Arthritis & Rheumatology

AN OFFICIAL JOURNAL OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

ABSTRACT SUPPLEMENT

ACR Convergence 2020

November 5–9, 2020

Virtual

American College of Rheumatology
Empowering Rheumatology Professionals

WILEY

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of *209.25 AMA PRA Category 1 Credits*™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)*™ must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit*™ to EACCME credit should contact the UEMS.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)*™.

Disclosure Policy
As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships that occurred in the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content. Relevant relationships include, but are not limited to:

None: Has no relevant financial relationship to disclose.
1. Stock Shareholder (excluding mutual funds)
2. Grant/Research Support
3. Employee
4. Ownership Interest
5. Consulting Fees (e.g., advisory boards)
6. Officer or Board Member
7. Royalties
8. Speaker/Honoraria includes speakers bureau, symposia, and expert witness
9. Other Financial or Material Support

Abstract author disclosures are published online. Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Abstract Embargo Policy
Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR Abstract website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until **November 2 at 2:00 PM ET.** Journalists with access to embargoed information also cannot release articles before this time.

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying colleagues, institutions, communications firms, and all other stakeholders related to the development or promotion of the abstract about this policy. If you have questions about the ACR abstract embargo policy, please contact ACR abstracts staff at abstracts@rheumatology.org.

Media
Credentialed media press attend ACR Convergence to cover stories for consumer, trade, and other media outlets and are easily identified by their black press ribbons. Media Press has access to all general sessions and limited access (at the discretion of speakers) to Meet the Professor and Workshop sessions. Media Press may use handheld audio recorders and still cameras (assuming that intellectual property copyrights are respected); moving video recording is also permitted with the advance permission of the presenter(s). This policy refers to credentialed members of the press only. No photos or video are allowed in the Poster Hall

without prior permission from the poster presenter. **The exception to this policy is that no photos or video are allowed in the Exhibit Hall.** Press who would like general photos of the Exhibit Hall can obtain these after the meeting from the ACR. Attendees who have questions about the ACR's media policies should contact the ACR public relations department at pr@rheumatology.org.

Photographs and Video Recording Policy
As a courtesy to our presenters, ACR policy does not permit photographs or recordings during educational sessions, including poster sessions. The only exception to this is for registered media, who should review their registration materials for more information.

Abstract Reprint (Reproduction) Policy
Copyright law covers all ACR Convergence abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act.

For the purposes of this statement, the term **ACR Abstracts** refers to all ACR Convergence abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARP sessions and the late-breaking category.

For the purposes of this statement, the term **ACR Posters** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during ACR Convergence. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR and the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

- For the purposes of this statement, the term "reproduce" includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.
- For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during ACR Convergence, as identified through the abstract submission process.

Approval Process for ACR Abstracts

- Excerpts or the entirety of **ACR Abstracts** may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

Permissions Department
c/o John Wiley & Sons, Inc.
111 River Street
Hoboken, NJ 07030
Fax: 201-748-6008
wiley.com/go/permissions

- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to abstractreprints@rheumatology.org.
- Poster reproduction requests must include the following:
  – Abstract ID Number
  – Abstract Title
  – Presenting Author's Name
  – A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)

Reproducing ACR Abstracts and Posters for Dissemination Prior to ACR Convergence

- Requests to reproduce abstracts for dissemination prior to ACR Convergence *will not be approved*.
- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the ACR Embargo Policy; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.

- For more information regarding press releases, please contact the ACR public relations department at pr@rheumatology.org.

Reproducing ACR Abstracts and Posters for Dissemination During ACR Convergence

- Following approval (see approval process above), an exhibiting organization may:
- Following approval (see approval process above), an exhibiting organization may disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Following approval, an exhibiting organization may disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time. Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster.

Reproducing ACR Abstracts and ACR Posters for Dissemination After ACR Convergence

ACR Abstracts

Following approval from Wiley (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following ACR Convergence.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet:
  Abstract(s) reprinted from ACR Convergence held November 5–9, 2020. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., images from the poster presentation hung in the poster hall) may be reproduced.

1. Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).

- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:
  Reprinted from the ACR Convergence held November 5–9, 2020. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).

Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Has no relevant financial relationship to disclose.

1. Shareholder
2. Grant/Research Support
3. Employee
4. Ownership Interest
5. Officer or Board Member
6. Royalties
7. Speaker/Honoraria includes speakers' bureau, symposia, and expert witness
8. Other Financial or Material Support

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during ACR Convergence is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photo-

copied, transferred to electronic format, reproduced or distributed without the prior written permission of the ACR and the presenter.

- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Table of Contents

Monday, November 9

9:00 AM - 11:00 AM
Poster Session D
(#1527-1947)

10:00 AM – 1:00 PM; 3:00 – 6:00 PM
Oral Abstract Sessions
(#1948–1952) Cytokines & Cell Trafficking
(#1953–1957) Genetics, Genomics & Proteomics
(#1958–1962) Health Services Research
(#1963–1967) Measures & Measurement of Healthcare Quality
(#1968–1972) Osteoarthritis & Joint Biology – Basic Science
(#1973–1977) Osteoporosis & Metabolic Bone Disease
(#1978–1982) Patient Outcomes, Preferences, & Attitudes II: Engagement, Perceptions, & Quality of Life
(#1983–1987) Pediatric Rheumatology – Clinical II: Outcomes & Care Delivery
(#1988–1992) Pediatric Rheumatology – Clinical III: Systemic Autoimmune Disease
(#1993–1997) RA – Treatments I: Maximizing Health in RA
(#1998–2002) RA – Treatments II: Potential Harms & Adverse Events
(#2003–2007) RA – Treatments III: Predictors of Treatment Response
(#2008–2012) RA – Treatments IV: New Therapies & Strategies
(#2013–2017) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II
(#2018–2022) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes III: Imaging in SpA
(#2023–2027) Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Emerging Therapies
(#2028–2032) Spondyloarthritis Including Psoriatic Arthritis – Treatment III: Axial Spondyloarthritis
(#2033–2037) Systemic Sclerosis & Related Disorders – Clinical I: Stratification Strategies for Clinical Trials
(#2038–2042) Systemic Sclerosis & Related Disorders – Clinical II: Lessons Learned from Clinical Trials & Cohorts
(#2043–2047) T Cell Biology & Targets in Autoimmune & Inflammatory Disease
(#2048–2052) Vasculitis – ANCA-Associated

Late-Breaking Abstracts
Monday, November 9

9:00 - 11:00 AM
Poster Session D
(#L01–L05) Late-Breaking Posters

11:30 AM - 1:00 PM
Late-Breaking Oral Session
(#L06–L11) Late-Breaking Abstracts

Abstract Number: 0001

Management of Rheumatic Diseases During COVID-19: A National Veterans Affairs Survey of Rheumatologists

Jasvinder Singh[1], John Richards[2], Elizabeth Chang[3], Amy Joseph[4] and Bernard Ng[5], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Veterans Affairs Pittsburgh Healthcare System, Pittsburgh, PA, [3]PVAHCS, Phoenix, AZ, [4]Washington University / St. Louis VA, Saint Louis, MO, [5]VA Puget Sound HCS, Seattle, WA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess the experience, views and opinions of rheumatology providers at Veterans Affairs (VA) facilities about rheumatic disease healthcare issues during the COVID-19 pandemic.

Methods: We used the Qualtrics™ survey to perform an anonymized cross-sectional survey of all VA rheumatology providers, who were members of the VA Rheumatology Consortium, a volunteer organization of VA rheumatologists. Non-responders received reminders to complete the survey from April 16 to May 18, 2020. We assessed provider experience, views and opinions about various COVID-19 issues and resilience.

Results: Of the 153 eligible VA rheumatologists, 103 (67%) completed the survey. Potential participants were slightly older (16% vs. 11% were ≥65 yrs) and more likely to be male compared to the survey responders (45% vs. 38%).

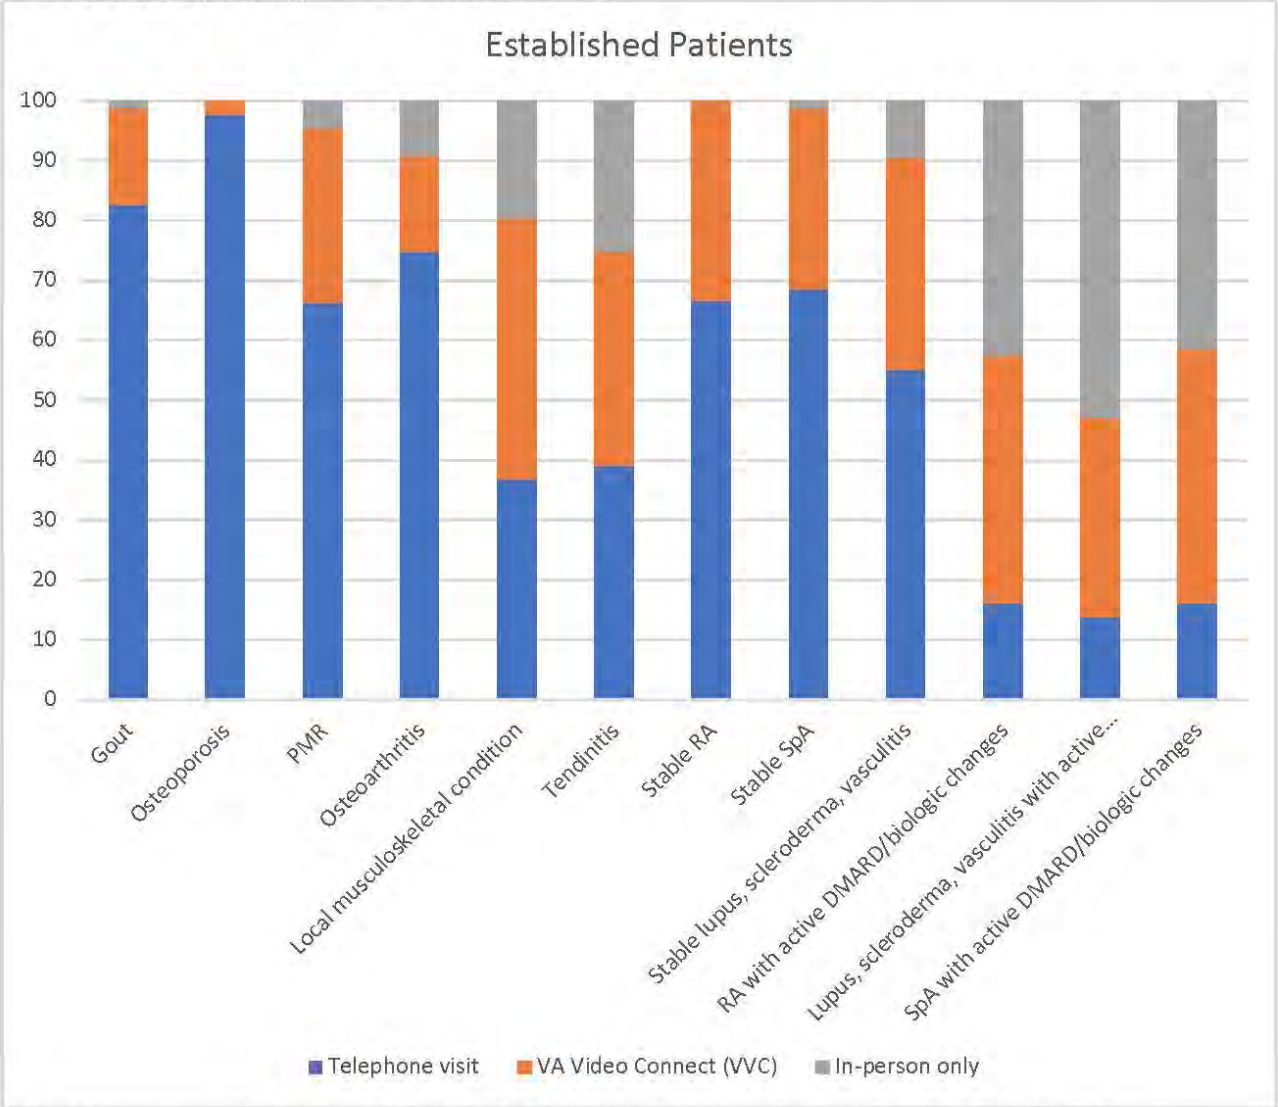
Established patients. Most/majority of rheumatologists considered that the following conditions were appropriate for telephone follow-up visits: gout, osteoporosis, polymyalgia rheumatica, sTable rheumatoid arthritis, sTable spondyloarthritis, and osteoarthritis (**Figure 1**). One-third or more rheumatologists considered it appropriate to have a video based VA video connect (VVC) visit for local musculoskeletal conditions, tendinitis, rheumatoid arthritis with active medication (DMARD/biologic) changes and patients with sTable lupus, scleroderma or vasculitis; 53% preferred an in-person for people with lupus, scleroderma, vasculitis with immunosuppressive or glucocorticoid dose changes (**Figure 1**).

Most/majority of the responders were somewhat or very comforTable with technology for providing healthcare to established patients during COVID-19 pandemic using: (1) telephone, 87%; (2) VA video connect (VVC), 64%; and (3) in-person visits, 54% (**Figure 2**). A smaller proportion were comforTable with technology providing healthcare to new clinic patients (**Figure 2**).

High provider resilience was independently associated with significantly higher odds ratio (OR) of more comfort with technology for telephone (OR, 3.1 (95% CI, 1.1-9.7)) and VVC visits for new patients (OR, 4.7 (95% CI, 1.4-15.7)), with no difference for in-person visits (OR, 1.8 (95% CI, 0.7-5.0)).

Live vaccine. Most responders would not hold hydroxychloroquine (95%) or sulfasalazine for a live COVID-19 vaccine (74%). A majority would hold methotrexate or leflunomide (66%) and glucocorticoids of 20 mg/day or higher (52%)

Figure 1. Provider preferred clinic follow-up appointment modality for established patients due to COVID-19, by the type of rheumatic disease



Y-axis represent the percent of all valid non-missing responses. The number of missing responses for each condition varied n=16 to n=18

Figure 1. Provider preferred clinic follow-up appointment modality for established patients due to COVID-19, by the type of rheumatic disease Figure 1 legend. Y-axis represent the percent of all valid non-missing responses. The number of missing responses for each condition varied n=16 to n=18. VA telehealth includes 3 modalities: (1) telephone care; (2) a video-based VA video connect (VVC) visit with the healthcare provider, usually with the patient at home; and (3) clinical video telehealth (CVT) visits with a facilitator, usually with a facilitator (nurse, technician, primary care provider) assisting patient examination at a healthcare facility close to patient's home. Due to limited relevance of CVT facilitator during the COVID-19 pandemic, choices offered were telephone care, video-based VVC or in-person visit

for 2 weeks or less (**Figure 3**); and would hold non-TNF biologics (76%), anti TNF-biologics (85%), Janus-kinase inhibitors (78%), anti IL-17/23 biologics (82%), belimumab (77%)immunosuppressive drugs such as azathioprine (64%), for 3-8 weeks (**Figure 3**).

Killed vaccine. A majority of responders (50% or higher) would not withhold these drugs for a killed COVID-19 vaccine; another 25% would hold them off for < 2 weeks (**Figure 3**).

Figure 2. Provider comfort with technology in providing care to new or established patients using each of the modality during COVID-19 pandemic

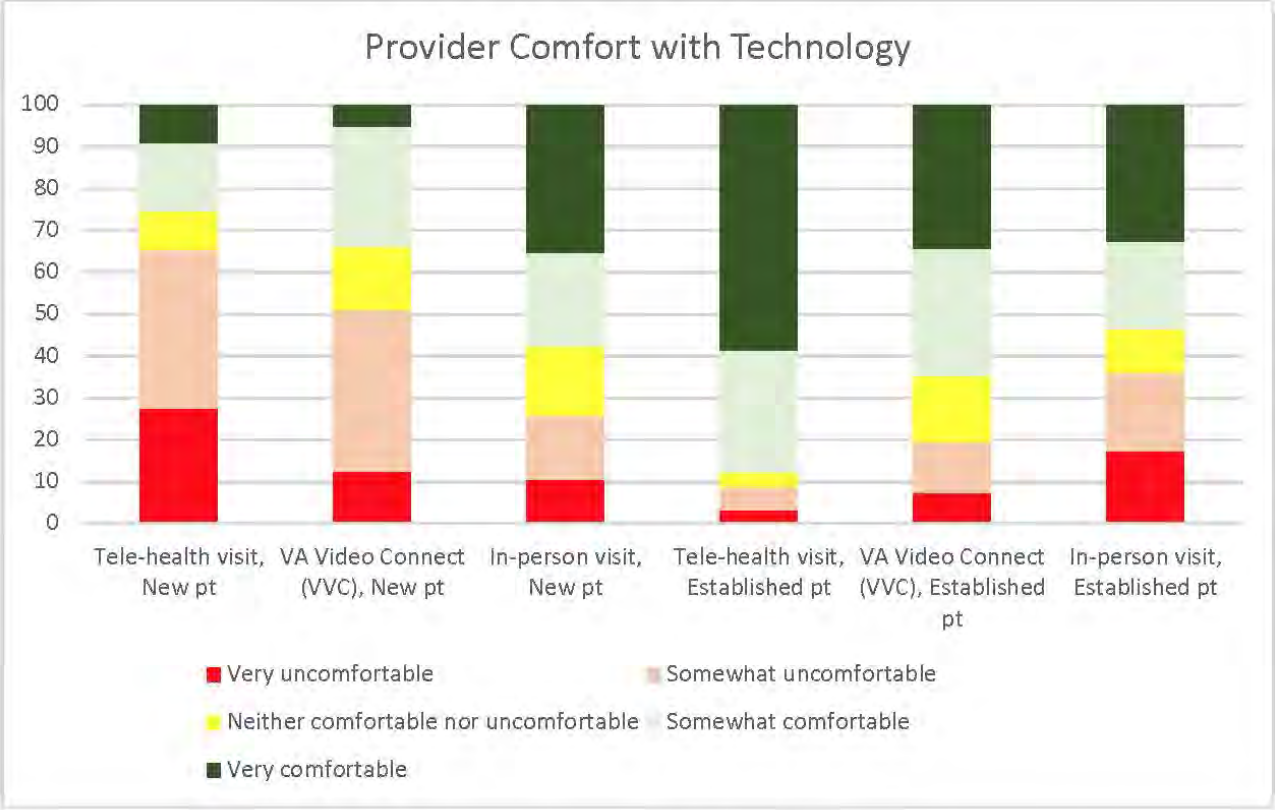


Figure Legend: The Y-axis represent the percent of all valid non-missing responses

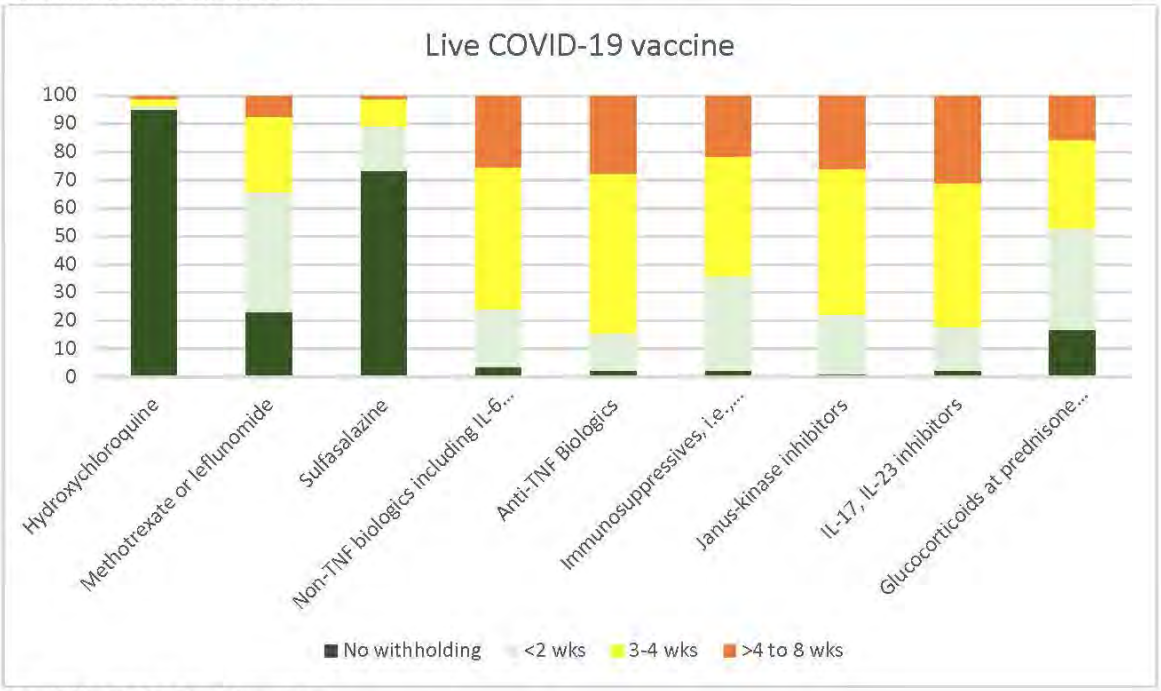
Figure 2. Provider comfort with technology in providing care to new or established patients using each of the modality during COVID-19 pandemic Figure Legend: The Y-axis represent the percent of all valid non-missing responses

Conclusion: A better understanding of COVID-19 rheumatic disease healthcare issues using a health-system approach can inform improve the care of Veterans with rheumatic disease and their providers.

Figure 3. Provider opinion on period of withholding of treatments for rheumatic diseases for administering a potential COVID-19 live (3A) or killed (3B) vaccine

3A. Live COVID-19 vaccine



3B. Killed COVID-19 vaccine

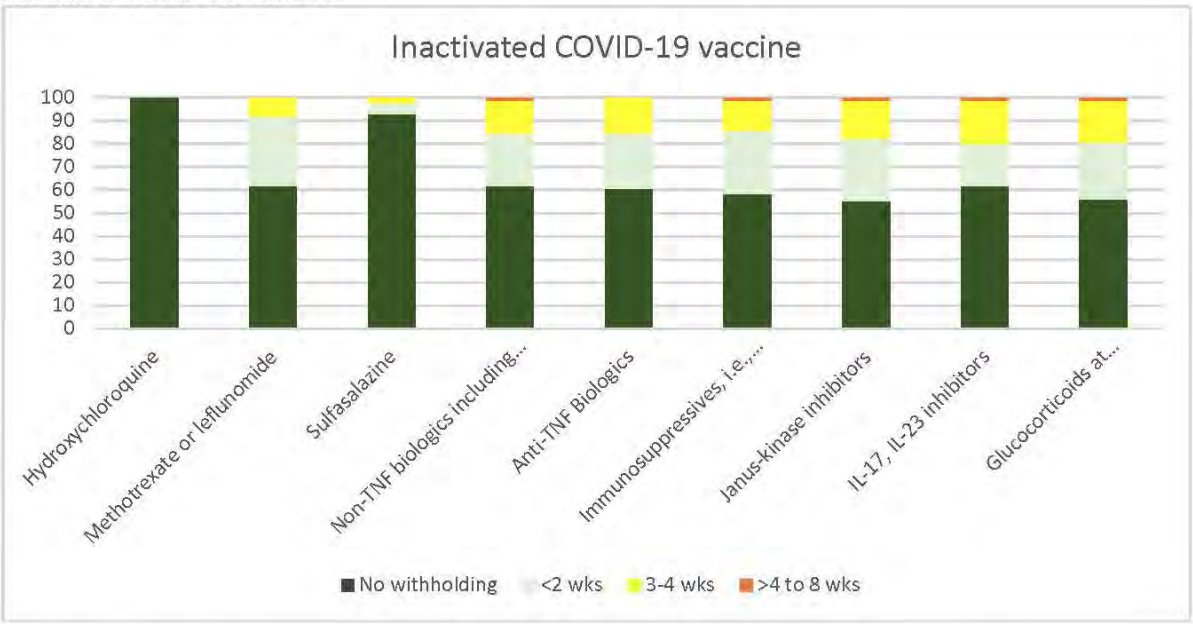


Figure Legend: The Y-axis represent the percent of all valid non-missing responses

Figure 3. Provider opinion on period of withholding of treatments for rheumatic diseases for administering a potential COVID-19 live (3A) or killed (3B) vaccine Figure Legend: The Y-axis represent the percent of all valid non-missing responses

Hydroxychloroquine and Chloroquine and Hospitalizations for Viral Infection in the Pre-COVID-19 Era

Cristiano Moura[1], Marina Machado[1], Celline Almeida-Brasil[1], Jeffrey R Curtis[2], Kevin Winthrop[3], Michal Abrahamowicz[1] and Sasha Bernatsky[4], [1]McGill University, Montreal, Canada, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]Oregon Health & Science University, Portland, OR, [4]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Chloroquine (CQ) and hydroxychloroquine (HCQ) have been shown to have antiviral properties and were considered as potential therapeutic options amid the COVID-19 pandemic. The purpose of the current study is to evaluate the risk of hospitalization for viral infections among patients previously exposed (or not) to HCQ/CQ in the pre-COVID-19 era.

Table 1 - Baseline characteristics of RA and SLE patients with outpatient viral infection, Marketscan 2011-2018.

Characteristic	RA/SLE cohort (n= 54,561)
Underlying condition	
SLE	9286 (17.0)
RA	45275 (83.0)
Female sex, N (%)	43668 (80.0)
Mean age (standard deviation), years	57.4 (13.9)
Comorbidities	
Diabetes	10416 (19.1)
Hypertension	29941 (54.9)
COPD/asthma	14611 (26.8)
Cardiovascular disease	7586 (13.9)
Congestive heart failure	3171 (5.81)
Renal disease	3767 (6.90)
Cerebrovascular disease	4632 (8.49)
Cancer	2185 (4.00)
Recent medications[2], N (%)	
Hydroxychloroquine/chloroquine	12473 (22.9)
Methotrexate	14446 (26.5)
Mycophenolate	791 (1.45)
Azathioprine	921 (1.69)
Other synthetic DMARDs[3]	4314 (7.91)
Biologics	12152 (22.3)
NSAIDs	11744 (21.5)
Corticosteroids	12923(23.7)

[1] Any time before the first episode of infection

[2] 90 days before the outpatient/emergency room diagnosis of viral respiratory infection, except for NSAIDS for which a 14-day time window was applied.

[3] Includes cyclophosphamide, sulfasalazine, and leflunomide

Table 2 – Multivariate Poisson analyses of hospitalized viral infection in RA/SLE patients

Model 1: Model without interaction			Model 2: Interaction between HCQ/CQ and underlying condition		
Variables	*RR**	*95% CI*	*Variables*	*RR*	*95% CI*
			HCQ/CQ vs non-HCQ/CQ in RA	0.86	0.66-1.13
HCQ/CQ*	0.89	0.70-1.12	HCQ/CQ vs non-HCQ/CQ in SLE	0.94	0.60-1.48
			SLE pts vs RA pts non treated	1.16	0.82-1.65
SLE	1.20	0.90-1.58	SLE pts vs RA pts treated	1.26	0.83-1.94
Female sex	0.93	0.75-1.15	Female sex	0.93	0.75-1.15
Age	**1.04**	**1.03-1.05**	**Age**	**1.04**	**1.03-1.05**
Comorbidities	**1.86**	**1.41-2.45**	**Comorbidities**	**1.86**	**1.41-2.45**

Mycophenolate	**2.54**	**1.51-4.28**	**MMF**	**2.54**	**1.51-4.26**
Azathioprine	**1.90**	**1.12-3.22**	**Azathioprine**	**1.89**	**1.12-3.20**
Other DMARDs	1.17	0.86-1.59	DMARDs	1.17	0.86-1.59
Corticosteroids	**1.57**	**1.29-1.91**	**Corticosteroids**	**1.57**	**1.29-1.91**
Biologic	1.10	0.87-1.37	Biologic	1.09	0.87-1.37
NSAID	0.88	0.69-1.12	NSAID	0.88	0.69-1.12
Emergency room	3.06	2.46-3.82	Emergency room	3.06	2.46-3.82

*RR=risk ratio; all drug exposures were at the time of initial outpatient

Methods: We studied adult rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) individuals identified in the MarketScan database with an outpatient diagnosis (including emergency room, ER) of viral pneumonia or other viral acute respiratory infections. We required patients to be covered in the medical/pharmacy plan at least one year before time zero (date of outpatient infection). The main exposure was recent use of HCQ/CQ in the 90 days prior to time zero. We defined the outcome as hospitalization for viral infection within the 30 days after time zero. We used multivariate Poisson regression models with a robust error variance to estimate hospitalization in relationship to exposure to these drugs. Our models included demographic variables (age, sex), setting in which viral infection was initially identified (ER or other), underlying condition (RA or SLE), comorbidities, and use of other medications (modeled in the same way as the main exposure): methotrexate (MTX), mycophenolate (MMF), azathioprine, other DMARDs (cyclophosphamide, sulfasalazine, and leflunomide), corticosteroids, biologics, and NSAIDs. Analysis were combined for RA and SLE patients, but interaction terms were included to allow for the effect of HCQ to differ in the two conditions.

Results: We identified 63,971 episodes of outpatient infections among 54,561 RA/SLE patients. Baseline characteristics are presented in Table 1. Individuals were mostly women (80%), with average age of 57.4 years (standard deviation, SD 13.9). During the 30-day period following outpatient infection, we found 480 occurrences of hospitalization for viral respiratory infections. In adjusted multivariate analyses, we were unable to detect a clear difference in the risk of hospitalized viral infection when comparing recent versus non-recent use of HCQ/CQ in the past 90 days before the initial outpatient viral infection (adjusted RR: 0.89, 95% CI: 0.70–1.12; Table 2). In the same model, we found that comorbidity, ER presentation, older age, and MMF, azathioprine, and corticosteroids were all significantly associated with hospitalized viral infection.

Conclusion: While we saw no clear effect of HCQ/CQ, comorbidity, ER presentation, older age, and MMF, azathioprine, and corticosteroids were all significantly associated with hospitalized viral infection in RA and SLE.

Baseline characteristics of RA and SLE patients with outpatient viral infection, Marketscan 2011-2018.

Assessing Cytokine Profiles and COVID Serology in Patients on Immunosuppression to Guide Care Recommendations

Quinn Pritchett[1], Rebecca Overbury[1], Dorota Lebiedz-Odrobina[1], Julie Thomas[1], Tawnie Braaten[2], Stacey Clardy[1], Marc Elgort[3], Emily Spivak[1], Patricia Slev[3], Lisa Peterson[3] and Tracy Frech[4], [1]University of Utah, Salt Lake City, UT, [2]University of Utah, Salt Lake City, [3]ARUP, Salt Lake City, UT, [4]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic is especially terrifying for patients on immunosuppression for autoimmune disease. With the exception of social isolation, experts do not have clear guidelines for these patients due to the concern that stopping medications may increase risk of autoimmune disease flares and pro-inflammatory cytokine/chemokine response. These same inflammatory molecules are thought to be responsible for virus-induced immunopathological events and death in COVID-19. The purpose of this project is to establish guidelines for management of immunosuppression in autoimmune disease patients and collect pilot data to develop strategies at the healthcare system level to address barriers and facilitators in the treatment of high-risk populations.

Methods: Participants were consented prior to blood collection for routine toxicity monitoring (IRB #00131823). Patients verified their autoimmune diagnosis; current immunosuppression medication list; and whether they believe they currently have or had symptoms of COVID-19. They were asked if they had previous COVID PCR testing and those results. A cytokine panel developed by ARUP (Test #0051394) assessed the concentrations of interleukin (IL)-2 receptor (IL-2r), soluble, TH1 cytokines (interferon (IFN)-γ, IL-2, IL-12); TH2 (IL-4, IL-5, IL-10, IL13); Monokines (tumor necrosis factor (TNF)-α, IL1β, IL6, IL8) and IL-17. COVID-19 IgG serologic testing developed by ARUP for research purposes was performed. We summarized demographics and clinical outcomes of interest using median and range for distribute skew continuous variable; we reported counts for categorical variables.

Results: Thirty-nine patients with autoimmune disease on immunosuppressive/immunomodulatory therapy were enrolled between April 18 and May 21, 2020. The clinical features of these patients shown in Table 1. The median age of participants was 45 years within the range of 23 to 76 years. Most participants were white (n=27, 69%), females (n=35, 90%) and had a diagnosis of systemic sclerosis (n=27, 69%). Half of these patients were on hydroxychloroquine (n=20, 51%). One patient reported current COVID symptoms and five patients were previously symptomatic for COVID-19 infection. One patient that obtained COVID PCR testing while symptomatic was positive. There was minimal elevations in cytokine profiles including, IL-2r (n=2), IL-10 (n=1), and IL-6 (n=1). Serology testing of The Utah COVID cases by testing day are described in Figure 1. Only one patient of the five reporting previous symptoms was positive for COVID IgG. This subject had rheumatoid arthritis (RA) and was on Enbrel. She reported diarrhea and a

Table 1. Characteristics of the 2163 participants in the survey

Methods: A web-based cross-sectional survey was designed by the Arab Adult Arthritis Awareness group (AAAA) consisting of 16 rheumatologists representing countries from the Arab League of Associations for Rheumatology (ArLAR) and was validated by the ArLAR scientific committee. The survey was disseminated through social media and patients' associations' channels between May 8 and May 22, 2020. The steering committee developed recommendations to improve the care of patients with chronic rheumatic diseases during the COVID-19 pandemic.

Results: A total of 2163 patients were included in the analysis; 72% were females; their mean age was 40 years (SD 11.9). The Levant, the Gulf, and North Africa contributed almost equally to the sample (Table 1). The COVID-19 pandemic had a significant negative impact on rheumatology visits in 82% of cases, including 27% where it had been impossible to contact the rheumatologist. The negative impact was also significant on the access to hydroxychloroquine (HCQ) (47% of cases), and on chronic medication persistency (partial or complete discontinuation in 28%) (Table 2). The negative impact on rheumatology visits was associated with the female gender, the country of residence, the medication non-persistency, the isolation due to COVID-19, and the impact on mental health (Table 3). The pandemic had an impact on mental health in 73% of the participants (minor in 48%, major in 25%). The impact on mental health was associated with the country of residence, the rheumatology visits, the medication non-persistency, the decreased access to HCQ, the personal infection with SARS-CoV-2, the isolation due to COVID-19 and the negative impact on income. Sixty-one patients (2.8%) stated that they had COVID-19, 5% said that a close contact was infected, and 47% were in isolation because of COVID-19. When asked about their attitude towards telemedicine, 98.8% said that they would accept a teleconsultation (50% through the internet and 48.8% through a telephone contact).

Impact of COVID-19 pandemic	Type of impact	N	%
Impact on rheumatology visit	Not affected	371	17.2
	I can see my rheumatologist only in emergencies	511	23.6
	I can only have a remote contact with my rheumatologist	625	28.9
	It is impossible to see my rheumatologist	578	26.7
Impact on access to Hydroxychloroquine (HCQ)	No impact	872	52.8
	Shortage of HCQ	297	18
	Difficulty to access HCQ	481	29.2
Impact on persistency on chronic medication	No impact	1495	69.1
	I stopped all medication because of the fear of infection	98	4.5
	I stopped some medication because of the fear of infection	177	8.2
	I stopped some medication because of drug shortage	317	14.7
Impact on mental health	No impact	511	23.6
	Minor effect	1044	48.3
	Major effect	540	25.0
Impact on income	Not affected	821	38.0
	Slightly affected	657	30.4
	Significantly affected	589	27.2
Personal infection with SARS-Cov-2	Yes	61	2.8
Contact infection with SARS-Cov-2	Yes	106	4.9%
Personal isolation due to COVID-19	Yes	1009	46.6%

Table 2. Impact of COVID-19 pandemic on patients with chronic rheumatic diseases

	OR*	95% CI		p-value

Mental impact of COVID-19	1.49	1.07	2.07	0.018
Accepting a teleconsultation	0.27	0.08	0.93	0.006

* After adjusting on: HCQ difficulty, Mask, Precautions, Personal COVID infection, Contact COVID infection, Impact on income, Impact on mental health

Table 3. Factors associated with a negative impact of the COVID-19 pandemic on the patient's visit to the rheumatologist

Conclusion: The current study highlights the deleterious consequences of the COVID-19 pandemic on the continuity of rheumatology care, the persistence on chronic medication, and the patients' mental health, all key predictors of disease prognosis. Therefore, an action plan, including establishing a telemedicine platform, securing drug availability, and promoting medication persistence through the appropriate communication channels, is strongly recommended.

Geographical Variations in COVID-19 Perceptions and Patient Management: A National Survey of Rheumatologists

Bella Mehta[1], Deanna Jannat-Khah[2], Carol Mancuso[3], Anne Bass[1], Carine Moezinia[4], Allan Gibofsky[3], Susan Goodman[5] d Said Ibrahim[6], [1]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [2]Hospital for Special Surgery, New York City, NY, [3]Hospital for Special Surgery, New York City, [4]Hospital for Special Surgery, New York, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [6]Weill Cornell Medicine, Cleveland, OH

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the perceptions and behaviors of rheumatologists in the United States (US) regarding the risk of COVID-19 for their autoimmune patients and the subsequent management of immunosuppressive and anti-inflammatory medications.

Methods: We administered an online survey to a convenience sample of rheumatologists in the US from 4/8/20-5/4/20 via social media and group emails. Survey respondents provided demographic information such as, age, gender, state of practice, and practice type. We asked questions about what they perceived their rheumatic patients COVID-19 risk to be, and furthermore what their management of immunosuppressive (steroids, biologics) and non-steroidal anti-inflammatory (NSAID) medications has been during the pandemic. Descriptive analyses were performed.

Results: 271 respondents completed the survey nationally. 48% of respondents either agreed or strongly agreed with the statement "Patients with rheumatic diseases are at a *higher risk* of COVID-19 irrespective of their immunosuppressive medications".(Figure 1) 50% disagreed or strongly disagreed with the statement "The pandemic has led you to reduce the use/dosage/frequency of biologics", while 56% agreed or strongly agreed with the statement "The pandemic has led you to reduce the use/dosage/frequency of steroids". A third of respondents indicated that at least 10% of their patients had self-discontinued or reduced at least one immunosuppressive medication to mitigate their risk of COVID-19. Responses to these questions as well as to questions regarding NSAID prescription patterns were significantly different in the Northeast region of US compared to other regions.(Figure 2)

Conclusion: In this national sample of rheumatologists, there are variations regarding perceptions of patients' risk of COVID-19, and how to manage medications such as NSAIDs, biologics and steroids during the pandemic. These variations are more pronounced in geographical areas where COVID-19 disease burden was higher. Limitations include difficultly to obtain a survey response rate; this was an online survey advertised through social media and email campaigns, so we cannot estimate how many rheumatologists had the opportunity to participate. Of those who the survey reached, the rheumatologists who chose to respond may reflect a respondent bias.

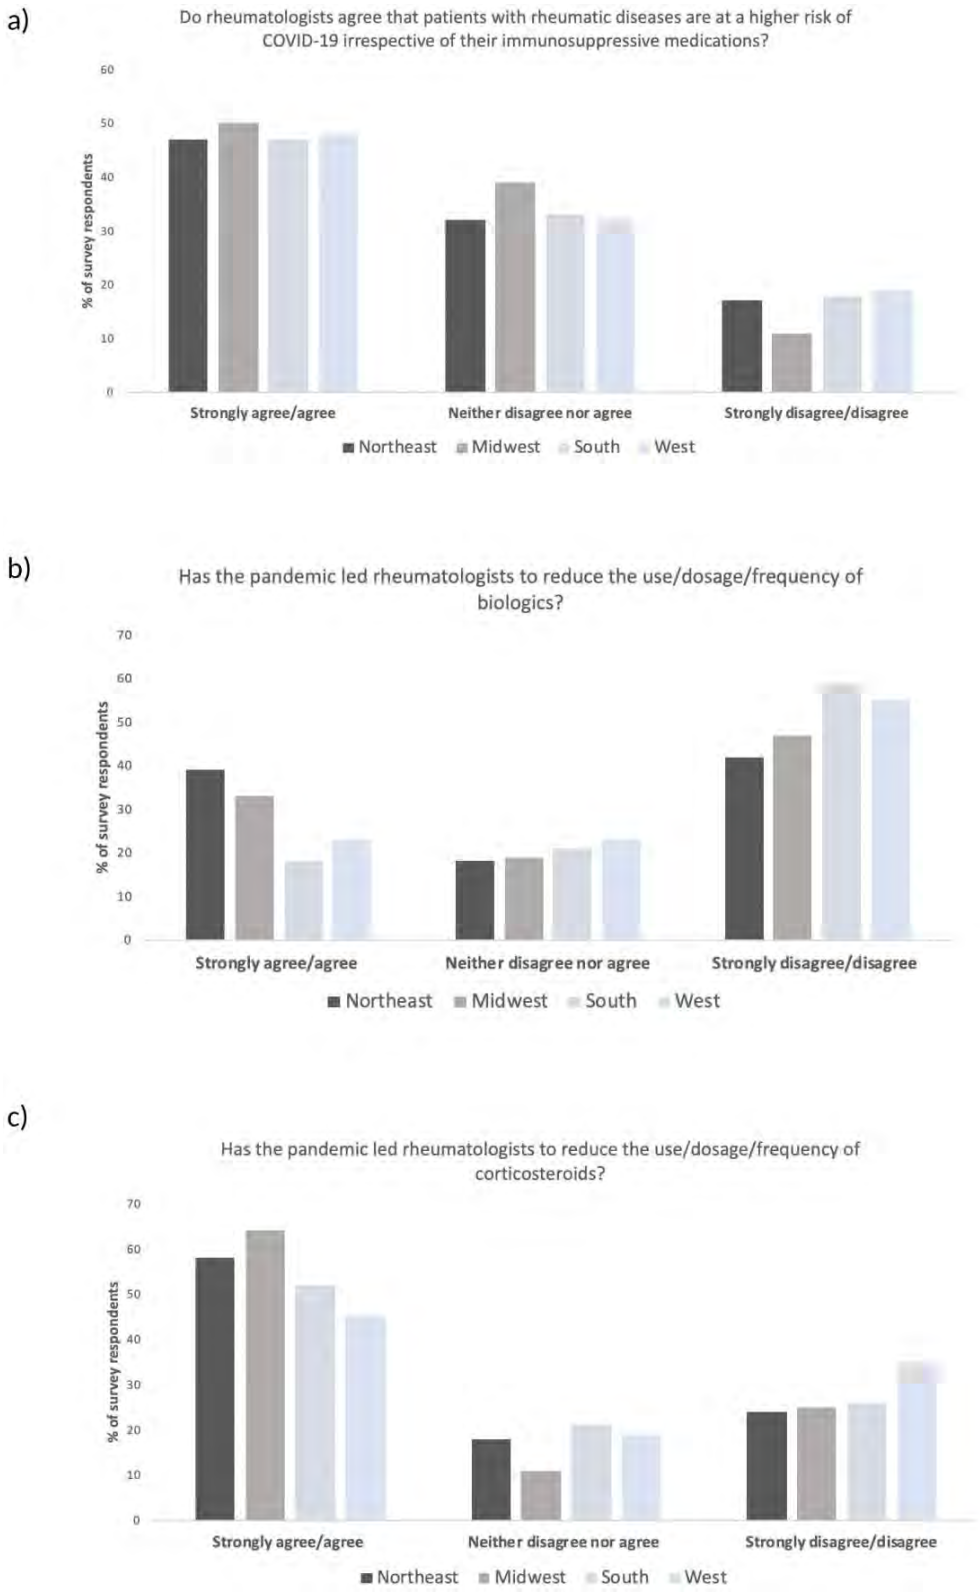

Figure 1. 1a) Responses to whether rheumatologists think their patients are at higher risk for COVID-19 1a) Responses to whether rheumatologists are altering biologic regimes during the pandemic 1c) Responses to whether rheumatologists are altering corticosteroid regimes during the pandemic

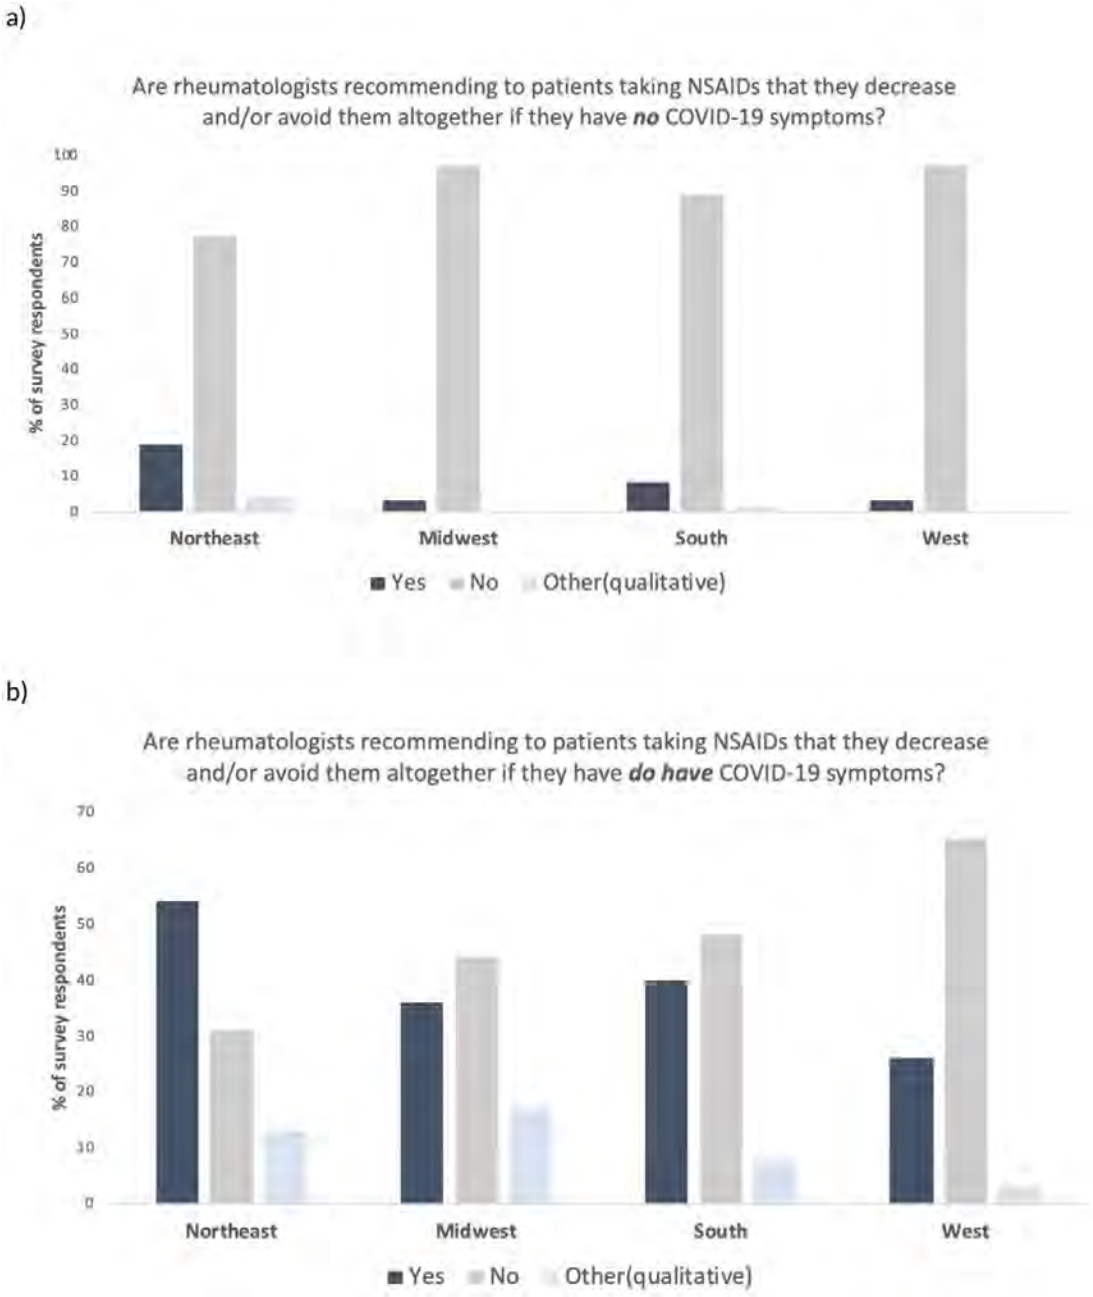

Figure 2: 2a) Responses to whether rheumatologists are recommending patients with no COVID-19 symptoms to decrease or avoid NSAIDs. 2b) Responses to whether rheumatologists are recommending patients with COVID-19 symptoms to decrease or avoid NSAIDs

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with rheumatic disease, particularly those on immunosuppressive medications, have a higher risk of developing severe infections. However, whether these patients experience more severe outcomes of COVID-19 is unknown, as is whether outcomes vary by race/ethnicity as has been demonstrated in the general United States (US) population. The aim of this study was to examine the association between race/ethnicity and COVID-19 hospitalization, ventilation status, and mortality in people with rheumatic disease using data from the largest case series to date.

Methods: Patients with rheumatic disease and COVID-19 from the COVID-19 Global Rheumatology Alliance physician registry from March 24, 2020 to May 22, 2020 were included. The analysis was limited to patients in the US. Race/ethnicity was defined as white, black, Latinx and other. COVID-19 outcomes included hospitalization status (yes/no), requirement for ventilatory support (not hospitalized/no supplementary oxygen; supplementary oxygen or non-invasive ventilation; invasive ventilation/ECMO), and death (yes/no). Multivariable logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) of hospitalization; ordinal logistic regression was used to estimate ORs and 95% CIs of ventilatory support; and Poisson models were used to estimate ORs and 95% CIs of mortality. All models were controlled for age, sex, smoking status, rheumatic disease diagnosis (RA, SLE, PsA, AS or other spondyloarthritis, other), comorbidities (hypertension/cardiovascular disease, lung disease, diabetes, and chronic renal insufficiency/end stage renal disease), rheumatic disease medications taken prior to infection (conventional synthetic DMARD (csDMARD) monotherapy; biologic and targeted small molecule DMARD monotherapy (b/tsDMARD); csDMARD + b/tsDMARD combination therapy), NSAID use, prednisone-equivalent glucocorticoid use, and rheumatic disease activity (remission/low vs. moderate/high).

Results: A total of 694 patients were included. Disease characteristics and outcomes by race/ethnicity are shown in Table 1. In multivariable models, racial/ethnic minorities were more likely to experience poor outcomes, including hospitalization and requirement for ventilatory support, compared to white patients (Table 2). Black and Latinx patients had 2.70 and 1.98 higher odds of being hospitalized compared to white patients, respectively ($P< 0.01$, $P=0.01$).

