Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) with available DAS28-ESR over two years of follow-up were included. Using a latent growth curve modelling (LCGM), subgroups of patients following distinct pattern of DAS28-ESR change over time were identified. Model selection was based on Bayesian information criterion (BIC).

Results: A total of 1273 patients were included, 454 (36%) with early RA and 819 (64%) with established RA. At baseline, patients with early RA were significantly younger (57.3 vs. 59.1 years) and with higher DAS28-ESR (4.6 vs. 4.3), and were less likely to have an erosion (25.0% vs. 59.7%), to be RF-positive (70.3% vs. 76.8%), and to use biologic DMARDs (7.0% vs. 29.2%).

In patients with early RA (Figure 1A), three subgroups of patients were identified by LCGM with a better fit (BIC: -3070.84). Almost 88% patients with moderate disease activity reached remission (group 1: 48.4%) or low disease status (group 2: 39.3%) at year 2, while 12% of patients with high disease profile remained in a moderate state (group 3).

In patients with established RA (Figure 1B), seven subgroup of patients were identified by LCGM with a better fit (BIC: -5378.13). After 2 years' follow-up, 37.5% of patients in remission or low disease state at baseline remained

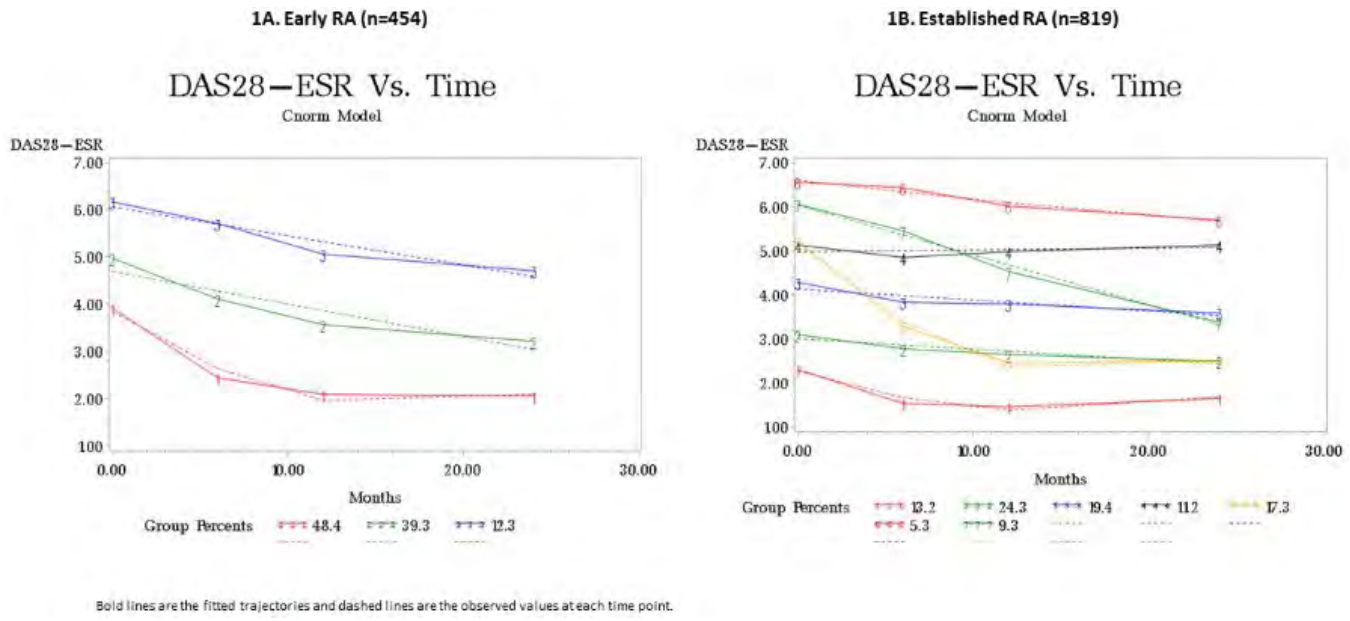

Figure 1. Observed and fitted trajectories from latent growth curve analysis in patients with early and established RA.

or reached to remission (group 1 and 2, respectively). Only 17.3% of patients with high disease activity at baseline reached remission (group 5). 16.5% patients with high disease activity at baseline remained in high disease status at year 2 (group 4 and 6). Two other group of patients (group 3 and 7) with moderate or high disease activity at baseline remained in a moderate state after two years.

Conclusion: Disease course is different between early and established RA. While 70% of early RA patients with moderate or high disease profiles reached remission, only 17% of established patients with high disease activity achieved remission after 2 years of follow-up. These findings suggest the potential effects of receiving early treatment and health care. The impact of sociodemographic, clinical and medication profile on disease course will be examined as future work for this study.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis and rapid initiation of DMARDs following a treat-to-target approach have made remission a realizable goal for many persons living with RA. Despite contemporary improvements in early RA remission outcomes, less is known about: How often, and how long remission is sustained for, and what factors may contribute to loss of remission/ disease control over time. The objective of the present study was to describe longitudinal patterns of remission in real-world early RA patients over a 12-24 months follow up period.

Methods: Data were from participants enrolled in the Canadian Early Arthritis Cohort (CATCH), a prospective study of "real-world" early RA patients (symptoms < 1 year) treated in rheumatology clinics across Canada from 2007-2019. The study sample was limited to patients with active disease at enrolment who later reached remission (SDAI<=3.3) and were followed for 12-24 months post-remission. SDAI remission status over the 12-24m follow up period was classified into 3 patterns: Pattern 1 - Sustained remission (REM → REM); Pattern 2 - Transient remission (REM → LDA), and Pattern 3 - Transient remission (REM → MDA/HDA). Multi-adjusted multinomial regression was used to identify predictors of transient remission patterns (Pattern 2 and Pattern 3) vs. sustained remission (Pattern 1), respectively.

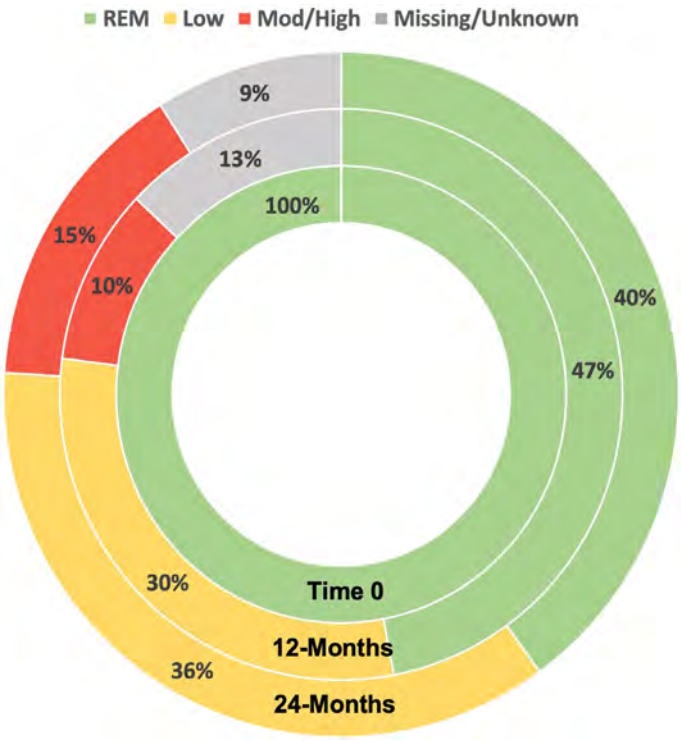

Figure. Distribution of Disease Activity Status 12-24 after RA Patients First Reach SDAI REM

	Pattern 2 (REM → LDA) vs. Pattern 1 (REM → REM) OR (95% CI)	Pattern 3 (REM →HDA/MDA) vs. Pattern 1 (REM → REM) OR (95% CI)
Age, years	1.01 (1.00, 1.02)	1.01 (0.99, 1.02)
Sex, Female vs. Male	**1.78 (1.33, 2.39)**	**1.63 (1.09, 2.44)**
Current smoker vs. past or never smoker	**1.57 (1.09, 2.28)**	**1.53 (0.95, 2.47)**
Comorbidities, RDCI ^ (range 0-9)	**1.11 (0.99, 1.25)**	**1.30 (1.13, 1.50)**
RF+ or ACPA +	**1.38 (1.03, 1.85)**	**1.21 (0.81, 1.80)**
Early MTX treatment (≦ 3-months)	1.18 (0.85, 1.63)	0.76 (0.51, 1.12)
Time to first SDAI remission, (months)	1.01 (1.00, 1.01)	1.01 (1.00, 1.02)
Treatment reduction after REM vs. No Change	1.33 (0.96, 1.86)	1.01 (0.62, 1.64)

Table. Multi-Adjusted Multinomial Regression Results of Predictors of Transient Remission Patterns over 24-Month Follow Up

Results: Among all early RA patients enrolled in CATCH, 1691/ 3054 (55%) had ever reached SDAI remission. Among those that reached remission, 1,419 completed at least 12-24 months of study follow-up post remission and were included in the present study. At study enrolment, most were female (70%), mean(sd) SDAI disease activity was high (27(15)) and most patients (92%) were being treated with csDMARDs. Over the follow up period, 47% of patients sustained remission by 12-months and, only 40% by 24 months (Figure). Transitions from REM→LDA (36%) were more common than REM→MDA/HDA (15%) by 24 months (Figure).Female sex, smoking, higher comorbidity index and positive serology, were significantly associated with transient remission patterns (Table). Results also suggest possible associations between transient remission patterns and older age, longer time to first remission, lack of early MTX treatment and reducing treatment after remission, but confidence intervals were inconclusive (Table).

Conclusion: Results of this large longitudinal study suggests that < 50% of real-world early RA patients that reached remission, sustained remission for 12-24m. Closer monitoring of RA patients with prognostic indicators for transient

remission, and additional research aimed at improving the understanding of why remission is lost may help more patients sustain remission for longer periods.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a common and debilitating symptom in patients with rheumatoid arthritis (RA). In early RA it is usually due to ongoing inflammation and synovitis, but over time a substantial proportion of patients experience pain without laboratory or clinical signs of inflammation.

The objective of this study was to investigate predictors of unacceptable pain and unacceptable pain with low inflammation one year after diagnosis in patients with RA.

Methods: Consecutive patients with early RA (symptom duration < 12 months, fulfilling the 1987 ACR criteria and/or the 2010 ACR/EULAR criteria) were recruited between January 2012 and March 2016 from a defined geographical area. Patients were managed according to usual care, and were followed for one year after diagnosis. Pain was assessed using a visual analogue scale (VAS; 0-100 mm). Unacceptable pain was defined as VAS pain > 40 based on

Table 1. Baseline predictors of unacceptable pain one year after diagnosis in patients with early RA.

Variable	Odds ratio	95 % Confidence interval
Female sex	2.59	1.09 – 6.13
RF seropositivity	1.31	0.60 – 2.87
Anti-CCP seropositivity	0.59	0.29 – 1.22
Age	1.07	0.72 – 1.60
Symptom duration	1.04	0.73 – 1.50
VAS pain	1.35	0.91 – 2.02
DAS28	1.06	0.69 – 1.63
SJC28	0.96	0.67 – 1.40
TJC28	1.07	0.76 – 1.49
HAQ	1.58	1.08 – 2.30
CRP	0.99	0.72 – 1.35
ESR	1.01	0.94 – 1.46
VAS PGA	1.26	0.83 – 1.92

Univariate logistic regression analysis. Odds ratios are calculated per standard deviation for continuous variables. Unacceptable pain: VAS pain > 40. RF = rheumatoid factor; anti-CCP = anti-cyclic citrullinated peptide; VAS = Visual Analogue Scale; DAS28 = Disease Activity Score in 28 joints; SJC28 = Swollen Joint Count in 28 joints; TJC28 = Tender Joint Count in 28 joints; HAQ = Health Assessment Questionnaire; CRP = C-reactive protein; ESR = erythrocyte sedimentation rate; PGA = patient global assessment.

Table 2. Baseline predictors of unacceptable pain with low inflammation one year after diagnosis in patients with early RA.

Variable	Odds ratio	95 % Confidence interval
Female sex	3.72	1.22 – 11.34
RF seropositivity	0.82	0.36 – 1.87
Anti-CCP seropositivity	0.67	0.30 – 1.50
Age	1.26	0.79 – 2.01
Symptom duration	1.07	0.72 – 1.60
VAS pain	1.40	0.90 – 2.17
DAS28	1.09	0.68 – 1.74
SJC28	0.90	0.60 – 1.35
TJC28	0.96	0.66 – 1.41
HAQ	1.50	1.00 – 2.25
CRP	0.72	0.43 – 1.19
ESR	0.83	0.53 – 1.30
VAS PGA	1.38	0.87 – 2.20

Univariate logistic regression analysis. Odds ratios are calculated per standard deviation for continuous variables. Unacceptable pain: VAS pain > 40. Low inflammation: CRP < 10 mg/l. RF = rheumatoid factor; anti-CCP = anti-cyclic citrullinated peptide; VAS = Visual Analogue Scale; DAS28 = Disease Activity Score in 28 joints; SJC28 = Swollen Joint Count in 28 joints; TJC28 = Tender Joint Count in 28 joints; HAQ = Health Assessment Questionnaire; CRP = C-reactive protein; ESR = erythrocyte sedimentation rate; PGA = patient global assessment.

the patient acceptable symptom state (PASS) (1), and low inflammation as CRP < 10 mg/l (2). Baseline predictors of unacceptable pain, and unacceptable pain with low inflammation, were evaluated using logistic regression analysis.

Results: A total of 263 patients with early RA (mean age 59 years, 73 % female, 67 % anti-CCP positive, median symptom duration 5 months) were included, and 183 attended the 1-year follow-up. After one year 32 % had unac-

ceptable pain and 22 % had unacceptable pain with low inflammation, the latter thus accounting for 69 % of all unacceptable pain. High scores for the Health Assessment Questionnaire (HAQ) disability index at baseline, and female sex were associated with unacceptable pain (Table 1) and also with unacceptable pain with low inflammation (Table 2) at 1 year in univariate analysis, whereas there were no such associations for swollen joint count or laboratory markers of inflammation (Table 1, Table 2). In multivariate logistic regression analysis, there was an independent association between higher HAQ and unacceptable pain after 1 year [adjusted odds ratio (OR); 1.56 per SD (95 % CI 1.06-2.28) (SD 0.65)] with a similar trend for patients with unacceptable pain and low inflammation (OR 1.47 per SD; 95 % CI 0.98 – 2.21).

Conclusion: Almost 1/3 of early RA patients reported unacceptable pain one year after diagnosis, implying the need for improvement in pain treatment. Patients with high self-reported disability at baseline were at increased risk of unacceptable pain at 1 year. This could be due to ineffective coping strategies and inactivity. The association between female sex and persistent unacceptable pain could indicate sex differences in disease severity, or in propensity for chronic pain. Unacceptable pain 1 year after RA diagnosis was not associated with any objective baseline measures of disease activity, indicating the need to find other predictors for long time severity of pain.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term observational studies on the prediction of favorable outcome (FO) in rheumatoid arthritis (RA) have mostly considered patients baseline characteristics and have rarely evaluated the specific impact of treatments in real world settings.

The objective of this study was to assess the impact of treatments exposure on the 10-year FO in early rheumatoid arthritis (RA).

Exposure tested	Reference	OR (95%CI)
Treatments intakes during the last 120 months		
csDMARD & bDMARD for last 10 years	No treatment for last 10 years	1.10 (0.88-1.38)
Testing the interest of an early initiation of csDMARDs (not combined with bDMARD)		
csDMARD started at inclusion (month 0)	csDMARD after 3 months of follow-up	1.05 (1.03-1.07)
csDMARD started at inclusion (month 0)	csDMARD after 6 months of follow-up	1.19 (1.11-1.27)
csDMARD started at inclusion (month 0)	csDMARD after 12 months of follow-up	1.53 (1.29-1.83)
Testing the interest of an early initiation of bDMARDs (in association with csDMARD)		
bDMARD after 3 months of follow-up	csDMARD started at inclusion (month 0)	0.99 (0.82-1.20)
bDMARD after 6 months of follow-up	csDMARD started at inclusion (month 0)	0.99 (0.82-1.19)
bDMARD after 12 months of follow-up	csDMARD started at inclusion (month 0)	1.03 (0.86-1.23)
bDMARD after 24 months of follow-up	csDMARD started at inclusion (month 0)	1.16 (0.99-1.38)

Table 1. odd ratios for the association of patterns of drug regimen with 10-year favorable outcome

Methods: The 349 patients of the Etude et Suivi des Polyarthrites Indifférenciées Récentes (ESPOIR) cohort fulfilling ACR/EULAR 2010 criteria at baseline and having complete DAS28 and HAQ data at 10 years were considered in the present study. FO was defined at 10 years as DAS28 $\leq$ 2.6 and HAQ $\leq$ 0.5. Three RA treatments were considered: glucocorticoids (GC), conventional synthetic and biologic Disease-Modifying Anti-Rheumatic Drugs (csDMARDs and bDMARDs), which posologies were standardized by the mean of dose quotients (DoseQ). Drug exposure was modelled with Weighted Cumulative Exposure (WCE) variables [1], considering the intensity of drug exposure defined as a weighted function of past doses, and was incorporated into a logistic regression model that also included baseline clinical, biological and radiological characteristics. The predictive performance of this WCE model was compared to models considering on the one hand only baseline characteristics (BSL model) and on the other, baseline characteristics and binary treatments exposure - in other terms, “ever exposed, yes or no” (BIT model).

Results: Overall, FO at 10 years occurred in 158 (45.3%) patients. GC exposure was significantly associated with favorable outcome in univariate analysis only, and therefore was not included in the final WCE combined model.

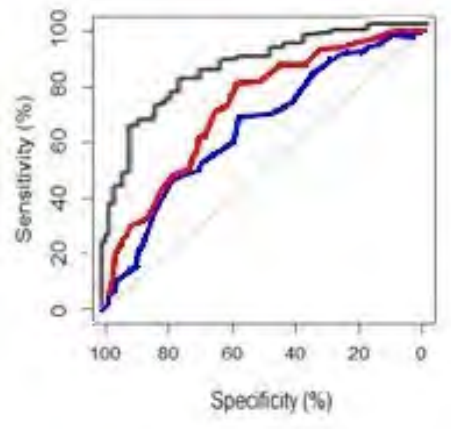

Figure 1. Receiver Operating Characteristic curves of BSL model (blue), BIT model (red) and WCE combined model (black) for 10-year favorable outcome

In the final WCE model, the joint exposure to 1 DoseQ of csDMARD and 1 DoseQ of bDMARD during the 10-year follow-up was not significantly associated with FO compared to patients receiving no treatment: OR=1.10 (95% CI: 0.88-1.38).

Early csDMARD initiation, i.e., as soon as the cohort inclusion, was significantly associated with the occurrence of FO at 10 years (Table 1).

Initiation of a bDMARD between the 3rd month and 2nd year of follow-up in combination with a csDMARD was not significantly better compared to early csDMARD initiation (Table 1).

The final WCE model was better at predicting FO at 10 years compared to the BSL and BIT models: AUC=0.85 (95% CI: 0.81-0.89), AUC=0.65 (95% CI: 0.60-0.71) and AUC=0.72 (95% CI: 0.66-0.79) respectively (Figure 1).

Conclusion: The early initiation of csDMARDs is associated with the occurrence of favorable outcome at 10 years in RA patients. This study confirms that initiating a csDMARD as 1st line treatment and keeping targeted DMARD as 2nd (or more) line is associated with favorable outcome at 10 years, with no loss of chance for the early RA patient.

Table 1. Odd ratios for the association of patterns of drug regimen with 10-year radiographic progression

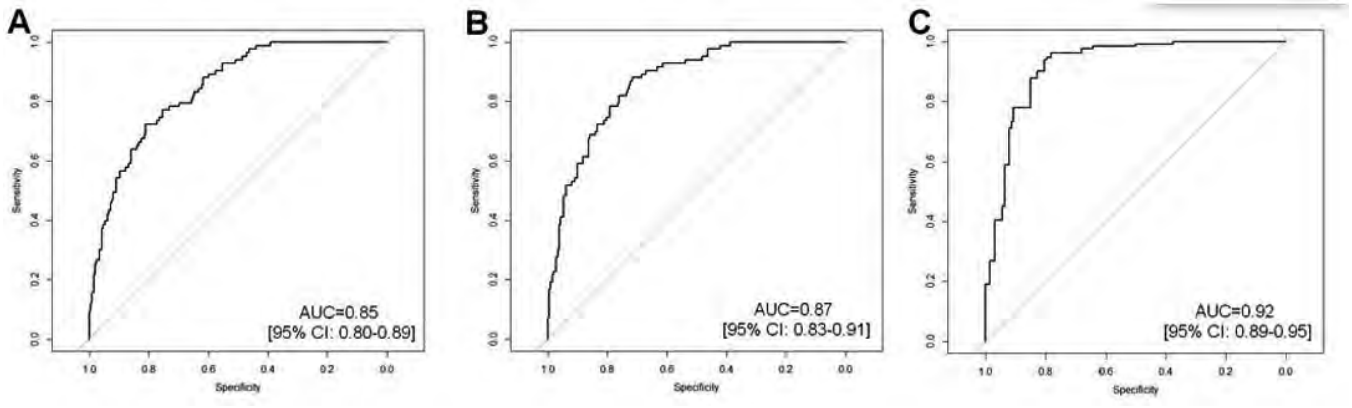

Figure 1. Receiver Operating Characteristic curves of BSL model (A), BIT model (B) and WCE combined model (C) for 10-year radiographic progression

Background/Purpose: Long-term observational studies on the prediction of structural damage progression (SDP) in rheumatoid arthritis (RA) have mostly considered patients baseline characteristics and have rarely evaluated the specific impact of treatments in real world settings.

The objective of this study was to assess the impact of treatment exposure on the 10-year radiographic progression in early rheumatoid arthritis (RA).

Methods: The 310 patients of the Etude et Suivi des Polyarthrites Indifférenciées Récentes (ESPOIR) cohort fulfilling ACR/EULAR 2010 criteria at baseline and having complete radiographic data at baseline and 10 years were considered in the present study. SDP was defined at 10 years as a significant increase of the Sharp/van der Heijde score, i.e., superior to the Smallest Detectable Change (SDC) of 11.5 at 10 years. Three RA treatments were considered: glucocorticoids (GC), conventional synthetic and biologic Disease-Modifying Anti-Rheumatic Drugs (csDMARDs and bDMARDs), which posologies were standardized by the mean of dose quotients (DoseQ). Drug exposure was modelled with Weighted Cumulative Exposure (WCE) variables [1], considering the intensity of drug exposure defined as a weighted function of past doses, and was incorporated into a logistic regression model that also included baseline clinical, biological and radiological characteristics. The predictive performance of this WCE model was compared to models considering on the one hand only baseline characteristics (BSL model) and on the other, baseline characteristics and binary treatments exposure - in other terms, “ever exposed, yes or no” (BIT model).

Results: Overall, SDP at 10 years occurred in 85 (27.4%) patients. In the final WCE model, the combined exposure to 1 DoseQ of csDMARD and 1 DoseQ of bDMARD during the 10-year follow-up was associated with a significant protective effect on SDP compared to patients receiving no treatment: OR=0.04 (95% CI: 0.002-0.72). Early csDMARD initiation, i.e., as soon as the cohort inclusion was associated with a significantly lower risk of SDP compared to later initiation (after month 3 or more) (Table 1).

Initiation of a bDMARD between the 3rd month and 3rd year of follow-up in combination with a csDMARD was not significantly superior to early csDMARD initiation (Table 1).

The final WCE model was better at predicting SDP at 10 years compared to the BSL and BIT models: AUC=0.92 (95% CI: 0.89-0.95), AUC=0.85 (95% CI: 0.80-0.89) and AUC=0.87 (95% CI: 0.83-0.91) respectively (Figure 1).

Of note, GC exposure was significantly associated with SDP only in the univariate analysis and did not remain significant when baseline characteristics are considered.

Conclusion: CsDMARDs and bDMARDs have a protective effect on radiographic progression at 10 years in RA patients. This effect is better captured by the WCE model compared to models with binary treatments exposure and should be more frequently used in further studies.

Prevalence and Trajectory of Erosions, Synovitis, and Bone Marrow Edema in Feet of Patients with Early Rheumatoid Arthritis

Zechen Ma[1], Hanyan Zou[2], Mary-Clair Yelovich[2], Saara Totterman[3], Karen Beattie[2] and Maggie Larche[2], [1]McMaster University, Mississauga, ON, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]QMetrics Technologies, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Imaging studies have shown that erosions emerge early in RA and is associated with worsening pain and function. Despite erosions being just as prevalent in feet as in hands in patients with RA, their development in relation to synovitis and bone marrow edema (BME) have mainly been studied in the hands. This study examines the prevalence and longitudinal trajectory of erosions, BME, and synovitis in metatarsophalangeal joints (MTPJs) in patients with early RA over 2 years of treatment. We also describe correlations between changes in erosions, synovitis, and BME at the joint level.

Methods: Treatment naïve patients with early RA (symptom duration < 2 years) were recruited from an academic rheumatology clinic. MRI of the most symptomatic forefoot was acquired at baseline, year 1 and ≥2 years using a 1.0T peripheral scanner (GE Medical). Metatarsophalangeal joints 2-5 were semi-quantitatively graded by a MSK radiologist for erosions (0-10), synovitis (0-3) and BME (0-3) according to OMERACT guidelines. Synovitis was graded per joint, while erosions and BME were graded for the metatarsal head and phalangeal base individually so the maximum scores per MTPJ were 20 for erosions and 6 for BME. The MSK radiologist was blinded to clinical assessments and previous imaging. Patients were treated per standard of care. Descriptive statistics characterized the study population. Paired t-tests were performed for changes in erosions, synovitis, and BME over time. Correlations between changes in erosions, synovitis, and BME were conducted per joint using Pearson's correlation coefficient.

Results: 32 patients with early RA were included. 87.5% of patients were female and the average age was 51.7 (SD=10.4). At baseline, 29 patients (90.6%) had at least one grade ≥1 erosion, 21 (65.6%) had at least one MTPJ with grade ≥1 synovitis, and 19 (61.3%) had at least one joint with grade ≥1 BME. The proportion of MTPJs with ero-

BL: baseline; 1Y: 1-year; 2Y: 2+-years; BME: bone marrow edema; MTPJ: metatarsophalangeal joint

Table 1. Proportion of joints with erosions, synovitis, and BME over time

sions, synovitis, and BME are shown in Table 1. Overall changes in erosions, synovitis, and BME are shown in Figure 1. Erosions overall did not significantly change over time. Significant reductions in overall synovitis scores, MTPJ2, and MTPJ3 synovitis scores were seen between year 1 and ≥2 years. Overall BME scores improved in year 1 and were sustained at ≥2 years. BME improved in MTPJ2, MTPJ3, and MTPJ4. Positive correlations were seen between changes in synovitis and BME in MTPJ2 and MTPJ5.

Conclusion: In patients with early RA, standard of care saw overall reductions in synovitis by year 2, BME by year 1, and no progression in overall erosion scores on MRI. MTPJ2 and MTPJ3 appeared to be the most active joints. Overall improvements in synovitis is attributed to MTPJ2 and MTPJ3, while other MTPJs did not progress. Over all reductions in BME is attributed to MTPJ2, MTPJ3, and MTPJ4, while other MTPJs did not progress.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals at high-risk for future rheumatoid arthritis (RA) may be identified by screening for circulating RA-related autoantibodies including antibodies to citrullinated protein antigens (ACPA). The purpose of this study was to evaluate a new cohort of ACPA+ individuals to identify factors associated with progression to and timing of inflammatory arthritis (IA) onset in order to develop prediction models and to identify factors that may be target candidates for prevention.

Table 1. Baseline characteristics of enrolled population			
	Anti-CCP3 negative	Anti-CCP3 positive	p-value
n	156	86	
Age	57.8 ± 12.2	57.6 ± 12.4	0.914

Table 1. Baseline characteristics of enrolled population

Table 2. Unadjusted hazard ratios (HR) for each risk factor treating time-to-RA as the outcome*			
Risk factors	HR	95% CI	p-value
Age (decade)	1.05	0.71, 1.57	0.80
Gender (male)	0.87	0.31, 2.5	0.80
BMI	1.12	1.02, 1.2	0.020
Current smoker	1.35	0.18, 10.31	0.77
Any alcohol intake in past year	0.22	0.08, 0.60	0.005
Total servings of alcohol per month	0.94	0.88, 1.00	0.040
One or more alleles containing the shared epitope	3.14	1.01, 9.75	0.048
CRP level (z-score)	1.03	0.62, 1.72	0.90
Anti-CCP3 level (z-score)	1.50	1.00, 2.24	0.050
Number of RF isotypes positive (IgA, IgG, or IgM)	1.91	1.30, 2.82	<0.001
RFIgA, IgG and IgM positive	7.82	2.80, 21.85	<0.001
*These data were analyzed with univariate Cox regression models. Abbreviations: BMI, body mass index; CCP3, cyclic citrullinated protein 3; RF, rheumatoid factor; IgA, immunoglobulin A; CRP, C-reactive protein.			

Table 2. Unadjusted hazard ratios (HR) for each risk factor treating time-to-RA as the outcome

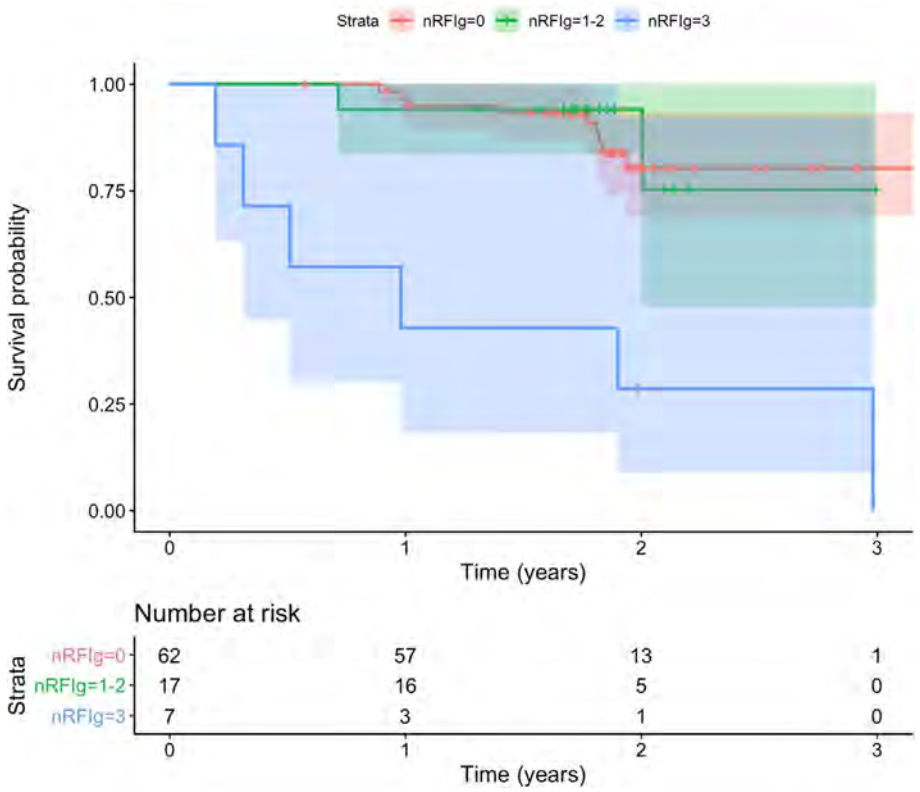

Figure 1. RA-free survival stratified by baseline RF Ig status. Note, nRFIg=0 (red line) if neither IgM, IgA, nor IgG were positive, RFIg=1-2 (green line) if any 1 or two of RF isotypes were positive, and RFIg = 3 (blue line) if all three RF isotypes were positive.

Methods: ACPA- healthy controls (n=156) and ACPA+ subjects without IA at baseline (n=86) were enrolled in the Targeting Immune Responses for Prevention of Rheumatoid Arthritis (TIP-RA) study. Subjects were identified through clinics, and screening of relatives of patients with RA, and health-fairs. Clinical characteristics and laboratory results were obtained every year for up to 3 years' follow-up. ACPA was evaluated by anti-CCP3 (IgG, Inova) and rheumatoid factor (RF) by ELISA for IgA, IgG and IgM isotypes (Inova). Other biomarkers included assessment of C-reactive protein and the shared epitope (SE). Baseline clinical and biomarker characteristics were compared between ACPA-positive individuals who developed RA and those who did not. In addition, univariate Cox regression analyses were used to estimate hazard ratios (HRs) for each risk factor of RA development.

Results: Characteristics of the ACPA- and ACPA+ subjects are presented in Table 1. Among the 86 ACPA+ subjects, 18 (20.9%) developed RA after a mean of 470 days from baseline, with 15/18 (83.3%) meeting ACR/EULAR classification criteria at the time of presentation of IA. Within the ACPA+ subjects, a higher BMI was associated with an increased risk for developing IA/RA (Table 2); in contrast, any alcohol intake in the past year was associated with decreased risk of IA/RA. Past or current smoking was not associated with increased risk for IA/RA, although rates of smoking were low. The presence of one or more alleles containing the SE was also associated with increased risk of incident IA/RA. Furthermore, within the ACPA+ subjects, for every additional RF isotype that was positive, the risk for incident IA/RA increased by 91%. In particular, baseline positivity of RFIgA, IgG and IgM was associated with the highest risk of development of IA/RA (Table 2 and Figure 1).

Conclusion: The findings of an increased risk of incident IA/RA in ACPA+ subjects associated with higher BMI and lower risk associated with alcohol intake replicate findings from other studies (de Hair 2012; Scott 2013). Moreover, these findings suggest that BMI and alcohol are mechanistically related to biologic pathways in propagation from autoimmunity to clinically-apparent IA/RA; these findings also support that modification of these factors may be con-

sidered in RA prevention (Zacchardeli 2019). In addition, the increased risk of incident IA/RA with SE and RF isotype positivity, respectively, suggests these markers can be used to improve prediction of the imminent onset of RA; these latter findings also highlight the importance of the SE and RFs in the pathophysiology of RA development and especially in the transition from Pre-RA to clinically-apparent disease.

Abstract Number: 1721

Increasing Autoantibody Positivity During Pre-RA Is Associated with the Imminent Development of Classifiable RA

Heinrich-Karl Greenblatt[1], Ted Mikuls[2], Jess Edison[3], Marie Feser[4], Mark Parish[5], LauraKay Moss[5], Elizabeth Mewshaw[6] and Kevin D. Deane[7], [1]University of Colorado School of Medicine, Aurora, CO, [2]University of Nebraska Medical Center, Omaha, NE, [3]Walter Reed National Military Medical Center, Bethesda, [4]Division of Rheumatology, University of Colorado School of Medicine, Anschutz Medical Campus, Aurora, CO, USA, Colorado, [5]University of Colorado Anschutz Medical Campus, Aurora, CO, [6]Walter Reed National Military Medical Center, Bethesda, MD, [7]2 Division of Rheumatology, University of Colorado School of Medicine, Anschutz Medical Campus, Aurora, CO, USA, Colorado

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies including rheumatoid factor (RF) and antibodies to citrullinated protein antigens (ACPA) may be elevated during a period that can be termed 'Pre-RA'. In addition, there are findings supporting that there is an expansion of autoimmunity in Pre-RA; however, this has typically been demonstrated using research grade assays and therefore the increasing positivity of commercially available ACPA and RF is less well known. As such, the purpose of this study was to evaluate how an increasing number of commercially-available autoantibodies testing during Pre-RA relates to the development of imminent RA.

Methods: Two-hundred and fifteen RA cases, each with approximately 3 pre- and 1 post-RA serum samples, were identified from the Department of Defense Serum Repository. All case samples were tested by ELISA for anti-CCP2 (IgG, Axis-Shield), CCP3 (IgG, Inova), RF-IgM, A and G (Inova). Manufacturer suggested cut-offs were used for the CCP assays, and a level present in < 2% of 156 controls was used for the RF's. Comparison of autoantibody prevalence within a time point was performed using chi-squared and Fisher's exact testing. Analyses of autoantibody positivity over time within cases as individual biomarkers or as an overall count were performed using analyses that account for repeated measures within subjects (e.g. ANOVA).

Results: Characteristics of the 215 cases are reported in **Table 1**, and the positive rates of all autoantibodies as individual tests and counts are presented in **Table 2**. The prevalence of all antibodies increased from the earlier pre-RA time point (a mean of 11.6 years prior to RA diagnosis) to immediately pre-RA diagnosis (a mean of 0.9 years prior to RA diagnosis) although there was no significant increase in positive rates of any of these autoantibodies when comparing the immediate pre- and post-RA diagnosis samples. There were no significant differences in rates of positivity

Table 1. Characteristics of the 215 subjects who developed rheumatoid arthritis	
n	215
Female (%)	48.0
Age at diagnosis of RA (or sample testing), mean (SD)*	37.0 (7.9)
Non-Hispanic White (%)	58
Ever smoker (%)	32

Table 1. Characteristics of the 215 subjects who developed rheumatoid arthritis

Table 2. Autoantibody prevalence and counts over time pre- and post-RA diagnosis in 215 RA cases					
	Earliest Pre-RA Sample	Intermediate Pre-RA Sample	Immediate Pre-RA Sample	Post-RA Sample	p-value*
Mean time (years) pre- or post-RA diagnosis	-11.5 (5.2)	-2.7 (1.5)	-0.9 (0.8)	1.3 (0.9)	n/a
CCP2	18.6	53.3	71.4	71.5	<0.001
CCP3	22.3	59.3	73.7	75.2	<0.001
RFIgM	8.8	35.0	52.6	52.3	<0.001
RFIgG	4.2	13.1	18.8	16.4	<0.001
RFIgA	7.4	28.0	40.4	40.2	<0.001
Overall count of number of positive autoantibodies, mean (SD)	0.61 (1.15)	1.89 (1.71)	2.57 (1.70)	2.56 (1.61)	<0.001
*This p-value is for the comparison of the rates of positivity of each autoantibody or autoantibody counts over time and uses models that account for repeated samples. **at all time points, the prevalence of positivity of CCP2 and CCP3 was significantly higher ($p<0.05$) when compared to any RF.					

Table 2. Autoantibody prevalence and counts over time pre- and post-RA diagnosis in 215 RA cases

at any time period between CCP2 and CCP3 although CCP3 had a slightly higher prevalence of positivity at earlier time points. At all times points, both CCP2 and CCP3 were positive in a greater number of subjects than any of the RF isotypes. The number of positive autoantibodies also increased over time, with the highest mean count of autoantibodies of 2.57 at the immediate pre-RA diagnosis period.

Conclusion: In these subjects CCP2 and CCP3 perform in a similar manner, although both are present in a higher number of subjects in the earlier time periods than RF. In addition, higher mean counts of antibodies are present in the immediate pre-RA period. These findings suggest that there is an expansion of autoantibody positivity across ACPA and RF assays. Furthermore, testing for these widely-available assays and identifying a high number of positives may be useful to identify subjects in Pre-RA who may imminently transition to clinically-apparent and classifiable RA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Accurate prediction of rheumatoid arthritis (RA) development in persons at risk can help to select individuals for early intervention trials. At-risk individuals exhibit a high prevalence of diverse symptoms [1,2] and information on the predictive ability of symptoms or symptom complexes is still largely lacking. We investigated if symptoms could predict RA development in persons at risk, using the validated 'Symptoms in Persons At Risk of Rheumatoid Arthritis' (SPARRA) questionnaire.

Methods: Individuals at-risk of RA from four different cohorts from the Netherlands (n=122), United Kingdom (n=77), Sweden (n=13) and Switzerland (n=20), were asked to complete the SPARRA questionnaire, consisting of 69 questions (previously described [3]). Individuals were persons with anticitrullinated protein antibodies (ACPA) and/or rheumatoid factor (RF; n=135), having relevant symptoms (arthralgia suspicious for progression to RA) with or without RA-specific antibodies, (n=77) or first degree relatives (FDR, n=20) of RA patients. Follow up was ≥ 24 months or until clinical arthritis development. Univariable analyses preselecting possible predictors (Cox regression, $p < 0.2$) was followed by stepwise forward selection ($p < 0.1$) to create a multivariable prediction model. To test the added value of the SPARRA items over the clinical prediction model by van de Stadt et al [4], the likelihood ratio (LR) test was used to compare the van de Stadt model with and without SPARRA items

Results: The mean age of all participants was 51 years, 69% was female. In total, 58 persons (25%) developed clinical arthritis (n=23, 26, 7, 2 respectively in the 4 groups) after a median of 7 months (IQR 5.3 – 17.8). In total, 22 SPARRA questions were preselected and entered in the stepwise forward selection procedure. The symptoms that predicted time to development of arthritis are shown in table 1. The symptom 'pain that moves from one side to the other' showed added value to the van de Stadt model in predicting arthritis (LR test $p = 0.012$, AUC 0.73 (extended model) versus AUC 0.71 (van de Stadt model)).

Conclusion: Specific symptom details such as pattern of pain or degree of joint swelling can provide useful additional information to estimate a person's RA risk. Our next steps are 1) to develop a new prediction model using both SPARRA data and clinical data and distinguishing between seropositive and seronegative individuals and 2) to create a shortened version of the SPARRA questionnaire to be used in prospective at-risk cohorts to enable homogenous symptom data collection. This will further improve our understanding of the prevalence and predictive ability of greatly diverse symptoms in different at-risk populations.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

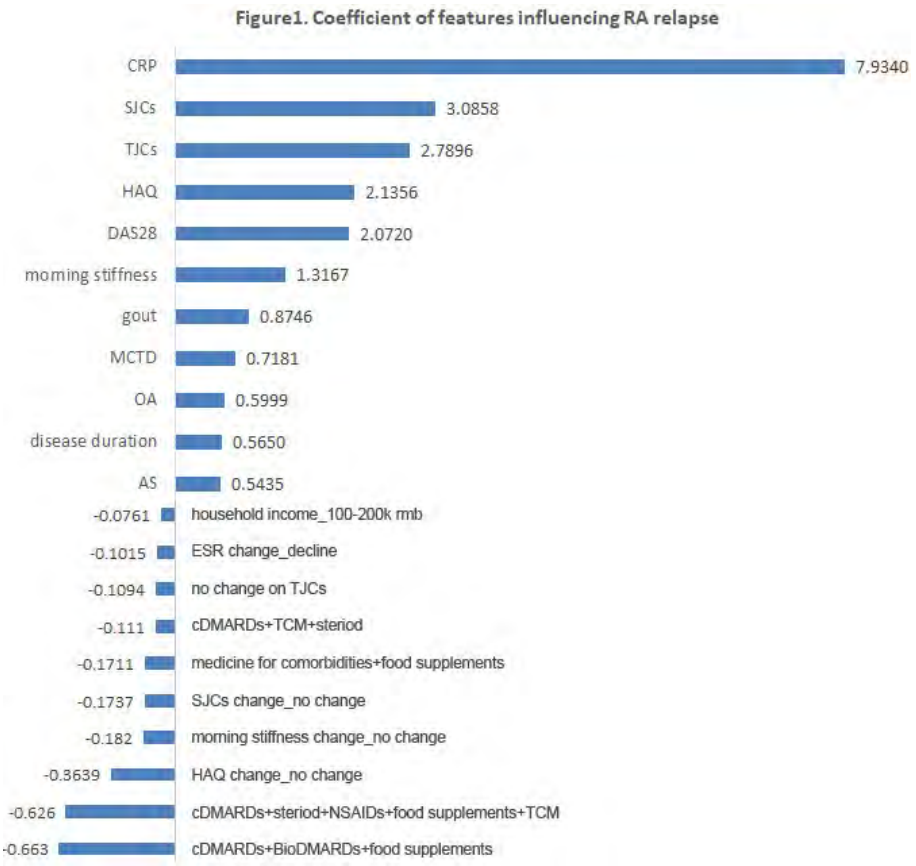

Figure 1. Coefficient of features influencing RA relapse.

Background/Purpose: Flare, relapse from status of treat-to-target (T2T, DAS28< =3.2), is hard predicted. We try to make it predictable by applying machine learning to a database from smart system of disease management (SSDM). SSDM is an interactive mobile disease management APPs. The aim of this study is to develop and validate machine learning algorithms for flare prediction in RA.

Methods: Patients were trained using SSDM and input their data, including demographic, comorbidities (COMBs), lab test, medications and monthly self-assessments, including DAS28, HAQ, SF-36, Hospital Anxiety and Depression Scale (HADS). The data was uploaded to cloud and synchronized to the mobile of authorized rheumatologists. The COMBs were by ICD-9, and medications were listed as cDMARDs, Bio (BioDMARDs), NSAIDs, Steroid, FS (food supplements), MC (medicine for COMBs), TCM (Traditional Chinese Medicine), and combinations.

Results: From Jan of 2015 to Jan of 2020, 8811 RA patients, 85% female and 15% male, used to reach T2T. 4556 were flare-free and 4255 suffering at least one flare. The average 160 attributes were extracted from each flare-free patient at time of reaching T2T, and each flare patients at time of 3 months before the flare. Patients were randomly assigned as model setup (training) group (70%) and validation (testing) group30%.

For training, data were processed using Python with statistical analyses in R. In R, random forests were implemented. Logistic regression via glm in base R. The random forest comprises a set of decision trees. “Splits” in the decision trees reflect binary (i.e., yes/no) respect to attributors. Bootstrapping was used to assess, quantify, and adjust for model optimism. Model performance was evaluated using AUC, precision and recall metrics. Brier scores for accuracy of probabilistic predictions ranged from 0 to 1 (0 is perfect discrimination).

The testing showed model performance for prediction windows are 0.78 for AUC (95% CI), 0.71 for Recall (sensitivity), 0.195 for Brier score, and 0.68 for precision (true positive 893, false positive 417, false negative 367, true negative 966).

Based on weighing in the random forest, the top 10 pro-flare attributes were CRP, swollen joint count (SJC), tender joint count (TJC), HAQ, DAS28, morning stiffness, gout, MCTD, OA, duration; while top 10 anti-flare attributes were cDMARDs+Bio, cDMARDs+steroid+NSAIDs, stable on HAQ, on morning stiffness, on SJC, medicine on COMBs, cDMARDs+TCM, stable on TJC, on ESR, income at 100-200k (Fig.1). The top weighing COMBs for pro-flaring were gout (0.81), MRD (0.75), OA (0.56), AS (0.48). The monotherapies with either Bio or NSAIDs, or steroid, or TCM was pro-flare; while with cDMARDs was anti-flare (-0.21).

Conclusion: The attempt to develop a machine learning algorithm for RA flare prediction is successful. The discrimination was acceptable. The attributes of both pro-flare and anti-flare are identified, which may inspire the proactive intervention.

A Feasible and Efficient Approach to Implementing Rheumatoid Arthritis Disease Activity Measure in a Busy Rheumatology Clinic: A Quality Improvement Project

Ali H.Ali[1], Amani Elghafri[2], Mosaab Mohameden[3], Mandeep Sidhu[2] and Candice Reyes Yuvienco[4], [1]University of California San Francisco Fresno, Fresno, CA, [2]University of California San Francisco Fresno, Fresno, [3]University of Cincinnati, Cincinnati, OH, [4]University of California San Francisco Fresno, Clovis, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment of Rheumatoid Arthritis (RA) has witnessed a substantial change over last the 20 years, with disease remission becoming an achievable goal. Treat-to-target philosophy, which shows improvement in outcome, is the recommended approach to managing RA. This includes regular evaluation of the disease activity and adjusting patient's therapy as necessary to achieve the target of remission or low disease activity. The American College of Rheumatology recommends five tools for the measurement of disease activity in RA. Patient Activity Score II (PAS II) is one of these validated tools that quantify disease activity using patient-reported outcomes (PROs). Using these tools consistently can help guide therapy plans to achieve treat-to-target approach. We aim to enhance the use of PAS II in a busy rheumatology clinic using animation video and infographics.

Methods: The project was conducted over a 10-month period and was divided into two months pre-intervention period and eight months intervention period. Pre-intervention data about the use of any disease activity measure scale for all RA patients who were seen in the rheumatology clinic were collected. The intervention included distributing infographics (figure 1) and an animation video (see the link below) that explains the project to our rheumatology clinic

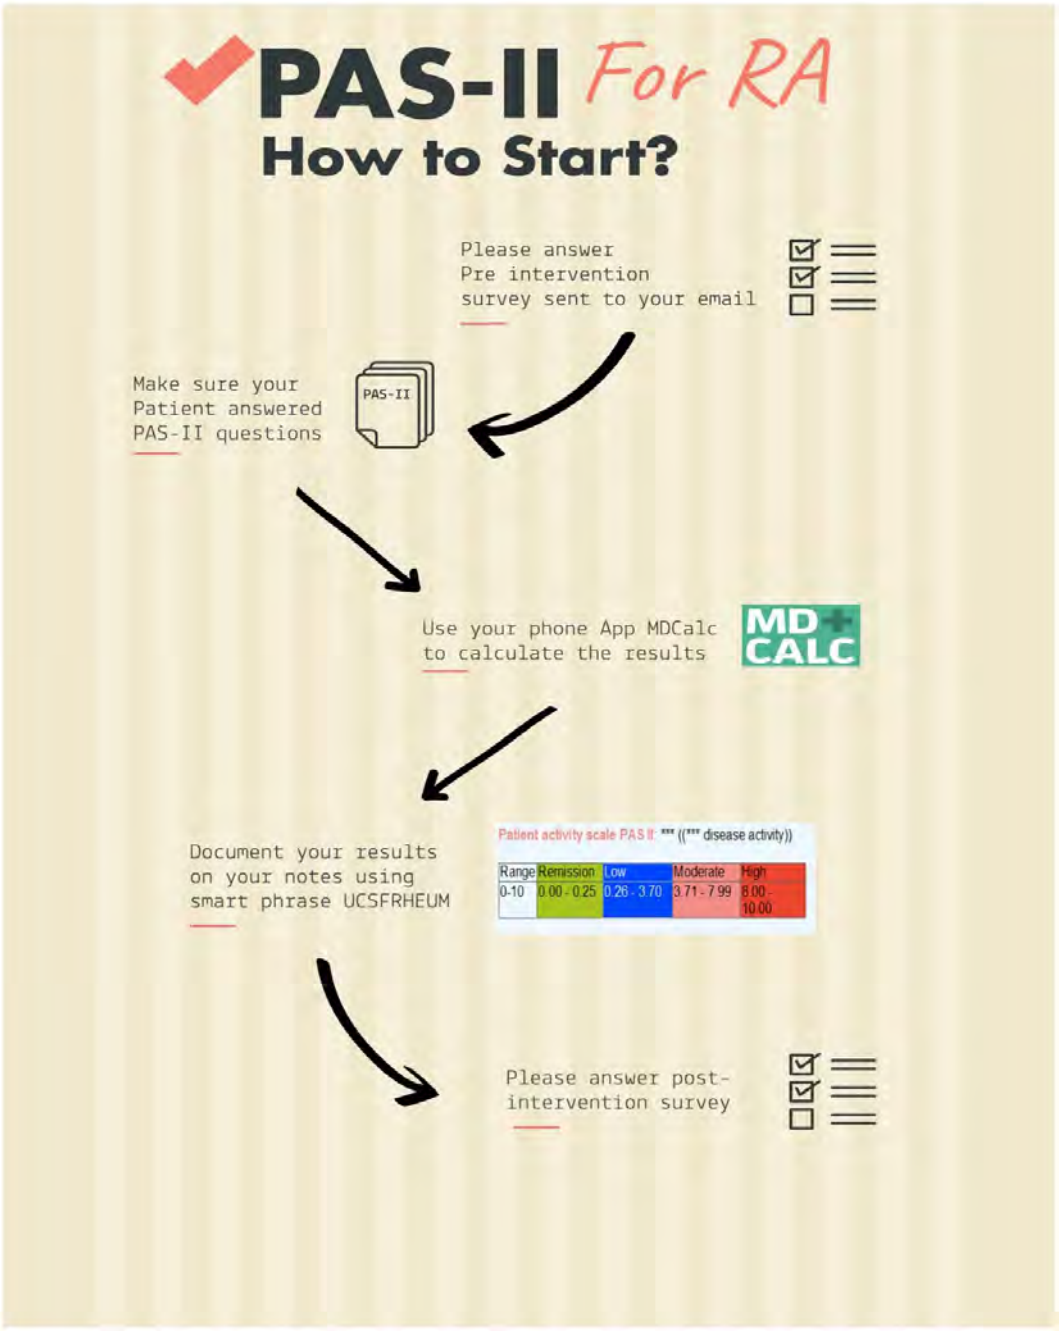

Figure 1. Workflow infographic

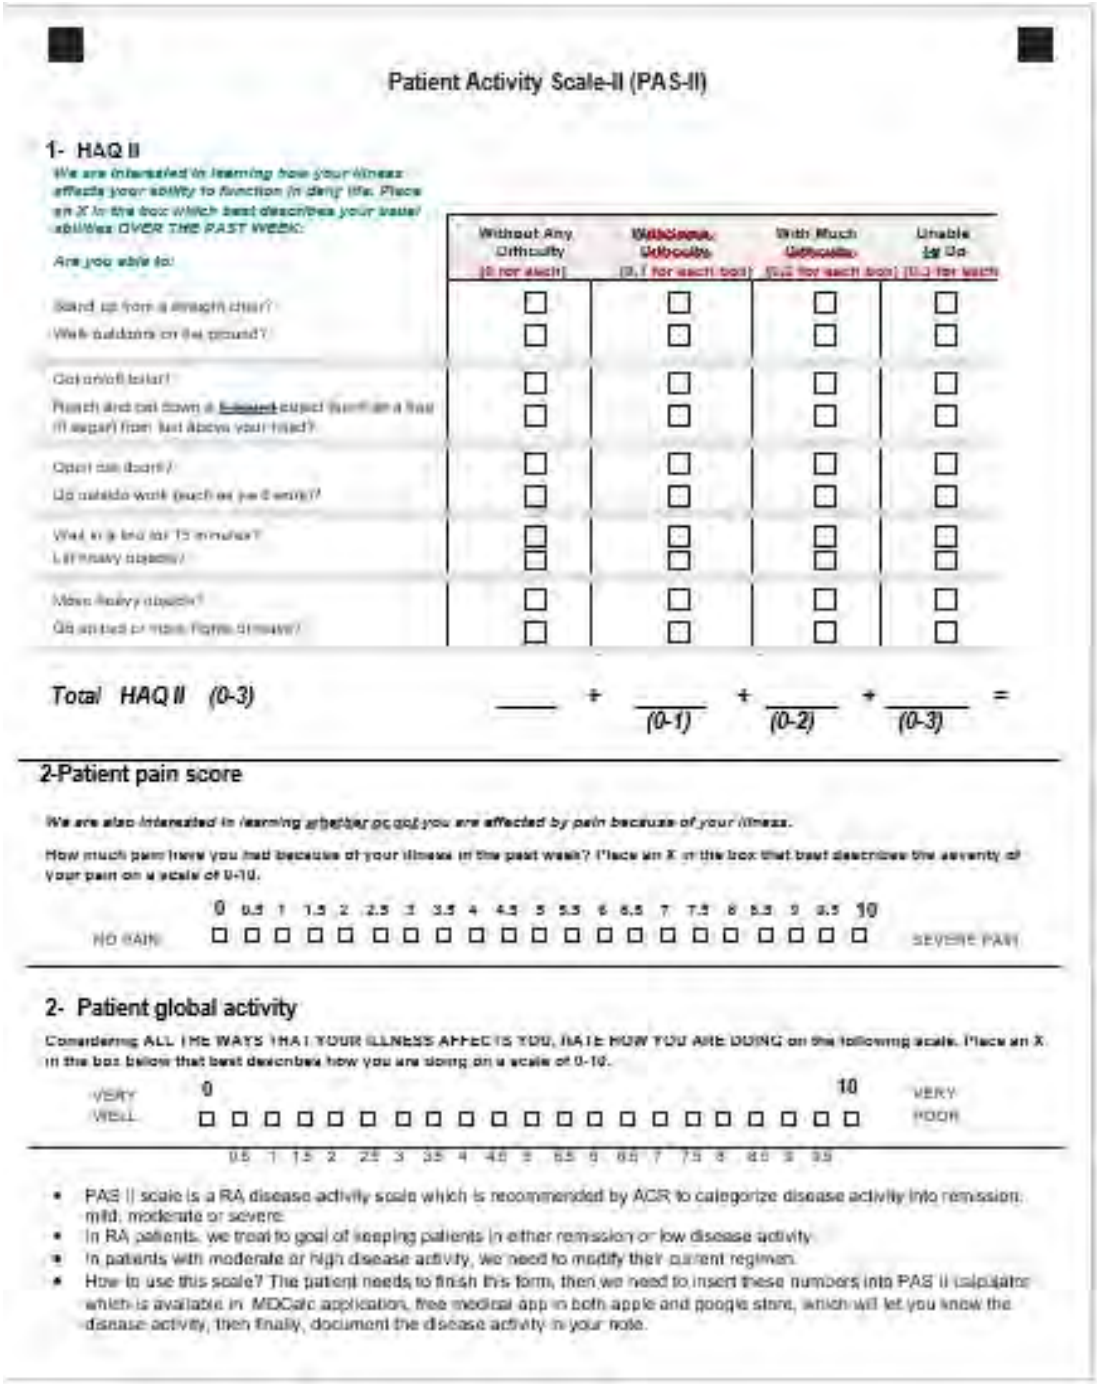
providers. These were sent through emails and provided on-site our rheumatology clinic providers. The clinic staff received a brief session about the workflow process. PAS II questionnaire (figure 2) was distributed to all RA patients who have confirmed RA diagnosis to complete at the time of check-in. MDCalc (A free medical mobile application) was used by providers to calculate the PAS II score and insert the results in the visit note. The intervention period data about the use of PAS II was collected and compared with the pre-intervention data.

Results: Pre-intervention data showed that 4% (1/24) of RA patients had a documented disease activity measure in their charts. Intervention period data showed that 106 RA patients were seen in our clinic and 76% (81/106) had a documented PAS II scale in their charts. Most of them were seropositive 88%. In terms of disease activity, 56% had



Patient Activity Scale-II (PAS-II)

1- HAQ II

We are interested in learning how your illness affects your ability to function in daily life. Place an X in the box which best describes your usual abilities OVER THE PAST WEEK:

Are you able to:

	Without Any Difficulty (0 for each)	With Some Difficulty (0.7 for each box)	With Much Difficulty (1.3 for each box)	Unable to Do (1.3 for each)
Stand up from a straight chair?	☐	☐	☐	☐
Walk outdoors on flat ground?	☐	☐	☐	☐
Get on/off toilet?	☐	☐	☐	☐
Reach and get down a 5-pound object (such as a bag of sugar) from just above your head?	☐	☐	☐	☐
Open car doors?	☐	☐	☐	☐
Do outside work (such as yard work)?	☐	☐	☐	☐
Walk in a line for 15 minutes?	☐	☐	☐	☐
Lift heavy objects?	☐	☐	☐	☐
Move heavy objects?	☐	☐	☐	☐
Do sports or more rigorous activities?	☐	☐	☐	☐

Total HAQ II (0-3) ____ + ____ (0-1) + ____ (0-2) + ____ (0-3) =

2-Patient pain score

We are also interested in learning whether or not you are affected by pain because of your illness.

How much pain have you had because of your illness in the past week? Place an X on the box that best describes the severity of your pain on a scale of 0-10.

0 0.5 1 1.5 2 2.5 3 3.5 4 4.5 5 5.5 6 6.5 7 7.5 8 8.5 9 9.5 10

NO PAIN ☐ SEVERE PAIN

2- Patient global activity

Considering ALL THE WAYS THAT YOUR ILLNESS AFFECTS YOU, RATE HOW YOU ARE DOING on the following scale. Place an X in the box below that best describes how you are doing on a scale of 0-10.

VERY WELL 0 ☐ 10 VERY POOR

0.5 1 1.5 2 2.5 3 3.5 4 4.5 5 5.5 6 6.5 7 7.5 8 8.5 9 9.5

- PAS II scale is a RA disease activity scale which is recommended by ACR to categorize disease activity into remission, mild, moderate or severe.
- In RA patients, we treat to goal of keeping patients in either remission or low disease activity.
- In patients with moderate or high disease activity, we need to modify their current regimen.
- How to use this scale? The patient needs to finish this form, then we need to insert these numbers into PAS II calculator which is available in MDCalc application, free medical app in both apple and google store, which will let you know the disease activity, then finally, document the disease activity in your note.

Figure 2. PAS II questionnaire

moderate disease activity, 23% had high disease activity and 21% were in remission or had low disease activity. We noticed that 45% of our RA patients are on biologics and 92% of these patients have PAS II scale in their charts.

Conclusion: We achieved our goal of implementing and maintaining the use of PAS II in a busy rheumatology clinic efficiently through the usage of infographics, simple animation video, PAS II questionnaire paper form, free mobile application, and single educational sessions for rheumatology clinic staff. We believe that our project may be applicable to other busy clinics as it is efficient, cost-effective, and feasible. PROs measures such as PASII, when consistently and judiciously used, may also help facilitate the acquisition of highly expensive biologic treatments that would have

Video link: https://vimeo.com/329981657

Video link and Bar code

encountered extreme health insurance coverage hurdles. Furthermore, regular documentation of disease activity can help researchers who target RA treatments to collect and analyze data more efficiently and more uniformly.

Abstract Number: 1725

An Investigation of the Relationship Between Patient Reported Outcomes and Biomarkers in a Community Rheumatology Practice

Elston He[1], Pratyusha Yalamanchi[2], William Arnold[3] and **Erin Arnold**[4], [1]Synovium, Inc., Philadelphia, PA, [2]Michigan Medicine, Ann Arbor, MI, [3]Retired, Wilmette, IL, [4]Private Practice, Orthopaedics and Rheumatology of the North Shore, Wilmette, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease presentation and progression in rheumatoid arthritis (RA) is highly heterogeneous and requires careful consideration of outcome measurements to be used for individual patients. Here we explore the relationship between disease activity as measured by a standard patient report outcome measure (RAPID3) and multi-biomarker disease activity score (MBDA) across patient phenotypes and therapy regimens within a single community rheumatology practice.

Methods: Unstructured and structured de-identified data from 2019 of patients who satisfied ACR classification criteria for rheumatoid arthritis, were extracted from the electronic health record, including patient demographics, medication history, comorbidities, laboratory values, patient-reported outcomes, swollen joint counts (SJC), and ultrasound evaluation findings (US). The last available disease activity measures were recorded for each patient in

Table 1. Patient Demographics, Comorbidities, and Outcome Measurements Based on Medication Regimens

2019, and stable RA patients were defined as those with no change of DMARD therapy for at least 6 months prior to their last visit in 2019. Differences in patient outcomes and laboratory values were determined based on standard correlation analysis.

Results: Out of 757 RA patients with at least one medication script in 2019, 516 (68%) patients with stable RA were identified. Baseline demographics (Table 1) include mean [SD] age, 61.8 [14.7] years; 80% female; and mean [SD] BMI 28.1 [6.5]. Patient demographics, comorbidities, and outcome measurements based on medication regimens are summarized in Table 1. As shown in Figure 1, patients routinely displayed higher disease activity when measured using RAPID3 as compared to MBDA, and this effect was more pronounced in seronegative patients. While highly significant (p=0.006), the Pearson's correlation coefficient between RAPID3 and MBDA was 0.14 among all patients, and 0.30 among seropositive patients (p=0.0004). There was no significant correlation between RAPID3 and MBDA (p=0.18) among seronegative patients. In the subset of patients maintained on methotrexate or hydroxychloroquine monotherapy, there was also no significant correlation between RAPID3 and MBDA in either MTX or HCQ monotherapy groups (MTX: r = -0.07, p = 0.68; HCQ: r = -0.27, p = 0.18). For patients maintained on bDMARD therapy, there was a significant but weak correlation between RAPID3 and MBDA (r = 0.15; p=0.01). These findings are summarized in Table 2.

Conclusion: Here we characterize the rheumatoid arthritis patient panel in a community rheumatology practice and demonstrate a significant difference between patient reported outcomes (as measured by RAPID3) and serum inflammatory markers (MBDA). Patients frequently had a higher RAPID3 disease activity level compared to their MBDA disease activity level, suggesting the need for a multi-faceted approach to measuring RA disease activity in individual patients. Further studies exploring optimal outcome metrics for different patient phenotypes within rheumatoid arthritis are indicated.

Table 2: Characteristics and Disease Activity Measurement Relationships by Serology Finding		
Characteristic	**Seropositive Patients (n = 137)**	**Seronegative Patients (n = 179)**

Abstract Number: 1726

Assessment of the Components of RAPID3 Patient Reported Outcomes in an Community Rheumatology Practice

Elston He[1], Pratyusha Yalamanchi[2], William Arnold[3] and **Erin Arnold**[4], [1]Synovium, Inc., Philadelphia, PA, [2]Michigan Medicine, Ann Arbor, MI, [3]Retired, Wilmette, IL, [4]Private Practice, Orthopaedics and Rheumatology of the North Shore, Wilmette, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient reported outcomes are integral to measuring patient response to treatment for rheumatoid arthritis (RA). RAPID3 is a patient reported outcome metric that consists of three categories: pain, global assessment of health, and physical functional assessment. Here we investigate the relationship between the components of RAPID3 and serum biomarkers as measures of disease activity among RA patients within a private rheumatology practice.

Methods: Unstructured and structured de-identified data from 2019 of patients who satisfied ACR classification criteria for rheumatoid arthritis were extracted from the electronic medical record, including medication history, laboratory values, and patient reported outcomes. The last available RAPID3 composite score, RAPID3 component variable scores, and multi-biomarker disease activity (MBDA) values were recorded for each patient in 2019. Stable RA patients were defined as those with no change of DMARD therapy for at least 6 months prior to their last visit in 2019. Relationships between variable and aggregate scores were determined based on standard t-test and correlation analysis.

Results: Among a total of 516 patients with stable RA, 477 patients had available RAPID3 composite and component variable scores, and 407 patients had MBDA values. There was a weak, though significant correlation between RAPID3 composite score and MBDA score (Pearson's correlation coefficient 0.16; p=0.0012). Considering the component RAPID3 variables, pain scale and patient global score were most highly correlated (r=0.83; p< 0.0001), while physical functional was the least correlated, with r=0.61 (p< 0.0001) and r = 0.59 (p< 0.0001) between patient global and pain, respectively. Interestingly, patient global and pain scores were not significantly different (p=0.36), but physical function assessment scores were significantly different from both patient global and pain assessments (p< 0.0001; p< 0.0001, respectively). The distribution of component variable scores is shown in Figure 1. Comparing the components of RAPID3 with the composite RAPID3 score, physical function was the least correlated of the three (r=0.77; p< 0.0001). All three component variables of RAPID3 had significant correlations with MBDA, with physical function assessment score as the most significantly correlated (r=0.18; p< 0.0001).

Table 1: Correlation Matrix Between Each RAPID3 Component, RAPID3, and MBDA (Pearson's correlation coefficient [p-value])

Characteristic	Patient Global	Pain Score	Physical Function	RAPID3	MBDA
Patient Global		0.83 (<0.0001)	0.61 (<0.0001)	0.94 (<0.0001)	0.14 (0.005)
Pain Score			0.59 (<0.0001)	0.93 (<0.0001)	0.13 (0.005)
Physical Function				0.77 (<0.0001)	0.18 (<0.0001)

Table 1. Correlation Matrix Between Each RAPID3 Component, RAPID3, and MBDA (Pearson's correlation coefficient [p-value])

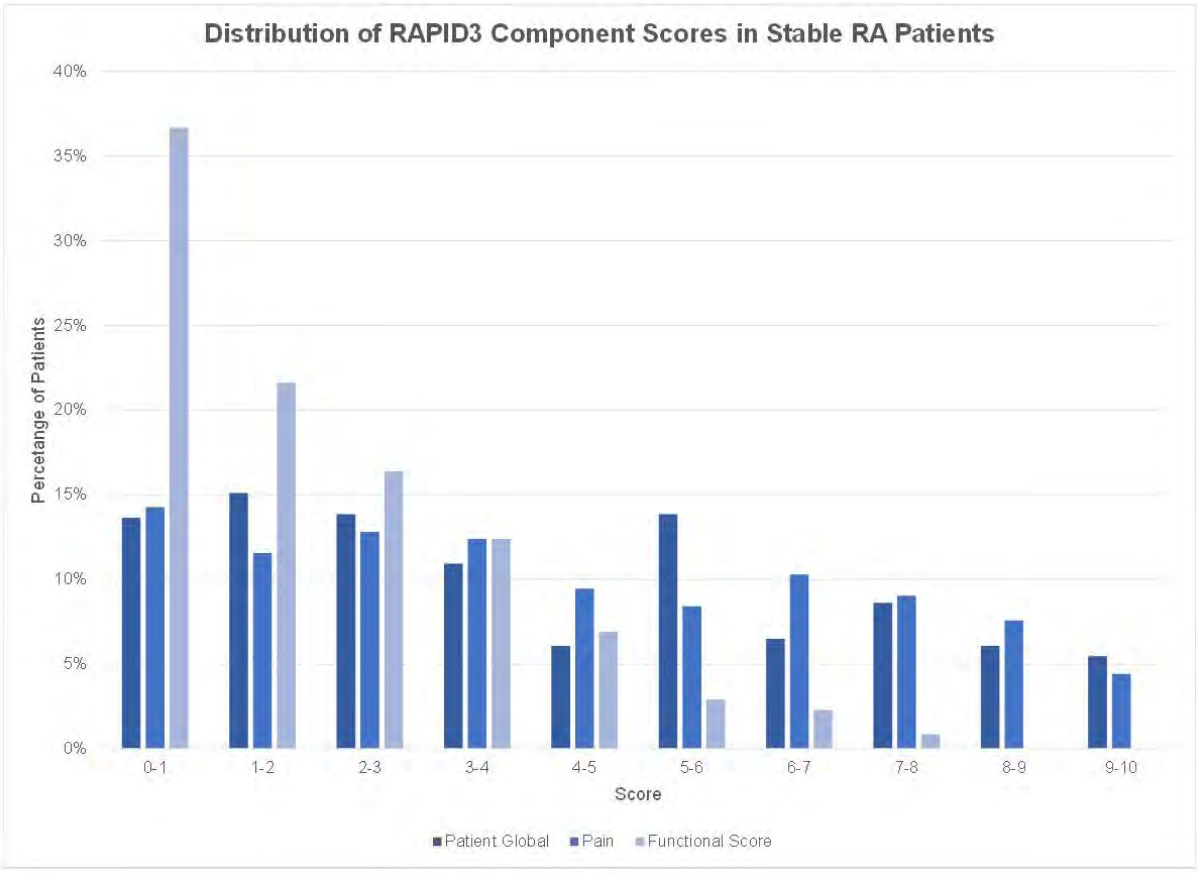

Figure 1. Distribution of RAPID3 Component Scores in a Stable RA Population

Conclusion: Here we identify a strong positive correlation between patient reported outcomes for the categories of pain and global assessment in the RAPID3 assessment among a large rheumatoid arthritis patient panel within a community rheumatology practice. While pain and patient global assessment appear to be the primary drivers of overall RAPID3 scores, the functional component of RAPID3 more closely correlates with serum biomarkers reflecting inflammation such as the MBDA. While RAPID3 reflects patient pain and response to pain, it fails to correlate with markers of inflammation like the MBDA score, which drive changes in medication regimen in our own practice. Further research is needed to understand the relationship between RAPID3 and serum inflammatory markers in various patient phenotypes within the rheumatoid arthritis patient population.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: to determine and characterize fatigue trajectories over 10 years of follow-up in a cohort of early RA patients.

Methods: We selected patients fulfilling the 2010 ACR/EULAR criteria for RA included in the ESPOIR cohort. Cluster analysis with Ward's method was used to obtain fatigue trajectories over the course of 10 years from enrolment. To evaluate differences between baseline variables and fatigue trajectories, Chi-square analyses and ANOVA were used. A multivariate linear regression model with repeated measures was developed to determine the relationship between score of fatigue and other variables over 10 years of follow-up.

Results: We analysed 598 patients. Cluster analysis revealed 3 trajectories: high (18%), moderate (52%) and low fatigue (30%). At baseline, patients with high fatigue trajectory reported significantly higher duration and intensity of morning stiffness, higher HAQ score, higher number of tender joints, higher levels of pain, higher number of awakenings due to arthritis, higher DAS28 levels, increased psychological distress and higher levels of physician and patient global assessment than patients with moderate or low fatigue trajectory (Table 1).

The multivariate linear regression mixed model confirmed that young age, increased psychological distress, high pain level, high morning stiffness intensity, high levels of patient and physician global assessment were related to high levels of fatigue over time (Table 2).

Conclusion: Baseline clinical measures and baseline patient-reported measures of functional status better distinguished the three fatigue trajectories. We did not find differences between trajectories in baseline laboratory measures. Patients with higher levels of pain, psychological distress, morning stiffness intensity also experienced more severe fatigue over time.

Table 1. Baseline chactereristics by fatigue trajectory groups

	Trayectory groups

Patient-Reported Outcomes of Upadacitinib versus Abatacept in Patients with Rheumatoid Arthritis and an Inadequate Response to Biologic Disease-Modifying Antirheumatic Drugs: 12-Week Results of a Phase 3 Study

Martin Bergman[1], Jeffrey Enejosa[2], Naomi Martin[2], Jessica Suboticki[2], Debbie Goldschmidt[3], Yan Song[3] and Namita Tundia[2], [1]Drexel University College of Medicine, Philadelphia, PA, [2]AbbVie Inc., North Chicago, IL, [3]Analysis Group, Inc., Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with active rheumatoid arthritis (RA), treatment with upadacitinib (UPA) has resulted in clinically meaningful improvements in patient-reported outcomes (PROs). This *post hoc* analysis of SELECT-CHOICE (NCT03086343), a phase 3, double-blind randomized clinical trial, evaluated the benefits of UPA vs intravenous (IV) abatacept (ABA) with background conventional synthetic DMARDs (csDMARDs) on PROs in patients with active RA and inadequate response or intolerance to biologic DMARDs (bDMARD-IR).

Methods: Patients in SELECT-CHOICE received UPA (oral 15 mg once daily) or ABA (IV) while on stable csDMARD therapy. PROs included: Patient Global Assessment of Disease Activity (PtGA) by visual analog scale (VAS), patient's assessment of pain by VAS, Health Assessment Questionnaire Disability Index (HAQ-DI), duration and severity of morning (AM) stiffness, 36-Item Short Form Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy-Fatigue, Work Productivity and Activity Impairment (WPAI), and EuroQol 5-dimension 5-level (EQ-5D-5L) index score. Least squares mean (LSM) changes from baseline (BL) to Week 12 were based on an analysis of covariance model. The proportions of patients reporting improvements from BL to Week 12 that were ≥ minimal clinically important differences (MCID) or scores ≥ normative values were calculated for UPA and ABA treatment; comparisons used chi-square tests. Time to response, defined as improvement ≥ MCID, was assessed by Kaplan-Meier analysis and compared using the log-rank test.

Results: Data from 612 patients were analyzed (303 received UPA and 309 received ABA). The mean age was 56 years and mean duration of RA was 12 years. Thirty-two percent received >1 prior bDMARD and 72% received concomitant MTX at BL. At Week 12, UPA treatment resulted in statistically significant LSM changes from BL vs ABA in PtGA, pain, HAQ-DI, severity of AM stiffness, EQ-5D-5L, WPAI activity impairment domain, and in 3/8 SF-36 domains and physical component summary (PCS) score (**Table**). Compared with ABA at Week 12, significantly more UPA-treated patients reported improvements ≥ MCID in HAQ-DI and in 4/8 SF-36 domain scores and PCS score. The proportion of UPA- vs ABA-treated patients reporting scores ≥ normative values were significantly greater in PtGA (37% vs 23%), HAQ-DI (18% vs 10%), EQ-5D-5L (22% vs 13%), and SF-36 PCS (17% vs 8%), including physical

*P<0.05 for UPA vs ABA. P values represent statistical significance between groups. [a]MCID was defined as reduction of ≥10 mm for PtGA and pain, ≥1 for severity of morning stiffness, reduction of ≥0.22 units for HAQ-DI, increase of ≥4 points for FACIT-F, proxied at 1/2 standard deviation for duration of morning stiffness, increase of ≥0.05 points for EQ-5D-5L, reduction of 7% in score for WPAI, increase of ≥2.5 points for SF-36 PCS and MCS, and an increase ≥5.0 for all SF-36 domains. [b]Assessed on a numeric scale of 1–10, with 10 being the worst level. [c]Duration in minutes.

ABA, abatacept; AM, morning; BP, bodily pain; EQ-5D-5L, EuroQol 5-dimension 5-level index score; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; GH, general health; HAQ-DI, Health Assessment Questionnaire Disability Index; LSM, least squares mean; MCID, minimal clinically important difference; MCS, mental component summary; MH, mental health; PCS, physical component summary; PF, physical functioning; PRO, patient-reported outcome; PtGA, Patient Global Assessment of Disease Activity; QD, once daily; RE, role emotional; RP, role physical; SF, social functioning; SF-36, 36-Item Short Form Health Survey; UPA, upadacitinib; VAS, visual analog scale; VT, vitality; WPAI, Work Productivity and Activity Impairment.

functioning (21% vs 11%), bodily pain (33% vs 23%), and general health (24% vs 17%) domains. The median time to response was significantly shorter (P< 0.01) for UPA- vs ABA-treated patients in HAQ-DI (2 weeks vs 4 weeks).

Conclusion: Among bDMARD-IR patients with moderate to severely active RA, treatment with UPA or ABA resulted in clinically meaningful improvements in PROs at Week 12. Overall, greater improvements in PROs especially in the key domains of physical functioning, pain, and general health, were observed with treatment with UPA compared with ABA; improvements in HAQ-DI were observed earlier in UPA- vs ABA-treated patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Disease burden and subjective symptoms of rheumatoid arthritis (RA) remain even after achieving clinical remission or low disease activity. Impairments to work and societal/daily activity are relevant burdens for patients with RA. However, detailed analyses are rarely performed. For exploring a better strategy aiming at less burden beyond Treat-to-Target strategy, it is essential to evaluate details of subjective symptoms collected as patient-reported-outcomes (PROs) and their relationship to work productivity and activity impairment (WPAI). The purpose of this study was to explore patient-reported outcomes (PROs) related to WPAI in patients with RA who achieved clinical remission.

Methods: The Institute of Rheumatology Rheumatoid Arthritis (IORRA) database is an established cohort database with RA in Tokyo Women's Medical University since 2000. RA patients ≥18 years who met the 1987 American College of Rheumatology classification criteria for RA and SDAI remission criteria (SDAI≤3.3) within the IORRA dataset col-

	Pain VAS	Pt-GA	J-HAQ-DI	Duration of MJS

Contribution to variance in WPAI score. WPAI, Work Productivity and Activity Impairment; RA, Rheumatoid arthritis; BMI, Body Mass Index; TJC, Tender joint count; SJC, Swollen joint count; CRP,C-reactive protein; ESR, Erythrocyte sedimentation rate; Ph-GA, Physician's global assessment; CCI, Charlson Comorbidity Index; PRO, patient-reported outcomes; VAS, visual analogue scale; Pt-GA, Patient's global assessment; J-HAQ-DI, Japanese version of Health-care Assessment Questionnaire-Disability Index; MJS, morning joint stiffness

lected in October 2017 were used for this analysis. Pain-VAS [0–100 mm], patients' global assessment VAS (Pt-GA) [0–100 mm], Healthcare Assessment Questionnaire-Disability Index (Japanese version; J-HAQ-DI), and duration of morning joint stiffness (MJS) were evaluated. To measure impact on work productivity during the past 7 days, the WPAI-RA instrument (absenteeism, presenteeism, work productivity loss, and daily activity impairment) was used. Spearman's rank correlation coefficient with 95% confidence interval (95% CI) was calculated to evaluate correlation between each WPAI item and each PRO. To evaluate the degree of contribution of each PRO to WPAI, an ANOVA model was constructed. The contribution of each PRO was calculated based on the sum squares of each PRO divided by total sum squares.

Results: Mean age of the 2,614 patients was 62.4 years; 85.1% were female; and mean DAS28-ESR and SDAI was 2.0 and 1.3, respectively. Mean scores of WPAI were 1.1% for absenteeism (percent work time missed due to RA), 6.5% for presenteeism (percent impairment while working due to RA), 7.4% for work impairment, and 10.2% for activity impairment. Mean pain VAS and Pt-GA were 7.1 and 7.5, respectively, and mean J-HAQ-DI score was 0.3. MJS was reported in 17.6% of patients with a mean duration of 45.3 minutes. Pain VAS showed the strongest pos-

itive correlation with each score of WPAI except for absenteeism (Spearman's rank correlation coefficient [95% CI] 0.52 [0.47, 0.56] for presenteeism, 0.50 [0.45, 0.55] for work impairment, and 0.60 [0.57, 0.63] for activity impairment) (Table 1). MJS contributed the most to absenteeism (18.0%) while pain-VAS contributed the most to presenteeism (57.4%), work productivity loss (51.1%), and daily activity impairment (53.7%) (Table 2). J-HAQ-DI was the second most contributing factor to all scores of WPAI (6.0% for absenteeism, 17.4% for presenteeism, 16.3% for work productivity loss, and 26.0% for daily activity impairment).

Conclusion: Pain-VAS and J-HAQ-DI highly contributed to WPAI. This study indicates that improvement in these PROs may lead to less burden of RA patients in clinical remission.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the abilities of MBDA score, patient global assessment (PGA) and evaluator global assessment (EGA) to assess risk for radiographic progression (RP), and to assess the ability of MBDA score to predict RP among patients with concordant or discordant PGA and EGA.

Methods: Patients were pooled from two RCTs of patients with recent onset RA treated with conventional and biologic DMARDs (OPERA and SWEFOT, N=386) and from a registry of patients with predominantly established RA and diverse treatments (BRASS, N=380). Pearson correlations were determined between MBDA scores (adjusted for the effects of age, sex and adiposity) (scale 1-100), PGA and EGA (each on a scale of 1-10) at baseline. PGA and EGA were considered discordant when they differed by >2.5. Univariate logistic regression assessed ability to predict RP (ΔTSS >5 over 1 year) for MBDA score, PGA and EGA as continuous variables; and for discordance of PGA and EGA as 2-level (concordant vs. discordant) or 3-level (PGA >EGA, concordant, EGA >PGA) categorical variables. Multivariable regression considered the main effect and interaction terms of the MBDA score, as a continuous variable, paired with each other variable, to test the ability of each pair to assess risk of RP. All models included a random effect on cohort. Odds ratios were reported for every 10-unit increase in MBDA score. Frequency of RP was determined in subgroups with MBDA score low (< 30), moderate (30-44) or high (>44) for patient groups based on PGA/EGA concordance or discordance.

Results: The 766 patients studied were 76% female, 76% positive for RF and/or anti-CCP Ab, with mean age 55 years, DAS28-CRP 4.7, CRP 22 mg/L, CDAI 26, SJC 9.1, PGA 4.4, EGA 3.4, MBDA score 53. No interaction was

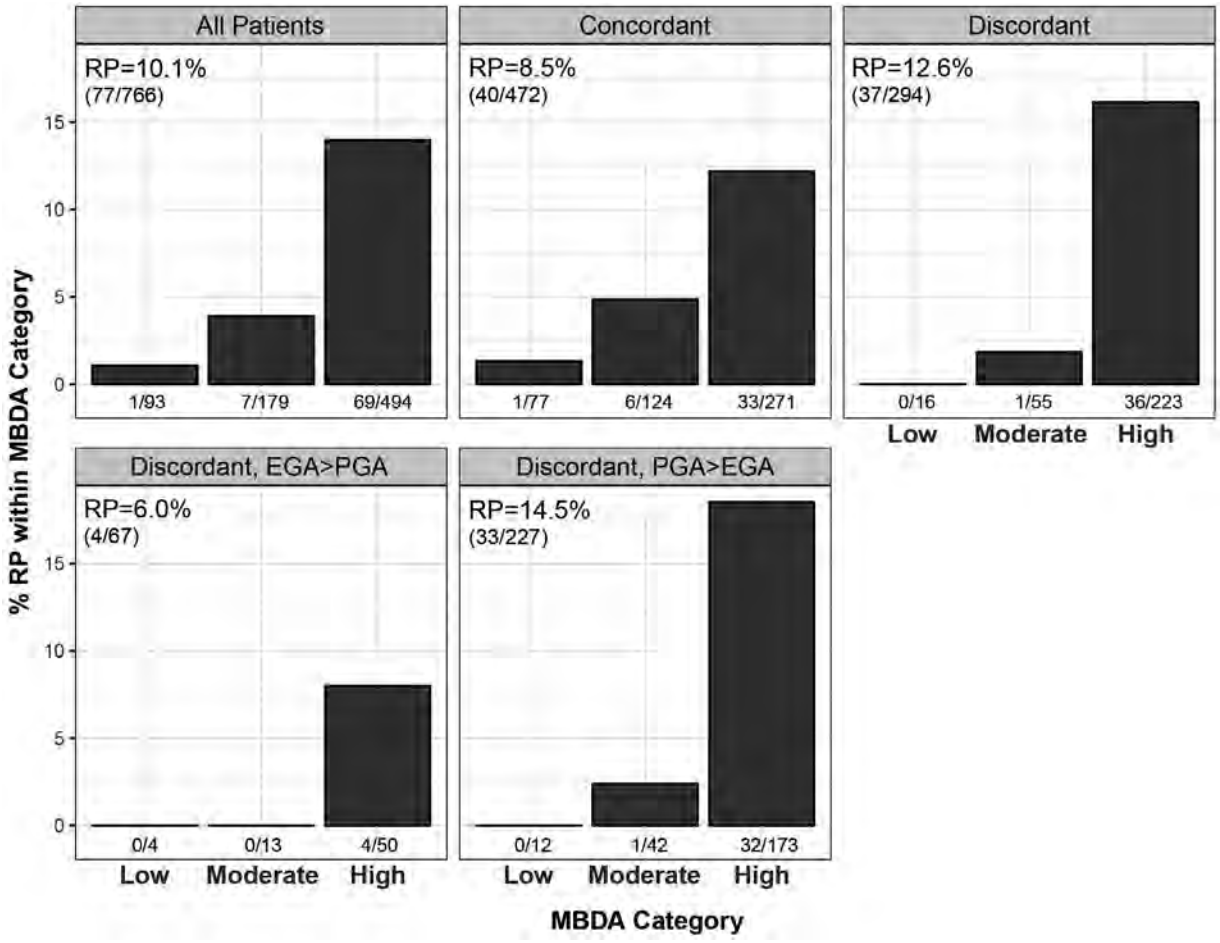

Figure 1. Rate of radiographic progression (RP) by MBDA category for patient groups based on concordance or discordance of Patient Global Assessment (PGA) and Evaluator Global Assessment (EGA).

seen between MBDA score and type of cohort (early vs established RA). PGA and EGA were discordant in 294 of 766 (38%) patients and were weakly to moderately correlated (r=0.38). Among discordant patients, PGA was >EGA in 227 cases and EGA was >PGA in 67 cases. Correlations between MBDA score and PGA or EGA were r=0.41 and r=0.34, respectively. In univariate analyses, MBDA score was a statistically significant predictor of radiographic progression (OR=1.53, $p=6.3x10^{-8}$) whereas PGA, EGA, 2-level discordance and 3-level discordance were not (p=0.38, 0.47, 0.74, 0.83, respectively). In multivariable analyses, significant interactions were observed between MBDA score and discordance (2-level, p=0.0029; 3-level, p=0.0087). The interaction analysis demonstrated, in PGA/EGA-concordant patients, low risk of radiographic progression when MBDA score was low and elevated risk when it was high (OR=1.33 [1.1, 1.59]). A relationship between MBDA score and RP risk was also demonstrated, with heightened trend, among discordant patients with PGA >EGA (OR=2.04 [1.53, 2.81]) and EGA >PGA (OR=3.43 [1.37, 13.8]) (Figure 1).

Conclusion: MBDA score was a significant predictor of radiographic progression, whereas PGA and EGA were not. MBDA score predicted progression whether PGA and EGA were concordant or discordant. These results suggest that MBDA score detects joint-damaging disease activity more accurately than PGA and EGA and it does so whether or not PGA and EGA are in agreement.

Development of a Disease Activity Index for Rheumatoid Arthritis Patients Using the HandScan

Maxime Verhoeven[1], Paco Welsing[1], Janneke Tekstra[1], Jacob van Laar[1], Floris Lafeber[1], Johannes Jacobs[1] and Anton Westgeest[2], [1]UMC Utrecht, Utrecht, Netherlands, [2]Máxima MC Eindhoven, Eindhoven, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease activity in rheumatoid arthritis (RA) patients is usually measured by an index like DAS28,[1] a composite measure consisting of 28 swollen and/or tender joint counts (SJC28/TJC28), an acute phase reactant (APR, e.g. ESR/CRP) and patient's general health, typically using a visual analogue scale (VAS). Particularly assessment of joint counts is time consuming, requires a trained health professional and its inter-observer variety is high. The HandScan is developed to measure inflammation in hand joints using optical spectral transmission (OST, score 0-66) within 5 minutes, without taking time of a health professional.[2] The correlation between DAS28 and a sin-

Table 1 Patient demographics and clinical data

Patient demographics (N=1505)	
Females	976 (65%)
Age in years	65.5 (12.1)
Disease duration in years	11.5 (8.3)
RF positive patients	1068 (71%)
Clinical data	
Number of observations	3358
DAS28	2.5 (1.3)
ESR in mm 1st hr	9.0 (5.0–21.0)
SJC	0 (0 – 2)
TJC	0 (0 – 2)
VAS	30.0 (10.0–50.0)
OST	12.6 (5.0)

Data are n (%), or mean (SD), or median (IQR).

Table 2 Diagnostic values of DAS-OST

DAS28 disease activity state	AU ROC	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)
Remission	0.93	84	86	89	79	85
LDA	0.92	88	75	91	69	85
HDA	0.97	49	99	75	98	98

AU ROC= area under the receiver operating characteristic curve, Remission= DAS28<2.6, LDA= low disease activity (DAS28<3.2), HDA= High disease activity (DAS28≥5.1), PPV= positive predictive value, NPV= negative predictive value.

gle measurement of OST is moderate.[3] We hypothesised that a composite measure consisting of OST (representing joint inflammation), VAS and APR would lead to an appropriate disease activity index.

Objective:

To develop and validate a composite disease activity index for assessing RA patients using OST values obtained by the HandScan.

Methods: At a single Rheumatology centre routinely using the Handscan, RA patients with at least one concurrent OST-score and DAS28 measurement were included. Data was extracted from medical records. A random sample of 2/3 of the patients was used as development cohort, the remaining 1/3 was used as validation cohort. In the development cohort, linear regression analyses with DAS28 as outcome were performed to create a disease activity index (DAS-OST). In these analyses, OST-score, ESR and VAS, as well as gender, age, disease duration and RF-status, were evaluated as predictor variables. A final model was derived, based on statistical significance and model fit. Patients were classified as being in DAS28 based remission, low and high disease activity by DAS-OST using the established DAS28 cut-offs. In the validation cohort, agreement of DAS28 and DAS-OST was estimated with a two-way mixed effect intra-class correlation coefficient (ICC) and the measurement error was estimated using the Bland and Altman method. Diagnostic accuracy were determined for DAS-OST using the cut-offs as defined above for all disease activity states.

Results: Data of 3358 observations within 1505 unique RA patients were extracted. Patients' demographic and clinical data are shown in Table 1.

The formula for DAS-OST derived in the development cohort was: -0.44 + OST*0.03 + male*-0.11 + LN(ESR)*0.77 + VAS*0.03.

In the validation cohort, the explained variance of DAS-OST was 78%. For agreement, the ICC was 0.88 (95%CI 0.87-0.90) and the measurement error was 0.58. Diagnostic accuracy of DAS-OST for DAS28 based remission, LDA and HDA remission is shown in Table 2.

Conclusion: Using the HandScan, disease activity can be accurately estimated in RA patients, when its score is combined with ESR, VAS and gender into an objective disease activity index (DAS-OST).

Machine Learning Coupled with Patient Reported Outcome Data to Classify & Predict RA Disease Activity

Jeffrey R Curtis[1], Fenglong Xie[2], Shelly Kafka[3] and Shawn Black[3], [1]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Janssen Scientific Affairs, LLC, Horsham, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient reported outcome (PRO) data have assumed increasing importance in the care of rheumatoid arthritis (RA) patients. However, physician-derived disease activity measures such as CDAI remain the most-accepted metrics to assess RA. The possibility that newer, longitudinal PRO might proxy for the CDAI has not been evaluated.

Methods: Using data from the Comparative and Pragmatic Study of Golimumab IV vs. Infliximab (AWARE), we evaluated RA patients initiating one of these two therapies who started in moderate or high disease activity and remained under observation through 6 months or stopped due to lack of efficacy. The prediction target was CDAI and CDAI disease activity category at Month 6. Candidate predictors included baseline CDAI, baseline PROs including those from the NIH PROMIS system (e.g. Pain Interference, Fatigue, Physical Function, Sleep Disturbance), and followup PROs at month 1 and 6 (+-30 days). Data were randomly partitioned into training (2/3) and test (1/3) datasets. Multiple machine learning (ML) methods (e.g. Gradient Boosting: XGBoost, Random Forests: RF, elasticnet regularization: ER, support vector machine: SVM) were used to both predict CDAI, and classify CDAI disease activity category (remission/low vs. moderate/high). Feature selection was conducted using R package mlr3 and hyper-parameter tuning was conducted using a random search method. Model performance evaluated cross-validated error comparing different ML approaches using both train and test data.

Results: A total of 391 AWARE patients were analyzed. Of these, the distribution of disease activity by CDAI at month 6 was remission (4.9%), low (26.6%), moderate (31.4%), and high (37.1%). In univariate analysis examining outcomes at 6 months (Table 1), and depending on which modeling method was used, the most important features included

Feature	Attained Remission/LDA by CDAI (n=123)	Remained in moderate/high disease activity by CDAI (n=268)	P value	SMD
Age	60.2 (13.1)	59.3 (13.0)	0.5255	0.0691

XGBoost	0.65	0.71	0.44	0.69	0.35	0.90	0.55	0.76
Support vector machine	0.32	0.94	0.65	0.78	0.18	0.97	0.67	0.76

Table 2. Model performance in Test data

pain intensity, PROMIS measures (social participation, pain interference, pain intensity, and physical function), baseline CDAI, and age. Among all ML methods , random forest performed best. To classify LDA/remission vs. moderate/high based on regression, accuracy ranged from 0.69 (XGBoost) to 0.80 (RF) (Table 2, left). VM, ER, and RF had high specificity, ranging from 0.93 for SVM to 0.99 for RF; but low sensitivity, ranging from 0.26 for RF to 0.38 for ER. XGBoost had adequate sensitivity (0.65) and specificity (0.71). Predicted vs. observed CDAI (Figure) showed some patients had higher observed than predicted CDAI at month 6. Direct classification generated somewhat similar or lower model performance (Table 2, right).

Conclusion: Machine learning methods coupled with longitudinal PRO data appear useful and can achieve 80-90% accuracy to classify RA disease activity among patients starting a new biologic. This approach has promise for

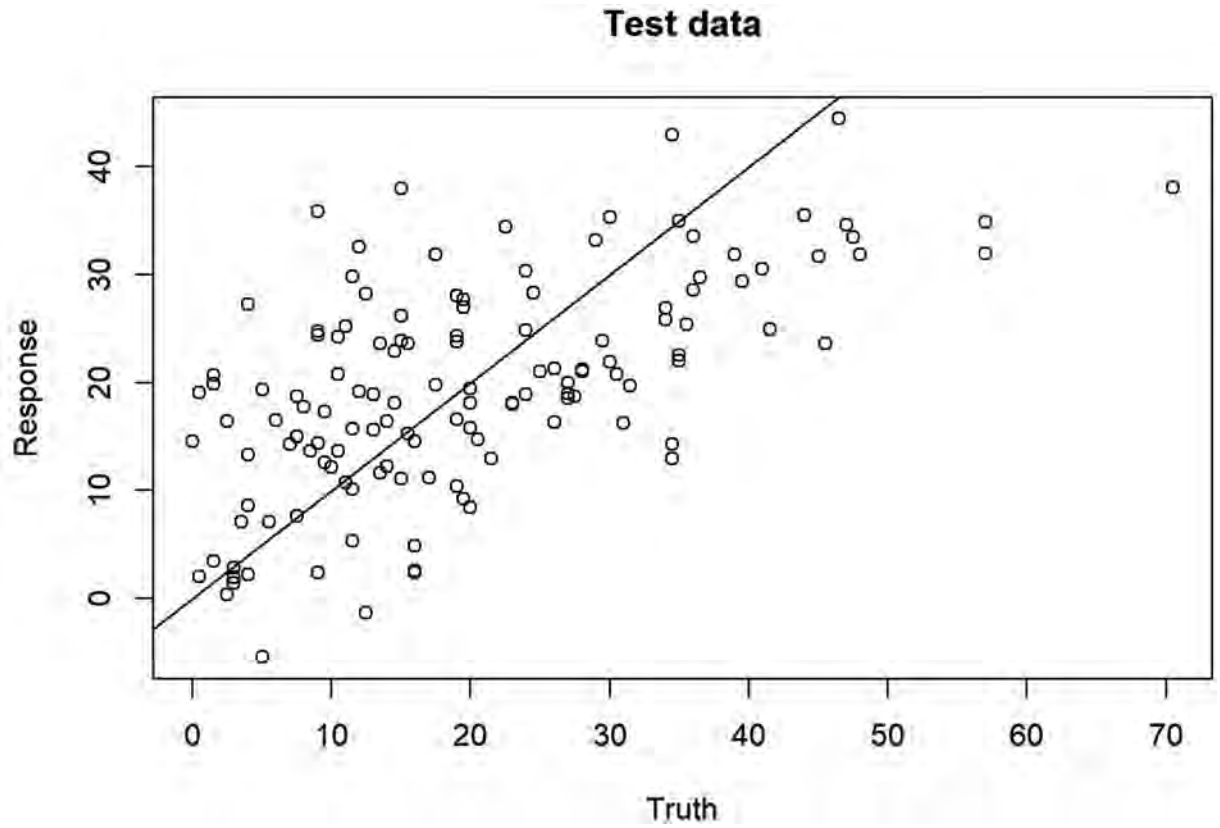

Figure. Predicted vs. Observed CDAI at visit 3 (month 6) by RandomForest

real-world evidence generation in the common circumstance where physician-derived disease activity data is not available yet PRO measures are.

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have higher comorbid depression and/or fibromyalgia (FM) than the general population. A multidimensional health-assessment questionnaire (MDHAQ) includes two queries concerning depression that provide a depression index (MDHAQ-DEP) which gives similar results to 2 widely used depression scales, Patient Health Questionnaire-9 (PHQ-9) and Hospital Anxiety and Depression Scale (HADS-D)[1]. The MDHAQ also provides 2 other indices: 1. RAPID3 (routine assessment of patient index data) to assess clinical status with similar results to DAS28 and CDAI, 2. FAST3 (fibromyalgia assessment screening tool), with similar results

	Range	All patients	Negative MDHAQ-DEP Screen	Positive MDHAQ-DEP screen	p

Table. Mean scores and # of RA patients according to MDHAQ depression (MDHAQ-DEP) negative or positive status

to formal FM criteria. We analyzed routine care RA patients for scores for RAPID3, FAST3, MDHAQ-DEP and 2 depression scales, PHQ-9 and HADS-D.

Methods: RA patients in routine care in Barcelona, Spain completed an MDHAQ, which includes 0-10 scores for physical function (FN), pain (PN), patient global assessment (PATGL), fatigue (FT), 0-48 -report RA disease activity index (RADAI) painful joint count, 0-60 symptom checklist (SX), one of which is depression, and a query concerning depression in the patient friendly HAQ format, scored 0–3.3 to give a 0–9.9 psychological MDHAQ index. MDHAQ indices include 0–30 RAPID3=FN+PN+PATGL, 3 cumulative indices to screen for FM: 0-3 FAST3-P - 1 each for PN ≥6, RADAI≥16, and SX≥16 (2/3=FM), 0-3 FAST3-F - 1 each for FT≥6, RADAI≥16, and SX≥16 (2/3=FM), and 0-4 FAST4 - 1 each for PN≥6, FT≥6, RADAI≥16, and SX≥16 (3/4=FM) and MDHAQ-DEP, based on a positive response on the depression SX query (Yes/No) or a score of ≥2.2 on the HAQ-like depression scale. Patients also completed the 0-27 PHQ-9 (≥10=depression), and 0-21 HADS-D (≥8=depression) scales. We compared RA patients who were MDHAQ-DEP positive and negative according to demographic data, scores for MDHAQ measures, RAPID3 and FAST3 indices, and PHQ-9 and HADS-D depression scales, using Student t tests, Wilcoxon rank-sum tests, chi-square tests or Fisher's exact tests as appropriate.

Results: Among 102 patients, mean age was 58.8 years, mean education level 11.8 years, and 82% were female (Table). Mean RAPID3 was 11.6 (moderate severity), including 8.9 in 68 DEP-negative versus 17.2 in 33 DEP-positive patients ($p< 0.0001$), with similar patterns for all component scores (Table). High or moderate severity was seen in 97% of DEP-positive versus 63% of DEP-negative patients. FM FAST3-P, FAST3-F, and FAST4 screening were positive in 52-64% of DEP-positive vs 15-19% of DEP-negative patients. Scores on PHQ-9 and HADS-D also differed significantly in the 2 groups (Table, $p< 0.0001$).

Conclusion: RA patients positive for depression showed higher mean RAPID3 and FAST indices for FM. These associations must be considered in interpreting RAPID3 scores in clinical care in relation to treat-to-target recommendations.

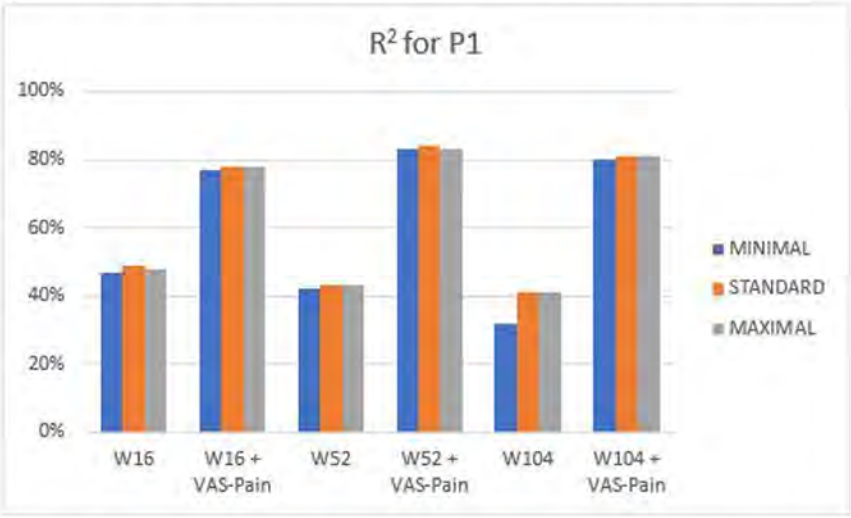
W104 + VAS-Pain	7.0	10.6	9.4	9.4	9.5	8.9	17.9	16.2	21.8

RMSE (0-100) = root mean square error. Lower values indicate better fit. Thresholds lower than 10 in green, between 10 and 20 in orange, and over 20 in red.

Figure 2: Comparison of standard model with minimal and maximal input sensitivity analyses



Sensitivity analyses were regression models (1 - MINIMAL) only including the common predictors from previous models or (2 - MAXIMAL) selecting all predictors present in ≥1 model. Proxy P1 was chosen as example. Results for P2/P3 were similar.

Background/Purpose: Although more effective therapeutics and treatment strategies for Rheumatoid Arthritis (RA) have improved many patient-reported outcomes (PROs), still a sizeable number of patients in clinical remission report reduced wellbeing.Therefore, we explored PROs contributing to wellbeing of patients with early RA.

Methods: Patients from the 2-year pragmatic treat-to-target Care in Early Rheumatoid Arthritis (CareRA) trial were included. Patients were treated intensively, with combinations of csDMARDs and glucocorticoids, except 1 group starting MTX only in a tight-step-up approach.

Eight different validated questionnaires were taken, including the Arthritis Self-Efficacy Scale (ASES), the multidimensional Fatigue Inventory (MFI), the Pittsburgh Sleep Quality Index (PSQI) the Revised Illness Perception Questionnaire (IPQ-R), the Utrecht Coping List (UCL), the Short Form 36 (SF-36), RA Quality of Life questionnaire (RA-QOL) and the Social Support List (SSL). Questionnaires were obtained at baseline, week (W)16, 52 and 104 except for the IPQ and UCL, which were only taken at baseline and W16.

Regression models were constructed to define wellbeing at W16, 52 and 104. Three proxies for patient wellbeing were chosen, on a scale of 0-100: (P1) Patient Global Assessment (PGA) on a Visual Analogue Scale (VAS); (P2) a patient factor derived from a previous principal component analysis combining PGA, pain and fatigue on VAS and the Health Assessment Questionnaire (HAQ)[1]; and (P3) based on the time-weighted average of reconstructed EuroQoL-5 Dimension (EQ-5D) scores based on HAQ, age, pain on VAS and gender[2]. Three patients` groups per time point were created including all patients, patients in remission (DAS28crp< 2.6) and not in remission. As predictors, all subscales of the 8 validated questionnaires, summing to 83 variables, with and without VAS-Pain were used per time point in 54 models in total. Data reduction used forward, backward and stepwise selection based on the Aikake information criteria. Missing data was handled by multiple imputation (n= 15).

Models were validated by randomly splitting the data in a training (75%) and test (25%) set. The root mean square error (RMSE) compared these 2 datasets to test model robustness. We performed sensitivity analyses with regression models (1 - MINIMAL) only including the common predictors from previous models or (2 - MAXIMAL) selecting all predictors present in ≥1 model.

[1]Pazmino et al. Ann Rheum Dis. 2020;79 (S1):578

[2]Pazmino et al. Ann Rheum Dis. 2020;79(5):556-565

Results: In total, 379 patients were included. Overall, 63 of the 83 predictors were used in the regression analyses. Figure 1 shows the complexity versus the predictive capacity per model. Table 2 gives the RMSE per model. R^2 for the original models was between 3-92%, for minimal models 6%-86%, and for maximal models 1%-87%. Figure 2 compares the standard to the sensitivity analyses for PGA.

Conclusion: VAS-pain remains essential in determining patient wellbeing, even in patients in remission where pain levels should be theoretically lower. Determining uniformly patient wellbeing is challenging as different definitions lead to ambiguous results.

Abstract Number: 1735

Effect of Aerobic Land-based Exercise Intervention on Fatigue in Rheumatoid Arthritis: A Systematic Review and Meta-analysis

Samar Aboulenain[1], Arezo Farhangi[2], Elie Donath[1] and Ozlem Pala[3], [1]University of Miami Miller School, West Palm Beach, FL, [2]University of Miami Miller School, Palm Beach Gardens, FL, [3]University of Miami Miller School, Fort Lauderdale, FL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Persistent fatigue can be debilitating for patients with rheumatoid arthritis (RA). Although fatigue partially improves after the initiation of DMARDs, suggesting an inflammatory process, it does not fully resolve with control of the disease activity. There is a glaring need for effective treatment options for the management of fatigue in patients with RA. This study is aimed to evaluate the efficacy of aerobic exercise intervention programs on lowering fatigue levels in patients with RA.

Methods: A systematic review of the literature was conducted through Pubmed, Embase and Cochrane Library from April 2014 to March 2020. This research was partially drawn from a prior meta-analysis/systematic review of the literature in which five studies were identified from 1985 to April 2014. Rongen-van Dartel, S. A., Repping-Wuts, H., Flendrie, M., Bleijenberg, G., Metsios, G. S., van den Hout, W. B., van den Ende, C. H., Neuberger, G., Reid, A., van Riel, P. L., & Fransen, J. (2015). Effect of Aerobic Exercise Training on Fatigue in Rheumatoid Arthritis: A Meta-Analysis. Arthritis care & research, 67(8), 1054–1062. https://doi.org/10.1002/acr.22561 Randomized controlled trials (RCTs) evaluating the effect of supervised land-based aerobic moderate-to-high physical activity on clinical outcomes of adult patients who meet the ACR/EULAR classification criteria of RA were considered for inclusion. Those studies implementing exercise interventions for less than 15 minutes duration in each session, less than two sessions per week, or less than four weeks follow up duration were excluded. Meta-analyses were conducted using fixed-effects modeling to estimate the pooled effect sizes. Standardized mean difference (SDM) and 95%Confidence intervals (CI)

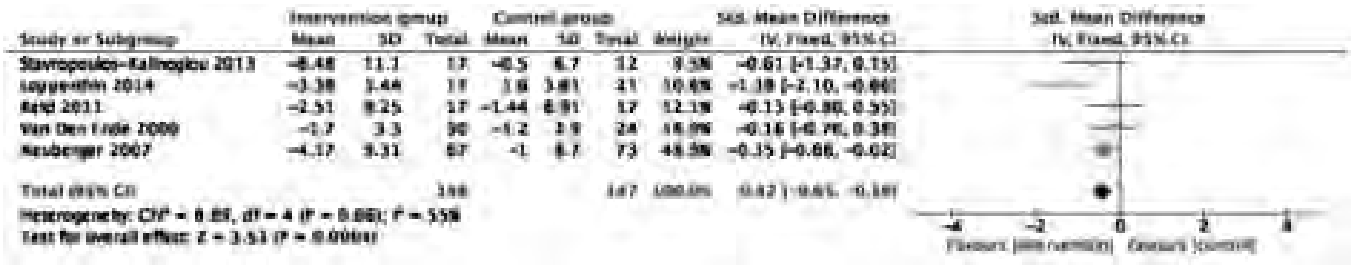

Figure 1. Forest plot of the short-term analysis for the effect of physical activity intervention on fatigue level on patients with rheumatoid arthritis. SD: standard deviation. IV: inverse variance. CI: confidence interval.

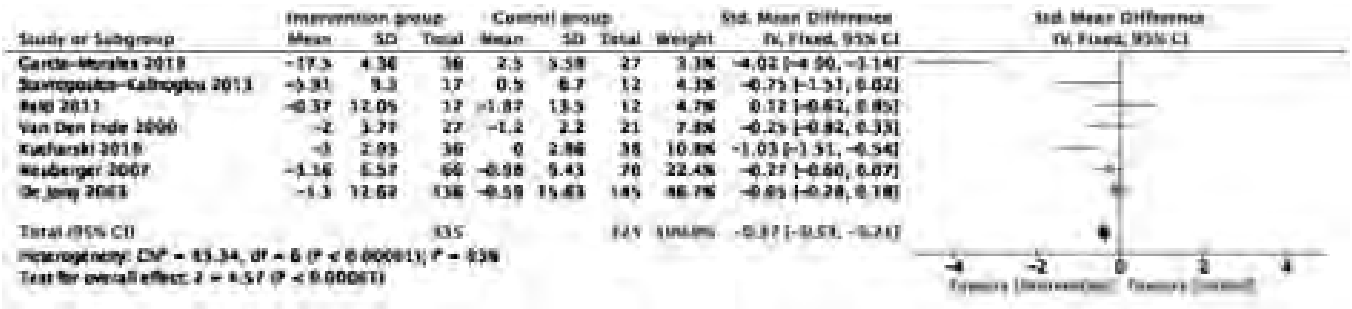

Figure 2. Forest plot of the long-term analysis for the effect of physical activity intervention on fatigue level on patients with rheumatoid arthritis. SD: standard deviation. IV: inverse variance. CI: confidence interval.

are reported at short-term follow up (4-12 weeks) and long-term follow-up (20-24 weeks) after enrollment. Heterogeneity was further explored with I-squared testing and sub-group analyses.

Results: Eight RCTs were selected with a total of 713 participants. There were five and seven studies, respectively, conducting short-term and long-term analyses. Aerobic land-based physical activity interventions were found to improve fatigue score at short-term follow-up (-0.42, 95%CI [-0.65, -0.19], $p < 0.001$) (Figure 1) and long-term follow-up (-0.37, 95%CI [-0.53, -0.21], $p < 0.001$) (Figure 2). Heterogeneity was moderately elevated in the short-term analysis and significantly elevated in the long-term analysis. The high heterogeneity in the long-term analysis was markedly reduced when excluding studies that selected special populations (n=2), including only women in one study or only elderly in the other study.

Conclusion: Moderate-to-high land-based aerobic exercise for at least 4 weeks is an effective intervention to improve fatigue in adult patients with rheumatoid arthritis. Physical activity may have a more potent effect on fatigue in women and elderly patients with rheumatoid arthritis. More RCTs are needed to evaluate the effect of exercise in these special populations.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with RA are at greater risk of mortality than the general population. Higher HAQ disability has been associated with hospitalizations and mortality in established RA; whether HAQ disability predicts mortality in early RA (ERA) is unknown.

Methods: Data were from adult early RA patients (symptoms < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) between 2007 and 2017; who initiated treatment with 1 or more DMARDs and had completed HAQ data at baseline and 1 year. Descriptive statistics, t-tests and chi-square tests were used to summarize and compare baseline patient characteristics including sociodemographic variables, RA characteristics and comorbidities amongst deceased and non-deceased patients. Discrete-time proportional hazards models were used to estimate crude and multi-adjusted associations between HAQ at baseline and 1 year, respectively, with all-cause mortality in each year of follow up.

Results: 1724 patients with early RA; mean age 55 years and 72% female were included. Over 10 years, 62 deaths (2.4%) occurred. Deceased patients had higher HAQ scores and DAS28(disease activity) scores at baseline and 1 year versus the non-deceased group. Age, male sex, lower education, smoking, more comorbidities, higher baseline disease activity and steroid use were associated with mortality in unadjusted survival models. Contrary to HAQ at baseline, the association between all-cause mortality and HAQ at 1 year remained significant even after adjusting for age, gender, comorbidities, disease activity, smoking, education, seropositivity, symptom duration and steroid use in adjusted survival models. HAQ baseline unadjusted hazard OR was 1.46 (CI 1.02-2.09) and adjusted 1.25 (CI 0.81-1.94) vs. HAQ at 1 year unadjusted hazard OR was 2.58 (CI 1.78-3.72) and adjusted 1.75 (CI 1.10-2.77).

Conclusion: Higher self-reported disability (high HAQ) at 1 year was significantly associated with all-cause mortality in a large early RA cohort suggesting that poorer disease control and function in the first year of RA contributes to higher mortality.

What Influences Fatigue Improvement in Rheumatoid Arthritis? A Prospective Cohort Study

Samar Aboulenain[1], Elie Donath[1] and Ozlem Pala[2], [1]University of Miami Miller School, West Palm Beach, FL, [2]University of Miami Miller School, Fort Lauderdale, FL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a common and debilitating complication in patients with rheumatoid arthritis (RA). Its mechanism is not fully elucidated, and when persistent is often challenging to manage. It often does not fully resolve despite treatment with DMARDs thus raising the necessity to uncover other factors that might influence its improvement. This study aimed to explore the characteristics that might have an influence on fatigue improvement in adult patients with RA.

Methods: A single-centered prospective cohort study of patients ≥18 years old who were enrolled in the Corrona RA Registry from 2011 to 2020. Fatigue level was measured using the fatigue Visual Analog Scale (VAS-F) 0-100 at the time of enrollment and 6, 12 and 24 months follow-up appointments. The minimal clinically important difference (MCID) for the fatigue VAS (6.7% change from baseline) was used to assess the change in fatigue level compared to baseline. Univariate and multivariate (adjusting for age, gender and BMI) logistic regression analyses were performed to examine the association between fatigue improvement at 12 months and a wide variety of baseline demographics and disease characteristics.

Results: One hundred and eleven patients with RA were identified, of which 52 reported fatigue scores at 12 months. The median (interquartile range [IQR]) for age was 55 (44-61) years and the majority were Caucasian (67%), females (88%), and with an above-average BMI (71%). The median (interquartile range [IQR]) of the fatigue scores at enrollment and 12 months were 40 (8-70) and 38 (5-58), respectively. At 12 months, fatigue level improved in half of the population (Table 1).

	6 months	12 months	24 months
VAS-F [Median (IQR)]*	35 (5-60)	38 (5-58)	13 (5-52.5)
Improved %	53%	50%	69%
Worsened %	31%	31%	21%
Unchanged %	16%	19%	10%

VAS-F; fatigue Visual Analog Scale. IQR; interquartile range. *Scores reported on a scale of 0-100 mm on which higher numbers indicate greater fatigue.

Table 1. Fatigue score and progression in the study participants at 6, 12 and 24 months compared to baseline.

In a univariate analysis, several predictors were noted to be associated with improved fatigue scores. These included female gender ($p< 0.001$), non-smokers ($p< 0.01$) and increased baseline fatigue levels ($p=0.04$). Several other variables, including depression, showed a trend towards significance. These variables were further investigated by multivariate analyses (adjusting for age, gender and BMI). As may be expected, each additional unit in baseline fatigue was associated with a 2.7% increased likelihood of improvement in fatigue at one year (OR 1.027, 95% CI 1.006-1.048, $p=0.01$). Additionally, non-smokers were found to be highly likely to improve fatigue levels at year-end (OR 7.63, 95% CI 1.11-52.63, $p=0.04$) and those with baseline depression were found to be highly unlikely to improve fatigue levels (OR 0.17, 95% CI 0.03-0.82, $p=0.03$).

Many other variables were examined, and none found to be significantly associated with the outcome of interest including BMI, employment status, physical activity level, pain control, number of comorbidities, duration of RA, change in CDAI score, starting biological DMARDs, or RF and CCP seropositivity.

Conclusion: We observed in this cohort study an improvement in fatigue level in half of the population. Fatigue improvement was associated with female gender, non-smokers, lack of depression and higher levels of fatigue at baseline.

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-Target (T2T) strategy are critical for the treatment of RA, but Chinese rheumatologists can hardly provide patients with a complete assessment in the clinic due to limited time. According to DAS28 scores, disease activity of the cohort was divided into four groups: remission (Rem), low (LDA), moderate (MDA) and high (HDA) disease activity. T2T, achieving a DAS28 score lower than 2.6 (Rem) or below 3.2 (LDA), is the main management strategy recommended by ACR and EULAR. To evaluate the patterns of T2T and related influential factors among RA patients after applying SSDM with repeated self-assessment in the real world.

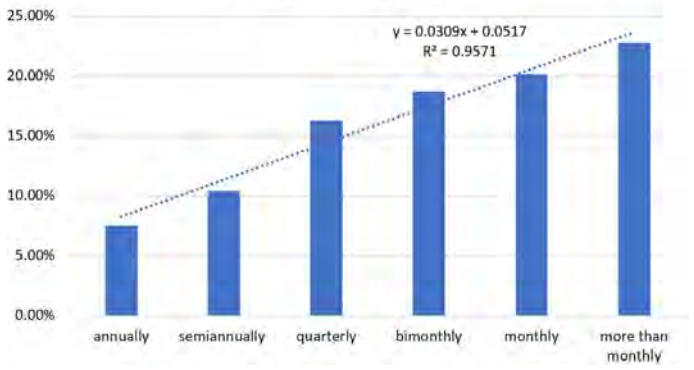
Methods: SSDM is a mobile application for disease management. Patients were trained to do DAS28 assessment with SSDM and required for repeating self-assessment after leaving the hospital. After entry by patients, data can be synchronized to the SSDM terminal of authorized rheumatologists. Based on the patients' data, rheumatologists will provide medical advices to them.

Results: From Jan 2015 to Jan 2020, 68,103 RA patients enrolled in SSDM. The mean age of 51.58±12.86 years old and median disease duration is 3.83 years. 52,355 patients performed self-assessment of DAS28, HAQ and morning stiffness duration totally for 114,792 times. Proportion of patients in Rem, LDA, MDA and HDA was 26%, 17%, 44% and 13% respectively at baseline. Among them, 5,488 RA patients from 219 hospitals across China were followed up for more than 12 months through SSDM.

The rate of T2T achievers were 50.20% (2,755/5,488) at baseline, and improved significantly to 65.14% (3,575/5,488) after 12 months follow up, $p< 0.05$. Among T2T achievers at baseline, 77.20% (2,127/2,755) maintained T2T, 22.80% (628/2,755) relapsed. Of patients who didn't achieve T2T at baseline, only 56.75% (1,551/2,733) achieved T2T after 12 months follow up.

The frequency of self-assessment for DAS28 on T2T has been analyzed. Results indicated that the more frequent of the self-assessments being performed by patients, the higher improvement of T2T rate will be. The improvement rates of T2T in the subgroups which self-assessed with SSDM by annually, semiannually, quarterly, bimonthly, monthly and more frequent than monthly were 7.49%, 10.40%, 16.29%, 18.73%, 20.13% and 22.77% respectively.

Figure 1. The improvement rate of T2T in the subgroups with assessment frequency



The improvement rate (y) of T2T was positively correlated with the frequency of self-assessment for DAS28(x) independently. The regression equation as "y = 0.0309x + 0.0517", r = 0.9785, p< 0.01 (Figure 1).

Conclusion: Significant improvement was observed under applying SSDM through empowering RA patients. After proactive disease management via SSDM for more than 12 months, patients with DAS28< =3.2 score at baseline had a significantly higher retention rate of Rem disease activity. The patients who performed more frequent self-assessments had lower probability of relapse and higher rate of T2T. SSDM is a valuable tool for long term follow-up through empowering patients.

Patients with Early Rheumatoid Arthritis Considered to Have a Favourable Risk Profile and Treated According to a Step-up Strategy Have an Increased Risk of Chronic Analgesic Consumption

Sofia Pazmino[1], Annelies Boonen[2], Diederik De Cock[1], Veerle Stouten[1], Delphine Bertrand[1], Johan Joly[3], Rene Westhovens[4] and Patrick Verschueren[5], [1]KU Leuven, Leuven, Belgium, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]University Hospitals Leuven, Leuven, Vlaams-Brabant, Belgium, [4]University Hospitals Leuven, Belgium, Leuven, Belgium, [5]University Hospital Leuven, Leuven, Belgium

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain remains the highest priority for improvement to patients with Rheumatoid Arthritis (RA). Analgesic prescription in RA was historically a stand-alone approach and afterwards in conjunction with different strategies incorporating early introduction of DMARDs.

We aim to explore the analgesics prescribed in patients with early RA with a favourable risk profile during the first 2 years in the Care in early RA (CareRA) trial.

Methods: Patients with early RA (≤1 year) and a low-risk profile recruited in the 2-year pragmatic investigator-initiated treat-to-target CareRA trial were studied. Low-risk patients (fulfilling 2/3: absence of erosions, negativity to rheumatoid factor and anti-citrullinated protein antibodies, low disease activity score) were randomized to either methotrexate (MTX) 15mg/week with a step-down glucocorticoid (GC) scheme (prednisone 30mg)-COBRA Slim-, or to MTX 15mg/week and no oral GC -Tight-Step-Up-(TSU). All concomitant prescriptions for analgesics for each patient were recorded, including name, dosage, frequency, start/end date and indication as free text. Chronic intake (≥90 days during the trial) of NSAIDs, acetaminophen, or opioids including tramadol, and antidepressants prescribed for musculoskeletal (MSK) pain were considered.

Comparisons were performed with chi-square when appropriate and corrected for multiple testing with Holm's method.

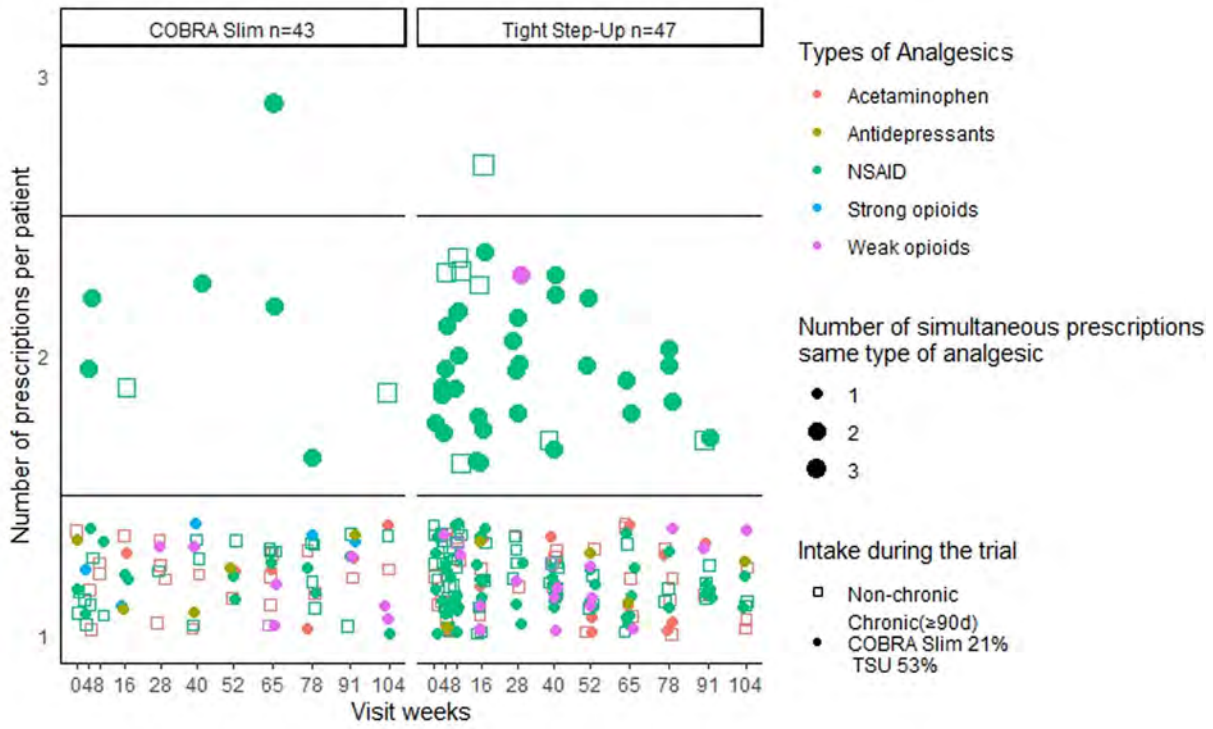

Figure 1. Graphical representation of drug intake at every visit-week during the trial

Results: Of the 90 patients recruited in the *low-risk* group, 43 were randomized to COBRA Slim and 47 to TSU. COBRA Slim, had a total of 67 analgesic prescriptions for MSK pain during the trial for 26/43 (60%) patients of which 9/43(21%) daily chronically (DC). TSU had a total of 107 analgesic prescriptions for 43/47 (92%) patients of which 25/47(53%) DC. At baseline, 18/43 (42%) patients starting COBRA Slim and 28/47 (60%) starting TSU used analgesics (p=0.14). Before the start of the study 33/43 (77%) of patients in the COBRA Slim and 32/47 (68%) in the TSU arm had been using analgesics (p=0.5). The total number of patients on analgesics at any time during the study (p< 0.001) and chronically (p< 0.01) was significantly different between treatment arms. Number of patients DC on NSAIDs was also significantly different (p< 0.05) between COBRA Slim 6/43 (14%) and TSU 19/47 (40%). Figure 1 is a graphical representation of the drug intake at every visit week during the trial. Each mark is a prescribed analgesic per patient, per time point; a bigger mark means more than one prescription of the same analgesic type per patient per timepoint.

Conclusion: Almost every patient in TSU was prescribed an analgesic for MSK pain compared to 60% in the group treated with MTX and a step-down GC scheme (COBRA Slim). Chronic analgesic intake was more than double in TSU. It is notable that even in patients considered to have a favourable risk profile, when the initial treatment did not include oral GC bridging, there was a significant consumption of analgesics becoming chronic for a significant proportion of them. To benefit maximally from the window of opportunity for treating early RA, intensive remission induction strategies (with GCs) should be applied even in patients without traditional factors of poor prognosis.

Determinants of Influenza Vaccine Hesitancy in Rheumatoid Arthritis According to the WHO-SAGE Matrix

Mariana Useche[1], Valeria Valerio[1], Mianbo Wang[2], Elizabeth M. Hazel[3], Pantelis Panopalis[3], Sasha Bernatsky[4], Brian Ward[5] and Ines Colmegna[1], [1]The Research Institute of the McGill University Health Centre, Montreal, Canada, [2]Lady Davis institute for Medical Research, Montreal, QC, Canada, [3]McGill University Health Centre, Montreal, Canada, [4]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada, [5]The Research Institute of the McGill University Health Centre, Monreal, QC, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), influenza infection and its complications are important causes of hospitalization and death. Although routine annual inactivated influenza vaccine (IIV) is recommended in RA, a significant proportion of patients delay the acceptance or refuse vaccines despite the availability of vaccine services (i.e. vaccine hesitancy). Understanding the causes of vaccine hesitancy in RA is key to improve vaccination coverage and thus reduce the burden of influenza.

Methods: Between November and March 2020, we conducted a cross-sectional study of consecutive RA patients presenting to a rheumatology clinic at a large Canadian tertiary hospital. Patients completed a survey on determinants of influenza vaccine hesitancy developed by the WHO-Strategic Advisory Group of Experts (SAGE) on immunization. Questions addressed individual, group, and contextual influences, as well as vaccine-specific issues involved in vaccine acceptance. Patients were classified into 3 groups based on how likely it was for them to get the IIV: 'unlikely' (refused IIV), 'likely' (accepted IIV) or 'uncertain'. Multivariate logistic regression was performed to evaluate factors associated with vaccine refusal.

Results: We studied 101 patients with a mean age (±SD) of 54±19 years, and RA duration 10±8.8 years; 74% were females. Over a third (38%) of the patients did not receive IIV the previous year, and 47% reported not having received the IIV on a yearly basis since RA onset. In total, 58% accepted IIV, 28% refused IIV, and 14% were uncertain. Among the contextual influences of vaccine acceptance: (a) 73% of RA patients trust that the government was making decisions in their best interest with respect to IIV, (b) 29% considered that the IIV should be compulsory, and (c) 42% trust pharmaceutical companies to provide safe and effective flu vaccines. Individual and group experiences identified to influence vaccine acceptance in RA included: (a) previous bad reactions (27%), (b) not enough information about IIV and its safety (37%), (c) concerns about IIV safety (46%), and (d) uncertainty about IIV benefits (39%). Almost half (42%) were willing to pay for IIV, and the same percent (42%) were willing to take time off from work to get the IIV. In multivariate analysis, RA patients who refused IIV were less likely to trust pharmaceutical companies to provide safe and effective vaccines (odds ratio-OR, 95% confidence interval-CI) 43.46 (1.41, >999); and were less likely to consider that IIV should be compulsory 50.89 (1.51, >999).

Conclusion: Over 40% of RA patients living in a universal, publicly funded health-care system have some degree of IIV hesitancy. Contextual and individual influences contribute to this complex and context-specific phenomenon. Actionable hesitancy determinants include those that relate to education on the benefits and safety of the IIV.

Abstract Number: 1741

Does Preventive Care Matter? (in RA)

Morgan Greenwald[1], JoAnn Ball[1], Shannon Lopez[1], Monica Berg[1] and Maria Greenwald[1], [1]Desert Medical Advances, Palm Desert, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Preventive medical care improves morbidity and mortality. The assessment included 28,105 RA patients from prospective randomized trials.

Methods: Nested data from a single site was compared to global data in 34 pivotal studies using immune therapies for RA. Another 5 studies in long term follow up in older RA patients were also analyzed. Data was extracted from NDAs submitted for FDA approval for 5 TNFi therapies, 5 JAKi therapies, rituximab, abatacept, IL-1, and IL-6 therapy. The nested site participated in each study, so entry criteria, age, concomitant medication, and intervention were identical. All subjects fulfilled the ACR criteria for RA and trials had IRB approval. Safety results for the global sites in the NDA are available to the public from accessdata.fda.gov. Safety data of special interest were incidence of death from any cause, MACE, pneumonia, and zoster. The nested site instituted 10 specific preventive care measures. These included:

1) vaccination for influenza, pneumonia, and zoster; 2) hypertensive treatment for blood pressure >140/90; 3) diabetes treatment if HbA1C >9; 4) treatment for uric acid >7; 5) statin therapy if LDL >120; 6) treatment if BMI >30 including staff dietician every 3 months; 7) chewable aspirin 81 mg/d; 8) prenatal vitamin for 1 mg folate; 9) daily sinus wash to decrease URI (NeilMed); 10) no use of corticosteroids or narcotics. All preventive measures were conducted at the nested site.

Results: (tables 1, 2, 3)

Zoster: There were 18,696 subjects in JAKi trials in the global population and 562 at the nested site. Zoster incidence in trials using JAKi decreased between 2005-2020. Key to this decline was Zostavax approval in 2006 and Shringrix approval in 2017. At the nested site, zoster vaccines for all started in 2006.

Pneumonia and Death due to Infection: There were 28,105 subjects in the global population and 924 subjects at the nested site. Pneumonia events were lower in the nested site than the global population, both in the long term trials (ages 63-70) and in the shorter trials (ages 51-53). All nested site subjects had pneumonia vaccination. Deaths due to infection were lower at the nested site (about one third of deaths in RA were due to pneumonia).

Mortality: There were 4469 global subjects and 154 at the nested site in the older population of the long term trials. Mortality was less at the nested site in these older subjects. In the shorter trials with younger subjects, of the 28,105 global subjects and 924 in the nested site, overall mortality was not different.

Mace: MACE events were not better at the nested site for the older population (followed 3-7 years) nor the younger population (followed 6 months to 2 years).

ZOSTER Events Time Line (RA patients on JAKi)

2006 Zostavax approved — 2017 Shringrix approved

	2005	2006	2012*	2020*
Global events	5.8% (CI 4.5-6.7)	4.4% (CI 3.7-9.2)	2.6% (CI 1.6-3.8)	3.4% (CI 0.8-4.9)
Nested site events	12% (CI 1.1-16)	2%* (CI 1-3.3)	1%* (CI 0.2-1.4)	0.7%* (CI .07-1.3)
p	ns	ns	<0.02*	<0.02*
* All patients in the nested site were vaccinated for zoster				

Table 1

Long term JAKi studies f/u for 3-7 years (Avg age 63 at BL to 70 at f/u)

Rate % (95%CI)

Global	Mortality*	Pneumonia*	InfectionDeath*	URI	Zoster*	MACE	Thrombosis*
N= 4969	2.8%(1.1-3.8)	5.6%(4.4-9.3)	1%(0.5-1.4)	47%(41-54)	3.3%(2.9-3.6)	0.9%(0.3-2.0)	1.3%(0.5-1.5)
Nested site							
N = 154	0.3%(0.1-0.8)	0.5%(0.4-0.9)	0	40%(35-47)	0.5%(0.4-0.7)	0.5%(.4-.7)	0.6%(.4-.9)
p value	<0.007	<0.002	<0.002	ns	<0.001	ns	<0.03

*Nested site events were significantly lower for infectious endpoints of pneumonia, infectious deaths, and zoster.
Nested site had lower mortality and thrombotic events over 3-7 years.
JAKi included are tofacitinib, baricitinib, upadacitinib, and filgotinib.
TB was very rare in all studies (<0.2%)
81% female subjects, 22% from USA.

Table 2

Thrombotic events

The nested site had fewer thrombotic events in the JAKi trials and subjects took chewable aspirin 81 mg/d.

Conclusion: This is a causal inference study using prospective data from 39 trials. Vaccination is a likely explanation for less zoster, pneumonia, infectious deaths, and mortality at the nested site. The lack of any data over 10 years limits efforts to measure reduction of uncommon MACE events (control of blood pressure, diabetes, cholesterol and diet). Vaccines are clearly necessary in medical care for RA. Vetted data from NDAs can yield insight for healthcare.

Patients' and Rheumatologists' Perceptions on Preventive Intervention in Rheumatoid Arthritis and Axial Spondyloarthritis

Laurette van Boheemen[1], Janne Bolt[2], Marieke ter Wee[3], Henriëtte de Jong[2], Marleen van de Sande[4] and Dirkjan van Schaardenburg[5], [1]Amsterdam Rheumatology and immunology Center | Reade, Amste, Netherlands, [2]Amsterdam Rheumatology and immunology Center | Amsterdam UMC, Amsterdam, Netherlands, [3]Amsterdam Rheumatology and Immunology Center, location Amsterdam UMC, VUmc, Amsterdam, Netherlands, [4]Amsterdam UMC, AMC/University of Amsterdam, Department of Rheumatology and Clinical Immunology, Amsterdam Infection & Immunity Institute and Amsterdam Rheumatology and Immunology Center (ARC), Amsterdam, Netherlands, [5]Amsterdam Rheumatology and immunology Center | Reade and Amsterdam UMC, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Persons at risk of developing rheumatoid arthritis (RA) may benefit from lifestyle[1] or pharmacological[2] interventions aimed at primary prevention. Although less studied, the same may apply to persons at risk of axial spondyloarthritis (axSpA)[3]. Our aim was to investigate and compare the willingness of individuals at risk of RA or axSpA and rheumatologists to initiate preventive intervention.

Methods: Individuals at risk of RA (arthralgia and anti-citrullinated protein antibodies (ACPA) and / or rheumatoid factor (RF) positivity without arthritis (RA risk cohort; n=100)), healthy first degree relatives of HLA-B27 positive axSpA patients (SpA risk cohort; n=38) and Dutch rheumatologists (n=49) completed a survey on preventive intervention in the at risk phase of RA (RA risk cohort and rheumatologists) or axSpA (SpA risk cohort) which included questions on

Disease risk	At risk of RA (%)	At risk of axSpA (%)	Rheumatologists (%)	At risk of RA versus axSpA	at risk of RA versus rheumatologists
	100% effective medication, no side effects				
30%	53	55	74	p = 0.812	**p = 0.017**
70%	69	92	92	**p = 0.005**	**p = 0.002**
	100% effective medication, minor side effects or immune suppression				
30%	26	29	31	p = 0.727	p = 0.554
70%	40	66	76	**p = 0.007**	**p < 0.001**
	100% effective medication, minor general side effects				
30%	40	47	88	p = 0.433	**p <0.001**
	Medication postpones disease development for 10 years, no side effects				
70%	61	66	57	p = 0.604	p = 0.652

axSpA: axial spondyloarthritis, RA: rheumatoid arthritis

Table 1. Willingness to start preventive medication

disease perception, lifestyle intervention (i.e. smoking, alcohol consumption, exercise and various dietary changes) and preventive medication[4].

Results: Participants considered RA and axSpA to be a serious disease (median VAS (0-10) 6.5 (RA) and 6 (SpA)). Despite some concern about their increased risk, most did not expect to develop the disease (median VAS 3 for both). Participants were willing to change a median of 7 out of 13 lifestyle components in multiple areas, whereas only 35% of rheumatologists gave lifestyle advice to >50% of at risk patients. The willingness to use 100% effective preventive medication without side effects was 53% (RA), 55% (SpA) and 74% (rheumatologists) at a 30% disease risk. This increased to 69% (RA) and 92% (SpA and rheumatologists) at a 70% disease risk. With minor side effects, willingness was 26%, 29% and 31% (30% risk) versus 40%, 66% and 76% (70% risk), respectively. Differences are shown in table 1.

Conclusion: Disease risk perception and willingness to start preventive intervention are similar between patients at risk of RA or axSpA. They seem highly willing to make several lifestyle changes to decrease disease risk and are generally willing to use medication in case of a clearly increased risk. Rheumatologists are overall more likely than at-risk patients to start preventive medication. Lifestyle advice was not given by the majority of rheumatologists contrasting with patients' high willingness to adjust lifestyle.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Optimal perioperative glucocorticoids (GC) dosing for rheumatoid arthritis (RA) patients on chronic GCs undergoing total joint replacement is unknown. Ideal GC dosing prevents perioperative hypotension while also avoiding the complications associated with higher GC exposure. The purpose of this study was to determine whether preoperative GC exposure or perioperative GC dosing was associated with risk of complications in a large cohort of RA patients undergoing TJA.

Methods: A retrospective chart review was performed to identify patients with RA undergoing TJA at a single, high-volume institution. Glucocorticoid usage was recorded for all patients as well as cumulative perioperative GC dose during hospitalization. GC exposure was assessed by the number of doses, single or multiple, and cumulative amount of GC administered over the hospitalization period (in milligrams). Outcomes of interest included incidence of perioperative hypotension and inpatient complications (hyperglycemia, defined as blood glucose level > 180mg/dL, local or systemic infection, and cardiovascular events). Multivariable logistic regression was performed to evaluate the impact of GC dosing on these adverse events.

Results: Four hundred and thirty two RA patients undergoing TJA were included with 233 (54%) undergoing TKA. Mean age was 64±12 years and 78% were women. One hundred and thirty (30%) RA TJA patients were on chronic GC treatment (mean daily dose 7±4mg) and median cumulative perioperative GC dose was 37mg [IQR 27, 57]. Cumulative inpatient dose of GC was not associated with risk for perioperative hypotension during the hospitalization [unadjusted OR 1.00 (0.99-1.01) p=0.66]. Patients who received multiple doses had more post-operative adverse events compared to those who received single GC doses. Multivariable logistic regression adjusting for age, BMI and Charlson Comorbidity Index, showed patients with higher cumulative GC dose had higher risk for short-term complications with every 10 mg increase in GC dosing increasing inpatient complication risk by 8.4%, (p=0.02).

Conclusion: This study of 432 RA patients undergoing TJA found a 32% incidence of chronic preoperative GC usage. GC dosing during the intra- and early post-operative period was not associated with risk of hypotension. However, patients with higher GC exposure were more likely to have hyperglycemia and catheter-associated urinary tract infection (CAUTI). These findings suggest lower GC dosing does not increase risk of hypotensive perioperative events and avoids the increased risk of inpatient complications associated with high GC dosing regiments. Further research is needed to determine the optimal perioperative regimen for patients with RA undergoing arthroplasty.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Persons at high risk of developing rheumatoid arthritis (RA) may benefit from a low-risk pharmacological intervention aimed at primary prevention. Previous studies demonstrated disease-modifying effects of statins in RA patients[1] as well as an association between statin use and a decreased risk of RA development[2]. We designed a multi-center, randomized, double-blind, placebo-controlled trial to investigate if atorvastatin use for 3 years could prevent arthritis. Subsequently, we conducted qualitative research to determine barriers and facilitators for prevention trial participation.

Methods: Individuals at high risk of RA, i.e. arthralgia without arthritis and anti-citrullinated protein antibody (ACPA) >3xULN or both ACPA and rheumatoid factor (RF), were randomized to atorvastatin 40 mg daily or placebo for 3 years. The primary endpoint was clinical arthritis development. The pre-calculated sample size was 220 participants. After trial inclusions were stopped, we conducted focus group interviews with individuals who participated or declined participation in the STAPRA trial or the Arthritis Prevention In the Pre-clinical Phase of RA with abatacept (APIPPRA) trial[3].

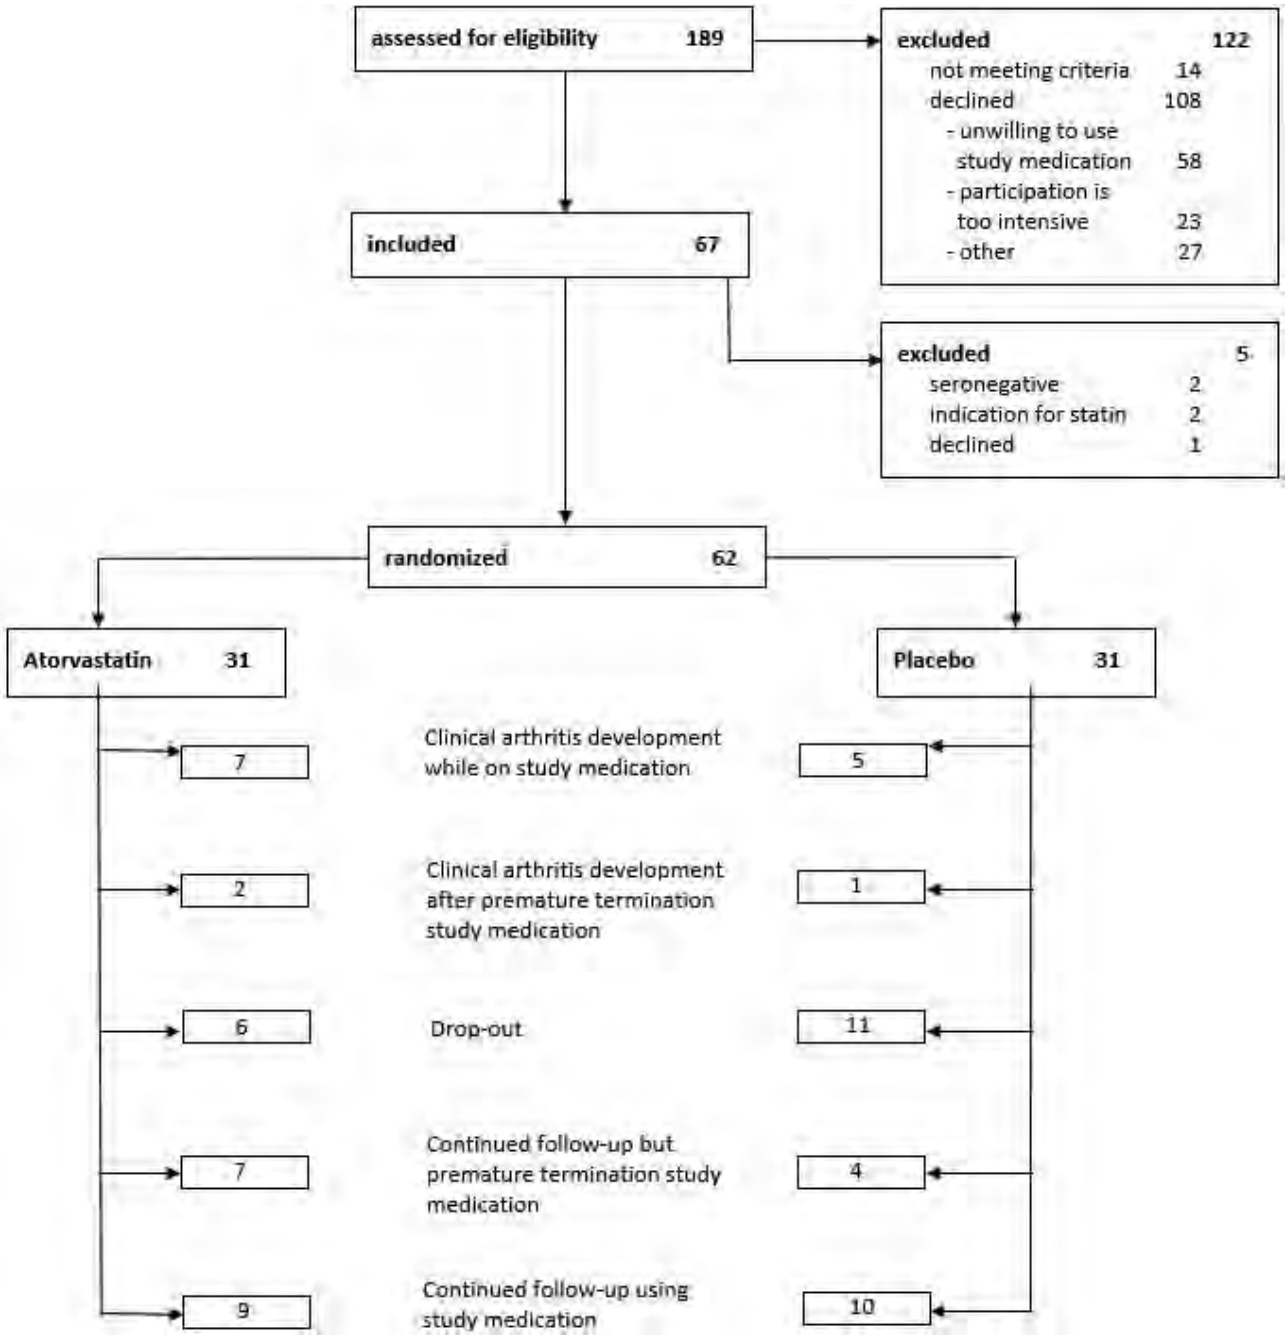

Figure 1. Flowchart STAPRA study

Results: Sixty-seven individuals were included in the STAPRA trial (figure 1). Inclusion was stopped after 38 months due to the low inclusion rate, and analyses were performed 1 year later. Mean age was 48 years, 74% was female, mean follow up was 18 (0-36) months. Fifteen individuals (24%) developed clinical arthritis: 9/31 (29%) in the atorvastatin group and 6/31 (19%) in the placebo group after a median period of 9 (IQR 5.5-26.5) months (atorvastatin) and 4 (0-14.8) months (placebo): HR 0.71, 95% CI 0.3-2.0. In our center, 4 out of 14 eligible individuals participated in the APIPPRA trial. Eighteen individuals participated in the focus group discussions, 3 were asked for APIPPRA of which 1 participated, 15 were asked for STAPRA of which 8 participated. Seven barriers or facilitators for prevention trial participation emerged: (1) trial medication, (2) symptom severity, (3) treatment options, (4) study burden, (5) feeling of acknowledgement (6) own risk assessment and (7) altruism.

Conclusion: The results of the STAPRA trial are inconclusive due to severe difficulties with patient inclusion and low treatment adherence. The focus group study revealed several themes that play an important role in at-risk individuals' decision whether or not to participate in a prevention trial. These should be taken into account when designing preventive trials and will be important in optimizing acceptance and adherence to preventive treatment.

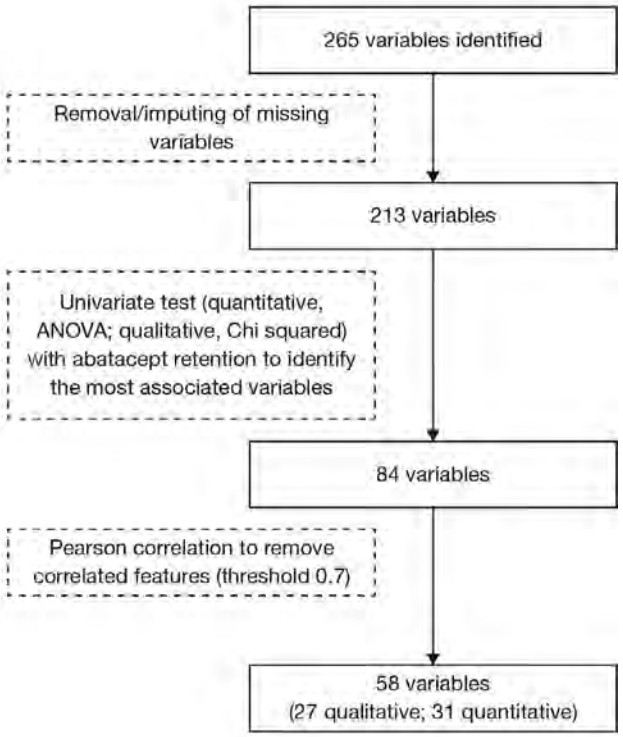
[a]Precision, recall and F1-score are weighted average based on retention (1) and no retention (0).

AUC=area under the curve; ROC=receiver operating characteristic; SVC=support vector classification.

Figure 1. Variables used in the modeling



ANOVA=analysis of variance.

cardiac disorders were identified as predictors of 1-year retention to ABA tx.[1] The objective of our study was to use machine learning as an innovative and complementary approach in order to identify pts with 1-year ABA retention.

Methods: Supervised learning was used for classification. A binary variable was used where retention=1 and no retention=0. Retention was defined as tx for >365 days or ≤365 days in pts who achieved remission or major clinical response. The number of variables identified and used in the models is shown in **Figure 1**. A subset of features was selected to prevent under-fitting or over-fitting. Label and OneHot encoding were applied for categorical variables and MinMax scaling was applied to convert all continuous variables to the same scale. The models tested for predictive performance were: logistic regression, support vector machine, naïve Bayes, decision tree, random forest, gradient boosting and multi-layer perceptron. For each model, a recursive feature elimination with cross validation was applied. For the best performing model (gradient boosting), the database was divided into two sets: a training/validation set (n=2021) and a test set (n=329). Accuracy was defined as the number of correct predictions divided by the total number of predictions. Precision, recall and F1-score were estimated for predictions on both retention and no retention and were then weight-averaged to obtain overall performance scores. The importance score of each variable was estimated.

Results: In total, 2350 pts included from May 2008 to December 2013 had a mean retention rate of 59.3% at 1 year. The gradient boosting classifier model had the best prediction testing accuracy (67%) and was the most interpretable

model for feature importance (**Table 1**). The importance score for each predictor did not describe a linear correlation with retention or directionality; rather, the higher the score, the more important the variable for retention prediction. Predictive information was shared between all 51 variables; 8 of which overlapped with those identified in the Cox regression model.[1] The five most influencing variables were the duration of previous biologic DMARDs, pt global pain assessment, RA duration, physician global disease activity assessment and HAQ-DI.

Conclusion: The gradient-boosting model identified predictors of retention in addition to those identified by multivariable Cox regression models in ACTION.[1] The models and predictors identified could be further improved by including other RA datasets. Machine learning offers a complementary approach to biostatistics and may lead to better identification of pts with RA, and their tx retention, hence supporting personalized, clinical decision making in a real-world setting.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity affects 30-40% of RA patients and is associated with higher clinical disease activity measures and progressive disability. Studies suggest that obesity may be associated with poor response to TNF inhibitors (TNFi), but the degree to which these prior results were impacted by unmeasured confounding factors is unclear. We aimed to evaluate differences in response to MTX and TNFi across BMI categories among RA patients in a real-world setting, accounting for multiple confounding factors.

Methods: We conducted a retrospective cohort study within the Veterans Affairs RA registry. Adult patients initiating a course of MTX or TNFi (with no use in prior 90 days) who had at least moderate disease activity (DAS28 >3.2) at baseline and one or more clinical visit with DAS28 30 days to 6 months later were included. BMI (kg/m^2) was categorized as underweight (< 20), normal (20-25), overweight (25-30), class 1 obesity (30-35) and class 2-3 obesity (>35). Response was defined as achieving at least low disease activity (LDA; DAS28 < 3.2) *or* the minimally clinically

Table 1. Baseline characteristics of MTX and TNFi initiators stratified by BMI category

important difference (MCID) in DAS28 (>=1.2) within 6 months. We also extracted disease duration, Multi-Dimensional HAQ score, smoking status, and extra-articular features of disease from the database. Comorbidities were obtained from medical record databases within 1-year prior to initiation. Anti–CCP antibody and RF were measured in banked serum obtained at the time of enrolment. Concurrent RA medications, including prior courses of conventional DMARDs and biologic therapies were determined from VA pharmacy data. The association between BMI and response to treatment within 6 months was estimated in logistic regression models adjusted for demographics, calendar year, RA severity factors, prior/concomitant therapies, and comorbidities at baseline.

Results: We identified 738 eligible MTX courses (471 unique patients) and 1165 TNFi courses (509 unique patients). In both cohorts, the population was primarily male (90% in MTX, 92% in TNFi), and two-thirds were either overweight or obese (73% in MTX, 70% in TNFi). Median baseline DAS28 score was higher among severely obese MTX initiators.

*Adjusted for CCP and RF positivity, use of leflunomide/sulfasalazine/hydroxychloroquine/MTX/biologic at baseline, other concurrent csDMARD initiation, prednisone use, baseline MD-HAQ, baseline pain scale, prior MTX use, number of prior biologics used, number of prior csDMARDs used, smoking category, comorbidities such as lung disease, psychiatric disorders, neoplasms, osteoarthritis, diabetes, hypertension, osteoporosis, fractures, spine disease, vascular disorders, NSAID/opiate use, anemia, and physician documented presence of nodules/radiographic changes.

Table 2. Univariate and multivariate analyses reporting response percent and fully adjusted odds ratio, respectively, among methotrexate and tumor necrosis factor inhibitor initiators

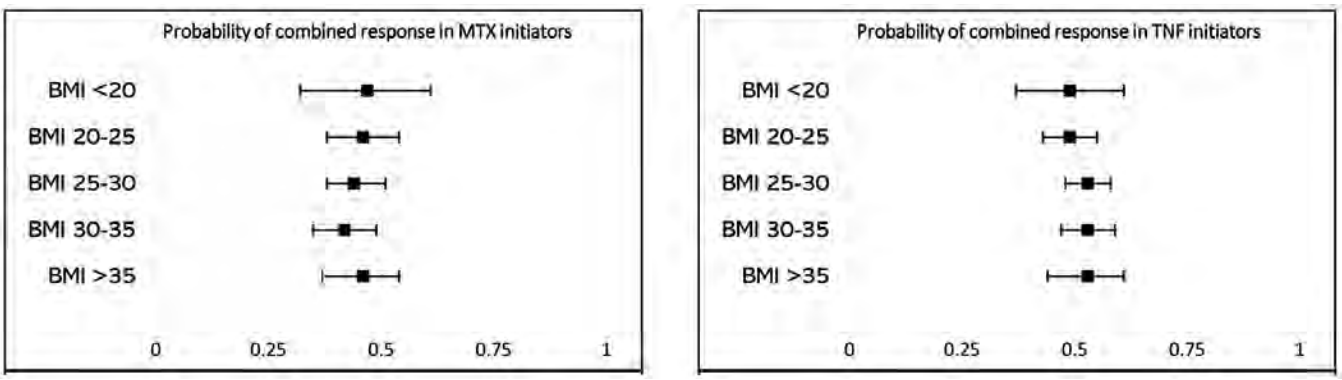

Figure 1. Predicted probabilities of combined (primary) response in methotrexate and tumor necrosis factor inhibitor initiators based on logistic regression models

Other characteristics are depicted in **Table 1**. The overall unadjusted response was achieved in 45% of MTX courses and 52% of TNFi courses. While the response rates were numerically lowest among underweight patients in TNFi cohorts before and after adjustment, responses were not associated with BMI categories in either cohort with or without adjustment (all p >0.10). In adjusted models, the odds of clinical response for all outcomes were similar across BMI categories in both cohorts (**Table 2**; **Fig 1**).

Conclusion: In this predominantly male veteran population, clinical response following the initiation of MTX or TNFi for RA in a real-world registry data did not meaningfully differ by BMI categories after controlling for a robust set of covariates. These findings argue against a biological basis for differences in treatment response in RA patients with higher BMI. Future head to head comparison studies among obese patients may be necessary to determine whether a particular treatment strategy is more efficacious in this group.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Personalization of RA treatment is not optimal due to lack of predictors. We previously demonstrated in RA patients that central nervous system (CNS) pain response to tender joint compression, measured by using functional MRI (fMRI) of the brain rapidly wanes after 24 hours of anti-TNF administration and that a higher pre-treatment BOLD signal volume seems to predict clinical response to treatment with certolizumab-pegol (CZP)1,2. We therefore hypothesized that the CNS pain response upon compression of a painful joint could predict subsequent anti-TNF treatment response.

Methods: Adult RA patients fulfilling the 2010 ACR/EULAR classification criteria with a DAS28 >3.2 under stable DMARD treatment for at least 3 months were eligible. Patients underwent fMRI scanning of the brain at screening for stratification by CNS pain response. Whole brain BOLD-signal-voxel-count of 700 units classifying between low and high, and were randomized to CZP or placebo (2:1) The primary outcome was low disease activity (LDA, DAS28 ≤3.2) after 12 weeks of treatment.

Results: 156 RA patients, inadequate responders to csDMARD, signed the informed consent. 139 patients (46/47, 46/49 and 42/43) (99 females, 71%) with moderate-high disease activity (mean (SD) DAS-28: 4.83 (1.03)) could be included respectively and completed the 12-week study treatment. Geometric mean (SD) numbers of baseline BOLD

joints (28), mean (SD)		7.9 (5.3)	7.0 (4.4)	8.7 (6.3)	8.0 (4.8)
global VAS, mm, mean (SD)		58.0 (20.0)	57.2 (19.9)	59.1 (17.8)	57.6 (22.5)
n global VAS, mm, mean (SD)		49.6 (18.7)	46.0 (20.2)	49.5 (19.2)	53.1 (16.2)
S, mm, mean (SD)		55.2 (19.3)	53.5 (18.0)	57.1 (17.0)	54.9 (22.7)
s/h, mean (SD)		25.8 (19.9)	23.7 (19.0)	25.2 (17.1)	28.2 (23.2)
/L, mean (SD)		8.7 (13.0)	6.8 (12.7)	7.9 (8.7)	11.2

signal positive voxels were 559 (10), 81 (12) and 2498 (3) in the 3 arms respectively. The mean DAS28 (SD) scores after 12 weeks of study treatment were Placebo: 3.89 (1.29), CZP-L: 3.42 (1.06) and CZP-H: 3.06 (1.04). LDA was achieved in 12/47 patients (25.5 %) in placebo, 22/49 (44.9%) in the CZP-L, and 25/43, (58.1%) in the CZP-H arm. The linear effect term for the ordinal study group variable supported a linear trend of increasing CZP treatment effect with increasing baseline CNS pain response. RR (95% CI) for achieving LDA with each unit increase in treatment category over placebo was 1.79 (1.24 to 2.74, p=0.003).

Conclusion: A higher pre-treatment brain activity in response to pain measured with fMRI predicts the chance of achieving low disease activity with CZP treatment.

Effects of Abatacept and Tumor Necrosis Factor Inhibitor on the Normal Glycosylated Hemoglobin Level in Patients with Rheumatoid Arthritis

Yusuke Miwa[1] and Yuko Mitamura[2], [1]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Yokohama, Kanagawa, Japan, [2]Department of Nursing, Showa University School of Nursing and Rehabilitation Sciences, Tokyo, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and diabetes mellitus (DM) are associated with inflammation. Abatacept has been reported to be effective for type 1 diabetes. We aimed to investigate the influence of tumor necrosis factor inhibitors (TNFi) and abatacept (ABT) on the glucose metabolism of patients with RA.

Methods: Patients with RA treated with TNFi or ABT from 2008 to 2018 were studied based on the All Showa University of RA (ASHURA) database. The association between glycosylated hemoglobin (HbA1c) level reduction and treatment was evaluated. Of 629 patients treated with these biologic agents, 159 with available HbA1c medical records were included (TNFi, n = 111; ABT, n = 48). The following background factors were investigated: age; sex; type of biological disease-modifying antirheumatic drugs (bDMARDs); dosage of methotrexate (MTX) and prednisolone (PSL); usage of conventional synthetic DMARD and nonsteroidal anti-inflammatory drugs; body mass index (BMI); smoking history; HbA1c; presence or absence of hypertension and dyslipidemia; and serum creatinine, C-reactive protein, and matrix metalloproteinase-3 levels. We also used the simplified disease activity index (SDAI) to evaluate RA disease activity. Propensity was calculated based on age; sex; BMI; smoking history; PSL dosage; MTX dosage; SDAI; creatinine; estimated glomerular filtration rate; presence or absence of diabetes, hypertension, and dyslipidemia; and HbA1c, and 44 patients in each group were extracted by propensity score matching. The primary endpoint was HbA1c levels before, and after 6 months and 1 year, which was determined using the repeated-measures analysis of variance (ANOVA).

Results: The HbA1c level decreased from 5.9 ± 0.79 to 5.7 ± 0.29 and 6.0 ± 2.20 in the TNFi group and from 5.9 ± 0.66 to 5.8 ± 0.00 and 5.8 ± 0.64 in the ABT group before treatment and after 6 months and 1 year, respectively. No interaction was observed among the groups. A significant difference was not observed among the groups ($p = 0.76$) and even during the treatment period ($p = 0.85$) by repeated-measures ANOVA.

Conclusion: Our study suggests that neither ABT nor TNF treatment may affect normal HbA1c levels in patients with RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with rheumatoid arthritis (RA) with poor prognostic factors (PPF) are at risk for RA progression if disease activity is not rapidly controlled. In FINCH 3 (NCT02886728), filgotinib (FIL) — an oral, potent, selective JAK1 inhibitor — was effective relative to methotrexate monotherapy (MTX mono) in MTX-naïve patients with ≥1 PPF—erosions, seropositivity for rheumatoid factor (RF) or anti-cyclic citrullinated peptide (CCP), or hsCRP ≥4 mg/L.[1] This post hoc analysis examined FIL efficacy in FINCH 3 pts with multiple PPF.

Methods: The global, phase 3, double-blind, active-controlled FINCH 3 study randomized MTX-naïve pts with moderately to severely active RA 2:1:1:2 to oral FIL 200 mg once daily + MTX ≤20 mg weekly, FIL 100 mg + MTX, FIL 200 mg mono, or PBO + MTX up to week (W)52. This subgroup analysis included pts with all 4 of the following PPF at baseline (PPF pts): erosions, seropositivity for RF or anti-CCP, hsCRP ≥4 mg/L, and DAS(28)CRP >5.1. Comparisons were not adjusted for multiplicity.

Results: Of 1249 pts randomized and treated in FINCH 3, 510 had all 4 PPF. At baseline, relative to the overall FINCH 3 population, PPF pts had longer mean disease duration (2.4 vs

2.2 years); higher mean hsCRP (27.9 vs 17.5 mg/L), mTSS (17.9 vs 13.3), DAS28(CRP) (6.3 vs 5.7), HAQ-DI (1.76 vs 1.56), CDAI (44.3 vs 39.8), and SDAI (47.1 vs 41.5); and greater frequency of seropositivity for RF (90.6% vs 67.9%), anti-CCP (92.4% vs 68.5%), or both

(82.9% vs 59.6%). Efficacy in PPF pts was comparable to data from all FINCH 3 pts (**Table, Figures 1–2**). PPF pts receiving FIL 200 mg with or without MTX vs MTX mono had higher frequencies of ACR20/50/70 response and greater improvement in HAQ-DI at W24; responses were numerically greater for FIL 200 mg + MTX vs FIL 100 mg + MTX or FIL 200 mg mono (**Table**) and were evident by W12 (data not shown). Radiographic progression at W24 was lower in PPF pts receiving FIL 200 mg + MTX or FIL 200 mg mono vs MTX mono (**Figure 1**).

Table. Efficacy outcomes in patients with 4 PPF and all FINCH 3 patients at W24

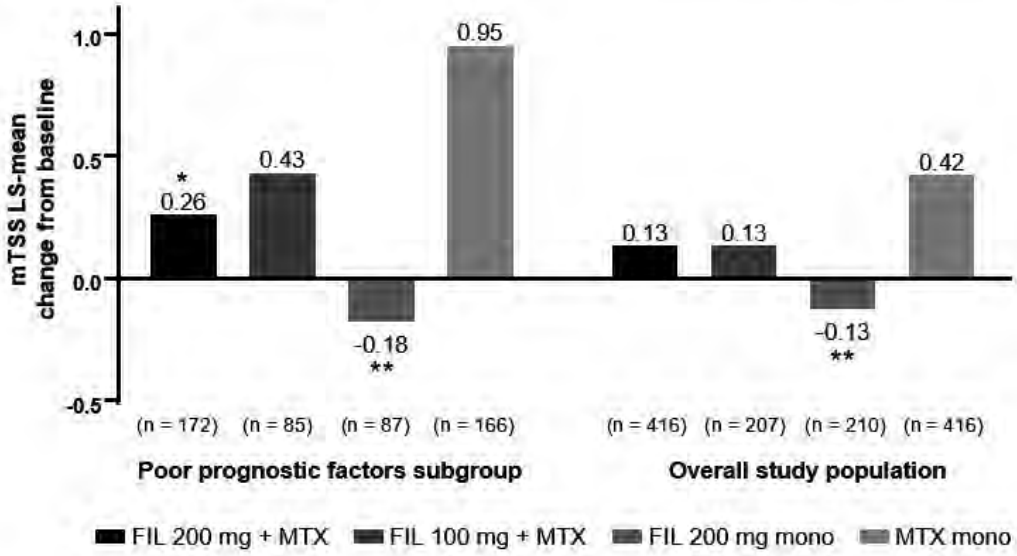
	FIL 200 mg + MTX		FIL 100 mg + MTX		FIL 200 mg mono		MTX mono	
	PPF	All	PPF	All	PPF	All	PPF	All
n	172	416	85	207	87	210	166	416
ACR20, %	85.5*	81.0***	83.5	80.2*	81.6	78.1	74.7	71.4
ACR50, %	70.3***	61.5***	58.8	57.0**	59.8	58.1**	48.2	45.7
ACR70, %	54.1***	43.8***	37.6	40.1***	43.7*	40.0***	28.3	26.0
HAQ-DI[a]	−1.2***	−0.94***	−1.0*	−0.90**	−1.0*	−0.89*	−0.9	−0.79

[a]Mean change from baseline.

*, p <0.05; **, p <0.01; ***, p <0.001 vs MTX mono, not adjusted for multiplicity.

FIL, filgotinib; mono, monotherapy; MTX, methotrexate; PPF, poor prognostic factors.

Figure 1. Change in mTSS from baseline at W24 in FINCH 3 patients with 4 poor prognostic factors and all FINCH 3 patients

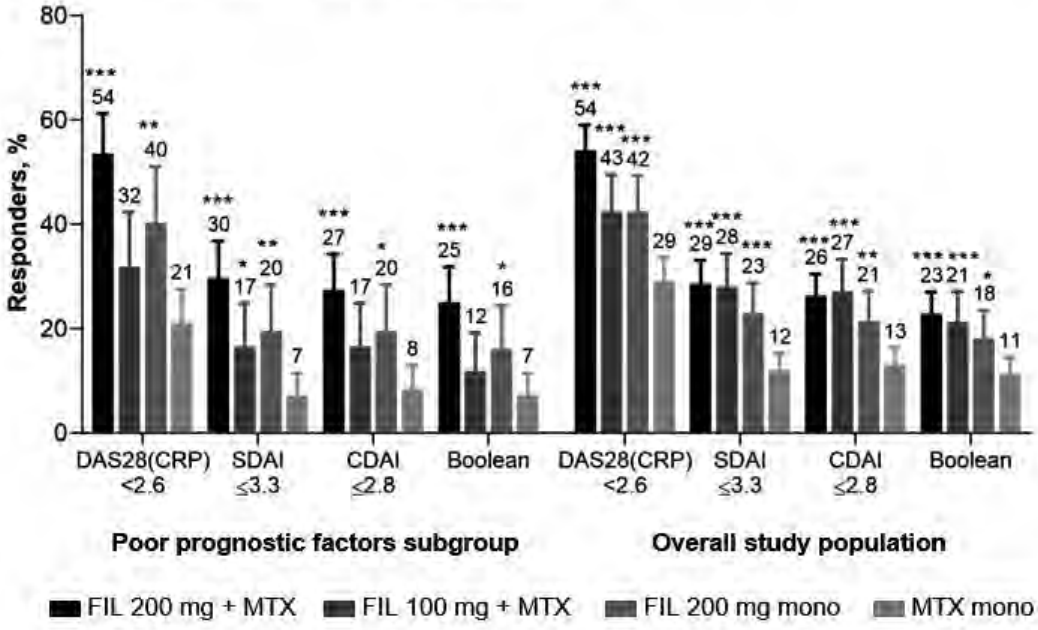


*, p <0.05; **, p <0.01 vs MTX mono; not adjusted for multiplicity.

FIL, filgotinib; LS, least-squares; mono, monotherapy; mTSS, van der Heijde modified total Sharp score; MTX, methotrexate; W, week.

Proportions of PPF pts receiving FIL 200 mg with or without MTX who achieved DAS28(CRP) < 2.6, CDAI ≤2.8, SDAI ≤3.3, and Boolean remission at W24 (**Figure 2**) were larger vs pts receiving MTX mono and numerically greater vs pts receiving FIL 100 mg + MTX.

Figure 2. Rates of DAS28(CRP) <2.6, CDAI ≤2.8, SDAI ≤3.3, and Boolean remission at W24 in FINCH 3 patients with 4 PPF and all FINCH 3 patients



*, p <0.05; **, p <0.01; ***, p <0.001 vs MTX alone; not adjusted for multiplicity.

FIL, filgotinib; mono, monotherapy; MTX, methotrexate; PPF, poor prognostic factors; W, week.

Conclusion: FIL treatment provided rapid and deep disease control including higher rates of remission and other clinical outcomes, improved physical function, and less radiographic progression compared with MTX alone in MTX-naïve pts with RA with 4 PPF, a population at risk for severe progressive disease. In pts with 4 PPF, W24 remission rates following FIL 200 mg with or without MTX were higher vs MTX mono and numerically higher vs FIL 100 mg + MTX.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Biologicals - bring a hope of recovery or amelioration to people suffering from RA, but only half of the patients respond to such treatment. Therefore, finding reliable biomarkers predicting response is very valuable. Previously we demonstrated that central nervous system (CNS) response to nociceptive stimuli, measured by fMRI of the brain, decreases already after 24 hours and that a higher pre-treatment BOLD signal volume seems to predict clinical response to treatment with certolizumab-pegol (CZP). 1,2 Therefore we hypothesized that the CNS response upon compression of a painful joint could predict subsequent anti-TNF treatment response.

To follow the longitudinal effect of CZP treatment on brain activity in RA patients stratified byhigh and low brain activation volumes measured by BOLD fMRI at baseline and to compare their brain activity during 24 weeks of treatment to that of placebo in DMARD-refractory RA patients.

Methods: Adult RA patients fulfilling the 2010 ACR/EULAR classification criteria with a DAS28 >3.2 under stable DMARD treatment for at least 3 months were eligible. Patients underwent the first fMRI at screening for stratification. Whole brain BOLD-signal-voxel-count of 700 classifying between low and high and patients were randomized to CZP or placebo (2:1 ratio) resulting in 3 study arms (CZP low voxel count (CZP-L), CZP high voxel count (CZP-H), and placebo). The second fMRI was performed after 12 and the third fMRI – after 24 weeks. In parallel control stimulation we measured brain activation during non-painful finger tapping.

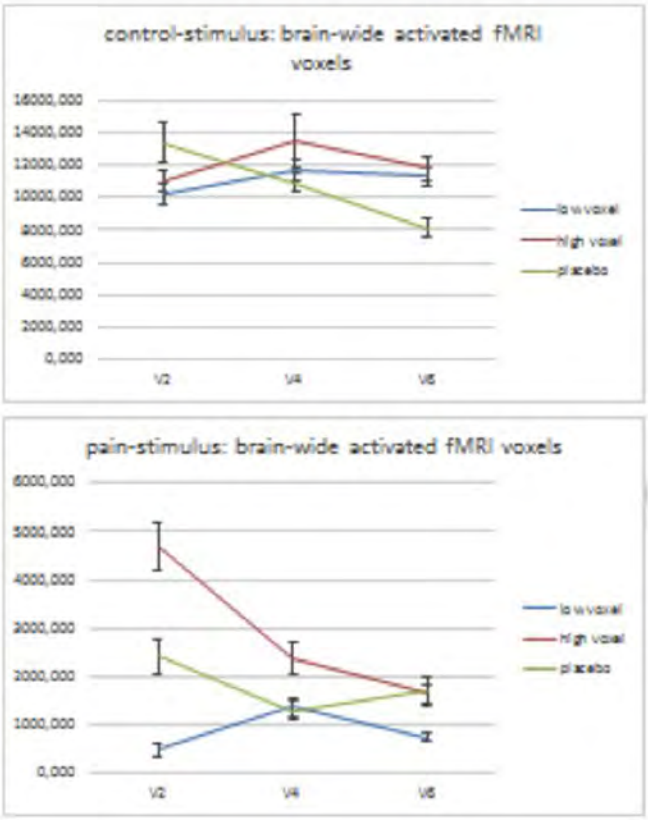

Fig-1: BOLD fMRI responses to painful stimulation (A: compression of a painful joint) and control stimulation (B: finger tapping) over the 3 consecutive MRI measurements. Plotted are mean values + SEM with respective n.

Results: 156 patients, inadequate responders to csDMARD signed the informed consent. In the finger tapping control paradigm, fMRI showed no significant changes in the number of brain-wide activated voxels in CZP-L and CZP-H arms, but, surprisingly, there was a significant decrease (p=0.043) in the placebo arm in fMRI-3 compared to the pre-treatment fMRI-1 value. By painful stimulation in CZP-L fMRI showed significant increase in the number of brain-wide activated voxels (p=0.043) in fMRI-2 as compared to fMRI-1 with no further significant changes. Most importantly, in CZP-H the number of activated voxels was significantly reduced (p=0.037) in fMRI-2 and continued to decrease further in fMRI-3 (p=0.007).

Conclusion: As revealed by our study high pre-treatment fMRI BOLD brain activity in response to pain seems to serve as a (long-term) positive predictor of patient's response to CZP treatment.

Forecasting Healthcare Utilization in Rheumatoid Arthritis: A Machine Learning Predictive Model of Emergency Department Visits and Prednisone Initiation in a Single Tertiary Academic Center

Elston He[1], Eli Cornblath[2], Pratyusha Yalamanchi[3], Alexis Ogdie[2], Joshua Baker[2] and **Michael George**[2], [1]Synovium, Inc., Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite recent advances in therapy, 42% of patients with rheumatoid arthritis (RA) nationwide had moderate or high disease activity at their most recent visit. Given that uncontrolled disease often results in increased healthcare utilization through emergency department (ED) visits and initiation of prednisone use, early identification and intervention offers the opportunity to identify high risk populations and optimize allocation of healthcare resources. Therefore, our objective was to develop and validate a longitudinal machine learning model to predict ED visits and prednisone initiation for patients with RA.

Methods: Patients with RA at a tertiary care center 2010-2018 were identified based on ≥2 diagnoses of RA from a rheumatology outpatient encounter and DMARD use. Structured electronic health record data was used to identify demographics, lab values, medication history, comorbidities, and healthcare visits. Follow-up was divided into 6 month intervals, and a longitudinal machine learning model using gradient boosting machines (GBMs) was used to predict (1) ED visits within 6 months (limited to visits within the health system) and (2) prednisone initiation within 6 months (excluding patients with use in the preceding 6 months). Nested, patient-stratified cross-validation was used to ensure GBMs could accurately predict outcomes of interest in unseen data. Model performance was quantified using the area under the receiver operating characteristic curve with Youden's J used to choose a cut-point optimizing sensitivity and specificity.

Results: A total of 1831 patients with RA were identified from 2010-18. Baseline demographics included mean [SD] age, 55.05 [14.47] years; 1499 [81.87%] female; and 991 [54.12%] white. 714 patients with ED visits were identified,

Table 1: Gradient Boosting Machines Model Performance Predicting Utilization Within RA Population

	Frequency of Outcome Per Six Month Outcome Window	
	ED Visit	Prednisone Initiation
Area Under the Receiver Operating Characteristic Curve (AUC [95% CI])	0.86 [0.84-0.87]	0.71 [0.70-0.73]
Sensitivity	0.7715	0.7052
Specificity	0.7933	0.6354
Number of Qualifying Six Month Outcome Windows	32958	27114
Number of Outcomes	2006	1604
Incidence Rate (Frequency of Outcome Per Six Month Outcome Window)	0.0609	0.0592
Positive Predictive Value	0.1900	0.1077
Negative Predictive Value	0.9818	0.9715

Table 1. Gradient Boosting Machines Model Performance Predicting Utilization Within RA Population

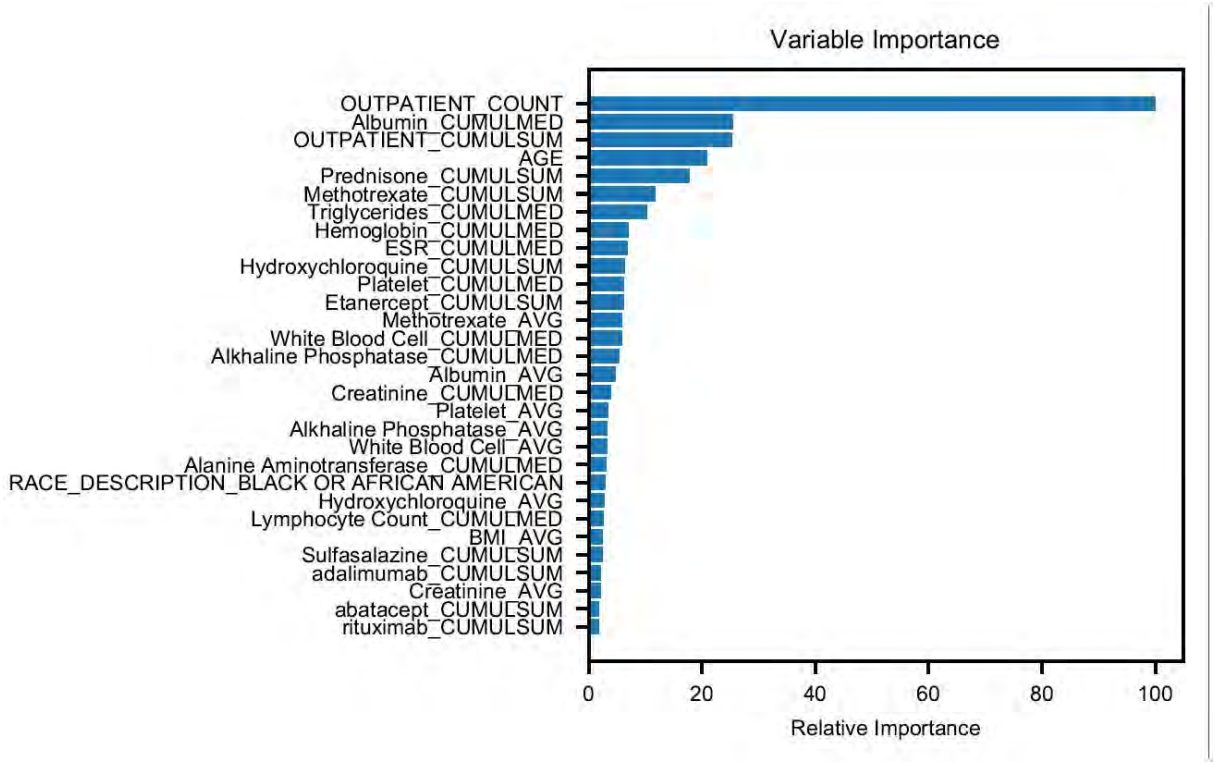

Figure 1. Importance of each predictor variable for ED visits, measured by the decrement in accuracy created by randomly permuting each variable. Key: _AVG: non-weighted average value of measurements within previous 6 month window; _COUNT: the number of visits in previous 6 month time window; _CUMULSUM: cumulative total of measurement for entire history up to the current time point; _CUMULMED: median value of measurement for entire

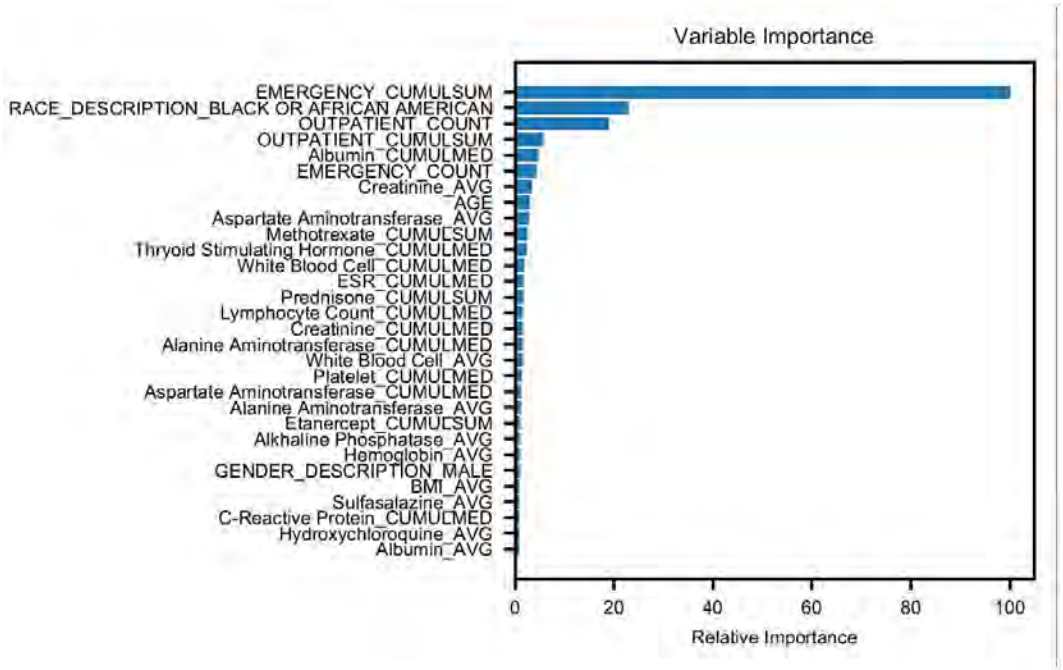

Figure 2. Importance of each predictor variable for prednisone initiation, measured by the decrement in accuracy created by randomly permuting each variable. Key: _AVG: non-weighted average value of measurements within previous 6 month window; _COUNT: the number of visits in previous 6 month time window; _CUMULSUM: cumulative total of measurement for entire history up to the current time point; _CUMULMED: median value of measurement for entire history up to the current time point.

and 1318 patients were identified as having a prednisone prescription at any time during follow-up. The AUCs for prediction of prednisone initiation and ED visits were of 0.71 (95% CI: 0.70-0.73) and 0.86 (95% CI: 0.84-0.87) respectively, with a sensitivity of 0.77 and a specificity of 0.79 for ED visits. Importantly, GBM performance exceeded that of ridge regression (prednisone initiation: AUC of 0.65, 95% CI: 0.61-0.68; emergency visits, AUC of 0.75, 95% CI: 0.72-0.77), suggesting capture of important non-linearities. Significant predictors of ED visits within 6 months include total number of prior ED and outpatient visits, black race, age, elevated white blood cell count, prednisone use, elevated BMI, kidney function (as measured by creatinine), prior conventional DMARD use (methotrexate or hydroxychloroquine), elevated liver enzymes, and elevated TSH. Predictors of ED visits and initiation of prednisone use are shown in Figures 1 and 2, respectively.

Conclusion: Here we demonstrate an internally validated, predictive model for ED visits and initiation of prednisone usage in patients with rheumatoid arthritis using machine learning methodology. This demonstrates that models built on electronic health record data can accurately predict complex disease outcomes within a health system and have the potential to optimize care delivery for diverse patient populations.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: [Background]

Oral Janus kinase inhibitors (JAKi) show dramatical efficacy to reduce the disease activity in patients with rheumatoid arthritis (RA). However, there remain some patients who respond to inadequately JAKi treatment (JAKi-IR)[1,2] and the clinical characteristics of JAKi-IR in RA have not been fully demonstrated.

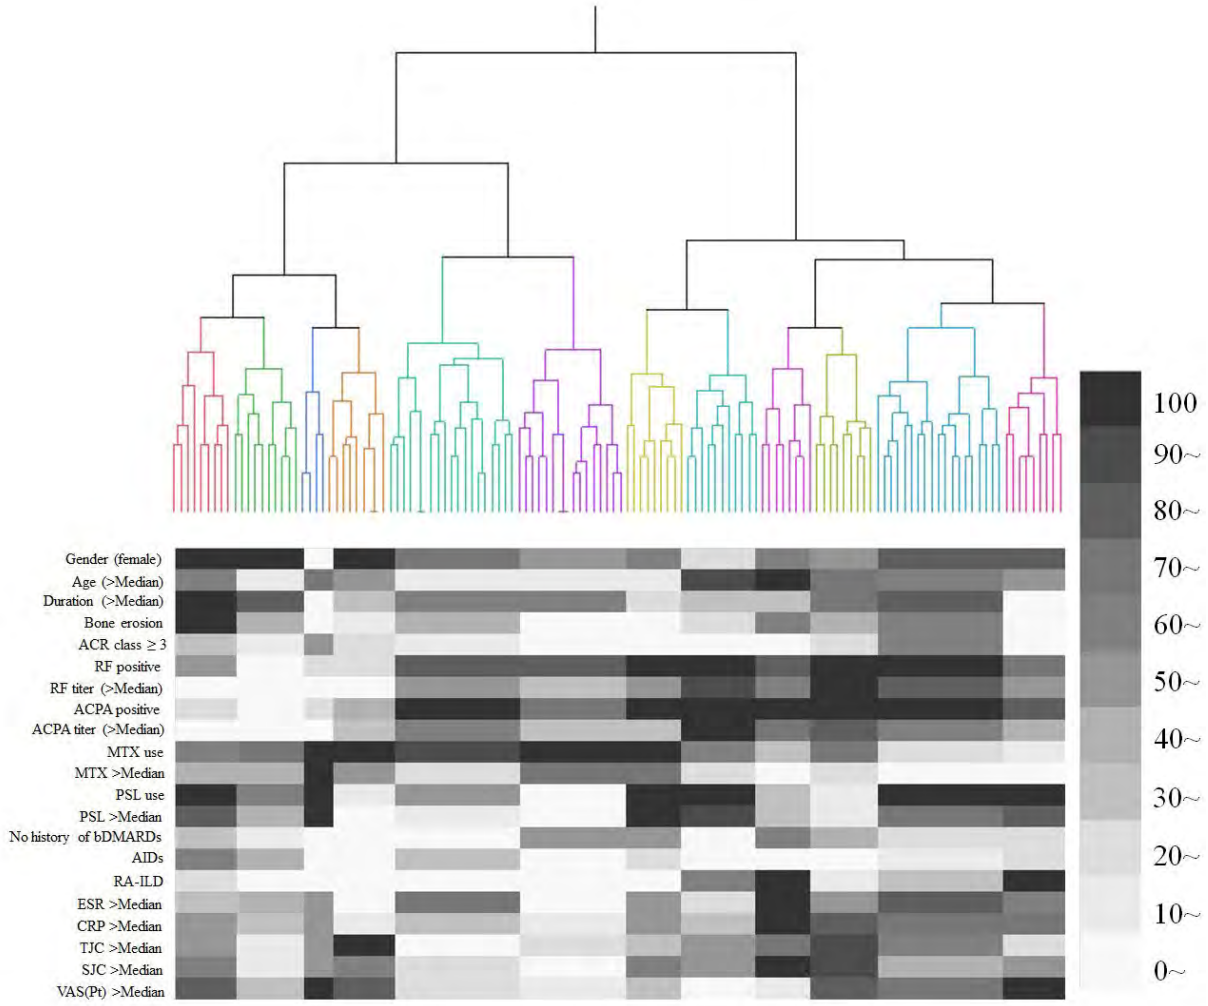

Figure 1

[Objective]

To clarify the characteristics of JAKi-IR in patients with RA based on cluster analysis.

Methods: This retrospective study comprised 132 RA patients who were treated with JAKi (Tofacitinib or Baricitinib) between July 2013 and September 2019 in five facilities. We assessed the disease activity at the baseline, at 12 weeks after JAKi treatment or at the time point of withdrawing JAKi using the Disease Activity Score (DAS28) and the American College of Rheumatology (ACR) response criteria. JAKi-IR was defined as patients with non-response to JAKi depending on ACR20 non-response or non-improvement in DAS28-CRP (△DAS28-CRP< 1.2 from baseline) in 12 weeks. Discontinuation of JAKi due to remission achievement was excluded from the latter. Hierarchical cluster analysis was performed with the following variables at baseline: gender, age, disease duration, bone erosion, ACR functional classification (Class ≥3), rheumatoid arthritis related interstitial lung disease (RA-ILD) or other autoimmune disease (AID), anti-citrullinated protein antibody (ACPA), rheumatoid factor (RF), use/dose of methotrexate (MTX) and prednisolone (PSL), serum ESR/CRP, tender/swollen joint counts (TJC/SJC), visual analog scale by patients (VAS-Pt), and history of biologic disease-modifying antirheumatic drugs (DMARDs).

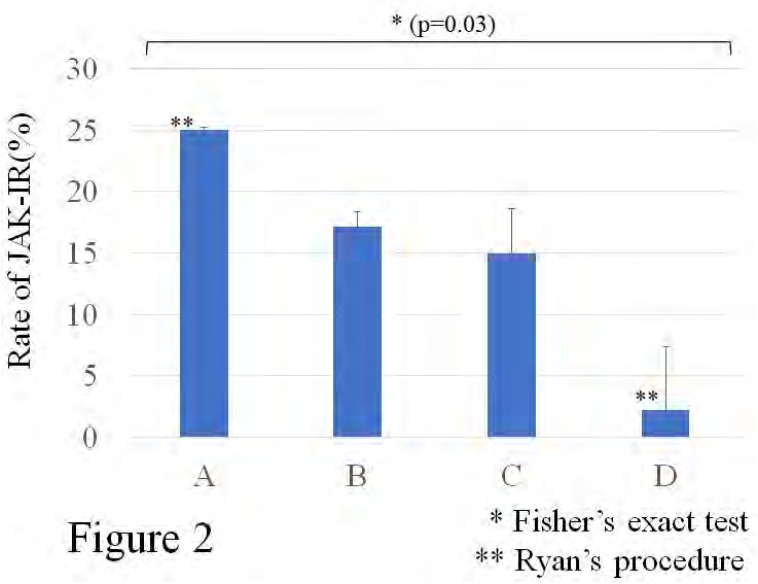

Figure 2

Results: The 132 enrolled patients were classified into four groups (Group A, B, C and D) by cluster analysis (Figure1). The characteristics of each group are as follows, Group A(n=32): seronegative, presence of bone erosion, absence of RA-ILD. Group B(n=35): younger age, seropositive, absence of bone erosion and RA-ILD. Group C(n=20): male, seropositive, presence of RA-ILD. Group D (n=45): older age, seropositive, without MTX treatment, presence of bone erosion and RA-ILD. The rate of JAKi-IR was found in Group A:25%, Group B:17%, Group C:15%, and Group D:2.2%, respectively (Figure2). Notably, Group A showed higher rate of JAKi-IR compared with Group D (Fisher's exact test (p=0.03) and Ryan's procedure).

Conclusion: We identified the characteristics of JAKi-IR. Seronegative but destructive phenotype without lung disease may less benefit from JAKi treatment.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with restrictions on occupational participation caused by periods of sick leave (absenteeism), reduced productivity at work due to disease (presenteeism) and occupational disability, which account for a significant proportion of indirect costs. We investigate the prevalence and development of occupational participation with a sole focus on absenteeism and employment after drug therapy intervention.

Methods: Data from the multi-center German study "Effectivity of nurse-led care" which examined patients with rheumatoid factor and/or APCA-positive RA after T2T regimen prospectively over 12 months from 01/2018 to 12/2019 were analyzed. A total of 178 patients of working age (18 to 67 years) were included in this evaluation. Disease activity presented through DAS28(CRP) and ability to work measured by the Work Productivity and Activity Impairment Questionnaire (WPAI) were examined at baseline and month 12.

Results: The mean age of the patients was 54 years (median 55; standard deviation (SD) 9.01) and 133 (74.3%) of the patients were female. During the course of the study, there was a significant decrease in DAS28 from 4.27 (SD 1.13) at baseline to 2.52 (SD 1.09; $p< 0.001$) after 12 months. At the end of the study 63% of the patients were in remission (DAS28< 2.6) and 11.2% had low disease activity (DAS28 2.6-3.2). At baseline, 38.8% (n=69) and at the end of the study 41.9% (n=67) of patients were not working. Of the working population, 34.7% were in part-time employment (< 32 hours per week) at baseline and 35.6% at 12 months. The weekly working time also remained almost unchanged during the course of the study, with 29.5 hours (median 32) at baseline and 30.8 hours (median 33) at 12 months. Of those working full-time (n=89), 31.5% (n=14) were absent at the beginning of the study, which tended to decline to 19.1% (n=17) at month 12 (p=0.089). In patients with absenteeism, sickness-related absence from work accounted for 47.6% (SD: 36.8) of total working hours at baseline and 73.5% (SD: 30.03) at the end of the study. Patients with no restrictions on occupational participation showed a significantly greater drop in DAS28 from 3.99 (SD 0.99) at baseline to 2.14 (SD 0.90) at baseline than patients with restrictions (DAS28 4.42 (SD 1.14) at baseline to 2.69 (SD 1.12) at baseline; $p< 0.001$).

Conclusion: Despite T2T and good therapeutic effect according to DAS28, there are clear and persistent limitations in occupational participation. Patients with restricted occupational participation show a significantly increased disease activity. To reduce indirect costs in RA, further optimization of disease management is necessary.

The research leading to these results has received funding from the German Innovationsfunds, Agreement No 01NVF16029.

The Point of No Return? Functional Disability in Patients with Rheumatoid Arthritis versus the General Population: Results from a Population-based Cohort Study

Elena Myasoedova[1], John Davis[1], Vanessa Kronzer[1], Rachel Giblon[1], Elizabeth Atkinson[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the advances in treatment of rheumatoid arthritis (RA), many patients do not achieve remission or full physical functioning. We have previously shown that patients with RA have a significantly higher prevalence of functional disability (FD) than non-RA subjects across RA disease duration, age and calendar time. However, the pattern of improvement or worsening of functional status in RA vs non-RA patients over time has not been studied. We aimed to assess time spent in FD and transition probability between different levels of FD in patients with RA vs the non-RA subjects after RA incidence/ index date.

Methods: This retrospective population-based cohort study included residents of a geographical area who met 1987 ACR criteria for RA in 1999-2013 and a cohort of non-RA subjects from the same area matched by age and sex. Index date was RA incidence date for RA subjects and incidence date of the matching RA patient for non-RA subjects. Activities of Daily Living (ADL) were recorded annually since 1999 based on patient provided information about performing 6 ADLs without assistance: feeding oneself, dressing, using the toilet, bathing, walking and housekeeping. FD was defined as having difficulty with ≥1 of the 6 ADLs. Changes in the number of disabilities were considered to be state transitions. Multi-state modeling was used to estimate the probability of transitioning between FD states, with

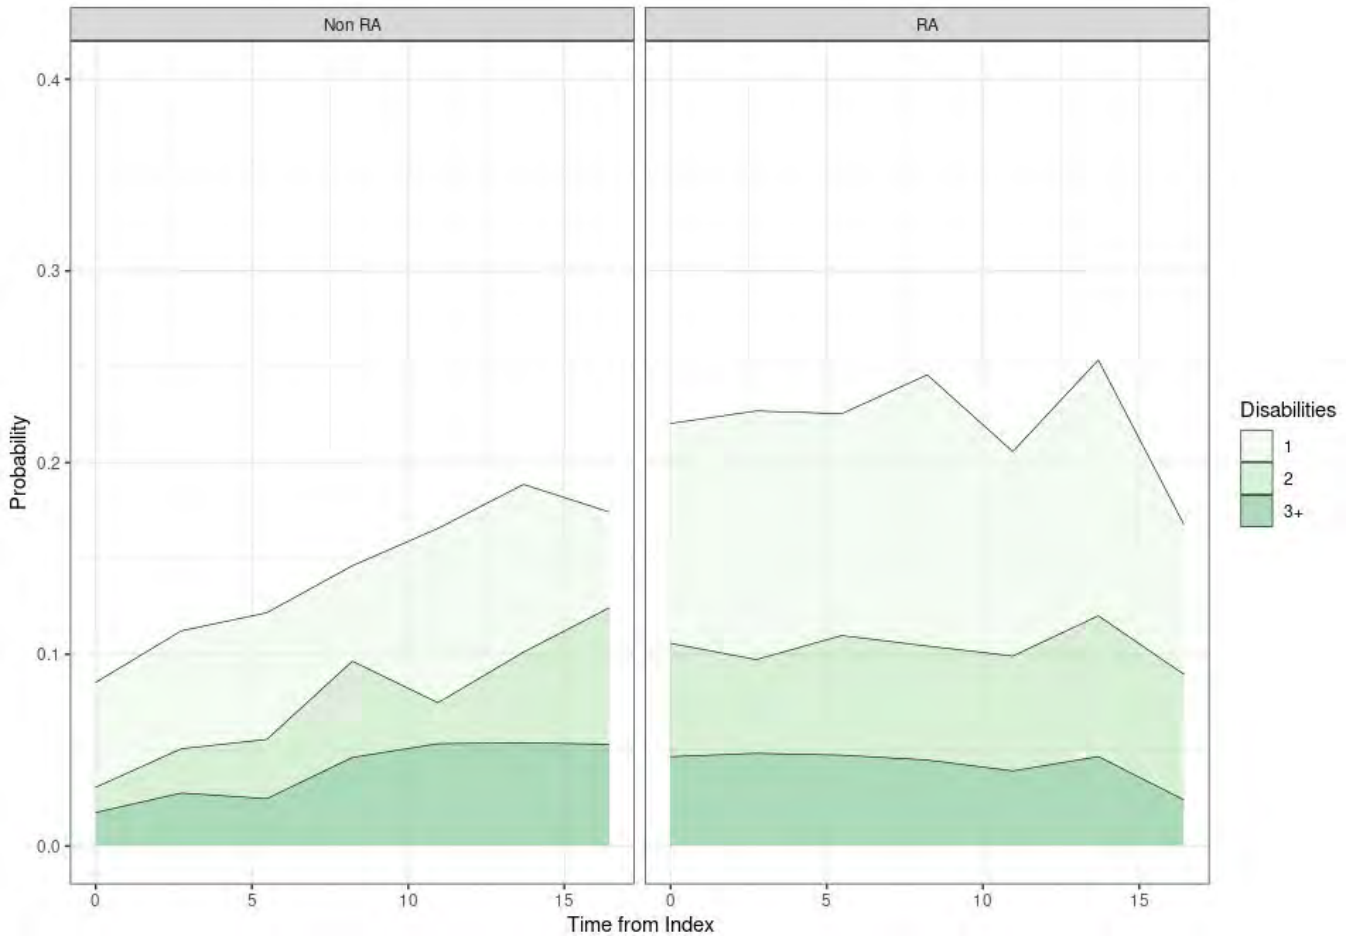

Figure 1. Probability of functional disability in 558 rheumatoid arthritis (RA) versus 457 non-RA patients after RA incidence/ index date

death as a final state. Cox models of multistate data were used to assess the risk of transition with 95 percent confidence intervals (CI) between the levels of FD, adjusting for age, sex, calendar year of index, smoking, and obesity.

Results: A total of 558 patients with RA (mean age 55.4 years, 71% females, 64% RF/CCP positive) and 457 non-RA subjects (mean age 56.5, 70% females) completed 6,594 questionnaires (3,875 RA and 2,719 non-RA) from 1/5/1999 to 1/5/2018 on or after index date. Figure 1 shows probability of FD in RA vs non-RA patients after the index date. In the first 15 years of disease, patients with RA expect to spend 10.1 years without FD and 1.7 years with 1 FD vs 11.6 years ($p< 0.001$) and 0.9 years ($p< 0.001$) in non-RA subjects, respectively. Probability of no FD at index is 78% in RA and 92% in non-RA. By 10 years after index date, probability of no FD in RA is 65%; probability of 1 disability 11%; 2 disabilities 6%, and ≥3 disabilities 1%, compared to 73%; 7%; 5% and 1% in the non-RA subjects, respectively. Risk of transitioning from no FD to FD is significantly higher in RA vs non-RA subjects: Hazard Ratio (HR) 2.4; 95%CI 1.9-3.0. Patients with RA and non-RA subjects have similar risk of returning from FD to no FD (HR 1.2; 95%CI 0.93-1.6). Results did not differ by RF/CCP status.

Conclusion: Patients with RA have a significantly higher probability of any level of FD over RA disease duration, less time spent with no FD, and a 2-fold increased risk of transitioning from no FD to FD, but a similar risk of transitioning back to normal functional status during RA disease course compared to their non-RA counterparts. Our findings suggest that in the era of advanced therapeutics for RA disease management, FD remains an area of ongoing concern, leaving an ample room for improvement of functional outcomes in RA.

Abstract Number: 1755

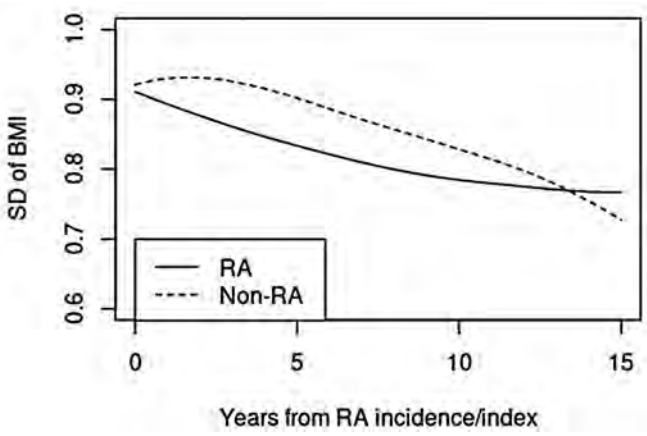
Body Mass Index Trajectory and Variability in Rheumatoid Arthritis

Gregory Challener[1], Elena Myasoedova[1], Cynthia Crowson[2], Rachel Giblon[1] and John Davis[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Past studies have examined associations between BMI and disease activity [1, 2, 3], but few studies have characterized BMI trajectory over the disease course of RA, and there are no known prior studies assessing BMI variability over time in RA patients. We compared BMI trends and variability over time between RA and matched non-RA subjects.

Methods: The study population comprised residents of a geographically defined area with incident RA (age ≥18 years, 1987 ACR criteria met in 1995-2009) and non-RA subjects from the same underlying population with similar age, sex and calendar year of index. All subjects were followed until death, migration, or 01/July/2019. Follow-up was truncated for comparability. Visit-to-visit BMI variability was defined as the within-subject standard deviation (SD) for BMI. Generalized additive models with smoothing splines and random effects to account for multiple measurements per subject were used to illustrate trends in BMI measurements over time.



Results: The study included 558 patients with RA (mean age 55.6 years; 69% female) and 556 patients without RA (mean age 55.7 years, 69% female). Mean (±SD) BMI of patients with incident RA (28.8 ±6.4 kg/m^2) was not significantly different from that of non-RA subjects (28.9 ±6.8 kg/m^2, p=0.94). Models of time trends in BMI demonstrated no significant change in BMI over time for the non-RA subjects (-0.01 kg/m^2 per year, 95% CI:-0.05, 0.5, p=0.58) and a non-significant decline over time for the RA (-0.05 kg/m^2 per year, 95% CI: -0.10, 0.0, p=0.058). Among patients with RA, no differences were found for BMI trend according to sex (p=0.93) or RF/CCP-positivity (p=0.32). There was no evidence of higher variability of BMI measurements over time in patients with RA compared to subjects without RA (SD of random effects: 6.5 RA vs 6.7 non-RA). The figure shows the trends in within-subject SD for RA and non-RA based on consecutive sets of 6 BMI measures.

Conclusion: Our findings demonstrate a minimal decline in BMI over time in the RA population, perhaps reflecting the phenomenon of rheumatoid cachexia. While we were surprised that the RA population did not demonstrate higher BMI variability over time compared to the non-RA population due to weight variation secondary to corticosteroid use, further studies are needed to understand the reasons and implications of these trends.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare long-term clinical and radiographic outcomes among five sets of remission criteria [four clinical and one Ultrasound (US)-based] in a cohort of RA patients in a clinical care setting.

Methods: RA patients in remission (DAS28-ESR < 2.6) were selected. Hand US assessments were performed, and serum levels of inflammation/angiogenesis biomarkers were determined at baseline. Changes in baseline treatment and radiographic progression, defined as the variation in the modified Sharp van der Heijde score (mSHS) at 5 years, were analyzed.

To define remission, five different concepts were used, as follows: DAS28-ESR< 2.6, SDAI< 3.3, CDAI< 2.8, Boolean criteria and score Power Doppler (PD)=0.

Results: Eighty-seven patients with DAS28-ESR< 2.6 were included (table 1). One third fulfilled SDAI (33.3%), CDAI (31%) and Boolean (35.6%) remission criteria and 25.3% had no PD signal in the US evaluation.

26 patients (29.9%) changed the therapy, ranging from 13.6% (PD remission) to 33.3% (CDAI remission) (p=0.11) (Table 2).

Serum levels of ANG (p=0.015) and TNFa (p=0.025) were significantly lower in patients with Boolean remission, whereas IL-18 levels were significantly lower in those with PD remission (p=0.049). Patients without PD in the US assessment had significantly lower mSHS erosion progression (p=0.014) at 5 years (Figure).

Conclusion: Patients with established RA in DAS28-ESR remission had comparable clinical and radiographic outcomes than SDAI, CDAI and Boolean definitions in a clinical care setting. US remission remained as the closest to structural damage abrogation.

High-Intensity Interval Training Increases Rheumatoid Arthritis Cardiorespiratory Fitness in Association with Improvements in CD4+ T Cell and Skeletal Muscle Mitochondrial Metabolism

Brian Andonian[1], David Bartlett[1], Alec Koss[1], Deborah Muoio[1], Timothy Koves[1], Eugene St Clair[1], Elizabeth Hauser[1], William Kraus[1] and Kim Huffman[1], [1]Duke University, Durham, NC

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Persons with rheumatoid arthritis (RA) have poor cardiorespiratory fitness and are at increased risk for cardiometabolic co-morbidities. Endurance exercise training improves cardiorespiratory fitness in RA and lessens risk for cardiovascular disease and mortality in the general population; however, the pathways that contribute to the beneficial effects of exercise are largely unknown. In this study of RA participants completing a high-intensity interval training (HIIT) program, our goal was to identify relationships between improvements in cardiorespiratory fitness with changes in peripheral T cell and skeletal muscle mitochondrial metabolism.

Methods: Previously sedentary RA participants (n=12), who all satisfied 1987 ACR criteria, underwent phlebotomy and skeletal muscle biopsies before and after 10 weeks of HIIT. Available paired samples of peripheral blood mononuclear cells (n=6) and skeletal muscle (n=9) were used for primary analyses. Isolated peripheral CD4+ T cell mitochondrial respiration and glycolytic metabolism were assessed via Seahorse XF extracellular flux analyzer. Peripheral lymphocyte and CD4+ T cell subpopulations were measured by flow cytometry. Skeletal muscle mitochondrial metabolism was assessed via citrate synthase (CS) and carnitine acetyltransferase (CrAT) enzyme activity assays, and electron transport chain Western blot protein quantification. To inform mitochondrial metabolism analyses, targeted skeletal muscle and plasma metabolomic profiling (n=12) were performed. Relationships were assessed using Spearman's correlations.

Results: Increases in RA cardiorespiratory fitness following HIIT were significantly associated with increases in RA peripheral CD4+ T cell basal and maximal respiration (rho=0.89, p=0.019 for both) and skeletal muscle CrAT activity (rho=0.70, p=0.036). Increases in CD4+ T cell mitochondrial respiration were significantly associated with increases in circulating naïve CD4+CCR7+CD45RA+ T cells (rho=0.89, p=0.019) and multiple skeletal muscle acylcarnitines. There was large interindividual variability in RA immune cell and skeletal muscle mitochondrial metabolism responses; however, skeletal muscle CrAT activity (mean increase=23.19%, SD=8.24%; p=0.035) significantly improved following HIIT.

Conclusion: In RA, exercise training-related increases in cardiorespiratory fitness associate with improvements in peripheral helper T cell and skeletal muscle oxidative metabolism, which are themselves related. Monitoring of cardiorespiratory fitness with individualized exercise prescription may be valuable in the management of chronic inflammation and cardiometabolic risk in RA.

Table 2

Background/Purpose: RA patients have an increased risk of infection[1] and venous thromboembolism (VTE)[2]. Although rates of serious infection and VTE have been reported for Medicare recipients with RA, the scope of previous publications has been limited to a select number of targeted immunomodulators[3,4]. This study examined the prevalence and incidence of infection and VTE in US Medicare RA patients initiating any of the available DMARDs.

Methods: Within the 20% sample of Medicare fee-for-service beneficiaries, the study population comprised of RA patients (without malignancy or non-RA autoimmune disease) with first initiation (index date; 01/2013–12/2015) of various classes of DMARDs: csDMARD, TNF-a inhibitor (TNFi), anti-IL6, anti-CD20, anti-CD80/86, and/or Janus kinase inhibitor (JAKi). The observation period involved baseline (one-year prior to index date) and follow-up (from index date until discontinuation, Medicare disenrollment, death, or 12/31/2016). Conditions of interest included VTE

Table 3. Incidence (P100PY) of VTE or infection while on index DMARD regimen

Index DMARD	Overall	csDMARD	TNFi	anti-IL6	anti-CD20	anti-CD80/86	JAKi	*P* value§
Incidence, P100PY								
VTE (DVT or PE)†	2.4	2.4	2.1	2.7	*	3.0	2.2	.1192
Deep vein thrombosis (DVT)	1.9	2.0	1.6	2.7	*	2.3	*	.1055
Pulmonary embolism (PE)	0.9	0.9	0.8	*	*	*	*	.1126
Infection, any‡	249.6	321.5	147.8	167.3	340.9	164.7	159.9	< .0001
Serious infection	17.6	17.0	18.3	19.3	30.2	15.4	21.9	.0036
Opportunistic infection	10.2	9.6	10.3	10.9	18.3	10.2	15.8	.0003
Herpes zoster	4.1	3.7	4.1	5.2	*	3.3	8.6	< .0001

* value suppressed if number of events < 11 as required by Medicare report policy;
† VTE, venous thromboembolism, identified based on diagnosis code for DVT or PE; patients with VTE during baseline were excluded from incidence estimate;
‡ Infection identified by diagnosis code for infection or use of antibiotics or antivirals; patients with infection within 60 days prior to initiation of index therapy were excluded from the incidence estimate;
§ *P* values estimated from univariate Cox regressions comparing among the different DMARD classes;
csDMARD, conventional synthetic DMARD; JAKi, Janus kinase inhibitor; P100PY, per 100 patient-years; TNFi, TNF-α inhibitor

Table 3

(deep-vein thrombosis and pulmonary embolism, defined based on diagnosis codes), overall infection (based on diagnostic codes or use of antibiotics/antivirals), serious infection (based on inpatient or emergency department diagnostic codes in any position, or outpatient use of intravenous antibiotics), opportunistic infection (based on diagnostic codes), and herpes zoster (HZ, based on diagnostic codes). We calculated baseline prevalence (%) and on-treatment incidence (number of new events per 100 patient-years [P100PY] during index DMARD treatment) of these conditions. Incident infection analyses excluded patients with infection within 60 days before index date. Incident VTE analyses excluded patients with any pre-index VTE.

Results: The 13,041 RA patients (78.1% female; mean age 68.9 years at index date) initiated the following index therapies: csDMARD (64.3%), TNFi (19.3%), anti-IL6 (4.3%), anti-CD20 (1.1%), anti-CD80/86 (6.5%), and JAKi (4.5%). The median follow-up time ranged 2.2–2.5 years, and median time on index therapy ranged 0.5–1.1 years (Table 1).

In the 12 months prior to initiating index therapy, patients experienced VTE (prevalence 4.4%) and infections (81.9%), serious infections (16.6%), opportunistic infections (9.7%), and HZ (3.4%). (Table 2). The on-therapy incidence P100PY was 2.4 for VTE (range 2.1–3.0), 249.6 for infection (range 147.8–340.9), 17.6 for serious infection (range 15.4–30.2), and 10.2 for opportunistic infection overall (range 9.6–18.3), including 4.1 for HZ (range 3.3–8.6) (Table 3).

Conclusion: VTE and infection affected Medicare beneficiaries with RA before initiating a new DMARD therapy. While on the new treatment regimen, patients developed recurrent or novel infections or novel VTE cases. Understanding the prevalence and incidence of these conditions can help clinicians and population-health decision makers optimize treatment choices.

Rheumatoid Arthritis Affects the Ossicular Joints: A Human Otopathologic Study

Melissa Castillo-Bustamante[1], Marc Polanik[1], Dhrumi Gandhi[1], Elliott Kozin[1] and Aaron Remenschneider[1], [1]Massachusetts Eye and Ear Infirmary/Harvard University, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation of synovial joints in small and large extremities is commonly seen in Rheumatoid arthritis (RA). To date little is known about how this disease affects the synovial, diarthroidal incudomallear (IMJ) located in the middle ear. Previous clinical reports of hearing impairment and altered middle ear impedance in patients with RA have not been substantiated with defined changes along the ossicular chain. Herein, we performed an otopathologic analysis in human specimens with a history of RA during life.

Methods: The National Temporal Bone Registry was queried for cases with history of RA during life. Otopathologic analysis was performed in individuals with RA and compared to age matched controls. Outcomes included descriptive middle ear pathology, volumetric measurements of the IMJ synovial space and immunohistochemical analysis of the IMJ using CD3 and CD20.

Results: Twenty-one ears (specimens) with RA and 18 controls were identified. Mean age was not significantly different between RA and control groups: 65.3 vs 69.3, (p=0.441). In RA and control group females were mainly affected, 75% and 80%, respectively. Middle ear findings in specimens with RA included: IMJ disarticulation, bone erosion of incus and malleus and demineralization of IMJ. These findings were not present in any control specimen. In specimens with RA, diminished spaces between the osseous surfaces in the lateral sides of the ossicles were seen. A loss of total, calcified and hyaline cartilage in lateral and medial sides of the incus was found in RA specimens compared to controls. Diminished synovial space volume of the IMJ was found in RA specimens but not in controls [(2.62 mL (SD 0.49mL) vs 38.4 mL(SD 81.1 mL), (p=0.004)]. CD3 and CD20 staining was intensely positive within the IMJ space of RA specimens, while controls showed weak IMJ space staining with CD3 and no staining with CD20.

Conclusion: The incudomalleolar joint in patients with RA demonstrate pathologic differences when compared to controls. Cartilage areas and synovial spaces of the RA group were smaller than controls. CD3/CD20 positivity in RA suggests distinct inflammatory involvement of the IMJ. Further study of the functional affects of observed changes on sound transmission is needed.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an immune-mediated synovial disease with chronic inflammation. Systemic inflammation is considered one of risk factors for venous thromboembolism (VTE), which includes both deep venous thrombosis (DVT) and pulmonary embolus (PE). RA patients are thought to be at risk of developing thromboembolic events due to multiple factors. However, less is known about association of systemic inflammation and VTE in patients with RA. We aimed to clarify the clinical features and risk factors of VTE in RA patients.

Methods: We retrospectively reviewed the prevalence of VTE in RA patients who visited Hokkaido University Hospital with more than 2 years follow-up from 2010 to 2019. In this study, 28 cases diagnosed with VTE were identified during that period. All patients fulfilled 2010 American College of Rheumatology (ACR)/ European League Against Rheumatism (EULAR) classification criteria. VTE was confirmed by the venous ultrasound and/or enhanced CT regardless of symptoms. The patients who had been diagnosed with DVT or PE prior to 2010, or had used anticoagulant and/or antiplatelet drugs were excluded. To evaluate the risk factors for the development of VTE, we randomly selected 144 patients without VTE (non-VTE) and registered demographic, clinical, and treatment profile. Disease Activity Score-28 for Rheumatoid Arthritis (DAS28) were calculated in VTE cases and in non-VTE cases at the last regular follow-up visits before onset of the VTE and within the study period, respectively. The risk factors were identified by multivariate logistic regression analysis. The study was approved by the Institutional Review Board of Hokkaido university Hospital.

Results: This study comprised a total of 1379 cases (1076 women/303 men; median age at diagnosis 54 years [Interquartile range (IQR) 42-64]) and median follow up duration was 7 years (IQR 5-9). The prevalence of VTE was 0.20 % (28 of 1379 cases) and the median age at the time of diagnosis of VTE was 74 years (IQR 65.5-79). The rate of female patients was 72.9 %. In the VTE cases, five (17.9%) and three (10.7%) patients had history of orthopedic surgery and malignant disease, respectively. Univariate analysis showed no difference between VTE and non-VTE in the presence of smoking history, hypertension, dyslipidemia, diabetes mellitus, chronic kidney disease, and treatment with JAK inhibitor or NSAIDs. Body mass index (BMI), the presence of interstitial lung diseases and glucocorticoid usage were identified as risk factors of VTE (p=0.001). Furthermore, the rates of moderate and high disease activity in RA (DAS-28CRP > 2.7) were higher in VTE cases compared to non-VTE cases (p=0.01). In multivariate logistic regression analysis, high disease activity in RA was significantly associated with the development of VTE (p= 0.02, Odds Ratio 5.88, 95% Confidence Interval 1.32-26.17).

Conclusion: High disease activity in RA was identified as a risk factor of VTE, suggesting that clinical remission would be beneficial for preventing VTE.

Rheumatoid Arthritis Inpatient Mortality: An Analysis of the National Inpatient Sample

Ehizogie Edigin[1], Precious Eseaton[2] and Augustine Manadan[3], [1]John H Stroger Jr. Hospital of Cook County, Chicago, IL, [2]University of Benin Teaching Hospital, Benin, [3]Cook County Hospital/Rush University Medical center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease with increased mortality. Little national-level data is available on inpatient mortality in RA patients. In this report, we use a large Unites States (U.S) population-based database to analyze the principal discharge diagnosis for RA patients experiencing inpatient mortality.

Methods: Data were abstracted from the National Inpatient Sample (NIS) Database. This is the largest inpatient hospitalization database in the U.S. It is a nationally representative sample of 20% of hospitalizations from approximately 1000 hospitals. The numbers in the databases are weighted to optimize national estimates. The NIS was searched for hospitalizations in 2017 with an ICD-10 RA codes M05 and M06 as the principal or secondary diagnosis. The total number of RA discharges, number of in-hospital deaths, percentage of in-hospital deaths, length of stay (LOS), total hospital charges were recorded. The "principal discharge diagnosis" in RA patients experiencing in-hospital death was divided into 19 ICD 10 code categories.

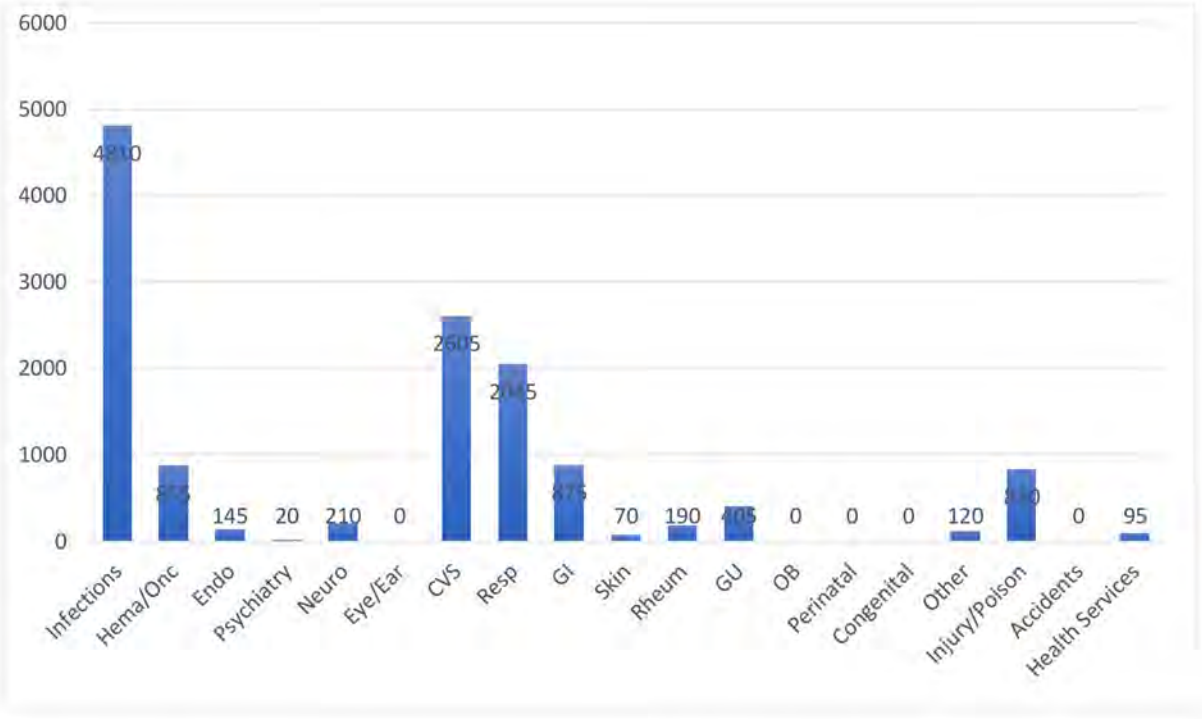
Results: There were over 30 million discharges included in the 2017 NIS database. Of those, 565,440 hospitalizations were for patients aged 18 years or above, who had either a principal or secondary ICD 10 code for RA. 13,285 of these patients (2.35%) experienced in-hospital mortality. These patients were mainly female 70.19%, whites 64.85%, average age of 74.31 years, average LOS of 7.04 days and mean total hospital charges of $101,210. The top 5 principal discharge ICD 10 code categories in RA patients experiencing inpatient mortality in descending order of frequency were as follows (see table 1 and figure 1): infections 4810 (36.20%), cardiovascular 2605 (19.60%), respiratory 2045 (15.39%), digestive system 875 (6.59%), hematology/oncology 865 (6.51%). The most common principal diagnoses in RA patients with in-hospital mortality were sepsis, followed by acute and chronic hypoxic respiratory failure, aspiration pneumonitis, non-ST segment myocardial infarction, and acute kidney injury in descending order of frequency.

Conclusion: For adult RA patients experiencing in-hospital mortality, infections were the most common ICD 10 code category, and sepsis was the most common specific ICD 10 code principal diagnosis of hospitalization. Preventive

Admission Category	Number of Deaths
Certain infections and parasitic diseases	4810
Neoplasms & diseases of the blood and blood-forming organs and certain disorders involving the immune mechanism	865
Endocrine, nutritional and metabolic diseases	145
Mental, behavioral and neurodevelopmental disorders	20
Diseases of the nervous system	210
Diseases of the eye and adnexa and Ear	0
Diseases of the circulatory system	2605
Diseases of the respiratory system	2045
Diseases of the digestive system	875
Diseases of the skin and subcutaneous tissue	70
Diseases of the musculoskeletal system and connective tissue	190
Diseases of the genitourinary system	405
Pregnancy, childbirth, and puerperium	0
Certain conditions originating in the perinatal period	0
Congenital malformations, deformations, and chromosomal abnormalities	0
Symptoms, signs, and abnormal clinical laboratory findings, not elsewhere classified	120
Injury, poisoning, and certain other consequences of external causes	830
External causes of morbidity (accidents & violence)	0
Factors influencing health status and contact with health services	95

Table 1. ICD-10 code admission category for Rheumatoid arthritis hospitalizations with inpatient mortality

measures, prompt diagnosis, and management of sepsis are needed to reduce the rate of inpatient mortality for RA patients.



N/B: Numbers represent number of deaths for each ICD 10 category

Abbreviations: RA: Rheumatoid Arthritis, OB: Obstetrics & gynecology, GU: Genito-urinary, Rheum: Rheumatological, GI: Gastrointestinal, Resp: Respiratory, Hema/onc: Hematologic/Oncology, Endo: Endocrine, Neuro: Neurological, CVS: Cardiovascular

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: In clinical practice, drug treatment decisions must account for the expected benefit from a drug along with its potential risks. Evaluating the number needed to treat (NNT) and the number needed to harm

Trial	RA-BEACON[1]		ORAL STEP[3]		SELECT BEYOND[2]	
NNT or NNH and Response (percentage of patients) at Week 12	BARI (N=174)	PBO (N=176)	TOFA (N=133)	PBO (N=132)	UPA (N=164)	PBO (N=169)
NNT						
ACR20						
NNT (95% CI)	5 (4, 9)		6 (4, 17)		3 (3, 4)	
Response	48.9	27.3	41.7	24.4	64.6	28.4
ACR50						
NNT (95% CI)	9 (6, 20)		6 (4, 11)		5 (4, 8)	
Response	20.1	8.0	26.5	8.4	34.1	11.8
ACR70						
NNT (95% CI)	10 (7, 20)		9 (6, 17)		20 (10, ∞*)	
Response	12.6	2.3	13.6	1.5	11.6	6.5
NNH						
AEs leading to discontinuation						
NNH (95% CI)	56 (17, ∞*)		143 (not reported)		NA**	
Event	4.0	2.3	6.0	5.3	2.4	5.3
SAEs						
NNH (95% CI)	NA**		NA**		21 (not reported)	
Event	1.7	4	1.5	4.5	4.9	0.0

* ∞ : when the difference between treatment and PBO is positive, but the CI includes 0, the upper bound for the CI is set to ∞

**NA: the AE was more frequent with PBO than active treatment; the difference between treatment and PBO is ≤0

Abbreviations: ACR20/50/70: proportion of patients achieving ≥20%, 50%, or 70% improvement from baseline, respectively, with American College of Rheumatology response; AE: adverse event; BARI: baricitinib 2 mg/day; PBO: placebo; SAE: serious adverse events; TOFA: tofacitinib 5 mg twice daily; UPA: upadacitinib 15 mg/day

Number needed to treat and number needed to harm at Week 12 for baricitinib, tofacitinib, and upadacitinib

(NNH), together, is one approach to inform about the benefit-risk profile of a drug. The objective of this analysis is to report the NNT and NNH of Janus kinase (JAK) inhibitors approved in the US, baricitinib 2 mg/day (BARI), tofacitinib 5 mg twice daily (TOFA), and upadacitinib 15 mg/day (UPA), in RA patients who have an inadequate response to TNF inhibitors (TNFi-IR).

Methods: Data were from published Phase 3 randomized, double-blind clinical trials (RCTs) in TNFi-IR RA patients. In the BARI and UPA RCTs, patients were required to have an RA diagnosis defined by the 2010 ACR classification criteria,[1,2] whereas patients in the TOFA RCT were required to have an RA diagnosis based on the 1987 ACR criteria.[3] The respective treatment and placebo (PBO) sample sizes included 174 and 176 BARI and PBO patients,[1] 133 and 132 TOFA and PBO patients,[2] and 164 and 169 UPA and PBO patients.[3] Endpoints were evaluated at 12 weeks and included the reported proportion of patients who achieved American College of Rheumatology 20%, 50%, or 70% response (ACR20, ACR50, ACR70, respectively) for NNT and percentage of patients who experienced adverse events (AEs) leading to study discontinuation or serious AEs (SAEs) for NNH. NNT and NNH were calculated as 100 / difference (95% CI) of response or event rate between treatment and PBO.

Results: Across trials, patient age ranged from an average of 54 to 58 years (yrs) and 99-100% of patients had prior use of at least one biologic DMARD or TNFi, specifically. The duration of disease ranged from 11-15 yrs. The percentage of patients experiencing the given endpoints with treatment vs. PBO and the associated NNT or NNH are presented in the Table by study. The NNTs were < 10 for BARI, TOFA, and UPA with ACR20 and ACR50. The NNH values varied by JAK inhibitor and by event type.

Conclusion: There is no methodology that can be considered a gold-standard to evaluate the benefit and risk profile of a drug in a specific population. Across different studies of patients with refractory RA, JAK inhibitors have a favorable benefit and risk profile. Each drug delivers benefits with an associated level of risk, and these are not the same from drug to drug. NNT and NNH is one strategy for clinicians to standardize the benefit-risk assessment across different clinical programs that can be useful to support better informed decision making in clinical practice.

Blending Hierarchical Cluster Analysis and Cluster-Specific Regressions to Predict Clinical Outcome to Tofacitinib Treatment in Patients with Rheumatoid Arthritis

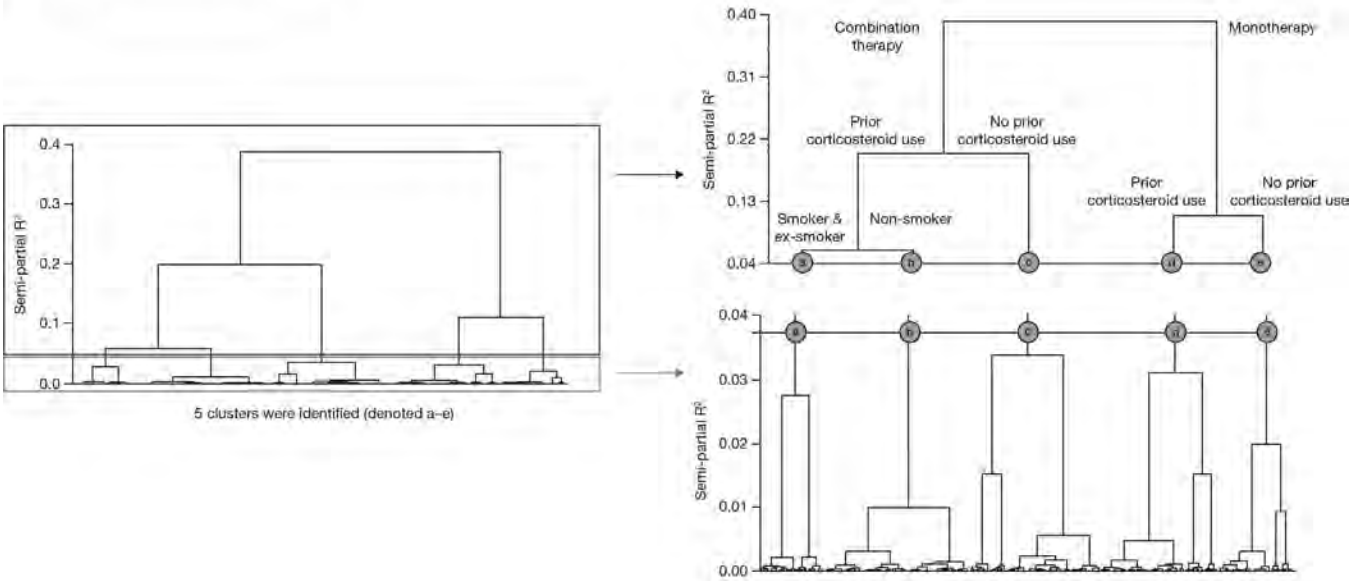
Robert Landewé[1], Daniel H Solomon[2], Gianluca Bonfanti[3], Luigi Manca[3], John C Woolcott[4], Jasper Deuring[5], Stephen Watt[6], Pritha Bhadra Brown[6], Rebecca Germino[6], Birol Emir[6] and Roger A Edwards[7], [1]Amsterdam University Medical Center & Zuyderland Hospital, Amsterdam, Netherlands, [2]Brigham and Women's Hospital, Boston, MA, [3]Fair Dynamics Consulting, SRL, Milan, Italy, [4]Pfizer Inc, Collegeville, PA, [5]Pfizer Inc, Rotterdam, Netherlands, [6]Pfizer Inc, New York, NY, [7]Health Services Consulting Corporation, Boxborough, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Lifespan of a Disease
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with RA exhibit wide variations in response to therapy. Early treatment response profiles may help us to better predict subsequent treatment response, thus expediting treatment optimization, improving outcomes, and reducing exposure to ineffective therapies. This exploratory study aimed to predict treatment outcomes to tofacitinib in patients with RA using hierarchical cluster analysis of baseline (BL) data, and cluster-specific regressions using BL data only vs BL data + early treatment response profiles.

Methods: This analysis included data from Phase 3 (NCT00814307; NCT00847613; NCT00856544; NCT00853385) and Phase 3b/4 (NCT02187055) randomized controlled trials (RCTs) of tofacitinib in patients with RA. Data were included from patients randomized to receive tofacitinib 5 mg twice daily (BID; monotherapy or + MTX/other csDMARDs) with ≥ 4 Clinical Disease Activity Index (CDAI) data points during 6 months of treatment and moderate/high BL CDAI severity; patients who discontinued the RCTs were assessed case-by-case for inclusion. A bottom-up hierarchical cluster analysis (using BL data) was conducted to improve prediction of tofacitinib response by identifying patient subgroups for cluster-specific regression models (using BL data ± early response profiles). The primary outcome was prediction of CDAI responder status at Month (M)6, using BL, M1, and M3 data, defined as achievement of minimum clinically important difference (MCID; CDAI change of 11/6/2 for patients with high/moderate/low BL CDAI severity); achievement of low disease activity (2.8< CDAI ≤ 10) or remission (CDAI ≤ 2.8) (ie treat-to-target approach for response) was also assessed. For cluster-specific regressions, patients of each cluster were randomized to a training (model development) or testing (model evaluation) dataset. The algorithm for outcome prediction consisted of all fixed BL demographics (eg age) ± time-lagged (M1 and M3) covariates (eg CDAI).

