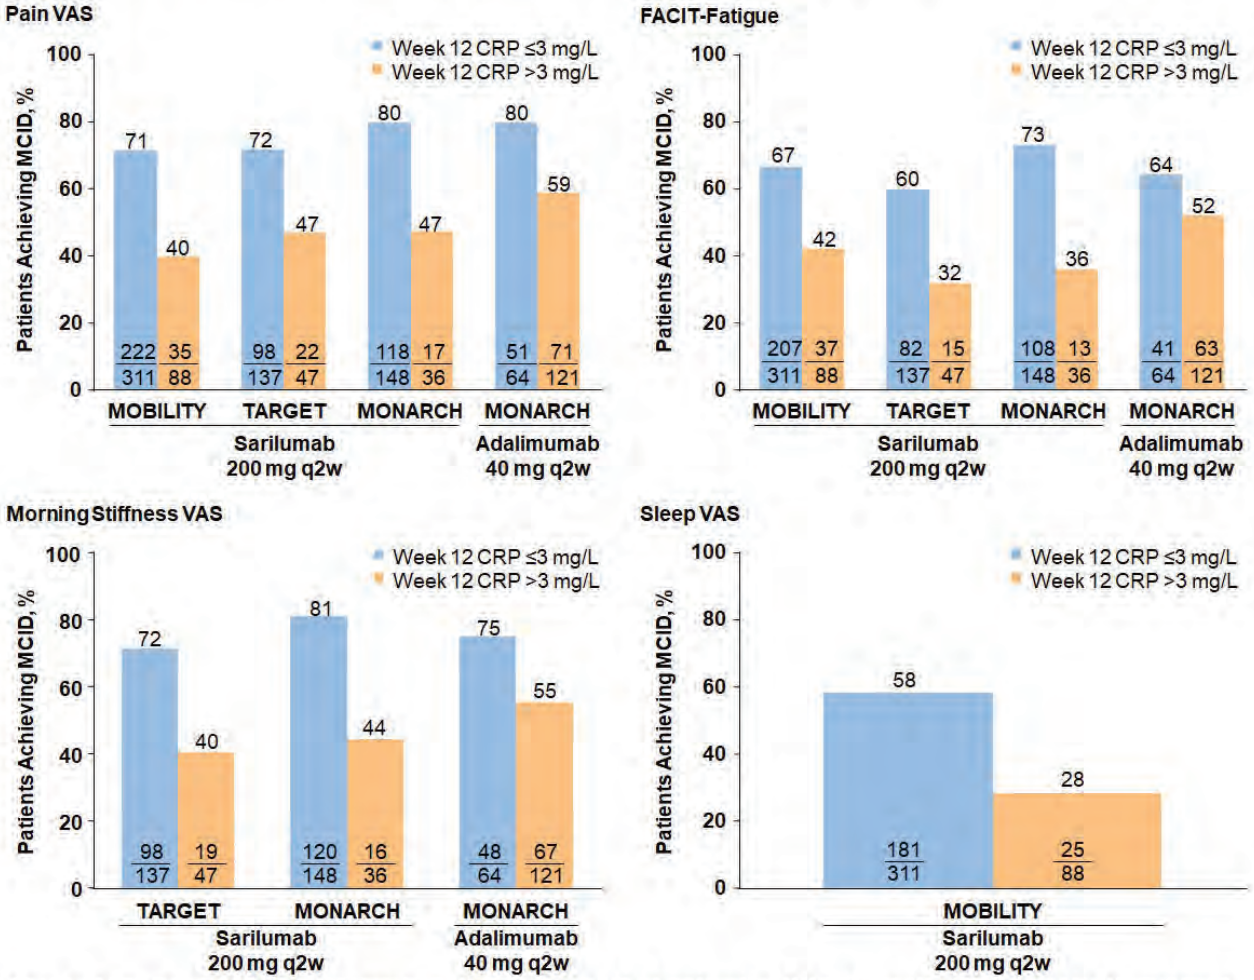
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Evaluation of response to RA therapy at 12 weeks after initiation is recommended in treatment guidelines. CRP response after 12 weeks of therapy may indicate favorable subsequent improvement in patient-reported outcomes (PROs). Here, we describe the association between CRP response to sarilumab at Week 12 and PRO improvements at Week 24, using data from 3 pivotal studies.

Methods: The analysis included patients with RA who took part in MOBILITY (NCT01061736), TARGET (NCT01709578), or MONARCH (NCT02332590) and were treated with sarilumab 200 mg every 2 weeks (q2w) or adalimumab 40 mg q2w (MONARCH only). Patients who achieved a CRP response at Week 12 (defined as serum concentration ≤3 mg/L) were evaluated for PROs at Week 24. Response for PROs was defined as an improvement from baseline in visual analog scale score of ≥10 mm for pain, sleep, and morning stiffness, and an improvement of ≥4 points for the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score. Odds ratios (ORs) and 95% confidence intervals (CIs) were generated for the likelihood of achieving PRO responses at Week 24, based on patients' achievement of CRP response at Week 12.

Results: Data for pain and fatigue were available in all 3 trials, for morning stiffness in TARGET and MONARCH only, and for sleep in MOBILITY only. After 12 weeks of treatment with sarilumab 200 mg every 2 weeks, CRP ≤3 mg/L was attained in 74% (137/184), 78% (311/399), and 80% (148/184) of patients from TARGET, MOBILITY, and MONARCH, respectively; in MONARCH, treatment with adalimumab 40 mg q2w was associated with CRP response in 35% (64/185) of patients. Across all 3 trials and all 4 PROs assessed, attainment of CRP ≤3 mg/L at Week 12 was associated with a higher proportion of PRO responders at Week 24 (Figure). These data suggest higher odds of achieving

Figure. Proportions of PRO responders at week 24, by CRP level status at Week 12



Values at the base of each column denote the numbers of patients; CRP=C-reactive protein; MCID=minimal clinically important difference; PRO=patient-reported outcome; q2w=twice weekly; VAS=visual analog scale

Figure

Table. Odds ratios (95% CI) of achieving PRO response at Week 24

	Treatment/Phase 3 Trial			
	Sarilumab 200 mg q2w			Adalimumab 40 mg q2w
	MOBILITY	TARGET	MONARCH	MONARCH
Pain VAS	3.8 (2.3, 6.2)	2.9 (1.4, 5.7)	4.4 (2.0, 9.5)	2.8 (1.4, 5.6)
FACIT-fatigue	2.7 (1.7, 4.5)	3.2 (1.6, 6.4)	4.8 (2.2, 10.3)	1.6 (0.9, 3.1)
Morning stiffness VAS	–	3.7 (1.9, 7.4)	5.4 (2.5, 11.6)	2.4 (1.2, 4.7)
Sleep VAS	3.5 (2.1, 5.9)	–	–	–

FACIT=Functional Assessment of Chronic Illness Therapy; PRO=patient-reported outcome; q2w=every 2 weeks; VAS=visual analog scale

Table

Week 24 PRO response in sarilumab-treated patients who did versus those who did not attain CRP ≤3 mg/L at Week 12 (Table). In MONARCH, sarilumab-treated patients who attained CRP ≤3 mg/L at Week 12 had numerically higher odds of achieving Week 24 PRO response than their adalimumab-treated counterparts (Table).

Conclusion: This post hoc analysis suggests that, in patients with moderate to severe RA treated with sarilumab 200 mg q2w or adalimumab 40 mg q2w, attainment of a CRP level ≤3 mg/L at Week 12 could predict improvements in pain, sleep, morning stiffness, or fatigue at Week 24.

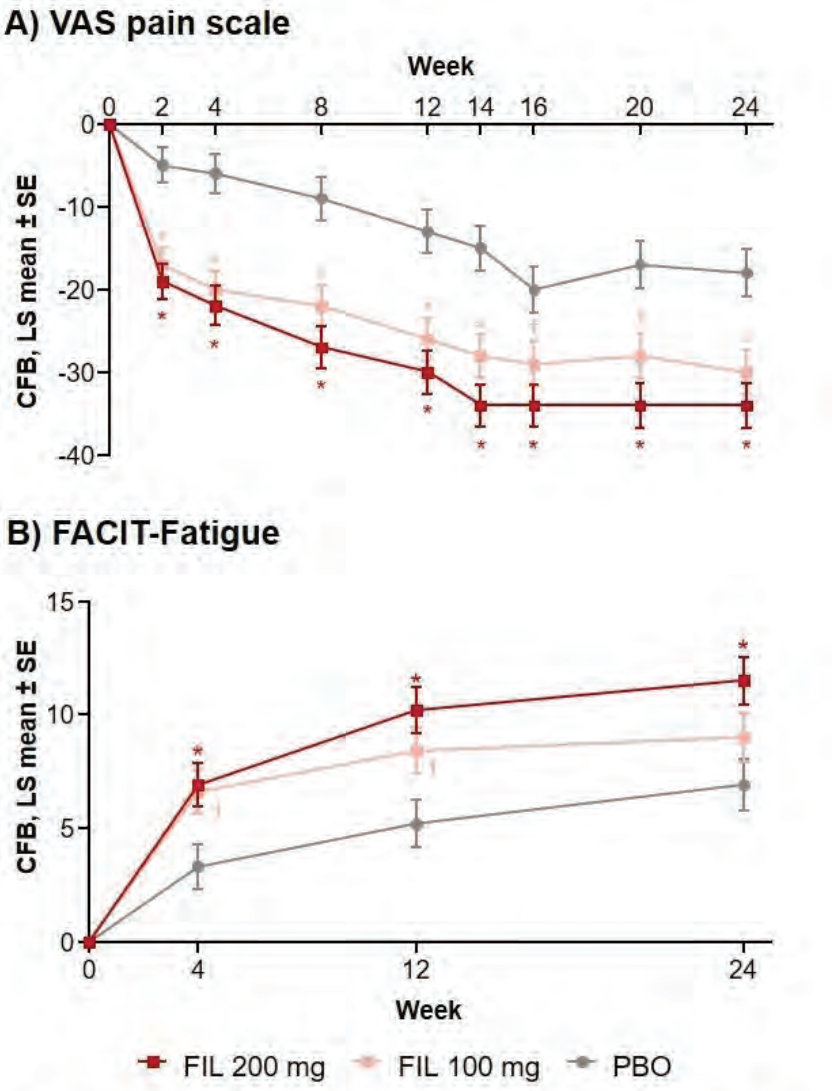
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: EULAR guidelines recommend a treat-to-target approach focusing on reducing inflammation to prevent joint damage, physical disability, and mortality.[1] However, patients consider reduction in pain and fatigue, along with maintenance of physical function, and improvement in health-related quality of life (HRQoL) important areas for improvement with RA treatment.[2] In the FINCH 2 study, filgotinib (FIL)—a potent, selective, oral small molecule Janus kinase 1 inhibitor—in combination with conventional synthetic (cs)DMARD therapy significantly improved the signs and symptoms of rheumatoid arthritis (RA) in patients with an inadequate response to a biologic (b)DMARD compared with placebo (PBO).[3] In addition, patients experienced significant improvements in HAQ-DI at week (W)12 and W24 with FIL 100 mg ($p < 0.001$, $p = 0.003$) or 200 mg ($p < 0.001$ for both) compared with PBO.[3] The rate and magnitude of change in patient-reported outcomes (PROs) from FINCH 2 assessing pain, HRQoL and fatigue were evaluated.

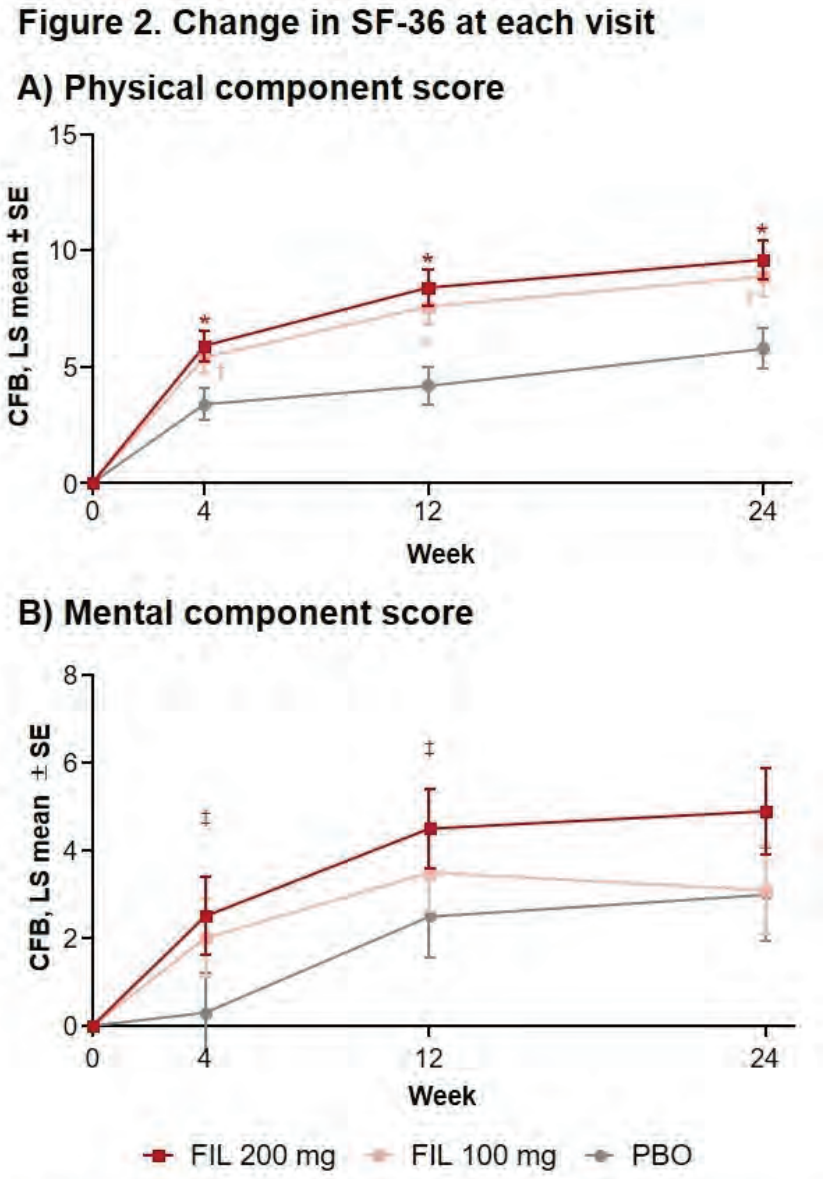
Figure 1. Change in patients' pain and fatigue at each visit



*p ≤0.001, †p <0.01 for LS mean difference between the FIL arm vs PBO.
CFB, change from baseline; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; FIL, filgotinib; LS, least squares; PBO, placebo; SE, standard error; VAS, visual analog scale.

Methods: Patients in this double-blind, randomized study (NCT02873936) received FIL 200 mg, FIL 100 mg, or PBO while continuing csDMARD therapy. PROs were collected prospectively on day 1 and at the W2, W4, W8, W12, W14, W16, W20, and W24 visits for assessment of pain (VAS pain scale]) and on day 1 and at W4, W12, and W24 for assessment of fatigue (FACIT-Fatigue) and HRQoL (SF-36). Changes from baseline for each PRO at each time point up to W24 were analyzed longitudinally using a mixed-effects model for repeated measures. P values for the difference between each FIL arm and PBO at each time point were calculated.

Figure 2. Change in SF-36 at each visit



*p ≤0.001, †p <0.01, ‡p <0.05 for LS mean difference between the FIL arm vs PBO.
CFB, change from baseline; FIL, filgotinib; LS, least squares; PBO, placebo; SE, standard error; SF-36, Short-Form 36.

Results: Among the 448 patients randomized and treated (FIL 200 mg, n = 147; FIL 100 mg, n = 153; PBO, n = 148) 381 (85.0%) completed the study. Baseline mean (SD) VAS pain scale was 67 (21.0), SF-36 physical component summary (PCS) was 31.1 (7.89), SF-36 mental component summary (MCS) was 44.3 (11.6), and FACIT-Fatigue score was 24.4 (11.6); baseline values did not vary between treatment groups. Significantly greater improvements in VAS pain scores began at W2 and were maintained through W24 for patients who received either dose of FIL vs PBO (**Fig 1A**). FIL also significantly improved patients' fatigue at W4, W12, and W24 compared with PBO for those receiving 200 mg doses, and at W4 and W12 for those receiving 100 mg doses (**Fig 1B**). HRQoL related to physical functioning (SF-36 PCS) was significantly enhanced at W4, W12, and W24 with both doses of FIL as compared with PBO (**Fig 2A**). Improvements to mental-health-related QoL (SF-36 MCS) were reported for FIL as early as W4 and maintained through W24, with statistically significant improvements at W4 and W12 for FIL 200 mg vs PBO (**Fig 2B**).

Conclusion: In a patient population with refractory disease that had inadequate response to prior bDMARDs and had significant disease at baseline, FIL treatment—coadministered with csDMARD therapy—was able to provide rapid and sustained improvements in key measures of pain, HRQoL, and fatigue as reported by patients.

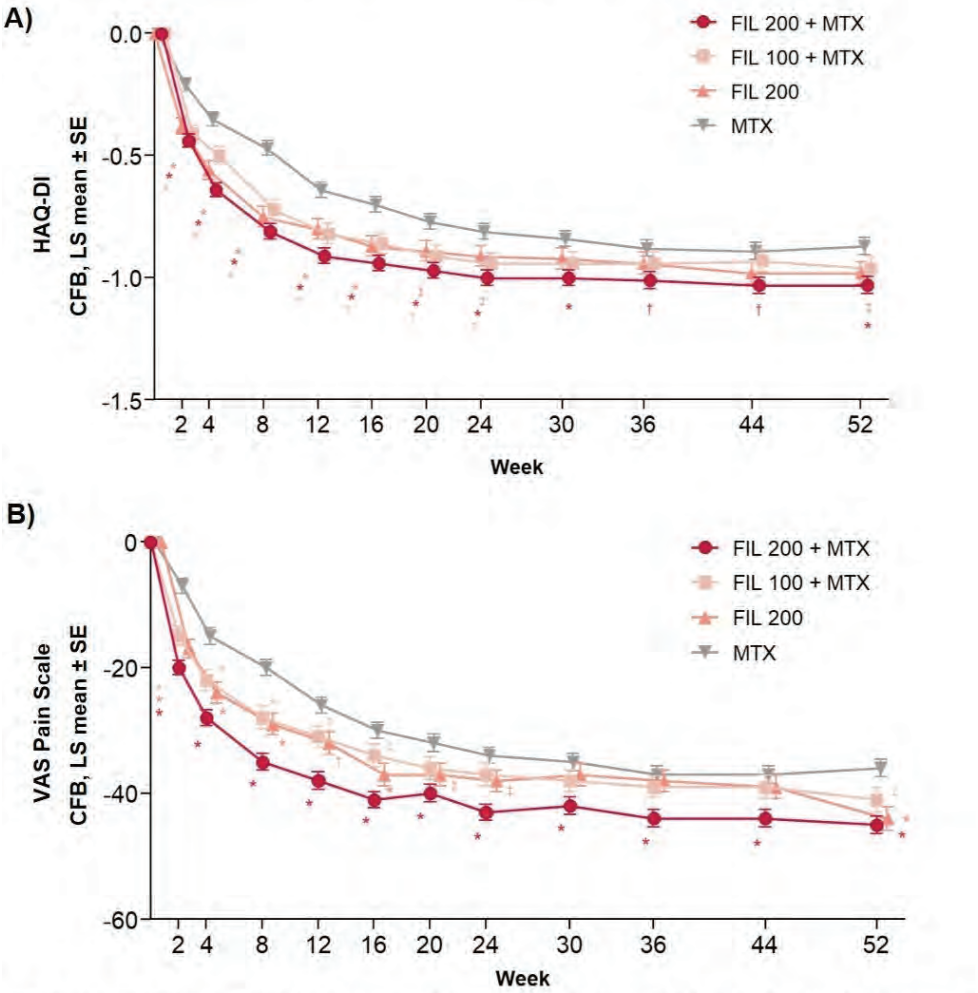
Filgotinib Provided Rapid and Sustained Improvements in Functional Status, Pain, and Health Related Quality of Life, and Reduced Fatigue over Time in Patients with Rheumatoid Arthritis Who Are Methotrexate-Naïve: Results from a Phase 3 Study

Rieke Alten[1], William F. C. Rigby[2], Alena Pechonkina[3], Zhaoyu Yin[4], Ken Hasegawa[4], Thijs Hendrikx[5], Tatsuya Atsumi[6] and Rene Westhovens[7], [1]Schlosspark-Klinik, Universitätsmedizin, Berlin, Germany, [2]Geisel School of Medicine at Dartmouth, Lebanon, NH, [3]Gilead Sciences, Inc., Foster City, [4]Gilead Sciences, Inc., Foster City, CA, [5]Galapagos BV, Leiden, Netherlands, [6]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine, Hokkaido University, Sapparo, Hokkaido, Japan, [7]University Hospitals Leuven, Belgium, Leuven, Belgium

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In FINCH 3, filgotinib (FIL)—a potent, selective, oral JAK1 inhibitor[1]—in combination with methotrexate (MTX), demonstrated significant improvements in signs and symptoms of rheumatoid arthritis (RA) vs MTX alone in patients (pts) who were MTX-naïve.[2] For pts with RA, rapid control of pain and fatigue along with maintenance of physical function and health-related quality of life (HRQoL) are important outcomes.[3] Patient-reported outcomes (PROs) can provide physicians with evidence to guide treatment decisions beyond guideline-recommended treatment targets of reducing immune inflammation to prevent joint damage, physical disability, and mortality.[4] Here, we evaluated rate and magnitude of change in PROs assessing functional status, pain, HRQoL, and fatigue from FINCH 3 (NCT02886728).

Figure 1. Change in HAQ-DI and VAS pain scale at each visit



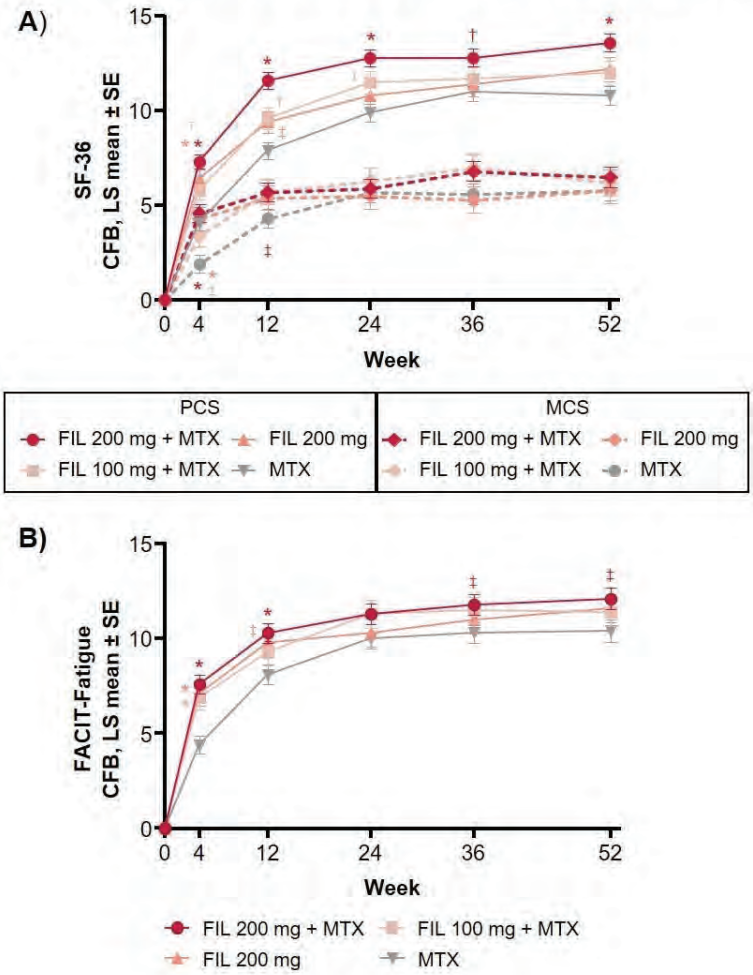
*p <0.001, †p <0.01, ‡p <0.05 for LS mean of the difference between FIL arm vs MTX. P values were not adjusted for multiplicity, except for HAQ-DI CFB at W24 for FIL 200 mg + MTX and FIL 100 mg + MTX vs MTX.
CFB, change from baseline; FIL, filgotinib; LS, least squares; MTX, methotrexate; SE, standard error; VAS, visual analog scale.

Methods: Pts with active RA and MTX-naïve received FIL 200 mg daily+MTX, FIL 100 mg+MTX, FIL 200 mg+placebo (PBO), or MTX+PBO for up to 52 weeks. PROs, recorded prospectively, included HAQ-DI (functional status) and VAS pain scale (day 1, week [W]2, W4, W8, W12, W16, W20, W24, W30, W36, W44, W52), SF-36 (HRQoL), and FACIT-Fatigue (day 1, W4, W12, W24, W36, W52). The least squares mean of the change from baseline (CFB) at each time point up to W52 and p values (each FIL arm vs MTX) were analyzed using mixed-effects model for repeated measures.

For HAQ-DI, proportion of pts who achieved the minimum clinically important difference (MCID; reduction ≥0.22) between each FIL arm and MTX was analyzed using logistic regression analysis. P values for comparisons of PROs were not adjusted for multiplicity, except for HAQ-DI CFB at W24 for FIL 200 mg + MTX and FIL 100 mg + MTX vs MTX.

Results: Of 1249 pts randomized and treated (FIL 200 mg + MTX, n=416; FIL 100mg + MTX, n=207; FIL 200mg, n=210; MTX, n=416), 82.1% completed the study. Compared with MTX alone, a nominally significantly greater CFB

Figure 2. Change in SF-36 and FACIT-Fatigue at each visit



*p <0.001, †p <0.01, ‡p <0.05 for LS mean of the difference between FIL arm vs MTX. P values were not adjusted for multiplicity.
CFB, change from baseline; FIL, filgotinib; LS, least squares; MCS, mental component score; MTX, methotrexate; PCS, physical component score; SE, standard error.

in functional status and pain from W2 to W24 was observed in all FIL arms; the benefit was sustained from W30 to W52 (**Fig 1**). By W2, a nominally significantly greater proportion achieved the HAQ-DI MCID or greater (≥0.22) in all FIL arms (FIL 200 mg + MTX: 61.9%, p < 0.001; FIL 100 mg + MTX: 58.5%, p < 0.001; FIL 200 mg: 53.9%, p=0.004) compared with MTX (42.2%). By W8, ≥72% of pts in all FIL arms vs 63% of pts in the MTX arm achieved the HAQ-DI MCID; a numerically greater proportion of pts in FIL arms vs MTX achieved HAQ-DI MCID through W52. SF-36 physical component summary and FACIT-Fatigue scores were nominally significantly improved with FIL treatment vs MTX alone at various time points (**Fig 2A, B**). Improvements in SF-36 mental component summary scores were nominally significant for pts in all FIL arms vs MTX alone as early as W4, and the CFB reached at W12 for FIL arms was generally sustained up to W52 (**Fig 2A**).

Conclusion: For pts with moderate to severe RA who were MTX-naïve, FIL—with or without concomitant MTX—led to rapid and sustained improvements in functional status, pain, fatigue, and HRQoL, compared with MTX alone.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Janus kinase (JAK) family is comprised of JAK1, JAK2, JAK3 and tyrosine kinase 2 (TYK2). JAKs form homo- or hetero-complexes, the combination of which plays crucial role in various cytokine signaling. JAK inhibitors (JAKis) have been approved for the treatment of RA. Granulocyte Macrophage colony-stimulating Factor (GM-CSF) could be implicated in the pathophysiology of RA by activating innate immune cells. We assessed the effects of isoform-specific JAKis on GM-CSF-primed human innate immune cells.

Methods: Human monocytic cell line, THP-1 cells or primary human neutrophils pretreated with tofacitinib (TOF), baricitinib (BAR) and upadacitinib (UPA) were stimulated with GM-CSF (20 ng/mL). JAK/ signal transducer and activator of transcription (STAT) phosphorylation and subsequent interleukin-1β (IL-1β) production were investigated using western blot and ELISA method.

Results: All JAKis blocked GM-CSF induced JAK2 phosphorylation at high concentration (400 nM) in THP-1 cells. BAR and UPA also inhibited JAK2 phosphorylation at lower concentrations (25 and 100 nM). Similarly, not TOF but BAR and UPA suppressed STAT5 phosphorylation at higher concentrations (100 and 400 nM) in THP-1 cells. BAR

and UPA significantly suppressed the IL-1β at lower concentrations (25 and 100 nM) compared to TOF in THP-1 cells. Consistent with THP-1 cells, all JAKis inhibited IL-1β production at high concentration (400 nM) in human neutrophils. However, BAR significantly suppressed IL-1β at lower concentration (25 nM) compared to TOF in human neutrophils. All JAKis suppressed the expression of NLR family pyrin domain-containing 3 and casepase-1 (p20) release at high concentration (400 nM) whereas only BAR suppressed them even at lower concentration in human neutrophils.

Conclusion: The inhibition of JAK2-dependent cytokine signals varies depending on the type of JAKis. This suggests difference of JAK selectivity among JAKis may affect the modulation of innate immune cell activation.

Filgotinib Provided Rapid and Sustained Improvements in Functional Status, Pain, Health-related Quality of Life, and Fatigue in Patients with Rheumatoid Arthritis and Inadequate Response to Methotrexate

Alan Kivitz[1], Yoshiya Tanaka[2], Susan Lee[3], Lei Ye[3], Hao Hu[3], Robin Besuyen[4] and Bernard Combe[5], [1]Altoona Center for Clinical Research/Altoona Arthritis and Osteoporosis Center, Duncansville, PA, [2]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Gilead Sciences, Inc., Foster City, CA, [4]Galapagos BV, Leiden, Netherlands, [5]University of Montpellier, Montpellier, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

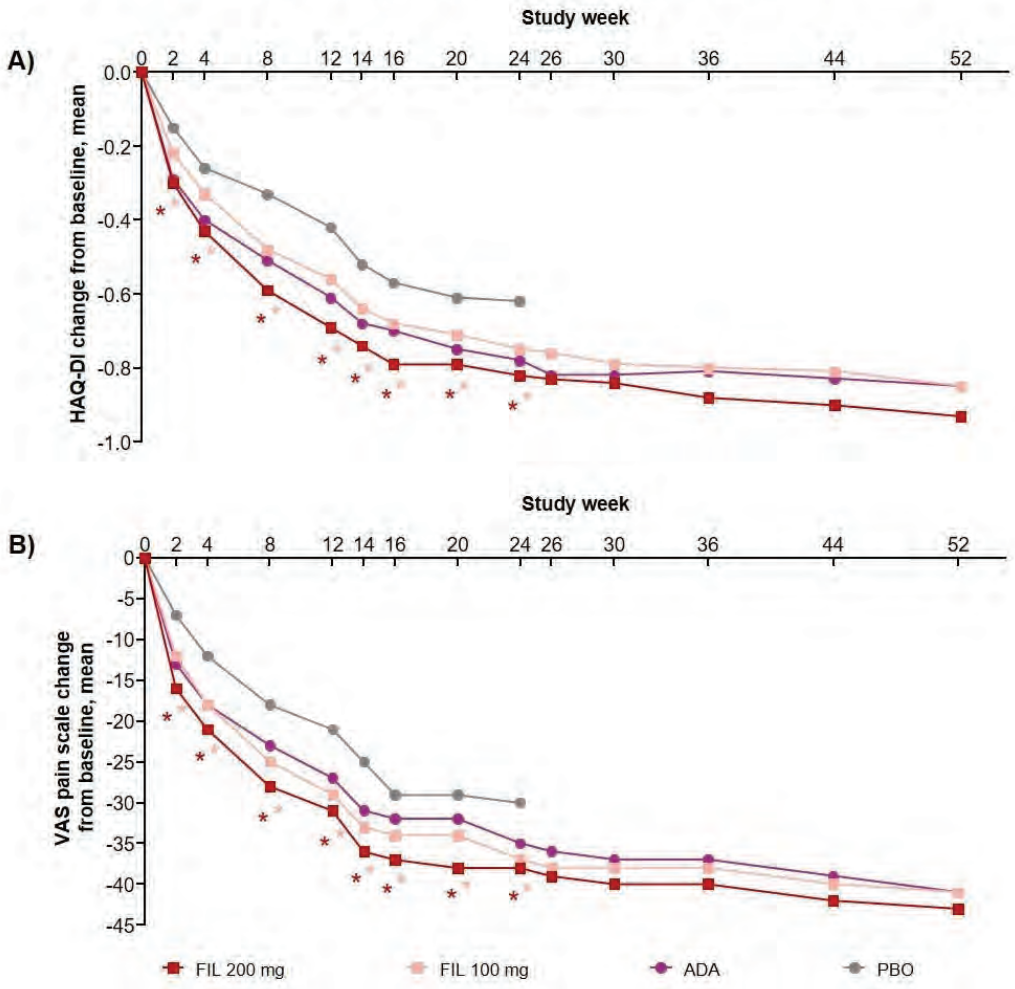
Background/Purpose: In the FINCH 1 study, filgotinib (FIL)—an oral, potent, selective JAK1 inhibitor—plus methotrexate (MTX) provided significant improvements in signs and symptoms of rheumatoid arthritis (RA) in patients (pts) with inadequate response to MTX.[1] EULAR guidelines recommend a treat-to-target approach focused on reducing inflammation to prevent joint damage, physical disability, and mortality, but pts consider pain and fatigue control, and maintenance of physical function and health-related quality of life (HRQoL), to be important aspects of care.[2,3] Here, we present the rate and magnitude of change in PROs from FINCH 1.

Methods: In FINCH 1 (NCT02889796), pts with active RA received oral FIL 200 mg + MTX, FIL 100 mg + MTX, PBO + MTX, or subcutaneous adalimumab (ADA) 40 mg + MTX for up to 52 weeks (W); pts receiving PBO at W24 were rerandomized 1:1 to FIL 100 or 200 mg.

PROs included the HAQ-DI and VAS pain scale, SF-36, and FACIT-Fatigue questionnaire. The change from baseline (CFB) at each time point was assessed up to W52 for each treatment group. Mixed-effects model for repeated measures was used to compare each FIL group with PBO for the CFB at each time point through W24. logistic regression model was used to compare each FIL group with PBO for the proportion of pts achieving the minimum clinically important difference (MCID) of ≥0.22 reduction in CFB in HAQ-DI at each time point through W24.

Results: Of 1755 pts randomized and treated (475 FIL 200 mg + MTX; 480 FIL 100 mg + MTX; 325 ADA + MTX; and 475 PBO + MTX), 1417 (80.7%) received study drug through W52. As early as W2 through W24, pts receiving

Figure 1. Change from baseline in A) HAQ-DI and B) VAS pain scale at each visit

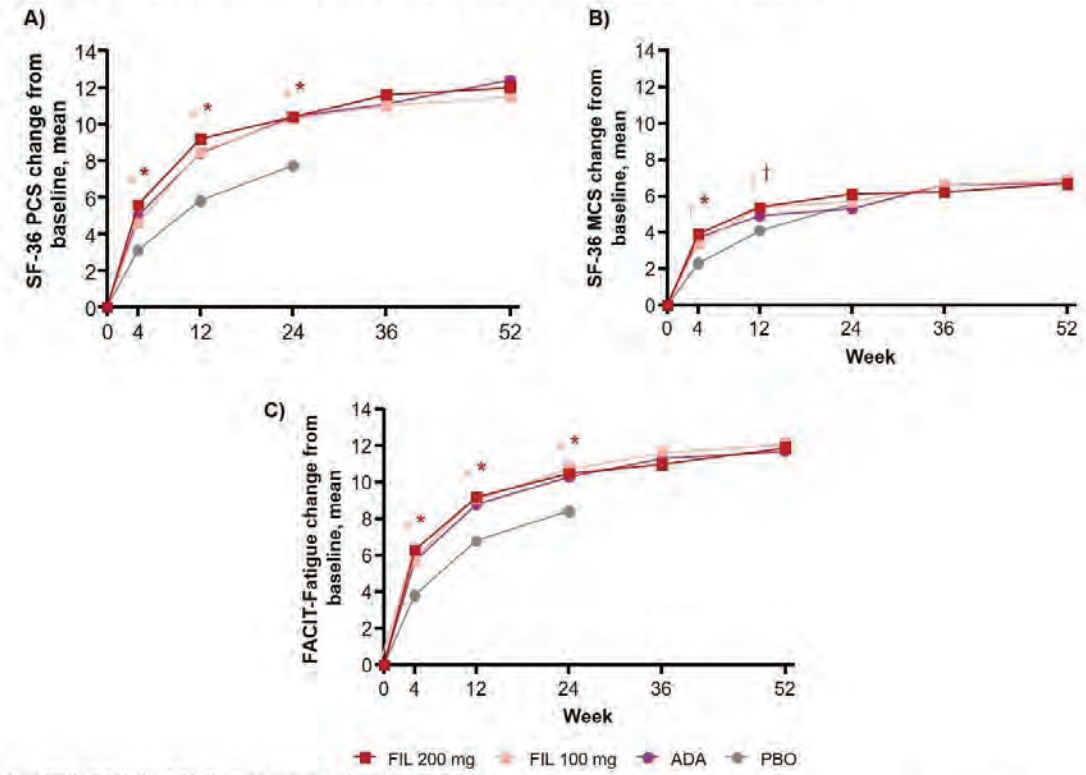


*p vs PBO <0.001, not adjusted for multiplicity except at week 12 for HAQ-DI.
Patients receiving PBO were rerandomized 1:1 to FIL 100 or 200 mg at week 24.
ADA, adalimumab; FIL, filgotinib; HAQ-DI, Health Assessment Questionnaire Disability Index; PBO, placebo; VAS, visual analog scale.

either FIL dose experienced nominally significantly greater ($p < 0.001$) CFB in HAQ-DI and VAS pain scale than those receiving PBO; CFB improvements were maintained through W52 (**Fig 1A, B**). At W2, compared with PBO (40.2%), a nominally significantly greater proportion of pts achieved the HAQ-DI MCID in both the FIL 200 (52.5%; $p < 0.001$) and 100 mg (46.7%; $p = 0.043$) groups. This benefit vs PBO was maintained up to W24 and the proportion of pts who achieved a HAQ-DI reduction ≥0.22 remained ≥75.8% in the FIL 200 mg group and ≥71.5% in the FIL 100 mg group from W12 through W52. FIL provided nominally significantly greater improvement in HRQoL vs PBO at W4 and W12 for both the CFB of the SF-36 Physical Component Summary (PCS; $p < 0.001$) and Mental Component Summary (MCS;$p \leq 0.006$); nominal significance was also seen at W24 for CFB of SF-36 PCS (**Fig 2A, B**). By W4, pts receiving either dose of FIL reported a nominally significantly greater mean CFB in FACIT-Fatigue scores vs PBO ($p < 0.001$); significance was maintained through W24 and improvement in reported fatigue continued through W52 in the FIL groups (**Fig 2C**). In general, CFB for HAQ-DI, VAS pain scale, and FACIT-Fatigue observed for the FIL groups was higher or comparable to ADA at various time points (**Fig 1, 2**).

Conclusion: Both doses of FIL provided rapid and sustained improvements in functional status, pain, HRQoL, and fatigue vs PBO for pts with RA and inadequate response to MTX throughout the 52-week period.

Figure 2. Change from baseline in SF-36 A) PCS and B) MCS and C) FACIT-Fatigue



*p vs PBO ≤0.001; †p ≤0.01. P values were not adjusted for multiplicity.
Patients receiving PBO were rerandomized 1:1 to FIL 100 or 200 mg at week 24.

Abstract Number: 1219

Reaching Remission by IL-1 Inhibition in Rheumatoid Arthritis Patients with Type 2 Diabetes Improves the Glucose Homeostasis: Long-term Findings from TRACK Study, a Multicentre, Open-label, Randomised, Controlled Trial

Piero Ruscitti[1], Onorina Berardicurti[1], Paola Cipriani[1] and Roberto Giacomelli[1], [1]University of L'Aquila, L'Aquila, Italy

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The inflammatory contribution to type 2 diabetes (T2D) has suggested new therapeutic targets by using biologic DMARDs designed for rheumatoid arthritis (RA), and IL-1 would be a common pathogenic mediator, suggesting a possible common therapeutic target. In TRACK study, a multicentre open-label, randomised controlled trial, anakinra, a human interleukin-1-receptor antagonist, showed to induce a significant improvement of metabolic alteration whereas TNFi did not show any significant improvement on that, after 6 months of therapy (crude difference of 0.93 of glycated haemoglobin, HbA1c% between groups). Concerning RA, a progressive reduction of disease activity was observed in both groups.

Since TRACK study has been prematurely stopped for "early benefit" after 6 months of follow-up, in this work, we aimed at investigating how long lasted the improvement of HbA1c% and of RA disease activity, including the rate of reduction and discontinuation of both antidiabetic drugs and glucocorticoids (GCs).

Methods: In this study, participants with RA and T2D, were randomised to anakinra or to a TNFi and the primary endpoint was the change in HbA1c% (EudraCT: 2012-005370-62; ClinicalTrial.gov: NCT02236481). In this further evaluation, we assessed how long lasted the improvement of HbA1c% and of RA disease activity.

Results: In TRACK study, 39 participants with RA and T2D (age 62.72 ± 9.97, 74.4% female gender) were randomised to anakinra or to TNFi; the majority of participants had seropositive RA disease with active disease (DAS28: 5.54 ± 1.03; C-reactive protein 11.84 ±9.67 mg/L) and all participants had T2D (HbA1c%: 7.77 ±0.70, fasting plasma glucose: 139.13 ±42.17 mg). Considering the last available observation, a maintenance of reduced levels of HbA1c% was observed in anakinra-treated participants (Baseline: 7.73% ±0.67; 6 months: 6.70% ±0.67; last follow-up: 6.60% ±0.52). Paralleling with HbA1c%, a significant reduction of dosages of antidiabetic therapies was observed in anakinra-treated participants, with a percentage of participants who discontinued any anti-diabetic therapy. Conversely, an intensification of antidiabetic therapies was reported in TNFi-treated participants. Concerning RA, the clinical response was maintained during the whole follow-up, although a larger percentage of anakinra-treated participants discontinued the concomitant GCs therapy. Analysing the safety profile, as observed in first 6 months of the study, only minor side effects were recorded during the whole follow-up with no difference between groups, except for self-limited urticarial lesions at the injection site which were more frequently in anakinra-treated participants.

Conclusion: Data deriving from the long-term extension of participants with RA and T2D, enrolled in the TRACK study, showed that the benefits of IL-1 inhibition on metabolic and inflammatory parameters lasted longer than the first 6 months of follow-up. Thus, the presence of T2D could identify a subset of RA patients likely benefitting of IL-1

inhibition. Finally, the achievement of optimal therapeutic targets for both RA and T2D might significantly improve the cardiovascular burden of these patients.

Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Presence of citrullinated protein fragments in the circulation of patients with Rheumatoid Arthritis (RA) is a highly disease-specific phenomenon. Vimentin is often a target for citrullination and MMP-mediated degradation as a consequence of disease initiation and progression. Generation of citrullinated or non-citrullinated vimentin fragments (VICM and VIM) are associated with chronic inflammation and can be of high biomarker potential for disease and treatment monitoring. In this study, we aimed to investigate if two different monotherapies, Tocilizumab (TCZ) and Methotrexate (MTX) can differently modulate serum levels of VIM and VICM in RA patients at the early therapy time-point.

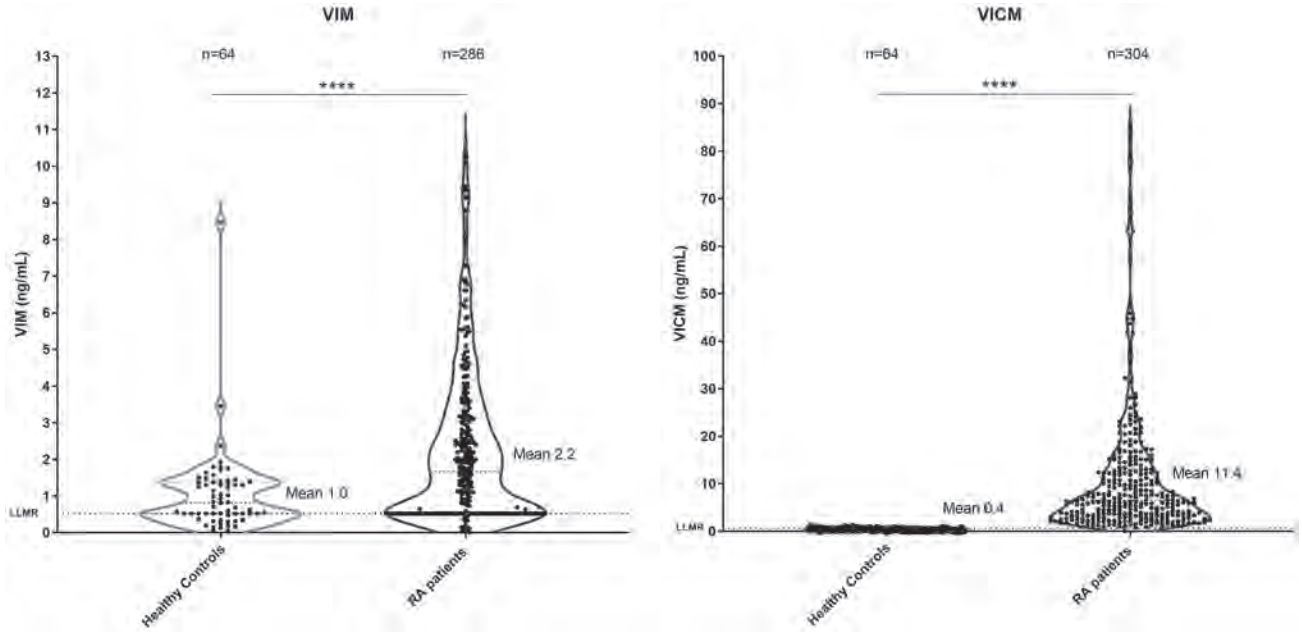

Figure 1. Figures represent differences in serum levels of VIM and VICM biomarker between healthy controls and RA patients at baseline.

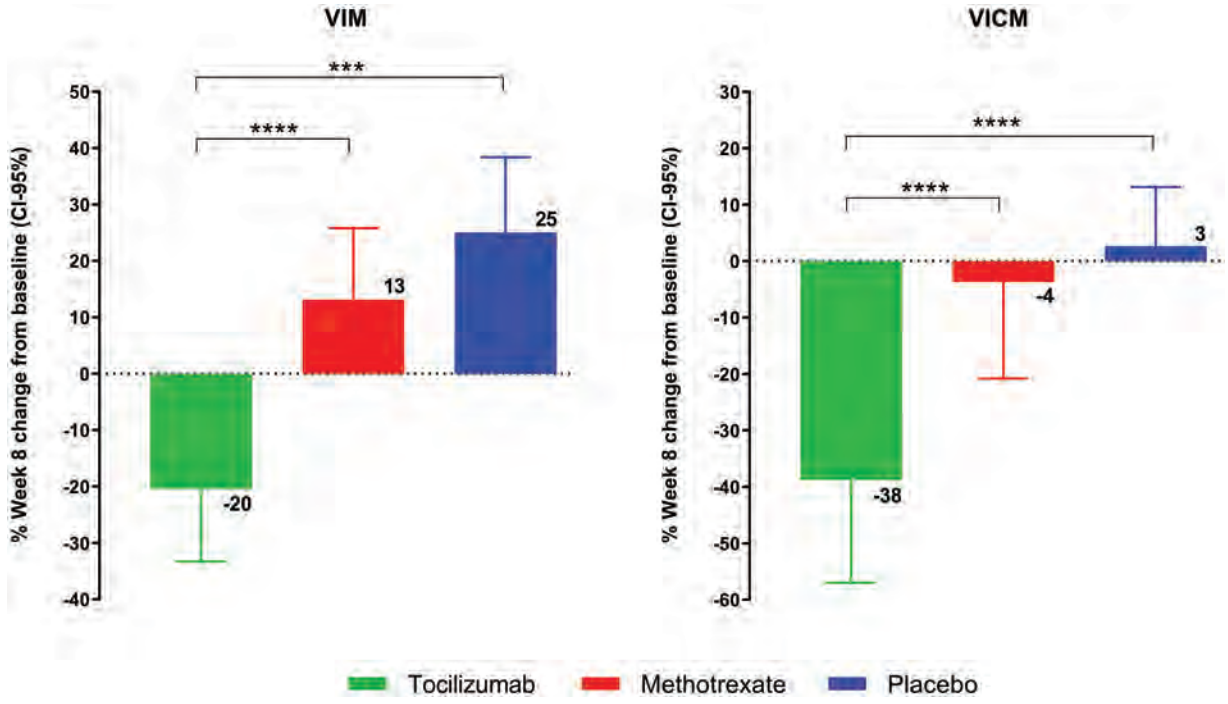

Figure 2. Figures represent differences in modulation of VIM and VICM biomarker levels according to treatment group from baseline to week 8. Data are shown as mean with confidence interval CI-95%.

Methods: Patients with moderate to severe RA in phase III randomized controlled clinical trial were exposed to either TCZ monotherapy (8 mg/kg every 4 weeks) or MTX monotherapy (starting at 7.5 mg/kg and titrated to 20 mg/kg) over 24 weeks. Serum levels of VIM and VICM were measured at baseline and 8-weeks sera from 304 RA patients and 64 healthy controls by validated ELISA assays. We investigated the comparison between treatment and response groups using ANCOVA and correlations using Spearman's rho adjusted for patient demographic characteristics (gender, age, BMI and disease duration).

Results: Serum levels of VIM and VICM were significantly higher in RA patients than in healthy controls ($P < 0.0001$) (Fig. 1). RA patients with the greatest disease activity had the highest serum levels of VICM ($P < 0.01$). VIM and VICM biomarkers were significantly inhibited at week 8 by TCZ compared to placebo patients ($P < 0.001$ and $P < 0.0001$, respectively) (Fig. 2). The inhibition of VIM and VICM levels with TCZ was respectively 33% and 34% greater than that of MTX (both $P < 0.0001$). Biomarker profiles of VIM and VICM revealed a significant inhibition difference in MTX ACR50 treatment responding and non-responding patients ($P < 0.05$ and $P < 0.01$), whereas no statistically significant difference was observed in TCZ ACR50 patients. Change in serum levels of VICM to week 8 in MTX patients correlated significantly with change in disease activity score-28 (DAS28) at week 8, 16 and 24 (rho 0.31 to 0.23, $P = 0.0006$ to 0.01).

Conclusion: Present findings show that patients treated with TCZ for 8 weeks have clearly higher suppression of VIM and VICM biomarkers over patients treated with MTX. The differences in biomarker profiles of ACR50 patients enable for their stratification and identification of those who benefit from the treatment at the early time-point. The correlation of serum VICM with DAS28 at different time-points may suggest its treatment prognostic value in RA.

Abstract Number: 1221

Evaluation of Methotrexate Efficacy and Exploration of Metabolites Associated with Disease Activity in Collagen-induced Arthritis Mouse Model

Yu Kyoung Cho[1] and **Ryan Funk**[1], [1]UNIVERSITY OF KANSAS, Kansas City, KS

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is cornerstone of therapy for rheumatoid arthritis. However, response to MTX is variable and unpredicTable among patients. Therefore, there is a critical need to identify potential biomarkers to improve drug response to MTX in arthritis. This study aims to evaluate MTX and circulating folates in the response to MTX treatment, and to explore metabolomic data to identify potential biomarkers associated with disease activity in collagen-induced arthritis (CIA) mouse.

Methods: The study included untreated healthy control group (n=10), MTX treated control group (n=10), untreated CIA group (n=8), and MTX treated CIA group (n=9). As endpoint analysis, disease activity score using an established scoring system were determined and paw volume using limb water volume displacement were measured. Plasma or erythrocyte samples were collected and submitted to the National Institutes of Health West Coase Metabolomics Center to measure intermediates of primary metabolism, biogenic amines, and lipids. Raw peak intensity data was utilized to identify and rank metabolites using MataboAnalyst 4.0. The metabolites with significant fold change and false discovery rate adjusted R values in the induction of disease or in the treatment of MTX were subjected to enrichment analysis using Chemical Similarity Enrichment Analysis for Metabolomics (ChemRich) and mapping data were visualized using Cytoscape 3.7.2.

Results: MTX efficacy in CIA and control mice with or without MTX treatment was evaluated. Compared to control group, CIA mice appeared significant induction in both disease activity scores (Mean±S.E.M., 9 ± 1 vs 0 ± 0, $P < 0.001$) and paw volume (0.48 ± 0.02 ml vs 0.35 ± 0.01 ml, $P < 0.001$). CIA group treated with MTX had reduced disease activity scores (1 ± 0.4 vs 9 ± 1, $P < 0.001$) and paw volume (0.37 ± 0.01 ml vs 0.48 ± 0.02 ml, $P < 0.001$) compared to the CIA untreated group. A concentration of 5mTHF in RBCs was significantly influenced by the induction of disease ($P < 0.05$) and the exposure of MTX ($P < 0.001$). Similarly, a significant diffrence in a concentration of 5mTHF in plasma was observed between untreated CIA group and MTX treated CIA group (9.34 ± 3.18 nM vs 45.03 ± 10.84 nM, $P < 0.01$). RBC 5mTHF was postiviely correlated with disease activity score ($\rho = 0.740$, $P = 0.001$) and paw volume ($\rho = 0.709$, $P = 0.001$) in CIA mice. Metabolomic analysis using ChemRich revealed most significant changes in the unsaturated triglycerides in the induction of disease and unsaturated phosphatidylcholines in the treatment of MTX.

Conclusion: Our study demonstrated that MTX treatment recovered a reduction in arthritis disease activity in the CIA mouse model. Associations of pharmacologic folates level with MTX efficacy suggest that erythrocyte 5mTHF levels as a potential predictor of MTX response. Metabolomic analysis of plasma generated a list of metabolites that significantly correlated with disease activity. The results suggest that metabolomic approach may lead to identify potential biomarkers in MTX response in autoimmune arthritis.

Iron Management in Patients with Rheumatoid Arthritis

Wojciech Tański[1], Mariusz Chabowski[2] and Ewa Jankowska[3], [1]4th Military Teaching Hospital, Wrocław, Poland, [2]4th Military Teaching Hospital, Wroclaw Medical University, Wrocław, Poland, [3]Wroclaw Medical University, Wrocław, Poland

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic connective tissue disease with immune background, which affects approximately 0.3-2% of the population. Anaemia is the most common hematologic disorder in patients with RA, has a multifactorial origin with the significant contribution of inflammatory processes and the deficiencies of several erythropoiesis modulators. Anaemia occurring in the course of RA intensifies the severity of primary disease and makes favorable conditions for more extensive joint structure damage. There is evidence showing a clinical significance of iron deficiency (ID) seen in inflammatory diseases, regardless of concomitant anaemia. There is no comprehensive analysis of this problem in rheumatological patients.

Aim of the study was to evaluate iron metabolism in patients with RA using standard laboratory parameters. The influence of tocilizumab on iron status parameters and the course of primary disease in patients with RA have been evaluated.

Methods: Sixty-two RA patients hospitalized in the Department of Internal Medicine. The diagnosis of RA was made in accordance of the American Rheumatology Society. The patients were divided: group A - observational and group B -interventional. In the part A, patients with RA and healthy persons were examined. In the part B, patients included in tocilizumab therapy. Patientsfrom B group were examined twice, before and after the 3-month therapy with tocilizumab. Patients with RA were treated with standard disease modifying medications in accordance with recommendations.

Results: ID was found in patients with or without anaemia (66% vs 55%; $p > 0.2$). Patients with RA in comparison to healthy subjects had lower transferrin saturation, lower serum ferritin and hepcidin, and increased serum soluble transferrin receptor ($p < 0.05$). Patients with RA and ID in comparison to those without ID had lower serum hepcidin ($p < 0.05$). In patients with RA there were correlations between lower hemoglobin, lower red cell indices and parameters describing iron status. In univariable models, there were no associations between the prevalence of ID and some inflammatory parameters and those describing immune abnormalities in patients with RA. In multivariable models, two strongest determinants of ID prevalence in patients with RA were identified: lower hemoglobin and higher DAS28 score. In addition the three-month therapy with tocilizumab reduced the severity of RA assessed on the reduction of both CRP level and DAS28 score ($p < 0.05$). The therapy also influenced parameters of iron status: reduced serum ferritin and hepcidin and reduced the magnitude of ID as expressed by the reduction in the percentage of patients with TSAT< 20% and the decrease in serum soluble transferrin receptor.

Conclusion: Among patients with RA iron deficiency is more common than anaemia. Tocilizumab therapy in patients with RA along with the improvement in clinical status and the attenuation of inflammatory processes partially normalizes iron status assessed on circulating biomarkers. The results constitute premises to take into consideration the assessment of iron status parameters in the standard clinical evaluation of patients with RA.

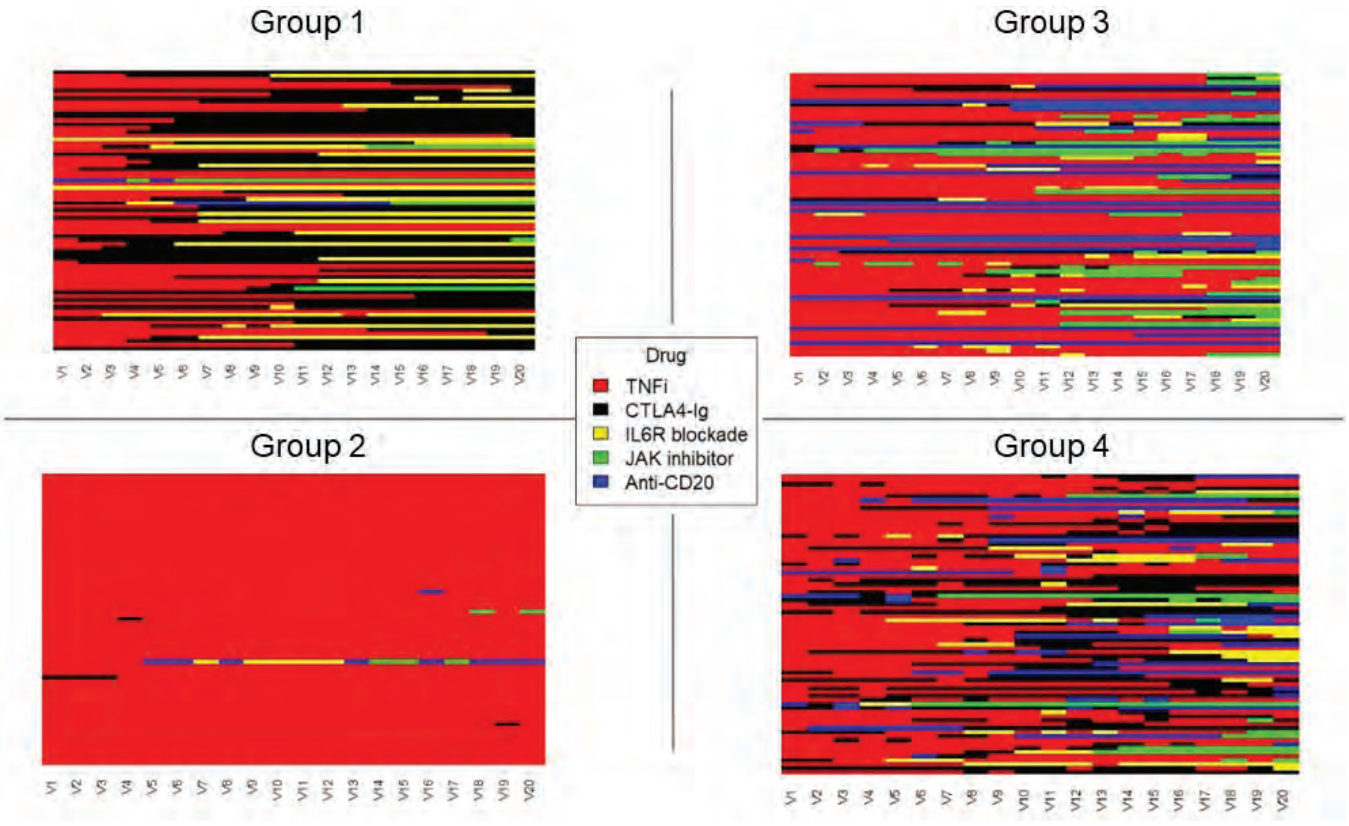
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: IIn rheumatoid arthritis (RA), a patient's biologic disease modifying anti-rheumatic drug (bDMARD) history and the duration of time they remain on each drug may provide an alternative approach to studying treatment efficacy. Due to the complexity of these data, how to determine if patients are similar based on their past bDMARD use is challenging. Bioinformatics methods designed to study genetic sequences are now available that



Visualization of the 4 groups identified from clustering bDMARD sequences. Data from 75 random patients from each group shown with x-axis denoting the first 20 states (V1-V20) for each patient.

Clinical characteristic	Group			
	1	2	3	4
Age, mean (SD)	50.3 (14.7)	47.8 (15.6)	53.7 (16.1)	49.3 (14.6)
% female	83.0	70.6	74.8	83.3
RA follow-up time (months)	94.2	73.5	60.8	71.1
% seropositive	80.5	64.7	70.4	72.1
Charlson comorbidity index, mean	1.7	1.4	2.8	1.6
Short description	Abatacept & tocilizumab	TNFi	Rituximab & TNFi	Multiple bDMARD use

Comparison of clinical characteristics at the time of first bDMARD prescription across the 4 groups.

cluster sequences by similarity. In this proof of concept study, we applied and modified this bioinformatics approach to cluster RA patients by similar sequences of bDMARD prescriptions.

Methods: We studied patients from a validated electronic health record cohort of RA patients from two tertiary care centers and extracted data on all subjects who initiated a bDMARD 1/1/2008 through 07/31/2019. Inclusion criteria included subjects with ≥6 months of data prior to 1/1/2008 and no bDMARD prescription. The sequence of bDMARD for each subject was initiated with the 1st bDMARD prescription. Sequences were defined by 5 bDMARD drug classes: tumor necrosis factor inhibitors (TNFi), CTLA4-Ig/abatacept, IL6R blockade/tocilizumab, JAK inhibitor/tofacitinib (small molecule grouped as bDMARD for this study), and anti-CD20/rituximab. A change in bDMARD was defined as a change in bDMARD therapy ≥3 months from the prior bDMARD prescription. A sequence by drug class was constructed for each subject. The sequences were then analyzed using mixture Markov chain analysis. We consider the transitions of drug classes of a patient over the time as Markov chains where each of the drug classes was considered a state. We clustered the patients based on the sequence of drug classes. We calculated descriptive statistics for demographics, and obtained the Charlson comorbidity index at the time of the 1st bDMARD prescription to compare across clusters.

Results: We studied 8684 RA subjects who initiated a bDMARD after 1/1/2008. The mean age was 48.9 years, 73% female, 82% white, 68% seropositive, with mean follow-up time of 6.2 years; each subject had a unique sequence, thus there were 8684 sequences. The sequences clustered in 4 main groups (Figure). Descriptively, group 1 included patients who persisted on abatacept and tocilizumab therapy. Group 2 contained patients on TNFi for the majority of their follow-up. Group 3 contained a mixture of patients persisting on rituximab and TNFi. Group 4 included patients who tried multiple bDMARDs for variable lengths of time. The lowest % of females was observed in Group 2 (70%) compared to Group 4 (83%) which had the highest ($p< 0.0001$) (Table). The highest % seropositive was observed in group 1 (80.5%) compared with group 2 (65%) which had the lowest ($p< 0.0001$).

Conclusion: Transforming bDMARD prescription histories into a sequence allowed us to cluster RA patients into 4 main groups which demonstrated differing clinical characteristics at the time of the 1st bDMARD prescription. Future studies will examine whether the clinical profiles of patients in these clusters can be used to inform optimal bDMARD choices among RA patients prospectively.

Glucocorticoid Reduction in Different Profiles of Patients with Rheumatoid Arthritis and Treatment with Sarilumab

Esteban Rubio Romero[1], Alejandro Muñoz Jiménez[2], Rosalia Martinez Perez[3] and Lara Mendez Diaz[4], [1]VIRGEN DEL ROCIO UNIVERSITY HOSPITAL, SEVILLE, Spain, [2]H. U. Virgen del Rocío (Sevilla), Sevilla, Spain, [3]Virgen del Rocío University Hospital, seville, Spain, [4]Virgen del Rocío Hospital, sevilla, Spain

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoid reduction in different profiles of patients with rheumatoid arthritis and sarilumab treatment. Real clinical practice studies are tasked with providing clinically relevant data that may clarify the benefits of this new IL-6 receptor blocking alternative, with higher affinity and dosing every two weeks. Beyond the magnitude of the effect that a drug can give us in a randomized, double-blind, control group clinical trial, the well-known selection biases of these studies do not always offer a representative picture of reality when using that drug on the day consultation day.

Methods: The data, hereafter commented, is the result of a retrospective analysis carried out in March 2020 on patients who were assigned to Sarilumab from September 2018 to November 2019 and therefore have at least a first clinical evaluation carried out 12 weeks after their Start. This study offers in our opinion several novelties: Firstly, almost two thirds of the analyzed cohort are patients naïve to another biological treatment (58.6%). This fact allows us to assess “the best opportunity” for a drug. We found it interesting to analyze two variables: the reduction of glucocorticoid doses secondary to the use of sarilumab and the efficacy depending on its association or not with a csDMARD.

A descriptive study was carried out; For the parametric distribution numerical variables, the mean and standard deviation are performed, reserving the median for those non-parametric distribution numerical variables. For qualitative variables, a study was carried out using frequency Tables. And for the non-parametric ones, the Wilconxon test was

used, which also show values of $p < 0.05$ For inferential studies, a 95% CI was used. All of them analyzed using SPSS 19.

Results: The evolution in prednisone dose for the total of patients was striking and satisfactory. For a variable of temporary drug exposure, such as the one previously mentioned, we went from an average dose of 12mg / day to 5.2mg / day, a dose very close to the dose recommended in EULAR clinical practice guidelines, for the maintenance of a effective therapeutic strategy in an accepTable safety range. As in the case of efficacy assessed by an activity index, we stratified patients between those over 6 months exposed to Sarilumab and those with 6 or less months of treatment duration. In both cases the change had an effect size with clinical significance. In the population 6 months or less from the start of Sarilumab, the prednisone dose went from 11.2mg / day to mean prednisone 3.8mg / day and in patients with more than 6 months of treatment 12.9mg / day. at 6.7 mg / day.

Conclusion: In general, it could be stated that the drug Sarilumab presents in accepTable clinical practice an accepTable and predicTable safety profile. From the point of view of the efficacy variable, we highlight one aspect: A good ability to reduce the steroid dose in a short time.

Targeting to IL-6 or Specific JAKs for RA Treatment: Seeking a Rationale for Switching Each Other If One of These Treatments Resulted in Lack of Efficacy

Yoshinobu Koyama[1], Yoshiharu Sato[2], Hiroshi Iijima[2], Moe Sakamoto[3] and Toshie Higuchi[3], [1]Okayama Red Cross Hospital, Japanese Red Cross Society, Okayama, Japan, [2]DNA Chip Research Inc, Tokyo, Japan, [3]Division of Rheumatology, Okayama Red Cross Hospital, Japanese Red Cross Society, Okayama, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inhibition of IL-6 signaling is one of the most established strategies for RA treatment. Tocilizumab (TCZ) is the pioneer which blocks IL-6 signaling by preventing IL-6 from binding to its receptors. Tofacitinib (TOF) inhibits Janus kinase (JAK) 1, JAK3 and, to a lesser extent, JAK2. Recently, Baricitinib (BAR), JAK 1 and JAK2 selective kinase inhibitor, were also approved to treat RA. These JAK inhibitors are known to inhibit cytokine signaling IL-6. It is very important to know whether these treatments affect common biological processes or disparate, because it will provide a rationale for switching each other if one of these treatments resulted in lack of efficacy. In this study, we investigate the gene-expression modification profiles among TOF, BAR and TCZ treatments.

Methods: Total of 38 RA cases were analyzed, including TOF (n=15), BAR (n=10:) and TCZ (n=13) treatment groups. Peripheral blood was drawn at just before (pre) and 3 months after (post) these treatments. Total RNAs were then extracted with using PAXgene miRNA kit. After quantifying the expressions of transcripts by multiplex sequencing, differentially expressed genes (DEGs) were selected by paired comparison (post vs. pre) with using paired T-test. And then, hierarchical clustering analysis and enrichment analysis using gene ontology (GO) terms were performed.

Results: From the comparison of post- vs. pre-treatment of TOF, BAR and TCZ, the 120, 62 and 193 genes were selected as DEGs respectively. It seems to be discrete depending on the treatment, because overlapped genes were only 1.0% in up-regulated and 5.7% in down-regulated genes. The hierarchical clustering with expression profiles of these DEGs showed major 4 clusters. 92.3% of TCZ and 70% of BAR cases were segregated into 1st and 3rd clusters respectively, while those of TOF cases fell into 2nd and 4th clusters. Disparate GO terms were enriched in each DEGs group. For example, genes relevant to viral defense including ‘response to type I interferon (IFN)’ were suppressed in TOF group. Meanwhile, down regulation of genes involved in phosphorylation process including ‘IL-7 signaling’ seemed to be significant in BAR group. It is noteworthy that terms related to wound healing such as ‘platelet activation’ were enriched in the down-regulated genes of TCZ group.

Conclusion: It is speculated that the downstream biological cascade for TOF, BAR and TCZ treatment might be shared, as IL-6 signaling is mediated by JAK1/JAK2/TYK2 activation. However, the influence of these treatments over the transcriptome in the peripheral blood seems to be disparate. Enrichment analysis using GO terms also indicated that different biological processes were involved in the effect of each treatment. Our findings will support a rationale for switching each other if one of these treatments resulted in lack of efficacy. An increased risk of herpes zoster by a treatment with JAK inhibitors has been well recognized. It makes sense because IFN signaling is also mediated by JAK/STAT pathway. On the other hand, we have experienced a case with exacerbation of skin ulcer during TCZ treatment despite the activity of RA was absolutely under control. It is accounted for by the suppression of genes involved in wound healing after TCZ treatment.

Outcomes and Efficacy of Selective versus Automatic Switching from Etanercept to a Biosimilar in Inflammatory Arthritis Using Electronic Health Records from UK

Roxanne Cooksey[1], Sinead Brophy[1], Muhammad Azizur[1], Jonathan Kennedy[1] and **Ernest Choy**[2], [1]Swansea University, Swansea, Wales, United Kingdom, [2]CREATE Centre, Cardiff University, Cardiff, Wales, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Biosimilars have been approved for the treatment of inflammatory arthritis and evidence from randomised controlled trials have demonstrated equivalent efficacy to biologics. Etanercept biosimilar, SB4, is licensed for use to treat inflammatory arthritis. While some patients may selectively switch from reference etanercept (ETN) to SB4 by a rheumatologist or rheumatology nurse specialist, others may be automatically switched, by pharmacy. Currently, it is the policy of one Health Board area in Wales to use SB4 in place of ETN and to automatically switch ETN patients to SB4. While in a neighboring Health Board area, patients are not automatically switched but can selectively switch or commence SB4 treatment.

Methods: Using electronic health records we will investigate the safety and efficacy of switching of ETN to SB4 in one health region (Automatic SB4 area), compared with selective use and switching in a neighboring health region (Selective SB4 area). Data from the Secure Anonymised Information Linkage (SAIL) databank in Wales, United Kingdom was used to create a retrospective cohort study using linked, general practitioner, hospital and rheumatology clinic records. Patients aged 18 years or over with diagnosis codes for Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing spondylitis (AS) and treated with SB4 were included. Data was included from 2014 to 2019 to coincide with the introduction of biosimilar therapies in UK clinical practice.

Table 1: Characteristics and treatment outcomes of SB4 treated patients at selective SB4 area compared to automatic SB4 use area.

	Selective SB4 area (n=55)	Automatic SB4 area (n=184)	Difference 95% (CI)
Female	60% (33)	57.6% (106)	2.4 (-12.5 to 16.3)
Age at diagnosis	38.7 (SD:14.9)	39.7 (SD:12.7)	1 (-5.0 to 3.0)
Disease duration	23.2 (SD:3.5)	23.5 (SD:11.8)	0.3 (-3.5 to 2.9)
BMI	25.6 (SD:5.2)	27.9 (SD:5.8)	2.3 (0.6 to 4.0)*
RA diagnosis	61.8% (34)	70.1% (129)	8.3 (-22.9 to 5.3)
PsA diagnosis	20% (11)	11.4% (21)	8.6 (-1.4 to 21.5)
AS diagnosis	23.6% (13)	19.6% (36)	4.1 (-7.2 to 17.8)
Previous Etanercept	12.7% (7)	33.2% (61)	20.5 (7.5 to 30)*
Previous biologics	18.2% (10)	41.8% (77)	23.6 (9.7 to 34.4)
Mean previous csDMARDs	4.3 (SD: 1.8)	4.0 (SD: 1.7)	0.3 (-0.2 to 0.8)
SB4 treatment failure	No failure	16.8% (31)	-
Time to treatment failure (days)	N/A	515.9 (SD: 319.7)	-
Mean DAS28 pre-SB4	4.4 (SD: 1.1)	4.6 (SD: 1.0)	0.2 (-1.2 to 0.8)
Mean DAS28 post-SB4	2.6 (SD: 1.3)	4.2 (SD: 1.2)	1.6 (0.4 to 2.8)*
Difference in DAS28 score pre-and post-SB4	1.8 (SD: 1.5)	0.4 (SD: 0.8)	1.4 (0.4 to 2.4)*
Mean reduction in GP visits post-SB4	45 (SD: 46.9)	20.8 (SD: 75.5)	24.2 (19.1 to 45.4)*

*p=<0.05

Results: There were 239 patients with inflammatory arthritis treated with SB4 included in the study (Table 1). The majority of the patients had RA. In the automatic switching area, 184 patients were treated with SB4, compared to 55 in selective use area, where most patients were biologic naïve (45/55). Here, 7 of these patients (12.7%) were selectively switched from ETN to SB4 (Table 1). In the automatic switching area, 61 out of 181 (33.2%) were automatically switched; the remaining patients would have automatically commenced SB4 in place of reference ETN. Following treatment with SB4, the DAS28 reduced by 1.8 ± 1.5 in the selective SB4 area compared to a reduction of 0.4 ± 0.8 in the automatic SB4 area. This confirmed patients were switched from sTable disease. The GP visits were reduced in both selective (45 ± 46.9) and the automatic SB4 area (20.8 ± 75.5). The GP visit reduction was significantly larger in patients from the selective area compared to automatic area (difference 24.2 visits, 95% CI: 3.0 to 45.4).

Sensitivity analyses compared changes in DAS28 scores pre- and post-SB4 treatment between biologic naïve and biologic experienced SB4 patients. No significant difference was found in the change in DAS28 scores between biologic naïve and biologic experienced SB4 patients (difference 0.1, 95% CI: -1.2 to 1.4).

Conclusion: SB4 was effective in etanercept naïve patients. Automatically switching did not lead to disease worsening significant. Furthermore, treatment with SB4 reduced healthcare utilisation of patients, as measured by GP visits, whether automatically or selectively treated with the drug.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Biological therapies, as TNF inhibitors (TNFi) are increasing remission rates in rheumatoid arthritis (RA) patients although these are still limited. This study aims to explore whether TNFi modulate peripheral blood mononuclear cells (PBMC) after 6 months (m) of treatment and to identify a cellular profile associated with clinical remission (REM) in patients with RA.

Baseline patients' characteristics	Total patients (n=78)	DAS28>2.6 (n=49; 63%)	DAS28≤2.6 (n=29; 37%)	p-value
Age (years)	54±12	55±13	51±11	0.1
Female	67 (86)	43 (88)	24 (83)	0.5
Disease duration (years)	6 (3-11)	8 (4-12)	6 (3-10)	0.7
RF positive	60 (77)	35 (71)	25 (86)	0.1
ACPA positive	65 (83)	38 (78)	27 (93)	0.07
Smoking habit (n=64)				0.4
Non-smokers	29 (45)	19 (50)	10 (38)	
Smoker	35 (55)	19 (50)	16 (62)	
Body mass index (kg/m2)	25.4 (22.8-30.2)	25.6 (23.0-30.2)	24.7 (22.4-30.4)	0.6
DAS28	4.9±1.0	5.3±0.9	4.2±0.9	**<0.001**
Concomitant csDMARDs	75 (96)	48 (98)	27 (93)	0.7
MTX [±OD]	58 (74)	39 (80)	19 (68)	0.2
Only OD	17 (22)	9 (18)	8 (25)	0.2
Prednisone	45 (58)	30 (61)	15 (54)	0.5

Methods: A prospective and observational bi-center study including 78 patients with RA treated with standard doses of their first TNFi and followed-up during 6m was carried out. All included patients fulfilled the ACR/EULAR 2010 classification criteria for RA, were adults, with moderate or high disease activity (DAS28 >3.2). PBMC were analysed by flow-cytometry at the baseline and 6m. Clinical activity at baseline and after 6m was assessed by DAS28, establishing DAS28≤2.6 as the criteria for REM. Depending on data distribution, comparisons were conducted using unpaired t, Mann-Whitney U or Fisher's exact tests. The association between REM and the percentage of change (Δ, 6m-0m) within each PBMC subset was evaluated by uni- and multi-variable logistic regression. The presence of interactions with covariates (age, sex, disease duration, RF, ACPA, smoking habit, body mass index, baseline DAS28 and concomitant methotrexate (MTX)) was tested, stratifying the results if this was significant ($p< 0.05$). In case of no interaction, the model was later adjusted for these covariates.

Results: After 6m of TNFi treatment, 37% patients achieved REM. Univariable analyses (odds ratio; 95% CI; p-value) were performed to investigate the association between REM and the baseline variables. A significant association was found for lower baseline DAS28 (OR: 0.28; 95% CI: 0.19-0.51; $p< 0.001$). Associations of REM with other baseline patients' characteristics, such as for age (OR: 0.97; 95% CI: 0.94-1.01; p=0.1), RF positivity (OR: 2.50; 95% CI: 0.73-8.50; p=0.1) and ACPA positivity (OR: 3.91; 95% CI: 0.80-19.07; p=0.09), were found, although not significant. Therefore, further analyses were adjusted by age, RF, ACPA and baseline DAS28. In addition, a significant association were found for reducing the percentage of naïve B cells (OR: 0.85; 95% CI: 0.73-0.99; p=0.04). A significant interaction between the change in the percentage of naïve B cells and the use of concomitant MTX was identified (Wald chi-square value=4.56; p=0.03), for the outcome of achievement of REM. Therefore, further analyses about the association between the change in the percentage of naïve B cells and REM were stratified according to the use of concomitant MTX. No significant interactions with other variables were found.

A reduction in the percentage of naïve B cells after 6m of TNFi treatment was associated with achieving REM, mainly in patients who received concomitant MTX (OR: 0.58; 95% CI: 0.38-0.90; p=0.015). However, no association was found for patients who did not received concomitant MTX (OR: 0.78; 95% CI: 0.45-1.35; p=0.4).

Conclusion: A reduction of naïve B cells was associated with the achievement of REM by TNFi therapy, mainly in patients who received concomitant methotrexate. Our results suggest that naïve B cells may be useful as a marker of REM in patients with RA cotreated with TNFi and MTX.

Baseline characteristics of patients included in the study, stratified by remission at 6 months of TNFi treatment The Table shows mean±SD, median (IQR) or absolute number (percentage) for all patients included (n=78). RF, rheumatoid factor; ACPA, anti-citrullinated protein antibodies; DAS28, Disease Activity Score-28; csDMARD, conventional synthetic disease-modifying anti-rheumatic drug; MTX, methotrexate; OD, other conventional synthetic disease-modifying anti-rheumatic drugs than methotrexate. The differences between groups were analysed considering p-value<0.05 as statistically significant result.

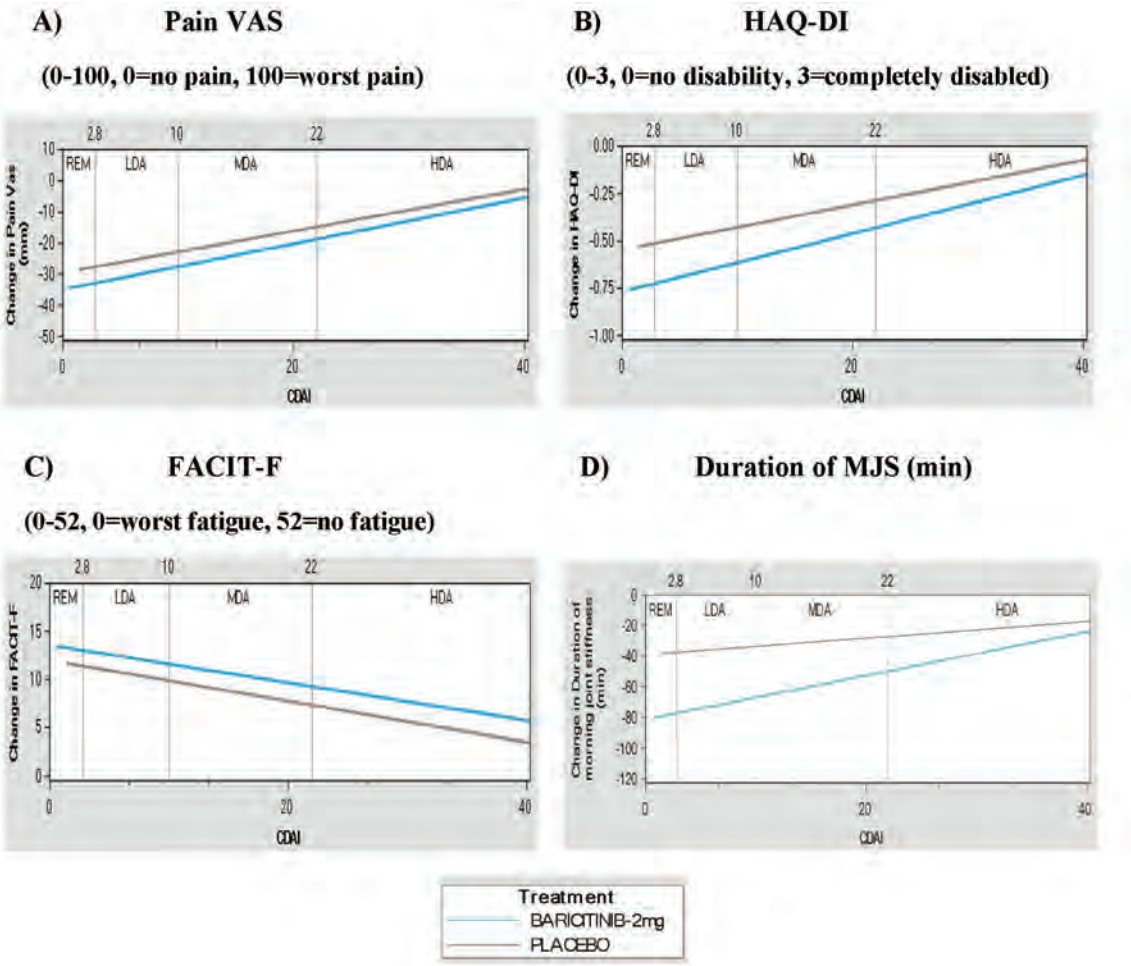
Baricitinib 2-mg Provides Greater Improvements in Patient-Reported Outcomes Across All Disease Activity Levels Compared to Placebo: Post-hoc Analyses of RA-BEACON and RA-BUILD Trials

Clifton Bingham III[1], Bochao Jia[2], Jianmin Wu[2], Amanda Quebe[2], Carol Kannowski[2], Susan Otawa[2], Yun-Fei Chen[2], Kirstin Griffing[2], Dongyi He[3] and Dalton Sholter[4], [1]Johns Hopkins University, Baltimore, MD, [2]Eli Lilly and Company, Indianapolis, IN, [3]Shanghai Guanghua Hospital, Shanghai, Shanghai, China (People's Republic), [4]University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib (BARI) improved patient-reported outcomes (PROs) in patients with insufficient response or intolerance to ≥1 tumor necrosis factor inhibitors (TNFi) or other biological disease-modifying antirheumatic drugs (bDMARDs) as well as in patients with inadequate response (IR) to conventional synthetic DMARDs (csDMARDs).[1,2] The purpose of this analysis was to determine the association between improvement in PROs (pain, physical function, fatigue, and morning joint stiffness) and disease activity (measured using Clinical Disease Activity Index [CDAI] at 12 weeks. We evaluated whether BARI 2-mg provided greater PRO improvement compared to placebo (PBO), across all levels of disease activity.

Methods: Data for these post-hoc analyses were taken from two phase 3 studies, RA-BEACON (NCT01721044; bDMARD-IR patients) and RA-BUILD (NCT01721057; csDMARD-IR patients). Pain was assessed on a 0-100 mm visual analog scale; physical function was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI); and fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale. Duration of morning joint stiffness (MJS, minutes) was also reported by the patient. Disease activity was assessed with the Clinical Disease Activity Index (CDAI) and categorized as: remission (≤2.8), low disease activity (LDA; >2.8 to ≤10), moderate disease activity (MDA; >10 to ≤22), high disease activity (HDA; >22). To evaluate the extent of benefit in PROs with BARI across disease activity levels at Week 12 relative to PBO, we used linear regression to model the relationship between change in PROs at Week 12 (response), and CDAI values at Week 12 (primary explanatory variable). Two additional variables included were treatment group and the interaction term between treatment and CDAI. We used last observation carried forward to impute missing values.



Estimated Changes at Week 12 (Mean)	CDAI=2.8		CDAI=10		CDAI=22	
	PBO	BARI 2-mg	PBO	BARI 2-mg	PBO	BARI 2-mg
Pain-VAS	-27.6	-32.8	-22.7	-27.5	-14.7	-18.7
HAQ-DI	-0.5	-0.7	-0.4	-0.6	-0.3	-0.4
FACIT-F	11.4	13.0	9.9	11.6	7.3	9.3
Duration of MJS (min)	-37.5	-77.6	-33.7	-67.3	-27.2	-50.0

BARI=Baricitinib; bDMARD-IR= biological disease-modifying antirheumatic drugs (bDMARDs)-inadequate response. Figure 1. Estimated changes in PROs by CDAI disease activity at Week 12 in RA-BEACON (bDMARD-IR) trial. A) Pain VAS, B) HAQ-DI, C) FACIT-F, D) Duration of MJS.

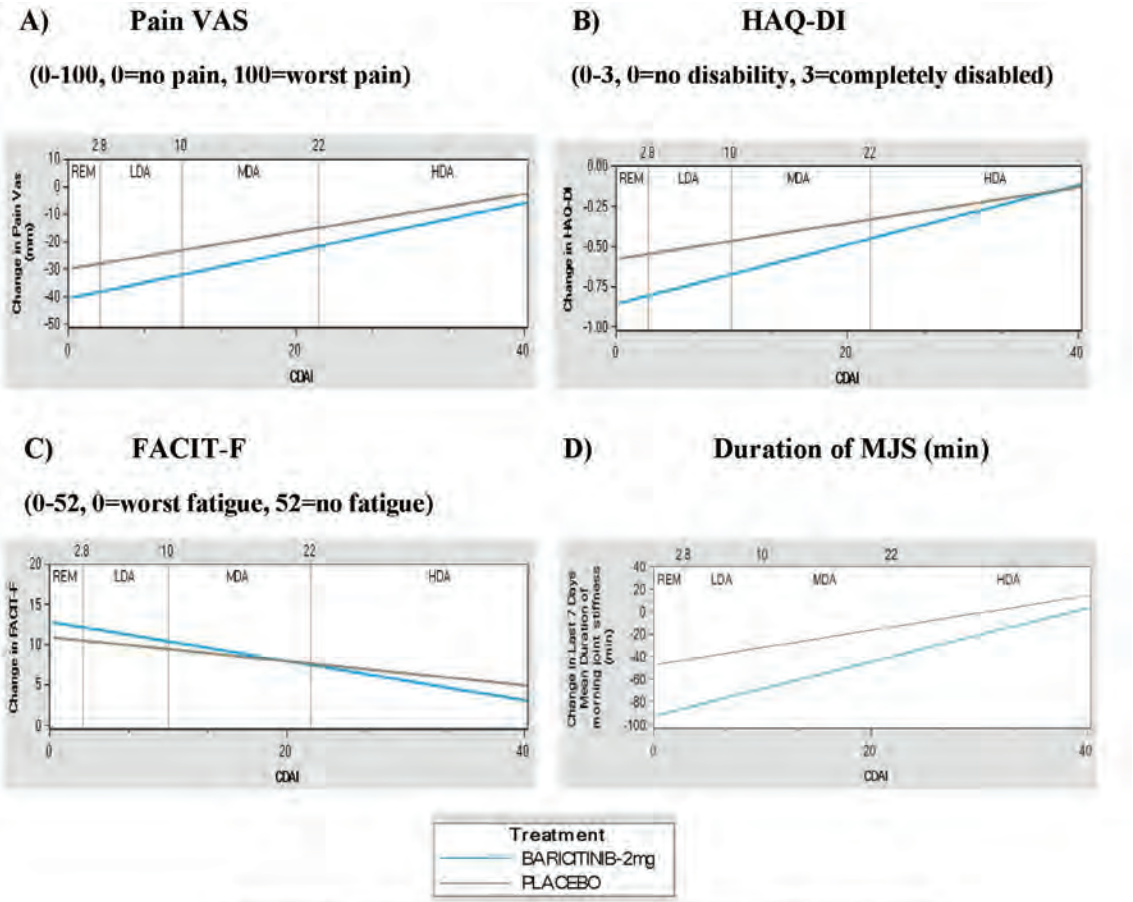
Results: At 12 weeks in bDMARD-IR patients, BARI 2-mg demonstrated greater improvements in pain, physical function, fatigue and MJS duration across all disease activity levels vs. placebo group (Figure 1). In csDMARD-IR patients, BARI 2-mg provided greater improvement in PROs (pain, HAQ-DI, MJS and fatigue) for patients who achieved disease control (remission or LDA) compared to placebo group. Greater reduction in pain and MJS duration were also observed in BARI 2-mg patients with MDA or HDA relative to placebo (Figure 2).



Estimated Changes at Week 12 (Mean)	CDAI=2.8		CDAI=10		CDAI=22

Blood Lymphocyte Subsets for Early Identification of Non-Remission to TNF Inhibitors in Rheumatoid Arthritis

Eulalia Rodriguez-Martín[1], Israel Nieto-Gañán[1], Borja Hernández-Breijo[2], Cristina Sobrino[3], Carlota García-Hoz[1], Javier Bachiller-Corral[4], Ana Martínez-Feito[5], Victoria Navarro-Compán[6], Paloma Lapuente-Suanzes[1], Gema Bonilla[7], Dora Pascual-Salcedo[8], Garbiñe Roy[1], Teresa Jurado[2], Pilar Nozal[2], Mónica Vázquez[4], Alejandro Balsa[7], Luisa M Villar[1] and Chamaida Plasencia[7], [1]Hospital Universitario Ramón y Cajal-IRYCIS, Madrid, Spain, [2]Hospital Universitario La Paz-Idipaz, Madrid, Spain, [3]Hospital Ramón y Cajal-IRYCIS, Madrid, Spain, [4]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [5]Hospital Unversitario La Paz- idipaz, Madrid, Spain, [6]Hospital Universitario La Paz IdiPaz, Madrid, Pais Vasco, Spain, [7]Rheumatology, La Paz University Hospital-IdiPAZ, Madrid, Spain, [8]Hospital Universitario La Paz-Idipaz, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: TNF inhibitors (TNFis) are widely used for the treatment of rheumatoid arthritis (RA), although the response rates to this therapy in patients with RA remains heterogeneous and less than 50% achieve remission (REM).

Our aim was to analyze baseline peripheral blood leukocytes profiles in order to search for biomarkers identifying patients who will most likely not achieve REM under TNFi treatment.

Methods: A prospective bi-center pilot study including 98 RA patients treated with TNFis and followed-up during 6 months. Patients were classified according to DAS28 as follows: those who achieved REM (DAS28≤2.6) and those who did not (DAS28 >2.6) at 6 months after starting TNFis. These rates were also assessed by simplified disease activity index (SDAI ≤3.3 and SDAI >3.3, respectively). Peripheral blood immune cells were studied by flow cytometry before treatment initiation.

Results: At 6 months, 61% or 80% of patients did not achieve REM by DAS28 or SDAI, respectively. Basal leukocyte profiles differed between REM versus non-REM patients. Non-REM patients showed lower percentages of total and naïve B cells at baseline than REM subjects. A B lymphocyte/CD4+ lymphocyte ratio (BL/CD4 ratio) < 0.2 clearly associated with a higher probability of non-REM status based on DAS28 at 6 months (OR=9.2, p=0.006). These data were confirmed when patient response was evaluated by SDAI index.

Conclusion: Our results strongly suggest that BL/ CD4 ratio could be considered as a useful biomarker for the early identification of non-remitters to TNFi in clinical practice.

Curcumin: Prevalence and Perceived Efficacy in the Treatment of Rheumatoid and Psoriatic Arthritis

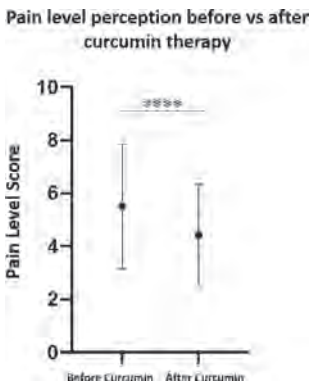
Neha Bhaskar[1], **Lilian Otalora Rojas**[2], Tara Jehu[1], Shazia Beg[1] and Neha Bhanusali[1], [1]University of Central Florida College of Medicine, orlando, [2]University of Central Florida HCA Healthcare GME, Orlando

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Ancient Eastern medicine has valued the Curcuma longa (turmeric) plant for its powerful medicinal properties. Curcumin is suggested to possess potent anti-inflammatory, antioxidant, antimicrobial, anticarcinogenic, and anticoagulant properties. There is currently no research relating symptom exacerbation or alleviation with curcumin therapy in patients with Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA). The focus of this study is on determining the prevalence and perceived efficacy of curcumin in RA and PsA populations.

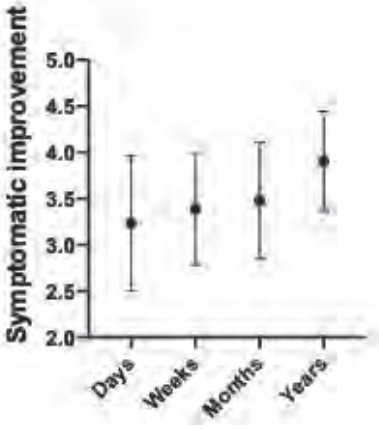
Methods: We conducted an observational, cross-sectional study of patients with active RA and PsA who visited a rheumatology outpatient clinic from October 2019 to March 2020. We used a voluntary, brief and anonymous Qualtrics survey questionnaire of concrete questions regarding curcumin use, source, form, method, and dosage, as well as patient perceptions of efficacy and any experienced side effects. Descriptive and correlation analyses were performed.

Results: A total of 291 patients were included. 84.9% RA, 5.1% PsA. 82.3% women and 17.7% men. 37.2% of patients reported having taken curcumin supplementation. No statistical differences between demographics (age, gender and diagnosis) were found in patients taking vs not taking curcumin. The majority of patients sourced the curcumin from a local store (54.3%), supplemented once a day (53.4%) in the form of capsules (59.2%), and took either 0-200 mg/day or 200-500 mg/day of Curcumin. Amongst those who chose not to supplement, the majority of patients reported potential side effects as being the main deterrent to supplementation.

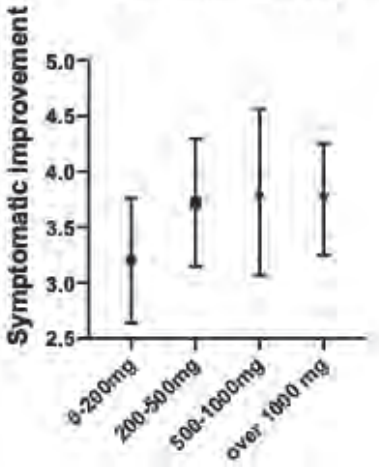


Statistically Significant difference between patient pain perception (scores from 1 to 10) reported before vs after Curcumin therapy. Paired t test (P <0.0001 r2 0.36).

Correlation between symptomatic improvement and duration of curcumin therapy



Correlation between symptomatic improvement and curcumin dosed



Pain scores were significantly decreased after curcumin therapy was started ($P < 0.0001$). Patients who were taking curcumin for years perceived improvement of symptoms (pain, swelling, stiffness, and fatigue) and better symptomatic control when compared with patients taking it for months (P 0.01), weeks (P 0.02) or days (P 0.02). There was a significant difference in symptom improvement in patients taking 200 to 1000 mg when compared with patients taking < 200 mg (P 0.01). Patients taking curcumin once or twice daily reported significant symptom improvement when compared with patients taking it rarely. Symptomatic improvement was reported as follows: pain (35.7%), swelling (25%), stiffness (23.21%) and fatigue (16.07%).

Conclusion: Patients with RA and PsA who were taking curcumin in the study population perceived associated improvement in pain and other symptoms. There is an interesting association between perception of symptomatic improvement in patients taking curcumin and treatment's frequency, dosages (200-1000mg), and length (years). These result suggest curcumin's efficacy for symptom alleviation in patients with RA and PsA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

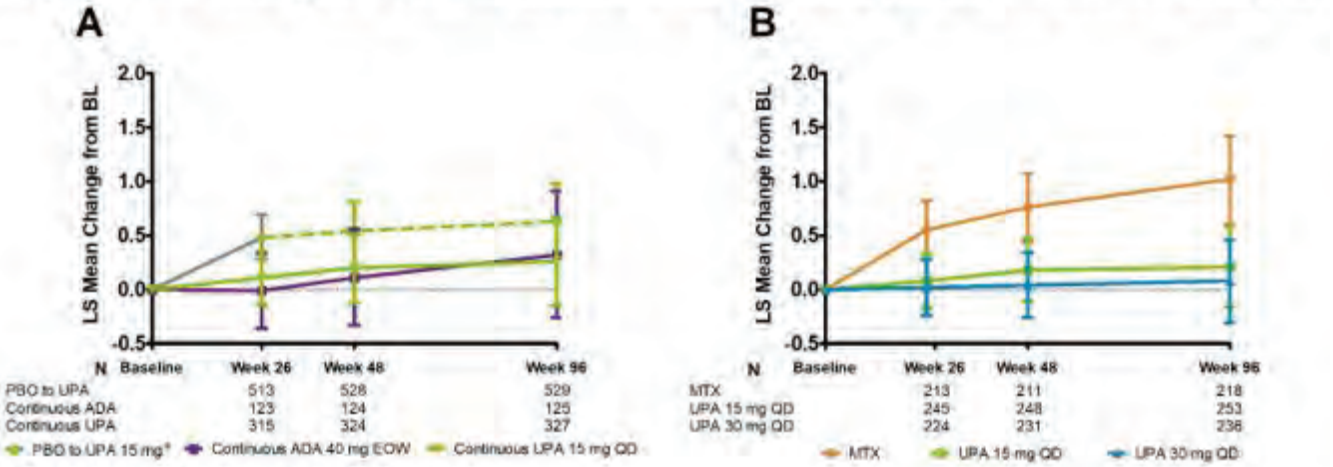
Session Time: 9:00AM–11:00AM

Background/Purpose: For patients with rheumatoid arthritis (RA), long-term prevention of structural joint damage is a key treatment goal.[1] In the SELECT-EARLY and SELECT-COMPARE trials, upadacitinib (UPA), an oral JAK inhibitor, inhibited the progression of structural joint damage at 6 months and 1 year when used either as monotherapy or in combination with methotrexate (MTX) in patients (pts) with active RA.[2] We describe the radiographic progression up to 2 years (96 wks) among pts with RA receiving UPA either as monotherapy or in combination with MTX.