Table 1. Rheumatic Disease Characteristics and COVID-19 Outcomes by Race/Ethnicity (N=694)

Table 2. Association between race/ethnicity and COVID-19 outcomes*

	Hospitalization N=599	Ventilation N=540	Death N=681
Race/Ethnicity			
White	*Ref*	*Ref*	*Ref*
Black	2.70 (1.66, 4.42), *P*<0.01	3.10 (1.77, 5.41), *P*<0.01	1.10 (0.49, 2.50), *P*=0.81
Latinx	1.98 (1.17, 3.33), *P*=0.01	2.97 (1.63, 5.41), *P*<0.01	1.78 (0.84, 3.78), *P*=0.13
Other/Mixed Race	1.79 (0.93, 3.44), *P*=0.08	2.34 (1.11, 4.95), *P*=0.03	1.22 (0.35, 4.26) *P*=0.76

*Models adjusted for sex, age greater than 65, rheumatic disease, comorbidities, ever smoking, medication prior to COVID-19, NSAID use, glucocorticoid use, and disease activity; sample size varies due to missing data on outcomes

Black and Latinx patients also had a three-fold increased odds of requiring ventilatory support compared to white patients ($P < 0.01$). No differences in mortality based on race/ethnicity were found.

Conclusion: Similar to findings in the general US population, we found that racial/ethnic minority patients with rheumatic disease had increased odds of hospitalization and invasive ventilation in the rheumatic disease population even after adjustment for disease and comorbidities. These results further illustrate health disparities related to COVID-19 and suggest that attention should be drawn to addressing the needs of vulnerable populations during public health emergencies.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Early in the COVID-19 pandemic, hydroxychloroquine and chloroquine were empirically promoted and used for treatment and prevention of SARS-CoV-2 infection. The repurposing of these drugs before robust efficacy data were available led to potentially harmful shortages for people with rheumatic diseases. The aims of this study were to assess (1) whether the use of antimalarials in patients with rheumatic disease was associated with a lower risk of COVID-19 infection, and (2) the prevalence and impact of drug shortages during the COVID-19 pandemic.

	All Patients (n = 9393)	Patients on antimalarials (n = 3872)	Patients not on antimarials (n = 5521)

Table 1. Demographic and clinical characteristics of adults according to use of antimalarials in the C19-GRA Patient Experience Survey (n=9393). Participants may have more than one condition and take more than one type of medication. csDMARD medications included: antimalarials (hydroxychloroquine, chloroquine), azathioprine, cyclophosphamide, cyclosporine, leflunomide, methotrexate, mycophenolate mofetil/mycophenolic acid, sulfasalazine, tacrolimus. bDMARD included: abatacept, belimumab, CD-20 inhibitors, IL-1 inhibitors, IL-6 inhibitors, IL-12/IL-23 inhibitors, IL-17 inhibitors, and anti-TNF. tsDMARD included: Janus Kinase inhibitors. Other included: IVIG, apremilast, thalidomide. bDMARD, biologic DMARD; csDMARD, conventional synthetic DMARD; tsDMARD targeted synthetic DMARD, DMARD, disease-modifying antirheumatic drug..

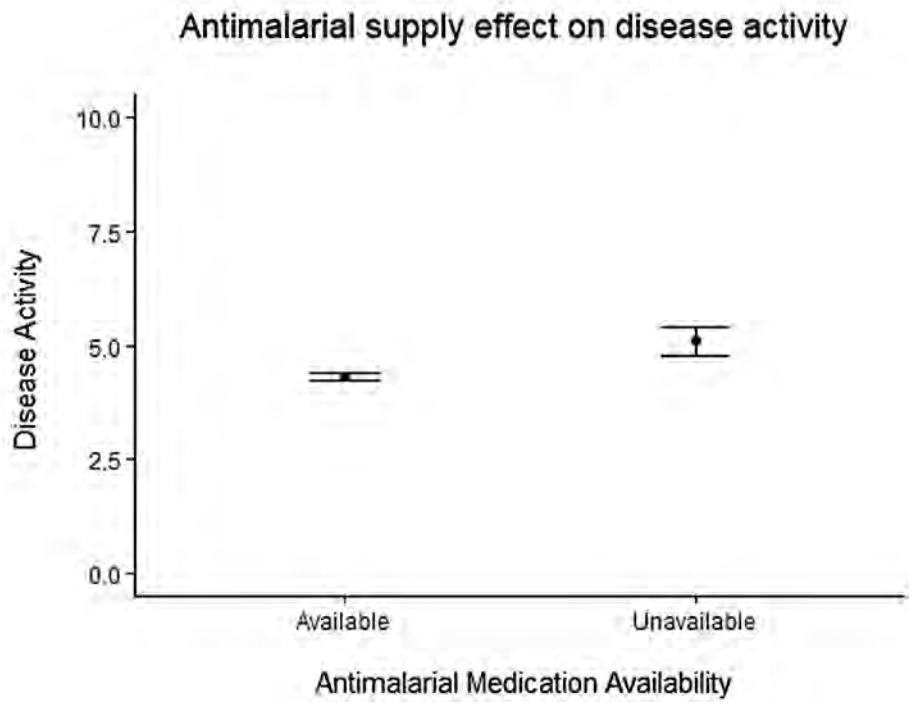

Figure 1. Antimalarial supply effect on disease activity in rheumatic disease patients.

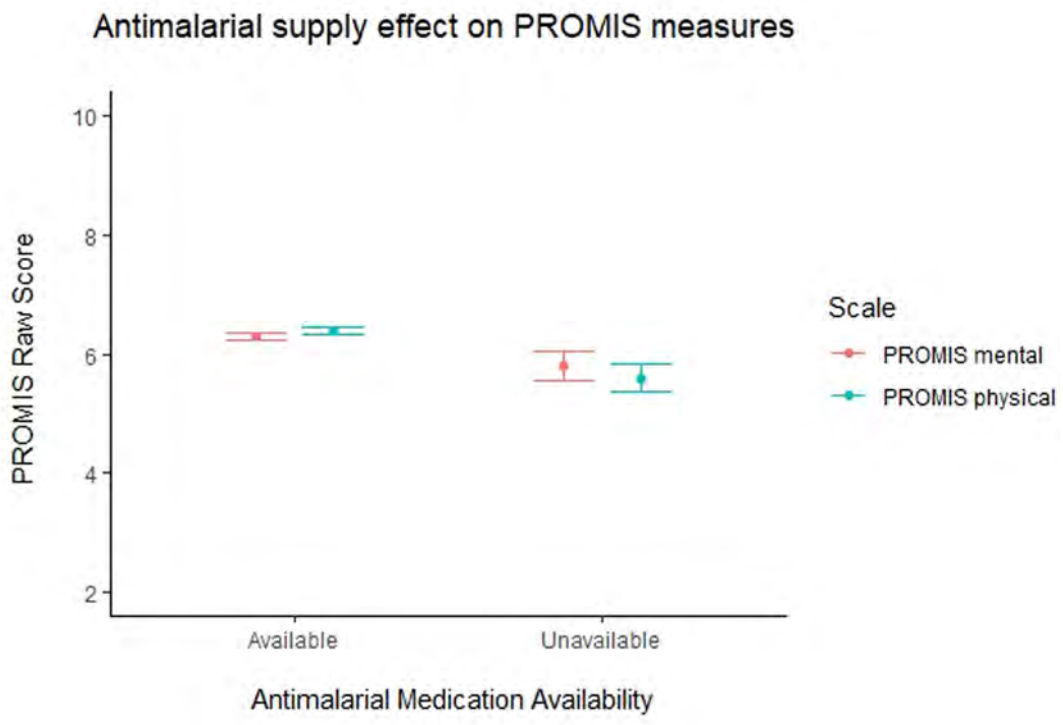

Figure 2. Antimalarial supply effect on PROMIS measures in rheumatic disease patients.

Methods: The COVID-19 Global Rheumatology Alliance (C19-GRA) Patient Experience Survey was distributed online through patient support organizations and on social media. Patients with rheumatic diseases (or the parents of pediatric patients) anonymously entered data including their rheumatic disease diagnosis, medications, COVID-19 status, and disease outcomes. Impact of drug shortages was evaluated for the effect on patient disease activity,

mental health and physical health states by comparing mean values with two-sided independent t-tests to identify significant differences.

Results: From 9,393 respondents (mean age 46.1 (SD 12.8) years, 90.0% female), 3,872 (41.2%) were taking antimalarials (Table 1). Of these, 230 (6.2%) were unable to continue taking antimalarials because of a lack of supply at their pharmacy. 21.4% of patients in South-East Asia and 26.7% in African regions reported an inadequate supply of antimalarials in pharmacies, in contrast to 6.8% of patients in the Americas and 2.1% in European regions.

There were similar rates of COVID-19 infection among patients on antimalarials as compared to patients not on these drugs (6.7% vs. 4.7%). A total of 28 patients (10.8%) with COVID-19 who were taking antimalarials were hospitalized. Of 519 patients diagnosed with COVID-19, 68 (13.1%) indicated they were prescribed antimalarials as a treatment for their COVID-19 infection.

Patients who were unable to obtain antimalarials from their pharmacies compared to those who did not experience medication shortages experienced higher levels of rheumatic disease activity ($5.1 > 4.3$, $t(244) = 4.44$, $p < 0.001$) (Figure 1) and poorer mental ($5.8 < 6.3$, $t(252) = 3.82$, $p < 0.001$) and physical health ($5.6 < 6.4$, $t(254) = 5.97$, $p < 0.001$) (Figure 2).

Conclusion: Patients in African and South-East Asian regions reported greater difficulty obtaining antimalarial drugs to treat their rheumatic disease in contrast to patients in the Americas and European regions. Patients who experienced antimalarial drug shortages reported worse mental and physical health outcomes than those able to obtain their medications. Antimalarials did not protect patients with rheumatic disease from COVID-19 or from hospitalization as a result of COVID-19. The unintended harmful consequences of repurposing antimalarials, without adequate evidence for benefit, highlights the importance of maintaining scientific rigor even in the context of a pandemic. Regional disparities of access to medications should be addressed to ensure all people, particularly those living in developing countries, receive fair and equiTable access to these essential medications.

Abstract Number: 0008

COVID-19 Infection Among Patients with Rheumatic Disease on Biologic & Targeted Therapies: A Systematic Review

Akhil Sood[1], Arbi Galestanian[1], Vijaya Murthy[2], Emilio Gonzalez[1] and Mukaila Raji[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Medical Branch, League City, TX

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Information about the outcomes of patients with rheumatic disease with SARS-CoV-2 infection is scarce. Patients with rheumatic disease on immunosuppressive medications might represent a population at increased risk of SARS-CoV-2 infection or serious infection. Interestingly, few studies have suggested protective role of these drugs for COVID-19. We thus conducted a systematic review of studies reporting outcome of COVID-19 infection among patients with rheumatic diseases on biologic & targeted therapies.

Methods: We systematically searched PubMed/Medline and Scopus from January 1, 2020 to June 1, 2020 to identify studies that reported outcome of COVID-19 among patients with rheumatic disease. Demographic information, use of biologic (anti-TNF, IL-1, IL-6, IL-17, IL-12/IL-23, B cell, or T cell) or targeted therapy (Janus kinase inhibitor) were extracted from studies. The outcome measured was hospitalization, ICU admission, and death. Based on the clinical symptoms and need for hospitalization and ICU care, patients were grouped into severe (increased risk of respiratory failure or life-threatening complications) or non-severe.

Results: Our systematic review included eight observational cohort studies which comprised of 6095 patients with rheumatic disease. Of these, 123 patients (2%) were positive or highly suspicious for COVID-19 infection based on clinical features. The most common rheumatic diseases were rheumatoid arthritis (28%) and psoriatic arthritis (7%). The proportion of COVID-19 patients on biologics across all studies was 68%. The most common biologic agent was anti-TNF agents (31%). The percentage of users of JAK inhibitors was 6%. Among those with SARS-COV2 infection, 91 patients (73%) were not hospitalized. Among those hospitalized, 13 patients (11% of total) required ICU admission and 4 patients died (3.2% of total).

Conclusion: In this systematic review, the incidence of COVID-19 infection was low in patients with rheumatic disease. The majority had a mild clinical course and case fatality was low. However, larger cohort studies are necessary to examine outcomes of COVID-19 among biologic and non-biologic users. Furthermore, factors such as disease severity index and duration of biologic & targeted therapy use need to be considered in future studies.

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Antimalarial drugs (ADs), including chloroquine (CQ) and hydroxychloroquine (HCQ), have anti-inflammatory, immunomodulatory, antiparasitic, anti-thrombotic, and antiviral properties. Their indications in rheumatology have been known for many years, especially in systemic lupus erythematosus, Sjogren's syndrome, or rheumatoid arthritis. Their recent use in treatment protocols for COVID-19 has been the subject of controversy for a number of reasons, including their potential side effects (SEs). The purpose of this study is to determine the

Table 1. Characteristics of the population.

- : not reported

Table 3. Number of side effects leading to definitive cessation of antimalarial drugs.

prevalence of SEs, and to study the association between their characteristics and the type of ADs in a rheumatologic population.

Methods: We conducted a retrospective study on medical records of patients hospitalized then followed up in the Department of Rheumatology of the University Hospital of Ibn Rochd, between January 2010 and April 2020, who were treated with CQ or HCQ. The SEs were recorded from a pre-established exploitation sheet. Drug causality was assessed using the World Health Organization Uppsala Medical Center (WHO-UMC) system for standardized case causality assessment. SEs were included if they pertained to the categories of "Certain", "Probable/Likely", or "Possible"; and they were excluded if they pertained to the categories of “Unlikely”, “Conditional/Unclassified”, and “Unassessable/Unclassifiable”. The prevalence of SEs is estimated with a confidence interval of 95%, and the study of the factors associated with SEs is performed with univariate analysis with a significance threshold of $p < 0.05$.

Results: 115 patients received ADs, of which 96% were females, with a mean age of 47 (16 – 82). The indications for ADs were systemic lupus erythematosus (31%), rheumatoid arthritis (30%), and primary Sjogren’s syndrome (18%). The overall prevalence of SEs is 39% (30% – 48%). The specific prevalence of SEs is 37% (26% – 47%) under HCQ, and 45% (28% – 63%) under CQ. 57% of the SEs are ophthalmic, 33% are cutaneous, and 2.2% are cardiovascular.

36% of SEs resulted in the definitive cessation of ADs, 24% under HCQ and 12% under QC. Maculopathy was the main reason for definitive cessation of ADs (43%). The average duration of treatment is significantly different ($p < 0.01$) with HCQ (3.5 years) versus CQ (7 years). There was no significant association between the categories of SEs and the type of ADs.

Conclusion: n our study, almost two fifths of the patients under ADs presented SEs, with a higher prevalence in the CQ group than in the HCQ group. In addition, prolonged use of ADs is mainly limited by the risk of maculopathy, which is the most frequent cause of definitive cessation. However, the administration of short-course ADs with high doses, as in COVID-19, is likely to modify the prevalence of ADs, compared to those found in rheumatology practice.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Antirheumatic disease therapies have been used to treat coronavirus disease 2019 (COVID-19) and its complications. There has been particular interest in the antimalarial agent hydroxychloroquine (HCQ) and in agents that inhibit interleukin-1 (IL1) or interleukin-6 (IL-6). We conducted a systematic review and meta-analysis to describe the current evidence.

Methods: A search of published and preprint databases in all languages was performed on 3/19/2020 and updated on 05/07/2020. Included studies described one or more relevant clinical outcomes in five or more people who were infected with SARS-CoV-2 and were treated with antirheumatic disease therapy. Pairs of reviewers screened articles and extracted data. The risk of bias was assessed using the Newcastle-Ottawa Scale for cohort studies and the Risk of Bias 2.0 tool for randomized controlled trials (RCTs). A meta-analysis of effect sizes using random-effects models was performed when possible.

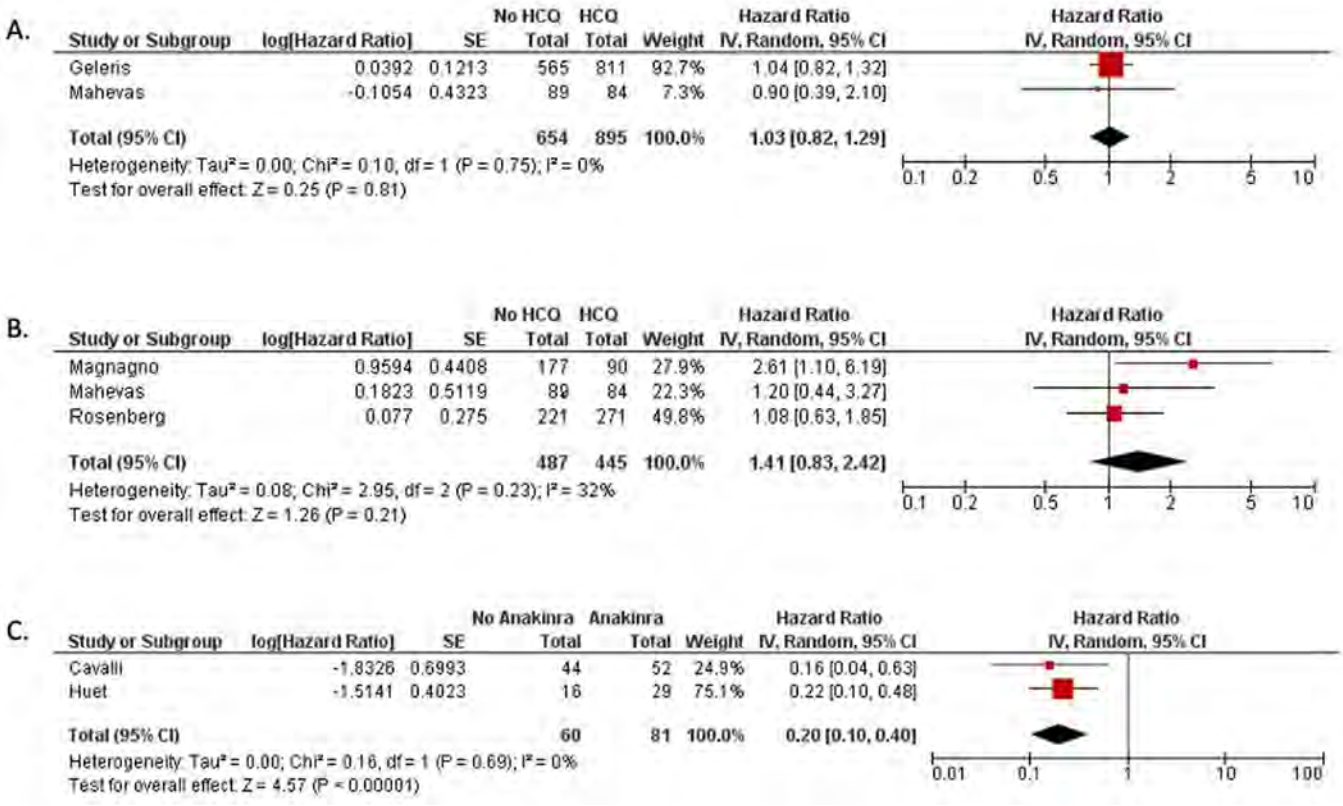

Figure 1A Meta-analysis of two observational studies investigating hydroxychloroquine and the composite outcome of death or intubation among patients hospitalized with COVID-19 Figure 1B: Meta-analysis of three observational studies investigating hydroxychloroquine and mortality among patients hospitalized with COVID-19 Figure 1C: Meta-analysis of two observational studies investigating anakinra and mortality among patients hospitalized with COVID-19.

Results: The searches identified 3,935 articles, of which 275 were included for full text review. After full text exclusion, 45 studies were included in qualitative review (4 randomized controlled trials, 29 cohort studies, and 12 case series) and six studies were included in meta-analyses (4 cohort studies of HCQ, 2 cohort studies of anakinra). All studies evaluated hospitalized patients and 29 out of 45 had been published in a peer-reviewed journal. In a meta-analysis of three cohort studies with a low risk of bias, hydroxychloroquine use was not significantly associated with mortality (pooled hazard ratio (HR) 1.41, 95% confidence interval (CI) 0.83-2.42) (Figure 1A, Figure 1B, Table 1). In a meta-analysis of two cohort studies with some/high risk of bias, anakinra use was associated with lower mortality (pooled HR 0.2, 95% CI 0.1-0.4) (Figure 1C). A meta-analysis could not be performed on interleukin-6 inhibitor studies, which were frequently conflicting and had some/high risk of bias (Table 2). Studies that assessed glucocorticoids, intravenous immunoglobulin, and baricitinib also had conflicting results and the majority had a high risk of bias.

Conclusion: In this systematic review and meta-analysis, hydroxychloroquine use was not associated with benefit or harm with regard to COVID-19 mortality. The IL-1 inhibitor anakinra was associated with lower mortality, but this should be interpreted with caution given substantial risks of bias. Evidence supporting the effect of other antirheumatic disease therapies in COVID-19 is currently inconclusive, though randomized controlled trials are ongoing.

TABLE 1: Included studies investigating antimalarial therapies and COVID-19 (n = 14)

Author (citation)	Design (n)	Outcome and Inference	Bias Assessment*	Direction of Effect†
Hydroxychloroquine				
Mortality				
Rosenberg	Cohort (1,438)	No significant difference in mortality (adjusted HR 1.08, CI 0.63-1.85)	Low	QS
Magagnoli	Cohort (368)	Increased mortality in HCQ group (adjusted HR 2.6, CI 1.1-6.2)	Low	QS
Mahevas	Cohort (173)	No difference in overall survival at 21 days (weighted HR 1.2, CI 0.4-3.3) or survival without transfer to intensive care unit (weighted HR 0.9, CI, 0.4 - 2.1)	Low	QS
Yu	Cohort (568)	Lower mortality in HCQ group among those critically ill (adjusted HR 0.33, CI 0.17-0.64)	High	+
Ashraf	Case Series (100)	Higher rate of survival in HCQ group (OR 61.9, CI 9.0 - 424.7)	High	NA
Mathian	Case Series (17)	2 out of 14 hospitalized patients taking HCQ died	High	NA
Composite of Intubation and Death				
Mahevas	Cohort (173)	No difference in the combined outcome of ICU care or death (HR 0.9, CI 0.4-2.1)	Low	QS
Geleris	Cohort (1,376)	No difference in the combined outcome of IMV or death (HR 1.04, CI 0.82-1.32)	Low	QS
Escalation of Care (ICU transfer, intubation and mechanical ventilation)				
Magagnoli	Cohort (368)	No difference in IMV (adjusted HR 1.43, CI 0.53-3.79)	Low	-
Mathian	Case Series (17)	Out of 17 patients taking HCQ, 14 admitted to hospital and 7 to the ICU	High	NA
Hospital or ICU Discharge				
Mahevas	Cohort (173)	No difference in discharge (RR 1.0, CI 0.9-1.3) at 21 days	Low	NA
Clinical Improvement				
Tang	RCT (150)	No difference in symptom resolution at 28 days (60% vs 67% SoC, p = 0.97)	High	+
Chen	RCT (62)	Shorter recovery for fever (2.2 days vs 3.2 days, p < 0.001) & cough (2.0 days vs 3.1 days, p = 0.002)	High	+
Mahevas	Cohort (173)	No difference oxygen weaning at 21 days (RR 1.1, CI 0.9-1.3)	Low	+
Gautret	Case Series (80)	81% with "favorable outcome" and only 15% required oxygen	High	NA
SARS-CoV-2 Clearance				
Tang	RCT (150)	No difference in viral clearance at 28 days (85% vs 81% SoC, p = 0.34)	High	+
Mallat	Cohort (34)	Longer duration of SARS-CoV-2 test positivity in HCQ (17 days vs 10 days SoC, p = 0.023)	Some	-
Gautret	Cohort (42)	Higher rate of viral clearance at 6 days (70% vs 13% SoC at other hospitals, p = 0.001)	High	+
Molina	Case Series (11)	Viral load persistent 6 days after treatment in 8/10 patients	High	NA
Million	Case Series (1,061)	Persistent SARS-CoV-2 test positivity at 10 days in 47 patients	High	NA
Gautret	Case Series (80)	74 out of 80 patients had viral clearance at 8 days	High	NA

* Bias assessment using the Newcastle-Ottawa Scale for cohort studies and the Risk of Bias 2.0 tool for randomized controlled trials; case series assumed to be high risk by default
†Direction of effect quantified using the Cochrane vote counting method for data syntheses. Studies eligible for quantitative synthesis and case series were excluded

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Therapeutic interventions for Immune-mediated inflammatory diseases (IMIDs) target cytokines, such as TNF-a, IL-6, IL-17 and IL-23, which are involved in the physiological and pathological host response elicited by SARS-CoV-2 [1]. We therefore questioned whether IMID patients receiving cytokine inhibitors might be at lower risk for SARS-CoV-2 infection and measured the development of anti-SARS-CoV-2 IgG responses [2] in IMID patients treated with cytokine inhibitors and respective controls during the outbreak of COVID-19 in Europe.

Methods: IMID patients with sTable (> 3 months) treatment with cytokine inhibitors (TNFi, IL-6i, JAKi, IL-17i, IL-23i, IL-12/23i; N=534) were analyzed. As controls, (i) IMID patients receiving no cytokine inhibitors (N=259), healthy control subjects unrelated to health care (NHC, N=971) and health care professionals involved in the treatment of these patients (HC, N=285) were recruited. Respiratory and other infectious symptoms as well as social behavior during the outbreak of COVID-19 in Europe between February 1st to April 30th 2020 were recorded for a period of 12 weeks. To test for exposure to SARS-CoV-2 we used an S1 domain-based antibody ELISA for the initial testing (commercial enzyme–linked immunosorbent assay from Euroimmun (Lübeck, Germany)). A cut-off of ≥0.8 (OD450nm) was considered as positive. Relative risks (RR) of seropositivity in study groups using the NHC group as the reference and adjusting for age, sex and sampling-date using a Poisson regression model with robust sandwich standard errors weres estimated. Adjustment for sampling date was achieved using the cumulative confirmed COVID-19 case-counts in the region where the study was conducted.

Results: Positive anti-SARS-CoV-2 IgG was observed in 22 of 971 NHC with a prevalence (95%CI) of 2.27% (1.42% to 3.43%), 12 of 285 HC with a prevalence of 4.21% (2.18% to 7.25%), 8 of 259 IMID patients without cytokine blockade with a prevalence of 3.09% (1.33% to 6.09%) and 4 of 534 IMID patients under cytokine blockade with a prevalence of 0.75% (0.20% to 1.92%) (Fig. 1B). After age-, sex- and sampling date adjustment, the prevalence of anti-SARS-CoV-2 IgG was significantly lower (RR: 0.32, 95%CI: 0.11 to 0.99, p=0.048) in IMID patients receiving cytokine inhibitors compared to NHC. In contrast, IMID patients receiving no cytokine inhibitors had similar (RR: 1.21, 95%CI: 0.50 to 2.90, p=0.676) prevalence of anti-SARS-CoV-2 IgG. Standardized Pearson's residuals of the expected frequencies for self-reported contact with individuals having a respiratory tract infection, workplace attendance and travel to risk areas were similar in IMID patients with and without cytokine inhibitors (Fig. 1C).

Conclusion: Patients with IMIDs receiving cytokine inhibitors are not at enhanced but rather at lower risk for SARS-CoV-2 infection compared to the general community and IMID patients not receiving such drugs. These data support a pathogenic role of cytokines, targeted by treatment of IMIDs, in COVID-19 and clearly speaks against stopping cytokine inhibitor treatment in patients with IMIDs during the current SARS-CoV-2 pandemic.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic diseases such as RA and lupus have increased risk of infection and are treated with medications that may increase this risk yet are also hypothesized to help treat COVID-19. We expanded upon our previously published work on the early few weeks of the COVID-19 pandemic[1] to the early few months to better understand how patients have been impacted.

Methods: Participants were enrolled in FORWARD, The National Databank for Rheumatic Diseases, a longitudinal registry of patients with rheumatic diseases. Participants with active email were invited to answer 5 COVID-19 surveys sent every 2 weeks from March 25 through June 2, 2020. Participants were asked about new symptoms, COVID-19 testing, changes in their rheumatology care, safety measures, social contact, economic impact, and more. Responses were linked to each participant's most recently completed semiannual questionnaire for demographics, diagnosis, patient-reported outcome measures, and medication use. Student's t tests, X^2 tests, and logistic regression were used to assess significance ($p< 0.05$) as appropriate. Two of the authors (YS and TAS) independently read and open coded optional free text comments using a grounded theory approach and organized them into themes.

Results: total of 7217 participants were invited, and 2000 (28%) responded to one or more COVID-19 questionnaires. RA was the most frequent diagnosis (63%). Geographic distribution was diverse, with respondents representing all 50 states. Respondents and non-respondents had slight demographic differences, and respondents had lower disease

	Respondents n=2000	Nonrespondents n=5216	p

Table 1. Characteristics of participants who were emailed the COVID-19 supplemental questionnaire by response status.

activity (Table 1). More than half (59%) of respondents experienced one or more changes in their rheumatology care due to COVID-19. Patients with higher disease activity or who met COVID-19 screening criteria were significantly more likely to experience a change in care (Table 2). Nearly all (99%) respondents reported taking safety measures to reduce risk, 6% received COVID-19 testing, 0.8% tested or were presumed positive, and 16% reported a negative economic impact. Qualitative analysis of the free text comments from 762 respondents revealed 5 key themes: emotions in response to the pandemic, perceptions of risk from immunosuppressive medications, protective measures to reduce risk, disruptions in accessing medications, and limited access to COVID-19 testing (Table 3).

Conclusion: In the first few months of the COVID-19 pandemic in the US, most patients with rheumatic diseases had important changes to their healthcare, with many changing medical appointments, altering medications with and without professional consultation, and unable to access prescriptions. Those with higher disease activity and those who met CDC priority testing criteria were significantly more likely to experience changes in their rheumatology care

Change in Care[a]	All (n=2000) %	Disease Activity[b] Low (n=1384) %	High (n=616) %	Screening Criteria[c] No (n=1220) %	Yes (n=780) %

[b]Disease activity was defined by PAS-II (PAS-II≤3.7 low, PAS-II>3.7 high)

[c]Based on April 27, 2020 CDC COVID-19 testing priorities (healthcare wokers, workers in congregate living settings, first responders, residents in long-term care facilities with 1 or more symptoms; people with cough or shortness of breath; people with 2 or more other symptoms of COVID-19)

Table 2. Changes in rheumatology care during the COVID-19 pandemic reported March through May 2020.

even after controlling for demographic and medication differences. The relatively low rate of positive COVID-19 tests may be due to reporting bias and future follow up will be necessary to identify changes in care for COVID-19-positive patients.

Themes	Subthemes
Emotions in response to COVID-19 related experiences	Anxiety/nervousness/worry/fear
	Motivated to take actions to reduce personal risk of COVID-19 infection
	Not worried about COVID-19
	Uncertainty about whether symptoms are due to COVID-19
	Frustration over difficulties accessing medications, treatment, or testing
	Anger/despair over how the crisis has been managed by local or national leaders
	Sadness/grief from being separated from/mourning the loss of family, friends, and others
	Gratitude for economic stability or the ability to limit personal exposure to COVID-19
	Hope
	Desire to help others by not using limited testing resources or by helping those in need
	Managing negative emotions/stress
Perceptions of risk	Increased risk due to age, chronic conditions, or potential exposure to infected people
	Increased risk due to taking immunosuppressive medications
	Personal limit for acceptable/unacceptable risk
	Doubts about the seriousness of the risks of COVID-19
Protective measures to reduce risk of COVID-19 infection	Self-isolation/social distancing
	Cancelling medical appointments that can be postponed
	Working from home
	Cancelling travel plans
	Wearing masks or gloves when in close contact with others
Impacts on healthcare, health, and well-being	Stopping arthritis medications to lessen risk of COVID-19
	Reduced access to medications (including hydroxychloroquine and tocilizumab)
	Reducing medication dose/frequency to make it last longer
	Medical consultations cancelled/switched to telephone or video consultations
	Cancellation/postponement of procedures/services that must be conducted in person
	Reduction in physical activity
	Loss of health care coverage
	Lost employment/income
	Exposure to COVID-19 among essential workers
Access to COVID-19 testing	Limited testing available for those with symptoms or exposure to COVID-19
	Long wait times for test results
	Interest in antibody testing

Table 3. Themes and subthemes identified from COVID-19 questionnaire optional free response comments.

Colchicine to Weather the Storm in Hospitalized Patients with COVID-19

Luigi Brunetti[1], Oumou Diawara[1], Andrew Tsai[2], Bonnie Firestein[3], Ronald Nahass[4], George Poiani[5] and Naomi Schlesinger[6], [1]Rutgers Ernest Mario School of Pharmacy, piscataway, NJ, [2]Center of Excellence in Pharmaceutical Translational Research and Education, piscataway, NJ, [3]Department of Cell Biology and Neuroscience, Rutgers, The State University of New Jersey, piscataway, NJ, [4]Robert Wood Johnson University Hospital Somerset, somerset, NJ, [5]Rutgers Robert Wood Johnson Medical School, somerset, NJ, [6]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Coronavirus disease 2019 (COVID-19), caused by severe acute respiratory syndrome–coronavirus-2 (SARS-CoV-2) infection, is a global pandemic causing havoc. There is a knowledge gap regarding the use of use of immunomodulation and anti-inflammatories in patients with COVID-19 and the optimal treatment is yet to be defined. The repurposing of colchicine for the treatment of COVID-19 has been suggested based in its immunomodulatory, anti-inflammatory, and anti-viral properties.

Methods: single-center propensity score matched cohort study, including all consecutive COVID-19 patients, with confirmed SARS-CoV-2 infection admitted to community teaching hospital between March 1, 2020 and May 12, 2020 was performed. Patients were stratified according to the receipt of colchicine. The primary endpoint was defined as all-cause in-hospital death within 28-day follow-up.

Results: In total, 50 patients were included in the 1:1 matched cohort study. The mean age of the total study population was 58.3 years (range: 26 – 90 years), and 24% (n=12) were female. The most prevalent chronic comorbidities included hypertension (54%; n=27), diabetes (40%; n=20), obesity (46%, n=23), and chronic pulmonary disease (16%; n=8). At the end of the 28 day follow-up, patients receiving colchicine were approximately 2 times more likely to be discharged from the hospital (odds ratio, 2.11; 95% confidence interval, 0.63 – 7.1; p=0.225) and when comparing mortality, there were 3 deaths (12%) in patients receiving colchicine versus 10 deaths (40%) in the groups receiving standard of care (odds ratio, 0.21; 95% confidence interval, 0.05 – 0.87; p=0.032).

Conclusion: To our knowledge, this is the first cohort report using colchicine for the treatment of COVID-19. Treatment with colchicine led to a higher rate of discharge from the hospital and was associated with a decrease in mortality in patients with severe COVID-19. These observations warrant further investigation in large colchicine controlled clinical trials.

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with inflammatory rheumatic diseases (IRD) have an increased risk for infection related to immunosuppression secondary to their disease, treatment and comorbidities. Nonetheless recent studies

Table 1. Risk for hospital admission in adult patients with IRD compared with patients with no IRD

	Patients in HAC (n)	Admitted to hospital due to COVID 19			
		n	Rate (%)	RR†	95% (CI)
No IRD patients	475,183	2,375	0.49%	1	
IRD patients	4,592	48	1.04%	2.09	(1.57-2.78) *
RA	1,708	17	0.99%	1.99	(1.24-3.2) *
PsA	515	7	1.35%	2.72	(1.3-5.68) *
SpA	862	1	0.11%	0.23	(0.03-1.65)
SS	175	5	2.85%	5.72	(2.41-13.57) *
SLE	254	4	1.57%	3.15	(1.19-8.34) *
Vasculitis	165	4	2.42%	4.85	(1.84-12.78) *
IIM	88	0	0%	-	
PMR	474	8	1.68%	3.38	(1.7-6.72) *

† Comparisons were made between patients without IRD and each IRD subtype.
HAC= hospital's area of care, IIM=idiopathic inflammatory myopathy, PsA=psoriatic arthritis, PMR=polymyalgia rheumatica, RA=rheumatoid arthritis, RD= rheumatic disease, SLE=systemic lupus erythematosus, SpA=spondyloarthritis, SS= Sjögren's Syndrome.

Table 2. Risk for hospitalization in adult IRD patients on bDMARDs and JAK inhibitors compared with IRD patients with classic or no DMARD

	Total patients	Admitted to hospital			
		n	Rate (%)	RR†	CI (95%)
IRD patients without biologics/JAK inhibitors	3684	33	0.89%	1	
Rituximab	71	8	11.26%	12.58	(6.03-26.25) *
TNF inhibitors	604	6	0.99%	1.11	(0.47-2.64)
Abatacept	40	1	2.5%	2.79	(0.39-19.91)
Tocilizumab	72	0	0%	-	-
JAK inhibitors	17	0	0%	-	-

† comparisons were made between IRD patients without biologics/JAK inhibitors and each treatment group.

don't support a higher risk for SARS-CoV-2 infection (COVID19) or a more severe disease in the patients. Analysis of individual risk factors among IRD related to their disease group and treatment is necessary.

The aim of this study is to assess the risk for hospital admission due to COVID 19 in adult patients with different IRDs and targeted immunosuppressive treatments.

Methods: Patients with confirmed COVID19 that were hospitalized in Ramón y Cajal University Hospital between February the 1st and May the 22nd 2020 were included. Confirmed infection was established by positive nasopharyngeal swab for SARS-CoV-2 or characteristic bilateral infiltrates on chest radiograph/computerized tomography. We identified among hospitalised patients those diagnosed with IRD followed in the Rheumatology department. Demographic and clinical data were collected, and risk for hospital admission was compared between patients with and without IRD. Individual risks according to specific IRD and treatments were analysed.

Results: A total of 2423 patients (0.5% of the population in hospital's area of care) were hospitalized due to COVID19 during the study period and 48 of them had a previous diagnosis of IRD (1.04% of all IRD patients). Median age was 62 years (range 19 to 88), and 62.8% were female. Risk for hospital admission was significantly higher in patients with IRD older than 65 years, with arterial hypertension, diabetes and/or interstitial lung disease related to IRD (data not shown).

Rates and relative risk ratios for infection and hospital admission regarding IRD and immunosuppressive treatments are represented in Tables 1 and 2. There was no difference in hospital admission rates among patients on bDMARDs with or without methotrexate.

Conclusion:

- Patients with IRD had a higher risk for hospital admission due to severe COVID 19. Sjögren syndrome and systemic vasculitis had the highest risk for hospitalization among IRD patients.
- We found a higher risk for hospitalization in patients treated with rituximab, but not in patients with anti-TNF drugs or other biologic treatment.

threatening pneumonia. A proportion of patients develop ARDS. Although evidence is emerging on risk factors, not much is known about the morphologic and molecular changes in the lungs of patients with Covid-19. Radiographically, peripheral ground glass opacities on CXR and CT scan fulfil the criteria for ARDS but are still not well characterized. What seems consistent is that ARDS and critical illness appear to develop most commonly between 1–2 weeks after the onset of symptoms. Some Covid-19 patients are at increased risk of developing respiratory failure

Table 2: Baseline Clinical parameters of the Cohort

CRP	.009	.001	34.801	.000	1.008(1.005-1.01)	1.009	1.006	1.011
Creatinine	.002	.001	3.407	.065	1.003(1.001-1.005)	1.002	1.000	1.005
Age	.050	.009	28.671	.000	1.05(1.04-1.07)	1.051	1.032	1.071
Constant	-3.703	.833	19.741	.000		.025		

Variable(s) entered on step 1: Gender, Comorbidities >2, SFR, NLR, CPAP, CRP, Creatinine, Age, Total LOS
Ref1: comorbidities <2
Model(x^2) =162.36, p<.001*; NagelkerkeR^2=40.2% (model could explain 40% of variance in Mortality outcome)

which appears to be driven by hyper-inflammation, resembling cytokine storm syndrome (CSS). There are currently no approved pharmacological treatments; however several trials are on going at present. The lack of reliable clinical

and serological predictors for deterioration is making it harder to triage and manage these patients appropriately. This study aimed at identifying potential predictors for outcomes, using baseline clinical parameters.

Methods: or this study, demographics, clinical and laboratory data, imaging and outcomes were collected for 592 patients with COVID 19 between February 20th and May 7th 2020 from a single centre in Essex, United Kingdom. 500 were included in final analysis. We used multivariable logistic regression models to identify risk factors.

Results: Refer to Tables 1&2. Mean age of the cohort was 69.4, 300(60%) were males. Majority were Caucasians, 436 (87%) and our cohort comprised of patients over 70, 290(58%). Most patients had 2 or more comorbidities 280(56%). Most common were hypertension 186(37 %), Cardiovascular disease 178(36 %) and Diabetes 128 (26 %). Cough was the common presentation 295(59%) followed by dyspnoea 294(58.8%) and fever 248(50 %.). Mean CRP was very high at baseline 111, neutrophil-lymphocyte ratio was 11.64 and baseline mean creatinine was 114. 44(8.8 %) had secondary bacterial infection.

The mean SpO 2/FIO 2 ratio (SFR) was 371 and 56 (11%) of patients fell into ARDS criteria and 181(36.7%) had acute lung injury. 66.4% had significant CXR findings including bilateral ground glass opacities and consolidation. 348(69.6%) required Oxygen, 56(11.2%) required CPAP and 64(12.8%) needed mechanical ventilation.

Of the 500, 193(38.6%) died and mean length of stay was 8.43 days. Baseline predictors for mortality were: comorbidities >2 OR 2.13(95% CI 1.30 – 3.48), CRP OR 1.01(95% CI 1.01 – 1.01), Creatinine OR 1.00 (95% CI 1.00 – 1.01), Age OR 1.05(95% CI 1.03 – 1.07). SFR had a trend towards increase mortality OR 0.99 (95% CI 0.99 – 0.10)

Conclusion: In this single centre study, older patients, comorbidities, baseline CRP and creatinine were risk factors for worse outcomes. Real-time consistent monitoring of SFR and inflammatory markers are essential in monitoring disease course, allowing for early intervention to improve patient outcomes.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: SARS COV 2 pandemic has been an issue which has challenged the health care systems around the world. Rheumatology has been involved in two ways: on the one hand, due to the use, in its treatment, of specific agents usually indicated in rheumatologic conditions and, on the other hand, the fear that our patients could be at higher risk due to the use of immunosuppressive agents.

The main objective of our study was to analyze which features were associated with a serious course of the infection in a cohort of inflammatory rheumatologic patients and COVID-19 infection.

Methods: All patients with rheumatologic inflammatory conditions and COVID infection (confirmed by PCR of nasopharyngeal swab or serology) followed at three university referral centers from Basque Country were identified. Severe course was defined as those who required hospital admission or die. Comparisons of those with serious and non-serious disease course were performed using standard tests.

Results: Among 97 rheumatologic patients with COVID-19 infection, 37 (38%) presented with a severe course, 29 (29.9%) were admitted to hospital, 2 (2%) transferred to an intensive care unit and 12 (12.4%) died. Comparisons between those with severe and non-severe course can be seen in 'Table 1'. Multivariate analysis of those variables found to be significant in the univariate analyses showed that only glucocorticoid (GC) use [0R 95%CI: 9.4 (2.3-39.0)] was associated with a severe course. Similar analyses also showed that death was associated with elder age, obesity and GC use.

Table 1

	Severe	Non-severe	p
Age, mean (±SD)	66.9±13.9	58.0±17.0	0.006
Sex (%female)	64.9	61.7	0.830
Obesity (%)	18.9	5	0.040
Heart disease (%)	29.7	15.0	0.120
HBP (%)	54.1	51.7	0.837
Lung disease (%)	35.1	20.0	0.151
Diabetes mellitus (%)	16.2	11.7	0.551
scDMARD (%)	62.2	55.0	0.531
Targeted therapies (%)	18.9	25	0.620
GCs (%)	70.3	33.3	0.001
CRP mg/L, mean (±SD)	217.7±341.8	87.3±122.4	0.040
Ferritin mg(dl, mean (±SD)	676.5±718.5	945.6±1416.2	0.603
LDH mg/dl, mean (±SD)	296.6±152.1	275.8±94.4	0.592
D dimer mg/dl, mean (±SD)	1067.4±1207.6	1249.7±1134.9	0.684
Lymphocytes, mean (±SD)	813.4±575.8	1541.7±1134.9	0.008

Conclusion: A severe course of COVID infection was observed in almost forty patients. GC were associated with either bad outcome and death whereas elder age and obesity were also associated with fatal outcome.

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The global COVID19 pandemic has had a major impact on healthcare. The effect on rheumatology patients and providers is unclear, as is the role of telemedicine service to meet unique challenges posed by the pandemic.

Methods: Using the Columbus data warehouse of the AARA rheumatologist network, we examined calendar trends in the frequency of kept vs. missed/cancelled office visits and intravenous (IV) infusions of immunomodulatory medications (e.g. abatacept, golimumab, infliximab, tocilizumab) from January to May, 2020. We compared results by primary diagnosis, driving distance from physician office, and socieoeconomic status(SES), proxied by the Area

Table Partial List of Factors Associated with Missed/Cancelled vs. Kept Office Visits and Infusions Associated with the Temporal Evolution of the COVID19 Outbreak

Deprivation Index (ADI). Descriptive statistics and multivariable logistic regression were used to identify factors associated with missed/cancelled visits, controlling for clustering (visits within patients), with results as odds ratios (OR) with 95% confidence intervals(95%CI).

Results: Before March 15th (i.e. Pre-COVID), mean weekly visit volume overall was 17,203 visits/week among 121,843 unique rheumatology patients, which decreased minimally (3.1%) Post-COVID. Among return patient visits (mean 10,678/week, dropping 9.1% Post-COVID), 100% pre-COVID were in-person visits, but dropped to 70.3%, and were supplemented by 29.7% telemedicine visits. In addition to the decline in office visit volume and the transition to telemedicine visits, the frequency of missed/cancelled in-person appointments Post-COVID also increased. It peaked during week 12 (March 23-28) in which 15.2% of all appointments were missed/cancelled overall, 17.9% for in-person visits vs. 5.1% for infusions ($p< 0.0001$).

Univariate characteristics of patients keeping vs. missing visits and infusions is shown (Table). After adjustment, and referent to week 1 (Jan 5-11), the OR (95% CI) for cancellations associated with the pandemic at its peak was 1.30 (1.27, 1.34). Compared to follow-up visits for rheumatoid arthritis, new patient visits and return patient visits for osteoarthritis and osteoporosis were associated with a greater likelihood of missed/cancelled office visits, with corresponding OR (95% CI) of 1.59 (1.51, 1.67), 1.34 (1.31, 1.37) and 1.75 (1.71, 1.80), respectively. Patients with lower SES had a 5-20% higher likelihood to miss/cancel office visits compared to those in the highest SES quintile. Multivariable-adjusted factors also associated with missing/cancelled office visits included greater driving distance to the rheumatologist office, female sex, smoking, comorbidities (e.g. anxiety, asthma, back pain, diabetes, fibromyalgia, GERD, sleep disorder); and region.

Conclusion: The impact of COVID19 on both rheumatology practice visit volume and immunomodulatory treatments has been substantial. Telemedicine and other technology-focused tools for remote digital patient data capture and monitoring are essential to optimize rheumatology care and outcomes.

Sleep Disturbance	52.7 [32.0, 69.1]	51.7 [32.0, 69.1]	<0.0001

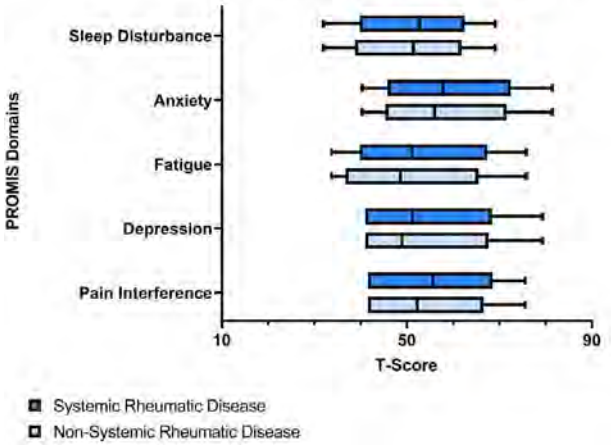
Higher scores=worse outcomes; 50=population mean

± Patients seen by a rheumatologist and with self-reported RA, Lupus, Psoriatic Arthritis, Spondyloarthritis, Scleroderma, Vasculitis, Myositis, Undifferentiated Connective Tissue Disease, Mixed Connective Tissue Disease, Sjogren's Syndrome, Polymyalgia Rheumatica, and Juvenile Idiopathic Arthritis

Background/Purpose: Little is known about the general health and wellbeing of patients with systemic rheumatic diseases (SRD) during the COVID pandemic. We sought to compare health related quality of life in patients with and without SRD during the height of the COVID-19 pandemic in New York City.

Methods: We emailed a secure web-based survey to 26,045 patients aged ≥18 years who were evaluated at least once by a rheumatologist during the two years prior to April 1, 2020 at a tertiary care academic center in New York City. Patients were invited to complete the survey by email or phone between April 24, 2020 and May 26, 2020. Information collected included self-reported COVID-19 diagnosis, potential COIVD-19 symptoms, rheumatic disease diagnosis, and sociodemographic factors. Respondents completed 5 domains from the PROMIS-29 (depression, anxiety, sleep disturbance, fatigue, pain interference). PROMIS-29 results were transformed to T-scores, with 50 being the mean for the US population, and a difference of 5 points considered to be clinically meaningful. Wilcoxon

Figure. The Effects of the COVID-19 Pandemic on Patients with Systemic and Non-Systemic Rheumatic Diseases as Measured by the PROMIS-29



rank-sum, Fischer's exact or chi-square tests were used, as appropriate, to compare demographics and PROMIS-29 scores in patients who reported having an SRD vs. those who did not.

Results: 6,584/26,045 (25.3%) respondents completed the PROMIS-29, and 4,147/6584 (62.9%) self-reported having an SRD. Most common SRDs included RA (N=1081, 26%), Psoriatic Arthritis/Spondyloarthritis (N=521,12.6%) and SLE (N=310, 7.5%). Patients with SRD were younger, less likely to be white and more likely to be Hispanic/Latino. Patients self-reporting an SRD were statistically significantly more likely to have had a confirmed close contact with a person with COVID-19 (22% vs. 20%; p=0.04), and spend > 95% of their time homebound (74% vs. 70%; p=0.0008). Those SRD patients who reported COVID-19 symptoms were more likely to exhibit their COVID-19 like symptoms for > 4 days compared to those without an SRD (42% vs. 37%; P< 0.0001) **(Table 1).** Across the five measured PROMIS-29 domains, patients with an SRD had worse scores than the population mean, and statistically significantly worse scores compared to those without SRD; however these differences were not clinically meaningful **(Table 2 and Figure 1).**

Conclusion: During the COVID-19 pandemic, patients with SRDs reported statistically significantly worse pain interference, depression, fatigue, and anxiety than the mean of the US population and those without SRD; however, these differences were not clinically meaningful. Patients with SRD were more likely to have had a confirmed close contact with someone with COVID-19, COVID-19 like symptoms for > 4 days, and were more likely to spend >95% of their time homebound compared to those without SRD. These data suggest that while patients with and without SRD had similar mental and physical health domains during the pandemic, SRD patients' quality of life may be differentially impacted by COVID-19, due to longer disease course, increased social exposure to COVID-19 cases, and greater social isolation. Further study is needed to evaluate whether COVID-19 continues to differentially impact the life of patients with SRD as the pandemic progresses.