Figure 1. Hierarchical cluster analysis dendrogram



The semi-partial R^2 measures the homogeneity of merged clusters. This value reflects decreasing homogeneity of members in a cluster as clusters are combined to make new clusters.
Semi-partial R^2 values ranging from 0.034 to 0.058 were deemed to reflect an appropriate tradeoff of low semi-partial R^2 and not too many fragmented clusters.
Cluster 'a' (n=192) = smoker/ex-smoker>prior corticosteroid use>combination therapy; cluster 'b' (n=446) = non-smoker>prior corticosteroid use>combination therapy;
cluster 'c' (n=401) = no prior corticosteroid use>combination therapy; cluster 'd' (n=354) = prior corticosteroid use>monotherapy; and cluster 'e' (n=224) = no prior corticosteroid use>monotherapy

Figure 2. Prediction of CDAI responder status at Month 6 in the testing dataset, as defined by MCID or T2T responder criteria,[a] in optimized, cluster-specific regressions using data for a) BL variables only or b) baseline + time-lagged covariates. Prediction of responder status was compared with the true responder status to determine whether the prediction was correct or incorrect. The total proportion of patients for whom prediction of outcome (response or non-response) was correct may differ slightly from the sum of correct response and correct non-response, due to number rounding

a)

MCID

Total patients with correct predictions: 353/435 (81.1%)		True MCID responder status at Month 6	
		No response	Response
Predicted MCID responder status at Month 6	No response	5/435 (1.2%)	15/435 (3.4%)
	Response	67/435 (15.4%)	348/435 (80.0%)

T2T

Total patients with correct predictions: 272/435 (62.5%)		True T2T responder status at Month 6	
		No response	Response
Predicted MCID responder status at Month 6	No response	233/435 (53.6%)	148/435 (34.0%)
	Response	15/435 (3.4%)	39/435 (9.0%)

b)

MCID

Total patients with correct predictions: 367/435 (84.4%)		True MCID responder status at Month 6	
		No response	Response
Predicted MCID responder status at Month 6	No response	13/435 (3.0%)	9/435 (2.1%)
	Response	59/435 (13.6%)	354/435 (81.4%)

T2T

Total patients with correct predictions: 352/435 (80.9%)		True T2T responder status at Month 6	
		No response	Response
Predicted MCID responder status at Month 6	No response	209/435 (48.0%)	44/435 (10.1%)
	Response	39/435 (9.0%)	143/435 (32.9%)

[a]CDAI response was defined as achievement of MCID (CDAI change of 11/6/2 for patients with high/moderate/low BL CDAI severity) or achievement of low disease activity (2.8< CDAI ≤10) or remission (CDAI ≤2.8) (ie T2T approach for clinical response)
BL, baseline; CDAI, Clinical Disease Activity Index; MCID, minimum clinically important difference; T2T, treat-to-target

Results: Data from 1,617 patients with RA using tofacitinib 5 mg BID were included. Hierarchical cluster analysis using BL data had 6 clustering variables (tofacitinib monotherapy/combination therapy, prior corticosteroid use, smoking status, BL CDAI, BL HAQ-DI, BL pain discordance) and 5 unique clusters (ie subgroups; Figure 1). The train-

ing dataset (1,182 patients; 73.1%) was used to develop cluster-specific regressions which were then assessed in a testing dataset (435 patients; 26.9%). When regression models were used to predict outcome in the testing dataset using only BL data, prediction of MCID-defined CDAI responder status at M6 was correct for 81.1% of patients (Figure 2). Using BL + time-lagged covariates, prediction of MCID-defined CDAI responder status was correct for 84.4% of patients (Figure 2).

Conclusion: This hybrid of clustering and cluster-specific regressions, taking into account early treatment response profiles, is an interesting approach worthy of further exploration for predicting and improving long-term tofacitinib treatment outcomes in patients with RA.

Abstract Number: 1764

Disease Modifying Anti-rheumatic Drug and Biologic Therapy in Pregnancy: A Single-center Mixed Methods Study

Lauren Glick[1], Justin Shamis[2], Taneisha McGhie[3] and Dharini Mahendira[4], [1]University of Toronto, Toronto, ON, Canada, [2]North York General Hospital, Toronto, ON, Canada, [3]Cornwall University Hospital, Kingston, Saint Andrew, Jamaica, [4]University of Toronto - Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases including rheumatoid arthritis, seronegative inflammatory arthritis and systemic lupus erythematosus can be associated with significant morbidity in women of child-bearing age. Both these diseases themselves and their treatments have been shown to impact fetal and maternal outcomes. Although there is growing evidence outlining safety of many anti-rheumatic drugs (ARDs) in pregnancy, many patients discontinue treatments in the peripartum period due to concern of fetal harm. This study sought to identify perinatal medication use patterns at a single tertiary care center and to understand patient perspectives surrounding their use.

Methods: Electronic medical records were reviewed for women attending the rheumatic diseases in pregnancy clinic, a rheumatology clinic with subspecialty input, at St. Michael's Hospital in Toronto, Canada, from January 2013 until November 2019. A 12-item questionnaire was administered to women attending this clinic to explore patient perspectives. Data was analyzed using descriptive statistics.

Results: Thirty-eight women and forty-five pregnancies were identified, with rheumatoid arthritis (N=12, 32%), systemic lupus erythematosus (N=18, 27%) and seronegative arthritis (n=8, 16%) representing the majority. Twenty-nine patients (60%) were exposed to disease modifying anti-rheumatic drugs (DMARDs) and eight patients (16%) were exposed to biologics during pregnancy. Of those who experienced medication changes in the perinatal period, the highest proportion (57%) occurred pre-partum, with fewer changes in each trimester, as pregnancy progressed. Patients who received pre-pregnancy counselling were more likely to have pre-pregnancy medication adjustments and were more likely to utilize a DMARD or biologic during pregnancy. The survey was completed by 19 respondents. Fourteen women (74%) reported that they would consider ARD use in pregnancy with the highest degree of comfort reported for DMARDs (N=16, 84%), compared to steroids (N=3, 16%), non-steroidal anti-inflammatory drugs (N=6, 32%) and biologics (N=2, 11%). Fifteen participants (79%) felt that their questions were adequately answered by health care providers with the majority (79%) describing their rheumatologist as their primary information source. Most patients believed that information received from healthcare providers was helpful (N=15, 79%) and felt that they were provided adequate resources to inform decisions about medication use in pregnancy (N=11, 58%).

Conclusion: While the majority of women with rheumatic diseases in our cohort continued on ARD therapy during pregnancy, most survey respondents reported discomfort with use of steroids, NSAIDs, biologics and DMARDs, despite evidence of their safety in recent literature. This discrepancy between patient perspectives and available evidence is important to consider when counseling patients on ARD use in pregnancy. Survey respondents relied on their rheumatologist as their primary information source, highlighting the important role specialists can play in informing patient perspectives surrounding ARD use in pregnancy.

Obstetric Outcomes in Younger Women Less Than 21 Years of Age Compared to Women Between Age 21 and 25 Years with Rheumatic Disease

Chelsey Smith[1], Christina Chambers[1], Rebecca Baer[2], Laura Jelliffe-Pawlowski[3] and Gretchen Bandoli[1], [1]University of California San Diego, La Jolla, CA, [2]University of California San Diego, La Jolla, [3]University of California San Francisco, San Francisco

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Very young maternal age has been described as a risk factor for several adverse obstetric outcomes. This study aimed to investigate whether younger women with rheumatic diseases had differential risk for adverse obstetric outcomes compared to older age groups.

Methods: We queried a retrospective California birth cohort of 3 million singleton live births between 2011-2017 created from linked birth certificates and hospital discharge summaries. ICD-9/10 codes were used to classify women with rheumatoid arthritis (RA), juvenile idiopathic arthritis (JIA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), and systemic lupus erythematosus (SLE). Outcomes of interest were preterm birth, very preterm birth, small for gestational age offspring, offspring requiring NICU admission, gestational diabetes, preeclampsia, and caesarean

delivery. In multivariable log-linear regression, risk of each outcome was assessed in women less than 21 years of age compared to women between 21 and 25 years of age. Models were adjusted for maternal race/ethnicity, body mass index, payer source, anxiety, depression, bipolar disorder, smoking, drug abuse, alcohol abuse, and history of hypertension or diabetes. Risk ratios were first estimated for women with any rheumatic disease, and then repeated for women with RA/JIA or SLE.

Results: A total of 1,769 women 25 years or younger with any rheumatic disease were identified, with 394 under the age of 21. Women with any rheumatic condition under age 21 overall had a lower risk for caesarean delivery (aRR 0.67, 95% CI 0.55-0.81) and gestational diabetes (aRR 0.55, 95% CI 0.36-0.84) than women age 21-25. When analyzed by specific rheumatic disease, women with RA or JIA under age 21 had a higher risk for preterm birth (aRR 1.45, 95% CI 1.01-2.08) as compared to women age 21-25. This increased risk was not observed in very young women with SLE.

Conclusion: The majority of obstetric outcomes did not differ between very young women and women age 21-25 with rheumatic diseases. Risk of caesarean delivery and gestational diabetes may be decreased in younger women compared to older women with rheumatic diseases. Our study did suggest that for RA or JIA, younger age may be associated with a higher risk of preterm delivery.

Abstract Number: 1766

Trends of Pregnancy Outcomes in a Large Electronic Health Record Cohort of Systemic Lupus Erythematosus Patients

April Barnado[1], Alex Camai[1] and Lee Wheless[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Studying pregnancy in systemic lupus erythematosus (SLE) is difficult given its relative rarity. Electronic health record (EHR) contain longitudinal data to serve as a powerful tool. Using a previously validated algorithm, we identified SLE pregnancies in a large EHR. We then examined demographics, medications, and outcomes in SLE pregnancies from 1991 to 2017.

Methods: We used a de-identified EHR with over 3 million subjects. We selected individuals using a validated algorithm of ≥ 4 counts of the SLE ICD-9 (710.0) or ICD-10 codes (M32.1*, M32.8, M32.9) and ≥ 1 ICD-9 or ICD-10 code for pregnancy-related diagnoses yielding 234 potential subjects. We extracted demographic, disease characteristics, medications, and pregnancy outcomes from chart review. SLE cases were diagnosed by a rheumatologist. We primarily analyzed only pregnancies that occurred after SLE diagnosis but then compared pregnancy outcomes before and after SLE diagnosis. SLE medication use was defined as ever use during pregnancy. In addition to a cross-sectional analysis of pregnancy outcomes, we assessed outcomes and medication use over time in 5 year increments.

Table 1. Characteristics of Systemic Lupus Erythematosus Pregnancies.

Characteristics	SLE pregnancies that occurred after SLE diagnosis (n = 168)
Race (%)	
White	58%
African American	33%
Unknown	4%
Asian	3%
Other	2%
Ethnicity (%)	
Hispanic	6%
Mean age at delivery ± standard deviation (range)	28 ± 6 (16-41)
SLE nephritis	45%
Antiphospholipid antibody syndrome	29%
Ever SLE medication use during pregnancy	
Hydroxychloroquine	42%
Corticosteroids	63%
Azathioprine	14%
Aspirin	28%
Anticoagulants	21%
Pregnancy Outcomes	
Live Birth	85%
Caesarean section	49%
Mean gestational age (weeks) ± standard deviation	35 ± 4
Mean birthweight (kg) ± standard deviation	2.37 ± 0.97
Pre-term birth	42%
Preeclampsia	24%
Preterm preeclampsia	82%

Results: Of the 234 potential SLE subjects with pregnancies, there were 208 total pregnancies to definite SLE cases with 168 pregnancies occurring after SLE diagnosis and 40 pregnancies occurring before SLE diagnosis. Of 168 pregnancies that occurred after SLE diagnosis, 58% were to White women and 33% to African American women with 45% complicated by SLE nephritis and 29% antiphospholipid antibody syndrome (Table 1). Overall, SLE medication use was low with 42% of pregnancies with antimalarial use and 28% with aspirin use. Aspirin use was low over time. Antimalarial use increased over time with a peak of 62% in 2015 (Figure 1). Overall, live birth rate was 85% with 49% delivering surgically. The preterm birth rate was 42%. Preeclampsia complicated 24% of pregnancies with most occurring preterm at 82%. Mean gestational age was 35 weeks. Over time, live birth rates were similar with an increase in Caesarean section and preterm deliveries in 2005 with a subsequent decline (Figure 2). Rates for pregnancy outcome were not significantly different in pregnancies occurring before vs. after SLE diagnosis.

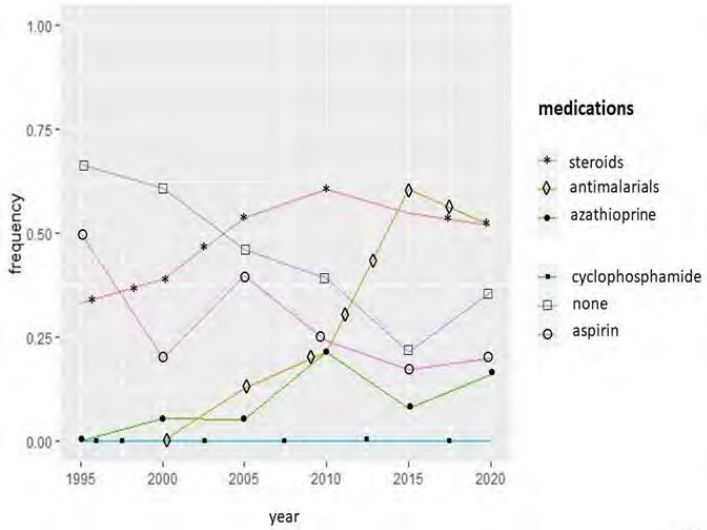

Figure 1. Trends of medication use in Systemic Lupus Erythematosus pregnancies from 1991 to 2017. The x axis shows year in the electronic health record ranging from 1991 to 2017. The y axis shows frequency of ever use of medications during pregnancy. Medications are listed to the right of the figure.

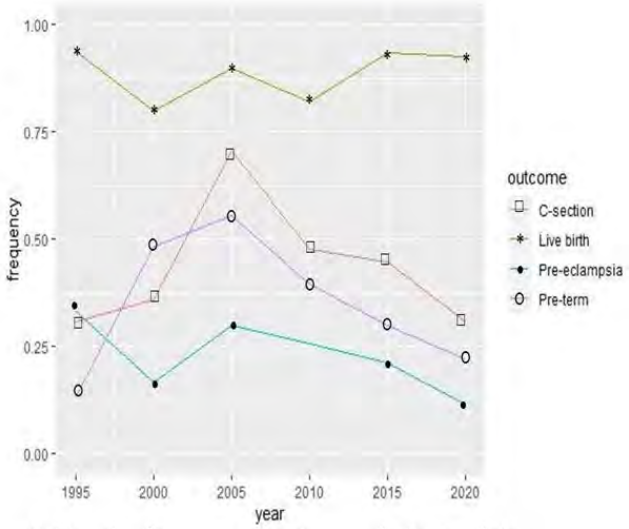

Figure 2. Trends of pregnancy outcomes in Systemic Lupus Erythematosus pregnancies from 1991 to 2017. The x axis shows year in the electronic health record ranging from 1991 to 2017. The y axis shows frequency of the pregnancy outcome. Pregnancy outcomes are listed to the right of the figure.

Conclusion: Using a large EHR, we demonstrate higher than expected rates of preterm birth and preeclampsia in SLE. These rates have not improved over time. Recommended medications in SLE pregnancy, particularly aspirin, are not dramatically increasing over time despite recommendations for use in all SLE pregnancies. These trends demonstrate the need for guideline implementation to improve SLE pregnancy outcomes.

Maternal Peripartum Outcomes Are Similar to the General Population in Rheumatoid Arthritis Pregnancies

Sarah Tarplin[1], Alex Camai[1] and April Barnado[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Data on birth outcomes to women with rheumatoid arthritis (RA) are limited and conflicting. Some studies indicate that women with well controlled RA have birth outcomes similar to the general population, while others show higher rates of preterm birth and cesarean section. There are few studies assessing how RA impacts maternal peripartum outcomes such as maternal infection rates and blood transfusions. Using a real-world, electronic health record (EHR) cohort, we assessed RA medication use, fetal, and maternal peripartum outcomes.

Methods: In a large, de-identified EHR with over 3 million subjects and data from 1990 to 2019, we identified possible RA births. We used at least 1 delivery-related ICD-9 or ICD-10-CM code and a validated RA algorithm requiring

[c]Rheumatoid arthritis diagnosis based on chart review.
[d]Time in years from Rheumatoid arthritis diagnosis based on chart review to delivery date.

at least 1 ICD-9 (714*) or ICD-10-CM RA codes (M05*, M06.0, M06.2, M06.3, M06.8, M06.9), ever mention of a RA medication, and a RA keyword with a positive predictive value of 90%. RA cases were diagnosed by a rheumatologist, and we included pregnancies that occurred after RA diagnosis. We assessed seropositivity, age at RA diagnosis, and presence of erosive RA based on keyword search of notes and radiology reports. Medication use was defined as ever use during the pregnancy and at time of delivery. We assessed maternal and fetal outcomes with preeclampsia diagnosed by an obstetrician. Maternal peripartum outcomes included rates of blood transfusion, rates of infection at up to 6 weeks postpartum as defined by a clinician, and length of hospital stay in days.

Results: We identified 82 pregnancies that occurred after RA diagnosis. Our RA cohort was predominantly White (77%) with 54% being seropositive and 15% having erosive disease (Table 1). Prednisone use ever during pregnancy and at the time of delivery was common (40% and 39%, respectively). Disease modifying anti-rheumatic drugs

Table 2: Maternal peripartum and fetal outcomes in pregnancies to women with rheumatoid arthritis.

Median	9

[a]All pregnancies occurred after Rheumatoid arthritis diagnosis.
[b]Apgar scores range from 1 to 9.

(DMARDs) and tumor necrosis factor inhibitor (TNFi) use during pregnancy were low (9% and 6%) with only 16% of pregnancies occurring before the first TNFi approval. For most cases, TNFis were discontinued prior to delivery. Rates of preterm delivery were higher than the general population (20% vs. 10%) but similar to rates in other RA studies (15-20%). Rates of preeclampsia (6%) and caesarean section (39%) for our cohort were no different than the general population and were similar to other RA studies (Table 2). Overall, infection rates were low with only 5 pregnancies (6%) having any infection. Of these 5 pregnancies with infection, 4 had endometritis and 1 cellulitis with no surgical site infections. In our cohort, the rate of peripartum red blood cell transfusions was 1%, which was similar to the general population. Median length of stay of 4 days was similar to the general population.

Conclusion: We identified pregnancies to RA mothers in a real-world, large EHR cohort. Corticosteroid use was common during pregnancy and at the time of delivery while DMARD and TNFi use was rare. Women with RA were at in-

creased risk for preterm birth but had rates of preeclampsia and caesarean section similar to the general population. Compared to the general population, women with RA also had similar rates of peripartum infection and transfusions.

Abstract Number: 1768

The Importance of Pregnancy Planning in Lupus Pregnancies

Aardra Rajendran[1], Amanda Eudy[2], Stephen Balevic[3] and Megan Clowse[4], [1]Duke University, Lewisville, NC, [2]Duke University, Durham, NC, [3]Duke University, Hillsborough, NC, [4]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Given the clinical importance of the pre-conception period in lupus pregnancy management and because pregnancy planning can be potentially improved, this study explores the role of planning on lupus pregnancy outcomes. We hypothesize that women with lupus with planned pregnancies will have fewer pregnancy complications.

Methods: The Maternal Autoimmune Disease Research Alliance (MADRA) was reviewed for lupus pregnancies (1/1/2018 to 4/1/2020) and SLE diagnosis was confirmed by Systemic Lupus Collaborating Clinics (SLICC) criteria. The London Measure of Unplanned Pregnancy (LMUP) classified lupus pregnancies as Planned or Not Planned (Am-

DELIVERY OUTCOMES[1]	Overall	LMUP Not Planned	LMUP Planned	p-value
	N=35	n=15	n=20	
PROMISSE-APO[2]	20/33 (61%)	11/14 (79%)	9/19 (47%)	0.09
PROMISSE APO-SEVERE[3]	6/33 (18%)	6/14 (43%)	0/19 (0%)	0.003
Severe Neonatal Outcome[4]	13/29 (45%)	7/10 (70%)	6/19 (32%)	0.06
Non-live Births:	6 (17%)	5 (33%)	1 (5%)	0.06
Termination	1 (3%)	1 (7%)	0 (0%)	0.4
Miscarriage	4 (11%)	3 (20%)	1 (5%)	0.3
Stillbirth	1 (3%)	1 (7%)	0 (0%)	0.4
Live Births:	29 (83%)	10 (67%)	19 (95%)	0.06
Gestational age at delivery, weeks (mean ± S.D.) (range)	36.2 ± 3.4 (24-39)	35.3 ± 5.1 (24-39)	36.7 ± 2.2 (30 – 39)	0.4
Preterm Birth	10/29 (34%)	4/10 (40%)	6/19 (32%)	0.7
SGA < 10th percentile	7/29 (24%)	4/10 (40%)	3/19 (16%)	0.2
Preeclampsia	8/30 (27%)	5/11 (45%)	3/19 (16%)	0.1

1. Delivery outcomes were missing for 8 pregnancies as patients had either not delivered as of 4/1/2020 (n=7) or data was unavailable through chart review (n=1).
2. PROMISSE-APO: neonatal death, fetal death > 12 weeks, preeclampsia, pre-term delivery < 36 weeks, or small for gestational age (SGA) < 5th percentile. Pregnancy losses < 12 weeks were excluded as in the PROMISSE study (Kim et al., 2016).
3. PROMISSE-APO SEVERE: neonatal death, fetal death > 12 weeks, preeclampsia and pre-term delivery < 34 weeks, or pre-term delivery < 30 weeks. Pregnancy losses < 12 weeks were excluded as in the PROMISSE study (Kim et al., 2016).
4. Severe neonatal outcomes: neonatal death, NICU stay > 1 week, APGAR < 7 at 5 minutes, or SGA < 5th percentile

Figure 1. Demographics and Comorbidities

Figure 2. Delivery Outcomes

bivalent or Unplanned), and the Physician's Global Assessment (PGA) quantified disease activity. Adverse outcomes were defined using the composite PROMISSE-APO SEVERE (neonatal death, fetal death > 12 weeks, preeclampsia and pre-term delivery < 34 weeks, or pre-term delivery < 30 weeks) and a composite severe neonatal outcomes variable (neonatal death, NICU stay > 1 week, APGAR < 7 at 5 minutes, or SGA < 5th percentile).

Results: This study included 43 lupus patients with 43 pregnancies (no twins). Average maternal age was 29.4 years with 42% identifying as Black or African American. Overall, 60% of pregnancies were Planned and 40% were Not Planned (37% Ambivalent, 2% Unplanned). Women with Not Planned pregnancies were more likely to be younger, have less than a college education, have an income less than $50,000 per year, and require Medicaid. Additionally, women with Not Planned pregnancies had higher pre-pregnancy SLE activity (Fig. 1). Of the 35 pregnancies with delivery outcomes, women with Not Planned pregnancies had increased PROMISSE-APO SEVERE and severe neonatal outcomes as compared to those with Planned pregnancies (Fig. 2). Pre-conception SLE activity, race, and socio-economic disadvantage were not independently associated with adverse maternal-fetal outcomes. Women with Not Planned pregnancies were more likely to discontinue all pregnancy-compatible SLE medications in the peri-conception period (23% vs 0%; p=0.03) and require addition of at least one SLE medication during pregnancy (100% vs 30%; p < 0.0001). They were also less likely to receive pre-conception counseling with a rheumatologist (19% vs 58%; p=0.02) and take prenatal vitamins (6% vs 77%; p< 0.0001). Overall, 76% of women with Not Planned pregnancies did not use contraception prior to pregnancy, while 24% reported using contraception sometimes.

Conclusion: Whether a woman with lupus had a planned pregnancy or not was the primary predictor of adverse outcomes in this cohort. Women with planned pregnancies had higher rates of pre-conception counseling, increased adherence to pregnancy compatible SLE medications, and were more likely to conceive when disease activity was quiescent or low, all of which can help improve outcomes. Avoiding conception when a woman with lupus is not

medically prepared for pregnancy is a modifiable intervention that can decrease morbidity and mortality for mother and baby.

Patient-reported COVID-19 Infection in Pregnant Women with Rheumatic Disease: Data from the COVID-19 Global Rheumatology Alliance Patient Experience Survey

Jonathan Hausmann[1], Emily Sirotich[2], Bonnie Bermas[3], Megan Clowse[4], Milena Gianfrancesco[5], Pedro M Machado[6], Helen Robinson[7], Anja Strangfeld[8], Jinoos Yazdany[9] and Philip Robinson[10], [1]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Cambridge, MA, [2]McMaster University, Hamilton, ON, Canada, [3]UTSouthwestern.edu, Dallas, TX, [4]Duke University, Chapel Hill, NC, [5]University of California, San Francisco, San Francisco, CA, [6]University College London, London, United Kingdom, [7]University of Queensland School of Medicine, HERSTON, Queensland, Australia, [8]German Rheumatism Research Center, Berlin, Germany, [9]UCSF, San Francisco, CA, [10]University of Queensland, Herston, Queensland, Australia

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The impact of COVID-19 on pregnancy in patients with rheumatic disease is unknown. We describe COVID-19 outcomes in pregnant women with rheumatic disease who self-reported to the COVID-19 Global Rheumatology Alliance (C19-GRA) Patient Experience Survey.

Methods: The C19-GRA launched the Patient Experience Survey for adults and parents of children with rheumatic disease, with or without COVID-19 infection. This patient-reported survey was distributed online through patient support organizations and on social media. The survey was available to an international audience and collected data on rheumatic disease diagnosis, medications, COVID-19 outcomes, and pregnancy status. The survey launched on April 3, and we report data until May 26, 2020. The study was approved by the IRB at Boston Children's Hospital.

Results: Out of more than 10,000 patients who answered the survey, six patients self-reported with COVID-19 infection and pregnancy. Four were white, one pacific islander, and one pacific islander/south Asian. The mean age was 36 years, range 26-45 years. Four were pregnant at the time of COVID-19 infection, one was within six weeks of delivery, and one became pregnant within six weeks of infection. Two were current smokers, four were non-smokers. Their rheumatic diagnoses were rheumatoid arthritis & Sjögren syndrome (n=1), undifferentiated connective tissue disease (n=1), SLE & Sjögren syndrome (n=1), anti-phospholipid antibody syndrome (n=1), Bechet's disease (n=1) and psoriatic arthritis, Sjögren syndrome, and scleritis/uveitis (n=1). The patients reported taking the following medications: TNF inhibitor (n=1), glucocorticoid monotherapy (prednisone 10mg, n=1), antimalarial monotherapy (n=1), antimalarial & glucocorticoid (prednisone 40mg, n=1) and cyclosporine (n=1) and none (n=1). Symptoms of COVID-19 included cough (n=6), malaise/fatigue (n=5), muscle aches (n=5), sore throat (n=5), myalgia (n=5), fever (n=4), shortness of breath (n=4) and loss of taste (n=2). The diagnosis was made by a doctor based on a positive test (n=1), by a doctor based on symptoms (n=3), and self-diagnosis by the patient (n=2). The one patient who had a positive test re-

ceived colchicine and azithromycin for treatment of COVID-19 and another patient reported receiving steroids. Three cases had work-related exposures: two healthcare employees and a patient that was exposed to an ill co-worker in her office; three others reported potential exposures in healthcare facilities. No patient was hospitalized, two patients reported no difficulties performing activities of daily living (ADLs), and four did report difficulties performing ADLs.

Conclusion: In this small series of patients with rheumatic disease and COVID-19, patient-reported outcomes were favorable. Although patient-reported outcomes have limitations especially with regard to the accuracy of self-diagnosis, they may add to the knowledge on the course of COVID-19 in pregnant patients. Future studies should follow the long-term effects of COVID-19 on the pregnancy, mother, and child.

Lupus Low Disease Activity State Protects Against Pre-Term Birth

Michelle Petri[1], Jessica Li[2] and Daniel Goldman[3], [1]Johns Hopkins University School of Medicine, Baltimore, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Timonium, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus low disease activity state (LLDAS) (Ann Rheum Dis. 2016;75:1615–21.) combine both low disease activity (SLEDAI score of ≤4, PGA >=1 no flare, no severe organ involvement) and prednisone reduction (>= 7.5 mg). Being in LLDAS for 50% or more of follow-up visits results in a 50% reduction in organ damage (Arthritis Rheumatol 2018;70:1790-5). LLDAS has been a useful secondary outcome measure in randomized clinical trials. We asked whether being in LLDAS at the start of pregnancy predicted the pregnancy outcome.

Methods: All patients met revised ACR or SLICC classification criteria. At each visit, LLDAS was calculated. The start date of each pregnancy was determined. At each visit, we created a variable to indicate the trimester of the pregnancy. To evaluate whether LLDAS at the first pregnancy visit associated with pregnancy outcomes, a GEE model was used to account for the same patient contributing more than one pregnancy.

Results: There were 636 pregnancies (from 435 patients: 36% African American, 54.5% Caucasian) that had LLDAS status determined at the first pregnant visit. Of these 636 pregnancies, there were 537 births, 77 miscarriages, and 22 terminations. 291 patients had 1 pregnancy, 100 had 2, and 44 had 3 recorded. There was no association between reaching LLDAS at the first pregnancy visit and miscarriage (OR 0.71, 95% CI 0.44, 1.15, p=0.16, adjusted for age and race). Table 1 shows the association between LLDAS at the first pregnancy visit and preterm birth, with 537 pregnancies eligible for analysis. There was strong evidence of an association between LLDAS at first pregnant visit and preterm birth. Next, we looked at pregnancies that had the first visit in the first trimester. There were 462 pregnancies included. Once again, there was no association with miscarriage (OR 0.76, 95% CI 0.45, 1.29 p=0.312 adjusted for

	Reaching LLDAS at first pregnancy visit	n (%)	Adjusted OR (95% CI)	Adjusted p-value
Prematurity (GA<37 weeks)	No	100/225 (44.4%)	1.00 (ref)	
	Yes	69/213 (22.1%)	0.41 (0.29, 0.59)	<0.0001

Prematurity (GA<37 weeks)	No	71/164 (43.3%)	1.00 (ref)	
	Yes	51/232 (22.0%)	0.43 (0.28, 0.67)	0.0001
Extreme prematurity (GA<28 weeks)	No	13/164 (7.9%)	1.00 (ref)	
	Yes	4/232 (1.7%)	0.25 (0.08, 0.80)	0.0197
n represents the number of pregnancies OR and p-value were adjusted for the contribution of multiple pregnancies from the same patient, age at the visit, and race				

Table 2. Association between LLDAS at first trimester visit and preterm birth

age and race). Table 2 shows the analysis of being in LLDAS at the first trimester and preterm birth (396 pregnancies were eligible for analysis). The same strong protective effect of being in LLDAS against preterm birth was found.

Conclusion: Currently, women with SLE are told that their SLE should be "in remission" for 6 months prior to conception. Our data suggest that being in LLDAS may be sufficient to protect against preterm birth, which numerically remains the most frequent adverse pregnancy outcome in SLE. LLDAS does not protect against miscarriage (likely because antiphospholipid antibodies contribute to miscarriage risk). LLDAS is a more realistic pre-pregnancy clinical goal, as durable remission is difficult to achieve in SLE.

Fertility and Pregnancy Outcomes in Women with Spondyloarthritis: A Systematic Review and Meta-analysis

Sabrina Hamroun[1], Aghilès Hamroun[2], Jean-Joël Bigna[3], Frauke Foerger[4], Edem Allado[5] and Anna Molto[1], [1]Rheumatology Department, Cochin Hospital, Paris, Paris, France, [2]Lille University, Faculty of Medicine, Lille, France, Lille, France, [3]School of Public Health, Faculty of Medicine, University of Paris Sud XI, Le Kremlin-Bicêtre, France, Paris, France, [4]University Hospital and University of Bern, Bern, Switzerland, Bern, Switzerland, [5]Rheumatology Department, University Hospital of Nancy, France, Nancy, France

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with spondyloarthritis (SpA) are often affected by the disease during their reproductive years[1]. However, little is known about the impact of the disease and its treatments on fertility and pregnancy outcomes, as well as the effect of pregnancy itself on disease activity[2].

The aim of the study was to determine the effects of spondyloarthritis on fertility and pregnancy outcomes in women with SpA.

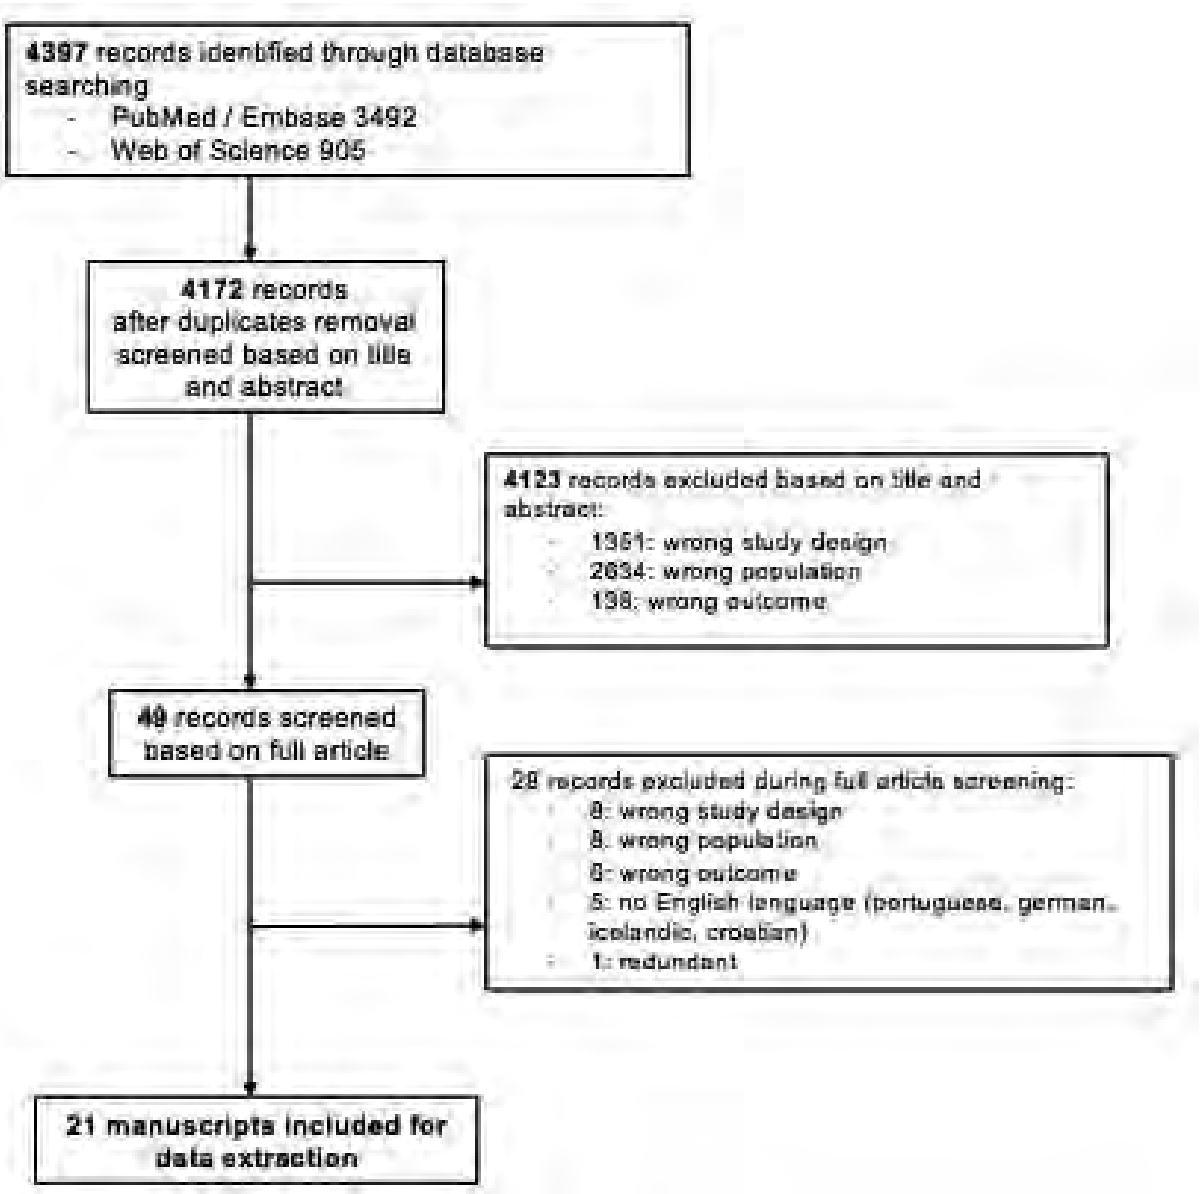

Figure 1. Flow Chart

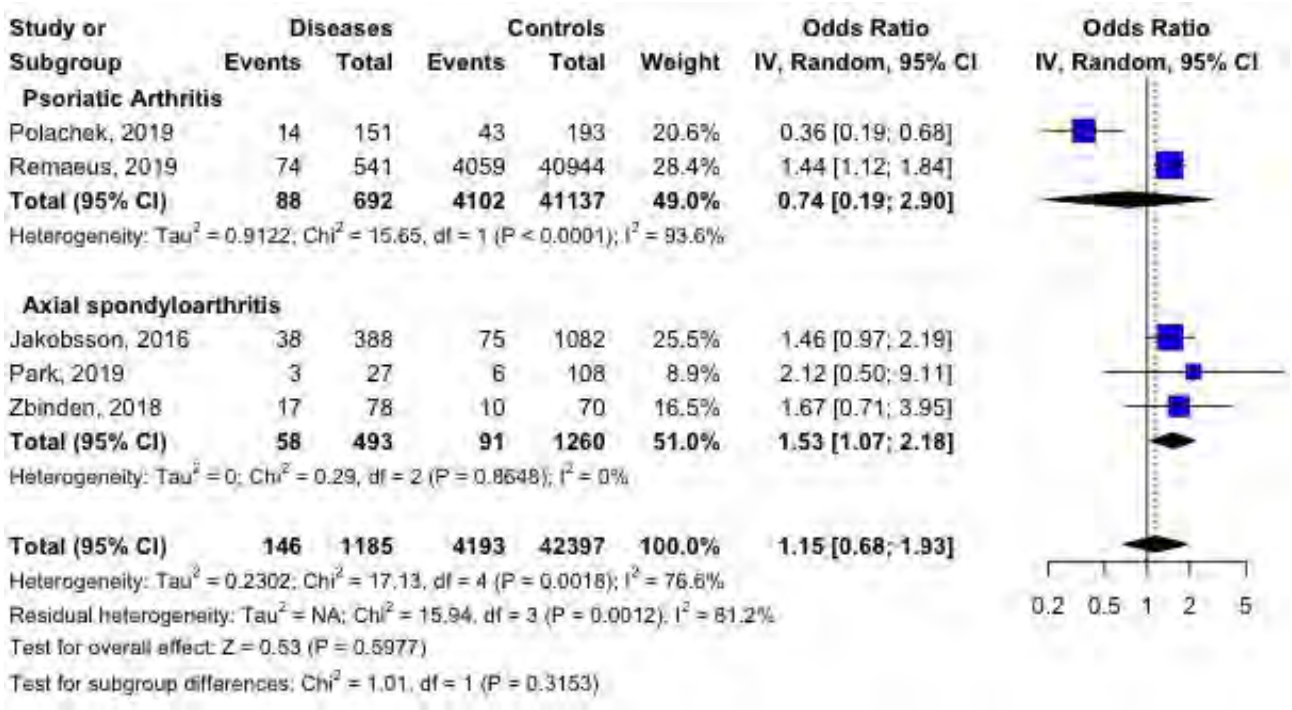

Figure 2 Risk of emergency caesarean section in psoriatic arthritis and axial spondyloarthritis patients

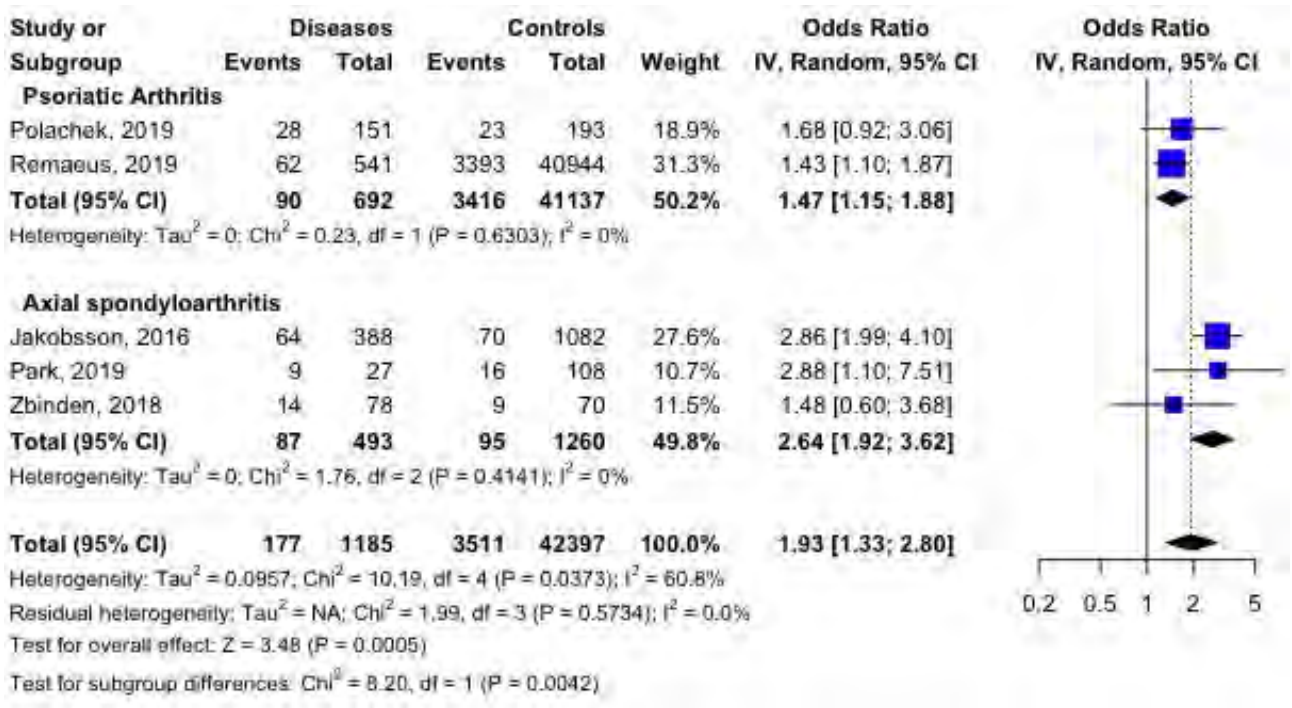

Figure 3 Risk of elective caesarean section in psoriatic arthritis and axial spondyloarthritis patients

Methods: We searched Pubmed, Embase, and Web of Science until 1 November 2019, without any language restriction. All studies assessing fertility, pregnancy outcomes and disease activity during pregnancy in women with spondyloarthritis (axial SpA (axSpA) but also peripheral SpA, including psoriatic arthritis (PsA)) were eligible. The heterogeneity between studies was quantified (I^2), and multiple meta-regressions were carried out to identify potential

sources of heterogeneity. In case I^2 was < 50%, a random-effects model was used to pool the available data. Prevalence of events was described as percentages. The odds ratio (OR) and corresponding 95% confidence interval (CI) were used to assess the associations between the disease and the pregnancy outcomes.

Results: Within 4397 eligible studies, 21 articles fulfilling the selection criteria were included in the review, assessing overall 3306 patients (2578 with axSpA and 728 with PsA) and 4104 pregnancies compared to 42248 healthy controls (in 11 studies with a control group). Among the included studies, the risk of bias was evaluated as high, moderate and low in respectively 12, 1 and 8 studies.

Regarding pregnancy outcomes, several studies report an increased risk of preterm birth (pooled OR 1,64 [1,15-2,33], I^2=24% in axSpA and pooled OR 1,62 [1,23-2,15], I^2=0,0% in PsA), small for gestational age (pooled OR 2,05, [1,09-3,89], I^2=5,8% in axSpA), preeclampsia (pooled OR 1,59, [1,11-2,27], I^2=0% in axSpA) and caesarean section (pooled OR 1,70 [1,44-2,00], I^2=19,9% in axSpA and pooled OR 1,71 [1,14-2,55], I^2=74,3% in PsA), without any other unfavourable pregnancy outcome (miscarriage, stillbirth or gestational diabetes). Further analysis found a significant higher risk for elective caesarean (pooled OR 2,64, [1,92-3,62], I^2=0,0% in axSpA and pooled OR 1,47, [1,15-1,88], I^2=0,0% in PsA), without increased risk for emergency caesarean in PsA. There was no substantial heterogeneity in the majority of meta-analyses.

Conclusion: Although based on observational data, this work is to our knowledge, the first systematic review and meta-analysis concerned with this subject. SpA seems to be associated with an increased risk of preterm birth, small for gestational age, preeclampsia and caesarean section. The analysis of the impact of pregnancy on disease activity in this setting is currently ongoing.

Abstract Number: 1772

Vaccinations of Infants Born to Mothers on TNF Inhibitors: Safe Administration of Live-vaccines Given Per the National Immunization Program

Eman Satti[1], Nawal Hadwan[1] and Samar Al Emadi[1], [1]Hamad medical corporation, DOHA, Qatar

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic Disease-Modifying agents (bDMARDs) including TNF inhibitors are increasingly used during pregnancy over the last few decades for a variety of autoimmune conditions. Nevertheless, limited data is available regarding their safety through pregnancy, particularly in the third trimester. Previous reports of discriminated BCG and severe neonatal neutropenia has made many practitioners defer live-attenuated vaccines from the routine schedule. The international guidelines still recommend holding most TNF inhibitors for several half-lives before delivery, due to the significant levels found in the neonates. Many mothers are advised to adjust the immunization schedule of their infants accordingly.

Recent accumulating data from IBD in pregnancy started to support the safety of infliximab use throughout pregnancy. Due to the paucity of data in this regard, we have planned this study.

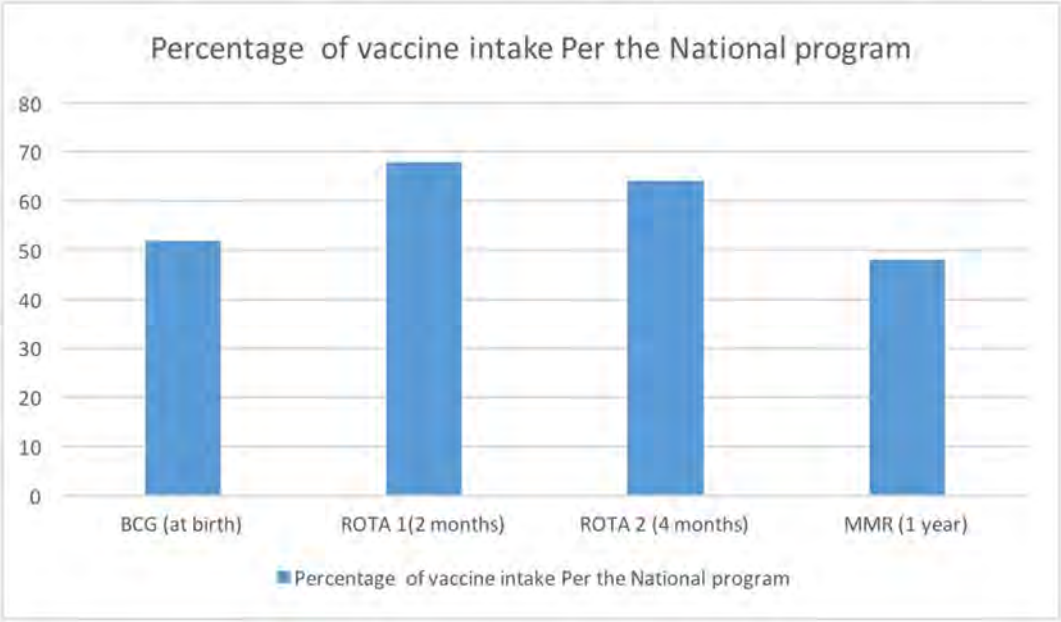
Methods: We surveyed the electronic records of two registries from the IBD and Rheumatology clinics at the largest tertiary hospital in Qatar. We included all women who completed their pregnancies on biologics (minimum of 3 months of biologic use during pregnancy). Cases of abortion, IUFD, and neonatal death were excluded. We have analyzed the clinical data of infants who were 6 months of age or older. Data were recorded in a pre-specified datasheet. Then we ran a descriptive analysis using SPSS software.

Results: Since 2017, we identified 30 completed pregnancies on TNF blockers. Out of these, twenty-five infants were more than 6 months of age.

Mean maternal age at pregnancy was 29.5 years (22-42)
Underlying autoimmune diseases: IBD (13), RA (7), PSA(2), SPA (3).
TNF inhibitors used: Infliximab(7), Adalimumab(5), Etanercept(2), and Certolizumab (10).
The mean duration of TNF inhibitor use during pregnancy was 6.8 months (5-9 months).
TNF inhibitors were taken throughout pregnancy in 15 cases: certolizumab (6), Infliximab (4), and adalimumab (2).
In 2 pregnancies, Etanercept was taken for 7 months followed by Certolizumab until birth.

Mean gestational age at birth was 36.8 weeks (34-41).
Prematurity was recorded in 7 cases (34-37 weeks) and LBW in 1 case.
Two neonates required NICU admission for ARDS.
Five cases of neonatal jaundice were identified. No congenital anomalies reported.

Immunization Data:
Live attenuated vaccines: Thirteen infants (52%) received BCG vaccine at birth, 17(68%) received ROTA vaccine at 2 months, 16 (64%) received ROTA booster at 4 months and 12 (46%) infants received MMR at 1 year.
No complications related to the vaccines were recorded.



Infections during Infancy:
Mean number of infection encounters during infancy was 2 encounters (0-5).
Infections reported were: URTI, bronchiolitis and otitis media. One infant got COVID19 mild infection.
Mean number of encounters that required antibiotics was 10 in 9 infants.

Conclusion: We have identified high rate of infants who received live-attenuated vaccines per the national immunization program without complications. This observation was also associated with high rate of maternal TNF inhibitor use throughout pregnancy. No alarming concern about repeated infections reported in this study.

Disclosure: E. Satti, None; **N. Hadwan**, None; **S. Al Emadi**, None.

Worse Maternal and Fetal Outcomes Among Hospitalized U.S. Pregnant Women with Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA)

Christine Anastasiou[1], Laura Trupin[1], Patricia Katz[2], Zara Izadi[3], Milena Gianfrancesco[1], Gabriela Schmajuk[4] and Jinoos Yazdany[5], [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, Novato, CA, [3]University of California San Francisco, San Francisco, CA, [4]University of California, San Francisco, Atherton, CA, [5]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior studies suggest women with SLE and RA may have higher age-adjusted risk of adverse pregnancy outcomes. We evaluated maternal and fetal complications and racial/ethnic disparities among pregnant women with SLE and RA using a national sample of hospital admissions.

Methods: We used the National Inpatient Sample (NIS), which after weighting provides annual estimates for more than 35 million community hospitalizations in the US. Analysis was limited to pregnant women without missing relevant variables hospitalized in 2016 and 2017. Admissions with SLE and RA were captured in ICD-10-CM codes (M32.1x, M32.8, M32.9 and M05, M06.0, M06.2, M06.8, M06.9, M08.0 respectively). We compared the proportion of discharge outcomes with maternal death, intrauterine fetal demise (IUFD), preeclampsia/eclampsia, premature rupture of membranes (PROM), and placental complications (placental disorders, placenta previa, or abruptio placentae) among patients with SLE, RA, and neither condition using chi-squared tests. We used Poisson regression to model outcomes as a function of disease, including age, race/ethnicity, insurance, and income level in the ZIP Code of residence as covariates. To evaluate racial/ethnic disparities across disease groups, we included an interaction term for race/ethnicity and disease (SLE, RA, neither) if the interaction was significant in the model. Weighted population estimates are presented, except if otherwise specified. All analyses accounted for the complex sampling design of the NIS.

Results: An estimated 11,100 (0.15%) community hospital admissions for pregnant women with SLE, 10,065 (0.13%) with RA, and 7,612,897 for women with neither condition occurred in the U.S. in 2016 and 2017. Maternal death

Table 1. Maternal and Fetal Outcomes among U.S. Hospitalized Pregnant Women with SLE, RA, and Neither Condition

	IUFD		Preeclampsia/Eclampsia		PROM		Placental complications	
	% of discharges	RR	% of discharges	RR	% of discharges	RR	% of discharges	RR
No RA/SLE (n=7,612,897)	1.02%	Ref	5.70%	Ref	7.47%	Ref	2.58%	Ref
SLE (n=11,100)	2.11%	2.06 (1.57, 2.71)*	11.57%	2.03 (1.80, 2.28)*	6.59%	0.88 (0.75, 1.03)	3.71%	1.44 (1.17, 1.77)*
RA (n=10,065)	1.11%	1.09 (0.71, 1.66)	7.45%	1.31 (1.11, 1.53)*	9.59%	1.28 (1.12, 1.47)*	3.39%	1.31 (1.06, 1.62)*

IUFD = intrauterine fetal demise; PROM = premature rupture of membranes; placental complications include ICD-10-CM codes for placental disorders, placenta previa, or abruptio placentae. Percent of discharges based on marginal predictions from adjusted Poisson model. RR= adjusted relative risk obtained from Poisson model including age, race, income quartile in ZIP Code of residence, insurance as covariates. Models for IUFD and preeclampsia/eclampsia also include an interaction term for race/ethnicity and disease. Ref = reference group. *Signifies statistical significance, p <0.05. n weighted based on NIS guidelines to generate national estimates.

Table 2. Risk of Outcome for Pregnant U.S. Hospitalized Blacks Compared to Whites

	IUFD	Preeclampsia/Eclampsia
	RR Black vs. white	RR Black vs. white
No RA/SLE	1.98 (1.90, 2.07)*	1.58 (1.54, 1.62)*
SLE	3.31 (1.78, 6.15)*	1.32 (1.01, 1.74)*
RA	2.41 (0.90, 6.46)	1.39 (0.91, 2.13)

IUFD = intrauterine fetal demise; PROM = premature rupture of membranes; placental complications include ICD-10-CM codes for placental disorders, placenta previa, or abruptio placentae. RR= adjusted relative risk obtained from Poisson model including age, race, income quartile in ZIP Code of residence, insurance as covariates, and an interaction term for race/ethnicity and disease. *Signifies statistical significance, p <0.05.

was a rare event, accounting for less than 10 observations for admissions with either SLE or RA, and approximately 0.01% of general pregnancy related admissions. Admissions with a diagnosis of IUFD, preeclampsia/eclampsia, and placental complications were more likely among patients with SLE than the general pregnant population ($p< 0.05$) (Table 1). Similarly, admissions for patients with RA were more likely to have a diagnosis of preeclampsia/eclampsia, PROM, and placental complications compared to the general pregnant population ($p< 0.05$). The risk of IUFD and preeclampsia/eclampsia was higher among Blacks compared to whites ($p< 0.05$) both among the general pregnant population and those with SLE, but not among those with RA (Table 2).

Conclusion: Pregnant patients with SLE and RA have worse maternal and fetal outcomes including increased risk of intrauterine fetal demise, preeclampsia/eclampsia, PROM, or placental complications compared to other hospitalized pregnant women. Admitted pregnant Black patients with SLE, like those in the general population, continue to be at higher risk of poor maternal and fetal outcomes compared to whites. In contrast, there was no significant difference in the risk of analyzed maternal and fetal complications for Black compared to white RA patients. Women with SLE and RA continue to be at increased risk of pregnancy complications suggesting that additional obstetric research and interventions are indicated to improve outcomes in these patients.

Making Decisions About Medication Use, Pregnancy, and Having Children Among Women with Rheumatoid Arthritis: A Constructivist Grounded Theory Study

Nevena Rebic[1], Ria Garg[2], Sarah Munro[2], Glen Hazlewood[3], Neda Amiri[2], Nick Bansback[2], Stephanie Ensworth[2], Corisande Baldwin[4], Laurie Proulx[5] and Mary De Vera[1], [1]Arthritis Research Canada, University of British Columbia, Vancouver, BC, Canada, [2]University of British Columbia, Vancouver, BC, Canada, [3]University of Calgary, Calgary, AB, Canada, [4]University of British Columbia, Calgary, AB, Canada, [5]Canadian Arthritis Patient Alliance, Ottawa, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite guidelines for managing rheumatoid arthritis (RA) in pregnancy, high rates of discontinuation of disease-modifying anti-rheumatic drugs (DMARDs) considered safe for women with RA during pregnancy may suggest a translation gap of emerging clinical knowledge to patients. We examined the process of making treatment and pregnancy decisions among women with RA.

Methods: *Study design.* We conducted a mixed-methods qualitative research study. *Participants.* Through collaborations with rheumatologists and patient partners, we used poster and social media advertisements to recruit a purposive sample of female participants who were 18 years or older, had an RA diagnosis confirmed by a rheumatologist, lived in Canada, and were able to communicate in English or French. *Data collection.* We collected data through semi-structured focus group and individual interviews using telephone and video conferencing technology. Focus groups were composed of participants with similar pregnancy and medication use experiences. *Data analysis.* We analysed data using a Constructivist Grounded Theory approach within a feminist theoretical framework, which involved steps of line-by-line coding, focused coding and categorizing, and theoretical coding. Data collection and analysis were iterative and continued until saturation of themes was achieved.

Results: We recruited 22 participants across Canada who had a mean age of 34 years, median 7 years since RA diagnosis, and most (86%) were married or co-habited with a partner. Overall, 36% had never been pregnant, 55% had previously been pregnant, and 9% were pregnant at the time of interview. Of those who had experienced pregnancy, 58% had at least one pregnancy while diagnosed with RA and of those, a further 67% used DMARD(s) during a pregnancy. Over half (55%) reported intending to have future children through childbearing or other means. We constructed a framework (see **Figure 1**) depicting the dynamic relationships between 4 identified decision-making processes: 1) using medications, 2) having children, 3) planning pregnancy, and 4) parenting. Moreover, we elicited the complex influence of contextual factors on these processes, particularly attitudes towards health and medications, disease onset and severity, familial support system, and healthcare provider relationship.

Conclusion: Our framework provides insight into how women have made reproductive health decisions in the context of managing RA. By understanding the practical and emotional aspects of this process, healthcare providers can identify opportunities for intervention or care adaptation leading to improved health outcomes for women and babies. Our findings demonstrate that a patient-centred approach to care supports women with RA in making better reproductive choices that align with their individual values.

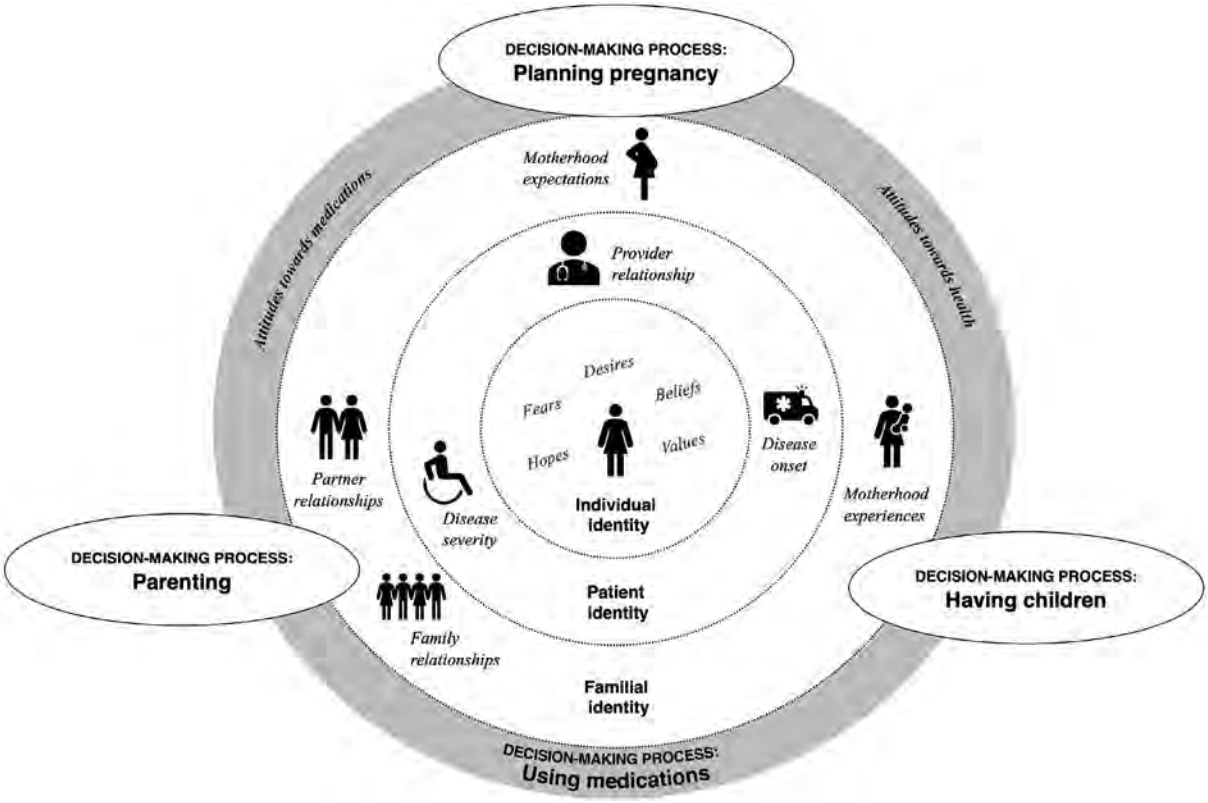

Figure 1. A constructivist, woman-centred, grounded theory framework for making pregnancy and family decisions in relation to living with rheumatoid arthritis. INDIVIDUAL IDENTITY: encompasses a woman's personal hopes, desires, beliefs, values, and fears about her life. PATIENT IDENTITY: encompasses a woman's experiences of being a patient, including the timing of disease onset, disease experience and severity, and relationships with healthcare providers. FAMILIAL IDENTITY: encompasses a woman's experience of being a member of a family, including expectations of motherhood, motherhood experiences, and relationships with family and/or romantic partner(s). Dotted lines: demonstrate that a woman's identities are fluid, overlapping, and influence one another. Gray shading: demonstrates that medication decisions occur in a dynamic context between a woman's identities and other decision-making processes.

Abstract Number: 1775

Risk Factors for Adverse Pregnancy Outcomes of Women with Positive for Antiphospholipid Antibodies Treated with Conventional Therapies

Hiromi Shimada[1], Risa Wakiya[2], Mai Mahmound Fahmy Mansour[1], Shusaku Nakashima[1], Mikiya Kato[1], Koichi Sugihara[1], Yusuke Ushio[1], Tomohiro Kameda[1] and Hiroaki Dobashi[3], [1]Department of Internal Medicine, Division of Haematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University., Kita-gun, Kagawa, Japan, [2]Department of Internal Medicine, Division of Haematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University., Kagawa, Kagawa, Japan, [3]Department of Internal Medicine, Division of Haematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan

Session Date: Monday, November 9, 2020

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibodies induce several obstetric complications including recurrent spontaneous abortion, preterm birth, intrauterine fetal death. EULAR recommendations for antiphospholipid syndrome (APS) indicates low dose aspirin (LDA) and/or low weight molecule heparin (LWMH) as a conventional therapy for APS[1]. However, Pregnant women with antiphospholipid antibodies sometimes had adverse pregnancy outcomes (APOs) under the appropriate conventional treatment. We hereby investigated the risk factors for APOs in the patients with antiphospholipid antibodies under the conventional therapies.

Methods: We retrospectively examined 28 patients who were positive for antiphospholipid antibodies and treated with conventional therapies (LDA and/or LWMH). They were managed from planning for pregnancy to delivery in our institution. We analyzed whether history of obstetric complications, types or numbers of positive auto-antibodies,

	n=38
Mean age at delivery (years old)	31.1 ± 5.0
Disease duration (years)	5.5 ± 4.7

LDA and LWMH (n (%))##	3 (27.3)	8 (53.3)	0.25

Table 2. The analysis of risk factors for adverse pregnancy outcomes. Values are presented as mean ± standard deviation or number (percentage). #; Wilcoxon rank sum test, NULL; Fisher exact test, *; P<0.05. APOs; adverse pregnancy outcomes, LDA; low dose aspirin, LWMH; low weight molecule heparin.

and treatment agents except for APS during pregnancy influenced on APOs (including spontaneous abortion, stillbirth, preterm birth, low birth weight, and preeclampsia).

Results: Fifty-three cases (28.5%) of all 186 pregnancies cases complicated with connective tissue disease was positive for antiphospholipid. Patients characteristics in this study was shown in *Table 1*. Twenty-eight cases (52.8%) were treated with conventional therapies (LDA and/or LWMH). As for the type of CTD complicated, nine cases (32.1%) were systemic lupus erythematosus. The type of antiphospholipid antibodies was as followed; presence of triple antiphospholipid antibodies was 6 cases, double was 1 case, single was 21 cases. Eleven cases (39.3%) were treated with both LDA and LWMH, and the others were treated with either of them. APOs occurred in 11 cases (45.8%), which excluded 2 cases of induced abortion. In the group which had occurred APOs, the rate of positive for lupus anticoagulant (LAC) was significantly higher than the other group (P< 0.05, Table 2). In addition, the frequency of glucocorticoid use and mean glucocorticoid dose was also significant higher (Both of them was P< 0.01) in patients with APOs. However, there was no significance focusd on history of obstetric and thrombotic complications, the number of positive auto-antibodies, treatment regimen for APS such as LDA and/or LWMH.

Conclusion: In our study, LAC positivity, glucocorticoid use and mean glucocorticoid administration during pregnancy amount is associated with the development of APO in antiphospholipid antibody-positive pregnant patients under conventional treatment. It was shown that there was no significant difference in the development of APOs between LDA + LWMH, LDA alone and LWMH alone. Treatment with at least one or more anticoagulant drugs reduced APO

development in women with positive antiphospholipid antibodies. Additionally, in other treatments, it is needed to note the risk of glucocorticoid use for APOs in CTD patients with APS.

Safety and Beneficial Effects of Hydroxychloroquine on Pregnancy Outcomes in Women with Systemic Lupus Erythematosus

Isabell Haase[1], Matthias Schneider[1], Ralph Brinks[1] and Rebecca Fischer-Betz[1], [1]Department of Rheumatology and Hiller Research Unit Rheumatology, Heinrich Heine University, Duesseldorf, Germany, Duesseldorf, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of hydroxychloroquine (HCQ) has long been established in Systemic Lupus Erythematosus

(SLE) and especially as applicable drug during pregnancy. Recently, beneficial effects and safety of HCQ have been re-discussed in the light of a change in the summary of product characteristics in some countries. More current studies are required to provide patients with evidence-based advice regarding this essential drug when counselling for pregnancy.

We therefore sought to examine the impact of HCQ on pregnancy outcomes of SLE women in a real-world cohort.

Methods: Pregnancies of women with SLE from an outpatient pregnancy clinic were prospectively evaluated before and throughout gestation. Maternal and fetal outcomes in women without HCQ therapy (group A) were compared to pregnancies under HCQ treatment from 1st trimester on (group B). A multiple logistic regression was performed with adjustment for confounding factors.

Results: We enrolled 184 live births from singleton pregnancies in 145 women (n=77 with HCQ and n=107 w/o HCQ). One neonatal death (group B) occurred after severe preeclampsia at 24 weeks of gestation (w/g) linked to noncompliance in a woman with high-risk aPL profile. One child (group B) was born with mycophenolate mofetil embryopathy.

Women in the HCQ group had a significantly lower rate of preterm births [aOR 0.31 (95%-CI: 0.15-

0.64), p = 0.026]. Regarding preeclampsia, we found a tendency towards less incidence with the use of HCQ [aOR 0.49 (95%-CI: 0.23-1.03), p = 0.24]. These improved outcomes are opposed by a higher frequency of risk factors in group B (lupus nephritis, high-risk aPL profile, slightly more hypertension) and a tendency towards more severe SLE (expressed in terms of increased use of Azathioprine) (Table 1). Nevertheless, women with HCQ therapy experienced significantly less flares during pregnancy [aOR 0.18 (95%-CI: 0.09-0.38), p = 0.013].

Conclusion: Compared to pregnancies without HCQ, those with HCQ showed significantly lower rates of flares and preterm births and tended to have fewer pre-eclampsia. Like other studies on HCQ in lupus pregnancy, this one is

Low Dose Aspirin to Prevent Pre-eclampsia in SLE Pregnancies – Counselling Helps to Realize Our Full Potential

Isabell Haase[1], Matthias Schneider[1], Ralph Brinks[1] and Rebecca Fischer-Betz[1], [1]Department of Rheumatology and Hiller Research Unit Rheumatology, Heinrich Heine University, Duesseldorf, Germany, Duesseldorf, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with Systemic Lupus Erythematosus (SLE) face a higher risk of pre-eclampsia, especially those with additional risk factors. Low dose aspirin (LDA) is known to protect against pre-eclampsia in non-autoimmune patients. Consequently, the EULAR recommends starting LDA in those women at risk preconceptionally or latest until gestational week 16. We sought to examine the use of LDA in a real-world cohort in relation to different risk factors and the provision of preconception counselling.

Methods: Pregnancies of women with SLE from an outpatient pregnancy clinic were evaluated before and throughout pregnancy. Clinical characteristics including pre-eclampsia risk factors, disease activity (SLEDAI) and medication use were analysed. Association of Aspirin use (latest from week 16 on) with different risk factors or preconception counselling was analysed using χ^2 tests.

Results: We enrolled 201 pregnancies in 136 women. 57.8% of pregnancies showed a high-risk profile for pre-eclampsia (history of pre-eclampsia, multifetal gestation, chronic hypertension, lupus nephritis or aPL), another 26.6% had at least one moderate risk factor (nulliparous, body mass index >30 or age >35).

LDA was administered in 43.3% of pregnancies. LDA use was significantly higher in those with a high-risk profile (63.5% vs. 16.7%) [OR 8.59 (95%-CI: 4.19-18.62), p< 0.001], but not in those with a moderate-risk profile. Still, 36.5% of those at high risk and 83% of those at moderate risk did not receive Aspirin. In a descending order, aPL, multifetal gestation, lupus nephritis and nulliparity were associated with a higher LDA use, whereas the other risk factors were not.

Preconception counselling significantly increased Aspirin administration [OR 2.36 (95%-CI: 1.23-4.63), p< 0.01], especially in those at high risk [OR 4.12 (95%-CI 1.72-10.16), p< 0.001]. Overall, LDA use increased from 1995 to 2019 (χ^2 test for trend in proportions, p< 0.001).

Conclusion: We found a high prevalence of pre-eclampsia risk factors in our real-world cohort of pregnant SLE patients, which was contrasted by an overall infrequent use of LDA during pregnancy. Preconception counselling prior to conception allows more women, especially those with an additional risk profile, to receive LDA at an early stage, which may contribute to a better pregnancy outcome.

Improving Teratogenic Medication Consent and Sexual Activity Screening in Adolescent and Young Females: A Pediatric Rheumatology Reproductive Health Initiative

Veronica Mruk[1], Kelly Wise[2], Stacy Ardoin[2], Edward Oberle[2], Stephanie Lemle[3], Vidya Sivaraman[4], Kyla Driest[2], Elise Berlan[2], Cagri Yildirim-Toruner[5], Jackie Maher[2], Sarah Jones[2] and Fatima Barbar-Smiley[6], [1]The Ohio State University / Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Nationwide Children's Hospital, Columubus, OH, [4]Nationwide Children's Hospital, Bexley, OH, [5]Nationwide Children's Hospital, Houston, TX, [6]Nationwide Children's Hospital/The Ohio State University, Columbus, OH

SESSION INFORMATION

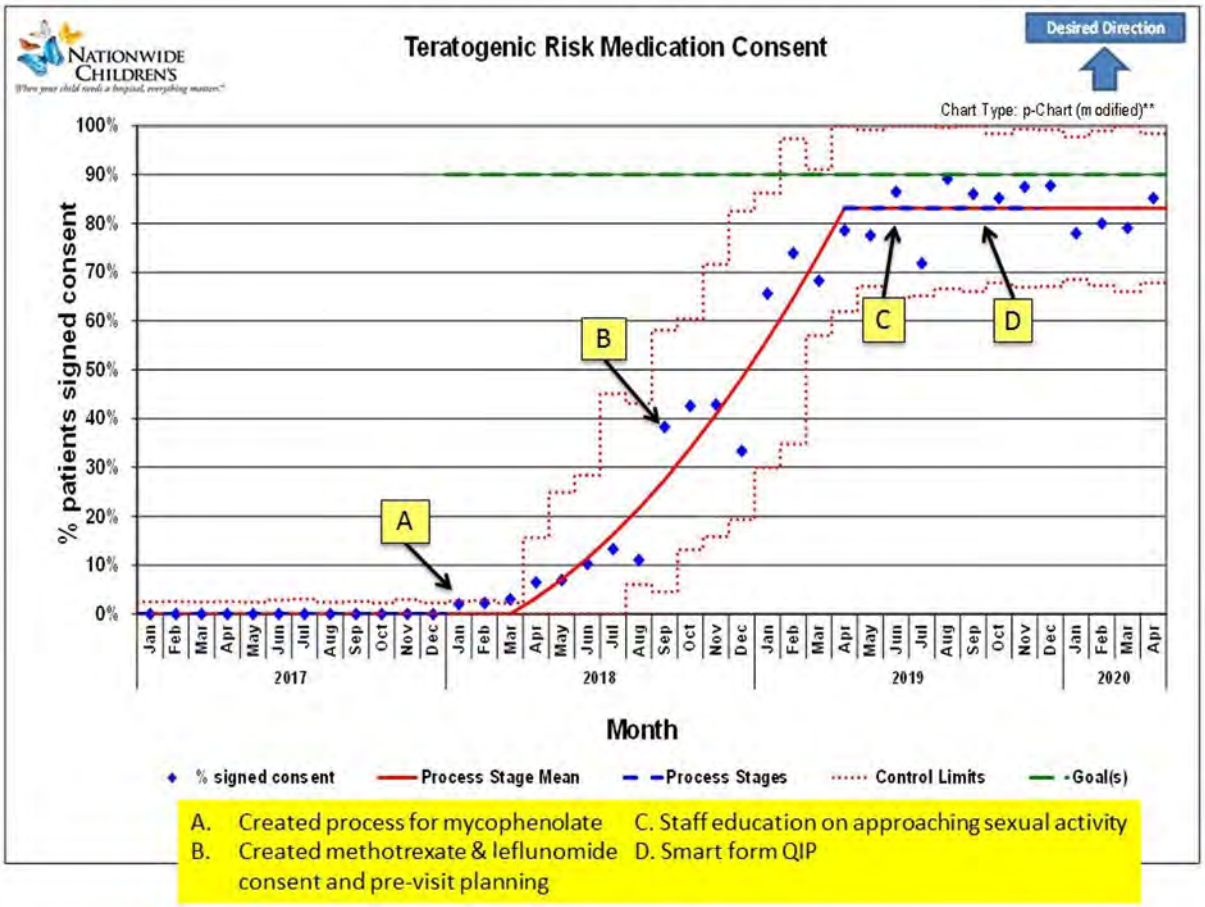
Session Date: Monday, November 9, 2020

Session Title: Reproductive Issues in Rheumatic Disorders Poster

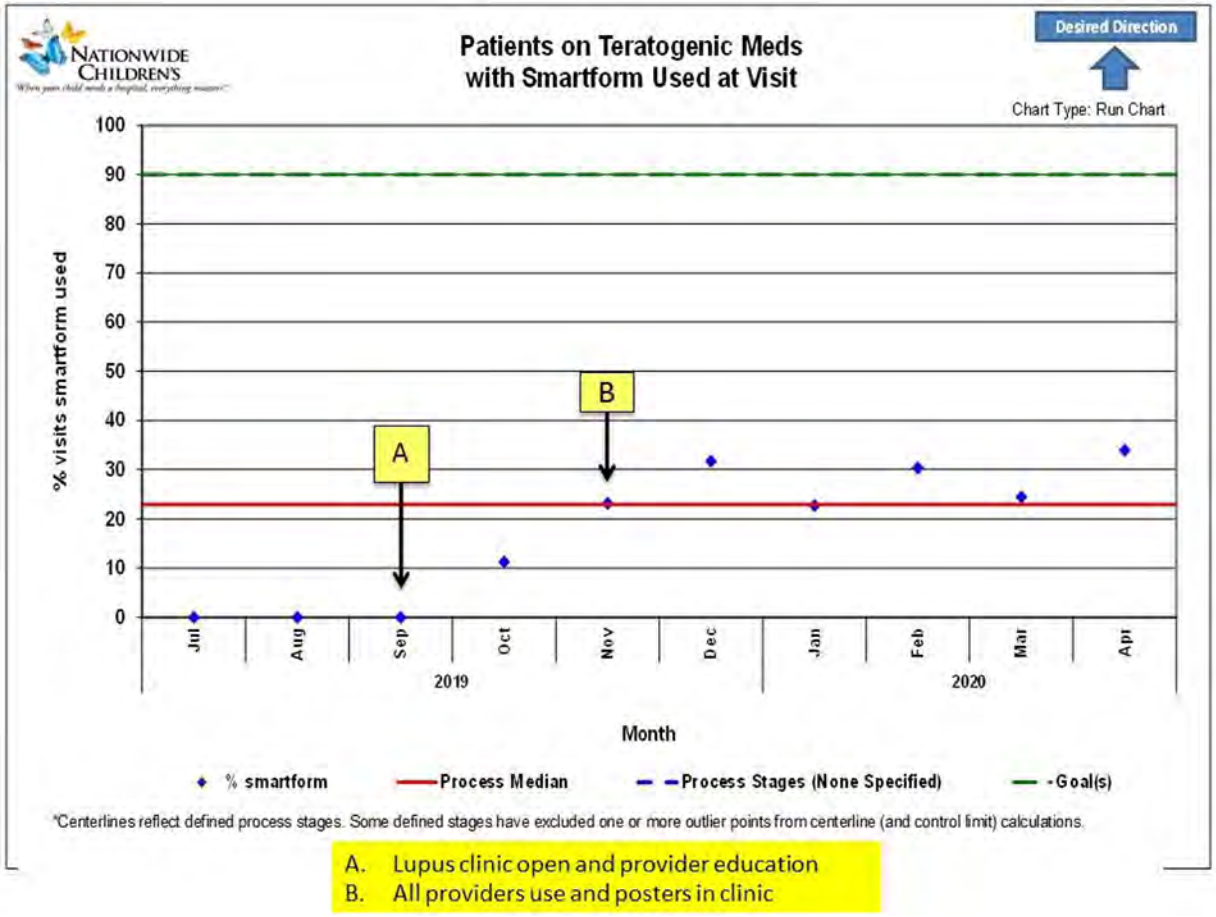
Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Adolescent and young women with rheumatic diseases are often prescribed teratogenic medications to manage their disease. Published reports indicate that the frequency of reproductive health counseling



Run chart for sexual history documentation within electronic health record smartform at each visit for all patients on teratogenic medications age 12 years and older with annotated QI PDSA interventions.

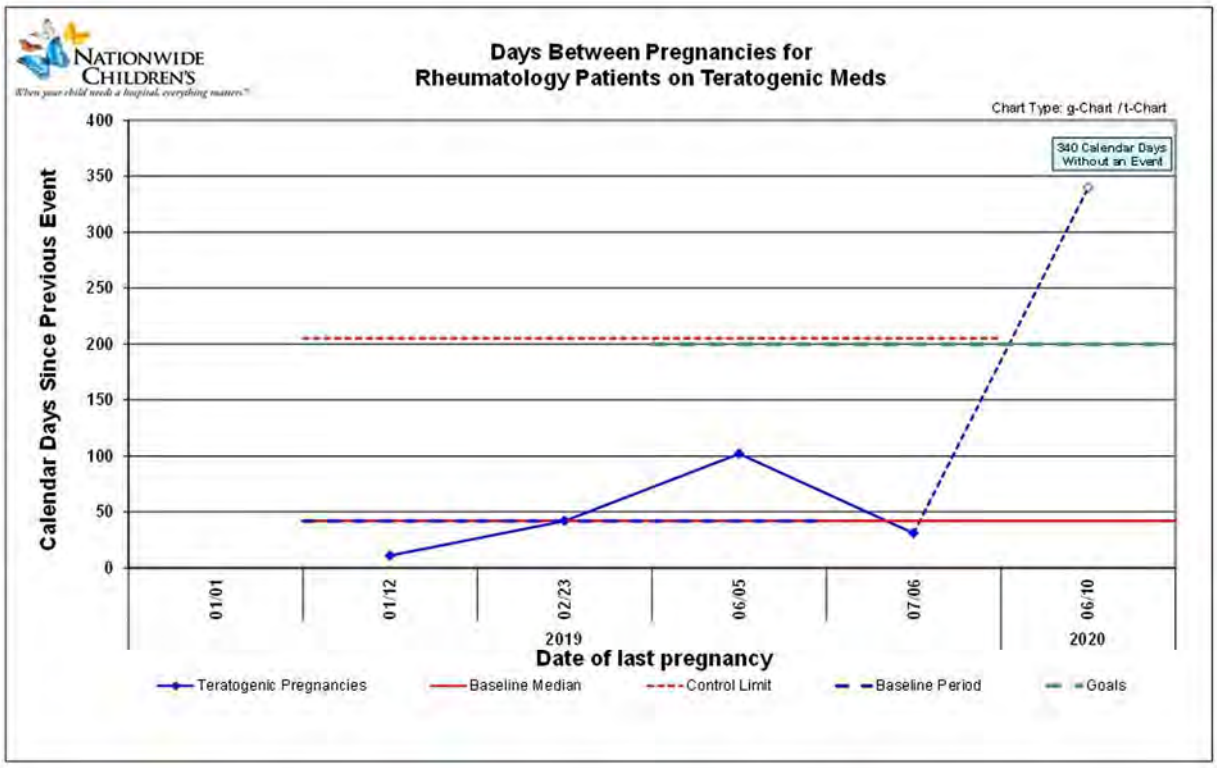


P-chart for teratogenic risk medication consent for all females patients 12 years and older on teratogenic medications with annotated QI PDSA cycle interventions.

is low in this population, allowing a significant risk of fetal exposure to teratogenic medications. This three-year project aimed to prevent pregnancies in adolescent and young women on teratogenic medications and consisted of two phased initiatives: annual teratogenic medication consents and sexual history documentation at every visit.

Methods: The Institute for Healthcare Improvement model for quality improvement (QI) was used for this project. Each phase included a baseline assessment review and several PDSA cycles. In 2018, annual teratogenic medication consents were created and implemented to facilitate education about teratogenic and fetotoxic risks associated with certain medications. At baseline, there was no consistent documentation of teratogenic medication and/or counseling received by females who were prescribed teratogenic medications. In 2019, we developed sexual history form that was incorporated into the electronic health record to help guide provider discussions with patients and families at every visit and to develop pregnancy prevention plans. Baseline data revealed that none of our female patients who were prescribed teratogenic medications had appropriate sexual history documentation during their clinic visits. To assess the success of reaching our aim of among adolescent and young women using teratogenic medications, we measured days between pregnancies for females on teratogenic medications. In January 2019, days between pregnancies for females on teratogenic medications was determined to be 42 days.

Results: The percentage of females that received annual teratogenic consents increased from 0% to 85% after 18 months. After 8 months, the proportion of female patients that had appropriate sexual history documentation at every visit increased from 0% to 35%. For females on teratogenic medications, the days between reported pregnancies increased from 42 days between pregnancies in January 2019 to >340 days in June 2020.



G-chart indicating days between pregnancies for patients on teratogenic medications followed in rheumatology clinic.

Conclusion: The implementation of a phased QI project to prevent pregnancies among adolescent and young women using teratogenic medications has been successful within our institution. Coming initiatives, such as routine pregnancy screening and ongoing pregnancy-prevention plans, will help to prevent exposure of teratogenic medications to pregnant females and enhance safe use of these medications. We hope expand aspects of this project to other divisions within our institution and potentially across institutions, as well.

MTX, methotrexate, MMF, mycophenolate mofetic or mycophenolic acid; LFN, leflunomide; CP, cyclophosphamide; edu, educated; BC, birth control.

Background/Purpose: Teratogenic disease-modifying anti-rheumatic disease modifying drugs (DMARDs) are often prescribed to women of childbearing age. Contraception represents an important area of reproductive health for female patients with rheumatic diseases. Counseling prior to starting DMARDs can help prevent the potential pregnancy risks associated with such medications. Methotrexate (MTX), cyclophosphamide (CP), leflunomide (LFN) and mycophenolate (MMF) are commonly used DMARDs, which can be highly teratogenic.

Methods: The use of high-risk medications was retrospectively evaluated in 484 female rheumatic disease patients of childbearing age (13 to 45 years old) as documented in the electronic medical records of Upstate University Hospital between 2013-2019. Charts were reviewed for medication use, documentation of education and use birth control (medication, sterilization, or postmenopausal) (Table 1 &2). Statistical analysis was performed with chi-square or Fisher's exact test using GraphPad version 8.0 software. Two-tailed $p < 0.05$ was considered significant.

Table 2: Percent of patients educated on teratogenic medications.

Vasculitis	6	(1/0) 100%	n/a	(0/3) 0%	(0/1) 0%

SLE, systemic lupus erythematosus; RA, rheumatoid arthritis; PsA, psoriatic arthritis; JIA, juvenile inflammatory arthritis; AS, ankylosing spondylitis. MTX, methotrexate, MMF, mycophenolate mofetic or mycophenolic acid; LFN, leflunomide; CP, cyclophosphamide; edu, educated; BC, birth control.

Results: 484 DMARD-treated patients were evaluated for documentation of education on drug teratogenicity and compliance with use of birth controls. 76% of patients were Caucasian, 18% were African American or Hispanic and 6% were Indian, Asian or Native American. 50% (243/484) of patients were educated regarding potential teratogenic complications that only resulted in greater use of contraceptives in methotrexate-treated patients with rheumatoid arthritis (Table 1).

Conclusion: In the USA, it is estimated that about 5.8% of all pregnancies are exposed to category D or X medications [1]. More than 50% of all pregnancies in the USA are unplanned [2]. This is concerning, especially for our rheumatic disease patients who are already at risk. Potential teratogenic medications should be thoroughly reviewed with patients so that preventive measures could be employed. Despite the common consensus for contraceptive education, there still remains a gap in implementing this standard clinical practice, especially among patients with SLE [3,4]. In our facility, teratogenicity of potential drugs and family counseling was provided only 50% of the time, indicating major gaps in family planning counseling among childbearing aged women with rheumatic diseases. To ensure that our patients receive proper family planning and counseling, a collaboration among rheumatologist, primary care physicians and obstetrician-gynecologists is critical. Our study demonstrates critical gaps in counseling and compliance with use of teratogenic medications. Future intervention should address barriers in counseling, compliance and documentation of teratogenic medication use.

aOR: adjusted odds ratio; aRR: adjusted risk ratio; NR: not reported; NS: non-significant; OR: odds ratio.

Maternal and fetal outcomes in PsA patients.

Background/Purpose: The onset of psoriatic arthritis (PsA) often occurs between the ages of 30 and 50 years. Accordingly, many female patients are diagnosed during childbearing age, potentially impacting their pregnancy outcomes. However, there is a paucity of data concerning the fetal and maternal outcomes in this population and most of the information is extrapolated from studies on rheumatoid arthritis (RA). We aim to review the available evidence on the relationship between PsA and adverse pregnancy outcomes.

Methods: We systematically searched two databases, PubMed and Embase, for original studies from inception of the databases until May 31, 2020, addressing fetal and maternal outcomes in pregnant women with PsA. A variety of terms adjusted to the specificities of the two databases and related to key subject areas of the review question were used. The search was filtered to only include human participants and publications in English. The eligible studies had to present a comparator group (healthy individuals or patients without known auto-immune rheumatic diseases – ARD's), as well as at least one clinical outcome of interest. Studies including patients with other ARD's were eligible only if results from patients with PsA were presented separately. Two authors independently selected studies and extracted data.

Results: Of a total of 708 references, 5 observational studies fulfilled the inclusion criteria: 3 prospective and 2 retrospective studies (table 1).

Concerning maternal outcomes, the odds of delivery by caesarian section was higher among PsA women compared with the control groups, in 3 out of 4 studies. However, the majority of studies did not find an increased risk of pre-eclampsia or gestational hypertension among PsA patients. Likewise, no study has found an increased risk of gestational diabetes in pregnant women with PsA.

Regarding fetal outcomes, 3 studies revealed an increased risk of preterm birth in PsA patients, out of 4 studies reporting this outcome. Spontaneous miscarriages, stillbirths, neonatal deaths and small for gestational age newborns occurred at similar rates in women with PsA and the comparator groups, across the different studies.

Only one of the included studies, has assessed the influence of disease activity in the outcomes. Smith et al observed that active disease (defined as RAPID3 score ≥ 7 and HAQ >0.5) at 32 weeks of gestation increased the risk for preterm birth in PsA.

Conclusion: Despite the limited available data, these studies suggest an increased risk for delivery by caesarian section and preterm births among pregnant women with PsA. Increased disease activity seems to contribute to a higher risk of preterm birth as in RA. Nonetheless, this effect should be further examined.

Abstract Number: 1781

Pregnancy After Bariatric Surgery in Women with Rheumatic Diseases and Association with Adverse Birth Outcomes

Namrata Singh[1], Rebecca Baer[2], Maya Swaminathan[3], Shireesh Saurabh[4], Jeffrey Sparks[5], Gretchen Bandoli[6], Elena Flowers[7], Laura Jelliffe-Pawlowski[2] and Kelli Ryckman[8], [1]University of Washington, Bellevue, WA, [2]University of California San Francisco, San Francisco, [3]University of Washington, Seattle, WA, [4]Kaiser Permanente WA, Bellevue, WA, [5]Brigham and Women's Hospital, Boston, MA, [6]University of California San Diego, La Jolla, CA, [7]UCSF, San Francisco, CA, [8]University of Iowa, Iowa City

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune rheumatic diseases (ARD) and bariatric surgery are each risk factors for adverse birth outcomes. To date, no study has investigated their combined impact on birth outcomes. The objective of this study was to evaluate the impact of bariatric surgery on pregnancy in patients with ARD with and without bariatric surgery.

Methods: This retrospective cohort study included infants born between 20–44 weeks of gestation in California between 2011–2018. Birth certificates were linked to maternal and infant hospital and emergency department discharge records. History of maternal bariatric surgery and ARD was identified from discharge records. We compared combinations of ARD and bariatric surgery to women with an ARD and no bariatric surgery for adverse maternal and infant outcomes.

Results: The study included 3,574,165 pregnancies, of whom 10,823 (0.3%) had an ARD and 8,172 (0.22%) of the total women had a history of bariatric surgery. There were 86 women (0.0022%) with both an ARD and a history of bariatric surgery. Among women with bariatric surgery and no ARD, the incidence of preterm birth was 13.9%. Among women with ARD and no bariatric surgery it was 18%. Among women with both an ARD and a history of bariatric surgery the incidence was 19.8%. Women with a history of bariatric surgery and an ARD had similar risk of having a preterm birth, small for gestational age or large for gestational age infant, or a cesarean delivery compared

Table 1. Relative risk of adverse outcomes among women with a history of bariatric surgery stratified by ARD

	Any ARD		No ARD	
	With bariatric surgery	Without bariatric surgery	With bariatric surgery	Without bariatric surgery
Pregnancies	86	10,737	8,086	3,555,256
Perinatal mortality, n (%)	*	65 (0.6)	51 (0.6)	10,260 (0.3)

to women with an ARD and no history of bariatric surgery (Table 1). Over 20% of infants born to women with a history of ARD and bariatric surgery were admitted to the NICU compared to 13.0% of infants born to those with an ARD and no history of bariatric surgery (adjusted relative risk, aRR, 1.7, 95% CI 1.1 to 2.8).

Conclusion: Our study shows that women with ARD already have a high occurrence of several adverse birth outcomes, and this was not further increased by a history of bariatric surgery. The infants born to women with a history of ARD and bariatric surgery were admitted to the NICU significantly more than the infants born to women with an ARD and no history of bariatric surgery.

aRR (95%CI)	0.9 (0.4, 1.7)	1.0 (Ref)	**0.5 (0.5, 0.6)**	1.0 (Ref)

Use of a Patient-reported Survey to Document Contraceptive Use and Interest in Pregnancy to Identify Patients with Unmet Pregnancy Prevention and Planning Needs

Megan Clowse[1], Amanda Eudy[2], Lisa Criscione-Schreiber[3], Jayanth Doss[2], Kai Sun[2], Rebecca Sadun[2] and Jennifer Rogers[4], [1]Duke University, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]Duke University School of Medicine, Durham, NC, [4]Duke, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancies in women with lupus who conceive when their disease is active or they are taking a teratogen are at increased risk for pregnancy loss, as well as preterm delivery and birth defects, with long-term consequences for their children. To avoid potentially catastrophic outcomes, pregnancy should coincide with periods when disease quiescence can be maintained with pregnancy-compatible medications. To achieve this, rheumatolo-

gists need to identify the women in need of pregnancy planning or contraceptive guidance. Our goal is to assess the pregnancy planning and prevention needs within a university lupus clinic.

Methods: All study participants were enrolled in a prospective registry, met SLICC criteria for SLE, were female, and age 18 to 45. On an intake form for each lupus clinic visit, women answered 1) "Would you like to get pregnant in the next 12 months," and 2) contraceptive use and type. Demographics, medications, and disease activity parameters were collected within the lupus registry. Women who did not complete the survey were excluded from analysis. Fisher's and t-tests compared women with and without contraceptive use and pregnancy intention.

Results: The survey was completed by 95% of the 134 women of reproductive age. Of these, 61% were black, 8% Hispanic, 46% were married and 64% had a college degree.

Contraception: 60% of women with lupus reported contraceptive use. Of these, 44% were using highly effective contraception, including an IUD (n=20), implant (n=7), or surgical sterilization (n=7). There were similar rates of contraceptive use by race, education, income, and marital status. Contraceptive use did not differ by severity of lupus symptoms, with similar rates in women with and without proteinuria, and with or without active Type 1 or Type 2 SLE symptoms.

The rate of contraception use was higher among women taking a teratogen (76%) compared to those not taking a teratogen (49%, p=0.004). While there was no difference in contraception use with or without HCQ, fewer women used contraception when taking AZA (30%, p< 0.001) and more women used contraception when taking MMF (77%, p=0.04).

Pregnancy Intention: 21 (17%) of women were interested in getting pregnant in the following year. These women were just as likely to report using contraception (62%) as women not interested in pregnancy (58%). There was no difference in demographic characteristics or lupus activity between women who did and did not want to conceive, though only one woman of 14 with active nephritis was interested in pregnancy. Both married (22%) and unmarried women (9%, p=0.06) were interested in pregnancy. Significantly more women on pregnancy-compatible medications than teratogens were interested in pregnancy (25% vs 8%, p=0.01).

Conclusion: This study demonstrates that systematic, patient-reported measures of pregnancy interest and contraceptive use are effective tools to identify women with unmet reproductive health needs. There were no demographic or lupus activity characteristics that would have otherwise identified these women for specific attention, highlighting the importance of routine screening to target pre-conception counseling and contraception guidance to the appropriate women at the appropriate time

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: We aimed to evaluate the experience of pregnant rheumatology patients during the peak of the COVID-19 pandemic in New York City.

Methods: We emailed a secure web-based survey to 26,045 patients aged ≥18 years who were evaluated at least once by a rheumatologist from April 1, 2018-April 1, 2020 at a tertiary academic center in New York City. Patients received three secure e-mail invitations to complete the survey; a subset of patients with missing or incorrect e-mails were contacted by telephone. We collected detailed information including COVID-19 exposure and symptoms, rheumatic disease history and medications, sociodemographic factors, and 5 domains from the PROMIS-29 to assess psychosocial factors. We requested pregnancy data from any women aged 18 to 50. Women were asked to indicate

P-value threshold of <0.05 considered to be significant and indicated in bold

pregnancy status on January 1, 2020 or at the time of survey completion. T-tests and Chi-square tests were used when appropriate to compare pregnant and non-pregnant patients.

Results: 6,908 patients responded to our survey overall, of whom 1,510 were women aged 18 to 50 (22%). 61/1,510 (4%) were either pregnant on January 1, 2020 or pregnant at the time of completing the survey. Mean age of the 61 pregnant women was 36.1±4.9 years, 74% were white, 85% not Hispanic or Latino, and 88% were married/partnered ($p < 0.001$). Pregnant survey respondents were significantly younger, more likely to be married, have higher household income, and less likely to be Hispanic than non-pregnant patients **(Table 1)**. Although fewer pregnant women took biologics, DMARDs, or corticosteroids the differences were not significant. Nearly one-third of patients in both groups reported taking antimalarials in the previous 6 months. Both groups lived with an average of 2.3 other people, and a similar percent had confirmed or suspected COVID-19 (by positive nasopharyngeal PCR test or physician indicated) (8% and 11%). Among patients who were employed, significantly more pregnant patients indicated a high risk of COVDI-19 exposure at work. Depression and pain interference were significantly worse in non-pregnant patients based on PROMIS-29 scores, but not clinically significant**(Table 2)**. In the pregnancy group, 57% noted changes to prenatal OB/GYN care during the COVID-19 pandemic; in-person OB/GYN visits were rescheduled to telemedicine visits (28%) and some in-person OB/GYN visits were cancelled and not rescheduled (16%). By the time of survey completion, 22/61 pregnancies were complete, with a mean gestational age of 38.1±1weeks. Pregnancy outcomes included: 10 (45%) vaginal deliveries, 5 (23%) C-Sections, and 3 (14%) miscarriage/termination. 23% of women who

Table 3. Pregnancy Outcomes and Changes to Pre-Natal Care in 61Rheumatology Patients who Reported Pregnancy During the COVID-19 Pandemic	

Pregnancy Outcomes
• Total Pregnancies

	22
	10 (45%)
	5 (23%)
	3 (14%)
	4 (18%)

Changes to Prenatal OB/GYN Care during the COVID-19 Pandemic (N, %) • Prenatal care unchanged • Regular in-person OB/GYN visits are rescheduled to telemedicine • In-person OB/GYN visits cancelled not rescheduled; • OB/GYN in-person visits only for urgent issues and procedures) • Other *	 20 (33%) 17 (28%) 18(29%) 12(20%)
COVID-19 Affected Delivery (N, %) Yes	**n=22** 5 (23%)
Effect of COVID-19 Pandemic on delivery (N, %) • Not permitted to have anyone (e.g. partner, family member, doula, midwife with me when I delivered) • Other **	**n=5** 1(5%) 4 (18%)
* Other changes to prenatal care: Changed OB/GYN due to visitor policy at hospital post-delivery; regular OB visits curbside and high-risk visits in-person with extra precautions; some appointments in-person while some were via telemedicine. ** Other reasons cited: No visitors; partner had to leave soon after delivery, pediatrician stopped taking new patients and had to switch to new practice.	

delivered stated the pandemic affected their deliveries, with the most frequent reason being no visitors permitted in the hospital or spouses needing to depart shortly after delivery **(Table 3)**.

Conclusion: During the peak of the COVID-19 pandemic in New York City, pregnant rheumatology patients had unique experiences that influenced their prenatal OB/GYN care and pregnancy experience. Future longitudinal studies will investigate the underlying risk factors and impact of the COVID-19 pandemic on pregnancy outcomes in rheumatic disease patients.

Roles and Perspectives of Partners of Women with Rheumatoid Arthritis on Reproductive Decision Making: A Constructivist Grounded Theory Study

Ria Garg[1], Nevena Rebic[2], Neda Amiri[1], Glen Hazlewood[3], Corisande Baldwin[4], Stephanie Ensworth[1], Laurie Proulx[5] and Mary De Vera[2], [1]University of British Columbia, Vancouver, BC, Canada, [2]Arthritis Research Canada, University of British Columbia, Vancouver, BC, Canada, [3]University of Calgary, Calgary, AB, Canada, [4]University of British Columbia, Calgary, AB, Canada, [5]Canadian Arthritis Patient Alliance, Ottawa, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Reproductive Issues in Rheumatic Disorders Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Partners of women with rheumatoid arthritis (RA) often take on caregiving roles given the debilitating nature of RA. No research to date has explored partners' roles with respect to reproductive decision-making. Our objective was to explore the perspectives, attitudes, and experiences of partners of women with RA regarding reproductive decisions around family building.

Methods: Study Design: We conducted a qualitative research study involving semi-structured interviews. **Participants:** Individuals were eligible if they were 18 years or older, had a partner with RA who participated in our related study on how women with RA make family-building decisions, and were able to communicate in English. We define 'partners' as individuals within an intimate relationship. **Data gathering:** We conducted semi-structured telephone and video conference interviews lasting 30 to 60 minutes. Each interview followed an intensive approach characterized by use of open-ended questions. **Analysis:** We applied a constructivist grounded theory approach, which involved initial line-by-line coding, a strategy which promotes conceptualization of emerging themes. Afterwards we conducted focused coding which led to development of themes as indicated by theoretical saturation.

Results: We interviewed 9 partners of women with RA. All participants identified as male with a median age of 34 years. Overall, 44% had at least one child with a woman with RA while the rest had not had children with a women with RA. Additionally, 77% were considering conceiving children with their significant other with RA. Emerging themes from our analysis indicate that couples discuss reproductive options early and throughout their relationship and share the decisions for building a family. In an effort to aid their significant other, partners also discussed methods of providing support. Partners described impacts on their mental health and well-being related to additional stressors of supporting their significant other and making reproductive decisions, as well as expressing a desire for childcare support from extended family. After having children with women with RA, partners indicated a change in perspective towards pregnancy and RA management, often resulting in the decision to have fewer children. **Table 1** shows themes and representative quotes.

Conclusion: Our findings demonstrate the far-reaching impacts of RA and reproductive decision-making on the partners of women with RA. Participants expressed taking part in shared decision-making with their partner, concern for their significant others' physical health during pregnancy, and described impacts on their own mental health. Overall, our findings highlight the need for comprehensive supports for *both* women with RA and their partners throughout family building and pregnancy. Healthcare providers can identify opportunities for intervention or care adaptation that involves women with RA and their partners minimizing stress and the negative impacts on the family.

Theme 1: Discussing reproductive decisions early and throughout the relationship
'When we first started our relationship, she was very clear and up front about it at the beginning. It was almost just like a, it was just a hurdle.' (Partner 5)
'It's been like an ongoing sort of conversation over the last few years, […] it's been like a few discussions for short periods of time over a long period of time.' (Partner 4)
Theme 2: Sharing family building decisions
'I think it's been very much a mutual effort. I think it's a shared load, so we have explored IVF, we've explored egg donation, we've gone to the clinic together, I've done all the testing.' (Partner 3)
'When we were thinking about having another child and we actually kind of decided not to because of the requirements again to go off medication for family planning.' (Partner 7)
Theme 3: Providing support to partner with RA
'I've never had to go through that so I, the only thing I can do is just be supportive and try to be you know like just as pleasant as I can about the subject and support her whatever way she needs.' (Partner 5)
'At the end of the day it's not my decision a lot of the times, right, and it's more so just being supportive. Like I can give my opinion and say where what I believe is right but at the end of the day it's really her decision.' (Partner 4)
Theme 4: impacting mental health and well-being
'It's definitely had an impact for sure, just a lot of, definitely a lot of added stress […] how she's feeling today physically and mentally. Is she gonna have a flare?' (Partner 9)
'It's pretty difficult to see your partner go through that kind of level of kind of pain and angst […] that's obviously hard. And then again, when you kind of paint a picture in your head of like I said how things you think are gonna go and then they don't really go that way, it's also very difficult.' (Partner 7)
Theme 5: Seeking childcare support from extended family
'Which side of the family we'd get more support from because we need to be realistic and say that look, if she's going through pain or I'm going through pain, you know somebody needs to look after that child.' (Partner 2)
'Basically help taking care of the kids sort of thing because I guess with two kids and if I'm basically a caretaker to two children and potentially a caretaker to my wife, that's a bit of a workload.' (Partner 6)
Theme 6: Changing perspective towards pregnancy and RA management
'So definitely both wanted more kids but just looking at kind of reality and the risk factors, it wasn't worth the risk to either of us to keep having children.' (Partner 6)
'"I see you more mortal than myself after the pregnancy," because she nearly died three times […]I said, "for the first time ever, the reality has hit to me where your life is more fragile than mine."' (Partner 8)

Session Date: Monday, November 9, 2020

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The importance of safe and effective contraception for women with rheumatic diseases has been increasing. Several studies have demonstrated that carefully planned pregnancies are related with better outcomes making the use of contraceptive methods (CM) more significant. The objective is to describe the use of methods of contraception among Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE).

Methods: A Cross-sectional study, where women aged 18-45 followed in our outpatient clinic of reproductive health, pregnancy and rheumatic diseases (CEER), at Monterrey, Mexico, were questioned about the use of CM. Sociodemographic data was collected from the medical record. CM were classified as Ineffective (10-25% pregnant each year), effective (6-9% pregnant each year) and highly effective (< 1% pregnant each year). Methotrexate, Mycophenolate, Cyclophosphamide, Thalidomide and Leflunomide were considered as teratogenic drugs. The statistical analysis was performed using SPSS 24.0. A $p < 0.05$ was taken to indicate statistical significance.

Results: A total of 91 patients were included, 35 (38.5%) SLE patients with a median age of 30 years (22-39) and 56 (61.5%) RA patients with a median age of 34.5 years (27.25-40). From the total population, 58 (63.7%) reported the use of teratogenic drugs, with a higher use in RA patients ($p < .001$). Socio-demographic characteristics are listed in Table 1.

	RA (N=56)	SLE (N=35)	P
AGE, YEARS, MEDIAN (IQR)	34.5 (27.25 - 40)	30 (22-39)	
DISEASE DURATION, YEARS, MEDIAN (IQR)	3.5 (1.2 - 7.7)	4 (1-7)	
ONSET OF SEXUAL ACTIVITY,N (%)	46 (82.1)	24 (68.6)	.135
ONSET OF SEXUAL ACTIVITY AGE, MEDIAN (IQR)	18 (17-20)	14 (17-20)	
SEXUALLY ACTIVE, N (%)*	34 (60.7)	18 (51.4)	.384
USE OF TERATOGENIC DRUGS, N (%)	44 (78.6%)	14 (40%)	<.001

Table 1. Socio-demographic characteristics. RA: Rheumatoid Arthritis; SLE: Systemic Lupus Erythematosus. *Sexual activity in the last month.

		GRADE OF EFFECTIVENESS		
	Contraceptive counseling n (%)	Ineffective n (%)	Effective n (%)	Highly effective n (%)
RA (n= 46)	30 (65.2)	12 (40)	1 (3.3)	17 (56.6)
SLE (n= 24)	19 (79.1)	9 (47.3)	1 (5.2)	9 (47.3)
Total n= 70*	49 (70)	21 (42)	2 (4)	26 (53)

Table 2. Methods according to effectiveness in patients who received contraception counseling. RA: Rheumatoid Arthritis; SLE: Systemic Lupus Erythematosus. * Total of patients that have started sexual activity.

Graphs 1. Use of contraceptive methods among patients who had started sexual activity. This graphic shows the percentage (%) of contraceptive methods used by Rheumatoid Arthritis (RA) n= 46 and Systemic Lupus Erythematosus (SLE) n=24 patients, which are categorized by the grade of effectiveness. IUD: Intrauterine Device. Only were included patients that had started sexual activity.

Among the patients that had started sexual activity (SLE n=24, RA n=46), highly effective methods were the most frequent, used by a total of 39 (55.7%) women. The most common CM in RA was tubal ligation reported by 20 (43.5%) patients, nevertheless 9 (37.5%) SLE patients mentioned that they did not used any method. Graphs 1.

From the group who started sexual activity, 49 (70%) patients received contraceptive counseling, however, 21 (42%) patients were using ineffective CM. Table 2.

Conclusion: Only 70% of the women with rheumatic diseases received a contraceptive counseling and despite this 42% continued using an ineffective method. It is necessary to promote the counseling and use of contraception and provide a multidisciplinary support among this high-risk population.

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: RA improves in pregnancy and flares postpartum. Active disease causes adverse fetal outcomes. In PsA, the data is less clear as many of these studies are retrospective, lack validated disease activity scores and predate biologic use. We sought to compare disease activity plus maternal and fetal outcomes between RA and PsA.

	RA(n=23)	PsA (n=11)
Age		
Median (range)	36 (27-43)	36 (27-39)

1). Nationally=3.49kg 2). General population rate 3%

Table 3. Maternal and fetal outcomes

Methods: This is a prospective study of women attending our multidisciplinary combined rheumatology obstetrics service. Patients were seen pre-pregnancy, once per trimester and at 3 months postpartum. DAS28CRP-3 was used to assess disease activity as this is validated in pregnancy. Between group differences were analyzed using Pearson Chi square, Fischer's exact test or Mann-Whitney U test as appropriate.

Results: 34 patients were included in the study (Table 1). Overall, disease activity scores decreased during pregnancy and increased postpartum (Table 2). Maternal and fetal outcomes are shown in Table 3.

Conclusion: In this small study, disease activity generally improved in pregnancy and flared postpartum. There were adverse maternal outcomes in 33% of RA and 20% of PsA patients. Adverse fetal outcomes were seen in the offspring of 7% of RA and 20% of PsA patients. Compared to the general Irish population, birthweights were similar, maternal age was older and rates of Caesarean section were higher.

Differences in Chromatin Architecture Between Treatment Naïve Pediatric and Adult Lupus Patients

Joyce Hui-Yuen[1], Frank Jenkins[2], Kaiyu Jiang[3], Susan Malkiel[4], Betty Diamond[4] and James Jarvis[5], [1]Northwell LIJ Health System, Manhasset, NY, [2]Northwell Health, Manhasset, [3]University at Buffalo, Buffalo, NY, [4]Northwell Health, Manhasset, NY, [5]University at Buffalo Jacobs School of Medicine, Buffalo, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is possibly triggered by gene-environment interactions. We showed most of the SLE haplotypes encompass genomic regions enriched for epigenetic marks associated with enhancer function in immune cells, suggesting altered gene regulation. Data remain scarce on how epigenetic variance contributes to disease risk in pediatric SLE (pSLE). Our objectives were to identify differences in chromatin architecture in treatment-naïve pSLE compared to healthy children (HC) and to compare these differences to epigenetic data from treatment-naïve adult SLE patients.

Methods: We used the assay for transposase-accessible chromatin-sequencing (ATACseq) in 8 treatment-naïve pSLE patients and 5 HC to investigate whether regions of open chromatin unique to pSLE patients demonstrate enrichment for transcriptional regulators, using standard computational approaches and a false discovery rate of < 0.05. We used similar methodology to interrogate adult SLE data from a public GEO set to compare our pSLE findings.

Results: The mean age of onset was 13.75 (range 7-17) years in pSLE, and mean SLEDAI was 12.8 (range 6-24). We identified 245 differentially accessible regions (DAR) around peaks unique to pSLE, of which over 50% appear to be more accessible in pSLE than HC. Of the unique peaks, 46-60% are located more than 100kb from the nearest transcription start site (nTSS), implying many transcription factors may be acting on distal enhancers to regulate transcription. Variant calling within DAR found 3864 genes belonging to 129 different biologic processes (BP), most

notably cellular activation in immune response, regulation of proliferation, and responses to external stimuli. Similar results were seen in adult SLE data: over 50% of peaks in adult SLE are located distal to nTSS, and 3263 genes within DAR belong to 135 different BP, including cellular activation in immune response and complement activation.

Conclusion: We demonstrate an epigenetically-distinct profile in pSLE B cells when compared to HC, indicating pSLE B cells are predisposed for disease development. Pathways of significance analyses identified immunologic pathways important in the pro-inflammatory response in pSLE and adult SLE patients. Thus, increased chromatin accessibility in genomic regions controlling activation of the inflammatory and immune responses suggest transcriptional dysregulation of key players in immune cell activation plays an important role in pathogenesis of SLE.

Assessment of the Impact of Interferon Levels on Cognitive Dysfunction in Patients with SLE

Andrew Kwan[1], Joan Wither[2], Juan Pablo Diaz-Martinez[2], Robin Green[3], Dorcas Beaton[4], Mahta Kakvan[2], Lesley Ruttan[3], Carmela Tartaglia[5], Marvin Fritzler[6], May Choi[7], Jiandong Su[2], Dennisse Bonilla[2], Nicole Anderson[2], Patricia Katz[8] and Zahi Touma[9], [1]University of Toronto, Department of Medicine, Toronto, ON, Canada, [2]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [3]Toronto Rehabilitation Institute, University Health Network, Toronto, ON, Canada, [4]Institute for Work & Health, Toronto, ON, Canada, [5]University of Toronto, Krembil Neurosciences Centre, Toronto, ON, Canada, [6]Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [7]Brigham and Women's Hospital | Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [8]University of California, San Francisco, Novato, CA, [9]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) is among the earliest and the most prevalent manifestations of SLE. Previous studies have demonstrated that the increased levels of interferon (IFN)-induced gene expression in SLE are positively correlated with SLE disease activity and severity. The aim of this study is to examine the relationship between IFN levels and cognition as measured by the American College of Rheumatology neuropsychological battery (ACR-NB).

Methods: 301 consecutive consenting SLE patients (18 – 65 years old) attending a single center between Aug 2017 and Jan 2019 were enrolled in the study. IFN-induced gene expression was quantified by nanoString on RNA isolated from whole peripheral blood archive in TEMPUS tubes. The $\log_2$ transformed normalized levels of five IFN-induced genes were summed to produce the IFN5 score. Cognition was measured using the ACR-NB (19 tests) representing manual dexterity, processing speed, language, simple attention, memory and executive function domains. Using age and gender stratified normative data, patients were classified on the ACR NB as having CI if a z-score of ≤-1.5 was observed in ≥ 2 domains or z ≤-2.0 in ≥1 domain. Principal Component Analysis (PCA) was used to explore the relationships among cognitive tests, interferon levels and SLE disease duration.

Figure 1. Distribution of individual participants in the cohort classified by (A) presence or absence of cognitive impairment, (B) interferon levels

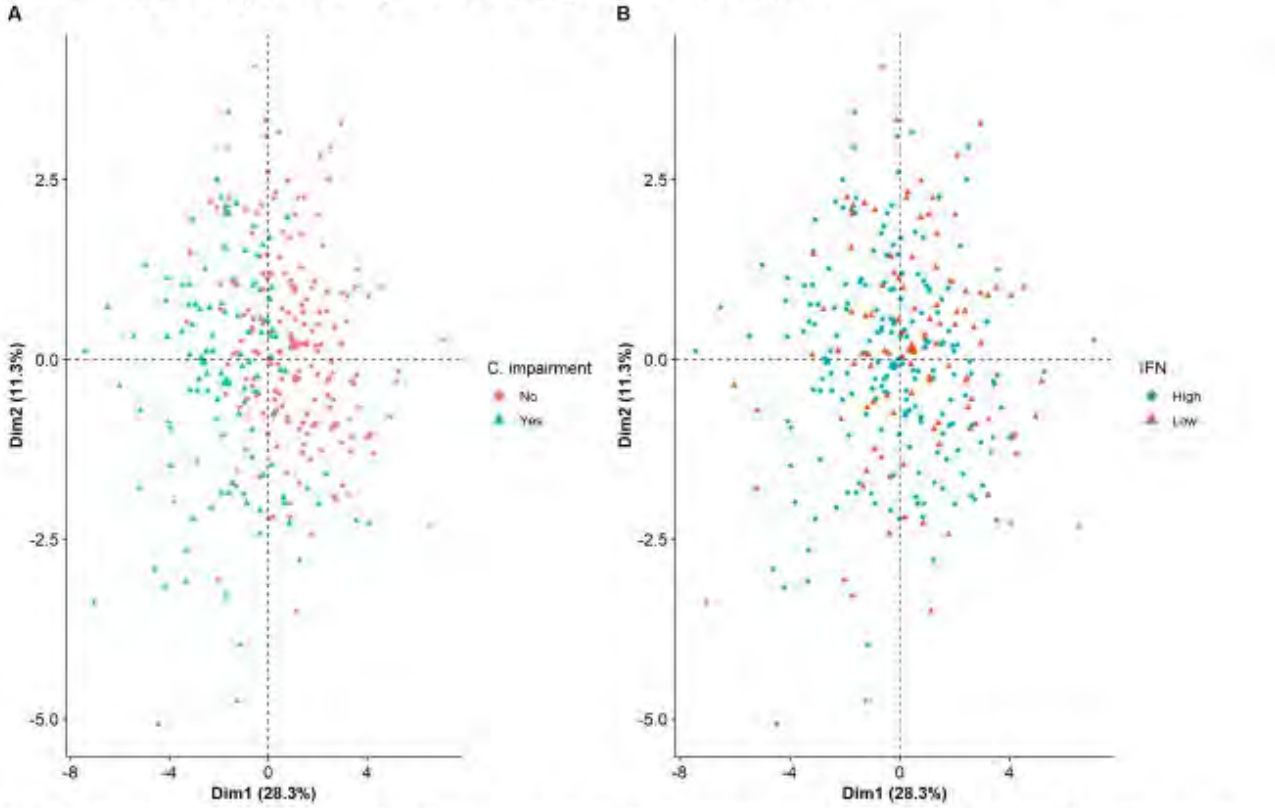

Figure 1. Axis x represents the first cognitive dimension (explaining 28.3% of the variance) and axis y represents the second dimension. Distribution of individual participants in the cohort classified by presence or absence of cognitive impairment (A), and interferon level (B). CI was operationalized as a z-score of ≤-1.5 on ≥2 domains or z ≤-2.0 on ≥1 domain.

In PCA, the variance-covariance matrix of the cognitive tests was decomposed into a series of eigenvectors with corresponding eigenvalues. Each eigenvalue constitutes the variance of the linear combination of all test scores weighted by values contained in the corresponding eigenvector. This method reduces the dimensionality of the experimental data and to summarize the association between the variables in the data. To preserve the largest portion of the total variance explained by PCA, we only retained the first two components.

Moreover, we included IFN levels and SLE disease duration as supplementary variables.

Results: Of 301 patients, 89.0% were women, mean age 40.9 ± 12.1 and mean disease duration 14 ± 10.1 years at study entry. PCA cognitive tests loaded onto 2 dimensions explained 39.6% of the variance in neuropsychological performance. The 1st dimension (explained 28.3% of the total variance) was correlated mainly with more complex cognitive tests and primarily explained CI status of participants. The second dimension (11.3%) was mainly explained by measures of simple information processing or motor speed.

Fig 1a shows the patients' component scores coloured by ACR-NB binary definition for CI and non-CI. This 1st dimension splits CI and non-CI patients at baseline. No clustering was observed when participants were categorized based on interferon level (Fig. 1b). No relationship was found between the cognitive tests and IFN levels or disease duration (Fig. 2). A weak negative correlation was also observed between interferon levels and RCFT and hand tapping, though this was not significant (Fig. 2).

Figure 2: Relationship between Interferon levels and neuropsychological tests

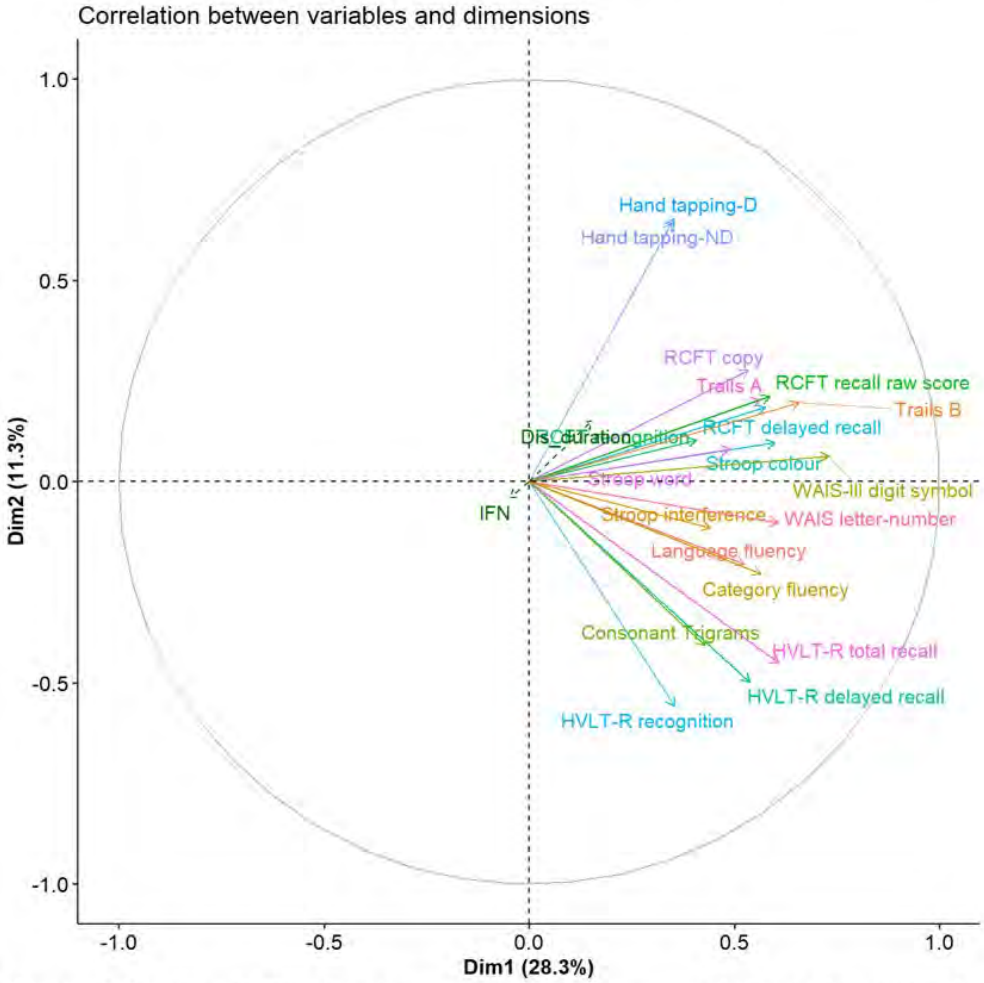

Figure 2. Results of PCA showing representative neuropsychological tests in relation to the two cognitive dimensions. Axis x represents the first dimension explaining 28.5% of the variance in cognition and axis y represents the second dimension. The length of each arrow represents the strength of the relationship between the variable it represents, and the cognitive dimensions found in our PCA. Variables whose representative arrows are close in proximity are more strongly related. Moreover, we observe that IFN was not related neither with the 1st dimension nor the second one.

Conclusion: This study assessed the relationship between IFN levels and cognitive function in patients with SLE. Using PCA analysis, we found no association between IFN levels and any cognitive tests, even after considering factors such as SLE disease duration.

Abstract Number: 1789

Time to Renal Insufficiency Based on 25(OH)-Vitamin D Levels

Michelle Petri[1], Jessica Li[2] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D is correctly classified as a sterol-hormone rather than a vitamin (Semin Nephrol 1986;6:4-20). It has multiple immunomodulatory effects, as well as cardiovascular and hematologic benefits (such as reduction in thrombosis). In SLE patients who are vitamin D insufficient/deficient, vitamin D supplementation clearly improves proteinuria (Arthritis Rheum 65:1865-71, 2013) with a plateau at a 25(OH)-vitamin D level of 40 ng/mL. In fact, vitamin D helps proteinuria in diverse renal diseases (Int J Environ Res Public Health 2018;15:1773).

Methods: The SLE patients met revised ACR or SLICC classification criteria. This analysis included 73,221 person months (6,102 person years) from 1,220 patients (93% female, 38% African-American, 52% Caucasian). 48.5% were

Rate ratios and p-values were adjusted for age, sex, race, BMI							

Table 2. Rates of renal insufficiency events by 25(OH)-vitamin D levels

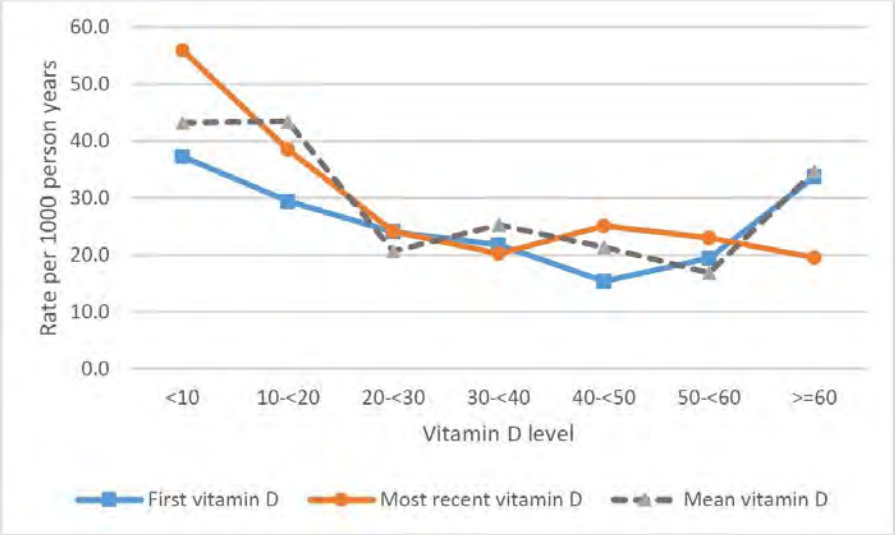

Figure 1. Rates of renal insufficiency by 25(OH)-vitamin D levels

diagnosed at age < 30 years. Vitamin D levels were measured regularly starting mid-2009. Renal insufficiency was defined as creatinine (CR) ≥1.5 mg/dl or < 50% function. For this analysis, a dataset with one record for each month of follow up for each person was constructed. Mean prior vitamin D levels were calculated over all previous months. Patients were followed from the first measure of 25(OH)-vitamin D level to first incident of renal insufficiency or their

last recorded visit. To calculate the rate of renal insufficiency in each demographic or clinical subgroup, the number of renal insufficiency events was divided by the number of person months at risk and then converted to rates per 1,000 person years. Pooled logistic regression was used to assess the relationship between vitamin D blood levels and rates of renal insufficiency.

Results: Table 1 shows the association between patient characteristics and the rate of renal insufficiency. Renal insufficiency was more common in males, African-Americans and obese patients. Table 2 shows the association between Vitamin D level tertiles and the rate of renal insufficiency. There was a significantly elevated risk of renal insufficiency among those in the extremely low levels of 25(OH)-vitamin D (< 20 ng/mL). Figure 1 shows the trend of rates of renal insufficiency by vitamin D levels. The effect of 25(OH)-vitamin D < 20 ng/mL was clearly shown regardless if we used first, most recent or mean level of 25(OH)-vitamin D. Results were adjusted for race, age, sex and BMI.

Conclusion: The benefit of vitamin D supplementation to reduce proteinuria in SLE brought the benefit of this sterol-hormone as an immunomodulatory to the forefront. Now our data show that very low 25(OH)-vitamin D levels < 20 ng/mL are associated with renal insufficiency (adjusted for ethnicity, as African-Americans have lower levels).

Abstract Number: 1790

Association of Telomere Length and the Systemic Lupus International Collaborating Clinics Frailty Index (SLICC-FI) in Long Standing Systemic Lupus Erythematosus

Kaitlin Lima[1], Alexandra Legge[2], John Hanly[2], Jungwha Lee[3], Jing Song[3], Anh Chung[3], Carly Skamra[4], QiQuan Huang[1], Richard Pope[5] and Rosalind Ramsey-Goldman[6], [1]Northwestern University, Chicago, IL, [2]Dalhousie University, Halifax, NS, Canada, [3]Northwestern University, Chicago, [4]Northwestern University, Brookfield, IL, [5]McGaw Medical Center of Northwestern University, Chicago, IL, [6]Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty, an emerging concept in SLE, represents an individual's ability to respond to physiologic stress. The first lupus-specific frailty index, the SLICC-FI, was recently shown to predict mortality and damage accrual in the SLICC disease inception cohort. Multiple studies confirm that telomere length is significantly shorter in patients with SLE, however there is conflicting evidence regarding the role of telomeres in mediating frailty in the geriatric population. The objectives of this study were 1) to assess if frail patients with SLE have shorter telomere length compared to non-frail patients and 2) to examine the relationship between telomere length and changes in frailty over time.

Table 1: Patient Characteristics of patients in SOLVABLE cohort

Patient Characteristics (N=131) *	Mean (SD) or n (%)
Age (yrs), mean (SD)	46.28 (10.16)
Race, n (%)	
White	80 (61.07%)
African American	34 (25.95%)
Hispanic	9 (6.87%)
Asian	8 (6.11%)
Education, n (%)	
Less than high school diploma	5 (3.82%)
High school diploma	35 (17.71%)
College graduate	56 (42.75%)
Advanced degree	36 (26.72%)
Body Mass Index (kg/m^2), mean (SD)	28.20 (7.74)
SLE Characteristics	
Age at diagnosis (yrs), mean (SD)	30.78 (10.90)
Disease duration (yrs), mean (SD)	15.51 (8.84)

Plaquenil, n (%)	106 (80.92%)
Immunosuppressants, n (%)	54 (41.22%)

* At SOLVABLE 3-year follow up visit

Methods: Data was analyzed from 131 of 185 adult women who met the following criteria: 1) 1997 revised ACR criteria for definite lupus, 2) enrolled in the Study of Lupus Vascular and Bone Long-Term Endpoints (SOLVABLE) cohort consisting of adult women from the Chicago Lupus Database and 3) telomere length measured from whole blood by PCR at 3-year follow up visit, which is the baseline time point for this study. Adapted SLICC-FI scores consisting of 46 health deficits were calculated at baseline (3-year follow-up visit) and 2 years after baseline (5-year follow-up visit). Using baseline SLICC-FI scores, patients were categorized as frail (SLICC-FI >0.21), least fit (0.10< SLICC-FI≤0.21) or relatively fit (SLICC-FI ≤0.10). We used median quantile regression models to calculate unadjusted and age-adjusted median telomere length (95% confidence limit [CI]) among all participants and by the three frailty categories. Median quantile regression was used to examine the association of baseline telomere length with subsequent change in frailty.

Results: At baseline, 131 patients had mean (SD) age of 46.28 (10.16) years, mean disease duration of 15.51 (8.84) years, and mean (SD) SLICC-Damage Index score of 2.24 (2.13). Mean (SD) SLICC-FI score was 0.17 (0.09), with 29.77%, 44.27%, and 25.95% of patients categorized as frail, least fit, and relatively fit respectively. Frail patients had the shortest median telomere length of 3.25 (95% CI 2.43, 4.27) kb, while least fit and relatively fit patients had telomere length of 3.51 (95% CI 2.83, 4.23) kb and 3.35 (95% CI 2.77, 4.97) kb respectively; these differences were

Table 2: Median and 95% Confidence Limits of Telomere Length Stratified by Frailty Status in SOLVABLE cohort

Telomere Length (kb)	Overall	Frailty Status			P value*
		Relatively Fit (SLICC-FI ≤ 0.10)	Least Fit (0.10<SLICC-FI ≤ 0.21)	Frail (SLICC-FI > 0.21)	
	Median (95% Confidence Limits) N=131	Median (95% Confidence Limits) N=34	Median (95% Confidence Limits) N=58	Median (95% Confidence Limits) N=39	
Unadjusted	3.35 (2.76, 3.95)	3.35 (2.77, 4.97)	3.51 (2.83, 4.23)	3.25 (2.43, 4.27)	0.94
Age-adjusted (centered at mean, 46.28 years)	3.32 (3.07, 3.75)	3.21 (2.79, 4.87)	3.52 (2.70, 4.30)	3.19 (2.40, 4.26)	0.88

* P-value from Wald test comparing median telomere length by frailty status.

not statistically significant (p=0.94). The results were similar after adjusting for baseline age. Baseline telomere length was not associated with median of subsequent change in frailty score (coefficient = 0.0002, 95% CI -0.004, 0.003).

Conclusion: Cross-sectionally, there was not a statistically significant association between telomere length and frailty status. Telomere length was not associated with subsequent change in frailty score in our study, though this may be limited by short follow up time and the small sample size. Further studies are needed to determine the predictive value of telomere length as a biomarker of frailty in lupus patients.

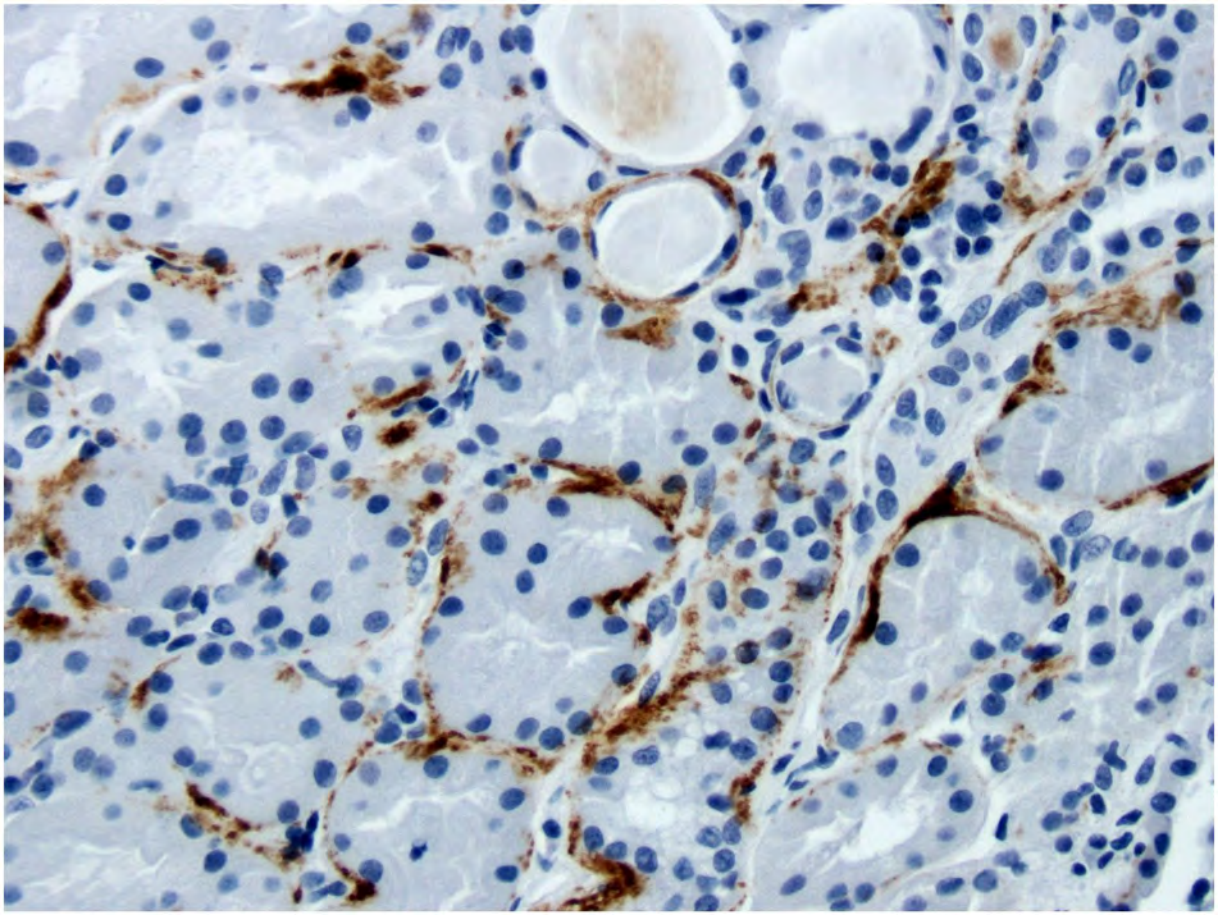
C9 deposition, non-tubular			
Glomerular (score >0), n (%)	3 (42.9%)	10 (43.5%)	>0.99
Arterioles/arteries (score >0), n (%)	6 (85.7%)	12 (52.2%)	0.19

Background/Purpose: Tubulointerstitial damage in lupus nephritis (LN) is a strong predictor of progression to chronic kidney disease (CKD) and end stage renal disease (ESRD). While prior studies showed complement activation mediates glomerular injury, the role of complement in renal tubular damage has not been evaluated. The objective of this study is to investigate the association between complement activation as measured by tubular complement 9 (C9) deposition with interstitial fibrosis and tubular atrophy (IFTA) in LN.

Methods: LN biopsies from July 2014 to July 2016 were evaluated. Chromogenic immunohistochemistry was performed on formalin-fixed, paraffin-embedded, 4-µm human renal biopsy sections using unconjugated, murine anti-human Complement C9 (Hycult Biotech, clone X197) as a marker of the membrane attack complex (MAC) activation. C3 glomerulopathy was used as a positive control and normal kidney served as a negative control. Tubular basement membrane C9 staining intensity was analyzed as absent (0) versus present (1 to 3) scored on a semi-quantitative scale by a renal pathologist. IFTA was categorized as 0–10%, 11–20%, and >20%. Clinical parameters were assessed at the time of biopsy and 6 months post biopsy.

Results: Renal biopsies from 30 LN patients were studied, of which 23 (77%) were proliferative LN. There were 24 (80%) women, mean age 33 (standard deviation) (12) years. Positive tubular C9 staining (C9+) was observed in 7 (23%) biopsies. At the time of renal biopsy, C9+ patients had significantly higher proteinuria, compared to C9- patients: median (interquartile range) 6.2g (3.3-13.1) vs. 2.4g (1.3-4.6), p< 0.01. The differences persisted at 6 months after induction therapy: 1.08g (1.0-8.3) in C9+ vs. 0.68g (0.2-2.1) in C9- patients, p=0.06. Tubular C9 deposition was associated with the finding of interstitial fibrosis on biopsy: 3 out of 7 (42.9%) had >20% interstitial fibrosis as com-



Patient with LN Class V, 2+ tubular C9 deposition and 30 to 40% IFTA.

pared to none in the C9- group, p=< 0.01. Higher proportion of C9+ patients had moderate NIH Chronicity index: 3 out of 7 (42.9%) vs 2 out of 23 (8.7%) in the C9- group, p=0.07. There was no significant difference in eGFR at renal biopsy between the two groups.

Conclusion: Tubular C9 deposition is associated with proteinuria, interstitial fibrosis and increased chronicity which are predictors of progression to ESRD. Complement activation may play an important role in tubulointerstitial damage in LN.

Platelet-bound C4d Is Associated with an Increased Risk of Arterial and Venous Thromboses in SLE

Yevgeniya Gartshteyn[1], Roberta Vezza Alexander[2], John Conklin[3], Thierry Dervieux[4] and Anca Askanase[5], [1]Columbia University College of Physicians and Surgeons, Glen Rock, NJ, [2]Exagen Inc, Vista, CA, [3]Exagen Inc., Vista, CA, [4]Prometheus Biosciences Inc, San Diego, CA, [5]Columbia University College of Physicians and Surgeons, New York, NY

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Platelet-bound complement activation products (PC4d), defined as PC4d20 net mean fluorescent intensity [MFI], or a thrombotic risk score that includes PC4d, C3 and anti-phosphatidylserine/prothrombin antibodies (anti-PS/PT IgG) (1) correlate with venous thromboses in SLE. The current study was initiated to further evaluate the association between PC4d and arterial and venous thrombotic events.

Methods: Using a cross-sectional design, we examined the association of PC4d, measured by flow cytometry, with thrombosis. PC4d was dichotomized and we evaluated the ability of different cutoff values, ranging from 5 to 20 net MFI, to discriminate for the history of vascular events. The thrombotic risk was calculated as previously described (1).

Results: 150 SLE patients (40 ±13 years old, 91% female, 33% Hispanic, 26% African American) were included; 38% had antiphospholipid antibodies (aPL). Thirty-one vascular events (18 venous, 13 arterial) occurred within five years of study enrollment. Arterial and venous events, as compared to no events, were associated with higher PC4d levels (median [IQR] 13.6 [4.4-24.0] and 13.2 [3.2-22.3] vs. 4.0 [2.5-8.3] net MFI, respectively, $p< 0.05$). In a multivariable model adjusting for all significant co-variates identified in the univariable analysis (aPL, smoking, antimalarial use and prednisone ≥7.5mg/day), the association between all vascular events and PC4d (natural log transformed) remained significant (OR 1.7 95%CI 1.2-2.5, p=0.005).

	Sensitivity	Specificity	Youden J Statistic		Sensitivity	Specificity	Youden J Statistic
Venous Events:				Arterial Events:			
PC4d ≥ 20	44%	89%	0.34	PC4d ≥ 20	39%	89%	0.28
PC4d ≥ 15	44%	84%	0.29	PC4d ≥ 15	39%	84%	0.23
PC4d ≥ 10	56%	78%	0.33	PC4d ≥ 10	62%	78%	0.39
PC4d ≥ 5	67%	57%	0.23	PC4d ≥ 5	69%	57%	0.26
PC4d levels are expressed as net MFI.							

Table 1. Sensitivity and specificity of different PC4d cutoff levels for history of venous and arterial vascular events.

Event	Sensitivity (%) [95% CI]	Specificity [95% CI]	OR [95% CI]
Any thrombosis	35 [17, 56]	86 [78, 91]	3.15 [1.21, 8.19]
Arterial thrombosis	45 [17, 77]	84 [77, 90]	4.44 [1.24, 15.91]
Venous thrombosis	33 [13, 59]	84 [77, 90]	2.65 [0.89, 7.88]
CVA	25 [3, 65]	82 [75, 88]	1.56 [0.30, 8.18]
DVT	25 [5, 57]	83 [75, 89]	1.58 [0.40, 6.29]
MI	100 [29, 100]	84 [77, 89]	∞ [NaN, ∞]

Table 2. Sensitivity, specificity, and odds ratio (OR) with 95% confidence intervals [95% CI] are reported for thrombotic score ≥ 2. The thrombotic score was calculated using cutoff for PC4d of 10 MFI. CVA: cardiovascular accidents, DVT: deep vein thrombosis, MI: myocardial infarction, NaN: not a number.

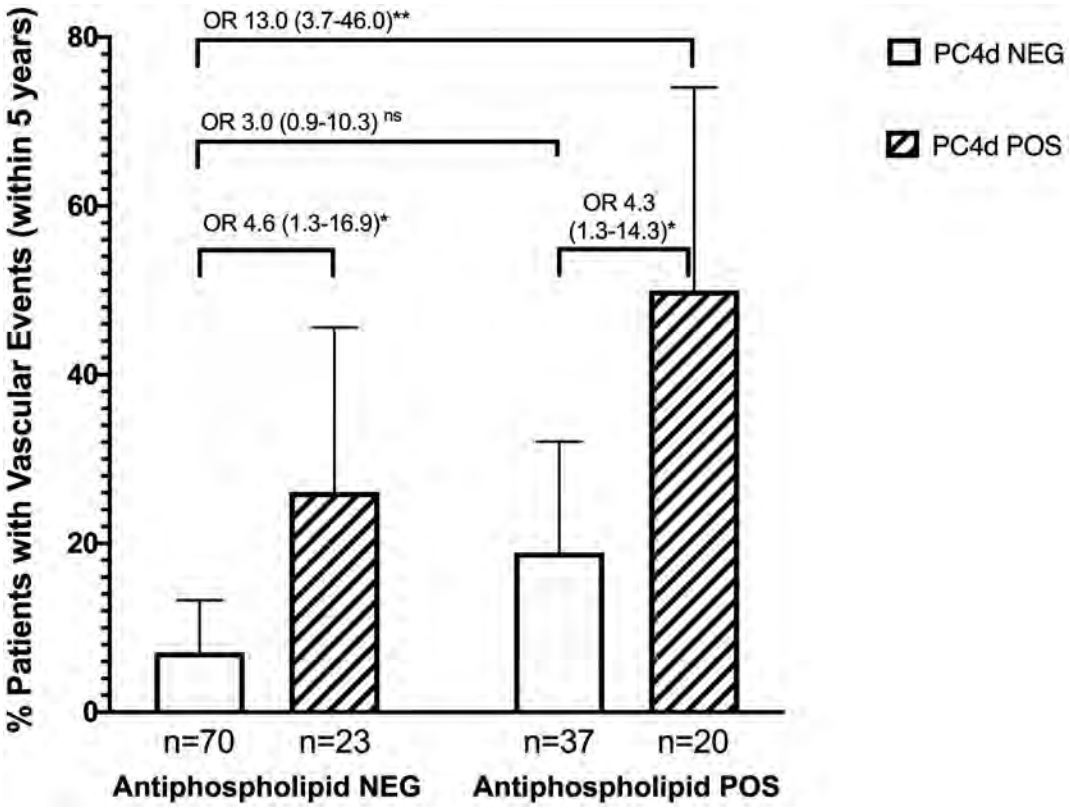

Figure 1. Vascular Events in SLE Stratified by Antiphospholipid Antibody (aPL) status and PC4d. Percent patients with a history of a vascular event within five years of study enrollment, stratified by aPL presence (NEG=negative; POS=positive) and PC4d status (NEG=PC4d 0.05.

The optimal PC4d cut-off point for vascular thromboses was identified to be 10 net MFI, with a sensitivity and specificity for venous events of 56% and 78%, and for arterial 62% and 78% (Table 1); PC4d≥10 net MFI, as compared to PC4d≥20 net MFI, resulted in a greater detection of individuals with vascular events (16/28 vs 11/28 respectively). Stratifying by aPL status, PC4d10 was associated with a history of any vascular event, with a stronger association seen in patients positive for both aPL and PC4d - OR 4.6 95% CI 1.3-16.9 for PC4d+/aPL- and OR 13.0 95% CI 3.7-46.0 for PC4d+/aPL+ as compared with PC4d-/aPL- patients (Figure 1). A thrombotic score ≥ 2 (calculated using PC4d≥10) was associated with all events (arterial and venous) – OR 3.15 [95% CI 1.21, 8.19] and with arterial thrombosis - OR 4.44 [95% CI 1.24, 15.91] (Table 2).

Conclusion: PC4d and the thrombotic score associate with thrombotic events in SLE. The 10 net MFI PC4d cutoff was optimal for identifying patients with thromboses, and more specifically arterial events. PC4d10 could function more effectively as a biomarker of cardiovascular events, providing a novel risk indicator independent of aPL antibodies.

Session Date: Monday, November 9, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a major complication of systemic lupus erythematous (SLE) and affects ~60% of patients during the course of their disease, leading to significant morbidity and mortality. Previous studies examining the safety of percutaneous kidney biopsy to diagnose LN have found variable complication rates depending on disease type studied, ranging from 4-11% in autoimmune/SLE patients to 15-17% in safety studies of any kidney disease. The purpose of our study was to define the safety of obtaining additional tissue for research during clinically indicated renal biopsies in a SLE cohort.

Methods: Patients were enrolled across 15 clinical US sites in the SLE Accelerating Medicines Partnership (AMP). Kidney biopsies were clinically indicated to evaluate proteinuria (urine protein creatinine ratio [uPCR] > 0.5). Patients with a history of renal transplant, use of rituximab within 6 months of biopsy, and current pregnancy were excluded. Ultrasound/CT-guided kidney biopsies were performed by interventional radiologists/nephrologists generally using an 18-gauge needle although technique, number of routine passes and core lengths varied. An additional core taken solely for research purposes, or a piece of core with sufficient glomeruli remaining from the routine passes and not required for clinical diagnosis, was collected. All adverse events (AEs) occurring within 30 days of biopsy were reported, including duration, severity, type, and resolution.

Results: 482 patients underwent a renal biopsy between 2014 and 2020. All patients met criteria for SLE (ACR or SLICC) and the majority were female (85%). Pathologic assessment of clinical biopsies revealed ISN/RPS Class I-VI for most biopsies, although 45 biopsies (9%) yielded a non-LN diagnosis (Table 1). Overall, 37 patients (8%) experienced an AE with several more than one, with a total of 41 AEs reported. Of these AEs, 8 (20%) were considered by the site investigator to be unrelated or unlikely to be related (included pain, shortness of breath, cardiac arrest, fall, and hemoglobin decrease due to sepsis) and 33 (80%) were deemed possibly, probably, or definitely related to the study procedure. Of these events, 9/33 (28%) were mild, 10 (30%) were moderate, and 12 (36%) were deemed severe. In 18 patients (4%) the AEs were considered serious as defined by inpatient or prolonged hospitalization, significant incapacity, or requiring intervention to prevent permanent impairment. The most common related AEs

Clinical Laboratory Values			
Random uPCR, mean	3.00	2.92	3.89
Serum creatinine, mean	1.4	1.4	1.18
Research biopsy length (mm), mean	8.4	8.5	6

Table 1. Patient characteristics at time of kidney biopsy.

were bleed-related complications, including hematoma, hemorrhage, and hemoglobin decrease (N= 29). Of these, 18 required hospitalization, with 4 of these patients receiving a blood transfusion. All 29 bleed-related complications resolved. The length of the research biopsy did not associate with an AE.

Conclusion: Procurement of an additional kidney biopsy core for research purposes in SLE patients undergoing a clinically-indicated kidney biopsy did not result in an increase in adverse events compared to the adverse event rate

in prior studies of the safety of percutaneous kidney biopsy. Accordingly, inclusion of a research core should be considered feasible for future studies to advance discovery of new therapeutic targets and prognostic indicators in LN.

Systemic Lupus Erythematosus and Geomagnetic Disturbances: A Time Series Analysis

George Stojan[1], Flavia Giammarino[2] and Michelle Petri[3], [1]Johns Hopkins University, BALTIMORE, MD, [2]Deutsche Bank, London, United Kingdom, [3]Johns Hopkins University School of Medicine, Baltimore

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: To examine the influence of solar cycle and geomagnetic effects on SLE disease activity.

Methods: The data used for the analysis consisted of 327 observations of 27-day Physician Global Assessment (PGA) averages of patients with SLE seen in the Hopkins Lupus Center from 1996-2020. The considered geomagnetic indices were the AP index (geomagnetic activity), sunspot number index R (area of solar surface covered by spots), the F10.7 index (noise level generated by the sun at a wavelength of 10.7 cm at the earth's orbit), the AU index (upper auroral electrojet index), and high energy (> 60 Mev) proton flux events. Geomagnetic data were obtained from the Goddard Space Flight Center Space Physics Data Facility. A time series decomposition of the PGA averages was performed as the first step. The linear relationships between the PGA and the geomagnetic indices were examined using parametric statistical methods such as Pearson's correlation and linear regression, while the nonlinear relationships were examined using nonparametric statistical methods such as Spearman's rho and Kernel regression.

Results: After time series deconstruction of PGA averages, the seasonality explained a significant fraction of the variance of the time series (R^2 =38.7%) with one cycle completed every 16 years. Increases in the number of high energy proton fluxes were associated with decreases in the PGA ($p< 0.05$). Increases in sunspot number index R anticipated decreases in the PGA ($p< 0.05$). Increases in the Ap index were associated with decreases in the PGA ($p< 0.1$).

Conclusion: The seasonality of the PGA averages (one cycle every 16 years) explains a significant fraction of the variance of the time series. Geomagnetic disturbances, including the level of geomagnetic activity, sunspot numbers, and high proton flux events may explain part of the described seasonality seen in SLE.

Intracellular Homocysteine and Homocysteine Metabolites in Systemic Lupus Erythematosus (SLE)

George Stojan[1], Jessica Li[1], Amrita Raj[2], Maureen Kane[3] and Michelle Petri[4], [1]Johns Hopkins University, BALTIMORE, MD, [2]Johns Hopkins University, Baltimore, [3]University of Maryland School of Pharmacy, Baltimore, [4]Johns Hopkins University School of Medicine, Baltimore

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In SLE, homocysteine has been shown to be a potentially modifiable, independent risk factor for stroke and thrombotic events. All previous epidemiological studies used total plasma homocysteine as a disease marker, but it remains unclear whether plasma or intracellular homocysteine is causing detrimental effects. Folic acid (0.5 mg/day) supplementation does lower homocysteine in plasma as expected, but homocysteine and all its metabolites in white bloods cells remain unaffected (1). We hypothesized that intracellular homocysteine and homocysteine metabolite levels in patients with SLE are disproportionately elevated compared to the levels seen in healthy subjects and that intracellular homocysteine and homocysteine metabolite levels are independently associated with coronary plaque in SLE.

Methods: A liquid chromatography coupled to tandem mass spectrometry absolute quantification assay was used for the determination of 6 analytes in both plasma and PBMCs: homocysteine (Hcy), S-adenosylmethionine (SAM), S-adenosylhomocysteine (SAH), methionine (Met), cystathionine (Cysta), and 5-methyltetrahydrofolate (5m-THF). We then compared intracellular (PBMC) and extracellular (plasma) homocysteine and homocysteine metabolite (SAM, SAH, Met, Cysta, 5m-THF) concentrations in 10 patients who met ACR or SLICC classification criteria for SLE and in 10 age, sex, and ethnicity matched controls. Subjects with a history of diabetes mellitus, cardiovascular disease, hypertension, alcohol consumption in excess of 3 units per day, anemia, renal insufficiency (serum creatinine >1.5mg/dl), and pregnancy were excluded. All SLE patients had two coronary CT angiography (CCTA) studies (follow up mean=3.77 years, SD=0.94 years) as screening for occult coronary atherosclerotic disease in asymptomatic individuals. Fisher's t-test was used to analyze the differences between homocysteine and homocysteine metabolite levels in SLE and controls. The correlation between metabolite levels and coronary plaque volumes was analyzed using Pearson correlation.

Results: Plasma from SLE patients had higher levels of homocysteine ($P < 0.0001$), SAH ($P < 0.05$), SAM ($P < 0.001$), and lower levels of Met ($P < 0.05$) and Cysta ($P < 0.001$) compared to controls. PBMC intracellular concentrations from SLE patients had higher levels of Cysta ($p < 0.05$), SAH ($p < 0.05$), SAM ($p < 0.001$) and lower levels of 5m-THF ($p < 0.001$). Plasma SAH showed a positive correlation to the total coronary plaque, calcified plaque, and noncalcified plaque measured by CCTA ($p < 0.05$).

Conclusion: Intracellular concentrations of homocysteine metabolites were significantly different between SLE patients and controls, despite similar intracellular homocysteine levels. Plasma S-adenosylhomocysteine was positively

correlated to total coronary plaque, calcified plaque, and noncalcified plaque. Further studies are needed to clarify the importance of intracellular homocysteine metabolites as cardiovascular risk factors in SLE.

A Panel of Urinary Proteins Predicts Active Lupus Nephritis and Response to Rituximab Treatment

Jennifer Davies[1], **Emil Carlsson**[1], Angela Midgley[1], Eve Smith[1], Ian Bruce[2], Michael Beresford[1] and Christian Hedrich[3], [1]Department of Women's and Children's Health, Institute of Life Course and Medical Sciences, Liverpool, England, United Kingdom, [2]Centre for Epidemiology Versus Arthritis, The University of Manchester and NIHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]University of Liverpool, Liverpool, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 30% of patients with adult-onset systemic lupus erythematosus (SLE) develop lupus nephritis (LN). Presence and/or severity of LN are currently assessed by renal biopsy, but biomarkers in serum or urine samples may provide an avenue for non-invasive routine testing.

Methods: 197 SLE patients and 48 healthy controls were recruited, and urine samples collected. 75 of the SLE patients had active LN and 104 had no or inactive renal disease. Concentrations of lipocalin-like prostaglandin D synthase (LPGDS), transferrin, alpha-1-acid glycoprotein (AGP-1), ceruloplasmin, monocyte chemoattractant protein 1 (MCP-1) and soluble vascular cell adhesion molecule-1 (sVCAM-1) were quantified by MILLIPLEX® Multiplex Assays using the MAGPIX Luminex xMAP platform. Binary logistic regression was conducted to examine whether proteins levels associate with active renal involvement and/or response to rituximab treatment.

Results: Urine levels of transferrin ($p< 0.005$), AGP-1 ($p< 0.0001$), MCP-1 ($p< 0.001$) and sVCAM-1 ($p< 0.005$) were significantly higher in SLE patients when compared to healthy controls. Furthermore, levels of transferrin, AGP-1, ceruloplasmin, MCP-1 and sVCAM-1 (all $p< 0.0001$) were significantly higher in SLE patients with active LN when compared to patients without active LN. A combination of five urine proteins, namely LPGDS, transferrin, ceruloplasmin, MCP-1 and sVCAM-1 was a good predictor of active LN (AUC 0.898). A combined model of LPGDS, transferrin, AGP-1, ceruloplasmin, MCP-1 and sVCAM-1 predicted response to rituximab treatment at 12 months (AUC 0.818).

Conclusion: Findings support the use of a urinary protein panel to identify active LN and potentially predict response to treatment with rituximab in adult SLE patients. Prospective studies are required to confirm findings.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: We reported previously (R*amsey-Goldman et al., Arthritis Rheumatol 2020)* that score > 0.8 of a multianalyte assay panel (MAP) with algorithm predicts fulfillment of a 4th ACR criterion 9-18 months (median 12) after enrollment in patients with probable systemic lupus erythematosus (pSLE). We continued to follow pSLE to better evaluate transition to classifiable SLE.

Methods: pSLE, defined as fulfilling 3 ACR criteria, were followed at academic lupus centers. At enrollment, 35 (38%) of the 92 pSLE fulfilled SLICC criteria. CB-CAPs - C4d bound to erythrocytes (EC4d) and B-cells (BC4d) - were measured by quantitative flow cytometry, serum C3 and C4 by turbidimetry, and autoantibodies by ELISA. Anti-dsDNA positivity was confirmed by immunofluorescence (IFA). MAP index consists of an algorithm with CB-CAPs and autoantibodies (Dervieux et al., *J Immunol Methods* 2017). Initial decision analysis with Youden index showed that MAP > 0.8 and EC4d > 20 mean fluorescence intensity units (MFI) reflected the optimal cutoffs for transition to ACR classifiable SLE; the same cutoffs were used for analysis of all follow-up visits. Time to fulfillment of ACR criteria was evaluated by Kaplan-Meier analysis; associations were analyzed by log-rank test and Cox proportional hazards model and are expressed as hazards ratio (HR).

Results: Of the 92 pSLE, 74 had 1 or 2 follow-up visits 9-35 months after enrollment for a total of 128 visits. Overall, 28 pSLE (30.4%) transitioned to ACR classifiable SLE: 16 (57%) in the 1st year and 12 (43%) in the 2nd. The clinical or laboratory features that defined fulfillment of ACR criteria are in Table 1. Use of hydroxychloroquine and immunosuppressants was similar in those who did and did not transition to SLE. Of the 17 subjects who accrued hematological criteria during the study (11 as the sole criterion and 6 as one of the new criteria), a minority were on immunosuppressants: 6 at enrollment, 5 at the 1st visit, and 3 at the 2nd. Neither SLICC criteria nor individual biomarkers were significantly associated with transition to SLE (Table 2). Only MAP > 0.8 had significantly high HR for transition to SLE; EC4d > 20 MFI, low complement, and anti-dsDNA were not significant (Table 2).

Conclusion: The majority of pSLE transitioned within a year. MAP > 0.8 predicted disease evolution into classifiable SLE better than other biomarkers or fulfillment of SLICC criteria.

	New ACR criteria from baseline to 12 months	New ACR criteria from 13 to 26 months
Hematological	10	7
Ulcers	4	2
Pleuritis or pericarditis	2	0
Immunological	2	4
Arthritis	2	1
Discoid rash	1	0
Photosensitivity	1	2
Renal	0	1

Table 1. Clinical and laboratory features leading to the transition of pSLE to SLE. The 16 individuals who fulfilled ACR criteria within 1 year (≤365 days) accrued a total of 22 new ACR criteria, with hematological being the most common. The 12 subjects who fulfilled ACR criteria after the 1st year of follow up (>365 days) accrued a total of 15 criteria, with hematological being again the most common. Of note, 2 subjects who fulfilled ACR criteria within 12 months accrued additional criteria after this time point (an immunological criterion and ulcers); these criteria are included in the table.

Variables at enrollment	HR	95% CI	p-value
SLICC criteria	1.82	0.86 – 3.84	0.116
Low C3 and/or C4	1.02	0.24 – 4.29	0.984
Anti-dsDNA (IFA)	2.04	0.71 – 5.91	0.188
Positive CB-CAPs (EC4d and/or BC4d)	1.36	0.61 – 3.01	0.454
EC4d>20 MFI	2.07	0.86 – 4.94	0.103
MAP>0.8	2.72	1.25 – 5.93	0.012

Table 2. Hazard ratio (HR) of variables measured at enrollment in predicting fulfillment of ACR classification criteria in the pSLE population. Data of 128 follow-up visits (n=127 for MAP) that occurred 9 to 35 months after enrollment were analyzed. CB-CAPs: cell-bound complement activation products; MAP: multianalyte assay panel with algorithm; HR: hazard ratio; CI: confidence intervals.

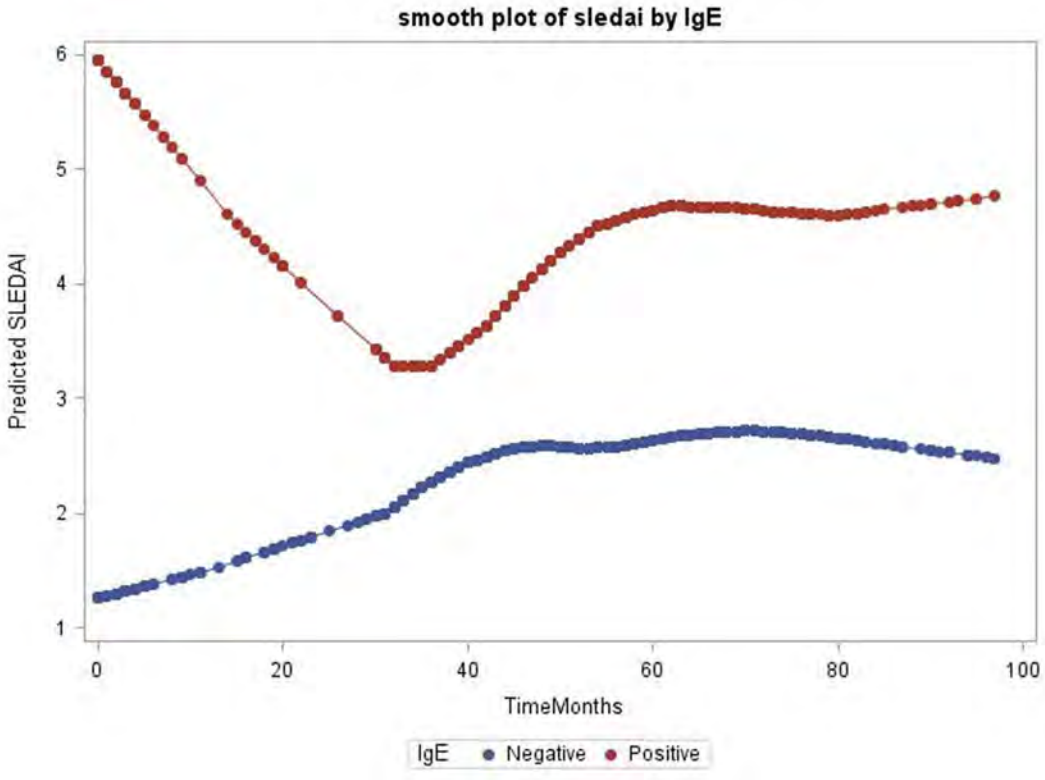
Session Type: Poster Session D

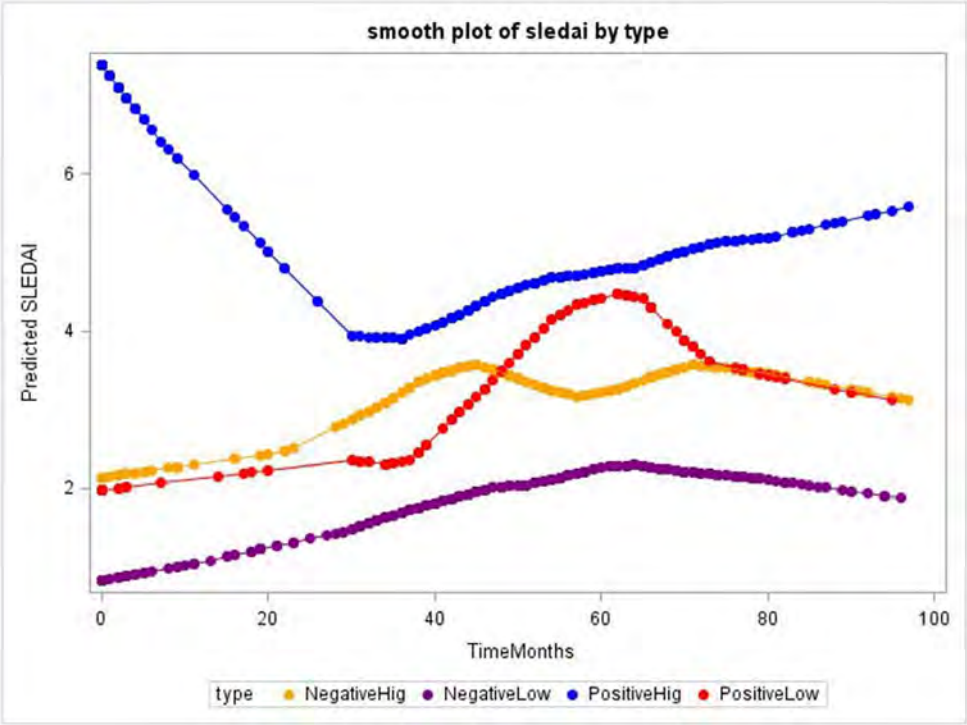
Session Time: 9:00AM–11:00AM

	dsDNA IgE-positive	dsDNA IgE-negative
n (F/M)	28 (24/4)	67 (57/10)
Age (mean±SD)	40±13.7	43.5±15.5
African-American, n (%)	6 (21.4)	23 (34.3)
Hispanic, n (%)	8 (28.6)	10 (14.9)
Asian, n (%)	7 (25)	9 (13.5)
White, n (%)	7 (25)	25 (37.3)
Nephritis, n (%)	18 (64.3)	36 (53.7)
High IFN score, n (%)	17 (60.7)	22 (32.8)*

Demographic and clinical features of the SLE patients.



SELENA-SLEDAI scores of patients during the study by dsDNA-IgE autoantibody.



SELENA-SLEDAI scores of patients by dsDNA-IgE autoantibody and IFN score.

Background/Purpose: Recent reports indicate that autoreactive anti-dsDNA IgE autoantibodies and IgE immune complexes and can activate innate and adaptive immunity leading to amplification of lupus immune dyeregulation including induction of type I Interferon (IFN) responses. The aim of this study is to understand the differences in long-term outcomes of SLE patients with or without IgE autoantibodies with high vs. low IFN gene score at baseline.

Methods: The study included 95 adult SLE subjects who fulfilled the 1997 ACR SLE criteria and were enrolled in an IRB approved long-term natural history study. In addition to clinical evaluation, Safety of Estrogen in Lupus National Assessment - SLE Disease Activity Index (SELENA-SLEDAI) scores were recorded at baseline, 36, 60, and 84 month follow-up periods. Anti-dsDNA-IgE autoantibodies were measured by ELISA and a 21-Type I IFN inducible gene composite score was derived from whole blood RNA sequencing at baseline. A high IFN score was defined as an IFN score of >4. The patients were divided into four groups: IgE-positive/high IFN score, IgE-positive/low IFN score, IgE-negative/high IFN score, and IgE-negative/low IFN score. SLE flare was defined as an increase of ≥4 points in the SELENA-SLEDAI score. The locally weighted scatter plot smoother (LOESS) curves were generated for each group to identify longitudinal trends in SELENA-SLEDAI scores. Wilcoxon ranked sum test was used to compare the IgE-positive subjects with the IgE-negative subjects, and to compare the IgE-positive/high IFN score with IgE-negative/low IFN score subjects.

Results: The clinical and demographic features of the SLE subjects are shown in Table 1. Patients with IgE anti-dsDNA antibodies (n=28) were found to have high IFN scores (p=0.012). The IgE-positive group had higher SELENA-SLEDAI scores at baseline and during follow-up (p values, < 0.001, 0.008 and 0.04, at baseline, 60 and 84 months, respectively) (Fig 1). The subset of patients with anti-dsDNA-IgE-positive/high IFN score(n=17) were found to have significantly higher baseline SELENA-SLEDAI scores that remained elevated during the study period (p values, < 0.001, 0.03, 0.07 and 0.009 at baseline, 36, 60 and 84 month, respectively) (Fig 2). The IgE-negative/Low IFN score group (n=45) had the lowest SLE disease activity compared to the other groups (47.7% vs. 64.7%, p=0.09) and the longest flare-free interval (74 months) when compared to the other groups.

Conclusion: SLE patients that are positive for anti-dsDNA-IgE autoantibodies display higher lupus disease activity and IFN scores compared to the anti-dsDNA-IgE negative group. A combination of IgE positive antibodies and high IFN score is associated with significantly enhanced lupus disease activity during longterm follow-up. Our study suggests that presence of IgE autoantibodies and elevated IFN gene score represents a subset of patients with persistently active disease despite standard of care. As omalizumab, a monoclonal antibody against IgE, can modulate type I IFN responses, this study further supports that strategies that target IgE autoantibodies may benefit specific subgroups of SLE subjects.

High Fat-Diet as a Catalyst to Lupus Development and Autoimmunity in MRL/lpr Mice

Hiba Ali[1], Juan Meng[2], Xuhua Shi[2], Linh Hellmers[3], Swathi Dhulipala[4], Patricia Kachur[4], Therese Posas-Mendoza[4], Robert Quinet[5], William Davis[5], Jerald Zakem[4], Zongbing You[2] and Xin Zhang[3], [1]Dept. of Rheumatology, Ochsner Medical Center, New Orleans, [2]Tulane University Health Science Center, New Orleans, [3]Institution of Translational Research, Ochsner Medical Center, New Orleans, [4]Dept of Rheumatology, Ochsner Medical Center, New Orleans, [5]Dept of Rheumatology, Ochsner Medical Center, New Orleans, LA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with features of autoantibodies, skin rash, kidney and other multiple organ involvement. Evidence shows that obesity is a major factor contributing to the onset and progression of autoimmune diseases including SLE and is highly linked to their cumulative organ damage. Our previous study and others have shown that circulating T follicular helper (Tfh) cells are implicated in promoting B cells production of autoantibodies and shape the composition of the gut microbiota thus modulating obesity. In this study, we evaluated the impact of high fat diet (HFD) on the development of SLE and obesity, and the pathophysiologic link of obesity, SLE, and Tfh cells in MRL/lpr lupus prone mice.

Methods: Thirty MRL/lpr mice were fed a regular diet (RD, 10% calories from fat) or high fat diet (HFD, 60% calories from fat) beginning at 2 months of age, half male and half female. Their body weights and skin lesions were recorded weekly. Urine protein was assessed weekly by Bradford assay. Blood was collected monthly for serum IgG, anti-dsDNA antibody, and anti-nuclear antibody (ANA) detection. At week 14, mice were euthanized, their spleen were measured and weighed. Kidney and skin biopsy were embedded in paraffin and tissue sections for H&E, PAS, and Masson's staining to detect lupus histopathological lesions and quantified as kidney index and histological skin score based on glomerular cellularity, glomerular deposits, interstitial inflammation, and inflammatory dermatitis. Tfh cells ($CD4^+CXCR5^+$) were examined in blood and splenic sections by flow cytometry and immunofluorescent staining.

Results: The HFD group induced a significant increase in mouse body weight by week 3 and continued until week 14 compared to RD group ($p< 0.05$ to $p< 0.01$). Skin lesions on the dorsum of neck, forehead, and ears in HFD group, resembling human discoid lupus, manifested as earliest as week 6 and occurred in 55.6% of the HFD group vs 11.1%

of the RD group ($p< 0.05$). Splenomegaly was observed in the HFD mice ($p< 0.05$). Proteinuria was increased from week 11 to week 14 in HFD group. There was an increase trend of anti-dsDNA antibody and serum IgG titer in HFD group, but no difference of ANA was observed between HFD and RD groups. HFD mice also had a higher histological score of skin ($p< 0.05$) and higher acute and chronic index of kidney than RD mice. Significant increase of $CD4^+CXCR5^+$ Tfh cells was observed in both blood and spleen in HFD group mice.

Conclusion: Our results show that a high fat diet induced an accelerated and more severe form of lupus development and autoimmunity in MRL/lpr mice. This indicates that HFD exacerbates the development of SLE. The elevated disease course in HFD mice was accompanied by increased of Tfh cells. Interventions of healthy diet or targeting Tfh cells may improve both lupus symptoms and outcomes in genetically predisposed SLE patients.

Association of Air Pollution with Systemic Lupus Erythematosus Disease Activity in the Central Valley of California

Mosaab Mohameden[1], Ali H.Ali[2], Zi Ying Li[2], Yabsira Abejie[3], Ratnali Jain[2] and Candice Reyes Yuvienco[4], [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of California San Francisco Fresno, Fresno, CA, [3]Floyd B. Buchanan High School, Fresno, CA, [4]University of California San Francisco Fresno, Clovis, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex multisystem autoimmune disease that affects at least 300,000 people in the United States creating a substantial socioeconomic burden. The exact etiology of SLE remains largely unknown. Both genetic factors and environmental exposures have been implicated in the etiology and progression of SLE. Air pollution is one of the major environmental factors that have been proposed in the study of SLE exacerbation. Fine and ultrafine particles measuring 2.5μm (PM2.5) are major contributors to air pollution. Wildfires can increase PM2.5 significantly and affect individuals' health negatively. Due to topographical and meteorological conditions in the central valley of California, the area is prone to air pollution and this can be well pronounced during active wildfires in the surrounding areas. In this study, we aim to study the correlation between the frequency of SLE flares and air quality measures.

Methods: This is a retrospective study. Data for SLE patients with the following criteria were collected: age 18 or above, confirmed diagnosis of SLE (by ACR 2019 criteria, tissue diagnosis, or rheumatologist-confirmed), who had an ED visit or were admitted during the year 2018 for SLE flare. The following data for Fresno county covering the year 2018 were collected using the environmental protection agency website: PM2.5, Ozone, and average daily temperature. The data were averaged for each week of the year and the counts of SLE flares were examined during each week. Pearson correlation tests were used to analyze the correlation of air quality measures with the frequency of SLE flares (Pearson correlation coefficients and 2- tailed p values were reported).

Results: A total of 432 SLE ED and inpatient encounters were reviewed, of those 257 met the study criteria for SLE with 94 SLE flares. The mean age was 40 with 93% of patients being females. Pearson correlation coefficient for the Ozone

air quality index and SLE flares was found to be -0.244 (p value= 0.08). Correlation coefficient results for PM2.5 levels air quality index and average temperature were -0.103 (p value= 0.465) and -0.198 (p value= 0.155) respectively.

Conclusion: In our study, there was no statistically significant correlation between SLE flares and levels of different pollutants including PM2.5 and Ozone. There was also no statistically significant correlation between the average daily temperature and the frequency of SLE flares. We suggest there might be a signal that it is in our unique population's genetics or cultural differences that might be paving way for their flares or their healthcare access. Our study is an important pilot to support the need for assessing the possibly unique genetic makeup in our population, considering that weather might not be the major flare trigger. Larger studies are needed to assess the association and causation between SLE flares and air pollution.

An Engineered Extracellular Matrix-rich Decellularized Substrate Based Podocytes Culture System to Study Intracellular Complement Production and Activation

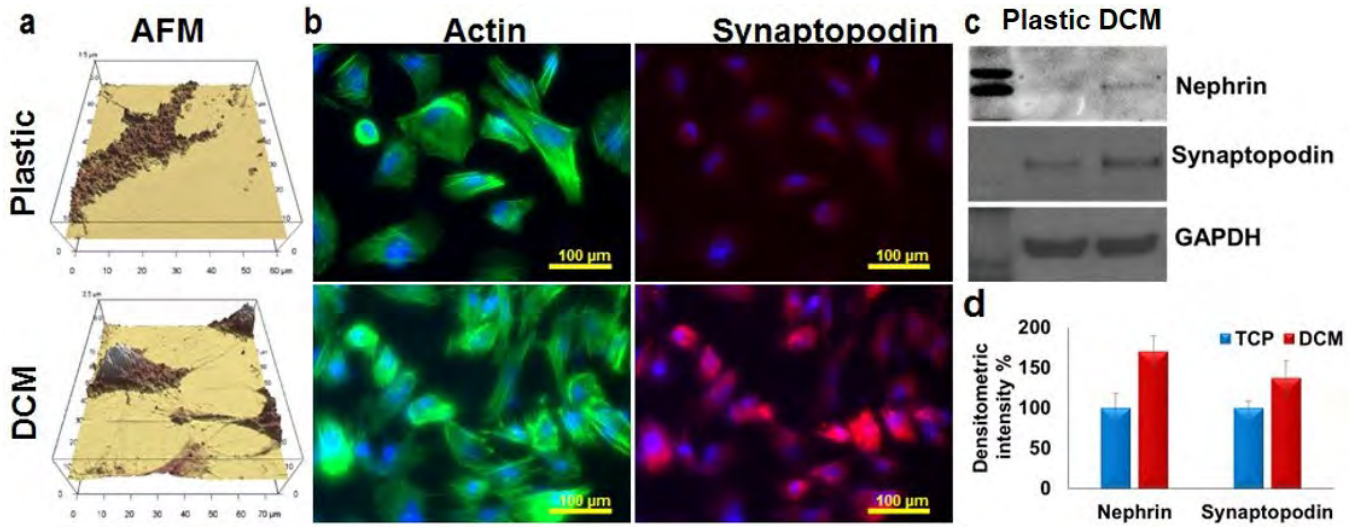
Abhigyan Satyam[1], Maria Tsokos[2] and George Tsokos[2], [1]Division of Rheumatology & Clinical Immunology/Beth Israel Deaconess Medical Center/Harvard Medical School, boston, [2]Division of Rheumatology & Clinical Immunology/Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

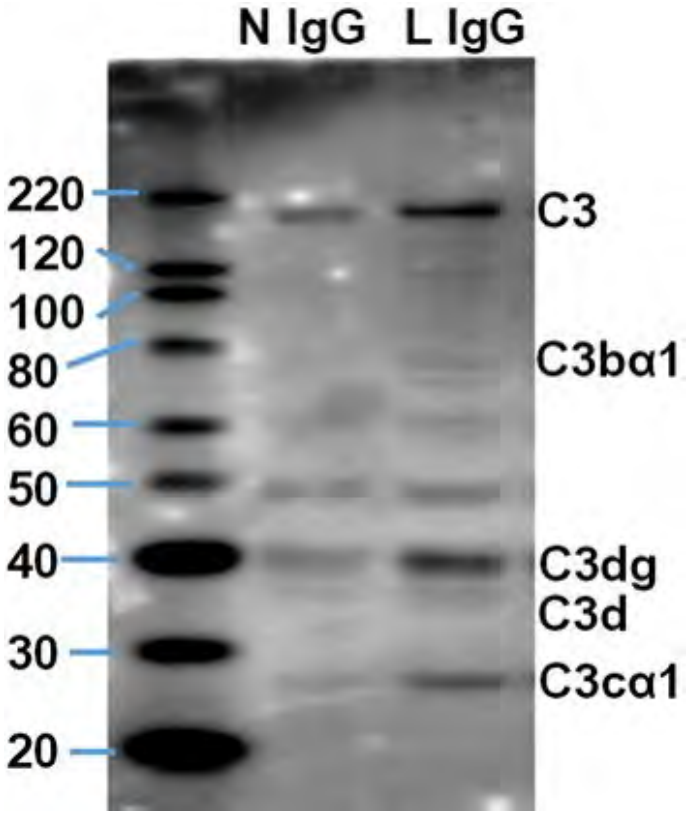
Background/Purpose: Current technologies do not support long-term cell viability, differentiation and maintenance of podocytes. We developed a biophysical approach, termed macromolecular crowding (MMC), to create extracellular matrix (ECM)-rich tissue equivalents and decellularization. This approach generates decellularized grafts that scaffold podocytes to grow in an environment similar to native conditions. To show a potential application of this newly designed culture system we studied complement (C) activation in podocytes exposed to IgG from individuals with lupus nephritis (LN) and hypoxia.

Methods: Human skin fibroblasts were cultured under MMC and then decellularized. Human immortalized podocytes were cultured on the decellularized matrix (DCM) at 33°C for 7 days and at 37°C for 14 days (https://doi.org/10.1002/adfm.201908752). ECM deposition in the DCM-coated dishes was analyzed by SDS-PAGE, immunofluorescence (IF) and atomic force microscopy and expression of podocyte markers by western blotting (WB) and IF. Podocytes were then exposed to IgG from patients with LN or Dimethyloxalylglycine (DMOG) and C activation was studied (WB and IF).

Results: We found that DCM-coated dishes contained all major ECM molecules (laminin, fibronectin, collagen I and IV) and podocytes survived and differentiated on DCM-coated plates significantly better than on non-coated plates, as shown by the development of interdigitating foot process and increased expression of nephrin and synaptopodin (fig. 1). Podocytes exposed to LN IgG (fig. 2) or DMOG (fig. 3) displayed increased levels of complement molecules (C3, C4, C5, C5b9) and C3 activation products.

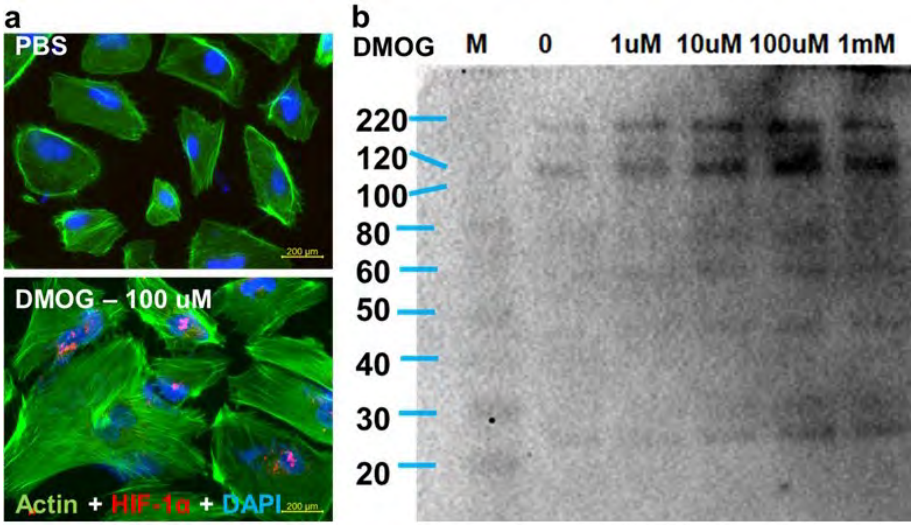


(a) Atomic Force Microscopy (AFM) shows better podocyte morphology with interdigitating foot processes on DCM-coated dishes. (b) Immunofluorescence shows enhanced expression and co-localization of actin and synaptopodin on DCM-coated dishes. Western blotting (c) (densitometric readings d,) confirmed higher expression of nephrin and synaptopodin on decellularized ECM rich substrate.



Lupus IgG enhances production of activated C3 molecules. Lupus IgG (L IgG), Normal IgG (N IgG).

Conclusion: Engineering in vitro microenvironment with decellularized matrix enhances podocyte viability, native physiology and morphology. This novel system enabled us to demonstrate increased complement factor production by podocytes exposed to LN IgG or hypoxia and intracellular complement activation.



(b) DMOG enhances production of activated C3 molecules.Exposure of podocytes to DMOG (a) upregulates expression of HIF-1α and (b) enhances production of C3 split products. Western blotting analysis of activated C3 using a pan-C3 antibody that detects activated C3 split molecules.

Vitamin D Level: Predictor of SLE Disease Activity in AA Cohort with CLE?

Ileannette Robledo-Vega[1], John Scheinuk[2], Emmanuel Pardo[2], Ansley Pratt[2], Soham Mahato[3], Andrew G. Chapple[2] and Myriam Guevara[4], [1]Louisiana State University Health Sciences Center, New Orlenas, LA, [2]Louisiana State University, New Orleans, LA, [3]LSUHSC School of Public Health, New Orleans, LA, [4]Lousiana State University Health Sciences Center, New Orleans, LA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: There are few predominant African American (AA) epidemiological studies in Cutaneous Lupus Erythematosus (CLE). The Gilliam classification divides CLE into lupus specific, acute cutaneous LE (ACLE), subacute cutaneous lupus (SCLE) and chronic variants (CDLE). Evidence shows SLE can lead to lower vitamin D levels since patients are usually photosensitive and advised to practice sun protection measurements. Also, it is important to consider the probability that vitamin D (Vit. D) deficiency could have a role in the prediction of disease activity given its role on the immune system. The aim of our study was to evaluate the correlation between vitamin D level and disease activity based on laboratory markers, in an AA CLE cohort.

Methods: From Rheumatology and Dermatology clinic at University Medical Center, New Orleans, a total of 182 patients' charts were retrospectively reviewed from 2015 to 2019. Using ICD-10 codes we cross reference the diagnosis of SLE, DLE, other local LE and SCLE. A total of 67 patients' data extracted including: age, ethnicity, smoking, ANA,

Table 1: Demographics

Skin manifestation	Numbers (%)	Ethnicity (%) AA	Gender (%) F	Smoking	ANA +	SSA +	dsDNA +	C3(<80) low	Pr/Cr (<450) normal	Vit. D Def (<12)
SCLE	14 (21)	14 (100)	14 (100)	6 (43)	8 (57)	9 (64)	7 (50)	3 (21)	3 (21)	3 (21)
CCLE	53 (79)	48 (91)	42 (79)	31 (58)	28 (53)	13 (25)	11 (21)	10 (19)	12 (23)	16 (30)

SCLE: Subacute Cutaneous Lupus Erythematosus; CCLE: Chronic Cutaneous Lupus Erythematosus; AA: African American; F: Female; Pr/Cr: Protein/Creatinine ratio; Vit. D Def: Vitamin D Deficiency.

Table 1. Demographics

Table 2: Basic Descriptive Statistics for the Independent Variables:

	N (%)	Estimate change in Vitamin D (ng/ml)	p-value
ANA			
No=0	26 (47)		
Yes=1	29 (53)	3.8	0.14
SSA positive			
No=0	33 (60)		
Yes=1	22 (40)	-5.13	0.05*
C3			
Below 80=1	13 (24)		
Above 80=2	42 (76)	8.24	<0.05**
Protein-Creatinine been considered			
SSA			
No=0	33 (60)		
Yes=1	22 (40)	-6.28	<0.05**
protein-creatinine ratio			
High	14 (25)		
Normal	41 (75)	10.26	<0.05**

** significant based on 0.05 level of significance, * significant based on 0.1 level of significance. C3 measured in mg/dl.

Table 2. Basic Descriptive Statistics for the Independent Variables

SSA and anti-ds DNA positivity, complement 3 (C3) and complement 4 (C4) levels, Protein/Creatinine ratio (Pr/cr) (< 450 mg/g normal), and Vit. D levels (< 12 ng/ml deficiency). 5 of those patients were excluded since not AA and 4 additional for missing data. In analysis including variable "Pr/cr ratio", 4 patients had missing data with a total of 54 patients included. Vit. D value was the dependent variable and the remaining were independent variables. For all variables, we calculated frequency and percentage (Table 1). Fisher's exact test found there was correlation in ANA, SSA, C3, pr/cr ratio in predicting patient's vitamin D. Only these variables were considered for a stepwise linear regression.

Results: Demographic description in Table 1(mean age: 45 yrs.; female: n=56, male = 11). First, we considered the non-stratified group and excluded pr/cr variable. Assuming equal power for all variables a stepwise linear regression predicted the following variables associated with low Vit D: CD3 value < 80 had a decrease in Vit. D level by 8.3 ng/ml compared with CD3 value > 80 ($p < 0.05$); SSA positive, associated with decrease of Vit. D by 5.13 ng/ml compared to SSA negative patients ($p = 0.05$) (Table 2). When data was stratified based SCLE and CCLE (Table 1), only CCLE patients C3 values < 80 had significant association with lower Vit. D by 7.90 ng/ml ($p< 0.05$) (Table 3). There was not significant predictor for SCLE possibly due to small sample size. Finally, adding pr/cr ratio as independent variable to the whole group, SSA positivity, C3 by association and increase pr/cr ratio are significantly associated with low Vit D. When all variables are considered as equal then we can expect patients with increased pr/cr ratio had a decrease in Vitamin D level of 10.26 ng/ml compared with patients whose values are normal ($p < 0.05$).

Table 3: Basic Descriptive Statistics for CCLE Patients

	Estimate change in Vitamin D (ng/ml)	p-value
Gender		
Female		
Male	6.22	0.13
ANA		
No=0		
Yes=1	5.61	0.09*
SSA positive		
No=0		
Yes=1	-6.80	0.06*
C3		
Below 80=1		
Above 80=2	7.90	<0.05**
Protein-Creatinine is considered		
SSA		
No=0		
Yes=1	-6.28	<0.05**
protein-creatinine ratio		
High		
Normal	10.26	<0.05**

** significant based on 0.05 level of significance, * significant based on 0.1 level of significance

Table 3. Basic Descriptive Statistics for CCLE Patients

Conclusion: To the best of our knowledge this is the first AA CLE cohort. Our findings showed decreased C3 levels, SSA positivity and increased pr/cr ratio correlate with Vitamin D deficiency. This association was statistically significant and carries a clinically importance given Vitamin D could be used as a surrogate marker for systemic disease activity in AA with CLE.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease driven by complex immune dysregulation, involving altered immune mediators and accumulation of autoantibody (AutoAb) specificities. We have previously identified patterns of disordered immunity associated with development of SLE (Munroe et al. Ann Rheum Dis. 2016; Lu et al. J. Autoimmun. 2016). This study seeks to determine an optimal panel of markers that can distinguish those SLE patients with active disease and help to refine a Lupus Disease Activity Immune Index (LDAII).

Methods: We procured 200 samples from 150 patients classified with SLE on dates of low disease scores measured by the hybrid SLEDAI (hSLEDAI) (< 4, range 0-3, n=100) or active disease (≥ 4, range 4-30, n=100). Race/sex/age-matched healthy control (Ctl) samples (n=50) were also evaluated. SLE-linked plasma immune mediators (n = 35) were evaluated by Ella™ microfluidic immunoassay and serum SLE-associated AutoAb specificities, including dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, RNP, and ribosomal P, were assessed by Bioplex® 2200 xMAP assay. A subset of 24 log-transformed immune mediators were further evaluated using random forest applied machine learning modeling to determine an optimal subset of mediators to inform the LDAII. The LDAII is the sum of log-transformed, standardized immune mediators, weighted by the Spearman r correlation coefficient of immune mediator levels vs. either hSLEDAI scores or number of SLE-associated AutoAb specificities, which correlates with clinical disease activity (Spearman r = 0.289, $p< 0.0001$).

Results: No difference in age, ethnicity, or sex was noted between low or active clinical disease. After adjusting for multiple comparisons (Bonferroni corrected $p< 0.0021$), IFN-α, IL-2Rα, TNF-α, TNFRII, IP-10, MIG, and IL-10 remained significantly correlated with hSLEDAI scores (Spearman r=0.221-0.388), and 22/35 soluble mediators significantly correlated with accrued SLE-associated autoantibodies, including the top 12 LDAII informative mediators listed in the **Table**. Forward selection of the 24 mediators ranked by variable importance (**Figure [A]**) drew 12 mediators that best distinguished between controls, low disease and active disease (**Table**). These top 12 immune mediators best informed and maximized the performance of a newly refined LDAII (**Figure [B]**). The LDAII, weighted either by hSLEDAI score ($p< 0.0001$) or number of AutoAb specificities ($p=0.0060$), significantly correlated with disease activity in SLE patients and identified patients with renal involvement ($p< 0.01$), where SCF and TNFRII ($p< 0.0001$) were significantly altered. In addition, the LDAII distinguished patients with dsDNA binding and low complement as well as clinically and serologically active vs. quiescent disease states ($p< 0.0001$), differentiated by TNF-α, IL-2Rα, IP-10, and IL-10 levels ($p\leq 0.001$)

Conclusion: We have refined the LDAII in order to characterize SLE patients with active clinical disease. Treatment to target using a sensitive and objective biologic surrogate for clinical disease activity could help improve disease management and prevent organ damage in SLE.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Tryptophan (TRP) is metabolized to kynurenine (KYN), quinolonic acid [QA, a N-methyl D-aspartate receptor (NMDAR) agonist] and kynurenic acid (KA, an NMDAR antagonist). KYN/TRP pathway stimulation by IFNa may create a potential neurotoxic QA/KA imbalance in SLE. We investigated QA/KA ratios in SLE subjects vs. healthy controls (HC) and their associations with cognition and depression.

Methods: We recruited 74 SLE subjects who met ACR criteria and had no focal neurologic or primary neuropsychiatric (NP) disorders and 74 HC. We assessed cognition and mood with the Automated Neuropsychological Assessment Metrics (ANAM), depression with the Beck Depression Index, and serum levels of KYN, TRP, QA, and KA with HPLC. Exclusion criteria included alcohol or illicit drug abuse, infection, and current narcotic/psychiatric medication use.

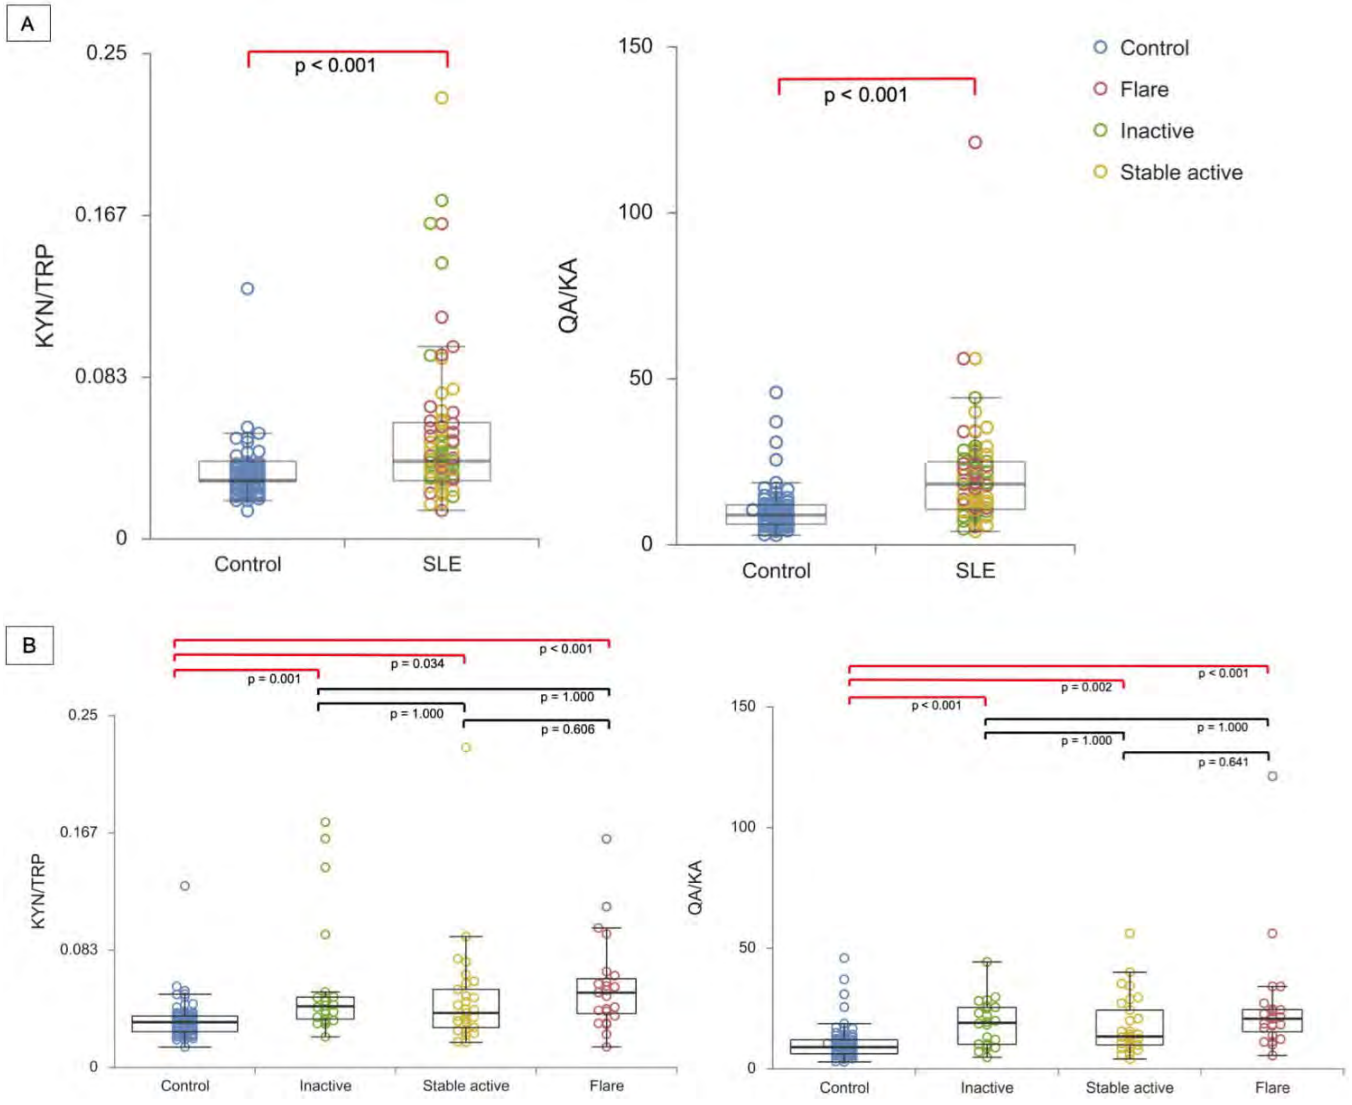

Figure 1. Serum KYN/TRP pathway metabolite ratios in SLE subjects and healthy controls (HC). The serum KYN/TRP and QA/KA ratios measured by HPLC are displayed both in all SLE subjects compared to HC (A) and in SLE subjects grouped by disease activity and HC (B). Circles represent a particular subject, and the color represents the disease activity group of that subject.

Table 2 Results of multivariable analysis to determine predictors of neuropsychological test performance. Results of multivariable models that included all subjects ("SLE and HC combined," top section) and those that included only SLE subjects ("SLE Only," bottom section) are displayed. Variables with a significant, negative impact on a particular ANAM test (see Table 1) are indicated with an "X." The Spatial Processing (SP) test column is grayed-out since SLE subjects did not perform significantly worse than HC on this test. # All of the test scores were significantly lower in SLE compared to HC except for the Spatial Processing test (SP) *p<0.05 **p<0.01

SLE disease activity (DA) was defined as Inactive [clinical SLEDAI=0 and PGA≤0.5 and prednisone≤10 mg, and lack of flare on the SELENA-SLEDAI Flare Index]; Stable Active (clinical SLEDAI >0 or PGA >0.5 or prednisone >10 mg and lack of flare) or Flare (mild/moderate or severe flare on the Flare Index). We assessed differences in demographic and clinical characteristics, NP test scores, and KYN/TRP pathway metabolites between SLE and HC and among the SLE DA groups, and the association of variables with NP performance (Spearman's correlation/t-test/Mann-Whitney/ANOVA/Kruskal-Wallis/chi square/Fisher's exact test). Multivariable modeling was used to assess the impact of variables on NP task performance in SLE and HC combined, and SLE only; variables on univariate screen ($p< 0.1$) were included.

Results: There were no demographic or educational differences in SLE vs. HC. SLE subjects performed worse than HC on all behavioral tasks and most cognitive tests (Table 1). Among SLE, there was a significant positive correlation between SLEDAI and MTS scores ($r = 0.236$, $p=0.04$), SLE with active disease had higher depression scores vs. Inactive ($p< 0.01$) and Inactive trended towards worse scores on most cognitive tests vs. Flare. Prednisone dose did not associate with cognitive or depression scores. Serum KYN/TRP and QA/KA ratios were elevated in SLE vs. HC ($p< 0.01$) (Fig. 1A), and there were no differences in either ratio among SLE DA groups (Fig. 1B). In SLE and HC combined, elevated QA/KA significantly correlated with increased SRT ($r = 0.217$, $p< 0.01$), poor performance on MTS ($r = -0.307$, $p< 0.01$) and RMCPT ($r = -0.311$, $p< 0.01$), and with higher depression scores ($r = 0.335$, $p< 0.01$) (Table 1). In SLE alone, an elevated QA/KA correlated with poor performance on MTS ($r = -0.237$, $p=0.04$), and trended towards slightly higher odds of depression (OR = 1.03, 95% CI=0.99-1.06, $p=0.09$). Multivariable modeling revealed that the QA/KA ratio negatively impacted MTS scores (Table 2), while increased SLEDAI had a positive impact.

Conclusion: Elevated serum KYN/TRP and QA/KA ratios indicate KYN/TRP pathway activation in SLE. Surprisingly, DA associated with improved cognitive performance. An increased QA/KA ratio, after controlling for other factors, associated with poor cognitive performance on a working memory task, supporting its further study as a potential biomarker for SLE-related cognitive dysfunction.

Longitudinal Analysis of IFN Status and Disease Characteristics in SLE

Melissa Northcott[1], Alberta Hoi[2], Rachel Koelmeyer[3] and Eric Morand[4], [1]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Victoria, Australia, [2]Monash University, Melbourne, Victoria, Australia, [3]Monash University, Clayton, Victoria, Australia, [4]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The type 1 interferon (IFN) cytokine family is key to the pathogenesis of SLE, evidenced by the expression of IFN stimulated genes (ISGs) in most patients. Phenotypic differences between SLE patients who express ISGs (IFN high) and those who do not (IFN low) are not well understood. With the emergence of IFN blocking drugs, it is important to examine the clinical utility of IFN status testing. We report the results of longitudinal analysis of IFN and clinical status in SLE.

Methods: 205 patients meeting ACR criteria for SLE were recruited at a tertiary centre where extensive clinical data are collected prospectively on consenting subjects. Whole blood RNA samples were collected in PAXgene tubes. IFN status was determined using the IFN module from Modular Immune Profile Test (DxTerity Diagnostics).

Results: 729 results (205 patients, 142 with longitudinal samples) were analysed. At baseline, 62.9% of patients were IFN high, 30.2% IFN low and 6.8% borderline. Compared to IFN low patients, IFN high were more likely to be of Eastern Asian ethnicity (45.0 vs 25.8%, p = 0.01), were younger at SLE onset (median [IQR] 27[18-35] vs 33 [25-47] years, p = 0.0001), and were more likely to be positive for anti-Ro (65.3 vs 34.7% p = < 0.0001), anti-La (29.2 vs 11.3% p = 0.01) and anti-RNP (36.1% vs 15.1% p = 0.007) antibodies. In patients with multiple samples, 87.3% had stable ISG status. In longitudinal follow up (median 630 [459-707] days), IFN high patients had higher disease activity (median [IQR] time adjusted mean SLEDAI2K (4.2 [2.8-5.7] vs 2.0 [1.3-4.2], p=< 0.0001), more flares (mild/moderate 53.5 vs 25.8%, p = 0.0003; severe 26.4 vs 6.5%, p = 0.0009) and spent less observed time in lupus low disease activity state (LLDAS) (median 55.5% [26.3-85.5] vs 84.0 [53.0-100]%, p = 0.0003). IFN high patients were more likely to have active arthritis (21.7 vs 6.5%, p = 0.007), skin disease (38.8 vs 14.5%, p = 0.007), leukopenia (26.4 vs 6.5%, p = 0.0009) and haematuria (20.2 vs 8.1%, p = 0.03). More IFN high patients required DMARD therapy (74.6 vs 55.9%, p = 0.02) and IFN high patients had higher prednisolone exposure (median time-adjusted mean dose 1.7 [0-5.7] vs 0.0[0-2.9] mg, p = 0.004). There was no difference in overall SLICC damage index, however there were differences in damage domains. IFN low patients had more malignancy (11.6 vs 2.4%, p = 0.01) and diabetes (13.3 vs 1.6%, p = 0.002). IFN high patients trended towards more mucocutaneous damage (19.2 vs 8.3%, p=0.08). However, in individual patients, there was no association between ISG level and any disease activity marker over time.

Of 18 patients with varying IFN status over time, 12 had ISG fluctuations that were < 2SD from the mean fluctuation seen in stable ISG patients. Of the remaining 6 patients with larger ISG fluctuations, 5 had high dose (≥25mg) prednisolone or cyclophosphamide therapy temporally associated with ISG reduction.

Conclusion: IFN high SLE patients had significantly more disease activity than IFN low patients. They were more likely to be of Asian than Caucasian ethnicity, had younger onset of disease and displayed more auto-antibodies.

The majority of patients had stable IFN status, and major changes in ISG expression related to high dose immunosuppression.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Type I IFN contributes to SLE pathogenesis and stimulates the kynurenine/tryptophan (KYN/TRP) pathway, producing elevated quinolinic acid (QA) levels relative to kynurenic acid (KA) and thus creating a potential neurotoxic imbalance. We found that SLE subjects have elevated KYN/TRP and QA/KA ratios vs. healthy controls (HC), and that the QA/KA ratio correlated with poor working memory performance after controlling for other factors (submitted abstract). We hypothesized that peripheral blood interferon stimulated gene (ISG) expression would associate with QA/KA ratios in these same subjects.

Figure 1. Principal component analysis (PCA) of gene expression in SLE compared to healthy controls (HC). PCA conducted on DESeq2 normalized and variance stabilized gene expression values using the function prcomp in R version 3.5 is displayed[1]. The default top 500 most highly variant genes were selected. 1. Kolde, R., 2012 Package 'pheatmap'. Bioconductor 1–6. Available at: https://CRAN.R-project.org/package=pheatmap

Table 1. SLE subject and healthy control (HC) characteristics and KYN/TRP pathway metabolite ratios. All data is reported either as a mean (or median where indicated) +/- standard deviation (or interquartile range), or as a frequency (%). All data refers to that which was collected at the time of evaluation.

Methods: We measured ISG expression (whole blood RNA sequencing) and serum levels of KYN, TRP, QA, and KA (HPLC) in 72 SLE subjects and 73 HC. ISG were identified based on published gene sets, and the Interferome database.[1, 2] IFN scores were derived for each subject to quantify individual ISG expression and analyze associations with metabolite ratios. Since it is unknown which ISG contribute most to an "IFN signature," we used 4 approaches to define IFN scores (Table 2). Expression was measured by fold change (FC) relative to HC, a point system for FC, or z-scores. Differences in characteristics and metabolite ratios in SLE vs. HC were assessed (t-test, Mann-Whitney, or chi square), and Spearman's correlations were determined between metabolite ratios and IFN scores among SLE subjects; significance was set at $p < 0.05$.

Results: There were no demographic differences between SLE and HC, and SLE subjects had higher median metabolite ratios (Table 1). There were 933 genes that had ≥2-fold differential expression in SLE vs. HC ($p < 0.05$). Of 110 ISG reported by Arazi et al, 108 had ≥2-fold higher expression in SLE vs. HC. Unsupervised principal component analysis (PCA) distinguished SLE from HC (Figure 1); of the top 100 most variant genes, 70 were ISG. IFN scores, based on the first 3 objective approaches, correlated with KYN/TRP but not with QA/KA ratios (Table 2). However, 82 of the 933 differentially expressed genes correlated with QA/KA ratios ($p < 0.05$), and 38 (46%) were ISG; 31/38 (82%) of these were type I responsive ISG. A Targeted IFN score (approach 4a) using these 38 ISG correlated with QA/KA and

Approach		IFN score method	KYN/TRP	p	QA/KA	p
1		FC	r = 0.269	0.022	r = 0.080	0.504
		Adjusted FC	r = 0.271	0.021	r = 0.080	0.502
		Z-score	r = 0.271	0.021	r = 0.062	0.607
2		FC	r = 0.252	0.033	r = 0.085	0.479
		Adjusted FC	r = 0.248	0.035	r = 0.084	0.482
		Z-score	r = 0.226	0.056	r = 0.060	0.617
3		FC	r = 0.272	0.021	r = 0.106	0.375
		Adjusted FC	r = 0.266	0.024	r = 0.102	0.394
		Z-score	r = 0.294	0.012	r = 0.120	0.314
4	a. Targeted IFN score (38 genes*)	FC	r = 0.278	0.018	r = 0.453	<0.001
		Adjusted FC	r = 0.294	0.012	r = 0.460	<0.001
		Z-score	r = 0.296	0.012	r = 0.447	<0.001
	b. Targeted-Modular IFN score (CCL8, CXCL10, LAP3)	FC	r = 0.253	0.032	r = 0.433	<0.001
		Adjusted FC	r = 0.245	0.038	r = 0.410	<0.001
		Z-score	r = 0.234	0.048	r = 0.418	<0.001

Table 2. Correlations Between IFN Scores, Defined by 4 Approaches, and KYN/TRP Pathway Metabolite Ratios in SLE subjects. Approach 1 derived an IFN score from the 70 ISG that were in the top 100 most variably expressed genes between SLE and HC determined by PCA, Approach 2 included all of the 110 ISG reported by Arazi et al in their single cell RNA sequencing analysis of IFN response in infiltrating cells in lupus nephritis, and Approach 3 included 19 ISG from the 110 ISG included in Approach 2 that are more responsive to type I IFN than type II IFN, according to the Chiche et al modules of co-expressed ISG. Approach 4a included ISG that had significant, positive correlations with the QA/KA ratio, and 4b included 3 ISG from 4a that were also included in the 110 Arazi ISG set and in the Chiche modules and are associated with neuroinflammation.[1, 2] Scores were computed using fold change (FC) relative to HC, adjusted FC (point system) and z-scores. Spearman's correlation coefficients (r) are shown between each IFN score (grouped by approach, and the method used to compute the score) and the metabolite ratios. Significant correlations are highlighted in red. *Refers to the 38 ISG that had a significant, positive correlation with the QA/KA ratio in SLE subjects 1. van Weering, H.R., et al., CXCL10/CXCR3 signaling in glia cells differentially affects NMDA-induced cell death in CA and DG neurons of the mouse hippocampus. Hippocampus, 2011. 21(2): p. 220-32. 2. Banisor, I., et al., Involvement of beta-chemokines in the development of inflammatory demyelination. J Neuroinflammation, 2005. 2(1): p. 7.

KYN/TRP ratios (Table 2). A separate Targeted-Modular IFN score comprised of 3 type I ISG (CCL8, CXCL10, LAP3) included in published ISG sets and associated with neuroinflammation, also correlated with both ratios (Table 2, 4b).

Conclusion: This is the first study in SLE subjects to demonstrate an association between ISG expression, KYN/TRP pathway activation, and an elevated QA/KA ratio. The targeted IFN scores need validation in a separate cohort to justify their utility as a biomarker for IFN-mediated KYN/TRP pathway activation, and their potential use in measuring success of anti-IFN therapies in SLE to ameliorate a potential neurotoxic QA/KA imbalance.

Abstract Number: 1807

The Extent of Tubulointerstitial Inflammation in Lupus Nephritis Identifies Two Distinctive Subgroups: Impact on Inflammation Characteristics and Prognosis in Patients with Lupus Nephritis

Sang Jin Lee[1], Eon Jeong Nam[1], Man-Hoon Han[2] and Yong Jin Kim[2], [1]Department of Internal Medicine, Kyungpook National University Hospital,, Daegu, Republic of Korea, [2]Department of Pathology, Kyungpook National University Hospital,, Daegu, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis is common clinical manifestation and contributes significantly to mortality in systemic lupus erythematosus (SLE).

Recently several studies has been reported that severity of tubulointerstitial inflammation (TII) is associated with subsequent renal failure. However, it has not yet been reported histologic characteristics and prognosis by extent of TII in patients with lupus nephritis who had conventional treatment.

Methods: Ninety-four patients with lupus nephritis, who had conventional treatment and renal biopsy, were enrolled in this study. The extent of tubulointerstitial lymphocytic infiltrates was semi-quantitated (grade 1-4) using standard histochemical staining. Quantified apoptotic regulator protein, the B cell lymphoma 2 protein (Bcl-2), expressions in selected lymphocyte subsets were measured using novel computational approaches when applied to multicolor confocal images. Histologic characteristics and prognosis as well as clinical and laboratory characteristics were compared between mild (grade 1-2) and severe (graded 3-4) TII. Follow-up datas were obtained and survival analysis was carried out to determine.

Results: TII was a common pathologic finding, 61.7% percent of biopsy samples were graded as 1, 13.8% as 2, 14.9% as 3, and 9% as 4. When TII was divided into mild (grade 1-2) and severe (grade 3-4), patients with severe TII were significantly higher in serum creatinine, but not with double-stranded DNA (ds DNA) antibodies, serum complement 3/4, SLE disease activity (SLEDAI) and degree of proteinuria at the time of biopsies. Expression of bcl-2 and bcl-2 in CD4 positive cells were significantly higher in severe TII compared to in mild TII in lupus nephritis (p=0.040 and p=0.003, respectively) while those were not significant in IgA vasculitis. The mean follow-up time was 150.3 ± 7.0 months and overall, 9 patients died as a result of disease progression (n=6) and infection (n=3). Patients with severe TII were at greater risk for renal failure compared to those with mild TII (p=0.001). However, both glomerular proliferation and laboratory markers including baseline ds DNA, complement, SLEDAI and degree of proteinuria did not affect on long term renal failure. After multivariate logistic analysis including age and sex, severe TII provided poor prognostic information for renal failure (hazard ratio 4.5, 95% confidence interval 1.4–14.5; p = 0.011).

Conclusion: A significantly higher elevated bcl-2, especially in CD4 positve cells, was found in severe TII compared to mild TII in lupus nephritis whereas there was comparable bcl-2 expression in IgA vasculitis irrespective of inflammation extent. TII severity was independent predictor for a worse outcome in lupus nephritis patients with conventional treatment.

Erythrocyte Complement Receptor 1 (ECR1) and Erythrocyte Bound C4d (EC4d) Associate with Adverse Pregnancy Outcomes and Preeclampsia in Pregnant Women with Systemic Lupus Erythematosus (SLE)

Jill Buyon[1], John Conklin[2], Michael Golpanian[1], JoAnne Ligayon[3], Thierry Dervieux[4], Peter Izmirly[1], H. Michael Belmont[1], Jane Salmon[5] and Roberta Vezza Alexander[3], [1]New York University, New York, NY, [2]Exagen Inc., Vista, CA, [3]Exagen Inc, Vista, CA, [4]Exagen Inc, San Diego, CA, [5]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite improvement in management and outcomes of pregnancies complicated by SLE, the risk of adverse events and preeclampsia (PE) continues to exceed that of healthy women. Activation of the complement system has been associated with adverse pregnancy outcomes (APO). This study extends prior observations and addresses whether detection of erythrocyte complement receptor 1 (ECR1) and C4d bound to erythrocytes (EC4d) predict APO

Methods: Pregnant women fulfilled ACR or SLICC criteria for SLE. Serum complement proteins C3 and C4 were measured by immunoturbidimetry and anti-dsDNA by ELISA. ECR1 and EC4d were measured by quantitative flow cytometry and are expressed as net mean fluorescence intensity (MFI). Disease activity was evaluated by the SLE Pregnancy Disease Activity Index (SLEPDAI) and the physician global assessment (PGA on a 0 to 3 scale) without knowledge of study analytes. Statistical analysis consisted of t-test and determination of diagnostic odds ratio (DOR) to evaluate association of inflammatory biomarkers (including ECR1 and EC4d) with APO (defined as neonatal death, pre-term delivery [< 36 weeks due to placental insufficiency], < 5th percentile for gestational age [SGA]) and PE at any time.

Results: A total of 51 women (33% white, 27% black, 18% Asians, 18% Hispanics, 4% of other races) had a total of 56 pregnancies (mean age 32 years, range 17 to 42) and 168 visits (median=3) during their pregnancy (n=34, 59, and 49 in first, second, and third trimesters, respectively) or postpartum period (n=26). The average SLEPDAI was 2.8, 3.5, and 2.9 in first, second, and third trimesters, respectively and PGA was 0.39, 0.54, and 0.40. APO and PE data are reported in the **Figure**. Overall 22% of pregnancies resulted in an APO. Specifically, 12 pregnancies resulted in a total of 19 APO (3 neonatal deaths; 8 births < 36 weeks [range 25 – 35.9 weeks] and 8 SGA). Eleven pregnancies in 10 women resulted in PE. ECR1, EC4d, and C4 were significantly associated with APO when all visits that occurred during pregnancy (n=142) were analyzed. ECR1 and EC4d also associated with PE. Anti-dsDNA and C3 were not associated with any of these outcomes (**Table; top**). Analysis of the individual APO showed that ECR1 was associated with preterm delivery (**Table; top**). For preterm delivery, area under the receiver operating characteristic curve of ECR1 was 0.697 (95% CI: 0.585-0.808). At ECR1 < 5.5 net MFI (optimum cutoff), sensitivity and specificity were 72% and 79%, respectively (Youden index = 0.51). Low ECR1 (< 5.5 net MFI) remained significant for preterm delivery when only baseline visits that occurred in the first trimester (n=32 visits with 7 pregnancies experiencing 9 APO) were analyzed (DOR = 30.67) (**Table; bottom**).

Conclusion: This prospective study demonstrates that low ECR1 and elevated EC4d are associated with APO and late PE in SLE pregnancies. Of the traditional biomarkers in SLE (C3, C4, dsDNA) only low C4 associated with APO.

ECR1 (net MFI; < 5.5 net MFI)	0.09	9.33 [1.36, 63.96]	0.58	3.75 [0.59, 23.66]	**<0.01**	30.67 [2.52, 373.55]
EC4d (net MFI; > 14 net MFI)	0.32	1.79 [0.29, 11.13]	0.15	5.08 [0.53, 48.86]	0.41	0.94 [0.13, 6.63]
C3 (mg/dL; < 81.1 mg/dL)	0.85	0.50 [0.05, 5.04]	0.88	0.50 [0.05, 5.04]	0.80	0.83 [0.08, 8.95]
C4 (mg/dL; < 12.9 mg/dL)	0.14	0.80 [0.13, 5.07]	0.32	0.28 [0.03, 2.70]	0.17	0.47 [0.05, 4.88]
Anti-dsDNA (units; > 301 Units)	0.78	0.56 [0.09, 3.49]	0.67	0.56 [0.09, 3.49]	0.75	0.34 [0.03, 3.49]

Table. T-test and diagnostic odds ratio (DOR) of complement markers (EC4d, ECR1, serum C3, and serum C4) and anti-dsDNA to evaluate association and prediction of APO, preeclampsia (PE) and preterm delivery. Data of all visits during pregnancy (post-partum visits excluded, n=142; TOP) and of baseline visits that occurred in the first trimester (n=32; BOTTOM) were analyzed. Two women had 2 visits each in the first trimester; thus, there was a total of 34 visits in the first trimester, of which 32 were baseline. Note that some patients had baseline visits after the first trimester. For t-test, continuous variables were analyzed, while variables were considered positive or negative (based on the cutoffs indicated in the table) for DOR calculation. DOR is reported with 95% confidence intervals [95% CI]. Significant p values (<0.05) are bolded.

Importantly, low ECR1 early in pregnancy predicted preterm delivery and, to a lesser extent, other APO. In conclusion, complement activation as measured by EC4d and ECR1 may be a predictor of pregnancy complications.

Serum Cytokine Profiling in Systemic Lupus Erythematosus, Analysed Using Unsupervised Machine Learning, Reveals Clinically Relevant Clusters

Fabien Vincent[1], Jannina Ong[1], Alberta Hoi[2], Sarah Boyd[1], Hieu Nim[1] and Eric Morand[3], [1]Monash University, Clayton, Victoria, Australia, [2]Monash University, Melbourne, Victoria, Australia, [3]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a heterogeneous disease, where a better understanding of molecular differences between patients is needed in order to direct therapy. Existing approaches generally examine mRNA expression, whereas therapeutic targets are mostly soluble or cellular proteins. We aimed to evaluate whether a serum cytokine proteomic profile of SLE patients analysed using an unbiased approach would yield clinically meaningful results.

Methods: Demographic and clinical data of SLE patients (ACR criteria) including disease activity (SLEDAI2K) and organ damage (SLICC Damage Index (SDI)), and matching serum samples, were collected prospectively. A wide-angled serum cytokine proteomics analysis was conducted using Quantibody, Luminex, and ELISA platforms. To reduce heterogeneous data complexity and remove redundant variables, unsupervised feature selection methods were

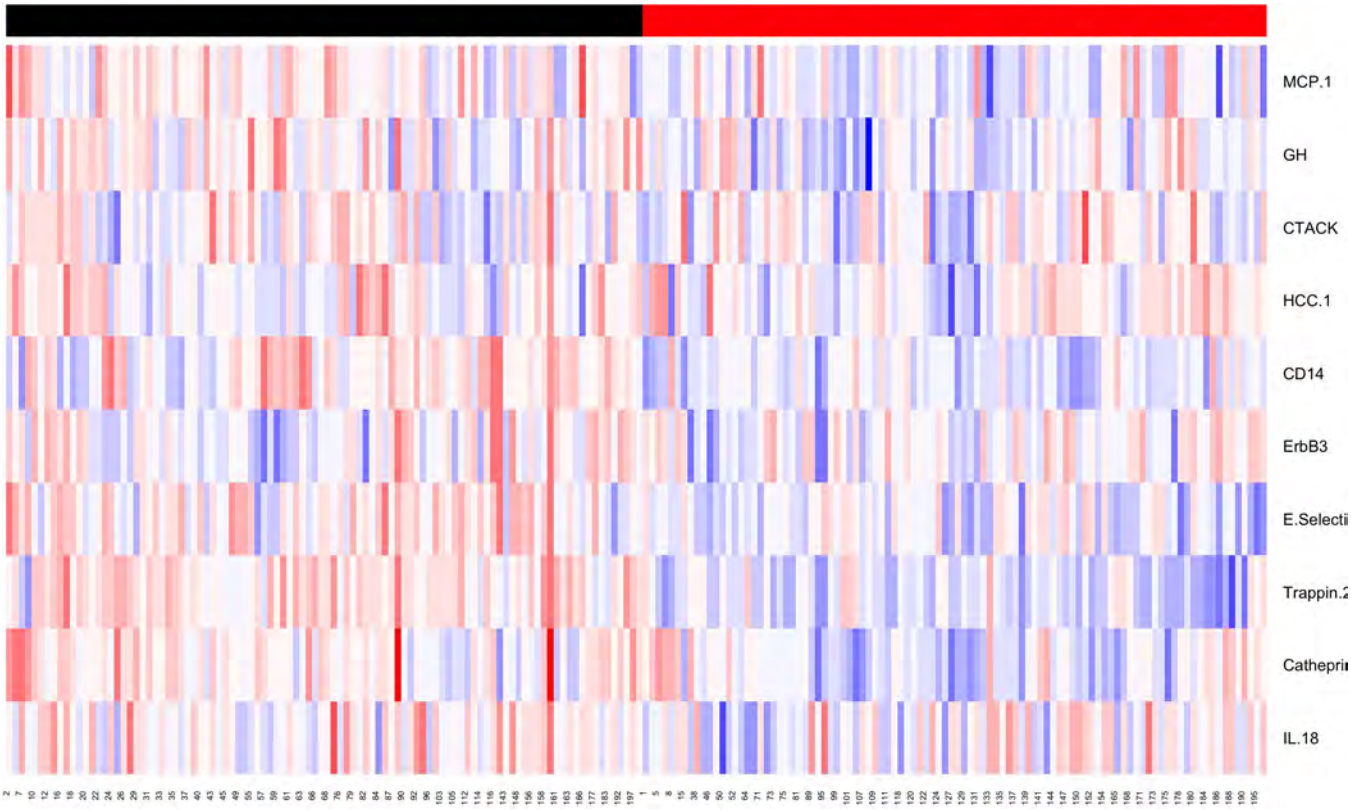

Figure 1. Heat map of 10 analytes, selected using unsupervised feature selection on 211 analytes measured in healthy subjects and SLE patients and clustered using k-means techniques, in SLE patients (n=198). Two clusters (indicated by red or black on top row) were identified in SLE.

applied. For clustering, machine learning approaches were used, and optimal cluster number confirmed by consensus clustering.

Results: 198 SLE patients (median [IQR] age 46.7 [36.7, 56.3] years, 88.4% female, median SLEDAI2K 4 [2, 6], 52.5% with organ damage) and 37 sex/ethnicity-matched healthy subjects were recruited. 211 serum analytes were measured. Using unsupervised feature selection methods, we identified a reduced set of 10/211 analytes (MCP-1, GH, CTACK, HCC-1, CD14, ErbB3, E-Selectin, Trappin-2, Cathepsin S and IL-18). The dataset was then clustered, according to the analytes that remained after feature selection, using unsupervised machine learning approaches. k-means analysis produced a distinct result in terms of separability of two clusters that associated only in SLE (**Figure 1)**, and was chosen as the final clustering algorithm. We analysed clinical parameters in patients categorised by these biomarker clusters, and found the clusters differed in clinical characteristics including organ damage (P = 0.04), proportion of patients with high ESR (P = 0.03), and SLEDAI2K (P = 0.08). Using multivariable linear regression models, cross-sectional associations with patient clinical characteristics were found for 8/10 analytes. We next assessed associations of baseline analytes with longitudinal disease outcomes, using multivariable logistic regression models. Trappin-2 and IL-18 were significantly associated with damage accrual. IL-18 and CTACK had positive and negative associations respectively with lupus low disease activity state (LLDAS) attainment, and converse associations with indices of active disease over time.

Conclusion: Unsupervised analytics of wide-angle serum cytokine profiles in SLE yielded a tractable reduced analyte set, which in turn revealed two biologically distinct clusters of patients who had significant differences in clinical profile, individual analytes from which were associated with longitudinal outcomes. These findings indicate the potential for biological subsets of SLE to be based on serum cytokine profiling.

Complement Activation in Systemic Lupus Erythematosus Patients with Low Disease Activity Is Not Inhibited by Hydroxychloroquine

Anne Margrethe Troldborg[1], Annette Hansen[2], Kristian Stengaard-Pedersen[2] and Steffen Thiel[2], [1]Aarhus University Hospital, Arhus, Denmark, [2]Aarhus University, Aarhus, Denmark

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Mortality in patients with systemic lupus erythematosus (SLE) is significantly higher than in the general population. Treatment of SLE patients has improved, however, a majority of patients still experience symptoms like fatigue, pain and cognitive deficits even when they are clinically evaluated to have low disease activity (LDA) or being in remission. Immunosuppressants are tapered after clinical remission and patients are typically continued on hydroxychloroquine (HCQ).

Activation of the complement system is evident in most SLE patients with active disease. This is usually assessed by low C3 or C4 as a proxy for complement activation (CA). When levels normalize or stabilize, we assume CA has been controlled.

The aim of this project is to examine if SLE patients in remission or with LDA have ongoing CA. This is investigated by measuring the C3 breakdown product C3dg. In addition, we show that *in vitro* HCQ does not inhibit any of the CA pathways.

Methods: In 166 SLE patients and 145 age and gender-matched controls we measured the C3 breakdown product C3dg (37 kDa fragment), which is only present after activation of C3. Disease activity was assessed using SLEDAI-2K, LLDAS, PGA and remission criteria (SLEDAI-2K=0, corticosteroid-free and immunosuppressant-free, HCQ allowed). The association between CA measured by C3dg and disease activity was estimated. Further, we examined the inhibitory effect of HCQ on CA *in vitro* in erythrocyte cell lysis assays and by measuring deposition of activation fragments of C3 and C4 on relevant surfaces in microtiter wells, i.e. examining activation through the lectin, the classical and the alternative pathway.

Results: In this cross-sectional cohort of SLE patients the median SLEDAI-score was 4 (range 0-14), median PGA was 1 (range 0-3), 61.4 % of patients were in LLDAS (102/166) and 7.8% were in complete remission (13/166).

C3dg was significantly higher in SLE patients than in controls ($p< 0.0001$), whereas no significant difference was observed for C3 ($p=0.67$). Ongoing CA was seen in all SLE patients independently of disease activity assessment (SLEDAI-2K, PGA, LLDAS and PGA). No difference was observed between patients treated or not treated with HCQ ($p=0.07$). Physiological and supraphysiological concentrations of HCQ did not inhibit CA through any of the complement pathways (fig.1) or in erythrocyte cell lysis assays.

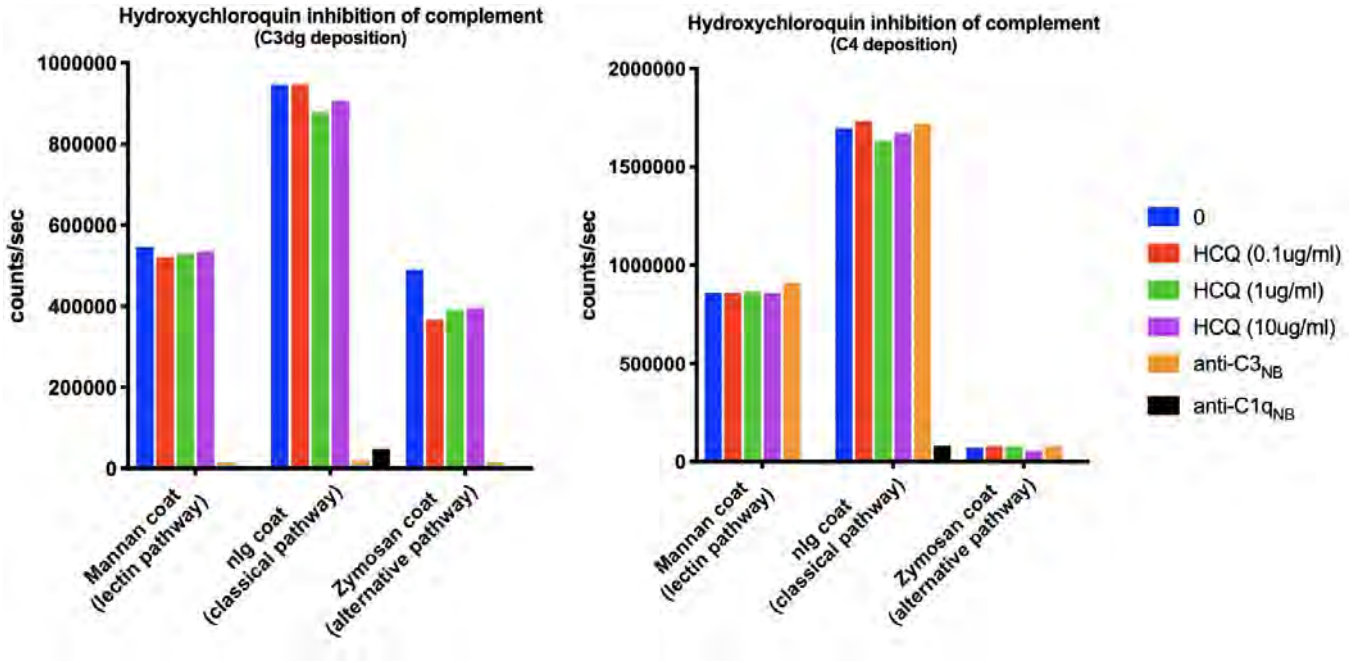

Figure 1. No inhibition of complement activation by hydroxychloroquine in vitro (HCQ).

Conclusion: SLE patients have ongoing CA even when our disease assessments scores show remission or LDA.

CA is not affected by HCQ treatment in patients, which in most cases is the drug-of-choice for SLE patients in remission. This is supported by our in *vitro* studies demonstrating that HCQ does not inhibit CA.

Our current disease activity scores do not include the best measures of biochemically active disease like CA measures. Ongoing CA is not captured by validated clinical disease activity scores and could be an explanation for persistent symptoms reported by many patients and potentially one of the pathogenic mechanisms leading to increased mortality in SLE.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: By using integrative transcriptomic and protein analyses, this study aimed at identifying and characterize distinctive molecular signatures between childhood-onset (cSLE) and adult-onset Lupus (aSLE) patients, along with their involvement in immunological and clinical features, and to analyze the relevance of the sustained positivity for anti-dsDNA antibodies.

Methods: Ninety-four subjects were enrolled, comprising two main combined study groups: 1) eleven consecutive children with pediatric-onset SLE (cSLE) and 11 age and sex matched healthy children (cHD); 2) sixty aSLE patients and 20 healthy adults (aHD). Total RNA was extracted from purified monocytes and pools from 5 subjects of each study group were obtained. Then, a nanostring autoimmune profiling array was used for mRNA expression data generation.

Results: Gene expression array identified 279 altered genes in monocytes from cSLE vs cHD. Comparatively, less than a half of genes (130) were found altered in monocytes from aSLE vs aHD. The analysis of common altered genes between the two study groups revealed 19 genes as upregulated in both patients' cohorts. Interestingly, Gene Ontology enrichment analysis identified as main biological processes integrated by these genes the interferon signature (IFNs). Moreover, cSLE displayed at least a double fold change in the levels of these genes *vs* cHD than aSLE *vs* aHD.

Correlation and association studies demonstrated that in the cSLE cohort the altered expression of a number of genes integrating the IFNs was linked to several clinical features. Specifically, increased levels of IFI27 were associated to the occurrence of lupus nephropathy (LN) and positivity for anti-dsDNA, and correlated positively with the activity of the disease (SLEDAI), CV-risk factors (atherogenic index and ApoB/ApoA ratio) and plasma levels of proteins of the IFN family such as IP-10.

Accordingly, in aSLE, altered expression of IFNs was associated to the presence of LN and low levels of complement factors C3 and C4, as well as to increased plasma levels of IFNγ. Interestingly, most of them were further associated with the positivity for anti-dsDNA. A deeper study in this cohort demonstrated that a third of the aSLE patients' displayed a sustained positivity for anti-dsDNA for more than 7 years. Moreover, these patients showed altered expression of several IFN genes, and presented LN along with a pathologic increase in the Carotid Intimae Media Thickness, and impaired microvascular endothelial function, thus supporting the potential role of the IFNs in the severity of the disease and the development of cardiovascular disease.

Conclusion: 1. Gene expression profile allowed the identification of distinctive molecular pathways among monocytes of cSLE and aSLE 2. An interferon signature, more strongly deranged in cSLE than in aSLE patients, is closely related to the activity of the disease and the renal involvement. 3. The sustained positivity for anti-dsDNA in aSLE, further linked to that deranged IFNs and to the development of lupus nephritis, might fosters the establishment of an atherothrombotic status in these autoimmune patients.

Supported by ISCIII (PI18/0837 and RIER RD16/0012/0015), Co-funded with FEDER.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Cross-sectional studies have shown associations between DNA methylation differences in whole blood with Systemic Lupus Erythematosus (SLE) status and outcomes such as lupus nephritis. However, DNA methylation is not static and a proportion of DNA methylation changes in response to environmental cues and with the effects of time. To study the trajectory of DNA methylation in whole blood in SLE we examined 101 participants at two time points in a well-characterized SLE cohort.

Methods: 101 participants from the California Lupus Epidemiology Study (CLUES), a longitudinal cohort of individuals with rheumatologist-confirmed SLE were studied. Participants are followed every 2 years through in-person research visits. DNA extracted from blood at cohort enrollment and after 2 years was analyzed on the illumina EPIC Beadchip. Single nucleotide polymorphism (SNP) genotype data was generated on the Affymetrix LAT1 World Array. First we performed a paired t-test between methylation at cohort enrollment and 2 years after, after adjusting for cell composition and methylation plate. We then applied a mixed linear model on methylation values adjusting for age, sex, population stratification and cell proportions. We previously reported 256 differentially methylated CpGs

Table 1. Top 10 results CpGs with significant changes in methylation between Time 1 and Time 2 adjusted for age, sex, population stratification and cell proportions

Top 10 results CpGs with significant changes in methylation between Time 1 and Time 2 adjusted for age, sex, population stratification and cell proportions

according to disease severity at cohort enrollment.[1] We performed focused analysis on these 256 CpGs as well as exploratory genome-wide analysis.