Methods: Both the SELECT-EARLY and SELECT-COMPARE phase 3, randomized controlled trials enrolled pts at high risk for progressive structural damage with baseline (BL) erosive joint damage and/or seropositivity.[3,4] In SELECT-EARLY, MTX-naïve pts (N=945) were randomized to UPA 15 mg or 30 mg once daily (QD) or MTX monotherapy. In SELECT-COMPARE, pts with an inadequate response to MTX (N=1629) were randomized to UPA 15 mg, placebo (PBO), or adalimumab (ADA) 40 mg every other wk, with all pts continuing background MTX; at wk 26, all pts receiving PBO were switched to UPA 15 mg, regardless of response. In both trials, mean changes from BL in modified Total Sharp Score (mTSS), joint space narrowing, and joint erosion as well as the proportion of pts with no radiographic progression (change in mTSS $\leq$0) were evaluated based on X-rays taken at wks 24/26, 48, and 96 for those patients in whom wk 96 X-rays were available. Data are reported as observed (AO).

Results: BL demographics have been reported previously.[3,4] In the SELECT-EARLY study, at wk 96 UPA monotherapy (15 mg and 30 mg doses) significantly inhibited radiographic progression compared with MTX as measured by mean change in mTSS and by the proportion of patients with no radiographic progression (**Figures 1 and 2**). When patients who were rescued (MTX added to UPA or UPA added to MTX) were removed from the analysis, changes in mTSS from baseline remained similar. By the same measures, in SELECT-COMPARE, the degree of inhibition of structural progression observed was comparable between UPA and ADA. Following the switch of all PBO patients to UPA, the rate of progression slowed and was comparable to that observed in pts receiving UPA from BL. Among pts from both studies that had no radiographic progression at wk 24/26, >90% remained without radiographic progression at wk 48 and 96.

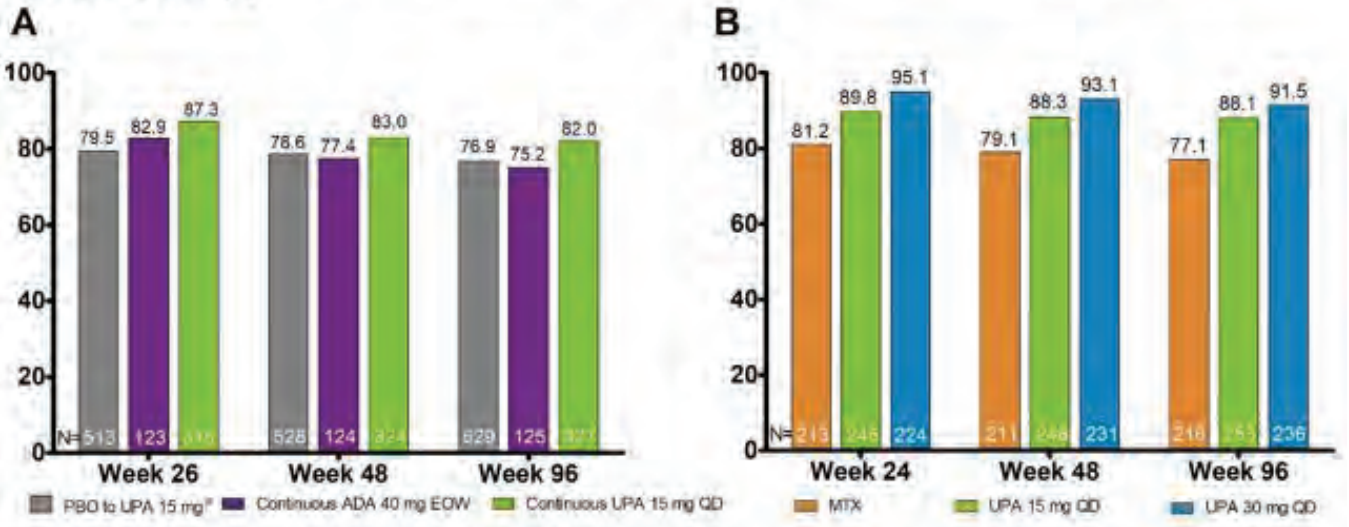
Figure 1. Mean Change in mTSS from Baseline in SELECT-COMPARE (A) and SELECT-EARLY (B)



*Per study design, all patients in the PBO group who were not previously rescued were switched to UPA 15 mg at wk 26.

Least squares mean estimator is based on an ANCOVA model with treatment and prior bDMARD (SELECT-COMPARE) or geographic region (SELECT-EARLY) as fixed factors and baseline value as a covariate. Error bars represent 95% confidence interval.

Figure 2. Proportion of Patients with No Radiographic Progression in SELECT-COMPARE (A) and SELECT-EARLY (B)



*Per study design, all patients in the PBO group who were not previously rescued were switched to UPA 15 mg at wk 26.

Conclusion: UPA was effective in inhibiting the progression of structural joint damage through 2 years both in MTX-naïve patients receiving UPA monotherapy and MTX-inadequate responder patients receiving UPA in combination with MTX.

Association of Low Hemoglobin with Efficacy and Patient-reported Outcomes in Three Phase III Studies of Sarilumab (TARGET, MOBILITY and MONARCH)

Andrea Rubbert Roth[1], Daniel Furst*[2], Stefano Fiore[3], Amy Praestgaard[4], Vivian Bykerk[5], Clifton Bingham III[6] and Christina Charles-Schoeman[7], [1]Klinik für Rheumatologie, Kantonsspital St Gallen, St Gallen, Sankt Gallen, Switzerland, [2]Department of Medicine, Division of Rheumatology, University of California at Los Angeles, Los Angeles, California, USA, Los Angeles, CA, [3]Sanofi, Bridgewater, NJ, [4]Sanofi, Cambridge, MA, [5]Hospital for Special Surgery, New York, NY, [6]Johns Hopkins University, Baltimore, MD, [7]University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anemia is a common comorbidity in patients (pts) with RA, and changes in hemoglobin (Hb) levels are associated with changes in inflammatory disease activity. Since IL-6 is a central mediator and is known to impact iron metabolism/bioavailability it could contribute to anemia of chronic disease. We hypothesize that if IL-6 inhibition by sarilumab improves Hb levels, resulting in better clinical efficacy and patient-reported outcomes (PROs) in anemic RA pts vs comparators (placebo [PBO]+MTX or adalimumab), it might do so through its effects on Hb. In this *post hoc* analysis we assessed the association of low Hb level with clinical efficacy measures and PROs in 3 sarilumab phase III studies: TARGET (NCT01709578), MOBILITY (NCT01061736), MONARCH (NCT02332590).

Methods: Patients enrolled in MOBILITY and TARGET received either PBO or sarilumab 150 mg or 200 mg subcutaneously (SC) every 2 wks (q2w), in combination with MTX (52 wks) or in combination with weekly csDMARD (24 wks). Analysis used combination therapy pooled data from TARGET and MOBILITY through 24 wks. In MONARCH, pts received either adalimumab 40 mg or sarilumab 200 mg SC q2w monotherapy (24 wks). We evaluated mean changes

Table 1. Baseline demographics and disease characteristics of patients in the TARGET+MOBILITY pooled study group and MONARCH study group

	TARGET and MOBILITY pooled		MONARCH	
	Low Hb (N=600)	Normal Hb (N=1143)	Low Hb (N=92)	Normal Hb (N=277)
Age, years	50.1 (13.1)	52.0 (11.2)	50.0 (13.3)	53.0 (11.9)
Female, n (%)	515 (85.83)	909 (79.53)	78 (84.78)	229 (82.67)

GABA use, n (%)	10 (1.67)	15 (1.31)	1 (1.09)	2 (0.72)

N = Number of patients with low or normal Hb subgroup. All values are mean (SD), unless specified otherwise.

[a] TARGET+MOBILITY, N= 599 for "Low Hb" and N = 1142 for "Normal Hb"; MONARCH, N = 276 for "Normal Hb" group

[b]TARGET+MOBILITY, N= 599 for "Low Hb" and N = 1142 for "Normal Hb" group

[c]TARGET+MOBILITY, N = 1142 for "Normal Hb" group

[d]TARGET+MOBILITY, N = 186 for "Low Hb" and N=360 for "Normal Hb" group; MONARCH, N = 276 for "Normal Hb" group

[e]TARGET+MOBILITY, N=1137 for "Normal Hb" group; MONARCH, N = 276 for "Normal Hb" group

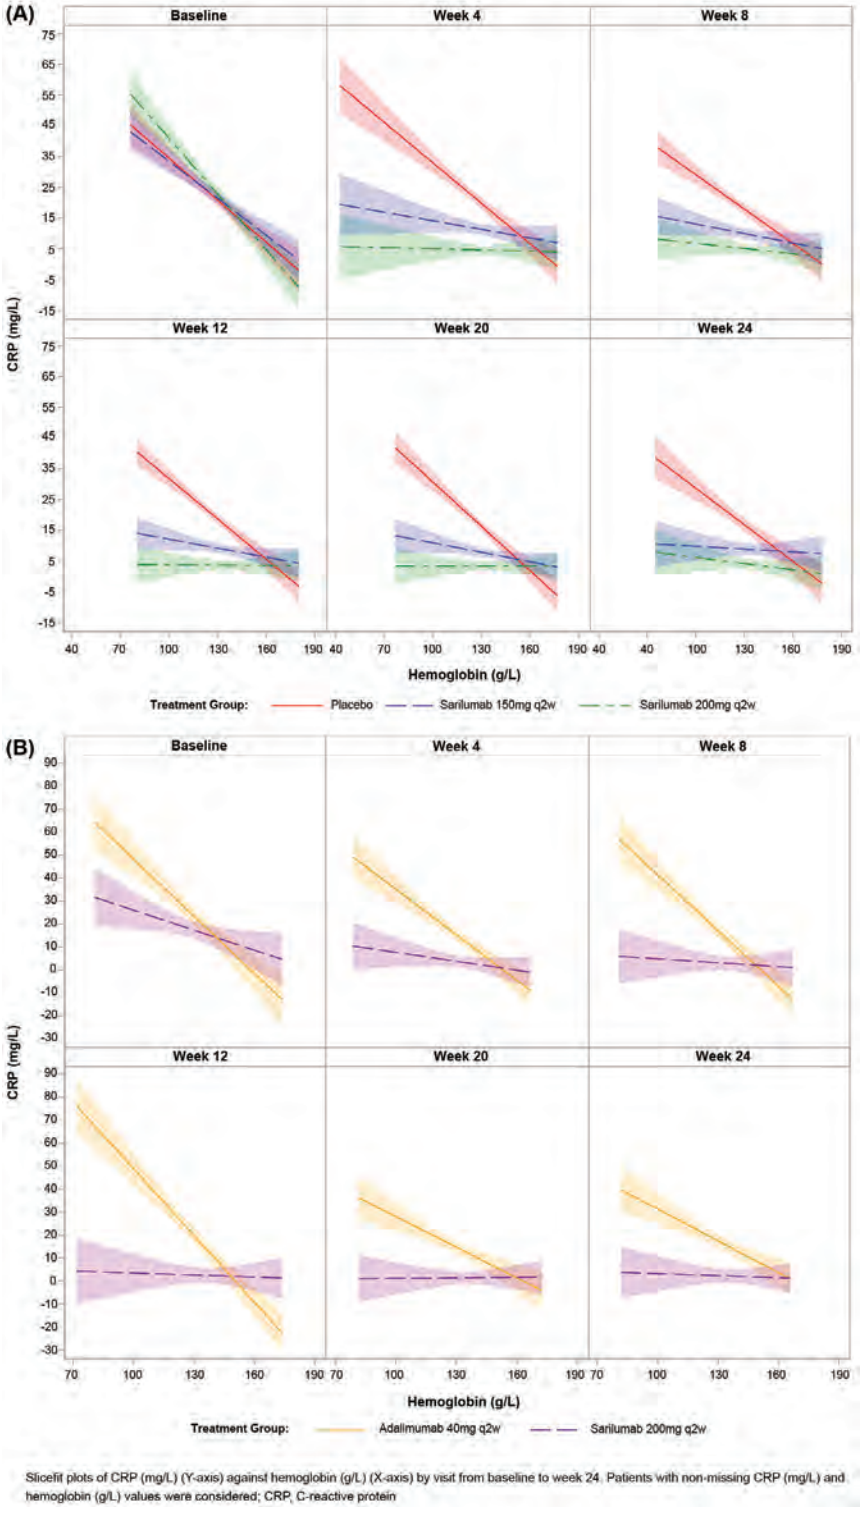
SD: Standard deviation, SE: Standard error, HAQ-DI: Health Assessment Questionnaire-Disability Index, TJC28: Tender joint count based on 28 joints, SJC28: Swollen joint count based on 28 joints, CRP: C-reactive protein, CDAI: Clinical Disease Activity Index, DAS28-CRP: Disease Activity Score 28-C-reactive protein, VAS: Visual analogue scale, NSAID: Nonsteroidal anti-inflammatory drug, SSRI: Selective serotonin reuptake inhibitors, GABA: Gamma-aminobutyric acid

from baseline to Wk 24 in Clinical Disease Activity Index (CDAI), CRP, 28-joint Disease Activity score-CRP (DAS28-CRP), pain visual analogue scale (VAS), patient global assessment (PtGA), stratified by Hb levels as low (Hb< 12.0 g/dL [females]/< 13.0 g/dl [males]) vs normal (Hb 12.0 to 15.5 g/dL[females]/13.5 to 17.5 g/dL [males]). Bivariate linear regression was performed to evaluate relationships between Hb level and outcomes from baseline to Wk 24. Mean change from baseline in efficacy measures and PROs were summarized as mean (SD) values.

Results: Low Hb was observed in 34% of pts in the pooled group (N = 1743, TARGET+MOBILITY) and in 25% of pts in the monotherapy group (N = 369, MONARCH). Baseline characteristics, demographics and concomitant medications were similar between groups (Table 1). Over 24 wks, higher Hb levels were associated with better clinical efficacy/pain outcomes in all evaluated study groups. Fig 1 shows a steady disassociation between Hb level and CRP in sarilumab-treated pts from baseline to Wk 24 in both study groups. A similar trend was also observed for other efficacy measures and PROs (data not shown). Mean change from baseline to Wk 24 in CDAI, DAS28 CRP, Pain VAS, PtGA

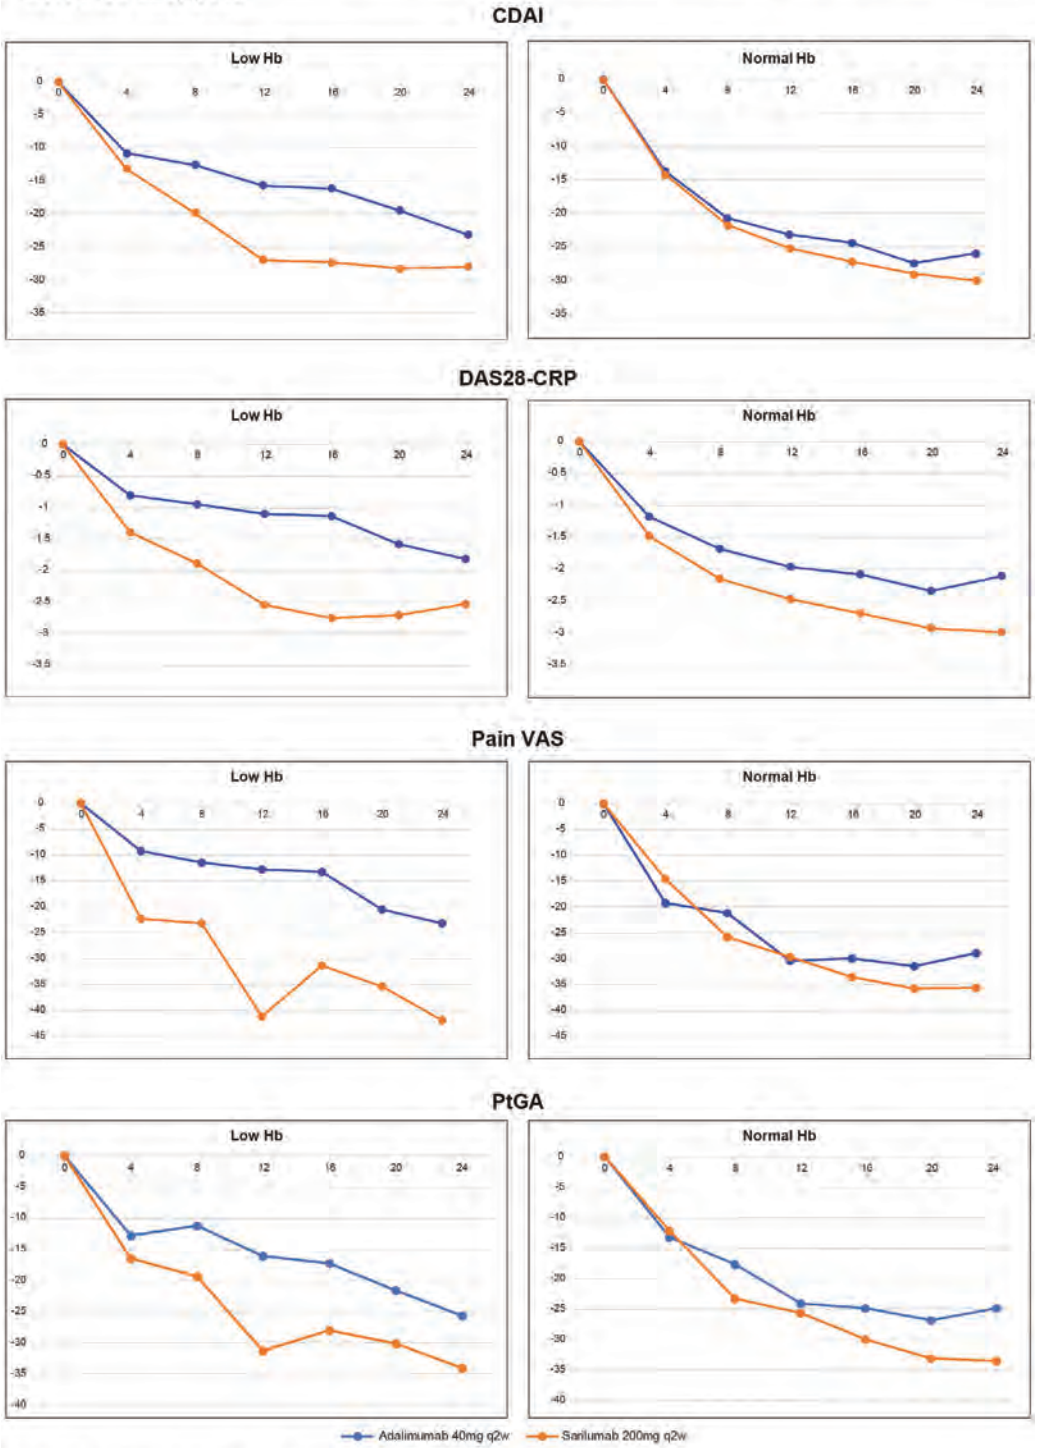
was similar in both groups, irrespective of the baseline Hb levels (low vs normal; Fig 2). Effect size (difference between sarilumab and adalimumab) was larger for low Hb subgroup, especially in MONARCH (Fig 2; combination therapy, data not shown). The safety profile of sarilumab has been previously reported and was not part of this analysis.

Figure 1: Relationship Between Outcomes and Hb Over Time (Baseline to Week 24): CRP **(A)** TARGET+MOBILITY B pooled and **(B)** MONARCH



Slicefit plots of CRP (mg/L) (Y-axis) against hemoglobin (g/L) (X-axis) by visit from baseline to week 24. Patients with non-missing CRP (mg/L) and hemoglobin (g/L) values were considered; CRP, C-reactive protein

Figure 2: Mean Change in Treatment Outcomes from Baseline to Week 24 (Stratified by Hb level at Baseline) - MONARCH study group



All values are represented as mean change from baseline (SD) till Week 24

CDAI, Clinical Disease Activity Index; CRP, C-reactive protein; DAS28-CRP, 28-joint Disease Activity using C reactive protein; Hb, hemoglobin; PtGA, patient-global assessment; SD, standard deviation; VAS, visual analogue scale.

Conclusion: In this analysis, by Week 24, in sarilumab-treated patients with low Hb levels, we observed better clinical efficacy measures and PROs than with adalimumab in the MONARCH Study. Furthermore, the positive effect of sarilumab was independent of the baseline Hb level (low vs normal). The observed dissociation indicates that the drug's efficacy is not 'solely' mediated by its effects on Hb.

Use of Multi-Biomarker Disease Activity Scores to Compare Biosimilar Adalimumab-afzb (PF-06410293) with EU-Sourced Reference Adalimumab in a Phase 3, Randomized, Double-Blind Trial in Patients with Active RA

Jonathan Kay[1], Amy Bock[2], Noriko Iikuni[3], Wuyan Zhang[4] and Daniel Alvarez[5], [1]University of Massachusetts Medical School, Worcester, MA, [2]Pfizer, Cambridge, MA, [3]Pfizer, New York, NY, [4]Pfizer, New York, [5]Pfizer, Collegeville, PA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

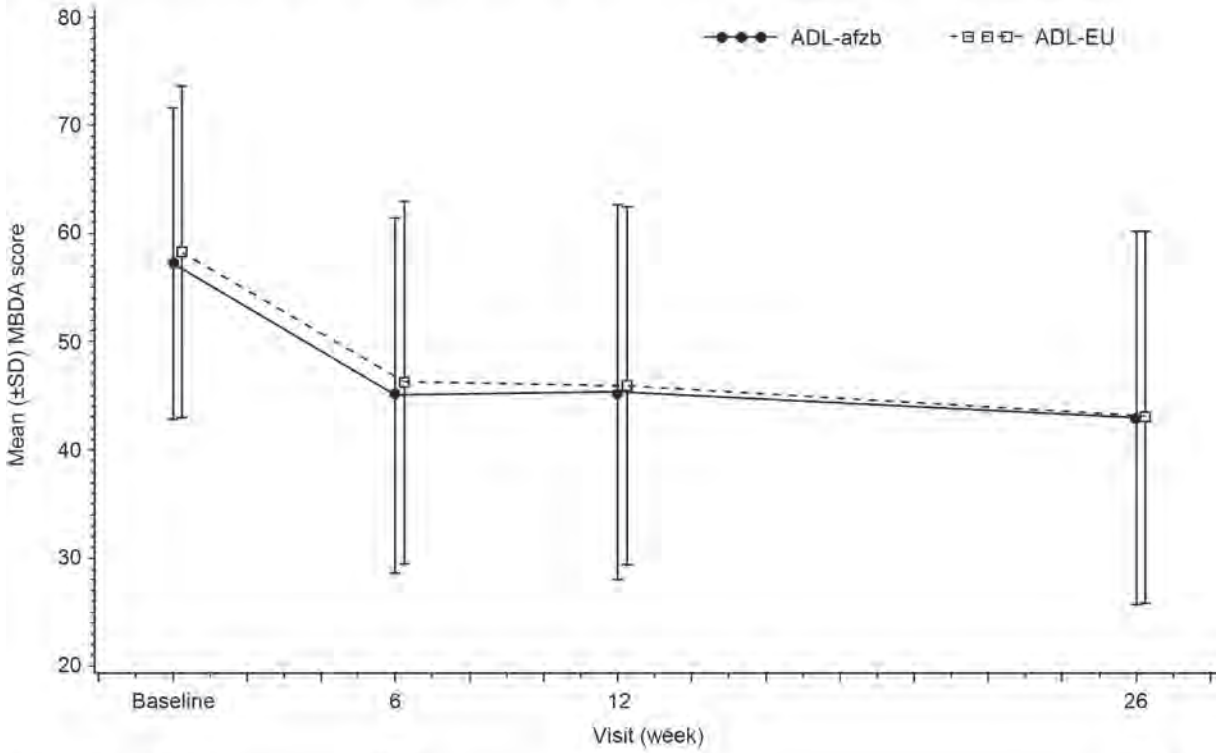
Session Time: 9:00AM–11:00AM

Background/Purpose: Traditional efficacy endpoints of disease activity (DA) in studies of anti-rheumatic drugs can be confounded by subjective (patient-/physician-reported) assessments, comorbidities, and pre-existing joint damage. Limitations of these efficacy endpoints have prompted regulatory authorities to encourage use of biomarkers as endpoints in clinical trials evaluating biosimilars. The multi-biomarker disease activity (MBDA; Vectra® DA, Myriad Genetics, Inc.) score provides a validated, objective, and composite measure of DA in patients with RA based upon concentrations of 12 serum protein biomarkers. An exploratory analysis was performed to compare MBDA scores between treatment groups in a randomized, double-blind trial to determine the utility of this approach as an assessment for biosimilarity. Biosimilar adalimumab-afzb (ADL-afzb; PF-06410293) was compared with reference adalimumab sourced from the European Union (ADL-EU; AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany) in adult patients with active moderate to severe RA inadequately responsive to MTX (Fleischmann et al. *Arthritis Res Ther*. 2018;20:178).

Methods: All 597 patients in the study met the 2010 ACR/EULAR classification criteria for RA and had disease duration of ≥4 months. Patients were randomized 1:1 to ADL-afzb (n=297) or ADL-EU (n=300) (40-mg subcutaneously every other week) and continued to receive MTX. The concentrations of 12 biomarkers were measured and combined using the Vectra® DA algorithm. Mean MBDA scores (low, ≤29; moderate, 30–44; high, >44–100) were calculated at baseline and at weeks 6, 12, and 26. Mean MBDA scores were compared between treatment groups. Data were summarized using descriptive statistics in the intent to treat population.

Results: At baseline, mean (± standard deviation [SD]) MBDA scores for ADL-afzb and ADL-EU groups were 57.2 (± 14.44) and 58.3 (± 15.34), respectively. Mean values of MBDA scores were comparable between treatment groups at all measured time points through 26 weeks (**Figure**). Similar proportions of patients in the ADL-afzb (78.5%) and ADL-EU (81.7%) treatment groups had high MBDA scores (>44) at baseline; the proportions of patients with high MBDA scores decreased to 45.5% and 41.7%, respectively, at week 26. Mean MBDA scores decreased from baseline in the ADL-afzb and ADL-EU groups by 11.9 and 12.4 at week 6, by 11.7 and 12.4 at week 12, and by 14.3 and 15.5 at week 26, respectively. Mean log-transformed values for each of the individual 12 biomarkers over time up to week 26

Figure: MBDA scores over time up to week 26 (intent-to-treat population)[a]



[a] Baseline, last non-missing measurement taken on or before study day 1.

Table: Correlations between MBDA scores and hs-CRP (intent-to-treat population).

	Pearson's correlation coefficient (r)		
MBDA score vs hs-CRP[a]	**ADL-afzb**	**ADL-EU**	**Overall**
Baseline[b]	0.782	0.720	0.749
Change from baseline to week 12	0.809	0.733	0.770
Change from baseline to week 26	0.835	0.718	0.776

[a] hs-CRP (mg/L) log-transformed values.
[b] Baseline, last non-missing measurement taken on or before study day 1.

were consistently similar between ADL-afzb and ADL-EU groups. MBDA scores correlated with the high-sensitivity CRP (hs-CRP) assay results (**Table**).

Conclusion: Over 26 weeks, mean values for MBDA scores were similar between the ADL-afzb and ADL-EU groups throughout this randomized, double-blind trial in which the adalimumab biosimilar was compared with its reference product. MBDA score based on 12 serum biomarkers provides a sensitive and objective clinical assessment of biosimilarity that does not require physical examination of the patient or subjective patient global assessment of DA.

Noninflammatory Pain Is a Frequent Phenomenon in Rheumatoid Arthritis and Responds Well to Treatment with Sarilumab

Ernest Choy[1], Vivian Bykerk[2], Yvonne Lee[3], Gregory St John[4], Hubert van Hoogstraten[5], Kerri Ford[6], Amy Praestgaard[6] and Anthony Sebba[7], [1]CREATE Centre, Cardiff University, Cardiff, Wales, United Kingdom, [2]Hospital for Special Surgery, New York, NY, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [5]Sanofi, Bridgewater, NJ, [6]Sanofi, Cambridge, MA, [7]Arthritis Associates, Palm Harbor, Tampa, FL

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation is a key driver of pain in rheumatoid arthritis (RA). However, in some patients the level of pain exceeds what would be expected based on the amount of synovitis observed and acute phase reactants, which may indicate the presence of noninflammatory pain (NIP). Interleukin-6 (IL-6) has been shown in animal models to increase sensitization to pain and may play a role in NIP.

Methods: The analysis included data from three Phase 3 studies of sarilumab: MOBILITY (NCT01061736), MONARCH (NCT02332590), and TARGET (NCT01709578). Patients received double-blind placebo or sarilumab 150 mg or 200 mg subcutaneously (SC) every 2 weeks (q2w), plus weekly csDMARD (MOBILITY and TARGET), or adalimumab 40 mg or sarilumab 200 mg SC q2w as monotherapy (MONARCH). This analysis assessed the effect of sarilumab, a human IL-6 receptor inhibitor approved for the treatment of adults with moderate to severely active RA, on NIP and disease activity, stratified by baseline (BL) NIP status.

NIP was defined using an established formula: tender 28-joint count (TJC) – swollen 28-joint count (SJC) ≥7 [1,2]. Patients were assessed for NIP at study BL and for change in NIP status at Weeks 12 and 24. The proportion of patients achieving ACR20/50/70, Clinical Disease Activity Index (CDAI) ≤10, and DAS28-CRP < 3.2 at Week 24 was assessed in patients with and without BL NIP.

No inferential statistics were performed.

Results: Of 2112 patients in the analysis, 490 (23%) met the criteria for NIP at study BL: MOBILITY, n = 294/1197 (25%); MONARCH, n = 90/369 (24%); TARGET, n = 106/546 (19%). BL demographics were similar for patients with or

Table 1. Baseline characteristics

	Patients with TJC – SCJ ≥7	
Mean (SD)	Yes (n = 490)	No (n = 1622)
Duration of RA, years	9.1 (8.6)	9.7 (8.4)
TJC, 0–28	21.7 (4.7)	14.3 (6.2)
SJC, 0–28	10.7 (4.3)	13.1 (6.0)
CRP, mg/L	22.7 (27.0)	22.9 (24.0)
HAQ-DI, 0–3	1.8 (0.6)	1.7 (0.6)
DAS28-CRP	6.4 (0.7)	5.9 (0.9)
CDAI	46.0 (9.4)	40.4 (13.0)
Pain VAS	72.3 (18.2)	67.0 (20.7)

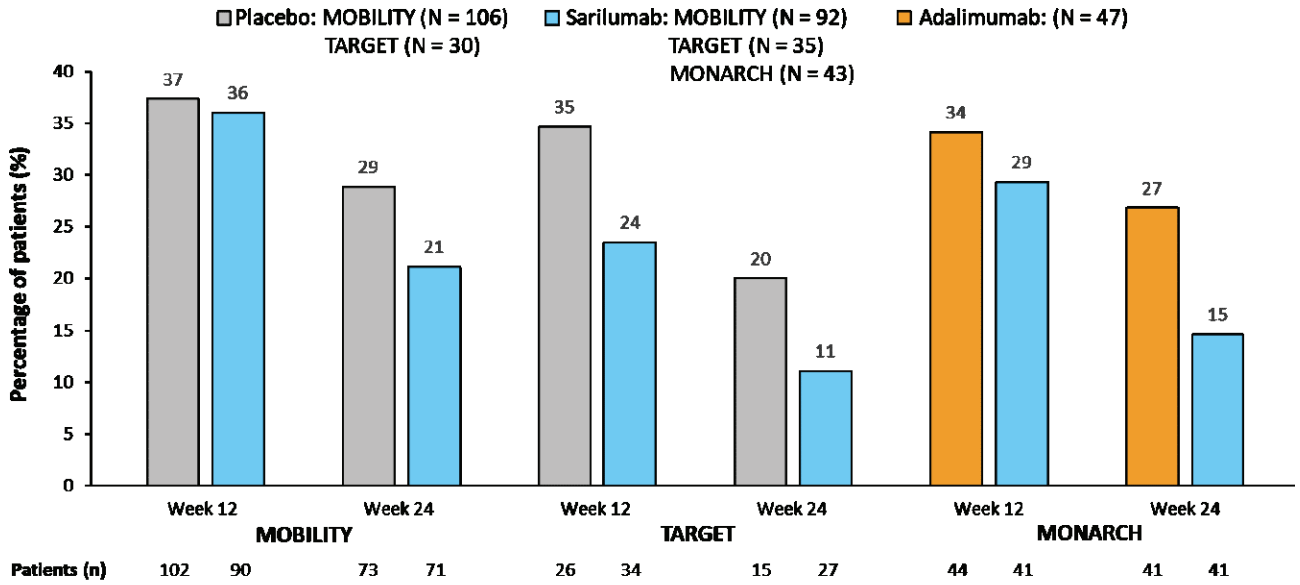

Figure 1 Percentages of patients with baseline noninflammatory pain who had noninflammatory pain at Weeks 12 and 24*

*For MOBILITY and TARGET, data are shown only for patients who received sarilumab 200 mg

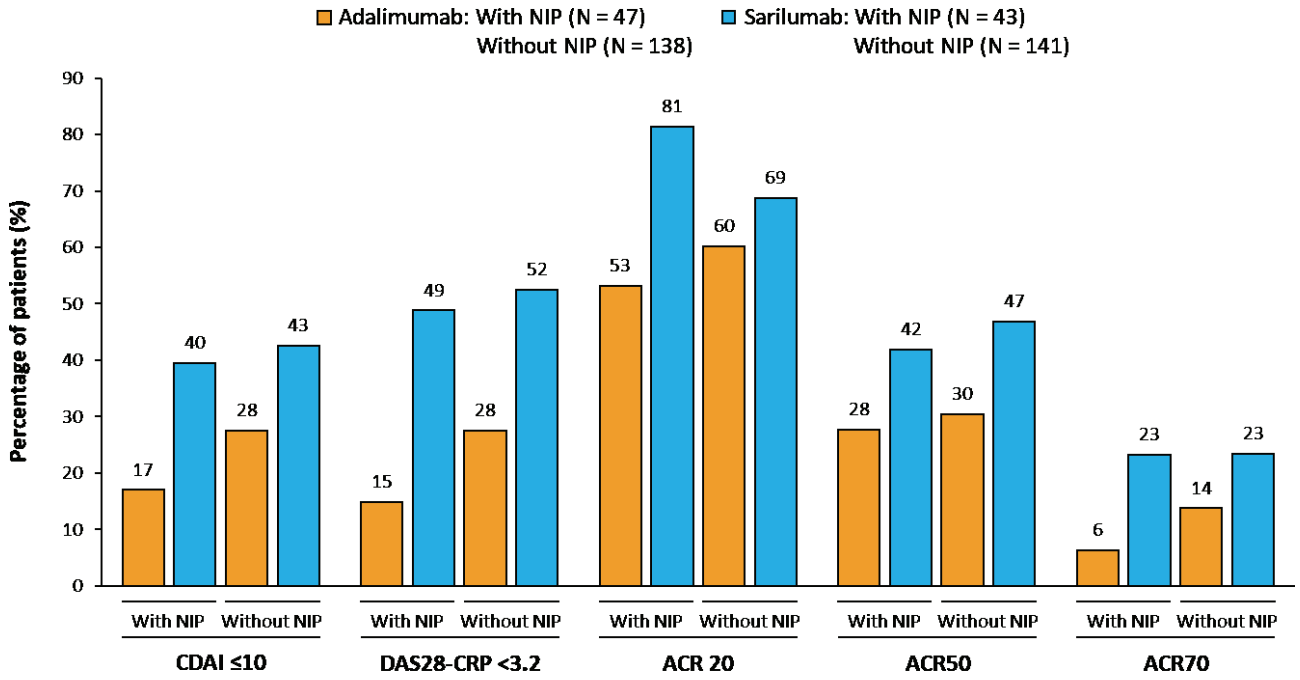

Figure 2 Percentages of sarilumab and adalimumab responders at Week 24 by baseline noninflammatory pain status

without BL NIP: mean age (SD) was 52.6 (10.7) versus 51.2 (12.3) years, and 85% versus 81% were female. Patients with BL NIP had higher CDAI, DAS28-CRP, pain Visual Analog Scale (VAS), and TJC at BL versus patients without NIP (**Table 1**). Of patients with NIP at BL, those who received sarilumab were more likely to have no NIP at Weeks 12 and 24 versus patients who received placebo or adalimumab (**Figure 1**). The percentage of patients achieving improvements in disease activity at Week 24 was greater for sarilumab versus adalimumab among both patients with and without BL NIP, and these differences were larger among patients with BL NIP for all assessments except ACR50 (**Figure 2**).

Conclusion: NIP was prevalent at BL in the patient populations assessed. Among patients with BL NIP, a lower proportion continued to have NIP at Weeks 12 and 24 when treated with sarilumab versus placebo or adalimumab. Patients with and without BL NIP had greater improvements in pain when treated with sarilumab versus adalimumab. The difference in clinical improvement was greater among patients with BL NIP versus without BL NIP for most measures. These trends support the emerging concept that mechanisms other than direct inflammation may contribute to pain in RA, potentially mediated via IL-6 signaling.

Radiographic Progression of Structural Joint Damage over 5 Years of Baricitinib Treatment in Patients with Rheumatoid Arthritis: Results from RA-BEYOND

Désirée van der Heijde[1], Cynthia E Kartman[2], Li Xie[2], Scott Beattie[2], Douglas Schlichting[2], Patrick Durez[3], Yoshiya Tanaka[4] and Roy Fleischmann[5], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Eli Lilly and Company, Indianapolis, IN, [3]Division of Rheumatology, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium, [4]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, [5]Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib (BARI) is an oral, reversible and selective Janus kinase 1 and 2 inhibitor. Treatment with once-daily oral BARI resulted in low rates of radiographic progression for up to 2 years in patients with rheumatoid arthritis (RA). The objective of this paper is to evaluate radiographic progression of structural joint damage in patients with RA over 5 years of treatment with BARI.

Methods: This study included patients who completed three phase 3 trials, RA-BEGIN (DMARD-naïve), RA-BUILD (csDMARD-IR) or RA-BEAM (MTX-IR), and enrolled in the long-term extension study, RA-BEYOND. Patients receiving blinded BARI at the conclusion of phase 3 trials remained on that dose (2mg or 4mg, once daily) in RA-BEYOND. At 52 weeks, DMARD-naïve patients receiving methotrexate (MTX) or combination therapy (BARI 4mg + MTX) were

Table 1. Changes from baseline in mTSS and its components in different patient populations

switched to BARI 4mg monotherapy; MTX-IR patients receiving adalimumab (ADA) were switched to BARI 4mg on background MTX. At 24 weeks, csDMARD-IR patients receiving placebo (PBO) were switched to BARI 4mg on background csDMARD. Analysis population included patients who had baseline and at least one radiograph collected after 2 years. Radiographic progression of structural joint damage (Years 3-5) was determined by changes from baseline in van der Heijde modified Total Sharp Score (ΔmTSS), erosion score, and joint space narrowing. Proportion of patients showing no progression was assessed based on change from baseline mTSS (Δ mTSS) from the originating study, using thresholds of 0.5 or the smallest detecTable change (SDC). Mixed model repeated measures and logistic regression models were used to analyze continuous variables and categorical variables, respectively; linear extrapolation was used for imputation of missing data (maximum of 1 year).

Results: Overall, 82.6% (2125/2573) of patients entered the long-term extension study. Among DMARD-naïve patients, those on initial BARI monotherapy or in combination with MTX had significantly slower radiographic progression (ΔmTSS) compared to those on initial MTX at years 3, 4, and 5 (Table 1; p≤0.05). These patients also had significantly fewer erosions at these time points (p≤0.05). A greater proportion of patients who had received initial BARI therapy and BARI in combination with MTX had no radiographic progression compared to initial MTX monotherapy using thresholds of 0.5 (Table 2; p≤0.05). Among MTX-IR patients, patients on initial BARI treatment had slower radiographic progression compared to PBO and the results were comparable to those on initial adalimumab treatment at years 3, 4, and 5 (Table 1). A greater proportion of patients who had received initial BARI therapy had no radiographic progression compared to initial PBO using thresholds of SDC (Table 2; p≤0.05). Among csDMARD-IR patients, although differences between groups were small, patients on initial BARI 4mg had slowest radiographic progression

Association Between Change in Health Assessment Questionnaire Disability Index and Treatment Response in Patients with Rheumatoid Arthritis in Tocilizumab Clinical Trials

Sebastian Unizony[1], Joseph Dang[2], Jian Han[3], Margaret Michalska[2] and Jennie H. Best[2], [1]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [2]Genentech, Inc., South San Francisco, [3]Genentech, South San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

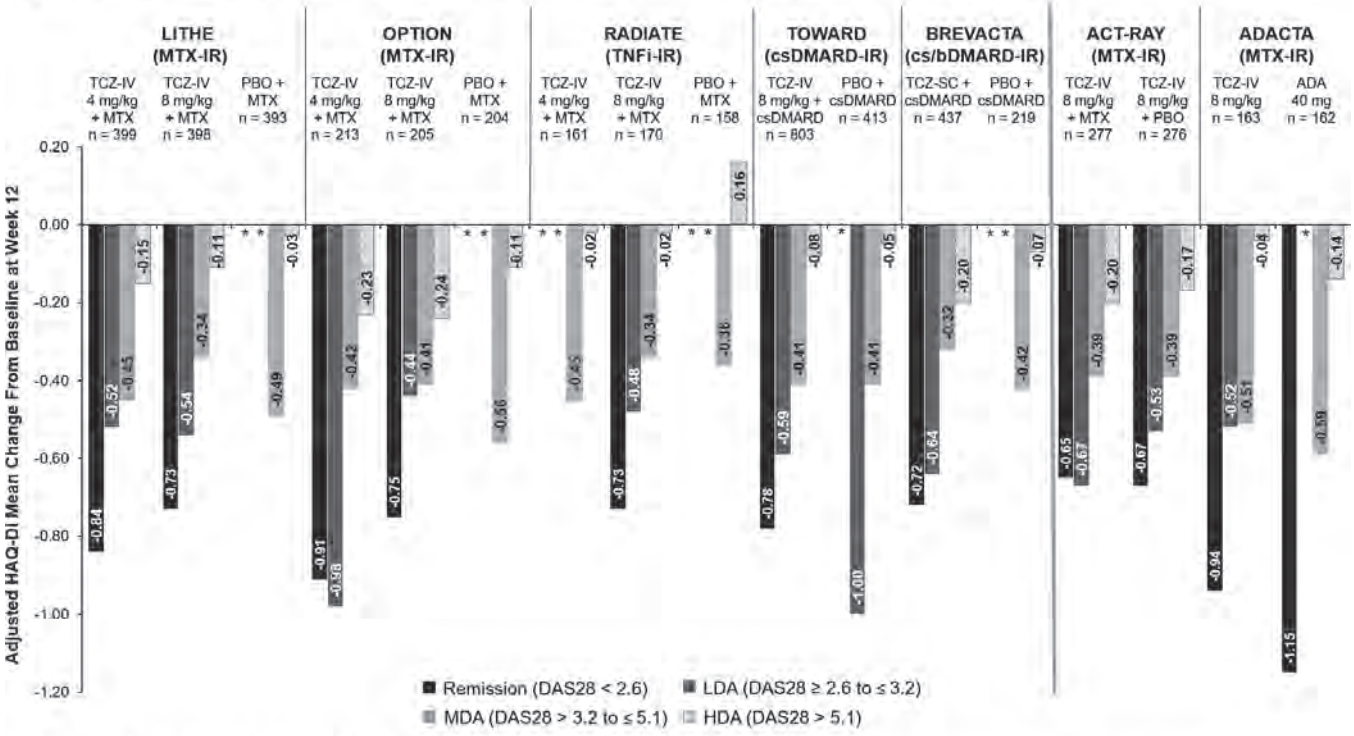
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

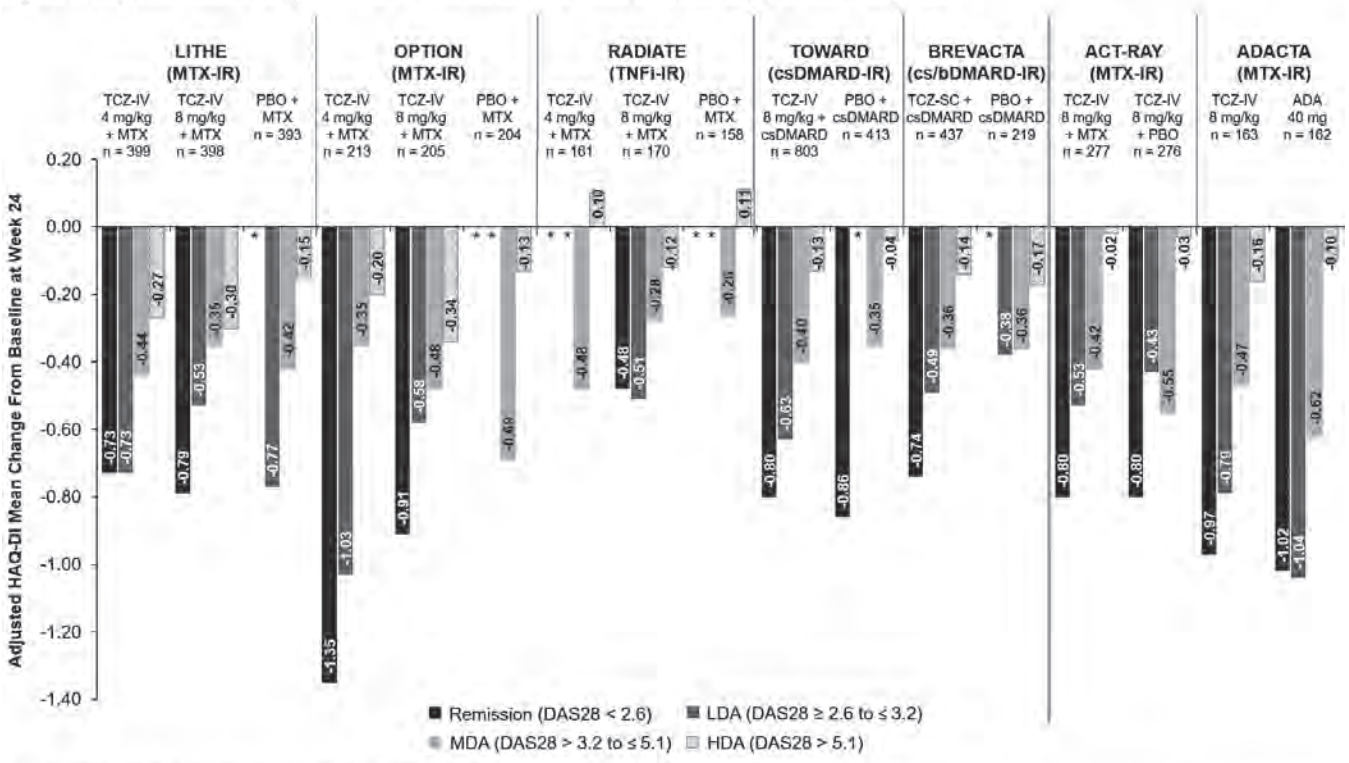
Background/Purpose: The efficacy and safety of intravenous (IV) and subcutaneous (SC) tocilizumab (TCZ) in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and as monotherapy in patients with rheumatoid arthritis (RA) has been demonstrated in large clinical trials and real-world data studies. The Health Assessment Questionnaire Disability Index (HAQ-DI) is commonly used to assess physical function in patients with RA. While HAQ-DI outcomes at Week 24 in TCZ clinical trials have been reported, outcomes at Week 12 and results stratified by treatment response categories at Weeks 12 and 24 have not been previously described. The

Figure 1. Adjusted Mean Change in HAQ-DI from Baseline to Week 12 Stratified by DAS28 Disease Activity Level*



*Mean change not shown for groups with ≤ 10 patients in the DAS28 response category.
ADA, adalimumab; bDMARD, biologic disease-modifying antirheumatic drug; csDMARD; conventional synthetic disease-modifying antirheumatic drug; DAS28; disease activity score based on 28 joints; HAQ-DI, Health Assessment Questionnaire Disability Index; HDA, high-disease activity; IR, inadequate response; IV, intravenous; LDA, low-disease activity; MDA, moderate-disease activity; MTX, methotrexate; PBO, placebo; SC, subcutaneous; TCZ, tocilizumab; TNFi; tumor necrosis factor inhibitor.

Figure 2. Adjusted Mean Change in HAQ-DI from Baseline to Week 24 Stratified by DAS28 Response*



*Mean change not shown for groups with ≤ 10 patients in the DAS28 response category.
ADA, adalimumab; bDMARD, biologic disease-modifying antirheumatic drug; csDMARD; conventional synthetic disease-modifying antirheumatic drug; DAS28; disease activity score based on 28 joints; HAQ-DI, Health Assessment Questionnaire Disability Index; HDA, high-disease activity; IR, inadequate response; IV, intravenous; LDA, low-disease activity; MDA, moderate-disease activity; MTX, methotrexate; PBO, placebo; SC, subcutaneous; TCZ, tocilizumab; TNFi; tumor necrosis factor inhibitor.

objective of this study was to report the association between change in HAQ-DI from baseline to Weeks 12 and 24 and Disease Activity Score in 28 joints (DAS28) response categories in patients who received TCZ or comparators in TCZ clinical trials.

Methods: Data from patients with active RA who received TCZ or a comparator from 6 Phase 3 or 4 TCZ-IV studies (OPTION [NCT00106548], RADIATE [NCT00106522], TOWARD [NCT00106574] LITHE [NCT00109408], ACT-RAY [NCT00810199] and ADACTA [NCT01119859]) and 1 Phase 3 TCZ-SC study (BREVACTA [NCT01232569]) were analyzed. Mean change in HAQ-DI score at Weeks 12 and 24 was assessed in patients stratified by DAS28 disease activity level (DAS28 < 2.6 [remission], DAS28 ≥ 2.6 to ≤ 3.2 [low disease activity; LDA], DAS28 > 3.2 to ≤ 5.1 [moderate disease activity; MDA], DAS28 > 5.1 [high disease activity; HDA] at Weeks 12 and 24. The adjusted least squares mean (LSM) change from baseline was estimated using a mixed model with repeated measures, including region (North America vs non-North America), RA duration (> 2 years vs ≤ 2 years), baseline HAQ-DI and DAS28, treatment, visit, visit by treatment and visit by baseline HAQ-DI.

Results: Data from 5051 patients were included. Across all studies, the mean duration of RA ranged from 6.3 to 12.6 years. At baseline, patients had severe RA with a mean DAS28 ≥ 6.3; baseline HAQ-DI was ≥ 1.5. At Week 12, patients who achieved remission or LDA had greater improvements in HAQ-DI than those in MDA or HDA (**Figure 1**). Results were similar at Week 24 (**Figure 2**). Among patients who received TCZ and achieved remission or LDA, mean improvement in HAQ-DI was ≥ 0.65 and ≥ 0.44, respectively, at Week 12 (**Figure 1**) and ≥ 0.48 and ≥ 0.43 at Week 24 (**Figure 2**). Mean changes in HAQ-DI were similar between patients who received TCZ-IV in combination with MTX or as monotherapy (ACT-RAY) and in those who received TCZ-IV or ADA as monotherapy (ADACTA).

Conclusion: Patients with long-standing, severe RA who received IV or SC TCZ as monotherapy or in combination with csDMARDs had improvement in physical function and disease activity at Week 12 that was maintained at Week 24. Overall, across all the trials, response to treatment was associated with improvement in patient-reported physical function.

Pain and Other Patient-Reported Outcomes in Patients with Rheumatoid Arthritis Who Did or Did Not Achieve Treatment Response Based on Improvement in Swollen Joints in Tocilizumab Clinical Trials

Anthony Sebba[1], Jian Han[2] and Shalini V. Mohan[2], [1]Arthritis Associates, Palm Harbor, Tampa, FL, [2]Genentech, South San Francisco, CA

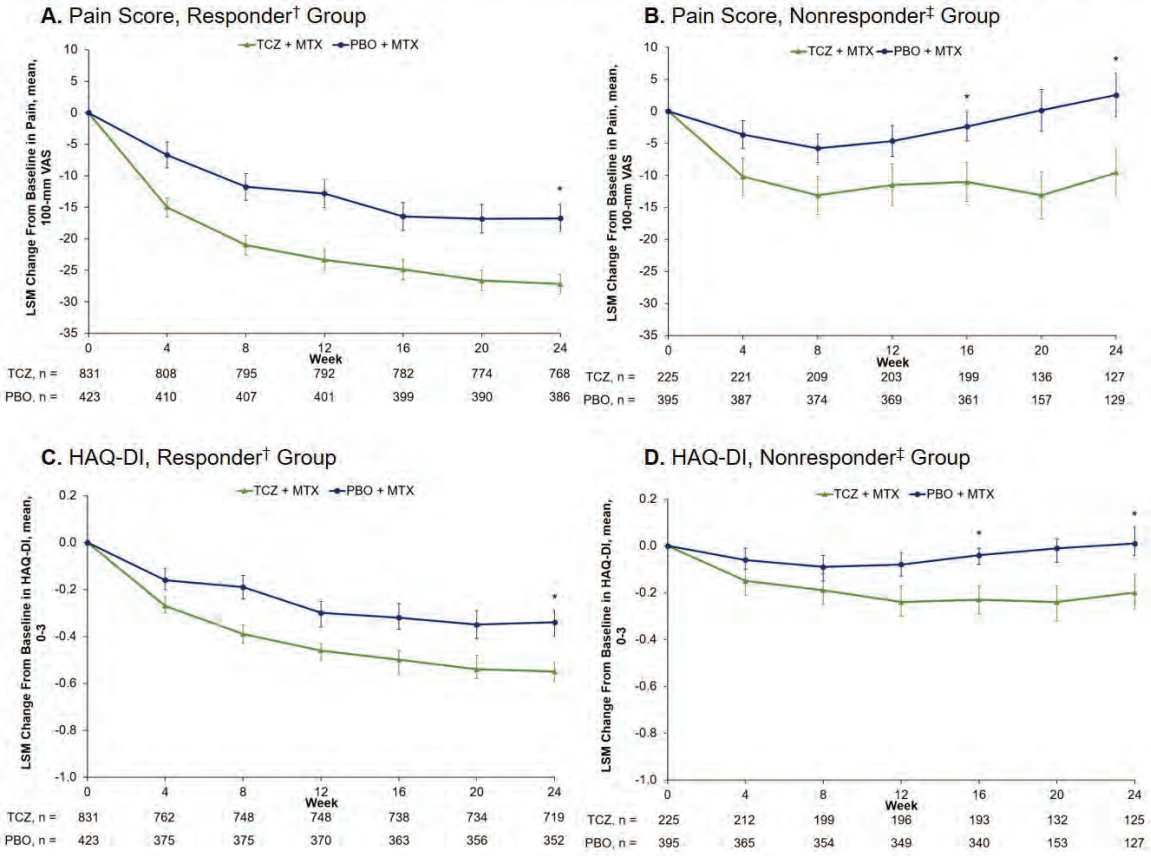
SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent data suggest that rheumatoid arthritis (RA) pain may be noninflammatory and inflammatory, and improvement in pain scores and other patient-reported outcomes (PROs) may be seen in patients who do not respond to treatment based on disease activity measures that evaluate inflammation. This study evaluated changes in pain scores and other PROs in patients with RA who did or did not achieve ≥ 20% improvement in swollen joint count (SJC) in tocilizumab (TCZ) clinical trials.

Methods: Data from patients with active RA who received intravenous TCZ 8 mg/kg + methotrexate (MTX) or placebo (PBO) + MTX in 3 Phase III studies (OPTION [NCT00106548], TOWARD [NCT00106574] and LITHE [NCT00109408]) were included. Changes in pain (visual analog scale [VAS], 0-100 mm), Health Assessment Questionnaire Disability Index (HAQ-DI, 0-3), 36-Item Short Form Survey (SF-36) physical component score (PCS) and mental component score (MCS; 0-50) and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score (0-52) from baseline to Week 24 were evaluated. Results were compared between patients receiving TCZ + MTX and those receiving PBO + MTX in both patients who achieved ≥ 20% improvement in SJC (responders) and those who did not (nonresponders). The changes from baseline were analyzed using a mixed model with repeated measures, including the following covariates and interactions: treatment, visit, baseline of endpoint, region, baseline DAS28 and interactions of visit with treatment and baseline of endpoint.

Results: Data from 1254 responders (TCZ + MTX, n = 831; PBO + MTX, n = 423) and 620 nonresponders (TCZ + MTX, n = 225; PBO + MTX, n = 395) were included. Patients receiving TCZ + MTX had significantly greater improvement in pain and HAQ-DI than PBO + MTX in the responder group (–27.19 vs –16.77 and –0.55 vs –0.34, respectively; $P < 0.0001$ for both) and nonresponder group (–9.59 vs 2.53 and –0.20 vs 0.01; $P < 0.0001$ for both) at Week 24 (**Figure 1**). Similar results were seen at Week 16 in the nonresponder group (–11.06 vs –2.38 and –0.23 vs –0.04; $P < 0.0001$ for both). At Week 24 in the responder group, patients receiving TCZ + MTX had significantly greater improvements compared with PBO + MTX in SF-36 PCS and MCS (9.16 vs 5.71 and 6.55 vs 3.79, respectively; $P < 0.0001$ for both) (**Figure 2**) and FACIT-F (8.39 vs 5.11; $P < 0.0001$). In the nonresponder group, patients receiving TCZ + MTX had

Figure 1. LSM Change in Pain Score and HAQ-DI From Baseline to Week 24 in Responder and Nonresponder Groups

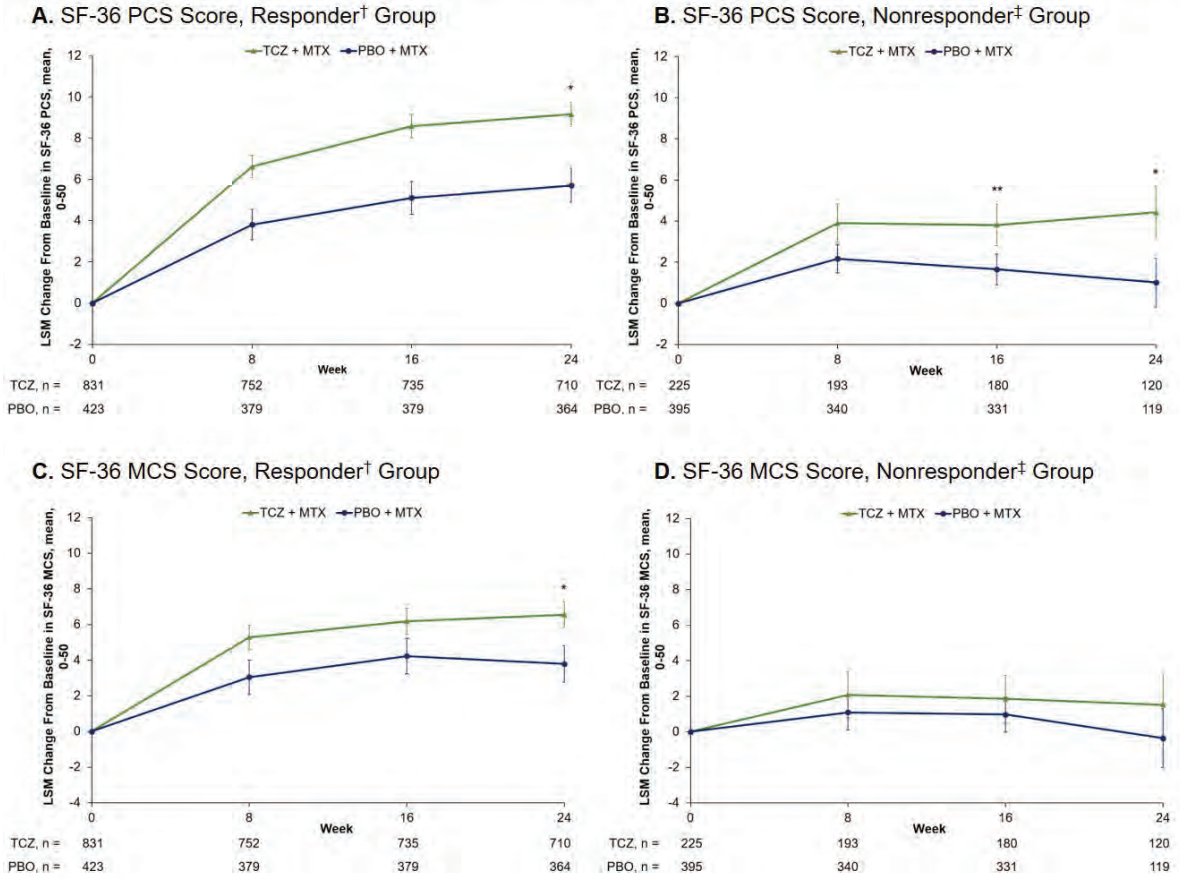


HAQ-DI, Health Assessment Questionnaire Disability Index; LSM, least squares mean; MTX, methotrexate; PBO, placebo; TCZ, tocilizumab; VAS, visual analog scale.
*$P < 0.0001$ for comparison between TCZ + MTX and PBO + MTX.
†Patients who achieved ≥ 20% improvement in swollen joint counts.
‡Patients who did not achieve ≥ 20% improvement in swollen joint counts; at Week, 16 patients were permitted to receive rescue therapy.

significantly greater improvements compared with PBO + MTX in SF-36 PCS at Week 16 (3.81 vs 1.65; $P = 0.0006$) and Week 24 (4.42 vs 1.01; $P < 0.0001$) (**Figure 2**) and FACIT-F at Week 16 (3.82 vs 1.32; $P = 0.0039$) and Week 24 (3.90 vs 1.40; $P = 0.0111$).

Conclusion: Patients with RA who received TCZ + MTX had significantly greater improvements in pain and other PROs than those who received PBO + MTX regardless of whether they achieved ≥ 20% improvement in SJC. Clinical outcome at Week 24 correlated well with PROs, with a relatively larger improvement in PROs in the responder group than in the nonresponder group; relative to PBO + MTX, these improvements appear numerically similar in the responder and nonresponder groups. The consistent effect of TCZ on PROs in responder and nonresponder groups warrants further study on TCZ's impact on pain sources independent of that caused by joint inflammation.

Figure 2. LSM Change in SF-36 PCS and MCS From Baseline to Week 24 in Responder and Nonresponder Groups



LSM, least squares mean; MTX, methotrexate; MCS, mental component score; PCS, physical component score; PBO, placebo; SF-36, 36-Item Short Form Survey; TCZ, tocilizumab.
*P < 0.0001 for comparison between TCZ + MTX and PBO + MTX.
**P < 0.001 for comparison between TCZ + MTX and PBO + MTX.
†Patients who achieved ≥ 20% improvement in swollen joint counts.
‡Patients who did not achieve ≥ 20% improvement in swollen joint counts; at Week 16, patients were permitted to receive rescue therapy.

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarilumab is a human IL-6 receptor inhibitor approved for the treatment of adults with moderately to severely active RA. The relationship between disease activity, sarilumab treatment, and improvements in patient-reported outcomes (PROs) has not been well studied. Here, we assess the association between disease activity and PROs in 3 sarilumab phase 3 trials.

Methods: This post hoc analysis included patients from 2 placebo-controlled trials (MOBILITY [NCT01061736] and TARGET [NCT01709578], with sarilumab dose groups of 150 mg and 200 mg every 2 weeks [q2w] combined for this analysis) and the active-controlled MONARCH (NCT02332590; sarilumab 200 mg vs adalimumab 40 mg q2w) trial. Associations between PRO improvement and achievement of low disease activity (LDA) were tested at Week 24. All statistics are descriptive.

[a]Placebo n=398, sarilumab n=799; [b]Placebo n=181, sarilumab n=365, sleep not assessed; [c]Adalimumab n=185, sarilumab n=184, SDAI and sleep not assessed. Disease activity thresholds per trial protocols. CDAI=Clinical Disease Activity Index; FACIT=Functional Assessment of Chronic Illness Therapy; Q=quartile; SDAI=Simplified Disease Activity Index; VAS=visual analog scale

Results: Across all trials, PRO improvements were numerically larger in patients who achieved LDA than in those who did not (Table). Sarilumab was associated with numerically larger PRO improvements than placebo, in patients who did and also in those who did not achieve LDA (Table). In the active-comparator trial, improvements in PROs were generally comparable between sarilumab and adalimumab (Table).

Conclusion: In this post hoc analysis, achieving LDA was associated with increased PRO improvements. In patients who did not achieve LDA, the improvements were numerically more favorable with sarilumab than with placebo. There is an emerging concept that changes in PROs may also occur via different mechanisms than just suppression of inflammation, potentially via IL-6 inhibition (Taylor PC, et al. *J Clin Med. 2*019;8[6]:831), which may account for some of the results seen here.

Peripheral Protein Biomarker Changes Following Selective Inhibition of Janus Kinase 1 (JAK1) by Filgotinib in Methotrexate Naïve Adults with Moderately-to-Severely Active Rheumatoid Arthritis

Peter Taylor[1], Amer Mirza[2], Bryan Downie[2], Jinfeng Liu[2], Rachael Hawtin[2] and Emon Elboudwarej[2], [1]Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Gilead Sciences, Inc., Foster City

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL), an oral selective JAK1 inhibitor, has shown efficacy and safety in phase 3 studies in adults with moderately-to-severely active rheumatoid arthritis (RA), including those naïve to methotrexate (MTX) (FINCH3;NCT02886728). A longitudinal study of protein biomarkers related to JAK signaling[1], bone biology[2], immune cell migration[2] and inflammation[2] was conducted in FINCH3 patients (pts) to identify disease-relevant biomarkers altered by FIL vs MTX.

Methods: MTX-naive RA pts enrolled in FINCH3 received a sTable dose of MTX (MTX), FIL200mg monotherapy (FIL200mg), FIL100mg+MTX, or FIL200mg+MTX. Up to 27 disease relevant biomarkers were evaluated. Baseline (BL) correlation between biomarkers and clinical response measures were analyzed by Spearman Rank. Multiscale bootstrap resampling was used to evaluate significant intra-cluster biomarker membership. Mean changes from BL to weeks (wks) 4, 12 and 24 were compared using MTX-adjusted estimates from a linear mixed effects model. A false discovery rate of 5% was applied.

Results: At BL, distinct clusters (CL) of biomarkers differentiated by JAK signaling were identified. The strongest intra-group correlations were in biomarkers upstream of JAK2 signaling (CL1; Rho range 0.88–0.98) and cytokines associated with JAK1 signaling (CL2; Rho range 0.72–0.77). Within MTX-naïve RA pts, there were significant BL correlations between 15 biomarkers and clinical measures. The strongest associations observed were between DAS-28CRP and IL6, CXCL10, TNFRI, YKL-40, and CXCL13 (Rho >0.3).

Relative to MTX, 23 biomarkers exhibited significant *early responses* (any arm, wk 4). The strongest treatment effect observed at wk 4 was a reduction for CXCL13 (FIL100mg+MTX: -28.2%; FIL200mg+MTX: -40%; FIL200mg: 34%). This reduction was sustained through 24 wks, with the greatest reduction by FIL200mg+MTX (-37.8%). Dose differences were observed relative to FIL100mg+MTX, where FIL200mg+MTX led to an *early* (wk 4) and significantly greater reduction of 9 biomarkers. There was a significant dose difference as a *delayed* response (wk 24) with a greater reduction by FIL200mg+MTX for 8 biomarkers.

FIL200mg produced a greater effect on 18 biomarkers vs MTX, significant through wk 24. The greatest effects in FIL200mg were reductions by wk 24 in CTX1 (-29.1%), CXCL13 (-33.2%), and IL6 (-29.5%); biomarkers associated with DAS28CRP at BL. Four biomarkers were different between FIL200mg and FIL200mg+MTX arms by wk 24: greater increase of MMP7 and decrease of GMCSF in FIL200mg+MTX; greater decrease of TRACP5B and ICAM1 in FIL200 alone.

Conclusion: Treatment through 24 weeks with FIL200mg ±MTX reduced many disease-relevant biomarkers tested; markers related to JAK signaling[1], bone biology[2], inflammation[2], and immune cell migration[2] in MTX-naïve RA setting. Changes were significantly reduced relative to MTX mono at wk 4, supporting the rapid onset of FIL clinical efficacy. The current study identified significant reductions of RA-associated disease markers unique to FIL mono, supporting the FIL mechanism of action in RA treatment.

An Increase in Red Cell Mean Corpuscular Volume by Methotrexate Is Potentiated by Hydroxychloroquine and Predicts Clinical Response in Rheumatoid Arthritis

Muhammad Shipa[1], Su-Ann Yeoh[1], Dev Mukerjee[2] and Michael Ehrenstein[1], [1]University College London, LONDON, United Kingdom, [2]North Middlesex University hospital NHS Trust, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) can result in an increase in mean corpuscular volume (MCV) of red blood cells. The range of MCV change varies between patients on treatment with MTX. We investigated MCV as a biomarker of response to MTX treatment in early rheumatoid arthritis (RA) patients.

Methods: This is a real-world data of biologic-naïve RA patients (as per 2010 ACR/EULAR classification) in a teaching hospital who were started on oral MTX. Results were validated by using a second cohort from a different hospital.

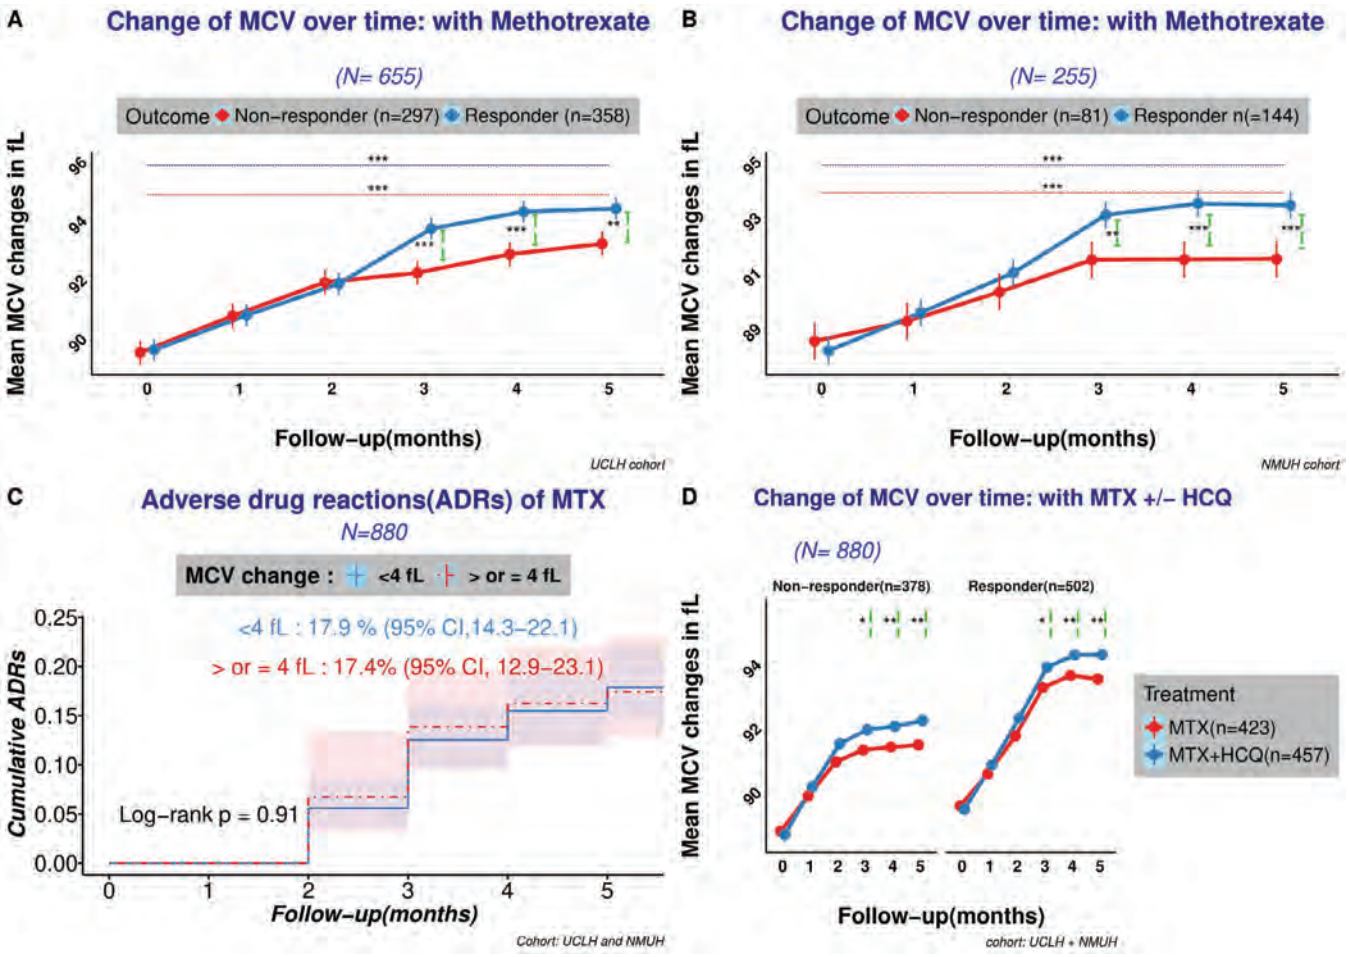

Figure 1 (A-D): A. MCV (mean corpuscular volume) change after initiation of methotrexate (MTX). Overall, MCV increased significantly from baseline for both MTX responder and non-responder groups. A significantly higher increase in MCV is demonstrated in the responder group from month 3 and onwards. B. The changes in MCV seen in 1A were confirmed in a second cohort of patients. C. Kaplan-Meier survival curves of adverse drug reactions (ADRs) event in the first 6 months after initiation of methotrexate (MTX) stratified by mean corpuscular volume (MCV) change (either <4 or ≥ 4 fL) from baseline did not reveal any difference. Overall adverse effect was noted for 17.4% (95% CI 12.9-23.1) of patient who had an MCV increment of ≥ 4 fL, compared to 17.9% who had an MCV increase of <4 (95% CI 14.3-22.1). Both cohorts have been combined for ADRs. ADRs include: MCV change <4: 20 deranged liver function (10 resulting in drug discontinuation), 2 suspected pneumonitis, 2 infections, 1 pancytopenia, 29 gastrointestinal (GI) side effects, 3 other causes. MCV ≥ 4: 31 deranged liver function (13 resulting in drug discontinuation), 33 GI side effects, 2 thrombocytopenia, 1 hypersensitivity reaction, 13 other causes. D. adding hydroxychloroquine (HCQ) to MTX potentiated the MCV changes. Each error bar (lime green) represents the p value between MTX monotherapy patient and MTX+HCQ group each time point.

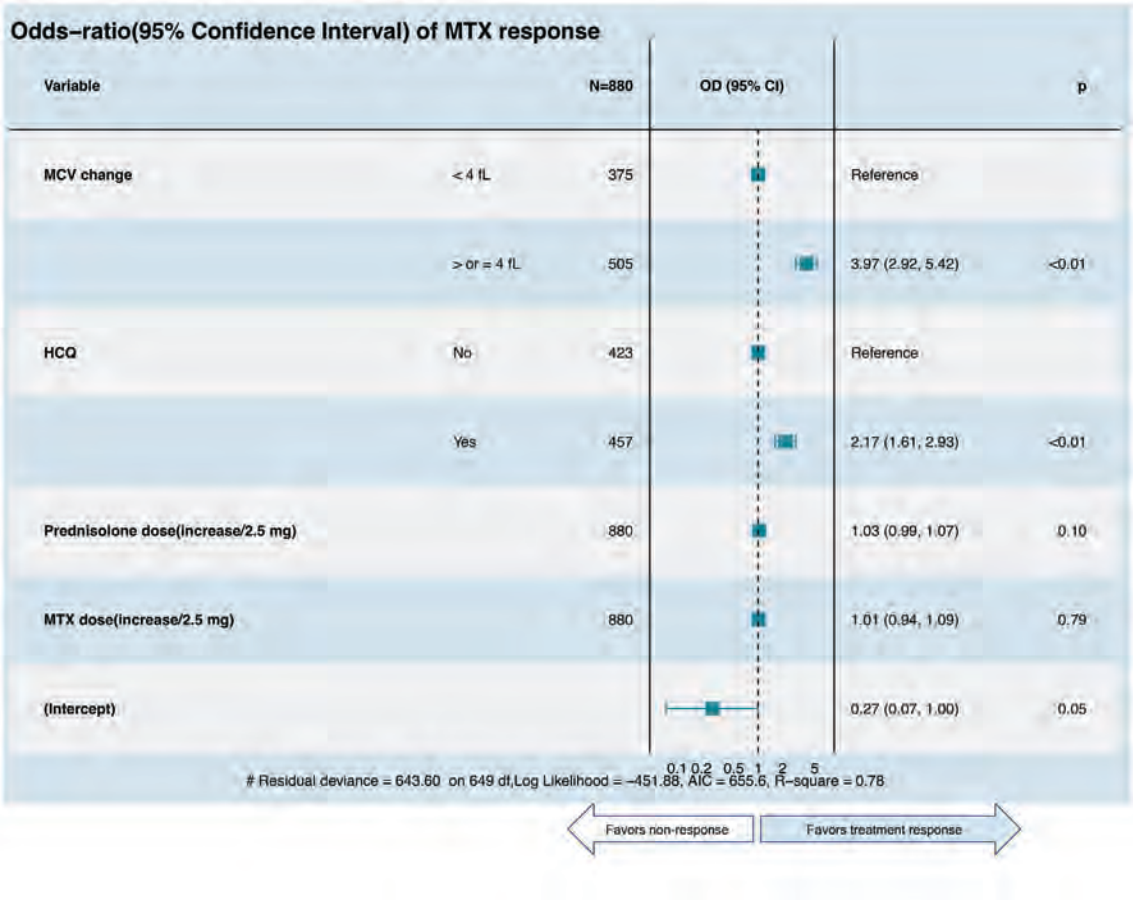

Figure 2. Random- and fixed-effects multivariate logistic regression model of predictors of treatment response of methotrexate (MTX). The final model was selected by stepwise regression using Akaike information criterion (AIC), which included: - Change of MCV (used as categorial variable), disease duration (not shown, not significant in the final model) - Adjusted by concomitant prednisolone (if applicable), MTX dose, and concomitant use of disease-modifying antirheumatic drugs (DMARDs) which includes hydroxychloroquine (HCQ), sulfasalazine (SSZ) or leflunomide (LEF).

Treatment response to oral MTX was defined as at least moderate to good EULAR response and no initiation of additional conventional, synthetic or biologic disease-modifying agents within 6 months. After initiation of MTX, MCV changes were analysed (stratified by responder and non-responder groups), by using linear mixed model analysis. Receiver operating characteristic (ROC) curve analysis (area under the curve [AUC]) was employed to identify the optimal cut-point of MCV change. Kaplan-Meier analysis captured the cumulative adverse drug reactions (ADRs) over 6 months due to MTX. Multivariate logistic regression was applied to identify predictors of treatment response within patient demographics, baseline characteristics, antibody status and concomitant treatment. Latent classes were then identified based on MCV changes.

Results: Although the MCV increased from baseline to 3 months and beyond in both responders and non-responders, MTX-responder showed a significantly greater increase of MCV from 3 months post-MTX compared to non-responders ($p < 0.001$, **Fig. 1A)**. This finding was validated in a second cohort **(Fig. 1B)**. An increase in MCV of 4 femtolitres (fL) at 3 months was associated with better treatment response using a ROC analysis with an AUC of 0.76 (95% CI 0.73- 0.80). AUC was 0.75 (95% CI 0.69- 0.83) for increase in MCV by 4.2 fL in the second cohort. However, a raised MCV ≥ 4 fL was not associated with increased ADRs **(Fig. 1C**). Hydroxychloroquine (HCQ) therapy potentiated the MCV changes when combined with MTX, in both treatment responder and non-responder group **(Fig. 1D)**.

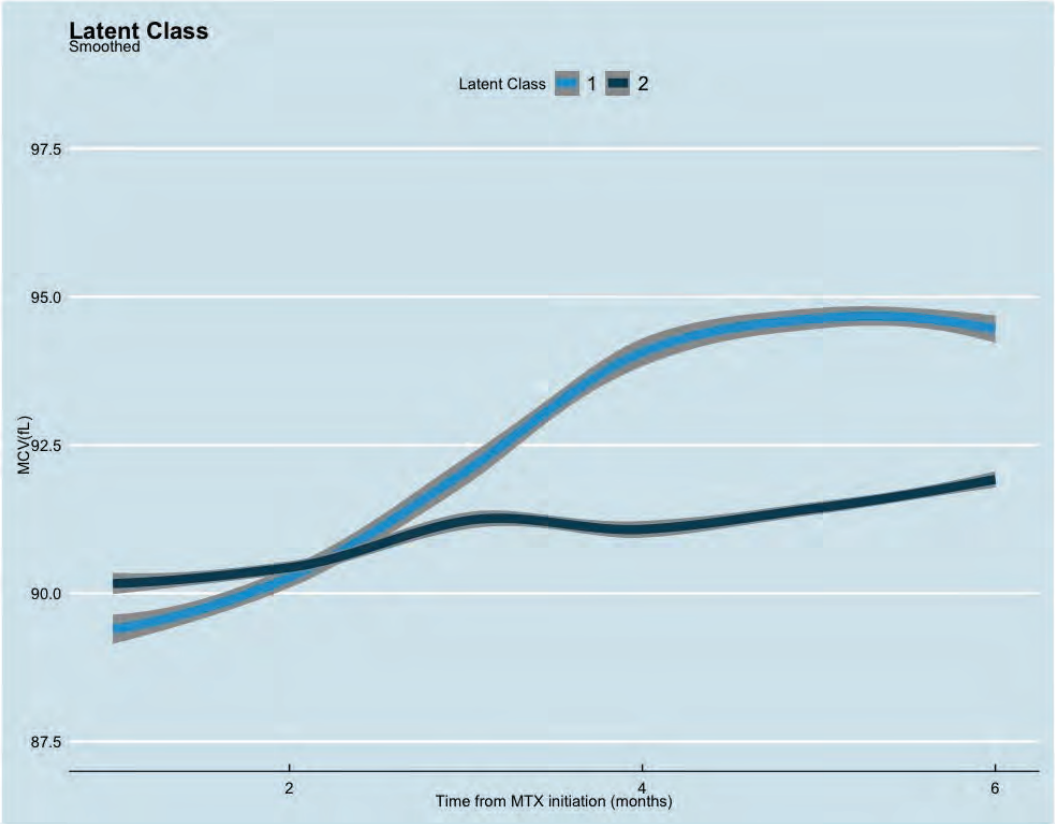

Figure 3. Mean profile change of mean corpuscular volume (MCV) over 6 months from initiation of methotrexate (MTX) after combining both cohorts and stratified by predicted class membership. Class 1: greater increase in MCV (light blue): N=496, 56.64% Class 2: minimal increase in MCV (dark blue): N=384, 43.63%. (entropy - 0.9863)

There was no change in MCV when HCQ was given without methotrexate suggesting a synergistic effect with MTX (data not shown).

Multivariate logistic regression revealed an increment of MCV by ≥ 4 fL [Odds Ratio (OR), 3.97 with 95% CI of 2.92-5.42; p=0.001] and concomitant use of HCQ (OR 2.17 with 95% CI 1.61-2.93; p=0.003) predicted clinical response **(Fig. 2)**.

Two latent classes were identified based on MCV changes **(Fig. 3)**: a greater increase in MCV group (class 1) which was associated with more treatment responders [Log (OR) 5.93, SE 0.85, p=0.001)] compared to the other class (class 2) with minimal increase in MCV. Higher MCV over time in class 1 was associated with lower C-reactive protein (CRP) [Log (OR) 0.97, SE 0.24, p=0.001] and concomitant use of HCQ [Log (OR) 0.28, SE 0.7, p=0.000)]. This effect was in the opposite direction for class 2 [Log (OR) for CRP was 0.33 with SE 0.04, p=0.000 and for HCQ -0.38 with SE 0.07, p=0.000].

Conclusion: Our data suggests that an increase of MCV increase of 4 fL from 3 months predicts response to MTX therapy in biologic-naïve RA patients and that concomitant HCQ potentiates the increase in MCV and the therapeutic effect of MTX.

Patient-Reported Outcomes in Rheumatoid Arthritis Patients Treated with Tofacitinib or Biological DMARDs in Real Life Conditions in Two Latin America Countries

Hugo Madariaga[1], Juan Reyes[2], Magda Gutierrez[3], Dario Ponce de Leon[4], Tatjana Lukic[5] and Luisa Amador[2], [1]Centro Medico CEEN, Arequipa, Arequipa, Peru, [2]Pfizer, Bogota, Cundinamarca, Colombia, [3]Pfizer, Santiago, Region Metropolitana, Chile, [4]PFIZER, LIMA, Peru, [5]Pfizer Inc, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: RA – Treatments Poster III: PROs, Biomarkers, Systemic Inflammation & Radiographs
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The objective of this study was to describe the efficacy, safety and patient reported outcomes in Latin-American patients with Rheumatoid Arthritis (RA) treated with tofacitinib 5mg (BID) or biological DMARDs (bDMARDs) after failure to respond to conventional DMARDs in real-life conditions. The primary objective of this study was to compare the disease activity measured by RAPID3 at 0- and 6-months follow-up.

Methods: This was a prospective and retrospective non-interventional study (NIS) comparing tofacitinib to bDMARDs treatments in patients with RA after failure of conventional DMARDs; the study was performed in 13 sites from Colombia and Peru between 2017 to 2019. Convenience sampling in the tofacitinib arm and randomized in the bDMARDs arm was performed. Demographic and clinical information was collected at baseline and follow up. The following questionnaires were applied at baseline and Month 6 (±1 month) of follow-up: RAPID3 (Routine Assessment of Patients Index Data) to measure Disease activity; HAQ-DI (Health Assessment Questionnaire) to measure Functional status; EQ-5D-3L (EuroQol Questionnaire) to measure Quality of life. Frequency of Adverse Events (AE) was taken from clinical records retrospectively and collected during visits when spontaneously reported. The clinical outcomes were adjusted through linear regression by demographic, clinical and access variables. Unadjusted and adjusted differences from baseline were reported in Standardized Mean Difference (SMD).

Results: Data from 100 RA patients treated with tofacitinib and 70 RA patients with bDMARDs (85% treated with etanercept, rituximab, tocilizumab and infliximab) was collected and patients were recruited between April 2017 and February 2019. At baseline, patients mean age was 53.53 years (SD 13.77), mean disease duration was 6.31 years (SD 7.01) and mean DAS28 was 5.48 (SD 2.97). There was a significant difference in the following baseline demographic and clinical characteristics of the patients: previous methotrexate therapy, complementary access mechanism and time to supply were higher in the tofacitinib group, while prednisolone treatment and concomitant use of leflunomide were higher in the biologics. At month 6, there was no statistical difference in the adjusted SMD [Standard Error] from baseline for tofacitinib versus bDMARDs for RAPID 3 (-0.20 [0.69] vs. -0.32 [0.71]), HAQ-DI (-0.56 [0.07] vs. -0.50 [0.08]), EQ-5D-3L (0.23 [0.06] vs. 0.29 [0.06]) and DAS28 (-3.86 [0.59] vs. -4.23 [0.61]). Patients with tofacitinib and biologics presented a similar proportion of non-serious AE (30.0% and 28.6%, respectively); there were two serious AE in the tofacitinib group (2.0%) that were not related to the treatment. These results have limitations (heterogeneity among groups, sample size) given the specific characteristics of NIS.

Conclusion: There were no differences between patients with RA treated with tofacitinib and biological DMARDs regarding the disease activity, quality of life and functional status. Tofacitinib had similar safety profile to biological DMARDs in Latin American RA patients.

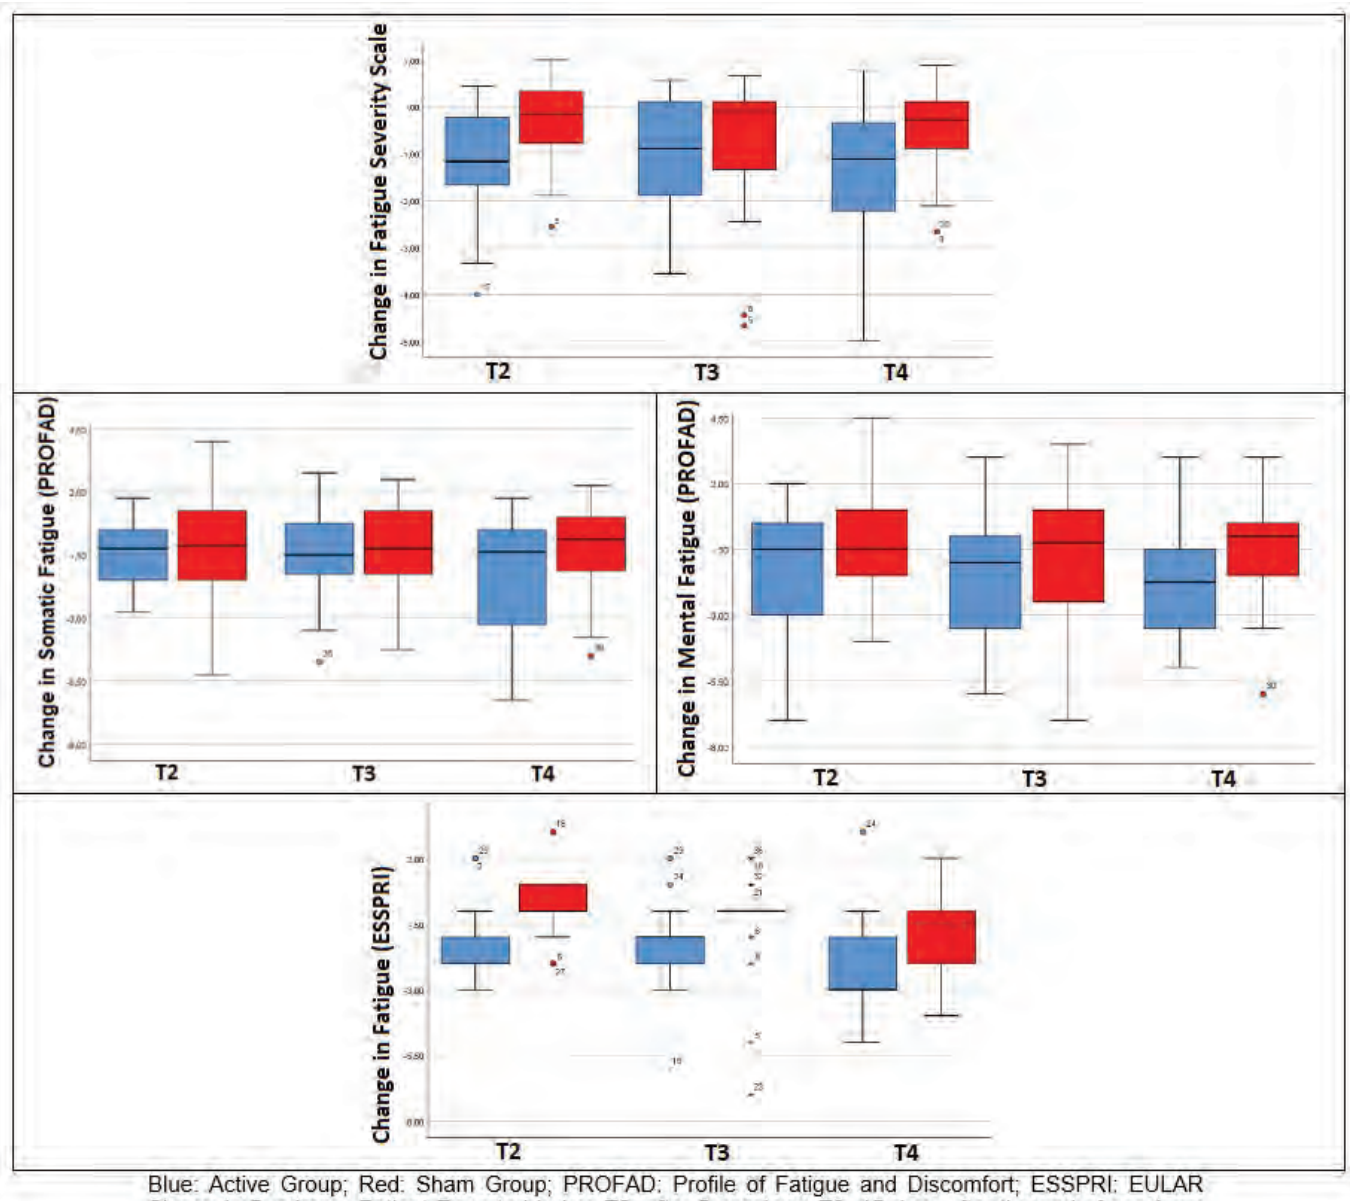
n: number of participants; SD: standard deviation; CI: confidence interval; PROFAD: Profile of Fatigue and Discomfort; ESSPRI: EULAR Sjogren's Syndrome Patient Reported Index; HRQoL: Health-related Quality of Life; SF-12: Short-form 12 Health Survey; VAS; Visual analogue scale; T2: after 5 sessions; T3: 15 days after the end of sessions; T4: 30 days after the end of sessions; Changes were calculated between time points T2, T3 and T4 from baseline values. In FSS, PROFAD, ESSPRI, and VAS assessments, higher values represent worse outcomes; for HRQoL higher values represent better outcomes. **One patient in the active group did not attend their follow-up appointment 15 days after the end of stimulation.

Table 2. Primary and secondary outcomes at each time point, change scores from baseline, and group comparison of change scores at each time point. Active Group (n=18); Sham Group (n=18)

Background/Purpose: Transcranial direct-current stimulation (tDCS) has shown promise to decrease fatigue. However, it has never been examined in primary Sjogren Syndrome (pSS). We aimed to assess the effect of a tDCS protocol on fatigue in patients with pSS.

Methods: This is a parallel, double-blind pilot study (**NCT04119128).** Women aged 18-65 years, with pSS, on sTable pharmacological therapy, with complaints of fatigue for at least three months, and with scores > 5 on Fatigue Severity Scale (FSS) were included. We randomized 36 participants to receive five consecutive or sham tDCS sessions, with an intensity of 2mA, for 20 minutes/day.

Results: After five tDCS sessions, fatigue severity assessed by the FSS (primary outcome) demonstrated a mean group difference of -0.85 [95% confidence interval (CI) -1.57, -0.13; effect size 0.80] favoring the active group. The



Blue: Active Group; Red: Sham Group; PROFAD: Profile of Fatigue and Discomfort; ESSPRI: EULAR Sjogren's Syndrome Patient Reported Index; T2: after 5 sessions; T3: 15 days after the end of sessions; T4: 30 days after the end of sessions; Changes were calculated between time points T2, T3 and T4 from baseline values.

The central box spans the interquartile range (IQR - first to third quartile). The segment inside the box shows the median values. Whiskers sprout from the two ends of the box until they reach the sample maximum and minimum values. Outliers are either 3×IQR or more above the third quartile or 3×IQR or more below the first quartile. Outliers are displayed as dots above and below the whiskers.
**One patient in the active group did not attend their follow-up appointment 15 days after the end of stimulation.

Figure 1. Box-plots presenting changes in Fatigue Severity Scale, somatic fatigue, mental fatigue and patient self-reported fatigue. Active Group (n=18); Sham Group (n=18).

active group presented significantly greater reductions in fatigue as measured by the EULAR Sjögren's Syndrome Patient Reported Index after five tDCS sessions [mean group difference: 1.40; 95%CI -2.33, -0.48; effect size 1.04]. Although there were no between-group differences in the secondary outcomes of sleep, mood and anxiety, within-group comparisons evidenced a small but significant difference in the active group for depression and sleep. There were no significant cortisol changes. All reported adverse events were mild and transitory.

Conclusion: tDCS seems to be safe and reduce fatigue in pSS. Given that tDCS treatment may have a differential effect on mood and sleep but not on cortisol levels, the dorsolateral prefrontal-affective network may mediate tDCS effects on fatigue.

Abstract Number: 1243

Self-reported Fatigue in Patients with Primary Sjögren's Syndrome Is Associated with an Objective Decline in Physical Performance and Symptoms of Pain and Depression

Roeland Prak[1], Suzanne Arends[2], Greetje van Zuiden[1], Frans Kroese[1], Hendrika Bootsma[1] and Inge Zijdewind[1], [1]University Medical Centre Groningen, Groningen, Netherlands, [2]University Medical Centre Groningen and Medical centre Leeuwarden, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a major complaint in autoimmune diseases including primary Sjögren's syndrome (pSS). For many pSS patients, fatigue is their most dominant and disabling symptom. In a conceptual framework[1], fatigue is defined as a self-reported symptom derived from 2 attributes: 1. performance fatigability, an objective decline in performance, and, 2. changes in anticipated capabilities of the performer (modulated by factors such as pain and depression). In multiple sclerosis, studies have already demonstrated a relation between performance decline and self-reported fatigue[2]. So far, no data are available on performance fatigability in pSS. Our objectives were to assess

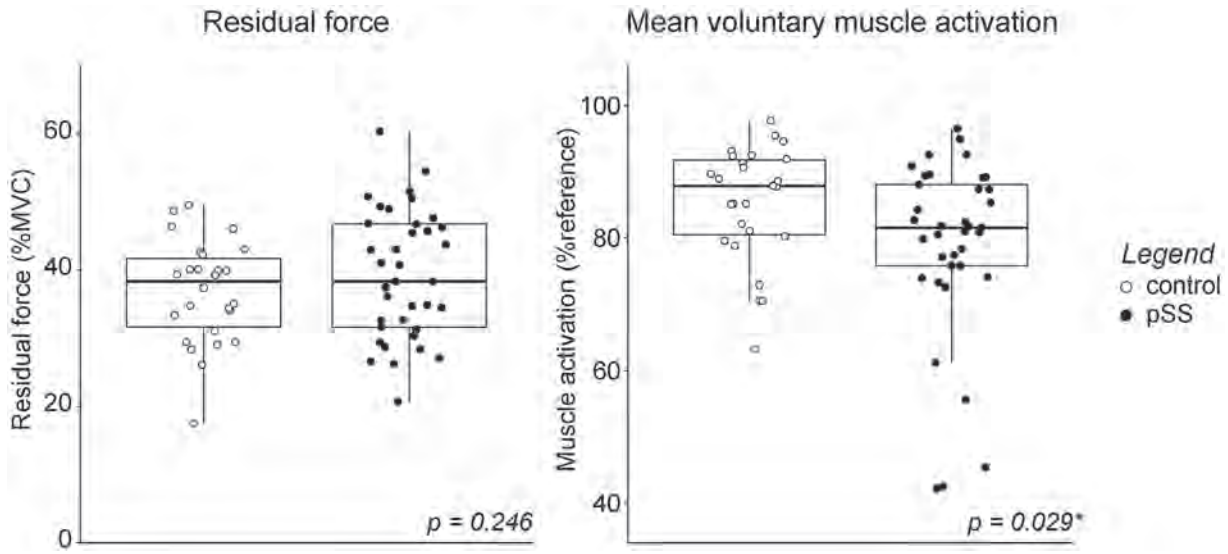

Figure 1. Measures of performance fatigability. A) Residual force following the sustained maximal voluntary contraction, expressed as a percentage of maximal force (MVC). B) Voluntary muscle activation (mean across 7 time-points) during the sustained maximal voluntary contraction. Voluntary muscle activation of 100% indicates that the muscle is firing at its maximal capacity, and that central nervous system drive is optimal. P-values are shown in both graphs.