Abstract Number: 0019

Lasting COVID-19 Impacts on US Rheumatology Practices

Lynn Price[1], Gianna Melendez[1] and Phil Pouliot[1], [1]spherix global insights, Exton, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In late 2019, a novel, highly contagious coronavirus (COVID-19), was discovered in China and quickly spread throughout the world, equating to arguably the largest and most impactful modern-day world-wide pandemic. By March of 2020, the virus had fully spread to the US, forcing all but essential-working individuals to practice self-isolation in their homes, businesses to temporarily close their doors, and widespread social, economic, and medical impacts.

Methods: An independent market analytics firm collaborated with US specialists (n=257), including rheumatologists (n=50) from June 5 to 8, 2020 in order to gain insights on the impact of COVID-19 on their practice. Data collected included physician demographics, greatest impacts to date, attitudinal survey responses, and projected lasting change. Data has been collected on a rolling basis weekly, biweekly, or monthly since March 20, 2020.

Results: As of early June 2020, 36% of rheumatology practices have fully re-opened with appropriate social distancing pre-cautions in place; however, while improving, the majority continue to report high negative impacts of the COVID-19 crisis on their practice, with 70% agreeing that the COVID-19 experience will have a lasting impact on how they operate their practice. Half or more of rheumatologists report the areas of high impact include use of telemedicine, the financial health of their practice, the number of patient visits, and patient-outreach regarding COVID-19.

Specifically, while the use of telemedicine has grown week over week despite lifting the social distancing/stay at home requirements, overall in-person patient visits remain down 65% compared to pre-COVID levels. Furthermore, rheumatologists do not anticipate their use of telemedicine to cease once the crisis has abated, as 72% agree telemedicine will continue and estimate that 26% of their weekly patient engagements will be conducted virtually once the COVID-19 crisis is over. Although this new treatment modality has increased in popularity, rheumatologists largely remain unsatisfied and unclear exactly how they will be compensated or reimbursed for this type of care.

Other long-term projected practice impacts include rheumatologists' use of PPE, attendance of medical conferences, and interaction with pharmaceutical industry representatives. Of note, just one-fifth (or less) of rheumatologists project that their use of specific brands for rheumatologic conditions, their in-office administration of drugs, and the stocking of product inventory will be vastly different than pre-COVID.

Conclusion: While rheumatologists largely anticipate that their use of products and stocking/administration of specific products for rheumatologic conditions will largely revert to pre-COVID-19 levels, other aspects of how they manage their practice will likely undergo permanent changes. Specifically, elements of their profession that can be done virtually in the future likely will maintain some element of change once the crisis has fully abated—with emphasis and consideration to the use of telemedicine, the way physicians interact with industry, and conference attendance.

Characteristics of Rheumatology Outpatients with Suspected or Confirmed COVID-19 During the Pandemic in New York City

Medha Barbhaiya[1], Gregory Vitone[2], Marianna Frey[3], Deanna Jannat-Khah[4], Candace Feldman[5], Lindsay Lally[3], Anne Bass[6], Jane Salmon[3], Mary Crow[3], Michael Lockshin[1], Vivian Bykerk[3] and Lisa Mandl[3], [1]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY, [2]Hospital for Special Surgery, New York, [3]Hospital for Special Surgery, New York, NY, [4]Hospital for Special Surgery, New York City, NY, [5]Brigham and Women's Hospital, Boston, MA, [6]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The incidence and disease severity of COVID-19 in rheumatic disease patients, who may be at higher risk due to underlying immune dysregulation and use of immunomodulatory medications, remains poorly understood. We evaluated the characteristics of rheumatology outpatients with suspected or confirmed COVID-19 in New York City during the pandemic "surge".

Methods: We emailed a secure web-based survey to 26,045 patients ≥18 years old evaluated at least once by a rheumatologist between April 1, 2018-April 21, 2020 at a tertiary care academic center in New York City. Patients were invited to complete the survey by email or phone between April 24, 2020 and May 26, 2020. Information collected included potential COVID-19 exposures, symptoms, and diagnoses, rheumatic and general medical history, and medication use. COVID-19 was suspected if patients were diagnosed by a healthcare worker or was confirmed if they reported a positive nasopharyngeal PCR test. T-tests, Fischer exact tests or chi-squares were used as appropriate to compare characteristics in patients with suspected/confirmed COVID-19 compared to those without, and in the subgroup of suspected/confirmed COVID-19 patients whose presentation was severe enough to require emergency room (ER) visit or hospitalization.

Results: Of the 7,057/26,045 (27.1%) who responded to our survey, 430/7,057 (6.1%) reported suspected/confirmed COVID-19. Mean age of patients with suspected/confirmed COVID-19 was lower than those without COVID-19 (53.6 [14.6] years vs. 60.0[15.6] years). There was a higher prevalence of Hispanic ethnicity, obesity, and current smoking or vaping in patients with suspected/confirmed COVID-19, as well as asthma, cancer, fibromyalgia and hypertension **(Table 1).** Although not significant, suspected/confirmed COVID-19 patients had a higher prevalence of SLE. Patients with COVID-19 had higher use of hydroxychloroquine, abatacept and belimumab in the preceding 6 months, and were more likely to have had a close contact with a person with COVID-19 **(Table 2).** In the subgroup with suspected/confirmed COVID-19, 79/430 (18.4%) presented to the ER or were hospitalized; age, race, ethnicity, education, income, BMI and smoking status were similar compared to those who did not **(Table 3).** However, ER/hospitalized patients were more likely to report SLE or Fibromyalgia and to use anti-malarials and conventional DMARDs**.** No difference in COVID-19 exposure status from close contact with an affected individual (p 0.24) or time spent at home (p 0.61) was noted in those who went to ER/hospitalized.

Conclusion: During the peak of the COVID-19 pandemic, 6.1% of rheumatology patients surveyed at a large, specialty hospital in NYC reported suspected/confirmed COVID-19, of whom 18.4% went to the ER or were hospitalized. This is likely a conservative estimate as those ill from COVID-19 may not have responded to our survey. Our findings provide insight into potential characteristics associated with the incidence and disease severity of COVID-19 in rheumatic disease patients in a COVID-19 "hot spot" during the pandemic.

Prioritizing Patient Safety While Maintaining Study Integrity During COVID-19: Lupus Intervention Fatigue Trial Modifications and Lessons Learned

Dominique Kinnett-Hopkins[1], Linda Ehrlich-Jones[2], Holly Milaeger[3], Alanna Kenney[3], Lorena Rosiles[3] and Rosalind Ramsey-Goldman[4], [1]Northwestern University, Chicago, IL, [2]Shirley Ryan AbilityLab, Chicago, [3]Northwestern University, Chicago, [4]Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Rheumatic Disease
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The coronavirus disease 2019 (COVID-19) global pandemic has drastically impacted the health system and the research community. Many research institutions and funding agencies recommended a moratorium on conducting in-person research and study enrollment until protocol changes to protect patient safety were implemented and approved. We turned the guidance provided by the Institutional Review Board (IRB) into actionable items without compromising the integrity of the primary, secondary, and exploratory outcomes of the study. The purpose of this project is to detail the modifications made to the Lupus Intervention Fatigue Trial (LIFT) and to summarize the lessons learned to meet the varied challenges created by the highly transmissible virus.

Methods: The research team evaluated current study protocols to determine which components required modification. The research team determined that the following protocols required modifications: 1) the intervention that included four individual coaching sessions and 2) four, two-hour, in-person assessments, including a physician exam, blood draws, and urine samples along with online patient-reported outcomes (PROs) at a University Medical Center Research Unit. The team made modifications that would allow for all interventions and assessments to be safely conducted remotely without compromising the integrity of the study aims.

Results: The intervention components were revised immediately to convert all individual coaching sessions to remote sessions. Next, we reviewed all study assessments and modifications were made to electronically consent participants, provide links for completion of online PROs, and perform telemedicine visits for the physician assessment. Collection of safety labs presented the biggest challenge since this required an in-person visit at a laboratory and we elected to delay this up to one month after the physician assessment, or used standard of care test results if they were done within a month of the physician assessment. We also offered the option of not doing the lab tests. With these modifications, we were able to complete all follow-up visits and no patients dropped out of the study. We were not able to collect the protocol extra blood for future research testing and some patients could not measure their vital signs at home.

Conclusion: The LIFT study was severely impacted by COVID-19. We provide insight into how our study protocol was modified without compromising the integrity of the primary, secondary, and exploratory outcomes of the study. The modifications utilized by the LIFT study and lessons learned while revising the LIFT protocols resulted in efficiencies that will be included in a revised protocol and will foster additional ideas to overcome the challenges in areas where we missed data collection and may serve as a useful example for other behavioral interventions to adapt their research studies given COVID-19 restrictions.

Pain facilitation		
Δ TS[3] Arm	0.04	(-0.10, 0.18)
Δ TS[3] Wrist	0.08	(-0.07, 0.22)
Pain inhibition		
Δ CPM[4]	0.03	(-0.11, 0.17)

[1] Sample size for each measure: wrist PPT N = 194; knee PPT N = 191; trapezius PPT N = 194; thumbnail PPT N = 194; arm TS N = 189; wrist TS N = 190; CPM = 190
[2] Pressure pain threshold in kpf/s. [3] Temporal summation. [4] Conditioned pain modulation. [5] Disease activity score in 28 joints using C-reactive protein.
Correlations are Pearson's correlations reported with 95% confidence intervals
Significant correlations are bolded

Background/Purpose: Patients with rheumatoid arthritis (RA) have abnormalities in central nervous system regulation of pain, leading to enhanced pain sensitivity at joint sites (peripheral sensitization) and in a widespread distribution (central sensitization). Pain sensitization is important because it is associated with elevations in composite disease activity measures and patient-reported pain. It is unknown whether treatment with disease modifying anti-rheumatic drug (DMARD) therapy can modify pain sensitization. The objective of this study was 1) to examine changes in pain sensitization in RA following 12 weeks of DMARD therapy and 2) to determine the association between changes in pain sensitization and changes in disease activity.

Methods: This study included 236 participants with active RA who were changing DMARD therapy per standard of care. Participants underwent quantitative sensory testing (QST) to assess pressure pain thresholds (PPTs) at the wrist and knee to assess peripheral sensitization and PPTs at the trapezius and thumbnail to assess central sensitization.

Temporal summation (TS) was assessed as a specific measure of central sensitization involving pain facilitation, and conditioned pain modulation (CPM) was measured to assess pain inhibition. Disease activity was assessed using the disease activity score in 28 joints using C-reactive protein (DAS28-CRP). Differences in QST measures between baseline and 12-weeks after DMARD initiation were assessed using paired t-tests. Associations between changes in QST measures and changes in DAS28-CRP and its components were assessed with Pearson's correlation coefficients.

Results: PPTs increased (reflecting lower pain sensitivity) from baseline to follow-up; however, changes were small (ΔPPT wrist = 0.44 kpf/s, p = < 0.0001; ΔPPT knee = 0.43 kpf/s, p = 0.0002; ΔPPT trapezius = 0.37 kpf/s, p = < 0.0001; ΔPPT thumb = 0.44 kpf/s, p=< 0.0001) (Table 1). TS and CPM did not change significantly from baseline to follow-up. Negative correlations between changes in PPTs and changes in DAS28-CRP were strongest at joint sites (wrist r = -0.29, 95% confidence interval (CI) = -0.41 to -0.15; knee r = -0.31, 95% CI = -0.43 to -0.18) and weaker at non-joint sites (trapezius r = -0.18, 95% CI = -0.31 to -0.04; thumb r = -0.20, 95% CI = -0.33 to -0.06) (Table 2). Changes in TS or CPM were not significantly correlated with changes in DAS28-CRP.

Conclusion: All PPTs increased with DMARD treatment reflecting decreasing pain sensitivity. Correlations with DAS28-CRP were strongest with measures of peripheral sensitization. This is consistent with the idea that peripheral sensitization is driven by joint inflammation. However, changes in PPTs were small in magnitude. Treatment with DMARDs alone may not be sufficient to address pain sensitization in RA.

Abstract Number: 0023

Hypophosphatasia May Be Misdiagnosed as Fibromyalgia: A Single Center Experience

Patil Injean[1], Sandy Lee[1] and Christina Downey[1], [1]Loma Linda University Medical Center, Redlands, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypophosphatasia (HPP) is a rare disease characterized by incomplete or defective bone mineralization due to a mutation in the alkaline phosphatase gene (ALPL). Given the heterogeneity of gene mutation, phenotypes, and mode of inheritance, the disease has several presentations, including femoral and stress fractures, tooth loss, muscle weakness, chondrocalcinosis, nephrolithiasis, chronic pain, and osteoarthropathy, and chronic pain syndromes similar to fibromyalgia (FM). HPP diagnosis is marked by consistently low levels of alkaline phosphatase (ALP), elevated levels of inorganic phosphate, pyridoxal-5'- phosphate, a breakdown product of vitamin B6, phosphoethanolamine, and genetic testing. Although this patient population is prone to fractures and osteoporosis, the use of bisphosphonates is contraindicated due to worsening bone demineralization disease. There are very few

Table 1: Characteristics of patients with Fibromyalgia and consistently low ALP

	Normal ALP n (%)	ALP ≤25 on at least 2 occasions n (%)	ALP ≤ 35 on at least 3 occasions n (%)
Total number of patients	246 (80)	12 (4)	57 (19)
Age (mean)	51	56	53
Male	40 (16)	2 (17)	10 (18)
Female	206 (83)	10 (83)	47 (82)
Normal Bone Density	11 (4)	2 (16)	2 (4)
Osteopenia	18 (7)	1 (8)	6 (11)
Osteoporosis	5 (2)	1 (8)	7 (12)
History of fractures	88 (35)	7 (58)	23 (40)

Table 1: Characteristics of patients with Fibromyalgia and consistently low ALP

case reports showing patients diagnosed with hypophosphatasia were initially misdiagnosed with fibromyalgia however there are no larger studies done on the subject. Our objective was to determine the prevalence of hypophosphatasia in a population of patients diagnosed with fibromyalgia

Methods: We performed a retrospective chart review of all patients 18 years or older at a single academic center diagnosed with FM based on ICD 10 Code "Fibromyalgia**"** M79.7 and at least one ALP level ≤ 35 were reviewed. Number of consecutively low ALP levels were noted. Gender, age, history of fragility fracture, bone mineral density screening, complete blood counts and medications were reviewed. For patients who have undergone HPP evaluation, genetic testing, and vitamin B6 levels were noted.

Results: Out of 305 patients diagnosed with fibromyalgia and at least one low ALP level, 57 (19%) had at least 3 consecutively low measurements of ALP ≤ 35 while 12 (4%) of patients had at least 2 consecutively low measurements of ALP ≤25. Mean age was 52 (range 18-94), 41% of patients were female, and 59% were male. Of the patients with at least 3 consecutively low ALP ≤ 35, 23 (40%) had a history of fractures. Fifteen patients had bone density scans: 2 (4%) had normal results, 6(11%) had osteopenia, and 7 (12%) patients had osteoporosis. No patients had Vitamin B6 levels checked. None of the patients had previous genetic testing for HPP. Of the patients with consistently low ALP levels, 16 (28%) were taking bisphosphonates.

Conclusion: Up to 19% of FM patients in our population were found to have consistently low levels of ALP and high suspicion for undiagnosed underlying HPP. None of the patients had Vitamin B6 level checked or genetic testing done which suggests the diagnosis was not suspected despite the similarity of clinical symptoms and low ALP levels. It is increasingly important to diagnose these patients with HPP given treatment availability and to avoid bisphosphonate use to prevent worsening bone fragility. Furthermore, our data supports screening for this condition as a part of the initial workup of FM.Table 1: Characteristics of patients with Fibromyalgia and consistently low ALP

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) impacts directly on health and quality of life (QoL) of patients and associates with a large health economic burden. Non-pharmacological interventions are recommended as first-line treatment for FM[1]. However, there are no evidence-based recommendation for which intervention(s) to offer to patients with different manifestations of FM as core and adjunctive treatments. The aim of this Delphi exercise was to prioritise non-pharmacological treatments for FM based on the results of our meta-analysis[2].

Methods: A three-stage Delphi exercise was designed. Panel members were selected from the author list of EULAR, American Pain Society and Canadian FM guidelines and local clinicians with expertise in FM. In the first round Delphi survey, participants were asked to select interventions that they thought should be offered to people with FM, and then rate these interventions as either core or adjunctive treatments separately for pain, fatigue, sleep and depression. They were provided a summary of current research evidence from our recent meta-analysis to support their decision-making. Items receiving more than 70% votes were accepted, those receiving less than 30% were rejected and those obtaining between 30-70% were recirculated in the following rounds.

Results: Seventeen of 48 invitees agreed to participate and completed the 3 rounds of the survey. There were 7 rheumatologists, 2 physiotherapists, 1 pain specialist,1 psychologist, 1 nurse and 5 other professionals. This Delphi exercise identified 14 non-pharmacological interventions for pain, 11 for fatigue, 12 for sleep and 11 for depression that were considered potentially accessible and beneficial for the four common manifestations of FM (Table 1). Aerobic exercise, education, sleep hygiene and cognitive behavioural therapy were supported as core treatments for all manifestations. Other interventions, including music, periods of relaxation/enjoyment during the day, use of hot baths and local heat, achieved consensus as adjunctive treatments for certain outcomes (Table 2).

Interventions	Pain	Fatigue	Sleep	Depression
Aerobic exercise	94*	94*	88*	94*
Education	94*	94*	88*	76*
Sleep hygiene	94**	100**	100**	76**
Cognitive behavioural therapy	94*	88*	88*	88*

Music	NR	NR	0	NR

NR: not recommended

All values are percentages. Text in bold shows interventions recommended as core and non-bold text as adjunctive interventions. For example, aerobic exercise was voted as core by 88% of the panel members for pain and 94% for fatigue.

Table 2. The classification of accepted non-pharmacological interventions as core or adjunctive for pain, fatigue, sleep and depression

Conclusion: This Delphi exercise provides an up-to-date consensus of expert practitioners and researchers on core and adjunctive non-pharmacological treatments for four manifestations of FM, specifically pain, fatigue, sleep and depression. This information will inform the development of a complex non-pharmacological treatment package for FM which will subsequently be tested in clinical research.

CRP, mg/dL	14.9 (4.1, 36.1)	27.9 (3.0, 54.7)	0.152
ESR, mm/h	43.5 (17, 70.8)	50.5 (16.8, 76.5)	0.518

DAS28: disease activity score in 28 joints; TJC: tender joint counts; SJC: swollen joint counts; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein;

Table3 Quality of life and functional status of RA patients with FM *vs.* those without FM

Feature	RA (n=160)	RA-FM (n=42)	P-value
HAQ	0.66 (0.2, 0.9)	1.24 (0.26, 1.5)	**P<0.001**
VAS, cm	3 (2, 5)	5 (3, 7)	**0.01**
SF-36	58.22 (47.26, 73.17)	28.63 (19.8, 39.97)	**P<0.001**

HAQ: health assessment questionnaire; VAS: visual analogue score;

Table4 Psychological and fatigue characteristics of RA patients with FM *vs.* those without FM

Feature	RA (n=160)	RA-FM (n=42)	P-value
Anxiety	4 (1, 7)	10 (7.75, 12.25)	**P<0.001**
Depressed	6 (3, 8)	12 (9.75, 15)	**P<0.001**
Fatigue, n%	81/160 (50.6%)	37/42 (88.1%)	**P<0.001**
Fatigue VAS(0-10)	3.6 (1, 4.7)	5.6 (4.6, 5.9)	**P<0.001**

Hospital Anxiety and Depression Scale, HADS.

Background/Purpose: To assess the clinical features and psychological status of the rheumatoid arthritis(RA) patients with fibromyalgia(FM) in a real-world observational setting.

Methods: Between December 2018 to April 2019, 202 patients with RA were enrolled from the inpatients in Rheumatology and Immunology Department in Peking University People's Hospital. All the patients were evaluated whether incorporating FM translation using the 1990 ACR-FM classification criteria. Disease activity, functional and psychological status were accessed by Disease Activity Score in 28 joints (DAS-28), Short Form-36 survey (SF-36), Health Assessment Questionnaire(HAQ), Hospital Anxiety and Depression Scale (HADS) and 0-10 visual analogue scale (VAS).

Results: Among the 202 RA patients, 42(20.8%) were concomitant with FM. Compared to those patients without FM, RA patients with FM (RA-FM patients) had higher DAS-28 score (6.0 *vs.* 4.4, *p*=0.011) and much more 28-tender joint counts (TJC) (16.5 *vs.* 4.5, *P*< 0.001). RA-FM patients had worse HAQ (1.24 *vs.* 0.66, *P*< 0.001) and lower SF-36 (28.6 *vs.*58.2, *P*< 0.001). Fatigue is more common in RA-FM patients (88.1% *vs.* 50.6%, P< 0.001). RA-FM patients also had higher anxiety (10 *vs.* 4, *P*< 0.001) and depression scores (12 *vs.* 6, *P*< 0.001). ESR, CRP, morning stiffness time and 28-swollen joint counts (SJC) showed no difference between these two groups.

Conclusion: From these real world data, fibromyalgia is more common than generally regard in RA patients. RA patients with FM result in higher disease activity, worse functional and psychological status. RA patients with FM also have poorer quality of life. DAS-28 scores may be overestimated in RA patients with FM. In RA patient that does not reach remission, the possibility of fibromyalgia should be considered.

A Modified Version of the 2016 ACR Fibromyalgia Criteria Cognitive Items Results in Stronger Correlation Between Subjective and Objective Measures of Cognitive Impairment

Valerie Aloush[1], Chen Yaalon[2], Sheer Raev[2], Noy Sobol[2], Jacob Ablin[1], Ran Shorer[3] and Odelia Elkana[2], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Academic College Tel Aviv Jaffa, Tel Aviv, Israel, [3]Tel Aviv Medical Center, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In a previous study, we showed that the subjective item assessing cognitive impairment (SSS-Cog) for fibromyalgia (FM) did not correlate with objective cognitive measures. In the current study we describe two modifications designed to enhance this correlation: extending the current SSS-cog scale from 0-3 to 1-5, and a new questionnaire that specifically targets cognitive impairments associated with FM.

Methods: Sixty-two FM patients underwent a computerized cognitive assessment battery. FM symptoms were assessed on the Fibromyalgia Impact Questionnaire (FIQ); the Widespread Pain Index (WPI); the Symptom Severity Scale (SSS), the new SSS-Cog scale ranging from 1 to5, the Beck Depression Inventory (BDI) and the new cognitive questionnaire developed by the authors.

Results: ignificant correlations were found between the new SSS-Cog scale, the global cognitive score and all indices [Global Score r= -. 532, p= .00; Indices: Memory r= -.305, p= .01; Executive function r = -.514, p= .00; Attention r = -.471, p= .00; Processing Speed r = -.468, p= .00; Motor Skills r= -.495, p= .00]. Significant correlations were found between the questionnaire items developed by the authors and the global cognitive score and all indices except the memory index [Global Score r= -. 522, p= .00; Indices: Memory r= -.163, p= .212; Executive function r= -.477, p= .00; Attention r= -.439, p= .00; Processing Speed r= -.496, p= .00; Motor Skills r= -.532, p= .00].

Conclusion: Given the simplicity of the extending scale, we suggest incorporating this modification into the American College of Rheumatology (ACR) FM diagnostic criteria.

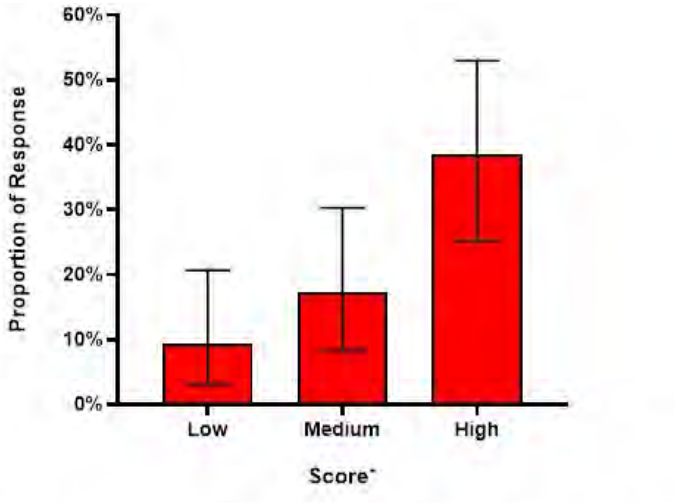
CYP2D6 Genotype and Reduced Codeine Analgesic Effect in Real-World Clinical Practice

Daniel Carranza Leon[1], Alyson Dickson[2], Andrea Gaedigk[3], C. Michael Stein[2] and Cecilia Chung[2], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, [3]University of Missouri, Kansas City

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Codeine, a widely prescribed analgesic, is an inactive pro-drug that is metabolized to morphine, the active drug, by cytochrome P450 2D6 (CYP2D6), a highly polymorphic enzyme. However, the impact of CYP2D6 metabolizer status on pain control in patients receiving codeine in real-world clinical practice is still poorly defined. We examined the hypotheses that among patients prescribed codeine (1) CYP2D6 poor and intermediate metabolizers have poorer pain control than normal or ultrarapid metabolizers; and (2) a response score combining clinical data with CYP2D6 phenotype is associated with pain response in real-world clinical practice.

Methods: We studied 157 patients with a baseline pain score higher than 4 (0-10 scale) who received codeine and had complete clinical data using a DNA biobank linked with electronic health records (EHRs). The primary outcome was pain response, defined as pain score of 4 or lower while receiving codeine. Clinical variables were collected from



*Score Group	Standardized Score Range	Observed Proportion (95% CI)
Low	0.0-55.6	9.4 (3.1-20.7)
Medium	55.7-73.3	17.3 (8.2-30.3)
High	73.4-100.0	38.4 (25.3-53.0)

EHRs and a propensity score developed to adjust for potential confounders. Patients were classified as poor (PM), intermediate (IM), normal (NM), or ultrarapid CYP2D6 metabolizers (UM) based on *CYP2D6* genotyping. To discriminate between patients who responded and who did not respond to codeine, we built a score that included clinical variables and CYP2D6 phenotype.

Results: There were 69 PM or IMs and 88 NM or UMs. Among the PM and IMs, the response rate was 14% (10 out of 69), compared to 27% among the NM or UM metabolizers (24 out of 88), p=0.08. After propensity score adjustment, the odds ratio of achieving a pain score of 4 or lower was 0.35 (95% CI: 0.14-0.84, p=0.02) among PM or IMs. The response rate was 38.5% (95% CI=25.3-53.0%) among patients in the high, 17.3% (95% CI: 8.2-30.3%) in the intermediate, and 9.4% (95% CI: 3.1-20.7%) in the low response score groups, respectively (p=0.001) (Figure).

Conclusion: The analgesic effect of codeine was lower among PM and IMs than in NM and UMs. A score based on CYP2D6 phenotype and clinical variables improved the discrimination between analgesic response and non-response to codeine in real-world clinical practice.

Pain in the Time of Corona: Impact of COVID 19 Outbreak on Fibromyalgia Patients

Valerie Aloush[1], Avital Gurfinkel[2], Noam Shachar[3], Jacob Ablin[1] and Odelia Elkana[4], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Academic College TelAviv- Jaffa, Tel Aviv, Israel, [3]Acamedic College Tel Aviv- Jaffa, Tel Aviv, Israel, [4]Academic College Tel Aviv Jaffa, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia is a chronic pain disorder, characterized by abnormal pain processing in the central nervous system. Acute or chronic stress may trigger or aggravate symptoms. We aimed to evaluate the physical and mental health of fibromyalgia (FMS) patients during the COVID 19 outbreak, and to identify related protective and risk factors.

Methods: An online survey was published via social media dedicated to fibromyalgia patients (FMS associations) in May 2020, following two months of lockdown and social distancing due to the COVID 19 outbreak. The survey included questionnaires regarding demographic and socio-economic characteristics, access to medical services, anxiety, depression, life approach, coping strategies and perception of social support. Fibromyalgia severity was assessed using the widespread pain index (WPI) and symptoms severity scale (SSS), insomnia severity index (ISI) and patient global assessment

Results: A total of 262 fibromyalgia patients were recruited of which 233 (90% women, median age 46.1 years) completed the entire study questionnaire and thus were included in the analysis. During the lockdown, 43% of patients stopped contact with their treating physician and 98% were forced to discontinue complementary - alternative treatments. On the other hand, all patients undergoing psychotherapy continued online follow-up. Among the 41% of responders who had been treated with medical cannabis, 30% were forced to discontinue treatment due to

logistic difficulties and this was associated with significantly higher scores of WPI/SSS compared with patients who continued cannabis treatment (p=0.024). Higher levels of anxiety and depression were significantly correlated with higher levels of pain, sleep disorders and subjective perception of deterioration (p=0.00). Higher scores of social support and positive life approach were correlated with less anxiety and depression (p< 0.01), lower levels of pain (p< 0.05) and less sleep disturbances (p< 0.01). Avoidant coping style such as denial and behavioral disengagement was strongly associated to higher levels of pain, sleep disturbances, anxiety, depression and subjective perception of worsening (p< 0.01).

Conclusion: The current study documented high levels of anxiety, depression, sleep disturbances and pain among fibromyalgia patients during the COVID-19 outbreak, with a large proportion of patients reporting a worsening of symptoms during this period. While general stress associated with the pandemic is an obvious possible culprit for this course, additional factors such as difficulty in accessing medical and complementary treatments, as well as specific medications such as medical cannabis, may play a central role. Protective factors such as social support and a positive life approach appear to be particularly important.

Urine Proteomic Classifiers Predict Renal Histological Activity and Chronicity Indices and May Predict Treatment Response in Lupus Nephritis

Emma Weeding[1], Andrea Fava[1], Jill Buyon[2], H. Michael Belmont[3], Peter Izmirly[4], Robert Clancy[5], Jose Monroy-Trujillo[6], Derek Fine[6], William Apruzzese[7], Harald Mischak[8] and Michelle Petri[9], [1]Johns Hopkins University, Baltimore, MD, [2]Department of Medicine, NYU School of Medicine, New York, NY, [3]NYU School of Medicine, New York, NY, [4]Department of Medicine, New York University School of Medicine, New York, NY, [5]New York University School of Medicine, New York, NY, [6]Johns Hopkins University, Baltimore, [7]., Boston, [8]Multiple Institutions, Glasgow, United Kingdom, [9]Johns Hopkins University School of Medicine, Baltimore

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Current management of lupus nephritis (LN) is guided by histopathological features on kidney biopsy and measurement of proteinuria. Urine proteomics is a non-invasive source of novel biomarkers which may better reflect the complex dynamic immunobiology of LN in real time. Two composite measures include CKD273, which can predict the risk of progression of chronic kidney disease in the general population, and LN120, which was designed to diagnose LN. Both are multidimensional urine proteomic classifiers consisting of 273 or 120 peptides, respectively, with major components including collagen fragments, abundant blood-derived proteins, and proteins involved in inflammation. We investigated the ability of these classifiers to predict traditional biopsy features and disease response in LN.

Methods: A total of 31 adults with biopsy-proven LN were included in this study. All participants met the SLICC and 2019 EULAR/ACR Classification Criteria for SLE based on a spot urine protein-to-creatinine ratio of >0.5 and class III, IV, and/or V LN on renal biopsy. Urine samples were collected at week 0 (at the time of renal biopsy) and week 12 and then subjected to peptidome analysis using a capillary electrophoresis-mass spectrometry (CE-MS) platform.

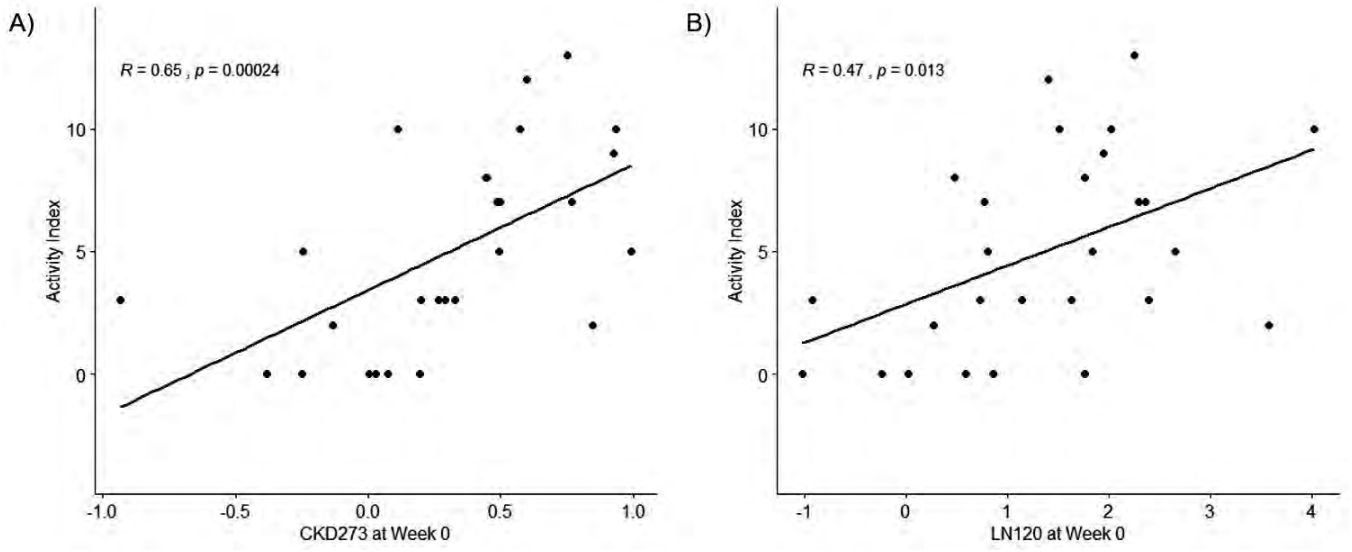

Figure 1. A) Correlation between CKD273 and activity index on renal biopsy at week 0. B) Analogous correlation between LN120 and activity index at week 0. R = Spearman's rank correlation coefficient.

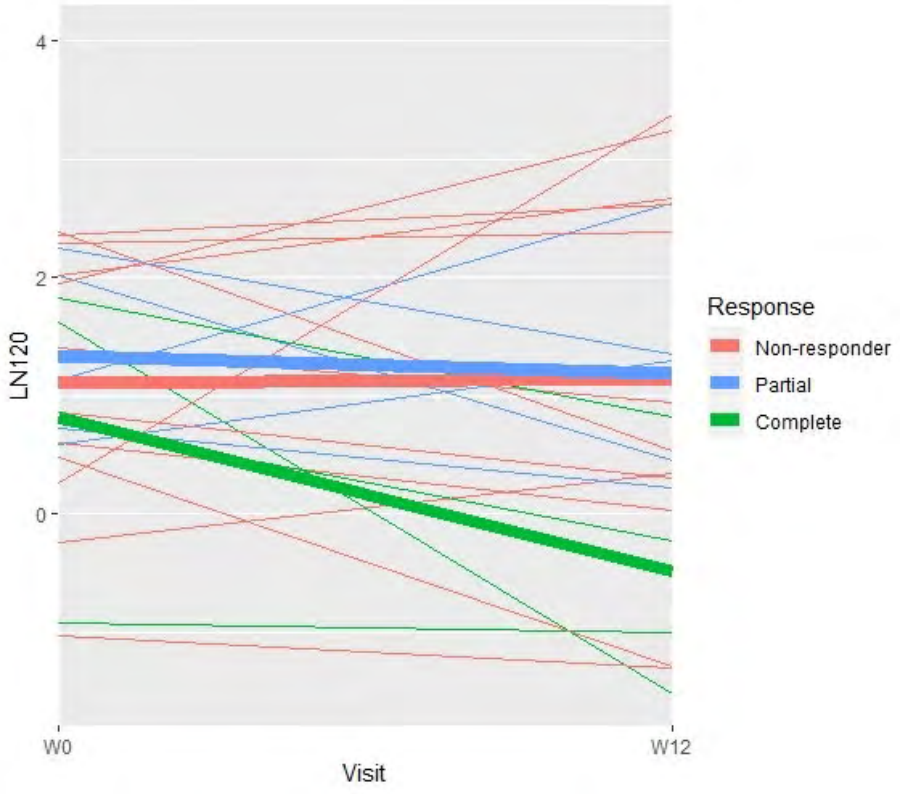

Figure 2. Change in LN120 from week 0 (W0) to week 12 (W12) by response group. Thin lines represent individual participants, and thicker lines represent the average LN120 per response group. Only individuals with urine peptidome data from both time points were included in this Figure (4 complete responders, 5 partial responders, and 12 non-responders).

This peptidome data was used to calculate CKD273 and LN120 classifiers at each time point. LN response status was determined at week 52 based on proteinuria, creatinine, and prednisone dosage (no more than 10 mg daily). Spearman's rank correlation and t-tests were used to compare proteomic classifiers with renal biopsy characteristics and response.

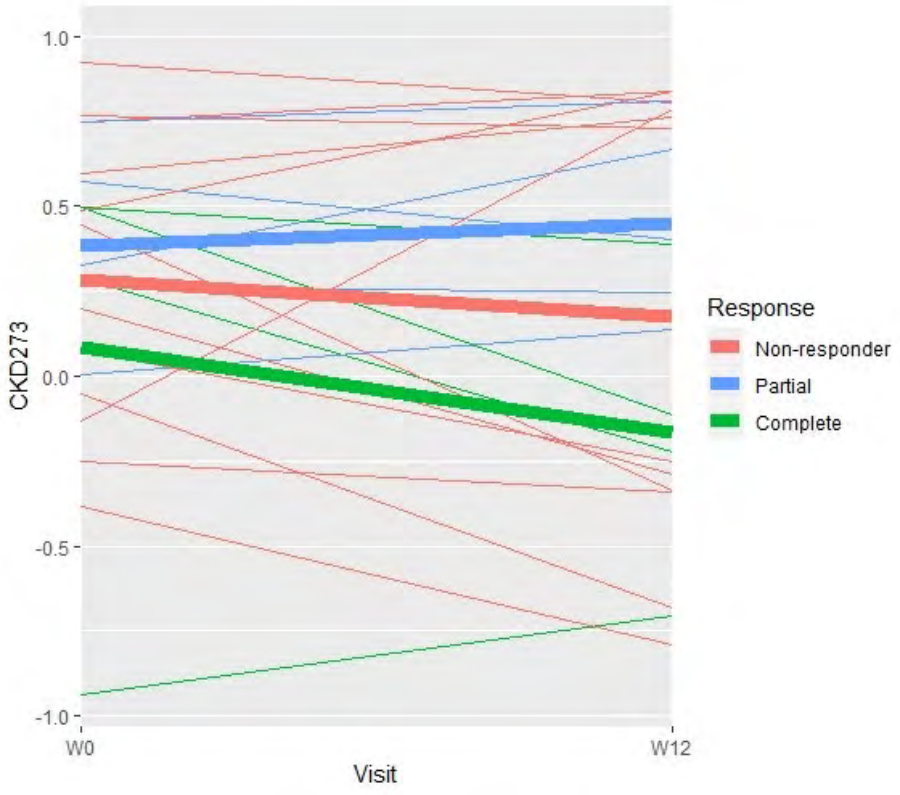

Figure 3. Change in CKD273 from week 0 (W0) to week 12 (W12) by response group. Thin lines represent individual participants, and thicker lines represent the average CKD273 per response group. Only individuals with urine peptidome data from both time points were included in this Figure (4 complete responders, 5 partial responders, and 12 non-responders).

Results: At week 0, both CKD273 and LN120, but not proteinuria, exhibited a moderate to strong correlation with histological activity index on renal biopsy (**Figure 1**; $\rho = 0.65$ with $p = 0.00024$ for CKD273; $\rho = 0.47$ with $p = 0.013$ for LN120). CKD273 also correlated with chronicity index ($\rho = 0.54$, $p = 0.0037$). Neither classifier significantly correlated with lupus nephritis ISN class. With respect to response, CKD273 and LN120 were not significantly different between groups at week 0. However, a reduction in LN120 was observed in 100% of complete responders, 60% of partial responders, and 50% of non-responders at week 12 (**Figure 2**). The magnitude of this change in LN120 in complete responders versus non-responders did not reach statistical significance ($p = 0.13$), though this is potentially because of the small number of responders with CE-MS data available at both time points ($n = 4$). CKD273 did not significantly change with time in any response group (**Figure 3**).

Conclusion: This work provides proof of concept that urine proteomic classifiers can noninvasively predict histological activity and chronicity in LN. Complete responders, but not partial responders or non-responders, exhibited an impressive numerical decrease in LN120 by week 12, suggesting that proteomic scores may track with and predict a durable treatment response. Larger studies are needed to validate these findings.

Distinct DNA Methylation Patterns of Rheumatoid Arthritis Peripheral Blood and Synovial Tissue T Cells

Rizi Ai[1], Gary Firestein[2], David Boyle[3] and Wei Wang[4], [1]University of California San Diego, San Diego, CA, [2]University of California, San Diego, La Jolla, CA, [3]UCSD, La Jolla, CA, [4]UCSD, La Jolla

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To understand the epigenetic patterns of T cells accumulated in rheumatoid arthritis (RA) synovium, we characterized DNA methylation of CD3+ T cells in peripheral blood and synovial tissue in RA and osteoarthritis (OA) patients.

Methods: Genomic DNA of CD3+ T cells was isolated from RA (synovial tissue: n = 8, with 3 matched peripheral blood) and matched OA (5 matched synovial tissue and peripheral blood) patients after separating peripheral blood cells using antibodies and magnetic beads. Methylation was measured using the Illumina Infinium Methylation EPIC Kit chip. Differentially methylated loci (DMLs) were identified using Welch's *t*-test and mapped to gene promoter regions to define differentially methylated genes (DMGs). Principal component analysis (PCA) and hierarchical clustering were used to represent the relationship among each group. To compare enriched biological pathways, pathway analysis was applied using Reactome and MSigDB.

Results: PCA results showed that methylation differences in T cells primarily distinguished based on location (blood vs. synovium PCA1 95%) compared with by disease (RA vs OA), mainly with more diversity in synovial T cells (peripheral blood CD3+ cells were clustered within PC3 0.35%) (Figure 1). By comparing DNA methylation differences

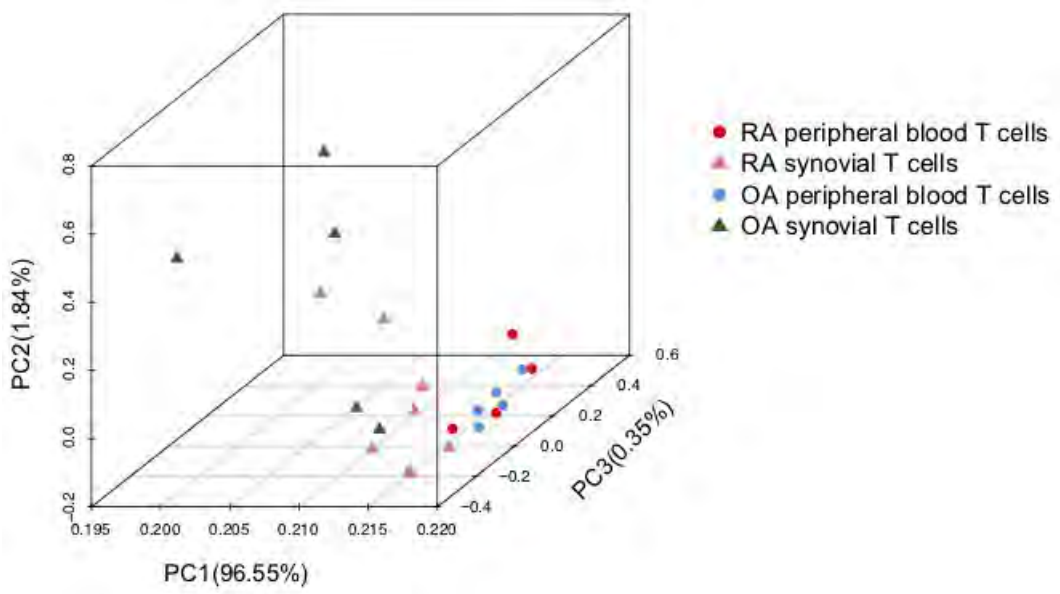

Figure 1. PCA plot shows the segregation of samples are more distinguishable between T cell location (peripheral blood and synovium) than disease. The greatest differences were observed between RA synovial and peripheral blood T cells.

and DMGs of CD3+ T cells between peripheral blood and synovial tissue, we found 4615 and 832, respectively, for RA but only 164 DMLs and 36 DMGs for OA (q value < 0.05). Therefore, significant blood/synovium methylation differences were mainly identified in RA. By comparing RA and OA to each other, we found 1120 DMLs (p value < 0.05) in 363 DMGs in blood CD3+ T cells and 4104 DMLs (p value < 0.01) in 870 DMGs in synovial CD3+ T cells, respectively. Differentially modified pathways were significantly enriched between RA blood and synovial T cells, especially in genes related to complement, integrin cell surface interactions and the P53 pathway. Only a small number of significantly different pathways were observed between RA and OA peripheral blood. Three significantly enriched pathways between RA and OA in synovial T cells show that the main differences are related to metabolic pathways. Although 870 DMGs were identified between RA and OA in synovial T cells using p value < 0.01, most do not fall into pathways, possibly due to the small sample size. No significant pathways distinguished OA peripheral blood CD3+ T cells compared to OA synovium as only 36 DMGs were identified.

Conclusion: The patterns of DNA methylation in RA show disease and location specific differences in immune pathways including cell contact interactions (compliment and integrins) and survival. The RA joint-specific signatures could be due to selective accumulation of T cell populations, epigenetic modification *in situ*, or expansion of differentially marked adaptive immune cells. Identifying epigenetic patterns could provide clues to site and event specific targeTable T cells in the RA.

Metabolomics Profiling Predicts Outcome of Tocilizumab in Rheumatoid Arthritis

Jessica Murillo-Saich[1], Cesar Diaz-Torne[2], M. Angeles Ortiz[2], Roxana Coras[1], Arthur Kavanaugh[3], Hector Corominas[2], Silvia Vidal[2] and Monica Guma[4], [1]University of California San Diego, La Jolla, CA, [2]Institut Rec. Hospital de la Santa Creu I Sant Pau., Barcelona, Spain, [3]Division of Rheumatology, Allergy, & Immunology, University of California San Diego Medical School, San Diego, CA, [4]Division of Rheumatology, University of California San Diego, Department of Medicine, Autonomous University of Barcelona, La Jolla, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Metabolomics may provide information about the activity and severity of specific diseases and potentially help discriminate between diseases. Choosing the right biological therapy earlier in the course of rheumatoid arthritis (RA) could help to reach the goal of remission. We hypothesized that characterization of patients' metabolic profiles, utilizing high resolution ^{1}H-nuclear magnetic resonance (NMR), may predict response to tocilizumab therapy prior to treatment in patients with RA.

Methods: 41 patients meeting the 2010 ACR/EULAR classification criteria had initiated treatment with 8 mg/kg of tocilizumab every 4 weeks following usual clinical practice were included in the study. Clinical outcomes were determined at baseline and at 6 months after treatment. Using EULAR response criteria, patients were categorized as responders (good response) or non-responders (moderate response and no response) . Blood was collected at baseline and at 6 months after tocilizumab therapy. A 600 MHz Bruker Avance III spectrometer ^{1}H-NMR was used to acquire NMR spectra of serum samples. Software Chenomx NMR suite 8.5 professional was used for metabolite

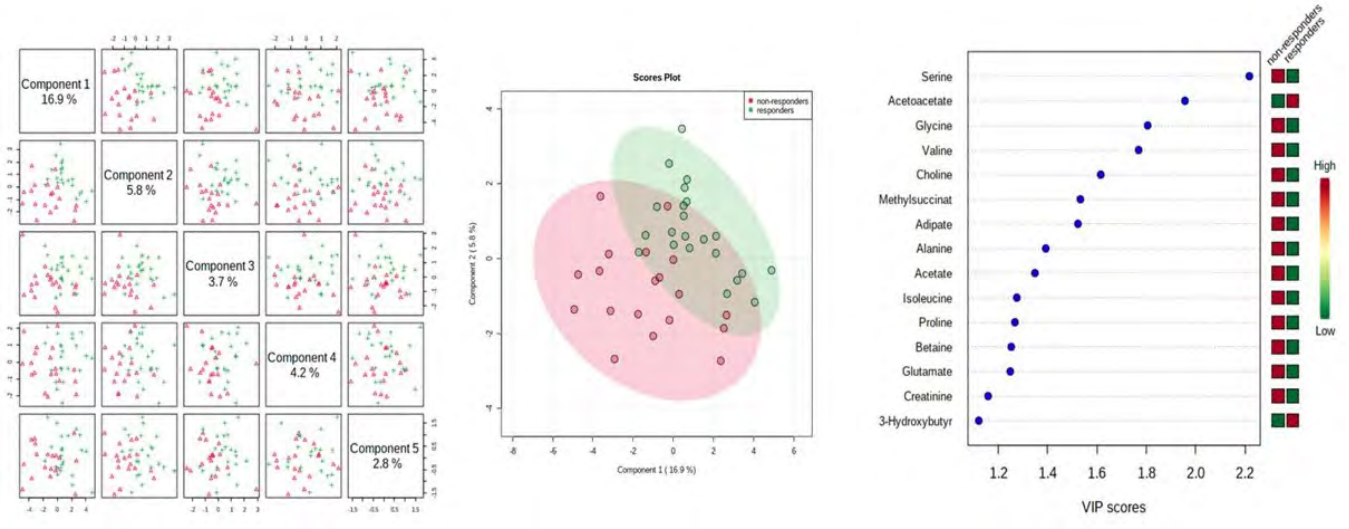

Figure 1. PLS-DA (explaining 16.9% of the total variance) confirmed that metabolites profiles differ among groups. A total of 15 metabolites had VIP scores >1.

identification and quantification. Significantly metabolites were identified and the relationship between metabolites and clinical outcome was studied. SPSS and MetaboAnalyis 4.0 KEGG 2019 were used for statistical and pathway analysis.

Results: 41 patients (average age 53 , standard deviation (SD) 11) were analyzed. The patients had an initial DAS-28CRP of 5.7±1.1. Multivariate statistical analysis of the ^{1}H-NMR baseline spectra successfully discriminated between RA patients classified as tocilizumab responders (n = 22) and non-responders (n = 19), at baseline and 6 months after tocilizumab treatment. A two sample t-test produced p-values of less than 0.05 for seven metabolites which were increased significantly at baseline in responders: 3-hydroxybutyrate, Isobutyrate, Lysine, O-phosphocholine, Phenylalanine, Tryptophan, and Tyrosine. Several metabolites varied their levels following treatement with tocilizumab in both responders and non responders. Of interest, acetoacetate and acetone significantly decreased in non-responders at 6 months of treatment. A PLS-DA (explaining 16.9% of the total variance) confirmed that metabolites profiles differ among groups, although a certain overlap existed (Figure 1). A total of 15 metabolites had VIP scores >1. Individual metabolites yielded area under the curve (AUC) values lower than 70%, indicating relatively poor specificity and sensitivity. A multivariate diagnostic model, showed that concentrations of hydroxybutyrate, leucine, tryptophan, and alanine, improved the sensitivity and specificity of the diagnosis with an AUC of 92.7%. Using this biomarker model, 85% of the patients were correctly classified.