[1]Lanata et al, Nat Comm **10**, 3902 (2019)

Results: After quality control 806,000 CpGs were analyzed. Of the 256 CpGs previously associated with disease severity, 55 CpGs (21.4%) had a significant change in methylation between the 2 time points ($p < 2E-04$, effect size > 0.03, paired t-test), 52 with a decrease and 3 with an increase in methylation. The largest effect size was observed for cg13452062 in *IFI44L* with a mean decrease of 0.16 (p=6.4e-25) and the most represented genes were *IFI44L*, *IFITM1, PARP9* with 4 CpGs each. In the mixed linear model, the 55 CpGs remained significant ($p < 2E-04$) although we found a significant effect of cell proportions with changes in methylation. As representative examples, we find a significant effect of CD8 proportions with cg07285983 in *RAPGAP1L,* B cell proportions with cg13452062 in *IFI44L* and monocyte proportions with cg10959651 in *RDAD2* (Table 1). Disease activity ((SLE Disease Activity Index score) did not vary significantly between time 1 and time 2 (p=1.0, paired t-test). Exploratory genome-wide analyses found 151 CpGs (0.02%) with a significant change in methylation between the 2 time points ($p < 6.2E-08$, effect size > 0.03 paired t-test). Of these, 55 (33%) were in the previously described 256 CpGs. Of the remaining CpGs, top associations included CpGs in *TLR6, RSAD2, MSRA and COPS8*.

Conclusion: In this study, a small proportion of DNA methylation signatures in blood previously associated with SLE phenotypes fluctuated over time. These changes in methylation associate with circulating cell proportion in SLE patients. Additional longitudinal studies will be needed to further describe and validate candidate CpGs that represent stable biomarkers of disease state as well as CpGs that change in relationship to cell proportions and other unmeasured factors.

A Comprehensive Method to Study Environmental Chemicals in Serum in Patients with SLE

Cristina Lanata[1], Kim Taylor[2], James Hurst-Hopf[1], Laura Trupin[1], Patricia Katz[3], Jinoos Yazdany[1], Maria Dall'Era[4], Dimitri Abrahamsson[1], Lindsey Criswell[5] and Roy Gerona[1], [1]UCSF, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]University of California, San Francisco, Novato, CA, [4]Division of Rheumatology, University of California, San Francisco, CA, [5]Rosalind Russell/Ephraim P. Engleman Rheumatology Research Center, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Environmental exposures may play a substantial role in the pathogenesis of Systemic Lupus Erythematosus (SLE), however it has been challenging to measure and capture relevant exposures in a comprehensive manner. The goal of this study is to develop a novel method to characterize the serum levels of circulating environmental chemicals and metabolites in a well-characterized cohort of SLE patients and controls.

Methods: Participants from the California Lupus Epidemiology Study (CLUES), a longitudinal cohort of individuals with rheumatologist-confirmed SLE were included (n=332). A cohort of healthy individuals matched by age, ethnicity and sex was recruited (n=100). Serum was analyzed by liquid chromatography quadruple time-of-flight Mass Spectrometry (**LC-QTOF/MS**). Feature detection, peak alignment, and abundance normalization using internal standards was performed using Agilent Mass Profiler and adjusted for batch effects using ComBat[1].Principal Components Analysis was used to assess batch adjustment and correct for residual batch effects. Compounds detected in at least 25% of participants were selected for association testing between chemical abundances and SLE status. We analyzed differences between cases and controls using linear models of feature abundances, adjusting for censoring below the detection limit, residual batch effects, and covariates age, sex, and ethnicity. Results of potential detected environmental chemicals were matched into a curated database of hazardous environmental chemicals.

[1]Johnson et al, Biostatistics. 2007; 8(1):118–27

Results: We detected 66,861 features in our cohort; with 3,192 present in at least 25% of samples and analyzed for association with case status. Out of the 3192 features, 70 were significantly different, including 4-Hexyloxyphenol and 39 additional formula-matched compounds.

Conclusion: LC-QTOF/MS can identify a wider range of potential chemical exposures in SLE, and may aid in prioritizing chemicals for further research and intervention. We found that patients with SLE had different chemicals and endogenous metabolites compared to healthy controls.

The Association of Urinary Membrane Attack Complex (C5b-9) with Proteinuria and Glomerular Activity in Lupus Nephritis

Shudan Wang[1], Erica Moore[2], Brianna Lally[3], Beatrice Goilav[4], Chaim Putterman[3] and Anna Broder[5], [1]Montefiore Medical Center / Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, [3]Albert Einstein College of Medicine, Bronx, NY, [4]The Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY, [5]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY

Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Complement activation is known to play a major role in lupus nephritis (LN). Urinary membrane attack complex (C5b-9) has been shown to correlate with proteinuria and renal injury in other diseases such as diabetic nephropathy, IgA nephropathy and ANCA vasculitis, but its role is unclear in LN. This study aims to determine whether urine C5b-9 is associated with proteinuria and markers of glomerular or tubular disease activity in LN.

Methods: Urine samples from 42 adult and pediatric lupus patients with clinically indicated renal biopsies performed between 2010 and 2019, and 3 normal controls were collected. The urine C5b-9 levels were measured using specific enzyme linked immunosorbent assay kit (Quidel Corporation) and normalized by urine creatinine excretion. The urine

samples were ran immediately after thawing in duplicate and analyzed on a standard curve. Urine C5b-9 levels were correlated with demographic and laboratory parameters at time of urine collection (Table 1) and with renal pathology 0 to180 days prior to time of renal biopsy (Table 2).

Results: Patient with LN (n=42) had higher median (IQR) urine C5b-9 of 12.8 ng/mg (2.0, 27.3) as compared to 0 ng/mg (0, 2.4) among normal controls (n=3), p=0.03. Of the 42 LN patients, the median age (IQR) is 32 years (19, 41), 37 (88.1%) females and 19 (45.2%) Hispanic. Patients with low serum albumin (< 3.5 g/dL) had higher median (IQR) urine C5b-9 as compared to those with normal albumin: 18.9 ng/mg (8.1, 60.3) vs. 5.8 ng/mg (0.3, 16.9), p=0.02. Similarly, patients with elevated urine protein creatinine (>1000mg/g) had significantly higher median (IQR) urine C5b-9: 14.8ng/mg (8.1, 46.8) vs. 1.8ng/mg (0.3, 8.2), p=0.004. There was no significant association in eGFR, serum C3, C4, dsDNA and urine C5b-9 levels. 19 of the 42 LN patients had urine sample collected 0 to180 days prior to time of renal biopsy, of which 10 had urine sample collected on the day of renal biopsy. Of the 19 LN patients, 9 (47.4%) had proliferative/mixed class. LN patients with proliferative/mixed class had higher median (IQR) urine C5b-9 compared with membranous class: 21.6 ng/mg (10.2, 90.3) vs. 7.3 ng/mg (1.8, 18.5). However, tubular interstitial fibrosis and inflammation was found not to be associated with urine C5b-9 levels.

Table 2: Urine C5b-9 levels normalized by creatinine (ng/mg), by renal pathology 0 to 180 days prior to time of renal biopsy, N=19

	N (%)	Urine C5b-9, median (IQR), mg/ng	p-value
Glomerular Activity			
LN Class			
Proliferative/Mixed (4, 4+5, 3+5)	9 (47.4%)	21.6 (10.2, 90.3)	0.05
Membranous (5)	10 (52.6%)	7.3 (1.8, 18.5)	
Presence of Crescents			
Yes	3 (15.8%)	90.3 (10.2, 190.1)	0.14
No	16 84.2%)	12.3 (3.1, 20.1)	
Chronicity of lesions			
Active (A, or A/C)	5 (55.6%)	90.3 (10.2, 173.6)	0.55
Chronic (C)	4 (44.4%)	17.5 (10.8, 29.4)	
Tubular Activity			
Interstitial Fibrosis/Tubular Atrophy			
None	7 (36.8%)	13.4 (3.5, 39.1)	0.97
Present (mild to severe)	12 (63.2%)	14.3 (4.7, 29.4)	
Tubulointerstitial Inflammation			
None	8 (42.1%)	17.7 (10.0, 38.1)	0.27
Present (mild to severe)	11 (57.9%)	10.2 (1.8, 21.5)	

Conclusion: Although limited by sample size, this pilot study suggested that urine C5b-9 is associated with low serum albumin and proteinuria in LN. In addition, urine C5b-9 levels checked before or at time of biopsy may be a potential marker of glomerular activity in LN. More studies are needed to investigate urine C5b-9 as a biomarker of glomerular or tubular activity.

Dynamic Changes in Microbiota Representation of a Gut Pathobiont and Clinical Disease Activity in Patients with Lupus Nephritis

Doua Azzouz[1], Ze Chen[2], Zhi Li[3], Peter Izmirly[4], Jing Deng[1], David Fenyo[3], Jill Buyon[1], Alexander Alekseyenko[5] and **Gregg Silverman**[6], [1]Department of Medicine, NYU School of Medicine, New York, NY, [2]Department of Microbiology, NYU School of Medicine, New York, NY, [3]Institute for Systems Genetics, NYU School of Medicine, New York, NY, [4]Department of Medicine, New York University School of Medicine, New York, NY, [5]Medical University of South Carolina, Charleston, SC, [6]Laboratory of B cell immunobiology, Department of Medicine, NYU School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: From a cross-sectional cohort, we have recently identified a candidate human gut pathobiont, Ruminococcus gnavus (RG) of the Lachnospiraceae family and Blautia genus that was linked to active Lupus nephritis (LN)(1). LN patients often displayed gut blooms of RG, concordant with serum IgG anti-RG antibody responses that appeared intertwined with anti-dsDNA responses implicated in renal pathogenesis. The dynamics of

RG representation within SLE microbiota ecosystems have not been investigated. The genomic sequences of few RG strains have been reported, and these vary greatly in genome structure, gene representation and sequence.

Methods: A total of 53 fecal samples from 16 SLE patients and 63 samples from 11 CTL, at 2-12 time-points were studied, and patients were characterized for demographics, and clinical disease activity. High-throughput 16S rRNA amplicon libraries from fecal samples were analyzed using QIIME 2 and DADA2 (1). Hundreds of individual fecal RG colonies from two active LN patients were isolated and subjected to whole genome sequencing (WGS), with phylogenetic assignments in part based on inter-strain average nucleotide identity, multi-locus sequence typing and reference-guided genomic assemblies.

Results: Our analysis confirmed highly conserved patterns of gut community representation in SLE patients that displayed reduced microbiota richness, which was most pronounced in patients with high SLEDAI (p= 0.0023) and LN (p=0.002), confirming earlier reported findings [1]. Beta diversity analysis showed significant heterogeneity in SLE microbiome compared to CTL (p= 0.001). Similarly, RG abundance was greater in patients with high SLEDAI (p= 0.0021) and LN compared to CTL (p= 0.003). Tracking of the dynamic representation of RG at different time points within individual subjects, in CTL and many Lupus patients showed little or no detectable perturbations. Strikingly, in LN patients examined, there was a direct correlation between representation of RG and the SLEDAI score of overall disease activity in 53% of LN patients overtime. WGS analysis of the RG isolated colonies discovered four distinct RG strains with large genomic variations, which differ from previously reported RG strains from other diseases and healthy donors.

Conclusion: Our findings suggest that intestinal blooms of the RG candidate pathobiont correlate with serious increases in Lupus disease activity, and especially LN. In pilot studies we have isolated and characterized the genomes of the first RG strains from active SLE patients. Our findings suggest that both dynamic representation and colonization by specific RG strains identified by their genomic composition, may have implications for the host-pathobiont relationship and the immune activation that is integral to Lupus pathogenesis.

urine biomarkers of tubular damage has recently been developed to detect acute kidney injury.[1] This study sought to determine whether these biomarkers of tubular injury collected around the time of clinically indicated biopsies for lupus nephritis were associated with the presence of IFTA/TII.

Methods: Urine samples from 29 adult and pediatric lupus patients with clinically indicated renal biopsies performed between 2010 and 2019 were included. Samples were evaluated for tubular injury markers KIM-1, interleukin-18 (IL-18), clusterin, calbindin, and glutathione S-transferase-π (GST- π) using the Bio-Plex Pro™ kidney assay. Biomarkers (Table 1) were correlated with presence or absence of IFTA/TII on biopsies performed within 180 days prior to and 21 days after sampling. These biomarkers were normalized to urine creatinine excretion.

Table 3. Association between IFTA and biomarkers of tubular injury (ng/mg; median [IQR])

Biomarker	IFTA- n=11	IFTA+ n=18	p-value
KIM-1	0 (0, 0)	0.5 (0, 2)	0.06 2-sided; 0.04 one-sided
IL-18	0 (0, 0)	0 (0, 0)	0.42
Clusterin	83 (55, 384)	94 (25, 383)	0.89
Calbindin	54 (31, 128)	149 (26, 265)	0.54
GST-π	94 (26, 196)	68 (34, 141)	0.96

Results: Of 29 patients, 18 (62%) had evidence of IFTA on renal biopsy (Table 2). IFTA+ patients had a median age (IQR) of 36 (27, 50) vs. 20 (14, 59) in the IFTA group, p = 0.25. BMI was significantly higher in IFTA+ patients (median (IQR) 30 (24, 36) kg/m^2 vs. 23 (20, 26) kg/m^2, p < 0.001), as was blood pressure on day of biopsy. KIM-1 levels were higher when IFTA was present, median (IQR) 0.5 (0, 2) ng/mg vs. 0 (0, 0) ng/mg for IFTA+ and IFTA-, respectively, one sided p-value 0.04. KIM-1 was detectable (> 0) in 9 (50%) of IFTA+ and in 2 (18%) IFTA-, p = 0.09. No association between KIM-1 and TII was observed. There was no association between the other 4 biomarkers and IFTA or TII (Table 3). KIM-1 levels did not differ by age, sex, race, ethnicity, or lupus nephritis class, and were not associated with serum C3, C4, or dsDNA at time of sample collection. KIM-1, calbindin, GST-π and clusterin were associated with proteinuria.

Conclusion: Though limited by sample size, these pilot results suggest that urinary KIM-1, a kidney injury marker secreted by the proximal tubules, in samples collected around the time of biopsies may serve as a non-invasive biomarker for the presence of IFTA in lupus nephritis.

Changes in Macular Capillary Network Measured with Optical Coherence Tomography-angiography in Patients with Systemic Lupus Erythematosus

Laura Pelegrin[1], Marc Figueras-Roca[1], Alvaro Olate-Perez[1], Javier Zarranz-Ventura[1], Ricardo Casaroli-Marano[1], Montse Morató[1], Vanesa Budi[1], José Ríos[2], Ricard Cervera[3], Alfredo Adan[1] and **Gerard Espinosa**[1], [1]Hospital Clinic, Barcelona, Catalonia, Spain, [2]Universitat Autonoma de Barcelona, Barcelona, Catalonia, Spain, [3]Hospital Clinic de Barcelona, Barcelona, Catalonia, Spain

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Eye involvement in systemic lupus erythematosus (SLE) occurs in approximately one-third of patients, usually related to disease activity. An early diagnosis and treatment could prevent structural eye damage and visual acuity worsening in these cases. The purpose of the present study was t o describe macular vascular

findings by optical coherence tomography angiography (OCT-A) in SLE patients related to the duration of disease and SLE activity/damage scores.

Methods: A cross-sectional, single-center study was carried out in 78 patients with SLE followed at Autoimmune Diseases and Ophthalmology Departments of the Hospital Clínic, Barcelona. As a control group, 80 sex and age-matched individuals were also analyzed. Clinical and immunological data, SLE activity and damage scores, and macular vascular parameters by OCT-A (CIRRUS ™ HD-OCT model 5000, Carl Zeiss Meditec, Inc., USA) were collected.

Results: Perifoveal vessel density in SLE patients was reduced compared to the control group (median 10.3 mm^{-1}[range 9.6-11.4] versus median 12.5 mm^{-1} [range 11,7-13,7]) (p=0.001) as well as vascular perfusion proportion compared to controls (0.35 [0.34-0.37] versus 0.38 [0.37-0.39]) (p=0.001). Likewise, SLE patients with >10 years of disease showed lower figures of vessel density (19.1 [18.2-20.2] versus 20.2 [19.7-20.9]) (p=0.04) and perfusion (0.34 [0.32-0.37] versus 0.36 [0.35-0.37]) (p=0.0017) compared to those with < 10 years of disease, respectively.

Patients with SLE damage index score >0 had worse values in area (median 0.18 mm^2 [range 0.15-0.21] versus 0.27 mm^2 [range 0.23-0.31]) (p=0.002) and perimeter foveal avascular zone (FAZ) (median 1.84 mm^2[range 1.70-2.12] versus 2.19 mm^2 [range 2.07-2.37]) (p=0.003). Likewise, patients with a clinical SLE disease activity index >4 showed a decrease in vessel density (14.6 mm^{-1} [11.7-18.3] versus 17.6 mm^{-1} [17.1-18.1])(p=0.02) and vascular perfusion (0.33 mm^{-1} [0.23-0.44] versus 0.43 mm^{-1} [0.42-0.45])(p=0.012).

Conclusion: The macular capillary network of SLE patients shows lower vessel density and perfusion proportion than healthy controls. In addition, retinal vascular findings in SLE patients could be associated with the duration of disease, SLE activity, and damage index. Retinal vascular imaging explorations based on OCT-A could be of great interest in future studies in SLE in order to further clarify systemic implications of such characteristics.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside

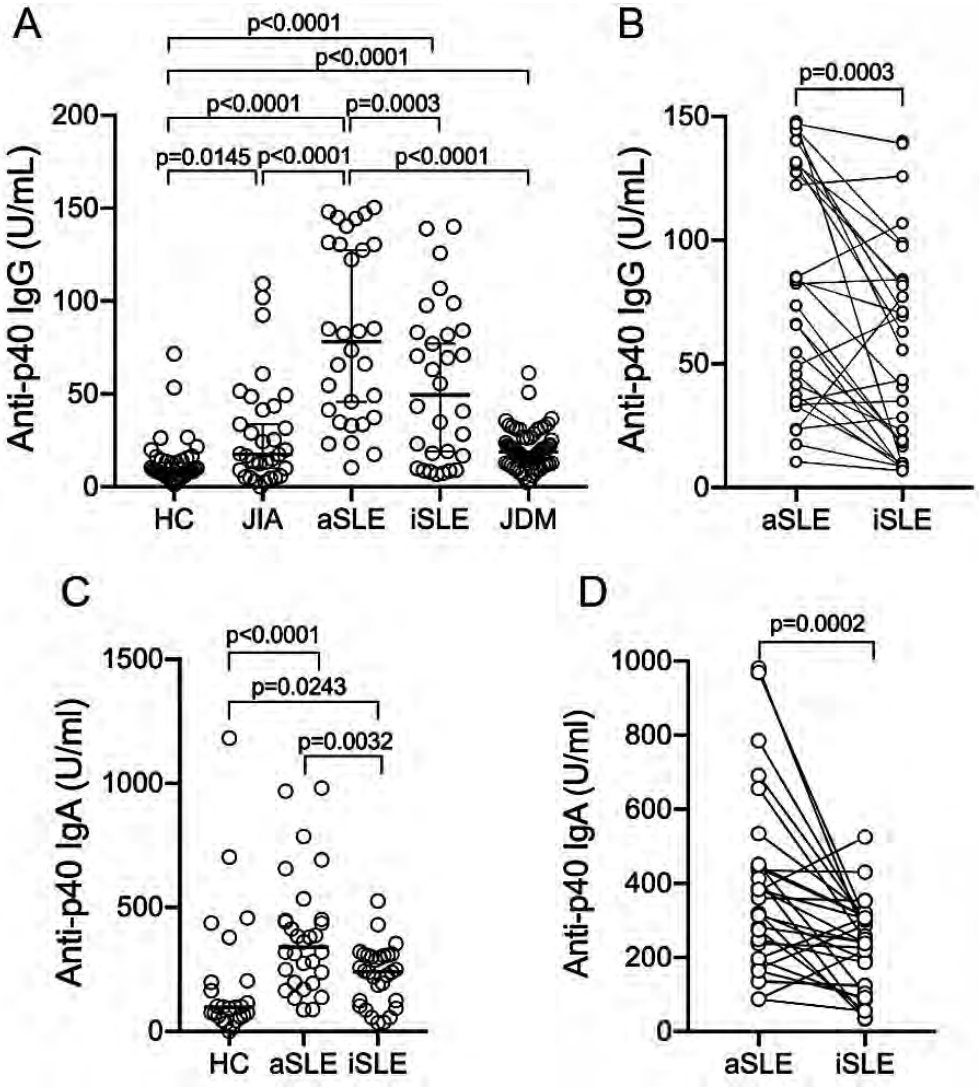
Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

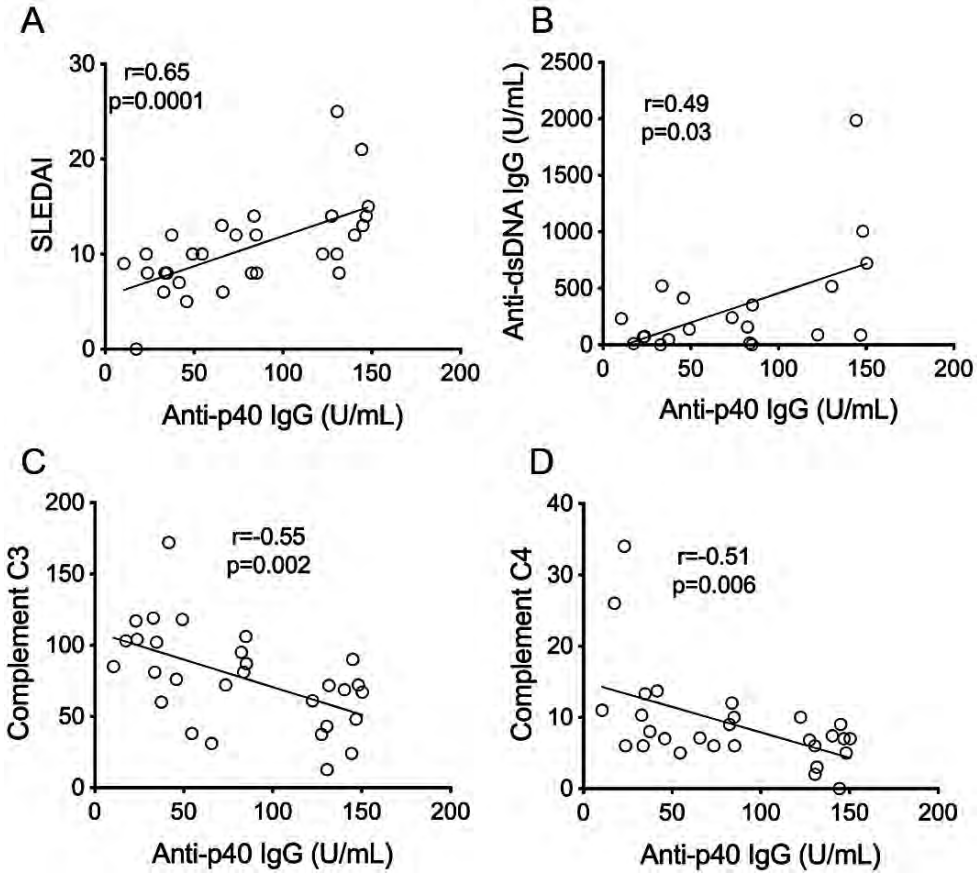
Background/Purpose: To quantitate autoantibodies against the RNA-binding p40 (ORF1p) protein encoded by the L1 retroelement, expression of p40 itself, and markers of neutrophil death in patients with pediatric systemic lupus erythematosus (pSLE), and to determine if correlations exist between these and disease activity.

Methods: Autoantibodies in the plasma of pSLE patients (n=30), healthy children (n=37), and disease controls juvenile idiopathic arthritis (JIA) (n=32) and juvenile dermatomyositis (JDM) (n=60), were measured by ELISA. Expression of p40 in immune cells was assessed by immunoblotting and flow cytometry. Markers of neutrophil activation were quantitated by ELISA.

Results: IgG and IgA autoantibodies reactive with p40 were detected in the pSLE patients, but were low in healthy controls and in JIA or JDM. pSLE patients with active disease (13 of them newly diagnosed) had higher titers than the same patients after effective therapy (p=0.0003). IgG titers correlated with SLEDAI (r=0.65, p=0.0001), ESR (r=0.43, p=0.02), and anti-dsDNA antibodies (r=0.49, p< 0.03), and inversely with complement C3 (p=0.002) and C4 (p=0.006). p40 protein was detected in a subpopulation of $CD66b^{+}$ granulocytes in pSLE, as well as in adult SLE patients. My-



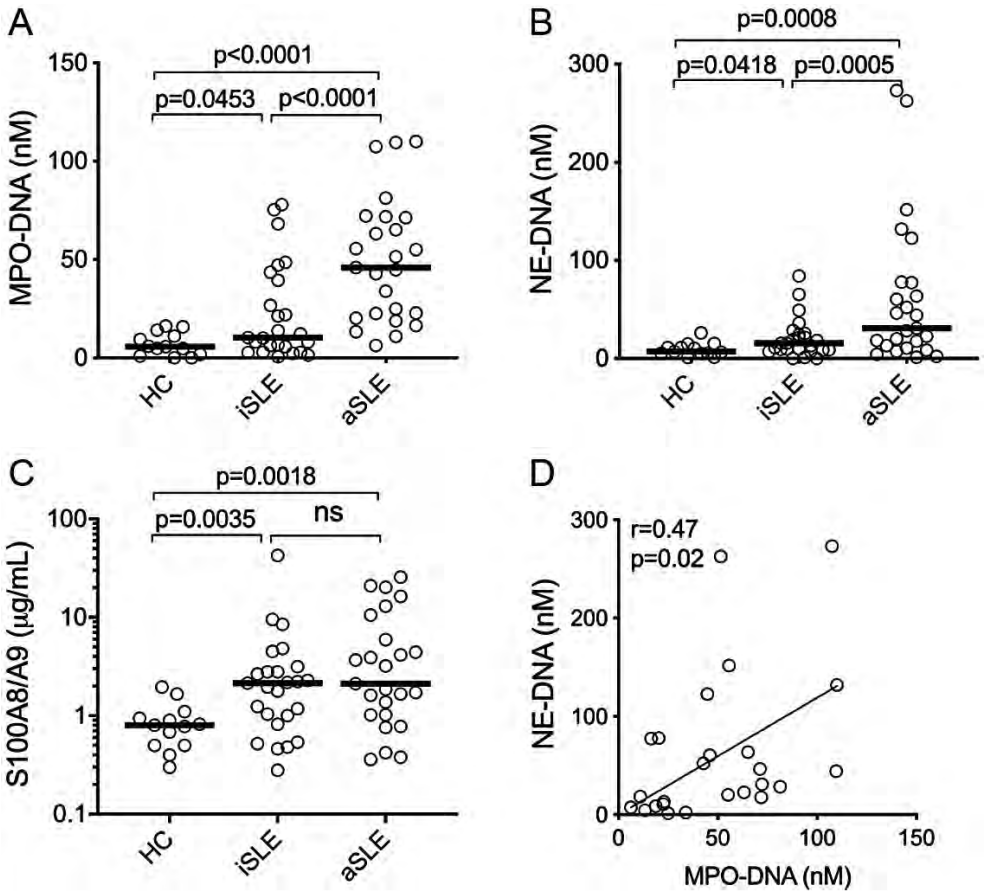
Anti-p40 and disease state correlations



Anti-p40 and disease activity correlations

eloperoxidase and neutrophil elastase complexed with DNA and the neutrophil-derived S100A8/A9 were elevated in plasma from pSLE patients with active disease and correlated with anti-p40 autoantibodies and disease activity.

Conclusion: Children with active SLE have elevated IgG and IgA autoantibodies against L1 p40, a protein found in circulating granulocytes. P40 expression and autoantibody levels correlate with disease activity and suggest that neutrophils are a source of retroelement expression.



Neutrophil activation and disease state correlations

Background/Purpose: Cognitive dysfunction (CD) is very prevalent in SLE and significantly affects quality of life. Altered functional brain mechanisms are associated with CD in SLE. We previously used functional magnetic resonance imaging (fMRI) to show altered mechanisms in the Default Mode Network (DMN), a network involved in self-reflection and is acquiescent during cognitive tasks. In this study, we examined the effects of disease activity on functional connectivity (FC) within the DMN using resting state (rs) fMRI. We hypothesised that those with SLE, and specifically those with active disease, would have reduced FC within the DMN compared to healthy controls.

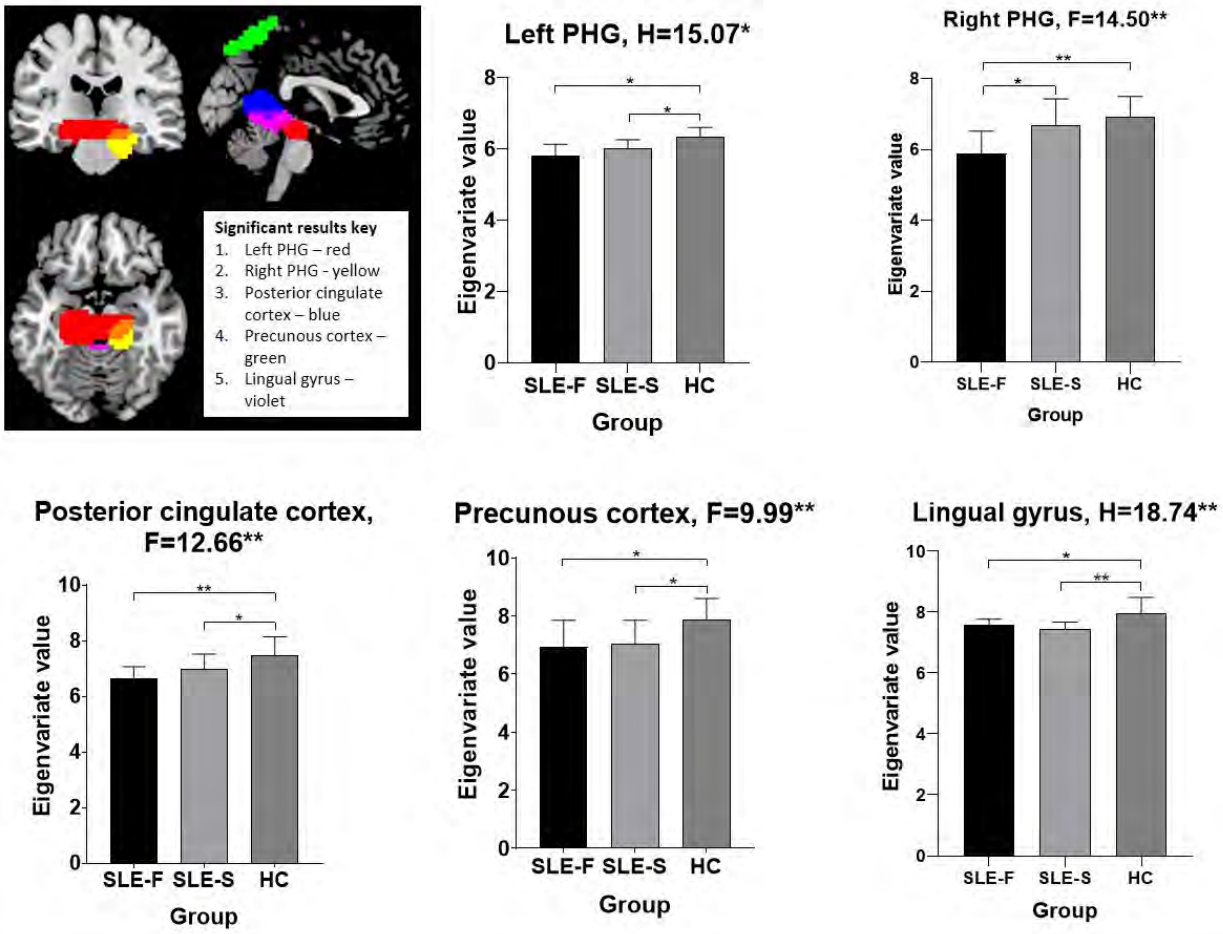
Methods: 19 SLE-active (SLE-F) and 23 SLE-stable (SLE-S) all meeting 1997 ACR or SLICC criteria and 30 healthy controls (HC) were recruited. In the SLE participants, active disease was defined as BILAG A or B with a change in treatment. Stable disease was defined as SLEDAI-2K ≤4. Demographic, clinical and psychiatric data were collected for all participants. A T2-weighted scan was undertaken and reviewed by a neuroradiologist to provide a Scheltens score for brain abnormalities. A T2*-weighted rsfMR scan was acquired. These images, after preprocessing, were analysed using independent component analysis (ICA). Fischer's z-scores were extracted from those temporospatial nodes associated with the DMN and entered into ANOVAs or Kruskal-Wallis tests.

Results: Participants were well matched on key demographics. Significant differences were found between the SLE groups on factors associated with disease activity and psychological factors (Table 1).

14 DMN nodes were defined using ICA. Significant group differences ($p< 0.001$) were found in five of the nodes: precunous cortex, right parahippocampal gyrus (PHG), posterior cingulate cortex, lingual gyrus and left PHG. In all regions, except the right PHG, the SLE groups had reduced FC compared to the HC group. In the right PHG the SLE-F group had reduced FC compared to the other two groups (Figure 1).

Correlations comparing the significant nodes with Scheltens score and depression and anxiety measures for the SLE groups combined were undertaken. Depression score (MADRS) was negatively correlated with FC in both the left and right PHG (r_s=-0.476, p=0.001 and r_s=-0.494, p=0.001, respectively).

Figure 1: Default mode network (DMN) regions with significant group differences



*p<0.01, **p<0.001
PHG = Parahippocampal gyrus

Conclusion: Altered FC was evident in DMN nodes for SLE groups irrespective of disease activity. Reduced FC in these areas could be indicative of fatigue. The inability to "switch off" the DMN during cognitive tasks may impact the FC of the DMN in SLE. The DMN is involved in self-reflective processes and altered FC is associated with major depression. Our SLE groups had higher, but not clinically significant, depression scores compared to HC and our correlations found altered FC associated with depression scores. When considering rsfMRI as a potential marker for CD in SLE other contributing factors, such as depression, must also be considered.

Serum α-Klotho Is Decreased in Older Systemic Lupus Erythematosus Patients and Correlate with Markers of Disease Activity

Margaret Markiewicz[1], Dayvia Russell[2] and Jim Oates[1], [1]Medical University of South Carolina, Charleston, SC, Charleston, SC, [2].Research Services, Ralph H. Johnson VA Medical Center, Charleston, SC,, Charleston

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, debilitating autoimmune disease characterized by heterogeneous, multiorgan involvement with female predominance. Lupus nephritis is one of the key complications of SLE with 10% of patients developing end-stage renal failure, and major risk for overall morbidity and mortality in SLE. The Klotho gene plays an important role in the process of aging, inflammation, and autoimmunity. Diminished levels of a-Klotho (Kl) were reported in age related diseases such as cancer, hypertension, and kidney disease. Significantly low a-Klotho levels were associated with an increased risk of progressive decline in renal function. The aim of our study was to evaluate the serum concentration of a-Klotho in patients with SLE only [Group I] ; SLE with hypertension (HTN)[Group II]; and SLE with lupus nephritis (LN) and HTN [Group III], and compare to that of healthy control and/or control with HTN to determine associations with disease and disease activity.

Methods: We used banked serum samples from patients and controls enrolled in a prospective longitudinal cohort study. Our study consisted of 20 paired serum samples from patients with SLE and/or LN and/or HTN (5 in each group) and 15 controls with or without HTN. SLE patients had serum collected during paired visits (first and second visit) with lower and higher disease activity determined through clinical and laboratory elements of the SLEDAI (SLE Disease Activity Index).The serum samples were analyzed through an enzyme-linked immunosorbent assay (ELISA) development system for the determination of human soluble a-Kl (R&D Systems).

Results: The serum concentration of Kl was 0.84 ± 0.599 ng/ml and 0.86 ± 0.449 ng/ml in SLE patients during inactive and active disease, respectively. Serum Kl averaged 0.82 ± 0.667 ng/ml in No HTN controls and 1.21 ± 1.252 ng/ml in HTN controls. Serum Kl negatively correlated with age among female SLE patients from all groups during active disease ($r = -0.524$, $p = 0.032$). Interestingly, serum Kl concentration positively correlated with anti-dsDNA antibody levels in all females with active disease ($r = 0.525$, $p = 0.046$). Moreover, the serum Klotho concentration positively correlated with protein/creatinine ratio in females with active disease and LN ($r = 0.974$, $p = 0.004$). There was no association between Kl concentration and C3, C4 levels in SLE patients.

Conclusion: This is the first study measuring Kl levels in serum from the inactive and active stage of SLE with hypertension as a covariable. Klotho levels negatively correlated with age of SLE patients, which is similar to the diminished concentration of Kl seen with chronological aging. We initially postulated that Kl levels would decrease in SLE patients since serum Kl acts as an anti-inflammatory molecule, but did not see this in our study. Surprisingly, we found an association between Kl levels and the positivity of dsDNA titers and protein/creatinine ratio. The positive correlation between elevated levels of Kl and laboratory measures of disease activity may be a compensatory response to inflammation, while decreases with age may reflect accelerated immune senescence.

Early Assessment of Left Ventricular Assessment Using Speckle Tracking Echocardiography and It´s Relationship with Insulin Resistance in Women with Systemic Lupus Erythematosus

Pamela Munguía-Realpozo[1], Claudia Mendoza-Pinto[2], Socorro Méndez-Martínez[2], Liliana Pérez-Aquino[3], Ivet Etchegaray-Morales[1] and Mario Garcia-Carrasco[2], [1]Facultad de Medicina, Benemérita Universidad Autónoma de Puebla, Puebla, Puebla, Mexico, [2]Instituto Mexicano del Seguro Social, Puebla, Puebla, Mexico, [3]Facultad de Medicina, Beneméria Universidad Autónoma de Puebla, Puebla, Puebla, Mexico

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Bench to Bedside
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus patients (SLE) have increased cardiovascular risk. Patients with SLE are associated with significant alterations in cardiac structure and function as demonstrated by echocardiography. Insulin resistance (IR), which is higher in SLE patients than controls, adversely impacts left ventricular (LV) remodeling and function at middle age. Although IR may not play as marked role in determining LV dysfunction as is hypertension, the impact of IR on ventricular dysfunction is unknown in SLE patients.

The aim of this research were: 1) to determine the role of speckle tracking echocardiography in early detection of LV dysfunction in SLE and 2) to examine the influence of IR measured by Quantose score on subclinical LV dysfunction using speckle tracking echocardiography in normotensive SLE patients.

Methods: This cross-sectional study included SLE adult women without diabetes mellitus (DM), hypertension or obesity. All participants underwent detailed two- dimensional Doppler and two-dimensional speckle tracking echocardiography. Global longitudinal strain (GLS%) and global circumferential strain (GCS%) were determined from three standard apical views, using a combination of speckle tracking and tissue Doppler imaging to track regions of interest. The lower limits of normality for the strain components were < 18.5% for the longitudinal strain, and –15.4% for the circumferential. Left ventricular diastolic dysfunction (LVDD) was verified according to current guidelines. Blood sample were drawn to estimate the Quantose score for IR, which is derived from fasting measurements of insulin, α-hydroxybutyrate, linoleoyl-glycerophosphocholine, and oleate, three nonglucose metabolites shown to correlate with insulin-stimulated glucose disposal.

Results: Seventy female patients were included (mean age: 39.0 ± 9.9 years, mean disease duration 11.6 ± 4.9 years, mean disease activity: 1.8 ± 1.4). The frequency of IR was high (65%). Despite a normal ejection fraction in all participants, eleven (15.7%) patients had abnormal LV systolic GLS. Twenty-three (32.8%) patients had LVDD. The GLS% and GCS% did not differ in patients with and without IR (-20.8 ± 3.1 vs. -20.5 ± 2.1; p= 0.61 and -27.9 ± 4.4 vs. -27.4 ± 3.7; p= 0.57, respectively). The prevalence of LVDD was 38.1% in patients with IR vs. 25.0% in patients without IR (p= 0.30). E/E' and E/A ratios did not differ significantly between groups (6.6 ± 1.9 vs. 6.6 ± 1.5; p= 0.98 and 1.3 ± 0.3 vs. 1.3 ± 0.2; p= 0.27).

Conclusion: Although IR was high in our patients with SLE, IR was not associated with either left ventricular systolic dysfunction or LVDD in SLE patients without DM or hypertension.

Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The ALLURE study compared efficacy and safety of abatacept (ABA) vs placebo (PBO) on background MMF and CS for the treatment of active proliferative LN.[1] The primary endpoint of improvement in complete response (CR) rate at 1 year (ABA 35.1%, PBO 33.5%; p=0.73) was not met; however, the ABA-treated patient (pt) group had an earlier, more pronounced improvement in urine protein/creatinine ratio (UPCR; ABA –2.95, PBO –2.68) and estimated glomerular filtration rate (eGFR; ABA 109, PBO 105 mL/min/1.73 m^2) and a higher rate of sustained CR (sCR; ABA 48%, PBO 38%; hazard ratio estimate [95% CI] 1.41 [0.9942, 2.0068]) at 1 year. In this serum proteomic analysis, correlations between protein biomarkers, baseline (BL) disease characteristics and treatment outcomes were studied to better understand disease pathogenesis and treatment effects.

Methods: Serum samples from pts with SLE (ACR 1982 criteria)[2] and biopsy-proven LN (122 ABA, 119 PBO) in ALLURE (NCT01714817) were analyzed for 122 protein biomarkers. Associations between biomarkers, categorical disease measurements and clinical responses were assessed by Wilcoxon-Mann-Whitney test, and between biomarkers and continuous disease activity measurements by Spearman's rank correlation.

Results: Serum proteins at BL were comparable in both treatment groups. At BL, 17 serum proteins significantly correlated with UPCR, 33 with eGFR and 26 with BILAG score (adjusted $p< 0.01$); these included albumin, CD40, TNFR2, SCF and CD27. Several protein biomarkers were differentially expressed between pts with International Society of Nephrology and the Renal Pathology Society Class III and IV LN (**Figure 1**). Class IV LN was associated with lower levels of IFN-α, MDC, MIP-3B and IL12p14 than Class III LN, suggesting differential cytokine regulation. Some proteins (eg, TNFR1, SCF) correlated with changes from BL in eGFR and UPCR over time. Thirteen biomarkers, including MCP2, IGFBP2, AXL, SCF and MMP-2, correlated with early (Day 85) UPCR improvement in the ABA, but not PBO, group. Pts with lower BL CD40, B2M and MMP7 levels had better treatment outcomes for eGFR (achieving normal eGFR or >85% of the BL value) at Day 365 in both treatment groups. BL levels of myoglobin, CD27, APRIL, SCF, IGFBP7 and EGFR were associated with favorable eGFR outcomes in the ABA group, while TNFR1, Fib-1C,

Figure 1. Differential expression of serum proteomics at baseline between patients with Class III or IV LN

Medical writing: Rachel Rankin (Caudex)

6CKine, HCC4 and FGF23 were associated with favorable eGFR outcomes in the PBO group. Similar patterns were observed for categorical improvement of UPCR (< 0.5, or >50% decrease from BL) at Day 365 with different serum protein biomarkers. A panel of BL protein biomarkers was identified including CD40, CD27, TNFR2 and FAS that strongly correlated with the achievement of sCR by Day 365 in the ABA, but not PBO, group.

Conclusion: Pts with active LN had distinct serum proteomic profiles that correlated with features of LN and treatment outcomes. Specific associations with abatacept are consistent with its immunomodulatory mechanistic effects. Clinical trials should endeavor to apply precision medicine approaches to improve understanding of LN and treatment strategies.

Mycophenolate Mofetil for Systemic Lupus Erythematosus: Our 20-year Experience

Michael Trevisonno[1], Alexander Hall[1], Cristina Sorrento[1] and Ellen M Ginzler[2], [1]State University of New York Downstate Medical Center, Brooklyn, NY, [2]SUNY Downstate Health Sciences University, Brooklyn

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Mycophenolate Mofetil (MMF) has been long used in the treatment of systemic lupus Erythematosus (SLE). Despite its proven effectiveness, particularly in the treatment of lupus nephritis, further studies are warranted to investigate its role in long-term maintenance therapy. The purpose of this study was to describe our 20 years of practice experience using MMF with regards to its indications, safety, tolerability and treatment efficacy. Among patients on long-term maintenance therapy, we sought to identify rates of renal flare and of progression to end-stage renal disease (ESRD).

Methods: In this retrospective chart review, we identified all patients with SLE who were treated with MMF between 1999 and 2019. We recorded data about indications, duration of treatment, reason for discontinuation, and side effects. Treatment efficacy for lupus nephritis was evaluated by occurrence of remission, occurrence of renal flare, and of progression to ESRD.

Results: Six hundred and sixty patients with SLE were evaluated; among them, 101 were treated with MMF. The indications for starting MMF were lupus nephritis (89%), interstitial lung disease (7%), and use as a steroid-sparing agent (4%). The mean duration of treatment was 69 months. Treatment was discontinued due to inefficacy in 9% of patients, and due to side effects in 8% of patients. The most common side effects were Leukopenia (9%), nausea (7%) and diarrhea (6%). Among patients with lupus nephritis, 60% achieved complete remission and 16% achieved partial remission at 1-year follow-up. Of those who did not achieve remission after one year, 7/14 (50%) did by second year. Among the 25 patients treated for at least 5 years, 1 developed a flare between the 5 and 10-year follow-up

period. Among the 15 patients treated for at least 10 years, no patients developed any flare at subsequent follow-up. Among patients on maintenance therapy, 3 progressed to ESRD.

Conclusion: Maintenance treatment with MMF constitutes an effective long-term treatment for lupus nephritis. Our practice demonstrates its tolerability over many years with few adverse effects, prevention of renal flares, and a low progression rate to ESRD.

Selective Expansion of Regulatory T Cells in Patients with Systemic Lupus Erythematosus by a Novel IL-2 Conjugate, NKTR-358

Christie Fanton[1], **Richard Furie**[2], Neha Dixit[1], Cat Haglund[1], Lin Lu[1], Suresh Siddhanti[1], Vishala Chindalore[3], Robert Levin[4], Isam Diab[5], Brian Kotzin[1] and Jonathan Zalevsky[1], [1]Nektar Therapeutics, San Francisco, CA, [2]Division of Rheumatology, Northwell Health, Great Neck, NY, [3]Pinnacle Research Group, Anniston, AL, [4]Clinical Research of West Florida, Clearwater, FL, [5]Paramount Medical Research and Consulting, Middleburg Heights, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Treg dysfunction and impaired IL-2 production have been implicated as key immunological defects in the breakdown of immune self-tolerance in SLE. Low-dose IL-2 can expand Tregs, but this therapy has a narrow therapeutic window for stimulation of Tregs versus conventional T cells (Tcons), and a short half-life. NKTR-358, a polyethylene glycol (PEG) conjugate of recombinant human IL-2 (aldesleukin sequence), has altered IL-2 receptor binding and prolonged biological activity compared with native IL-2. In healthy volunteers, single SC administration led to a dose-dependent increase in Tregs with no elevation of Tcons.

Methods: In this double-blind, multiple ascending dose, Phase 1b study (NCT03556007), 48 patients with mild to moderate SLE activity (per ACR criteria) received 3 SC doses q2w of NKTR-358 in 4 cohorts ranging from 3 to 24 μg/kg (9 active: 3 placebo per cohort) and were followed for 50 days after the last dose. The time course and extent of activation and proliferation of peripheral blood Tregs, Tcons, and NK cells were assessed. Changes in gene expression and epigenetic markers were also investigated.

Results: There were no dose-limiting toxicities, deaths, or clinically significant abnormalities in vital signs or electrocardiograms. Adverse events attributed to NKTR-358 were primarily limited to mild (grade 1 or 2) injection site reactions. Dosing was stopped in 1 subject due to elevated eosinophil levels, without clinical sequelae. NKTR-358 demonstrated dose-dependent numerical improvements in the Cutaneous Lupus Erythematosus Disease Area and Severity Index score; however, the small number of patients per dose, low entry disease activity, and short treatment duration limited comprehensive assessment of disease activity.

The primary effect of NKTR-358 was seen on Tregs. In the 3 to 24 μg/kg cohorts, dose-dependent, sustained increases in absolute number, percentage, and proliferation (Ki67+) of circulating FoxP3+CD25^{bright} Tregs were observed, with levels remaining elevated throughout the dosing period. At 24 μg/kg, the maximum mean peak increase in number of CD25^{bright} Tregs was 12-fold above baseline and the maximum mean percentage of Ki67+ CD25^{bright} Tregs was

5-fold above baseline, not returning to predose levels until 20–30 days after the last dose. No increases in CD4+ or CD8+ Tcon numbers were detected, and low-level increases in the percentage of NK cells were noted at the highest dose tested. Induction of Tregs was further supported by a correlation of number of Tregs identified by flow cytometry and extent of demethylated FoxP3 at ≥12 μg/kg. Expression of Treg activation markers CD25, Helios, and CTLA4 were induced at ≥12 μg/kg, and NKTR-358 also led to dose-dependent induction of genes associated with Treg regulation, such as IDO1.

Conclusion: These results extend findings previously reported in healthy volunteers. In the current study in patients with SLE, NKTR-358 was safe and well tolerated, and led to a sustained and selective dose-dependent increase in $CD25^{bright}$ Tregs. Induced Tregs displayed increased levels of activation markers. Together, these data provide strong support for continued development of NKTR-358 in patients with SLE as well as in other inflammatory diseases.

Risk Factors for Antimalarial-Induced Retinal Toxicity in Systemic Lupus Erythematosus and Other Rheumatic Diseases

Gemma Cramarossa[1], Hsin-Yen Liu[2] and Janet Pope[3], [1]Western University, Kleinburg, ON, Canada, [2]Western University, London, ON, Canada, [3]Department of Medicine, University of Western Ontario, St. Joseph's Health Centre, London, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) and chloroquine (CQ) are antimalarial (AM) medications prescribed for a variety of rheumatic diseases, including systemic lupus erythematosus (SLE). Many patients will remain on these medications for years, and possibly lifelong. HCQ and CQ are associated with irreversible vision loss secondary to retinal toxicity. The prevalence of AM-induced retinopathy varies between studies and few studies have compared prevalence rates between rheumatologic conditions. The purpose of this study was to describe the pattern and risk factors for AM-associated retinopathy.

Methods: A retrospective chart review was conducted at an urban academic Canadian centre after obtaining ethics approval. Each patient was classified as SLE, based on ACR criteria, or non-SLE. The minimum duration of AM therapy was three months. AM-induced retinopathy was classified as possible or definite, which was determined based on characteristic visual field loss, abnormal retinal imaging and eye specialist's opinion. Univariate and multivariate regression analyses were performed to determine factors associated with definite AM-induced retinopathy. Sensitivity analyses included stratification of analysis by diagnosis and by HCQ versus CQ.

Results: A total of 680 patient charts were reviewed of whom 282 patients had SLE and the remaining had rheumatoid arthritis (N=224), cutaneous lupus (N=41) or other connective tissue diseases (N=133). Ninety percent of patients had a baseline eye examination within the first five years of AM treatment, and 74% had regular follow up exams beyond five years. Definite AM-induced retinal toxicity was observed in 12 patients, 11 of whom had SLE and 7 had been prescribed CQ (Figure 1). The earliest diagnosis of toxicity occurred after 5.4 years of AM therapy, and the prevalence beyond five years was 2.7% but increased over time. In univariate analysis (Table 1), a diagnosis of SLE (P=0.008; OR=16.1; 95% CI=[2.1, 125]), the daily weight-based dose of HCQ (P=0.035; OR=1.5; 95% CI=[1.0,

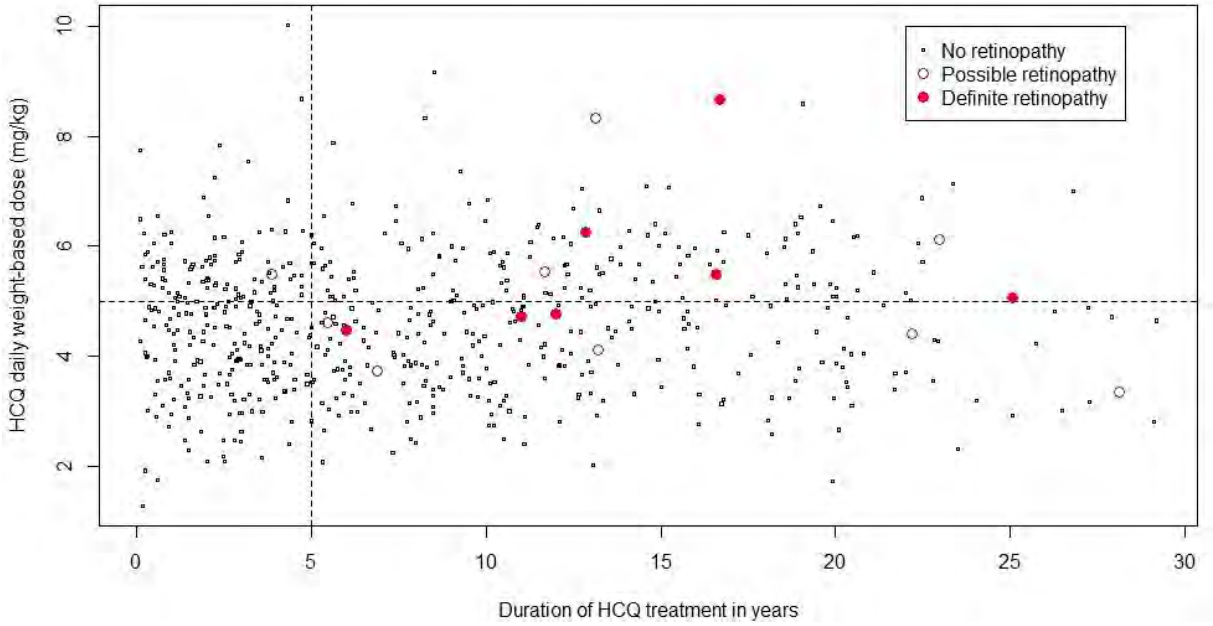
Diabetes	61 (9%)	1 (8%)	0.924	59 (9%)	3 (11%)	0.765

Figure 2: Hydroxychloroquine daily weight-based dose and retinopathy



2.3]), daily weight-based dose of CQ (P< 0.001; OR=1.9; 95% CI=[1.4, 2.6]), and cumulative CQ dosage (P=0.011; OR=5.0; 95% CI=[1.4, 17.3]) were significantly associated with definite AM-induced retinopathy. In multivariate analysis, diagnosis of SLE (P=0.015; OR=13.2; 95% CI=[1.6, 111.3]) and CQ daily weight-based dose (P=0.004; OR=2.0; 95% CI=[1.2, 2.3]) were significantly associated with ocular toxicity after adjusting for CQ/HCQ dosages, age, sex, weight, and renal impairment. When possible retinopathy was included in the univariate analysis, SLE and CQ dosages remained significant (Table 1). Total AM duration and hypertension also had significant associations. Patients prescribed HCQ doses less than the recommended maximum of 5mg/kg/day did develop retinopathy (Figure 2).

Conclusion: The risk of AM-induced retinal toxicity increases after five years of therapy. There may be higher rates of AM-induced retinopathy in SLE patients due to longer duration of treatment, more chloroquine use in this population, and SLE may be an independent risk factor.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Treatment Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Both IL-12 and IL-23 have been implicated in the pathogenesis of SLE. In a phase 2 study, treatment with the anti-IL-12/23 p40 monoclonal antibody ustekinumab (UST) resulted in greater improvement in several SLE disease measures through week (wk) 24 compared with placebo (PBO)[1], and efficacy was maintained through 1 year.[2] Here we report long-term safety and efficacy of ustekinumab through 2 years in patients (pts) with active SLE.

Methods: This was a PBO-controlled phase 2 study in 102 pts with seropositive active SLE (defined by SLICC criteria; SLEDAI score ≥6; ≥1 BILAG A and/or ≥2 BILAG B scores). Pts were randomized (3:2) to UST (~ 6 mg/kg single IV infusion, then 90 mg SC q8w at wk8) or PBO, both added to standard background therapy. Patients receiving PBO crossed over to UST (90 mg SC q8w) at wk24. The majority of pts were eligible to enter a voluntary open-label study extension after wk40; the final UST administration was at wk104. The primary endpoint was SLE Responder Index (SRI)-4 response at wk24. Treatment failure rules and nonresponder imputation were used through wks 24 & 48;[1,2] observed data are reported from week 48 - week 112. Disease flare was defined as ≥1 new BILAG A or ≥2 new BILAG B scores. Safety was assessed through wk120.

Results: 102 pts were randomized at wk0 (UST, n=60; PBO, n=42). The primary endpoint (SRI-4 response rate at wk24) was met,[1] and efficacy was sustained at 1 year.[2] 46 pts entered the extension (UST, n=29; PBO → UST, n=17), 26 pts at wk48, and 20 pts at wk56. SRI-4 response rates were maintained during the extension and were 79% in the UST group and 92% in the PBO → UST group at wk112. In both groups, response rates in joint and skin measures were maintained from wk48 through wk112 (Figures). At wk112, 92% in both the UST and PBO → UST groups had ≥4-point improvement from baseline in SLEDAI-2K score, 79% and 93% had ≥30% improvement from baseline in PGA, 86% and 91% had ≥50% improvement in active joint (pain and inflammation) count, and 79% and 100% had ≥50% improvement in CLASI score. During the extension period, the incidence per 100 pt-years of a BILAG 1A/2B flare was 0 in the PBO → UST group and 1.95 in the UST group. Improvements ≥2.5 points (Minimal Clinically Important Difference [MCID]) in SF-36 PCS scores were observed and maintained from baseline through wk72 (UST group) and at most timepoints from wk40 to wk112 (PBO → UST). No deaths, malignancies, opportunistic infections,

Table. Efficacy at week 112 and adverse events through week 120.

Clinical Efficacy and Health-Related Quality of Life at Week 112		
	PBO → UST	UST
Patients entering study extension, n	17	29
SRI-4	12/13 (92.3)	19/24 (79.2)

Patients with ≥ 1 SAE	4 (9.5)	5 (15.2)	12 (20.0)	17 (18.3)
Serious infections	0	2 (6.1)	7 (11.7)	9 (9.7)
Deaths	0	0	0	0

Data presented as n/N (%) or n (%) unless otherwise noted.
AE = adverse event; CLASI = Cutaneous Lupus Erythematosus Disease Area and Severity Index (response defined as ≥ 50% improvement from baseline in patients with a baseline CLASI activity score ≥4); PGA = Physician's Global Assessment (response defined as ≥ 30% improvement from baseline); SAE = serious adverse event; SF-36 PCS = 36-item short-form survey physical component summary; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000 (response defined as ≥ 4-point improvement from baseline); SRI-4/5/6 = SLE responder index, defined as ≥ 4/5/6-point reduction in SLEDAI-2K total score, no new BILAG A and no more than 1 new BILAG B domain score and no worsening (<10% increase) from baseline in the PGA. Joint response (defined as ≥ 50% improvement from baseline in the number of active joints in patients with ≥4 active joints at baseline).

or tuberculosis cases occurred through week 120. Of 93 pts who received ≥1 dose of UST through wk120, 17 (18%) had a serious AE. Safety events were consistent with the known UST safety profile.

Conclusion: UST provided sustained clinical benefit in global and organ-specific SLE-activity measures through 2 years with safety results consistent with the established profile.

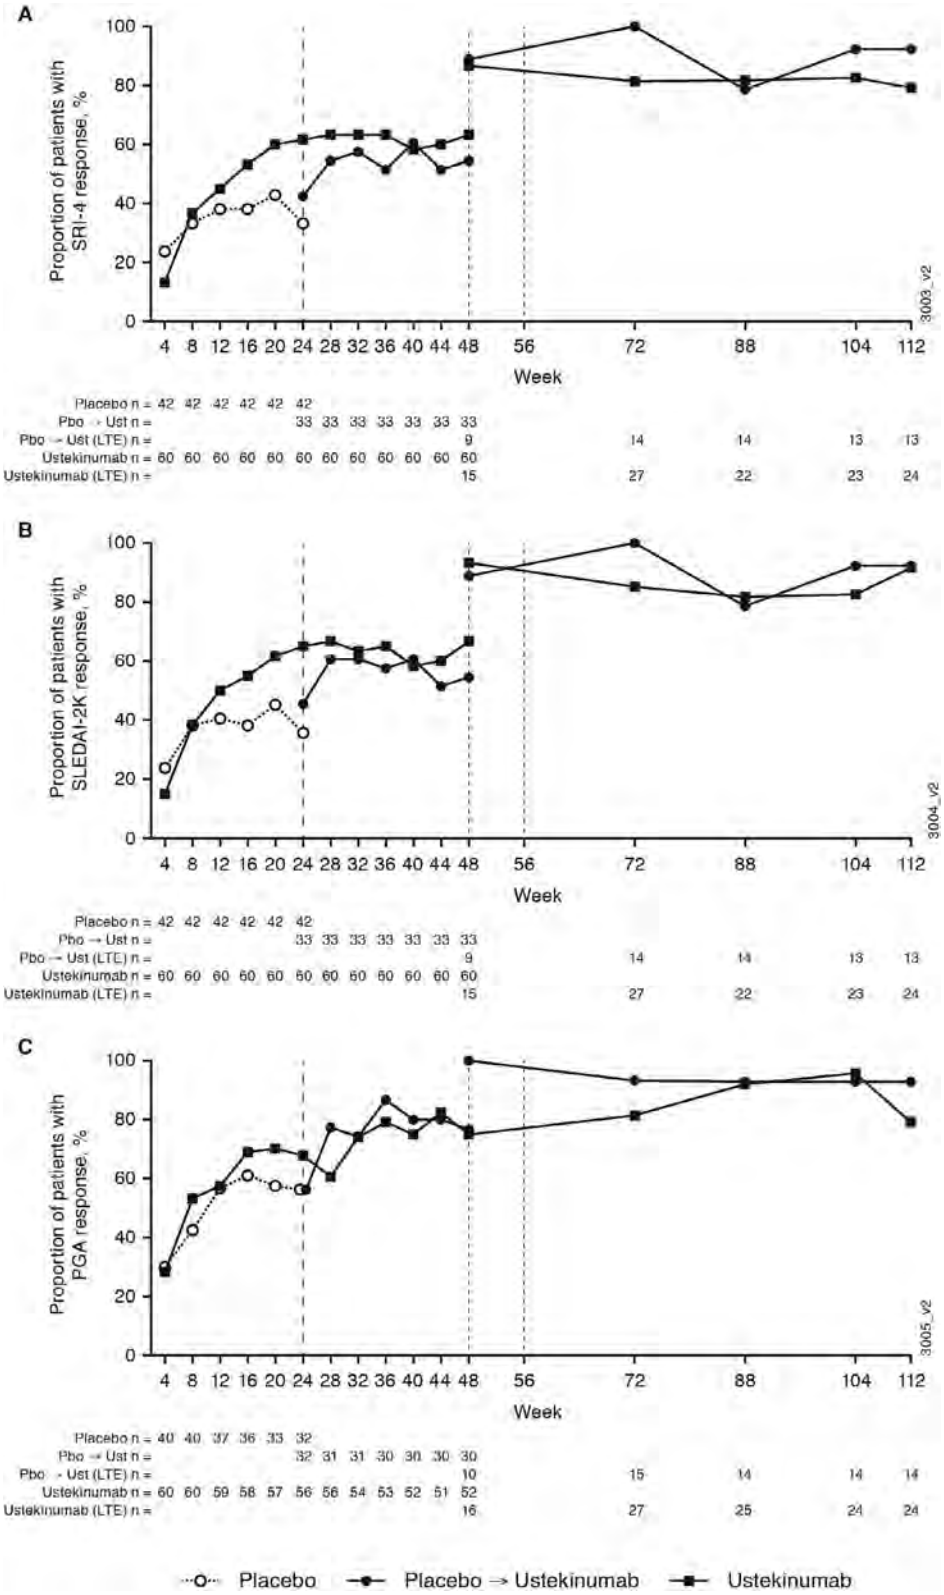

Figure 1. Proportions of patients with SRI-4 (A), SLEDAI-2K (B), and PGA (C) responses through week 112. SRI-4 = SLEDAI-2K responder index, defined as ≥ 4-point reduction in SLEDAI-2K total score, no new BILAG A and no more than 1 new BILAG B domain score and no worsening (<10% increase) from baseline in the PGA. SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000 (response defined as ≥ 4-point improvement from baseline). PGA = Physician's Global Assessment (response defined as ≥ 30% improvement from baseline). The study protocol was amended to add the extension period after the interim analysis, and some patients had already completed or discontinued from the main study. Patients participating in the study extension entered either at Week 48 or Week 56.

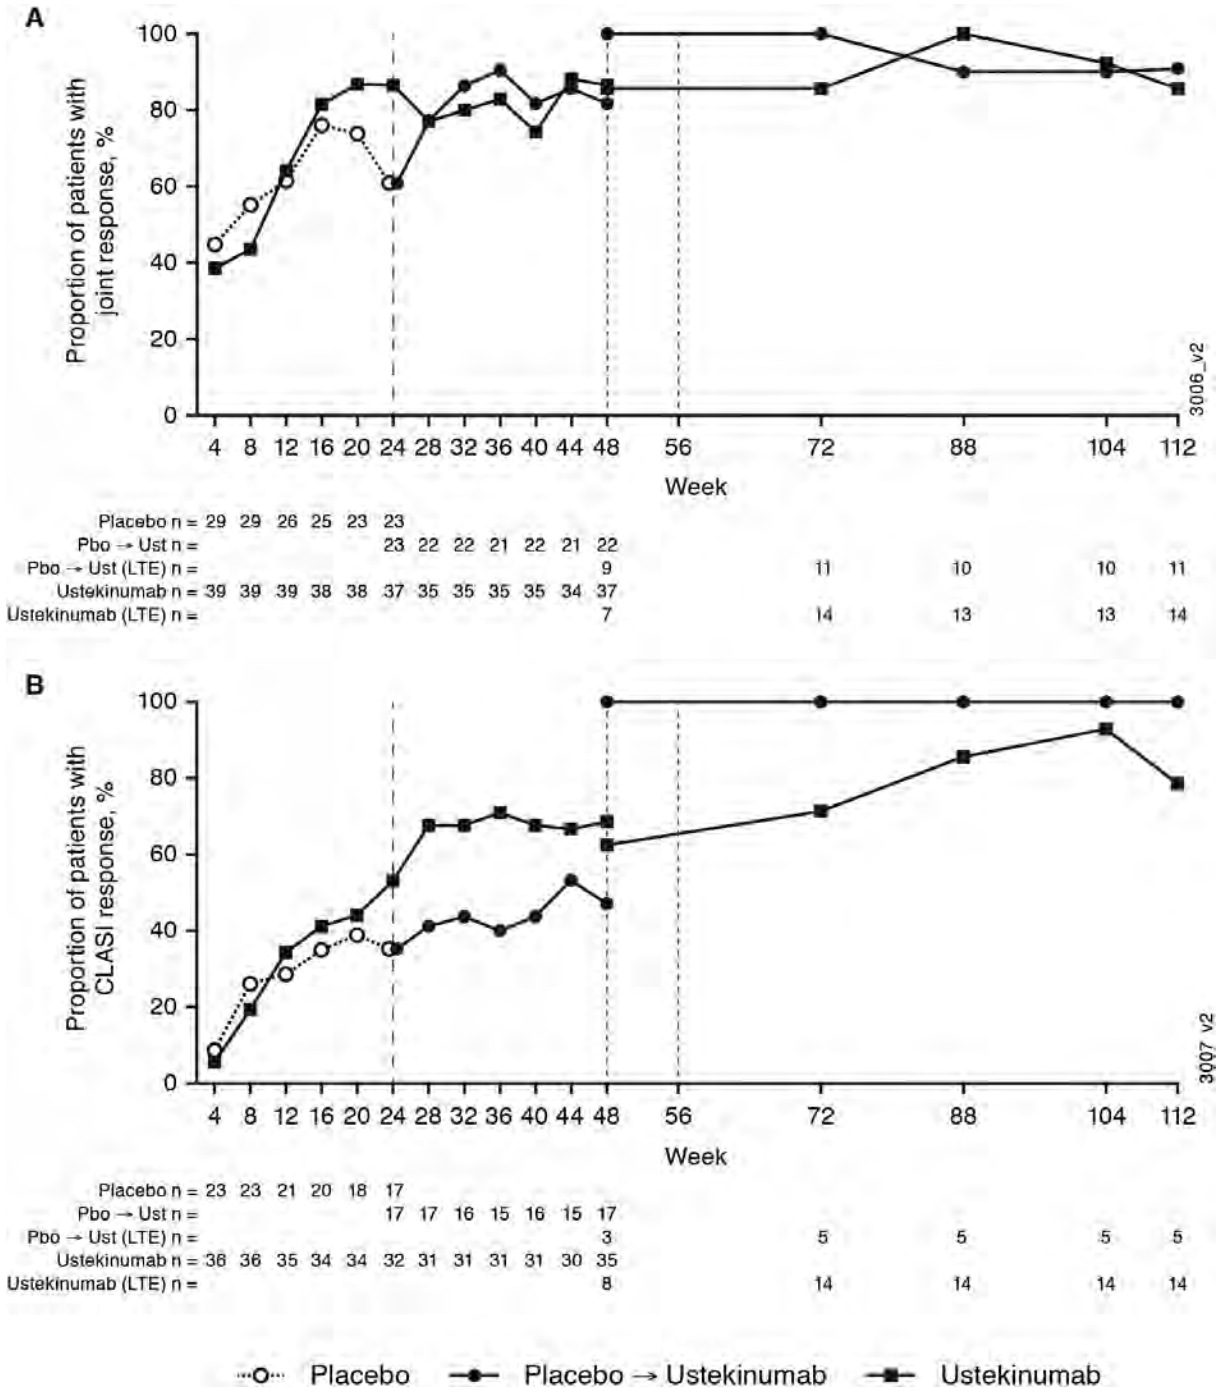

Figure 2. Proportions of patients with joint (A) and CLASI (B) responses. The study protocol was amended to add the extension period after the interim analysis, and some patients had already completed or discontinued from the main study. Patients participating in the study extension entered either at Week 48 or Week 56. Joint response (defined as ≥ 50% improvement from baseline in the number of joints with pain and inflammation [active joints] in patients with ≥4 active joints at baseline). CLASI response (defined as ≥ 50% improvement from baseline in patients with a baseline CLASI activity score ≥4).

Abstract Number: 1827

Flare Reduction and Oral Corticosteroid Taper in Patients with Active SLE Treated with Anifrolumab in 2 Phase 3 Trials

Richard Furie[1], Eric Morand[2], Anca Askanase[3], Ed Vital[4], Joan Merrill[5], Rubana Kalyani[6], Gabriel Abreu[7], Lilia Pineda[6] and Raj Tummala[6], [1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, [2]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, [3]Columbia University College of Physicians and Surgeons, New York, [4]University of Leeds; NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]Oklahoma Medical Research Foundation, Oklahoma City, [6]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, [7]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Objectives of long-term SLE management are not only to reduce disease activity, but also to prevent flares and minimize exposure to oral corticosteroids (OCS), which are associated with organ damage accrual.[1,2] As tapering OCS increases flare risk, a therapy that both prevents flares and permits safe reductions of OCS is desirable. Flare rates were lower in patients with SLE who received anifrolumab vs placebo, and greater numbers of patients were able to taper OCS with anifrolumab vs placebo in the phase 3 trials, TULIP-1 and TULIP-2.[3,4] We evaluated pooled TULIP trial data to further assess the capacity of anifrolumab to simultaneously prevent flares and permit OCS dosage reduction.

Methods: TULIP-1 and TULIP-2 were 52-week trials that evaluated the efficacy and safety of anifrolumab (300 mg IV Q4W for 48 weeks) or placebo in patients with moderately to severely active SLE despite standard-of-care treatment. Flares were defined as ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B domain scores vs the prior visit. Patients receiving OCS ≥10 mg/day at baseline were required to attempt tapering to ≤7.5 mg/day between Weeks 8 and 40; this reduction had to be sustained through Week 52. TULIP-1 and TULIP-2 were analyzed using restricted medication rules per the TULIP-2 protocol, and data from both trials were pooled. We analyzed flare occurrence in all patients, area under the curve (AUC) of OCS dosage among patients on OCS ≥10 mg/day at baseline, and flare rates among patients on OCS ≥10 mg/day at baseline who were able to sustain OCS dosage reduction to ≤7.5 mg/day from Week 40 to Week 52.

Results: Overall, 360 patients received anifrolumab and 366 received placebo. In total, fewer patients had ≥1 flare with anifrolumab vs placebo (33.6% vs 42.9%) (**Table 1**). In pooled TULIP data, 375/726 (51.7%) patients were taking OCS ≥10 mg/day at baseline; among these patients, OCS cumulative dosage through Week 52 was reduced with anifrolumab vs placebo (mean [SD] AUC 3947.1 mg [3655.5] vs 4275.8 mg [1859.0]). Among patients who were able to sustain OCS taper to ≤7.5 mg/day, fewer experienced ≥1 flare through Week 52 with anifrolumab vs placebo in

Patients with flare, n (%)	Placebo (n=366)	Anifrolumab 300 mg (n=360)
0	209 (57.1)	239 (66.4)
≥1	157 (42.9)	121 (33.6)
1	89 (24.3)	74 (20.6)
2	49 (13.4)	28 (7.8)
≥3	19 (5.2)	19 (5.3)

A flare was defined as ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B items compared with the prior visit.

Table 1. Number of Flares Through Week 52 in Pooled Data From the TULIP-1 and TULIP-2 Trials

Trial and treatment group (n=patients with OCS ≥10 mg/day at baseline)	Flares through Week 52	Sustained OCS dosage reduction from Weeks 40 to 52	
		Yes	No
TULIP-1			
Placebo (n=102)	No flares, n (%)	20 (58.8)	31 (45.6)
	≥1 flare, n (%)	14 (41.2)	37 (54.4)
	Total, n	34	68
Anifrolumab (n=103)	No flares, n (%)	41 (80.4)	24 (46.2)
	≥1 flare, n (%)	10 (19.6)	28 (53.8)
	Total, n	51	52
TULIP-2			
Placebo (n=83)	No flares, n (%)	12 (48.0)	30 (51.7)
	≥1 flare, n (%)	13 (52.0)	28 (48.3)
	Total, n	25	58
Anifrolumab (n=87)	No flares, n (%)	35 (77.8)	23 (54.8)
	≥1 flare, n (%)	10 (22.2)	19 (45.2)
	Total, n	45	42
Pooled TULIP			
Placebo (n=185)	No flares, n (%)	32 (54.2)	61 (48.4)
	≥1 flare, n (%)	27 (45.8)	65 (51.6)
	Total, n	59	126
Anifrolumab (n=190)	No flares, n (%)	76 (79.2)	47 (50.0)
	≥1 flare, n (%)	20 (20.8)	47 (50.0)
	Total, n	96	94

OCS, oral corticosteroid.
Sustained OCS dosage reduction was defined as OCS dosage of ≤7.5 mg/day achieved by Week 40 and sustained to Week 52. OCS are described as "prednisone or equivalent." OCS administered when necessary are not considered in the calculation of the daily dose. Flares were defined as ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B domain scores vs the prior visit. Overall patient n values, TULIP-1: anifrolumab, n=180; placebo, n=184; TULIP-2: anifrolumab, n=180; placebo, n=182. Randomization in TULIP-1 and TULIP-2 was stratified by OCS dosage (<10 vs ≥10 mg/day), SLEDAI-2K score (<10 vs ≥10), and type I interferon gene signature (high vs low).

Table 2. Flares and Sustained OCS Dosage Reduction at Week 52 in Patients With OCS ≥10 mg/day at Baseline in TULIP-1, TULIP-2, and Pooled Data

pooled data (20.8% vs 45.8%) (**Table 2**). In contrast, in patients who were not able to taper OCS, there was no difference in the flare rates between anifrolumab and placebo (50.0% vs 51.6%). Overall, with anifrolumab, 76/190 (40.0%) patients were able to taper OCS without experiencing a flare through 52 weeks, compared with only 32/185 (17.3%) with placebo in pooled data.

Conclusion: In the phase 3 TULIP-1 and TULIP-2 trials, compared with placebo, anifrolumab was associated with reduced OCS cumulative dosage and, among patients who were able to taper and sustain OCS dosage to ≤7.5 mg/

day to Week 52, a >2-fold reduction in flares. TULIP data support the capacity of anifrolumab to reduce flares while permitting the tapering of OCS, an important management goal for patients with SLE.

Abstract Number: 1828

Comprehensive Efficacy of Anifrolumab Across Organ Domains in Patients with Active SLE: Pooled Data from 2 Phase 3 Trials

Eric Morand[1], Richard Furie[2], Ian Bruce[3], Ed Vital[4], Maria Dall'Era[5], Emmanuelle Maho[6], Lilia Pineda[7] and Raj Tummala[7], [1]Monash University, Melbourne, Australia, [2]Zucker School of Medicine at Hofstra/Northwell, Great Neck, [3]Centre for Epidemiology Versus Arthritis, The University of Manchester and NIHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [4]University of Leeds; NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]Division of Rheumatology, University of California, San Francisco, CA, [6]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom, [7]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a heterogeneous autoimmune disease with clinical manifestations across multiple organ systems. In the phase 3 TULIP-1 and TULIP-2 trials, anifrolumab treatment resulted in greater percentages of patients with SLE achieving a BILAG-based Composite Lupus Assessment (BICLA) response vs placebo at Week 52.[1,2] We further evaluated the effects of anifrolumab on organ domain–specific SLE disease activity using pooled data from TULIP-1 and TULIP-2.

Methods: TULIP-1 and TULIP-2 were 52-week, randomized, double-blind, placebo-controlled trials that evaluated the efficacy and safety of anifrolumab (300 mg IV every 4 weeks for 48 weeks) in patients with moderately to severely active SLE despite standard-of-care treatment. Using pooled data, we compared BILAG-2004 and SLEDAI-2K responses across individual organ domains in patients receiving anifrolumab vs placebo. Organ improvement was

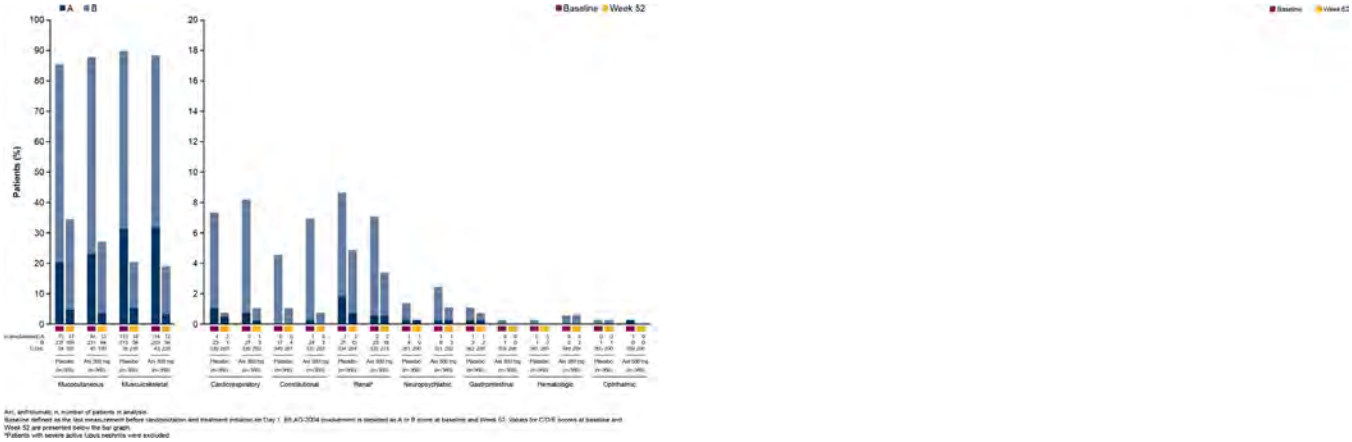

Figure 1. BILAG-2004 Organ Involvement at Baseline and Week 52 for Patients With SLE Receiving Anifrolumab or Placebo in Pooled Data From the TULIP-1 and TULIP-2 Trials

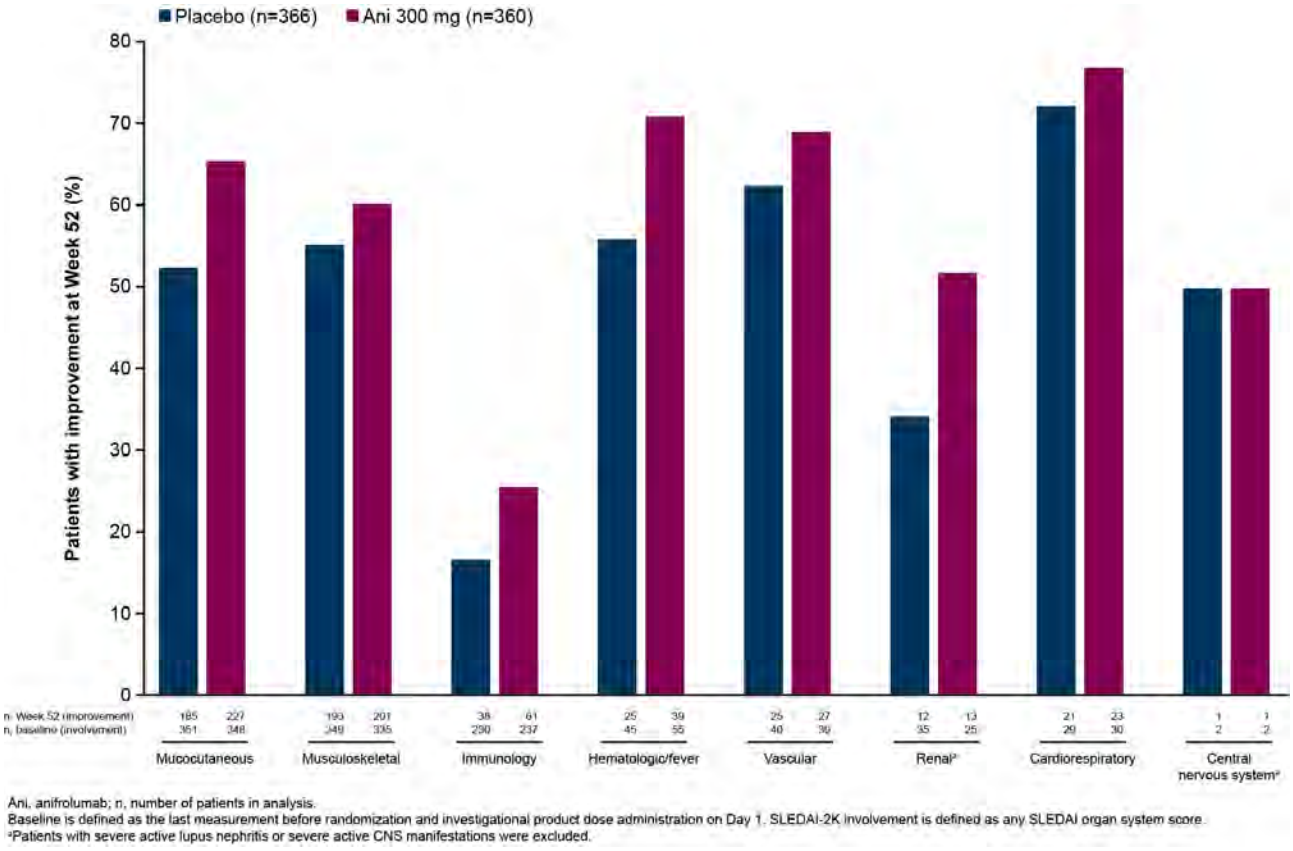

Figure 2. SLEDAI-2K Organ Improvement at Week 52 for Patients With SLE Receiving Anifrolumab or Placebo in Pooled Data From the TULIP-1 and TULIP-2 Trials

defined as a reduction in baseline BILAG-2004 or SLEDAI-2K organ domain scores and was assessed at Week 52. Tender and swollen joint counts were recorded, and an improvement was defined as a reduction of ≥50% from baseline in counts of both tender and swollen joints.

Results: In total, 360 patients received anifrolumab and 366 received placebo. The percentages of patients with BILAG-2004 A or B and SLEDAI-2K organ domain scores at baseline were generally similar between treatment groups across all organ domains. The most frequently affected organ domains at baseline were mucocutaneous and

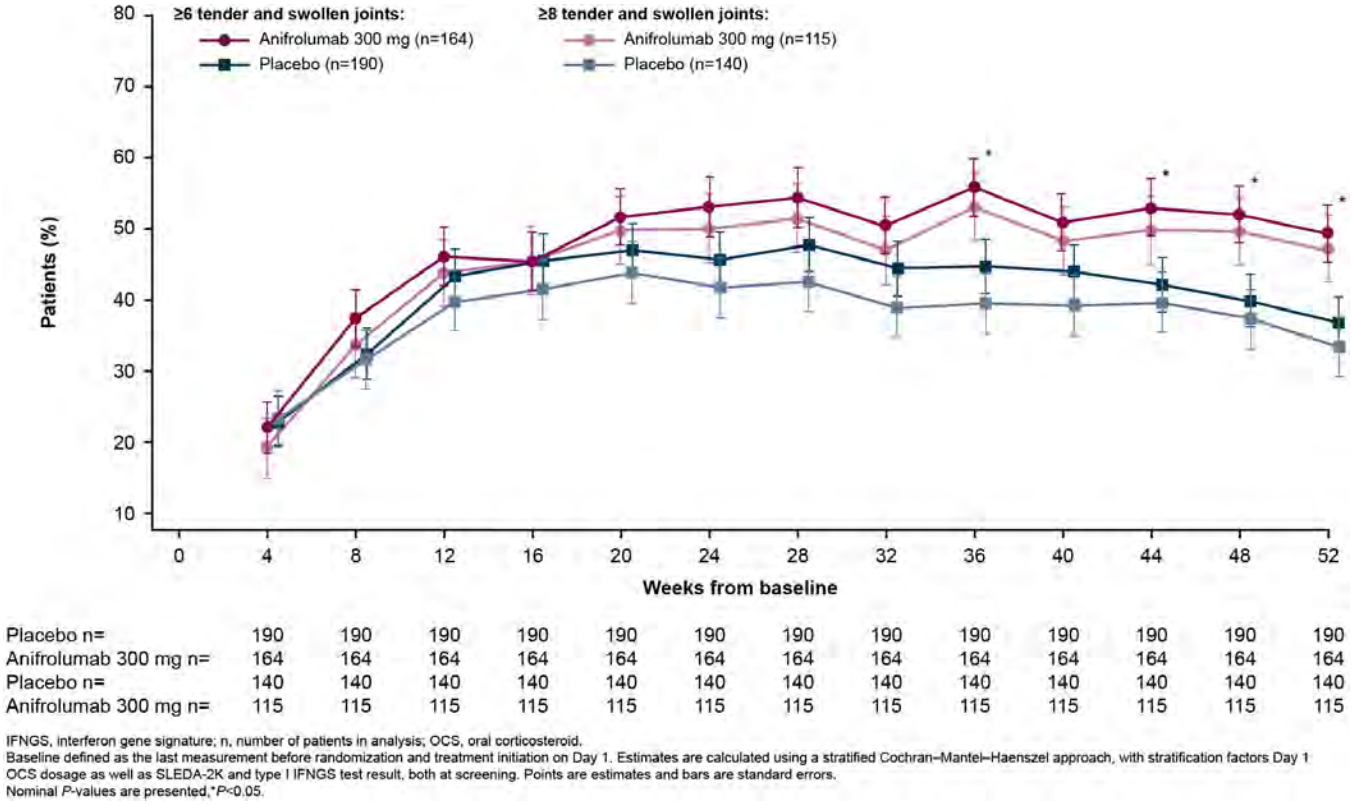

Figure 3. Percentage of Patients Who Achieved ≥50% Reductions in Baseline Tender and Swollen Joint Counts Over Time in Patients With ≥6 and ≥8 Tender and Swollen Joints at Baseline in Pooled Data From the TULIP-1 and TULIP-2 Trials

musculoskeletal by both BILAG-2004 and SLEDAI-2K, and immunology by SLEDAI-2K. Baseline BILAG-2004 A or B scores occurred less frequently in the cardiorespiratory, constitutional, renal, neuropsychiatric, gastrointestinal, hematologic, and ophthalmic domains, and baseline SLEDAI-2K activity was less frequent in the hematologic, fever, vascular, renal, cardiorespiratory, and central nervous system domains. At Week 52, a greater number of patients treated with anifrolumab vs placebo had improvements in the mucocutaneous and musculoskeletal domains by both BILAG-2004 and SLEDAI-2K (**Figures 1** and **2**). Improvements were also observed in the majority of less frequently affected domains (**Figures 1** and **2**). Higher percentages of patients treated with anifrolumab vs placebo achieved ≥50% reductions in baseline tender and swollen joint counts at Weeks 36, 44, 48, and 52 in those with baseline tender and swollen joint counts of ≥6 and ≥8 (**Figure 3**).

Conclusion: Higher percentages of patients treated with anifrolumab compared with placebo had improved BILAG-2004 and SLEDAI-2K domain scores at Week 52 in the 2 most frequently affected domains (mucocutaneous and musculoskeletal) and in less frequently affected domains, as well as reductions in arthritis scores. These data provide evidence of the benefit of anifrolumab across multiple organ domains in patients with active SLE.

Abstract Number: 1829

Lupus Disease Activity After Cessation of Anifrolumab Treatment During the Phase 2b MUSE Trial Follow-up Period

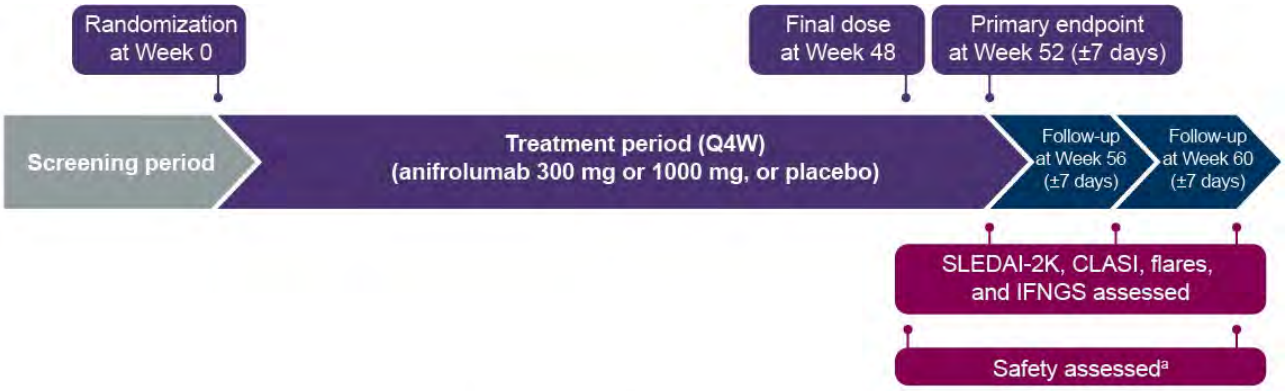
Richard Furie[1], Kenneth Kalunian[2], Joan Merrill[3], Gabriel Abreu[4] and Raj Tummala[5], [1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, [2]School of Health Sciences, University of California, La Jolla, [3]Oklahoma Medical Research Foundation, Oklahoma City, [4]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [5]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In the randomized, double-blind, phase 2b MUSE trial, anifrolumab reduced disease activity vs placebo across multiple endpoints in patients with moderately to severely active SLE.[1] Here, we assess changes in disease activity and safety in patients after cessation of anifrolumab treatment during the follow-up period in MUSE.

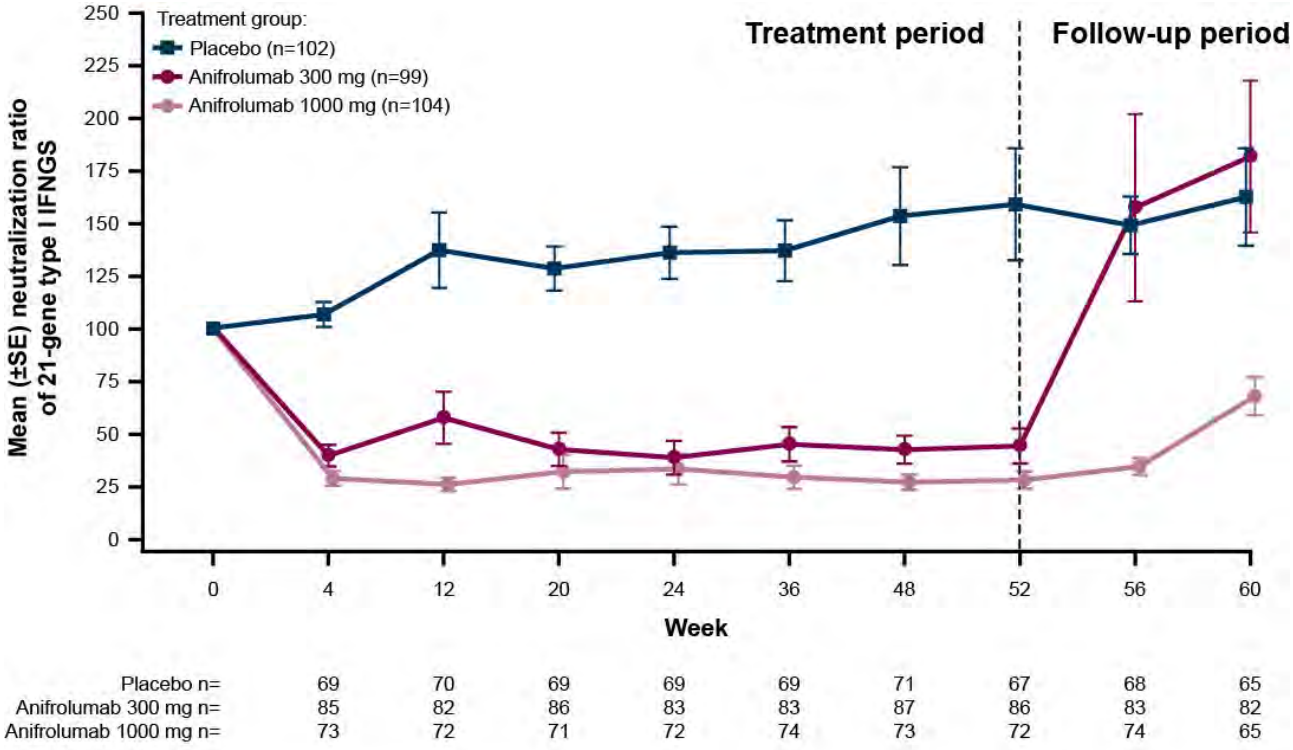
Methods: Patients were randomized 1:1:1 to receive placebo or anifrolumab 300 or 1000 mg IV every 4 weeks (wks). The final study dose was at Wk 48, and key efficacy endpoints were assessed at Wk 52. After receiving the final dose of study medication, patients were required to complete a follow-up period during which visits were conducted every 4 wks (±7 days) (**Figure 1**). Disease activity (measured with SLEDAI-2K and BILAG-2004 global scores, and Cutaneous Lupus Erythematosus Disease Area and Severity Index [CLASI] activity score), flares (defined as either ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B domain scores), adverse events (AEs), and 21-gene type I IFN gene signatures (IFNGS) were assessed. Disease activity scores, flares, and IFNGS were assessed over 8 wks from Wk 52 through Wk 60, and safety was evaluated over 12 wks from Wk 48 through Wk 60 or upon study discontinuation.

Results: Of 305 patients randomized in MUSE, 229 completed the last study visit (Wk 52): 86, 75, and 68 in the anifrolumab 300-mg, 1000-mg, and placebo groups, respectively. From Wk 52 to the end of the follow-up period (Wk 60), mean SLEDAI-2K global scores increased in patients ceasing treatment of anifrolumab 300 mg (mean change: 0.7) and 1000 mg (0.3), but not placebo (–0.1) (**Table 1**). A numeric worsening was also observed in mean BILAG-2004 global scores in patients ceasing anifrolumab 300-mg treatment (mean change: 2.4) vs placebo (0.8); in the 1000-mg group, mean change was 0.7. Of the various domains, worsening activity scores were most frequently observed in the mucocutaneous and musculoskeletal domains. Overall, 15.2% and 6.7% of patients ceasing treatment of anifrolumab 300 or 1000 mg, respectively, had ≥1 BILAG flare from Wk 52 through Wk 60 vs 2.0% with placebo. Mean CLASI activity scores increased slightly from Wk 52 to Wk 60 across the anifrolumab 300-mg (mean change: 0.4), 1000-mg (0.4), and placebo groups (0.5). From Wk 52 to Wk 60, IFNGS expression increased more rapidly in the anifrolumab 300-mg group vs the 1000-mg group, with negligible changes in the placebo group (**Figure 2**). AEs during the 12-wk safety follow-up period were similar between the anifrolumab 300-mg and 1000-mg vs placebo groups (≥1 AE: 29.3% and 26.7% vs 24.8%; ≥1 serious AE: 3.0% and 3.8% vs 5.0%).



CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; IFNGS, type I interferon gene signature; Q4W, every 4 weeks.
[a]Safety also assessed after final dose upon study discontinuation.

Figure 1. Trial Design for MUSE



IFNGS, type I interferon gene signature; n, number of nonmissing values; SE, standard error.

Figure 2. Change in Neutralization Ratio of the 21-Gene Type I IFNGS From Start of the MUSE Trial to End of Follow-up (Week 60)

Conclusion: No new or unexpected safety findings were observed in the MUSE follow-up period. There was a larger numeric worsening of disease activity in patients ceasing anifrolumab compared with placebo. A rebound in IFNGS was observed in patients previously treated with anifrolumab; this effect was more apparent with 300 vs 1000 mg. An analysis is underway evaluating the relationship between changes in IFNGS and disease activity.

Disease activity measure		Placebo (n=66)	Anifrolumab 300 mg (n=84)	Anifrolumab 1000 mg (n=73)
SLEDAI-2K score	Week 52, mean	5.9	4.3	3.8
	Week 60, mean	5.8	5.0	4.1
	Mean (SD) change[a]	−0.1 (2.4)	0.7 (3.5)	0.3 (2.3)
BILAG-2004 score	Week 52, mean	8.3	6.0	5.9
	Week 60, mean	9.1	8.5	6.6
	Mean (SD) change[a]	0.8 (3.8)	2.4 (6.7)	0.7 (5.3)
CLASI activity score	Week 52, mean	3.5[b]	1.9	1.8
	Week 60, mean	4.0[b]	2.4	2.2
	Mean (SD) change[a]	0.5 (2.3)[b]	0.4 (1.9)	0.4 (2.0)

CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; SD, standard deviation.
Values rounded to 1 decimal place; n varied between analyses depending on available data.
[a]Mean change may not equal difference between Week 52 and 60 owing to rounding; [b]n=65.

Table 1. Mean Change in SLEDAI-2K, BILAG-2004, and CLASI Activity Scores From MUSE Trial Efficacy Endpoint (Week 52) to End of Follow-up (Week 60)

Abstract Number: 1830

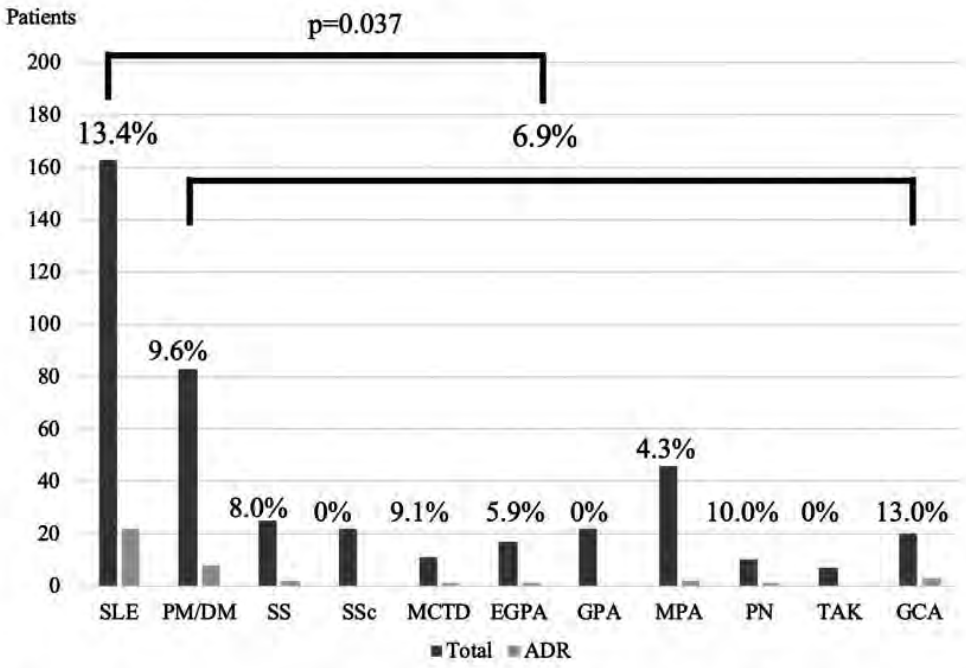
Adverse Drug Reactions to Trimethoprim-sulfamethoxazole as a Prophylactic Agent Against Pneumocystis Pneumonia in Patients with Systemic Lupus Erythematosus: anti-Sm Antibody as a Possible Risk Factor

Shinji Izuka[1], Hiroyuki Yamashita[2], Yuko Takahashi[2] and Hiroshi Kaneko[2], [1]Devision of Rheumatic Disease, National Center for Global Health and Medicine, Toshima-Ku, Tokyo, Japan, [2]Devision of Rheumatic Disease, National Center for Global Health and Medicine, Shinjuku, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Pneumocystis pneumonia (PCP) is a life-threatening infection in immunocompromised patients, including those with connective tissue diseases (CTDs), treated with corticosteroids or immunosuppressive

Figure: Prevalence of ADRs caused by TMP-SMX.



ADR; adverse drug reaction, SLE; systemic lupus erythematosus, PM; polymyositis, DM; dermatomyositis, SS; Sjögren syndrome, SSc; systemic sclerosis, MCTD; mixed connective tissue disease, GPA; granulomatosis with polyangiitis, EGPA; eosinophilic granulomatosis with polyangiitis, MPA; microscopic polyangiitis, PN; polyarteritis nodosa, TAK; Takayasu arteritis, GCA; giant cell arteritis.

agents. Trimethoprim-sulfamethoxazole (TMP-STX) is widely used as a prophylactic agent against PCP. Although its efficacy is well-established, TMP-STX may cause adverse drug reactions (ADRs) among patients with CTDs. Previous studies showed that patients with systemic lupus erythematosus (SLE) are at high-risk of ADRs to TMP-SMX, but the prevalence varies among studies and the difference in risks between patients with SLE versus other CTDs is unclear. We examined the prevalence of ADRs to TMP-STX among patients with SLE and other CTDs, and identified specific risk factors for ADRs in SLE.

Methods: The in-patient database of our hospital was examined, and the records of CTD patients administered TMP-STX as a prophylactic agent against PCP between January 2009 and April 2020 were reviewed retrospectively. Baseline data were obtained at the time of TMP-STX initiation. Patients with human immunodeficiency virus, and those who did not suffer ADRs but who received TMP-SMX within 1 month, were excluded. ADR prevalence was compared between SLE patients and those with other CTDs. Univariate and multivariate analyses were conducted to identify the risk factors for ADRs in SLE patients.

Results: Among 427 patients with CTDs (SLE, n = 164; polymyositis or dermatomyositis, n = 83; Sjögren syndrome, n = 25; systemic sclerosis, n = 22; mixed connective tissue disease, n = 11; eosinophilic granulomatosis with polyangiitis, n = 17; granulomatosis with polyangiitis, n = 22; microscopic polyangiitis, n = 46; polyarteritis nodosa, n = 10; Takayasu arteritis, n = 7; giant cell arteritis, n = 20), 40 patients (9.4%) developed ADRs (thrombocytopenia, n = 10; skin rash, n = 9; liver function test abnormality, n = 7; fever, n = 7; others, n = 12). The prevalence of ADRs in SLE patients was 13.4% and 6.9% in control group. The odds ratio (OR) of an ADR for SLE patients was 2.12 (95% con-

Table. Risk factors for ADRs due to TMP-SMX in SLE patients

	ADRs (n = 22)	Non-ADRs (n = 142)	p value
Age, years [IQR]	39.5[27-50]	40.5[30-62]	0.35
Sex, Female (%)	19(86.3)	99(79.2)	0.13
Specific antibody			
anti-dsDNA (%)	15/22 (68.2)	79/139 (56.8)	0.36
anti-Sm (%)	13/22 (59.1)	28/125 (20.7)	<0.001
anti-RNP (%)	14/21 (66.7)	48/125 (38.4)	0.018
anti-Ro/SS-A (%)	16/22 (72.8)	66/137 (48.2)	0.039

fidence interval (CI) 1.05–4.35, p=0.037). By contrast, the ORs of ADRs for all other CTDs did not differ significantly. Univariate analyses of SLE patients revealed that positivity for anti-Sm antibody (OR 5.44, 95% CI 1.93–16.06, p< 0.001), anti-RNP antibody (OR 3.19, 95% CI 1.11–10.02, p = 0.018) and anti-Ro/SS-A antibody (OR 2.87, 95% CI 1.06–7.77, p = 0.039) was significantly associated with ADRs. In the multivariate analyses, only anti-Sm antibody was significantly associated with ADRs in SLE patients (OR 3.34, 95% CI 1.10–11.10, p = 0.048).

Conclusion: SLE patients prophylactically administered TMP-STX are at high risk of ADRs. In particular, anti-Sm antibody positivity was significantly associated with ADR. SLE patients showing anti-Sm antibody, anti-RNP antibody, or anti-Ro/SS-A antibody positivity who receive prophylactic TMP-SMX should be especially carefully monitored for ADRs.

Biomarkers Linked to Anti-IFN-I and Ustekinumab Suggest Distinct Mechanism of Action in Systemic Lupus Erythematosus

Thomas Dörner[1], George Tsokos[2], Kenneth Kalunian[3], Ronald van Vollenhoven[4], Ashley Orillion[5], Matteo Cesaroni[5], Jacqueline Benson[6], Marc Chevrier[7], Shawn Rose[8], Stanley Marciniak[5], Zhenling Yao[5], Bhaskar Srivastava[5], Jessica Schreiter[5], Frédéric Baribaud[5], Tatiana Ort[5], Jarrat Jordan[5] and Loqmane Seridi[5], [1]DRFZ and Charité University Hospitals, Berlin, Germany, [2]Division of Rheumatology & Clinical Immunology/Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, MA, [3]University of California San Diego, La Jolla, CA, [4]Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands, [5]Janssen Research & Development, LLC, Spring House, PA, [6]Janssen Research & Development, LLC, South San Francisco, CA, [7]Janssen Research & Development, LLC, Collegeville, PA, [8]Janssen Research & Development, LLC, Princeton Junction, NJ

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical and biological heterogeneity pose a significant hurdle in SLE, making biomarkers that define patient subsets crucial for developing tailored therapies. Interventional SLE trials using inhibitors of the IL-12/ IL-23 and type I interferon (IFN-I) pathways revealed gene signatures linked with each mechanism. We reported that response to the IL-12/IL-23 p40 inhibitor (Ustekinumab, UST) associates with baseline expression of a cytotoxic-cell associated gene signature (CTS). IFN-I gene signature (IGS) may serve as a patient selection tool and pharmacodynamic biomarker for IFN-I inhibitors. Here, we examined the expression of IGS and CTS signatures in two SLE trials:

UST Ph2 (NCT02349061) and JNJ-839, anti-IFN-α/ω antagonist, Ph1B (NCT02609789) to test whether the CTS association with response was specific to the mechanism of action of UST.

Methods: We conducted Gene Set Variation Analysis (GSVA) of CTS and IGS on whole blood transcriptomes from moderate-to-severe SLE patient samples collected in two distinct randomized, double-blind, placebo (PBO)-controlled trials (UST Ph2 [N=102] and JNJ-839 Ph1B [N=28]). In UST Ph2, patients were randomized (3:2) to receive UST IV ~6 mg/kg or PBO at Week 0, then UST SC ~90 mg or PBO every 8 weeks. In JNJ-839 Ph1B, IFN positive patients were randomized (3:1) to receive JNJ-839 IV 10 mg/kg or PBO every 2 weeks. Clinical response was defined by SLE Responder Index (SRI)-4 at Week 24 and Day 100, respectively.

Results: Unlike in UST Ph2, where CTS was lower at baseline in UST-nonresponders (NR) compared to UST-responders (R) (p=0.0087), CTS expression did not correlate with response to, nor was it modulated by JNJ-839. UST did not modulate IGS, and the treatment effect (difference in response rate UST vs. PBO) was similar between IFN-I high and IFN-I low patients. IGS expression was comparable in JNJ-839-R and JNJ-839-NR at baseline and rapidly decreased after JNJ-839 treatment and throughout the dosing period (Day 1-71). After the last dose, JNJ-839-R exhibited durable IGS suppression through Day 86 before returning to baseline levels and was comparable to levels observed in patients receiving PBO at Day 130. In contrast, JNJ-839-NR IGS levels rapidly reached PBO levels by Day 79.

Conclusion: Biomarkers linked to UST response did not associate with anti-IFN-α/ω response in SLE. Likewise, IFN-I pathway biomarkers did not specifically associate with UST response. These data support a distinct mechanism of action between UST and agents targeting IFN-I and provide a foundation for future biomarker response-based studies using additional therapies in SLE.

Barriers to Medication Adherence and Degree of Nonadherence in a Systemic Lupus Erythematosus Outpatient Population

Courtney Hardy[1], Dafna Gladman[2], Jiandong Su[3], Nathalie Rozenbojm[4] and Murray Urowitz[5], [1]University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [4]University Health Network, Toronto, ON, Canada, [5]University Health Network, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been reported that 50% to 75% of patients with SLE do not adhere to their medications. However, the reasons for nonadherence are not clear. We aimed to estimate the level of medication adherence and barriers to adherence among patients attending the Lupus Clinic.

Methods: Patients taking at least one medication to treat SLE including antimalarials, immunosuppressives, or steroids were included. All patients satisfied the ACR classification criteria for SLE. Adherence was measured using the Medication Adherence Self-Report Inventory (MASRI). Patients were defined as nonadherent with adherence rates < 80% or sufficiently adherent with adherence rates ≥ 80%, based on the MASRI visual analog scale (VAS). Pill counts

**P-value represents differences between groups from all five categories of responses (strongly agree, agree, neither agree nor disagree, disagree, strongly disagree)

Table 2. Barriers to Adherence

were conducted in a proportion of participants. Barriers to medication adherence were identified using the Identification of Medication Adherence Barriers Questionnaire (IMAB-Q).

Descriptive statistics were used.

Results: A total of 94 patients were recruited to the study and 28 pill counts were conducted. Ten patients were classified as nonadherent and 84 patients as sufficiently adherent. There were no statistically significant differences between groups in terms of demographics. The mean age of participants was 46.6 years, female: male ratio was approximately 9:1, mean disease duration was 18.0 years, mean SLEDAI score was 3.1, and mean SLICC score was 1.6. Forty-five percent of patients were taking steroid, 77.7% antimalarial, and 55.3% immunosuppressive medications. Eighty-eight percent of patients were taking at least one medication for non-SLE conditions (Table 1).

The mean medication adherence rate for the SLE patients was 90.7%, based on the MASRI VAS. Adherence rates were corroborated by pill counts. Important barriers to medication adherence reported by nonadherent patients were: concern about harmful medication side effects (50%), being easily distracted from taking medications as prescribed (50%), life getting in the way of taking medications as prescribed (50%), being unsure or disagreeing that their condition will worsen without taking medications as prescribed (50%), and having personal reasons for not taking medications as prescribed (50%). Patients defined as nonadherent reported significantly more barriers to medication adherence than patients defined as sufficiently adherent, based on IMAB-Q total scores ($p < 0.001$). Specific barriers to medication adherence that were experienced by nonadherent participants significantly more often ($p < 0.001$), included: being easily distracted from taking medications as prescribed, remembering to take medications as prescribed, having system(s) in place to help manage medications, taking medications as prescribed not fitting in their daily routine, not prioritizing or having the intention to take medications as prescribed, and having personal reasons for not taking medications as prescribed (Table 2).

Conclusion: The adherence rate in our population was higher than expected, reaching 90% on the MASRI, confirmed by pill count. A number of barriers to medication adherence were identified. These barriers to medication adherence need to be addressed on an individualized basis to improve patient outcomes.

Abstract Number: 1833

Hydroxychloroquine and Vitamin D Both Reduce Proteinuria in SLE

Michelle Petri[1], Jessica Li[2] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) and vitamin D are both immunomodulators in SLE, but work through different mechanisms. Hydroxychloroquine has been proven to triple renal response to mycophenolate in membranous nephritis (Lupus 2006;15: 366–70) and may reduce end stage renal disease (Arthritis Rheum

	Proteinuria		Persistent renal insufficiency		Proteinuria or persistent renal insufficiency	
	OR (95% CI)	p-value	OR (95% CI)	p-value	OR (95% CI)	p-value

Effect of vitamin D and hydroxychloroquine on proteinuria, within person analysis using GEE.

2009;61:830–39). Vitamin D reduces proteinuria in SLE (Arthritis Rheum 2013;65:1865–71) and in other renal diseases as well. We asked whether these effects were synergistic or additive.

Methods: SLE patients met revised ACR or SLICC classification criteria: 332 patients with biopsy-proven lupus nephritis (89% female, 54% African-American, 28% Caucasian) also had subsequent measurements of HCQ blood levels (method of Füzéry et al. Clin Chim Acta 2013;421:79–84) at the visits. After removing visits that had a large gap of more than 1 year, there were 324 patients with 3,444 visits. The number of HCQ blood level measures per patient ranged from 1 to 34 with a median of 11 measures. Generalized estimating equations (GEE) were used to look at the relationship between proteinuria (by urine pr/cr) and HCQ blood levels at the same visit, accounting for repeated measures in the same person. A conditional logistic regression was used to perform a "within-person" analysis to

look at the renal outcomes more closely. In this analysis, each person served as his/her own control, by comparing visits with increased proteinuria to visits with less proteinuria with respect to mean HCQ blood level.

Results: There were no significant differences between mean HCQ blood levels and sex (p=0.7166), ethnicity (p=0.5402), or mean body mass index (r=-0.02, p=0.6970), but significant results were observed for age (r=0.19, p=0.006). Using GEE models which account for repeated measures from the same person, the effects of vitamin D and of HCQ blood level on proteinuria were still significant after adjusting for each other (Table 3). However, the effect of HCQ blood level diminished (borderline significance) after further adjustment for sex, age, and race. Vitamin D appeared to be the stronger predictor of proteinuria. Because the probability of proteinuria changed for HCQ levels when vitamin D level was below or above approximately 20 ng/ml, we looked at the effects of HCQ blood levels on proteinuria stratifying by vitamin D levels. Results were adjusted for repeated measures in patients. There was no evidence of an association between HCQ blood levels and proteinuria if vitamin D was below 20 (OR 1.02, 95% CI 0.98, 1.07). When vitamin D levels were >=20, there was a reduced risk of proteinuria with higher HCQ blood levels (OR 0.97, 95% CI 0.95, 0.99, p=0.009).

Conclusion: Although both HCQ and vitamin D reduce proteinuria, in multivariate GEE models, vitamin D had the more important benefit. When vitamin D levels were >= 20 ng/mL, there was reduced proteinuria with higher HCQ blood levels. In clinical practice and in randomized clinical trials, prescribed HCQ and vitamin D (as well as adherence to them) will benefit proteinuria and thus improve renal response.

Biomarker Analysis of IFN-I Modulation in JNJ-839: First-in-Human Study for Systemic Lupus Erythematosus

Ashley Orillion[1], Loqmane Seridi[1], Matteo Cesaroni[2], Jessica Schreiter[1], Jacqueline Benson[3], **William Stohl**[4], Walter Winn Chatham[5], Richard Alan Furie[6], Thi-Sau Migone[7], Stanley Marciniak[1], Zhenling Yao[1], Bhaskar Srivastava[1], Marc Chevrier[2] and Jarrat Jordan[1], [1]Janssen Research & Development, LLC, Spring House, PA, [2]Janssen Research & Development, LLC, Spring House, [3]Janssen Research & Development, LLC, South San Francisco, CA, [4]University of Southern California Keck School of Medicine, Los Angeles, CA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Feinstein Institutes for Medical Research, Northwell Health, Manhasset, NY, [7]Independent Consultant, Spring House

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: JNJ-839 is a fully human neutralizing antibody selective to human IFN-ω and IFN-α subtypes. Here we report the exploratory biomarker analyses of a Phase 1 study in mild to moderate SLE participants with elevated baseline IFN-I scores.

Methods: A screening strategy was implemented to enroll participants exhibiting elevated IFN-I scores using a whole blood qPCR 10 gene signature. The signature was calculated based on the following genes: *DHX58*, *EIF2AK2*, *HERC5*, *IFI44*, *IFI44L*, *IFI6*, *IRF7*, *PARP9*, *PLSCR1*, and *SAMD9L*. Patients with a score below the pre-defined signature cutoff were excluded, resulting in 28 SLE participants randomized (3:1) to receive six bi-weekly IV treatments of JNJ-839 (10 mg/kg) or placebo (PBO), response was defined as a ≥4-point improvement of SRI-4 at Day 100. The IFN-I gene signature was measured longitudinally using RNAseq analysis of PAXgene blood samples to assess the pharmacodynamic (PD) effect of treatment vs. PBO. A novel precision medicine tool, *in vitro* perturbation assay, was developed to assess *ex vivo* exposure as a means to potentially predict clinical response. Participant blood was collected directly into a tube resulting in a final concentration of 200 μg/mL JNJ-839 or null tubes prior to dosing patients with PBO or JNJ-839 and incubated *in vitro* for 24h, followed by transcriptome profiling using microarray.

Results: At baseline, *in vivo* IFN-I signature levels were not significantly different between treatment groups, irrespective of response status. IFN-I signature suppression was observed in treated participants vs. PBO. IFN-I suppression was similar in JNJ-839 non-responders (NR) and responders (R) throughout the dosing period. After the final dose of JNJ-839 at Day 71, R exhibited a sustained suppression through Day 86, reaching PBO levels only at Day 130, while the NR promptly returned to PBO levels at Day 79. In the *in vitro* perturbation assay, using blood from participants prior to *in vivo* dosing, the magnitude of IFN-I signature suppression between JNJ-839 treated vs. untreated samples was statistically significant (p=0.032) using blood from R. In contrast, IFN-I signature suppression was not statistically significant between JNJ-839 treated vs. untreated samples in NR blood.

Conclusion: A sustained PD effect on the IFN-I signature was noted in JNJ-839 treated participants relative to PBO. Transient longitudinal PD differences were observed between R and NR only after the final dose. Differential expression analyses using samples from the *in vitro* perturbation assay indicated downmodulation of IFN-inducible transcripts in treated samples relative to untreated, suggesting that the IFN-I signature is perpetuated under these *in vitro* conditions. Further, *in vitro* exposure revealed a significant change between treated and untreated blood in R, indicating that this assay may have utility for future use to identify R to anti-IFN-I agents without exposing patients to these immunomodulatory agents. Despite the limitations of sample size, these results support further testing with inhibitors of the IFN-I pathway in SLE.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: SLE – Treatment Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Infection is major cause of morbidity and mortality in systemic lupus erythematosus (SLE) patient. The past exploratory study suggested various infection risk in SLE patients, such as administration of higher than 7.5mg prednisolone daily or equivalent, high disease activity of SLE, therapy of intravenous administration of cyclophosphamide and leukocytopenia. High dose glucocorticoids (GCs) administration is known to increase the risk of infection in SLE patients; however, the risk of infection in SLE patients receiving low-dose GCs remains unclear. In this study, we evaluated the risk of severe infection requiring hospitalization in SLE patients receiving low-dose GCs as remission maintenance therapy.

Methods: Study design was prospective cohort study. We enrolled SLE patients who fulfilled standardized SLE criteria and could follow up more than a year using the database from multicenter registries of SLE patients in Japan (Lupus registry of nationwide institutions: LUNA). We exclude the patients who are in the induction remission therapy phase (PSL >15mg or equivalent). We extracted data on the patient's sex, age, daily GC doses, and comorbidities that could potentially affect the infection occurrence. Our main exposure was the daily GC doses at the onset of infection. We divided the daily GC doses into four categories; 0-2.5mg of PSL or equivalent doses, 2.6-5.0mg, 5.1-7.5mg, and 7.6-15mg. Outcome measurement was infection occurrence that needed hospitalization. We used logistic regression model to analyze the correlation between GC doses and infection occurrence with adjustment for age, sex, immunosuppressants.

Results: Two hundred ninety patients were enrolled, and the mean age of patients was 47.3 years. The female rates were 88%, immunosuppressants were used in 44% of patients, the mean SLE disease activity index was 5.8 and diabetes mellitus patients were 4%. The overall infection occurrence was 57 events. In each group, 3 of 68 patients in PSL 0-2.5mg group, 28 of 111 patients in PSL 2.6-5.0mg group, 9 of 51 patients in PSL 5.1-7.5mg group, 17 of 60 patients in PSL 7.6-15mg group developed an infection. Compared with PSL 0-2.5mg group, the odds ratio for the development of infection was 8.0 (95% confidence interval (CI), 2.29-28.0) in PSL 2.6-5.0mg group, 5.3 (95% CI, 1.29-21.8) in PSL 5.1-7.5mg group, and 11.2 (95% CI, 2.92-43.0) in PSL 7.6-15mg group.

Conclusion: Even when relatively low doses of PSL are administered to patients with SLE in the maintenance phase, the risk of infection may remain.

Session Time: 9:00AM–11:00AM

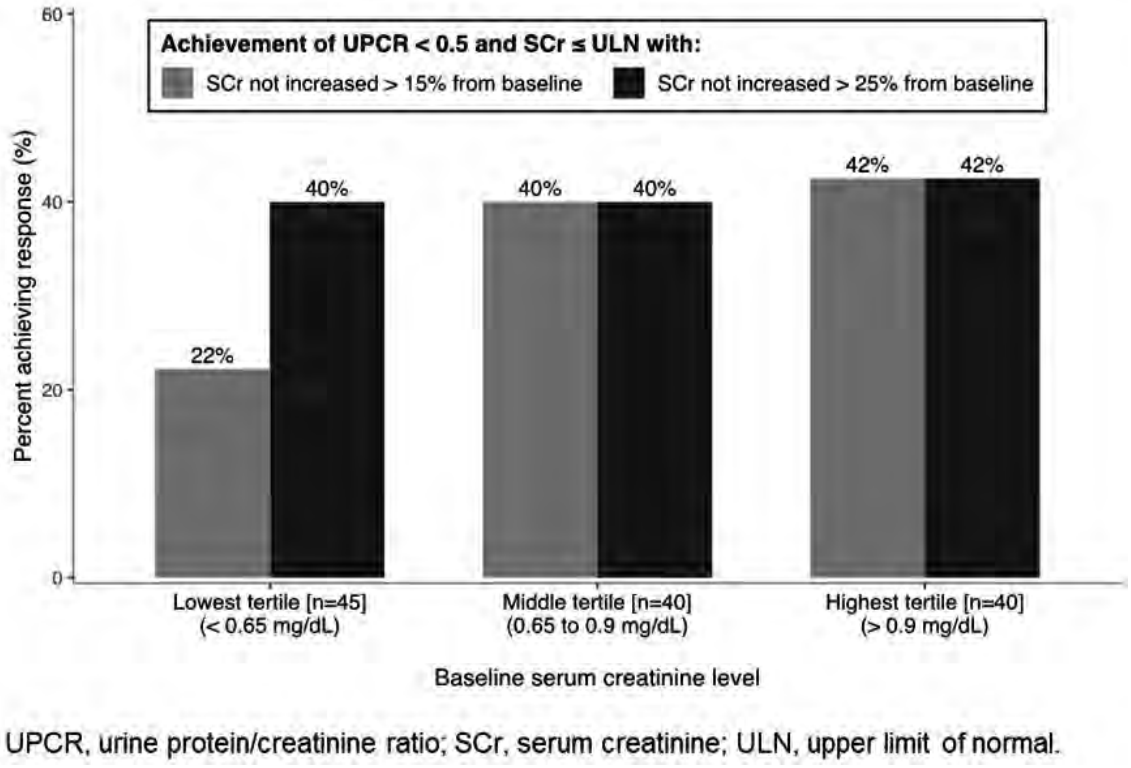

Figure. Week 76 response in NOBILITY by baseline serum creatinine level

Definition of response	Week 52			Week 76		
	OBI (n = 63)	PBO (n = 62)	Diff.	OBI (n = 63)	PBO (n = 62)	Diff.
NOBILITY complete response UPCR < 0.5, SCr ≤ ULN and not increased > 15% from baseline SCr, and < 10 RBC/hpf without casts	35%	23%	12%*	40%	18%	22%**
REGENCY complete response UPCR < 0.5, SCr ≤ ULN and not increased > 25% from baseline SCr	43%	29%	14%*	54%	31%	23%**
UPCR < 0.8 only	64%	48%	15%*	64%	47%	17%*
UPCR < 0.8 with SCr requirement UPCR < 0.8 and SCr ≤ ULN or not increased > 15% from baseline SCr	60%	48%	12%*	64%	45%	18%**
NOBILITY overall response CRR or ≥ 50% reduction in UPCR[a] with SCr not increased > 15% from baseline and urinary RBCs not increased > 50% from baseline	56%	36%	20%**	51%	29%	22%**
REGENCY overall response CRR or ≥ 50% reduction in UPCR[a] with SCr not increased > 25% from baseline	68%	45%	23%**	67%	50%	17%**

OBI, obinutuzumab; PBO, placebo.
* P < 0.2 vs. placebo group.
** P < 0.05 vs. placebo group.
[a] ≥ 50% reduction in UPCR to a value < 1 (< 3 if the baseline UPCR was ≥ 3).
All response definitions required no use of rescue medications or early withdrawal.

Table. Data from NOBILITY at weeks 52 and 76 using several response definitions

Background/Purpose: Obinutuzumab, a type II anti-CD20 mAb, resulted in rapid and complete B-cell depletion and improved renal responses in proliferative lupus nephritis (LN) in the Phase 2 NOBILITY trial and will be further evaluated in the Phase 3 REGENCY trial. Recent analyses suggest alternative urinary sediment, serum creatinine (SCr), and urine protein/creatinine ratio (UPCR) requirements may be better measures of response in LN than those used in NOBILITY [1,2]. The objective of this analysis was to evaluate the NOBILITY response definitions and to report the results of NOBILITY using alternative definitions of renal response.

Methods: 126 patients with active Class III/IV LN were randomized to obinutuzumab or placebo in combination with mycophenolate and glucocorticoids. NOBILITY complete renal response (CRR) required UPCR < 0.5, SCr ≤ the upper limit of normal (ULN) of the reference laboratory and not increased > 15% from baseline SCr, and inactive urinary sediment. Exploratory analyses were conducted, and alternative response definitions were evaluated post hoc.

Results: NOBILITY CRR was increased with obinutuzumab over placebo at Week 52 (35% vs. 23%, P = 0.11) and Week 76 (40% vs. 18%, P = 0.007). Response rates were low among patients with baseline SCr < 0.65 mg/dL (n = 45) due to the requirement that SCr not increase > 15% from baseline; increasing this threshold to 25% increased the response rate to a level similar to other groups (Figure). Alternative response definitions demonstrated increased rates of response in both treatment groups and similar benefits of obinutuzumab over placebo at Weeks 52 and 76 (Table).

Conclusion: Obinutuzumab resulted in consistent treatment benefits across a range of renal response definitions in NOBILITY and will be further evaluated in REGENCY. A requirement that SCr not increase > 15% from baseline may be overly restrictive in patients with low baseline SCr (< 0.65 mg/dL), where a change of 15% represents < 0.1 mg/dL and is of questionable clinical relevance. These findings may inform LN clinical trial design and more accurately reflect clinical practice.

Clinical Outcomes in Lupus Nephritis by Renal Response Status: A Retrospective Analysis of the Hopkins Lupus Cohort

Michelle Petri[1], Qinggong Fu[2], Yulia Green[3], Anuradha Madan[4], Daniel Goldman[5] and Selin Cooper-Blenkinsopp[6], [1]Johns Hopkins University School of Medicine, Baltimore, [2]GlaxoSmithKline, Upper Providence, [3]GlaxoSmithKline, Uxbridge, [4]GlaxoSmithKline, Collegeville, [5]Johns Hopkins University School of Medicine, Timonium, MD, [6]GlaxoSmithKline, Stevenage, United Kingdom

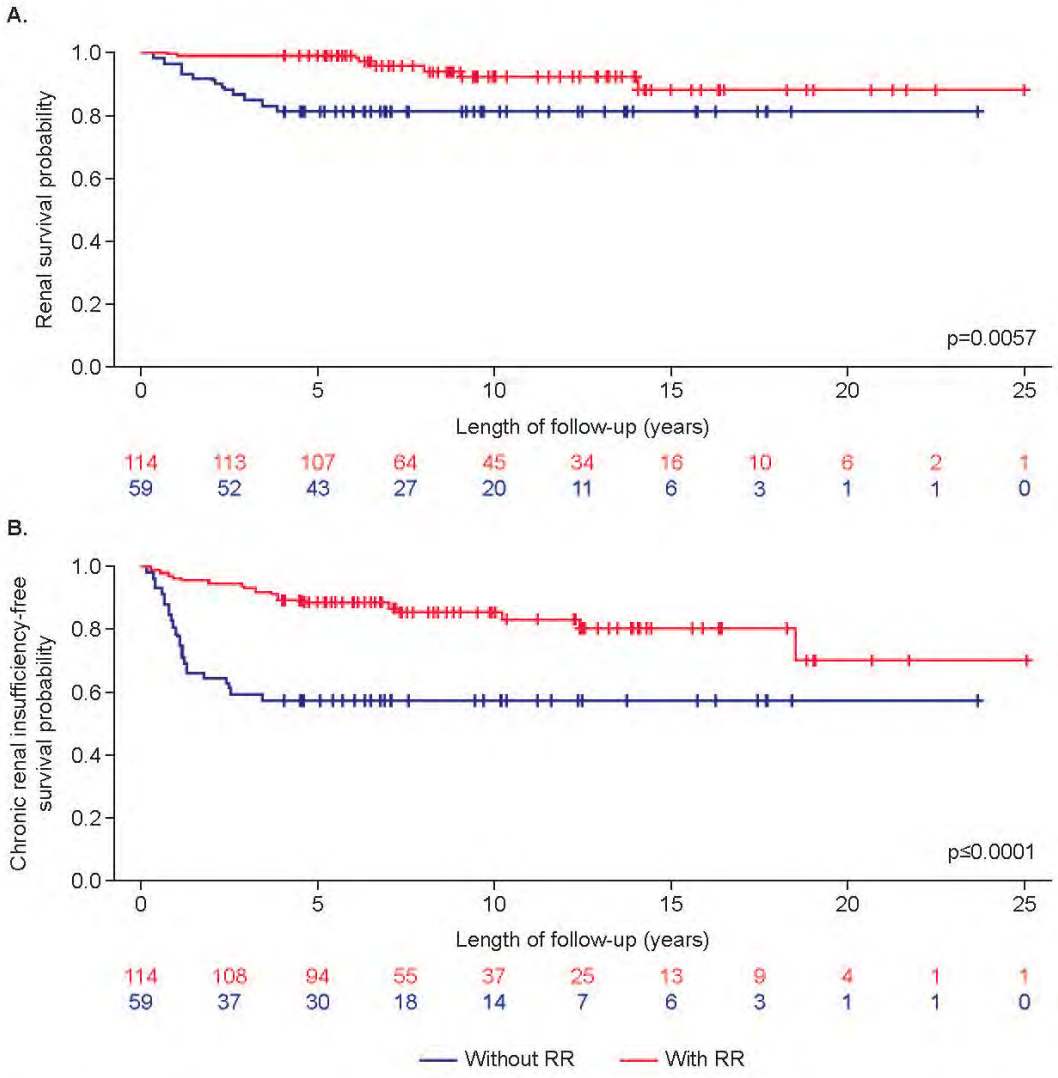
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: A retrospective analysis of the Hopkins Lupus Cohort (a prospective, longitudinal study of patients [pts] with systemic lupus erythematosus) reported that renal response (complete/partial/none) at 24 months post-diagnosis of lupus nephritis (LN) predicts long-term renal survival.[1] Here, we compare long-term renal survival and chronic renal insufficiency-free survival in pts with and without a renal response (RR) to standard LN therapy, as defined by primary endpoint in the Phase 3 BLISS-LN study (GSK Study BEL114054; NCT01639339).

Methods: This retrospective analysis (GSK Study 213039) of the Hopkins Lupus Cohort included pts with biopsy-proven class III, IV, or V LN. Endpoints were: long-term renal survival (no end-stage renal disease [ESRD] and/or mortality) and long-term chronic renal insufficiency-free survival by RR status at 24 months post-biopsy, both assessed by Kaplan–Meier plots with log-rank test and Cox proportional hazards regression.

Results: 173 pts with LN were included; 91.3% were female and mean (SD) age at biopsy was 36.2 (11.8) years. At 24 months post-biopsy, 114 (65.9%) pts achieved RR. Pts with RR at 24 months were less likely to experience an ESRD/mortality event and chronic renal insufficiency (**Figure**), even after adjusting for covariates (HR [95% CI] 0.33 [0.13, 0.87], p=0.0255; and HR [95% CI] 0.26 [0.14, 0.47], p< 0.0001, respectively).

Figure. Renal survival (A) and chronic renal insufficiency–free survival* (B) by RR status at 24 months



*New kidney damage OR new occurrence of glomerular filtration rate <60 ml/min/1.73m^2 on ≥2 consecutive occasions ≥3 months apart

Conclusion: Achieving BLISS-LN primary endpoint defined RR at 24 months post-biopsy is associated with long-term renal survival and chronic renal insufficiency-free survival in pts with LN.

Prior presentation: Submitted to ASN 2020. If accepted (notifications due August 7), to be presented at Kidney Week 2020 from October 20, 2020 – October 25, 2020 and published in the ASN Abstract Supplement PDF, which will be posted online by October 9, 2020.

Session Title: SLE – Treatment Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease of female predominance. One of the most debilitating symptoms experienced by SLE-patients is persistent fatigue. Prior research from our group suggests that fatigue, as measured by the Fatigue Severity Scale (FSS), is independent of SLE disease activity, as measured by Safety of Estrogen in Lupus Erythematosus National Assessment Group-Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) scores. Mitochondrial dysfunction and the type I Interferon pathway may contribute to fatigue in SLE. The purpose of this study is to characterize the responses and adaptations to a program of aerobic exercise in SLE patients with significant fatigue and minimal disease activity. Here we present preliminary analysis of our study.

Table-1-Demographics and SELENA-SLEDAI score of patients enrolled in Exercise Study

Variables	*N=16*
Age (Years)	
Mean ±SD	**42.0 ± 10.3**
Disease Duration (years)	
Mean ±SD	**9.1 ± 6.5**
BMI	
Mean ±SD	**28.2 ± 5.2**
Race/Ethnicity, N (%)	
African American	**3 (18.8 %)**
Asian	**3 (18.8 %)**
Caucasian	**2 (12.5 %)**
Hispanic	**8 (50.0 %)**
Gender, N (%)	
Female	**16 (100.0%)**
SELENA-SLEDAI	
Mean ±SD	**1.4 ± 1.9**

Table-2- Pre and post exercise Fatigue Severity Scale (FSS) measures.			
Fatigue Severity Scale Parameters	**Pre-Exercise Median (Q1- Q3)**	**Post-Exercise Median (Q1-Q3)**	***p-value***
FSS LOW MOTIVATION	6 (3--7)	4 (1--7)	**0.0342**
FSS EXERCISE BRINGS	5 (2--6)	2 (1--5)	**0.0002**
FSS EASILY FATIGUE	4 (3--6)	3 (1--6)	**0.0293**
FSS INTERFERES PHYS FNCTN	5 (1--7)	3 (1--6)	**0.0005**
FSS CAUSE FREQ PROB	5 (1--7)	2 (1--7)	**0.0002**
FSS PREVNTS SUSTND PHYS FXN	4 (1--7)	2 (1--6)	**0.0205**
FSS INTERFERES DUTIES	5 (1--7)	2 (1--6)	**0.0022**
FSS AMONG 3 DISABLNG SX	6 (2--7)	2.5 (1--7)	**0.0088**
FSS INTERFERES WORK	5 (1--7)	3 (1--7)	**0.0234**
FSS AVERAGE	4.6 (3--6.3)	2.9 (1.2--5.9)	**<0.0001**

Table-3- Pre and post exercise Patient-Reported Outcomes Measurement Information System (PROMIS) measures.			
PROMIS Parameters	**Pre-Exercise Median (Q1--Q3)**	**Post-Exercise Median (Q1--Q3)**	***p-value***
PHYSICAL FUNCTION	4.6(3.9--4.8)	4.8(4.1--5)	**0.0342**
ANXIETY	1.8(1.1--2.8)	1.6(1--2.5)	**0.0391**
DEPRESSION	1.5(1.2--1.9)	1.1(1--1.6)	**0.0469**
FATIGUE	2.3(1.9--3.1)	1.9(1.5--2.1)	**0.0002**
SLEEP DISTURBANCE	2.6(2.2--2.8)	2.3(1.7--2.6)	**0.0161**
SATISFACTION WITH SOCIAL ROLES	1.6(1.2--2.5)	1.7(1.1--2.2)	0.6003
PAIN INTERFERENCE	1.9(1--2.2)	1.1(1--1.9)	0.1343
PAIN INTENSITY	2(1--3.5)	1.5(1--2.5)	0.0847

Methods: A cohort of 20 SLE patients with minimal disease activity (SELENA-SLEDAI < 4) and self-reported presence of fatigue (FSS ≥ 3) are being enrolled in an open label monitored, aerobic exercise intervention program. The exercise program consists of treadmill exercise for 30 minutes, three times a week for 12 weeks. Vascular endothelial dysfunction and arterial stiffness are measured by performing non-invasive vascular studies. The primary outcome measure of this study is the time it takes the subjects to reach their anaerobic threshold during a cardiopulmonary exercise test (CPET), which is performed before and after the exercise program. Secondary outcome measures such as the FSS, SELENA-SLEDAI scores and the Patient-Reported Outcomes Measurement Information System (PROMIS) survey assesses disease activity and fatigue. Other outcomes such as distance walked during a 10-minute walk test and peak O_2 consumption during a CPET assesses changes in physical capacity and function. Furthermore, mechanistic studies are planned to measure mitochondrial dysfunction and interferon gene signature.

Results: To date, 16 SLE patients have completed the protocol. The average age of recruited SLE patients was 42 ± 10.3 years and the average disease duration was 9.1 ± 6.5 years (Table 1). 50% of the patients were Hispanic, 18.8% were African- American and Asian, and 12.5% were Caucasian. The average SLEDAI score at baseline was 1.4 ± 1.9, which remained constant throughout the study. The median FSS score at baseline was 4.6 (3--6.3), which decreased to 2.9 (1.2--5.9) by the end of the study ($p < 0.0001$) (Table 2). The PROMIS survey demonstrated an improvement across most of the parameters at the end of the study, when compared to baseline (Table 3).

Conclusion: In this preliminary analysis, patients reported a significant improvement in their fatigue and overall health following participation in an exercise program. There was no increase of SLE disease activity. The data produced from this study will provide an understanding of the mechanisms leading to fatigue in SLE patients, and the potential role of exercise in mediating these improvements. These findings will be utilized in the planning of a larger randomized controlled study to address pathophysiology of fatigue in SLE patients and recommendations for exercise interventions to modulate this disease manifestation

Medication Adherence Barriers and Opportunities to Overcome Them Among Patients with SLE

Lena Eder[1], Megan Clowse[2], Amanda Eudy[3], Jennifer Rogers[4], Rebecca Sadun[3], Lisa Criscione-Schreiber[5], Jayanth Doss[3], Mithu Maheswaranathan[6], Amy Corneli[7], Hayden Bosworth[6] and Kai Sun[6], [1]Duke University Hospital, Chapel Hill, NC, [2]Duke University, Chapel Hill, NC, [3]Duke University, Durham, NC, [4]Duke University Hospital, Durham, DE, [5]Division of Rheumatology and Clinical Immunology, Department of Medicine, Duke University Medical Center, Durham, NC, [6]Duke University Hospital, Durham, [7]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication non-adherence in SLE is as high as 80%, yet little is known about adherence barriers faced by patients or interventions that improve adherence in SLE. We developed an intervention based on our prior study results in collaboration with lupus clinic stakeholders and pilot-tested it in a tertiary care lupus clinic. As part of the intervention, providers shared objective pharmacy refill data with patients during the encounter to elicit adherence barriers and discussed approaches to overcoming barriers. These were then documented in the clinic note via a dropdown menu with multiple choice options (Table 1). Here we describe adherence barriers elicited and approaches suggested to overcome them as noted by lupus providers during this pilot intervention.

Methods: We conducted the pilot intervention during regular clinic visits over 12 weeks on consecutive follow-up SLE patients who were prescribed ≥1 SLE medication. Adherence was assessed by medication possession ration (MPR) based on Surescripts refill data available in the EMR supplemented by phone calls to patients' pharmacies. Adherence was assessed for the 3-month periods before and after the intervention visit, using MPR ≥80% as a cutoff for being adherent. Approaches to overcome barriers documented by providers were collected via chart review.

Results: Among 134 SLE patients seen during the intervention period, 70 (median age 40, 96% female, 66% African-American) were inconsistent at refilling at least one SLE medication (MPR < 80%). Lupus clinic providers identified and documented adherence barriers for 39 (56%) of the 70 patients with low refills. The most common barriers were busyness or forgetting (51%), cost or insurance issues (28%), side effects (15%), pill burden (8%), and lack of motivation (8%). Three months following the intervention visit, 33 (47%) of 70 patients with low refill rates now are considered adherent. There was no significant difference in the distribution of barriers between those with and without improved adherence after the intervention visit. Approaches to overcoming barriers documented by providers

Table 1. Dropdown menu choices for adherence barriers used in the clinic note template and distribution of adherence barriers among 39 patients who were non-adherent 3 months prior to the intervention visit and 33 patients who had improved adherence 3 months after the intervention visit.

Adherence Barriers	Non-adherent patients with barriers documented at intervention visit (n=39)*	Patients with improved adherence 3 months after the intervention visit (n=33)*
Cost, n (%)	7 (18%)	3 (9%)
Insurance, n (%)	4 (10%)	2 (6%)
Pharmacy issues, n (%)	2 (5%)	1 (3%)
Busyness or forgetting, n (%)	20 (51%)	9 (27%)
Pill Burden, n (%)	3 (8%)	2 (6%)
Side effects, n (%)	6 (15%)	4 (12%)
Concerns about side effects, n (%)	1 (3%)	0 (0%)
Believing medicines are not needed if feeling well, n (%)	0 (0%)	0 (0%)
Lack of knowledge, n (%)	1 (3%)	0 (0%)
Lack of motivation, n (%)	3 (8%)	1 (3%)
Depression, n (%)	1 (3%)	1 (3%)
Other, n (%)	6 (15%)	2 (6%)
*Among 70 patients who were non-adherent prior to the intervention visit based on refill data, 39 patients had adherence barriers documented by providers, and 33 patients had improved adherence 3 months after the intervention visit.		

included: strategies to help with remembering, for example, using a reminder, app, or pill box, moving pills to a more visible area, or involving a family member to remind the patient (n=10); modifying the medication schedule or prescription (n=7); eliciting help from the pharmacist and/or social worker for cost and insurance issues (n=5); providing education or clearer instructions (n=5); treating side effects (n=2); and addressing depression (n=1).

Conclusion: We found that the most frequent medication adherence barriers faced by SLE patients related to the logistics of taking medications, financial burden, and side effects. The most common approach to address barriers suggested by providers were strategies to help with logistics of taking medications. The similar distribution of adherence barriers between those who did and did not have improved adherence after the intervention visit suggests that most of the barriers are modifiable.

A Novel Biomarker Identifies Systemic Lupus Erythematous (SLE) Patients Who Benefit from Obexelimab (XmAb®5871) Treatment

Ying Ding[1], Debra Zack[1], Bart Burington[1], Allen Yang[1], Joan Merrill[2], Judith James[3], John Desjarlais[1], Raphael Clynes[1] and **Joel Guthridge**[4], [1]Xencor Inc, Monrovia, CA, [2]New York University, New York, [3]Oklahoma Medical Research Foundation, Oklahoma City, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously reported Phase 2 SLE trial results for obexelimab, a CD19-targeted FcγRIIb engager that suppresses B-cell activation [1]. The primary endpoint, which measured loss of baseline response to steroids, was not met, but a strong trend in favor of obexelimab and statistically significant efficacy in secondary endpoints supported further analysis. Here, we describe a novel whole blood gene expression biomarker that characterized patients with improved outcomes on obexelimab therapy.

Methods: Expression of individual genes and gene pathway scores were evaluated for 68 patients who either completed the study or terminated early for loss of response using a five-fold cross validation framework. The relevance

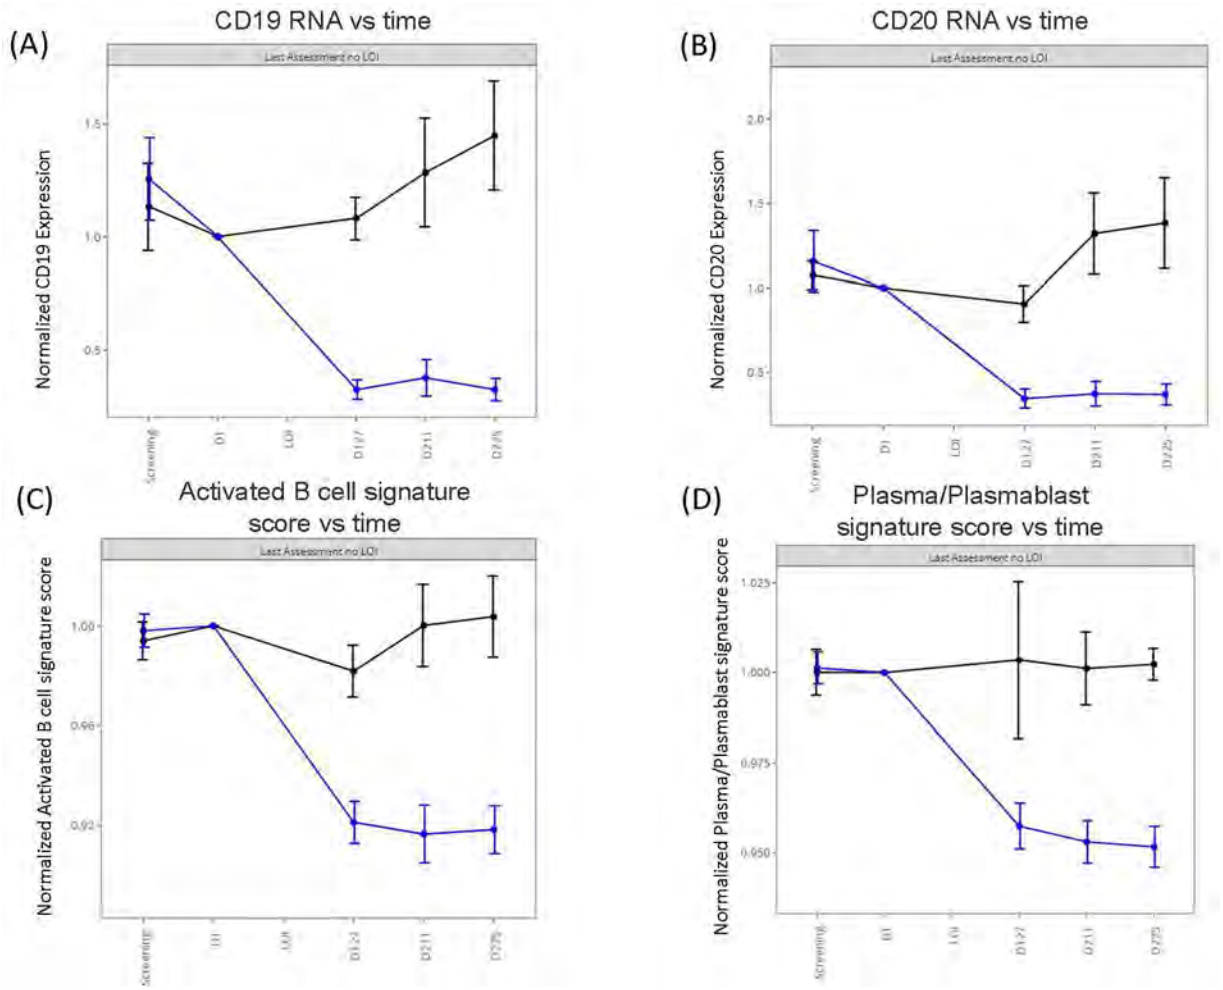

Figure 1. Pharmacodynamic effects of obexelimab (blue curve) compared with placebo (black curve) in patients with systemic lupus erythematosus (SLE) who had evaluable baseline whole blood transcriptomic (RNA-seq) data and either completed the study without a flare or experienced a flare on study. The RNA expression and signature scores are relative to baseline. Signature scores are based on immune cell signatures described in [3] and generated by the Singscore method[4] (A) B-cell marker gene CD19 gene expression over time (B) B-cell marker gene CD20 (transcript MS4A1) gene expression over time. (C) Activated B-cell signature score over time (D) Plasma/plasmablast signature score over time. [3] Arazi, A. et al. Nat. Immunol. 2019. 20;902-914. [4] Foroutan M, et al. . BMC Bioinformatics, 2018 19; 404.

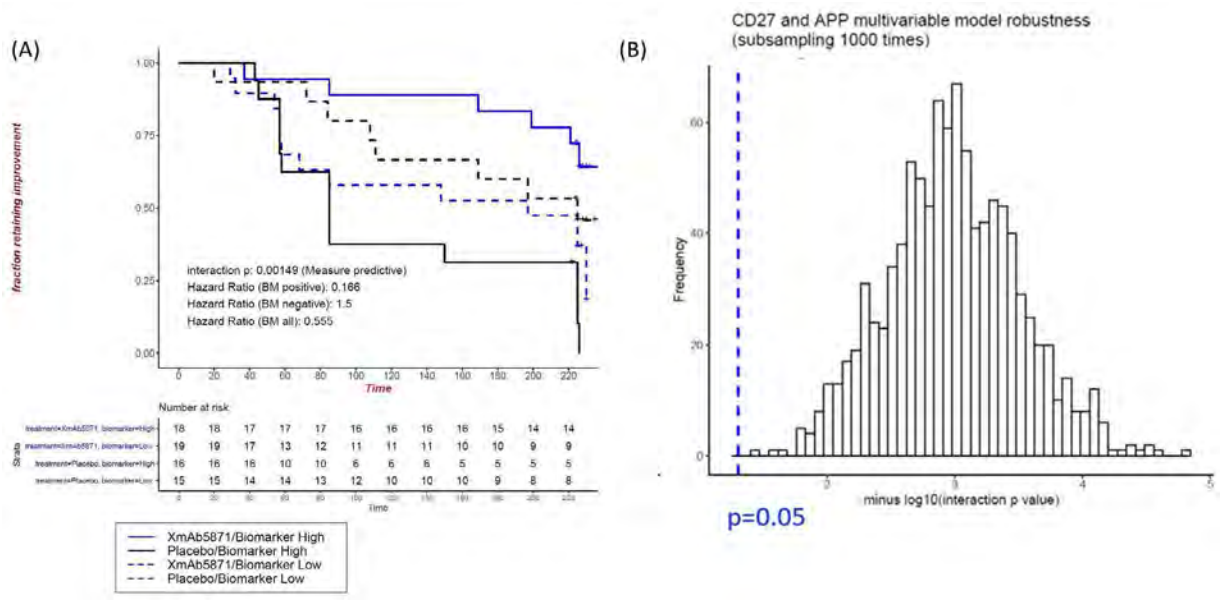

Figure 2. Two-gene predictive model (CD27 and APP). A five-fold cross validation framework was developed to ensure the generalizability of the results and to determine the number of genes needed and what fraction of patients to assign as cDx+. Classifications are based on a simple threshold for the sum of gene expression levels that have been normalized by the training sample mean and standard deviation. (A) Normalized expression levels of two genes classify patients as cDX+ or cDx-, with an estimated 50% of patients assigned to each group. The benefit from obexelimab over placebo in the cDx+ group (solid blue and solid black curves) was significantly greater than the benefit in the cDx- group (dashed blue and dashed black curves) (p=0.000149, HR cDx+ = 0.166 vs HR cDx- =1.5). (B) Robustness of the two-gene predictive model as shown by the distribution of the interaction p-value based on subsampling 80% of the datasets 1000 times.

of each gene to a potential biomarker predictive model was measured by the degree to which high or low expression identified a patient subgroup (cDx+) with greater reduction in risk of flare by obexelimab than in cDX- patients.

Results: Obexelimab treatment was associated with reduction of B-cell genes and gene-sets reflective of activated B-cells and plasma cells/plasmablasts (Figure 1), as previously reported [2]. Importantly, our cross-validated analyses determined that the baseline expression levels of 2 predictive genes, CD27 and APP, identified a cDx+ group (50% of all patients) with greatly reduced risk of flare on obexelimab (cross-validated HR=0.262, full data set HR=0.166) (Figure 2). Conversely, in the placebo group, the CDx+ subjects had higher flare risk, thus cDX+ also identifies poor-prognosis patients who might particularly benefit from obexelimab. The cDx+ group demonstrated increased obexelimab effects compared to cDx- patients over a range of clinical endpoints (SRI-4: 56% cDx+ vs 14% cDx-, SRI-6: 33% vs 6.2%, LLDAS: 50% vs 6.2%, BICLA: 33% vs 12.5%) (Figure 3). CD27, the top predictive biomarker, is highly expressed by T-naïve and memory cells. Consistent with the notion that CD27 expression is important within the T-cell lineage, increased expression of other T-cell genes was also associated with reduced flare risk, including CD28 (p=0.04), TCF7(p=0.03) and FOXP3 (p=0.05). Taken together with the reduction of B cell signatures seen on treatment, this new identification of CD27 as a potential T-cell associated predictive biomarker suggests an important therapeutic role of obexelimab in suppression of B-cell and T-cell interactions.

Conclusion: A novel two-gene classifier developed from whole blood transcriptomic data by RNA-sequencing identifies a biomarker positive group of patients with a high baseline resting and stem-like T-cell (CD27+, CD28+ and TCF7+) signature. These cDx+ patients had superior response rates compared to placebo across multiple clinical endpoints, suggesting that adaptive immune responses such as B-cell antigen presentation and/or T-cell costimulation may be key components of obexelimab effects. This exploratory biomarker analysis supports further assessment of the two gene signature as a patient stratification/companion diagnostic strategy in obexelimab clinical development for SLE and other autoimmune conditions.

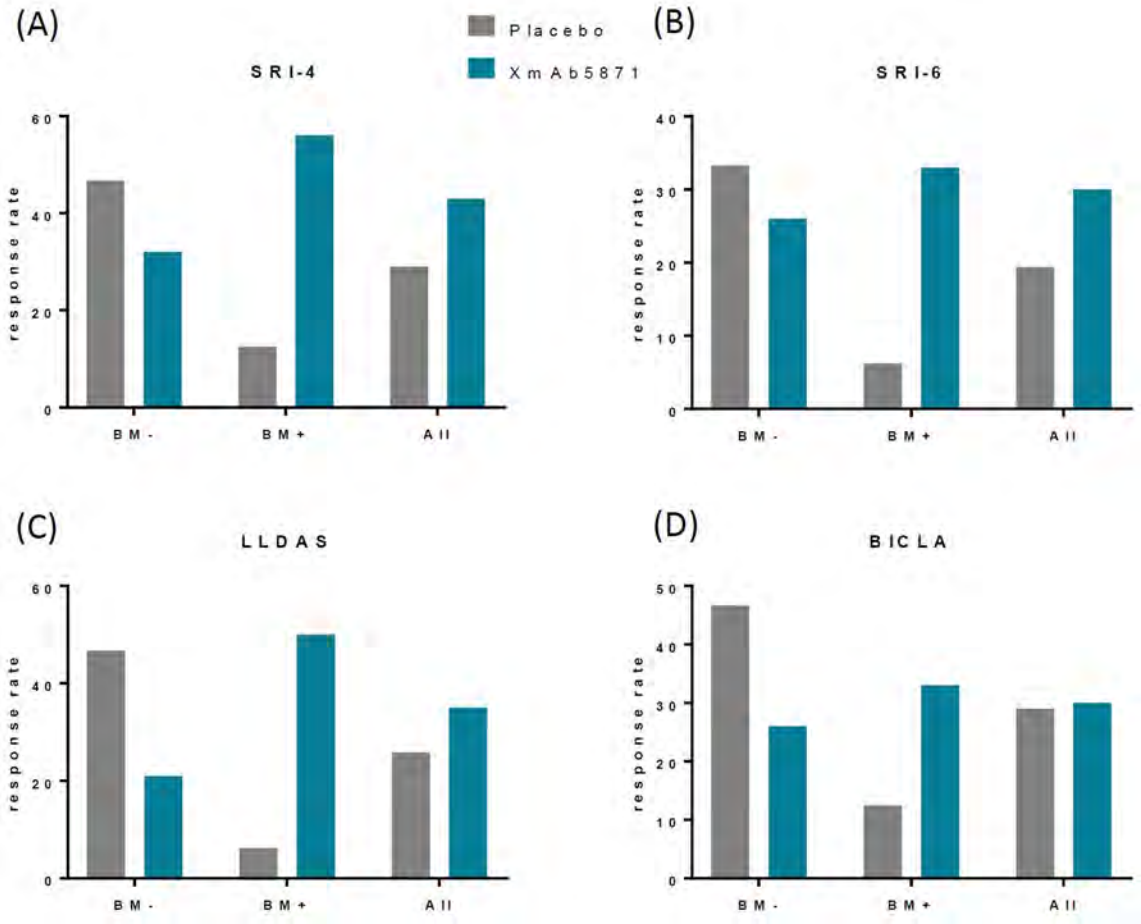

Figure 3. Response rates are enriched among cDX+ (50%) patients' four landmark endpoints at 32 weeks. (A) SRI-4 (B) SRI-6 (C) LLDAS (D) BICLA.

Session Title: SLE – Treatment Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a cornerstone treatment for several autoimmune diseases including Systemic Lupus Erythematosus (SLE). Recently, concerns arose regarding HCQ shortages for SLE patients, due to its use as a potential COVID-19 treatment. Although some patients may remain well after reducing or stopping therapy, others will have potentially life-threatening complications related to SLE flares. We evaluated if HCQ reduction or discontinuation is associated with increased risk of poor outcomes.

Methods: We analyzed prospective data from the Systemic Lupus International Collaborating Clinics (SLICC) cohort, which includes SLE patients from 33 sites in Europe, Asia, and North America, enrolled within 15 months of diagnosis and followed annually, from 1999 to 2019. In patients receiving HCQ, we identified two sub-cohorts, one who reduced HCQ and one who stopped HCQ. We did not require patients to be in disease remission at the time of HCQ reduction/discontinuation for these analyses. Time zero for these sub-cohorts was the date of the first HCQ reduction/discontinuation. For comparison, we identified a third group of patients remaining on HCQ. A poor outcome was defined as either subsequent need for SLE therapy augmentation (steroids or other immunosuppressives), increase of ≥4 points in the SLE Disease Activity Index-2000 (SLEDAI-2K) or hospitalization for SLE. We estimated adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for poor outcomes among the three HCQ exposure groups. Models were adjusted for demographics and baseline clinical characteristics.

Table 1. Hazard ratios (HRs), and 95% confidence intervals (CIs) for poor outcomes in HCQ-exposed SLE patients

Characteristics*	HR (95% CI)	aHR (95% CI)
HCQ Group		
Maintenance	Reference	-
Taper	**1.35 (1.19, 1.53)**	**1.40 (1.22, 1.59)**
Discontinuation	**1.36 (1.17, 1.56)**	**1.48 (1.27, 1.73)**
Male sex	1.01 (0.85, 1.21)	0.96 (0.79, 1.15)
Race/ethnicity		
Caucasian	Reference	-
Asian	**1.26 (1.09, 1.46)**	0.91 (0.77, 1.07)
Black	**1.22 (1.03, 1.44)**	0.94 (0.78, 1.13)
Others	**1.49 (1.28, 1.74)**	1.07 (0.91, 1.27)
Age at SLE diagnosis in years	0.99 (0.99, 1.00)	1.00 (0.99, 1.00)
No college/university education	**1.17 (1.04, 1.31)**	1.03 (0.92, 1.16)
Active disease (SLEDAI-2K ≥ 4)	**1.36 (1.22, 1.52)**	**1.13 (1.01, 1.27)**
Renal damage	**1.25 (1.01, 1.55)**	0.89 (0.71, 1.13)
Body mass index	0.99 (0.98, 1.00)	1.00 (0.99, 1.02)
Smoker	0.93 (0.82, 1.05)	0.98 (0.86, 1.11)
Prednisone use	**2.19 (1.95, 2.47)**	**1.73 (1.50, 1.99)**
Immunosuppressive use	**2.27 (2.04, 2.54)**	**1.77 (1.56, 2.01)**
Biologic use	0.98 (0.68, 1.40)	0.74 (0.51, 1.07)
Time on HCQ	1.01 (0.98, 1.03)	0.97 (0.94, 1.00)

*At baseline, except for age. Other race/ethnicity includes Hispanic, Mixed and First-Nations. Immunosuppressives included azathioprine, mycophenolate, and methotrexate. Biologics included belimumab, rituximab and abatacept.

Hazard ratios (HRs), and 95% confidence intervals (CIs) for poor outcomes in HCQ-exposed SLE patients

Results: A total of 1460 patients were included (89% female, 52% Caucasian). Patients in the HCQ reduction group contributed 1087 person-years, those discontinuing HCQ contributed 677 person-years, and those maintaining HCQ contributed 1649 person-years. HCQ dose reduction or discontinuation occurred in many patients (40%) with a SLEDAI-2K >4. The crude poor outcome rate was significantly lower in the HCQ maintenance group (31.6 events per 100 person-years, 95% CI 29.0, 34.5) than in the reduction (43.0, 95% CI 39.3, 47.1) and in the discontinuation (43.0, 95% CI 38.3, 48.2) groups. Patients reducing or discontinuing HCQ had higher adjusted HRs for poor outcomes versus those maintaining HCQ (Table 1). Other factors independently associated with poor outcomes included active SLE and use of prednisone or immunosuppressive drugs, all measured at time zero.

Conclusion: Patients reducing or discontinuing HCQ are at greater risk of having a poor outcome versus those maintaining the drug. These analyses do not account for reasons HCQ was reduced/discontinued. Regardless, baseline disease activity, prednisone and immunosuppressive drugs were associated with the risk of poor outcomes in SLE patients reducing, discontinuing, or maintain HCQ.

Repository Corticotropin Injection (Acthar® Gel) for Persistently Active Systemic Lupus Erythematosus: Post Hoc Analyses of Patient-Reported Outcomes from a Phase 4, Multicenter, Randomized, Double-blind, Placebo-Controlled Trial

Anca Askanase[1], George Wan[2], Mary Panaccio[2], Enxu Zhao[2], Julie Zhu[2], Roman Bilyk[2] and Richard Furie[3], [1]Columbia University College of Physicians and Surgeons, New York, NY, [2]Mallinckrodt Pharmaceuticals, Bedminster, NJ, [3]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY

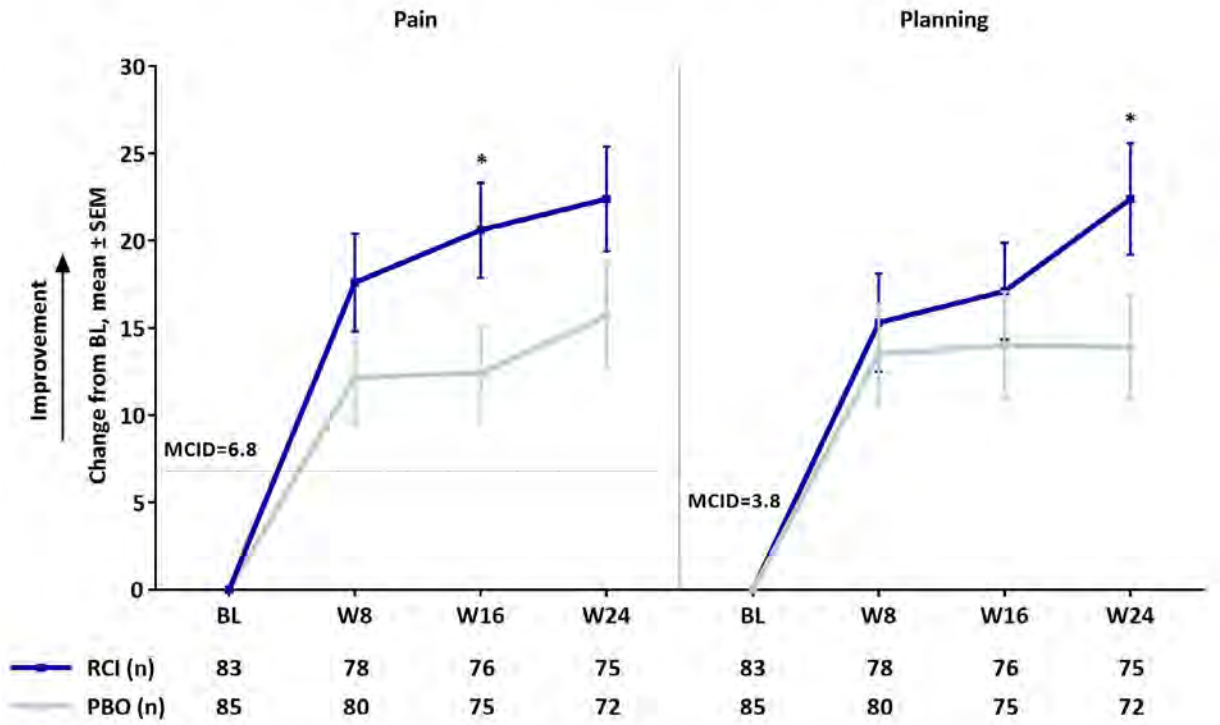
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Repository corticotropin injection (RCI, Mallinckrodt Pharmaceuticals) is a naturally sourced complex mixture of adrenocorticotropic hormone analogs and other pituitary peptides approved for the treatment of SLE flares and as maintenance therapy. This post hoc analysis of patient-reported outcomes (PROs) from a multicenter, double-blind, randomized, placebo (PBO)-controlled study of RCI in patients with persistently active SLE despite use of moderate-dose glucocorticoids (GCs) was conducted to assess RCI-dependent quality of life (QOL) improvements (NCT02953821).

Methods: Patients were ≥18 years old with active SLE (≥4 of 11 ACR criteria; SLEDAI-2000 [SLEDAI-2K] ≥6) and moderate-severe rash and/or arthritis by BILAG despite stable GC doses (7.5-30 mg/d prednisone equivalent), antimalarials, NSAIDs for ≥4 weeks (Ws), and/or immunosuppressants for ≥8 Ws before screening. Patients were randomized to 80 U RCI subcutaneously or PBO every other day to W4 followed by twice-weekly dosing to W24. Stable GC doses were required through W16 with optional taper from W16 to W24. Primary analyses evaluated the change from baseline (BL) in the LupusQOL and Work Productivity and Activity Impairment (WPAI)-Lupus questionnaires through W24. Post hoc analyses stratified these results by BL SLEDAI-2K (< 10 vs ≥10), Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity [CLASI-A (< 11 vs ≥11)], and BILAG (< 20 vs ≥20) scores and by BILAG-based Combined Lupus Assessment (BICLA) response (patients with BICLA responses at both W20 and W24). Analyses were performed in the modified intention-to-treat population (mITT-P; patients who received ≥1 dose of study drug and contributed any post-BL efficacy data).

Results: The mITT-P (RCI, n=84; PBO, n=85) was predominantly female (91.7%) with a mean age of 39.7 years, mean BL GC dose of 11.1 mg, and mean BL SLEDAI-2K score of 9.9. RCI treatment resulted in significantly greater improvement in the LupusQOL *pain* domain at W16 and *planning* domain at W24 compared with PBO (Figure 1) and exceeded the minimal clinically important difference at all time points. Post hoc analyses demonstrated significant improvements in the *pain*, *planning*, and *fatigue* domains at multiple time points in RCI-treated patients with higher

Figure 1. Change From BL in LupusQOL Domains in the Primary Analysis, mITT-P[a]



[a]Patients who received ≥1 dose of study drug and contributed any post-BL efficacy data.

*$p<0.05$ for the LS mean difference using ANCOVA models with the change from BL as the dependent variable, treatments as the factor, and BL values of corresponding endpoints as the covariate, with stratification for location (US and outside the US) and BL GC dose (≤20 and >20 mg/d).

Abbreviations: ANCOVA, analysis of covariance; BL, baseline; GC, glucocorticoid; LS, least square; LupusQOL, Lupus Quality of Life; MCID, minimal clinically important difference; mITT-P, modified intention-to-treat population; PBO, placebo; RCI, repository corticotropin injection; SEM, standard error of the mean; W, week.

disease activity by BL SLEDAI-2K, CLASI-A, and BILAG and in BICLA responders (Figure 2). No significant differences between treatment groups were observed for any WPAI-Lupus parameter through W24 in the primary analysis or with higher disease activity in post hoc SLEDAI-2K, BILAG, or CLASI-A subgroups. However, RCI treatment resulted in significant improvements in *percent work time missed* at W24 in patients with BL CLASI-A < 11 (RCI mean change –8.4 [standard deviation (SD) 25.1]; PBO mean change 7.8 [SD 21.9]; p=0.0182 for least square mean difference) and in *percent impairment while working* at W16 in BICLA responders compared with PBO (Figure 3).

Conclusion: RCI treatment resulted in greater improvements in several PROs compared with PBO. These results suggest that treatment with RCI may improve QOL and *work productivity* in patients who have persistently active SLE despite treatment with standard SLE therapy, particularly in those with higher disease activity.

Figure 2. Change From BL in LupusQOL Domains in the Post Hoc Subgroups on the Basis of BL SLEDAI-2K (A), CLASI-A (B), and BILAG (C) and on BICLA Response (D), mITT-P[a]

Abstract Number: 1843

Integrated Efficacy of the AURORA 1 and AURA-LV Trials Confirms Voclosporin Rapid Proteinurea Reduction in the Presence of Low-Dose Steroids

Ellen M Ginzler[1], Joshua Kaplan[2], Laura Lisk[3], Ray Federico[4], Neil Solomons[5] and Robert Huizinga[5], [1]SUNY Downstate Health Sciences University, Brooklyn, [2]Rutgers University, New Brunswick, NJ, [3]Aurinia Pharmaceuticals Inc., Victoria, BC, Canada, [4]Aurinia Pharmaceuticals, Inc., Victoria, Canada, [5]Aurinia Pharmaceuticals, Victoria, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Voclosporin (VCS) is a novel calcineurin inhibitor (CNI) with a favorable metabolic profile and a consistent predictable dose response potentially eliminating the need for therapeutic drug monitoring.

Voclosporin has been evaluated for the treatment of lupus nephritis (LN) in two double blind RCTs, the Phase 2 AURA-LV and Phase 3 AURORA 1 trials representing the largest successful LN program to date. Previously reported results from these studies demonstrated that the addition of VCS to MMF and low-dose steroids resulted in statistically superior renal response at 24 weeks and at one year (AURA-LV 48 weeks, AURORA 1 52 weeks).

Methods: The AURORA 1 and AURA-LV studies were of similar design and conducted in comparable patient populations. The results of the efficacy and safety analyses from AURORA 1 were consistent with and confirmed the conclusions from the AURA-LV study. The data from both studies for subjects treated with the recommended VCS dose of 23.7 mg BID(AURORA 1; n=179, AURA-LV; n=89) or with matching placebo (AURORA 1; n= 178, AURA-LV; n=88) were therefore pooled for an integrated analysis of efficacy.

The primary endpoint in both studies was renal response (RR), defined as UPCR of ≤ 0.5 mg/mg, eGFR ≥ 60 mL/min, or no confirmed decrease from baseline in eGFR of > 20%, ≤ 10 mg/d prednisone for at least 8 weeks prior to endpoint assessmentand no administration of rescue medication.

Results: In the integrated analysis, treatment with VCS resulted in a clinically meaningful and statistically significant higher renal response (RR) rate (43.7%) compared to placebo (23.3%) at 1 year (OR 2.76, 95% CI: 1.88, 4.05; $p < 0.0001$) and at 6 months (VCS 31.7%; placebo 20.3%), [OR: 2.01; 95% CI: 1.34, 3.01; p=0.0008].

Furthermore, a 50% reduction in UPCR from baseline at any time was achieved by 93.7% of subjects treated with VCS compared with 75.2% of subjects receiving placebo, with a median time to 50% reduction in UPCR of 29 days versus 58 days, respectively. The time taken to reach a 50% reduction in UPCR was significantly shorter for the voclosporin group than the placebo group (HR 1.96; 95% CI: 1.61, 2.38; p< 0.0001). At one year 160 (75.8%) patients in the VCS arm and 150 (73.9%) patients in the placebo arm were on oral prednisone ≤ 2.5 mg/d.

Conclusion: Integrated efficacy analysis further supports efficacy results from the AURORA 1 and AURA-LV trials. Adult patients with LN treated with VCS on top of MMF and steroids achieve meaningful reductions in proteinuria and achieve that reduction faster compared to patients on MMF and steroids alone.

Abstract Number: 1844

Hydroxychloroquine and QTc Prolongation in a Cohort of SLE Patients

Mayce Haj-Ali[1] and H. Michael Belmont[2], [1]NYU Langone Health, new york, [2]NYU School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is an antimalarial drug used in the treatment of systemic lupus erythematous (SLE). Cardiac toxicity is very rare in SLE, but has been reported in patients with ESRD. The normal corrected QT (QTc) interval is defined as 450 ms in males and 470 ms in females. Severe prolongation of QTc is defined as > 500 ms and is associated with higher risk of developing life threatening arrhythmias such as Torsades de pointes (Tdp). The purpose of this study was to compare QTc intervals in a cohort of SLE patients based on HCQ exposure and with and without chronic kidney disease (CKD).

Methods: Retrospective Epic EMR review of 194 SLE patients fulfilling criteria in a faculty practice at NYU Langone Health between 3/12/12 – 5/1/20. Data was collected on EKG, QTc of first and last EKG (QTc prolongation defined as: > 450 ms in males or > 470 ms in females. Severe QTc prolongation defined as > 500 ms), creatinine and demographics. CKD defined as eGFR < 60 ml/min.

Results: 90 of the 194 patient had at least one EKG. Of these 90 patients, 91% were female, 32.2% African Americans, 6.6% Asian, 38.8% Caucasian, 20% Hispanic, 2.2% other and 75 on HCQ and 15 not on HCQ. QTC was prolonged in 8/75 HCQ and 1/15 without HCQ (table 1). There was no significant difference in mean QTc interval based on HCQ use (p= 0.586). In the 23 patients with CKD, QTC was prolonged in 4/19 on HCQ and 0/4 without. In patients with CKD there was no significant difference in mean QTc interval based on HCQ use (p= 0.784). No patients had documented tachyarrthymia or Tdp.

Conclusion: In a cohort of SLE patients, at least one EKG was available in 46%. There was no significant difference in mean QTc based on HCQ use. Patients with CKD were more likely to have prolonged QTc when compared to those without CKD, but there was no significant difference in mean QTc based on HCQ use as well in this subset. Severe prolongation of QTc was rare in all groups and no episodes of serious tachyarrhythmia or Tdp were observed. A role for more severe stages of CKD, underlying heart disease, or concurrent use of drugs that also affect QTc was not studied. The data supports current standard of care which does not require monitoring with baseline and serial EKGs in the routine management of SLE patients on HCQ. It remains uncertain if the effect of HCQ on the conducting system is limited to a physiological result yet is clinically inconsequential absent other risk factors.

Total (n= 90)	HCQ (n= 75)	No HCQ (n= 15)	P-value
Prolonged QTc, (n, %)	8 (10.6%)	1 (6.6%)	
Severely prolonged QTc, (n, %)	3 (4%)	1 (6.6%)	
QTc, ms (mean, +/- SD)	437.91 ± 20.02	434.6 ± 27.49	p = 0.5859

Long-Term Clinical Outcomes of Patients with Lupus Nephritis Treated with an Intensified B-Cell Depletion Protocol: A Matched Case-Control Study

Dario Roccatello[1], Savino Sciascia[2], Roberta Fenoglio[2] and Rossi Daniela[2], [1]S Giovanni Hospital, Univ of Turin, Turin, Italy, [2]University of Torino, Torino, Italy

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Targeting B-cells remains an attractive option in Lupus Nephritis (LN) despite the negative results of RCTs.

Methods: Sixty patients with active LN were included in the present study. Thirty patients were administered an intensified B-cell depletion therapy (IBCDT; 4 weekly Rituximab 375mg/sm and 2more doses after 1and2 months;2 infusions of 10 mg/kg cyclophosphamide (CYC),3 methylprednisolone pulses), followed by oral prednisone (rapidly tapered to 5mg/day by the end of the 3rd month). No further immunosuppressive maintenance therapy was given. Thirty patients matched for LN class and age were selected as controls: 20 received 3 methylprednisolone pulses days followed by oral prednisone and mycophenolate mofetil (MMF) 2-3 g/day, while 10 were given the Euro Lupus CYC.

Results: At 12 months, complete renal remission was observed in 93% of patients on IBCDT, in 62.7% on MMF, and in 75% on CYC. When assessed at 12 months, the dose of oral prednisone was lower in the IBCDT group (mean±SD 2.9±5.0mg/dl) than in those on MMF (10.5±8.0 mg/day, p< 0.01) or in the CYC group (7.5±9.0mg/day,p< 0.01). Mean follow-up after treatment was 44.5 months (ICQ36–120months), 48.6 months (ICQ36–120months), and 45.3 (ICQ36–120months) for IBCDT, MMF and CYC, respectively. At their last follow-up visit, we observed no significant differences in terms of proteinuria, serum creatinine, nor in the frequency of new flares among the three groups.

Conclusion: When compared to conventional regimens with MMF and CYC, sustained clinical remission even without maintenance immunosuppressive therapy was obtained by the IBCDT. Moreover, IBCDT had a significant steroid-sparing effect and a lower rate of flares compared to either MMF- or CYC- based conventional protocols.

Evaluating the Risk of QT-prolongation Associated with Hydroxychloroquine Use with and Without Antidepressants in SLE Patients with Fibromyalgia

Jacinta Renaldi[1], Fotios Koumpouras[1] and Mei Xue Dong[1], [1]YALE SCHOOL OF MEDICINE, New Haven, CT

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex systemic autoimmune disease predominantly affecting woman of child-bearing age. Concurrent fibromyalgia syndrome (FMS) has been reported in up to 40% of patients with SLE, which markedly affects their daily functionality and life satisfaction. Anti-depressants are used for the pharmacological therapy of FMS in both the general population and patients with connective tissue diseases. These agents include selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs) and atypical antidepressants. Hydroxychloroquine (HCQ) is widely used in patients with SLE due to its immunomodulatory action on reducing lupus disease activity and good overall tolerance and safety profiles. However, both antidepressants and HCQ are reported to cause QT interval prolongation, a cardiac measure that serves as a surrogate indicator for increased risk of torsade de pointes, a potential lethal ventricular arrhythmia that can result in sudden death. A recent study of hospitalized COVID-19 patients being treated with combination HCQ and azithromycin observed prolonged QT intervals and events of torsade de pointes, raising concern of additive risk for arrhythmic mortality when HCQ is used concomitantly with other QT-prolonging medications including antidepressants. Our objective is to investigate the risk of QT prolongation associated with hydroxychloroquine use with and without concurrent use of antidepressants in SLE patients with fibromyalgia.

Methods: This is a retrospective analysis using electronic medical records sampling SLE patients who participated in Yale Lupus Wellness Program from 2016 to 2019. All patients included met 2012 SLICC classification criteria for SLE. 97 patients in the program had 12-lead ECG with QTc interval measures. 52 patients used HCQ alone, while 45 patients concomitantly used both HCQ and antidepressants including SSRI, SNRI, TCA, or tramadol. QTc intervals were compared in groups taking HCQ alone versus those taking HCQ and antidepressants.

Results: The average QTc interval was found to be 430 milliseconds at baseline, which was increased to 441 milliseconds after HCQ usage for 3 months or greater ($p < 0.05$). The average QTc interval was 436 milliseconds in total HCQ dose less than 720 g versus 447 milliseconds in total HCQ dose greater than 720 g ($p > 0.05$). However, QTc interval was found to be similar with and without concurrent use of antidepressants (451 milliseconds in patient on HCQ alone vs. 447 milliseconds in patients on HCQ with antidepressants) in this cohort study.

Conclusion: Our study indicates that chronic use of HCQ is associated with QTc interval prolongation in patients with SLE. However, concurrent use antidepressants for fibromyalgia did not appear to further increase QTc interval.

Delayed and Immediate Release Prednisone Decrease Fatigue Comparably in Patients with Systemic Lupus Erythematosus

Hope Rainey[1], Kristy Bell[1], Violeta Rus[2], Daniel Wallace[3], Claire Dykas[1], Mary Mora[1], Maggy Comberg[1] and Peter Lipsky[1], [1]AMPEL BioSolutions LLC., Charlottesville, VA, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Cedars-Sinai Medical Center/UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: SLE – Treatment Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Morning stiffness and fatigue are common symptoms in patients with SLE. Increased cytokines and disturbed sleep patterns may contribute to morning symptoms and fatigue in SLE. We, therefore, hypothesized that delayed release (DR) prednisone given in the evening might suppress morning symptoms of stiffness and fatigue better than standard immediate release (IR) prednisone given in the morning.

Methods: This was a multicenter randomized double-blind active comparator double baseline crossover study designed to compare the impact of morning IR prednisone to the same dose of evening DR prednisone in SLE patients with increased fatigue (NCT03098823). Eligible patients met ACR classification of SLE, had a Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score ≤30 and were prescribed oral IR prednisone at 5-15 mg/day. Patients were randomized in a 1:1 ratio to receive either daily active DR prednisone (RAYOS) at 10pm and daily morning placebo or daily active morning IR prednisone and daily placebo capsules at 10pm at the same total dose they had previously been prescribed. After 3 months, the treatment regimens were reversed, and the patients continued for another 3 months. The primary endpoint was change in fatigue assessed by FACIT-F.

Results: 62 patients were enrolled and randomized and 60 were evaluable for treatment response. At 3 months, there was significant improvement in fatigue measure by FACIT-F, as well as by the Fatigue Severity Score (FSS) and the vitality questions of the SF-36. The mean degree of improvement in fatigue exceeded the minimal clinically important difference (MCID) (see Figures 1 and 2). However, there was no significant difference between the groups in the degree of improvement in fatigue. Following the crossover there was persistent improvement in fatigue compared to

Figure 1. FACIT-F results over study duration (mean ± SEM).

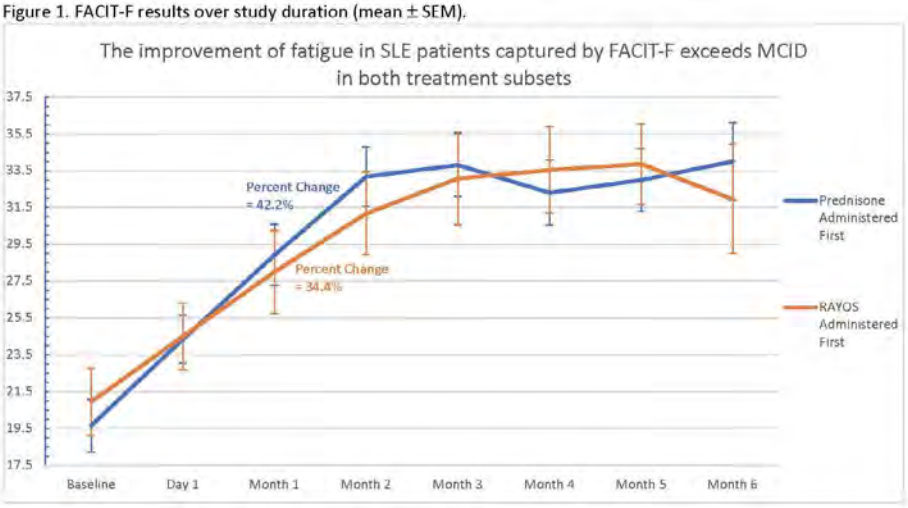

Figure 2. FSS results over study duration (mean ± SEM).

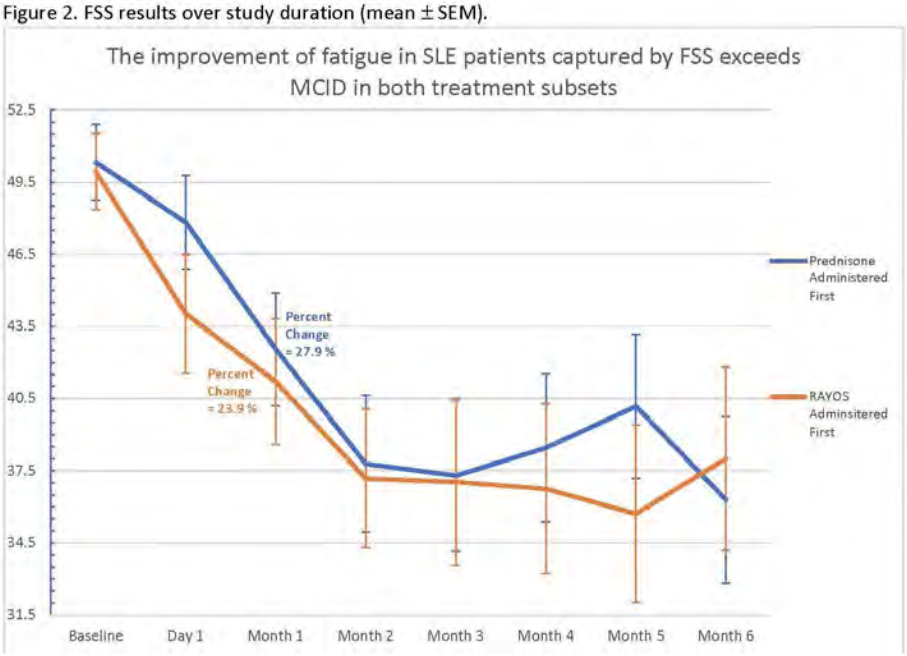

baseline, but again no significant difference between the groups. Daily estimates of morning stiffness assessed with a mobile app did not differ between the groups. The frequency of adverse events did not differ between the groups.

Conclusion: DR and IR prednisone were comparable in improving fatigue in patients with SLE. Despite no change in daily prednisone dosage from prescribed doses at entry, fatigue significantly improved, implying that one contributor to fatigue in SLE may be differences between prescribed and actual administered doses of prednisone.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory joint disease with no serological biomarkers, hence diagnosis is based on clinical evaluation alone. PsA is closely associated with Psoriasis (PsO), with up to 1/3 of psoriatic patients developing PsA via unknown mechanism.

PsoP27 -SF

Cit-PsoP27- Serum			
Median	0.317	0.232	0.321
SD	0.298	0.143	0.160
P value (comp. to HC)	0.49	0.507	-
P value (comp. to RA)	0.065	-	0.507

PsoP27 Ab level (OD) in sera of patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA), and healthy controls (HC).

PsoP27 is an autoantigen found in skin lesions of PsO patients (1) and its levels correlate with psoriasis activity (2). PsoP27 is speculated to be involved in other inflammatory processes, yet it was not investigated in regard to PsA or RA.

The most common autoantigens in RA are citrullinated autoantigens which are formed by PAD (peptidylarginine deiminase enzymes) and can drive the autoimmune response (3). Although known to be present in other diseases, citrullination is commonly associated with RA.

Our aim was to characterize native and citrullinated PsoP27 antibodies (Ab) in synovial fluids (SF) and sera of PsA and RA as compared to osteoarthritis (OA) patients and healthy controls, respectively.

Methods: SF of PsA (*n=35*), RA (*n=11*) and OA (*n=13*) patients and sera of PsA (n=32), RA (n=32) patients and healthy controls (*n=31*) were analyzed by ELISA for native and citrullinated PsoP27 Ab.

Results: In SF, both native and citrullinated PsoP27 Ab were significantly higher in PsA and RA compared to OA patients (Table 1). Significant correlation was observed between both forms of PsoP27 Ab in SF and swollen joints count (Native: *p=0.029, r=0.39*, Cit: *p=0.041, r=0.369*), psoriasis area and severity index (PASI) score (Native: *p=0.011, r=0.56*, Cit: *p=0.008, r=0.369*), and CRP levels (Native: *p=0.017, r=0.446*, Cit: *p=0.03, r=0.408*). In contrast, in RA patients there was no correlation between levels of PsoP27 Ab in SF and swollen joint count or CRP levels. No difference in PsoP27 Ab were detected in sera of all groups (Table 2).

Conclusion: We determined for the first time the presence of antibodies to psoriatic-related autoantigen PsoP27, in SF of PsA and RA patients. Furthermore, we showed a positive correlation between levels of PsoP27 Ab and disease activity in

PsA, but not in RA. Also, we demonstrated the presence of citrullinated antibodies in PsA, commonly thought to be specific to RA. Our results suggest that PsoP27 Ab in SF may be utilized for diagnosis and disease assessment in PsA.

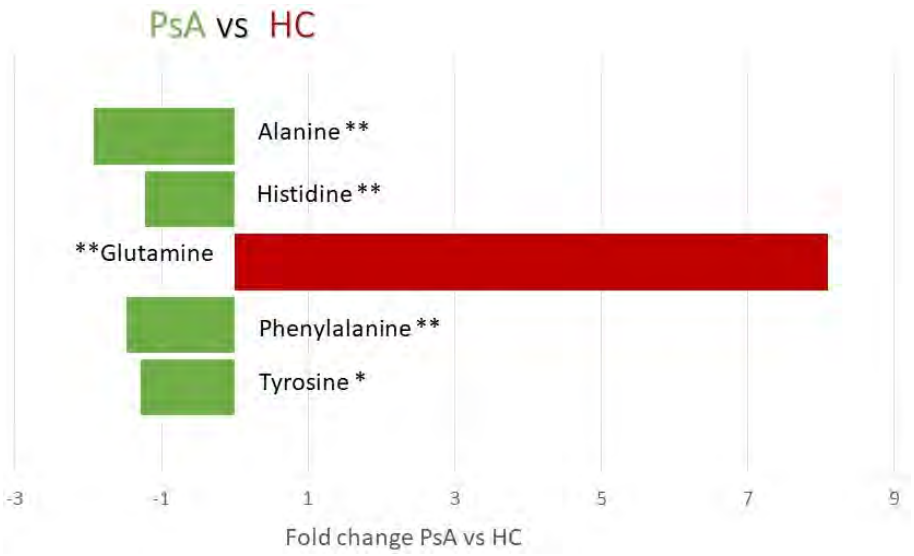
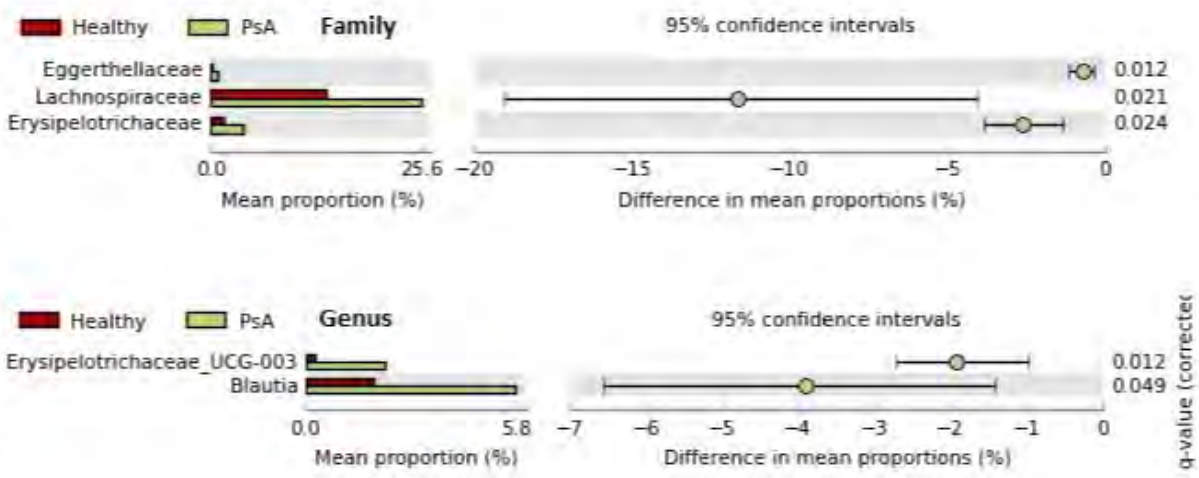
Serum multivariate analysis techniques (A) Serum - PCA (B) Serum O-PLS after 1000 permutations (p-value = 0.0250)



Changes in the two groups of participants in the study (19 PsA ; 12 HC). * **p-value <0.005** ** **p-value < 0.005. Quantification of small molecules was performed with a simplex approach based algorithm developed in-house and implemented in MatLab**



16s rRNA gene sequencing. Illumina MiSeq Regions V1-V2

Background/Purpose: Perturbations of the gut microbiota have been associated with Psoriatic Arthritis (PsA), a chronic inflammatory disease. We aim to test the microbiome-metabolic interface of patients with PsA when compared to healthy controls (HC), this phenomic approach study the microorganism composition of the gut and specific gut-microbial-related metabolites

Methods: This was an observational study conducted in two centres at the United Kingdom. Stool, urine and serum samples from 19 PsA patients and 12 HC were collected. Stool microbial profiles were generated using 16S rRNA gene sequencing (using Illumina MiSeq and Oxford Nanopore Sequence). Fecal, serum and urine supernatants were analysed using a Bruker Avance IIII 600 MHz spectrometer. In-house scripts were used to process NMR spectra (Figure 1).

Results: Quantification of small molecules in serum samples; Tyrosine (*p-value < 0.05*), Phenylalanine (*p-value < 0.05),* Histidine (*p-value < 0.05*) and Alanine (*p-value < 0.005*) were increased in PsA participants and Glutamine (*p< 0.005)* was increased in the HC (Figure 2). The 16s rRNA gene sequencing reported an increase in the relative abundance of the family, *Lachnospiraceae* (*p-value < 0.005*) and one of its genus, *Blautia (p-value < 0.005*), taxa that have been positively associated with serum alanine levels in the literature (Figure 3).

Conclusion: While there are confounders in this pilot study which may contribute to findings, we found significant changes in the amino acids related to the gut microbiome in PsA patients. New associations were made for PsA when compare with previous studies of chronic inflammatory diseases. Further work will validate these results and disclose further links between PsA and the gut microbiota.

The Association Between Imaging Sub-phenotypes of Psoriatic Arthritis and Gene Expression Profiles

Lihi Eder[1], Lee Quan[2], Sara Rahmati[3], Iris Eshed[4], Proton Rahman[5], Igor Jurisica[6] and Vinod Chandran[7], [1]Women's College Research Institute, University of Toronto, Toronto, ON, Canada, [2]University of Toronto, Toronto, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Sheba Medical Center, Tel-Aviv, Israel, [5]Memorial University of Newfoundland, Department of Medicine, St John's, Canada, [6]Krembil RI, Toronto, Canada, [7]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

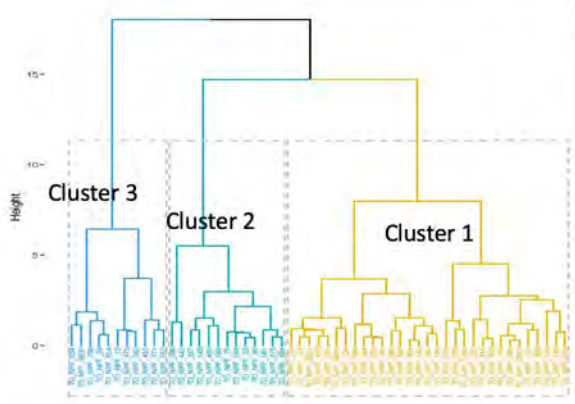
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Heterogeneity is a hallmark of psoriatic arthritis (PsA), which is reflected in diverse clinical, imaging and molecular features, various disease courses and treatment responses. We hypothesized that specific molecular markers underlie the various imaging manifestations of PsA. The study objective was to identify imaging sub-phenotypes in patients with PsA and determine their association with whole blood mRNA expression markers.

Methods: 55 patients with PsA ready to initiate treatment for active disease were prospectively recruited. An ultrasound assessment of the extent of musculoskeletal inflammation in 64 joints, 34 tendons and 16 entheses was performed. Sonographic inflammation (in greyscale and Doppler) of the following domains was graded for: a) synovitis; b) peritenonitis; c) tenosynovitis; and d) enthesitis. A global inflammatory score was calculated for each tissue domain. Peripheral blood was profiled with RNAseq, and gene expression data were obtained. Analyses were performed in two stages: 1) Unsupervised cluster analysis was performed to define imaging sub-phenotypes in PsA that reflected the predominant tissue involved; 2) Principal component analysis was used to determine the association between imaging-defined clusters and peripheral blood gene expression profile. Pathway enrichment analysis was performed to identify underlying mechanisms that characterize individual imaging clusters.

Results: The patients could be divided into 3 groups based on unsupervised hierarchical clustering of images indicating the predominant involved tissue (Figure 1): 1) Synovitis predominant (N=31 [56%]); 2) Enthesitis predominant (N=13 [24%]); 3) Peritenonitis predominant (N=11 [20%]). There were no significant differences in the demograph-

Figure 1 – Hierarchical clustering of imaging data based on tissue-level inflammation



Standardized Ultrasound Scores by Imaging Cluster (median and IQR)

	Cluster 1 Synovitis predominant (N=31)	Cluster 2 Enthesitis predominant (N=13)	Cluster 3 Peritenonitis predominant (N=11)	P value
Synovitis score	1.86 (0.64)	1.15 (0.34)	1.59 (1.40)	0.004
Enthesitis score	0.24 (0.34)	0.83 (0.19)	0.50 (0.45)	<0.001
Peritenonitis score	0.29 (0.70)	0.13 (0.27)	1.13 (0.22)	<0.001
Tenosynovitis score	0 (0.39)	0 (0.27)	0.27 (0.43)	0.59

*Standardized scores= total sonographic score in the domain divided by the total number of affected articular/tendon/entheseal sites

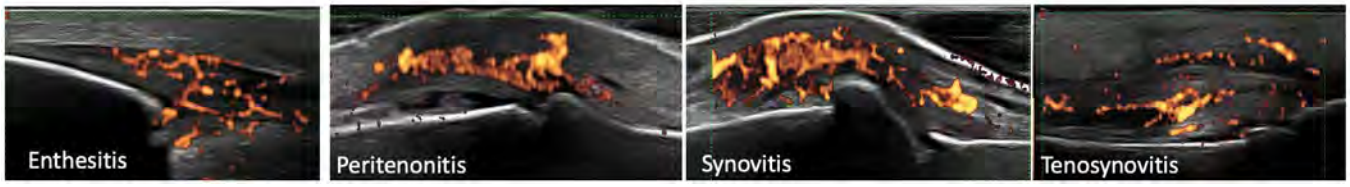


Figure 1. Hierarchical clustering of imaging data based on tissue-level inflammation

Figure 2 – Gene Expression Data by Imaging Clusters

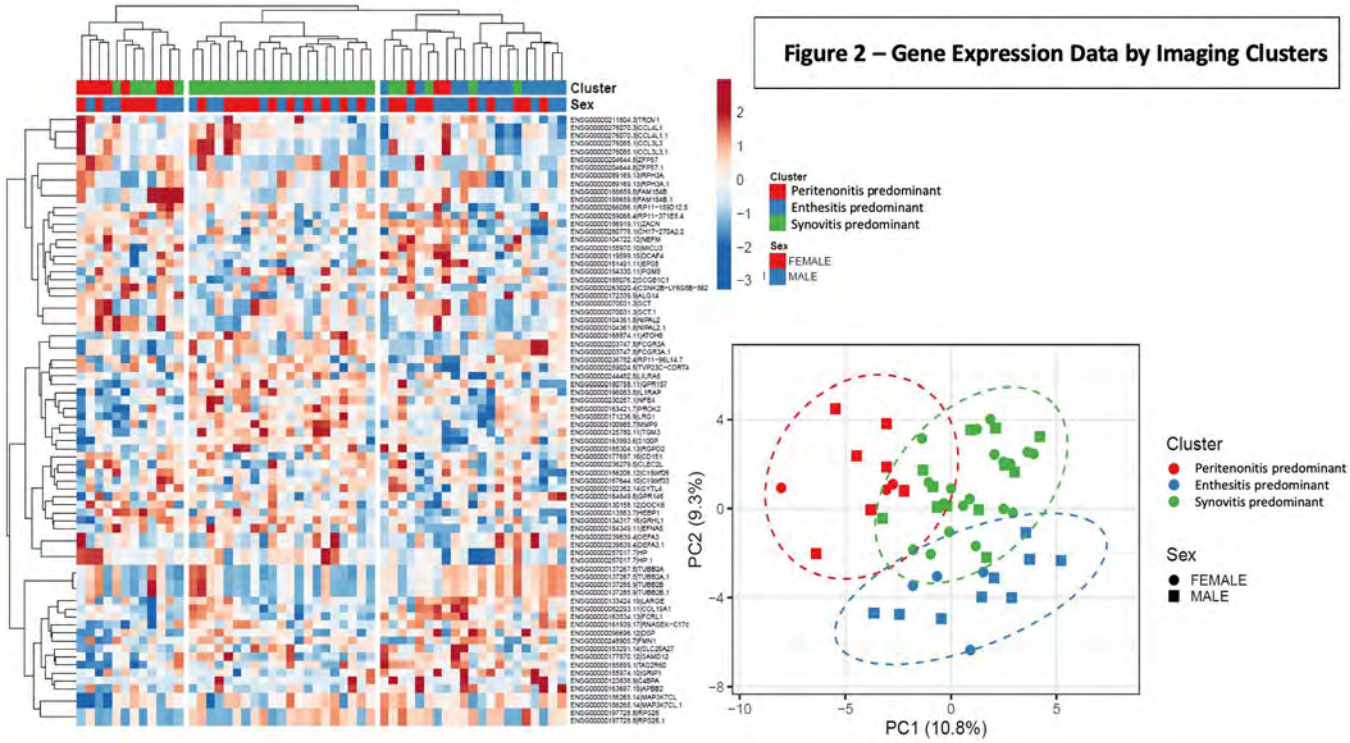

Figure 2. Gene Expression Data by Imaging Clusters

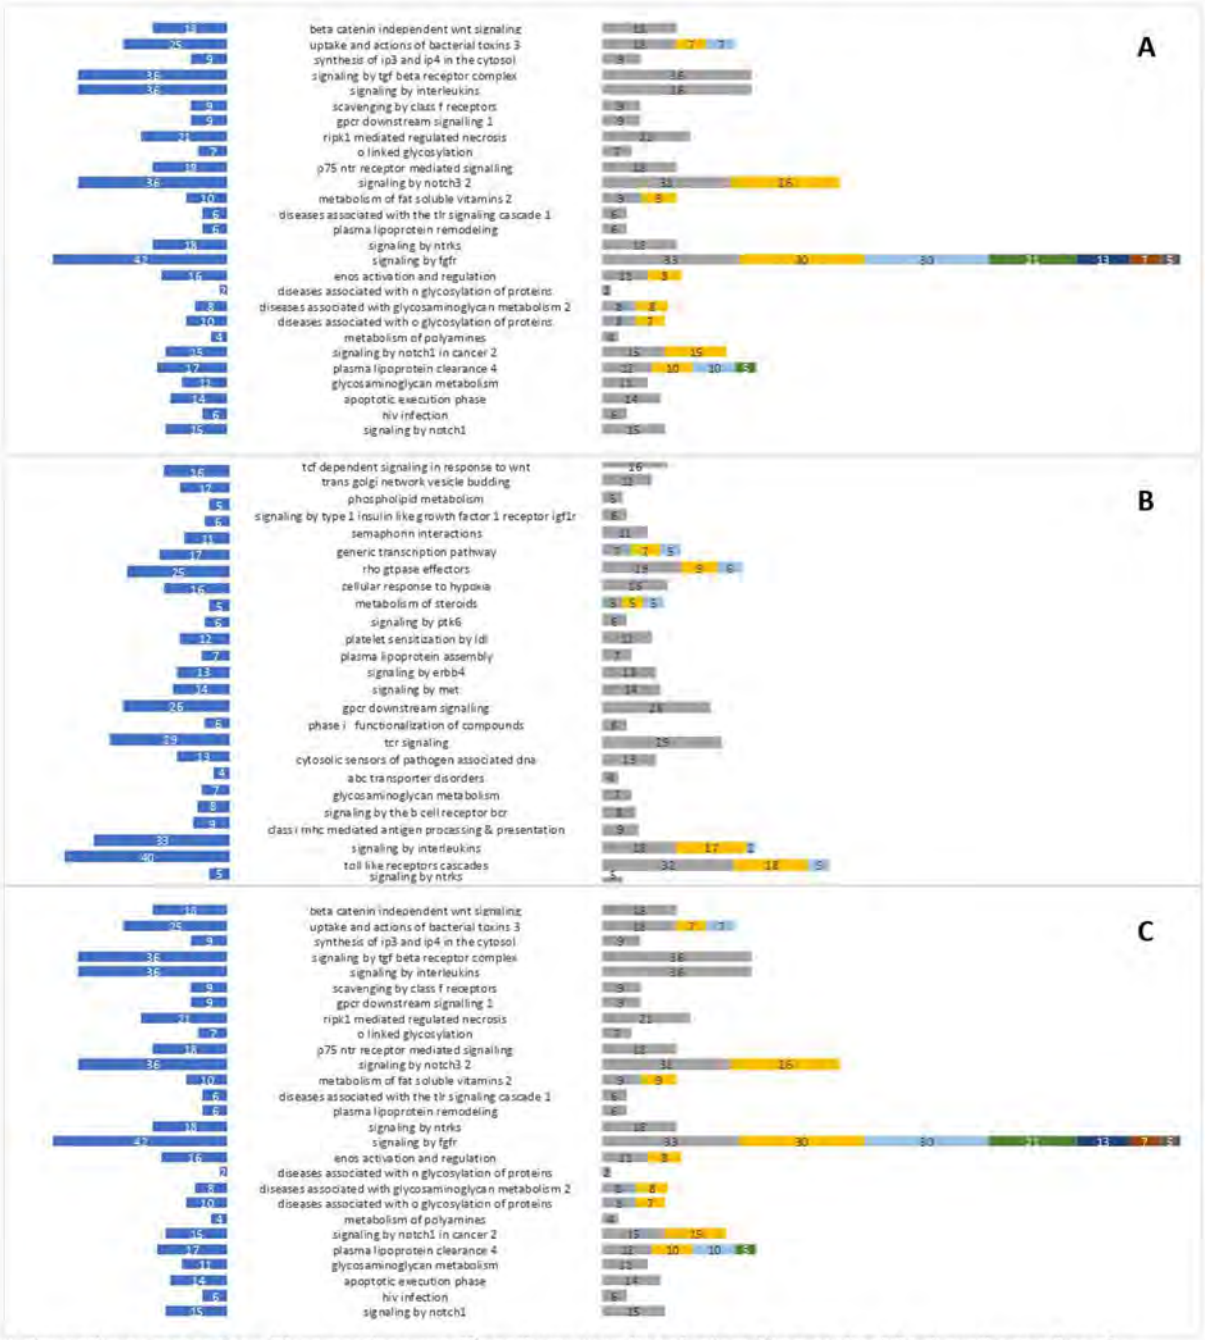
Figure 3 – Differentially Expressed Pathways Across the Imaging Clusters



Major pathway categories with comparison-specific pathway. Number of colored bars at the right show the number of comparison-specific pathway in each category and numbers on the bars show counts of genes in each pathway. Bars at the left show union of all genes whose breakdown across pathways is shown at the right.

A. Enthesitis vs. Peritenonitis predominant clusters; **B.** Synovitis vs. Enthesitis predominant clusters, **C.** Synovitis vs. Peritenonitis clusters

The three comparisons show low overlap: only one pathway category is shared in these figures. Pairwise overlap of categories across figures have sizes 3, 3, and 5.

Figure 3 . Differentially Expressed Pathways Across the Imaging Clusters

ics, duration of PsA and psoriasis characteristics between the clusters (Figure 1). The primary differences between the clusters were related to the severity of clinical joint ad entheseal involvement. Unsupervised clustering of gene expression data identified three clusters that partially overlapped with the imaging clusters (Figure 2). Overall, 344 genes were differentially expressed ($p< 0.05$) in two of the three comparisons between the imaging clusters. Enriched differential pathways included: toll-like receptor cascade, cytokine (TNF, IL-23, TGF-b) signaling, VEGF signaling, complement cascade and integrin signaling (Figure 3).

Conclusion: We identified three different imaging clusters based on the predominant tissue involved in patients with active PsA. Distinct biologic pathways may underlie these imaging clusters seen in PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: AxSpA is a heterogeneous disease, leading to different treatment and follow-up modalities depending on the presentation, along with other elements (socio-economic, gender, etc..). In a previous work, we identified some disease activity trajectories in early axSpa[1], but we did not evaluate the long-term impact for patients in terms of outcomes such as function, work impairment or structural progression.

Objectives: To identify and describe different trajectories of activity over 5 years in patients with early axSpA and to determine the impact of each on long-term outcomes.

Methods: Prospective, multi-centre study (DESIR cohort) of patients with early inflammatory back pain suggestive of axSpA.

Disease activity trajectories were identified using the k-means method, which provides longitudinal clusters. Baseline characteristics were described and the probability to be associated with one Trajectory assessed by a multinomial regression.

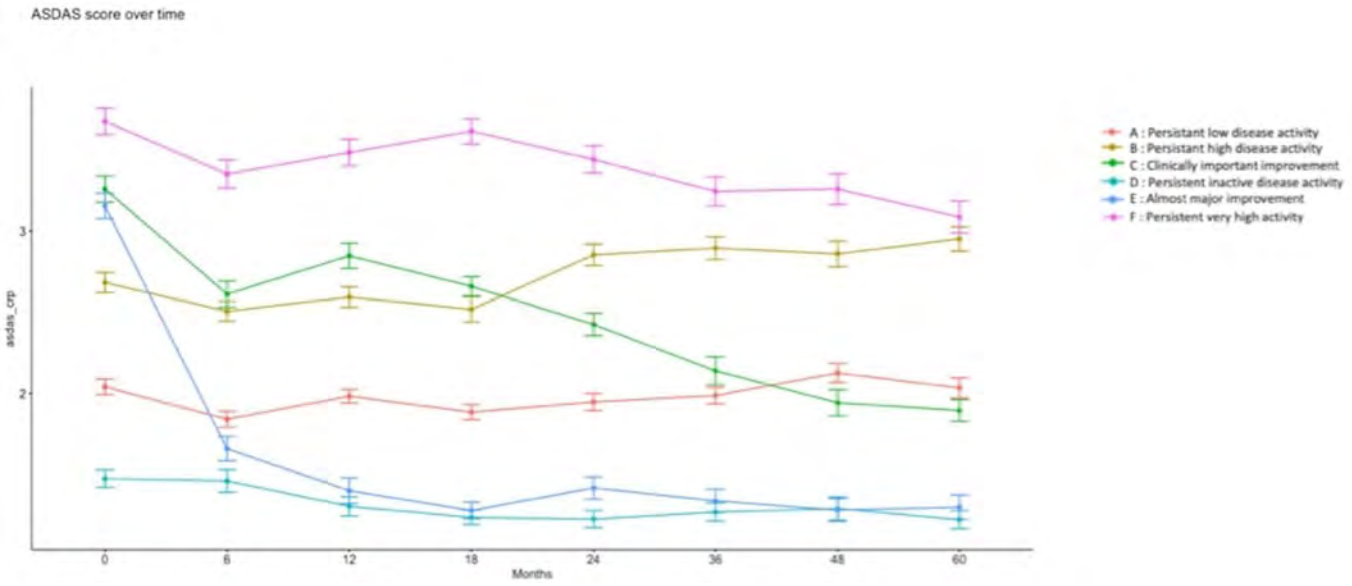

Figure. Trajectories of disease activity in early axial spondyloarthritis according to k-means technique. ASDAS, Ankylosing Spondylitis Disease Activity Score.

Table. Outcomes associated with distinct disease activity trajectories in early axial spondyloarthritis (mixed model)

Long term outcomes such as TNFi prescription, function (BASFI), work impairment, quality of life (SF36 scale) and structural progression, associated with each trajectory were identified using mixed models.

Results: 633 patients were included. Six trajectories of disease activity were identified: Trajectory A (n=140 patients, 25.4% of all patients): 'Moderate disease activity'; B (n=94, 17.1%) : 'Persistent high disease activity'; C (n=94,

17.1%) :'Clinically important improvement' (improvement of 1.36 points on the ASDAS between baseline and year 5) ; D (n=79, 14.3%) :'Persistent inactive disease activity'; E (n=78, 14.2%) :'Almost major improvement' (improvement of 1.8 points) ; F (n=66 (12%) : 'Persistent very high activity'.

The 'Persistent low disease activity' Trajectory was set as the reference trajectory: a university level of education was found to be predictive of belonging to the 'Inactive disease' trajectory (OR=3.04, 95% confidence interval [1.46 to 6.78]). Male gender (OR=2.99 [1.56 to 5.92]), and a history of articular peripheral involvement (OR=4.34 [2.14 to 9.10]) were predictive of belonging to the 'Almost major improvement' trajectory, whereas a low degree of education (OR=0.27 [0.14 to 0.52]), and female gender (OR=2.01 [1.03 to 4.34])were associated with the 'Persistent very high disease activity' trajectory.

All trajectories were associated with a higher TNFi prescription. Higher activity trajectories were associated to other poorer outcomes : the 'Persistent very high disease activity' and 'Persistent high disease activity' Trajectories presented respectively a mean of 189 and 95 more days of sick leave over 5 years than the reference Trajectory, but also significantly lower SF-36 scores, poorer BASFI and BASMI. However, no higher likelihood of structural progression was observed in high disease activity groups.

Conclusion: We identified 6 trajectories of ASDAS-CRP. Gender, a university level of education, and peripheral joint involvement were the main factors differentiating trajectories at baseline. Higher disease activity trajectories were significantly associated with poorer function, more days of sick leave, and poorer quality of life. Interestingly, no Trajectories were found to be predictive of structural progression.

Abstract Number: 1852

Intestinal Permeability in the Adjuvant Induced Arthritis Model: Preliminary Study and Impact of NSAIDs

Sophie Hecquet[1], Romain Bordy[2], Clement Prati[1], Daniel Wendling[3], Céline Demougeot[2] and Frank Verhoeven[1], [1]Rheumatology, University Teaching Hospital, Besançon, France, [2]EA4267 Laboratory, Besançon, France, [3]CHU Besançon, department of rheumatology, Besancon, France

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The gut is no longer considered as a simple element associated with spondyloarthritis but as a real actor of the disease. In patients with spondyloarthritis, the presence of intestinal inflammation and an increase in digestive permeability responsible for bacterial translocation has been described. No data are available on the effect of non-steroidal anti-inflammatory drugs (NSAIDs) on this bacterial translocation in patients with spondyloarthritis. Zonulin and lipopolysaccharide (LPS) have been described as good biomarkers of intestinal permeability and bacterial translocation, respectively. Adjuvant-induced arthritis (AIA) is a model of recent arthritis characterized by ossification and ankylosis in the post arthritis period. This model can be considered as a model of reactive arthritis in which our previous work has reported a clear efficacy of NSAIDs with differences between molecules at the structural

and vascular levels.To test the hypothesis that there is an increase in digestive permeability and bacterial translocation in the AIA model and to show the influence of different NSAIDs on these two parameters.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6-week-old male Lewis rats by an injection at the base of the tail of Mycobacterium butyricum in incomplete Freund's adjuvant. A group of non-AIA (control) rats received saline. At the first signs of arthritis, the AIA-rats were evaluated (arthritis score 0-6) and treated daily intraperitoneally with naproxen (10 mg/kg/day), diclofenac (5mg/kg twice daily), celecoxib (3 mg/kg/day) or saline solution (AIA-vehicle group). After 21 days of treatment, the rats were sacrificed and serum levels of zonulin and LPS were evaluated by ELISA and liquid chromatography-mass spectrometry, respectively. Circulating levels of TNF-α and IL1-β were measured as well as the hind paw radiographic score.

Results: Compared to the control group, there was a significant increase in zonulin concentration ($p < 0.001$) in the AIA group. There was no significant difference in the concentration of LPS between the two groups. The levels of zonulin were correlated with the TNF-α levels (R= -0.42; p=0.032) and the arthritis score (R=0.45; p=0.013) but not with the level of IL1-β (R=; p-0.018; p=0.39). Treatment with NSAIDs significantly and equivalently decreased the arthritis score in each group. Compared to the vehicle group, treatment with naproxen significantly decreased the radiographic score ($p< 0.001$), TNF-α, IL1-β ($p < 0.01$), zonulin ($p< 0.001$) and LPS ($p < 0.05$). Celecoxib decreased radiographic score ($p < 0.001$), IL1-β ($p < 0.01$), TNF-α ($p < 0.01$) but increased zonulin levels ($p < 0.05$) without effect on LPS. Diclofenac also decreased radiographic score ($p < 0.001$), TNF-α ($p < 0.01$), and IL1-β ($p < 0.01$) but increased both zonulin ($p < 0.01$) and LPS ($p < 0.001$).

Conclusion: We have demonstrated an increase in serum zonulin levels in the AIA model and a beneficial effect of naproxen on intestinal permeability and bacterial translocation in contrast to celecoxib and diclofenac. Moreover, the plasmatic zonulin levels were correlated with TNF-α but not with IL1-β supporting a pivotal role of TNF-α on the tight junctions in this model.

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The etiopathogenesis of axial spondyloarthritis (AxSpA) is multifactorial. The possible role of alteration in gut microbiome (dysbiosis) has been recently suggested. However, the association of dysbiosis with structural damage is still unknown and further studies are needed to assess its association with disease activity. Objectives: To determine the alterations in the gut microbiota in AxSpA patients. To evaluate whether changes in the gut microbiota in AxSpA patients are associated with radiographic and enthesis involvement or disease activity.

Methods: Cross-sectional study of 33 patients with AxSpA (according to ASAS criteria) and 7 sex-age matched healthy donors (HDs) was studied. Disease activity variables such as C-reactive protein and ESR were measured. The enthesis affectation was evaluated using ultrasound to obtain the Madrid Sonographic Enthesitis Index (MASEI). Gut microbiota was evaluated using the Ion Torrent S5 platform and the sequences were processed using the QIIME2 analysis platform. Chi-square and Mann-Whitney tests were used for qualitative and quantitative variables, respectively, correlations between quantitative variables were determined using the Spearman Rho test and univariate analysis with a simple linear regression. Significant differences were considered $p < 0.05$.

Results: α and β diversity data showed non-significant differences between AxSpA patients and HDs. The analysis demonstrated a significant increase in *Coprococcus comes* in AxSpA patients compared to HDs. Also, we observed

	AxSpA patients (n=33)	Healthy donors (n=7)	p

Table 2. Microbial composition according to disease activity, radiographic and enthesis affectation. Values are expressed as relative abundance (sqrt/arcsin).

	Spearman Rho test		Univariate analysis	
	r	p	R^2	p
G_Roseburia	0.509	0.005	0.166	0.016
S_Roseburia faecis	0.481	0.008	0.162	0.017

Table 3. Correlation studies and univariate analysis between gut microbiota an disease duration.

that patients tend to differ from HDs in the families *Bacteroidaceae* and *Bifidobacteriaceae* and the genera *Bacteroides*, *Bifidobacterium* and *Dialister*.

AxSpA patients were divided in two groups: patients with active and patients with inactive disease. We observed that α-diversity indicator such as Shannon index was significantly decrease in patients with active disease (ASDAS >2.1). Family *Brucellaceae* was significantly decreased and family *Peptostreptococcaceae* was significantly increased in active group compared to inactive group. Moreover, species such as *Alistipes finegoldii*, *Alistiper putredins* and *Paraprevotella clara* were significantly decreased in active group.

Moreover, families *Peptostreptococcaceae* and *Streptococcaceae* were significantly increased in patients with pathological enthesis ultrasonography (MASEI >17) compared with patients with normal enthesis.

Finally, AxSpA patients were divided in other two groups: patients with a radiographic AxSpA and non-radiographic AxSpA. We observed that patients with radiographic AxSpA had an increase in family *Erysipelotrichaceae*, genus *Ruminococcus* and species *Ruminococcus gnavus versus* non-radiographic AxSpA. Further, positive correlation was observed between genus *Roseburia* and species *Roseburia faecis* with disease duration.

Conclusion: 1) AxSpA patients had a significant alteration of the gut microbiota. 2) These alterations are associated with disease activity and duration, and enthesis and radiographic involvement.

NGF/TrkA System Regulates Pain and the Pannus Formation: Targeting NGF-TrkA in Psoriatic Arthritis

Siba Raychaudhuri[1] and Smriti Raychaudhuri[2], [1]UC Davis, School of Medicine, Davis, CA, [2]VA Sacramento Medical Center, Davis, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

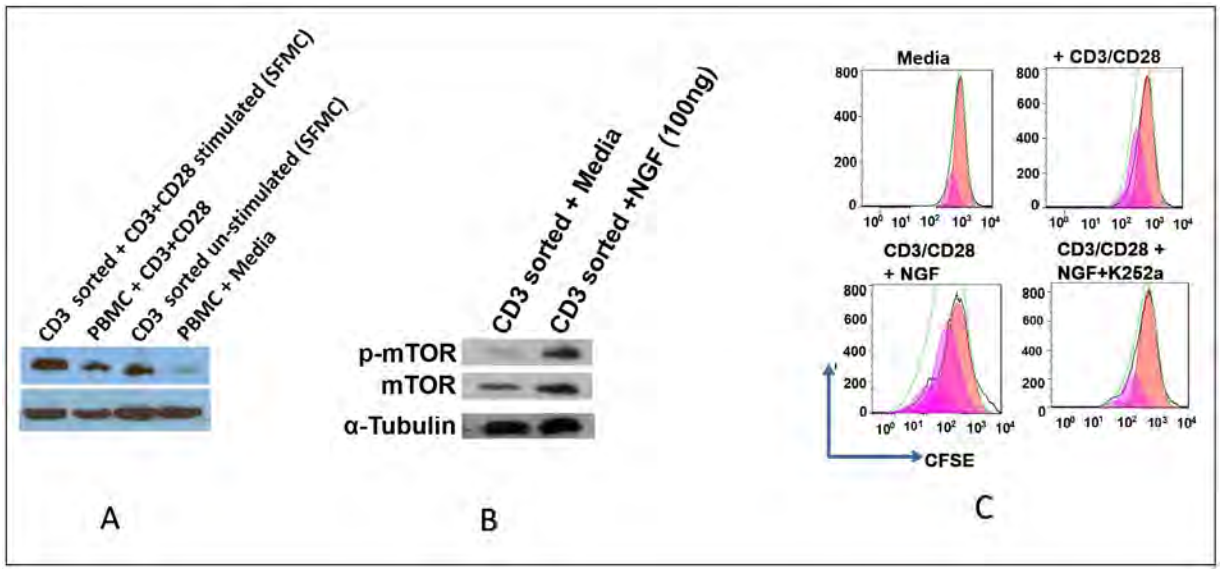

Figure 1. Here we are briefly providing our observations in the Fig 1 that in Psoriatic Arthritis (PsA) - (i) Synovial fluid (SFMC) T cells have higher levels of TrkA compared to the PBMC T cells (ii) NGF induces progrowth/survival mTOR kinase signaling in T cells (iii) NGF/TrkA regulates human T cell function such as T cell proliferation. A. Expression of TrKA on CD3/CD28 stimulated and unstimulated T cells derived from the synovial fluid (SFMC) and PBMC of a PsA patients. Western-blot assay was performed in 5 PsA patients. Expression of Trk-A was found to be significantly high in CD3/CD28 stimulated T cells ($p<0.05$) compared to the unstimulated T cells. B. NGF regulates mTOR signalling kinases in T cells: Enriched T cells from peripheral blood mononuclear cells (PBMC) were cultured in serum free media for 24hrs and then exposed to NGF (100ng/ml) for 2 hrs. Cells stimulated with NGF were found to have increased p-mTOR in comparison to the unstimulated T cells. Data was obtained from n=5 individual set of experiments and was compared at significance level p=0.05. C. NGF induces significant proliferation of T cells. CD3+ T cells were magnetically sorted from peripheral blood followed by staining with CFSE. Then cells were seeded in CD3/CD28 precoated 24 well plates with respective treatment (NGF: 100 ng/ml; K252a: 100 ng/ml) and cultured for 5 days at 370C with 5% CO2. Cells were collected and data acquired in flow cytometer followed by analysis in FlowJo software. This is a representative profile of CFSE dilution assay of CD3+ T lymphocytes from one subject (n=10). NGF (100 ng/ml) induced T cell proliferation (as shown by more generation as well as more number of cells in each generation) than CD3/CD28 stimulated alone ($p<0.01$). TrkA inhibitor, K252a (100 ng/ml) effectively inhibited the NGF induced T cell proliferation which in turn prove the relevance of NGF in T cell proliferation through its functional receptor TrkA.

Background/Purpose: Function of Nerve Growth Factor (NGF) in the nervous system and its regulatory role in pain is well defined. We have shown earlier that NGF levels are increased in synovial fluid (SF) from psoriatic arthritis (PsA) and rheumatoid arthritis (RA) patients (Raychaudhuri SP, eta al. Arthritis Rheum. 2011;63:3243-52) Here we are providing defined mechanism(s) through which NGF acts on human T cells, and provide a model which substantiates a key role of NGF in the pathogenesis of PsA

Methods: We investigated whether NGF and its high affinity receptor (TrkA) is upregulated at the disease site, the cellular source of NGF and the regulatory role of NGF in the inflammatory cascades of PsA. Untreated psoriatic arthritis (n=15) and osteoarthritis (OA, n=15) patients were recruited after proper IRB approval. PBMC/SFMC T cells and FLS were cultured as per our earlier studies (Raychaudhuri SP, eta al. Arthritis Rheum. 2011;63:3243-52; Saxena A, et al. Arthritis Rheum. 2011; 63:1465-6). We used ELISA, western blot and FACS analysis to determine NGF, TrkA and cellular phenotypes. Student t test and ANOVA were used for statistical analyses.

Results: In unstimulated T lymphocytes low level expression of TrkA was detected; whereas physiologically activated CD3+ T lymphocytes showed distinct upregulation of TrkA. SF collected from PsA was enriched with HLA-DR+CD3+ TrkA+ T lymphocytes. NGF significantly stimulated the proliferation of T lymphocytes. We have further noticed NGF induced phosphorylation of mTOR and this could be the possible mechanism for the pro-survival effect of NGF on T lymphocytes. Finally we showed that T cell activation could be inhibited by TrkA inhibitors such as K252a (Fig 1).

FLSs from patients with PsA produced significantly higher levels (< .001) of NGF (200±22 pg/ml) compared to FLS of patients with OA (42±15 pg/ml). Furthermore, we observed that NGF significantly stimulated the proliferation of FLS derived from PsA synovial tissue

Conclusion: Our observations suggest: (i) NGF is produced by FLS at the disease site in PsA (ii) NGF acts as a T cell growth factor, promotes survival of the pathologic effector T cells and thus, help to escape them from peripheral immuno-tolerance mechanisms. We show here enrichment of TrkA+ activated memory T cells in PsA and, we identified synovial cells (FLS) as the prime source for NGF. We propose that NGF as a T cell growth factor promotes survival of the pathologic effector T cells, contributes in sustaining the chronic inflammatory cascades of autoimmune diseases; and NGF/TrkA targeted therapies as a novel approach for PsA.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Fecal calprotectin (FC) is a well bio-marker related to mucosal inflammation. Digital chromo-endoscopy (DCE) with magnification is a technique to identify microscopic inflammation. The objective of the study is to establish the association between FC levels and DCE/histology for the detection of early bowel lesions related to structural inflammatory changes in patients with SpA without IBD (inflammatory bowel disease)

Methods: In total, 180 patients with SpA fulfilling ASAS classification criteria were assessed by rheumatologist. Of them, 42.2% met the selection criteria and 48.7 % had an indication by a gastroenterologist to perform DCE for co-

lon e ileum plus histological analysis. FC, CRP, and HLA-B*27 were performed. The association between FC levels and CDE/histological and clinical parameters were evaluated using Chi-square or Fisher's exact test with multivariate evaluation by principal components analysis (PCA)

Results: The average age of the patients included for DCE was 45,1±10.3 years, 56.8% were men, 40.9% were HLA-B*27:05 positive and 89.2% had axial involvement and 91.9% inflammatory back pain. Positive levels of FC (PFC >120ng/mL) and high levels (HFC) >250ng/Ml, were observed in 27% and 16% respectively. BASDAI >4 was found in 54.1% of patients and ASDAS-PCR >2.1 in 78.4%. High levels of PFC were associated with BASFI >4 (p = 0.036), BASDAI >4 (p = 0.047). More than 70% of these patients a loss of the vascular pattern in the ileum (LVPI) was observed (p = 0.005). Moreover, 77% of the patients having PFC with abdominal bloating, simultaneously had LVPI (p = 0.020) in addition to villous atrophy and microscopic inflammation in 66.7% (p = 0.012). In those patient having PFC plus abdominal pain the presence of LVPI was observed in 75% (p= 0.007). The HFC associated with alterations at the level of the ileum mucosa (p= 0.009), with LVPI (p= 0.001). At microscopic analysis, the HFC levels were associated with inflammation (p= 0.046) and a chronic pattern (p = 0.014) in 83.3%. Overall, 27.3% of patients had HFC and diarrhea, associated with LVPI and presence of erosions in ileum (p=0.026) and (p=0.031), respectively. Microscopically, ileum chronic inflammation was observed in 25% (p=0.037). All patients having increased HFC levels and ASDAS-CRP >2.1,the following findings were observed: alteration of ileum mucosa (p = 0.09), request for vascular pattern (p = 0.001) and villous atrophy reflected microscopically as a chronic pattern (p=0.014) in 66.7%. The PCA with Kaiser normalization of 0.642 and Bartlett test (p=0.0001), showed three factors:1) Micro and macroscopic changes of chronic inflammation and HFC (CC = 0.837, 2),increased CRP and microscopic acute inflammation (CC = 0.792) and 3) clinical activity scores ASDAS-PCR and BASDAI (CC = 0.914)

Conclusion: FC levels were significantly higher in patients with SpA group in which CDE showed LVPI as main finding with associations with disease activity score.FC levels may be used to guide patient management in SpA and further investigation is required. The presence of villi atrophy may suggest a shared immune pathway related to chronic damage in the intestinal tissue when the joint manifestations are active

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular risk factors are increased in Psoriatic Arthritis (PsA). Latest studies suggested that inflammatory and metabolic disorders may be under epigenetic control, including DNA methylation. DNA methylation is an unexplored area in the field of PsA.

Objective: To study the alterations in the genome-wide DNA methylation profile of CD4+T cells from PsA patients and its relationship with its pathology and the risk of cardiovascular comorbidity.

Methods: Twenty healthy controls (HC) and 20 PsA patients were included in the study. PsA patients were classified into insulin resistant and non-insulin resistant according to HOMA-IR index. CD4+ T lymphocytes were isolated from peripheral blood by positive immunomagnetic selection. The Illumina Infinium MethylationEPIC Beadchip was used to obtain DNA methylation profiles across approximately 850,000 CpGs (TSS1500, TSS200, 5UTR, 3UTR, first exon, gene body). Beta values (β) estimating methylation levels were obtained at each CpG site, and differentially methylated genes (DMG) between PsA and HC were identified. Functional classification of these genes was carried out through gene ontology analysis (PANTHER database). Gene expression analysis of the selected genes was also evaluated by RT-PCR. Vascular parameters including carotid intima-media thickness (cIMT) and endothelial function was analyzed by ecodoppler and periflux respectively.

Results: The genome-wide methylation analysis identified 112 DMGs including 41 hypomethylated and 71 hypermethylated. These differentially methylated genes were enriched with several signaling pathways and disease categories including immune response, metabolic processes, oxidative stress, vascular and inflammatory pathways. The altered gene expression of selected genes with altered methylation levels in PsA was also validated. Correlation and association analysis of these DMGs with clinical and analytical variables, cardiovascular risk factors and endothelial microvascular function revealed that the degree of methylation of these genes was significantly associated with cIMT (IGF1R, NDRG3, SMYD3, HLA-DRB1, WDR70), arterial pressure (METT5D1, NRDG3, ADAM17, SMYD3, WNK1, CBX1), insulin resistance (AKAP13, SEMA6D, PLCB1), altered lipid profile and atherogenic index (MYBL1, METT5D1, MAN2A1, SLC1A7, SEMA6D, PLCB1, TLK1, SDK1, CBX1), inflammation (MYBL1, NDUFA5, METT5D1, SEMA6D, PLCB1, TLK1), and endothelial dysfunction (ADAMST10, GPCPD1,

CCDC88A). In addition, this analysis also identified 435 DMGs including 280 hypomethylated and 155 hypermethylated in CD4+ T cells from IR-PsA vs non IR-PsA patients. Between these two groups of PsA patients, CHUK, SERINC1, RUNX1, TTYH2, TXNDC11, FAF1, BICD1, SCD5, PDE5A, FAS, NFIA and GRP75 displayed the most significantly altered methylation, suggesting the role of these genes in the metabolic complications associated with PsA.

Conclusion: These findings help our understanding of the pathogenesis of PsA and advance epigenetic studies in regards to this disease and the cardiometabolic comorbidities associated. Funded by ISCIII (PI17/01316 and RIER RD16/0012/0015) co-funded with FEDER and FAR.

KIR3DL2 Is Not Overexpressed on CD4+ T Cells and NK Cells in Patients with Axial Spondyloarthritis csDMARD and bDMARD Naive

Guillaume Larid[1], Sophie Trijau[1], Clothilde Barral[1], Pierre Lafforgue[1] and Thao Pham[2], [1]Aix Marseille Univ, APHM, Rheumatology department, Marseille, France, [2]Aix Marseille Univ, APHM, department of rheumatology, Marseille, France

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Overexpression of KIR3DL2 on CD4+ T-cells and NK-cells has been reported in patients with ankylosing spondylitis (AS) HLAB27+. We aimed to 1) analyse KIR3DL2 expression in patients with active axial spondyloarthritis, radiographic (AS) and non radiographic (nr-axSpA), HLA B27+ and HLA B27 – and 2) to assess the impact of pharmacological stimulation on CD4+ T-cells of those patients.