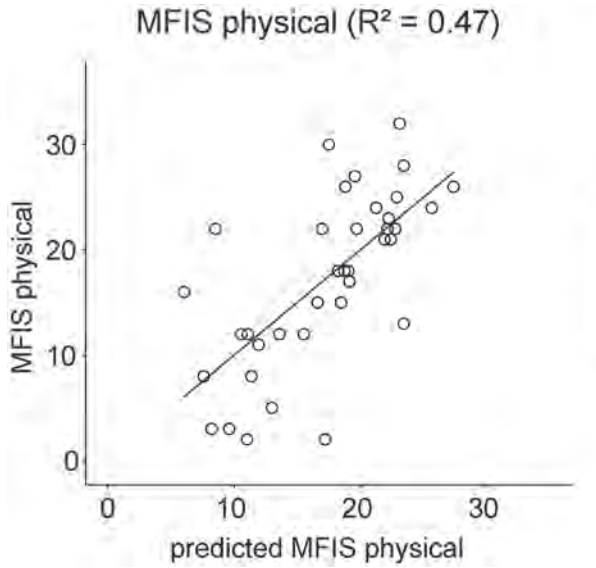

Predictor	*standardised β*	*p-value*
HADS depression	0.479	0.001
ESSPRI pain	0.343	0.019
Residual force	0.314	0.023

Figure 2. Relationship between self-reported fatigue (MFIS physical) and performance fatigability, pain, and depression. Predicted MFIS physical score is based on results of the multivariable regression. Standardized beta's and p-values of the model predictors are shown on the right. MFIS = Modified Fatigue Impact Scale; HADS = Hospital Anxiety and Depression Scale.

whether performance fatigability is affected in pSS, and to explore its relations with self-reported fatigue, pain, and depression.

Methods: Thirty-nine pSS patients (fulfilling the 2016 ACR-EULAR criteria; 5 males, age 27-65 years) and 27 healthy control participants (5 males, age 27-65 years) were included in the study. To assess performance fatigability, participants generated a sustained (124 s) maximal voluntary contraction (MVC) with the index finger abductor muscle; force was recorded using force-transducers. During the contraction, voluntary muscle activation was indexed by electrical stimulation of the ulnar nerve (for details:[2]). Self-reported fatigue was quantified using questionnaires: Fatigue Severity Scale (FSS) and, in patients only, Modified Fatigue Impact Scale (MFIS). The MFIS distinguishes a physical and cognitive domain. Pain and depression were measured using the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI pain) and Hospital Anxiety and Depression scale (HADS), respectively. Differences between pSS and controls were assessed using ANOVAs or Mann-Whitney U tests. Linear regression analysis was performed to determine which factors could explain increased levels of self-reported fatigue in pSS.

Results: With regard to performance fatigability, residual force after the sustained MVC did not differ between groups. However, voluntary muscle activation was reduced in pSS ($p = 0.029$, Fig. 1). Self-reported fatigue was significantly higher in pSS than controls (FSS median: 4.8 vs. 2.3, $p< 0.001$), and 67% of the pSS patients reported significant fatigue (FSS >4) versus none of the controls. In pSS, 47% of the variance in MFIS physical could be explained by residual force after the sustained MVC, and partly by pain and depression ($p< 0.001$, Fig. 2). FSS and MFIS cognitive could be best explained by HADS depression scores.

Conclusion: Performance fatigability in pSS was compromised by reduced voluntary muscle activation. Furthermore, self-reported fatigue in pSS was related to objectively measured performance decline (i.e. performance fatigability), as well as symptoms of pain and depression. These findings indicate that performance fatigability should be considered when investigating fatigue, and may serve as an important outcome measure for future clinical trials.

Clinical Characteristics and Outcomes in Patients with Primary Sjögren's Syndrome-Associated Interstitial Lung Disease

Joanna Marco[1], Gregory Gardner[1] and Nishant Gupta[2], [1]University of Washington, Seattle, WA, [2]University of Cincinnati, Cincinnati

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic autoimmune exocrinopathy that features interstitial lung disease (ILD) in up to 16% of patients. The clinical characteristics and natural history of pSS-associated ILD (pSS-ILD) are not well defined.

Methods: Patients with pSS-ILD were identified at two academic institutions: University of Cincinnati and University of Washington. Clinical data including demographics, diagnosis dates, serologies, imaging findings, histopathology, pulmonary function testing results, and treatments were abstracted from chart review. ILD patterns were assigned on the basis of histopathology (when available) and radiology characteristics on chest high-resolution CT scans. Categorical variables are summarized as frequencies and percentages, and continuous variables are summarized as median and range. Survival analysis was conducted using Kaplan-Meier method.

Results: There were a total of 81 patients with pSS-ILD in our cohort. The majority of the patients (86%, 70/81) were women. Sjögren's-related antibodies were common. Positive SSA alone was observed in 49%, positive SSB alone was observed in 3%, and both SSA and SSB were observed in 40%. ILD was the presenting manifestation of pSS in 17 (21%) patients. ILD and pSS were diagnosed concurrently in 34 (43%) patients. In the remaining patients (36%, 28/79), the diagnosis of ILD was established after a median of 6 years (range 1-31 years) following the diagnosis of pSS.

The most common ILD pattern in our cohort was usual interstitial pneumonia (UIP) (32%, 25/78), followed by nonspecific interstitial pneumonia (NSIP) (28%, 22/78), lymphocytic interstitial pneumonia (LIP) (21%, 16/78), and organizing pneumonia (OP) (10%, 8/78). Over a median follow-up of 4 years, 70% (46/66) had a sTable or improving functional vital capacity, and 75% (47/63) had a sTable or improving diffusion capacity for carbon monoxide.

The diagnosis of pSS-ILD led to a new immunomodulatory therapy in 54 (67%) patients. The most common steroid-sparing immunomodulatory medications utilized were mycophenolate (49%), hydroxychloroquine (44%), azathioprine (25%), and rituximab (7%). 21 patients (26%) with pSS-ILD died during follow-up. The median survival time after ILD diagnosis was 11 years (95% confidence interval: 6-12 years).

Conclusion: ILD is frequently seen and can be the presenting manifestation in patients with pSS. UIP and NSIP are the most common ILD patterns in patients with pSS-ILD. Although most patients with pSS-ILD have sTable to improving pulmonary function tests over time, approximately one-fourth may continue to decline over time. Close serial monitoring is warranted to identify the subset of patients that are declining and institute timely interventions. The diagnosis of ILD has a substantial impact on pharmacological therapy and overall patient survival.

Smoking Might Reduce Odds of Sjögren's Syndrome Among Rheumatoid Arthritis Patients

Sara McCoy[1] and Christie Bartels[2], [1]University of Wisconsin, Madison, [2]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking increases the risk of many rheumatic disease, including rheumatoid arthritis (RA). Previous studies have identified that current smoking might reduce the risk of primary Sjögren's syndrome (SS), but it remains unknown whether smoking is positively or negatively associated with SS among RA patients. The objective of this cross-sectional study was to examine the relationship between smoking and RA-SS overlap in a large RA cohort.

Methods: Electronic health records from a rural, population-based cohort were screened for RA cohort eligibility. Inclusion criteria include age ≥18 years, at least two RA diagnosis codes from a rheumatologist on distinct dates within a two year period or positive rheumatoid factor or ant-CCP antibody between 1/1/2005 and 12/31/2018. Index date was defined by the first RA diagnosis code. The baseline period for evaluation of comorbidities and medication use began twelve months before the index date. The independent variable of smoking status was defined as never, current, or past (quit) smoker at or before the index date. The dependent variable of SS was defined by ICD 9 code 710.2. Descriptive statistics were performed using chi square for categorical and unpaired student's t-test for continuous variables. Multivariable logistic regression was performed to determine odds ratios (ORs) of SS as the primary outcome by smoking status. Models were adjusted for age, sex, and race.

Results: Among 1861 patients with RA identified for cohort inclusion, 1296 patients had a reported smoking status available. Current smokers were younger and had lower female predominance than never and past smokers (Table 1). Fewer current smokers had anemia, congestive heart failure, hypertension, hypothyroidism, and renal disease. Descriptive analysis of RA patients with or without SS revealed that SS patients were more likely to be female and less likely to be anemic or smoke (Table 2). Adjusted OR of female sex was positively associated with SS (OR 2.56 [95% Confidence Interval (CI) 1.48-4.73]; Table 3). Current smoking was negatively associated with SS (OR 0.2 [95% CI 0.06-0.68]). Because data on smoking before cohort entry were missing for 565 patients, we repeated analysis on smoking status of patients captured before cohort exit (38 patients missing) and reproduced these results (data not shown).

Table 1. Demographics of RA Patients by Smoking Status at Cohort Entry (n=1861)

	Never Smoker (n=589)	Past Smoker (n=406)	Current Smoker (n=301)	p

CHF=Congestive Heart Failure; COPD=Chronic Obstructive Pulmonary Disease; DM=Diabetes Mellitus; HCQ=Hydroxychloroquine; Missing n=565.

Conclusion: We report for the first time that RA patients who smoke had 80% lower odds of SS. Previously, studies have shown reduced risk of primary SS in current smokers, supporting our findings. We found female sex in RA had a greater than 2.5 fold association with SS. Our data suggest a negative correlation between smoking and SS among RA patients. Our cross-sectional observational study cannot exclude reverse causality of quitting smoking with SS symptoms. Future studies should prospectively examine pack year dose relationships with overlap RA-SS incidence to further examine risk reduction and causality.

Sjogren's Syndrome and Its Risk of Cervical Lesions

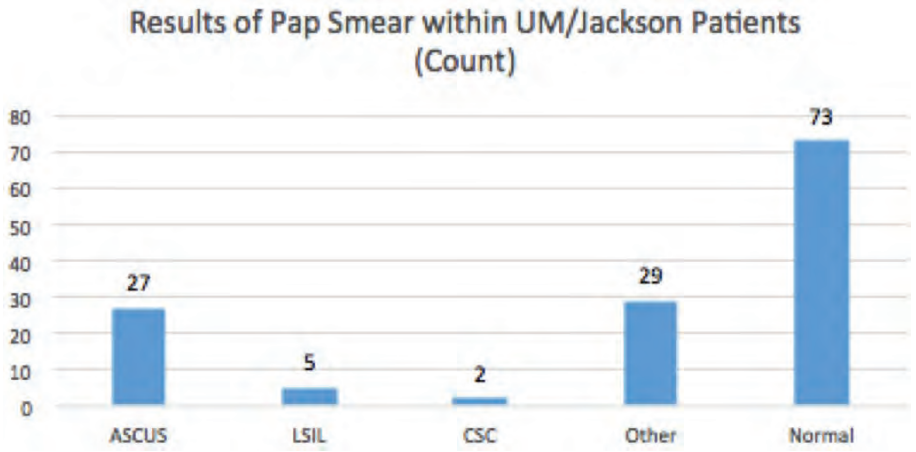
Kelly Corbitt[1], Isis Lopez[2] and Schartess Culpepper[3], [1]Jackson Memorial Hospital/University of Miami Internal Medicine Residency Program, Miami, [2]Baylor College of Medicine Rheumatology Fellowship Program, Miami, [3]University of Miami Hospital System, Miami

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjogren's syndrome is chronic inflammatory disease that results in lacrimal and salivary dysfunction and can include extra-glandular manifestations. While it is well established that patients with auto-immune conditions such as systemic erythematous lupus and rheumatoid arthritis have an increased risk of cervical dysplasia, the risk of Sjogren's syndrome and cervical malignancy has not been determined due scarce data. Epidemiological data shows that 5% of all national papanicolaou smears results in atypical squamous cells of undetermined significance (ASCUS), while low-grade squamous intraepithelial lesions (LSIL) is found in 2% of pap smears, and less than 1% result is cervical cancer. Determining the risk of cervical lesions from Sjogren's syndrome, may lead to better understanding of its risk of cervical dysplasia, possibly affecting cervical cancer screening guidelines for these patients.

Methods: Retrospective chart review of women between the age of 21-65 years of age in the Jackson Health care system and University of Miami was performed using ICD 9 and 10 codes for Sjogren's syndrome (710.2, M35.0) between the years 2010 to 2019. Cervical pathology results were recorded for each patient as well as their HPV status, HIV status, immunosuppression history, and other auto-immune diagnoses. Descriptive analysis of these data points was conducted.

Results: We identified 136 women with an ICD 9 or 10 diagnosis of Sjogren's from the Jackson Memorial hospital and University of Miami Health systems. Out of the 136 women, 34 women had abnormal cervical cells, which consisted of 27 pap smear samples resulting with ASCUS, 5 with LSIL, and 2 with cervical squamous carcinoma. This amounted to 25% having concerning pap smears, with 62.3% of these samples infected with high risk HPV strains. Out of the women with reported ASCUS, 16 were positive for high risk HPV, and out of the women with LSIL 1 was



positive for high risk HPV. The rest of the 102 women had pap smears negative for cervical dysplasia, however 29 of those women had pap smears that resulted in inflammatory, reactive, or atrophic changes.

Conclusion: Results revealed that women from our retrospective study diagnosed with Sjogren's syndrome were found to have abnormal cervical cells on pap smears at a rate much higher than the national average. Although 62.3% of these women with ASCUS/dysplasia were also infected with high risk HPV, the increased rate of ASCUS results at 19.9% is significantly higher than the national rate of 5% in U.S women. There was also an increase in pap results yielding in inflammatory and reactive changes. Although there is limited data published on Sjogren's syndrome and cervical dysplasia, our results poses interest in the possibility of Sjogren's leading to increased cervical inflammation, as well as susceptibility to HPV-infections that may lead to cervical dysplasia. These findings suggest we should be vigilant about offering our Sjogren's patients appropriate HPV vaccination and ensure appropriate cervical cancer screening has been done.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjogren's syndrome (SS) is an autoimmune chronic disease characterized by inflammation of exocrine glands, but it can affect other organs as well. This study aims to describe childhood SS (cSS) features by reviewing pediatric published cases with individual data.

Methods: We conducted a literature review of cSS (age < 18 years). Eligible papers were identified through a Medline search of English language articles published in the PubMed database until February 2020. Statistical analysis was performed to detect associations between clinical/laboratory features.

Results: Two-hundred-forty patients were identified (191 female); the median age at disease onset was 10 years (range 3 months-17 years). Main clinical features are shown in Figure 1. The most frequently reported clinical SS-specific feature was parotitis (134/198 patients; bilateral:unilateral=2.5:1); fewer patients had sicca symptoms (89/159 with dry eyes; 85/144 with dry mouth). Arthritis was the most frequent extraglandular manifestation. Renal tubular acidosis represented the typical expression of renal involvement (19 cases). Neuromyelitis optica and aseptic meningoencephalitis (6 and 9 cases, respectively) were the most typical neurologic manifestations. Two cases of interstitial lung disease and one of pulmonary hypertension were reported. Investigations are shown in Figure 2. Almost all patients had autoantibodies, mostly ANA (200/224 patients) and anti- SSA/Ro (170/208 patients). The Schirmer test was per-

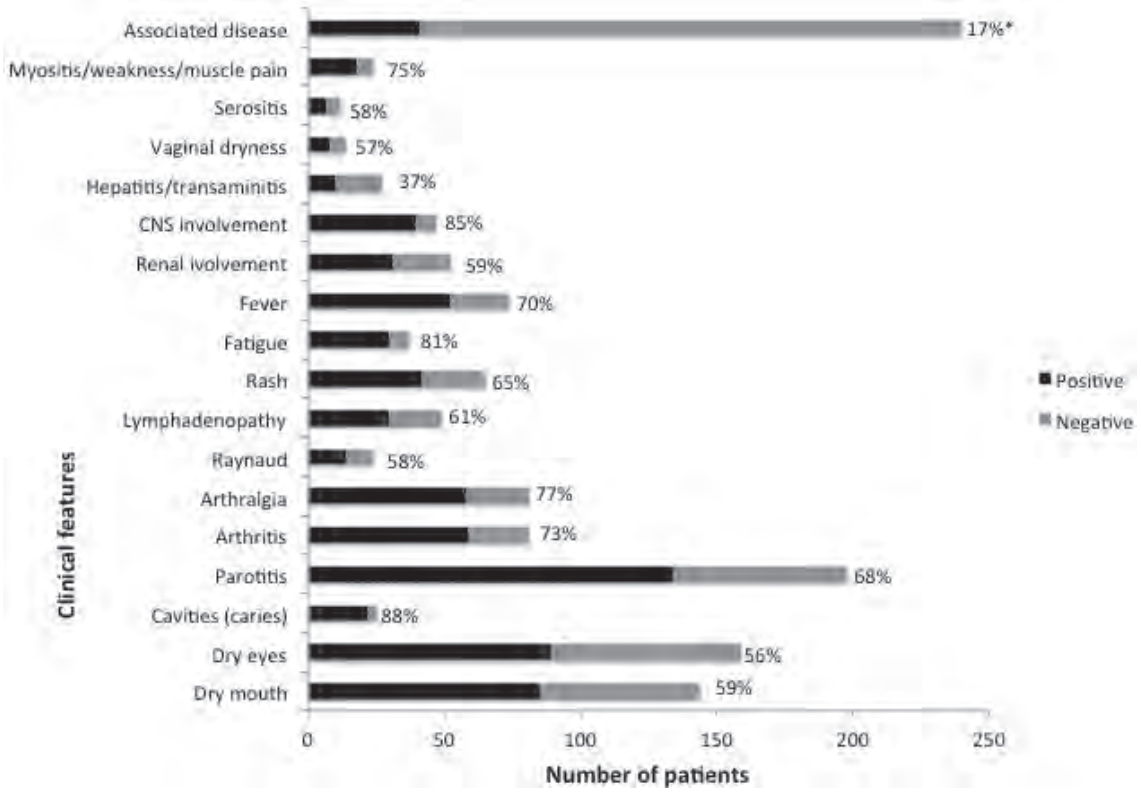

Figure 1. Main clinical features. *Values are the number of patients with positive findings/patients with available information (%). CNS: central nervous system

formed in less than half of the patients, of whom 62% tested positive. A positive result of minor salivary biopsy was reported in 129/140 cases with available data. Juvenile idiopathic arthritis was the most frequently associated disease, followed by systemic lupus erythematosus (16 and 8 cases, respectively). No significant differences between patients with or without parotitis were found except that patients with parotitis showed increased levels of CRP more frequently than those without it (p= 0.00). Patients with anti-SSA/Ro had more frequently a positive Schirmer test (p= 0.04). The presence of RF was significantly associated with dry mouth (p= 0.00), arthritis (p= 0.00), and rash (p= 0.04). A positive minor salivary biopsy was more common in children with dry eyes than in those without this clinical feature (p= 0.02). Arthritis was more frequent in patients with other diseases than in those with primary SS (p= 0.00). We further investigated SS features according to the age groups (≤ 6 years, 7-11 years, ≥ 12 years). Parotid involvement was inversely proportional to the age and occurred more frequently in younger patients (79% of those ≤ 6 years; p= 0.03). Interestingly, the rate of anti-SSA/Ro positivity increased with age (97% of those ≥ 12 years; p= 0.00).

Conclusion: Even though parotitis was the most frequently reported feature, a wide range of clinical manifestations in children with SS has been reported so far. A better knowledge of cSS features will help to pave the way for the development of cSS specific diagnostic criteria.

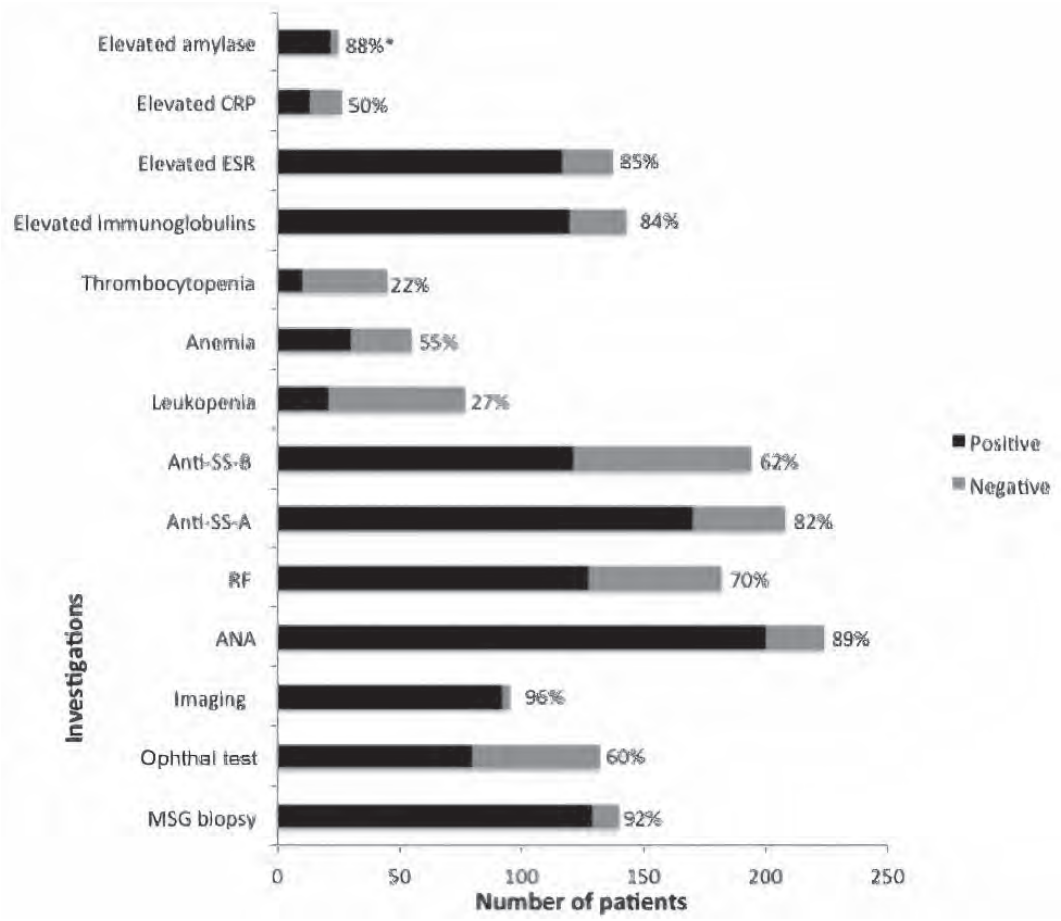

Figure 2. Investigations. *Values are the number of patients with positive findings/patients with available information (%). CRP :C-reactive protein; ESR: erythrocyte sedimentation rate; RF: rheumatoid factor; ANA: antinuclear antibodies; Opthalm test: Ophthalmological test (Schirmer test or Rose Bengal staining); MSG biopsy: minor salivary gland biopsy.Imaging: parotid ultrasound or computed tomography, sialogram, scintigraphy

Patients Seropositive for La/SSB Without Ro/SSA Differ from Those Displaying La/SSB with Ro/SSA in a Single Center Sjogren's Cohort

Rana Mongroo[1], **Samira Chowdhury**[2] and Steven Carsons[2], [1]Mount Sinai South Nassau Hospital, Mineola, NY, [2]NYU Winthrop Hospital, Mineola, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's disease (SS) is characterized by the presence of antibodies against protein-small RNP complexes designated Ro/SSA and La/SSB. Both are included in the 2002 American-European Consensus Group Criteria (AECG) for SS, however La/SSB was excluded from the 2016 ACR-EULAR on the basis of findings[1,2] demonstrating that SS patients seropositive for La/SSB without Ro/SSA (La/SSB) lacked an association with the phenotypic features of SS. We examined our single-center rheumatology division based primary SS cohort for the presence of patients SS displaying La/SSB. The phenotypic characteristics of this subset was compared to SS patients seropositive for La/SSB and Ro/SSA.

Methods: We retrospectively reviewed the charts of 318 patients for primary SS to determine the prevalence of La/SSB . Patients suspected of having secondary SS on the basis of the presence of another major connective tissue disorder were excluded. One hundred and twenty-eight fulfilled AECG. La/SSB were matched by age and symptom duration to an equal number of patients who were positive for La/SSB and Ro/SS-A. Groups were examined for sex, race, sicca symptoms, number of extraglandular manifestations (EGM), fulfillment of AECG, presence of ANA, RF, and IgG level at presentation. The difference between continuous variables was determined by the Wilcoxon ranked sign test. Differences in proportions among categorical variables was determined by Fisher's exact test.

Results: Of the 318 evaluated charts, 17 had La/SSB without Ro/SSA (5.3%). When compared to 17 with La/SSB and Ro/SSA, differences in clinical and laboratory characteristics were noted. La/SS-B displayed significantly fewer EGM, fulfilled AECG less often, and had significantly lower levels of RF, ANA and serum IgG. La/SSB were more often Caucasian (NS) (see Table 1 for details). The 5 La/SSB who fulfilled AECG represented 3.9% of the 128 patients fulfilling AECG; all 5 had positive labial salivary gland biopsies.

Conclusion: Consistent with results from the SICCA cohort[1] and the OMRF cohort[2], a small percentage (3.9%) of our rheumatology division based SS cohort who fulfilled SS criteria had La/SSB in the absence of Ro/SSA. In the majority of cases, La/SSB appears to constitute an atypical form of SS or represent a related but distinct autoimmune disorder.

The Impact of Anti-Ro Antibodies on the Pregnancy Outcome in Relation to Maternal Disease Presentation: A Descriptive Analysis of 231 Pregnancies

Eman Satti[1], Nawal Hadwan[1], Hadil Ashour[1], Rawan Saleh[1], Fiaz Alam[1], Omar Alsaed[1] and Samar Al Emadi[1], [1]Hamad medical corporation, DOHA, Qatar

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Ro antibody positivity is linked to adverse fetal outcomes like congenital heart block CHB (2%) and neonatal lupus. The incidence of CHB increases to 6-13% with subsequent pregnancies.

These antibodies are present in cases of primary Sjogren, SLE, Rheumatoid as well as asymptomatic population. It's unclear if the virulence of these antibodies is linked to the underlying disease.

Many asymptomatic women are identified retrospectively after having a baby with Congenital Heart block.

The purpose of this study is to describe the impact of anti-Ro positivity on the pregnancy outcome and it's relation to the underlying maternal disease.

Methods: We retrospectively collected data from a specialized Pregnancy and Rheumatic Disease clinic at the largest tertiary hospital in Qatar. We targeted this clinic due to the standardized approach and treatment.

All cases with anti-Ro positivity were included and stratified according to the underlying disease. The analysis was performed using SPSS software.

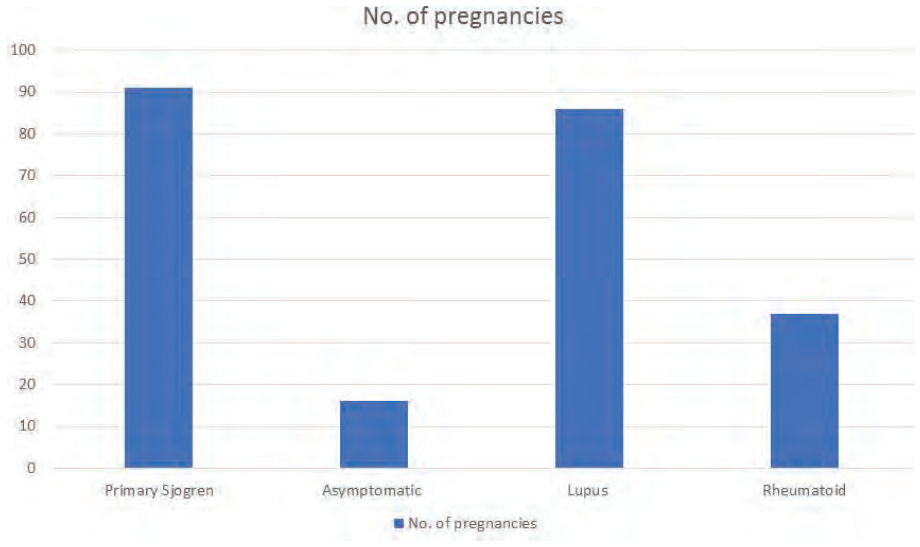

Chart 1. Number of pregnancies per Rheumatic diseases.

Fetal complication	Frequency in Total	Highest rate in:
Miscarriage	25.5%	SLE, Primary Sjogren
Prematurity	14.7 %	SLE, Primary Sjogren
IUFD	3%	Primary Sjogren
Congenital Heart Block	1.2 %	Asymptomatic mothers

Table1. Adverse Fetal Outcomes

Anti Ro titer	Frequency of adverse events (N)
< 50	14
51-100	19
101-200	9
>200	48

Table 2. Anti- Ro titer (u/ml) in relation to the rate of adverse fetal outcomes.

Results: We identified 231 pregnancies of 62 mothers from our records between 2017-2020.

One hundred and sixteen pregnancies occurred after the diagnosis.

Disease Stratification: Primary Sjogren (92 pregnancies), SLE(86 pregnancies), Rheumatoid (37 pregnancies), and Asymptomatic (16 pregnancies). Chart 1.

Adverse outcomes: eleven pregnancies (4.8%) were complicated by pre-eclampsia, while (6.5%) had gestational diabetes.

Fetal adverse events: Miscarriage was the most prominent (25.5%), followed by prematurity (4.7%), then IUFD (3%). These adverse events occurred more frequently in patients with SLE and primary Sjogren (Table 1).

Asymptomatic anti-Ro positivity and congenital heart block: CHB occurred in 3 asymptomatic cases. Two of them required permanent pacemaker and 1 developed transient bradycardia.

These Asymptomatic women had 11 healthy pregnancies in total before this event. And 2 of them had healthy pregnancies on hydroxychloroquine after their babies with CHB.

No cases of CHB were identified among the other diseases.

Hydroxychloroquine role: HCQ was used in 94 pregnancies as treatment of the underlying diagnosis. None of them developed CHB, and it was associated with a lower rate of miscarriages.

Anti-Ro titer (u/ml): Sixty women out of 62 were tested at least once for anti-Ro titer. Fetal adverse events were more frequent in patients with high titers. (Table 2).

Anti-La antibodies tested positive in 12 patients only (titer range: 14-320 u/ml).

Conclusion: In this study, we observed low incidence of congenital heart block in general. Interestingly, it happened only in asymptomatic women with high antibody titer.

Miscarriage and IUFD were more frequent than CHB in patients with Primary Sjogren.

Hydroxychloroquine was associated with a lower frequency of fetal adverse events.

Early Sjögren Antibodies: Potential Biomarker for Abnormal Minor Labial Salivary Gland Biopsy in Juvenile Sjögren's Syndrome

Akaluck Thatayatikom[1], Sthorn Thatayatikom[1], Indraneel Bhattacharyya[2], Melissa Elder[1], Renee Modica[1] and Seunghee Cha[2], [1]Department of Pediatrics, University of Florida, Gainesville, FL, [2]College of Dentistry, University of Florida, Gainesville, FL

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Sjögren's Syndrome Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Sjögren's Syndrome (jSS) is a perplexing systemic autoimmune disease in children presenting with positive autoantibodies, glandular, and/ or extraglandular symptoms. In pediatric practice, the diagnosis has relied upon the positivity of ANA and SSA/ SSB antibodies, so-called classic Sjögren antibodies (cSjA). Children with negative cSjA autoantibodies or exclusively extraglandular symptoms become a diagnostic challenge. Early Sjögren antibodies (eSjA) including IgG, IgA and IgM autoantibodies to salivary protein 1 (SP-1), carbonic anhydrase 6 (CA6), and parotid secretory protein (PSP), are 9 novel salivary gland autoantibodies. The eSjA were found to be early biomarkers in adults, especially in negative cSjA cases. The roles of ANA, cSjA, and eSjA as biomarkers and predictors for abnormal minor labial salivary gland biopsy (MSGB) have been unknown in jSS. The goal of this study is to determine if ANA, cSjA, and eSjA can serve as biomarkers and predictors for abnormal minor salivary gland biopsy (MSGB) in the University of Florida (UF) cohort with jSS.

Methods: Forty children with a new-onset jSS diagnosed at the UF Health Shands Children's hospital and the UF Health Oral Medicine between January 2017-May 2020 were evaluated retrospectively. Autoantibodies were positive if ANA was 1:160 or higher or one of cSjA and eSjA were higher than normal values. A MSGB was abnormal if the focus score was 1 or more. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of ANA, cSjA, and eSjA were analyzed using the MSGB as a gold standard.

Table 1: Comparision of sensitivity, specificity, PPV and NPV of ANA, classic Sjögren antibodies (cSjA), and early Sjögren antibodies (eSjA) in 32 children with jSS based upon the MSGB results

	Sensitivity	Specificity	PPV	NPV
ANA	51.8%	50%	87.5%	11.5%
cSjA	40.7%	60%	84.6%	15.8%
eSjA	74%	60%	90.9%	30%
ANA and cSjA	63%	40%	85%	16.7%
ANA and eSjA	85.2%	20%	85.2%	20%
cSjA and eSjA	88.9%	40%	88.9%	40%
ANA and cSjA and eSjA	89.2%	25%	89.2%	25%

Table 1. Spearman's rho correlation coefficients for salivary gland target lesions scored by ultrasound and MRI.

Results: Thirty-two children 5-17 years of age (mean 12.28, median 14) who underwent testing for ANA, cSjA, eSjA, and MSGB were included. Twenty-three children fulfilled the 2016 ACR/EULAR SS classification criteria. Abnormal MSGB results were found in 5 of 9 children who have not fulfilled the criteria. One child with normal MSGB has fulfilled the criteria. Twelve and five of the children had positive SSA and SSB antibodies respectively. All but 1 of the positive SSB patients were also SSA positive. Twenty-two children had at least one positive eSjA with anti-CA6 IgG, the most prevalent novel antibodies (52%). Abnormal MSGB with a focus score of 1 and more than 1 were found in 2 and 25 children, respectively. Three of the four children with all negative autoantibodies still had abnormal MSGB. The sensitivity, specificity, PPV, and NPV of each autoantibody is shown in Table 1. The eSjA has the highest PPV and NPV. The combination of eSjA and ANA or cSjA or both slightly increased sensitivity, but not specificity, PPV or NPV of eSjA.

Conclusion: eSjA are a potential biomarker and reliable predictor of abnormal MSGB in jSS. Patients with negative autoantibodies did not entirely exclude a diagnosis of jSS since these biomarkers have a low NPV. MSGB should still be considered in any case with a high index of suspicion with negative autoantibodies.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Imaging techniques such as salivary gland ultrasound and magnetic resonance imaging (MRI) are able to diagnose primary Sjögren syndrome (pSS) patients with high sensitivity and specificity. Recently, the OMERACT ultrasound novel scoring system for major salivary gland (SG) lesions in patients with pSS was developed showing good inter-reader and excellent intra-reader reliability. The aim of the OMERACT Sjögren ultrasound subtask group exercise was to assess the validity of the OMERACT ultrasound novel scoring system for major salivary

Table 2. Spearman's rho correlation coefficients of MRI and US scores of salivary glands with salivary flow rates (SFR).

gland (SG) lesions compared with MRI of parotid (PGs)/submandibular glands(SMGs) and salivary flow rates (SFRs) in patients with pSS.

Methods: Nine sonographers and two radiologists participated in the validity exercise, evaluating the parenchymal changes of bilateral PGs and SMGs in 11 pSS patients using greyscale ultrasound and MRI. Nine sonographers examined the superficial lobe of the PGs in both longitudinal and transverse plane, while the SMGs were evaluated in longitudinal plane only. Machine settings were not allowed to modify during scanning. The OMERACT novel four grade semiquantitative ultrasound score was applied: Grade 0, normal parenchyma; Grade 1: minimal change: mild inhomogeneity without anechoic/hypoechoic areas; Grade 2: moderate change: moderate inhomogeneity with focal anechoic/hypoechoic areas; Grade 3: severe change: diffuse inhomogeneity with anechoic/hypoechoic areas occupying the entire gland surface or fibrous gland. MRI images were evaluated by two radiologists with at least ten years of expertise in head and neck practice. The PGs parenchyma were graded by modifying the protocol as proposed by Kojima et al., i.e. , grade 0 definitely normal, grade 1 slightly heterogeneous, grade 2 clearly abnormal, and grade 3 severely heterogeneous destroyed parenchyma. Differences in opinion between radiologists, if any, were resolved by reevaluating those cases. Furthermore, both stimulated and unstimulated salivary flow rates (SFRs) were assessed in 11 pSS patients.

Results: OMERACT novel ultrasound score was strongly correlated with MRI score for the PGs and for the SMGs (Table 1). Correlation was similar for both the PGs and the SMGs combined (r:0,8 p=0.002). Moreover, both unstimulated and stimulated SFRs as objective criteria were associated with total OMERACT novel ultrasound score (r:0,7 p=0.04; r: 0,7 p=0.027) and total MRI score (r:0,8 p=0.004; r: 0,8 p=0.013). Similar trend was observed in PGs and SMGs (Table 2).

Conclusion: The OMERACT novel ultrasound scoring system for the evaluation of SG in pSS showed strong correlation with MRI assessment. Furthermore, both imaging methods strongly correlate with unstimulated and stimulated SFRs.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: With the diagnostic capability of the parotid gland biopsy similar to minor salivary gland biopsy in Sjögren's syndrome, the parotid gland biopsy may also provide information on treatment response and development of lymphoma. Comparing complications of both procedures, facial nerve damage represents a risk of parotid gland biopsy, while transient numbness of the lower lip incision area may occur after minor salivary gland biopsy. Avoiding the facial nerve during the parotid gland biopsy, therefore, is essential. In recent years, high-frequency (15–25 MHz) ultrasound probes have become available for clinical use, facilitating high-resolution visualization of small nerves or nerve fascicles.

We aimed to evaluate the diagnostic capability and safety of parotid gland biopsy in cadavers avoiding the region of the facial nerve under high-frequency (15–25 MHz) ultrasound guidance.

Methods: Prior to the parotid biopsy ultrasound exercise, an ultrasound training session on healthy subjects was conducted with the aim of assessing the most suitable facial nerve-free area for biopsy was determined in healthy subjects using high-frequency ultrasound (Figure 1). Thereafter, nine rheumatologists with experience in salivary gland ultrasound performed ultrasound-guided biopsies from four parotid glands in two different cadavers with 18 G core biopsy needles (Figure 2).

Results: A total of 36 pathology specimens were evaluated histologically by the expert pathologist for the presence of parotid gland tissue and any vascular and neuronal tissue of the gland. Eighty percent of the 36 pathology prepa-

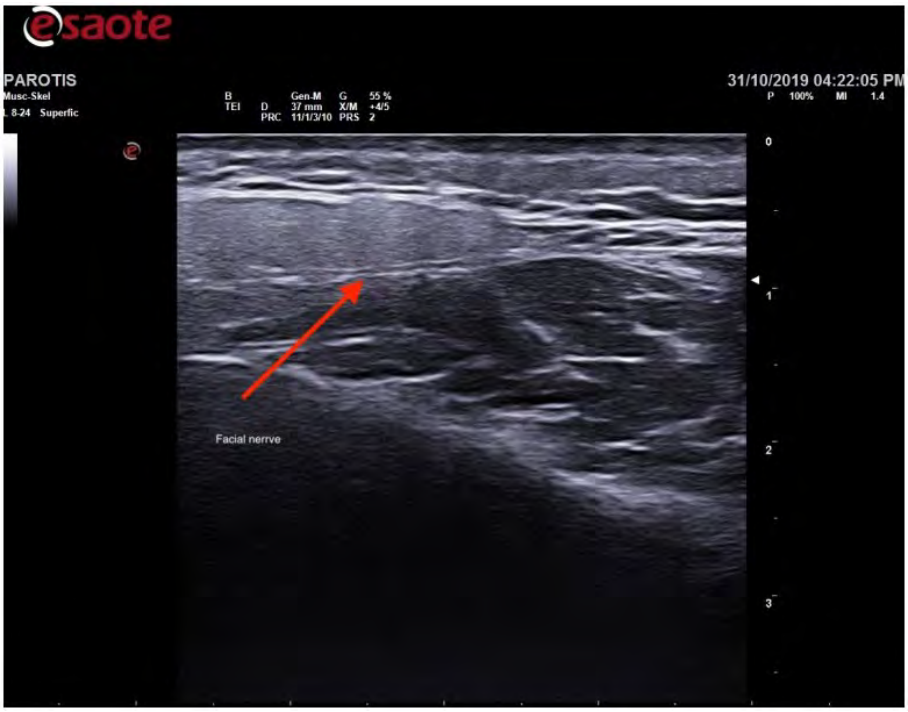

Figure 1. Ultrasound image of a parotid gland. The facial nerve appears as a linear tubular like hypoechoic structure with hyperechoic rim inside the homogenous relatively hyperechoic parotid gland (Esaote MyLab 9 equipped with 6-24 MHz probe).

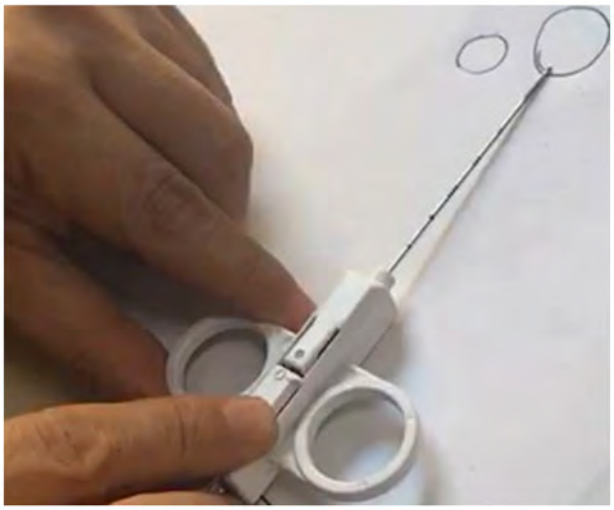

Figure 2. Core biopsy needle.

rations showed evidence of parotid gland tissue. Neuronal tissue was present in 2 specimens (5.5%), one with a very small amount of neuronal tissue. Vascular tissue was found in another 2 specimens (5.5%).

Conclusion: The present study has demonstrated that ultrasound-guided core needle biopsy of the parotid gland allows obtaining salivary gland tissue in the vast majority of cases. Longer procedural training would most likely improve the capability to obtain glandular samples.

Re-evaluation of the Extent of Lymphocytic Infiltration May Improve the Diagnostic Accuracy of Lip Biopsy in Primary Sjögren's Syndrome (pSS)

Chiara Baldini[1], Francesco Ferro[1], Gianmaria Governato[1], Giovanni Fulvio[2], Elena Elefante[3], Marta Mosca[1], Stefano Bombardieri[1] and Valentina Donati[4], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, [3]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa; Department of Medical Biotechnology, University of Siena, Pisa, Italy, [4]Pathology Unit, AOUP, Pisa

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Focus score (FS) remains the key element for the histological diagnosis of pSS; nonetheless, additional parameters have been proposed for clinical trials including the analysis of ectopic lymphoid structures (ELS) and the percentage of lymphocytic infiltration. Relatively few information are available regarding the feasibility and the usefulness of these additional histomorphological parameters in improving the diagnostic assessment of pSS in daily clinical practice.

Methods: Consecutive minor salivary gland biopsies (MSGBs) were collected and centralized to the same Pathology Unit from January 1st 2017 to January 1st 2020. An expert pathologist evaluated the samples focusing on: glandular tissue areas, assessment of focal lymphocytic sialoadenitis (FLS) versus non-specific chronic sialoadenitis (NSCS), number of foci, presence of ELS and. the percentage of lymphocytic infiltration (area of lymphocyte infiltration / total assessed surface area).

Results: We collected 267 MSGBs: 79 (29.6%) presenting a FLS with a FS≥1, 50 (18.7%) with a 0< FS< 1 and 114 (42.7.8%) with a NSCS. Moreover, the area of 24/267 (9%) further biopsies was lower than 4 mm2 and those samples were read only according to the Chisolm and Mason grading. The diagnosis of pSS was confirmed in 123 cases (46.1%). A FS≥1 was detected in 76/123 (61.8%) pSS patients and in 3/144 (2.1%) of no-SS patients, a 0< FS< 1 was observed in 13/123 (10.6%) pSS patients and in 37/144 (25.7%) no-SS patients, and a NSCS was found in 14 (11.4%) pSS patients and in 100/144 (69.4%) (p=0.000). Therefore, the FS did not support the diagnosis of pSS in 47/123 (38%) cases. In those samples with a 0< FS< 1 or with an uncertain FS due to an area lower than 4 mm2, the percentage of lymphocytic infiltration appeared significantly higher in pSS patients with respect to patients with no-SS (9.8% ± 4.1% vs 5.2% ± 3.6%, p=0.01) and correlated with anti-Ro/SSA positivity (r=0.443, p=0.02). ELS were present in the 30% samples and correlated with several ESSDAI domains including: lymphadenopathy, glandular, haematological and biological (p< 0.05). ELS correlated with the percentage of infiltration (r=0.733, p=0.001) highlighting the critical role of the size of the foci besides their numbers in determining the complexity of the infiltrate.

Conclusion: The percentage of lymphocytic infiltration and the assessment of ELS may provide complementary information to improve the diagnostic assessment of patients with suspected pSS, particularly in patients with a 0< FS< 1. Moreover, additional histomorphological parameters may also contribute to the identification of patients subgroups with more homogeneous glandular and extra-glandular manifestations.

Lack of Efficacy of Early Treatment with Hydroxychloroquine in a Group of Hispanics with Primary Sjögren's Syndrome

Ariana González-Meléndez[1], Patricia Jordán-González[1], Ricardo Gago-Piñero[1], Noemí Varela-Rosario[1], Naydi Pérez-Ríos[1] and Luis Vilá[1], [1]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of primary Sjögren's syndrome (pSS) with hydroxychloroquine (HCQ) has been evaluated in the past but with conflicting results regarding its efficacy. While earlier studies showed its effectiveness on the treatment of sicca symptoms and some extra-glandular manifestations, recent randomized controlled trials have found limited clinical benefit. However, the impact of early treatment with HCQ has not been examined. Thus, we sought to determine the clinical outcome of pSS patients receiving early HCQ therapy.

Methods: A cross-sectional study was performed in a cohort of Hispanics from Puerto Rico with pSS. All patients fulfilled the 2012 American College of Rheumatology classification criteria for pSS. Demographic features, cumulative extra-glandular and comorbidities, disease activity (per EULAR Sjögren's Syndrome Disease Activity Index [ESSDAI]), disease damage (per Sjögren's Syndrome Disease Damage Index [SSDDI]), and pharmacologic profile were assessed. Early treatment was defined using the following cutoff periods: initiation of HCQ < 6 and < 12 months from onset of symptoms attributable to pSS, and < 6 and < 12 months from pSS diagnosis. Statistical analyses were performed using Fisher's exact test, Pearson Chi-squared test, and Wilcoxon rank-sum test, as appropriate.

Results: Of the entire cohort (n=100), 84 were treated with HCQ. Of those who received HCQ, the mean age was 51.9 years and 82.1% were females. Results of the bivariate analysis are depicted in tables 1 and 2. No differences were found for age, gender, extra-glandular manifestations, comorbidities, and disease damage between all study groups. Patients who received HCQ therapy < 6 months from onset of pSS symptoms were more likely to be treated with methotrexate than those who received HCQ ≥6 months after onset of symptoms. Those that had HCQ treatment ≥12 from pSS diagnosis were more likely to have higher mean ESSDAI score when compared to those who received HCQ < 12 months from diagnosis. However, when ESSDAI score was adjusted for disease duration, statistical significance was not retained.

Conclusion: In this group of Hispanics with pSS, no major differences were found for extra-articular manifestations, comorbidities, disease activity, damage accrual, and exposure to immunosuppressive medications. This study suggests that early HCQ has limited effect on the clinical outcome of pSS patients.

Table 1. Demographic, clinical, and pharmacologic features in pSS patients receiving early HCQ treatment <6 and <12 months from onset of pSS symptoms.

Features	< 6 months (n=15)	≥ 6 months (n=69)	p-value	< 12 months (n=24)	≥ 12 months (n=60)	p-value

Sjögren's Syndrome Minor Salivary Gland Mesenchymal Stromal Cells Derived Deploy Intact Immune Plasticity and Display Myofibroblast-Like Properties

Sara McCoy[1], Jayeeta Giri[1], Rahul Das[1], Pradyut Paul[1], Andrea Pennati[1], Maxwell Parker[1], Yun Liang[1] and Jacques Galipeau[1], [1]University of Wisconsin, Madison

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is the second most common systemic autoimmune disease with hallmark features of severe ocular and oral sicca, leading to reduced quality of life. Minor salivary glands are central to the diagnosis and prognosis of pSS. The exact pathogenesis of pSS remains unclear, but focal lymphocytic infiltrate, and ultimately, increased fibrosis of the minor salivary gland, is a key feature of pSS. Mesenchymal stromal cells (MSCs), a cell type with the potential to abrogate inflammation/fibrosis, have been isolated from human minor salivary glands but little is known of their immunobiology. The objective of this study is to define the immunobiology of culture-adapted MSCs derived from endogenous salivary minor salivary gland (MSG)-MSCs.

Methods: All pSS subjects (N=11) fulfilled ACR/EULAR criteria for pSS. Control subjects (N=12) were referred for minor salivary gland biopsy but did not have features or diagnosis of autoimmune disease. MSG-MSC phenotype was assessed by morphology and flow cytometry using typical MSC surface markers (CD19-,CD45-,HLADR;CD105+,CD90+,CD73+). The immunomodulatory capacity of pSS and control MSG-MSCs was evaluated using flow cytometry for programmed death-ligand 1 (PD-L1), indoleamine 2,3-dioxygenase (IDO), and intercellular adhesion marker (ICAM-1) with and without IFNg pre-treatment. Co-culture of MSCs and peripheral blood mononuclear cells was performed by treating MSG-MSCs with IFNg then culturing MSG-MSCs with PBMCs at ratios of 1:10, 1:50, and 1:500. Co-culture was followed by Ki-67 staining and flow cytometry. RNA-Sequencing was performed on three pSS and control samples with MedGenome. Differentially expressed genes had p-value < 0.1 and log2 fold change >1 for upregulated genes and < -1 for down regulated genes. Gene ontology and pathway analysis was then performed on the differentially expressed genes. Western blot was performed with α smooth muscle actin primary antibody and GAPDH loading control. Immunocytochemistry was performed with anti-αSMA antihuman primary antibody after MSG-MSC fixation. Real-time PCR was performed using primers for COL6A6 and COL22A1.

Results: We found that MSG-MSCs deploy normal immunoregulatory functionality after IFNg stimulation as demonstrated by increased protein level expression of IDO, PD-L1, and ICAM-1 (Figure 1a-c) We also found that MSG-MSCs were able to suppress T cell proliferation in a dose-dependent manner (Figure 1d). Gene ontology and pathway analysis highlighted extracellular matrix deposition as a possible difference between pSS and control MSG-MSCs (Figure 2a-c). MSG-MSCs demonstrated increased αSMA expression. MSCs indicating a partial myofibroblast-like adaptation in MSG-MSC (Figure 3a-d).

Conclusion: These findings establish similar immunoregulatory function of MSG-MSCs in both pSS and control patients that precludes intrinsic MSC immune regulatory defects in pSS. pSS MSG-MSCs show a partial imprinted myofibroblast-like phenotype which may arise in the setting of chronic inflammation and provide a plausible etiology for pSS related mucosal fibrosis.

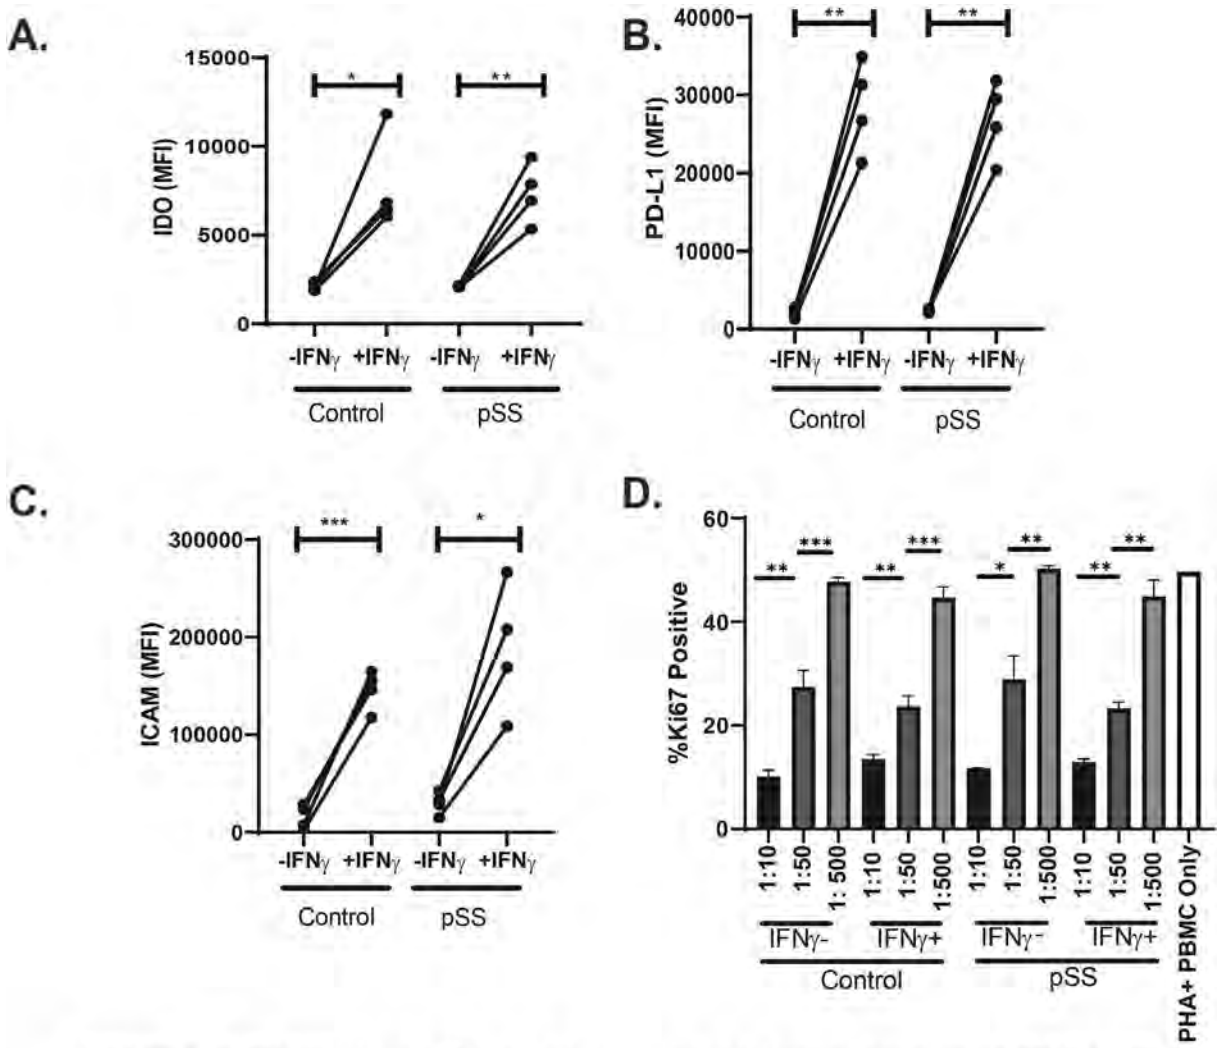

Figure 1. IFNy licensing effects on immunomodulatory properties of MSG-MSCs. pSS (n=3) and control (n=3) MSG-MSCs licensed with IFNγ(25 ng/mL) for 48 hours were harvested and stained with antibodies anti-IDO, PD-L1, and ICAM-1. Flow cytometry was performed after staining. Median fluorescence intensity (MFI) of MSC immunomodulatory markers A) IDO; B) PD-L1; C) ICAM-1; D) T cell suppression assay with MSG-MSCs with Ki-67 on pSS (n=3) and control (n=3). Values are means ± SEM. *=p<0.05, **=p<0.01, ***=p<0.001.

Mast Cells Contribute to the Development of Sialadenitis Associated with Sjögren's Syndrome via Inducing Tissue Fibrosis by TGFβ Production

Shinjiro Kaieda[1], Kyoko Fujimoto[1] and Hiroaki Ida[1], [1]Kurume University School of Medicine, Kurume, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Sjögren's Syndrome Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Mast cells have been implicated in many immune-inflammatory disorders. They mediate a variety of inflammatory and fibrotic conditions, but their role in sialadenitis in patients with primary Sjögren's syndrome (pSS) is unclear. We examined whether mast cells play a critical role in the pathogenesis of pSS.

Methods: Labial salivary gland samples were collected from 22 individuals with pSS and 10 with sicca syndrome (controls). Saliva production was evaluated by Saxon's test. Mast cell density in minor salivary glands was calculated at 400 magnification. The degree of fibrosis in minor labial salivary gland was graded on a quantitative scale as previously reported (Clin Exp Rheumatol.1998;16:63-65). We used immunohistochemistry to identify and quantify tryptase or TGFβ-positive mast cells and vimentin-positive fibroblasts. Fibrous tissue was identified by using EVG stain. Conditioned medium for fibroblast culture was obtained from human mast cell line-1 (HMC-1)cells stimulated

Figure1

Tryptase immunohistochemistry on labial salivary glands from sicca patients (A) and pSS patients (B).
Immunohistochemistry with an antibody to tryptase revealed the upregulation of mast cells in labial salivary glands .

Figure2

Mast cells contribute to the decreased salivary secretion via inducing tissue fibrosis rather than lymphoid infiltration

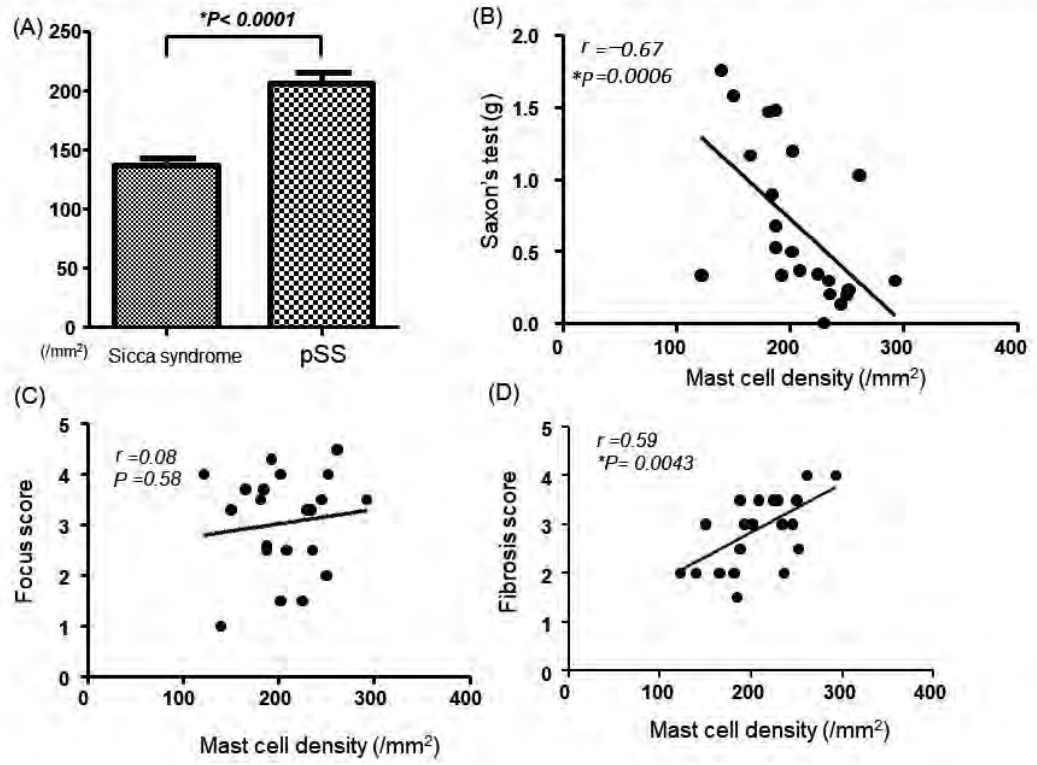

Figure3 **Mast cell-derived TGFβ induces type I collagen synthesis in fibroblasts**

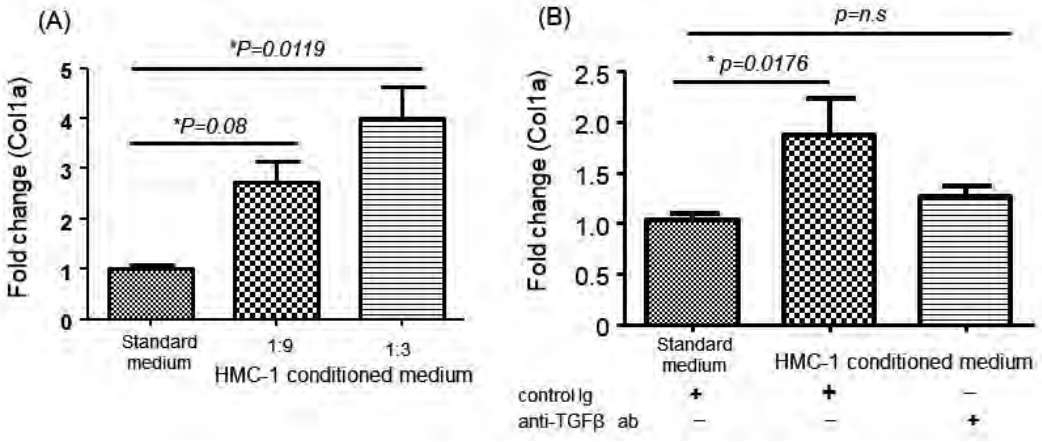

with recombinant human IL-33 and SCF for 24 hours. Fibroblasts were treated with HMC-1 conditioned medium for 24 hours and type I collagen synthesis in fibroblast was evaluated by RT-qPCR. Neutralization antibodies for human TGFβ was utilized during fibroblast culture with HMC-1 conditioned medium or standard culture medium.

Results: We found that the number of mast cells in labial salivary glands of patients with pSS was significantly increased compared to that in control subjects (Figure 1 and Figure 2A). There was a significant negative correlation between the Saxon's test results and the number of mast cells, suggesting the involvement of mast cells in the decreased salivary secretion (Figure 2B). There was no correlation between the intensity of lymphoid infiltration as-

sessed by focus score and the mast cell density (Figure 2C). In contrast, a significant correlation between the number of mast cells and the degree of fibrosis was observed (Figure 2D). Consistent with these findings, mast cells were proximal to EVG-stained fibrous tissue and vimentin-positive fibroblasts. We hypothesized that mast cells were involved in the development of tissue fibrosis via modulation of fibroblast immune function. Significant up-regulation of Col1a mRNA was observed in fibroblast with HMC-1 conditioned medium as inverse proportion to the degree of dilution compared to that of fibroblast with standard culture medium (Figure 3A). Furthermore, neutralization for TGFβ abolished upregulation of Col1a mRNA in fibroblast in HMC-1 conditioned medium, thus suggesting that HMC-1-derived TGFβ contributes to upregulation of type I collagen synthesis (Figure 3B). Immunohistochemistry revealed that tryptase-positive mast cells exhibited positive signal of TGFβ in serial section.

Conclusion: These results suggest a novel role for mast cells in the development of sialadenitis in patients with pSS by induction of tissue fibrosis via fibroblast collagen synthesis by TGFβ production.

Gestational Diabetes Mellitus in Pregnant Women with Systemic Lupus Erythematosus

Sofia Gernaat[1], Julia Simard[2], Elisabet Svenungsson[3] and Elizabeth Arkema[4], [1]Karolinska Institutet, Stockholm, Stockholms Lan, Sweden, [2]Stanford Medicine, Stanford, CA, [3]Karolinska University Hospital, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased insulin resistance is pivotal in the development of gestational diabetes mellitus (GDM). Women with SLE may be at higher risk of GDM due to their increased risk of insulin resistance and use of glucocorticoids. In contrast, use of hydroxychloroquine may lower the risk of GDM. This study investigated the risk of GDM in women with SLE compared to women from the general population.

Methods: Women with SLE and comparators without SLE from the general population were identified from the Swedish Lupus Linkage (SLINK) cohort. Briefly, SLINK includes all individuals with SLE identified in the Swedish National Patient Register (NPR) and 5 randomly selected individuals without SLE matched on sex, birth year, calendar time, and county of residence between 1964-2013. SLE (International Classification of Diseases (ICD) 10: M32) was defined by ≥2 visits in the NPR and Medical Birth Register (MBR) with ≥1 of these visits preceding pregnancy. Women in the study population with singleton births in the MBR (Nov 2006-2016) were included. GDM (ICD 10: O24.4) was defined by ≥1 visit in the NPR and MBR during pregnancy. Glucocorticoid and hydroxychloroquine dispensations 6 months before and during pregnancy, and anti-diabetic drug dispensations at any time before and during pregnancy were collected from the Prescribed Drug Register. Women with drug-induced SLE (ICD 10: M32.0), diabetes mellitus (ICD 10: E10-E11, H36.0, O24 excluding O24.4) or filling anti-diabetic drugs (Anatomical Therapeutic Chemical (ACT) codes: A10A, A10B) at any time before pregnancy or during the first trimester were excluded. Risk ratio (RR) of GDM associated with SLE comparing SLE pregnancies with non-SLE pregnancies was estimated for first births only and all births using a Modified Poisson Regression model adjusted for age, year of birth and previous GDM.

Results: We identified 695 pregnancies among 502 women with SLE and 4,637 pregnancies among 3,243 women without SLE. Of these, 18 (2.6%) pregnancies among 14 women with SLE and 58 (1.3%) pregnancies among 44 women without SLE were diagnosed with GDM. Among GDM pregnancies, mean age at delivery was higher in women with SLE (35 years) than in women without SLE (33 years). The adjusted RR of GDM associated with SLE was 1.2 (95% Confidence Interval (CI) 0.5-2.9) for first births and 1.8 (95% CI 1.2-2.8) for all births. The proportion of SLE pregnancies without any glucocorticoid or hydroxychloroquine dispensation before or during pregnancy were similar between those with GDM (61.1% or 61.1%, respectively) and those without GDM (55.5% or 58.5%, respectively). In 5 out of 18 SLE pregnancies with GDM (27.7%) and in 207 out of 677 SLE pregnancies without GDM (30.6%), women received ≥1 glucocorticoid dispensation both before and during pregnancy. In 6 SLE pregnancies with GDM (33.3%) and in 184 SLE pregnancies without GDM (27.2%), women received ≥1 hydroxychloroquine dispensation both before and during pregnancy.

Conclusion: Although the number of SLE pregnancies with GDM (2.6%) were small, the RR of GDM was almost 2 times higher in pregnancies with SLE than in pregnancies without SLE. Neither glucocorticoids nor hydroxychloroquine differed by the GDM outcome.

Trajectory of Damage Accrual in African-American vs. Caucasian Systemic Lupus Erythematosus

Romy Kallas[1], Jessica Li[2], Daniel Goldman[3] and Michelle Petri[3], [1]Johns Hopkins Medical Institution, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Timonium, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: African-Americans have a higher incidence/prevalence of SLE, more lupus nephritis, higher rates of end stage renal disease and higher mortality than Caucasians. The aim of this study was to look at the trajectory of cumulative and individual organ damage accrual in a large longitudinal prospective SLE cohort in which African-American and Caucasian ethnicities were well represented, with a mean follow-up time of 13 years.

Methods: We analyzed data on 2,436 patients (43% African-American, 57% Caucasian, and 92% female) until January 2020. Patients met the revised ACR or SLICC classification criteria. The SLICC/ACR Damage Index (DI) was calculated based on organ damage that occurred after diagnosis until the last visit. Poisson regression allowing for overdispersion for each organ system with an offset term accounting for time followed since diagnosis was used. The outcome variable was the damage score of each organ system at the last available cohort visit. The associations were adjusted for sex, age, income, education, and insurance. We used Cox regression model to determine the association between individual damage items and ethnicity. These associations were adjusted for sex, age, and education.

Results: The mean total SLICC/ACR DI was 1.9 (SD=2.3). There was a linear relationship between time since diagnosis and mean DI with no plateau. By 5 years after SLE diagnosis, 44% of African-Americans vs. 36% of Caucasians had accrued damage. The rate of cumulative damage accrual was significantly higher in African-Americans

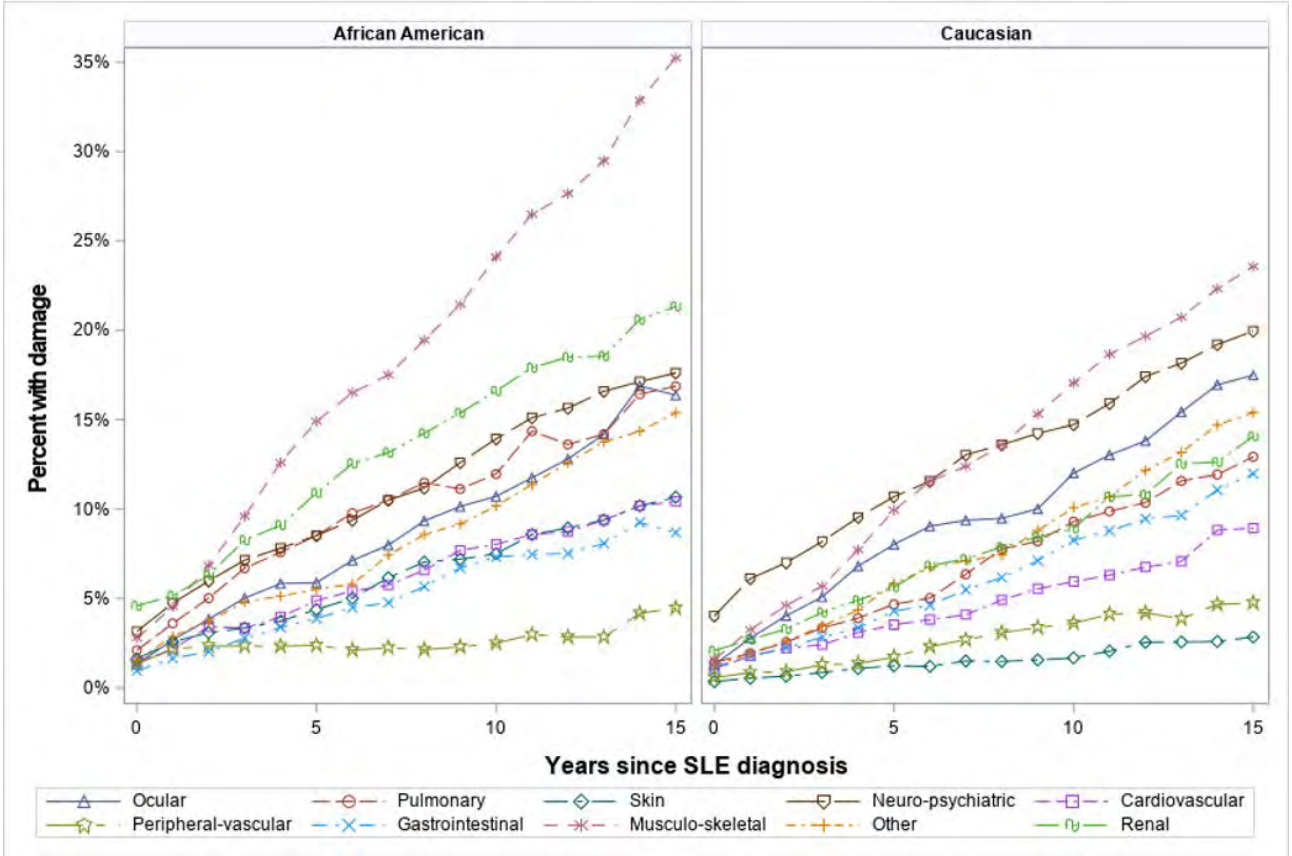

Figure 1. Damage accrual rate of each organ over time in African-American and Caucasian patients

Table 1: Associations between Time to Damage Index Items and Ethnicity (African-American vs. Caucasian)

		African-American vs. Caucasian	
	# of events	HR[1] (95% CI)	p-value[1]
Estimated or measured GFR < 50%	416	1.53 (1.25,1.87)	**<0.0001**
Proteinuria 3.5g/24hrs	156	2.47 (1.76,3.47)	**<0.0001**
End-stage renal disease	112	2.57 (1.72,3.85)	**<0.0001**
Pulmonary hypertension	184	1.93 (1.43,2.61)	**<0.0001**
Pulmonary fibrosis	173	1.57 (1.15,2.14)	**0.0043**
Cardiomyopathy	79	2.39 (1.48,3.84)	**0.0004**
Pericarditis>6 months, OR pericardiectomy	29	2.92 (1.3,6.53)	**0.0091**
Infarction or resection of bowel	204	0.7 (0.53,0.94)	**0.0174**
Deforming or erosive arthritis	219	2.1 (1.59,2.78)	**<0.0001**
Osteoporosis with fracture or vertebral collapse	311	0.51 (0.4,0.66)	**<0.0001**
Avascular necrosis	200	2.12 (1.59,2.84)	**<0.0001**
Scarring chronic alopecia	65	6.3 (3.27,12.14)	**<0.0001**
Extensive scarring or panniculum other than scalp and pulp space	37	2.8 (1.34,5.83)	**0.0060**
Diabetes	130	1.89 (1.32,2.72)	**0.0006**

[1]Adjusted for sex, age at diagnosis, years of education

(p-value 0.01). The mean time to onset of damage was 6.6 (SD 7.1) years from SLE diagnosis in Caucasian and 5.5 (SD 6.3) years in African-Americans. The divergence of the curves started early in the disease course. Renal (p-value < 0.0001), pulmonary (p-value 0.0066), and skin (p-value < 0.0001) damage in African-Americans accumulated at a

higher rate compared to Caucasians (Figure 1). African-Americans had a higher risk of renal insufficiency, proteinuria 3.5g/24hrs, end-stage renal disease, pulmonary hypertension, pulmonary fibrosis, cardiomyopathy, pericardial damage, deforming or erosive arthritis, avascular necrosis, skin damage, and diabetes than Caucasians at any time during follow-up. On the other hand, Caucasian patients were at higher risk for osteoporosis with fracture or vertebral collapse and infarction or resection of bowel (Table 1).

Conclusion: At any point during the disease, the SLICC/ACR DI was higher and accrued at a faster rate in African-American compared to Caucasian SLE. Damage in most organ systems progressed at a faster rate in African-Americans with the exception of osteopenic fracture and bowel infarction/resection. Of particular concern was the linear increase in damage in both ethnicities over time.

The Impact of Antimalarial Agents on Traditional and Non-traditional Cardiovascular Markers in Patients with Systemic Lupus Erythematosus: A Systematic Review and Meta-analysis

Claudia Mendoza-Pinto[1], Mario Garcia-Carrasco[1], Pamela Munguía-Realpozo[2], Ivet Etchegaray-Morales[2] and Socorro Mendez-Martínez[1], [1]Instituto Mexicano del Seguro Social, Puebla, Puebla, Mexico, [2]Facultad de Medicina, Benemérita Universidad Autónoma de Puebla, Puebla, Puebla, Mexico

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular morbidity and mortality is a well-established problem in patients with systemic lupus erythematosus (SLE). Hydroxychloroquine (HCQ) has been seen as a potential atheroprotective agent. The aim of this systematic review was to assess the impact of HQC on traditional and nontraditional cardiovascular markers in patients with SLE.

Methods: A search of MEDLINE, Embase and the Cochrane library for randomized controlled trials (RCTs) or cohort studies evaluating the impact of antimalarials on cardiovascular (CV) markers in patients with SLE was conducted up to January 2020. Data extraction included traditional (lipid profile, diabetes, blood pressure [BP]) and nontraditional CV markers (glycosylated hemoglobin levels, insulin resistance, high sensitivity C-reactive protein, homocystein concentrations, IgG anti-apolipoprotein A1 [anti-apoA1], endothelial function, arterial stiffness, arterial elasticity and coronary artery calcification [CAC]). The methodological quality was assessed using the QUIPS risk of bias tool for observational studies and the Cochrane Risk of Bias Assessment Tool for RCTs. A narrative synthesis of the findings was presented, and a meta-analysis will be conducted if appropriate. The review was registered on PROSPERO (CRD42020162067).

Patients or population: Patients with SLE				
Setting: Hospital				
Prognostic factor: Antimalarial therapy				
Outcomes or subgroup title	**Number of participants**	**Number of studies**	**Mean difference (95% CI)**	**GRADE assessment**
Continuous (with and without antimalarial)				
Total cholesterol	1135	14	-11.12 [-24.71, 2.47]	Very low
LDL cholesterol	891	13	-5.93 [-12.67, 0.80]	Very low
HDL cholesterol	643	11	**3.05 [0.46, 5.61]**	Very low
VLDL cholesterol	258	5	**-10.29[-15.35, -5.24]**	Very low
Triglycerides	395	8	**-15.68 [-27.51, -3.86]**	Very low
HOMA-IR	218	2	-0.09 [-0.75, 0.55]	Very low
Systolic BP	174	3	-3.25 [-12.02, 5.51]	Very low
Diastolic BP	174	3	**-3.42 [-5.62, -1.23]**	Very low
Homocysteine concentrations	134	2	0.06 [-1.05, 1.17]	Very low
Continuous (before and after antimalarial)				
Total cholesterol	211	4	**-14.01 [-21.71, -6.31]**	Very low
LDL cholesterol	30	2	**-13.41 [-26.42, -0.40]**	Very low
HDL cholesterol	30	2	0.58 [-6.15, 7.31]	Very low
Triglycerides	35	2	-3.89 [-23.80, 16.03]	Very low
Dichotomous (with and without antimalarial)			**OR/HR (95% CI)**	
Prevalence of Diabetes	70	2	**0.08 [0.01, 0.41]**	Very low
Prevalence of Hypertension	475	5	0.70 [0.47, 1.04]	Very low
Prevalence of CAC	233	2	1.13 [0.50, 2.54]	Very low
Prevalence of IgG anti-apoA1	583	2	0.85 [0.51, 1.42]	Very low
Incidence of Diabetes	10199	3	**0.44 [0.24, 0.83]**	Low

Table 1. Modified GRADE summary of findings on the influence of antimalarial therapy on cardiovascular outcomes

Results: The search strategy produced 715 articles, of which 24 and 14 were extracted (16,717 SLE patients) for quantitative and qualitative analysis, respectively. Only one RCT and 37 observational studies were included. The follow-up period varied widely in longitudinal studies, ranging from 3 months to 9.3 years. Table 1 shows a summary of findings with mean differences or effect size from pooled studies. The mean differences in VLDL-cholesterol, triglycerides, and diastolic BP were significantly lower in patients on antimalarial therapy compared to those without antimalarial therapy, and HLD-cholesterol was significantly higher in the former group. Within-group analysis showed significantly lower total cholesterol and LDL-cholesterol after antimalarial therapy. Moreover, patients on antimalarials had a lower risk of prevalence and incidence of diabetes than patients not on antimalarials. HCQ use was protective and was associated with lower BP variability. However, the risk of prevalent hypertension or IgG anti-apoA1 was not significantly lower in patients with antimalarial therapy. The benefit of antimalarial therapy on endothelial function and arterial stiffness was unclear. The QUIPS tool showed a low-to-high RoB, and GRADE showed very low to low quality of evidence per outcome.

Conclusion: There is some evidence from observational studies on associations between antimalarial therapy and some CV outcomes. However, the data on which this conclusion was based was of very low to low evidence. This emphasizes the need for higher quality studies to resolve uncertainties.

Longitudinal Relationships Between Depression, Anxiety and Cognition in Lupus

Kathleen Bingham[1], Juan Pablo Diaz-Martinez[2], Mahta Kakvan[2], Robin Green[3], Dorcas Beaton[4], Lesley Ruttan[3], Carmela Tartaglia[5], Marvin Fritzler[6], May Choi[7], Jiandong Su[2], Denisse Bonilla[8], Nicole Anderson[2], Joan Wither[2], Patricia Katz[9] and Zahi Touma[10], [1]Department of Psychiatry, University of Toronto, Toronto, ON, Canada, [2]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [3]Toronto Rehabilitation Institute, University Health Network, Toronto, ON, Canada, [4]Institute for Work & Health, Toronto, ON, Canada, [5]University of Toronto, Krembil Neurosciences Centre, Toronto, ON, Canada, [6]Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [7]Brigham and Women's Hospital | Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [8]University Health Network, Toronto, Canada, [9]University of California, San Francisco, Novato, CA, [10]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: There is a consistent relationship between cognition and depression and anxiety (affective symptoms) in lupus. Together, affective and cognitive symptoms represent among lupus' most common and disabling neuropsychiatric symptoms. Although the relationship between cognitive and affective symptoms is well established, less is known about i) which cognitive domains are most related to affective symptoms, and ii) the longitudinal relationship between cognitive and affective symptoms. The primary aim of this study is to examine the relationship between cognitive performance across domains and affective symptoms over time in lupus.

Methods: This is an analysis of data from a cohort of 301 lupus patients from the Toronto Lupus Clinic enrolled between Aug 2017 and Jan 2019. Cognition was measured using the ACR battery with tests representing manual dexterity, processing speed, language, memory and executive function. Raw scores were transformed to z-scores using age- and gender-adjusted normative data. Participants were classified as cognitively impaired if they received a z-score of less than or equal to 1.5 on two or more pre-defined domains. Depression and anxiety were measured

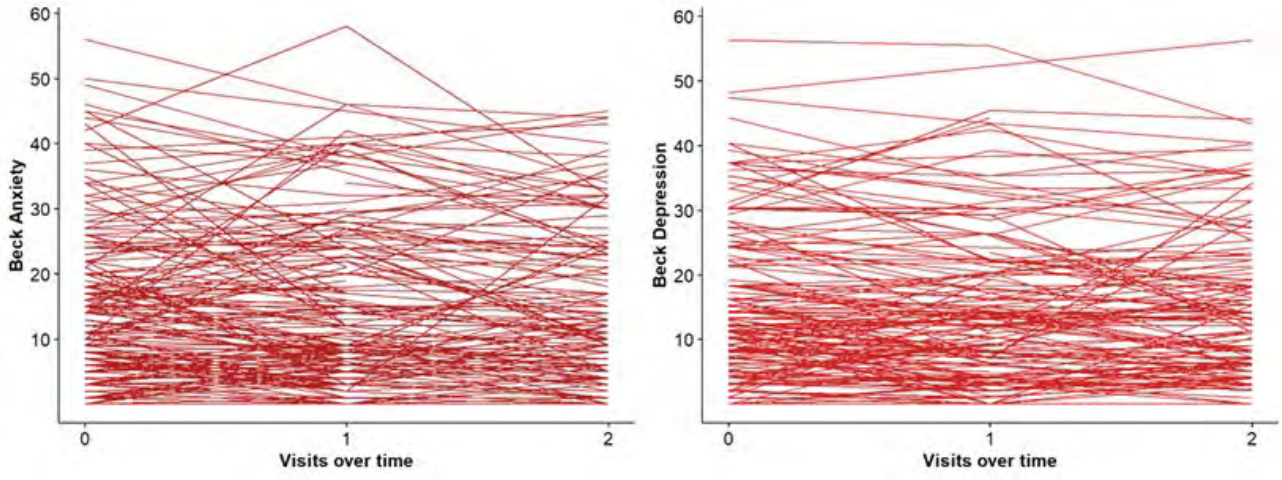

Figure 1. Participants' scores on BAI and BDI-II across three timepoints (baseline, 6 months and 12 months). Mean (SD) baseline BAI scores were 16.6 (13) and mean (SD) baseline BDI-II scores were 15.3 (12.5).

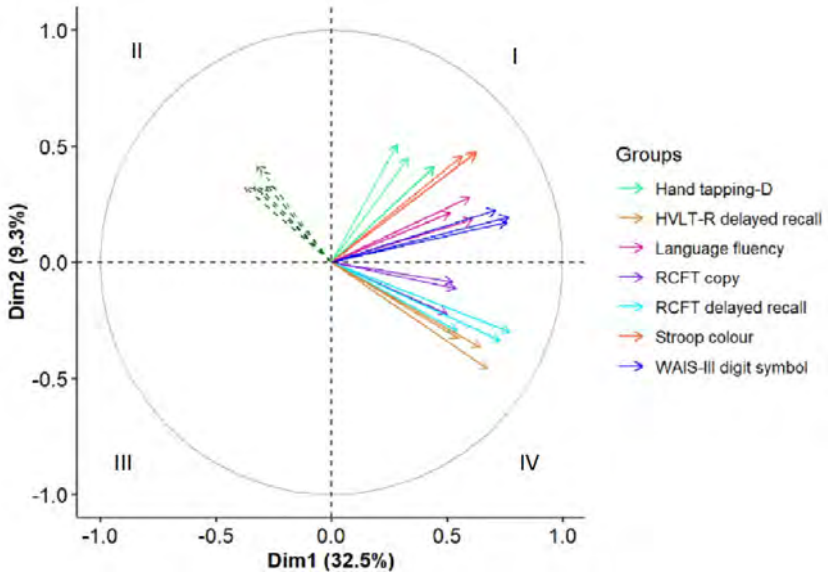

Figure 2. Results of MFA showing representative neuropsychological tests at each timepoint in relation to the two cognitive dimensions. Axis x represents the first dimension explaining 32.5% of the variance in cognition and axis y represents the second dimension. Affective symptoms at each time point are shown as supplementary variables (six dark green, dotted arrows in quadrant II). The length of each arrow represents the strength of the relationship between the variable it represents and the cognitive dimensions. Variables whose representative arrows are close in proximity are more strongly related (e.g. depression and anxiety are highly correlated, and the cognitive tests are highly correlated to each other across timepoints). The closer to 180 degrees the angle between the arrows representing anxiety and depression and those representing the cognitive tests, the stronger the relationship between the variables they represent. For example, affective symptoms are most strongly related to HVLT-R delayed recall and RCFT delayed recall (verbal and visual memory). If the angle between two arrows is 90 degrees, the two variables are independent. Hence, anxiety and depression have no relationship with hand tapping and Stroop color scores (motor dexterity and simple information processing speed).

using the Beck Depression Inventory-II (BDI-II) and Beck Anxiety Inventory (BAI). Participants were classified as having depression if they scored greater than 17 on the BDI-II and anxiety if they scored greater 18 on the BAI. Data was taken from baseline, 6 and 12 months. Data from all neuropsychological tests were entered into multiple factor analysis (MFA) across all three timepoints, for the purposes of item reduction and to explore relationships among cognitive domains and affective symptoms.

Results: Mean (SD) participant age was 41 (12), with 89% women. Mean (SD) disease duration at study entry was 14 (10.1) years. Anxiety and depression scores were stable across time (see Fig 1). Cognitive tests loaded onto two dimensions explaining 41.8% of the variance in neuropsychological performance. The first dimension (32.5%) consisted mainly of more complex cognitive tests and primarily explained the cognitive impairment status of participants. The second dimension (9.3%) was mainly explained by measures of simple information processing or motor speed. Affective symptoms were most strongly negatively related to verbal (r = -0.35) and visual memory domains (r = -0.32) (see Fig 2). The relationships were stable across all timepoints. Fig 3 demonstrates the distribution of participants with cognitive impairment, depression and anxiety. 38.2% of participants were categorized cognitively impaired at baseline, (36.2% were anxious and 33.2% were depressed). There is substantial overlap among these classifications (see quadrant II Fig 3 graphs), though there is a group of participants classified as having cognitive impairment without affective symptoms (quadrant III Fig 3).

Conclusion: Lupus patients exhibit a negative relationship between affective symptoms and cognition, particularly in the memory domains, that is highly stable across time. Future research should examine whether change in affective symptoms results in memory improvement, as well as potential mechanisms underlying this relationship.

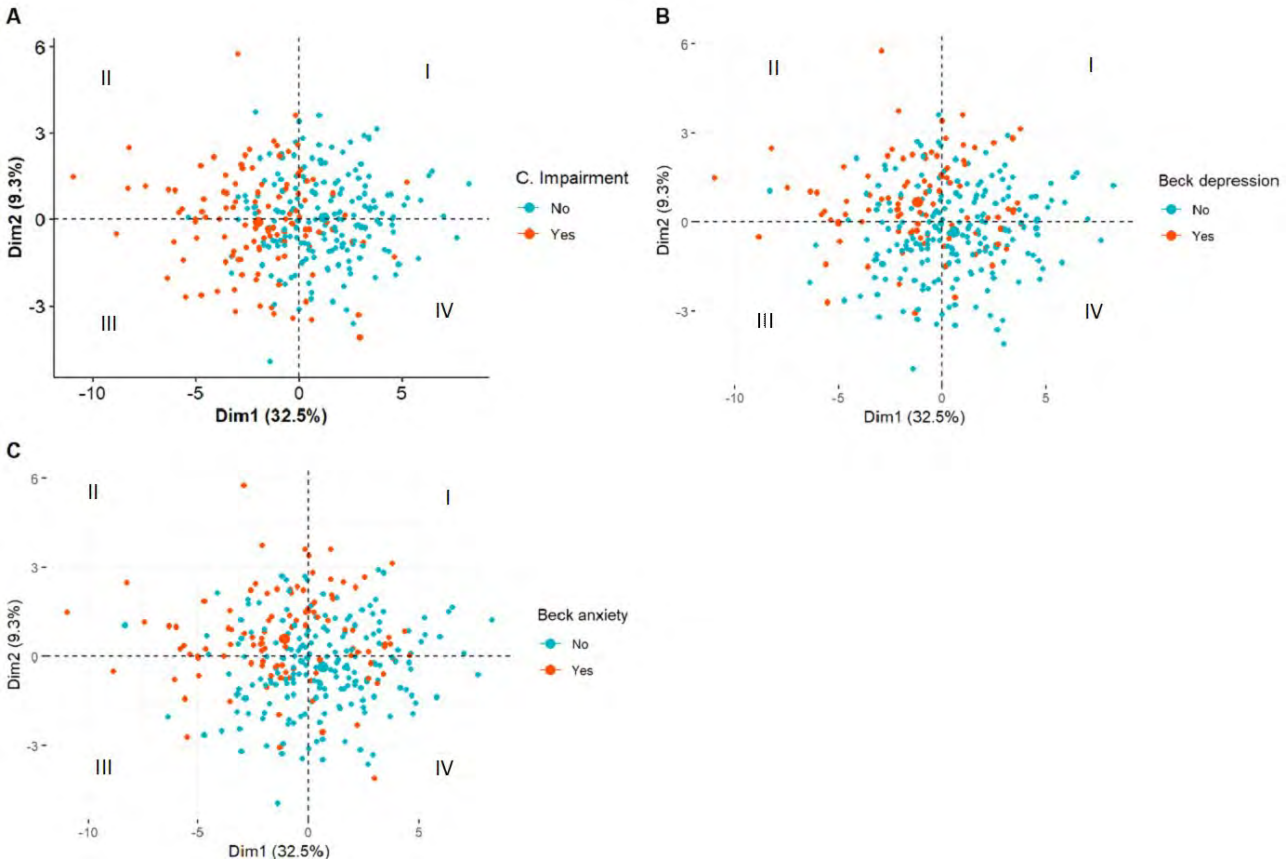

Figure 3. Axis x represents the first cognitive dimension (explaining 32.5% of the variance) and axis y represents the second dimension. Distribution of individual participants in the cohort classified by presence or absence of cognitive impairment (A), depression (B), or anxiety (C). There is substantial overlap in participants classified as having cognitive impairment, depression and anxiety. For example, many participants quadrant II of the graphs demonstrate cognitive impairment plus anxiety and depression. However, there is a subset of participants with cognitive impairment (shown in quadrant III of the graphs) who are classified as having cognitive impairment without anxiety and depression.

Background/Purpose: Antiphospholipid syndrome (APS) has been classified as the development of venous and/or arterial thromboses, and/or pregnancy morbidity, in the presence of persistently raised levels of the circulating antiphospholipid antibodies, namely lupus anticoagulant (LAC), anticardiolipin (aCL) and anti-β2-glycoprotein I. APS is

a significant cause of morbidity and mortality in patients with Systemic Lupus Erythematosus (SLE). It is well known that LAC positivity is more strongly associated with both arterial and venous thrombosis than either aCL or anti-β2glycoprotein I antibodies in SLE. An unanswered question is the contribution of different combinations of positive antiphospholipid antibodies to thrombosis risk. We evaluated which antiphospholipid antibody combinations increased the risk of future thrombosis in patients with SLE.

Methods: This prospective analysis included SLE patients who had been tested for all 7 antiphospholipid antibodies: lupus anticoagulant (LAC), anticardiolipin (aCL) isotypes IgM, IgG, IgA, and anti-β2-glycoprotein I isotypes IgM, IgG, IgA. We excluded RVVT measures if patients were taking anticoagulants (warfarin/ heparin). We constructed a dataset with one record per month of follow up for each patient. Rates of thrombosis for each antiphospholipid or each combination of antiphospholipid antibody were calculated as the number of thromboses divided by the number of person-months at risk and the results are converted to rates per 1000 person-years. To assess the relationship between antiphospholipid antibodies and thrombosis, we used pooled logistic regression.

Results: There were 821 patients with a complete profile of 7 antiphospholipid antibodies with a total of 75048 person-months of follow up. Among these patients, there were 88 incident cases of thrombosis: 48 patients with arterial, 37 patients with venous and three patients both with arterial and venous thrombosis.In individual models; LAC was the most predictive of any [3.56 (2.01, 6.30) p< 0.0001], venous [4.89 (2.25, 10.64) p< 0.0001], and arterial [3.14 (1.41, 6.97) p= 0.005] thrombosis. Anti-β2-glycoprotein I IgA positivity was a significant risk factor for any [2.00 (1.22, 3.3) p=0.0065] and venous [2.8 (1.42, 5.51) p=0.0029] thrombosis. We looked at patients who were LAC positive and asked if having another positive antiphospholipid antibody increased the risk ratio for any, venous, and arterial thrombosis. We found that having anti-β2-glycoprotein I IgA appeared to add significant risk to any [1.73 (1.04, 2.88) p=0.0362], and venous [2.27 (1.13, 4.59) p=0.0218] thrombosis among those with or without LAC.

Conclusion: Our study shows that LAC is still the best predictor of risk of any, arterial and venous thrombosis in SLE. Moreover, anti-β2glycoprotein I IgA positivity appeared to add significant risk for any and venous thrombosis. The clinical significance of IgA anti-β2glycoprotein I deserves further investigation in SLE patients.

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is classified as the development of venous and/or arterial thromboses, and pregnancy morbidity, in the presence of antiphospholipid antibodies (aPL); lupus anticoagulant, moderate-to-high titer anticardiolipin (aCL) and anti-β2- glycoprotein I. LAC positivity is more strongly associated with both arterial and venous thrombosis than either aCL or anti-β2glycoprotein I antibodies in SLE (1).Some studies found that thromboembolic events were significantly higher in "triple positive" patients. The rate of pregnancy loss was also higher in "double positive" patients (2). In contrast, PROMISSE found only LAC to predict adverse pregnancy outcomes. We investigated the risk of thrombosis in Systemic Lupus Erythematosus patients with single LAC positivity versus double and triple positivity in the Hopkins Lupus Cohort.

Methods: Anticardiolipin and anti-Beta2 glycoprotein I were defined as positive when the antibody titer exceeded 20 units.The lupus anticoagulant was determined by dilute Russell's viper venom time (dRVVT) and confirmatory mixing studies, if prolonged. It was defined as positive if a patient had a dRVVT of 45 or more seconds and a positive confirm ratio of more than 1.4. For each aPL, we defined the patient as positive at a given month of follow up if they ever had a positive value in the previous measures. Logistic regression analysis was used to identify the independent predictive antiphospholipid antibody patterns for risk of lifetime occurrence of any/venous/arterial thrombosis. The odds ratios were adjusted for age. Thrombosis was defined as: arterial thrombosis (C VA, MI, other arterial thrombosis or digital gangrene); and venous thrombosis (D V T, PE or other venous thrombosis)

Results: There were 805 patients with a complete profile of 7 antiphospholipid antibodies, with a total of 73417 person months (6118 person years) of follow up. For any thrombosis when compared to patients with LAC positivity only, double positivity with any isotypes [1.15(0.50, 2.66) p=0.7484] and triple positivity with any isotypes [1.68(0.74, 3.80), p=0.2145] showed higher point estimates but not statistically significant.

Table1. Single, double and triple positive patterns and the risk of any thrombosis.

Pattern	Number of events	Person-years	Rate per 1000 person-years	adjusted RR (95% CI)	p-value
LAC positivity only	10	633	15.8	1.00 (Ref)	
Never any aPL	33	2581	12,8	0.73(0.36, 1.47)	0.3819
any aCL positivity only	6	793	7,6	0.43(0.16, 1.18)	0.1028
any aB2-GPI positivity only	7	517	13,5	0.78(0.30,2.05)	0.6195
any aCL and aB2-GPI positivity only	5	404	12,4	0.71(0.24,2.04)	0.5211
LAC and aCL positivity	7	406	17,3	1.15(0.50,2.66)	0.7484
LAC and aB2-GPI positivity	12	490	24,5		
Triple positivity	0	147	0,0	1.68(0.74,3.80)	0.2145

Conclusion: Triple or double positive aPL profiles are not superior to single LAC positivity in their association with any thrombosis in SLE patients.

Association of the Systemic Lupus International Collaborating Clinics Frailty Index (SLICC-FI) and Damage Accrual in Long Standing Systemic Lupus Erythematosus

Kaitlin Lima[1], Alexandra Legge[2], John Hanly[2], Jungwha Lee[3], Jing Song[3], Anh Chung[3] and Rosalind Ramsey-Goldman[4], [1]Northwestern University, Chicago, IL, [2]Dalhousie University, Halifax, NS, Canada, [3]Northwestern University, Chicago, [4]Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

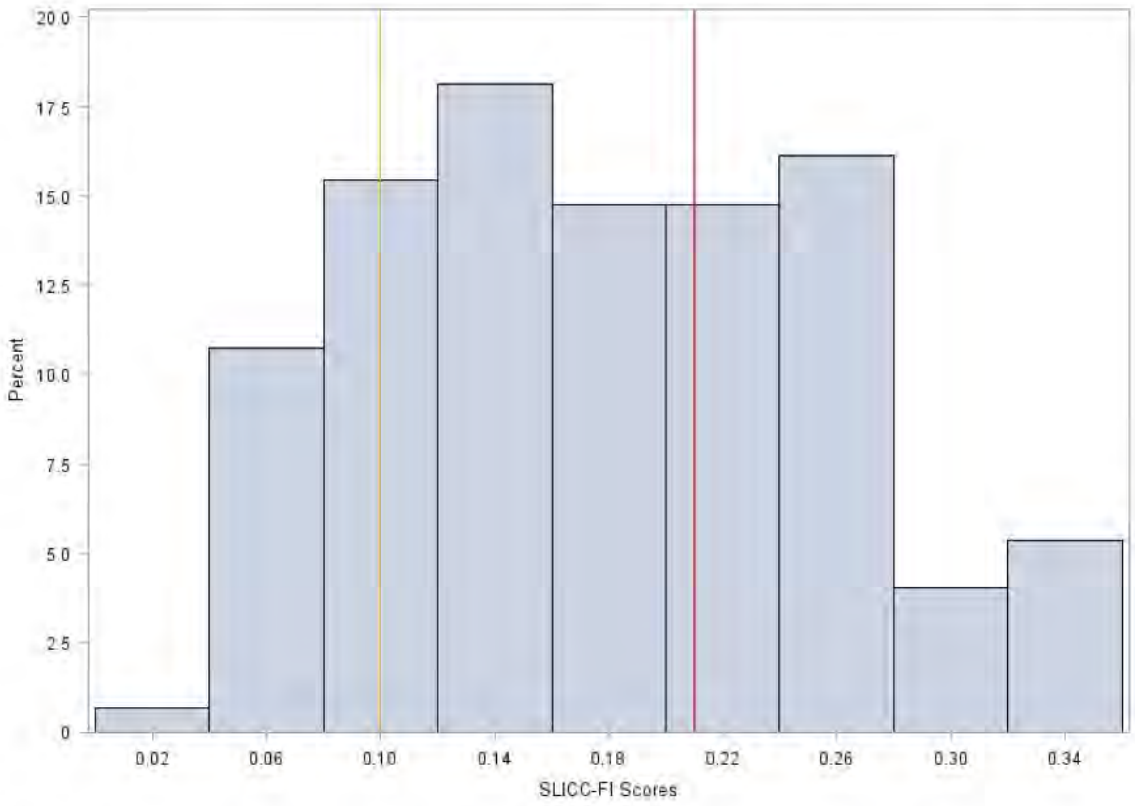
Background/Purpose: The Systemic Lupus International Collaborating Clinics Frailty Index (SLICC-FI) was recently shown to predict mortality and damage accrual in the SLICC inception cohort. The objective of this study was to apply the SLICC-FI to a prevalent SLE cohort and assess the ability of the SLICC-FI to predict damage accrual among individuals with more longstanding SLE.