Conclusion: The clear relationship between blood profiles and patient response to tocilizumab therapy suggests that the application of ^{1}H-NMR profiling is a promising clinical tool for RA therapy optimization. More metabolic profiles studies are needed to determine if metabolic profiling can predict response to other biological therapies in RA patients**.**

A Prospective, Multicenter, Clinical Performance Evaluation Study for an in-vitro Diagnostics Medical Device (PREDYSTIC® Infliximab RA) for Prediction of Infliximab Responsiveness in the Treatment of Rheumatoid Arthritis

Miklos Sebeszta[1], Katalin Tauberne Jakab[1], Tamas Ponyi[1], Gyula Poor[2], Zsolt Hollo[1], Laszlo Szilagyi[1], **Emese Kiss**[2] and Gabor Zahuczky[3], [1]Egis Pharmaceuticals, Budapest, Hungary, [2]ORFI, Budapest, Hungary, [3]UD Genomed, Debrecen, Hungary

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 30-40% of RA patients fail to respond to first biological therapy. Predicting the patient's responsiveness to the first biological therapy is still an unmet need in the clinical setting. In the case of non-responder (NR) patients it leads to unnecessary exposure, delay of adequate therapy, disease progression and therapy cost increase. By identifying those bio-naive RA patients who are likely responders (Rs) or NRs to infliximab (both intravenous and subcutaneous) treatment, a predictive in vitro testing would have a significant effect on the administration of TNF-α inhibitor therapy, on the real life implementation of effective personalized therapy.

The purpose of this in vitro diagnostic medical device performance evaluation study was to demonstrate that – gene expression profiles of a selected gene set as genomic biomarkers (i.e. the IVD medical device) and a proprietary algorithm for data analysis – predict month 6 therapeutic response to infliximab, discriminate between Rs and NRs. Rs were defined if they reached DAS target value DAS28≤3.2 at 6 month (M6).

Methods: Two hundred twenty bio-naive RA patients were enrolled with moderate-high activity RA (DAS28-CRP >3.2), who have responded inadequately to DMARDs (including methotrexate), after they have been assigned to infliximab treatment. All patients received commercially available infliximab, procured according to SmPC, local guidelines and regulations in this non-interventional clinical study. The clinical response was evaluated according to the change from baseline in disease activity at M6. Clinical characteristics (RA duration, smoke, steroid treatment) and serological parameters (RF, ACPA, aCVM) were collected. A 3rd visit was scheduled around week 22 (M6) and change of DAS28-CRP value from the baseline has been evaluated. Gene expression profiling was performed from blood samples taken at month 0 (M0) – just before the first infliximab infusion. Global gene expression profiling was performed to identify differentially expressing genes using RNA sequencing.

Results: A total of 250 genes were identified by a combination of differential gene expression analyses, feature elimination techniques and various machine learning modelling methods of which 44 genes showed significant differences between NR and good Rs groups The expression of the reduced gene set was confirmed and further analyzed

using reverse-transcription and quantitative real-time PCR. Interim analysis identified associations between gene expression and clinical response/ non-response to infliximab therapy.

Table: Three models containing gene expression + clinical data sets illustrates some statistical characteristics

Conclusion: This set of genes and selected clinical parameters are predictive markers for infliximab specific response in RA patients. The complete results of the ongoing clinical validation in an independent patient cohort (n=56) is expected in September 2020. This novel in vitro diagnostic test method, for the prediction of infliximab treatment responsiveness before treatment initiation of RA patients, is a tool to personalize infliximab therapy.

Abstract Number: 0033

Pre-pregnancy Long Non-coding RNA Expression Signatures Among Women with Rheumatoid Arthritis Who Improve or Worsen During Pregnancy

Matthew Wright[1], Mette Kiel Smed[2], J Lee Nelson[3], Jørn Olsen[4], Merete Hetland[5], Vibeke Zoffmann[2] and Damini Jawaheer[6], [1]UCSF Children's Hospital Oakland Research Institute, Oakland, CA, [2]The Juliane Marie Center, Copenhagen, Denmark, [3]Fred Hutchinson Cancer Res Ctr and U of WA, Seattle, WA, [4]Aarhus University Hospital, Aarhus, Denmark, [5]The DANBIO Registry, Rigshospitalet, Glostrup, Denmark, [6]UCSF Benioff Children's Hospital Oakland Research Institute, Oakland, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancy is known to have disease-modifying effects on rheumatoid arthritis (RA). A role for long non-coding (lnc) RNAs in the improvement or worsening of RA during pregnancy has not previously been investigated. We have examined lncRNAs signatures associated with RA before and during pregnancy, when the disease improves or worsens, and their co-expression with protein coding genes.

Methods: Data and samples collected at pre-pregnancy (T0) and 3rd trimester (T3) from women with RA (n=21) and healthy women (n=14) enrolled in our prospective pregnancy cohort were included in this analysis. Disease activity was assessed using the Clinical Disease Activity Index (CDAI). Total RNA from whole blood were sequenced (RNA-seq). Following mapping of RNA-seq reads (HISAT2) and transcript assembly (StringTie), lnc and coding RNA transcripts were quantified (featureCounts) and normalized. At each time-point, RA-associated expression signatures were identified using differential expression analysis (edgeR), comparing each RA group (subsequently improved or worsened during pregnancy) to healthy women (significance threshold: $q < 0.05$ and fold-change≥ 2). lnc and coding RNAs were examined for co-expression. Functional analysis was performed using Cytoscape.

Results: Of the 21 women with RA,15 improved by T3 ($RA_{improved}$), while 6 worsened ($RA_{worsened}$). At T0, 311 lncRNAs (99 known, 212 novel) were differentially expressed (DE) between $RA_{improved}$ and healthy women. Of these, 48 were co-expressed ($r > 0.95$) with 264 protein-coding genes, many of which were also DE ($RA_{improved}$ vs healthy at T0). Several had been previously associated with RA (e.g. *FCGR2A, IL1R1, IL1R2, IL6R, S100A6* and *TLR4*). The co-expressed

genes were enriched in gene ontology (GO) terms leukocyte activation ($q=1.2x10^{-15}$), immune response ($q= 1.4x10^{-14}$) and neutrophil activation ($q= 2.4x10^{-14}$). At T3, when RA improved, 287 of the 311 lncRNAs (92%) in the T0 RA signature were no longer DE between $RA_{improved}$ and healthy women. Among the $RA_{worsened}$ women, a very different RA lncRNA signature was identified at T0, although disease activity was similar in both RA groups at baseline (p=0.9): 81 lncRNAs (26 known, 55 novel) were DE ($RA_{worsened}$ vs healthy), of which only 23 overlapped with the RA lncRNA signature of $RA_{improved}$ women at T0. Many of these lncRNAs (n=57) were co-expressed with protein-coding genes, most of which were not DE. At T3, when RA worsened, only 41 of the 81 (51%) lncRNAs DE at T0 lost their differential expression, and an additional 34 became newly DE.

Conclusion: In our dataset, there was little overlap in pre-pregnancy RA-associated lncRNA expression signatures between women with RA who improved during pregnancy and those who worsened. Further, many of the lnc and coding RNAs DE at T0 in the improved group were co-expressed, and were no longer DE at T3 when RA improved. We speculate that those lncRNAs could have a role in regulating expression of the coding RNAs during pregnancy, contributing to RA improvement.

Gene Expression Signatures in C-Reactive Protein High and Low Rheumatoid Arthritis

Adam Cornish[1], **Kristin Wipfler**[1] and Kaleb Michaud[2], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Transcriptome profiling has expanded our ability to identify biomarkers and therapeutic targets and better understand disease progression in a wide variety of conditions. Serum C-reactive protein (CRP) is a marker of inflammation and is widely used to assess disease activity in RA. The aim of this study was to identify differentially expressed genes in CRP high and low patients with RA.

Methods: Whole blood samples were collected from participants in the Arthritis Internet Registry and FORWARD, The National Databank for Rheumatic Diseases. The biosamples are associated with demographic and clinical data from comprehensive biannual questionnaires. RNA was extracted and sequenced for 60 participants with RA (30 with high inflammatory levels and 30 with low inflammatory levels, assessed using blood concentrations of CRP). Version 1.2.3 of the bcbio pipeline was used to perform alignments (hisat2), read data qc (qualimap, fastqc), and transcript quantification (salmon). For differential expression analysis, DESeq2 was used in conjunction with the bcbioRNAseq R package. Student's t tests and X^2 tests were performed to assess significant demographic and clinical differences between the high and low disease activity cohorts.

Table 1. Demographic and clinical characteristics of high and low disease activity groups. Bold p values indicate statistical significance.

Results: After restricting the dataset to samples from participants with an associated comprehensive questionnaire fewer than 90 days from the date of sample collection, the high disease activity (CRP >0.8 mg/dL; CRP-high) cohort included 27 participants and the low disease activity (CRP< 0.1 mg/dL; CRP-low) cohort included 25 participants. There were no statistically significant differences in demographics or medications between the two groups, with the exception of BMI, which was higher in the CRP-high group. As expected, the CRP-high group had significantly higher scores on measures of disease activity. All participants in both groups were RF and/or anti-CCP positive (Table 1). Differential Gene Expression analysis with an alpha of 0.01 revealed 32 genes dysregulated between the CRP-high and CRP-low groups. Clustering with Ward's method using these genes as input generated two distinct clusters: one included 30 samples (5 CRP-high, 25 CRP-low) and the other exclusively contained CRP-high samples (22).

Conclusion: NoTable gene signatures resulted in two distinct clusters each comprised almost exclusively of the high and low disease activity groups. Significantly differentially expressed genes identified in this study include several that have previously been implicated in RA and other autoimmune diseases (KLRC1, RAP1GAP, IFI27, LY6E, ISG15, PIM2) as well as several genes not clearly associated with RA, including a group of genes related to cell signaling by receptor tyrosine kinases (EFNA1, SHC2, RHBDF1). RHBDF1, which encodes a catalytically inactive rhomboid protein, may be of particular interest due to its regulatory relationship with ADAM17, a key regulator of TNF that has been implicated in the development and progression of several autoimmune diseases, including RA.

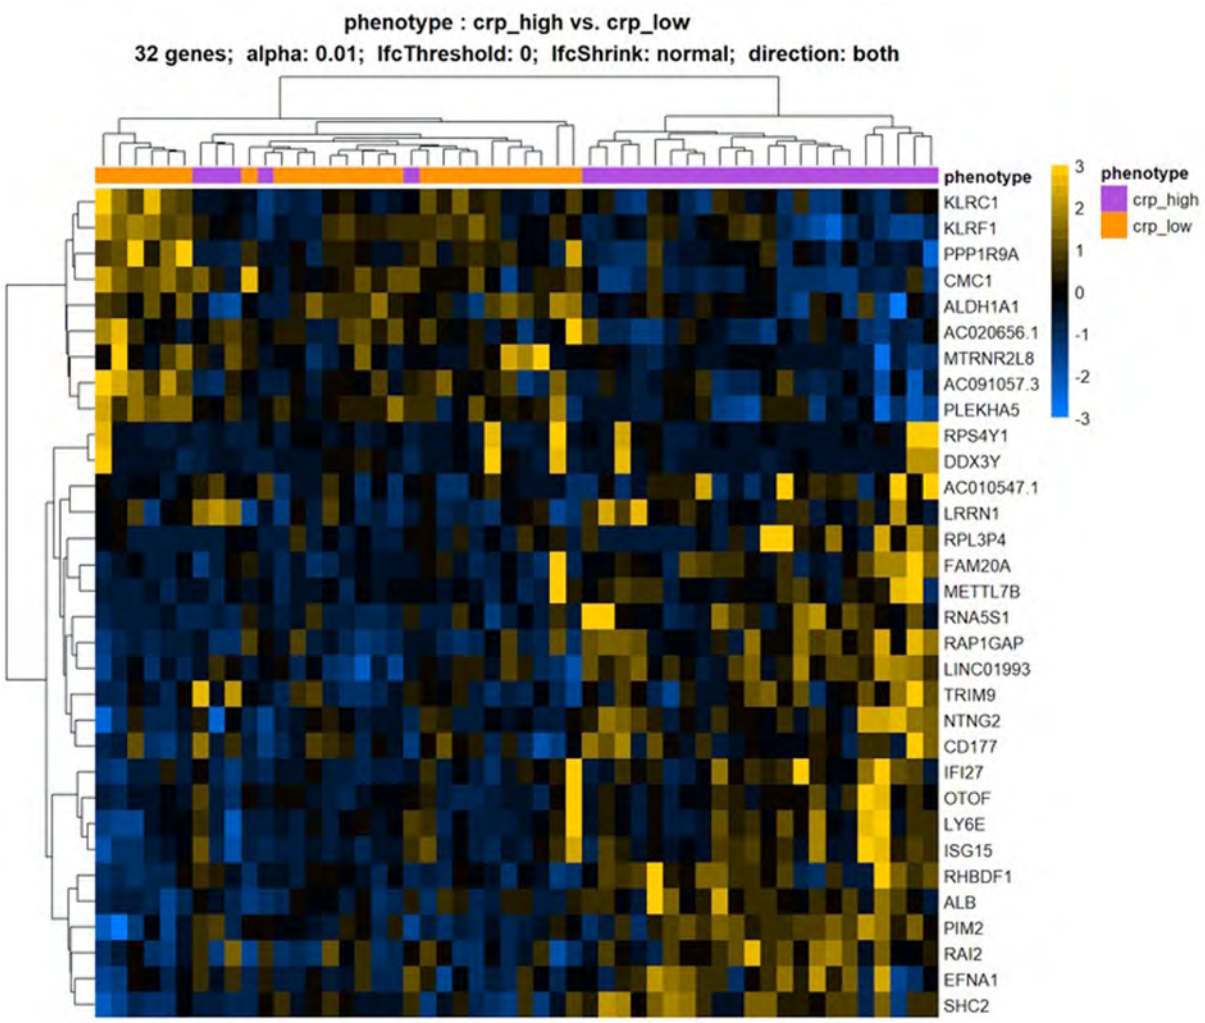

Figure 1. Heat map of dysregulated genes labeled by disease activity (CRP high vs low) and grouped using hierarchical clustering.

Distinct Biological Pathways in Both Blood and Kidney Further Define Molecular Profiles Across Diverse Nephritides

Loqmane Seridi[1], Matteo Cesaroni[1], Qingxuan Song[2], Ashley Orillion[1], Frédéric Baribaud[1], Tatiana Ort[1], Sheng Gao[2], Tomas Parker[3], James Chevalier[3], Dan Levine[3], **Alan Perlman**[3] and Jarrat Jordan[1], [1]Janssen Research & Development, LLC, Spring House, PA, [2]Janssen Research & Development, LLC, Spring House, PA, USA, Spring House, PA, [3]The Rogosin Institute, New York Presbyterian Hospital-Weill Medical College of Cornell University New York, NY, USA., New York, NY

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 40% of SLE patients will develop Lupus Nephritis (LN), of which 10-30 % will progress to end-stage renal disease. To further understand LN pathogenesis, we conducted transcriptomic profiling of blood and kidney biopsy samples from LN patients, healthy control (HC), and from four other nephritides.

Methods: Blood and kidney biopsies from healthy subjects (n=28 and 20 respectively), LN (26,21), Diabetic Nephropathy (DN; 10,6), Hypertensive kidney disease (HT;8,3), Minimal change disease (MC; 7,4), and Membranous nephropathy (MB; 4,4) were collected under informed consent. Gene expression profiling was conducted using RNA-Sequencing (RNASeq). Genes differently expressed between any two conditions (FDR < 0.05) were identified and clustered into co-expressed signatures.

Results: We detected 5 and 6 gene signatures in blood and kidney, respectively. The signatures were enriched in distinct biological pathways, including "Interferon Signaling," "Natural killer cell-mediated cytotoxicity (NK_CMC)," and "Aquaporin-mediated transport (AMT)." When compared to HC, Gene Set Variation Analysis (GSVA) showed an increase of "Interferon Signaling" expression in LN (p = 2.8E-6) and DN (p= 0.0038) blood and in LN (p=8.7E-8), DN (p=3.8E-4), HT (p=0.018) and MB (p=0.018) kidney. In LN and HT blood, we observed a decreased enrichment of the NK_CMC signature (p =1E-13, p=6.3E-3). A bimodal enrichment was observed in DN and MC blood, and ~40% of those patients showed an expression level comparable to that of the LN population. Also, the NK_CMC signature was upregulated in LN (P=0.011) and DN (P=0.016) kidney. Finally, the AMT signature was downregulated in kidney in all indications compared to healthy (p< 0.05).

Conclusion: Co-expression clustering of dysregulated genes unveiled signatures enriched in distinct biological pathways in both blood and kidney of nephritides. IFN signature upregulation in blood was specific to LN and DN, with a more prominent signal observed in LN. The IFN signature was upregulated in the kidney in all indications except MC. An NK-mediated cytotoxicity gene signature was down-regulation in the blood of LN and HT and upregulated in the kidney of LN and DN, suggesting a possible role of NK mediated cytotoxicity in LN and DN pathogenesis. A signature enriched in aquaporin-mediated transport genes was downregulated in the kidney and might reflect kidney damage. Although this analysis was adequately powered for LN, trends observed in other indications require further validation with larger cohorts.

Molecular Phenotyping of Late-Stage Knee Osteoarthritis Synovium Through Total RNA-Sequencing

Anusha Ratneswaran[1], Chiara Pastrello[1], Pratibha Potla[2], Osvaldo Espin-Garcia[2], Starlee Lively[2], Anthony Perruccio[3], Raj Rampersaud[2], Rajiv Gandhi[2] and Mohit Kapoor[4], [1]University Health Network, Toronto, ON, Canada, [2]Krembil RI, Toronto, Canada, [3]Krembil Research Institute, UHN; University of Toronto, Toronto, ON, Canada, [4]Krembil RI, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Knee Osteoarthritis (OA) is a painful, disabling condition and molecular mechanisms underlying this disease are poorly understood. In recent years, OA is increasingly viewed as a disease with differing phenotypes which may contribute to its pathogenesis. Characterizing these phenotypes could play an integral role in the development of appropriate therapies. The synovium is a key driver of pathological changes in OA and to date there are few studies examining total RNA sequencing in synovial tissue. This study uses total RNA sequencing to profile the synovium of patients with advanced radiographic knee OA, and elucidates whether these patients have differing endogenous molecular phenotypes.

Methods: Total RNA sequencing was performed on synovium samples from 50 end-stage knee OA patients (KL 3/4). After filtering, 19,857 genes were expressed in synovium. Genes with a mean, and variance greater than 30 across samples were kept for further downstream analysis (4267). To objectively identify number of distinct clusters within the patient cohort, mean silhouette width was plotted, and peaked at 3; indicating this was the optimal cluster number. Genes differentially expressed between clusters were used for pathway analysis. Identified pathways with a q-value less than 0.01 and a gene-ratio higher than 0.05 were retained and annotated to pathways. Interactions among genes were collected using Integrated Integrations Database (University of Toronto), and networks were constructed. Pearson correlation was calculated in each cluster for long-noncoding (lnc) and circular (circ) RNA from differentially expressed genes between clusters. Only correlations with absolute rho greater than 0.95 (lncRNA) or 0.85 (circRNA) were retained and used to construct Protein-Protein Interaction networks.

Results: Unbiased gene clustering indicated 3 clusters of patients distinguished by endogenous molecular differences. These groups do not demonstrate significant differences in measured clinical or anthropometric characteristics including sex, BMI, blood pressure, cholesterol, synovial inflammation, and patient reported pain. The clusters share signaling pathways such as EGFR1, innate and adaptive immune system. Differentially regulated pathways include: signaling by receptor tyrosine kinase, cytokine signaling, and TCR (cluster 2 vs 1) as well as neutrophil degranulation, skeletal muscle, EMT regulation, apoptosis, membrane trafficking, vesicle mediated transport, toll-like receptor signaling and hemostasis (cluster 3 vs 2). We have identified several lnc and circRNA that interact with genes in each distinct pathway and have defined their associated clusters and their positive or negative gene interactions.

Conclusion: Overall, we have observed that endogenous molecular signatures derived from synovium of end-stage OA patients cluster into 3 groups. Pronounced differences in gene expression between clusters indicate both shared and distinct actively transcribed pathways. Identified lnc and circRNA contribute to unique molecular mechanisms differentially expressed between clusters. These differences in endogenous molecular mechanisms may play a role in heterogenous disease development.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: B-cell non-Hodgkin's lymphoma (B-NHL) is one of the major complications of primary Sjögren's syndrome (SS). Chronic inflammation and macrophages in SS minor salivary glands have been previously suggested as significant predictors for lymphoma development among SS patients. Extracellular lipoprotein-associated phospholipase A2 (Lp-PLA2) -a product of tissue macrophages- is found in the circulation associated with lipoproteins and has been previously involved in cardiovascular, autoimmune and malignant diseases, including lymphoma.

The purpose of the current study was to investigate the role of Lp-PLA2 as a potential biomarker for the development of B-NHL in the setting of primary SS.

Methods: Lp-PLA2 activity in serum samples collected from 50 primary SS patients with no lymphoma (SS-nL), 9 primary SS patients with lymphoma (SS-L) and 42 healthy controls (HC) was determined by detection of [^{3}H]PAF degradation products by liquid scintillation counter (Cohort 1). Additionally, sera from an independent cohort of 50 SS-nL, 30 SS-L and 32 HC were tested for Lp-PLA2 activity using a commercially available ELISA kit (Cohort 2). Lp-PLA2 mRNA and protein expression in minor salivary gland (MSG) tissue samples from SS-nL, SS-L patients included in the 2 cohorts and sicca controls (SC) were analyzed by real-Time PCR, western blot and immunohistochemistry.

Results: Serum Lp-PLA2 activity was significantly increased in SS-L compared to both SS-nL and HC in the two independent cohorts included in the study [mean±SD (nmol/min/ml): 62.0±13.4 vs 47.6±14.4 vs 50.7±16.6, p-values: 0.003 and 0.04, respectively (Cohort 1) and 19.0±4.7 vs 15.3±3.2 vs 14.5±3.0, p-values: 0.0005 and 0.0001, respectively (Cohort 2)]. Lp-PLA2 expression in MSG tissues was also increased in SS-L compared to SS-nL and SC at both mRNA and protein level. No significant difference in either serum Lp-PLA2 activity or MSG tissue expression was observed between SS-nL and HC.

Conclusion: Lp-PLA2 serum activity and MSG tissue mRNA/protein expression could serve as a novel biomarker for B-cell lymphoproliferation in the setting of SS.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis (AS) is amongst the most common forms of inflammatory arthritis. Widely used in the treatment of axSpA, adalimumab is an engineered antibody holding only human peptide sequences with high affinity and specificity to soluble and transmembrane TNFα, blocking its interaction with receptors p55 and p75. However, the response to TNFi is heterogeneous and might be linked with some side effects. A priori identification of patients more propense to respond to TNFi is critical in clinical practice.

Methods: The proteomic analysis involved 33 patients with AS from the Bioefficacy SpA Study, of which 19 responders and 14 non-responders after 14 weeks treatment with adalimumab, according to ASAS20 criteria. Serum samples were collected at baseline, 3-5 days, 2 weeks and 14 weeks after treatment. The experimental workflow combined immunoaffinity depletion of the high-abundant serum proteins, tryptic digestion of the proteins extracted from the depleted serum, HPLC separation of tryptic peptides, MS/MS based identification and MS quantification of the detected proteins. Uni- and multivariate statistical analysis of the differentially abundant proteins was used to select the more sensitive and specific serum biomarkers related with therapeutic response. Protein function association network analysis of differential proteins was performed with STRINGdb.

Results: LC-MS/MS method allowed the identification of 333 proteins with at least 2 non-ambiguous peptides. A set of new putative biomarkers was identified with 8 proteins displaying differences between R and NR ($p < 0.05$) at

baseline. Of these, 3 proteins were highly linked with a good clinical response, while the other 5 proteins were strongly related with a non-response to adalimumab therapy at W14. This set of proteins was confirmed to be predictive of the type of response to treatment with an area under the Receiver Operating Characteristics (ROC) curve of 1. Additionally, our analysis showed that the pathways dysregulated in both groups were relatively similar.

Conclusion: Proteomic approaches constitute a very promising strategy to the identification of biomarkers to predict a therapeutic response. These results provide evidence that a panel of biomarker proteins might be identified even before the beginning of treatment which is of utmost importance for clinical practice.

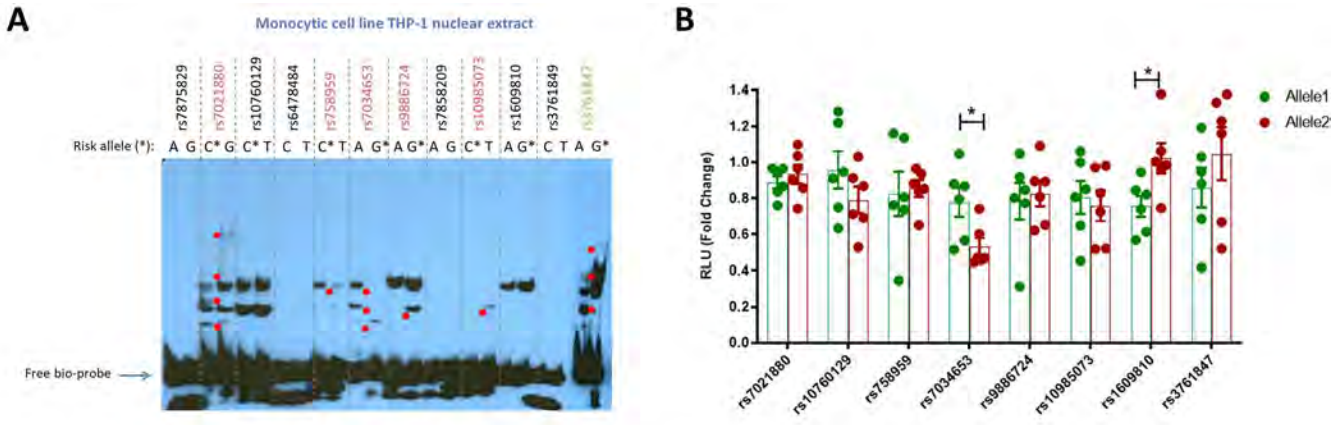

Figure 1 EMSA and luciferase reporter assay for candidate fSNPs from SNP-seq screening. (A) EMSA for 12 SNPs candidates. Allele-specific gel shift/binding are shown as red dots.(*n* = 3 independent biological replicates with similar results). (B) Luciferase reporter assay showing relative luciferase activity in human THP-1 cells between the non-risk (green) and risk (red) alleles of 8 candidate fSNPs. (mean ± s.d., *n* = 3 biological replicates, *t* test with two tails without correction for multiple hypothesis testing, * shows p<0.05).

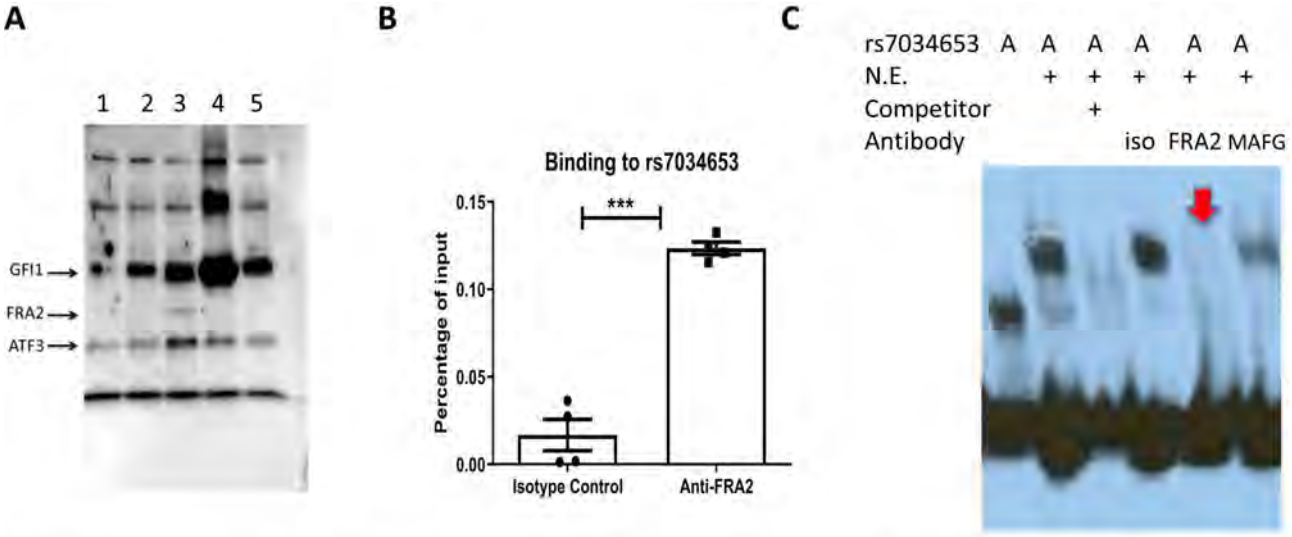

Figure 2 FRA2 binding to rs7034653 validation. (A) oligo pulldown western blot assay. 1: rs1609810-G; 2: rs1609810 –G with non-biotinylated competitor (30x); 3: rs7034653-A; 4: rs7034653-A with non-biotinylated competitor (30x) ;5: control SNP rs3768056-A. FRA2 binds specifically to rs7034653-A, control antibodies GFI1 and ATF3 bind to all five samples. (*n* = 3 independent biological replicates with similar results). (B) CHIP-qPCR shows FRA2 binding to rs7034653 in human THP-1 cells (mean ± s.d., *n* = 2 biological replicates, *t* test with two tails without correction for multiple hypothesis testing, *** shows p<0.0001). (C) EMSA supershift assay shows specific binding of rs7034653-A to FRA2. The addition of antibody to FRA2 in the oligo/nuclear extract (THP-1) mixture caused the disappearance of shift band (arrow), whereas isotype control antibody and antibody to MAFG did not.

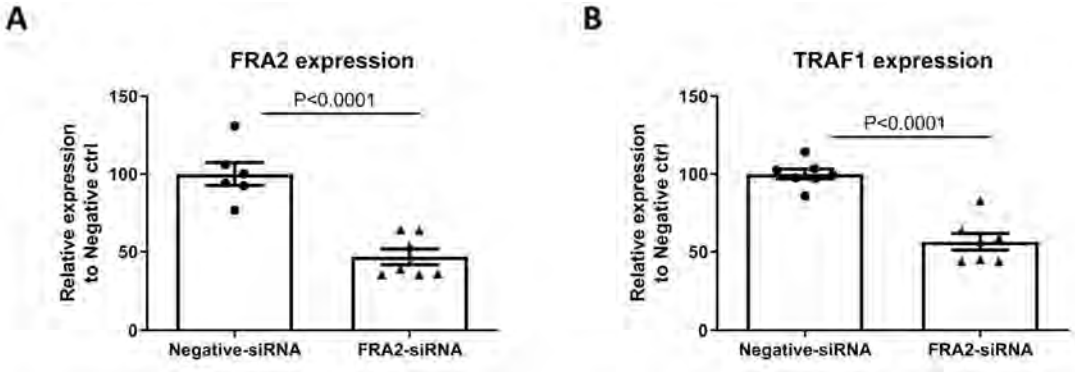

Figure 3 RT-qPCR mRNA gene expression for gene FRA2 and TRAF1 after FRA2 siRNA knockdown in THP-1 cells. (A) FRA2 mRNA expression relative to negative siRNA treated control (mean ± s.d., *n* = 2 biological replicates, *t* test with two tails without correction for multiple hypothesis testing, p<0.0001). (B) TRAF1 mRNA expression relative to negative siRNA treated control (mean ± s.d., *n* = 2 biological replicates, *t* test with two tails without correction for multiple hypothesis testing, p<0.0001).

Background/Purpose: Over the past decade, genome-wide association studies (GWAS) have identified TRAF1/C5 locus as a risk locus for rheumatoid diseases including RA and JIA(Plenge, Seielstad et al. 2007, Behrens, Finkel et al. 2008), and TRAF1 negatively regulates Toll-like receptor signaling(Abdul-Sater, Edilova et al. 2017). However, the exact risk variant within that locus and its underlying mechanism regulating TRAF1 expression are still not known. We aim to identify non-coding variant in TRAF1/C5 locus governing the expression of TRAF1 gene and its regulatory pathway.

Methods: Single-nucleotide polymorphisms (SNPs) in linkage disequilibrium (LD) with the most disease-associated SNP in TRAF1/C5 locus from immunochip data (5 thousand JIA patients and 14 thousand health controls) were high-throughput screened by SNP-seq(Li, Martinez-Bonet et al. 2018). Top candidates' regulatory function were further validated by electrophoretic mobility shift assay (EMSA) and luciferase reporter assay. Then the transcriptional factor that might bind to the functional variant after validation was tested by CHIP-qPCR, oligo pulldown assay as well as supershift assay. Finally, the association between this transcriptional factor and TRAF1 gene expression was analyzed by RNAi knockdown experiment.

Results: After screening by SNP-seq, EMSA, and luciferase reporter assay, rs7034653 was found to be the best functional non-coding variant in TRAF1/C5 locus that is associated with JIA. EMSA shows that protein from monocyte nuclear extract has a preferential binding to protective allele A than the risk allele G of rs7034653, and that binding preference likely regulates higher gene expression as shown by luciferase reporter assay, which is consistent of existing eQTL data that shows higher expression of TRAF1 in protective allele A than risk allele G in human monocytes. Furthermore, this variant is found to be able to bind to AP1 transcriptional factor FRA2. Suppressed expression of FRA2 by RNAi leads to lower expression of TRAF1 after LPS stimulation in the THP-1 monocytic cell line.

Conclusion: Non-coding variant rs7034653 in TRAF1/C5 locus likely regulates TRAF1 gene expression in monocytes through binding to transcriptional factor FRA2.

Whole Blood RNA Expression in Clinically Suspected Arthralgia Patients Shows a Potential Value in Prediction of Inflammatory Arthritis

Ellis Niemantsverdriet[1], Erik van den Akker[1], Debbie Boeters[1], Susan van den Eeden[1], Annemieke Geluk[1] and Annette van der Helm - van Mil[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA)-patients have differently expressed genes involved in cytokine/chemokine-mediated immunity compared to healthy controls, which are changed years before RA-diagnosis. It is unclear, if immunity genes differ between patients with clinically suspect arthralgia (CSA), the phase that precedes IA-development, that do and do not develop clinically evident inflammatory arthritis (IA), which was investigated in this study with whole blood RNA expression.

Methods: Between April 2012-March 2015, 234 patients were consecutively included in the Leiden CSA-cohort. Follow-up ended when patients developed clinically apparent IA (determined at physical examination), or else after 2-years. RNA expression in whole blood, at the moment of inclusion, was determined for 135 genes of the innate and adaptive immune system by dual color Reverse-Transcription Multiplex Ligation-dependent Probe Amplification (dcRT-MLPA) profiling. Cox proportional hazard models were used to associate time-to-event with gene expression

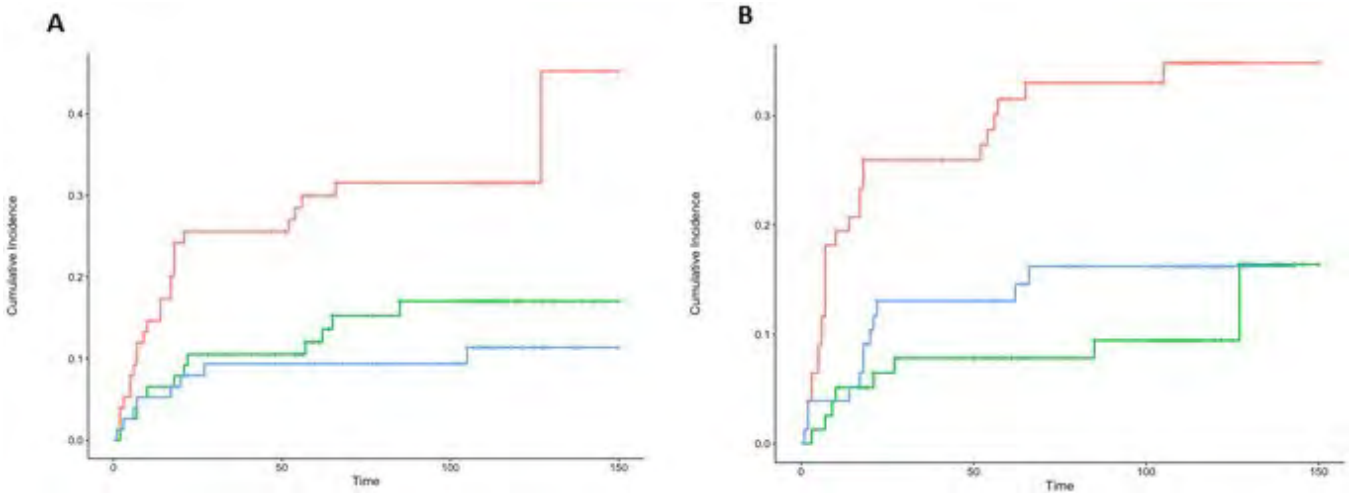

Figure 1. Association between RNA expression divided in tertiles of IGF-1 (A) and IL7R (B), and development of inflammatory arthritis

level at inclusion, while adjusting for age, gender, and assay plate. The false discovery rate was used to correct for multiple testing. Genes with significantly different expression were subsequently studied for reproducibility by qPCR, and mutual independence in their association with IA-development. Resulting mutually independent genes were further investigated for their added predictive value over known risk factors, CRP, ACPA, and subclinical joint inflammation.

Results: 20% of CSA-patients developed IA after mean 3.6 months (IQR:1.6-10.7) follow-up. After correction for multiple testing, six genes were significantly associated with IA-development, namely IFN-G, PHEX, IGF-1, IL7R, CD19, or CCR7 (ordered by significance). For all six genes, a lower expression at inclusion was associated with an increased risk of IA-development. IFN-G was only weakly expressed in peripheral blood, hampering the technical reproducibility between MLPA and qPCR results, and was excluded for further analyses. PHEX and IGF-1 were highly correlated (R^2 0.97) and only IGF-1, but not PHEX, was included in further analyses. Of the remaining significant genes (IGF-1, IL7R, CD19, CCR7), an independent association with IA-development was observed for IGF-1 and IL7R, but not for CD19 or CCR7. qPCR data of IL7R correlated with MLPA results ($p< 0.001$), confirming the robustness of the transcriptomic outcome. Lastly, when analysing IGF-1 and IL7R with known clinical predictors, both IGF-1 and IL7R remained independently associated with progression to IA.

Conclusion: IGF-1 and IL-7R were differentially expressed between CSA-patients that did or did not progress to IA, which was independent of known predictors. This also supports T cell mediation in the phase of arthralgia, before progression to IA.

Association of the *RPA3-UMAD1* Locus with Interstitial Lung Diseases Complicated with Rheumatoid Arthritis in Japanese

Yuya Shirai[1], Suguru Honda[2], Katsunori Ikari[3], Masahiro Kanai[4], Yoshito Takeda[5], Yoichiro Kamatani[6], Takayuki Morisaki[7], Eiichi Tanaka[8], Atsushi Kumanogoh[9], Masayoshi Harigai[10] and Yukinori Okada[11], [1]Osaka university, Suita, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan, [3]Tokyo Women's Medical University, Shinjuku, Japan, [4]Harvard Medical School, Boston, [5]Osaka university, Osaka, [6]Graduate School of Frontier Sciences, the University of Tokyo, Tokyo, Japan, [7]The institute of Medical Science, the University of Tokyo, Tokyo, Japan, [8]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Tokyo, Japan, [9]Osaka university, Osaka, Japan, [10]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan, [11]Osaka University Graduate School of Medicine, Osaka, Japan

SESSION INFORMATION

Session Date: Friday, November 6, 2020

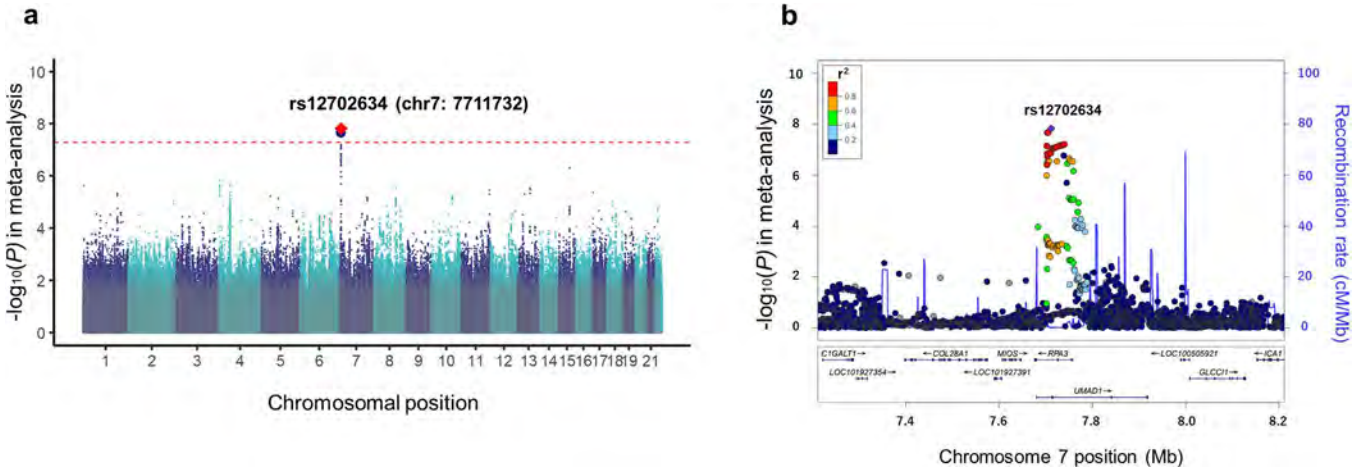
Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

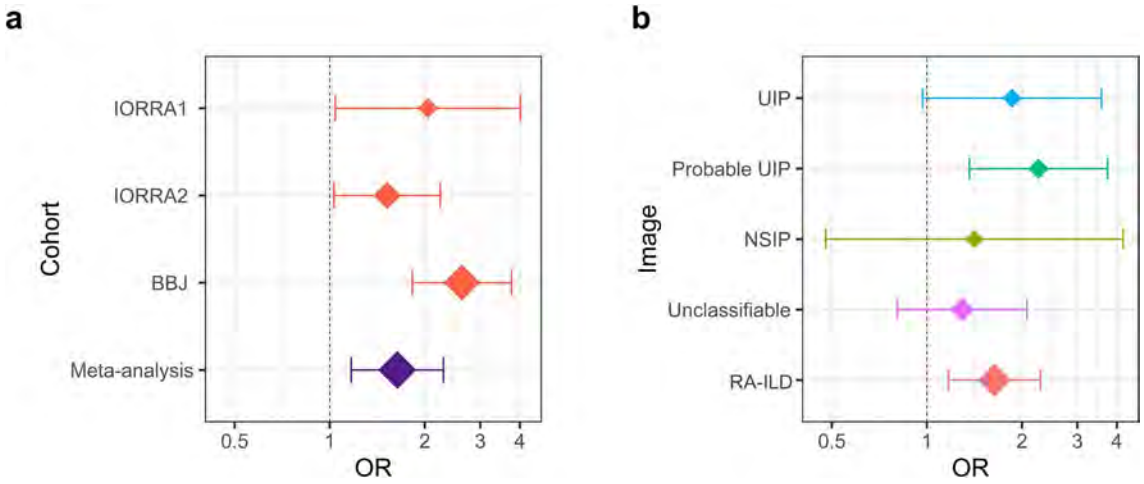
Session Time: 9:00AM–11:00AM

Background/Purpose: The genetic background of rheumatoid arthritis-interstitial lung disease (RA-ILD) has been evaluated in Europeans, but little knowledge has been obtained in non-Europeans. In particular, The *MUC5B* promoter variant (rs35705950) has been noted as a common risk variant with large effect on both IPF and RA-ILD in Europeans. However, the frequency of the variant varies heterogeneously among ancestral populations. While its minor allele frequency (MAF) was common in Europeans (= 0.107 in 1000 Genomes Project Phase 3; 1KGP3), it was as low as 0.008 in east Asians. This observation implies that genetic underpinning of RA-ILD is heterogeneous among populations, and identification of additional risk variants other than *MUC5B* in east Asians should be warranted. Furthermore, previous studies assessed RA-ILD risk of the mutations in specific genes implicated with risk of pulmonary fibrosis through candidate gene approaches. There have been no studies that investigated genome-wide risk of RA-ILD. This study aimed to elucidate genome-wide risk of RA-ILD in non-Europeans.

Methods: This study enrolled 1,117 and 3,899 individuals affected with rheumatoid arthritis (RA) from Institute of Rheumatology Rheumatoid Arthritis (IORRA) and BioBank Japan (BBJ), respectively. IORRA is a RA cohort which was established in 2000 at Tokyo Women's Medical University, Japan. In the IORRA cohort, we extracted the RA subjects who had normal CT scans and chest CT image of each subject was reviewed by an experienced physician, and



Association results of the GWAS meta-analysis for the three datasets.



The odds ratio and the 95% confidence interval of rs12702634-C in each dataset and CT image pattern.

Table1 Genome-wide significant variant associated with RA-ILD

SNP	Chr	Position(bp)	Positional candidate gene(s)	eGene	Alleles		Cohort	No. subjects		REF allele frequency		OR(95%CI)	P
					REF	ALT		Case	Control	Case	Control		
rs12702634	7	7711732	RPA3 UMAD1	RPA3	C	G	IORRA1	60	176	0.17	0.11	2.05 [1.04-4.02]	3.80E-02
							IORRA2	195	681	0.11	0.08	1.52 [1.03-2.24]	3.40E-02
							BBJ	103	3693	0.19	0.08	2.62 [1.83-3.77]	1.74E-07
							Meta-analysis	358	4550	0.14	0.08	2.04 [1.59-2.60]	1.50E-08

Genome-wide significant variant associated with RA-ILD.

findings were confirmed based on the concordance with those by the radiologist's report. BBJ is a hospital-based cohort with multi-omics data from genotype to multitude phenotype. The status of RA or ILD in the BBJ cohort was examined through interviews and reviews of medical records. GWAS genotyping and imputation were conducted for all the subjects. After the quality control, we performed a GWAS meta-analysis of the IORRA cohort and the BBJ cohort, which included 358 RA-ILD cases and 4,550 RA subjects without ILD. We then conducted the stratified analysis of the effect of the GWAS risk allele in each computerized tomography (CT) image pattern.

Results: We identified one novel RA-ILD risk locus at 7p21 that satisfied the genome-wide significance threshold (rs12702634, odds ratio [OR] = 2.04, 95% confidence interval [95%CI] = 1.59-2.60, P = 1.5×10-8). Subsequent stratified analysis based on the CT image patterns demonstrated that the effect size of the RA-ILD risk allele (rs12702634-C) was large with the UIP pattern (OR = 1.86, 95%CI = 0.97-3.58, P = 0.062) and the probable UIP pattern (OR = 2.26, 95%CI = 1.36-3.73, P = 0.0015). The RA-ILD risk variant of rs12702634 was located in the intron region of *RPA3* and *UMAD1* and within the enhancer histone marks in several immune cells. The GTEx data showed that the rs12702634-C risk allele increased *RPA3* expression levels in various tissues including lung.

Conclusion: We revealed one novel genetic association with RA-ILD in Japanese. The RA-ILD risk of the identified variant at *RPA3-UMAD1* was relatively high in the CT image patterns related to fibrosis. Our study should contribute to the elucidation of the complicated etiology of RA-ILD.

Racial and Ethnic Differences in a Multiple Biochemical Measure of Rheumatoid Arthritis Disease Activity

Rahaf Baker[1], Jonathan Graf[2], Laura Trupin[2], Sarah Goglin[3], Patricia Katz[4], Jennifer Barton[5], Jean Liew[6] and Katherine Wysham[7], [1]Highland Hospital Internal Medicine, Oakland, CA, [2]UCSF, San Francisco, CA, [3]University of California San Francisco, Burlingame, CA, [4]University of California, San Francisco, Novato, CA, [5]VAPORHCS/OHSU, Portland, OR, [6]University of Washington, Seattle, WA, [7]VA Puget Sound/University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Although management of RA has improved greatly over the past two decades with the advent of novel therapeutics, racial/ethnic and socioeconomic disparities persist. Traditional RA disease activity measures, including the Clinical Disease Activity Index (CDAI) and DAS28-ESR, are influenced by provider and patient subjectivity which may impact racial/ethnic differences observed in prior studies. A multiple-biochemical measure of disease activity (MBDA) score, a composite of 12 serum biomarkers, was designed to be a more objective measure of RA disease activity. This study examined racial and ethnic differences in MBDA scores within a diverse cohort of RA patients.

Methods: Data are derived from the University of California, San Francisco RA Cohort, a longitudinal observational cohort, in which disease activity was measured as part of routine clinical care and MBDA was obtained at the time of each clinical encounter. All participants were from a safety-net hospital thereby reducing variations in income and insurance. Participants with ≥1 MBDA measure and self-reported race/ethnicity were included. Multivariable linear regression evaluated the association between race/ethnicity groups and mean MBDA score, adjusting for age at enrollment, sex, smoking history, RA symptom duration at enrollment, number of study visits, ACPA status, mean BMI, mean conventional DMARD (cDMARD) use, mean biologic DMARD (bDMARD) use and mean prednisone use. Missing data elements were estimated using multiple imputation with chained equations (MICE). Sensitivity analyses substituted CDAI and DAS28-ESR for the MBDA in multivariable linear regression models.

Results: There were 267 subjects, 86% female, mean age 52.7±13.3, and the majority were Hispanic (n=137, 51%) followed by Asian (n=91, 34%). Participants were followed an average 8.4±3.4 years and had moderate disease activity by all three measures (Table 1). After adjustment, Hispanic participants had the highest mean MBDA score (40.6), compared with White participants (33.0) (p=0.032). Black (36.2) participants had the second highest mean MBDA followed by Asian participants (36.0), although neither were significantly different from White participants (Table 2). The trends observed in the sensitivity analyses were similar to those in the primary analysis.

Table 1. Baseline demographics and clinical characteristics of the RA cohort categorized by race/ethnicity. (n=267).