Methods: We analysed by flow cytometry whole blood and PBMC samples from those patients using fluorescent antibodies against CD45, CD14, CD3, CD19, CD4, CD8, TCR GD, CD56, CD16, CD45RA, CXCR3, CCR6, KIR3DL1, KIR3DL2, IL17A, IL22, IL2, and IFN g. Positivity thresholds were set using control isotypes. Overnight pharmacological stimulation was performed with PMA/Ionomycin. All statistical analyses were performed using Graph Pad Prism

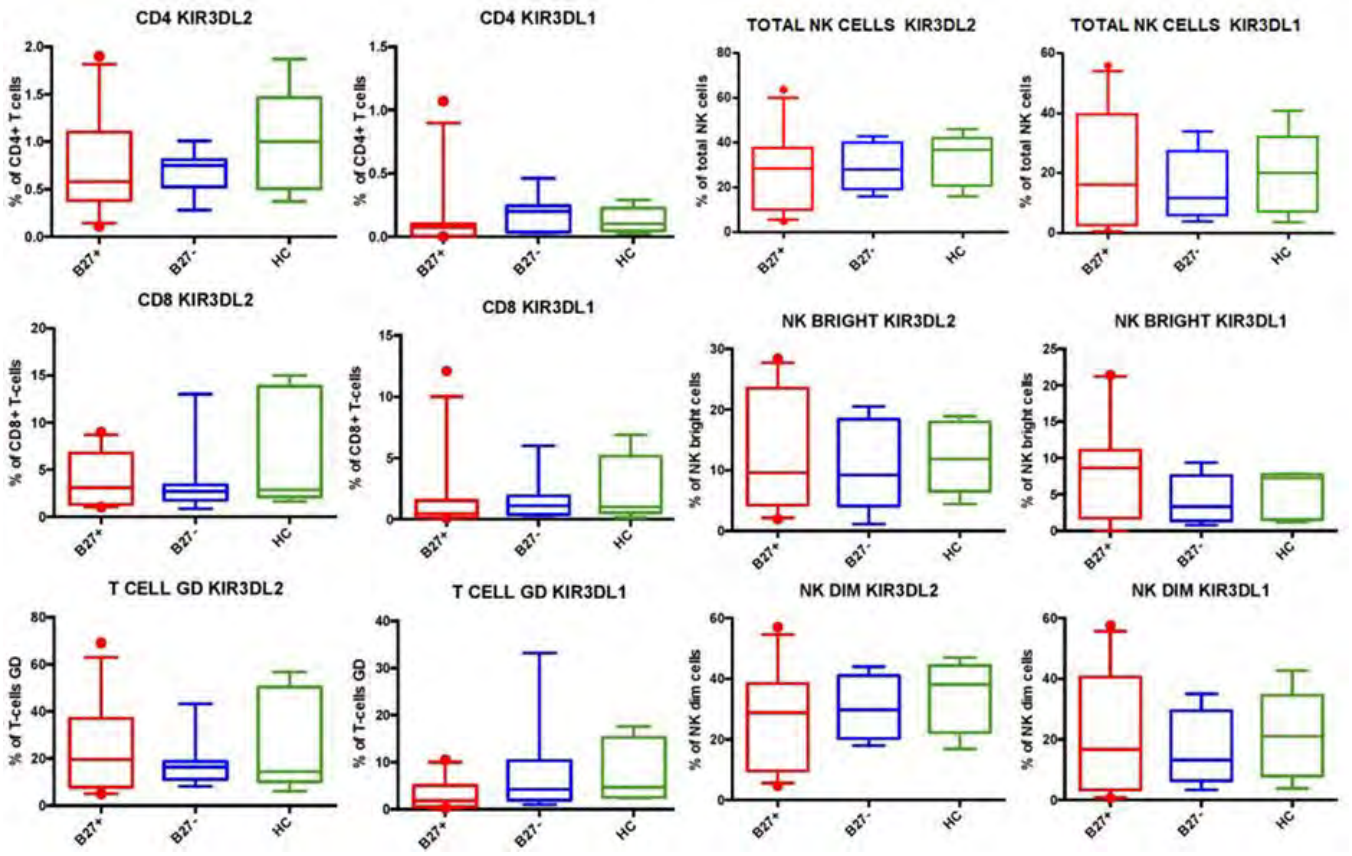

Figure 1. Expression of KIR3DL1 and KIR3DL2 on T-cells and NK cells.

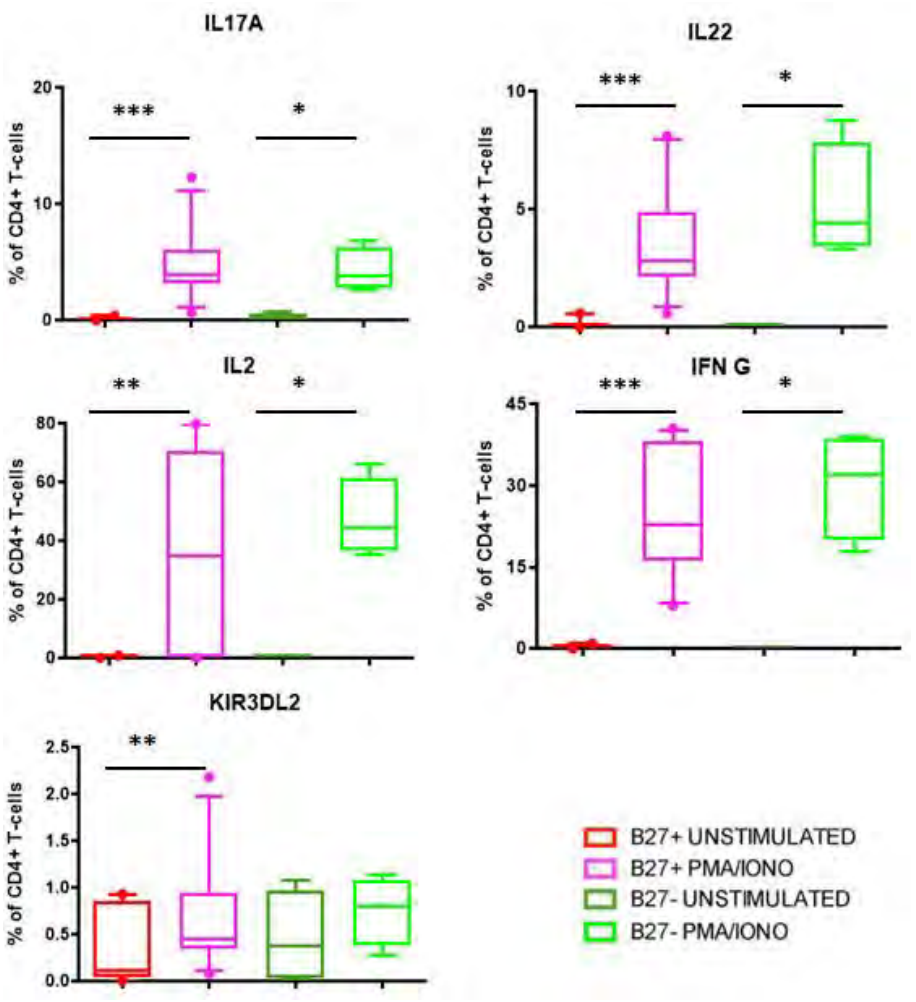

Figure 2. Cytokine production and KIR3DL2 expression on CD4+ T-cells upon PMA/Ionomycin stimulation

(GraphPad Software, San Diego, CA). Paired data were analysed with Wilcoxon test, and unpaired data with Mann Whitney test. P values < 0.05 were considered to be significant.

Results: We included 16 AS, 4 nr-axSpA patients, all fulfilling the 2009 ASAS criteria and 5 healthy controls. Their main characteristics were: 11 HLA B27+, 9 HLA B27-, 14 males, mean disease duration of 15.23 years, mean BASDAI of 4.56/10, all csDMARD and bDMARD naive. Analysis of CD4+ T-cells and NK cells of our patients shows similar expression of KIR3DL2 both in HLA B27+, HLA B27- patients and healthy controls (Fig. 1). PMA/Ionomycin stimulation induced a significant increase of IL17A, IL22, IL2, and IFN gamma in CD4+ T cells of both HLA B27+ ($p< 0.001$, $p< 0.001$, $p< 0.01$, and $p< 0.001$ respectively) and HLA B27- patients ($p < 0.05$ for all) as well as an increased KIR3DL2 expression in both groups but only significant in the HLA B27+ one ($p < 0.01$) (Fig. 2). Concerning KIR3DL2+ CD4+ T-cells (Fig. 3A), significantly increased production of IL17A was observed in HLA B27+ patients ($p < 0.01$), while increase of IL2 and IL22 production was observed in both HLA B27+ ($p < 0.01$) and HLA B27- group ($p < 0.05$). Concerning activated CD4+ Th17 cells (Fig. 3B), significantly increased production of IL17A, IL2, and IFN gamma was observed in both HLA B27+ ($p< 0.001$, $p< 0.01$, and $p< 0.001$ respectively) and HLA B27- patients ($p < 0.05$ for all) as well as significantly increased production of IL22 in the HLA B27+ one only ($p < 0.001$). No significant overexpression of KIR3DL2 was observed in this cell subtype after stimulation. Furthermore, no statistically significant difference between HLAB27+ and HLAB27- patients was observed for all previously cited analysis, as well as between AS and nr-axSpA patients.

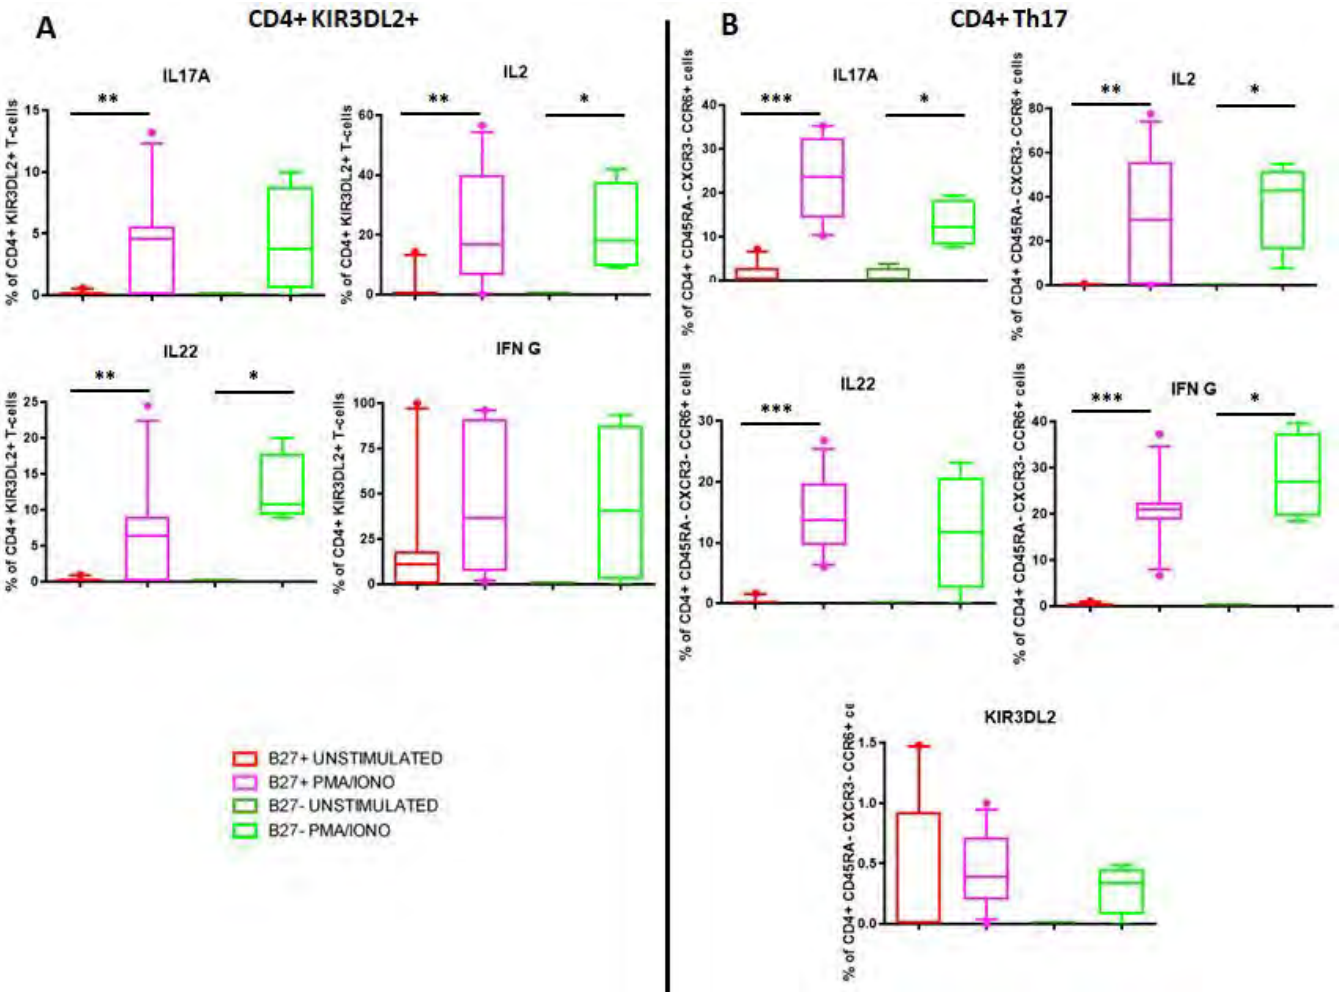

Figure 3. A. Cytokine production by KIR3DL2+ CD4+ T-cells upon PMA/Ionomycin stimulation B. Cytokine production and KIR3DL2 expression on Th17 CD4+ T-cells upon PMA/Ionomycin stimulation

Conclusion: No overexpression of KIR3DL2 on CD4+ T-cells and NK cells was observed in patients with active axial spondyloarthritis whatever their phenotype (AS vs nr-axSpA) and their HLA B27 status.

Increased Proportion of TH17, TH22 and TC17 Cells and the Correlation to IL-22 and Clinical Parameters in Patients with Ankylosing Spondylitis from Northern Sweden

Kristina Lejon[1], Urban Hellman[2], Lan Do[2], Anjani Kumar[2] and **Helena Forsblad-d'Elia**[3], [1]Department of Clinical microbiology, Infection and Immunology, Umeå University, Umeå, Sweden, [2]Department of Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden, [3]Department of Public Health and Clinical Medicine/Rheumatology, Umeå University, Umeå, Vasterbottens Lan, Sweden

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased levels of TH17 and TH22 as well as TC17 and TC22 cells have previously been associated with ankylosing spondylitis (AS). The correlation between these inflammatory T cell subsets and clinically relevant parameters as well as cytokines has also been reported. However, the status of these inflammatory cells in a well characterized AS cohort from northern Sweden has not been studied. The purpose of this study was to confirm the increased presence of inflammatory T cell subsets in peripheral blood of patients with AS from northern Sweden in relation to age and sex-matched controls. In addition, associations of clinically relevant parameters with the level of the inflammatory T cell subset(s) and cytokines of interest were performed.

Methods: Peripheral blood mononuclear cells (PBMCs) from a cohort of 50 patients with AS from Region Västerbotten (Modif NY, mean age 52±9.1 years, 33 (66 %) men, 50 (100 %) HLAB27) and 50 pair wise matched blood donor controls (mean age 54±8.8 years, 33 (66 %) men) were stained with a combination of antibodies allowing for the detection of surface expressed CD45, CD3, CD4, CD8, intracellular IL-17 and IL-22 and analyzed by flow cytometry. In addition, levels of IL-17 and IL-22 in plasma were determined by the Meso Scale Discovery platform. The patient with AS were examined with spinal x-ray for radiographic alterations assessed with mSASSS. CRP and ESR were measured and physical function and disease activity were registered with BASMI and BASFI respectively ASDAS-CRP and BASDAI.

Results: Pair wise comparison of AS patients and controls showed a 1,5 to 2-fold increase of TH17, TH22 and TC22 cells among CD45+CD3+ lymphocytes in PBMCs of male patients (p=0,013, p=0,003 and p=0,024 respectively). Levels of IL-22 in plasma and proportion of TC17 correlated in male patients (R_s=0,499 p=0,003) and plasma levels of IL10 showed an inverse correlation in relation to TC17 in all patients (R_s=-0,276 p=0,05). In female AS patients there was a negative correlation between TC22 and CRP (R_s = -0,573, p=0,016). In addition, after splitting the group of female into pre- and postmenopausal correlation between TC17 and mSASSS (R_s = 0,845, p=0,034), TC22 and BASFI (R_s = 0,986, p=0,0003) (premenopausal) and TC22 and BASMI (R_s = 0,764, p=0,006) (postmenopausal) was observed.

Conclusion: We confirm an increased proportion of TH17, TH22 and TC17 cells in blood in AS male patients from northern Sweden. In addition, positive correlation of the proinflammatory cytokine IL-22 and negative correlation of anti-inflammatory cytokine IL-10 in relation to TC17 corroborate the influence of these cells in the disease process. Interestingly, in female AS patients there was a correlation between clinical relevant parameters to particular inflammatory T cell subset dependent on the menopausal status, suggesting a role of female sex hormones in AS pathogenesis.

Curdlan-induced Villous Permeability, Luminal Pathobiont Translocation to the Ileal Crypts, Ileitis and Arthritis Are Mitigated by Clostridia in Colonised Germ-free SKG Mice

Anne-Sophie Bergot[1], Rabina Giri[2], Amy Cameron[1], Emily Duggan[3], Jeimy Jimenez Loayza[1], Mark Morrison[4], Linda Rehaume[3], Jakob Begun[2] and Ranjeny Thomas[5], [1]University of Queensland, Brisbane, Australia, [2]Mater Research Institute UQ, Brisbane, Australia, [3]University of Queensland, Brisbane, Queensland, Australia, [4]University of Queensland Diamantina Institute, University of Queensland, Brisbane, Queensland, Australia, [5]University of Queensland Diamantina Institute and Rheumatology Department, Princess Alexandra Hospital, Brisbane – Australia., Brisbane, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: IL-23 dependent spondylitis, arthritis and inflammatory bowel disease (IBD) recapitulate human spondyloarthropathy (SpA) in 1,3 beta glucan (curdlan)-treated SKG mice. Human SpA and SKG mice have fecal dysbiosis, with increased *Bacteroidaceae* and *Porphyromonadaceae*. In SKG mice, anti-IL-23 supports homeostatic bacteria, including *Clostridiaceae*, which produce the short chain fatty acid (SCFA) butyrate. Similarly, the butyrate-producing Clostridium *F. prausnitzii* is beneficial in IBD. To study how pathobionts and commensals impact SpA, we colonised Germ-Free (GF) SKG mice with a single pathobiont or a mix of pathobionts and commensals.

Methods: GF SKG mice were gavaged with *Parabacteroides* sp., *Lactobacillus murinus*, or altered Schaedler flora (ASF), comprising Parabacteroides, *L. murinus*, *Mucispirullum* and *Clostridium* spp. for 4 weeks, then given i.p. curdlan. Some groups received anti-IL-23p19 or isotype before curdlan. *Parabacteroides*-colonised SKG mice received sodium butyrate in the drinking water, or were gavaged with *F. prausnitzii* for 4 weeks. Ileal cytokines were measured by Q-PCR, bacterial translocation was analysed in ileal sections by FISH, and goblet cells were enumerated after Alcian blue staining. Ileitis and arthritis were monitored by weight loss, visual and histological scoring.

Results: SKG mice monolonised with either *Parabacteroides*, *L. murinus*, or both bacteria, but not GF mice, developed IL-23-dependent ileitis and arthritis within 5 weeks of curdlan. At week 1 post curdlan, expression of *Il23a*, *Grp78* and *sXbp1* (ER stress genes), antimicrobial peptide *Reg3b* and *Reg3a* mRNA (released by Paneth cells) was significantly increased and goblet cells decreased in the ileum of SKG mice colonised with either *Parabacteroides* or *L. murinus*, relative to GF SKG, or colonised BALB/c ileum. Concomitantly, within 1 week of curdlan, *Parabacteroides* or *L. murinus* translocated from the ileal lumen to the crypts. In contrast, SKG mice colonised with ASF, containing *Clostridia*, were protected from ileitis. SKG mice receiving sodium butyrate in the drinking water or gavaged with *F. prausnitzii* developed less weight loss and arthritis, with reduced ileal disruption.

Conclusion: *Lactobacillus* or *Parabacteroides* monocolonisation is sufficient for IL-23-dependent arthritis and ileitis progression after curdlan-mediated systemic inflammation. Pathobiont colonisation is required for curdlan to trigger ER stress, IL-23, goblet cell loss and villous permeability, permitting luminal bacterial translocation to the lamina propria. Supplementation with *Clostridia* or sodium butyrate reduces the ileal damage caused by pathobionts and mitigates arthritis severity.

An Integrative Approach to Identify Heritable and De Novo Genomic Variations in Psoriatic Arthritis Mutilans and Understand Its Systems Biology

Sara Rahmati[1], Quan Li[1], Dafna Gladman[2], Proton Rahman[3] and Vinod Chandran[2], [1]University Health Network, Toronto, ON, Canada, [2]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]Memorial University of Newfoundland, Department of Medicine, St John's, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is a chronic autoimmune skin disease that burdens ~3% of North Americans. ~24% of psoriatic patients develop psoriasis arthritis (PsA), an inflammatory disease which is often progressive and in its extreme form, PsA mutilans, causes permanent joint damage and functional disability. PsA is highly heritable; ~40% of patients with PsA have at least one close relative with psoriasis or PsA. Characterizing heritable and de novo genomic variations and cellular processes behind extreme cases of PsA is a promising approach for understanding molecular mechanisms behind PsA and identifying patients at high-risk of PsA mutilans early.

Methods: We conducted Whole Exome Sequences (WES) of 7 trios with PsA mutilans trios (probands with PsA satisfying CASPAR criteria and with arthritis mutilans and their parents), using NovSeq 6000 (Illumina) at depth 100X. We developed a bioinformatics pipeline to identify genes and pathways involved in PsA mutilans with three modules: 1) characterization of genetic variants using WES of PsA mutilans trios; 2) their integration using network-based methods to highlight pathways relevant to identified variants; 3) network analysis to identify genes and pathways to cellular mechanisms involved in PsA mutilans.

We used three available algorithms for detection of genomic variations. To discover systems level dependencies among genes and proteins to perform cellular tasks we integrated these variations with physical protein interaction networks. Next, we applied a graph-mining technique to detect network modules and several novel genes involved in PsA mutilans. Finally, we performed pathway enrichment analysis and characterized several statistically significant pathways involved in PsA mutilans.

Results: We found a subnetwork of 44 proteins [Figure 1A-B] having physical interactions with protein products of the genes identified by three variation detection methods [Table 1] suggesting implication of these 44 genes in triggered pathways in PsA mutilans. Pathway enrichment analysis highlighted WNT, NOTCH, NOTCH1, Adherens, Autophagy, and Apoptosis, suggesting their disruption in PsA mutilans [Figure 1C]. These pathways have been previously studied in psoriasis, PsA, and autoimmunity supporting relevance of identified genes and pathways to PsA mutilans. *NTRK1* has the highest rank in the identified subnetwork. NTRK1, its interaction with NGF, and its mutations have previously been linked to autoimmune diseases, inflammatory arthritis, and psoriasis, and some groups are working on developing novel NGF/NTRK1-targeted therapies for these diseases. EED is another highly ranked gene in our list. Mutations in EED have been reported in several cases of over-growth disorders such as Cohen-Gibson and Weaver Syndromes.

Method	Gene set
Varscan	*ABHD5, ALOXE3, CDC27, GOLGA3, MSH3, PDE4D, PLXNA2, RBM14, RXFP4, SHARPIN, TTC28, ZNF492*
Tridenovo	*DSPP, FAM30A, GGTLC2, IFRD1, IRF2BPL, KRT6C, KRTAP10-4, KRTAP9-4, LINC01225, LSS, MUC20, MUC4, NAV2, PKD1L2. SFTPD, TBX19*
DNAcopy	*CDSN, GHR, KRT77, OR2T11, OR2T10, CFHR1, CFHR3, RHD, CHAC1, GBP3, OR52N5, COL11A2, OR52N5, GBP3, LILRA3, CYB561D1, SPAG11B, C18orf56, PRDX4, SPAG11B, MRGPRX1, TBCK, PPIG, PSMA8, ZNF43, KPNA4, C9orf24, JAK2, SYCP2, SYCP1, PGAP1, TTK, ZNF638, SYCP1, CENPE, ADAM2, PROS1, STX19, GNGT1, BET1, CXorf59, HECTD2, USP25, STAG2, LIPF, RIF1, TBK1*

Table 1. List of genes with variants based on different methods.

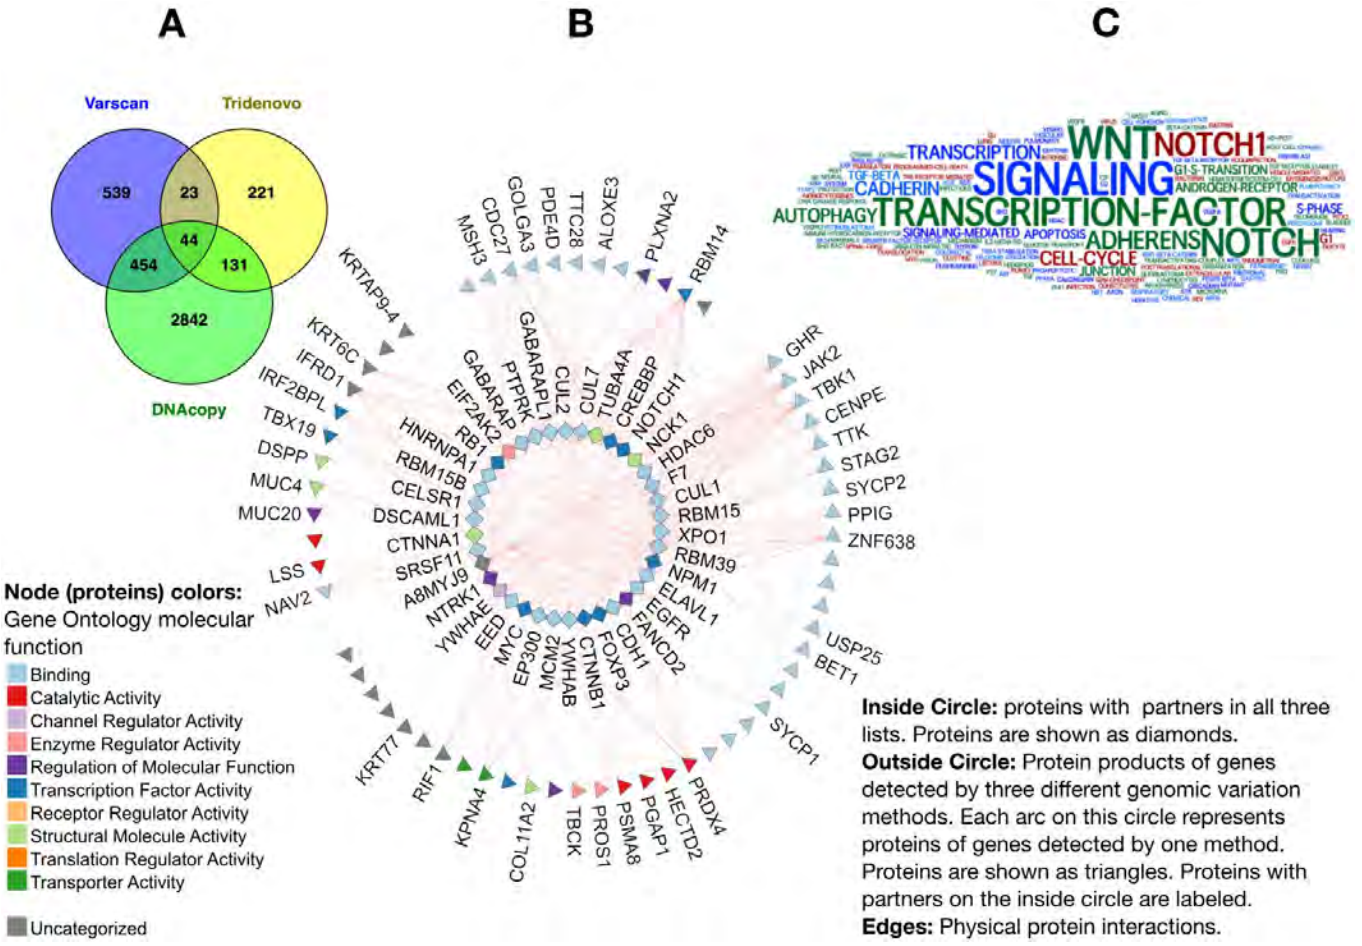

Figure 1 A. Venn diagram summarizing overlapping protein partners of genes detected through different methods (listed in Table 1). B. Protein interaction network of genes in the three lists. For details see legend. C. Results of pathways and term enrichment analysis of the 44 genes in the center of Venn diagram (ordered on the central circle in the network).

Its interaction with EZH2 (present in the list- not shown in Figure 1) has been reported to be important in psoriasis. EED mediates repression of gene activity through histone modifications.

Conclusion: Detecting heritable and de novo genomic variations by WES of PsA mutilans trios and application of network analysis has identified novel genes and pathways associated with PsA mutilans.

T Cells with IL-17A+ Signature in Psoriatic Arthritis Are of Different Subpopulations and Are Polyfuntional

Siba Raychaudhuri[1] and Smriti Raychaudhuri[2], [1]Division of Rheumatology, Allergy & Clinical Immunology, University of California School of Medicine, Davis, and VA Medical Center Sacramento, Sacramento, CA, [2]VA Sacramento Medical Center, Davis, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: A variety of T cells such as Th1, Th2, Th9, Th17, NKT, MAIT, etc have been attributed to multiple autoimmune diseases. In psoriatic arthritis (PsA) contributing role of the Th17 cells have been observed and lately success of IL17/IL-23 targeted therapies has further substantiated this. Here we will share our cumulative data on Th17 cells in PsA collected over last 2 decades.

Methods: PBMCs and synovial fluid mononuclear cells (SFMCs) were collected from age/sex matched with active untreated PsA, rheumatoid arthritis (RA) and osteoarthritis patients (OA, n=50, each). Patients were recruited after proper IRB approval. Magnetically sorted $CD3^+$ T cells were isolated from PBMCs and SFMCs; were activated (10^6 cells/ml) with anti-human CD3/CD28 antibody cocktail and cultured in RPMI medium for 5 days. Hi-D FACS studies were performed; lymphocytes were gated first based on FSC and SSC, then $CD3^+CD11a^+CD45RO^+17A^+$ cells were gated. In these gated population MAIT cells were identified as $CD3^+CD161^+V\alpha7.2TCR^+$ cells, γδ-T cells as $CD3^+$ $\gamma\delta TCR^+$, NKT cells as $CD3^+CD161^+$ and αβ-T cells as $\alpha\beta TCR^+$. NKT cells ($CD3^+CD161^+$) were further gated for *TCR* Vα24-Jα18 (iNKT cell) ab positivity.

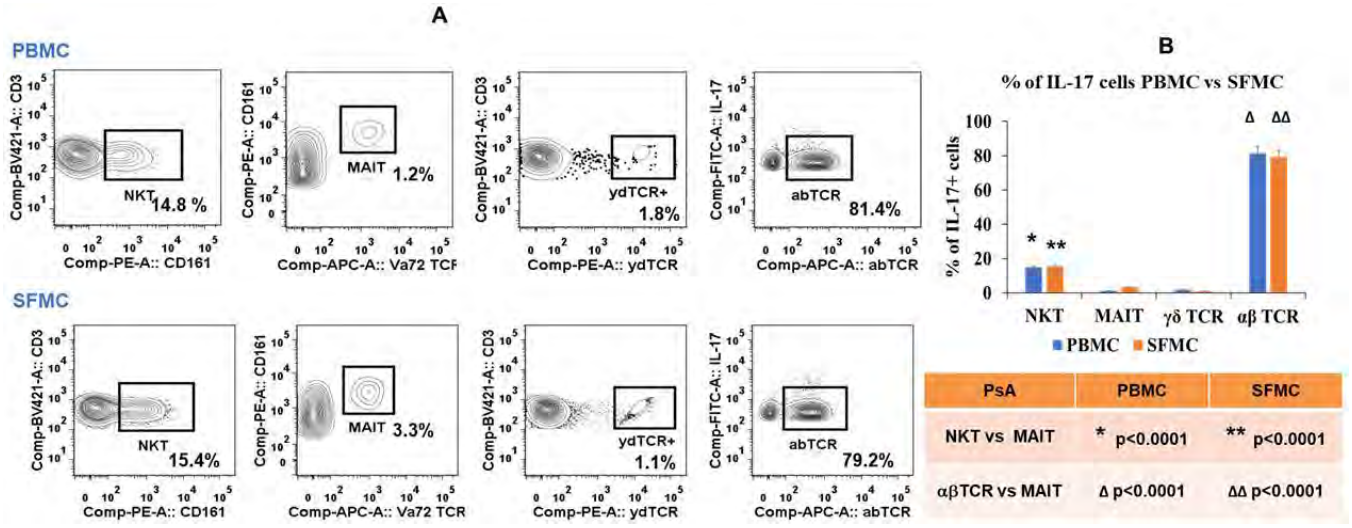

Figure 1. IL-17A+ cells in peripheral blood and synovial fluid of PsA patients. Peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) were isolated from PsA (n=15) and stimulated with with anti-human CD3/CD28 antibody cocktail. Lymphocytes were gated first based on FSC and SSC, then CD3+CD11a+CD45RO+17A+ T cells were gated. **αβ** TCR+, **γδ** TCR+ T cells, iNKT and MAIT cells were identified in these gated CD3+CD11a+CD45RO+17A+. (A) Representative FACS plots showing the frequencies of different IL-17A+ immune cells in PsA. (B) Bar diagram (n=15) showing the frequencies of IL-17A producing **αβ**, NKT, **γδ** T cells and MAIT cells in PBMC and SFMC of PsA patients.

Results: In OA activated Effector Memory T Cells (TEM cells) were < 1%. We noticed a marked polyfunctionality in PBMC/SFMC T cells both in PsA and RA. In PsA SFMC, memory T cells (CD3+CD4+CD45RO+) had IL-17A+ (18±0.5%), IL-22+(7±0.3%) and IL-23R+ (8.5±0.5%) T cells compared to SFMC memory T cells of RA (6.8±0.3%, 2.5±0.5%, 2.1±0.7%, respectively; p< 0.001). TEM cells in PsA and RA at single cell level also produced IL-9 and TNF-α.

IL-17A$^+$ TEM phenotypes in SFMC of PsA demonstrated both invariant and conventional αβT cell Immune response (Fig 1): αβTCR$^+$ (79.8±0.9%), γδ TCR$^+$ (1.5±0.2%), iNKT (15.5±1.1%) and MAIT (4.5±0.8%) cells. Majority of the αβTCR$^+$ T cells were CD4+ (>85%) whereas MAIT were predominantly CD8$^+$ (~ 90%).

Conclusion: In PsA TEM cells were polyfunctional in respect to their cytokines (IL-9, IL-17A,IL-22, TNF-α) however more skewed towards conventional activated memory αβTh17 cells. Our finding clearly suggests that TEM cells of adaptive as well as innate immune response produce IL-17A in PsA, but the major amount of IL-17A comes from the conventional CD4$^+$ (αβTCR$^+$) cells (~80%). The fact that synovial T cells of innate immune response also express IL-17A (~20%), suggest a bridge between adaptive and innate immune response.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the recurrence rate (RR) of ankylosing spondylitis (AS) over a lifespan, probands with clinically diagnosed AS and their first-degree relatives (FDRs) were studied in a Swiss cohort during 35 years of follow-up.

Methods: In 1985 members of the Swiss AS Patient Society who had been diagnosed as having AS by their own physicians, as well as their FDRs, were invited to participate in the current study. After obtaining ethical approval and informed consent, 363 probands and 715 first-degree relatives were recruited to the study. Participants completed questionnaires on disease manifestations, underwent rheumatological examination of axial and peripheral joints, and were genotyped for HLA-B27. 360 probands and all 713 relatives aged ≥ 18 year underwent pelvic radiography unless pregnant, which were then scored according to the modified New York AS (mNYAS) criteria. Participants with a

clinical diagnosis of AS with or without radiographic evidence of disease were deemed to have 'axial spondyloarthritis' (axSpA), those meeting the mNYAS criteria were said to have AS, and those with a clinical diagnosis of AS but not meeting the mNYAS criteria nr-axSpA. Following further ethics review and approval, a follow-up study was performed in 2019. A total of 462 surviving consenting original participants completed a 157 item disease related questionnaire, with diagnosis of AS determined by self-report. RR of axSpA amongst siblings and children of probands were analysed.

Results: The overall RR for FDRs was 41/411 (10%), the parent-child RR being 24/193 (12.4%) and sibling RR 17/218 (7.8%). Considering FDRs of mNYAS probands, the RR was even higher (41/351, 11.7%), with the parent-child RR being 24/154 (15.6%) and sibling RR 17/197 (8.6%). Amongst FDRs of probands with nr-axSpA, lower RRs were observed: overall FDR RR was 6/98 (6.1%), parent-child RR 2/39 (5.1%), sibling RR 4/59 (6.8%). AS occurred in only one HLA-B27(-) relative, with nr-axSpA, and no case of HLA-B27(-) mNYAS was observed amongst FDRs. Considering HLA-B27(+) FDRs of mNYAS probands, the RR was very high (overall 41/288, 14.2%; mNYAS probands 24/142, 16.9%). Mother-child RR was substantially higher than father-child RR, particularly amongst children of parents with mNYAS (11/27 vs 13/127 respectively, odds ratio = 6.0, $P=3.8x10^{-4}$, Fisher's exact test). No difference in risk of transmission from affected parents to daughters compared with sons was observed (parent-daughter 15/105 (14.3%), parent-son 9/88 (10.2%), P=0.40), including if the parent was a mother or father.

Conclusion: This study demonstrates that particularly amongst axSpA patients with mNYAS, the RR of axSpA in both siblings and children is very high, particularly amongst HLA-B27 positive relatives (16.9%). The relatively higher prevalence of mother to child transmission compared to father to child transmission suggests that female AS patients appear to be genetically "enriched" regarding transmission of the disease predisposing genes to their offspring. This is consistent with polygenic models of AS, in which women with AS require a higher genetic load to develop disease, and are thus more likely to have affected children.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Table 1. Questions that have sensitivity and/or specificity > 70% and LR > 2 by anatomical region

Question	Sensitivity (number/total)	Sensitivity (percent)	Specificity (number/total)	Specificity (percent)	LR+	LR-	*p*-value
Chronic inflammatory backpain (CIBP)	64/87	73.6%	109/130	83.8%	4.55	3.17	< 0.00001
Lumbar Spine region							
insidious onset of back pain	72/86	83.7%	74/130	56.9%	1.94	3.50	< 0.00001
more than 3 months duration	67/86	77.9%	95/130	73.1%	2.89	3.31	< 0.00001
associated with morning stiffness > 30 min	66/86	76.7%	95/130	73.1%	2.85	3.14	< 0.00001
back pain starting before age 40	84/86	97.7%	82/130	63.1%	2.65	27.12	< 0.00001
pain & stiffness	68/87	78.2%	98/130	75.4%	3.18	3.45	< 0.00001
worsening at early morning	56/86	65.1%	118/129	91.5%	7.64	2.62	< 0.00001
waking up during the night because of complaints	56/86	65.1%	114/130	87.7%	5.29	2.51	< 0.00001
leaving bed and walking around during the night	50/84	59.5%	123/128	96.1%	15.24	2.37	< 0.00001
pain radiating into gluteal region	64/82	78.0%	85/130	65.4%	2.25	2.98	< 0.00001
usage of analgesics	82/86	95.3%	79/130	60.8%	2.43	13.07	< 0.00001
relief of symptoms due to analgesics	73/88	83.0%	81/129	62.8%	2.23	3.68	< 0.00001
Thoracic region							
complaints at thoracic region *ever*	67/84	79.8%	100/126	79.4%	3.87	3.92	< 0.00001
pain and stiffness	47/88	53.4%	123/130	94.6%	9.92	2.03	< 0.00001
complaints at early morning	54/86	62.8%	110/130	84.6%	4.08	2.27	< 0.00001
morning stiffness at thoracic spine region	45/84	53.6%	125/129	96.9%	17.28	2.09	< 0.00001
complaints if body position does not change	52/83	62.7%	113/129	87.6%	5.05	2.35	< 0.00001
usage of analgesics	48/85	56.5%	122/129	94.6%	10.41	2.17	< 0.00001
relief of symptoms due to analgesics	46/87	52.9%	123/130	94.6%	9.82	2.01	< 0.00001
Ventral chest wall region							
complaints at ventral chest wall region *ever*	62/86	72.1%	105/128	82.0%	4.01	2.94	< 0.00001

Table 2. Three Region (3R) Clinical History Tool for Diagnosis or Classification of Ankylosing Spondylitis (Axial Spondyloarthritis)

Chest	Have you *ever* had pain or discomfort at the ventral (anterior) chest wall region?
Thoracic spine	Have you *ever* had pain or discomfort at the thoracic spine region?
Lumbar spine	Have you *ever* had chronic inflammatory back pain (≥ 4 items should be present) - insidious onset - duration > 3 months - morning stiffness > 30 minutes - back pain started < age 40 - persistent complaints

Any 2 of 3 fulfilled: sensitivity 83.1% - specificity 86.4%
All 3 items fulfilled: sensitivity 47.0% - specificity 97.6%

Background/Purpose: Lack of sensitivity or specificity of symptoms may induce uncertainty in diagnosis and classification of AS/axSpA. We investigated if balanced sensitivity and specificity of tools from the patient's clinical history may help better define the 'Gestalt' of AS/axSpA

Methods: In 1985 members of the Swiss AS Patient Society who had been diagnosed as having AS by their own physicians, as well as their first degree relatives (FDRs) were invited to participate in the current study. After obtaining ethical approval and informed consent, 1178 subjects, 363 of them probands, formed our study cohort; they completed questionnaires on disease manifestations, underwent rheumatological examination of axial and peripheral

joints, and provided blood samples for genetic studies, including HLA-B27. Probands also provided a recent pelvic radiograph to document presence of sacroiliitis. If their pelvic radiograph was not available, it was performed on-site. Relatives aged ≥18 years underwent pelvic radiography, unless pregnant. Pelvic radiographs were available for 360 probands and 713 relatives. Radiographs were blindly assessed twice by each of 4 readers. The assessment could only be performed once for 164 (46%) of the 360 radiographs of the probands (available only for a few hours). The sacroiliitis score for each sacroiliac (SI) joint ranged from 0 (normal) to 4 (ankylosis). Scores were added and then divided by the number of assessments. Scores below bilateral grade 2.0 or grade 3.0 unilaterally were considered not meeting New York radiographic criteria (NYRC).

In 2018 the ethical committee of the Swiss Kanton of Bern approved the follow-up study. Many Swiss city and village administrations provided current addresses of former participants. By December 2019, 123 probands and 39 FDRs had died, and 462 consenting participants completed a 157 item postal disease related questionnaire dealing with symptoms at lumbar and gluteal region, thoracic spine, and front part of the chest.

The gold standard for sensitivity was AS patients meeting NYRC for AS. The gold standard for specificity was the HLA-B27(-) relatives of HLA-B27(+) probands, as this group have a near zero chance of developing axSpA. Statistical analysis was performed by chi-square test.

Results: Sensitivity was assessed in 88 (85 of them HLA-B27(+)) AS patients (mean age 72.1 ± 7.5 years) meeting the NYRC, and specificity in the group of 130 HLA-B27(-) relatives (mean age 62.8 ± 9.2 years). Table 1 shows by anatomical region the questionnaire items that have sensitivity or specificity > 70% and likelihood ratio (LR) values ≥ 2. None of the criteria individually demonstrate sensitivity and specificity values that both surpass 80%. But a 3-item 3-region index of ”chronic inflammatory back pain” and two one-question items (Table 2) show 83.1% sensitivity and 86.4% specificity with likelihood ratios >5, if any 2 of 3 index items are met.

Conclusion: We propose a simple 3-item index assessing complaints at 3 regions that might be a useful tool to better define and classify the “Gestalt” of AS/axSpA, and also to improve the specificity of the current classification criteria. Validation of our results is needed in other data sets.

* Psoriasis, uveitis, inflammatory bowel disease ** Bilateral ≥grade II or unilateral ≥grade III according to the grading system of the modified New York criteria. CRP: C-reactive protein; LR: Likelihood ratio; MRI: magnetic resonance imaging; n.a.: not applicable; NSAIDs: non-steroidal anti-inflammatory drugs; prob.: probability; SpA: spondyloarthritis.

Background/Purpose: The diagnosis of axial spondyloarthritis (axSpA) is often delayed by several years and reducing that gap between symptom onset and diagnosis poses a major challenge in rheumatology. The objective of this study was to evaluate the diagnostic value of SpA parameters and their combination for the diagnosis of axSpA in patient populations with different a priori probabilities of this disease.

Methods: For the aim of the present analysis we used data from the Optimal Referral Strategy for Early Diagnosis of Axial Spondyloarthritis (OptiRef) study comprising a total of 361 patients who presented to a rheumatologist because of chronic back pain and suspicion of axSpA. Of those, 181 were referred by primary care physicians or orthopaedists and 180 patients were recruited via an online screening tool. All patients received a structured rheumatologic examination which included the evaluation of SpA features and resulted into a diagnosis of axSpA/no axSpA. Sensitivities, specificities, and likelihood ratios (LRs) for SpA features were determined in the entire group and in both subgroups with different referral pathways. The respective post-test probabilities of axSpA were calculated.

Results: The prevalence of axSpA was 30% in the entire group, 20% in the online screening subgroup and 40% in the physician-referred subgroup. These frequencies were used as pre-test probabilities in the calculation of the post-test probabilities among the respective groups. It could be shown that differences in the pre-test probability affect not only the post-test probability of the disease, but also the relative diagnostic value of single SpA features. For instance, the presence of inflammatory back pain increased the probability of the presence of axSpA from the background 20% to 29% in the online screening group (positive LR of 1.67) (Table 1) and from the background 40% to 59% in the physician-referred group (positive LR of 2.16) (Table 2), whereas its absence decreased the respective probabilities to 8% and 14%, respectively.

Furthermore, combinations of parameters performed differently in the studied groups. For instance, combining IBP with anterior uveitis did not increase the post-test probability for axSpA in the online screening group (it remained 67%), but in the physician-referred group (from 76% to 93%). Using HLA-B27 positivity and active sacroiliitis on

Table 3 Post-test probabilities of spondyloarthritis features in patients referred via an online screening tool and/or a physician-based referral tool.

SpA feature 1	SpA feature 2	SpA feature 3	Post-test probability			Post-test probability†		
			Online screening group*	Physician-referred group**	Total ***	Online screening group*	Physician-referred group**	Total ***
IBP, current (+)	Uveitis, ever (+)		0.67	0.93	0.85	0.78	0.87	0.83

IBP, current (+)	HLA-B27 positive (-)	Active sacroiliitis on MRI (+)	0.69	0.41	0.57	0.67	0.44	0.57

† Calculated under the assumption that diagnostic tests are independent. *Pre-test probability = 20%. **Pre-test probability = 40%. ***Pre-test probability = 30%. CRP: C-reactive protein; IBP: inflammatory back pain; MRI: magnetic resonance imaging; NSAIDs: non-steroidal anti-inflammatory drugs; SpA: spondyloarthritis.

MRI in combination with IBP resulted in a surge in the post-test probability of the presence of axSpA to over 95% in all groups (Table 3). Using a simplified formula to calculate the post-test probabilities for axSpA for combinations of parameters, which is based on the product of the respective LRs and holds if the diagnostic tests are independent, could lead to differences of more than 10% (Table 3).

Conclusion: The diagnostic value of SpA features is not fixed and may vary substantially depending on the characteristics of the patient group including their referral pathway and their pre-test probability of axSpA. This should be taken into account in the diagnostic approach of axSpA.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of Axial Spondyloarthritis (axSpA) is crucial for timely access to specialist care and effective treatment. The aim is to assess the current diagnostic delay in axSpA and identify the parameters associated with increased diagnostic delay in a European sample.

Methods: Data from unselected patients participating in the European Map of Axial Spondyloarthritis (EMAS) study through an online survey (2017- 2018) across 13 countries were analysed. Mean differences in diagnostic delay were analysed using Mann-Whitney and Kruskal-Wallis tests, among sociodemographic and disease-related factors. A multivariate linear regression analysis was carried out to identify the relative weight of the associated parameters in determining diagnostic delay.

Results: 2,846 patients participated in EMAS. Mean age was 43.9 years, 61.3% were female, 48.1% had a university degree, and 53.9% were employed. Of the 2846 participants, 2652 provided information for calculating diagnostic delay. Mean age at symptom onset was 26.6 ± 11.1, mean age at diagnosis was 33.7 ± 11.5, and mean diagnostic delay was 7.4 ± 8.4 (Fig. 1). The following variables were associated with longer diagnostic delay in the bivariate anal-

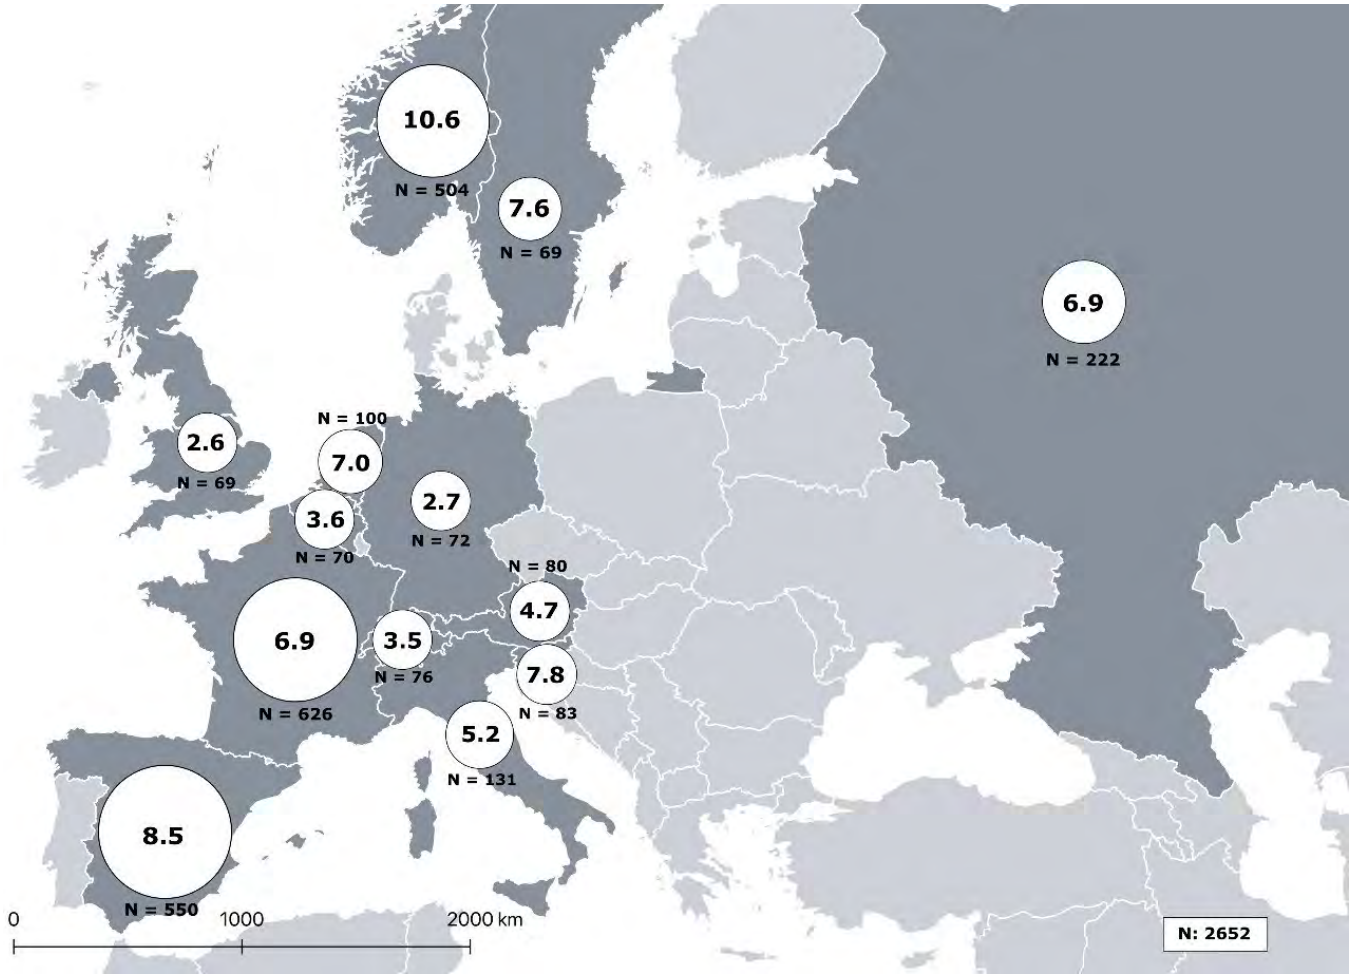

Figure 1. Average years of diagnostic delay across EMAS countries (N: 2,652)

ysis: older age, female gender, being diagnosed by a rheumatologist (Table 1). In the multivariate regression analysis younger age at symptom onset, number of HCPs seen before were associated with diagnostic delay (Table 2).

Conclusion: In this large sample of axSpA patients from 13 different European countries, the average diagnostic delay was more than seven years. The fact that one of the most strongly associated parameters to diagnostic delay was number of HCPs seen before diagnosis suggests the need for urgent action to reduce incorrect referrals to shorten the patient journey to diagnosis across Europe.

Variable		Diagnostic Delay, Mean ± SD	P-value

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) impacts negatively on multiple dimensions of patient's life, including their working life. The present study aims to evaluate working status, work-related issues and their associated factors in a Spanish sample of patients with axSpA.

Methods: The Atlas 2017 based its results on an extensive cross-sectional patient survey conducted in Spain (2016), validated by a multidisciplinary group of experts on spondyloarthritis. Participants were recruited through an on-line panel and patient organizations. Participants were classified as active (employed, unemployed between 15-64 years) and inactive (retirees, on sick leave, students and homemakers). Those employed were asked to report work-related issues due to axSpA (sick-leave, difficulty fulfilling work hours, missing work for doctors' appointments, reducing working hours or taking days off) in the past 12 months. Diagnostic delay, disease activity (BASDAI), spinal stiffness (3-12), functional limitation (0-54) and psychological distress (General Health Questionnaire, GHQ-12 [0-12]) were compared between employed patients with or without work-related issues using a Mann-Whitney and Kruskal-Wallis test. Regression analysis was conducted to determine explicative disease outcome related factors (enter method for BASDAI, self-reported spinal stiffness, functional limitation and GHQ-12) over work-related issues.

Population	N	%	Employment status	N	%
Active population*	415	63.6	Employed	325	78.3
			Unemployed	90	21.6
			Total	415	100.0

Table 3. Differences between employees with/without work-related issues and between employed/unemployed participants in relation to sociodemographic characteristics and patient-reported outcomes

Results: Data from 680 patients were collected: mean age was 47±11 years, 52.5% were female and 36.9% were university educated. Mean disease duration and diagnostic delay were 20.9±12.2 and 8.5±7.7 years, respectively, and mean BASDAI was 5.5±2.2. A total of 63.6% (n=415) were considered active population, of which 49.8% (n=325) were employed (Table 1). Of those employed, 54.3% reported a work-related issue, specifically 37.1% took sick leave, 44.1% had difficulties in fulfilling the working hours and 42.9% missed work due to doctor's appointments (Table 2). Among all patients, 95.5% faced (or believed they would) difficulties finding a job due to axSpA. Experiencing work-related issues due to axSpA was significantly associated with higher disease activity, self-reported spinal stiffness, longer diagnostic delay, higher functional limitation and higher level of psychological distress ($p< 0.001$). However, the highest levels of disease burden were reported by unemployed participants (Table 3).

Conclusion: Results reveal a relevant impact of axSpA in patient working life. Approximately two out of three patients employed experienced work-related issues due to axSpA, being associated to worse disease outcomes and poorer psychological health. However, those who were unemployed faced a harsher situation reporting even poorer disease-related and psychological health outcomes. As psychological health appears impaired severely in axSpA patients regardless of their employment status it should be key for a holistic approach to patient care.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: A diagnosis of (early) axial spondyloarthritis (axSpA) is based on pattern recognition, which can be challenging and may change over time. The aim of this study was to investigate consistency of diagnosis over two years in patients with chronic back pain (less than two years symptoms) suspected of axSpA.

Methods: In the SPACE cohort, patients over 16 years of age referred to the rheumatology outpatient clinic with chronic back pain (≥3 months and < 2 years) starting before the age of 45, suspected of axSpA were included. Follow-up was performed only in patients with at least two SpA features or one SpA feature with a positive likelihood ratio ≥6.4 (Rudwaleit, van der Heijde, Khan, Braun, & Sieper, 2004).

According to protocol, all SpA features as well as MRI and radiographs of the sacroiliac joints were performed at baseline and two years. Physicians were asked to report whether the diagnosis was axSpA or no axSpA at both timepoints, for which they had information available on all SpA features and locally read imaging.

Only patients with complete data on diagnosis and imaging at baseline and 2 years were included.

Patients were labelled with a consistent axSpA diagnosis if they had a diagnosis of axSpA at baseline and at two-year follow-up. Those patients whose diagnosis switched from axSpA to no axSpA; or from no axSpA to axSpA were labelled inconsistent axSpA diagnosis.

Results: Over two years the diagnostic consistency rate was 84%. The rate of change from axSpA to no axSpA was 9% and from no axSpA to axSpA 7% (table 1).

The patients who only had an axSpA diagnosis at baseline were more often female and less often HLA-B27 positive compared to the other two groups (table 2).

Furthermore, both groups with an inconsistent diagnosis had fewer SpA features and a lower level of confidence of the diagnosis (LoC) compared to the group with a consistent diagnosis of axSpA, especially at baseline.

Table 1 Consistency of diagnosis over 2 years

	Diagnosis axSpA at 2 years	Diagnosis no axSpA at 2 years
Diagnosis axSpA at baseline	184 (62%)	26 (9%)
Diagnosis no axSpA at baseline	19 (7%)	66 (22%)

axSpA, axial Spondyloarthritis; bDMARD, biological Disease Modifying Anti-Rheumatic Drug; CRP, C-reactive protein; ESR, Erythrocyte Sedimentation Rate; HLA-B27, Human Leucocyte Antigen B27; IBD, Inflammatory Bowel Disease; IBP, Inflammatory Back Pain; LoC, Level of Confidence regarding diagnosis (either axSpA or no axSpA); MRI, Magnetic Resonance Imaging; NSAIDs, Non-Steroidal Anti Inflammatory Drugs; SpA, Spondyloarthritis.

Table 2 Characteristics at baseline and 2-year follow up of the group with a consistent diagnosis over 2 years and the groups whose diagnosis changed between baseline and 2-year follow up

At two-year follow-up the LoC in the group with an axSpA diagnosis at 2 years only was much lower than in the other two groups. In the group that only had an axSpA diagnosis at baseline, the LoC regarding the diagnosis increased most compared to baseline: physicians were more certain of the diagnosis no axSpA at two-year follow-up than they were of the diagnosis axSpA at baseline.

The number of patients with sacroiliitis on radiographs and MRI was much higher in the group with a consistent diagnosis of axSpA. Although the percentage of patients with sacroiliitis on MRI increased in the group with a diagnosis of axSpA at two-year follow-up only, this was still much lower (21%) as compared to the patients with a consistent diagnosis (81%). This was in line with a low LoC in this group.

Conclusion: In a cohort of patients with chronic back pain suspected of axSpA the diagnostic consistency rate was high. Interestingly, in the group that only had a diagnosis axSpA at baseline, rheumatologists were more certain about the absence of axSpA at two years than the presence of axSpA at baseline.Table 1 Consistency of diagnosis over 2 years

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to compare quality of life (QoL) between chronic back pain (CBP) patients with and without a diagnosis of axial spondyloarthritis (axSpA), after two-years of protocolised follow-up.

Methods: Patients over 16 years of age referred to the rheumatology outpatient clinic with chronic back pain (≥ 3 months and < 2 years) starting before the age of 45, suspected of axSpA were included in the SPACE cohort. Follow-up was performed only in patients with at least two SpA features or one SpA feature with a positive likelihood ratio ≥6.4 (Rudwaleit, van der Heijde, Khan, Braun, & Sieper, 2004).

QoL was assessed using the Medical Outcomes Study 36-Item Short-Form Health Survey (SF-36). Age, sex and country weighted scale scores were calculated for each of the 8 subscales. Numeric scales ranged from 0 (worst health) to 100 (best health), after recoding and recalibration. The physical (PCS) and mental component summary (MCS) scores were calculated from the adjusted scores; and transformed to enable comparison to the general population mean of 50.

Additionally, the proportion of patients with an improvement or worsening of the PCS and MCS above the minimal clinically important difference (MCID) were assessed. We applied the commonly used MCID in clinical trials with bDMARDs in axSpA of 3 points for the PCS and MCS.

In this study we included patients with a diagnosis axSpA or no axSpA (CBP group), all with a level of confidence ≥7 (on a 0-10 scale) after locally read imaging, who had data available on the PCS and MCS at both timepoints.

Table 1 Baseline characteristics of patients with an axSpA diagnosis and those with CBP

Characteristic	Diagnosis axSpA (N=183)	CBP (N=74)
Male, n(%)	105 (57)	20 (27)
Age (years), mean (SD)	30 (8)	31 (8)
Symptom duration (months), mean (SD)	13 (7)	13 (7)
HLA-B27 positive, n(%)	137 (75)	23 (31)
Number of SpA features, mean (SD)	5 (2)	3 (1)
Use of NSAIDs, n(%)	139 (76)	52 (70)

Table 1. Baseline characteristics of patients with an axSpA diagnosis and those with CBP.

Table 2 PCS and MCS scores at baseline and 2-year follow-up for the group with an axSpA diagnosis and those with CBP

Characteristic	Diagnosis axSpA (N=186)		CBP (N=74)		
	Baseline	2 years	Baseline	2 years	p-values
SF-36 PCS, mean (SD) %	28.0 (14.8)	40.5 (12.3)†	26.4 (13.6)	34.7 (15.6)†	P<0.001*
Improvement >MCID, n(%)		143 (78)		49 (66)	
Worsening >MCID, n(%)		22 (12)		12 (16)	
SF-36 MCS, mean (SD) %	47.3 (13.7)	47.9 (11.8)	46.5 (11.2)	48.9 (10.6)	p=0.364
Improvement >MCID, n(%)		76 (42)		35 (47)	
Worsening >MCID, n(%)		69 (38)		26 (35)	

*Significant difference between groups at two years; after correction for baseline PCS scores and NSAID use over time (p<0.05); †Significant improvement within group over time

axSpA, axial Spondyloarthritis; CBP, Chronic Back Pain; MCID, Minimal Clinically Important Difference; MCS, Mental Component Summary; PCS, Physical Component Summary; SF-36, Medical Outcomes Study 36-Item Short-Form Health Survey

Table 2. PCS and MCS scores at baseline and 2-year follow-up for the group with an axSpA diagnosis and those with CBP

Linear regression models were used to test the difference between groups at two-year follow-up for PCS and MCS scores. Baseline PCS and MCS scores and NSAID-use over time were tested as confounders.

Results: Patients with a diagnosis of axSpA were more frequently male and HLA-B27 positive and had more SpA features at baseline compared to the patients with CBP (Table 1). Age, symptom duration and NSAID-use were similar between groups.

In both groups the PCS significantly improved over two years. However, the PCS was significantly better in the group with an axSpA diagnosis compared to the CBP group at two-year follow-up, after correction for baseline PCS scores and NSAID-use over time (table 2). Despite the improvements over time, PCS scores were still well below the general population mean of 50 in both groups at two-year follow-up. MCS scores were not significantly different between groups at follow-up, and they were close to the general population mean.

In these regression models with baseline values and NSAID-use over time as covariates, axSpA was an independent predictor of better PCS scores (data not shown).

The majority of patients in both groups improved their PCS scores with more than the MCID over two-years of protocolised follow-up. In contrast, the proportion of patients who improved or worsened more than the MCID in MCS scores are similar. Also the percentage of patients with an improvement or worsening larger than the MCID for either PCS or MCS is similar in axSpA and CBP patients.

Conclusion: After two years of protocolised follow-up the physical functioning as assessed by the SF-36 PCS was better in patients with an axSpA diagnosis compared to patients with CBP.

"Rheum to Diagnosis": Uncovering Impediments to Accurate Diagnosis of Non-radiographic Axial Spondylarthritis (nr-axSpA)

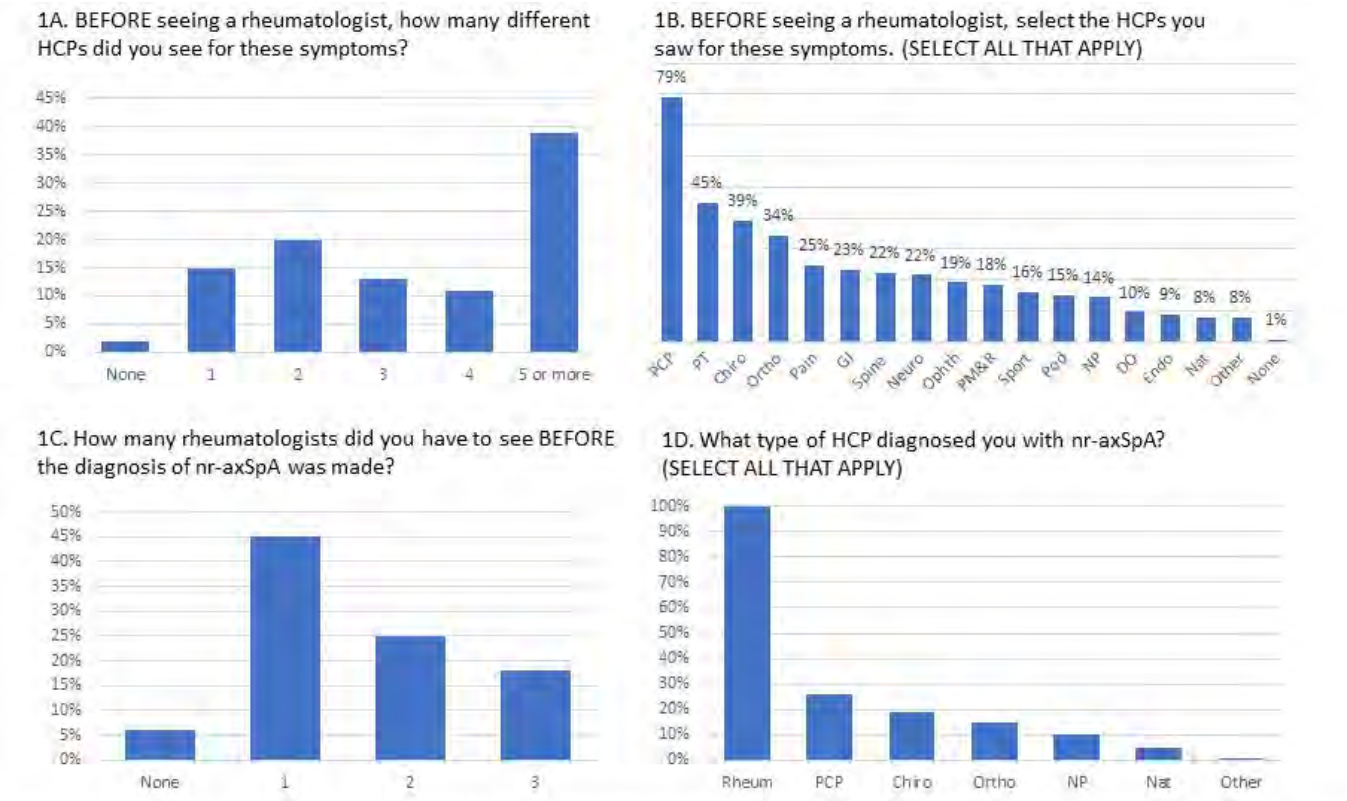
Sonam Kiwalkar[1], Atul Deodhar[1] and Richard Howard[2], [1]Oregon Health & Science University, Portland, OR, [2]Spondylitis Association of America, Van Nuys, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: In the US, there is up to a 14-year delay in axSpA diagnosis, which is likely greater for nr-axSpA.[1] Impediments to timely diagnosis of nr-axSpA are unknown. This two-phased study used a grounded theory analytical approach to understand the healthcare journey leading to nr-axSpA diagnosis and factors contributing to diagnostic delay.

Methods: Adults with nr-axSpA fulfilling the eligibility criteria of rheumatologist-confirmed diagnosis of nr-axSpA, chronic back pain for ≥3 months starting before age 45, and presence of characteristic SpA symptoms were recruited from February-May 2020 via the Spondylitis Association of America newsletter, social media channels, and from back pain patient databases. In the qualitative component of the study, semi-structured telephone interviews with 25 patients and 15 rheumatologists were conducted to identify barriers and overarching themes. For the quantitative component, patients completed a detailed online questionnaire.

Results: Quantitative analysis was conducted on 125 patients (mean age, 43.5 years [range: 18-73 years]; female 74%; white 84%, LatinX 3%, and black 2%; bachelor's or advanced degree in 72%). Half of patients had seen ≥4 different healthcare providers (HCPs) before seeing a rheumatologist (Figure 1) and 50% saw ≥2 rheumatologists before receiving the nr-axSpA diagnosis. The interval from symptom onset to nr-axSpA diagnosis ranged between ≤2 years in 40% to ≥11 years in 25% (Figure 2). Both qualitative interviews and quantitative survey responses found that patients often perceived their symptoms as a typical consequence of activity or their age (Table 1). When patients did seek medical care, clinicians frequently minimized, overlooked, or misinterpreted signs and symptoms of inflammatory disease, particularly in young and female patients. Survey participants perceived these issues as leading barriers to timely diagnosis.



Abbreviations: Chiro, chiropractor; DO, osteopath; Endo, endocrinologist; GI, gastroenterologist; HCP, healthcare provider; Nat, naturopath; Neuro, neurologist; NP, nurse practitioner; nr-axSpA, non-radiograph axial spondyloarthritis; Ophth, ophthalmologist; Ortho, orthopedist; Pain, pain specialist; Pod, podiatrist; PCP, primary care physician; PM&R, physical medicine and rehabilitation; PT, physical therapist; Spine, spine specialist; Sport, sports medicine;

Figure 1. Health Encounters Leading to nr-axSpA Diagnosis

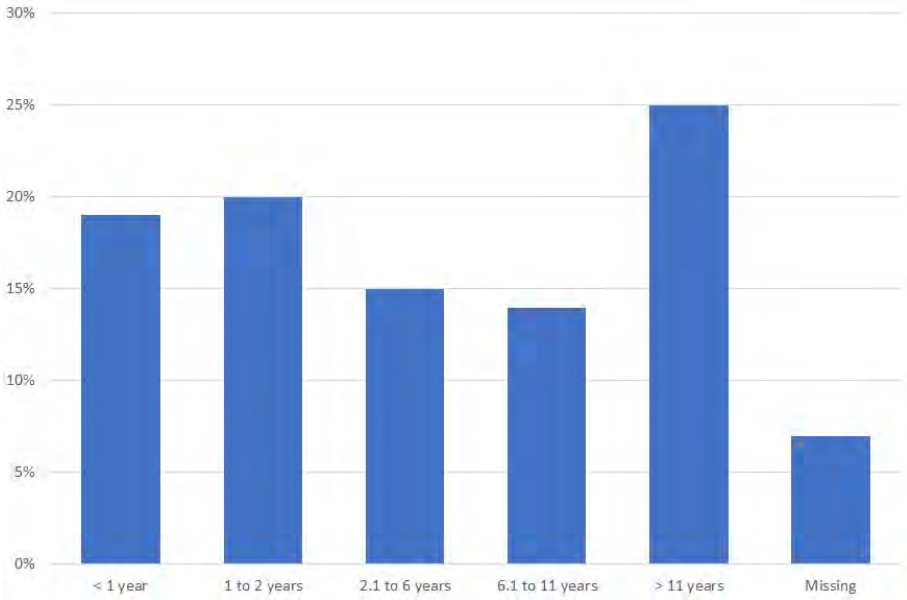


Figure 2. Duration of nr-axSpA Symptoms Before Diagnosis Established (N = 125)

Themes from Qualitative Interviews Patients (n = 25) and Rheumatologists (n = 15)	Quantitative Survey Findings Patients (N = 125)
Patients initially attribute back pain to normal wear and tear or age-related processes that do not require prompt medical care	58% initially thought their joint pains were due to activity or injury 26% thought their back pain was due to aging 20% thought their symptoms were growing pains due to their young age
Clinicians often minimize persistent symptoms, especially if they occur in young and/or female patients	34% reported their healthcare providers thought my symptoms were "in my head" 23% reported being told nr-axSpA is a "man's disease" (and so they couldn't have it). [female respondents only]
Physicians, including rheumatologists, do not know enough about nr-axSpA or inflammatory back disease	47% thought their HCPs attributed symptoms to activity or injury 28% reported that they were initially misdiagnosed
Specific biomarkers to facilitate diagnosis are currently lacking	38% thought that their normal x-rays or MRI were a barrier to timely diagnosis 13% felt that their negative HLA-B27 status contributed to delayed diagnosis
Delayed referral to rheumatologist	34% think medical professionals did not know to refer them to a rheumatologist 19% reported limited access to rheumatologists 12% requested a referral to a rheumatologist, but were denied
Seeing a rheumatologist does not necessarily lead to a prompt diagnosis	48% saw ≥2 rheumatologists before the diagnosis of nr-axSpA was made 25% reported receiving conflicting diagnoses from the rheumatologists they saw 13% reported that the rheumatologists they saw were unaware of nr-axSpA

Table 1. Barriers to nr-axSpA Diagnosis - Comparison of Qualitative and Quantitative Findings

Conclusion: Patients with nr-axSpA often see multiple HCPs before arriving at the diagnosis. While rheumatologists play a critical role in diagnosis, disease recognition by clinicians in other specialties is key for early referral. Findings suggest that both patients and clinicians may be unfamiliar with inflammatory back pain, and nr-axSpA—particularly in young, or female patients, or in those with normal x-rays. Education on the cardinal features, epidemiology, burden, and benefits of timely diagnosis of nr-axSpA is warranted for providers who commonly manage back pain.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The lack of pediatric classification criteria for axial disease is a major impediment to the conduct of clinical trials for juvenile spondyloarthritis (SpA). Classification criteria for axial disease in children with SpA are being developed. The objective of this study was to identify and grade a set of items that maximizes the likelihood of accurate classification of children and adolescents with axial disease.

Methods: First, we conducted an item-generation exercise with an international group of pediatric rheumatologists to generate a comprehensive list of clinical, laboratory, and imaging features used to decide whether or not a child/adolescent has clinical evidence of axial involvement. Second, we performed a literature review to formulate a list of features used in juvenile and adult SpA clinical study inclusion criteria and adult axial SpA classification criteria. Next, we completed a grading exercise in which respondents in the item generation survey rated the features generated from the first 2 steps for specificity (-3 to +3), with anchors "much less likely to have axial disease" and "much more likely to have axial disease", respectively. Items with a mean score of zero or close to zero and redundant items were removed. The final list of items was reviewed by a panel of juvenile SpA experts and split into "entry criteria", which would be required for classification applicability, potential "additive criteria", and potential "exclusion" or "negatively weighted criteria". Additive and negatively weighted criteria were grouped into domains by an iterative process.

Results: One hundred and ninety-nine physicians from 45 countries proposed 108 items useful in the determination of axial involvement or not. Responses showed broad coverage but also high consistency. Responses were grouped into 15 domains with a range of 38-141 unique respondents noting ≥1 item in a domain. Most items were related to imaging, location of pain or stiffness, pattern of pain, genetics, range of motion, laboratory markers, and comorbidities. Literature review did not identify any additional clinical features to include in the item reduction exercise. In the grading exercise, 87 items had a mean score of ≥1.5 and 5 items ≤1.5. The expert panel reviewed the candidate items, grouped them into 6 independent domains, and identified 2 entry criteria, 2 exclusion criteria, 23 potential additive criteria, and 4 negatively weighted criteria (Table). The expert panel also voted to align criteria within the imaging domains with definitions provided by the OMERACT Juvenile Arthritis MRI Score (JAMRIS) international Working Group (1) when possible and to exclude radiographs and spinal MRI. Final additive and negatively-weighted criteria

Table. Inclusion, exclusion, additive, and negatively-weighted criteria

Eligibility criteria	Items
Inclusion criteria	PRINTO provisional revised updated criteria for enthesitis/spondylitis-related JIA (2):
	• Peripheral arthritis* and enthesitis OR
	• Arthritis* or enthesitis, plus ≥3 months of inflammatory back pain^ and sacroiliitis on imaging #, OR
	• Arthritis* or enthesitis plus ≥2 of the following:
	○ Sacroiliac tenderness
	○ Inflammatory back pain^
	○ Presence of HLA-B27
	○ Acute (symptomatic) anterior uveitis
	○ History of SpA in a 1st degree relative
	OR
	Physician diagnosis of spondyloarthritis
Exclusion criteria	High fevers
	Presence of rheumatoid factor or anti-cyclic citrullinated peptide
Domains	
Additive features	
Pain	Lumbar or sacroiliac or buttock daily pain for ≥6 weeks
	Hip or groin daily pain for ≥6 weeks
	Sacroiliac pain elicited on exam with deep palpation or by FABER/Mennell/Gaensien's maneuvers
Stiffness	Lumbar or sacroiliac or buttock stiffness
	Hip or groin stiffness
	Duration of stiffness
	Frequency of stiffness
	Improvement with exercise
	Improvement with rest
	Occurrence at night
Genetics	Family history of HLA-B27-associated disease in a 1st degree relative
	Presence of HLA-B27
Imaging: Active Inflammation	Subchondral inflammation/bone marrow edema
	Capsulitis
	Joint space enhancement
	Inflammation at the site of erosion
	Joint space fluid
	Enthesitis
Imaging: Chronic Inflammation/damage	Erosion
	Fat lesion/ fat metaplasia
	Fat metaplasia in an erosion cavity (Backfill)
	Sclerosis
	Ankylosis
Negatively-weighted features	Acute onset of pain
	Accompanying neurologic/radicular symptoms
	Total body pain
	Extreme tenderness to light touch (allodynia)

*Peripheral arthritis should be present for ≥6 weeks. ^≥4 of the following: improvement with exercise, pain at night, insidious onset, age at onset <40 years, and no improvement with rest (3). # modified NY criteria for radiographs(4) and ASAS MRI working group definitions of active sacroiliitis (5).

Acknowledgements: Volunteers for the initial Delphi exercise were solicited from the memberships of the Australian and New Zealand Paediatric Rheumatology groups, Canadian Rheumatology Association, the Childhood Arthritis and Rheumatology Research Alliance (CARRA), the international pediatric electronic bulletin board, Paediatric Rheumatology International Trials Organization (PRINTO), Pediatric Rheumatology Society of India, Pediatric section of the Brazilian Rheumatology Society, and the Society for Pediatric Rheumatology in Germany, Austria and Switzerland.

will be determined after evaluation of the sensitivity and specificity of potential criteria in a development cohort of juvenile SpA cases.

Conclusion: The item-generation exercise, grading exercise, and expert panel's iterative work resulted in inclusion, exclusion, candidate additive and negatively weighted criteria. Refinement and weighting of criteria as well as determination of threshold for classification will be ascertained in the next phase.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to compare work-productivity and activity impairment outcomes after two-year follow-up between chronic back pain (CBP) patients with and without an axSpA diagnosis

Methods: Patients over 16 years of age referred to the rheumatology outpatient clinic with chronic back pain (≥ 3 months < 2 years) starting before the age of 45, suspected of axSpA were included in the SPACE cohort. Follow-up was performed only in patients with at least two SpA features or one SpA feature with a positive likelihood ratio ≥6.4 (Rudwaleit, van der Heijde, Khan, Braun, & Sieper, 2004).

Work productivity was assessed using the Work Productivity and Activity Impairment (WPAI) general health version 1.0 questionnaire. Presenteeism was defined as a reduction in performance while at work due to disease; absenteeism was time missed from work due to disease; work productivity loss (WPL) was a combined measure of presenteeism and absenteeism; and activity impairment was impairment due to disease in all non-work related activities. All WPAI outcomes were presented as percentages between 0-100; higher scores implying greater impairment. Additionally, the proportion of patients with any (>0%) absenteeism, presenteeism, WPL and activity impairment were given.

Assessment of presenteeism, absenteeism and WPL was restricted to the working population, defined as having paid work at baseline and 2-year follow-up. Activity impairment was assessed for the entire study population. The employable population was defined as everyone of working age (>16), who was not a fulltime student.

In this study we included patients with a diagnosis axSpA or no axSpA (CBP group) all with a level of confidence ≥7 (on a 0-10 scale) after locally read imaging. Additionally, data had to be available on the WPAI questionnaire at both timepoints.

Regression models were used to test the difference between groups at two-year follow-up for each of the WPAI variables. Baseline WPAI values and NSAID-use over time were tested as confounders.

Table 1 Baseline characteristics of patients with a diagnosis of axSpA and those with CBP.

Characteristic	Diagnosis axSpA (N=181)	CBP (N=74)
Male, n(%)	101 (56)	22 (30)
Age (years), mean (SD)	30 (8)	31 (8)
Symptom duration (months), mean (SD)	13 (7)	13 (7)
HLA-B27 positive, n(%)	133 (73)	23 (31)
Number of SpA features, mean (SD)	5 (2)	3 (1)
Use of NSAIDs, n(%)	137 (76)	52 (70)
Employable population	*163 (90)*	*68 (92)*
Paid work, n(%)*	140 (86)	58 (85)

* Paid work at baseline, calculated based on the employable population.

axSpA, axial Spondyloarthritis; CBP, Chronic Back Pain; HLA-B27, Human Leucocyte Antigen B27; NSAIDs, Non-Steroidal Anti Inflammatory Drugs; SpA, Spondyloarthritis

Table 1. Baseline characteristics of patients with a diagnosis of axSpA and those with CBP.

Table 2 Work-productivity outcomes at baseline and two-year follow-up for the group with a diagnosis of axSpA and the group without a diagnosis.

Characteristic	Diagnosis axSpA		CBP		
	Baseline	2 years	Baseline	2 years	p-values
Working population	*N=124*		*N=52*		
Presenteeism, mean (SD) %	31 (28)	18 (24)†	40 (29)	30 (30)†	p=0.003*
Presenteeism present, %	73	52	87	67	
Absenteeism, mean (SD) %	7 (18)	4 (14)†	12 (25)	6 (21)†	p=0.334
Absenteeism present, %	22	7	27	12	
Overall work impairment, mean (SD) %	33 (29)	22 (27)†	43 (30)	35 (33)	p=0.005*
Overall work impairment present, %	72	46	87	65	
Total population	*N=181*		*N=74*		
Activity impairment, mean (SD) %	38 (28)	22 (24)†	50 (29)	33 (29)†	p=0.001*
Activity impairment, n(%)	86	64	93	70	

* Significant difference between groups at two years; after correction for baseline values and NSAID use over time ($p<0.05$).
†Significant improvement within group over time

Table 2. Work-productivity outcomes at baseline and two-year follow-up for the group with a diagnosis of axSpA and the group without a diagnosis.

Results: Patients with a diagnosis of axSpA were more frequently male and HLA-B27 positive and had more SpA features at baseline compared to the patients with CBP (Table 1). Age, symptom duration, NSAID-use and the percentage of patients with paid work at baseline were similar between groups.

The population having paid work at baseline and 2 years consisted of 124 patients (69%) in the axSpA group and 52 patients (70%) in the CBP group. In both groups the proportion of patients with any as well as the mean WPL reduces. This reduction was apparent in both presenteeism and absenteeism. Nevertheless, presenteeism, WPL and activity impairment were significantly higher at two-year follow-up in the group with CBP (Table 2). In these regression models with baseline values and NSAID-use over time as covariates, axSpA was an independent predictor of lower presenteeism, overall work impairment and activity impairment at two-year follow-up (data not shown).

Conclusion: Despite significant improvements in both groups, patients with a diagnosis of axSpA have significantly better work-related outcomes after two years of protocolised follow-up compared to patients with CBP.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies from Latin America have shown an association with peripheral arthritis in patients with spondyloarthritis with HLA-B*15 (as opposed to HLA-B27). We aimed to examine sociodemographic and clinical associations along with HLA-B alleles with peripheral arthritis and enthesitis in a longitudinal cohort of AS patients.

Methods: AS patients were derived from the Prospective Study of Outcomes in Ankylosing Spondylitis (PSOAS)/ Australo-Anglo-American Spondyloarthritis (TASC) Cohort. All patients met the modified New York Criteria for AS. In addition to a baseline visit (where a history of peripheral arthritis, heel pain and other comorbidities was ascer-

Table 3. Associations of Enthesitis by Physical Exam at any Study Visit

tained), study visits were conducted every 4 to 6 months consisting of an evaluation of spinal mobility, joint swelling/tenderness count, examination of enthesitis (using the UCSF Enthesitis Index) and disease activity (BASDAI, C-reactive protein [CRP], erythrocyte sedimentation rate [ESR]) and functional measures (Bath Ankylosing Spondylitis Functional Index [BASFI], exercise history) and medication use (NSAIDs, anti-TNF blockers, sulfasalazine (SSZ) and methotrexate (MTX). Relative predispositional effects analysis (RPE) was used to adjust for the effect of HLA-B*27 at the HLA-B locus to mask the alleles and analyze the other alleles for associations. Statistics were done using univariable and multivariable analyses for peripheral arthritis and enthesitis in association with clinical, sociodemographic factors, medications and HLA-B alleles.

Results: There were 1076 white AS patients with HLA-B typing included in this analysis. In the case of heel pain by history, at baseline visit affected AS patients were less likely to be taking NSAIDs, but more likely to be exercising >120 minutes a week and to have elevated ESR or CRP at baseline visit, even on multivariable analysis. For those found to have Achilles tendonitis or plantar fasciitis on physical exam, affected individuals were more likely to be female, to have concomitant joint swelling, to be functionally impaired (BASDAI > 40 mm), to be using anti-TNF agents and either MTX or SSZ (Table 1). For those with arthritis on physical exam (defined as joint swelling), again, associations were found with female gender, functional impairment (BASFI) >40 mm), to be exercising < 120 minutes/week, and to be using anti-TNF agents as well as MTX or SSZ (Table 2). Enthesitis at any point in the UCSF Enthesitis Index at any visit was associated with nonwhite ethnicity, concomitant joint swelling, a lower likelihood of regular exercise, and anti TNF use, as well as (marginally) with functioning less well (Table 3). No HLA-B association was found with heel pain, Achilles tendonitis or plantar fasciitis or enthesitis elsewhere, though the association with HLA-B15 persisted with peripheral arthritis.

Conclusion: This association study in a large prospective AS cohort shows a higher prevalence of peripheral musculoskeletal manifestations of AS in women, and the impact on physical function and activity and the concomitant use biologic and nonbiologic DMARDS. Further work is underway examining modifiable factors that might actually predict the future presence of arthritis and enthesitis in these patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare disease characteristics, comorbidities, and medication utilization of 573 patients with ankylosing spondylitis (AS) with short (< 20 years) disease duration (from symptom onset) and 568 patients with long disease duration (≥ 20 years) enrolled in the Prospective Study of Outcomes in AS (PSOAS)/Australo-Anglo-American (TASC) study over three different periods of time (2003-2006, 2007-2015, 2015-2019) and followed longitudinally.

Table 1. Demographic/Clinical Characteristics and Medication Utilization of Patients across time periods with Baseline Disease Duration <20 years At Latest Interval Visit

Variable	Patients Enrolled 2002-2006*	All Patients Seen 2007-2014**	All Patients Seen 2015-2019**	p-value [a]
	N=220	N=433	N=267	
BASDAI, median (IQR)	3.5 (1.7, 5.7)	2.7 (1.2, 4.8)	2.0 (1.0, 3.9)	<0.0001

a: p-values for the comparison between two groups based on regression models (logistic regressions for categorical variables; linear regressions for normally distributed continuous variables (age, age at disease onset, disease duration); Poisson regressions for non-negative continuous variables that are highly skewed) after adjusting for sites and early-adherence (4.4%, 28.6%, 0%, 11.2% for each of four groups, respectively)

Table 3. Characteristics of Australian Patients Compared to US Patients

Methods: Study visits were carried out every 6 months examining disease activity (Bath AS Disease Activity Index (BASDAI), C-reactive protein, erythrocyte sedimentation rate), functional impairment, depression, and medication utilization as well as clinical assessments of joint and entheseal involvement as well as spinal mobility and radiographic severity. Groups were compared with regression models using generalized estimating equation, linear and Poisson regressions after adjusting for sites and for patients withdrawing from the study at less than two years follow-up.

Results: Looking at those 573 U.S. patients with short disease duration (< 20 years), NSAID and non-biologic DMARD (particularly methotrexate) and prednisone use decreased over time and TNFi use rose between the initial period of enrollment (2002-2006) and the last period (2015-2019) (Table 1). During the middle period of the study (2007-2014) there was a slightly higher frequency of cardiovascular disease and opioid use that fell in the latest period of the study. No differences were seen over time in marital status, education level, frequency of exercising or either comorbidities associated with AS such as uveitis or psoriasis or comorbidities not directly disease related such as diabetes or osteoporosis (data not shown). Looking at those 568 U.S. patients with longer disease duration (≥20 years), there was a fall in functional impairment, current smoking rates and NSAID use comparing the initial study visits as well as the most recent study visits over the three phases of the study (data not shown). Disease activity, depression scores and NSAID use decreased and anti-TNF use increased between baseline and last followup visits in those followed > 8 years despite an increase in mSASSS scores over time (Table 2). The 91 Australian patients enrolled were more likely to be white (100% versus 74.3% of US patients, p< 0.00001), had lower disease activity (BASDAI, ESR, CRP), functional impairment and depression scores, and less NSAID and much more TNF inhibitor usage (Table 3) and secukinumab usage (4.1% vs 2.2% of US patients), despite having lower educational levels and a higher frequency of smoking.

Conclusion: Patients with AS enrolling in this multicenter longitudinal cohort have improved disease profiles and different medication utilization over time, including gr perhaps reflecting innovations in treatment and increasing disease awareness. The improved disease parameters seen in the Australian patients may be due to the much higher use of TNF blockers provided from their National Health Care Service compensating for other bad prognostic factors in this cohort (smoking, lower educational status).

Differences Between Men and Women in the Patient Pathways to Diagnosis of Ankylosing Spondylitis

Mark Hwang[1], Martin Rozycki[2], Theresa Arndt[2], Esther Yi[3] and Michael Weisman[4], [1]McGovern Medical School at the University of Texas Health Science Center at Houston, Houston, TX, [2]HVH Precision Analytics, LLC, Wayne, PA, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [4]Cedars Sinai Medical Center, David Geffen School of Medicine at UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Healthcare claims databases can be used to identify patients with ankylosing spondylitis (AS) prior to diagnosis. This study explores differences in pathways to AS diagnosis between men and women by examining the coding of health events over the 2 years prior to AS diagnosis.

Methods: This retrospective cohort study collected administrative claims data from patients in the Truven Health MarketScan® Commercial and Medicare Supplemental Databases from January 2006 to April 2019. The AS population included all patients aged ≥ 18 years with ≥ 2 diagnoses of AS (ICD-9-CM/ICD-10-CM) ≥ 30 days apart who had ≥ 2 years of continuous enrollment prior to first AS diagnosis. Male patients with AS were matched 1:1 to female patients with AS by age, date of AS diagnosis, insurance type, and enrollment duration. Diagnosis codes and physician types were examined over the 2 years prior to AS diagnosis and stratified by men vs women. A set of 1906 AS-related codes in men and women was examined using univariate χ^2 tests.

Results: A total of 7744 patients met the inclusion criteria for diagnosis of AS. The mean (SD) age for men and women, respectively, was 45.1 (14.4) and 45.3 (14.1) years; women were less likely than men to be working full time (41.2% vs 47.1%) (**Table 1**). Of 1906 codes examined for differences between men and women, 281 codes showed significant differences, some of which are highlighted in **Tables 2** and **3**. In general, women had more overall coding than men across diagnoses and providers. The greatest difference between men and women in categorized disease features was observed for peripheral symptom coding (57.7% of women vs 43.9% of men) (**Table 2**). Compared with men, women also showed much greater levels of other MSK coding (52.8% vs 40.0%), unspecified coding (59.6% vs 46.9%, and depression (21.2% vs 9.8%). Only gout was significantly more common in men vs women (6.5% vs 2.2%). These differences were observed throughout the 2 years prior to AS diagnosis. However, coding for backache

Table 1. Baseline Demographics of Men and Women Diagnosed With AS

AS, ankylosing spondylitis.

gradually increased in men starting at 12 months before AS diagnosis, whereas axial and sacroiliitis coding increased sharply in men immediately before AS diagnosis, suggesting differences between men and women in pathways to AS or in presentation of disease. When looking at physician types visited in the 2 years prior to AS diagnosis, the greatest difference was observed for rheumatologists (64.2% of women vs 45.1% of men; difference = 19.1%) (**Table 3**).

Conclusion: This analysis revealed differences between men and women in the time leading up to diagnosis of AS, with the greatest variations observed for peripheral vs axial coding, unspecified coding, MSK symptoms, and depression. These findings, over a range of codes, are consistent with differences in disease phenotype between men and women that result in divergent pathways to diagnosis of AS. Women showed greater levels of coding regardless of the code being examined. A greater number of visits to community rheumatologists for women vs men support the hypothesis that there is a greater challenge in diagnosing the AS disease spectrum in women vs men by clinicians, which merits further investigation. These differences potentially contribute to a delayed, burdened journey to diagnosis of AS in women compared to men.

Table 2. Differences in the Proportion of Men and Women Who Had Different Categorized Diagnosis Features in the 2 Years Prior to AS Diagnosis

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) includes both ankylosing spondylitis (AS) and non-radiographic axial disease (nr-axSpA). Our purpose was to investigate genetic heterogeneity of clinically diagnosed axSpA.

Table 1:

Affection Status	Gender	HLA-B27+	HLA-B27-	PRS (SE)
Unaffected	Male	69 (37.9%)	113 (62.1%)	0.0754 (0.023)
	Female	94 (43.5%)	122 (56.5%)	0.0376 (0.023)
	Total	163	235	
nr-axSpA	Male	19 (79.2%)	5 (20.8%)	0.104 (0.067)
	Female	17 (53.1%)	15 (46.9%)	0.322 (0.068)
	Total	36	20	
mNYAS	Male	115 (91.3%)	11 (8.7%)	0.418 (0.020)
	Female	40 (95.2%)	2 (4.8%)	0.377 (0.019)
	Total	155	13	
Clinical AS	Male	134 (89.3%)	16 (10.7%)	
	Female	57 (77%)	17 (23.0%)	
	Total	191 (85.3%)	33 (14.7%)	

1. Li Z, de Guzman E, Harris J, et al. Genetic Risk Score Prediction in Ankylosing Spondylitis. Arthritis Rheum 2018;70:1-3553.

Methods: In 1985 members of the Swiss AS Patient Society who had been diagnosed as having AS by their own physicians, and also their first-degree relatives whether or not they had any rheumatic disease, were invited to participate in this study. 1178 subjects, 355 of them probands, formed our study cohort. Participants completed questionnaires on disease manifestations, underwent rheumatological examination of axial and peripheral joints, and radiography of the sacroiliac joints. Further, they provided blood samples for genetic studies, including HLA-B27. Radiographs were graded according to the modified New York (mNYAS) criteria for AS. Patients diagnosed clinically with AS but with negative radiographs were considered to have nr-axSpA, whereas those with negative clinical diagnoses and radiographs were considered healthy. DNA from 702 participants was genotyped using Illumina CoreExome arrays, and a polygenic risk score (PRS) calculated from this genotype data, as previously reported[1]. Discriminatory capacity of the PRS between diagnostic groups, and comparing males and females was examined by receiver operator characteristic area under the curve (AUC) analysis.

Results: HLA-B27 was present in 191/224 (85.3%) probands, with HLA-B27 carriage being more common in men than women (odds ratio (OR)= 2.50, p=0.015). The lower HLA-B27 carriage amongst women clinically diagnosed with AS was due to a higher proportion of women with nr-axSpA than with AS being HLA-B27 negative (OR=3.35, P=0.044), with no difference in the HLA-B27 carriage rates of men and women with mNYAS (P=0.41). Considering PRS, both men and women with mNYAS, but only men with nr-axSpA, had higher PRS than healthy subjects ($P< 5x10^{-4}$ all comparisons). The PRS was higher in men than women with nr-axSpA (0.32 vs 0.10, P=0.029), whereas no difference in PRS was observed comparing men and women with mNYAS (0.80 vs 0.78, P=0.60). Whilst the PRS clearly distinguished males with nr-axSpA from healthy subjects (AUC=0.73, $P=1.9x10^{-4}$), it was not able to distinguish females with nr-axSpA from healthy subjects (AUC=0.51, P=0.90). The PRS was not able to distinguish men with mNYAS from those with nr-axSpA (AUC=0.50), whereas it clearly distinguished women with mNYAS from those with nr-axSpA (AUC=0.73, $P=6.4x10^{-4}$).

Conclusion: Whilst men and women with mNYAS have disease that is genetically similar, and men with nr-axSpA had PRS that was similar to mNYAS and distinct from healthy subjects, women with nr-axSpA had similar PRS to healthy subjects and distinct from women with mNYAS. This indicates that women clinical diagnosed with AS, but who are x-ray negative, as a group have a disease that is distinct from mNYAS overall, and from nr-axSpA in men. This study also demonstrates that PRS have good discriminatory performance for nr-axSpA in men.

Abstract Number: 1876

The Role of HLA B27 in Axial Spondyloarthritis: Prevalence and Performance as a Marker in an Argentinian Cohort

Rodrigo Garcia Salinas[1], Santiago Ruta[1], Einer Sanchez Prado[1], Jessica Torres Chichande[1], Alvaro Ruta[1], Facundo Salvatori[1] and Sebastian Magri[1], [1]Hospital Italiano La Plata, La Plata, Argentina

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: HLA B27 prevalence in Latin America are heterogeneous and timeless, we propose to estimate the prevalence of HLA B27 in an Argentinian cohort of axial spondyloarthritis (SpA) and to evaluate the differences between positive and negative patients and to analyze its performance as a diagnostic biomarker.

Methods: An observational study included patients older than 18, with axial SpA diagnosis performed in a fast track evaluation program (Reuma-check SpA) between 2017-19. In this circuit, all patients underwent: blood tests, HLA B27, sacroiliac Rx, sacroiliac MRI and enthesitis ultrasound. Sociodemographic data and education level were also collected. SpA symptoms: Age of onset and characteristic of low back pain, SpA features, NSAIDs use and response, VAS: pain and night pain, time of morning stiffness. BASDAI, BASFI, MASES, HAQ was consigned. The clinical assessor was blinded to the complementary studies. For the sensitivity and specificity analysis, a group of patients with chronic low back pain who performed the same circuit in the same period of time were used as a control, paired 1:1 (gender and age).

Statistical analysis: descriptive statistics, Chi2 test or Fisher's exact and Student or Mann Whitney test were performed. Binomial logistic regression was performed, and sensitivity, specificity, PPV, NPV and LR were calculated.

Results: 150 patients were included, 75 with axial SpA and 75 controls, the characteristics are showed in Table 1. The prevalence of HLA B27 in SpA patients was 43% (CI95: 30-53). The differences between positive and negative patients are shown in table 2. In the logistic regression analysis, BASFI values and the SpA features showed independent differences. When this prevalence was compared with those of the control group the difference was 43% vs 9% OR: 7.7 (IC95: 2.8-24), HLA B27 had a sensitivity: 43%, specificity: 91 %, PPV: 85%, NPV: 58% and LR: 4.9 (IC95: 3-8).

Table 1: Characteristics of SpA Patients vs. non-SpA controls.

Varables	SpA axial(N: 75)	Cronic back pain (N:75)
Age (SD)	46 (12)	43 (10)
Male (%)	43	44
Low back pain onset age (SD)	39 (11,5)	39 (11,6)
Low back pain time (months)	37,2 (13-121)	33 (12-75)
Smoking (%)	42	48
SpA features (%)	41	24
SpA family history (%)	29	23
NSAIDs good response (%)	59	42
SI x-ray + (%)	52	17
SI MRI + (%)	63	15
Entesitys untrasound + (%)	46	17
VAS pain (SD)	7,1 (1,3)	6,1 (2,1)
VAS night pain (SD)	5,8 (2,5)	4,9 (2,6)
Morning stiffness (mint)	30 (15-40)	15 (7,5-30)
BASFI (SD)	4,4 (1,8)	3,3 (1,5)
BASDAI (SD)	5,5 (1,4)	3,6 (2,69)
MASES (SD)	1,9 (3)	0,73 (1,4)
HAQ (IQR)	0,75 (0,5-1)	0,5 (0,3-1)
CRP mg/L (IQR)	2 (1-6)	1 (1-3)
GSV 1 hr (IQR)	17 (10-25)	11 (6-20)

Conclusion: The prevalence of HLA B27 in axial SpA was 43%, positive patients had an earlier age of onset (36 years) and negative BASFI higher and more SpA features. For the diagnosis of SpA, HLA B27 had a good specificity but low sensitivity (91% vs 43).

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Assessors	Mean % Concordance (range) for diagnosis of axSpA		
	Stage 1	Stage 2	Stage 3
Experts in axSpA	64.2 (45-80)	75.8 (65-85)	84.2 (70-95)
Local rheumatologist vs Experts in axSpA	73.8 (70-80)	83.8 (80-85)	83.8 (80-90)
pF rheumatologist 1 vs Experts consensus	78.9	94.4	94.7
pF rheumatologist 2 vs Experts consensus	89.5	61.1	68.4
pF rheumatologist 3 vs Experts consensus	63.2	72.2	84.2
pF rheumatologist 4 vs Experts consensus	89.5	66.7	68.4

Background/Purpose: Diagnosis of axial spondyloarthritis (axSpA) is challenging because of absent physical findings in early disease and the limited diagnostic performance of laboratory markers. Considerable reliance is placed on imaging of the sacroiliac joints (SIJ). We aimed to identify what might be the primary unmet educational needs of rheumatologists completing fellowship training within the past 6 years (post-F) by using clinical and imaging data from an inception cohort of consecutive patients presenting with undiagnosed back pain. We hypothesized that concordance between post-F rheumatologists and axSpA experts would increase after imaging data is reviewed following the clinical data.

Methods: The diagnosis of axSpA was compared between local site rheumatologists recruiting patients for the cohort, axSpA experts who reviewed the diagnostic ascertainments, and post-F rheumatologists who assessed clinical and imaging data from the multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study. In this inception cohort, consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain undergo routine diagnostic evaluation by a local SASPIC rheumatologist, including imaging of the SIJ, who then records a global evaluation of presence/absence of axial SpA. This is done at 3 consecutive stages: 1.After the clinical evaluation. 2.After the results of labs (HLA B27, CRP) and radiography. 3.After review of the local MRI report. In this exercise, 20 cases were selected from the SASPIC cohort with an equal distribution of axSpA and non-axSpA cases. Four experts in axSpA reviewed the clinical and imaging data in each eCRF in a sequential manner and provided their global diagnostic evaluations blinded to the assessments of local site rheumatologists for stages 1, 2, and 3 of these 20 cases. Subsequently, 4 post-F rheumatologists conducted the same exercise blinded to the assessments of the local site rheumatologist and experts in axSpA. Concordance (% agreement) between the assessors was analyzed.

Results: Diagnosis of axSpA by the local SASPIC rheumatologist was made in 90%, 65%, and 75% of cases after stages 1, 2, and 3, respectively. Majority diagnosis of axSpA by experts was made in 84.2% (16/19), 57.9% (11/19), and 63.2% (12/19), after stages 1,2, and 3, respectively. Majority diagnosis of axSpA by post-F rheumatologists was made in 94.4% (17/18), 100% (16/16), and 93.8% (15/16). Concordance among experts and between experts and local SASPIC rheumatologists increased after review of imaging data. For post-F rheumatologists concordance with experts increased after review of imaging for 2 assessors and decreased for the other 2 assessors. For the latter, the primary reason for decrease in concordance with experts was false positive diagnosis of axSpA in 35% and 30% of the cases after review of the imaging.

Conclusion: A structured case-based and sequential evaluation of clinical and imaging data suggests a gap in the training of recently graduated rheumatologists, with over-interpretation of imaging leading to false positive diagnosis of axSpA.

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: A broad spectrum of MRI lesions has been described in the spine of patients with axial spondyloarthritis (axSpA) and a recent consensus from the ASAS MRI group has culminated in updated spine lesion definitions (ASAS_MRI_def^{n})[1]. There has been no central reader evaluation of MRI spine scans from the ASAS Classification Cohort (ASAS-CC)[2]. We aimed to determine the spectrum and compare the frequencies of active and structural lesions on MRI images of the spine from the ASAS-CC according to the consensus ASAS_MRI_def^{n} update, the diagnosis of axSpA, and the presence of radiographic sacroiliitis.

Methods: ASAS_MRI_def^{n} were recorded by 9 central readers in an eCRF that comprises global assessment (MRI indicative of axSpA yes/no) and detailed scoring of each discovertebral unit as well as lateral and posterior structures. Detailed scoring is based on slices viewed in sagittal orientation and for the thoracic and lumbar spine is subdivided into assessment of central and lateral slices that include or do not include the spinal canal, respectively. Vertebral

Table 1. Spinal corner lesions stratification according to rheumatologist diagnosis of axial spondyloarthritis data.

Vertebral Corner MRI lesions	majority of readers (>=5)			≥2 readers

Corner BME ≥3	5 (50%)	6 (12.2%)	0.014	5 (50%)	11 (22.4%)	0.12
Corner BME ≥4	5 (50%)	3 (6.1%)	0.002	5 (50%)	7 (14.3%)	0.022
Corner BME ≥5	5 (50%)	2 (4.1%)	0.001	5 (50%)	3 (6.1%)	0.002

corner bone marrow edema (VCBME) and corner fat (VCFAT) lesions were recorded if present on 2 slices; facet joint, lateral slice, and posterior element inflammatory lesions were recorded if present on a single slice. Vertebral corner erosion, bone spurs, and ankylosis (intervertebral, facet) were each scored on a single slice. Comparison of active and structural lesion frequencies according to local rheumatologist diagnosis of axSpA and the presence of radiographic sacroiliitis was assessed descriptively according to individual, ≥2, and majority reader (≥5/9) concordant data.

Results: MRI scans of the entire spine were available from 69 cases and rheumatologist diagnosis in 64. AxSpA was diagnosed in 44 (68.8%). VCBME was most frequent, ≥1 lesion being recorded in 32(46.4%) and 19 (27.5%) by ≥2 and majority of readers, respectively. VCFAT was the most frequent structural lesion, ≥1 lesion being recorded in 24 (34.8%) and 14 (20.3%) by ≥2 and majority of readers, respectively. There were significantly more VCBME lesions in axSpA patients (mean(SD):1.8 (2.7)) than non-axSpA (mean(SD):0.3 (0.5)) ($p< 0.001$) while differences in VCFAT were not significant (Table 1). The presence of ≥2 VCBME lesions had 90-95% specificity for axSpA. Significantly more VCBME and VCFAT were observed in the setting of radiographic sacroiliitis (modified New York criteria (mNY)) (Table 2).

Conclusion: Spine lesions on MRI are relatively frequent in patients with undiagnosed back pain presenting to the rheumatologist. The presence of at least 2 VCBME lesions (each on 2 consecutive sagittal slices and without degenerative disc disease), but not VCFAT, may have some diagnostic utility.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The magnetic resonance imaging (MRI) of the sacroiliac joints (MRI-SIJ) represents an essential tool in the evaluation of patients with spondyloarthritis (SpA). However, despite a clear definition of positive and negative MRI-SIJ formulated by the ASAS/OMERACT working group, the inter-reader agreement between readers is never perfect. Moreover, in daily practice, the radiologists in charge of the evaluation of the SIJ-MRI images are rarely experts in musculoskeletal radiology. The aim of this pilot study is to predict a positive or negative MRI-SIJ according to the ASAS definition in patients with in recent axial SpA (axSpA) applying Artificial Intelligence (AI) and machine learning.

Methods: Patients from the DESIR cohort with MRI-SIJ available at baseline and in full agreement for positive or negative MRI-SIJ according to the three central readers were included.

We first segmented the iliac and sacrum bones in each MRI-SIJ slice. Then, we extracted the right and left joint on each slice of MRI. Finally, we reported the presence of inflammatory lesions on each joint of the MRI-SIJ. Once all the inflammatory lesions of the joints have been reported, we defined the positiveness of the MRI-SIJ based on a decision rule. All of these steps were conducted without human intervention.

We solved two tasks in this work:

Task 1: Segmentation of iliac and sacrum bones in semi-coronal axis MRIs.

Task 2: Detection of inflammation in the MRI-SIJ.

For task 1, we manually segmented 51 MRIs. We found that using two independent U-Net [1] for each bone performed better than using a single one that predicts the two bones.

For task 2, we use a ResNet-18 [2] to determine if each half-slice presents inflammation or not.

Metric \ Bones	Iliac	Sacrum
IOU	0.73	0.56
DICE	0.84	0.67

Table 1. Segmentation results on 14 patients.

Readers	2	3	ResNet18 (k = 10)
1	87	84	62.96 +- 1.92
2	-	83	66.08 +- 1.41
3	-	-	56.99 +- 1.43

Table 2. Results of presence of inflammation in a selected region. Matthews Correlation Coefficient (multiplied by 100 for clarity).

Readers	2	3	ResNet18 (k = 10)
1	100	100	77.75 +- 4.50
2	-	100	77.75 +- 4.50
3	-	-	77.75 +- 4.50

Table 3. Results of positive MRI-SIJ. Matthews Correlation Coefficient (multiplied by 100 for clarity). Decision rule: each MRI must have at least 3 regions with inflammation.

Results: Task 1: We trained two U-Net, one for each bone. We split 51 patients in 31 train, 6 validation, 14 evaluation. The results on the evaluation set are presented on table 1. We segmented successfully 104 new patients out of the 114 tested.

Task 2: We had a total of 155 segmented patients (51 manually and 104 automatically). We extract 1790 joints regions of T1 and STIR sequence. We trained a ResNet-18 classifier to determine the presence or absence of inflammatory lesions. We split the 155 patients (1790 regions) into 105 (1220 regions) train, 14 (164 regions) validation and 36 (406 regions) evaluation. We trained k = 10 identical networks. The results are shown on table 2. We compared the opinion of the three readers for each region. The positiveness for an MRI-SIJ is presented on table 3 (decision rule: #inflammation >= 3).

Conclusion: We propose a novel method to determine the presence of positive MRI-SIJ in SpA patients. We successfully segmented the iliac and sacrum bones and extracted the regions of interest. We achieved good results on the classification of inflammation for each joint region. While the results are still not on a par with the performance of a radiologist, we are optimistic that future work bill be able to reach it.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatments for ankylosing spondylitis (AS) have been shown to improve patient-reported outcome (PRO) measures in clinical studies; however, healthcare decision makers have limited ability to translate these improvements to healthcare resource utilization (HCRU) or cost savings. Few studies have assessed the economic impact of functional status and patient-reported disease burden in US patients with AS. The purpose of this study was to evaluate the association of PRO measures with HCRU and medical costs in patients with AS from a national US registry.

Methods: FORWARD is a longitudinal observational databank for rheumatic diseases that collects patient-reported data through questionnaires administered every 6 months. Data collected include demographics, clinical characteristics, symptoms, health and functional status, health-related quality of life, and HCRU. This cohort study included adult participants with a diagnosis of AS enrolled in FORWARD between July 2009 and June 2019 who completed ≥ 1 questionnaire between January 2010 and December 2019 and had completed the Health Assessment Questionnaire Disability Index (HAQ-DI) and/or Bath Ankylosing Spondylitis Disease Activity Index (BASDAI; added in 2018). Patient demographics, clinical characteristics, and PRO data were collected from the most recent questionnaire. HCRU and medical costs (USD 2019) for all hospitalizations, emergency department (ED) visits, outpatient visits, diagnostic tests, and procedures were assessed for the 6 months prior to survey completion. The relationships between HAQ-DI or BASDAI and HCRU and cost outcomes were assessed using negative binomial regression models for HCRU outcomes and generalized linear models with gamma distribution and log-link function for cost outcomes adjusted for confounders.

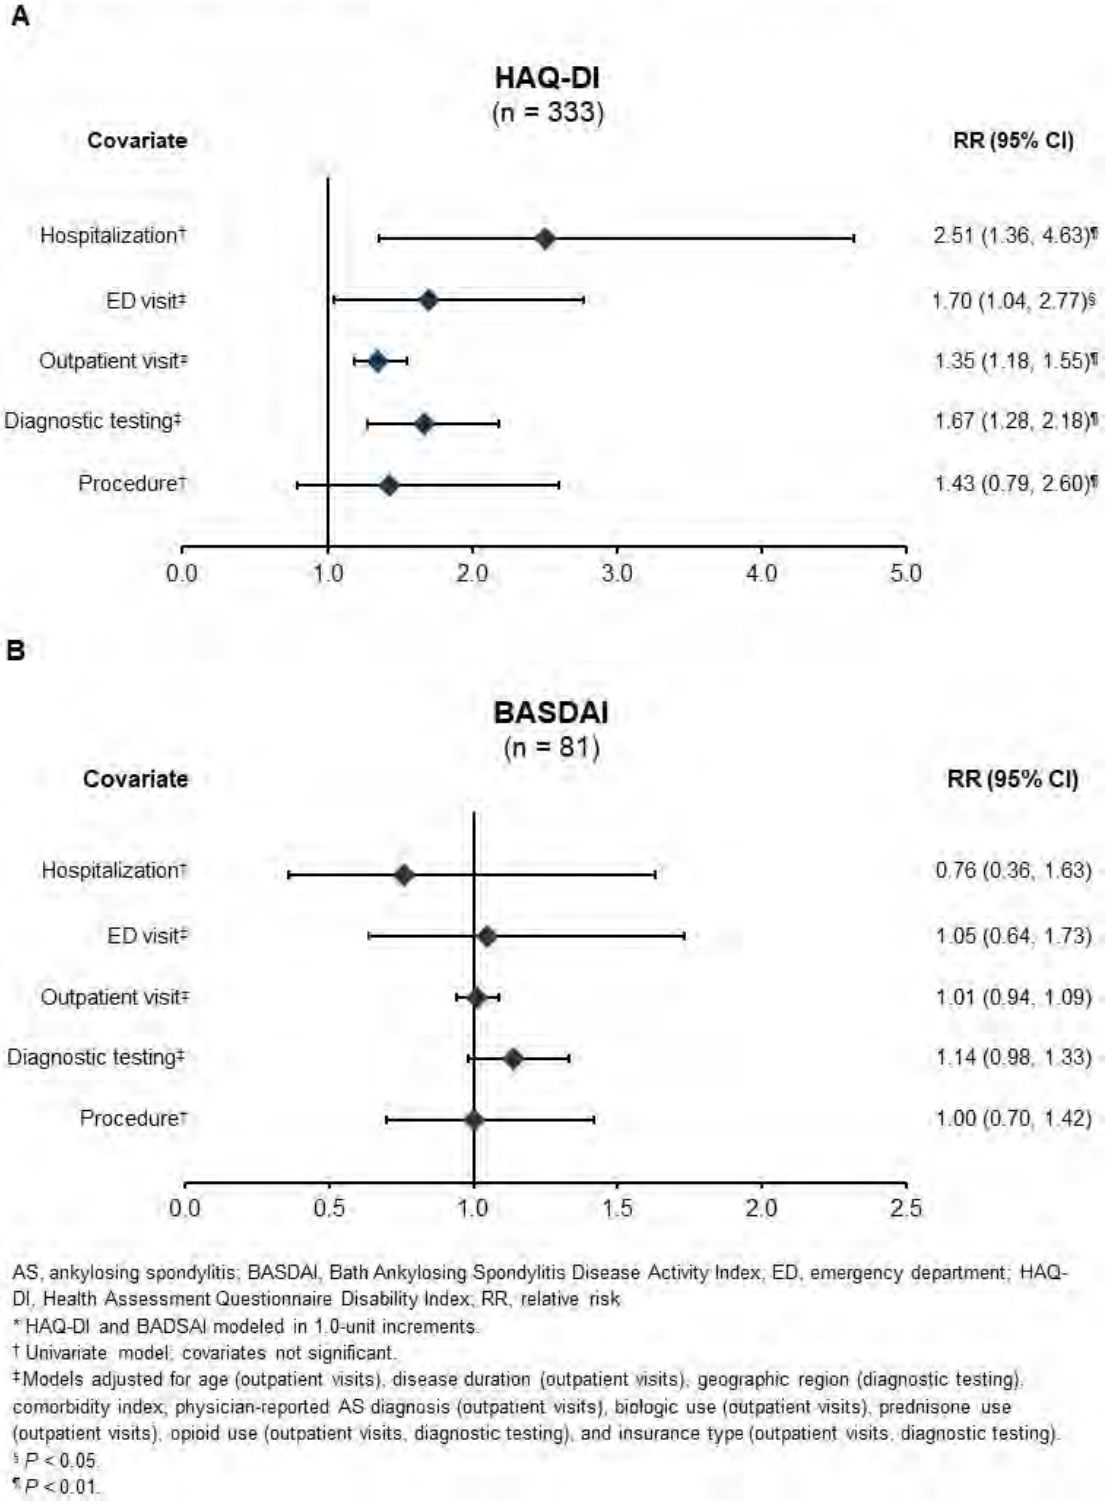
Table 1. Demographics, Clinical Characteristics, and Disease Activity Measures in Patients With AS Who Responded to HAQ-DI and/or BASDAI

Characteristic	Patients With AS (n = 334)
Age, mean (SD), years	54.4 (14.3)
Female, n (%)	206 (61.7)
White, n (%)	282 (94.6)
Insurance status, n (%)	n = 334
Private	114 (34.1)
Medicare	135 (40.4)
Medicaid	30 (9.0)
Other	43 (12.9)
None	12 (3.6)
Geographic location, n (%)	n = 323
Urban	229 (70.9)
Rural	94 (29.1)
Rheumatic disease comorbidity index, n (%)	n = 334
0	54 (16.2)
1	93 (27.8)
2	62 (18.6)
≥ 3	125 (37.4)
Disease duration, mean (SD), years [n]	17.5 (12.4) [303]
AS treatment history (current and past use), n (%) [n]	
DMARDs	114 (35.5) [321]
Biologics	141 (43.9) [321]
Prednisone	33 (11.3) [291]
NSAIDs	160 (49.8) [321]
Opioids	101 (30.2) [334]
AS disease activity, mean (SD) [n]	
HAQ-DI	0.9 (0.7) [333]
PROMIS-29 categories	
Physical function	42.6 (9.2) [169]
Anxiety	51.2 (14.3) [13]
Depression	50.8 (12.9) [13]
Fatigue	54.4 (11.5) [158]
Pain interference	57.8 (9.7) [94]
Sleep disturbance	52.4 (8.6) [158]
Satisfaction with social roles	48.5 (10.0) [158]
BASDAI	3.7 (2.3) [81]
Current work status, n (%)	n = 325
Unemployed	15 (4.6)
Employed	140 (43.1)
Retired	76 (23.4)
Disabled	69 (21.2)
Other	25 (7.7)
% Missed work time, mean (SD) [n]	14.7 (72.4) [132]

AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; DMARD, disease-modifying antirheumatic drug; HAQ-DI, Health Assessment Questionnaire Disability Index; NSAID, nonsteroidal anti-inflammatory drug; PROMIS-29, Patient-Reported Outcomes Measurement Information System 29-item form.

Results: A total of 334 patients with AS who completed the HAQ-DI and/or BASDAI questionnaires were included. The mean (SD) age and disease duration were 54.4 (14.3) and 17.5 (12.4) years, respectively. Overall, 61.7% of patients were female and 94.6% were white. The mean (SD) HAQ-DI and BASDAI at time of patients' most recent survey were 0.9 (0.7) and 3.7 (2.3), respectively (**Table 1**). HAQ-DI was positively associated with number of hospitalizations,

Figure 1. Association of Annualized Healthcare Resource Utilization With **(A)** HAQ-DI and **(B)** BASDAI Among Patients With AS Who Responded to HAQ-DI and/or BASDAI Questionnaires*



AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; ED, emergency department; HAQ-DI, Health Assessment Questionnaire Disability Index; RR, relative risk.

†Univariate model; covariates not significant.

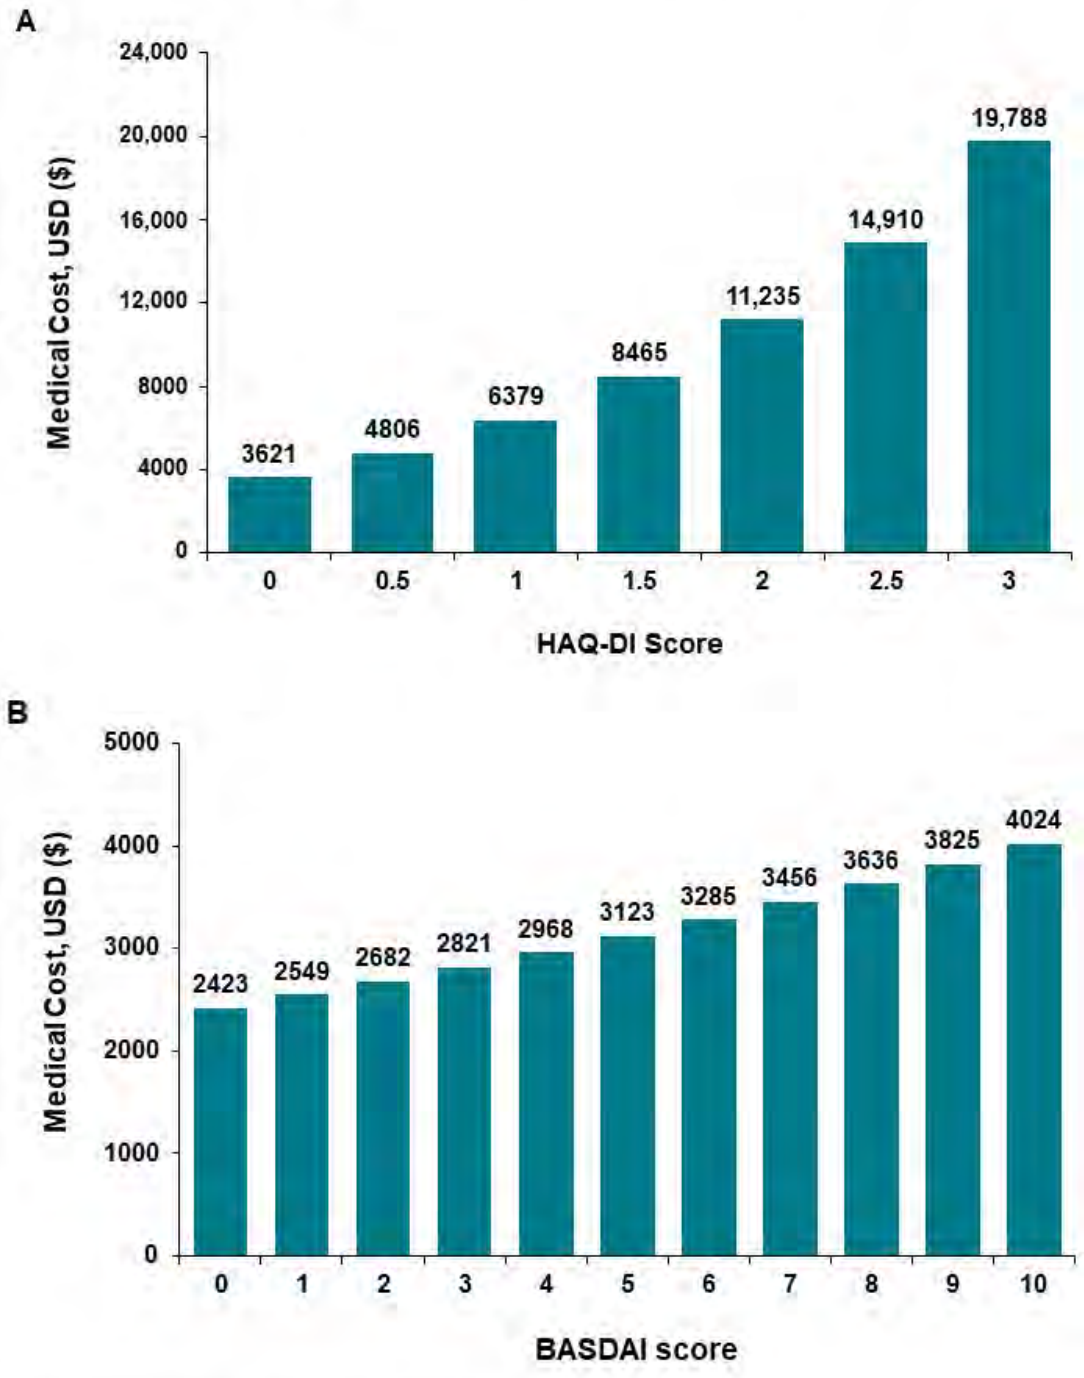
‡Models adjusted for age (outpatient visits), disease duration (outpatient visits), geographic region (diagnostic testing), comorbidity index, physician-reported AS diagnosis (outpatient visits), biologic use (outpatient visits), prednisone use (outpatient visits), opioid use (outpatient visits, diagnostic testing), and insurance type (outpatient visits, diagnostic testing).

§ $P < 0.05$.

¶ $P < 0.01$.

ED visits, outpatient visits, diagnostic tests, and procedures, whereas BASDAI was not associated with HCRU outcomes (**Figure 1**). Overall mean (SD) direct medical costs for patients with AS were $6520.50 ($12,732.90). There was a significant positive association (coefficient [95% CI]) between medical costs and HAQ-DI (1.76 [1.22-2.55]; *P*

Figure 2. Average Annualized Patient Medical Costs Across **(A)** HAQ-DI and **(B)** BASDAI Scores Among Patients With AS*



AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; HAQ-DI, Health Assessment Questionnaire Disability Index.
* Adjusted for geographic region, rheumatic disease comorbidity index, and opioid use.

< 0.01), but not with BASDAI (1.05 [0.91-1.22]). Adjusted average medical costs increased with increasing HAQ-DI and BASDAI scores (**Figure 2**).

Conclusion: Higher HAQ-DI scores were associated with greater HCRU and higher medical costs among patients with AS included in FORWARD, but BASDAI scores were not. These findings indicate that greater functional impair-

ment may impose an increased economic burden compared with other patient-reported aspects of AS throughout the course of the disease. Therapies that effectively improve functional impairment may reduce costs for patients and the healthcare system.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: In radiographic axial spondyloarthritis (r-axSpA), spinal damage manifests as syndesmophytes and facet joint ankylosis (FJA). Whether there is an order in which lesion develops first is unknown.

Methods: Data were used from the Sensitive Imaging in Ankylosing Spondylitis (SIAS) cohort from Leiden and Herne. Inclusion criteria were: clinical r-axSpA diagnosis, ≥1 inflammatory lesion on spinal Magnetic Resonance Imaging (MRI), ≥1 and ≤18 syndesmophytes on conventional radiography of lateral cervical and lumbar spine, and fulfillment of the modified New York criteria. Patients underwent low-dose Computed Tomography (ldCT) at baseline and two-years. LdCT images were scored independently by two trained readers. Vertebrae were scored according to the Computed Tomography Syndesmophyte Score (CTSS) for presence and size of syndesmophytes; facet joints were scored as not-ankylosed and ankylosed. Analyses were performed on the vertebral unit (VU) level and using individual-reader data (Figure). Two hypotheses were tested: 1) presence of bridging syndesmophyte(s) is associated with FJA on the same VU two years later, and 2) presence of FJA is associated with syndesmophyte(s) on the same VU two years later. Generalized Estimating Equations (GEE) models were used to take into account the correlations between VUs from the same patient and adjusting for reader to account for individual reader scores. Two models were tested per hypothesis using different outcomes. Model 1 uses the presence of syndesmophytes or FJA as outcome adjusting for the outcome at baseline. Model 2 uses development of new syndesmophytes or FJA at two years plus an increase in the number of syndesmophytes or FJA.

VU	Segment	≥1 bridging synd at BL reader 1	≥1 bridging synd at BL reader 2	≥1 FJA at BL reader 1	≥1 FJA at BL reader 2
1	Cervical	22%	26%	12%	35%
2		28%	28%	14%	21%
3		26%	30%	23%	20%
4		32%	33%	28%	27%
5		22%	27%	27%	27%
6		26%	21%	32%	30%
7	Thoracic	26%	28%	29%	25%
8		32%	36%	22%	27%
9		50%	48%	26%	31%
10		56%	56%	24%	36%
11		46%	54%	22%	36%
12		48%	46%	24%	26%
13		56%	54%	28%	26%
14		52%	54%	22%	28%
15		52%	56%	22%	32%
16		58%	60%	24%	34%
17		54%	52%	26%	28%
18		47%	47%	27%	33%
19	Lumbar	24%	27%	14%	20%
20		27%	22%	10%	20%
21		20%	20%	10%	12%
22		18%	20%	8%	18%

Figure. Percentage of occurrence of syndesmophytes and facet joint ankylosis per vertebral unit and per reader at baseline. Figure displaying percentages of patients with a bridging syndesmophyte and with facet joint ankylosis at baseline, per reader. The image on the left illustrates the vertebral unit level (VU) at which analyses were performed. Seven VUs are illustrated in dashed boxes as example. Synd, syndesmophyte; FJA, facet joint ankylosis; BL, baseline.

	Model 1: development of new FJA/syndesmophytes at FU OR (95% CI)	**Model 2**: development and/or increase FJA/syndesmophytes at FU OR (95% CI)
Hypothesis 1 Presence bridging syndesmophytes at BL on development of FJA at FU	**3.35 (2.18-5.14)**	**2.23 (1.19-4.16)**
Hypothesis 2 Presence FJA at BL on development of syndesmophytes at FU	1.60 (0.88-2.91)	1.12 (0.76-1.66)

Table: Results of the GEE analyses of the two hypotheses Model 1 was adjusted for the outcome at baseline and both models were adjusted for the reader level, not shown in the table. Statistically significant odds ratios are presented in bold. FJA, facet joint ankylosis; BL, baseline; FU, follow-up

Results: In total, 50 patients were included (mean age 49, 84% male, 82% HLA-B27+). At baseline, there was a higher percentage of bridging syndesmophytes (range: 10-60%) than FJA (range: 8-36%) considering all VUs and both readers (Figure). In both models, presence of bridging syndesmophytes was associated with development of FJA two years later (OR (95%CI) Model 1: 3.35 (2.18-5.14); Model 2: 2.23 (1.19-4.16)) while presence of FJA at baseline did not have a statistically significant association with development of syndesmophytes two years later (Table).

Conclusion: The data showed a higher occurrence of bridging syndesmophytes than FJA at baseline and showed significantly increased odds to develop FJA when bridging syndesmophyte(s) are present on the same VU two years

prior. This mechanism did not hold true for the other direction. These results cautiously imply that in our study population with advanced r-axSpA bridging syndesmophytes precede FJA, rather than FJA preceding syndesmophytes.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Complete ankylosis of the entire spinal column is a severe condition seen in spondyloarthritis. This study aims to investigate the possible risk factors associated with the bamboo spine in axial Spondyloarthritis (axSpA) patients treated with biological DMARDs.

Methods: *TReasure*; is a multicentre database, started in December 2017, in which clinical and demographic data of inflammatory arthritis patients using biological and synthetic DMARDs are recorded (1). This database contains 4911 SpA patients using bDMARD therapy. axSpA patients fulfilling the ASAS classification criteria (Sacroiliitis defined either according to the mNY- or ASAS positive MRI criteria) were analyzed. Patients with complete cervical and lumbar x-rays were divided into three groups. Group-1 consists of patients with a bamboo spine, Group-2 consists of patients with bridging (advanced radiographic involvement) bridging of two vertebrae in a row, Group-3 consists of patients with syndesmophytes in at least one vertebra, and Group-4 consists of patients with no syndesmophytes. The demographic and clinical features of these patients were recorded. One hundred and ten patients were selected as a matched control group based on the disease duration of patients with a bamboo spine.

Results: Out of the 4911 patients in the TReasure database, sacroiliac joint MRI and/or cervical and lumbar lateral radiographs were available for 1381 patients. AS (1071, 77.6%), psoriatic arthritis (102, 7.4%), non-radiographic (144, 10.4%), peripheral SpA (128, 9.3%), enteropathic arthritis (39, 2.8%) in 1381 patient. The bamboo spine was seen in 111 (8.0%), bridging of two vertebrae in a row in 125 (9.0%), syndesmophytes in at least one vertebra in 329 (23.8%), and 816 (59.2%) had no syndesmophytes.

The comparison between the patients with a bamboo spine to those with no syndesmophytes revealed that; male gender (85.6% vs 61.8%, $p < 0.001$), age (51 (45-61) vs 43 (36-50), $p < 0.001$), BMI (27.9 (25.9-31.2) vs 25.9 (22.9-29.3) , $p < 0.001$), smoking as package/year (12.2 (1-30) vs 3 (0-11), $p < 0.001$), delay in diagnosis of SpA (61 (19-134) vs 12 (5-47), $p < 0.001$), hip involvement (53.7% vs 17.8%, $p < 0.001$), family history of SpA (40.8% vs 24.8%, $p = 0.014$), and uveitis (25.6% vs 13.6%, $p = 0.030$) were associated with bamboo spine.

Bamboo spine was less common in patients with peripheral arthritis (9.6% vs 21.3%, $p = 0.019$) and psoriasis (4.5% vs 12.7% , $p = 0.031$).

Disease activity (BASDAI) and functional status (BASFI) of both patient groups were similar before bDMARD treatment.

Table 1. Demographic and clinical parameters of study patients

	Group-1 N=111	Group-2 N=125	Group-3 N=329	Group-4 N=110
Age (Q1-Q3)	52 (45-61)	49 (43-57)	47 (41-55)	43 (36-50)
Male n (%)	95 (85.6)	103 (82.4)	216 (65.7)	68 (61.8)
Disease duration (month)	217 (124-290)	143 (83-229)	131 (81-180)	185 (119-241)
Delay in diagnosis (month)	61 (19-134)	49 (24-119)	37 (5-110)	12 (5-47)
BMI	27.9 (25.9-31.2)	27.6 (24.7-31.2)	27.3 (24.4-30.1)	25.9 (22.9-29.3)
Smoking (ever)	81/105	103/119	201/320	66/106
BASFI	5.5 (3.0-7.7)	4.4 (3.4-6.0)	4.3 (2.7-6.2)	5.0 (4.0-6.2)
Peripheral arthritis	10 (9.6)	5 (4.0)	45 (14.0)	108 (21.3)
Enthesitis	25 (29.1)	26 (28.6)	57 (26.4)	10 (16.7)
Psoriasis	5 (4.5)	6 (4.8)	37 (11.3)	14 (12.7)
Uveitis	28 (25.2)	29 (23.2)	60 (18.2)	15 (13.6)
IBH	3 (2.8)	6 (4.8)	14 (4.3)	7 (6.4)
Family history of SpA	42 (40.8)	41 (36.9)	103 (33.8)	26 (24.8)
HLA-B27	40/57 (70.2)	55/74 (74.3)	123/204 (60.3)	36/61 (63.9)
Hip involvement	58 (53.7)	51 (42.9)	66 (21.4)	19 (17.8)
MTX* (ever)	37 (33.3)	29 (23.2)	106 (32.2)	40 (36.4)
SSZ** (ever)	79 (71.2)	88 (70.4)	235 (71.4)	71 (64.5)

* MTX: Methotrexate

** SSZ: Sulfasalazine

In multivariate analysis, male gender OR 9.3 (95% CI 3.2-26.9), hip involvement OR 4.2 (1.8-9.5), family history for SpA OR 2.9 (1.3-6.6), delay in diagnosis 1.013 (1.005-1.021), age 1.11 (1.06 -1.116) as a risk factor.

Conclusion: Male gender, delay in diagnosis, family history of SpA, and hip involvement is the most important risk factors associated with a bamboo spine in axSpA patients, after a disease duration of more than 15 years. Interestingly, the presence of peripheral arthritis and psoriasis were protective.

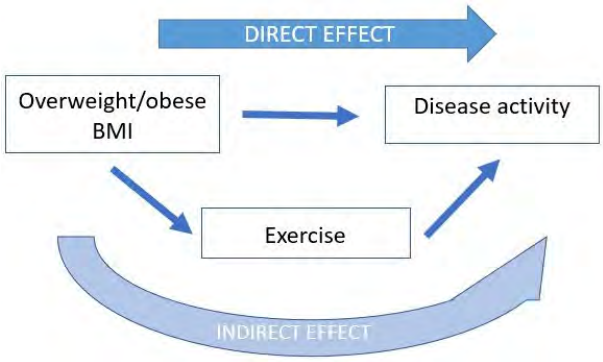
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) patients have elevated cardiovascular (CV) morbidity and mortality compared to general population comparators of the same age and sex. Although obesity is an important and modifiable CV risk factor, there are few prospective studies addressing the impact of higher body mass index (BMI) on clinical outcomes in AS. The aim of this study is to assess the relationship of BMI with disease activity in AS patients, and the extent to which the effect is mediated through exercise.

Methods: Data were available for 283 adults with AS meeting the 1984 modified New York criteria from a prospective cohort, who were followed at a single site at visits every 6 months with a median follow-up of 7 years. BMI (kg/m^2) and disease activity as measured by the Ankylosing Spondylitis Disease Activity Score (ASDAS) represented the exposure and outcome, respectively. In the main analysis, we included 183 subjects who had at least one available BMI and



Directed acyclic graph demonstrating the direct effect of an overweight/obese BMI on disease activity, and the indirect effect of overweight/obese BMI on disease activity through exercise.

one available ASDAS measure during any study visit; missing values were imputed using multiple imputation with chained equations. To determine the association of BMI and disease activity, we used generalized estimating equations to account for repeated measures per subject. We adjusted for age, sex, race, current smoking, nonsteroidal anti-inflammatory drug (NSAID) use, tumor necrosis factor inhibitor (TNFi) use, and follow-up time, and for interactions between BMI and sex and BMI and time. We then performed a causal mediation analysis to estimate the direct effect of BMI on disease activity, and the indirect effect through exercise.

Results: Among 183 subjects, 77% were male, 70% were white, and the mean±standard deviation age was 40.8±13.3 years. In adjusted analyses, higher BMI was significantly associated with higher disease activity over time; on average, for a 1 kg/m^2 higher BMI, the ASDAS was 0.06 units higher (95% CI 0.02-0.09). This association did not differ by sex (p=0.89) but did differ over time (p=0.03). The direct effect of an overweight/obese BMI accounted for most of the total effect on disease activity, with a much smaller indirect effect mediated by exercise (9%).

Conclusion: Higher BMI was associated with higher disease activity in a prospective AS cohort. We found that being overweight/obese largely influences disease activity directly, rather than indirectly through exercise. This suggests that other mechanisms such as increased inflammation may better explain the obesity-disease activity association. Interventions targeting obesity may improve both disease activity and CV risk in this population.

Abbreviations: AS, ankylosing spondylitis; CRP, C-reactive protein; NSAID, nonsteroidal anti-inflammatory drug; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index.

Continuous variables are reported as mean (SD) and categorical variables as n (%).

Data were missing for 43 respondents for BASDAI.

Biologic use includes infliximab, etanercept, adalimumab, golimumab, certolizumab pegol, secukinumab, and ixekizumab. Cardiovascular disease is defined as history of myocardial infarction, stroke, or cardiovascular revascularization in the electronic medical record. Other cardiac disease includes heart failure, valvulopathy, arrhythmia, and angina. Cancer includes all but non-melanoma skin cancers. Hypertension, diabetes, depression, and anxiety are defined by the presence of either problem listed in the problem list, and/or medication use in the electronic medical record.

Table 1. Baseline characteristics for survey respondents (n=203) stratified by Perceived Stress Scale score

Background/Purpose: Response to the global coronavirus disease (COVID-19) pandemic has resulted in shelter-in-place orders and major changes to how people go about their daily lives. The impact of such stressors on disease activity in individuals with axial spondyloarthritis (axSpA) is unclear. The primary aim of this study is to examine whether stress and anxiety are associated with disease activity, after accounting for important factors.

Methods: We administered a survey to an axSpA cohort from a single center with well-defined demographic and disease characteristics. The survey included questions about changes in job status, exercise, medication use, disease activity (by the Bath Ankylosing Spondylitis Disease Activity Index [BASDAI]), and psychological factors (stress, depressive symptoms, and anxiety). Two separate multivariable linear models examined the associations between perceived stress with BASDAI, and anxiety with BASDAI.

Results: After adjustment for potential confounders, those with higher levels of stress had a statistically significant 0.54-point higher BASDAI, on average, compared to those with lower levels of stress (95% confidence interval [CI] 0.11, 0.97). Those with higher levels of anxiety also had a statistically significant higher BASDAI, on average, compared to those with lower levels of anxiety (β 0.95, 95% CI 0.18, 0.99). We did not find differences in these associations among subgroups of age, job status, or county of residence.

Conclusion: Individuals with axSpA with higher levels of stress and anxiety had significantly higher disease activity levels. Further studies are needed to evaluate the trajectory of disease activity as the pandemic continues to evolve.

Performance of SASDAS (Simplified Axial Spondyloarthritis Disease Activity Score) versus ASDAS in a Post Hoc Analysis of a Randomized Controlled Clinical Trial

Emilce Schneeberger[1], Gustavo Citera[2], Dario Ponce de Leon[3], Annette Szumski[4], Kenneth Kwok[5], Mariel Cutri[6] and Maxime Dougados[7], [1]Department of Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [3]PFIZER, LIMA, Peru, [4]Syneos Health, Princeton, [5]Pfizer, New York, NY, [6]Pfizer, Buenos Aires, Argentina, [7]Department of Rheumatology, Hopital Cochin, Université de Paris, Paris, France

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The Ankylosing Spondylitis Disease Activity Score (ASDAS) assesses axial spondyloarthritis (axSpA) with good internal consistency and discriminative capacity. However, a scientific calculator or electronic application is required for its calculation. SASDAS (simplified ASDAS) is the sum of the ASDAS´s components, which includes C-reactive protein (CRP), and is easy to perform in daily practice. The objective of this analysis was to compare the SASDAS index against the standard ASDAS index (CRP version) at baseline and post-baseline in a randomized controlled trial (EMBARK).

Methods: EMBARK assessed etanercept (ETN) 50 mg/week in early active NSAID-refractory non-radiographic axSpA patients receiving background NSAID. Subjects received ETN or placebo (PBO) for 12 weeks (double-blind) followed by ETN only (open-label). Continuous ASDAS and SASDAS were evaluated by Spearman's Correlations, and agreement in ASDAS vs SASDAS disease categories (minimal, low, high, very high disease activity) by Cohen's weighted kappa for individual and pooled treatments. The capacity to discriminate between treatments was evalu-

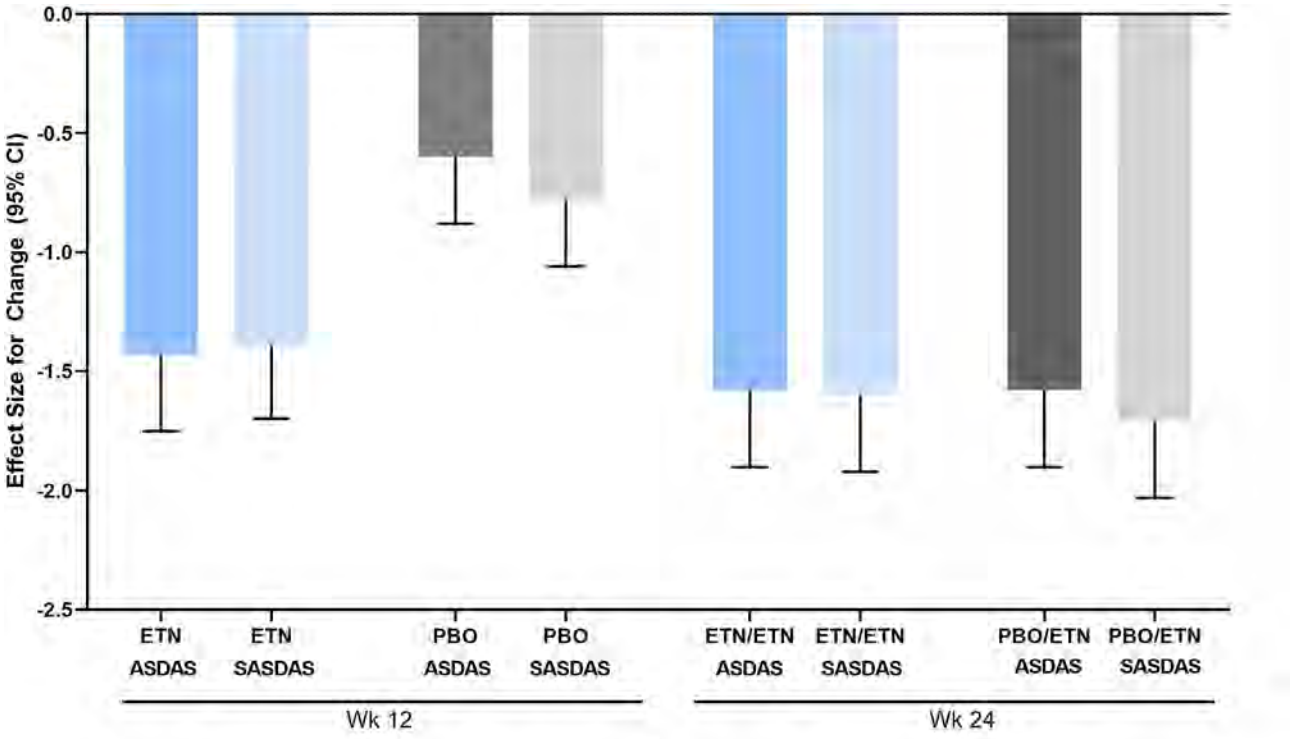

Figure 1: Responsiveness to change between ASDAS and SASDAS by treatment and time point

Table 1: ASDAS by SASDAS Categories at Baseline (mITT and observed cases; pooled treatments)

		SASDAS				
	Disease categories	Inactive	Moderate	High	Very high	Cohen's weighted kappa*
ASDAS	Inactive	2/213 (0.9%)	0/213 (0.0%)	0/213 (0.0%)	0/213 (0.0%)	0.58 (0.49, 0.67)
	Moderate	**3/213 (1.4%)**	13/213 (6.1%)	**20/213 (9.4%)**	0/213 (0.0%)	
	High	0/213 (0.0%)	**4/213 (1.9%)**	83/213 (39.0)	**18/213 (8.5%)**	
	Very high	0/213 (0.0%)	0/213 (0.0%)	**19/213 (8.9%)**	51/213 (23.9%)	

* Cohen's weighted kappa (95% CI)
CI, confidence interval

ated by treatment effect size (ES) for ETN vs PBO at Week 12, and the sensitivity to change from baseline at Weeks 12 and 24 by ES for change.

Results: Of 215 patients in the modified intention-to-treat (mITT) population (ETN, n=106; PBO, n=109), 208 entered the open-label phase (ETN/ETN, n=102; PBO/ETN, n=106). The mean age was 32 years, 64% (ETN) and 58% (PBO) were male, and average disease duration was 2.4 (ETN) and 2.5 years (PBO). There was a strong correlation between

continuous ASDAS and SASDAS. At baseline, Spearman's correlation was 0.82 (ETN) and 0.87 (PBO); at Weeks 12 and 24 it was 0.89 (ETN), 0.90 (PBO), and 0.88 (both treatments), respectively. The evaluation of categorical SASDAS placed more patients in high or very high disease activity compared with categorical ASDAS; for example, at baseline, in the whole population, 38/213 patients (17.8%) with moderate and high disease activity by ASDAS were categorized with higher disease activity by SASDAS (20/213 moderate, 18/213 high), and 26/213 patients (12.2%) categorized with lower disease activity (3/213 moderate, 4/213 high, 19/213 very high) (Table 1). A similar pattern was seen post-baseline. Cohen's weighted kappa statistics range from 0.54 – 0.73 for all individual/pooled treatments and time points, reflecting moderate-to-substantial agreement. The discriminant capacity evaluated by the treatment ES was higher with ASDAS compared with SASDAS (ES [95% CI], ASDAS: -0.74 [-1.03,-0.46]; SASDAS: -0.51 (-0.79, -0.23), but the sensitivity to change was similar (Figure 1).

Conclusion: Despite the simplicity of SASDAS, these data suggest a moderate-to-substantial agreement with ASDAS for classifying patients with active disease and a lower treatment discriminant capacity. Further evaluation of this composite index is required before implementation in daily practice and/or clinical trials.

Measuring Physical Activity in AxSpA:Content Validity and Measurement Properties of the New AxSpA-SQUASH

Marllies Carbo[1], Davy Paap[2], Fiona Maas[1], Mark Siderius[3], Hendrika Bootsma[1], Freke Wink[3], Suzanne Arends[3] and Anneke Spoorenberg[3], [1]University Medical Centre Groningen, Groningen, Netherlands, [2], Department of Rehabilitation Medicine, University of Medical Centre Groningen, Groningen, Netherlands, [3]University Medical Centre Groningen and Medical centre Leeuwarden, Groningen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The ASAS-EULAR recommendations for management of axial Spondyloarthritis (axSpA) includes that patients should be encouraged to exercise. There is no validated instrument for measuring physical activity in axSpA. Our previous study recommends to adapt the Short QUestionnaire to Assess Health-enhancing physical activity (SQUASH) to improve the validity in axSpA patients. Our goal was to mak an AxSpA-disease specific adaptation of the physical activity questionnaire SQUASH to improve content validity and measurement properties.

Methods: This study was conducted according to the OMERACT-filter within the Groningen Leeuwarden AxSpA (GLAS) cohort and was performed in two parts. Part 1: adaptation and evaluation of content validity using a qualitative stepwise approach with in-depth interviews with different healthcare professionals (n=9) and patients (n=8), field testing in patients (n=10), and consensus meeting for final adaptations. Thereafter, content validity (n=45) was tested by filling out axSpA-SQUASH and SQUASH in random order two weeks apart. Part 2: measurement properties were tested using the International Physical Activity Questionnaire (IPAQ) as comparator. Criterion validity (n=40): Spear-

	SRM	95% CI	BASDAI T1	BASDAI T2
Improved (n=12)	-0.36	-0.99 to 0.28	5.01 (2.10)	3.93 (1.60)
Stable (n=21)	0.28	-0.18 to 0.73	3.76 (2.05)	3.76 (2.05)
Decreased (n=14)	0.75	0.18 to 1.33	4.71 (1.96)	5.79 (2.42)

Table 1. Responsiveness of the axSpA-SQUASH versus change in BASDAI

man's correlation with accelerometer as golden standard and classification accuracy of intensity. Construct validity (n=106): Spearman's correlation with disease activity, physical functioning and quality of life as clinical outcome with expected fair to moderated associations. Test-retest reliability (n=45): intraclass correlation coefficients (ICC) after 2 weeks. Responsiveness (n=47): standardized response mean (SRM) after 3 months stratified by Ancor method.

Results: In total 156 patients were included: mean age 48±13 years, 56% males, 72% HLA-B27 positive, symptom duration 21±13.3 years and ASDAS 2.0±1.0. Part 1: main adaptations were better explanation of intensities, adding answer option "not applicable", examples were modernized, physiotherapy and activity "shopping" were added. Compared to the original SQUASH, the adapted axSpA-SQUASH measured a systematically higher activity count and had less missing values (8% vs. 32%). Part 2: criterion validity: axSpA-SQUASH correlated better with accelerometer compared to IPAQ (ρ=0.51 vs. ρ=0.35). Classification accuracy: accelerometer defined most activity as light (97%), whereas axSpA-SQUASH and IPAQ defined most activity as moderate intensity (55% and 62% resp.). Construct validity: correlations were low to moderate and strongest for axSpA-SQUASH compared to IPAQ. Construct validity: correlations were low to moderate and stronger for axSpA-SQUASH compared to IPAQ (BASDAI -0.27 vs -0.15, BASDAI –0.27 vs. -0.15, ASDAS -0.24 vs -0.09, BASFI -0.39vs. -0.21, ASQoL -0.39 vs. -0.35). Test-retest reliability: ICC axSpA-SQUASH: 0.80. Responsiveness: axSpA-SQUASH changed over time in the corresponding direction (Table 1). Feasibility: considered comprehensible and average completion time was 7 minutes.

Conclusion: The new axSpA-SQUASH resulted in improved content validity and measurement properties. It seems the most appropriate questionnaire and can be used to assess daily physical activity in patients with axSpA.

Spinal Mobility and Function: How Closely Do They Associate in Axial Spondyloarthropathy?

Sinead Maguire[1], Phil Gallagher[2] and Finbar O'Shea[1], [1]St James' Hospital, Dublin, Ireland, [2]St Vincents University Hospital, UCD, Dublin, Ireland

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthropathy (axSpA) is a form of inflammatory arthritis affecting the axial skeleton. Persistent disease activity can result in restricted spinal mobility over time, and is presumed to lead to functional impairment although evidence to date on this subject has been limited. The Ankylosing Spondylitis Registry of Ireland (ASRI) is a source of epidemiological data on patients with axSpA in Ireland. The aim of this study was to examine the relationship between degree of spinal mobility (as assessed by BASMI score) and effect on functional ability (as assessed by BASFI score).

Methods: IBM SPSS version 24 was used to run the analysis of the patient population registered in the ASRI to date. Patients with both BASFI and BASMI scores were included in the analysis. Both variables were assessed with a Shapiro-Wilk's test for normal distribution. Variables were also assessed for presence of a monotonic relationship by visual inspection of a scatterplot of the two variables. Once a monotonic relationship was established a Spearman's rank-order correlation between BASMI and BASFI was analyzed. Further analysis with a Pearson's partial correlation was preformed to control for gender. Records were then split by gender and a Spearman's rank-order correlation was undertaken to assess strength of correlation of scores within each gender.

Results: In total 847 patients were assessed for inclusion. Data on both BASMI and BASMI scores were available on 647 of these patients, which were included in the analysis. Variables were not normally distributed as assessed by Shapiro-Wilk's test ($p < 0.01$). Preliminary analysis showed the relationship between these measures to be monotonic (as the BASFI score increases, so too does the BASMI score), as determined by visual inspection of the scatterplot. There was a statistically significant, strong positive correlation between BASMI and BASFI scores in axSpA patients, $r_s(645) = 0.509$, $p = 0.001$(figure 1) based on calculations by Spearman's rank-order correlation. A Pearson's partial

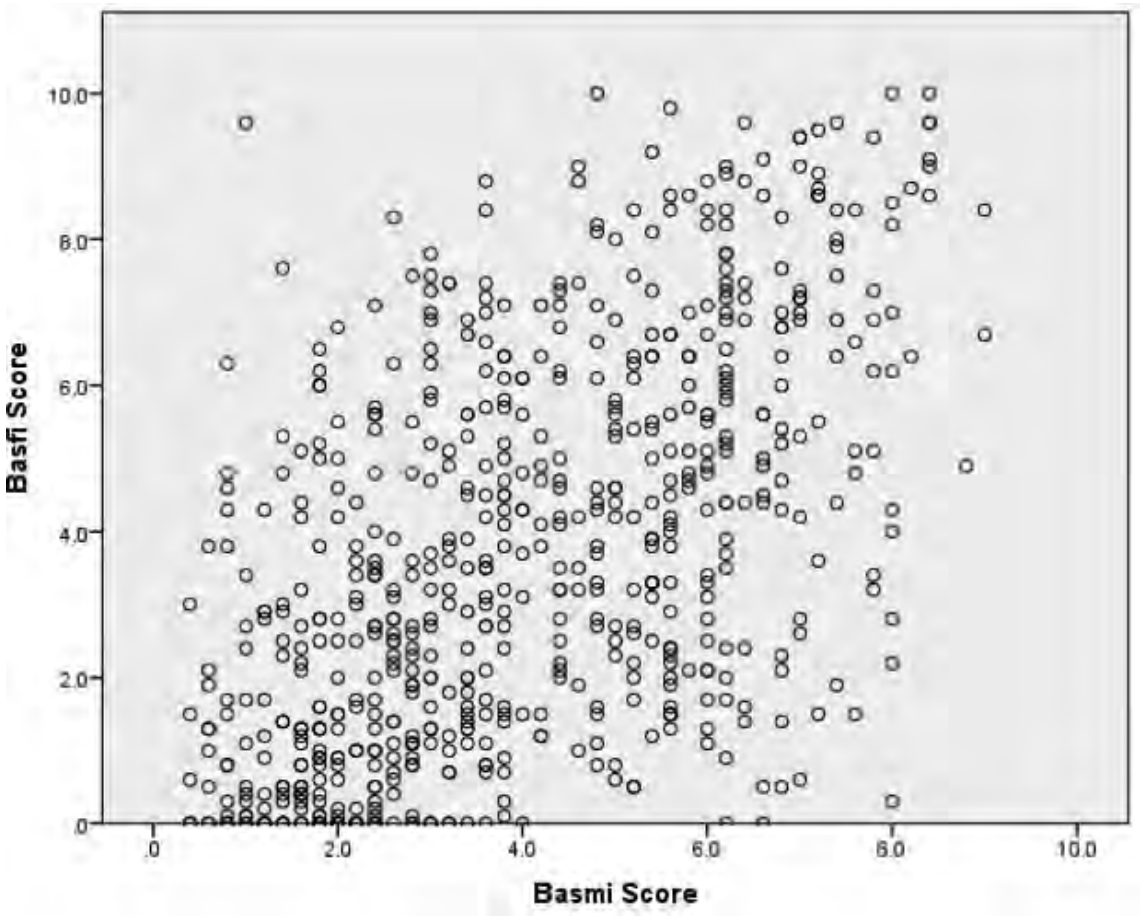

Figure 1. Correlation between BASFI and BASMI in the ASRI population

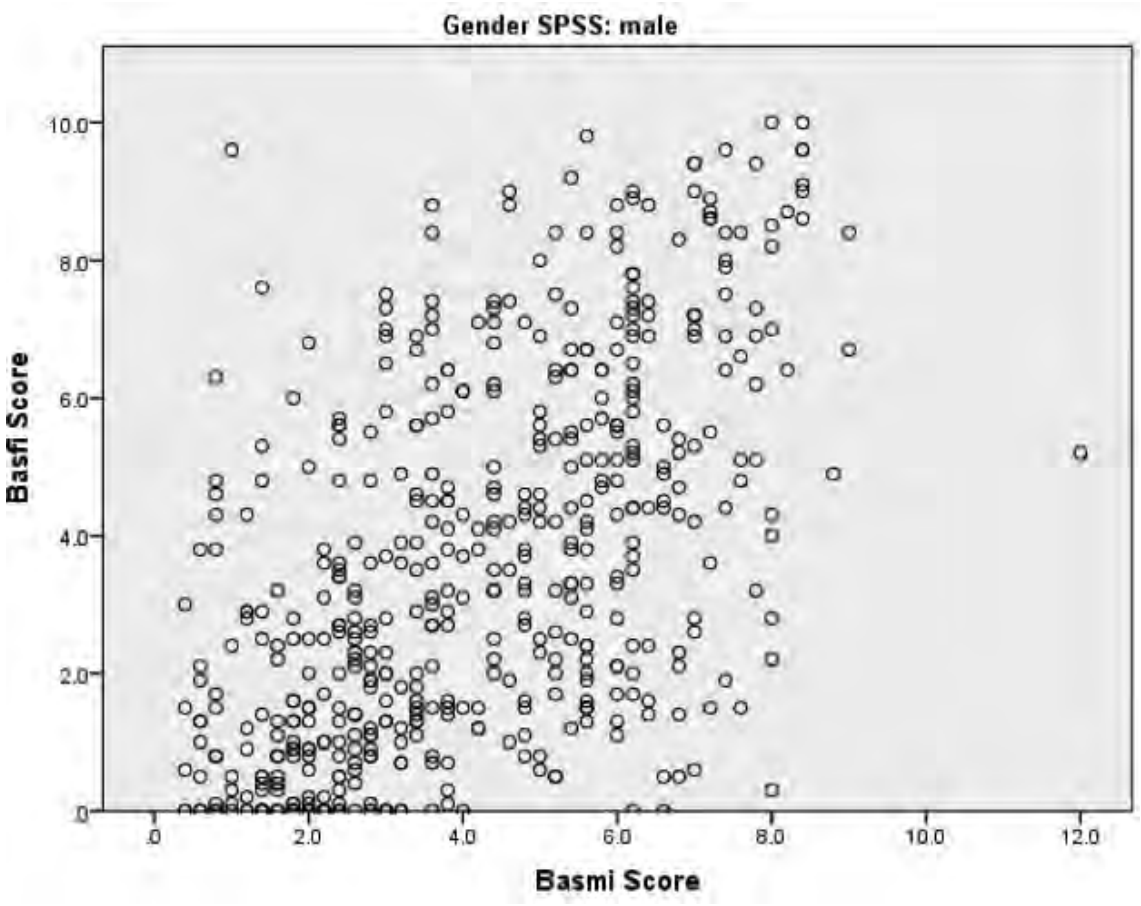

Figure 2a. Correlation between BASMI and BASFI in Males

correlation showed that the strength of this correlation was stronger when controlled for gender, rpartial(645) =0.521, and remained statistically significant p< 0.001. A Spearman's rank-order correlation analysis following splitting of records by gender showed the correlation becomes stronger if assessed within each gender (Females rs(144)= 0.577, p< 0.01; Males rs(509) =0.576, p< 0.01) and has a slightly stronger association with in females(figure 2).

Conclusion: BASFI scores have a strong positive correlation with BASMI scores in patients with axSpA. In clinical terms, patients with worse limitation of spinal mobility are likely to have greater level of functional impairment and vice versa. Analysis by gender shows this correlation is more significant if compared within each gender, and is slightly stronger in females with axSpA.

Enlarged comprehensive model incl. BASFI	0.857	0.783	0.931	80.6 (29/36)	80.5 (66/82)

Table 2. Results of ROC curves for modeling r-axSpA of covariable-adjusted models of single derived ES variables, standardized questionnaires, the comprehensive model, and the enlarged comprehensive model incl. BASFI axSpA: axial spondyloarthritis, ES: Epionics SPINE, RoM: Range of Motion, RoK: Range of Kinematics, BASDAI: Bath ankylosing spondylitis (AS) disease activity score, BASFI: Bath AS functional index, BASMI, Bath AS metrology index, BAS-G: Bath patient global score, ASDAS: AS disease activity score, AS-HI: AS health index, PCS: physical component score of SF-12, MCS: mental component score of SF-12. AUC: area under the curve; LCL: lower confidence limit; UCL: upper confidence limit

Background/Purpose: Axial spondyloarthritis (axSpA) comprising radiographic (r-) and non-radiographic (nr)-axSpA is often associated with loss of mobility and impaired physical function. Established assessments of spinal mobility based on physical examination (BASMI) were shown to have limited reliability, whereas questionnaires (BASFI) are largely based on subjective perception of physical functioning. Epionics SPINE (ES) is a novel device that uses electronic sensors to measure spinal movements including range (RoM) and speed (RoK) of motion, it has already been validated in healthy individuals and in patients with mechanic back pain. The objective of this study was to evaluate the ES device for of the assessment of spinal mobility in patients with axSpA.

Methods: Spinal mobility was assessed in 153 individuals (40 nr- and 94 r-axSpA and 19 healthy controls (HC) using ES, BASMI, BASFI and other questionnaires. Mean scores were calculated to compare groups and modeling was performed using multivariable logistic regression.

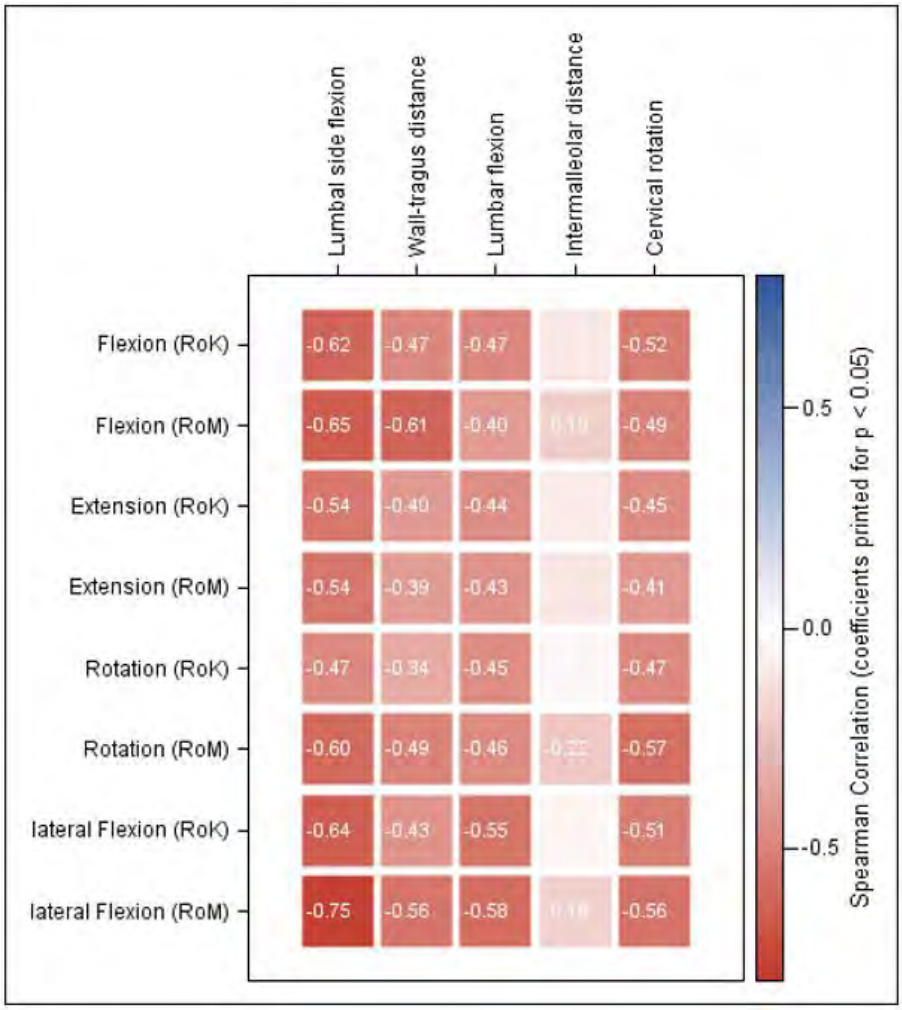

Figure 1. Heatmap of results of Spearman correlation analyses between Epionics SPINE variables and BASMI sub-scores for axSpA patients axSpA: axial spondyloarthritis, BASMI: Bath ankylosing spondylitis metrology index Correlation coefficient (r) values are only depicted in case of significance.

Results: ES scores showed meaningful differences between axSpA patients and HC (all p< 0.001) and between r- and nr-axSpA (p< 0.01) (Table 1 and 2). In axSpA patients, ES results correlated negatively with BASMI (Fig.1) and patients with r-axSpA had worse spinal mobility than those with nr-axSpA. RoK and RoM decreased significantly with age. ES scores showed only a weak negative correlation with BASFI (r >-0.39) and almost no correlation with other patient reported outcomes (BAS-G, ASAS-HI, PCS, MCS all r between -0,26 and 0,28).

Conclusion: ES measurements are a valid and objective measure to assess spinal mobility in patients with axSpA. Since rotation and time are new elements of assessment novel information is also provided. The exact measurement of spinal mobility in different planes with ES may improve our understanding of the functional status of patients with axSpA. It is likely that this will be more useful than standardized questionnaires only.

Reliability and Validity of the PROMIS-29 Health Profile in Ankylosing Spondylitis Patients

Yvette Farran[1], Alexis Ogdie[2], John Reveille[3] and Mark Hwang[4], [1]McGovern Medical School at the University of Texas Health Sciences Center, Houston, TX, [2]University of Pennsylvania, Philadelphia, PA, [3]Department of Internal Medicine, University of Texas, Houston, TX, [4]McGovern Medical School at the University of Texas Health Science Center at Houston, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The Patient Reported Outcomes Measurement Information System 29-Item Profile Measure (PROMIS-29) is a generic measure of health-related quality of life (HRQOL) that has seven health domains: Physical Function, Anxiety, Depression, Fatigue, Sleep Disturbance, Ability to Participate in Social Roles/Activities and Pain Interference. We hypothesized that the physical aspects of Ankylosing Spondylitis (AS) may have more impact on sleep disturbance than mental factors, which are more impactful in the general population.

Methods: Participants from the Prospective Study of Outcomes in Ankylosing Spondylitis (PSOAS) cohort completed the PROMIS-29 from 2017-2019(2). Test-retest reliability and internal consistency was assessed using intraclass correlation coefficients (ICC) and Cronbach's alpha, respectively, of all PROMIS-29 domains. We conducted confirmatory factor analysis (CFA) using our hypothesized model (Figure 1a) as well as the general population model as described by *Hays et al* (Figure 1b) to study structural validity. The practical fit of the models was evaluated using the chi-squared goodness-of-test ($\chi 2$), comparative fit index (CFI) and the root mean square error of approximation (RMSEA). Good model fit was defined by a $\chi 2$ p-value >0.5, CFI > 0.95 and RMSEA < 0.06. Anxiety and Depression domains were combined into an 'Emotion' domain as studied in the *Hays* model(1). Construct validity of the PROMIS-29

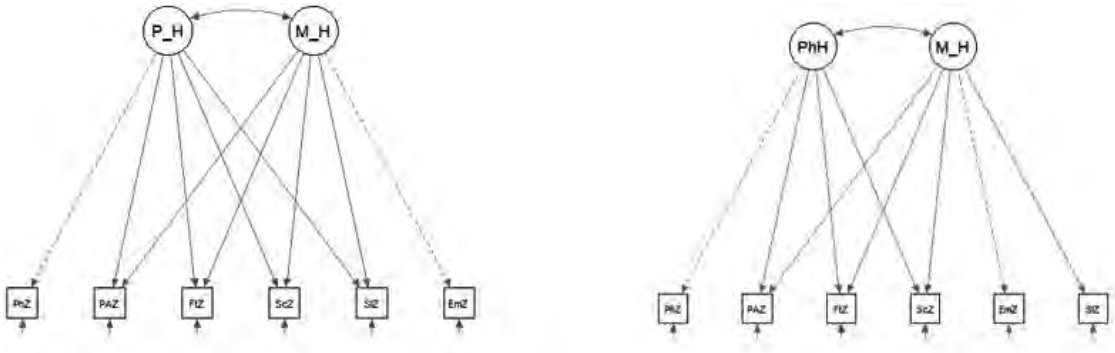

Figure 1. Schema of the Factor Structures of the PROMIS-20 v 2.0 Health Profile Literature 2-factor model of the PROMIS-29 v 2.0 Health Profile a) Hypothesized AS Model b) General Population Literature Model. The Hypothesized model has Sleep Disturbances (SlZ) related to Physical Health (P_H) and Mental Health (M_H) Factor.

Table 1. Participant characteristics (N=119)

Characteristic	N	Value (%)
Age (Mean SD; years)	119	50.85 ± 14.77
Male Gender	119	82 (69%)
Race	119	
White		96 (81%)
Other		23 (19%)
Education	119	
High School		16 (13%)
College		103 (87%)
Employment status	119	
Full time		76 (64%)
Not Working		32 (27%)
Disabled		11 (9%)
Self-Reported Depression	119	16 (13%)
AS Symptom Duration (Mean SD; years)	119	25.47 ± 13.32
ASDAS *	90	
Inactive		25 (31%)
Moderate		30 (33%)
High-Very High		35 (36%)
Biologic DMARD usage †	110	66 (56%)
Last mSASSS (Median [IQR])‡	85	4 (0-34)

* Missing = 29 due to lack of CRP labs.
† Missing = 9 due to incomplete medication list
‡ Missing = 34 due to incomplete radiographs

Table 2. Correlation of AS Legacy Measures with the 2-factor PROMIS-29 model

	Physical Health	Mental Health
BASDAI	.802**	.280**
BASFI	.767**	.311**
CRP	.282**	0.118
Pain NRS	.704**	.217*
Global NRS	.843**	.420**

**. Correlation is significant at the 0.01 level (2-tailed).
*. Correlation is significant at the 0.05 level (2-tailed).

were studied by studying Spearman's correlation coefficients of the factors with C-reactive protein and AS legacy measures: BASDAI, BASFI, Pain Numeric Rating Scale (NRS), and Global NRS.

Results: A total of 119 patients were enrolled (Table 1). All domains of the PROMIS-29 showed good test-retest reliability (ICC > 0.8) and excellent internal consistency with Cronbach's alpha ranging from 0.91(Physical Function) to 0.98(Sleep). In CFA of the hypothesized 2-factor model, we found a $\chi 2$ goodness-of-fit p-value of 0.081, a CFI of 0.988 and RMSEA of 0.095. In the general population, we found a similar $\chi 2$ goodness of fit (p-value of 0.081) and CFI (0.988), and a RMSEA of 0.090. In both CFAs, a 2-factor model was found with the physical function domain and emotional domain, respectively, having the highest loadings on Factor 1 and Factor 2. We thus named Factor 1 'Physical Health' Factor and Factor 2 'Mental Health' Factor in both analyses. Using Spearman's correlation coefficient, all AS legacy measures showed strong correlation, rho >0.7, with the 'Physical Health' factor (Table 2). C-reactive protein was weakly correlated (rho 0.28) with the Physical Health factor.

Conclusion: PROMIS-29 is reliable in AS and the physical component of PROMIS-29 has construct validity with AS legacy measures. The general population two-factor model showed a better fit than our hypothesized model in CFA of our patient sample but did not meet predetermined cutoffs of good fit. Thus while our results may provide guarded support for the validity of the PROMIS-29 health profile in AS, future study of this HRQOL instrument is needed to elucidate the clinical utility in AS patients.

Daily Management of Patients with Axial Spondyloarthritis: Self-monitoring of Disease Activity with a Smartphone App Is Feasible – a Proof of Concept Study

Uta Kiltz[1], Robin Kempin[1], Jutta Richter[2], Anna Schlegel[1], Xenofon Baraliakos[1], Styliani Tsiami[3], Ioana Andreica[1], Bjoern Buehring[4], David Kiefer[1] and Juergen Braun[1], [1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany, [2]Rheumatology and Hiller Research Unit, Heinrich-Heine-University Duesseldorf, Medical Faculty, Duesseldorf, Germany, Duesseldorf, Germany, [3]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany, [4]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Velbert, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Assessment and monitoring of disease activity and functioning is of major importance for the course of axial spondyloarthritis (axSpA). This is equally important for patient monitoring in daily routine as also for tight control strategies. Even though there is evidence that a closer monitoring of patients is better than routine care, more intensive treatment schedules are often not realized in daily practice for several reasons including shortage of time and personal resources. Using application software devices (apps) in clinical routine for the recording of disease-specific patient reported outcomes (PRO) may facilitate monitoring and improve clinical decision processes but there is a lack of data on the use of apps.To investigate the use of such App technology in respect to usability, feasibility and equivalence of data in daily care of patients with axSpA. In more detail, it will be first determined how many patients are capable and ready to use the technology in a routine setting. Furthermore, the usage and behavior of patients using the app will be studied, the usability of the app and the equivalence of the collected parameters as well as the adherence to the documentation of disease activity over time

Methods: Patients diagnosed with axSpA were consecutively included in this ongoing monocentric prospective cohort study. In addition to patient and disease characteristics, information on previous experience with digital health apps was collected. Patients were asked to submit BASDAI and BASFI scores regularly every 2 weeks. The free to use AxSpA Live App is available for Android and iOS as a Class I certified medical device.

Results: Out of 103 axSpA patients asked, 69 patients with axSpA (mean age 41.5 ± 11.3, 58% male, 76.8% use of bDMARDs, BASDAI 4.3 ± 2.0, BASFI 3.8 ± 2.5) out of 103 patients (67%) agreed to use participate, while 5 did not have a smartphone, 1 was unable to download the app for technical reasons, 28 reported other personal reasons). Of the 69, 62 patients (89.9%) reported using electronic media frequently and had used digital health apps (mean apps used 1.0 ± 1.3) in everyday life before. There were no systematic differences between pain levels documented on paper or by app at baseline (ICC 0.9 (95%CI 0.82 – 0.93). Out of 55 patients who completed week 2, only 33 patients (60%) used the App regularly to transmit their BASDAI/BASFI responses within the first two weeks (60%). Patients who started a new drug treatment because of high disease activity, reported BASDAI values more often than patients without a treatment change within a follow-up period of 5.5± 2.4 weeks (Table).

	Patients without change in their medication (n=53)	Patients with change in their medication (n=16)
Age, years	42.0 (11.9)	39.8 (9.3)
Sex, male (%)	62.3	43.8
BASDAI, baseline	4.1 (2.1)	4.9 (1.7)
BASFI, baseline	3.8 (2.6)	3.8 (2.3)
Time of follow-up, in weeks	5.4 (2.4)	5.6 (2.5)
Number of transmitted BASDAI values at week 2	22 (41%)	11 (69%)
Median number of transmitted BASDAI values during follow up	1.0 (3.6)	1.5 (1.4)

Conclusion: The majority of patients with axSpA were able to use the AxSpA Live App. Most patients report scores regularly. The current disease activity seems to influence the adherence to reporting.

Impact of Utilising Smart Phone Application in Ankylosing Spondylitis: SMART- as Study

Ashit Syngle[1], Nidhi Garg[2] and Kanchan Chauhan[1], [1]Healing Touch City Clinic, Chandigarh, Chandigarh, India, [2]Chitkara University, Rajpura, Punjab, India

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that primarily affects the axial skeleton and characterized by inflammatory back pain, leading to decreased mobility, function, and quality of life. Management of the disease includes the use of DMARDs, physical therapy, and other lifestyle remedies. There is a global challenge in meeting patients' needs and discrepancies in access to AS care, highlighting the urgent need to implement cost-effective disease management programs and deliver equal access to care. In modern era, most people having access to smart phones create opportunities for patient care in chronic diseases. This study aims to investigate the impact of smart phone application (HealthCius) on inflammatory disease activity and quality of life in AS patients over a period of one year.

Methods: A total of 80 patients were recruited in this observational study fulfilling the Modified New York Criteria, 1984 for AS. These patients were allocated to two groups: Intervention group (n=50) and Control group (n=30). The ones having facility of smart phones as well as patients who accepted to use the HealthCius application were assigned to the Intervention group and patients who did not have the facility of smart phones were grouped as Control. The patients in the two groups received standard treatment of AS. The application was designed after obtaining feedback from health care providers, patient counselors and AS patients using a questionnaire. To the patients, the app was their individual treatment plan. It helped them comply with the plan by providing an easy to refer checklist, reminders, alerts and a visual dashboard of their progress through the day. The app served as the doctor's virtual

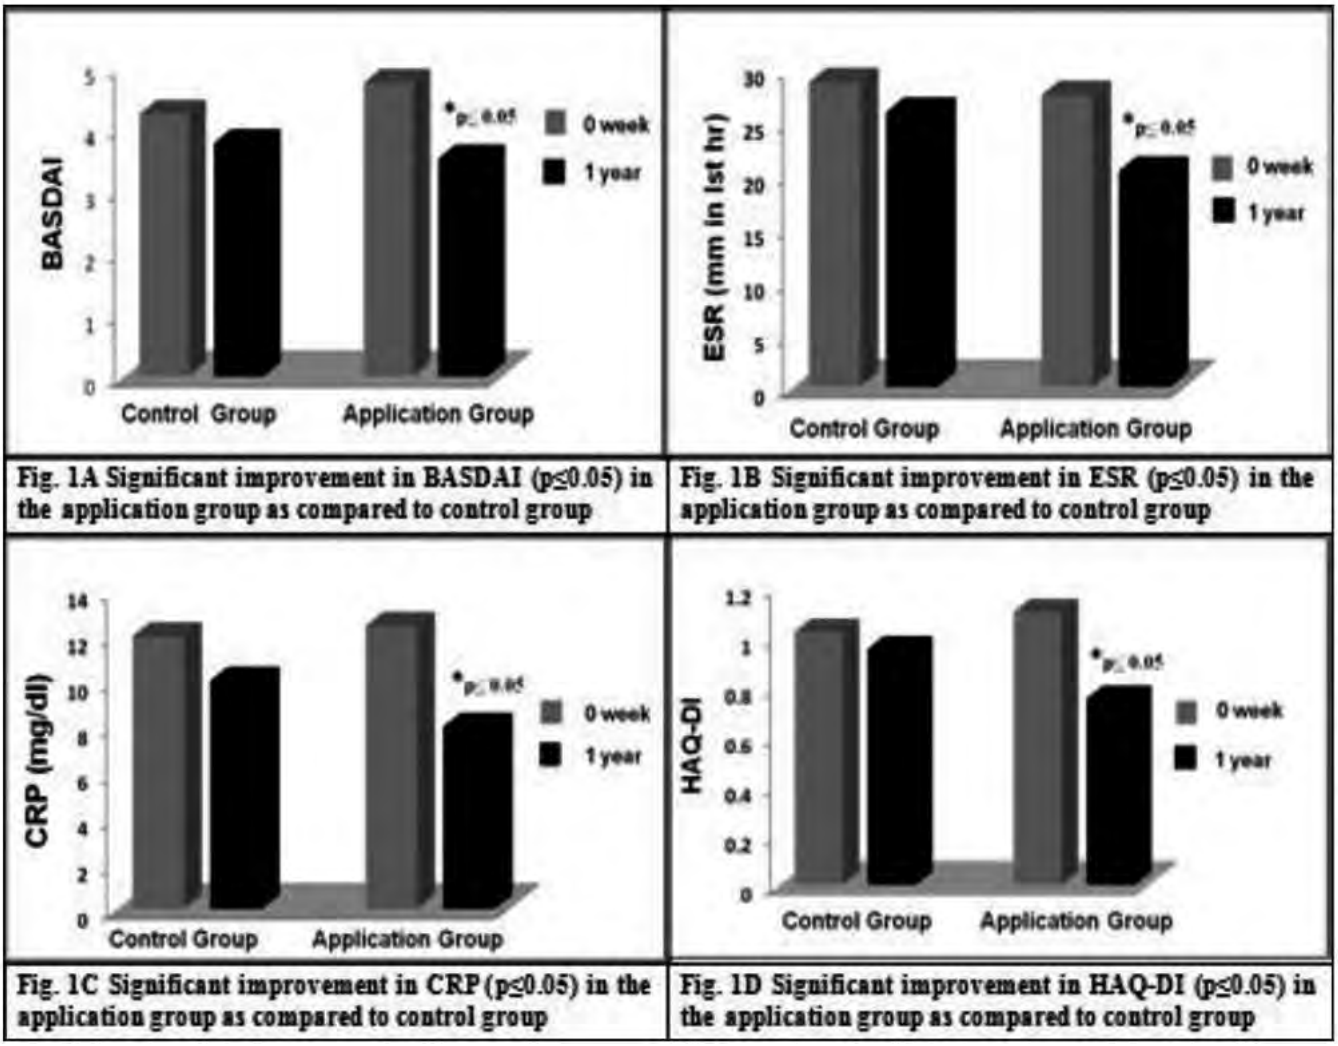

Fig. 1A Significant improvement in BASDAI (p≤0.05) in the application group as compared to control group

Fig. 1B Significant improvement in ESR (p≤0.05) in the application group as compared to control group

Fig. 1C Significant improvement in CRP (p≤0.05) in the application group as compared to control group

Fig. 1D Significant improvement in HAQ-DI (p≤0.05) in the application group as compared to control group

assistant inside the patient's smart phone. For the doctor, it was a live dashboard of all patients and their real time compliance levels. The data reported by the patients was available to the doctor in the form of time sliced charts and trend lines. Therefore, this app is designed to leverage technology to shift the patients' focus every day on to their treatment plan thereby driving up compliance and better health outcomes. Outcome measures included ESR, CRP, BASDAI, BASFI and health assessment questionnaire disability index (HAQ-DI) at baseline and after 1 year.

Results: Baseline characteristics were similar between groups with no significant difference. There was a significant difference between the control and intervention group for BASDAI (p ≤0.05), BASFI (p≤0.05), ESR (p≤0.05), CRP (p≤0.05) and HAQ-DI (p≤0.05) after 1 year in favor of smart phone application. Analysis within the groups revealed significant improvement in BASDAI (p≤0.05) (Fig.1A), ESR (p=0.02) (Fig.1B), CRP (p=0.01) (Fig.1C) and HAQ-DI (p=0.01) (Fig.1D) in the application group as compared to control group. Impact of DMARDs usage was also evaluated at the end of the study and it was found that the average drug usage of DMARDs was more in control group than the intervention group.

Conclusion: The study suggested that there was greater improvement in inflammatory disease activity and quality of life in smart phone application assisted AS patients suggesting that smart phone technology can be used to leverage health benefits in AS.

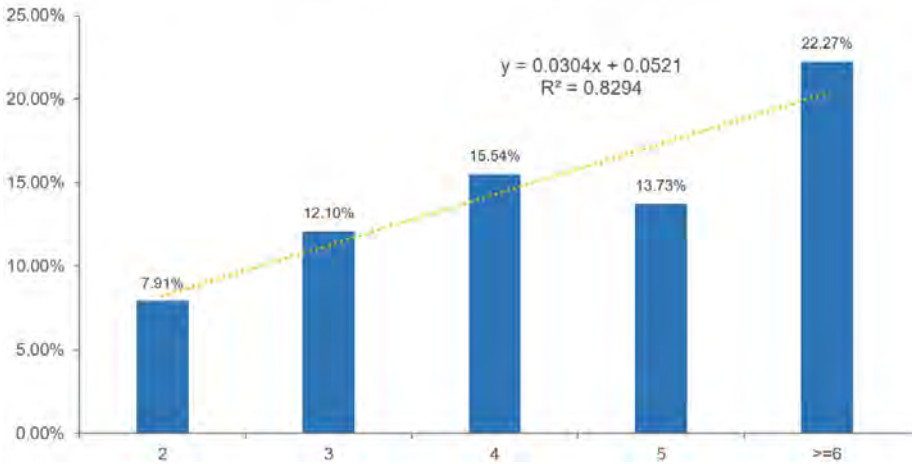
Figur1. The correlation between the improvement of T2T rate(y) and the times of self-assessment for ASDAS(x)



Background/Purpose: Ankylosing Spondylitis Disease Activity Score (ASDAS) is adopted to evaluate the degree of disease activity and the inflammatory response in AS patients. ASDAS score < = 1.3 represents inactive disease status and achievement of T2T. SSDM is a mobile application for disease management.

The purpose of this study is to evaluate the patterns of T2T and related influential factors among AS patients after applying SSDM in the real world.

Methods: AS Patients were trained to master SSDM by healthcare professionals (HCPs) and to conduct ASDAS self-assessments. Patients were also required for repeating self-assessments after leaving the hospital. After entry by patients, data can be synchronized to the SSDM terminal of authorized rheumatologists. Based on these data, the patients can apply for consultation to their physicians and rheumatologists can provide medical advices to their patients.

Results: From Jan 2015 to Jan 2020, 17,870 AS patients enrolled in SSDM with the mean age of 34.62±10.98 years old and the median disease duration of 3.58 years. Among them, 1,127 AS patients from 150 hospitals were followed up for more than 6 months through SSDM. The results at baseline and in final follow up were summarized in Table 1.

The rate of T2T achievers were 27.95% (315/1,127) at baseline, and improved significantly to 41.08% (463/1,127) after 6 months follow up, $p< 0.01$. Among T2T achievers at baseline, 65.40% (206/315) maintained T2T, 34.60% (109/315) relapsed. Of patients who didn't achieve T2T at baseline, only 31.65% (257/812) achieved T2T after 6 months follow up.

The impact of the online interaction between patients and physicians and the frequency of self-assessment for ASDAS on T2T has been analyzed. Compared with 544 patients who didn't interact online with their physicians and self-assessed less than 3times, 104 patients with online interaction and monthly assessments achieved significant higher improvement rate of T2T (9.19% vs 23.08%, $p< 0.01$). The more frequent of the self-assessments being performed by patients, the higher improvement of T2T rate will be. The improvement of T2T rate(y) was positively correlated with times of self-assessment for ASDAS(x) independently. The regression equation as "$y = 0.0304x + 0.0521$", $r = 0.9107$, $p< 0.01$ (Figure 1).

Conclusion: Significant improvement was observed under applying SSDM through empowering AS patients. After proactive disease management via SSDM for more than 6 months, patients with ASDAS< =1.3 score at baseline had a significantly higher retention rate of inactive disease activity. The patients who performed more frequent self-assessments had lower probability of relapse and higher rate of T2T. Online interaction between patients and physicians contributed to promote the improvement rate of T2T. SSDM is a valuable tool for long term follow-up through empowering patients.

Predictors of Response in Secukinumab-treated Patients with Ankylosing Spondylitis: Logistic Regression and Machine Learning Analyses

Corinne Miceli-Richard[1], Denis Poddubnyy[2], Atul Deodhar[3], Weibin Bao[4], Craig Parman[5], Brian Porter[6] and Effie Pournara[5], [1]Paris Descartes University, Department of Rheumatology - Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Paris, France, [2]Charité – Universitätsmedizin Berlin, Berlin, Germany, [3]Oregon Health & Science University, Portland, OR, [4]Novartis Pharmaceuticals Corporation, East Hannover, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Predicting outcomes early in the disease course in patients (pts) with ankylosing spondylitis (AS) is challenging, owing to heterogeneity of symptoms, varying disease severity, and the various outcome measures being mainly patient-reported, apart from radiographic progression. Using logistic regression analyses and machine learning (ML) techniques to predict the response to therapy may result in improved patient selection for optimized treatment regimens and setting the right expectations for individual patients[1,2]. We explored whether baseline (BL) disease characteristics could predict the response of secukinumab (SEC) therapy in AS pts, using logistic regression and ML analyses.

Methods: This post hoc analysis was performed on a pooled data of pts treated with SEC 300/150 mg from four phase 3 MEASURE studies (MEASURE 1–4)[3-5] in AS (N=860). SEC 300 mg (n=113) group included 76 pts originally randomized to 300 mg and 37 pts initially randomized to placebo and then switched to 300 mg. In SEC 150 mg (n=747) group, 504 pts initially randomized to 150 mg and 243 pts initially randomized to placebo and then switched to 150 mg. A univariate logistic regression analysis was applied to search for potential BL predictors ($P < 0.2$) commonly collected in the MEASURE trials as demographics, disease activity parameters, prior medications etc. Various BL factors including sex, TNF status (treatment naïve vs inadequate responder), HLA-B27 status, current smoking status, concomitant NSAID use, BMI (< 30 kg/m^2 vs ≥30 kg/m^2), and hsCRP (elevated ≥5 mg/L vs normal < 5 mg/L) [binary variables], as well as age, MASES score, patient global assessment(PGA), and BASMI parameters [continuous variables] were assessed. Potential predictors identified in the univariate analyses were subsequently included in multivariate logistic regression models for further selection to assess their association with the response to SEC in AS pts on the following outcomes measures: ASAS40, ASDAS-Inactive Disease(ASDAS-ID), and BASDAI50. Additionally, ML Random Forest methods were applied and optimized using a grid search to find the best set of predictors.

Results: The BL factors with a significant ($P < 0.05$) association with the assessed outcomes of ASAS40, ASDAS-ID and BASDAI50 in multivariate logistic regression at Week 52 are presented in the **Table**. Age, hsCRP, occiput-to-wall distance score and MASES score were associated with ASAS40 and BASDAI50 responses. BMI, TNF status, occiput-to-wall distance score and PGA were associated with ASAS40 and ASDAS-ID responses. Additional modeling attempts using ML tree-based classification models showed similar results, without demonstrating sufficient predictive power.

Predictors*	Odds Ratio (95% CI)		
	ASAS40	ASDAS-ID	BASDAI50
Age (years)	0.98 (0.97, 0.99)	_	0.98 (0.96, 0.99)
Sex (Male vs Female)	_	1.67 (1.07, 2.41)	_
BMI (<30 kg/m^2 vs ≥30 kg/m^2)	1.44 (1.04, 2.01)	2.35 (1.42, 3.89)	_
Current Smoker (No vs Yes)	1.41 (1.04, 1.92)	_	_
TNF status (Treatment Naïve vs Inadequate Responder)	1.58 (1.15, 2.18)	2.30 (1.42, 3.73)	_
hsCRP (Elevated ≥5 mg/L vs Normal <5 mg/L)	1.67 (1.24, 2.26)	_	1.59 (1.16, 2.18)
BL Occiput-to-wall distance	0.96 (0.94, 0.99)	0.89 (0.84, 0.93)	0.97 (0.94, 1.00)
BL PGA (every 10 unit increment on VAS 100 scale)	1.16 (1.06, 1.26)	0.82 (0.74, 0.91)	_
BL MASES Score	0.96 (0.92, 1.00)	_	0.92 (0.88, 0.96)

* Only predictors with P <0.05 are kept in the final multivariate model
AS, ankylosing spondylitis; ASAS, Assessment of SpondyloArthritis international Society; ASDAS-ID, AS Disease Activity Score-Inactive Disease; BASDAI, Bath AS Disease Activity Index; BASMI, Bath AS Metrology Index; BL, baseline; BMI, body mass index; CI, confidence intervals; hsCRP, high sensitivity C-reactive protein; MASES, Maastricht AS Enthesitis Score; PGA, patient global assessment

Table. Multivariate Logistic Regression analysis for baseline predictors of ASAS40, ASDAS-ID and BASDAI50 at Week 52: Significant Associations

Conclusion: The current analysis identified younger age, higher hsCRP, lower BMI, TNF naïve status, lower occiput-to-wall distance score and lower MASES score as factors associated with greater response that could potentially predict outcomes in AS pts treated with SEC.

Abstract Number: 1894

Use of Facebook and Electronic Patient Portal to Identify Axial Spondyloarthritis in Patients with Chronic Back Pain

Yuliya Afinogenova[1], Swetha Alexander[2], Andrew Haims[3] and Abhijeet Danve[4], [1]Yale University, Orange, CT, [2]University of Connecticut, New Haven, [3]Yale University, New Haven, CT, [4]Yale University, Rocky Hill, CT

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Delay in diagnosis of Axial Spondyloarthritis (axSpA) remains a significant unmet need and can be partially attributed to lack of timely rheumatology referral. Current referral strategies advocate formal patient referral by non-rheumatologists, and this may be difficult given busy primary care practices and lack of awareness among non-rheumatologists of axSpA. In the ongoing Finding Axial Spondyloarthritis Study (FaxSpA), we are reaching out directly to patients by distributing online screening tool (A-tool) that we developed via electronic patient portal and Facebook. With increasing use of social media and patient participation in electronic medical record (EMR), we believe this may be a feasible approach for screening.

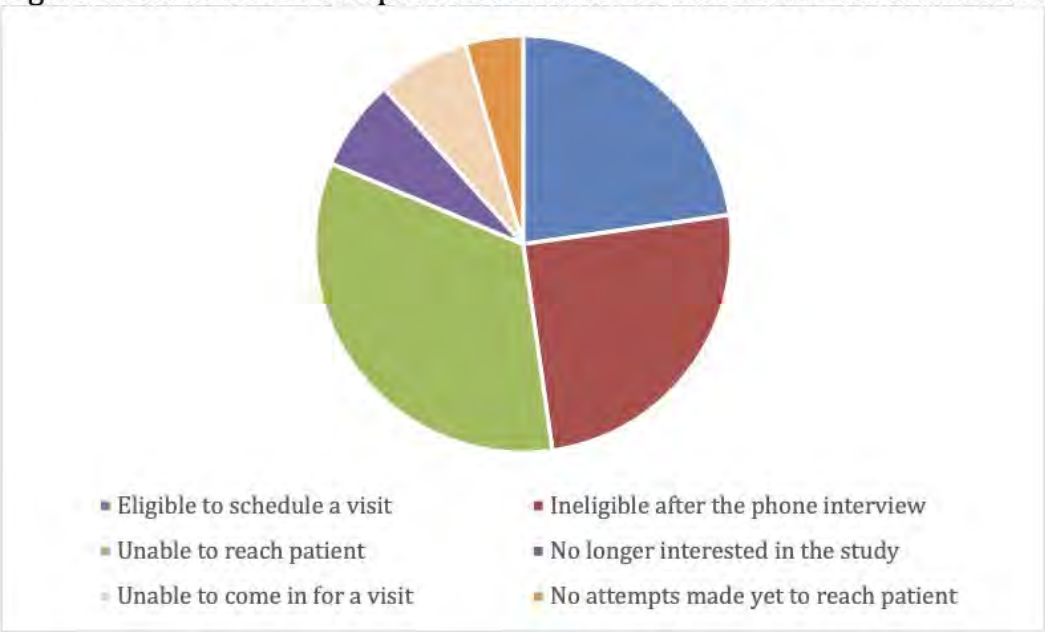
Methods: FaxSpA is a prospective study to evaluate the effectiveness of A-tool in identification of axSpA. A-tool contains 3 item prescreen followed by a clinical questionnaire that includes high yield axSpA features with good sensitivity and specificity. A-tool is distributed via Facebook to individuals in our geographic area and via MyChart to patients ages 18 to 65 with chronic back pain in EMR problem list. MyChart is the patient communication portal in EPIC EMR. Patients fulfilling pre-specified criteria on A-tool are contacted over the phone to confirm eligibility and then invited for clinical evaluation, labs (CRP, HLA B27) and imaging (x-ray and MRI of SI joints). Patients with diagnosed axSpA, spine surgery and age > 65 are excluded. We also collect and store blood samples for future translational biomarker research. SPSS v25 software was used for descriptive statistics and independent t-tests.

Results: Between 4/2019 and 4/2020, 634 subjects completed the survey. Average age (44.3±13.4) was not different for MyChart vs. Facebook groups. Persistent back pain for more than 3 months was reported by 593 (94%); 495 (78%) had gradual onset back pain and 547 (86%) had back pain that started before age 45. Of 634 subjects, 428 passed pre-screen (62% vs. 74% in MyChart vs. Facebook, p=0.002). A-tool was positive in 268 (40% vs. 45% in MyChart vs. Facebook, p=0.20). Out of 268 subjects, an attempt was made to reach 256 by phone and email to confirm their eligibility and schedule a research visit. We were unable to reach 90 subjects (35%), despite multiple attempts. Sixty seven subjects (26%) were deemed ineligible after a telephone interview (15 due to history of previous surgery, 20 due to alternative explanation for their back pain, 18 due to no longer meeting criteria for pre-screen

Table 1. Survey Results of Pre-screen and A-tool

	Total	MyChart	Facebook	p-value
Total number of survey responses	634	332	302	-
Mean age (years)	44.3±13.4	44.2±13.7	44.5±12.9	0.73
Positive pre-screen (out of total survey responses)	428	206 (62%)	222 (74%)	0.002
Positive A-tool (out of total survey responses)	268	132 (40%)	136 (45%)	0.20

Figure 1. Outcomes of Telephone Screen in Patients with a Positive A-Tool



or A-tool, 14 for other reason). Another 38 subjects (15%) were either unable to come or no longer interested in the study when contacted over the phone. So far, 50 patients have been seen in the study.

Conclusion: Using electronic patient portal and social media is a feasible and efficient strategy to screen for patients with suspected axSpA. The gap between the number of patients found eligible on A-tool and those who actually came for a visit may convey that there is need to improve awareness and education about axSpA among patients. It will be interesting to evaluate the effectiveness of A-tool based referral strategy in identifying axSpA.

ASDAS, Anklyosing Spondylitis Disease Activity Score; AS, Ankylosing spondylitis; HLA-B27, human leucocyte antigen B27; NSAID, non-steroidal anti-inflammatory drug; BMI, body mass index; CRP, c-reactive protein, TNFi, tumor necrosis factor inhibitor: IBD, inflammatory bowel disease; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BASMI, Bath Ankylosing Spondylitis Metrology Index; mSASSS, modified Stoke Ankylosing Spondylitis

Background/Purpose: Clinical efficacy of TNF inhibitors (TNFi) in axial spondyloarthritis (axSpA) has been widely probed in randomized control trials. In clinical practice, some studies suggested that long-term treatment with TNFi (more than 4 years) could slow down radiographic progression in axSpA. Furthermore, it is thought that the effect of TNFi on radiographic progression may be mediated by reducing disease activity.

To evaluate the effect of maintenance of low disease activity on radiographic progression in axSpA patients treated with TNFi.

Methods: Of the initial 204 patients a total of 101 patients with axSpA, 31 starting TNFi and 75 previously treated with TNFi, from the Spanish Register of Biological Therapy in Spondyloarthritides (REGISPONSERBIO) were included in the analysis based on the availability spinal radiographs (cervical and lumbar spine lateral views) at two time points and clinical data. Paired cervical and lumbar spine radiographs were available on all patients at a minimum interval of 2 years (mean 3.45±0.978 years; range 2 to 5 years). Two trained readers, independently and with known chron-

Table 2. Impact of persistent low disease activity on spinal radiographic progression

Variable	OR	95% CI	p value
Persistent low disease activity (ASDAS <2.1)	0.21	0.05-0.91	0.04
Duration of radiographic interval	0.87	0.48-1.60	0.67
Presence of syndesmophytes at baseline	5.82	1.26-26.8	0.02
Male	1.46	0.23-9.21	0.69
Current smoking	0.58	0.14-2.44	0.46
AS	0	0	0.99
HLA-B27	0.84	0.42-1.72	0.65
TNFi use during at least 4 years before radiographic interval yes/no	0.39	0.10-1.49	0.17
Disease duration (years)	0.99	0.93-1.04	0.65

Multivariable analysis of 93 patients with radiographic spinal progression defined as development of new syndemosphytes. ASDAS, Anklyosing Spondylitis Disease Activity Score; AS, Ankylosing spondylitis; HLA-B27, human leucocyte antigen B27; TNFi, tumor necrosis factor inhibitor

ological order, scored lateral cervical and lumbar spine images according to the mSASSS system (0-72). Following definitions for progression were used: change of the absolute scores, change of ≥2 points, development of new syndesmophytes, and development of new syndesmophytes or growth of the existing syndesmophytes. Disease activity was reported with ASDAS-PCR every 6 months in a 3-year period.

Results: Baseline characteristics of patients at first radiograph are presented in Table 1. Reliability of both readers was excellent with intraclass correlation coefficients (ICCs) of 0.986 (0.979-0.990) at inclusion and 0.981 (0.972-0.987) at follow-up. The mean±SD score at inclusion was 16.46±20.92, the change score between inclusion and follow-up was 1.98±0.83 and the smallest detectable change of progression was of 2.26 mSASSS units. Development of new syndesmophytes was present in 20 patients (15.2%) and growth of the existing syndesmophytes or new syndesmosphytes was present in 22 (21.8%). Data on disease activity in at least 3 time point in a 3-year period was available in 93 patients, of those 25 (26.9%) patients remain with persistent inactive disease and 65 (69.9%) with persistent low disease activity. In the multivariate analysis, adjusted for multiple baseline clinical and demographic characteristic, only the maintenance of low disease activity was significantly associated with a lower development of new syndesmophytes, OR 0.21 (95% CI 0.05-0.91) p=0.04 (Table 2).

Conclusion: Persistence of low disease activity in patients under TNFi seems to be the most important factor to slow down spinal radiographic progression in axSpA.

No Relationship Between Lumbar Bone Mineral Density and Syndesmophyte Formation at the Same Level - A Multilevel Analysis in Patients with Radiographic Axial Spondyloarthritis

Mary Lucy Marques[1], Sofia Ramiro[2], Pedro M Machado[3], Désirée van der Heijde[4] and Floris van Gaalen[5], [1]Leiden University Medical Center, Coimbra, Portugal, [2]Leiden University Medical Center, Bunde, Netherlands, [3]University College London, London, United Kingdom, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Leiden University Medical Center (LUMC), Leiden, Netherlands

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: In radiographic axial spondyloarthritis (r-axSpA) it has been hypothesized that inflammation-driven bone loss triggers bone repair but at anatomically distinct sites of the same vertebra (i.e. bone loss occurring in the trabecular bone and bone repair in the periosteum)[1]. However, the possible association between bone loss and new bone formation at the same individual vertebra has never been studied. The purpose of this study was to investigate if in r-axSpA low vertebral bone mineral density (BMD) is associated with development of new syndesmophytes at the same vertebral level.

Methods: In a post-hoc analysis from the ASSERT trial (infliximab vs placebo) dual-energy X-ray absorptiometry was used to measure baseline BMD (g/cm^2) of the lumbar spine L1 to L4. Syndesmophyte formation was assessed in the same vertebrae on conventional radiographs defined as an increase in modified Stoke Ankylosing Spondylitis Spine Score from 0 or 1 to 2 or 3 after 2 years. Radiographs were scored by two readers. Generalized estimating equations (GEE) adjusted for within-patient correlation across multiple vertebrae, taking potential confounders into account (Table 1).

Table 1. Relationship between baseline BMD and 2-year syndesmophyte formation as reported by both readers and at least one of the readers - multivariable analysis (adjOR (95% CI))

Independent variables	New radiographic syndesmophyte formation according to both reader 1 and reader 2	New radiographic syndesmophyte formation according to reader 1 or reader 2
BMD (g/cm^2)	0.56 (0.01, 44.45)	0.26 (0.03, 2.63)
Age (years)	1.03 (0.95, 1.11)	1.04 (1.00, 1.09)*
Gender (male)	0.82 (0.10, 6.85)	1.42 (0.50, 4.01)
Disease duration (years)	1.05 (0.97, 1.14)	1.00 (0.96, 1.05)
ASDAS-CRP	1.79 (0.66, 4.86)	1.09 (0.63, 1.87)
HLA-B27	0.13 (0.02, 0.89)	0.54 (0.15, 1.89)
Treatment with NSAIDs	0.41 (0.07, 2.47)	0.82 (0.21, 3.13)
Treatment with infliximab	1.82 (0.22, 15.31)	1.11 (0.45, 2.69)
Presence of MRI VCI at baseline	4.00 (0.99, 16.13)	4.32 (1.95, 9.60)*
Presence of MRI VCFD at baseline	0.69 (0.16, 3.01)	1.23 (0.60, 2.54)
Presence of syndesmophytes at baseline	20.20 (0.96, 424.63)	3.14 (1.14, 8.66)*

BMD, bone mineral density; **VCI,** vertebral corner inflammation; **VCFD,** vertebral corner fat deposition. *p<0.05

Results: We analyzed 599 vertebrae in 165 r-axSpA patients (78% male, mean (SD) age 38 (10) years, 67% with at least one syndesmophyte anywhere in the spine). In total, 24 to 74 new syndesmophytes developed in 9 (5%) to 30 (18%) patients and 13 (2%) to 39 (7%) vertebrae, if either a syndesmophyte was seen by both or only one of the readers (i.e. specific and sensitive definitions) respectively. Analyses with both definitions, and both uni- and multivariable, showed no significant association between baseline local vertebral BMD and new syndesmophyte formation after two years in the same vertebra (multivariable analysis adjOR (95%CI): 0.56 (0.01, 44.45) (specific definition) and 0.26 (0.03, 2.63) (sensitive definition)) (Table 1).

Conclusion: In patients with active and established r-axSpA, with an observed low incidence of lumbar spine syndesmophyte formation over two years, no relationship was found between baseline BMD and new radiographic syndesmophyte formation in the same vertebra.

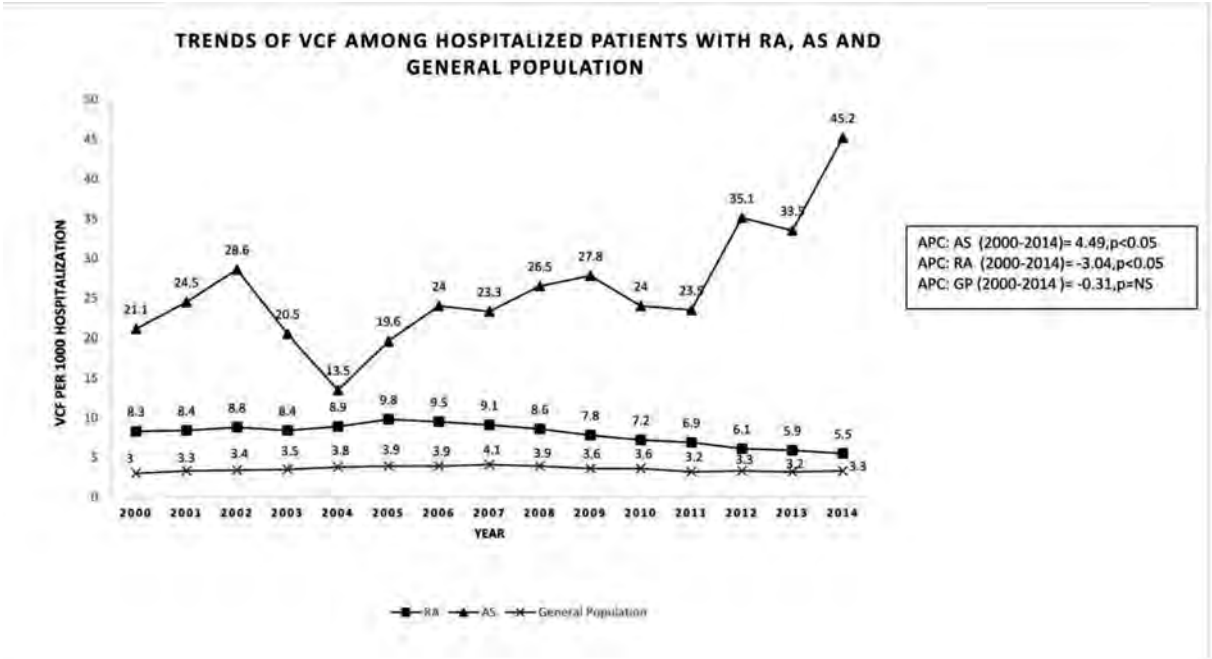
Trends in Hospitalizations for Vertebral Compression Fractures in Ankylosing Spondylitis: Data from the National Inpatient Sample 2001-2014

Anish Paudel[1], Rashmi Dhital[2], Dilli Poudel[3], Anthony Donato[1] and Paras Karmacharya[4], [1]Reading Hospital and Medical Center, West Reading, PA, [2]Reading Hospital and Medical Center, West Reading, [3]University of Pennsylvania, Philadelphia, PA, [4]Mayo Clinic, Rochester MN, ROCHESTER, MN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease predominantly affecting the spine, leading to syndesmophyte formation, ankylosis, and osteoporosis. These factors have been associated with an increased risk of vertebral fractures after minor trauma. Whether improved recognition of AS and more effective management including biologics have impacted the risk of vertebral fractures is unclear. The aim of our study was to assess the yearly trends of vertebral compression fractures (VCF) among hospitalized patients with AS compared to RA and the general population.



Trends in Hospitalizations for Vertebral Compression Fractures in Ankylosing Spondylitis compared to Rheumatoid Arthritis and General Population

Methods: National Inpatient Sample (NIS) database from the years 2000-2014 was used to identify adult (≥18 years age) hospitalizations. NIS is the largest all-payer inpatient database in the US and represents 20% stratified sample of all hospital discharges. Previously validated ICD-9 diagnosis codes at secondary diagnosis positions were used to identify hospitalizations with AS (720.0) and RA (714.0, 714.1, 714.2). We created 3 mutually exclusive groups of cohorts: AS, RA and a third group from the general population without diagnoses of AS or RA as controls. VCF hospitalizations were identified in these 3 groups using validated ICD-9 codes (805.2, 805.4, 805.8, 733.13) at the primary diagnosis position. ICD-9 codes for malignant neoplasms, bone and plasma cell neoplasms, or non-specific hemangiomas (140.xx-208.xx, 228.09, 238.0, 238.6, 239.2) were used to exclude patients with malignancies and pathologic bone processes except osteoporosis. STATA version 16 and Joinpoint regression were used to analyze trends in VCF hospitalizations.

Results: In the years 2000-2014, there were a total of 4,364 (2.70%), 45,218 (0.77%), and 1,432,232 (0.35%) VCF hospitalizations in AS, RA and in the general population controls, respectively. Females accounted for 28.1%, 84.6%, and 67.3% VCF hospitalizations in AS, RA, and general population controls, respectively. Mean ages for VCF hospitalization were 71.4, 75.1, 71.6 years for AS, RA, and general population controls, respectively.

From the year 2000 to 2014, an overall increasing trend of VCF hospitalizations in AS (APC= 4.49, $p < 0.05$) was seen, in contrast to a decreasing trend in RA (APC= - 3.04, $p < 0.05$). The trend of VCF in the general population was stable over the years studied (APC = -0.31, p= NS) (**Fig 1**).

Conclusion: The trend of VCF hospitalizations in AS was noted to be increasing compared to a declining trend in RA and a stable trend in the general population. Early diagnosis and improved management of RA might have led to lower VCF hospitalizations in RA over time. While the trends in RA are encouraging, findings in AS suggest the need to improve screening and prevention of osteoporosis and VCF in patients with AS.

Abstract Number: 1898

Comparative Effectiveness of Secukinumab, Adalimumab and Other Tumor Necrosis Factor Inhibitors in the Treatment of Axial Spondyloarthritis

Loïc Choquette Sauvageau[1], Denis Choquette[2], Louis Bessette[3], Isabelle Ferdinand[1], Boulos Haraoui[4], Frédéric Massicotte[1], Jean-Pierre Pelletier[2], Jean-Pierre Raynauld[2], Marie-Anaïs Rémillard[1], Diane Sauvageau[1], Édith Villeneuve[1] and Louis Coupal[1], [1]Institut de Rhumatologie de Montréal, Montréal, QC, Canada, [2]Institut de Rhumatologie de Montréal, Montreal, Canada, [3]Centre de l'Ostéoporose et de Rhumatologie de Québec, Quebec, QC, Canada, [4]Rheumatology Institute of Montréal, Montreal, Canada

SESSION INFORMATION

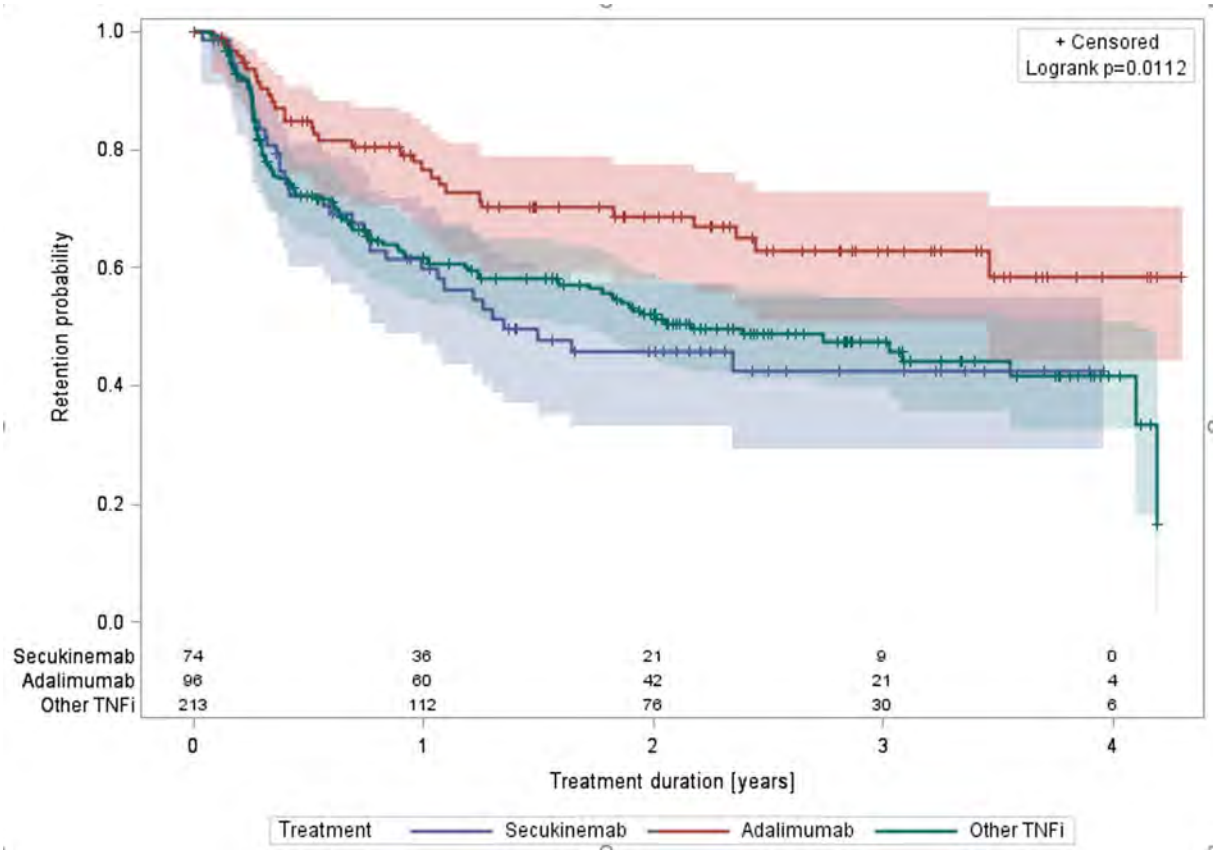
Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Studies comparing the effectiveness of biologics in the treatment of axial spondyloarthritis (axSpA) are sparse [1]. One study comparing secukinumab and adalimumab biosimilar is ongoing. Secukinumab is an agent targetting Il-17. The aim of our analysis is to compare the effectiveness of the most frequently used biologic

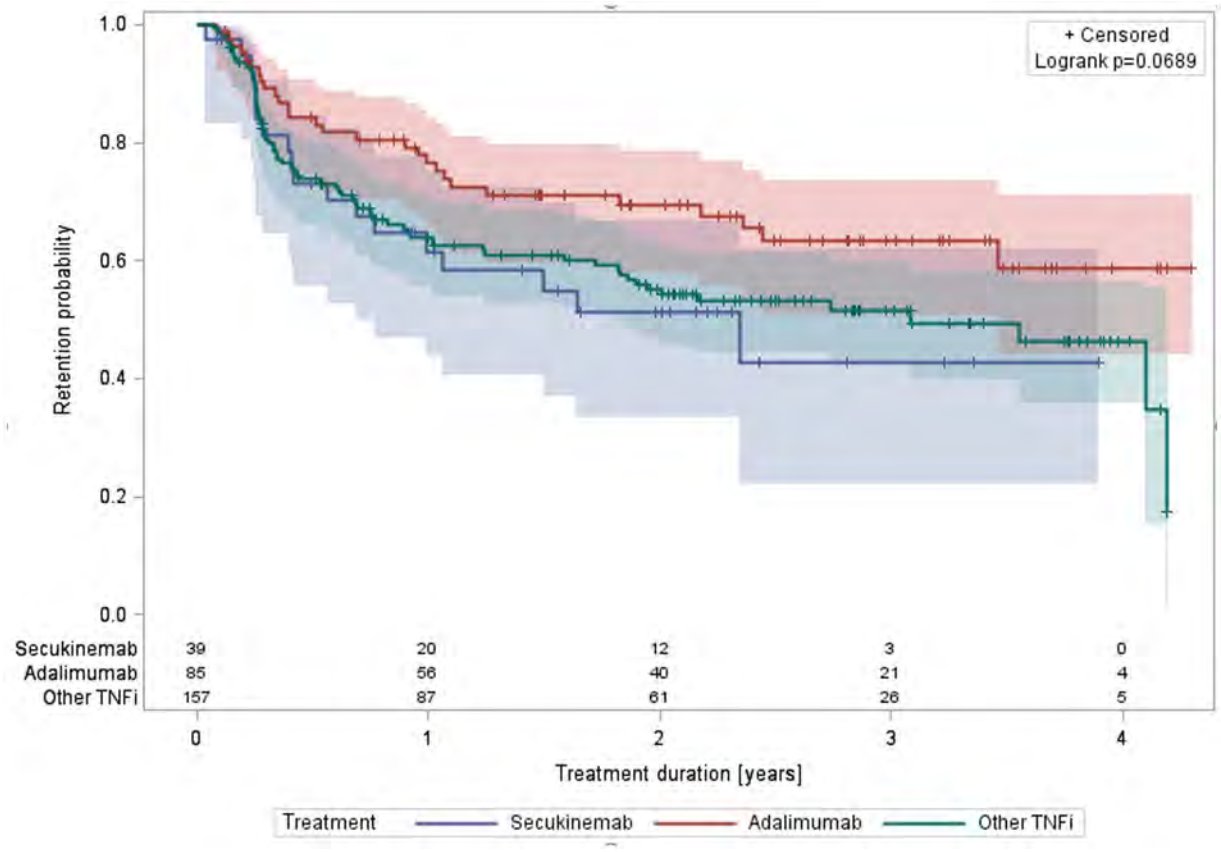


Retention of ADA, SEC and TNFi - all intentions

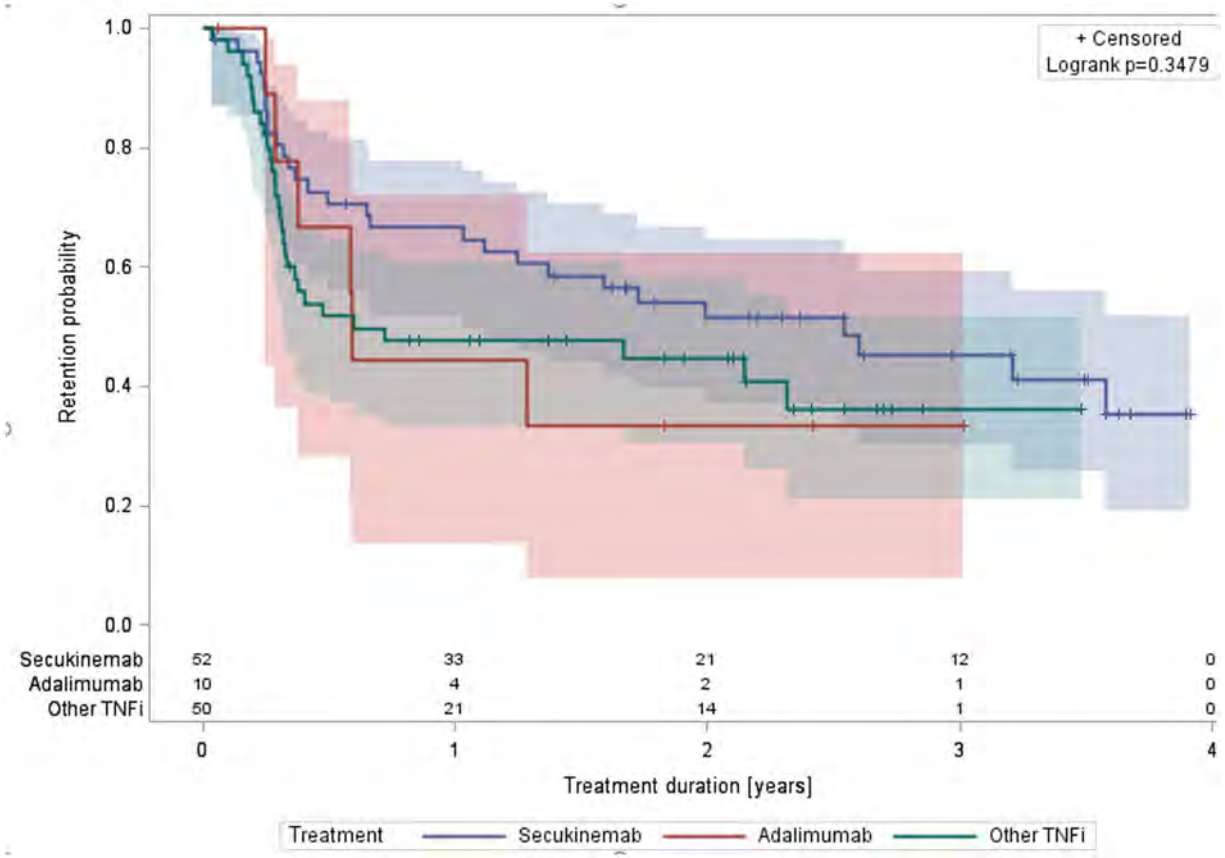
in axSpA since the marketing of secukinumab in all, first and second and third intention or more. Results are presented here.

Methods: Patients diagnosed with axSpA enrolled in RHUMADATA® giving informed consent and treated with secukinumab (SEC), adalimumab (ADA) or other TNF inhibitors (TNFi) on or after January 1, 2016 were extracted from the RHUMADATA® clinical database and registry. RHUMADATA® provides socio-demographics, comorbidities, patient-reported outcomes, disease activity indices, laboratory variables, rheumatologist exam report data, use of concomitant medications and axSpA treatment and reasons for treatment cessation. Kaplan-Meier survival curves and proportional hazard models were used to analyze time to treatment cessation.

Results: A total of 383 patients with axSpA were extracted from the RHUMADATA® registry. Seventy-four were treated with SEC, 96 with ADA and 213 with other TNFi (certolizumab, etanercept, golimumab or infliximab). Overall, 47.3% were women, the average age and disease duration at treatment initiation were respectively 44.8 (±standard deviation (STD)=13.3) and 6.0 (8.4) years. The overall age adjusted Charlson Comorbidity Index (aCCI) was 1.3 (2.1). The proportion of patients diagnosed and/or treated for diabetes and hypertension respectively were 14.9 and 40.5% (SEC), 5.2 and 25.0% (ADA) and 12.7 and 30.5% (TNFi). Overall BASDAI and BASFI scores were 6.0 (2.3) and 5.0 (2.6). SEC, ADA and TNFi were used in first intention in 18.9, 61.5 and 41.3% of patients respectively. Kaplan-Meier logrank p-values were 0.0112, 0.0689, and 0.3479 when comparing the three groups in all, first and second and third or more intentions. Pairwise comparisons showed better retention for ADA treated patients in all and first and second intentions (early treatments). A Cox proportional hazard model adjusting for age at diagnosis, disease duration at treatment initiation, aCCI, the number of prior advanced treatments and concomitant use of methotrexate at treatment initiation demonstrated a statistically better retention of ADA over TNFi.



Retention of ADA, SEC and TNFi - first and second intentions



Retention of ADA, SEC and TNFi - third + intentions

Conclusion: Based on our real-world datasets, ADA had better retention than SEC in treating early axSpA.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate life expectancy of a Swiss cohort of patients with ankylosing spondylitis (AS) versus general population during 35 years of longitudinal follow up, and to study the association of HLA-B27 with mortality in the general population.

Methods: In 1985 AS-affected members of the Swiss Ankylosing Spondylitis Patient Society were contacted to participate in this study, together with their first-degree relatives (FDRs). After ethical approvals and informed written consent, 1178 subjects completed questionnaires on disease manifestations, underwent rheumatological examination of axial and peripheral joins, and provided blood samples for genetic studies. Pelvic radiographs of 363 probands and 713 relatives were assessed blindly for presence of sacroiliitis according to the modified New York (mNY) radiographic criteria. Patients previously clinically diagnosed with AS irrespective of the findings of their pelvic radiographic studies were deemed to have axial spondyloarthritis (axSpA), those meeting the mNY criteria mNYAS, and those with axSpA but not meeting the mNY criteria, non-radiographic axial spondyloarthritis (nr-axSpA).

Approval of a follow-up study was obtained in 2019 from the ethical committee of the Swiss Kanton of Bern. City and village administrations provided current addresses of former participants, and also the deceased persons' year of death, but not its cause. Among the 411 AS patients from the 1985 study, 182 were alive and 123 had died by December 31, 2019. For the remaining 106 patients who were lost to follow up, the year they moved away was taken as their year of last follow-up. Life expectancy was analysed in comparison with age- and gender-matched Swiss general population data, using Cesaro averaging methods and Kaplan-Meier analyses.

Survival in relation to HLA-B27 individuals in the general population was studied in the UK Biobank cohort (n=485,545, with 13,782 deaths).

Results: Patients meeting the mNYAS criteria have an increased standardized mortality rate (SMR) compared with the general population (1.21, 95% confidence interval 0.97-1.51, P=0.049). This was restricted to HLA-B27(+) mNYAS (SMR HLA-B27(+)=1.241, P=0.034, Figure 1; HLA-B27(-)=1.038, P=0.92). Mortality was increased amongst

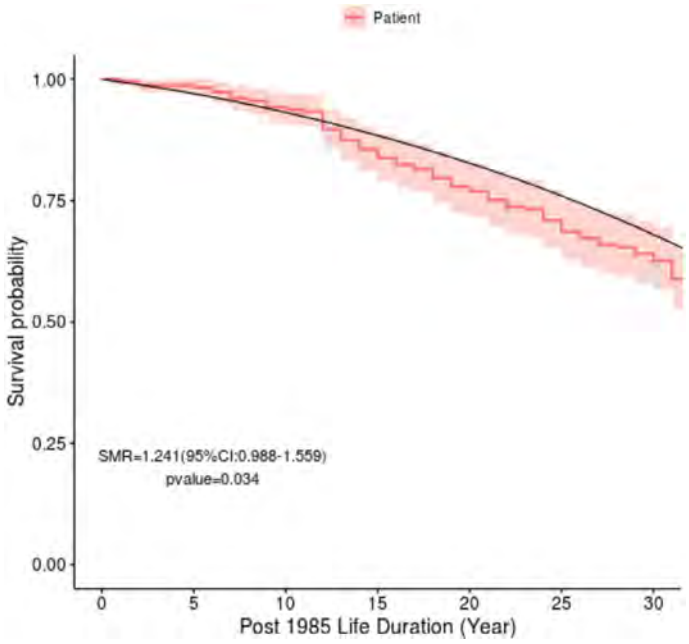

Figure 1. Kaplan-Meier survival probability plot for HLA-B27(+) AS patients.

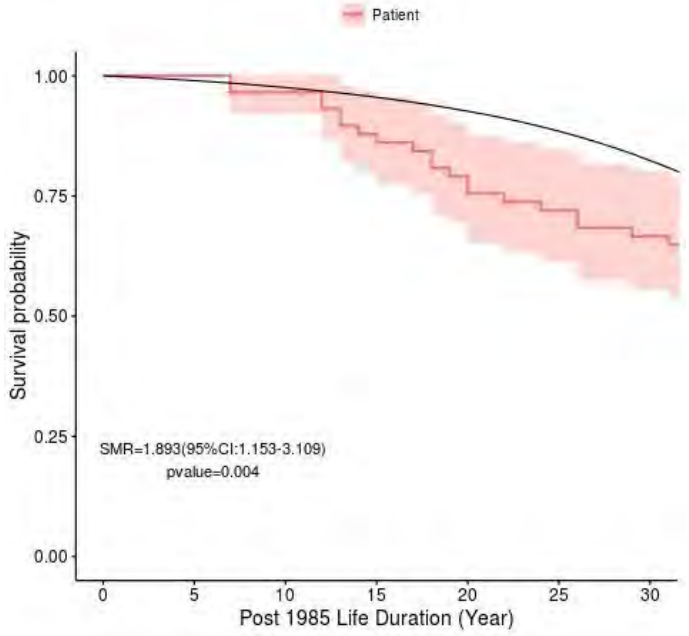

Figure 2. Kaplan-Meier survival probability plot for female HLA-B27(+) AS patients.

HLA-B27(+)mNYAS(+) women (SMR=1.89, P=0.004, Figure 2) but not men (SMR=1.14, p=0.26). No difference in survival was noted amongst HLA-B27(-)mNYAS(+) patients (SMR=1.04, p=0.92). Patients with nr-axSpA had reduced SMR compared with the general population (SMR=0.372, P=0.001). In the UK Biobank general population cohort, HLA-B27 carriage was not associated with mortality (hazard ratio (HR)=0.97, P=0.28), in either males (HR=1, P=0.96) or females (HR0.91, P=0.09).

Conclusion: We report in this 35 year longitudinal study that mNYAS patients, but not nr-axSpA patients, have a significantly shortened life expectancy. Increased mortality was particularly significant amongst women with HLA-B27(+)

mNYAS, perhaps a reflection of their more severe disease. It also provides additional clinical evidence indicating heterogeneity of AS. HLA-B27 carriage in the general population does not influence survival.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the impact of central sensitization (CS) on axial spondyloarthritis (AxSpA) patients' clinical and functional situation and quality of life.

Methods: Subjects with axSpA according to ASAS criteria and healthy controls were recruited. The central sensitization (CS) was evaluated by the central sensitization inventory (CSI). Quantitative sensory testing, which consists of pressure pain threshold (PPT), temporal summation (TS), and conditioned pain modulation (CPM), were applied. The algometer was used in all kinds of pain parameters' assessment. The spinal hyperalgesia was evaluated from C3 and C7; T6 and T2; L3 and L5 levels. The sacroiliac PPT scores were obtained from 4 points. Trapezius muscle was

			AxSPA (n:100)			Healthy controls (n: 50) Mean (SD)	*Diff. Sig. between AxSPA and controls p-value*

used to evaluate distant control point. TS scores were evaluated over the trapezius muscle, sacroiliac joints, C7, T6, and L3 spine. In the evaluation of TS, a pressure as much the PPT value of each point was applied with pain pressure algometer ten times with a 1-second interstimulus interval. TS was calculated was by subtracting the rating at 0 seconds from the rating at 10 seconds. For the assessment of conditioned pain modulation (CPM), the first stimulus was applied to trapezius with the pressure that induced a pain intensity of 4/10 points on a VAS. After that, the right hand of the patient was immersed in 7 ^{0}C water for 20 seconds to create a conditioning stimulus. The second stimulus was applied to the trapezius. The ratio between the first and second VAS values was defined as CPM. Disease activity (BASDAI), disability (Istanbul Low Back Pain Disability Index: ILBPDI), quality of life (Ankylosing Spondylitis Quality of Life Questionnaires: ASQoL), sleep quality (Pittsburg Sleep Quality Index: PSQI), VASpain, depression (Beck Depression Inventory: BDI) and fatigue (Fatigue Severity Scale: FSS) were assessed. Comorbidities, fibromyalgia (Fibromyalgia Rapid Screening Tool: FIRST) were noted.

Results: One hundred patients (64 female) and 50 controls (32 female) were recruited. The mean age of patients and healthy controls were 42.31 (SS: 1.0) and 43.64 (SS:1.5), respectively. Central sensitization was detected in 60 of 100 AxSpA patients. When QST results were compared between the patient and control groups, all PPT scores were found lower ($p< 0.05$) in patients, but there was no significant difference between TS values. Regarding the comparison of the patients with and without CS, sacroiliac, and trapezius PPT scores were found lower in the patients with CS ($p< 0.05$). On the other hand, there was no significant difference between the groups in the mean measures of the other PPT and TS scores ($p >0.05$). CPM scores were significantly lower ($p=0.048$) and BASDAI, ASQoL, BDI, ILBPDI, PSQI, FSS, and FIRST scores were significantly higher ($p< 0.001$) in the patients with CS (Table). In regression analysis, female gender, morning stiffness duration, CPM, BDI, and FSS scores were detected as related parameters with CSI scores.

Conclusion: Central sensitization is an essential entity in axSpA patients, which affects their clinical and functional situation and quality of daily life negatively. The central sensitization assessment should be taken into consideration to determine the treatment strategy in axSpA patients.