Table 1: Baseline demographic and clinical characteristics for patients in SOLVABLE cohort *(n=149)

Baseline Characteristics	Mean (SD) or n (%)
Age (yrs), mean (SD)	43.30 (10.15)
Race, n (%)	
White	91 (61.07)
African American	41 (27.52)
Hispanic	8 (5.37)
Asian	9 (6.04)
Education, n (%)	
Less than high school diploma	5 (3.36)
Highschool diploma	44 (29.53)
College graduate	61 (40.94)
Advanced degree	39 (26.17)
Disease duration (yrs), mean (SD)	11.93 (8.46)
SLEDAI-2K score, mean (SD)	3.85 (3.56
SLICC Damage Index score, mean (SD)	1.64 (1.83)
Medication Use, n (%)	
Corticosteroids	59 (39.60)
Plaquenil	114 (76.51)
Immunosuppressants	51 (34.23)

SD=standard deviation, BMI= body mass index, SLEDAI-2K= SLE Disease Activity Index 2000
* Patients with 5-year follow-up

Figure 1: Distribution of Baseline SLICC-FI Scores in SOLVABLE cohort (n=149)



Note: Yellow line represents cut off between relatively fit and least fit, red line represents cut off between least fit and frail

Table 2: Logistic regression models for damage accrual (from baseline to 5 years), n=149

	Unadjusted Model (n =149)		Adjusted model * (n = 149)	
	Odds Ratio (95% CI)	p value	Odds Ratio (95% CI)	p value
Model 1: SLICC-FI cont. (0.05-unit)	1.28 (1.03, 1.60)	0.024	1.28 (1.01, 1.63)	0.042
Model 2: SLICC-DI (1-unit)	1.02 (0.85, 1.22)	0.809	1.02 (0.83, 1.25)	0.856
Model 3: SLICC-FI (0.05-unit)	1.41 (1.08, 1.84)	0.011	1.39 (1.05, 1.85)	0.016
SLICC-DI (1-unit)	0.87 (0.69, 1.09)	0.216	0.88 (0.68, 1.12)	0.291

Notes: SLICC = Systemic Lupus International Collaborating Clinics; FI = Frailty Index; DI=Damage Index

* Model 1 and 2 adjusted for age, race, and disease duration; Model 3 adjusted for age, race, disease duration, and baseline SDI

Methods: This was a secondary analysis of data from the Study of Lupus Vascular and Bone Long-Term Endpoints (SOLVABLE) cohort, which consists of adult women from the Chicago Lupus Database (age >18) who met at least 4 of the 1997 revised ACR classification criteria for definite SLE. A total of 185 SLE patients were enrolled, of which 149 patients were included in a 5-year follow up analysis. Baseline SLICC-FI was adapted based on available data in the SOLVABLE cohort, maintaining 46 health deficits for calculation of SLICC-FI scores. Damage accrual was defined as

Table 2: Logistic regression models for damage accrual (from baseline to 5 years), n=149

	Unadjusted Model (n =149)		Adjusted model * (n = 149)	
	Odds Ratio (95% CI)	p value	Odds Ratio (95% CI)	p value
Model 1: SLICC-FI cont. (0.05-unit)	1.28 (1.03, 1.60)	0.024	1.28 (1.01, 1.63)	0.042
Model 2: SLICC-DI (1-unit)	1.02 (0.85, 1.22)	0.809	1.02 (0.83, 1.25)	0.856
Model 3: SLICC-FI (0.05-unit)	1.41 (1.08, 1.84)	0.011	1.39 (1.05, 1.85)	0.016
SLICC-DI (1-unit)	0.87 (0.69, 1.09)	0.216	0.88 (0.68, 1.12)	0.291

Notes: SLICC = Systemic Lupus International Collaborating Clinics; FI = Frailty Index; DI=Damage Index

* Model 1 and 2 adjusted for age, race, and disease duration; Model 3 adjusted for age, race, disease duration, and baseline SDI

any increase of SLICC-Damage Index (SLICC-DI) at 5-year follow-up. Unadjusted and adjusted logistic regression models were conducted using baseline SLICC-FI (per 0.05 increase) to predict damage accrual.

Results: Among the 149 patients with 5-year follow up data, mean (SD) age was 43.30 (10.15) years, mean (SD) disease duration was 11.93 (8.46) years, and mean (SD) SLICC-DI score was 1.64 (1.83) at baseline. The mean (SD) baseline SLICC-FI score was 0.18 (0.08) with a median (interquartile range) of 0.17 (0.10-0.23). At baseline, 36% (53 out of 149) of participants were categorized as frail, based on SLICC-FI values >0.21. About 40% of these patients (58 out of 149) had damage accrual at 5-year follow-up (minimum-maximum 1-11). In unadjusted analysis, each 0.05-unit increase in baseline SLICC-FI score was associated with a 28% higher odds of subsequent damage accrual (odds ratio [OR]=1.28, 95% CI 1.03-1.60). In the adjusted model (adjusted for age, race, disease duration, and baseline SLICC-DI score), each 0.05-unit increase in baseline SLICC-FI score was associated with a 39% higher odds of subsequent damage accrual (OR=1.39, 95% CI 1.05, 1.85).

Conclusion: In a prevalent SLE cohort, higher baseline SLICC-FI scores were associated with higher risk of subsequent damage accrual at 5-year follow up, after adjusting for age, race, disease duration, and baseline SLICC-DI scores. This demonstrates the utility of the SLICC-FI as a predictive tool for adverse outcomes among individuals with longstanding SLE.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

	NPSLE (n = 149)	Minor/non-NPSLE (n = 202)
Deaths (n, %)	13 (8.7)	17 (8.4)
Age at death (median, range)	49 (32 – 79)	59 (20 – 89)
Follow-up time (years)	906	1047
Crude mortality rate (per 1000 PY)	14.3	16.2
All-cause mortality*		
Female	5.5 (2.8 – 9.6)	3.4 (1.9 – 5.7)
Male	2.3 (0.1 - 12.8)	6.2 (1.3 – 18.2)
Combined	5.0 (2.6 – 8.5)	3.7 (2.2 – 6.0)

**Standardized mortality ratio, ratio of the observed and expected number of deaths*

Background/Purpose: Little is known about mortality in patients with systemic lupus erythematosus (SLE) presenting with neuropsychiatric (NP) symptoms. We aimed to evaluate all-cause and cause-specific mortality in patients with SLE and NP symptoms.

Methods: All patients with the clinical diagnosis of SLE visiting the tertiary referral NPSLE clinic of the LUMC between 2007-2018 were included in this study. Patients were classified as NPSLE if NP symptoms were attributed to SLE (either at current assessment or in the past) and immunosuppressive or anticoagulant therapy was initiated, otherwise patients were classified as minor or non-NPSLE (minor/non-NPSLE). Municipal registries were checked for current status. Electronical medical files were studied for clinical characteristics and cause of death. Standardized mortality ratios (SMRs) and 95% confidence intervals were calculated using data from the general Dutch population. In addition, a rate ratio (RR) was calculated using direct standardization to compare mortality in NPSLE with minor/non-NPSLE patients.

Results: 351 patients with NP symptoms and the clinical diagnosis of SLE were included, of which 149 patients were classified as NPSLE (42.5%). Compared with the general population, mortality was increased five times in NPSLE (SMR 5.0, 95% CI: 2.6-8.5) and nearly four times in minor/non-NPSLE patients (SMR 3.7, 95% CI: 2.2-6.0), as shown in *Table 1*. Risk of death due to cardiovascular disease (CVD) was increased in minor/non-NPSLE patients (SMR 6.2, 95% CI: 2.0-14.6) and an increased risk of death to infections was present in both NPSLE and minor/non-NPSLE patients (SMR 29.9, 95% CI: 3.5 – 105 and SMR 91.3 95% CI: 18.8 – 266) respectively. However, mortality did not differ between NPSLE and minor/non-NPSLE patients (RR 1.0, 95% CI: 0.5 – 2.0).

Conclusion: Mortality was increased in both NPSLE and minor/non-NPSLE patients in comparison with the general population, but there was no difference in mortality between NPSLE and minor/non-NPSLE patients. This is different than expected and might imply that major NPSLE does not influence prognosis when recognized and treated.

Abstract Number: 1265

2019 Lupus Classification Criteria Score Predicting Cost of Future Hospitalizations

Saurav Suman[1], Amna Batool[2], Joshua Keller[2] and William Neal Roberts[2], [1]University of Kentucky, Horseheads, NY, [2]University of Kentucky, Lexington, KY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The latest 2019 Lupus Classification criteria score (CCS) is based on weighted criteria and has been shown to predict 10-year mortality[1]. Our previous study also suggests that lupus score greater than 19 increases the risk of future hospitalizations[2]. We attempt to test the hypothesis that 2019 lupus classification criteria score can predict the cost of future hospitalizations.

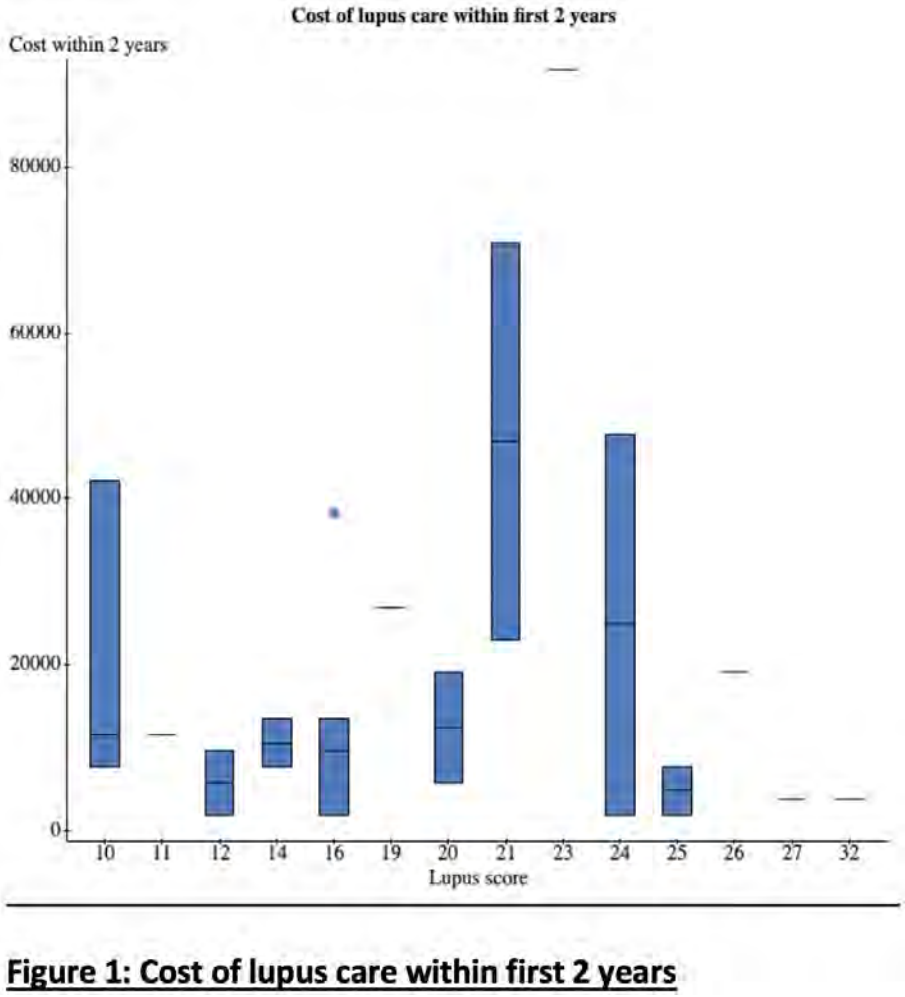

Figure 1. Cost of Lupus Care within first 2 years

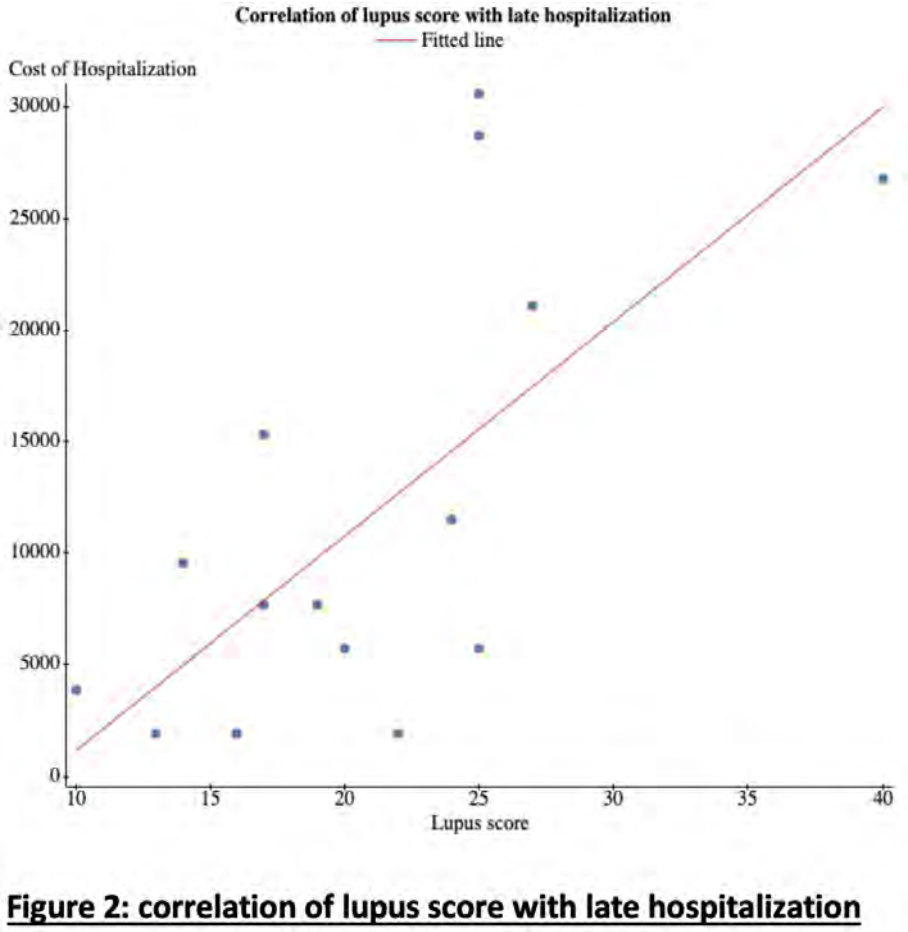

Figure 2. Correlation of Lupus Score with late hospitalization

Methods: Retrospective chart review was done at University of Kentucky (UK) between 2013 – 2019 to ascertain risk factors for hospitalization of lupus patients[2]. Post hoc analysis was applied to calculate cost of care.

Inclusion criteria: At least 3 outpatient rheumatology visits at UK with an ICD 9/10 diagnosis code for Lupus. Total of 217 patients met the inclusion criteria and 42 patients were hospitalized. 2019 Lupus classification score was calculated from first outpatient rheumatology visit. Total hospitalization cost was calculated by using hospital expense data[3]. Hospital expense data avoided variability of charges and reimbursement based on the type of insurance.

Results: Among 42 patients hospitalized, 26 (62%) were hospitalized within 2 years of their index rheumatology visit (Figure 1). Of 26, 15 were hospitalized due to lupus related causes with total mean hospital cost of 20426 usd. 11 patients were hospitalized unrelated to lupus with total mean cost of 17060 usd.

Patients whose 1st hospitalization was after 2 years of their index visit showed a trend toward overall lower mean hospitalization cost: 11370 usd as compared to patients hospitalized earlier than 2 years: 21065 usd (p value: 0.05). In addition, later hospitalization cost showed strong linear correlation with lupus score (r: 0.68, p value: 0.003) (Figure 2).

Patients who scored > 19 on the lupus CCS had almost twice the cost (28725 usd) due to inpatient hospitalization as compared to patients with CCS 19 or less in the subsequent two years of their index visit. In analysis of hospitalization any time after their index visit rather than the initial 2 years, patients with higher lupus score (>19) still incurred higher cost compared to those with a lower CCS score (23841 usd vs 11490 usd, $p < 0.07$) (Table 1).

	Lupus Score (19 or less)	Lupus Score > 19	P value:
Mean Cost of Hospitalization per patient (for 1st 2 years after index rheumatology visit)	14,499 (n: 14)	28725 (n: 12)	0.255
Mean Cost of hospitalization per patient (anytime after index outpatient rheumatology visit)	11490 (n=22)	23841 (n= 20)	0.0761

Table 1: Cost of hospitalization by lupus score (19 or less vs > 19)

Table 1. Cost of Hospitalization by Lupus score (19 or less vs > 19)

Conclusion: Our study found that late first hospitalization expense (1st hospitalization after 2 years of index visit) correlate well with the lupus score (p value: 0.05). In addition, higher lupus score (> 19) increased hospitalization cost almost twofold as compared to lupus score 19 or less. These data could help to create models using 2019 Lupus classification criteria scores as a surrogate to predict future lupus hospitalization and cost of care, supporting Interventions designed to bring the cost down.

Relationships Between Predictors and MI/Stroke Based on a Multivariable Model

ham Risk Score and the ACC/AHA Risk Equation combine stroke and myocardial infarction as the outcomes. The prospective SLE Cardiovascular Risk Equation took the same approach. The model found that traditional risk factors (age, sex, ethnicity, systolic blood pressure, total cholesterol, smoking, and diabetes mellitus) and SLE-specific risk factors (low C3 and lupus anticoagulant) were independent predictors of a later cardiovascular event (Lupus Sci Med. 2019;6:e000346). In this study, we took a different approach, and examined risk factors separately for myocardial infarction and for stroke.

Methods: SLE was defined by the revised ACR or SLICC classification criteria. Cardiovascular events were defined as myocardial infarction (MI) or stroke (ACC/AHA definition). In our cohort of 2,398 patients, 1,029 were African-American and 1,369 Caucasian. Nineteen were missing a SLE diagnosis date and 9 had missing data on events. There were 230 strokes and 116 myocardial infarctions.

Results: Table 1 shows the multivariate model of predictors of myocardial infarction and of stroke in SLE. Surprisingly, demographic variables such as age at diagnosis and African-American race were not risk factors. Male gender was a risk factor only for MI. Traditional cardiovascular risk factors were present for both outcomes, but overlapped only for hyperlipidemia and diabetes. Smoking was a risk factor only for MI. Hypertension was a risk factor only for stroke. The lupus-specific risk factors, low C3 and lupus anticoagulant, were only risk factors for stroke.

Conclusion: SLE is different from the general population in the predictive value of traditional cardiovascular risk factors for MI and stroke, with only hyperlipidemia and diabetes being risk factors for both. SLE-specific risk factors, low C3 and lupus anticoagulant, were important only for stroke. Attention to both traditional and SLE-specific risk factors remains paramount to lessen the cardiovascular morbidity of SLE. It is disappointing, however, that we do not have a clinically available SLE measure that predicts MI. We must still depend on non-invasive tests such as coronary CT or CT angiogram to identify patients early with atherosclerotic plaque.

Perceived Stress During the COVID-19 Pandemic Independently Associates with Worse Patient-Reported Outcomes in Systemic Lupus Erythematosus (SLE)

Sarah Patterson[1], Laura Trupin[2], Kimberly DeQuattro[1], Cristina Lanata[1], Maria Dall'Era[3], Jinoos Yazdany[2] and Patricia Katz[2], [1]UCSF, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]Division of Rheumatology, University of California, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Causes and risk factors for variations in SLE disease activity and symptom severity are incompletely understood. Prior studies suggest a link between stressful life events (e.g. trauma), perceived stress, and greater disease severity. We examined whether (1) high levels of stress during the COVID-19 pandemic—both generalized and attributed to COVID-19—were associated with worse patient-reported outcomes (PROs) among patients with lupus, and (2) increases in perceived stress concurrent with the pandemic associated with increases in symptoms and/or incident SLE flares.

Methods: Participants, drawn from the California Lupus Epidemiology Study (CLUES), were ≥18 years old and met ACR criteria for SLE. Data derive from interviews conducted during the COVID-19 pandemic and study assessments during the prior year. General stress was measured using the 4-item Perceived Stress Scale (PSS, range 0-16). Scores in the top quartile were categorized as high stress. High stress from COVID-19 was assessed by asking whether it had caused "a great deal of stress or worry" and/or "the most stressful situation I have been through". PROs included: self-report disease activity (SLE Activity Questionnaire, SLAQ), pain severity (scale 1-10), fatigue (PROMIS fatigue scale), cognitive function (PROMIS cognitive ability scale), and self-report SLE flares (prior month). Multivariable linear and logistic regression first evaluated associations of generalized and COVID-19-specific stress with PROs during the pandemic while controlling for potential confounders (age, sex, race, education, income, smoking, disease duration, and disease damage), and then modeled changes in PROs from pre-pandemic to during the pandemic as a function of change in perceived stress (by PSS). We calculated adjusted means for each outcome based on the multivariable regression.

Results: The sample (n=201) was 91% female; 36% white, 27% Asian, 24% Hispanic, and 9% African American; mean age 50 (± 14) years; 17% with poverty-level income; and mean disease duration 22 (± 10) years. During the COVID-19 pandemic, 29% reported severe stress related to the health crisis. The mean PSS score in the high stress group was 10.1 (± 1.4), compared with 4.4 (± 2.6) among the rest of the cohort. In the cross-sectional multivariate regression model, high stress by both measures (PSS and COVID-19 stress question) was associated with worse scores for each PRO: greater self-reported disease activity, more pain, more fatigue, lower cognitive function, and higher frequency of flares (Table 1). In the longitudinal analysis, increase in stress independently associated with an increase in disease activity, increase in fatigue, and decrease in cognitive function, but no significant change in pain severity or flares (Table 2).

Conclusion: In a racially diverse SLE cohort, psychological stress during the COVID-19 pandemic independently associated with worse PROs including self-reported disease activity, fatigue, and cognitive dysfunction. Evidence-based

Table 1. Cross-sectional Analysis: Adjusted* Means (95% CI) for Patient Reported Outcomes and Prevalence of Lupus Flares by Perceived Stress During the COVID-19 Pandemic

	High General Perceived Stress**			High COVID-19-Associated Stress***

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) can lead to neuropsychiatric manifestations including cognitive impairment (CI). The gold standard for assessment of SLE cognitive function is the American College of Rheumatology comprehensive neuropsychological battery (NB), which was introduced in 1996 and assesses 6 cognitive domains. COnsensus-based Standards for the selection of health Measurement INstruments (COSMIN) define structural validity as "*the degree to which the scores of an instrument are an adequate reflection of the dimensionality of the construct being measured".* Our primary aims were to explore the number of latent factors encompassed by the NB and assess the battery's structural validity, i.e., determine if identified latent factors can be mapped to NB's intended cognitive domains.

Methods: 300 consecutive consenting SLE patients aged 18-65 years attending a single center, were enrolled (Jul 2016 – Nov 2019) and completed the NB. The NB includes the following tests: Finger tapping, Trail Making Test A and B, Stroop Color and Word Test, Rey-Osterrieth Complex Figure Test (RCFT), Controlled Oral Word Association Test (COWAT), Animal Naming, Hopkins Verbal Learning Test – Revised (HVLT-R), Wechsler Adult Intelligence Scale Digit Symbol Substitution Test (WAIS III), Letter-Number Sequencing, and Consonant Trigrams.Structural validity was examined with exploratory factor analysis (EFA) using squared multiple correlations as prior communality estimates. The maximum likelihood method was used to extract factors, followed by a varimax (orthogonal) rotation. A scree plot was developed to examine the underlying factors of NB. Factors with Eigenvalues of >1 were extracted. The sample size met standards for EFA of more than 100 participants or at least 5 times the number of variables being analyzed. A multiple imputation model was used to account for missing data.

Results: 300 participants entered the cohort (89.0% female, mean age at enrollment 41.1±12.1 years, mean disease duration 14.1±10.0 years) (**Table 1**). 54 (18.0%) of patients had at least one test score missing.

Characteristics	N= 300
Sex (F)	267 (89%)
Age at diagnosis (Mean ± SD)	27.0 ± 10.5
Age at study enrolment (Mean ± SD)	41.1 ± 12.1
Disease Duration at study enrolment (Mean ± SD)	14.1 ± 10.0
Ethnicity	
Black	59 (19.7%)

High school completed	48 (16.2%)
Post-secondary education (College/University)	239 (80.8%)

Table 1. Patient demographics at enrolment

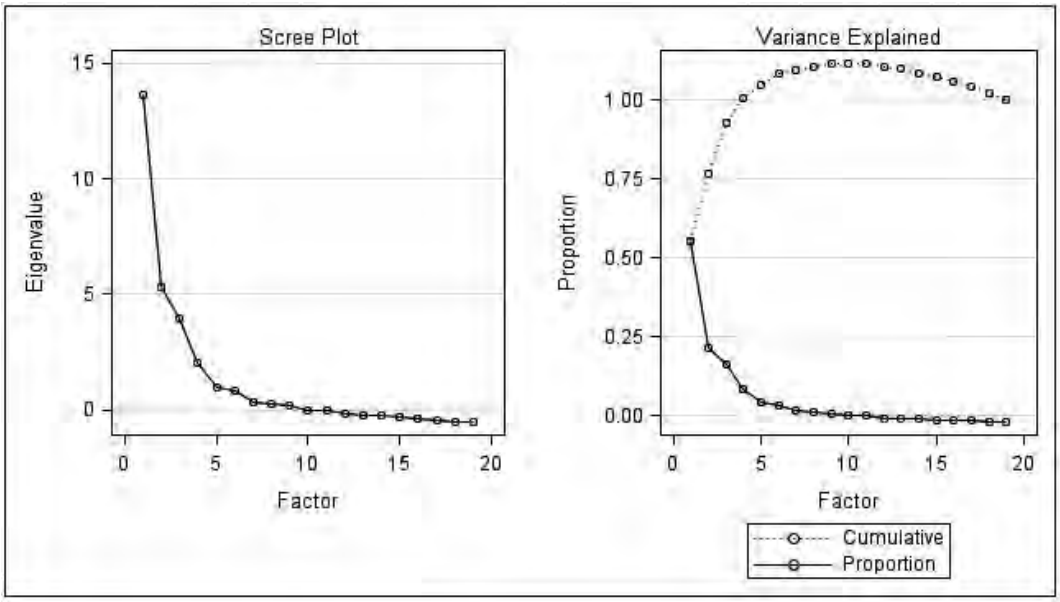

Figure 1. Scree and Variance Plots confirming a 6 factor model

EFA model fitting indicated a six-factor model as the best fit, with Akaike Information Criterion (AIC) -24 and Tucker and Lewis Reliability Coefficient of 95% comparing to models with less or more factors. The choice of model was confirmed with Scree and Variance Explained plots with cumulative variance of 100% explained by six factors (**Figure 1**).

Individual NB tests primarily loaded on the factors representing the intended cognitive domains (**Table 2**), although the strength of weights of individual tests varied within each factor. The one exception was Consonant Trigrams, which loaded on the Memory factor, although its second highest loading was on its intended factor.

Conclusion: EFA indicates that a six-factor model fits the structure of the NB. The factors identified by EFA closely resemble the structure of the 1996 NB and confirms its structural validity. Variations in strength of weights raises the

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty has been associated with increased disability and mortality in SLE. To our knowledge, no patient-reported frailty tool has been evaluated alongside a standard frailty measure in SLE. We aimed to assess 1) the prevalence of frailty according to both the standard Fried phenotype (FP) and a validated self-reported frailty

Table 1. Baseline characteristics by frailty classification

Characteristic (Median and IQR)	Fried phenotype (N=72)			FRAIL scale (N=67)

Table 1

instrument, 2) differences between frail and non-frail women according to each definition, 3) the association of each frailty measure with patient-reported disability, and 4) the correlation between frailty definitions.

Methods: Adult women < 70 years old with validated SLE and mild/moderate disease were recruited from a single center. Measures included: frailty (FP and the self-reported FRAIL Scale [FS] [1]); disease activity (SELENA-SLEDAI); disease damage (SLICC/ACR Damage Index); inflammatory/metabolic biomarkers; and patient-reported outcome measures (PROMs), including Valued Life Activities disability. Differences between frail and non-frail participants were evaluated using Fisher's exact or Wilcoxon rank sum tests and the association of frailty with disability using logistic regression. Correlation between the FP and the FS was determined using Spearman's correlation.

Results: 72 women enrolled; 67 (93%) completed the FS. 17% and 27% were frail according to the FP and the FS, respectively. Frail women according to either definition had greater disease damage (FP: p=0.002; FS: p=0.0006),

*PROMIS: Patient Reported Outcome Measurement Information System. Scored using a T score metric, with 50 representing the population mean and a difference of 5 considered clinically significant.
**LupusQOL: Scores range from 0-100, with higher scores indicating higher health-related quality of life.
†Valued Life Activities: Scores range from 0-3, with higher scores indicating greater disability.
‡Center for Epidemiologic Studies Depression Scale: Scores range from 0-60, with high scores indicating greater depression.

Table 2

significantly greater high-sensitivity CRP (FP and FS: p=0.02) and interleukin 6 (FP: p=0.0005; FS: p=0.003), and significantly worse PROMS across multiple domains (Tables 1 and 2). Compared with non-frail women, frail women classified by the FP had greater comorbidity burden (p=0.02), higher prevalence of smoking (p=0.01), and higher ESR (p=0.01); when classified by the FS, frail women were significantly older (p=0.04) with lesser educational attainment (p=0.0009) (Tables 1 and 2). Frailty according to either definition was significantly associated with disability after adjustment for age, comorbidity burden, and disease activity (FP: p=0.02; FS: p=0.0003), but this relationship was attenuated for the FP after adjustment for disease damage (p=0.08) (Table 3). There was moderate correlation between the FS and the FP (r=0.48; p< 0.0001).

Conclusion: The prevalence of patient-reported frailty was high in this cohort of women with SLE. Frail women had generally worse PROMs, providing face validity for both definitions. The FS was strongly associated with disability even after adjustment for multiple confounders. While estimates are imprecise, these data suggest that the FS may be an informative point-of-care tool to identify frail women with SLE.

Trend of Survival of a Cohort of Patients with Systemic Lupus Erythematosus over 25 Years

Chi Chiu Mok[1], Ling Yin Ho[1], Kar Li Chan[2], Sau Mei Tse[2] and Chi Hung To[3], [1]Tuen Mun Hospital, Hong Kong, China (People's Republic), [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Pok Oi Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose

Background: Few studies of systemic lupus erythematosus (SLE) have a follow-up duration long enough to evaluate the time trend of survival, particularly in Asian countries.

Objectives: To revisit the trend of survival of SLE in a cohort of southern Chinese patients over 25 years.

Methods: Patients who fulfilled the 1997 ACR criteria for SLE and were followed in our hospital since 1995 were included. Patients were stratified into 2 groups according to the year of diagnosis: (1) 1995-2004; and (2) 2005-2018.

Survival of patients was studied by Kaplan Miere's analysis. For those who died or lost to follow-up, data were censored at their last clinic / hospital visits. Organ damage was assessed by the Systemic Lupus International Collaborating Clinics (SLICC) damage index (SDI) and causes of death in the first 10 years of SLE onset were compared between the two groups. Cox regression was used to study factors associated with survival.

Results: A total of 1098 SLE patients were registered in our database. After excluding 157 patients diagnosed outside the time period of 1995-2018, 941 patients were studied (92% women). All were ethnic Chinese. The mean age of SLE onset was 35.1±14.4 years and the mean follow-up duration by the same groups of physicians was 13.1±6.6 years. Seventy-seven patients were lost to follow up. Groups 1 and 2 consisted of 364 and 577 patients, respectively. The mean SDI score at 10 years of disease onset was significantly higher in group 1 than group 2 patients (1.01±1.43 vs 0.57±0.94; p< 0.01), particularly in the neuropsychiatric, musculoskeletal and gonadal domains. The proportion of patients with organ damage in these 3 systems was also significantly higher in this group of patients. Within 10 years of SLE onset, 32 (8.8%) patients in group 1 and 25 (4.3%) patients in group 2 died (p=0.005). The 5- and 10-year cumulative survival rates were 93.6% and 91.0% in group 1; and 96.5% and 94.2% in group 2 patients, respectively (log rank test p=0.048). Infection accounted for more than half of the deaths in both groups. More group 1 than group 2 patients died of vascular events but the difference was not statistically significant. Univariate Cox regression analysis showed that age of onset, male sex and SDI score at 10 years were associated with survival. Group 2 patients showed a better survival than group 1 but statistical significance was borderline (HR 0.61[0.38-1.001]; p=0.05). Multivariate analysis revealed only the age of onset (1.06 [1.04-1.08] per year; p< 0.001) and SDI at 10 years (1.65 [1.47-1.85] per point; p< 0.001) were significantly associated with survival. The period in which SLE was diagnosed was not a significant factor determining survival (HR 0.68[0.41-1.14]; p=0.14).

Conclusion: The survival of our Chinese SLE patients has improved significantly from 1995-2004 to 2005-2018, which is contributed by lower organ damage accrual.

Post-Traumatic Stress Disorder (PTSD) and Risk of Systemic Lupus Erythematosus (SLE) Among Medicaid Recipients

Siobhan Case[1], Candace Feldman[1], Hongshu Guan[1], Laura Kubzansky[2], Karestan Koenan[2] and Karen Costenbader[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Post-traumatic stress disorder (PTSD), the sentinel stress-related mental disorder, may be associated with increased risk of developing autoimmune disease, including systemic lupus erythematosus (SLE). This study aimed to study the relationship between PTSD and risk of SLE in a large, diverse population of Medicaid enrollees. We hypothesized patients with incident SLE would be more likely to have a prior diagnosis of PTSD than those without SLE.

Methods: We performed a case-control study using patients ages 18 to 65 years old in the Medicaid Analytic eXtract (MAX) database between January 1, 2007 and December 31, 2010. Cases of SLE were defined as having ≥3 ICD-9

Table 1. Characteristics of US Medicaid Patients with SLE vs. Matched US Medicaid Patients without SLE (2007-2010), matched at the Index Date for SLE

Characteristic	SLE Cases (n=10,942)	Matched General Medicaid Population Controls (n= 109,420)
Mean age, years (SD)*	40.8 (12.4)	40.8 (12.4)
Female, %*	93.5	93.5
Race, %*		
African American	39.8	39.9
White	37.5	37.5
Asian	2.3	2.3
Hispanic	16.9	16.9
Native American	0.95	0.87
Other	2.5	2.5
Median zip code level income, %		
1st Quartile	25.9	24.8
2nd Quartile	25.8	24.9
3rd Quartile	23.8	25.4
4th Quartile	24.6	25.0
US Region of Residence, %		
South	37.4	38.9
Northeast	21.8	19.4
Midwest	20.4	23.1
West	20.3	18.6
Smoking, %	11.3	7.3
Obesity, %	7.1	4.2
Oral contraceptive use (among women only), %	8.8	10.5

*Matching factor
IQR: interquartile range, SD: Standard deviation

codes for SLE from hospital discharge diagnoses or physician visit claims, occurring at least 30 days apart. Index date was defined as the date of the first code for SLE. Controls were matched to SLE cases for age, sex and race using a 1:10 ratio. Controls were patients without any claims for SLE, but who had another inpatient or outpatient claim in Medicaid on the SLE index date of the matched case. Exclusion criteria included having less than 12 months of continuous Medicaid enrollment prior to the index or matched control date. The exposure was PTSD, defined as having ≥2 ICD-9 codes for PTSD on different dates within 4 months of each other, occurring prior to the index date for SLE (Gravely, 2011; PPV 82%). We used conditional logistic regression to calculate the odds ratio (OR) and 95% confidence interval (CI) for history of PTSD prior to index date in cases vs. controls. Finally, we used multivariable analysis to adjust for variables collected prior to the index date, including area-level socioeconomic status (SES), smoking, obesity, oral contraception use, and time enrolled in Medicaid.

Results: We identified 10,942 cases of incident SLE, who were matched to 109,420 controls. There were significant differences at the index date in several characteristics, including zip code level income as a measure of socioeconomic status (SES), US region of residence, smoking, obesity, and oral contraceptive use (Table 1). 1.46% of Medicaid enrollees with SLE met the definition of PTSD prior to the index date, compared to 0.75% of controls ($p< 0.001$). The OR for PTSD and risk of incident SLE was 1.96 (95% CI 1.66-2.33, $p< 0.001$) in conditional logistic regression, and 2.02 (95% CI 1.65-2.48, $p< 0.001$) after multivariable adjustment (Table 2). Further adjustment for the matching factors did not alter risk estimates.

Conclusion: In this large, racially and sociodemographic diverse US patient population, we found a near doubling of odds of SLE associated with prior PTSD diagnosis. Chronic stress leading to hypothalamic-pituitary axis dysregulation and inflammatory cytokine upregulation are postulated mechanisms. Future studies are needed with longer

Table 2. Conditional logistic regression models for PTSD in relation to incident SLE, comparing PTSD to no PTSD

	Conditional logistic regression			Multivariable-adjusted conditional logistic regression*		
	OR	CI	p-value	OR	CI	p-value
No PTSD	1.00	Ref		1.00	Ref	
PTSD	1.96	1.66-2.33	<0.0001	2.02	1.65, 2.48	<0.0001

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: To determine whether remission and low disease activity state (LDAS) reduce hospitalizations in systemic lupus erythematosus (SLE) patients.

Methods: A multi-ethnic, multi-national Latin-American SLE cohort was studied.

Variable	Univariable HR (95% CI)	p value	Multivariable HR (95% CI)	p value
Disease activity status				
Remission on treatment	0.39 (0.25-0.61)	<0.0001	0.46 (0.29-0.72)	0.001
LDAS	1.19 (0.94-1.51)	0.139	1.20 (0.94-1.53)	0.135
Active	Ref.		Ref.	
Age at diagnosis	0.88 (0.82-0.95)	0.001	0.89 (0.82-0.96)	0.002
Gender, Female	1.02 (0.77-1.34)	0.914	1.11 (0.84-1.46)	0.477
Ethnicity

Mestizo	1.20 (1.00-1.44)	0.051	1.03 (0.85-1.24)	0.771
ALA	1.10 (0.83-1.46)	0.514	0.99 (0.75-1.33)	0.986
Others	1.46 (0.92-2.30)	0.109	1.29 (0.82-2.05)	0.276
Rural residence	0.91 (0.67-1.22)	0.520		
Socioeconomic status				
High	Ref.		Ref.	
Medium	1.90 (1.28-2.84)	0.002	1.81 (1.21-2.71)	0.004
Low	2.52 (1.72-3.67)	<0.0001	2.02 (1.37-2.96)	0.001
Medical insurance, Full coverage	0.91 (0.77-1.08)	0.363		
Previous hospitalization	1.41 (1.20-1.67)	<0.0001	0.99 (0.83-1.20)	0.953
Increase on the SDI, per 1 unit	1.33 (1.26-1.40)	<0.0001	1.27 (1.20-1.35)	<0.0001
Antimalarial use	0.53 (0.44-0.63)	<0.0001	0.61 (0.51-0.72)	<0.0001
Prednisone (highest dose)				
None	Ref			
<7.5mg/d	0.90 (0.51-1.61)	0.730		
7.5-15mg/d	1.00 (0.73-1.37)	0.997		
15-60mg/d	0.97 (0.79-1.20)	0.793		
>=60mg/d	0.99 (0.76-1.28)	0.922		

Table 1. Impact of disease activity status on hospitalization: univariable and multivariable analyses. LDAS: low disease activity status; ALA: Afro-Latin American; SDI: SLICC/ACR damage index; HR: Hazard ratio; 95% CI: 95% confidence interval; Ref: reference group

Visits were performed every six months. Variables were ascertained at each visit. The first hospitalization following cohort entry was evaluated in the interval between two visits. Based on the definitions of remission in SLE (DORIS) framework, for each visit remission on treatment was defined as a SLEDAI of 0, prednisone ≤5 mg/day and maintenance treatment with immunosuppressants. LDAS was defined as a SLEDAI ≤4 with no SLEDAI scores for renal, central nervous system, serositis, vasculitis, and constitutional components, no increase in any SLEDAI component since the previous visit, and prednisone dose ≤7.5 mg/day. Immunosuppressants at maintenance doses were allowed for LDAS. Antimalarial treatment was allowed for both states. Potential confounders of hospitalization included sociodemographic factors, baseline damage (Systemic Lupus International Collaborating Clinics Damage Index or SDI), previous hospitalizations, glucocorticoids and antimalarials (users and non-users). Both, disease activity status and antimalarials were evaluated as time-dependent covariates. Cox regression model was used to evaluate whether remission on treatment and LDAS protected against hospitalizations after controlling for important confounders. A multivariable model was built by selecting covariates using a backward elimination procedure.

Results: One thousand three hundred and forty-one patients were included; 1201 (89.6%) were female. The median (IQR) age at diagnosis was 27 (20-37) years and the median (IQR) follow up time 27.5 (4.7-62.2) months. A total of 508 patients were hospitalized, of those 455 (89.6%) were female.

There were 6,089 intervals for these 1,341 patients. The median number of intervals per patient was 4 (2-7), and the median length of the intervals was 7.1 (5.1-11.7) months. Of the intervals examined, the most frequent status was non-optimally controlled, with 4,269 (75.1%) intervals, followed by remission on treatment 772 (13.6%) and LDAS 643 (11.3%) intervals. In the multivariable analysis, remission on treatment (HR 0.46; 95% CI 0.29–0.72) but not LDAS was found to decrease the hazard ratio of hospitalization, after adjusting for confounders. Of interest, antimalarials were found to be protective (HR: 0.61; 95% CI 0.51-0.72).

Conclusion: In this large Latin American multiethnic, multinational lupus cohort, remission on treatment reduced the risk of hospitalization after adjusting for other well-known risk factors. It is worth pointing out that antimalarial use seemed to protect against the occurrence of hospitalizations, supporting its role as a cornerstone treatment in SLE. Our findings call for seeking remission as a fundamental target in the management of patients with SLE.

Acknowledgments: The authors are grateful to Jennifer H Lofland, Federico Zazzetti, and Chetan Karyekar for their contributions.

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Many patients with SLE experience symptoms of chronic pain and fatigue, often meeting criteria for fibromyalgia (FM). In this study, we sought to examine whether FM symptoms improved or worsened following the outset of the COVID-19 pandemic.

Methods: On Maya 6, 2020, 287 patients in the Duke Lupus Registry (DLR) were emailed an invitation to take a survey about the impact of the COVID-19 pandemic. Responses to the ACR 2016 FM diagnostic criteria questions (defined as post-pandemic responses) were compared to the 53 patients' responses to the same questions collected at their most recent clinic visit prior to March 18, 2020 (defined as pre-pandemic responses). Significant clinical improvement was defined as a 3+ decrease in fibromyalgia severity score (FSS), a patient reported outcome scored as 0-31; significant clinical worsening was defined as 3+ increase in FSS. A two-tailed student t-test was used to

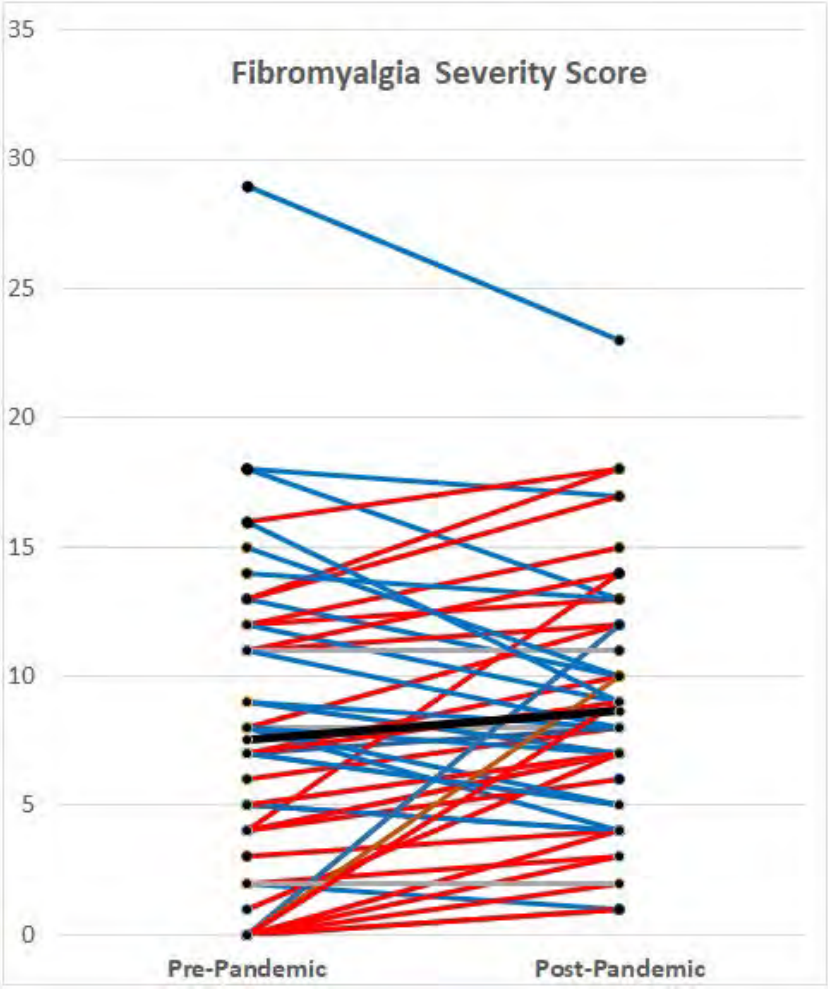

Figure 1. FSS change over time. For each patient participating in the survey, a pre-pandemic FSS (FSS from the most recent clinical visit prior to March 18, 2020) was compared to the post-pandemic FSS (collected from the online survey distributed on May XX, 2020). Red lines indicate patients with worsening FSS; blue lines indicate patients with improving FSS; grey lines indicate patients with unchanged FSS. The thick black line highlights the pre-pandemic mean (7.5) compared to the post-pandemic mean (8.7).

performed a paired analysis of pre-pandemic FSS to post-pandemic FSS. Finally, the polysymptomatic distress scale (PDS) was used to characterize symptoms as mild (0-3), moderate (4-7), or severe (12-19).

Results: Survey responses were received from 53/287 (18%) of the Duke Lupus Registry participants, 92.5% of whom were women, 34% Black, and 60% Caucasian, compared to 93.4%, 53.8%, and 39.4%, respectively, in the registry as a whole. The mean pre-pandemic FSS for these patients was 7.5 ± 0.8 (SEM), compared to 8.7 ± 0.7 (SEM), post-pandemic (p=0.05). Pre-pandemic, 15 patients (28%) met criteria for mild polysymptomatic distress, 12 (23%) moderate, and 7 (13%) severe; post-pandemic, 21 patients (40%) met criteria for mild polysymptomatic distress, 15 (28%) moderate, and 8 (15%) severe (see Figure 1). Of the 53 survey respondents, 8 (15%) demonstrated significant clinical improvement during the pandemic, whereas 14 (26%) experienced significant clinical worsening. Of the 14 patients with worsened FSS, 12 (86%) did not identify any specific pandemic-related stressors or challenges in the domains of physical health, mental health, or personal life (work, family, and finances); the other 2 patients only mentioned worsening symptoms (pain, anxiety, and depression) as challenges. In contrast, of the 8 patients with improving FSS, 4 (50%) did not describe specific challenges, whereas the other 4 patients described symptoms in addition to articulating themes of isolation, missing extended family and family events, struggling with job loss, working to find opportunities for exercise, and grappling with balancing childcare and work responsibilities.

Conclusion: The experience of the COVID-19 pandemic is heterogeneous for SLE patients. In average, patient's FM symptoms worsened following the onset of the pandemic, with 14 patients experiencing significant clinical worsening and only 8 patients experiencing significant clinical improvement in FM symptoms. Interestingly, the patients who improved articulated more pandemic-related challenges, perhaps suggesting that insight into one's challenges is key to healthy coping. Further research is needed to identify risk factors and protective factors for SLE patients in the setting of the COVID-19 pandemic.

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) represent a unique population in considering risk for coronavirus disease 2019 (COVID-19) with biologic, genetic, demographic, clinical and treatment issues all at play. By the nature of their chronic inflammatory autoimmune condition and regular use of immunosuppressive medications, these individuals would traditionally be considered at high risk of contracting the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and having a worse prognosis. Accordingly, we aimed to characterize

	Hospitalized* N = 24

patients with SLE affected by COVID-19 in New York City (NYC) and analyze associations of comorbidities and medications on outcomes.

Methods: Patients with SLE and COVID-19 (confirmed by RT-PCR testing), were identified through a longitudinal survey of an established NYU lupus cohort, query of New York University Langone Health and Bellevue Hospitals systems and referrals from rheumatologists at those institutions. All patients were age 18 or older and met SLE classification criteria or carried a rheumatologist's diagnosis of SLE. Only English-, Spanish- or Mandarin-speaking patients were included in the study. Data were prospectively collected via a web-based questionnaire and review of electronic medical records. Baseline characteristics and medications were compared between the hospitalized and ambulatory patients with COVID-19. A logistic regression analysis was performed to identify independent predictors of hospital admission.

Results: A total of 41 SLE patients were confirmed COVID-19 positive by RT-PCR. The patients were predominantly female and encompassed the major racial/ethnic demographics seen in NYC. The most common symptoms of

COVID-19+ Patients	Hospitalized (N = 24)	Ambulatory (N = 17)	P-value*
Age	49.38 ± 17.81	43.65 ±16.26	0.30
Gender			1.00
Female	22 (91.7%)	16 (94.1%)	
Male	2 (8.3%)	1 (5.9%)	
Race			0.15
White	4 (16.7%)	7 (41.2%)	
Non-White	20 (83.3%)	10 (58.8%)	
Hispanic Ethnicity	10 (41.7%)	5 (29.4%)	0.52
BMI†	29.0 (25.7, 37.1)	27.4 (24.7, 30.7)	0.34
SLE Risk Factors			
APLS	3 (12.5%)	0 (0%)	0.25
History of LN	11 (45.8%)	3 (17.7%)	0.10
Medications			
Hydroxychloroquine	18 (75.0%)	14 (82.4%)	0.71
Systemic steroids	13 (54.2%)	5 (29.4%)	0.20
Immunosuppressants‡	15 (62.5%)	9 (52.9%)	0.75
NSAIDs	1 (4.2%)	1 (5.9%)	1.00
Comorbidities (≥1)	15 (62.5%)	5 (29.4%)	0.06

Table 2. Comparison of hospitalized and ambulatory SLE patients with confirmed COVID-19. Values are expressed as % (N) for categorical variables and mean ± standard deviation (SD) or median (interquartile range [IQR]) for continuous variables. * Categorical variables compared using Fisher's exact test; continuous variables compared using the two-sample T-test or Mann Whitney U Test. Age: T-test; BMI: Mann Whitney U Test (chosen by whichever gave more conservative p-value). † Median (IQR); N=23 for Hospitalized group ‡ Immunosuppressants include non-biologic agents (azathioprine, cyclophosphamide, mycophenolate mofetil, mycophenolic acid, sirolimus, tacrolimus) and biologic agents (anakinra, abatacept, belimumab, rituximab, tocilizumab). § Comorbidities refers to at least one of the following: congestive heart failure, active malignancy, pregnancy, diabetes mellitus, asthma, chronic obstructive pulmonary disease. APLS, Antiphospholipid Syndrome; BMI, Body Mass Index; COVID-19, Coronavirus Disease 2019; COVID-19+, positive testing for SARS-CoV-2 by polymerase chain reaction; LN, Lupus Nephritis; SLE, Systemic Lupus Erythematosus.

COVID-19+ patients were cough (78.4%), fever (64.9%), and shortness of breath (64.9%). Of those SLE patients with COVID-19, 24 (59%) were hospitalized, 4 required ICU level of care, and 4 died, all of hypoxic respiratory failure, Table 1. Hospitalized patients tended to be older, non-white, Hispanic, and have higher BMI, antiphospholipid syndrome, a history of lupus nephritis and at least one medical comorbidity, Table 2. There was no difference between the groups in use of hydroxychloroquine, systemic steroids or immunosuppressants. Logistic regression analysis identified the following independent predictors of being hospitalized with COVID-19: race (OR = 7.78 for non-white vs. white; 95% CI: 1.13 to 53.58; p=0.037), the presence of at least one comorbidity (OR=4.66; 95% CI: 1.02 to 21.20; p=0.047), and BMI (OR = 1.08 per increase in kg/m^2; 95% CI: 0.99 to 1.18; p=0.096).

Conclusion: Patients with SLE and COVID-19 have a high rate of hospitalization but similar mortality rate to the general population in NYC. Risk factors such as non-white race, higher BMI, and the presence of one or more comorbidities were identified as independent predictors of hospitalization in SLE patients who develop COVID-19. The use of hydroxychloroquine and immunosuppressants did not appear to influence the outcomes of patients with SLE in the setting of COVID-19. Further studies are needed to understand additional risk factors for poor COVID-19 outcomes in patients with SLE.

Unexpected Changes in Physical and Psychological Measures Among Georgia Lupus Patients During the Early Weeks of the COVID-19 Pandemic in the United States, March 30–April 21, 2020

S. Sam Lim[1], Kristina Theis[2], Charmayne Dunlop-Thomas[1], Gaobin Bao[1], Charles Helmick[2], Caroline Gordon[3] and Cristina Drenkard[4], [1]Emory University, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]University of Birmingham, Birmingham, England, United Kingdom, [4]Division of Rheumatology, Department of Medicine, Emory School of Medicine, Atlanta, GA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: An infectious disease outbreak can lead to negative physical and psychological consequences in the general public, as shown by the early COVID-19 pandemic, through significant negative global impacts on depression, anxiety, and stress. These outcomes are also known to be common among people with lupus. To evaluate the early impacts of the COVID-19 pandemic, we examined changes in standardized patient-reported outcomes in a cohort of patients with SLE between 2018–2019 and early 2020 and evaluated how the pandemic's impact on physical and psychological health differed by subgroups, particularly among black persons, who are at higher risk for adverse outcomes from both SLE and COVID-19.

Methods: Georgians Organized Against Lupus (GOAL) is a Centers for Disease Control and Prevention-supported population-based validated cohort of patients with SLE in Atlanta who complete patient-matched annual surveys across multiple domains. We analyzed sociodemographics and validated measures of lupus characteristics and physical and psychological parameters (see table footnotes) from surveys before (2018–2019) and during the pandemic's early onset (March 30–April 21, 2020). The 2020 surveys closely corresponded to the statewide shelter-in-place order in Georgia (April 3–24). We conducted descriptive analyses of prevalence (%) estimates with standard deviations (SD) and temporal changes in scale scores and paired t-tests for statistically significant differences (α=0.05); analyses were examined overall and stratified by sex and race.

Results: Overall, 316 participants had survey data from both time points. Most were black (76.6%) and female (93.4%); more than a quarter live in poverty (28.5%) (Table 1). Compared with before the pandemic, no physical or psychosocial measure worsened during the early onset of the pandemic. Rather, there were small, statistically significant improvements in stress, pain interference, fatigue, depression, anger, everyday discrimination, and emotional support overall, particularly in females and black persons (Table 2). Only Pain Interference improved significantly in males and Discrimination in white respondents (Table 2). No changes were observed in disease activity, disease damage, insurance, or poverty status.

Table 1. Descriptive Characteristics Among Georgians Organized Against Lupus (GOAL) Cohort Patients Before the COVID-19 Pandemic, 2018-2019

Category	Characteristic	Result (n=316)
Demographics	Race, n (%)

SD=standard deviation; P-values in bold are <0.05

Conclusion: We expected to see worsening in most measures among patients with SLE early in the COVID-19 pandemic, so the absence of deterioration and even minor improvements is notable and may be explained by several hypotheses. These findings may reflect baseline severity of many outcomes for people with SLE. The study period was early in the pandemic, so potential negative financial pressures may not have been fully realized and may have been mitigated by economic impact payments from acute policy measures. Many negative consequences of living with SLE (isolation, reduced activity, anxiety, and fear of stigma) became a reality for the general population. This may have made those with SLE feel closer to the norm while limiting opportunities for certain negative experiences, including discrimination. Importantly, longer-term impacts of the pandemic may reverse these findings and ultimately lead to more severe negative outcomes, requiring continued close study.

SESSION INFORMATION

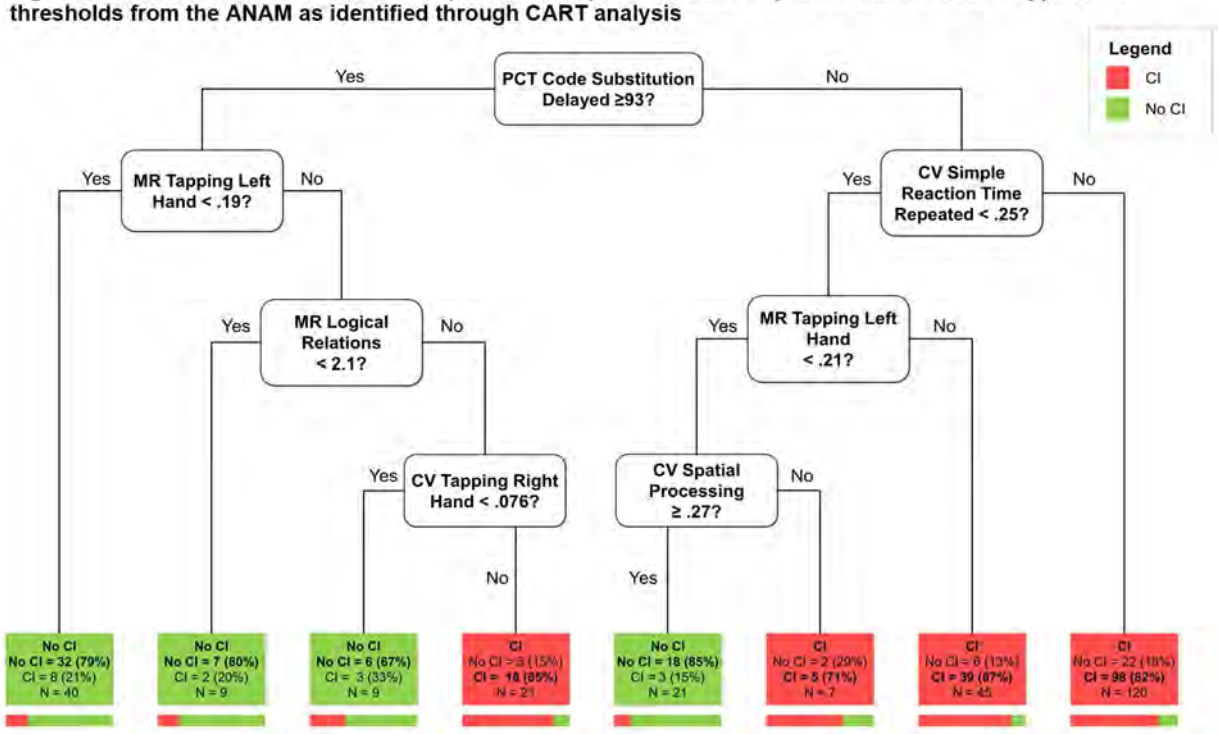
Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Figure 1. Decision tree of the best model (PCT, MR, CV) and the most important subtests, scoretypes and thresholds from the ANAM as identified through CART analysis

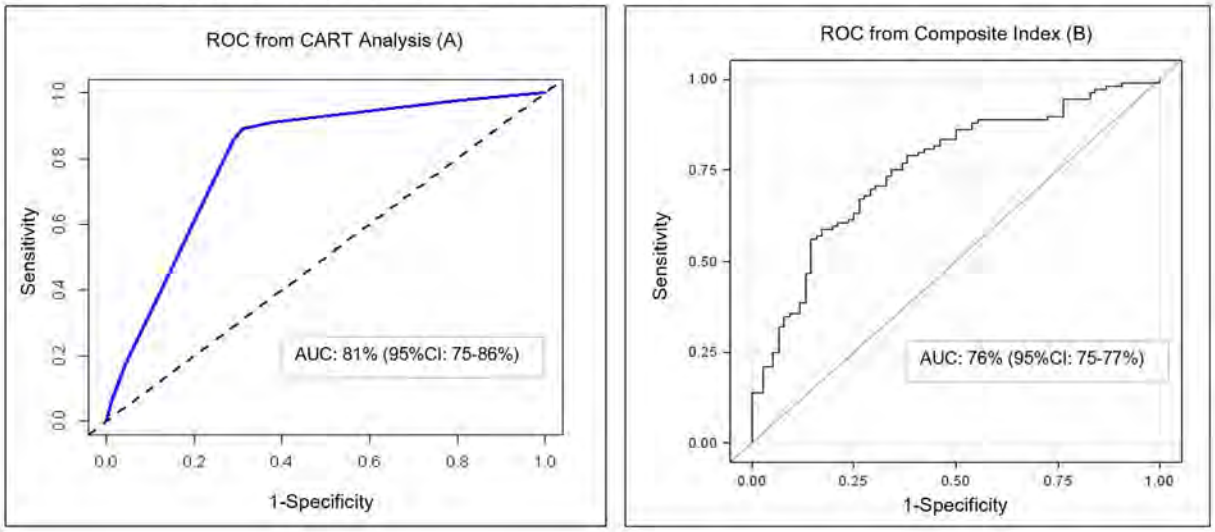


CI: cognitive impairment; PCT: percentage correct responses; MR: mean reaction time; CV: coefficient of variation of mean reaction time; TP: throughput For most of the ANAM tests, there are 4 score types provided. PCT represents accuracy. MR represents the average reaction time. TP is a measure of cognitive efficiency and is derived as the number of correct responses per minute. CV is an index of the patient's consistency of response speed within a given timed subtest. It is a derived score (standard deviation of MR divided by MR). Better cognitive performance is indicated by higher PCT and TP scores, and lower MR and CV scores. Code substitution delayed measures delayed memory and requires the participant to compare a symbol-digit pair with previously defined and memorized symbol-digit pairs. The participant presses designated buttons to indicate whether the pair was correct or incorrect based on their memory. Tapping left hand and tapping right hand measure motor skill and reaction time. The participant is required to press the spacebar with the designated hand as many times as possible in a single trial. Simple reaction time repeated measures reaction time and requires the participant to respond as quickly as possible to a target stimulus. The "repeated" session is administered later in the battery and is also designed to measure fatigue. Logical relations measures abstract reasoning and verbal fluency whereby the participant evaluates the truth of statements and describes the order of two symbols displayed on the screen. Spatial processing measures visual spatial skills whereby the participant compares two histograms displayed side-by-side in different orientations.

Background/Purpose: Cognitive impairment (CI) is common in systemic lupus erythematosus (SLE) patients, however there is no standard screening tool available. The American College of Rheumatology Neuropsychological Battery (ACR-NB) is the gold standard diagnostic tool but requires trained personnel and 1-hour to complete. The Automated Neuropsychological Assessment Metrics (ANAM) is a promising screening tool as it is a shorter, self-administered battery. We previously developed a composite index for interpreting ANAM, and in this study we aimed to provide further evidence on the construct validity of the ANAM as a screening tool for detecting CI in SLE compared to ACR-NB. Objectives: 1) to determine the best subtests and score types of ANAM to predict CI using Classification and Regression Tree (CART) analysis, 2) provide a new approach for interpreting ANAM results, and 3) compare the performance of ANAM composite index to the best CART model.

Methods: 300 consecutive consenting adult SLE patients attending a single center between 2016 and 2019 completed the ANAM and ACR-NB on the same day. Patients were classified CI or non-CI based on ACR-NB. CI was defined by a z-score of ≤-1.5 in ≥ 2 domains; non-CI if no domain had a z-score of ≤-1.5. ANAM has 15 subtests with each test comprising different score types (percentage of correct responses [PCT], mean reaction time [MR],

Figure 2. Receiver operating characteristic (ROC) curve of the best model (PCT, MR, CV) from CART Analysis (A) and Composite Index (B) for identifying cognitive impairment compared to ACR-NB



CART: Classification and Regression Tree; AUC: Area under the curve; PCT: Percentage of correct responses; MR: Mean reaction time; CV: Coefficient of variation The ROC curve of the best model (PCT, MR, CV) from CART analysis reported an AUC of 81% compared to ACR-NB. The composite index formula (which was derived using logistic regression from our previous study) based on the model with PCT, MR, CV was applied to the current dataset and reported an AUC of 76% compared to ACR-NB.

throughput [TP], and coefficient of variation [CV]). We built 6 models including all subtests, but each model included a different set of score types. Each model was run through CART analyses with k-fold cross validation. The data was split into k-subsets (k=10). Each subset randomly selected 90% of patients as training data and 10% as testing data, repeated 3 times. A decision tree was generated for each model separating patients into CI or non-CI based on ANAM subtests, score types, and thresholds that best predict CI. We hypothesized ANAM would identify CI with good Area Under the Receiver Operating Characteristics (ROC) curves (AUC = 0.71-0.80) and a sensitivity ≥ 80%. The performance of the best CART model was compared to ANAM composite index using ROC analysis and kappa statistic. Composite Index: 3.88-0.05*Code Substitution Delayed$_{PCT}$ - 8.4*Spatial Processing$_{CV}$ + 2.44*Code Substitution Learning$_{MR}$ + 9.87*Tapping Left$_{MR.}$

Results: 145 patients were defined as CI and 90 as non-CI based on ACR-NB. The best model included 6 ANAM subtests and PCT, MR, CV score types (**Figure 1**), with 89% sensitivity, 69% specificity, AUC of 81% (95% confidence interval: 75-86%), 81% accuracy, 82% positive predictive value, and 79% negative predictive value compared to ACR-NB. The most important subtests, score types, and thresholds were displayed in a decision tree (**Figure 1**). Concordance between the best CART model and ANAM composite index was 74%, κ = 0.48 (95% confidence interval: 0.37-0.59) (**Figure 2**).

Conclusion: Our findings extend the evidence on the construct validity of the ANAM as a screening tool for CI in SLE patients. Good concordance was found between the ANAM composite index and best CART model. Six most important subtests and scores for detecting CI from the ANAM were identified. A decision tree was generated to simplify the interpretation of ANAM and enhance clinical utility.

Abstract Number: 1277

Low Cost Composite Markers to Differentiate Infection from Disease Activity in a Febrile Patient with Systemic Lupus Erythematosus

Pankti Mehta[1], Komal Singh[1], Amita Aggarwal[1] and Seema Sharma[1], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) are at an increased risk of infection owing to immunosuppressive therapy along with coexistent immune dysregulation. It is often difficult to differentiate between infection and disease activity in a patient with SLE who presents with fever. Though many markers have been studied, markers like procalcitonin, which has high specificity, are expensive and not available in resource poor countries. Thus, we planned to see if low cost markers can be useful to differentiate infection from disease flare in a patient of SLE with fever.

Methods: Patients with SLE (SLICC criteria) presenting with fever of more than 48 hours duration, from December 2018 to February 2020 were included in the study. Detailed history, clinical examination and investigations were done to assess for infection. In addition, neutrophil to lymphocyte ratio (N/L), neut-x, y, z indices[1], Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), C3, C4, anti-dsDNA antibodies and procalcitonin levels were measured.

Table 1: Comparative analysis of variables between those with infection and disease activity

	Infection, n= 12	Disease Flare, n= 22	p
Age, years	29.5 (21.5-39.25)	22 (19.5-30)	0.12
Gender, female	11	20	0.7
Disease duration (months)	24(4.5-18.75)	18 (7.5-42)	0.8
Steroids >7.5 mg	8 (66.7%)	10 (45.4%)	0.3
Steroid sparing drug	9 (75%)	6 (27.3%)	0.01* OR8, 95% CI (1.6-39.9)
Duration of fever, days	7.5 (4.5-18.75)	15(6-21)	0.4
SLEDAI 2K	6.5 (2-13.75)	12 (5.5-18)	0.2
N/L ratio	6.8(3.1-11.25)	3.5(2.35-5.27)	0.04*
Neutrophil-x	130.9 (126.9-137.5)	126 (123-129)	0.01*
Neutrophil-y	50.15 (47-52.18)	44.5 (43-49.25)	0.04*
Neutrophil-z	141.5 (136.3-146.8)	134.7 (131.1-139.4)	0.02*
Anti-dsDNA	10 (10-58.5)	232.4 (48.7-300)	0.002*
C3, mg/dl	87 (71.8-128)	53.1 (41.5-95.8)	0.02*
C4, mg/dl	30.8 (15.5-40.6)	11.7 (9.2-16.8)	0.0001*
ESR, mm/hour	102.5(47.8-127.5)	98 (60-125.5)	0.9
CRP, mg/dl	4.1 (2.13-11.5)	0.99 (0.5-3.7)	0.03*
ESR/CRP ratio	26.5 (6.9-38.4)	67.78(24.5-167.4)	0.02*
MRP 8/14, IU/L	72.5 (29.9-121.9)	41.9 917.4-82)	0.12
CD 64 %	95.75 (88.9-99.1)	82.1 (63.2-98.1)	0.2

CRP- C Reactive Protein, dsDNA- double stranded Deoxy Ribonucleic Acid, N/L- Neutrophil to Lymphocyte, SLEDAI 2K- Systemic Lupus Erythematosus Disease Activity Index 2000

Table 1. Comparative analysis of variables between those with infection and disease activity

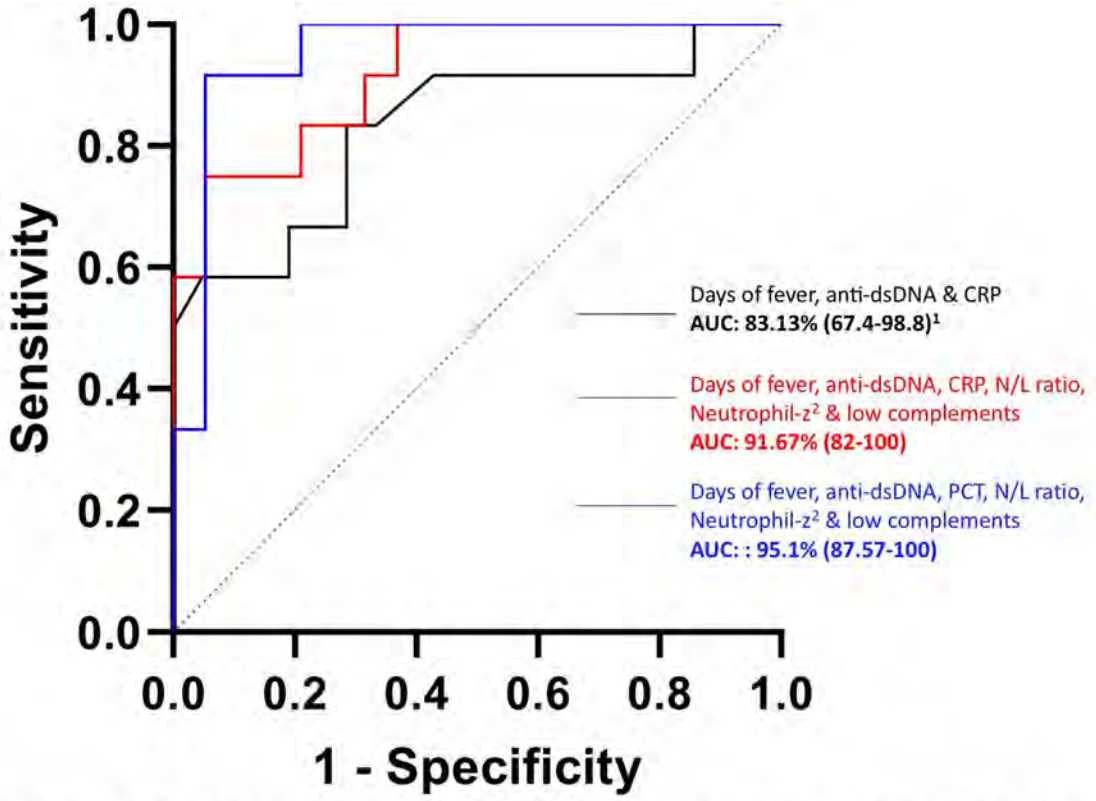

Figure 1: ROC curves demonstrating the composite of various variables used to determine infection

ROC- Receiver Operator Curve, CRP- C Reactive Protein, dsDNA- double stranded Deoxy Ribonucleic Acid, N/L- Neutrophil to Lymphocyte ratio, PCT- Procalcitonin. References, 1. Luo Y, Lin J, Chen H, Zhang J, Peng S, Kuang M. Utility of neut-X, neut-Y and neut-Z parameters for rapidly assessing sepsis in tumor patients. Clinica Chimica Acta. 2013 Jun 25;422:5-9.
2. Beça S, et al, Development and validation of a risk calculator to differentiate flares from infections in systemic lupus erythematosus patients with fever, Autoimmun Rev (2015)

Figure 1. ROC curves demonstrating the composite of various variables used to determine infection

Neut-x and y indices are parameters obtained by objective evaluation of toxic granulation and the nuclear maturity of neutrophils by the Sysmex counter and Neut-z refers to the vector sum of the two.

Based on clinical assessment and laboratory data, fever episode was classified as infection, disease flare or both. The differences in variables between infection episode and disease flare were analyzed using Mann Whitney-U test for continuous and chi-square for categorical variables respectively, Binary logistic regression and ROC for multivariate analysis were used for analysis. In addition, a previously proposed low-cost calculator by Beca etal[2]was also validated and improved upon by addition of other variables.

Results: 42 episodes of fever were seen in 40 patients with SLE, and among these 18 were due to infection, 22 were related to disease activity and in 2 both infection and disease activity contributed to fever. The median age of the patients was 26.5 years with 90% being women. Two-thirds had a major organ involvement, distributed equally across the groups. Six patients with tuberculosis, viral and fungal infection were excluded from further analysis. High anti-dsDNA (p=0.002) and low complements(C3, p=0.02 and C4, p=0.0001) were characteristic of disease flare whereas high N/L ratio (p=0.04), high Neut-x (p=0.01), -y (p=0.04), -z (p=0.02), CRP (p=0.03), low ESR to CRP ratio (p=0.02) and high procalcitonin (p=0.0001) were seen with infection.

Using the 3 variables suggested by Beca etal i.e. days of fever, anti-dsDNA antibody and CRP the ROC curve had an area under curve (AUC) of 0.81 which increased to 0.91 when low complement levels, N/L ratio and Neut-z was added to this model. Replacing CRP with procalcitonin had higher AUC but it increased the cost.

Conclusion: A composite score oflow cost and routinely available parameters like days of fever, anti-dsDNA, low C3/C4, neutrophil to lymphocyte ratio and Neut-z gives a good discrimination between infection and flare in a febrile patient with SLE.

Abstract Number: 1278

Does Co-existing Systemic Lupus Erythematosus Affect Outcomes of Hospitalizations for Ischemic Stroke?

Ehizogie Edigin[1], Precious Eseaton[2], Pius Ojemolon[3] and Augustine Manadan[4], [1]John H Stroger Jr. Hospital of Cook County, Chicago, IL, [2]University of Benin Teaching Hospital, Benin, [3]St. George's University, St. George's, Grenada, [4]Cook County Hospital/Rush University Medical center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Various studies have shown that individuals with Systemic Lupus Erythematosus (SLE) have a higher risk of stroke and cerebrovascular events than the general population. These events represent a significant cause of death in SLE patients. It is however unclear if SLE patients who develop cerebrovascular events have different outcomes compared to stroke patients without SLE. The aim of this study is to compare the outcomes of patients primarily admitted for ischemic stroke with and without a secondary diagnosis of SLE.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. This database is the largest collection of inpatient hospitalization data in the United States (U.S). The NIS was searched for hospitalizations for adult patients with ischemic stroke as principal diagnosis with and without SLE as secondary diagnosis using ICD-10 codes. The primary outcome was inpatient mortality. Hospital length of stay (LOS), total hospital charges, odds of receiving tissue plasminogen activator (TPA), and mechanical thrombectomy were secondary outcomes of interest. Multivariate logistic and linear regression analysis was used accordingly to adjust for confounders. Confounders adjusted for include age, sex, Charleston co-morbidity index, and cardiovascular comorbidities. STATA software was used to analyze the data.

Results: There were over 71 million discharges included in the combined 2016 and 2017 NIS database. Out of 525,570 patients with ischemic stroke, 2,280 (0.43%) had SLE. SLE group was younger (58 vs 70 years, P< 0.0001) and had more females (83% vs 50%, P< 0.0001). The adjusted odds ratio (AOR) for inpatient mortality for ischemic stroke with co-existing SLE compared to without co-existing SLE was 0.95 (95% CI 0.58-1.54, P=0.824). Hospitalizations for ischemic stroke with co-existing SLE had higher mean total hospital charges ($80,306 vs $70,157, P=0.019) and less odds of receiving TPA (OR: 0.61, 95% CI 0.41-0.90, P=0.012) compared to those without co-existing SLE.

Conclusion: Patients admitted primarily for ischemic stroke with a secondary diagnosis of SLE had similar inpatient mortality, more total hospital charges, and less likelihood of receiving TPA compared to those without SLE. LOS and

	Stroke with SLE (n=2,280)	Stroke without SLE (n=523,290)	Adjusted OR	P-value
	% (95% CI)	% (95% CI)	(95% CI)	
Primary outcome				
In-hospital mortality	4.61 (3.03-6.94)	5.53 (5.36-5.70)	0.95 (0.58-1.54)	0.824
Secondary outcomes				
TPA	7.02 (5.02-9.72)	9.30 (9.08-9.54)	0.61 (0.41-0.90)	0.012*
Mechanical thrombectomy	6.14 (4.29-8.71)	5.05 (4.76-5.37)	0.75 (0.49-1.14)	0.179
			Adjusted mean difference	
LOS, mean (SE), days	7.10 ± 0.69	5.68 ± 0.04	0.10 ({-1.25}-1.46)	0.882
Total charges, mean $	$80,306 \pm 5100$	$70,157 \pm 913$	-10,394 (-{19,091-1,697})	0.019*

Abbreviations: SLE: Systemic Lupus Erythematosus, TPA: Tissue Plasminogen Activator, LOS: Hospital length of stay, OR: Odds Ratio; C.I: Confidence Interval, SE: Standard Error, * Statistically significant

Table 1 Clinical outcomes of ischemic stroke hospitalizations with and without SLE

odds of receiving mechanical thrombectomy were similar between both groups. Though SLE is known to increase the risk of cerebrovascular events, SLE does not negatively affect outcomes of patients primarily admitted for ischemic stroke based on this large U.S hospital database.

Baseline and clinical characteristics of SLE patients with and without COVID-19.

Methods: An observational and descriptive study was conducted, which included patients with SLE from our Rheumatology Department. Clinical data and diagnosis of suspected or confirmed COVID-19 infection were extracted from electronic health records. We registered information about the clinical course of COVID-19 and performed a survey about the impact of the pandemic on the behavior and treatment of our patients.

Results: We included 251 patients with SLE, meeting the SLICC or 2019 ACR/EULAR criteria. 93,2% were women, with a mean age of 48,59 ± 13,25 years. 33 patients (13,1%) were diagnosed with suspected or confirmed COVID-19. Eight patients were confirmed by positive RT-PCR assay in nasopharyngeal swabs or by positive serology tests, while 25 patients were considered suspected cases with compatible clinical findings according to the general practitioner but without microbiological confirmation. The most frequent COVID-19 symptoms were cough (78,8%), fever (51,5%) and diarrhea (36,4%). 3 patients had contact with other SARS-CoV-2 positive individuals. Six patients (18,2%) had high disease activity according to SLEDAI-2K prior to the pandemic. 18,2% had secondary antiphospholipid syndrome. Five subjects (15,2%) attended the emergency department and all of them required hospital admission. One patient was admitted to the intensive care unit. Nine patients (39,4%) received specific treatment for COVID-19. The most frequent antiviral drugs were hydroxychloroquine (24,2%) and azithromycin (21,2%). Three individuals received corticosteroids (9,1%) and one received anti-IL6 (3%). Two patients (6,1%) died due to COVID-19, who were receiving rituximab and mycophenolate mofetil, respectively. We compared the characteristics of SLE patients with and without COVID-19 as shown in the table. The survey was responded by 27 patients. During the current COVID-19

	Suspected/confirmed COVID-19 (n=33)	No COVID-19 (n=218)	p value
Age, years (mean ±SD)	46,52 ±11,70	48,91 ±13,47	0,266

Diabetes	0 (0%)	10 (4,58%)	0,209
Hypertension	9 (27,27%)	48 (22,02%)	0,502
Asthma	3 (9,09%)	4 (1,83%)	0,018
COPD	1 (3,03%)	3 (1,37%)	0,479
Chronic kidney disease	1 (3,03%)	2 (0,92%)	0,298
Hydroxychloroquine	24 (72,72%)	157 (72,69%)	0,996
Prednisone < 10mg per day	12 (36,36%)	77 (35,32%)	0,336
Immunosuppressant therapy	12 (36,36%)	87 (39,91%)	0,698
Cyclophosphamide	0 (0%)	1 (0,46%)	
Azathioprine	4 (12,12%)	21 (9,63%)	
Mycophenolate mofetil	3 (9,09%)	36 (16,51%)	
Methotrexate	4 (12,12%)	28 (12,84%)	
Leflunomide	0 (0%)	1 (0,46%)	
Cyclosporine	0 (0%)	2 (0,92%)	
Tacrolimus	1 (3,03%)	5 (2,29%)	
Everolimus	1 (3,03%)	0 (0%)	
Biological therapy	6 (18,75%)	12 (5,51%)	0,007
Rituximab	2 (6,06%)	5 (2,29%)	
Belimumab	4 (12,12%)	6 (2,75%)	
ACE inhibitors	6 (18,18%)	23 (10,60%)	0,205
Angiotensin II receptor blockers	4 (12,12%)	26 (11,98%)	0,982

Baseline and clinical characteristics of SLE patients with and without COVID-19.

pandemic, 63% lived with their families with a median of 3 people (IQR 2-4), while 18,5% lived alone. 74,1% did complete lockdown and 18,5% occasionally left home interacting with other people. 55,5% had telematic follow-up by our Rheumatology department. Regarding rheumatological therapy, 74,1% maintained their usual treatment, 7,4% discontinued biological therapy and 3,7% completely interrupted their current treatment. 63% defined their rheumatic disease as stable whereas 37% experienced more flares during the period under review.

Conclusion: Despite the limited number of patients in our series, there does not appear to be an increased frequency of SARS-CoV-2 in SLE patients. A higher proportion of patients with biological treatment and a history of asthma was found among those who presented suspicious symptoms of COVID-19. This pandemic has had a major impact on the behavior and treatment of our patients; therefore, we emphasize the importance of encouraging patients to maintain current treatment and reinforce preventive measures.

COVID-19 Infections May Increase the Risk of SLE Flares

Leila Khalili[1], Yevgeniya Gartshteyn[2], Nancyanne Schmidt[3], Teja Kapoor[4], Laura Geraldino-Pardilla[5] and Anca Askanase[3], [1]Columbia University Medical Center, New York, NY, [2]Columbia University College of Physicians and Surgeons, Glen Rock, NJ, [3]Columbia University College of Physicians and Surgeons, New York, NY, [4]Columbia University College of Physicians and Surgeons, Leonia, NJ, [5]Division of Rheumatology, Columbia University Vagelos College of Physicians and Surgeons, New York

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 has overwhelmed the healthcare systems in New York City. Initial data from the Columbia Lupus Cohort suggests that 4% of patients with systemic lupus erythematosus (SLE) developed symptomatic COVID-19 infection, compared to the community transmission of 2% in New York City (Gartshteyn et al., 2020). There is no data about the impact of COVID on disease activity in SLE.

Methods: This study updates the earlier data with newly identified patients with SLE and COVID and describes post infection flares.

Results: From our cohort of 450 patients we identified and treated 27 SLE patients with COVID-19 infections (6%): 8 patients were hospitalized, 8 patients with confirmed infections were treated in an outpatient setting, and 11 patients with symptoms highly suggestive of COVID-19 were also treated as outpatient. Of the 16 confirmed cases, 12 patients had positive SARS-CoV-2 RT-PCR nasopharyngeal swabs and 4 patients had positive anti-SARS-CoV-2 antibodies.

77.8% of patients were female, mean age 40 ±10, 55.6% were Hispanic, 33.3% were Black, 3.7% were Asian, 7.4% were Caucasian, 81.5% of patients were taking antimalarials (hydroxychloroquine or chloroquine), 66.7% were taking non-biologic immunosuppressants, 11.1% had been treated with rituximab in the last 6 months, and 22.2% were either on prednisone or had taken prednisone within a week of their diagnosis. Their COVID-19 symptoms included fever (85.2%), myalgia (22.2%), cough (55.6%), shortness of breath (37%), chest pain (18.5%), and anosmia (7.4%).

Out of the 8 hospitalized patients 3 were critically ill with severe hypoxemic respiratory failure, one required mechanical ventilation. All received empiric antibiotics, 3 received high-dose IV methylprednisolone and tocilizumab. One non-critically ill patient required supplemental oxygen via nasal cannula. All hospitalized patients survived and were discharged (2 to acute rehab). Of the 19 SLE patients treated outpatient, 7 (36.8%) received azithromycin as treatment for COVID-19, 3 were prescribed aspirin for empiric thromboprophylaxis, and one patient not already on HCQ, received a 5 day course of HCQ. All had resolution of symptoms without further escalation of care. Hospitalized patients were less likely to be taking HCQ at the time of COVID diagnosis compared to those treated as outpatient (p=0.04). No other SLE treatment differences were identified between the groups.

Of the 27 patients, 6 (22.2%) experienced an SLE disease activity flare within 22 days post-COVID (range 3-49 days). Of the 6 flares, 5 were mild/moderate and 1 severe using the SELENA Flare Index (SFI) definitions. The flare symptoms included arthritis -5, alopecia -2, low C3/C4 -3, positive dsDNA -2, rash -1 and pleurisy -1.

Table 1. Demographics and Medications for patients with COVID-19 and SLE

	CONFIRMED (N=16)		CLINICALLY SUSPECTED (N=11)
	HOSPITALIZED (N=8)	OUTPATIENT (N=8)	OUTPATIENT (N=11)

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: One in four Medicare hospitalizations with systemic lupus erythematosus (SLE) results in readmission within 30 days, with "injuries and poisonings" as the second most common cause. This finding, which could be driven by opioid use, coupled with a recent study reporting that as many as 31% of patients with lupus received at least one opioid prescription in a year (Sommers 2019), raised new questions as to whether a focus on opioids could inform mechanistic-focused readmission reduction strategies. To begin to test the strength of this premise, we examined the extent to which prior opioid-related encounters in the baseline year predicted risk for 30-day readmission.

Methods: One in four Medicare hospitalizations with systemic lupus erythematosus (SLE) results in readmission within 30 days, with "injuries and poisonings" as the second most common cause. This finding, which could be driven by opioid use, coupled with a recent study reporting that as many as 31% of patients with lupus received at least one opioid prescription in a year (Sommers 2019), raised new questions as to whether a focus on opioids could inform mechanistic-focused readmission reduction strategies. To begin to test the strength of this premise, we examined the extent to which prior opioid-related encounters in the baseline year predicted risk for 30-day readmission.

Results: Table 1 shows that compared to the overall Medicare admissions cohort, the SLE cohort (n=23,309) was younger, and more often female, Black, disabled or on Medicaid, or had end stage renal disease (ESRD). In SLE, those with prior opioid-related codes were younger and more often female or receiving Medicaid or disability. Readmissions occurred in 18% of overall Medicare and 24% of SLE admissions. In SLE, observed readmission rates were 10% higher among those with opioid history (33% vs 23%, $p< .001$). The SLE group was over twice as likely as the overall Medicare group to have had opioid-related encounters in the prior year (9.0% vs 4.1%, $p< .001$; Table 2). Opioid-related codes were highest in the youngest SLE group; 25% of admissions of 18-32 year olds had prior opioid-related encounters (vs. 20% in Medicare cohort, $p< .001$).

Adjusted multivariable models showed 20% higher odds of readmission (aOR 1.201 (1.041, 1.384)) with opioid history (Table 3). This was similar in magnitude to an increase in composite comorbidity (HCC aOR 1.199 (1.180, 1.218)), and slightly less than ESRD (ESRD aOR 1.294 (1.122, 1.491)).

Limitations include the absence of Medicare Part D pharmacy claims to further examine opioid history, thus rates may not reflect actual opioid use.

Medical school affiliation		1.119 (1.034, 1.211)	1.009 (0.930, 1.094)

Conclusion: Hospitalized Medicare beneficiaries with SLE were twice as likely to have prior opioid-related encounters, and exposure to these opioid-related encounters was associated with a substantially increased readmission risk even after adjusting for comorbidities. Future studies should investigate readmission reduction interventions to help SLE patients with opioid histories.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Although there is abundant literature on healthcare utilization in SLE patients, the impact of disease activity in SLE patients is not well understood.

To quantify the impact of disease activity, as measured by SLEDAI score and drug burden, in SLE patients on health care resource utilization (HCRU), health related quality of life (HRQoL) and work productivity (WP).

Methods: Data were collected from a cross-sectional survey of 300 rheumatologists completing 752 patient record forms in US and EU5 from the Adelphi Real World 2010 & 2013 Lupus Disease Specific Programmes (DSP). Physicians were asked to complete patient record forms (PRFs) for the next 5 prospectively consulting SLE patients; the same patients were asked to complete patient self-completion (PSC) forms describing how SLE affected them. PRFs collected data pertaining to the patient's diagnosis, disease history, current clinical outcomes, treatment and management history. PSCs focused on similar data collection and included patient reported outcome measures (PROs). Propensity score matching was used to assess differences in HCRU and PRO scores between SLE patients who had a low disease activity and those who had a high disease activity. Low disease activity was defined as a SLEDAI score of ≤4, a steroid dose of < 7.5mg/day, and not on immunosuppressant or biologic. High disease activity was a

Table 1 Demographic data

Variable	Low disease activity	High disease activity
Mean age (years)	38.1	40.0
% Female	90.7	88.2
% White/Caucasian	76.7	67.7
Mean years diagnosed	5.5	5.0

Table 2 Propensity score matching results

Outcome variable	Low activity mean	High activity mean	Coefficient	95% CI	p-value
Flared in the last 12 months	11.63	37.97	-0.26	[-0.38 – -0.14]	<0.001
Number of flares in last 12 months	0.21	0.70	-0.49	[-0.72 – -0.26]	<0.001
Hospitalized in last 12 months	4.65	14.98	-0.10	[-0.17 – -0.04]	0.001
Number of consults in last 12 months	2.84	3.52	-0.68	[-1.19 – -0.17]	0.009
EQ-5D-3L	0.88	0.78	0.10	[0.03 – 0.17]	0.004
FACIT Fatigue	39.86	34.68	5.19	[0.80 – 9.57]	0.02
WPAI overall percentage work impairment	14.42	45.35	-30.93	[-45.32 – -16.54]	<0.001

SLEDAI score of >4, or on an immunosuppressant, biologic, or steroid dose of >7.5mg/day. Patients were matched on age, sex, and ethnicity.

Results: Data was extracted from 752 PRFs, and 388 PSCs. Using the estimated propensity score each low disease activity patient (n=43) was matched with a high disease activity patient (n=709). Using 1:1 matching, with replacement and allowing for ties, matching resulted in 257 high disease activity patients being used as matches for 43 low disease activity patients. Demographic data are reported in Table 1. Patients with a low disease activity were significantly less likely to be currently flaring, lower number of flares in last 12 months, less likely to have been hospitalized in the last 12 months, had fewer consultations in the last 12 months, reported better HrQoL (EQ5D), more favourable levels of fatigue (FACIT), and lower work impairment (WPAI). (Table 2).

Conclusion: Systemic lupus erythematosus patients with lower levels of disease activity are less burdensome to the healthcare system and experience a significantly better HRQoL and lower levels of productivity impairment. There is a need to establish a universal definition of low disease activity as a treatment goal to benefit patient quality of life and reduce HCRU.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The mortality in Systemic Lupus Erythematosus (SLE) varies largely across different countries most probably due to social, healthcare and ethnic differences.

To analyze the causes and identify predictive factors of mortality of SLE in Spain in the present century.

Methods: We performed a cross-sectional and retrospective study analyzing data from the RELESSER cohort (Spanish Registry of Systemic Lupus Erythematosus of the Spanish Society of Rheumatology). We included all patients diagnosed with SLE since the year 2000 and recorded sociodemographic, clinical and serological variables, comorbidities and treatments, as well as indicators of disease activity, damage and severity. The characteristics of the deceased patients were compared with those of the survivors, and variables with clinical significance or statistical significance were grouped into multivariate models to determine which ones were independently associated with the outcome of the disease.

Results: A total of 2004 patients were included, 88.6% female, the mean age at diagnosis was 38.3 (± 15.3) years, with a mean delay in diagnosis of 28.9 (± 52.6) months. Up to 2.84% of the individuals had died. The leading cause of death was SLE activity (n=16), followed by infections (n=14), vascular events (n=12) and cancer (n=6). The mean age of death was 54.68 (± 20.13) years, and neither age, sex nor delay in diagnosis was independently associated

Table 1. Summary Multivariate Statistical Analysis

with mortality. The presence of nephritis, depression, severe infections, organ damage (SLICC/ACR DI) or disease activity (SLEDAI), as well as the use of cyclophosphamide, rituximab or high doses of corticosteroids, were predictors of mortality in our cohort. Antimalarial treatment and skin manifestations were linked to improved survival.

Conclusion: In the RELESSER cohort, clinical factors, co-morbidities, as well as therapeutic attitudes were associated with a significant increase in mortality in SLE. Interestingly, depression was independently associated to mortality. The activity of the disease and infections continue to be the main causes of death at the beginning of the 21st century amongst our patients.

Table 3

Methods: Cross sectional dual energy x-ray absorptiometry (DXA) data from 2 prospective cohorts of women with validated SLE were analyzed. Age, sex, and race/ethnicity-specific ALM index (ALMI, kg/m^2) and FM index (FMI, kg/m^2) Z-scores, as well as fat-adjusted ALMI Z-scores, reflecting the number of standard deviations from average for a given level of adiposity, were generated using National Health and Nutrition Examination Survey reference ranges. Associations between fat-adjusted and unadjusted ALMI Z-Scores, as well as FMI Z-scores, and natural log of Valued Life Activities disability were determined using univariate and multivariate linear regression models and adjusted for

age, race/ethnicity, natural log of high-sensitivity CRP, and study center. A kappa statistic was calculated to assess concordance between low and normal fat-adjusted and unadjusted ALMI scores, with low lean mass for age defined as fat-adjusted or unadjusted ALMI Z-Score ≤-1 (< 16th percentile for reference data).

Results: In the combined cohort of 237 women with SLE, mean unadjusted ALMI, FMI, and fat-adjusted ALMI Z-scores were -0.34, -0.34, and -0.18, respectively, suggesting modest deficits compared to national reference data (Table 1). Although there were significant associations between ALMI Z-score and disability (p=0.05) and separately FMI Z-score and disability (p< 0.001), fat-adjusted ALMI Z-score was not significantly associated with disability (p=0.07) (Table 2). The association of ALMI Z-score with disability was attenuated after adjustment for multiple covariates (p=0.37) while the association of FMI Z-score with disability remained significant (p=0.02). The correspondence between fat-adjusted and unadjusted ALMI definitions of low lean mass for age was fair (κ 0.28, p< 0.001) (Table 3).

Conclusion: Women with SLE had muscle deficits relative to a national reference population without SLE before and after adjustment for adiposity. However, these muscle deficits, unlike fat mass, were not independently associated with self-reported disability. Further study is needed to determine the association of body composition with additional measures of health-related quality of life.

Association of Frailty with Disability Is Not Attenuated by Lean Body Mass in Women with SLE

Sarah Lieber[1], Patricia Katz[2], Joshua Baker[3], Deanna Jannat-Khah[4], Dina Sheira[1] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]University of California, San Francisco, Novato, CA, [3]University of Pennsylvania, Philadelphia, PA, [4]Hospital for Special Surgery, New York City, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty has been associated with disability and mortality in SLE. Whether this association is confounded by sarcopenia, a degenerative loss of muscle mass and quality typically associated with aging, has not been explored. This aim of this study is to evaluate the cross-sectional association of frailty with self-reported disability, adjusting for lean body mass.

Methods: Adult women with validated SLE and mild/moderate disease were recruited from 2 centers. Frailty and pre-frailty were measured according to Fried frailty criteria (unintended weight loss, weakness, slow gait, poor endurance, inactivity) and disability according to Valued Life Activities. Dual energy x-ray absorptiometry was used to compute sarcopenia based on 2 definitions (Foundation for the National Institutes of Health Biomarkers Consortium Sarcopenia Project [1] and European Working Group on Sarcopenia in Older People 2 [2]) incorporating measures of muscle strength and quantity. Associations between frailty and disability were determined using univariate and multivariate linear regression models adjusted for age, race/ethnicity, SLE duration, current steroid use, high-sensitivity CRP (hsCRP), and 2 measures of lean body mass, appendicular lean mass index (ALMI) and adiposity-adjusted ALMI

Table 1

Z-score, reflecting the number of standard deviations from average for a given level of adiposity using National Health and Nutrition Examination Survey reference ranges.

Results: In the combined cohort of 210 women with SLE, 20% of participants were frail and 58% were pre-frail (Table 1). Frail women were significantly older (p=0.05), with lesser educational attainment (p=0.02), greater disease activity (p< 0.001), more damage (p=0.04 for SLICC/ACR Damage Index; p< 0.001 for Brief Index of Lupus Damage), higher hsCRP (p=0.01), and more frequent steroid use (p=0.01) and cigarette smoking (p=0.02). Sarcopenia was more prevalent among frail women with SLE as compared to pre-frail and non-frail women according to both definitions (p<

Table 2. Associations between frailty and disability in unadjusted and adjusted linear regressions

	Frailty classification	ß coefficient	95% confidence interval	p-value
Unadjusted	Frail	0.93	0.72, 1.14	<0.001

	Pre-frail	0.43	0.23, 0.63	<0.001

All adjusted models controlled for age, race/ethnicity, disease duration, current steroid usage, and high-sensitivity CRP.
*ALMI Z-score: Appendicular lean mass index.
***$ALMI_{FMI}$ Z-score: Adiposity-adjusted appendicular lean mass index Z-score. More negative reflects greater fat-adjusted muscle mass deficit relative to the general population.