	Hispanic (n = 137)	Asian (n = 91)	Black (n = 24)	White (n = 15)

bDMARD use, proportion of visits	0.3 ± 0.3	0.3 ± 0.4	0.2 ± 0.3	0.5 ± 0.4
Prednisone use ever	129 (94%)	80 (88%)	21 (88%)	8 (53%)
Mean prednisone dose	4.5 ± 3.3	3.4 ± 2.6	4.4 ± 4.2	2.1 ± 2.5
Disease Activity Measures*				
Mean MBDA	41.2 ± 12.7	35.0 ± 14.2	38.0 ± 14.7	30.6 ± 12.7
Mean CDAI	17.5 ± 9.3	13.6 ± 7.4	15.1 ± 9.9	12.6 ± 8.7
Mean DAS28-ESR	4.4 ± 1.4	4.1 ± 1.3	3.9 ± 1.3	3.3 ± 1.2

-Continuous variables are reported as mean ± SD and categorical variables as n (% of column total).
-Abbreviations: ACPA = anti-cyclic citrullinated protein antibodies; CDAI = clinical disease activity index, DAS28 = 28-joint disease activity score, cDMARD = Conventional disease modifying anti-rheumatic drug (includes methotrexate, sulfasalazine, hydroxychloroquine, leflunomide); bDMARD = Biologic DMARD (includes tocilizumab, etanercept, certolizumab, adalimumab, anakinra, abatacept, infliximab, rituximab, golimumab). MBDA- multiple biomarker disease activity.
CI = 95% confidence interval
*Disease activity measures calculated as the overall mean disease activity score of each participant's mean disease activity scores. MBDA score range 0-100 (Disease activity ranges: low<30, medium 30-44, high >44); DAS28-ESR range 2-10 (Disease activity ranges: low ≤3.2, moderate >3.2-5.1, high >5.1); CDAI range 0-76 (disease activity ranges: low ≤10, moderate 10.1-22, high >22.1).
-Values are missing for the following variables: smoking: n = 41; BMI: n = 60; symptom duration: n = 23, DAS: n = 2, CDAI: n = 1.

Conclusion: In a diverse observational RA cohort, Hispanic participants had the highest mean MBDA score, which was significantly higher than that of White participants after adjustment in the multivariable model. Black and Asian participants also had higher disease activity scores than White participants, although these differences did not reach statistical significance. Regardless of the method of assessment, racial/ethnic differences in disease activity are observed in RA. MBDA scores appear to add no additional information beyond standard, ACR-endorsed measures of disease activity in this analysis. Further studies focusing on early access to care, mitigating language barriers and addressing racial disparities should be done to enable improvement of disease outcomes across minority racial/ethnic groups.

Table 2. RA disease activity score predictions by race/ethnicity after adjustment in multivariable linear regression (n=267). Data presented for the primary model (MBDA score) as well sensitivity analyses with DAS28-ESR and CDAI.

Race/Ethnicity	MBDA (95%CI)	DAS28ESR (95%CI)	CDAI (95%CI)
Hispanic	40.6 (26.4-39.5)*	4.3 (4.1-4.5)*	16.9 (15.5-18.3)
Asian	36.0 (38.4-42.7)	4.3 (4.0-4.5)*	14.5 (12.7-16.3)
Black	36.2 (31.1-41.4)	3.7 (3.2-4.3)	14.2 (10.8-17.5)
White	33.0 (23.4-39.5)	3.4 (2.7-4.1)	14.2 (9.9-18.5)

-Controlled for age at enrollment, sex, smoking history, RA symptom duration at enrollment, number of study visits, anti-cyclic citrullinated peptide status, body mass index, cDMARD use (proportion of visits using), bDMARD use (proportion of visits using) and mean prednisone use. Missing data elements were estimated using multiple imputation with chained equations (MICE).

* indicates p-value <0.05 in the multivariable linear regression using White race as the reference group.

-Abbreviations: CDAI = clinical disease activity index, DAS28 = 28-joint disease activity score, cDMARD = Conventional disease modifying anti-rheumatic drug (includes methotrexate, sulfasalazine, hydroxychloroquine, leflunomide); bDMARD = Biologic DMARD (includes tocilizumab, etanercept, certolizumab, adalimumab, anakinra, abatacept, infliximab, rituximab, golimumab). MBDA- multiple biomarker disease activity.

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: In the US, health care systems vary, as does cost sharing and access to various RA therapies. However, the burden of RA – a systemic disorder – is often a confounder in management decisions. Whether the burden of RA disease is homogeneous in various regions of the US, and independent of race/ethnicity and/or health care coverage, is unknown.

Methods: US Rheumatology practices from the Northeast, South, and West regions enrolled RA outpatients. Socio-demographics, RA disease status, activity and therapies, and comorbidities were collected, and rheumatic comorbidity disease index (RDCI) was calculated. Primary insurance coverage type (Private, Medicare, Medicaid) was documented, and copay for office visits and medications stratified. Univariable pairwise differences between regions was conducted using Tukey post-hoc corrected analysis of variance for continuous variables, Bonferroni-adjusted

Table. Clinical Characteristics of RA patients in US Geographic Regions

Chi-square for categorical variables, and Bonferroni-adjusted logistic regression for dichotomous variables. Multivariable regression models were estimated to investigate disparities in RDCI between insurance variables as well as race while controlling for region.

Results: 402 RA patients were enrolled from 10 outpatient practices (Table). A predominantly Caucasian, female population, with established disease, most received government sponsored primary insurance (40% vs 27.9%). Copay for office visits and medications were < $10 in 45% and 31.8% of observations, respectively, and more prevalent in the Northeast/West subsets than in the South. Office copays > $25 were more frequent in South patients, while more often in Northeast patients for medications. Tobacco use was similar in all subsets. Disease activity scores inclusive of physician/laboratory core measures were higher for South than Northeast patients. RDCI was higher in the South group, 1.7 [1.7], compared to both other subsets and the cohort mean 1.3[1.5]. Hispanics had significantly less RDCI than Blacks (RDCI -0.78, 95% CI [-1.35, -0.21], P=0.008) and Whites (RDCI -0.68, 95% CI [-1.18, -0.17], P=0.009), independent of region. RDCI was significantly lower for privately insured than Medicare (RDCI -0.78, 95% CI [-0.41, -1.15], P< 0.001) and Medicaid (RDCI -0.83, 95% CI [-0.13, -1.54], P=0.020), independent of region. [Figure 1]. However, RDCI was significantly higher for office visit copays < $10 than $25-50 (RDCI +0.61, 95% CI [0.16, 1.06], P=0.008) and $50+ (RDCI +0.89, 95% CI [0.17, 1.62], P=0.016), as well as for medication copays both < $10 (RDCI

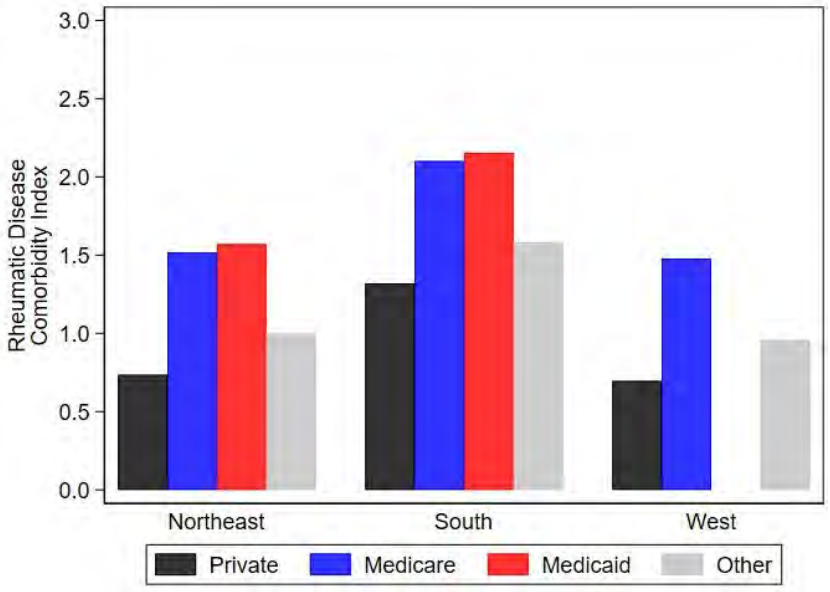

Figure 1. Rheumatic Disease Comorbidity Index by Region and Insurance Type

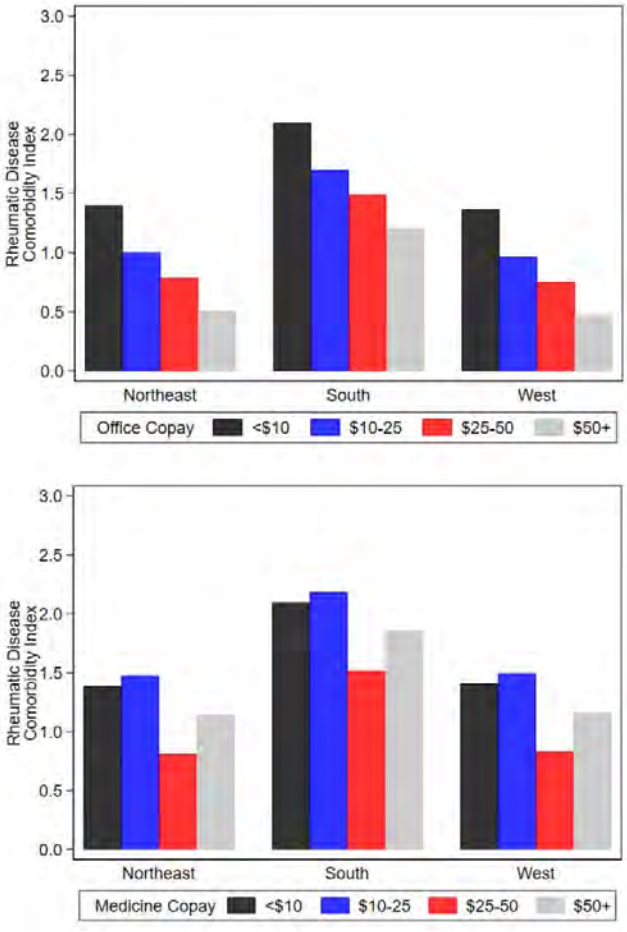

Figure 2. Rheumatic Disease Comorbidity Index by Region and Office and Medication Co-pay

+0.58, 95% CI [0.12, 1.03], P=0.013) and $10-25 (RDCI +0.67, 95% CI [0.03, 1.31], P=0.041) compared to $25-50, both independent of region. [Figure 2].

Conclusion: While RA disease burden was evident in patients receiving care in Southern practices, it was independent of race/ethnicity. Government health care rather than private insurance plans covered complicated RA patients, regardless of site of care. Cost sharing may further complicate access to optimum care. Application of this analysis to a larger dataset that includes additional US regions, expanded insurance parameters and potential founders such as socioeconomic status, is needed.

Characterization of Racial Disparities in Rheumatoid Arthritis Treatment Choice and Location of Care

Elston He[1], Eli Cornblath[2], Pratyusha Yalamanchi[3], Alexis Ogdie[2], Joshua Baker[2] and **Michael George**[2], [1]Synovium, Inc., Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Racial disparities in access to care and treatment regimens exist but remain poorly characterized in the rheumatoid arthritis (RA) patient population. Previous studies using the Ethnic Minority RA Consortium (EMRAC) have demonstrated non-Caucasian RA patients have a lower frequency of biologic use versus Caucasian patients despite controlling for comparable disease activity and access to treatment. Here we explore longitudinal racial disparities in rheumatoid arthritis treatment and emergency department (ED) use in a single tertiary academic center.

Methods: Structured de-identified data from 2010-2018 of patients who had at least two diagnoses of RA from a rheumatology outpatient encounter and at least one DMARD script during the follow-up period were extracted from the electronic health record of a single tertiary care center. Follow-up was measured from each patient's first visit to each patient's last visit within the 2010-2018 timeframe. Patient demographics were measured at the baseline visit, with medication use and comorbidities measured at baseline or at any point during follow-up. The average number of outpatient visits and ED visits per year (limited to ED visits within the health system) during follow-up were also measured. Differences in patient characteristics and visits were compared in patients who were black versus white based on standard t-test and χ^2 analysis.

Characteristic	Black or African American (n=639)	White (n=991)	Comparing Black and White Patients
Age, mean (SD), years	57.05 (14.67)	54.25 (14.21)	P=0.0002
Female (%)	87.32	77.90	
BMI, mean (SD)	31.02 (7.62)	27.99 (6.55)	P<0.0001
Smoking Status (% Former or Current)	40.85	33.20	P=0.0017
Diabetes (%)	201 (31.46%)	101 (10.19%)	P<0.0001
Cardiovascular Disease (%)	456 (71.36%)	446 (45.01%)	P<0.0001
Medications			
Prednisone	507 (79.34%)	685 (69.12%)	P<0.0001
Biological DMARD	428 (66.98%)	737 (74.27%)	P=0.0013
Conventional DMARD	618 (96.71%)	927 (93.54%)	P=0.0049
Tofacitinib	35 (5.48%)	56 (5.65%)	P=0.88
Median Duration of Follow-Up [IQR]	8.44 [6.26-8.89]	8.02 [5.21-8.83]	P=0.0004
Median Number of ED Visits Per Patient Per Year [IQR]	0.24 [0.00-0.79]	0.00 [0.00-0.00]	P<0.0001
Median Number of Outpatient Office Visits Per Patient Per Year [IQR]	5.76 [3.32-9.53]	3.93 [2.44-6.37]	P<0.0001
Median Number of Outpatient Rheumatology Office Visits Per Patient Per Year [IQR]	2.15 [1.23-3.02]	1.82 [1.08-2.69]	P<0.0001

Comparison of Patient Characteristics

Results: A total of 1831 patients with rheumatoid arthritis were identified from 2010-2018. Baseline demographics were measured at each patient's first visit and include mean [SD] age, 55.05 [14.47] years; 1499 [81.87%] female; and 991 [54.12%] white. Average [SD] duration of follow-up for all patients was 6.97 [2.28] years. Comparing black (n=639) and white (n=991) patient demographics, significant findings include that black patients were more likely to be older, have higher BMI, former or current smoking status, and have higher rates of diabetes and cardiovascular disease ($p< 0.0001$). Prednisone and csDMARD use were significantly more frequent in black patients compared to white patients (79.3% vs 69.1% $p< 0.0001$; 96.7% vs 93.5%, $p=0.005$, respectively). Biologic use was significantly more common among white patients compared to black patients (white 74.3%, black 67.0% $p=0.001$). In terms of site of care delivery, black patients had significantly more ED visits, with a median 0.24 ED visits per patient per year versus 0.00 for white patients. A summary of the findings are shown in Table 1.

Conclusion: Patients who were black were less likely to receive a biologic and more likely to use glucocorticoids. ED visit use was higher in black patients, which could be related to higher rates of comorbidities, although differences in geographic location could also influence whether patients visited an ED or saw non-rheumatology providers within or outside the health system. Further studies identifying drivers of racial disparities in access to care and outcomes are needed.

Abstract Number: 0045

Healthcare Practitioner Confidence Assessing Rashes in Patients of Skin of Color with Lupus

Vijay Kannuthurai[1], Jacob Murray[2], Lisa Zickuhr[3] and Ling Chen[2], [1]Washington University in St. Louis School of Medicine, Hazlehurst, MS, [2]Washington University in St. Louis School of Medicine, St. Louis, MO, [3]Washington University/B-JH/SLCH Consortium, St. Louis, MO

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Medical education can promote bias that disproportionately affects patients of color. Patients of color with lupus are especially vulnerable as they often carry a greater disease burden, yet studies show that individuals with darker skin tones are underrepresented in medical educational materials. Given this disparity, we surveyed practitioners' confidence assessing rashes in patients with lupus and skin of color (SOC) and identified factors that may influence confidence.

Methods: We designed a survey to collect demographic information and measure providers' confidence assessing any rash and rashes in patients with lupus and varied skin tones. We invited providers in the Greater St. Louis Area to participate, distributing surveys in person and via Qualtrics. For our primary outcome, we compared Likert scores for providers' confidence assessing rashes in patients with lupus and SOC with least square means and pairwise differences. To identify variables that correlate with practitioners' confidence, we created univariate linear models and multivariate generalized linear models using Spearman's rank correlation coefficients and backward selection. We set statistical significance at $p< 0.05$ for all analyses.

Results: In total, 132 providers participated (Table 1). The mean confidence level diagnosing any rash was significantly higher than diagnosing lupus rashes, including in patients with fair skin and SOC ($p=0.03$; 0.049; < 0.0001). The mean confidence diagnosing lupus rashes in patients with fair skin was also significantly higher than confidence diagnosing lupus rashes in patients with SOC ($p=0.0090$). Mean confidence levels for each specialty were collected (Table 2). Univariate analysis found that provider specialty, years in practice, extent of training, experience in diagnosing, and frequency of treating white or African American patients correlated with confidence level diagnosing lupus rashes in patients of color. However, in the final multivariate model, only practitioners' self-reported experience level diagnosing rashes in patients with lupus and SOC correlated with their confidence doing the same ($p=< 0.001$). Lastly, 92% of participants indicated interest in education about lupus rashes and 93% wanted to learn about rashes in patients of color.

Conclusion: Healthcare providers are less confident evaluating lupus-related rashes in SOC compared to fair skin, representing a disparity between provider confidence and the patient population lupus traditionally affects. While our univariate model demonstrated correlations among confidence in diagnosing rashes in patients with lupus and SOC and several factors, the multivariate model revealed a relationship between confidence and experience alone. Based upon the principle of collinearity, we believe specialty, years in practice, extent of training, and frequency of treating

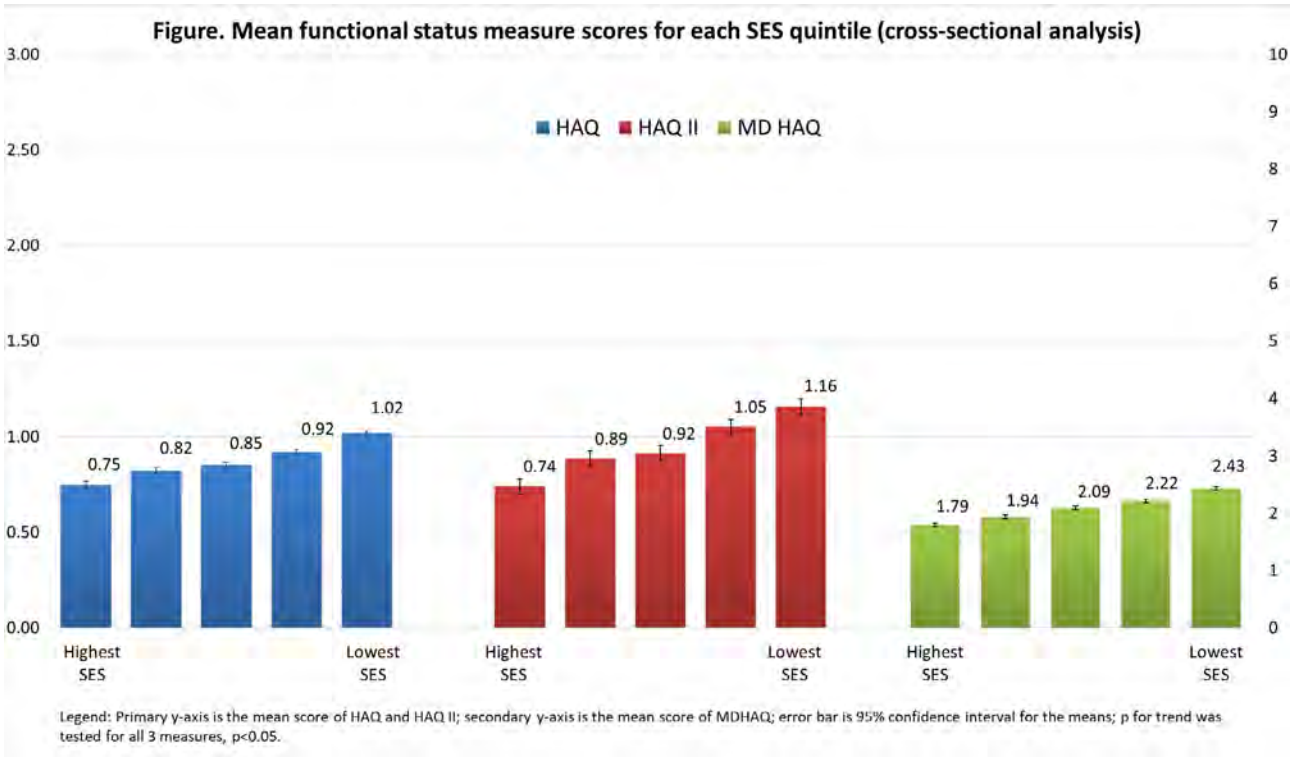
ship between RA functional outcomes and SES at the national level. We used the ACR's Rheumatology Informatics System for Effectiveness (RISE) registry to investigate the relationship between individual SES and functional status (FS) among individuals with RA across U.S. rheumatology practices.

Methods: Data derived from RISE, a national EHR-enabled registry that passively collects data on all patients seen by participating rheumatology practices. As of 2018, RISE held validated data from 1,113 providers in 226 practices,



representing about 32% of the U.S. clinical rheumatology workforce. Patients included in this study were ≥18 years old, had ≥ 2 visits with RA codes ≥ 30 days apart, and ≥ 1 FS measure (MDHAQ, HAQII, or HAQ) in 2016-2018. As a proxy for SES, we used the Area Deprivation Index (ADI) score, a 9-digit ZIP-code-based indicator of neighborhood socioeconomic disadvantage (range 1-100, higher score = lower SES).

We investigated cross-sectional and longitudinal relationships between FS and SES. In a cross-sectional analysis, we calculated the mean FS scores for each quintile of SES. We used only the most recent FS measure for patients with ≥ 1 score recorded during a calendar year. In a longitudinal analysis, patients with ≥2 of the same FS measure, at least 12 months apart, were categorized as worsening (Y/N) based on the minimal clinically important difference for each tool. We used multi-level logistic regression to assess the association of worsening FS for each quintile of SES, accounting for age, sex, race, baseline FS score, and clustering by practice.

Results: 83,965 patients from 109 practices were included (characteristics in Table). MDHAQ was the most commonly reported FS measure (67.8% of patients), followed by HAQ (24.4%) and HAQII (7.8%). Overall, mean (SD) FS scores for these measures were 2.1 (2.0), 0.89 (0.58), 0.9 (0.6), respectively.

In the cross-sectional analysis, mean FS score was worse at lower SES levels, regardless of the measure used (p-trend< 0.05, see Figure). Among 24,846 RA patients included in the longitudinal analysis with MDHAQ scores, the proportion of patients with a worsening score increased modestly as lower SES levels, even after adjustment (p< 0.05): in the highest SES quintile, 12.7% (95% CI 8.9%-16.5%) patients worsened; in the lowest SES quintile, 16.6% (95% CI 12.1%-21.1%) worsened. The same trend was observed for patients with HAQ and HAQII.

Conclusion: We found evidence of significant disparities in FS across SES in this national cohort of individuals with RA, with worse functional status across each successive lower quintile of SES. In addition, FS declined more rapidly over time in those with lower SES. Future research is needed to identify the source of these disparities, which exist in spite of access to rheumatologic care for all patients in the cohort.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Administrative Barriers to Enrollment of Ethnic Minorities in Clinical Research of Rheumatic/Immune-Mediated Diseases

Brittany Banbury[1], Sharon Dowell[1], Gail Kerr[2], Mercedes Quinones[2], Ginette Okoye[1] and Ilona Jileaeva[1], [1]Howard University Hospital, Washington, DC, [2]Washington DC VA Medical Center, Washington, DC

Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Inclusion of ethnic minority subsets in clinical research remains subpar despite mandates for increased participation. Lack of trust, cultural sensitivity and bias, stereotyping, health literacy are all acknowledged barriers that are active areas of rehabilitation [4, 5]. Ethnic minority patients are often cared for by ethnic minority physicians, and despite their limited health coverage, target academic institutions to receive care[1, 2].Therefore, academic institutions with ethnic minority clienteles and physicians are the prime targets for recruitment of non-Caucasians in clinical trials. However, whether administrative operations at ethnic minority institutions can facilitate this process, and in timely fashion, is unknown. We examined the time intervals for approval of administrative procedures for clinical research at a predominantly ethnic minority academic institution.

Objective: To assess time intervals for the administrative approval procedures for clinical research at a predominantly ethnic minority institution.

Methods: At a single historically Black academic institution (HBCU), we examined the time points for multiple clinical trials between submission and responses to institutional review board review, and contract negotiations. The agreed contractual numbers for each study and their unit reimbursement were also obtained. Time to approval of each stage was documented, including the final approval in relation to study initiation.

Results: The average time for IRB approval across 8 clinical trials was 3.75 months, ~ 6 weeks longer than other local academic institutions (1.5-3m). The most frequent reason for delay was multiple, repetitive queries, which could have been avoided by systematic review processes. Additionally, contract approval for 4 funded clinical trials was 8.5 months, resulting in the inability to recruit patients before study closure, with potential loss of institutional funds ($10, 226/patient).

Conclusion: At a single HBCU academic site, there was a consistent, prolonged interval for each step of approval of clinical research. Although it is unknown if enrollment would have met targets, these results suggest a significant lost opportunity for inclusion of ethnic minority subsets in clinical trials. Further, the potential loss of revenue to the insti-

tution due to these inefficiencies, cannot be ignored. Measures to improve the process must therefore be an integral requirement of the overall process for increased ethnic minority involvement in clinical research.

Determinants of Participation in Clinical Trials Among Patients with Lupus in the United States

Onengiya Harry[1], Carl Langefeld[2], Miranda Marion[3], Trent Younts[3], Lori Crosby[4], Mara Vitolins[3] and Avani Modi[4], [1]Wake Forest School of Medicine, Clemmons, NC, [2]Wake Forest School of Medicine, Winston Salem, NC, [3]Wake Forest School of Medicine, Winston-Salem, [4]Cincinnati Children's Hospital Medical Center, Cincinnati

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient and family participation in research is critical to improving health outcomes, and identifying factors that contribute to participation or lack of participation in clinical trials is a necessary first step. There is limited data regarding why patients with lupus choose to participate in clinical trials. Research in other conditions has identified factors including age, race/ethnicity, gender, presence of co-morbidities, and disease severity. The primary objective of this study was to examine whether age, race/ethnicity, sex, or greater disease organ involvement are associated with *previous* clinical trial participation in patients with lupus.

Methods: Data were collected by The Lupus and Allied Diseases Association, the Lupus Foundation of America, and the Lupus Research Alliance for their Externally-led Patient-Focused Drug Development (PFDD) Initiative. From this dataset, we examined the influence of age, sex, race/ethnicity, and organ involvement on clinical trial participation. Data was available for 2,100 individuals with lupus or their parents/legal guardians for children. Participants completed a 46-question survey (in English or Spanish) electronically or on paper, which was distributed online or at lupus events. Logistic regression was used to test a model including demographic and disease characteristics; it was expanded to include duration of illness, number of medications, number of comorbidities, and number of other autoimmune diseases.

Results: Survey participants' characteristics are summarized in Table 1. More than 50% of respondents had not participated in a clinical trial. Univariate analysis suggests that race/ethnicity, age of symptom onset, illness duration, lupus type, and history of organ transplant were associated with trial participation. The expanded model indicated that African Americans (OR=1.71) and Hispanics (OR=1.42) were more likely to participate than whites, respondents reporting longer illness duration were more likely to participate (OR=1.52), and respondents with a greater number of medications (OR=1.13) and other self-reported autoimmune diseases (OR=1.07) were more likely to participate in a clinical trial (Table 2).

Conclusion: Several medical (i.e., illness duration, number of medications and comorbid autoimmune disorder) and demographic (i.e., race/ethnicity) factors appear to be important determinants of participation in clinical trials. Compared to previous studies, these data suggest that African American and Hispanic individuals are willing to

Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Many aspects of rheumatic and musculoskeletal disease (RMD) management require a high level of patient agency and open avenues for patient-provider contact. In the era of COVID-19 and social distancing the shift to virtual care has become essential for the continued care of our patients. More so than ever before, patient portal and health technology use has become crucial in the care of patients with RMDs around the country.

Many studies have shown positive effects on outcomes and satisfaction when patients are more engaged in their care through digital technology use. However, several studies have shown that low health literacy, lower educational

attainment, residence in a rural area, being of minority race/ethnicity, and older age are associated with lower rates of technology ownership and use.

To date there have been limited studies examining inequities in health technology use among patients with RMDs. Our goal is to identify characteristics of technology users versus non-users from a group of patients in a large hospital-based rheumatology clinic.

Methods: Epic (electronic medical record, EMR) data was queried to identify established patients of the University of North Carolina Hospitals adult rheumatology clinic between November 1, 2017 through November 30, 2019. Demographic and clinical data were collected and used to compare patients who have activated Epic's patient portal (MyChart) to patients who have not activated MyChart. MyChart use was modeled using logistic regression and adjusted odds ratios and confidence intervals were estimated.

Results: We identified 5287 established patients who were seen at our clinic during the study period. The mean age was 54.4 years and 73.6% were female. Fifty-one percent of established patients identified as white/Caucasian and 26.6% as black/African American. Eighty-nine percent identified English as their primary language. Patients were evenly split between urban, suburban, and rural residences. Two-thirds had a median adjusted gross income between $25,000 - < $50,000. Thirty-six percent had Medicare and 25.4% had commercial insurance.

Using data from complete cases among North Carolina residents (n=4756), we found that younger age, suburban residence, commercial/state/military insurance, and median income $50,000 or greater were associated with significantly higher odds of MyChart activation.

Characteristics significantly associated with lower odds of MyChart use were male gender, black/African American or "other" race, Spanish as primary language, rural residence, Medicaid as primary payor, and median annual income < $25,000.

Conclusion: These results support the findings of previous studies that show that residence in a rural area, being of minority race/ethnicity, and older age are associated with lower rates of health technology use. We also noted that lower median income, having Medicaid as primary insurance, and non-English primary language are associated with lower odds of patient portal activation. We hope that by studying factors associated with lower EMR use we can identify at-risk populations who may benefit from targeted interventions to close the gap in health technology use among patients with RMDs.

Demographic characteristics of zip codes with the highest number of patients referred for CoV-CRS

Background/Purpose: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has led to the present coronavirus disease (COVID-19) pandemic. Multiple epidemiologic reports across the country show that COVID-19 disproportionately affects minorities.

San Bernardino and Riverside counties comprise two of the geographically largest and ethnically diverse counties in California and in the United States. Much of its population is indigent and relies on public health services.

A rheumatology-driven protocol was developed in March 2020 for the management of patients with cytokine release syndrome due to COVID-19 (CoV-CRS) at a university-based and a county hospital. This study analyzes the demographic disparities among this patient population.

Methods: 150 patients were included in this retrospective chart review study with data collected between March 15-May 30, 2020. Hospital-based electronic medical records were utilized to collect information on patients referred to the rheumatology consult service for the evaluation of CoV-CRS. Demographic data, including age, sex, ethnicity, and postal zip code entered on hospital admission was collected. Co-morbidities, medications used and various laboratory data, including CBC with differential, ferritin, fibrinogen, complete metabolic profile, autoantibody profiles were included. Hospital-based and county-reported data were utilized to determine general populations affected by COVID-19. Descriptive statistics were used for analysis.

Results: 71.3% (107/115) of patients were within the 51-80 year-old age group (mean age 61.7 years). Males comprised 72.7% of the cohort. Hispanics represented the majority of this population (43.3%), followed by White non-Hispanics (29.3%), Asians (16%) and Blacks (9.3%). Public insurance was used in 68%, and private insurance in 30%. Thirty-five patients (23.3%) were incarcerated at the time of hospitalization; while 28 (18.7%) were from various healthcare facilities including skilled nursing facilities.

Patients came from a total of 53 postal zip codes, but 52% resided in 7 zip codes: 91710 (30); 92553 (11); 92324 (13, including 7 from one healthcare facility); 92551 (7); 92571 (7); 92501(5); 92555 (5). Census data shows that the population at these zip codes are predominantly Hispanic (47.6-74.5%). Four of these zip codes are represented by 18.4-41.5% greater poverty rates compared to their respective counties. Of 31 patients who died in our cohort, 18 (58%) were residents of these zip codes.

Of note, 29/30 patients located at zip code 91710 were incarcerated at a local state prison for men. Twenty (69%) were white non-Hispanic; 7 (24.1%) were Hispanic; 1 (3.4%) Asian and 1 (3.4%) Black. There was a total of 10 Covid-19 related deaths in the California prison system, 4 of which were part of this cohort.

Conclusion: A higher percentage of patients affected with CoV-CRS in this rheumatology-managed cohort from Southern California were largely male, of Hispanic ethnicity, used public insurance, living in an area with higher poverty rate, or were incarcerated or residents at a healthcare facility. More than half of deaths in the cohort were observed in this particular population.

COVID-Related Distress and Mental Health in Adult Rheumatology Patients During the COVID-19 Pandemic

Shereen Mahmood[1], Laura Curiel-Duran[2], Ruchika Darapaneni[2], Dalynah Maldonado[2], Lindsay Pattison[2], Emilee Tu[2] and Tamar Rubinstein[3], [1]Albert Einstein College of Medicine / Montefiore Medical Center, Wantagh, NY, [2]Albert Einstein College of Medicine / Montefiore Medical Center, Bronx, NY, [3]Albert Einstein College of Medicine / Montefiore Medical Center, White Plains, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The novel coronavirus disease 2019 (COVID-19) pandemic has significantly affected all aspects of society, especially in the epicenters of New York City (NYC) and the Bronx. The Bronx patient population is characterized by a high percentage of individuals from racial/ethnic minorities and low socioeconomic status. Black and Hispanic individuals have been disproportionately affected by COVID morbidity and mortality, with the Bronx accounting for the highest number of cases per capita in NYC. Low-income Bronx residents also may have been more susceptible to financial losses brought on by the pandemic. With the added concern of increased risk of infection and poorer outcomes in rheumatology patients, Bronx rheumatology patients may be particularly susceptible to emotional suffering during the COVID-19 pandemic. We sought to investigate the burden of mental health symptoms on rheumatology patients and the association with COVID-related distress from the Bronx following the peak of the outbreak.

Methods: A registry was created of Montefiore Medical Center (MMC) rheumatology patients consisting of 1,692 adult and pediatric patients. Patients were contacted over email or phone to consent and participate in a survey on the impact of the COVID-19 pandemic. Participants completed surveys by email or phone. To assess stress we used the Perceived Stress Scale (PSS), to assess depression symptoms we used the Patient Health Questionnaire 8-item depression screen (PHQ-8), and to assess anxiety we used the Generalized Anxiety Disorder-7 item screen (GAD-7). The PSS, GAD and PHQ-8 are all scales (0-40, 0-21, 0-27, respectively) and can be categorized as mild, moderate, severe. Participants were asked to rate their distress related to the COVID pandemic over the last 30 days on a scale from 0-10 (0 no distress, 10 extreme distress). Spearman rank correlations were used to determine whether COVID-related distress scores were correlated to mental health scales.

Results: Of the 361 survey participants , 202 (56%) had complete data on mental health scales. Among those with complete data, 123 (56%) had at least mild symptoms of depression, 36 (16%) had moderate, 27 (12%) had severe, with median score 5 (IQR 2, 11); 106 (48%) had at least mild symptoms of anxiety, 31 (14%) had moderate, 20 (9%) had severe, median score 4 (IQR 1,9). Based on the Perceived Stress Scale, 182 (83%) had moderate stress, and 32 (15%) had severe stress, median score 21 (IQR 18-24) . The median level of COVID-related distress was 6 (IQR 3,8). All mental health scales were moderately correlated with the COVID-related distress scale; PSS (rho 0.6, $p< 0.0001$), PHQ-8 (rho 0.5, $p< 0.0001$), GAD-7 (rho 0.7, $p< 0.0001$).

Conclusion: Surveyed rheumatology patients reported high levels of COVID-related distress and perceived stress. COVID-related distress levels correlated with levels of anxiety, depression, and overall perceived stress. These results underscore the importance of addressing mental health symptoms in rheumatology patients during the pandemic.

Loneliness and Social Isolation Are Important Social Determinants Among Patients from Minority Communities with Rheumatic Diseases

Allen Anandarajah[1], Nancy Shelton[2], Leta Yi[3], Meredith Graham[4], Emily Papa[5] and Robyn Carter[5], [1]university of rochester medical center, rochesteruniversity, NY, [2]Coordianted Care Services Inc, Rochester, NY, [3]University of Rochester Medical Center, rochester, NY, [4]Collaborative Health Research, Rochester, NY, [5]St. Joseph's Neighbourhood Center, Rochester, NY

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Loneliness and social isolation have detrimental effects on health and are associated with risk of an earlier death, depression and poor self-rated health. Few studies have investigated the prevalence of these social determinants among patients with rheumatic conditions and none have focused on minority communities. We therefore set about to determine the prevalence and pervasiveness of loneliness and social isolation among African American and Latinx communities.

Methods: This is an ongoing community based participatory research conducted by physicians from the University of Rochester Medical Center (URMC) in conjunction with members of the Rochester community. The study aims to survey a 1,000 patients and conduct 5 focus group meetings, from the African American and Latinx communities seen at the URMC Center and two community health centers. The *Campaign to End Loneliness Measurement Tool*, a short and academically rigorous took with a simple scoring method was used to assessed loneliness. Scores range from 0-12 with higher scores representing more pronounced loneliness. The *Lubben social network scale -6* was used to calculate the presence and extent of social isolation; scores range between 0 and 30, with a lower score indicating less social engagement. The questionnaires also gathered information on age, gender, zip code, presence of chronic medical conditions, disease duration and the number of hospitalizations.

Results: To date, 367 surveys have been provided of which 154 surveys have been returned. Of these, 110 had complete data for analysis and comprised of 78 females and 32 males with a mean age of 50.2 years. A total of 40

	Patients with no chronic medical conditions (n=40)	Patients with rheumatic disease (n=48)	p-value	Patients with other chronic diseases (22)
Loneliness score (Campaign to End Loneliness)	2.6	3.5	0.01	5.7
Social isolation score (Lubben-6)	18.3	14.4	0.40	12.6
Female: male	24: 16	38:10		16:6
Mean age (median)	43.3 (38.5)	54.4 (55)		54.3 (56)
Disease duration (<5 vs. >5 years)	N/A	10:38		8: 14
Hospitalizations	8	12		10

Table shows scores for loneliness and social isolation among patients with chronic medical conditions compared to those with no chronic medical conditions along with demographics for all groups

respondents, comprised of 24 females with a mean age of 43.3 years reported no arthritis or chronic medical conditions. Another 48 patients, with 34 females and a mean age of 54.4 years, noted arthritis or other rheumatic conditions. There were an additional 22 patients who disclosed other chronic medical conditions (heart disease, diabetes and mental health). The mean loneliness score for patients with arthritis was 3.5 with 8 patients having total scores of 8 or higher and compared with a mean score of 2.6 (p=0.01) among those without chronic medical conditions with only 2 patients in this group noted to have a score of 8 or above. The mean Lubben score for the arthritis cohort was 14.4 compared with 18.30 (p=0.4) for those without chronic medical conditions. Most patients with chronic disease had >5 years disease duration. Hospitalization rates were surprisingly similar between the groups (see Table).

Two focus group meetings have been completed and included 28 subjects (21 females and 7 males). Preliminary quantitative analysis revealed an emphasis of family in relation to loneliness and the relevance of spirituality with regards to overcoming social isolation. The role of race and not fitting in to the "white society" was highlighted as a contributor to loneliness and social isolation.

Conclusion: Loneliness and social isolation are common and more pronounced in members of minority communities with rheumatic diseases. Efforts to measure these social determinants and develop methods to address them are important steps in implementing strategies to overcome healthcare disparities.

Abstract Number: 0053

¿Comprende? Assessing the Readability of Freely Available Spanish-Language Online Patient Education Materials for Rheumatologic Diseases

Carleigh Zahn[1], Bharat Kumar[1] and Cindy Puga[2], [1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]Carver College of Medicine, Iowa City

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Spanish is the second most popular language in the United States and third most commonly spoken language internationally. Despite the high prevalence of Spanish and the increasing recognition that language barriers and low health literacy contribute to healthcare disparities, there is little information about Spanish-language patient education materials (PEMs) regarding rheumatologic diseases. In this investigation, we systematically examine and appraise the accuracy and readability of Spanish-language online PEMs using validated measures.

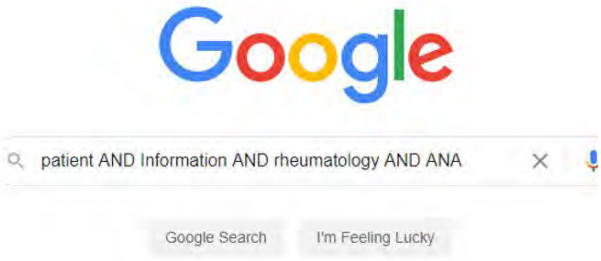
Methods: Three investigators compiled a set of common rheumatologic terms in both Spanish and English (Table 1). Two investigators independently conducted a search to identify Spanish-language PEMs using a Boolean search strategy (Figure 2) and compared results for consistency. The Spanish-language PEMs resulting from this search were then reviewed for medical accuracy by two investigators. Spanish spelling, grammatical, and syntactical errors were noted by a native Spanish speaker. The PEMs were further evaluated for readability based on (1) Fry Graph calculations, (2) the Fernandez-Huerta modification of the Flesch Reading Ease Score, and (3) the Flesch-Kincaid Grade Level.

Table 1

Rheumatology	Antinuclear antibodies	Lupus	Sjogren	RS3PE	Rheumatic Fever
Arthritis	Rheumatoid Factor	Rheumatoid	Sicca	CRMO	Lyme Disease
Arthropathy	Citrullinated peptide	Felty	Keratoconjunctivitis	CAPS	HIV
Arthralgia	Westergren	Caplan	Polychondritis	FMF	Human Immunodeficiency Virus
Joint pain	Erythrocyte Sedimentation Rate	Spondyloarthropathy	Behcet	HIDS	AIDS
Joint swelling	C-Reactive Protein	Spondyloarthritis	Adamantiades	PFAPA	Acquired Immunodeficiency Syndrome
Rheumatism	Vasculitis	Ankylosing Spondylitis	Gout	TRAPS	Hepatitis
Rheumatica	Arteritis	Psoriasis	Pseudogout	Periodic Fever Syndrome	HCV
Rheumatic	Capillaritis	Psoriatic	Calcium pyrophosphate	Autoinflammatory	HBV
Myositis	Polyangiitis	Osteoarthritis	Basic calcium	Juvenile Idiopathic Arthritis	Tuberculosis
Myopathy	Antiphospholipid	Lumbar stenosis	Crystalline arthropathy	Still's Disease	Parvovirus
Tendinitis	Inflammation	Spinal stenosis	Crystal arthropathy	Kawasaki	Measles
Bursitis	Inflammatory	Diffuse Idiopathic Skeletal Hyperostosis	Crystal arthritis	Giant cell arteritis	Mumps
Tendinopathy	Inflamed	DISH	Crystalline arthritis	Takayasu	Rubella
	Immunity	Lumbago	Fibromyalgia	Osteoporosis	Ehlers-Danlos
	Immune	Spondylolysis	Amplified Musculoskeletal	Osteonecrosis	Crohn Disease
	Anti-neutrophil cytoplasmic antibodies	Spondylolisthesis	Hypermobility	Osteopenia	Ulcerative Colitis
	ANCA	Spondylosis	Scleroderma	Paget's Disease	Celiac Disease
	HLA-B27	Degenerative disk disease	Systemic Sclerosis	Osteitis Deformans	
	Enthesitis	Degenerative joint disease	CREST	Granulomatosis with Polyangiitis	
	Dermatomyositis	Sarcoidosis	CRST	Wegener	
	Polymyositis		Raynaud	Henoch Schonlein	
				IgA Nephropathy	
				IgG4-related disease	

107 terms were searched in both English and in Spanish (Table lists English only)

Logistics of the search:



- Term A: (Patient OR Caregiver) AND
- Term B: (Information OR Resources) AND
- Term C: (Bold terms from first column of Appendix A) AND
- Term D: (Other terms from Appendix A)

- Searching in both Spanish and English
  - Results in Spanish

Demonstration of the Boolean Search Strategy independently conducted by two investigators

Results: The investigators identified 134 Spanish-language PEMs from 14 sources for the 107 terms utilized. Major medical inaccuracies were noted in only 3% of cases (4/134). However, 53.7% had at least one spelling or grammatical error (72/134) and 7.4% (10/134) had more than three spelling or grammatical errors. The Grade Level was determined to be >15 ('College' Level) in 94% of PEMs (126/134), per Fry Graph calculations. Similarly, The Flesch-Kincaid Grade Level was 17.3 (SD=2.3) and Flesch readability score was 5.4 (SD=0.6), signifying "very confusing" text.

Conclusion: Freely available rheumatologic Spanish-language PEMs do not meet accepted standards for patient education. While the majority of Spanish-language PEMs were considered medically accurate, the vast majority of Spanish-language PEMs greatly exceeded the recommended maximum 5th grade reading level. Based on these data, we advocate for the development and dissemination of new Spanish-language PEMs that prioritize both accuracy and readability.

"Is It Spiritual?" Complexities of Understanding Health-Seeking Behaviour in Patients with Chronic Autoimmune Rheumatic Diseases in Sub-Saharan Africa

Maame-Boatemaa Amissah-Arthur[1], Anna Gyaban-Mensah[2], Vincent Boima[1], Ernerst Yorke[1], Dzifa Dey[1], Delali Fiagbe[3], Vincent Ganu[2], Kelvin Acquaye[4] and Christopher Mate-Kole[5], [1]UGMS, Korle Bu Teaching Hospital, Accra, Greater Accra, Ghana, [2]Korle Bu Teaching Hospital, Accra, Greater Accra, Ghana, [3]UGMS, Accra, Greater Accra, Ghana, [4]Univesity of Ghana, Accra, Greater Accra, Ghana, [5]University of Ghana, Accra, Greater Accra, Ghana

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Challenges exist in the management of autoimmune inflammatory rheumatic diseases (AIRDs) in low and middle income countries due to factors, such as poverty and under-resourced healthcare infrastructure. Patient-dependent factors, determined by societal, religious and cultural practices are also contributory factors. We examined the impact of knowledge and perception, socio-economic and cultural factors on health-seeking behaviour and access to healthcare in Ghanaian patients with AIRDs, specifically assessing the factors that contribute to delay in receiving care from formal medical and specialist rheumatology services.

Methods: A cross-sectional study using an explanatory sequential mixed methods design. Structured questionnaires and standardised research instruments assessing demographics, health seeking patterns and contemporary and alternative medicine use were used to obtain quantitative data. Twenty individuals were further divided into two groups; ten for in-depth interviews and ten focus group discussions. Association between the socio-demographic variables, knowledge and perception; predictors of knowledge and access to health care; and duration of symptoms and delay in diagnosis were analysed.

Results: 110 patients enrolled (45.4% RA; 36.4% SLE; 14.5% MCTD, 3.6% SSc). 86.4% were female and the mean age was 36.8 years (SD=14.6 years). The median duration from onset of symptoms until diagnosis was 18 months (IQR = 43.94) across all disease groups. The maximum duration of *seeking help for the first time from onset of*

symptoms was 204 months, minimum of 2 weeks, and a median of 0.23 months (IQR= 3) [i.e. 1 week]. The median duration *from seeking help at the first facility to obtaining a final diagnosis* was 12 months (IQR = 33). The first facilities visited were pharmacies, non-specialist medical centres, churches and traditional healers, which were determined by multiple factors [X^2 (12, N = 107) = 32.29, p = .001]. Twenty-one participants (19.6%) had knowledge of their disease prior to diagnosis and causality was attributed to spiritual, lifestyle and biological factors. Education predicted having prior knowledge [OR = 2.6 (95% CI = .66 - 10.12), p< .021]. Unemployment increased the odds of seeking help after

Main themes	Sub-themes	Quotations
Knowledge and perception about condition	Biological	I know it is about our immune system (*FGD; Participant 2, female)*
	Lifestyle	Lack of exercise and if you don't eat well *(FGD; Participant 10, female)*
	Spiritual	When the symptoms started I did not understand, the way the sickness is, you will think maybe someone is causing it. *(FGD; Participant 5, female)*
Care seeking: Personal actions of relief	Rest or sleep	I sleep because of the pain *(IDI; Participant 4, female)*
	Visit health professionals	I go to the pharmacy *(FGD; Participant 2, female)*
	Self-medication	I use first aid *(IDI; Participant 10, female)*
Care seeking: Desperate actions for permanent treatment	Healer shopping	I visited several private hospitals which were of no help so my husband took me to a prayer camp. After, I visited Esukuma Government Hospital and they gave me drugs based on the symptoms I talked about but it wasn't working so I decided to try herbal centres which were of no help too. After, I went to Apam Hospital and they referred me to Korle Bu. *(IDI; Participant 6, female)*
	Search for information	I read about it in pamphlets, and online but sometimes the things you see are scary. We also have a WhatsApp group where we can ask questions and the doctors help us there. *(FGD; Participant 10, female)*
Effects of condition: Social Reactions	Relationships	I want to quit because of my condition. He does not treat me the way he is supposed to treat me. When he is supposed to help me he doesn't. When I ask for something he gets angry… *(IDI; Participant 6, female)*
	Education	"When I was sick I wasn't able to go to school; I was always at home feeling weak. I wasn't able to write exams. It has affected me" *(FGD; Participant 4, female)*
	Child bearing	"Yes, I am 32 and I have not given birth, that will push men away, maybe they will want a child." *(FGD; Participant 5, female)*
	Non-disclosure	Ooohh! Noo! If you don't know, you don't know. That's how it is. I am not that type of person who prefers to keep things, because if I tell you, there's nothing that you can do to it. So if you know, you know. If you don't know, that's all *(IDI; Participant 9, female)*
Effects of condition: Negative Feelings	Anxiety	Like sometimes when you want to do something, even when you work and you feel tired then it seems like you are feeling the sickness again, then you are in pain. Then it comes to mind, is it (illness) coming back. So I have to relax. *(IDI; Participant 5, female)*
	Pessimism	There are periods when I get very emotional. It is like the world is coming to an end. But you start getting guilty within yourself. It goes on and off. *(FGD; Participant 2, female)*
Coping strategies	Spiritual	It hasn't been long since this happened, but it's like God has given me the courage……Since I have God I have a future. *(FGD; Participant 5, female)*
	Significant others	My family have been so supportive I couldn't have done it without them *(FGD; Participant 2, female)*
	Knowledge of diagnosis	Knowing about it has helped me manage it well *(IDI; Participant 9, female)*

Table 2. Main themes, Sub-themes and quotations from thematic analysis

a month compared to those who were employed [Odds ratio = 2.60 (95% CI = 1.14 - 5.90), p = .02]. Forty (36.4%) participants utilised complementary and alternative treatment options. Thematic analysis of transcripts resulted in five key themes: *knowledge and perceptions of AIRDs, care-seeking behaviour, social reactions and stigma, negative feelings and coping strategies*.

Conclusion: Our study, the first of its kind to report health-seeking behaviour among Ghanaian patients with AIRDs, observed poor understanding of disease and recognised a multiple health-seeking medical culture which is significant among Ghanaian patients with a heavy reliance on religious, spiritual and traditional beliefs. Access to healthcare is determined by locality, availability and affordability of formal health facilities and alternative centres. These factors are associated with significant diagnostic and therapeutic delays, which can consequently lead to unfavourable clinical outcomes.