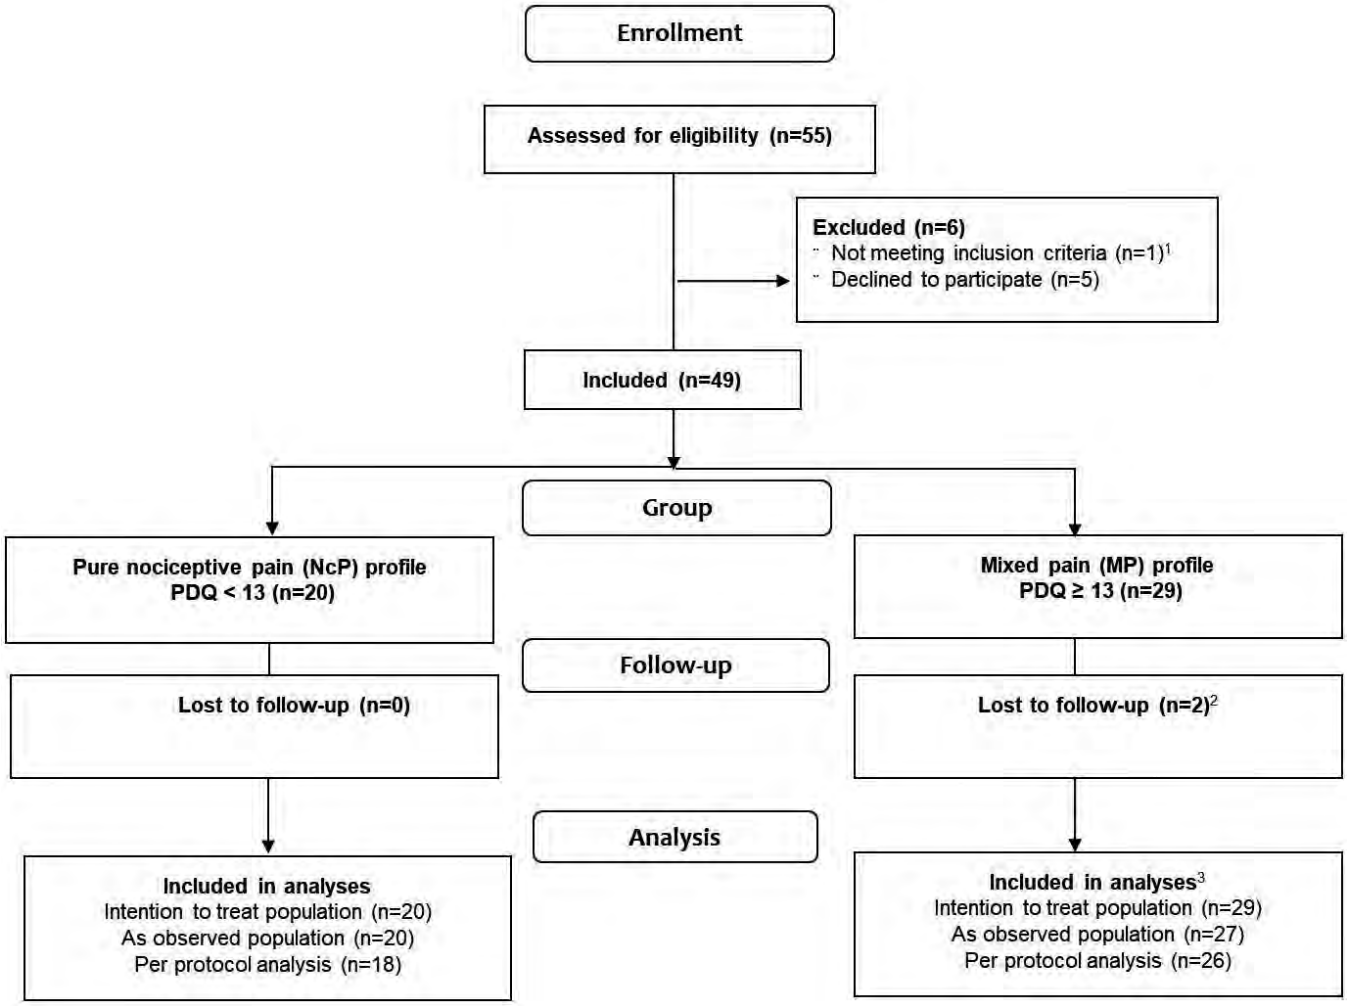
Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

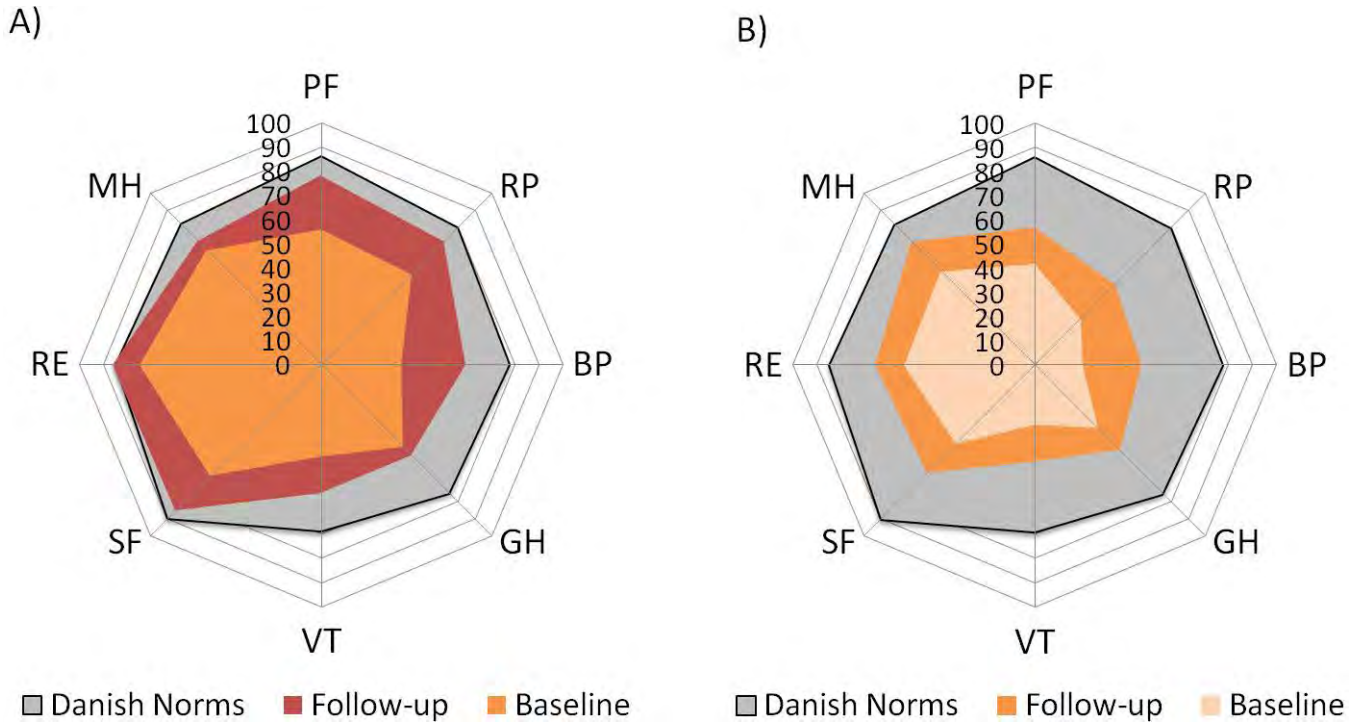


Flow chart 1Did not fulfill axSpA classification criteria. 2Resons for drop out: One participant moved to another hospital and one participant was hospitalized. 3As observed refers to participants with available data for analyses, and per protocol to participants with available data for analyses and adherence to the pre-specified protocol.

Background/Purpose: Despite better control of inflammation, many patients with axial spondyloarthritis (axSpA) still report pain, although they could be in remission. This suggests that in these patients chronic pain may prompt central sensitization. Our objective was to explore the prognostic value of the painDETECT questionnaire (PDQ) in relation to treatment outcomes in axSpA

Methods: AxSpA patients with high disease activity as an indication to initiate or switch a bDMARD were eligible. The PDQ score was used to distinguish participants with nociceptive pain (NcP) mechanisms from participants with mixed pain (MP); NcP was defined by a PDQ score < 13 vs. ≥13. The primary outcome was BASDAI50 responses at 12 weeks; logistic regression analysis models were used to determine the prognostic value of the NcP. Changes in continuous outcomes such were analyzed using analysis of covariance. Health related quality of life (HR-QoL) was addressed using SF-36.

Results: 49 axSpA patients were included; twenty (41%) had an NcP phenotype according to the PDQ score. BASDAI50 responses were reported by 40% (8/20) and 28% (8/29) NcP and MP groups, respectively. However, a prognostic value was not found in relation to the primary outcome (crude odds ratio [95% confidence interval] 1.75 [0.52



Mean SF-36 scores for Danish axSpA patients stratified by pain profiles. (A) axSpA patients classified as pure nociceptive pain (NcP) profile at baseline (B) axSpA patients classified as mixed pain (MP) profile. Mean SF-36 scores for Danish norms are also shown. PF, physical function; RP, role physical; BP, bodily pain; GH, general health; VT, vitality; SF, social functioning; RE, role emotional; MH, mental health.

to 5.87]. Across most of the secondary outcomes, axSpA NcP phenotype patients reported to have the most improvements in the HR-QoL measures.

Conclusion: These data indicate influence of personalized management strategies according to patients' pain phenotypes for stratification of axSpA patients in RCTs.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatic and musculoskeletal diseases, physician global assessment (PhGA) is a major factor of treatment decision. However, it is not well-known which disease manifestations contribute to PhGA in early axSpA and if contextual factors have an impact. The objective of this study is to investigate determinants of PhGA and the influence of contextual factors on this relationship in patients with early axSpA.

Methods: Five-year data from DESIR, a cohort of early axSpA, were analysed. Clinical data were collected every 6 months up to 2 years and annually thereafter. The primary analysis included all patients, and the subgroup analysis patients with follow-up MRI at 2 and/or 5 years. PhGA over 5 years was the outcome of interest. Univariable generalized estimating equation (GEE) models were used to investigate relationships between potential determinants and PhGA. Longitudinal relationships were investigated in autoregressive models. Effect modification by contextual factors (educational level, gender and age) was tested and, if significant, models were stratified. Univariable analyses were chosen to better assess the contributory explanatory effects of each of the determinants in each of the strata.

Results: A total of 708 patients were included, mean age 33.7 (SD 8.6) years, 46% male, 41% lower educated. The subgroup consisted of 220 patients with similar characteristics. Higher BASDAI questions 1-6, SJC28, TJC53, Maas-

Table 1. Factors associated with PhGA over time in gender/age-stratified groups in univariable analysis

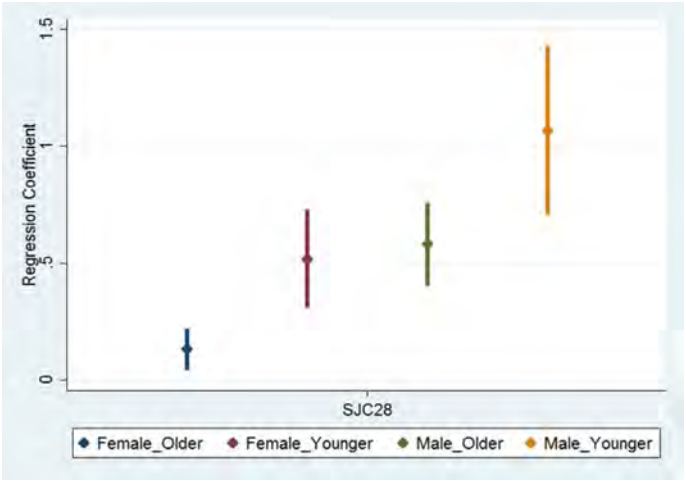

Figure 1. Impact of swollen joint count on physician global assessment across gender and age groups. Regression coefficients (95% CI) of the effect of SJC28 on PhGA in the univariable GEE analyses across gender/age-stratified groups (in an ascending order).

tricht Ankylosing Spondylitis Enthesitis Score (MASES), CRP and BASMI were associated with a higher PhGA (Table 1). Gender and age were effect modifiers of SJC28; the effect was largest in the younger male stratum (β [95% CI]; 1.07 [0.71, 1.43]), and smallest in the older female stratum (0.13 [0.04, 0.22]) (Figure 1). Autoregressive GEE models revealed the same determinants of PhGA and the same pattern of effect by gender and age.

Conclusion: Patient's subjective symptoms, peripheral arthritis, enthesitis, higher CRP and impaired spinal mobility contribute to explain PhGA in patients with early axSpA irrespective of gender and age. But physicians consider the presence of swollen joints as more important in males than in females.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: Axial SpA

Session Type: Poster Session D

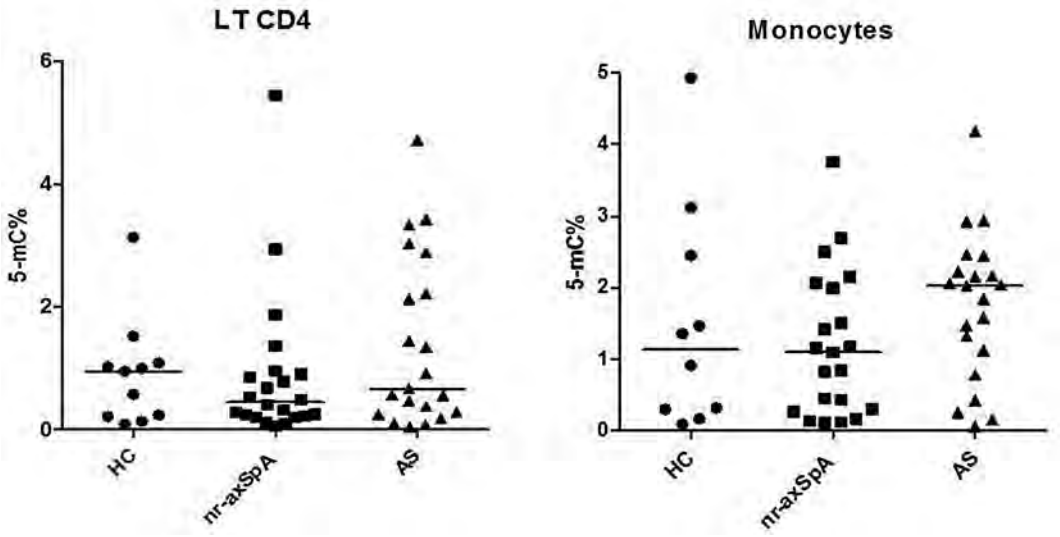
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (ax-SpA) corresponds to a group of chronic inflammatory disease mainly affecting the axial skeleton. TNFα and IL-17A have been identified as key inflammatory mediators driving the inflammatory process of ax-SpA. Epigenetics refers to different mechanisms that alter gene expression without involving changes in DNA sequence. The mechanisms of epigenetics include microRNA, histone modifications or DNA methylation. DNA methylation is associated with a repressed chromatin state and inhibition of gene expression. It is recognized that aberrant DNA methylation can result in immune cell autoreactivity. Epigenetics have been rarely evaluated in ax-SpA. We previoulsy reported that patients with ankylosing spondylitis (AS) had an imbalance between HAT and HDAC activities (Toussirot E et al, PlosOne 2013). In this study, we aimed to evaluate the global DNA methylation of patients with ax-SpA.

Methods: Case-control study (NCT03092583). Patients with radiographic (AS) or non radiographic (nr) ax-SpA (ASAS criteria) and healthy controls (HC) were evaluated. All the patients were biologic naïve and under NSAIDs. Disease activity was evaluated by BASDAI and ASDAS. CD4+T cells and CD14+ monocytes were isolated form peripheral blood and then DNA was extracted (E.Z.N.A. Blood DNA kit, Omega Bio-Tek). Global DNA methylation (5-mC) was determined using MethylAmp global DNA methylation quantification kit (Epigentek) using 150ng of total DNA.

Results: 25 patients with AS (18 M; mean age ± SEM: 48.9 ± 3.5 y; mean disease duration: 14.9 ± 2.2 y; B27+: 84%), 21 with nr-axSpA (11 M; age: 42 ± 3.3 y; disease duration: 7.9 ± 2.3 y; B27+: 68%) and 11 HC (7 M; age: 48.4 ± 3.9 y) were evaluated. Patients had active disease (BASDAI and ASDAS in AS and nr-axSpA: 5.1 ± 0.4 and 5.4 ± 0.5; 4.7 ± 0.4 and 5 ± 0.4, respectively). In CD4+ T lymphocytes, global DNA methylation was lower in the whole group of patients (AS and nr-ax-SpA) compared to HC (0.91 ± 0.26 *vs* 1.08 ± 0.19 % of 5-mC) (NS). Conversely, DNA methylation was higher in monocytes from patients compared to HC (1.43 ± 0.16 *vs* 1.15 ± 0.5 % of 5-mC) (NS). When analysing the results between ax-SpA subgroups, an hypomethylation was more evident in the CD4+T lymphocytes from patients with nr-axSpA compared to AS and HC, a result that was not observed in the monocyte subpopulation (Figure).

Figure: global DNA methylation of CD4+ T lymphocytes and monocyctes from patients with ankylosing spondylitis (AS), non radiographic axial spondyloarthritis (nr-ax-SpA) and healthy controls (HC)



Conclusion: A global DNA hypomethylation is observed in patients with ax-SpA, especially in the nr-axSpA subgroup. These results were more evident in T CD4+ lymphocytes. Additional analysis on a larger series of patients is required to confirm these preliminary results. In addition, we aim to examine the specific DNA methylation status of the TNF promoter gene.

Notes: [1] Unless otherwise noted variables are mean (SD)

Abbreviations: ADA, adalimumab; ASDAS, assessment of disease activity; axSpA, Axial spondyloarthritis; BASDAI, bath ankylosing spondylitis disease activity index; CRP, C-reactive protein; IXE, ixekizumab; MRI, magnetic resonance imagining; N, number of patients with non-missing ASAS40 assessment; n, number of patients in variable; Non-Resp, ASAS40 non responsive; Resp, ASAS40 responsive; SD, standard deviation; SIJ, sacroiliac joints; SPARCC, Spondyloarthritis Research Consortium of Canada

Background/Purpose: Biologic therapy is recommended in patients with active ankylosing spondylitis (AS) despite adequate trial of NSAIDs. Biologic treatment in AS are currently limited to TNF and IL-17A inhibitors (IL-17Ai). It is unknown whether there are predictors of AS patients who only respond to 1 of these mechanisms of action or respond to switching from TNF-blocker to IL-17Ai. This post-hoc analysis evaluated whether patients who did not respond to TNF inhibitor adalimumab (ADA) but did subsequently respond to IL-17Ai ixekizumab (IXE) differed from those that responded to both ADA and subsequent IXE.

Methods: The analysis included patients from the phase-3 COAST-V trial in bio-naive patients with active AS (BASDAI ≥4 and back pain ≥4 on VAS of 0-10). There were 341 patients randomized 1/1/1/1 to IXE 80 mg/2 weeks (wks) (Q2W), IXE 80 mg/4 wks (Q4W), ADA 40 mg Q2W (reference arm), and placebo (PBO) for the 16-week blinded-treatment period. Of these, 329 entered the dose double-blind extended treatment period (wks 16 to 52). Those who received PBO or ADA were re-randomized to receive IXE 80 mg Q4W or Q2W. Patients were stratified as responders or non-responders based on their Assessment of Spondyloarthritis International Society (ASAS) 40 response at wks 16 and 52. Data for the 2 IXE dose groups were pooled.

Results: Overall, more patients responded to IXE than ADA at wk 16.[1] Based on ASAS40 response at wks 16 and at wk 52, 30.9% of patients responded to both initial ADA and subsequent IXE, 23.5% of patients did not respond to initial ADA but did respond to subsequent IXE, 45.9% of patients responded to IXE at both time points, and 12.3% of patients did not respond to IXE at wk 16 but did so at wk 52. Across the groups, patients were of similar age and predominantly males, though there were proportionally more women among those who did not respond to either ADA or IXE at wk 16. No meaningful differences were observed in disease duration or baseline clinical disease activity. However, ADA non-responders at wk 16/IXE responders at wk 52 had numerically lower baseline (mean[SD]) C-reactive protein (11.2 [11.2]), lower magnetic resonance imaging (MRI) Spondyloarthritis Research Consortium of Canada (SPARCC) scores of the spine (11.6 [12.1]), and lower MRI SPARCC score of the sacroiliac joints (1.1 [2.2]) than ADA responders at wk16/IXE responders at wk 52 patients (16.0 [17.1], 24.6 [32.6], and 5.5 [9.8]), respectively (Table 1).

Conclusion: In this analysis, patients who did not respond to ADA but subsequently responded to IXE exhibited overall lower levels of inflammation, as measured by CRP and MRI of the spine or sacroiliac joints, compared with patients who responded on ADA and also after switching to IXE. Along with comparative findings in patients who continuously received IXE and responded at both wks 16 and 52 or wk 52 only, these data indicate that IXE is efficacious in patients with active AS irrespective of inflammation level, assessed by CRP and MRI. Alternatively, lower baseline inflammation may be a predictor of delayed response.

SESSION INFORMATION

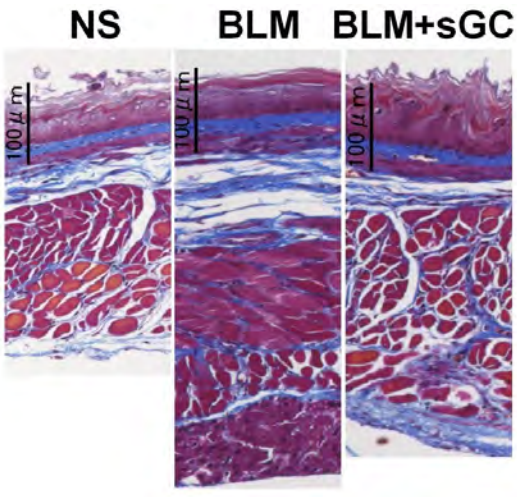
Session Date: Monday, November 9, 2020

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

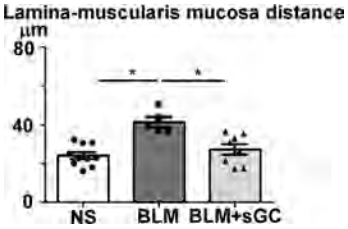
Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

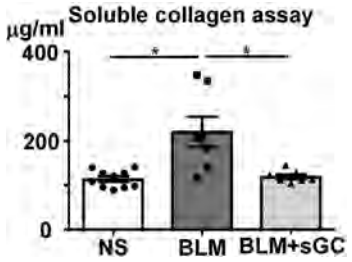
Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune-mediated connective tissue disorder. Although the etiology of the disease remains undermined, SSc is characterized by fibrosis and proliferative vascular lesions of the skin and internal organs. SSc involves the gastrointestinal tract in more than 90% of patients. Soluble guanylate cyclase stimulator (sGC) is used to treat pulmonary artery hypertension (PAH), and has been shown to inhibit experimental skin fibrosis. The aim of this study is to investigate whether bleomycin (BLM) -treated mice show gastrointestinal fibrosis, and find a therapeutic strategy to the lesion.



Blomycin caused gastrointestinal fibrosis



Bleomycin induced mice reduced ITR%



The treatment of sGC improved gastrointestinal fibrosis

Methods: Female C57BL/6J mice were treated with BLM or normal saline by subcutaneous implantation of osmotic minipump. These mice were sacrificed on day 28 or day 42. Gastrointestinal pathologies were examined by Masson Trichrome staining. The expression of fibrosis-related genes in gastrointestinal tract were analyzed by real-time PCR, and the levels of collagen in the tissue was measured by Sircol collagen assay. To evaluate peristaltic movement, the small intestinal transport (ITR%) was calculated as [Dyeing distance×(Duodenum- Appendix)] -1 ×100 (%). We treated BLM-treated mice with soluble guanylate cyclase (sGC) or DMSO orally and analyzed them on day 42.

Results: Histological examination revealed that fibrosis from lamina propria to muscularis mucosa in the esophagus was significantly increased in BLM-treated mice, suggesting that BLM induces esophageal fibrosis in C57BL/6J mice. In addition, the levels of Col3a1 and CTGF were significantly increased in BLM-treated mice. More severe fibrosis was observed in the mice sacrificed on day 42 than the mice sacrificed on day 28. The ITR% was found to be significantly lower in BLM-treated mice, suggesting that gastrointestinal peristaltic movement was reduced in BLM-treated mice. Furthermore, we demonstrated that sGC treatment significantly reduced fibrosis of esophagus and intestine in BLM-treated mice, by histological examination and Sircol collagen assay.

Conclusion: These findings suggest that BLM induces gastrointestinal fibrosis in C57BL/6J mice, and treatment with sGC improves the BLM-induced gastrointestinal lesion.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Our previous study demonstrated that Heat shock protein 90 (Hsp90) is overexpressed in the skin of patients with systemic sclerosis (SSc), in cultured SSc fibroblasts and preclinical models of SSc. HSP90 is a new regulator of canonical TGF-β signalling and its inhibition prevents the stimulatory effects of TGF-β on collagen synthesis and dermal fibrosis in three preclinical models of SSc. Herein, we aimed to evaluate the efficacy of Hsp90 inhibitor (17-DMAG) in the treatment of established experimental dermal fibrosis induced by bleomycin.

Methods: Design consisted of three control groups, I (NaCl-s.c./6 weeks), II (bleomycin-s.c./3w and NaCl-s.c./3w), III (bleomycin-s.c./6w), and 2 treatment groups (bleomycin-s.c./6w). During the last 3 weeks, one group was treated with 17-DMAG 0.5mg/kg-i.p. every third day, whereas one group (with nintedanib 50mg/kg-p.o. twice daily) served as a comparator with already published efficacy in this setting. Total of 40 BL6 mice were examined weekly for weight, activity and fur texture. The effects of 17-DMAG were determined by assessment of dermal thickness (HE-staining), collagen content (hydroxyproline assay), myofibroblast counts (α-SMA staining) and of 23 serum inflammatory cytokines/chemokines (Mouse-Cytokine-23-plex, Bio-Rad-Laboratories).

Results: 17-DMAG decreased dermal thickening by 53±3% ($p< 0.001$) (nintedanib by 46±2%,$p< 0.001$), collagen content by 48±5% ($p=0.004$) (nintedanib by 50±4%,$p=0.003$), myofibroblast counts by 42±9% ($p< 0.001$) (nintedanib by 44±7%,$p< 0.001$), and the count of CD3+ cells in the dermis by 46±7% ($p< 0.001$) and serum levels of IL-1a, IL-6, IL-12(p40), CXCL1, MCP-1, MIP-1a/b, RANTES (in all: $p< 0.05$) compared to vehicle-treated mice injected with bleomycin for 6w. Moreover, 17-DMAG also induced regression of pre-established fibrosis to below the levels of vehicle-treated mice injected with bleomycin for 3w and NaCl for 3w, i.e. the pre-treatment levels, (dermal thickness by 14±3%, collagen content by 20±5%, myofibroblast counts by 13±9%; whereas in nintedanib by 10±3%, 21±4%, 17±7%, respectively; in all: $p< 0.05$), and the count of CD3+ cells in the dermis by 22±7% ($p=0.006$) and levels of IL-12(p40), CXCL1, MCP-1, MIP-1b, RANTES (in all: $p< 0.05$). No significant weight loss, decrease in activity or changes in fur texture were observed upon 17-DMAG treatment.

Conclusion: This is the first study on effects of Hsp90 inhibitor 17-DMAG in the treatment of established dermal fibrosis. We demonstrate that 17-DMAG effectively prevents the progression and induces regression of established bleomycin-induced dermal fibrosis, in an extent that was comparable to nintedanib in this study (which was recently FDA approved for slowing the rate of decline in lung function in adults with SSc-ILD). 17-DMAG also reduced the T-cell infiltrate in the dermis and the systemic levels of inflammatory cytokines/chemokines. 17-DMAG was well tolerated without obvious clinical signs of toxicity. These data suggest that Hsp90 could be a novel potential target in the treatment of SSc dermal fibrosis.

DNASE1L3 R206C Polymorphism, a Systemic Sclerosis Risk Factor, Causes Impaired Digestion of Genomic DNA in Apoptosis-derived Extracellular Vesicles

Brian Skaug[1], Julio Charles[1], Jacob Couturier[2], Dorothy Lewis[2], Maureen Mayes[3] and Shervin Assassi[3], [1]University of Texas Houston, McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX, [2]University of Texas Houston McGovern Medical School, Division of Infectious Diseases, Houston, TX, [3]University of Texas Houston McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Two independent studies on genetic risk factors for systemic sclerosis (SSc) identified a polymorphism of Deoxyribonuclease 1-like 3 (*DNASE1L3)* associated with increased SSc risk. This polymorphism is located in a coding region and results in an amino acid substitution of Arg 206 to Cys (R206C). The mechanisms by which *DNASE1L3* R206C polymorphism increase SSc risk are unknown. Based on prior studies indicating that DNASE1L3 is secreted into the circulation and digests DNA in apoptosis-derived extracellular vesicles (EVs), we sought to determine the effect of *DNASE1L3* R206C polymorphism on this activity. We tested plasma samples from SSc patients and healthy controls (HCs) with vs. without *DNASE1L3* R206C polymorphism for their ability to digest genomic DNA in apoptosis-derived EVs.

Methods: Plasma from SSc patients and HCs were previously collected as part of the Scleroderma Family Registry and DNA Repository based in Houston. Groups of SSc patients and HCs homozygous for the major allele (*DNASE1L3* R206 wild-type, or WT), heterozygous, or homozygous for *DNASE1L3* R206C were identified and matched for age and sex (with the exception of HCs homozygous for *DNASE1L3* R206C, since there were only two HCs with this genotype in the Registry). SSc patients were also matched for disease duration, limited vs diffuse cutaneous subtypes, and SSc-associated autoantibodies (Table 1). DNA-containing EVs were prepared by inducing apoptosis of cultured Jurkat cells with staurosporine, followed by isolation of the apoptosis-derived EVs by centrifugation. EVs were added to plasma samples and incubated for one hour, followed by extraction of the DNA. Each plasma sample was tested in triplicate. The extracted genomic DNA was quantified by qPCR (Figure 1), and the percent of genomic DNA digested in each sample was compared to that of a reference HC with *DNASE1L3* R206 WT. The relative DNA digestion in each group was compared by one-way ANOVA.

Results: Plasma from SSc patients and HCs heterozygous for *DNASE1L3* R206C polymorphism had less digestion of EV-associated DNA on average than plasma from *DNASE1L3* R206 WT SSc patients and HCs. Minimal to no digestion of EV-associated DNA was observed in plasma from individuals homozygous for *DNASE1L3* R206C (Figure 2).

Conclusion: Plasma from SSc patients and HCs harboring *DNASE1L3* R206C polymorphism has impaired ability to digest EV-associated genomic DNA. These findings solidify the hypotheses that circulating DNASE1L3 is a major determinant for digestion of DNA in apoptosis-derived EVs and that the R206C polymorphism reduces this activity.

Table 1

Demographics and disease characteristics of healthy controls and systemic sclerosis patients whose plasma was assayed

	Healthy control (n = 22)			Systemic sclerosis (n = 29)		
***DNASE1L3* genotype**	R206 WT (n = 10)	R206C heterozygous (n = 10)	R206C homozygous (n = 2)	R206 WT (n = 10)	R206C heterozygous (n = 10)	R206C homozygous (n = 9)
Age (years), mean (SD)	57.1 (8.4)	57.4 (11.9)	35.5 (13.4)	57.7 (8.1)	57.4 (7.7)	58.2 (6.8)
Female, n (%)	9 (90)	9 (90)	2 (100)	9 (90)	9 (90)	8 (88.9)
Disease duration in years, mean (SD)				9.3 (7.8)	8.8 (5.7)	9.4 (7.8)
Diffuse skin involvement, n (%)				4 (40%)	4 (40%)	4 (44.4%)
SSc-associated autoantibody, n (%)						
anti-Topoisomerase I				2 (20%)	2 (20%)	2 (22.2%)
anti-RNA Polymerase III				2 (20%)	3 (30%)	2 (22.2%)
anti-Centromere				4 (40%)	5 (50%)	3 (33.3%)

WT: wild type (homozygous for the major allele encoding Arg 206, R206C: Arg-->Cys at amino acid 206, SD: standard deviation, SSc: systemic sclerosis

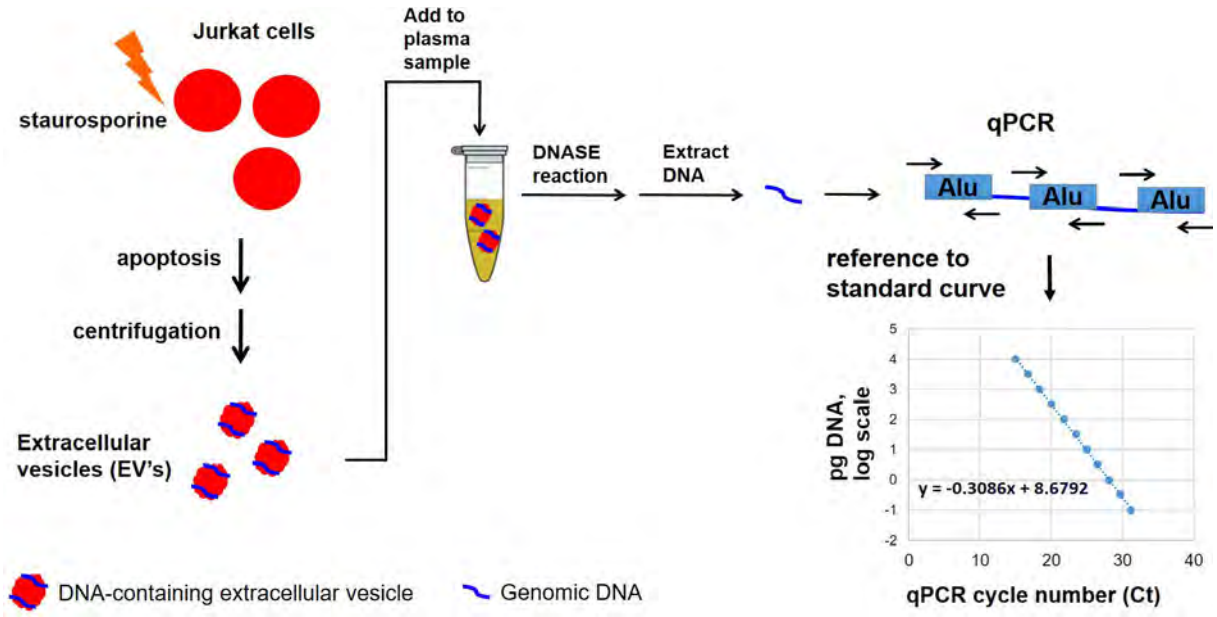

Figure 1. Schematic of assay to measure digestion of genomic DNA in apoptosis-derived extracellular vesicles (EVs) by plasma samples

Given that the *DNASE1L3* R206C polymorphism is a robustly-replicated risk factor for SSc, these results suggest that excess DNA in apoptosis-derived EVs may have a pathogenic role in SSc.

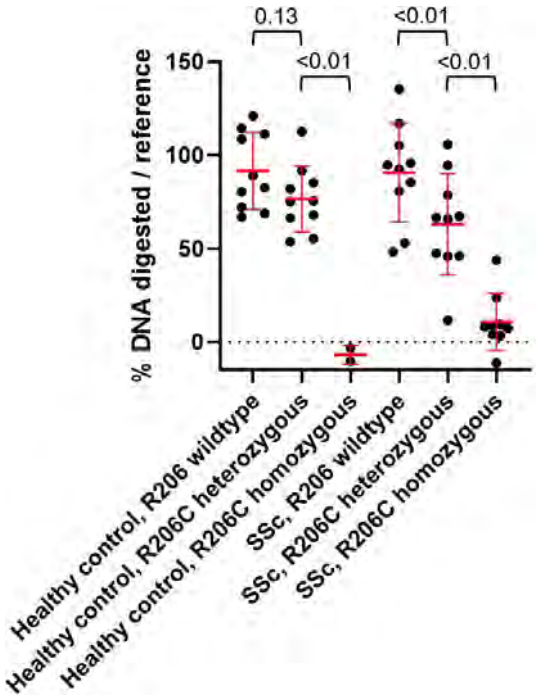

Figure 2. Impaired digestion of EV-associated genomic DNA in plasma from DNASE1L3 R206C SSc patients and healthy controls. Relative percentage of genomic DNA digested in each sample is plotted for each individual based on the mean of triplicates for each plasma sample. Each sample was compared to a reference healthy control with DNASE1L3 R206 WT. Red midlines and error bars indicate the mean and standard deviation for each group, respectively. Groups were compared by one-way ANOVA, with p values shown at top. SSc: systemic sclerosis

Abstract Number: 1908

Establishment of iPSc and Differentiated Endothelial Cells of Systemic Sclerosis Associated Pulmonary Arterial Hypertension ; Functional and Molecular Analysis

Yuki Kudo[1], Masaru Kato[2], Yuhei Shibata[1], Michihito Kono[2], Yuichiro Fujieda[2], Olga Amengual[2], Kenji Oku[2] and Tatsuya Atsumi[3], [1]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [2]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [3]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine, Hokkaido University, Sapparo, Hokkaido, Japan

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) occurs either primarily or in association with other diseases such as connective tissue diseases. PAH associated with systemic sclerosis (SSc-PAH) is of particularly clinical significance since its outcomes remain unfavorable despite modern PAH therapies, suggesting its distinctive

pathogenesis. Previous studies have indicated the abnormality of endothelial cells (ECs) in the lung of SSc-PAH, but its details have yet to be clarified owing to the poor accessibility to lung samples from those patients. To overcome the problem and to elucidate the pathogenesis of SSc-PAH, we established SSc-PAH specific ECs differentiated from induced pluripotent stem cells (iPSc) and performed their functional and molecular analysis.

Methods: Peripheral blood mononuclear cells were obtained from a patient with SSc-PAH and a healthy donor. Yamanaka factors, including OCT3/4, SOX2, KLF4 and L-MYC, were transfected into peripheral blood mononuclear cells using sendai virus vector to establish iPSc. Following more than five passages of iPSc, ECs were differentiated with the culture system containing BMP-4, Activin, bFGF, CHIR99021, Y-27632, VEGF and SB431542. Differentiated ECs were confirmed by immunocytochemistry with specific markers, including VE-cadherin, KDR and CD34. The vasculogenesis and cell proliferative capacity of ECs were evaluated by the tube formation assay and the BrdU assay, respectively. RNA-sequencing was performed to evaluate differentially expressed genes between SSc-PAH ECs and healthy ECs.

Results: SSc-PAH ECs and healthy ECs equally VE-cadherin, KDR and CD34 with similar morphologies, but were functionally distinct. The cellular uptake of BrdU was higher (0.49±0.05(abs) vs 0.30±0.01(abs), $p< 0.05$, n=3) while the tube formation was impaired (31.2±2.0(mm) vs 47.0±1.3(mm), $p< 0.01$, n=3) in SSc-PAH ECs compared to healthy ECs, indicating disproportionately reduced vasculogenesis despite accelerated proliferation of SSc-PAH ECs. RNA-sequencing revealed some differentially expressed genes (DEGs) and significantly enriched Gene Ontology terms, including blood vessel development, vascular endothelial growth factor-activated receptor activity, regulation of cell proliferation and cell adhesion. From these terms, we detected some important DEGs, geneX, Y and Z, which have a potential to be involved in the pathogenesis of SSc-PAH.

Conclusion: We detected, at a cellular level, the alterations of ECs in patients with SSc-PAH, such as impaired vasculogenesis, facilitated cell proliferation, differentially expressed genes, enriched Gene Ontology terms. The current findings might be related to the pathogenesis of SSc-PAH.

High-density Proteomic Analysis of Skin Blister Fluid and Plasma in Systemic Sclerosis Identifies Local and Systemic Differences for Key Proteins

Kristina Clark[1], Corrado Campochiaro[2], Eszter Csomor[3], Adam Taylor[3], Katherine Nevin[3], Mary Morse[3], Voon Ong[4], Emma Derrett-Smith[5], Nicolas Wisniacki[3], Shaun Flint[3] and Christopher Denton[1], [1]University College London, London, United Kingdom, [2]Royal Free Hospital NHS trust, London, United Kingdom, [3]GlaxoSmithKline, Stevenage, United Kingdom, [4]UCL, London, United Kingdom, [5]University College London Division of Medicine, London, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Simultaneous analysis of multiple proteins in biological fluids offers insight into the pathogenesis of SSc. Here, we report a proteomic analysis of plasma and dermal interstitial fluid in SSc compared with healthy controls (HC).

Methods: The prospectively collected BIOPSY cohort recruited 52 SSc patients (21 early dcSSc, 15 established dcSSc, 16 lcSSc) and 16 matched HC. 36 (69%) of the SSc patients are female. Mean baseline skin score (MRSS) for early dcSSc was 21 (sd 11.2). This analysis utilised forearm skin blister fluid obtained using the dermal suction blister method and paired simultaneous plasma samples from early dcSSc and HC at baseline. These were assayed using the Olink antibody platform with proximity extension assay (www.olink.com) and reported as normalized protein expression (NPX), corresponding to log2 (expression). T-test with FDR correction ($p< 0.05$) assessed statistical significance. Pathway analysis was conducted by STRING consortium 2020.

Results: 1196 proteins were analysed in paired blister/plasma samples from 14 early dcSSc patients and 16 HC. 447 proteins were significantly different in the blister fluid of early dcSSc patients compared with HC (see Table 1), whereas in plasma this was only 183 proteins. Of these, 130 proteins were simultaneously different in both blister fluid and plasma of early dcSSc including key cytokines associated with fibrosis and vasculopathy such as IL-6, VEGF-1, MCP-1, COL4A1, COMP, Thy1 and THBS4. No correlation was seen between any of these proteins and MRSS.

There were 310 proteins significantly elevated in blister fluid alone in early dcSSc patients compared to HC. These included cytokines (IL7, IL18, OSM), chemokines (CCL7, CCL18, CCL3), matricellular proteins (CYR61 and osteopontin). Pathway analysis using all significantly elevated proteins in blister fluid in early dcSSc compared to HV identified the top GO biological processes as immune system, response to stimulus, immune response and cell communication (FDR< 0.01). KEGG pathway analysis highlighted cytokine-cytokine receptor interaction, cell adhesion molecules, MAPK signalling pathway and the PI3K-AKT signalling pathway (FDR< 0.01).

Table 1. Top 20 most upregulated proteins in skin blister fluid for early dcSSc (n=14) compared with healthy control (HC, n=16)

Conclusion: Numerous dysregulated proteins were identified in dermal blister fluid and plasma of early dcSSc patients. Substantially more were identified in dermal blister fluid, highlighting the potential of this technique for providing detailed information on local pathologic processes. A subset of proteins were dysregulated in both plasma and blister fluid, suggesting these may reflect systemic abnormalities. Further work will utilise this cohort to integrate gene and protein expression across the full spectrum of early dcSSc, established dcSSc and lcSSc.

Integrated Molecular Analysis of Systemic Sclerosis Skin and Blood Highlights Significant Differences Between Major Autoantibody Subgroups

Kristina Clark[1], Corrado Campochiaro[2], Eszter Csomor[3], Adam Taylor[3], Katherine Nevin[3], Nicholas Galwey[3], Mary Morse[3], Voon Ong[4], Emma Derrett-Smith[5], Shaun Flint[3] and Christopher Denton[1], [1]University College London, London, United Kingdom, [2]Royal Free Hospital NHS trust, London, United Kingdom, [3]GlaxoSmithKline, Stevenage, United Kingdom, [4]UCL, London, United Kingdom, [5]University College London Division of Medicine, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: The major antinuclear autoantibodies of systemic sclerosis (SSc) associate with different skin score trajectories and risk of internal organ manifestations. To elucidate molecular differences between ANA-defined subgroups, we utilised the prospective BIOPSY cohort of well-characterised SSc patients.

Methods: The prospectively collected BIOPSY cohort recruited 52 SSc patients (21 early dcSSc, 15 established dcSSc, 16 lcSSc) and 16 matched HC. 36 (69%) of the SSc patients are female. Mean disease duration in the early dcSSc cohort was 24 months (sd 12 months). ANA frequency in BIOPSY reflected the overall dcSSc population: anti-topoisomerase-1 (ATA) n= 14 (27%), anti-RNA pol III (ARA) n= 12 (23%) and other n=26 (50%). Mean baseline skin score (MRSS) for early dcSSc was 21 (sd 11.2).At a group level mRSS peak was 21.9 (11.8) at 3 months and fell to 19.1(10.5) at 12 months. For comparison, the BIOPSY cohort also included cases of established dcSSc (n=15, mean disease duration 11.3 years), lcSSc (n=16) and matched health controls (HC) (n=16). Serum biomarkers of ECM turnover and fibrosis were measured every three monthly and genome-wide transcriptomic profiling of whole skin and whole blood performed by RNA-Seq. Statistical analysis used RStudio with ANOVA, and Tukey post-hoc test. Differential gene expression used the Bioconductor limma software, with standard thresholds for significance.

Results: We found clear differences when early dcSSc patients were analysed by major ANA subset for longitudinal change in serum markers of fibrosis and in whole skin gene expression, suggesting a mechanistic basis for the distinct clinical phenotypes associated with hallmark ANAs. At baseline, there was no significant difference in soluble markers by major ANA subset. During follow-up, significant differences were observed in HA, TIMP1, and PIIINP at 6

Table 1. Sample genes (60 of 854) with the greatest differential expression in skin of early dcSSc compared to healthy controls with adjusted p value.

and 12 months ($p< 0.05$), revealed by Tukey post-hoc analysis to reflect stable levels in ATA+ patients compared to progressively increased levels in the other subgroups.

There were 854 significantly differentially expressed genes in skin between early dcSSc and HC (Table 1) and unsupervised clustering also differentiated ARA and ATA patients with early dcSSc. 68 genes were significantly differentially expressed in skin between ATA and ARA patients (Table 2). Whilst 206 genes were differentially expressed in PBMC between early dcSSc compared with HC, only 2 genes were significantly different between ATA and ARA PBMCs (CACNG6; PLXNA2). Functional analysis suggested key biological processes distinguishing ARA and ATA skin included lipid metabolic process (PDE3B, ADIPOQ, GPAM), PPAR signaling pathway process (CD36, FABP4, PLIN1), and response to endogenous stimuli (FGF2, GPD1, FGF10)

Abstract Number: 1911

IL-11 Expression in Systemic Sclerosis Pulmonary Fibroblasts Is Mediated by Caspase-1

Caya McFalls[1] and Carol Artlett[1], [1]Drexel University College of Medicine, Philadelphia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin-11 (IL-11) has been shown to be associated with idiopathic pulmonary fibrosis, cardiac and kidney fibrosis. However, conflicting data shows IL-11 can be either pro- or anti-fibrotic. Scleroderma (SSc) is a fatal fibrotic disease of the vasculature, skin, and internal organs. Patients die of scarring and dysfunction of organs due to uncontrolled deposition of collagen and other extracellular matrix proteins. Our laboratory has been studying the signaling cascade mediated by caspase-1 in fibrosis. Caspase-1 activates downstream profibrotic cytokines including IL-1β, IL-18, and IL-33. We hypothesize that IL-11 may be linked to the fibrotic process in SSc through activation of caspase-1. Our purpose is to investigate the expression of IL-11 in SSc pulmonary fibroblasts and to determine the role for caspase-1 in this expression.

Methods: Fibroblasts were derived from fibrotic lung from 8 female patients with SSc with diffuse disease who developed pulmonary fibrosis. SSc patients were classified according to the ACR classification criteria for their disease. Pulmonary fibroblasts were also derived from 12 normal individuals who had died of acute events without pulmonary disease. Fibroblasts were cultured at low passage and treated with the caspase-1 inhibitor (Z-YVAD-FMK) or IL-1 receptor antagonist (IL-1RA). RNA was extracted and gene expression for IL-11, IL-11Rα1, and COL1A1 was analyzed using RT-PCR normalized to β-actin.

Results: SSc fibroblasts display a statistical trend for higher basal expression of IL-11 compared to normal fibroblasts ($p=0.07$) with a significantly increased expression of the IL-11 receptor, IL-11Rα1 ($p=0.0002$). When caspase-1 activity is inhibited with Z-YVAD-FMK, IL-11 expression is reduced ($p< 0.0001$), whereas receptor expression is not altered. We further show that IL-11 expression is mediated by IL-1β, as blockade of the IL-1 receptor with IL-1RA significantly reduces IL-11 ($p=0.03$). It did not alter IL-11Rα1 expression. Further studies show that bleomycin induces IL-11 expression in normal lung fibroblasts, and this is inhibited with either Z-YVAD-FMK ($p=0.008$) or IL-1RA ($p=0.02$). However, in our studies, we were unable to induce COL1A1 expression with IL-11 alone.

Conclusion: Our experiments show IL-11 and its receptor, IL-11Rα1, are elevated in SSc. We observed IL-11 expression is dependent on the inflammasome activation of caspase-1 as inhibition of this protein abrogates IL-11 expression. Furthermore, we identify the role for IL-1β in IL-11 expression. Further studies are warranted to determine the role for IL-11 in SSc fibrosis.

Novel Role of Thy-1 (CD90) in the Pathogenesis of Skin Fibrosis

Roberta Goncalves Marangoni[1], Stacey Duemmel[2], Marc Nuzzo[2], Ananta Paine[1], Christopher Ritchlin[3] and Benjamin Korman[3], [1]University of Rochester Medical Center, Rochester, NY, [2]Department of Medicine, University of Rochester Medical Center, Rochester, [3]Department of Medicine, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Thy-1 (CD90) is a GPI-anchored cell surface protein that is highly expressed in subsets of fibroblasts. Previous work has shown that Thy-1 deficiency exacerbates lung fibrosis. In inflammatory arthritis, Thy-1 marks a subset of pathogenic fibroblasts. Thy-1 is overexpressed in skin of patients with systemic sclerosis (SSc), and we previously showed that Thy-1 can serve as an *in vivo* marker of cutaneous fibrosis progression, but its role in pathogenesis remains unclear. This study focuses on the effect of Thy-1's modulation of cutaneous fibrosis.

Methods: To induce fibrosis, Thy-1 deficient mice were treated with subcutaneous bleomycin or crossed with TSK1 mice. Mice were fed chow or high fat diet for 12 weeks before starting bleomycin injections. Bleomycin time-course experiments were performed and skin was harvested at days 5, 12, 21, 35 and 52 and was processed for histology, qPCR and immunohistochemical staining. RNA sequencing was performed on affected skin from both wildtype and Thy-1 null mice treated either with bleomycin or PBS (n=12). Differential gene expression analysis was performed using deSeq2, and pathway analysis was performed using Enrichr. To assess Thy-1's role in SSc severity, Thy-1 expression was correlated to modified Rodnan skin score (MRSS) in publicly available datasets.

Results: Skin biopsies from SSc patients have elevated expression of Thy-1 compared to healthy controls ($p< 0.0001$). Patients with diffuse cutaneous and early disease have increased Thy-1 expression ($p< 0.001$), and this is associated with severity of skin involvement (Spearman 0.63, $p< 0.0001$). Mice lacking Thy-1 show protection from chemically-induced and genetically-mediated cutaneous fibrosis at both the histologic and biochemical levels. Fibrosis was attenuated in the Thy-1 null mice with a ~65% reduction in dermal thickness. While wildtype mice demonstrated resolution of fibrosis by later time-points, Thy-1 null mice showed a defective resolution response implicating different mechanisms of Thy-1 in early and late stages of fibrosis. RNA-seq clustering analysis differentiated control and bleomycin-treated Thy-1 null from wildtype mice. Bleomycin upregulated leukocyte chemotaxis, inflammatory response, and muscle contraction pathways regardless of genotype. In Thy-1 null mice, bleomycin specifically upregulated IL-17 and TNF pathways. Fatty acid metabolism pathways were the main feature that distinguished Thy-1 null from control mice treated with bleomycin. However, feeding Thy-1 null mice a high fat diet did not alter their anti-fibrotic phenotype.

Conclusion: Thy-1 expression is increased in SSc and associated with severity of skin involvement. In complementary murine models of cutaneous fibrosis, Thy-1 deficiency has an anti-fibrotic effect which appears to be mediated by TNF, IL-17 and fatty acid metabolism. Thy-1 appears to have different effects on the temporal stages of fibrosis indicating that targeting Thy-1 early in disease may be a rational approach.

Abstract Number: 1913

Investigation of the Cellular Mechanism for Estradiol-Induced Dermal Fibrosis

DeAnna Baker Frost[1], Alisa Savchenko[2], Adeyemi Ogunleye[3], Milton Armstrong[2] and Carol Feghali-Bostwick[4], [1]The Medical University of South Carolina, Charleston, [2]Medical University of South Carolina, Charleston, SC, [3]University of North Carolina Chapel Hill, Chapel Hill, NC, [4]The Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Estradiol (E2), one of the three forms of estrogen, is pro-fibrotic in the skin because it positively influences ECM production in the dermis. In addition to the direct influence that E2 has on ECM production, E2 also induces pro-fibrotic mediators such as TGFβ1 in a wound healing model[1,2]. Yet, few experiments discuss E2-induced pro-fibrotic mediator production or the transcriptional regulation of these protein(s). Since TGFβ1 is central in the development of organ fibrosis, especially in systemic sclerosis (SSc), delineating the regulation of TGFβ isoforms is important in understanding disease pathogenesis and developing potential therapeutics. Therefore, we investigated which ECM components are directly stimulated by E2-induced TGFβ signaling and the important regulatory proteins for TGFβ transcription and translation.

Methods: We received skin samples from healthy donors of various ages who underwent skin-resection procedures in the Division of Plastic Surgery at the Medical University of South Carolina under an approved IRB protocol. The *ex-vivo* human skin model organ culture was used as previously described[3]. Human primary dermal fibroblasts were isolated from human dermal tissue using the outgrowth method[4]. For experimentation, we used 6-well tissue cul-

ture dishes with 4-3mm punches/well or fibroblasts plated at 1.5-2.0 x 10^5 cells/well in serum-free, phenol red-free DMEM. Steady-state mRNA levels were measured using quantitative PCR (qPCR) and signals normalized to *B2M* and G*APDH* levels. Primary dermal fibroblasts were transfected with siRNA targeted to early growth response 1 (*EGR1*) or control prior to vehicle or E2 treatment.

Results: We report that the transcription of TGFβ1, TGFβ2 and collagen 22A1 (Col22A1), the TGFβ responsive gene, are induced in response to E2 stimulation *in vitro* and *ex vivo*. Mechanistically, Col22A1 induction is blocked by the TGFβ receptor inhibitor SB-431542 despite E2 stimulation. Additionally, blocking E2-induced MAPK activation and *EGR1* transcription inhibit TGFβ1, TGFβ2 and Col22A1 transcription.

Conclusion: We conclude that E2-induced dermal fibrosis occurs in part through induction of TGFβ1, TGFβ2 and Col22A1 which is regulated though EGR1 and the MAPK pathway. Dermal fibrosis is a feature of pro-fibrotic diseases, such as SSc, emphasizing the necessity to understand the underlying mechanism of fibrosis. Here, we suggest a cell signaling mechanism for E2-induced fibrosis and TGFβ regulation. Based on the realization that E2-induced TGFβ1 and TGFβ2 directly increase Col22A1 and contribute to ECM accumulation, therapies that inhibit E2 signaling may reduce dermal fibrosis and present a novel therapeutic alternative in pro-fibrotic diseases.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is characterised by tissue fibrosis of the major organs of the body including the skin, lungs and heart. We have previously reported that the lncRNA HOTAIR plays a central role in the activation of SSc myofibroblasts, the key cellular elements of fibrosis. HOTAIR induces fibroblast activation though H3K27me3 mediated activation of the Notch signalling pathway. Here we aimed to identify the signalling events downstream of Notch that drive SSc myofibroblast activation.

Methods: Patient fibroblasts were obtained from full thickness forearm skin biopsies of 3 adult patients with SSc of recent onset. The lncRNA HOTAIR was expressed in healthy dermal fibroblasts by lentiviral transduction. Hedgehog signalling pathway was inhibited with GANT61 and GLI2 siRNA. Gamma secretase inhibitors RO4929097 and DAPT were used to block Notch signalling. GSK126/503 were used to inhibit Enhancer of Zeste 2 (EZH2).

Results: Overexpression of HOTAIR in dermal fibroblasts induced the expression of the Hedgehog pathway transcription factor GLI2. This is mediated by activation of Notch signalling following epigenetic downregulation of miRNA-34a expression. Inhibition of H3K27 methylation and Notch signalling reduced expression of GLI2 in HOTAIR expressing fibroblasts as well as in SSc dermal fibroblasts. Importantly, the inhibition of GLI2 function using GANT61 or siRNA mitigates the pro-fibrotic phenotype induced by HOTAIR.

Conclusion: Our data indicates that GLI2 expression is stably upregulated in SSc myofibroblasts through HOTAIR and that GLI2 mediates expression of pro-fibrotic markers downstream of Notch.

Leptin Plays a Critical Role in Modulating Dermal Adipose Tissue, Inflammation and Skin Fibrosis

Roberta Goncalves Marangoni[1], Stacey Duemmel[2], Marc Nuzzo[2], Christopher Ritchlin[3] and Benjamin Korman[3], [1]University of Rochester Medical Center, Rochester, NY, [2]Department of Medicine, University of Rochester Medical Center, Rochester, [3]Department of Medicine, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously demonstrated that systemic sclerosis (SSc) patients have substantial reduction in dermal white adipose tissue (dWAT) which correlates with skin fibrosis. In animal models the loss of dWAT precedes dermal fibrosis indicating that this process may be a primary event. Leptin is a major adipokine involved in glucose homeostasis and known to be profibrotic in models of cardiac and lung fibrosis. We previously reported increased serum levels of leptin in patients with SSc. Given the important role of dWAT in SSc and skin fibrosis, we sought to investigate the role of leptin in *in vivo* fibrosis by comparing mice deficient in leptin (*ob*/*ob*) which have a substantially expanded dWAT with mice on diet-induced obesity which is known to increase levels of leptin.

Methods: *ob*/*ob* mice which lack functional leptin and littermate controls were treated with subcutaneous bleomycin or PBS. Wildtype mice were fed chow or high fat diet (60% kcal fat) for 12 weeks at libitum, and then treated with bleomycin or PBS injections. Skin was harvested and processed for histology, qPCR and immunohistochemical analysis. To assess the relevance of this pathway in disease, leptin expression in SSc was evaluated in publicly available gene expression datasets.

Results: *ob*/*ob mice* demonstrated significant protection from bleomycin-induced dermal fibrosis and loss of dermal white adipose tissue at both histological and gene expression level as compared to littermate mice. Conversely, although wildtype mice fed a high-fat diet showed significant expanded dWAT, bleomycin led to a complete loss of dWAT and fibrosis was comparable to mice fed a chow diet. Whereas *ob*/*ob* mice demonstrated a relative lack of inflammatory cellular infiltrate in response to fibrotic stimuli, the diet-induced obesity model showed an exuberant macrophage-rich inflammatory response. Interrogating skin biopsy transcriptome data, we found increased leptin pathway activation ($p< 0.0001$) in patients with SSc and mice treated with bleomycin ($p=0002$).

Conclusion: Our results implicate leptin as a profibrogenic mediator in skin fibrosis. Moreover, while these results continue to implicate the role of dWAT in skin fibrosis, they indicate that the quality rather than the quantity of dermal adipocytes is a key determining factor. A complex interplay between fibroblasts, adipocytes and macrophages define cutaneous fibrogenic potential.

KZR-616, a First-in-class Selective Inhibitor of the Immunoproteasome, Ameliorates Polymyositis in a Murine Model

Marta Del Rio Oliva[1], Michael Basler[1], Darrin Bomba[2], Diana Lam[2], Jennifer Brandl[2], Christopher Kirk[2] and Marcus Groettrup[1], [1]University of Konstanz, Konstanz, Germany, [2]Kezar Life Sciences, Inc, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyositis (PM) is a chronic autoimmune inflammatory myopathy affecting striated muscles and resulting in muscle weakness. PM is a rare disease, and there are limited approved therapies available. High-dose corticosteroids or IV immunoglobulin are commonly used to treat PM, however response is poor and both treatments contribute to comorbidity. Here we have investigated KZR-616, a first-in-class selective inhibitor of the immunoproteasome in C protein-induced myositis (CIM), a mouse model of PM that closely resembles the human disease. Positive results from this study support the rationale for PRESIDIO (KZR-616-003, NCT: NCT04033926), an ongoing Phase 2 clinical trial of KZR-616 in patients with PM and dermatomyositis (DM).

Methods: CIM was induced in female C57BL/6 mice (5/treatment group) immunized subcutaneously (SC) with 200 µg of fragment 2 (amino acids 284-580) of recombinant skeletal muscle fast-type C protein in complete Freund's adjuvant combined with intraperitoneal (IP) administration of 2 µg of pertussis toxin. Diseased mice (Day 13 post immunization) were treated with 10 mg/kg KZR-616 or ONX 0914 (a structural analog of KZR-616) or vehicle three times per week until Day 28. Endpoints included muscle strength assessed by a grip strength meter, serum creatine kinase activity and immunohistology and immunohistochemistry of the triceps brachii muscle.

Results: Treatment with KZR-616 or ONX 0914 completely blocked the loss of grip strength in mice after vaccination for CIM induction while vehicle treated animals displayed progressive muscle weakness. Compared to vehicle, immunoproteasome inhibition resulted in lowered PM-associated leukocyte infiltration of the triceps brachii muscle, including $CD8^+$ T-cells and $F4\text{-}80^+$ macrophages, and prevented an increase in serum creatine kinase.

Conclusion: Selective immunoproteasome inhibition shows therapeutic efficacy in a preclinical mouse model of PM with suppression of muscle inflammation and prevention of muscle weakness. These results strengthen the hypothesis that KZR-616, currently under evaluation in PRESIDIO (KZR-616-003, NCT: NCT04033926), a Phase 2 placebo-controlled, cross-over study of KZR-616 for patients with PM and DM evaluating safety, tolerability, and exploratory efficacy such as muscle function and disease activity over a 32 week treatment period, will elicit similar results.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis are characterized by weakness and muscle inflammation. They encompass heterogeneous conditions, which include dermatomyositis (DM), inclusion body myositis (IBM) and polymyositis (PM) according to the EULAR/ACR 2017 criteria. We recently recorded a high prevalence of IBM in a cohort of primary Sjögren's syndrome (SS). Our objective was to refine the signification of SS in the setting of myositis.

Methods: Among a monocentric myositis cohort (according to the EULAR/ACR 2017 criteria), SS patients (according to the ACR/EULAR 2016 criteria) were identified (myositis/SS+ group) and compared to myositis patients without SS (myositis/SS- group).

Results: Among 417 myositis patients, SS criteria were available for 99 patients. Thirty-four (34%) presented SS. Patients with SS tended to be more frequently women (F/M ratio 10.3 vs 3.1, p = 0.058). Age at diagnosis of myositis was similar in both groups (53 years [range 21-74] vs 53 years [range 16-77], p = 0.45).

Myositis subtypes repartition (as defined by EULAR/ACR 2017 criteria) was different in myositis/SS+ and myositis/SS- groups (p = 0.020), IBM being four-fold more prevalent in myositis/SS+ group (24% vs 6%, p = 0.020). Accordingly, the delay between the first muscle symptoms and myositis diagnosis was longer in myositis/SS+ group (6 months [0-336] vs 4 months [0-122], p = 0.057). Moreover, aside anti-cN1A antibodies, myositis-specific antibodies were less frequently found in myositis/SS+ patients than in myositis/SS- ones (53% vs 72%, p = 0.054).

Anti-cN1A antibodies were more prevalent in myositis/SS+ patients (38% vs 6%, p = 0.0005). However, in myositis/SS+ group, anti-cN1A were frequent in each of the EULAR/ACR 2017 myositis subtypes and the association between SS and anti-cN1A positivity was maintained in a multivariate analysis taking into account the diagnosis of IBM (p = 0.020).

Specificity of anti-cN1A for IBM was 0.96 [95% CI, 0.87 – 0.99] in the myositis/SS- group but dropped to 0.70 [95% CI, 0.48 – 0.85] in the myositis/SS+ group.

9 (26%) of the myositis/SS+ patients had systemic involvement typical of SS (vs 5 [7%] of the myositis/SS- patients, p = 0.11) including polyneuropathy (8 [24%] vs 5 [8%]) and type 2 cryoglobulinaemic vasculitis (1 [3%] vs none). In addition, 2 (6%) myositis/SS+ patients developed a lymphoma (one B diffuse large cell lymphoma of the parotid and one non-Hodgkin lymphoma), vs none of the myositis/SS- patients (p = 0.11). 2 (6%) of the myositis/SS+ patients developed myositis-associated cancer (diagnosed within 3 years of myositis diagnosis) versus 6 (8%) of the myositis/SS- patients.

Aside hydroxychloroquine, more frequently used in myositis/SS+ group (38% vs 16%, p = 0.012), no significant difference was found in the management of the patients (taking into account the myositis subtype).

Conclusion: Myositis patients with SS have more frequently IBM (without response to immunomodulatory drugs) than myositis patients without SS. They also have more frequently anti-cN1A antibody, independently of IBM diagnosis.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) is a large- and medium-sized vessel vasculitis affecting patients >50 years-old. High-doses of glucocorticoids (GCs) should be initiated promptly to induce remission in active GCA.

Adjunctive therapy with methotrexate (MTX) was tested in four randomized-controlled trials but only one met its primary endpoint. Our aim was to evaluate the effectiveness and safety of MTX in clinical practice, using data from a cohort of Portuguese patients with GCA.

Methods: Bicentric observational study using data from the Rheumatic Diseases Portuguese Register (Reuma.pt). We included patients with biopsy- or ultrasound-proven GCA treated with GCs with/without MTX. Clinical features of patients treated with GCs alone or GCs+MTX were compared using exact Fisher and Mann-Whitney U tests, as adequate. Association between continuous variables was assessed with Spearman's correlation coefficient. For pa-

Characteristics	GCs alone N=64	GCs+MTX N=66	p-value
Age at diagnosis, years	75.5 (13.0)	74.8 (10.6)	0.117

CRP at 12-months after index date, mg/dL	0.3 (0.8)	0.3 (1.0)	0.960
Active disease 6-months after index date, n (%)	6 (9.4)	7 (10.6)	0.334
Active disease 12-months after index date, n (%)	3 (4.7)	6 (9.1)	0.916

Data for continuous variables are presented as median (IQR), and for categorical variables as absolute number (%). Index date relates to the time of MTX initiation in the GCs+MTX group and correspondent date in the GCs alone group.
CRP – C-reactive protein; GCs – glucocorticoids (prednisolone equivalent); ESR – erythrocyte sedimentation rate; MTX – methotrexate; PMR – polymyalgia rheumatica.

Table 1. Characteristics of the patients with GCA treated with GCs alone compared with patients treated with GCs+MTX

tients on the GCs alone group, an index date, correspondent to the median time to MTX start in the GCs+MTX group, was established for comparison of disease activity and total GCs dose at 6- and 12-months. Active disease was defined according to the presence of GCA-related symptoms and/or increased inflammatory markers. Relapse rate was defined as the number of events per patient-years (p-y) of follow-up, and relapse rates with or without exposure to MTX were compared using mid p-value test.

Results: We included 130 patients, with a median age at diagnosis of 74.9 years (IQR 11.8), 66.9% female. Sixty-six (50.8%) patients received MTX with a median time to start of 174 days (IQR 314), a median starting dose of 10 mg/week (range 5-15) and a median maximum dose of 15 mg (range 5-25). Characteristics of patients in the two treatment groups are summarized in Table 1. Inflammatory markers and proportion of patients with active disease at 6- and 12-months were not reduced in patients receiving MTX. Patients on the GCs+MTX group had a significantly higher median GC dose at index date and total GC cumulative dose, but a longer time to start MTX positively correlated with total GC cumulative dose (r=0.32, p=0.01). Relapses occurred in 28 patients, in a median of 13.5 (IQR 43.0) months from diagnosis: relapse rate in patients exposed to MTX was 2.75/100 p-y vs. 6.72/100 p-y in patients not exposed to MTX, with a rate ratio reduction of 0.41 (95%CI: 0.17-0.91). In subgroup analysis, comparing patients with or without relapses, neither demographic, baseline disease features or cumulative GC dose were different between groups. Twenty-one patients (31.8%) stopped MTX: 2 due to disease remission and 19 due to adverse events (AEs) - 10 mild, 7 moderate, and 2 severe AEs (pneumonitis and Kaposi sarcoma).

Conclusion: Treatment with MTX in GCA was associated with a reduced relapse rate during follow-up. Cumulative GC dose was higher in patients in the GCs+MTX group. In subgroup analysis, GC dose was not different in patients with or without relapses. The proportion of severe AEs was similar to previous studies. This is not a randomized study: the results may have been affected by confounding by indication, co-medication and other sources of bias. They suggest, however, that MTX provides a safe and effective contribution to prevent relapse in GCA.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ), an IL-6 receptor blocker is approved to treat relapsing, refractory Giant cell arteritis (GCA) We here report our real-life clinical experience with the the efficacy and safety of TCZ in GCA. Furthermore, we assessed the effect of TCZ on imaging, i.e. ultrasound (US) and FDG-PET/CT, during the first year of treatment.

Methods: We included 22 consecutive patients with GCA, who were treated with TCZ. EULAR core data set was collected since July 2018. Data on disease activity, quality of life and treatment-related complications were collected. Pre-TCZ ultrasound and FDG-PET/CT findings were available for 21 patients and 4 patients, respectively. The effect of TCZ on the following parameters was determined: US halo thickness (n=21), US Temporal Artery Halo Score (n=5), US Axillary Artery Halo Score (n=8) and Total Vascular Score on FDG-PET/CT (n=4)

Results: The 22 patients with GCA (10 cranial GCA, 10 large vessel GCA, 2 cranial/large vessel GCA) had a median disease duration of 58.5 weeks (range 1-370) prior to initiation of TCZ. Half of patient had used prior csDMARD treatment. TCZ was indicated due to refractory (50%), ischemic (36%) or relapsing (14%) disease. Median follow up was 43 weeks (IQR 12-52). TCZ was discontinued due to SAEs in ?? patients. Upon treatment with TCZ, 13 patients went into remission with a median daily dose of ≤ 5mg prednisolone (equivalent), whereas 20 patients only required a median dose of 2.5 mg. Four patients were able to fully discontinue prednisolone treatment. Almost 50% of the patients claimed their QoL improved on TCZ. Overall, the US halo thickness decreased in 23 of arterial segments evaluated. The median Temporal Artery Halo Score decreased from 11 to 0. The median Axillary Artery Halo Score remains 6. The median Total Vascular Score on FDG-PET/CT showed a reduction of 11.5 to 6.5.

Conclusion: In our real-life clinical experience, TCZ showed an excellent response with acceptable safety in GCA. TCZ treatment was also associated with improvement on US and FDG-PET/CT imaging.

Efficacy and Safety of Tocilizumab in Patients with Giant Cell Arteritis and Visual Impairment

Andrea Rubbert Roth[1], Scott Tschuppert[2], Thomas Neumann[2], Ulf Benecke[3], Ian Pirker[3] and Johannes von Kempis[3], [1]Klinik für Rheumatologie, Kantonsspital St Gallen, St Gallen, Sankt Gallen, Switzerland, [2]Kantonsspital St Gallen, St.Gallen, Switzerland, [3]Kantonspital St Gallen, St. Gallen, Switzerland

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ) represents a potent new therapeutic principle for patients with GCA, however, data on efficacy and safety in patients who present with visual affection is still limited. We sought to study the outcome of patients with GCA and visual affection treated with TCZ.

Methods: This retrospective analysis was performed on all patients with GCA and visual disturbances consecutively recruited between April 2013 and May 2020 who underwent treatment with tocilizumab in addition to corticosteroids.

Results: 19 GCA patients (14 women, 5 male) with a mean age of 73.4 ± 10 yrs at GCA diagnosis and 28 affected eyes were treated with tocilizumab in addition to corticosteroids.

4/19 patients presented with visual disturbances on oral prednisone and 2/19 patients were on csDMARDs (leflunomide, MTX) for polymyalgia. 2 patients experienced unilateral blindness while receiving iv pulse corticosteroids. AAION was diagnosed in 23/28 eyes, PION in 1/28 eyes and occlusion of the central retinal artery in 4/28 eyes. Loss of vision below 0.1 BCVA occurred in 12/28 eyes. Non patients had bilateral blindness at baseline. 5/28 eyes were affected by sectorial anopsia, impaired vision was reported in 11/28 eyes. 17 patients were treated with TCZ iv 8mg/kg every 4 weeks, 2 patients received TCZ sc at 162mg every 2 weeks.

All patients with visual symptoms received intravenous steroid boluses, followed by predni-sone 1mg/kg/day with subsequent tapering.

Mean disease duration before initiation of tocilizumab was 1.8 $\pm$ 1.7 months. 11/19 patients started with TCZ within 6 weeks after diagnosis of GCA, in 3 patients TCZ was started because of refractory and/or relapsed disease.

Mean duration of TCZ therapy was 18.9 ± 11.5 months. 14/19 patients were able to stop steroids (GC) after a mean duration of 16.7 ± 14.8 months and have been steroid-free for an average time of 15 ± 10.4 months. In addition to cessation of GC, 8 patients have discon-tinued TCZ, 2 patients relapsed after 11 and 14 months. At present, 6 patients remain drug-free for 3 to 28 months (16 ± 11 months). None of the 12 eyes with vision < 0.1 BCVA recovered, but no new vision disturbances occurred during TCZ or after cessation of either TCZ or GC.

Two patients died during follow-up for reasons unrelated to GCA or TCZ. Overall tolerability of TCZ was good, complications were predominantly vascular (2 patients with VTE, one NSTEMI, one stroke and the development of an aortic aneurysm).

Conclusion: Inhibition of IL-6 with TCZ represents a valuable treatment option to prevent deterioration of visual complications in GCA patients with initial visual impairment.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ) has shown efficacy in large vessel vasculitis (LVV)-giant cell arteritis (LVV-GCA). Disease activity in LVV assessed by laboratory parameters (ESR, CRP) may be of less value with TCZ. Imaging assessment by ^{18}F-fluodeoxyglucose positron emission tomography (^{18}F-FDG PET/CT) may be useful to monitor LVV disease activity.

Our aim was to determine if clinical improvement correlated with decrease of vascular uptake in follow-up PET/CT scans.

Methods: Single center study of patients with refractory LVV-GCA treated with TCZ who had a baseline and follow-up PET/CT scan. For the visual analysis, FDG uptake at the thoracic aorta wall was visually grading compared to the liver uptake (0: no uptake, 1: less than liver, 2: equal to liver, 3: uptake greater than liver uptake). We defined a total vascular score (TVS) which included 5 vascular regions (supra aortic trunks, thoracic aorta, abdominal aorta, iliac arteries, femorotibial arteries) ranging from 0 to 15. Besides, a semiquantitative analysis was performed as a target to background ratio (TBR)= SUVmax thoracic aorta wall/SUVmax aortic vascular pool. The baseline and follow-up TVS and TBR were compared. Clinical and analytical improvement and and reduction of prednisone dose (mg/day) were also assessed.

Results: We included 30 patients (24 women/6 men); mean age 65.7± 9.8 years. Baseline PET/CT scans were performed due to active disease at a median [interquartile range-IQR] of 1.5 [0.0-4.0] months before TCZ onset. Follow-

TABLE.

	Baseline (n=30)	Follow-up (n=30)	p
Clinical improvement			
Remission, n (%)		25 (83.3)	
Laboratory markers			
ESR (mm/1st hour), median [IQR]	24.0 [10.0-53.0]	2.0 [2.0-3.0]	< 0.001
CRP (mg/dL), median [IQR]	1.0 [0.5-2.4]	0.1 [0.1-0.1]	< 0.001
Glucocorticoid therapy			
Prednisone dose (mg/day), median [IQR]	7.5 [5.0-10.0]	2.0 [0.0-5.0]	< 0.001
18F-FDG vascular uptake			
Thoracic TBR, mean ± SD	1.70 ± 0.52	1.48 ± 0.25	0.005
Total vascular score, mean ± SD	4.97 ± 2.62	3.13 ± 1.89	< 0.001
Normalization of TBR*, n (%)		9 (30)	
Normalization of TVS**, n (%)		3 (10)	

CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; TBR: target-to-background ratio. * Normalization of TBR was considered when TBR < 1.34. ** Normalization of TVS was considered when TVS=0.

ing TCZ therapy, 25 (83.33%) patients achieved clinical remission and reduction of FDG vascular uptake was also observed after a mean of 10.8±3.7 months. TBR decreased from 1.70 ± 0.52 to 1.48 ± 0.25 (p=0.005) and TVS from 4.97±2.62 to 3.13±1.89 (p< 0.001). However, only 9 (30%) patients showed complete normalization of TBR and only 3 (10%) normalization of TVS (**TABLE**).

Conclusion: Most of patients with LVV under TCZ therapy experienced a rapid and effective clinical and analytical improvement. However, less than one-third show normalization of 18F-FDG vascular uptake.

Association of Leukocyte Populations in Peripheral Blood and Arterial Wall Inflammation Assessed by FDG-PET in Takayasu's Arteritis and Giant Cell Arteritis

K. Bates Gribbons[1], Kaitlin Quinn[2], Mark Ahlman[3], Peter Merkel[4] and Peter C. Grayson[5], [1]McGovern Medical School UT Houston, Houston, TX, [2]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, [3]National Institutes of Health, Clinical Center, Radiology and Imaging Sciences, Bethesda, MD, [4]University of Pennsylvania, Philadelphia, PA, [5]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Positron emission tomography (PET) is useful to demonstrate fluorodeoxyglucose (FDG) uptake in the large arteries in both Takayasu's arteritis (TAK) and giant cell arteritis (GCA). Delayed FDG-PET imaging at 2 hours rather than 1 hour after FDG injection has greater sensitivity to detect vascular wall inflammation as measured by FDG uptake. The specific cell populations responsible for FDG uptake within the large arteries are not well defined. The objective of this study was to assess whether vascular PET activity is associated with specific leukocyte subsets in peripheral blood at 1- and 2-hour post-FDG injection timepoints in patients with TAK and GCA.

Methods: Patients with TAK and GCA were recruited into a prospective, observational cohort. All patients received PET imaging 2 hours after FDG injection, and a random subset of these patients had additional PET imaging 1 hour after FDG injection. PETVAS, a qualitative summary score of arterial uptake in 9 arterial territories, was used to quantify vascular PET activity. Absolute neutrophil, monocyte, and lymphocyte counts were determined by complete blood counts. CD8+ and CD4+ T lymphocytes, and CD19+ B lymphocytes were quantified by flow cytometry. CRP and ESR were measured. All laboratory tests were performed within 24 hours of PET imaging. Mixed model linear regression was used to identify associations between PETVAS and leukocyte populations, ESR, and CRP at both timepoints, adjusting for daily prednisone dose.

Results: 91 patients (TAK = 38, GCA = 53) contributed 201 visits for the 2-hour imaging timepoint. A subset of 75 patients (TAK = 31, GCA = 44) contributed 158 visits for the 1-hour imaging timepoint. Baseline characteristics were as follows: female gender (TAK: 79%, GCA: 75%), average age (TAK: 36.1±11 years, GCA: 70±8 years), average

prednisone dose (TAK: 3.8±6 mg/day, GCA: 14.3±19 mg/day), ESR (TAK: 20.8±11 mm/hr, GCA: 25.3±24 mm/hr), and CRP (TAK: 10.6±12 mg/L, GCA: 10.2±21 mg/L).

At the 2-hour time point, PET activity was associated with absolute monocyte count in TAK (β estimate: 1.47, 95%CI: 1.04-2.08) and GCA (β estimate: 1.20, 95%CI: 1.02-1.42). PET activity at the 2-hour timepoint was not associated with other leukocyte populations. At the 1-hour timepoint, CD8+ T lymphocyte count was weakly associated with PET activity in patients with TAK (β estimate: $1+4.6e^{-4}$, 95%CI: $1+3.1e^{-6}$ - $1+9.0e^{-4}$) but not in patients with GCA (β estimate: 1.00, 95%CI: 0.99-1.02). Other leukocyte populations, including absolute monocyte count, were not associated with PET activity at the 1-hour timepoint. There was no association between CRP or ESR with PET activity in TAK or GCA at either timepoint.

Conclusion: In both TAK and GCA, delayed FDG-PET imaging is associated with a patient's absolute monocyte count. The monocyte/macrophage lineage likely contributes to FDG uptake in large-vessel vasculitis and could be an important cell population to target therapeutically in these diseases. Circulating biomarkers related to monocytes may constitute novel biomarkers for vascular PET activity. Future studies that compare circulating biomarkers to vascular PET activity should employ delayed imaging approaches.

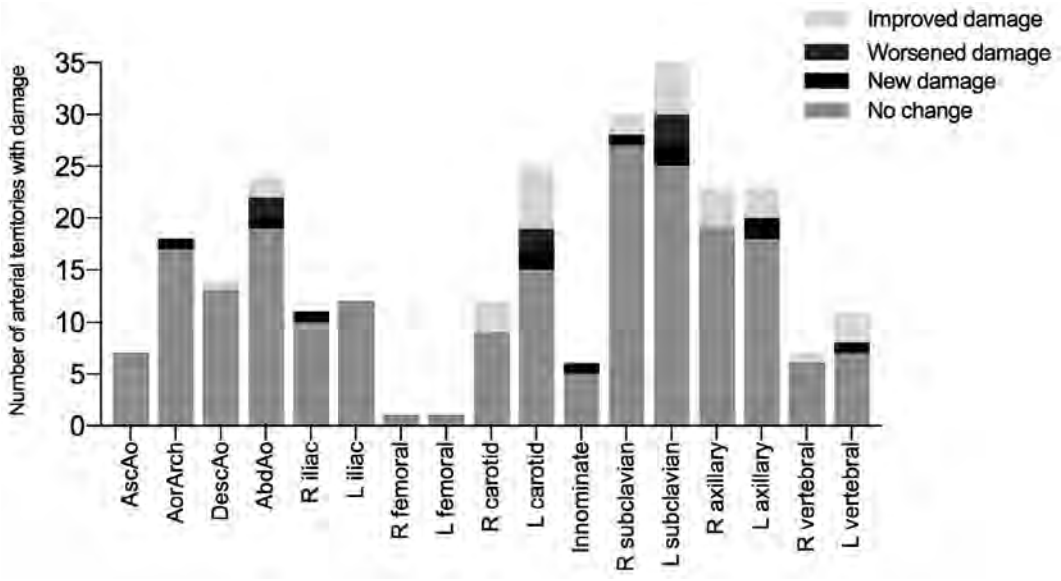
Angiographic Progression of Disease in Large-Vessel Vasculitis

Kaitlin Quinn[1], Himanshu Dashora[2], Mark Ahlman[3], Elaine Novakovich[2] and Peter C. Grayson[2], [1]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Washington, DC, [2]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD, [3]National Institutes of Health, Clinical Center, Radiology and Imaging Sciences, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Angiography is essential to detect vascular disease in patients with large-vessel vasculitis (LVV). Guidelines differ on the role of periodic angiography to monitor patients with LVV, in part due to limited prospective data regarding the natural history of angiographic disease. The objective of this study was to characterize angiographic progression of disease over time in Takayasu's arteritis (TAK) and giant cell arteritis (GCA).

Methods: Patients with GCA or TAK were recruited into a prospective, observational cohort. All patients underwent baseline magnetic resonance (MR) or computed tomography (CT) angiography and a follow-up study (same modality) at least one year after baseline per a standardized imaging protocol. Angiographic lesions, defined as stenosis, occlusion, or aneurysm, were evaluated by visual inspection in 4 segments of the aorta and 13 branch arteries by a single reader blinded to clinical status. On follow up angiography, the development of new lesions was recorded and existing lesions were characterized as improved, worsened, or unchanged. Change over time was evaluated at the patient level and within each individual arterial territory.



Results: 1162 arterial territories were evaluated from 70 patients with LVV (TAK=38; GCA=32). Baseline characteristics were as follows: Age [TAK=29.5 years (18.4-39.5), GCA=69.6 years (60.7-75.5)], Female gender [TAK=30 patients (79%), GCA=23 patients (72%)], Disease duration [TAK=2.2 years (0.6-5.5), GCA=0.7 years (0.1-2.6)], Active clinical disease [TAK=17 patients (45%), GCA=20 patients (63%)]. The median time from initial study to follow up study was 1.6 years (1.0-2.7).

At the patient level, there were 12 new arterial territories that developed in 9 (13%) patients and occurred more frequently in patients with TAK=8 than GCA=1; p=0.03. Sixty patients (86%) had ≥1 territory affected at baseline (TAK=33, GCA=27). Angiographic lesions improved in 17 (28.3%) patients, with greater frequency in TAK=13 than GCA=4; p=0.05. Lesions worsened in 6 (10%) patients with no differences between diseases (TAK=4, GCA=2). In 7 (11.7%) patients (TAK=6, GCA=1), specific arterial territories improved while other territories worsened over follow up within the same patient.

At the arterial territory level, 248 territories were affected at the baseline visit (TAK=145 territories, GCA=103 territories). At follow up, existing arterial lesions improved in 30 (12.1%) territories, worsened in 7 (2.8%) territories, and stayed the same in 211 (85.1%) territories. There were no significant differences in angiographic progression of disease at the territory level between GCA and TAK. Change in the branch arteries was more dynamic than change in the aorta (Figure).

Conclusion: Dynamic change in arterial lesions is observed in patients with TAK and GCA. Development of new angiographic lesions is infrequent and occurs more often in patients with TAK. Arterial lesions do not necessarily represent permanent damage, as a substantial number of lesions can improve. Discordant areas of improvement and worsening can occur within the same patient. These data may inform guideline recommendations for imaging monitoring in LVV.

Low Immunogenicity in Patients with Giant Cell Arteritis Treated with Tocilizumab: 3-Year Results from the Randomized Controlled Portion and the Open-Label Follow-Up of a Phase 3 Trial

John H. Stone[1], Navita L. Mallalieu[2] and Min Bao[3], [1]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [2]Roche Innovation Center, New York, NY, [3]Genentech, South San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ) has low immunogenicity in patients with rheumatoid arthritis (RA).[1] The risk for TCZ immunogenicity remains to be determined in patients with giant cell arteritis (GCA). TCZ administered subcutaneously every week (QW) or every other week (Q2W) plus 26-week prednisone tapering was superior to placebo (PBO) plus 26-week (PBO+26) or 52-week (PBO+52) prednisone tapering for achievement of sustained remission in patients with GCA in the 52-week, double-blind part (part 1) of the GiACTA trial.[2] Part 2 was a 2-year, open-label, long-term, follow-up in which patients were treated at the investigators' discretion; part 2 treatment could include initiation/termination of TCZ QW with or without glucocorticoids or methotrexate. The objective of this analysis was to investigate immunogenicity of TCZ QW and Q2W regimens over the course of parts 1 and 2 of GiACTA.

Methods: In parts 1 and 2 combined, anti–TCZ antibodies (ADA) and corresponding pharmacokinetic (PK) parameters were assessed in serum samples at weeks 0, 8, 24, 36, 52, 76, 100, 136, and 156 or at early withdrawal, with additional assessments in patients who interrupted blinded TCZ for ≥4 weeks in part 1 and patients who withdrew because of anaphylaxis/hypersensitivity at any time. All samples were tested sequentially by screening assay and confirmation assay to verify specificity. If the confirmation assay was positive, 2 additional tests were performed to

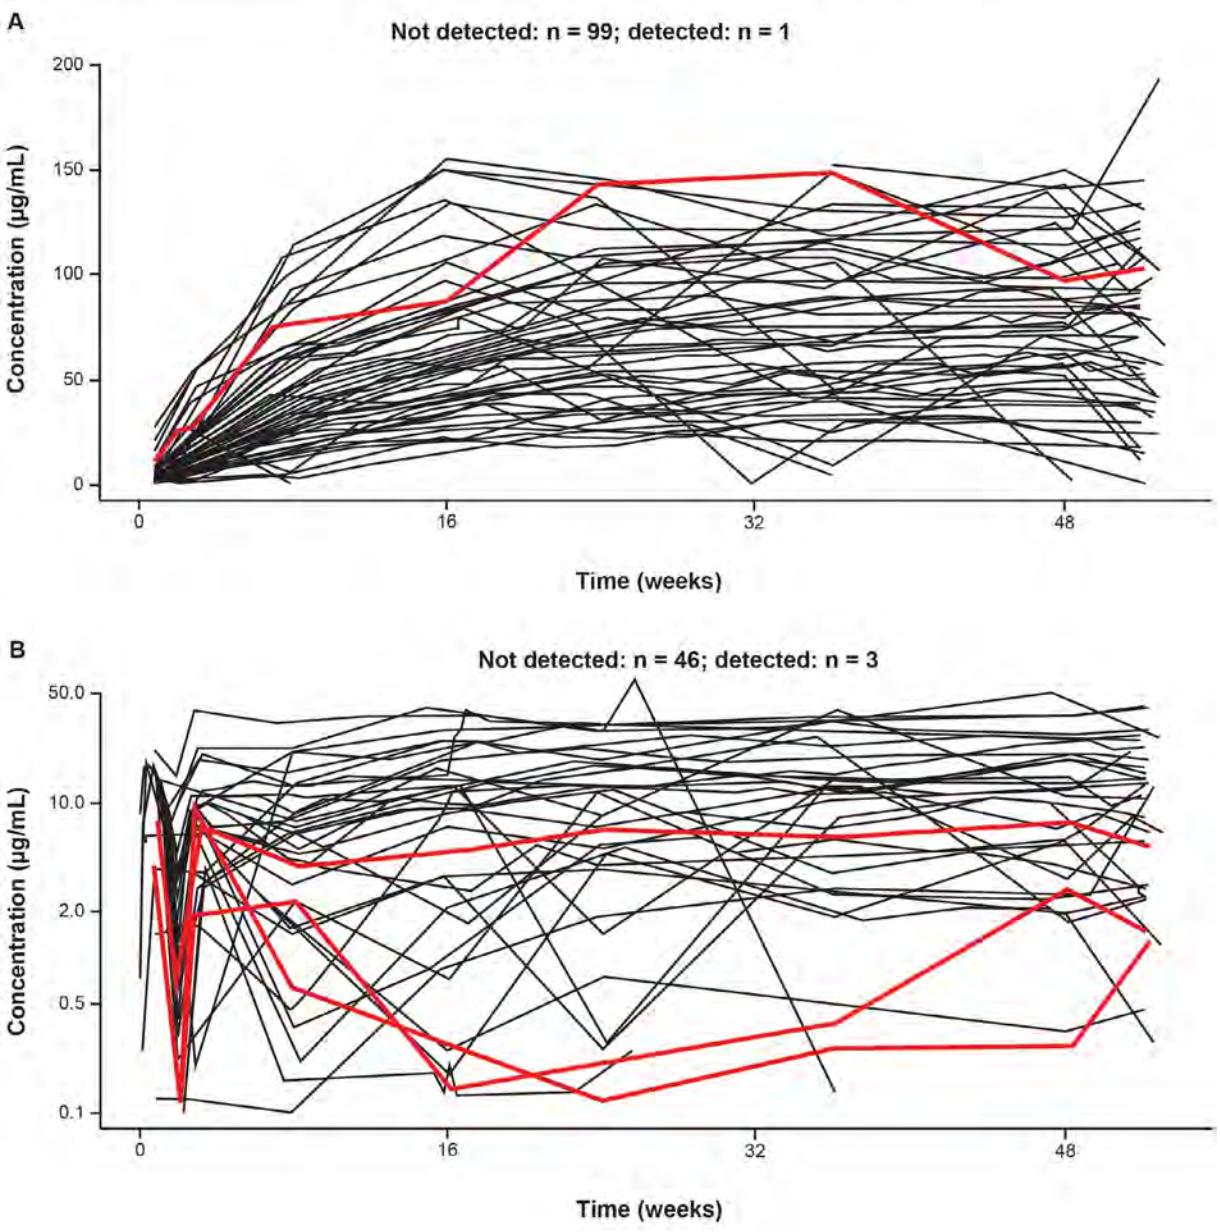
Table 1. Immunogenicity in Patients Who Received TCZ (part 1 + part 2)

	Patients Who Received TCZ N = 199
Baseline	
Evaluable patients	194 (97.5)
Positive screening assay	12 (6.0)
Positive confirmation assay	6 (3.0)
Postbaseline	
Evaluable patients	193 (97.0)
Treatment-induced ADA	13 (6.7)
Characterizaton of ADA	
Neutralizing potential	8 (4.1)
IgE	1 (0.5)

Data are number (%) of patients based on N at baseline and on number of evaluable patients postbaseline.

Table 1

Figure. Time-Concentration Profiles of TCZ in Part 1 by TCZ Dosing Regimen. (A) QW. (B) Q2W.



Patients in whom TCZ-induced ADA developed in part 1 are shown in red.

Figure 1

characterize the detected ADA: a neutralizing assay to test the neutralizing potential of ADAs and an assay to determine whether the ADAs were of the IgE isotype. Proportions of patients in whom ADA developed were summarized for the safety population. ACR GCA classification criteria were fulfilled by 78% of enrolled patients. The study was conducted in accordance with the principles of the Declaration of Helsinki and received IRB approval.

Results: Among evaluable patients (had baseline and ≥1 postbaseline ADA assessments and received ≥1 dose of study treatment) in part 1, ADA developed in 1 of 95 (1.1%) and 3 of 46 (6.5%) patients after TCZ QW and Q2W dosing, respectively. One of 49 (2.0%) and 1 of 47 (2.1%) patients in the PBO+26 and PBO+52 groups, respectively, tested positive for ADA but had not received TCZ and were considered false positives. In parts 1 and 2 combined,

among 199 patients who received ≥1 dose of TCZ, 193 (97%) were evaluable (Table 1); TCZ-induced ADA developed in 13 patients (6.7%) postbaseline (4 during part 1, 9 during part 2). Of these 13 patients, 8 (4.1%) had ADA with neutralizing potential and 1 (0.5%) had IgE ADA. Most TCZ-induced ADA were transient. There was no clear impact of TCZ-induced ADA on TCZ PK (Figure 1). No patients with TCZ-induced ADA experienced anaphylaxis, hypersensitivity reactions, or injection site reactions, and none withdrew because of lack of efficacy.

Conclusion: In patients with GCA, treatment-induced ADA developed in a minority of patients and had no clear impact on TCZ PK, efficacy, or safety. The immunogenicity of subcutaneous TCZ treatment was low, consistent with that observed in patients with RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US) plays an important role in diagnosis of giant cell arteritis (GCA). To date it is unknown how intima-media-thickness (IMT) of affected arteries changes under therapy and time.

Methods: Prospective US examination of the common superficial temporal artery and the axillary artery in patients with newly diagnosed GCA, at time of diagnosis, three and six months later. All patients fulfilled ACR criteria for GCA and showed IMT values above published cut-off values of the respective artery [1]. On each visit US-examination with IMT measurement of the arteries mentioned above was performed. Glucocorticoid dose and c-reactive protein (CRP) values were recorded.

Patients were divided into four subgroups: Group 1, GCA and affection of large and intermediate vessels, group 2, GCA with affection of intermediate vessels only, group 3, GCA and polymyalgia rheumatica (PMR) and affection of large and intermediate vessels and group 4, GCA and PMR and affection of intermediate vessels only.

Group	Visit	Intima-media-thickness (mm)			
		Right axillary artery	Left axillary artery	Right common temporal artery	Left common temporal artery
1 (n=14)	1	1.2 (±0.3)	1.0 (±0.2)	0.5 (±0.1)	0.5 (±0.1)
	2	0.9 (±0.2)	0.9 (±0.2)	0.4 (±0.1)	0.4 (±0.1)
	3	0.9 (±0.2)	1.0 (±0.2)	0.4 (±0.1)	0.4 (±0.1)
2 (n=6)	1	0.8 (±0.1)	0.6 (±0.1)	0.6 (±0.1)	0.5 (±0.1)
	2	0.7 (±0.1)	0.6 (±0.1)	0.4 (±0.1)	0.4 (±0.1)
	3	0.8 (±0.1)	0.8 (±0.1)	0.4 (±0.1)	0.4 (±0.1)
3 (n=7)	1	1.2 (±0.3)	1.0 (±0.4)	0.6 (±0.3)	0.5(±0.2)
	2	1.0 (±0.3)	1.0(±0.1)	0.5 (±0.1)	0.5 (±0.1)
	3	0.8 (±0.2)	0.9(±0.2)	0.4 (±0.1)	0.5 (±0.2)
4 (n=3)	1	0.8(±0.3)	0.7(±0.3)	0.5 (±0.1)	0.5 (±0.2)
	2	0.8(± n.d.)	0.6 (±n.d.)	0.4 (±n.d.)	0.4 (±n.d.)
	3	0.8(±0.0)	0.7 (±0.0)	0.5 (±0.1)	0.4 (±0.0)
Visit 1: time of diagnosis Visit 2: after 3 months Visit 3: after 6 months n: number of patients in each group at time of diagnosis			Group 1: GCA, affection of large and intermediate vessels Group 2: GCA, affection of intermediate vessels only Group 3: GCA+PMR, affection of large and intermediate vessels Group 4: GCA+PMR, affection of intermediate vessels only		

Table 1. Reduction of intima-media-thickness of the axillary and common superficial temporal artery for each group over an observation time of 6 months.

Results: We included a total of 30 patients, 18 (60 %) females. Mean age was 74 years (SD±10). At time of diagnosis, mean CRP-values were 59.9 mg/L (SD±58.8) and mean glucocorticoid dose was 171.3 mg (SD±312.5) per day. After three months, mean CRP was 8.2 mg/L (SD±16.4) and mean glucocorticoid dose was 10.7 mg (SD±4.4) per day while after six months mean CRP was 1.8 mg/L (SD±2.1) and mean glucocorticoid dose was 3.5 mg (SD±2.9) per day.

Overall a decrease of IMT values over three and six months could be observed. Exact values of each group are depicted in Table 1. Figure 1 and 2 show the decrease of IMT-values with the use of boxplots.

Conclusion: A relevant decrease of IMT-values over 6 months of therapy was observed in axillary and common superficial temporal arteries. During the first 3 months, IMT decrease was greatest. Mean CRP-values and glucocorticoid doses decreased over time and therapy. Further research in other arteries typically affected in GCA and a longer observation time in a larger cohort is obligate.

Efficacy of Adjunctive Methotrexate in Patients with Giant Cell Arteritis Treated with Tocilizumab Plus Prednisone Tapering: Subanalysis of a Phase 3 Trial

John H. Stone[1], Jian Han[2] and Shalini V. Mohan[2], [1]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [2]Genentech, South San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: There is conflicting evidence for methotrexate (MTX) efficacy in giant cell arteritis (GCA).[1,2] Subanalysis of data from the 52-week, double-blind, randomized controlled GiACTA trial in patients with GCA who received tocilizumab (TCZ) or placebo (PBO) with prednisone tapering was performed to assess efficacy and safety in patients who received adjunctive MTX.

Methods: In GiACTA, patients were randomly assigned to receive subcutaneous TCZ every week or every other week plus 26-week prednisone tapering or PBO every week plus 26-week or 52-week prednisone tapering for 52 weeks.[3] The two TCZ groups and the two PBO groups were pooled for this analysis. Stable doses of MTX could be initiated at screening, continued in the double-blind period, and reduced/discontinued at the investigator's discretion. Efficacy was defined as sustained remission (absence of GCA flare and C-reactive protein < 1 mg/dL from weeks 12 to 52 and adherence to the prednisone taper).[3] ACR GCA classification criteria were fulfilled by 78% of enrolled patients. The study was conducted in accordance with the principles of the Declaration of Helsinki and received IRB approval.

Results: Overall, 30 of 250 (12%) treated patients received adjunctive MTX for a median duration of 52.1 weeks: 15 of 149 (10%) TCZ-treated patients received MTX for a median of 52.1 weeks and 15 of 101 (15%) PBO-treated patients received MTX for a median of 52.0 weeks. Baseline characteristics (Table 1) were balanced, except for longer disease duration, higher proportion of patients with relapsing GCA, and lower baseline prednisone doses among patients who received MTX. The median cumulative glucocorticoid dose over 52 weeks was similar between patients who received MTX and those who did not in the PBO groups (2730 mg and 3694 mg, respectively) and the TCZ groups (1385 mg and 1862 mg, respectively). Sustained remission was achieved by 7 of 15 (47%) patients treated with MTX and 75 of 134 (56%) patients without MTX in the TCZ groups and by 1 of 15 (7%) patients treated MTX and 15 of 86 (17%) patients without MTX in the PBO groups (Figure 1). In the primary analysis,[3] 82 of 149 (55%) patients in the TCZ groups and 16 of 101 (16%) patients in the PBO groups achieved sustained remission. The mean annualized relapse rate at 52 weeks was not different between MTX-treated and MTX-untreated patients for the TCZ (0.71 with MTX vs 0.47 without MTX; $p = 0.3305$) or PBO (1.77 vs 1.48; $p = 0.6019$) groups. Adverse event rates per 100 patient-years were numerically higher in MTX-treated than MTX-untreated patients: 1207 and 862, respectively, in the TCZ groups and 1270 and 957, respectively, in the PBO groups.

Conclusion: Preliminary data from a small subgroup of patients suggest that adjunctive MTX does not increase the likelihood of sustained remission, reduce disease relapse rate, or improve steroid sparing in patients with GCA. Re-

Ultrasonographic Halo Score as a Marker for Diagnosis and Monitoring of Disease Activity in GCA

Alwin Sebastian[1], Abdul Kayani[1], Sue Innes[2], Jo Jackson[2], Kornelis S. M. van der Geest[3] and Bhaskar Dasgupta[1], [1]Rheumatology, Mid and South Essex University Hospital NHS Foundation Trust, Southend University Hospital, United Kingdom, Westcliff on sea, England, United Kingdom, [2]School of Sport, Rehabilitation and Exercise science, Colchester Campus, University of Essex, United Kingdom, Colchester, England, United Kingdom, [3]Rheumatology and Clinical Immunology, University Medical Center Groningen, Netherlands, Groningen, Netherlands

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: EULAR recommendations highlights ultrasound (US) as the first line imaging investigation for giant cell arteritis (GCA). Traditionally, the halo sign and compression sign have been used to discriminate between GCA and non GCA patients. We propose a novel Halo Score (HS) as a potential marker to diagnose and assess disease activity in follow up GCA patients.

Methods: Preliminary data was collected from the ongoing prospective multicentre HAS GCA study (IRAS# 264294) from referrals of suspected GCA to UK fast track clinics with GCA follow up at months 1,3,6 and 12. Based on the GCA clinical pre-test probability score (PTPS)[1], patients were stratified in to Low , Intermediate and High risk categories[2]. US Halo Score was calculated from the halo thickness and extent in bilateral temporal arteries and branches (TA Halo Score) and bilateral axillary arteries (AA Halo Score) summed up to a Total Halo Score. GCA was diagnosed based on the clinical symptoms and signs, positive US or additional test results with CRP >5 mg/dl. The objective is to recruit 270 patients including 68 patients with GCA.

Mann Whitney U test was used to compare controls and baseline GCA

Wilcoxon signed rank test was used to compared baseline GCA and 1m GCA (only patients that had two measurements)

Results: Total of 47 patients have been recruited so far into HAS GCA with 1 month follow up assessments. Demographics, clinical features and US results are shown (Table 1).

Twelve (26%) were confirmed GCA (9 cranial, 2 large vessel and 1 cranial plus large vessel) and 35 (74%) confirmed non-GCA. Median age 72 years in GCA and 71.5 years in controls (42% females in GCA and 77% non GCA). GCA patients stratified by PTPS to Low risk (0%), Intermediate risk (33%) and High risk (66%) whereas the 35 non GCA were categorised by PTPS as Low risk 51%. Intermediate risk 37% and High risk 11%.

Table 1: Demographics, Clinical feature, US results and Laboratory data

In High risk 1 LV GCA patient had negative US and FDG PET/CT confirmed bilateral vertebral arteritis. Another patient with axillary artery US positive LV-GCA had a negative FDG PET/CT without other pathologies. In the Intermediate risk, one patient had negative US and negative MRA.

Jaw claudication (42%) and polymyalgic symptoms (33%) were the dominant features in GCA patients contrast to controls. 4 had permanent visual loss prior to the assessment. a Median Total Halo Score in GCA was 20 and control group was 4 (p=0.0001). 9/12 patients with GCA have completed at least 1 month follow up (Table 2). Median TA Halo Score and Total Halo Score was reduced from 8 to 3 and 16 to 11 respectively (Image). AA Halo Score increased from 6 to 9 in 1 month. All the GCA patients were on glucocorticoids (GC) (prednisolone 40-60 mg daily) at presentation compare to 43% (15) in control group (in all GC discontinued after the assessment).

GCA – 9 out of 12 patients completed 1 month follow up

Number	ID	Age	Gender	GCA type	PTPS	Probability category	TA Halo Score-Baseline	TA Halo Score-1M	AA Halo Score-Baseline	AA Halo Score-1M	Total Halo Score-Baseline	Total Hal Score-1M
1	**1**	77	Female	Cranial	15	High	6	3	0	0	6	3

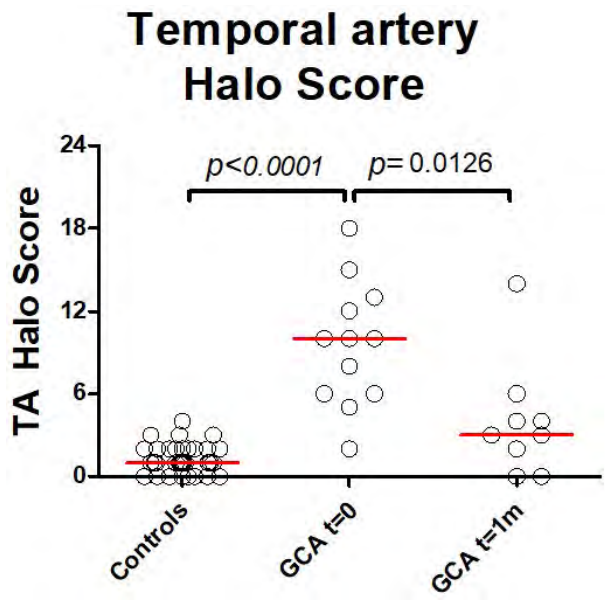
3	**9**	72	Female	Both	13	High	6	2	15	9	21	11
4	**15**	70	Male	Cranial	12	Intermediate	13	14	12	6	25	20
5	**19**	71	Male	Cranial	13	High	5	3	3	3	8	6
6	**20**	75	Female	LVV	17	High	2	0	0	9	2	9
7	**24**	92	Male	Cranial	12	Intermediate	10	4	6	9	16	13
8	**25**	80	Male	Cranial	10	Intermediate	12	4	9	12	21	16
9	**34**	64	Female	Cranial	14	High	8	0	6	3	14	3
Median HS							**8**	**3**	**6**	**9**	**16**	**11**



Conclusion: Along with GCA clinical PTPS, US Halo Score successfully discriminates GCA from non GCA mimics. TA Halo Score and Total Halo Score is effective in showing 4-week response and may be a useful marker to monitor GCA disease activity. The ongoing viral pandemic may have an effect on protocol-based US assessments.

Quantitative Ultrasound of Temporal, Axillary and Subclavian Arteries to Monitor Tocilizumab Treatment in Patients with Newly Diagnosed Giant Cell Arteritis: A 24 Week Analysis

Luca Seitz[1], Lisa Christ[1], Godehard Scholz[1], Fabian Lötscher[1], Jennifer Amsler[1], Florian Kollert[1], Stephan Reichenbach[1] and Peter Villiger[1], [1]Department of Rheumatology, Immunology and Allergology, University of Bern, Inselspital, Switzerland, Bern, Switzerland

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

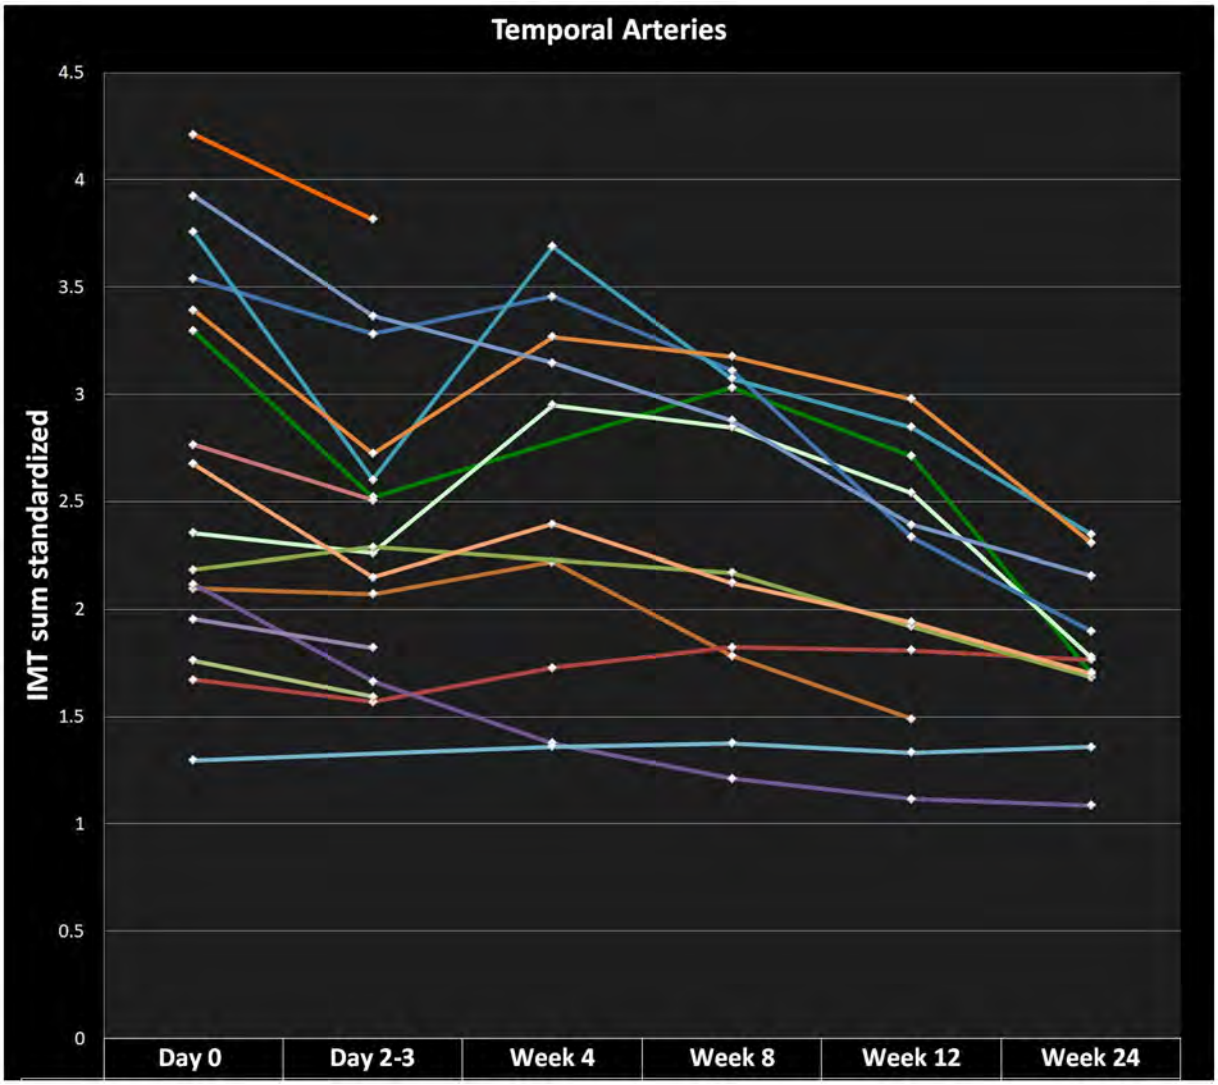
Background/Purpose: Tocilizumab (TCZ) suppresses CRP. Thus, CRP cannot be used as a marker for disease activity in GCA patients treated with TCZ and monitoring of disease activity is based on clinical signs and symptoms only. Novel methods to monitor disease activity in GCA under IL-6 blocking therapies are needed.

The **G**iant Cell Arteritis treated with **U**ltra-**S**hort Glucocorticoids and **TO**cilizumab (GUSTO) study (NCT03745586) offered a unique opportunity to test monitoring of the intima-media thickness (IMT) of arterial vessel walls with ultrasound (US) as a surrogate for disease activity.

Methods: In this single-arm, single-center, open-label clinical trial, 18 patients with newly diagnosed GCA were enrolled. They received 500 mg methylprednisolone intravenously for three consecutive days. Thereafter, glucocorticoids were discontinued and TCZ (8mg/kg body weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 to week 52. Change of IMT was an exploratory secondary outcome.

US of temporal (TA), axillary (AA) and subclavian (SA) arteries was performed at baseline, on day 2-3, at week 4, 8, 12 and 24. The sonographer was not blinded. The maximum IMT of the compressed TA (mainstem, frontal/parietal branch) and single wall IMT at landmarks of AA/SA were measured with an 18-22 or 9-11 MHz probe in B-mode. Biopsied branches and incompressible TA mainstems were excluded from follow-up. Diagnostic cut-offs and mean normal values for IMT of TA and AA were taken from Schäfer et al. (Rheumatology 2017;56(9):1479-1483). For the SA, the diagnostic cut-off and mean normal IMT of the AA were used. For each examination, the IMT of each TA segment was standardized by dividing it by (2 x (mean normal IMT)), the sum of these values was then divided by the number of segments. The same was done for the AA/SA separately.

Results: According to diagnostic IMT cut-offs for GCA, at baseline 16/18 (89%) patients had involvement of the TA and 3/18 (17%) of the AA/SA. At week 12, the IMT was above the cut-off in 11/14 (79%) in the TA (1 missing value (MV)) and in 6/14 (43%) in the AA/SA (1 MV). At week 24, the IMT was above the cut-off in 10/13 (77%) in the TA and in 6/13 (46%) in the AA/SA. Of the individual segments of the TA at baseline, 66/92 (72%) were above the diagnostic cut-off, at week 12 and 24 the proportions fell to 34/50 (68%) and 27/50 (54%) respectively. Of the individual segments of the AA/SA at baseline, 10/70 (14%) were above the diagnostic cut-off, at week 12 and 24 the proportions rose to 19/52 (37%) and 20/52 (38%) respectively. At week 4, in 7/14 (50%) patients (5 MV), IMT values of TA were higher compared to day 2/3 and in three patients, new onset AA or SA involvement was seen. Figure 1 shows the sum of standardized IMT of the TA from baseline to week 24.



Conclusion: A three day glucocorticoid pulse, followed by TCZ monotherapy leads to a gradual reduction of IMT of the TA until week 24.

This is the first study to document the usefulness and feasibility of IMT monitoring with US in GCA patients treated with TCZ.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this study was to characterize the frequency of visual ischemia (VI) as a manifestation of relapse or during follow-up in patients with GCA through performance of a systematic literature review.

Methods: Potentially eligible studies were identified from Medline and EMBASE databases from inception to November 31, 2019 using a search strategy that comprised of terms for "giant cell arteritis," "temporal arteritis," or "Horton's disease," with "relapse," "recurrence," "flare," "outcome," "follow-up," or "prognosis." VI was defined as transient or permanent, full or partial, monocular or binocular visual field loss. VI occurring within 4 weeks of GCA diagnosis was considered due to active disease and not included as a relapse event. Inclusion criteria used: (1) original research reported in English, (2) GCA definition provided, (3) VI outcome described as one of the following: (a) relapse rate/frequency denoting the presence or absence of VI, or (b) absolute number of VI events (> 4 weeks after GCA diagnosis) even if total cohort relapse rate/frequency was not provided. In order to reduce bias from under-reporting of negative results, studies that reported relapse rates/frequencies with accompanying relapse characteristics but did not provide initial detail regarding the presence/absence of VI were also identified. In such circumstances, the pri-

ACR, American College Rheumatology; APR, acute phase reactants (ESR/CRP); Dx, diagnosis; GCA, giant cell arteritis; ND, not defined; PVL, permanent vision loss; Sx, symptoms; TAB, temporal artery biopsy; TVL, transient vision loss (includes amarousis fugax, double vision); UK, United Kingdom, USA, United States of America; VI (visual ischemia). *Graham 1982, total cohort 90 but relapse calculated based on patients alive at end of follow up period; **Langford 2017, 1 patient had VL as relapse during study and 1 additional patient in post-treatment follow-up after study completion; †Initial RCT data not included as VI data not available

mary authors were directly contacted for patient-level data regarding VI and these studies were included in the final analysis if such data were available and provided.

Results: A total of 913 unique articles were identified and underwent screening (K.B. and M.J.K). Among these, 148 articles underwent independent full-text review by two physicians (K.B. and M.J.K). 33 articles met full inclusion criteria and an additional 21 articles included data on relapse but did not report VI patient data in the publication. Responses were received from authors of 11 of these 21 studies allowing for inclusion. 44 studies accounting for 3,649 patients with GCA were identified (Table 1). Average percentage of baseline VI was 19% (range 0-66%). The average length of follow-up was 3.4 years (range 0.4 to 8.7). VI developing > 4 weeks after GCA diagnosis was recorded in a total of 53 patients (1.5%).

Study-defined relapses were reported in 36 studies. A total of 1,215 patients with at least one or more relapses were recorded among 2,592 patients under observation (47%). Among these 36 studies, VI occurred in 37 patients (3.0%) with at least one study defined relapse event.

Comparing trial design, retrospective studies (n=25) reported 27 of 2,718 (1%) patients developed VI during follow-up whereas 19 of 541 (3.5%) patients in randomized controlled trials (n=8) developed VI during the trial or post-trial follow-up (Table 2).

Table 2: Randomized clinical trial design and reported visual ischemia outcomes

Author (Year)	Drug under study	Trial arms: (# patients)	Prednisone taper	Visual ischemia
Jover 2001	Methotrexate 10 mg/wk	SD: N=20 PBO: N=19	20 mg TID x 1wk, 60 mg/d x 1wk; ↓ 10 mg/wk to 40 mg; then down by 5 mg/wk to 20mg; then down by 2.5 mg/wk until off	SD: None PBO: None
Spiera 2001	Methotrexate 7.5 mg / wk	SD: N=12 PBO: N=9	Suggested (not-required) taper: 1mg/kg/day then ↓ 10mg/wk to 40mg/d then ↓ 5mg/wk to 20mg then ↓2.5 mg/wk until off	SD: None PBO: None

Mazlumzadeh (2006)	Intravenous methylprednisolone 1000mg daily x 3 days	SD: N=14 PBO: N=13	40mg/d x2wks, 30mg/d x2wks, 25mg/d x2wks, 20mg/d x2wks, 17.5mg/d x2wks, 15mg/d x2wks, 12.5mg/d x2wks, 10mg/d x2wks, then ↓1mg every 2wks to off	SD: None PBO: None
Hoffman (2007)	Infliximab 5mg/kg week 0, 2, 6 then Q8wks	SD: N=28 PBO: N=16	Standardized taper: ↓10mg each wk to 20mg/d then ↓2.5mg every 2wks, to 10mg then ↓ 1mg every week until off	SD: 6 patients PBO: 1 patient
Martinez-Taboada (2008)	Etanercept 25 mg SubQ twice weekly	SD: N=8 PBO: N=9	↓10mg/wk to 30mg/d, then ↓5mg/wk to 15 mg/d; then ↓ 2.5mg/wk until off	SD: None PBO: None
Langford (2017)	Abatacept 10mg/kg every 4 wks	SD: N=22 PBO: N=21	Initial dose 40-60 mg with standard taper to week 12 (20mg/d), following which tapered off by week 28	SD: 2 patients* PBO: None
Stone (2017)	Tocilizumab (TCZ) 162mg SubQ weekly 162mg SubQ every other week	SD1: TCZ QW N=100 SD2: TCZ QOW N=50 PBO1: 26wk pred N=50 PBO2: 52wk pred N=51	Baseline prednisone 20-60mg/d, then tapered to off by Wk 26	SD1: None SD2: 1 patient (A-AION) PBO1: 1 patient (AF) PBO2: None
A-AION, arteritic anterior ischemic optic neuropathy; AF, amaurosis fugax; PBO, placebo arm; SD, study drug arm; SubQ, subcutaneous; QW, every week; QOW, every other week; *Langford 2017 – 1 patient with VI during treatment portion, 1 patient in post-treatment follow-up				

Conclusion: This report outlines the first systematic review evaluating VI as a manifestation of relapse and during follow-up in GCA. Overall, VI > 4 weeks after GCA diagnosis is uncommon (1.5%) but is noted in up to 3% of patients with at least one relapse event. Frequencies of reported VI were 3.5 times higher in randomized controlled trials compared to retrospective studies.

Thirty-Day Readmission Rate in Patients Who Were Initially Admitted for Active Giant Cell Arteritis

Shu Cao[1], Caroline Bresnan[2], Si Li[3], Yichen Wang[3] and Yih Chang Lin[1], [1]University of South Florida, Morsani College of Medicine, Tampa, FL, [2]University of South Florida, Morsani College of Medicine, Tampa, [3]The Wright Center for Graduate Medical Education, Scranton

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis with high potential for morbidity leading to frequent hospitalizations and significant economic burden to the healthcare system. The goal of this study is to use

Table 1. Most common principal diagnoses on readmissions

Diagnosis	Patients readmitted
Giant Cell Arteritis	52
Acute Kidney Failure	33
Sepsis, unspecified organism	30
Paroxysmal Atrial Fibrillation	18
Type 2 Diabetes Mellitus with Hyperglycemia	14
Headache	13
Pneumonia, unspecified organism	10
Cerebral Infarction, unspecified	10
Syncope and Collapse	9
Gastrointestinal Hemorrhage, unspecified	9

Nationwide Readmissions Database (NRD) to determine the 30-day readmission rate of patients that were initially admitted for active GCA, to identify the reasons and predictors for readmission.

Methods: This is a retrospective cohort study using the NRD from 2016 and 2017. The International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) was used to identify diagnoses. The primary outcome was rate of all-cause readmission within 30 days of discharge for all patients with principle diagnoses of GCA on index admission. Secondary outcomes were principle diagnoses for readmission, predictive factors and resource use. We compared baseline demographics and calculated all-cause 30-day readmission rates in patients who survived their index hospitalization. Proportions were compared using the Fisher exact test, and continuous variables were compared using the Student t-test. Logistic regressions were used for binary outcomes and linear regressions were used for continuous outcomes. Multivariate logistic regression was conducted using Stata, version 16.0 to determine the predictors for readmission. All p-values were two-sided, with 0.05 as the threshold for statistical significance.

Results: There were 4,841 patients admitted for active GCA flares in the NRD from 2016 to 2017, of which 68.7% were female. The mean age was 72.4±11.9 years. The all cause 30-day readmission rate was 13.1%. The 30-day mortality rate was 0.7%. The five most common reasons for readmissions were GCA, acute kidney failure, sepsis, paroxysmal atrial fibrillation, type 2 diabetes mellitus with hyperglycemia. The adjusted odds ratios (aOR) and p-values were calculated and independent predictors of GCA readmission were identified: Coexisting heart failure (aOR 1.63, 95% CI 1.14- 2.34, p= 0.007) and higher Charlson comorbidity score (aOR 1.16, 95% CI 1.08- 1.23, p< 0.001). Discharge from teaching hospitals was associated with lower odds of being readmitted (aOR 0.72, 95% CI 0.55-0.95, p=0.019). The total hospital days associated with readmission were 3,894 days, with a total healthcare cost of $8.54 million.

Conclusion: This study showed 13.1% of the patients who were initially admitted for active GCA were readmitted within 30 days, creating a significant economic burden. Patients with coexisting heart failure and higher Charlson comorbidity core were significantly more likely to be readmitted.

We should be more cognizant of the poor outcomes and high disease burden of active GCA and its treatment complications which may lead to unnecessary readmission including infection, hyperglycemia and renal failure. More study on preventing GCA readmission is warranted.

Effect of Cumulative Glucocorticoid Dose and Inflammation on Weight Change During Treatment of Giant Cell Arteritis

Naomi Serling-Boyd[1], Xiaoqing Fu[2], Yuqing Zhang[3], Sebastian Unizony[1], Zachary Wallace[4], Hyon Choi[5] and John H. Stone[6], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Quincy, MA, [4]Massachusetts General Hospital, Newton, MA, [5]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA, [6]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a form of large vessel vasculitis that requires treatment with high-dose, long-term glucocorticoids (GC). Weight gain, among other side-effects of GC therapy, is a major concern for patients and is associated with increased morbidity and mortality. Prior studies have shown varying results regarding the independent association of GC dose and weight gain. Weight changes in GCA patients being treated with GC or in GCA patients receiving tocilizumab are poorly understood.

Methods: We analyzed GCA patients enrolled in the GiACTA (Tocilizumab in Giant Cell Arteritis) trial. Cumulative GC dose and weight were obtained at weeks 0, 12, 24, and 52. We used multivariable mixed-effects modeling to examine the effects of age, gender, cumulative GC dose, baseline GC exposure, disease status (newly-diagnosed versus relapsing), randomization to tocilizumab, and flares over 52 weeks on changes in weight. We used Student's unpaired t-test to evaluate weight change from 0 to 52 weeks and the Wilcoxon rank test to evaluate the cumulative prednisone from 0 to 52 weeks.

Results: 250 patients were included; 187 (75%) were female and the mean age ± SD was 69 ± 8 years. The mean baseline weight ± SD was 70.8 ± 14.9 kg, and the mean ± SD weight gain among all subjects was 3.2 ± 5.4 kg. Cumulative prednisone dose at 52 weeks was associated with weight change over this time (0.63kg per 1000mg of prednisone; p< 0.001) (**Table 1**). Furthermore, relapsing disease at baseline and flares over 52 weeks were significant-

Table 1. Multivariable mixed-effects modeling evaluating weight change (kg) according to glucocorticoid exposure

Variable	Estimate	p-value
Cumulative prednisone exposure during weeks 0-52 (/1,000mg)	0.63	< 0.001
Relapsing disease	-1.15	0.002
Randomized to tocilizumab	0.37	0.33
Baseline weight (/kg)	0.98	< 0.001
Male	-0.30	0.52
Age (/year)	-0.02	0.32
Baseline prednisone greater than 30mg daily	-0.08	0.83
Flares (/flare)	-0.39	0.04

Table 1. Multivariable mixed-effects modeling evaluating weight change (kg) according to glucocorticoid exposure

Table 2. Cumulative prednisone exposure and weight change per treatment group, stratified by primary endpoint of sustained, glucocorticoid-free remission at 52 weeks

	Tocilizumab groups			Prednisone groups		
	Did not meet primary endpoint (n=68)	Met primary endpoint (n=81)	p-value	Did not meet primary endpoint (n=85)	Met primary endpoint (n=16)	p-value
Cumulative prednisone over 52 weeks, mg, median (IQR)	3017.3 (2527.8, 4180.8)	1356.0 (952.0, 1604.5)	<0.0001	4284.8 (2813.8, 5818.0)	2150.8 (1862.0, 2397.5)	<0.0001
Weight change from 0-52 weeks, kg, mean (sd)	4.0 (5.2)	3.0 (5.0)	0.31	2.8 (6.2)	3.7 (4.1)	0.59

IQR: interquartile range

Table 2. Cumulative prednisone exposure and weight change per treatment group, stratified by primary endpoint of sustained, glucocorticoid-free remission at 52 weeks

ly associated with less weight gain. Among patients who received tocilizumab, those who met the primary endpoint of sustained, glucocorticoid-free remission at 52 weeks received less prednisone than did those who failed (median 1356 vs. 3017mg; p< 0.0001), but these subgroups experienced similar changes in weight (mean 3.0 vs. 4.0kg; p=0.31) (**Table 2**). Among patients who received prednisone alone, those who met the primary endpoint received less prednisone (median 2150 vs. 4284mg; p< 0.0001), yet those patients experienced numerically higher gains in weight compared with those who did not meet the primary endpoint (mean 3.7 vs. 2.8kg; p=0.59).

Conclusion: GC use and weight gain are linked tightly in the minds of providers and patients, but the relationship is actually complex. We found that cumulative GC exposure over 52 weeks is significantly associated with weight gain. However, the degree to which disease activity is controlled also contributes to weight gain, and modest weight gain may be an indicator of effective disease control. Additional research is required to better elucidate this relationship and to understand other determinants of excessive weight gain in this patient population.

Abstract Number: 1932

Giant Cell Arteritis – the Relationship Between the Extensiveness of Vasculitis and the Clinical Presentation

Alojzija Hocevar[1], Rok Jese[1], Matija Tomsic[1] and Ziga Rotar[1], [1]University Medical Center Ljubljana, LJUBLJANA, Slovenia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent data show that the extensiveness of inflammation observed on colour Doppler ultrasonography (CDS) may indicate the risk for ocular ischaemia giant cell arteritis (GCA) patients. [1]

The aim of our prospective study was to evaluate potential correlation between the clinical presentation of GCA and the extensiveness of vascular involvement assessed by CDS in preselected cranial and aortic arch arteries.

Methods: We performed CDS in incipient GCA patients between October 2013 and May 2020, using a Philips IU22 with 5–17.5 MHz linear probe or Philips Epiq 7 with 5–18.5 MHz linear probe. A total of 14 arteries were examined: bilateral temporal (main, frontal and parietal branch were considered as one vessel territory), facial, occipital, thyroid, carotid, vertebral, subclavian, and axillary arteries. A halo with positive compression sign was considered a positive finding. We explored correlations were explored between GCA clinical features and the number of involved vessels using Spearman test.

Results: During the 80-month observation period we diagnosed GCA in 267 patients (66.3% females, median (IQR) age 74.9 (67.0–80.4) years), median (IQR) symptom duration time 30 (21; 60) days). The CDS was positive in 263/267 (98.5%) patients in at least one of the examined arteries (range from 1 to 12). Table 1 shows the number of patients by number of involved vessels.

We observed a very weak positive correlation between symptom duration and the number of affected vessels (0.14 (95%CI 0.02; 0.25), p=0.024), and very weak inverse correlation between headache and the number of affected vessels (-0.14 (95%CI -0.24;-0.02), p=0.023). There was no significant correlation between patient age, sex, the presence of constitutional symptoms, polymyalgia rheumatica, vision manifestations (including severe manifestations), jaw claudication, ESR, CRP, haemoglobin level, platelet count, and the extensiveness of vascular involvement in GCA.

Conclusion: In our incipient GCA cohort, we found no strong correlation between the extent of vascular involvement, assessed by CDS of cranial and aortic arch arteries, and clinical symptoms, but there was a trend for patients with longer symptom duration to have more extensive vessel involvement.

No. of vessels	No. of GCA	No. of vessels	No. of GCA

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic vasculitides are complex and heterogeneous diseases with overlapping features that frequently pose a diagnostic challenge to clinicians. The temporal artery biopsy (TAB) is the gold standard for the diagnosis of giant cell arteritis (GCA) with cranial involvement. Occasionally, the TAB shows small vessel vasculitis (SVV) surrounding a normal temporal artery as the only pathological finding. Ultimate diagnosis and, consequently, optimal treatment remain uncertain in these patients.

The aim of this project is to characterize biomarkers with diagnostic potential in TAB disclosing SVV surrounding a spared temporal artery.

Methods: 51 Patients with TAB showing SVV surrounding a normal temporal artery were subjected to a pre-established diagnostic algorithm combining clinical, imaging and serological data (Fig 1). The algorithm led to the following classification: 19 GCA; 20 systemic vasculitis (ANCA-associated vasculitis (AAV) and other vasculitis); and 12 could not be classified. TAB samples from 15 SVV patients (8 classified as GCA[SVV-GCA] and 7 systemic vasculitis [SVV-SV]: 4 AAV and 3 other vasculitis) and 16 controls with negative temporal artery biopsies, were used for RNA isolation and microarray hybridization (Human Clariom S, Affymetrix). Genes differentially expressed were identified by a multivariate permutation t test using the BRB ArrayTools 4.6 software package (Biometric Research Branch, NCI). We set parameters in the univariate 2-sample t test permutation with a random variance model. Permutation P values for significant genes ($P < 0.001$) were computed based on 10,000 random permutations that result in an estimated false discovery rate below 1%.

Results: We compared gene expression in normal temporal arteries and the different subgroups of SVV. The expression level of 42 genes was found to be significantly different between normal arteries and SVV-GCA, whereas the expression level of 65 genes was significantly different between normal arteries and SVV-SV. Interestingly, an unsupervised hierarchical clustering based on this subset of 107 genes was able to cluster subgroups of SVV: SVV-GCA and SVV-SV (Fig 2). In addition, a hierarchical clustering analysis yielded a subset of 8 genes with significant different

Fig 1 51 patients with TAB showing SVV surrounding a normal temporal artery were subjected to the following algorithm.

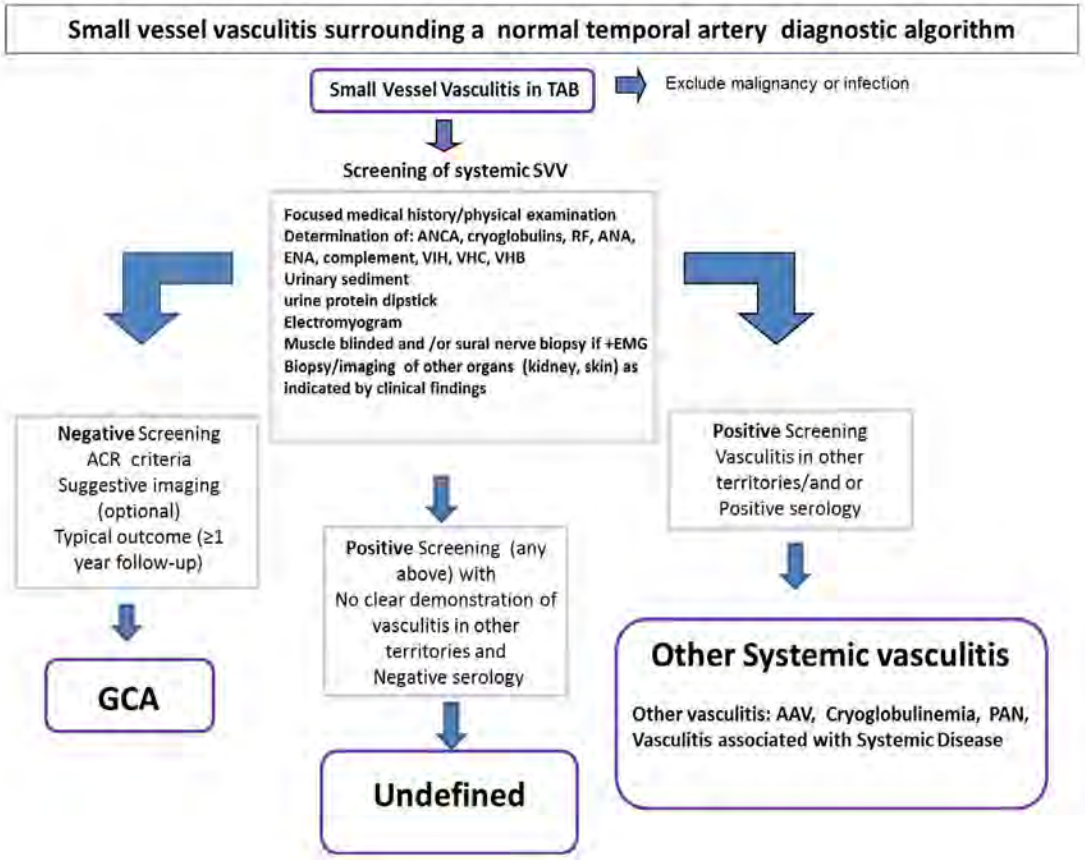

Fig 2 An unsupervised clustering annalysis based on 107 genes with different expression level between Controls and SVV, identified two major clusters of SVV: SVV-GCA and SVV-SV

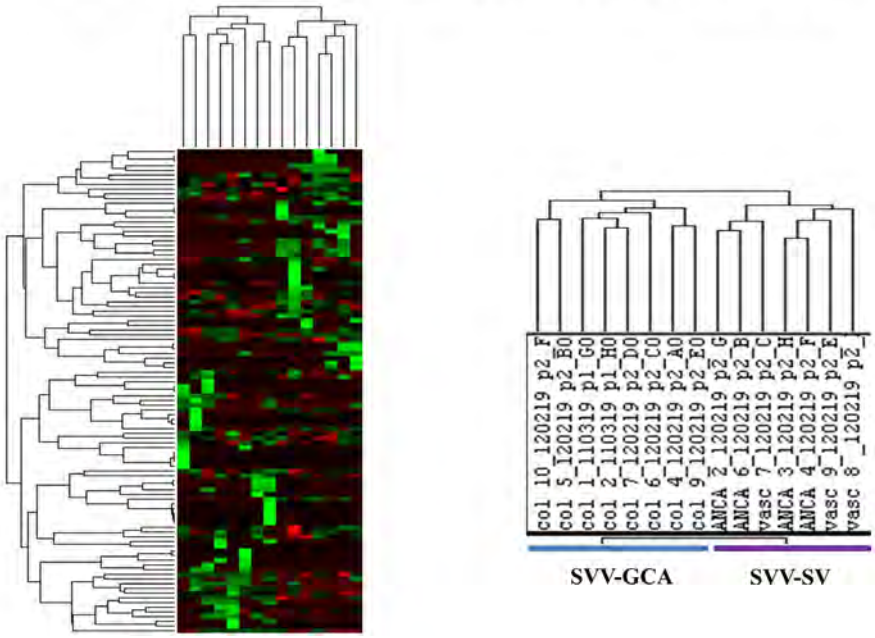

Fig 3 A hierarchical clustering analysis yielded a subset of 8 genes with significant different expression between SVV-GCA and SVV-SV

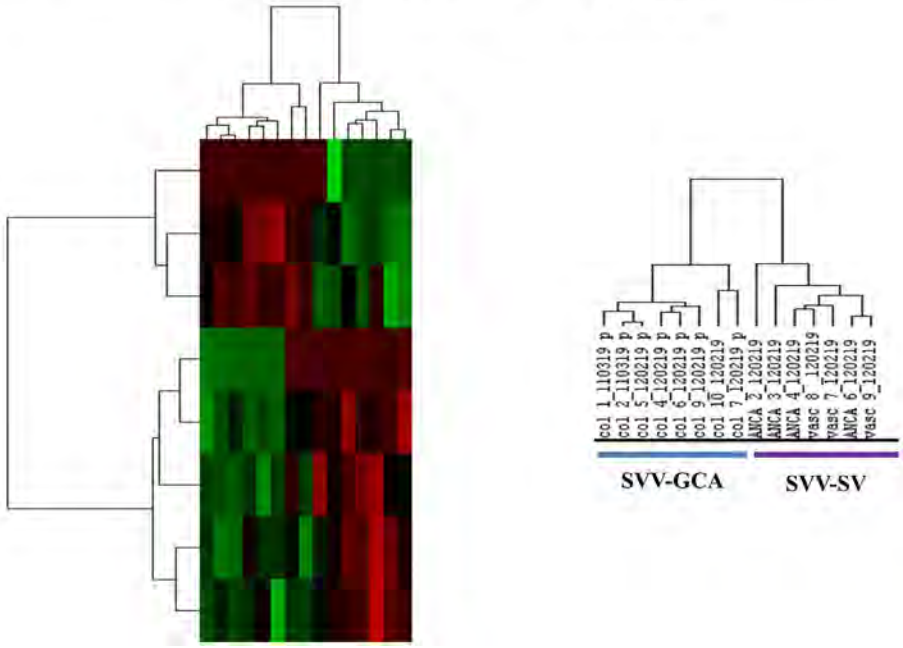

expression between SVV-GCA and SVV-SV (Fig 3). Sub-analysis between SVV-GCA and SVV-AAV and SVV-GCA and SVV-other vasculitis, showed significant differences in expression level of 17 and 23 genes respectively.

Conclusion: SVV surrounding a spared TA is a relevant but equivocal finding. After a detailed diagnostic work-up most patients can be diagnosed with GCA or other systemic vasculitis although diagnosis remains uncertain in some cases. Cluster analysis of the gene expression profile differentiates diagnostic subgroups of SVV. Further studies are needed to validate differentially expressed genes.

What Is the Significance of Periarterial Temporal Small Vessel Inflammation (SVI) on Temporal Artery Biopsy (TAB) in the Diagnosis of Vasculitis? A Systematic Review and Meta-analysis

Elise Belilos[1], Steven Carsons[2] and **Sonya Mehta**[1], [1]NYU Winthrop Hospital, Mineola, NY, [2]NYU Long Island School of Medicine, Mineola, NY

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Isolated inflammation of small vessels including capillaries, venules and arterioles surrounding a normal temporal artery (SVI) in patients suspected of having giant cell arteritis (GCA) has been described in the literature. However, the significance of this finding remains controversial. Authors have described SVI as highly suggestive of vasculitis while others consider it to be a non-specific finding associated with aging, infection and malignant disease. We performed a systematic review of the literature in order to characterize the diagnoses, clinical, and laboratory manifestations of patients with periarterial temporal small vessel inflammation as a sole finding on TAB

Methods: A search of the English language literature from 1990-2019 was performed using the following search terms: temporal artery, giant cell arteritis, vasculitis, small vessel, inflammation, vasa vasorum, and periarteritis. Data was extracted for cases that displayed isolated inflammation of small blood vessels external to a spared temporal artery on TAB. Clinical diagnosis, clinical and laboratory manifestations and treatment were recorded and included age, sex, presence of headache, polymyalgia rheumatica (PMR), temporal artery (TA) abnormality, fever, visual symptoms, and corticosteroid therapy. Data was extracted from individual studies and pooled odds ratios were calculated.

Results: Eleven studies were identified that provided data on 324 TAB demonstrating inflammation of small blood vessels external to the temporal artery. One hundred and fifteen (35.5%) were classified as definite or probable GCA and 80 of these (69.6%) had PMR symptoms. Fifty (15.4%) had isolated PMR. Twenty (6.2%), especially those having neutrophilic infiltrates had other forms of vasculitis. The remainder (42.9%) had other illnesses including infection, malignancy or undiagnosed conditions. Five studies reported clinical data on patients with SVI classified as GCA. The mean age was 73.2 years, 65.8% were male, 43.8% had headache, 9.8% had jaw claudication 23.7% had abnormal TA, 22.3% had fever and 30.5% had visual symptoms. Corticosteroid (CS) was administered to 79.4% (range- 39-100); 79% (range 59.6-100) responded. When SVI was compared to classical GCA, three studies reported significantly fewer SVI patients with jaw claudication whereas 2 studies reported a significant increase in PMR in SVI. Meta-analysis of 4 studies reporting jaw claudication and PMR revealed a significant increase of PMR in SVI (pooled OR 5.92; CI 3.32-10.55; P< 0.001) and less jaw claudication in SVI (pooled OR 0.248; CI 0.13-0.50; P< 0.0001).

Conclusion: Inflammation of capillaries, venules and arterioles surrounding a normal temporal artery on TAB in patients suspected of having giant cell arteritis (GCA) should not be ignored. While the clinical phenotype differs from classical GCA, the high prevalence of PMR, and response to CS suggests that this finding is associated with the PMR-GCA spectrum in a significant proportion of patients.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of primary systemic vasculitis, typically affecting patients aged > 50 years. If left untreated, GCA can lead to permanent visual loss and other ischaemic complications. During the first two years of diagnosis, mortality is significantly higher in GCA than in the general population, with a significant contribution of infections to mortality in the first year of treatment. Identifying patients with a higher risk of mortality at the time of diagnosis could be crucial for prevention and tailored treatment; however, independent predictors of early mortality have never been reported in the literature.

Methods: Bicentric observational study using data from the Portuguese Register of Rheumatic Diseases (Reuma.pt). Patients with biopsy- or ultrasound-proven GCA were included. Early mortality was defined as death occurring in the first two years after diagnosis. Univariate analysis was performed using Chi-Square, Fischer's Exact Test and Mann-Whitney Test, as appropriate. Multivariate analysis was

performed using binary logistic regression modelling. The linearity of the continuous variables with respect to the logit of the dependent variable was assessed via the Box-Tidwell procedure.

Results: The study included 133 patients with 85 (66.4%) females and a median age at diagnosis of 75.0 (interquartile range [IQR] 12.0) years. Fourteen (10.5%) deaths occurred during the first two years after diagnosis. Early mortality was significantly associated with: (i) cranial ischaemic event, anterior ischaemic optic neuropathy, permanent loss of vision and tongue claudication at disease presentation; (ii) older age, atrial fibrillation, chronic kidney disease, creatinine level and treatment with bisphosphonates at diagnosis; and (iii) treatment with anticoagulants before disease onset (Table 1).

The multivariate analysis included 124 patients (5 patients had missing information, 4 patients were outliers) with 81 (65.3%) females, a median age at diagnosis of 75.0 (IQR 12.0) years, and 10 (8.1%) deaths in the first two years of diagnosis. The logistic regression model was statistically significant, $\chi 2$ (7) = 42.0, p< 0.001. The model explained 66.9% (Nagelkerke R2) of the variance in early mortality and correctly classified 96.0% of all cases. Older age at diagnosis (OR 1.3/year, 95%CI: 1.0-1.6, p=0.032), tongue claudication at disease presentation (OR 2106.8, 95%CI: 4.2-1057334.5, p=0.016), previous treatment with anticoagulants (OR 42.1, 95%CI: 2.6-682.0, p=0.009) and treatment with bisphosphonates at diagnosis (OR 0.0, 95%CI: 0.0-0.4, p=0.019) were identified as independent predictors of early mortality and survival, respectively (Table 2).

Conclusion: In our cohort, older age at diagnosis, tongue claudication at disease presentation and previous treatment with anticoagulants were independent predictors of early mortality. On the other hand, treatment with bisphosphonates at diagnosis was an independent predictor of early survival. These findings are novel and require replication. However, they highlight the need for a disease management not only focused on clinical manifestations but also drug adverse effects and comorbidities.

Table 1 - Results of the univariate analysis testing the association between the outcome variable (early mortality) and predictor variables

Variables	Early mortality (n=14)	Early survival (n=119)	p-value
Demographic and anthropometric data at diagnosis

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of systemic vasculitis in patients aged 50 years and older.[1] Visual symptoms as amaurosis and temporary or permanent loss of visual field secondary to optic

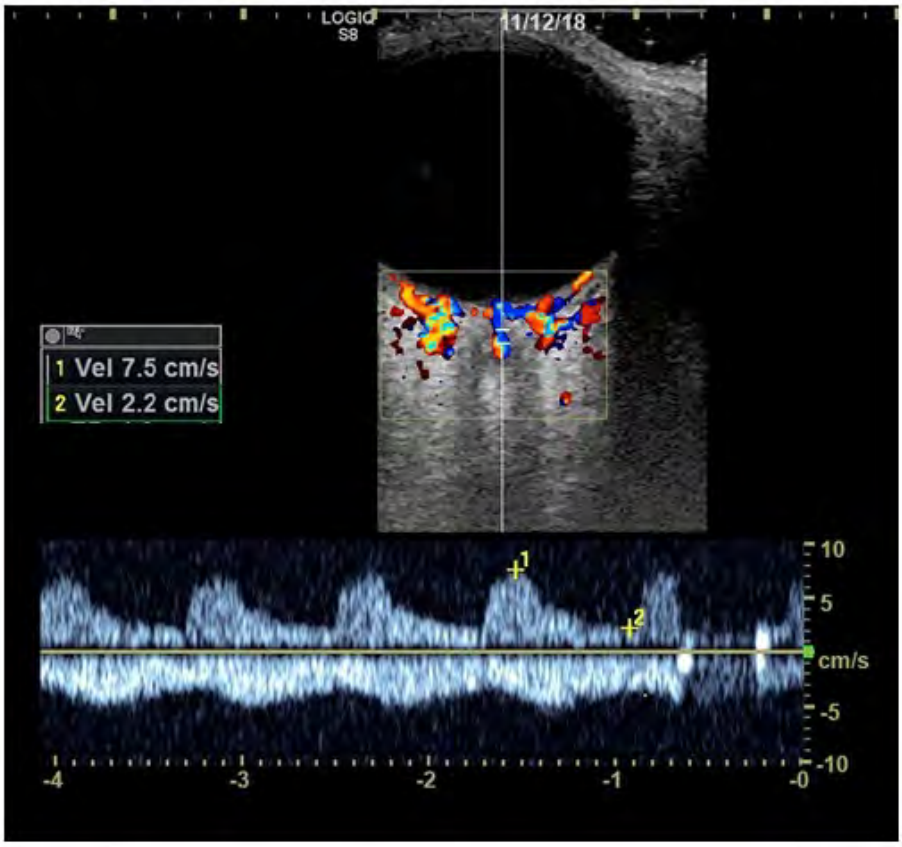

Figure 1. Transocular ultrasound of an affected eye in giant cell arteritis with reduced flow velocities.

nerve ischemia are common manifestations.[2] The role of ultrasound in diagnosis of GCA is known.[3] Transocular ultrasound of the central retinal artery in GCA patients with visual symptoms has not yet been examined.

Methods: Prospective analysis of flow velocities of the central retinal artery in newly diagnosed GCA patients with visual symptoms and eye-healthy controls. Visual symptoms were defined as amaurosis and temporary or permanent loss of visual field. For each eye, peak systolic values (PS) and end-diastolic values (ED) were recorded.

Results: We included 27 newly diagnosed consecutive GCA patients with visual symptoms (GCA-group) and 25 eye-healthy controls. Thirty of 54 eyes (55%) of 27 GCA patients were symptomatic. The control group consisted of 50 central retinal arteries of 25 eye-healthy individuals. Mean age and gender distribution was 75 years (SD± 8.1) with 17 females (63 %) in the GCA group and 67 years (SD± 8.9) with twelve females (48%) in the control group, respectively. Mean flow velocity of the central retinal artery was in 10.9 cm/s (SD± 4.6) in PS and 3.5 cm/s (SD± 1.5) in ED in the GCA group, while values of 14.4 cm/s (SD± 3.2) in PS and 5.1 cm/s (SD± 1.6) in ED were observed in the control group. Mean reduction in flow velocity in the GCA-group was 3.5 cm/s (p-value 0.001) in PS and 1.6 cm/s (p-value 0.000099) in ED, therefore highly significant. Figure 1 shows an ultrasound image of a pathological flow velocity of the central retinal artery in GCA. Figure 2 displays differences in flow velocities between the two groups.

Conclusion: In GCA patients with visual symptoms, a significant reduction of flow velocities of the central retinal artery compared to the eye-healthy control group was observed. Longitudinal data will show, if the flow velocities normalized under treatment.

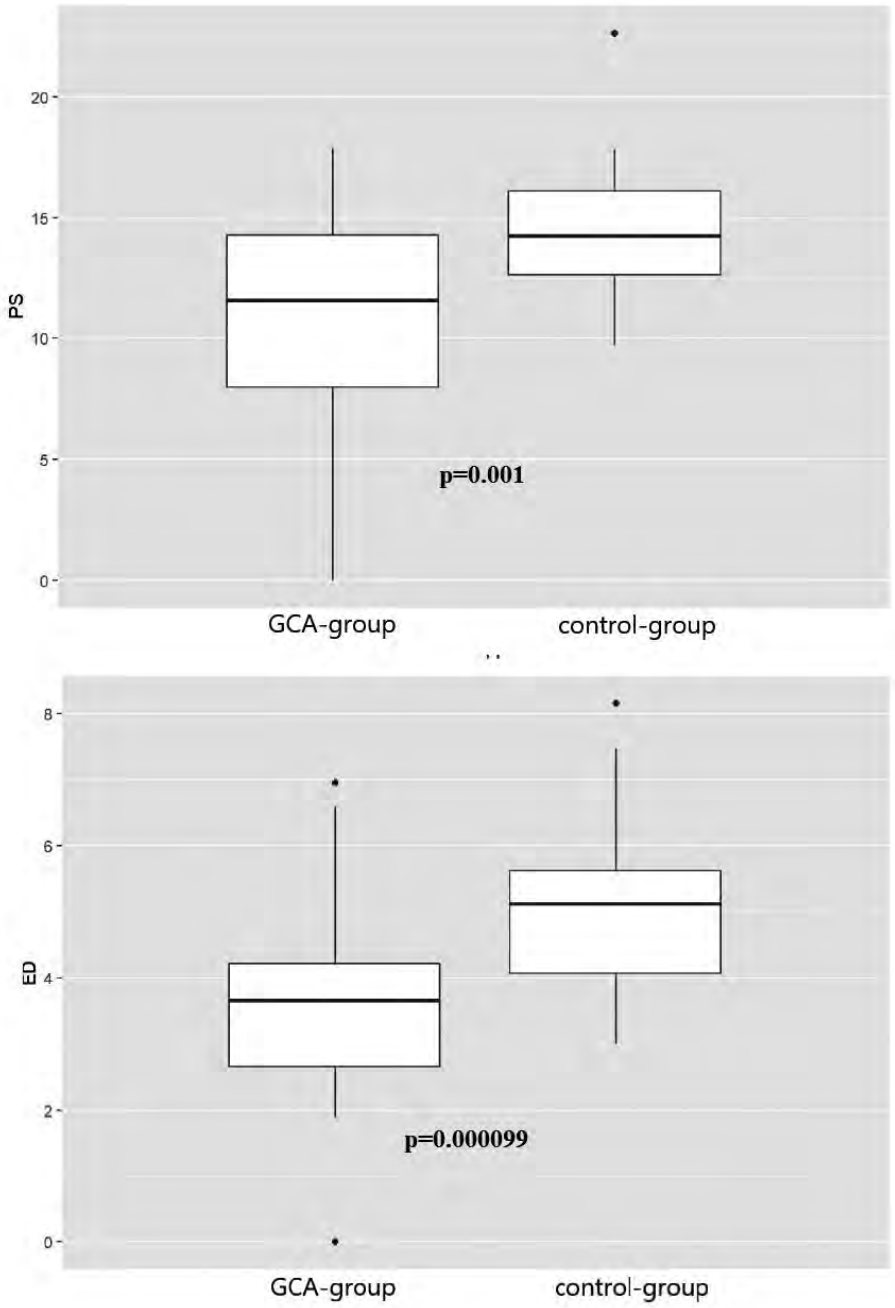

Figure 2. Differences in peak systolic (PS) and end-diastolic (ED) flow between the two groups. GCA-group: Patients with GCA and visual symptoms Control-group: eye-healthy control patients

Aortic Aneurysm in Giant Cell Arteritis: A Nationwide Analysis

Jiayi Zheng[1], Ruoning Ni[2], Yan Tang[3] and Liangjing Lu[4], [1]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, Shanghai, China (People's Republic), [2]St. Agnes Hospital, Baltimore, MD, [3]Department of Stomatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, Shanghai, China (People's Republic), [4]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is an inflammatory vasculopathy affecting primarily medium and large sized arteries. Previous studies have demonstrated a higher prevalence of aortic aneurysm in patients with GCA. The current study was conducted to better describe the characteristics as well as predictors of aortic aneurysm in patients with GCA in US population using data from a large national database.

Methods: This is a retrospective cross-sectional study using data from National Inpatient Sample (NIS) spanning the period from January 2006 to December 2010. Diagnoses were identified using the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. STATA/MP Version 15 and R 4.0.0 were used for statistical analyses. Categorical variables were calculated using chi-square tests and continuous variables were compared using Student's t-test or Wilcoxon rank-sum test based on the distribution of data. We also performed a multivariate logistic regression analysis to identify the potential risk factors and protective factors of aortic aneurysm in patients with GCA.

Results: We identified 263,384 records with a diagnosis of aortic aneurysm, 21,698 records with a diagnosis of GCA, and 387 records with concurrent GCA and aortic aneurysm. Among patients with aortic aneurysms, those with GCA were more likely to be older (mean age 78.6 vs 74.7, $p < 0.01$), to be female (33% vs 64%, $p < 0.001$), and to develop ruptured aortic aneurysms (9.3% vs 5.8%, $p < 0.01$). Patients with GCA were more likely to have thoracic aortic aneurysms (31.3% vs 16.0%, $p < 0.001$), whereas those without GCA were prone to abdominal aortic aneurysms (62% vs 79%, $p< 0.001$). In patients with thoracic aorta involvement, those with GCA had a longer hospital stay (8.2 vs 7.0 days, $p < 0.01$, Wilcoxon rank-sum test), but the mortality rates between the two groups were similar ($p = 0.8$). The multivariate logistic regression analysis showed that in patients with GCA, the presence of other aneurysms (OR 13.7, 95% CI: 6.1 – 27.3), aortic valve disorders (OR 3.02, 95% CI: 2.22 – 4.02), current or previous tobacco use (OR 2.03, 95% CI: 1.55 – 2.64), and hyperlipidemia (OR 1.29, 95% CI: 1.03 – 1.59) were possibly linked to the development of aortic aneurysm, while female gender (OR 0.65, 95% CI: 0.53 – 0.81) and diabetes mellitus (OR 0.46, 95% CI: 0.35 – 0.61) were potential protective factors.

Conclusion: Consistent with previous studies, GCA is more common in females, and it has a predilection to affect the thoracic aorta. Our study also suggests that GCA could be associated with the rupture of aortic aneurysms. The presence of other aneurysms, aortic valve disorders, tobacco use and hyperlipidemia are possible risk factors for the development of aortic aneurysm in patients with GCA, while female gender and diabetes mellitus are potential protective factors.

Abstract Number: 1938

Risk for Vision Loss and Relapse in Patients with Giant Cell Arteritis

Anne Bull Haaversen[1] and Andreas Diamantopoulos[2], [1]Martina Hansens Hospital, Hosle, Norway, [2]Martina Hansens Hospital, Baerum, Norway

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) involves both the cranial and large vessels. Studies have shown that while the vision loss rates are higher, the relapse rates may be lower in patients with cranial arteritis without large vessel involvement (pure cranial arteritis). However, in many studies, the definition of pure cranial arteritis has not been accurate, as the supraaortic tree has not been thoroughly examined and they are based mainly on retrospectively collected data. This study aimed to investigate the rates of vision loss and relapse in patients with pure cranial GCA in a Norwegian prospective cohort of GCA patients.

Methods: Patients with new-onset GCA referred to the Department of Rheumatology, Martina Hansens Hospital in Bærum, Norway are prospectively included and followed-up. The diagnosis is based on typical for GCA clinical manifestations and ultrasound findings. All the patients are scanned by ultrasound using the anteromedial approach for the supraaortic vessels (carotid, vertebral, subclavian, axillary proximally, and distally) and cranial vessels (temporal, facial) as well. The examination utilizes a General Electric S8 ultrasound machine with a 9-12 MHz linear probe for the large vessels and an 18 MHz hockey stick probe for the cranial arteries and a Canon Aplio 700 with an 11 MHZ and 22 MHz probes for the large and cranial vessels respectively. The age, gender, CRP, Prednisolone dose, distribution of vasculitis in the vessels, vision loss, and relapse rates are recorded and relative risks (RR) are calculated.

Results: Seventy-nine patients, 58 (73%) females, and 21 (27%) males were diagnosed with GCA until May 2020. The mean age was 72 years. Mean CRP was 96 mg/dl (95% CI (63-96)). Of the 79 GCA patients, 20 had involvement of the cranial vessels only (pure cranial CGA), 19 patients have involvement of the large supraaortic vessels only, and 50 of both cranial and large supraaortic vessels. Seven patients suffered from vision loss (9%) and all these patients had a concomitant cranial disease. The GCA patients with pure cranial disease had a RR for visual loss of 1.14 (95% CI (0.3-3.9)) while GCA patients with both cranial and large vessel disease had a RR of 1.35 (95% CI (1.2-1.5)). No patients with pure large vessel GCA suffered from vision loss. The median Prednisolone dose at the first relapse was 10 mg (IQR 8). Of the 20 GCA patients with cranial arteritis, only 3 (4%) relapsed during the study period, while 33 (25 %) patients of the 59 GCA patients with concomitant large supraaortic vessels involvement relapsed. The Relative Risk for relapse in patients with pure cranial arteritis was 0.3 (95%CI 0.1-0.8).

Conclusion: In a prospective cohort of GCA patients, pure cranial disease appears to have a 14 % higher risk of vision loss and a 70% lower risk of relapse. It seems that concomitant large supraaortic vessel involvement does not reduce the risk of vision loss. We continue to recruit GCA patients in our prospective cohort and examine the RR of the vision loss and relapse in larger numbers of patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The OMERACT Ultrasound (US) large vessel vasculitis task force has recently defined the US appearance of normal axillary arteries (AA) and the key elementary US lesions in acute giant cell arteritis (GCA) of the AA (i.e.:“non-compressible halo sign”). The aim of the present study was to assess the reliability of a new OMERACT definition for the US appearance of chronic GCA lesions of the AA in a web-based reliability exercise (Table 1)

Methods: The reliability exercise was performed using a REDCap. One-hundred-fifty anonymized still images from AA, were assessed (50 each from chronic and acute GCA, and 50 from healthy individuals). Chronic GCA patients had a disease duration of more than one year and were in remission. Acute GCA patients had new-onset disease with glucocorticoid treatment duration ≤1 week. The members of the OMERACT Large Vessel Vasculitis Ultrasound Working Group (n=23, all ultrasound experts in GCA) were asked to assign all images to the categories of normal, acute GCA or chronic GCA applying the definitions agreed in previous Delphi exercises. In order to assess the intra-observer reliability, all task force members were asked to repeat the reliability exercise in a time range of at least two weeks later and using the same images presented in a different order. Light’s κ were used for evaluating intra- and inter-reader reliability, respectively. κ values of 0–0.2 were considered slight, 0.2–0.4 fair, 0.4–0.6 moderate, 0.6–0.8 substantial and 0.8–1 excellent.

Table 1 – Ultrasound definitions of normal, acute and chronic GCA of the axillary artery

	Definition of US appearance of normal axillary artery	Definition of US appearance of vasculitis- "Halo Sign"	Definition of US appearance of chronic GCA changes
Axillary artery	Pulsating, hardly compressible artery with anechoic lumen; the intima-media complex presents as a homogenous, hypoechoic or anechoic echostructure delineated by two parallel hyperechoic margins ('double line pattern'), which is surrounded by mid-echoic to hyperechoic tissue.	Homogenous, hypoechoic wall thickening, well delineated towards the luminal side, visible both in longitudinal and transverse planes, most commonly concentric in transverse scans.	Mostly homogenous, mid- to hyperechoic long-segmental thickening of the intima-media complex (IMC) > 0.9 mm, displaying several visible lines with loss of the typical double line pattern, well delineated towards the luminal side, visible both in longitudinal and transverse planes, most commonly concentric in transverse scans. Doppler sonography can be of help depicting stenosis, collaterals and occlusion. Atherosclerotic changes may coexist.

Table 2 – Results of the web exercise on still images of acute and chronic GCA of the axillary artery and normal axillary arteries

Section	Inter observer agreement round 1	Inter observer agreement round 2	Intra observer agreement
Normal vessels mean prevalence, %	34.5	34.5	34.5
Vessels with acute changes mean prevalence, %	33.5	31.5	32.4
Vessels with chronic changes mean prevalence, %	31.9	34.0	33.1
Agreement,mean, %	87	86	92
Agreement,range	66-99	63-99	75-99
Light's κ, mean	0.8	0.79	0.88
Light's κ, range	0.5-0.99	0.49-0.98	0.75-0.99

Results: The response rate for both rounds was 100%. The reliability of the new OMERACT definition for the US appearance of chronic GCA of the AA was substantial to excellent with Light's kappa values of 0.79-0.80 for inter-reader reliability and mean Cohen-kappa values of 0.88. The mean inter-rater agreements were 86-87%. The mean intra-reader agreements were 92% (Table 2).

Conclusion: Inter- and intra-observer agreement on the evaluation of US still images from normal, acute and chronic GCA AA was substantial to excellent when applying the new OMERACT definitions for key elementary US lesions in GCA of the AA. Further exercises are planned in order to test the reliability in patients with chronic GCA US changes of the AA.

Abstract Number: 1940

In Newly Diagnosed Giant Cell Arteritis in a Real Life Setting Relapses Are Seen in More Than a Third of Patients – and Despite Faster Early Reduction High Cumulative Glucocorticoid Doses Are Reached

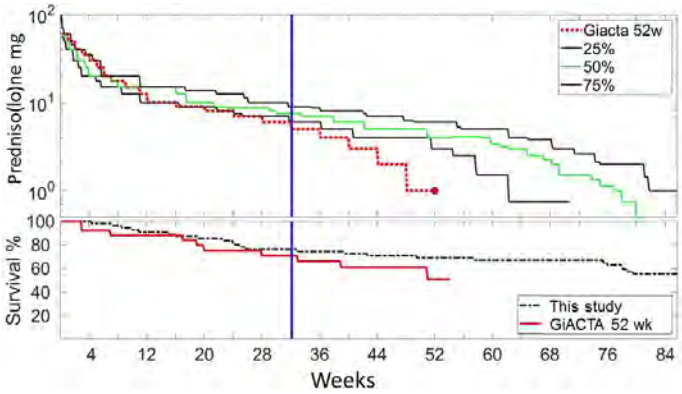
Laura Felten[1], Nicolai Leuchten[1] and **Martin Aringer**[2], [1]University Medical Center and Faculty of Medicine TU Dresden, Dresden, Germany, [2]Rheumatology, Medicine III, University Medical Center & Faculty of Medicine, TU Dresden, Dresden, Germany, Dresden, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate real life glucocorticoid (GC) dosing and relapse rates in patients with new onset giant cell arteritis (GCA) in a single center.

Methods: Complete clinical data taken from the inpatient and outpatient records of consecutive GCA patients followed beyond stopping GC were retrospectively analyzed for GC doses, other immunomodulatory agents and relapses. We excluded patients with incomplete follow-up, in interventional trials and on tocilizumab treatment. All patients consented to anonymous workup of their data, which was approved by the local ethics committee.

Results: 55 patients with GCA (71% female, age 71.4±10.2 (mean±SD) years), diagnosed by biopsy or FDG-PET were included. Of these, 24 (42%) patients relapsed. Methotrexate treatment was not significantly associated with fewer relapses. Of the 31 patients without relapse, one had additional GCs because of another condition. From the prednisolone equivalent data of the remaining 30 patients we calculated 25%, 50% and 75% quartiles. Patients were grouped according to prednisolone start doses of ≤100 mg (standard dose, n=17) and >100 mg (pulse, n=13). In the 25% percentile, patients reached a dose of 15 mg or lower at days 40 (standard) and 49 (pulse), of 7.5 mg prednisolone or lower on day 169 (after 24 weeks) in either arm, and were off prednisolone on days 496 (70 weeks) and 546 (78 weeks) for low dose and high dose start, respectively. Four of the 24 patients with relapses had relapsed after stopping prednisolone clearly (17 to 58 weeks) earlier than the 25% quartile. Of the 20 other patients with relapses, only one was distinctly (>10%) below the 25% glucocorticoid percentile, 13/20 (65%) were on GC doses between the 25% and 75% percentiles. The 50% quartile was largely overlapping the medium recommended doses of the British Society of Rheumatology (BSR) and the GiACTA 52-week GC taper (Stone et al, N Engl J Med 2017), but with shorter time spans on doses of 20 mg and above (Figure). On the other hand, the duration on low doses (< 5 mg q.d.) exceeded those of the minimum dose recommendations of the BSR and of the GiACTA 52-week arm (Figure). The respective cumulative prednisolone doses reached in this real-life cohort were 3.74 g for the 25% quartile and 6.22



Prednisolone doses and survival without flares of this cohort as compared to the GiACTA 52 week arm. 50% (green), 25% and 75% quartile of the GC doses in the standard dose group of this cohort vs the 52 weeks GC only (pacebo) arm with higher starting dose in the GiACTA trial.

g for the 75% quartile in the standard dose, and even higher (6.30 g and 8.98 g, respectively) for those starting with high dose GC pulses.

Conclusion: Despite a long-term GC regimen with slow rates of reduction in the low dose range, 44% of the patients relapsed. Only five of these relapses may have been prevented by adhering to the recommended GC regimen, for a still resulting rate of 35% of relapses. Typical cumulative prednisolone doses were slightly lower than those according to the BSR recommendations, because of a probably safe earlier reduction, but still ranged from 3.74 to 8.98 g. These data suggest that GC monotherapy for GCA may be suboptimal.

Outcome of Giant Cell Arteritis Patients Who Were Primarily Admitted for Venous Thromboembolism Events

Shu Cao[1], Caroline Bresnan[2], Si Li[3], Yichen Wang[3] and Yih Chang Lin[1], [1]University of South Florida, Morsani College of Medicine, Tampa, FL, [2]University of South Florida, Morsani College of Medicine, Tampa, [3]The Wright Center for Graduate Medical Education, Scranton

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) has been shown to have an increased risk of developing deep venous thrombosis (DVT), pulmonary embolism (PE) and combined thromboembolism (VTE) events in many studies. However, the impact of GCA on hospital stay outcomes in these patients with VTE including mortality, length of stay (LOS) and hospitalization cost is unknown. The aim of this study is to assess whether patients with GCA are experiencing more negative outcomes when compared with the general population during their in-hospital stay for VTE events utilizing the National Inpatient Sample (NIS) database.

Table 1. Characteristics of adult patients admitted with VTE

Patient characteristics (%)	Without GCA	With GCA	P value
Female	52.2	81.2	<0.001
Chronic kidney disease	13.2	21.8	<0.001
Hypertension	58.7	70.8	<0.001
Coronary artery disease	17.8	17.3	0.8484
Congestive heart failure	12.7	13.8	0.6244
Diabetes mellitus	23.0	22.3	0.8121
Peripheral vascular disease	4.7	6.9	0.1272
Hyperlipidemia	33.0	42.1	0.0065
Obesity	18.7	13.4	0.0513
Race			0.0607
White	72.1	80.4

Hispanic	6.3	2.7	
Asian or Pacific Islander	0.9	1.6	
Native American	0.4	0.5	
Other	2.3	2.7	
Charlson Comorbidity Index score			0.1129
0	38.6	30.7	
1	22.4	24.7	
2	15.3	17.3	
3	8.7	12.4	
≥4	15.0	14.8	
Insurance provider			<0.001
Medicare	54.4	91.0	
Medicaid	10.9	0.5	
Private	29.3	8.4	
Other	5.3	0	

Abbreviations: GCA, giant cell arteritis; VTE, venous thromboembolism

Methods: We conducted a retrospective study on the association between GCA and VTE. Adult patients admitted with a principal diagnosis of DVT or PE were included. GCA patients were identified among these patients if they also carry a diagnosis of GCA on admission. We used data from the NIS database between the period of 2012 to 2014. We used the International Classification of Diseases, Ninth Revision, Clinical Modification/Procedure Coding System (ICD-9-CM) to identify co-morbid conditions and in-hospital complications. Multivariate regression analysis via STATA 16.0 was used to examine the association of in-hospital mortality, LOS and cost between GCA and non-GCA patients during their VTE admissions. A p-value of 0.05 was selected as the statistical significance threshold.

Results: We identified 897,180 admissions with VTE, among which 1,010 had GCA. Patients with GCA were older (mean age 78.5 vs. 62.5), more likely to be female (81.2% vs. 52.2%), have Medicare insurance (91.0% vs. 54.4%), chronic kidney disease (21.8% vs. 13.2%), hypertension (70.8% vs. 58.7%) and hyperlipidemia (42.1% vs. 33.0%). After adjustment of possible confounding variables within the patient and hospital level, there was no statistically

significant difference in the in-hospital mortality, LOS, and cost of hospitalization when comparing GCA and non-GCA in VTE admissions (p = 0.752, 0.640, and 0.392, respectively).

Conclusion: GCA patients who were primarily hospitalized for VTE events do not have worse outcomes as compared to non-GCA patients in terms of mortality, LOS or cost of hospitalization. Future research will be warranted to investigate and confirm this finding.

Analysis of Vasculitis Patterns in Patients with Giant Cell Arteritis Compared to Patients with Giant Cell Arteritis and Polymyalgia Rheumatica

Lara Burg[1], Peter Brossart[2], Charlotte Behning[3] and **Valentin Schaefer**[4], [1]Clinic for Internal Medicine III, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [2]Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [3]Institute for Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [4]Clinic of Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) often coexist.[1] The role of modern ultrasound (US) in diagnosis of GCA as well as PMR is well known.[2]

To date it is unknown, whether patients with GCA and PMR have different vasculitis patterns in US examination of the vessels commonly affected than patients with GCA only.

Affected artery	Group					
	PMR-GCA-group (n=27)			GCA-group (n=18)		
	Unilateral	Bilateral	None	Unilateral	Bilateral	none
Axillary artery	9 (33%)	12 (45%)	6 (22%)	5 (28%)	7 (39%)	6 (33%)
Common superficial temporal artery	3 (11%)	21 (78%)	3 (11%)	5 (28%)	13 (72%)	0 (0%)
Frontal branch	6 (22%)	17 (63%)	4 (15%)	3 (17%)	11 (61%)	4 (22%)
Parietal branch	5 (18%)	21 (78%)	1 (4%)	3 (17%)	13 (72%)	2 (11%)
Facial artery	7 (26%)	17 (63%)	3 (11%)	4 (22%)	11 (61%)	3 (17%)

PMR-GCA-group: patients with diagnosis of giant cell arteritis and polymyalgia rheumatica
GCA-group: patients with diagnosis of giant cell arteritis only.

Table 1. Prevalence of vasculitis in patients with giant cell arteritis and polymyalgia rheumatica and patients with giant cell arteritis only.

Methods: Prospective analysis of newly diagnosed consecutive patients with GCA and PMR (GCA/PMR group) as well as GCA only (GCA group), who met ACR and ACR/EULAR criteria for GCA and PMR. US examination was performed of the arteries commonly affected in GCA, such as axillary arteries, vertebral arteries, superficial temporal arteries with both frontal and parietal branches and facial arteries.

Arteries were defined as pathological, if measured intima-media-thickness by US was above published cut-off values.[3]

Results: The GCA-PMR-group consisted of 27 patients, the GCA-group of 18 patients. In the GCA-PMR-group, a total of 206 arteries were affected, while in the GCA-group 131 arteries were affected.

Mean age and gender distribution of the GCA-PMR-group was 74 years (SD± 9) with 10 (37%) females in the GCA-PMR-group, and 76 years (SD± 9) with 10 (55%) females in the GCA-group, respectively. Median values of C-reactive protein (CRP) were 57.2 (IQR 31.7-75.7) in the GCA-group and 48.3 (IQR 17.5- 79.9) in the GCA-PMR-group, respectively. CRP values did not differ significantly between the two groups (p= 0.3577). Mean number of affected arteries per patient was 7.63 in the GCA-PMR-group and 7.28 in the GCA-group. Altogether we did not detect a significant difference in vascular pattern between the two groups. Exact numbers, distribution and IMT-values for all measured arteries are depicted in table 1.

Conclusion: We did not observe a significant difference in vascular patterns between GCA and PMR patients and GCA only patients.

In bold statistically significant differences (p<0.05); HADS – Hospital Anxiety (A) and Depression (D) Scale; IQR –interquartile range; SF-36 – Short Form-36

Table 2. Differences between the values of SF-36 in patients with HADS ≥8 and <8 and HADS ≥ 11 and <11.

GCA, mainly using Short Form 36 (SF-36), a generic patient-reported outcome (PRO) with a mental health component. Hospital Anxiety and Depression Scale (HADS) is a validated PRO to assess depression and anxiety and to the best of our knowledge has never been evaluated in patients with GCA. We aimed to assess the prevalence of anxiety and depression in patients with GCA using HADS and compare its results to SF-36.

Methods: HADS and SF-36 questionnaires were prospectively collected from patients with biopsy- or imaging-proven GCA evaluated from July 2018 to January 2020 in a tertiary centre. An age- and gender-matched control group was retrieved from a population-based dataset - the EpiReumaPT (the largest Portuguese epidemiologic study on rheumatic diseases). HADS-A and -D ≥8 defined possible and HADS-A and -D ≥11 defined probable anxiety and depression, respectively. Univariate analysis was performed using Chi-Square, Mann-Whitney and Fischer's exact tests, as appropriate. Multivariate analysis was performed using binary logistic regression. Association between values of HADS and SF-36 was assessed using Spearman's correlation coefficient.

Results: We included 72 patients diagnosed with GCA, 52 (72.2%) females, with a mean ± SD age of 78.3 ± 7.7 years. The control group consisted of 288 individuals. **Table 1** shows the comparison between groups. Patients with GCA had higher median [IQR] HADS-A than controls (7 [7] vs. 5 [5], p< 0.001), as well as a higher prevalence of HADS-A ≥8 and ≥11 (48.6% vs. 26.4%, p< 0.001; 30.6% vs. 12.2%, p< 0.001; respectively). Patients with GCA had higher median [IQR] HADS-D (7 [7] vs. 5 [5], p=0.013) and prevalence of HADS-D ≥11 (33.3% vs. 18.1%, p=0.004) than controls, but prevalence of HADS-D ≥8 did not differ between groups (48.6% vs. 37.2%, p=0.075). Multivariate analyses adjusted for neoplastic disease, hyperuricemia/gout, GCA and history of mental disease showed that GCA and history of mental disease were independent predictors of HADS-A ≥8 (OR 2.0 95%CI: 1.1-3.5, OR 4.4 95%CI: 2.3-8.7; respectively) and HADS-A ≥11 (OR 3.8 95%CI: 2.0-7.4, OR 2.5 CI95%: 1.1-5.5; respectively), but only GCA was an independent predictor of HADS-D ≥11 (OR 2.6 95%CI: 1.4-4.7). Patients with HADS-A or -D ≥8 or ≥11 had inferior levels of SF-36 in all categories except for physical role limitation in HADS-A ≥8 (Table 2). Moreover, values of

HADS and mental health component of SF-36 showed significant correlation (HADS-A: r=-0.780, HADS-D: r=-0.742; both p< 0.001).

Conclusion: Patients with GCA showed a higher prevalence of anxiety and depression when compared to the general population. HADS appeared to be an efficient screening tool for these psychiatric manifestations in GCA, correlating well with SF-36. Future replication of these results in independent cohorts are warranted; however, they currently raise awareness for the fact that mental health should not be overlooked when managing GCA.

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common primary vasculitis in patients (pts) aged over 50 years. It is a medical emergency due to the potential occurrence of severe ischaemic events (SIEs), namely vision loss (VL) and cerebrovascular accidents (CVAs), largely responsible for the high burden of this disease. Identifying patients at a higher risk of developing VL and CVAs is clinically relevant to determine prognosis and tailor treatment.

Methods: Bicentric observational retrospective study using data from the Rheumatic Diseases Portuguese Registry (Reuma.pt). Pts with biopsy or ultrasound-proven GCA were included. VL and CVAs (stroke or transient ischaemic attacks) were considered the SIEs of interest. Clinical features of patients with or without SIEs were compared using Chi-square and Mann-Whitney U tests, as appropriate; multivariate logistic regression was used to identify predictors of SIEs.

Results: A total of 134 pts diagnosed with GCA between 1998 and 2019 were included. Median (IQR) age at diagnosis was 76.4 (70.2-82.4) years and 66% of pts were females. At least one SIE was reported in 65 (48.5%) pts; 8 pts had more than one SIE. A total of 73 SIEs were recorded: 44 cases of ischaemic optic neuropathy (29 anterior, 2 posterior, 13 not specified), 61% with unilateral involvement and 74% leading to permanent visual loss (PVL); 6 cases of central retinal artery occlusion with 100% PVL; 16 ocular events of non-specified cause (6 transient visual

Table 1. Differences between GCA patients with and without severe ischaemic events. SIEs: severe ischaemic events; GCA: Giant cell arteritis; PMR: polymyalgia rheumatica; TA: temporal artery. Continuous variables are expressed as median (IQR). Categorical variables are expressed as n/modified(m)N (total N -missing data), %. * Fatigue, anorexia, weight-loss, fever, night sweats or lymphadenopathies. ** Thickness, tenderness, and reduced or absent pulse.

loss, 5 PVL, 5 diplopia); 6 ischeamic strokes; and 1 transient ischaemic attack. Table 1 presents the differences between pts with and without SIEs. On univariate analyses, pts with SIEs were older ($p< 0.001$), and more often had previous hypertension (OR: 3.0, 95%CI: 1.4-6.3), jaw claudication (OR 3.0, 95%CI: 1.5-6.5) and temporal artery (TA) abnormalities on clinical examination (OR 4.5, 95%CI: 1.8-10). By contrast, musculoskeletal (MSK) features including polymyalgia rheumatica (PMR) were negatively associated with the occurrence of SIEs (OR 0.37, 95%CI: 0.2-0.7). In terms of laboratory results, only creatinine levels at diagnosis were significantly higher ($p=0.014$) in pts with SIEs;

Table 2 - Multivariate logistic regression model for prediction of severe ischaemic events

	B	S.E.	Wald	df	p	OR	95% C.I. for OR	
							Inferior	Superior
Age at diagnosis	0.061	0.032	3.636	1	0.057	1.063	0.998	1.132

B – coefficients in log-odds units; CI – confidence interval; df – degrees of freedom; OR – odds ratio, p - Wald 2-tailed p-value; SE – standard errors associated with the coefficients; Wald – Wald chi-square value.

no differences were seen between groups for baseline inflammatory markers or haemoglobin levels. Likewise, anti-platelet therapy started before GCA diagnosis did not seem to prevent severe SIEs. By multivariate logistic regression (Table 2), hypertension, jaw claudication and abnormalities of TA on palpation were independently associated with SIEs. The presence of MSK symptoms significantly decreased the risk of SIEs.

Conclusion: Almost half the pts in this cohort presented VL and/or CVAs, highlighting the need for an earlier recognition of symptoms and a fast-track approach to pts with suspected GCA to improve outcome. High blood pressure, jaw claudication and abnormalities of TA on palpation were associated with an increased risk of SIEs, while the presence of MSK symptoms including PMR had a protective role. The identification of pts with these high-risk features should prompt immediate treatment and tight follow-up. Future studies are warranted to determine the value of more aggressive immunosuppression in these cases.

Abstract Number: 1945

Characterization of Visual Manifestations and Identification of Risk Factors for Permanent Vision Loss in Patients with Giant Cell Arteritis

Hussein Baalbaki[1], Darya Jalaledin[2], Catherine Lachance[2] and Jean-Paul Makhzoum[3], [1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada, [2]Universite de Montreal, Montreal, QC, Canada, [3]Vasculitis Clinic, Canadian Network for Research on Vasculitides (CanVasc), Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Permanent vision loss (PVL) is a feared complication and a leading cause of morbidity in Giant Cell Arteritis (GCA). Multiple risk factors for ocular involvement have been identified with variable consistency, including older age, male sex, presence of cardio-vascular risk factors, transient ischemic symptoms, jaw claudica-

tion and thrombocytosis. The objective of this study is to describe visual manifestations and identify risk factors that predict ocular involvement in patients with GCA.

Methods: The retrospective database, CAPHECO-GCA (Characteristics, Phenotype, Evolution and Complications of patients with GCA at Hopital du Sacre-Coeur de Montreal) was used to collect data between January 1st, 2000 and December 31st, 2019. The presence of GCA was based on the treating physician's diagnosis and confirmed retrospectively by a separate GCA expert. Descriptive statistics comparing patients with and without visual symptoms and PVL were performed. Funding for the creation of the CAPHECO-GCA database was provided by CanVasc (Canadian Network for Research on Vasculitides).

Results: A total of 100 patients with GCA were included. Of these, 95 patients met the 1990 ACR classification criteria for GCA, and 53 patients had visual symptoms. Visual symptoms included blurred vision (30% of patients), diplopia (16% of patients), amaurosis fugax (14% of patients) and blindness (19% of patients). Out of the 19 patients with blindness, 16 did not recuperate and had PVL. Patients with PVL were older (79,2 ± 6,7 vs 74,2 ± 7,6 years; p = 0,008), more likely to have coronary artery disease (31% vs 10%; p = 0,018) and peripheral artery disease (19% vs 5%; p = 0,044) than patients without PVL. However, patients with PVL were less likely to have other cranial symptoms (81% vs 96%; p = 0,019), mainly headaches (64% vs 92%; p= 0,003). A total of 58 patients underwent ophthalmologic examination: 10 patients had anterior ischemic optic neuropathy, 3 patients had central retinal artery occlusion, 1 patient had branch retinal artery occlusion and 3 patients had cranial nerve palsy. Risk factors associated with an abnormal ophthalmologic examination were the same as for PVL, but patients were also more likely to have diabetes (29% vs 7%; p = 0,026) and less likely to have constitutional symptoms (53% vs 80%; p = 0,033). Presence of visual symptoms was associated with a lower mean C-reactive protein level (73,7 ± 59,3 vs 104,3 ± 80,3 mg/L; p = 0,035). There was no statistically significant difference for sex, prior eye disease, delay to presentation, polymyalgia rheumatica, abnormal temporal artery on physical examination, extra-cranial large vessel vasculitis and platelet count.

Conclusion: Patients with GCA and PVL and/or abnormal ophthalmologic examination were older and more likely to have baseline diabetes, coronary artery disease and peripheral artery disease. A predisposing vascular vulnerability might therefore increase the risk of ocular involvement in GCA.

Fast-Track Giant Cell Arteritis Clinic Experience in the United States

Mark Matza[1], Minna Kohler[2], John H. Stone[3] and Sebastian Unizony[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Fast-track clinics incorporating ultrasound into the initial evaluation of patients suspected of having giant cell arteritis (GCA) have been implemented throughout Europe leading to reduced incidence of blindness and decreased overall cost of care. Ultrasound is now recommended as one of the initial diagnostic modalities for GCA, assuming availability and expertise per EULAR guidelines. In the United States, the use of ultrasound for GCA

diagnosis has been limited to date. Here we report our fast-track GCA clinic experience at Massachusetts General Hospital.

Methods: A fast-track GCA clinic was developed at our tertiary care academic medical center which serves as a referral center for GCA patients. A standardized algorithm was created for referred patients with suspected GCA. Clinical evaluation and a dedicated ultrasound exam of the bilateral temporal and axillary arteries were completed in a single clinic session within 48 hours of referral if the patient was able. Bilateral common superficial, parietal, and frontal branches of the temporal arteries were evaluated for both halo and compression signs, and bilateral axillary arteries for halo sign. Clinical evaluation and ultrasound exam were performed and interpreted by one rheumatologist (MAM). Ultrasound images were reviewed separately by a blinded rheumatologist (MJK), both with expertise in vasculitis ultrasound.

Results: Between September 2019 and March 2020, 18 patients were evaluated in the fast-track GCA clinic. Overall, 15 patients (83%) were seen within 48 hours, 11 patients (61%) within 24 hours and 2 patients within 1 hour of referral. Mean age was 72 years, 67% were female and 83% were Caucasian (17% Hispanic). Temporal headache was reported by 89% of patients. Mean ESR was 24.7 mm/h, mean CRP was 40.6 mg/L, and 6 patients had acute phase reactants within normal limits. Four patients (22%) had a positive temporal (n = 3) or axillary (n = 1) artery ultrasound confirmed by the blinded reviewer. Three of the 4 patients with a positive ultrasound also had a positive temporal artery biopsy (TAB). The remaining patient had relapsing GCA previously diagnosed with TAB, therefore a new biopsy was not pursued. In total, 10 patients underwent TAB after ultrasound. Mean time from fast-track evaluation to TAB was 6 days. There were no conflicting results between ultrasound and TAB. Four patients with negative results on both ultrasound and TAB and one additional patient who declined TAB went on to be treated for GCA given clinical suspicion. The remaining patients were diagnosed with headache (n = 5), infection (n = 2), cardioembolic transient vision loss (n = 1) and vasculitis not otherwise specified (n = 1). Of note, 1 patient with classic symptoms of GCA and a clearly positive ultrasound was found to have normal acute phase reactants and positive TAB. No patients developed vision loss attributed to GCA.

Conclusion: Ultrasound at the point of care is an effective diagnostic tool in GCA, assuming adequate training and availability. TAB can be obtained to confirm ultrasound findings particularly during the initial phase of a fast-track clinic. For a subset of patients with negative ultrasound and TAB, the diagnosis of GCA was made on clinical grounds.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common primary vasculitis affecting patients aged above 50 years. Its clinical manifestations such as headache, jaw claudication and blindness, as well as its treatment with high doses of glucocorticoids (GCs) can have an impact on patients' mental health. Hospital Anxiety and Depression Scale (HADS) is a validated patient-reported outcome tool to assess anxiety and depression. We aimed to explore GCA-specific and non-specific contributive factors to mental status using HADS.

Methods: HADS questionnaires were prospectively collected from patients with biopsy- or imaging-proven GCA evaluated from July 2018 to January 2020 in the Vasculitis clinic of a tertiary centre. HADS-A and HADS-D ≥8 defined possible and HADS-A and HADS-D ≥11 defined probable anxiety and depression, respectively. A cross-sectional analysis comparing different clinical and demographic features of GCA patients with HADS scores ≥8 or < 8 and ≥11 or < 11 was performed. Univariate analysis was performed using T-student, Chi-Square, Mann-Whitney and Fischer's exact tests, as appropriate. Binary logistic regression was used to identify independent predictors of HADS ≥8 and HADS ≥11. Association between values of HADS and age was assessed using Spearman's correlation coefficient.

Results: We included 72 patients with GCA, 52 (72.2%) females, with a mean ± SD age of 78.3 ± 7.7 years. Patients presented a mean ± SD HADS-A of 8.2 ± 4.6 and mean ± SD HADS-D of 7.9 ± 5.0. Possible and probable anxiety was observed in 35 (48.6%) and 22 (30.6%) patients, respectively; possible and probable depression was observed in 35 (48.6%) and 24 (33.3%) patients, respectively. **Table 1** shows the differences between patients with HADS ≥8 and < 8, and HADS ≥11 and < 11. Patients with HADS ≥8 were more frequently under GC treatment and all patients

	HADS-A						HADS-D					
	HADS-A <8 (N=37)	HADS-A ≥8 (N=35)	p-value	HADS-A<11 (N=50)	HADS-A ≥11 (N=22)	p-value	HADS-D <8 (N=37)	HADS-D ≥8 (N=35)	p-value	HADS-D <11 (N=48)	HADS-D ≥11 (N=24)	p-value

*In bold statistically significant differences (p<0.05) * Prednisolone equivalent. GCs – glucocorticoids; HADS – Hospital Anxiety (A) and Depression (D) Scale; IQR – interquartile range; LV – large vessel; SF-36 – Short Form-36*

Table 1. Results of univariate analysis comparing patients with HADS ≥8 and HADS <8 and HADS ≥11 and HADS <11.

with HADS ≥11 were on GCs. Patients with HADS-A ≥8 had higher levels of ESR and lower prevalence of diabetes mellitus, whereas HADS-D scores of ≥8 or ≥11 were associated with older age. Multivariate analyses adjusted for sex, age, disease duration > 1 year and treatment with GCs showed that only GC therapy was an independent predictor of HADS-A ≥8 (OR 10.40 95%CI: 1.15-94.23) and age was an independent predictor of HADS-D ≥8 (OR 1.20 95%CI: 1.08-1.34). Multivariate analysis adjusted for age, sex and treatment with GCs showed that older age was also an independent predictor of HADS-D ≥11 (OR 1.12 95%CI: 1.03-1.22); no independent predictors were identified for HADS-A ≥11. Moreover, age and scores of HADS-D and HADS-A showed correlation (r=0.53, p< 0.001 and r=0.26, p=0.03; respectively).

Conclusion: In our cohort, around half the patients with GCA showed possible anxiety and depression. Older patients had more depression and patients under GCs were more likely to present anxiety. Although these results require replication, they highlight the importance of including the evaluation of mental health as part of the disease management in GCA, particularly in the most elderly patients under GC treatment.

Identification of Small Molecules with Efficacy as Steroid Sparing Suppression of Chemokine and Cytokine Production by Rheumatoid Arthritis Fibroblast-like Synoviocytes

Tadashi Hosoya[1], Nikunj Shukla[2], Yuya Fujita[3], Shiyin Yao[4], Fitzgerald Lao[4], Hiroyuki Baba[1], Shinsuke Yasuda[5], Howard Cottam[4], Dennis Carson[4], Tomoko Hayashi[4] and Mary Corr[6], [1]Department of Rheumatology, Tokyo Medical and Dental University (TMDU), Tokyo, Tokyo, Japan, [2]Moores Cancer Center, University of California San Diego, San Diego, CA, [3]Department of Medicine, University of California San Diego, San Diego, CA, [4]Moores Cancer Center, University of California San Diego, San Diego, [5]Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (TMDU), Tokyo, Tokyo, Japan, [6]Department of Medicine, University of California San Diego, San Diego

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Target-based drug discovery has expanded our therapeutic armamentarium in the treatment of inflammatory and autoimmune diseases. Despite these advances, glucocorticoids (GC) remain reliable agents that are used in many of these conditions. In this study we utilized a discovery based approach to identify small molecular weight synthetic compounds that reduced NF-κB signaling activity in cell-based assays. We assessed the potency of specific chemotypes in reducing pro-inflammatory cytokine production by stimulated RA fibroblast-like synoviocytes (RASF) and synergy with GC.

Methods: We re-analyzed existing data from two prior high throughput screens (HTS) which utilized a library from the Small Molecule *Discovery* Center (UCSF) and a Forster resonance energy transfer based NF-κB reporter assay in THP-1 cells. NF-κB activation resulted in beta-lactamase production, which shifted the fluorescence emission of the substrate from 530 nm to 460 nm. Hit compounds were rescreened with LPS (10ng/ml) stimulated NF-κB reporter

cells at 5 and 16 hours with an IκB kinase inhibitor (IKKI) and dexamethasone (DEX) as controls for variability. Compounds (5μM) were tested for toxicity by MTT. Selected lead compounds were commercially repurchased. CXCL8 production by THP-1 cells when stimulated with LPS (10ng/ml), TNFα (2ng/ml) or IL-1ß (2ng/ml) was measured by ELISA. Human synovial tissue derived RASF were treated with TNFα (1ng/ml) and graded amounts of lead compounds and DEX, and the levels of IL-6 and CXCL8 produced were measured by ELISA.

Results: Reanalyzing prior data we identified 1843 compounds that attenuated NF-κB activities in both HTS similar to the GCs included in the original 166,000 compound library. We performed confirmation screens with these hit compounds (5μM) for their effects on the kinetics of NF-κB activity in LPS stimulated reporter cells at peak (5 hours) and decay (16 hours) timepoints. There were 270 compounds that met the following criteria: NF-κB activity < 50 % max at 5 hours or < 25% max at 16 hours. Excluding compounds with < 90% viability by MTT, the remaining compounds were clustered into 15 chemotype families. Promising representatives from the largest chemotype families were commercially purchased for further testing. Amongst these index compounds two chemotypes: 1H-pyrazolo[3,4-*d*] pyrimidin-4-amine and bis-aryl urea, effectively suppressed CXCL8 production by THP-1 cells when stimulated with LPS, TNFα or IL-1ß ($p < 0.05$, by one-way ANOVA with Dunnett's post hoc tests). These lead compounds also reduced IL-6 and CXCL8 production by TNFα stimulated RASF ($p < 0.05$). Importantly a lead 1H-pyrazolo[3,4-*d*] pyrimidin-4-amine compound demonstrated a dose sparing effect for DEX when co-administered with TNFα stimulated THP-1 cells and had a synergistic effect with DEX in suppressing RASF chemokine production($p < 0.05$, and Bliss independence-based analysis).

Conclusion: In summary, using a broad cell-based HTS approach, lead compounds were identified that reduced NF-κB activity and chemokine/cytokine secretion induced by potent immunologic stimuli, and acted synergistically with glucocorticoids as anti-inflammatory agents.

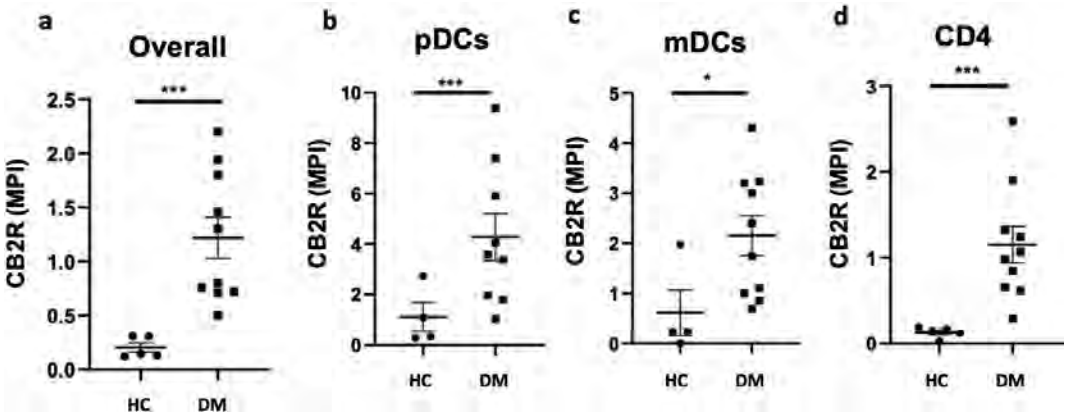
CB2 Receptor Distribution and Effects of Lenabasum™ in Dermatomyositis *In Vitro*

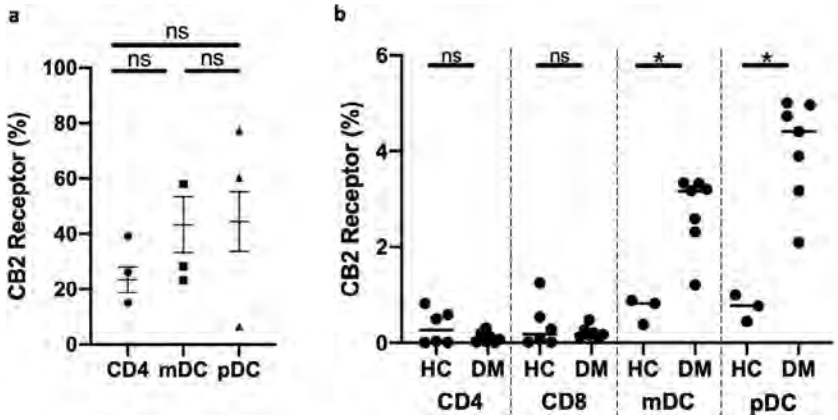
Spandana Maddukuri[1], Jay Patel[2], Christina Bax[3], Maria Wysocka[3] and Victoria Werth[4], [1]University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Montville, NJ, [2]University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Philadelphia, [3]University of Pennsylvania, Department of Dermatology, Philadelphia, [4]University of Pennsylvania and Corporal Michael J. Crescenz Veterans Administration Hospital, Philadelphia

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Dermatomyositis (DM) patients report poor quality of life due to disease activity and persistent itch. Lenabasum is an oral non-immunosuppressive, non-psychoactive cannabinoid type 2 receptor (CB2R) reverse agonist being investigated for use in DM. Our previous studies showed increased IFNγ in DM compared to healthy controls (HC) and a decrease in IFNγ as a result of Lenabasum use. Literature also suggests upregulation of



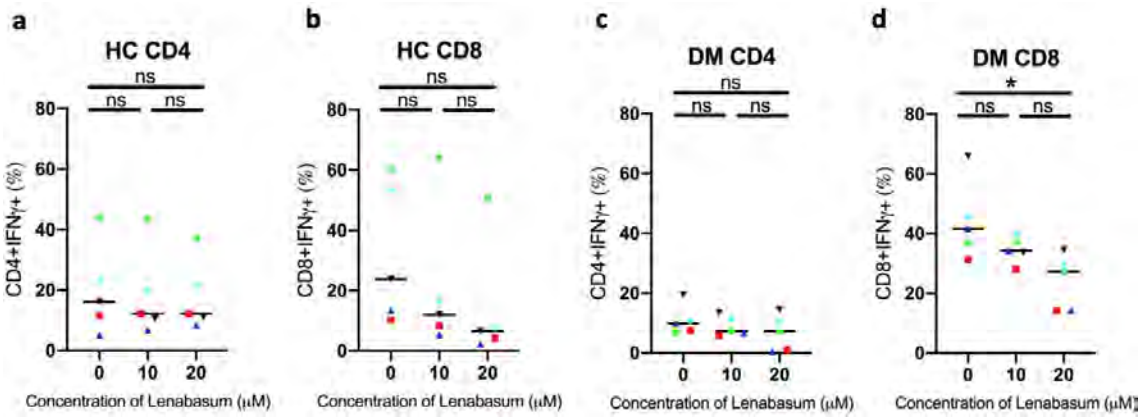
(a) Flow cytometry results from eluted DM skin cells show highest CB2R expression on pDCs (48.0% ± 21.4), followed by mDCs (36.4% ± 10.9) and CD4 T cells (26.7% ± 6.9). Skin CD8 T cells could not be analyzed because the population was too small. (b) Flow cytometry on HC and DM PBMCs shows significantly higher expression of CB2R in mDCs (p=0.0167) and pDCs (p=0.0167) in DM compared to HC. No significant difference in CB2R expression was noted in CD4 and CD8 T cells from PBMCs (b). Overall, CB2R expression is higher in eluted skin cells compared to PBMCs.



In vitro experiments in stimulated PBMCs treated with Lenabasum show no significant decreases in IFNg production in (a) HC CD4 T cells, (b) HC CD8 T cells, and (c) DM CD4 T cells. There was a significant decrease in IFNg production in (d) DM CD8 T cells treated with 20uM compared to 0uM (p=0.0207).

CB2R in the presence of IFNγ. The purpose of our study is to investigate the distribution of CB2R among immune cells in DM blood/skin and the *in vitro* effects of Lenabasum on these immune cells.

Methods: Image mass cytometry (IMC) was used on 5 HC and 10 DM patients; biopsies were stained with 37 cell markers and 1mmx2mm regions were ablated using the Hyperion Imaging System. Cells were segmented using a nuclear app-based algorithm in Visiopharm. Per cell mean pixel intensity analysis was done with histoCAT. The Phenograph algorithm was used to cluster cells based on expression of cell markers. FC was used on peripheral blood mononuclear cells (PBMCs) isolated from 6 HC and 7 DM patients and on eluted skin cells from 9 DM biopsies. Cells ($1x10^6$/mL) were stimulated with PMA/Ionomycin/Brefeldin A or Resiquimod/Brefeldin A if they were being stained for T cells or myeloid dendritic cells (mDCs) and plasmacytoid dendritic cells (pDC), respectively. For *in vitro* experiments, samples were treated with Lenabasum (0, 10, or 20μM) for 1 hour before stimulation. Samples were acquired on a BD FACS CANTO and analyzed with FlowJo.



(a) Image mass cytometry findings show that CB2R is significantly upregulated in lesional DM skin compared to HC skin. Mean pixel intensity of CB2R expression is highest on (b) pDCs. CB2R expression in lesional DM skin when compared to HC skin is greater on (b) pDCs, (c) mDCs, and (d) CD4 T cells. * $p<0.05$, ** $p<0.01$, *** $p<0.001$

Results: We found that CB2R expression is higher in DM lesional skin compared to HC skin ($p< 0.001$). CB2R expression is upregulated on pDCs ($p< 0.001$), mDCs ($p< 0.05$) and CD4 T cells ($p< 0.001$) in DM skin compared to HC skin. When evaluating CB2R distribution among lymphocytes, dendritic cells, monocytes, macrophages, NK cells, and endothelial cells, pDCs were found to be major expressors followed by mDCs. FC results from eluted skin cells corroborated these findings, showing a greater percentage of pDCs (48.0% ± 21.4) expressing CB2R compared to mDCs (36.4% ± 10.9) and CD4 T cells (26.7% ± 6.9). FC results revealed lower expression of CB2R on DM PBMCs (1.8% ± 0.3) than in cells eluted from DM skin (37.0% ± 7.8) ($p< 0.0001$). There was no significant difference in CB2R expression in PBMCs between HC and DM CD4 T cells. No difference was noted between HC and DM CD8 T cells as well. Significantly greater CB2R expression was noted in PBMC mDCs ($p=0.0167$) and pDCs ($p=0.0167$) in DM compared to HC, but CB2R expression on mDCs and pDCs in the periphery was about 12-fold and 18-fold lower than that of skin cells, respectively. Preliminary *in vitro* experiments examined Lenabasum's effects on T cells in the blood. A significant decrease in IFNγ production by lenabasum-treated DM CD8 T cells compared to lenabasum-untreated DM CD8 T cells was noted ($p=0.0207$). No significant decrease in IFNγ production was observed in DM CD4 T cells or HC CD4 or HC CD8 T cells.

Conclusion: We found that CB2R expression differs between the skin and blood of DM patients, with higher expression occurring in skin. pDCs were found to be major expressors of CB2R in DM skin through IMC and FC, suggesting that these cells may be most affected by Lenabasum in DM.

Elevated Serum Gasdermin D N-terminal Implicates Macrophage Pyroptosis in Adult-onset Still's Disease and Systemic Juvenile Idiopathic Arthritis

Hideto Nagai[1], Yohei Kirino[2], Hiroto Nakano[3], Yosuke Kunishita[1] and Michael Ombrello[4], [1]Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan, [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]NIAMS, NIH, Bethesda, [4]Translational Genetics and Genomics Unit, NIAMS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Elevation of serum IL-18 in adult-onset Still's disease (AOSD) and systemic juvenile idiopathic arthritis (sJIA) suggests involvement of one or more inflammasome in these diseases, but their pathogenesis is still uncertain. We aimed to elucidate the auto-inflammatory mechanisms in AOSD and sJIA.

Methods: Patients with AOSD, sJIA, hemophagocytic lymphohistiocytsis (HLH), and Behçet's disease followed at Yokohama City University (YCU), or U.S. National Institutes of Health (NIH) were included in the study. Disease activity was evaluated by the modified Pouchot score. Ferritin and N-terminal gasdermin D (a pore-forming protein playing central roles in inflammasome-mediated inflammation) levels in serum and culture supernatant were measured by ELISA. Primary monocytes (Mo) were stimulated with GM-CSF or M-CSF and differentiated into M1 macrophages (Mφ) or M2Mφ, respectively. The number of Mo/Mφ and their viability were monitored over time.

Results: Patients with active AOSD and sJIA had increased levels of serum gasdermin D N-terminal, which correlated with serum ferritin and IL-18 levels. Mo-derived Mφ from active AOSD patients showed reduced cell viability and increased cell death. The number of cultured Mφ cells on day nine was negatively correlated with the serum ferritin and gasdermin D levels. Higher ferritin and gasdermin D levels were observed in the M1Mφ culture supernatant of active AOSD patients.

Conclusion: Elevation of serum gasdermin D N-terminal and increased Mφ cell death suggests that Mφ pyroptosis is associated with AOSD and sJIA.

Possible Involvement of Fractalkine/CX3CR1 Axis in Peripheral $CD14^{++}CD16^{+}$ Monocytes in Disease Development of Patients with Systemic Lupus Erythematosus

Keiko Yoshimoto[1], Katsuya Suzuki[1], Noriyasu Seki[2], Shuntaro Saito[3], Jun Kikuchi[1] and Tsutomu Takeuchi[4], [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, [2]Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [4]Division of Rheumatology, Department of internal Medicine, School of Medicine, Keio University, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Fractalkine (FKN) binds its receptor, CX3CR1 and accelerates chemotaxis of immune cells by inducing cell surface molecules and mediating adhesion of the cells to vascular endothelial cells. Several lines of evidence suggest that the FKN/CX3CR1 axis plays a crucial role in local infiltration of inflammatory cells at the sites of injury, which may result in impairments of organs in systemic lupus erythematosus (SLE). Our previous data showed that the expression level of CX3CR1 in peripheral $CD14^{++}CD16^{+}$ monocytes was remarkably decreased in SLE active patients as compared with SLE inactive patients and healthy controls (HC). In this study, we investigated the possible involvement of FKN/CX3CR1axis in immunological abnormalities and clinical features of SLE.

Methods: Fifty-nine SLE patients (SLE_H; high disease activity, SLEDAI: >10, n = 32, $SLE_{M+L;}$ moderate and low disease activity, SLEDAI: < 10, n = 27) and 34 healthy controls (HC) were enrolled in this study. The expression level of CX3CR1 in peripheral $CD14^{++}CD16^{+}$ monocytes was analyzed by FACS using whole blood samples from patients and HC. The serum level of FKN was measured by a Slow Off-rate Modified DNA Aptamer (SOMAmer)-based capture array. Disease activities of SLE patients were quantified based on the SLEDAI scores. The serological data of the patients was collected by clinical records. Differences between the groups were examined for statistical significance by a *t*-test for single comparisons. Pearson's correlation analysis was employed to evaluate the relationship between two continuous variables.

Results: FACS analysis revealed that the proportion of CX3CR1 positive cells among $CD14^{++}CD16^{+}$ monocytes was significantly lower in SLE_H patients than in patients with SLE_{M+L} (p = 0.007) or HC (p = 0.007), whereas the difference was not significant between SLE_{M+L} and HC. Moreover, the $CX3CR1^{+}/CD14^{++}CD16^{+}$ ratio was negatively and positively correlated with the SLEDAI score (p = 0.031) and serum level of C3 (p = 0.045), respectively, of all SLE patients. In addition, serum level of FKN was significantly higher in SLE_H patients than those of SLE_{M+L} patients (p = 0.005) and HC (p = 0.001). Interestingly, the serum FKN level was positively and negatively correlated with SLEDAI score (p = 0.0004) and C3 (p = 0.0043), respectively, of all SLE patients. Notably, the $CX3CR1^{+}/CD14^{++}CD16^{+}$ ratio was negatively and significantly correlated with serum FKN level of the patients (p = 0.0078).

Conclusion: These results raised the possibility that reduced expression of CX3CR1 in peripheral $CD14^{++}CD16^{+}$ monocytes and the enhanced serum FKN level lead to acceleration of migration of FKN-stimulated $CD14^{++}CD16^{+}$ monocytes to organs.

Activated Memory T Cells Produce Ligands That Cause NF-κB-dependent Inflammatory Activation of the Endothelium: Identification of Novel Therapeutic Targets

Kim Jeucken[1], Jan Piet van Hamburg[1], Lotte Kocken[1] and Sander Tas[2], [1]Amsterdam Rheumatology and Immunology Center (ARC), Department of Rheumatology and Clinical Immunology, Department of Experimental Immunology and Amsterdam Infection and Immunity Institute, Amsterdam UMC; location AMC, University of Amsterdam, Netherlands, Amsterdam, Netherlands, [2]Amsterdam Rheumatology and Immunology Center (ARC), Department of Rheumatology and Clinical Immunology, Department of Experimental Immunology and Amsterdam Infection and Immunity Institute, Amsterdam UMC; location AMC, University of Amsterdam, Netherlands, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Endothelial cells (EC) are important contributors to inflammation via expression of inflammatory mediators, including cytokines, chemokines and adhesion molecules. Production of these inflammatory mediators can be induced via canonical and NF-κB-inducing kinase (NIK)-dependent noncanonical NF-κB signalling. The ligands activating these pathways are well studied, but less is known about the cells producing ligands that can activate NF-κB signalling in EC. In this study, we investigated the effects of factors produced by activated memory T (T_m) cells on NF-κB dependent inflammatory activation of EC.

Methods: $CD4^+CD45RO^+$ memory T cells were isolated from healthy PBMC using MACS sorting and cultured in presence of anti-CD3 and anti-CD28 for 72h, after which supernatant was harvested. Endothelial cells were stimulated for 72h with 50% T_m supernatant (T_m sup) after which protein and RNA was harvested followed by analysis of NF-κB signalling and downstream expression of inflammatory mediators using qPCR and western blot. Culture supernatants were analysed by ELISA for various inflammatory mediators. To repress canonical NF-κB signalling an inhibitor of IKKβ (iIKKβ) was used and to repress NIK-dependent NF-κB signaling an inhibitor of NIK (iNIK) was used in the EC cultures.

Results: Stimulation with T_m sup led to activation of both canonical NF-κB signalling (increased levels of phosphorylated IκBα) and noncanonical NF-κB signalling (increased p100 to p52 processing). After stimulation with T_m sup EC had increased mRNA levels of all tested inflammatory mediators compared to non-treated cells. Gene expression of chemokines, cytokines, and growth factors (CXCL1, CXCL5, IL6, IL8 and GM-CSF) in T_m sup stimulated EC was significantly reduced after treatment with iIKKβ and to a lesser, but still significant, extent after treatment with iNIK. Treatment with iIKKβ also led to a reduction in mRNA levels of the adhesion molecules VCAM-1 and ICAM-1, while this effect was less pronounced after iNIK treatment. Of note, treatment with either IKKβ or iNIK led to a significant reduction of CXCL5 in the culture supernatant of T_m sup stimulated EC. Results of bioinformatic analysis of RNA-sequencing derived data are pending.

Conclusion: This study provides new insights into the cellular interactions leading to production of inflammatory mediators by EC. Our findings demonstrate that activated T_m cells produce factors that can cause NF-κB-dependent inflammatory activation of EC. Targeting canonical NF-κB signaling via IKKβ or NIK-dependent NF-κB signaling reduces inflammatory activation of the endothelium and may be a potential novel therapeutic target.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Genetics, Genomics & Proteomics

Session Type: Abstract Session

Session Time: 12:00PM–12:50PM

Background/Purpose: Identifying the causes of adult-onset rheumatic diseases remains a challenge, and limits diagnosis, prognosis, and targeted treatment. We hypothesized that mutations in genes regulating the post-translational modification ubiquitin, previously implicated in two autoinflammatory diseases, may define new rheumatic disorders.

Methods: We analyzed peripheral blood exome sequence data from 2,560 individuals with inflammation-related diagnoses for deleterious mutations in >800 ubiquitin-related genes. After discovering three patients with novel *UBA1* mutations, we identified additional cases based on clinical similarities. Sanger sequencing, digital droplet PCR, immunoblotting, immunohistochemistry, flow cytometry, and transcriptome/cytokine profiling were performed. CRISPR/Cas9 knockout zebrafish provided an *in vivo* model to assess *UBA1* gene function.

Results: Twenty-eight adult males were identified with somatic mutations at methionine 41 in *UBA1*, an X-linked gene, encoding the major E1 enzyme that initiates ubiquitylation. Methionine 41 is highly conserved in UBA1, and these somatic mutations were not observed in exome sequences from over 80,000 healthy controls. Among affected individuals, mutations were found in more than half of hematopoietic stem cells, exclusively in peripheral blood myeloid cells, and not in lymphocytes or fibroblasts. Patients developed an often-fatal, treatment-refractory inflammatory syndrome in late adulthood, with fevers, cytopenias, characteristic vacuoles in myeloid and erythroid precursors cells, dysplastic bone marrow, neutrophilic cutaneous and pulmonary inflammation, chondritis, and vasculitis. Patients fulfilled clinical criteria for inflammatory (relapsing polychondritis, Sweet syndrome, polyarteritis nodosa, giant cell arteritis) and hematologic (myelodysplastic syndrome or multiple myeloma) conditions. Mutations at p.Met41 resulted in loss of the cytoplasmic isoform of UBA1 and decreased ubiquitylation and, unexpectedly, the expression of a novel, catalytically inactive, toxic isoform, in mutant, but not wildtype, lineages. Mutant peripheral blood cells exhibited activated innate immune pathways and evidence for unfolded protein response (UPR). Knockout of the zebrafish UBA1 cytoplasmic isoform homologue caused systemic inflammation.

Conclusion: By querying exomes for mutations in ubiquitylation genes, we have defined a novel disorder, VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome, which connects seemingly unrelated adult-onset inflammatory syndromes and establishes a precedent for a new molecular taxonomy of rheumatic diseases. Our work also reveals somatic mutations as an underrecognized cause of adult-onset rheumatic diseases.

Session Date: Monday, November 9, 2020
Session Title: Genetics, Genomics & Proteomics
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Sjögren's syndrome (SS) is a complex autoimmune disease with exocrine gland dysfunction leading to substantial morbidity, and 10 published genetic susceptibility loci. Our genome-wide association study (GWAS) aimed to identify additional risk loci of genome-wide significance (GWS; p< 5E-08) in European-derived primary SS.

Methods: Study received IRB approval. All SS patients met 2002 AECG criteria for SS. A total of 3232 cases and 17481 controls genotyped on GWAS arrays and 619 cases and 6171 controls genotyped on ImmunoChip (IC) arrays were imputed after quality control. Logistic regression was calculated, adjusting for ancestry using the first 4 principal components to identify SS-associated SNPs. GWAS and IC results were meta-analyzed using weighted Z-scores. Bayesian statistics were used to assign posterior probabilities and define credible SNP sets for each locus. Bioinformatic analyses were used to predict functionality.

Results: Seven novel loci exceeded GWS in the GWAS analysis: *NAB1*, *MIR146A-PTTG1*, *XKR6*, *MAPT-CRHR1*, *RPTOR-CHMP6-BAIAP2*, *TYK2* and *SYNGR1*. Meta-analysis with IC data identified three more novel loci exceeding GWS: *CD247*, *PRDM1-ATG5* and *TNFAIP3*. Additional loci with suggestive association (p< 1E-05) were also identified: *ADAMTSL2*, *CGNL1* and *PHRF1*.

Several identified loci have reported functional implications in immune regulation and autoimmune disease. In lupus, rs2431697 correlated with rs2431098, which was shown to alter *MIR146A* expression, resulting in type I interferon pathway imbalance. Similarly, *TYK2* risk association reportedly drives interferon-g, IL10 and RET signaling pathways. *PRDM1* encodes Blimp-1, a master regulator of immune cell differentiation. *CD247* encodes the zeta subunit of the T cell receptor complex. *XKR6* is implicated in apoptotic cell ingestion. *ATG5* is also involved in apoptosis, as well as autophagy and antigen presentation.

Additional bioinformatics analyses (Haploreg, Regulome DB, ENCODE, etc.) revealed immune-relevant functional implications for each risk locus. The SS-associated credible set included variants downstream of *TNFAIP3* in a region reported to abolish looping between an enhancer and the*TNFAIP3* promoter in lupus and a coding variant that has been shown to alter NF-κB activity and neutrophil extracellular traps. The rs2293765 in the 5' UTR of *NAB1* showed evidence of enhancer/promoter activities. The rs2069235 in the *SYNGR1* locus showed enhancer and transcription start site activities in B and T cells. The rs7210219 in the *MAPT-CRHR1* locus showed enhancer/promotor activities in various tissues.

Conclusion: We have identified 10 novel genetic susceptibility loci associated with SS pathology. Our finding doubles the current number of GWS regions in SS patients of European origin from 10 to 20. Future work is needed to identify and characterize the functional variants in each locus.

Session Time: 12:00PM–12:50PM

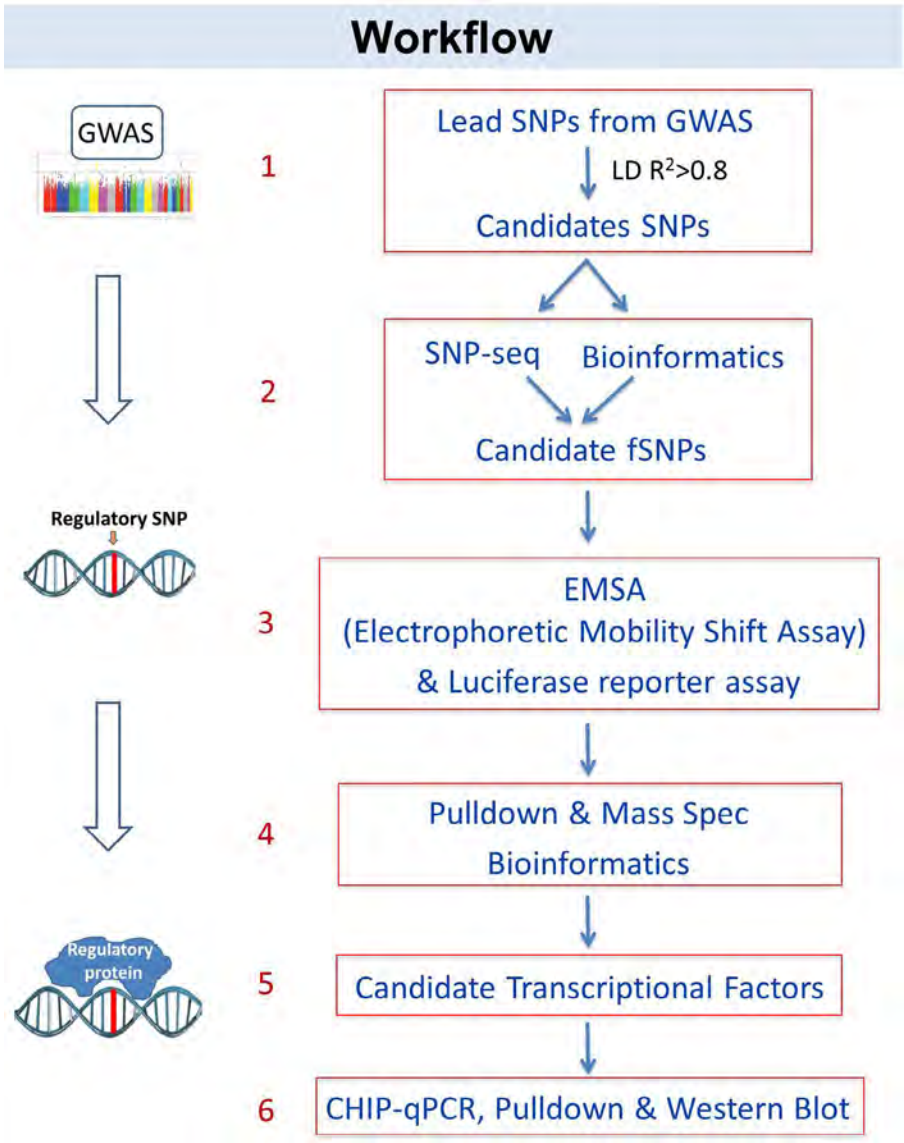

Figure 1. Workflow of identify variant-protein associations. 1-3: Identify novel regulatory variants that modulate SLE risk; 4-6: identify variant-protein associations in SLE.

Background/Purpose: Systemic lupus erythematosus (SLE) is a disease involves the complex interplay of many genes, reflected in more than one hundred loci linked with disease risk by genome-wide association studies (GWAS). Decoding GWAS is, therefore, a promising strategy to identify novel drug targets in SLE. However, most of the identified disease-associated hits are noncoding single-nucleotide polymorphisms (SNPs), and cannot be distinguished from others that reside incidentally within risk loci. To address this longstanding challenge of finding the real functional regulatory SNPs (fSNPs) from GWAS hits in SLE, we utilized an unbiased high-throughput screen method to investigate GWAS hits.

Methods: From 4 GWAS for SLE (Gateva, Sandling et al. 2009, Bentham, Morris et al. 2015, Morris, Sheng et al. 2016, Langefeld, Ainsworth et al. 2017, Zhang, Zhang et al. 2018), 87 disease-associated SNPs were chosen as lead SNPs and SNPs in linkage disequilibrium (LD)(R^2>0.8) with them are also included as the screening library. In a total of 2176 SNPs were screened by three different high-throughput methods, SNP-seq (Li, Martinez-Bonet et al. 2018), H3K4me3 epigenetic modification (Trynka, Sandor et al. 2013), and Combined Annotation Dependent Depletion (CADD) (Rentzsch, Witten et al. 2018). Top candidates from the screening were further tested for regulatory function

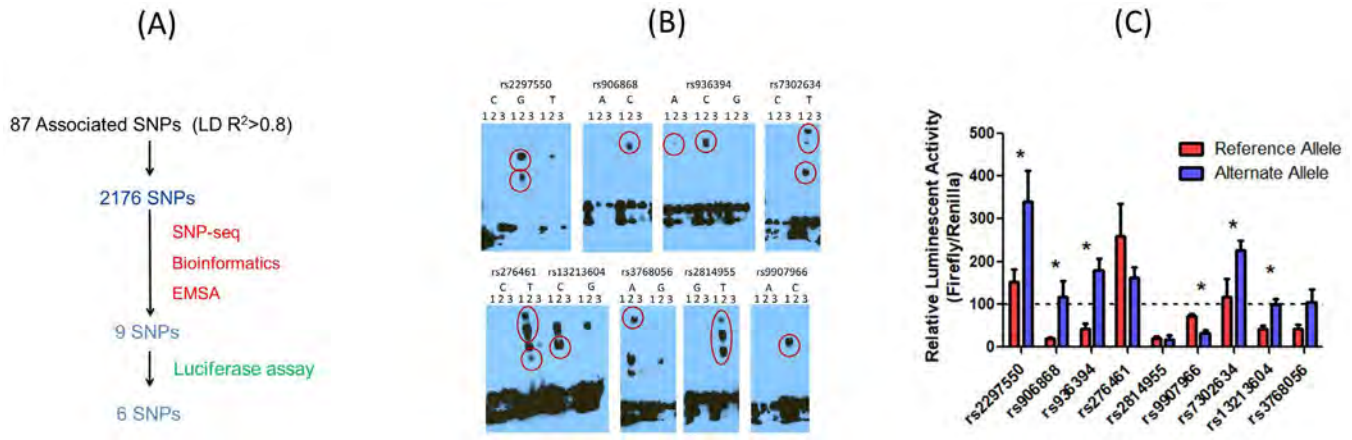

Figure 2. Identify Novel Regulatory Variants that Modulate SLE risk. (A): SNPs associated with SLE screening, 6 out of 2176 are found to be regulatory variants; (B): EMSA for 9 SNPs candidates that show allele-specific gel shift/binding (shown as red dots).1: biotinylated oligo alone; 2: biotinylated oligo with nuclear extract; 3: oligo with nuclear extract and non-biotinylated competitor. (n = 3 independent biological replicates with similar results). (C): Luciferase reporter assay shows allelic specific regulatory activity for 6 SNPs associated with SLE (* represents p<0.05).

(A)

SNPs ID	Associated gene (protein)	Candidate TF Binding Preference	EMSA Preferential binding	Luciferase assay
rs2297550	IKBKE(IKKε) Up in lupus	IKZF1 (G>C)	G>C	G>C>ctrl

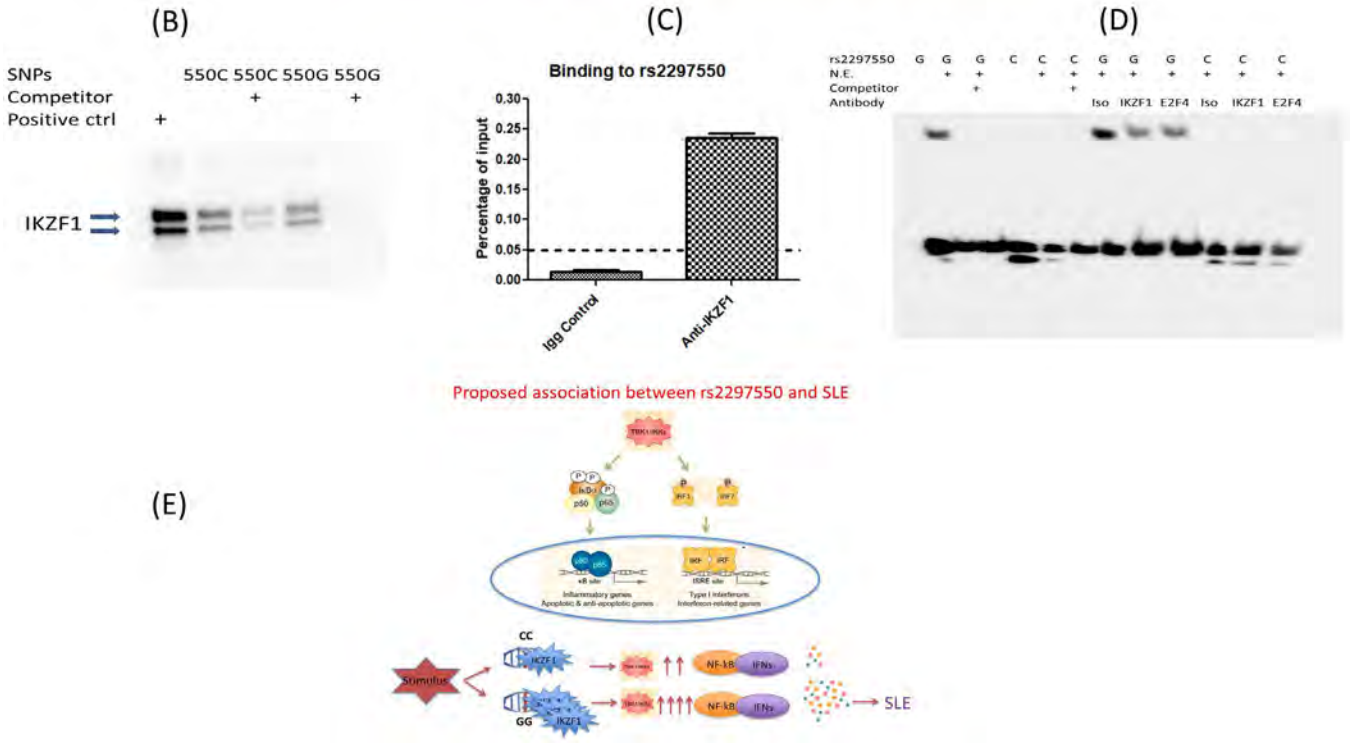

Figure 3. Identify Novel variant-protein association in SLE. (A): Table shows candidate TF (IKZF1) bound to variant rs2297550 after pulldown assay & MS and bioinformatics prediction. (B, C, D): Pulldown assay & WB and Chromatin Immunoprecipitation–qPCR and EMSA supershift assay show IKZF1 binds rs2297550, more specifically to G allele than C. (D): Proposed association between rs2297550 and SLE.

by electrophoretic mobility shift assay (EMSA) and luciferase reporter assay to get the final fSNPs candidates. Then through bioinformatics binding motif prediction and mass spectrometry for oligo pulldown assay, the transcriptional factor that might bind to the fSNPs was found and later validated by CHIP-qPCR, western blot for oligo pulldown assay as well as supershift assay.

Results: Fifty-four candidate fSNPs from 2176 SNPs after three screening methods were found to be possible regulatory variants and tested for regulatory function. After EMSA, 9 SNPs showed allelic specific binding to proteins from both BL2 cells (B cell line) and PBMC nuclear extract. Six out of these 9 SNPs showed allelic differential gene expression in luciferase reporter assay in a B cell line (Daudi). After bioinformatics predictions as well as mass spectrometry for oligo pulldown assay, two fSNPs (rs2297550 and rs9907966) were found to be able to bind to transcriptional factor IKZF1 and YBX1 in B cells respectively by allelic specific pulldown assay, CHIP-qPCR, and EMSA-supershift assay.

Conclusion: Our unbiased high-throughput screening for SLE GWAS hits, followed by a step-wise validation leads to the identification of real functional regulatory SNPs that are capable of binding to transcriptional factors and regulate gene expression, which establish a working model to bridge the gap between SLE GWAS and disease mechanism.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Genetics, Genomics & Proteomics
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune disease characterized by inflammatory destruction of the exocrine glands. Long non-coding RNAs (lncRNAs) are a functionally diverse class of non-protein coding RNA (ncRNA) with implications in immune cell regulation. The role of lncRNAs in SS pathogenesis is unknown.

Methods: Study received IRB approval. All SS cases met 2002 AECG criteria. RNA-seq was used on whole blood from SS patients (n=30 antibody negative (Ro^-); n=27 antibody positive (Ro^+)) and healthy controls (HC, n=27) to identify differentially expressed (DE) lncRNAs (log_2 fold change (FC) ≥ 2 or ≤ 0.5; $p_{adj} < 0.05$). Bioinformatic and pathway analyses were used to predict *LINC01871* function. CRISPR-targeted *LINC01871* deletion in the T lymphoblastic cell line HSB-2 was performed by RNP transfection and assessed by using an enrichment method that increases the sequencing reads across the region using Oxford Nanopore Minion sequencing. Transcripts of interest were measured by qRT-PCR. Protein expression was analyzed using flow cytometry and multiplex bead-based ELISAs.

Results: We identified 1054 unique DE ncRNAs between Ro^+, Ro^- and a combined analysis relative to HC. *LINC01871* (SS^{Ro-}: FC=2.85; $p_{adj}=1.1x10^{-4}$) was a previously uncharacterized lincRNA that was co-expressed in the SS^{Ro-} transcriptome with several protein coding RNAs involved in immune regulation (*TBX21*, *IL10RA*, *IL2RB,* etc.). DE of *LINC01871* was confirmed in an independent set of 35 SS cases and 21 HCs using qPCR. Bioinformatics analyses identified shared immune-related pathways including cytotoxic cell, cell migration, and T cell regulation. The Expression Atlas database showed DE of *LINC01871* in several published RNA-seq studies in cancer, autoimmune diseases (such as discoid lupus), and T cell states. CRISPR-targeting in HSB2 generated a single cell *LINC01871*$^{-/-}$ clone (one of ~100) with no RNA expression by qPCR. Using Nanopore Minion sequencing, the *LINC01871*$^{-/-}$ cell line was found to have a homozygous deletion encompassing the entire coding interval for *LINC01871* that was confirmed using PCR. RNA-seq analysis of *LINC01871*$^{-/-}$ compared to unmodified HSB-2 cells identified 1166 DE transcripts. Pathway analyses clustered the DE transcripts into SS^{Ro-}-similar immune regulatory, cytotoxic, and T cell pathways, with the addition of cancer/cellular growth and cell signaling. The *LINC01871*$^{-/-}$ clone displayed impaired growth at 4 days ($p< 0.05$) and exhibited significant modulation of many T cell regulatory transcripts (*CD8a*, *TBX21*, *IKZF3*, *CXCR3*, *PDCD1*, and *TIGIT*) and secreted growth factors (*IGFBP4*, *CSF1*, *CSF2*, *FGFPB2*). Changes were confirmed by protein analyses using flow cytometry and multiplex ELISA assays ($p< 0.05$), indicating loss of *LINC01871* resulted in widespread cellular changes affecting growth and immune regulatory pathways.

Conclusion: RNA-seq, bioinformatic data, and CRISPR technology identified and functionally characterized *LINC01871* as a potential mediator of the dysregulated T cell inflammatory response pathways implicated in SS pathogenesis.

Background/Purpose: Pro-inflammatory fibroblasts have been independently implicated in the pathogenesis of rheumatoid arthritis (RA), inflammatory bowel disease (IBD), interstitial lung disease (ILD), and Sjogren's syndrome (pSS). While these fibroblasts are likely affected by disease modifying antirheumatic drugs that target broad cytokine pathways such as TNF, IL6, and GM-CFS, recent work suggests the possibility of *fibroblast-specific therapeutics*, such as Notch3 inhibition to disrupt $FAP^{+}THY1^{+}$ inflammatory fibroblasts in arthritis. The presence of common fibroblast phenotypes expanded in multiple inflamed tissues would suggest that one fibroblast therapeutic could be effective for multiple indications. Clinically, these common states would provide a molecular basis for rheumatology "basket" trials to select patients based on common disease etiology across diverse diagnoses. We therefore constructed a cross-tissue atlas to (1) identify shared inflammatory fibroblast states and (2) map new tissue samples to define the composition of their fibroblast phenotypes.

Methods: Inflamed and non-inflamed tissue samples were collected from 71 donors in the (1) synovium: RA and osteoarthritis; (2) intestine: IBD (inflamed and adjacent non-inflamed) and healthy; (3) salivary gland: pSS and Sicca syndrome; (4) lung: ILD and non-chronic inflammatory conditions. We constructed and analyzed an integrated reference of 73,260 single cell RNAseq (10X Genomics) fibroblast profiles using novel methods based on our published Harmony and MASC algorithms. We mapped external scRNAseq data from mouse disease models (serum transfer arthritis, DSS-colitis, and bleomycin lung fibrosis) onto our atlas using our novel Symphony algorithm and analyzed the distribution of inflammatory fibroblasts in each model.

Results:

1. Atlas of fibroblast phenotypes. We identified 9 conserved fibroblast states, including $THY1^{+}CD34^{+}$ interstitial, $NOTCH3^{+}$ perivascular, and $CCL19^{+}$ cytokine producing, and 3 tissue-specific states, including $CD55^{+}$ synovial lining and $MYH11^{+}$ myofibroblasts.
2. Phenotypes expanded in inflammation. Two fibroblast states were significantly expanded with inflammation in all four tissues. $CCL19^{+}$ fibroblasts, enriched in interferon-gamma signaling, may be involved in T cell recruitment. $NOTCH3^{+}$ fibroblasts, enriched in collagen production and proliferation, may orchestrate vascular remodeling.
3. Evaluation of mouse models. We mapped scRNAseq profiles from pre-clinical disease models to our fibroblast atlas. $CCL19^{+}$ cells were expanded with inflammation in all tissues, while $NOTCH3^{+}$ cells were expanded in lung and synovium but not in the intestine.