Table 2

0.001). There was a significant dose-dependent association between frailty and pre-frailty and disability ($p< 0.001$), which was not attenuated after adjustment for multiple confounders and either measure of lean body mass (Table 2).

Conclusion: Frailty was significantly associated with disability. Sarcopenia was more common among frail than pre-frail and non-frail women with SLE. The association of frailty with disability was not attenuated by multiple covariates, including lean body mass. These data suggest that frailty is a distinct phenotype not fully described by direct measures of low muscle mass. Further study is needed to determine the relative contributions of frailty and sarcopenia to other adverse health outcomes in SLE.

Personalizing Cardiovascular Risk Prediction for Patients with Systemic Lupus Erythematosus by Physician Global Assessment of Disease Activity

May Choi[1], Emma Stevens[2], Hongshu Guan[2], Daniel Li[3], Jack Ellrodt[4], Benjamin Kargere[4], Tianrun Cai[2], Kazuki Yoshida[5], Brendan Everett[2] and Karen Costenbader[6], [1]Brigham and Women's Hospital | Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard, Columbus, OH, [4]Williams College, Williamstown, [5]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of cardiovascular disease (CVD), including myocardial infarction and stroke, is higher in SLE than in the general population. The excess risk of premature CVD has been attributed to SLE-related systemic inflammation and its treatment. CVD risk prediction algorithms perform poorly in SLE populations because they do not capture SLE-related inflammation. The purpose of this study was to quantify the excess CVD risk, beyond that predicted by a traditional risk calculator, in strata of patients defined as mild/remission, moderate or severe SLE by the Physical Global Assessment (PGA) of disease activity.

Methods: We included SLE patients enrolled in a local SLE cohort and collected their one-year baseline data on traditional CVD risk factors, demographic and clinical features from the electronic medical record (EMR) at cohort enrollment. Subjects were required to have one or more visits for SLE during the baseline period. Their overall disease activity representing all encounters during the entire baseline year was rated independently by two reviewers (KC and MC) using a modified PGA tool (**Table 1**). PGA scores ranged from 1 (remission/mild), 2 (moderate), to 3 (severe). A 10-year follow-up period for CVD events began day +1 at end of baseline period (index date). The first MI or stroke in the follow-up period was identified in the EMR using ICD-9/10 codes and adjudicated by medical record

Table 1. Modified SLE Physician Global Assessment definitions generated using the European League Against Rheumatism (EULAR) SLE management guideline[1] and the SLE disease severity algorithm that was developed for claims data[2]

Score	Disease Activity	Keyword in Visit Notes[2]	EULAR Definition of Disease Activity[1]	Medications
1	Remission or mild	"Remission", "quiescent", "burnt out", "mild", "low activity"	Constitutional symptoms/mild arthritis/rash ≤9% BSA/PLTs 50-100 x $10^3/mm^3$; SLEDAI ≤6; BILAG C or ≤1 BILAG manifestation	No SLE medication or low-dose anti-malarial, low-dose steroids, anti-malarial, NSAID, stable dose of DMARD
2	Moderate	"Moderate"	RA-like arthritis/rash 9-18% BSA/cutaneous vasculitis ≤18% BSA; PLTs 20-50 x $10^3/mm^3$; SLEDAI 7-12; ≥2 BILAG B manifestations	Moderate dose steroids, biologics, multiple/escalating dose of DMARDs
3	Severe	"Severe"	Major organ threatening disease (nephritis, cerebritis, myelitis, pneumonitis, mesenteric vasculitis; PLTs <20 x $10^3/mm^3$, TTP-like disease or acute hemophagocytic syndrome; SLEDAI >12; ≥1 BILAG A manifestations	High dose/pulse steroids, cyclophosphamide, plasmapheresis

Table 2. Baseline characteristics and cardiovascular disease (CVD) risk factors in patients with SLE with and without CVD outcome events (myocardial infarction or stroke)

Baseline Characteristic	With CVD event n= 212	Without CVD event n=1,031	P*
SLE disease duration in years, mean (SD)	13.8 (10.9)	10.0 (8.3)	<0.0001
Age in years, mean (SD)	47.8 (14.6)	40.3 (12.7)	<0.001
Female, n (%)	196 (92.5)	960 (93.1)	0.73
Treated Systolic BP in mmHg, mean (SD)	131.6 (25.5)	124.4 (17.9)	0.001
Untreated Systolic BP in mmHg, mean (SD)	125.6 (14.9)	118.5 (15.2)	0.0001
Current smoker, n (%)	30 (14.2)	124 (12.0)	0.39
Diabetes mellitus, n (%)	26 (12.3)	60 (5.8)	<0.001
Total cholesterol in mg/dL, mean (SD)	195.2 (91.3)	179.1 (43.1)	0.004
High-density lipoprotein cholesterol in mg/dL, mean (SD)	55.5 (18.3)	55.8 (20.3)	0.90
Physician Global Assessment			
Remission/mild	162 (76.4)	841 (81.6)	0.12
Moderate	23 (10.9)	88 (8.5)	0.72
Severe	27 (12.7)	102 (9.9)	0.67

* Two-tailed P value for t-test and Fisher's exact test, for continuous and binary risk factors, respectively.
Abbreviations: BP, blood pressure; SD, standard deviation

review. We excluded subjects with CVD events prior to the index date. Relative excess risk of CVD event in 10 years was determined by comparing the risk expected according to the 2013 American College of Cardiology (ACC) and the American Heart Association (AHA) risk equation and to the observed outcomes, stratified by PGA. The Greenwood-Nam-D'Agostino calibration test was used to compare observed to expected in each PGA category.

Results: We included 1243 patients; 93.0% female and mean age of 41.6 (SD 13.3) years (**Table 2**). 80.6% patients had remission/mild disease, while 8.9% had moderate and 10.3% had severe disease. Inter-rater agreement of PGA's was substantial with 93.5% agreement corresponding to weighted k of 0.75 (SE 0.08, $p< 0.001$), respectively. There were 212 CVD events, 173 MIs and 64 strokes, over the follow-up period of 8242.92 person-years (PY). The incidence rate (IR) for the entire cohort was 26 [22, 29]/1000 patient PY. When stratified by PGA, the IRs were 24 [21, 28] for remission/mild, 32 [22, 49] for moderate, and 35 [24, 51] for severe. The observed vs expected ratio of CVD events using the ACC/AHA risk equation was highest among patients with severe disease (35.93 [95%CI 8.74,72.86]), followed by moderate (16.03 [95%CI 7.59, 26.02]) and remission/mild disease (12.39 [95%CI 7.88,17.00]) (**Table 3**). All calibrations were $p< 0.01$ meaning the calibration of observed events to risk predicted by the ACC/AHA algorithm was significantly off for all PGA categories.

Conclusion: The excess risk of CVD events in SLE patients is underestimated by traditional cardiovascular prediction tools, although the degree of underestimation may be increased in patients with more severe SLE disease activity over the past year. Therefore, more SLE-specific CVD risk prediction algorithms are needed.

Prevalence of Morbidity Prior to Diagnosis of Incident Systemic Lupus Erythematosus in the Danish Population

Julia Simard[1], Mikkel Faurschou[2], Soeren Jacobsen[2] and **Renata Hansen**[2], [1]Stanford Medicine, Stanford, CA, [2]Copenhagen Lupus and Vasculitis Clinic, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE experience a high burden of various comorbidities at disease onset and during disease progression. Studies of excess morbidity prior to SLE diagnosis are limited. We thus estimated the cumulative prevalence of common comorbidities (defined by validated morbidity indices) in incident SLE patients before SLE diagnosis and compared it with matched population comparators in Denmark.

Methods: Patients ≥18years of age with a first registration of SLE (defined by International Classification of Diseases (ICD) codes) from Jan 1, 1996 to July 31, 2018 in the Danish National Patient Register (DNPR), and who had no SLE ICD codes prior to 1996 were identified. For a registration of SLE to qualify for the case definition, it had to be a primary or secondary SLE ICD code from rheumatology, nephrology or dermatology departments (inpatient or outpatient) or a primary SLE ICD code from any inpatient department. The first-ever SLE registration was set as SLE diagnosis date (the index date), and the case definition fulfillment date was used for matching. Patients with >12 months between these dates were excluded. Up to 19 comparators per SLE case, matched by age and sex, were selected from the general population. ICD-coded diagnoses during outpatient and inpatient care were retrieved from the DNPR and DNPR-Psychiatry. To identify comorbid conditions, the initial date of diagnosis from DNPR based on ICD codes or the date of the first prescription filled for osteoporosis, hypertension, or diabetes, were used. We estimated cumulative prevalence and prevalence ratios (PR) with corresponding 95% confidence intervals (CI) of morbidities as defined by Charlson, Elixhauser, and SLICC-ACR damage indices at 10, 5, 2, and 1 year before and at index date in SLE patients and the population comparators, adjusted for age and sex.

Results: 3,010 patients with incident SLE were matched to 57,046 population comparators. 84% of the subjects were female; the mean age at index date was 47 years. Except for malignancy, all morbidities appeared more prevalent 10 years before index date or at index date compared to the population comparators (Table). The PRs were

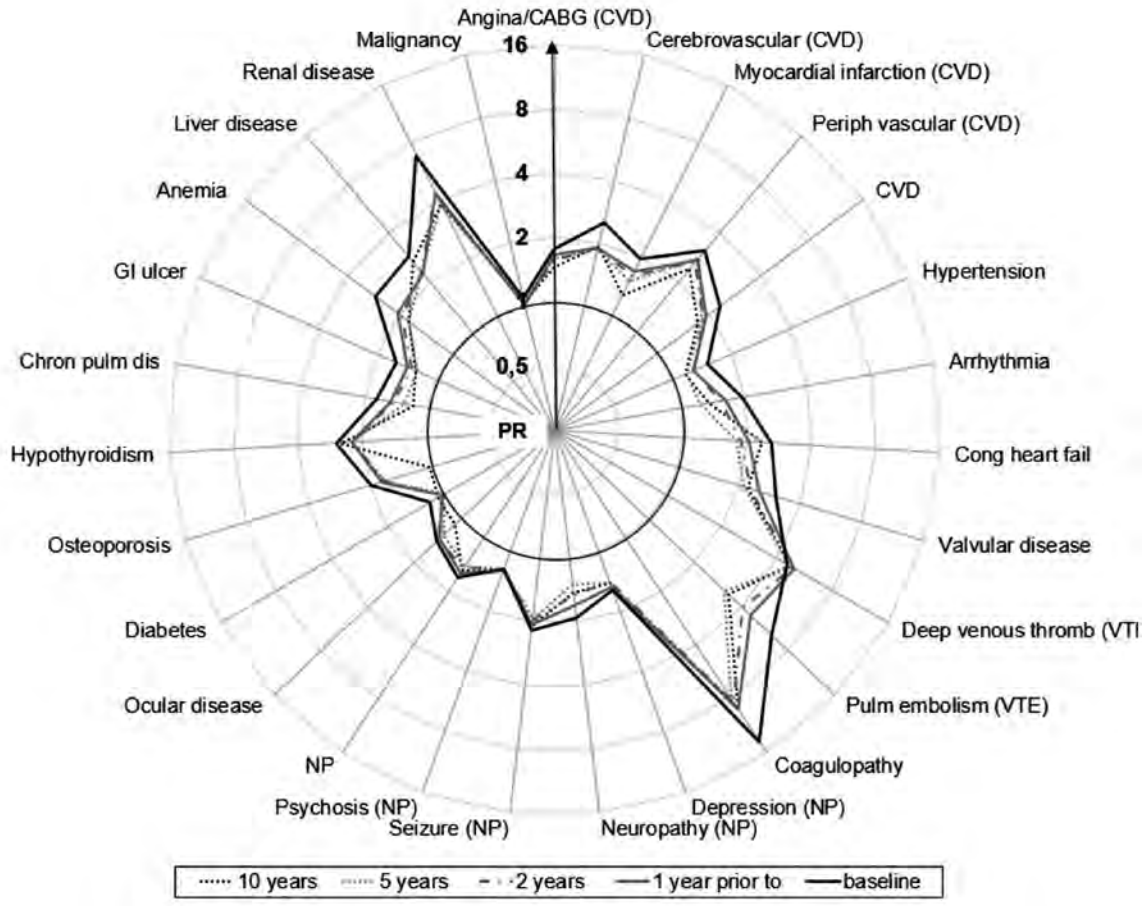
particularly high for venous thromboembolic events, coagulopathy, valvular diseases, and renal diseases with PRs ranging from 3.0 to 14. Also, cardiovascular, neurologic, hematologic, gastrointestinal, and endocrine diseases were significantly overrepresented before the index date. A striking finding is the stability of the overrepresentation for the mentioned morbidities even 10 years before index date among SLE patients as depicted in the Figure.

Figure. Spidergram of comorbidity prevalence ratios (PR) at 10, 5, 2, 1 and 0 years before index date; incident SLE patients (n=3,010) versus matched population comparators (n=57,046).



Conclusion: We found a higher than expected prevalence of multiple morbidities - not only at the time of SLE diagnosis but also during the 10-year pre-diagnosis period among the individuals with incident SLE. These findings may have implications on our understanding of SLE pathogenesis and the subsequent accumulation of morbidity after SLE diagnosis. In a clinical setting, these findings underscore the importance of a broad screening for various comorbidities at SLE diagnosis as early awareness and treatment of multimorbidity is expected to improve outcomes in SLE.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty, defined as a generalized vulnerability to stressors, has emerged as a relevant concept in SLE[1], although its origins are in geriatrics. As defined by the Fried Frailty Phenotype (FFP)[2], frailty is an aggregate of 5 constructs: weight loss, exhaustion, low physical activity, slowness, and weakness. Other means of identifying frailty have been suggested that may be easier to implement in clinical settings, including a shorter performance-based method, the Short Physical Performance Battery (SPPB)[3]. We examined the prevalence of frailty using the SPPB in a well-characterized SLE cohort.

Methods: Data are from the California Lupus Epidemiology Study (CLUES), a longitudinal cohort of individuals with rheumatologist-confirmed SLE. Data are collected annually through in-person research visits and structured interviews. At one visit, the SPPB was administered to a subset of the cohort. SPPB consists of balance tests, time to complete 5 chair stands, and gait speed over 4 meters. Scores range from 0 – 12; a score of < 10 identifies frailty.

Table 1. Differences in characteristics of individuals with SLE classified as frail or not frail

	Not frail (n=78)	Frail (n=72)	p
Age	43.9 ± 13.1	45.5 ± 15.0	.50
Female	85.9 (67)	91.7 (66)	.31
Race/ethnicity			.0003
White, non Hispanic	32.1 (25)	19.4 (14)	
Black	3.9 (3)	12.5 (9)	
Hispanic	12.8 (10)	37.5 (27)	
Asian	51.3 (40)	30.6 (22)	
Income below poverty	11.0 (8)	30.8 (20)	.005
Physical inactivity	29.5 (23)	47.2 (34)	.03
Obese (BMI≥30)	14.1 (11)	26.4 (19)	.07
Disease duration	16.4 ± 10.0	14.1 ± 9.6	.15
SLEDAI	2.9 ± 3.2	3.3 ± 3.2	.57
SDI	1.1 ± 1.6	1.1 ± 1.1	.98
SLAQ	7.5 ± 5.9	10.2 ± 7.4	.01
Glucocorticoid use, current	46.2 (36)	45.8 (33)	.99

p-values from t-tests or chi-square analyses comparing frail and non frail.
SLEDAI = SLE Disease Activity Index; SLAQ = Systemic Lupus Activity Questionnaire; SDI = SLICC Damage Index
SPPB = Short Physical Performance Battery

Table 2. Predictors of frailty, multivariate analysis		
	Model 1	Model 2
Race/ethnicity		
White, non Hispanic	(ref)	(ref)
Black	3.0 (0.6, 14.5)	5.1 (1.0, 26.3)
Hispanic	3.2 (1.1, 9.5)	4.4 (1.4, 14.1)
Asian	0.8 (0.3, 2.0)	1.1 (0.4, 2.8)
Income below poverty	2.0 (0.4, 3.1)	1.4 (0.5, 4.1)
Physical inactivity	1.6 (0.7, 3.6)	0.9 (0.3, 2.6)
Obese (BMI≥30)	1.1 (0.4, 3.2)	0.9 (0.4, 2.7)
SLEDAI	1.0 (0.9, 1.1)	---
SLAQ	---	1.03 (0.97, 1.1)

PROMIS Cognitive Ability	-2.2	.19
PROMIS Satisfaction with Social Roles	-5.2	.007
PROMIS Satisfaction with Discretionary Roles	-3.6	.06
Depressive symptoms (PHQ)	1.3	.18
Results from multivariate regression analyses adjusted for race/ethnicity, income, obesity, and SLEDAI. Tables values are beta and p-value from regression analyses. PROMIS = Patient Reported Outcomes Measurement Information System PHQ = Patient Health Questionnaire		

Differences in participant characteristics for frail/not frail were examined using t-tests or chi-square analyses. Multivariate logistic regression analyses identified independent predictors of frailty, including age, sex, race/ethnicity, l, obesity, SLE duration, SLE disease activity, and steroid use. Separate models were constructed to include either physician-assessed (SLE Disease Activity Index, SLEDAI) or patient-reported disease activity (Systemic Lupus Activity Questionnaire). The impact of frailty on patient-reported outcomes (PROs) was examined with multiple regression analyses.

Results: Among the 150 individual who completed the SPPB, mean age was 45 ± 14 years, disease duration 15 ± 10 years, 89% were female, 41% Asian, 25% Hispanic, 26% white non-Hispanic, and 8% African American. The proportion of individuals classified as frail was 48% (Table 1). Factors associated with frailty in bivariate analyses were low income, obesity, physical inactivity, and patient-reported disease activity (Table 1). In multivariate analysis, only race/ethnicity remained a significant independent predictor of frailty (Hispanic only when adjusting for SLEDAI, Hispanic and African America when adjusting for SLAQ). In post-hoc analyses, obesity and inactivity were found to be significantly more common among Hispanics and African Americans ($p < .01$, not shown). Frailty was associated with worse scores on most PROs, even after adjusting for race/ethnicity, income, obesity, and physician-assessed disease activity (Table 3).

Conclusion: Using the SPPB, nearly half of this sample was identified as frail. A previous study using the FFP found 20% prevalence of frailty and 50% pre-frailty. Racial/ethnic differences were noted, but may be due to greater prevalence of obesity and inactivity among Hispanics and African Americans. Patient-reported outcomes were consistently worse among individuals classified as frail, even after adjusting for covariates. Interventions aimed at reducing inactivity may reduce frailty among individuals with SLE.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) predominantly affects young women. It is usually more aggressive in men and carries a worse prognosis. Information about gender differences on psychiatric disorders, quality of life (QoL), patient-doctor relationship and adherence to treatment is limited, as men with SLE are often underrepresented.

Methods: We performed a cross-sectional study in a third-level hospital in Mexico City, from June to December 2019. We included SLE patients who met ACR criteria and recorded demographic and clinical data, including disease activity (*SLEDAI 2K*) and disease damage (*SLICC-DI*). We assessed depression (*CES D-20*) and anxiety (*BAI*), with tools validated to Spanish language. We also evaluated QoL (*LupusPRO*), patient-doctor relationship (*PDRQ-9*) and adherence to treatment (*Morisky-8)*.

Results: A total of 65 men and 140 women with SLE were recruited. There were no differences in demographic and clinical aspects (years from diagnosis, treatment strategies, and damage index), except for disease activity at the time of inclusion; men had higher SLEDAI scores [4(0-5) vs 2 (0-4), p=0.017] (Table 1). Conversely, there was no significant difference between genders in satisfaction with patient-doctor relationship and low adherence to treatment was reported by both groups (Figure 1).

On the other hand, QoL, as measured by LupusPRO, had lower scores in all domains for women, with a global score of 76 (64-83) in women vs 83 (73-88) in men, p=0.003 (Figure 2). Female patients more frequently reported high scores in the depression [46 vs 31%, p=0.042] and anxiety [29 vs 11%, p=0.004] scales than their male counterparts. We found that anxiety had a negative weak correlation with patient-doctor relationship satisfaction (r=-0.179, p=0.010)

	Men (n=65)	Women (n=140)	p
Age (median, p25-p75)	34 (27-44)	36 (26-45)	0.937
With a significant other (n, %)	35 (54.7%)	58 (42.6%)	0.111
Secondary education (n, %)	51 (82.3%)	101 (74.8%)	0.248
Low socioeconomic status (n, %)	32 (49.2%)	78 (55.7%)	0.386
Years from SLE diagnosis (median, P 25-P75)	9 (4-16)	10 (5-16.5)	0.286
Treatment with prednisone (n, %)	40 (62.5%)	75 (53.6%)	0.233
Number of immunosuppressants prescribed (median, p25-p75)	2 (1-2)	2 (1-2)	0.877
SLEDAI 2K (median, p25-p75)	**4 (0-5)**	**2 (0-4)**	**0.017**
SDI (median, p25-p75)	0 (0-1)	0 (0-1)	0.056

Table 1. SLEDAI 2K= Systemic Lupus Erythematosus Disease Activity Index 2000, SDI= Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index

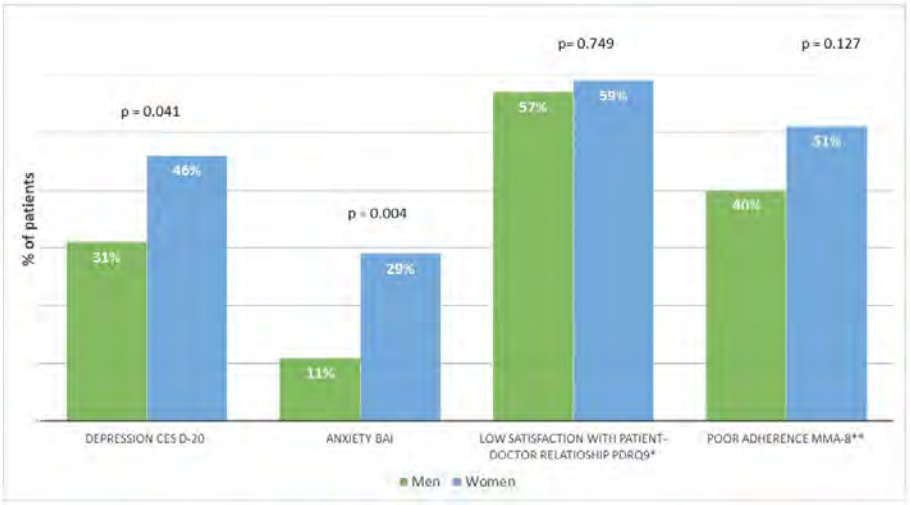

Figure 1. CES D-20= Center for Epidemiologic Studies Depression Scale, BAI= Beck Anxiety Inventory, PDRQ9= 9-item Patient-Doctor Relationship Questionnaire, MMA-8= 8-item Morisky medication adherence. *Patients that reported scores below the threshold for satisfaction in their patient-doctor relationship. **Patients with poor adherence according to the MMA-8 tool, using < 6 to define poor adherence.

and adherence to treatment (r=0.266, p< 0.005) in the whole group. Depression also negatively correlated with these two scores (patient-doctor relationship: r=-0.194, p=0.005; and adherence to treatment: r=-0.206, p=0.003).

In the multinomial logistic regression model, we found that women with SLE had a significantly higher prevalence of anxiety, depression or both (OR 2.57, 95%CI 1.36- 4.8, p=0.004).

Conclusion: This is the first study to demonstrate that being female is an independent risk factor for anxiety, depression, or both, in patients with SLE. It also demonstrates that, even though men have higher disease activity, women have lower scores in QoL and often report more SLE-associated symptoms. It is important that rheumatologists take these findings into account, in order to establish optimal support according to gender.

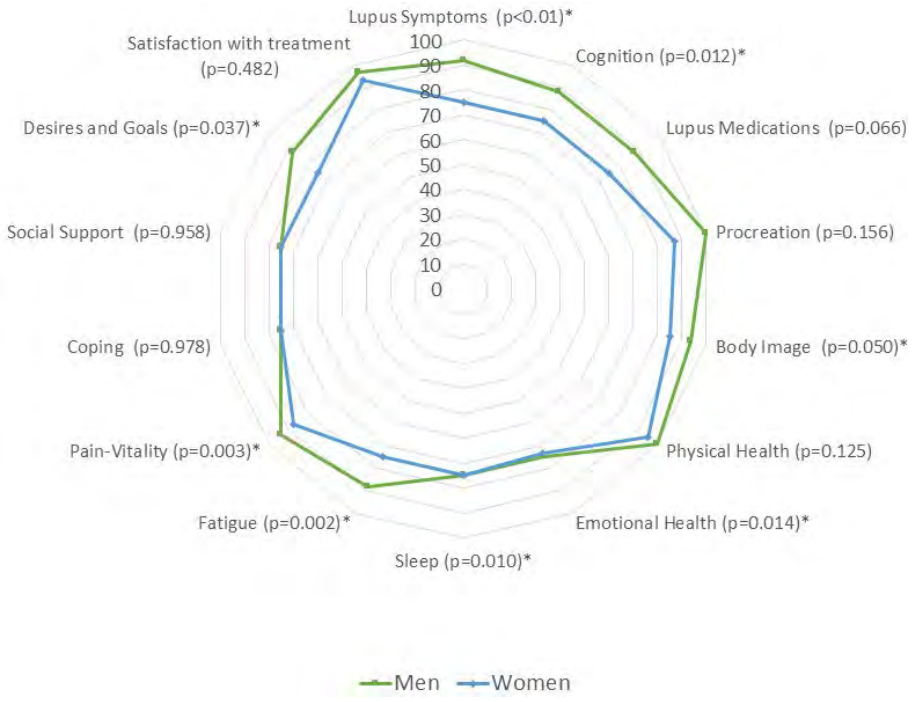

Figure 2. Quality of life spydergram for men and women with systemic lupus erythematosus measured by LupusPRO, * values are statistically significant.

Fatigue	0.61	0.76	0.65	**0.85**	0.67	0.64	0.54	0.73	0.85	0.66
Anger	0.37	0.50	0.46	0.54	**0.55**	0.43	0.64	0.51	0.55	0.49
Anxiety	0.34	0.51	0.40	0.52	**0.61**	0.45	0.78	0.56	0.61	0.51
Depression	0.43	0.58	0.49	0.60	**0.65**	0.47	**0.80**	0.67	0.72	0.54
Ability to participate in social roles	0.76	0.79	0.64	0.68	0.71	0.61	0.47	**0.78**	0.78	0.67
Satisfaction with social roles	0.68	0.74	0.60	0.69	0.70	0.58	0.54	**0.71**	0.71	0.65

In columns of SF-36 domains the **bolded** values represent a priori expected convergent correlations within a domain; unbolded values represent a priori expected divergent correlations. All spearman correlations were statistically significant.
*Average convergent and divergent correlations within a domain were compared using multitrait-multimethod approach

Construct validity was also tested using additional five a priori hypotheses to explore the relationships of PROMIS-CAT domains with corresponding SF-36 domains. We hypothesized that the following associations would be found, with at least moderately positive associations (r >0.3):

1) PROMIS-CAT Physical Function the SF-36 domains of Physical Function and Role Physical.

2) PROMIS-CAT Anger, Anxiety, and Depression with SF-36 Emotional Health scores.

3) PROMIS-CAT Ability to Participate in Social Roles and Satisfaction with SF-36 Social Roles.

4) PROMIS-CAT Fatigue with SF-36 Vitality.

5) PROMIS-CAT Depression with SF-36 Mental Health.

Results: Of the 227participants in the cohort, 90.3% were female, mean age at study enrolment was 48.6 ± 14.1 years, and mean disease duration was 18.5 ± 12.4 years (Table 1). The multitrait-multimethod matrix examining construct validity confirmed that the average convergent correlations were greater than the average divergent correlations for all domains (Table 2). All five a priori hypotheses were satisfied with moderate to strong correlations (Spearman correlation, r=0.55-0.87) between PROMIS-CAT and most SF-36 domains.

Conclusion: Our results provide evidence on the validity of PROMIS-CAT in an SLE Canadian cohort. The use of multi-trait multimethod analyses highlighted the convergent and divergent construct validity compared to legacy instrument. This is the first study to use multitrait-multimethod matrix analysis to establish validity support for the PROMIS-CAT and our results demonstrate encouraging results.

Depressed Symptomatology Persists over Time in the Majority of Systemic Lupus Erythematosus Patients and Is Independent of Disease Activity

Sara Kellahan[1], Xinliang Huang[1], Daphne Lew[2], Hong Xian[3], Seth Eisen[1] and Alfred Kim[4], [1]Division of Rheumatology, Washington University in St. Louis School of Medicine, St. Louis, [2]Division of Biostatistics, Washington University in St. Louis School of Medicine, St. Louis, [3]Department of Epidemiology and Biostatistics, College for Public Health and Social Justice, Saint Louis University, St. Louis, [4]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression is a prevalent (24-30%) and significant comorbidity in patients with systemic lupus erythematosus (SLE) (1). As the American College of Rheumatology (ACR) classifies depression as a neuropsychiatric manifestation of SLE (2), many clinicians assume that depressed affect fluctuates with SLE disease activity. In the present study, we leveraged the well-characterized longitudinal SLE cohort at Washington University Lupus Clinic to address the following questions: 1) what is the longitudinal course of depressed affect among outpatients with SLE, and 2) what is the relationship between SLE disease activity and depressed affect.

Methods: Longitudinal data from patients with ACR or SLICC-classified SLE managed in the Lupus Clinic were analyzed. Depressed symptoms were assessed at each visit using the Center for Epidemiologic Studies Depression Scale, Revised (CESD-R). Scores were obtained from individual patients over an average of 30.2 months (SD: 13.3; range: 2.6-48.0). Standard CESD-R scores of < 16, 16-21, and >21 were used to define no depression, depressed affect, and major depression. SLE disease activity was measured via the SLEDAI2K Responder Index-50 (S2K RI-50).

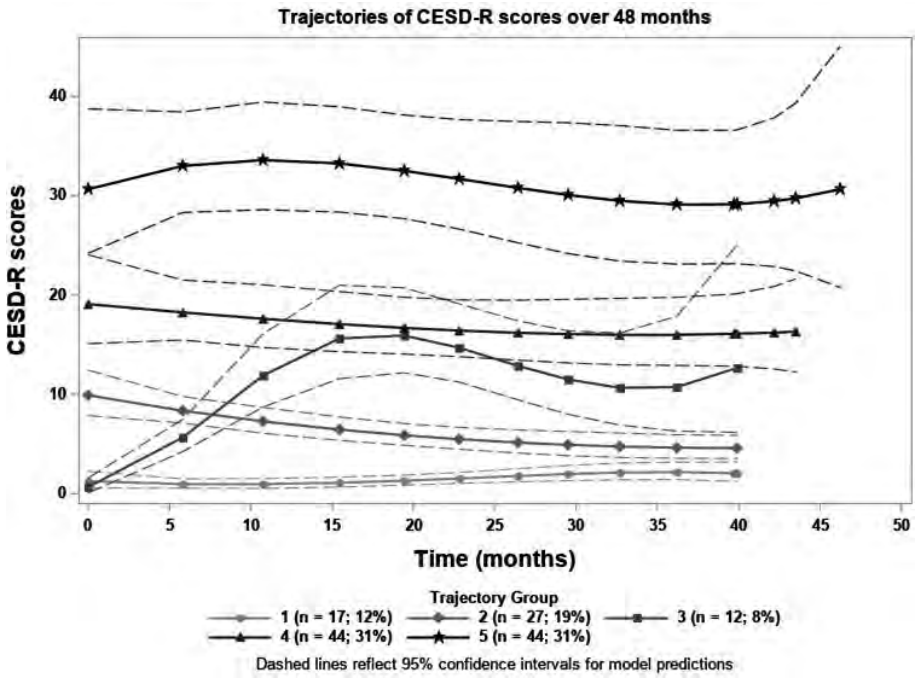

Figure 1. Identified trajectories of depression scores over time

Group-based trajectory modeling (GBTM) was applied to identify groups of patients with similar temporal trajectories of depressed symptoms over time. Baseline characteristics of individuals in each depressed trajectory group were compared using chi-square tests, Fisher's exact tests, or ANOVA. The relationship between disease activity and depression over time was assessed using multilevel linear regression models.

Results: The sample (n=144) was 91.0% female, 56.3% African American, and 38.9% White, with a mean age of 40.4 (SD: 12.6; range: 19-74). GBTM revealed 5 distinct groups of patients who demonstrated consistent trends in depression overtime (Figure 1). Members of groups 1 and 2 (n=17, 11.8%; n=27, 18.8%) had consistently normal CESD-R scores, group 3 (n=12, 8.3%) had rising CESD-R scores over time, and groups 4 (n=44, 30.6%) and 5 (n=44, 30.6%) demonstrated symptom patterns consistent with depressed affect and major depression, respectively. While visit-to-visit scores varied considerably, patterns remained durable over time documenting the prevalence of persistent major depression. Of note, African American patients were much more common in Group 5 (n=32, 72.7%, $p< 0.02$). Analyses did not identify an association between CESD-R and disease activity over time.

Conclusion: 61.2% of patients had scores indicating persistent depressed affect or major depression for up to 4 years. A relatively small group of patients (8.3%) reported CESD-R scores increasing from the 'normal' to depressed during the study. These data reinforce the disquieting pervasiveness of depression in SLE patients. The lack of a relationship of CESD-R to SLE disease activity highlights the need to identify non-clinical factors, particularly race, that contribute to and moderate this co-morbidity.

Frequency and Predictors of Influenza Vaccine Hesitancy in Systemic Autoimmune Rheumatic Diseases

Valeria Valerio[1], Mariana Useche[1], Mianbo Wang[2], Sasha Bernatsky[3], Christian Pineau[4] and Ines Colmegna[1], [1]The Research Institute of the McGill University Health Centre, Montreal, Canada, [2]Lady Davis institute for Medical Research, Montreal, QC, Canada, [3]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada, [4]McGill University Health Center, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic autoimmune rheumatic diseases (SARDs) benefit from getting annual inactivated influenza vaccine (IIV). However, vaccine uptake among SARDs is suboptimal. The delay in acceptance or refusal of vaccines despite the availability of vaccine services is known as vaccine hesitancy. This constitutes one of the ten threats to global health (World Health Organization, WHO 2019). In order to promote vaccine uptake in SARDs, it is key to understand the determinants of hesitancy. We assessed the frequency and predictors of influenza vaccine hesitancy in SARDs.

Methods: Between 11/2019 and 03/2020, consecutive SARDs patients presenting to the rheumatology clinics of a large tertiary care center completed an anonymous survey. We collected demographic data, factors reported to affect vaccine uptake (e.g. education, employment), SARDs specific information (e.g. diagnosis, disease duration, treatment), and questions proposed by the WHO to assess causes of vaccine hesitancy. The likelihood of a patient to get the flu vaccine was assessed based on a 10-point scale ('0 = I definitely will not get the flu vaccine' to '10 = I unquestionably will get the flu vaccine'). Patients were classified as (a) likely to refuse IIV (values 0-2); (b) likely to accept IIV (values 8-10), or (c) IIV uncertain (values 3-7). Multivariate logistic regression models were performed to determine predictors of influenza vaccine hesitancy.

Results: A total of 107 SARDs patients completed the survey. Patients' age ranged from 18 to 89 years (mean ± SD: 51.6 ± 17.0), 69.8% were female (n=74), and disease duration was (mean ± SD) 9.8 ± 10.8. Fifty-four patients (52.4%) had a university-level education and almost half were employed (n=51, 48.1%). Patients self-reported diagnoses were: SLE (n=57, 53.3%), vasculitis (n=27, 25.2%) myopathies (n=8, 7.5%), and others (n=15, 14.0%). Seventeen percent of SARDs had never received IIV, and 39% did not receive IIV in the previous season. Over one third of SARDs patients (38%) reported safety concerns about IIV, and 23% were uncertain if the benefits of IIV were larger than its risks. Twenty-three (23.5%) patients were likely to refuse IIV, 55 (56.1%) likely to accept IIV, and 20 (20.4%) were uncertain. Patients 'likely to refuse IIV' had more often rejected IIV (43.5% vs 7.5% of the likely to accept vs 15% of the uncertain). Compared to patients 'likely to accept IIV', those 'likely to refuse IIV' more often had never received IIV (OR 147.4, 95% CI 6.9 - >999). Eighty percent of those 'likely to refuse IIV' feel they should get IIV. Neither demographic data, employment status, disease duration or treatment predicted IIV acceptance. Bad reactions (personal or in known contacts) to IIV predicted vaccine refusal (OR 26.4, 95% CI 2.1 - 324.6).

Conclusion: Vaccine hesitancy in SARDs contributes to reduced IIV uptake. Despite most SARDs patients feel they should receive IIV, a third of them are concerned about the safety of the IIV. Adverse reactions to IIV strongly predict its refusal in SARDs. Reassuring SARDs patients about vaccine safety may enhance IIV uptake.

Factors Associated with Early Hospital Readmission in Systemic Lupus Erythematosus: Data from National Readmission Database

Rashmi Dhital[1], Joshua Baker[2], Paras Karmacharya[3], Anthony Donato[4] and Dilli Poudel[2], [1]Reading Hospital and Medical Center, West Reading, [2]University of Pennsylvania, Philadelphia, PA, [3]Mayo Clinic, Rochester MN, ROCHESTER, MN, [4]Reading Hospital and Medical Center, West Reading, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Early hospital readmission is a major healthcare burden. Studies evaluating factors associated with readmissions in rheumatic diseases are sparse. Our aim was to use a large national database to identify rates and the predictors of readmission in SLE as compared to common medical conditions with known high readmission rates including congestive heart failure (CHF) and chronic obstructive pulmonary disease (COPD).

Methods: We used the US nationwide readmission database (NRD, 2010-2014) to identify index adult (≥ 18 years) discharges with SLE, CHF, and COPD using ICD-9 codes in the first 5 diagnosis positions, and assessed their rates of readmission (defined as "early" readmission within 30 days). Index discharges with same-day transfers or those discharged as deceased were excluded. Discharges with the same diagnosis after 30 days from the previous index discharge date could count as another index, thus, allowing one patient to contribute to multiple observations. We performed multivariate regression to identify factors independently associated with early readmission, including demographic, hospital, and clinical factors. Comorbidities that were significant in univariate analysis ($p \leq 0.05$) were included in the multivariate model. We accounted for the clustering of multiple index discharges within the same patient using generalized estimating equations.

Results: In the combined data from 2010-2014, we identified 351,219 index SLE discharges, and compared them to 3,022,240 CHF, and 4,052,574 COPD index discharges. The readmission rate was 16.9% for SLE compared to 21.3% for CHF and 18.4% for COPD. Readmission was higher in males (19.5 %, 21.4 % and 19.4%) compared to females (16.6%, 21.2% and 17.7 %) for SLE, CHF and COPD, respectively.

Some demographic and hospital factors associated with higher odds of readmission in SLE included non-private insurance, longer length-of-stay at index hospitalization, and lowest income quartile. Age >65 and female sex were associated with reduced odds of readmission. Discharges against medical advice (AMA) had a higher odds of readmission in all cohorts (**Table 1**).

Among select diagnoses present in the index SLE discharges, the top 5 comorbid conditions associated with highest odds of readmission were chronic kidney disease (OR: 1.31, 95% CI: 1.23 – 1.39, $p < 0.001$), alcoholic liver disease

Table 1. Multivariate analysis of demographic, hospital and clinical factors associated with early readmission in systemic lupus erythematosus (SLE), congestive heart failure (CHF) and chronic obstructive pulmonary disease (COPD)

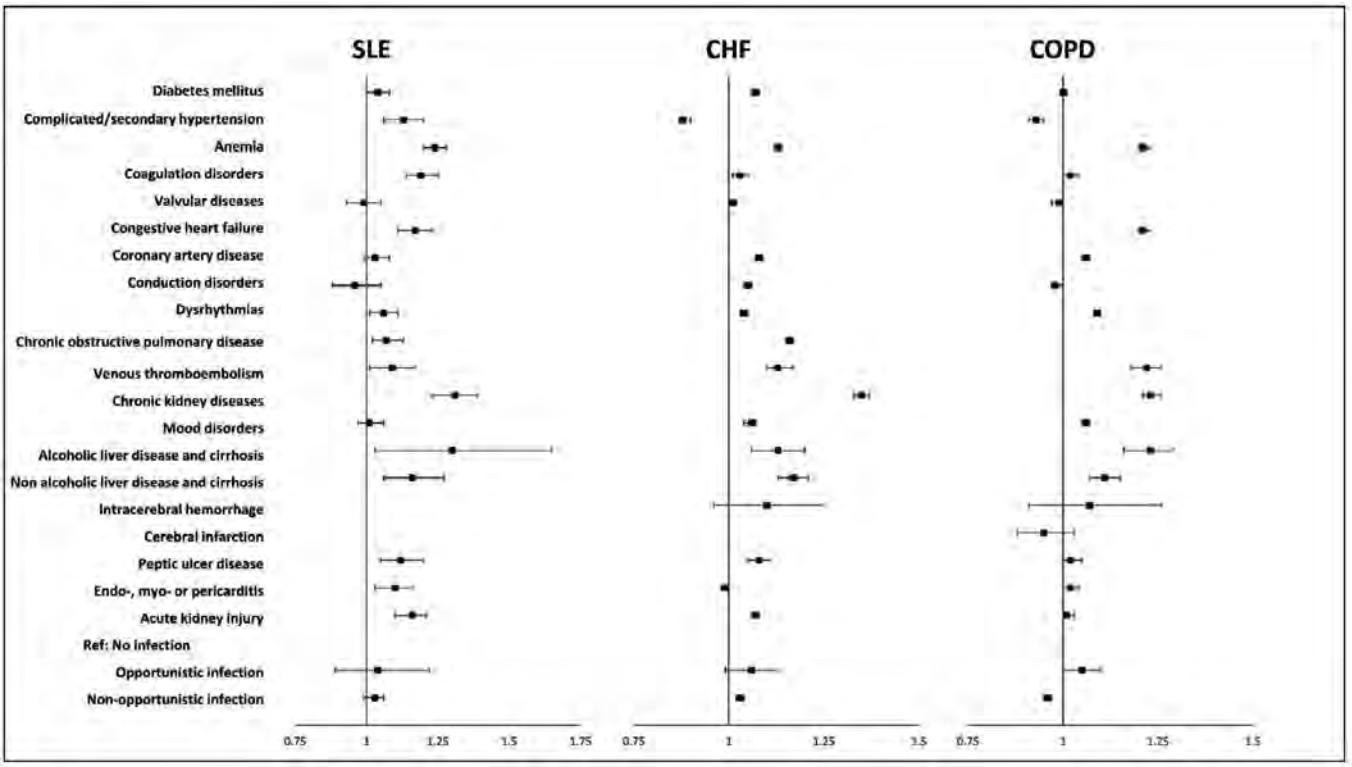

Figure 1. Multivariate analysis of comorbidities present at index discharges associated with early readmission in systemic lupus erythematosus (SLE), congestive heart failure (CHF) and chronic obstructive pulmonary disease (COPD)

(OR: 1.30 , 95% CI: 1.02 -1.65, p=0.03), anemia (OR 1.24, 95% CI: 1.20 – 1.28, p< 0.001) , coagulation disorders (OR: 1.19, 95% CI 1.14 – 1.25, p< 0.001), and CHF (OR: 1.17, 95% CI: 1.11– 1.23, p< 0.001). Acute kidney injury was associated with early readmission in CHF and SLE. Carditis (peri-, myo- and endocarditis) and cardiomyopathy were associated with increased readmission only in SLE (**Fig 1**).

Conclusion: We found readmission in SLE to be comparable to that in CHF and COPD. Higher readmission in younger SLE patients likely reflects the more severe phenotype in this group. Similarly, the presence of anemia, coagulopathy, and myopericarditis conferred higher readmission risk, likely reflecting more severe SLE with organ involvement. Studying the role of various common and unique predictors in a prospective setting could identify avenues for improving inpatient and transitional care in SLE.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A key goal of treatment of SLE is the prevention of irreversible organ damage. The ability to identify patients at increased risk for damage could select patients for early intervention but is currently lacking. Conventional studies of damage outcomes in SLE utilize composite disease activity scores, and associations with damage are only modest. We evaluated whether using all available data in an unbiased fashion, including continuous laboratory data usually analysed dichotomously in disease activity scores, could give rise to superior predictive algorithms for organ damage in SLE.

Methods: Prospectively collected longitudinal data from a 13-centre multinational cohort were used. Each visit was assigned yes/no as being in a damage-transition period based on whether the nearest subsequent annual measurement of organ damage (SLICC damage index) increased. Candidate variables included demographic (3), baseline serology (4), medication classes (anti-malarial, immunosuppressant, and glucocorticoid), routine clinical laboratory parameters (14) and SLEDAI-2K. Logistic regression models were selected to predict the probability of damage transition using backward, forward, and hybrid stepwise selection methods, either including or excluding SLEDAI-2K. The primary metric evaluating performance was area under the receiver operating characteristic curve (AUC) for association with damage transition.

Results: Data from 15,625 visits of 1,621 patients were split randomly 80:20 into training and test datasets; a separate cohort (2,178 visits, 188 patients) was used for independent validation. As there were only 1,157 damage transition visits in the training dataset, oversampling was used to create a dataset with 23,120 visits with a 'transition visit' ratio of 50%.

Altogether 2^{21} (~ 2 million) models with different combinations of predictors were analysed. After excluding models with >20 variables or training AUC < 0.62 we ranked 43,332 models excluding SLEDAI, and 224,349 models including SLEDAI, according to the mean of the training, test, and validation set AUC.

The highest performing model (mean AUC=0.659) included age, sex, and ethnicity; baseline ANA, anti-Sm, and anti-phospholipid antibody positivity; prednisolone use; and routine clinical lab variables ESR, eGFR, haemoglobin,

platelet & neutrophil count, and urine protein & red cells. All top 20 models included age, sex, ethnicity, some baseline serology, prednisolone use, and both ESR & eGFR, with anti-phospholipid status, haemoglobin, platelet and neutrophil count and urine protein and red cells in most. In this analysis, the inclusion in model selection of clinician measurement of disease activity using SLEDAI2K did not improve performance (highest AUC including SLEDAI2K=0.651).

Conclusion: We have derived algorithms predictive of organ damage, an important clinical outcome in SLE, using an unbiased 'big data' approach. Continuous laboratory variables contributed to damage risk, while clinician measured disease activity did not improve prediction. This suggests continuous laboratory measures should be included in future SLE clinical trial endpoints.

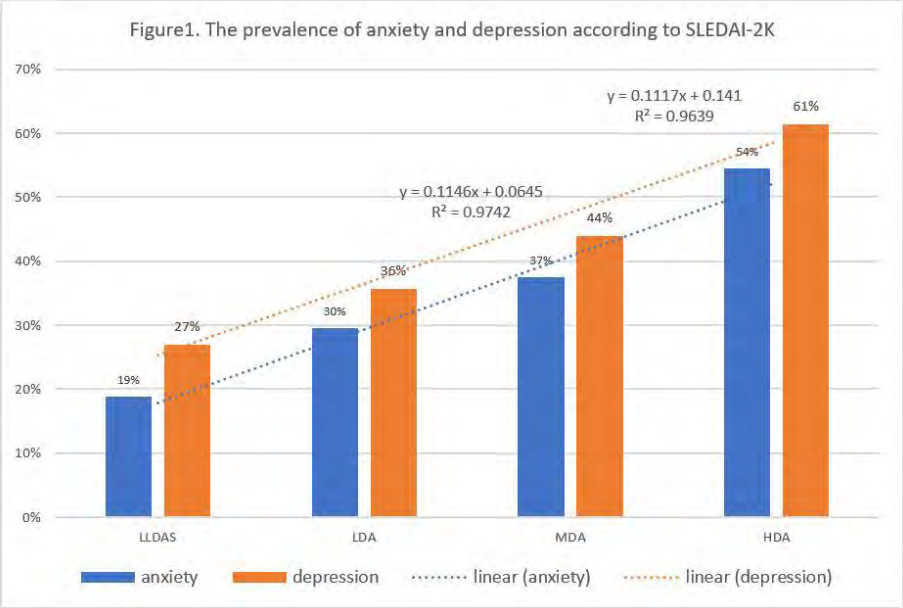
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Figure 1. ↵



Background/Purpose: WHO survey showed that the prevalence of anxiety and depression in Chinese population and Chinese patients with chronic diseases were between 3.1% - 4.2% and 3.1% - 7.3%, respectively. SLEDAI-2K and Hospital Anxiety and Depression Scale (HADS) are commonly used to evaluate SLE patients' disease activity and mental health. All the Assessments were mainly performed by health professionals (HCPs) with paper questionnaire previously. SSDM is a novel smart disease management tool that allows patients to do self-assessments on SLEDAI-2K and HADS by mobile App.The purpose of this study is to investigate the prevalence of anxiety and depression in Chinese patients with SLE and to analyze the potential association between disease activity of SLE and mental health.

Methods: Under the guidance and training by HCPs, SLE patients downloaded SSDM and performed self-assessments bundle of SLEDAI-2K and HADS with SSDM. SLEDAI-2K < =4, 5-9, 10-14 and >=15 are defined SLE inactive, low (LDA), moderate (MDA) and high (HDA) disease activity, respectively. SLEDAI-2K score < = 4 is set as the main criteria for Lupus Low Disease Activity State (LLDAS) and achievement of T2T. HADS score >=8 can be diagnosed with anxiety or depression.

Results: From June 2016 to Jan 2020, 3,332 SLE patients (199 male, 3,133 female) with a mean age of 36.34 ± 12.80 (10-91) years and the median disease duration of 3.43 years from 216 hospitals performed bundle self-assessments for 4,967 times in total. According to the HADS and SLEDAI-2K Assessment results, the prevalence of anxiety and depression in all patients was 36.7% and 39.3% respectively, which was significantly higher than that in the WHO survey in Chinese population and chronic disease patients. The proportion of patients achieved and failed on LLDAS was 53% and 47%, respectively. The prevalence of anxiety (A) and depression (D) was 19% and 27% among LLDAS achievers; 41% and 47% among LLDAS failures, respectively (pA< 0.01, pD< 0.01).

According to SLEDAI-2K, in LLDAS, LDA, MDA and HDA subgroups, the prevalence of anxiety and depression was 19%, 30%, 37%, 54% and 27%, 36%, 44%, 61%, respectively. The correlation coefficients of anxiety (A) and depression (D) with SLEDAI-2K were rA=0.9957 and rD=0.9819. It suggested that with the increase of disease activity, the proportion of SLE patients with anxiety and depression increased significantly. (Figure 1)

Conclusion: Conclusion: Higher prevalence of anxiety and depression were Associated with higher levels of disease activity in SLE patients. SSDM is an effective mobile interface to monitor and study entanglement of disease activity and mental health in SLE patients, which build a foundation for proactive interventions physically and mentally in future.

Associations of Metabolic Syndrome and Adipokines in SLE

Diane Apostolopoulos[1], Fabien Vincent[2], Rachel Koelmeyer[2], Alberta Hoi[1] and Eric Morand[3], [1]Monash University, Melbourne, Victoria, Australia, [2]Monash University, Clayton, Victoria, Australia, [3]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Metabolic syndrome (MetS) is a chronic pro-inflammatory and pro-thrombotic state associated with increased atherosclerosis, cardiovascular events and type 2 diabetes. It is diagnosed in the presence of at least 3 of 5 metabolic risk factors (obesity, hypertension, hypertriglyceridemia, low high-density lipoproteins (HDL) and insulin resistance [1]). The pathophysiology of MetS remains incompletely understood, but may share mechanisms with inflammatory states such as SLE. Visceral adiposity is known as a source of pro-inflammatory cytokines by adipocytes, the so-called adipokines. The contribution of glucocorticoids to the development of MetS in SLE is not clear, even though their use is associated with cardiovascular comorbidities [2]. We aim to characterize the prevalence and associations of MetS, including serum levels of adipokines, in a multi-ethnic cohort of patients with SLE.

Methods: Using a standardised protocol, baseline demographics, per visit disease activity (SLEDAI2K) and treatment data, and annual recording of organ damage accrual (SLICC damage index (SDI)) were prospectively captured on SLE patients from a single tertiary centre. The presence of MetS,defined using the updated joint consensus criteria [1], was assessed retrospectively at the last recorded visit. Serum levels of adipokines (resistin, lipocalin-2, TNF, MCP-1) and insulin were measured by Quantibody.

Results: 116 patients (median (IQR) age at enrolment 39.5 (31.4-51.1) years, median disease duration 6.1 (1.4-12) years) were followed for a median of 6.7 (4.1-8.1) years. 80% of patients were exposed to glucocorticoids (median time-adjusted mean dose 3.7 (0.5-7.0) mg/day and 50% accrued organ damage during follow-up. The prevalence of MetS in this cohort was 29%. The prevalence of the components of MetS included: hypertension (59%), low-HDL (51%), hypertriglyceridemia (32%), obesity (16%) and hyperglycaemia (22%). In univariable analysis, MetS was associated with baseline organ damage (SDI) (OR 4.34; 95% CI 1.80-10.48; P< 0.01) and organ damage accrual (OR 2.34; 1.02-5.36; P=0.04). The association between MetS and baseline organ damage remained significant in multivariable analysis (adjusted OR 3.36; 95% CI 1.32-8.59; P=0.01). Unexpectedly, glucocorticoid use was not associated with MetS or any of its five components. High serum levels of resistin were significantly negatively associated with MetS (OR 0.17; 95% CI 0.04-0.70; P=0.014); no other adipokine were associated with MetS.

Conclusion: MetS is common in SLE patients, with the most frequent components being hypertension and low-HDL. An independent association was found of MetS with baseline organ damage, and low serum resistin, but not glucocorticoid exposure or disease activity.

Lupus Antibodies in Relation to Malignancy

Sarah Huse[1], Jim Oates[2], Gary Gilkeson[3] and Diane Kamen[1], [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, SC, Charleston, SC, [3]Division of Rheumatology, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) a chronic inflammatory autoimmune disease that has the potential to affect every organ system. Studies have shown increased risk of certain malignancies among patients with SLE, with a potentially decreased risk of breast and prostate cancer related to anti-dsDNA antibodies (abs). This study examines the prevalence of malignancy types and relationships between clinical characteristics, autoantibody positivity and malignancy risk among patients with SLE.

Methods: Data was obtained from an ongoing longitudinal registry of patients with SLE (≥4 ACR classification criteria) and non-SLE population-matched controls. Information on demographics, medical and social history, and SLE characteristics (if applicable) was gathered from in-person interviews and medical record review. Disease damage was determined by SLICC/ACR Damage Index (SDI) with the malignancy item removed from scoring ("any damage present" if score ≥1). Children (age< 18 years) and those missing data on malignancy status were excluded from the study population. Analysis included descriptive statistics, Pearson's chi-squared testing for categorical measures and two-sample t-tests for continuous measures.

Results: A total of 750 SLE patients and 548 controls were included (Table 1). The mean age at SLE diagnosis was 31.1 years (SD ±13.8), mean age of malignancy diagnosis was 37.9 years (SD ±15.3), with mean age at last follow-up of 50.9 years (SD ±16.1). Comparing malignancy types between patients with SLE and controls, there was a higher incidence of gynecologic cancers (1.6% vs. 0.2%, p=0.01) and non-melanoma skin cancers (1.7% vs. 0.2%) among the patients. The 65 malignancies among the 54 patients with SLE are described in Table 2. The data did not show an association between BMI with either SLE or malignancy, but other clinical manifestations were associated with malignancy, as shown in Table 3. SLE patients that were lupus autoantibody negative (defined as being negative for dsDNA, SM, antiphospholipid, SSA and SSB antibodies), were statistically significantly more likely to have a malignancy history.

Conclusion: We found in this population of patients with SLE, that despite an overall increased risk of cancer, especially skin and gynecologic malignancies, compared to population-matched controls, the presence of certain SLE-associated autoantibodies decreased the likelihood of having a cancer history. These results support further studies to examine the relationship of autoantibodies, including anti-SM, anti-SSA and anti-SSB, and malignancy risk.

Lupus Damage Free-Survival by Age at Diagnosis: A Retrospective Incident Lupus Cohort

Maria Schletzbaum[1], Nnenna Ezeh[2], Trevor McKown[3], Shivani Garg[4] and Christie Bartels[5], [1]University of Wisconsin-Madison School of Medicine and Public Health, Department of Population Health Sciences, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Milwaukee, WI, [3]William S. Middleton Memorial Veterans Hospital, Madison, WI, [4]UW Madison, Madison, WI, [5]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: While medical comorbidities increase with age, younger age at onset of Systemic Lupus Erythematosus (SLE) has been associated with greater risk of some types of end-organ damage. Few studies have reported damage-free survival by age at diagnosis which would be useful for prognosis discussions. Using a large single-center retrospective cohort of incident SLE patients, the objectives of this study were to estimate new damage and mortality-free median survival time and 1-, 5-, and 10-year survival probabilities and to compare damage-free survival by age at diagnosis and within organ systems.

Methods: Electronic Health Records (EHR) from a single academic health system were queried for patients with SLE diagnosis codes in 2003-2016 and at least one visit to both a rheumatology and a primary care provider to better capture damage events. Trained abstractors manually validated cases meeting either 1997 ACR or 2012 SLICC SLE criteria and recorded damage event dates, including events pre-EHR. Age at diagnosis used the earliest date of a SLE diagnosis code from a rheumatologist or date of meeting SLE criteria. Patients with less than 30 days of observation after diagnosis were excluded.

All observed events within the post-diagnosis follow-up period were compared by age group at diagnosis (< 30, 30-44, 45-59, and 60+ years). Gross damage rates were calculated using Poisson regression. Kaplan-Meier was used to estimate new damage and mortality-free median survival time and 1-, 5-, and 10-year survival probabilities by age group at diagnosis. Differences in organ-specific damage-free survival by age group at diagnosis were assessed with logrank tests on Kaplan-Meier curves.

Results: The cohort included 462 patients with incident SLE followed for a median of 6 years. There were 86 (19%) patients diagnosed before age 30, and the median diagnosis age was 45 (Table 1). Patients diagnosed before age 30 were more likely to be Asian, Black or to receive Medicaid. Of SLE damage events observed after diagnosis, the most common were neuropsychiatric (18% of events), ocular (17%), and musculoskeletal (14%). Increasing age group correlated with gross damage rate, from 10% per year risk in those < 30, to 39% per year risk in those 60+ (Table 2). Survival until first damage event after diagnosis was similar in patients diagnosed before age 30 and ages 30-44; survival decreased in older age groups. In the first year, patients younger than 30 years experienced damage rates similar to older age groups (45-59 year olds) (Figure 1). For most organ systems, survival without damage negatively correlated with age. However, cardiovascular and pulmonary damage-free survival was similar or shorter in patients diagnosed < 30 compared to those diagnosed decades later in life.

Table 1. Characteristics and Observation Time of Incident SLE Patients by Age at Diagnosis

Table 2. Gross Damage Rates, Median Damage- and Death-Free Survival Time, and 1-, 5-, and 10-year Damage- and Death-Free Survival Probabilities by Age Group at SLE Diagnosis

	Total Cohort N= 462	Age < 30 N=86	Age 30-44 N=149	Age 45-59 N=145	Age 60+ N=82
Total Damage Events	562	60	116	206	180
Observation Time (Years) (median, IQR)	6.0 (3.6-9.3)	6.6 (3.8-10.1)	6.6 (3.8-9.4)	5.9 (3.2-9.5)	5.5 (2.9-7.3)
Gross Damage Rate (% per person-year) (mean (95%CI))	16.2 (14.7, 17.8)	9.8 (7.5, 12.6)	11.1 (9.3, 13.4)	21.8 (19.0, 25.0)	39.4 (34.0, 45.6)
Median Damage & Death-Free Survival Time (median (95%CI))	6.00 (5.30, 6.84)	11.15 (7.06, NE)	8.40 (6.33, 10.51)	4.64 (3.57, 5.79)	1.42 (0.79, 2.41)
1-year Damage & Death-Free Survival Probability (mean % ± SE)	83 ± 2	89 ± 3	93 ± 2	83 ± 3	56 ± 6
5-year Damage & Death-Free	57 ± 3	72 ± 5	70 ± 4	48 ± 5	28 ± 5
10-year Damage & Death Free	31 ± 3	55 ± 7	40 ± 6	13 ± 7	0 ± 0

NE = Not estimable based on data

Conclusion: Younger patients (< 30), who were more likely to be non-White and Medicaid beneficiaries, experienced a relatively high rate of first damage in the first year after diagnosis and similar damage rates to patients decades older within cardiovascular and pulmonary systems. Overall damage rates in SLE correlated with age at diagnosis, with a 30% per year difference in damage risk between the youngest (< 30) and oldest (>60) patients at SLE diagnosis.

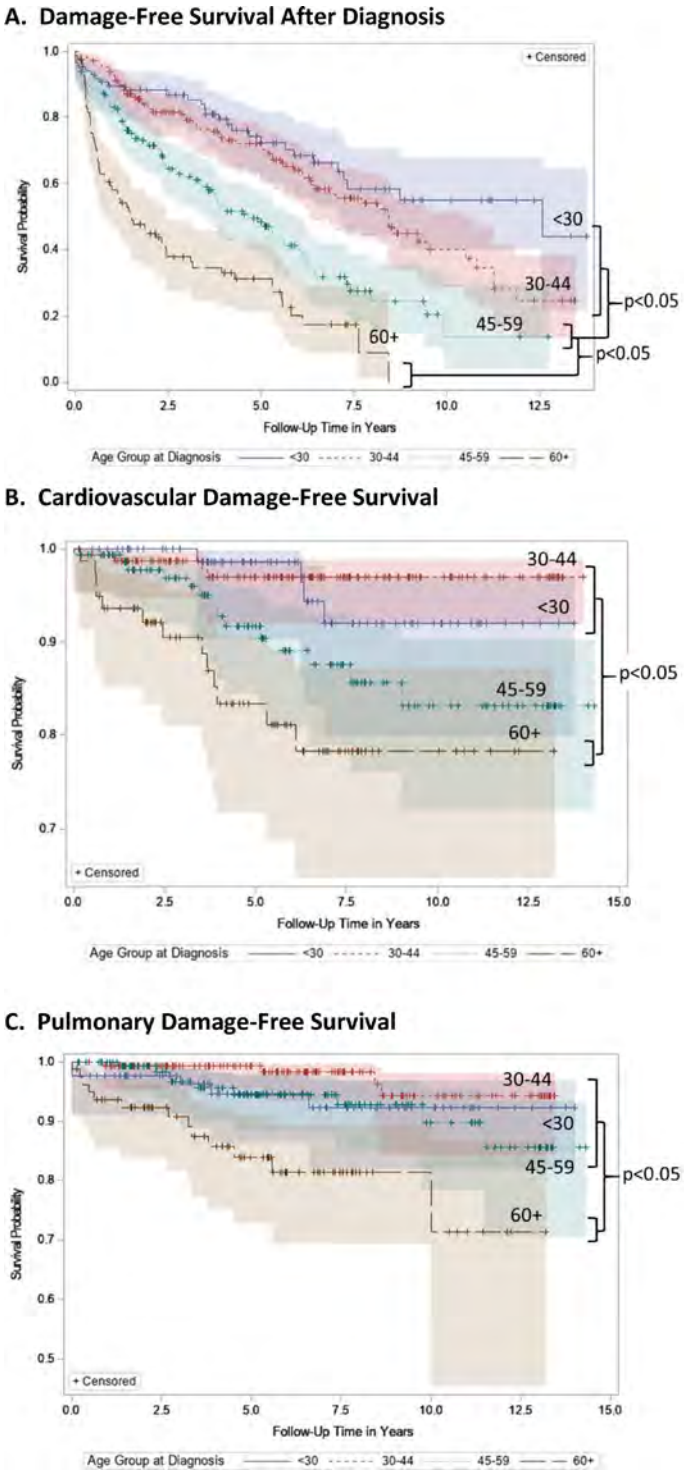

Figure 1. Damage, Cardiovascular, and Pulmonary Damage-Free Survival by Age Group at Diagnosis. Kaplan-Meier survival curves for damage after lupus diagnosis by age group at diagnosis with death as a censoring event for select organ systems. Panel A shows survival until first new damage event after diagnosis. Survival time was longer in patients diagnosed before age 45 and decreased with increasing age group. Panel B shows cardiovascular damage-free survival, which was longer for patients diagnosed before 45 compared to those after age 60. Panel C displays pulmonary damage-free survival which was shorter for patients diagnosed after age 60 than those diagnosed younger.

Longitudinal Patterns of Anxiety Symptomology Among Patients with Systemic Lupus Erythematosus (SLE) Remain Stable over Time and Do Not Associate with SLE Disease Activity

Daphne Lew[1], Xinliang Huang[2], Sara Kellahan[2], Hong Xian[3], Seth Eisen[4] and Alfred Kim[5], [1]Washington University in St. Louis School of Medicine, Saint Louis, MO, [2]Division of Rheumatology, Washington University in St. Louis School of Medicine, St. Louis, [3]Department of Epidemiology and Biostatistics, College for Public Health and Social Justice, Saint Louis University, St. Louis, [4]Washington University School of Medicine, St Louis, MO, [5]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Almost 40% of patients with SLE have comorbid mental health conditions.[1] Though depression is most commonly reported (24% to 30%), many SLE patients also experience some form of anxiety disorder.[2] The mechanisms underlying the association of psychiatric disorders with neuropsychiatric SLE are unclear. Moreover, the relationship between the longitudinal course of anxiety symptomology and SLE disease activity remains largely unstudied. Thus, the aims of this study are to identify patterns of anxiety symptomology over time among patients with SLE, and to assess the longitudinal relationship between anxiety symptomology and SLE disease activity.

Methods: Longitudinal data from patients with ACR or SLICC-classified SLE treated in the Washington University Lupus Clinic were analyzed. Anxiety symptomology was assessed at each visit using the validated Patient-Reported Outcomes Measurement Information System (PROMIS) Emotional Distress: Anxiety Short Form 8a. Patients with at

Table 1. Baseline sociodemographic characteristics of patients in each of the identified anxiety trajectory groups * Statistically significant at $p < 0.05$

least 3 PROMIS anxiety and SLEDAI2K Responder Index-50 scores obtained at the same clinic visit over 2 to 48 months were included. The PROMIS anxiety scale scores are converted to t-scores with a mean of 50, reflecting average levels of anxiety in the general adult population, with standard deviation of 10.[3] T-scores between 60-70 and above 70 reflect moderate and severe symptomology, respectively. Group-based trajectory modeling (GBTM) identified groups of patients with similar temporal trajectories of anxiety symptomology. Baseline characteristics of individuals in each anxiety trajectory group were compared using chi-square tests, Fisher's exact tests, or ANOVA. The relationship between disease activity and anxiety over time was assessed using multilevel linear regression models.

Results: 139 patients had at least 3 PROMIS anxiety scores over an average of 30.9 months (SD: 13.0; range: 2.6-48). Mean patient age was 40.2 (SD: 12.7; range: 19-74), 90.1% were female and 56.1% African American. GBTM identified 4 unique temporal trajectories of anxiety symptomology (Figure 1), labeled: low (LA), average (AA), moderate (MA), and high anxiety (HA). Of note, 88.9% of individuals classified in the HA group were African-American, compared to only 44.4% of individuals in the LA group (Table 1). SLEDAI score was not significantly associated with anxiety levels longitudinally (β=0.07, p=0.3).

Conclusion: Anxiety symptomology over time remained relatively stable in this patient cohort. More than 50% of patients experienced persistent moderate or severe anxiety symptomology, and a higher proportion of African-American patients demonstrated moderate or severe anxiety. SLE disease activity was not significantly associated with anxiety symptomology over time. These findings emphasize the importance of better understanding psychosocial factors that contribute to the persistence of anxiety symptomology. Patients with SLE should be regularly screened for mental health conditions and provided access to appropriate mental health resources.

Identifying Cognitive Impairment in Patients with Systemic Lupus Erythematosus Using Hidden Markov Models: A Bayesian Approach

Juan Pablo Diaz-Martinez[1], Kathleen Bingham[2], Robin Green[3], Dorcas Beaton[4], Mahta Kakvan[1], Lesley Ruttan[3], Carmela Tartaglia[5], Marvin Fritzler[6], May Choi[7], Jiandong Su[1], Dennisse Bonilla[1], Nicole Anderson[1], Joan Wither[1], Patricia Katz[8] and Zahi Touma[9], [1]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [2]Department of Psychiatry, University of Toronto, Toronto, ON, Canada, [3]Toronto Rehabilitation Institute, University Health Network, Toronto, ON, Canada, [4]Institute for Work & Health, Toronto, Canada, [5]University of Toronto, Krembil Neurosciences Centre, Toronto, ON, Canada, [6]Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [7]Brigham and Women's Hospital | Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [8]University of California, San Francisco, Novato, CA, [9]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network; Krembil Research Institute, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) is usually operationalized on the American College of Rheumatology Neuropsychological Battery (ACR-NB) as a z-score of ≤-1.5 on ≥2 domains or z ≤-2 on ≥1 domain.

Given that this binary classification may miss participants who have CI but score just below the cut-off, we explored using continuous z-scores, instead of the binary approach of the ACR-NB, to facilitate the interpretability of the results. This framework is developed based on Hidden Markov Models (HMMs) and on existing data over time.

Methods: 301 consecutive consenting SLE patients aged 18-65 years attending a single center were assessed for CI at baseline using the ACR-NB and 187 patients completed visits at 6 and 12 months.

ACR-NB includes 19 tests and 6 cognitive domains. Age and gender matched normative data were used to obtain z-scores.

The **1st step** of our approach reduces the high-dimensional aspect of the ACR-NB tests using principal component analysis (PCA) to create a single component score which explains the most variance (1st dimension). The **2nd step** builds a 2-state cognitive status based on a discrete-time HMM with the dimensionality reduction gained in the first step. The HMM assumes that the change of the component score over time in patients with SLE can be segmented into 2 distinct cognitive states, where each state captures if a patient is CI or not at time t, using the component score obtained at each time point. We assumed that the component score is Normal with unknown mean and variance, and the mean and variance are different between the two hidden states (CI or non-CI). Additionally, we specified that the mean of the Normal outcome depends linearly on education level; this adjustment means that the hidden states will capture the unobserved heterogeneity not explained after controlling by education level. All the statistical analysis was done from a Bayesian perspective using Stan through R which implements the Hamiltonian Markov Chain Monte Carlo method.

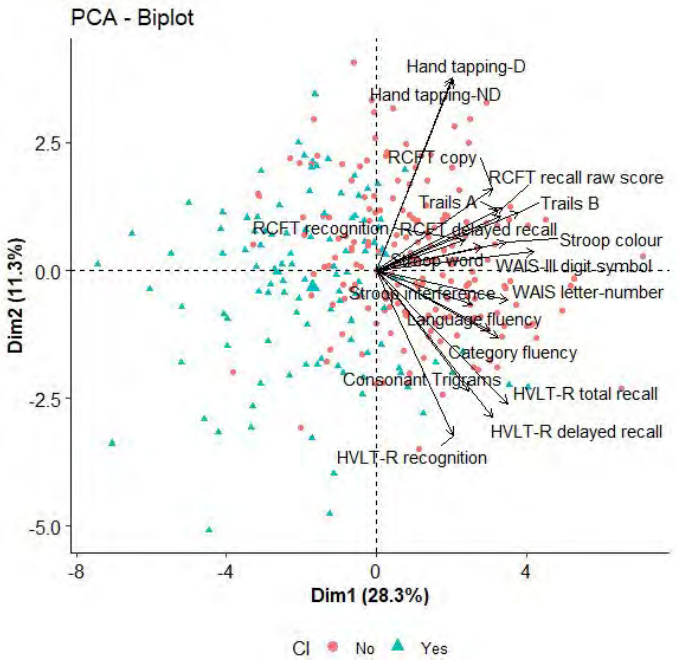

Figure 1. Biplot at baseline. PCA where patients' component scores are colored by ACR-NB CI binary definition (turquoise for CI and orange for non-CI). The 1st dimension separates patients into CI and non-CI at baseline. Axis x represents the first dimension (explaining 28.3% of the variance) and axis y represents the second dimension. The length of each arrow represents the strength of the relationship between the ACR-NB subtests, and the cognitive components found in our PCA. The angle between variables represents the strength of the correlation between them. The ACR-NB included the following domains: Manual motor speed and dexterity, simple attention and processing speed, visual-spatial construction, verbal fluency, learning and memory, executive function.

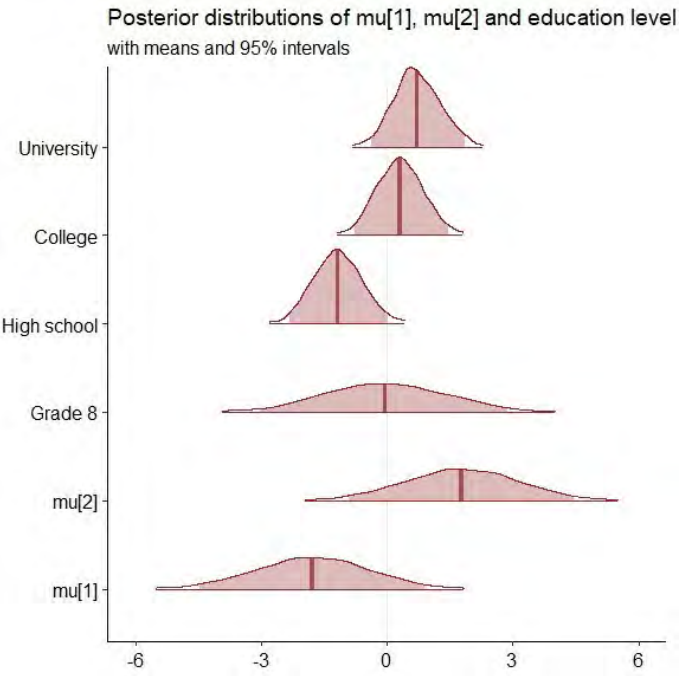

Figure 2. Posterior estimates from the HMM. X axis represents the distribution of the parameters of interest. Y axis represents the parameters where inference is made. The dark shaded region represents the point estimate from a frequentist point of view and the light shaded region represents the 95% uncertainty interval, i.e., with 95% of probability the estimate would lie in that region. As an example mu[1] represents the inference made on the unknown mean of the observed component score given that it comes from the CI state after adjusting for education level. The point estimate is -1.78 with 95 % CrI (-4.47, 0.91).

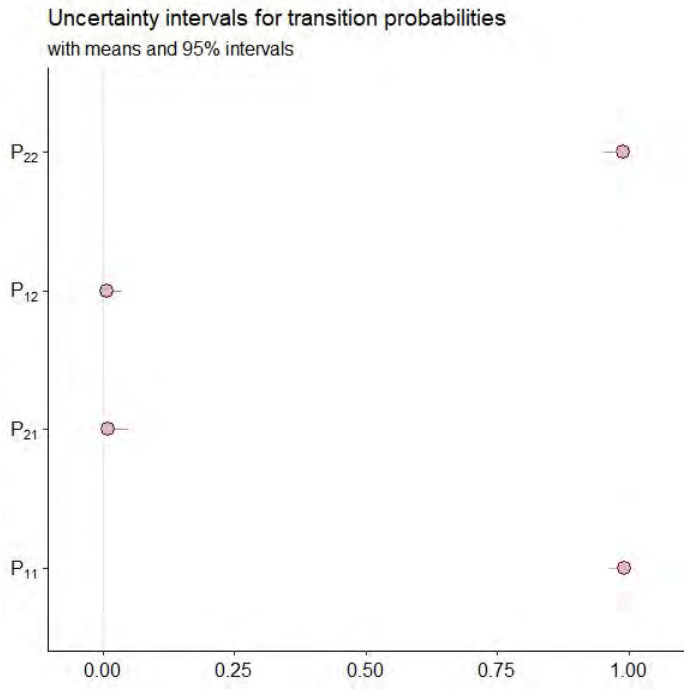

Figure 3. Posterior uncertainty intervals for the transition probabilities in the HMM. X axis represents the transition probability and Y axis represents the parameters where inference is made. We labeled '1' as the CI state and '2' as the non-CI. Therefore, over discrete time points, P11 is the probability of remaining in the CI state, P12 is the probability of moving from the CI state to non-CI state and so on (P21 and P22). The dot on the graph represents the point estimate and the line represents the 95% CrI.

Results: Of 301 patients, 89.0% were women, mean age 40.9 ± 12.1 and mean disease duration 14 ± 10.1 years at study entry. Figure 1 shows the results of the PCA; at baseline, 1st dimension separates patients into CI and non-CI and 2nd dimension was mainly explained by measures of simple information processing or motor speed.

From the HMM analysis, the estimated mean for the CI state was -1.78 (95% Credible Interval [CrI]: -4.47, 0.91) and 1.78 (95% CrI: -0.92, 4.46) for the non-CI state. A patient will be classified as CI if their observed component score lies on the area of mu[1] (Fig. 2) and as non-CI if it lies on the area of mu[2].

We found higher education level associates with an increase mean component score (implies less CI). We also found that patients did not transition between CI and non-CI over time (Fig. 3).

Conclusion: This is the first framework which aimed to classify patients with SLE as CI or not using an unsupervised method. This approach relies on the observed z-scores from the 19 tests on the ACR-NB and not on the binary classification. We found that the probability of changing between CI and non-CI over 1 year is low.

Characterizing How SLE Patients Access Health Information Pre and During COVID-19

Francesca Cardwell[1], Susan Elliott[2], May Choi[3], Ricky Chin[4] and Ann Clarke[5], [1]University of Waterloo, Burlington, ON, Canada, [2]University of Waterloo, Waterloo, ON, Canada, [3]Brigham and Women's Hospital | Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [4]University of Calgary, Calgary, AB, Canada, [5]University of Calgary, Calgary, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The spread of misinformation related to COVID-19 has been especially acute for SLE patients as unsubstantiated claims regarding the efficacy of antimalarials for COVID-19 first jeopardized drug supplies, and then misinformation regarding toxicity provoked abrupt discontinuation. Conflicting health messages based on unfounded information can contribute to detrimental health decisions, exacerbate stress, and precipitate SLE flares. In attempt to mitigate the adverse consequences of accessing, spreading, and acting on misinformation, we assessed how SLE patients access health information pre and during COVID-19.

Methods: SLE patients fulfilling the ACR or Systemic Lupus International Collaborating Clinics (SLICC) Classification Criteria for SLE from a patient cohort in Alberta, Canada completed an online survey in June 2020 regarding the sources of health information they accessed in the 12 months preceding (pre March 11, 2020) and during the COVID-19 (post March 11, 2020) pandemic. Descriptive statistics were used to calculate the percentage of patients accessing each source of information, their preferred sources, and the level of trust in each source. McNemar tests were used to compare frequencies preceding and during the pandemic.

Table 1: Health Information Source Frequency of Access Pre and Post March 11, 2020

	Health Information Source Accessed [a]		
	Pre 11/03/20	Post 11/03/20	95% CI for Difference
Family Physicians	72.6%	52.8%	-19.8% (-30.3%, -9.3%)
Lupus Specialists (e.g., rheumatologists, nephrologists, hematologists, dermatologists)	66%	48.1%	-17.9% (-27.5%, -8.4)
Pharmacists	57.5%	46.2%	-11.3% (-21.4%, -1.2%)
Alternative Care Providers (e.g., chiropractor, naturopath)	28.3%	14.2%	-14.2% (-21.7%, -6.6%)
Peers (e.g., family, friends, colleagues)	36.8%	36.8%	0.0% (-10.7%, 10.7%)
Advocacy Organizations (e.g., provincial/national lupus organization)	18.9%	20.8%	1.9% (-5.5%, 9.2%)
News Media (e.g., newspaper, online news, radio, television)	38.7%	56.6%	17.9% (7.3%, 28.6%)
Social Media (e.g., Facebook, Instagram, Internet blogs, Twitter)	34%	38.7%	4.7% (-3.8%, 13.2%)

[a] *Respondents who reported health information source access sometimes/often/always*

Table 2: Preferred Health Information Sources Pre and Post March 11, 2020

	Overall Rank	
	Pre 11/03/20	Post 11/03/20
Lupus Specialists	1	1
Family Physicians	2	2
Pharmacists	3	4
Advocacy Organizations	4	6
Peers	5	7
Alternative Care Providers	6	8
News Media	7	3
Social Media	8	5

Table 3: Trustworthiness of Health Information Source Pre and Post March 11, 2020

	Trust in Source [a]		
	Pre 11/03/20	Post 11/03/20	95% CI for Difference
Family Physician	86.8%	80.2%	-6.6% (-14.6%, 1.4%)
Lupus Specialists	90.6%	86.8%	-3.8% (-9.9%, 2.4%)
Pharmacists	77.4%	72.6%	-4.7% (-11.7%, 2.3%)
Alternative Care Providers	36.8%	27.4%	-9.4% (-17.1%, -1.8%)
Peers	24.5%	27.4%	2.8% (-4.8%, 10.4%)
Advocacy Organizations	50.9%	45.3%	-5.7% (-12.4%, 1.0%)
Newspaper	27.4%	23.6%	-3.8% (-11.1%, 3.5%)
Online news media	35.9%	38.7%	2.8% (-4.8%, 10.4%)
Radio	31.1%	29.3%	-1.9% (-7.3%, 3.6%)
Television	38.7%	42.5%	3.8% (-2.4%, 9.9%)
Facebook	10.4%	10.4%	0.0% (-3.6%, 3.6%)
Instagram	5.7%	7.6%	1.9% (-2.7%, 6.5%)
Internet blog	9.4%	7.6%	-1.9% (-7.3%, 3.6%)
LinkedIn	5.7%	5.7%	0.0% (-0.9%, 0.9%)
Pinterest	2.8%	3.8%	0.9% (-1.8%, 3.7%)
Reddit	1.9%	1.9%	0.0% (-0.9%, 0.9%)
TikTok	2.8%	2.8%	0.0% (-0.9%, 0.9%)
Twitter	5.7%	5.7%	0.0% (-3.6%, 3.6%)
YouTube	10.4%	8.5%	-1.9% (-5.4%, 1.6%)
[a] Respondents who reported source as somewhat/very trustworthy			

Results: 106 of 248 patients completed the survey (43% response rate); 91.5% were female, 71.7% Caucasian, and the mean age at diagnosis was 35.9 years (SD 14.0) and mean disease duration was 16.6 years (SD 12.8). 73.6% had completed some form of post-secondary education, and 83% reported taking antimalarials in the past 12 months. No participants reported a doctor diagnosis of COVID-19. Patients accessed news media more frequently during the pandemic (38.7% accessed sometimes/often/always pre vs 56.6% post), while access to family physicians, SLE specialists, pharmacists and alternative care providers decreased during the pandemic (Table 1). Lupus specialists and family physicians were ranked the most preferred (Table 2) and considered the most trustworthy sources (Table 3) pre and during the pandemic. News and social media were ranked more highly as preferred sources post vs pre March 11 (Table 2), but were considered much less trustworthy than physicians (86.8% rated lupus specialists as somewhat/very trustworthy post vs 38.7% for online news media).

Conclusion: Although SLE specialists and family physicians are ranked as the most preferred and trustworthy sources of health information, patients accessed these sources less frequently during the pandemic and accessed news media, a less preferred source, more frequently. This study is currently being expanded to include additional Canadi-

an and international centers to further investigate the sociodemographic and geographic factors influencing access to and use of health information. This research will improve existing information dissemination pathways valued by SLE patients and enhance public health response during the pandemic and beyond.

Table 2. Performance Characteristics of Four Machine Learning Models in Predicting Hospitalization for Systemic Lupus Erythematosus, Overall and by Cluster

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous disease associated with increased morbidity and mortality, and severe SLE flares can lead to hospitalizations. Our objective was to apply machine learning methods to predict hospitalizations for SLE from electronic health record (EHR) data.

Methods: We identified 1,996 patients with SLE in a longitudinal academic medical center EHR-based cohort since 2016. Patients were identified with a previously validated SLE phenotype algorithm (PPV 92%) (Jorge A et al. *Semin Arthritis Rheum* 2019). K-means cluster analysis was used to identify groups of SLE patients with similar autoantibody patterns (dsDNA, SSA, SSB, Smith, RNP, and B2 glycoprotein 1 antibodies). The outcome of interest was hospitalization with a discharge diagnosis code of SLE (ICD10 M32, excluding M32.0, or ICD9 710.0) in the most recent year of follow up. We applied multiple machine learning methods to predict hospitalizations for SLE, including decision tree, random forest, logistic regression, and support vector machines. Candidate predictors were derived from coded EHR features and included demographics, laboratory tests, medications, ICD-9/10 codes for SLE manifestations (e.g., nephritis, acute lupus rash, and pericarditis), and healthcare utilization including specialist visits. We applied these methods to the overall SLE cohort and within clusters. The performance of each model was evaluated by sensitivity, specificity, accuracy, the F statistic, and the area under the receiver operator curve (AUC).

Results: Four distinct autoantibody clusters were identified (**Table 1**). SLE patients were 91% female, with mean age 52 years. Overall, 7.7% of patients were hospitalized for SLE in the last year of follow-up. Race/ethnicity and SLE manifestations varied among the clusters as did the proportion of patients with hospitalizations for SLE. Model performance was greatest within cluster 1, the largest cluster (**Table 2**). The most common predictors of SLE hospitalizations overall from the various machine learning methods included age, hemoglobin/hematocrit, ESR, and albumin. Top 5 predictors for SLE hospitalizations varied among clusters of SLE patients (**Table 3**).

SLE Patient Subset	Rank	Decision Tree	Random Forest	Logistic Regression	Support Vector Machines
All data	1	albumin	albumin	age	hemoglobin
	2	hemoglobin	hematocrit	hemoglobin	hematocrit
	3	ESR	ESR	# outpatient clinics*	# outpatient clinics*
	4	dsDNA Ab(binary)	hemoglobin	AST	ESR
	5	age	age	creatinine	age
Cluster 1	1	albumin	albumin	venous thrombosis	albumin
	2	ESR	hematocrit	Albumin	hemoglobin
	3	hemoglobin	ESR	hemoglobin	hematocrit
	4	hematocrit	hemoglobin	hematocrit	ESR
	5	ALT	CRP (mg/L)	ESR	venous thrombosis
Cluster 2	1	hemoglobin	hematocrit	hemoglobin	hemoglobin
	2	hematocrit	hemoglobin	white race	venous thrombosis
	3	CRP (mg/L)	albumin	venous thrombosis	hematocrit
	4	albumin	CRP (mg/L)	chloroquine	white race
	5	ALT	ALT	hematocrit	RBC - UA - 0
Cluster 3	1	SS-A(Ro) Ab(combined)	SS-A(Ro) Ab(combined)	SS-A(Ro) Ab(combined)	SS-A(Ro) Ab(combined)
	2	C4	C4	dsDNA Ab(binary)	C4
	3	C3	age	No urine protein	C3
	4	Rheumatology visits	hematocrit	hematocrit	dsDNA Ab(binary)
	5	age	hemoglobin	Asian race	age
Cluster 4	1	albumin	albumin	age	2+urine protein
	2	creatinine, random urine	# outpatient clinics*	azathioprine	3+ urine protein
	3	WBC	CRP (mg/L)	Protein - UA - 2	2+ urine blood
	4	RNP Ab	creatinine, random urine	methotrexate	RNP Ab
	5	C4	ALT	acute lupus rash	Urine RBCs

*Number of outpatient clinics in addition to 'Rheumatology', 'Nephrology', 'Dermatology' visits

Table 3. Comparison of Top Five Predictive Features of Four Machine Learning Models

Conclusion: We have demonstrated that machine learning methods can be used to predict SLE hospitalizations and to identify predictors of these events. Future work will incorporate natural language processing of narrative text to capture additional predictors of SLE hospitalizations.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients presenting with back pain and psoriasis, acute anterior uveitis (AAU), or inflammatory bowel disease (IBD), represent a high-risk population for the presence of axial spondyloarthritis (axSpA) but may remain undiagnosed for many years. Several referral strategies have been proposed aiming at pre-selecting patients with a high probability of having axSpA among the common condition of non-specific back pain in primary care. The Berlin criteria include inflammatory back pain (IBP), B27 and sacroiliitis by imaging. The ASAS modification excludes IBP as a mandatory entry item. The Dublin Evaluation Tool (DUET) restricted to AAU is based on joint pain, B27 and cutaneous psoriasis, but not on IBP. Validation of these algorithms in inception cohorts is limited.

We aimed to: (1) compare the performance of referral algorithms in an inception cohort of patients with extra-articular manifestations presenting to a rheumatologist with undiagnosed back pain, when tested against the final local rheumatologist; (2) determine whether different IBP criteria impact the performance of the algorithms.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study at 11 sites is aimed at early detection of axial SpA in consecutive patients presenting with undiagnosed back pain to the rheumatologist. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or IBD undergo routine clinical evaluation by a rheumatologist for axSpA. The rheumatologist determines the presence or absence of axSpA at 3 consecutive stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. Final diagnosis by the rheumatologist was used as external standard to test the performance of the algorithms. We tested the following criteria for IBP in the algorithm: ASAS, Berlin, rheumatologist global for likelihood of IBP >5 (0-10 scale), and DUET in AAU.

Results: 246 patients were recruited, 73 presented with AAU, 46 with psoriasis, and 127 with IBD. 47.6% were diagnosed with axSpA (68.5% B27-positive). The diagnosis of axSpA was established in 45.7%, 61.6%, and 40.2% of patients with psoriasis, AAU, and IBD, respectively. The performance of the ASAS-modification of the Berlin algorithm was superior to the original algorithm as reported previously[3], primarily for enhanced sensitivity, and this was observed irrespective of the IBP criteria (Table 1). Conversely, the DUET algorithm in the subset of patients with AAU performed worse than previously reported[1].

Algorithm	Sensitivity (%)	Specificity (%)	Correct diagnosis (%)	False negative (%)	False positive (%)
Original Berlin (ASAS criteria for IBP)	65.3	76.6	71.1	16.7	12.2
Original Berlin (Berlin criteria for IBP)	64.4	76.6	70.7	17.1	12.2
Original Berlin (IBP global >5)	67.8	78.1	73.2	15.4	11.4
ASAS Modification 2 of Berlin algorithm (ASAS criteria for IBP)	73.7	75.8	74.8	12.6	12.6
ASAS Modification 2 of Berlin algorithm (Berlin criteria for IBP)	73.7	75.0	74.4	12.6	13.0
ASAS Modification 2 of Berlin algorithm (IBP global >5)	76.3	77.3	76.8	11.4	11.8
DUET	84.4	50.0	71.2	9.6	19.2

Conclusion: The ASAS modification of the Berlin algorithm showed the optimal balance between sensitivity and specificity and represented the preferred referral strategy for patients presenting with undiagnosed back pain and extra-articular features.

Uveitis Occurrence in Early Inflammatory Back Pain: Five Years Data from a Prospective French Nationwide Cohort

Daniel Wendling[1], Clement Prati[2], Thierry Lequerre[3], Corinne Miceli-Richard[4], Maxime Dougados[5], Anna Molto[6] and Xavier Guillot[7], [1]CHU Besançon, department of rheumatology, Besancon, France, [2]Rheumatology, University Teaching Hospital, Besançon, France, [3]Rheumatology, University Teaching Hospital, Rouen, France, [4]Paris Descartes University, Department of Rheumatology - Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Paris, France, [5]Department of Rheumatology, Hopital Cochin, Université de Paris, Paris, France, [6]Rheumatology Department, Cochin Hospital, APHP, Paris, France, Paris, France, [7]CHU Reunion, Saint Denis, Reunion

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis is the most frequent extra rheumatological manifestation in axial Spondyloarthritis (SpA). DESIR is a prospective multicenter cohort of patients with early inflammatory back pain suggestive of SpA.

We reported previously a 8.5% baseline prevalence of uveitis for the patients included in the cohort; this history of uveitis at the first visit of the cohort was associated with inflammatory bowel disease (IBD) and preceding infection (1).

The aim of the study was to evaluate the prevalence and incidence of uveitis over the first five years of prospective follow-up of the cohort, and to evaluate its associated factors.

Methods: DESIR is a prospective observational cohort of patients with recent onset inflammatory back pain (more than 3 months, less than 3 years), suggestive of axial SpA, All available factors in the database were compared between patients with and without uveitis at 5 years, by uni and then multivariate analysis. Baseline factors associated with new cases of uveitis occurrence over the 5 years were also analyzed. Significance: p less than 0.05.

Results: After 5 years, 91 patients (out of 480 with complete follow-up) had at least one uveitis episode, giving an estimated prevalence of 18.9% [95%CI : 15.4-22.4]. In multivariate analysis, uveitis was associated with dactylitis (OR 2.92 [2.06 – 4.14] ; p=0.002**), ESR > 7mm (median value) (OR 2.19 [1.57 – 3.06] ; p=0.018*).

New incident uveitis occurred in 31 cases over 5 years, giving an estimated incidence rate of 1.29 / 100 patient-years [0.84 – 1.74]. New incidence of uveitis was associated in multivariate analysis with the following baseline factors: diagnosis of SpA (OR 9.65 [3.21 – 28.96] ; p=0.039*), total sacro iliac MRI inflammatory SPARCC score (central reading) over median (OR 3.98 [2.26 – 7] ; p=0.015*), dactylitis (OR 4.7 [2.65 – 8.36] ; p=0.007**), syndesmophyte score over median (central reading) (OR 0.22 [0.1 – 0.45] ; p=0.039*).

No significant association was found with HLA-B27, cs or b DMARDs, BASDAI, ASDAS, BASFI.

Conclusion: Five-years data of the DESIR cohort allowed an estimation of incidence rate of uveitis of 1.3/100p-y; over five years, uveitis was associated with dactylitis, biologic and sacro iliac MRI inflammation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 30% of HLA-B27(+) patients with ankylosing spondylitis (AS) have one or more episodes of acute anterior uveitis (AAU), a condition that is also seen in HLA-B27(+) individuals without AS. We sought to investigate whether the occurrence of AAU is linked primarily to AS rather than to HLA-B27 allele.

Methods: In 1985 members of the Swiss AS Patient Society who had been diagnosed as having AS by their own physicians, as well as their first degree relatives, were invited to participate in the current study. After obtaining ethical approval and informed consent, 1178 subjects, 363 of them probands, formed our study cohort. They completed questionnaires on disease manifestations, underwent rheumatological examination of axial and peripheral joints, and provided blood samples for genetic studies, including HLA-B27. Probands also provided a recent pelvic radiograph to document presence of sacroiliitis. If their pelvic radiograph was not available, it was performed on-site. Relatives aged ≥18 years underwent pelvic radiography, unless pregnant. Pelvic radiographs were available for 360 probands and 713 relatives. Radiographs were blindly assessed twice by each of 4 readers. The assessment could only be performed once for 164 (46%) of the 360 radiographs of the probands (only available a few hours). The sacroiliitis score for each sacroiliac (SI) joint ranged from 0 (normal) to 4 (ankylosis). Scores were added and then divided by the number of assessments. Scores below bilateral grade 2.0 or grade 3.0 unilaterally were considered not meeting New York (NY) radiographic criteria.

Table. Prevalence of eye symptoms that together suggest acute anterior uveitis (AAU) among HLA-B27 positive probands with ankylosing spondylitis (AS) and their healthy HLA-B27 positive and HLA-B27 negative relatives

Questionnaire item	AS Probands HLA-B27 positive number positive/total (percentage)	Relatives HLA-B27 positive Number positive/total (percentage)	Relatives HLA-B27 negative number positive/total (percentage)	HLA-B27 positive AS Probands *<versus>* HLA-B27 negative Relatives LR+ LR- *(p-value)*	HLA-B27 positive Relatives *<versus>* HLA-B27 negative Relatives LR+ LR- *(p-value)*
Have you *ever* had a painful, red inflamed eye?	49/83 (59.0%)	40/111 (36.0%)	43/129 (33.3%)	1.77 1.63 *(0.00023)*	1.08 1.04 *(0.66)*
If so, how many eyes were affected at the same time?					
• one eye?	30/85 (35.3%)	30/110 (27.3%)	29/130 (22.3%)	1.58 1.20 *(0.03694)*	1.22 1.07 *(0.37)*
• both eyes	20/85 (23.5%)	10/110 (9.1%)	16/130 (12.3%)	1.91 1.15 *(0.03119)*	0.74 0.96 *(0.424)*
Did you have any such eye inflammation more than once?	42/84 (50.0%)	22/111 (19.8%)	24/129 (18.6%)	2.69 1.63 *(0.00000)*	1.07 1.02 *(0.81)*

In 2018 the ethical committee of the Swiss Kanton of Bern approved the follow up study. Many Swiss city and village administrations provided current addresses of former participants and reported the year of death of 182 deceased persons, including 123 AS probands. A total of 462 consenting participants completed a 157 item postal disease related questionnaire that included questions addressing AAU-related symptoms (Table 1). We compared the responses (to our questions suggestive of AAU) by the 85 HLA-B27(+) AS patients meeting the NY radiographic criteria for sacroiliitis with those of the 130 unaffected ("healthy") HLA-B27(-) relatives, and also the responses of the 111 unaffected ("healthy") HLA-B27(+) relatives with those of the 130 HLA-B27(-) "healthy" relatives. Scores were compared by chi-square testing and likelihood ratio analysis.

Results: Eye symptoms that suggested previous occurrence(s) of AAU episode(s) were reported significantly more often by the 85 HLA-B27(+) AS patients fulfilling the NY radiographic criteria than by the 130 HLA-B27(-) relatives (of the HLA-B27(+) AS probands) (Table). Interestingly, we found no differences in responses suggestive of AAU episodes between HLA-B27(+) and HLA-B27(-) relatives.

Conclusion: It should be noted that our questionnaire has not yet been validated. However, although one cannot exclude selection or detection bias (for AS patients), the results support the view that HLA-B27(+) AAU is more closely related to the disease AS/axSpA than to the HLA-B27 allele itself.

Abstract Number: 1306

High Prevalence of Previously Undiagnosed Axial Spondyloarthritis in Patients Referred with Anterior Uveitis and Chronic Back Pain

Rianne van Bentum[1], Frank Verbraak[2], Sanne Wolf[3], Maarten Boers[4], Stevie Tan[5] and Irene van der Horst-Bruinsma[1], [1]Department of Rheumatology, Amsterdam UMC, location VU University Medical Centre, Amsterdam, Netherlands, [2]Amsterdam UMC, location VU University Medical Centre, Amsterdam, Netherlands, [3]Amsterdam University Medical Center location VUmc, Amsterdam, Netherlands, [4]Amsterdam Rheumatology and immunology Center | Reade and Amsterdam UMC, Amsterdam, Netherlands, [5]Amsterdam University Medical Center, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To reduce the diagnostic delay in axial spondyloarthritis (axSpA), Rheumatology and Ophthalmology guidelines recommend to refer patients with acute anterior uveitis (AAU) and chronic back pain (CBP) to a rheumatologist. The impact of these recommendations in daily practice, has not yet been described. This study evaluated the prevalence of previously unrecognized axSpA in AAU patients with CBP, referred by ophthalmologists following a short instructional course to increase awareness. Secondary aims were to evaluate the timing of onset of AAU and CBP, and gender differences.

Methods: This cross sectional study included AAU patients referred with CBP (≥3 months, started < 45 years of age), from five Ophthalmology clinics. Patients with a previously diagnosed rheumatic disease, or an established other cause of AAU, were excluded. All patients underwent thorough rheumatologic evaluation, including assessment of ASAS inflammatory back pain (IBP), ASAS SpA features, laboratory examination and pelvis radiography (evaluated

Table 1. Patient characteristics at referral, subdivided for the clinical diagnoses.