Abstract Number: 0055

Racial and Sex-based Disparities in Health Care Utilization: Eye Inflammation as a Paradigm

Krati Chauhan[1] and James Rosenbaum[2], [1]Southern Illinois University - School of Medicine, Springfield, IL, [2]Oregon Health & Science University, Portland, OR

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Healthcare Disparities in Rheumatology Poster

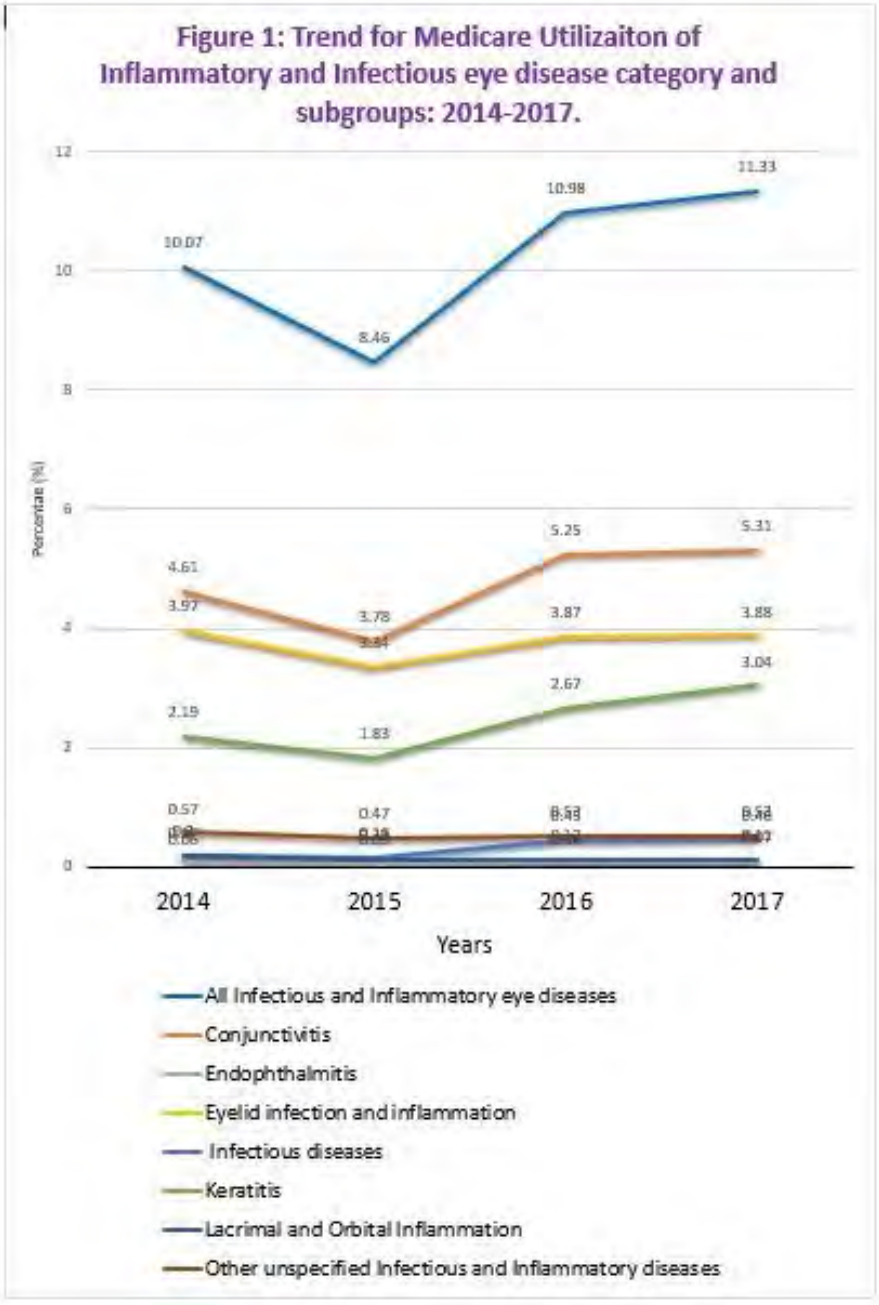

Figure 1. Trend for Medicare Utilizaiton of Inflammatory and Infectious eye disease category and subgroups: 2014-2017.

Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Disparities in health care utilization based on sex, race, education, or income affect outcomes in rheumatologic care. We have used ocular inflammatory and infectious disease, which complicates many rheumatic diseases, to study some of these disparities. These eye conditions, significantly increase disease burden, especially in people greater than 65 years of age and disproportionately affect females and racial minorities. However, there is lack of national level data in the US regarding influence of age, sex and race on utilization of medical care for inflammatory and infectious eye disease in people > 65 years. We have conducted an epidemiologic study using the Medicare database to analyze these trends and the influence of age, sex and race.

Methods: We have used Medicare data available through National Vision and Eye Health Surveillance System (VEHSS). Medicare data are collected from research identifiable files obtained through the Center for Medicare and Medicaid Services (CMS) and include all fee for service beneficiaries.

VEHSS uses ICD-10 codes to identify ocular disorders and organizes them into two level categorization, which are category and subgroup. Each code is categorized in one subgroup and multiple subgroups are combined to form a

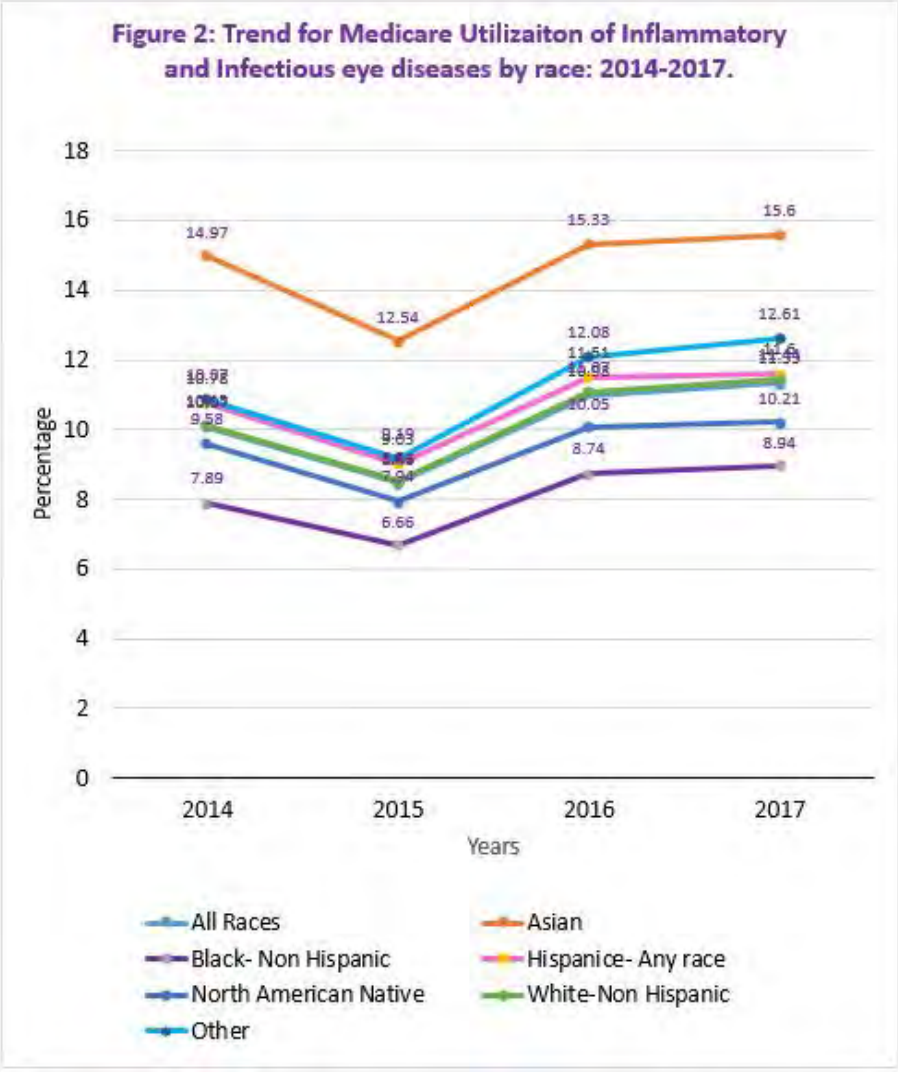

Figure 2 Trend for Medicare Utilizaiton of Inflammatory and Infectious eye diseases by race: 2014-2017.

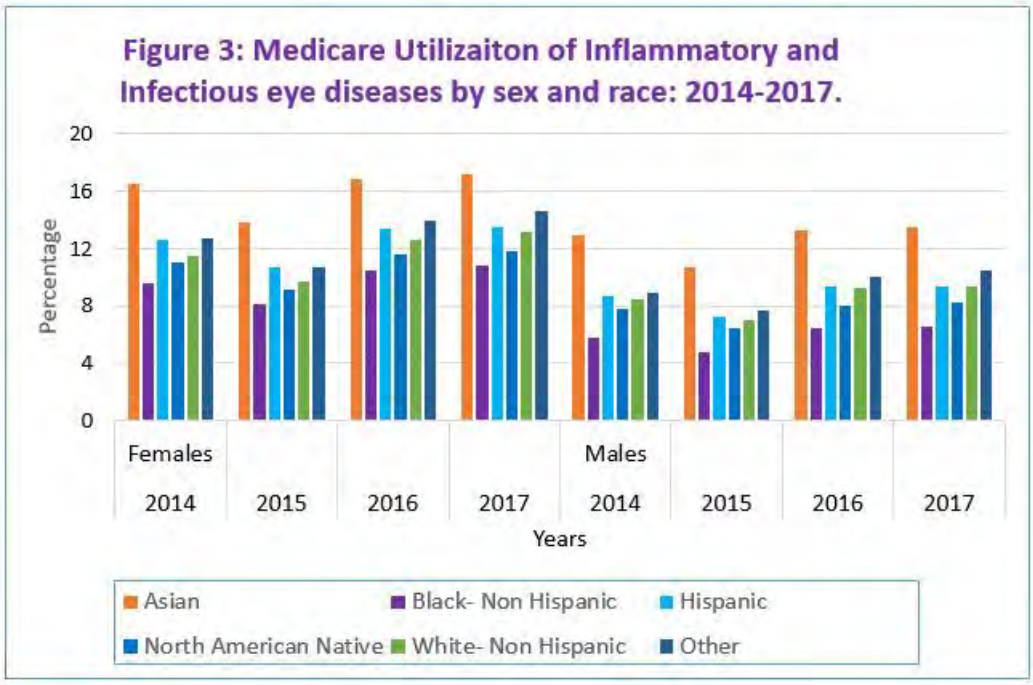

Figure 3. Medicare Utilization of Inflammatory and Infectious eye diseases by sex and race: 2014-2017.

category. Inflammatory and infectious eye disease category includes subgroups of ocular inflammatory conditions, lacrimal system and orbital inflammation, keratitis, conjunctivitis, eyelid inflammation and infection and endophthalmitis.

Utilization for the inflammatory and infectious eye disease caterogory, is stratified by age, sex and race. We have measured trends of utilization for the category and for the individual subgroups for the years 2014-2017. We have identified the effect of stratification on utilization; by race, sex, age alone; combining race and sex; age and sex; and the combination of race, sex and age.

Results: There were 29,971,000, 30,027,208, 30,423,400 and 30,238,300 million Medicare beneficiaries enrolled for the years 2014 to 2017 respectively. There was a decrease in utilization for inflammatory and infectious eye diseases category and subgroups from the year, 2014 to 2015 followed by a steady increase from 2015-2017 (Figure 1). This trend remains, when utilization is stratified by sex, race and age.

Asians and Hispanics have higher utilization for the inflammatory and infectious eye diseases category, and for the individual subgroups, for both males and females (Figure 2). This higher utilization remains, when further stratified by age.

Females have higher utilization across all races. This holds true when utilization is stratified by race; an Asian female has higher utilization than an Asian male (Figure 3). And remains steady when we further stratify by age groups. An Asian female of age group: 65-84 has higher utilization than an Asian male of the same age group; for all the years of the study 2014 to 2017.

Conclusion: Females, Asians and Hispanics have higher Medicare utilization for inflammatory and infectious eye diseases. These results may be due to higher disease prevalence or service utilization in these subgropus. Racial and sex-based disparitiies should be considered when making health care policy decisions

Role of Socioeconomic and Cultural Factors in Racial Disparities in Disease Severity and Health Status of Patients with Axial Spondyloarthritis

Leila Muhieddine[1], Shakaib Hayat[2], Katja Reuter[3], Charles Thomas[4] and Marina Magrey[5], [1]Case Western Reserve University- Metrohealth Medical Center, Cleveland, OH, [2]Case Western Reserve University-Metrohealth Medical Center, Cleveland, OH, [3]University of Southern California, Keck School of Medicine, Los Angeles, CA, [4]Case Western Reserve University, School of Medicine, Cleveland, OH, [5]Case Western Reserve University School of Medicine, Cleveland, OH

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To confront the persistent racial and ethnic disparities in health outcomes in the United States, it is imperative to study cultural and socioeconomic differences as potential contributors of worse disease severity among Black patients with AxSpA. In this two-phase, cross-sectional survey study, we aimed to identify differences in cultural, socioeconomic factors, and education levels among the Black and White patients with AxSpA in the United States.

Methods: The first phase consisted of qualitative research to develop a questionnaire. A focus group including Black patients with AxSpA was convened at an urban medical center to investigate participants' knowledge about SpA symptoms, disease course, and barriers to management of the disease. The focus group was audio-recorded, transcribed, and the feedback obtained was tabulated for trends. The survey content was generated using feedback from the focus group. Phase two of the study involved the distribution of the survey in person in a single rheumatology practice and nationwide electronically via social media (Facebook) and search engine marketing (Google search pages). The survey assessed respondent's demographics, understanding of their disease, educational level, income level, employment status, information about medication use including biologic use, availability of primary and specialty care, shared decision-making, cultural and family influences, and trust of the medical system. Categorical variables were analyzed with Fischer's Exact Test and ordinal variables with the Kruskal-Wallis Test. All tests were two-sided, with $p< 0.05$ considered significant.

Results: A total of 120 surveys were completed (62.5% web-based, 37.5% in person). The total was was composed of 65% White participants with a mean age 51.9 ± 13.0 years, 25% Black participants with a mean age 56.3 ± 11.1 years, and 10% other. The mean BASDAI, BASFI, and ASAS HI among the two groups were not different as shown

	Blacks	Whites	P Value
BASDAI (mean ± SD)	6.5 ± 2.7	6.6 ± 2.3	0.90
BASFI (mean ± SD)	5.9 ± 2.8	6.4 ± 2.5	0.52
ASAS-HI (mean ± SD)	9.4 ± 4.3	10.8 ± 4.3	0.15

Table 1. Disease Activity, Function and Health Status between Black and White participants.

	Blacks	Whites	P Value
Male (%)	79.3%	39.7%	**<0.001**
Post-Secondary Education (%)	25.9%	51.4%	**0.02**

Table. 2 Socioeconomic, cultural and other factors between Black and White participants.

in Table 1. Black patients were less likely to have a post-secondary education (25.93% vs. 51.35%, P=.0256), be employed (24.14% vs. 45.45% p=.0491), use home remedies (23.33% vs. 51.32 p=.0079), and be fearful of medication side effects (30.00% vs. 62.34% p= .0046). Black participants were more likely to be male (79.31% vs. 39.74% p= .0004). There was no significant difference in other survey questions among the two groups as shown in Table 2.

Conclusion: While this study demonstrated a difference in three areas among Black and White patients with AxSpA (i.e., cultural beliefs, education, employment), we did not find significant differences in terms of diagnostic delays, access to physicians, rapport with physicians, access to medication, income, disease activity, function, and health status. Interventions to address the AxSpA health disparity gap can build on these findings.

*Immune as defined as rubeola IgG > 30 AU/mL.

Table 1. Demographics of Patients Tested for Measles Immune Status

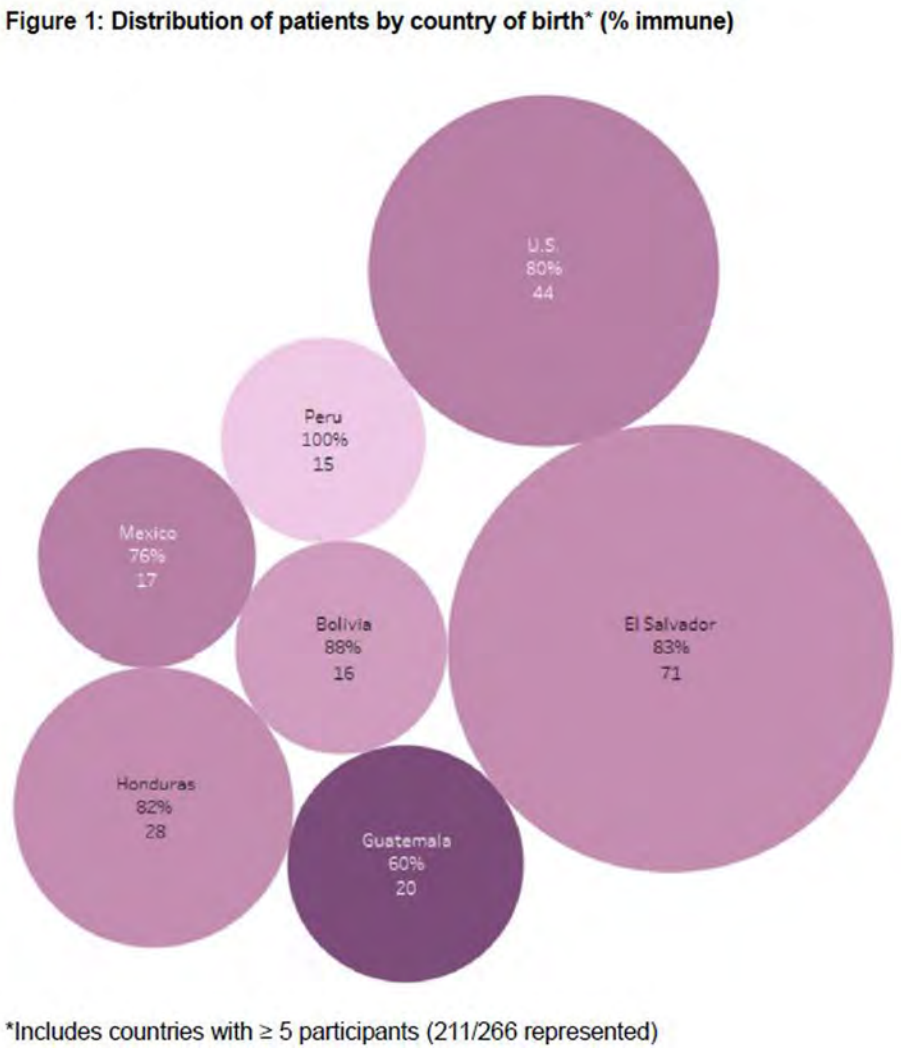

Figure 1. Distribution of patients by country of birth* (% immune)

outbreaks were associated with communities opposed to vaccination for varying reasons. With increased outbreaks, little attention has been given to communities at increased risk for measles secondary to limited access to care. Current guidelines for infectious disease screening prior to immune modulating therapy do not discuss measles. The Centers for Disease Control defines measles immunity as a positive titer, or evidence of two MMR vaccines, or birth prior to 1957. Seroprevalence studies of Central American countries have shown less than optimal rates of immunity to measles. We describe measles immune status in our cohort of majority underserved, Hispanic, non-U.S. born patients with rheumatic diseases.

Methods: Cross-sectional with a convenience sample of 266 patients born after 1957 who were seen in a rheumatology clinic from May 2019 to February 2020. All patients were participants in a rheumatic disease natural history study. Titer for anti-rubeola IgG was requested for each patient with their routine clinical lab draw. Immunization records were requested from primary care providers for patients whose titers were negative or equivocal. Demographic information including age, sex, place of birth, rheumatic disease diagnosis, and willingness to be vaccinated at a future visit were collected. To compare immune and non-immune groups, t tests and chi square tests were used on demographic variables where appropriate.

Results: The cohort was comprised of 86.8% women, 66.9% Hispanic ethnicity, and 52.6% from Central America or Mexico. Forty-five patients (17%) had negative or equivocal titers (Table 1), and none had records documenting prior

measles immunization. Patients born in Central America or Mexico (64.4%, n=29) were more likely to be non-immune (p=0.04) than patients born elsewhere (35.6%, n=16) . Nineteen of the 45 non-immune patients (42%) were potentially eligible to receive a live vaccine. Each of these patients indicated willingness to receive the MMR vaccine at a future visit. Patients from Guatemala had the highest percentage of non-immune titers, while those from Peru had the lowest percentage non-immune titers (Figure 1).

Conclusion: Our study demonstrates susceptibility to measles in our cohort with those from Central America or Mexico more likely to be non-immune. We highlight an underserved immigrant community affected by rheumatic diseases at increased risk for morbidity and mortality related to measles outbreaks. Evidence of measles susceptibility in our cohort coupled with the finding that 42% of our non-immune patients were eligible to receive live vaccines highlights an unmet need to evaluate measles immunity in rheumatology patients prior to immune-modulating therapy particularly in underserved populations. Clinicians can avoid missed opportunities to reduce infection risk in these at-risk communities by integrating immunizations into daily practice.

Drug Retention and Discontinuation of Biological DMARDs and Novel Small Molecules: Data from the Singapore National Biologics Registry

Li Wearn Koh[1], Man Hua Aw[2], Preeti Dhanasekaran[3], Rosa Lim Mui San[1], Stephanie Wong[4], Xanthe Chua[5], Wei Joo Choy[1], Manjari Lahiri[6] and Siaw Ing Yeo[2], [1]Tan Tock Seng Hospital, Singapore, Singapore, [2]Singapore General Hospital, Singapore, Singapore, [3]National University of Singapore, Singapore, Singapore, [4]Clinical Research and Innovation Office, Tan Tock Seng Hospital Singapore, Singapore, Singapore, [5]Tan Tock Seng Hospital, Singapore, Singapore, Singapore, [6]National University Hospital, Singapore, Singapore

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To describe drug retention rate and reasons for discontinuation of biological disease modifying anti-rheumatic drugs (bDMARD) and novel small molecules in patients from the Singapore National Biologics Register (SNBR).

Methods: The SNBR is a prospective cohort started in 2016 in collaboration between the Rheumatology departments of National University Hospital, Tan Tock Seng Hospital and Singapore General Hospital to collect data about the epidemiology, disease activity, adverse effects and the development of comorbidities in patients treated with biologics and small molecules in patients with rheumatoid arthritis (RA) and spondyloarthropathy (SpA).

Patients with physician-diagnosed RA and SpA (axial (AS), peripheral and psoriatic arthropathy (PsA)) who were newly started on a bDMARD or small molecule, were recruited into this multi-centre, inception cohort. Data was collected via face-to face, telephone consultations and review of medical records at baseline, 6, 12, 18 and 24 months. Kaplan-Meier analysis for survival on drug by clinical diagnosis, income, educational level and financial assistance was performed.

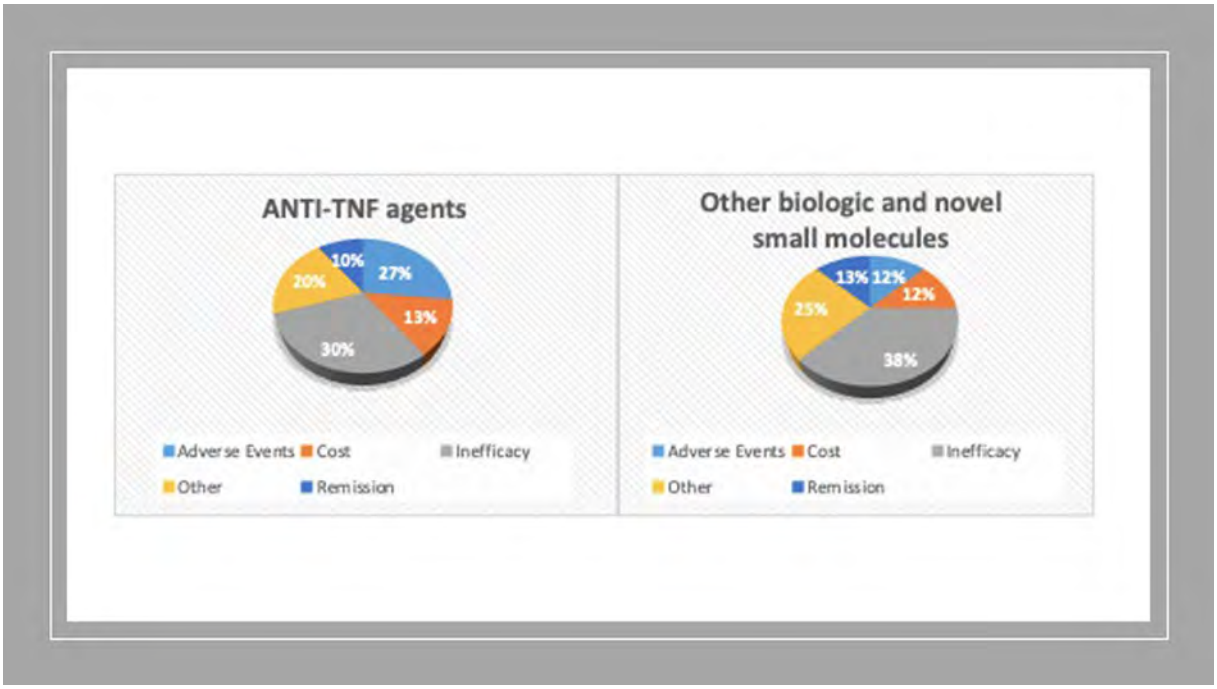

Figure 1. Reasons for discontinuation of biologic/novel small molecules

Results: 126 patients had completed 2-years follow-up and were included in our analysis. 67.5% were female and 32.5% were male. 118 were initiated on bDMARDS and 8 on small molecules at the baseline visit (48.4% RA, 22.2% AS, 21.4% PsA and 7.9% other SpA). Baseline disease activity scores (mean) of DAS28-ESR in RA was 4.95 (SD 4.64-5.26) and in PsA was 3.97 (SD 3.55-4.39) while the mean BASDAI in AS was 4.38 (SD 3.56 -5.21) and in other SpA 5.59 (SD 4.1-7.08). At the end of 24 months, Kaplan-Meier estimated retention rate of the original bDMARD/ small molecule was 41.1% (SD 33.0% -51.1%).

Reasons for discontinuation of these treatments are demonstrated in Figure 1. The commonest reason for discontinuation was inefficacy of the treatment (30% in patients on anti-TNF agents and 38% on other biologics and novel small molecules respectively).

The survival on drug was higher in patients with axial spondyloarthropathy (AS) compared to those with peripheral SpA, PsA and RA (Figure 2). Educational level, funding source and income group did not significantly influence retention rate of these medications.

Conclusion: In our cohort at the end of a 2 year follow up, fewer than half of our patients on high cost bDMARDs/ small molecules remained on their original bDMARD/small molecule. The retention rate of these medications was influenced by clinical diagnosis and inefficacy of the treatment was the main reason for discontinuation.Figure 1: Reasons for discontinuation of biologic/novel small molecules

Kaplan-Meier estimated drug retention rate by (clockwise from top left): underlying diagnosis (logrank p 0.0183), education (logrank p 0.1031), income group (logrank 0.2748) and financial assistance (logrank p 0.211).

EHR-Supported Staff Protocol Improves Smoking Cessation in a Diverse Rheumatology Clinic: Results of Quit Connect Dissemination Project

Jennifer Brandt[1], S. Sam Lim[1], Edmond Ramly[2], Monica Messina[3] and Christie Bartels[4], [1]Emory University, Atlanta, GA, [2]University of Wisconsin School of Medicine and Public Health, Department of Family Medicine and Community Health;, Madison, [3]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Rheumatology Division, Madison, WI, [4]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking is a key risk factor for rheumatologic conditions such as rheumatoid arthritis and lupus that disproportionately impacts disadvantaged patients and predicts worse outcomes. Both smoking and rheumatic diseases increase risk for cardiovascular disease, yet rheumatology clinics address cessation in fewer than 10% of visits and offer referrals to free state-run tobacco quit lines (TQLs) in < 1% of visits. TQLs are proven to increase cessation 4-fold through free coaching and nicotine replacement.

Quit Connect supports rheumatology staff medical assistants or nurses with electronic health record (EHR) tools to *Ask* smokers about 30-day readiness to quit or cut back, *Advise* cessation support, and *Connect* ready patients via EHR orders to receive a TQL call (Figure 1). *Quit Connect* increased TQL referrals 26-fold in our prior study, and required < 90 seconds. We disseminated *Quit Connect* to the Grady Rheumatology Clinic, a public clinic in Atlanta, GA to test generalizability and increase TQL and smoking cessation class referrals.

Methods: We engaged medical assistants, nurses, clinic administrators, and rheumatologists to tailor *Quit Connect* implementation in a focus group. One-hour training offered cessation evidence and practice with talking points and EHR tools (Figure 2). Adults in the rheumatology clinic with current tobacco use were targeted. EHR tags captured process steps for when a patient was *Asked* about smoking/quit readiness, *Advised* regarding TQL and cessation class, or *Connected* via referral to TQL or cessation class. We compared performance before and after active implementation of the protocol, and we report 3 month midpoint data. Chi-square tests and unadjusted odds ratios compared findings months 1 to 3.

Results: At baseline, 83% of patients were Black, 40% were uninsured, and 52% received Medicare/Medicaid. During the 3 months of *Quit Connect* implementation, among 780 visits, 16% were smokers (Table 1). Among smokers, rates of triage staff asking readiness to quit increased from 13% in month 1 to 51% in month 3 (OR 8.6), compared to 0% before the project. Among smokers who were asked (n=30), 76% said that they were ready to quit or cut back in the next 30 days. Among those ready (n=23), 82% were offered referral to the TQL or class. Among those offered (n=19), 63% accepted the e-referral to the TQL and 68% accepted a referral to the class (p=0.99) compared to zero referred before *Quit Connect* implementation.

Conclusion: In a low resource rheumatology clinic with a majority of Black patients with limited insurance, many were ready to quit but had not been offered support. Within three months, *Quit Connect* dramatically increased referrals to a tobacco quit line and cessation class. This process is easily integrated into the EHR, engages staff, and leverages

Figure 1. Quit Connect trains medical assistants and nurses to ASK smokers about readiness to quit, ADVISE cessation, and CONNECT patients to cessation resources such as a tobacco quit line or cessation class in under 90 seconds during clinic rooming.

Figure 2. Quit Connect implementation steps and timeline. Participants included study team, clinic manager, nurses, medical assistants and rheumatologists. Participants were engaged with a focus group and then trained with evidence-based information regarding effects of smoking on rheumatologic disease and how to connect patients to TQL or a cessation class using EHR referrals. Staff received monthly audit feedback regarding process of ASK, ADVISE, CONNECT to smoking cessation resources.

Table 1. Quit Connect process steps before and after implementation

	Before n=2674 visits/yr.		Month 1 n=289		Month 2 n=300		Month 3 n=191		Unadjusted OR Month 3 vs Month 1	Total n=780 visits

ANCA-associated Vasculitis in Caucasian and Hispanics of the Inland Empire of Southern California

Sandy Lee[1], Patil Injean[1], Paulina Tran[2], Deepa Panikkath[1] and Christina Downey[1], [1]Loma Linda University Medical Center, Redlands, CA, [2]UC Riverside School of Medicine, Riverside, CA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is often studied in the Caucasian population with few studies looking at the disease in other races. Disease presentation and treatment implications of autoimmune conditions vary by ethnicity, as seen in systemic lupus erythematous. A 2014 study of the Chicago area compared AAV in Hispanic and Caucasian patients and found increased disease severity, as defined by the Birmingham Vasculitis Activity Score (BVAS) and the Vasculitis Disease Index (VDI), with greater renal involvement in Hispanics. We performed a similar study examining the differences in AAV in the Hispanic and Caucasian populations living in the Inland Empire region of Southern California.

Methods: A retrospective study was conducted on data extracted from the Loma Linda University Medical Center and the Riverside University Health System's Electronic Medical Record, using ICD 9 and ICD 10 CM codes pertaining to vasculitis. Data span the dates of January 1, 2003 to December 31, 2019. Vasculitis cases were classified using the Diagnostic and Classification of the Systemic Vasculitis (DCVAS). Data extracted from the electronic charts include demographics, ICU admission due to vasculitis flare, presence of chronic kidney disease or end stage renal disease (ESRD), BVAS on presentation and VDI as detailed on recent clinic visit. We calculated odds ratios for the categorical data and ran Independent sample T-test for the continuous data with alpha equal to 0.05 for statistical significance.

Results: 129 charts were included in the analysis with 66 Hispanics and 63 Caucasians (see Table 1). 72 cases of Granulomatosis Polyangiitis (GPA), 47 cases of Microscopic Polyangiitis (MPA) and 10 cases of Eosinophilic Granulomatosis Polyangiitis (EGPA) were identified. Hispanics had a 49% increase in odds of being admitted to the ICU secondary to vasculitis when compared to Caucasians [OR 1.49 (95% CI 0.72, 3.07)]. Hispanics were noted to have more flares with a maximum recorded number of flares for a single patient to be 15 compared to 7 for a Caucasian patient. They also had a 71% increase in odds of having kidney disease in comparison to Caucasians [OR 1.71 (95% CI 0.85, 3.43)]. Of the patients with kidney disease, Hispanics had a 95% increase in odds of having ESRD when compared to Caucasians [OR 1.95 (95% CI 0.68, 5.55)]. See Table 2. The BVAS and VDI averages between Hispanics and Caucasians were comparable at 8.53 ± 7.3 vs 7.69 ± 6.3 and 2.32 ± 2.0 vs 2.2 ± 1.5, respectively (p = 0.49; p =

Table 1. Observed Attributes of Hispanic and Caucasian patients with ANCA-associated Vasculitis.

	Total N = 129	Hispanic N = 66	Caucasian N = 63
Male	42 (32.6%)	18 (27.3%)	24 (38%)
Female	87 (67.4%)	48 (72.7%)	39 (61.9%)
GPA	72 (55.8%)	31 (47%)	41 (65.1%)
MPA	47 (36.4%)	31 (47%)	16 (25.4%)
EGPA	10 (7.8%)	4 (6.1%)	6 (9.5%)
# of deaths	16 (12.4)	6 (9.1%)	10 (15.9%)
Chronic Kidney Disease	62 (48.1%)	36 (54.5%)	26 (41.3%)
ESRD	39 (62.9%)	25 (69.4%)	14 (53.8%)
Renal transplant	13 (21.0%)	10 (27.8%)	3 (11.5%)
ICU admission	47 (36.4%)	27 (40.9%)	20 (31.7%)

Table 1. Observed Attributes of Hispanic and Caucasian patients with ANCA-associated Vasculitis.

Table 2. Odds Ratio for Ethnicity

	OR (Hispanic/Caucasian)	95% CI
ICU Admission	1.49	0.72 – 3.07
Chronic Kidney Disease	1.71	0.85 – 3.43
ESRD	1.95	0.68 – 5.55
Renal Transplant	2.95	0.72 – 12.0

Table 2. Odds Ratio for Ethnicity

Table 3. Independent Sample T-test of BVAS and VDI.

	P-value	Ethnicity	N	Mean	Std. Deviation
BVAS	0.49	Hispanic	62	8.53	7.3
		Caucasian	61	7.69	6.3
VDI	0.70	Hispanic	62	2.32	2.0
		Caucasian	61	2.20	1.5

Table 3. Independent Sample T-test of BVAS and VDI.

0.70). See Table 3. Although we observed differences in disease severity proportions between Hispanics and Caucasians, the measures of association were not statistically significant.

Conclusion: Like the Chicago study, we saw greater incidences of renal disease and increased severity in Hispanics compared to Caucasians, as defined by increased rates of ICU admissions and vasculitis flares, despite analogous average BVAS and VDI scores. Our data shows that conventionally used disease activity scores may not convey the seriousness of renal or pulmonary vasculitis in Hispanic populations. Clinicians treating Hispanic patients with AAV should have a high index of suspicion for more severe disease in this patient population when compared to Caucasians.

Rheumatologists' Attitudes Toward Palliative Care and Medical Assistance in Dying

Alexandra Saltman[1], Caroline McGuinty[2], Gursimran Chandhoke[3], Simon Oczkowski[4], Heather McDonald-Blumer[1], Ebru Kaya[5] and Kirsten Wentlandt[6], [1]University Health Network and Sinai Health System, University of Toronto Faculty of Medicine, Toronto, ON, Canada, [2]Ottawa Heart Institute and University of Ottawa, Ottawa, ON, Canada, [3]Lakeridge Health, Oshawa, ON, Canada, [4]Juravinski Hospital and McMaster University, Hamilton, ON, Canada, [5]University Health Network,, University of Toronto Faculty of Medicine, Toronto, ON, Canada, [6]University Health Network, University of Toronto Faculty of Medicine, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite major advances in the treatment of systemic rheumatic diseases, a population remains—including those with systemic vasculitis, inflammatory myositis and systemic sclerosis—who suffer from life-limiting disease. Typically, these patients have little access to palliative care services, and there is a paucity of data on this potential care gap. This study aims to define the referral practices of Canadian Rheumatologists to pal-

liative care services and to explore rheumatologists' attitudes toward palliative care and medical assistance in dying (MAiD).

Methods: All rheumatologists who are members of the Canadian Rheumatology Association were invited to complete an online questionnaire using *Survey Gizmo*. Responses were received anonymously by the online survey program, aggregated and analyzed using descriptive statistics.

Results: 37 (19%) of rheumatologists completed the survey. 22 (60%) self-identified as academic physicians. The majority were general rheumatologists (n=30, 83%), caring primarily for adult patients (n=33, 89%). 68% reported exposure to elements of palliative care during medical training, covering pain management (n=23, 77%), management of other physical symptoms (n=21, 70%), end-of-life planning (n=19, 63%) or communication skills (n=21, 70%).

Rheumatologists categorized up to 50% of their inpatients and up to 10% of their outpatients as having advanced rheumatologic disease with significant functional limitation or low estimated 1-year survival. 44% (n=16) reported access to palliative care unit or hospice services for their patients, and 36% (n=13) were aware of local palliative home care services. 54% (n=19) had never referred a patient to palliative care services. For those who had, they did so most often for uncontrolled symptoms and prognosis less than 1 year (n=22, 66%), or for terminally ill inpatients who required assistance with discharge planning (n=24, 60%). 14% (n=5) reported feeling "very comforTable" identifying patients with life-limiting rheumatic conditions that might benefit from a palliative care approach to care, and 22% (n=5) were "very comforTable" discussing such an approach with their patients. 42% indicated they were "not very comforTable" (n=10, 28%), or "not at all comforTable" (n=5, 14%) engaging in advance care planning conversations with their patients.

While 33% (n=12) of rheumatologists had been approached by a patient requesting MAiD, a large number rated their knowledge of eligibility criteria (n=17, 47%) and of the assessment and approval process (n=19, 53%) as "poor".

Conclusion: This study is the first to describe self-reported referral practices of rheumatologists to palliative care services, and to identify attitudes of these physicians towards palliative care consultation. The results expose gaps in knowledge of, and comfort with, palliative care services for patients with life-limiting rheumatic diseases, as well as barriers to accessing these services for patients with non-cancer illnesses. Further work is needed to engage rheumatologists about the role that palliative care teams can play in providing higher quality care to patients with advanced systemic rheumatic illnesses toward the end of life.

Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lyme Disease is caused by the spirochete *Borrelia Burgdorferi (Bb).* The infection often begins in the skin, following a tick bite, and spreads to the joints, heart, and other tissues. The pathogenesis of Lyme disease is multifactorial, involving both pathogen-derived factors that influence dissemination, and host factors that are responsible for the inflammation and modulation of infection. PGLYRP1, a member of the peptidoglycan recognition proteins, is a host immune factor associated with the innate immune response. PGLYRP1 has been linked to pro-inflammatory processes in many chronic inflammatory diseases. The goal of this study is to understand the function of PGLYRP1 in Lyme Borreliosis.

Methods: Flow cytometry and ELISA were used to characterize the ability of *Bb* to recognize PGLYRP1. Wild type (WT) and PGLYRP1 knockout (KO) BALB/C mice, 6-8 weeks old, were infected subcutaneously with $1x10^6$ spirochetes. Pathogen burden was measured by qPCR in heart, joint, and skin tissues in WT and KO mice at 25 days post infection. Blood samples were collected in both groups of mice to determine antibody titers against *Bb*. Serum cytokine profile was assessed, using a mouse chemokine/cytokine array. Histopathology was used to evaluate the severity of inflammation in both heart and joint tissues.

Results: In vitro assays showed a concentration-dependent interaction between *Bb* and PGLYRP1. Infected KO mice had significantly higher pathogen burden in hearts and joints, but no difference in skin samples compared to WT mice. There was a significant reduction in *Bb* specific IgG titers in sera obtained from infected KO mice. Similar to overall IgG, levels of IgG1, IgG2a, IgG2b, and IgG3 against Bb were significantly lower in PGLYRP1 infected KO mice than in WT. NoTable increases in pro-inflammatory cytokines IFN-y, CXCL-9, and CXCL-10 were observed in infected KO mice. There was no significant difference in arthritis and carditis severity in WT and KO mice.

Conclusion: These studies suggest that PGLYRP1 plays a role in the host modulation of *Bb* in the systemic phase of infection and immune response. This leads to a better understanding of the pathogenesis of Lyme Disease.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

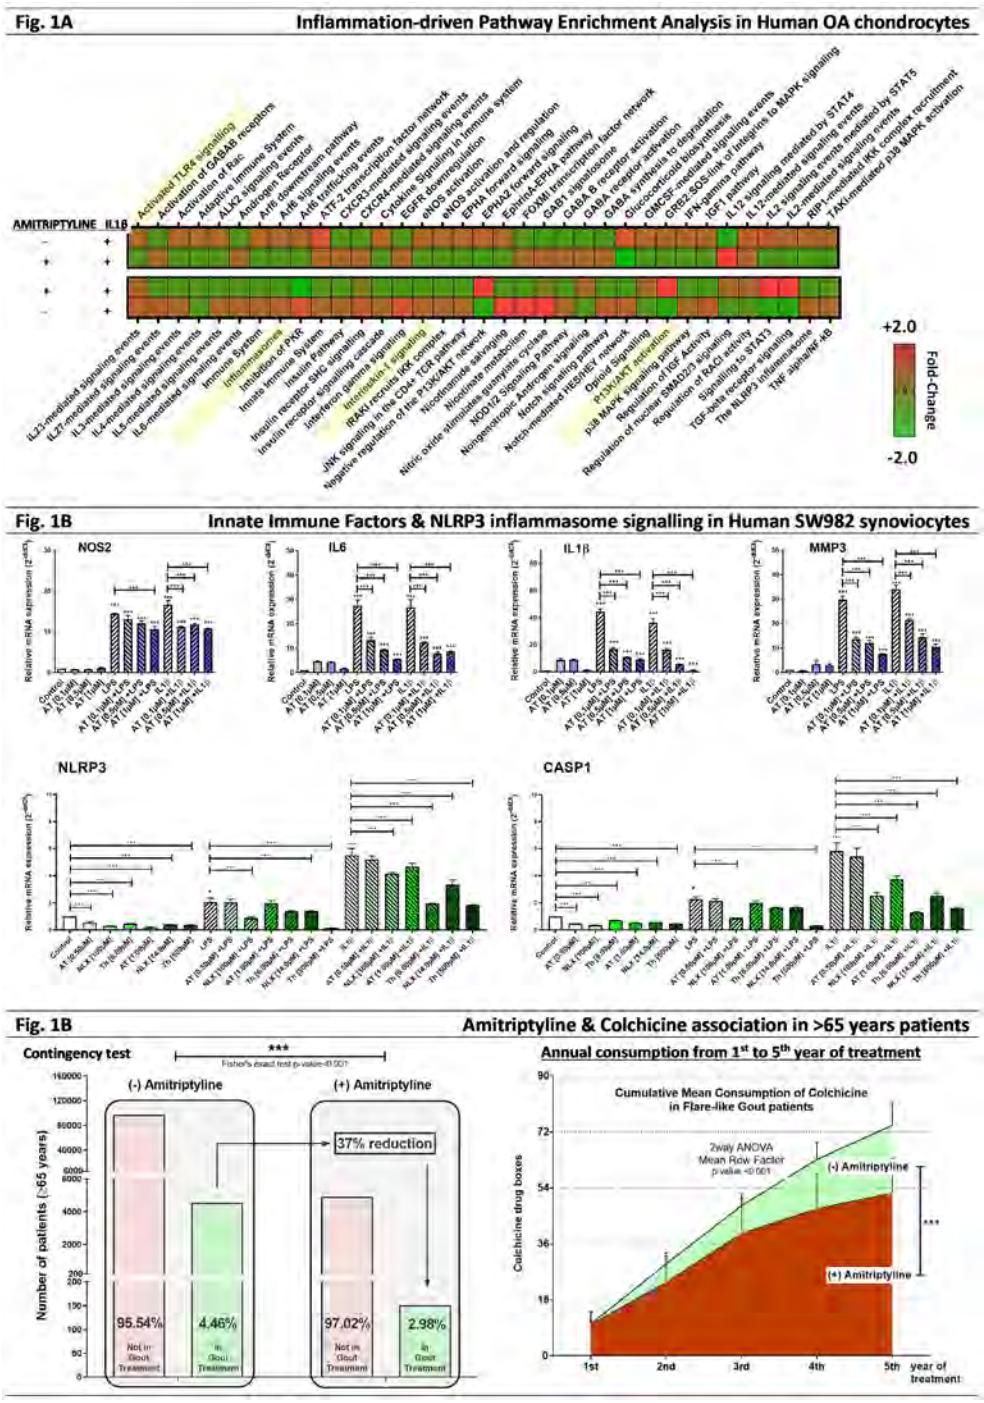

Figure 1. Amitriptyline blocked the proteome of IL1R–mediated innate immune response factors Fig. 1A.- Inflammatory-driven Pathway Enrichment Analysis of proteins quantified (SWATH) on primary human OA chondrocytes co-treated 24h with AT [1μM] and IL1β [0.1ng/ml]. Fig. 1B.- Blocking effects of amitriptyline (AT), naloxone (NLX) and thalidomide (Th) were evaluated on TLR4 (LPS [100ng/ml]) & IL1R (IL1β [0.1ng/ml])– activated human SW982 synoviocytes. Innate immune factors (NOS2, IL6, IL1β and MMP3) and NLRP3 inflammasome signalling were analysed by RT-PCR. Fig. 1C.- Contingency test comparing the number of patients requiring colchicine in both amitriptyline and non-amitriptyline consumers against the whole population (>65 years). Cumulative mean consumption of colchicine drug boxes in colchicine gout-patients who suffered of flare-like episodes, namely those who consumed >18 colchicine boxes in at least a single year. Statistics: SWATH data were filtered by FDR 1% and at least a p-value <0,05. Data of three independent experiments was used and "Control" was used to normalise RT-PCR. Clinical data was obtained from the healthcare area of EOXI Santiago de Compostela (Spain) that covers a 400.000 citizen area. Contingency test was analysed by Fisher's exact test. Cumulative mean tests were analysed by 2-way ANOVA Row factor, and other data was by one-way ANOVA. Tukey post-test was used, and results were expressed as the mean ± standard error of the mean (SEM) with the significance NEJM system (*p<0,05; **p<0,01; ***p<0,001). Abbreviations: Toll like receptor 4 (TLR4), interleukin 1 receptor (IL1R), amitriptyline (AT), naloxone (NLX) and thalidomide (Th), human OA chondrocytes (hOC), lipopolysaccharide (LPS), interleukin 1 beta (IL1β), interleukin 6 (IL6),

Background/Purpose: Joint inflammation is a common feature across multiple rheumatic diseases. To deal with the induction of innate immune factors, targeting therapeutic targets such as TLR4 and IL1R is required. We have recently reported the use of amitriptyline (AT), thalidomide (Th), and naloxone (NLX) to block TLR4 & IL1R-mediated innate immune responses in OA cartilage. Now we explore their use in synovia and gout inflammation.

Methods: The ethics committee approved (CAEIG 2016/258) the use of human samples and aggregated and dissociated clinical data from 440.000 citizens.

The activity and expression of TLR4, IL1R, and NLRP3 signaling pathways were determined by docking analysis (Autodocks-Vina), MTT cell viability assay, RT-PCR, and Western Blot, ELISA or MALDI-TOFF in human OA chondrocytes and synoviocytes (SW982 cell line). Statistics were performed using GraphPad Prism 9.0.

Results: The docking of AT, Th, and NLX towards TLR4 was confirmed by *in silico* binding affinity analysis. In human synoviocytes, the use of therapeutic doses of AT [0.1-1μM], NLX [1.4-100μM], and Th [3-500μM]) prevented the induction of several factors including NOS2, IL6, IL1B and MMP9 at the mRNA and protein level (up to -97%). The inhibition of the NLRP3 inflammasome pathway, which is linked to both synovitis and gout-associated inflammation, was verified by RT-PCR & MALDI-TOFF in OA chondrocytes and synoviocytes. Considering this link, we requested access to clinical data and found that amitriptyline consumers are less prone to require colchicine drug for gout treatment.

Conclusion: Amitriptyline, naloxone, and thalidomide prevent the induction of TLR4 & IL1R-mediated innate immune factors in OA chondrocytes and synoviocytes. Moreover, amitriptyline consumption reduced the dose of colchicine needed for gout treatment.

Considering that these drugs are being used in other indications, their repurpose might be a novel tool to manage inflammation across diverse rheumatic diseases.

Neutrophil Extracellular Traps Are Sufficient to Activate the Alternative Pathway of Complement

Rebecca Schriefer[1], Michelle Elvington[2], Priyan Weerappuli[3] and **Alfred Kim**[4], [1]Washington University School of Medicine, Saint Louis, MO, [2]Kypha, Inc., Saint Louis, MO, [3]University of Michigan, Ann Arbor, MI, [4]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) replies on complement activation to drive many of the pathophysiologic features of disease. We and others have noted that SLE patients have constitutive activation of the complement component C3 (1). Elevated C3 activation products such as C3(H_2O) suggest that the alternative pathway is preferentially used to drive this process. Importantly, the production of C3(H_2O) is also critical for the com-

plosome, the intracellular C3 activation pathway that confers functional changes in numerous cells types (2). Furthermore, prior work has shown that stimulated neutrophils can drive C3 activation, which in turn further activates neutrophils (3). As NETs are a key feature of SLE pathophysiology, we hypothesized that neutrophil extracellular traps (NETs) promote alternative pathway activation, producing C3(H_2O) which is in turn used to drive intracellular C3 activation.