Conclusion: Our identification of two distinct inflammatory fibroblast states synthesize findings from multiple tissue-specific studies. Our comparison to mouse models predict that Notch3 based therapeutic approaches that are successful pre-clinical models of arthritis may also work on bleomyocin-induced pulmonary fibrosis but not in DSS-induced colitis. This study serves as a template for larger drug response studies to inform the feasibility of multi-tissue "basket" trials for Immune Mediated Inflammatory Diseases.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Health Services Research
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: One-quarter to one-third of RA patients use long-term glucocorticoids (GCs) despite their known, dose-dependent association with increased risk of major adverse cardiovascular (CV) events (MACE). Little is known about patterns of GC use among RA patients with MACE risk factors (e.g. diabetes, smoking), or how GC use may potentiate these risk factors.

Methods: In this retrospective cohort study, we used administrative data to identify 6,090 RA patients with ≥1 visit to Veterans Health Administration rheumatology clinic during 2013-2017. We excluded patients with no disease-modifying anti-rheumatic drug use (n = 686) and confounding disorders also treated with GCs (n = 2,520). In the resulting 2,884-patient cohort, we used logistic regression to evaluate associations between incident MACE during 2013-2018 (outcome), recent long-term GC use (predictor), and baseline MACE risk factors (covariates). We included 5 MACE risk factors: hypertension, diabetes, hyperlipidemia, tobacco use, and prior MACE. To examine how GC use influences the effects of MACE risk factors, we included two-way interaction terms between GC use and each of the five MACE risk factors defined above.

We used a validated claims-based algorithm to define MACE as any of acute myocardial infarction, ischemic stroke, transient ischemic attack, sudden death, or coronary revascularization, occurring between index date and December 31, 2018. Index date was defined as the patient's first rheumatology visit after meeting RA diagnostic criteria. We defined recent long-term GC use as ≥90 days' supply dispensed during the two years preceding index date.

Results: Among 2,884 RA patients, 1,553 (54%) had MACE risk factors, and 97 (3%) had prior MACE (Table 1). Overall, 16% of patients recently used long-term GC, compared to 17% of patients with MACE risk factors, and 22% of patients with prior MACE. Incident MACE occurred in 308 (11%) patients, 24% of whom had recent long-term GC use. Recent long-term GC use was independently associated with increased incident MACE (Table 2). While no interaction term was statistically significant overall, differences in odds of incident MACE were seen across levels of recent GC use for several risk factors, particularly diabetes (OR 2.10, 95% CI [0.93-4.77]), tobacco use (OR 2.88, 95% CI [1.16-7.14]) and prior MACE (OR 2.41, 95% CI [0.73-7.95]) (Table 3).

Conclusion: Long-term GC use is common among RA patients with MACE risk factors, including those with prior MACE. In this cohort, a quarter of patients with an incident MACE had recently used long-term GC. Long-term GC use may potentiate the effect of comorbidities like diabetes and tobacco use, disproportionately increasing MACE risk in certain patients. Further work is needed to evaluate the effect of persistent long-term GC use after MACE events, and to explore how GC use may amplify the effects of other CV risk factors.

Abstract Number: 1959

Epidemiology of Hospitalizations and Associated Mortality in Vasculitis: A National Study

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Health Services Research
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

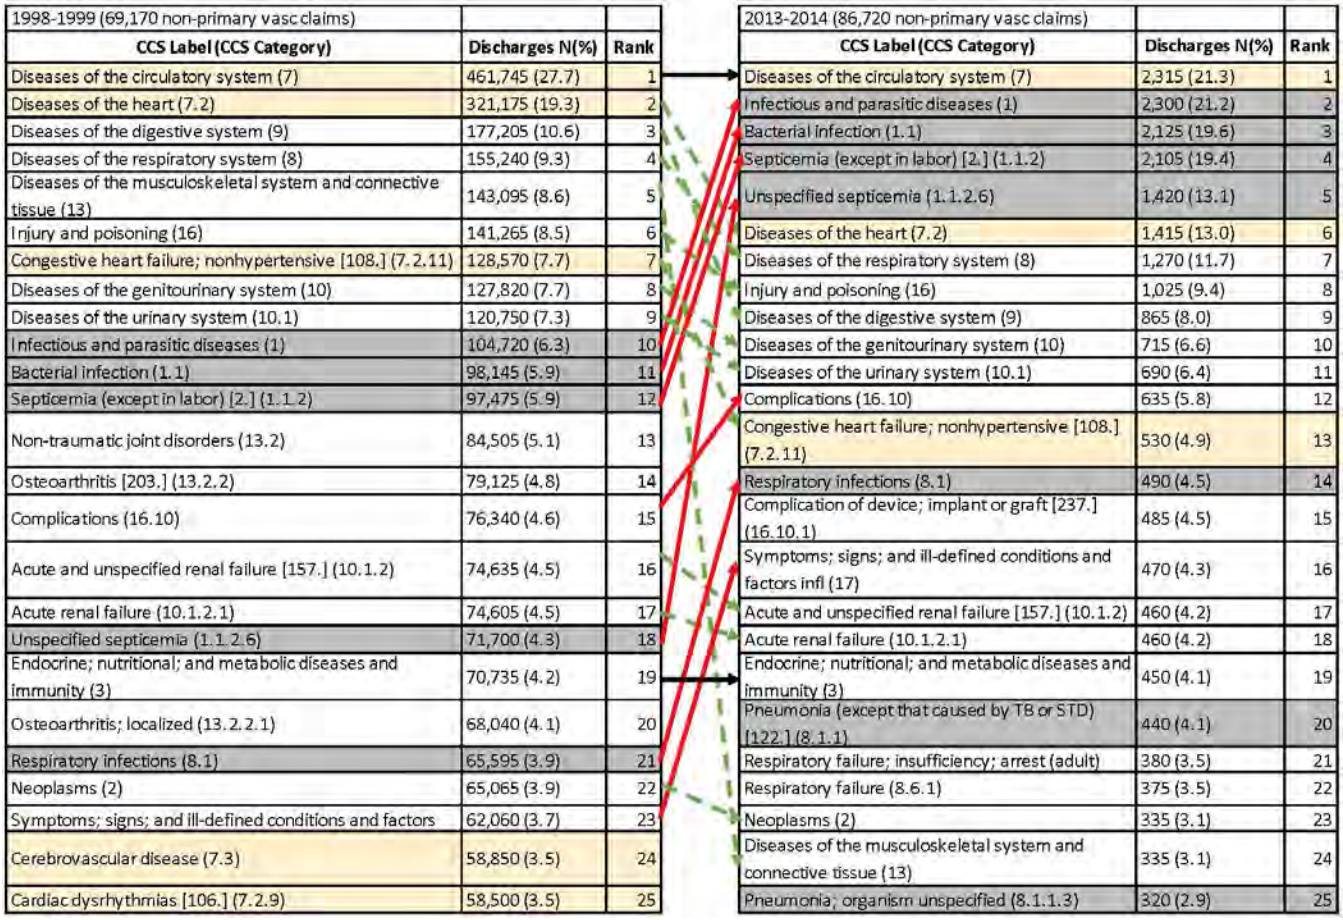
Background/Purpose: To assess whether comorbid diseases frequently associated with primary hospitalizations for non-vasculitis causes in people with vasculitis are changing over time in people with vasculitis in the U.S.

Methods: We identified people with vasculitis hospitalized with a non-primary/secondary diagnosis of vasculitis in the 1998-2014 U.S. National Inpatient Sample (NIS). We compared the rank (and percent) of top 25 Clinical Classification Software (CCS) categories (a standardized system for clustering diagnoses and procedures) associated with hospitalizations and in-hospital mortality in people with vasculitis, between 1998-99 versus 2013-14.

Results: In 1998-99, there were 69,170 non-primary vasculitis hospitalizations compared to 86,720 in 2013-14. The top 5 CCS categories associated with non-primary vasculitis hospitalizations in people with vasculitis in 1998-99 were circulatory system disease, heart disease, digestive system disease, respiratory disease, and musculoskeletal disease (Ranks 1-5 in order, respectively; **Figure 1**). In 2013-2014, the top 5 CCS (and change in rank from 1998-1999) categories were circulatory system disease (rank #1 to #1), infections/parasitic diseases (rank #10 to #2), bacterial infection (rank #11 to #3), septicemia (rank #12 to #4), and unspecified septicemia (rank #18 to #5; **Figure 1**). Compared to 27.7% non-primary vasculitis hospitalizations associated with circulatory system disease in 1998-99, 21.3% were associated in 2013-14.

In 1998-99, there were 817 deaths during non-primary vasculitis hospitalizations in people with vasculitis compared to 766 in 2013-14. The top 5 CCS categories associated with in-hospital death for non-primary vasculitis hospitalizations in 1998-99 were respiratory disease, circulatory system disease, heart disease, respiratory infection and pneumonia (Ranks 1-5 in order, respectively; **Figure 2**). In 2013-2014, these were infections/parasitic diseases (rank #6 to #1), bacterial infection (rank #7 to #2), septicemia (rank #9 to #3), unspecified septicemia (rank #22 to #4), and circulatory system disease (rank #1 to #5; **Figure 2**). In 1998-99, the top 3 CCS categories were all cardio-pulmonary diseases; in 2013-14, the top three CCS categories were all infections (**Figure 2**). Compared to 26.4% non-primary vasculitis hospitalization deaths associated with circulatory system disease in 1998-99, 20.5% were associated in 2013-14.

Conclusion: Infectious causes replaced cardio-pulmonary disease over time as the top causes of non-primary vasculitis hospitalizations and associated in-hospital mortality in people with vasculitis. Future studies should examine the modifiable factors associated with infection in vasculitis and design interventions to reduce this burden.



1998-1999 (69,170 non-primary vasc claims)

Figure 1. Top 25 healthcare cost and utilization project (HCUP) Clinical Classifications Software (CCS) categories for hospitalizations in people with vasculitis, comparing 1998-1999 to 2013-2014, with respective ranks Figure 1 legend The figure shows the top 25 CCS categories for hospitalization for the first period, 1998-1999 (left) and the last study period, 2013-2014 (right). Each CCS category label and category are shown in the first column, followed by the number and percent of discharges of all hospitalizations in the next column, followed by the relative rank from 1-25. Square brackets show the single-level CCS categories and regular brackets show multi-level CCS categories. Red arrows indicate any category that went to a higher rank in 2013-2014 and green indicates those any category that descended to a lower rank in 2013-2014. Solid black arrows show the categories whose rank remained the same. Number of discharges (percent) for each CCS category and rank is shown next to each CCS category. CCS categories included diagnoses in primary or non-primary position with vasculitis in non-primary position for hospitalizations in people with vasculitis. CCS consists of two related classification systems, single-level and multi-level. Single-level CCS system classifies all diagnoses and procedures. The single-level diagnosis CCS aggregates illnesses and conditions into 285 mutually exclusive categories. Most of these categories are homogeneous; for example, CCS category #100 is “Acute myocardial infarction and #101 is “Coronary atherosclerosis and other heart disease”. Some CCS categories combine several less common, individual conditions, such as CCS category #3, which is "Other Bacterial Infections. Similarly, the single-level procedure CCS aggregates procedures into 231 mutually exclusive categories, most representing single types of procedures. For example, #43 is “Heart valve procedures”, #44 is “Coronary artery bypass graft (CABG)” and #45 is “Percutaneous transluminal coronary angioplasty (PTCA)”. The multi-level CCS expands the single-level CCS into a hierarchical system. The multi-level CCS groups single-level CCS categories into broader body systems or condition categories. It also splits single-level CCS categories to provide more detail. The multi-level system has four levels for diagnoses and three levels for procedures, which provide the opportunity to examine general groupings or to assess very specific conditions and procedures.

Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Growing numbers of knee osteoarthritis (KOA) patients are morbidly obese (BMI ≥ 35 kg/m^2). Evolving evidence suggests weight reduction may delay the structural progression of KOA, reduce knee pain, and improve total knee replacement (TKR) outcomes. The cost-effectiveness of surgical and non-surgical weight loss strategies among morbidly obese patients with KOA has not been assessed.

Table. Cost-effectiveness of weight reduction strategies* in morbidly obese (BMI ≥ 35 kg/m^2, obesity classes II and III) KOA patients

Strategy	QALE	Costs	ICER	%opioids	%TKR
SOC	13.58	$239,902	--	12.5%	65.1%
SOC + NSWL	13.61	$240,618	$24,384	12.4%	65.1%
SOC + NSWL + RYGB	15.01	$307,195	$47,523	8.9%	31.7%
SOC + RYGB	15.17	$316,236	$55,764	7.7%	26.6%

*For NSWL, subjects lost a maximum of 20% of their initial BMIs, and weight loss was not maintained beyond 3 years; for RYGB, weight loss ranged from 23-47% of initial BMI, and this weight loss was largely sustained.

Figure.

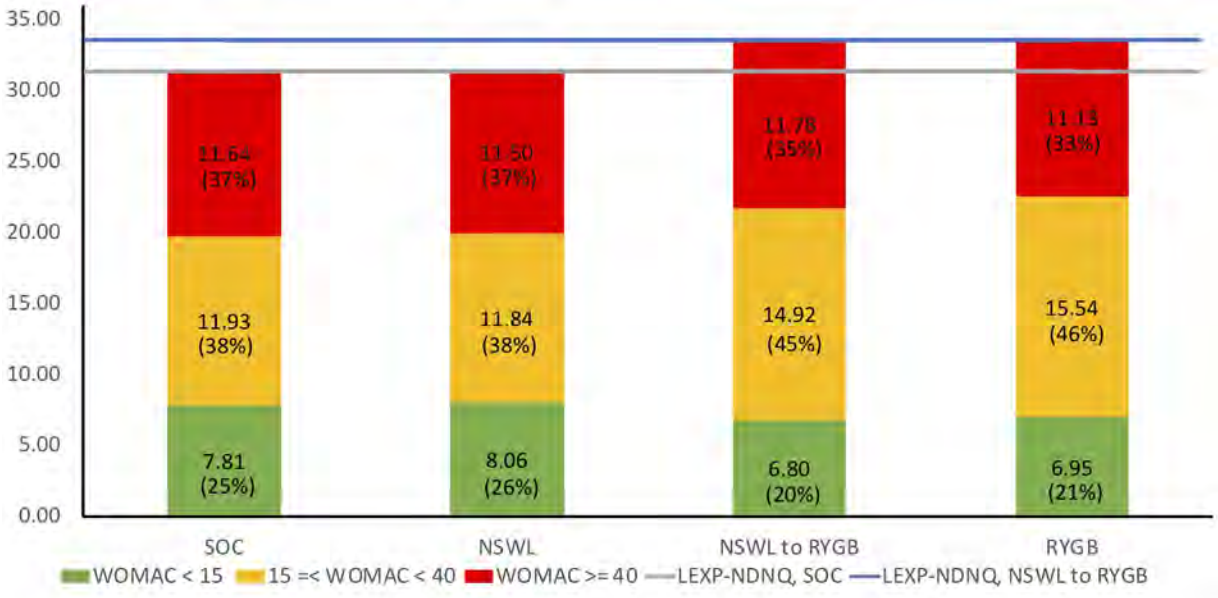

Figure. Number of non-discounted and non-quality adjusted (NDNQ) years spent by subjects in different WOMAC pain groups by treatment strategy. Solid lines indicate the NDNQ life expectancy (LEXP) of subjects from age 45 for the SOC (gray) and SOC+NSWL+RYGB (blue) strategies.

Table.

Methods: We used the Osteoarthritis Policy Model, a validated widely published microsimulation of KOA, to evaluate the cost-effectiveness of adding weight loss strategies to a KOA-related standard of care (SOC) in morbidly obese persons with KOA. The SOC includes physical therapy, NSAIDs, intra-articular injections, tramadol, oxycodone, TKR, and revision TKR. We considered 4 strategies: SOC only; SOC + a non-surgical weight loss (NSWL) program; SOC + Roux-en-Y Gastric Bypass (RYGB) surgery; and SOC + NSWL with RYGB after NSWL failure. For all strategies, we followed subjects until death, recording quality-adjusted life years (QALYs) accrued, lifetime medical costs, cumulative time in WOMAC pain states, and likelihoods of opioid and TKR use. We examined a KOA cohort with demographic and clinical characteristics consistent with those of patients enrolled in a long-term study of RYGB (mean age: 45, BMI: 46.6, WOMAC pain: 46.5). We used national databases and published data to estimate KOA structural progression, quality of life and background medical costs (stratified by pain, number of comorbidities, age, and BMI), treatment efficacy and costs ($14,819 for RYGB in year one and $251 in later years; $819 for NSWL in year one and $294 in later years), and costs and risks of complications. In sensitivity analyses we varied: the cost of health consequences of class III obesity (BMI ≥ 40) relative to class II (35 ≤ BMI < 40)($0 to $1,555 (base case = $1,555)), the likelihood of adverse events from RYGB (-50% to 50% relative to base case), and the maximum years weight loss from RYGB is maintained (5 to 20 (base case = 20)). We discounted costs and QALYs at 3%/year and conducted analysis from a healthcare perspective. We evaluated cost-effectiveness by calculating incremental cost-effectiveness ratios (ICERs) as the ratio of change in costs to change in QALYs for competing strategies in 2019 USD.

Results: Among morbidly obese patients with KOA, adding NSWL to the SOC added 0.3 QALYs and $716 in medical costs, resulting in an ICER of $24,384. Relative to the SOC + NSWL strategy, adding RYGB after NSWL added 1.4 QALYs and $66,577 in costs, leading to an ICER of $47,523. Relative to NSWL + RYGB, RYGB alone added 0.16 QALYs and $9,041 in costs with an ICER of $55,764. Relative to the SOC, the RYGB alone and NSWL + RYGB strategies reduced opioid use from 12.5% to 7.7-8.9%, and TKR use from 65.1% to 27-32% (Table). Number of years spent in different WOMAC pain groups are reported for each strategy (Figure). In sensitivity analyses, the additional cost of class III obesity was the most influential parameter affecting the cost-effectiveness of RYGB.

Conclusion: RYGB is cost-effective when preceded by NSWL at a willingness to pay (WTP) threshold of $50K/QALY. Proceeding directly to RYGB is cost-effective at a WTP threshold of $60K/QALY or higher.

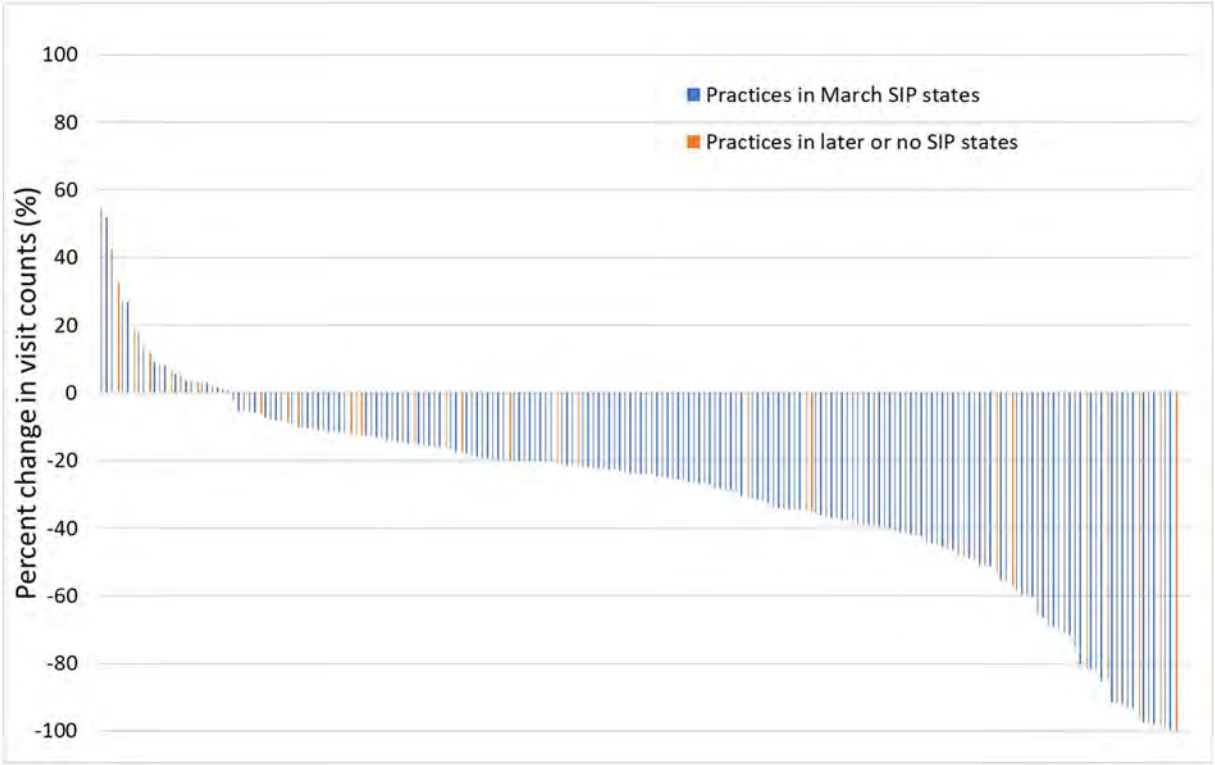
Decreased Visits in RISE Practices Due to the SARS-CoV-2 Global Pandemic

Jing Li[1], Sarah Ringold[2], Jeffrey R Curtis[3], Kaleb Michaud[4], Tracy Johansson[5], Jinoos Yazdany[6] and **Gabriela Schmajuk**[7], [1]University of California, San Francisco, San Francisco, CA, [2]Seattle Children's, Seattle, WA, [3]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [4]University of Nebraska Medical Center, Omaha, NE, [5]Adult / ACR Test Training Program #4, Atlanta, GA, [6]UCSF, San Francisco, CA, [7]University of California, San Francisco, Atherton, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Health Services Research
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM



Percent change in visit counts for RISE practices, March 2020 compared to March 2019 1: https://www.usatoday.com/story/news/nation/2020/03/30/coronavirus-stay-home-shelter-in-place-orders-by-state/5092413002/

Background/Purpose: The SARS-CoV-2 global pandemic has resulted in major disruptions to medical care, including rheumatology. We aimed to understand the changes in clinical visit counts from rheumatology practices across the U.S.

Methods: RISE is a national, EHR-enabled registry that passively collects data on all patients seen by participating practices, reducing the selection bias that may be present in more highly selected data sources. As of March 2020, RISE held data from 1,383 providers in 325 practices, representing ~39% of the U.S. clinical rheumatology workforce. Practices included in this study were required to have been participating in RISE from January 2019 through March 2020 and have visit data available (N=204). We obtained state-specific information on shelter-in-place (SIP) orders related to the pandemic and categorized each practice as being in a state where SIP was instituted in March 2020 vs. later or not at all.1 We analyzed visit counts (of all types – face-to-face and virtual visits combined) from RISE practices in the month of March 2020 and compared these to visit counts from March 2019. We also compared the change in visit counts according to the timing of SIP orders by state.

Results: 204 practices were included: 57% were single specialty group practices, with a median of 3 providers. Characteristics of patients seen at these practices were similar at the 2 time points (66% white, 75% female, mean (SD) age of 62 (15)). Overall, we found visit counts decreased by 34% (178,875 to 118,065) from March 2019 to March 2020 (see Figure). 168,126 unique patients were seen in March 2019 vs. 111,238 in March 2020, representing a 32.6% decrease. Almost 90% (179/204) of practices had reduced visit counts, regardless of the timing of the SIP order in their state. However, reductions were more dramatic in states where SIP orders were in place earlier: 64.4% (114/177) of March SIP practices had a > 20% decrease in visits vs. 44.4% (12/27) for those with later or no SIP orders (p=0.047)

Conclusion: We detected a significant decrease in rheumatology visits in March 2020 during the SARS-CoV-2 global pandemic compared to one year prior. The decrease in face-to-face visits may be underestimated because we were unable to distinguish between face-to-face and virtual (telemedicine) visits. Future work should address possible changes in patient outcomes due to decreased contact with clinicians. In addition, research using large observational datasets such as RISE will likely need to take this secular event into account.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Utilization of Telehealth Among Patients with Rheumatic Diseases in the Early Months of the COVID-19 Pandemic

Kristin Wipfler[1], Yomei Shaw[2], Teresa Simon[3], Adam Cornish[1], Patricia Katz[4] and Kaleb Michaud[5], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]FORWARD, The National Databank for Rheumatic Diseases, East Lansing, MI, [3]Bristol-Myers Squibb Company (at time of analysis), Princeton, NJ, [4]University of California, San Francisco, Novato, CA, [5]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Health Services Research
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Many health care providers replaced in-person clinical visits with telehealth visits or expanded their telehealth offerings due to the COVID-19 pandemic. We sought to better understand the frequency of these changes and satisfaction with telehealth appointments among patients with rheumatic diseases during the first months of the COVID-19 pandemic in the US.

Methods: The study population included participants in FORWARD, The National Databank for Rheumatic Diseases who completed a supplemental COVID-19 questionnaire between May 20 and June 2, 2020. Respondents were asked about the number of telehealth appointments they had between March 1, 2020 and the date of questionnaire completion. If they had at least one telehealth appointment, they were asked to rate their satisfaction with the appointment(s) on a Likert scale. Logistic regression models were used to identify factors associated with having telehealth appointments and with telehealth satisfaction. Respondents' optional free text comments were qualitatively analyzed to assess reasons for satisfaction/dissatisfaction with telehealth.

Results: A total of 1,213 participants were included in this study, with 617 (51%) reporting at least one telehealth appointment between March 1, 2020 and questionnaire completion. Of those who had at least one telehealth appointment, 447 (72%) reported being "somewhat satisfied" or "very satisfied" with their appointment(s) (Table 1). Satisfaction appeared to decrease as the number of telehealth appointments increased (Table 2; X^2 p=0.01) but this was attenuated when considering demographic and clinical covariates. Younger age, higher Rheumatic Disease Comorbidity Index (RDCI), higher PAS-II, and prednisone use were associated with having at least one telehealth appoint-

5+	5 (16.1)	2 (6.5)	1 (3.2)	14 (45.2)	9 (29.0)	31
Total	54 (8.8)	41 (6.6)	75 (12.2)	179 (29.0)	268 (43.4)	617

Table 2. Satisfaction with telehealth appointments by number of telehealth appointments reported. Values are n (%).

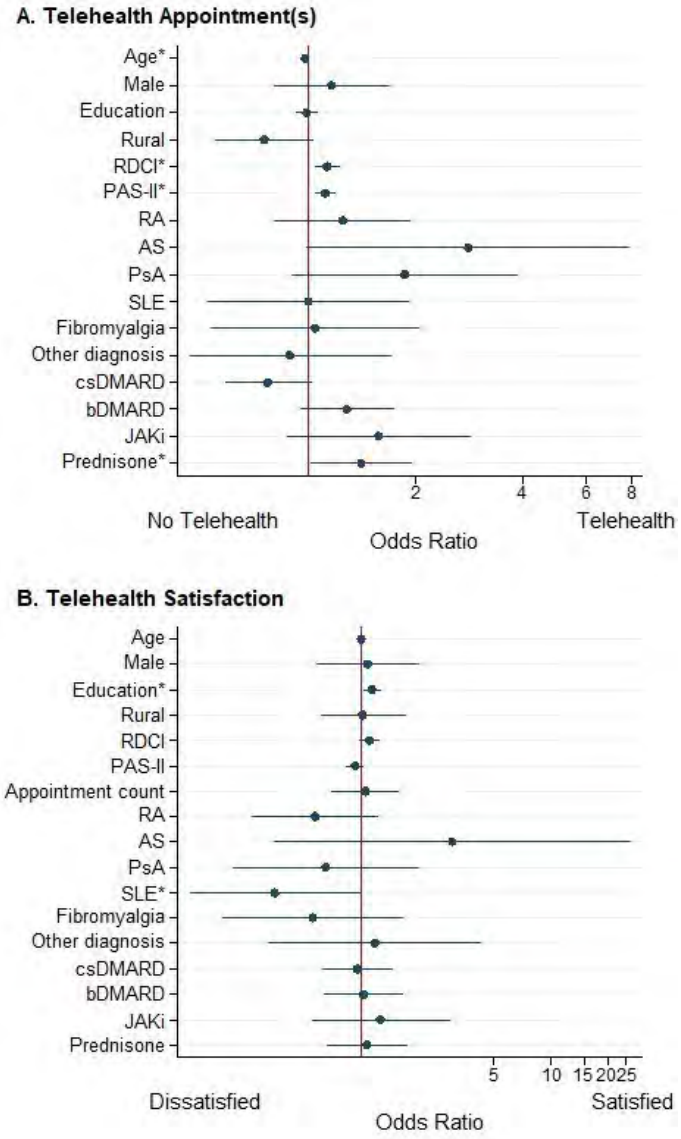

Figure 1. Factors associated with having one or more telehealth appointments (A) and with patient satisfaction with telehealth (B). OA was the comparator for diagnosis. Statistically significant covariates are labeled with an asterisk (*).

Respondents reported dissatisfaction with telehealth due to technical difficulties, perceptions that telehealth visits were less useful than in-person visits, and not being able to get needed services through telehealth.

Conclusion: About half of rheumatology patients in this cohort reported having one or more telehealth appointments during the first several months of the COVID-19 pandemic in the US, and most of them were satisfied with the ap-

pointment(s). Utilization of telehealth has expanded dramatically in a short period of time, with those with the greatest need (comorbidities and high disease activity) most likely to use these services. As clinics adapt to having more telehealth visits, it will be important to ensure quality of care and satisfaction is met for populations that are most at risk.

Variation in Quality of Care Among Patient Sociodemographic Groups in RISE Practices

Zara Izadi[1], Gabriela Schmajuk[2] and Jinoos Yazdany[3], [1]University of California San Francisco, San Francisco, CA, [2]University of California, San Francisco, Atherton, CA, [3]University of California, San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Previous studies have shown that sociodemographic factors are associated with quality of care. Using the Rheumatology Informatics System for Effectiveness (RISE) registry, we assessed whether the area deprivation index (ADI) and/or race/ethnicity was associated with provider performance on quality measures among patients with rheumatoid arthritis (RA).

Methods: We analyzed data collected on all patients with a diagnosis of RA who had at least one clinic visit between January 2015 and December 2017. We examined performance on disease activity assessment, functional status assessment, tuberculosis (TB) screening prior biologic start and blood pressure (BP) control. Using mixed-effects regression, we assessed the effect of area deprivation (as measured by the ADI, above or below the median percentile, where higher scores reflect more deprivation) and race/ethnicity on measure performance and on change in performance over time. Since practice characteristics could mediate this effect, we controlled for practice type, number of providers, region, and eHR software. Analyses accounted for clustering by practice and by patient.

Results: Data from 58,432 patients from 54 practices was examined. Mean age was 63±14 years, 77% were female, and 69% were Caucasian. Over time, there were significant improvements in performance on functional status assessment (+13.5% per year) and disease activity assessment (+8.8%), smaller improvements in performance on TB screening (+2.9%) and no improvements in performance on BP control. Performance on disease activity assessment and functional status assessment was comparable across all subgroups (Table). Both measures improved faster over time among patients with higher ADI, but improvements were slower among African Americans and Hispanics than Caucasians. Performance on TB screening was higher among African Americans (59.0%) and Hispanics (58.0%) than Caucasians (54.7%) and improved faster over time among Hispanics (+7.7% points per year) than Caucasians (3.9%, $p< 0.05$) and among patients with higher ADI (+4.7%) than those with lower ADI (+2.7%, $p< 0.001$). Performance on BP control was lower among African Americans (59.6%) and patients with higher ADI (62.7%) than Caucasians (64.5%, $p< 0.001$) and patients with lower ADI (65.3%, $p< 0.001$), respectively.

Conclusion: Although performance on quality measures is improving overall, we found important differences across sociodemographic groups. Non-Caucasians and those with lower socioeconomic status (SES) had less improvement

compared to Caucasians and those with higher SES. TB screening seems to be improving more among higher risk groups. Consistent with studies in the general medical literature, BP control was lowest among African Americans. To address health disparities, future quality improvement initiatives should target patient groups with persistent gaps in quality of care.

Engaging Patients in the Development of a Quality Measure of Functional Status to Improve Care Among Patients with Rheumatoid Arthritis

Sarah Hopkins Gillespie[1], Liana Fraenkel[2], Lisa Suter[3], Gabriela Schmajuk[4], Patricia Katz[5], Alex Limanni[6] and Alexis Ogdie[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Yale School of Medicine; West Haven VA; Berkshire Medical Center, Lenox, MA, [3]Yale School of Medicine, New Haven, CT, [4]University of California, San Francisco, Atherton, CA, [5]University of California, San Francisco, Novato, CA, [6]n/a, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: The ACR Quality of Care committee is working to develop a quality measure to reflect functional assessment in rheumatoid arthritis (RA). One proposed approach is to measure functional status over the course of one year. Scores on currently available functional status instruments may be affected by factors other than RA (e.g. comorbidities). The objective of this study was to identify factors associated with change in measures of functional status in RA. We used a mixed methods approach in which we performed a systematic literature review (SLR) followed by two focus groups to examine patients' perspectives.

Methods: In the SLR, we identified studies examining independent predictors of functional change as measured by the health assessment questionnaire (HAQ), multidimensional HAQ (MDHAQ), or PROMIS physical function in longitudinal studies. Next, we conducted two focus groups at different sites to elicit patients' views on what may affect scores and change in scores on functional status measures, using the MDAHQ as the example functional status instrument. Focus groups were audio-taped, transcribed, and analyzed via content analysis in NVivo, the code list was iteratively refined.

Results: In the SLR, all studies meeting inclusion criteria utilized the HAQ as the outcome of interest. Statistically significant factors associated with change in HAQ included disease activity, treatment of RA, disease duration, age, baseline activity level, adaptation, stress, mood, lifestyle factors (in particular smoking), education level, and comorbidities. Two focus groups with 3 and 5 patients with RA, respectively were conducted. Patients described factors that influenced functional status scores which included family responsibilities, types of activities participated in during the week (i.e., child care, cooking, cleaning, physical activity), seasonal variation, having a good relationship with the rheumatologist, having a responsive rheumatologist, and the patient's understanding of their disease (i.e., expectations about improvement, understanding what may be related to the disease, etc). While patients identified with some of the questions in the MDHAQ, they felt that many important activities/functions were missing and that function should be more broadly defined and incorporate facets of participation, in particular work and social participation. Patients also felt that stable function over a year was an acceptable performance measure, however, they also stressed the importance of incorporating individual patient goals (i.e., a newly diagnosed patient with early disease and moderate disease activity would be expected to improve over one year whereas an elderly patient with significant disease-related damage may be happy staying the same).

Conclusion: In RA, several external factors affect both static scores and change in measures of functional status. Patient focus groups provided additional factors to those identified in the literature. This study demonstrates the

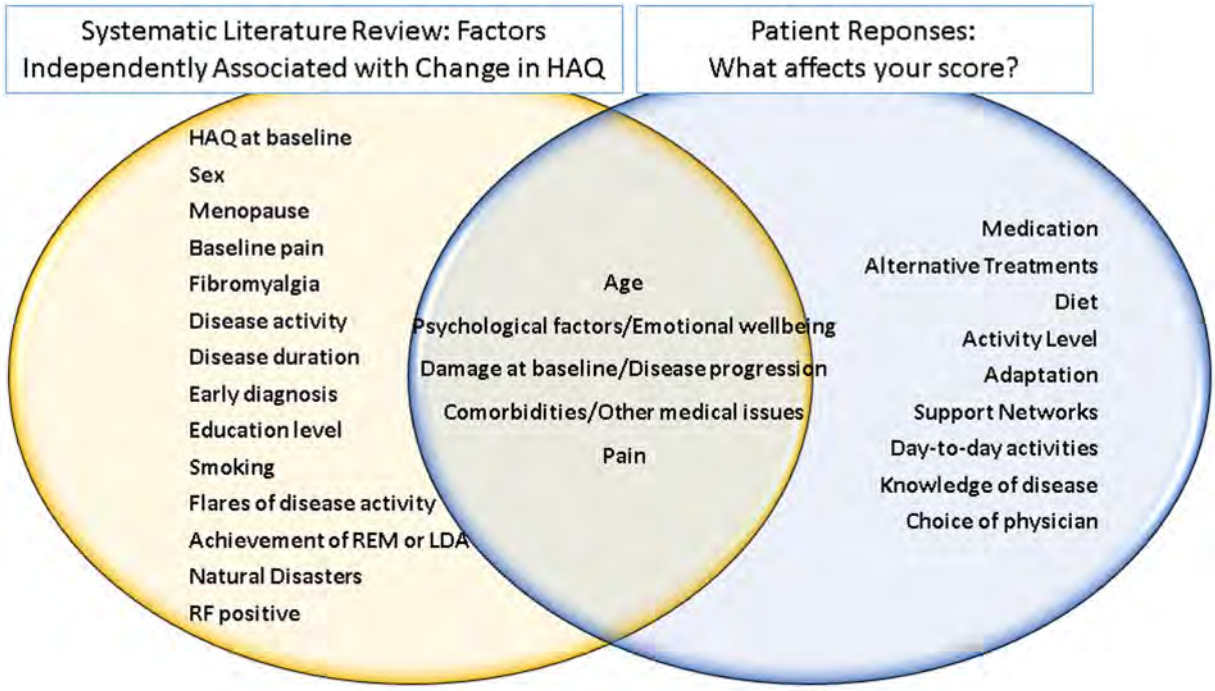

Figure 1. Factors that affect change in functional status measures: findings from a SLR and patient focus groups

importance of engaging patients in development of quality measures.Figure 1. Factors that affect change in functional status measures: findings from a SLR and patient focus groups

Reducing Delays for Biologic Medication Approval in Outpatient Rheumatology

Josh Waytz[1], Dahlia Sultan[1] and Veena Patel[2], [1]University of Chicago, Chicago, IL, [2]Dell Medical School - UT Health Austin, Austin, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Biologic medications are commonly used for numerous rheumatologic conditions. A significant proportion of these medications are denied for non-medical reasons by insurance companies causing delays in patients getting medication which can have negative downstream effects. The aim of this project was to develop an intervention to decrease delays and subsequent associated costs in the approval process of biologics denied for non-medical reasons in rheumatology clinic. Furthermore, we aim to have a 25% usage rate of our intervention by October 1st, 2020.

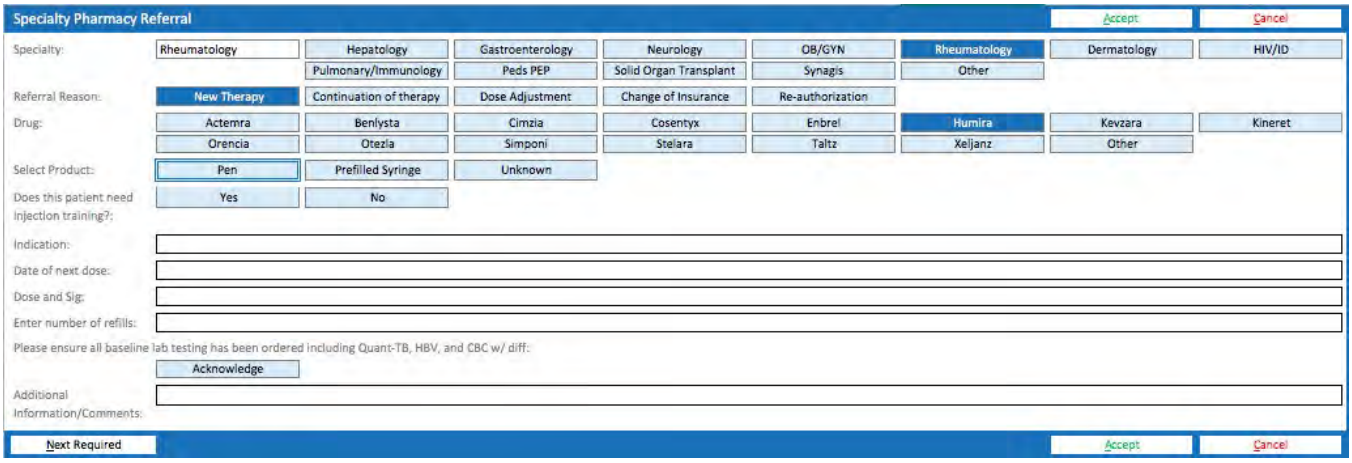

Figure 1a. Pre-Intervention Referral Shell. The previous order only allows providers to select a single medication without any alternatives in the event that the medication is denied.

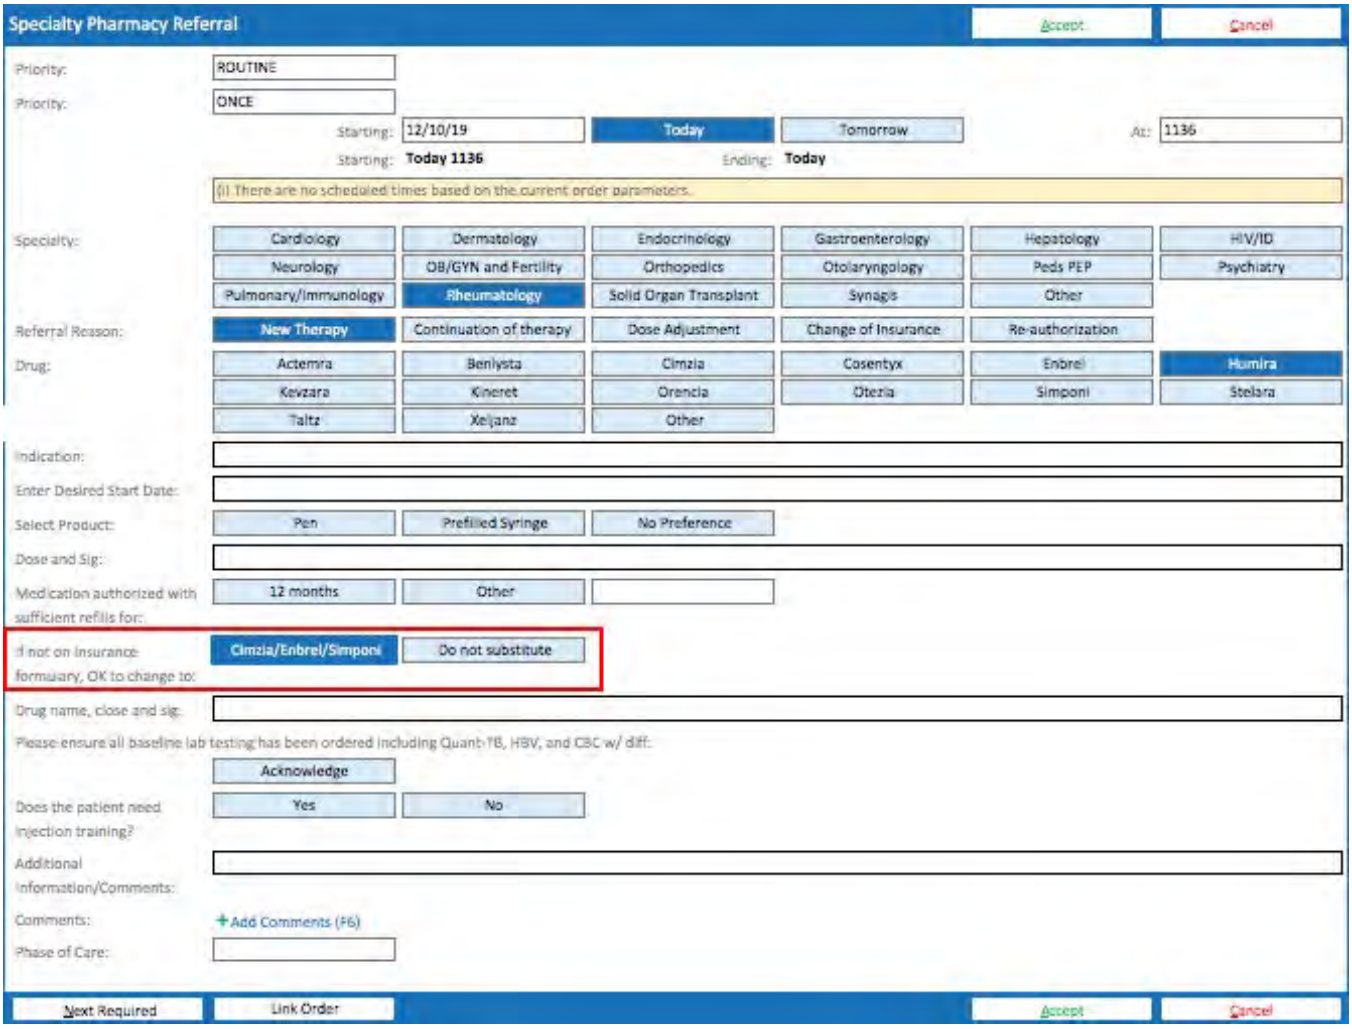

Figure 1b. Post-Intervention Referral Shell. The new order allows providers to select a replacement medication within the same class if the initial medication is not approved as shown by the red box.

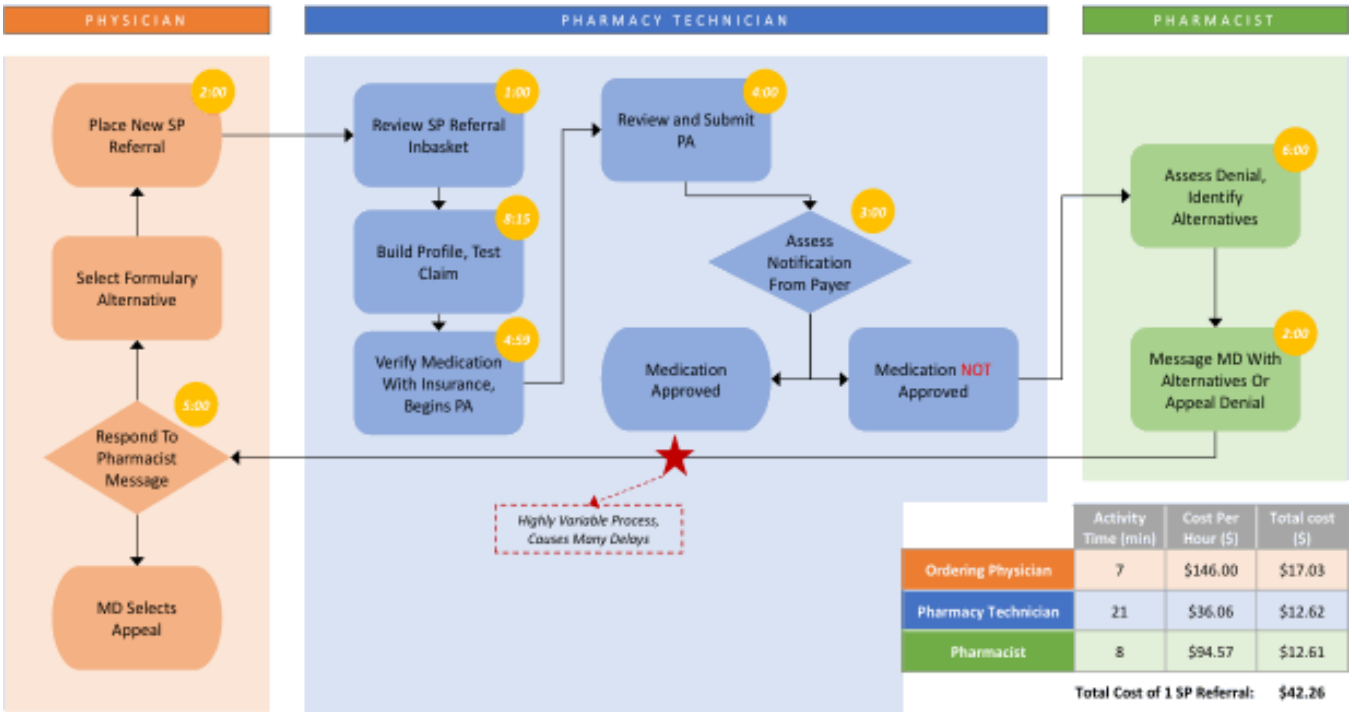

Figure 2. Specialty Pharmacy (SP) Referral Process Map. This map was created by our multidisciplinary group to identify all steps in our SP referral process and identify areas of delay within the process. Using time-driven activity-based costing (TDABC), a tool used to estimate the cost of processes in different sectors such as health care, we measured the amount of time (in minutes), noted in yellow circles, needed to complete each step in the process. This allowed us to generate an estimate for the cost of each SP referral.

Methods: To prescribe a biologic in rheumatology clinic, providers fill out a specialty pharmacy (SP) referral through our electronic medical record. They select which medication they would like to use and indication (Figure 1a). This is then sent to our pharmacy department for further review. We assembled a multidisciplinary team of pharmacy, medicine and rheumatology personnel and created a process map of the SP referral process and identified several causes of delay (Figure 2). The longest delay identified was waiting for provider approval of the subsequent, preferred, medication. We recorded the amount of time each step of the process took and their associated costs. We used Kaplan and Porter's time-driven activity-based costing (*Harv Bus Rev,* 2011*, 89(9), 46-52*) to estimate the resulting cost of this process.

Our intervention modified the SP referral to give the ordering physician the ability to allow the pharmacist to switch within the same class of biologic medication if the initial medication is denied (Figure 1b). This extra prompt was created for TNF-α, IL-6, IL-1 and IL-17A inhibitors.

Results: Pre-intervention, we found that 25% of rheumatologic SP referrals at our institution were denied by insurance. On 10/21/2019, our intervention was implemented. Subsequently, we analyzed all SP referrals between 10/21/2019-5/4/2020 and found 210 that were eligible for the ordering provider to use our intervention. The usage rate of our intervention was 15.7% (33/210 referrals). Of these 33 referrals, 21(64%), 7 (21%), and 5 (15%) were for TNF-α, IL-6 and IL-17A inhibitors, respectively. Four (12.1%) were denied by insurance and were appropriately switched to a same-class replacement. Three of these four referrals were for TNF-α inhibitors—the remaining referral was for an IL-17A inhibitor. Notably, the average time between initial referral—including insurance denial—and subsequent approval of the second, insurance-preferred medication, was 19 days post-intervention, compared to an average time of 64 days pre-intervention. Using time-driven activity-based costing, the amount saved each time the intervention was used was estimated to be $42.16.

Conclusion: There is significant time- and cost-related burden when medications are denied for non-medical reasons. Our early results show promise that our intervention will reduce cost and time delays and allow patients to start necessary treatment in a timely fashion. Though close, we have not yet met our desired usage rate but anticipate that we will be able to raise further awareness of the tool and also expand this intervention to other medications.

Improving Value Concordant Care Through Increased Use of Subcutaneous Methotrexate in Rheumatoid Arthritis

Jason Bankert[1], Jonida Cote[2], Joseph Chronowski[1] and Eric Newman[1], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Medical Center, Danvile, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Rheumatoid Arthritis (RA) is an expensive disease which untreated can lead to disability and socioeconomic burden. This high cost of treatment impacts the use of limited medical resources. Subcutaneous (SC) methotrexate (MTX) has higher bioavailability, greater efficacy and better tolerability when compared with oral MTX. Furthermore, it is a less costly treatment prior to starting biologics. In our study, we aimed to provide Treat-to-Target and value concordant care by increasing the use of SC MTX.

Figure 1: Percent of methotrexate-treated Rheumatoid Arthritis patients using subcutaneous (SC) methotrexate (MTX)

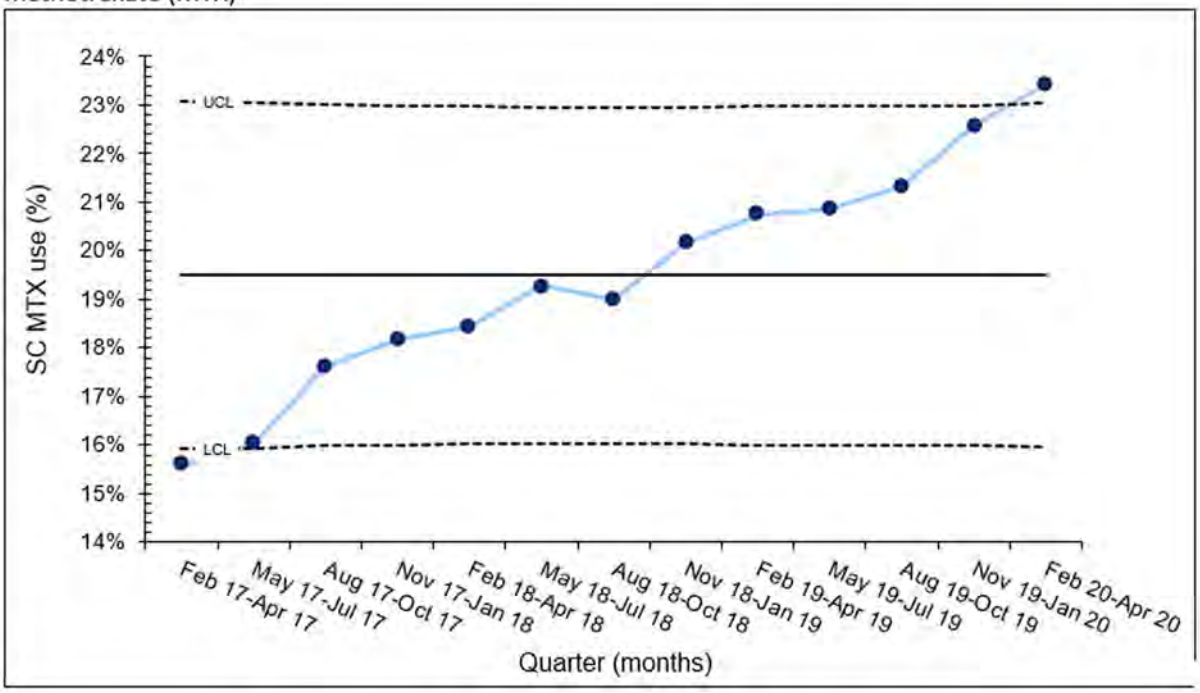

Figure 2. The relative increase of subcutaneous (SC) methotrexate (MTX) use per individual rheumatologist

Physicians	Baseline SC MTX use 2/28/2017 (%)	Post-intervention SC MTX use 4/30/2020 (%)	Relative increase of SC MTX use (%)
A	7.4	30.6	314
B	13.3	35.3	165
C	16.7	43.8	162
D	8.9	20.3	128
E	28.4	63.2	123

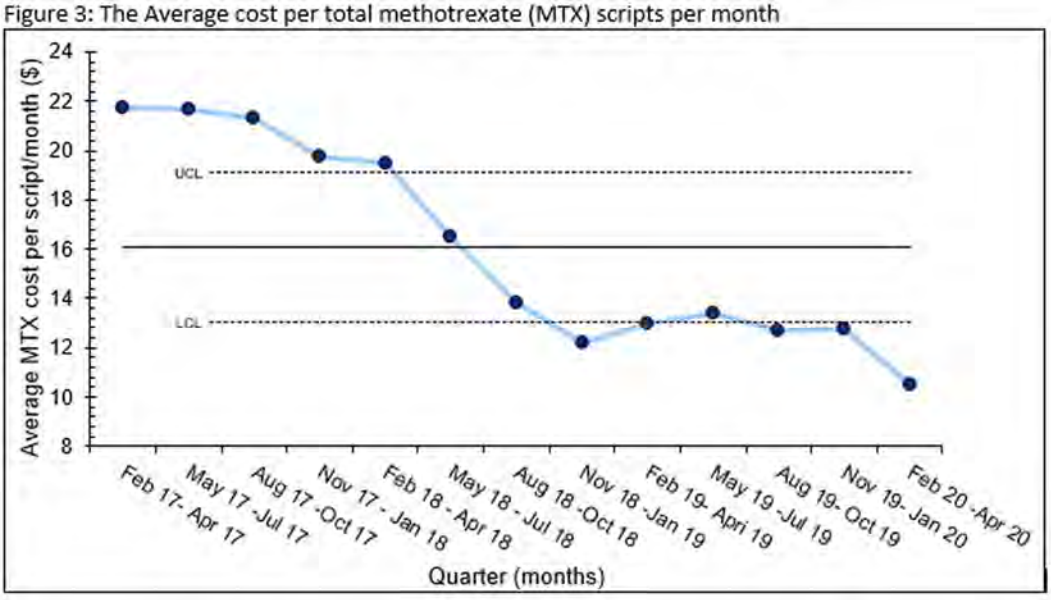
I	37.5	57.7	54
J	22.4	33.9	51
K	35.9	54.1	51
L	37.5	50	33
M	8.3	10.6	28
N	6.2	6.7	8
O	16.2	17.1	6
P	16.7	15.8	-5
Q	17.1	14	-18

Figure 3: The Average cost per total methotrexate (MTX) scripts per month



Methods: Baseline and prospective data on RA patients treated with MTX were obtained from the EHR (Epic) 2/1/2017 -4/2020 with intervention starting 11/2018. Prior to testing, a Treat-to-Target plan for increasing the use of SC MTX was discussed with the rheumatologists. A value concordant DMARD table was built and available in the EHR during each visit. Patients received medication education via the physician or rheumatology pharmacist. Data on value concordant MTX use, Clinical Disease Active Index (CDAI) and financial costs was collected and analyzed quarterly pre and post intervention. SC MTX was designated as value concordant while oral MTX was designated as non-value concordant. The percentage of value concordant MTX use was calculated by dividing SC MTX by total MTX use. The mean uncontrolled CDAI was calculated by dividing the number of RA patients with CDAI >10 by the total RA population with a CDAI. The MTX cost was determined by calculating the average cost per MTX script per

month (both oral and SC methotrexate). Shewhart charts were used to analyze data. The SC MTX use per individual physician pre and post intervention was determined by finding the absolute and relative increase for each.

Results: The use of total SC MTX among RA patients showed an absolute and relative increase of 8% and 50% respectively between 2/2017 at baseline to 4/30/2020 post intervention (Figure 1). The Shewhart P-Chart analysis met statistical significance for increased SC MTX use. 88% of individual physicians prescribing MTX had a relative increase of 93% SC use with high to low range varying between (+)315% to (-)18% (Figure 2). The % of RA patients with CDAI > 10 remained stable during the study. The average cost per MTX script per month within our health care plan steadily decreased from $21.73 (2/1/17- 4/30/17) pre intervention to $10.53 (2/1/20 - 4/30/20) post intervention for an absolute cost decrease of 49% meeting statistical significance per Shewhart I-chart (Figure 3).

Conclusion: The healthcare cost associated with RA treatment is substantial, and it creates a financial and economic burden. Patients and rheumatologists can work together to create individualized treatment plans to control the disease without causing excessive financial strain. Our study showed that the increased use of SC methotrexate provided a more cost-effective treatment plan for our RA population by reducing the average methotrexate cost per script per month by 49% without compromising the quality of care. It also suggested that the intervention we used was successful in modifying our rheumatologists' decision making to provide greater value concordant care.

Combating Rheumatologist Burnout: Use of Protocol Driven Medication Refill by Pharmacists

Eva Rottmann[1], Jonida Cote[2], Swana Thomas[3], Dante Grassi[1], Joseph Chronowski[1], Lisa L. Schroeder[1], David Pugliese[4] and Eric Newman[1], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Medical Center, Danvile, PA, [3]Geisinger Medical Center, Wilkes-Barre, PA, [4]Geisinger Health System, Wilkes Barre, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Increased electronic health record (EHR) administrative workload is a great source of physician dissatisfaction. We embedded pharmacists into our Rheumatology team in 2019. This study explored the impact of pharmacist integration on reducing physician workload and burnout.

Methods: The monthly volume of medication refills by rheumatologists was measured as a baseline from 1/30/2019 to 9/30/2019 within our EHR (Epic). Protocol driven medication refill parameters for DMARDs and non-DMARDs were created per American College of Rheumatology guidelines. Using these refill parameters, physician time needed per refill was derived by averaging the time per message for 40 refills across 5 physicians. After implementation of pharmacists, the monthly volume of refills by pharmacists and physicians was measured from 10/1/2019 to 3/31/2020. Total physician time saved was calculated by multiplying the number of pharmacist refill encounters with average physician refill time. The time saved per month was divided by the number of clinical full-time equivalents to calculate the time saved per rheumatologist. Shewhart P-charts were used to measure significance for volume and time saved. Rheumatologists' satisfaction with EHR work was gauged via anonymous electronic survey pre- and post-pharmacist addition. Satisfaction was rated from 1 (not happy) to 5 (high satisfaction). Two additional questions were asked

Figure 1. Rheumatologists vs Rheumatology Pharmacists Monthly Refill Volume

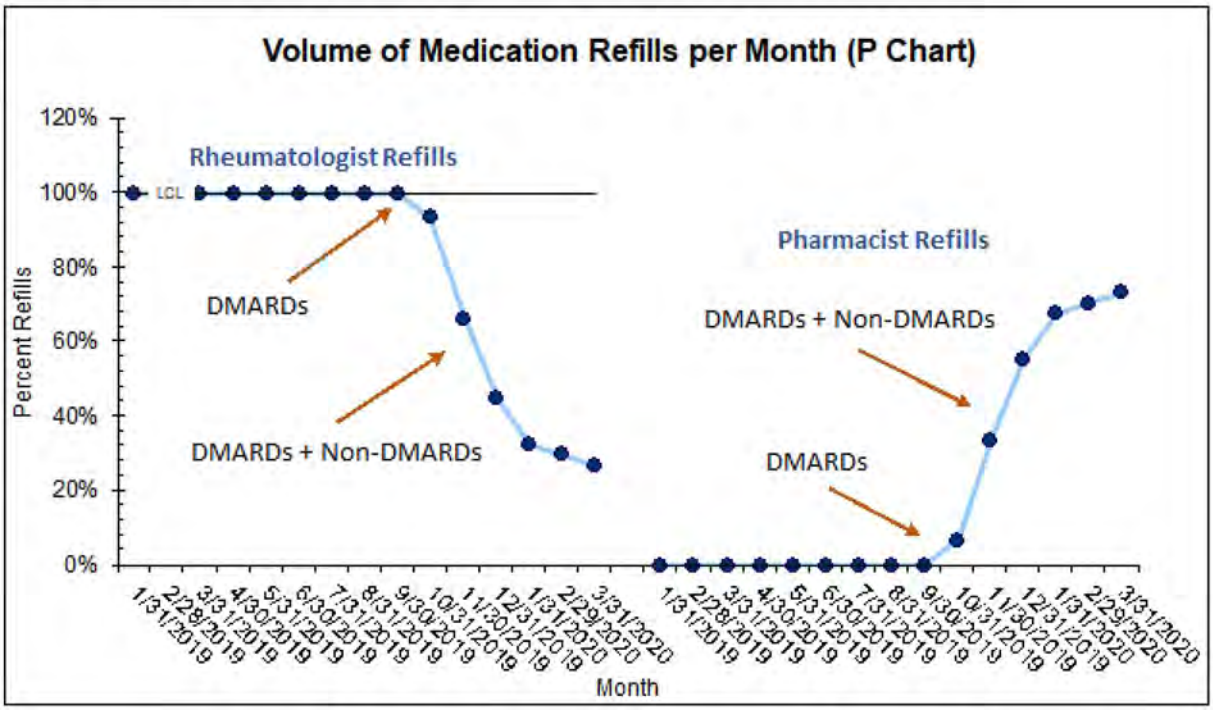

Figure 2. Time Saved for the Rheumatologist Group by the Introduction of Pharmacists

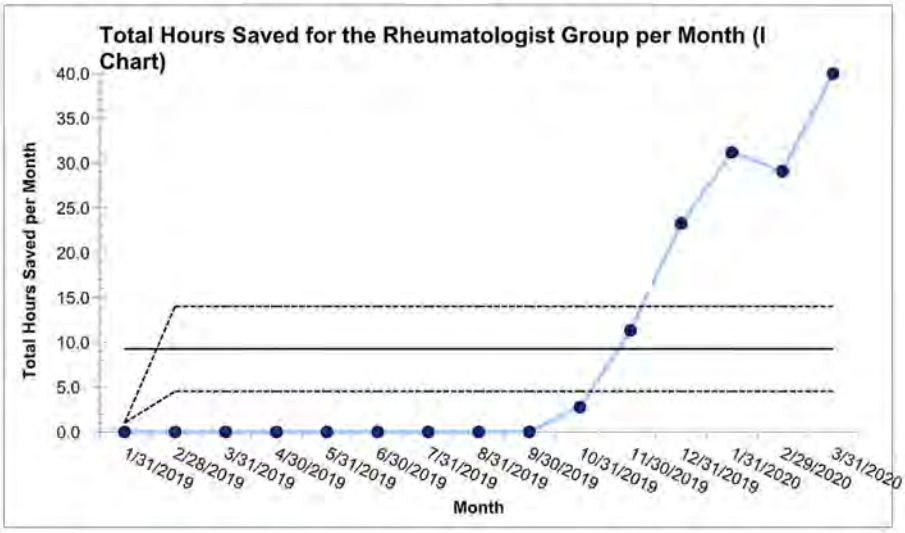

in the post pharmacist survey related to effect on work and burnout. 100% of physicians responded to the pre-survey and 93% of physicians responded to the post survey.

Results: The volume of medication refills by physicians decreased from about 1201 refills per month (or 100% of all refills) pre-pharmacist to 464 refills per month (or 27% of all refills) post-pharmacist integration (Figure1). The total time saved for all the rheumatologists (15 physicians, 7.75 FTEs) increased from 0 hours per month pre-pharmacist in September 2019 to 41.5 hours per month post-pharmacist in March 2020 (Fig.2). The time saved per physician FTE increased from 0 hours per month in September 2019 to 5.4 hours per month in March 2020 (Fig.3). Shewhart P

Figure. 3. Time Saved per Rheumatologist FTE by the Introduction of Pharmacists

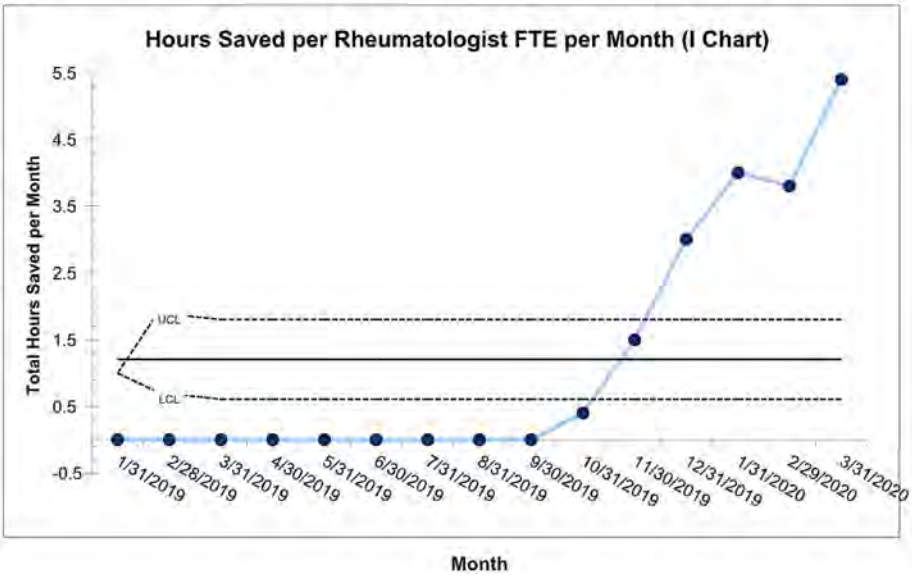

chart analysis met statistical significance for time saved per the individual and group of rheumatologists respectively with the implementation of pharmacists in our team. The surveys showed that the mean satisfaction with EHR refill work improved from 1.4 +/-0.2 at baseline to 4.3 +/-0.2 ($p< 0.001$) post pharmacist introduction. 100% of physicians reported that the pharmacist addition to their daily workflow helped them leave work on time and their workload interfered less with life outside of work (n=14), and 79% of physicians reported less burn out.

Conclusion: In early 2020, 51% of rheumatologists reported burnout in the workplace. This negatively impacts physician work effort, patient outcomes, and healthcare costs. Our study showed that pharmacists' medication refills alone have decreased physician EHR work and burnout. This shows great potential for other areas of improvement through pharmacist integration. Implementing a pharmacist into practice has brought us closer to achieving the 4th Aim of Quadruple Aim-improving the work life of the rheumatologist.

Abstract Number: 1968

Cathepsin S Gene Expression Measured in the Peripheral Blood of Osteoarthritic Patients Prior to Surgery as a Biomarker of Post-operative Pain Development

Elena Tchetina[1], Kseniya Glemba[1], Galina Markova[1], Maksim Makarov[1] and Aleksandr Lila[1], [1]Nasonova Research Institute of Rheumatology, Moscow, Russia

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoarthritis & Joint Biology – Basic Science

Session Type: Abstract Session

Session Time: 12:00PM–12:50PM

Background/Purpose: Osteoarthritis (OA) is a chronic rheumatic disease, which involves pain, limited inflammation, and local destruction of the knee joint. OA pain is a major clinical symptom, which limits working capacity and denotes an important indication for joint replacement in the end-stage OA. In spite of significant number of positive outcomes, chronic postoperative pain represents a major adverse consequence of surgery, which is observed in 10-40% of OA patients. Therefore, identification of patients potentially capable of developing chronic postoperative pain prior to surgery could significantly improve therapy outcome. Here we aimed to identify genes whose expression in the peripheral blood prior to surgery would indicate OA patients under risk of post-operative pain development.

Methods: We examined peripheral blood of 26 healthy volunteers (55±8.3 years) and 40 end-stage OA patients (56.5±8.9 years) undergoing knee joint replacement surgery. Patients were examined prior to surgery and 6 months' post-surgery. Nociceptive pain was assessed using VAS index whereas neuropathic pain, using DN4 and PainDETECT questionnaires prior to surgery. Functional activity was evaluated by WOMAC. Pain indices after surgery according to VAS of 30% and higher were considered. MMP-9 and caspase 3 protein levels were quantified by ELISA. Total RNA isolated from whole blood was used in expression studies for caspase 3; metalloproteinase (MMP)-9; cathepsins K and S genes. These were performed with quantitative real-time RT-PCR prior to surgery.

Results: Out of 40 patients pain complaints were obtained from 9 patients (22,5%) after 6 months' post-surgery. Prior to surgery all the examined genes were significantly upregulated in the patients who developed post-operative pain and those subjects who did not develop pain after surgery compared to healthy controls. However, no difference in the clinical levels of the pain-related and functional indices in the examined patients was observed before surgery. ROC curve analyses confirmed significant associations ($p< 0.05$) between expressions of the examined genes prior to surgery with the likelihood of pain development after surgery. The cut-off values for the examined gene expressions were 11.34 for cathepsin S, 10.11 for caspase 3, 10.09 for cathepsin K. Among the examined genes cathepsin S expression was the most appropriate predictor of post-operative pain development [AUC= 0.857, 95%CI (0.708-1.000)].

Conclusion: High cathepsin S gene expression in the peripheral blood of the end-stage OA patients measured prior to joint replacement surgery could serve an important biomarker of post-operative pain development.

The Dynamics of Macrophage Sub-Populations in the Inflammatory Phase Following Joint Trauma

Samuel Hamilton[1], Anna Montgomery[1], Niamh Fahy[2], Maximilian Mayr[1], Shang-Yang Chen[1], Gaurav Gadhvi[1], Yvonne Bastiaansen-Jenniskens[2] and **Deborah Winter**[3], [1]Northwestern University, Chicago, IL, [2]Erasmus MC, Rotterdam, Netherlands, [3]Northwestern University Division of Rheumatology, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Macrophages fulfill critical functions in maintaining tissue homeostasis in steady-state, as well as in inflammation and immune response. In the joint synovium, we have previously shown using single-cell RNA-seq that four distinct populations of macrophage co-exist in steady state: synovial lining, interstitial, antigen-present-

ing, and infiltrating. Our goal is to understand the role of these different macrophages in the inflammatory phase that follows joint trauma. Synovial inflammation has been shown to key in the development of long term cartilage damage and osteoarthritis (OA): thus, macrophages may provide a therapeutic target for prevention and treatment.

Methods: We used a mouse model of post-traumatic OA (CIOA) where mice develop cartilage damage a few weeks after intra-articular injection of collagenase into the synovial space of the knee. We euthanized male mice (aged 8-12 weeks) at days 0, 3, 7, 11, and 28 post-CIOA. Knees were dissected, extraneous muscle tissue resected, and joints processed for Fluorescence-Activated Cell Sorting (FACS). Macrophages were identified as CD45+CD11B+Ly6G-Ly6C-CD64+ cells and further subdivided into four populations by expression of MHCII and CX3CR1. RNA was extracted from these cells and RNA-seq was performed using full-length SMART-seq v4 Ultra Low Input Kit. After sequencing on Illumina Nextseq, bcl files were demultiplexed and resulting fastq files were trimmed with Trimmomatic, aligned to mm10 with tophat, and mapped to genes with HTseq to generate a table of gene expression for analysis.

Results: All macrophage populations were increased in number during peak inflammation on day 3 post-CIOA and returned to approximately steady-state levels by day 28. We found that each macrophage sub-population exhibited distinct gene expression at day 0 but their transcriptional profiles appeared to converge on day 3. By resolution of inflammation on day 28, the transcriptional profile of each sub-population resembled steady-state. The transcriptional signatures over time suggested two dominant trends drove macrophage response: genes that were differentially expressed primarily in the synovial lining population and genes that were differentially expression in all four sub-populations in the same pattern. Synovial lining macrophages up-regulated of cell cycle and monocyte genes suggesting this population may expand through a combination of proliferation and differentiating monocytes. This population down-regulated genes associated with its specific synovial lining phenotype, which was confirmed by overlap with genes from human data. The expression patterns observed in all macrophages included the up-regulation of genes associated with IL-1B/IL-6 inflammation and down-regulation of homeostatic genes.

Conclusion: Understanding the function of macrophages following joint trauma is likely to provide insight into the resulting joint instability that leads to the development of cartilage damage and OA. By investigating the role of specific macrophage subsets, we may elucidate potential targets for the prevention or attenuation of OA-associated cartilage damage.

Mimicking Cytokine-driven Key Features of Arthritis Using a Human *in Vitro* 3D Joint Model

Alexandra Damerau[1], Moritz Pfeiffenberger[1], Annemarie Lang[1], Timo Gaber[1] and Frank Buttgereit[2], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Charité University Medicine, Berlin, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Our ultimate goal is to study potential drug candidates in an experimental setting of arthritis. Therefore, we aim to develop a human *in vitro* 3D joint model mimicking key features of arthritis by applying inflammatory conditions namely immune cells and pro-inflammatory cytokines. Our i*n vitro* 3D joint model consists of different components: i) osteogenic and ii) chondrogenic part, iii) joint space with synovial fluid and iv) synovial membrane. Developed as an alternative *in vitro* approach to animal experiments, our 3D joint model will enable us to study efficiently the effects of potential drug candidates in a more translational setup.

Here, we aimed to demonstrate the suitability of our human *in vitro* 3D osteochondral tissue model (OTM) by analyzing the influence of the main cytokines involved in the pathogenesis of RA as well as the impact of approved drugs.

Methods: The OTM was engineered by co-cultivation of human mesenchymal stromal cell (hMSC)-derived bone and cartilage components in a 3D environment and comprehensively characterized (e.g. cell vitality, morphology, structural integrity) using histological, biochemical and molecular biological methods, µCT and scanning electron microscopy. In brief, to establish the osteogenic component, we populated β-tricalcium phosphate (TCP) – mimicking the mineral bony part – with hMSCs, while the scaffold-free cartilage component was generated by cellular self-assembly and intermittent mechanical stimulation (fzmb GmbH). To test the suitability of our OTM, we applied a cocktail of TNFα, IL-6 and MIF using concentrations reported from RA synovial fluid alone or in combination with approved therapeutic drugs and analyzed their impact by qPCR.

Results: We verified the osteogenic phenotype of our 3D bone component by demonstrating an increase in mineralized bone volume and the induction of bone-related gene expression (*RUNX2*, *SPP1*, *COL1A1, OC)* as compared to the corresponding control. Secondly, we verified the chondrogenic phenotype of our cartilage component by HE and Alcian Blue staining as well as by the reduced expression of *COL1A1* and an abundant expression of *COL2A1*. Interestingly, co-cultivation of both components for up to 3 weeks demonstrated colonization, connectivity and initial calcification implying a transitional bridging area. The exposure of OTM to TNFα, IL-6 and MIF caused cell- and matrix-related changes, such as the significant induced expression of the metabolic marker *LDHA,* the angiogenic marker *VEGF* and the inflammation markers *IL8* and *TNF* in both bone and cartilage, while *IL6* is downregulated in bone compared to the unstimulated control. Moreover, a cytokine-related significant upregulation of *MMP1* and *MMP3* expression was observed in cartilage compared to bone. Due to the specific drug treatment (adalimumab, tocilizumab, milatuzumab), the induction of inflammation and degradation could be prevented.

Conclusion: The results of our study showed that our human *in vitro* 3D OTM mimics cytokine-driven cell- and matrix-related changes - key features of RA. By combining the components in a 96-well format, we aim to provide a mid-throughput system for preclinical drug screening.

Gut Microbiome Transplantation from MRL/MpJ Mice Prevents Post-Traumatic Osteoarthritis in C57BL6/J Mice

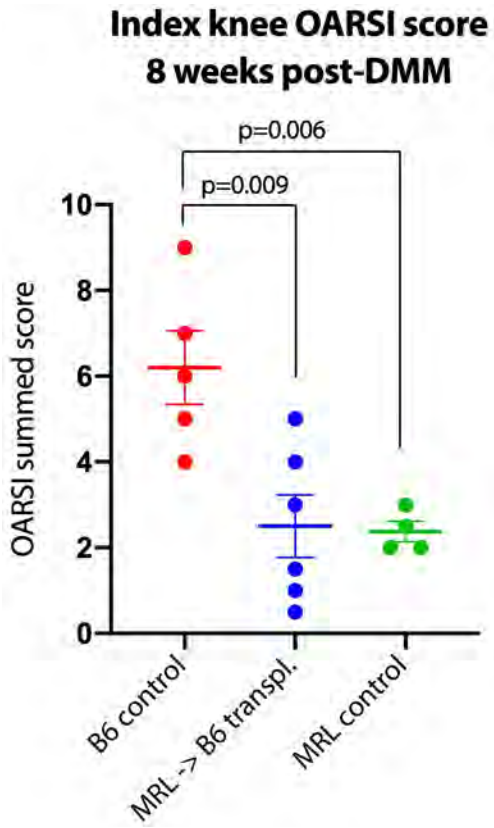
Matlock Jeffries[1], Jake Martin[1], Vladislav Izda[1], Cassandra Garman[1], Cassandra Velasco[1] and Christopher Dunn[2], [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]University of Oklahoma HSC, Edmond, OK

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

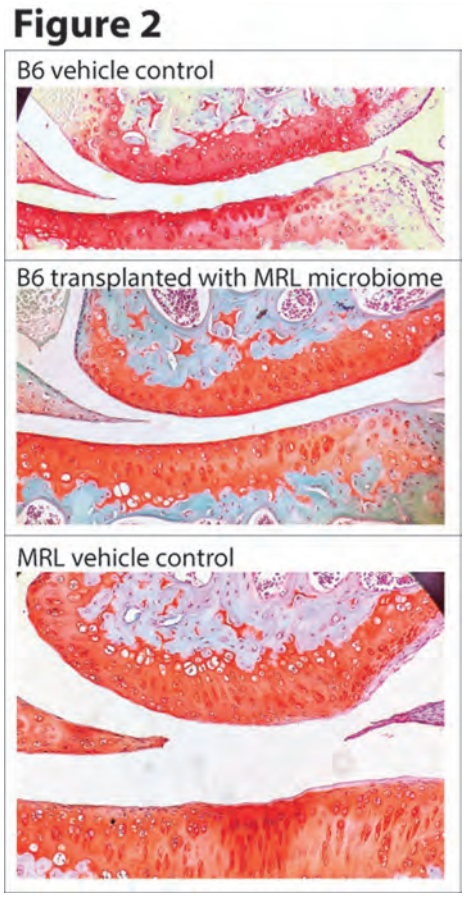
Background/Purpose: MRL/MpJ mice are substantially protected from developing post-traumatic osteoarthritis (OA), a trait with strong correlation to the ability to heal ear wounds. We have previously shown that this ear wound healing trait is partially determined by the gut microbiome, and that gut microbial transplantation into non-healer mice can confer the ear wound healing phenotype. In this study, we sought to examine whether microbiome-mediated cartilage regeneration extended to protection against post-traumatic osteoarthritis.

Methods: Twelve-week-old C57BL6/J mice were inoculated by oral gavage with diluted cecal contents from adult male MRL/MpJ mice (n=6). Separate groups of age-matched male C57BL6/J (n=5) and male MRL/MpJ mice (n=4) were gavaged with vehicle control. Destabilization of the medial meniscus (DMM) surgery was then performed unilaterally to induce OA. Eight weeks after DMM, mice were sacrificed, knee joints fixed in paraformaldehyde, decalcified, embedded in paraffin, stained with Safranin-O and histologically graded using the OARSI histopathology initiative recommendations by a blinded investigator. Differences in mean summed OARSI score per joint per group were determined by a Student t-test, $p \leq 0.05$ was considered significant.

Results: Adult male MRL/MpJ were protected against post-traumatic OA when compared to adult male C57BL/6J mice (mean summed OARSI score 2.4±0.2 vs. 6.2±1, p=0.006, Figure 1). MRL-transplanted adult male C57BL/6J mice were also protected against PTOA development (mean summed OARSI score 2.5±0.7, p=0.009 vs. B6 vehicle,



OARSI scoring of mouse knee following DMM surgery in microbiome transplanted and control animals.



Example histology images of mouse knee following DMM surgery in microbiome transplanted and control animals.

Figure 1) and were indistinguishable from MRL vehicle mice (p=0.90). Representative histologic sections are presented in Figure 2. Gut microbiome profiling and associations of specific gut microbial clades with OA susceptibility are forthcoming.

Conclusion: Gut microbiome transplantation from OA-protected MRL mice to OA-susceptible B6 mice is sufficient to confer protection against post-traumatic OA, consistent with previous data indicating microbiome transplantation-mediated transference of the MRL earhole healing phenotype. Future research should define the pathophysiological changes underlying this phenotype and may offer new insights into potential future therapies for articular cartilage regeneration.

Abstract Number: 1972

NGF-Responsive Neurons Are Sensitized in Experimental Osteoarthritis

Rachel Miller[1], Shingo Ishihara[1], Alia Obeidat[1] and Anne-Marie Malfait[1], [1]Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Nerve growth factor (NGF) is under investigation as a promising target for osteoarthritis (OA) pain. NGF exerts its potent pro-algesic effects through sensitization of nociceptors. Sensitization is a key process in chronic pain states, including OA, characterized by exaggerated responses to innocuous stimuli. However, the precise biological mechanisms underlying the pain-producing effects of NGF in OA are incompletely understood. Here, we tested whether nociceptors become sensitized to NGF in experimental OA.

Methods: DMM surgery was performed in the right knee of 10-week old male $Na_V1.8$ cre-GCaMP6s loxp mice. *In vivo* calcium imaging: $Na_V1.8$-GCaMP6s loxp mice 20 weeks after DMM (n=8) or age-matched naïve control (n=6) were used. These mice express the fluorescent calcium indicator, GCaMP6s, in nociceptors. *In vivo* calcium imaging of the L4-DRG was performed as described (Miller RE et al, Arthr Rheum 2018, PMID: 28992367). A series of compounds were injected IA into the right knee of anesthetized mice while imaging was performed: (1) Saline; (2) CCL2 (100 mg/mL); (3) 2.5S NGF (100 mg/mL); (4) Pam3CSK4 (1 mg/mL); (5) LPS (5 mg/mL); (6) capsaicin (10 mM). For each injection, a 30 G needle was inserted in the joint cavity, imaging was started, the compound was injected from frame 15-20, and imaging continued until frame 100. For each mouse, change in fluorescence over time was calculated using a custom ImageJ macro in order to identify responding sensory neurons. The area under the peak was calculated using GraphPad Prism. Knee hyperalgesia: 3 mL NGF (100 ng/mL, n=4 mice) or 3 mL of vehicle, n=4 mice) was injected IA in the right knee of 10-week old naïve mice. Knee hyperalgesia was assessed prior to injection and 30 mins, 2, 4, and 24 hours after injection using a Pressure Application Measurement device by a person blinded to treatment.

Results: Injection of NGF into the knee joints of anesthetized $Na_V1.8$-GCaMP6s mice elicited intracellular calcium increases in a similar number of neurons in naïve and DMM mice (mean±SEM; naïve: 1.7±1.0%; DMM: 2.6±0.7%; p=0.47), suggesting that the NGF receptor is expressed by a similar number of cells at this time point after DMM. As a comparison, we have previously shown that 15% of L4-DRG neurons innervate the knee joint in healthy mice.

Examining the intracellular calcium responses in each neuron, we found that responses were greater after DMM, as assessed by peak area under the curve (naïve: 0.9±0.2 peak AUC; DMM: 1.7±0.2 peak AUC; p=0.02), suggesting that neurons expressing the NGF receptor have become sensitized to NGF after DMM. Neurons that responded to NGF after DMM also responded more to CCL2 and LPS compared to NGF-responsive neurons in naïve mice (p=0.04 for both NGF-CCL2 and NGF-LPS), further suggesting that NGF-responsive neurons are sensitized in OA.

The neuronal response to NGF was reflected in the behavioral response, where IA administration of NGF, but not vehicle, induced knee hyperalgesia in naïve wild-type mice (NGF: 311±16 g; vehicle: 439±5 g; p=0.01).

Conclusion: These findings suggest that NGF directly binds to neuronal receptors in the IA space, and sensitizes neurons to mediators present in the OA joint.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoporosis & Metabolic Bone Disease

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Prior studies of anabolic/antiresorptive treatment sequences indicate that using teriparatide first followed by an antiresorptive results in greater bone mineral density (BMD) gains, particularly at the total hip, vs using an antiresorptive first followed by teriparatide (Cosman JBMR 2017). Romosozumab (Romo) increases bone formation while decreasing bone resorption, significantly increasing BMD and reducing fracture risk within 1 year. Here we summarize BMD data with Romo prior to or following an antiresorptive (alendronate [Aln] or denosumab [DMAb]).

Methods: We evaluated percentage change from baseline in BMD at the total hip and lumbar spine from four trials where patients received Romo prior to an antiresorptive (Phase 3 ARCH [Saag NEJM, 2017] and Phase 3 FRAME [Cosman, NEJM 2016]) or Romo following antiresorptive therapy (Phase 3 STRUCTURE [Langdahl, Lancet 2017] and Phase 2 [Kendler, OI 2019]). Percentage change from baseline BMD was assessed by either an ANCOVA (FRAME) or repeated measures (ARCH, STRUCTURE) model adjusting for baseline covariates, or as summary statistics (Phase 2).

Results: Total hip BMD (Figure 1): In ARCH, BMD increased 6.2% with 1 year of Romo, and a total of 7.1% with the 2-year Romo/Aln sequence; and in FRAME, patients gained 6.8% with 1 year of Romo and a total of 8.8% with the 2-year Romo/DMAb sequence. Patients in STRUCTURE, who were previously treated for ≥1 year with Aln, gained 2.9% with 1 year of Romo. In a Phase 2 study, following 1 year of DMAb, 1 year of Romo increased BMD by 0.9%, for a total gain of 3.8% with the 2-year DMAb/Romo sequence.

Lumbar Spine BMD (Figure 2): In ARCH, BMD increased 13.7% with 1 year of Romo, and a total of 15.2% with the 2-year Romo/Aln sequence; and in FRAME, patients gained 13.3% with 1 year of Romo and a total of 17.6% with the 2-year Romo/DMAb sequence. Patients in STRUCTURE (previously on Aln for ≥1 year) gained 9.8% with 1 year of Romo. In the Phase 2 study (after 1 year of DMAb), 1 year of Romo increased BMD by 5.3%, for a total gain of 11.5% with the 2-year DMAb/Romo sequence.

Conclusion: These data demonstrate that treatment with Romo first produces substantial BMD gains at the total hip and lumbar spine within 1 year, and that subsequent transition to a potent antiresorptive can augment those gains. In patients treated with Aln or DMAb, transition to Romo can improve BMD, though gains are not as large as those seen when Romo is used first. Since BMD on treatment is a strong surrogate for bone strength, our findings support

Figure 1

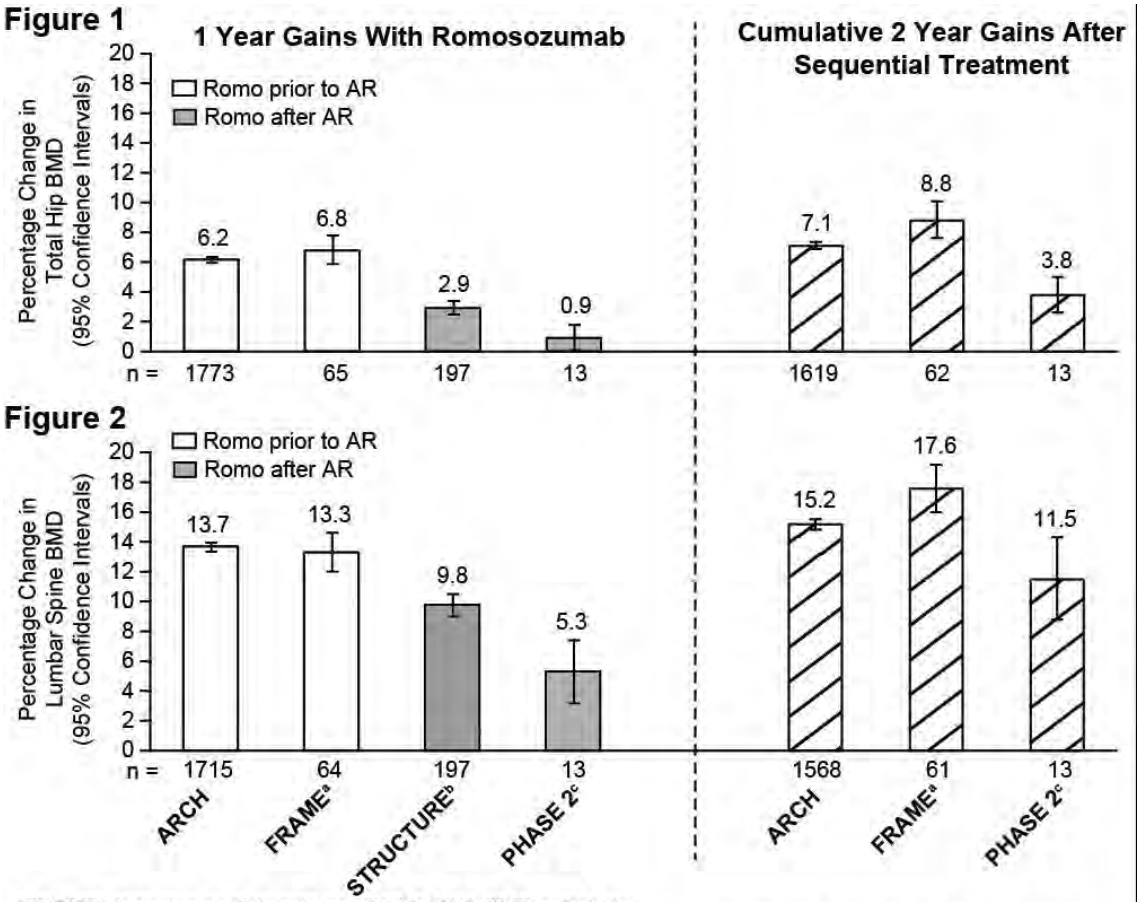

Figure 2

[a]FRAME: Includes participants enrolled in DXA BMD substudy.
[b]Participants had received oral bisphosphonate for ≥3 years before screening and alendronate (70 mg QW) ≥1 year immediately before screening; total study time was 1 year.
[c]A subset of participants in the Phase 2 study received placebo during months 0–24, denosumab during months 24–36 and romosozumab during months 36–48. Cumulative gains are relative to the month 24 baseline.

Validation of a Deep Learning Based Algorithm to Diagnose Vertebral Compression Fractures

John Page[1], **Franklin Moser**[2], Marcel Maya[3], Ravi Prasad[3] and Barry Pressman[2], [1]Amgen, Inc, Thousand Oaks, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Cedars-Sinai Medical Center, Los Angeles

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoporosis & Metabolic Bone Disease
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Vertebral Compression Fractures are common in patients above age 50, but are often undiagnosed. Patients with one VCF are at higher risk of other osteoporotic fractures. Zebra Medical Imaging developed a VCF detection algorithm, utilizing a combination of traditional machine vision segmentation and convolutional neural network (CNN) technology, to detect VCFs from evaluating CT images of the chest, and/or abdomen/pelvis.

Methods: We conducted an independent and blinded validation study to estimate the operating characteristics of the Zebra VCF detection algorithm in identifying VCFs on de-identified data from previously completed CT scans of chest and/or abdomen/pelvis from 1200 women and men aged 50 or older who had those scans (for multiple reasons) at the clinics and hospitals affiliated with the Cedars Sinai Medical Center. Each set of scans were independently read by two of three board certified, practicing neuroradiologists to identify and grade VCF at each evaluable vertebra (using the semiquantitative scale of Genant and colleagues). When there was disagreement between radiologists, the respective scans were reviewed by a senior neuroradiologist who provided a final evaluation. The final determination of presence and severity of VCF by the neuroradiologists was used as the reference standard. The Zebra VCF detection algorithm evaluated the CT scans in a separate workstream from that used by the neuroradiologists (The algorithm and neuroradiologists were blind to each other's evaluations).

		Combined Radiologist Diagnosis						
Zebra Detection Algorithm Diagnosis		Yes	No	Total N	Sensitivity (95%)	Specificity (95%)	Positive Likelihood Ratio (95%)	Negative Likelihood Ratio (95%)
Mild, Moderate or Severe versus No VCF	Yes	149	82	1087	0.66 (0.59, 0.72)	0.90 (0.88, 0.92)	6.88 (5.32, 8.44)	0.38 (0.31, 0.45)
	No	78	778					
Moderate or Severe versus Mild or No VCF*	Yes	107	124	1087	0.78 (0.70, 0.85)	0.87 (0.85, 0.89)	5.98 (4.87, 7.10)	0.25 (0.17, 0.33)
	No	30	826					
Severe versus No, Mild or Moderate VCF*	Yes	47	184	1087	0.84 (0.72, 0.92)	0.82 (0.80, 0.84)	4.70 (3.88, 5.52)	0.20 (0.08, 0.31)
	No	9	847					
³ 2 fractures versus none/one VCF*	Yes	90	141	1087	0.78 (0.70, 0.85)	0.85 (0.83, 0.88)	5.40 (4.42, 6.37)	0.25 (0.17, 0.34)
	No	25	831					

*Results include different cut-points for maximum VCF severity and number of fractures
95% confidence limits for the sensitivity and specificity were calculated using an exact binomial distribution.

Comparison of diagnoses by radiologists and Zebra VCF detection algorithm (Operating Characteristics)

Results: The Zebra VCF algorithm was not able to evaluate CT scans for 113 patients. Of the remaining 1087 CT patients, 588 (54%) were women. Median age was 73 (range 51, 102; interquartile range 66, 81). The four neuroradiologists who evaluated the CT scans each had over 10 years of experience in neuroradiology. For the 1087 Zebra evaluated patients, 227 had at least one VCF (90 with mild VCF, 81 with moderate VCF, and 56 with severe VCF; 115 of the 1087 Zebra evaluated patients (10.6%) presented with two or more VCFs). The sensitivity and specificity of the Zebra VCF algorithm in diagnosing any VCF were 0.66 (95% confidence interval 0.59, 0.72) and 0.90 (95% confidence interval 0.88, 0.92) respectively; and for diagnosing moderate/severe VCF were 0.78 (95% confidence interval 0.70, 0.85) and 0.87 (95% confidence interval 0.85, 0.89) respectively.

Conclusion: The Zebra VCF algorithm works to identify approximately three-quarters of moderate to severe VCF in patients, aged 50 and above, who receive CT scans for other reasons. Implementing the Zebra VCF algorithm within radiology systems may help to identify patients at increased fracture risk and could support the diagnosis of osteoporosis, and thus be a valuable adjunct for population health.

Predicting Bone Mineral Density of Lumbar Vertebrae by Assessing Plain Film with Deep Learning

Chen-I Hsieh[1], Chang-Fu Kuo[1], Shun Miao[2], Kang Zheng[2] and Le Lu[2], [1]Chang Gung Memorial Hospital, Taoyuan, Taiwan (Republic of China), [2]PAII labs, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoporosis & Metabolic Bone Disease
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Osteoporosis is a silent disease characterized by a decrease in bone mineral density (BMD), causing bone fragility and increased risk of fracture. The most widely used screening tool for osteoporosis involves the use of dual-energy x-ray absorptiometry (DXA) to measure BMD. Vertebral plain films may serve as an opportunistic screening for osteoporosis to improve screening rates at no additional cost or radiation to patients. We describe a novel approach to assess vertebral BMD using plain film with deep learning and compare the performance with the DXA measurement.

Methods: In this study, we identified 2171 patients who underwent DXA and lateral plain film of lumbar vertebrae within six months. The dataset was split into a training set with 1796 patients and a testing set with 412 patients. First to fourth lumbar vertebrae images were detected automatically by using the Deep Adaptive Graph (a landmark detection technique based on graph convolutional network) and regions of interest (ROI) in each lumbar vertebra were segmented. The ROIs are processed using a regression neural network with a VGG11 backbone that was applied to each ROI to predict the BMD (Figure 1). During training, five-fold cross-validation is performed with an 8:2 split ratio of training/validation sets. The five models obtained from the cross-validation are all used to predict BMD on the input image of the testing set, and the predictions are averaged to produce the final output. Images with vertebral fractures were excluded from the analysis. Pearson's correlation coefficient was used to assess the correlation between predicted and reference BMD.

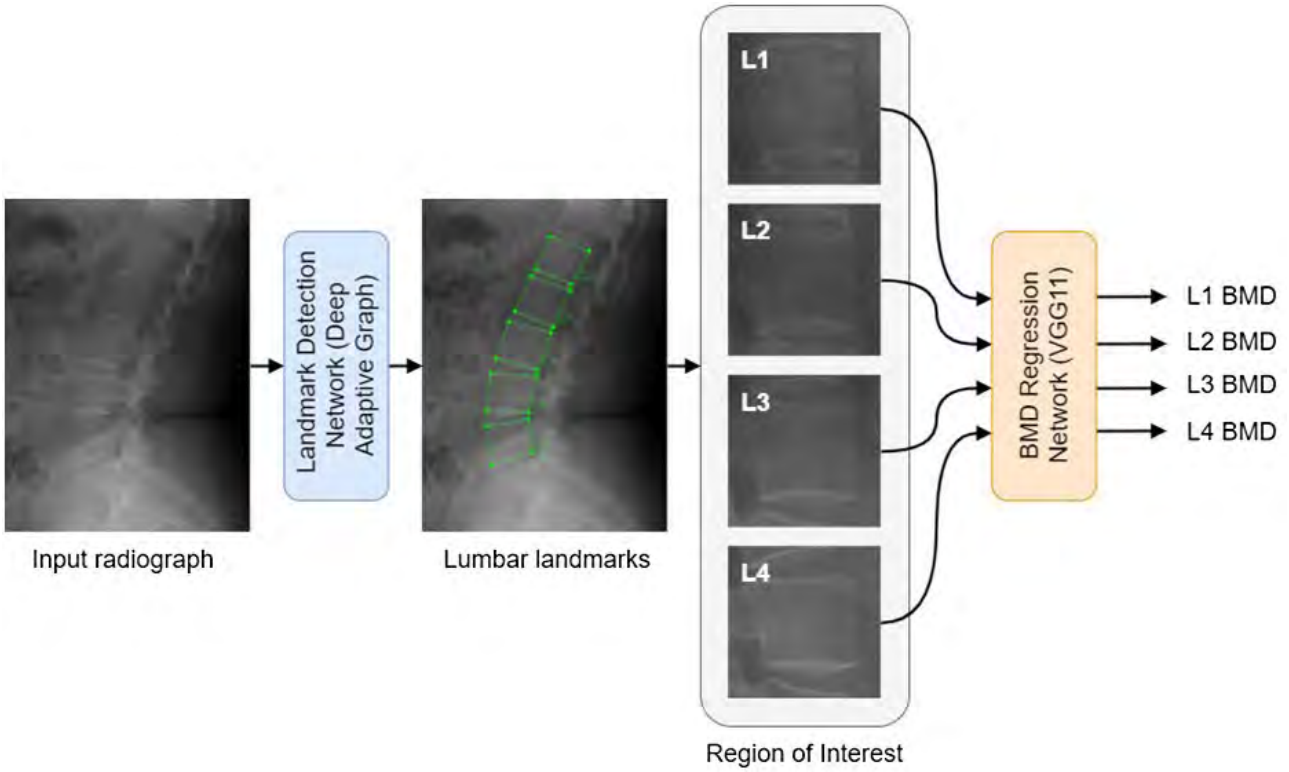

Figure 1. Schematic representation of deep learning models to extract image features for estimation of lumbar vertebral BMD.

Lumbar regions (n=412)	Mean BMD predicted by the model (g/cm^2)	Mean BMD measured by DXA (g/cm^2)	Absolute difference (g/cm^2)	Absolute difference percentage (%)	Pearson's correlation coefficient
L1 (n=347)	0.840±0.127	0.846±0.207	0.118±0.09	14.60%	0.68
L2 (n=371)	0.909±0.147	0.903±0.221	0.125±0.106	14.64%	0.67
L3 (n=367)	0.965±0.145	0.969±0.227	0.126±0.101	13.46%	0.71
L4 (n=358)	1.006±0.129	0.997±0.229	0.133±0.108	14.23%	0.67
Overall	0.930±0.123	0.926±0.206	0.126±0.084	14.23%	0.68

Table 1. Performance of prediction model for BMD using plain film compared with the measured BMD

Results: We included 395 women and 71 men in the testing dataset (female, 84.8%; mean age, 69.5 ± 10.7 years). The mean predicted BMD of first to fourth lumbar vertebrae was 0.930 g/cm^2 compared with that measured by DXA of 0.929 g/cm^2 (Student's t-test, p = 0.65). The mean absolute difference was 0.126±0.084 g/cm^2, with an absolute percentage difference of 14.6%. Pearson's correlation coefficient between predicted and true BMD was 0.68. The performance of the model to predict BMD and Pearson's correlation coefficient between predicted and measured BMD for each lumbar vertebra were shown in Table 1.

Conclusion: This study demonstrated that the deep learning model could predict vertebral BMD with reasonable precision, which might support automatic opportunistic bone density screening.\

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Osteoporosis & Metabolic Bone Disease

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Rheumatoid arthritis (RA) is a risk factor for osteoporosis and fractures yet the disease specific contributions to osteoporotic fractures (OFX) are not well understood. Chronic inflammation stimulates bone loss leading to low bone mineral density and also has negative effects on muscle mass and function, further amplifying the risk of falls and fractures. Our goal was to study whether RA disease activity, and its subcomponents, were independently associated with incident OFX.

Methods: We used the multicenter Veterans Affairs RA (VARA) registry, including participants with at least 1 DAS28-CRP measure in the analysis. Extremity, spine, and hip OFX were identified by ICD9/10 codes from inpatient and outpatient encounters and were confirmed by chart review. Cox proportional hazard models were used to assess the association between time-variant disease activity (averaged over all prior intervals) and incident OFX controlling for baseline sex, race, high ACPA (>60 units), rheumatic disease comorbidity index, osteoporosis status and time-variant age, BMI, smoking, prednisone use, conventional synthetic DMARDs (csDMARDs) and biologic use. Baseline osteoporosis diagnosis was defined by ICD9/10 code or prior fracture. We used DAS28-CRP in our primary analysis but also considered clinical disease activity index (CDAI) and individual RA disease activity components (Tender Joint Count (TJC), Swollen Joint Count (SJC), Patient Global Assessment (PatGA), Provider Global Assessment (PrGA), and CRP) in secondary analyses.

Results: Among 2,531 Veterans followed for 10,661 patient-years (including 25,694 unique observations), 145 incident OFX were identified at a rate of 1.4 per 100 person-years. Veterans were on average 71.2±10.5 years old, 11% were female, 79% were seropositive, and 10% had a diagnosis of osteoporosis at baseline (Table 1). High disease activity by average DAS28-CRP was associated with a significantly greater risk of incident OFX [HR 2.02 (1.22-3.33), p=0.006] (Table 2) compared to those in remission. In secondary analyses, high RA disease activity by CDAI was also associated with an increased risk of OFX [HR 3.56 (1.24-10.17), p=0.018]. All of the individual disease activity components were associated with a greater risk of OFX except TJC (Table 3). Female sex and high ACPA were significantly associated with higher and lower risks for OFX [HR 2.31 (1.44-3.71) and HR 0.69 (0.49-0.96), p< 0.05].

Conclusion: High RA disease activity is associated with twice the risk of OFX compared to those whose disease is in remission. All of the individual disease activity components were associated with a greater risk of OFX except TJC. The degree of control of RA disease activity may represent a modifiable risk factor for OFX. Studies evaluating the

Delivering Fracture Prevention Through Telemedicine: A Process Evaluation

Karla Miller[1], Melissa Steffen[2], Aaron Seaman[2], Zachary Anderson[1], Janiel Green[1], Shardool Patel[1], Shylo Wardyn[2] and Samantha Solimeo[2], [1]Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT, [2]Iowa VA Healthcare System, Iowa City, IA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Osteoporosis & Metabolic Bone Disease
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Guidelines recommend osteoporosis screening using dual-energy X-ray absorptiometry (DXA) in men and women at risk for osteoporosis, but screening remains low, especially in men and in rural populations. System level approaches to aid in identification of at-risk populations have been suggested to close this clinical gap. An informatics-driven population health clinic, the "Bone Health Team" (BHT) was implemented to identify and treat rural Veterans lacking evidence of bone health care. We report the results of our process evaluation conducted to understand BHT feasibility.

Methods: The primary outcome of the process evaluation was the number of at-risk Veterans screened with DXA; a secondary outcome was the number of eligible Veterans who initiated prescription therapy to reduce fracture risk. Outcomes were measured between 5/1/2017-9/30/2018 and analyzed descriptively. Qualitative data to understand successful implementation were collected concurrently by conducting in-person interviews with clinical personnel interacting with BHT, interviews with BHT staff, and observations of BHT processes at three site visits. Data analyses followed the Promoting Action on Research Implementation in Health Services (PARIHS) Framework to characterize context, evidence, and facilitation.

[a] Veterans can be diagnosed with osteoporosis by DXA and osteoporosis by clinical fracture history

BHT Enrollment Table

Results: Of the 4500 rural Veterans identified for osteoporosis screening, 292 (6%) were women, and 1081 (24%) completed screening (Table). Among these Veterans, 399 (37%) were found to have normal bone density, 527 (48%) osteopenia, and 156 (14%) osteoporosis with 338 (31%) eligible for prescription therapy to reduce fracture risk (Table). Of the Veterans eligible for prescription therapy, 306 (90%) initiated pharmacotherapy. Qualitative analysis identified contextual factors of rural geography and population characteristics including rugged terrain, harsh seasons, long distances between services, and limited access to cellular, internet, and mail services as barriers to the potential for travel, communication, and care delivery. The primary evidence factor acting as an implementation barrier was implementation complexity due to the requirement of significant infrastructural resources to sustain BHT processes. Factors of facilitation and evidence such as data infrastructure, evidence base for care delivery, stakeholder buy-in, formal and informal facilitator engagement, and focus on teamwork facilitated BHT implementation and expansion success.

Conclusion: The population telehealth model employed by the BHT is a feasible approach to delivering preventative osteoporosis care to rural Veterans and identified 31% of at-risk rural Veterans as eligible for prescription therapy to reduce fracture risk with 90% of those eligible choosing to initiate prescription therapy. The identified barriers and facilitators to implementing this model in the VHA will inform future model refinement and efforts to improve bone health care delivery systems for the Veteran population. Further evaluation to understand why more Veterans do not engage when offered osteoporosis screening, as well as the clinical and sociodemographic factors that predict Veteran acceptance of osteoporosis care, is ongoing.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes II: Engagement, Perceptions, & Quality of Life

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: Some rheumatoid arthritis (RA) patients rate their disease activity worse than their physician does, but recent prevalence and factors associated with such discordance have not been reviewed in a large real-world database. This study describes discordance at biological initiation (index visit) and over time. We hypothesized that higher levels of pain, morning stiffness, fatigue, Health Assessment Questionnaire (HAQ) score, Clinical Disease Activity Index (CDAI), and depression are associated with discordance at the index visit.

Methods: We included patients enrolled in the Corrona RA Registry who initiated their first biological or Janus kinase inhibitor on or after 2/1/2015 with both 6- and 12-month (± 3 mo) follow-up visits. Patient global assessment (PtGA) - physician's global assessment (PhGA) (disease severity) ≥ 30 points on a 0-100 VAS scale was defined as positive discordance; > -30 to < 30 as concordance; and ≤ -30 as negative discordance. Patients with negative discordance were excluded based on prior studies. Positive discordance at all three (index, 6-, 12-mo) visits was classified as persistent discordance. Differences between discordant and concordant patients at index visit were quantified using effect sizes (standardized differences) based on Cohen's descriptions for continuous variables (|*d*|): ~0.2 small effect size, ~0.5 medium, ~0.8 large; for categorical variables (w): ~0.1 small, ~0.3 medium, ~0.5 large. Mixed-effects logistic regression was used to test our *a priori* hypothesis.

Results: Among 54,307 patients in the registry, 758 patients met the inclusion criteria for analysis at the index visit, and of these, 752 were included in the analysis of persistent discordance. A total of 80 patients with negative discordance at any visit were excluded. Discordance prevalence was similar at the index (27%), 6- (30%), and 12-mo (30%) visits; 10% (n=65) had persistent discordance.

At the index visit (Table 1), large differences for discordant vs concordant patients included RAPID3 score (mean 16 vs 7.3, |*d*| = 1.5), pain (mean 63 vs 32, |*d*| = 1.2), fatigue (mean 61 vs 35, |*d*| = 0.9), morning stiffness severity (61 vs 40, w = 0.9), and HAQ (0.7 vs 0.3, w = 0.9), and a medium effect size for DAS28-ESR (mean 4.3 vs 3.6, |*d*| = 0.5). Results were similar for patients with persistent discordance (Table 2).

In a logistic regression model regressed on age, CDAI, opioid (including tramadol) use, pain, morning stiffness, fatigue, HAQ, depression, academic site; discordance (vs concordance) was positively associated with pain (OR=1.04, p=0.001) and HAQ (OR=1.72, p=0.053), and inversely associated with CDAI (OR=0.94, p=0.001). Morning stiffness, fatigue, and depression were not associated with discordance (Table 3).

Conclusion: About 30% of RA patients who initiated DMARDs had patient-physician discordance at any visit, and one-third of these (10% total) persisted at all three visits. Greater patient-reported pain and functional impairment

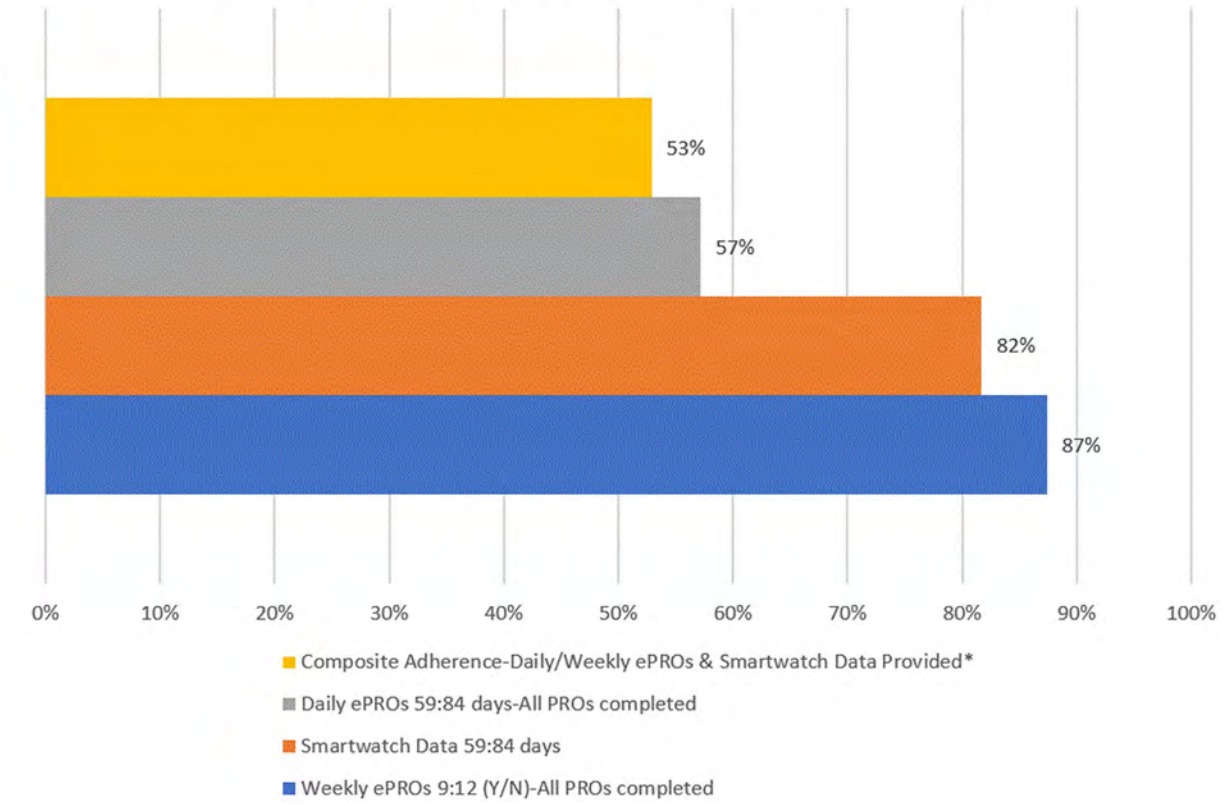
*Statistical significance between groups of pts who qualified and did not qualify for Main Study, $p < 0.05$; t tests were performed for continuous variables and chi square tests for categorical variables; p values are nominal in nature and should be interpreted in an exploratory manner † DMARDs = disease modifying antirheumatic drugs csDMARDs = conventional synthetic DMARDs (e.g. methotrexate, sulfasalazine) bDMARDs = biologics or biologic DMARDs (e.g. TNFi, IL-6, IL-7) tsDMARDs = targeted synthetic DMARDs (e.g. JAKi) None of the above = on NSAIDs or corticosteroids, but no DMARD or cs/b/tsDMARD

Background/Purpose: Characterization of how different types of patient-generated data reflect patients' experience is needed to guide integration of electronically collected patient-reported outcome (ePRO) measures and passive biometrics into real-word evidence (RWE) platforms. Our objective was to characterize engagement, protocol adherence, and data completeness in an ongoing study in rheumatoid arthritis (RA) participants (pts) enrolled in the Digital Tracking of Arthritis Longitudinally (DIGITAL) study, an ancillary study of the ArthritisPower® registry.

Figure. Participant Adherence During Main Study Period by Data Collection Platform (N=278)



Methods: Pts were invited to join the app-based study which included a 2-week (14-day) Lead-In and 12-week (84-day) Main Study Period. Study-specific customization of the ArthritisPower mobile application collected ePROs. For at least 10 days of the Lead-In period, pts were required to electronically complete: a) two daily single-item Pain and Fatigue numeric rating scales and b) longer weekly sets of ePROs. Successful completers of the Lead-In were mailed a smartwatch (Fitbit® Versa™) and study materials. Main Study Period included automated and manual prompts to complete ePROs, wear the smartwatch and regularly sync it. Study coordinators monitored pt data and contacted pts via email, text and/or phone to resolve adherence issues per a priori rules triggering pt contact due to consecutive spans of missing data. Adherence to data collection during the Main Study was defined as providing requested data > 70% of 84 days (daily ePRO, smartwatch data), or ≥ 9 of 12 weeks.

Results: As of 4/2020, and referent to the 470 pts expressing initial interest, 278 (59.1%) completed the Lead-In and qualified for the Main Study. Of the 278 pts enrolled, 91.7% female, mean (SD) age 50.2 (11.1), 9.4 (10.1) years since RA diagnosis (Table 1). Those qualifying for the Main Study were more likely to be currently employed (55.4% vs. 39.6%, p< 0.01) and on biologic monotherapy (63.3% vs. 49.5%, p< 0.01). Over the 84-day Main Study period, the proportion of pts meeting the definition of adherence to protocol-specified data collection was lowest (57%) for daily ePRO data capture, highest for weekly ePRO data (87%), and intermediate (82%) for smartwatch data. A total of 147 (53%) of pts met composite adherence (Figure), while 27/278 met neither smartwatch/PRO adherence, 80/278 met smartwatch adherence but not PRO adherence, and 24/278 did not meet smartwatch adherence but met PRO adherence. Pts experiencing high levels of pain and low levels of physical function at Lead-In were more likely to complete ePROs but not adhere to smartwatch use when they advanced to the Main Study period (Table 2).

Conclusion: Compared to other digital health RA studies, a short lead-in period appears useful to identify pts likely to engage in a longitudinal digital health study collecting data on a mobile app and was associated with subsequent pt adherence, and this adherence may vary by data collection platform. RWE studies involving passive data collection

Table 2. Demographic and Clinical Characteristics of Main Study Participants at Baseline and During Lead-In Period, by Whether Composite Adherence Was Met During Main Study Period (N=278)

	Met Composite Adherence (n=147)	Did Not Meet Composite Adherence (n=131)

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes II: Engagement, Perceptions, & Quality of Life

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: SLE disproportionately strikes Latinos, who are also at high risk for poor outcomes. Self-efficacy (SE) to manage chronic disease correlates with outcomes through self-management behavior. Illness perceptions (IP) are modifiable mental representations that vary among populations and may impact SE. This study aimed to explore IP and SE in this population and determine if one IP domain, emotional distress, increases the odds of low SE to manage symptoms.

Methods: We collected self-reported measures through an anonymous survey posted on the *Hablemos de Lupus* (Let's Talk about Lupus) education Facebook page (followed by 74,000 Spanish-speakers). Participants were eligible if they were 18 or older, located in the American continent and self-reported a SLE diagnosis by a physician. The Brief Illness Perception Questionnaire (BIPQ) Likert scale was used to assess IP and the Patient Reported Outcomes Measurement Information System (PROMIS) to assess SE (to manage symptoms, treatment, emotions and social interactions). A higher BIPQ score (range 0-10) indicates more of the IP domain being measured, and a lower SE T-score indicates worse SE. We reported the mean score and SD of each BIPQ question; emotional distress IP was

Figure 1. Illness Perception Mean Scores* by Domain among 1401 Latino SLE Patients

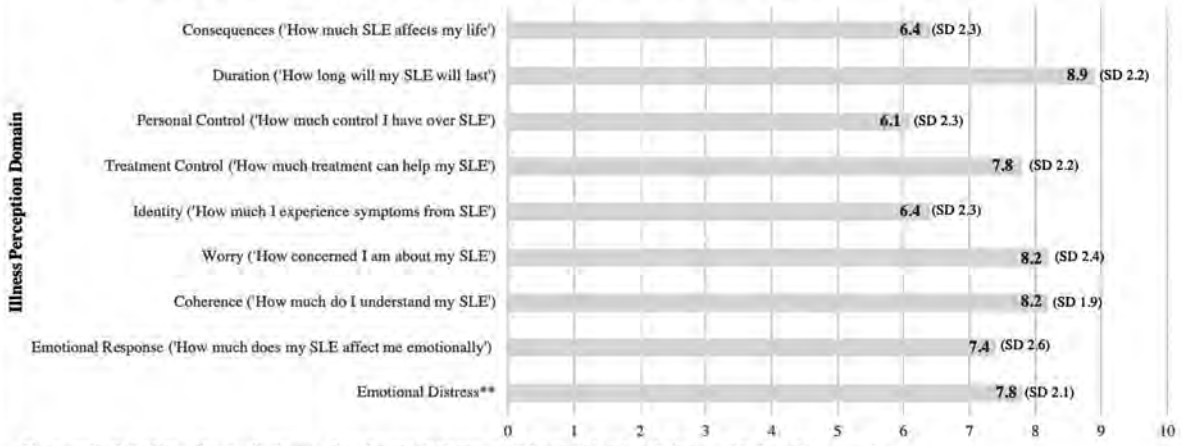

Figure 2. Self-efficacy Mean T-Scores* by Domain among 1401 Latinos with SLE

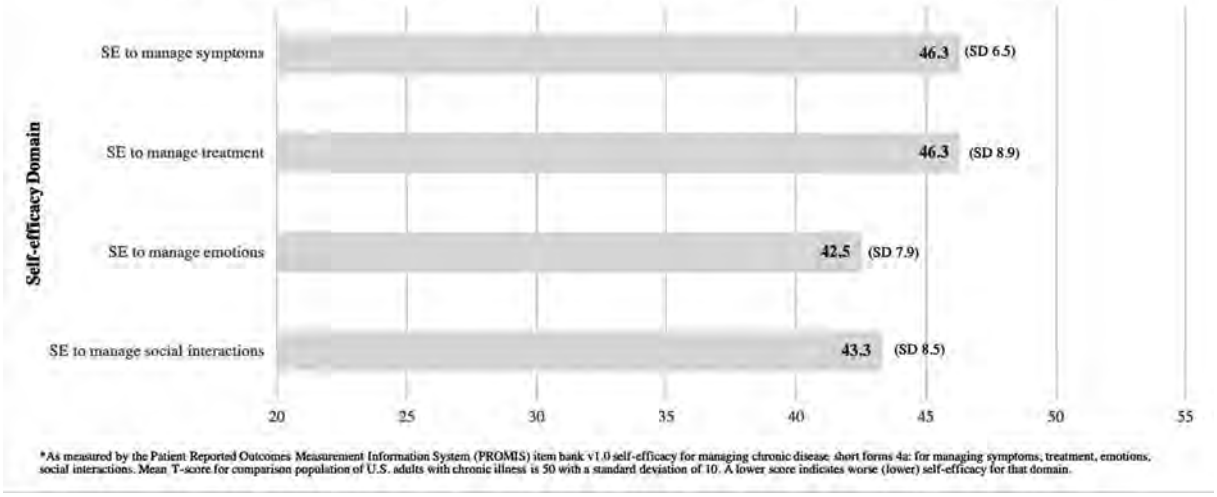

*As measured by the Patient Reported Outcomes Measurement Information System (PROMIS) item bank v1.0 self-efficacy for managing chronic disease short forms 4a: for managing symptoms, treatment, emotions, social interactions. Mean T-score for comparison population of U.S. adults with chronic illness is 50 with a standard deviation of 10. A lower score indicates worse (lower) self-efficacy for that domain.

Table. Association of Emotional Distress Illness Perception and Low Self-Efficacy* to Manage Symptoms among Latinos with SLE. Multivariate Logistic Regression

Variable	Odds Ratio	95% CI	P-value
Emotional distress (1-unit increase)**	**1.44**	**1.29 – 1.61**	**<.0001**
Female sex	1.21	0.58-2.51	0.61
Age (ref 36-55)			
18-35	1.22	0.88-1.69	0.24
56 and older	1.34	0.65-2.73	0.43
No college degree (ref college or higher)	1.26	0.93-1.73	0.14
Insurance (ref private)			
Uninsured or disabled	1.25	0.81-1.93	0.32
Public insurance	1.38	0.95-2.00	0.09
Monthly financial strain	1.58	1.01-2.47	0.04
Time since diagnosis (ref >5 years)			
≤1 year	2.03	1.26-3.27	0.004
1-5 years	1.31	0.93-1.85	0.12
Lack of social support∝	2.75	1.95-3.87	<.0001
Severe SLE^	0.92	0.67-1.27	0.61
Low *HdL* user (watched <5 *HdL* educational videos)	0.66	0.48-0.90	0.01

*Low self-efficacy was measured with PROMIS self-efficacy to manage symptoms; a T-score <= 40 indicates low SE. **Emotional distress score was measured with the Brief Illness Perception Questionnaire (BIPQ); BIPQ score ranges 0 to 10; a higher score indicates higher emotional distress. ∝Lack of social support defined as a 'no' response when a participant was asked if felt emotionally supported by family or friends. ^Severe SLE: endorsed central nervous system, renal, pulmonary, or vascular SLE manifestations. Abbreviations: CI= confidence interval, HdL=*Hablemos de Lupus* Facebook page.

calculated using the average score of 'worry' and 'emotional response' questions. SE domains were reported as mean T-scores and SD, with the U.S. population with chronic illnesses as reference. Logistic regression was used to examine the association of emotional distress IP and low SE to manage symptoms (defined as a T-score ≤40) after controlling for confounders.

Results: There were 1401 eligible participants who started the survey and 100% completed. Participants were from 19 countries; ages 18-80; 95% females; 33% diagnosed in past 3 years; 46% reported renal, neurologic, vascular or pulmonary SLE manifestations, and 79% were under the care of a rheumatologist. Figures 1 and 2 depict mean IP and SE scores, with perceived emotional distress of 7.8 (SD 2.1). SE mean T-scores were lower than the reference population (T-score=50), ranging between 42.5 for managing emotions to 46.3 for treatment and symptom manage-

ment (Figure 2). Per 1-unit increase of emotional distress the OR of low SE to manage symptoms was 1.44 [95% CI 1.29-1.61], after controlling for covariates (Table). Lack of social support and recent diagnosis were independently associated with low SE to manage symptoms in the multivariate model (Table).

Conclusion: Our findings underscore high illness-related emotional distress in Latinos with SLE, despite reporting relatively high understanding of SLE and its treatment. Moreover, SE levels in Latinos with SLE were below the average U.S. population across multiple domains. We found that those who perceive SLE as more emotionally distressing had lower SE to manage symptoms, suggesting that emotional illness perception may be a promising target for Latino SLE interventions. Our data also suggest that patients recently diagnosed or lacking social support may benefit from SE interventions. Education to modify perceived SLE emotional distress may improve SE to manage symptoms among Latino patients, potentially contributing to better patient-centered and clinical outcomes in this population.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes II: Engagement, Perceptions, & Quality of Life

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: Adherence to both medications and physical activity is insufficient in patients with inflammatory arthritis (IA), such as spondyloarthritis (axSpA), rheumatoid arthritis (RA) or psoriatic arthritis (PsA). Are there patterns towards adherence to both of these aspects of management?

Objectives: to assess and compare adherence to medication and levels of physical activity collected through Apps, in patients with IA.

Methods: This was an international, multicentric, cross-sectional study performed between October 2019 and June 2020 (ClinicalTrial NCT04426747). Consecutive patients were included if they had definite axSpA, RA or PsA, were aged above 18 and able to walk, with smartphones compatible with Apps measuring steps. Adherence to medication

was assessed using the Medication Adherence Report Scale MARS-9 (ranging from 9 to 45 with higher scores indicating higher adherence). Physical activity was measured by steps per day over the past week, through the patient's smartphone apps. The link between the MARS-9 score and physical activity was assessed by linear and logistic regression. For the logistic regression, patients were considered less adherent for the lowest tertile of the MARS score. They were compared to more adherent patients by univariable and multivariable logistic regression. There was no imputation of missing data.

Results: Of 130 patients included, 101 had analyzable data (46 (46%) axSpA, 26 (26%) RA, 27 (27%) PsA). Mean age was 45.2 years (standard deviation 13.1), mean disease duration 10.0 (8.5) years and 47% were women. 67% were receiving a biologic, and disease activity was moderate. Adherence to medication was high: the mean MARS score was 38.9 (7.0) with a median of 41. Physical activity was moderate: the mean steps per day collected with apps was 5631 (4286), median 4244 with 29% walking over 7000 steps per day. The linear regression between adherence to medications and steps per day did not indicate a link (R=-0.04, p=0.72). Furthermore, patients with a lower adherence to medication (lowest tertile scores, ie, < =38) did not differ in terms of physical activity 5703 (4014) versus 5602 (4419) steps per day, p=0.80 in multivariable analysis.

Conclusion: In this population of long-standing IA, adherence to medication was high whereas physical activity was insufficient. Patients with IA who were more adherent to treatment were not more physically active than those less adherent. Adherence to medication and adherence to lifestyle changes may be linked to different coping mechanisms.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes II: Engagement, Perceptions, & Quality of Life
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: Cutaneous Lupus Erythematosus (CLE) is an autoimmune skin disease that may occur with or without systemic lupus erythematosus (SLE). Active CLE lesions present with erythema and scale on photoexposed areas that can lead to dyspigmentation and scarring. This study aims to compare the QoL of patients with CLE on the face versus patients without facial lesions, and to determine the impact of facial lesion activity (erythema, scale) and damage (pigmentation, scarring) on patient QoL.

Methods: This is a cross-sectional study of a prospectively collected database of CLE patients seen at the Autoimmune Skin Diseases Unit of the University of Pennsylvania from 2007 to 2019. Patients were included if a Cutaneous

Table 1. Characteristics of CLE patients

Lupus Erythematosus Disease Area and Severity Index (CLASI) assessment and Skindex-29+3 questionnaire were completed on the initial visit. The CLASI is a validated instrument that quantifies CLE disease activity and damage in several exposed and covered areas of the body. Skindex-29+3 is a skin-specific QoL questionnaire that includes several domains such as symptoms, emotions, functioning and three additional lupus-specific questions on alopecia, photosensitivity and limitation of outdoor activities. A higher Skindex-29+3 domain score translates to poorer patient QoL. Based on clinical findings, patients were categorized into one of four groups, defined as those with: 1) active facial disease, 2) facial damage, 3) both facial activity and damage, or 4) no facial lesions. A one-way analysis of variance (ANOVA) and Bonferroni correction were used to compare QoL across the four groups. In addition, a multi-variable regression analysis was used to determine the relationship of facial disease and other pre-determined clinical variables to the QoL of CLE patients.

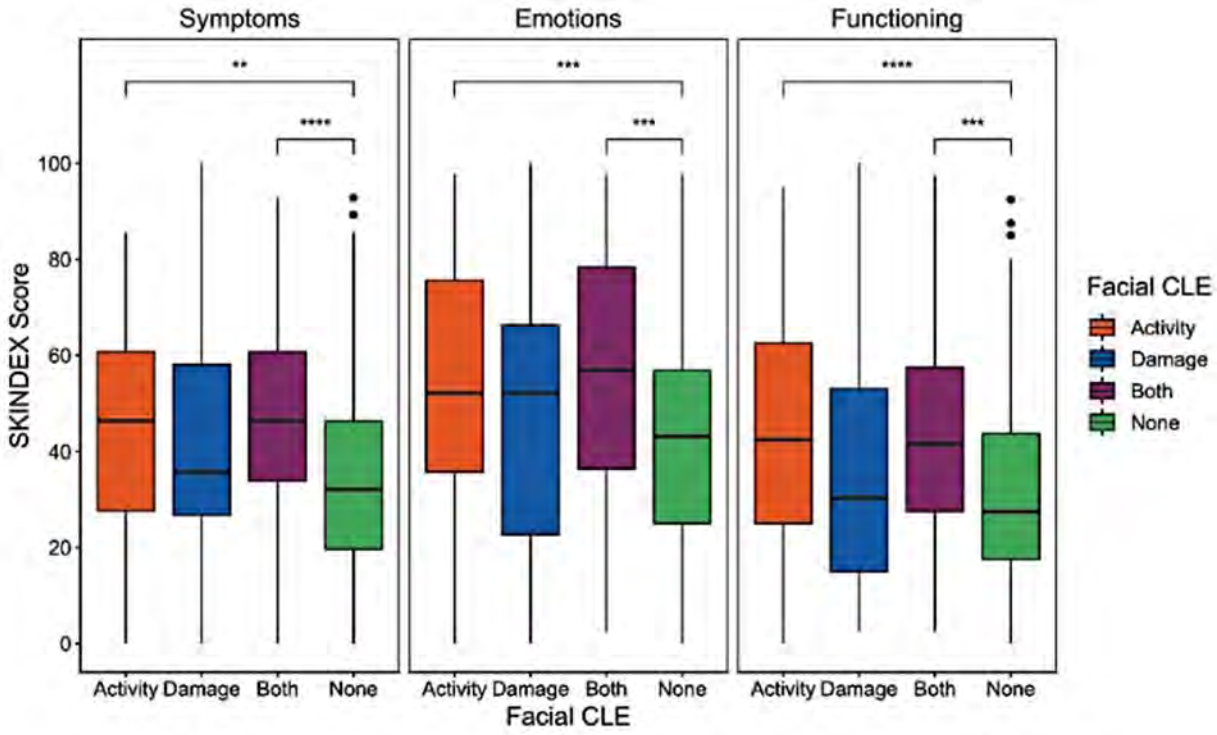
*"Asian" (n=14) was arbitrarily chosen to be dependent on "African-American", "Caucasian" and "Other" in this model
"No FCLE" (n=111) was the constant variable in the regression analysis.
Bold figures represent statistically significant values.

Table 2. SKINDEX-29+3 scores in patients with facial cutaneous lupus erythematosus – multivariable regression



Mean Skindex symptoms, emotions, and functioning scores of patients with facial disease who had both activity and damage, or activity alone, were higher and significantly different from those who had no facial lesions. Scores of patients who only have lesions of damage on the face did not significantly differ from those who have no facial lesions. (** = $p \leq 0.01$, *** = $p \leq 0.001$, **** = $p \leq 0.0001$)

Results: A total of 366 CLE patients were included in the study. Among them, 255 (68%) had facial CLE. Specifically, 99 (27%) patients had both activity and damage, 124 (33%) had activity only, and 32 (8%) had damage only (Table 1). The mean Skindex-29 Symptoms (S), Emotions (E) and Functioning (F) scores of facial CLE patients who had both activity and damage (S=47.34, E=55.06, F=43.45) or activity alone (S=43.55, E=53.72, F=43.91) were significantly higher compared to those who had no facial lesions (S=35.05, E=42.50, F=31.78) ($p < 0.05$) (Figure 1). Further, having both activity and damage on the face and having active facial CLE alone were significantly associated with poorer QoL across all three Skindex-29+3 indices, even after controlling for female gender and current smoking status, which are known to be associated with poor QoL scores in CLE patients (Table 2).

Conclusion: Patients with facial CLE have worse QoL compared with patients having no facial lesions. Facial CLE activity has a more significant effect on QoL than facial damage. A possible explanation for this finding is that patients with facial activity are concerned about potential systemic flares, while the damage is typically persistent but less worrisome to the patient. Clinicians should be aware that patients with facial activity are more affected in terms of quality of life and their fears of systemic disease should be addressed.

Trajectories of Disease Activity in Patients with Newly Diagnosed Juvenile Idiopathic Arthritis in the Childhood Arthritis and Rheumatology Research Alliance Registry

Natalie Shiff[1], Peter Shrader[2], Colleen Correll[3], Anne Dennos[4], Thomas Phillips[2] and Timothy Beukelman[5], [1]Florida, Gainesville, FL, [2]Duke University, Durham, [3]University of Minnesota, Minneapolis, MN, [4]Duke University, Durham, NC, [5]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical II: Outcomes & Care Delivery
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: To describe data-derived 2-year trajectories of disease activity in patients with recently diagnosed juvenile idiopathic arthritis (JIA) as measured by the clinical Juvenile Arthritis Disease Activity Score measured in 10 joints (cJADAS10), and to identify key baseline characteristics associated with disease trajectories.

Methods: The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry includes a large cohort of children with JIA with clinical and medication data. JIA patients eligible for this study were enrolled between April 15, 2016 and December 6, 2019, within 3 months of JIA diagnosis, had at least 2 follow-up (FU) visits with cJADAS10 scores, and had 24 months of FU. Latent trajectory analysis of cJADAS10 using maximum likelihood estimation technique was performed. Model of best fit was selected by a combination of Bayesian information criterion (BIC), posterior probabilities, and clinical judgement. Select pairwise comparisons of baseline characteristics by trajectory were performed.

Table 1: Pairwise comparisons of baseline* characteristics between cJADAS10[β] trajectories with High, Rapidly Decreasing as the reference category.

Characteristic	High, Slowly Decreasing (N=154) OR (95% CI)	P	High, Increasing (N=39) OR (95% CI)	P
Age at diagnosis, per year	1.09 (1.04-1.14)	0.0003	1.08 (1.00-1.16)	0.05
Sacroilitis by clinical exam	2.13 (0.99-4.58)	0.05	1.20 (0.32-4.48)	0.79
ANA[€], yes vs. no	1.12 (0.72-1.75)	0.61	0.40 (0.18-0.89)	0.02
Abnormal ESR[¶]	0.54 (0.31-0.94)	0.03	0.53 (0.22-1.26)	0.15
Abnormal CRP[Φ]	0.36 (0.20-0.65)	0.0008	0.51 (0.19-1.33)	0.17
Taking any non-biologic DMARD[§] at baseline	0.92 (0.60-1.41)	0.69	0.48 (0.24-0.96)	0.04
Taking any biologic DMARD at baseline	0.65 (0.39-1.08)	0.10	0.69 (0.30-1.60)	0.39
Time from diagnosis until first biologic, per month	1.07 (1.02-1.12)	0.003	1.06 (1.01-1.12)	0.03
Physician global assessment	0.87 (0.78-0.97)	0.009	0.88 (0.74-1.05)	0.16

*baseline=within 3 months of diagnosis; [β]cJADAS10=clinical Juvenile Arthritis Disease Activity Score,10 joints; [€]ANA=antinuclear antigen [¶]ESR=erythrocyte sedimentation rate; [Φ]CRP=c-reactive protein; [§]DMARD=disease modifying anti-rheumatic drug. Only characteristics with p values ≤0.10 in one of the trajectories are shown.

Table 2: Pairwise comparisons of baseline* characteristics between cJADAS10[β] trajectories with Moderate, Decreasing as the reference category.

Characteristic	Moderate, Persistent OR (95% CI)	P
Age at diagnosis (per year)	1.08 (1.03-1.13)	0.0009
Time from onset to diagnosis (per month)	1.05 (1.01-1.10)	0.008
Number of joints with limited range of movement	1.33 (1.09-1.61)	0.004
Time from diagnosis until first biologic, per month	1.04 (1.00-1.08)	0.06
Physician global assessment	1.18 (1.03-1.35)	0.02
Taking any non-biologic DMARD at baseline	1.60 (1.02-2.49)	0.04
cJADAS10	1.18 (1.10-1.26)	<.0001
CHAQ	2.58 (1.51-4.40)	0.0005
Pain intensity in the past 7 days	1.31 (1.16-1.47)	<.0001
Pediatric global health survey T-score	0.90 (0.85-0.95)	<.0001

*baseline=within 3 months of diagnosis; [β]cJADAS10=clinical Juvenile Arthritis Disease Activity Score,10 joints; [Ψ]CHAQ=Childhood Health Assessment Questionnaire, Only characteristics with p values ≤0.10 in one of the trajectories are shown.

Results: There were 8,736 JIA patients in the Registry; 746 met study selection criteria. Clinician assigned JIA categories were: 32.6% rheumatoid factor (RF) negative polyarticular, 26.0% oligoarticular, 13% enthesitis related arthritis, 10.6% RF positive polyarticular, 8.7% systemic, 7.0% psoriatic, and 2.1% undifferentiated. Figure 1 shows the model of best fit, which identified 5 disease trajectories: High, Rapidly Decreasing (HRD) (n=199, 26.7%); High, Slowly Decreasing (HSD) (n=154, 20.6%); High, Increasing (HI) (n=39, 5.2%); Moderate, Persistent (MP) (n=218, 29.2%); and Moderate, Decreasing (MD) (n=136, 18.2%). When compared to the HRD trajectory, patients with a HSD trajectory were more likely to be older, have normal erythrocyte sedimentation rate and c-reactive protein, longer time from diagnosis to first biologic, and a lower baseline physician global assessment (PGA). Those with a HI trajectory were more likely to be ANA negative, have a longer time from diagnosis to first biologic, and less likely to be taking a non-biologic disease modifying anti-rheumatic drug (DMARD) at baseline (Table 1). Patients starting with moderate cJADAS10 scores with MP trajectory were more likely to be older, have a longer time from onset to diagnosis, more joints with restricted range, taking a non-biologic DMARD at baseline, have higher PGA, cJADAS10, CHAQ, and pain intensity, and lower pediatric global health survey scores at baseline (Table 2).

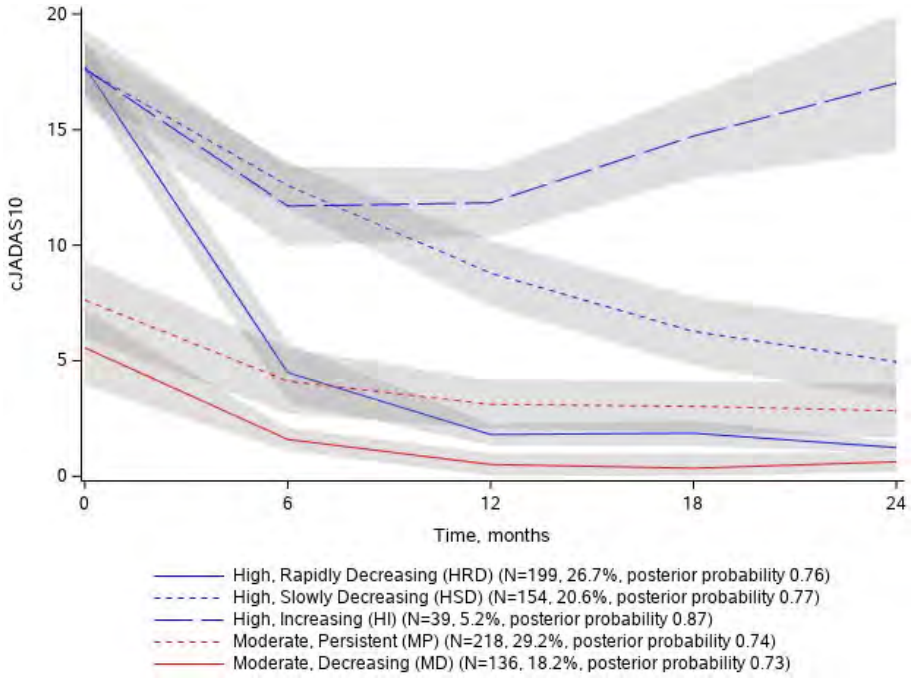

Figure 1. Trajectories of cJADAS10 with 95% CIs in patients with juvenile idiopathic arthritis (n=746)

Conclusion: This study identified 5 distinct data derived trajectories of JIA disease activity. Baseline variables associated with concerning trajectories are described, and could assist with targeting patients for more aggressive intervention shortly after diagnosis.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical II: Outcomes & Care Delivery

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: The relative roles of disease activity and disability as determinants of health-related quality of life (HRQoL) in children with JIA have been controversial; sometimes their statistical significance disappears when pain is added to multivariate models. We explored whether structural equation modelling (SEM) may help clarify the causal pathways leading to decreased HRQoL in children with JIA. SEM estimates direct and indirect effects of candidate determinants along a causal pathway and uses multiple indicators to study determinants that are imperfectly quantified, such as disease activity and treatment intensity.

Methods: We used data from the Research in Arthritis in Canadian Children emphasizing Outcomes (ReACCh-Out) cohort. Based on published literature and clinical plausibility we proposed *a priori* models with explicit root causes (disease activity, treatment intensity) and mediators (pain, disease symptoms, function) leading to HRQoL measured with the Quality of my Life scale (QoML, 0=worst, 10=best) and the Juvenile Arthritis Quality of Life Questionnaire (JAQQ, 1=best, 7=worst), at five stages of disease: 1) diagnosis (within 28 days), 2) 3-9 months after diagnosis, 3) flare, 4) remission on medications, and 5) remission off medications. SEM was applied to the data and *a posteriori* models were selected based on fit statistics, parameter estimates, and plausibility. Here we focus on the models for QoML at diagnosis.

Results: We included 563 children with assessments of HRQoL within 28 days of diagnosis (Table 1). The *a priori* model is shown in Figure 1, where the direction and magnitude of hypothesized effects are depicted by the number of + or – signs. Figure 2 shows the *a posteriori* model with the best fit, where path coefficients estimated by SEM (numbers in Figure 2) quantify the observed direction and magnitude of effect. Comparison of the two figures shows that most hypothesized effects were supported, with a few modifications: 1) Drug categories and Discomforts and concerns were eliminated due to overlap or for lack of measures; 2) The paths from disease activity first to pain, functional deficit (CHAQ DI) and disease symptoms are supported; 3) Participation restrictions is a subsequent common intermediary, as proposed; 4) A direct path from treatment to QoML is the only one supported, whereas the path through side effects is not significant; 5) Pain, participation restrictions and effects of treatment not mediated by side effects are then the immediate determinants of QoML. In results not shown, models for 3-9 months after diagnosis

Characteristic	Median (IQR) or n (%)
Age at diagnosis, years	9.7 (4, 13) *
Female sex	361 (65)
Months from diagnosis to enrolment	0 (0, 0.1)
JIA category:	
Oligoarthritis	232 (41)
Polyarthritis RF negative	110 (20)
Enthesitis-related arthritis	84 (15)
Psoriatic	35 (6)
Systemic	25 (4)
Polyarthritis RF positive	19 (3)
Undifferentiated	58 (10)
Active joint count	2 (1,7)
Physician Global Assessment of Disease Activity	3.2 (1.9, 5.4)
Erythrocyte Sedimentation Rate, mm/h	18 (7, 38)
C-Reactive Protein, mg/L	2.8 (0.4, 13)
Pain intensity in a 10cm visual analogue scale	3.4 (0.9, 6.1)
Childhood Health Assessment Questionnaire score	0.5 (0.1, 1.1)
QoML scale	7.5 (5, 9.1)
JAQQ score	3 (2, 4.1)

Table 1. Baseline characteristics of 563 children with HRQoL assessments within 28 days of diagnosis in the ReACCh-Out cohort

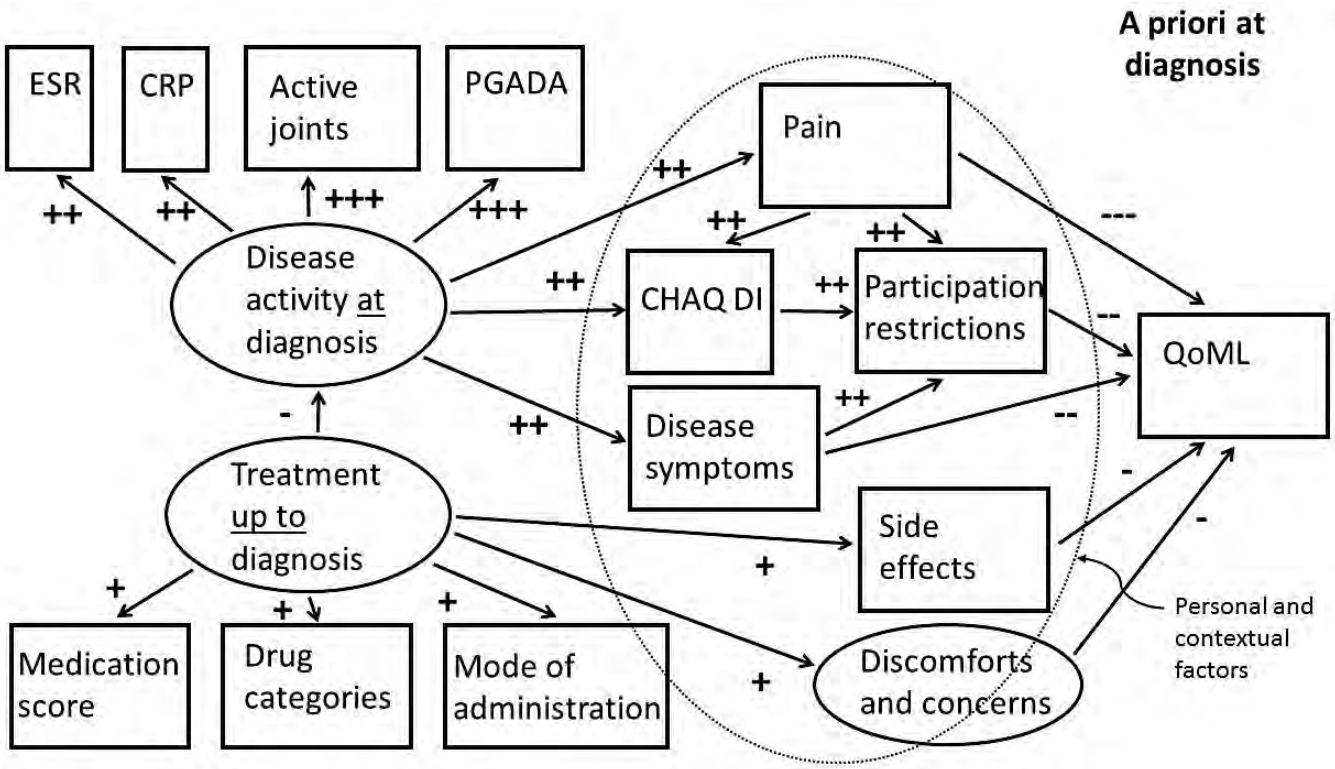

Figure 1. Hypothesized a priori model of the causal pathways leading to HRQoL at diagnosis as measured by QoML. ESR, CRP, active joint count and physician global assessment of disease activity (PGADA) are proposed as measures of disease activity; and medication score, drug categories and mode of administration as measures of treatment intensity. Disease activity and treatment intensity have proposed effects on mediators, such as pain, other symptoms and function which in turn impact HRQoL. Personal and contextual factors were not analysed.

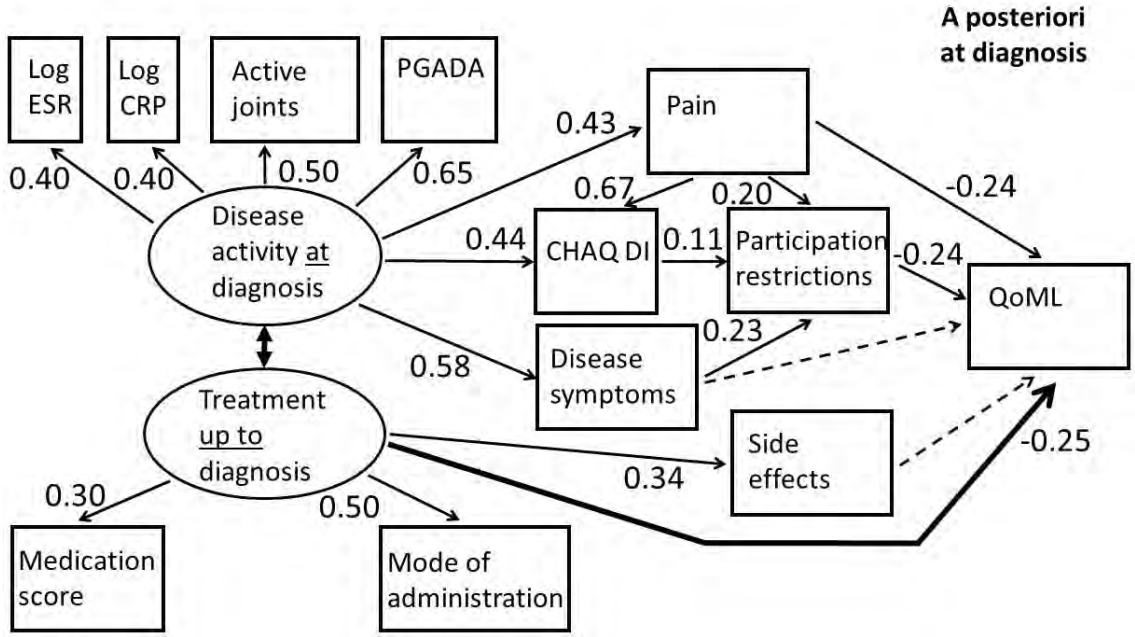

Figure 2. A posteriori model of best fit at diagnosis. Drug categories and Discomforts and concerns were removed due to overlap or lack of measures. Dashed lines represent postulated relationships not supported ($p>0.05$) and bold lines represent new paths that improve fit. Numbers signify path coefficients for the relationship between the variable at the arrow tail and the variable at the arrow head. A positive path coefficient of 0.5 means that a 1.0 standard deviation increase in the variable at the arrow tail corresponds to a 0.5 standard deviation increase in the variable at the arrow head. A negative path coefficient means an increase in the arrow tail variable corresponds to a decrease in the arrow head variable; and a path coefficient close to 0 reflects negligible impact.

and flare were similar to that at diagnosis and largely supported the hypothesized relationships (path coefficients 0.1 to 1.0 in the expected direction). Models for JAQQ provided greater specificity as to the domains of HRQoL affected. Models for remission stages were unsatisfactory.

Conclusion: Using SEM, we found support for disease activity and treatment intensity as root determinants of decreased HRQoL in children with JIA. Disease activity acts mainly via pain, functional impairments and participation restrictions. Treatment main effects at diagnosis were not mediated by side effects.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical II: Outcomes & Care Delivery
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: In the last years, the interest in the assessment of parent- and child-reported outcomes (PCROs) in paediatric rheumatic diseases is gaining increasing importance. These measures reflect the parent and child perception of the disease course and effectiveness of therapeutic interventions and may facilitate concordance with physician's choices, improve treatment adherence, and participation in a shared decision -making strategy. Moreover, the availability of reliable PCROs could be crucial for remote monitoring of patients when in person clinical evaluation may be difficult or even not possible. Aim of this work is to provide further evidence of validity and reliability for four PCRO measures included in the OMERACT JIA core domain set: the evaluation of the child's pain and of the child's level of disease activity, the assessment of the morning stiffness (MS) duration, and an active joint count for parent/patient proxy or self-assessment.

Methods: Pain and disease activity were rated on a 21-numbered circle scale ranging from 0 (best result) to 10 (worst result). MS was measured with a 5-point Likert scale. The proxy- and self-assessment of active joints was obtained by rating the presence of pain or swelling in the following joints or joint groups: cervical spine, lumbo-sacral spine, shoulders, elbows, wrists, small hand joints, hips, knees, ankles, and small foot joints. To each joint or joint group, one point was given in case of monolateral involvement, two points in case of bilateral involvement. Patients were included in a multinational dataset of patients enrolled in the Epidemiology Treatment and Outcome of Childhood Arthritis study. Criterion validity was assessed by examining the correlation of the four tested measures with physician centered measures, ESR, and composite disease activity scores. Correlations of the measure with the cJADAS10 were also computed after grouping patients by ILAR category, by geographic area, and by education level. Reliability

was assessed in a subset of subjects with Spearman correlations and intraclass correlation coefficients (ICC), comparing two visits 7-14 days apart.

Results: A total of 8,848 parents and 6,204 patients had all the evaluations available. Correlations of tested measures were moderate (0.4–0-7) with physician centered measures and poor (< 0.4) with ESR. The level of correlation of the tested parent measures with the cJADAS10 remained stable after grouping patients by ILAR category. In the same analysis with patients grouped in eight geographic areas, correlation levels were similar, although, on average, they were higher in Latin America and slightly lower in North America. The levels of correlation with the cJADAS10 were similar in subjects in which the level of education of the parent filling the questionnaire was elementary or lower, high school, or degree, respectively. In 442 parents and 344 children, correlations between first and second assessment was > 0.7 for all measures; ICC ranged between 0.79 and 0.87 for parents and 0.81 and 0.88 for children.

Conclusion: The four tested PCROs showed good criterion validity and excellent reliability. These tools can be considered for remote patient assessment, when in person evaluation might not be possible.

Determinants of Variation in Pediatric Systemic Lupus Erythematosus Care Delivery

Jon Burnham[1], Rosemary Peterson[1], Joy Ukaigwe[1], Lynsey Cecere[1], Andrea Knight[2] and Joyce Chang[1], [1]Children’s Hospital of Philadelphia, Philadelphia, PA, [2]Division of Rheumatology, The Hospital for Sick Children and Department of Paediatrics, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical II: Outcomes & Care Delivery
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Patients with pediatric systemic lupus erythematosus (pSLE) receive only a fraction of recommended care. Moreover, variation in care delivery likely contributes to pervasive racial and ethnic disparities in pSLE outcomes. We aimed to begin improving pSLE and mixed connective tissue disease (MCTD) care delivery by defining and assessing variation in performance of a pediatric lupus care index (p-LuCI).

Methods: This was a cross-sectional study of pSLE quality measure performance in the context of an improvement project conducted in the Division of Rheumatology at a large tertiary-care pediatric hospital. Providers included nine attending pediatric rheumatologists and 4 fellow trainees. The project team identified four key drivers of high-quality pSLE care potentially linked to improved outcomes: 1) accurate tracking of pSLE characteristics and treatments, 2) point-of-care outcome assessment, 3) comorbidity assessment and prevention, and 4) timely follow up. To address key drivers, we defined 13 metrics that were bundled into the p-LuCI (**Table 1**). The p-LuCI was scored from 0-1

Table 1. Pediatric systemic lupus erythematosus care index component performance.						
Domain	**Metric**	**Specification**	**Performance**	**Index values above mean**	**Index values below mean**	**p-value**
Clinical / Outcome focus	SLEDAI score documented[a]	Yearly	62% (61/99)	75%	25%	<0.001
	SLICC-DI score documented	Yearly	31% (34/111)	48%	5%	<0.001
	PGA score score documented	Each visit	67% (74/111)	82%	43%	<0.001
	Target attestation[ad]	Each visit	61% (60/99)	69%	34%	<0.001
	Disease characteristics review[e]	Yearly	63% (70/111)	87%	27%	<0.001
Comorbidity care	Pneumococcal vaccination	Up to date	69% (77/111)	81%	52%	0.002
	Influenza vaccination[b]	Up to date	52% (49/95)	53%	50%	0.80
	Blood pressure assessment[f]	Each visit	53% (59/111)	69%	30%	<0.001
	Lipid testing	Every 2 years	76% (84/111)	87%	59%	0.001
	Vitamin D testing	Yearly	59% (66/111)	72%	41%	0.001
	Stress-dose steroid plan[acg]	Documented	62% (31/50)	68%	42%	0.10
	Steroid-sparing agent prescribed[ach]	Each visit	96% (48/50)	97%	92%	0.38
Population management	Visit scheduling[i]	Up to date	20% (22/111)	24%	14%	0.19

The p-value is based on a χ^2 test of metric completion comparing those with p-LuCI values above versus below the division mean.

SLEDAI: Systemic lupus erythematosus disease activity index 2000 version

SLICC-DI: Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index modified for pSLE

[a] SLEDAI and target attestation measures only used for patients with pSLE. Therefore, the p-LuCI denominator in MCTD patients was reduced by two for a maximum of 11.

[b] Influenza vaccination metric includes only patients with visits after August 1 of the flu year and do not refuse the influenza vaccine.

[c] Stress-dose steroid plan and steroid-sparing agent measures only assess among individuals with steroid prescriptions for greater than 14 consecutive days within the previous 18 months. Therefore, the p-LuCI denominator for patients not exposed to chronic steroids was reduced by two for a maximum of 11.

[d] Target attestation: Completion of visit note element indicating that patient's disease activity is at target – no clinical active disease, at target – minimal disease activity, not at target.

[e] Disease characteristics review: Clinician confirmation of up to date disease summary form in the electronic health record.

[f] Blood pressure assessment: Classification of age and sex-specific blood pressure status according to the National Institutes of Health National Heart Lung and Blood Institute guidelines.

[g] Stress-dose steroid plan: Documentation of secondary adrenal insufficiency in the electronic health record.

[h] Steroid-sparing agent prescribed: Steroid-sparing agents included cyclophosphamide, mycophenolate mofetil, mycophenolic acid, azathioprine, methotrexate, cyclosporin A, tacrolimus, sirolimus, rituximab, belimumab, abatacept, ustekinumab, or other biologic medication documented in a standard electronic health record note element.

[i] Visit scheduling: Appointment scheduled within 30 days after clinician-specified follow-up interval at last visit. If no follow-up interval was specified, 180 days was used as the recommended follow-up interval. Performance on the visit scheduling metric was lower because this sample was drawn during the SARS-CoV2 pandemic with altered patient scheduling procedures.

Table 1. Pediatric systemic lupus erythematosus care index component performance.

based on the number of metrics completed divided by the number of eligible metrics. We combined discrete data from a pSLE visit template along with prescribing and appointment data to capture index components in an automated pSLE report.

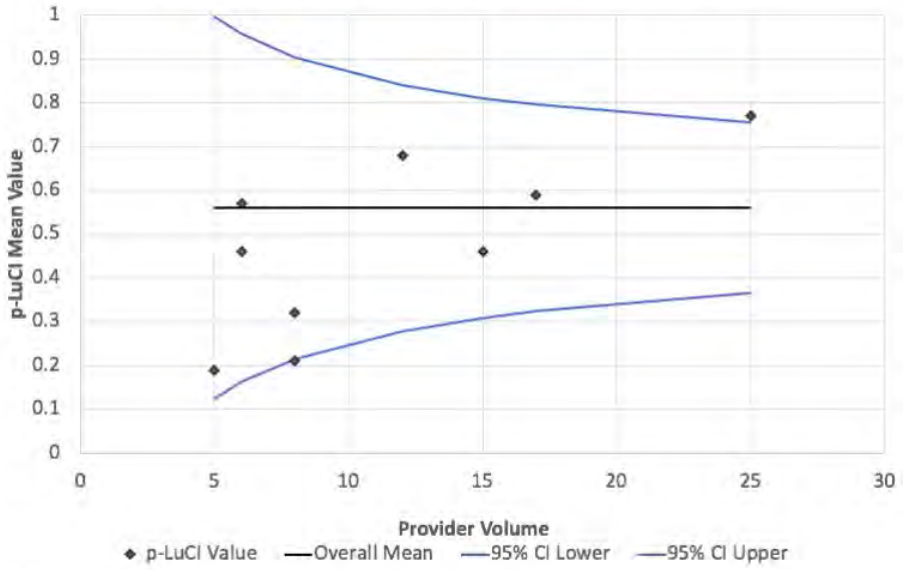
We included patients clinically diagnosed with pSLE and MCTD with at least one visit in the Division of Rheumatology within the prior 15 months. After bivariate analyses, independent p-LuCI predictors were identified using multivariable linear regression with clustering by provider. Provider-level variation was defined as +/- 2 SD from the p-LuCI mean.

Results: We included 111 patients (99 SLE, 12 MCTD) with a mean age of 16.9 ± 3.0 years. 88 (79%) were female, 39 (35%) were black, and 12 (11%) were Hispanic. 10 (9%) had families who were not English-speaking. Of 33 patients with nephritis, 16 (48%) had prior visits in a multi-disciplinary Rheumatology/Nephrology Clinic.

Table 2. Predictors of performance on the pediatric systemic lupus erythematosus care index.				
Variable	**Unadjusted**		**Adjusted**	
	β (95% CI)	**p-value**	**β (95% CI)**	**p-value**
Age (years)	-0.01 (-0.02, 0.01)	0.50		
Sex (Female)	-0.04 (-0.13, 0.05)	0.33		
Black race	0.05 (-0.04, 0.13)	0.26		
Hispanic ethnicity	0.20 (0.10, 0.30)	0.001	0.11 (0.04, 0.18)	0.005
Chronic steroid exposure	0.15 (0.05, 0.25)	0.006	0.08 (0.02, 0.15)	0.02
Nephritis	0.17 (0.04, 0.30)	0.01	0.09 (0.01, 0.03)	0.01
Provider volume (per patient)	0.01 (0.00, 0.03)	0.01	0.02 (0.01, 0.03)	0.001
Rheumatology fellow assigned	0.14 (-0.12, 0.41)	0.09	0.37 (0.03, 0.41)	0.01
Note: Linear regression with clustering according to provider was performed for all models.				

Table 2. Predictors of performance on the pediatric systemic lupus erythematosus care index.

Figure: Funnel plot demonstrating provider-level p-LuCI performance.



* Only providers with ≥ 5 pSLE patients are included.

Figure. Funnel plot demonstrating provider-level p-LuCI performance.

The mean p-LuCI was 0.56 ± 0.25. p-LuCI component performance is shown in **Table 1**. Patients with higher p-LuCI values were more likely to receive care across nine of 13 metrics. The predictors of p-LuCI performance are shown in **Table 2**. Independent predictors of higher p-LuCI values were Hispanic ethnicity, chronic steroid exposure, history of nephritis, higher provider pSLE/MCTD volume, and fellow provider assignment. Among providers with ≥ 5 patients under care, p-LuCI values ranged from 0.19 to 0.77. One provider each was significantly above and below the cohort mean (**Figure**).

Conclusion: We demonstrated that pSLE patients received 56% of p-LuCI measures with significant variation at the provider level. In addition, we identified demographic, disease-specific, and provider characteristics associated with

higher performance. Future p-LuCI components should include reproductive counseling, transition preparation, and mental health screening. Multicenter studies are needed to assess the impact of efforts to decrease p-LuCI variation and increase performance on disease activity and damage accrual, disparities in health care utilization, and patient/caregiver satisfaction.

Predictors of Adverse Outcomes in Patients with Childhood-Onset Systemic Lupus Erythematosus Transitioning to Adult Care

Nicole Bitencourt[1], Una Makris[1], Elizabeth Solow[1], Tracey Wright[2] and Bonnie Bermas[3], [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Plano, TX, [3]UTSouthwestern.edu, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Pediatric Rheumatology – Clinical II: Outcomes & Care Delivery
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The transition from pediatric to adult care is a vulnerable period and is linked to increased healthcare utilization and poor outcomes. We sought to identify risk factors associated with an unsuccessful transfer to adult care in childhood-onset systemic lupus erythematosus (cSLE).

Methods: A retrospective analysis of patients with cSLE seen in adult public or private rheumatology clinics was performed. Outcomes of interest were development of end-stage renal disease (ESRD) or death and time to first hospitalization following the final pediatric rheumatology visit. Independent variables included sociodemographic and disease characteristics. Pediatric factors influencing ESRD or death were assessed using Chi-square, Fisher's test, or the Wilcoxon rank-sum test. A stepwise multivariable logistic regression model to predict ESRD or death was used. Pediatric factors influencing time to first hospitalization were assessed using the log-rank test. Stepwise multivariable Cox regression analysis was performed to define predictors of time to adult hospitalization.

Results: Of 190 patients with cSLE, 21 (11%) developed ESRD and 9 (5%) died following the final pediatric rheumatology visit. As seen in Figure 1, ESRD or death were more common among patients of Black race or Hispanic ethnicity, those with public insurance, a history of child protective services (CPS) involvement or abuse, an outpatient narcotic prescription for non-procedural pain management during pediatric care, a history of unscheduled hospitalization, emergency department (ED) visit, or at least one no-show visit during the final year in pediatric care, and prior cyclophosphamide therapy ($p < 0.03$). Gender, age at transfer, SLE disease duration, and income based on zip-code were not significantly related to development of ESRD or death. In logistic regression, public insurance, history of CPS involvement or abuse, and an unscheduled pediatric hospitalization were associated with development of ESRD or death (Table 1).

Of 114 patients for whom healthcare utilization data were available following final pediatric visit, 53% had a hospitalization in adult care. Time interval to first adult hospitalization was shorter for patients of Black race or Hispanic ethnicity, those with public insurance, a history of CPS involvement or abuse, an outpatient narcotic prescription for non-procedural pain management during pediatric care, a history of unscheduled hospitalization, ED visit, and no-

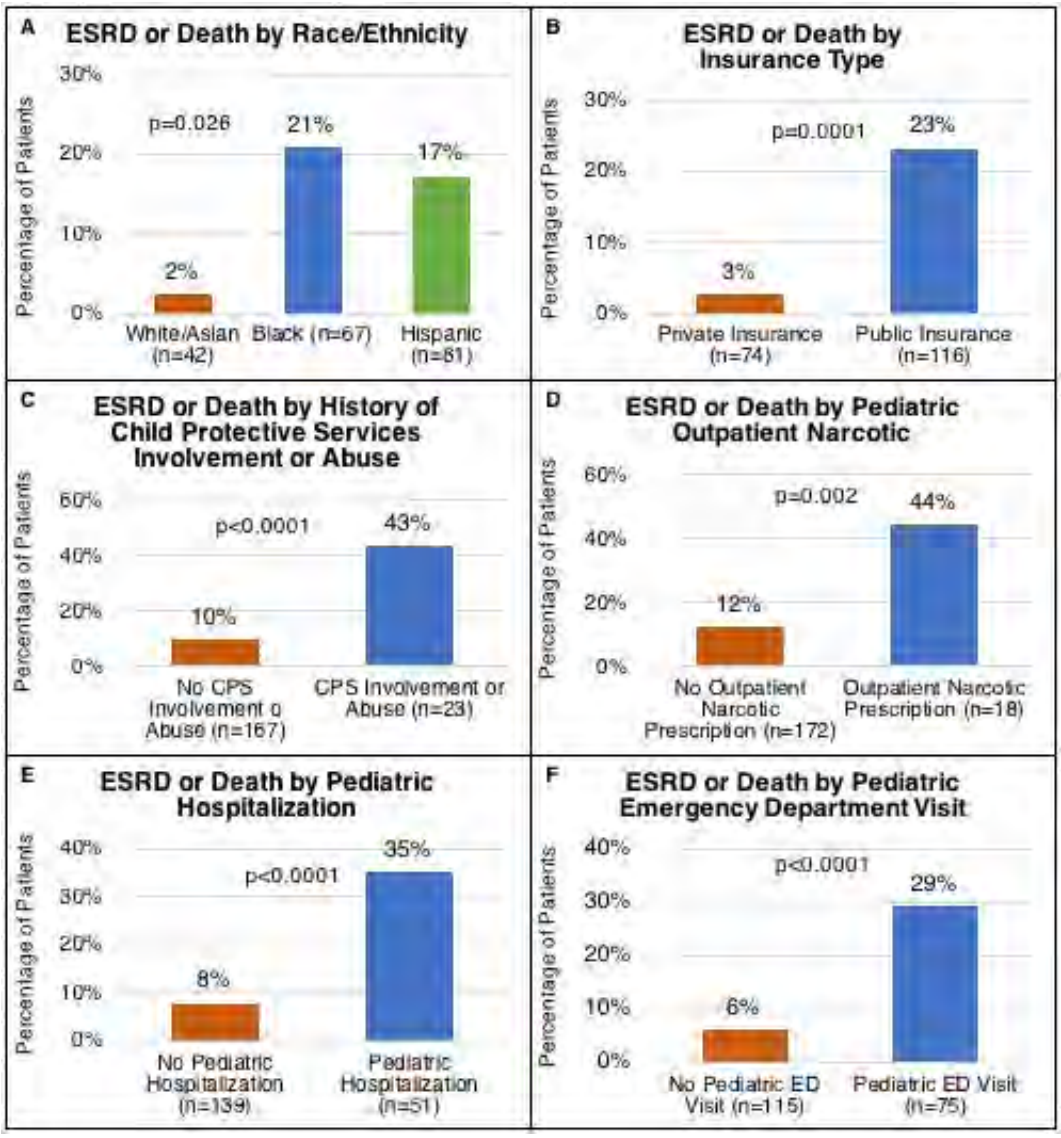

Figure 1. Pediatric Factors Associated with ESRD or Death after Transfer to Adult Care

show visit during the final year in pediatric care ($p< 0.03$) (Figure 2). In Cox regression analysis, a pediatric outpatient narcotic prescription was associated with shorter time to hospitalization while White or Asian race was associated with longer time to first hospitalization ($p< 0.007$).

Conclusion: Our findings indicate that efforts to improve transition outcomes among patients with cSLE should focus on high risk individuals in pediatric care, including those of Black race or Hispanic ethnicity, patients with public insurance, a history of CPS involvement or abuse, outpatient narcotic prescription for non-procedural pain management, and history of hospitalization, ED visit or no-show visit in the final year of pediatric care.

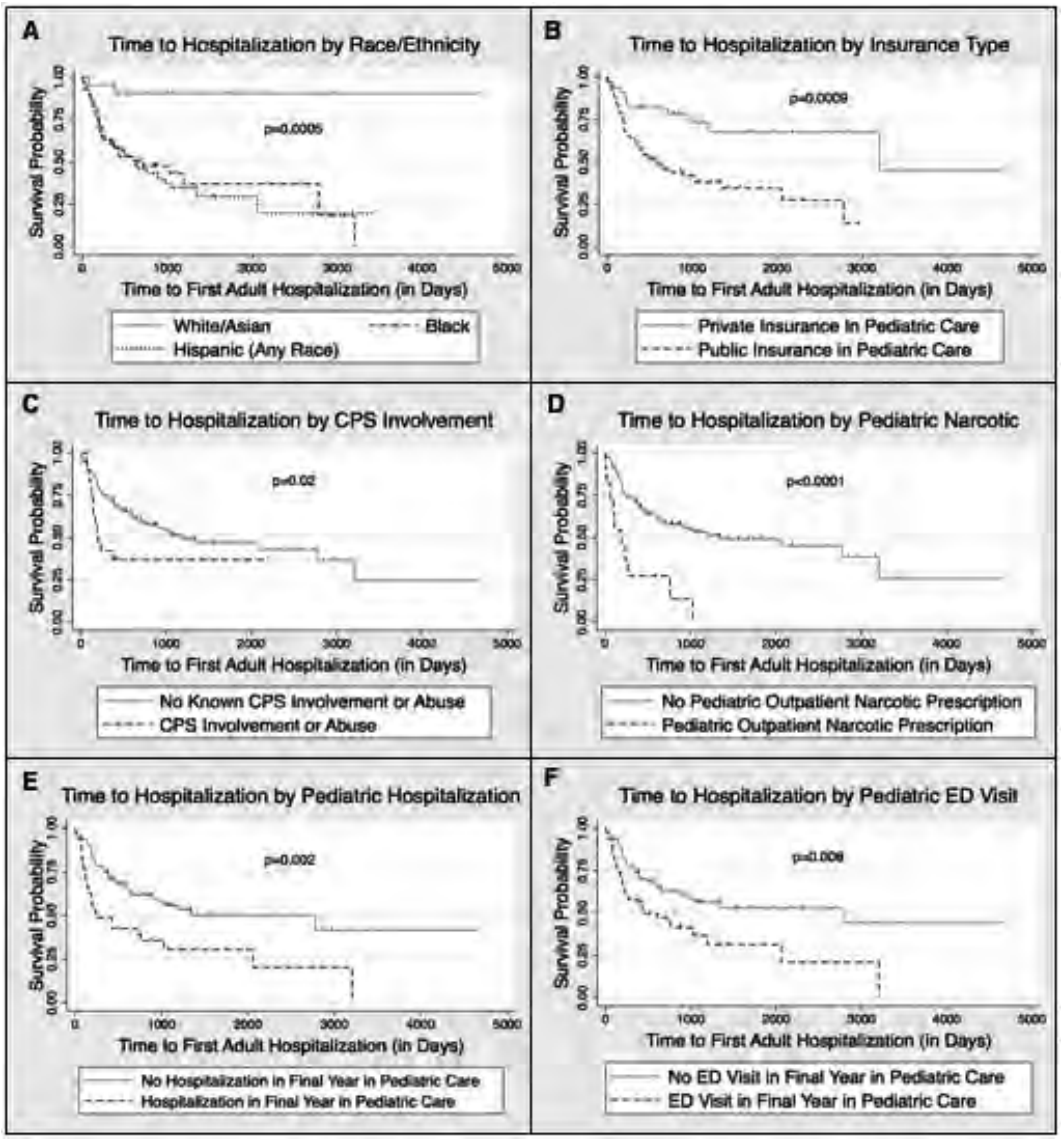

Figure 2. Time to Adult Hospitalization by Pediatric Factors

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical III: Systemic Autoimmune Disease

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: Persistent skin manifestations, in particular calcinosis, contribute to significant morbidity in patients with JDM. The goal of this study was to compare the course of skin vs muscle symptoms and document the frequency of calcinosis in children with JDM.

Methods: Data were extracted from the Lurie Children's CureJM Center of Excellence's Juvenile Myositis Registry, a dataset that includes all children diagnosed with definite/probable JDM based on Bohan and Peter criteria (n=485). The duration of untreated disease (DUD), the interval between first symptom and start of therapy was calculated. The children were assessed for calcifications and for extent of disease, using the JDM Disease Activity Score (DAS) for skin (DAS-S), muscle (DAS-M) and total (DAS-T). Among this dataset were data on 184 untreated children with JDM, seen from July, 1971 to May, 2019. A paired t-test was used to analyze differences in mean DAS scores at baseline and 6, 12, 24, and 36 months on medication; as well as time to reach clinically inactive skin vs. muscle scores (DAS 0, ≤1, ≤2). Differences in time for abnormal vascular elements in DAS-S to resolve was calculated using a one-way ANOVA.

Results: 138 girls (75%) and 46 boys (25%) with untreated JDM and a mean age of 7.1±3.9 (mean±SD) years were enrolled and followed for 6.6±5.5 years. At baseline, the mean DAS-Muscle (DAS-M) score was 4.9±1.4 compared to DAS-Skin (DAS-S) score of 5.8±3.0 ($p< 0.01$). DAS-S was persistently higher than DAS-M at 6, 12, 24, and 36 months of treatment and reached 0/clear, ≤1/almost clear, and ≤2/mild later than DAS-M. The mean time to reach a DAS score of 0 was 18.4±20.4 months for skin compared to muscle of 9.5±9.9 months ($p< 0.001$). Altogether, 92% reached clinical inactivity for skin compared to 97% for muscle ($p< 0.05$). Of the vascular features in DAS-S, eyelid margin capillary dilatation was seen most frequently (54%) and persisted longest before clearance at a mean duration of 7.8±14.5 months. This was significantly longer than recovery time for periungual capillary telangiectasia (3.5±4.0 months) ($p< 0.05$) and palate vessel dilatation (3.3±3.2 months) ($p< 0.05$). 9 (5%) patients had calcifications at baseline and an additional 23 (15%) developed calcifications during the course of disease. The majority (83%) of calcifications were classified as mild. Calcifications developed after a mean of 64.7±71.5 months on medication and took an average of 6.1±7.0 months to resolve. 26% (6 out of 23) of patients had a recurrence of calcification at the same site; calcifications never resolved in 7 patients, 5 of whom (71%) had calcifications at first visit. These 7 children had a mean duration of untreated disease (DUD) at diagnosis of 60.2±44.5 months, in comparison to the children whose calcifications resolved, who had a mean DUD at diagnosis of 12.5±14.8 ($p< 0.001$).

Conclusion: Skin disease presents with greater activity and persists longer than muscle disease in children with JDM. Vascular features within skin, particularly eyelid margin capillary dilatation, tend to be most persistent. Early and aggressive treatment can limit the severity and persistence of calcifications that recur late in the disease course.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical III: Systemic Autoimmune Disease

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Figure 1.

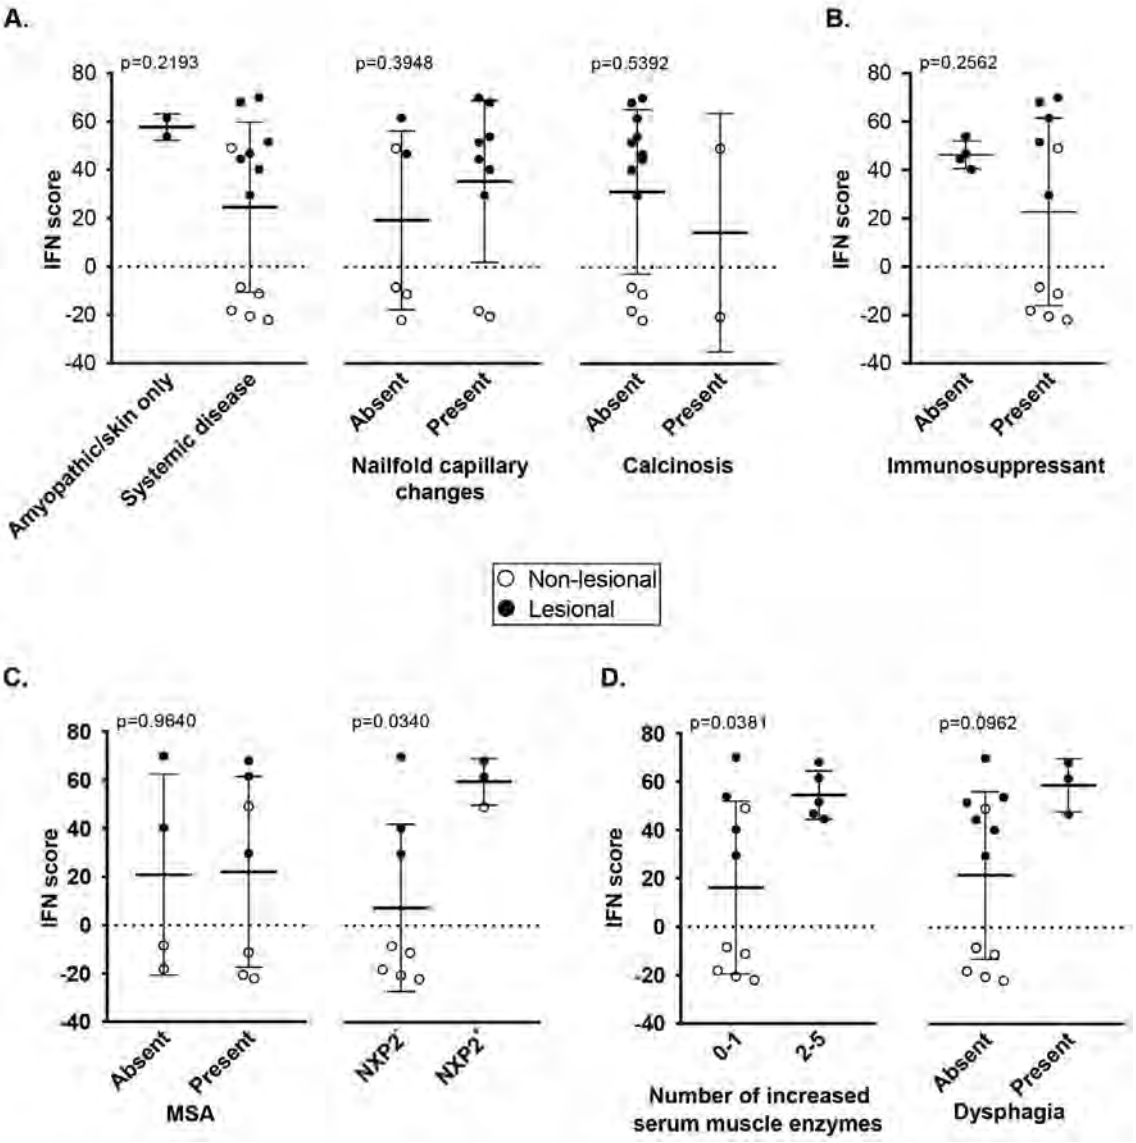

Figure 1. JM IFN score with clinical variables. A. The IFN score is not significantly modified by the presence of systemic disease, nailfold capillary changes or calcinosis. B. The IFN score is not significantly changed by treatment status. C. The presence alone of a myositis-specific autoantibody (MSA) does not significantly alter the IFN score; however, NXP2+ JM patients have a significantly higher IFN score (p-value=0.034). D. An increased overall number of serum muscle enzymes was associated with a higher IFN score (p-value=0.0381). A higher IFN score demonstrated a trend toward presence of dysphagia.

Background/Purpose: Skin inflammation can herald systemic disease in juvenile myositis (JM), yet we lack an understanding of pathogenic mechanisms driving skin inflammation in JM. The goals of this study were to 1) define JM cutaneous gene expression signatures in the context of patient data, and 2) identify key genes and pathways differentiating skin disease in JM from childhood-onset systemic lupus erythematosus (cSLE).

Methods: We utilized formalin-fixed paraffin-embedded (FFPE) skin biopsies from 15 JM (9 lesional, 6 non-lesional), 5 cSLE (all lesional), and 8 controls to perform transcriptomic analysis and identify significantly differentially expressed genes (DEGs; q-value ≤ 5%) between patient groups. Ingenuity Pathway Analysis (IPA) was used to highlight enriched biological pathways and Genomatix Pathway System (GePS) to characterize regulated genes within biological networks. We validated DEGs using immunohistochemistry and quantitative real-time PCR. Interferon (IFN) scores

Figure 2.

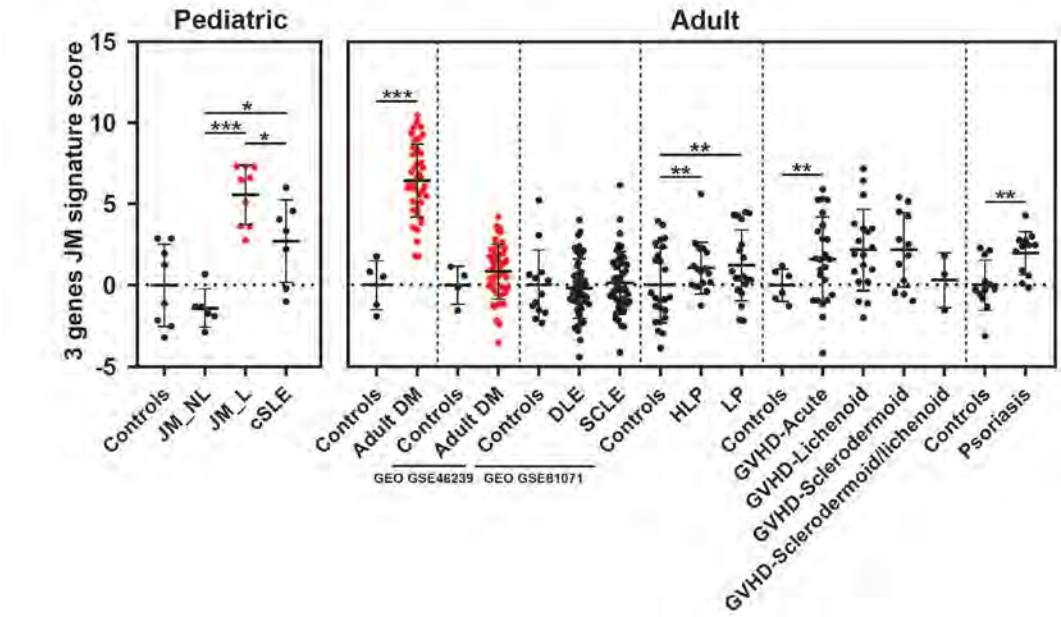

Figure 2. JM disease signature: comparison with transcriptomic datasets of skin lesions from adult DM and other inflammatory skin diseases. The 3-gene JM transcriptomic signature identified is the highest in juvenile and adult dermatomyositis compared to other skin disease lesions. Dermatomyositis lesional samples are represented in red. Vertical dashed lines separate the studied datasets. Each dataset had its control sample set. DLE: discoid lupus erythematosus, SCLE: subacute cutaneous lupus erythematosus, HLP: Hypertrophic lichen planus, LP: lichen planus, GVHD: graft versus host disease. * p-value<0.05; ** p-value<0.01; *** p-value<0.0001.

were calculated and compared amongst patient groups and between JM clinical features. A JM-specific signature was derived from comparison of cSLE and lesional JM (JM_L) skin transcriptomes relative to controls and compared to adult skin disease array datasets. Cell type enrichment analysis was then performed using the xCell webtool.

Results: Comparison of JM_L to control revealed 221 DEGs, with the majority of upregulated genes representing IFN-stimulated genes. *CXCL10*, *CXCL9* and *IFI44L* represented the top three DEGs (fold-change respectively = 23.2, 13.3, 13.0, q-value < 0.0001). While IFN scores in JM did not differ based on individual skin disease manifestations or treatment status, NXP2+ JM patients exhibited the strongest IFN signature (Figure 1) and also demonstrated the most extensive MX1 immunostaining, both in keratinocytes and perivascular regions. When compared to cSLE, JM_L skin showed no difference in IFN scores and shared a similar gene expression pattern, with only 28 unique DEGs. The top most significant unique DEGs in JM_L included *FBLN2*, *CHKA* and *SLURP1*, genes with diverse roles in extracellular matrix structure, keratinocyte proliferation and differentiation, calcium signaling and phospholipid metabolism. A 3-gene JM-specific skin signature derived using *FBLN2*, *CHKA* and *SLURP1* was higher in dermatomyositis (both pediatric and adult) as compared to other skin diseases, including cutaneous lupus (Figure 2). cSLE skin had 722 unique DEGs compared to JM_L, notably increased expression of IFNγ relative to control. Cell type enrichment analysis showed that cSLE skin exhibited an overall higher inflammatory cell signature compared to JM_L, with increased T-cells, B-cells, macrophages and plasmacytoid dendritic cells (Figure 3).

Conclusion: JM lesional skin demonstrates a prominent IFN signature, similar to cSLE. A candidate JM-specific skin signature was derived using *FBLN2*, *CHKA* and *SLURP1*, all genes not typically considered to have immunomodulatory roles but instead functions in cellular structure and metabolism. Further investigation into the association of a higher IFN score with NXP2 autoantibodies may lend insight into JM disease endotypes and pathogenesis.

Figure 3.

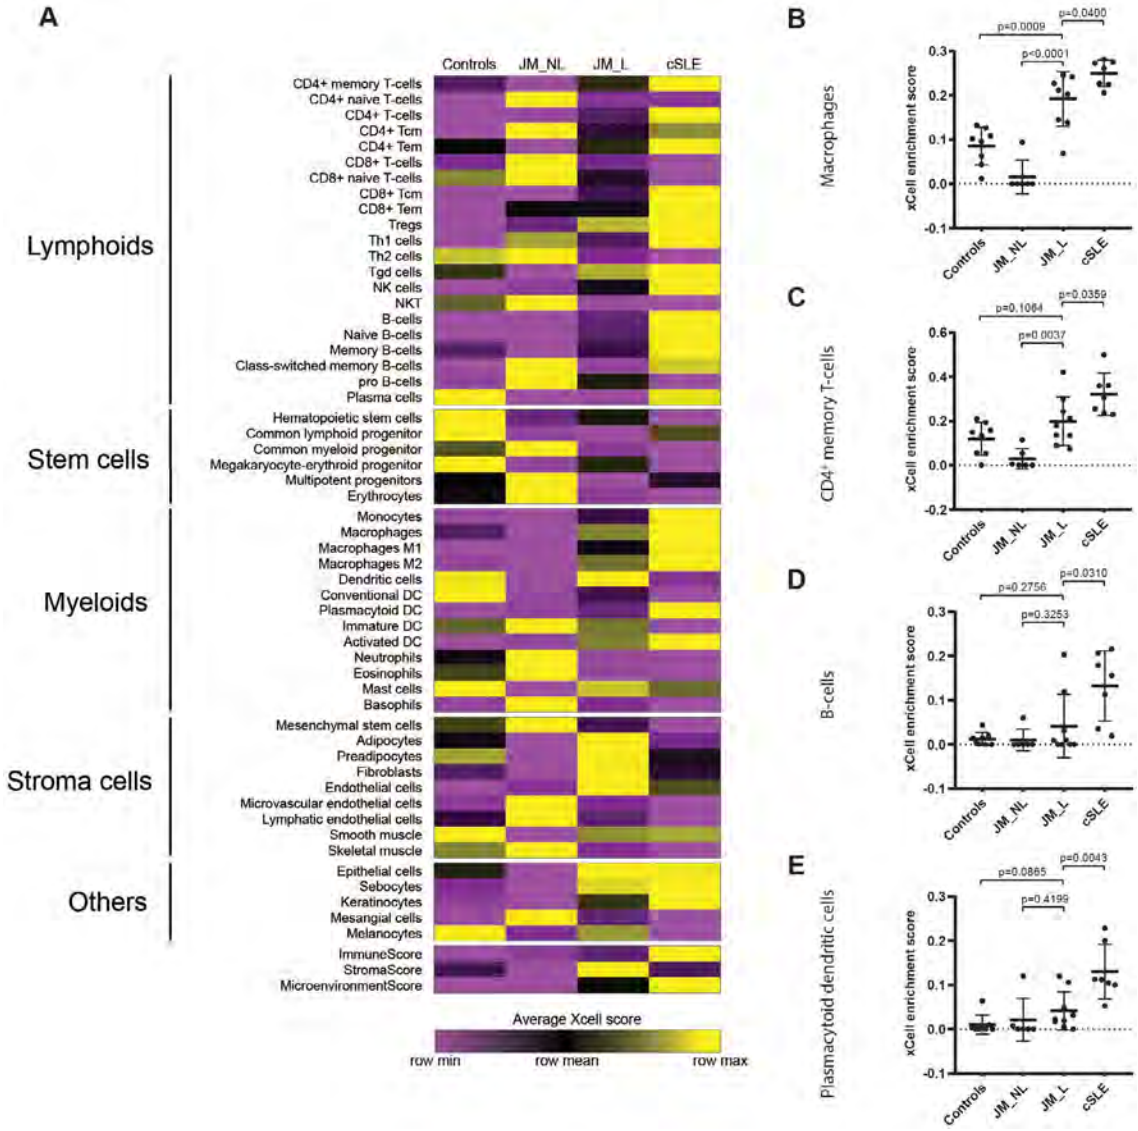

Figure 3. Cell type enrichment analysis using xCell webtool. A. Heatmap of relevant cell types representing average xCell enrichment score for controls, JM_NL, JM_L and cSLE. B. Graph of the macrophage xCell score, showing a significantly higher score in JM_L compared to JM_NL and controls and in cSLE compared to JM_L. C. Graph of the CD4+ memory T-cells xCell score, showing a significantly higher score in JM_L compared to JM_NL and in cSLE compared to JM_L. D. Graph of the B-cells xCell score showing a significantly higher score in cSLE compared to JM_L. E. Graph of the plasmacytoid dendritic cells xCell score, showing a significantly higher score in cSLE compared to JM_L. For (B-E) comparisons were made via unpaired Students' t-test.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical III: Systemic Autoimmune Disease

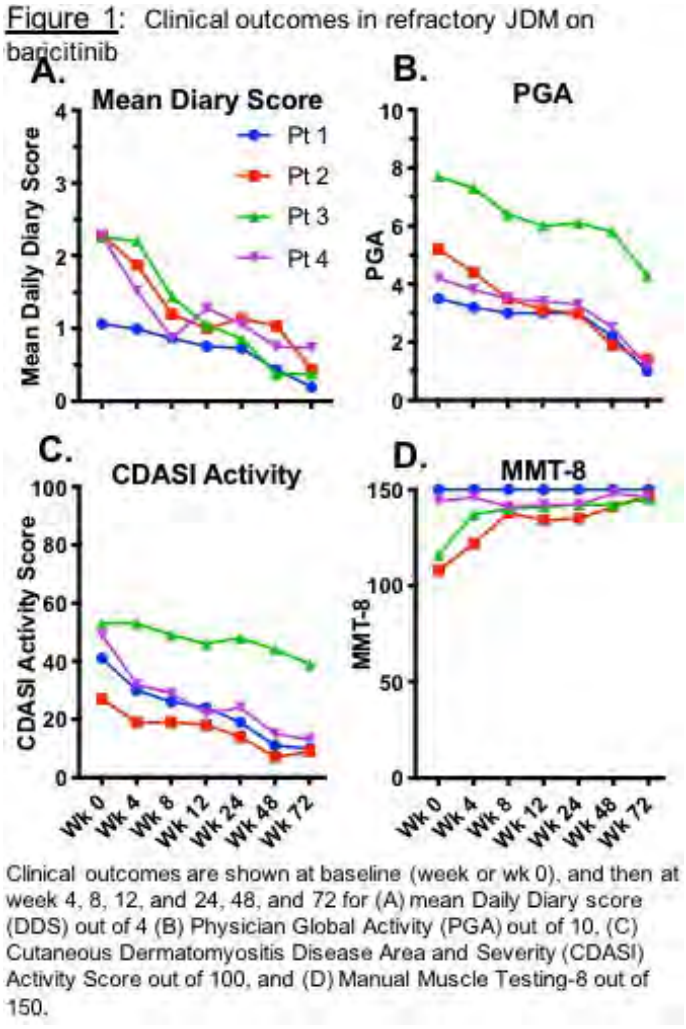
Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic autoimmune disease with a prominent interferon (IFN) signature. Treatment often requires prolonged high-dose steroids and other immunosuppressive medications. In a compassionate use program, we assessed efficacy and safety of baricitinib (JAK 1/2 inhibitor) in active refractory JDM.

Methods: Active (based on ≥3 core set measures (CSM)) and refractory (use of high dose steroids and ≥2 other medications, including ≥1 biologic therapy) patients with JDM were enrolled after washing out biologic agents other than IVIG. Baricitinib was dosed based on weight and renal function. Primary outcome was reduction in symptom daily diary score (DDS) of weakness, fatigue, musculoskeletal pain, and rash. Other assessments included International Myositis Assessment and Clinical Studies (IMACS) disease activity CSMs and Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI). STAT-1 phosphorylation (pSTAT1) and peripheral IFN markers (IFN-regulated gene score, CXCL10/IP-10) were assessed. Linear mixed models were used to compare measures to baseline. Safety and tolerability were assessed.

Results: Four paitents with JDM (5.8-20.7 years old) were enrolled (NCT01724580). Patients received baricitinib 4-12 mg/day PO divided BID. There were clinically relevant improvements up to 72 weeks after baricitinib. DDS changed from a mean of 2.0 (range 1.1-2.3) to 0.4 (0.2-0.7; 68-83% decrease, $p< 0.01$) (Fig 1A). Physician Global Activity visual analog scale (VAS) decreased from a mean of 5.2 (3.5-7.7) to 2.0 (1.0-4.3; 44-73% decrease, $p< 0.01$) (Fig 1B). Extramuscular Global Activity VAS decreased from mean 5.1 (3.0-7.3) to 1.8 (0.5-4.5; 38-83% decrease, $p< 0.01$). CDASI activity score reduced from mean 43 (27-53) to 18 (9-39; 14-36 point decrease, $p< 0.01$) (Fig 1C). In 2/4 pts with baseline weakness, manual muscle testing (MMT8) increased from 108 to 147 and 116 to 145 (mean improvement 24%) (Fig 1D). By the ACR-EULAR JDM response criteria, the Total Improvement Score at 72 weeks was mean 60.6, range 42.5-80 (1 minimal, 1 moderate, 2 major improvement). Three patients reduced prednisone: mean 13.7 (range 10-21) to 4 (3.5-4.5) mg/day; 1 patient remained on 5mg/day. IFN-alpha stimulated pSTAT1 in different immune cell subsets negatively correlated with plasma baricitinib levels. All IFN markers decreased. Baricitinib was generally well tolerated. There were no serious adverse events (AEs). Infections were the most common AE. No AEs required holding/discontinuing baricitinib.



Clinical outcomes are shown at baseline (week or wk 0), and then at week 4, 8, 12, and 24, 48, and 72 for (A) mean Daily Diary score (DDS) out of 4 (B) Physician Global Activity (PGA) out of 10, (C) Cutaneous Dermatomyositis Disease Area and Severity (CDASI) Activity Score out of 100, and (D) Manual Muscle Testing-8 out of 150.

Conclusion: Preliminary data on the use of baricitinib (JAK 1/2 inhibitor) in four patients with refractory JDM are encouraging, showing steady and prolonged improvement in symptom DDS as well as in validated disease activity measures, including both skin and muscle. All patients met clinically significant improvement by the ACR-EULAR response criteria. A corresponding decrease in pSTAT1 and IFN markers was observed. Baricitinib was generally well tolerated and further evaluation in JDM should be considered.

Disclosures: Baricitinib provided by Eli Lilly and Company, expanded access program sponsor. Other support: IRP of NIH, NIAMS, NIEHS, CC.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical III: Systemic Autoimmune Disease

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: Juvenile localized scleroderma (jLS) is an autoimmune disease commonly associated with damage. Damage includes dyspigmentation, tissue atrophy, arthropathy, hemiatrophy, vision loss, and seizures. To limit damage severity, methotrexate (MTX), with or without glucocorticoids (GC), is recommended to treat patients with active disease. This regimen is effective in ~70% of patients. Evidence on how to treat non-responders is limited, with some patients having persistently active disease for decades.

Many studies have identified T cells and their associated cytokines in patients with active disease, which suggests abatacept (ABA), a selective T cell co-stimulatory signal inhibitor, could be an effective treatment. A good response to ABA has been reported in small case series of adult onset patients who failed MTX. We report our experience using ABA to treat refractory jLS patients.

Methods: This was a multi-center retrospective cohort study of jLS patients that initiated ABA treatment prior to 7/1/18. Inclusion criteria included diagnosis of jLS, with onset < 16 years. Charts were reviewed to extract demographics, disease characteristics, medication history, and reasons for ABA use. Data was collected at start of ABA (baseline), and at 6 month intervals up to 24 months, or ABA discontinuation, whichever was sooner. Descriptive statistics analysis was performed.

Results: 18 patients were evaluated, median age 13.4 years, disease duration 3.7 years. Most had linear scleroderma (Table 1). All had been previously treated with glucocorticoids, and MTX (17) and/or mycophenolate mofetil (MMF, 16), each for a median duration of >1 year (Table 1). Reasons for ABA use included persistent disease or flare (14, 78%), intolerance of other medications (5, 28%), and GC dependence (4, 22%). ABA was dosed per JIA recommendations, with 16 treated intravenously. All patients concurrently received other treatment: MTX (12), MMF (10), hydroxychloroquine (1), and GC (14).

Median scores for physician global assessment of disease activity and skin activity measures all declined by 12 months, and then stabilized or further declined (Figure 1). At 12 months, 17 (94%) patients were rated as improved in activity status compared to baseline, and 9 of the 12 patients with joint involvement were rated as improved. At 24 months, 9 of 11 patients (82%) on ABA were rated as improved, and 7 with joint involvement were all rated as improved. During ABA treatment, 10 patients were able to discontinue GC (71% of patients on GC, Figure 2).

Eight patients had an adverse event (AE); 7 were on concomittant medications. AE included fatigue, moodiness, behavioral change, and one infection (upper respiratory infection). No laboratory abnormalities were attributed to ABA. Two patients discontinued ABA because of mood and/or behavioral issues.

Number of patients	18
Sex: Female, no (%)	12 (66.7)
Race White, no (%)	18 (100)
Age of onset, years (IQR)	8.7 (7.5, 10.3)
Age at start of ABA, years (IQR)	13.4 (11.4, 15.0)
Disease duration at start of ABA, years (IQR)	3.7 (2.8, 6.5)
Subtype, no (%)	
Circumscribed Deep Morphea	1 (5.6)
Linear Head	2 (11.1)
Linear Trunk/Limb	9 (50)
Generalized Morphea	1 (5.6)
Mixed Morphea	5 (27.8)
Pansclerotic Morphea	1 (5.6)
Eosinophilic fasciitis	2 (11.1)
Extracutaneous involvement, no (%)	13 (72.2)
Joint involvement (%)	12 (66.7)
Muscle involvement (%)	9 (50)
Elevated CK/aldolase (%)	7 (38.8)
ANA Positivity (% of 17 performed)	8 (47.1)
Family History of rheumatic disease, no (%)	6 (33.3)
Duration of other treatment prior to ABA	
GC, months (IQR)	15.9 (10.1, 29.2)
MTX, months (IQR)	20.4 (15.6, 45.8)
MMF, months (IQR)	12.3 (6.5, 16.8)
Duration of ABA treatment, months (IQR)	23.2 (15.1, 25.3)

Table. Characteristics of the 18 jLS patients who were treated with abatacept. All of the patients received other jLS treatment prior to being treated with abatacept: 17 were treated with methotrexate, 16 with mycophenolate mofetil, and 17 with glucocorticoids. The median duration of these treatments are listed. The median duration of abatacept treatment for the patients during their study follow-up is shown. ABA:abatacept; ANA: anti-nuclear antibody; CK: creatine kinase; GC: glucocorticoid; IQR: interquartile range; MMF: mycophenolate mofetil; MTX: methotrexate; no: number.

Conclusion: ABA was found to be a safe and effective treatment for jLS patients who previously failed MTX and/or MMF. There were no serious AE. Patients treated with ABA had a decrease in both skin and joint activity. Seventy percent of GC treated patients were able to discontinue GC. Prospective studies should be done to further evaluate ABA's efficacy, potentially as stand-alone therapy and/or in combination with DMARDs.

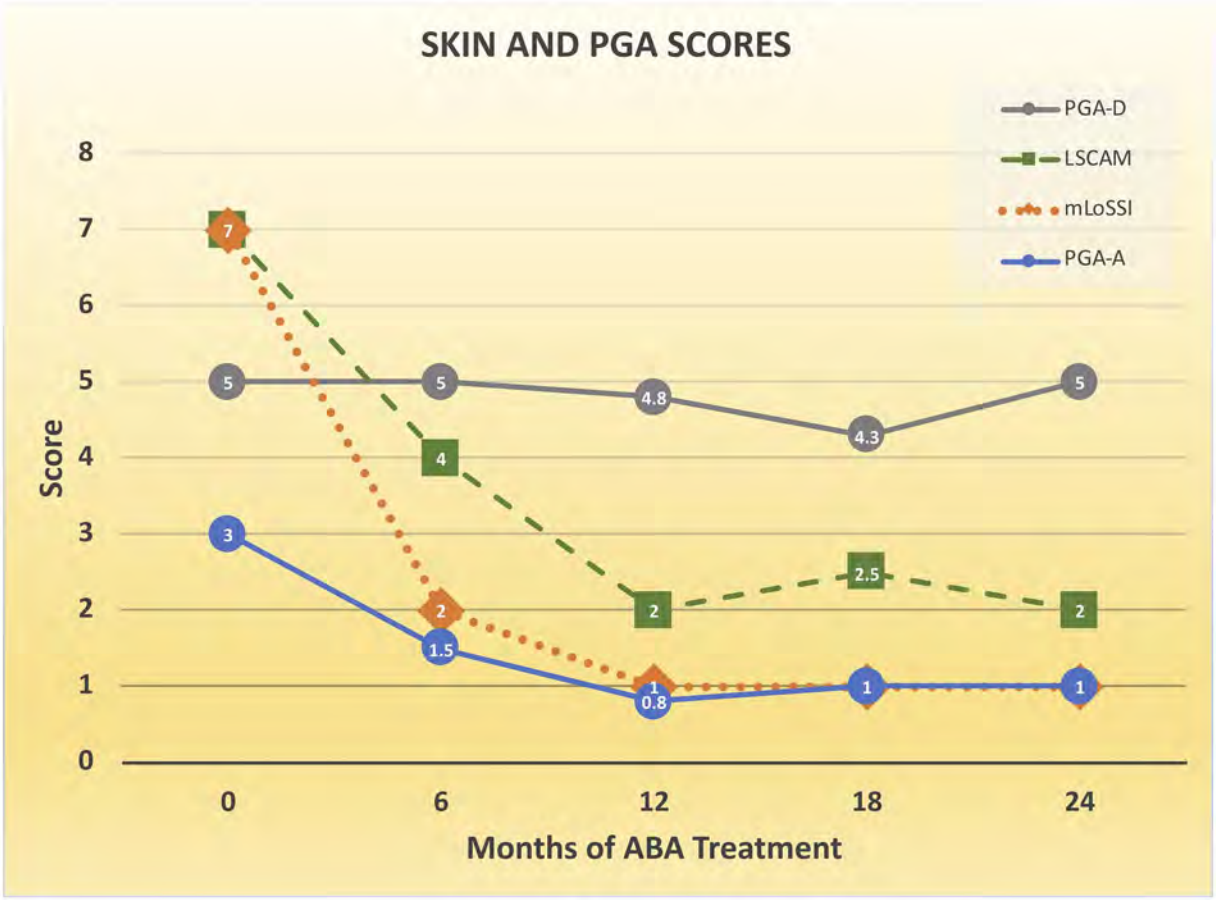

Figure 1. Change in skin activity and physician global assessment scores on ABA. Skin Activity measures were mLoSSI and LSCAM. Physician global assessment were of activity (PGA-A) and damage (PGA-D). mLoSSI sums 3*disease extension + erythema + skin thickening across affected sites, LSCAM sums same variables without weighting disease extension, and also includes scoring for violaceous color, waxy white/ yellow, and tactile warmth features. Number of patients that were scored at each time point: 18 at 0, 6 months; 17 at 12 months; 14 at 18 months, 11 at 24 months. Reasons for missing visits were: discontinuation of abatacept prior to 24 months (because of adverse event [2], pregnancy [1], persistent disease activity [1]), end of study collection period (2), and patient moved out of state (1). LSCAM: Localized scleroderma cutaneous activity measure mLoSSI: modified localized scleroderma severity index PGA-A = Physician global assessment of disease activity PGA-D = Physician global assessment of disease damage

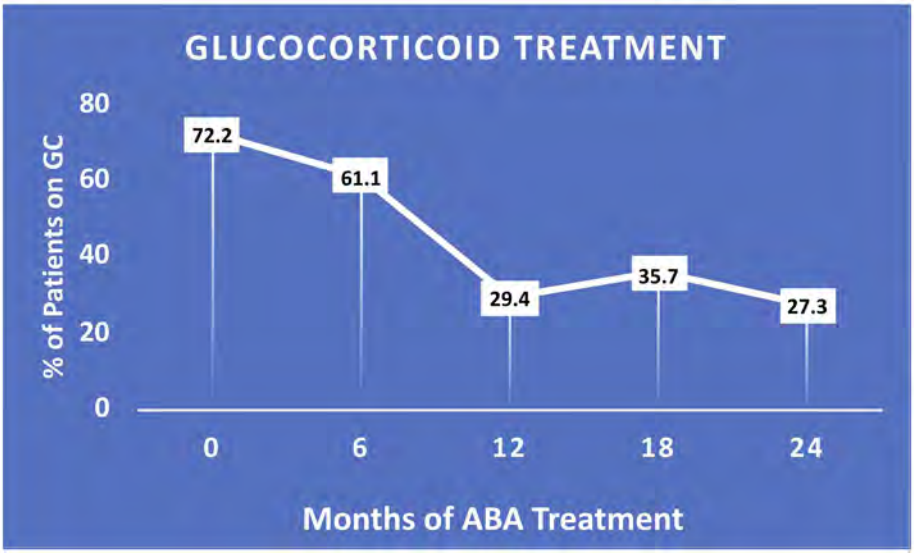

Figure 2. Concomitant glucocorticoid treatment with Abatacept treatment The percent of patients on glucocorticoid treatment at each study visit is shown. Overall, 14 patients were treated with glucocorticoids during the study, 13 begun at baseline and an additional 1 by 6 month visit. Percentages shown are based upon total number of patients at each study visit; 18 patients at 0 and 6 month, 17 at 12 month, 14 at 18 month, and 11 at 24 month visit. Ten patients discontinued glucocorticoids by their last study visit.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Pediatric Rheumatology – Clinical III: Systemic Autoimmune Disease

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: To analyze 1H-MRS brain metabolites in a longitudinal study and to determine clinical, laboratory and treatment features associated with its occurrence. To determine, additionally if sera Th1 (IL-12, TNF-α, IFN-γ), Th2 (IL-6 and IL-10), Th17 (IL-17) cytokines levels, neurofilament (NF-H) and S100β influence brain metabolite levels.

Methods: We included 123 consecutive cSLE patients [median age 16 years (range 7-31)] from the Pediatric Rheumatology outpatient unit and 76 healthy controls (HC) [median age 18 years (8-33)]. All patients underwent two magnetic resonance imaging (MRI) exams during a period of 13.5 ± 9.4 months. We performed multi voxel 1H-MRS using point resolved spectroscopy sequence over the superior–posterior region of the corpus callosum (3T Phillips®scanner) and signals from N-acetylaspartate compounds (NAA), choline-based compounds (Cho); creatine containing compounds

(Cr), glutamate (Glu), glutamine (Gln) and lactate (Lac) were measured and metabolites/Cr ratios were determined. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Mood and anxiety disorders were determined through Beck Depression and Beck Anxiety Inventory. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Th1 (IL-12, TNF-α, IFN-γ), Th2 (IL-6 and IL-10), Th17 (IL-17) cytokines levels, S100β and NF-H levels were measured by ELISA using commercial kits. Data were compared by non-parametric tests.

Results: NAA/Cr ratio (p=0.021) and Lac/Cr ratio (p=0.009) levels were significantly decreased and Glu/Cr ratio (0.004) and Gln/Cr ratio levels (p=0.042) were increased in cSLE patients when compared to HC. During follow-up time, no significant fluctuation in metabolites was observed in both groups. We observed that persistent reduction of NAA/Cr ratio was associated with neuropsychiatric manifestations [symptoms of anxiety (p=0.04), symptoms of depression (p=0.006)], presence of autoantibodies [antiphospholipid antibodies (p=0.03)] and cytokine levels [TNF-α (r=-0.546; p=0.0023) and INF γ (r=-0.746; p=0.0002)]. Persistent increased Cho/Cr ratio was associated with cognitive dysfunction (0.003), anti-SM (0.005), and correlated with S100β (r=0.641; p=0.005) and NF-H (r=-0.225, p=0.05). Increased Glu/Cr ratio was associated with stroke (0.043) and symptoms of depression (p= 0.0007).

Conclusion: We observed significant persistent axonal dysfunction in cSLE associated with increased inflammatory markers, autoantibodies and neuropsychiatric manifestations. Persistent axonal dysfunction could be a marker of future structural damage and patients should be followed-up closely.

Cardiovascular Risk in Rheumatoid Arthritis Patients Treated with Methotrexate versus Hydroxychloroquine

Mengdong He[1], Ajinkya Pawar[1], Rishi Desai[1], Robert Glynn[1], Hemin Lee[1], Michael Weinblatt[1], Daniel H Solomon[1] and Seoyoung Kim[1], [1]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments I: Maximizing Health in RA
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Rheumatoid arthritis (RA) is a known risk factor for cardiovascular (CV) events. While most RA patients use conventional disease-modifying antirheumatic drugs (DMARDs) such as methotrexate (MTX) and hydroxychloroquine (HCQ) as the 1st line DMARD, little is known about the comparative cardiovascular safety of these DMARDs. The objective of this study was to compare the incidence rate of CV events in RA patients initiating MTX versus HCQ as their 1st line therapy.

Methods: We conducted a cohort study of RA patients who initiated MTX or HCQ using Medicare claims data (Parts A/B/D 2008-2016) linked with the National Death Index. All patients were required to be ≥65 years old and have ≥365 days of continuous insurance enrollment and no prior use of any DMARDs at the cohort entry (i.e. MTX or HCQ initi-

Table 1. Selected baseline characteristics in the 1:1 propensity score matched cohort

Patient characteristics	MTX (N = 22,923)	HCQ (N = 22,923)	Standardized Difference
Demographics			
Age in years, mean (SD)	74.12 (6.64)	74.11 (6.63)	0.003

Abbreviations: SD- Standard deviation; IQR- Interquartile range; NSAIDs- Nonsteroidal anti-inflammatory drugs; Coxibs- Cyclooxygenase inhibitors; ARBs- Angiotensin II receptor blockers; ACEis- Angiotensin-converting enzyme inhibitors; PTCA- Percutaneous transluminal coronary angioplasty; CABG- Coronary artery bypass grafting.

ation date). Patients with a hospitalization for myocardial infarction (MI), unstable angina, stroke, transient ischemic attack, or heart failure (HF), or a procedure for coronary revascularization within 60 days prior to the cohort entry were excluded. The primary outcome was a composite endpoint of major adverse CV event (MACE) including MI, stroke, or CV mortality. Secondary outcomes included a modified definition of MACE (MI, stroke, or all-cause mortality), individual components of MACE, and hospitalized HF. To control for 59 baseline covariates, we used 1:1 propensity score (PS) matching. For the primary as-treated analysis, Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) of the primary and secondary outcomes.

Results: We included a total of 22,923 PS-matched pairs of MTX and HCQ initiators with a mean (standard deviation) age of 74 (7) years and 80% female. Even before PS matching, baseline characteristics were similar between the two groups except 6% higher steroids use among MTX initiators. After PS matching, all the patient characteristics were well balanced (**Table 1**). Over a median of 212 days (interquartile range 105-529 days) on treatment, 660 MACE occurred in MTX initiators and 610 in HCQ initiators. The incidence rate (per 1,000 person-years) of MACE was 23.38 (95% CI 21.63-25.23) in the MTX group and 24.32 (95% CI 22.43-26.33) in the HCQ group (**Table 2**). The HR for MACE associated with MTX versus HCQ initiation was 0.96 (95% CI 0.86-1.08). The two groups had no different

Table 2. Incidence rates and hazard ratios (95% CI) of primary and secondary outcomes in the 1:1 propensity score matched cohort

Outcome	Exposure group	Number of events	Total person-years	Incidence rate per 1,000 person-years (95% CI)	Hazard ratio (95% CI)
Primary outcome					
MACE (MI, stroke, or CV mortality)	MTX	660	28,234	23.38 (21.63-25.23)	0.96 (0.86-1.08)
	HCQ	610	25,080	24.32 (22.43-26.33)	Ref.
Secondary outcome					
Modified MACE (MI, stroke, or all-cause mortality)	MTX	1,173	28,221	41.56 (39.22-44.01)	0.95 (0.88-1.03)
	HCQ	1,092	25,074	43.55 (41.01-46.21)	Ref.
MI	MTX	241	28,403	8.49 (7.45-9.63)	0.80 (0.67-0.95)
	HCQ	269	25,197	10.68 (9.44-12.03)	Ref.
Stroke	MTX	226	28,471	7.94 (6.94-9.04)	1.33 (1.08-1.63)
	HCQ	152	25,278	6.01 (5.10-7.05)	Ref.
CV mortality	MTX	256	28,671	8.93 (7.87-10.09)	0.86 (0.72-1.02)
	HCQ	263	25,411	10.35 (9.14-11.68)	Ref.
All-cause mortality	MTX	821	28,656	28.65 (26.72-30.68)	0.91 (0.82-1.00)
	HCQ	795	25,404	31.29 (29.16-33.55)	Ref.
Hospitalized heart failure	MTX	244	28,484	8.57 (7.53-9.71)	0.60 (0.51-0.71)
	HCQ	358	25,141	14.24 (12.80-15.79)	Ref.

Abbreviations: CI- Confidence interval; MACE- Major adverse cardiovascular event; MI- Myocardial infarction; CV- Cardiovascular; Ref.- Reference.

risk for the modified MACE (HR 0.95, 95% CI 0.88-1.03), CV mortality (HR 0.86, 95% CI 0.72-1.02), and all-cause mortality (HR 0.91, 95% CI 0.82-1.00). However, comparing MTX with HCQ initiators, we observed an increased risk of stroke (HR 1.33, 95% CI 1.08-1.63), but a decreased risk of MI (HR 0.80, 95% CI 0.67-0.95) and hospitalized HF (HR 0.60, 95% CI 0.51-0.71) (**Table 2**).

Conclusion: In this large observational study of 45,846 older RA patients enrolled in Medicare, we found no difference in the risk of MACE between patients who newly received MTX versus HCQ. However, results from the secondary analyses were different with respect to individual endpoints – a greater stroke risk but a lower risk of MI and hospitalized HF in MTX than HCQ initiators.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Treatments I: Maximizing Health in RA

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: A new dimension has been added to the link between diet and health, the gut microbiome. Of particular interest is the influence of diet on the microbiome and how this affects pain/inflammation by modifying circulating pro/anti-inflammatory metabolites. Microbiome-derived metabolites have been related to beneficial or deleterious effects on the host. Thus, changes in diet and microbiome might change the systemic metabolite profiling and influence pain and inflammation in rheumatoid arthritis (RA). We recently described that RA patients exposed to an anti-inflammatory ITIS diet had improvement of clinical outcomes. Here, we examine the effect of the ITIS diet on gut microbiome and fecal and plasma metabolome in RA patients.

Methods: We conducted an open-label pilot trial to evaluate feasibility and efficacy of a 2-week anti-inflammatory diet (ITIS) in RA patients. 17 patients with active RA (at least 3 tender and 3 swollen joints) participated. Physical examination and collection of fecal and plasma samples for microbiome and metabolomics were performed at each visit. Using a 50% pain improvement, patients were categorized as responders (R, N=11) or non-responders (NR, N=6). 16S rRNA gene amplicon profiling of the stools and untargeted mass spectrometry (MS)-based metabolomics in stool and plasma were performed. Dietary adherence was evaluated based on food logs and metabolomics readouts.

Results: Clinical outcomes showed significant improvements (pain: 3.9±2.3 before vs 2.45±2.4 after diet, $p< 0.01$; Clinical Disease Activity Index (CDAI): (29±11.7 before vs 12.7±11.3 after diet, $p< 0.001$). A diet score (up to 200) showed good adherence, with an average improvement of 148.18 (± 58.10). Changes due to diet intervention were captured by MS analysis and reflected the prescribed diet as well as the individual dietary diary entries (Figure 1A). Alpha diversity was higher at baseline in R (Figure 1B). Interestingly, R had a smaller change in alpha diversity after diet than NR suggesting that an already high alpha diversity with relatively limited capacity for further change may be necessary for response with this dietary intervention (Figure 1C). *Ruminococcaceae, Clostridium, Bacteroides and Lachnospira* genera negatively correlated with measures of disease activity at baseline, while *Enterobacteriaceae* positively correlated with the same measures. (Figure 1D). Baseline plasma metabolites profiles were different in R

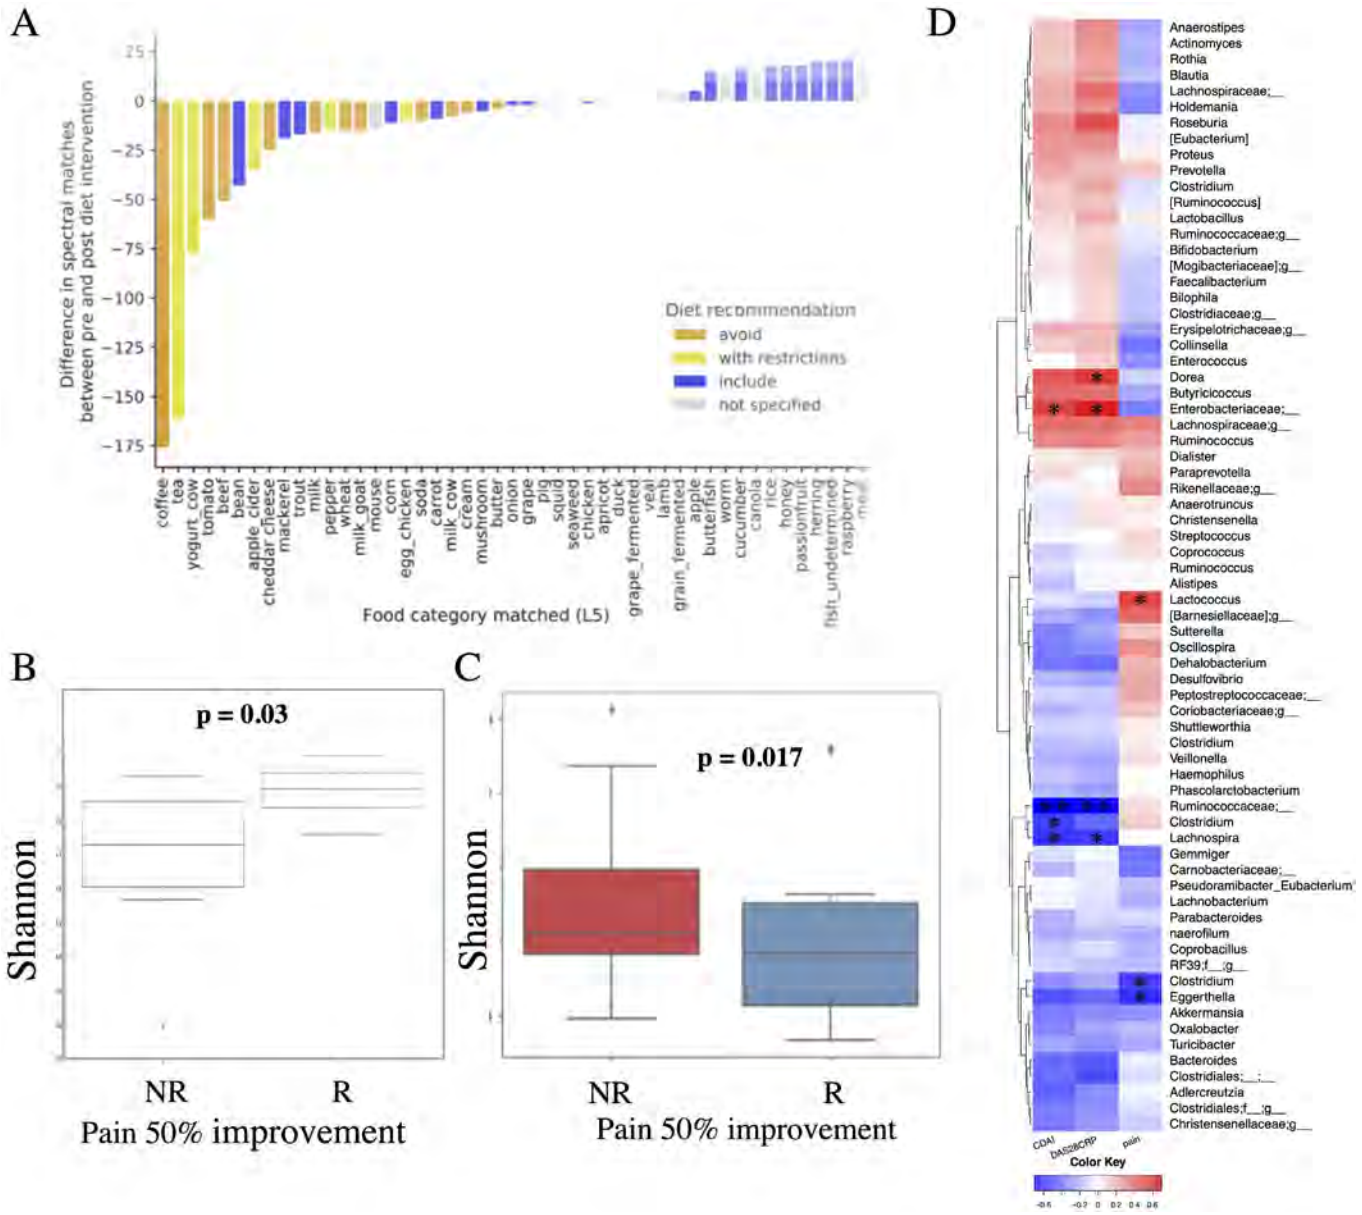

Figure 1. Adherence to diet and microbiome at baseline. A) Adherence to diet evaluated by the plasma metabolomics readout. B) Alpha diversity (Shannon) at baseline is significantly higher in patients with at least 50% pain improvement (R) compared to patients with a less than 50% improvement in pain (NR). C) Change in alpha diversity from day-14 (before diet) to day +14 (after diet) in R versus NR, assessed by at least 50% pain improvement. Boxes represent group means with standard deviations. D) Correlation (Spearman rank correlation) of bacterial genus with clinical outcomes at baseline (CDAI – clinical disease activity index, DAS28CRP – disease activity score using 28 joint count and C reactive protein). The significant correlations are marked with * ($p < 0.05$) or ** ($p < 0.01$).

compared to NR (Figure 2A). The differential analysis showed that responders of both Pain 50 and CDAI 70 were enriched for both conjugated linoleic acid (CLA) and Mollicutes or depleted in taurocholic acid, phosphocholines and Coriobacteriales (Figure 2B-C). Of interes, CLA is an anti-inflammatory metabolite previously associated with dietary changes in the number of types of plants eaten.

Conclusion: The "ITIS" diet induced changes in both metabolome and microbiome which correlate with clinical outcome measures. Further studies are needed to provide insight into specific long-term dietary interventions or supplements as a complementary treatment in RA, and to establish the scientific basis for using diet to adjust the gut microbiome to improve RA management.Figure 1. Adherence to diet and microbiome at baseline. A) Adherence to diet evaluated by

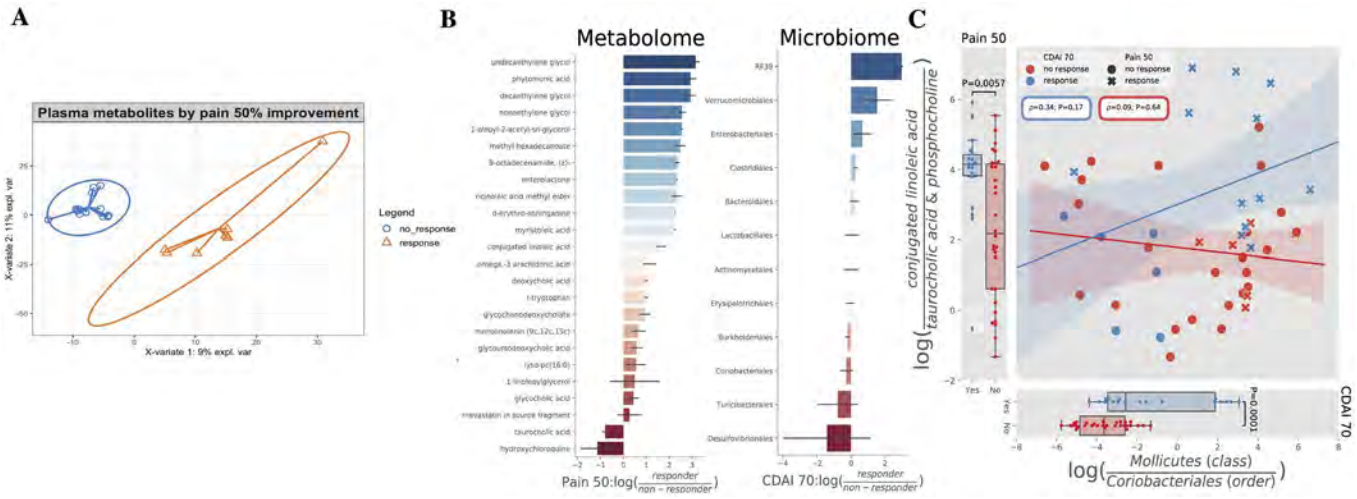

Figure 2. Plasma metabolome is different in R versus NR. A) Partial least square regression showing that plasma metabolome is different in R versus NR. B) Differential metabolites (left) and microbes (right) by chemical name and taxonomic order (y-axis) between responders and non-responders (x-axis). C) In the analysis of differential metabolomics Pain50 responders are enriched in conjugated linoleic acid (CLA) compared to non-responders (NR), while the Pain50 NR are enriched in the biliary metabolite taurocholic acid and phosphocholines compared to R (left). This trend was verified with a log-ratio between the two metabolite groups which is significant between R and NR (T=2.9, P=0.006). In the analysis of differential sub-operational taxonomic units by CDAI 70, Mollicutes were found to be enriched and Coriobacteriales depleted in R compared to NR (right). This trend was verified with a log-ratio between the two taxonomic orders which is significant between R and NR (T=4.22, P=0.0001). Error bars in all figures shaded by standard error. Correlation performed through spearman rank-order correlation. Log-ratio significance determined through two-sided T-test.

the plasma metabolomics readout. B) Alpha diversity (Shannon) at baseline is significantly higher in patients with at least 50% pain improvement (R) compared to patients with a less than 50% improvement in pain (NR). C) Change in alpha diversity from day-14 (before diet) to day +14 (after diet) in R versus NR, assessed by at least 50% pain improvement. Boxes represent group means with standard deviations. SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: RA – Treatments I: Maximizing Health in RA
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Vagus nerve stimulation (VNS) has been shown to improve rheumatoid arthritis (RA) disease severity in patients with refractory disease (1,2). A multi-center pilot study investigated the safety and efficacy of a wearable device to treat RA via electrical stimulation of the auricular branch of the vagus nerve.

Methods: Patients with active RA defined by ≥4 tender/swollen joints (28 jt count), DAS28-CRP >3.8, active synovitis detected on ultrasound and MRI, and who had inadequate response to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) were enrolled in the open-label pilot study. The primary endpoint was the change in the DAS28-CRP score at Week 12. Secondary endpoints included the mean change in HAQ-DI, the proportion of patients achieving ACR20/50/70, and the proportion of patients achieving a HAQ-DI of 0.22. Low disease activity (LDA) and remission were assessed based on DAS28-CRP (LDA if < 3.2; remission if < 2.6). MRI was performed at Weeks 0 and 12 and changes in synovitis, osteitis and bone erosion were assessed using the OMERACT-RAMRIS method. Safety and adverse events were assessed throughout the study.

Results: Thirty patients were enrolled and 27 completed the study. The mean age was 54 years, 90% were female, and the mean duration of disease was 7.3 years. The mean change in DAS28-CRP at Week 12 was -1.4 ($p < 0.001$) (Figure 1). Eleven patients (37%) attained LDA and 7 (23%) achieved remission. The mean percent change in the DAS28-CRP at Week 12 for patients with moderate and high disease activity was 24% and 27% respectively (Figure 2). ACR20/50/70 response rates were 53%, 33%, and 17% respectively. Individual components of DAS28-CRP and ACR scoring for all observed data appear in Table 1. The change in HAQ-DI from baseline was -0.47 ($p < 0.05$), and 57% of patients achieved an overall HAQ-DI reduction of 0.22 or more. The mean change in the OMERACT-RAMRIS synovitis, osteitis, and bone erosion scores at week 12 compared to baseline were -0.10 (p=0.16), -0.43 (p=0.46), and 0.047 (p=0.80), respectively. Four adverse events (AEs) were reported: 1 device-related AE due to a superficial skin abrasion where the earpiece contacts the ear and 3 non-device related AEs -- 2 accidental patient falls and one report of mucous build-up in the throat. All 4 AEs resolved without intervention or further sequelae.

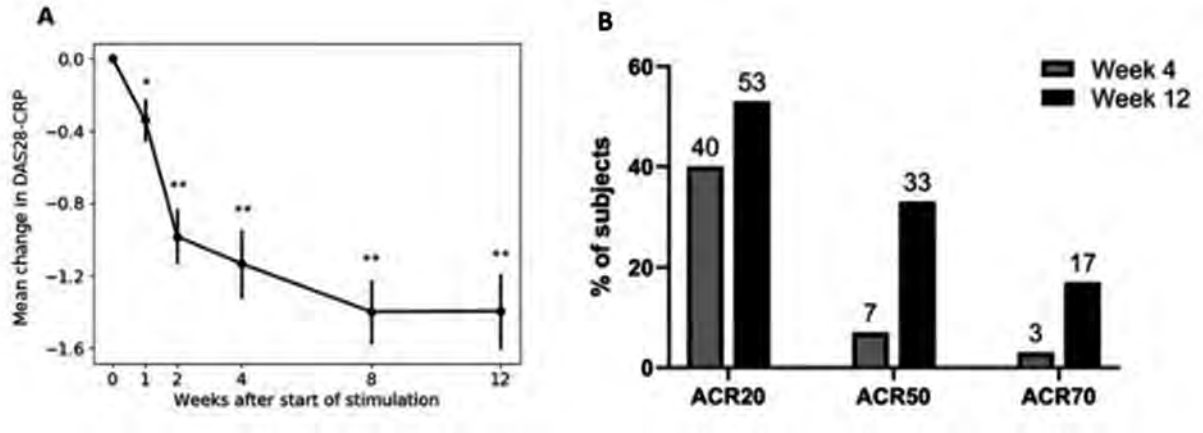

Figure 1. Primary and secondary endpoint. A) Mean change in DAS28-CRP score for each study visit. For the 27 patients who completed the study, there is a significant reduction in the DAS28-CRP after Week 1, and it continues to decrease through the end of the study. At Week 12, there is a mean reduction of 1.40 in the DAS28-CRP relative to Baseline. B) Percentage of all 30 patients that achieved ACR20/50/70 at Week 4 (grey) and Week 12 (black). The percentage of patients who met ACR20/50/70 is provided at the top of each bar. Patients who did not complete the study were deemed non-responders. One (*) asterisk indicates $p < 0.05$ and two (**) asterisks indicate $p < 0.01$. P-values were calculated using paired two-tail t-tests.

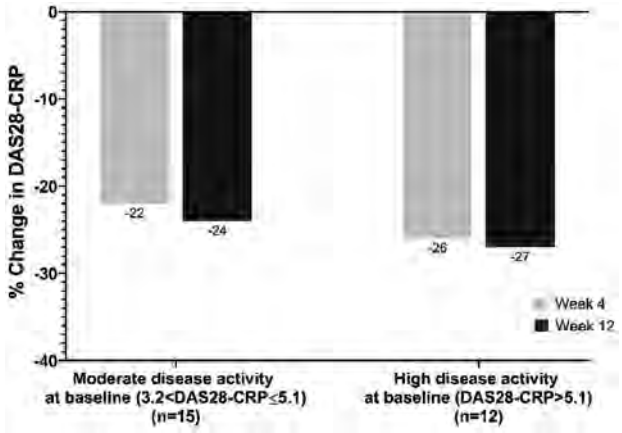

Figure 2 The mean change in DAS28-CRP score for patients with moderate or high disease activity at Baseline. The DAS28-CRP percentage change from Baseline is provided at the bottom of each bar.