Legend: Numbers are mostly depicted as number of patients (%), unless stated otherwise (mean (±SD) or median (Q1-Q3). *p-value of <0.002 was regarded statisticall significant, after Bonferroni correction for multiple testing. 1. Caucasian 72%, African 6%, Hindustan 5%, Turkish 5%, Moroccan 4%, Asian 1%, Latin American 3%, mixed ethnicity 4%; 2. Patients fulfilling the ASAS classification criteria for axSpA (radiographic or non-radiographic); 3. IBP according to the ASAS IBP criteria. AAU, acute anterior uveitis; ASAS, Assessment of Spondyloarthritis international Society; axSpA, axial spondyloarthritis; CRP, C-reactive protein; HLA-B27, Human Leukocyte Antigen B27; NSAIDs, nonsteroidal anti-inflammatory drugs.

Table 1. Patient characteristics at referral, subdivided for the clinical diagnoses

based on the modified New York (mNY) criteria for sacroiliitis). The primary endpoint was a clinical axSpA diagnosis (definite/possible/no axSpA), made by the rheumatologist. Patients with a definite- or possible diagnosis were classified according to the ASAS classification criteria for axSpA.

Results: Of the 101 referrals, 81 patients fulfilled the referral criteria (52% male, median age 41 years, median back pain onset 10 years before referral, Table 1). IBP was present in 53%, 56% was HLA-B27 positive, and 32% had some level of radiographic sacroiliac joint abnormalities (of whom 42% fulfilled the mNY criteria). Eventually, 23% (n=19) was clinically diagnosed with definite-axSpA (100% fulfilling the ASAS axSpA criteria; 53% radiographic) and 41% (n=33) with possible-axSpA (55% fulfilling the ASAS axSpA criteria; 6% radiographic). Importantly, of the 47 patients with recurring AAU, 87% had already had CBP during previous AAUs. Men had the same chance of fulfilling

the ASAS axSpA criteria as women (57%, vs 56%), and did not differ in number of SpA features, HLA-B27, back pain duration and IBP. However, men were more likely to be clinically diagnosed with axSpA (33% versus 13% in women).

Conclusion: The referral of AAU patients with CBP resulted in 23% new axSpA diagnoses (more prevalent in men), and another 41% required follow up because of a suspicion of early axSpA. There was a substantial diagnostic delay in the majority of patients with recurring AAU, as many already had back pain during previous AAU. In AAU, screening for CBP and prompt referral has a high diagnostic yield, and should consistently be promoted among ophthalmologists and rheumatologists.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

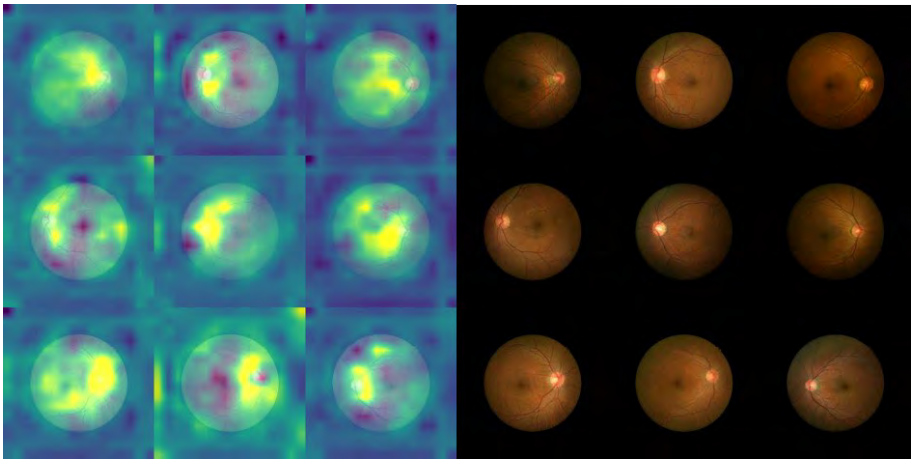
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

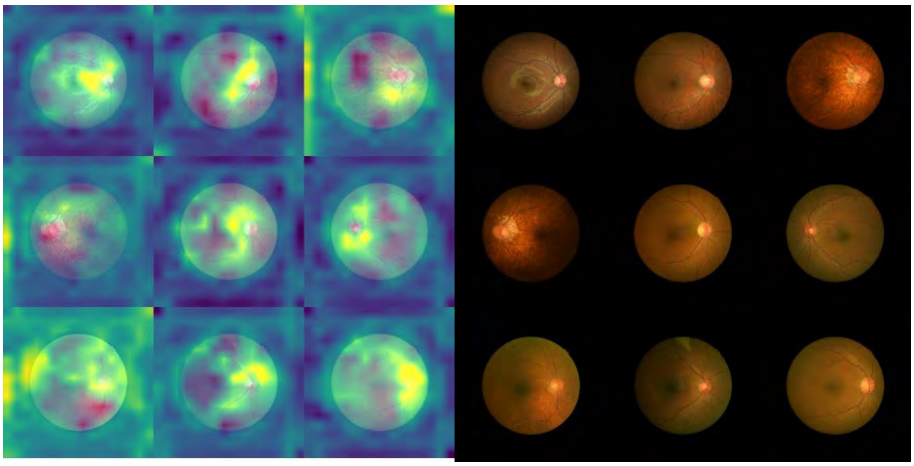
Background/Purpose: Fundoscopy is essential to identify the retinopathy of patients with autoimmune diseases. However, the classification of different autoimmune diseases is difficult by human eyes using traditional fundoscopy. We hypothesized that patients with axial spondyloarthritis (SpA) might have subtle differences in retinal images that are sufficient to classify SpA. We aimed to develop a deep learning model to detect the difference in retinal images between patients with SpA and other autoimmune diseases.

Methods: We prospectively collected 342 retinal images from 218 patients with or without SpA, which diagnosis was based on the Assessment of SpondyloArthritis international Society classification criteria for axial spondyloarthritis. The population was divided into a training group, a validation group and testing group (5:1:1). The retinal images were fed to a model based on the EfficientNet-B1, which was trained to classify SpA. The performance of the model was tested on a hold-out dataset of 31 patients whose retinal images were not used in the model training. The essential pixels that the models used to classify SpA was visualized using the Gradient-weighted Class Activation Mapping (Grad-CAM). Overall model performance was measured by accuracy, sensitivity, specificity, area under the curve of the receiver operator curve (AUROC).

Results: We included 51 women and 93 men with SpA (mean age, 42.9±12.8 years) and 74 non-SpA individuals (F: M, 57:17; mean age, 49.4±13 years). Among them, images from 187 patients were used for training and validation, while 31 of them were used to test the model performance. The overall model performance was 0.735 by AUROC. The sensitivity and specificity to classify SpA was 87% and 62.5%, respectively. Figures 1 and 2 showed the results from Grad-CAM, which highlighted the model interpretability.



Highlighting important regions of fundoscopy localized by Grad-CAM(left) and original fundoscopy(right) in SpA patients.



Highlighting important regions of fundoscopy localized by Grad-CAM(left) and original fundoscopy(right) in non-SpA patients.

Conclusion: This exploratory study indicates that subtle changes in retinal images may be distinctive for SpA which may be detected by deep learning models.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory bowel disease (IBD) and specifically Crohn's disease (CD) is known to be associated with spondyloarthritis (SpA) (1). However, only little is known about factors associated with the development of spondyloarthritis in CD. The purpose of this study is to identify factors associated with the presence of SpA in a cohort of patients with CD.

VARIABLE		TOTAL n=108	SpA n=23	No SpA n=85	p *
Age, years, mean ± SD		36.6 ± 12.7	37.5 ± 11.3	36.3 ± 13.1	0.44

* U-Mann Whitney test for numerical variables and Fisher's exact test for categorical variables

Table. Baseline demographic and clinical characteristics of the included patients with Crohn's disease with or without spondyloarthritis.

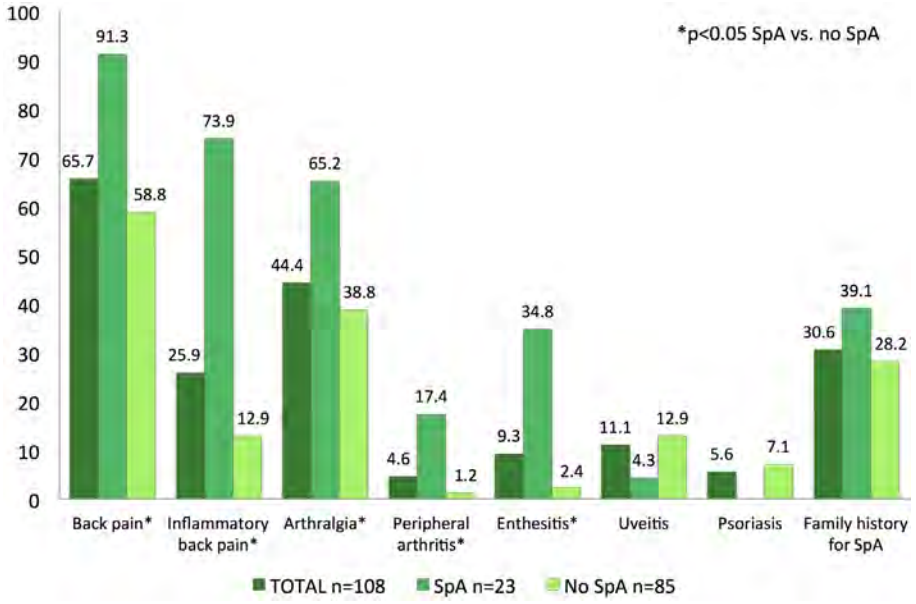

Figure. Spondyloarthritis manifestations in patients with Crohn's disease.

Methods: Patients with a definite diagnosis of CD naïve to or not being treated with biological agents for at least 3 months were included in a CD-arm of the German Spondyloarthritis Inception Cohort (GESPIC-Crohn). Gastroenterologists were encouraged to include consecutively recently diagnosed CD patients. Patients were classified according to the Montreal classification including location and behavior of CD. Patients received a structured assessment of SpA manifestations (including magnetic resonance imaging of sacroiliac joints and spine) by a rheumatologist who was responsible for the final diagnosis of SpA / no SpA. Clinical activity of CD was assessed by the Harvey-Bradshaw Index (HBI). In addition, colonoscopy was performed, Simple endoscopic Score for Crohn's Disease (SES-CD) was determined and fecal calprotectin was measured.

Results: A total of 108 patients with CD were enrolled. The mean (mean ± SD) age was 36.6 ± 12.7 years, and CD symptom duration was 5.3 ± 7.4 years. At baseline, 44 (40.7%) patients were treated with non-biologic immunomodulating drugs: 16 (14.8%) patients received mesalazine, 27 (25.0%) azathioprine, and 1 (0.9%) methotrexate. Oral steroids were given to 38 (35.2%) patients. A total of 103 (96.3%) patients were biologics naïve. SpA was diagnosed in 23 (21.3%) patients: 12 had axial SpA and 11 peripheral SpA. Patients with SpA had higher prevalence of HLA-B27, of clinical SpA features (back pain, inflammatory back pain, peripheral arthritis, enthesitis), higher level of CRP and higher activity of CD as measured by the HBI. There were not substantial differences between SpA vs. non-SpA patients in terms of CD duration, endoscopic activity, disease location or behavior, or treatment, except for mesalazine, which was more frequently administered in patients with SpA than non-SpA (39.1% vs. 8.2%, p=0.001, respectively).

Conclusion: SpA was present in 21% of patients with CD in this early cohort with almost equal proportions of axial and peripheral forms. Presence of HLA-B27 and higher clinical activity of CD were associated with the presence of SpA.

Prevalence of Undiagnosed Axial Spondyloarthritis Among Patients with Inflammatory Bowel Disease: A Secondary Care Cross-Sectional Study

Chong Seng Edwin Lim[1], Mark Tremelling[1], Louise Hamilton[1], Alexander MacGregor[1], Tom Turmezei[1], Matthew Kim[1] and Karl Gaffney[2], [1]Norfolk and Norwich University Hospital, Norwich, United Kingdom, [2]Norfolk and Norwich University Hospital NHS Foundation Trust, Norfolk, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is closely related to inflammatory bowel disease (IBD), however contemporary data on the burden of hidden disease in the IBD population is lacking. This is despite significant advances in imaging and improved understanding of the axSpA disease spectrum. Recognition of the association between axSpA and IBD is important in order to bridge the gap of diagnostic delay and streamline referral for treatment. This study aims to elucidate the hidden prevalence of axSpA in IBD patients in secondary care.

Methods: Screening questionnaires were sent to consecutive IBD patients attending routine clinics (September 2017 to February 2019) in a large teaching hospital serving an estimated 3000 IBD patients. Patients fulling the eligibility criteria (gastroenterologist-verified diagnosis, 18 to 80 years old, biologic therapy naïve, no previous diagnosis of axSpA); and a moderate-diagnostic-probability of axSpA (self-reported chronic-back-pain (CBP) onset before 45 years old) were invited for rheumatological assessment. This included a medical interview, physical examination (including joint and tender point count, MASES, dactylitis count, BASMI), patient reported outcomes (BASDAI, BASFI, BASGI, Harvey-Bradshaw-Index, Partial-Mayo-Index), relevant laboratory tests (CRP, ESR, HLA-B27), pelvic radiograph, axSpA protocol MRI, and remote review by a panel of expert axSpA rheumatologists.

Results: The prevalence of rheumatologist-verified diagnosis of axSpA was 5% (95% CI 1.3,12.0) with a mean delay to diagnosis of 12 (S.D. 12.4) years. Using contemporary classification criteria, the prevalence of axSpA was 39% (ESSG), 12% (ASAS), (mNYC) respectively. Of the 470 patients approached, 41% (n=191) responded. Of the 173 valid completed questionnaires, 53% (n=91) had CBP onset < 45 yr and 90% (n=82) attended for clinical assessment. The mean age was 52 yr, 37% male. 74% ulcerative colitis, 26% crohn's disease, 66% disease remission. The prevalence of physician verified inflammatory back pain (IBP) was 20%. However, 38%, 35%% and 29% fulfilled Calin, Berlin and ASAS classification criteria respectively. Previous history of acute anterior uveitis (AAU), skin psoriasis, other peripheral musculoskeletal (MSK) axSpA manifestations were reported by 5%, 7% and 16% respectively. Thirty-five percent (n=29) had a positive family history of axSpA-related conditions (62% IBD, 52% skin psoriasis, 4% axSpA). Mean CRP and ESR were 4.3mg/L and 14mm/h respectively; 7% HLA-B27 positive; 4% ASAS positive MRI (active sacroiliitis); 6% fulfilled mNYC radiological criteria.

Conclusion: The hidden prevalence of rheumatologist-verified diagnosed axSpA in IBD patients seen routinely in a hospital setting with self-reported CBP which started before 45 years old is conservatively estimated at 5%. This

represents a significant hidden disease burden. Greater awareness and education are still needed. We need to get it right first time by appropriate identification and referral from gastroenterology to rheumatology, in order to potentially shorten the delay to diagnosis and allow access to effective therapy.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

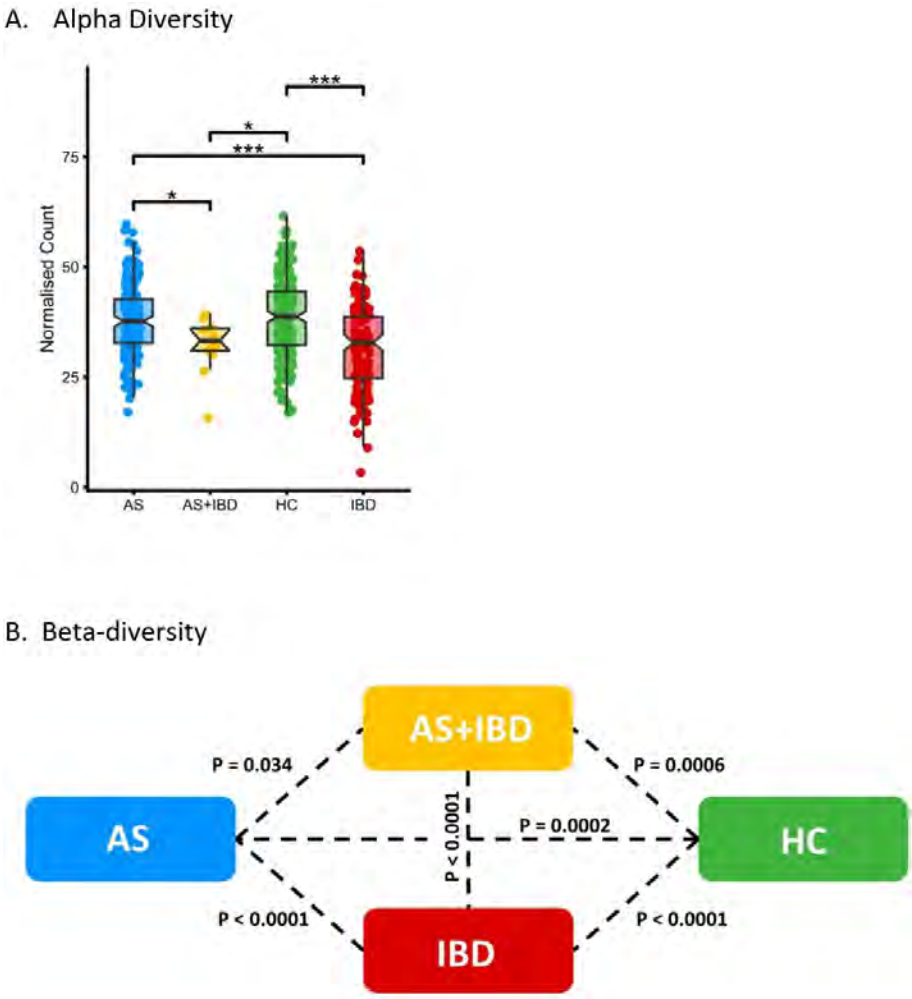
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple studies have confirmed that the gut and stool microbiome in ankylosing spondylitis (AS) and inflammatory bowel disease (IBD) are distinct from healthy controls, and it is known that ~60% of AS cases have subclinical IBD, and 5-10% have clinical IBD. As different microbiome studies of these diseases have used different sequencing and analytic methods, it has not been possible to determine if these diseases have similar or different gut microbiomes. This study aimed to test the hypothesis that the gut microbiome in AS and IBD is different, and whether the gut microbiome in AS correlated with disease activity.

Methods: After ethics approval and written informed consent, stool samples, terminal ileal biopsies, colonic biopsies and/or rectal biopsies were obtained from 192 AS patients (136 Swedish, 33 Australian (5 with concomitant IBD, 'AS-IBD') and 23 Italian), 59 Australian IBD patients, and 112 controls undergoing colon cancer screening studies but with no ill-health (105 Australian and 7 Italian). Metagenomic profiling was performed using 16S rRNA sequencing and processed using Qiime2. Alpha-diversity, beta-diversity and taxonomic comparisons were controlled for age, BMI, country of origin, BMI, smoking status, gender, and TNF-inhibitor usage.

Results: AS, AS-IBD and IBD patients differed from one another and from healthy controls in both alpha and beta-diversity (Figure 1). Considering patients with either fecal calprotectin (FCP)< 100 or >100, AS patients differed in both alpha and beta-diversity from IBD patients (P< 0.01 all comparisons). FCP >100 was also associated with



Comparison of Australian, Swedish and Italian AS patients, Australian IBD patients, and Australian and Italian healthy controls sampled from four body sites: terminal ileum, right colon, rectum, and stool.

microbiome differentiation in AS and IBD patients. AS patients with and without clinical IBD could be distinguished from one another with moderate accuracy using stool microbiome (AUC=0.754), similar to the performance of FCP (AUC=0.752) and better than the Dudley Inflammatory Bowel Symptom Questionnaire (AUC=0.716). Stool microbiome also accurately distinguished IBD patients from healthy controls (AUC=0.757). Amongst AS patients, beta- but not alpha-diversity differed between those with BASDAI 0-2.5, 2.5-5.0, 5.0-7.5 and 7.5-10 (P=0.015). TNFi usage was associated with differentiation of the gut microbiome in IBD patients. Increased *Haemophilus* carriage was observed in AS, AS-IBD, AS patients with elevated BASDAI (7.5+), and IBD patients with FCP >100. Apart from *Streptococcus* and *Haemophilus*, no other indicator taxa were shared between AS and IBD patients.

Conclusion: AS and AS-IBD patients have a distinct gut microbiome compared with IBD patients and healthy controls. This is consistent with immunological and genetic evidence suggesting that the gut plays a different role in driving AS compared with IBD. AS and IBD disease activity is associated with changes in the gut microbiome.

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with a clinical diagnosis of Spondyloarthritis (SpA) and Psoriatic Arthritis (PsA) may have predominant axial or predominant peripheral symptoms. However, a huge clinical overlap exists and clear patterns of distribution are lacking. The objective of this study was to identify patterns of peripheral involvement according to the specific location of these symptoms in the whole spectrum of SpA and PsA.

Methods: International, cross-sectional and multicentre study with 24 participating countries. Consecutive patients considered by their treating rheumatologist as suffering from either PsA, axial SpA (axSpA), peripheral SpA (pSpA), inflammatory bowel disease (IBD)-related SpA, reactive arthritis or juvenile SpA were enrolled. A specific cluster analysis for each peripheral musculoskeletal manifestation (i.e., peripheral articular involvement, enthesitis and dactylitis) was conducted using data concerning the specific location of these symptoms at any time during the course of the disease. Multiple correspondence analyses and k-means clustering methods were used. Distribution of peripheral manifestations and clinical characteristics were compared across the different clusters.

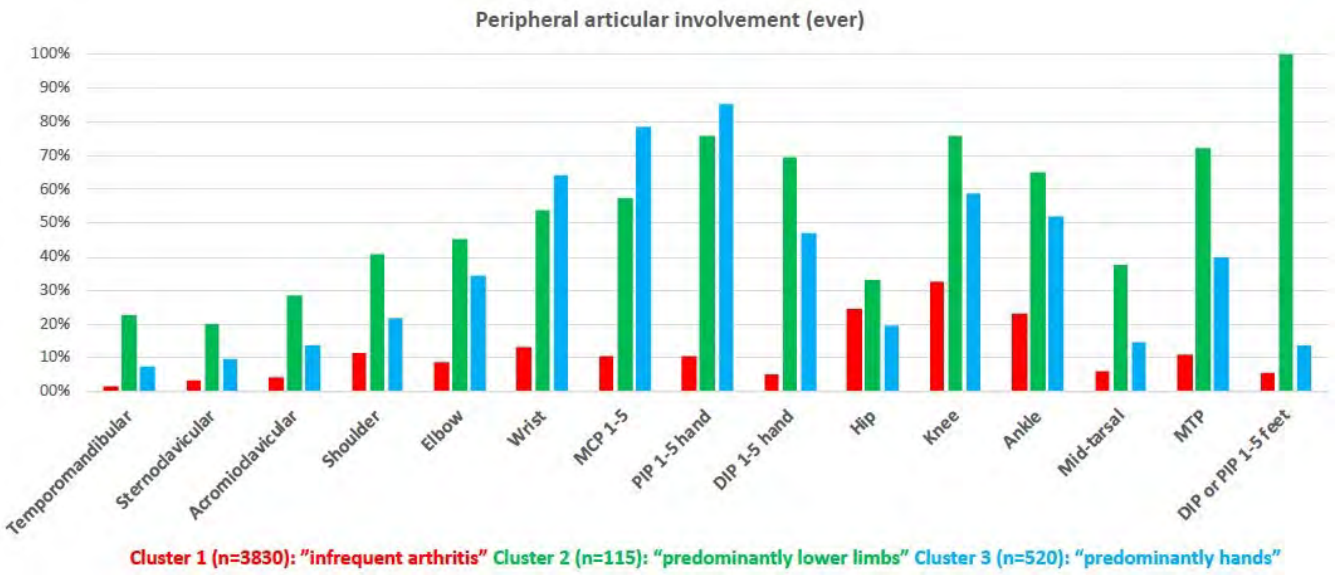

Figure 1. Cluster analysis for peripheral articular involvement: distribution of the affected joints with regard to the cluster.

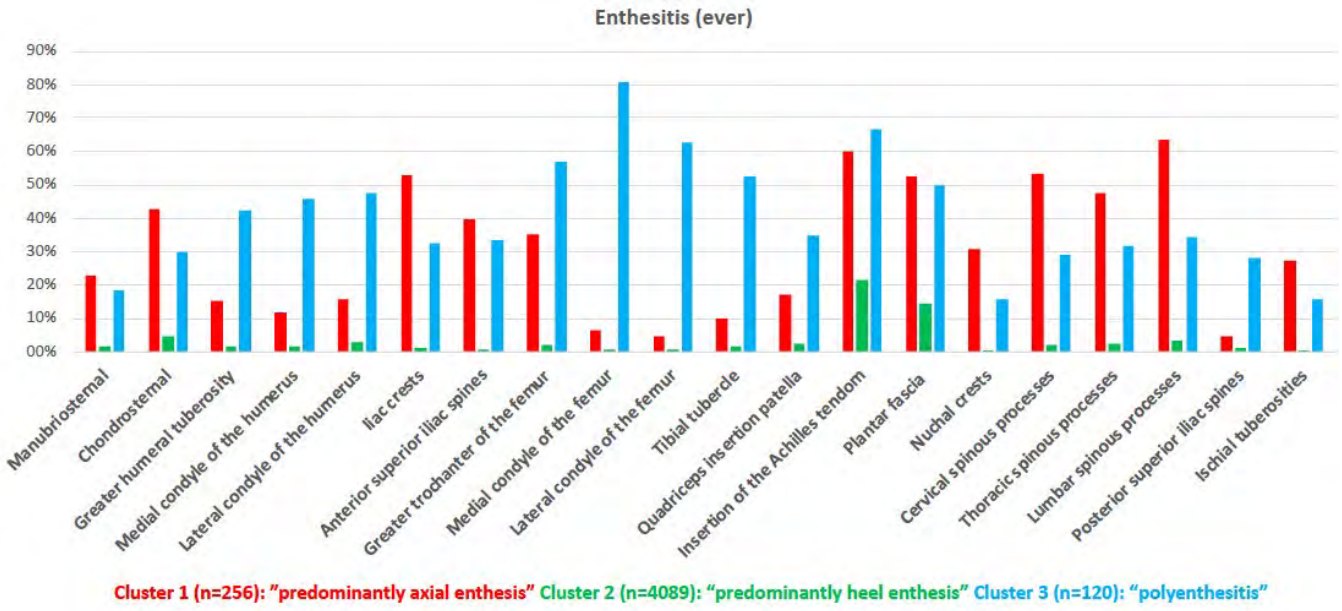

Figure 2. Cluster analysis for enthesitis: distribution of the affected enthesis with regard to the cluster.

Results: A total of 4465 patients were included in the analysis. Three clusters were found with regard to the location of peripheral articular involvement (Fig. 1), labelled as "infrequent arthritis (a)", "predominantly lower limbs (b)" and "predominantly hands (c)". Patients from the "a" group showed, in comparison with "b" and "c" groups, a higher prevalence of males (63.9% vs 51.3% vs 41.5%), HLA-B27 positivity (79.8% vs 48.2% vs 34.8%) and SpA diagnosis (axSpA or pSpA) (76.7% vs 30.6% vs 35.2%), but lower prevalence of psoriasis (23.2% vs 67.8% vs 59.6%) and PsA diagnosis (17.2% vs 61.7% vs 58.5%). Between "b" and "c" clusters, the first one showed a higher prevalence of uveitis (15.7% vs 8.7%), and a lower prevalence of IBD (3.5% vs 6.7%).

With regard to the location of enthesitis (Fig. 2), 3 clusters were also found, labelled as “predominantly heel enthesitis (d)”, “predominantly axial enthesitis (e)” and “polyenthesitis (f)”. Patients from the “f” group showed a higher prevalence of fibromyalgia according to the FiRST questionnaire (41.3% vs 17.4% vs 31.3%), psoriasis (48.3% vs 28.4% vs 23.4%) and PsA diagnosis than in the “d” and “e” groups (40.8% vs 22.7% vs 21.5%), and a lower prevalence of males (40% vs 61.9% vs 56.2%) and SpA diagnosis (52.5% vs 71.0% vs 73.1%).

Finally, 3 clusters were found with regard to the location of dactylitis, labelled as “absence of dactylitis (g)”, “predominantly toes (h)” and “predominantly fingers (i)”. The “g” group showed in comparison with the other two groups, the highest prevalence of males (61.4% vs 51.4% vs 52.9%), HLA-B27+ (66.6% vs 52.5% vs 50.0%) and SpA diagnosis (72.1% vs 30.7% vs 41.2%), and the lowest prevalence of psoriasis (26.9% vs 68.6% vs 79.4%) and PsA diagnosis (21.5% vs 65.7% vs 52.9%).

Conclusion: These results suggest the presence of heterogeneous patterns of peripheral involvement in SpA and PsA patients without clearly defined groups, confirming the clear overlap of these peripheral manifestations across the different underlying rheumatological diseases.

Time-dependent Analysis of Incident Extra-articular Manifestations and Comorbidities in Axial Spondyloarthritis

Gillian Fitzgerald[1], George Tomlinson[2], Steve Ramkissoon[3], Sophie Wojcik[4], Robert Inman[5] and Nigil Haroon[6], [1]Toronto Western Hospital, Toronto, ON, Canada, [2]Department of Medicine, University Hospital Network, Toronto, Toronto, ON, Canada, [3]UHN, Toronto, ON, Canada, [4]UHN, Montreal, QC, Canada, [5]University Health Network, Toronto, ON, Canada, [6]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) patients have higher morbidity and mortality compared to healthy controls. Much of this excess disease burden is related to extra-articular manifestations (EAM) and comorbidities that may develop over time. Knowledge of predictive factors for the development of extra-spinal events in axSpA is limited by a dominance of cross-sectional studies in this area. This study aims to use real-world data to longitudinally analyse the risk factors for the development of extra-spinal events in axSpA.

Methods: This is a longitudinal observational cohort study, consisting of consecutive adult-onset axSpA patients (age of onset of axial symptoms ≥ 16 years) from July 2003 onwards. Patients were reviewed on a standard protocol every six months, with comprehensive documentation of demographics, clinical, laboratory and radiographic data. EAMs were defined as acute anterior uveitis (AAU), psoriasis (PsO) and inflammatory bowel disease (IBD). Time-to-event analysis, with time-weighted covariate exposure lagged by one year, was performed using R statistical package to assess the cumulative burden of extra-spinal events.

Results: Of the 1148 axSpA patients included in the study, 66% (n=757) were male and mean age was 40 (SD 12) years at study entry. AAU was present in 22% (n=246), IBD in 5% (n=55) and PsO in 4% (n=47) at baseline. After excluding these patients in the longitudinal analysis, AAU was the most frequent EAM to develop (see Figure 1) and was associated with the use of DMARDs (HR 2.28, p=0.01; Table 1). There was no impact of sex or disease activity on the development of any EAM. Hypertension was the most prevalent comorbidity at study entry (11%, n=120), followed by peptic ulcer disease (7%), depression (7%) and hyperlipidaemia (6%). The prevalence of ischaemic heart disease (IHD) was low (1.2%). Hypertension was the most frequent comorbidity to develop in follow-up (n=198), followed by depression (n=152) and hyperlipidaemia (n=128). IHD remained low (n=35). Age was the most common predictor for the development of a comorbidity (Table 2). Being male significantly increased the risk of hypertension (HR 2.61) and high cholesterol (HR 2.96), and was protective against fibromyalgia (HR 0.21). Time-averaged exposure analysis of

BASDAI: Bath Ankylosing Spondylitis disease activity index; CVD: cerebrovascular disease; DMARD: disease-modifying anti-rheumatic drug; HLA: human leucocyte antigen; HR: hazard ratio; IHD: ischaemic heart disease; NSAID: non-steroidal anti-inflammatory drug; P: p-value.

Table 2 Regression analysis of predictors for the development of comorbidities over time.

medication usage showed an association between biologics and an increased incidence of hypertension (HR 2.35) and fibromyalgia (HR 6.5). NSAIDs (HR 2.15) were associated with an increased risk of hypertension (HR 2.15). A higher average BASDAI over the preceding five years significantly increased the risk of the development of sleep apnoea, depression and fibromyalgia.

Conclusion: To our knowledge, this is the largest longitudinal analysis of extra-spinal events in a real-world cohort of axSpA patients. Although overt IHD was uncommon, hypertension and high cholesterol were frequent. The traditional non-modifiable risk factors of age and male sex were associated with the development of cardiovascular comorbidity. Depression was associated with a higher average BASDAI in the five years preceding the diagnosis. Contrary to expectations, we saw no interaction between biologics and incidence of EAM.

Prevalence of Extra-Articular Manifestations in Early Ankylosing Spondylitis versus Non-Radiographic Axial Spondyloarthritis: A Systematic Literature Review and Meta-Analysis of 1504 Patients

Emre Bilgin[1], Umut Kalyoncu[1] and Laure Gossec[2], [1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, [2]Sorbonne Université and Hôpital Universitaire Pitié Salpêtrière, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis, psoriasis and inflammatory bowel disease (IBD) are Extra-articular manifestations (EAM) of axial spondyloarthritis (axSpA). A recent meta-analysis comparing EAMs in patients with ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA) (mean symptom duration: 1.2 to 17.7 years in AS, 1.0 to 12.1 years in nr-axSpa) reported higher prevalence of uveitis (23.0% vs. 15.9%, AS vs. nr-axSpA), however, similar prevalences of psoriasis (10.2% vs. 10.9%, AS vs. nr-axSpA) and IBD (4.1% vs 6.4%, AS vs. nr-axSpA) in patients with AS compared to nr-axSpA. Nonetheless, data comparing the prevalence of EAMs in early AS and nr-axSpA patients are lacking.

Methods: A systematic literature review was conducted in Pubmed up to 31.12.2019. Keywords referring to EAMs and early axSpA were used, publications reporting prevalence of at least one of the EAMs in patients with early AS and nr-axSpA (mean symptom duration ≤5 years). For longitudinal studies, article with largest participant number from that cohort was included. Case reports and reviews were excluded. Data were collected according to a pre-defined collection form. Prevalences of each EAM in AS and nr-axSpA were assessed by meta-analysis of proportions, using a random-effects model and the DerSimonian & Laird method. The prevalences were compared between the AS and nr-axSpA populations by calculating a pooled risk difference using R based software (Jamovi version 1.2).

Results: Of 667 articles, 6 were analyzed and all were cohort studies (details in **Table 1**). For uveitis and psoriasis 1504 (577 AS and 927 nr-AxSpA) patients and for IBD 1440 (531 AS and 909 nr-AxSpA) with early SpA were analyzed to compare the prevalence of each EAM in AS and nr-AxSpA patients: weighted mean ages 30.2±8.1 and 31.5±8.4 years (standardized mean difference: 0.6 (0.03, 1.1) years), weighted mean axSpA symptom duration 23.2±22.6 and 16.7±14.3 months (standardized mean difference: 2.9 (0.8, 5.1) months), 74.3% and 56.1% male (pooled risk difference: 16.5% (95% Confidence Interval (CI); 4.3, 28.7)) , 77.9% and 69.8% (pooled risk difference: 7.6% (95% CI; -1.3, 16.5)) carried HLA-B27, for AS and nr-AxSpA, respectively. In pooled analysis uveitis prevalence was 14.9% (95% CI; 9.1, 20.7) in AS and 9.7% (95% CI; 6.0, 13.4) in nr-axSpA, resulting in a difference in pooled prevalence of 3.5% (95% CI; 0.1, 6.8) (p=0.042); psoriasis prevalence was 8.2% (95% CI; 4.0, 12.4) in AS and 8.8% (95% CI; 2.7, 15.0) in nr-axSpA, resulting in a difference in pooled prevalence of -0.1 % (95% CI; -3.0, 2.7) (p=0.92) and IBD prevalence was 4.1 % (95% CI; 0.9, 7.4) in AS and 2.7% (95% CI; 0.8, 4.5) in nr-axSpA, resulting in a difference in pooled prevalence of -0.3 % (95% CI; -0.7, 2.7)(p=0.25) (details in **Figure 1**).

Conclusion: EAMs are frequent in early axSpA either AS or nr-axSpA. Higher prevalence of uveitis in AS patients compared to nr-axSpA patients may suggest the appearance of new cases over follow-up. Physicians need to screen carefully for EAMs at diagnosis and over follow-up especially for uveitis.

Table 2. Incremental impact of PsAID12 fatigue score on PROs. α PRO key for worse outcome (range): EQ5D utility (0-1.0) = lower; EQ5D VAS (1-100) = lower; WPAI (0-100) = higher; HAQ-DI (0-3) = higher; PsAID12 (0-10) = higher.

Background/Purpose: Fatigue is an important aspect of PsA for patients. Understanding the impact of fatigue on patient reported outcomes is important for effective management of PsA. The objective of this study was to compare clinical and patient-reported outcomes in patients who report fatigue and those who do not, and to describe the prevalence of fatigue in PsA patients from physician and patient perspective.

Methods: Cross-sectional study among patients with PsA recruited by rheumatologists and dermatologists in France, Germany, Italy, Spain, UK, and US. Data were collected from Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Physicians reported patient demographic and disease characteristics, and if patients experienced fatigue (yes/no). Patients also reported fatigue via PsAID12 domain scale (0-10 score, grouped for analysis as 0, 1-3, 4-7, >7), quality of life (EQ5D-5L), work productivity (WPAI), and disability (HAQ-DI). Patients were compared according to grouped fatigue scores using parametric tests and non-parametric tests. Multiple linear regression analyses examined impact of incremental PsAID12 fatigue score on patient reported outcomes (PROs) (EQ5D, HAQ-DI, PsAID12, WPAI). Models controlled for gender, age, BMI, body surface area psoriasis percent, number of joints affected, pain, and Charlson Comorbidity Index score. Regressions were run on patients for whom all variables were available.

Results: Data were collected from 932 physician-patient pairs. Regression analyses showed that patients with increasingly severe fatigue scores reported worse outcomes in terms of quality of life, work impairment, and disability than those with lower fatigue scores. Physicians reported fatigue in 27.5% of patients, while 80.7% of patients reported they experienced fatigue. 44.9% of physician-patient pairs agreed on fatigue presence or absence.

Conclusion: After adjusting for demographic and clinical factors, patients with severe fatigue were found to have worse clinical, quality of life, work productivity, and disability outcomes than those with mild or no fatigue. Differences between patient and physician reports of fatigue suggest that physicians may not be aware of the extent to which patients experience fatigue.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a cardinal symptom of axial spondyloarthritis (axSpA) that poses management challenges. Data on fatigue amongst Asian patients with axSpA is limited. Ethnicity and geographic differences may shape the disease manifestations, severity and comorbidities. In this study, we aim to evaluate the prevalence of fatigue and the factors associated with fatigue among patients with axSpA within a multi-ethnic Asian population.

Table 1. Baseline characteristics of patients with axSpA

Methods: We used the baseline data from a clinic registry in Singapore General Hospital. All patients fulfilled the 2009 Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA. Fatigue was assessed using the Bath Ankylosing Spondylitis Disease Activity Index fatigue item (BASDAI-fatigue) and the Short Form-36

BASDAI-F			
Variables	*b*	95% CI	*p*-value
BASDAI-axial pain	0.214	0.079, 0.348	0.002
BASFI	0.238	0.077, 0.399	0.004
BAS-G	0.024	0.006, 0.041	0.009
Ethnicity	0.894	0.119, 1.669	0.024
SF-36 VT			
Variables	*b*	95% CI	*p*-value
ASQoL	-2.346	-2.931, -1.760	<0.001
BASDAI-morning stiffness	-1.368	-2.348, -0.388	0.007

Variables entered into both models: gender, ethnicity (chinese/ non-chinese), age, education (1-7), housing type (1-7), BMI, duration of disease, $BASMI_{10}$, SPARCC enthesitis index, swollen joint count, clinically damaged joints, BASDAI-axial pain, BASDAI-peripheral pain, BASDAI-morning stiffness, BAS-G, BASFI and ASQoL.

Table 2. Factors associated with BASDAI-F and SF-36 VT on multiple linear regression

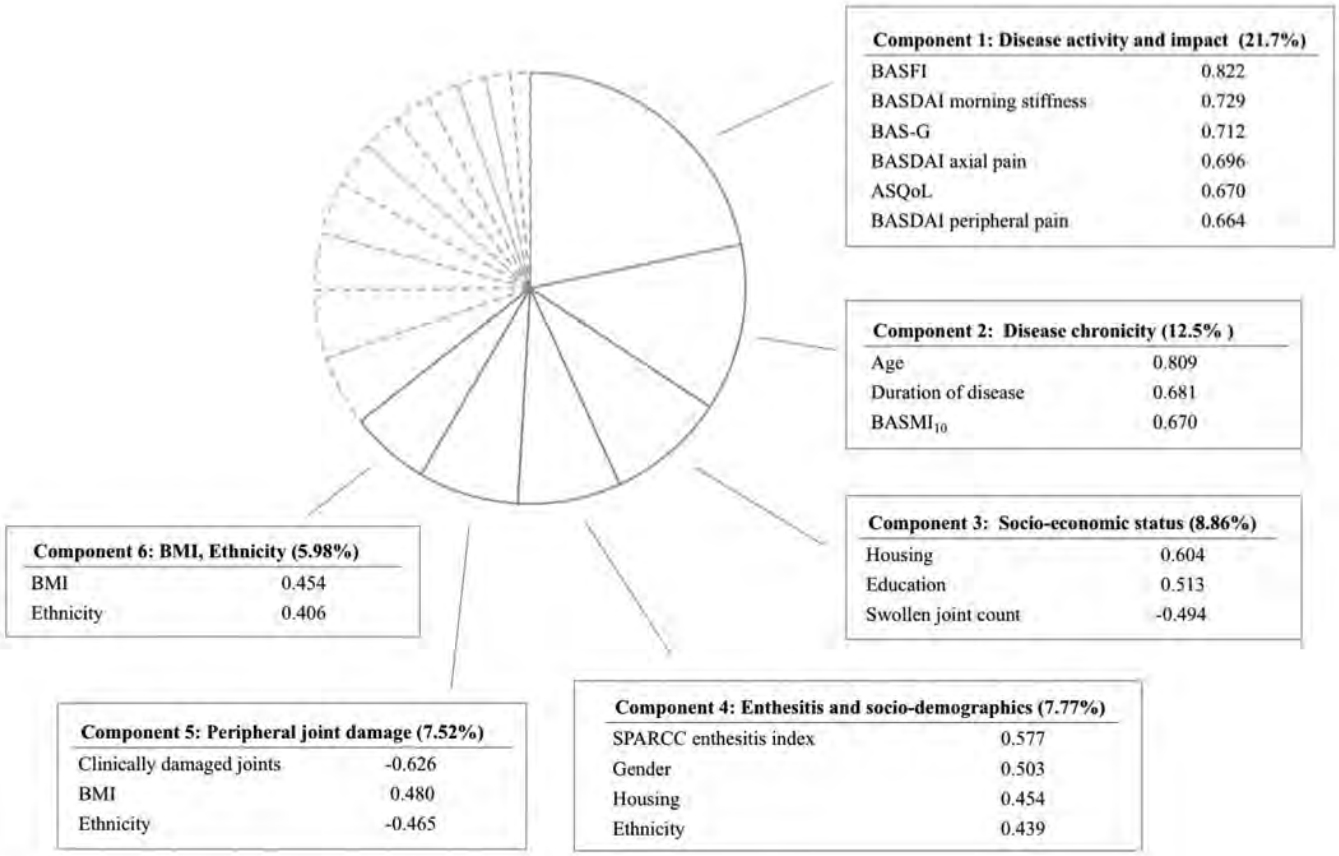

Figure 1. Principal component analysis yielding 6 components with eigenvalue greater than 1

Health Survey vitality domain (SF-36 VT). Severe fatigue was defined as BASDAI-fatigue ≥ 5/10 and SF-36 VT ≤ 10th percentile of the general Singaporean population.

Results: We included 262 consecutive patients with axSpA (79% men, 82.4% Chinese). The mean (standard deviation, SD) age and duration of disease were 41.7 (13.7) and 10.1 (8.3) years respectively. 145 (55.3%) patients reported severe fatigue by the BASDAI-fatigue criteria; 52 (31.1%) patients out of 167 with available SF-36 data had severe fatigue by the VT criteria. Patients with severe fatigue had worse scores across all disease activity assessments: BASDAI-axial pain, peripheral joint pain, morning stiffness and Spondyloarthritis Research Consortium of Canada (SPARCC) enthesitis index; and disease impact measures: Bath Ankylosing Spondylitis Patient Global Score (BAS-G), Bath Ankylosing Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life (ASQoL) and all SF-36 domains, compared to those without severe fatigue (Table 1). In the principal component analyses (Figure 1), disease activity and disease impact were statistically significantly associated with BASDAI-fatigue, while disease activity, disease impact and disease chronicity were associated with SF-36 VT. In the univariable analyses, all disease activity assessments and disease impact measures correlated with both BASDAI-fatigue and SF-36 VT; education level correlated with BASDAI-fatigue, while damaged joint count and age correlated with SF-36 VT. In the multivariable analyses, BASDAI-axial pain, BASFI, BAS-G and ethnicity were associated with BASDAI-fatigue, while ASQoL and BASDAI-morning stiffness were associated with SF-36 VT (Table 2).

Conclusion: Fatigue is prevalent amongst patients with axSpA in Asia and is associated with disease activity, disease impact as well as patient related factors including education level and ethnicity.

Patient Perceptions of Fibromyalgia Symptoms and the Overlap with Axial Spondyloarthritis

Kelly Gavigan[1], William Nowell[2], Regan Reynolds[1], Laura Stradford[1], Jeffrey R Curtis[3] and Alexis Ogdie[4], [1]Global Healthy Living Foundation, Upper Nyack, NY, [2]Global Healthy Living Foundation, New York City, NY, [3]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In clinical practice, it is often challenging to distinguish fibromyalgia syndrome (FMS) from axial spondyloarthritis (axSpA), which includes ankylosing spondylitis and non-radiographic axSpA. Early stages of axSpA may present with an onset similar to FMS, and likewise patients with FMS may have symptoms that are similar to axSpA. Differentiating between axSpA and FMS can also be challenging for patients and can cause confusion about their diagnosis. This study examined the prevalence of axSpA symptoms among patients with FMS and differences in the pathway to diagnosis among patients with and without concomitant axSpA.

Methods: Adult US patients with FMS without concomitant rheumatoid arthritis or psoriatic arthritis in the ArthritisPower registry received email invitations to participate. Participants (pts) were asked whether they had a diagnosis of axSpA or ankylosing spondylitis and completed patient-reported outcome measures including Patient Reported Out-

comes Measurement Information System (PROMIS) measures for Pain Interference, Sleep Disturbance and Fatigue, and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Pts then responded to a 57-item customized survey developed by the researchers in collaboration with patient partners. Results are descriptively reported.

Results: As of March 2020, 301 pts completed the survey; 97% female, 90% White, mean (SD) age of 53 (10). Mean (SD) Pain Interference score was 68 (5); Sleep Disturbance 64 (8); Fatigue 69 (6); and BASDAI 46 (8). Of the pts, 44 (15%) reported concomitant axSpA, 61% osteoarthritis, 6% gout, 5% Crohn's or ulcerative colitis, and 4% lupus. Half (52%) of all pts perceived their FMS to be 'rarely' or 'never' well managed and 80% ever felt that they have had an additional undiagnosed condition. Three-fourths (74%) of pts reported being able to differentiate between their FMS pain and pain from a concomitant disorder. Back pain lasting >3 months was reported by 93% of axSpA pts and 94% of non-axSpA pts; 11% reported all of the symptoms consistent with patient reported versions of the Assessment of SpondyloArthritis International Society (ASAS) criteria (back/buttock pain >3 months; age of symptom onset < 45; sacroiliitis diagnosis; at least one spondyloarthritis feature) (Figure 1), and of these, 32% reported an axSpA diagnosis. More pts with axSpA received their FMS diagnosis by a rheumatologist (45%) than without (41%) (Figure 2). Of the pts without an axSpA diagnosis (n=257), only 7% recalled their provider ever discussing with them the possibility of axSpA, including non-radiographic axSpA. Half (52%) of pts with axSpA believe that their axSpA should have been diagnosed earlier, with 39% reporting one reason for the delay as their doctors' belief that FMS was the cause of any axSpA symptoms.

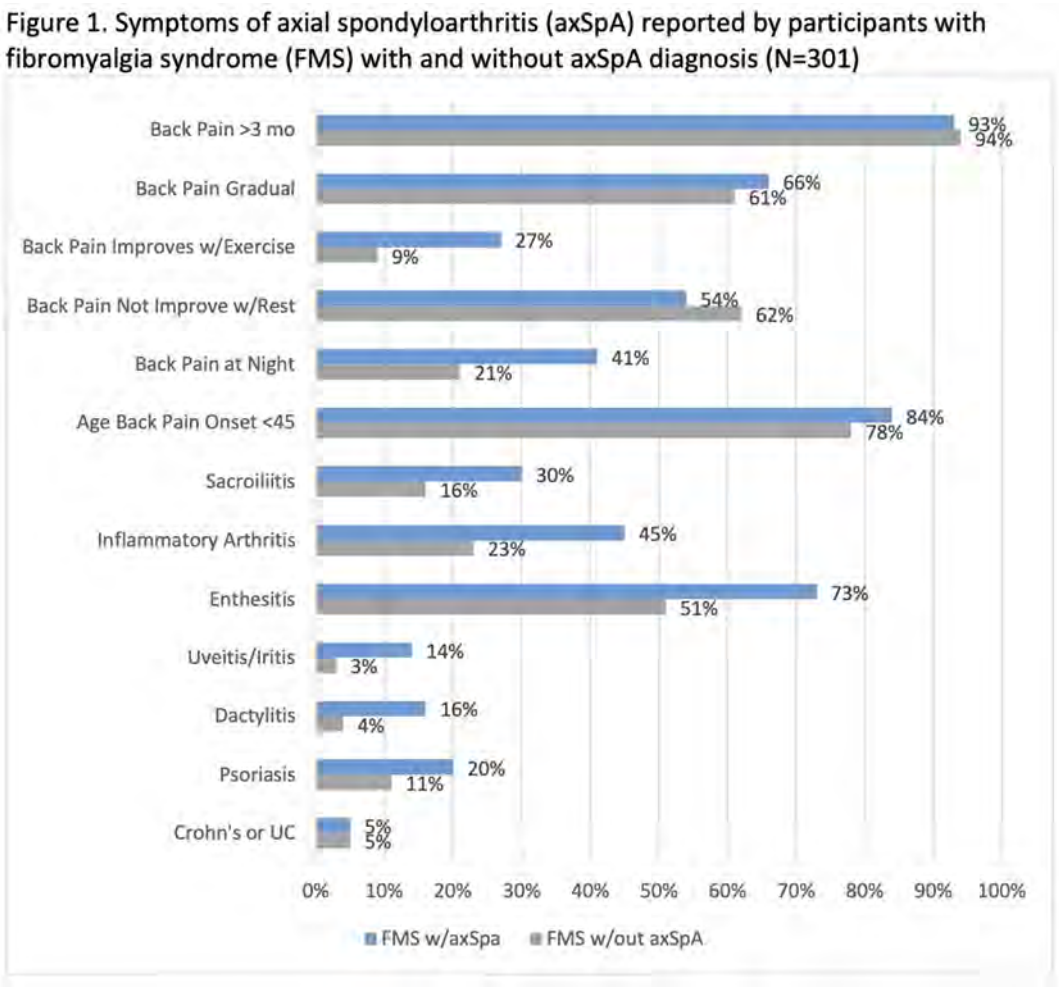

Figure 1. Symptoms of axial spondyloarthritis (axSpA) reported by participants with fibromyalgia syndrome (FMS) with and without axSpA diagnosis (N=301)

Figure 2. Provider giving fibromyalgia (FMS) diagnosis, by axial spondyloarthritis (axSpA) diagnosis status (N=301)

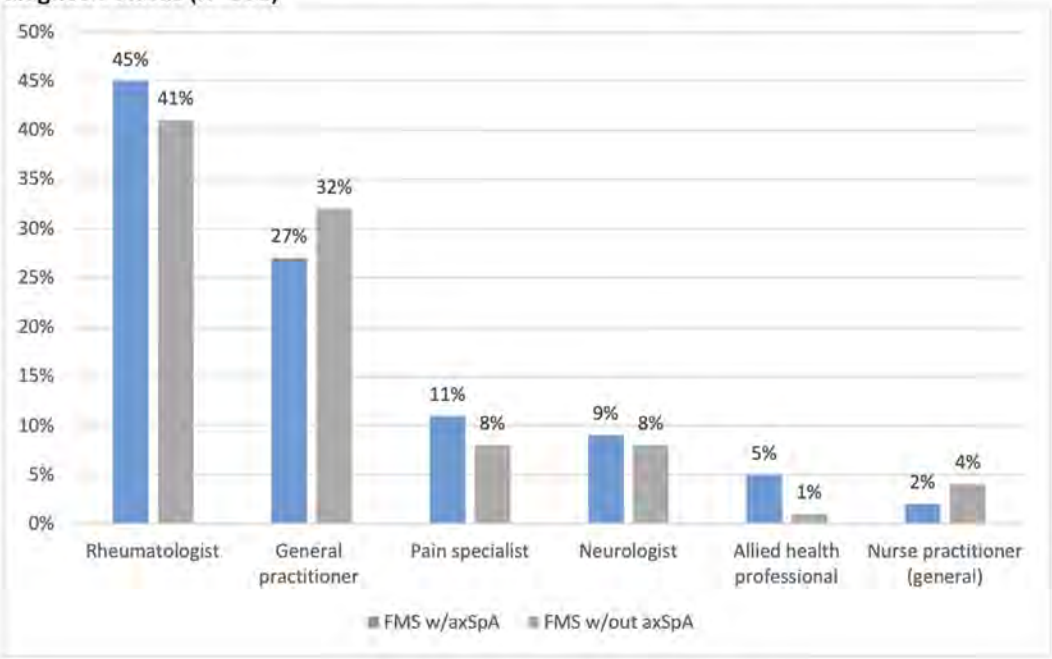

Figure 2. Provider giving fibromyalgia (FMS) diagnosis, by axial spondyloarthritis (axSpA) diagnosis status (N=301)

Conclusion: Patients with FMS often experience symptoms of axSpA and the two conditions can occur concomitantly. Additional research is needed to improve the triage, diagnosis, and education of patients with FMS and symptoms of axSpA.

Abstract Number: 1317

A Large Agreement Between the Pain Points of the ACR 1990 Fibromyalgia Criteria and the MASES Enthesitis Score Is Observed in Patients with Axial Spondylitis, Including in Patients Without Concomitant Fibromyalgia

Faten Hamitouche[1], Clementina Lopez-Medina[2], Laure Gossec[3], Serge Perrot[4], Maxime Dougados[5] and Anna Molto[6], [1]Rheumatology Department, Cochin Hospital, Paris, Ile-de-France, France, [2]Rheumatology Department, Cochin Hospital, Paris, Paris, France, [3]Sorbonne Université and Hôpital Universitaire Pitié Salpêtrière, Paris, France, [4]Paris Descartes University, Paris, Ile-de-France, France, [5]Université de Paris, Department of Rheumatology, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Paris, France, [6]Rheumatology Department, Cochin Hospital, APHP, Paris, France, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is the hallmark lesion in Spondyloarthritis (SpA). The Maastricht Ankylosing Spondylitis Enthesitis score (MASES), which assesses 13 enthesitic sites, is the most widely used. Fibromyalgia (FM) is characterized by chronic diffuse musculoskeletal pain and diffuse pain points assessed by the tender points of the ACR 1990 criteria. Coexistence of FM represents a difficulty in the evaluation of enthesitis due to a possible overlap between the tender points of the MASES and the ACR criteria for FM.

To assess the agreement between the MASES and the tender points of the ACR 1990 FM criteria in a population of patients with axial spondyloarthritis (axSpA).

Methods: Ancillary cross-sectional analysis of the French Predict-SpA study. Patients had a diagnosis of axSpA according to their rheumatologist and an indication to start a TNF blocker (TNFb). All patients were screened for FM according to the FiRST questionnaire, and all patients underwent a physical examination : 18 tender points of the ACR 1990 criteria and the 13 enthesitic sites of the MASES were evaluated in a random order. Analysis: the overlap/agreement between the MASES and the ACR/FM tender points was assessed by the intraclass correlation coefficient (ICC). The agreement for "high" values in both scores (i.e. >6 for MASES and >9 for ACR) was evaluated by the PABAK (Prevalence-Adjusted Kappa). The same analysis was performed in the group of patients with and without concomitant FM. The characteristics of patients with high ACR and MASES scores were compared with the rest of the population by univariate and multivariate analyses.

Results: The study involved 526 patients with axSpA diagnosis, and among them, 202 were screened as FM by the FiRST questionnaire (by a score ≥ 5/6) but only 86/526 (16.3%) fulfilled the 1990 ACR FM criteria. Among the 526 patients, 446 (84.8%) had at least one ACR 1990 point, 423 (80.4%) had a MASES ≥1 and 404 (76.8%) had both at least one ACR 1990 point and a MASES ≥1. The ICC between both scores was 0.7 (95%CI [0.6-0.8]). A total of 77/526 (14.6%) patients had high ACR and MASES scores simultaneously. The agreement for high scores, assessed by PABAK, was 0.7 (95%CI [0.6-0.7]).

Among the 202 patients with concomitant FM, 179 (88.6%) had at least one ACR 1990 point and a MASES ≥1, whereas this was the case for 225/324 (69.4%) of patients without FM. The ICC between both scores was 0.6 (95%CI [0.3-0.8]) and 0.7 (95%CI [0.6-0.8]) for patients with and without FM, respectively. The agreement for high scores assessed by PABAK was 0.5 (95%CI [0.4-0.7]) in patients with FM and 0.8 (95%CI [0.7 - 0.8]) in those without.

Patients with concomitantly high ACR and MASES scores were more often HLAB27 negative (OR (95%CI) = 2.4 [1.3-4.4]), had more often a history of talalgia (OR (95%CI) = 1.9 [1.0-3.5]), a BASDAI at inclusion >4 (OR (95%CI) = 4.2 [1.2-26.6]) and a FM (OR (95%CI) = 3.38 [1.87-6.29]).

Conclusion: These results suggest a great overlap between both scores in patients with axSpA, including in those without concomitant FM. However, the coexistence of FM was associated with the presence of many pain points (both in MASES and ACR). Additional studies assessing the metrological performance of MASES in axSpA patients with concomitant FM seem necessary.

Catastrophizing in Patients with Axial Spondyloarthritis and Psoriatic Arthritis

Baptiste Coste[1], Charlotte Traverson[1], Elisabeth Filhol[1], Soraya Benamar[1], Jacques Morel[2], Sabine Laurent-Chabalier[3], Bernard Combe[4], Claire Daien[2], Cédric Lukas[5], Charlotte Hua[1] and Cecile Gaujoux-Viala[6], [1]Department of Rheumatology, CHU Nîmes, University of Montpellier-Nîmes, France, Nimes, France, [2]Rheumatology department, CHU Montpellier and University of Montpellier, Montpellier, France, [3]Department of Biostatistics, Clinical Epidemiology, Public Health and innovation in Methodology, CHU Nîmes, University of Montpellier-Nîmes, France, Nimes, France, [4]University of Montpellier, Montpellier, France, [5]CHU Montpellier and University of Montpellier, Montpellier, France, [6]Department of Rheumatology, CHU Nîmes, University of Montpellier-Nîmes, France, EA2415, University of Montpellier, Montpellier, France, Nîmes, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Catastrophizing is a negative cognitivo-affective response to an anxiety-provoking stimulus, especially to pain. Catastrophism plays a role in maintaining chronic pain and is associated with several pain related outcomes.The objective was to assess catastrophizing prevalence and associated factors in axial spondyloarthritis (SA) and psoriatic arthritis (PsA).

Methods: In rheumatology departments of two hospitals, patients completed clinical and laboratory assessment (pain VAS, global VAS, tender and swollen joints, C-reactive protein, ESR, DAS28) and questionnaires on different outcomes: disease activity (BASDAI), catastrophizing (PCS), coping (CSQ), quality of life (Sf12, Eq5D), functional impact (BASFI, HAQ), fibromyalgia (FiRST), anxiety and depression (HADS, GAD7), and insomnia (ISI). Statistical analysis included samples t-test, one-way analysis of variance, Spearman's correlations, khi-2 test, Fisher's test, Wilcoxon test, linear and logistic regressions.

Results: In all, 253 patients were included (168 SA, 85 PsA). The prevalence of a PCS score ≥20 was 45.6% [95%CI 39.5;51.8]. It was 45.5% [38.0;53.0] in SA and 45.9% [35.3;56.5] in PsA. Median PCS score was 18 [Q1-Q3 6-18] in the global population. It was 18 [7-27] in SA and 16 [6-29] in PsA. Catastrophizing was significantly associated with anxiety, depression and disease activity in SA, and with anxiety, low quality of life and pain in PsA.

Conclusion: Almost half of patients with SA or PsA were high catastrophizers. Catastrophizing has a major impact on patient daily life. It may be interesting to detect catastrophizing in order to improve the management of our patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

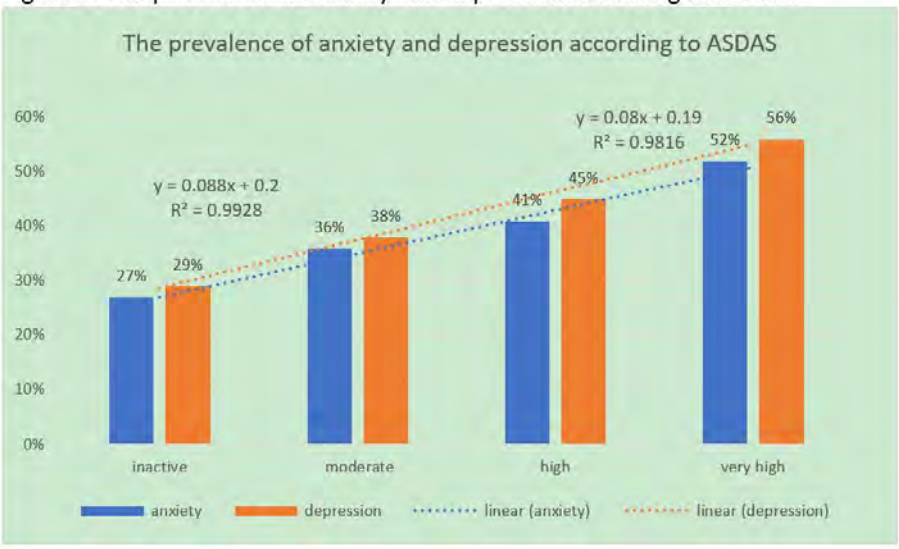
Background/Purpose: WHO survey showed that the prevalence of anxiety and depression in Chinese population and Chinese patients with chronic diseases were between 3.1% - 4.2% and 3.1% - 7.3%, respectively. Ankylosing Spondylitis Disease Activity Score (ASDAS) and Hospital Anxiety and Depression Scale (HADS) are commonly used to evaluate AS patients' disease activity and mental health. All those assessments were mainly performed by health professionals (HCPs) with paper questionnaire previously. SSDM is a novel smart disease management tool that allows patients to do self-assessments on ASDAS and HADS by mobile terminals.The purpose of this study is to estimate the prevalence of anxiety and depression in Chinese patients with AS and to analyze the potential association between disease activity and mental health.

Methods: Under the guidance and training by HCPs, AS patients downloaded SSDM and performed self-assessments bundle of ASDAS and HADS with SSDM. ASDAS< =1.3, 1.3-2.1, 2.1-3.5 and >3.5 are defined as inactive (IDA), moderate (MDA), high (HDA) and very high (VHDA) disease activity, respectively. ASDAS score < =1.3 represents inactive disease status and achievement of T2T. HADS score >=8 can be diagnosed with anxiety or depression.

Results: From June 2016 to Jan 2020, 1,931 AS patients (1,118 male, 813 female) with a mean age of 34.09 ± 11.86 (12-82) years and the median disease duration of 2.61 years from 207 hospitals performed bundle self-assessments for 2,477 times in total. According to the HADS and ASDAS assessment results, the prevalence of anxiety and depression in all patients was 36.7% and 39.3% respectively, which was significantly higher than that in the WHO survey in Chinese population and chronic disease patients. The proportion of patients achieved and failed on T2T was 29% and 71%, respectively. The prevalence of anxiety (A) and depression (D) was 25% and 23% among T2T achievers; and 37% and 32% among T2T failures, respectively (pA< 0.05, pD< 0.05).

According to ASDAS, in IDA, MDA, HDA and VHDA subgroups, the prevalence of anxiety and depression was 27%, 36%, 41%, 52% and 29%, 38%, 45%, 56%, respectively. The correlation coefficients of anxiety (A) and depression

Figure 1. The prevalence of anxiety and depression according to ASDAS.



(D) with ASDAS were rA=0.9908 and rD=0.9964. It suggested that with the increase of disease activity, the proportion of AS patients with anxiety and depression increased significantly. (Figure 1)

Conclusion: The prevalence of anxiety and depression in AS patients was significantly higher than that in the WHO survey in Chinese population and chronic disease patients. Higher prevalence of anxiety and depression were associated with higher levels of disease activity. SSDM is an effective mobile interface to monitor and study entanglement of disease activity and mental health in AS patients, which build a foundation for proactive interventions in future.

Table 1. Differences between the low, intermediate and high physical activity tertiles

coping strategies are commonly used in health-related coping. Our objective was to determine if coping strategies, anxiety and depression are associated with physical activity in patients with axSpA. To our knowledge this has not been studied before

Methods: Consecutive out-patients from the Groningen Leeuwarden AxSpA cohort (GLAS) participated in this study. Additionally to the standardized follow-up assessments, patients completed the axSpA-Short Questionnaire to assess health-enhancing physical activity (axSpA-SQUASH), the Coping with Rheumatic Stressors (CORS) and the Hospital Anxiety and Depression Scale (HADS). Uni- and multivariate linear regression analyses were used to explore associations of copings strategies, anxiety and depression, and patient- and disease related factors with daily physical activity. Patients were stratified into three tertiles of physical activity: low, intermediate and high. To identify group differences, Kruskal-Wallis test or the Chi-Square test were used with post-hoc testing.

Results: In total 85 patients were included; 59% were male, mean age was 49±14, median symptom duration 19.5 years (IQR 12.0-31.0), 71% were HLA-B27 positive and mean ASDAS was 2.1 (SD 1.0). Median axSpA-SQUASH total physical activity score was 9406.3 (IQR 5538.8;12081.3). Scores of HADS-Anxiety (scale 7-28) and HADS-Depression (scale 7-28) had median scores 5.0 (IQR 3.0;7.0) and of 3.0 (IQR 2.0;5.5). The mostly used coping strategies was comforting cognitions (for pain, range 9-36) median of 25.5(IQR 22.0;28.0).

Univariate analysis showed that lower daily physical activity was significantly associated with gender (female), higher disease activity (BASDAI), worse physical function (BASFI), worse quality of life (ASQoL), coping strategies "decreasing activities" and "pacing", higher depression score (HADS). In the multivariate linear regression model the coping strategy "decreasing activities" (β: -376.4; 95%-CI: -621.9; -130.8, p-value: 0.003) and BMI (β: -235.5; 95%-CI:

-450.9; -20.0, p-value: 0.03) were independently associated with physical activity. The multivariate model explained 22% of variance (R2: 0.2197, p-value: 0.001). In the group comparison similar results were seen. (Table 1)

Conclusion: In this cross-sectional study in axSpA patients with established disease, multiple patient and disease related factors were associated with daily physical activity. The evasive coping strategy "decreasing activities" and BMI were independently associated with the level of physical activity. These findings suggest that to improve daily physical activity in axSpA patients attention should be paid not only on targeting disease activity, but also to other patient and disease related aspects especially coping strategies used..

Abstract Number: 1321

Central Sensitization, Disease Perception and Obesity Should Be Taken into Account When Interpreting Disease Activity in Patients with Axial Spondyloarthritis

Stan Kieskamp[1], Davy Paap[2], Marllies Carbo[1], Freke Wink[3], Reinhard Bos[4], Hendrika Bootsma[1], Suzanne Arends[5] and Anneke Spoorenberg[5], [1]University Medical Centre Groningen, Groningen, Netherlands, [2], Department of Rehabilitation Medicine, University of Medical Centre Groningen, Groningen, Netherlands, [3]Medical Centre Leeuwarden, Leeuwarden, Netherlands, [4]Medical Centre Leeuwarden, Leeuwarden, [5]University Medical Centre Groningen and Medical centre Leeuwarden, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 40% of ankylosing spondylitis patients report persistently high pain scores of >4 (scale of 0-10) even after responding to long-term TNF-α blocking therapy.[1] In other rheumatic diseases, nociplastic pain (due to altered functioning of the nervous system leading to peripheral and central sensitization) is common.[2] In axial spondyloarthritis (axSpA), patient illness and pain perceptions were shown to influence disease outcome.[3] Therefore, we hypothesized that central sensitization and patients' illness perceptions are associated with persistently high disease activity in axSpA.

Our objective was to investigate to what extent central sensitization, pain catastrophizing and patients' perceptions play a role in axSpA and to explore associations with disease activity.

Methods: Between April and September 2019, consecutive outpatients from the Groningen Leeuwarden axSpA (GLAS) cohort,[4] an ongoing large prospective cohort, were included in this study. Besides the standardized assessments, patients filled out three additional questionnaires: Central Sensitization Inventory (CSI), Pain Catastrophizing Scale (PCS) and Revised Illness Perception Questionnaire (IPQ-R). Univariable and multivariable linear regression analyses were used to investigate the association of CSI, PCS and each of the eight subscales of the IPQ-R, and disease activity assessments $ASDAS_{CRP}$, BASDAI, and CRP. We also tested the following patient characteristics: gender, symptom duration, BMI class, educational level, smoking status and HLA-B27 status.

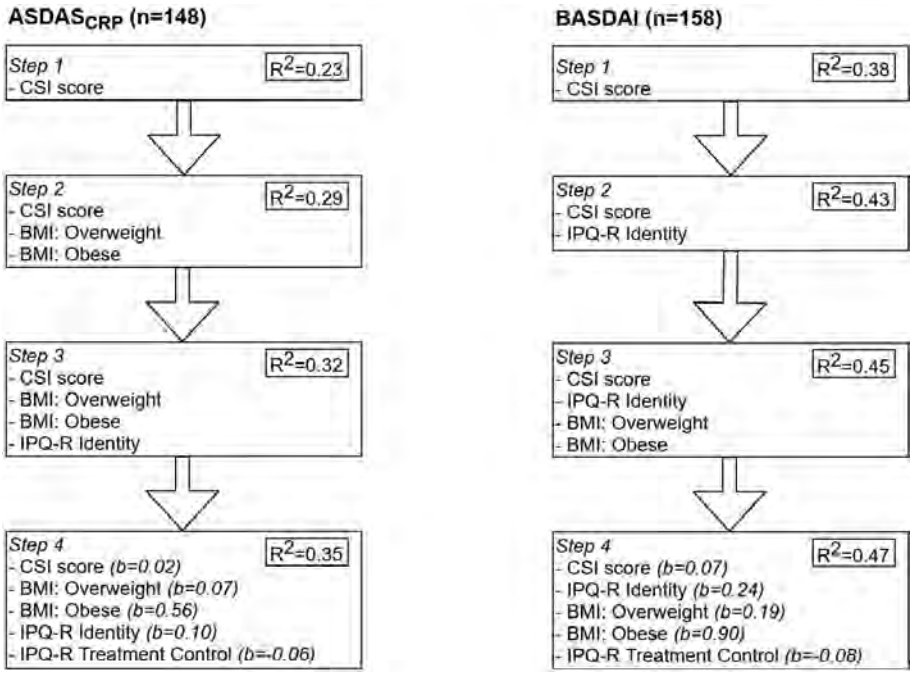

Figure 1. Results of multivariable linear regression analyses for ASDAS and BASDAI. ASDAS: Ankylosing Spondylitis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Score; CSI: Central Sensitization Inventory; IPQ-R: Revised Illness Perceptino Questionnaire; BMI: Body Mass Index.

Results: Of 182 included patients, 57% were male, 79% were HLA-B27 positive, median symptom duration was 21 (IQR 10-32), mean ASDAS$_{CRP}$ 2.1 ± 1.0, mean BASDAI 3.9 ± 2.2 and median CRP 2.9 (IQR 1.1-7.0). Mean CSI score was 38.0 ± 14.1 (scale of 0-100), and 45% of patients scored ≥40 on the CSI.[5] Median PCS score was 15 (IQR 8-22) (scale of 0-52), median IPQ-R illness identity subscore 3 (IQR 2-4) (scale of 0-14) and median IPQ-R treatment control subscore 18 (IQR 16-20). In univariable regression analysis, CSI, PCS and IPQ-R subscores all showed significant associations with ASDAS$_{CRP}$, and all except the IPQ-R subscale personal control showed significant associations with BASDAI. Only IPQ-R treatment control was significantly associated with CRP. Central sensitization, two IPQ-R subscales (perceived treatment control and the number of symptoms patients attributed to their axSpA: illness identity) and obesity were independently associated with disease activity assessments BASDAI (R^2=0.47) and ASDAS$_{CRP}$ (R^2=0.35) (Figure 1). Only obesity was independently associated with CRP.

Conclusion: In this axSpA population with long-term disease, 45% scored above the CSI cutoff point of 40, indicating a high probability of central sensitization. CSI score, illness identity, perceived treatment control and obesity were independently associated with disease activity assessments ASDAS$_{CRP}$ and BASDAI.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sleep is an essential health aspect that is often impacted in patients with axial spondyloarthritis (axSpA). This analysis aims to assess the prevalence and associated factors of sleep disorders in a large sample of European axSpA patients.

Methods: Data were analyzed from 2,846 unselected patients with self-reported clinician-given diagnosis of axSpA of the European Map of Axial Spondyloarthritis (EMAS) through an online survey (2017-2018) across 13 European countries. Socio-demographic data; BASDAI [0-10] scores; engagement in physical activity; axSpA influence on work

*As measured by the respective item of the BASDAI scale
**12-item General Health Questionnaire. A value of 3 or above indicates a risk of poor mental health

Table 2. Regression analysis to predict presence of sleep disorders (N = 2191)

choice (assessed with yes/no question “Was your current or past work choice in any way determined by axSpA?”),; risk of psychological distress (12-item General Health Questionnaire [GHQ-12; 0-12]); functional limitation [0-54] and self-reported anxiety and depression were evaluated. Presence of sleep disorders was assessed by the question: “Please indicate whether you have been diagnosed with any of the following: sleep disorders”. A Mann-Whitney test was used to compare the means of numerical variables between dichotomous variables, the Chi-Square test was used to compare the distribution between the categorical variables. Simple and multivariable logistic regression models were used to identify associations between sleep disorders and disease characteristics, mental health and work-related variables.

Results: Age of respondents was 43.9 years; 61.3% were female; 48.1% had a university degree; 67.9% were married and 71.3% were HLA-B27 positive. The prevalence of sleep disorders was 39.0%. In the bivariate analysis, presence of sleep disorders was associated with female gender (68.3% vs. 31.7%; p< 0.001); overweight/obese (56.5% vs. 49.8%; p< 0.001); increased BASDAI scores (6.1±1.8 vs. 5.0±2.1; p< 0.001); fatigue (7.0±2.0 vs. 5.8±2.4; p< 0.001); morning stiffness (5.8±2.4 vs. 4.8±2.4; p< 0.001), work impact (56.5% vs. 38.2%; p< 0.001); anxiety (56.8% vs. 12.5%; p< 0.001); depression (51.8% vs. 10.1%; p< 0.001) and higher GHQ-12 scores (6.4±4.0 vs. 3.9±3.9; p< 0.001) [Table 1]. However, factors that remained independently associated with sleep disorders in the multivariable analysis were anxiety (OR=3.8 p< 0.001) and depression (OR=3.1 p< 0.001) and female gender (OR=1.4; p=0.002) [Table 2]. According to employment status, the greatest prevalence of sleep disorders was concentrated in those on permanent sick leave (52.3%) and temporary sick leave (50.2%). [Table 3].

Conclusion: Sleep disorders were highly prevalent among axSpA European patients and strongly associated with female gender and reporting worse mental health, and spinal stiffness. Patients on permanent and temporary sick leave were more likely to report sleep disorders. The strong association between sleep disorders with both anxiety

	Sleep disorders		P-value

Pregnancy in Axial Spondyloarthropathy: A Systematic Review & Meta-Analysis

Sinead Maguire[1], Tom O'Dwyer[2], Fiona Wilson[3], David Mockler[3] and Finbar O'Shea[1], [1]St James' Hospital, Dublin, Ireland, [2]Independent Researcher, Dublin, Ireland, [3]Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthropathy (axSpA) is an inflammatory arthritis affecting the sacroiliac joints and the spine. Although this chronic condition affects a wide range of ages, many females affected are of childbearing age. At present it is unclear how axSpA affects pregnancy, in terms of prevalence of pregnancy related complications and foetal outcomes. Similarly, studies exploring the effects of pregnancy on axSpA disease activity and medication use have been limited, with divergent conclusions drawn. Studies of women with other forms of inflammatory arthritis have suggested improved disease control during pregnancy with increased risk of postpartum flares. It is unknown if axSpA follows this pattern.

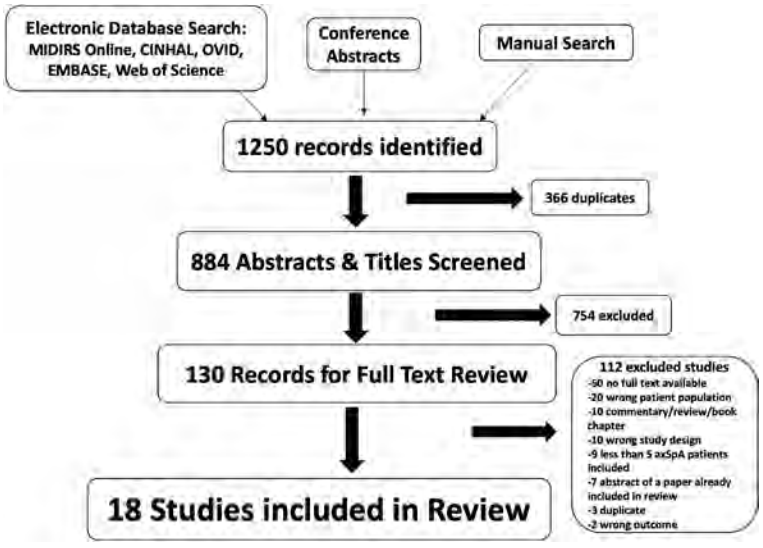

Figure 1. Study Selection

	OR	95% CI	AxSpA Weighted Pooled Mean (%)	Control Weighted Pooled Mean (%)
Cesarean Section	1.85	(1.46, 2.30)	37.3	18.6

Stillbirth	0.7	(0.26, 1.85)	0.7	1.1

Table 1. Summary of Pregnancy Complications

	OR	95% CI	axSpA Weighted Pooled Mean (%)	Control Weighted Pooled Mean (%)
LBW	1.47	(0.98, 2.21)	6.3	2.9
SGA	1.66	(0.93, 2.95)	8.7	11
Congenital abnormalities	1.34	(0.63, 2.84)	3.4	3
NICU admissions	1.55	(0.96, 2.51)	17.4	11.9

Table 2. Summary of Fetal Complications

Methods: A systematic review of case-controlled trials, observational studies, cross sectional studies and case series (n >5) focusing on axSpA in pregnancy. Studies were compiled by searching EMBASE, Medline (OVID), CINAHL, Maternity and Infant Care (MIDIRS online), and Web of Science from time of inception to September 2019 for key words related to axSpA, pregnancy, and pregnancy complications. Two reviewers independently reviewed articles to determine suitability for inclusion. The Newcastle & Ottawa Scale was used to asses risk of bias. Data extraction was performed using a standardized template to streamline data to allow comparison and meta-analysis. Where suitable data was assessed for suitability for pooling with a random effects model. Statistical heterogeneity was assessed by confidence interval overlap of the odds ratio, chi^2 test output and output of the I^2 statistic. Studies with high heterogeneity were assessed with sensitivity analysis and calculation of a weighted pooled means. The protocol for this review was prospectively registered with an international registry for systematic reviews (PROSPERO, Ref CRD42020147814).

Results: The search strategy returned 884 records. Of these, 130 full text articles were assessed for eligibility. Following assessment by two reviewers, 18 studies with a total of 3,166 axSpA women were eligible for inclusion in this review. There was an increase in the prevalence of pre-eclampsia (OR 1.3, 95% CI 0.92-1.82) and IUGR (OR 1.17, 95% CI 0.26-5.17) and a statistically significant increase in prevalence of cesarean section (OR 1.85, 95% CI: 1.46-2.30) in axSpA females (table 1). Prevalence of all analyzed fetal complications was higher in axSpA pregnancies (table 2), this did not reach significance. Disease activity during pregnancy varied significantly, but overall 47.8% of patients assessed by standardized outcomes reported increased disease activity in pregnancy. Few studies examined medication usage in pregnancy.

Conclusion: Females with axSpA overall have significantly higher prevalence of cesarean section then the general population. This analysis suggests a trend towards higher rates of pre-eclampsia, IUGR and a number of fetal complications, although further research is needed to explore this. There is a risk of active disease in pregnancy for a high proportion of axSpA females. Medication usage varied with time and country. Ongoing development of national registries could help to better understand axSpA in pregnancy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Women with Spondyloarthritis (SpA) seem at increased risk for adverse pregnancy outcomes (APO), however limited data have been published so far. The aim of this work was to assess pregnancy outcomes and to identify risk factors for APO in SpA pregnancies managed at two high-risk european pregnancy clinics.

Methods: Data on SpA pregnancies prospectively-followed in two centers between 2009-2019 were retrospectively analysed. Pregnancies complicated by APO were compared with uneventful pregnancies for demographic and clinical variables. Active disease was defined as a DAS-28-CRP >3.2 or an ASDAS-CRP > 2.1 according to peripheral or axial dominant disease, respectively.

Results: Ninety-four pregnancies in 82 patients (median age at conception 33 years, IQR 31-37) were analysed: 45 psoriatic arthritis, 23 axial SpA, 18 undifferentiated SpA, 5 enteropathic SpA, 2 reactive arthritis and 1 enthesitis-related juvenile idiopathic arthritis. APO occurred in 39 (41%) pregnancies: 7 (7%) early miscarriages; 6 (7%) preterm births (one < 34 gestational week; four for preterm premature rupture of membranes (PROM)); 2 (2%) PROM; 5 (5%) foetal growth restriction; 2 (2%) malformations – 1 central nervous system malformation leading to medical abortion, 1 case of oesophageal atresia; 14 (17%) small for gestational (SGA) new-borns; and 7 (7%) gestational diabetes. History of inflammatory bowel symptoms (IBS) (p=0.02) and an active disease before conception (OR: 18.3, 1.9-179.9) or during pregnancy (namely at the 2nd and 3rd trimester – OR: 2.7 CI: 1.0-7.2 and OR: 3.2 CI: 1.2-8.5, respectively) were associated with an increased risk for APO (Table 1). Likewise, APO occurred more frequently if a previous use of ≥2 conventional or biological DMARDs (OR: 2.5 CI: 1.05-6.02), suggesting a more aggressive disease phenotype. Although not significant, patients with APO were less often treated with low-dose acetylsalicylic acid (LDASA) during pregnancy. No differences were found regarding maternal age, use of corticosteroids or anti-phospholipid positivity.

Conclusion: The birth of SGA infants was the most frequent APO. History of IBS, a more aggressive disease phenotype and an active disease before conception or during pregnancy increased the risk for APO. Larger studies are warranted to confirm these data and to assess the potential protective role of LDASA.

	Pregnancies with APO N=39	Pregnancies without APO N=55	*p* value

Active joint count: Tender +/- Swollen joints *

Table 1.

tration < 30 g/L, a bone marrow (BM) plasma cell percentage < 10%, and absence signs and symptoms related to multiple myeloma (MM). The prevalence of MGUS in psoriatic arthritis (PsA) has been reported to be higher than the general population. However, no follow-up is available to determine whether these patients progress to MM.

Purpose: To determine the current **prevalence of MGUS in the PsA** cohort, evaluate the **outcome** of patients PsA – MGUS and determine any association **of MGUS development and TNF inhibitors**.

Methods: Included were patients followed at the PsA Clinic between January 2008 to January 2018. All patients fulfilled the CLASsification for Psoriatic Arthritis (CASPAR). MGUS was defined as the presence of a discrete band in the gamma- globulin region on at least 2 separate serum protein electrophoresis tests, performed 6 months apart. MM was the outcome of interest. Data extracted from our database included demographic variables, ESR level, use of conventional disease modifying antirheumatic drugs (cDMARD) and Biologic DMARDs (bDMARDs).

Analyses included descriptive statistics [mean (SD) for continuous variables and frequency (percent) for categorical values]. Patients with MGUS were compared to those without using t -test, Wilcoxon test and Fisher test.

Results: Of the 883 patients assessed, **46 (5.3%) had evidence of MGUS on at least 2 separate** blood tests. At the time of diagnosis **55.5%** of patients were already on bDMARDs. Patients with MGUS had mean PsA duration of 14 years, were less likely to use DMARDs (30%), had more damage joints (24%), higher ESR levels (p=0.0001), but equal number of actively inflamed joints compared to the control group. 1 patient evolved to MM. Both groups were similar in gender, race (Caucasian) and ages of PsA and PsO diagnosis.

Conclusion: The prevalence of MGUS among our cohort of patients with PsA was 5.2%, higher than the prevalence in whites (1.5% – 3%), but lower than the 9.7% reported by Eder et al.

Only 1 patient progressed and died of MM, less than that expected in the general population. The presence MGUS was associated with measures of disease activity/severity (higher ESR levels and more damaged joints). There was no relationship to bDMARDs.

Malignancy Risk Among Patients with Ankylosing Spondylitis in the United States: A Population-Based National Study

Sali Merjanah[1], Mohamad Bittar[2] and Marina Magrey[3], [1]Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH, [2]The University of Tennessee Health Science Center, Memphis, TN, [3]Case Western Reserve University School of Medicine, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased cancer risk has been reported with Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE), but the correlation is poorly studied in Ankylosing spondylitis (AS).

Objectives: To study the correlation between AS and cancer in the US and to further assess whether the biologic therapy imposes any cancer risk on AS patients.

Methods: This is a retrospective observational study using the IBM Explorys database, a pooled de-identified clinical database of > 60 million unique patients in the US with patient-level data. The Explorys collects aggregated, standardized, and normalized clinical data from different electronic health records automatically updated in near real-time. In Explorys, patient records are mapped into a single set of Unified Medical Language System ontologies to facilitate searching and indexing. Diagnoses, findings, and procedures are mapped into the systematized nomenclature of medicine – clinical terms (SNOMED-CT) hierarchy.

Criteria of AS included at least one visit with a rheumatologist and the diagnosis code of AS (N=14,310) between 2009-2019. We further stratified the cohorts by adding the following variables to the search tool: race, gender, smoking, laboratory data (elevated ESR and CRP, HLA-B27 status), extra-articular manifestations (psoriasis, inflammatory bowel disease or uveitis) and medication use (TNF inhibitors, secukinumab or NSAIDs). The index date was defined as the date of the first-ever malignant neoplastic disease diagnosis occurring after the qualifying AS diagnosis.

The controls group (24,542,770) included adults ≥ 18 years of age with the exclusion of positive ANA, diagnosis of RA, SLE, AS, or vasculitis, and at least one outpatient office visit during the study period. For both groups we excluded the previous diagnosis of cancer prior to 2009. A chi-square test of association was performed between the 2 groups (AS patients and controls) and the odds ratio (OR), its standard error, and the 95% confidence interval (CI) were calculated.

Results: Of the 14,310 patients with AS, only 1300 (9.08%) patients had a cancer diagnosis compared to 2,719,240 controls (11.07%). The AS patients found to have decreased odds of cancer compared to control group (OR 0.9, 95

	AS patients with Cancer (n=1300)	Controls with Cancer (n=2,719,240)
Caucasians	85.38%	82.09%
Males	53.08 %	45.53%
Smokers	30.00%	22.22%

Table 2. Risk factors for cancer in patients with AS using chi-square test.

% CI: 0.85 to 0.95, P = 0.0003). Demographics and clinical characteristics of AS patients and controls with cancer are shown in table 1. Risk factors for increased cancer risk in AS patients are shown in table 2.

Skin cancers (Squamous cell carcinoma (SCC), malignant melanoma and basal cell carcinoma), and SCC of head and neck were significantly increased in AS patients compared to controls as shown in table 3. Additionally, no significant difference in the skin cancer diagnosis was observed between AS patients who are TNFi-naive and AS patients exposed to TNFi (OR 0.9, 95% CI 0.73 to 1.1, p 0.3).

Conclusion: Our study demonstrated that skin and head neck cancers are more frequently seen in AS patients compared to controls with no rheumatic disease, but the overall cancer risk was found to be lower in the AS patients

Any comorbidity (of the above), n (%)	19 (22%)	34 (20%)

No significant between-group difference in any of the individual comorbidities by Chi2-test / Fisher´s Exact Test, as appropriate. a Systemic lupus erythematous, polymyositis, mixed connective tissue disease, polymyalgia rheumatica or moderate to severe rheumatoid arthritis. b One nr-axSpA patient with hemiplegia. c None with moderate or severe liver disease. d Two AS and one nr-axSpA patient with end organ damage. e One AS patient with metastatic solid tumor. Nr-axSpA, non-radiographic axial spondyloarthritis; AS, ankylosing spondylitis; axSpA, axial spondyloarthritis; SD, standard deviation.

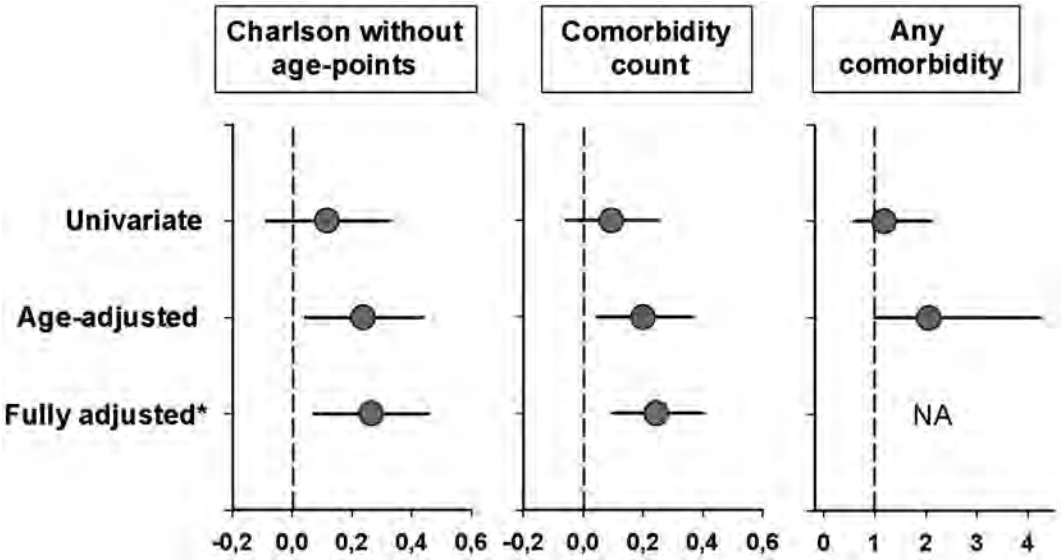

Figure. Differences between patients with nr-axSpA and AS (reference) regarding Charlson comorbidity index without age-points (left panel), comorbidity count (middle panel), and presence of any comorbidity (right panel). For the left and middle panels, data shown represent point estimate differences (dots) with 95% CI (whiskers) from unadjusted analyses, analyses adjusted only for age, and fully adjusted analyses (* adjustment for age, sex, education level, smoking, alcohol habits and body mass index). For the right panel, data shown represent odds ratios (dots) with 95% CI (whiskers) from unadjusted and age-adjusted analyses, respectively (further adjustment not possible due to too few events). NA, non-applicable.

Background/Purpose: Few studies have investigated the overall occurrence of comorbidities in patients with non-radiographic axial spondyloarthritis (nr-axSpA) in relation to ankylosing spondylitis (AS). Compared to nr-axSpA, AS patients are generally older and display higher inflammatory markers in blood, both known risk factors of comorbidity. The Charlson Comorbidity Index (CCI) is a commonly used instrument to assess comorbidity. Originally designed to predict mortality, the CCI assigns weighted points for both comorbidities and age, but can also be used without age-points.[1] The purpose of this study was to compare comorbidity burden between well-characterized patients with nr-axSpA and AS.

Methods: Patients with clinical axial spondyloarthritis diagnoses, consecutively enrolled in a population-based, cross-sectional cohort study, were thoroughly examined and classified as nr-axSpA (ASAS criteria; n=86) or AS (modified New York criteria; n=168). CCI scores without age-points were calculated from patient-reported data and compared between the nr-axSpA and AS groups. Age-points were omitted since we aimed to assess current comorbidity burden, rather than to predict mortality. A corresponding comparison was also conducted regarding the number of CCI associated comorbidities (comorbidity count; n=0-13, without weighted points) reported by each patient. Analyses were performed by linear regression, unadjusted as well as adjusted for age, sex, level of education (proxy for socioeconomic status), smoking, alcohol habits and body mass index. Due to the skewed distribution of CCI scores and comorbidity counts, confidence intervals were calculated by non-parametric bootstrapping with 10,000 iterations. Additionally, the proportion of patients in each group reporting ≥1 comorbidity (as defined by CCI) was compared by logistic regression, unadjusted and adjusted for age (further adjustment not possible due to few events).

Results: Patient characteristics for the nr-axSpA and AS groups are shown in Table 1. Compared to the AS group, nr-axSpA patients were younger and a greater proportion were women. Both groups showed a relatively small total number of comorbidities, and the occurrence of the individual comorbidities did not differ between the groups (Table 2). In unadjusted analyses, CCI without age-points, as well as comorbidity count, were not significantly different between the groups (Figure). However after adjustment for the younger age of the nr-axSpA patients, both CCI without age-points and comorbidity count were found to be significantly higher in the nr-axSpA group, and remained so also in the fully adjusted analyses (Figure). Finally, comparing the proportion of patients having ≥1 comorbidity produced analogous results (Figure).

Conclusion: Our results indicate that in a population-based, cross-sectional setting the burden of serious comorbidities, as assessed by CCI, is at least as high in patients with nr-axSpA as in AS. Despite the well-described lower systemic inflammation in patients with nr-axSpA, our results thus suggest that medical vigilance to target and prevent comorbidities in this group is equally important as in AS.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: N-terminal pro-brain-type natriuretic peptide (NT-proBNP) and troponin I (TnI) are established cardiac biomarkers that predict cardiovascular events (CVEs) and mortality in apparently healthy individuals and at-risk populations. While patients with psoriatic arthritis and psoriasis, collectively termed psoriatic disease (PsD), have an increased risk of developing CVEs, the use of these cardiac biomarkers to predict CV risk has not been investigated in this population. We aimed to evaluate the association between these cardiac biomarkers and incident CVEs, and assess their predictive value beyond the Framingham Risk Score (FRS).

Methods: A longitudinal cohort study was conducted in patients with PsD without prior history of CVEs. NT-proBNP and TnI concentrations were measured using automated clinical assays in the first available serum sample. The study outcome included any of the following CVEs occurring within the first 10 years of biomarker assessment: angina, myocardial infarction, congestive heart failure, transient ischemic attack, cerebrovascular accident, revascularization procedures and CV death. Associations with incident CVEs were analyzed separately for each biomarker using Cox proportional hazards regression models first adjusted for age and sex, and subsequently for the FRS. The added value of cardiac biomarkers to improve predictive performance beyond the FRS was assessed using the area under the receiver operator characteristic curve (AUC), net reclassification index (NRI) and integrated discrimination index (IDI).

Results: A total of 1000 patients with PsD were assessed between 2005 and 2019 (mean age 49 ± 12.8 years, 44.6% female) (**Table 1**). During a mean follow-up of 7.1 years, 72 (7.2%) patients developed incident CVEs. Both TnI (Hazard Ratio (HR) 3.63, 95% Confidence Interval (CI) 1.47, 8.95) and NT-proBNP (HR 1.78; 95% CI 1.16, 2.74) predicted CVEs independently of the FRS (**Figure 1**). The association was stronger in males than females. Including all cardiac biomarkers and the FRS in a single model, both TnI (HR 3.25, 95% CI 1.34, 7.88) and NT-proBNP (HR 1.68, 95% CI 1.12, 2.54) retained statistical significance. When comparing the predictive performance of the base model (FRS alone, AUC 74.3) to the expanded models, there was no significant improvement in any of the predictive indices with the addition of TnI (AUC 72.3, p = 0.26; NRI 0.10, p = 0.51; IDI 0.008, p = 0.29), NT-proBNP (AUC 74.2, p = 0.98; NRI 0.18, p = 0.13; IDI 0.011, p = 0.24), or both TnI and NT-proBNP (AUC 73.6, p = 0.78; NRI 0.23, p = 0.06; IDI 0.019, p =0.09) (**Figure 2**).

Table 1. Baseline characteristics of the study population

Current use of NSAIDs (daily use)	265 (26.5)	240 (25.9)	25 (34.7)
Current use of steroids	23 (2.3)	21 (2.3)	2 (2.8)

[1] Applicable only to patients with psoriatic arthritis

CVE indicates cardiovascular events; DMARD, disease-modifying antirheumatic drug; FRS, Framingham Risk Score; HDL, high-density lipoprotein; LDL, low-density lipoprotein; NSAID, non-steroidal anti-inflammatory drug; NT-proBNP, N-terminal pro-brain-type natriuretic peptide; PASI, Psoriasis Area Severity Index; PsA, psoriatic arthritis; PsC, psoriasis without arthritis

Conclusion: In patients with PsD, elevated NT-proBNP and TnI predict incident CVEs independent of the FRS. We did not observe a significant improvement in the performance of the predictive model when combining these cardiac biomarkers with the FRS.

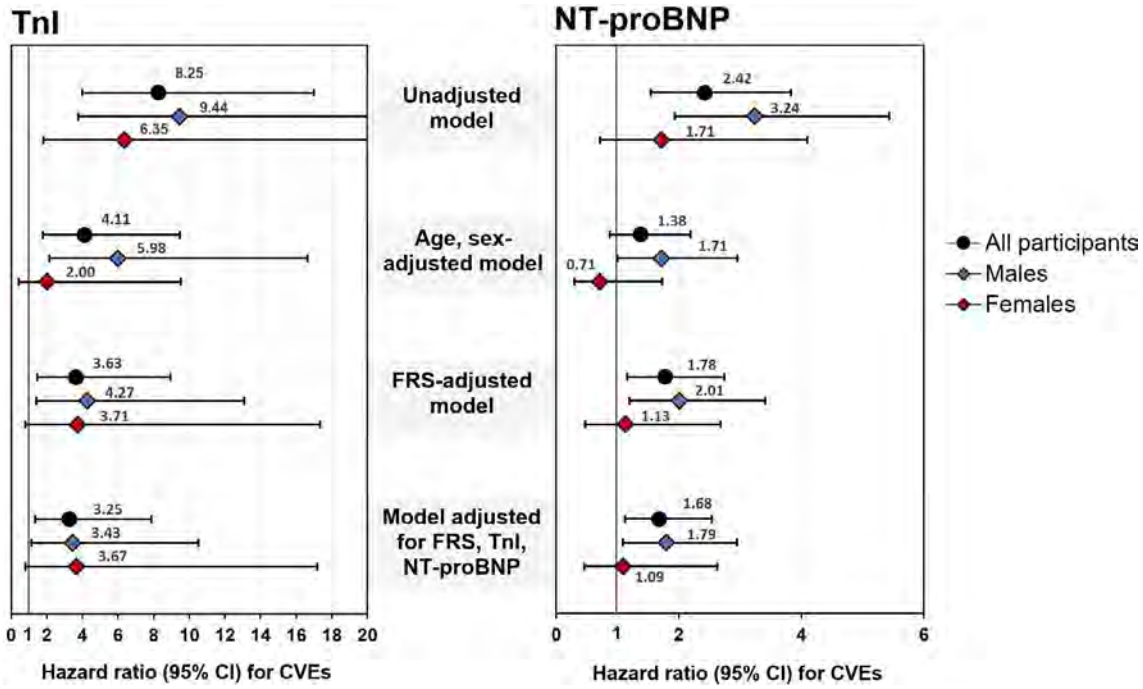

Figure 1. Hazard ratios of cardiac biomarker measures with incident cardiovascular events (n = 1000, 72 events). Error bars denote 95% confidence intervals. CI indicates confidence interval; CVEs, cardiovascular events; FRS, Framingham Risk Score; NT-proBNP, N-terminal pro-brain-type natriuretic peptide; TnI, troponin I.