Methods: To independently assess whether NETs can activate C3, we leveraged a recently developed acellular mimic of NETs, DNA-histone mesostructures (DHMs), that possess the ultrastructural and functional properties of NETs (4). Purified human native C3 and C2-depleted human serum (Complement Technologies, Tyler, Tx, USA) were added to DHMs or DNA-histone-free DHMs (control). C3(H_2O), factor Bb, C3a, C5a, and C5b-C9 were assessed using ELISA. Isolated human neutrophils were obtained from consented healthy controls and activated by either DHM-induced C3(H_2O) or phorbol myristate acetate (PMA), some in the presence of DNAse to digest NETs. Cell lysates were examined by western blot for intracellular C3 activation products (goat anti-human C3 polyclonal antibody, Complement Technologies). Images of neutrophils were obtained using a Zeiss LSM 880 Confocal with AiryScan.

Results: DHMs drove the rapid (< 5 minutes) and nearly complete (>90%) activation of native C3 into C3(H_2O), suggesting a contact mechanism promotes early C3 activation. When C2-depleted was added to DHMs, products of alternative (Bb) and common pathway (C3a, C3a, C5b-9) were observed. When DHM-induced C3(H_2O) was added to primary neutrophils, it was readily taken up both unstimulated and PHA-activated neutrophils as observed by AiryScan confocal microscopy. Interestingly, only PHA-activated neutrophils were able to generate intracellular C3a and C3b products. Finally, using DNase-treated PHA-activated neutrophils to digest NETs, only the addition of DHM-induced C3(H_2O), and not native C3, induced C3 uptake, further supporting the role of NETs in C3 activation.

Conclusion: We found that NETs are sufficient to activate the alternative pathway of complement. The C3(H_2O) generated through this process was internalized by neutrophils, but only activated neutrophils were capable of intracellular C3 activation. Given the high NET load in SLE, we suspect that this may be the etiology for constitutive C3 activation observed in SLE patients.

The Energy-dependent Hierarchy of Immune Functions in Human Monocytes

Pierre-Louis Kraußß[1], Thomas Buttgereit[2], Yuling Chen[1], Moritz Pfeiffenberger[1], Timo Gaber[1] and Frank Buttgereit[3], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Dermatology, Venerology, and Allergology, Berlin, Germany, [3]Charité University Medicine, Berlin, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: At sites of inflammation, monocytes carry out specific immunological functions while facing challenging bioenergetic restrictions. Here, we investigated the potential of human monocytes to adapt under conditions of reduced energy supply by gradually inhibiting oxidative phosphorylation (OXPHOS) under glucose free conditions.

Methods: We modelled this reduced energy supply with myxothiazol, an inhibitor of mitochondrial respiration, at 0, 2 and 4 pmol/10^6 cells to decrease mitochondrial ATP production for 0%, 25% and 66% under glucose free conditions. For the three energy levels, we assessed (i) phagocytosis of FITC-labelled *E.coli* using flow cytometry, (i) production of reactive oxygen species (ROS) through NADPH oxidase (NOX) as determined by VAS2870-sensitive OCR using a Clark-type electrode, (iii) ATP generation and steady state level using a Clark-type electrode and luminometric assessment (iv) expression of surface activation markers CD16, CD80, CD11b, HLA-DR and (v) production of the inflammatory cytokines IL-1β, IL-6 and TNF-α using flow cytometry in peripheral blood-derived human monocytes with and without LPS-stimulation.

Results: As a prerequisite for our study, we demonstrate that human monocytes survived strong inhibition of mitochondrial respiration without any sign of apoptosis as determined by flow cytometry. As a result of the inhibition of OXPHOS, we demonstrate a reduction of VAS2870-sensitive OCR (ROS production through NOX), ATPase-dependent OCR and ATP steady-state levels. Focusing on immune function, we observed that phagocytosis and the production of IL-6 were the least sensitive to reduced energy supply while surface expression of CD11b, HLA-DR, production of TNF-α and IL-1β were most affected by inhibition of OXPHOS.

Conclusion: Our data demonstrate an energy-dependent hierarchy of immune functions in monocytes, which may represent a potential therapeutic target in monocyte-mediated inflammatory diseases.

AMP Deaminase 2 Is Expressed on the Surface of Human Immune Cells as a Novel Regulator of Extracellular Adenosine Metabolism

Lisa Ehlers[1], Aditi Kuppe[1], Marieluise Kirchner[2], Alexandra Damerau[1], Cindy Strehl[1], Frank Buttgereit[3] and Timo Gaber[1], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Max Delbrück Center for Molecular Medicine, BIH Core Facility Proteomics, Berlin, Germany, [3]Charité University Medicine, Berlin, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Adenosine and its nucleotides represent crucial immunomodulators in the extracellular environment. ATP and ADP are released from stressed cells in states of inflammation, whereas adenosine serves as a key anti-inflammatory mediator. The ectonucleotidases CD39 and CD73 are responsible for the sequential catabolism of ATP to adenosine via AMP, thereby promoting an anti-inflammatory milieu induced by the "adenosine halo". Great importance has been attributed to these enzymes in the pathogenesis of autoimmune diseases such as rheumatoid arthritis (RA) and as targets in cancer therapy. AMPD2 mediates AMP deamination to IMP, thus constituting an ambiguous mediator both enhancing the degradation of inflammatory ATP and reducing the formation of protective adenosine. Here, we postulate that this pathway is also present on the cell surface of immune cells and modified under inflammatory conditions. Therefore, we analysed surface AMPD2 expression and its modulation on distinct cell lines and primary immune cells.

Methods: Firstly, AMPD2 surface expression was verified by immunoprecipitation from membrane fractions isolated from cell lines (HEK293 and HMEC1) and CD14+ monocytes analysed by western blot and mass spectrometry. In addition, surface biotinylation of the aforementioned cells was performed. Also, AMPD2 surface expression was evaluated by flow cytometry, analysing both cell lines (HEK293, HMEC1, THP1, and Jurkat) and primary human immune cells from healthy donors and patients with RA. Secondly, co-expression of surface AMPD2, CD39 and CD73 on PBMCs was analysed by flow cytometry directly after isolation as well as after a 24h culture period. Moreover, surface expression was assessed after immunostimulation and Golgi transport inhibition.

Results: AMPD2 surface expression was confirmed by western blot and mass spectrometry of (i) precipitated AMPD2 from membrane fractions and (ii) biotinylated surface molecules in HEK293 and HMEC1 as well as CD14+ monocytes. Surface expression was reduced after AMPD2 knockdown in HEK293. Flow cytometric analysis further verified AMPD2 surface expression and revealed a significant decrease after Golgi transport inhibition ($p< 0.01$). TLR stimulation strongly enhanced the surface expression of AMPD2 and CD39 on monocytes ($p< 0.05$), whereas dexamethasone at high therapeutic doses inversely affected AMPD2 surface expression on lymphocytes and monocytes ($p< 0.01$). Analysis of AMPD2 surface expression on PBMCs from RA patients revealed higher expression levels compared to sex- and age-matched healthy controls ($p< 0.05$).

Conclusion: We demonstrate AMPD2 surface expression on immune cells for the first time. Hence, we reveal a novel regulator of the extracellular ATP-adenosine balance that is differentially expressed in RA patients compared to healthy controls. The extracellular conversion of AMP into IMP may constitute a shunt-like mechanism adding to the CD39-CD73 system controlling immunomodulation.

Abstract Number: 0067

Functionally Mature CD1c$^+$ Dendritic Cells Contribute to Synovial Inflammation in Rheumatoid Arthritis via STAT3

Mary Canavan[1], Viviana Marzaioli[1], Vipul Bhargava[2], Sunil Nagpal[3], Phil Gallagher[4], Conor Hurson[5], Ronan Mullan[6], Douglas Veale[7] and Ursula Fearon[1], [1]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland, [2]Janssen Research & Development, Springhouse, PA, [3]Janssen Research & Development, Collegeville, PA, [4]St Vincents University Hospital, UCD, Dublin, Ireland, [5]St Vincents University Hospital, UCD, Dublin, Dublin, Ireland, [6]Adelaide and Meath Hospital, Dublin, Dublin, Ireland, [7]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Myeloid Dendritic Cells (DC) are potent antigen presenting cells that can be subdivided into CD141$^+$ and CD1c$^+$ DC. We have previously reported an unacknowledged role of CD141$^+$DC in the RA synovium. However, the identification and function of CD1c$^+$ DC in the RA synovium has yet to be fully elucidated. Therefore our aim was to investigate if CD1c$^+$DC reside in the RA synovium and ascertain if they represent a unique population, distinct from peripheral blood CD1c$^+$DC.

Methods: Synovial tissue (ST) biopsies and synovial fluid mononuclear cells (SFMC) were obtained via arthroscopy and healthy control (HC) ST was obtained during ACL surgery. Synovial biopsies were enzymatically and mechanically dissociated to yield a single cell suspension. SFMC and peripheral blood mononuclear cells (PBMC) in addition to synovial tissue digests were stained with a panel of fluorochrome conjugated antibodies and single cell analysis was performed by multicolour flow cytometry. CD1c$^+$DC were sorted from RA SF and peripheral blood (PB) and RNA-sequencing was performed. Principal Component Analysis (PCA), Enriched pathway analysis, heatmaps and hierarchical clustering were identified using the DeSeq2 R package and Ingenuity® Pathway Analysis (IPA). For functional experiments CD1c$^+$DC were magnetically sorted from RA SFMC and RA PBMC and phagocytosis was assessed using flow cytometry. Finally allogeneic T cell cocultures were performed with SF and PB CD1c$^+$DC in the presence or absence of the STAT3 inhibitor Stattic.

Results: CD1c$^+$DC are significantly decreased in RA PB compared to HC PB ($p< 0.01$) and express significantly higher levels of the chemokine receptors CCR7 ($p< 0.05$) and CXCR3 ($p=0.08$) compared to HC DC - suggestive of DC migration to the synovium. In support of this hypothesis, CD1c$^+$DC were identified in RA ST by multicolour flow cytometry and were significantly increased in RA ST compared to RA PB ($p< 0.01$). RA ST CD1c$^+$DC express significantly higher expression of the DC activation marker CD80 compared to RA PB ($p< 0.01$) or HC ST ($p< 0.05$). CD1c$^+$DC are also enriched in RA synovial fluid compared to RA PB ($p< 0.05$), express significantly higher levels of the maturation markers CD80,CD83,CD40,PD-L1 and BTLA (all $p< 0.05$) and are less phagocytic compared to matched PB. RNA-sequencing and PCA analysis revealed distinct transcriptional variation between synovial and PB CD1c$^+$DC. Moreover, IPA analysis revealed an enrichment in the STAT3 pathway in synovial DC. Synovial CD1c$^+$DC induce proinflammatory cytokines (TNFα, GMCSF, IFNγ) from CD4$^+$ T-cells in allogeneic cocultures, and effect which is abrogated in the presence of a STAT3 inhibitor.

Conclusion: CD1c$^+$DC are present in the RA synovium in a mature state, have distinct tissue specific characteristics and mediate their T cell stimulatory capabilities via STAT3.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Innate Immunity Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

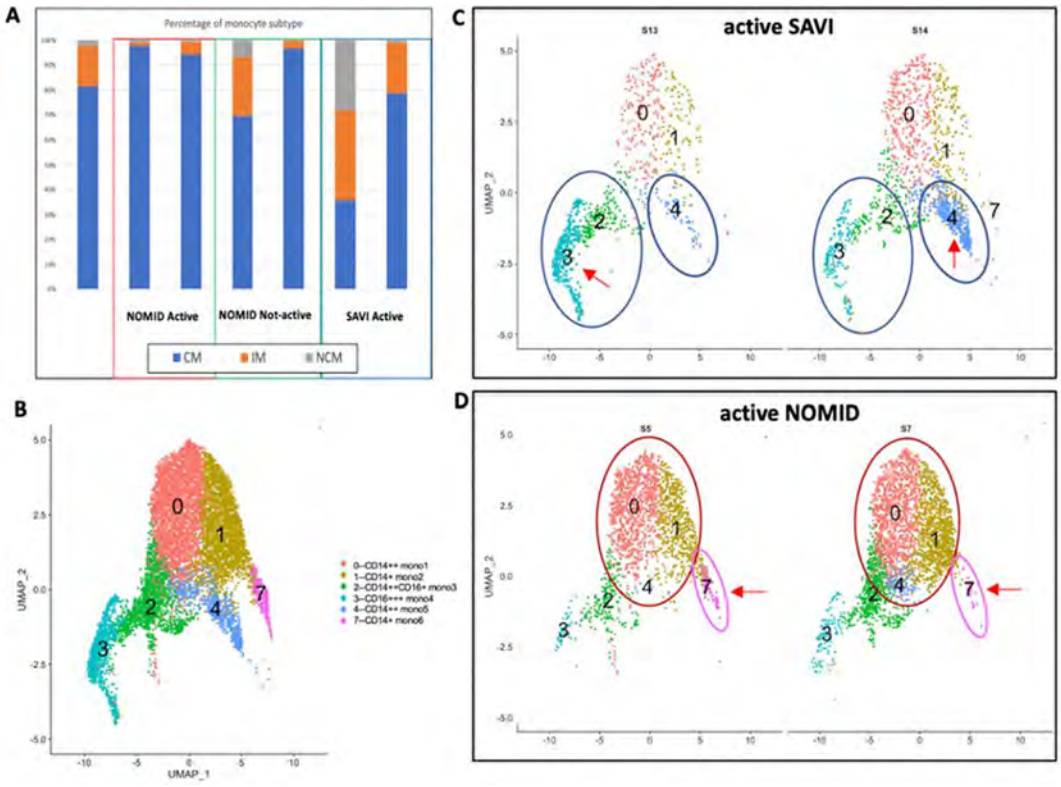

Figure 1. A. Each cell is annotated to be a classical (CM), intermediate (IM) or non-classical monocyte (NCM) by SingleR using MonacoImmuneData reference. Expansion of IM and NCM populations in one SAVI patient S13 and expansion of CM populations in mostly active NOMID patients and a patient who has been treated for 3 months with anakinra were quantified. B. Six monocyte subsets were identified by a shared nearest neighbor (SNN) modularity optimization- based clustering algorithm using Seurat. C, D. In active SAVI CD16+ mono3 (2), mono4 (3) and CD14+ mono5 (4) subsets were expanded, while in active NOMID expansion of CD14+ subsets mono1 (0), mono2 (1) and mono6 (7) were seen.

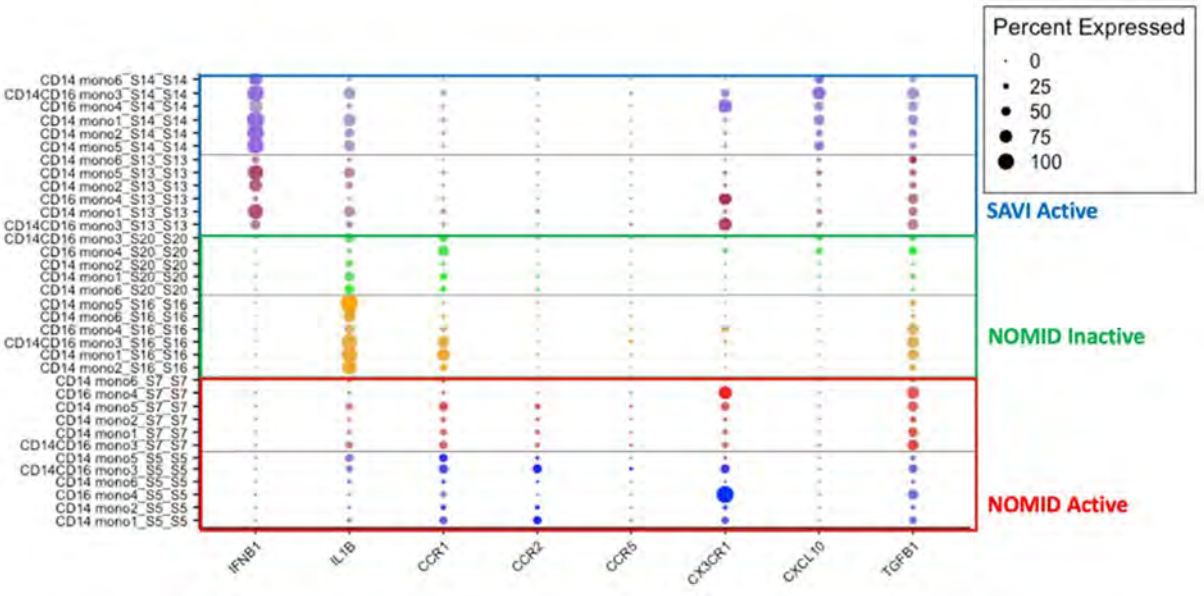

Figure 2. Selected gene expression patterns in SAVI and NOMID monocytes. In SAVI, active patients' monocytes have strong IFNB1 and moderate IL1B expression. CD16+ monocytes from active SAVI and NOMID pts. express CX3CR1 transcripts. NOMID patients do not express IFNB1. In inactive NOMID patients' monocytes express more IL1B but lower CCR2 transcript levels than in clinically active NOMID patients.

Background/Purpose: Monocytes are pivotal producers of key inflammatory cytokines that drive autoinflammatory diseases. In SAVI, constitutive STING activation causes chronic activation with increased type-I IFN response gene expression in whole blood, and in NOMID, constitutive activation of the NLRP3 inflammasome leads to IL-1β mediated chronic inflammation. The effects of the respective activation of STING or the NLRP3 inflammasome on monocyte activation and differentiation are poorly understood. We used single cell RNA sequencing (scRNAseq) to profile purified monocytes from 2 SAVI and 3 NOMID patients.

Methods: Monocytes were positively selected from peripheral blood using CD14+ MicroBeads (Miltenyi). Transcription profiles from bead-purified monocytes from 2 SAVI and 3 NOMID patients (pts) enrolled in an IRB approved protocol (NCT02974595) were generated; 3000 monocytes were prepared for scRNAseq using Chromium™ Single Cell 3' v2 Reagent Kit (10x genomics) and were sequenced (NextSeq®, Illumina) targeting 60,000 reads/cell. Files were demultiplexed and aligned to the GRCh38 transcriptome reference using Cell Ranger. Gene-barcode-matrices that passed quality control were analyzed individually and integrated; monocyte subsets were identified by a shared nearest neighbor (SNN) modularity optimization-based clustering algorithm (Seurat). Cell subsets were annotated based on cell-type specific marker expression. Each cell is also annotated as a classical (CM), intermediate (IM) or non-classical (NCM) monocyte (SingleR using MonacoImmuneData reference).

Results: Gene expression of *CD14* and *FCGR3A*/CD16 transcripts and SNN modularity optimization-based clustering algorithms identified 6 monocyte subsets for all samples (active SAVI (n=2), active NOMID (n=2) and inactive NOMID (n=2)) (Fig.1 A, B). In SAVI pts, CD16+ NCM and CD14+CD16+ IM are expanded. Interestingly, in SAVI all monocyte subsets strongly express IFNB1 with less IL1B expression. CX3CR1 is high in CD16 NCM subsets. In contrast, in NOMID pts, CD14+ CM subpopulations are expanded. NOMID monocytes do not express IFNB1 and IL1B expression was stronger in CD14+ CM from the 2 inactive than active NOMID pts. Comparing active and inactive NOMID, the percentage of CD14+ cells decreases as well as their CCR2 expression but not CCR1 expression. Furthermore, CX3CR1 expression drops in CD16+ NCM in inactive NOMID (Fig. 2).

Conclusion: In the active, NLRP3-inflammasome mediated disease, NOMID, classical monocytes (CM) subsets are expanded while in the Type-1 interferonopathy, SAVI, CD16+ NCM are expanded. The distinct expression of *IFNB1*

transcripts in SAVI only and the chemokine receptor modulation in active (SAVI and NOMID) and inactive (NOMID) disease, suggest disease-specific activation dependent monocyte subset heterogeneity in chronic autoinflammatory diseases. Gene expression profiling is ongoing and may contribute to the characterization of the monocyte diversity in NOMID and SAVI that propagates chronic inflammation and tissue damage.

Identification of CD13 as a Potential Cause for SARS-CoV-2-triggered Hyperinflammation and Thrombosis

Eliza Pei-Suen Tsou[1], Gautam Sule[1], Mikel Gurrea Rubio[2], M. Asif Amin[1], Yu Zuo[1], Jason Knight[1], Yogendra Kanthi[3] and David Fox[1], [1]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, University of Michigan, Canton, MI, [3]Division of Cardiovascular Medicine, Ann Arbor

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The ectopeptidase CD13, which is highly expressed on stromal and myeloid cells in joints, lung and other tissues, is a known receptor for many coronaviruses. Its soluble form (sCD13) is a powerful pro-inflammatory mediator with strong chemotactic, angiogenic and arthritogenic properties. Neutrophil extracellular traps (NETs) are known to trigger formation of thrombi in antiphospholipid syndrome (APS), and likely also in other inflammatory and rheumatologic conditions. Recently NET-associated markers have been shown to correlate with disease severity in COVID-19 patients. Moreover, sera from COVID-19 patients trigger healthy neutrophils to undergo NETosis. We hypothesized that CD13 is also a receptor for SARS-CoV-2, and that both the cell membrane-anchored and soluble forms of CD13 trigger aggressive inflammatory responses in SARS-CoV-2 infection, including NETosis.

Methods: Serum samples from healthy volunteers (n=53) and hospitalized COVID-19 patients (n=172) were used in this study. The levels of sCD13, citrullinated histone H3 (Cit-H3), and MPO-DNA complexes were measured by ELISA. NETosis was measured by SYTOX Green and NET-associated elastase activity. GraphPad Prism v8 was used for statistical analysis. The Mann-Whitney test or Kruskal-Wallis test was used to compare groups. Correlation was tested by Spearman's correlation coefficient. Statistical significance was defined as $p< 0.05$.

Results: Significant elevation of sCD13 was observed in COVID-19 patients as compared with healthy subjects (960 ± 81.2 vs. 94.7 ± 37.6 ng/ml, mean ± SEM, $p< 0.0001$), with the highest levels observed in patients who required mechanical ventilation. sCD13 levels were two-fold higher in African American compared to Caucasian patients ($p=0.02$). In addition, sCD13 positively correlated with inflammation-indicative markers, including ferritin ($r=0.252$, $p=0.002$) and lactate dehydrogenase ($r=0.374$, $p< 0.0001$), as well as NETosis-related markers, such as Cit-H3 ($r=0.243$, $p=0.001$) and MPO-DNA ($r=0.242$, $p=0.001$). Both sCD13 and anti-CD13 monoclonal antibodies induced robust NETosis in control neutrophils *in vitro*.

Conclusion: Although not yet identified as a cell surface receptor for cell entry of the novel coronavirus SARS-CoV-2, CD13—which is much more widely expressed than ACE2—could play several unique roles in viral pathogenesis. These data identify CD13 and a cell surface receptor for sCD13 as potential triggers for COVID-19-associated NETosis, vascular stress and thromboembolic complications. The powerful pro-inflammatory effects of sCD13 may account for an important component of the unusual hyperinflammatory complications of this viral infection. Receptors for sCD13, one of which we have recently identified as the bradykinin 1 receptor (B1R) could become therapeutic targets in patients with severe COVID-19.

Neutrophils Transiting Through Megakaryocytes During Emperipolesis Exhibit Distinct Fates and Acquire the Capacity to Guide Other Neutrophils via MK Trails

Frank Huang[1], Pierre Cunin[2], Felix Radtke[3], Ricardo Grieshaber-Bouyer[4], Roxane Darbousset[5] and Peter Nigrovic[6], [1]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany, Darmstadt, Baden-Wurttemberg, Germany, [2]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, Boston, MA, [3]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany, Boston, [4]Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany; Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, Heidelberg, Germany, [5]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, Boston, [6]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Megakaryocytes (MKs) can contribute directly to experimental arthritis via pro-inflammatory microparticles containing IL-1 (Cunin et al. *Journal of Clinical Investigation*, 2017). MKs also interact with immune cells via emperipolesis (EP), a novel cell-in-cell interaction whereby neutrophils pass through MKs before egressing without apparent harm to either cell. EP is common in bone marrow, but its cell biology and implications for MKs and neutrophils are unknown.

Methods: We compared the frequency of EP between healthy mice and different inflammatory models (K/BxN serum transfer arthritis, LPS injection, cecal ligation and puncture). We developed an *in vitro* model of EP by culturing bone marrow MKs with neutrophils and quantitated the time course using live cell spinning disk microscopy. We used transmission electron microscopy and immunofluorescence microscopy to explore intermediate stages of EP.

Results: P frequency increased 2-3-fold in inflammatory arthritis, after administration of LPS, and after cecal ligation and puncture (a model of polymicrobial sepsis). EP bifurcated into fast and slow events, with approximately 40% of

neutrophils transiting through MKs in less than 10 minutes whereas 35% persisted for 50 minutes or more. Slow EP was often associated with direct physical contact between neutrophils and the MK nucleus. Electron microscopy revealed that most neutrophils within MKs were encased by a phagosome-like compartment, termed the "emperisome". However, some neutrophils could be observed only exiting the emperisome to enter the MK cytoplasm, where we could observe physical association with the endoplasmic reticulum or the demarcation membrane system (the MK's platelet membrane reserve). These observations suggest the existence of different forms of EP. Intriguingly, we observed that neutrophils pull long tubes consisting of CD41+ MK membrane ("MK trails") during their egress from MKs. MK trails express markers for immune cell attachment and rolling. Post-EP neutrophils deposited fragments of these trails on endothelial cells during migration *in vitro*, marking paths then preferentially visited by other neutrophils.

Conclusion: EP increases markedly during inflammation, including inflammatory arthritis. We identified fast and slow modes of EP, as well as distinct intracellular areas of neutrophil localization within MKs, suggesting that EP can serve multiple functions. EP results in the generation of novel MK trails that are deposited by neutrophils on endothelial cells, suggesting a new mechanism by which EP enables coordination of neutrophil behavior and thereby an organized and efficient inflammatory response.

Significant Enrichment of Transcriptionally Distinct CD206+CD163+ Macrophage Population in Rheumatoid Arthritis Synovial Tissue

Megan Hanlon[1], Mary Canavan[2], Qingxuan Song[3], Candice Low[4], Phil Gallagher[5], Ronan Mullan[6], Conor Hurson[7], Sunil Nagpal[8], Douglas Veale[9] and Ursula Fearon[2], [1]Molecular Rheumatology, Trinity College Dublin, Dublin 2, Dublin, Ireland, [2]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland, [3]Janssen Research & Development, LLC, Spring House, PA, USA, Spring House, PA, [4]EULAR Centre for Arthritis and Rheumatic diseases, St Vincents University Hospital, UCD, Dublin, Ireland, [5]St Vincents University Hospital, UCD, Dublin, Ireland, [6]Adelaide and Meath Hospital, Dublin, Dublin, Ireland, [7]St Vincents University Hospital, UCD, Dublin, Dublin, Ireland, [8]Janssen Research & Development, Collegeville, PA, [9]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial tissue macrophages are an exquisitely plastic pool of innate cells that play a key role in RA disease progression. However, the precise nature, diversity and function of macrophage subsets within the inflamed joint remains unexplored.

Methods: Single cell analysis of Rheumatoid Arthritis, Psoriatic Arthritis, Osteoarthritis and healthy control synovial tissue biopsies and synovial fluid mononuclear cells was performed using advanced flow cytometry with the following panel (CD40, CD45, CD64, CD68, CD163, CD206, CD253, CCR4, CCR7, CXCR1, CXCR3). CD206+CD163+ and CD206-CD163- macrophages were sorted from RA synovial tissue by FACSAria sorter for subsequent RNAseq, FLIM analysis and autologous T-cell co-culture experiments.

Results: RA synovial tissue and fluid macrophages display markers typical of both M1 (CD40+CD253+) and M2 (CD206+CD163+) macrophages with a spectrum of macrophage activation states identified in RA synovial tissue that don't fully conform to the classic M1/M2 framework. Within this spectrum, significant enrichment of a dominant CD206+CD163+ macrophage-subtype is present in synovial tissue versus fluid ($p< 0.05$). CD206+CD163+ synovial tissue macrophages express significantly more CD40 compared to synovial fluid ($p< 0.0003$), positively correlate with disease activity ($r=0.6$, $p< 0.01$), with baseline levels predicting response to therapy ($p< 0.05$). Moreover, CD206+CD163+CD40+ macrophages are enriched in RA synovial tissue compared to PsA and OA pathotypes ($p< 0.05$) and display distinct chemokine receptor expression patterns. While the CD206+CD163+ macrophage subset is present in healthy synovial tissue, expression of CD40 is completely absent in the healthy synovium ($p< 0.05$). RNA-seq analysis indicates that the CD206+CD163+ population is transcriptionally distinct from synovial tissue CD206-CD163-, synovial fluid CD206+CD163+, and pure RA monocyte-derived M1/M2 macrophages, with unique tissue-resident gene signatures (TREM2+, FOLR2+, LYVE1+ C1QA+, TIMD4+, CD48-, CCR2-). Moreover, differing metabolic demands between CD206+CD163+ and CD206-CD163- subsets was demonstrated by RNAseq and FLIM analysis. Finally, CD206+CD163+ macrophages have the capacity to induce autologous T-cell responses and spontaneously secrete high levels of pro-inflammatory cytokines, thus further contributing to the local inflammatory response.

Conclusion: This data identifies enrichment of a previously undescribed dysfunctional dominant and transcriptionally distinct macrophage subtype in RA synovial-tissue.

Abstract Number: 0072

Characterizing Heterogeneity of Synovial Macrophages in Rheumatoid Arthritis Patients

Shang-Yang Chen[1], Yidan Wang[2], Anna Montgomery[2], Salina Dominguez[2], Carla Cuda[2], Gaurav Gadhvi[1], Harris Perlman[2] and Deborah Winter[3], [1]Northwestern University, Chicago, IL, [2]Northwestern University, Chicago, [3]Northwestern University Division of Rheumatology, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophages in the synovial lining of the joint are critical players in the pathogenesis of rheumatoid arthritis (RA). While they are potent producers of inflammatory molecules, there is also evidence that macrophage play a role in the resolution of inflammation. A better understanding of macrophage heterogeneity in humans could help pinpoint pathways and potential therapeutic targets for treating RA that are specific to particular subpopulations.

Methods: We obtained synovial tissue samples from the wrist joints of patients with active RA through minimally invasive ultrasound-guided synovial biopsy. Tissue was processed into single-cell suspension and enriched for CD45+ immune cells by Fluorescence Activated Cell Sorting (FACS). Next, droplet-based single cell RNA-sequencing (scR-

NA-seq) was performed using the 10X Genomics instrument. The sequenced reads were aligned and mapped to genes using CellRanger pipeline, followed by R package.

Results: We previously used single-cell RNA-sequencing to report the presence of 4 distinct subpopulations of mouse synovial macrophages. Based on their distinct transcriptional profiles, we characterize these populations as synovial lining, interstitial, antigen presenting, and infiltrating. Here, we examined the single cell expression profiles of RA synovial biopsy samples to investigate whether humans exhibit similar disposition of synovial macrophage heterogeneity as observed in mice. Using integrative gene module scoring of top 10 orthologous markers, the labels of 4 mouse subpopulations were projected onto human macrophages. Large variations in the composition of macrophage subppopulations was observed among patients. Strikingly, patients with higher proportions of synovial lining and interstitial macrophage subpopulations are significantly associated with lower clinical severity of RA, which is consistent with their anti-inflammatory phenotypes observed in mice. We also compared the 4 mouse subpopulations against an independent dataset generated by Accelerating Medicines Partnership (AMP) Consortium, where synovial myeloid cells from patients with RA or osteoarthritis (OA) were profiled. We observed the enrichment of synovial lining expression signatures in OA, which is generally associated with lower levels of inflammation. In contrast, signatures of antigen presenting and infiltrating subsets are enriched in the RA patients with high immune cell infiltration, supporting the expansion of these subsets by recruitment of circulating monocytes.

Conclusion: We were able to characterize human synovial macrophage heterogeneity by translating our findings from subpopulations in mice. Further investigation of the activation of these macrophages in the inflamed joint may lead to the development of therapies to target the pathogenic function of specific subpopulations in RA.

A Cross-Species Map of Neutrophil Inflammatory Responses

Felix Radtke[1], Frank Huang[2], Peter Nigrovic[3] and Ricardo Grieshaber-Bouyer[4], [1]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany, Heidelberg, Baden-Wurttemberg, Germany, [2]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany, Darmstadt, Baden-Wurttemberg, Germany, [3]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston, [4]Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany; Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, Heidelberg, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophils are important mediators of immune defense as well as key protagonists in immune-mediated disease. How these cells adapt differently to sterile and septic inflammatory conditions may offer opportunities to target neutrophils without disarming immune defense.

Methods: Here, we applied an in-depth, cross-species and cross-condition analysis of publicly available RNA sequencing data from 286 neutrophil populations from 26 different datasets. Condition-variance versus species-variance was calculated on a per-gene basis. Similarities and differences between conditions were examined by KEGG pathways, gene ontology (GO), and principal component analysis (PCA). The regulatory activity of transcription factors was predicted using ENCODE and ChEA3 libraries.

Results: 87% of human genes could be assigned one-to-one murine orthologs with high confidence according to ENSEMBL version 100. The overall transcriptional landscape of healthy human and murine neutrophils exhibited strong correlation (Pearson's R = 0.66; $P < 2.2 \times 10^{-16}$). By PCA, human blood neutrophils resembled murine blood neutrophils more than neutrophils from murine bone marrow, spleen and liver.

Within orthologous genes that exhibited a high dynamic range, 48% varied more between species than between experimental conditions. These genes were enriched for GO terms including cell-cell adhesion and metabolism. By contrast, 52% displayed higher variance between experimental conditions, reflecting conserved transcriptional responses in human and murine neutrophils. Condition-variant genes were associated with immune function and degranulation. A query of the GWAS catalog for SNPs associated with these genes identified association with immune-mediated conditions including allergy, psoriasis, rheumatoid arthritis and systemic lupus erythematosus.

We then compared different disease states. Neutrophils from aortic aneurysms, PAPA syndrome, influenza vaccination and CD200R-knockout mice exhibited few differences from healthy controls. By contrast, systemic juvenile idiopathic arthritis blood neutrophils differed from healthy human blood neutrophils by more than 300 genes. We identified a 151-gene transcriptomic inflammatory response program conserved across a broad range of conditions and between humans and mice, including elevation of *NFKBIA*, *TNFAIP3*, *SOCS3*, *IL1B* and *CCL2*. Transcription factor enrichment analysis implicated NFKB1, RELA, STAT1 and JUN as key drivers ($P < 1 \times 10^{-6}$), consistent with strong enrichment for the GO terms associated with NFkB activation and cytokine response.

Conclusion: Through a comparison of neutrophils across species and conditions, we identified substantially conserved transcriptomic responses between human and murine neutrophils. We define a conserved neutrophil inflammatory response program preserved across species and conditions. These findings provide new insight into the selection of potential targets for therapeutic manipulation of the contribution of neutrophils to sterile inflammatory diseases.

Abstract Number: 0074

The Intracellular DNA Sensor STING Protects Against Bone Loss Through Regulation of Type I Interferons

Susan MacLauchlan[1], Catherine Manning[2], Sijia Chen[3], Katherine Fitzgerald[4], Shruti Sharma[5] and Ellen Gravallese[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital, Boston, [4]University of Massachusetts medical school, Worcester, MA, [5]Tufts University, Boston, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The intracellular DNA sensor Stimulator of Interferon Genes (STING) is essential for detection of viral and bacterial pathogen DNA. As with other pathways in the innate immune system, hyperactivation of the STING pathway is associated with autoinflammatory and autoimmune diseases. Activation of STING promotes anti-viral responses through production of type I interferons, including IFNβ. A pleiotropic cytokine, IFNβ is a potent stimulus of the innate immune system and has also been shown to inhibit the formation of osteoclasts. We therefore sought to determine whether the STING pathway impacts bone homeostasis and osteoclastogenesis.

Methods: Osteoclast formation assays were performed using RANKL-stimulated bone marrow progenitors from STING deficient (KO) mice and myeloid-specific STING KOs. The immortalized myeloid cell line RAW294.7 was engineered to stably overexpress murine STING or an empty vector control. RANKL was used to stimulate osteoclast precursors to form osteoclast-like cells *in vitro*. Secreted IFNβ was monitored using ELISA. IFNβ activity was inhibited using an IFNaR1 blocking antibody (Biolegend). Trabecular and cortical bone parameters were determined in femurs from aging (6, 13, and 15 months) STING whole body KO mice and littermate controls using microCT. Ovariectomies in myeloid-specific-STING KOs ($STING^{flox/flox}$ $LysM^{+/-}$, hereafter referred to $STING^{LysM}$ KO) and littermate controls ($STING^{flox/flox}$ $LysM^{-/-}$), were performed in young female mice and bone parameters were evaluated by microCT 8 weeks after surgery.

Results: Osteoclast differentiation assays demonstrate that young STING KO bone marrow progenitors develop into osteoclasts faster than littermate controls. This phenotype of increased osteoclast formation is sustained in progenitors from aged (6 month old) STING KO mice. The $STING^{LysM}$ KO precursor cells recapitulate the osteoclast formation phenotype of STING KO cells *in vitro*. A reciprocal effect is observed in RANKL-stimulated RAW294.7 cells overexpressing STING, where fewer osteoclast-like cells are generated compared to RAW294.7 cells containing an empty vector. STING overexpressing RAW294.7 cells produce more IFNβ than empty vector controls, and blocking IFNaR1 downstream of IFNβ limited osteoclast formation in STING over expressing RAW294.7 cells. To determine the role of STING for bone turnover *in vivo*, microCT was used to characterize bone in aging cohorts of STING KO mice. Consistent with these *in vitro* observations, STING KO mice lose trabecular bone faster than wildtype (WT) littermate controls. Myeloid STING is sufficient for enhanced bone turnover, as ovariectomized $STING^{LysM}$ KO mice exhibit a larger decrease in trabecular bone compared to littermate controls.

Conclusion: Our results are the first to implicate any of the cytosolic DNA sensors in the maintenance of bone. We demonstrate thatincreased STING activity limits osteoclast formation, an effect which is mediated at least in part by IFNβ. Moreover, loss of STING activity results in accelerated bone loss. These data suggest that STING activation plays an important role inthe protection from bone loss in the settings of viral infection and inflammation in inflammatory rheumatic diseases.

$CD209^{+}/CD14^{+}$ Dendritic Cells Characterization in Rheumatoid versus Psoriasis Arthritis Patients

Viviana Marzaioli[1], Achilleas Floudas[2], Mary Canavan[1], Siobhán Wade[3], Kieran Murray[4], Ronan Mullan[5], Conor Hurson[6], Douglas Veale[7] and Ursula Fearon[1], [1]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland, [2]Molecular Rheumatology Trinity Biomedical Sciences Institute, Dublin, Dublin, Ireland, [3]Trinity College Dublin, Dublin, Ireland, [4]Saint Vincent's University Hospital, Dublin 4, Dublin, Ireland, [5]Adelaide and Meath Hospital, Dublin, Dublin, Ireland, [6]St Vincents University Hospital, UCD, Dublin, Dublin, Ireland, [7]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Dendritic cells (DCs) are a heterogeneous population of professional antigen-presenting cells which are at the interface between innate and adaptive immunity. There are different DCs subsets, classified according to their tissue location and their functions. A specific subset of DCs is known to derive from monocyte and has a key role in inflammation and infection. This study aimed to identify and characterize a specific subset of DC $CD209^+$/$CD14^+$ and evaluate their characteristics in the periphery of patients with inflammatory arthritic (IA). In addition, it aimed to evaluate the enrichment and activation of these cells at the site of inflammation, the join of rheumatoid (RA) and psoriatic arthritic (PsA) patients.

Methods: Peripheral blood and synovial fluid mononuclear cells (PBMC and SFMC) were isolated by Ficoll density gradient from healthy subject (HC), RA and PsA patients. Single cell synovial tissue suspension from RA and PsA patients was obtained by enzymatic digestion. PBMC, SFMC and synovial tissue cell suspensions were analysed by flow cytometry to identify the $CD209^+$/$CD14^+$ DC subset and its frequency. Expression of chemokines receptors (CCR6, CCR7, CXCR3, CXCR4 and CXCR5) and activation markers (CD40 and CD80) on the surface of the $CD209^+$/$CD14^+$ DC subset were also evaluated by flow cytometry.

Results: We identified, for the first time, the $CD209^+$/$CD14^+$ DC population in PBMC of RA and PsA patients and HC, with no significant differences among the groups. Interestingly, we observed that this population was enriched in SFMC of RA and PsA patients, with a further increased frequency demonstrated in the synovial tissue cell suspensions. This was paralleled by a more mature phenotype of the DC subset at the site inflammation compared to periphery, with a significant increase in CD40 ($p< 0.01$) in PsA patients and CD40 and CD80 in RA patient ($p< 0.01$). In addition, SPICE analysis identified a differential expression and co-expression of chemokine receptors at the periphery of RA and PsA patients, when compared to the HC, suggests that DCs in the periphery are already activated to migratory to sites of inflammation in IA. We further observed a unique profile of chemokines receptors in single cell analysis of synovial tissue cell suspension demonstrating increased expression of both and CXCR3 ($p< 0.01$) and CXCR5 ($p< 0.001$) in RA and PsA.

Conclusion: We identify for the first time a monocyte-derived DC population characterised as $CD209^+$/$CD14^+$ in the periphery of RA and PsA patients. This population was enriched at the site of inflammation and displayed a unique chemokine receptor profile and activation markers, suggesting these cells are already activated in the periphery of IA patients, and are recruited and further activated into the joint of IA patients.

Abstract Number: 0076

The Role of Interferon Kappa in Psoriasis

Mehrnaz Gharaee-Kermani[1], Shannon Estadt[2], Sonya Wolf-Fortune[1], Jianhua Liu[1], Tamra Reed[3], Johann Gudjonsson[4] and J. Michelle Kahlenberg[5], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ypsilanti, MI, [3]University of Michigan, Ann Arbor, [4]University of Michigan, Ann ArborUniversity of Michigan, [5]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is a common, chronic inflammatory autoimmune skin diseases characterized by hyperproliferation and abnormal differentiation of keratinocytes and infiltration of inflammatory cells. Early infiltration of plasmacytoid dendritic cells and detection of an interferon (IFN) signature occurs in many psoriasis lesions. Recently, we described keratinocyte production of interferon kappa (IFNk) as an important source of type I IFN production in the epidermis. We thus wanted to explore the role of IFNk in psoriasis.

Methods: We used the well-characterized imiquimod (IMQ) psoriasis model for these studies. 10-week old male and female wild type (WT) and mice transgenic for *Ifnk* (TG) expressed under the K14 promoter (thus inducing expression only in the epidermis) and mice deficient for *Ifnk* (KO) were used. Psoriasis was induced by topical application of IMQ on both ears for 8 consecutive days (n=6-10 mice per each group. Control mice received Vaseline (n=10 mice per each group). Animals were monitored daily for ear thickness, lesion severity, and body weight and photo were taken daily. On day nine, mice were euthanized, and disease severity were compared among all groups via RT-qPCR, immunohistochemistry, and flow cytometry.

Results: For all evaluations, untreated mice did not show any sign of inflammation or disease. While all IMQ treated mice exhibited psoriasis lesions in both ears after 8 days of treatment, development of splenomegaly, ear thickness, cutaneous lesion size and spleen weight were significantly higher in TG mice ($p < .001$) vs. WT for both male and female mice. The spleen size and ear thickness were significantly smaller in KO mice compared to WT ($p < .01$). Interestingly, the difference was more exaggerated in TG female vs. male mice. H&E staining revealed higher number of inflammatory cell infiltrates in IMQ treated TG vs. WT and fewer inflammatory infiltrates in KO mice. IL-17 and CD8 co-staining of ear tissues revealed greater number of CD8 and IL-17 double-positive cells in IMQ treated TG > WT >KO mice in both male and female groups. Gene expression for type I IFNs, the IFN-regulated gene *Mx1*, *Stat3,* and inflammatory cytokines, *Il1b*, *Il17*, *Tnfa*, *Il6, Il12* and *Il23* were significantly higher in IMQ treated TG >WT >KO ($p < 0.05$ for all genes tested). While both TG and WT mice demonstrated influx of monocytes by flow cytometry, KO mice did not exhibit a detectible increase after IMQ treatment. No difference in plasmacytoid dendritic cell recruitment was noted between groups.

Conclusion: Overexpression of *Ifnk* in the epidermis results in increased disease severity after topical application of IMQ, whereas deletion of *Ifnk* attenuated disease. Although, overexpression of *Ifnk* alone in the skin does not trigger skin inflammation, our data suggests that epidermal type I IFNs may trigger may act as a rheostat for psoriasis inflammatory responses, driving more inflammatory cells in the skin and promoting a heightened inflammatory and IL-17-oriented response. Together, these data suggest that overproduction of type I IFNs may impact psoriasis development and there may be a role of targeting IFNs in early disease. Further studies will need to elucidate the specific mechanisms that may be at play, especially in human skin.

Abstract Number: 0077

Mimickers of Immunoglobulin G4-Related Disease

Madiha Ahmad[1], Robert Spandorfer[2] and Arezou Khosroshahi[3], [1]Emory University, Decatur, [2]Emory University School of Medicine, Atlanta, GA, [3]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoglobulin G4-related disease (IgG4-RD) is a fibro inflammatory condition of unclear etiology. This rare condition can affect any organ system and has protean manifestations mimicking many other diseases. As the knowledge regarding this condition has increased among providers, there has been a tendency to over diagnose IgG4-RD. Therefore, the primary aim of this retrospective study is to identify common mimickers of IgG4-RD in an United States cohort.

Methods: The study design is a retrospective chart review**.** All patients referred to the IgG4 clinic at Emory University with specific diagnosis of IgG4-RD from August 2013- February 2020 were reviewed and categorized into mimickers versus IgG4-RD. The diagnosis of IgG4-RD and mimickers were made with clinicopathological correlation. Emory University Institutional Review Board approved this study.

Results: From August 2013- February 2020, a total of 198 patients were referred to the Emory IgG4- RD clinic. As outlined in Table 1, 85 or 43% were noted be mimickers of IgG4-RD. We classified the mimickers into infection (2%), neoplastic disease (21%), autoimmune disease (31%), and other (46%). Based on the IgG-RD classification criteria, 93% of these cases met exclusion criteria and only 7% met inclusion criteria, which had mean scores of 3 and ranged from 0-10 (greater than 20 meets criteria).

The neoplastic category included lymphoma (28%), plasma cell dyscrasia (17%), and histiocytosis (Rosai Dorfman, Langerhans's, Erdheim Chester Disease) (17%). Noteworthy, 75% of the neoplastic diagnoses were made when repeat biopsy was performed either due to clinical suspicion or lack of response to treatment.

Categories	Number of Cases	Serum IgG4 mg/dL* Mean (Range)	Average Serum IgG mg/dL*
Infection	2	70 (51-89	1129
Neoplasia	18	105 (8- 4090)	1411
Autoimmune Disease	26	41 (6-136)	1158
Other	39	88 (5-308)	1255
Total Mimickers	85	76 (5-4090)	1246

*Normal Reference Values:
Serum IgG levels: 610-1,616 mg/dL
Serum IgG4 levels: 1-123 mg/d

	IgA Nephropathy	1
	TOTAL	39

Table 2. Subcategories of Mimickers

Sjogren's syndrome was the predominant condition mistaken by IgG4-RD in the autoimmune category. We included cases that could not be proven to be IgG4-RD or any other specific diagnosis in the other category. Interestingly, in that category 60% had a GI manifestation, with half of those cases being recurrent pancreatitis as shown in Table 4.

The average serum IgG4 level across all mimickers was normal, but the levels ranged from 5-4,060 mg/dL (normal range 1-123 mg/dL). We identified 20 cases with elevated serum IgG4. Based on the IgG-RD classification criteria, these patients met exclusion criteria with 9 cases meeting pathologic criteria, 7 radiologic, 2 serologic, and 2 disease specific exclusions. Of note, 8 of these 20 cases had neoplastic disease and 4 cases had recurrent pancreatitis.

Conclusion: This study highlights that almost half of the patients referred for diagnosis of IgG4-RD actually were found to have a mimic of the disease. GI manifestations, particularly recurrent pancreatitis, were among the most

common referred diagnosis in our center. It should be emphasized that serum IgG4 levels are not diagnostic for the disease and can be elevated in other conditions. A tissue biopsy is indicated in majority of cases with atypical clinical presentation and repeating the biopsy is indicated if the patient's course is not typical for IgG4-RD. Also, a lymph node biopsy is not considered diagnostic. By identifying these mimickers, we hope to emphasize the necessity of considering these conditions while evaluating patients with IgG4-RD.

Abstract Number: 0078

Retrospective Analysis of Clinical Characteristics and Classification Criteria Performance in a Single Center Cohort of 114 Patients Diagnosed with IgG4-Related Disease

Robert Spandorfer[1], Madiha Ahmad[2] and Arezou Khosroshahi[3], [1]Emory University School of Medicine, Atlanta, GA, [2]Emory University, Decatur, [3]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoglobulin G4 Related Disease (IgG4-RD) is a fibroinflammatory condition that can involve almost any organ system. Diagnosis is made based on correlation of clinical, pathological and laboratory data. The 2019 American College of Rheumatology (ACR) / European League Against Rheumatism (EULAR) classification criteria for IgG4-RD were recently published to provide unified classification criteria in clinical research. The purpose of this study was to characterize demographics, disease attributes and treatments of patients referred to our specialized IgG4-RD clinic. We evaluated the performance of the new classification criteria on this cohort to understand its correlation to diagnosis.

Methods: This was a retrospective chart review of patients referred to the IgG4-RD clinic at Emory University Hospital from August 2013 through September 2020. Data collected include disease manifestations, histopathology, serological markers, and treatments used. Patients were categorized based on the clinician's decision for diagnosis as: 1) definite, if they had typical clinical findings supported by histopathology or serology and diagnosed as IgG4-RD; 2) probable, if the diagnosis of IgG4-RD was still considered but could not be proven; 3) mimickers, if the patient was diagnosed as not having IgG4-RD. An ACR/EULAR classification criteria score was calculated to compare performance in these categories. The Emory University Institutional Review Board approved this study.

Results: A total of 198 patients referred to the Emory IgG4-RD clinic were evaluated. 84 (42%) were mimickers. Of the remaining 114, 58 (51%) were defined as definite and 56 (49%) as probable cases of IgG4-RD by treating clinicians. Patient demographics are shown in Table 1. Our cohort has the most representation of black patients with IgG4-RD in the published literature.

The most common organ systems affected are displayed in Figure 1. Pancreas was the most common at 37% of patients. Nearly half of patients had a less common (i.e. < 10% of patients) organ system involved. 61% of patients had multi-organ disease. Serology and treatments are shown in Table 2.

	Definite IgG4-RD (*n*=58)	Probable IgG4-RD (*n*=56)
Age	59 ± 14	56 ± 16
Gender		
Male	34 (59%)	24 (43%)
Female	24 (41%)	32 (57%)
Race/Ethnicity		
White/Caucasian	32 (55%)	28 (50%)
Black/African American	20 (34%)	23 (41%)
Asian/ South Asian	5 (9%)	3 (5%)
Hispanic	1 (2%)	1 (2%)
Native Hawaiian	0 (0%)	1 (2%)
History of asthma	7 (12%)	3 (5%)
History of seasonal or food allergy	6 (10%)	2 (4%)

Table 1. Demographics of patients with definite or probable IgG4-RD.