Score or Component	Baseline (n=30), mean (SD)	Week 12 (n=27), mean (SD)	Change (n=27), mean (SD)	P-value
DAS28-CRP	5.30 (1.03)	3.76 (1.40)	-1.40 (1.16)	<0.0001
Tender joints	12.17 (3 – 28)	4.70 (5.83)	-6.74 (5.40)	<0.0001
Swollen joints	7.00 (2 – 16)	3.44 (3.90)	-3.15 (3.48)	<0.0001
HAQ-DI	1.59 (0.73)	1.05 (0.78)	-0.47 (0.61)	0.0004
Patient global health assessment	72.20 (19.97)	45.33 (31.60)	-24.89 (31.86)	0.0004
Physician global health assessment	56.17 (16.52)	29.62 (25.08)**	-27.16 (25.02)**	<0.0001
Pain score	75.23 (19.09)	43.30 (26.29)	-30.30 (28.67)	<0.0001
CRP (mg/L)	10.35 (11.63)	12.48 (21.27)	2.87 (16.05)	0.36

**Data only available for 25 patients
CRP = C-reactive protein; HAQ-DI = Heath activity questionnaire disability index

Table 1 Individual components of DAS28-CRP and ACR scoring for all observed data.

Conclusion: In this pilot study, transcutaneous stimulation of the auricular branch of the vagus nerve was well tolerated and improved signs and symptoms of RA. Further evaluation in larger controlled studies is needed to confirm whether this non-invasive vagus nerve stimulator might offer an alternative approach to the treatment of RA.

Evaluation of Response to Pneumococcal Vaccination in Patients with Rheumatoid Arthritis Receiving Upadacitinib: Results from a Phase 2 Open-Label Extension Study

Kevin Winthrop[1], Juan Vargas[2], Edit Drescher[3], Conrado Garcia[4], Alan Friedman[5], Jeffrey Enejosa[5], Nasser Khan[5], Yihan Li[5], Justin Klaff[5] and Alan Kivitz[6], [1]Oregon Health & Science University, Portland, OR, [2]Quantum Research, Puerto Varas, Chile, [3]Veszprém Csolnoky Ferenc County Hospital, Veszprém, Hungary, [4]Hospital General de México "Dr. Eduardo Liceaga", Mexico, Mexico, [5]AbbVie Inc., North Chicago, IL, [6]Altoona Center for Clinical Research/Altoona Arthritis and Osteoporosis Center, Duncansville, PA

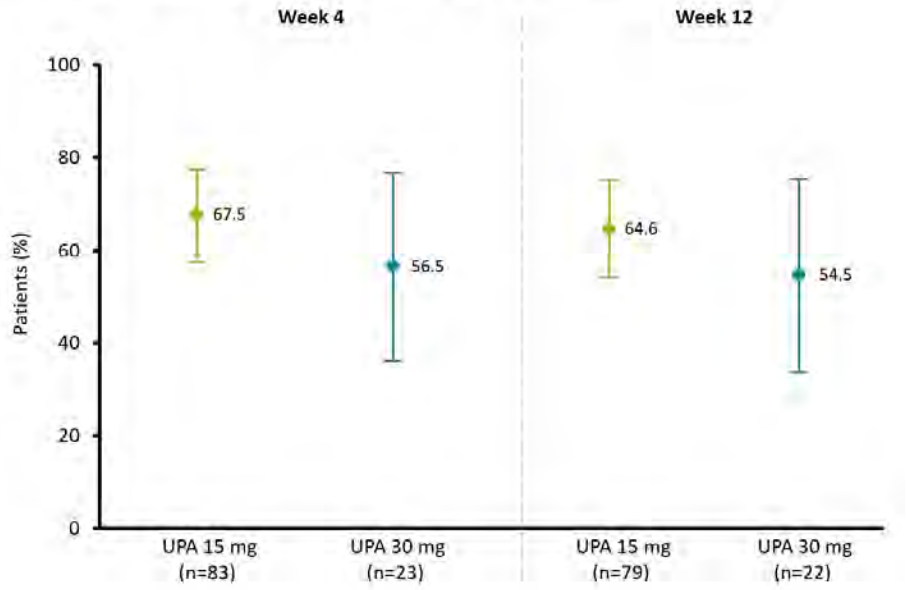
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments I: Maximizing Health in RA
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Pneumococcal vaccination is recommended in patients with RA who are receiving conventional synthetic/biologic DMARDs.[1] Upadacitinib (UPA) is an oral Janus kinase (JAK) inhibitor engineered to have a greater selectivity for JAK1 versus JAK2, JAK3, and tyrosine kinase 2, and is approved for the treatment of RA. The aim of this analysis was to assess the impact of long-term treatment with UPA + background MTX on immunologic responses to Prevnar 13® (Pneumococcal 13-valent Conjugate Vaccine [Diphtheria CRM_{197} Protein]; PCV13) in patients with RA enrolled in the ongoing Phase 2 open-label extension study BALANCE-EXTEND.

Methods: Patients from BALANCE-EXTEND receiving PCV13 vaccination were required to be on UPA 15 mg once daily (QD) or 30 mg QD and background MTX for ≥4 weeks prior to, and after, PCV13 vaccination; MTX was not interrupted prior to vaccination. Vaccination antibody titers were collected pre-vaccination (Week 0) and post-vaccination (Weeks 4 and 12). The primary variable was the proportion of patients with satisfactory humoral response to PCV13 (≥2-fold increase in antibody concentration from pre-vaccination [Week 0] in ≥6/12 pneumococcal antigens [1, 3, 4, 5, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F]) at 4 weeks post-vaccination.

Results: Of 111 patients (UPA 15 mg, n=87; UPA 30 mg, n=24), 86% were female, most (98%) were white, and mean (standard deviation) age was 58.4 (12.0) years. Prior to vaccination, patients had a median (range) duration of RA of 9.3 (3.4–35.0) years and had been receiving UPA for a median (range) of 3.9 (3.0–4.9) years. All but 3 patients were taking concomitant MTX, and 44.1% were taking a CS (median daily dose, 5.0 mg). All 111 patients received PCV13, none discontinued UPA during the first 4 weeks, and blood samples were available from 83/23 and 79/22 patients in the UPA 15/30 mg groups at Weeks 4 and 12, respectively. At 4 weeks, satisfactory humoral response to PCV13 occurred in 67.5% (95% confidence interval [CI]: 57.4–77.5) and 56.5% (95% CI: 36.3–76.8) of patients receiving UPA 15 and 30 mg, respectively. At 12 weeks, satisfactory humoral response to PCV13 occurred in 64.6% (95% CI: 54.0–75.1) and 54.5% (95% CI: 33.7–75.4) of patients receiving UPA 15 and 30 mg, respectively (**Figure 1**). There was no clear difference in response between patients receiving and not receiving concomitant CS. Within 30 days post-vaccination, 2 adverse events (AEs) were considered as possibly related to UPA (1 case of diverticulitis, UPA 15 mg; 1 case of anemia, UPA 30 mg) and no serious AEs were reported (**Table 1**). Two patients experienced pyrexia and 1 subject each experienced vaccination-site pain and headache within 1 day post-vaccination (all in UPA 15 mg group).

Figure 1. Proportion (%, 95% CI) of UPA-treated patients with satisfactory humoral response[a] to PVC13 at Weeks 4 and 12 (full analysis set)[b]



[a]Satisfactory humoral response was defined as ≥2-fold increase in antibody concentration from the vaccination baseline in ≥6 out of 12 pneumococcal antigens (1, 3, 4, 5, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F). [b]Number of patients based on availability of blood samples collected at Weeks 4 and 12. CI, confidence interval; PVC13, Pneumococcal 13-valent Conjugate Vaccine [Diphtheria CRM_{197} Protein]; UPA, upadacitinib

Table 1. Safety through 30 days post-PVC13 vaccination in UPA-treated patients (safety analysis set)

Event, n (%)	UPA 15 mg QD (n=87)	UPA 30 mg QD (n=24)
Any AE	15 (17.2)	3 (12.5)
Serious AE	0	0
AE leading to discontinuation of study drug	0	0
AE with reasonable possibility of being related to UPA[a]	1 (1.1)[b]	1 (4.2)[c]
Death	0	0

[a]As assessed by the investigator. [b]Diverticulitis. [c]Anemia. AE, adverse event; PVC13, Pneumococcal 13-valent Conjugate Vaccine [Diphtheria CRM_{197} Protein]; QD, once daily; UPA, upadacitinib.

Conclusion: Satisfactory humoral response to PCV13 at 4 weeks occurred in ~two-thirds of patients with RA receiving long-term treatment with UPA 15 mg QD + background MTX. This is broadly consistent with pneumococcal vaccine humoral responses observed in patients with RA treated with other JAK inhibitors, biologics, or placebo.[2–4]

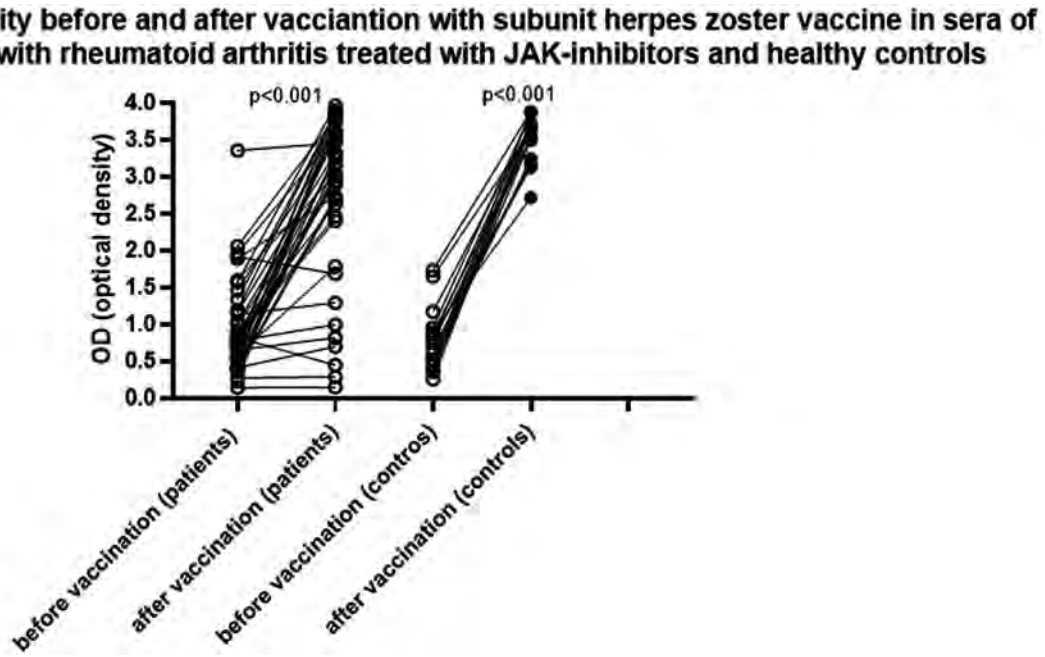
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments I: Maximizing Health in RA
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of contracting herpes zoster (HZ) and treatment with JAnus Kinase inhibitors (JAKi) further adds on to that risk. A novel subunit vaccine against HZ (HZ/su; Shingrix) composed of VZV glycoprotein E (gE) and adjuvant system $AS01_B$ has recently been licensed. The HZ/su vaccine has been shown safe and effective in healthy elderly but data on patients with rheumatic disease are scarce. The objective of this study was to investigate the antibody responses to the HZ/su vaccine in RA patients treated with JAKi and controls.

Methods: RA patients at the rheumatology outpatient department, Skåne University Hospital, Lund, Sweden, fulfilling the ACR87 criteria and receiving JAKi as monotherapy or in combination with other disease modifying anti-rheumatic drugs (DMARDs) and individuals ^{3}18 years without known rheumatic disease and not receiving immunosuppressive treatment for other conditions served as controls. All participants were immunized with two intramuscular doses of 50 mg HZ/su vaccine administered at least two months apart. Blood was sampled prior to first and 4-6 weeks after the second vaccine dose. ELISA using varicella zoster virus (VZV) glycoprotein E (gE) as the antigen was employed to measure anti-gE levels (1). Results are presented as optical density (OD). A positive antibody response was defined as a difference of ^{3}1.2 in OD between the post- and pre-vaccination sera. The difference between ODs before and after vaccination among patients and controls separately were calculated using Wilcoxon signed-rank test. Chi2 test was used to compare % of individuals with positive antibody response between the two groups.

Results: Data from 40 RA patients (mean age 62.3 years; 77.5% female, mean disease duration 16 years) treated with JAKi and 20 controls (mean age 61.5 years and 70% female) were analysed. Compared to prevaccination sera, OD levels increased significantly in both patients and controls ($p< 0.001$). Mean changes in anti-gE antibody OD between



post- and prevaccination sera were +1.8 and +2.6 for patients and controls respectively (Figure1). Positive humoral responses (delta OD[3]1.2) were observed in 75% of patients and 100% of controls (p=0.014). The majority of patients reported mild to moderate vaccine related side effects (pain and redness at the injection site, headache, fever for a few days) which resolved without any treatment. In total, 3 patients and 0 controls withdrew from the study prior to the second vaccine dose, 2 of these due to adverse events (diarrhoea, joint and muscle pain) and are not included in these preliminary results. No patient experienced worsening or flare of RA. No case of HZ has been reported yet (up to 15 months after start of enrolment in the study).

Conclusion: These preliminary results show satisfactory serological responses and acceptable tolerability of two doses HZ/su vaccine in RA patients treated with JAKi known to be at a particularly increased risk of HZ.

Session Date: Monday, November 9, 2020

Session Title: RA – Treatments II: Potential Harms & Adverse Events

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Although glucocorticoids (GC) remain an essential part of the therapeutic strategy in Rheumatoid Arthritis (RA), the long-term risk of adverse events of low-dose GC treatment is still controversial.

Methods: We analysed data from the early arthritis (less than 6 months' disease duration) ESPOIR cohort. Patients were stratified in two groups, with or without GC treatment at least once during their follow-up (median 10 years IQR [9-10]). The primary outcome was a composite of death, cardiovascular diseases (CVD) (including myocardial ischemia, cerebrovascular accident and heart failure), severe infection and fracture. In order to reduce the impact of treatment selection bias and potential confounding factors, the weighted Cox time-dependent analysis model was used with inverse probability of treatment weighting (IPTW) propensity score method.

Results: Among the 608 RA patients (480 women, mean age of 47.5 ± 12.1 years), 397 patients (65%) received low-dose prednisone (mean 2.8 ±2.8 mg/d, median 1.9 mg/day [IQR 0.6-4.2], mean cumulative GC dose of 8468 mg ±8376), mainly during the first 6 months (70%). The mean duration of GC treatment was 44.6 months ± 40.1. Overall,

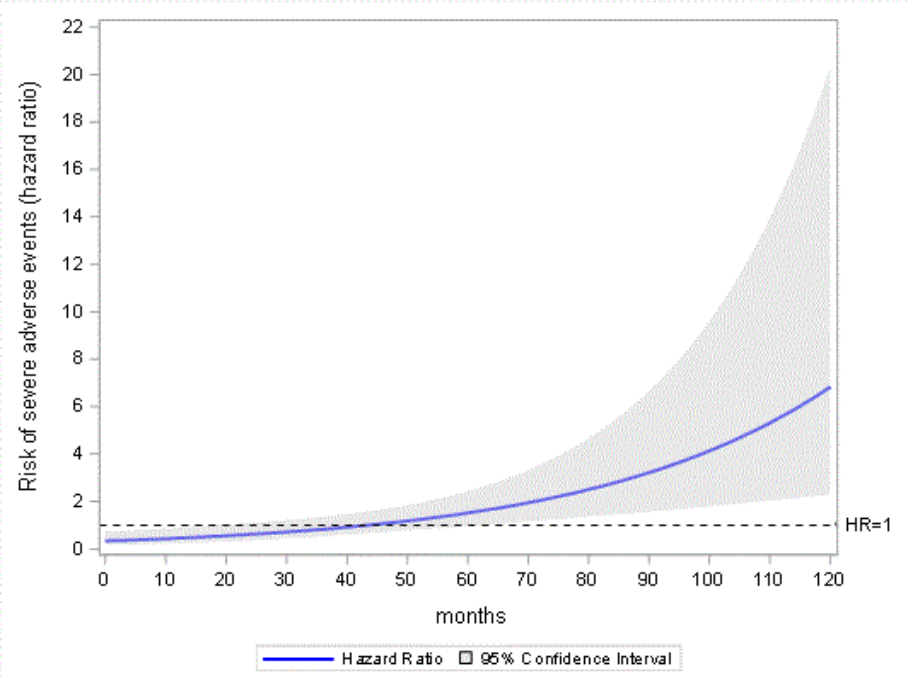
Table 1. Primary outcome at 10 years (death, cardiovascular disease, severe infection or fracture) in the total sample and with and without glucocorticoid (GC) (univariate analysis).

	Total study population (n=608)	Without GC	With GC	P Value
Primary outcome	95 (15.6%)	24 (11.4%)	71 (17.9%)	**0.035**
Death	10 (1.6%)	1 (0.5%)	9 (2.3%)	0.103
Cardiovascular diseases	18 (3%)	3 (1.4%)	15 (3.8%)	0.177
Severe infections	35 (5.8%)	5 (2.4%)	30 (7.6%)	**0.009**
Fractures	32 (5.3%)	15 (7.1%)	17 (4.3%)	0.137

Table 2: Time-dependent relationship between glucocorticoids treatment and risk of severe adverse events estimated by hazard ratio

Time (Years)	Hazard Ratio (95% CI)
1	0.46 (0.23 - 0.90)
2	0.62 (0.36 - 1.08)
3	0.83 (0.52 - 1.33)
4	1.12 (0.73 - 1.72)
5	1.52 (0.96 - 2.40)
6	2.05 (1.19 - 3.52)
7	2.77 (1.44 - 5.34)
8	3.74 (1.69 - 8.26)
9	5.05 (1.98 - 12.91)
10	6.83 (2.29 - 20.35)

Figure 1: Time-dependent relationship between glucocorticoids treatment and risk of severe adverse events estimated by hazard ratio (HR)



95 events were identified during the follow-up: 10 deaths, 18 CVD, 32 fractures and 35 severe infections. Based on univariate analysis at 10 years, patients taking GC experienced significantly more events (n=71) than those without GC (n=24) (p=0.035) (table1). Interestingly, we evidenced a significant cumulative dose-effect (p=0.007), particularly for the risk of severe infections (p=0.024) and CVD (p=0.001). On weighted Cox time-dependent analysis, using the IPTW propensity score method, the risk of events over time was significantly associated with GC treatment ($p < 0.001$), age, history of hypertension and erythrocyte sedimentation rate (figure1). The risk associated with GC treatment, estimated by the hazard ratio (HR), increased between the first follow-up visit (HR at 6 months = 0.39, 95% CI 0.19-0.82) and 10 years (HR=6.83, 95% CI 2.29-20.35) (table 2).

Conclusion: The 10-year analysis of this prospective early RA cohort supports a dose and time-dependent impact of very low-dose GC treatment, with a long-term high risk of severe outcomes.

Hydroxychloroquine Is Not Cardiotoxic in Patients with Rheumatoid Arthritis

Jose Felix Restrepo[1], Agustin Escalante[1], Daniel Battafarano[2], Carlos Lorenzo[3] and Inmaculada Del Rincon[1], [1]University of Texas Health Science Center at San Antonio/ Department of Medicine/ Rheumatology, San Antonio, TX, [2]San Antonio Military Medical Center, San Antonio, TX, [3]University of Texas Health Science Center at San Antonio, San Antonio, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments II: Potential Harms & Adverse Events
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Hydroxychloroquine (HCQ) has been proposed as a potential treatment for COVID-19, but early reports suggested that it could have cardiotoxic effects. Despite widespread and longstanding use to treat rheumatic diseases, cardiotoxicity was not on the risk radar of most rheumatologists prescribing HCQ. Our objective in the present analysis is to examine the risk of cardiotoxicity among members of a well-characterized RA cohort who were receiving HCQ.

Methods: We studied RA patients meeting the 1987 ACR criteria, recruited from public, private, military, and Veterans Administration rheumatology clinics. Patients were invited to participate in yearly follow up evaluations in which we ascertained clinical and laboratory features, including HCQ use. The assessment included an electrocardiogram and a detailed medical record review.

We ascertained cardiac events, including myocardial infarction (MI), cardiomyopathy, cardiac conduction disorders, or cardiac dysrhythmias in all patients. We also ascertained vital status in all participants, obtaining a certificate for all deaths. We compared the frequency of these events between patients who received HCQ and patients who did not receive it using generalized estimating equation (GEE) models, including all follow-up visits. We considered HCQ exposure in three categories: Those who did not receive HCQ during the study period, those who were receiving it during some of the visits, and those who were receiving it at all of the visits. We adjusted for the propensity to receive HCQ to control for potential bias for indication.

Results: We studied 1328 patients, 981 of whom were women (74%). These patients completed 5826 visits, for a total of 8336 patient-years (pt-yrs) of follow up. There were 114 patients who were receiving HCQ at every one of 338 visits, for 347 pt-yrs; 323 patients who were receiving HCQ during some of 1742 visits, for 2793 pt-yrs; and 891 patients who were not receiving HCQ at any of 3746 visits, for 5147 pt-yrs. We ascertained 120 cases of MI, 185 of cardiac dysrhytmias, 13 cardiomyopathies, and 21 cases with conduction disorders. The table below shows the number and incidence of these events per 100 pt-yrs for each of the HCQ exposure categories.

We did not find significant differences in the risk of cardiomyopathy, conduction disorders, or MI between the three HCQ exposure categories. Cardiac dysrhythmias were significantly less likely to occur in patients who were taking HCQ compared to patients who were not taking it (OR 0.61, 95% CI 0.37-0.96, p= 0.03). The GEE regression models according to HCQ exposure, adjusted by age and sex, did not uncover associations between HCQ and cardiac events use (Table), nor did adding a score for the propensity to receive HCQ to the models. Patients who were receiv-

	Visits Receiving Hydroxychloroquine		
Cardiac Events	**All**	**Some**	**None**
Myocardial Infarction	4, 1.1 (0.03, 2.9)	29, 1.0 (0.6, 3.7)	87, 1.6 (1.3,2.0)
Conduction Disorder	1, 0.2 (0.007, 1.6)	5, 0.1 (0.05, 0.4)	15, 0.2 (0.1, 0.4)
Cardiomyopathy	0	4, 0.1 (0.03, 0.3)	9, 0.1 (0.07, 0.3)
Cardiac Dysrhytmias	6, 1.7 (0.6, 3.7)	50, 1.7 (1.3, 2.3)	129, 2.5 (2.0, 2.9)

	Values represent the number of events observed, and incidence per 100 patient-years (95% confidence intervals)		

Table. Observed events and incidence of cardiotoxicity events according to HCQ exposure.

ing HCQ continuously had significantly lower mortality than those who were not receiving it at any of the visits (OR 0.55, 95% CI 0.40, 0.76, p < 0.0001).

Conclusion: Our findings suggest that HCQ is not associated with an increased risk of cardiotoxicity among RA patients. Moreover, HCQ exposure may be associated with a reduction in mortality among RA patients. HCQ appears to be safe among RA patients in terms of its cardiac effects.

Risk of Venous Thromboembolism in Rheumatoid Arthritis Patients Treated with Methotrexate versus Hydroxychloroquine

Mengdong He[1], Ajinkya Pawar[1], Rishi Desai[1], Robert Glynn[1], Hemin Lee[1], Michael Weinblatt[1], Daniel H Solomon[1] and Seoyoung Kim[1], [1]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments II: Potential Harms & Adverse Events
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Prior studies suggest an increased risk of venous thromboembolism (VTE) among patients with rheumatoid arthritis (RA). However, little is known about the comparative risk of VTE associated with the 1st line conventional disease-modifying antirheumatic drugs (DMARDs), methotrexate (MTX) and hydroxychloroquine (HCQ). The objective of this study was to compare the incidence rate of VTE in RA patients who were newly treated with MTX versus HCQ.

Methods: Using Medicare claims data (Parts A/B/D 2008-2017), we identified RA patients who were new users of MTX and HCQ and had no prior use of any DMARDs. Patients were required to be ≥65 years old at the cohort entry (i.e. MTX or HCQ initiation date) and have ≥365 days of continuous insurance enrollment. Patients with a diagnosis of VTE, cancer (except non-melanoma skin cancer), or lupus, or use of anticoagulants or chloroquine at baseline were excluded. The primary outcome was VTE, defined as an inpatient primary diagnosis of pulmonary embolism (PE) or deep vein thrombosis (DVT). Secondary outcomes included VTE defined as an inpatient or outpatient diagnosis of PE or DVT plus a dispensing of anticoagulants within 30 days, and separate PE and DVT based on an inpatient primary diagnosis. Using as-treated analysis, the study participants were followed from one day after the cohort entry until the earliest event of the outcome, treatment discontinuation or switch, insurance disenrollment, death, or end of data. To control for confounding, MTX and HCQ new users were 1:1 matched on the propensity score (PS) that was estimated based on patient baseline demographics, comorbidities, medication use, medical procedures, and healthcare utilization. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox proportional hazards models.

Results: We identified a total of 26,534 PS-matched pairs of MTX and HCQ initiators. Their mean (standard deviation) age was 74 (7) years and 79% were female. We observed a slightly higher proportion of steroids use in the MTX group before PS matching, but the patient baseline characteristics in the PS matched cohort were well balanced between the two treatment groups (**Table 1**). In the primary analysis, 208 MTX and 83 HCQ new users developed VTE during a median follow up of 190 days (interquartile range 93-452 days). The incidence rate (per 1,000 person-years) was 6.94 (95% CI 6.03-7.95) in the MTX group and 3.11 (95% CI 2.47-3.85) in the HCQ group (**Table 2**). The HR for incident VTE

Table 2. Incidence rates and hazard ratios (95% CI) of primary and secondary outcomes for MTX and HCQ new users in the propensity score matched cohort

Outcome	Exposure group	Number of events	Total person-years	Incidence rate per 1,000 person-years (95% CI)	Hazard ratio (95% CI)
VTE (Primary)*	MTX	208	29,963	6.94 (6.03-7.95)	2.26 (1.75-2.91)
	HCQ	83	26,723	3.11 (2.47-3.85)	Ref.
VTE (Secondary)**	MTX	371	29,780	12.46 (11.22-13.79)	1.64 (1.38-1.95)
	HCQ	203	26,605	7.63 (6.62-8.76)	Ref.
PE	MTX	132	30,045	4.39 (3.68-5.21)	3.30 (2.28-4.77)
	HCQ	36	26,752	1.35 (0.94-1.86)	Ref.
DVT	MTX	80	30,073	2.66 (2.11-3.31)	1.53 (1.07-2.19)
	HCQ	47	26,741	1.76 (1.29-2.34)	Ref.

Abbreviations: CI- Confidence interval; VTE- Venous thromboembolism; PE- Pulmonary embolism; DVT- Deep vein thrombosis; Ref.- Reference.

* The primary definition of VTE: ≥1 inpatient primary diagnosis of PE or DVT.

** The secondary definition of VTE: ≥1 inpatient or outpatient diagnosis of PE or DVT plus ≥1 dispensing of anticoagulants within 30 days.

comparing MTX with HCQ initiators was 2.26 (95% CI 1.75-2.91) using the primary definition and 1.64 (95% CI 1.38-1.95) using the more sensitive but less specific secondary definition. The results were consistent in the analyses of PE and DVT, separately (**Table 2**).

Conclusion: In this large cohort of older RA patients, we observed an approximately 2-fold increased risk of VTE among patients who were newly treated with MTX versus HCQ. The comparative thrombotic safety profile of MTX and HCQ should be considered when physicians treat newly diagnosed RA patients with known VTE risk factors.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments II: Potential Harms & Adverse Events
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Low dose methotrexate (LD-MTX), a cornerstone in the treatment of rheumatoid arthritis, is associated with a moderately increased risk of anemia and leukopenia, but the risk of myelosuppression during LD-MTX use of up to 20mg/week remains incompletely described. We examined the hematologic outcomes among patients taking LD-MTX versus placebo in a large randomized controlled trial (RCT).

Methods: We pre-specified secondary analyses of a double-blind placebo-controlled RCT that included adults with known cardiovascular disease plus diabetes or metabolic syndrome in the US and Canada. Subjects with rheumatic disease were excluded. Subjects were randomly allocated to LD-MTX (20mg/week maximum) or placebo, and all subjects received folic acid 1mg daily for six days/week. Laboratory monitoring was performed every 1-2 months. Abnormal cell count definitions were pre-specified according to the Common Terminology Criteria for Adverse Events (CTCAE v.5.0). We assessed the frequency of blindly adjudicated hematologic adverse events (AEs) and laboratory abnormalities.

Results: 2,391 subjects were randomized to LD-MTX (mean dosage 14.9 mg/week) and 2,395 to placebo. Simultaneous two-line cytopenias were infrequent in both the LD-MTX arm (n=92, 3.9%) and the placebo arm (n=70, 2.9%) during follow-up. Pancytopenia was rare but numerically more common among patients randomized to LD-MTX (n=13, 0.5%) versus placebo (n=6, 0.3%). We examined the cases of LD-MTX-associated pancytopenia in detail (see **Table 1**). Pancytopenia developed as soon as 4 months and as late as 3.5 years after beginning LD-MTX, though the latter subject was diagnosed with multiple myeloma a week prior. The median age of subjects who developed pan-

Case	Age (years)	Sex	LD-MTX Dose at time of event (mg/week)	Duration of LD-MTX use prior to event (months)	BMI (kg/m2)	Alcohol use at baseline	Tobacco use at baseline	Aspirin use at baseline	Other Anti-coagulant use at baseline	Hgb (g/dL)		WBC (k/μL)		PLT (k/μL)		Study Drug Change

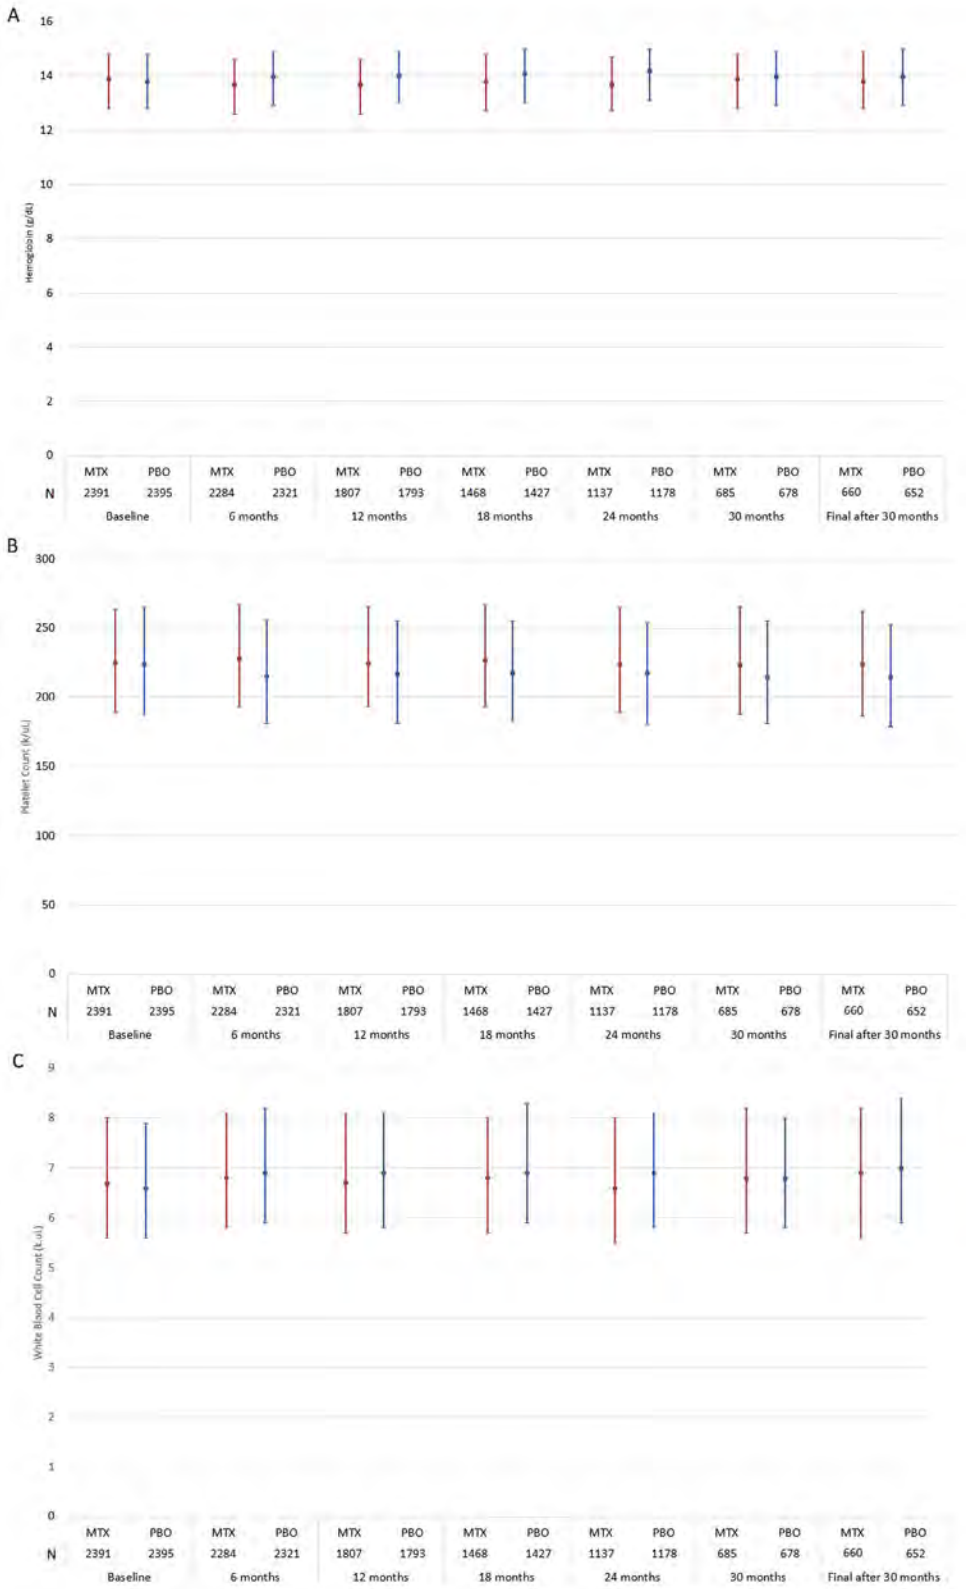
Hgb, hemoglobin; WBC, white blood cell count; PLT, platelet count; LD-MTX, low dose methotrexate

cytopenia was 70.5 years (interquartile range, IQR 69, 75), compared to a median age of 65.6 years (IQR 59.7, 71.8) in the entire LD-MTX arm. The platelet counts in all 13 cases showed only mild reductions.

Figure 1 presents median hemoglobin levels and platelet and leukocyte counts during follow-up. Baseline values represent the end of the active follow-up period immediately before randomization. Between baseline and final study visits, median hemoglobin decreased in both arms: by 0.40g/dL (IQR -0.90, 0.10) in the LD-MTX arm and by 0.10g/dL (IQR -0.60, 0.30) in the placebo arm. White blood cell counts did not change in the LD-MTX arm (median change 0.00k/uL; IQR -0.90, 0.80) and increased by 0.20k/uL in the placebo arm (IQR -0.70, 1,10). The median platelet count did not change in the LD-MTX arm (median change 0.00k/uL; IQR, -18, 16k/uL) but decreased by 9k/uL (IQR -26, 9) in the placebo arm.

Conclusion: Among subjects using LD-MTX, simultaneous two-line cytopenias and pancytopenia were uncommon. The absolute reductions in hemoglobin were small, white blood cell counts did not change between baseline and end of follow-up, and platelet counts decreased in the placebo arm but not in LD-MTX. These findings offer reassurance about the hematologic safety of LD-MTX.



This figure represents the median (filled circle) and interquartile range for (A) hemoglobin, (B) platelet count and (C) white blood cell (WBC) count during the CIRT trial. Compared to baseline, by the end of the study, the median hemoglobin value among patients randomized to LD-MTX decreased by 0.4 g/dL (IQR -0.90, 0.10) and decreased by 0.1 mg/dL (IQR -0.60, 0.30) among those randomized to placebo. The median platelet count did not change in the LD-MTX arm (IQR -18, 16 k/uL) and decreased by 9 k/uL (IQR -26, 9) among those randomized to placebo. The median WBC count did not change in the LD-MTX arm (IQR -0.90, 0.80) and increased by 0.2 k/uL (IQR -0.70, 1.10) in the placebo arm. LD-MTX, low dose methotrexate. PBO, placebo.

Incidence and Risk Factors for Herpes Zoster in Rheumatoid Arthritis Patients Receiving Upadacitinib

Kevin Winthrop[1], Peter Nash[2], Kunihiro Yamaoka[3], Eduardo Mysler[4], Leonard Calabrese[5], Nasser Khan[6], Jeffrey Enejosa[6], Yanna Song[7], Jessica Suboticki[6] and Jeffrey Curtis[8], [1]Oregon Health & Science University, Portland, OR, [2]School of Medicine Griffith University, Brisbane, Queensland, Australia, [3]Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan, [4]Organización Medica de Investigación, Buenos Aires, Argentina, [5]Cleveland Clinic, Cleveland, OH, [6]AbbVie Inc., North Chicago, IL, [7]AbbVie Inc., North Chicago,, IL, [8]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Treatments II: Potential Harms & Adverse Events

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

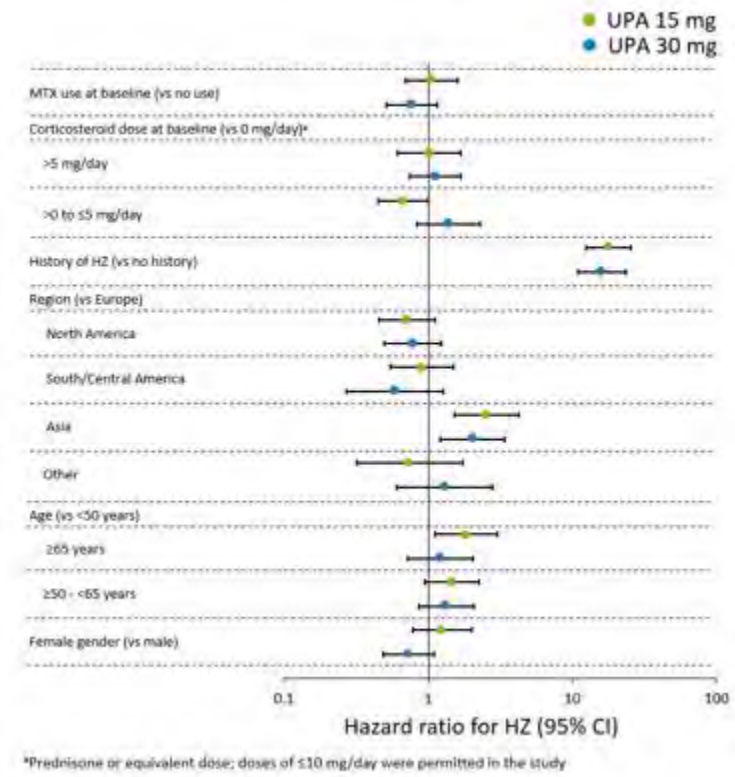
Background/Purpose: Upadacitinib (UPA) is an oral JAK inhibitor approved for the treatment of rheumatoid arthritis (RA). The background rate of herpes zoster (HZ) in patients (pts) with RA is around 0.98/100 person years (PY)[1]. Pts with RA receiving JAK inhibitors have been reported to have an increased risk of HZ. We evaluate the incidence and risk factors for HZ in pts with RA receiving UPA relative to active comparators in the Phase 3 clinical trial program.

Table. Summary of extent of involvement in pts with HZ

Categories, n (%)[a]	Any UPA 15 mg QD (N=2629)	Any UPA 30 mg QD (N=1204)
Total patients with ≥1 HZ event	142 (5.4)	126 (10.5)
Single dermatome	101 (71.1)	89 (70.6)
Ophthalmic involvement	6 (4.2)	3 (2.4)
HZ Oticus (Ramsay Hunt Syndrome)	2 (1.4)	1 (0.8)
Multidermatomal (unilateral)[b]	26 (18.3)	23 (18.3)
Disseminated, cutaneous only (no CNS involvement)[c]	7 (4.9)	8 (6.3)
Disseminated with CNS or visceral involvement	0	1 (0.8)[d]
Missing	8 (5.6)	5 (4.0)

[a]Pts may fall into >1 category; [b]≤2 adjacent dermatomes; [c]≥3 dermatomes, unilateral nonadjacent dermatomes, or bilateral dermatomes; [d]HZ meningitis

Figure: Multivariable-adjusted risk factors for HZ in pts receiving UPA



*Prednisone or equivalent dose; doses of ≤10 mg/day were permitted in the study

Methods: The incidence rate of HZ was determined in pts receiving UPA (as monotherapy [mono] or combination therapy) in five randomized Phase 3 trials (SELECT-EARLY, SELECT-MONOTHERAPY, SELECT-NEXT, SELECT-COMPARE, and SELECT-BEYOND), of which 4 evaluated both the UPA 15 and 30 mg once-daily (QD) doses and 1 trial (SELECT-COMPARE) evaluated only the 15 mg QD dose. Incidence of HZ was also determined in pts receiving adalimumab (ADA) + methotrexate (MTX) in SELECT-COMPARE and MTX mono in SELECT-EARLY. Risk factors for HZ were assessed using univariate and multivariate Cox regression models. Data cut-off was 30 June 2019.

Results: Overall, 2629 pts who received UPA 15 mg QD (4565.8 patient-years [PY]), 1204 pts who received UPA 30 mg QD (2309.7 PY), 579 pts who received ADA + MTX (768.6 PY), and 314 pts who received MTX mono (456.0 PY) were analyzed. Fewer than 5% of pts across the treatment groups reported prior HZ vaccination. HZ (n/100 PY [95% CI]) occurred in 142 pts (3.1 [2.6–3.7]) with UPA 15 mg, 126 pts (5.5 [4.5–6.5]) with UPA 30 mg, 8 pts (1.0 [0.4–2.1]) with ADA + MTX, and 5 pts (1.1 [0.4–2.6]) with MTX mono. Most of the HZ cases (~71%) with UPA (Table) and all cases with ADA + MTX and MTX mono involved a single dermatome. Ophthalmic involvement was seen in 6 (4.2%) and 3 (2.4%) cases in the UPA 15 and 30 mg groups, respectively, and unilateral involvement with multiple dermatomes was seen in 26 (18.3%) and 23 (18.3%) cases. There was a single case of HZ meningitis reported in a Japanese pt on UPA 30 mg. In multivariate analyses, prior history of HZ and Asian region were associated with an increased risk of HZ in both the UPA groups ($p \leq 0.01$; Figure). In addition, pts ≥65 years old had increased risk of HZ in the 15 mg group.

Conclusion: HZ events in pts with RA receiving UPA were more common in the 30 mg vs 15 mg group, and in both UPA groups compared with the ADA + MTX and MTX groups.

Individualized Prediction of Response to Methotrexate Treatment in Patients with Rheumatoid Arthritis: A Pharmacogenomics-driven Machine Learning Approach

Elena Myasoedova[1], Arjun Athreya[1], Cynthia Crowson[2], Richard Weinshilboum[1], Liewei Wang[1] and Eric Matteson[3], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN, [3]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments III: Predictors of Treatment Response
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Methotrexate (MTX) is the most common anchor drug for rheumatoid arthritis (RA), but the risk of missing the opportunity for early effective treatment with alternative medications is substantial given the delayed onset of MTX action and 30-40% inadequate response rate. There is a compelling need to accurately predict MTX response before treatment initiation, in order to effectively identify patients at RA onset who are likely to respond to MTX. We aimed to test the ability of machine learning (ML) approaches with clinical and genomic biomarkers to predict MTX response in patients with RA.

Methods: Age, sex, clinical, serological and genome wide association study (GWAS) data on patients of European ancestry with early RA available through the PhArmacogenetics of Methotrexate in RA (PAMERA) consortium were used. A total of 647 patients were included: 336 recruited in the United Kingdom [UK]; 307 recruited across Europe (70% female; 72% rheumatoid factor [RF] positive; mean age 54 years; mean baseline Disease Activity Score with

28-joint count [DAS28] 5.65). The genomic data comprised 160 genome-wide significant single nucleotide polymorphisms (SNPs) with p< 1x10-5 that were associated with risk of RA and MTX metabolism. DAS28 scores were available at baseline and 3-month follow-up. Response to MTX monotherapy (>/=15 mg/week) was defined as good or moderate by the EULAR response criteria at 3-month follow-up. Supervised ML methods were trained with 5 repeats and 10-fold Cross validation using data from the UK patients. Class imbalance in training was accounted for by using simulated minority oversampling technique. Prediction performance was validated in the European patients (not used in training).

Results: Age, sex, RF positivity and baseline DASA28 data predicted response to MTX with area under the receiver operating curve (AUC) 0.54 in the UK subjects and 55% accuracy in European patients (p=0.98). However, supervised ML methods that combined demographics, RF status, baseline DAS28 and genomic SNPs predicted EULAR response at 3 months with AUC 0.84 (p=0.05) in UK patients, and achieved prediction accuracies of 76.2% (p=0.05) in the European patient's (sensitivity 72%, specificity 77%). The addition of genomic data improved the predictive accuracies of MTX response by 19% and achieved cross-site replication. Baseline DAS28 and SNPs in or near the CASC15 (rs12446816), B3GNT2 (rs13385025), PARK2 (rs113798271), and ATIC (rs2372536) genes were among the top predictors of MTX response.

Conclusion: Pharmacogenomic biomarkers including gene variants for cancer susceptibility genes (CASC15) and important MTX pathway enzymes (ATIC) combined with baseline DAS28 score predicted MTX response in patients with early RA more reliably than demographics and baseline DAS28 alone, with replication in an independent cohort. Using pharmacogenomic biomarkers for the identification of MTX responders in early RA may help to guide effective RA treatment choices, including timely escalation of RA therapies. Further studies of personalized prediction of response to MTX and other antirheumatic treatments are needed to optimize control of RA disease and improve outcomes in patients with RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments III: Predictors of Treatment Response
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: To evaluate changes produced in circulating inflammatory mediators and their regulatory miRNAs in RA patients after 3 and 6 months of treatment with TNF-α inhibitors (TNFi), in order to identify biomarkers of clinical efficacy and potential predictors of therapeutic response to TNFi therapies.

Methods: In a prospective RA cohort multicenter study, serum from125 RA patients with moderate/high disease activity was collected prior and after 3 and 6 months of TNFi treatment. Patients' response was determined according to EULAR response criteria. The inflammatory profile was analyzed by using a multiplex immunoassay and circulating levels of several microRNAs -whose potential targets were mRNAs encoding inflammatory proteins- were evaluated. Then, their discriminative ability was evaluated. To assess the added value of these biomolecules, logistic prediction models were created.

Results: Among RA patients, 79% (99/125) showed early response after 3 months of TNFi treatment, of which a 67% (66/99) showed clinical response after 6 months of therapy. Inflammatory mediators related to activation and proliferation (IL-6, IL-13), adhesion and migration (MIP-1a, RANTES, FGFb), chemotaxis (MIP1-b, IL8, IP-10) and angiogenesis (VEGF), showed a trend to reduction after 3 months, but were significantly downregulated only after 6 months of TNFi therapy. In addition, several molecules upregulated after 3 months of TNFi therapy -involved in cell activation and differentiation (IFNg, GM-CSF, IL-4, IL-5), immunoregulation (IL-1RA, IL-10) and migration (MCP-1, PDGFb)- were thereafter downregulated, consolidating the reduction in the inflammatory response. Moreover, a decline in 7 of these molecules correlated with DAS28 reduction.

In the search for predictors of response to this drug, clinical and molecular parameters were evaluated. High DAS28/SDAI scores or levels of auto-antibodies (RF or ACPA) at baseline were not predictive of response to the treatment. Instead, atherogenic index, smoking habit and hyperlipidemia at baseline were predictors of a worse response to TNFi therapy. Moreover, both, baseline microRNAs and inflammatory profiles clearly distinguished among patients with differential therapeutic response. High baseline levels of inflammatory mediators related to the leukocyte activation and proliferation, adhesion and migration, along with high baseline levels of several microRNAs (miR-106a-5p, miR-199a-5p, miR-346, miR-223-3p, and miR-143-5p) regulating their expression, were predictive of response to TNFi treatment both, at 3 and 6 months.

Receiver operating characteristic (ROC) analyses for those biomarkers allowed us to further identify specific signatures of circulating biomolecules that may serve as predictors of response to TNFi therapy with high sensitivity and specificity.

Conclusion: The extensive analysis of the serum inflammatory and microRNAs profiles allowed identifying specific and distinctive signatures of biomolecules that, in coordination with known clinical and serological profiles, might predict early and established response of RA patients to TNFi treatment.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments III: Predictors of Treatment Response
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: The results of the R4RA trial, the first biopsy-based RCT in TNF-i inadequate responders patients with Rheumatoid Arthritis (RA), showed that molecular stratification of RA synovial tissue in B-cell poor/rich had stronger associations with clinical responses compared to histopathological classification at baseline demonstrating that, in patients with low/absent B-cell lineage signature in synovial-tissue, Tocilizumab (TCZ) is significantly superior to Rituximab (RTX). Here, we investigate the relationship of synovial immune cells in matched pre- and post-treatment synovial biopsies and treatment response.

Methods: 164 patients underwent pre-treatment US-guided or arthroscopic synovial biopsy prior to randomization 1:1 to RTX (83) or TCZ (81). 65 patients had a repeated biopsy at 16 weeks, primary end-point Clinical Disease Activity Index (CDAI) ≥50% improvement. A minimum of 6 synovial samples/patient were paraffin-embedded and sections stained by immunohistochemistry, followed by semi-quantitative scoring (0-4) for CD20+ total B-cells, CD79a+ B cells, CD3+ T cells, CD138+ plasma cells and CD68+ lining (L) and sub-lining (SL) macrophages, and classification into lympho-myeloid (LM), diffuse-myeloid (DS) and fibroid/pauci-immune (F/PI) pathotypes, as previously described (Humby et al Ann Rheum Dis. 2019 Jun;78(6):761-772).

Results: At baseline, no significant differences were observed in semi-quantitative synovial immune scores in patients classified as CDAI≥50% responders and non-responders, both for RTX and TCZ. Looking at pathotypes, TCZ-treated patients with a DM pathotype had a significantly higher CDAI≥50% response compared to LM and F/PI (81% vs 48%, p=0.024), while no differences were found in RTX treated patients. When analysing matched pre and post-treatment biopsies (Table 1) RTX-treated patients showed a significant reduction of synovial CD20+ total B cells [-1.53 (-81%), p< 0.001], CD79a+ B cells [-0.87 (-49%) p< 0.001] and CD138+ plasma cells [- 0.76 ‡ (-45%) p< 0.05]. TCZ treated patients, on the other hand, showed a significant reduction of CD68+ sub-lining macrophages [-1.04 (-54%) p< 0.05] but not B-lineage cells. Finally, while CD20 and CD79a showed a significant reduction in all RTX-treated patients, including both responders and non-responders, a significant reduction of CD138 was only observed in responders. On the other hand, a significant reduction of CD68SL macrophages was only observed in responders to TCZ (Table 2).

Conclusion: Treatment of RA patients with RTX or TCZ has a different impact on synovial immune cells infiltration. In line with their mechanisms of action, RTX reduces synovial B cells, while TCZ affects sub-lining macrophages. Interestingly, the reduction of plasma cells and sub-lining macrophages identifies responders to RTX and TCZ, re-

spectively. These results indicate that the analysis of immune cell infiltration in synovia helps to define a biological response to immunomodulatory agents in RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments III: Predictors of Treatment Response
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Despite the existence of guidelines for DMARD treatment of RA, a more individualized approach to treatment is needed to maximize efficacy while minimizing risk of adverse events. In phase 3 trials, sarilumab, an IL-6 receptor (IL-6R) inhibitor approved for treatment of moderate to severe RA, has been shown to be superior to both placebo (clinical trials MOBILITY [NCT01061736] and TARGET [NCT01709578]) and the TNF-α inhibitor adalimumab (MONARCH [NCT02332590]). However, the characteristics of patients who are most likely to benefit from sarilumab treatment remain poorly understood. Here, we describe the application of machine learning to select from a predefined set of patient characteristics that could facilitate the choice between anti-IL-6R and anti-TNF-α treatment, using data from the sarilumab clinical development program.

Methods: A decision tree classification approach was used to build predictive models on ACR response criteria at Week 24 in patients from MOBILITY, using the Generalized, Unbiased, Interaction Detection and Estimation (GUIDE) algorithm (Version 27.9; available as free software). A total of 17 categorical and 25 continuous baseline variables were included as candidate predictors, chosen based on subject matter expertise. These included protein biomarkers, disease activity scoring, and demographic data (Table). The endpoints used were ACR20, ACR50, and ACR70 at Week 24. The resulting rule was validated through application on independent data sets from MOBILITY (N=1197; sarilumab [150 mg and 200 mg combined], 799; placebo, 398), TARGET (N=546; sarilumab [150 mg and 200 mg combined], 365; placebo, 181), and MONARCH (N=369; sarilumab, 184; adalimumab, 185), as well as on the tocilizumab-calibrator study ASCERTAIN (NCT01768572; N=202; sarilumab [150 mg and 200 mg combined], 100; tocilizumab, 102). The analysis focused on the 200 mg sarilumab dose.

Table 1

Results: The most successful GUIDE model was trained against the ACR20 response. Out of the 42 candidate variables, the combined presence of anti-citrullinated protein antibodies (ACPA) and CRP >12.3 mg/L was identified as a predictor (ie, rule) of better treatment outcomes with sarilumab. Rule-positive patients (34-51% in sarilumab groups across the 4 trials) had more severe disease and poorer prognostic factors at baseline. Rule-positive patients had a better outcome than rule-negative patients for most endpoints assessed, with the exceptions observed in patients with inadequate response to TNF inhibitors (TARGET; Figure 1). In addition, rule-positive patients had a better response to sarilumab but an inferior response to adalimumab, with the exception of HAQ-Disability Index minimal clinically important difference endpoint (Figure 2), equivalent to an approximately 5-fold difference in the chance of achieving ACR70 (34% versus 7%).

Conclusion: Machine learning ascertained a simple selection rule, ACPA positivity and CRP >12.3 mg/L, to identify patients with an increased chance of achieving clinical response with sarilumab. If verified in prospective studies, this rule could facilitate treatment decision-making for patients with RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Treatments III: Predictors of Treatment Response

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Filgotinib (FIL), a selective, oral JAK1 inhibitor, has shown efficacy and safety in phase 3 studies in adults with moderately-to-severely active rheumatoid arthritis (RA). We have previously described the molecular response to FIL in large-scale RNA sequencing studies of gene expression in other RA populations[1-3] and herein conducted a similar study in RA patients (pts) with prior inadequate response to methotrexate (MTX-IR; FINCH1; ClinicalTrials.gov NCT02889796).

Methods: RA pts with MTX-IR were enrolled and randomized to receive either stable dose of MTX with placebo (PBO+MTX), adalimumab (ADA+MTX), or one of two doses of FIL (FIL 100mg+MTX, FIL 200mg+MTX) once daily. Whole blood samples were collected using PAXgene tubes at baseline, weeks 4, and 12. RNA were extracted and sequenced on Illumina HiSeq 2500 platform following globin RNA depletion. Correlations between baseline gene expression and disease measurements were performed using Spearman's rank partial correlation with covariates. Differentially expressed genes (DEGs) were identified using voom-limma. Pathway analysis was performed on v6.1 of the Molecular Signature Database using single sample gene set enrichment analysis (GSEA) with the focus on immune signaling pathways from the Kyoto Encyclopedia of Genes and Genomes (KEGG). A false-discovery rate of 5% was applied for all analyses.

Results: Differential gene expression analyses comparing baseline samples with after-treatment samples revealed more rapid transcriptional kinetics for FIL-treated pts compared to ADA+MTX-treated pts. No significant DEGs were observed in PBO-treated pts. More significant DEGs were observed in FIL 200mg+MTX arm compared to FIL 100mg+MTX arm, consistent with superior clinical efficacy of FIL 200mg dosage. As with other FIL clinical trial RNA-seq studies and consistent with the selective MoA of FIL, JAK-STAT pathway-induced genes *SOCS2* and *CISH* were significantly downregulated across both FIL arms and timepoints, but not in ADA+MTX arm. RA disease activity associated genes[2-3] *FAM20A* and *METTL7B* were significantly reduced at both 4 and 12 weeks only in the FIL 200mg+MTX arm. While no significant changes in KEGG immune signaling pathways were observed in the PBO+MTX arm, a dose-dependent effect on pathway modulation was observed in the FIL arms. The most prominently down-regulated KEGG pathways included JAK-STAT signaling and leukocyte transendothelial migration.

Conclusion: More rapid and sustained changes of transcriptional activity were observed in the whole blood transcriptional profile of RA pts following FIL 200mg+MTX compared to ADA+MTX treatment. Dose-dependent changes were observed in FIL-treated pts, most notably in the KEGG JAK-STAT signaling pathway. These observations confirm an inhibition of JAK-STAT signaling by FIL and are consistent with the observed clinical efficacy of FIL in these pts.

Session Title: RA – Treatments IV: New Therapies & Strategies
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: The EULAR recommendations, updated in 2016[1] and 2019[2], propose the initiation of glucocorticoid (GC) therapy in combination with cDMARDs background therapy for every patient with early rheumatoid arthritis (ERA).

The aim of this study is to evaluate the proportion of patients with ERA who have been treated with GC in daily practice, to analyse the baseline characteristics of these patients, and to assess the clinical benefit and side effects of GC during 5 years of follow-up.

Methods: We included patients with ERA from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 classification criteria and were naïve to cDMARDs. Treatments were initiated based on the decision of a senior rheumatologist. We retrospectively collected patient characteristics prior to the introduction of cDMARDs with or without GC. Efficiency and serious adverse events were analysed at 6 months, 1 year, 3 years and 5 years.

Results: Data from 474 eligible ERA patients were collected. The average age of the population is 48.9 years. 70.5% of the patients are women. 27.3% are smokers and 68.8% are positive for anti-citrullinated protein antibody (ACPA).

178 patients (37.7 %) initiated GC compared to 294 patients (62.3%) who received only NSAIDs and/or analgesics in combination with cDMARDs.

At baseline, the elevation of CRP is the main factor that favors the initiation of GC (CRP 2.9 vs 2.0 mg/dl, p = 0.015) followed by smoking habits (34.2% vs 23.3%, p = 0.018), the absence of ACPA (37.2% vs 27.6%, p = 0.037), the prescription of methotrexate as a monotherapy (70.6% vs 50.5%, p < 0.001), and the age (50.6 vs 48.0, p = 0.050). Other parameters such as swollen joint count, tender joint count, DAS28-CRP, HAQ or baseline erosion were similar between groups.

5 years follow-up of DAS28-CRP, HAQ or VAS pain values did not differ between the two groups (Fig1A).

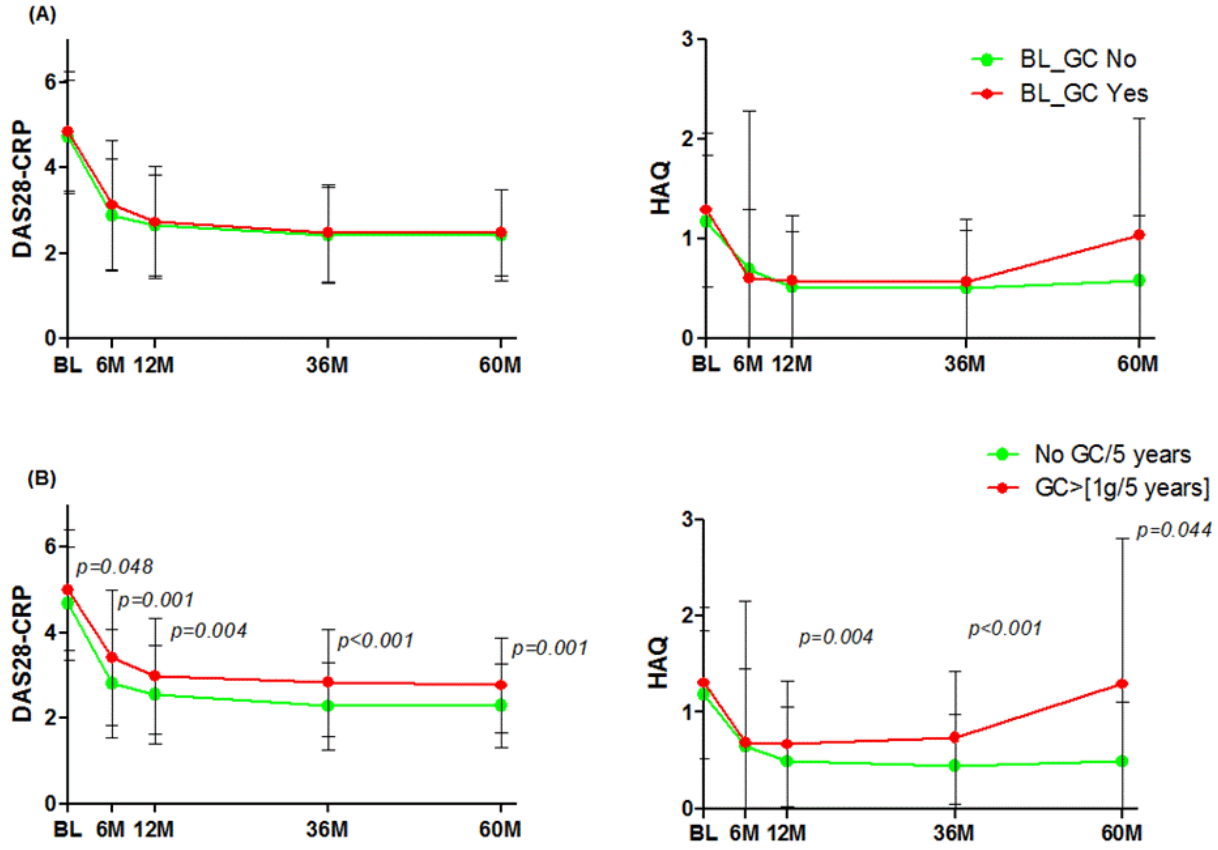

Figure 1. Comparison of DAS28-CRP and HAQ scores evolution. (A) in two groups of patients: treated with GC (BL-GC Yes) or without GC (BL_GC No) in combination with cDMARDs as first line treatment. (B) in two groups of patients: never treated with GC during 5 years follow-up (No GC/ 5 years) and those who received a high cumulative dose of GC ≥ 1 g/5years (GC>[1G/5years]).

Interestingly, patients not exposed at baseline to GC showed a higher remission rate (DAS28-CRP< 2.6) of 48.4% vs 44.3% at 6 months.

We also analysed a subgroup of patients (n=139) who received a cumulative dose of more than 1 g of prednisolone during the 5 years period. We confirmed the baseline differences for CRP, smoking habits, age and found in this subgroup more males (36.7% vs 28.2%, p=0.021) and higher DAS-28CRP values (5.0 vs 4.7, p=0.048). During the 5 years follow up, DAS-28CRP, VAS pain and HAQ remained significantly higher leading to a higher number of bi-oDMARDs prescribed in this group (Fig1B). More severe infections were reported in this subgroup (11.5% vs 4.2%). Bone densitometry values, number of fractures, and cardiovascular profiles were similar between groups.

Conclusion: In our ERA cohort, initiation of GC treatment does not add additional benefit for the short and long-term control of the disease.

GC were more prescribed in seronegative RA patients with higher level of inflammation and we confirm that patients exposed to higher cumulative doses of GC are at higher risk to develop severe infections.

Further studies are needed to support that GC induction therapy should not be offered to all ERA patients.Figure 1 Comparison of DAS28-CRP and HAQ scores evolution. (A) in two groups of patients: treated with GC (BL-GC Yes) or without GC (BL_GC No) in combination with cDMARDs as first line treatment. (B) in two groups of patients: never treated with GC during 5 years follow-up (No GC/ 5 years) and those who received a high cumulative dose of GC ≥ 1 g/5years (GC>[1G/5years]).

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments IV: New Therapies & Strategies
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: EULAR guidelines advise to start with methotrexate (MTX) for early rheumatoid arthritis (RA), either alone or combined with prednisolone. Since this strategy is not effective in all patients after 13 weeks, we

performed a randomized controlled trial to compare the effect of the addition of a second oral pulse of prednisolone versus continuation of MTX and prednisolone.

Methods: Newly diagnosed RA patients with symptom duration < 2 years were classified into a low- and high-risk group. High-risk patients either had DAS44 >3.7, or presented with at least 2 out of 3 unfavorable prognostic factors: CRP >10 mg/l; IgM RF or antiCCP with high titer; at least 1 erosion. The remaining patients were classified as low-risk. The treatment target was response (DAS44 < 1.6) or EULAR good response. Nonresponders at 13 weeks were randomized to treatment intensification or continuation, and the primary endpoint was % responders at 26 weeks.

Results: In total 189 patients were included. High-risk patients (n=150; mean age 51 years, 63% female, baseline DAS44 3.50, RF+ 75%, antiCCP+ 77%) were treated with COBRA-light (1, 2) (30 mg/day oral prednisolone, tapered in 8 weeks to 7.5 mg/day, and MTX increasing to 25 mg/week): 112 (75%) patients reached the treatment target at 13 weeks and 2 patients dropped out. On continued treatment, 92% of the responders retained the target. The 36 incomplete responders were randomized to treatment intensification with 60 mg/day prednisolone, tapered in 6 weeks to 7.5 mg/day, and addition of sulfasalazine 2000 mg/day and hydroxychloroquine 400 mg/day (COBRA-plus, n=17) or continuation (n=19). After 26 weeks the treatment target was met in 14 patients (82%) of the intensified group vs 9 (47%) of the control group (difference: 35%, [95%CI 6;64]; p=0.01).

The low-risk group (n=39; mean age 56 years, 59% female, baseline DAS44 2.66, RF+ 21%, antiCCP+ 26%) was treated with MTX monotherapy increasing to 25 mg/week: only 19 (49%) reached the target at week 13 and 4 patients dropped out. On continued treatment, 95% of the responders retained the target after 26 weeks. The 16 incomplete responders were randomized to treatment intensification with a COBRA-light oral pulse of prednisolone (n=9) or continuation (n=7). After 26 weeks the treatment target was met in 5 patients (56%) of the intensified group vs 3 (43%) in the control group (difference: 13%, [95%CI –36;62]; p=0.28).
1 den Uyl D, et al. Ann Rheum Dis 2014; 1071-8.
2 ter Wee M, et al. Ann Rheum Dis 2015; 1233-40.

Conclusion: With the COBRA-light strategy, 75% of RA patients with moderate to high disease activity or poor prognostic factors met the treatment target after 13 weeks. Remarkably, intensification at week 13 with added DMARDs and a second oral pulse of prednisolone even further improved the initial high response rate suggesting that patients not reaching the target at 13 weeks benefit from COBRA-plus. In the small low-risk group, only 49% met the treatment target after 13 weeks. Here, no effect of treatment intensification was found, possibly related to the small number of individuals. More treat-to-target trials are needed, particularly in patients with mild RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: RA – Treatments IV: New Therapies & Strategies

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Remission is the preferred treatment target in rheumatoid arthritis (RA), and many patients require biologic disease-modifying antirheumatic drugs (DMARDs) to reach this state. It is debated whether tapering of tumor necrosis factor inhibitor (TNFi) treatment to discontinuation should be considered in RA patients who sustain remission on treatment (1). The primary study objective was to assess the effect of tapering and withdrawal of TNFi on the risk of flares in RA patients in clinical remission.

Table: Baseline characteristics

	Stable, n=45	Tapering, n=47
Age, yrs	57 (11)	58 (13)
Female	30 (67%)	25 (53%)
ACPA+	35 (78%)	36 (77%)
Symptom duration, yrs	10 (7)	12 (7)
DAS	0.9 (0.4)	0.8 (0.3)
CRP mg/L, median (IQR)	1 (1 – 2)	1 (1 – 3)
No ultrasound power Doppler signal in any of 32 joints	42 (96%)	44 (94%)

Figure 1: Non-inferiority plot of stable vs tapered TNFi treatment in per protocol population, per protocol patients with csDMARD co-medication, and in the full analysis set. The broken vertical line represents the non-inferiority margin.

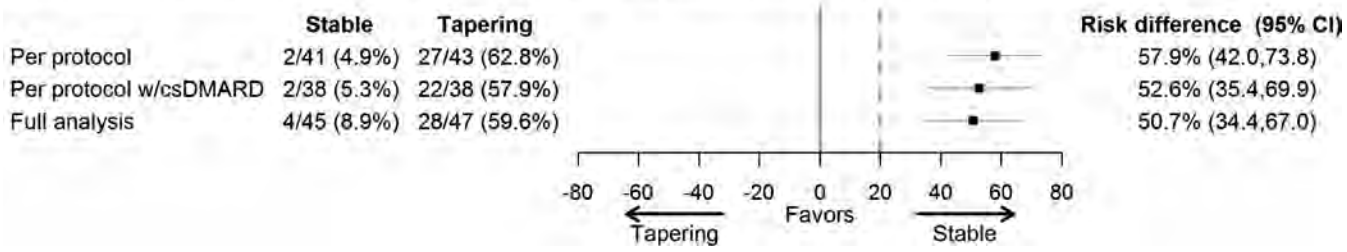

Figure 2: Secondary endpoints

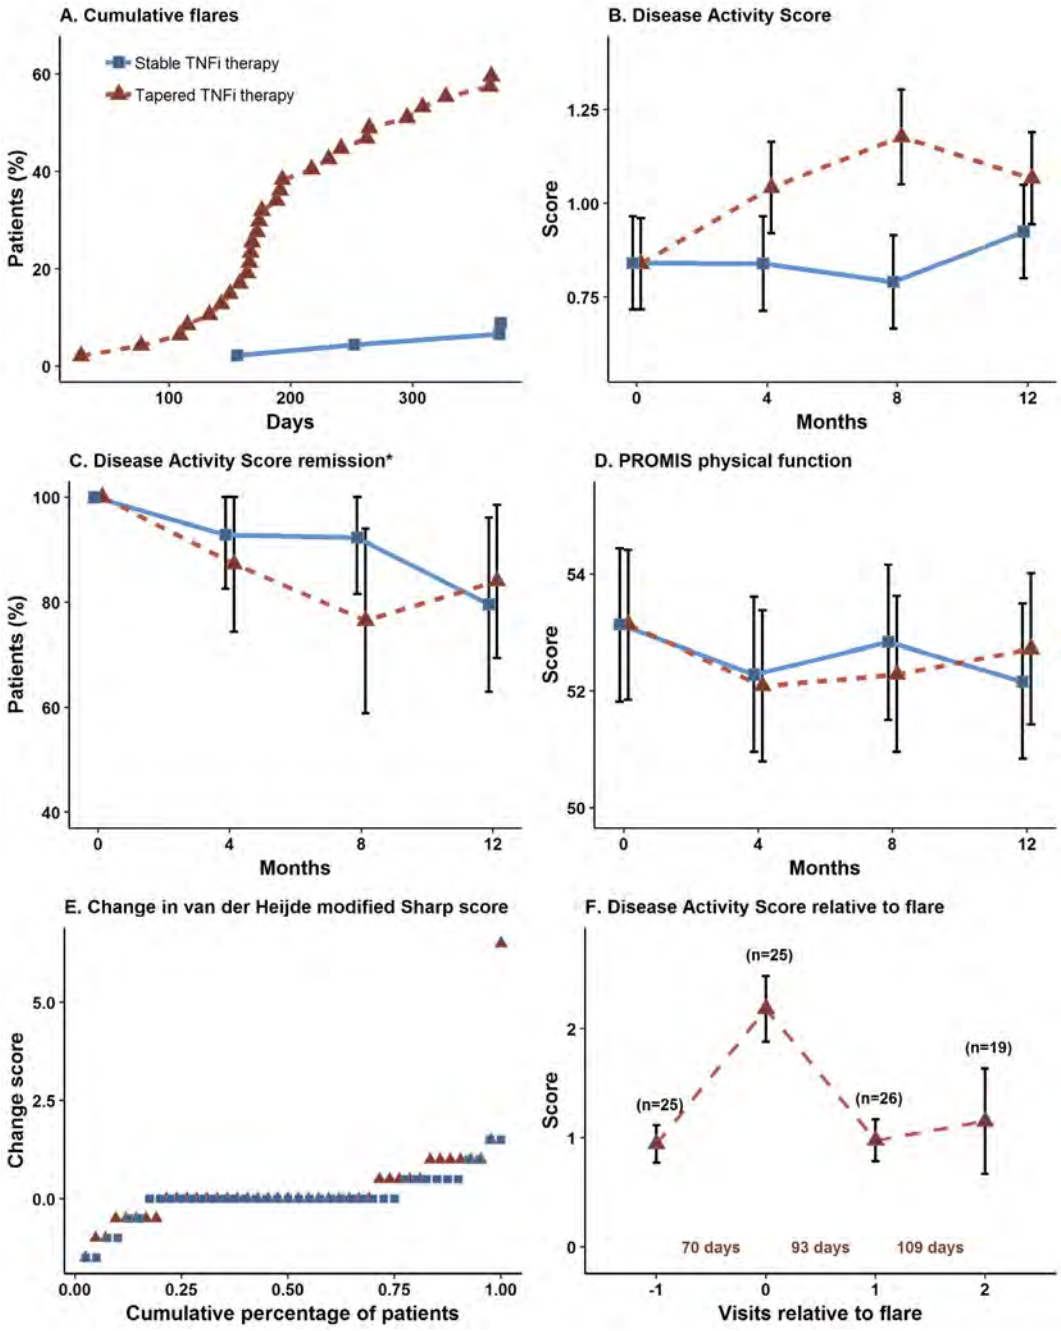

Methods: In the non-inferiority ARCTIC REWIND trial, RA patients in remission for at least 12 months on stable TNFi therapy were randomly assigned to continued stable TNFi or tapering (half-dose TNFi for 4 months, thereafter withdrawal of TNFi), with visits every four months. csDMARD co-medication was kept stable in both arms. Patients had to be in DAS remission at inclusion with 0 swollen joints of 44 assessed. The primary endpoint was the proportion of patients with disease flare during the 12-month study period (defined as DAS >1.6, change in DAS >0.6 and 2 or more swollen joints, or the physician and patient agreed that a clinically significant flare had occurred). Full-dose TNFi was reinstated in case of flares in the tapering arm. The non-inferiority margin was 20%, with a predefined superiority test if non-inferiority was not shown. The inferiority null-hypothesis was tested in the per-protocol population by mixed ef-

fect logistic regression. Radiographs were scored by van der Heijde modified Sharp score (0 and 12 months, average of two readers, progression: ≥1 unit change). Clinicaltrials NCT01881308.

Results: We randomized 99 patients, 92 received the allocated treatment strategy, 84 were included in the per-protocol population. Baseline characteristics, clinical and ultrasound disease activity were balanced (Table). csDMARD co-medication was used by 93% in the stable and 88% in the tapering arm. In the primary analysis, 5% of patients in the stable TNFi arm experienced a flare during 12 months, compared to 63% in the tapering TNFi arm. The risk difference (95% CI) was 58% (42% to 74%, Fig 1), with stable treatment being deemed superior to tapering. 90% in the stable and 81% in the tapering arm did not show progression of radiographic joint damage, difference (95% CI) -9% (-24%, 6%). At 12 months, DAS scores, DAS remission and function were similar between groups (Fig 2). The numbers of adverse events (AE)/serious AE in the stable and tapering arm were 57/2 and 50/3, respectively, with 26 and 15 infections.

Conclusion: In a randomized clinical trial assessing patients in prolonged and deep RA remission, we observed a large increase in the flare rate in patients who tapered and discontinued TNFi. Patients responded well to reinstated treatment and remission rates in the two study arms were comparable at 12 months.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments IV: New Therapies & Strategies
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: We previously reported positive efficacy and safety results of olokizumab (OKZ), an interleukin-6-inhibitor, in patients with RA inadequately controlled by MTX (NCT02760368; CREDO-1) [Nasonov E.et al. Arthritis Rheumatol. 2019; 71 (suppl 10); E. Nasonov,et al. 2020; EULAR Abstracts THU0176]. Here we present the patient reported outcomes (PRO) of CREDO-1 study and assess the effect of OKZ treatment comparing to placebo (PBO) on quality of life, work productivity and fatigue in patients with moderate to severe RA who have previously failed MTX therapy.

Methods: We compared PRO between three groups 1) subcutaneous injections of OKZ 64 mg every 2 weeks (q2w), 2) OKZ 64 mg every 4 weeks (q4w) and 3) PBO every q2w.

PRO included change from baseline in: Health Assessment Questionnaire-Disability Index (HAQ-DI); Patient's Global Assessment of Disease Activity (PtGA), Patient's Assessment of Arthritis Pain (Pain), Short Form-36 (SF-36) Physical (PCS) and Mental (MCS) components; European Quality of Life- Five-Dimension Questionnaire (EQ-5D), Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F) and Work Productivity Survey-Rheumatoid Arthritis (WPS-RA).

Results: 428 patients were enrolled and 396 completed the study. All PRO baseline characteristics were comparable across treatment arms: mean (SD) PtGA was 69.5 (15.5); Pain was 68.6 (17.5); HAQ-DI was 1.7 (0.5); SF-36 PCS was 32.1 (6.5); SF-36 MCS was 42.3 (10.0); EQ-5D was 40.3 (20.0) and FACIT-F was 26.8 (8.7).

Treatment with OKZ 64 mg q2w and 64 mg q4w resulted in significant improvement in PRO measures (Table 1). Improvements in all PRO measures observed at week 12 were sustained over week 24.

Mean improvements in both OKZ groups for PtGA, Pain, HAQ-DI, SF-36 PCS and MCS, and FACIT-F surpassed defined MCIDs for these measures. There were clear differences between both OKZ treatment groups and placebo in all

Table 1. **Changes from baseline at months 3 (12 week) and 6 (24 week) for PRO**

PtGA, Patient's Global Assessment of Disease Activity; Pain, Patient's Assessment of Arthritis Pain; PCS, HAQ-DI, Health Assessment Questionnaire-Disability Index; SF-36, Short Form-36; PSC, Physical Component Score; MCS, Mental Component Score; EQ-5, European Quality of Life-5 Dimensions; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue Scale; WPS-RA, Work Productivity Survey-Rheumatoid Arthritis.

PRO measures, with the exception of some WPS measures where differences between groups were variable. There were statistically significant changes between OKZ treatment groups and placebo for change from baseline in HAQ; however, no formal statistical testing was done for other PRO measures. No notable differences in PRO measures were observed between the two dose regimens of OKZ.

Conclusion:

1. Treatment with OKZ over a 24-week period was associated with significant improvements in PRO in patients with moderate to severe RA.
2. There were no discernible differences between the two regimens of OKZ from patient's perspective.

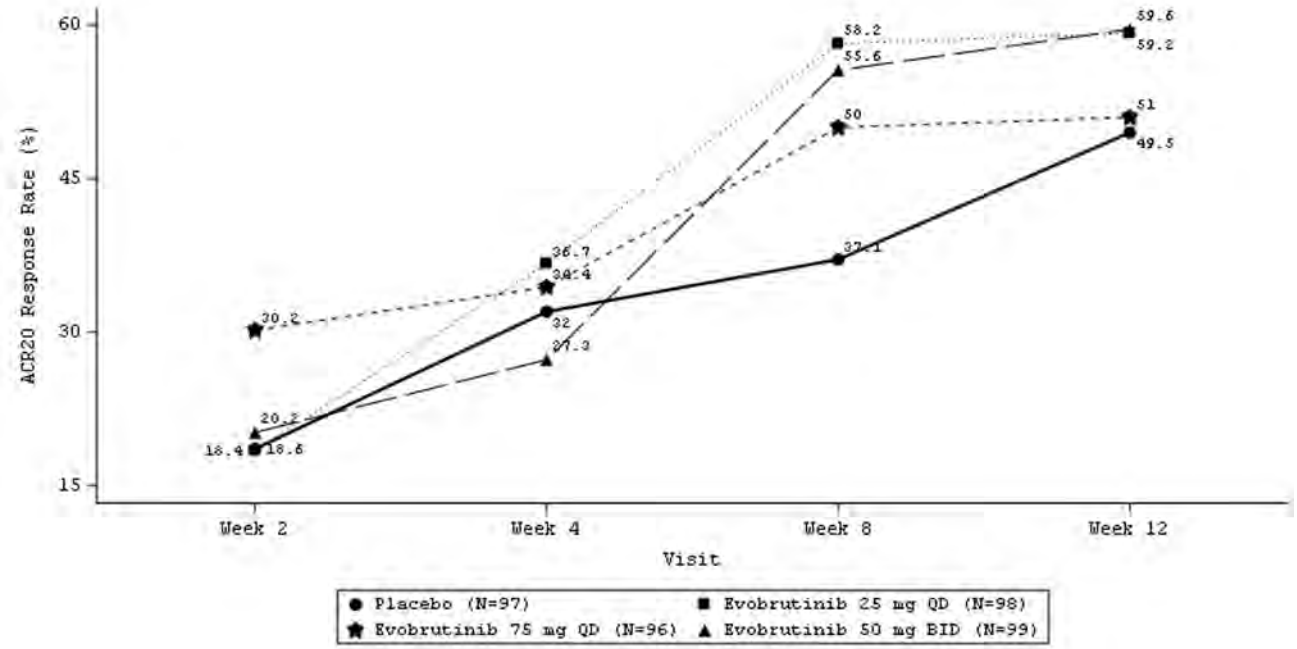
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: RA – Treatments IV: New Therapies & Strategies
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Bruton's tyrosine kinase (BTK) is involved in multiple signalling pathways potentially implicated in rheumatoid arthritis (RA). Evobrutinib is a highly selective, oral BTK inhibitor. This phase IIb, randomized, double-blind study evaluated efficacy, dose response, and safety to 12 weeks of treatment with evobrutinib versus placebo in RA patients with inadequate response to methotrexate (MTX).

Methods: Patients enrolled were 18–75 years of age, with confirmed diagnosis of RA ≥ 6 months duration (EULAR/American College of Rheumatology [ACR] criteria), with active disease at screening and randomization, defined by ≥ 6 swollen and ≥ 6 tender joints, and with high-sensitivity CRP (hsCRP) ≥ 5.0 mg/L. Participants had received MTX treatment 7.5–25 mg/week for ≥ 16 weeks at stable dose for ≥ 8 weeks, and had not received prior treatment with a biologic DMARD. They were randomized 1:1:1:1 to oral evobrutinib 25 mg once-daily (QD), 75 mg QD, 50 mg twice-daily (BID), or placebo. Stable use of NSAIDs and/or glucocorticoids (≤10 mg daily) was allowed. The primary endpoint was ACR 20% response (ACR20), assessed at Week 12, using hsCRP. Key secondary endpoints

Figure 1. Primary Endpoint: ACR20 Response Rate over Time



were ACR50 and ACR70 and disease activity scores (DAS28) CRP, DAS28CRP < 3.2 and DAS28CRP < 2.6. Safety endpoints included adverse events (AEs), serious AEs (SAEs), and laboratory studies. Other secondary endpoints included change from baseline in OMERACT RAMRIS scores and RAMRIQ scores for synovitis, osteitis and erosion for patients in an MRI substudy.

Results: 390 patients were randomized. Baseline age was 52.7±12.2 years (mean±SD), 80.0% were female, hsCRP 21.77mg/L ±24.1 (mean±SD), and time since diagnosis 6.9±6.7 years (mean±SD). The treatment groups were balanced for sex, race, age, time since diagnosis, joint counts, and other baseline disease characteristics. The primary endpoint of ACR20 response was not met (Figure 1). ACR20 response in the placebo group (49.5%) was higher than other trials in RA. Evobrutinib at all doses was nominally significant versus placebo on DAS28CRP < 3.2, and DAS-28CRP < 2.6. HsCRP decreased in all evobrutinib arms (Table 1). No dose response was observed. There were no significant differences in MRI scores between placebo and evobrutinib by either RAMRIS (Table 1) or RAMRIQ (data not shown). Evobrutinib was well tolerated at all doses (Table 2). Three patients showed Grade 3 elevations in ALT, all in the 75 mg QD arm. LFT elevations were reported across all groups. Very few patients experienced Grade 3 events, and only one patient experienced a Grade 4 event (unrelated to treatment).

Conclusion: This phase IIb study of evobrutinib in patients with RA with inadequate response to MTX did not meet its primary efficacy endpoint of ACR20 response. MRI endpoints did not show differences between evobrutinib and placebo. However, MRI placebo scores were not consistent with other studies, showing greater improvements in synovitis and osteitis, and less progression of erosions than typically reported. Evobrutinib was well tolerated at all doses. No dose effect was identified.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II

Session Type: Abstract Session

Session Time: 12:00PM–12:50PM

Background/Purpose: Familial occurrence of ankylosing spondylitis (AS) is well known. Our follow-up study aimed at assessing the incidence of clinically defined AS among first degree relatives (FDR) and to explore 'hidden' manifestations of axial spondyloarthritis (axSpA) among 'healthy' FDR.

Methods: Our cohort study started in 1985 when the Swiss Ankylosing Spondylitis Patient Society member patients clinically diagnosed with AS were contacted to participate in this study, together with their FDR, irrespective of whether they were known to have any disease. After ethical approval and Informed consent, 1178 subjects completed questionnaires on disease manifestations, underwent rheumatological examination of axial and peripheral joints, and provided blood samples for genetic studies, including HLA-B27. Pelvic radiographs of 363 probands and 713 FDR were assessed blindly for presence of sacroiliitis according to the New York (NY) radiographic criteria.

In 2018 the ethical committee of the Swiss Kanton of Bern approved the follow up study. City and village administrations provided current addresses of former participants. 124 Probands and 338 FDR were available for follow-up and were screened by questionnaire.

Results: First study (1985): 308 of 358 HLA-tested AS probands were HLA-B27(+) (86.0%). The mean age of the 672 FDR (311 males) was 26.9± 8.2 years. At that time 14 (7 males) of the 308 HLA-B27(+) FDR (4.5%) had sacroiliitis and met the mNY criteria for AS (mean age 33.5 ± 4.1 years). In contrast, none of the 278 HLA-B27(-) FDR of HLA-B27(+) probands showed sacroiliitis (p=0.00032), nor did anyone of the 83 HLA-B27(-) FDR of 50 HLA- B27(-) probands (p= 0.048). Considering FDR of probands with a clinical diagnosis of AS in the absence of sacroiliitis (now called non-radi-

Table 1. Prevalence of symptoms suggesting 'hidden' AS or axial SpA in healthy HLA-B27 positive relatives of HLA-B27 positive probands with AS compared with their HLA-B27 negative counterparts

Question	*Relatives HLA-B27* (n=111) # positive/total and percentage		*Relatives HLA-B27* (n=130) # positive/total and percentage		LR+	LR-	*p*-value

Change of body position causes exacerbation of complaints at the ventral chest wall	6/109	5.5%	1/130	0.8%	7.16	1.05	0.0305

ographic axSpA (nr-axSpA)), two of the 59 HLA-B27(+) FDR (3.4%) of 58 HLA-B27(+) nr-axSpA probands themselves had AS, compared with none of 47 HLA-B27(-) FDR of 28 HLA-B27(-) nr-axSpA probands (p=0.50).

In 2019, 36 of 152 (23.7%) HLA-B27(+) FDR reported themselves to have AS, including 6 of the 14 FDR who already met mNY criteria in 1985. In contrast, amongst HLA-B27(-) FDR only 3 of 173 HLA-B27(-) (1.7%) FDR reported themselves to have AS (odds ratio 18, p=1.2x10^{-9}). The current mean age of the 39 FDR is 58.4 ± 8.7 years.

Considering 'inflammatory' spinal arthritis symptoms assessed by questionnaire, eight of these were reported significantly more often by HLA-B27(+) than HLA-B27(-) FDR, in the absence of any rheumatic disease diagnosis (Table 1). These items individually have low sensitivity with low negative likelihood ratios, but are highly specific with high positive likelihood ratios. Interestingly, 8 of 111 (7.2%) HLA-B27(+) FDR share 4(*) items compared with 2 of 130 HLA-B27(-) FDR (1.5%) (odds ratio=5.0, p= 0.028). This points to 'hidden' AS/axSpA manifestations among HLA-B27(+) FDR.

Conclusion: For HLA-B27(+) FDR the risk of developing AS/axSpA over a period of more than 35 years is substantial (23.7%). This confirms our previous finding of a 21% risk figure in a Dutch family study (Arthritis Rheum 1984; 27:241). It is unlikely that the life-time incidence will increase further given the age of the cohort.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II
Session Type: Abstract Session
Session Time: 12:00PM–12:50PM

Background/Purpose: Patients with psoriasis, iritis, or colitis and back pain represent a high-risk population for the presence of axial spondyloarthritis (axSpA). Clinicians rely on the elicitation of features of inflammatory back pain (IBP) to discriminate between more common non-specific back pain and inflammatory conditions. Different criteria have been developed for classification purposes, but these have been developed and validated in patients with established idiopathic ankylosing spondylitis. It is unknown how these criteria, namely ASAS, Berlin and Calin criteria, perform in patients presenting with back pain and extra-articular features of axSpA. To address the circularity between elicitation of IBP and clinical diagnosis, we used not only rheumatologist diagnosis as benchmark, but also

Table 1. Rheumatologist diagnosis as external reference.				
	Sensitivity	**Specificity**	**LR+**	**LR-**

imaging. We aimed to assess the diagnostic utility of all available criteria for IBP in an inception cohort of patients with psoriasis, iritis, or inflammatory bowel disease (IBD) referred to a rheumatologist with undiagnosed back pain, using the final rheumatologist diagnosis and imaging as the benchmarks.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at early detection of axial SpA in consecutive patients presenting with undiagnosed back pain to the rheumatologist. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or IBD diagnosed by the relevant specialist undergo routine clinical evaluation by a rheumatologist for axial SpA. The rheumatologist determines the presence or absence of axial SpA at 3 consecutive stages: 1. After the clinical examination; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of

Calin IBP	90.0%	15.4%	1.1	0.7
All 3 criteria sets	65.0%	38.5%	1.1	0.9
IBP global >5	75.0%	38.5%	1.2	0.7
IBD				
ASAS IBP	92.3%	37.7%	1.5	0.2
Berlin IBP	76.9%	39.6%	1.3	0.6
Calin IBP	92.3%	17.0%	1.1	0.5
All 3 criteria sets	76.9%	45.3%	1.4	0.5
IBP global >5	92.3%	47.2%	1.8	0.2

local MRI evaluation. Imaging was also assessed centrally by 3 expert readers. Majority central reader evaluation of presence/absence of MRI indicative of axSpA and final diagnosis by the rheumatologist were used as external standards to test the performance (sensitivity, specificity, positive and negative likelihood ratios (LR+/LR-)) of the following criteria for IBP: ASAS, Berlin, Calin, rheumatologist global for likelihood of IBP >5 (0-10 scale).

Results: 246 patients were included, of whom 47.6% were diagnosed with axSpA by the local rheumatologist. The diagnosis of axSpA was confirmed in 45.7%, 61.6% and 40.2 % of patients with undiagnosed back pain and psoriasis, iritis, and IBD. The diagnostic utility for all IBP criteria was equally poor, especially showing a lack of specificity (Table 1). MRI was considered indicative of axSpA by central readers in 21.2%, 43.5% and 19.7% of patients with psoriasis, iritis, and IBD. When using MRI as external reference (Table 2), all IBP criteria performed even worse.

Conclusion: All IBP criteria, as well as rheumatologist global assessment, have poor diagnostic utility for diagnosis of axSpA in patients with undiagnosed back pain and extra-articular features. This should be a reminder to not rely only on the concept of IBP in daily routine, and also reinforces the desirability of less subjective assessment tools, especially imaging.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II

Session Type: Abstract Session

Session Time: 12:00PM–12:50PM

Background/Purpose: Peripheral musculoskeletal manifestations in patients with Psoriatic Arthritis (PsA) have been widely studied. However, there is a lack of knowledge on the distribution of such manifestations in the whole group

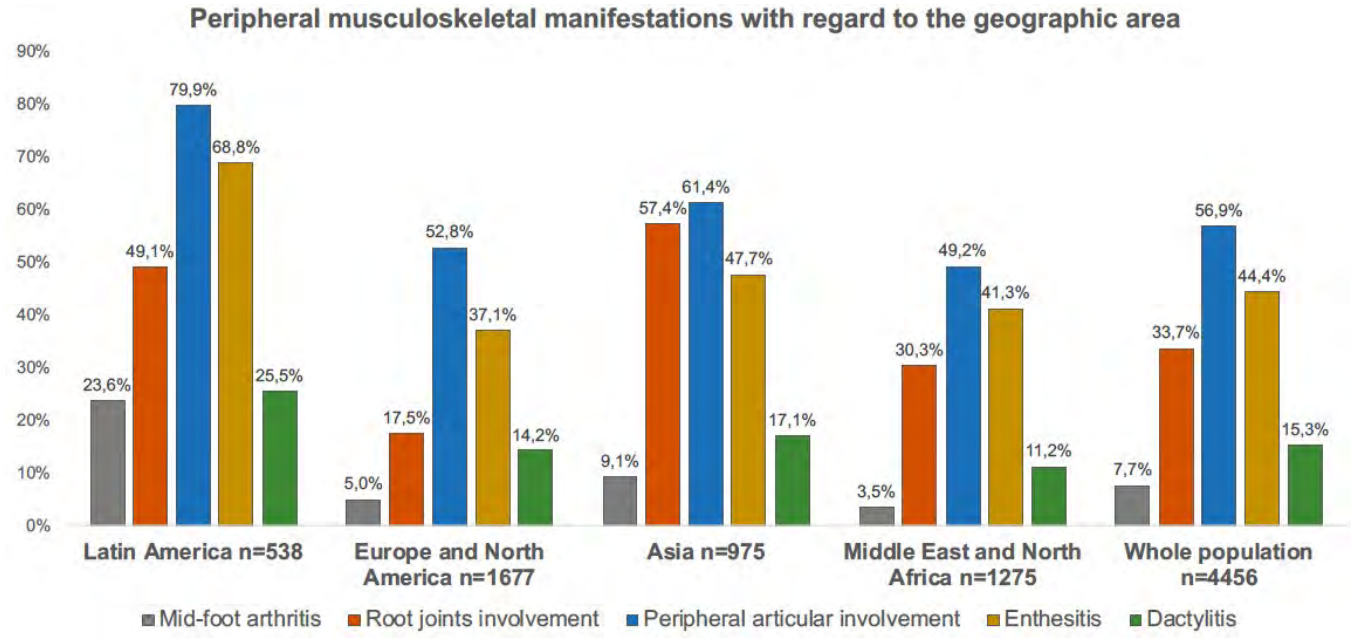

Figure 1. Peripheral musculoskeletal manifestations with regard to the geographic area.

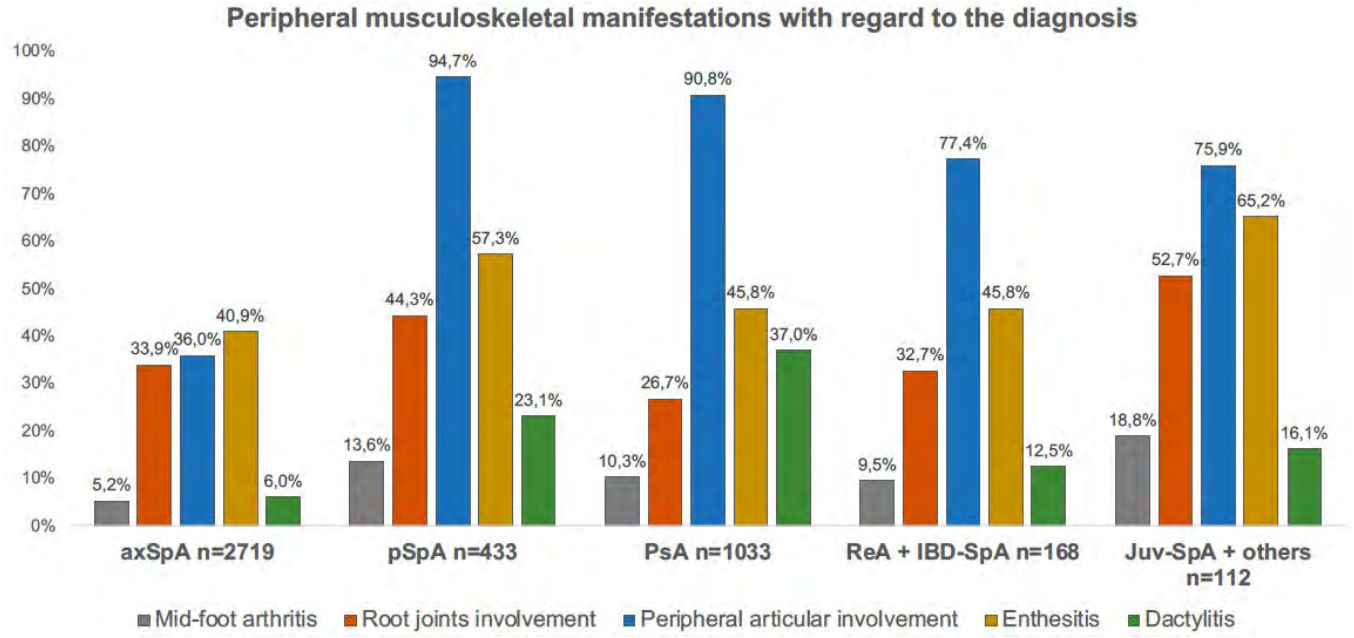

Figure 2. Peripheral musculoskeletal manifestations with regard to the diagnosis.

of spondyloarthritis (SpA) and specifically in axial SpA (axSpA), even though an important overlap exists between SpA subtypes and PsA. The ASAS-PerSpA study aimed to evaluate the prevalence, characteristics and treatment of peripheral musculoskeletal manifestations in patients with axSpA and peripheral SpA (pSpA) as well as in PsA across regions of the world.

Methods: Data was collected cross-sectionally in an international multicentre study with 24 participating countries. Consecutive patients diagnosed as having axSpA, pSpA, PsA, inflammatory bowel disease-associated SpA (SpA-IBD), reactive arthritis (ReA), juvenile SpA (JuvSpA) or other form of SpA were eligible for the study. Data concerning the presence of peripheral musculoskeletal manifestations, their localization and specific treatments were collected.

Results: A total of 4465 patients were included (61% men, mean (SD) age of 45 (14) years). Patients came from four geographic areas: Latin America (12.0%), Europe and North America (37.6%), Asia (21.8%) and Middle East and North Africa (28.6%). The most prevalent clinical diagnosis was axSpA (60.9%), followed by PsA (23.1%), pSpA (9.7%), SpA-IBD (2.5%), ReA (1.3%), JuvSpA (1.2%) and others (1.3%).

The prevalence of musculoskeletal manifestations were plotted against geographic area and diagnosis in Figures 1 and 2. The most prevalent peripheral manifestation was peripheral articular involvement (excluding root joints) (56.9%) (Figure 1, whole population), with polyarticular involvement more often found in PsA (58.9%) and monoarticular involvement in axSpA (20.1%) (Fig.2). Predominantly upper limb- and small joint involvement were found more often in PsA (52.0%). Predominantly lower limb- and large joint involvement were found more often in ReA and IBD-SpA (55.9%) and in pSpA (51.2%) (Figure 2). Root joint (i.e., hip or shoulder) involvement was found in 33.7% and, of these, 21.8% had both hip and shoulder involvement. Among the total patients with root joint disease, hip involvement alone was found in 57.1%, being most frequent in axSpA (65.0%). Enthesitis in the different groups ranged between 40.9% and 65.9%, with the lowest prevalence found for axSpA; PsA showed the highest mean number of locations of all episodes of enthesitis (4.3 (4.6)). Finally, the prevalence of dactylitis was 15.3%. Dactylitis of the fingers was more prevalent in the group of ReA and IBD-SpA (75.0%), but a higher prevalence of toe-involvement was found in Juv-SpA (66.7%). Only 8.1%, 12.1% and 14.3% of patients had received local injections of corticosteroids for peripheral enthesitis, dactylitis and root joint involvement, respectively.

Conclusion: Although all types of peripheral manifestations are present in the different subtypes of SpA, this study suggests a high inter-region and inter-diagnosis variability of the prevalence of the various peripheral musculoskeletal manifestations in patients with either SpA or PsA.

Visfatin	ng/ml	1.38 [3.26]	1.36 [2.21]	0.110	2.03 [2.25]	0.288

Table 1. Serum biomarker levels at baseline (before start of TNFi), after 3 months and 2 years. Values presented as medians [interquartile range (IQR)]. # Wilcoxon signed-rank test compared to baseline. HMW high molecular weight. MMP-3 matrix metalloproteinase-3. PIINP procollagen type II N-terminal propeptide. SAA serum amyloid A. VEGF vascular endothelial growth factor.

Background/Purpose: Radiographic spinal progression determinates functional status and mobility in ankylosing spondylitis (AS) (Poddubnyy et al, 2018). Our objective was to analyze whether biomarker levels at baseline or their change after 3 months or 2 years can predict spinal radiographic progression in AS patients treated with TNF-α inhibitors (TNFi).

Methods: Consecutive AS patients from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort (Maas et al, 2019) starting TNFi between 2004 and 2012 were included. The following serum biomarkers were measured at baseline, 3 months and 2 years of follow-up with commercially available ELISA: calprotectin, matrix metalloproteinase-3 (MMP-3), serum amyloid A (SAA), vascular endothelial growth factor (VEGF), osteoprotegerin (OPG), procollagen type II N-terminal propeptide (PIINP), sclerostin, high molecular weight adiponectin, leptin and visfatin. Two independent readers assessed spinal radiographs according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).

Logistic regression was performed to examine the association between biomarker values at baseline, their change after 3 months and 2 years and radiographic spinal progression (defined as mSASSS change ≥2 units or the formation of ≥1 new syndesmophyte over 2 years). Multivariable models for each biomarker were adjusted for mSASSS or syndesmophytes at baseline, elevated CRP (≥5mg/l), smoking status, male gender, symptom duration, BMI, and baseline biomarker level (the latter only in models with biomarker change).

Results: Of the 137 included AS patients, 72% were male, 79% HLAb27+, mean age was 42 years (SD 10.8) and baseline ASDAScrp 3.8 (SD 0.8). Serum levels of calprotectin, MMP-3, SAA and VEGF showed a significant reduction after 3 months and 2 years of TNFi therapy. OPG and PIINP decreased significantly after 3 months, but did not differ from baseline after 2 years. Sclerostin increased after 2 years.

Univariable logistic regression revealed a significant association of baseline visfatin (odds ratio (OR) [95% confidence interval] 1.106 [1.007-1.215]) and sclerostin serum levels (OR 1.006 [1.001-1.011]) with radiographic progression defined as mSASSS change ≥2 units after 2 years. In multivariable logistic analysis, only baseline visfatin level remained significantly associated (OR 1.337 [1.088-1.642]). Furthermore, baseline calprotectin showed a positive association (OR 1.146 [1,011-1,299]) when adjusting for known risk factors for radiographic spinal progression. Interestingly, the change of visfatin level after 2 years was associated with both measures of radiographic progression after 2 years – mSASSS progression (OR 1.108 [1.004-1.224]) and syndesmophyte formation (OR 1.115; [1.002-1.24]). However, those associations were lost in multivariate analysis.

Conclusion: While serum levels of biomarkers of inflammation (calprotectin, MMP-3, SAA, VEGF) and bone formation (OPG, PIINP, sclerostin) showed significant changes under TNFi therapy, adipokine levels (HMW-adiponektin, leptin, visfatin) were not altered. Independent of known risk factors, baseline calprotectin and visfatin levels were associated with radiographic spinal progression after 2 years of TNFi.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II

Session Type: Abstract Session

Session Time: 12:00PM–12:50PM

Background/Purpose: Assessment of radiographic joint damage extent and progression is important in clinical trials evaluating treatments for psoriatic arthritis (PsA). Joint damage in patients with PsA has substantial impact on

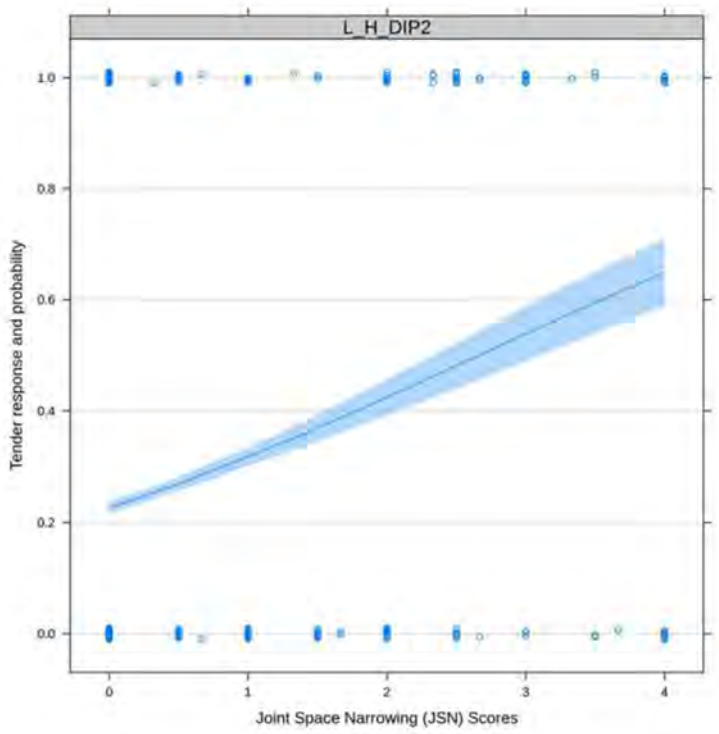

Figure shows one of the 42 joints on the hands and feet (i.e. left hand DIP2). The dots at y=0 and 1 (vertically jittered to reduce over-plotting) depict the assessed tenderness (no/yes) and JSN (x-axis) for each patient. The curves and associated standard error bands depict the (mostly increasing) probability of joint tenderness as a function of JSN.

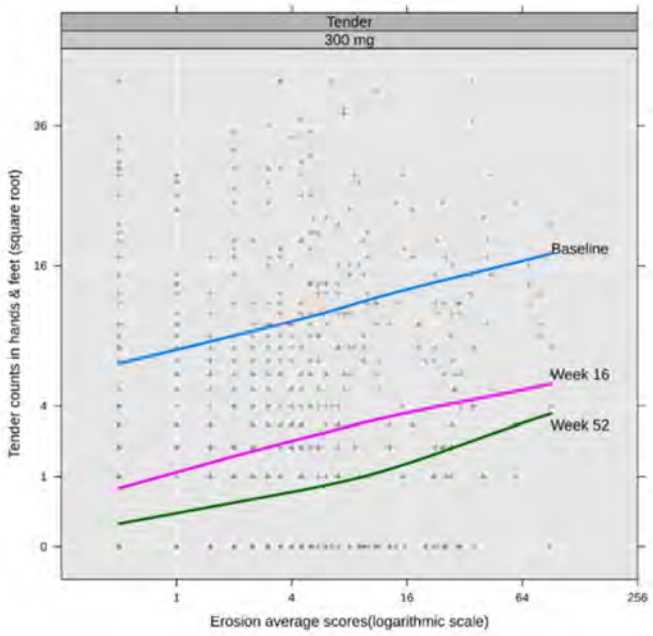
Association between tenderness and joint space narrowing on individual joints assessed radiographically across patients at baseline



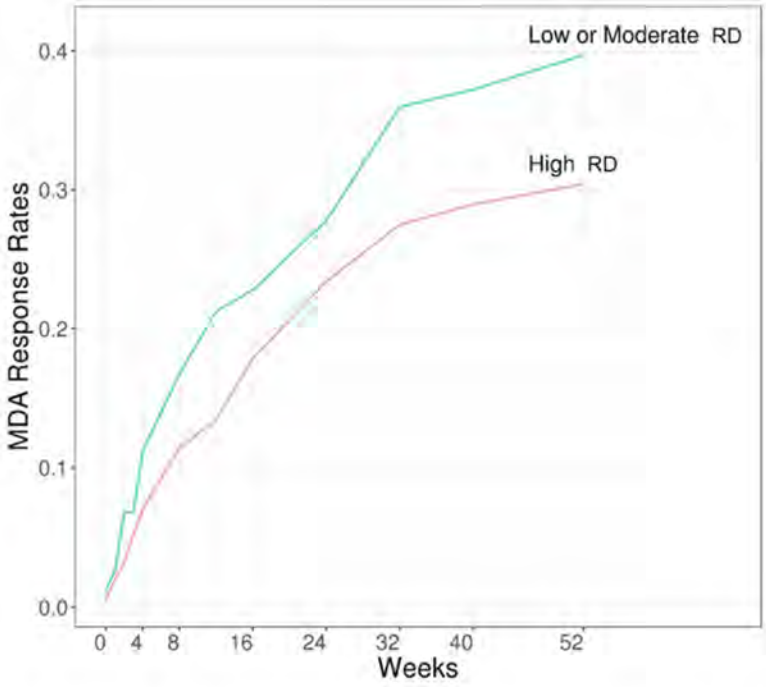
The lines depict average trend at baseline, Weeks 16, and 52. The roughly parallel decrease of the curves illustrates the effect of secukinumab on joint counts approximately uniformly across all values of erosion, although patients with very high levels of erosion would have lower probability of complete remission (counts=0).

Number of tender joint counts versus erosion scores for every patient at baseline, Week 16, and Week 52
MDA response rate through Week 52

physical function, quality of life and survival, therefore, inhibiting radiographic progression is one of the main goals of therapy.[1,2] Here we present results from a machine learning analysis of pooled data from two phase 3 secukinumab trials in PsA aimed to identify prevalence and magnitude of pre-existing radiographic damage at baseline and its association with clinical swollen and tender joint count; and investigate the extent to which radiographic damage at baseline could influence the response to secukinumab therapy.

Methods: Mixed-effects linear regression models were applied to data from FUTURE 1 and FUTURE 5 studies to investigate the association at baseline between overall radiographic damage and swollen / tender joint counts on a patient level and on a joint-within-patient / individual joint level; random effects were used to account for variability at both the levels. Visualization was used to explore joint activity progression patterns as functions of time and secukinumab dosing, and to estimate the probability of joint activity as a function of radiographic damage at each joint. Two additional mixed-effects models (one at overall patient level and another at joint segment level) were implemented to estimate the impact of radiographic damage, treatments and baseline patient characteristics on joint activity over time. Response to secukinumab therapy was assessed using swollen/tender joint count and proportion of patients achieving minimal disease activity (MDA) over time.

Results: Data for 1554 patients from FUTURE 1 and FUTURE 5 studies were pooled. At baseline, 69.4% and 50.1% of patients, respectively, showed detectable erosions and joint space narrowing (JSN; defined as patients with radiographic scores >1). Patients with early PsA diagnosis (≤2 years) showed strong prevalence of erosions and JSN, which progressively worsened over time. At an individual joint level, the probability of tenderness and swelling was strongly and significantly associated with the extent of radiographic damage **(Figure 1)**. At a patient level, significant reductions of swollen/tender joint count were observed in all secukinumab dose regimens regardless of the levels of



MDA response rates over time for high radiographic damage patients ($n_1 = 342$) compared with low or moderate radiographic damage patients ($n_2 = 645$). The response rates are 17.8%/22.8% at Week 16 and 30.4%/39.7% at Week 52 for high radiographic damage patients (defined as patients with mTSS≥8) and low or moderate radiographic damage patients (defined as patients with mTSS<8), respectively. The high radiographic damage patients at baseline tend to have around 10% lower response rate than low or moderate radiographic damage patients on an average at Week 52

MDA response rate Through Week 52

radiographic damage. However, patients with higher radiographic damage showed a lower proportion of complete remission of joint symptoms (swollen joint count and tender joint count = 0; **Figure 2**). The MDA response showed a similar pattern to the tender/swollen joint count responses corresponding to low and high levels of radiographic damage **(Figure 3)**.

Conclusion: A strong and significant association was demonstrated between disease activity and baseline radiographic damage at the individual joint level, whereas the analysis at patient level showed a weaker association. High radiographic damage at baseline was associated with a lower rate of achieving remission.

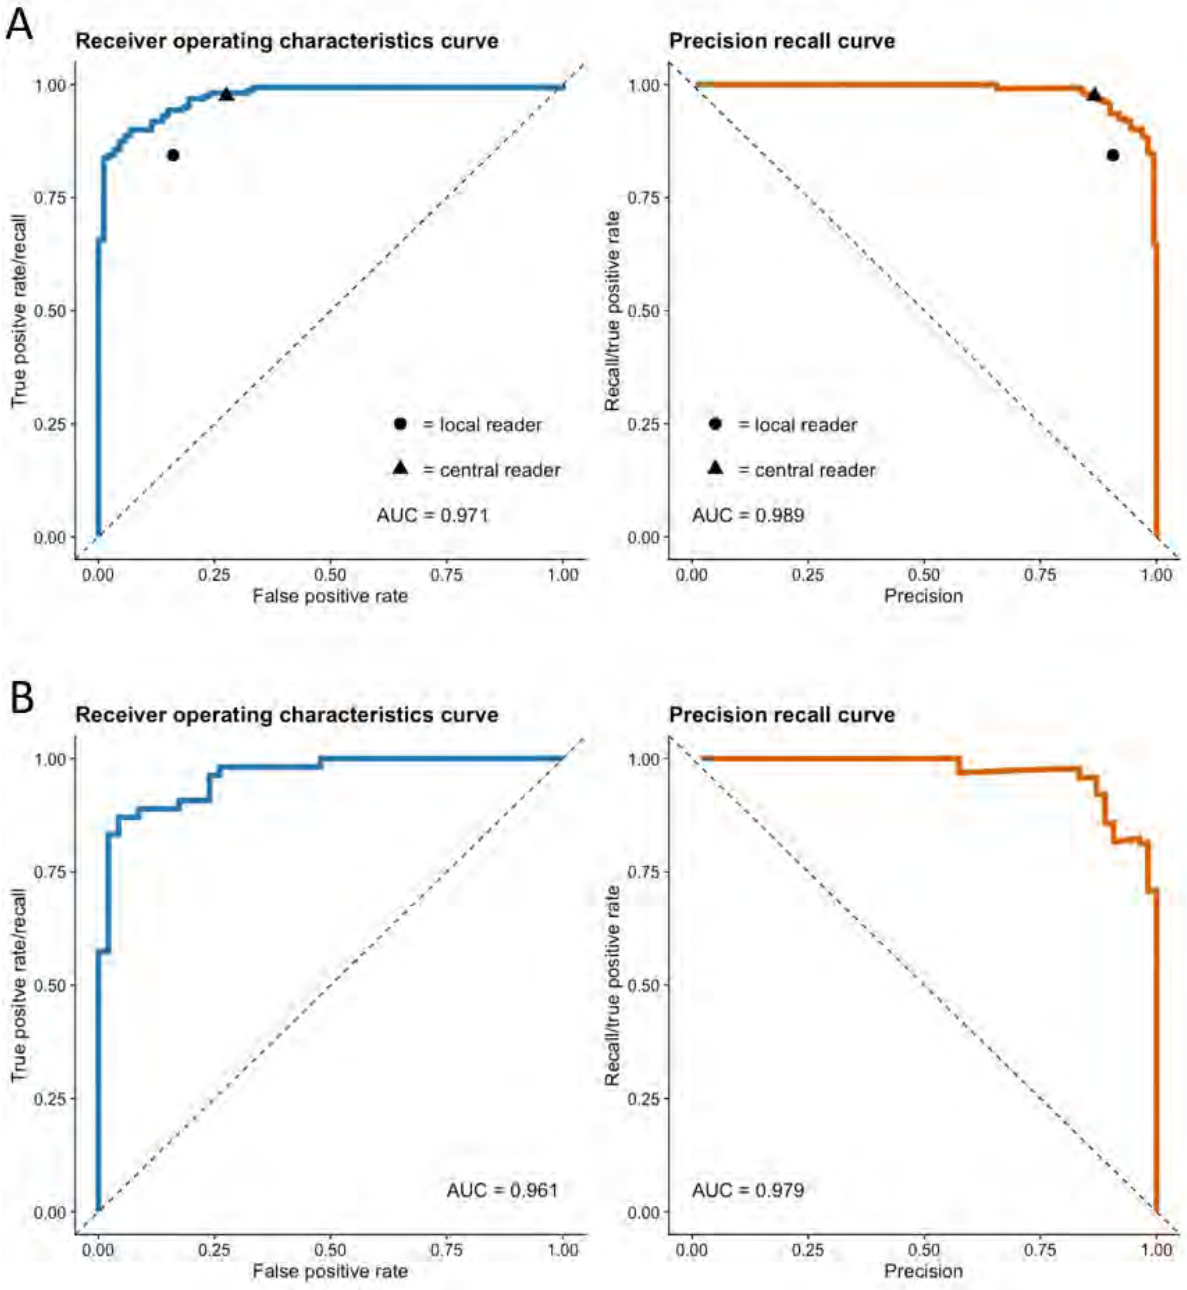
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes III: Imaging in SpA
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Conventional radiography of the sacroiliac joints is still recommended as the first imaging method if axial spondyloarthritis (axSpA) is suspected. Furthermore, radiographic sacroiliitis is included – together with sacroiliitis on magnetic resonance imaging – in the Assessment of Spondyloarthritis International Society (ASAS) classification criteria for axSpA. Depending on the presence or absence of definite radiographic sacroiliitis, axSpA can be classified either as radiographic axSpA (r-axSpA, synonymous to ankylosing spondylitis) or non-radiographic axSpA (nr-axSpA). Although conventional radiography of sacroiliac joints still plays an important role in clinical practice and for clinical trials, the reliability of radiographic sacroiliitis assessment has been reported in a number of studies as mostly poor, even if performed by expert readers. Furthermore, it was shown that untrained local readers perform worse than expert readers specialised in SpA. One possible solution to achieve a comparable high accuracy as an expert on detection of radiographic sacroiliitis, even in non-specialised clinics, could be development of an artificial intelligence-based model for analysis of radiographs.

The aim of this study was to develop and validate an artificial neural network for the detection of definite radiographic sacroiliitis as a manifestation of axial spondyloarthritis.

Methods: Conventional radiographs of sacroiliac joints from two independent cohorts of patients with axSpA were used. The first cohort (PROOF) consisted of 1669 radiographs and was used for training and validation of a neural network. The second cohort consisted of 100 randomly selected radiographs from GESPIC, which were used as an independent test dataset. In both cohorts all radiographs underwent central reading; the final decision on the presence or absence of definite radiographic sacroiliitis according to the radiographic criterion of the modified New York criteria was used as a reference. For performance evaluation of the neural network, areas under the receiver operating characteristic curves (AUROC) were calculated. Sensitivity and specificity for the prediction cut-offs were calculated. Cohen's Kappa and the absolute agreement were used to assess the agreement between the neural network and the human readers.

Figure 1. Receiver operating characteristic and precision recall curves for the validation (A) and independent test (B) data sets.



Results: The neural network achieved an excellent performance in recognition of definite radiographic sacroiliitis with AUROC of 0.97 and 0.96 for the validation and test datasets, respectively (Figure 1). Sensitivity and specificity for the cut-off weighting both measurements equally were 0.90 and 0.93 for the validation and 0.87 and 0.97 for the test set. The Cohen's kappa between the neural network and the reference judgements were 0.80 for both validation and test sets, and the absolute agreement on the classification yielded 91% and 90%, respectively (Table). Examples of the activation maps of the neural network are presented in Figure 2.

Table. Confusion matrices on the presence or absence of definite radiographic sacroiliitis for the validation and independent test data for the prediction cut-off with an optimal relationship between sensitivity and specificity.

Validation data set

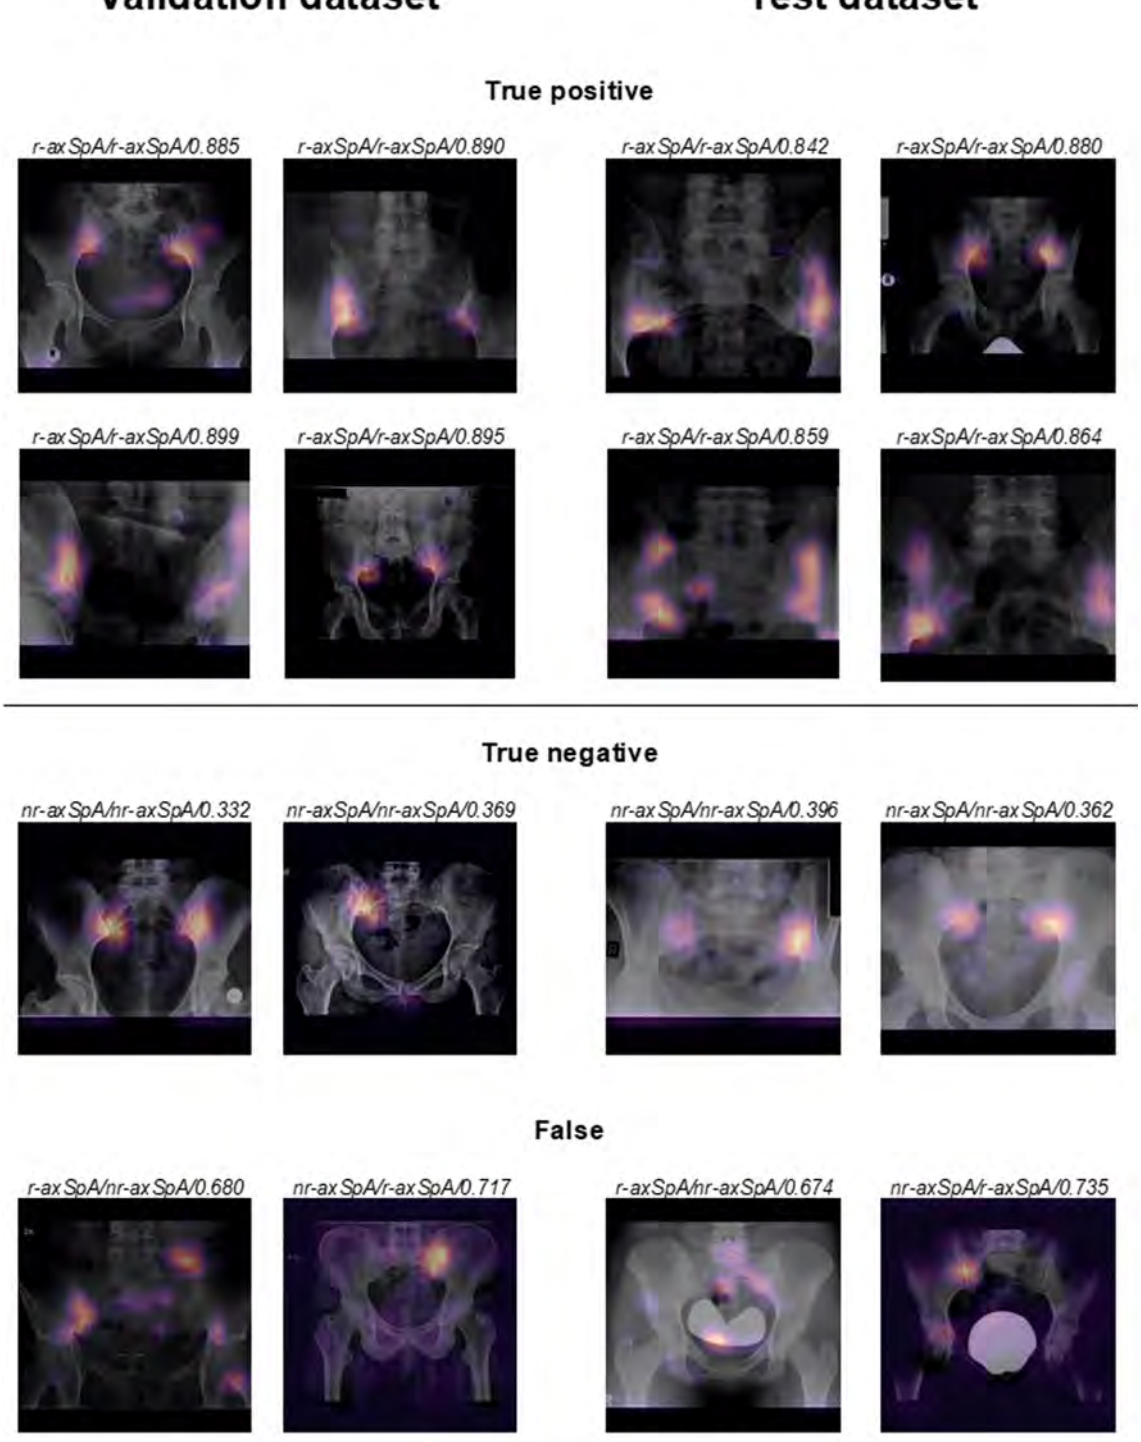
	Reference negative	Reference positive	
Model negative	81	17	98
Model positive	6	143	149
	87	160	247
Cohen's Kappa:	0.802 (95% CI 0.731 to 0.875)	Absolute agreement:	n=224 (90.7%)

Independent test data set

	Reference negative	Reference positive	
Model negative	44	8	52
Model positive	2	46	48
	46	54	100
Cohen's Kappa:	0.801 (95% CI 0.688-0.919)	Absolute agreement:	n=90 (90%)

Conclusion: Artificial neural networks enable the accurate detection of definite radiographic sacroiliitis relevant for the diagnosis and classification of axSpA.

Figure 2. Example activation maps of the neural network in the validation and test data sets.



Actual class, predicted class and the probabilities are shown

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes III: Imaging in SpA

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: The ASAS definition of a positive MRI for inflammation (ASAS-MRI+) is intended for classification of patients as having axSpA but is often misused for diagnostic purposes. This is problematic because bone marrow edema (BME) in the sacroiliac joints (SIJ) may occur in 20-40% of both healthy individuals and those with mechanical back disorders when only the quantitative aspect of the definition is applied (presence of BME in ≥2 locations on one slice or one location in ≥2 slices). The definition also requires that BME is considered "highly suggestive" of SpA but interpretation of this qualitative component may vary according to expertise. Revised definitions of MRI lesions in the SIJ have been validated by 7 readers from the ASAS-MRI group on images from the ASAS Classification Cohort[1-3]. We aimed to identify quantitative cut-offs based on numbers of slices and SIJ quadrants that define a positive MRI for active lesions typical of axSpA, the gold standard being majority central reader decision as to the presence of a definite active lesion typical of axSpA with high confidence.

Methods: MRI active lesions meeting ASAS definitions from 160 cases were recorded by 7 ASAS-MRI readers in an eCRF that comprises global assessment (Is there an active lesion typical of axSpA (yes/no) and degree of confidence (-4 (lesion absent) to +4 (lesion present)), and detailed scoring of lesions per SIJ quadrant and per slice. Detailed scoring was based only on assessment of DICOM images. We calculated sensitivity and specificity for numbers of SIJ quadrants and consecutive slices with BME where a majority of readers (≥4/7) agreed as to the presence of an active lesion typical of axSpA with high confidence (≥ +3). We selected cut-offs with ≥95% specificity. These cut-offs were analyzed for their predictive utility for rheumatologist diagnosis of axSpA at follow up (average of 4.4 years) by calculating positive and negative predictive values (PPV, NPV) and selecting those cut-offs with PPV of ≥95% and

Table 1. Majority readers agree active lesion indicative of axSpA is present with confidence ≥3/4 is the gold-standard external reference		
MRI cut-offs	**Sensitivity (95%CI)**	**Specificity (95%CI)**
Majority (≥4/7) reader agreement for definite active lesion		
BME in ≥1 SIJ quadrant	100.0 (86.8-100.0)	71.6 (63.2-79.1)
BME in ≥2 SIJ quadrants	100.0 (86.8-100.0)	85.8 (78.7-91.2)
BME in ≥3 SIJ quadrants	100.0 (86.8-100.0)	91.8 (85.8-95.8)
BME in ≥4 SIJ quadrants	**100.0 (86.8-100.0)**	**96.3 (91.5-98.8)**
BME in ≥2 consecutive slices	100.0 (86.8-100.0)	88.1 (81.3-93.0)
BME in ≥3 consecutive slices	**100.0 (86.8-100.0)**	**94.8 (89.5-97.9)**
BME in ≥4 consecutive slices	96.2 (80.4-99.9)	98.5 (94.7-99.8)
Majority (≥4/7) reader agreement for definite ASAS positive MRI		
BME in ≥1 SIJ quadrant	100.0 (86.8-100.0)	71.6 (63.2-79.1)
BME in ≥2 SIJ quadrants	100.0 (86.8-100.0)	85.8 (78.7-91.2)
BME in ≥3 SIJ quadrants	100.0 (86.8-100.0)	91.8 (85.8-95.8)
BME in ≥4 SIJ quadrants	**100.0 (86.8-100.0)**	**96.3 (91.5-98.8)**
BME in ≥2 consecutive slices	100.0 (86.8-100.0)	88.1 (81.3-93.0)
BME in ≥3 consecutive slices	**100.0 (86.8-100.0)**	**94.8 (89.5-97.9)**
BME in ≥4 consecutive slices	96.2 (80.4-99.9)	98.5 (94.7-99.8)

Table 2. Predictive values of cut-offs for baseline MRI SIJ lesion scores and slices according to the diagnostic ascertainment of the rheumatologist at follow-up after 4.4 years				
MRI cut-offs	**Sensitivity (95%CI)**	**Specificity (95%CI)**	**PPV**	**NPV**
BME in ≥2 SIJ quadrants	47.8 (35.6-60.2)	82.4 (56.6-96.2)	91.7 (79.3-96.9)	28.0 (22.1-34.8)
BME in ≥3 SIJ quadrants	34.8 (23.7-47.2)	88.2 (63.6-98.5)	92.3 (75.8-97.9)	25.0 (20.7-29.9)
BME in ≥4 SIJ quadrants	**31.9 (21.2-44.2)**	**94.1 (71.3-99.9)**	**95.7 (76.1-99.3)**	**25.4 (21.8-29.4)**
BME in ≥2 consecutive slices	43.5 (31.6-56.0)	82.4 (56.6-96.2)	90.9 (77.6-96.7)	26.4 (21.0-32.7)
BME in ≥3 consecutive slices	**30.4 (19.9-42.7)**	**100 (80.5-100.0)**	**100**	**26.2 (23.3-29.3)**
BME in ≥4 consecutive slices	26.1 (16.3-38.1)	100 (80.5-100.0)	100	25.0 (22.5-27.7)

comparable predictive utility with global MRI assessment. Both specificity of ≥95% for a definite lesion as well as a PPV of ≥95% were considered requirements for preliminary designation of MRI lesion cut-offs defining a positive MRI for active lesions.

Results: Active lesions typical of axSpA were observed by majority read in 39 (35.8%) of 109 cases diagnosed with axSpA, and 1 (2.0%) of 49 cases without axSpA and 26 cases were assigned a high degree of confidence (≥ +3) by a majority of readers. Cut-offs achieving specificity of ≥95% for a definite active lesion were BME at the same location in ≥3 consecutive slices (sensitivity 100%) and BME at any location in ≥4 SIJ quadrants (sensitivity 100%) (Table 1). Both of these cut-offs had very high positive predictive values (≥95%) for diagnosis of axSpA in cases diagnosed by the rheumatologist after 4.4 years follow up (Table 2).

Conclusion: ASAS-defined BME at the same location in ≥3 consecutive slices or in ≥4 SIJ quadrants at any location, are high priority candidates for defining an MRI active lesion typical of axSpA. This will require similar assessment in additional axSpA cohorts.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes III: Imaging in SpA

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: There is lack of international consensus as to what defines a structural lesion on MRI of the sacroiliac joints (SIJ) typical of axial spondyloarthritis (axSpA). The ASAS MRI group has generated updated consensus lesion definitions that describe each of the MRI lesions in the SIJ[1] which have been validated by 8 readers from the ASAS-MRI group on MRI images from the ASAS Classification Cohort[2,3]. We aimed to identify quantitative cut-offs based on numbers of slices and SIJ quadrants that define a positive MRI for structural lesions typical of axSpA,

Table 1. Majority readers agree structural lesion indicative of axSpA is present with confidence ≥3/4 is the gold-standard external reference

MRI cut-offs	Sensitivity (95%CI)	Specificity (95%CI)
Erosion in ≥1 SIJ quadrant	93.1 (77.2-99.2)	80.6 (72.4-87.3)
Erosion in ≥2 SIJ quadrants	93.1 (77.2-99.2)	90.8 (84.1-95.3)
Erosion in ≥3 SIJ quadrants	**89.7 (72.6-97.8)**	**95.8 (90.5-98.6)**
Erosion in 2 consecutive slices	**82.8 (64.2-94.2)**	**95.0 (89.3-98.1)**
Fat lesion in ≥1 SIJ quadrant	82.8 (64.2-94.2)	81.5 (73.4-88.0)
Fat lesion in ≥2 SIJ quadrants	69.0 (49.2-84.7)	86.6 (79.1-92.1)
Fat lesion in ≥3 SIJ quadrants	62.1 (42.3-79.3)	91.6 (85.1-95.9)
Fat lesion in ≥4 SIJ quadrants	62.1 (42.3-79.3)	94.1 (88.3-97.6)
Fat lesion in ≥5 SIJ quadrants	**62.1 (42.3-79.3)**	**97.5 (92.8-99.5)**
Fat lesion in ≥2 consecutive slices	55.2 (35.7-73.6)	93.3 (87.2-97.1)
Fat lesion in ≥3 consecutive slices	**51.7 (32.5-70.6)**	**97.5 (92.8-99.5)**
Fat lesion (>1cm extent) ≥1 SIJ quadrant	58.6 (38.9-76.5)	95.0 (89.3-98.1)
Fat lesion (>1cm extent) ≥2 SIJ quadrants	**55.2 (35.7-73.6)**	**95.8 (90.5-98.6)**

Table 2. Predictive values of cut-offs for baseline MRI SIJ lesion scores and slices according to the diagnostic ascertainment of the rheumatologist at follow-up after 4.4 years

MRI cut-offs	Sensitivity (95%CI)	Specificity (95%CI)	PPV	NPV
Erosion in ≥3 SIJ quadrants	38.1 (26.1-51.2)	93.8 (69.8-99.8)	96.0 (77.8-99.4)	27.8 (23.4-32.6)
Erosion in ≥2 consecutive slices	38.1 (26.1-51.2)	93.8 (69.8-99.8)	96.0 (77.8-99.4)	27.8 (23.4-32.6)
Fat lesion in ≥5 SIJ quadrants	31.8 (20.6-44.7)	93.8 (69.8-99.8)	95.2 (74.3-99.3)	25.9 (22.0-30.1)
Fat lesion in ≥3 consecutive slices	30.2 (19.2-43.0)	93.8 (69.8-99.8)	95.0 (73.3-99.2)	25.4 (21.7-29.5)
Fat lesion (>1cm extent) in ≥2 SIJ quadrants	25.4 (15.3-37.9)	100 (79.4-100)	100	25.4 (22.8-28.2)

the gold standard being majority central reader decision as to the presence of a definite structural lesion typical of axSpA with high confidence.

Methods: MRI structural lesions meeting ASAS definitions from 148 cases were recorded in an eCRF that comprises global assessment (Is there a structural lesion typical of axSpA (yes/no) and degree of confidence (-4 (lesion absent) to +4 (lesion present)), and detailed scoring of lesions per SIJ quadrant and per slice. We calculated sensitivity and specificity for numbers of SIJ quadrants and consecutive slices with erosion, sclerosis, and fat lesions where a majority of readers (≥4/7) agreed as to the presence of a structural lesion typical of axSpA with high confidence (≥ +3). We selected cut-offs with ≥95% specificity. These cut-offs were analyzed for their predictive utility for rheumatologist diagnosis of axSpA at follow up (average of 4.4 years) by calculating positive and negative predictive values (PPV, NPV) and selecting those cut-offs with PPV of ≥95% and comparable predictive utility with global MRI assessment. Both specificity of ≥95% for a definite lesion as well as a PPV of ≥95% were considered requirements for preliminary designation of MRI lesion cut-offs defining a positive MRI for structural lesions.

Results: Structural lesions typical of axSpA were observed by majority read in 33 (32.4%) of 102 cases diagnosed with axSpA, and 3 (6.8%) of 44 cases without axSpA and 29 cases were assigned a high degree of confidence (≥ +3) by a majority of readers. Cut-offs achieving specificity of ≥95% for a definite structural lesion were erosion at the same location in ≥2 consecutive slices (sensitivity 83%), erosion at any location in ≥3 SIJ quadrants (sensitivity 90%), fat lesion at any location in ≥5 SIJ quadrants (sensitivity 62%), fat lesion at the same location in ≥3 consecutive slices (sensitivity 52%), and 'deep' fat lesion (≥1cm extent) in ≥2 SIJ quadrant (sensitivity 55.2%) (Table 1). All of these had very high positive predictive values (≥95%) for diagnosis of axSpA in cases diagnosed by the rheumatologist after 4.4 years follow up (Table 2). Combinations of cut-offs for different structural lesions were not superior to single lesion cut-offs.

Conclusion: ASAS-defined erosion in ≥2 consecutive slices or in ≥3 SIJ quadrants, and ASAS-defined fat lesion in ≥3 consecutive slices or in ≥5 SIJ quadrants or 'deep' fat lesion (≥1cm extent) in ≥2 SIJ quadrants are high priority candidates for defining an MRI structural lesion typical of axSpA. This will require similar assessment in additional axSpA cohorts.

Inter-Rater Agreement for Scoring of Entheseal Lesions (N=262 entheseal Sites, 18 patients)

Background/Purpose: DUET is a study supported by the Group for Assessment for Psoriasis and Psoriatic Arthritis (GRAPPA) that aims to develop a novel sonographic scoring system for enthesitis to assist with PsA diagnosis. The objectives of the present study are to define the elementary lesions of enthesitis for the DUET study and to assess the inter-rater reliability of the central readers in scoring these lesions.

Methods: The DUET study steering committee, that included three experienced sonographers, reached a consensus regarding the definitions and grading of the sonographic elementary lesions for enthesitis that will be used in the study. The following elementary lesions were considered: hypoechogenicity (yes/no), thickening (yes/no and quantitative), enthesophyte (graded 0-3), erosion (yes/no), calcification (graded 0-3), bursitis (graded 0-2) and Power Doppler (graded 0-3). An atlas with images depicting each elementary lesion was created (Figure 1). For the inter-rater reliability assessment the three readers were asked to score 18 sets of short video clips of ultrasound scans from patients with active PsA. Each set included B-mode and Doppler scans that followed the DUET scanning protocol and included 16 entheseal sites around the knee, ankle, elbow and shoulder. The readers were blinded to the clinical data. Inter-rater reliability was calculated using Kappa statistics (K) for categorical variables and intraclass correlation coefficient (ICC) for continuous variables.

Results: A total of 262 entheseal sites were scored. The prevalence of the elementary lesions (range by reader) were: hypoechogenicity (53.4-54.8%), thickening (26-43.2%), erosion (7.7-10.9%), enthesophyte (48.2-61.3%), calcification (3.4-11.5%), Doppler signal (27.1-42.2%) and bursitis (12-22.5%). The inter-rater agreement ranged from excellent to fair as follows (Table 1): Doppler (K=0.87), enthesophyte (K=0.75), erosion (K=0.73), bursitis (K=0.60), hypoechogenicity (K=0.47), thickening (K=0.47), calcification (K=0.22). Thickness measurement and the total score per entheseal site showed very good inter-rater agreement (ICC of 0.78 and 0.82, respectively). The agreement for hypoechogenicity and thickening varied by site being lowest for the plantar fascia, supraspinatus, quadriceps and lateral epicondyle.

Conclusion: Good agreement was found between expert sonographers for scoring the majority of the entheseal sonographic lesions for the DUET study.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes III: Imaging in SpA
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: The clinical efficacy of TNFi in patients with axSpA is well established but its effect on new bone formation is still unclear. Positron emission tomography (PET) using bone-seeking ^{18}F-Fluoride [18F]F in combination with magnetic resonance imaging ([18F]F/MRI) can depict bone marrow edema (BME) but also shows the quantity of tracer uptake in the late phase of perfusion suggestive of remodeling and osteoblastic activity. We assessed the effect of TNFi on bone remodeling processes in the axial skeleton of r-axSpA patients using [18F]F/MRI prior (baseline, BL) and 4 months after (follow-up, FU) treatment.

Methods: Patients (11 male, 5 female, mean age 38.6±12.0 years) with clinically active AS (BASDAI >4, failure of NSAIDs, no previous biologics) prospectively underwent 3-Tesla and [18F]F PET/MRI (40 minutes after injection of a mean activity of 157 MBq [18F]F). Images of the SIJ (n=16 patients) and the whole spine (n=10 patients) were performed at BL and FU. Three readers (1 for [18F]F/MRI and 2 for conventional MRI) evaluated all images independently and blinded to timepoint allocation. Only lesions on which all readers agreed on were used for further analyses. Inflammation (bone marrow edema, BME), structural lesions (fat deposition (FD), sclerosis, erosions and ankylosis) and focal [18F]F uptake were recorded on the level of SIJ (SIJ-Q) and vertebral quadrants (V-Q), with each SIJ or vertebral body consisting of 4 VQs (superior and inferior sacral and iliac for the SIJ, and superior and inferior, anterior and posterior for the vertebral bodies).

Results: A total of 128 SIJ-Q and 920 VQs were analyzed at both BL and FU. In the SIJs, 75 (58.6%), 120 (93.8%), 69 (53.9%), 99 (77.3%) and 16 (12.5%) SIJ-Q showed BME, FD, sclerosis, erosions and ankylosis, while 111 (86.7%) SIJ-Q showed focal [18F]F-uptake at BL. Association with increased [18F]F-uptake was found most frequently in SIJ-Q with BME (70/75 SIJ-Q, 93.3%), sclerosis (65/69 SIJ-Q, 94.2%) and FD (105/120 SIJ-Q, 87.5%). At FU, 37 SIJ-Q still showed BME (improvement by 50.7%), while almost no changes were observed in chronic lesions. In comparison, improvement of focal [18F]F-uptake was found in all lesion combinations, with improvement of focal [18F]F-lesions associated with BME by 62.9%, with sclerosis by 33.8% and with FD by 22.9% of SIJ-Q.

In the spine, only 41 (4.5%), 61 (6.6%), 14 (1.5%) V-Q showed BME, FD and sclerosis, respectively, while 77 V-Q (8.4%) showed focal [18F]F-uptake. An association to increased [18F]F-uptake was found most frequently with sclerosis (7/14 V-Q, 50%) and FD (25/61 V-Q, 41%). At FU, 12 V-Q still showed BME (improvement by 70.7%), almost no changes were observed for chronic lesions. The largest improvement was found in focal [18F]F-lesions associated with BME 81.8% and with FD by 22.9% of V-Q.

Conclusion: In this first prospective study on whole spine and SIJ [18F]F/MRI in patients with AS, a significant decrease of osteoblastic activity was observed over 4 months of continuous anti-TNF treatment. These data support a short-term effect of anti-TNF treatment on osteoblastic activity, while the long-term effects need to be further studied

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Emerging Therapies

Session Type: Abstract Session

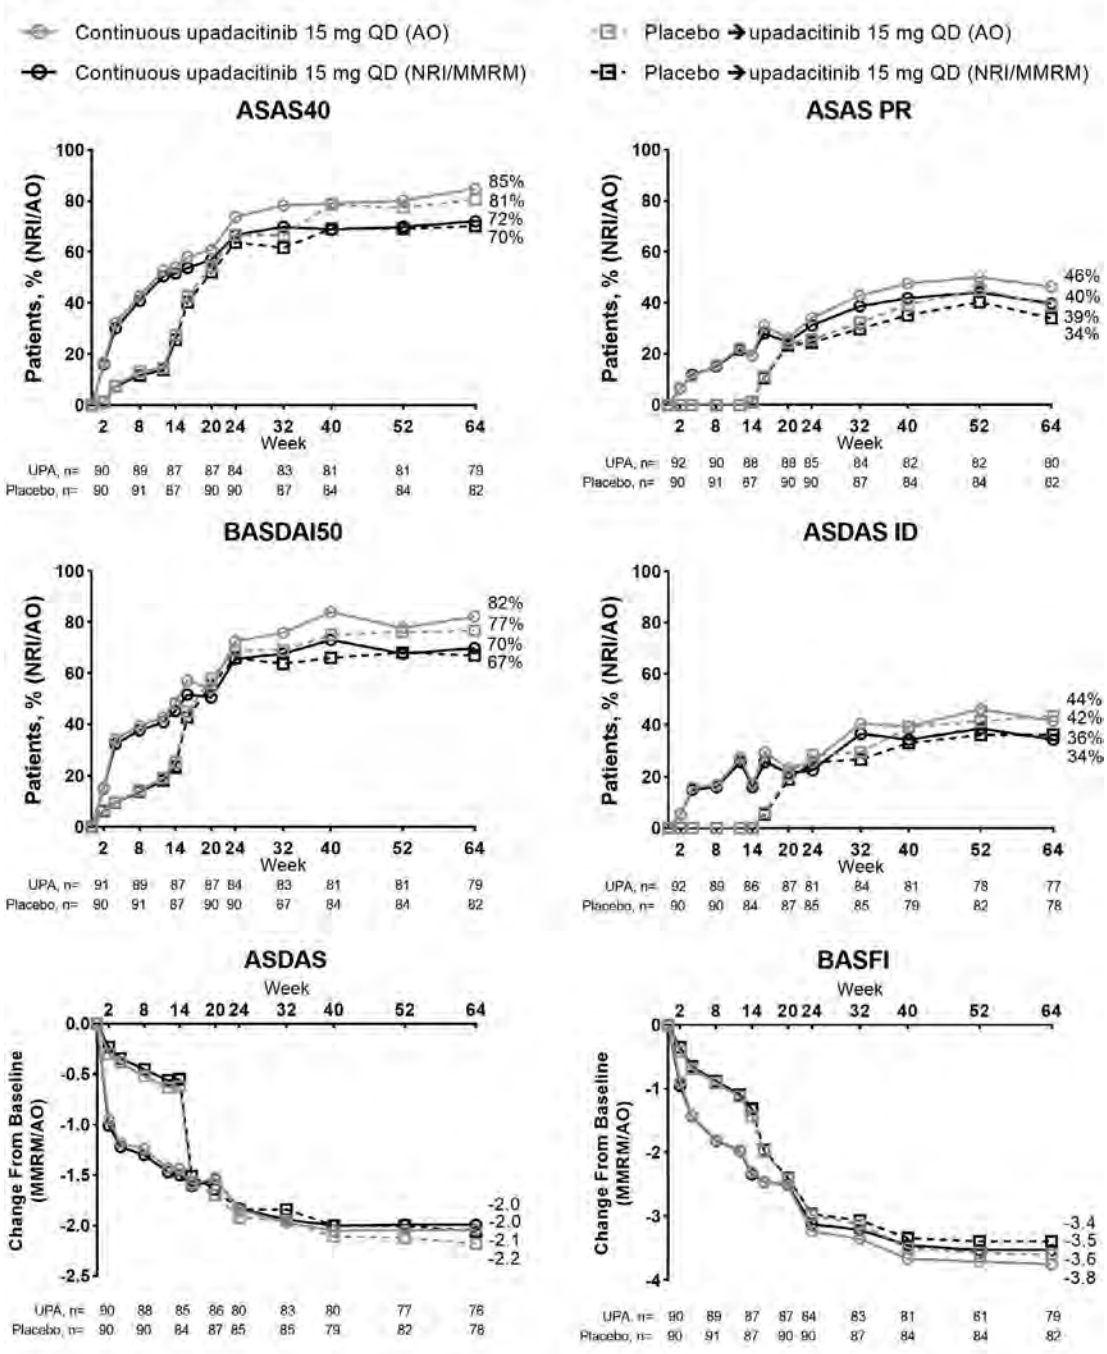
Session Time: 11:00AM–11:50AM

Background/Purpose: Upadacitinib (UPA), a Janus kinase (JAK) inhibitor, was efficacious and well tolerated vs placebo (PBO) during the first 14 weeks (wks) of the phase 2/3 SELECT-AXIS 1 study in patients (pts) with active ankylosing spondylitis (AS) who had an inadequate response to NSAIDs.[1] The objective of this interim analysis was to report efficacy and safety of UPA through 1 year in the SELECT-AXIS 1 study.

Methods: SELECT-AXIS 1 (NCT03178487) included a randomized, placebo-controlled, 14-wk period followed by 90-wk open-label extension; reported here are data up to wk 64. The study enrolled pts (≥18 y) with active AS (defined as BASDAI ≥4 and pt assessment of back pain ≥4 [numeric rating scale, 0–10] at screening and baseline [BL]) who had an inadequate response to ≥2 NSAIDs or intolerance to or contraindication for NSAIDs and were biologic DMARD naive. At BL, pts were randomized 1:1 to UPA 15 mg once daily (QD) or PBO; at wk 14, pts continued in the open-label extension and received UPA 15 mg QD. Efficacy assessments included the percentage of pts with Assessment of SpondyloArthritis international Society (ASAS) 20/40 response, ASAS partial remission, BASDAI50, and AS Disease Activity Score (ASDAS) responses over time and as change from BL in ASDAS and BASFI. Data are reported both as observed and by using non-responder imputation (NRI) for binary or mixed-effect model repeated measures for continuous efficacy endpoints for missing data. Treatment-emergent adverse events (TEAEs) were monitored throughout the study and reported as events per 100 patient-years (PY) up to January 31, 2020.

Results: Of 187 pts, 178 pts (each n=89 for UPA and PBO arms) completed wk 14 on study drug and entered the open-label extension; 160 pts completed wk 64. Efficacy was maintained or continued to improve throughout the study in the continuous UPA group: 85% (95% CI, 77%–93%) of pts achieved ASAS40 at week 64 in the as-ob-

Figure. Efficacy Endpoints Over Time



AO, as observed; ASAS, Assessment of SpondyloArthritis international Society; ASDAS, Ankylosing Spondylitis Disease Activity Score; ID, inactive disease; MMRM, mixed-effect model repeated measures; NRI, non-responder imputation; PR, partial remission; QD, once daily; UPA, upadacitinib.
Dashed line: all patients randomized to placebo received open-label UPA starting from week 14.
N's below the graphs are for as observed analysis. N's for NRI analysis were 94 for placebo to upadacitinib and 93 for continuous upadacitinib.
160 patients completed week 64; lack of efficacy (n=10) and adverse events (n=4) were the most common reasons for discontinuation between weeks 14 and 64.

Figure. Efficacy Endpoints Over Time

Table 1. TEAEs per 100 PYs

Events/(E/100 PY)	UPA 15 mg QD N=182 (237.6 PY)
Any AE	618 (260.1)
Serious AE	14 (5.9)
AE leading to discontinuation	15 (6.3)

Hepatic disorder§	24 (10.1)
Neutropenia‖	7 (2.9)
Anemia‖	3 (1.3)
Lymphopenia‖	2 (0.8)
Malignancy¶	1 (0.4)
Death	0

AE, adverse event; PY, patient-year; QD, once daily; TEAE, treatment-emergent AE; UPA, upadacitinib.
*Two non-serious events of esophageal candidiasis in the same patient.
†Five events in 4 patients; all non-serious and limited to 1 dermatome.
‡All events were non-serious and none led to study drug discontinuation; majority were asymptomatic.
§Majority based on asymptomatic alanine aminotransferase/aspartate aminotransferase elevations; all were non-serious and none led to study drug discontinuation.
‖All events were non-serious and none led to study drug discontinuation.
¶Squamous cell carcinoma of tongue in 61-year-old male former smoker; no reasonable possibility to be study drug related per investigator.

Table 1. TEAEs per 100 PYs

served analysis and 72% (63%–81%) in the NRI analysis (**Figure**). Pts who switched from PBO to UPA at wk 14 showed a similar speed of onset and magnitude of response compared with pts who were initially randomized to UPA: 81% (95% CI, 72%–89%) of pts in the as-observed analysis and 70% (61%–80%) of pts in the NRI analysis achieved ASAS40 at wk 64 (**Figure**). Similar results were observed for other efficacy endpoints (**Figure**). Among all 182 pts receiving UPA (237.6 PY), 618 AEs (260.1/100 PY) were reported. AEs leading to discontinuation (15 events [6.3/100 PY]) and serious AEs (14 events [5.9/100 PY]) were low (**Table 1**). No serious infections, active tuberculosis, venous thromboembolic events, gastrointestinal perforation, major adverse cardiovascular events, renal dysfunction, or deaths were reported.

Conclusion: UPA 15 mg QD showed sustained and consistent efficacy over 1 year. Pts who switched from placebo to UPA at wk 14 showed a similar efficacy response compared with those who received continuous UPA. No new safety findings were observed compared with safety data from the UPA clinical development program in other indications.[2]

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Emerging Therapies
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: The oral, selective Janus kinase 1 inhibitor filgotinib (FIL) significantly improved Spondyloarthritis Research Consortium of Canada (SPARCC) MRI inflammation scores (bone marrow edema) in the spine and sacroiliac joints vs placebo (PBO) in the Phase 2 TORTUGA trial (NCT03117270) in patients with active ankylosing spondylitis (AS; van der Heijde D, et al. *Lancet* 2018;392:2378–87). The current post hoc analysis evaluated the effects of FIL on Canada-Denmark (CANDEN) MRI measures of spinal inflammation and structural lesions in patients from the TORTUGA trial.

Methods: TORTUGA was a PBO-controlled, multicenter, double-blind, randomized trial in which 116 patients with active AS (as per modified New York classification criteria, with sacroiliitis confirmed by central reading) were treated with FIL 200 mg (n=58) or PBO (n=58) once daily for 12 weeks. MRIs of the total spine were conducted at baseline and at the end of treatment. Scans were re-evaluated post hoc by 2 independent experts (blinded to time point and assigned treatment) according to the detailed anatomy-based CANDEN method (Krabbe S, et al. *RMD Open* 2019;5:e001057); inter-reader discrepancies were resolved by an independent adjudicator. Observed changes from baseline were evaluated using analysis of covariance with factors for treatment, baseline value, and randomization stratification by prior TNF inhibitor use. Least-squares mean changes from baseline and between-group differences with 95% confidence intervals were calculated; p-values are nominal.

Results: MRI scans from 88 patients (47 FIL, 41 PBO) with an evaluable MRI at baseline and Week 12 (or early termination visit) were re-evaluated. Baseline characteristics were generally similar between subjects with and without an MRI scan. Of those with MRI scans, mean total spine inflammation score (which ranges from 0 to 614) was higher in the FIL vs PBO group and mean ankylosis score (which ranges from 0 to 460) was lower in the FIL group vs PBO at baseline (Table 1). Total spine inflammation scores decreased from baseline in the FIL group but not in the PBO group (Figure; Table 2; p=0.0003 for between-group difference). Cumulative probability plots favored FIL over PBO

Characteristic	Filgotinib (n=47)	Placebo (n=41)	All (N=88)
Age, years	40.4 (11.40)	42.0 (9.09)	41.1 (10.36)
Male sex, % of patients	76.6	73.2	75.0
Time since diagnosis, years	5.3 (5.38)	7.8 (8.44)	6.5 (7.04)
HLA-B27 positivity, % of patients	95.3	92.1	93.8
ASDAS	4.3 (0.53)	4.2 (0.71)	4.2 (0.62)
MRI SPARCC spine	20.6 (20.54)	15.6 (21.33)	18.2 (20.94)
MRI SPARCC SIJ	7.9 (11.58)	4.9 (6.28)	6.5 (9.56)
MASES	4.9 (2.74)	4.4 (3.01)	4.7 (2.86)
CANDEN ankylosis score, % of patients			
0–100	95.7	85.4	90.9
>100–200	2.1	12.2	6.8

Total CANDEN spine inflammation score	18.0 (21.35)	11.8 (17.05)	15.1 (19.61)
Total CANDEN spine fat score	15.4 (27.63)	11.9 (16.33)	13.8 (23.01)
Total CANDEN spine bone erosion score	0.5 (1.13)	0.3 (0.57)	0.4 (0.91)
Total CANDEN ankylosis score	15.4 (42.11)	31.1 (54.99)	22.7 (48.89)
Previous TNF inhibitor therapy, % of patients	8.5	12.2	10.2

Table 1. Demographics and baseline characteristics for patients with an MRI scan. Data are mean (SD) unless otherwise indicated. ASDAS, Ankylosing Spondylitis Disease Activity Score; CANDEN, Canada-Denmark; HLA, human leukocyte antigen; MASES, Maastricht Ankylosing Spondylitis Enthesitis Score; MRI, magnetic resonance imaging; SD, standard deviation; SIJ, sacroiliac joint; SPARCC, Spondyloarthritis Research Consortium of Canada; TNF, tumor necrosis factor

for change from baseline in subregion inflammation scores, including postero-lateral elements (i.e. sum of lesions in ribs, transverse processes, spinous processes, soft tissue inflammation and posterolateral vertebral body), facet joint (Figure), and vertebral body. Total spine fat lesion scores numerically increased from baseline in the FIL group but decreased in the PBO group (p=0.0878 for between-group difference; Table 2). There were no statistically significant differences between groups for changes in erosion (p=0.1956) or ankylosis (p=0.2203) scores (Table 2).

Conclusion: Compared with PBO, FIL decreased inflammation, including in the postero-lateral elements of the spine and facet joints, which has not been demonstrated previously in a PBO-controlled trial. As expected in a 12-week study period, no changes in erosion or ankylosis were seen. Due to the imbalance in MRI measures at baseline and post hoc nature of the analysis, our findings need to be confirmed in a large trial.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Emerging Therapies

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

Background/Purpose: Guselkumab (GUS), an interleukin-23 inhibitor, improved axial symptoms of active psoriatic arthritis (PsA) through week 24 in a pooled analysis from two phase 3 trials (DISCOVER-1 and DISCOVER-2).[1] We now report the efficacy of GUS through 1 year in PsA patients (pts) with imaging-confirmed sacroiliitis in DISCOVER-1&2.

Methods: In DISCOVER-1, 381 pts with active PsA (≥ 3 swollen joints, ≥ 3 tender joints; C-reactive protein ≥ 0.3mg/dL despite standard therapies) and in DISCOVER-2, 739 pts with active PsA (≥ 5 swollen joints, ≥ 5 tender joints, CRP ≥ 0.6mg/dL despite standard therapies) were randomized 1:1:1 to GUS 100mg q4w, GUS 100mg q8w (wk0, wk4, then q8w), or placebo (PBO). PBO pts crossed over to GUS 100mg q4w at wk24. Only pts with sacroiliitis at baseline who had either documented imaging confirmation of sacroiliitis in the past or pelvic radiograph confirmation of sacroiliitis at screening (based on investigators' judgment) were included in this analysis (pooled data from DISCOVER

Table. Efficacy results of GUS at weeks 24 and 52 in PsA patients with axial involvement.[a]

	GUS100 mg every 4 weeks (n=103)	GUS 100 mg every 8 weeks (n=91)	PBO →GUS 100 mg every 4 weeks (n=118)
Week 24			
LS Mean change in BASDAI (0-10)	-2.7*	-2.7*	-1.3
LS Mean change in spinal pain[b]	-2.5*	-2.7*	-1.2
LS Mean change in modified BASDAI[d]	-2.6*	-2.7*	-1.4
BASDAI50[c], %	(38%) 36/95**	(40%) 34/84 **	(19%) 21/110
LS Mean change in ASDAS	-1.4*	-1.4*	-0.7
Week 52			
LS Mean change in BASDAI (0-10)	-3.1	-2.8	-2.8
LS Mean change in spinal pain[b]	-3.0	-2.7	-2.7
LS Mean change in modified BASDAI[d]	-3.1	-2.7	-2.8
BASDAI50[c], %	48% (46/95)	43% (36/84)	49% (54/110)
LS Mean change in ASDAS	-1.7	-1.6	-1.6

[a]Pts with axial involvement consistent with sacroiliitis at baseline and either a history of imaging confirmation or pelvic radiograph at screening (pooled data from DISCOVER-1 & 2)
[b]Question 2 of the BASDAI.
[c] Excludes question 3 of the BASDAI.
[d]Pts with BASDAI > 0 at baseline.
Unadjusted p-values as noted: *$p < 0.001$, ** $p < 0.01$. No statistical comparisons were performed at week 52.

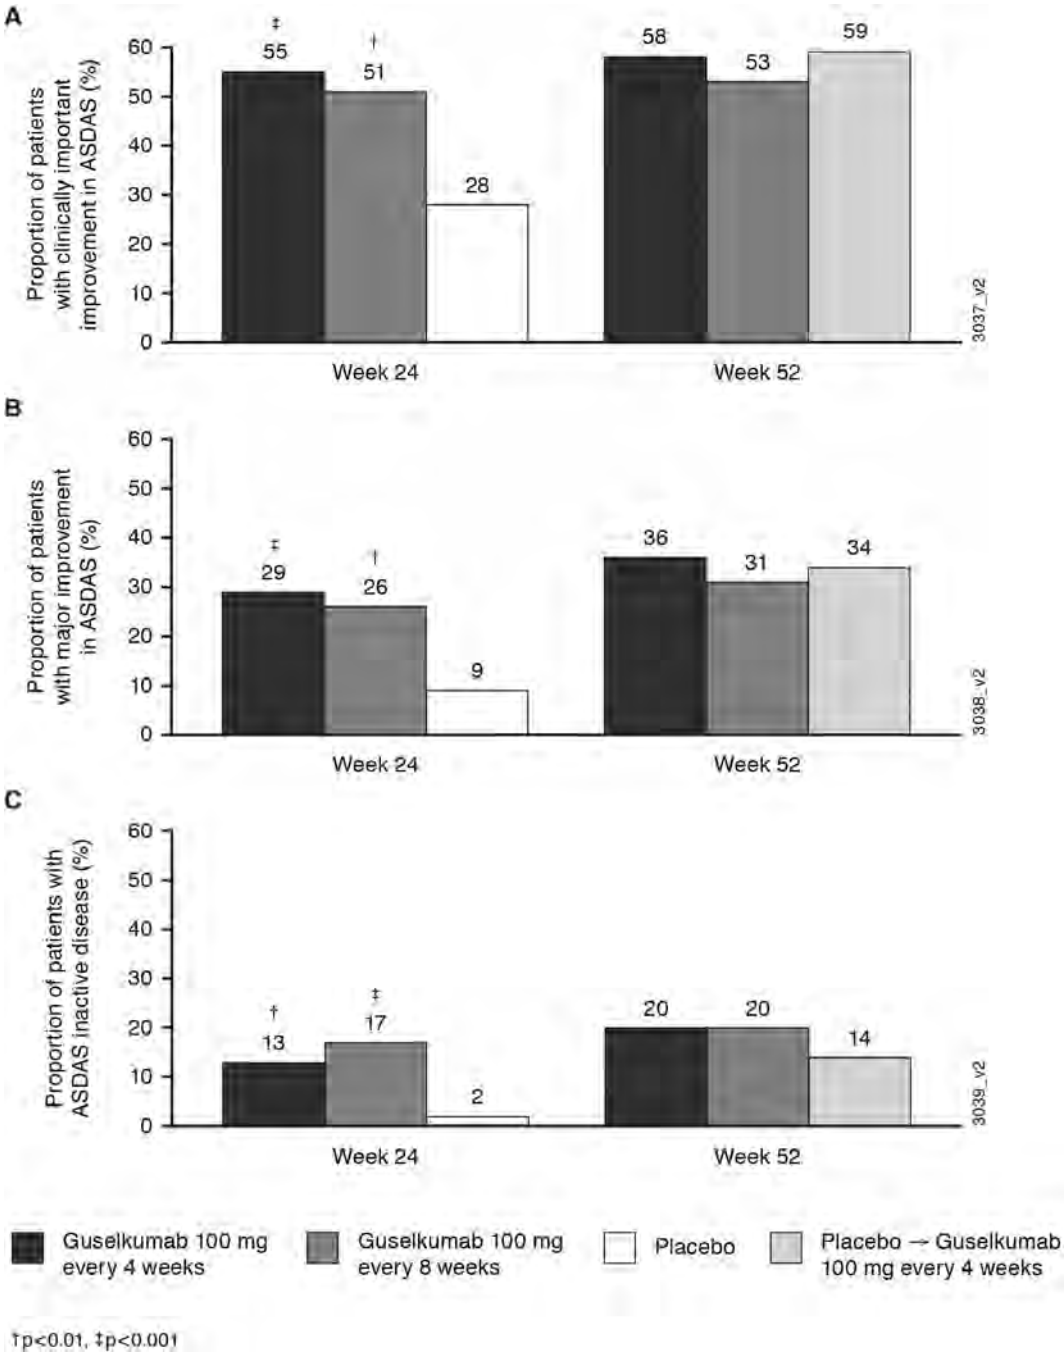

Figure. Proportion of patients with ASDAS clinically important improvement, major improvement, and inactive disease

1&2). Efficacy was assessed by BASDAI score, BASDAI50, modified BASDAI (mBASDAI; excludes Q#3), spinal pain (BASDAI Q#2), ASDAS(-CRP) score, and ASDAS responses of inactive disease (< 1.3), major improvement (decrease ≥2.0), and clinically important improvement (decrease ≥1.1) through week 52. For response endpoints, pts who met treatment failure rules or had missing data were counted as nonresponders through week 24; pts with missing data were counted as nonresponders from weeks 24-52. For changes in scores, a change of 0 was assigned for treatment failures through week 24, and pts who discontinued or had missing data were set to 0 for weeks 24-52. HLA-B27 was assayed in a subset of 190 of these pts.

Results: 312 pts across both studies presented with imaging confirmed sacroiliitis (PBO, n = 118; GUS q8w, n = 91; GUS q4w, n = 103). At baseline, mean BASDAI and ASDAS scores ranged from 6.5 - 6.6 and 3.9 - 4.0, respectively;

57/190 (30%) pts were HLA-B27+, and 133/190 (70%) were HLA-B27-. Improvements in axial symptoms of PsA were greater in the GUS q4w and q8w groups vs PBO through week 24. The LS mean changes from baseline in BASDAI, spinal pain, mBASDAI, and ASDAS were maintained from week 24 to week 52 in the GUS groups (Table); improvements from baseline to week 52 in the PBO pts who crossed over to GUS were similar to those in the GUS groups. Similar trends were observed for the proportions of pts achieving BASDAI50 (Table) and ASDAS responses of inactive disease, major improvement, and clinically important improvement (Figure) at week 52. Efficacy at week 52 trended similarly between HLA-B27+ and HLA-B27- pts.

Conclusion: Improvements in axial symptoms were maintained through week 52 in GUS-treated pts with active PsA who had imaging-confirmed sacroiliitis.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Emerging Therapies

Session Type: Abstract Session

Session Time: 11:00AM–11:50AM

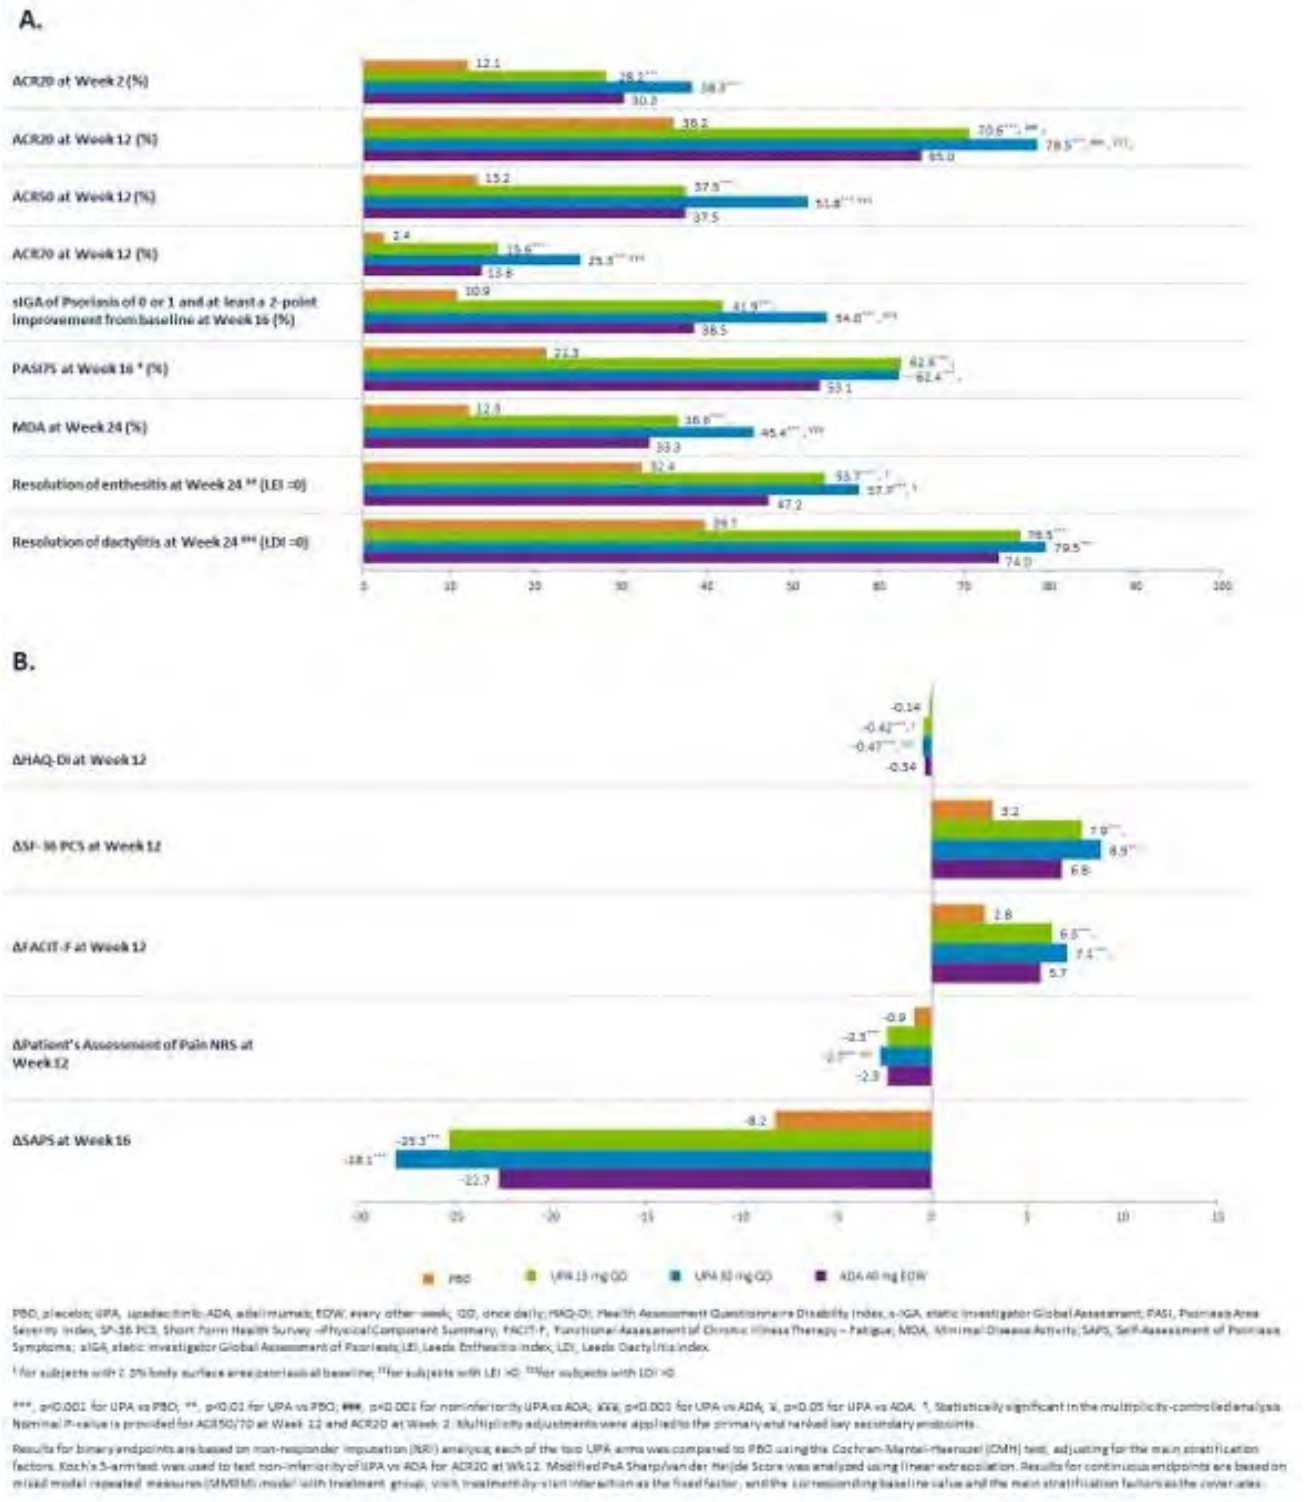
Background/Purpose: Upadacitinib (UPA), an oral, reversible, JAK inhibitor approved to treat rheumatoid arthritis (RA), is under evaluation for psoriatic arthritis (PsA). We assess efficacy and safety of UPA vs placebo (PBO) and adalimumab (ADA) in patients (pts) with PsA and prior IR or intolerance to ≥1 non-biologic DMARD (non-bDMARD).

Methods: Pts with active PsA (≥3 swollen and ≥3 tender joints), active or historical psoriasis, and on ≤2 non-bDMARDs were randomized 1:1:1:1 to once daily UPA 15 mg (UPA15), UPA 30 mg (UPA30), ADA 40 mg every other week, or PBO. Primary endpoint was proportion of pts achieving ACR20 for UPA vs PBO at Wk 12. Multiplicity controlled secondary endpoints for each dose of UPA vs PBO included change in HAQ-DI, FACIT-F, and SF-36 PCS (Wk 12); static Investigator Global Assessment of Psoriasis of 0 or 1, PASI75, and change in Self-Assessment of Psoriasis Symptoms (Wk 16); change in modified Sharp/van der Heijde Score (mTSS), proportion of pts achieving MDA, and resolution of enthesitis (LEI=0) and dactylitis (LDI=0) (Wk 24). For each dose of UPA, the multiplicity-controlled analysis also included non-inferiority and superiority vs ADA for ACR20 and superiority for HAQ-DI and pt's assessment of pain NRS (Wk 12). ACR50/70 at Wk 12 and ACR20 at Wk 2 were additional secondary endpoints. Adverse events (AEs) through 24 wks are reported for pts who received ≥1 dose of study drug.

Results: 1705 pts were randomized; 1704 received study drug (53.2% female, mean age 50.8 yrs, mean duration of PsA diagnosis 6.1 yrs). 82% were on ≥1 concomitant non-bDMARD, of whom 84% received MTX +/- another non-bDMARD.

At Wk 12, ACR20 rates were 70.6% with UPA15 and 78.5% with UPA30 vs 36.2% with PBO ($p < .001$ for UPA15/30 vs PBO) and 65.0% with ADA (non-inferiority, $p < .001$ for UPA15/30 vs ADA; superiority, $p < .001$ for UPA30 vs ADA). A greater proportion of pts achieved ACR50/70 with UPA15/30 vs PBO and UPA30 vs ADA. Improvements were observed with UPA15/30 vs PBO for all multiplicity controlled secondary endpoints and for UPA 15/30 vs ADA for HAQ-DI and UPA 30 vs ADA for improvement in pain (**Figure 1A and 1B**). At Wk 24, change in mTSS was 0.25 for PBO, -0.04 for UPA15, 0.03 for UPA30, and 0.01 for ADA ($p < 0.001$ for UPA15/30 vs PBO). AE/SAE rates, including serious infections, were similar in PBO, UPA15, and ADA arms and higher with UPA30 (**Figure 2**). Herpes zoster rates

Figure 1. Efficacy Outcomes



PBO, placebo; UPA, upadacitinib; ADA, adalimumab; EOW, every other week; QD, once daily; HAQ-DI, Health Assessment Questionnaire Disability Index; s-IGA, static Investigator Global Assessment; PASI, Psoriasis Area Severity Index; SF-36 PCS, Short Form Health Survey –Physical Component Summary; FACIT-F, Functional Assessment of Chronic Illness Therapy – Fatigue; MDA, Minimal Disease Activity; SAPS, Self-Assessment of Psoriasis Symptoms; sIGA, static Investigator Global Assessment of Psoriasis; LEI, Leeds Enthesitis Index; LDI, Leeds Dactylitis Index.

† for subjects with ≥ 3% body surface area psoriasis at baseline; ‡‡for subjects with LEI >0; ‡‡‡for subjects with LDI >0

***, p<0.001 for UPA vs PBO; **, p<0.01 for UPA vs PBO; ###, p<0.001 for non-inferiority UPA vs ADA; ¥¥¥, p<0.001 for UPA vs ADA; ¥, p<0.05 for UPA vs ADA; ↑, Statistically significant in the multiplicity-controlled analysis. Nominal P-value is provided for ACR50/70 at Week 12 and ACR20 at Week 2. Multiplicity adjustments were applied to the primary and ranked key secondary endpoints.

Results for binary endpoints are based on non-responder imputation (NRI) analysis; each of the two UPA arms was compared to PBO using the Cochran-Mantel-Haenszel (CMH) test, adjusting for the main stratification factors. Koch's 5-arm test was used to test non-inferiority of UPA vs ADA for ACR20 at Wk12. Modified PsA Sharp/van der Heijde Score was analyzed using linear extrapolation. Results for continuous endpoints are based on mixed model repeated measures (MMRM) model with treatment group, visit, treatment-by-visit interaction as the fixed factor, and the corresponding baseline value and the main stratification factors as the covariates.

were similar for PBO and UPA15/30. No MACE was reported with UPA. One malignancy occurred in each PBO and UPA15 arms, and 3 malignancies occurred in each UPA30 and ADA arms. VTE were reported in 1 pt on PBO, 1 pt on UPA30, and 2 pts on ADA. One death occurred in the PBO arm.

Figure 2. Safety Summary Through Week 24

	PBO N=423; n (%)	UPA 15 mg QD N=429; n (%)	UPA 30 mg QD N=423; n (%)	ADA 40 MG EOW N=429; n (%)

MACE (adjudicated)[d]	1 (0.2)	0	0	2 (0.5)
VTE (adjudicated)[e]	1 (0.2)	0	1 (0.2)	2 (0.5)
Deaths[f]	1 (0.2)	0	0	0

PBO, placebo; UPA, upadacitinib; ADA, adalimumab; QD, once daily; EOW, every other week; NMSC, non-melanoma skin cancer; MACE, major adverse cardiovascular event; VTE, venous thromboembolic events

[a]Opportunistic infections: UPA15, candida urethritis; UPA30, 1 pneumocystis jirovecii pneumonia, 1 cytomegalovirus infection. [b]Herpes zoster: All events of herpes zoster were mild or moderate in severity involving 1-2 dermatomes. [c]Malignancies: PBO, basal cell carcinoma; UPA15, 1 neuroendocrine carcinoma; UPA30, 2 basal cell carcinoma, 1 lung neoplasm malignant; ADA, 1 colon cancer, 1 ovarian cancer, 1 uterine cancer. [d]MACE (includes CV death, non-fatal myocardial infarction, non-fatal stroke): PBO, 1 non-fatal myocardial infarction; ADA, 1 non-fatal myocardial infarction, 1 cerebrovascular accident. [e]VTE: PBO, 1 deep vein thrombosis; UPA30, 1 pulmonary embolism; ADA: 2 deep vein thrombosis. [f]Deaths: PBO, 1 cardiac arrest (death adjudicated to unknown cause)

Conclusion: In this non-bDMARD-IR PsA population, treatment with UPA15/30 demonstrated improvement in musculoskeletal symptoms, psoriasis, physical function, pain, and fatigue and inhibited radiographic progression; improvements were observed by Wk 2. At Wk 12, UPA15/30 were non-inferior to ADA for ACR20, with superiority demonstrated for UPA30. Greater percentages of UPA vs PBO pts achieved stringent measures of disease control (MDA, ACR50/70, sIGA 0/1). No new safety signals were identified compared with the safety profile observed in RA.

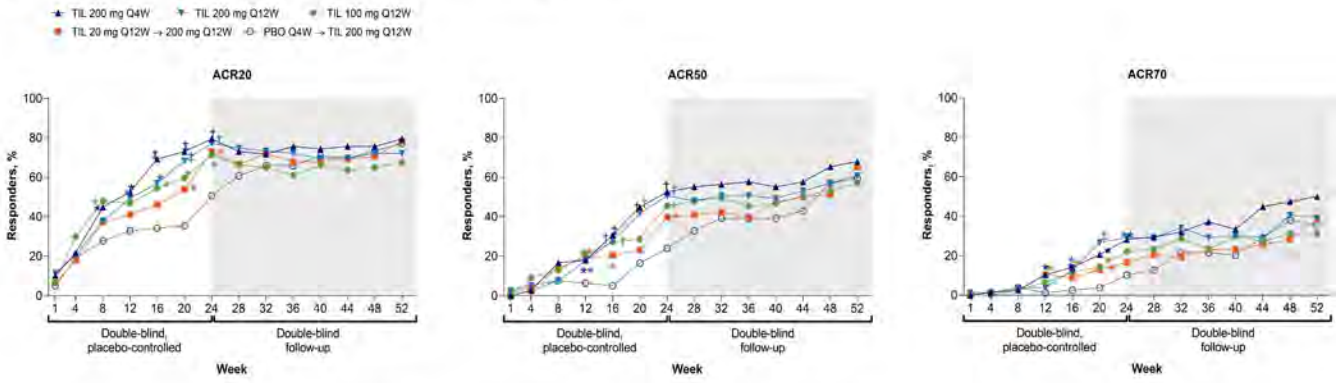
SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Emerging Therapies
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: Tildrakizumab (TIL), a high-affinity anti–interleukin-23p19 monoclonal antibody, is approved to treat moderate to severe plaque psoriasis.[1] The efficacy and safety of TIL up to week (W)52 in patients with psoriatic arthritis (PsA) was evaluated in a randomized, double-blind, placebo-controlled, multiple-dose, phase 2b study (NCT02980692).

Methods: Patients (pts) ≥18 years with active PsA[2] were randomized 1:1:1:1:1 to TIL 200 mg every 4 weeks (Q4W) to W52, TIL 200 mg Q12W to W52, TIL 100 mg Q12W to W52, TIL 20 mg Q12W until W24 then TIL 200 mg Q12W to W52, or placebo Q4W until W24 then TIL 200 mg Q12W to W52. Efficacy assessments included ACR20/50/70, 75%/90%/100% improvement in Psoriasis Area and Severity Index, proportion of pts with residual minimal disease

Figure 1. Response rates for (**A**) ACR20, (**B**) ACR50, and (**C**) ACR70 through week 52



Missing responses were imputed as nonresponses. Shown for randomized patients who received ≥1 dose of study drug.

*P <0.05; †P <0.001; ‡P <0.0001 vs PBO. P-values were not analyzed beyond week 24.

ACR, American College of Rheumatology; PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; TIL, tildrakizumab.

Table 1. Baseline patient characteristics and demographics

	TIL 200 mg Q4W (N = 78)	TIL 200 mg Q12W (N = 79)	TIL 100 mg Q12W (N = 77)	TIL 20→200 mg Q12W (N = 78)	PBO→TIL 200 mg Q12W (N = 79)
Age, years, mean ± SD	50.1 ± 13.3	49.3 ± 11.2	49.2 ± 11.9	47.2 ± 13.4	48.1 ± 13.3
Female, n (%)	46 (59.0)	37 (46.8)	47 (61.0)	41 (52.6)	44 (55.7)
Race, n (%)					
White	76 (97.4)	78 (98.7)	75 (97.4)	75 (96.2)	74 (93.7)
Black or African American	0	0	1 (1.3)	1 (1.3)	3 (3.8)
Other	2 (2.6)	1 (1.3)	1 (1.3)	2 (2.6)	2 (2.5)
Weight, kg, mean ± SD	85.1 ± 19.7	87.2 ± 19.5	83.7 ± 18.9	85.2 ± 18.1	85.3 ± 20.2
BMI, kg/m^2, mean ± SD	30.1 ± 6.5	30.2 ± 6.5	29.5 ± 6.8	29.4 ± 5.2	29.5 ± 6.0
Duration of PsA, years, mean ± SD	7.5 ± 8.5	6.2 ± 7.2	7.0 ± 6.6	6.6 ± 6.7	6.3 ± 6.1
Prior anti–TNF-α therapy, n (%)*	18 (22.8)	17 (21.8)	19 (23.8)	19 (24.4)	18 (23.7)

*For prior anti–TNF-α therapy, total patients analyzed (N) = 79, 78, 80, 78, and 76 for TIL 200 mg Q4W, TIL 200 mg Q12W, TIL 100 mg, TIL 20 mg, and PBO.

Shown for randomized patients who received ≥1 dose of study drug.

PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; SD, standard deviation; TIL, tildrakizumab.

activity response; and mean change from baseline (BL) in HAQ-Disability Index, Leeds Dactylitis Index (LDI, pts with BL LDI ≥1), and Leeds Enthesitis Index (LEI, pts with BL LEI ≥1) to W52. Treatment-emergent adverse events (TEAEs) were recorded.

Results: Of 500 pts screened, 391 were randomized and received ≥1 dose of drug. Demographics and baseline disease characteristics were generally consistent across treatment arms (**Table 1**). Proportions of ACR20/50/70 responders were superior with TIL vs PBO through W24; after W24 rates of responses further increased for TIL 20→200 mg Q12W and PBO→200 mg Q12W through W52 (**Figure**). Other efficacy results are shown in **Table 2**. Overall, 252 (64.5%) patients had a TEAE, the most common being nasopharyngitis (8.4%) and upper respiratory tract infection (6.4%). Most TEAEs, including infections, were mild. One (0.3%) malignancy (intraductal proliferative breast lesion) occurred in the TIL 20→200 mg Q12W arm. Serious TEAEs were observed in 13 (3.3%) patients. One serious infection (chronic tonsillitis) was reported in the TIL 20 mg Q12W arm during the first 24 weeks. One case each of pyelonephritis and urinary tract infection were reported as TEAEs of special interest (both in the same patient in the TIL 100 mg Q12W arm). No deaths or major adverse cardiac events occurred.

Conclusion: TIL was well tolerated and improved musculoskeletal and skin manifestations of PsA through W52.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: Axial Spondyloarthritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: RE-EMBARK was a phase 4, multicenter, open-label, 3-period study that evaluated etanercept (ETN) withdrawal and retreatment in adult patients with non-radiographic axial spondyloarthritis (nr-axSpA) and an adequate response to initial ETN treatment. The aim of the current analyses was to explore baseline predictors of the maintenance and regain of inactive disease during Period 2 and Period 3 of RE-EMBARK, respectively.

Table 1. Baseline predictors of the maintenance of inactive disease following etanercept withdrawal during Period 2 of RE-EMBARK

Univariate analyses (N=115[a])			
Patient characteristic[b]	**Inactive disease n/N (%)**	**Odds ratio (95% CI)**	**p value**
hs-CRP			
>3 mg/L	7/74 (9)		
≤3 mg/L	10/39 (26)	3.30 (1.14, 9.52)	0.027
Positive MRI and hs-CRP >3 mg/L			
Yes	2/47 (4)		
No	15/66 (23)	6.62 (1.43, 30.53)	0.015

Multivariate analysis (N=115[a])		
Baseline characteristic[b]	**Odds ratio (95% CI)**	**p value**
Positive MRI and hs-CRP >3 mg/L (No vs Yes)	6.58 (1.42, 30.43)	0.016

[a]Of the 119 patients who entered Period 2 and had etanercept withdrawn, 4 did not have ≥1 efficacy evaluation during Period 2 and were excluded from the analysis.

[b]Baseline characteristics investigated as potential predictors were: Age (<40 years vs ≥40 years); Body mass index (<25 vs ≥25); Disease duration (<2 years vs ≥2 years); Enthesitis (No vs Yes); HLA-B27 status (Negative vs Positive); hs-CRP (≤3 mg/L vs >3 mg/L); MRI sacroiliitis classification at screening (Negative vs Positive); MRI SIJ SPARCC score (≤2 vs >2); Positive MRI and hs-CRP >3 mg/L (No vs Yes); Race (Non-white vs White); Sex (Female vs Male); Weight (<70 kg vs ≥70 kg).

CI: confidence interval; hs-CRP: high-sensitivity C-reactive protein; MRI: magnetic resonance imaging; SIJ: sacroiliac joints; SPARCC: Spondyloarthritis Research Consortium of Canada.

Table 2. Baseline predictors of the regain of inactive disease following a flare and retreatment with etanercept during Period 3 of RE-EMBARK

Univariate analyses (N=87)

Baseline characteristic[a]	Inactive disease n/N (%)	Odds ratio (95% CI)	p value
Sex			
Female	16/32 (50)		
Male	48/55 (87)	6.86 (2.39, 19.65)	<0.001
Age			
≥40 years	8/20 (40)		
<40 years	56/67 (84)	7.64 (2.53, 23.03)	<0.001
Enthesitis			
Yes	19/32 (59)		
No	44/54 (81)	3.01 (1.12, 8.06)	0.028

Multivariate analysis (N=87)

Baseline characteristic[a]	Odds ratio (95% CI)	p value
Sex (Male vs Female)	5.46 (1.68, 17.72)	0.005
Age (<40 vs ≥40 years)	8.10 (2.10, 31.20)	0.002

[a] Baseline characteristics investigated as potential predictors were: Age (<40 years vs ≥40 years); Body mass index (<25 vs ≥25); Disease duration (<2 years vs ≥2 years); Enthesitis (No vs Yes); HLA-B27 status (Negative vs Positive); hs-CRP (≤3 mg/L vs >3 mg/L); MRI sacroiliitis classification at screening (Negative vs Positive); MRI SIJ SPARCC score (≤2 vs >2); Positive MRI and hs-CRP >3 mg/L (No vs Yes); Race (Non-white vs White); Sex (Male vs Female); Weight (<70 kg vs ≥70 kg).

CI: confidence interval; hs-CRP: high-sensitivity C-reactive protein; MRI: magnetic resonance imaging; SIJ: sacroiliac joints; SPARCC: Spondyloarthritis Research Consortium of Canada.

Methods: RE-EMBARK enrolled patients aged 18 to < 50 years with active nr-axSpA, an inadequate response to ≥2 non-steroidal anti-inflammatory drugs (NSAIDs), and on a stable dose of 1 NSAID for ≥2 weeks prior to first study dose of ETN. Active nr-axSpA was defined as the combination of meeting Assessment in SpondyloArthritis international Society (ASAS) criteria, having active symptoms of nr-axSpA, and having an Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS-CRP) ≥2.1. In Period 1, all patients received ETN (50 mg once weekly) and background NSAID for 24 weeks. Patients who achieved inactive disease (ASDAS-CRP < 1.3) at Week 24 were eligible to enter Period 2. In Period 2, ETN was withdrawn (without downward tapering) for up to 40 weeks while background NSAID was maintained. Patients who experienced a flare (ASDAS with erythrocyte sedimentation rate ≥2.1) during Period 2 were eligible to immediately enter Period 3 in which they were retreated with ETN (50 mg once weekly) for 12 weeks. Baseline characteristics of the patients who entered Period 2 and Period 3 (2 separate baselines) were analyzed post hoc as categorical predictors of the maintenance of inactive disease and the regain of inactive disease, respectively, using univariate logistic regression models and stepwise multivariate logistic regression models. Analyses were based on observed cases.

Results: A total of 209 patients were treated during Period 1 and 119 (57%) achieved inactive disease at Week 24 and had ETN withdrawn after entering Period 2. Univariate analyses showed that high-sensitivity CRP (hs-CRP) ≤3 mg/L and the absence of a combination of positive MRI and hs-CRP >3 mg/L were associated with the maintenance of inactive disease following ETN withdrawal (**Table 1**). Multivariate analysis showed that the absence of a combination of positive MRI and hs-CRP >3 mg/L was a significant predictor of maintaining inactive disease following ETN

withdrawal. There were 87 (73%) of the 119 patients in Period 2 who experienced a flare following ETN withdrawal and were retreated during Period 3. Univariate analyses showed that male sex, age < 40 years, and the absence of enthesitis were associated with the regain of inactive disease following retreatment, with multivariate analysis showing that male sex and age < 40 years were significant predictors (**Table 2**).

Conclusion: The absence of a combination of positive MRI and hs-CRP >3mg/L at baseline was a significant predictor of adult patients with nr-axSpA maintaining inactive disease following withdrawal of ETN over 40 weeks. Male sex and age < 40 years were significant predictors of a patient regaining inactive disease after a flare and subsequent 12-week retreatment with ETN.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: Axial Spondyloarthritis
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: A lack or loss of response to TNFα inhibitors (TNFi) has been associated with low serum drug levels and formation of anti-drug antibodies (ADAb). Therapeutic drug monitoring (TDM), an individualized treatment strategy based on regular assessments of serum drug levels, has been suggested to optimize efficacy of TNFi. It is still unclear if TDM improves clinical outcomes, and the value of TDM has recently been included in the research agenda across different specialties. This first randomized controlled trial on the effectiveness of TDM in a range of immune mediated inflammatory diseases including rheumatic diseases, the NORwegian DRUg Monitoring trial part A (NOR-DRUM (A)) focus on the induction period of infliximab (INX) treatment and aim to assess if TDM is superior to standard treatment in order to achieve remission.

Methods: In the investigator-initiated, randomized, open-label, multicenter NOR-DRUM (A) study, adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), spondyloarthritis (SpA), ulcerative colitis (UC), Crohn's disease

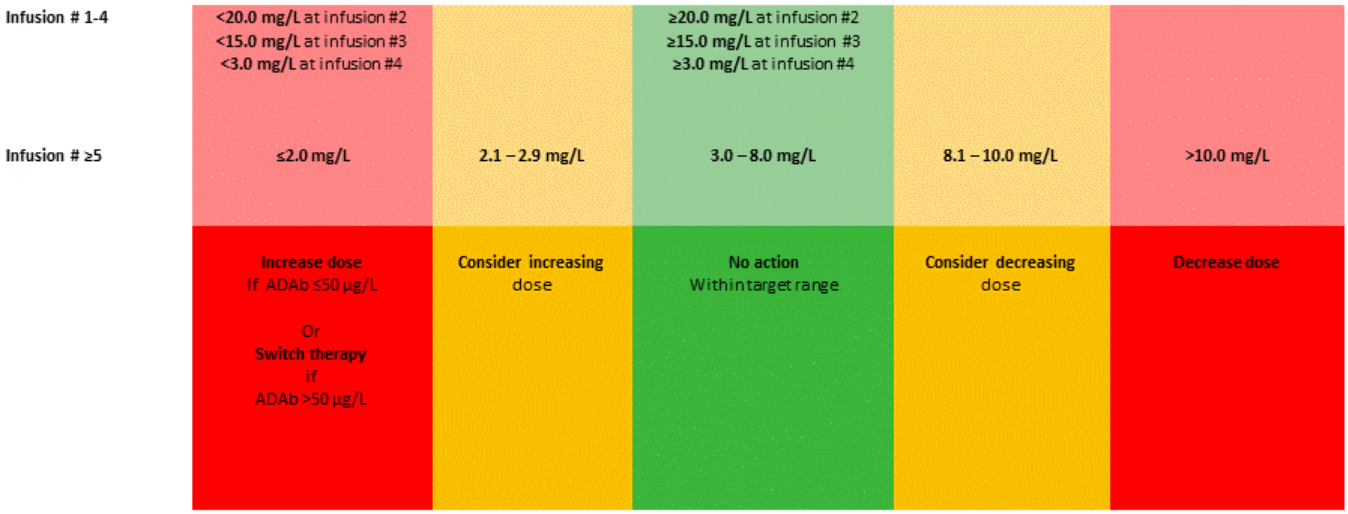

Figure 1. Treatment algorithm in the therapeutic drug monitoring group

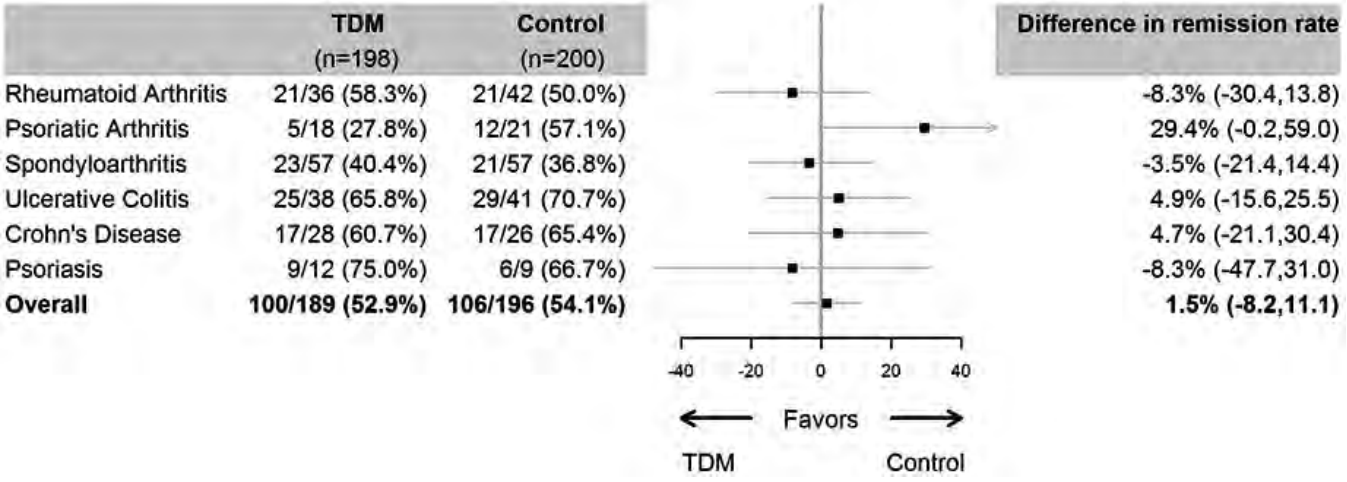

Figure 2. Forest plot of difference in clinical remission rates, overall results and according to disease Figure shows results of the main analysis (primary outcome) conducted in the full-analysis set TDM= therapeutic drug monitoring

(CD) and psoriasis (Ps) starting INX therapy were randomly assigned administration of INX according to a treatment strategy based on TDM (TDM arm) or to standard administration of INX without TDM (control arm). Study visits were conducted at each infusion. The primary endpoint was remission at week 30. In the TDM arm, the dose and interval were adjusted according to INX trough levels to reach the therapeutic range (Figure 1). If the patient developed significant levels of ADAb, INX was terminated. To guide the investigators, the TDM strategy was integrated in an interactive eCRF. The primary endpoint was analysed by mixed effect logistic regression in the full analyses set (FAS), adjusting for diagnoses. Infections and infusion reactions were specified as adverse events (AEs) of special interest.

Results: We enrolled 411 patients at 21 study centers between January 2017 and December 2018. 398 patients (RA 80, PsA 42, SpA 117, UC 80, CD 57, Ps 22) received the allocated strategy and were included in the FAS population. Demographic and baseline characteristics were comparable in both arms. TDM was not found to be superior to standard treatment with regard to the primary outcome. Remission at week 30 was reached in 100 (53%) and 106 (54%) of the patients in the TDM and control arm, respectively (adjusted difference, 1.5%; 95% confidence interval (CI), -8.2 to 11.1, p=0.78) (Figure 2). Consistent results were shown for all the secondary endpoints (Figure 3) and in the sensitivity analyses. Twenty patients (10%) in the TDM arm and 30 patients (15%) in the control arm developed

Figure 3. Generic (A-F) and disease specific (G-L) composite measures over study period.

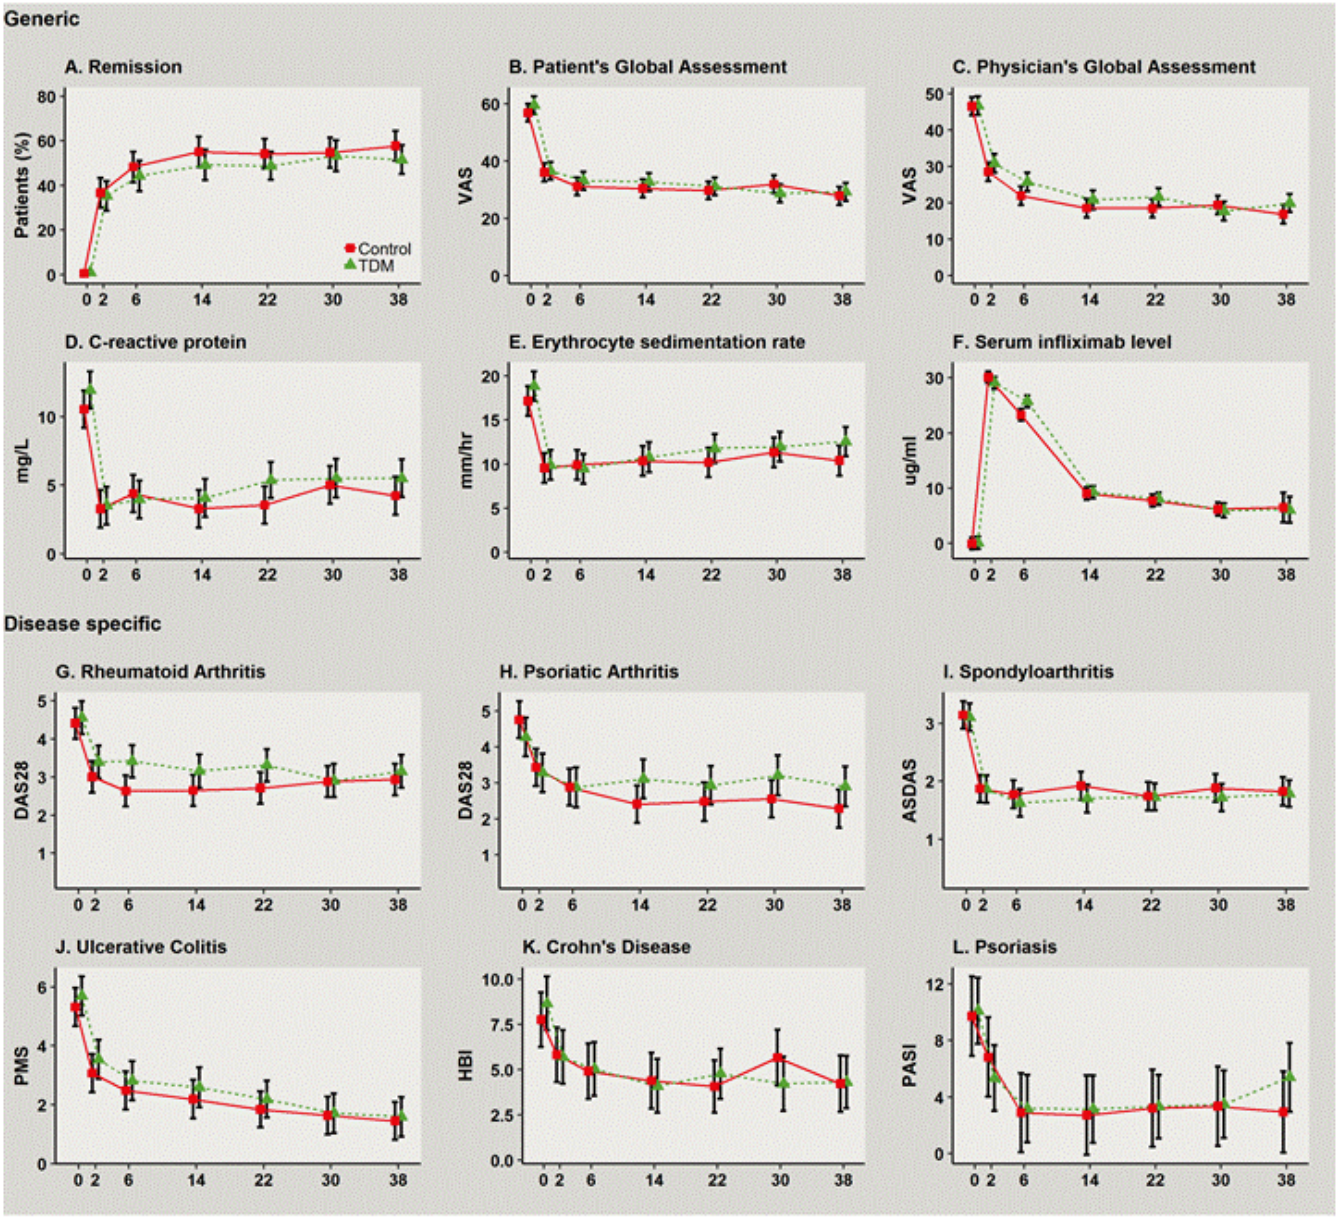

Figure 3 Main secondary outcomes A-F: Generic outcomes; A Proportion of patients in clinical remission, B Patient's Global Assessment Visual analogue scale 0-100 mm, C Physician's Global Assessment Visual analogue scale 0-100 mm, D C-reactive protein mg/L, E Erythrocyte sedimentation rate mm/hour, F Serum infliximab level mg/L. G-L: Disease specific activity measures; G: Rheumatoid Arthritis, Disease Activity Score 28 joints, H: Psoriatic Arthritis, Disease Activity Score 28 joints, I: Spondyloarthritis, Ankylosing Spondylitis Disease Activity Score, J: Ulcerative Colitis, Partial Mayo Score, K: Crohn's Disease, Harvey Bradshaw Index, L: Psoriasis, Psoriasis Area and Severity Index. All data except for serum infliximab levels (patients still on medication) are from the full-analysis set. Values are adjusted means with 95% CI.

significant levels of ADAb. The number of adverse events (AE) was similar in both groups, however infusion reactions were less frequent (5 patients (2.5%) vs 16 patients (8.0%)) in the TDM arm (difference 5.5% (95% CI 1.1, 9.8%))

Conclusion: NOR-DRUM (A) is the first randomized trial to address effectiveness of TDM in rheumatic diseases. In this study, TDM was not superior to standard treatment in order to achieve remission. Although improved safety is

indicated by a reduction in infusion reactions, implementation of TDM as a general strategy in the induction period of INX is not supported by the NOR-DRUM (A) study.

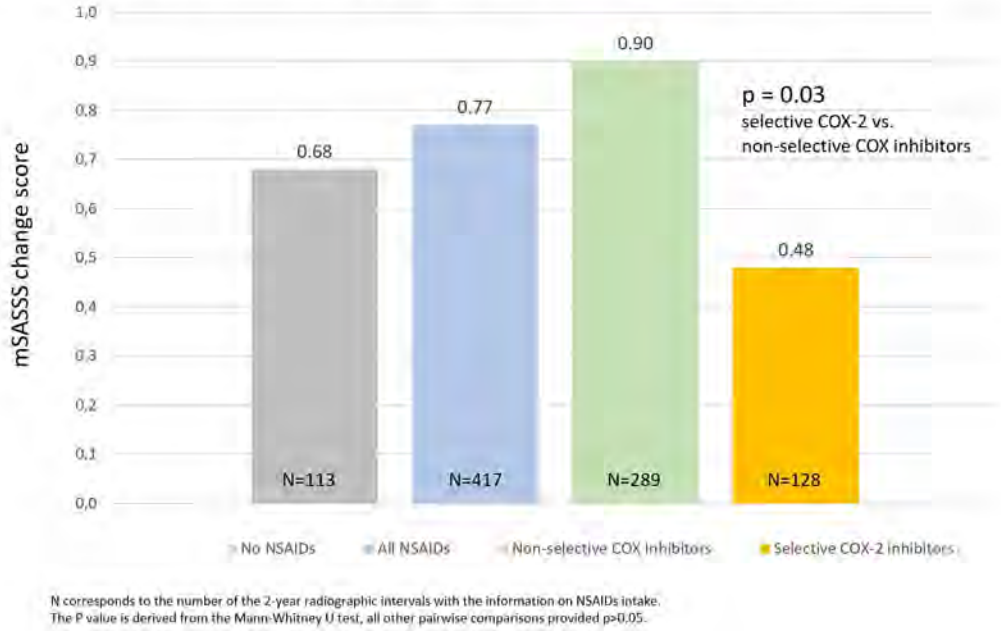
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: Axial Spondyloarthritis
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: There are conflicting data on the effect of non-steroidal anti-inflammatory drugs (NSAIDs) on radiographic spinal progression in axial spondyloarthritis (axSpA). One randomized controlled trial could show that continuous treatment with NSAIDs (mostly with a cyclooxygenase -2 – COX-2 – selective inhibitor celecoxib) was associated with inhibition of radiographic spinal progression, while another study showed no effect of continuous intake of the non-selective COX-inhibitor diclofenac on progression. In the analysis of the first 2 years of the German Spondyloarthritis Inception Cohort (GESPIC), higher NSAIDs intake was associated with retardation of radiographic progression, although it remained uncertain, whether COX-2-selective inhibitors have a stronger effect than non-selective ones.

The aim of the current analysis was to evaluate the effect of NSAIDs including non-selective and selective COX-2 inhibitors on radiographic spinal progression in patients with early axSpA in a long-term inception cohort.

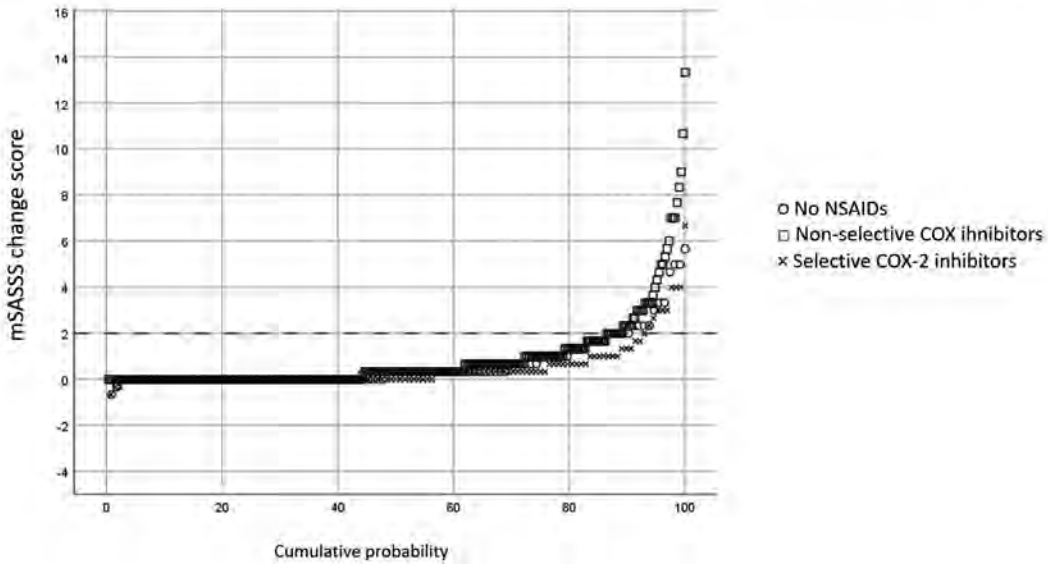
Methods: A total of 266 patients with early axSpA (with r-axSpA with symptom duration ≤10 years and nr-axSpA with symptom duration ≤5 years) from the German Spondyloarthritis Inception Cohort (GESPIC) with at least two sets of spinal radiographs obtained at least 2 years apart during a 10-year follow-up were included. These patients contributed with a total of 542 2-year radiographic intervals. Spinal radiographs were evaluated by three trained and calibrated readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). The final mSASSS was calculated as a mean of three reader scores. NSAIDs intake (NSAIDs type, daily dosage and frequency of intake) was

Figure 1. The mSASSS change scores over 2 years in patients with in patients with axial spondyloarthritis receiving no NSAIDs, non-selective COX inhibitors or selective COX-2 inhibitors.



N corresponds to the number of the 2-year radiographic intervals with the information on NSAIDs intake.
The P value is derived from the Mann-Whitney U test, all other pairwise comparisons provided p>0.05.

Figure 2. Cumulative probability plots depicting mSASSS change scores over 2 years in patients with axial spondyloarthritis receiving no NSAIDs, non-selective COX inhibitors or selective COX-2 inhibitors.



recorded at every visit. Coxibs (i.e., celecoxib, etoricoxib and rofecoxib) were considered selective COX-2 inhibitors, all other NSAIDs – as non-selective ones. The Assessment of Spondyloarthritis International Society (ASAS) NSAIDs intake score (0 – no NSAID intake, 100 – daily intake in the maximal anti-inflammatory dose dose) was calculated for 2-year intervals. The association between NSAIDs intake (NSAIDs type and NSAIDs score) and radiographic spinal progression defined as the absolute mSASSS change score over 2 years was analyzed using longitudinal generalized estimating equations (GEE) analysis.

Table. The association between the NSAIDs intake and radiographic spinal progression defined as mSASSS change score over two years in the longitudinal generalized estimation equation analysis.

Parameter	Reference	Model 1 β (95% CI)*	Model 2 β (95% CI)*	Model 3 β (95% CI)*	Model 4 β (95% CI)*
NSAIDs intake	No NSAIDs	0.25 (-0.19 to 0.70)	-	-	-
COX-2-selective inhibitors	Non-selective inhibitors	-	**-0.42 (-0.64 to -0.20)**	-	-
COX-2-selective inhibitors	No NSAIDs	-	-	0.21 (-0.70 to 1.12)	-
Non-selective inhibitors	No NSAIDs	-	-	-	-0.43 (-1.09 to 0.23)
NSAIDs intake score (0-100)	Per point of the score	**-0.007 (-0.012 to -0.001)**	-0.002 (-0.007 to 0.003)	-0.005 (-0.020 to 0.011)	-0.004 (-0.009 to 0.002)

*Parameter estimates from the multivariable models adjusted for sex, symptom duration at the beginning of the current 2-year interval, treatment with TNFi in the currents 2-year interval, time-averaged ASDAS in the current 2-year interval, smoking in the current 2-year interval and performing exercises in the current 2- year interval.

Results: At baseline, 67% of the patients received NSAIDs. A total of 289 2-year radiographic intervals were covered by non-selective NSAIDs, 128 intervals with COX-2 selective ones, while 113 intervals were not covered by NSAIDs. Overall, the intake of COX-2 selective inhibitors was associated with lower radiographic spinal progression across all 2-year intervals as compared to non-selective NSAIDs (figure 1 and 2). In the longitudinal multivariable GEE analysis, intake of COX-2 selective inhibitors was associated with a lower mSASSS progression (as opposed to the treatment with non-selective NSAIDs) after adjustment for the NSAIDs intake score, treatment with tumor necrosis factor inhibitors and disease activity (table).

Conclusion: An inhibitory effect of NSAIDs on radiographic spinal progression in this axSpA cohort was attributable to the COX-2 selective inhibitors.

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: Axial Spondyloarthritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Several disease activity response and status criteria are used to assess treatment efficacy in RCTs in axial spondyloarthritis (axSpA). Response criteria include: the Assessment of SpondyloArthritis international Society (ASAS)-based ASAS 20, ASAS 40, and ASAS 5/6; the Bath Ankylosing Spondylitis Disease Activity Index BASDAI 50; the Ankylosing Spondylitis Disease Activity Score (ASDAS)-based clinically important improvement (ASDAS-CII) and major improvement (ASDAS-MI). Additionally, the following disease activity status are used: ASAS partial remission (ASAS-PR), ASDAS-low DA (ASDAS-LDA) and ASDAS-inactive disease (ASDAS-ID). All these 9 are variably used in RCTs, but it remains unknown which one is the most discriminative. Our aim was to compare the ability of different criteria to discriminate the response in treatment and placebo arm in axSpA.

Methods: A systematic literature review was performed in Medline and Embase to identify RCTs of biological and targeted synthetic DMARDs (b- and tsDMARDs). Placebo-controlled RCTs meeting the primary endpoint have been included provided they reported ≥2 response/status criteria. Outcomes were collected at the timepoint of primary endpoint assessment. Risk of bias was evaluated by The Cochrane tool. Meta-analysis with the Mantel-Haenszel method was conducted to calculate the Chi-square between percentages of patients fulfilling each criterion in the treatment arm versus the placebo arm (higher Chi-square, better discrimination). Per meta-analysis, we pooled RCTs presenting the same sets of outcomes.

Results: Eleven articles fulfilling inclusion criteria were retrieved from a preceding SLR about RCTs in axSpA (2001-2013), and 12 from another SLR (2009-2016) [3,4]. The search update resulted in 6 additional articles out of 130 hits. Thus, 29 RCTs in total were eligible. Meta-analysis included 23/29 RCTs with primary endpoint at 12-16 weeks, all at a low risk of bias. Other 6 RCTs had later (e.g. 24 weeks) or earlier (e.g. 6 weeks) primary endpoint, thus could not be meta-analyzed due to heterogeneity. Out of the 23 RCTs, 2 studies reported 2 outcomes, 2 reported 3 outcomes and 19 RCTs reported ≥4 outcomes. The most frequently reported outcomes were ASAS 20, ASAS 40, ASAS-PR and BASDAI 50 (Set 1). Sixteen RCTs presented all outcomes from Set 1 (Table 1): the discriminative performances were, in descending order, ASAS 40 – ASAS 20 – BASDAI 50 - ASAS-PR. In 11/16 RCTs ASAS 5/6 was additionally included (Table 1, Set 2): this outcome showed the best performances among ASAS-based response criteria. 8/16 RCTs additionally included some ASDAS-based outcomes (Table 1, Set 3). Here, ASDAS-CII and -MI showed a much higher discrimination than the ASAS-based criteria. In only 3 trials all outcomes could be compared, with again the ASDAS-CII and -MI as the most discriminative criteria, followed by ASAS 5/6 (Table 1, Set 4).

Conclusion: ASDAS-based response criteria showed better discrimination than ASAS-based response criteria. ASDAS-CII and ASDAS-MI should be the preferred primary outcomes for future RCTs comparing a bDMARD or tsD-

Treatment Response to Biological Disease-modifying Anti-rheumatic Drugs Is Associated with Favorable Changes of the Body Composition in Patients with Ankylosing Spondylitis

Valeria Rios Rodriguez[1], Mikhail Protopopov[1], Fabian Proft[1], Judith Rademacher[1], Burkhard Muche[1], Anne-Katrin Weber[1], Susanne Lüders[1], Hildrun Haibel[1], Maryna Verba[1], Joachim Sieper[1] and Denis Poddubnyy[2], [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Charité – Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: Axial Spondyloarthritis

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: There is few data available regarding differences in body composition and its possible changes in patients with ankylosing spondylitis (AS) treated with biological disease-modifying anti-rheumatic drugs (bDMARDs). An increase of body weight and lean mass in patients receiving TNF inhibitors, as well as a possible muscle wasting by high disease activity have been previously described. Bioelectrical impedance analysis (BIA) is a valid method to assess body composition and allows to distinguish between fat, fat-free mass and skeletal muscle mass.

The aim of this study is to evaluate changes in body composition in patients with AS after 6 months of treatment with bDMARDs.

Methods: Patients with a diagnosis of AS, fulfilling the modified New York criteria and starting a bDMARD therapy were included in the extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC). All patients had high disease activity (BASDAI >=4 and/or ASDAS >=2.1) despite previous treatment with nonsteroidal anti-inflammatory drugs. Disease activity and body composition were assessed at baseline and after 6 months of bDMARD treatment. Body composition was assessed by the BIA with the seca© mBCA 515 device (SECA Deutschland GmbH, Hamburg/Germany) and included the following parameters: weight, body mass index (BMI), fat mass index (FMI), fat

	Mean±SD	Difference, mean±SD	95% CI		P*
			Lower	Upper	
Weight at baseline, kg	77.19±15.71	0.75±3.80	0.04	1.47	0.04
Weight at 6 months, kg	77.94±16.25				
BMI at baseline, kg/m^2	25.03±4.32	0.30±1.29	0.06	0.55	0.02
BMI at 6 months, kg/m^2	25.33±4.43				
FMI at baseline, kg/m^2	6.74±3.39	0.31±0.97	0.07	0.54	0.01
FMI at 6 months, kg/m^2	7.05±3.42				
FFMI at baseline, kg/m^2	18.27±2.18	0.15±0.48	0.04	0.27	0.01
FFMI at 6 months, kg/m^2	18.42±2.27				
SMM at baseline, kg	27.40±5.85	0.32±1.11	0.05	0.59	0.02
SMM at 6 months, kg	27.73±5.90				
VAT at baseline, liters	1.94±1.62	-0.12±0.63	-0.27	0.04	0.14
VAT at 6 months, liters	1.82±1.56				

BMI: Body Mass Index; FMI: Fat Mass Index; FFMI: Free Fat Mass Index; SMM: Skeletal Muscle mass; VAT: Visceral Adipose Tissue.
*Wilcoxon test

TABLE 1. Body composition parameter at baseline and after 6 months of treatment with a bDMARDs in patients with AS (n=77)

free mass index (FFMI), skeletal muscle mass value (SMM), and visceral adipose tissue value (VAT). Response to a bDMARD therapy was defined as achievement of clinically important improvement of ASDAS (>=1.1).

Results: A total of 129 patients (66.7% male) with AS were recruited in this cohort extension between 2015 and 2019. The mean (mean ± SD) age was 36.2 ± 10.3 years, and symptom duration was 10.7 ± 9.1 years. HLA-B27 test was positive in 89.1% patients. BIA was assessed in 77 patients; the baseline characteristics of these patients were similar to those of the whole cohort. Of these, 75 patients were treated with TNF inhibitors and 2 patients were treated with an IL-17A inhibitor.

After 6 months of a bDMARD treatment, body composition changed significantly with an increase of weight and BMI due to the gain of FMI but also of FFMI and SMM, while there was no increase of the visceral fat – table. In responders (improvement of ASDAS >=1.1 after 6 months) the results were similar to the whole group with a significantly gain (mean±SD) on BMI, FMI, FFMI and SMM (0.3 ± 1.4 kg/m^2, 0.3 ± 1.0 kg/m^2, 0.2 ±0.5 kg/m^2, 0.5 ± 1.2 kg, p< 0.05, respectively). In non-responders, there were no significant changes on the body composition after 6 months of treatment.

Conclusion: Treatment with bDMARDs is associated with favorable changes of the body composition with increase of the muscle mass but not of the visceral fat. These changes were evident in treatment responders only.TABLE 1. Body composition parameter at baseline and after 6 months of treatment with a bDMARDs in patients with AS (n=77)

Large-scale Examination of Longitudinal Skin Gene Expression and Its Associations with Skin Thickness in Systemic Sclerosis

Brian Skaug[1], Marka Lyons[1], William Swindell[2], Gloria Salazar[1], Julio Charles[1], Connor Vershel[1], Maureen Mayes[3] and Shervin Assassi[3], [1]University of Texas Houston, McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX, [2]The Jewish Hospital, Department of Internal Medicine, Cincinnati, OH, [3]University of Texas Houston McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical I: Stratification Strategies for Clinical Trials
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Numerous studies have revealed dysregulated gene expression in the skin of systemic sclerosis (SSc) patients, with varying degrees of inflammatory/immune and fibroblast upregulation. However, the progression of skin gene expression over time and the relationships between skin gene expression and clinical manifestations are incompletely understood. We sought to address these questions through transcriptomic profiling of skin biopsies from a large, diverse group of well-characterized SSc patients, the majority of whom underwent longitudinally-collected biopsies.

Methods: 339 total skin biopsies were obtained from the forearm of 113 SSc patients and 44 matched healthy controls. Disease duration was less than six years at initial biopsy (mean of 2.6 years), and 59.3% of patients had diffuse cutaneous involvement. 105 SSc patients underwent a second biopsy, and 77 underwent a third biopsy (mean of 0.8 years and 1.9 years after baseline biopsy, respectively). Biopsy samples were analyzed by microarray, and normalized transcript levels were analyzed for cell type-specific gene expression signatures comprising 15 cell types. Each SSc patient's cell type signatures were compared to the average amongst healthy controls.

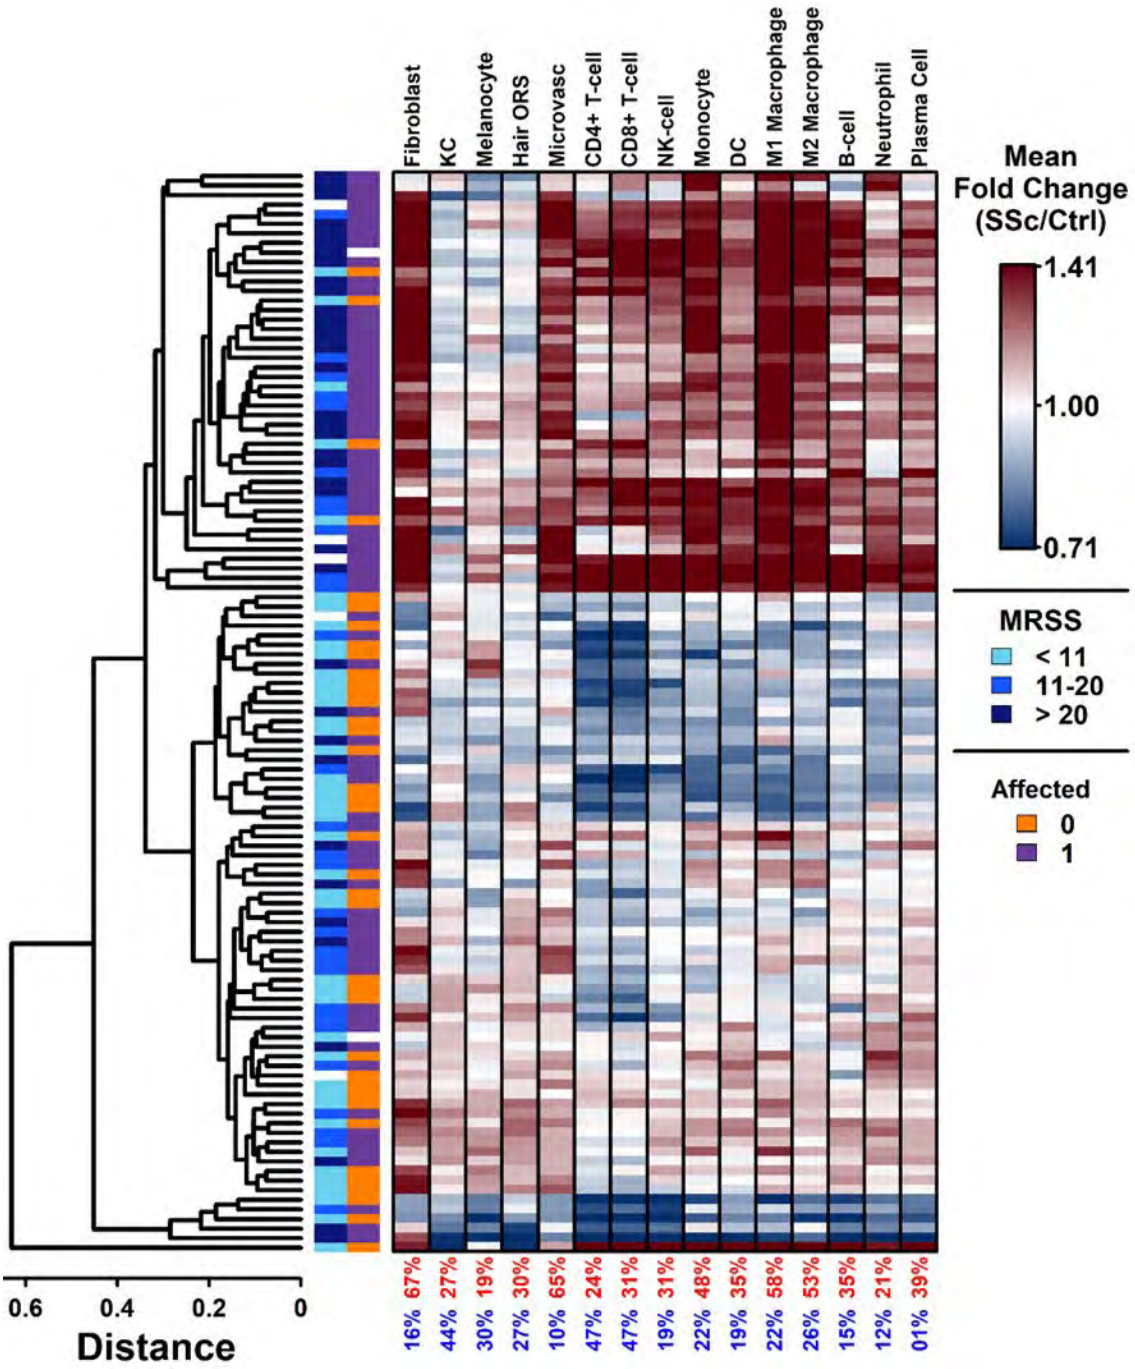

Figure 1. Cell type signatures in baseline skin biopsies of systemic sclerosis patients. Each row represents an SSc patient. Each patient's cell type signature scores were compared to the average amongst the 44 healthy controls. mRSS: modified Rodnan skin score, SSc: systemic sclerosis, Ctrl: healthy control, KC: keratinocyte, NK cell: natural killer cell, DC: dendritic cell

Table 1

Skin immune cell and fibroblast signatures correlated with earlier disease duration

	Disease duration	
	all SSc (n = 113)	diffuse SSc (n = 67)
M1 macrophage	-0.17 (0.07)	-0.32 (<0.01)
M2 macrophage	-0.18 (0.05)	-0.31 (<0.01)
CD4 cell	-0.08 (0.43)	-0.11 (0.36)
CD8 cell	-0.10 (0.30)	-0.15 (0.24)
B cell	-0.15 (0.11)	-0.19 (0.12)
NK cell	-0.13 (0.16)	-0.19 (0.13)
Fibroblast	-0.22 (0.02)	-0.41 (<0.01)

Spearman's rank order correlation coefficients between disease duration and cell type signatures are shown, with p values in parentheses. Red indicates p <0.05. Disease duration was defined as the time from the first non-Raynaud's symptom.

Results: 67% of baseline SSc biopsies had upregulation of the fibroblast signature, 58% and 53% had upregulation of M1 and M2 macrophage signatures, respectively, and 24%, 31%, 35%, and 31% had upregulation of CD4 T cell,

Table 2

Skin immune cell and fibroblast signatures predicted longitudinal mRSS, but were not independently predictive after adjustment for baseline mRSS

	Without adjustment			With adjustment for baseline mRSS

Mixed effects linear regression models of longitudinal mRSS as a function of baseline cell type signature scores, without vs. with adjustment for baseline mRSS. mRSS: modified Rodnan skin score

CD8 T cell, B cell, and NK cell signatures, respectively (Figure 1). Fibroblast and immune cell signatures correlated with local skin score and total modified Rodnan skin score (mRSS), with the strongest correlations observed for fibroblast, M1 macrophage, and M2 macrophage signatures. At baseline biopsy, fibroblast and immune cell signatures correlated with shorter disease duration, particularly amongst diffuse cutaneous SSc patients (Table 1). Longitudinal biopsies revealed that immune cell signatures tended to decline over time, particularly in diffuse cutaneous SSc. Immune cell and fibroblast signatures at baseline biopsy predicted subsequent skin fibrosis course, measured as longitudinal mRSS, based on mixed effects linear regression modeling. However, the predictive values were not statistically significant after adjustment for baseline mRSS (Table 2).

Conclusion: Immune cell and fibroblast signatures in the skin of SSc patients were associated with skin thickness and tended to decline over time. Baseline immune cell and fibroblast signatures did not provide predictive significance for the course of skin thickness beyond the information provided by the baseline mRSS.

Session Title: Systemic Sclerosis & Related Disorders – Clinical I: Stratification Strategies for Clinical Trials

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Radiomics describes the in-depth analysis of tissue phenotypes by computational retrieval of high-dimensional quantitative imaging features including tissue intensity, texture, and wavelet characteristics. Here, we aimed to evaluate high-resolution computed tomography (HRCT)-based radiomics for disease phenotyping and risk stratification in interstitial lung disease related to systemic sclerosis (SSc-ILD).

Methods: In this study, we investigated two independent, prospectively followed SSc-ILD cohorts including 90 patients (76.7% female, median age 57.5 years) from the University Hospital Zurich and 66 patients (75.8% female, median age 61.0 years) from the Oslo University Hospital. For every subject, we defined and extracted 1,386 radiomic features from semi-automated segmented HRCT images including 17 intensity, 137 texture, and 1,232 wavelet features using our in-house developed radiomics software Z-Rad. After filtering of robust radiomic features, we performed unsupervised k-Means clustering and supervised prediction modelling to 1) identify homogeneous imaging-based groups without any a priori assumptions, and 2) to derive a quantitative radiomic risk score for progression-free survival (PFS) in SSc-ILD. PFS was defined as the time to a relative decline in FVC% predicted ≥ 15%. Associations with clinical characteristics at baseline and PFS among the obtained clusters and risk score groups were assessed by Fisher's Exact and Mann-Whitney U test, or univariable Cox regression, respectively.

Results: Unsupervised cluster analysis of 1,355 robust radiomic features revealed two distinct patient clusters based on their radiomic profiles. The two patient clusters exhibited significant differences in their lung disease-specif-

ic baseline parameters, but not in serological or demographic characteristics. Cluster 2 presented a more severe ILD phenotype than cluster 1, and was significantly associated ($p< 0.05$) with a worse restrictive ventilation defect, pulmonary hypertension, a fibrosis extent on HRCT of ≥ 20%, and certain visual HRCT ILD patterns, including UIP radiological subtype and honeycombing. The clusters further significantly differed in their outcome with cluster 2 showing a decreased PFS and thus a higher risk of faster disease progression ($p=0.001$). We next derived a quantitative radiomic risk score (qRISSc) composed of the sum of 26 equally weighted radiomic features that accurately predicted PFS and showed prognostic power in both study cohorts (C-index = 0.67 for Zurich, 0.71 for Oslo). We also compared the prognostic potential of qRISSc to existing SSc-ILD stratification tools, including subgrouping of patients based on HRCT (< 20% or ≥20% fibrosis) or the FVC% predicted threshold of < 70%, respectively. In both cohorts, neither HRCT- nor FVC%-based risk stratification was prognostic for future lung function decline, overall indicating the superiority of qRISSc over current prognostic measures.

Conclusion: Our data suggests that radiomic features and radiomics-derived scores can capture important phenotypic and prognostic information thus showing great potential for risk stratification in SSc-ILD.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical I: Stratification Strategies for Clinical Trials

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Clinical trials in early diffuse systemic sclerosis (SSc) using the modified Rodnan skin score (mRSS) as the primary outcome have been largely negative. This may reflect limitations of clinical trial design or outcome measures, as opposed to therapeutic failures. Our objective was to assess if stratification could enhance early diffuse SSc clinical trial design and analysis. Our primary hypothesis was that given the predominance of RNA poly-

merase III (RNAP3) in recent clinical trials and its association with severe skin involvement, stratification by RNAP3 or other factors could improve trial design.

Methods: We used a large, observational Scleroderma Center cohort from a US tertiary care referral site. We identified early diffuse SSc patients first seen between 1980 and 2015. We included those with < 36 months from first non-Raynaud manifestation and ≥3 recorded mRSS scores in the analysis. Our modeling strategy reflected typical disease duration inclusion criteria for ongoing clinical trials: < 18 months and < 36 months of disease. We used descriptive, time to event, group-based trajectory modeling to determine mRSS trajectory groups, multivariable regression modeling as well as classification tree analyses (CTA) to assess contributing factors to predict mRSS trajectory groupings. We analyzed the following variables: age, gender, race, antibody, skin thickness progression rate (STPR), tendon friction rubs (TFR), elevated ESR and medication use.