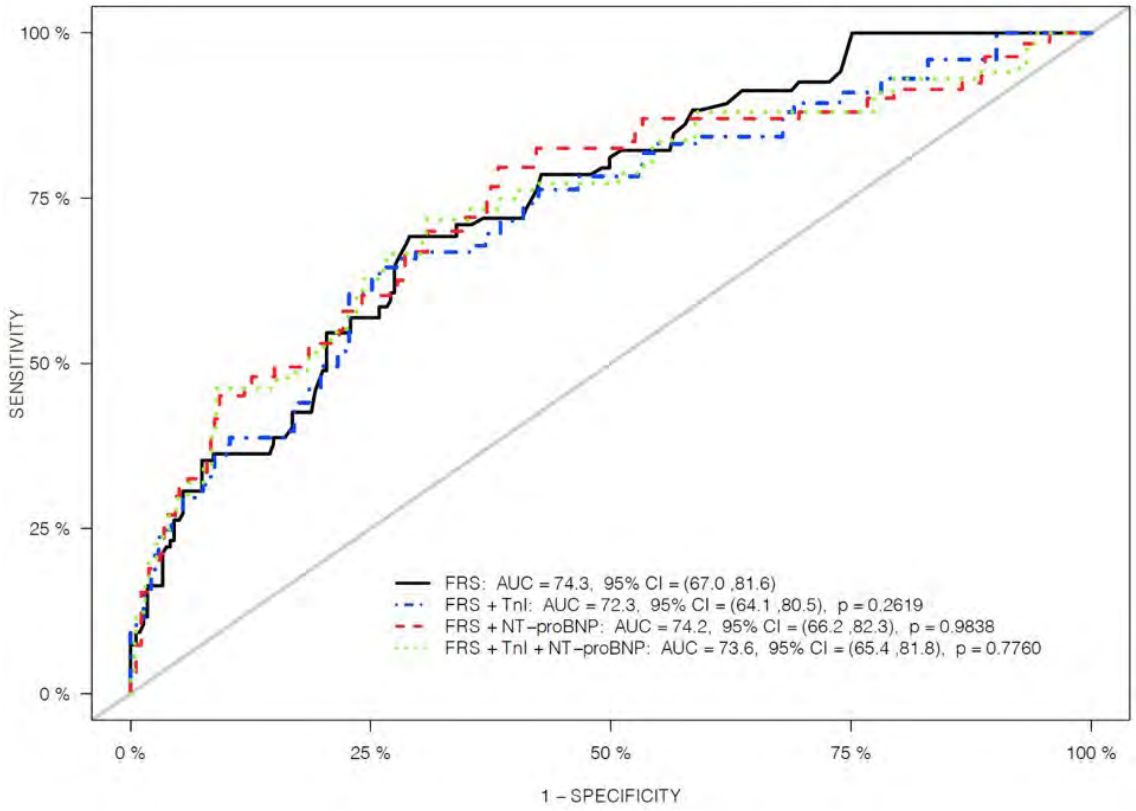

Figure 2. Comparison of the predictive performance of the base model (Framingham Risk Score alone) and expanded models for prediction of cardiovascular events in patients with psoriatic disease. AUC indicates area under the receiver operator characteristic curve; FRS, Framingham Risk Score; NT-proBNP, N-terminal pro-brain-type natriuretic peptide; TnI, troponin I.

HOMA-IR	0.25	0.023	S

Table 2. Correlation between CIMT and some parameters.
ESR, erythrocyte sedimentation rate; CRP, c-reactive protein; IL-1B, interlukin-1 beta; HOMA-IR, homeostatic model assessment of insulin resistance; CIMT, carotid intima-media thickenss; pg, picogram; ml, milliliter; ulU, micro-international unit; mm, millimeter; mg, milligram; hr, hour; dl, deciliter.

Background/Purpose: Psoriatic arthritis (PsA) is an immune-mediated inflammatory arthritis associated with psoriasis that can cause remarkable joint damage [(1)]. Subclinical cardiovascular disease (CVD) due to subclinical atherosclerosis is accelerated in PsA leading to overt cardiovascular events with increased mortality in those patients[(2)]. Chronic inflammation plays a crucial role in the pathogenesis of atherosclerosis in PsA, together with the conventional risk factors [(3)]. Intima-media thickness of the common carotid artery, evaluated by ultrasonography, is a good indicator of generalized atherosclerosis and coronary artery disease, giving early signs of subclinical atherosclerosis [(4)]. We aimed to investigate the role of interleukin-1 beta (IL-1β), homeostatic model assessment of insulin resistance (HOMA-IR), and insulin level as early predictors of subclinical atherosclerosis in patients with PsA.

Methods: The study included 81 patients with PsA and 69 matched healthy volunteers. Serum IL-1β, HOMA-IR, and insulin levels were assessed. Ultrasonographic measurement of carotid intima-media thickness (CIMT) was done for both common carotid arteries and the mean CIMT was calculated.

Results: Our patients and controls were matched regarding age, sex, and body mass index (BMI) ($P > 0.05$). Our study revealed a statistically significant difference between patients and controls regarding IL-1β, HOMA-IR, insulin level, and CIMT ($p < 0.05$) as illustrated in table (1). There was a statistically significant positive correlation between IL-1β, HOMA-IR, insulin level, and CIMT ($p< 0.05$), however, no significant correlation could be detected between ESR, CRP, and CIMT ($p >0.05$) as shown in table (2).

Conclusion: IL-1β, HOMA-IR, and insulin levels are correlated with CIMT in PsA. So, each of them can be used as a predictor of subclinical atherosclerosis in those patients. Consequently, IL-1β targeted therapy may have a pivotal role in the prevention of subclinical CVD in PsA.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular (CV) mortality and morbidity is increased in ankylosing spondylitits (AS) as compared to the general population. Carotid plaque, considered as a surrogate marker for atherosclerosis associated with very high CV risk, is more prevalent in AS patients than in healthy controls. Nevertherless, we have no consistent data about subclinical atherosclerosis (SA) in non-radiographic axial spondyloarthritis (nr-axSpA). In this study we assessed the SA in nr-axspA compared with AS in the largest series studied so far, and established a predictive model to identify patients with high CV risk.

Methods: This is a transversal observational study from the AtheSpAin cohort, a Spanish multicenter cohort to study atherosclerosis in axSpA. We compared patients with AS vs those with nr-axSpA according to ASAS criteria. Carotid ultrasound (US) examination was done in all patients, included the measurement of carotid intima-media wall thickness (cIMT) in the common carotid artery and the detection of plaques in the extracranial carotid tree bilaterally, according to the Mannhein consensus. CV risk was calculated according to the systematic coronary risk evaluation (SCORE).

Results: A set of 639 patients with AS and 167 patients with nr-axSpA were recruited in this study. Patients with AS were mainly men, older and had a higher prevalence of cardiovascular risk factors compared to nr-axSpA patients. They also had higher levels of C reactive protein and estimated (CPR) and erythrocyte sedimentation rate (ESR). Comparison of baseline characteristics and clinical features between patients with AS and nr-axSpA is shown in **table 1**. After adjusting data for age, sex and cardiovascular morbidity, no difference in the prevalence of carotid plaques or in the carotid IMT was found between both groups.

We then analyzed the prevalence of carotid plaques in the groups of low and moderate CV risk according to the SCORE, finding no differences between AS and nr-axSpA (10.7 % Vs 10.1%, p=0.9 and 40.5 % Vs 45.5 %, p=0.94 respectively)

Considering the comparable atherosclerotic burden observed in nr-axSpA and AS, we designed a model to identify those patients diagnosed with any of these conditions with very high CV risk because of the presence of carotid plaques. A predictive model which included SCORE plus age, BASFI and ESR at time of disease diagnosis in patients with moderate SCORE showed a high specifity (88%) to detect very high risk patients, but with a limited sensitivity (41%) **table 2**. The AUC of this model was found to have higher discrimination than the SCORE AUC (0.652 Vs 0.592, p= 0,025).

Conclusion: SA disease in patients with nr-axSp is similar to those with AS, despite the higher inflammatory state of the latter. Many patients with axSpA with a moderate risk of CV events according to the SCORE are reclassified into very high risk after carotid US examination. Patients with higher age, ESR at the diagnosis of axSpA and BASFI are more likely to present carotid plaques in US examination.

non-invasive tool useful in the identification of subclinical atherosclerosis[1]. However, carotid ultrasound differences between PsA patients and general population have not yet been well described.

The aim of this study is to compare the carotid ultrasound characteristics in PsA patients with controls.

Methods: This cross-sectional study included 69 PsA patients that fulfilled the CASPAR (Classification Criteria for Psoriatic Arthritis) criteria and 69 controls matched by age and comorbidities. Patients with a history of previous atherosclerotic CVD (ischemic heart disease, cerebrovascular accident or peripheral arterial disease) and pregnancy were excluded. A clinical history and blood tests were performed. Carotid B-mode ultrasonography was used for measurements of cIMT and the presence of plaques. *Increased cIMT was defined as ≥0.9 mm to 1.1 mm. CP was defined* as a *focal narrowing ≥0.5 mm of the surrounding* lumen or a *cIMT ≥1.2 mm.* Descriptive analysis was done with frequencies (%), mean (±SD) and median (q25-q75), and comparisons with Chi square, Student´s t and Mann-Whitney U tests.

Results: A total of 138 subjects were included. Clinical and demographic characteristics are shown in Table 1. Increased cIMT and right carotid plaque were significantly more prevalent in PsA patients compared to controls

(p=0.017 and p=0.049, respectively). No significant differences were found in the prevalence of carotid plaque and in the intima-media thickness between groups.

Conclusion: Patients with psoriatic arthritis have a higher cardiovascular risk, as proven by the increased cIMT found on carotid ultrasound results. Therefore, it is opportune to perform a carotid ultrasound in patients with PsA to attain an optimal management of the disease.

The rheumatologist must acknowledge the importance of performing a complete cardiovascular evaluation to provide a correct treatment to diminish future cardiac events.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory joint disease (IJD) associated with cardiac involvement particularly aortic valve regurgitation (AVR). AVR in AS is caused by inflammation of the aortic root and valves. Furthermore, HLA-B27 genotype is strongly associated with AS and with cardiac diseases in non-rheumatic patients. Therefore, the question arises whether HLA-B27 genotype results in an increased risk of developing AVR and aortic root dilatation in AS patients. In this study, we investigated the association between the aortic root diameter in HLA-B27 positive (+) versus HLA-B27 negative (-) patients in AS patients from the CARDAS cohort.

Methods: The CARDAS study is a cross-sectional study in AS patients between 50-75 years who were recruited from a large rheumatology outpatient clinic. Patients underwent cardiovascular screening including echocardiography, with 2D, spectral and colour flow Doppler. The aortic root was measured at sinuses of Valsalva during diastole. The aortic root diameter was corrected for body surface area (BSA) (aortic root index, cm/ m^2).

Results: 193 Consecutive AS patients were included of whom 158 (82%) HLA-B27 positive. HLA-B27+ and HLA-B27- AS subjects had a comparable disease duration, respectively 36 (±11) and 30 (±14) years, and a moderate disease activity assessed with the ASDAS-CRP, respectively 2.1 (±1.0) and (2.3 ±1.0). The aortic root index was higher in HLA-B27+ patients compared to HLA-B27- patients, respectively 1.76 ± 0.21 mm vs. 1.64 ± 0.14 mm, p< 0.001. Furthermore, HLA-B27+ AS patients compared to HLA B27- AS patients had more often aortic root dilatation (≥2.1 cm/

Table 1. Echocardiographic parameters

	HLA-B27 +	HLA-B27 -	p value
Echocardiography			
Aortic root, cm	3.35 ±0.43	3.25 ±0.28	0.12
Aortic root index, cm/m²	1.76 ±0.21	1.64 ±0.14	<0.001*
Aortic root dilatation (≥2,1 cm/m²)	11 (8)	1 (3)	0.3
Aortic regurgitation	34 (22)	8 (24)	0.8
Trace	13 (8)	3 (9)	
Mild	18 (12)	5 (15)	
Moderate	4 (3)	0	
Severe	1 (1)	0	
Prothesis	1 (1)	0	
Mitral regurgitation	52 (34)	17 (49)	0.25
Mild	49 (32)	16 (46)	
Moderate	3 (2)	1 (3)	
Severe	0 (0)	0 (0)	
Prothesis	0 (0)	0 (0)	

Values are displayed as mean ± standard deviation (SD) or frequencies with corresponding percentages (%). No cases of aortic valve stenosis and only one case of mitral valve stenosis were assessed. * Significance level of p ≤0.05.

m^2), respectively 11 (8%) and 1 (3%), p=0.3 (table 1). The presence of aortic root dilatation in HLA-B27+ AS patients was strongly associated with aortic valve regurgitation, p=0.003. Regression analysis showed a significant association between HLA-B27 and aortic root index corrected for age, sex and cardiovascular risk factors, B 0.091 (95%CI 0.015-0.168), p=0.02. Furthermore, male HLA-B27+ patients had a significant increased aortic root index compared to male HLA-B27- AS patients, respectively 1.76 (1.63-1.88) and 1.59 (1.53-1.68), p< 0.001.

Conclusion: In conclusion, our study demonstrates an increased aortic root index in elderly HLA-B27+ AS patients, specifically in male patients. Although, this did not result in an increased prevalence of aortic valve regurgitation in this subgroup, inflammation of the aortic root and valve in chronic inflammatory disease is progressive and may progress to severe complications. Therefore, to identify AS patients patient at risk for cardiac disease, we recommend echocardiographic monitoring in elderly male HLA-B27+ AS. Future studies should assess cost effectiveness of cardiologic screening in this subgroup.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The overall mortality rate in ankylosing spondylitis (AS) patients is increased by 60–90% compared with the general population. This higher mortality rate is predominately caused by cardiovascular disease (CVD) comprising an increased prevalence of cardiac diseases such as valvular heart disease, conduction disturbances and cardiomyopathies as well as atherosclerotic diseases such as myocardial infarctions. However, there is a lack of contemporary studies. Therefore, we investigated current prevalences of cardiac disorders in a well characterized cohort of Dutch patients with AS compared to osteoarthritis (OA) controls.

Methods: We performed a cross-sectional study in AS and OA patients between 50-75 years. Subjects were recruited from a large rheumatology outpatient clinic (Reade) in Amsterdam, the Netherlands. Patients underwent echocardiography with 2D, spectral and Color Doppler imaging. The echocardiogram was evaluated by an experienced and certified cardiologist. Diastolic dysfunction was assessed according to the ASE/EACVI 2016 guideline. Furthermore, blood sample, surveys and physical examination were done. Disease activity and function were measured with the BASFI, BASDAI and the ASDAS-CRP.

Results: A total of 193 consecutive AS patients were included with a median age of 60 (±7) years of which 72% men (138). The control group consisted of 70 OA patients (table 1). In the AS cohort the disease activity measures , BASDAI, ASDAS-CRP and BASFI, indicated moderate disease activity and were, respectively 3.1 (1.6-5.0), 2.1 (±1.0) and 3.5 (1.7-5.7). Anti-TNF was used by 43% of the AS patients. History of cardiovascular disease (CVD), i.e. angina pectoris, myocardial infarction, stroke and/or peripheral ischemia was comparable between the AS and OA cohort, respectively 9% (17) and 10% (7), p=0.81. Antihypertensives were significantly more often used in AS patients, 85

Table 1. Patient characteristics

	AS	OA	p
N	193	70	
Men (n, %)	138 (72)	40 (57)	0.028*
Age (years)	60 ±7	63 ±7	0.004*
Disease activity			
BASDAI	3.1 (1.6-5.0)	-	
ASDAS-CRP	2.1 ±1.0	-	
BASFI	3.5 (1.7-5.7)	-	
CVD			
History of CVD* (n, %)	17 (9)	7 (10)	0.81
Antihypertensives (n, %)	85 (44)	19 (27)	0.02
Aortic valve regurgitation (n, %)	41 (22)	7 (10)	0.04*
Trace (n, %)	16 (9)	6 (9)	
Mild (n, %)	23 (12)	6 (9)	
Moderate (n, %)	1 (1)	0	
Severe (n, %)	1 (1)	0	
Prosthesis (n, %)	1(1)	0	
Mitral valve regurgitation (n, %)	68 (36)	21 (33)	0.59
Diastolic dysfunction (n, %)	7 (3)	2 (3)	0.86

* Angina pectoris, myocardial infarction, stroke and/or peripheral ischemia

(44%) vs 19 (27%), p=0.02. Prevalences of systolic dysfunction and diastolic dysfunction did not differ significantly in AS and OA patients, respectively 6 (5%) vs 2 (5%), p=0.96 in systolic dysfunction and 7 (3%) vs 2 (3%), p=0.86 in diastolic dysfunction. Prevalence of aortic valve (AV) regurgitation was significantly higher in AS patients compared to OA patients, respectively 41 (22%) and 7 (10%), mostly with mild severity. The prevalence of mitral valve (MV) regurgitation did not differ between the AS and OA patients, respectively 68 (36%) vs 21 (33%), p=0.59. When corrected for age, gender and cardiovascular risk factors in a regression analysis, AS patients still had a substantially increased risk for AV regurgitation, odds ratio (OR) 2.8 95%CI 1.1-7.2, p=0.038.

Conclusion: This study demonstrates an almost tripled risk for developing AV regurgitation in Dutch AS patients. Although mostly mild in this age, due to the progressive nature of AV regurgitation in AS, echocardiographic screening should be considered in elderly AS patients.

Does Interstitial Lung Disease Represent a Real Comorbidity in Spondyloarthritis Patients? Results from an Ultrasound, Monocentric, Pilot Study

Andrea Delle Sedie[1], Emanuele Calabresi[1], Ilaria Romagnoli[1], Linda Carli[2] and Marta Mosca[2], [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Interstitial lung disease (ILD) is a frequent complication in rheumatoid arthritis (RA) where it represents the most common extra-articular involvement (with a prevalence of about 10-60%) and the second cause of mortality (after cardiovascular diseases). Spondyloarthritides (SpA) are chronic arthritides that share with RA both a similar disease burden and similar therapeutical approaches. ILD evaluation is challenging, given the low sensitivity of X-ray and pulmonary function tests, and radiation linked to repetitive HRCT. Lung Ultrasound (LUS) has shown potential in the evaluation of ILD in autoimmune diseases. The aim of this study was to assess the prevalence of ILD in a cohort of SpA patients (pts) using LUS with respect to healthy controls (HC).

Methods: Consecutive SpA out-pts were examined by LUS, applying the definition for pleural line irregularity (PLI) recently provided by the OMERACT taskforce for LUS in systemic sclerosis (1). Seventy-one intercostal spaces were studied (14 in the anterior chest, 27 lateral and 30 posterior) in all the pts/HC using an Esaote MyLab25 Gold US

Tab I: average PLI score (N±DS)

	Total	Anterior	Posterior	Lateral
HC	10.3 ± 7.7	4 ± 3.2	5 ± 3.7	1.4 ± 2.2
PsA	20.1 ± 12.5	6.8 ± 3.9	10.2 ± 6.9	2.9 ± 4.1
AS	22.1 ± 10.7	7 ± 2.8	12 ± 9.5	3 ± 3.1

machine with a linear 7.5-10 MHz probe. The scoring system by Pinal-Fernandez et al (2) was applied and a total pleural score was calculated. Each patient answered to Italian-validated PROs on respiratory function (Leicester and Saint-George), global health (SF-36) and dyspnea (mMRC scale). Clinical data on disease-duration, disease-onset, disease-activity (at the moment of the examination) and MTX/biologics treatment were collected from the medical records.

Results: Fifty-six SpA pts (35 psoriatic arthritis -PsA- and 21 ankylosing spondylitis -AS-) and 56 HC were studied. No significant differences were demonstrated between groups (SpA vs HC and PsA vs AS) for age, sex, BMI and smoking habits. The total pleural score was significantly higher in SpA pts than in HC (20.9+-11.8 vs 10.3+-7.7; $p< 0.001$). A positive correlation was found between total PLI score and PLI score from anterior, posterior and lateral chest. The posterior part of the chest showed a higher PLI score than the anterior and lateral one (with the latter resulting to be significantly lower than the posterior PLI score). Higher differences in the PLI average value between SpA pts and HC were registered for posterior and anterior part of the chest. No differences were found between PsA and AS (with a not statistically significant difference in the posterior PLI score, which was slightly higher in AS pts) (Tab.I).

Conclusion: LUS examination shows a higher amount of PLI in SpA with respect to HC. References: 1- Delle Sedie A et al. Ann Rheum Dis 2019;78(Suppl 2):A834 2- Pinal-Fernandez I et al. Clin Exp Rheumatol 2015;33(4 Suppl 91):S136-41

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To describe the demographic and clinical characteristics of patients with inflammatory arthritis (IA) initiating biologic disease modifying anti-rheumatic drugs (bDMARD) who use complementary and alternative medicine (CAM), and determine the impact of CAM on predicting residual functional disability at six months, as measured by the modified Health Assessment Questionnaire (mHAQ).

Methods: A prospective inception cohort study of all patients ≥ 21 years old initiating a bDMARD for IA after July 2016 was conducted in three public-sector hospitals in Singapore. Baseline and follow-up data were obtained via face-to-face or telephonic questionnaires and abstraction from medical records. Baseline characteristics were compared using chi-square test for categorical variables; and t-test and Wilcoxon signed-rank test for continuous variables in gaussian and non-gaussian distributions respectively. CAM as a predictor of mHAQ ≥ 1 at six months after

Variables were included in the multivariable model if they were significant at P ≤ 0.2 on univariate analysis. † Not included in the multivariable model due to collinearity with mHAQ. ‡ Hypertension and hyperlipidemia were statistically significant in the univariate analysis as well, but not included in the multivariate model due to collinearity with CCI. BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CAM, complementary and alternative medicine; CCI, Charlson's Co-morbidity Index; DAS-28, Disease Activity Score in 28 joints; mHAQ, modified Health Assessment Questionnaire; TNFi, tumour necrosis factor inhibitor.

starting a bDMARD was analysed using multivariate logistic regression, adjusting for other baseline characteristics. Further, interaction of CAM use and smoking was tested.

Results: 299 patients (36.2% males, 70.4% Chinese) of mean (SD) age 49.0 (13.4) years were recruited. 45.8% had rheumatoid arthritis with a mean (SD) Disease Activity Score in 28-joints (DAS-28) of 4.6 (1.2). 54.2% had a spondyloarthropathy with a mean (SD) Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) of 4.7 (2.2). The

median (IQR) disease duration was 12.7 (4.7, 38.5) months, with a median (IQR) mHAQ of 0.4 (0.1, 0.9). 93 patients were current or prior CAM users, most commonly acupuncture (64.5%), powder (46.2%), tablets (36.6%), herbs (33.3%), suction (19.4%). Compared to non-users, CAM users had a lower mean body mass index (24.5 vs 26.8kg/m^2, p=0.002), were less likely to be English-speaking (65.5% vs 85.8%, p< 0.001), more likely to be smokers (28.0% vs 16.7%, p=0.02) and to drink alcohol (33.7% vs 19.6%, p=0.009), and less likely to have cardiovascular disease (2.2% vs 8.8%, p=0.04) (Table 1). Of the 223 patients with 6-month follow-up data, 27.4% were no longer on their index bDMARD. mHAQ was available for 206 patients, median (IQR) 0.1 (0, 0.5), 12.1% with mHAQ ≥ 1. There was no association of CAM use with high mHAQ and no interaction with smoking. Advanced age (odds ratio [OR] < 0.001 [95% CI 5.3E-10 – 0.34]), smoking (OR 938.9 [95% CI 3.20 – 275884.1]), baseline mHAQ (OR 252.2 [95% CI 5.34 – 11899.2]) and Charlson's Co-morbidity Index (CCI) score of ≥ 4 (OR 237.4 [95% CI 1.22 – 46184.4]) were independent predictors of high mHAQ (Table 2).

Conclusion: CAM use was not associated with high mHAQ at 6 months. Association with advanced age may be attributable to a tendency for elderly patients to under-report scores. Smoking was an independent predictor of residual functional disability at 6 months, even after adjusting for age, comorbidity and baseline mHAQ. More emphasis on smoking cessation may be useful to improve long-term functional outcomes in IA patients on bDMARDs.

Bone Mineral Density, Trabecular Bone Score and Proximal Femur 3D-DXA Analysis in Psoriatic Diseases

Eric Toussirot[1], Renaud Winzenrieth[2], Maxime Desmarets[3], Daniel Wendling[4], Francois Aubin[5] and Gilles Dumoulin[6], [1]CIC biotherapies, Besançon University Hospital, Besançon, France, [2]GALGO medical, Barcelona, Spain, [3]INSERM CIC-1431, Besancon, France, [4]CHU Besançon, department of rheumatology, Besancon, France, [5]Dermatology, Besancon, France, [6]Laboratoire de Biochimie Médicale, UF de Biochimie Endocrinienne et Métabolique, Besancon, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: current data regarding areal bone mineral density (aBMD) in patients with psoriasis (PsO) or psoriatic arthritis (PsA) are conflicting. Results on Trabecular Bone Score (TBS) in these patients are lacking. 3D-analysis of cortical and trabecular bone from hip DXA is a new method for non-invasive bone structure assessment, providing separate assessment of the cortical layer and trabecular macrostructure.

Methods: Case-control study (NCT02849795) in which 52 PsO and 52 PsA cases (CASPAR criteria) were each paired to a control subject matched for age, sex and body mass index (BMI). aB MD measurements at (L2-4) lumbar spine (LS), femoral neck (FN) and total hip (TH) were performed using DXA, Lunar GE. TBS was calculated from antero-posterior L2-L4 BMD image using TBS iNsight V1.8 (Med-Imaps, Pessac, France). 3D-SHAPER software (version 2.10, Galgo Medical S.L, Barcelona, Spain) was used to derive a 3D analysis from the hip DXA scans.

Results: LS and TH aBMD measurements did not differ between patients with PsO or PsA and their respective controls. Left FN BMD was higher in patients with PsO compared to controls (p = 0.028), a difference not observed on the

	PsA (N = 52)	PsA controls (N = 52)	PsO (N = 52)	PsO controls (N = 52)

Table 1:

patients' clinical characteristics, areal bone mineral density (lumbar spine, femoral neck, total hip), trabecular bone score and proximal femur DXA-derived 3D analysis in patients with psoriatic arthritis and their paired controls and in patients with psoriasis and their paired controls

PsA : psoriatic arthritis ; PsO : psoriasis ; M: male; F : female; BMI: body mass index; PASI : psoriasis area severity index ; CPDAI : composite psoriatic disease activity index ; ESR : erythrocyte sedimentation rate ; CRP : C-reactive protein ; aBMD : areal bone mineral density ; LS: lumbar spine; FN : femoral neck ; TH: total hip; TBS: trabecular bone score; sBMD : surface bone mineral density; Cth : cortical thickness.

Quantitative data are mean ± standard deviation.

* and *** : paired *t* test comparing patients with psoriatic arthritis or psoriasis alone to their respective controls.

* $p < 0.05$; *** $p < 0.001$.

right FN. TBS was similar in PsA patients and their controls while decreased values were observed in PsO patients ($p = 0.04$). In 3D analysis, none of the parameters differed between patients with PsA and their controls. For patients with PsO, no difference was found with the controls for 3D-DXA parameters from the right FN, while total hip cortical surface BMD (sBMD) of the left FN was higher in PsO compared to their controls ($p = 0.037$). Similarly, cortical thickness (Cth) of the intertrochanteric and shaft regions of the left FN was also higher in PsO ($p = 0.032$ and $p = 0.033$). Finally, analysis by region (neck, intertrochanteric and shaft) showed higher values for cortical sBMD from each region of the left FN in the patients with PsO (all $p < 0.05$).

Conclusion: Our results showed comparable aBMD, TBS and 3D proximal femur parameters in patients with PsA and controls. This supports that PsA population is not at increased risk of osteoporosis. In patients with PsO, while LS bone microarchitecture seems impaired, FN displayed better cortical parameters than the controls. Although these results seem marginal, they support the fact that patients with PsO are not at high risk for osteoporosis and hip fracture.

Our results showed comparable aBMD, TBS and 3D proximal femur parameters in patients with PsA and controls. This supports that PsA population is not at increased risk of osteoporosis. In patients with PsO, while LS bone microarchitecture seems impaired, FN displayed better cortical parameters than the controls. Although these results seem marginal, they support the fact that patients with PsO are not at high risk for osteoporosis and hip fracture.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In the pathogenesis of psoriatic arthritis (PsA), increased inflammatory cytokines lead to increased RANGO-L activity and stimulation of osteoclasts, leading to osteoporosis. This comorbidity, closely related to other inflammatory joint diseases, has not been so documented in patients with PsA. Obesity is a frequent comorbidity in patients with PsA, in addition to being the basis of the metabolic syndrome, it affects the activity of the disease and

	C/C (Pro/Pro)	C/G (Pro/Ala)	P
Age	44,34(8,42)	44,88 (8,03)	0,82

Table 1

the response to treatment. PPAR g is a nuclear receptor that behaves like a ligand-activated transcription factor, involved in processes such as inflammation, adipogenesis, or bone metabolism. **Objective:** Relate PPARg polymorphism (rs1801282) with osteoporosis, inflammatory activity, and obesity in a group of patients with psoriatic arthritis (PsA).

Methods: We analyzed the Pro12Ala polymorphism of the PPARg gene in 126 patients with PsA. To assess osteoporosis, bone mineral density in the spine and hip (BMD) and markers of bone formation and resorption (PNP1 and β-CrossLabs respectively) were measured. As variables that influence BMD, the units of dairy consumed daily, smoking (non-smokers, ex-smokers, and active smokers) and physical activity were measured. Inflammatory activity was measured by the number of swollen joints (SJP), the rate of globular sedimentation (ESR) and the C-reactive protein (CRP). For obesity, the body mass index (BMI) was measured. All patients with any disease or treatment that could alter phospho-calcium metabolism were excluded.

Results: 82.5% of the patients presented a homozygous C / C genotype (Pro / Pro), the rest a heterozygous C / G genotype (Pro / Ala). The baseline characteristics of the patients, the factors that influence BMD, BMI, markers of bone formation and resorption, and the inflammatory variables are shown in Table 1.

Patients carrying the alanine allele showed a lower BMD in the hip compared to those carrying the proline allele (0.84 + 0.07 vs. 0.89 + 0.12; $p < 0.01$). We did not find this significance for BMD in the lumbar spine (0.96 + 0.6 vs. 1.01 + 0.16; $p = 0.34$).

Conclusion: The alanine allele of the Pro12Ala polymorphism of the PPARg gene may represent, in patients with PsA, a genetic marker related to osteoporosis. Studies with a larger sample size can demonstrate whether this effect is due to a direct action on the bone or associated with an increase in inflammation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of axial Spondyloarthritis (axSpA) represents a major clinical challenge nowadays. Increasing evidence has determined that early diagnosis, prompt treatment initiation and early achievement of remission are the best predictors of long-term clinical, functional and radiographic outcomes. New tools to support the diagnosis and new therapeutic targets are needed.

This study aims to identify differentially expressed genes, overall and focusing in genes related with muscle function, that may improve the current clinical diagnosis approach for early axSpA and new therapeutic targets.

Methods: A cross-sectional study was conducted on 48 participants, 24 patients with axSpA (according to ASAS criteria) and 24 Healthy Controls, matched by gender, age and levels of physical activity. Peripheral blood samples were collected and RNA-Seq technology was performed. Normalization of raw data, and identification of differentially expressed genes was obtained using edgeR and limma-voom R packages. Gene Set Enrichment Analysis (GSEA) and Functional Enrichment analysis using Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) annotations were also performed. A number of Differently Expressed Genes were highlighted.

Results: 76 genes were identified as being significantly differentially expressed between patients and controls. In detail, 59 downregulated (2 genes have Logfold change more than 1) and 17 upregulated genes (2 genes have Logfold change more than 1) are highlighted. These genes are mostly involved in Innate Immune Signalling and JAK/STAT pathways; some of them were already identified as conferring susceptibility for axSpa, as MICA, TLR5 and SOC3. In addition, several genes with functions of skeletal muscle development (gene1), muscle contraction (gene2) and formation of branched actin networks (gene3), were also identified.

Conclusion: The evidence disclosed that regulation of muscle development and contraction may be also engaged in physiopathology mechanisms of axSpA. Upon validation, these new findings could open new perspectives for diagnosis and therapeutic in axSpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Extra-MSK & Comorbidities

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic has quickly emerged as the most challenging global health crisis in a generation. Affecting initially China, New York City (NYC) quickly became the epicenter. Data has been scarce

for populations at the highest risk of infection, most notably immunosuppressed patients with underlying chronic inflammatory diseases or chronic use of anti-cytokine biologics and/or other immunomodulatory therapies. We aimed to characterize the hospitalization and death rates among patients with inflammatory arthritis (IA; rheumatoid arthritis and spondyloarthritis) affected by COVID-19 and to analyze the associations between comorbidities and immunomodulatory medications and infection outcomes.

Table. Comparison of baseline characteristics, medication use, and disease course in ambulatory and hospitalized IA patients with confirmed or highly suspected COVID-19 infection*

Characteristic	Total (n = 103)	Ambulatory (n = 76)	Hospitalized (n = 27)	p-value

Supplementary O2—n (%)			18 (66.7)	
Intensive care unit level care/mechanical ventilation—n (%)◊			4 (14.8)	
Death—n (%)◊			4 (14.8)	

* IA= inflammatory arthritis; ACE= angiotensin converting enzyme; ARB= angiotensin II receptor blockers; IL= interleukin; JAK= Janus Kinase; O2= oxygen.

◊ Of the four patients in the ICU, there were three death and one complete recovery. One other death occurred in unknown levels of care while hospitalized.

Methods: Recruitment stemmed from a larger NYU Langone Health study, namely Web-based Assessment of Autoimmune, Immune-Mediated, and Rheumatic Patients during the COVID-19 Pandemic (WARCOV). WARCOV is a prospective cohort of patients with established diagnosis of immune mediated inflammatory disease. Participants were referred from 46 NYU affiliated providers throughout NYC. Clinical, demographic, maintenance treatment, and disease course data and outcomes of individuals with IA with symptomatic COVID-19 were prospectively assessed via web-based questionnaire, individual phone calls, and electronic medical record review. Baseline characteristics and medication use were summarized for hospitalized and ambulatory patients, and outcomes were compared for each medication class using multivariable logistic regression.

Results: A total of 103 patients with IA were included in the study (n=80 confirmed and n=23 highly suspicious for COVID-19). 26% of participants required hospitalization, and 4% died. Patients who warranted hospitalization were significantly more likely to be older ($P< 0.001$) and have comorbid hypertension ($P=0.001$) and chronic obstructive pulmonary disease ($P=0.02$) (Table). IA patients taking oral glucocorticoids had a higher likelihood of being admitted for COVID-19 ($P< 0.001$) while those on maintenance anti-cytokine biologic therapies did not. After adjusting for age and sex, hypertension and oral glucocorticoid use remained significant risk factors for hospitalization (OR 3.33, 95% CI 1.16 to 9.60, $P=0.03$ and OR 21.12, 95% CI 4.09 to 109.03, $P<0.001$, respectively). Patients with rheumatoid arthritis were more likely to be hospitalized compared to those with spondyloarthritis, but were also older and more likely to be on oral glucocorticoids.

Conclusion: In patients with underlying IA, COVID-19 outcomes were worse in patients receiving glucocorticoids but, importantly, not in patients on maintenance anti-cytokine therapy. As with non-IA patients, age and hypertension were also associated with hospitalization. However, given our limitations of a relatively small number of hospitalizations and likely confounding by indication, caution should be taken in the interpretation of these results. Further work, currently underway, is needed to better understand whether immunomodulatory therapies affect COVID-19 incidence and its natural history.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with non-radiographic axial spondyloarthritis (nr-axSpA) suffer from comparable disease burden to patients with ankylosing spondylitis/radiographic axSpA (AS/r-axSpA), including inflammatory back pain, morning stiffness, fatigue, and reduced spinal mobility.[1] Secukinumab 150 mg has demonstrated sustained improvement in the signs and symptoms in patients with AS over 4 years.[2] Here, we report a post hoc analysis evaluating the effect of secukinumab treatment on back pain, morning stiffness, fatigue, and physical function in tumor necrosis factor inhibitor naïve (TNFi-naïve) patients with nr-axSpA from the PREVENT study (NCT02696031).

Methods: This study included patients with nr-axSpA receiving either subcutaneous secukinumab 150 mg with loading (LD), without loading (NL), or placebo (PBO).[3] Patients with inadequate response to treatment were permitted to switch to open-label secukinumab 150 mg or standard of care (TNFi) after Week 20 based on clinical judgement of disease activity by the investigator and the patient. This post-hoc analysis assessed nocturnal back pain scores (on visual analog scale [0–100]; ASAS outcome component), morning stiffness (overall level; on visual analog scale [0-10] ASAS outcome component), FACIT-Fatigue and SF-36 PCS scores in TNFi-naïve patients. Continuous values were imputed as mixed-effect model repeated measures (MMRM; valid under the missing at random assumption) for mean

†p<0.001, §p<0.01 and ‡p<0.05 vs. placebo.
Data presented using non-responder imputation at Weeks 4 and 16.
[a]Data presented as observed at Week 52.
[1]At Week 52 - number of evaluable patients were 139 for LD and 146 for NL groups; number of patients switched to open-label secukinumab 150 mg were 67 for LD and 68 for NL groups for both pain and morning stiffness.
[2]At Week 52 - number of evaluable patients were 146 for LD and 154 for NL groups; number of patients switched to open-label secukinumab 150 mg were 69 for LD and 71 for NL groups for fatigue and physical function.
[3]FACIT-Fatigue, SF-36 PCS was assessed at Weeks 16 and 52.

Table 2. Proportion of patients meeting MCID criteria up to Week 52 in TNFi-naïve population

change from baseline through Week 16 and as observed at Week 52. Minimal clinically important difference (MCID) data were assessed using non-responder imputation through Week 16 and as observed at Week 52.

Results: Overall, 501 TNFi-naïve patients were included in this analysis (LD, N=164; NL, N=166; PBO, N=171). Up to 64% of placebo and approximately 50% secukinumab treated patients switched to open label secukinumab 150 mg between Week 20 - 52. Secukinumab-treated patients vs PBO ($p< 0.05$) demonstrated a higher mean reduction from baseline in nocturnal back pain and morning stiffness, both at Weeks 4 and 16 which was sustained at Week 52 (**Table 1**). Also, improvements in secukinumab-treated patients vs PBO ($p< 0.05$) were reported in FACIT-Fatigue and SF-36 PCS scores from baseline at Weeks 16 and 52 (**Table 1**). At Week 16, a higher proportion of secukinumab-treated patients met the MCID criteria vs PBO ($p< 0.05$) across pre-specified efficacy assessments, which was sustained at Week 52 (**Table 2**).

Conclusion: Secukinumab provided clinically meaningful improvement in back pain, morning stiffness, fatigue, and physical function in TNFi-naïve patients with nr-axSpA over 52 weeks.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcomes (PROs) are important when evaluating treatment benefits in PsA. We present an analysis of PRO data from the SELECT-PsA 1 study.

Methods: SELECT-PsA 1 (NCT03104400) is a Phase 3, randomized, placebo- (PBO) and active-controlled trial in patients with active PsA and inadequate responses to ≥1 non-biologic DMARD. Eligible patients were randomized to receive upadacitinib (UPA) 15 mg once daily (QD), UPA 30 mg QD, adalimumab (ADA) 40 mg every other week, or PBO for 24 weeks, with the primary endpoint assessment at Week 12. PROs included: Patient Global Assessment of Disease Activity (PtGA), Patient's Assessment of Pain, HAQ-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue, 36-Item Short-Form Health Survey (SF-36), EuroQoL-5 Dimension, 5 level, Self-Assessment of Psoriasis Symptoms (SAPS), Work Productivity and Activity Impairment, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and morning stiffness (items 5 and 6 from the BASDAI). BASDAI was assessed in patients with presence of psoriatic spondylitis at baseline (BL). Least squares mean changes from BL to Week 12 (Week 16 for SAPS) were assessed. Percentages of patients reporting improvements ≥ minimal clinically important differences (MCID) from BL through Week 24 were compared between treatment groups. Number needed to treat (NNT) to achieve an additional MCID response was calculated at Weeks 12/24 for UPA vs PBO and ADA vs PBO.

Table. 1 Mean Change in PRO Scores From Baseline at Week 12

PRO	Placebo		UPA 15 mg QD		UPA 30 mg QD		ADA 40 mg EOW

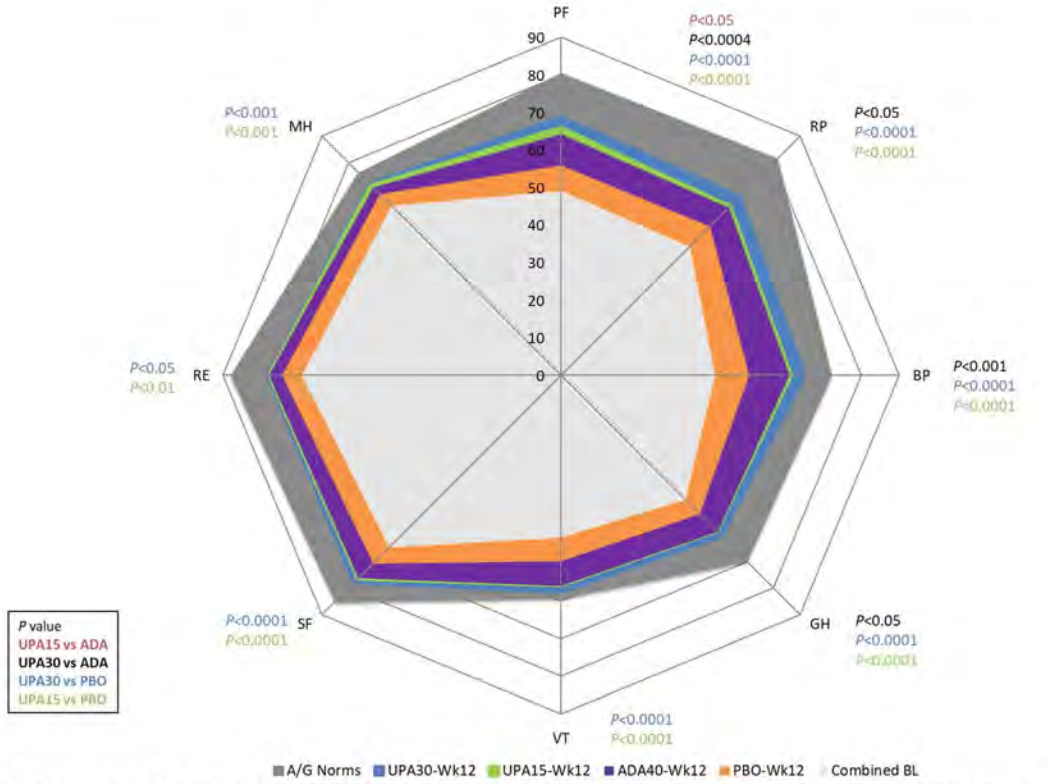
*$P<0.05$ for UPA vs PBO. †$P<0.05$ for UPA vs ADA. Note: No formal statistical comparisons were conducted for ADA vs PBO.
[a]Results presented at Week 16 as SAPS was not assessed at Week 12. [b]In subjects with psoriatic spondylitis at baseline. [c]Mean of BASDAI Q5 and Q6.
ADA, adalimumab; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; EOW, every other week; EQ-5D-5L, EuroQoL-5 Dimension, 5 level index score; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCS, mental component summary; NRS, Numerical Rating Scale; PBO, placebo; PCS, physical component summary; PRO, patient-reported outcome; PtGA, Patient Global Assessment of Disease Activity; QD, once daily; SAPS, Self-Assessment of Psoriasis Symptoms; SF-36, 36-Item Short-Form Health Survey; UPA, upadacitinib; WPAI, Work Productivity and Activity Impairment.

Figure 1. Spydergram of SF-36 Domain Changes From Baseline With UPA 15 mg, 30 mg vs PBO and ADA at Week 12



ADA, adalimumab; A/G Norms, age- and gender-matched normative values; BL, baseline; BP, bodily pain; GH, general health; MH, mental health; PBO, placebo; PF, physical functioning; RE, role-emotional; RP, role-physical; SF, social functioning; SF-36, 36-Item Short-Form Health Survey; UPA, upadacitinib; VT, vitality; Wk, week.

Results: Data from 1704 patients (UPA 15 mg: 429; UPA 30 mg: 423; PBO: 423; ADA: 429) were analyzed. At Week 12, both doses of UPA resulted in significant improvements from BL vs PBO across all PROs (**Table 1**). At Week 12, UPA 15 mg and 30 mg resulted in significant improvements from BL vs ADA in HAQ-DI, SAPS, and SF-36 physical component summary and UPA 30 mg vs ADA in 4 SF-36 domains (**Figure 1**). Compared with PBO, significantly more patients treated with UPA 15 mg and 30 mg reported improvements ≥ MCID in PtGA, pain, and HAQ-DI as early as

Figure 2. Proportion of Patients Reporting Improvements ≥ MCID[a] in PROs at Week 12

	PtGA NNT	Pain NNT	HAQ-DI NNT	FACIT-F NNT	EQ-5D-5L NNT	BASDAI NNT	SF-36 PCS NNT	SF-36 MCS NNT[b]
PBO	–	–	–	–	–	–	–	–
UPA 15 mg	4.2	4.6	4.1	6.6	5.3	3.4	4.3	11.4
UPA 30 mg	3.4	3.7	3.5	6.0	4.6	3.0	3.7	–
ADA 40 mg	4.5	4.7	7.3	7.1	5.2	4.4	5.2	10.8

*P<0.05 for UPA vs PBO. †P<0.05 for UPA vs ADA.

[a]MCID was defined as reduction of ≥1 point for PtGA, reduction of ≥1 point for pain, reduction of ≥0.35 units for HAQ-DI, increase of ≥4.0 points for FACIT-F, increase of ≥2.5 points for SF-36 PCS and MCS, increase of ≥0.05 for EQ-5D, and reduction of ≥1.1 points for BASDAI.

[b]NNTs vs PBO were not calculated for non-significant results.

ADA, adalimumab; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; EQ-5D-5L, EuroQoL-5 Dimension, 5 level index score; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCID, minimal clinically important difference; MCS, mental component summary; NNT, number needed to treat; PBO, placebo; PCS, physical component summary; PROs, patient-reported outcomes; PtGA, Patient Global Assessment of Disease Activity; SF-36, 36-Item Short-Form Health Survey; UPA, upadacitinib.

Week 2 (first post-BL visit) that were maintained through Week 24. At Week 12, the proportions of patients reporting improvements ≥ MCID were significantly greater with both doses of UPA vs PBO across all PROs except SF-36 mental component summary (UPA 30 mg) with NNTs ranging from 3.0–11.4 for all PROs (**Figure 2**). The proportions of UPA-treated (both doses) patients reporting improvements ≥ MCID at Week 12 were similar to ADA-treated patients across most PROs and significantly higher than ADA-treated patients in HAQ-DI; improvements were maintained through Week 24.

Conclusion: Treatment with UPA 15 mg or UPA 30 mg resulted in clinically meaningful improvements in PROs vs PBO at 12 weeks in biologic DMARD-naïve patients with active PsA, which were maintained or further improved at Week 24. Overall, improvements were similar between UPA 15 mg and UPA 30 mg and improvements with both doses of UPA were similar or greater than those reported with ADA.

Efficacy Outcomes Following Etanercept Withdrawal by Sustained Remission Status in Patients with Nr-axSpA: Results from RE-EMBARK

Filip Van den Bosch[1], Peter Nash[2], James Cheng-Chung Wei[3], Francisco Blanco[4], Vassilis Tsekouras[5], Chuanbo Zang[6], Daniela Graham[7], Edmund Arthur[8], Pamela Selema[6], Bonnie Vlahos[6] and Atul Deodhar[9], [1]Ghent University Hospital, Ghent, Belgium, [2]School of Medicine Griffith University, Brisbane, Queensland, Australia, [3]Chung Shan Medical University Hospital, Taichung, Taiwan (Republic of China), [4]INIBIC-Complejo Hospitalario Universitario A Coruña, A Coruna, Spain, [5]Pfizer, Nicosia, Cyprus, [6]Pfizer, Collegeville, PA, [7]Pfizer, Groton, PA, [8]Pfizer, Peapack, NJ, [9]Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Etanercept (ETN) is effective and well tolerated in patients with non-radiographic axial spondyloarthritis (nr-axSpA). However, there is limited information on the effects of withdrawing ETN treatment in patients who have achieved a significant clinical response. RE-EMBARK was a phase 4, multicenter, open-label, 3-period study that evaluated the effects of ETN withdrawal and retreatment on clinical efficacy in patients with nr-axSpA. The aim of this analysis was to evaluate differences in outcomes during treatment withdrawal (Period 2) based on sustained remission status during the active treatment phase (Period 1).

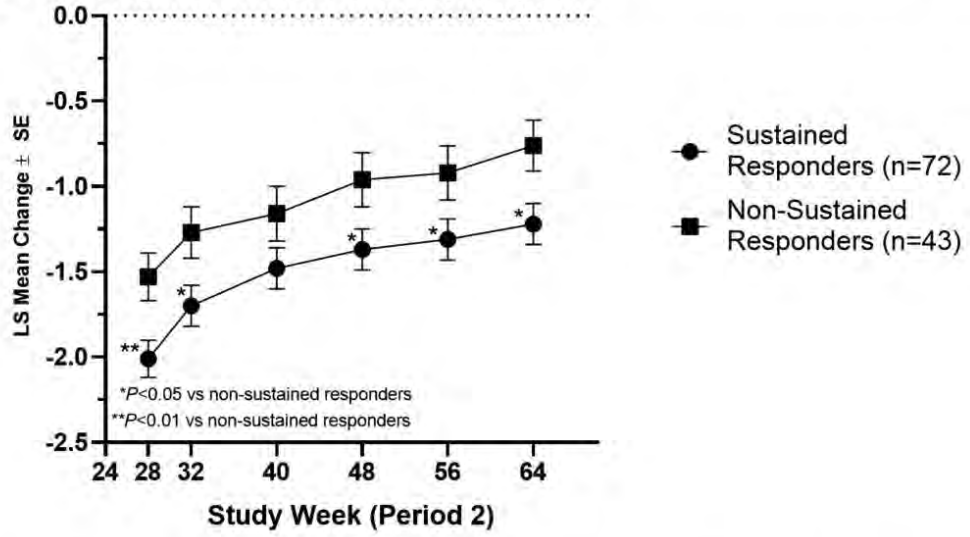
Methods: RE-EMBARK enrolled patients aged 18–49 years with active nr-axSpA who had an inadequate response to ≥2 nonsteroidal anti-inflammatory drugs (NSAIDs) and were taking a stable dose of an NSAID for at least 14 days before their first study dose of ETN. In Period 1, all patients received open-label ETN 50 mg once weekly and stable background NSAID for 24 weeks. Patients who achieved inactive disease (ASDAS-CRP < 1.3) at Week 24 were eligible to enter Period 2. In Period 2, ETN was withdrawn for up to 40 weeks. Patients with an nr-axSpA flare (ASDAS-ESR ≥2.1) during Period 2 were eligible to immediately enter Period 3. In Period 3, patients were retreated with open-label ETN 50 mg once weekly for 12 weeks. In this post-hoc analysis, sustained response (SR) during Period 1 was defined as ASDAS ESR inactive disease at week 24 and at either Week 12 or Week 16, and no flare at any of these time points.

Table 1. Baseline characteristics of patients with SR* versus non-SR patients during Period 1 of RE-EMBARK

Characteristics	SR patients (n = 72)	Non-SR patients (n = 43)
Age (years), mean ± SD	30.8 ± 7.7	36.3 ± 7.9
Men, n, (%)	56 (78)	18 (42)
White, n %	65 (90)	40 (93)
BMI, kg/m^2, mean ± SD	25.2 ± 3.9	26.4 ± 4.4
Duration (years) of disease symptoms, mean ± SD	1.4 ± 1.5	2.0 ± 1.4
Positive MRI sacroiliitis by ASAS criteria, n (%)	52 (72.2)	30 (69.8)
ASDAS-CRP score, mean ± SD	3.4 ± 1.0	3.4 ± 0.7
ASDAS-ESR score, mean ± SD	3.3 ± 1.0	3.7 ± 0.7
SPARCC MRI SIJ score, mean ± SD	12.9 ± 15.1	6.5 ± 11.0
SPARCC MRI 6 DVU spinal score, mean ± SD	2.6 ± 6.5	1.5 ± 3.0
HLA-B27-positive, n (%)	64 (88.9)	31 (72.1)
Concomitant DMARDs use, n (%)	2 (2.8)	0 (0.0)
Concomitant NSAID use, n (%)	72 (100.0)	43 (100.0)

*defined as ASDAS ESR < 1.3 at Week 24, plus ASDAS ESR <1.3 at Week 12 or Week 16 (where ASDAS ESR may not be >2.1 at either timepoint).
ASAS, Assessment in SpondyloArthritis international Society; ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score with C-reactive protein; ASDAS-ESR, Ankylosing Spondylitis Disease Activity Score with erythrocyte sedimentation rate; BMI, body mass index; DVU, discovertebra; MRI, magnetic resonance imaging; SD, standard deviation; SIJ, sacroiliac joint; SPARCC, Spondyloarthritis Research Consortium of Canada; SR, sustained remission.

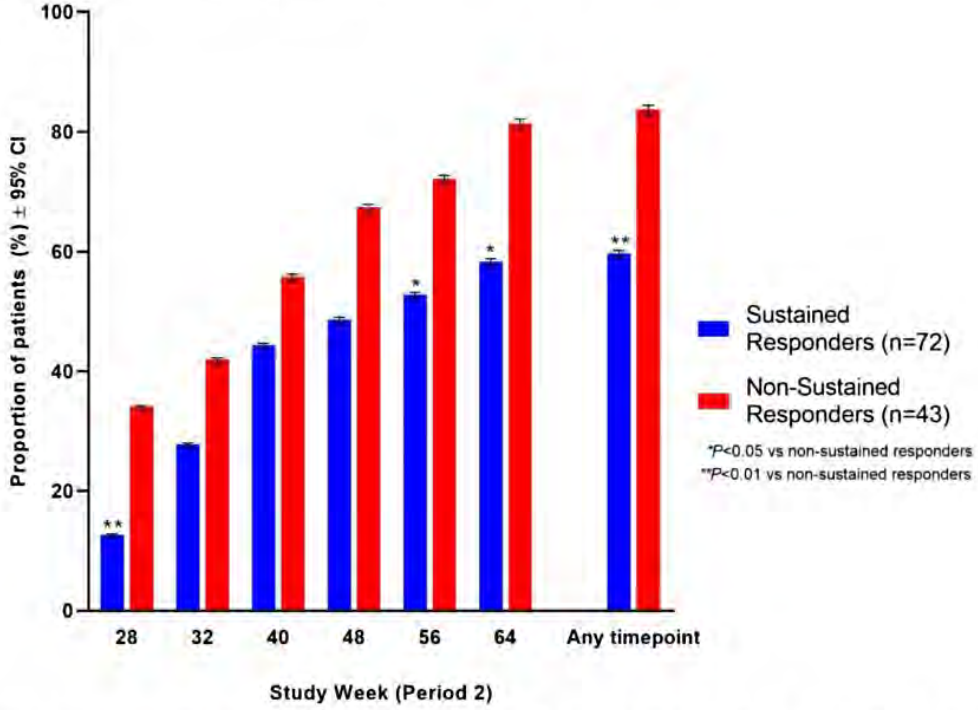
Figure 1. Least squares mean change over time in ASDAS-CRP from Period 1 baseline during Period 2 in sustained response and non-sustained response patients



Sustained response during Period 1 was defined as ASDAS ESR < 1.3 at Week 24, plus ASDAS ESR <1.3 at Week 12 or Week 16 (where ASDAS ESR may not be >2.1 at either timepoint).
ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score with C-reactive protein; LS, least squares; SE, standard error.

Baseline demographic and clinical characteristics of SR patients were compared with non-SR patients. Statistical analyses comparing SR versus non-SR patients were conducted using logistic models for binary endpoints and ANCOVA for continuous endpoints.

Figure 2. The proportion of sustained responders and non-sustained responders with flare (ASDAS-ESR ≥2.1) during Period 2



Sustained response during Period 1 was defined as ASDAS ESR < 1.3 at Week 24, plus ASDAS ESR <1.3 at Week 12 or Week 16 (where ASDAS ESR may not be >2.1 at either timepoint).
ASDAS-ESR, Ankylosing Spondylitis Disease Activity Score with Erythrocyte Sedimentation Rate; CI, confidence interval.

Results: A total of 209 patients were treated during Period 1, of which 119 (57%) achieved inactive disease and entered Period 2 (ETN treatment withdrawal). A total of 115 patients who had at least one efficacy evaluation during Period 2 were included in this post-hoc analysis, with 72 patients achieving SR versus 43 patients with non-SR. Period 1 SR patients were younger, had a higher SpondyloArthritis Research Consortium of Canada MRI sacroiliac joint score SIJ score, and were more likely to be HLA-B27 positive than non-SR patients (**Table 1**). In Period 2, Period 1 SR patients showed greater reductions in ASDAS-CRP than non-SR patients, which was statistically significant at Weeks 28, 32, 48, 56, and 64 (**Figure 1**). A significantly smaller proportion of Period 1 SR versus non-SR patients had a flare during Period 2 at Weeks 28, 56, 64, and all timepoints combined **(Figure 2**). When all timepoints were combined, 59.7% of Period 1 SR patients had a flare compared with 83.7% of non-SR patients.

Conclusion: Patients who demonstrated SR to ETN in Period 1 showed greater prolongation of efficacy and fewer flares when ETN treatment was withdrawn (Period 2) compared with non-SR patients. These results suggest on-treatment efficacy can affect how patients respond to withdrawal of ETN.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). It was approved in the US in December 2017 for use in combination with non-biologic DMARDs. This analysis of real-world data assessed demographic and baseline clinical characteristics, as well as treatment persistence/adherence, in patients (pts) with PsA who had newly initiated tofacitinib treatment.

Methods: This retrospective cohort study included pts aged ≥ 18 years in the Truven MarketScan™ US Commercial and Medicare Supplemental Claims and Encounters database with ≥ 1 tofacitinib claim (first = index) between December 14, 2017–April 30, 2019, and PsA diagnoses (≥ 1 inpatient or ≥ 2 outpatient [30–365 days apart]) on or within 12 months pre-index. Pts were continuously enrolled for 12 months pre-index and 6 months post-index, with no

[a]Excludes pts with a diagnosis of RA on or within 12 months pre-index and within 6 months post-index; [b]Pts with ≥1 claim for a csDMARD or apremilast on or within 90 days post-index; [c]Pts with <60-day gap without tofacitinib treatment; [d]Number of days covered divided by number of days in the 6-month post-index period; [e]Pts achieving ≥80% of days covered
csDMARD, conventional synthetic DMARD; DMARD, disease-modifying antirheumatic drug; IQR, interquartile range; N, number of pts in each cohort; n, number of pts in each category; PDC, proportion of days covered; PsA, psoriatic arthritis; pts, patients; RA, rheumatoid arthritis; SD, standard deviation

pre-index claims for tofacitinib. Pt demographic and clinical characteristics on the day of index, history of treatment with advanced therapies (≥ 1 claim for biologic DMARDs or apremilast within 12 months pre-index), and tofacitinib treatment regimen (monotherapy or combination therapy [≥ 1 claim for conventional synthetic DMARDs or apremilast on or within 90 days post-index]) were recorded. Outcomes at 6 months post-index included tofacitinib persistence (< 60-day gap without tofacitinib treatment) and adherence (proportion of days covered ≥ 80% and medication possession ratio [data not shown]). A sensitivity check was performed by analyzing a sub-cohort which excluded pts with a diagnosis of rheumatoid arthritis (RA) on or within 12 months pre-index and within 6 months post-index.

Results: Of 17,321 pts receiving tofacitinib, 440 pts met the inclusion criteria for the overall cohort, with 315 pts included in the sub-cohort. In the overall cohort, pts were mostly female, with a mean age of 52.3 years and a mean PsA duration of 738 days (Table 1). Most pts were exposed to ≥ 1 advanced therapy (mean = 1.1; range = 0–4) within 12 months pre-index; most commonly secukinumab (Table 2). Overall, 39.3% of patients received tofacitinib combination therapy post-index; most commonly methotrexate (Table 2). Persistence was similar in pts receiving tofacitinib monotherapy (71.2%) vs combination therapy (73.4%; Table 3) at 6 months post-index. Adherence was slightly lower in pts receiving tofacitinib monotherapy (56.9%) vs combination therapy (66.5%; Table 3) at 6 months post-index. All results were similar in the sub-cohort (Tables 1–3).

Conclusion: This analysis of US-based claims data indicated that pts newly initiated tofacitinib treatment an average of 2 years after PsA diagnosis, with the majority (> 60%) of pts receiving tofacitinib as monotherapy. High levels of persistence and adherence to tofacitinib were observed 6 months after treatment initiation. Findings were similar when pts with PsA who also had a diagnosis of RA were excluded. Data are limited in that claims data cannot confirm that pts took the medication for which they filed a claim for.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), a monoclonal antibody that specifically binds to the p19-subunit of IL-23, is approved to treat psoriasis (PsO). At Week 24 of the Phase 3, double-blind, placebo (PBO)-controlled trial in patients (pts) with active PsA who were biologic-naïve or prior TNFα inhibitor (TNFi)-treated (DISCOVER-1), GUS 100 mg, given every 4/8 weeks (Q4W/Q8W), demonstrated efficacy for joint and skin symptoms, physical function,

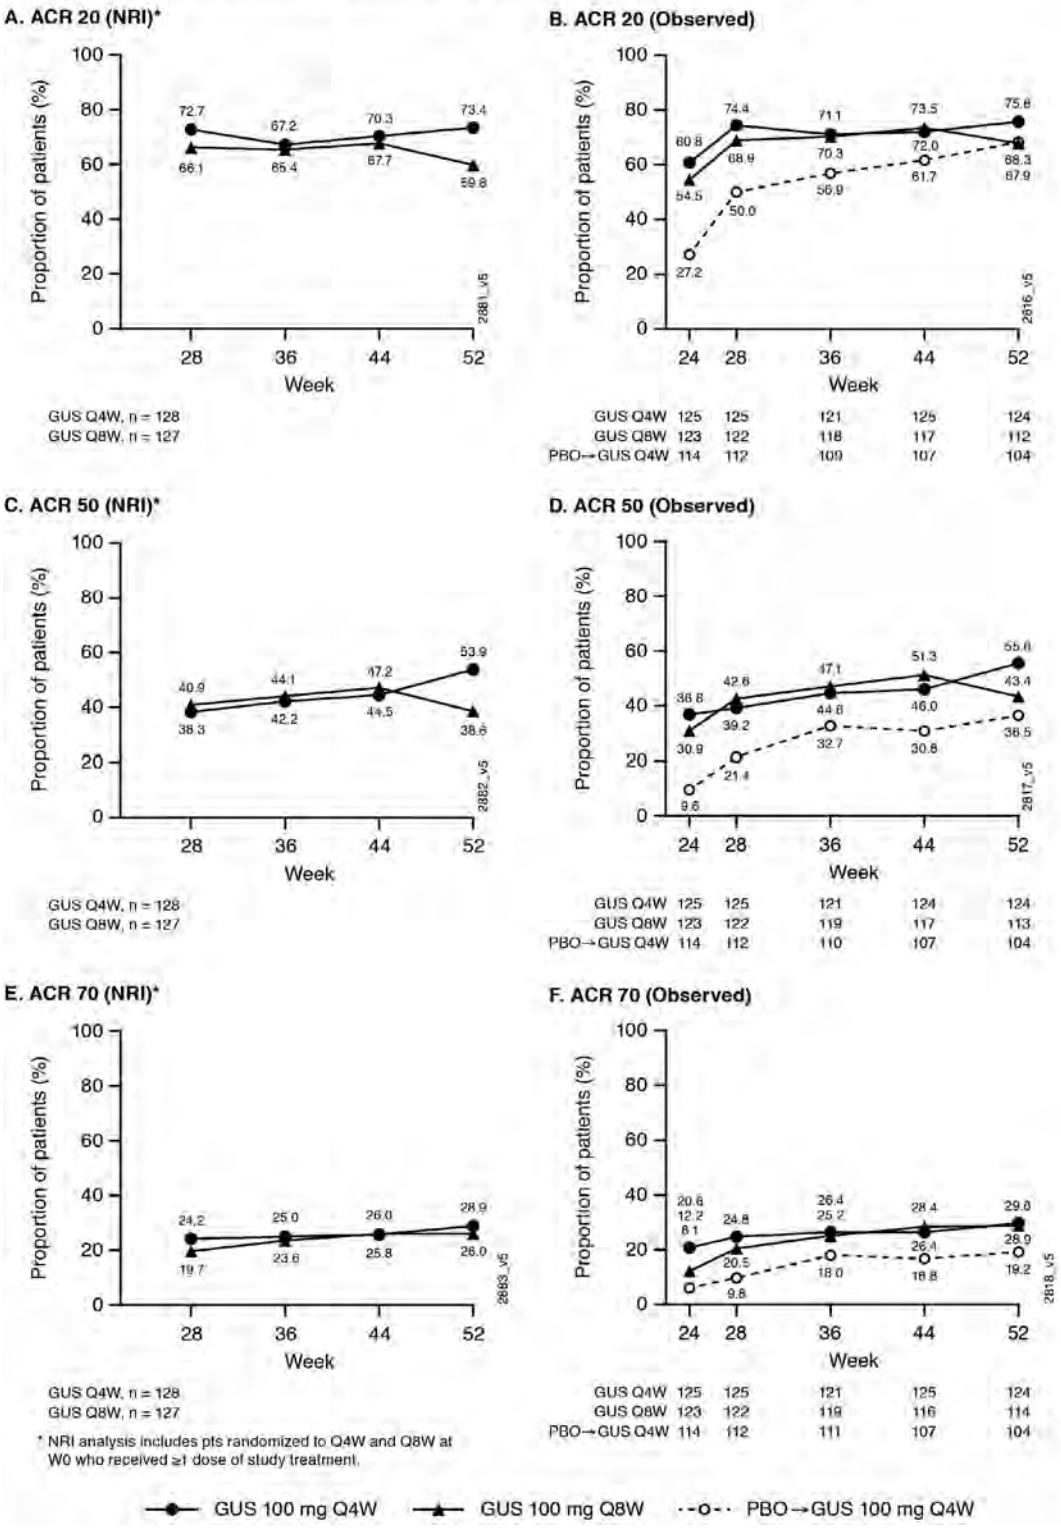
and quality of life vs PBO. Adverse events (AEs) were consistent with GUS safety in PsO. This study assessed GUS efficacy and safety in pts with PsA through 1 year.

Methods: Adults with active PsA (≥3 swollen + ≥3 tender joints; CRP≥0.3 mg/dL) despite standard therapies were eligible. Approximately 30% of pts could have previously received ≤2 TNFi. Pts were randomized 1:1:1, stratified by Week 0 DMARD (Y/N) and prior TNFi use (Y/N), to GUS 100 mg Q4W; GUS 100 mg at Weeks 0 and 4, and Q8W; or PBO. At Week 24, PBO pts crossed over to GUS 100 mg Q4W (PBO X Q4W). Week 48 marked the last dose of study agent. ACR response rates at Week 52, based on non-responder imputation (NRI) for missing data and as observed in pts still on study agent at Week 24, are shown. Observed data for additional endpoints are shown. AEs were reported through Week 60.

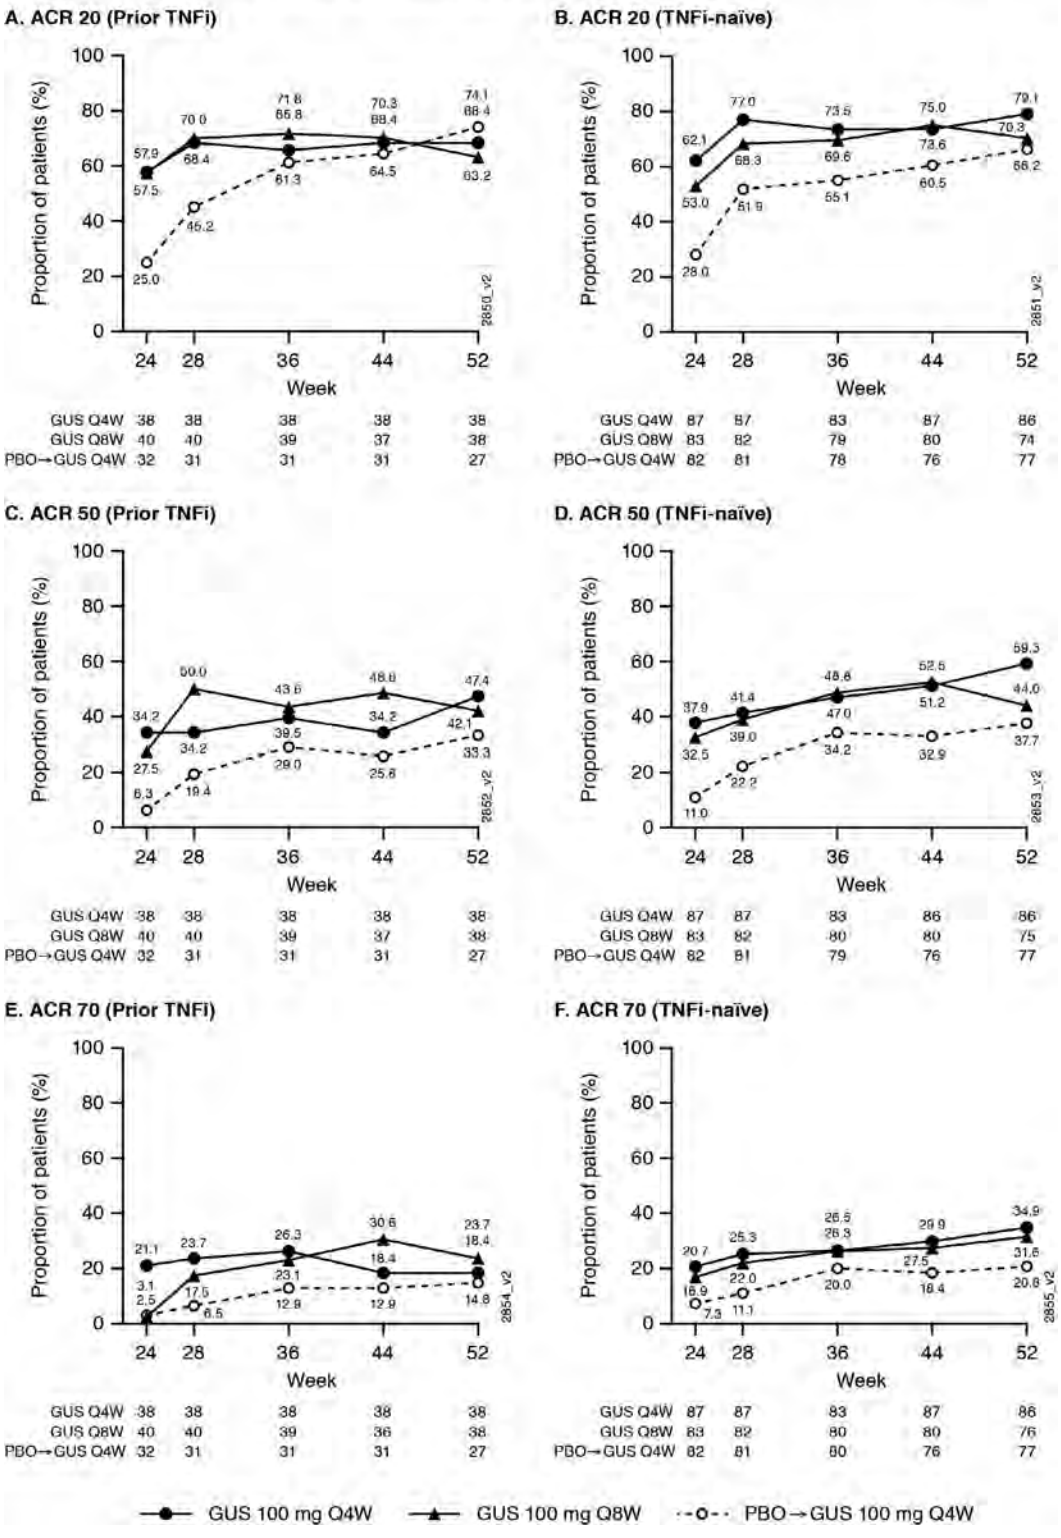
Results: 362/381 (95%) randomized pts continued study agent at Week 24 (125 Q4W, 123 Q8W, 114 PBO X Q4W), 347/381 (91%) pts completed treatment, and 343/381 (90%) completed the study. NRI ACR20 response rates were maintained at Week 52 (Q4W: 73%, Q8W: 60%; Fig. 1A). Similar response patterns were seen for the more stringent ACR50/70 criteria (Fig. 1C, E). Observed ACR responses, overall (Fig. 1B, D, F) and in pts with (Fig. 2A, C, E) and without (Fig. 2B, D, F) prior TNFi use, were also maintained at Week 52. Improvements in other clinical outcomes were also maintained at Week 52, and responses for pts crossing over from PBO X Q4W at Week 24 were generally consistent with other GUS-treated pts by Week 52 (Table 1). Through Week 24, 4 (2%) GUS- and 5 (4%) PBO-treated pts had serious AEs; no GUS-treated and 2 (2%) PBO-treated pts had a serious infection. Through Week 60, serious AEs and serious infections occurred in 4% and 1%, respectively, of all 369 GUS-treated pts. No GUS-treated pt died or had IBD, opportunistic infections or active tuberculosis, or anaphylactic or serum sickness-like reactions.

Fig 1. NRI and Observed ACR20 (**A & B**), ACR50 (**C & D**), and ACR70 (**E & F**) responses through W52
(Note: patients randomized to PBO crossed over to GUS Q4W at W24)



GUS, guselkumab; NRI, non-responder imputation; PBO, placebo; Q4W, every 4 weeks; Q8W, every 8 weeks; TNFi, tumor necrosis factor inhibitor.

Fig 2. Observed ACR20 (**A&B**), ACR50 (**C&D**), ACR70 (**E&F**) response rates from W24 through W52 by prior TNFi use (Note: patients randomized to PBO crossed over to GUS Q4W at W24)



GUS, guselkumab; PBO, placebo; Q4W, every 4 weeks; Q8W, every 8 weeks; TNFi, tumor necrosis factor inhibitor.

Conclusion: GUS Q4W and Q8W maintained improvements in joint symptoms through 1 year in pts with active PsA who were biologic-naïve or previously TNFi-treated. In pts continuing in the study, improvements in skin symptoms, dactylitis, enthesitis, physical function, and quality of life were also maintained through 1 year. GUS 100 mg Q4W and Q8W were safe and well-tolerated through study completion and consistent with GUS safety in PsO.[1]

Upadacitinib as Monotherapy and in Combination with Non-biologic DMARDs for the Treatment of Psoriatic Arthritis: Subgroup Analysis from Two Phase 3 Trials

Peter Nash[1], Pascal Richette[2], Laure Gossec[3], Antonio Marchesoni[4], Koji Kato[5], Erin Blondell[6], Elizabeth Lesser[6], Reva M McCaskill[6], Dai Feng[6], Jaclyn K Anderson[6] and Eric Ruderman[7], [1]School of Medicine Griffith University, Brisbane, Queensland, Australia, [2]Department of Rheumatology, Lariboisière Hospital, Paris, France, [3]Sorbonne Université and Hôpital Universitaire Pitié Salpêtrière, Paris, France, [4]ASST Gaetano Pini-CTO, Milano, Italy, [5]AbbVie Inc, North Chicago, IL, [6]AbbVie Inc., North Chicago, IL, [7]Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 40% of PsA patients (pts) on advanced therapy are on monotherapy.[1,2] Upadacitinib (UPA) has shown efficacy and safety in pts with active PsA in the Phase 3 SELECT-PsA 1 and SELECT-PsA 2 clinical trials.[3,4] This analysis assessed the efficacy and safety in the subgroups of pts who were treated with UPA as monotherapy or in combination with non-biologic disease-modifying antirheumatic drugs (non-bDMARDs).

Methods: The SELECT-PsA program enrolled pts with prior inadequate response (IR) or intolerance to ≥1 non-bDMARD (N=1705) and prior IR or intolerance to ≥1 bDMARD (N=642). Data from both trials was integrated for pts receiving placebo (PBO), UPA 15 mg once daily (QD) and UPA 30 mg QD; adalimumab data was excluded from this analysis as it was only evaluated in SELECT-PsA 1. Stable background treatment of ≤2 non-bDMARDs was permitted; background therapy was not required. This analysis includes comparison of UPA monotherapy and combination therapy for the endpoints: ACR20/50/70 responses and change from baseline in pain and HAQ-DI (Week 12); Static Investigator Global Assessment of Psoriasis of 0 or 1 and at least a 2-point improvement from baseline and PASI75/90/100 re-

CPK elevation	3 (1.6)	10 (5.3)	11 (5.6)	7 (1.6)	32 (7.1)	42 (9.5)

AE, adverse event; CPK, creatine phosphokinase; D/C, discontinuation; MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PBO, placebo; QD, once daily; UPA, upadacitinib; VTE, venous thromboembolic events.

combination therapy. Point estimates and 95% confidence intervals (CIs) of the PBO subtracted treatment effect were calculated. Treatment-emergent adverse events (TEAEs) were analyzed and summarized through Week 24.

Results: Of the 1916 pts included in the analysis, 574 (30%) received monotherapy and 1342 (70%) received combination therapy; 84% in the combination therapy group received MTX +/- another non-bDMARD. Both UPA monotherapy and combination therapy led to improvements in efficacy outcomes vs PBO (**Figure**). Across endpoints, for each UPA dose, generally consistent point estimates of the PBO subtracted treatment effect and associated overlapping CIs were observed between pts who were on UPA monotherapy and those who were on combination therapy. Generally, the frequency of AEs, including serious AEs, were comparable with UPA when administered as monotherapy and combination therapy (**Table**). The frequency of AEs of serious infections and hepatic disorder were lower with monotherapy while the frequency of AEs leading to discontinuation of study drug were lower with combination therapy. Most hepatic disorders were transient transaminase elevations.

Conclusion: In the SELECT PsA Phase 3 trials, the efficacy and safety of UPA was generally consistent when administered as monotherapy or when given in combination with non-bDMARDs. Results from this analysis support the use of UPA with or without concomitant non-bDMARDs.

• Steroid	12.00%
BASDAI (0 – 10), mean (SD)	6.0 (2.6)
BASFI (0 – 10), mean (SD)	5.3 (2.2)
Night pain (0 – 10), mean (SD)	6.3 (2.2)
Total back pain (0 – 10), mean (SD)	6.5 (1.9)
Patient global assessment (0 – 10), mean (SD)	6.5 (1.9)
ASAS40	51.30%

Table 1. Baseline characteristics of eligible subjects. SD: standard deviation; SpA: spondyloarthritis; BASDAI: Bath ankylosing spondylitis disease activity index; BASFI: Bath ankylosing spondylitis functional index; ASAS40: Assessment of SpondyloArthritis International Society (ASAS) 40% response criteria.

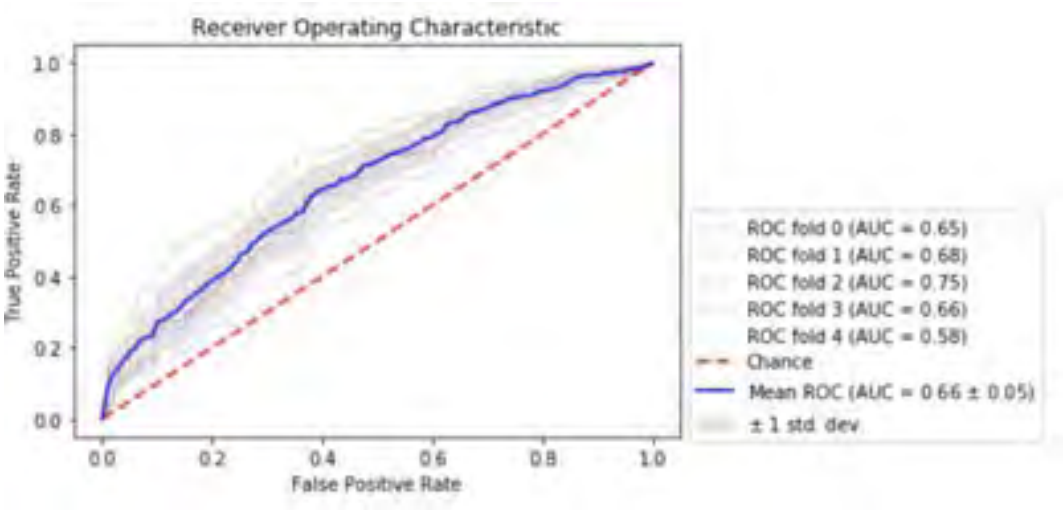

Figure 1. Performance of Random Forest Models in testing set using Receiver Operating Characteristic curves. ROC: receiver operating characteristic; AUC: area under the curve.

Background/Purpose: The treatment response to tumor necrosis factor inhibitors (TNFi) in patients with active ankylosing spondylitis (AS) is heterogeneous. In clinical practice, both patients and clinicians are interested to know how likely a patient will achieve a major response after initiating TNFi. The objective of this study is to develop a predictive model for a favorable response to TNFi based on baseline clinical features in patients with active AS.

Methods: We obtained individual patient data from randomized clinical trials of Adalimumab and Etanercept in active AS, and aggregated the participant data in the TNFi arms for a pooled analysis. The main outcome was major response at week 12, defined by achieving Ankylosing Spondylitis Assessment 40% (ASAS40) response. Baseline characteristics including age, sex, body mass index (BMI), disease duration, spondyloarthritis features, C-reactive protein (CRP), HLA-B27 positivity, and patient reported outcomes were included as predictors. The entire cohort was split by 5:1 for model development and validation. We used Random Forest algorithm to develop the predictive model with ranking of the importance of features, and the performance was examined using receiver operating characteristics area under the curve (ROC - AUC). The process was repeated independently for 5 times, and the final AUC was the average.

Results: A total of six RCTs of Adalimumab or Etanercept in patients with active AS were identified, and 1090 subjects who were in the TNFi arms were eligible and included in the analysis. Baseline characteristics are summarized in Table 1. Average age was 38.7 +/- 11.7 years, 75.3% were male patients, and 85.5% were HLA-B27 positive. Fifty-one percent of subjects achieved ASAS40 response at week 12. The Random Forest models had a small to medium effect with average AUC of 0.66 (Figure 1). At baseline, higher CRP level, worse night pain, younger age, worse patient global assessment, and lower BMI were the most important features that predicted a major response.

Conclusion: Using Random Forest algorithm, we developed a model to predict treatment response to TNFi in patients with active AS. Preliminary analysis showed a small to medium effect with AUC of 0.66. At baseline, higher CRP, worse night pain, younger age, worse patient global assessment, and lower BMI are the most important features in the prediction model.

Predictors of Response in Patients with Non-Radiographic Axial Spondyloarthritis Receiving Certolizumab Pegol in the C-axSpAnd Study

Walter Maksymowych[1], Thomas Kumke[2], Simone Auteri[3], Bengt Hoepken[2], Lars Bauer[2] and Martin Rudwaleit[4], [1]University of Alberta, Edmonton, AB, Canada, [2]UCB Pharma, Monheim am Rhein, Germany, [3]UCB Pharma, Milan, Italy, [4]Department of Internal Medicine and Rheumatology, Klinikum Bielefeld, Germany

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Identification of predictive clinical factors of long-term treatment response in non-radiographic axial spondyloarthritis (nr-axSpA) may contribute to improved management of patients with this chronic disease. Certolizumab pegol (CZP) is currently the only FDA-approved tumor necrosis factor inhibitor (TNFi) for treatment of nr-axSpA.[1] We aim to identify whether any demographic or baseline characteristics of nr-axSpA patients from the C-axSpAnd study[2] are predictive of achieving a clinical response after 1 year of CZP treatment.

Methods: C-axSpAnd (NCT02552212) is a phase 3, interventional multicenter study including a completed 52-week double-blind, placebo-controlled period. Full study design is reported elsewhere.[2] Multivariate stepwise logistic regression analysis was used to identify predictors of response for the primary efficacy variable (ASDAS – major improvement [ASDAS-MI] at Week 52) and the main secondary efficacy variable (ASAS40 at Week 52) in patients randomized to CZP 200 mg every 2 weeks (Q2W). Predictive factors used in the model included demographic and baseline characteristics, and clinical outcomes at Week 12. A p value ≤0.05 was required for forward selection into the model and p=0.1 for backward elimination from the model. Non-responder imputation was used to account for missing data or values collected after switching to open-label treatment. A sensitivity analysis was conducted to ac-

Table 1: Predictive factors of Week 52 response in CZP-treated patients

Predictive factors for ASDAS-MI	Odds ratio	95% Wald confidence limits
MRI+/HLA-B27+ (n=90) vs MRI−/HLA-B27+ (n=38)	5.78	1.59–21.0
MRI+/HLA-B27− (n=29) vs MRI−/HLA-B27+ (n=38)	1.64	0.33–8.15
BASDAI at baseline (continuous)	1.91	1.30–2.80
Week 12 change from baseline in ASDAS (continuous)	0.14	0.07–0.29
Predictive factors for ASAS40	**Odds ratio**	**95% Wald confidence limits**
MRI+/HLA-B27+ (n=90) vs MRI−/HLA-B27+ (n=38)	4.75	1.58–14.28
MRI+/HLA-B27− (n=29) vs MRI−/HLA-B27+ (n=38)	1.60	0.41–6.23
BASMI at baseline (continuous)	0.71	0.50–0.999
Week 12 change from baseline in PtGADA (continuous)	0.74	0.61–0.90
Week 12 change from baseline in ASQoL (continuous)	0.02	0.002–0.21

An odds ratio >1 indicates a higher probability of the first subgroup (binary) or of larger values (continuous) having a predictive effect. ASAS40: Assessment of SpondyloArthritis international Society 40% response; ASDAS-MI: Ankylosing Spondylitis Disease Activity Score – major improvement; ASQoL: Ankylosing Spondylitis Quality of Life questionnaire; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASMI: Bath Ankylosing Spondylitis Metrology Index; CZP: certolizumab pegol; HLA: human leukocyte antigen; MRI+/−: presence/absence of sacroiliitis on magnetic resonance imaging; PtGADA: Patient Global Assessment of Disease Activity.

count for patients who had changes in their non-biologic background medication during the 52-week placebo-controlled phase.

Results: 159/317 patients were randomized to CZP 200 mg Q2W and 158/317 to placebo. Predictive factors identified for Week 52 ASDAS-MI in the CZP-treated patients included those who were positive for both presence of sacroiliitis on MRI (MRI+) and human leukocyte antigen (HLA)-B27 (HLA+), those with a higher BASDAI at baseline, and those with a larger Week 12 improvement in ASDAS (**Table 1**). For ASAS40 response, MRI+/HLA-B27+ was also identified as a predictor of Week 52 response, along with a lower baseline BASMI and larger Week 12 improvements in PtGADA and ASQoL and (**Table 1**). Sensitivity analysis identified the same predictors for ASDAS-MI and ASAS40, with the exception of change from baseline in PtGADA as a predictor of ASAS40. Sensitivity analysis also identified achievement of Week 12 ASAS40 as a predictor of Week 52 ASAS40. In placebo-treated patients, no meaningful predictors of response at Week 52 were identified.

Conclusion: Presence of sacroiliitis on MRI and HLA-B27 positivity were identified as consistent predictors of Week 52 response (ASDAS-MI and ASAS40) in nr-axSpA patients treated with CZP. To our knowledge, this is the first report from an interventional 52-week placebo-controlled study in nr-axSpA to identify objective clinical features, particularly the presence of sacroiliac joint inflammation, as being predictive of response.

N = number of patients in the full analysis set. *P-values are nominal and are for comparison with methotrexate monotherapy.
BSA, (psoriasis-affected) body surface area; DAPSA, Disease Activity Index for Psoriatic Arthritis; LDI, Leeds Dactylitis Index; MDA, Minimal Disease Activity; mNAPSI, modified Nail Psoriasis Severity Index; PASDAS, Psoriatic Arthritis Disease Activity Score; SE, standard error; SPARCC, Spondyloarthritis Research Consortium of Canada.

Background/Purpose: Psoriatic arthritis is broadly characterized by clinical domains such as enthesitis, dactylitis, nail manifestations, and psoriasis. How these clinical domains influence the response to MTX and/or TNF inhibitor therapy remains unclear. Here we report the findings using data from the 48-week, SEAM-PsA trial.

Methods: In the SEAM-PsA trial, MTX and biologic-naïve adult patients with active PsA were randomized to three treatment arms; MTX (20 mg; N=284); ETN (50 mg; N=284); or Combo (ETN 50 mg + MTX 20 mg; N=283), given

weekly. Clinical outcomes (week 24) were measured as a percentage of patients achieving MDA, a change from baseline in PASDAS, and DAPSA scores. Patient subsets were based on clinical domains such as enthesitis (SPARCC), dactylitis (LDI), nail manifestations (mNAPSI) or psoriasis (BSA). Analyses comparing the ETN-containing arms with the MTX monotherapy arm used an ANCOVA model and was adjusted for baseline BMI status, prior non-biologic DMARD use, and a disease manifestation baseline status interaction term. P-values were unadjusted for multiplicity.

Results: The 3 treatment arms had similar baseline values (**Table 1**). Among patients with enthesitis, without dactylitis, and BSA< 10%, those patients receiving ETN monotherapy were more likely to achieve MDA compared with MTX monotherapy. The greater change in PASDAS scores observed in ETN monotherapy compared with MTX monotherapy were not influenced by the presence or absence of enthesitis, dactylitis or BSA≥10% (**Table 2**). Changes in DAPSA scores were similar across all clinical domains and treatment arms except for those patients with dactylitis in the Combo arm (**Table 2**).

Conclusion: For clinical domains that demonstrated differences between treatment arms, ETN arms presented better clinical outcomes when compared with MTX monotherapy. In addition, MDA and PASDAS reported consistent differences between treatment arms and are more sensitive at detecting therapy-mediated changes between clinical domains, whereas no differences were detected with DAPSA, except for dactylitis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS) is a human monoclonal antibody that specifically binds to the p19-subunit of IL-23. GUS has demonstrated efficacy across the various manifestations of PsA including skin, joint, soft tissue and structural damage at Week24 (W24) of DISCOVER-1[1] and DISCOVER-2[2], Phase 3 trials of patients (pts) with active PsA. Here we assess GUS efficacy through W24 in both studies utilizing composite indices.

Methods: Adult pts had active PsA despite standard therapies. DISCOVER-1 entry required ≥3 swollen & ≥3 tender joints and CRP ≥0.3 mg/dL; DISCOVER-2 required ≥5 swollen & ≥5 tender joints and CRP ≥0.6 mg/dL. 31% of DISCOVER-1 pts received 1-2 prior TNF inhibitors; DISCOVER-2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (Q8W); or placebo (PBO). Composite endpoints included: Psoriasis Disease Activity Score (PASDAS), Minimal Disease Activity (MDA), Very Low Disease Activity (VLDA), Modified Psoriatic Arthritis Responder Criteria (mPsARC; based on evaluation of 68 joints for tenderness and 66 for swelling),[3] Disease Activity Index for Psoriatic Arthritis (DAPSA), and clinical DAPSA (cDAPSA; determined by excluding CRP). Rates of achieving PASDAS Low/Very Low Disease Activity, MDA, VLDA, and DAPSA/cDAPSA Remission were pooled across studies (see **Fig1-2** for response criteria). GUS vs PBO comparisons employed a Cochran-Mantel-Haenszel test with baseline stratification factors or Fisher's exact test. Pts with missing data were imputed as nonresponders. P-values were not adjusted for multiplicity.

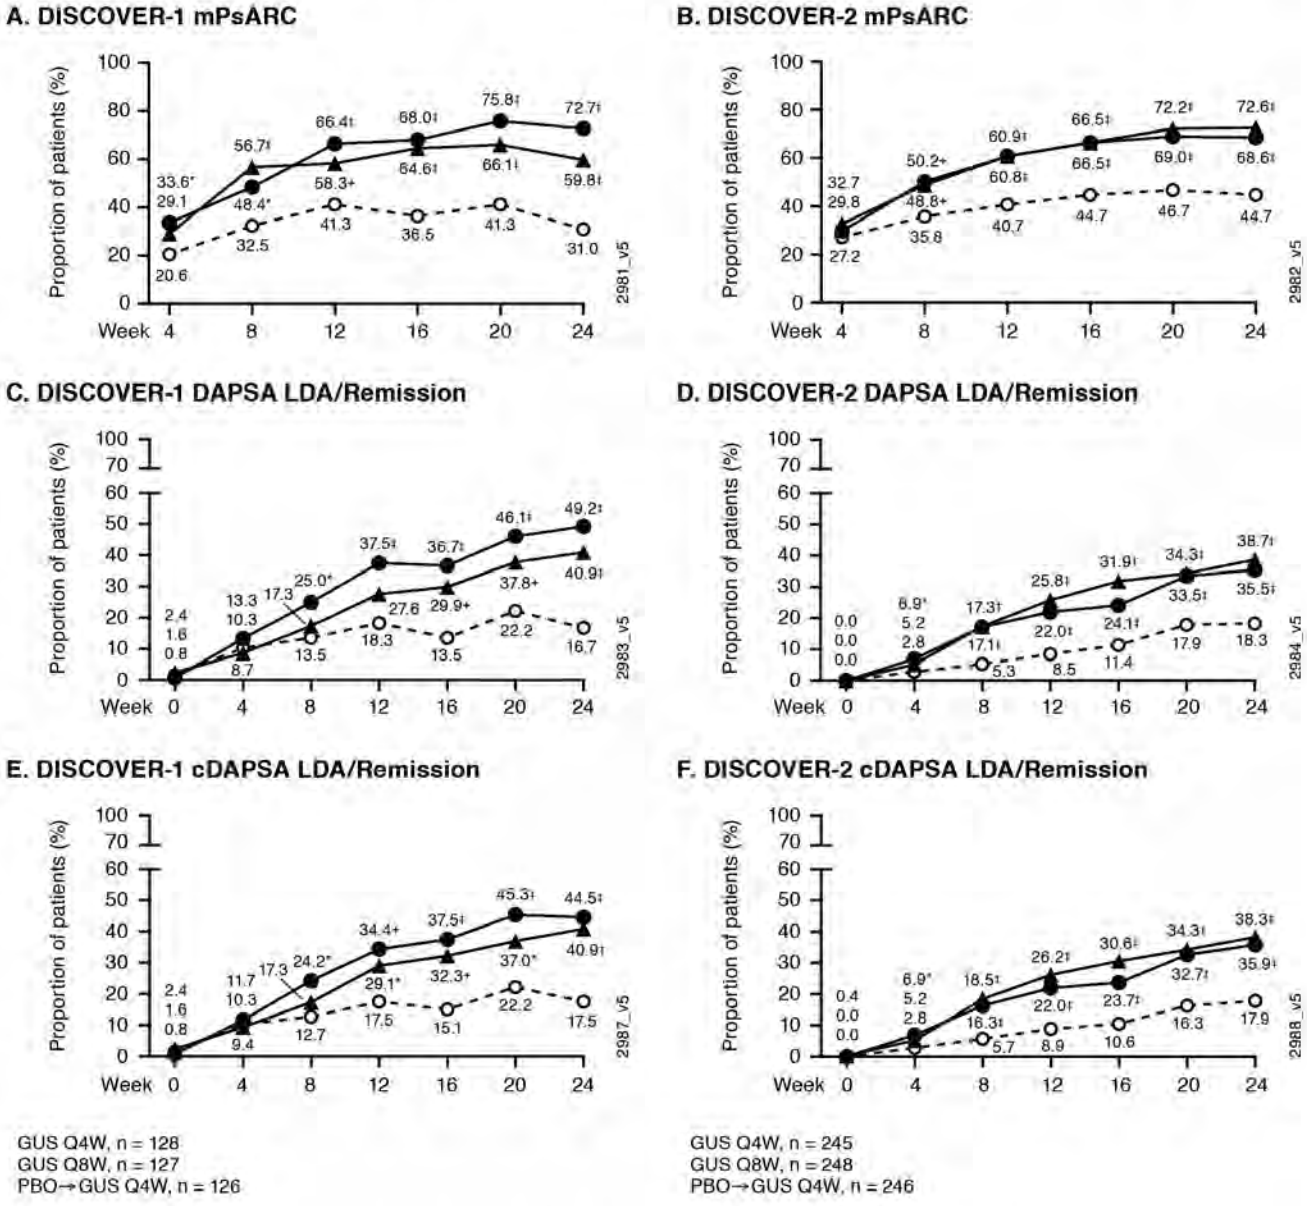
Table. Summary of baseline characteristics for DISCOVER-1 and DISCOVER-2 randomized and treated patients. Data are mean values unless stated otherwise.

	DISCOVER-1			DISCOVER-2		
	GUS Q4W	GUS Q8W	PBO	GUS Q4W	GUS Q8W	PBO
Randomized and treated patients	128	127	126	245	248	246
PsA duration (years)	6.6	6.4	7.2	5.5	5.1	5.8
Number of swollen joints (0-66)	8.6	10.9	10.1	12.9	11.7	12.3
Number of. tender joints (0-68)	17.7	20.2	19.8	22.4	19.8	21.6
Number of tender entheses (1-6)[a]	3.0	2.7	2.8	3.0	2.6	2.8
Patient pain score (0-10 VAS)	5.9	6.0	5.8	6.2	6.3	6.3
Patient global disease activity score (arthritis, 0-10 VAS)	6.1	6.5	6.1	6.4	6.5	6.5
Physician global disease activity score (0-10 VAS)	6.2	6.2	6.3	6.6	6.6	6.6
Median CRP (mg/dL)	0.6	0.7	0.8	1.2	1.3	1.2
Psoriasis Area and Severity Index (0-72)	9.5	8.4	7.7	10.8	9.7	9.3
Health Assessment Questionnaire Disability Index (0-3)	1.1	1.2	1.2	1.2	1.3	1.3
DAPSA score (remission ≤4; high disease activity >18]	39.4	45.2	43.3	49.7	46.3	48.8
PASDAS (low/very low ≤3.2; high >5.4)	6.1	6.3	6.2	6.6	6.6	6.6

[a] Among pts with Leeds enthesitis index (LEI) score >0 at baseline (DISCOVER-1 Q4W n=73; Q8W n=72; PBO n=77; DISCOVER-2 Q4W n=166; Q8W n=157; PBO n=175)

b Among pts with PASDAS score at baseline (DISCOVER-1 Q4W n=128; Q8W n=126; PBO n=126; DISCOVER-2 Q4W n=241; Q8W n=246; PBO n=241)

Figure 1. Proportions of DISCOVER-1 and DISCOVER-2 Patients Achieving mPsARC[a] Response (A, B), DAPSA LDA/Remission[b] (C, D), and cDAPSA LDA/Remission[b] (E, F) Through Week24.