Results: We found 514 patients who met criteria with < 36 months of disease, of which 403 had < 18 months of disease at first visit (Table 1). The median disease duration was 0.90 (IQR 0.59, 1.39) years at first visit, median follow-up 10.2 (4.5, 16.3) years with 14 (8, 23) SSc clinic visits. The majority, 273 (53%) were RNAP3 positive, and 137 (27%) were Scl-70 positive.

Initial time-to event analysis demonstrated a significant difference between time to peak mRSS for those positive for Scl-70 (p=0.04) or RNA3 positive (p=0.02). Trajectory modeling showed distinctly different mRSS trajectory patterns over 5 years by autoantibody regardless of disease duration (Figure 1). Regression analysis confirmed that STPR (p< 0.0001), TFR (p=0.002) and RNAP3 (p=0.01) were predictors of trajectory groupings. CTA analysis (Figure 3) demonstrated that measured characteristics performed better in predicting trajectory grouping for < 18 months than

	Disease duration <18 months (n=403)	Disease duration <36 months (n=514)
Mean age at first visit (±SD)	50.0 ± 13.8	49.4 ± 13.8
Female	205 (76%)	382 (74%)
Caucasian	370 (92%)	468 (91%)
Median disease duration (years) from first non-Raynaud manifestation (IQR)	0.76 (0.55, 1.04)	0.90 (0.59, 1.39)
Median follow-up time in years (IQR)	10.2 (4.6, 16.3)	10.2 (4.5, 16.3)
Median number of clinic visits (IQR)	16 (9, 24)	14 (8, 23)
SKIN CHARACTERISTICS		
Mean mRSS (±SD) at 1st visit	25 ± 11	25 ± 11
Maximum mRSS during follow-up (mean ±SD)	32 ± 11	31 ± 11
STPR rapid	141 (35%)	194 (38%)
intermediate	146 (37%)	163 (32%)
slow	113 (28%)	154 (30%)

Scl-70	106 (27%)	137 (27%)

Table 1. First Visit Demographic and Systemic Sclerosis Charcteristics

Figure 1: Pictorial comparison of 5-year skin score trajectory plots from the first visit by autoantibody

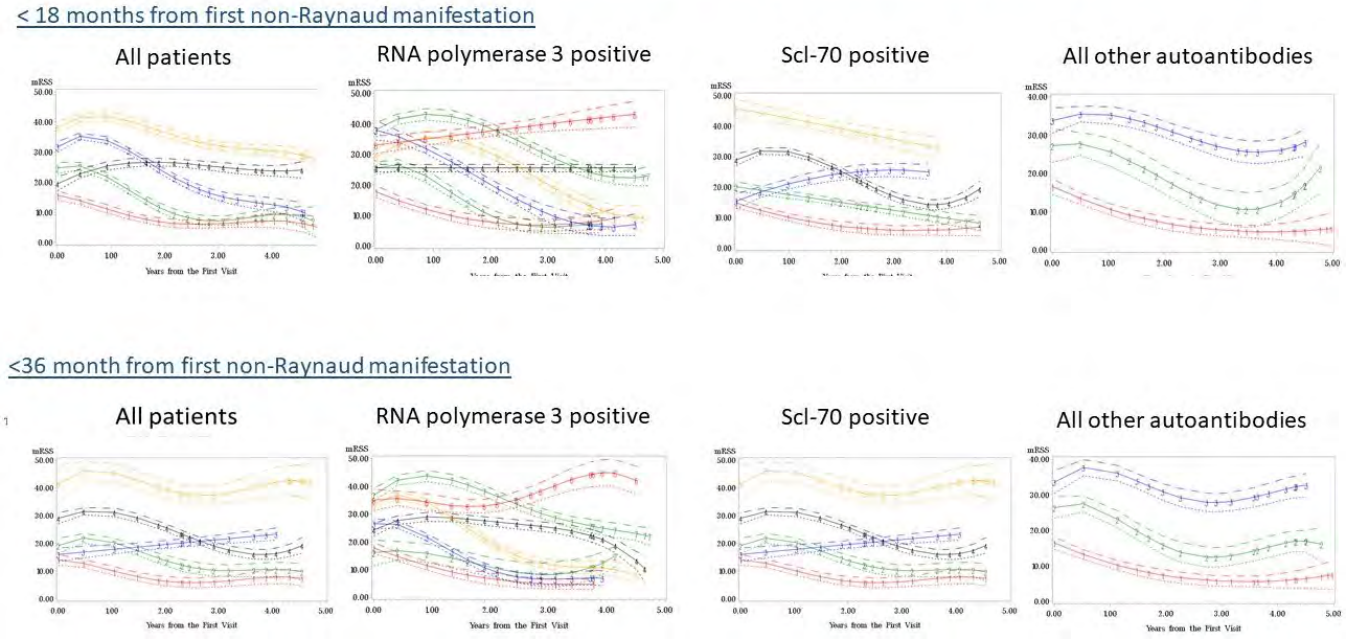

Figure 1: Pictorial comparison of 5-year skin score trajectory plots from the first visit by autoantibody

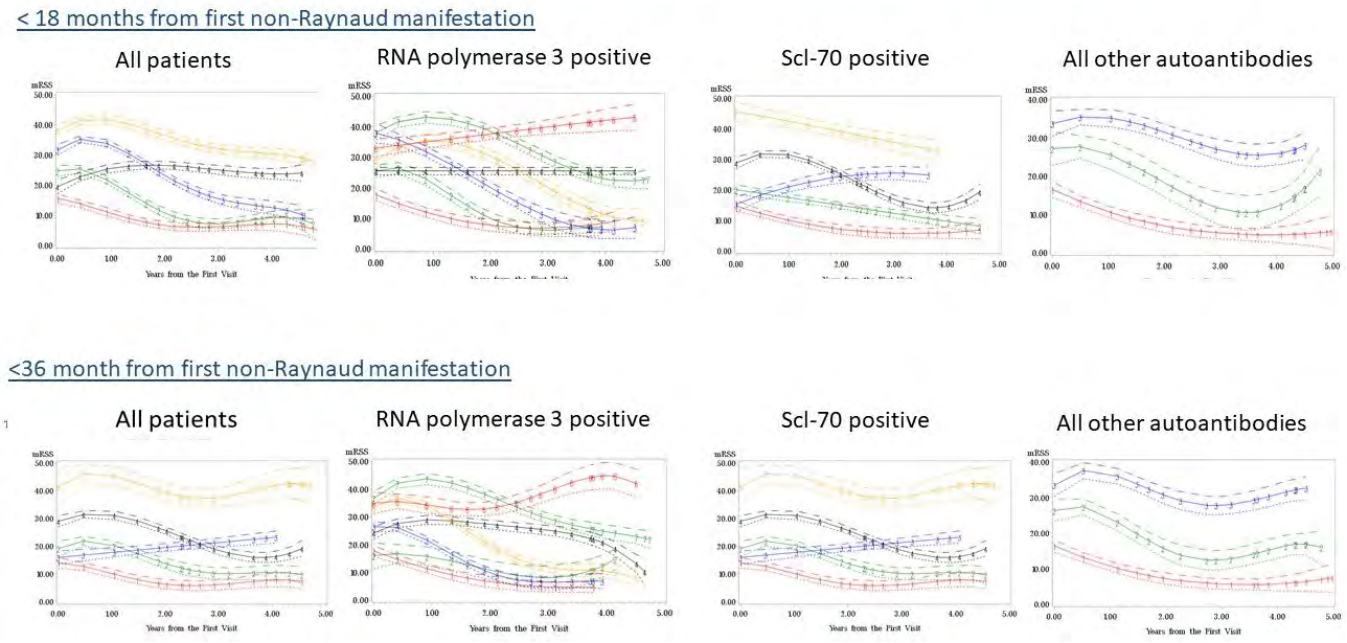

predicting trajectory groups for < 36 months of disease. STPR and presence of TFR were suggested as predictive factors for trajectory grouping for both < 18 months and < 36 months disease duration.

Conclusion: STPR, presence of TFR and RNAP3 antibody are consistently associated with mRSS trajectory patterns over time using multiple analysis methods. STPR and TFR are early nodal breaks in CTA analysis, suggesting they may be preferred stratification strategies over RNAP3 status. As STPR is intended to be used at the initial SSc clinic visit, TFR presence is the more feasible data-supported stratification strategy for early diffuse clinical trials.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical I: Stratification Strategies for Clinical Trials

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Systemic sclerosis (SSc) is a rare systemic autoimmune disease associated with a high mortality and characterized by the accrual of organ damage over time. The Scleroderma Clinical Trials Consortium Damage Index (SCTC-DI) is a recently validated tool to measure this damage (Ferdowsi et al., 2019). Identifying predictors of future damage is of utmost importance for prognostication and guiding research. This study aimed to identify if there are distinct trajectories of damage accrual from early in the disease and to determine which variables are associated with different trajectories, which could help guide when to initiate aggressive therapy early.

Figure - Group-based Trajectory Model of Scleroderma Clinical Trials Consortium - Damage Index at Yearly Visits

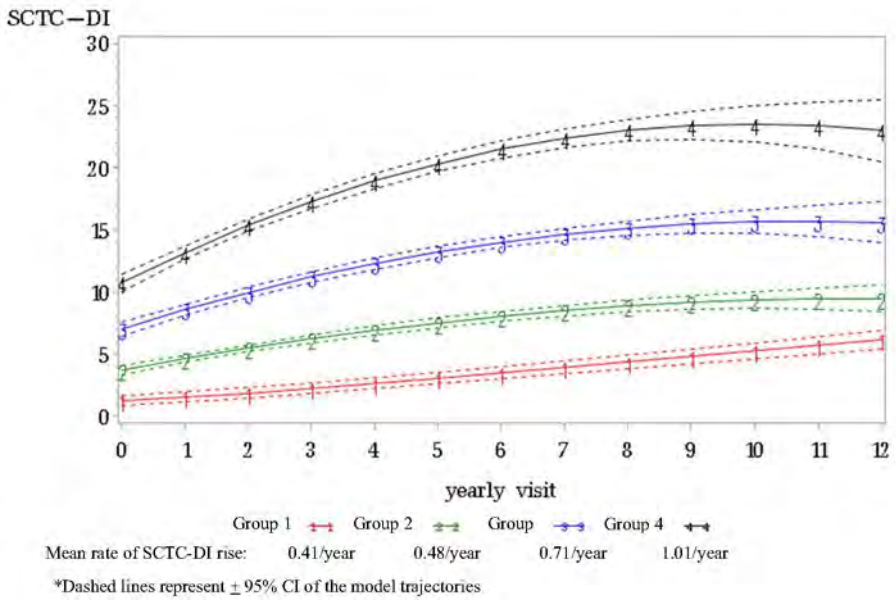

Table – Baseline Characteristics of Trajectory Groups

* Other environment exposure includes organic solvents, vinyl chloride & epoxy resins

** One-way analysis of variance (ANOVA) and Kruskal-Wallis Test were used to compare continuous variables. Chi-square test and Fisher's exact test were used for categorical variables.

Methods: Using a prospective cohort design, incident adult cases of SSc (disease onset < 2 years) were identified in two large databases. Patients from these databases are enrolled consecutively and followed with yearly standardized assessments. Patients who met the ACR-EULAR classification criteria for systemic sclerosis with at least two cohort visits and two SCTC-DI values were included. Due to missing data, three elements of the SCTC-DI were removed from the scoring (small joint contractures, pericardial effusion, GAVE). Group-based trajectory modelling (GBTM) was used to identify clusters of patients with similar DI trajectories. Their baseline characteristics were then compared for statistical significance using a one way-analysis of variance (ANOVA) and Kruskal-Wallis Test for continuous variables and chi-square test and Fisher's exact test for categorical variables.

Results: 409 patients were included in this study. Four trajectories (Figure) of damage accrual were identified, with increasing damage over time and a plateauing effect observed in the three groups with higher damage scores. The average of posterior probabilities of group membership assigned to each group was 0.92, suggesting our trajectory

model fits well. The groups were distinct at baseline, with patients who had the fastest damage accrual also having a higher baseline SCTC-DI. Clinical factors that were more prevalent in the worst damage trajectories were older age, male sex, current or previous smoking history, diffuse disease, tendon friction rubs, renal impairment, anti-RNA polymerase positivity and higher baseline inflammatory markers (Table). Anti-centromere antibody positivity was more prevalent in the lower disease damage groups.

Conclusion: We have identified four distinct trajectories of disease damage in a combined incident cohort of patients with SSc. Several clinical and serological characteristics were more prevalent in those with worse damage trajectories. These findings may be helpful in recognizing patients in whom early aggressive treatment is necessary.

Geographic Distribution and Environmental Triggers of Systemic Sclerosis in Massachusetts

Anastasiya Muntyanu[1], Bina Kassamali[2], Ruth Ann Vleugels[3] and Avery LaChance[3], [1]McGill University, Montreal, QC, Canada, [2]Harvard Medical School, Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical I: Stratification Strategies for Clinical Trials
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune sclerosing disease with a 10-year survival rate of less than 65%. This rate has remained unchanged for over 40 years. Although the exact pathogenesis remains unclear, it has been hypothesized that an environmental trigger leads to disease development in a genetically predisposed host. Assessment of high incidence geographic disease clusters can be an initial step in cause identification. ArcGIS is a geospatial processing program used to create and analyze geographic distribution and has recently been utilized to determine high incidence clusters for several cancers and autoimmune diseases. The objectives of this study are to analyze the geographic distribution of SSc in Massachusetts between 1989-2019, determine incidence rates, and evaluate potential environmental exposures.

Methods: Demographic and geographic patient data for SSc cases was obtained from two large, academic tertiary centers in Massachusetts. Incidence rates were calculated per year and per geographic area, based on zip code. Maps were created using ArcMap 10.7.1 to identify case clusters across the state. The SSc incidence maps were compared to maps of environmental exposures to determine potential contribution of pollutants to disease development.

Results: 4,579 patients diagnosed with SSc between 1989-2019 were identified. The crude incidence rate was 24.2 cases per million individuals per year. Geographic analysis revealed increased incidence in specific geographic regions in Massachusetts including Boston, Lynn, Revere, Chelsea, Newton Upper Falls, and Charlestown (Figure 1). The density of industry presence and waste sites was found to be significantly higher in the areas with elevated incidence of SSc compared to low incidence areas (8.5-fold increase; p=0.0087) (Figure 2). Particulate pollution ($PM_{2.5}$)

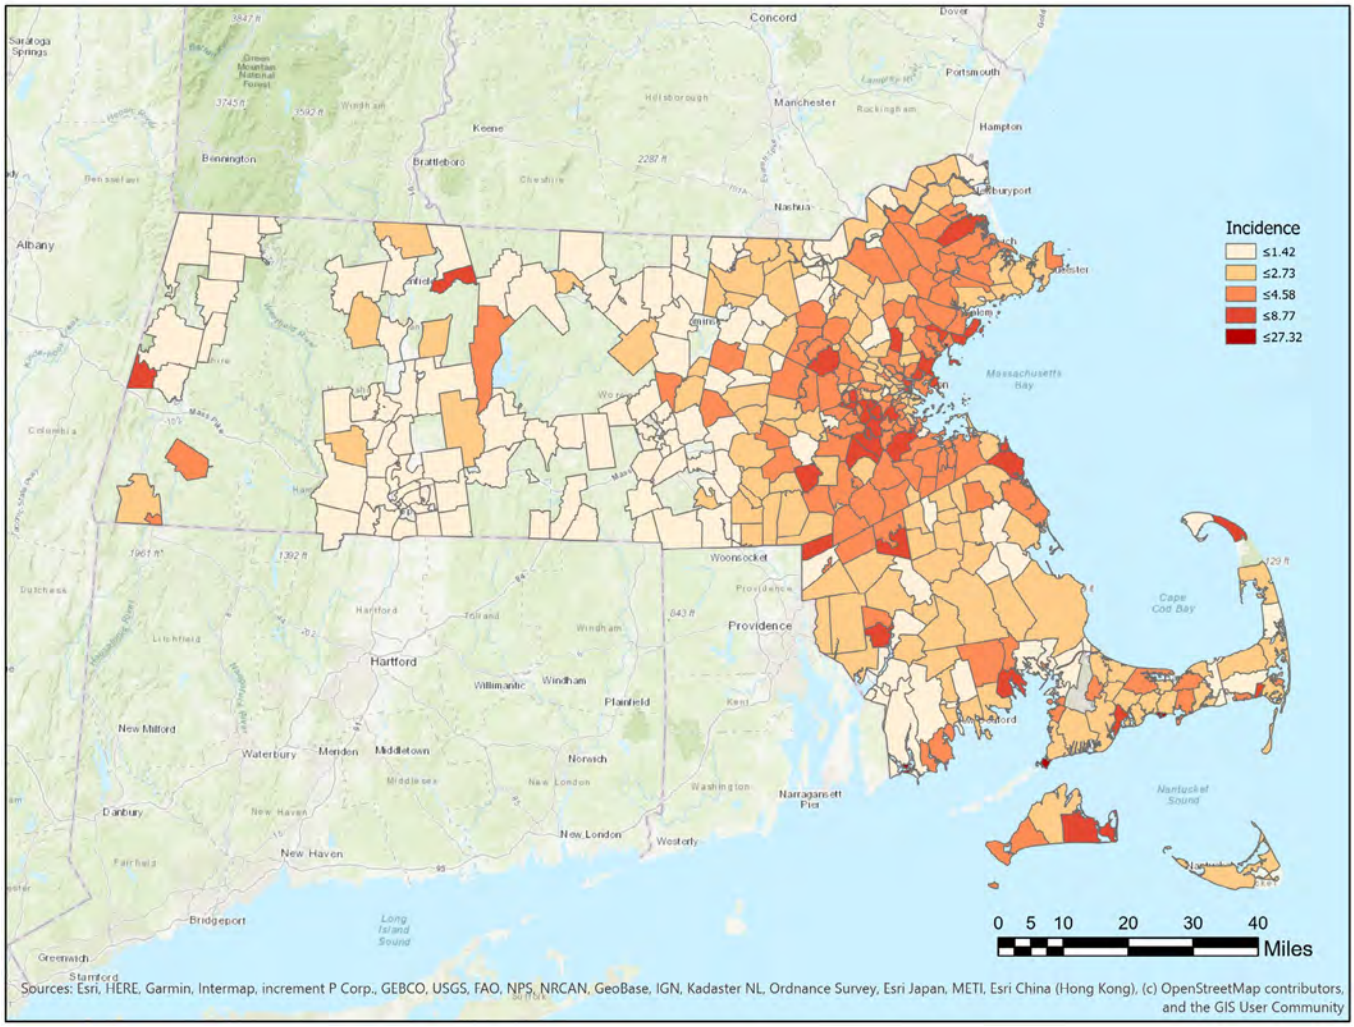

Figure 1. Incidence rates per zip code of SSc in Massachusetts

levels were increased in high incidence areas (Figure 3), and airborne benzene levels correlated well with incidence rates of SSc in the Boston area.

Conclusion: To our knowledge, this is the first study to explore geographic distribution of SSc and evaluate possible triggers for disease development in the United States. The presence of regional clustering and increased density of industry and waste sites in those areas suggests that multiple environmental factors may play a critical role in the development of SSc. Further investigation is warranted to explore these findings.

Table 1. Demographic and clinical characteristics of morphea by subtype

Morphea affects both adults and children, with approximately 50% of patients having childhood onset disease[1,2]. Numerous classification schemes for morphea exist, but none have been evaluated for accuracy in categorizing large patient cohorts. We aimed to determine which existing morphea classifications (i.e. Padua criteria, Peterson criteria, and European Classification scheme) best characterized and identified clinically relevant morphea patient subsets using cross sectional analysis of two large patient cohorts.

Methods: We conducted a cross-sectional study of adults and children from two prospective cohorts - The Morphea in Adults and Children (MAC) at UT Southwestern Medical Center (Dallas, Texas) and the National Registry for Childhood-Onset Scleroderma (NRCOS) at University of Pittsburgh (Pittsburgh, PA). Patient demographics, morphea subtype, quality of life measures, disease activity as measured by the Localized Scleroderma Cutaneous Assessment Tool scores during their initial visits were examined.

Results: A total of 944 adults and children were included in this study. The mean (IQR) age of patients was 16 (8-44) years, and 741 of 944 were female. Majority were white individuals and had the linear or generalized subtype. Utilizing the previously published Padua criteria, the majority of the patients were classified to have linear morphea (n=492, 52%), followed by generalized (n=222, 24%), plaque (n=95, 10%), and then mixed (n=3). Overall, the Padua criteria failed to classify 14% of patients that were found to be "indeterminate" in comparison to the Peterson criteria and European classification schemes which failed to classify 39% and 47% of patients, respectively.

Conclusion: The Padua criteria is widely used by clinicians to categorize morphea patients and performed best in classifying patients into groups with cohesive demographic and clinical features. However, it has ambiguities that might lead to misclassification particularly in terms of generalized and pansclerotic morphea and descriptors such as morphea profunda. Consensus based approaches are needed to address these ambiguities in order to develop a unified classification scheme.

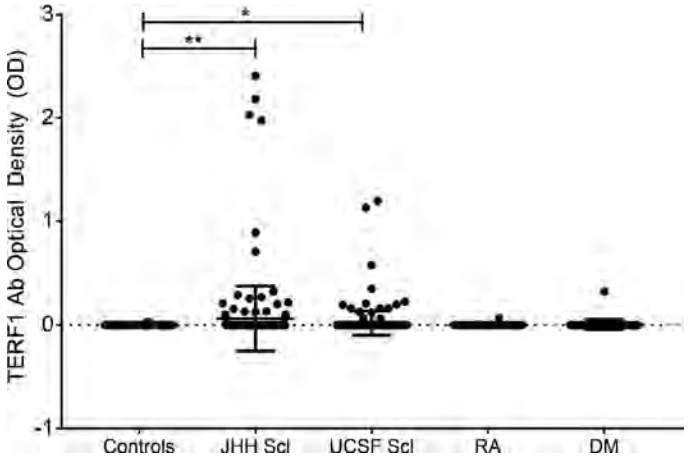
Short Telomeres and Autoantibodies Targeting Telomere-Associated Proteins in Scleroderma

Britany Adler[1], Ami Shah[2], Francesco Boin[3], Paul Wolters[3], Livia Casciola-Rosen[4] and Antony Rosen[1], [1]Johns Hopkins University, baltimore, MD, [2]Johns Hopkins University School of Medicine, Ellicott City, MD, [3]University of California, San Francisco, San Francisco, CA, [4]Johns Hopkins University, Johns Hopkins University, MD

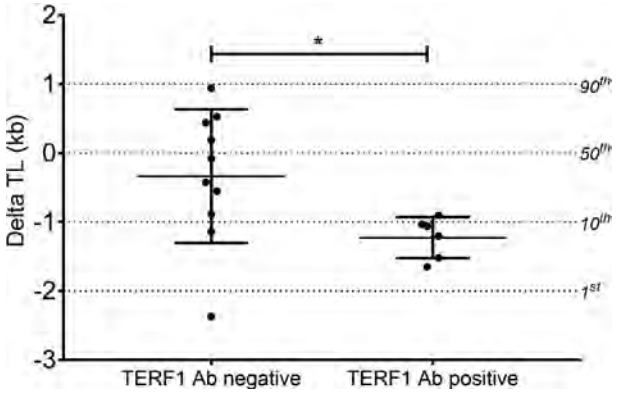
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical II: Lessons Learned from Clinical Trials & Cohorts
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Scleroderma is a systemic fibrosing disease of unknown etiology that often manifests with interstitial lung disease (ILD). Prior studies have found an association between telomere shortening in lymphocytes and scleroderma-ILD, but the mechanisms underlying this association are unclear. Because autoantibodies strongly predict clinical phenotype in scleroderma, we investigated whether patients with scleroderma and short telomeres have autoantibodies targeting telomerase (hTERT) and the shelterin complex which protects telomeres.

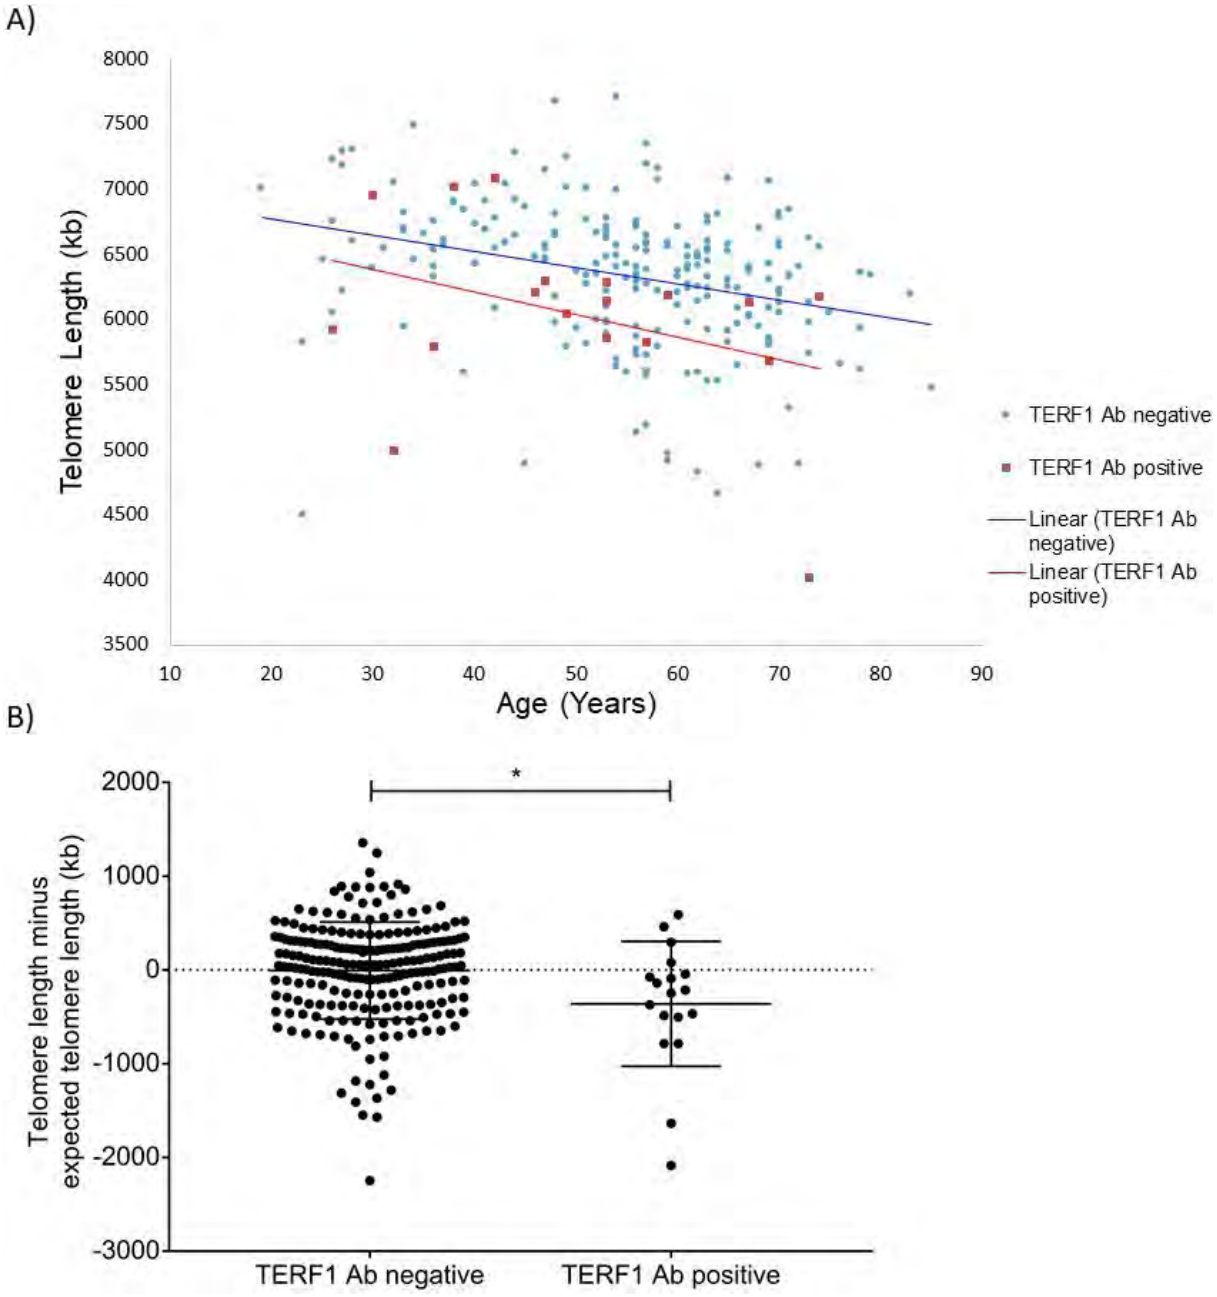
Methods: We screened patient sera from two separate longitudinal scleroderma cohorts from Johns Hopkins (JH, n=200) and the University of California, San Francisco (UCSF, n=242) for autoantibodies targeting hTERT and the six shelterin proteins TERF1, TERF2, POT1, TPP1, TIN2L, and RAP1. ELISA and immunoprecipitation assays were used for autoantibody detection. Peripheral leukocyte telomere length was measured in all patients from the UCSF Cohort using qPCR, and telomere length was measured in lymphocytes and granulocytes from a subset of the JH Cohort (n=16) using Flow Cytometry and Fluorescent in-situ Hybridization (Flow-FISH). To determine if telomere-associated



Telomere length measured by FlowFISH in lymphocytes of 6 TERF1 autoantibody positive scleroderma patients and 10 TERF1 autoantibody negative scleroderma patients. Patients with TERF1 autoantibodies have shorter telomere lengths in lymphocytes compared to TERF1 autoantibody negative patients. Delta TL is the difference between the patient telomere length and the median telomere length of a healthy control population. Statistics were done with the Wilcoxon rank sum, * $p < 0.05$.



Peripheral blood leukocyte telomere length measured by qtPCR in 242 scleroderma patients from the University of California, San Francisco Scleroderma Center. A) Relationship between leukocyte telomere length and age for TERF1 autoantibody positive (n=18) and negative (n=224) patients. B) Patients with TERF1 autoantibodies have a greater difference between the expected age-adjusted telomere length and their actual telomere length compared to TERF1 autoantibody-negative patients. Statistics done using Wilcoxon Rank Sum, * $p< 0.05$.



TERF1 autoantibodies detected by ELISA in healthy controls (n=78), the Hopkins Scleroderma cohort (n=200), the University of California, San Francisco Scleroderma Cohort (n=242), rheumatoid arthritis (n=50), and dermatomyositis (n=50). Chi-square test was used for to compare the frequency of TERF1 autoantibodies between different cohorts. * p< 0.05, **p<0.01.

autoantibodies are present in other diseases for which telomere dysfunction and lung fibrosis are prominent features, we screened a cohort of 153 UCSF patients with idiopathic pulmonary fibrosis (IPF) for autoantibodies targeting telomere-associated proteins.

Results: We identified a subset of scleroderma patients with multiple autoantibodies targeting hTERT and the six shelterin proteins, of which TERF1 autoantibodies were the most common. TERF1 autoantibodies were detected by ELISA in 22/200 (11%) of the JH Cohort and 18/242 (7%) of the UCSF Cohort, and were rarely present in patients with rheumatoid arthritis (1/50) or dermatomyositis (1/50). TERF1 autoantibodies were associated with shorter telomere lengths in both the JH and UCSF Cohorts. Compared to scleroderma patients without TERF1 autoantibodies,

a greater frequency of UCSF scleroderma patients with TERF1 autoantibodies had a shorter telomere length in leukocytes than the expected age-adjusted telomere length (78% vs 43%, Fisher's exact test, p=0.006). Similarly, JH scleroderma patients with TERF1 autoantibodies had a shorter age-adjusted telomere length in lymphocytes (-1.2 ± 0.3 vs -0.3 ± 1.0 kb, p=0.02, student's t-test). When the JH and UCSF Scleroderma Cohorts were combined, TERF1 autoantibodies were associated with a history of severe lung disease (OR 2.0, p=0.03, chi-square) and the presence of Ku (OR 5.4, p=0.02, chi-square) and U1RNP autoantibodies (OR 4.8, p=0.0006, chi-square). We further identified TERF1 autoantibodies in 12/153 (8%) of patients with IPF.

Conclusion: We have identified novel autoantibodies targeting multiple telomere-associated proteins in scleroderma and IPF, which are associated with short telomere length in peripheral lymphocytes and severe lung disease. Autoantibodies targeting telomere-associated proteins may have utility in the diagnosis and subtyping of scleroderma and may provide novel insights into the role of telomere dysfunction in scleroderma and other fibrotic lung diseases.

Session Title: Systemic Sclerosis & Related Disorders – Clinical II: Lessons Learned from Clinical Trials & Cohorts

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks by 44% compared with placebo, with adverse events that were manageable for most patients. The SENSCIS trial (NCT02597933) was followed by an open-label extension trial, SENSCIS-ON (NCT03313180), to provide safety data, including data on decline in FVC and adverse events, in patients treated with nintedanib over the longer term.

Methods: Patients who completed the SENSCIS trial on treatment (nintedanib or placebo) and attended a follow-up visit 28 days later were eligible to participate in SENSCIS-ON. Female patients with SSc-ILD who completed an open-label, drug–drug interaction study of nintedanib plus oral contraceptive (ethinylestradiol and levonorgestrel), in which patients received nintedanib for up to 28 days (NCT03675581), were also eligible to enter SENSCIS-ON to enable treatment continuation. In an interim analysis, we analyzed the change from baseline in FVC (mL) and adverse events over 52 weeks in SENSCIS-ON, a) in patients who had received nintedanib in the SENSCIS trial and contin-

Figure. Change from baseline in FVC (mL) over time in SENSCIS-ON

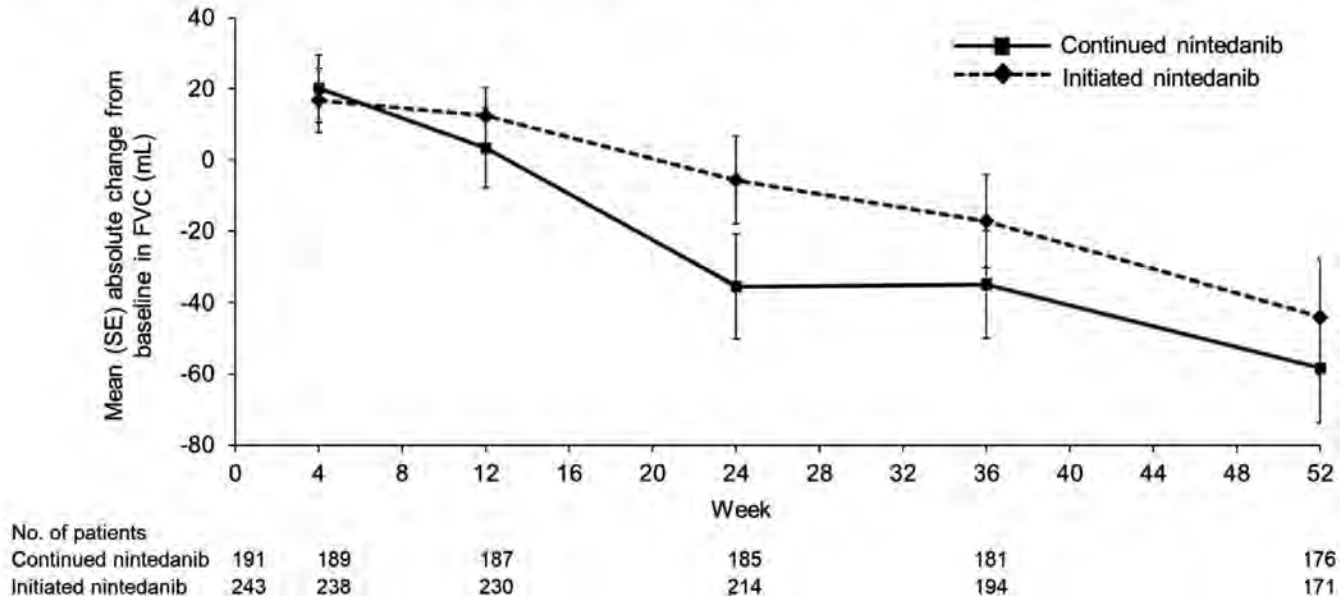

Table. Adverse events (reported irrespective of causality) over 52 weeks in SENSCIS-ON

	Continued nintedanib (n=197)	Initiated nintedanib (n=247)
Any adverse event(s)	191 (97.0)	243 (98.4)
Most frequent adverse events*		
Diarrhea	134 (68.0)	170 (68.8)
Nausea	32 (16.2)	60 (24.3)
Vomiting	27 (13.7)	53 (21.5)
Skin ulcer	36 (18.3)	43 (17.4)
Nasopharyngitis	28 (14.2)	33 (13.4)
Upper respiratory tract infection	27 (13.7)	26 (10.5)
Cough	24 (12.2)	21 (8.5)
Weight decreased	14 (7.1)	26 (10.5)
Abdominal pain	6 (3.0)	33 (13.4)
Serious adverse event(s)†	42 (21.3)	60 (24.3)
Adverse event(s) leading to treatment discontinuation	9 (4.6)	53 (21.5)

Adverse events were coded according to preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA). Data are n (%) of patients with ≥1 such event reported over 52 weeks (or until 7 days after last trial drug intake for patients who discontinued trial drug before week 52). *Events reported in >10% of patients in either treatment group are shown. †Adverse events that resulted in death, were life-threatening, resulted in hospitalization or prolongation of hospitalization, resulted in persistent or clinically significant disability or incapacity, were a congenital anomaly or birth defect, or were deemed to be serious for any other reason.

ued nintedanib in SENSCIS-ON ("continued nintedanib" group), and b) in patients who had received placebo in the SENSCIS trial and initiated nintedanib in SENSCIS-ON or who had received nintedanib in the drug-drug interaction study ("initiated nintedanib" group). Analyses were pre-specified and descriptive.

Results: In SENSCIS-ON, there were 197 patients in the "continued nintedanib" group and 247 patients (231 from SENSCIS, 16 from the drug-drug interaction study) in the "initiated nintedanib" group. In these groups, respectively, mean (SD) FVC at inclusion in SENSCIS-ON was 2379 (754) mL and 70.4 (18.1) % predicted and 2443 (814) mL and 70.8 (17.9) % predicted. Mean (SE) changes in FVC from baseline to week 52 of SENSCIS-ON were –58.3 (15.5) mL in patients who continued nintedanib in SENSCIS-ON, –44.0 (16.2) mL in patients who initiated nintedanib in SENSCIS-ON (Figure), and –51.3 (11.2) mL in all patients treated in SENSCIS-ON, similar to the change from baseline to week 52 in the SENSCIS trial (–42.7 [14.2] mL). Diarrhea was the most frequently reported adverse event (Table). Adverse events led to discontinuation of nintedanib in 9 patients (4.6%) who continued nintedanib in SENSCIS-ON and 53 patients (21.5%) who initiated nintedanib in SENSCIS-ON. Elevations in alanine aminotransferase and/or aspartate aminotransferase to ≥3 times the upper limit of the normal range were reported in 3 patients (1.5%) who continued nintedanib in SENSCIS-ON and 20 patients (8.1%) who initiated nintedanib in SENSCIS-ON.

Conclusion: The change in FVC in patients who received nintedanib over 52 weeks of SENSCIS-ON was similar to the change in FVC in patients who received nintedanib over 52 weeks of the SENSCIS trial. The adverse event profile of nintedanib over longer-term use was consistent with that reported over 52 weeks in the SENSCIS trial. These findings support a clinically meaningful benefit of nintedanib in slowing the progression of SSc-ILD.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical II: Lessons Learned from Clinical Trials & Cohorts
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Previous studies have demonstrated alterations in GI microbiota of patients with systemic sclerosis (SSc) compared with healthy controls [1]. However, these prior studies did not adequately examine the impact of disease features and patient characteristics on microbial composition. The purpose of the present study was to examine associations between specific SSc disease features/patient characteristics and GI microbial composition using two independent SSc cohorts and compare GI microbiota between cohorts.

Methods: Patients fulfilling the 2013 ACR/EULAR Classification Criteria for SSc were recruited from the rheumatology clinics at Lund University, Sweden and the University of California, Los Angeles (UCLA). Unaffected controls

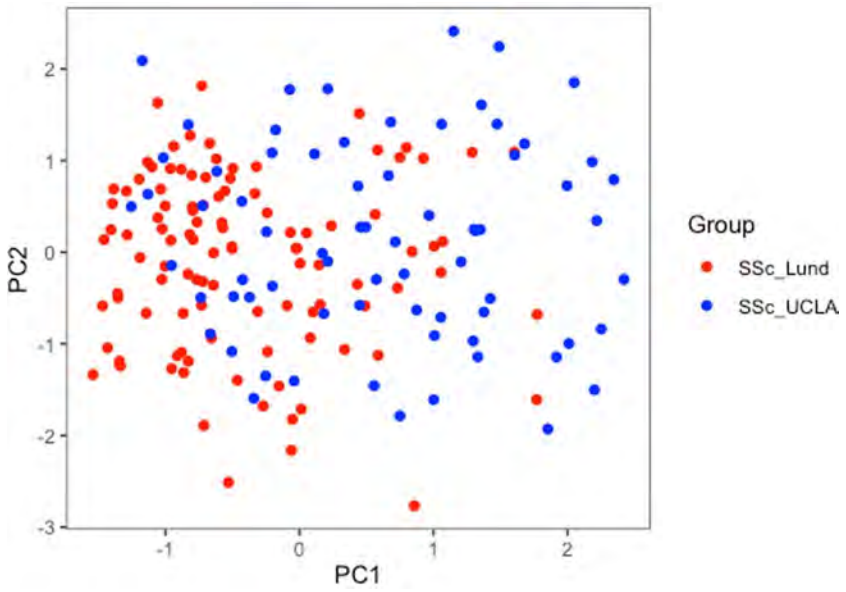

Figure 1. Significant differences in the beta diversity of the Lund-SSc (Red) and UCLA-SSc (blue) patients as demonstrated by principal coordinate analysis plots of the robust Aitchison distance. Each dot represents a patient sample. The P-value (0.0001) was calculated by analysis of variance using distance matrices.

were also recruited at Lund University. All participants provided stool specimens for 16S rRNA sequencing. Extensive clinical data were collected to evaluate the effects of specific disease features on lower GI microbiota. Alpha diversity was assessed by metrics of richness, evenness, and phylogenetic diversity. Beta diversity analysis was performed with DEICODE in QIIME2. Multivariate negative binomial models were used to identify differentially abundant bacterial genera associated with SSc disease features and cohort (UCLA SSc vs. Lund SSc; Lund SSc vs. Controls).

Results: Compared with the Lund SSc patients (N=106), UCLA SSc patients (N=71) had increased disease duration (median 7.1 vs. 2.0 years) and a higher prevalence of diffuse cutaneous disease (44% vs. 19%), interstitial lung disease (87% vs. 33%), Scl-70 antibody positivity (31% vs. 18%), and small intestine bacterial overgrowth [SIBO] (22% vs. 5%). However, both groups had a similar age, %female, and BMI. UCLA SSc patients had decreased alpha diversity ($P< 0.0001$ for all alpha diversity metrics) and altered beta diversity ($P=0.0001$; Figure 1) compared with Lund SSc patients. Factors significantly associated with alpha and/or beta diversity included age, sex, diffuse disease, disease duration, smoking history, and SIBO. After adjusting for the aforementioned factors, the Lund cohort had increased abundance of commensal genera (e.g. *Bifidobacterium*) and decreased abundance of potentially pathobiont genera (e.g. *Streptococcus*) compared with the UCLA cohort (Figure 2). Compared with unaffected controls from Lund (N=85), Lund SSc patients had increased abundance of pathobiont genera (e.g. *Desulfovibrio*) (Figure 3), consistent with our prior studies.

Conclusion: In the first study to examine the associations between specific disease features and GI microbial composition in two independent SSc cohorts, we found that both disease duration and SSc subtype independently affect microbial composition and should be considered in future SSc microbiome analyses. Even after controlling for potential confounders, genus level differences were observed between the two cohorts, suggesting that external factors, such as diet, geography and genetic factors, may affect GI microbial composition and should be taken into account in future studies.

Session Title: Systemic Sclerosis & Related Disorders – Clinical II: Lessons Learned from Clinical Trials & Cohorts

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Dietary restriction of short-chain fermentable oligosaccharides, disaccharides, monosaccharides and polyols (low FODMAP) has been found to reduce GI symptoms in patients with IBS and is often recommended to patients with SSc. However, no studies have evaluated whether a low FODMAP diet leads to a meaningful improvement in GI symptoms in patients with SSc. The purpose of this study was to (1) compare GI symptoms in SSc patients adhering to a low versus high FODMAP diet, and (2) determine whether GI microbial composition is altered in SSc patients adhering to a low FODMAP diet.

Table 1. Demographics, Clinical Characteristics and GIT 2.0 Scores of SSc Patients.

Characteristic	FODMAP High (N=16)	FODMAP Low (N=19)	P-value

Table 1. Demographics, clinical characteristics and GIT 2.0 scores of SSc patients.

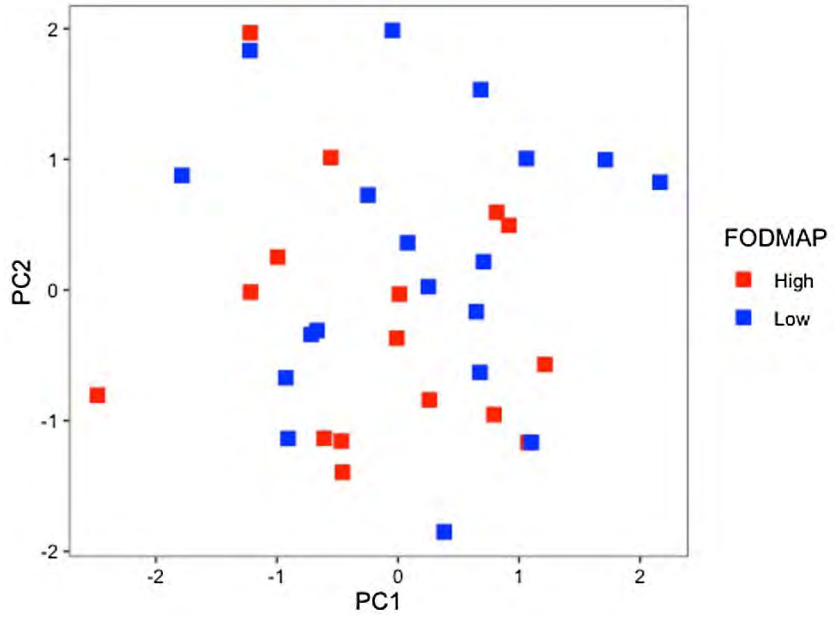

Figure 1. Beta diversity of the High (Red) and Low (blue) FODMAP group patients as demonstrated by principal coordinate analysis plots of the robust Aitchison distance. Each dot represents a patient sample. The P-value (0.264) was calculated by analysis of variance using distance matrices.

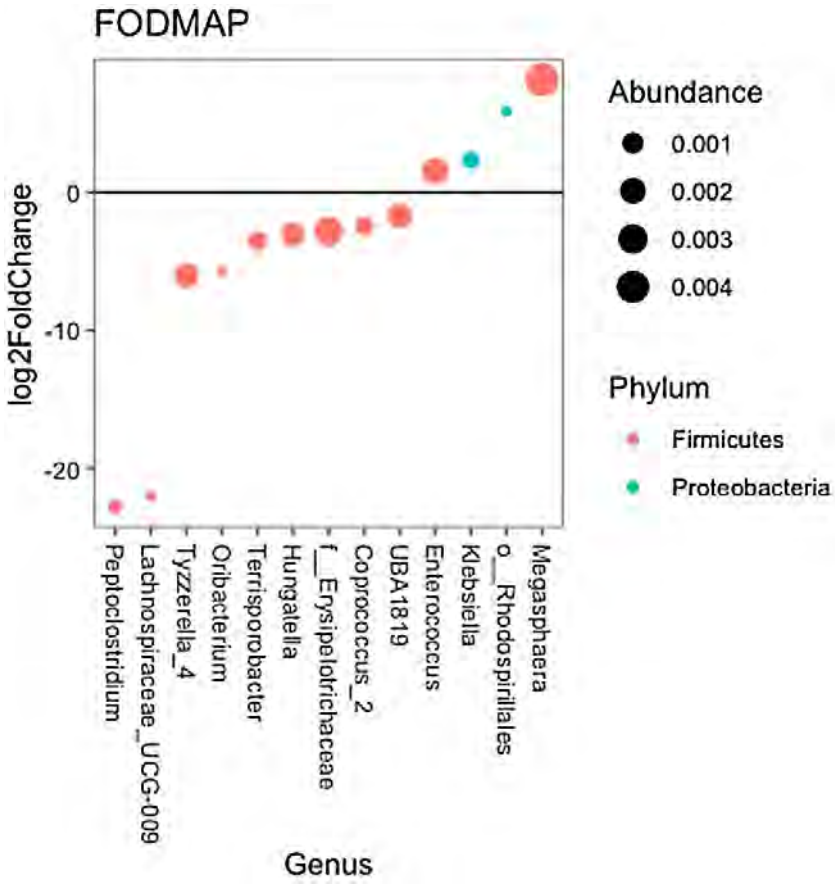

Figure 2. Genus level taxa with significant (q<0.1) differential abundance between low versus high FODMAP groups. Circles with a positive fold change represent genera with increased abundance in the high FODMAP group, and circles with a negative fold change represent genera with increased abundance in the low FODMAP group. The color of the circle signifies the phylum level of the genera with differential abundance. The size of the circle indicates the relative abundance of the specific genus.

Methods: Adult patients satisfying the 2013 ACR/EULAR Classification Criteria for SSc provided stool samples for 16S rRNA sequencing. Participants completed the Diet History Questionnaire (DHQ) II, a valid, 153-item food frequency questionnaire that assesses dietary recall in the past month. Forty DHQ II items were characterized as high FODMAP items using the Monash University FODMAP food database. Patients were dichotomized into low versus high FODMAP groups, and GI symptoms, as measured by the UCLA GIT 2.0, were compared between the two groups. Microbial community differences between the low and high FODMAP groups were assessed using 3 metrics of alpha diversity (richness, evenness, phylogenetic diversity), as well as beta diversity. Multivariate negative binomial models were used to identify differentially abundant bacterial genera in the high versus low FODMAP groups.

Results: Patients in the low (N=19) and high (N=16) FODMAP groups were similar in terms of age, %female, BMI, disease duration, %diffuse disease, smoking history and %small intestine bacterial overgrowth [SIBO] (Table 1). There were no significant differences in GIT 2.0 scores between the low and high FODMAP groups, although the scores for some of the domains (e.g., Reflux, Distension, Diarrhea) were numerically higher in the high FODMAP group; whereas scores for the constipation domain were similar for both groups. There were no significant differences in alpha diversity between the two groups on both univariate and multivariate analysis controlling for age, sex, SSc subtype, smoking, SIBO and disease duration. There was no significant difference in beta diversity between the two groups on univariate and multivariate analysis (Figure 1). Compared with the low FODMAP group, the high FODMAP group had increased abundance of *Enterococcus,* a genus considered in a number of studies to be pathobiont (Figure 2); however, in the multivariate analysis, there was no significant genus level differences between the two groups with the exception of *Parvimonas* enrichment in the low FODMAP group.

Conclusion: Evidenced-based dietary recommendations for SSc are lacking. This is the first study to examine the relationship between diet, GI symptoms, and GI microbial composition in patients with SSc. Although this was a small study, the results demonstrate that consuming a low FODMAP diet is not associated with significant alterations GI microbial composition, nor significant improvements in SSc-GI symptoms. Larger, prospective SSc-GI studies are needed to help guide the clinical management of this troubling and understudied dimension of SSc.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Citrulline (cit) autoimmunity is central in rheumatoid arthritis (RA), including both anti-citrulline protein antibodies (ACPA) and autoreactive CD4+ T cells. While the ACPA are abundant, studies of cit-reactive T cells have been hampered by their scarcity. Still, cit-reactive T cells have been reported in the RA joint and in peripheral blood by peptide-HLA tetramer technology. We have set up an *in-vitro* antigen(ag)-specific expansion method [1] for generating TCR sequences to dissect the diversity of the autoreactive T cell repertoire. Hereby we can look for dominant T cell clones amongst different patients sharing the same HLA genes.

Methods: We subjected synovial fluid-derived cells (SFMC) from HLA-DRB1*04:04 RA patients (n=4) and peripheral blood (PBMC) from HLA-DRB1*04:04 healthy controls (n=4) to our ag-specific expansion method [1]. A cit-peptide from cartilage intermediate layer protein (cit-CILP2) was used to query autoimmunity whereas an influenza matrix protein derived peptide (MP54) was used as positive control. *In-vitro* expanded tetramer positive cells were single sorted and processed for PCR based TCR amplification, followed by barcoding and TCR sequencing using miSeq. The data was demultiplexed by our in-house script and clones identified by comparison of both CDR3α and β amino acid sequences. TCRs were further validated for specificity by transient re-expression into HEK293 cells, followed by staining with the same tetramers initially used for sorting.

Results: Cit-CILP2+ T cells could be expanded *in vitro* in all samples and clonal TCR expansions were prominent. Collectively, we could get 27 cit-CILP2 specific (PB n=6 and SF n=21) and 56 MP54 specific (PB n=37 and SF n=19) expanded T-cell clones. We also captured another 101 cit-CILP2 specific and 190 MP54-specific unique TCRs. The proportion of unique and expanded clones for cit-CILP2 and MP54 was similar in the joint-derived samples. The CDR3 length distribution for cit-CILP2 specific clones was different from MP54 specific clones for both the TCR α and β chain. Longer CDR3 length were more common in cit-CILP2 specific clones and there were differences in distribution of amino acids at specific positions. Clones derived from same patient showed shared usage of V and J genes for both α and β chains. HEK cell Re-expression of TCRs validated their target specificity.

Conclusion: This method provides a rapid tool for generation and validation of ag-specific TCRs. So far, the gene usage and CDR3 profiles appear subject-driven with limited sharing among subjects. Today, many studies are generating transcriptomic data (including TCR) from sites of inflammation and generating orphan TCRs, i.e. without known ag-specificity. We are accumulating cit-peptide ag-specific TCR sequences, which may in the future be used to identify ag-specific TCR signatures among “orphan” TCRs in such public big data sets. Until then, cit-reactive TCRs will be used in functional *in vitro* studies as well as in establishing relevant mice models for RA. Finally, we will also evaluate longitudinal changes in the autoreactive TCR repertoire during disease progression and after therapeutic intervention.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: CD4$^+$ T cells are implicated in the pathogenesis of rheumatoid arthritis (RA) due to strong genetic association with HLA class II alleles, the presence of CD4$^+$ T cells in the rheumatoid joint and the efficacy of T cell directed therapies. In addition, CD4$^+$ T cells specific to citrullinated epitopes are increased in RA and their frequency is influenced by disease duration and by biologic therapy. However, technical challenges due to the rarity of citrulline (cit)-specific T cells have limited our understanding of how T cell phenotype and specificity can vary within and between individuals. To address this gap in knowledge, we characterized the frequency and phenotype of cit-specific CD4$^+$ T cells in a cross-sectional cohort of RA subjects using multiplex HLA class II tetramer staining combined with our new computational approach for phenotyping rare cell populations.

Methods: The cohort consisted of 77 seropositive RA subjects and 30 healthy control subjects matched for age, sex and race. All RA subjects met the 2010 American College of Rheumatology criteria, and had at least one HLA-DRB1*04:01 allele, and were ACPA positive. The multiplex HLA class II tetramer assay stained six distinct groups of epitope specificities: alpha-enolase, aggrecan, cartilage intermediate layer protein, a combined vimentin and fibrinogen peptide pool with influenza included as a reference for comparison to a known vaccine response. To facilitate unbiased assessment of the phenotypic distribution of rare, autoreactive T cells within and across subjects, we first clustered total CD4$^+$ T cells from each individual using Phenograph, and then performed hierarchical metaclustering

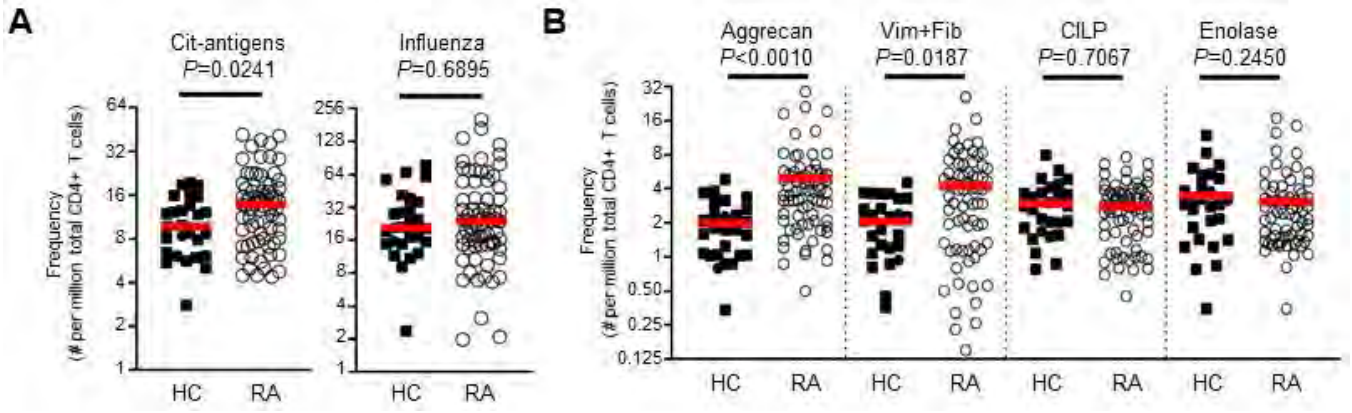

Figure 1. ncreased frequency of citrulline specific CD4 T cells in individuals with rheumatoid arthritis (RA) compared to healthy control (HC) subjects. (A) Ex vivo frequencies of T cells for all cit-antigens combined, and for influenza antigen. (B) Ex vivo frequencies of T cells specific for each cit-antigen specificity individually. For A and B, symbols represent individual subjects (n=30 for HC; n=77 for RA), and horizontal bars show the median. P-values were calculated with an unpaired non-parametric Mann-Whitney test.

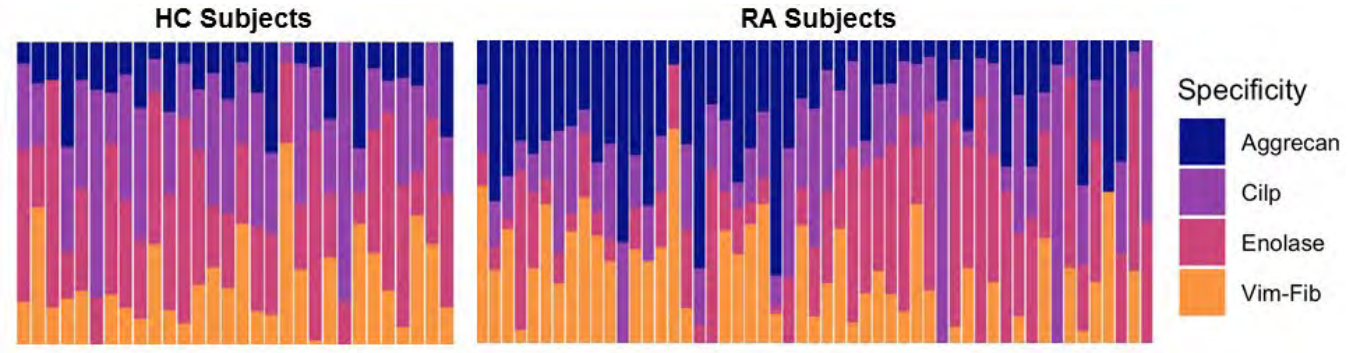

Figure 2. The dominant specificities of citrulline-specific CD4 T cells in rheumatoid arthritis differ between individual subjects. Stacked bar plot showing distribution of antigen specificity for each individual HC subject (n=30) and each individual RA subject (n=52) with >8 Tmr positive cells of any specificity.

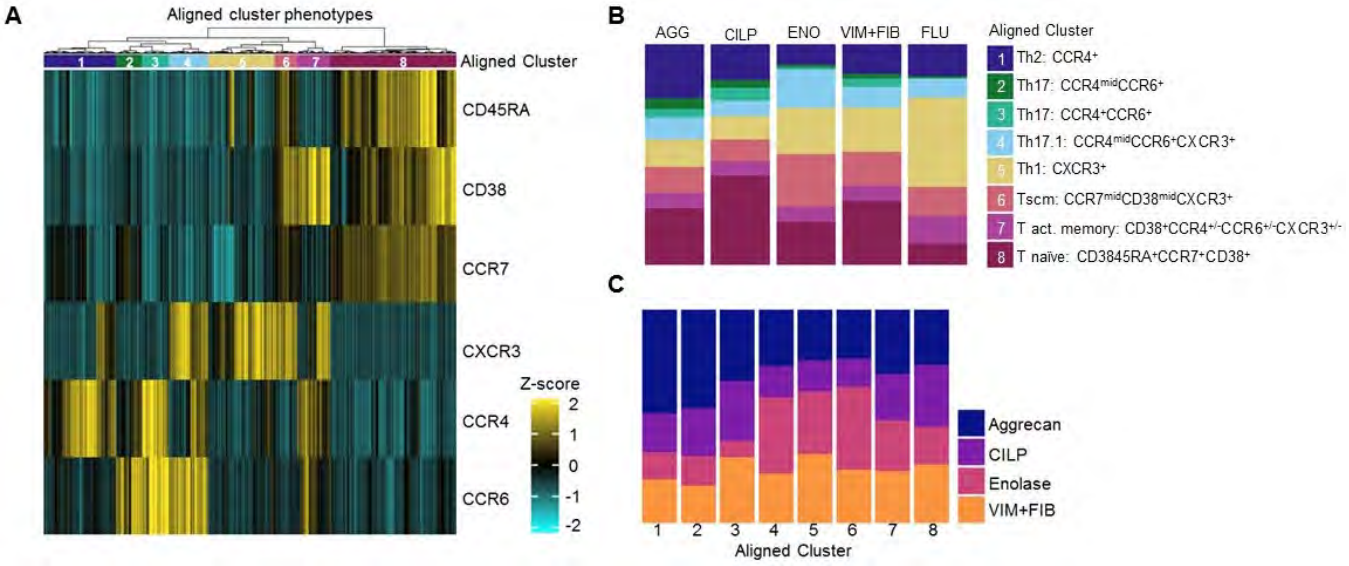

Figure 3. Cell phenotype is linked to specificity. To facilitate direct comparisons of complex surface phenotypes and unbiased assessment of the phenotypic distribution of rare, autoreactive T cells within and across subjects, we used our recently developed computational strategy DISCOV-R (DIStribution analysis across Clusters of a parent population OVerlaid with a Rare subpopulation). In brief, we first cluster total CD4+ T cells from each individual using Phenograph, and then perform hierarchical metaclustering to align clusters between individuals thereby generating a common CD4T cell landscape across all subjects. (A) Heat map showing all CD4+ T cell clusters from 66 RA subjects and 30 HC subjects hierarchically clustered (Euclidean distance, Ward's minimum variance linkage) by expression of six phenotyping markers as a z-score comparing mean cluster intensity to total CD4 T cell intensity for each subject. The resulting dendrogram is sliced into eight aligned clusters with color bar across top indicating aligned cluster assignment. (B) Stacked bar plot showing aligned clusters for each antigen specificity for 93 subjects (RA n=63, HC n=30) with >8 Tmr+ cells. Suggested lineage of aligned clusters representing CD4+ T cell landscape defined by the heatmap in A. (C) Distribution of antigen-specific T cells pooled from RA subjects across aligned clusters colored by specificity.

to align clusters between individuals. The relationship between clinical variables and cell frequencies was modeled using quasibinomial generalized linear models with age and sex as covariates.

Results: Consistent with our previous study analyzing single antigen specificities, the frequency of cit-specific $CD4^+$ T cells was significantly increased in RA subjects. Notably, individual RA subjects had $CD4^+$ T cells specific for multiple cit-specific antigens, yet the predominant specificities varied between individuals. Furthermore, the predominant immunophenotype of cit-specific CD4+ T cells varied based on antigen specificity. Importantly, we also observed

significant associations between immunophenotype and disease duration and disease activity for individual antigen specificities.

Conclusion: Here, we show that there is not a single dominant specificity or cellular phenotype present in individuals with RA. Instead, the immune response to cit-antigens targets multiple antigens with a broad range of phenotypes and these features are dynamic, which parallels reported characteristics of ACPA responses during development of RA. Serologic studies have demonstrated an expansion of frequency and targets of ACPA prior to RA development. Our findings suggest that a similar process may occur for cit-specific $CD4^+$ T cells, perhaps initiated by failed tolerance to a single initiating cit-antigen years prior to disease onset, followed by an expansion of the T cell response to multiple cit-antigens.

Session Date: Monday, November 9, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Resident memory T cells (T_{RM}) are site-specific memory T cells that take up long-term residence in peripheral tissues and aid in local immune defense. T_{RM} have also been implicated in autoimmune diseases by driving localized recurrent inflammation. As chronic arthritis is characterized by recurrent site-specific joint inflammation, we sought to investigate the role of T_{RM} in joint-specific memory.

Methods: We performed 10x genomics droplet-based single cell RNA sequencing and immune repertoire profiling on memory T cells disaggregated from human rheumatoid arthritis synovium to evaluate transcriptomic signature. We also used Mantra multispectral immunofluorescence microscopy to evaluate T cells expressing common T_{RM} protein markers in human arthritic synovial tissue sections. To assess the functional contribution of T_{RM} cells in arthritis in vivo, we generated a novel murine model of joint-specific recurrent synovitis. We utilized adoptive transfer, in vitro metabolic and migration assays, in vivo cell labeling, and localized depletion strategies to characterize T_{RM} cells in the synovium and their functional role in arthritis flare.

Results: We identified cells with the phenotypic and transcriptomic signature of T_{RM} within human arthritic synovium. These cells were primarily CD8+ and exhibited restricted T cell receptor clonotypes as well as a pro-inflammatory gene expression profile. Adoptive transfer studies in our animal model of joint-specific recurrent inflammation confirmed that arthritis flares were mediated by antigen-specific CD8+ T cells that remained within previously inflamed joints during remission. These cells were bona fide T_{RM}, as confirmed through surface signature, failure to migrate in vivo or in vitro, preferential uptake of free fatty acids, and long-term residency. Site-specific depletion of synovial T cells during remission markedly ameliorated disease recurrence, establishing a role of synovial T_{RM} in arthritis flares.

Conclusion: Here, we demonstrate that synovial T_{RM} present in human inflamed synovium are a targetable mediator of joint-specific memory in arthritis.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The cyclic citrullinated peptide (CCP) autoantibody is a highly specific and predictive marker for the clinical diagnosis of RA. Elevation in CCP titers can be detected several years before patients develop clinical arthritis and is also a predictive biomarker for RA risk. CCP+ RA is associated with increased levels of distinct synovial and circulating T cell immunophenotypes, including the expansion of PD-1^{hi} CXCR5- T peripheral helper (Tph) cells. However, whether these and other immune cell populations are altered in the peripheral blood of CCP+ individuals without RA is unknown.

Methods: We employed time of flight mass cytometry (CyTOF) with a panel of 39 surface markers to characterize T cells in cryopreserved peripheral blood mononuclear cells from a cohort of CCP- controls (n=23), CCP- first-degree relatives (FDRs) of patients with classified RA (n=27), CCP+ individuals at-risk of future RA (n=30), and active CCP+

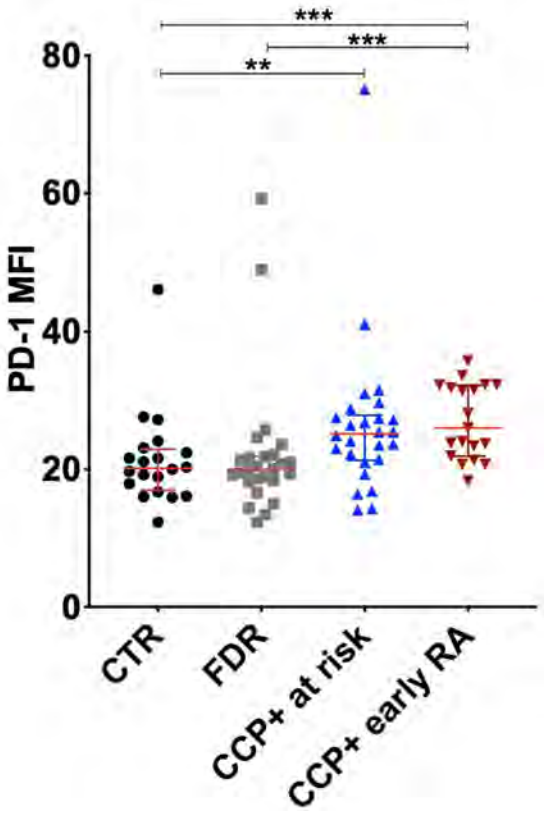

Figure 3. Increased PD-1 expression of CD39hi Tph cells in CCP+ at-risk individuals.

early RA patients (diagnosis within 1 year, n=20). RA patients fulfilled the 2010 ACR/EULAR criteria. We used CITRUS to define and quantify the clusters of PD-1^{hi} cells based on their multi-dimensional features. Expanded cell populations were confirmed by biaxial gating, and the statistical significance was determined by Mann-Whitney U test.

Results: Global T cell phenotypes were generally similar in CCP- groups, CCP+ at risk, and CCP+ early RA, including frequencies of naïve and memory CD4 and CD8 T cells and Tregs. By biaxial gating, both Tph cells and Tfh cells (PD-1^{hi} CXCR5+) were increased in this CCP+ early RA cohort (Figure 1). The number of Tph cells in CCP+ at-risk individuals was increased compared to CCP- controls, although not statistically significant. For a broader assessment of PD-1^{hi} T cells, we used CITRUS to cluster gated PD-1^{hi} cells, including both CD4 and CD8 T cells. Among PD-1^{hi} T cells, 2 specific subpopulations were identified as significantly expanded in CCP+ early RA patients (Figure 2A). Phenotypic assessment highlighted increased CD39 expression on the expanded subclusters. Biaxial gating confirmed the significant expansion of PD-1^{hi} CD39^{hi} CD4 memory T cells in CCP+ early RA patients compared to all the other groups (Figure 2B). In addition, the CD39^{hi} subset of Tfh or Tph cells, but not total Tph and Tfh cells, were significantly higher in CCP+ RA compared to CCP+ at-risk group. The frequency of CD39^{hi} Tph cells was not increased in CCP+ at-risk individuals compared to CCP- controls; however, the expression of PD-1 on these cells was increased in CCP+ at-risk compared to controls (p=0.003, 1.25-fold change), a finding also seen in CCP+ early RA patients (Figure 3). The mean expression intensity of PD-1 on CD39^{hi} Tph cells was significantly correlated with CCP titer across all donors (r=0.376, p< 0.0001).

Conclusion: Detailed immunophenotyping analyses highlighted a robust expansion of CD39^{hi} Tph cells in CCP+ early RA patients. In CCP+ individuals at risk of future RA, CD39^{hi} Tph cells were not clearly increased in frequency, but expressed higher levels of PD-1 compared to CCP- controls and PD-1 levels were correlated with CCP titer. These results suggest that alterations in T cell phenotypes may be detectable not only early in RA but even preceding clinical onset after CCP elevation.

Synovial CD8 T Cells in Rheumatoid Arthritis Exhibit High Antigen-independent Cytokine Production and Low Cytotoxic Potential

Anna Helena Jonsson[1], Fan Zhang[2], Emma Gomez-Rivas[3], Karishma Rupani[4], Gerald Watts[5], Kevin Wei[1], Runci Wang[4], Deepak Rao[4], Accelerating Medicines Partnership (AMP) - RA/SLE[6], Soumya Raychaudhuri[2] and Michael Brenner[1], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Division of Rheumatology, Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]Brigam and Women's Hospital, Boston, [6]., Boston

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: T cell-derived pro-inflammatory cytokines are major drivers of RA pathogenesis, and these cytokines have traditionally been attributed to CD4 T cells. However, single-cell RNA-sequencing (RNA-seq) of RA synovial tissue has revealed that CD8 T cells, which represent nearly half of T cells in inflamed RA synovium, are the predominant expressors of IFNγ and TNF transcripts[1]. Here, we present data indicating that synovial CD8 T cells are major cytokine producers in response to both TCR-mediated and cytokine-mediated stimulation and have low cytotoxic potential.

Methods: Blood, synovial fluid, and synovial tissue were obtained from RA patients meeting the 2010 ACR criteria for RA. Single-cell RNA-seq data sets were generated by integrating new and publicly available data from synovial tissue and fluid from patients with RA and from blood from healthy controls. For stimulation assays, peripheral blood mononuclear cells or synovial fluid mononuclear cells were stimulated with IL-12 and IL-15 for 20 hours or with anti-CD3/CD28 antibody-coated beads for 4 hours, with brefeldin A and monensin included during the last 4 hours of culture. Cytokine production was assessed by intracellular cytokine staining and flow cytometry. Additional flow cytometry experiments were performed on unstimulated cells.

Results: The majority of CD8 T cells in synovial tissue and fluid from patients with seropositive RA express granzyme K (GzmK), either alone or together with granzyme B (GzmB), a marked enrichment compared to blood (Fig. 1A). These cells express lower levels of GzmB and perforin compared to classical GzmB^{+} CD8 cytotoxic T lymphocytes (CTLs) in blood (Fig. 1B), and they do not express high levels of CD57 or CX3CR1, two surface markers associated with cytotoxicity. GzmK itself does not cleave caspases to activate apoptotic cell death pathways but instead signals synovial

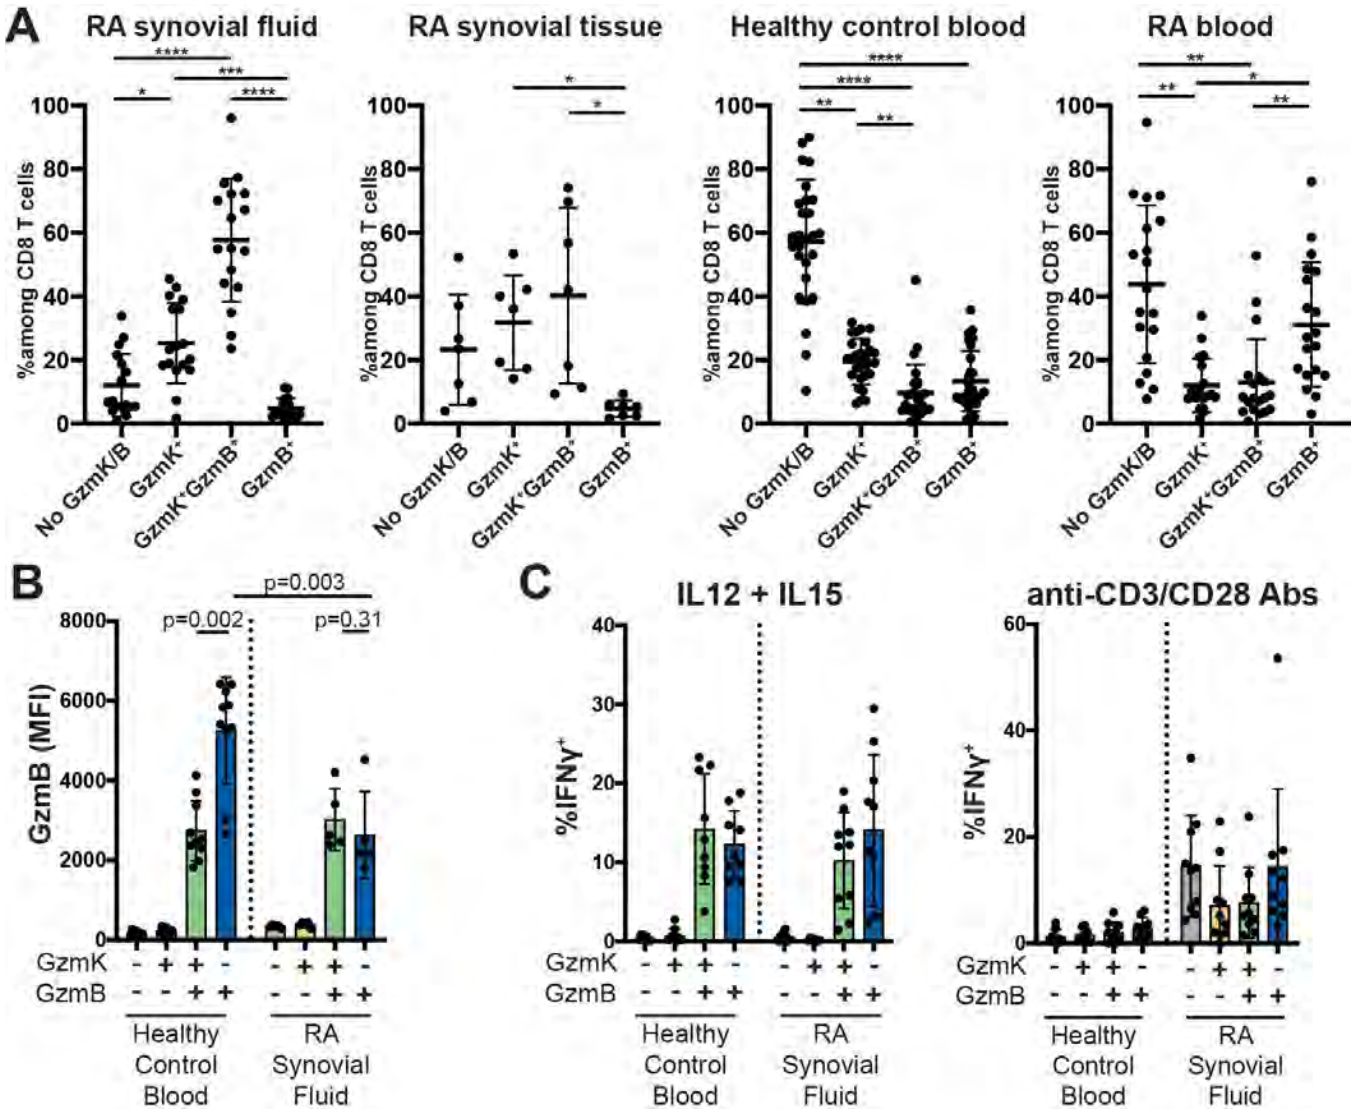

Figure 1. GzmK+ GzmB+ CD8 T cells, the predominant CD8 T cell population in RA synovial fluid and tissue, have low cytotoxic potential but can respond to antigen-independent stimulation. (A) Frequency of intracellular GzmK and GzmB expression among unstimulated CD8 T cells. (B) Mean fluorescence intensity of GzmB staining of unstimulated CD8 T cells categorized by GzmK and GzmB expression. (C) Intracellular cytokine staining after stimulation with IL-12 and IL-15 or anti-CD3/CD28-coated beads. Statistics by Friedman test (A) and Mann-Whitney and Wilcoxon signed rank tests (B). *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

fibroblasts to produce IL-6 and other inflammatory factors. Together, these results indicate that GzmK$^+$ GzmB$^+$ CD8 T cells have low cytotoxic potential.

In stimulation assays, GzmK$^+$ GzmB$^+$ CD8 T cells responded to stimulation with IL-12 and IL-15 as well as anti-CD3/CD28 antibody-mediated stimulation. CD8 T cells represented half or more of IFNγ-producing T cells in both conditions, matching or out-producing CD4 T cells. Antigen-independent stimuli are likely the predominant activation pathway for GzmK$^+$ GzmB$^+$ CD8 T cells *in vivo*, since they express low levels of Nur77, a marker of TCR-mediated stimulation, compared to the rare GzmB$^+$ CD8 T cells.

Conclusion: GzmK$^+$ GzmB$^+$ CD8 T cells are the largest CD8 T cell population in synovial fluid and tissue from patients with RA. These cells have low cytotoxic potential but produce cytokines such as IFNγ in response to antigen-independent stimulation. These findings argue that the dominant CD8 T cell population in RA synovium amplifies inflammation by producing IFNγ and other inflammatory mediators (including GzmK itself) in response to cytokines found

in inflamed RA tissue. This antigen-independent activation of CD8 T cells may represent a major mechanism for breaking self-tolerance in RA and other autoimmune diseases.

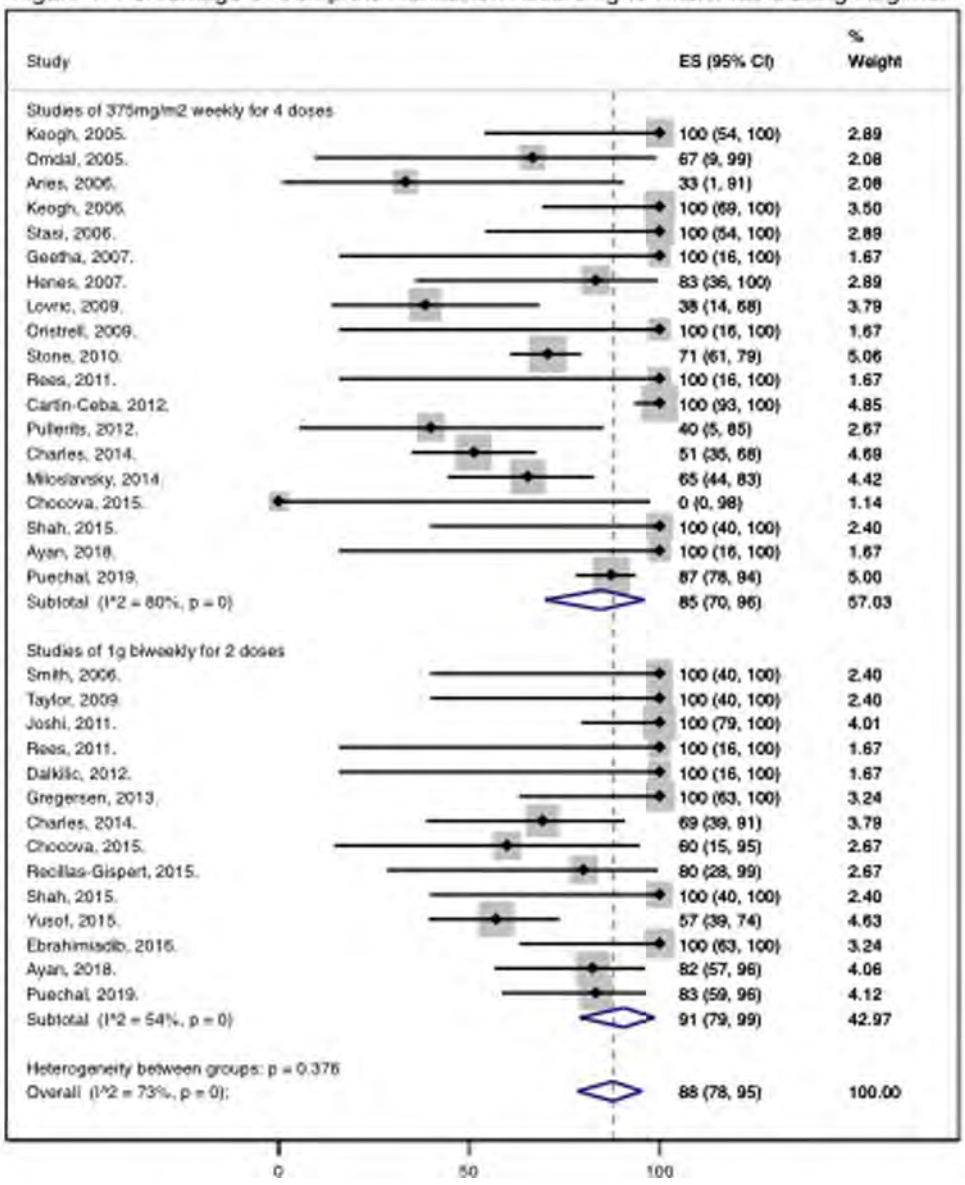
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – ANCA-Associated
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: Organ or life-threatening granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), two of the antineutrophil cytoplasm antibody-associated vasculitis (AAV), are treated with cyclophosphamide or rituximab (RTX) in combination with glucocorticoids. Different RTX regimens for induction of remission are available: the 4-dose AAV regimen at doses of 375 mg/m^2 I.V. weekly, and the 2-dose rheumatoid arthritis (RA) regimen at doses of 1000 mg I.V. on day 1 and 15. Although the 4-dose regimen has been most extensively studied for induction therapy in AAV, many clinicians choose to use the 2-dose RA regimen to reduce infusion frequency, total dose, and cost. Head-to-head comparative studies of these two regimens have not yet been conducted. Thus, strong evidence is lacking to demonstrate if they are equivalent for the treatment of severe AAV.

The objective of this meta-analysis was to compare the efficacy and safety of these two RTX regimens for the induction of remission in severe AAV.

Methods: A systematic review was performed (PubMed, Cochrane, Google scholar, ClinicalTrials.gov, MEDLINE, and CENTRAL) to identify studies using the 4-dose AAV and/or 2-dose RA rituximab regimens for induction of remission in severe AAV. Availability of disease status 6 months after RTX induction therapy was required for inclusion. Patients were excluded if they received concomitant cyclophosphamide or plasma exchange. The primary endpoint was the proportion of patients in complete remission, which was defined as a BVAS of 0 and/or as the absence of disease

Figure 1. Percentage of Complete Remission According to Rituximab Dosing Regimen



activity on clinical assessment. The pooled estimate was obtained using meta-analysis methods for proportions with random effects. Other secondary endpoints at 6 months included ANCA status, number of patients with B cell depletion, mean prednisone dose, infections, and death.

Results: Out of the 3619 studies identified, 27 met inclusion criteria, including 1 RCT, 4 prospective cohorts, 9 retrospective cohorts and 13 case series. A total of 506 patients with GPA or MPA were included for analysis: 361 patients were treated with the 4-dose AAV regimen and 145 patients with the 2-dose RA regimen. Mean age was 50 years, 52% were women, and 86% were ANCA-positive. Relapsing disease at inclusion accounted for 83% and 92% of patients in the 4-dose AAV and the 2-dose RA regimen group, respectively. Overall, complete remission at 6 months was achieved in 88 % (95% CI: 78–95) of patients. There was no significant difference between the 4-dose AAV and 2-dose RA regimens, complete remission reaching respectively 85% (95% CI: 70-96) and 91% (95% CI: 79-99) (fig 1). Results remained consistent after the exclusion of low-quality studies. At 6 months, the mean daily dose of prednisone was 8.1 mg and was comparable in both groups. Both regimens led to a similar proportion of patients with infections (12% in both) and death (1% vs. 0%), respectively, at 6 months, with insufficient data to conclude on other secondary endpoints.

Conclusion: No difference was found in terms of efficacy and safety between the 4-dose AAV and the 2-dose RA rituximab regimens for induction of remission in severe AAV.

Grayson[5], Hongzhe Lee[4], Ronald Collman[4] and Peter Merkel[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, [4]University of Pennsylvania, Philadelphia, [5]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – ANCA-Associated
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: Nasal bacteria have been linked to disease activity in granulomatosis with polyangiitis (GPA) with most studies focused on *Staphylococcus aureus*. Our previous study identified dynamic changes in the ratio of nasal *Corynebacterium* to *Staphylococcus* (at the genus level) prior to and during a relapse. Corynebacteria are a common commensal that inhabits the skin and nose and is known to directly interact with *S. aureus*. The objective of this study was to evaluate species-level identity of nasal bacteria and their association with disease activity and ANCA levels in GPA.

Methods: Nasal bacterial composition was examined using 16S rRNA gene sequencing of nasal swabs of 19 patients with GPA followed longitudinally approximately every 3 months (N = 76 visits, median time between visits 4 months). Nine patients had at least 1 visit with active disease and 10 patients remained in remission during follow-up. Disease activity was determined by BVAS/WG. Only PR3-ANCA results obtained by ELISA at the study site were included for ANCA analyses (11 patients with 29 visits). We evaluated the relative abundance of the 10 most abundant bacterial species across all visits as well as the ratios between these 10 species. Generalized estimating equations evaluated the association between bacteria and i) visit type (stable remission [n=41], pre-pre-relapse [n=4], pre-relapse [n=10], relapse [n=10], post-relapse [n=9]), and ii) ANCA levels, accounting for repeated measures within an individual. Test for trend examined linear trends in bacterial abundance across visit types. Models were adjusted for use of antibiotics, immunosuppressive medications, nasal irrigation, and, when analyzing Corynebacteria, presence of *S. aureus*.

Results: *Corynebacterium tuberculostearicum* featured prominently in our analyses. Specifically, we found the abundance of *C. tuberculostearicum* significantly increased across visit types in GPA when evaluating any relapse (adjusted P = 0.04; **Figure 1**) and relapse involving the sinonasal area (adjusted P < 0.01). The presence of *S. aureus* (32/76 visits [42%]) was independently associated with a higher *C. tuberculostearicum* abundance (adjusted P = 0.02). *C. tuberculostearicum* abundance was associated with higher levels of PR3-ANCA (adjusted P = 0.02; **Figure 2**). Analysis of bacterial ratios identified significantly increasing ratios of *C. tuberculostearicum* to *S. caprae* abundance and *C. pseudodiphtheriticum* to *S. caprae* abundance across visit types (both adjusted P < 0.01; **Figure 3**).

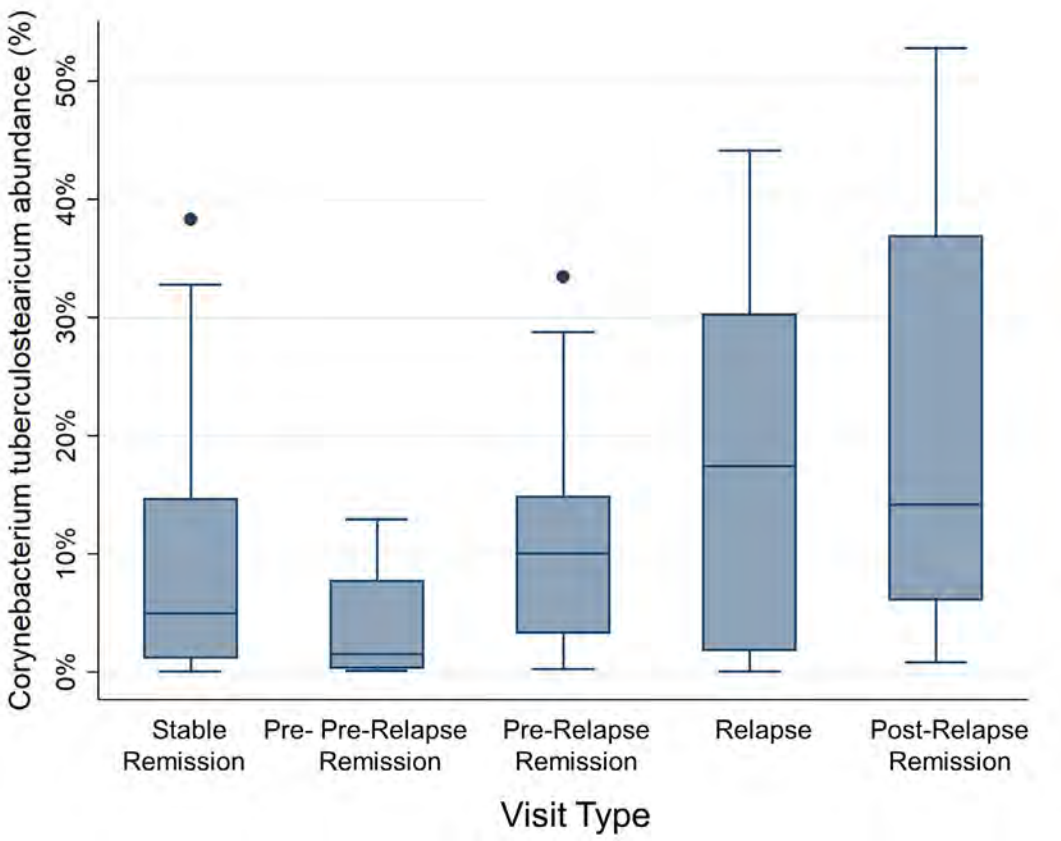

Figure 1. Increasing abundance of nasal Corynebacterium tuberculostearicum is associated with relapse in granulomatosis with polyangiitis (GPA). Longitudinal study visits categorized by visit type: stable remission (n=41), pre-pre-relapse remission (n=4), pre-relapse remission (n=10), relapse (n=12), and post-relapse remission (n=9). Test for trend detected a significant linear increase in nasal C. tuberculostearicum abundance across visits even after adjusting for antibiotics, immunosuppressives, nasal irrigation, and presence of S. aureus (adjusted P = 0.04). Similar results found when analyzing only relapses involving sinonasal area.

Conclusion: Our species-level analysis has uncovered a novel finding between *C. tuberculostearicum* and both disease relapse and ANCA levels in GPA. Our results also detected associations between *C. tuberculostearicum* and *Staphylococcus* species, including *S. aureus*. Prior studies demonstrated a pathogenic role for *C. tuberculostearicum* in chronic rhinosinusitis and direct interactions between *Corynebacterium* spp. and *S. aureus*. We propose that competitive interactions between Corynebacteria and Staphylococci induce nasal mucosal immune responses which, in susceptible hosts predisposed to autoimmunity and ANCA formation, lead to systemic relapse in GPA.

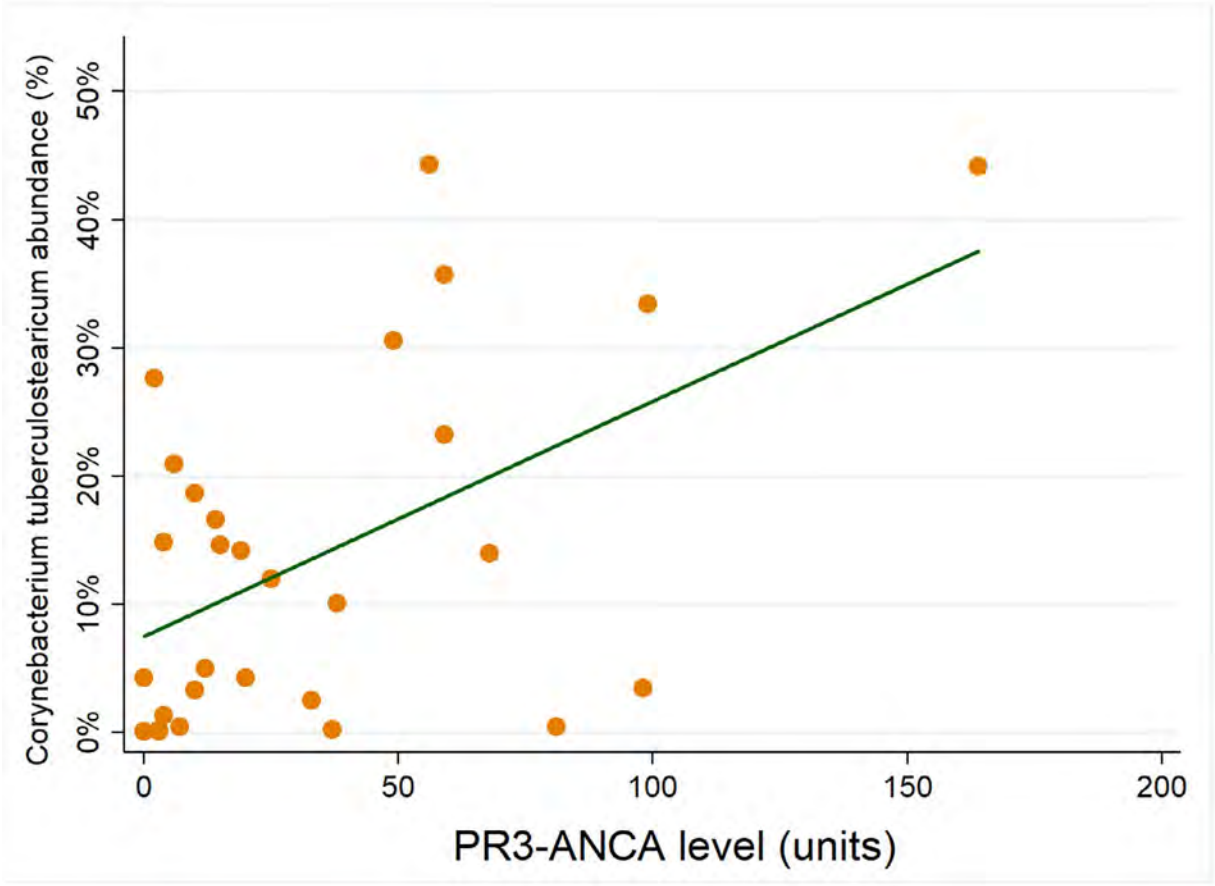

Figure 2. Relative abundance of nasal Corynebacterium tuberculostearicum is associated with PR3-ANCA level in granulomatosis with polyangiitis (GPA). Scatterplot demonstrates association between abundance of nasal C. tuberculostearicum and serum PR3-ANCA levels in 11 patients with total of 29 visits (unadjusted $P < 0.01$). Association remained significant even after adjusting for use of antibiotics, immunosuppressives, and nasal irrigation (adjusted $P = 0.02$). Reference range for normal PR3-ANCA < 20 units.

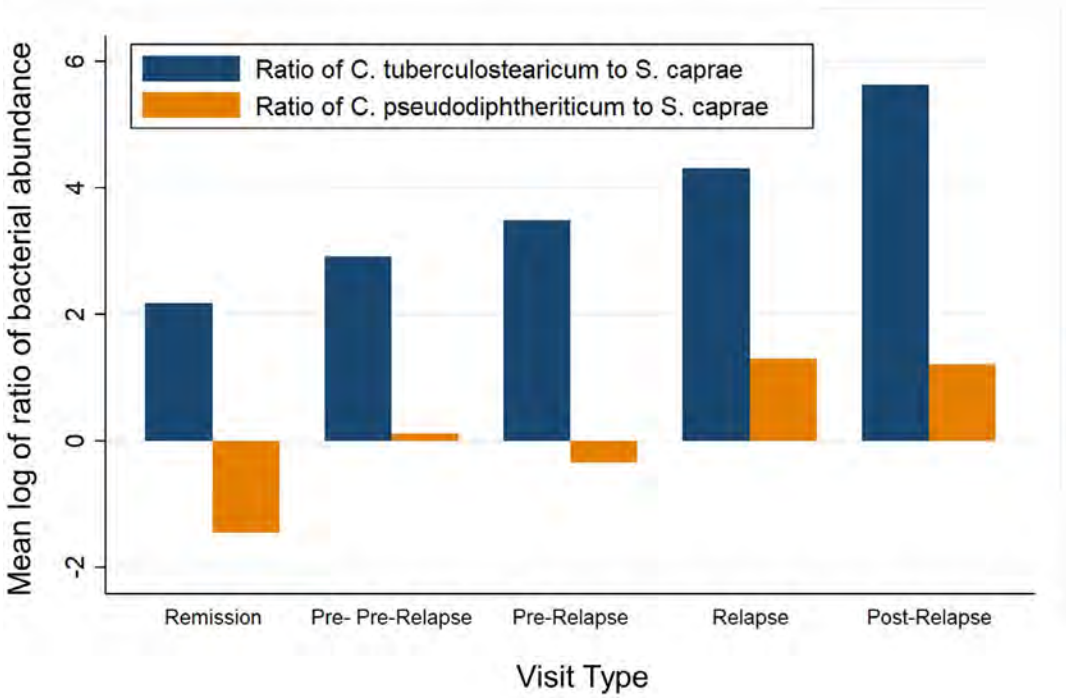

Figure 3. Ratio of bacteria associated with relapse in granulomatosis with polyangiitis (GPA). Ratio of bacterial abundance were log-transformed and test for trend evaluated for changes across visit types. An increasing ratio of Corynebacterium tuberculostearicum to Staphylococcus caprae and C. pseudodiphtheriticum to S. caprae were both associated with visit type, even after adjusting for antibiotics, immunosuppressives, and nasal irrigation (both adjusted $P < 0.01$).

SESSION INFORMATION

Session Date: Monday, November 9, 2020
Session Title: Vasculitis – ANCA-Associated
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: Activation of the alternative and common terminal complement pathways has been shown in ANCA-associated vasculitis (AAV). Circulating titers of the anaphylatoxin C5a are increased and correlate with disease activity in AAV. Binding to the corresponding G protein-coupled receptor (C5aR1/CD88) enhances the influx of neutrophils and their activation, leading to ROS generation and endothelial damage. Blocking of the receptor C5aR1 was protective in a murine model of NCGN in AAV (4). In humans, the oral C5aR1 inhibitor avacopan showed promis-

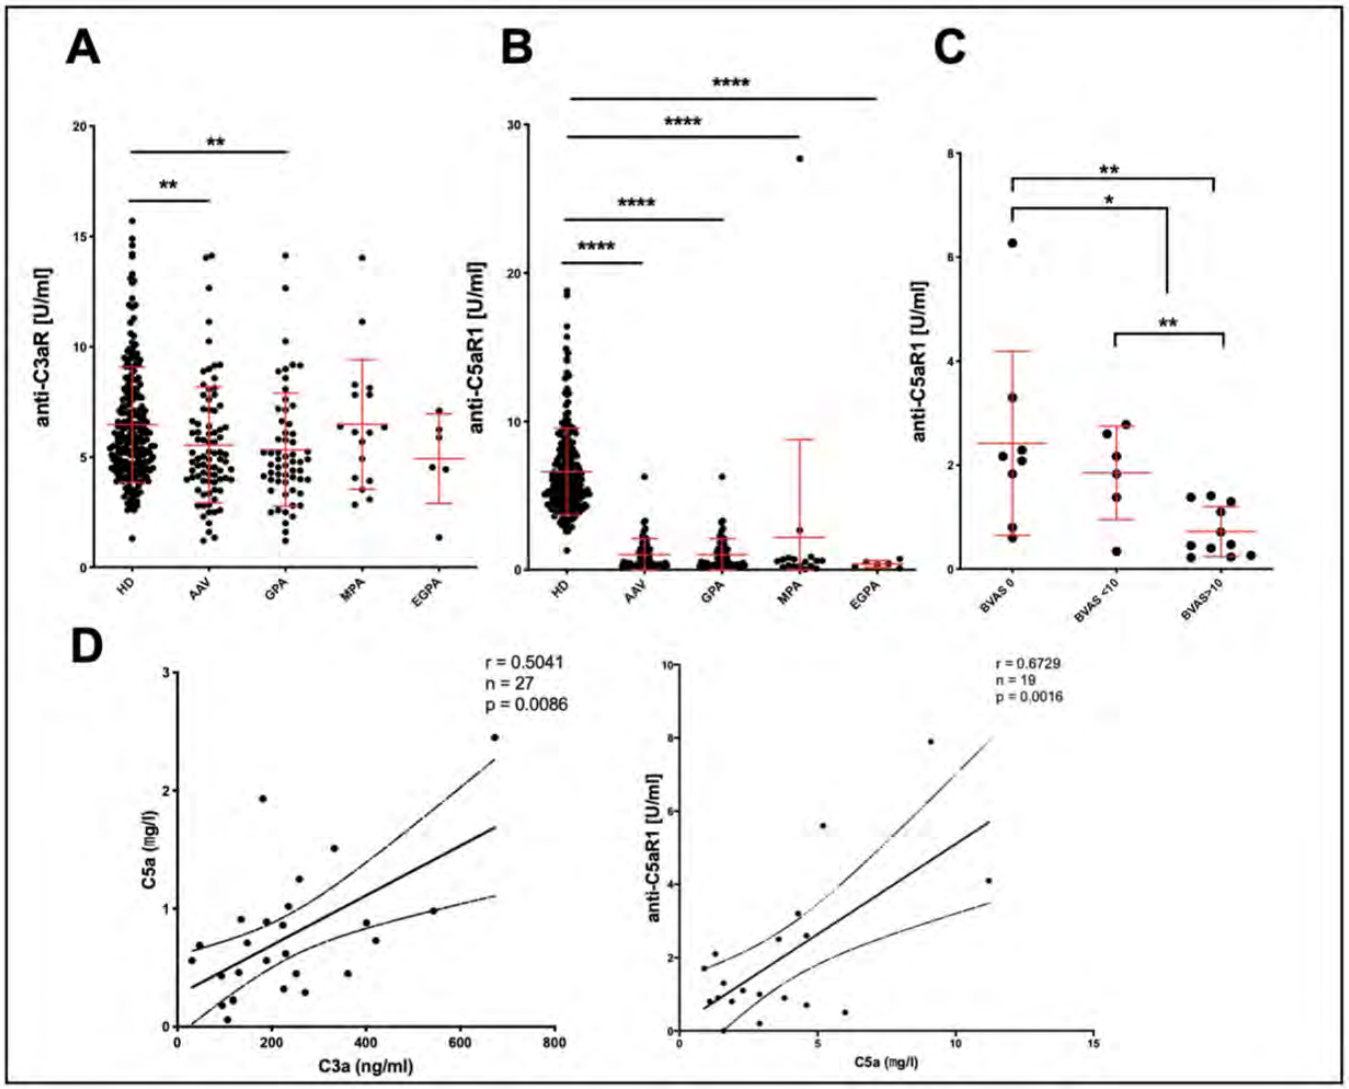

Figure 1. Anti-C3aR and anti-C5aR1 autoantibodies in AAV. A: GPA patients displayed significantly lower titers of circulating anti-C3aR aab in comparison to MPA, EGPA and HD. B: concentrations of anti-C5aR1 aab were decreased in AAV with the lowest titers in GPA compared to HD. C: GPA patients with a BVAS >10 showed the lowest levels of anti-C5aR1 aabs. D: Plasma levels of C3a and C5a correlated positively in GPA, whereas only C5a and anti-C5aR1 correlated positively in GPA patients performing the spearman's rank correlation coefficient. Data are presented as mean±SD; p values were determined using one-way ANOVA with Tuckey's multiple comparison post hoc test (A,B) or two-tailed Mann-Whitney U-test if two groups were compared (C,D) or Spearman's rho (E); *p≤0.05, **p≤0.01, and ****p≤0.0001; HD, healthy donors; AAV, ANCA-associated vasculitis; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; EGPA, eosinophilic granulomatosis with polyangiitis; aab, autoantibody; BVAS, Birmingham Vasculitis Activity Score

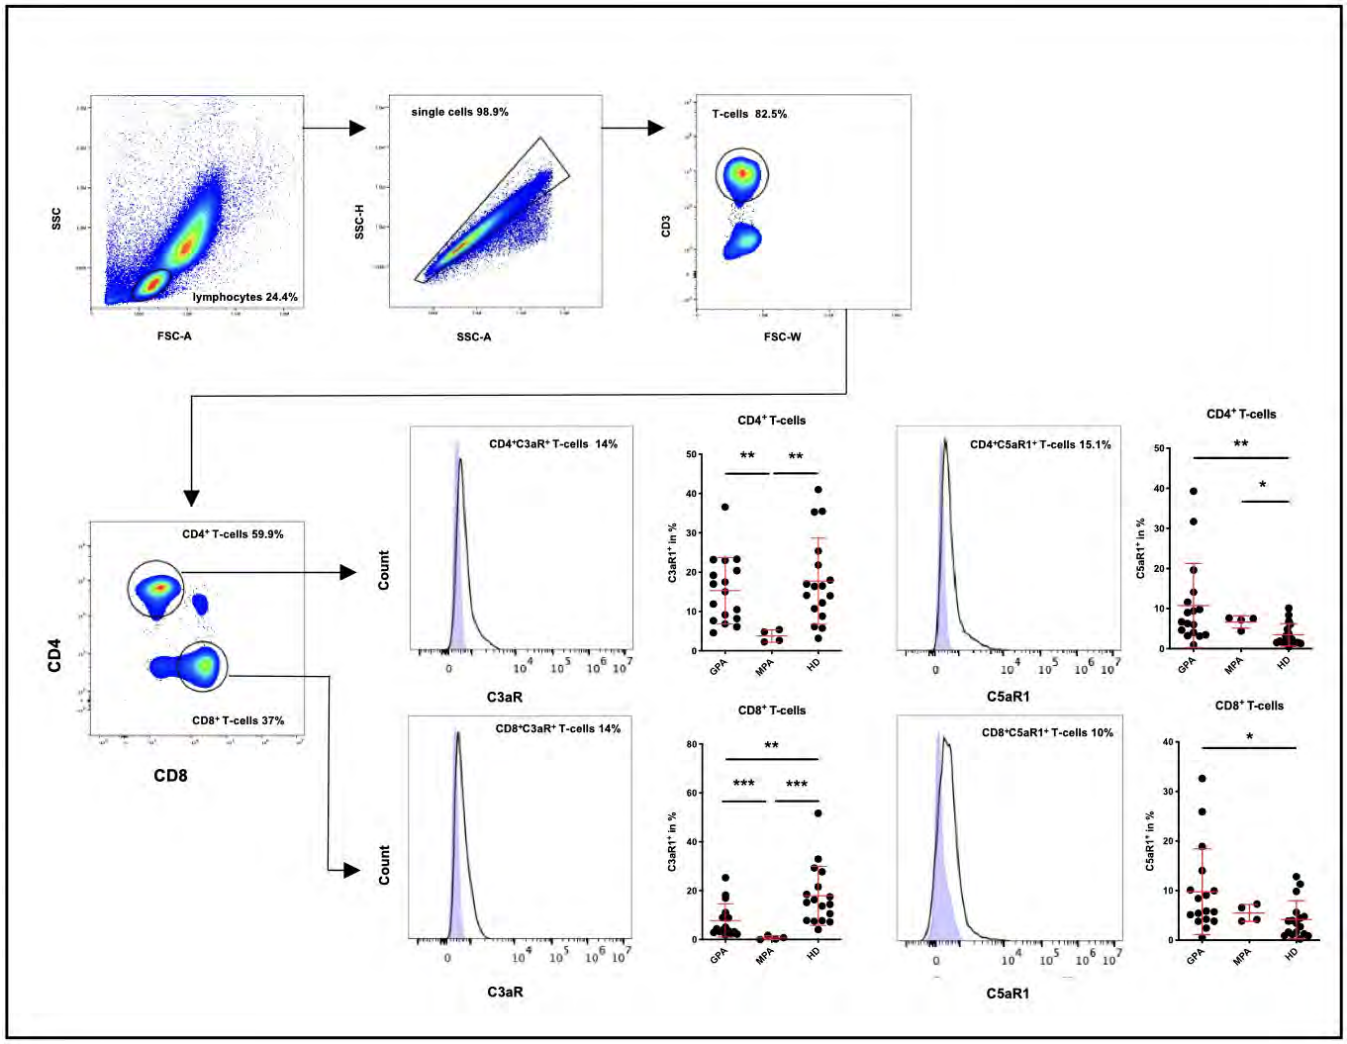

Figure 2. C5aR1 is overexpressed on CD4+ and CD8+ T-cells in GPA. Gating strategy of circulating CD4+ and CD8+ T-cells focused on the surface expression of C3aR and C5aR1 (Histogram: for comparison, shade blue area presented the isotype control). Data are presented as mean±SD; Mann-Whitney U-tests were used to determine significance *p≤0.05, **p≤0.01 and ***p≤0.001; HD, healthy donors; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; FSC, forward scatter; SSC, side scatter

ing results as glucocorticoid-sparing agent in two randomized phase 2 trials. The phase 3 trial was reported to have met its primary endpoints (NCT02994927). Notably, disease-specific anti-G protein-coupled receptor autoantibody (aab) signatures have been found in different autoimmune diseases, but have not been evaluated in AAV so far.

The aim of the present study was to examine whether circulating anti-C3aR and anti-C5aR1 autoantibodies (aabs) correlate with clinical findings in AAV and are linked to the clinical outcome. Values of anti-C3aR and anti-C5aR1 aabs AAV were analyzed and correlated with the clinical course.

Methods: Sera and plasma of AAV patients [granulomatosis with polyangiitis (GPA), n=64; microscopic polyangiitis (MPA), n=26; eosinophilic granulomatosis with polyangiitis (EGPA), n=11] were measured in a cross-sectional analysis by enzyme-linked immunosorbent assay (ELISA) for circulating autoantibodies against anti-C3aR and anti-C5aR1 aabs and plasma levels of C3a and C5a. Expression of C3aR and C5aR1 on T-cells and neutrophils was determined using flow cytometry. Clinical data including Birmingham vasculitis activity score (BVAS V3.0) were assessed at the time of serum sampling and during follow-up for 48 months.

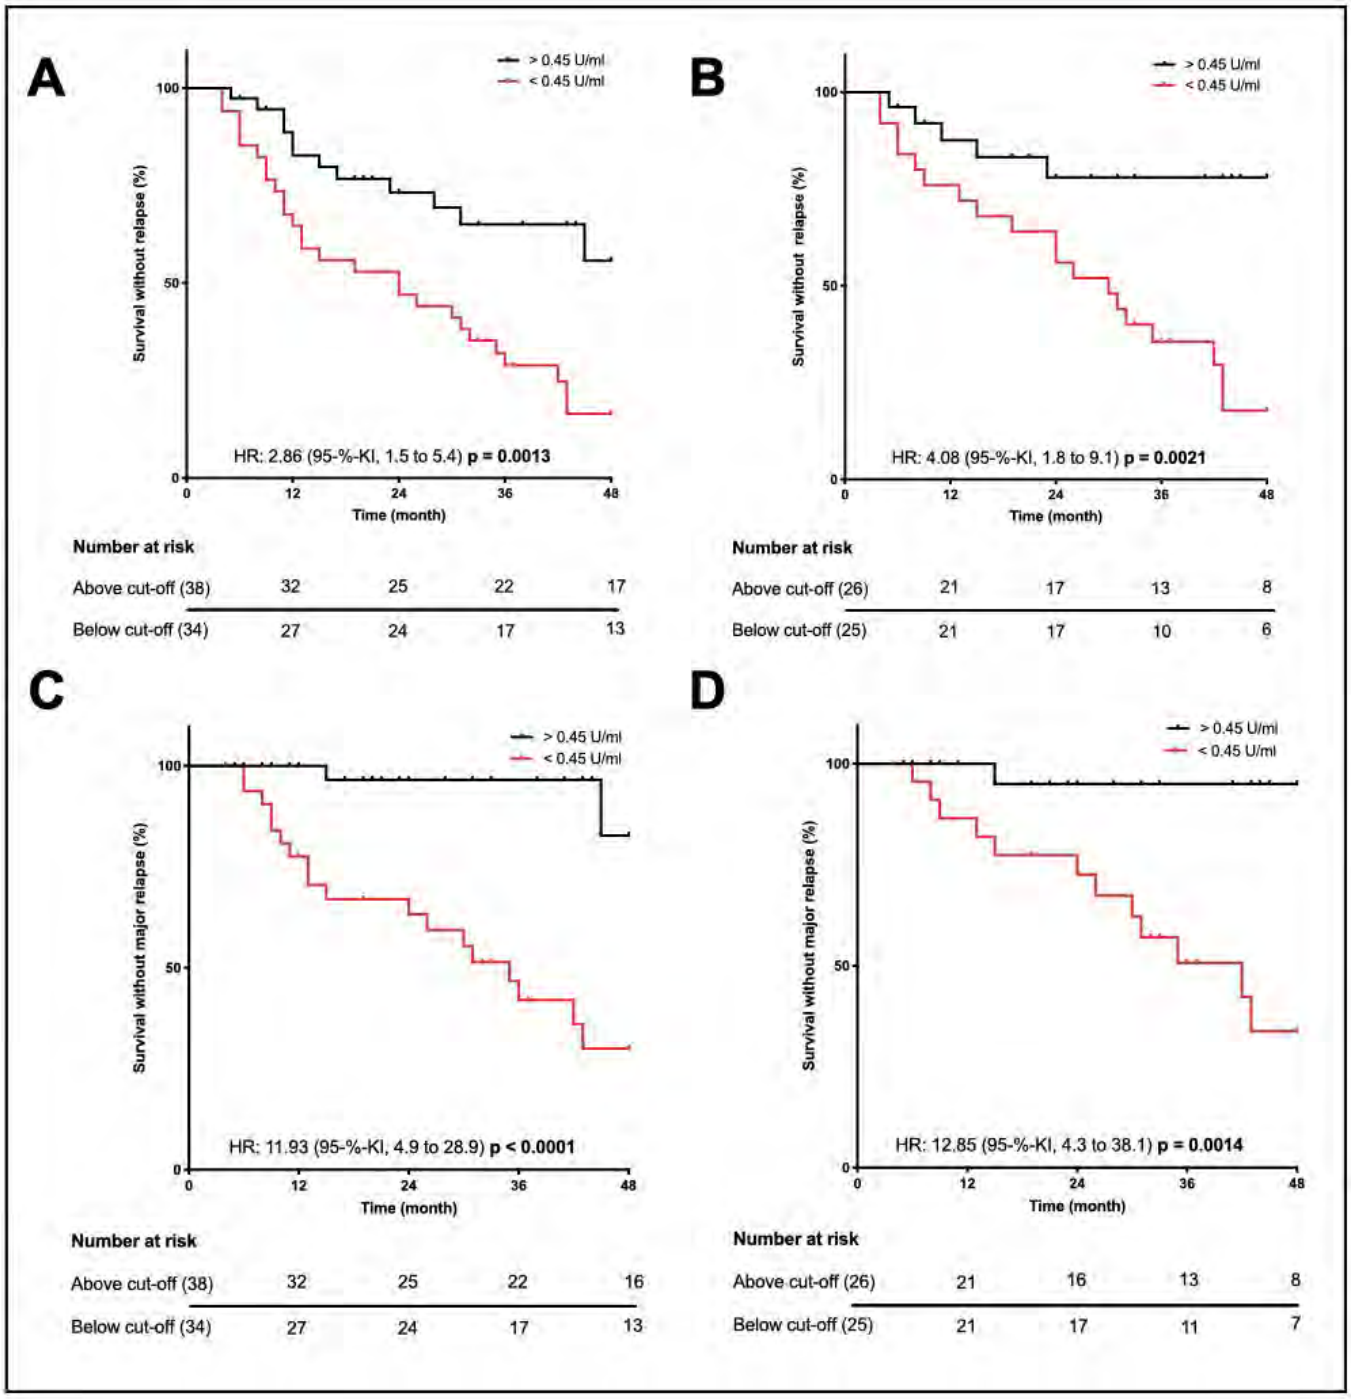

Figure 3. Anti-C5aR1 aab levels below 0.45 U/l were associated with higher relapse rates in AAV, especially in GPA A: AAV patients with reduced titers of anti-C5aR1 aab <0.45U/ml displayed an increased relapse risk, especially in GPA (B). C: Risk of major relapse for in AAV and GPA (D) (AAV: HR: 11.93, p<0.0001; GPA: HR: 12.85, p=0.0014); AAV, ANCA-associated vasculitis; GPA, granulomatosis with polyangiitis

Results: Patients with GPA displayed low titers of anti-C3aR aabs (Fig. 1a, p≤0.05). Anti-C5aR1 aabs were decreased in AAV, especially in GPA (Fig.1b, p≤0.0001). GPA patients with a high BVAS had the lowest levels of anti-C5aR1 aabs Fig. 1c, p≤0.01). Plasma levels of C3a and C5a correlated positively in GPA. C5a and anti-C5aR1 levels correlated positively in GPA (Fig.1d). C5aR1 expression was increased on T-cells in GPA (Fig. 2). Titers of anti-C5aR1 aabs < 0.45U/ml correlated with an increased relapse risk for major relapse in GPA (Fig. 3; HR 12.85, P=0.0014).

Conclusion: Anti-C5aR1 aabs reflect complement activation and disease activity in GPA. Moreover, Anti-C5aR1 aabs may be useful to monitor disease activity. C5aR1 expression on T-cells may also play a role in AAV-pathogenesis.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Vasculitis – ANCA-Associated
Session Type: Abstract Session
Session Time: 11:00AM–11:50AM

Background/Purpose: The clinical picture at onset and evolution of localized forms of granulomatosis with polyangiitis (L-GPA) have already been investigated but, to our knowledge, have not been directly compared to those of patients with initial systemic disease (S-GPA); nor have the risk factors for L-GPA progression to systemic disease (LS-GPA) or its main characteristics been examined in large samples. We undertook this study to describe the main L-GPA features at diagnosis and their evolution over time, with comparisons of L- vs S-GPA patients.

Methods: French Vasculitis Study Group Registry patients had an isolated orbital mass and/or met EULAR recommendations[1] for L-GPA, ie upper and/or lower respiratory tract, and, for S-GPA, categorizing them as early systemic, generalized or severe subset. All patients' demographics, disease manifestations at diagnosis and long-term clinical outcomes were extracted from the database for analyses and L-GPA vs S-GPA comparisons.

Results: Among the 795 FVSG-Registry GPA patients, 87 (10.9%) had L-GPA (M/F ratio 1; mean±SD age 45.8±18.0 years) involving upper and lower airways in 56 (64.4%). Most L-GPA patients were positive for anti-proteinase-3

(PR3) (56.3%) or anti-myeloperoxidase (MPO) (21.8%) ANCA. Their main clinical manifestations were rhinitis (54.0%), lung nodules (50.6%), sinusitis (42.5%) and otitis (26.4%), with 5.7% each having subglottic stenosis or saddle nose. Comparing L-GPA vs. S-GPA patients at diagnosis, respectively, they were younger (mean±SD 45.8±18.0 vs. 54.1±15.9 years; P< 0.001), more frequently had saddle nose (5.7% vs. 0.7%; P=0.001) or subglottic stenosis (5.7% vs. 1.1%; P=0.006), were less often PR3-ANCA–positive (56.3% vs. 76.6%;< 0.001) and had lower BVAS (7.2 vs. 18.6; P< 0.001). L-GPA induction therapy less frequently included intravenous cyclophosphamide (46.0% vs. 79.4%; P< 0.001) or glucocorticoids (90.8% vs. 97.9%; P< 0.001; mean dose 48.7 vs. 58.0 mg; P< 0.001) but more often methotrexate (14.9% vs. 3.2%; P< 0.001). L- and S-GPA patients' relapse-free–survival probability estimates (P=0.97), relapse rates (P=0.927) and refractory disease rates at each visit (P=0.543) were comparable, but the L-GPA overall survival rate from diagnosis was significantly higher (P< 0.0001). During follow-up (median 42 (range 6–241) months), 21 (24.1%) L-GPA progressed to LS-GPA after a median of 21 (range 3–93) months with peripheral/central neuropathy (n=8), ocular (n=8), renal (n=6), severe pulmonary (n=1), cardiovascular (n=1) and/or skin (n=1) relapses. No patient evolved into a severe renal subset. None of the evaluated demographic, clinical or serological factors predicted progression to LS-GPA.

Conclusion: The risk of L-GPA relapse was similar to that of S-GPA but L-GPA patients' overall survival rate was higher. About a quarter of L-GPA patients developed clinical S-GPA manifestations, but never life-threatening end-stage organ disease.

Table 1. Baseline characteristics of patients enrolled in RITAZAREM trial

Background/Purpose: Rituximab is an effective therapy for induction of remission in ANCA-associated vasculitis (AAV). However, the effect of rituximab is not sustained, and subsequent relapse rates are high, especially in patients with a history of relapse. The RITAZAREM trial (ClinicalTrials.gov identifier: NCT01697267) was an international, multi-center, open-labelled, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy, after induction of remission with rituximab, of two relapse-prevention strategies: repeat dosing of rituximab or daily oral azathioprine. The extended follow-up phase of the trial provides a unique opportunity to ask important questions about durability of effects of therapies, safety of extended courses of azathioprine and rituximab, and clinical and laboratory biomarkers of remission and relapse in AAV.

Methods: Patients with AAV were recruited at the time of relapse and received induction therapy with rituximab and glucocorticoids. If remission was achieved by month 4, patients were randomized in a 1:1 ratio to receive either rituximab (1000 mg every 4 months for 5 doses) or azathioprine (2 mg/kg/day) as maintenance therapy. Patients were followed for a minimum of 36 months, with most patients followed for 48 months. The primary outcome of the trial was time to disease relapse. The trial was completed in November 2019.

Results: 188 patients were enrolled and 170 randomized at 4 months (85 to rituximab; 85 to azathioprine). Median age was 59 years (range 19-89), with a prior disease duration of 5.3 years (0.4-38.5). 123/170 (72%) patients had a history of testing positive for anti-proteinase 3-ANCA; 47/170 (28%) for myeloperoxidase-ANCA. 104/170 (61%) were enrolled having suffered a major relapse, and 48/170 (28%) received a pre-specified higher dose glucocorticoid induction regimen (**Table 1**). 114 (67%) patients had prior renal involvement. Previously presented data demonstrated the superiority of rituximab over azathioprine during the maintenance treatment period. Results of the follow-up phase of the study after discontinuation of maintenance therapy will be presented at the meeting and include analyses of clinical courses and the utility of biomarkers to predict relapse and/or sustained remission, including ANCA titers, B cell counts, and immunoglobin levels.

Conclusion: The results of RITAZAREM through month 48 will demonstrate whether rituximab leads to sustained remission beyond the treatment period in patients with AAV with a prior history of relapse following induction of remission with rituximab. These data will also inform clinicians and patients about the longer-term safety of azathioprine and rituximab and provide important insight into the pathophysiology of relapse and remission in AAV.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Late-Breaking Posters

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of poor outcomes from COVID-19 among rheumatic disease patients compared to the general population remains poorly understood. Filling this knowledge gap is a high priority for patients and providers. We previously observed a higher risk of mechanical ventilation in patients with rheumatic diseases compared to the general population in a small cohort study early in the pandemic.

Table 1. Clinical characteristics of patients with systemic rheumatic disease with COVID-19 infection (N=143) and matched comparators (N=688) at the time of COVID-19 infection diagnosis.

Characteristic	Rheumatic Disease (N=143)	No Rheumatic Disease (N=688)	p-value

COVID-19: coronavirus disease 2019; SD: standard deviation; IQR: interquartile range. Statistically significant findings are in bold.

Table 1. Clinical characteristics of patients with systemic rheumatic disease with COVID-19 infection (N=143) and matched comparators (N=688) at the time of COVID-19 infection diagnosis.

Methods: We conducted a cohort study of COVID-19 patients (confirmed by polymerase chain reaction [PCR]) between January 30 and July 16, 2020, at a multicenter healthcare system including academic and community hospitals and longitudinal clinics. We compared each patient with systemic rheumatic disease to up to 5 matched (by age, sex, and date of COVID-19 PCR) comparators without rheumatic disease. In our primary analysis, we used multivariable Cox proportional hazard regression to estimate hazard ratios (HR) and 95% confidence intervals (CI) for COVID-19 outcomes, comparing patients with and without rheumatic disease and adjusting for potential confounders. Outcomes were evaluated through end of follow-up in the system or August 18, 2020. To further evaluate temporal trends in mechanical ventilation among rheumatic disease patients, we compared risk of this outcome in an early vs. recent cohort (PCR testing before vs. after the midpoint among rheumatic disease patients) using similar methods.

Results: We identified 143 rheumatic disease patients (mean age 60 years, 76% female) and 688 matched comparators (mean age 59 years, 76% female) out of 16,211 patients who had confirmed COVID-19 (**Table 1**). Median Charlson Comorbidity Index (CCI) scores and interquartile range (IQRs) were higher among patients with rheumatic disease (2 [IQR: 1, 4]) vs. comparators (0 [IQR: 0, 2]). The most common rheumatic diseases were rheumatoid arthritis

Table 2. Details of rheumatic disease diagnosis and management at the time of COVID-19 diagnosis (N=143).

Characteristic	N (%)
Rheumatic disease diagnosis	
Rheumatoid arthritis	44 (31)

Adjusted HR (95% CI)	1.51 (0.93, 2.44)	1.0 (Ref)
Death (N, %)	12 (8)	48 (7)
Total Follow-up Time (Person-days)	8790	33428
Incidence rate/1000 days (95% CI)	1.40 (0.60, 2.10)	1.40 (1.00, 1.80)
Unadjusted HR (95% CI)	1.16 (0.63, 2.13)	1.0 (Ref)
Adjusted HR (95% CI)	1.02 (0.53, 1.95)	1.0 (Ref)

HR = hazard ratio; CI = confidence interval.
*Adjusted for race, smoking, and Charlson Comorbidity Index (dichotomized as ≤2 or >2).

Table 3. COVID-19 outcomes in patients with systemic rheumatic disease (N=143) versus matched comparators (N=688).

(44, 31%) and systemic lupus erythematosus (27, 19%) (**Table 2**). Fifty-one (36%) rheumatic disease patients were on glucocorticoids, 30 (21%) were on hydroxychloroquine, 41 (29%) were on at least 1 biologic disease-modifying antirheumatic drug (DMARD), and 44 (31%) were on at least 1 conventional synthetic DMARD. Patients with rheumatic disease had higher unadjusted risk of mechanical ventilation than comparators (unadjusted HR 1.75, 95% CI: 1.12 to 2.74) (**Table 3**). After adjustment for race, smoking, and CCI, there were no significantly higher risks of hospitalization (HR 0.87, 95% CI: 0.68 to 1.11), intensive care unit admission (HR 1.27, 95% CI: 0.86 to 1.86), mechanical ventilation (HR 1.51, 95% CI: 0.93 to 2.44), or death (HR 1.02, 95% CI: 0.53 to 1.95) in rheumatic disease patients vs. comparators. We observed a trend toward improvement in the risk of mechanical ventilation in the recent vs. early rheumatic disease cohorts (10% vs. 19%, adjusted HR 0.44, 95% CI: 0.17 to 1.12).

Conclusion: Patients with rheumatic disease had similar risk of severe COVID-19 outcomes vs. comparators. There was a temporal trend toward improvement in risk of mechanical ventilation for rheumatic disease patients. These findings provide reassurance for rheumatic disease patients but close monitoring of rheumatic disease patients with other comorbidities is warranted.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Late-Breaking Posters
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinician-reported registry data suggest that use of biologics in people with immune-mediated inflammatory diseases (IMIDs) is associated with a lower risk of adverse COVID-19 outcomes compared with no treatment. However, the role of potentially confounding risk-mitigating behaviors is unclear. Given the variation in public health messaging between countries, it is possible that risk mitigating behavior in people with IMIDs will also vary, but this has not been explored to date. We sought to explore risk mitigating behavior using global patient survey data by: (1) determining associations with immunosuppressant treatment type, and (2) characterizing international variation.

Methods: Online surveys were completed by individuals with rheumatic diseases (UK only) and psoriasis (global) between 20th May and 7th September 2020. Data were collected on diagnosis, treatment types, demographics and risk mitigating behaviors. Multiple logistic regression assessed the association between treatment type and the most stringent risk mitigating behavior ('shielding', defined as quarantine/staying home/distancing within the home), adjusting for clinical and demographic characteristics. Incomplete covariates were accounted for using multiple imputation in sensitivity analyses. International variations in shielding were assessed in a mixed effects model, adjusted for clinical and demographic differences between nations and accounting for varying sample sizes. Observed and estimated findings were visualized using a caterpillar plot.

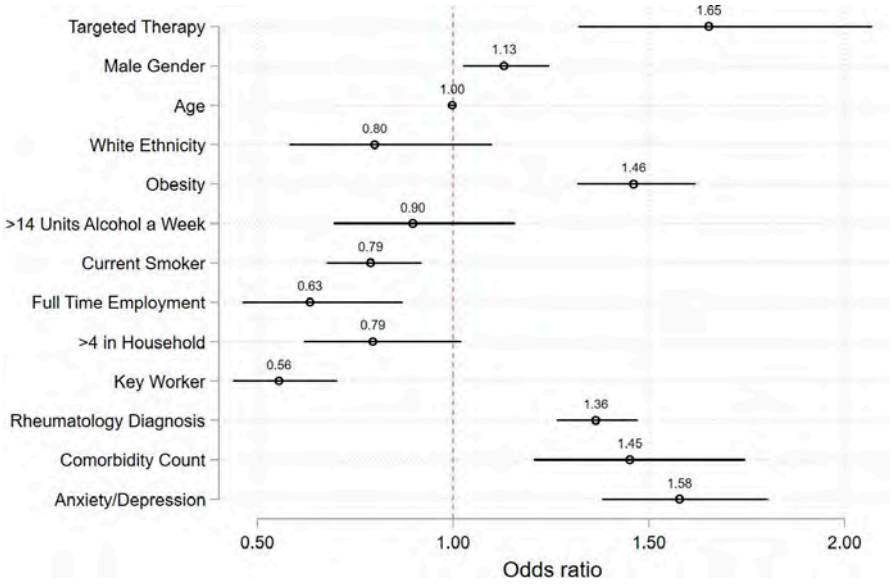

Figure 1. Multiple logistic regression effect estimates for risk mitigating behavior.

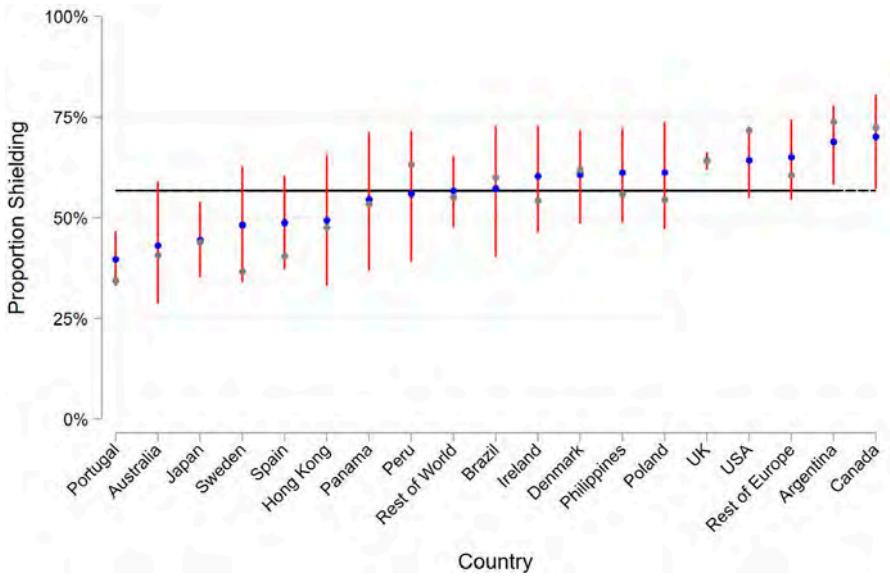

Figure 2. Caterpillar plot of observed and estimated risk mitigating behavior, by nation. The grey markers are the observed national proportions of survey respondents who shielded. The blue markers are the predicted random national effect on shielding from a mixed effects model, with 95% confidence intervals in red. The black horizontal line represents the overall mean.

Results: Of 3,714 participants from 74 countries, 2,259 (60.8%) reported the most stringent risk mitigating behavior (i.e. shielding). Use of biologics was associated with higher shielding rates compared to no systemic therapy (odds ratio [OR] 1.65, 95% CI 1.32-2.07) and standard systemic therapy (OR 1.37, 95% CI 1.23-1.52). No differences in shielding was found between standard systemic therapies and no therapy. Shielding was also associated with established risk factors for severe COVID-19 (male sex [OR 1.13, 95% CI 1.02-1.25], obesity [OR 1.46, 95% CI 1.32-1.62], comorbidity burden [OR 1.45, 95% CI 1.21-1.75]), rheumatic disease (OR 1.36, 95% CI 1.26 to 1.47) and a positive screen for anxiety or depression (OR 1.58, 95% CI 1.38-1.80). Findings were unchanged following multiple imputation. After accounting for sample size and clinical/demographic differences, modest differences in the mean proportion of patients shielding were observed across different nations.

Conclusion: Higher rates of shielding among people with IMIDs receiving biologics may contribute to the reported lower risk of adverse COVID-19 outcomes. The observed variation in shielding among treatment groups reinforces the need for clear patient communication on risk mitigation strategies. The findings help inform how clinicians discuss COVID-19 risks with vulnerable patients and will inform public health guidelines as the global COVID-19 pandemic continues to unfold.

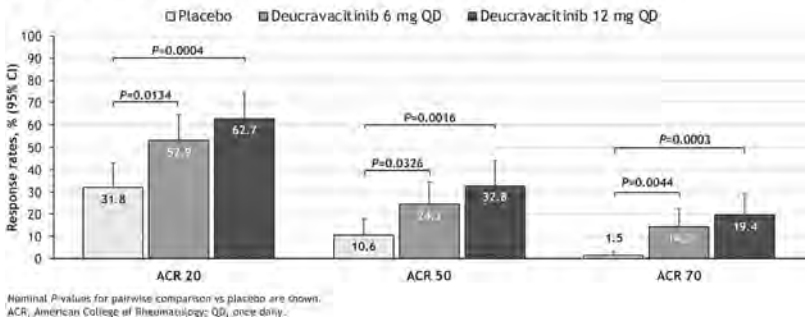
SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Late-Breaking Posters
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates signaling by key cytokines involved in psoriatic arthritis (PsA) pathophysiology. Deucravacitinib (BMS-986165) is a novel oral agent that selectively inhibits TYK2 through an allosteric mechanism by binding to the regulatory domain of TYK2 in contrast to inhibitors of the closely related Janus kinases (JAK1–3) that bind to the active site in the kinase domain.[1] In a previous Phase 2 trial in plaque psoriasis (PsO), 67%–75% of patients who received deucravacitinib ≥3 mg twice daily achieved PASI 75 at 12 weeks versus 7% for placebo (PBO; $P< 0.001$).[2] No deucravacitinib-related serious adverse events (AEs) were observed.[2] The current trial evaluated the efficacy and safety of deucravacitinib in PsA.

Methods: This is an ongoing, 1-year, randomized, double-blind, PBO-controlled (initial 16 weeks), multicenter, Phase 2 trial (NCT03881059). Eligible patients had a PsA diagnosis for ≥6 months, met CASPAR criteria, and had active disease (≥3 tender and ≥3 swollen joints), C-reactive protein ≥3 mg/L (ULN, 5 mg/L), and ≥1 psoriatic lesion (≥2 cm). Patients had failed or were intolerant (IR) to ≥1 nonsteroidal anti-inflammatory drug, corticosteroid, and/or conventional synthetic disease-modifying antirheumatic drug (csDMARD), or 1 TNF inhibitor (TNFi; ≤30%). Patients were randomized 1:1:1 to deucravacitinib 6 mg once daily (QD) or 12 mg QD, or PBO. The primary endpoint was ACR

Figure 1. ACR 20/50/70 responses at Week 16

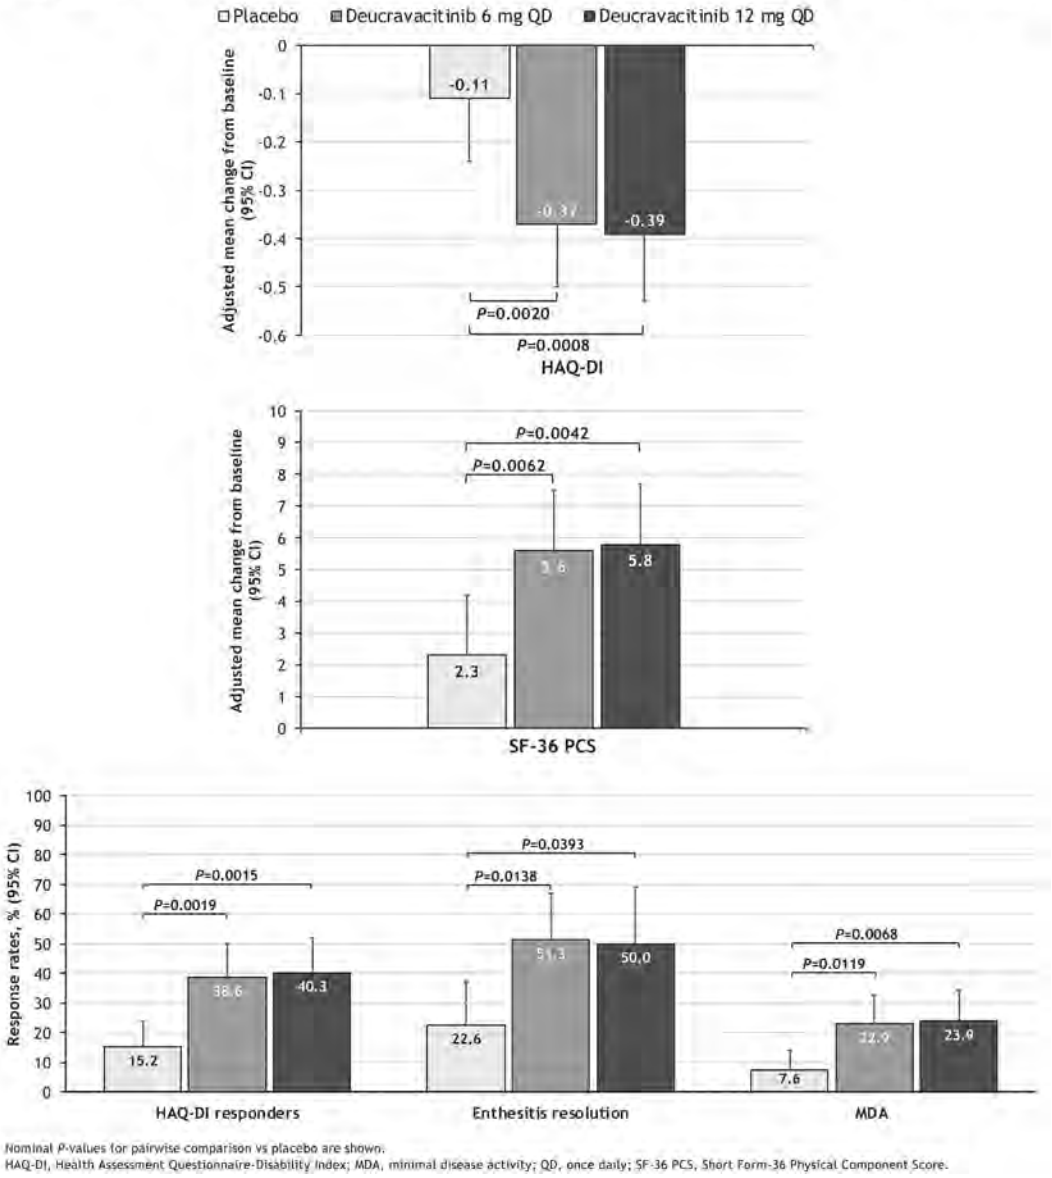


Nominal P-values for pairwise comparison vs placebo are shown.
ACR, American College of Rheumatology; QD, once daily.

20 response at Week 16. Key secondary endpoints included improvement from baseline in the Health Assessment Questionnaire–Disability Index (HAQ-DI) and Short Form-36 Physical Component Score (SF-36 PCS). Additional endpoints included the proportion of patients achieving ACR 50/70, HAQ-DI response (≥0.35 improvement from baseline), minimal disease activity, enthesitis resolution (Leeds Index), and AEs.

Results: Of 203 patients randomized, 180 (89%) completed 16 weeks of treatment. Demographic and baseline disease characteristics were similar across the 3 groups. Mean age was 49.8 years, median PsA duration was 4.5 years, 66% of patients were using csDMARDs at baseline, and 15% were TNFi-IR. The study met its primary objective of showing a dose-response relationship ($P< 0.001$), with both deucravacitinib 6 mg (n=70) and 12 mg QD (n=67) demonstrating significantly greater ACR 20 responses versus PBO (n=66) at Week 16 (52.9% and 62.7% versus 31.8%, respectively; **Figure 1**). Key secondary objectives were achieved with significant and generally similar improvements in secondary endpoints for both deucravacitinib doses versus PBO (**Figure 2**). Nasopharyngitis, sinusitis, headache, and rash were the most common AEs in deucravacitinib-treated patients (**Table**). Most AEs were mild or

Figure 2. Summary of other efficacy endpoints at Week 16



Nominal P-values for pairwise comparison vs placebo are shown.
HAQ-DI, Health Assessment Questionnaire-Disability Index; MDA, minimal disease activity; QD, once daily; SF-36 PCS, Short Form-36 Physical Component Score.

Table. Adverse events occurring in ≥5% of patients

Adverse event, n (%)	Placebo (N=66)	Deucravacitinib 6 mg QD (N=70)	Deucravacitinib 12 mg QD (N=67)
Total	28 (42.4)	46 (65.7)	44 (65.7)
Nasopharyngitis	5 (7.6)	4 (5.7)	12 (17.9)
Sinusitis	0	0	5 (7.5)
Headache	3 (4.5)	5 (7.1)	1 (1.5)
Rash	0	3 (4.3)	4 (6.0)
Upper respiratory tract infection	0	4 (5.7)	1 (1.5)
Bronchitis	1 (1.5)	4 (5.7)	0
Diarrhea	0	4 (5.7)	0

QD, once daily.

moderate. No serious AEs were reported in deucravacitinib-treated patients, including no serious infections, herpes zoster, opportunistic infections, or thrombotic events.

Conclusion: Deucravacitinib was efficacious versus PBO over 16 weeks of treatment in patients with active PsA. Treatment was well tolerated and the safety profile was consistent with that observed in the Phase 2 PsO trial.[2]

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Late-Breaking Posters

Session Type: Poster Session D

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with RA have increased susceptibility to seasonal influenza and its complications.[1] The COVID-19 pandemic highlights the need to understand acute respiratory RNA viral infections in pts receiving tofacitinib. We present data on influenza adverse events (AEs) in the tofacitinib RA clinical program.

Methods: Influenza AEs were evaluated in pts with RA from 21 Phase (P)1–3b/4 trials and two open-label, long-term extension (LTE) studies from 2005–2019. These were analyzed as two cohorts: P2–3b/4 cohort (pts who received tofacitinib 5 or 10 mg twice daily [BID] as monotherapy or with background conventional synthetic [cs]DMARDs, adalimumab [ADA], MTX, or placebo in P2–3b/4 controlled studies) and Overall cohort (pts who received ≥ 1 dose of tofacitinib, as monotherapy or with background csDMARDs, in P1–3b/4 and LTE studies; data were summarized by average tofacitinib dose [average tofacitinib 5 or 10 mg BID based on average total daily dose of < 15 or ≥ 15 mg, respectively]). Incidence rates (IRs; unique pts with events/100 pt-years of exposure; censored at day of first worst event or up to last dose +28 days) were evaluated for influenza AEs (a composite of several MedDRA preferred terms). In the Overall cohort, the time to resolution of influenza AEs by action taken was summarized descriptively.

Results: In total, 7,964 pts were included; 496 (6.2%) reported influenza AEs, three of which occurred outside the risk period. In the P2–3b/4 cohort (N=6,690), IRs for influenza AEs generally appeared similar across treatment arms (Table 1). In the Overall cohort, IRs for influenza AEs were also similar across average tofacitinib doses and pt age groups (Table 2). Mild, moderate, and severe influenza AEs were reported in 311 (62.7%), 170 (34.3%), and 15 (3.0%) pts, respectively. Nine (1.8%) pts had serious influenza AEs (average tofacitinib 5 mg BID, n=6; average tofacitinib 10 mg BID, n=3); eight (1.6%) of these were hospitalized (average tofacitinib 5 mg BID, n=6; average tofacitinib 10 mg BID, n=2), and two (0.4%) died (at time of death, one pt each was receiving tofacitinib 5 and 10 mg BID; both had H1N1 and risk factors for mortality due to influenza). In the majority of pts with influenza AEs, no change to tofacitinib treatment was made (69.6%, n=345) or tofacitinib was stopped temporarily (28.8%, n=143) for a mean duration of

Table 1. Summary of influenza AEs in pts with RA in the P2–3b/4 cohort

	Tofacitinib 5 mg BID (N=2,664) [PY=2,476.66][a]	Tofacitinib 10 mg BID (N=2,024) [PY=1,952.13][a]	ADA (N=643) [PY=518.62][a]	MTX (N=223) [PY=293.39][a]	Placebo (N=1,136) [PY=295.47][a]
Influenza AEs (overall)[b]					
n (%)	53 (2.0)	66 (3.3)	11 (1.7)	5 (2.2)	10 (0.9)
IR [95% CI]	2.07 [1.55, 2.71]	3.37 [2.61, 4.29]	2.00 [1.00, 3.58]	1.68 [0.55, 3.93]	3.23 [1.55, 5.94]
Influenza (PT)					
n (%)	47 (1.8)	59 (2.9)	10 (1.6)	3 (1.3)	9 (0.8)
IR [95% CI]	1.84 [1.35, 2.44]	3.01 [2.29, 3.88]	1.82 [0.87, 3.34]	1.01 [0.21, 2.94]	2.90 [1.33, 5.51]
Influenza-like illness (PT)					
n (%)	3 (0.1)	5 (0.2)	1 (0.2)	2 (0.9)	1 (0.1)
IR [95% CI]	0.12 [0.02, 0.34]	0.25 [0.08, 0.58]	0.18 [0.00, 1.01]	0.67 [0.08, 2.40]	0.32 [0.01, 1.79]
H1N1 (PT)					
n (%)	3 (0.1)	2 (0.1)	0 (0)	0 (0)	0 (0)
IR [95% CI]	0.12 [0.02, 0.34]	0.10 [0.01, 0.36]	0.00 [0.00, 0.67]	0.00 [0.00, 1.22]	0.00 [0.00, 1.19]
Avian, encephalitis, H2N2, H3N2, and pneumonia influenza (PTs)					
n (%)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
IR [95% CI]	0.00 [0.00, 0.14]	0.00 [0.00, 0.18]	0.00 [0.00, 0.67]	0.00 [0.00, 1.22]	0.00 [0.00, 0.19]

IRs were calculated as the number of unique pts (per 100 PY) with events during the time between the first and last dose plus 28 days, divided by the pt time accrued during the first and last dose plus 28 days, or up to the first event, whichever occurred earlier. If there were multiple events per pt, the worst event was selected according to the level of seriousness (yes/no) and the level of severity (in the order of 'severe', 'moderate', or 'mild'). 95% CI is based on the Exact Poisson method adjusted for exposure time.
The P2–3b/4 cohort included data from 9 P2, 6 P3, and 1 P3b/4 completed studies, which span influenza seasons 2004/2005–2015/2016.
[a]Total PY of study drug exposure for all pts in treatment group
[b]Includes all PTs (MedDRA v22.0) under the high-level term 'influenza viral infections', and includes PT 'influenza-like illness' during the Winter seasons, per geographic area
ADA, adalimumab; AE, adverse event; BID, twice daily; CI, confidence interval; IR, incidence rate (unique pts with events/100 PY of exposure); N, number of pts in the treatment group; n, number of unique pts with a particular AE PT; MedDRA, Medical Dictionary for Regulatory Activities; MTX, methotrexate; P, Phase; PT, preferred term; pt, patient; PY, pt-yrs; RA, rheumatoid arthritis; yrs, years

11.1 days; the mean number of days to resolution of influenza AEs was numerically similar irrespective of these actions (Table 3).

Conclusion: This post hoc analysis of influenza AEs across the RA clinical program, over 14–15 seasons, showed generally similar rates between tofacitinib, ADA, MTX, and placebo, and between tofacitinib doses and pt age groups. Limitations include varying exposure across treatment arms in the P2–3b/4 cohort. The majority of pts reported mild to moderate influenza AEs.

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Late-Breaking Posters
Session Type: Poster Session D
Session Time: 9:00AM–11:00AM

Background/Purpose: To understand medication and clinical care changes by patients with RA during the first 3 months (March through May 2020) of the COVID-19 pandemic in the US.

Methods: Data were provided by adults with RA participating in the FORWARD observational registry who answered COVID-19 web-based surveys in May/June 2020 and who previously provided baseline characteristics and medication use for 2019. We compared medication changes by pre-COVID DMARD exposure in logistic models first without adjustment and then adjusting for age, sex, comorbidities including pulmonary and cardiovascular diseases, educa-

tion, health insurance, RA activity (PAS-II), fatigue, and polysymptomatic distress (PSD). We also examined rates of medication change before and after the first COVID-19 ACR treatment guidelines in April.

Results: Of the 734 respondents, 221 (30%) reported medication changes. Changers were more likely to use glucocorticoids (GCs, 33% vs 18%) and less likely to use non-hydroxychloroquine (HCQ) csDMARDs (49% vs 62%) pre-COVID. While JAKi use was associated (OR 1.9 [95% CI 1.0, 3.4]) with change in bivariate analyses, only GCs remained as a strong factor (OR 3.0 [1.9, 4.9]) in multivariable models. Change in care was most associated with pulmonary disease (OR 2.9 [1.3, 6.5]) and GC use (OR 1.6 [1.0, 2.5]). While the incidence of medication change before and after April 15 was the same, patient-initiated changes due to COVID-19 were twice as likely before April 15, and physician-guided changes were more likely after.

Conclusion: Our findings confirm US patients with RA made substantial changes to their medication use during the first 3 months of the COVID-19 pandemic. Almost half of DMARD decrease or discontinuations were made without physician guidance, and all types of medication changes after ACR recommendations were made with increased physician guidance. While no direct causation was measured, our findings provide evidence of possible implementation of these recommendations.

Mean (SD) baseline characteristics of RA patients who changed their medications vs. those who did not.

Mavrilimumab (anti GM-CSF Receptor α Monoclonal Antibody) Reduces Time to Flare and Increases Sustained Remission in a Phase 2 Trial of Patients with Giant Cell Arteritis

Maria C. Cid[1], Sebastian Unizony[2], Lara Pupim[3], Fang Fang[4], Joseph Pirrello[3], Ai Ren[4], Manoj Samant[4], Teresa Zhou[4] and John F Paolini[4], [1]Hospital Clinic Barcelona, Barcelona, Spain, [2]Massachusetts General Hospital, Boston, MA, [3]Kiniksa Pharmaceuticals, Lexington, MA, [4]Kiniksa Pharmaceuticals, Lexington

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: T helper (Th)1 and Th17 lymphocytes play a role in the pathogenesis of giant cell arteritis (GCA). Current treatments (e.g., corticosteroids and tocilizumab) target primarily the Th17 axis, leaving substantial residual Th1 activity. Preclinical research in human GCA models implicate granulocyte macrophage colony stimulating factor (GM-CSF), an upstream mediator of both Th1 and Th17 cells, as a pathogenic factor for GCA. We evaluated the efficacy and safety of mavrilimumab (anti GM-CSF receptor α monoclonal antibody) for maintaining disease remission in patients with GCA.

Methods: Patients with active new onset (N/O) or relapsing refractory (R/R) GCA were enrolled in a randomized, double-blind, placebo-controlled phase 2 trial. GCA was confirmed by temporal artery biopsy or vascular imaging. Active disease was defined as presence of GCA symptoms and erythrocyte sedimentation rate (ESR) (≥30 mm/hr) and/or

C-reactive protein (CRP) (≥1 mg/dL) elevation within 6 weeks from randomization. Corticosteroid-induced remission (resolution of GCA symptoms and CRP < 1 mg/dL or ESR < 20 mm/hr) was required by baseline. Patients were randomized 3:2 to receive mavrilimumab 150 mg or placebo subcutaneously every two weeks in addition to a protocol-defined 26-week prednisone taper starting at 20-60 mg/day. Stratification by disease type (N/O vs. R/R) was applied.

The primary efficacy endpoint was time to first flare by Week 26 in all treated patients (modified intention-to-treat population). Flare, confirmed by an independent adjudication committee, was defined as ESR ≥30 mm/hr and/or CRP ≥1 mg/dL and re-appearance of GCA symptoms or new/worsening vasculitis determined by imaging. Sustained remission through Week 26 was a key secondary endpoint. Safety up to Week 30 was assessed.

Results: 70 patients (35 N/O, 35 R/R) were randomized to mavrilimumab (N=42) or placebo (N=28). Mean (SD) age was 69.7 (7.48) years and 71.4% were female. Disease flare by Week 26 occurred in 8 (19%) and 13 (46.4%) patients receiving mavrilimumab and placebo, respectively (27.4% reduction). Median time to flare by Week 26 could not be estimated in the mavrilimumab group due to too few events (Not Estimable [NE]) and was 25.1 weeks [95% CI: (16.0, NE)] in the placebo group (HR [95% CI] 0.38 [0.15, 0.92]; p=0.0263) (Figure). Sustained remission at Week 26 occurred in 83.2% of the patients receiving mavrilimumab and in 49.9% of those receiving placebo (33.4% increase; p=0.0038). Results were consistent across disease type subgroups (HR for flare: N/O patients 0.29 [95% CI: 0.06, 1.31; nominal p= 0.0873]; R/R patients 0.43 [95% CI: 0.14, 1.30]; nominal p=0.1231) (Table 1). Adverse events (AEs), mostly mild to moderate in severity, were comparable between groups. There were 5 serious AEs (mavrilimumab 2 [4.8%], placebo 3 [10.7%]), none drug-related (Table 2). No deaths or vision loss occurred.

Conclusion: Mavrilimumab was superior to placebo on the primary and secondary efficacy endpoints of time to flare and sustained remission at Week 26 in patients with GCA. Mavrilimumab was well tolerated, and no new safety signals were observed. Results with this novel treatment are encouraging for the management of GCA.

Figure. Time to Flare by Week 26 after randomization in All Patients.

	Patients at Risk, n														
Week	0	2	4	6	8	10	12	14	16	18	20	22	24	26	28
Mavrilimumab	42	42	42	40	40	40	40	40	39	35	35	34	34	28	0
Placebo	28	27	27	27	26	26	23	20	19	15	15	14	14	10	0

Table 2. Treatment-Emergent Adverse Events over 30 Weeks.

Category	Mavrilimumab 150mg (N=42) n (%)	Placebo (N=28) n (%)
Treatment Emergent Adverse Events	33 (78.6)	25 (89.3)
By Maximum Severity [1]		
Mild	18 (42.9)	13 (46.4)
Moderate	14 (33.3)	11 (39.3)
Severe	1 (2.4)	1 (3.6)
Related to Mavrilimumab or Placebo [2]	10 (23.8)	7 (25.0)
Related to Prednisone [2]	11 (26.2)	11 (39.3)
Serious Treatment Emergent Adverse Events	2 (4.8)	3 (10.7)
Related to Mavrilimumab or Placebo [2]	0	0
Related to Prednisone [2]	0	0
Non-serious Treatment Emergent Adverse Events	33 (78.6)	25 (89.3)
Treatment Emergent Adverse Events Resulting in Death	0	0
Treatment Emergent Adverse Events Leading to Dose Interruption	1 (2.4)	2 (7.1)
Treatment Emergent Adverse Events Leading to Withdrawal of Treatment	1 (2.4)	1 (3.6)
Treatment Emergent Adverse Events of Special Interest	0	1 (3.6)

Subjects with multiple events in the same category are counted only once in the category. Subjects with events in more than one category are counted once in each of those categories.
Treatment emergent AEs (TEAEs) are defined as AEs that begin after the first administration of investigational products or existing AEs that worsen after the first dose of study medication through the 90 days after the last dose date.
[1] Each subject has only been represented with the maximum severity.
[2] Possibly or probably related, as assessed by the investigator.
TEAE of Special Interest include: Hepatic function abnormality, Acute hypersensitivity reaction, Delayed hypersensitivity reaction, Clinically significant pulmonary abnormality, Neutropenia, and Serious infection.

Median time to flare by Week 26 could not be estimated in the mavrilimumab group due to too few events (Not Estimable [NE]) and was 25.1 weeks [95% CI: (16.0, NE)] in the placebo group (HR [95% CI] 0.38 [0.15, 0.92]; p=0.0263).

Median time to flare by Week 26 could not be estimated in the mavrilimumab group due to too few events (Not Estimable [NE]) and was 25.1 weeks [95% CI: (16.0, NE)] in the placebo group (HR [95% CI] 0.38 [0.15, 0.92]; p=0.0263). Sustained remission at Week 26 occurred in 83.2% of the patients receiving mavrilimumab and in 49.9% of those receiving placebo (33.4% increase; p=0.0038).

Adverse events, mostly mild to moderate in severity, were comparable between groups. There were 5 serious AEs (mavrilimumab 2 [4.8%], placebo 3 [10.7%]), none drug-related. No deaths or vision loss occurred.

Table 2. Treatment-Emergent Adverse Events over 30 Weeks.

Category	Mavrilimumab 150mg (N=42) n (%)	Placebo (N=28) n (%)
Treatment Emergent Adverse Events	33 (78.6)	25 (89.3)
By Maximum Severity [1]		
Mild	18 (42.9)	13 (46.4)
Moderate	14 (33.3)	11 (39.3)
Severe	1 (2.4)	1 (3.6)
Related to Mavrilimumab or Placebo [2]	10 (23.8)	7 (25.0)
Related to Prednisone [2]	11 (26.2)	11 (39.3)
Serious Treatment Emergent Adverse Events	2 (4.8)	3 (10.7)
Related to Mavrilimumab or Placebo [2]	0	0
Related to Prednisone [2]	0	0
Non-serious Treatment Emergent Adverse Events	33 (78.6)	25 (89.3)
Treatment Emergent Adverse Events Resulting in Death	0	0
Treatment Emergent Adverse Events Leading to Dose Interruption	1 (2.4)	2 (7.1)
Treatment Emergent Adverse Events Leading to Withdrawal of Treatment	1 (2.4)	1 (3.6)
Treatment Emergent Adverse Events of Special Interest	0	1 (3.6)

Subjects with multiple events in the same category are counted only once in the category. Subjects with events in more than one category are counted once in each of those categories.
Treatment emergent AEs (TEAEs) are defined as AEs that begin after the first administration of investigational products or existing AEs that worsen after the first dose of study medication through the 90 days after the last dose date.
[1] Each subject has only been represented with the maximum severity.
[2] Possibly or probably related, as assessed by the investigator.
TEAE of Special Interest include: Hepatic function abnormality, Acute hypersensitivity reaction, Delayed hypersensitivity reaction, Clinically significant pulmonary abnormality, Neutropenia, and Serious infection.

Table 1. Baseline Demographic and Clinical Features of the Trial Cohort, by Group.

Background/Purpose: The efficacy of interleukin-6 receptor blockade in hospitalized COVID-19 patients not on mechanical ventilation is unclear.

Methods: We performed a randomized, double-blind, placebo-controlled trial in patients with patients confirmed SARS-CoV-2 infection, elevated serum inflammatory markers, and at least two of: 1) pulmonary infiltrate; 2) supplemental oxygen requirement to maintain oxygen saturation >92%; or, 3) fever >38°C. Patients were randomized 2:1 to standard care plus intravenous tocilizumab 8mg/kg or placebo. The primary outcome was time to mechanical ventilation or death during the 28-day study period. The two secondary efficacy outcomes were time to clinical worsening and time to resolution of supplemental oxygen requirement.

Results: Two-hundred forty-three patients were enrolled. One-hundred forty-one (58%) were men, 102 (42%) women. Median age was 58.8 years (range 21.7-85.4 years). Forty-five percent self-identified as Hispanic/Latino. The hazard ratio (HR) for progression to intubation or death in the tocilizumab group was 0.83 (95% confidence interval [CI] 0.38, 1.81; P=0.64). The HR for disease worsening was 1.11 (95% CI 0.59, 2.10; P=0.73) in the tocilizumab group. At 14 days, 18.0% versus 14.9% (tocilizumab versus placebo) had experienced disease worsening. The median time to oxygen discontinuation was 5.0 days (3.8, 7.6 days) in the tocilizumab group and 4.9 days (3.8, 7.8 days) with placebo (P=0.69). At 14 days, 24.6% of tocilizumab-treated patients still required oxygen, compared with 21.2% in the placebo group. Tocilizumab-treated patients had fewer serious infections.

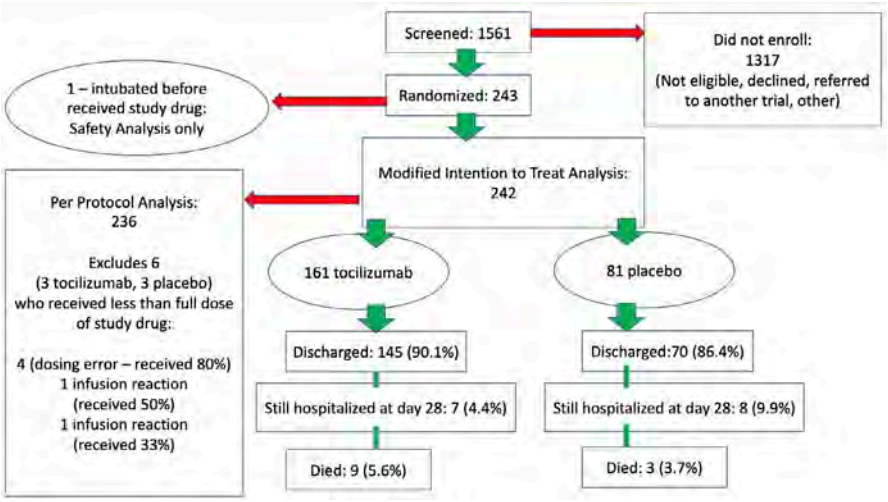

Figure 1. CONSORT Diagram

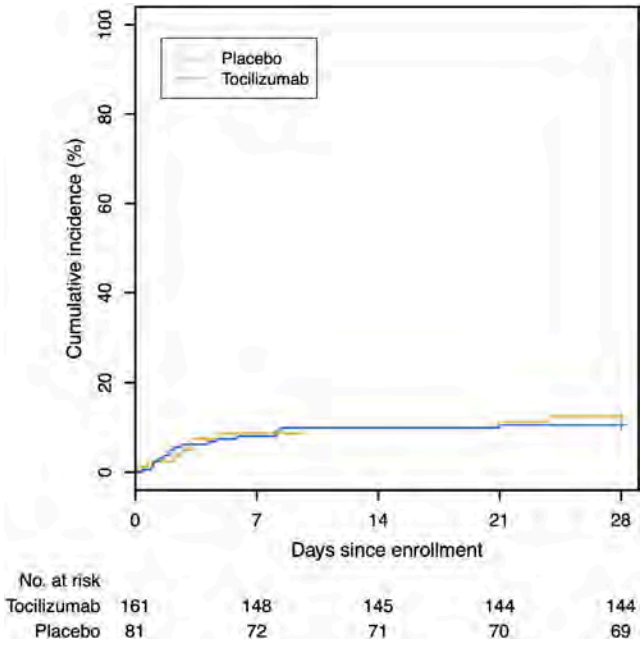

Figure 2. Time to Intubation or Death

Conclusion: Interleukin-6 receptor blockade is not effective for preventing mechanical ventilation or death among moderately ill patients with COVID-19 infection.

Disclosure: J. Stone, Genentech/Roche, 2.

Abstract Number: L08

Long Term Cardiovascular Safety of Febuxostat and Allopurinol in Patients with Chronic Gout: The Febuxostat versus Allopurinol Streamlined Trial (on Behalf of the FAST Investigators)

Thomas MacDonald[1], Isla Mackenzie[1], George Nuki[2] and Ian Ford[3], [1]University of Dundee, Dundee, Scotland, United Kingdom, [2]University of Edinburgh, Edinburgh, Scotland, United Kingdom, [3]University of Glasgow, Glasgow, Scotland, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Febuxostat and allopurinol are uric acid lowering agents. Following concerns about the cardiovascular safety of febuxostat, the European Medicines Agency (EMA) recommended a post-authorization study comparing the cardiovascular (CV) safety of febuxostat versus allopurinol.

Methods: We did a prospective, randomized, open-label, blinded endpoint (PROBE) trial of febuxostat versus allopurinol in patients with chronic symptomatic hyperuricaemia (gout) in the UK, Denmark, and Sweden. Eligible patients were 60 years or older, were currently treated with allopurinol, and had at least one additional cardiovascular risk factor. After increasing allopurinol dose if necessary to achieve serum uric acid (SUA) levels < 0·357 mmol/L (< 6 mg/dL), patients were randomly assigned to continue allopurinol (at optimised dose) or start febuxostat at a dose of 80mg daily, increasing to 120mg, if necessary, to achieve serum uric acid level < 0·357 mmol/L. A short washout period (7-21 days) was included before randomized therapy was started. The primary outcome was the composite of hospitalisation for non-fatal myocardial infarction/biomarker positive acute coronary syndrome, non-fatal stroke or cardiovascular death. The hazard ratio (febuxostat versus allopurinol) in a Cox proportional hazards model was assessed for non-inferiority (limit of 1·3) in an on-treatment (OT) analysis and then by intention to treat (ITT). This study is registered with the EU Clinical Trials Register (EudraCT 2011-001883-23) and ISRCTN (ISRCTN72443728).

Results: 6128 patients (mean age 71, 85·3% male, 33·4% prior established CV disease) were randomised to receive allopurinol (n=3065) or febuxostat (n=3063) and were followed up for a median of 4 years during which 5·5% and 6·2% respectively withdrew from all follow up. In both the on-treatment and intention-to-treat analyses, febuxostat was non-inferior to allopurinol for incidence of the primary endpoint (OT analysis: febuxostat 172 patients [1·72 events per 100 patient years]; allopurinol 241 patients [2·05 events per 100 patient years]; hazard ratio 0·85 [95% CI 0·70-1·03], p< 0·001; ITT analysis: febuxostat 256 patients [2·05 events per 100 patient years], allopurinol 285 patients [2·29 events per 100 patient years]; hazard ratio 0·89 [95% CI 0·75-1·06], p< 0·001). 222 (7·2%) patients died in the febuxostat group compared to 263 deaths (8·6%) in the allopurinol group.

Conclusion: Febuxostat was non-inferior to allopurinol therapy for the primary cardiovascular outcome. Long-term use of febuxostat was not associated with an increased risk of death compared with allopurinol.

Funding: Menarini provided funding. The University of Dundee was the sponsor and Menarini had no involvement in the running of the study.

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Late-Breaking Abstracts

Session Type: Late-Breaking Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: There is a high unmet need for systemic sclerosis (SSc) treatments. Ziritaxestat (ziri; GLPG1690) is an autotaxin inhibitor with a novel mechanism of action. NOVESA (NCT03798366) is a phase 2a randomized, double-blind, placebo (PBO)-controlled trial evaluating the efficacy, safety, and tolerability of ziri for diffuse cutaneous (dc) SSc.

	Ziritaxestat 600 mg (n=21)	Placebo (n=12)	Total (N=33)
Age (yrs), mean (SD)	50.4 (13.6)	47.3 (18.0)	49.3 (15.1)
Sex, n (%)

Baseline HAQ-DI			
Mean (SD)	1.24 (0.70)	0.84 (0.89)	1.10 (0.78)
Range	(0.00–2.38)	(0.00–2.75)	(0.00–2.75)
Receiving background immunosuppressive therapy*, n (%)	20 (95.2)	10 (83.3)	29 (87.9)
MTX	2 (9.5)	2 (16.7)	4 (12.1)
MTX + Pred	4 (19.0)	2 (16.7)	6 (18.2)
MYC	9 (42.9)	2 (16.7)	11 (33.3)
MYC + Pred	4 (19.0)	4 (33.3)	8 (24.2)
Pred	1 (4.8)	0	1 (3.0)

Table 1. Demographics and baseline patient characteristics. *Includes MTC, MYC, and Pred FVC, forced vital capacity; HAQ-DI, Health Assessment Questionnaire Disability Index; mRSS, modified Rodnan skin score; MTX, methotrexate; MYC, mycophenolate; Pred, prednisone; SD, standard deviation; yr, year

Methods: Patients with dcSSc were randomized (2:1) to receive oral ziri 600 mg once daily or matching PBO for 24 weeks. Protocol-defined immunosuppressive background therapies were allowed to continue unchanged if doses were stable for ≥3 months prior to ziri treatment. Eligible patients were adults with a confirmed diagnosis of dcSSc (by ACR/EULAR/Van den Hoogen/LeRoy 2013 criteria) and a modified Rodnan skin score (mRSS) >10 at screening. The primary endpoint was change from baseline mRSS at 24 weeks. Secondary endpoints were incidence of treatment-emergent adverse events (TEAEs), serious AEs and tolerability of ziri. Additional endpoints included changes in forced vital capacity (FVC), Health Assessment Questionnaire Disability Index (HAQ-DI) and Combined Response Index for Systemic Sclerosis (ACR CRISS) score. Analyses used a mixed-effects model for repeated measures. Least square (LS) mean (95% confidence interval [CI]) was calculated for the primary endpoint, descriptive statistics for other endpoints. Covariates included baseline mRSS and country.

Results: Thirty-three patients with active dcSSc were randomized: 21 to ziri; 12 to PBO. The majority of patients were female (69.7%); mean (standard deviation [SD]) age was 49.3 (15.1) yrs (Table 1). In the ziri and PBO groups, respectively, mean (SD) disease duration was 1.5 (1.0) and 2.6 (2.0) yrs; mean (SD) mRSS was 27.0 (8.8) and 22.5 (6.2). 95.2% and 83.3% of patients in the ziri and PBO groups were on background immunosuppressive therapy. A statistically significant difference was observed between groups for mRSS at Wk 24: LS mean difference (95% CI) was –2.8 (–5.6, –0.1) for ziri vs PBO (p=0.0411; Figure 1). Median CRISS score was 0.97 for ziri and 0.83 for PBO at Wk 24 (0.69 in the PBO group excluding a single outlier patient with implausible Wk 24 FVC change [+1381 mL]). ACR CRISS showed likelihood of improvement (score ≥0.60 on a 0.0–1.0 scale) in 64.7% and 62.5% of patients at Wk 24 in ziri and PBO groups, respectively (57.1% of PBO patients at Wk 24 with exclusion of the FVC outlier). No changes in FVC (mL) or HAQ-DI were observed. Ziri was well tolerated; most AEs were mild or moderate; no TEAEs led to study drug discontinuation. Serious TEAEs occurred in 2 patients in the ziri group (pharyngitis and sepsis; device-related infection and sepsis) and 1 patient in the PBO group (foreign body ingestion); these were considered unrelated or unlikely related to study drug. No deaths occurred. Preliminary data show target inhibition reflected by an average reduction in circulating lysophosphatidic acid of ~80%.

Conclusion: In the small NOVESA study, ziri significantly improved mRSS vs PBO at Wk 24 and was well tolerated when administered with standard-of-care immunosuppressive therapy. Results support a possible role for the autotaxin pathway in the pathogenesis of SSc skin disease and warrant further clinical research.

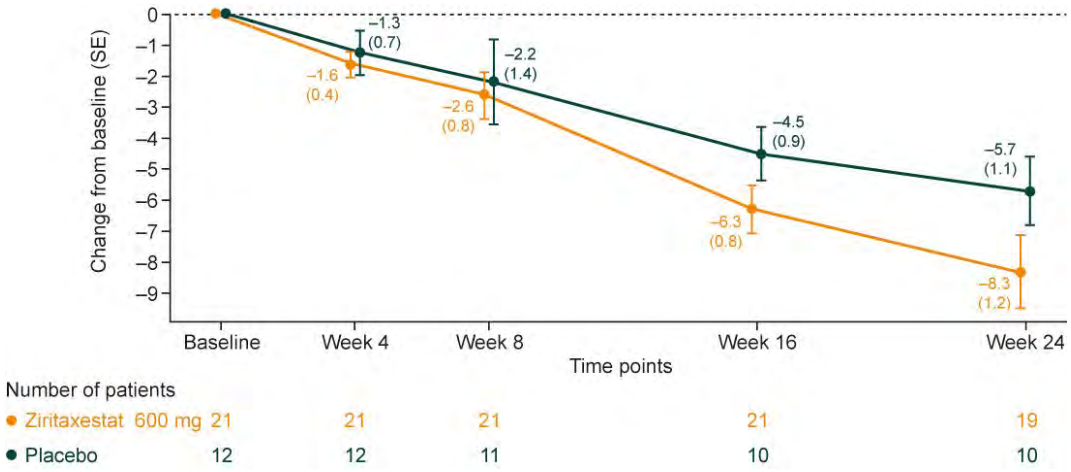

Figure 1. Change in mRSS from baseline. Changes in N are due to 1 patient being lost to follow-up and patients having the mRSS assessment outside the allowable window, due to COVID-19 restrictions limiting onsite visits COVID-19, coronavirus disease 2019; mRSS, modified Rodnan skin score; SE, standard error

Targeting Plasmacytoid Dendritic Cells Improves Cutaneous Lupus Erythematosus Skin Lesions and Reduces Type I Interferon Levels: Results of a Phase 1 Study of VIB7734

Victoria Werth[1], Jodi Karnell[2], William Rees[2], Nanette Mittereder[3], Li Yan[2], Yanping Wu[3], Jorn Drappa[2], Gabor Illei[2] and John Ratchford[2], [1]University of Pennsylvania, Philadelphia, PA, [2]Viela Bio, Gaithersburg, MD, [3]Viela Bio, Gaithersburg

SESSION INFORMATION
Session Date: Monday, November 9, 2020
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Plasmacytoid dendritic cells (pDCs) secrete large amounts of type I interferon (IFN) and other cytokines upon activation. pDCs migrate to sites of active disease in lupus. VIB7734 is a monoclonal antibody that selectively targets pDCs for antibody-dependent cellular cytolysis.

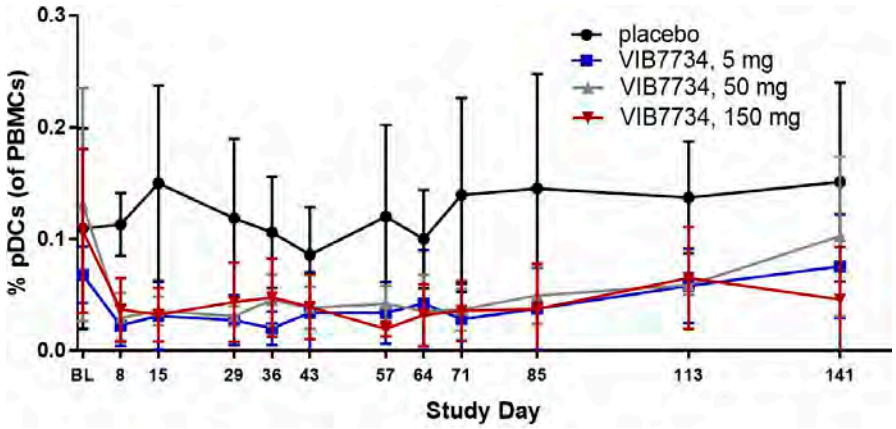

Figure 1: Mean Circulating pDC levels by treatment arm and time. Vertical bars represent standard deviation. PBMCs = peripheral blood mononuclear cells.

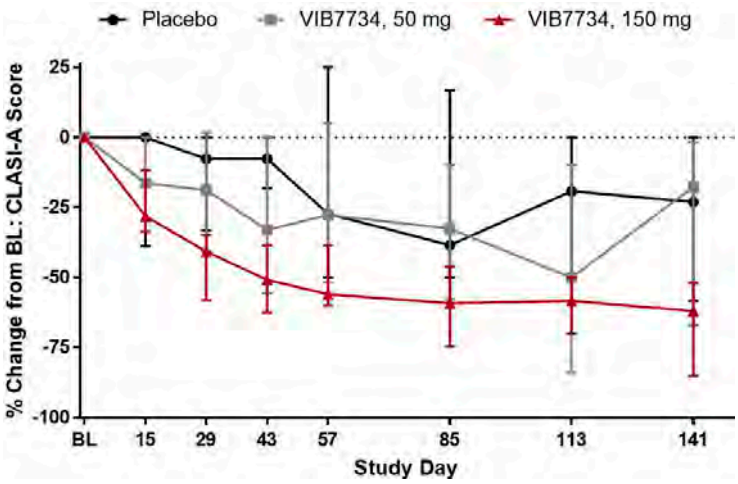

Figure 2: % change from baseline (BL) in median CLASI-A score by treatment arm and time. Vertical bars represent the interquartile range.

Methods: VIB7734 was tested in a phase 1, randomized, double-blind, placebo-controlled, multiple ascending dose clinical trial (NCT03817424). Adult subjects were enrolled in 3 sequential cohorts and received placebo (n=9) or 5 mg (n=6, cohort 1), 50 mg (n=8, cohort 2), or 150 mg (n=8, cohort 3) of VIB7734. Cohort 1 enrolled subjects with SLE or Sjogren's syndrome with no minimum disease activity requirement. Cohorts 2 & 3 included subjects with SLE or cutaneous lupus erythematosus (CLE) with a CLE Disease Area and Severity Index Activity score (CLASI-A) of ≥ 8. Subjects received VIB7734 or placebo subcutaneously every 4 weeks for 3 doses as an add-on to standard of care. In cohorts 2 and 3, a biopsy of affected skin was performed at baseline and Month 3. pDC levels were quantified in the blood and skin. The type I IFN signature was measured in blood. As a marker of IFN activity, myxovirus resistance protein A (MxA) was quantified within the epidermis as the percent of area reaching the positive staining threshold.

Results: 31 subjects were randomized and treated; all completed the study. Reductions in circulating pDCs were evident at Week 1 and persisted through the 3-month treatment period (Figure 1). A high type I IFN signature was present at baseline in 18 of 23 subjects (78%) in cohorts 2 and 3. The median change in IFN signature at Month 3 was -54% in the VIB7734 50 mg group, -83% in the VIB7734 150 mg group, and +8% in the placebo group. On the Month 3 biopsy the median change in pDC density was -87% for the 50 mg group, -99% for the 150 mg group, and -14% for the placebo group. The median area of MxA staining decreased with VIB7734 treatment (50 mg group: 50% to 1.7% affected area; 150 mg group: 90% to 1.1% affected area; placebo group: 5.5% to 18% affected area). The median change in CLASI-A from baseline to Month 3 was -5 in the 50 mg group, -9.5 in the 150 mg group, and -5 in the placebo group (Figure 2). At Month 3, a ≥50% improvement in CLASI-A was observed in 9 of 16 (56%) VIB7734-treated subjects and 2 of 7 (29%) placebo-treated subjects. No serious adverse events occurred in VIB7734-treated subjects. The proportion of subjects with an adverse event was similar in the VIB7734 and placebo groups (73% vs. 67%).

Conclusion: VIB7734 reduced blood and skin pDCs, thereby reducing type I IFN levels in blood and inflamed skin. More CLE subjects treated with VIB7734 than placebo had a clinically significant improvement in CLASI-A scores, and VIB7734 had an acceptable safety profile. Additional studies of VIB7734 in lupus are planned.

Tofacitinib for the Treatment of Adult Patients with Ankylosing Spondylitis: Primary Analysis of a Phase 3, Randomized, Double-blind, Placebo-controlled Study

Atul Deodhar[1], Paula Sliwinska-Stanczyk[2], Huji Xu[3], Xenofon Baraliakos[4], Lianne Gensler[5], Dona Fleishaker[6], Lisy Wang[6], Joseph Wu[6], Sujatha Menon[6], Cunshan Wang[6], Oluwaseyi Dina[7], Lara Fallon[8], Keith S Kanik[6] and Désirée van der Heijde[9], [1]Oregon Health & Science University, Portland, OR, [2]Reumatika Centrum Reumatologii, Warszawa, Poland, [3]Shanghai Changzheng Hospital, Shanghai, China (People's Republic), [4]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Bochum, Germany, [5]University of California San Francisco, San Francisco, CA, [6]Pfizer Inc, Groton, CT, [7]Pfizer Inc, New York, NY, [8]Pfizer Inc, Montreal, QC, Canada, [9]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Monday, November 9, 2020

Session Title: Late-Breaking Abstracts

Session Type: Late-Breaking Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Tofacitinib is an oral JAK inhibitor that is being investigated for the treatment of adult patients (pts) with AS.

Table 1. Demographics and baseline disease characteristics

	Tofacitinib 5 mg BID (N=133)	PBO (N=136)
Male, n (%)	116 (87.2)	108 (79.4)
Age (years), mean (SD)	42.2 (11.9)	40.0 (11.1)
Race, n (%)

Data cut-off Dec 19, 2019; data snapshot Jan 29, 2020; database was not locked, study was ongoing and data are subject to change in the final analysis
[a]Inflammation (morning stiffness) assessed as mean of questions 5 and 6 of the BASDAI
[b]Patients designated as TNFi-IR must have had an inadequate response and/or intolerance to at least one, but not more than two, approved TNFi
AS, ankylosing spondylitis; ASDAS(CRP), AS Disease Activity Score using C-reactive protein; ASQoL, AS Quality of Life; BASDAI, Bath AS Disease Activity Index; BASFI, Bath AS Functional Index; BASMI, Bath AS Metrology Index; BID, twice daily; bDMARD, biologic disease-modifying antirheumatic drug; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; hsCRP, high-sensitivity C-reactive protein; HLA-B27, human leukocyte antigen-B27; IR, inadequate responder; N, number of patients in full analysis set; n, number of patients with characteristic; NRS, numerical rating scale; NSAID, non-steroidal anti-inflammatory drug; PBO, placebo; PtGA, Patient Global Assessment of disease; SD, standard deviation; SF-36v2 PCS, Short Form-36 Health Survey Version 2 Physical Component Summary; TNFi, tumor necrosis factor inhibitor

Methods: This Phase 3, randomized, double-blind (DB), placebo (PBO)-controlled study (NCT03502616) enrolled pts aged ≥ 18 years with a diagnosis of active AS documented with centrally read radiographs, who met modified New York Criteria, and had an inadequate response or intolerance to ≥ 2 NSAIDs. In the 16-week DB phase, pts were randomized 1:1 to receive tofacitinib 5 mg BID or PBO. After Week (W)16, all pts received open-label tofacitinib until W48. We report the primary analysis of the study. Four separate families of efficacy endpoints were tested in hierarchical sequences to control for type I error: 1) ASAS20 response at W16 (primary endpoint), ASAS40 response at W16 (key secondary endpoint), change from baseline (Δ) to W16 in ASDAS(CRP), hsCRP, ASQoL, SF-36v2 PCS, BASMI–linear method, and FACIT-F total score; 2) Δ to W16 in ASAS components: PtGA, total back pain, BASFI, and Inflammation (morning stiffness); 3) ASAS20 response over time; 4) ASAS40 response over time. Statistical tests were conducted at the 2-sided 5% significance level. Safety data up to W16 and up to W48 are presented (data cut-off Dec 19, 2019; database was not locked and study was ongoing).

Results: 269 pts were randomized and treated (tofacitinib, n=133; PBO, n=136); 77.0% were bDMARD-naïve (Table 1). Efficacy results are shown in Table 2. At W16, the % of ASAS20 responders was significantly greater with tofacitinib (56.4%) vs PBO (29.4%) ($p < 0.0001$). The % of ASAS40 responders at W16 was significantly greater with tofacitinib (40.6%) vs PBO (12.5%) ($p < 0.0001$), and significant improvements with tofacitinib vs PBO were seen for Δ to W16 in ASDAS(CRP), hsCRP, ASQoL, SF-36v2 PCS, BASMI–linear method, and FACIT-F total score. Improvements in ASAS components were significantly greater with tofacitinib vs PBO. Significant improvements with tofacitinib vs

Table 2. Efficacy of tofacitinib 5 mg BID vs PBO up to W16: type I error-controlled primary and secondary endpoints[a]

W2, n (%)	38 (28.6)	14 (10.3)	0.0001
Type I error-controlled ASAS40 response over time,[b,g] tested in the sequence below			
W12, n (%)	57 (42.9)	16 (11.8)	< 0.0001
W8, n (%)	46 (34.6)	8 (5.9)	< 0.0001
W4, n (%)	36 (27.1)	5 (3.7)	< 0.0001
W2, n (%)	14 (10.5)	6 (4.4)	0.0548

Data cut-off Dec 19, 2019; data snapshot Jan 29, 2020. Efficacy assessments used only on-drug data up to W16; efficacy data final

[a]In each group of type I error-controlled endpoints, statistical significance could be declared only if the prior endpoint (or time points) in the sequence met the requirements for significance ($p \leq 0.05$)

[b]ASAS20 response was defined as ≥ 20% and ≥ 1 unit improvement in ≥ 3 components on a scale of 0–10 and no worsening of ≥ 20% and ≥1 unit in the remaining component. ASAS40 response was defined as ≥ 40% and ≥ 2 units improvement in ≥ 3 components on a scale of 0–10 and no worsening at all in the remaining component. Normal approximation adjusting for the stratification factor (prior treatment history: bDMARD-naïve vs TNFi-IR or bDMARD use (non-IR)) derived from clinical database via Cochran–Mantel–Haenszel approach was used. Missing response was considered as non-response

[c]Mixed model for repeated measures included fixed effects of treatment group, visit, and treatment-group by visit interaction, stratification factor derived from clinical database, stratification-factor by visit interaction, baseline value, and baseline-value by visit interaction; an unstructured covariance matrix was used. Missing values were not imputed

[d]Analysis of covariance model included fixed effects of treatment group, stratification factor derived from clinical database, and baseline value. Missing values were not imputed

[e]Statistical significance could be declared only if ASAS20 response at W16 (and all other prior timepoints, per footnote [a]) met the requirement for significance ($p \leq 0.05$); ASAS20 response at W16 data presented in the global type I error-controlled endpoints section

[f]Inflammation (morning stiffness) assessed as mean of questions 5 and 6 of the BASDAI

[g]Statistical significance could be declared only if ASAS40 response at W16 (and all other prior timepoints, per footnote [a]) met the requirement for significance ($p \leq 0.05$); ASAS40 response at W16 data presented in the global type I error-controlled endpoints section

Δ, change from baseline; AS, ankylosing spondylitis; ASAS20/40, Assessment in AS ≥ 20/40% improvement; ASDAS(CRP), AS Disease Activity Score using C-reactive protein; ASQoL, AS Quality of Life; BASDAI, Bath AS Disease Activity Index; BASFI, Bath AS Functional Index; BASMI, Bath AS Metrology Index; bDMARD, biologic disease-modifying antirheumatic drug; BID, twice daily; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; hsCRP, high-sensitivity C-reactive protein; IR, inadequate responder; LSM, least squares mean; N, number of patients in full analysis set; N1, number of patients with observation at visit; n, number of patients with response; NRS, numerical rating scale; PBO, placebo; PtGA, Patient Global Assessment of disease; SE, standard error; SF-36v2 PCS, Short Form-36 Health Survey Version 2 Physical Component Summary; TNFi, tumor necrosis factor inhibitor; W, week

PBO were seen from W2 (first post-baseline visit) in ASAS20 response and W4 in ASAS40 response. Up to W16, adverse events (AEs) were reported in 72 pts (54.1%) receiving tofacitinib and 70 pts (51.5%) receiving PBO; serious and severe AEs were each reported in 2 pts (1.5%) receiving tofacitinib and no pts receiving PBO; 3 pts (2.3%) receiving tofacitinib and 1 pt (0.7%) receiving PBO discontinued study drug due to AEs. Safety trends were similar up to W48 (Table 3). With tofacitinib: there were no deaths, DVT, PE, ATE, GI perforation, ILD, MACE, malignancies, or opportunistic infections up to W48; adjudicated hepatic events were reported in 1 pt (0.8%) up to W16 and 2 pts (1.5%) up to W48; 1 pt (0.8%) had a serious infection (meningitis) up to W16; 3 pts (2.3%) had non-serious HZ up to W48. With PBO: there were no deaths or AEs of special interest up to W16; 1 pt (0.7%) in the PBO → tofacitinib group had non-serious HZ up to W48.

Conclusion: Pts with active AS had a rapid clinical response to tofacitinib. Efficacy was significantly greater with tofacitinib vs PBO for primary and secondary endpoints. AEs were more frequent with tofacitinib vs PBO; there were no new safety risks.

Acknowledgments: Study sponsored by Pfizer Inc. Medical writing support was provided by Sarah Piggott, CMC Connect, and funded by Pfizer Inc.

Abstract Number: PP01

Impacting Change Through Facilitation and Advocacy for Lupus

Monica Watson[1], [1]Lupus Foundation of America, Darby, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: My story started as one of disbelief in 2009 with my Lupus diagnosis. How could a woman in the prime of her career be diagnosed with a disease with no cure? Being a female in a technical field, when I heard my diagnosis, I thought fix it. When I heard there was no fix, I was taken off guard. This disbelief had to quickly turn to how can I live well with this disease. It has been a journey, but a grateful one of self -discovery. Although this disease has caused me to be unable to work in my profession, brought about a myriad of other conditions and co-morbidities, I have discovered that I am resilient, persistent and a warrior.

Intervention: Navigating such a complex illness that drastically changes your life is no easy feat. One must adjust and accommodate to a "new you" in the process. Managing and adhering to treatment plans in coordination with my rheumatologist and other specialists is a way of life. A part of this new life led me to adding additional tools to my toolbelt in order to live well**.** One of which was attending a lupus support group. This opened up a whole new world of meeting people like me. They understood and connected over everyone's journey. My involvement led to becoming a support group facilitator. This group has developed into the largest lupus support group of the chapter. In this role, I continually serve as a conduit to bring information to attendees to encourage them to be empowered, engaged, educated and enlightened on their journey with Lupus. Facilitation has developed into advocacy. My voice as a patient to raise awareness, educate others and advocate for policies has been monumental. I have seen on a national and local level, the results of advocacy efforts and the ability to effect change.

Maintenance: My role as a support group facilitator and advocate has spawned continued education and learning. The sustained need to be engaged in your healthcare and total wellness are paramount. Doctor patient relationships have evolved into partnerships. Raising my voice through advocacy has served as a catalyst for others to raise their voices as well. Support group efforts have enlightened me and other patients on their road to self- discovery with Lupus. Promoting awareness for Lupus remains a key focus on this path. Advocating through sponsored events and meeting with both local and national political representatives still provides the ability to foster change.

Quality of Life: The people, experiences and knowledge I have gained on this path with Lupus have been invaluable. My service to others through my support group facilitator and advocacy roles has not only improved my quality of life but helped other patients as well. The expansion of my network through various engagements and forums has fostered additional relationships with other advocates, industry experts and increased doctor patient relationships. All this has led to providing not only valuable information for myself but serving as a gateway to share and impact the lives of patients. I always get inspired and invigorated by the synergy of those of us living with Lupus who come together to provide compassion, insights and determination to continue to fight on this journey. It has been a gratifying feeling to know that my voice along with others can make a difference.

Low- and Hi-Tech Tools for Enhancing Patient-Hospital Care Team Communication in the Context of Rare Disease

Ida Hakkarinen[1], [1]Vasculitis Patient-Powered Research Network (VPPRN) / Member, Vasculitis Foundation, Greenbelt, MD

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: For over two years, I experienced a variety of disparate symptoms including: joint aches, sinus congestion, shortness of breath and chronic cough. An episode of hemoptysis led to laryngoscopy in December 2011 and a diagnosis of subglottic stenosis (SGS). Test results showed a high ANCA titer. Referral to a rheumatologist resulted in a diagnosis of Granulomatosis with Polyangiitis (GPA). Eight years later, a recurrence of SGS required another laryngoscopy. My hospital experience the second time allowed the use of a high-tech tool for communication with the health care team.

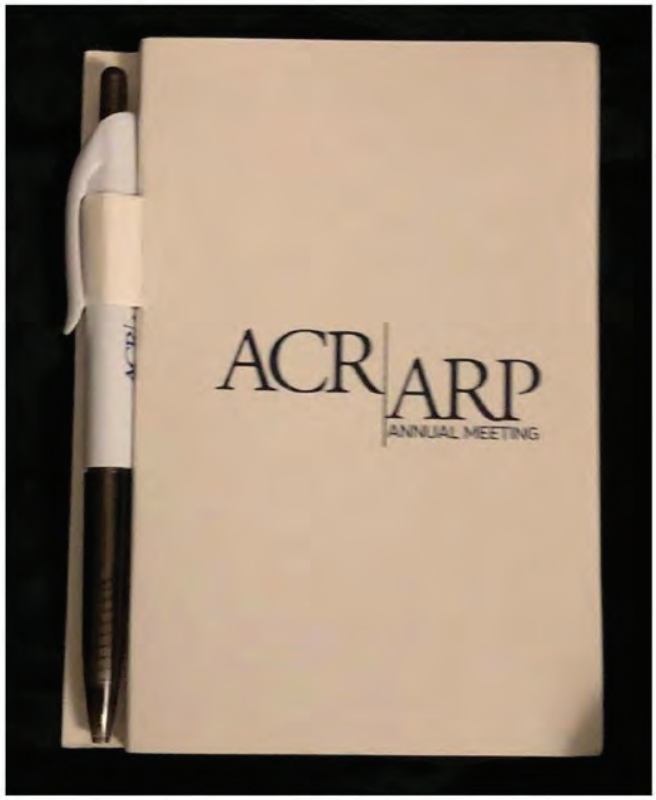

Fig. 1 – Notebook for observations and questions

Figure 1. Notebook for Observations and Questions

Date: MM/DD/YY

PENELOPE PROACTIVE PATIENT
DOB: MM/DD/YYYY

ABOUT ME
I'm a 58-year-old widow with one son. I work as a self-employed graphic artist. At my congregation, Grace Evangelical Lutheran Church in Anytown, MD, I'm on the board of directors, sing in the choir, and serve as an assisting minister.

MY SIX-WORD MEMOIR
Thanks to research, living with vasculitis.

TREATMENT PHILOSOPHY
Want to be an active participant in shared decision-making w/my medical team. My values: 1) use the least amount of medication to address the problem, and 2) reduce cost impact to health care system. My Risk/benefit view: Dr. Ruth Chang (Prof. of Jurisprudence, Oxford) says when choices are on par with each other, any of them is appropriate: "It's...in the space of hard choices that we get to exercise our normative power."

CONTACT INFORMATION
Cell: 123-456-7890

My son Jacob graduated from college in June and will be joining the U.S. Army in December. This is his graduation photo.

REASON FOR HOSPITALIZATION
Recurrence of symptomatic subglottic stenosis. Dr. Jodie Gargle, my otolaryngologist, will be performing the laryngoscopy and keeping me overnight for observation. She anticipates the stenosis is a result of scar tissue rather than active inflammation.

UPCOMING MEDICAL APPOINTMENTS
16 Oct 2020 – 3-mo check up with Dr. Michaela Joints, my rheumatologist
18 Nov 2020 – consultation with Dr. Julia Driller, my oral surgeon, regarding potential for second dental implant

MEDICAL CONDITIONS
GRANULOMATOSIS WITH POLYANGIITIS (GPA) Dx Jan 2012, **OSTEOPEROSIS** Dx Feb 2010, **HYPOTHYRODISM** Dx June 2000

MEDICATIONS
Rx: levothyroxine 200 mcg daily, dapsone 100 mg daily (prophylaxis for pneumocystis pneumonia)
OTC: aspirin 81 mg daily, calcium citrate (slow release) 1200 mg daily, vitamin D 1000 mg daily, olopadtadine ophthalmic solution 0.2% PRN

SURGICAL HISTORY
March 2017 – dental implant
Dec 2011 - laryngoscopy for subglottic stenosis (inflammation was due to GPA)

VACCINATIONS
15 Nov 2019 – high-dose influenza trivalent
16 Jun 2019 – Shingrix (1st dose), 16 October 2019 – Shingrix (2nd dose)
19 Jan 2018 - PPSV23 booster (initial shot 08 Jun 2012)
20 Apr 2014 - PCV 13
04 Jan 2014 - Hep-B (2nd booster 25 Feb 2014, 3rd booster 26 Jul 2014)
02 Jun 2012 - Hep-A - booster 15 Jan 2013 // 12 Apr 2011 - Tdap

TESTS
Mammogram – 16 May 2019
DXA – 08 Nov 2018, previous scans 11 Oct 2016, 07 Mar 2014, and 21 Feb 2012

ALLERGIES TO MEDICATIONS
Sulfa drugs, adhesive tape

SOCIAL HISTORY
Never smoked. Drink one glass of red wine 2-3 times per week.

FAMILY HISTORY
Mother - Dx hypertension @ age 35, Dx w/breast cancer @ 60, died @ 65 of cancer.
Father – Dx cardiovascular disease @ age 44, died @ 70 of heart attack.
Paternal grandmother - senility in elderly years, macular degeneration, died @ 81.
Paternal grandfather - profound hearing loss in elderly years, died @ 99.
Maternal grandmother - pernicious anemia, cataracts, died @ 80 of liver cancer.
Maternal grandfather - hypertension, heart attack, died @ 60 of stroke.

Figure 2. Health Resume Template

Intervention: I've used both low-tech and high-tech tools to enhance communications with my hospital care teams. For both my 2011 and 2019 surgeries, I used a small notebook with attached pen (Fig. 1) to document my observations and questions. Following my 2011 surgery, I was told to rest my voice. After I pressed the call button in my

hospital room, a disembodied voice asked “What do you need?”, and I squeaked out a response. In 2019, however, I sent multiple text messages to myself on my mobile phone the night before surgery. The next day in my hospital room after surgery, I used the text-to-speech capability of the phone to “read aloud” a text through the built-in speaker, e.g., “I would like an orange popsicle, please.”

Writer and mother Shannon Dingle shared on her twitter feed in June 2019 a picture of a “health resume” she uses to help remember important information to share with her doctors. Physicians responded favorably, and said they wished more patients used such resumes. Borrowing her idea, I’ve started to provide a resume to each new health care team member I see (template in Fig. 2), whether at a clinic, ER, or hospital visit.

Maintenance: Being hospitalized with a rare disease at an academic medical center often results in many visitors for rounds. Once, when hospitalized for a relapse, there were 14 people across the room at the foot of my bed. I gave a medical student a copy of the ACR patient education brochure on GPA (Fig. 3) as a way to share information about my rare disease. Use of low- and high-tech tools has fostered improved communication in my interactions with my health care team in both clinical and hospital settings.

Quality of Life: I’m deeply grateful to the team of medical professionals who work in partnership with me to monitor, manage, and treat my GPA. Fortunately, my disease has not flared since September 2013. I’m a lifetime member of the Vasculitis Foundation, a patient advocacy group. In 2014, I joined a natural history study in the Vasculitis Translational Research Program at the National Institutes of Health. My six-word memoir is: “Thanks to research, living with vasculitis.”

AMERICAN COLLEGE of RHEUMATOLOGY
Empowering Rheumatology Professionals

Granulomatosis with Polyangiitis (Wegener's)

Fast Facts

- Granulomatosis with polyangiitis (Wegener's) - GPA - is serious but treatable. To prevent complications, prompt diagnosis and treatment are essential.
- The cause of GPA is unknown.
- GPA often affects the sinuses, lungs, and kidneys. It can lead to kidney failure if not treated.
- Recurrences of disease is common.
- Significant side effects of medications used to treat GPA can be minimized with preventive strategies.

Granulomatosis with polyangiitis (Wegener's), also known as GPA, is a rare blood vessel disease. It can cause symptoms in the sinuses, lungs, and kidneys as well as other organs. It is a potentially serious disease. However, with prompt diagnosis, granulomatosis with polyangiitis can be treated effectively.

What is Granulomatosis with Polyangiitis (Wegener's)?

GPA is abnormal inflammation of the blood vessels, which is also called a vasculitis. GPA involves the small and medium-sized blood vessels throughout the body. The inflammation in the blood vessel does not allow blood to flow properly, so the cells do not get the oxygen they need. This causes tissue injury called granulomatous inflammation. A granuloma is a type of cellular inflammation that can usually be seen on biopsies of affected organs. The cause of GPA is not known.

Most commonly, GPA affects the sinuses, lungs, and kidneys, but also can affect the eyes, ears, skin, nerves, joints, and other organs. Symptoms can develop over days to months. The first symptoms generally appear in the respiratory tract (e.g., nose, sinuses, and lungs). The symptoms include nasal congestion, frequent nosebleeds, shortness of breath, and cough that may produce bloody phlegm. Other early symptoms can include joint pain, decreased hearing, skin rashes, eye redness and/or vision changes, fatigue, fever, appetite and weight loss, night sweats, and numbness or loss of movement in the fingers, toes, or limbs.

Updated March 2019 by Vaneet Sandhu, MD, and reviewed by the American College of Rheumatology Committee on Communications and Marketing.

Abstract Number: PP03

Connecting with Rheumatology Professionals and Thought Leaders Inspired the Creation of a New Program Focused on Relapsing Polychondritis ("RP"), a Rare Rheumatic Disease: Participating at ACR Annual Meetings Has Provided Exceptional Opportunities to Learn and Build Relationships

Nancy Linn[1], Catherine Bammert[2], David Bammert[3] and Michael Linn[4], [1]Relapsing Polychondritis Foundation, Palos Verdes Estates, CA, [2]MD Anderson, Houston, TX, [3]Relapsing Polychondritis Foundation, Houston, TX, [4]Relapsing Polychondritis Foundation, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2011, I was diagnosed with relapsing polychondritis ("RP"), a debilitating and sometimes fatal rheumatic disease that is characterized by inflammation of cartilage and other tissues. The disease affects multiple organs, particularly cartilaginous structures such as the ears, nose, airways, and joints as well as the eyes, skin, heart valves and brain. The cause of RP is unknown and there currently is no cure for the disease.

After diagnosis, I realized that I could focus on my specific case – or, I could combat RP more broadly and help others. I decided to live my life with the purpose of helping others.

Intervention: As a patient, I had the opportunity to be evaluated by an incredible team of multidisciplinary expert medical professionals. While interacting with these experts, it was evident that there were tremendous unmet needs in the areas of diagnosis and treatments. As a retired Registered Nurse, it was clear that targeted research initiatives would be required to combat RP.

Maintenance: While fighting RP, I met many highly skilled, collaborative research scientists, especially at ACR Annual Meetings.

In 2017 in San Diego, I participated in an RP study group that received a tremendous response from participating clinicians, clinical and basic scientist researchers, patients, and patient advocacy groups.

In 2018 in Chicago, I helped organize the RP Foundation's reception, co-hosted an event with the University of Michigan Division of Rheumatology, participated on a podcast of a news source dedicated to the field of rheumatology, and facilitated two ACR exhibitor booths.

In 2019 in Atlanta, I participated in an RP investigators meeting, which provided an update on a classification criteria project, introduced a new project to modify the disease activity index, and summarized RP-related projects.

With knowledge gleaned at ACR Annual Meetings, my husband and I collaborated with the RP Foundation to provide a substantial gift in 2020 to establish the Penn RP Fund, which will support a unique partnership between the University of Pennsylvania and the National Institutes of Health sponsored Vasculitis Clinical Research Consortium.

Quality of Life: Living with the purpose of helping other patients continues to improve the quality of my life. It affords me the opportunity to be excited about the extraordinary advances in patient care and cutting-edge research.

Participating at ACR Annual Meetings has provided exceptional opportunities to learn and collaborate with highly skilled research scientists. Further, I was able to build relationships with these scientists, which played a key role in the launch of the Penn RP program.

This program will allow researchers to pursue important projects, including the development of a world-class referral center to examine the impact of the microbiome on RP disease activity. Additionally, patients with RP will have the opportunity to be evaluated by multiple subspecialties in a coordinated patient-centered manner.

I am confident that the Penn RP program will significantly improve the quality of my life and other RP patients for years to come.

Photo collage of highly skilled, collaborative research scientists and relapsing polychondritis advocates

Abstract Number: PP04

My Multidisciplinary Healthcare Team and Patient Advocacy Groups Saved My Life

Tedi LaMere[1], Michael Linn[2] and David Bammert[3], [1]Relapsing Polychondritis Foundation, Kalispell, MT, [2]Relapsing Polychondritis Foundation, New York, NY, [3]Relapsing Polychondritis Foundation, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: I enjoyed being physically active my entire life – climbing mountains, hunting, and hiking. This drastically changed around 2012, when I noticed that I was increasingly experiencing shortness of breath and fatigue, despite being physically fit. I developed a nagging cough and my heart function decreased dramatically. I was tested for numerous conditions, but a diagnosis eluded me, and my health continued to deteriorate. Ironically, at the time, I was working as a respiratory therapist and was helping patients breathe, yet I could not breathe! I had to leave the career I was passionate about because my health became so poor. Eventually, my doctors ran out of potential diagnoses and began to discount my symptoms and brush me off. Meanwhile, my joints and tendons began to swell and become painful, my airways were collapsing, and I had to endure chemotherapeutic infusions to save my life.

Eventually, I was diagnosed with a rare autoimmune disease called relapsing polychondritis ("RP"), which is characterized by recurrent inflammation of cartilage in the body. RP is difficult to diagnose, challenging to treat and currently is not curable.

Intervention: After trying to schedule an appointment at the National Institutes of Health (NIH) for quite some time, I had to postpone my visit because I became too sick to travel. Living in Montana, traveling to Bethesda, Maryland was overwhelming and simply not feasible – both physically and financially.

Thankfully, the RP Foundation and Race for RP established a fund to support the Friends of Patients at the NIH program ("Friends of Patients") to offset travel costs and assist with providing for essential needs. The fund directly benefits RP patients and their families and advances RP research. Fortunately, I received assistance with transportation and made it to my appointments at the NIH! The clinicians and research scientists at the NIH identified several serious health conditions that could easily have cost me my life had they not been addressed, including cardiac amyloidosis, multiple pulmonary embolisms, and airways collapsing nearly 100%.

Maintenance: Currently, my medications are addressing the severe inflammation and heart condition caused by RP. High-dose corticosteroids have undoubtedly saved my life but have also resulted in significant damage to my body as well. Chimeric monoclonal antibody infusions also seem to manage my symptoms, and anticoagulant therapy reduces the risk of abnormal blood clot formation.

Quality of Life: I am grateful for the medical treatments that saved my life, yet I continue to have numerous daily struggles that I have learned to live with. I experience brain fog and joint pain all the time, and my heart and lung functions are greatly impaired. I have compression fractures in my back. I developed Cushing's disease and diabetes and

gained eighty pounds due to high-dose corticosteroids. However, my health is not declining at the rapid pace that it was prior to visiting NIH. Despite the severity of my symptoms, I remain hopeful that researcher scientists will unlock the mysteries of my disease and prolong my life – and the lives of others. I cannot thank NIH, Friends of Patients, RP Foundation, and Race for RP enough!

Tedi LaMere, a Registered Respiratory Therapist (RRT) with a Neonatal/Pediatric Specialist (NPS) certification, pictured outdoors prior to being diagnosed with relapsing polychondritis

Tedi LaMere, RRT-NPS and research advocate, pictured after being diagnosed with relapsing polychondritis

Tedi LaMere's patient advocacy groups (Relapsing Polychondritis Foundation, Friends of Patients at NIH, and Race for RP) worked together to facilitate her healthcare.

Abstract Number: PP05

Coping Through Advocacy - My Story Living with Relapsing Polychondritis

Allegonda Imeson[1], [1]The Canadian Society for Relapsing Polychondritis, Stony Plain, AB, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Becoming a mother was the most pivotal moment of my life. From early on, I instilled the importance of a physical, healthy lifestyle for my two boys. I encouraged adventure and exploration with biking, walking and swimming in our picturesque Canadian backdrop.

In 2011, I started to experience painful swelling of the cartilaginous portions of my ears - which was so intense, I could not function. I was treated consistently and unsuccessfully with antibiotics. I was weak, tired, and in a constant state of cloudiness - I could no longer keep up with my children. As time moved forward, the episodes increased in intensity and frequency, and I started experiencing debilitating joint pain. Everyday was a struggle.

After finally being referred to a rheumatologist in 2015, I was diagnosed with the rare and sometimes fatal disease Relapsing Polychondritis (RP). Although relieved to finally have an answer, I was distraught with the lack of resources and information available for RP.

Intervention: The complexities of RP require a multidisciplinary team. Although treatment was started swiftly, the doctors I met with admittedly knew little of the disease. I decided to do whatever I could to educate myself about the illness. In late 2015, I reached out to the Relapsing Polychondritis Foundation and became the first international advocate for the U.S based group - eventually meeting a fellow patient in person at the 2016 LA autoimmune walk.

After this inspiring encounter, I decided to expand my international mission of awareness for RP. In 2017, I spearheaded the creation of the Canadian Society for Relapsing Polychondritis (CSRP) and successfully established the first Canadian RP non-profit organization focused on awareness, education, and patient support.

Maintenance: As Chair of the CSRP, I lead in the organization of annual awareness campaigns in Canada. Our inaugural event featured medical professionals speaking about the illness to a crowd of 100, which was only a dream

a few years previous. Each subsequent CSRP event has seen an increase in attendees - promoting awareness and encouraging patient wellness while focusing on what those with RP **CAN** do.

I proudly represent the CSRP in partnerships with the RP Foundation and Race for RP, attending the past three American College of Rheumatology (ACR) conferences alongside these organizations. I have had the honor of meeting experts in the field of rheumatology and the privilege of attending the 2019 RP investigators meeting - an international collaboration of professionals and advocates interested in the advancement of research for RP.

Quality of Life: RP will forever be synonymous with who I am. Although I am plagued with the effects of the disease everyday, I am grateful for my ability to increase awareness.

Supporting those who feel like I did 5 years ago when I was first diagnosed has been the most rewarding aspect for me living with a rare autoimmune disease. I have solace in knowing that that my efforts, and the efforts of our international team, are helping others with RP.

Although it is difficult to be exactly who I was before RP, I am now instilling the power of knowledge and advocacy in my children. Teaching them that when life throws you obstacles, it is important to face them head on as there is strength in knowledge.

Allegonda Imeson and the Canadian Society for Relapsing Polychondritis (CSRP).

Abstract Number: PP06

Only in My Dreams Can I Do the Things I Used to Do: Where There Is Research, There Is Hope

Dan Smith[1], Robert Smith[1] and Jillian Covault[1], [1]Canton, MI

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In Mach 2020, I was diagnosed with relapsing polychondritis ("RP"), a multisystem, rheumatologic disease characterized by inflammation of cartilaginous structures including the ear, nose, joints, and airways. The cause of RP is unknown and there is no cure.

After my diagnosis, my family members contacted the RP Foundation to learn about this rare, debilitating disease. The RP Foundation was a tremendous resource and provided educational material and contact information for RP experts at the National Institute of Arthritis Musculoskeletal and Skin Diseases (NIAMS) at the National Institutes of Health (NIH). The RP Foundation also introduced me to an online RP support group.

Intervention: To share perspective and learn how to better manage my disease, I joined the support group. I learned the importance of lending hope to my peers and borrowing it from them, when needed. I am also learning new activities that provide a sense of well-being without requiring physical activity and robust breathing. One new hobby that I find personally rewarding is writing. I wrote the poem below:

Only in my dreams
Can I do the things I used to do
To take long walks in the woods
Go for bike rides with my love

Only in my dreams
Is my soul set free
To roam where it wants
To take the grandkids putt-putt
Or play yard games with them
On nice summer days

Only in my dreams
Can I work in my yard
Fiddle with landscaping
To putz in my man cave
Without gasping for air

Only in my dreams
Can I enjoy doing all the things
That made me “ME”
I guess you would say
You see I’m not a sitter or idle person

I will continue to fight and battle
That is what I know,
That’s what I was taught
But excuse me
If I turn to be early tonight
Because I can be me
Only in my dreams.

Maintenance: Recently, I was in the hospital fighting for my life after being infected with COVID-19. Thanks to my wife and family, a talented and dedicated medical team, the members of the RP Foundation, and the support group, my spirits were lifted, and I mustered the strength to fight my way back home. My family and team made a positive difference in my recovery.

I have been a life-long fan of professional hockey and was overjoyed when the local team won four Stanley Cup championships. While I was recently in the hospital, my peers posted videos with inspiring messages from professional hockey athletes. These athletes encouraged me (specifically) to keep fighting RP and the coronavirus. This support was fantastic, especially because hockey is an important part of our family.

For generations, hockey has provided great times together at ice rinks during tournament weekends with my children and grandchildren. One of the most difficult and frustrating things about RP is that I have had to stop attending family hockey games. My absence has been difficult for my family too. (One of my sons and one of my grandchildren are goalies on hockey teams.)

Quality of Life: The expertise of my medical team and the kindness of my wife, family, RP Foundation, and the RP support group helped me survive and has inspired me to help others. I will be forever grateful for the care and support that I received. I am also committed to advancing RP research. As one of my fantastic doctor says, “Where there is research, there is hope.” She is correct!

Dan & Debbie Smith and family

Abstract Number: PP07

Improving Communication with My Physician Drastically Improved My Health

Whitney Carter[1], [1]Lupus and Allied Diseases Association, Inc., Pleasanton, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2011, at the age of 14, I was sent to the emergency room with a platelet count of 19. The hematologist diagnosed me with idiopathic thrombocytopenic purpura (ITP). After further testing, I was diagnosed with systemic lupus erythematosus (SLE). After a severe reaction to intravenous immunoglobulin (IVIG), the doctors put me on hydroxychloroquine (HCQ), prednisone, and azathioprine (AZA). Three years later, at the age of 17, I was diagnosed with central nervous system lupus (CNS lupus) after a lumbar puncture. After the diagnosis of CNS lupus, I was switched from AZA to mycophenolate mofetil, cyclophosphamide (CYC), and IV steroids. After six months, I was put on rituximab. Three months later, I did nine courses of plasmapheresis followed by both rituximab and CYC with IV steroids.

Intervention: After years of trial and error with intensive and time consuming treatments, the solution I kept coming back to was communication. If my physician didn't understand what was going on, he/she couldn't diagnose or treat me appropriately. Research is an important component in finding new treatments and potentially cures, but there is a lot to be said about effectively using the resources and tools that we already have. A huge communication block that affected me getting proper treatment for over a year was simply the description of one of my symptoms—dizziness. There are so many different kinds of dizziness, and many of them indicate different causes and treatments. I lacked the ability to describe it more specifically, and my physician never asked or helped by giving examples. The understanding that I felt lightheaded sometimes and other times like the room was spinning was a key factor in determining one, vertigo, as part of CNS lupus and the other as autonomic dysfunction from CNS lupus—orthostatic hypotension. Until both were treated, I continued to feel "dizzy," so we believed that the treatment wasn't working even though it was in many ways. This is just one example in my medical story, and many, if not all, patients have also had a delay in medical care for the same reason.

Maintenance: Individually treating both kinds of dizziness has helped me to be more functional. The vertigo improved with the CNS lupus treatments, but the lightheadedness didn't improve until I was put on the blood pressure increasing medications midodrine and droxidopa in addition. Communicating effectively with my doctors has also helped in finding and treating new conditions—dizziness was just the tip of the iceberg in my healthcare communication. Proper communication is the reason why I could get out of my wheelchair and walk, return to school, and even play volleyball again.

Quality of Life: I have a very high quality of life, being able to attend school, be involved in my community, and maintain friendships. Going to social events and being able to leave the house at all were things I took for granted before, but thankfully, I can do them again.

Disclosure: W. Carter, None.

Abstract Number: PP08

Patient Participation in the COVID-19 Global Rheumatology Alliance as a Model for Involving Patients from the Ground Up

Carly Harrison[1], Rashmi Sinha[2], Emily Sirotich[3], Naira Ikram[4], Kristen Young[5], Christele Felix[1], Karen Durrant[6], Richard Beesley[7], Serena Mingolla[8], Ana Isabel Martín Mancheño[9], Dawn Richards[10], Evelyn Olmedo[11], Wendy Costello[12], Monique Gore-Massy[13], Laurie Proulx[14], Maria Marino[15] and Richard Howard[16], [1]LupusChat, New York, NY, [2]Systemic JIA Foundation, Cincinnati, OH, [3]LA Lupus Lady, Hamilton, ON, Canada, [4]Duke University, Austin, TX, [5]Phoenix, AR, [6]Autoinflammatory Alliance, San Francisco, CA, [7]Juvenile Arthritis Research, United Kingdom, [8]Associazione Nazionale Persone con Malattie Reumatolgiche e Rare APMARR APS, Brindisi, Italy, [9]CEADE, Madrid, Spain, [10]Canadian Arthritis Patient Alliance, Toronto, ON, Canada, [11]Buenos Aires, El Salvador, [12]iCAN, Bansha, Tipperary, Ireland, [13]Lupus Foundation of America, Brooklyn, NY, [14]Canadian Arthritis Patient Alliance, Ottawa, ON, Canada, [15]Arthritis Foundation; Vectra, Athens, GA, [16]Spondylitis Association of America, Van Nuys, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 Global Rheumatology Alliance (GRA) is a volunteer-driven organization that originated in response to the global pandemic. It was created to improve patient care, by collecting and disseminating information about the impact of COVID-19 on rheumatic disease. From the very beginning GRA involved patients in its activities.

Intervention: GRA was conceptualized in Twitter discussions between rheumatologists and patient representatives. More were invited to join through social media and patient organizations. A diverse group of patients from across the world, representing many rheumatic diseases, both adult and pediatric ended up joining the effort.

GRA involves patients at all levels of the organization, while Slack channels promote open communication between patients and researchers.

Maintenance:

Collecting and Disseminating Data

A key way that GRA collects information is through its Patient Experience Survey. The goal of this anonymous survey is to understand patients' experiences managing their care during COVID-19. Representatives actively collaborated with researchers to create the survey, translate it into 9 languages, and distribute to patient groups and promote on social media.

Accessible Scientific Information

Every GRA publication is summarized into lay summaries written in non-technical language. Patients help in creating and then disseminating these summaries back to their patient groups and broader networks on social media.

Figure 1: Patient involvement in GRA in numbers

GRA Patient Engagement Structures	Number of Individuals/Units
Patient Experience Survey Responses	12,499
Survey Language Translations	9
Patient Organizations	100
Patient Board	6
Patient Slack Channel	81
Subcommittees	
Steering Committee Patient Engagement Co-Leads	2
Research	23
Communications	10
Resources	13

Figure 1. Patient involvement in GRA in numbers

Patient Representation in Organizational Structure

Patient representation is reflected in several ways: (a) two patient representatives on the steering committee, (b) a patient board that serves as a conduit between the broader patient community and GRA steering committee, and (c) three teams led by patients. The research team coordinates and develops research initiatives, the resources team compiles and shares resources, and the communications team disseminates relevant information to the broader community.

Open Communication Channels

Global communication within GRA is facilitated by the use of open, asynchronous Slack channels enabling collaborationbetween the teams, researchers, and patient representatives.

Quality of Life: The collective impact of these patient engagement efforts has been positive. Considering GRA was founded in March 2020, there are many areas for growth, and as needs are identified, GRA tries to quickly address them by creating new patient roles. While many organizations are either centered around researchers or patients, GRA uniquely facilitates collaboration and conversation between both sides, serving as a model to involve patients from the ground up.

Abstract Number: PP09

An Integrative Approach to Managing Rheumatoid Arthritis (RA): Healing the Body, Mind & Spirit

Elisabeth Abeson[1], [1]Westport, CT

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 12:00PM–1:00PM

Background/Purpose: Diagnosed with RA in 2012, rheumatologists prescribed methotrexate or a biologic. As I was profoundly impacted by my mom's 30-year battle with RA, I wanted to explore natural healing modalities as well. In partnership with my rheumatologist, I took hydroxychloroquine while specialists addressed inflammation in different parts of my body. Despite expert care, I was intuitively drawn to treating my systemic condition more holistically.

Intervention: Two elements symbiotically restored me to health: Ayurveda & a hospital-based RA Support & Education Group. 1. Ayurveda is a traditional Indian system of medicine that equates good health with a balanced body, mind & spirit - treating them collectively through diet, lifestyle & herbal remedies. A pilot study presented at the ACR found Ayurveda equivalent in efficacy as methotrexate with fewer adverse events[1]. I became a patient of the allopathic & ayurvedic authors & followed an integrative protocol ever since. 2. My RA group made allopathic (conventional western) medicine accessible by explaining RA in a patient-centric manner & addressing it on the level of body, mind & spirit. Co-facilitated by a clinical social worker & rheumatology nurse, multi-disciplinary experts led lectures & discussions that made me feel whole, heard & valued. Together, we have built an empowered community.

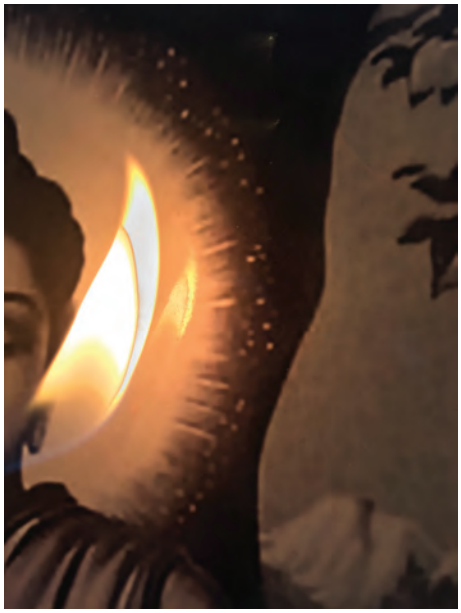
[1] __,__Double-blind, Randomized, Controlled, Pilot Study Comparing Classic Ayurvedic Medicine, Methotrexate, and Their Combination in Rheumatoid Arthritis. *J Clin Rheumatol*. 2011;17(4):185–192

Maintenance: 1. Ayurveda After 4 years on this integrative regimen, my rheumatologist shared significant improvement on several validated measures. Psychologically, Ayurveda helped heal childhood trauma, & spiritually, I reconnected with art after 25 years. At first, I processed treatment discomfort through art therapy. IMAGE 1. Later, I shared my healing journey through art to comfort others & inspire hope. 2. My RA group gifted an arsenal of clinical knowledge that made me the most valuable member of my wellness team. Emotionally, the safe environment enabled me to share my depression, deepen self-compassion & bond with peers sharing the same co-morbidity. Spiritually, our art therapy project helped me come to terms with my RA & see it as an opportunity for growth. IMAGE 2

[1] DAS, HAQ, x-rays, ultrasounds, MRIs, blood markers, ophthalmic & dental values

Quality of Life: I yearned to return to work, collaborate with kindred spirits & contribute to society. Being ill taught me I linked my identity & self-worth to professional status, so I vowed to rejoin the workforce with this awareness & value myself regardless of 'output'. I also chose to re-frame my healing journey as an asset rather than a liability. Leveraging my background in international development, I am building a practice that makes it easier for others (than it has been for me) to treat RA with ayurveda & allopathy's collective strength. Why settle on a geographic or culture-specific healing modality when battling an illness that knows no boundaries? IMAGE 3

RESTORATION TO FLIGHT © Elisabeth Abeson — IMAGE 1 OF 3 This illustration depicts a limping bird that is restored to flight – thanks to an expanded wingspan. Elisabeth created this mixed-media collage as a form of art therapy while undergoing medical treatment for her RA at an Ayurvedic Hospital in _____. The piece is composed of an x-ray of her left hand, a bird she cut out of a local newspaper, gouache, pencil & prayer beads from the Hospital's temple that honors the God of Healing. She was under the care of her long-time Ayurvedic Physician (Vaidya),_____,Chief Medical Director at___,in ___,___. Elisabeth became his patient based on his work as the Lead Investigator of the ayurvedic component of the previously-cited pilot study that was presented at ACR in 2011. She is also grateful to _____, the Lead Investigator of the allopathic component who became her Rheumatologist and supported her integrative treatment plan.



TOWARDS THE LIGHT © Elisabeth Abeson — IMAGE 2 of 3 TOWARDS THE LIGHT Depression and RA often fester together. RA has forced me to try to seek comfort and hope outside of myself. So, I have become more spiritual and faith-filled. For this I am grateful.

INTEGRATIVE MEDICINE © Elisabeth Abeson — IMAGE 3 of 3 This photo-installation is composed of organic Turmeric on an x-ray of Elisabeth's left hand. It celebrates the powerful fusion of Ayurveda, (symbolized by Turmeric, Curcuma longa, known for its anti-inflammatory properties), and Allopathic medicine, which is represented by a high-resolution radiograph. Using two different medical systems with their own distinct improvement markers & outcome measures, both Elisabeth's Rheumatologist & Vaidya (Ayurvedic Doctor) agree that a combination of the two healing modalities have improved her health.

Patients with Relapsing Polychondritis ("RP") and an Advocate Manufactured Custom Cloth Masks to Combat COVID-19: This Mask Project Provided a Sense of Purpose, Created Unity, Increased Awareness of RP, Facilitated Research, and Generated Hope

Isabel Bautista[1] and Michael Linn[2], [1]Relapsing Polychondritis Foundation, Wilmington, CA, [2]Relapsing Polychondritis Foundation, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 12:00PM–1:00PM

Background/Purpose: In 2013, I was diagnosed with Relapsing Polychondritis ("RP"), a systemic inflammatory disease of unknown etiology that can be fatal. The disease affects multiple organs, particularly cartilaginous structures such as the ears, nose, airway, and joints as well as eyes, skin, vasculature, heart valves, and brain.

After my diagnosis, I joined a private online support group (the "RP Support Group") to connect with other RP patients and gain a sense of empowerment and hope regarding this rare, debilitating disease.

Intervention: In April 2020, a member of the RP Support Group posted an inquiry asking her peers if the group could have masks created to protect our community from COVID-19. Soon after, the inquirer and five other members volunteered to donate their time and materials to make cloth masks and ear savers for RP patients, and together, became known as the "RP Mask Team."

The RP Mask Team received outstanding support from its community. Initially, we planned to work with the materials we had on hand. However, when the RP Foundation (polychondritis.org) and Race for RP (RaceForRP.org) donated custom fabric, the scope of the project grew and became an international disease awareness campaign. With funding from individual donors, the RP Mask Team was able to provide high-quality, handmade cloth masks "free of charge" to each RP patient who requested one, regardless of their geographical location.

Maintenance: With individual and institutional support, the RP Mask Team produced and shipped well over 300 masks and ear savers to patients throughout the United States, Canada, United Kingdom, France, Austria, Romania, Germany, Netherlands, Australia, and New Zealand.

Our "one of a kind" masks positively impacted international RP communities by combating the spread of COVID-19, while uniting patients, raising morale, increasing awareness of RP, and demonstrating success through collaboration.

The mask project also facilitated research. When posting information about the project, the RP Mask Team encouraged participation in the National Institutes of Health Patient Reported Symptoms Survey and a COVID-19 Patient Research Project being conducted with support from the Vasculitis Foundation, Vasculitis Clinical Research Consortium, and the RP Foundation.

Quality of Life: Having a rare disease is often extremely difficult and disheartening. Prior to the RP mask project, I was extremely stressed and had a sense of hopelessness because of COVID-19. I was especially concerned about how the pandemic would impact people with an autoimmune disease, like myself.

The RP mask project changed my perspective. It gave me a sense of purpose, created unity among the international RP communities, increased awareness about my disease, gave me an opportunity to help advance research, and perhaps most importantly, created hope. When I follow the #RPmaskteam, I see photos of other patients proudly wearing their custom RP masks increasing awareness, and this fills me with joy. When I wear my RP mask, I feel proud, strong, heard, and noticed. I believe that our custom masks give the RP community one voice that says, “we are strong, and we will triumph over relapsing polychondritis.”

Relapsing Polychondritis Mask Makers worked together to produce cloth masks to protect RP patients from COV-ID-19

Relapsing Polychondritis Ear Saver Makers worked together to protect RP patients from pain and combat COVID-19

Relapsing polychondritis patients often experience burning or throbbing ear pain, so the RP Mask Team manufactured ear savers to secure handmade cloth masks

"Knitting a Community of Hope"- Supporting, Empowering and Educating Those Living with Lupus, and Overlapping Conditions and Their Loved Ones via in Person and Virtual Support Groups That Include Art Therapy, and Wellness Techniques Is Key; Mental Health Is as Important as Physical Health

Juana Mata[1] and Ma. Estela Mata-Carcamo[2], [1]Looms for Lupus, La Puente, CA, [2]Looms for Lupus, Baldwin Park, CA

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 12:00PM–1:00PM

Background/Purpose: Juana was Diagnosed with Rheumatoid Arthritis in April 2009. In May 2009 she ended up in the hospital with a variety of symptoms and was sent home with a diagnosis of Anxiety because she insisted that something was wrong. She refused to go home unless she had testing done, after the testing was completed, She was admitted to ICU with platelet count of 2,000 (normal is 150,000-450,000), she was diagnosed with Thrombocytopenia and Lupus SLE. If she would have gone home that day she would have died. She was scared and knew very little about Lupus, she wanted to learn, and empower others about self advocacy.

Intervention: Learning about Lupus, treatments, tracking symptoms and becoming a better self advocate while working together with her care team was something that Juana and her support system had to do. Loom knitting was a great way for Juana to relieve her stress and every weekend all her family would gather to learn, support and loom knit together. Supporting each other and learning more about Lupus helped Juana and her family. Loom knitting had given Juana a stress relieving technique, it helped her fight depression and together with her family, they were knitting hope.

Maintenance: In 2011 the Mata Sisters co-founded Looms for Lupus, non profit organization that provides support, resources and awareness to minority families, those living with Lupus, overlapping conditions and their caregivers\loved ones. Juana and Estela, (caregiver\loved one) facilitate in person support group in Baldwin Park, CA and a virtual Facebook live Spanish Support Group every second Saturday of the month, where they include Art therapy such as loom knitting, painting, rock art, vision boards, other forms of art therapy and wellness techniques such as yoga, mindfulness and meditation. Living with an autoimmune and chronic condition can be hard not only physically but mentally, incorporating these modalities help in the overall health; Mental Health is as important as Physical Health.

Quality of Life: Juana and Estela are patients, advocates; together they support, empower, and educate others, helping others helps them. Educating others on different modalities to relief stress can help prevent flares and also help with their quality of life.

Empowering and supporting the caregivers by providing them with education and tools to be supportive and to also practice self care is essential for both the caregiver and the patient.

Empowering the patient on how to advocate for themselves and providing tools and resources to track their symptoms, prepare for their visits and work closely with their provider helps both the patient and the care team provide better treatments and have better patient outcomes. Educating them on insurance plans/authorizations and Maintaining copies of their medical record helps them keep track and be proactive with their care.

Art Therapy- incorporating Art Therapy can alleviate symptoms of depression, reduce stress, improve self esteem and improve mental health.

Social Media Platforms- Provide support\educate and connect via Twitter, Instagram and Facebook in English and Spanish. This helps bring up to date information and connect with others and ensure they are not alone.

Knitting a Community of Hope

COVID-19, Racism, and Gender Discrimination: The Function of Stress in Widening the Gap in Health Disparities

Carly Harrison[1] and Christele Felix[2], [1]LupusChat, Richmond, VA, [2]LupusChat, Rosedale, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2020
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 12:00PM–1:00PM

Background/Purpose: Populations experiencing rheumatic diseases are often at higher risk of increased levels of stress. This may result in disease complications and can potentially lead to escalation and development of new diseases as well. Because of the heterogeneity of many rheumatic diseases, it is difficult to understand which forms of stress could exacerbate one's condition. What is known however, is that stress intensifies mental health issues.The COVID-19 global pandemic and the national protest movement sparked by the latest round of police violence, both predominantly affect Black people. The events have caused immense stress on people with rheumatic conditions, a large percentage of which are Black, with 6.1 million Black people diagnosed with Rheumatoid Arthritis, and as many as 1 in 250 Black women diagnosed with and being treated for Lupus, according to the latest statistics for the United States.

Intervention: Because of the added danger, patients are often advised to avoid stress and/or reduce any stressful activities in their lives. We are reminded very often of the necessity of living a stress-free life as part of our care regimen for our rheumatic diseases. As is well known, mental health directly affects physical health. Added stress in patients' lives leads to increased consultations with rheumatologists and other specialists, because of the increased physical symptoms caused by stress. Additionally, psychological consults and support groups are recommended for mental and emotional support. Formal and informal support group settings are very beneficial to patients as a space to unpack their feelings and emotions.

Maintenance: The goal is to decrease stress, as stress negatively impacts patient health. To that effect, issues of health disparities as well as extrajudicial violence must be addressed. To protect the overall health of the patient, racism and gender discrimination must be highlighted and eradicated. Women, specifically Black cis women like ourselves and espcially Black women of trans experience, are dying at a disproportionate rate due to societal violence and negligence within the healthcare system. We must remember that when we protect the most vulnerable and marginalized among us, we ensure protections and a better quality of life for all.

Quality of Life: International Rheumatology organizations (and the medical community at large) should be invested in dismantling these inhumane systems that overwhelmingly affect the physical and mental health of their patients. Stress is defined as physiological disturbance or damage caused to an organism by adverse circumstances. Patients deserve a life free of such a burden as we work together with our care teams to manage our rheumatic diseases.