Missing data imputed as nonresponse.

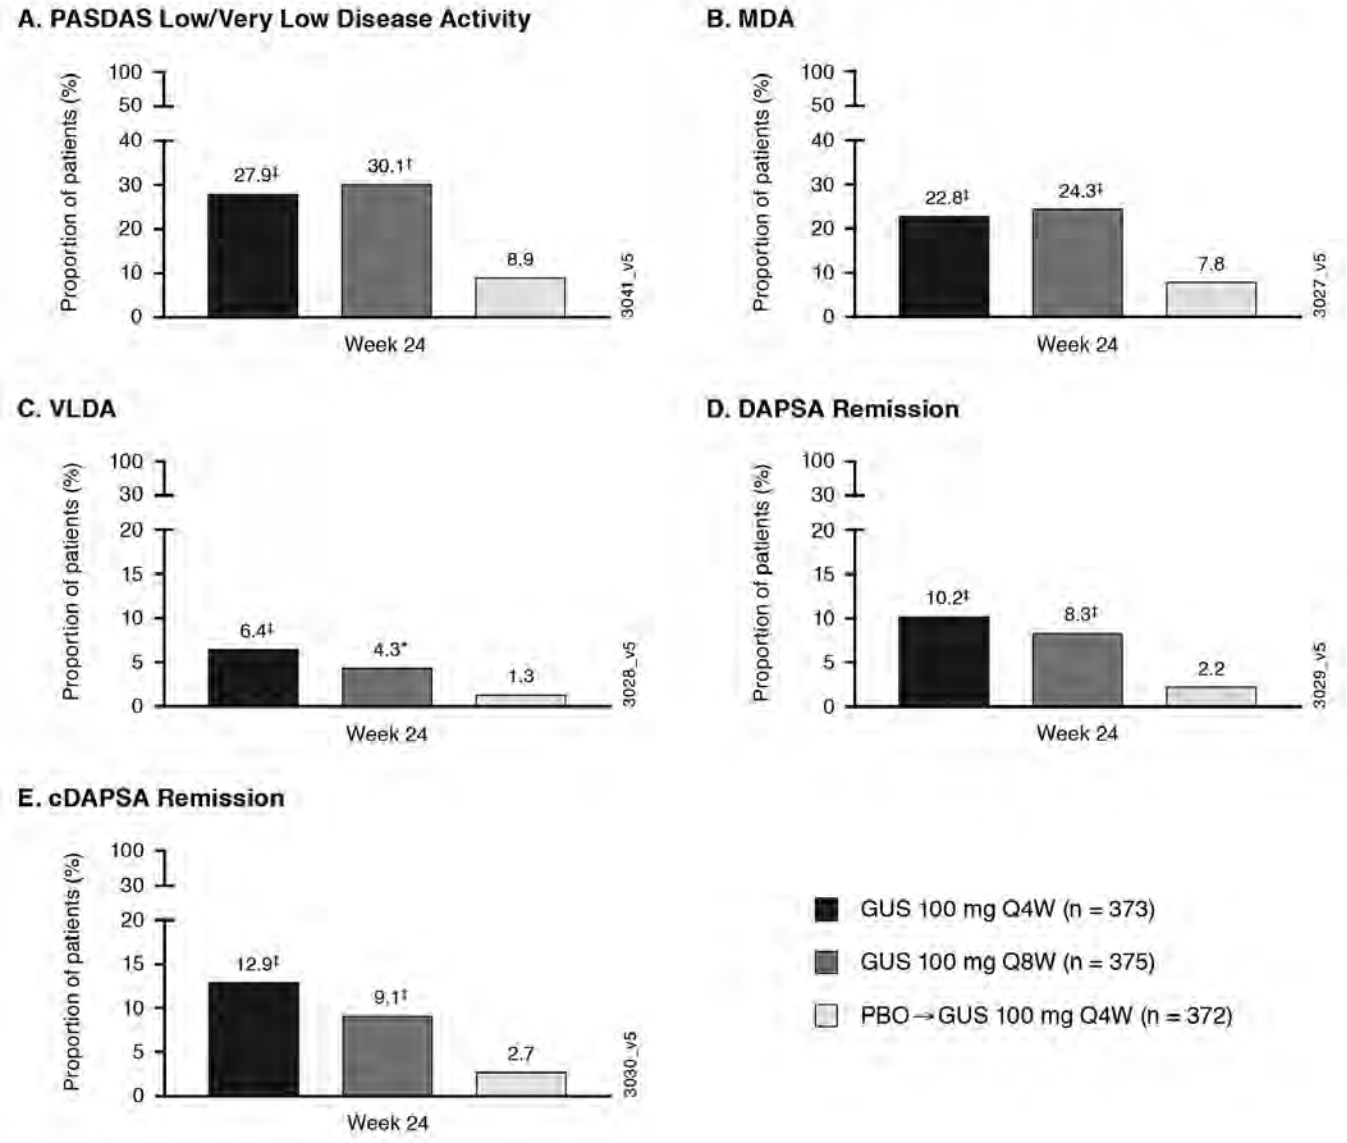
*, +, ‡ $p < 0.05$, 0.01, 0.001, respectively, vs placebo. Unadjusted (nominal) p values are not controlled for multiplicity and are descriptive/supportive only; no statistical significance should be implied.

a mPsARC response defined as ≥2 of 4 criteria (≥30% decrease in swollen joint count, ≥30% decrease in tender joint count, ≥20% improvement in patient's Global Assessment of Disease Activity (arthritis) on a visual analog scale [VAS]. 20% improvement in physician's Global Assessment of Disease Activity on a VAS), and ≥1 joint criteria with no deterioration in the other criteria.

b The DAPSA score sums tender joint count (0–68), swollen joint count (0–66), CRP (mg/dL), patient assessment of pain (0–10 VAS), and patient global assessment of disease activity (arthritis, 0–10 VAS). DAPSA LDA/Remission: ≤14. The cDAPSA score excludes CRP. cDAPSA LDA/Remission: ≤13.

Results: In randomized and treated pts in DISCOVER-1 (N=381) and DISCOVER-2 (N=739), baseline characteristics were generally well-balanced across groups and reflected moderate-to-severe disease activity (**Table**). Across studies, differences between GUS Q4W or Q8W and PBO were observed as early as Week 8 and continued to increase over time when response was assessed using the joint-focused mPsARC or DAPSA Low Disease Activity (LDA)/

Figure 2. Proportions of Pooled DISCOVER-1 and DISCOVER-2 Patients Achieving PASDAS Low/Very Low Disease Activity[a] (A), MDA[b] (B), VLDA[c] (C), DAPSA Remission[d] (D), and cDAPSA Remission[d] (E) at Week24.



Missing data imputed as nonresponse.

*, +, ‡ $p < 0.05$, 0.01, 0.001, respectively, vs placebo. Unadjusted (nominal) p values are not controlled for multiplicity and are descriptive/supportive only; no statistical significance should be implied.

a PASDAS calculated from the patient global assessment of arthritis and psoriasis (0-10 VAS), physician global assessment (0-10 VAS), swollen joint count (0-66), tender joint count (0-68), CRP, enthesitis score (measured by the Leeds Enthesitis Index), tender dactylitis count, and the 36-item Short-Form Health Survey Physical Component Summary Score. PASDAS Very low (≤1.9)/low (>1.9 to ≤3.2).

b MDA achieved if ≥5 of 7 criteria met (tender joint count ≤1, swollen joint count ≤1, psoriasis activity and severity index ≤1, patient's assessment of pain ≤15, patient's global assessment of disease activity ≤20, HAQ-DI score ≤0.5, tender entheseal points ≤1).

c VLDA achieved if 7/7 of the MDA criteria met

d The DAPSA score sums tender joint count (0–68), swollen joint count (0–66), CRP (mg/dL), patient assessment of pain (0–10 VAS), and patient global assessment of disease activity (arthritis, 0–10 VAS); DAPSA Remission: ≤4. The cDAPSA score sums tender joint count (0–68), swollen joint count (0–66), patient assessment of pain (0–10 VAS), and patient global assessment of disease activity (arthritis, 0–10 VAS); cDAPSA Remission: ≤4.

Remission composite endpoints. Also in both studies, response rates determined by omitting CRP in calculating cDAPSA were similar to DAPSA results (**Fig1**). Higher proportions of GUS Q4W- and Q8W-treated than PBO-treated pts also achieved PASDAS (28% and 30% vs 9%), MDA (23% and 24% vs 8%, respectively), VLDA (6% and 4% vs 1%), and remission determined using either DAPSA (10% and 8% vs 2%) or cDAPSA (13% and 9% vs 3%; **Fig2**).

Conclusion: Regardless of composite index employed or study population assessed, GUS 100 mg Q4W and Q8W provided robust benefits to patients with active PsA across multiple domains, indicating that GUS may offer a novel mechanism by which to treat the diverse manifestations of PsA. Excluding CRP from the DAPSA did not alter the instrument's ability to discern treatment effect.

Safety Profile of Upadacitinib in Psoriatic Arthritis: Integrated Analysis from Two Phase 3 Trials

Gerd Burmester[1], Kevin Winthrop[2], Peter Nash[3], Philippe Goupille[4], Valderilio F Azevedo[5], Carlo Salvarani[6], Reva M McCaskill[7], John Liu[7], Bosny J Pierre-Louis[7], Jaclyn K Anderson[7] and Eric Ruderman[8], [1]Charité University Hospital Berlin, Berlin, Germany, [2]Oregon Health & Science University, Portland, OR, [3]School of Medicine Griffith University, Brisbane, Queensland, Australia, [4]University Hospital and CIC1415, Tours, France, [5]Federal University of Paraná, Curitiba, Brazil, [6]Rheumatology Unit, Azienda USL-IRCCS di Reggio Emilia and Università di Modena e Reggio Emilia, Reggio Emilia, Italy, [7]AbbVie Inc., North Chicago, IL, [8]Feinberg School of Medicine, Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) has shown efficacy and safety in patients (pts) with active PsA in the Phase 3 SELECT-PsA 1 and SELECT-PsA 2 clinical trials. [1,2] Here we present the integrated safety data from the placebo (PBO)-controlled 24-week period of the clinical program.

Methods: The SELECT-PsA program enrolled pts with prior inadequate response (IR) or intolerance to ≥1 non-biologic DMARD (non-bDMARD) and prior IR or intolerance to ≥1 bDMARD. Both trials evaluated PBO, UPA 15 mg once

Table. Overview of Number and Percentage of Patients with TEAEs Through Week 24

Event, n (%)	PBO N=635	UPA 15 mg QD N=640	UPA 30 mg QD N=641	ADA 40 mg EOW N=429
AEs	391 (61.6)	422 (65.9)	476 (74.3)	278 (64.8)
Serious AEs	17 (2.7)	26 (4.1)	44 (6.9)	16 (3.7)
AEs leading to discontinuation	24 (3.8)	28 (4.4)	41 (6.4)	22 (5.1)
Deaths	2 (0.3)	0	0	0
AESIs				
Infection	213 (33.5)	240 (37.5)	291 (45.4)	146 (34.0)
Serious infection	5 (0.8)	6 (0.9)	17 (2.7)	3 (0.7)
Opportunistic infection	0	1 (0.2)	4 (0.6)	0
Herpes Zoster	5 (0.8)	7 (1.1)	13 (2.0)	0
Active tuberculosis	0	0	0	0
Non-melanoma skin cancer	1 (0.2)	1 (0.2)	3 (0.5)	0
Malignancy other than NMSC	0	3 (0.5)	3(0.5)	3 (0.7)
MACE (adjudicated)	1 (0.2)	1 (0.2)	0	2 (0.5)
VTE (adjudicated)	1 (0.2)	1 (0.2)	1 (0.2)	2 (0.5)
Gastrointestinal perforation (adjudicated)	0	0	0	0
Hepatic disorder	19 (3.0)	43 (6.7)	70 (10.9)	67 (15.6)
Anemia	6 (0.9)	7 (1.1)	34 (5.3)	1 (0.2)
Neutropenia	2 (0.8)	6 (0.9)	27 (4.2)	10 (2.3)
Lymphopenia	5 (0.8)	10 (3.5)	19 (6.8)	1 (0.5)
CPK elevation	10 (1.6)	42 (6.6)	53 (8.3)	24 (5.6)
Renal dysfunction	2 (0.3)	0	1 (0.2)	0

ADA, adalimumab; AE, adverse event; AESI, adverse event of special interest; CPK, creatine phosphokinase; EOW, every other week; MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PBO, placebo; QD, once daily; TEAEs, treatment-emergent adverse events; VTE, venous thromboembolism; UPA, upadacitinib.

daily (QD; UPA15) and UPA 30 mg QD (UPA30); SELECT-PsA 1 also included the active comparator adalimumab (ADA).[1,2] Data was integrated for pts randomized to PBO, UPA15, or UPA30. Pts were permitted to be on monotherapy or on up to 2 non-biologic DMARDs concomitantly. Treatment-emergent adverse events (TEAEs) from the trials were analyzed and summarized. The number and percentage of pts with TEAEs through Week 24 are presented.

Results: The number of pts who received ≥ 1 dose of study drug and AEs are presented in the **Table**. The rates of TEAEs, serious AEs, and AEs leading to study drug discontinuation (D/C) were similar with PBO and UPA15 and higher with UPA30. Rates of serious infection (SIs) and herpes zoster (HZ) were similar with PBO and UPA15 and higher with UPA30. The most common SI was pneumonia. Most HZ events involved one dermatome; no central nervous system infection was reported. Opportunistic infections included 1 event of candida urethritis with UPA15, and 1 event each of pneumocystis jirovecii pneumonia, cytomegalovirus, candidiasis of the trachea, and oropharyngeal candidiasis with UPA30. Malignancies other than NMSC were reported at similar rates with UPA15 and UPA30; no events were reported with PBO. The rate of NMSC was similar with PBO, UPA15, and UPA30. The number of adjudicated major adverse cardiovascular events (MACE) and venous thromboembolic events (VTE) was < 0.5% for all arms, with similar rates reported with PBO, UPA15, and UPA30; all pts had at least one risk factor. VTEs included 1 deep vein thrombosis in PBO and 1 pulmonary embolism each in the two UPA arms. There were no adjudicated gastrointestinal perforations. Hepatic disorders were mostly transient transaminase increases. CPK elevations were reported more frequently in the UPA arms vs PBO and were mostly asymptomatic, and rarely led to study drug D/C; no rhabdomyolysis was reported. AEs of anemia, neutropenia, and lymphopenia were generally mild or moderate, non-serious, and uncommonly led to study drug D/C. The safety profile was generally consistent between UPA15 and ADA, except for lower rates of HZ, anemia, and lymphopenia and higher rates of hepatic disorders and neutropenia in the ADA arm. In contrast, the rates of most AEs were higher with UPA30 compared to ADA except for hepatic disorders.

Conclusion: The safety profiles of UPA15 and ADA were generally consistent; the rates of most AEs were higher with UPA30 compared to ADA. Through Week 24, the safety profile of UPA15 and UPA30 in PsA pts demonstrated consistent results compared to what has been observed with UPA in RA pts.[3]

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

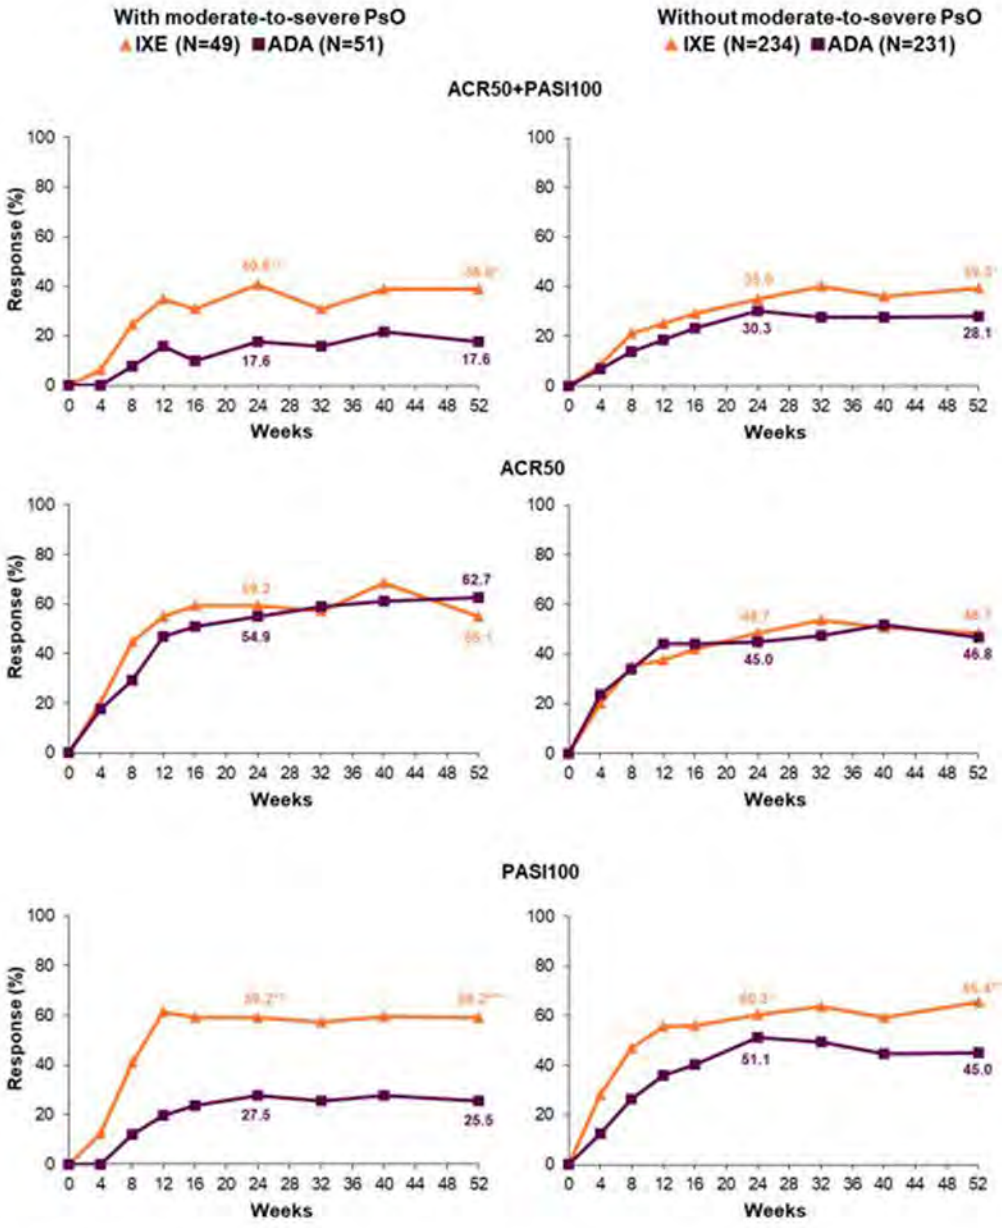
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE), a selective interleukin-17A antagonist, is approved for the treatment of active PsA, moderate-to-severe psoriasis (PsO), and radiographic/non-radiographic axial SpA in adults. The efficacy of IXE was compared to adalimumab (ADA) in patients (pts) with PsA and concomitant PsO in the SPIRIT-H2H (NCT03151551) study. Here we report results at weeks (wks) 24 and 52 from a subgroup analysis based on baseline PsO severity.

Methods: SPIRIT-H2H was a 52-wk, multicenter, randomized, open-label, rater-blinded, parallel-group study of biologic DMARD-naïve pts (N=566) with PsA and active PsO (≥3% body surface area involvement). Pts were randomized (stratified by concomitant use of conventional synthetic DMARDs and PsO severity) to IXE or ADA. Pts received on label dosing according to the severity of PsO. We report efficacy outcomes at wks 24 and 52 for the subgroup analysis of patients with/without moderate-to-severe PsO at baseline. The primary endpoint was the proportion of pts simultaneously achieving ≥50% improvement in ACR criteria (ACR50) and 100% improvement in PASI (PASI100) at

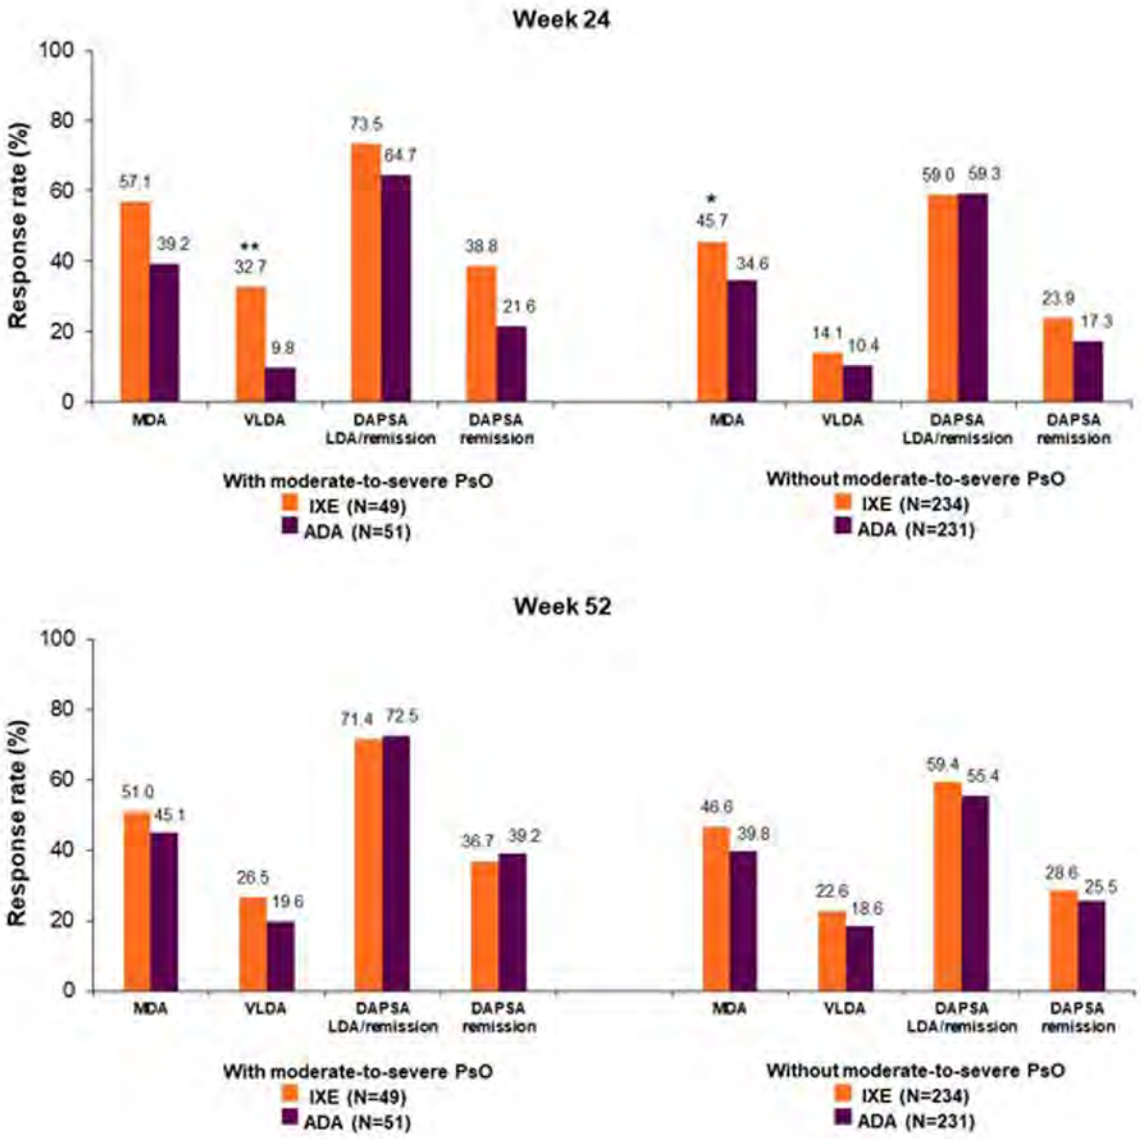
Figure 1. Key efficacy outcomes in pts with PsA based on PsO severity at baseline.



*p≤0.05, **p≤0.01, ***p≤0.001 vs. ADA. P-values from Fisher's exact test. †Interaction p≤0.10.
Patients with moderate-to-severe PsO (PASI ≥12, sPGA ≥3, BSA involvement ≥10%) received either IXE (160 mg at week 0, then 80 mg Q2W to week 12 and Q4W thereafter) or ADA (80 mg at week 0 then 40 mg Q2W). Patients without moderate-to-severe PsO received either IXE (160 mg at week 0, then 80 mg Q4W) or ADA (40 mg Q2W).
ACR50, ≥50% improvement in American College of Rheumatology criteria; ADA, adalimumab; BSA, body surface area; IXE, ixekizumab; PASI, Psoriasis Area and Severity Index; PASI100, 100% improvement in PASI; PsA, psoriatic arthritis; PsO, psoriasis; pts, patients; Q2W, every 2 weeks; Q4W, every 4 weeks; sPGA, static Physician's Global Assessment.

wk 24. Additional *post-hoc* analysis was performed for other endpoints. Logistic regression models were performed with treatment, baseline PsO severity and treatment-by-baseline PsO severity interaction as independent variables. Missing data were imputed using non-responder imputation. Differences in the proportion of responders between IXE and ADA in each subgroup were assessed using Fisher's exact test.

Figure 2. Composite outcomes and disease activity in pts with PsA based on PsO severity at baseline.



*p≤0.05, **p≤0.01 vs. ADA. P-values from Fisher's exact test. Data represent proportion of patients (%). Efficacy outcomes assessed in a *post-hoc* analysis. Interaction p-values at week 24 and 52, respectively: MDA, p=0.560 and p=0.931; VLDA, p=0.068 and p=0.784; DAPSA LDA/remission, p=0.371 and p=0.651; DAPSA remission, p=0.398 and p=0.571. Interaction p-values evaluated at the 0.10 significance level. Patients with moderate-to-severe PsO received either IXE (160 mg at week 0, then 80 mg Q2W to week 12 and Q4W thereafter) or ADA (80 mg at week 0 then 40 mg Q2W). Patients without moderate-to-severe PsO (PASI ≥12, sPGA ≥3, BSA involvement ≥10%) received either IXE (160 mg at week 0, then 80 mg Q4W) or ADA (40 mg Q2W).
ADA, adalimumab; BSA, body surface area; DAPSA, Disease Activity in PSoriatic Arthritis; IXE, ixekizumab; LDA, low disease activity; MDA, minimal disease activity (18 entheseal points); PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PsO, psoriasis; pts, patients; Q2W, every 2 weeks; Q4W, every 4 weeks; sPGA, static Physician's Global Assessment; VLDA, very low disease activity (18 entheseal points).

Results: At baseline, 49/283 IXE-treated pts and 51/282 ADA-treated pts had moderate-to-severe PsO. A greater proportion of IXE-treated pts achieved the combined endpoint of ACR50+PASI100, and PASI100 compared to ADA at wks 24 and 52, regardless of baseline PsO severity (Figure 1). Similar efficacy was observed on the joints for IXE and ADA across both pt subgroups (Table). Faster improvement was observed for IXE than for ADA with respect to

Table. Other efficacy outcomes by subgroup based on PsO severity at baseline.

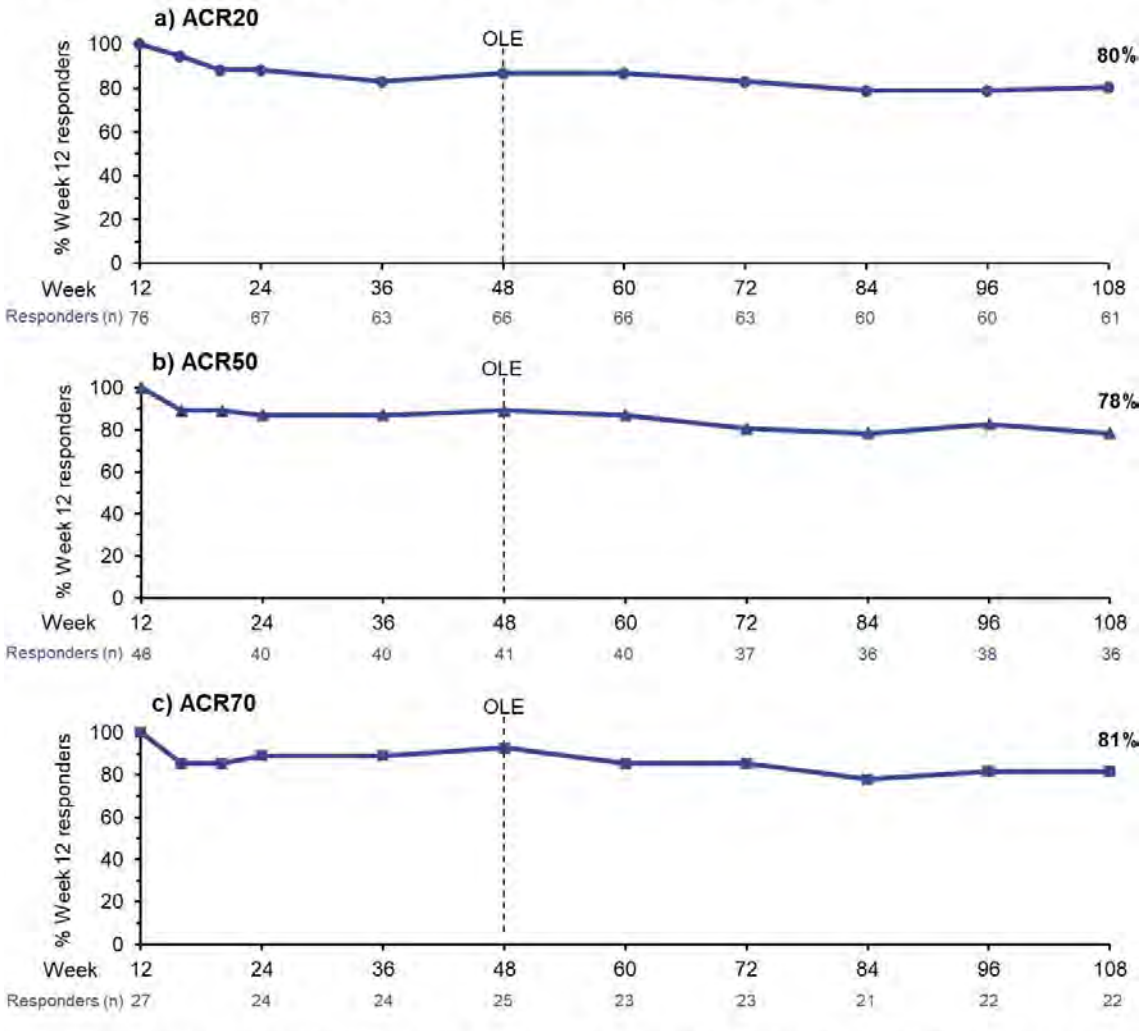
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ), a humanized monoclonal IgG1 antibody that selectively neutralizes interleukin (IL)-17A and IL-17F, has shown clinical improvements in joint and skin outcomes over 48 weeks (wks) in patients (pts) with active psoriatic arthritis.[1] The primary outcome of ACR50 response at Wk 12 of the dose-ranging BE ACTIVE study was achieved by 24–46% of pts across dosing arms.[1] Due to the chronic nature of PsA, maintaining a long-term treatment response at high levels of disease control is particularly important. We assess maintenance of response over approximately 2 years of BKZ treatment in pts who demonstrated a response to BKZ at Wk 12.

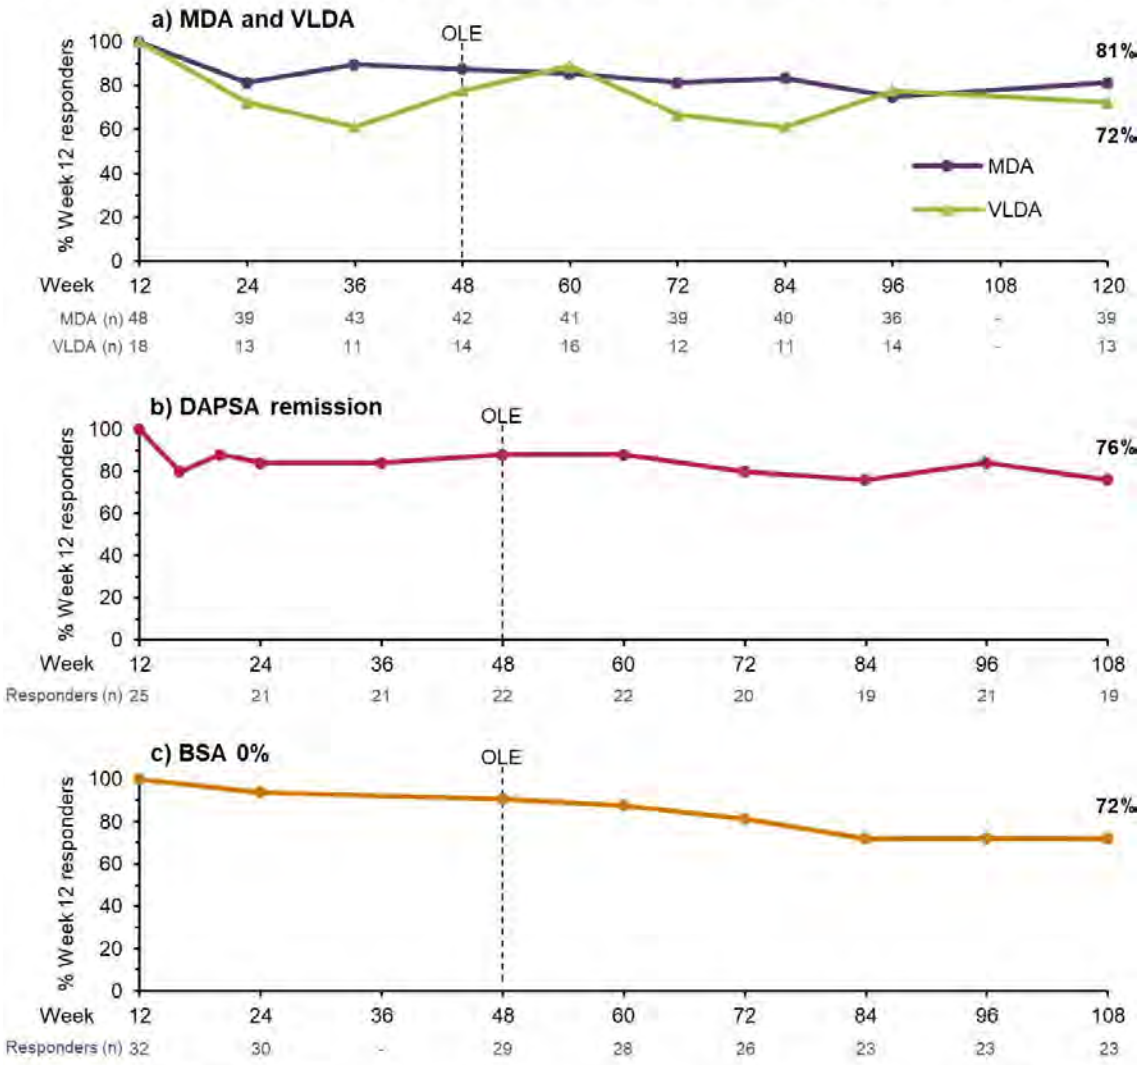
Methods: Pts who completed 48 wks of the BE ACTIVE study (NCT02969525; design described elsewhere)[1] without meeting withdrawal criteria, were eligible for BE ACTIVE 2 OLE entry (NCT03347110). BKZ was given at 160 mg every 4 wks (Q4W) regardless of previous dose. Analyses include pts randomized to the three highest BKZ doses at BE ACTIVE study baseline (BL): 160 mg, 160 mg with 320 mg loading dose (LD), and 320 mg. Maintenance of response

Figure 1: Maintenance of ACR20/50/70 response in Week 12 responders



123 patients were randomized to either BKZ 160 mg, BKZ 160 mg with a 320 mg loading dose, or BKZ 320 mg at baseline in the BE ACTIVE study. Non-responder imputation. BKZ: bimekizumab; OLE: open-label extension.

Figure 2: Maintenance of response to other outcomes in Week 12 responders, NRI



123 patients were randomized to either BKZ 160 mg, BKZ 160 mg with a 320 mg loading dose, or BKZ 320 mg at baseline in the BE ACTIVE study. 80 of 123 patients had BSA ≥3% at baseline. NRI was used for MDA, VLDA and BSA 0%. DAPSA remission is defined as DAPSA total score ≤4. For DAPSA remission data, if all components were missing, LOCF was used for DAPSA total score. BKZ: bimekizumab; BSA: body surface area; DAPSA: Disease Activity in PSoriatic Arthritis; LOCF: last observation carried forward; MDA: minimal disease activity; NRI: non-responder imputation; OLE: open-label extension; VLDA: very low disease activity.

is reported as the percentage (%) of BKZ-treated pts achieving a response at Wk 12, with maintained response over time. Outcomes include ACR20/50/70, minimal disease activity (MDA) and very low disease activity (VLDA), Disease Activity in PSoriatic Arthritis (DAPSA) remission, and body surface area (BSA) 0% (for those pts with BSA ≥3% at BL). Non-responder imputation (NRI) was used for missing data. Results are presented from Wk 12 (end of double-blind treatment) to Wk 108, or Wk 120 for outcomes not recorded at Wk 108. Rates of treatment-emergent adverse events (TEAEs) are reported for the Safety Set (pts who received ≥1 dose BKZ).

Results: At BL in the BE ACTIVE study, 123 pts were randomized to the three highest BKZ doses (160–320 mg). 109 pts entered the OLE, all receiving BKZ 160 mg Q4W. ACR20/50/70 were achieved by 76 (62%), 46 (37%), and 27 (22%) pts, respectively, at Wk 12 of the double-blind phase. MDA and VLDA criteria were met by 48 (39%) and 18 (15%) pts, respectively; likewise, the number of pts who achieved DAPSA remission and BSA 0% at Wk 12 were 25 (20%) and 32 (40% of the 80 pts with BSA ≥3% at BL), respectively. The majority of pts who achieved responses at Wk 12, across the different outcomes, maintained them to Wk 108 or Wk 120 (**Figures 1 and 2**). The % of pts

achieving ACR20/50/70 at Wk 12 who maintained the response to Wk 108 was 80/78/81%, respectively. MDA and VLDA responses were maintained at Wk 120 by 81% and 72% of Wk 12 responders, respectively; likewise, for DAPSA remission at Wk 108, the response from Wk 12 was maintained by 76%; for BSA 0%: 72%. TEAEs occurred in 87.7% of pts (exposure-adjusted event rate: 181.1/100 patient-years [PY]) and serious TEAEs in 9.3% (4.1/100 PY).

Conclusion: This BKZ-treated population, who achieved high levels of disease control as early as 12 weeks (including ACR50, MDA, VLDA, BSA 0% and DAPSA remission), demonstrated a consistent maintenance of response rate around 80% across both joint and skin outcomes. These results suggest that BKZ provides a robust maintenance of response over at least 2 years of treatment in pts with PsA.

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pre-existing structural damage in patients with psoriatic arthritis (PsA) has been suggested to impact therapeutic improvements in disease activity and functional outcomes.[1,2] Here we evaluate whether pre-existing structural damage in patients with active PsA limits functional improvements from treatment with certolizumab

Table: Baseline mean HAQ-DI score and number of patients with HAQ-DI ≤0.5 by mTSS quartile and DAPSA disease state

mTSS Quartiles	Q1 <1.38	Q2 1.38 to <5.25	Q3 5.25 to <19.54	Q4 ≥19.54	Total
DAPSA disease state	Mean (SD) no. pts HAQ-DI ≤0.5 / Nobs [%]				
HDA	1.29 (0.60) 5/39 [12.8]	1.44 (0.61) 5/55 [9.1]	1.49 (0.65) 4/54 [7.4]	1.51 (0.55) 2/53 [3.8]	1.44 (0.61) 16/201 [8.0]
L/MoDA[a]	0.90 (0.51) 8/23 [34.8]	0.77 (0.52) 8/17 [47.1]	0.91 (0.58) 6/20 [30.0]	1.26 (0.47) 1/12 [8.3]	0.93 (0.54) 23/72 [31.9]
Total	1.15 (0.60) 13/62 [21.0]	1.28 (0.65) 13/72 [18.1]	1.33 (0.68) 10/74 [13.5]	1.47 (0.54) 3/65 [4.6]	1.31 (0.63) 39/273 [14.3]

No reported patients in DAPSA remission at baseline; data were pooled for all patients randomized to CZP 200 mg and 400 mg at baseline. [a] Includes total of 4 patients in LDA. CZP: certolizumab pegol; DAPSA: Disease Activity Index for Psoriatic Arthritis; HAQ-DI: Health Assessment Questionnaire Disability Index; HDA: high disease activity; LDA: low disease activity; L/MoDA: low/moderate disease activity; mTSS: van der Heijde modified total Sharp score; no.: number; Nobs: number observed; pts: patients; SD: standard deviation.

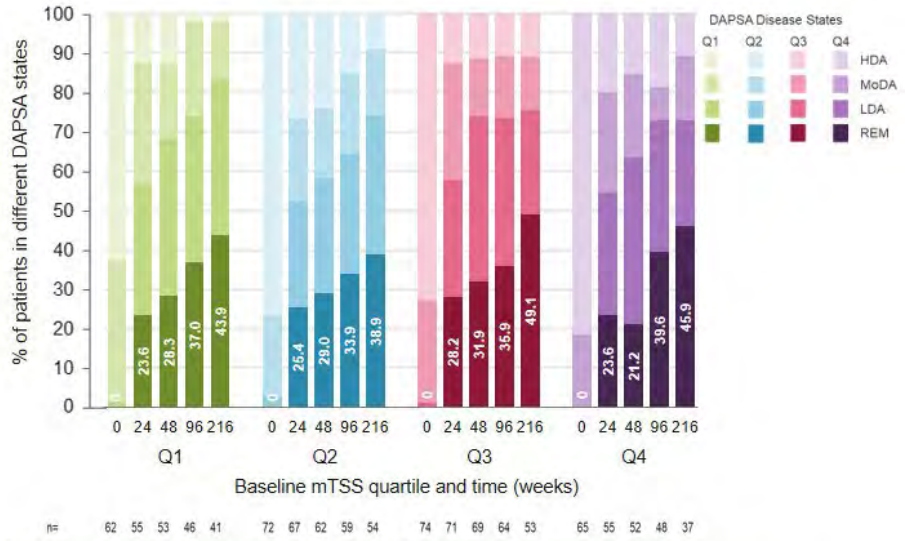
pegol (CZP) over 4 years. CZP is an Fc-free, PEGylated, tumor necrosis factor inhibitor that has shown long-term efficacy and safety in patients with PsA.[3]

Methods: Patients enrolled in RAPID-PsA (NCT01087788) with active PsA (≥3 tender joints; ≥3 swollen joints; ESR ≥28 mm/hour and/or CRP >upper limit of normal) who had failed treatment with ≥1 DMARD were randomized 1:1:1 to CZP 200 mg every 2 weeks (wks; Q2W), CZP 400 mg every 4 wks (Q4W) or placebo. Both CZP treatment arms received a loading dose of CZP 400 mg at Wks 0, 2, and 4, followed by the randomized dose regimen to Wk 216.[3] Current analyses are based on data pooled across active treatment arms. Radiographs taken at baseline and Wks 12, 24, 48, 96, 168 and 216/withdrawal were read using the van der Heijde modified Total Sharp Score (mTSS) for PsA (scores based on average of two readers). Patients were grouped according to baseline mTSS quartiles (Q1–Q4). Disease activity was assessed using Disease Activity Index for Psoriatic Arthritis (DAPSA; high disease activity [HDA]: >28; moderate [MoDA]: >14–≤28; low [LDA]: >4–≤14; remission: ≤4). Physical function was assessed using the Health Assessment Questionnaire Disability Index (HAQ-DI; ≤0.5 defined as no adverse impact on physical function).[4] The association of HAQ-DI, both change from baseline and achievement of ≤0.5, and concurrent DAPSA status was compared between the baseline mTSS groups using descriptive statistics.

Results: Of 409 patients randomized, 407 were assessed for mTSS. As expected, at baseline, HAQ-DI scores were numerically higher in patients in mTSS Q3 and Q4 than Q1 (**Table**). With CZP treatment, across all mTSS quartiles, the proportion of patients in DAPSA remission increased over time (**Figure 1**). Across all mTSS quartiles (Q1–Q4), at least 80% of patients who achieved DAPSA remission also achieved HAQ-DI ≤0.5 (no adverse impact on physical function) at Wk 24 of CZP treatment. Over 80% of patients in mTSS Q1 who achieved either DAPSA remission or LDA also achieved HAQ-DI ≤0.5 at Wk 24. However, for mTSS Q2–Q4, >90% of patients in DAPSA remission achieved HAQ-DI ≤0.5 as compared with only ~30–50% of patients with DAPSA LDA (**Figure 2**).

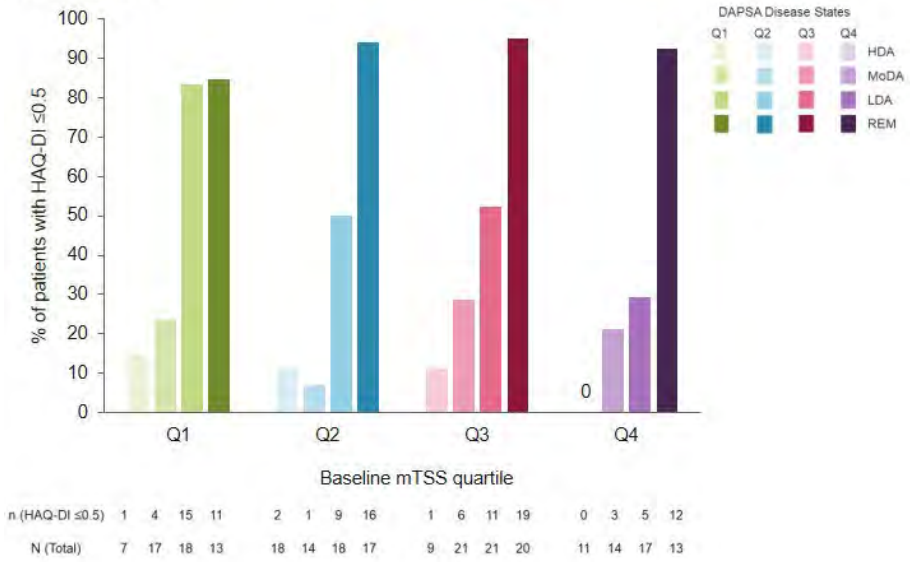
Conclusion: These data indicate that patients achieving a high level of disease control (DAPSA remission) over 4 years of treatment with CZP are likely to achieve a normative state in terms of physical function, regardless of pre-existing radiographic damage. However, a state of DAPSA LDA may not result in normalization of function in patients with pre-existing radiographic damage. This supports the rationale of aiming for remission in PsA.

Figure 1: Proportion of patients by DAPSA disease state over time and by baseline mTSS



Data were pooled for all patients randomized to CZP 200 mg and 400 mg at baseline; observed cases.
CZP: certolizumab pegol; DAPSA: Disease Activity Index for Psoriatic Arthritis; HDA: high disease activity; LDA: low disease activity; MoDA: moderate disease activity; mTSS: van der Heijde modified total Sharp score; REM: remission.

Figure 2: Achievement of HAQ-DI ≤0.5 at Week 24 by DAPSA disease state and by baseline mTSS



Data were pooled for all patients randomized to CZP 200 mg and 400 mg at baseline; observed cases.
CZP: certolizumab pegol; DAPSA: Disease Activity Index for Psoriatic Arthritis; HAQ-DI: Health Assessment Questionnaire Disability Index; HDA: high disease activity; LDA: low disease activity; MoDA: moderate disease activity; mTSS: van der Heijde modified total Sharp score; REM: remission.

Abstract Number: 1354

The Effect of 8 Years of TNF-α Blocking Therapy on Bone Mineral Density in Patients with Ankylosing Spondylitis

Mark Siderius[1], Freke Wink[1], Anneke Spoorenberg[1] and Suzanne Arends[1], [1]University Medical Centre Groningen and Medical centre Leeuwarden, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that mainly affects the axial skeleton. Bone loss reflected by low bone mineral density (BMD) is a common feature of AS and can already be observed at early stages of the disease. A recent cohort study of 135 AS patients reported 7.2% improvement in lumbar spine BMD and 2.2% improvement in hip BMD after 4 years of tumor necrosis factor-alpha (TNF-α) blocking therapy.[1] The objective of this study was to assess the effect of 8 years of TNF-α blocking therapy on BMD of the lumbar spine and hip in AS patients.

Methods: Included in this study were consecutive AS outpatients from the Groningen-Leeuwarden Axial SpA (GLAS) cohort who received TNF-α blocking therapy for at least 8 years. A maximum of one switch to another TNF-α inhibitor was allowed. Patients were excluded when they used bisphosphonates at baseline or during follow-up. BMD of the lumbar spine (anterior-posterior projection L1-L4) (LS-BMD) and hip (total proximal femur) (hip-BMD) was measured at baseline, 1 year, 2 years and then bi-annually using dual-energy X-ray absorptiometry (Hologic QDR Discovery (UMCG) or Hologic QDR Delphi (MCL), Waltman, MA, USA). Z-scores, the number of SD from the normal mean corrected for age and gender, were calculated using the NHANES reference database. Low BMD was defined as lumbar spine and/or hip BMD Z-score ≤1. Generalized estimating equations were used to analyze BMD over time within subjects. Pairwise contrast were used to compare baseline and follow-up visits. P values < 0.05 were considered statistically significant.

Results: In total, 131 AS patients were included; 73% were male, 83% HLA-B27+, mean age was 41.3 ± 10.8 years, median symptom duration 14 years (IQR 7-24), median CRP levels 13 mg/L (IQR 6-22), and 28% had poor vitamin 25(OH)D3 status (< 50) at baseline. 27% of patients switched to a second TNF-α inhibitor during follow-up and disease activity improved significantly during treatment: mean ASDASCRP 3.8 ± 0.8 at baseline and 2.1 ± 0.9 after 8 years (P< 0.001).

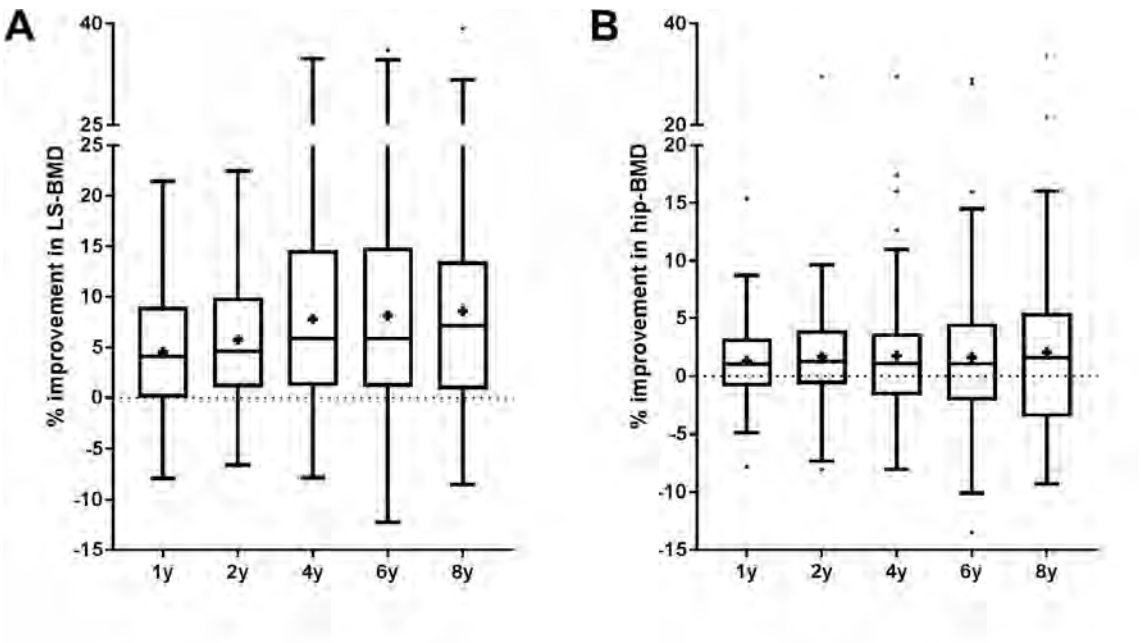

Figure 1. Percentage improvement during 8 years of TNF-α blocking therapy on LS-BMD (A) and hip-BMD (B) in patients with AS (n=131). Box-and-whisker plots (Tukey): boxes indicate medians with interquartile ranges, + indicates mean; whiskers indicate 1.5 times interquartile distances; • indicate outliers.

At baseline, low BMD at the lumbar spine and hip was present in 34% and 19% patients, respectively. Both LS-BMD and hip BMD Z-scores were significantly improved during TNF-α blocking therapy at all follow-up visits compared to baseline. Significant improvement compared to the previous time point was found up to and including 4 years for the lumbar spine and up to and including 2 years for the hip. Thereafter, flattening of improvement was observed. Median percentage of improvement in absolute BMD after 8 years of TNF-α blocking therapy compared to baseline was 7.1% (IQR 0.8-13.5) for the lumbar spine and 1.6% (IQR -3.5-5.5) for the hip (Figure 1).

Conclusion: In AS patients with established disease, both lumbar spine and hip BMD improved significantly at group level during 8 years of TNF-α blocking therapy. This effect was most pronounced in the lumbar spine, which corresponds to the disease process in AS. Main improvements in lumbar spine BMD were observed during the first 4 years of treatment.

offs based on the Disease Activity in PsA (DAPSA) score, and on the Psoriatic Arthritis Disease Activity Score (PASDAS) score.

We assessed the rates of patients (pts) achieving these criteria at Weeks 12 and 24 using data from the SELECT-PsA 1 and SELECT-PsA 2 Phase 3 studies.[1,2] Additionally, we assessed the distribution of individual MDA components among pts who did or did not achieve MDA criteria at Week 24.

Methods: This is a post-hoc analysis of 2 randomized controlled trials. In SELECT-PsA 1, pts with PsA and prior inadequate response (IR) or intolerance to ≥1 non-biologic DMARD (N=1705) were randomized to once daily upadacitinib (UPA) 15mg (UPA15), UPA 30mg (UPA30), adalimumab (ADA) 40mg every other week, or placebo (PBO). In SELECT-PsA 2, pts with prior IR or intolerance to ≥1 biologic DMARD (N=642) were randomized to UPA15, UPA30, or PBO. Remission and LDA were assessed using VLDA/MDA, DAPSA scores of ≤4/≤14, and PASDAS scores of ≤1.9/≤3.2, at Weeks 12 and 24 (**Table**).

For binary outcomes, non-responder imputation (NRI) was used for handling missing data. For MDA and related analyses, NRI was used for handling missing data; pts rescued at Week 16 were considered non-responders. Pairwise comparisons between UPA doses and PBO or ADA were conducted using the Cochran-Mantel-Haenszel test.

Results: Overall, 2345 pts were analyzed; mean age 51 years, 53% female. In both studies, higher rates of remission and LDA were observed with both UPA doses vs PBO at Weeks 12 and 24 (nominal P-values < 0.05 for both time points; **Table**). Generally, higher rates of remission and LDA were also observed with UPA30 vs ADA in non-biologic DMARD-IR pts (nominal P-values < 0.05). Greater rates of MDA/VLDA were observed at Weeks 12 and 24 with UPA15 and UPA30 vs PBO in both studies and with UPA30 vs ADA in non-biologic DMARD-IR pts (nominal P-values < 0.05 for all comparisons). The proportion of responder or non-responder pts receiving UPA15 or UPA30 was similar for each of the MDA components in both studies. At Week 24, more responder and non-responder pts in both studies achieved Swollen Joint Count (SJC) 66 ≤1, Psoriasis Area and Severity Index (PASI) ≤1 or Body Surface Area-Psoriasis (BSA-Ps) ≤3%, and Leeds Enthesitis Index (LEI) ≤1 (**Figure**). Conversely, the proportion of pts Achieving Tender Joint Count (TJC) 68 ≤1 and Pt's Global Assessment of Pain ≤1.5 tended to be lower.

Conclusion: Regardless of previous biologic DMARD failure, pts treated with UPA15 or UPA30 achieved a higher rate of remission or LDA measured by various disease activity measures vs PBO at Weeks 12 and 24; higher rates of response were observed in most of the remission and LDA measures with UPA30 vs ADA in non-biologic DMARD-IR pts. Among pts who did or did not achieve MDA criteria at Week 24, a greater proportion of UPA-treated pts achieved physician derived measures such as SJC ≤1, PASI ≤1 or BSA-Ps ≤3%, and LEI ≤1.

SESSION INFORMATION

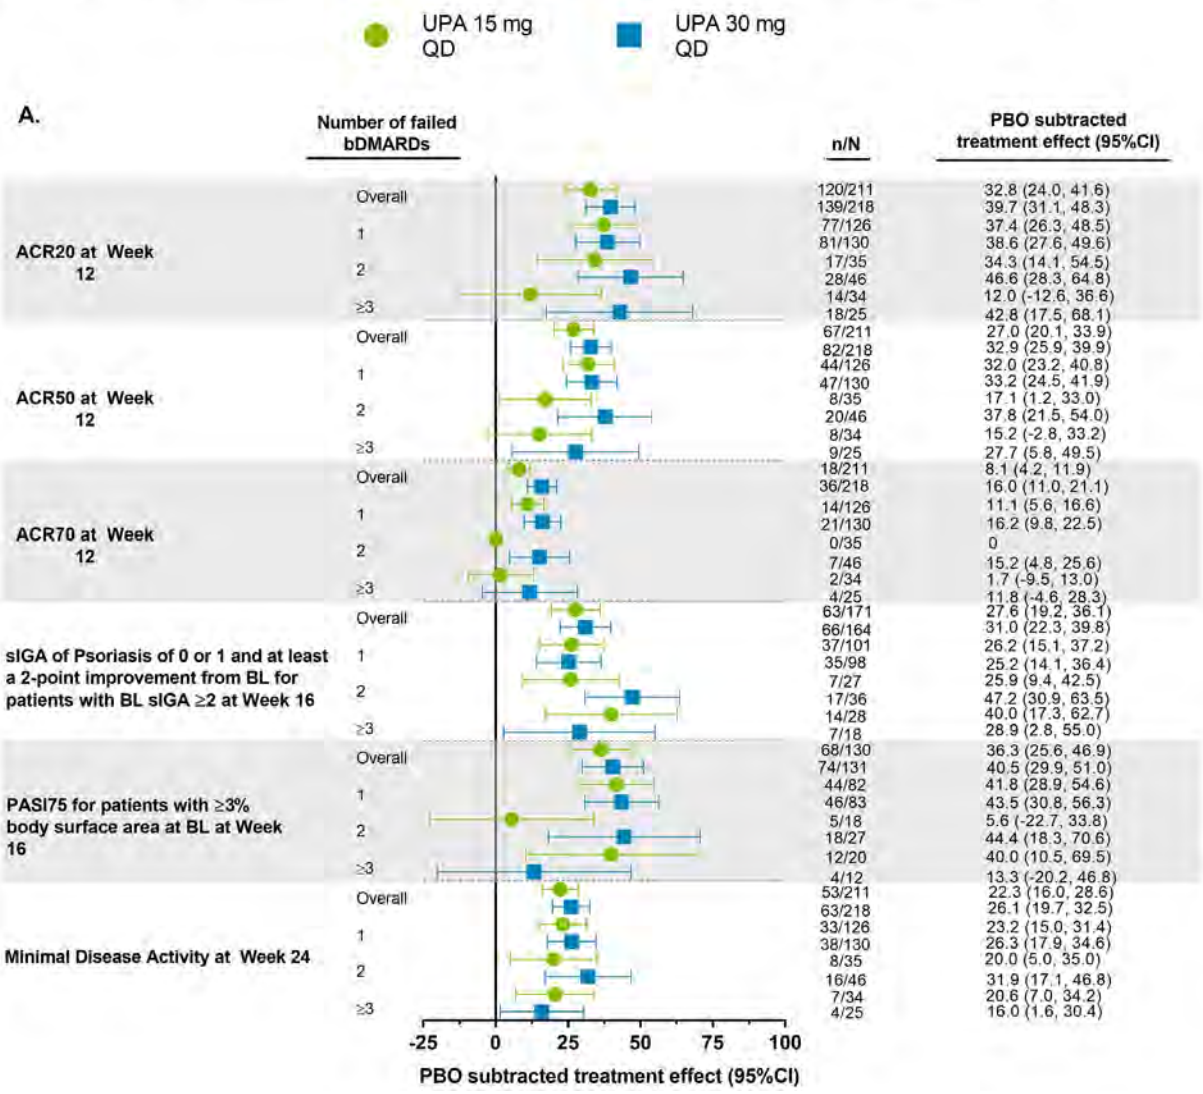
Session Date: Sunday, November 8, 2020

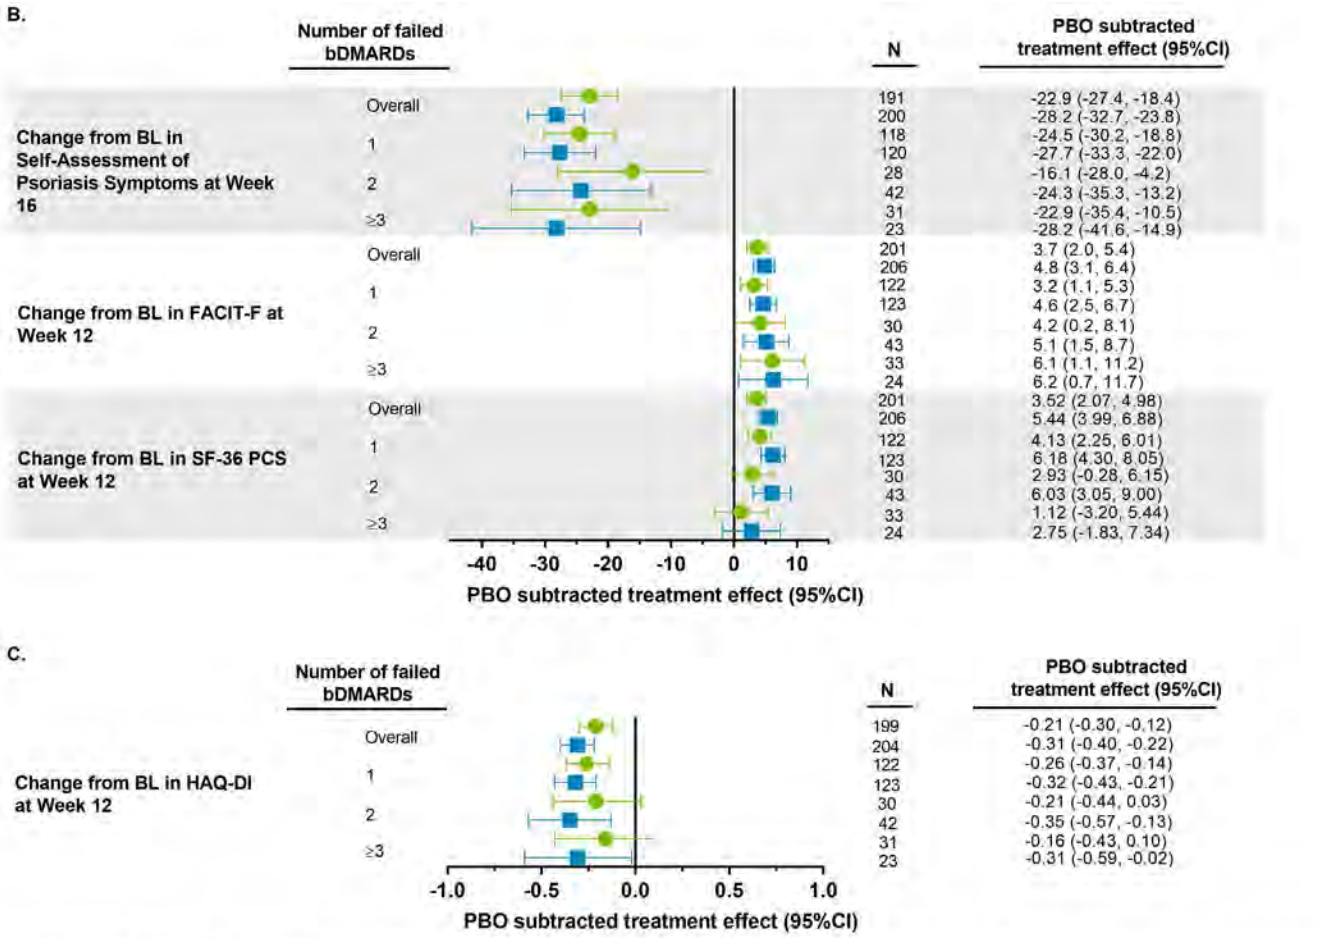
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Figure. Efficacy Outcomes by Prior bDMARD Exposure: Placebo Subtracted Treatment Effect





ACR20/50/70, American College of Rheumatology 20%/50%/70% improvement criteria;BL, baseline; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire - Disability Index; MDA, minimal disease activity; PASI, Psoriasis Area Severity Index; PBO, placebo; QD, once daily; SF-36 PCS, 36-Item Short Form Health Survey Physical Component Summary Score; sIGA, Static Investigator Global Assessment of Psoriasis.

Background/Purpose: Upadacitinib (UPA) has shown efficacy and safety in patients (pts) with active PsA in the Phase 3 SELECT-PsA 1 and SELECT-PsA 2 clinical trials.[1,2] Historically efficacy has been lower with second- and third-line therapy compared with first-line anti-TNF therapy in PsA;[3,4] however, clinical trial data that describe efficacy in pts who have had an inadequate response (IR) to multiple biologic DMARDs (bDMARDs) are limited. This analysis assessed the effects of prior bDMARD failure on UPA efficacy in the SELECT-PsA 2 trial.

Methods: The SELECT-PsA 2 study enrolled pts with prior IR or intolerance to ≥1 bDMARD (N=642). Pts were randomized to placebo (PBO), UPA 15 mg once daily (QD, UPA15), or UPA 30 mg QD (UPA30). Stable background treatment of ≤2 non-bDMARDs was permitted; background therapy was not required. Only the pts who had IR to ≥1 bDMARD were included in this analysis; pts were subgrouped based on the number of bDMARDs failed prior to enrollment (1, 2, or ≥3). This analysis includes assessment of proportion of pts achieving ACR20/50/70, and change in HAQ-DI, FACIT-Fatigue, and SF-36 Physical Component Summary at Wk 12; static Investigator Global Assessment of Psoriasis of 0 or 1 and at least a 2-point improvement from baseline, PASI75, and change in Self-Assessment of Psoriasis Symptoms at Wk 16; and proportion of pts achieving minimal disease activity (MDA) at Wk 24. Non-responder imputation was used for binary endpoints. Mixed-effects model for repeated measures was used for continuous endpoints. Point estimates and 95% confidence intervals (CIs) of the PBO subtracted treatment effect were calculated.

Results: 641 pts were randomized and received study drug; 92% were bDMARD-IR: 391 (61%) of pts failed 1 bDMARD, 116 (18%) failed 2 bDMARDs, and 83 (13%) failed ≥3 bDMARDs.

In the overall study population, UPA15 and UPA30 demonstrated superiority vs placebo for all endpoints evaluated. In this post hoc analysis, the PBO subtracted treatment effect demonstrates generally consistent efficacy as compared to the overall study population for UPA15 and UPA30 across efficacy endpoints in the subgroups of pts with IR to 1, 2, or ≥3 prior bDMARDs (**Figure**). Due to limited sample sizes for pts with IR to >1 bDMARD and the pt subsets analyzed for psoriasis-related endpoints, results should be interpreted with caution.

Conclusion: Upadacitinib demonstrated consistent efficacy in treating clinical manifestations of PsA including musculoskeletal symptoms, psoriasis, physical function, fatigue, and quality of life in pts with IR to 1 or multiple prior bDMARDs. In addition, comprehensive disease control as measured by MDA, was generally consistently achieved with upadacitinib regardless of number of prior bDMARDs tried.

Table 1. League table of pairwise comparisons for all treatments in the ASAS20 network meta-analysis.

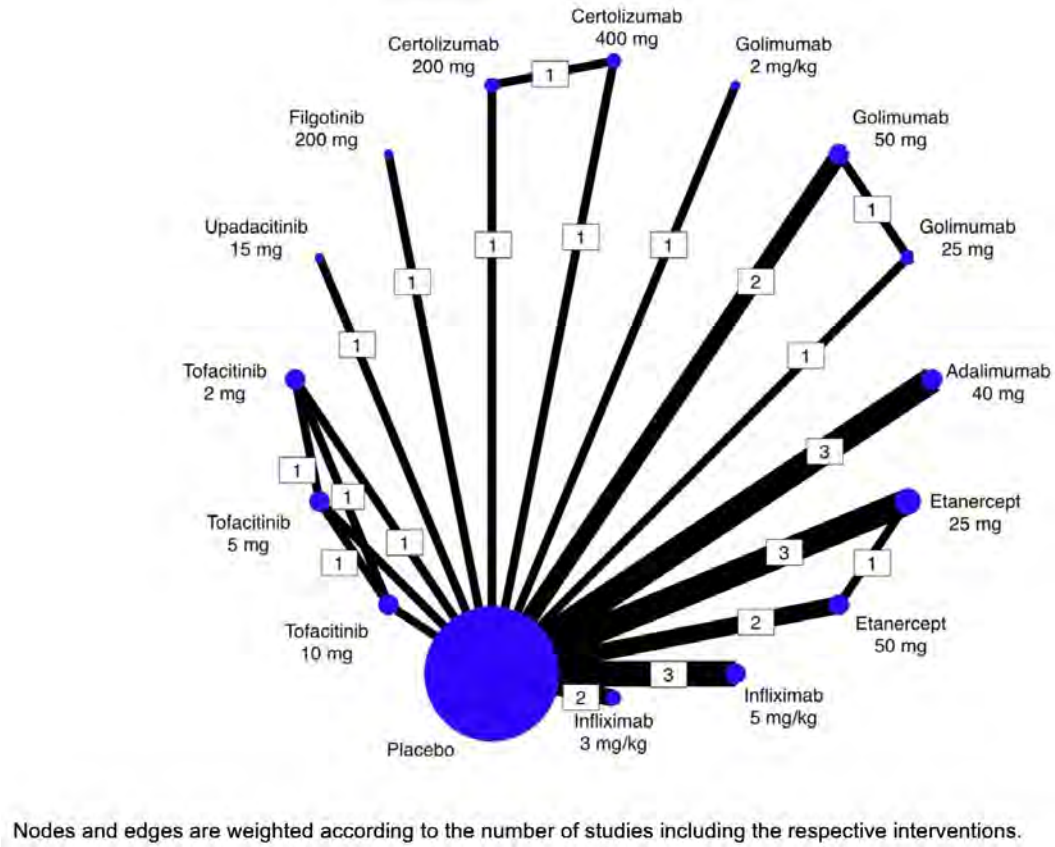

Figure 1. Network plot of the Active Ankylosing Spondylitis network (ASAS 20).

Background/Purpose: Active ankylosing spondylitis (AS) has been associated with poor quality of life and work disability in up to 50% of patients (1). There is an unmet medical need for treatment of patients with active axial disease who have an inadequate response to biologic DMARDs. Janus Kinase (JAK) inhibitors are not currently approved for use in active AS, but several clinical trials suggest their efficacy. Network meta-analyses (NMA) have been conducted to evaluate relative efficacy of JAK inhibitors and biologic therapies, however newer molecules like upadacitinib were

Probability of Best Outcome	Treatment	SUCRA

	Certolizumab SC 200mg	0.2

Abbreviations: IV: intravenous; PO: oral; SC: subcutaneous.

Table 2. The ranking probability of best outcome based on SUCRA.

not included (2). This study aims to compare the relative efficacy of JAK inhibitors and TNF inhibitors for the treatment of active AS.

Methods: We conducted a Bayesian NMA of randomized clinical trials (RCTs) examining the relative efficacy of TNF inhibitors and JAK inhibitors in patients with active AS who had inadequate response or intolerance to NSAIDs. Systematic review was performed in PubMed, EMBASE and Cochrane databases until February 2020. Studies of IL-17 inhibitors were excluded after analysis showed inconsistency likely due to high placebo responses. NMA was conducted by Stata 16.0 software using odds ratio (OR) with 95% credible interval (CrI) to assess the clinical effectiveness. Surface Under Cumulative Ranking curve (SUCRA) was used to analyze the relative efficacy ranking of different treatments in terms of achievement of ≥20% in the Assessment of Spondyloarthritis International Society Criteria (ASAS20) at 12-16 weeks.

Results: We identified 19 RCTs that enrolled 3,654 patients with active AS. There were 120 pairwise comparisons including 20 direct comparisons of 16 interventions (figure 1). Compared with placebo, all the interventions showed an improvement in ASAS20 response rate, except for tofacitinib 2mg twice a day (bid) and tofacitinib 10mg bid dose groups (Table 1). Golimumab IV 2mg/kg showed the highest response rate (OR 7.74, 95% CrI 4.18- 14.34). The ranking probability based on the SUCRA indicated that golimumab IV 2mg/kg (SUCRA = 0.9), infliximab IV 5mg/kg (SUCRA = 0.8) and tofacitinib 5mg bid (SUCRA = 0.8) had the highest probability of achieving the best (optimal) outcome. We subjectively ranked the best therapies, based on SUCRA cut-offs, as optimal (SUCRA ≥0.8), good (SUCRA 0.5-0.7), or effective (SUCRA ≤0.4) (table 2). There were no differences in effectiveness between TNF inhibitors and certolizumab was the lowest ranked (SUCRA=0.2). These analyses were not substantially different if we applied an ASAS40 outcome, although there were fewer studies reporting ASAS40 results. The comparisons involving certolizumab, tofacitinib 10mg and upadacitinib were limited in the number of participants and, thus, may have been underpowered to detect statistical significance.

Conclusion: In patients with active AS, golimumab 2mg IV, infliximab 5mg IV and tofacitinib 5mg bid were most efficacious in achieving ASAS 20. JAK inhibitors seem to be an efficacious alternative in management of AS for which larger clinical trials are warranted.

SESSION INFORMATION

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

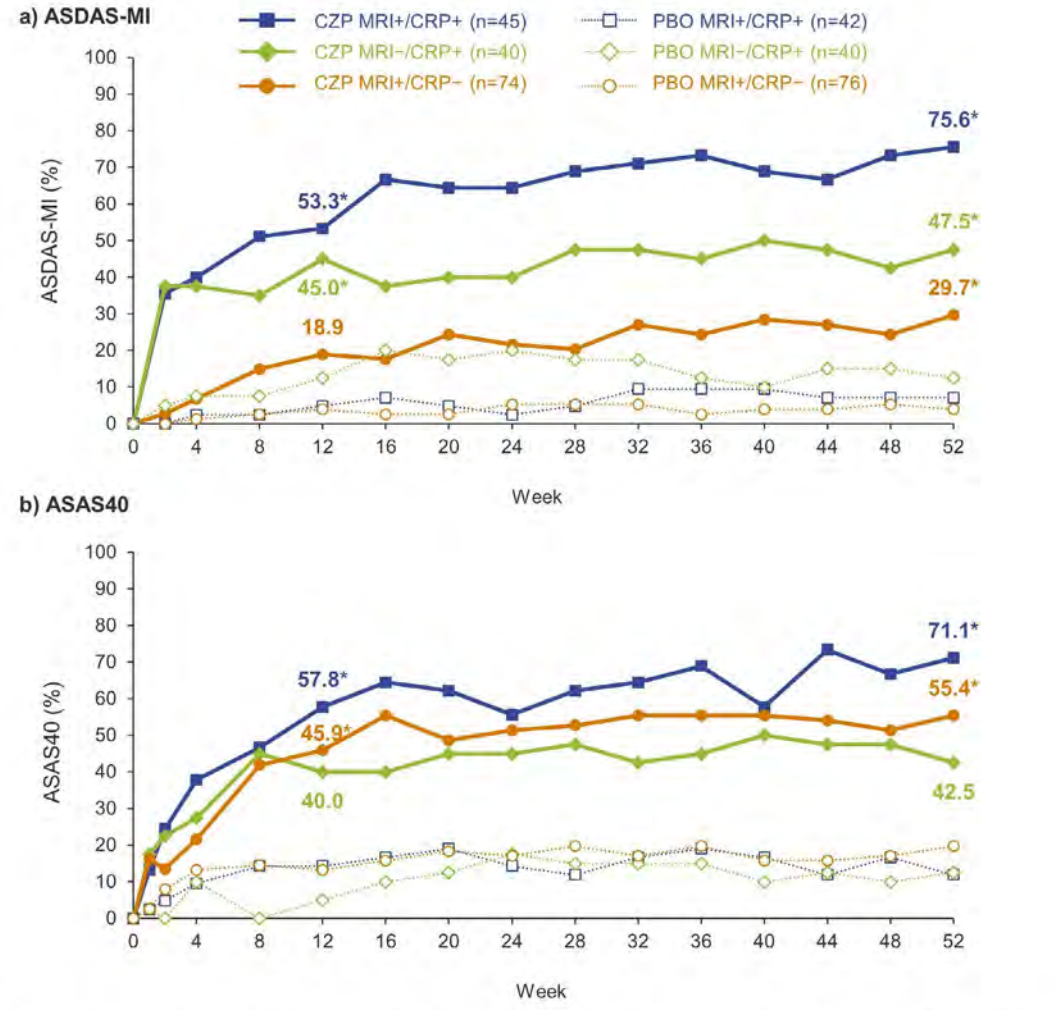
Session Time: 9:00AM–11:00AM

Background/Purpose: This post-hoc analysis from the phase 3 C-axSpAnd study aimed to evaluate whether the response to certolizumab pegol (CZP) in non-radiographic axial spondyloarthritis (nr-axSpA) is impacted by patients' baseline MRI and C-reactive protein (CRP) status.

Methods: C-axSpAnd (NCT02552212) is a 3-year, phase 3, multicenter study including a completed 52-week double-blind, placebo-controlled period.[1] Patients were adults with a diagnosis of axSpA, meeting Assessment of SpondyloArthritis international Society (ASAS), but not modified New York, classification criteria, active disease (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] >4, spinal pain >4), objective signs of inflammation (C-reactive protein [CRP] >10 mg/mL [CRP+] and/or evidence of sacroiliitis on MRI [MRI+]), who had failed ≥2 non-steroidal anti-inflammatory drugs (NSAIDs). Patients were randomized 1:1 to placebo or CZP (400 mg at Weeks 0, 2 and 4, then 200 mg every 2 weeks), which they received in addition to non-biologic background medication for 52 weeks. Adjustments to background medication or switching to open-label CZP (or other biologics) at any point was permitted. We report Ankylosing Spondylitis Disease Activity Score – major improvement (ASDAS-MI) and ASAS 40% response (ASAS40) for CZP-randomized patients according to prespecified subgroups based on MRI/CRP status (MRI+/CRP+, MRI–/CRP+, MRI+/CRP–). Comparisons between MRI/CRP subgroups are descriptive only; Week 12 (ASAS40) and Week 52 (ASDAS-MI) comparisons between CZP and placebo were pre-specified. Missing values, or values collected after switching to open-label treatment, were imputed using non-responder imputation.

Results: At baseline, a total of 317 patients were randomized, 159 to CZP (45 MRI+/CRP+, 40 MRI–/CRP+ and 74 MRI+/CRP–) and 158 to placebo (42 MRI+/CRP+, 40 MRI–/CRP+ and 76 MRI+/CRP–). At Week 52, ASDAS-MI was achieved in 47.2% and 7.0% of CZP and placebo-treated patients, respectively, and ASAS40 in 56.6% and 15.8%. When stratified by MRI/CRP status, response rates in all three subgroups for CZP-treated patients were also higher compared to placebo for both ASDAS-MI and ASAS40 at Week 12 and Week 52 (**Figure 1**). For ASDAS-MI, there was a greater difference in response rates between subgroups compared with ASAS40, with numerically higher response rates in the MRI+/CRP+ and MRI–/CRP+ subgroups vs the MRI+/CRP– subgroup (**Figure 1a**). Since the ASDAS value is largely dependent on the CRP value, this is to be expected. For ASAS40, the main secondary outcome, a

Figure 1. ASDAS-MI and ASAS40 response in patients stratified by baseline MRI/CRP status



Missing values, or values collected after switching to open-label treatment, were imputed using non-responder imputation. *p<0.001 for CZP vs PBO. ASAS40: Assessment of SpondyloArthritis international Society 40% response; ASDAS-MI: Ankylosing Spondylitis Disease Activity Score – major improvement; CRP: C-reactive protein; CZP: certolizumab pegol; PBO: placebo.

numerically higher response rate was also observed for the MRI+/CRP+ group, while response rates were comparable for the other groups (**Figure 1b**).

Conclusion: Clinically relevant responses were observed in nr-axSpA patients with either MRI and/or CRP positivity, with the highest response seen in the MRI+/CRP+ subgroup.

Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients with active ankylosing spondylitis (AS) with an inadequate response (IR) to nonsteroidal anti-inflammatory drugs (NSAID) therapy in the SELECT-AXIS 1[1] trial.

To identify pathways modulated by UPA in AS patients with emphasis on those associated with response to treatment.

Methods: A subgroup of patients from the SELECT-AXIS 1 study, with available baseline and at least one follow up plasma sample during the placebo-controlled period, were selected for analysis (PBO, n= 65; UPA 15 mg QD, n=63). The levels of 92 inflammation related protein biomarkers (BioMs) were analyzed using the Olink® platform; change from baseline were expressed as Log_2 Fold Change; a repeated measure mixed linear model identified BioMs differentially modulated by UPA. Relationship between change in BioMs and change in clinical disease activity measures were derived using Pearson's correlation (ASDAS-CRP, BASDAI, and CRP) and Spearman's correlation (MRI Spine SPARCC). Pathway analysis was performed with Ingenuity® Pathway Analysis (Qiagen Inc.).

Results: Treatment with UPA 15 mg QD reduced the levels of BioMs associated with IFN, IL6, T Cells, M1 or "inflammatory" Macrophages, and Dendritic Cells (DC); and increased those of BioMs associated with tissue repair and hematopoiesis (**Table 1**). The type of pathways, inferred *in silico* based on BM data, suggests that UPA exerts broad inhibitory activity directly on multiple JAK1-dependent (IFNα/β, IFNγ, IL6, IL2, IL5, IL7, and OSM) and indirectly on JAK1-independent upstream pathways (IL1, IL23, IL17, IL18, and TNFα), resulting in the inhibition of key functional pathways such as leukocyte activation and mobility, inflammatory response, and damage to connective tissue. Improvement in ASDAS-CRP, BASDAI, and MRI spine SPARCC correlated with increase in BioMs associated with tissue repair (FGF5, DNER [Delta/Notch Like EGF Repeat Containing]) and hematopoiesis (FLT3LG,and SCF/KITLG), while improvement in ASDAS-CRP and CRP correlated with decrease in CCL23, CSF1, IL-6, and MMP1; and reduction in only CRP correlated with decrease in IFN- and of TNFα-related BioMs (**Table 2**).

Conclusion: Treatment of NSAID-IR AS patients with UPA 15 mg QD resulted in the coordinated decrease in multiple BioMs associated with the innate and adaptive immune responses, and in the increase in BioMs generally associated

with tissue repair and hematopoiesis. In silico pathway prediction indicates that treatment with UPA directly inhibits JAK1-dependent and indirectly JAK1-independent pathways, resulting in the down modulation of functional pathways related to inflammation and tissue damage which are known to be dysregulated in AS[2]. Based on this observation and on the correlation of change in BioMs with change in clinical measures, we hypothesize that both increase in BioMs associated with tissue repair and hematopoiesis, and decrease in BioMs associated with inflammation may contribute to the clinical activity of UPA in AS patients.

Session Date: Sunday, November 8, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: A warning regarding safety of Interleukin 17 inhibitors (IL-17i) has been issued from data of randomized controlled trials (RCT) showing cases of new-onset inflammatory bowel diseases (NO-IBD). Real-world data are lacking. The objectives of the MISSIL (Maladies inflammatoires chroniques de l'Intestin SouS anti-IL 17) study are to describe NO-IBD associated with IL-17i, to identify risk factors, and to assess the incidence of NO-IBD in patients receiving treatment with IL-17i in France.

Methods: A French national registry was designed (MISSIL) to collect all cases of NO-IBD in patients treated with IL-17i from 2016 to 2019 in departments of rheumatology, dermatology and gastro-enterology, whatever the indication. A case–control study was performed with 3 controls per case randomly matched by gender, age (within 6 years), duration of disease (within 5 years) and underlying inflammatory disease from a database of previous studies of patients treated with IL-17i for spondyloarthritis and from centers participating in the MISSIL registry for psoriasis. NO-IBD events were analyzed using incidence rates (patient incidence rates per 100 patient-years – PY). We estimated the annual incidence rate of NO-IBD in patients treated with IL-17i. The numerator of the annual incidence rates consisted in the validated cases of NO-IBD from the MISSIL registry every year (from 2016 to 2019). The pharmaceutical firm provided its estimation of the annual number of patient-years (PY) treated with IL-17i for the denominator (from 2016 to 2019) in France.

Table 1 Characteristics of the 31 NO-IBD cases

	Cases of NO-IBD (n=31)
Age, years, SD	49.2 ± 14.6
Sex, female	14 (45%)
Underlying inflammatory disease	
-Spondyloarthritis	27 (87%)

IL-17i= Interleukin 17 inhibitors. IQR= Interquartile. NO-IBD= new-onset inflammatory bowel diseases. SD= Standard Deviation. TNFi= Tumour Necrosis Factor inhibitor

Table 1 Characteristics of the 31 NO-IBD cases IL-17i= Interleukin 17 inhibitors. IQR= Interquartile. NO-IBD= new-onset inflammatory bowel diseases. SD= Standard Deviation. TNFi= Tumour Necrosis Factor inhibitor

Results: 31 cases of NO-IBD under secukinumab (SEK) were collected between January 2016 and December 2019: 27 patients treated for spondyloarthritis and 4 patients for psoriasis (**Table 1**). No case of NO-IBD was identified under ixekizumab. Mean age was 49.2 ± 14.6 years old and 14/31 were female; 14/24 were HLA-B27 positive, 10/25 had a radiographic sacroiliitis and 15/25 a MRI sacroiliitis. Only 4 were biological Disease-modifying antirheumatic drug (bDMARD)-naïve. The median time to onset of NO-IBD symptoms was 4.0 (1.5-7.5) months. The main symptoms were diarrhoea and loss of weight. Median CRP at the onset of symptoms was 68.0 mg/L (34.0-177.5). SEK was discontinued in all patients. Treatments received after SEK were: corticosteroids in 19 cases, infliximab in 14 cases, adalimumab in 7 cases, golimumab in 3 cases, ustekinumab in 7 cases and colectomy in 2 cases. The evolution was favourable with complete resolution (17/31), improvement (7/31) or stabilization (5/31). 2 patients died: one due to a massive myocardial infarction related to the severe undernutrition due to NO-IBD and one due to post-operative complications. The incidence of NO-IBD was 0.69/100 PY (7/1010) in 2016, 0.23/100 PY (11/4704) in 2017, 0.11/100

Table 2 Risk Factor of NO-IBD receiving secukinumab

			Univariate analysis		Multivariate analysis	
	Case (n=28)	Control (n=82)	OR (95% CI)	p Value	OR (95% CI)	p Value
≥ 2 prior bDMARDs	17/28 (61%)	69/82 (84%)	0.33 (0.13 to 0.85)	0.02	0.53 (0.10 to 2.75)	0.45
Combination with csDMARD	3/28 (11%)	20/82 (25%)	1.2 (0.40 to 3.90)	0.7		
Previously treated with infliximab	8/28 (29%)	29/76 (38%)	0.54(0.20 to 1.47)	0.2		
Previously treated with etanercept	13/28 (46%)	54/76 (71%)	0.38(0.16 to 0.92)	0.03	0.61(0.15 to 2.4)	0.48
Previously treated with adalimumab	19/28 (68%)	59/76 (78%)	0.5617 (0.18 to 1.74)	0.32

bDMARD= biological Disease-modifying antirheumatic drug. csDMARD= conventional synthetic Disease-modifying antirheumatic drug. MTX= methotrexate

Table 2 Risk Factor of NO-IBD receiving secukinumab bDMARD= biological Disease-modifying antirheumatic drug. csDMARD= conventional synthetic Disease-modifying antirheumatic drug. MTX= methotrexate

PY(7/6550) in 2018 and 0.08/100PY (6/7951). There was no independent risk factor for NO-IBD in the case-control study (**Table 2**).

Conclusion: The outcome of NO-IBD was favorable after SEK discontinuation and introduction of IBD treatment in the vast majority of patients. No independent risk factor associated with NO-IBD in patients initiating SEK was identified.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Power Doppler (PD) ultrasonography (PDUS) is a sensitive non-invasive imaging technology used to assess joint synovitis and enthesitis of psoriatic arthritis (PsA) in clinical practice.[1,2] The European League Against Rheumatism and the Outcome Measures in Rheumatology (EULAR-OMERACT) developed a standardized and sensitive to change ultrasonography composite scoring system (the EULAR-OMERACT global synovitis score [GLOESS]) to detect and score joint synovitis.[3] Here we report primary (12-week) efficacy and safety results from the ULTIMATE study (NCT02662985), the first large, randomized, double-blind, placebo-controlled phase III study, primarily designed to assess the time course of response to subcutaneous secukinumab on joint synovitis with PDUS in patients with PsA.

Table: Efficacy of secukinumab at Week 12

Endpoints	Secukinumab (300 mg + 150 mg)[1] (N = 83)	Placebo (N = 83)	Difference/OR (95% CI)	*P*-values
Primary				
PDUS GLOESS, LS mean change (SE)[2,3]	–9.0 (0.9)	–5.8 (0.9)	Difference: –3.2[4] (–5.5; –0.8)	0.004
Secondary				
ACR20, % responders	68	34	OR: 4.1[5] (2.1; 8.0)	<0.0001
ACR50, % responders	46	9	OR: 8.9[5] (3.6; 22.0)	<0.0001
SPARCC enthesitis index, LS mean change (SE)[3]	–2.35 (0.28)	–1.65 (0.28)	Difference: –0.69[4] (–1.39; –0.002)	0.02

Data presented as non-responder imputation for binary variables and MMRM for continuous variables. Prespecified primary and secondary endpoints were analyzed according to a statistical hierarchy. Endpoints are shown in the order of testing. LS, least squares; MMRM, mixed-effect model repeated measures. N, total number of randomized patients.

1. Patients with psoriasis >10% of body surface area received 300 mg; remainder received 150 mg.
2. GLOESS using PDUS composite score of 24 paired joints; the range for the GLOESS is 0–144.
3. Adjusted means and mean change values are from MMRM including treatment, center, and analysis visit as factors, baseline score and weight as continuous covariates and treatment by analysis visit as an interaction term.
4. Difference in adjusted mean change.
5. Odds ratio.

Efficacy of secukinumab at Week 12

Methods: This is a 52-week study with a 12-week double-blind treatment period (TP 1) followed by 12-week open-label (TP 2) and 6-month open-label extension (TP 3). The study enrolled biologic-naïve patients with active PsA and inadequate response to conventional DMARD(s), with joint synovitis on PDUS (at least one joint [out of 48] with both total synovitis PDUS score and PD signal ≥2; or at least two joints with PDUS score ≥2 and PD signal ≥1) at screening and baseline and at least one clinical enthesitis site at baseline. Patients were randomized (1:1) to receive either secukinumab (300 or 150 mg according to severity of skin disease) or placebo weekly followed by 4-weekly dosing starting at Week 4. The primary endpoint was GLOESS, difference in mean change from baseline to Week 12 between secukinumab and placebo determined with mixed-effect model repeated measures analysis. Key secondary endpoints included proportion of patients with ACR20 and ACR50 responses at Week 12 and change in Spondyloarthritis Research Consortium of Canada (SPARCC) enthesitis index from baseline to Week 12. Safety analyses included all patients who received at least 1 dose of study treatment.

Results: Of 166 patients enrolled, 96% (160/166) completed 12-weeks treatment (secukinumab: 99% [82/83] and placebo: 94% [78/83]). Demographics and baseline clinical characteristics were comparable across groups; mean (SD) GLOESS was 24 (16) for secukinumab and 27 (17) for placebo. Mean baseline SPARCC enthesitis index was 4.2 (2.9) for secukinumab and 4.4 (3.3) for placebo. The primary endpoint was met; adjusted mean change in GLOESS was significantly higher with secukinumab vs placebo (–9.0 vs –5.8; $P = 0.004$) at Week 12 (Table), with statistical significance observed as early as Week 1. All key secondary endpoints were met (Table). No new or unexpected safety signals were reported.

Conclusion: Secukinumab demonstrated rapid and significant decrease in synovitis in a period of 12 weeks, as assessed by GLOESS in biologic-naïve patients with active PsA. Secukinumab also demonstrated superior efficacy on ACR20/50 responses and on SPARCC enthesitis vs placebo at Week 12. The safety profile of secukinumab was consistent with previous reports.

BASDAI Guided Treat-to-target Tapering of Tumor Necrosis Factor Inhibitors in Axial Spondyloarthritis: Results of the Retrospective TAPAS Study

Nathan den Broeder[1], Michelle Mulder[1], Mark Wenink[1], Alfons den Broeder[1], Lise Verhoef[2], Frank van den Hoogen[1] and **C.A.J Michielsens**[1], [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Gelderland, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor Necrosis Factor inhibitors (TNFi) have proven to be safe and effective in the treatment of axial spondyloarthritis (axSpA). However, they carry some disadvantages, such as adverse effects, patient burden, and costs, which could be reduced by treat-to-target (T2T) tapering. Although there is lack of high level evidence, guidelines suggest – based on experience in Rheumatoid Arthritis – that T2T tapering and discontinuation might be contemplated. However, there are no studies comparing T2T tapering and continuation in axSpA, with at least two studies ongoing (BIODOPT and DRESS-PS). As T2T treatment and tapering (BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) guided) has been usual care in our axSpA population since 2012, this creates the opportunity to perform a retrospective controlled study.

Our objective was to assess the effect of T2T TNFi tapering on disease activity and TNFi dosage in axSpA patients with low disease activity (LDA).

Table 1. Baseline characteristics of axSpA patients

Characteristic	axSpA (N=169)	
Female, n (%)	66	(39%)
Age in years at inclusion, mean (SD)	46	(13)
Disease duration at inclusion, years, median (IQR)	12	(4-18)
HLA-B27 positivity, n (%)*	115	(86)
ASAS Criteria, n (%)**	137	(81)
Sacroiliitis on radiographic imaging , n (%)	87	(51)
Number of previous bDMARD, n (%)		
- 0	90	(53%)
- 1	50	(30%)
- 2 or 3	29	(17%)
Number of previous csDMARD, n (%)		
- 0	110	(65%)
- 1	35	(21%)
- ≥ 2	24	(14%)
Current bDMARD use, n (%)		
- Adalimumab	74	(44%)
- Etanercept	55	(33%)
- Golimumab	21	(12%)
- Infliximab	19	(11%)
Current csDMARD use, n (%)		
- None	150	(89%)
- Methotrexate	10	(6%)
- Leflunomide	1	(1%)
- Sulfasalazine	8	(5%)
Current NSAID use, n (%)	92	(54%)
Duration of current bDMARD use at inclusion, years, median (IQR)	4	(2-6)
Duration of follow-up, months, median (IQR)	41	(26-56)

*Available for 133 of 169 patients
**Rudwaleit M, Landewe R, van der Heijde D. SpondyloArthritis international Society (ASAS) classification criteria for axial spondyloarthritis (part II): validation and final selection. Ann Rheum Dis. 2009;68(6):777–83.

Methods: We performed a retrospective cohort study in all axSpA patients (clinical diagnosis) using TNFi who visited our outpatient clinic between April 2012 and October 2018. Patients with concomitant inflammatory disease preventing tapering were excluded and patients had to be eligible for tapering, defined as ≥ 6 months of TNFi treatment and ≥ 6 months of LDA (BASDAI < 4 or by judgement of physician and patient). Three different time periods were defined: i) continuation of TNFi; ii) TNFi tapering; iii) stable TNFi dosage after tapering. A mixed-model analysis was used to estimate mean BASDAI during these three time periods. This model included: age, gender, sacroiliitis, disease duration, and the following time-varying components: current dose reduction status (three time periods mentioned above), time since eligibility for tapering and use of concomitant conventional synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs), and a random intercept and slope to account for inter-patient variability. Furthermore, a mean percentage of the Daily Defined Dose (%DDD) was calculated for each time period as secondary outcome.

Results: 169 patients were included, with a mean of 6.4 BASDAI measurements, of whom 118 attempted dose reduction at least once during follow-up. Median follow-up duration was 31 months (Inter Quartile Range (IQR) 20-47) for patients who never attempted dose reduction and 45 months (IQR 31-56) for those who did (table 1). The mixed

Table 2. Mixed Model results, estimation of mean BASDAI between three time periods corrected for potential confounders, with a random intercept and slope to account for inter-patient variability.

	Estimated effect	P-value	95 % CI Lower	Upper
Gender (reference is male)	1.05	<0.001	[0.57 - 1.54]	
Age (per year)	0.03	0.007	[0.01 - 0.05]	
Disease duration at baseline (per year)	0.03	0.047	[0.00 - 0.06]	
Time since baseline (per month)	0.03	0.394	[-0.04 - 0.11]	
csDMARD use (yes vs. no, time varying)	-0.12	0.649	[-0.64 - 0.40]	
Sacroiliitis at baseline (yes vs. no)	-0.18	0.462	[-0.67 - 0.31]	
Time period				
TNFi tapering vs. continuation	0.11	0.376	[-0.14 - 0.36]	
Stable TNFi dosage after tapering vs. continuation	0.21	0.172	[-0.09 - 0.51]	

model showed no significant difference in BASDAI between the three time periods. Higher age, female gender and longer disease duration were significantly associated with a higher BASDAI score (table 2). The mean percentage of the daily defined dose for the three time periods was 96% for the continuation period; 59% in the TNFi tapering period and 69% in the stable TNFi dosage period.

Conclusion: T2T tapering of TNFi appears to have no detrimental effect on disease activity in axSpA patients, compared with full dose continuation, and results in reduction in drug exposure. Trials are needed to investigate tapering in a prospective and randomized manner.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The phase 3 randomized controlled trial FUTURE 5 (NCT02404350) showed the efficacy of secukinumab (SEC) improving clinical signs, symptoms, and radiographic progression in patients with active psoriatic arthritis (PsA).[1] This post hoc analysis evaluated the efficacy of SEC improving patient-reported outcomes (PROs) in tumor necrosis factor inhibitor (TNFi)-naive and inadequate-responder (TNFi-IR) patients with PsA.