	Definite IgG4-RD (*n*=58)	Probable IgG4-RD (*n*=56)
Elevated Serum IgG4 level	42 (74%)	10 (18%)
Elevated IgG4/IgG Ratio (>20%)	19 (33%)	4 (7%)
Elevated Serum IgE level	23 (40%)	8 (14%)
Hypocomplementemia	6 (10%)	1 (2%)
ANA (> 1:40)	6 (10%)	4 (7%)
Rheumatoid Factor +	3 (5%)	6 (11%)
Treatment with Glucocorticoids	50 (86%)	50 (89%)
Treatment with Rituximab	34 (59%)	22 (39%)
Remission Rate	34 (59%)	30 (54%)

Table 2. Serology and treatment factors of patients with definite or probable IgG4-RD.

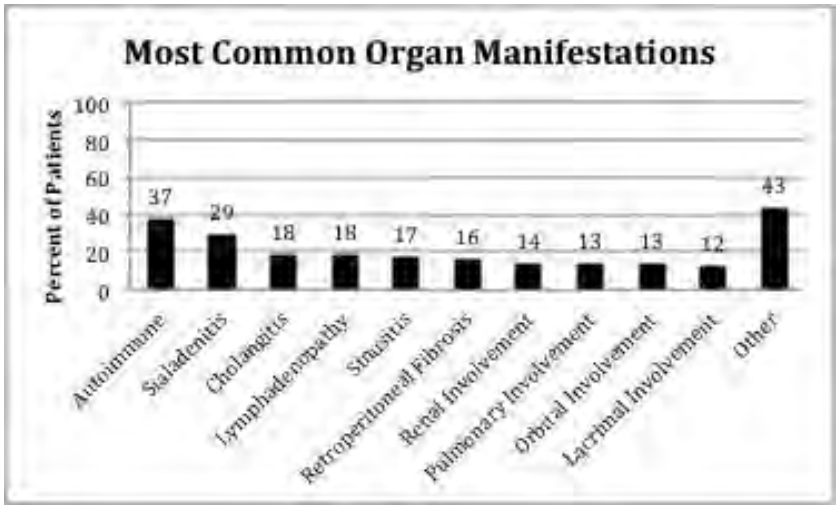

Figure 1. Organ system involvement in all definite and probable IgG4-RD cases expressed as a percentage of all patients

84% of patients with definite diagnosis were considered IgG4-RD based on classification criteria (i.e. score ≥ 20) with average score of 29 (range 4 -56). 9% in the probable category passed this threshold with an average score of 8 (range 0 – 31). None of the mimickers was classified as IgG4-RD based on classification criteria.

Conclusion: This study highlights that clinicians encounter many challenges in making a definitive diagnosis of IgG4-RD. In our cohort, 49% of patients fell into the category of probable diagnosis due to a lack of sufficient evidence to exclude or prove this condition. Patients with probable disease were treated similarly to those with definite disease and had similar rates of remission.

This is also the first study to evaluate the performance of ACR/EULAR IgG4-RD Classification Criteria in a single-center cohort. Patients with clinicopathological diagnosis of definite IgG4-RD largely met the scoring cutoff for diagnosis and mimickers did not, leaving the probable cases in a grey zone.

Abstract Number: 0079

Analysis of COVID-19 and Rheumatology Twitter Activity During the Pandemic Months

Mosaab Mohameden[1] and Ali H.Ali[2], [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of California San Francisco Fresno, Fresno, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Twitter is a popular social media platform that is widely used to publish information and exchange ideas. There are over 300 million active monthly users on Twitter with about 500 million tweets sent daily. Therefore, Twitter is a unique tool with the ability to distribute ideas and information rapidly and widely to a large audience. Social media platforms including Twitter are an important source of health information nowadays, especially during the COVID-19 pandemic. Rheumatology providers and patients are likely to utilize Twitter to send and receive information related to COVID-19. In this study, we aim to analyze COVID-19 and rheumatology Twitter activity during the pandemic months.

Methods: The advanced search function on Twitter was used to retrieve tweets (English language only) with both hashtags #COVID19 and #Rheumatology from 12/31/2019-06/10/2020. Tweets were categorized by author and content. Tweet authors were categorized into: 1. Professional organization/patient advocate groups, 2.Academic institutions, 3.Medical journals/websites/network, 4.Patients, 5.Rheumatologists, 6.Other physicians, 7.Other providers, 8.Pharmaceutical companies, 9.Others. Tweets contents were categorized into: 1.COVID19 global rheumatology alliance/EULAR COVID19 database, 2.Hydroxychloroquine (HCQ) use for COVID19, 3.HCQ shortage, 4.Biologics use for COVID19, 5.Providers guidance, 6.Patients guidance, 7.COVID19 risk in rheumatology patients, 8.Webinars/learning opportunities, 9.Miscellaneous: telemedicine, COVID19 pathophysiology, conversational, publications, patient care challenges, and legislation.

Results: The first tweet with both hashtags was sent on March 4th. A total of 511 tweets were sent during the study period. Twenty-six percent of tweets were by professional organizations (136/511), 25% by rheumatologists (128/511), 17% by medical journals/websites/networks (91/511), and 14% by others (71/511). Tweets by other physicians and patients were 6% (31/511) and 3% (18/511) respectively. Tweets in the miscellaneous category were 28%, followed by provider guidance category (14%), patient guidance (13%), tweets related to COVID19 global rheumatol-

ogy alliance/EULAR database (13%), webinars/learning opportunities (12%), HCQ use for COVID19 (6%), COVID19 risk in rheumatology patients (5%), HCQ shortage (4%), and biologics use for COVID19 (4%). The number of tweets was highest in April (220) followed by March (152) and May (115). The trend for certain topics appeared to change by month. HCQ shortage represented 0.9% of topics in May, 8% in April, and 3% in March. The topic of HCQ use for COVID19 was 13% in March, 3% in April with no tweets with this topic in May.

Conclusion: Twitter is an excellent tool for disseminating ideas and information that can be helpful for both providers and patients. This can be more pronounced during the COVID19 pandemic where there is a strong shift toward the online exchange of information. It is very encouraging to see that the number of professional organizations and rheumatologists using this tool is significant which can help spread credible information to rheumatology patients.

Understanding Ankylosing Spondylitis -

Arnd Kleyer[1], Milena Pachowsky[2], Louis Schuster[1], Larissa Valor-Mendez[3], Georg Schett[4], Axel Hueber[5] and David Simon[1], [1]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Bayern, Germany, [2]Department of Orthopedic and Trauma Surgery, FAU Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany, [3]Department of Internal Medicine 3, Rheumatology and Immunology, University Hospital Erlangen, Erlangen, Bayern, Germany, [4]Friedrich-Alexander-Universität Erlangen- Nuremberg, Erlangen, Germany, [5]Sozialstiftung Bamberg, Sektion Rheumatologie, Bamberg, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatology is underrepresented in the medical training of students in Germany. [1] Tools and methods are needed to inspire young students for specialist training as a rheumatologist.

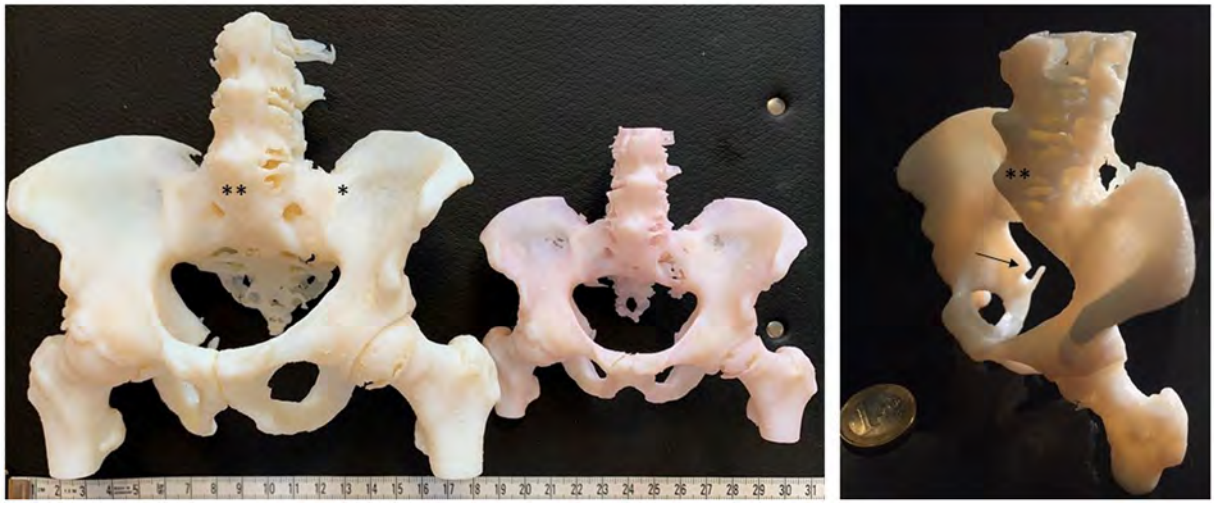

Figure 1. shows 3D prototypes of the pelvis and lumbar spine. * marks SI ankylosis ** ankylosis of the spine; the arrow marks large enthesiophytes at the tuber ischiadicum

Figure 2. Displays the print out of the spine, including ankylosing syndesmophytes as well as partially merged processi spinosi

3D printing as a rapid prototyping technology is a suiTable method to display bone pathologies vividly and realistically. Recently we could show the usage of 3D printed models of peripheral joints of patients with rheumatic diseases for patient education.[2] However the feasibility to 3D print pathologies from rheumatic disease affecting the axial skeleton and their possible application field in rheumatology training for students has not been assessed yet.

Methods: Routinely acquired computed tomography data (2mm layer thickness) from the pelvic and spine from two patients with longstanding ankylosing spondylitis were used.Both data sets were segmented (surface rendering Osirix Lite) and converted to an STL surface model (Osirix Lite). After post processing, these models were 3D printed with the polyjet polymer technique (Objet30, Stratasys).[2]

Results: This approach allowed the prototyping of the pelvis and thoracic spine illustrating typical pathologies such as ankylosing syndesmophytes of the spine, enthesiophytes of various enthesial sites as well as ankylosing SI joints in great detail. Images of the pelvis with lumbar spine as well as the thoracic spine are displayed in Figure 1 and 2. We were able to produce different sizes of these models. Sizes are displayed in Figure 1. Printing time was 24 hours with material costs of about 300 Euro for the largest prototype.

These models are now used in the multimodal teaching concept “Rheuma begreifen” (Understanding Rheumatism) at the the Skills Lab of the University Erlangen-Nuremberg.

Instructions for usage are given, an evaluation and interim examination are currently performed

Conclusion: Bone pathologies caused by spondylitis ankylosans can be presented and haptically understood by 3D printed models. This can supplement rheumatological teaching and also patient education in the future.

Abstract Number: 0081

Prevalence of Systemic Autoimmune Diseases in Polycystic Ovary Syndrome

Saika Sharmeen[1], Hafsa Nomani[2], Erin Taub[3] and Qingping Yao[3], [1]Stony Brook University Renaissance School of Medicine, Dix Hills, NY, [2]Stony Brook University Renaissance School of Medicine, West Babylon, NY, [3]Stony Brook University Renaissance School of Medicine, Stony Brook, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Polycystic ovary syndrome (PCOS) is characterized by hormonal abnormality, chronic anovulation, hyperandrogenism, and obesity. Due to the hormonal imbalance, we hypothesize that patients with PCOS may tend to develop inflammatory and immune disorders. To test this hypothesis, we sought to examine the frequency of systemic autoimmune diseases in PCOS.

Methods: A retrospective chart review of patients in a single center between January 2004 and February 2020 was conducted after approval by the Institutional Review Board. There were two groups consisting of PCOS patients aged 18 and older and age- and BMI-matched patients without PCOS in a ratio of 1:2. Exclusion criteria were endometrial or ovarian cancer. Electronic medical records (EMRs) were searched for individual rheumatic and systemic autoimmune diseases using ICD-9 and ICD-10 codes and for laboratory data. A comparison between PCOS and non-PCOS subjects was made in relevant parameters followed by a subgroup analysis between these groups based on weight categories: obese (BMI >=30), overweight (BMI 25-30), and nonobese (BMI< 25). Fisher Exact, Chi-square, Wilcoxon rank sum and Kruskal Wallis tests were used for statistical analysis.

Results: There were a total of 2,262 patients including 754 PCOS and 1,508 non-PCOS as control. The study population included 12.8% nonobese, 22.6% overweight, and 64.7% obese females with median age of 30.0 years and median BMI of 33.1. The rheumatic disorders and relevant laboratory data were compared between the two groups and are summarized (Tables 1 and 2). Our study showed that the frequency of RA was 2.25% in PCOS group and 1.26% in control (p=0.0747). The prevalence of RA in PCOS group more than doubled that (1%) in the general population, suggesting PCOS patients may tend to develop seropositive/seronegative inflammatory arthritis. There was no significant difference in positive RF (0.27% VS 0.33%, p=1.0) or CCP (0.27% VS 0.07%, p=0.26) between groups. Our study also showed that compared with non-PCOS group, both SSc (0.0% VS 0.04%, p=0.0369) and UCTD (0.0% VS 0.53%, p=0.0123) were more prevalent in PCOS patients. Interestingly, PCOS patients were more likely to have ANA (11.41% VS 7.56%, p=0.0024) and ESR tested (19.10% VS 13.13%, p=0.0002) compared to controls. However, there was no significant difference in the positivity rate of ANA and other serologic markers between the two groups even with subgroup analysis of weight categories. PCOS patients had significantly higher frequency of OA than non-PCOS patients (5.44% VS 2.92%, p=0.0030).

Table 1. Comparison of serologic markers between patients with polycystic ovary syndrome (PCOS) and those without

Conclusion: For the first time**,** our study suggests that PCOS patients may have higher frequency of systemic autoimmune diseases (seropositive/seronegative RA, SSc, and UCTD). The study is limited due to the inherent weakness of a retrospective study and search methodology using ICD codes. Future multicenter study with a larger sample size would be needed to validate the significance of our findings.

RA=Rheumatoid Arthritis; SLE=Systemic Lupus Erythematosus; UCTD=Undifferentiated Connective Tissue Disease; SSc=Systemic Sclerosis; OA=Osteoarthritis

Diffuse Sclerosing Osteomyelitis of the Jaw: An Underdiagnosed Disease in Maxillofacial Surgery Department

Pauline Preuss[1], Hélios Bertin[1], Pierre Corre[1] and Benoit Le Goff[2], [1]Nantes University Hospital, Nantes, France, [2]Nantes University Hospital, Nantes, Pays de la Loire, France

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Diffuse sclerosing osteomyelitis of the jaw is a rare and under-recognized disease. Many authors include this diagnosis in the spectrum of aseptic osteitis sometimes associated with the SAPHO syndrome.

Differential diagnosis with infectious osteomyelitis is difficult, therefore the final diagnosis might be delayed by several years. Although considered as an auto-inflammatory disorder, patients can primarily be addressed to maxillofacial surgeons and not to the rheumatologist.

In this work, we describe a cohort of patients addressed to the maxillofacial surgery department for a spontaneous osteomyelitis of the jaw in order to identify characteristics that can help the surgeon to suspect this disease, make an earlier diagnosis and appropriate management.

Methods: We extracted patient records coded either "Osteomyelitis" or "Inflammatory conditions of jaws"(International Classification of Diseases) then selected the cases of spontaneous osteomyelitis of the mandible. Patients included had clinical and radiographic osteomyelitis for at least 3 months. Exclusion criteria were history of local radiotherapy, osteonecrosis and post-surgical infections. The final diagnosis was based on clinical and radiological outcomes at least one year after the first symptoms.

Results: Of the 960 records extracted, 24 patients met the inclusions criteria: 16 were classified as aseptic, 5 as infectious osteomyelitis and no definite diagnosis could finally be made for 3 of them. Aseptic osteomyelitis mainly affected women (10 out of 16) in their forties (median of 40.5 years) presenting with painful swelling of the mandible since several months (median of 8 months). Two patients presented an associated palmoplantar pustulosis leading to the diagnosis of SAPHO syndrome. Initial radiological examinations showed early osteolytic lesions (50%) progressing to medullary sclerosis, solid periosteal appositions and bone hypertrophy (90%).

Eleven out of 36 biopsies remained sterile but the others were positive for commensal germs of the oral flora (69%).

Interestingly, out of 8 patients who had a bone scintigraphy, 4 had other osteitis localizations allowing the diagnosis to be integrated into a SAPHO syndrome or chronic multifocal recurrent osteitis (CMRO).

Over 80% of patients received iterative antibiotic cures with inefficiency or recurrence of the pathology in all of them. Mandibular decortication was followed by 100% of recurrence. Among the 16 patients, 12 were finally treated with NSAIDs effectively on relapses, and 2 were cured with anti-TNF alpha.

Conclusion: Aseptic osteomyelitis remains rare but patients might be addressed directly to maxillofacial surgeons for management. It must be differentiated as early as possible from infectious osteomyelitis by its clinical and radiological characteristics. Germs of the oral flora can be found in the biopsy but might be only contamination. Most of patients of our series underwent multiple antibiotics cures and even surgery. We recommend that rheumatologist should be included as soon as possible to perform a clinical examination for extra-mandibular involvement to integrate aseptic osteomyelitis of the jaw into a SAPHO syndrome or CMRO and discuss NSAIDs or biologics.

Chronic Nonbacterial Osteomyelitis Is Associated with HLA-B*27

Daire O'Leary[1], Orla Killeen[2] and Anthony Wilson[1], [1]UCD Centre for Arthritis Research, Dublin, Ireland, [2]National Centre for Paediatric Rheumatology, CHI at Crumlin, Dublin, Ireland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is an auto-inflammatory condition primarily affecting children with an estimated prevalence of 1 per 10^5 - 10^6. It is characterized by relapsing episodes of localised bone inflammation. Extraosseous manifestations, including psoriasis, Crohn's disease and enthesitis-related arthritis, frequently occur in patients and relatives. However, no increased frequency of HLA class I alleles associated with these diseases, such as HLA-B*27 and HLA-C*06, has been shown in patients with CNO. The aim of this study was to determine the frequency of HLA class I alleles in and Irish cohort of patients with CNO compared to Irish population frequencies.

Methods: 43 Irish children and adolescents currently attending paediatric rheumatology services with CNO were recruited. Whole exome sequencing was performed on blood using Agilent SureSelect XT Human All Exon V6 kits and Illumina HiSeq 3000 with 150bp paired-end reads. Reads were aligned to the hg19 reference genome using BWA software, duplicates removed using Picard tools and GATK software used to realign indels and call variants. HLA alleles were predicted from whole exome sequencing results using Optitype software through the Nextflow nf-core/hlatyping pipeline (version 1.1.5). Comparison was made with previously published Irish HLA allele frequencies. Statistical analysis was performed in RStudio (version 1.1.456).

Results: Whole exome sequencing and HLA allele prediction was performed on 43 patients, 40 unrelated and 3 siblings. All were ethnically Irish with a female:male ratio of 2.9:1, 88% had multifocal disease and 51% required a second-line agent for treatment. Psoriasis was present in 18.6% of patients a further 18.6% of $1^{st}/2^{nd}$ degree relatives. HLA class I prediction was successful in all patients. HLA-B*27:05 was present in 17.5% of patients compared to 6% of the Irish population (OR 3.28, 95%CI 1.18 – 7.8, p=0.011). Patients carrying HLA-B*27:05 allele did not have more frequent co-morbidity with HLA-B*27 associated diseases than the overall cohort. HLA-C*06:02 was present in 27.5% of patients compared to 17.5% (OR 1.96, 95% CI p=0.13). Patients carrying HLA-C*06:02 were not significantly associated with a personal or family history of psoriasis. All other alleles were found at frequencies close to the Irish population frequency.

Conclusion: There is a statistically significant association between the Irish CNO population and HLA-B*27:05 allele known to be associated with inflammatory diseases such as enthesitis-related arthritis. Results need to be replicated in a larger cohort for further stratification to be possible.

No comorbidity	650 (93.1%)	68 (100%)

Background/Purpose: The Paraguayan-Uruguayan cohort of patients with rheumatic inflammatory diseases (BIOBADAGUAY), collect clinical and epidemiological information on adults and children patients receiving biological therapies (BT). The obtained data enable to describe with comparative purposes the cohort of patients, considering the age of symptom onset (i.e. juvenile or adult)

Methods: BIOBADAGUAY cohort includes 18 centers (9 in Uruguay and 9 in Paraguay). The descriptive analysis was made in two phases. First, we have selected the adult population on BT and second, we have separated it in two groups according onset of disease considering the age when diagnosis of rheumatic disease was made. Clinical features of both populations were described in a second phase

Results: A total of 766 adult patients was included, in which 91,1% had adult-onset, and 8.9% had juvenile-onset rheumatic disease. Female predominance was observed in both adult-onset and juvenile-onset groups (74.1% vs 64.7%, respectively). Mean disease duration was 18.5 ± 11.2 years for juvenile-onset rheumatic disease and 13.1 ± 8.7 years for adult-onset rheumatic disease. Disease activity was similar for both rheumatoid arthritis and spondylarthritis in the two groups. All of juvenile-onset rheumatic disease patiets, did not have a comorbidity when starting a BT. Mean body mass index was 24.9 ± 4.5 for juvenile-onset rheumatic disease and 27.9 ± 6.0 for adult-onset rheumatic disease. Table 1 describes main clinical and epidemiological characteristics of analyzed populations.

Conclusion: Patients with juvenile-onset rheumatic disease present with particular characteristics (disease duration, comorbidities and mean body mass index) that differentiate them from adult-onset rheumatic disease patients. This should be taken into consideration when assessing and follow-up is being made on each patient

Classifications of Inflammatory Myopathies: Differentially Expressed Membrane-Bound Complement Regulators Allow Specific Patterns of Membrane Attack Complex Deposition

Fadi Charouf[1], Netanel Karbian[1], Itamar Altman[1], Yakov Fellig[1] and Dror Mevorach[1], [1]Hadassah-University Hospital, Jerusalem, Yerushalayim, Israel

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of heterogeneous disorders that typically present with proximal muscle weakness. According to the classification criteria, IMs are classified into five categories: polymyositis (PM); non-specific myositis (NSM); dermatomyositis (DM); necrotizing autoimmune myopathy (NAM); and sporadic inclusion body myositis (IBM), with further subgrouping by autoantibodies that are specific or non-specific to myositis. There is a need to develop optimal diagnostic and classification criteria with more reliable and reproducible markers of pathological and serological evidence for all subgroups of IIM.

Methods: Following ethical approval, paraffin- and frozen sections from muscle biopsies of patients meeting inclusion criteria and controls (patients with no diagnostic abnormalities on muscle biopsy) were obtained. The sections were stained with hematoxylin and eosin (H&E), membrane attack complex (MAC) C5b–9, and major histocompatibility complex (MHC) class I for CD59, CD55, and CD46. A blinded examination was then achieved by randomly mixing the specimen numbers.

Results: CD46, CD55, and CD59 were differentially expressed in endomysial capillaries and myofibers. Whereas CD59 was expressed in endomysial capillaries as well as myofibers, CD46 expressed in capillaries only, and CD55 expression was prominent in myofibers and only equivocal in capillaries. MAC C5b-9 pathological expression correlated with significant reduction of expression of membrane-bound complement regulators.

In DM, MAC C5b-9 deposition is present mainly in perifascicular endomysial capillaries with corresponding clear downregulation of CD59 and CD46, mainly in perifascicular areas. This and earlier findings suggest that much of the ischemic/inflammatory effect in DM is complement-mediated and related to classical pathway complement activation on capillary endothelium that is not protected by membrane-bound complement regulators. This early event in the process of injury occurs prior to inflammatory cell infiltrate.

In PM, MAC C5b-9 deposition in the general group of PM is in necrotic myofibers; however, there was clear but less pronounced staining in capillaries with weaker downregulation of membrane-bound regulatory proteins.

Conclusion: Complement activation should be determined in each subgroup of IIM

Geographic Distribution of Eosinophilic Fasciitis Cases in Massachusetts and Associated Environmental Triggers

Bina Kassamali[1], Anastasiya Muntyanu[2], Ruth Ann Vleugels[3] and Avery LaChance[3], [1]Harvard Medical School, Brigham and Women's Hospital, Boston, MA, [2]McGill University, Montreal, QC, Canada, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

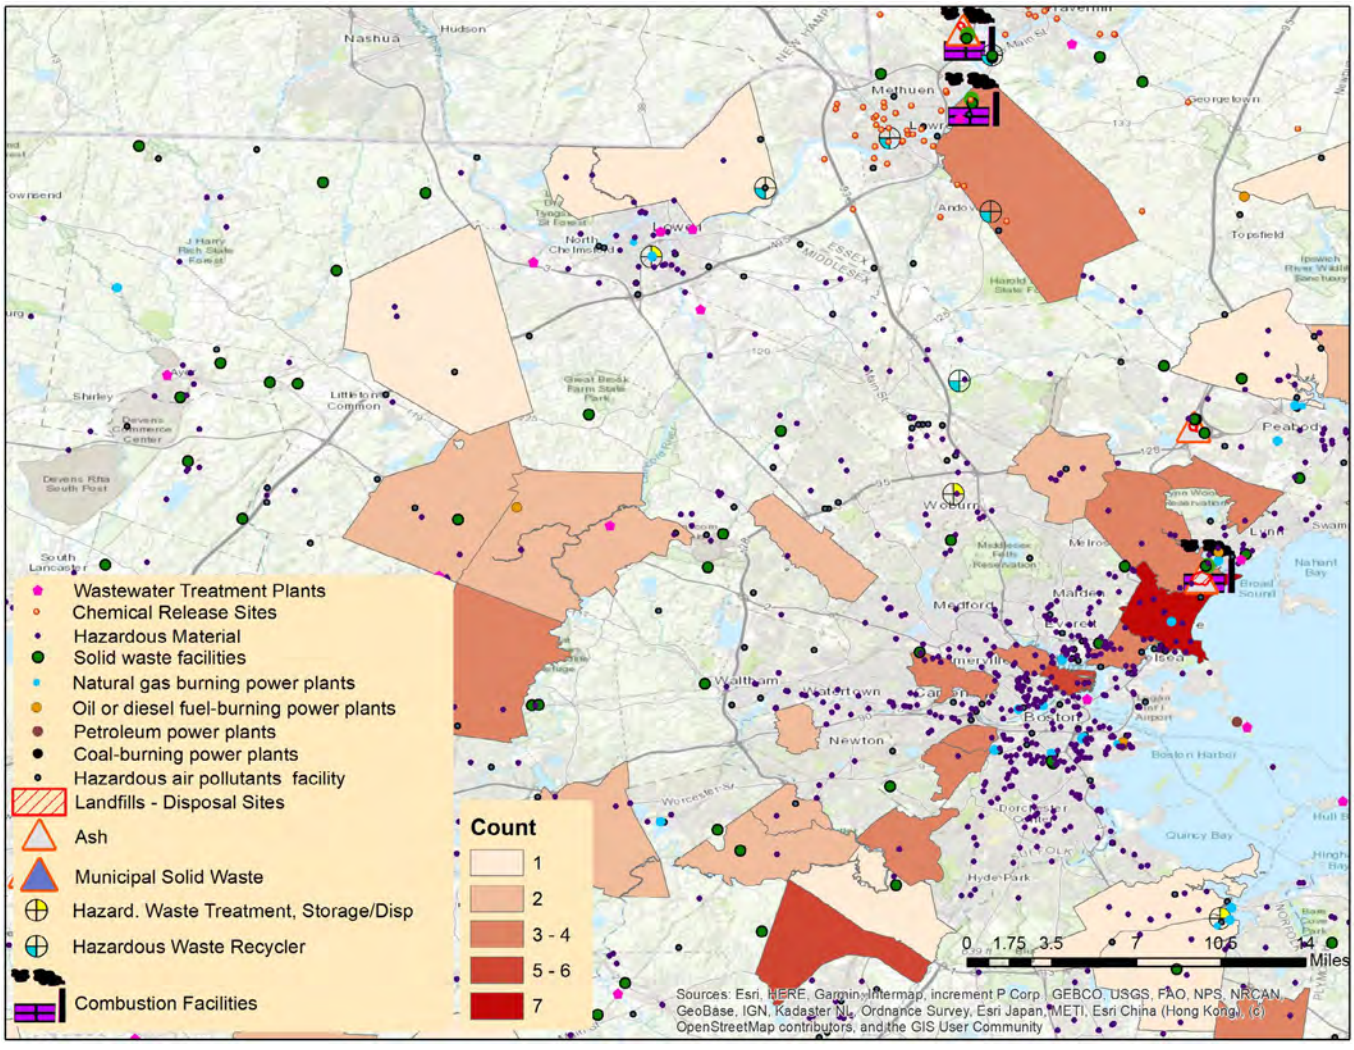

Figure 1 Locations of industries and waste sites in relation to EF case-counts

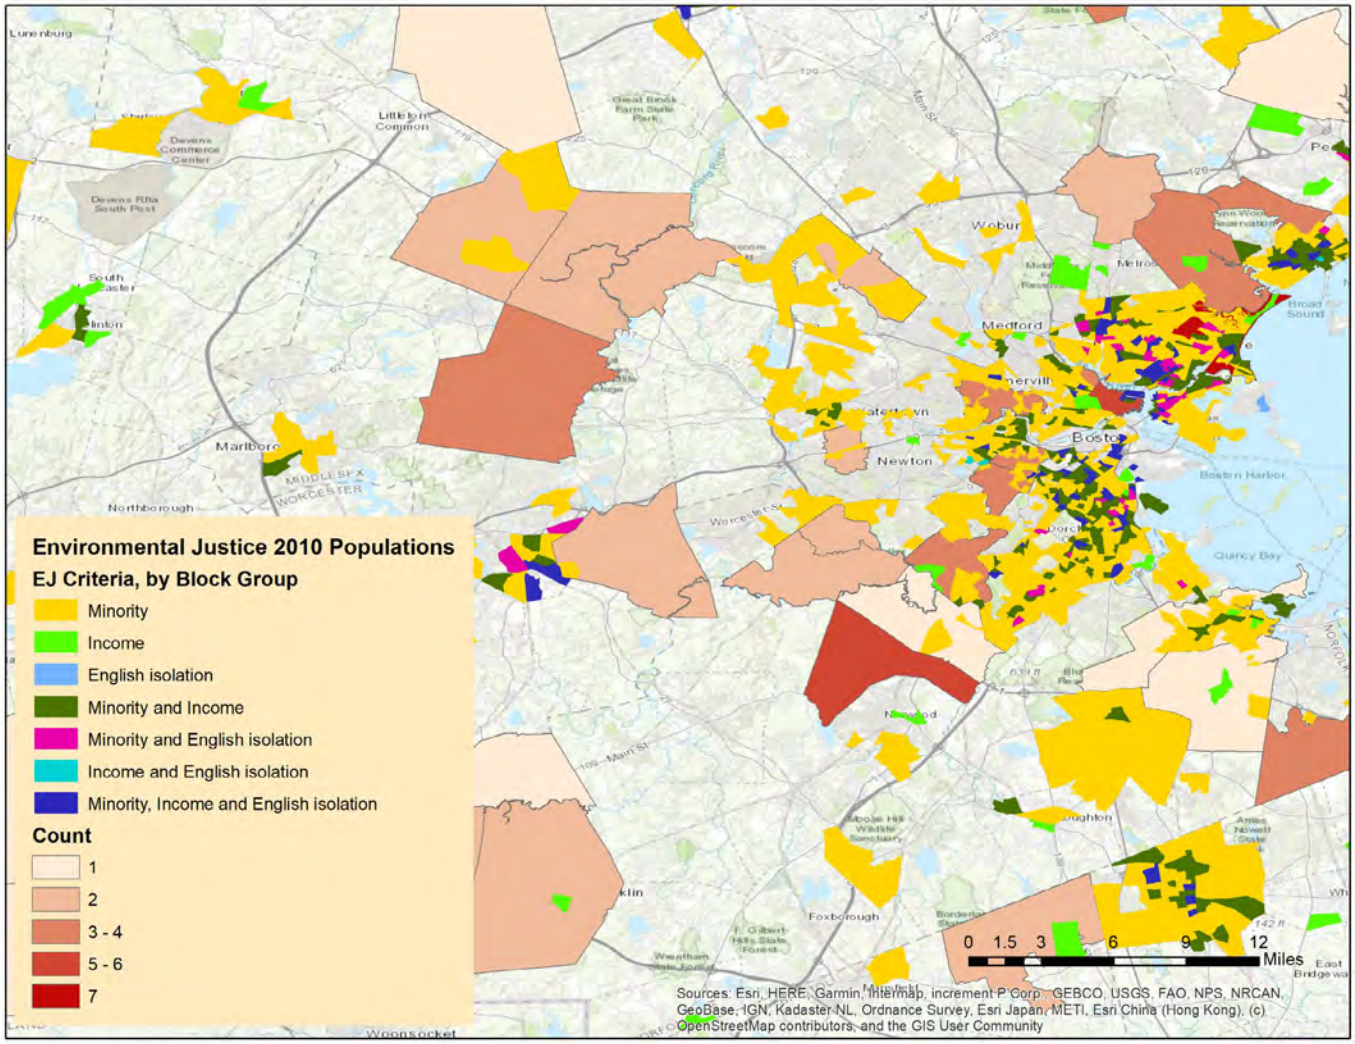

Figure 2. Social justice index and geographic distribution of EF cases

Background/Purpose: Eosinophilic fasciitis (EF) is a rare fibrosing disorder of the fascia characterized by induration progressing proximally along the upper and lower extremities. Given the potential impact on joint mobility, EF can be associated with a high degree of morbidity and have a major impact on quality of life. To date, the etiologic trigger leading to disease onset remains unknown. Assessment of high incidence geographic clusters may be a crucial initial step to cause identification. ArcGIS is a geospatial processing program used to create and analyze geographic distributions and has recently been utilized to determine high incidence clusters for several cancers and autoimmune diseases. The purpose of this study is to determine the geographic distribution of eosinophilic fasciitis (EF) cases in Massachusetts and evaluate for possible environmental triggers.

Methods: The Research Patient Data Registry, which combines medical records from two large, academic tertiary care centers in Boston, was utilized to identify 294 potential cases of EF. Eighty-one of these were confirmed by board certified dermatologists or rheumatologists and were included in the study. Demographic and geographic data was extracted. EF cases were mapped by zip code using ArcMap 10.7.1. These maps were then compared to environmental exposure maps including those for industry and toxic waste sites, as well as to social justice maps.

Results: Elevated case counts of EF were observed in specific geographic regions in Massachusetts, including Revere, Charlestown, Westwood, North Andover, and Saugus. These regions were in proximity to landfills, chemical release sites, ash pollution, and combustion facilities (Figure 1). Based on social justice maps, EF cases were found

to be more prevalent among low-income and minority communities (Figure 2). Review of medical records revealed that a high proportion of EF cases were smokers (49%) compared to the general population (~21% smokers). Of the patients with EF who underwent evaluation (n=40), 25% demonstrated a monoclonal gammopathy. Additionally, 26% of patients have a recorded past medical history of at least one more autoimmune disease in addition to EF.

Conclusion: To our knowledge, this is the first study to date assessing the geographic distribution of EF. The regional clustering of EF cases in proximity to ash, landfills, chemical release sites, and combustion facilities illustrates the potential contribution of environmental pollutants to the development of EF. Additional investigation using larger cohorts of patients with EF is warranted.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Hemophagocytic syndrome (HPS) is classified into primary and secondary. The secondary form is mainly associated with hematological malignancies (HN) such as lymphomas, and autoimmune diseases (AI) such as Systemic Lupus Erythematosus. The mortality rate varies between 20% and 90%. Underlying malignancies, thrombocytopenia, age, hyperferrhythmia and prolonged prothrombin time are considered an adverse prognostic factor. The present work aims to obtain clinical and laboratory findings that can guide us to an early etiological diagnosis and treatment.

Methods: This is a retrospective observational study, which was approved by the hospital's ethics committee. Any patient who met the diagnostic criteria for LHH proposed by Henter JI. or who presented hemophagocytic cells (HC) in bone marrow (BM) biopsy were included. We describe and identify clinical, laboratory findings and underlying disorder differences between HPS subgroups; and between patients who survived and did not survive to HPS at a tertiary hospital between 2005 and 2019. Continuous variables are described with the mean or median according to the degree of normality, and qualitative variables are shown with the absolute value and percentage. Kruskal Wallis, Fisher test and Mann-Whitney U test were used for the bivariate analysis.

Results: Thirty patients were found **(Table 1)**. The coincidence of an infectious disease with HPS was observed in 8 [AI: 5 cases (2 cytomegalovirus, 2 probably viral respiratory infections and 1 bacterial infection) and HM: 3 cases (2 Epstein Barr virus and 1 bacterial infection)]. In 2 patients with acute leukemia, allogeneic transplantation was related as a possible trigger of HPS; and in one patient with myelodysplastic syndrome it was related to the appearance of

Table 1: Etiologies and underlying disorders during admission of patients with Hemophagocytic Syndrome				
Etiological subgroups	n	Debut of etiology	Infectious trigger	Mortality

HIV: Human immunodeficiency Virus, NK: Natural Killer, *p = 0.029

graft-versus-host disease. Age at diagnosis of HPS was lower in the AI subgroup [40 (26.5 - 56.3); p 0.001]. The HM subgroup presented more severe cytopenias [platelets 4500 (650 - 15 750; p 0.009), leukocytes 2050 (20 - 728; p 0.0001) and neutrophils 0 (0 - 280; p 0.002)] **(Table 2)**. Overall intra-hospital mortality was 43.3%, being higher in the HM subgroup [8 patients (66.7%); p 0.029]. The group of patients who did not survive had a longer time of prolongation of the INR compared to those who survived [2.1 (1.2 - 3.7) versus 1.5 (1.1 - 1.6); p 0.028] and an older age at diagnosis of HPS compared to the group who survived [68 years (58.2 - 74.5) versus 40 years (34 - 57); p 0.043] **(Table 3)**.

Conclusion: The HM subgroup had higher mortality, and more and more severe cytopenias. The AI subgroup showed higher transaminase elevation and better prognosis. The non-survivor group had a longer time of prolongation of the INR and an older age at the time of the diagnosis of HPS compared to the survivor group.

The Spectrum of Hemophagocytic Lymphohistiocytosis: Autoimmunity vs. Malignancy

Samuel Good[1], Stefanie Wade[1] and Vasileios Kyttaris[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophage activation syndrome (MAS), a life-threatening condition resulting from aberrant immune activation, is a form of hemophagocytic lymphohistiocytosis (HLH) that develops in patients with an underlying rheumatologic disease, classically juvenile idiopathic arthritis. Patients may or may not have an established rheumatologic diagnosis at the onset of MAS, making the identification of an underlying trigger challenging. Moreover, the commonly used diagnostic tools, such as the H-score, were developed from an adult population with a paucity of autoimmune disease. We aim to identify clinical features that may distinguish MAS cases from malignancy-associated HLH.

	MAS	Malignancy-associated HLH	p-value
Patient Characterestics			
Total number of patients (n)	18	16	
Underlying disease process - SLE (n)	8 (44%)		
Underlying disease process - AOSD (n)	6 (33%)		
Underlying disease process - other rheumatologic condition (n)	4 (22%)		
DLBCL (n)		8 (50%)	
Other hematologic malignancy (n)		8 (50%)	
Hospital Course			
Days in hospital, mean	17.5 (13.1)	36.1 (13.5)	<0.001
Vasopressor requirement (n)	8 (47%)	5 (31%)	0.35
Intubation (n)	7 (39%)	5 (31%)	0.64
Transfusion (RBC or platelet) (n)	10 (56%)	16 (100%)	0.002
Death (n)	4 (22%)	7 (44%)	0.18
Repeat episode of MAS at any point (n)	0 (0%)	2 (25%)	0.043
Treatment			
Pulse corticosteroids (defined as methylprednisolone 1000mg x3 days) (n)	14 (78%)	2 (12%)	<0.001
Cumulative dose of corticosteroids over hospitalization in mg equivalents of methylprednisolone, mean (SD)	3981.7 (3410.6)	2468.9 (3042.1)	0.19
Cyclophosphamide (n)	2 (11%)	8 (50%)	0.013
Mycophenolate mofetil (n)	1 (6%)	0 (0%)	0.34
Etoposide/dexamethasone protocol (n)	0 (0%)	7 (44%)	0.002
IVIG (n)	4 (22%)	0 (0%)	0.045
Anakinra (n)	6 (33%)	0 (0%)	0.011

Table 1. hospital course and outcomes of MAS vs. malignancy-associated HLH (n=number of patients; MAS=macrophage activation syndrome; HLH=hemophagocytic lymphohistiocytosis; SLE=systemic lupus erythematosus; AOSD=adult onset Still's disease; DLBCL=diffuse large B-cell lymphoma).

Methods: We identified adult HLH patients using ICD9/10 coding for HLH at an academic center from 2004 to 2020. A diagnosis of HLH required fulfillment of the 2004 HLH diagnostic criteria and/or clinical diagnosis by an expert. We included HLH cases that were secondary to either a rheumatologic disease (MAS) or a hematologic malignancy. MAS cases were compared to malignancy-associated HLH using STATA®.

Results: Of the 162 patients identified, 34 fulfilled inclusion criteria: 18 patients with MAS and 16 patients with hematologic malignancy-associated HLH. As expected, rheumatologic patients were younger (39.7 years vs. 62.3 years, $p< 0.001$) and more likely to be female (78% vs. 44%, $p=0.042$). MAS patients were less likely to have hepatomegaly (0% vs. 25%, $p< 0.024$), and developed milder cytopenias (Neutrophils: 3.7 vs. 1.2 K/μL, $p=0.012$; hemoglobin: 9.1 vs. 7.2 g/dL, $p=0.004$, platelets: 59.7vs. 30.9 K/μL, $p=0.005$) than malignancy-associated HLH patients. Soluble IL-2 receptor serum concentration was higher in malignancy patients but the difference did not reach statistical significance (5797.5 vs. 81786.4 pg/mL, $p=0.11$). MAS and HLH patients did not differ in the initial need for ICU levels of care but those with malignancy had a more prolonged hospital stay and a non-statistically significant increased mortality (Table 1). MAS patients were exclusively treated with immunosuppressives including pulse corticosteroids, while HLH patients were treated with chemotherapy or etoposide-based protocols.

Conclusion: MAS patients had overall better outcomes including shorter hospital stays than malignancy-associated HLH patients. While there were numerically fewer deaths in the MAS versus the malignancy-associated HLH cohort, one in five patients died from MAS during their initial hospitalization. Some noTable differences in disease characteristics between the two groups include organomegaly and severity of cytopenias, which could be helpful in differentiating malignancy from rheumatologic etiologies of hemophagocytic syndromes.Table 1: hospital course and outcomes of MAS vs. malignancy-associated HLH (n=number of patients; MAS=macrophage activation syndrome; HLH=hemophagocytic lymphohistiocytosis; SLE=systemic lupus erythematosus; AOSD=adult onset Still's disease; DLBCL=diffuse large B-cell lymphoma).

Abstract Number: 0089

The Risk Factors of Recurrence in Relapsing Polychondritis; A Study of 41 Cases

Tsuneyasu Yoshida[1], Hajime Yoshifuji[2], Mirei Shirakashi[1], Koji Kitagori[1], Shuji Akizuki[2], Ran Nakashima[1], Kosaku Murakami[1], Motomu Hashimoto[3], Masao Tanaka[3] and Koichiro Ohmura[1], [1]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, Kyoto, Kyoto, Japan, [2]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, Kyoto, Japan, [3]Department of Advanced Medicine for Rheumatic Diseases, Kyoto University Graduate School of Medicine, Kyoto, Kyoto, Japan

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing

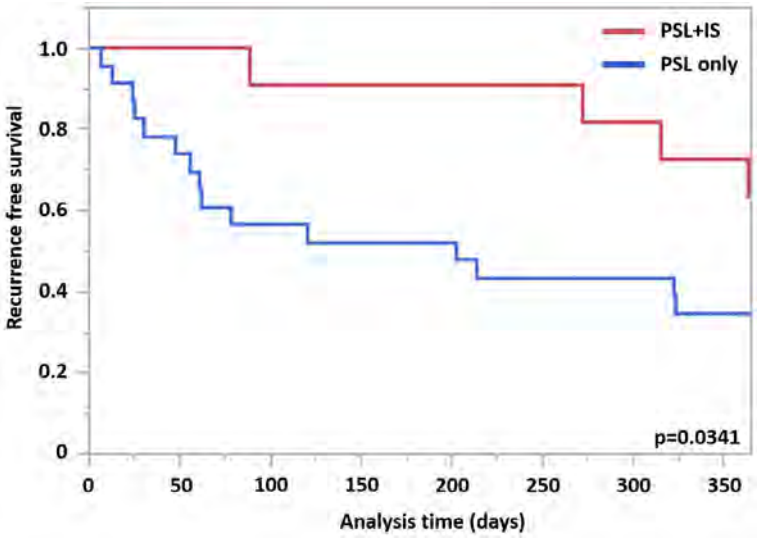
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare disease which causes inflammation in systemic cartilages. Although glucocorticoids (GC) and immunosuppressive drugs (IS) have been used, the recurrence rate remains high. It has been reported that tracheobronchial lesion is a poor prognostic factor, however, other risk factors have not been sufficiently investigated. We conducted a retrospective study on risk factors for recurrence.

Methods: We selected patients who had been diagnosed as RP according to Damiani's or Michet's criteria and treated at Kyoto University Hospital between 2001 and 2020. We excluded the patients with observation period less than one year and patients who had been taking oral GC for the treatment of other diseases at the time of the diagnosis of RP. Recurrence was defined as 1) aggravation of any symptoms or 2) worsening of the laboratory data that led to intensified treatments.

Results: Forty-one patients were extracted. The mean age at onset was 50±18 years, and the rate of women was 58.5%. The duration of observation was 6.6±5.8 years and the time from onset to diagnosis was 433±903 days. Of the 41 patients, 30 underwent recurrences (73.2%). The number of recurrences was 73 in total and 2.4 per person in



Recurrence free survival rate between prednisolone only therapy and prednisolone combinded with Immunosuppressant.

average. The median time to the initial recurrence was 202 days. The median dose of prednisolone (PSL) at the first relapse was 10 mg.

The patients were divided into recurrence and non-recurrence groups. In the recurrence group, the patients with tracheobronchial lesion as an initial symptom were more frequent (p=0.0108), and the activity index (RPDAI) (p=0.0178), serum CRP (p=0.0030) and IgG (p=0.0347) levels at the time of onset were higher than in non-recurrence group.

We next compared initial PSL monotherapy group (n=23) with initial PSL plus IS group (n=11) and found that the latter group showed significantly higher recurrence free survival rate at 1 year after initial treatment (p=0.0341, Figure 1).

Conclusion: We found tracheobronchial lesion, high RPDAI, high serum CRP and IgG as risk factors for recurrence. It was suggested that initial combination of PSL with IS could prolong recurrence-free period.

110 Patients with Monoclonal Gammopathy of Undetermined Significance (MGUS) in a Rheumatology Disease Unit: Fracture, Neuropathy, and Pernicious Anemia Are Clues to Recognition

Michael Lovy[1] and Andrew Dulalia[1], [1]Desert Oasis Healthcare, Palm Springs, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Monoclonal gammopathy of undetermined significance (MGUS) has been associated with osteoporosis, neuropathy, pernicious anemia, and low vitamin B12, and may precede multiple myeloma and lymphoplasmacytic disorders. The purpose of this study is to determine the characteristics of a group of MGUS patients diagnosed in an outpatient rheumatology disease unit.

Methods: A retrospective chart review was conducted of patients found to have MGUS, including history and physical, laboratory and x-ray studies. Patients were excluded if they had a preexisting lymphoproliferative disorder, if myeloma was subsequently diagnosed, or a repeat immunofixation did not show a paraprotein.

Results: There were 39 males and 71 females, ranging in age from 31 to 101 (mean 77 years). The reasons for referral included subacute fracture of spine or pelvis-59, osteoporosis evaluation-11, inflammatory arthritis-16, degenerative and crystal induced arthritis-20, neuropathy-1, and abnormal laboratory result-3. Preexisting conditions included: history of solid tumor-29, previous major osteoporotic fracture-63, hepatitis C-4,, RA-7, SLE-3, Sjogren's-2, ulcerative colitis-3, thyroid disease-17, myasthenia gravis-1, and primary biliary cirrhosis-1. Neuropathy defined by

a sensory loss above the ankle was found in 66 patients. Paraprotein was identified by serum immunofixation in 93 patients: IgG 68 %, IgM 18%, IgA-14% with 56 % lambda and 44% kappa chains. Serum protein electrophoresis failed to show M-spike in 20 of these patients. Light chains only were found among the remaining 17 patients; 3 kappa and 14 lambda. Urine immunofixation was positive in 32 out of 77 tested. Among the neuropathy patients,14 had IgM, 37 IgG, 4 IgA paraprotein, 8 lambda only and 3 kappa only light chains. Pernicious anemia was diagnosed in 15 patients based on low vitamin B12 levels and the presence of either intrinsic factor or anti-parietal cell antibody. 79 of the 110 patients had either osteoporotic fracture, neuropathy, or PA. Upon follow up one lupus patient was subsequently diagnosed with plasmablastic lymphoma and the one patient referred for neuropathy was diagnosed with follicular lymphoma

Conclusion: Rheumatologists will most likely encounter MGUS among patients evaluated for osteoporosis. Neuropathy, pernicious anemia, and previous fracture should prompt investigation with immunofixation as a screening test. If a MGUS is found and work up for myeloma is negative, studies for lymphoproliferative disorder should be considered in at risk patients.

Helicobacter Pylori Infection, Autoimmune Disease and Paraproteinemia Influence the Presentation of a Cohort of 150 Pernicious Anemia Patients Diagnosed in a Rheumatology Clinic

Michael Lovy[1], Norma Daniela Aguirre Vega[1] and Crystal Escobar[1], [1]Desert Oasis Healthcare, Palm Springs, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The most familiar presentation of pernicious anemia is an elderly Northern European woman with hematologic and neurologic manifestations. More recently the influence of Helicobacter pylori (H. pylori), autoimmune polyendocrine syndromes (APS) and paraproteinemia on the development of pernicious anemia has been recognized. The purpose of this study is to document the spectrum of pernicious anemia as manifest in a cohort of pernicious anemia patients diagnosed in a rheumatology clinic.

Methods: A retrospective chart review of the history and physical, laboratory and x-ray studies was conducted among patients diagnosed with pernicious anemia over a 10 year period. Pernicious anemia was diagnosed on the basis of a low vitamin B12 level and either intrinsic factor or anti-parietal cell antibodies.

Results: A total of 150 patients, 106 females and 44 males ranging in age from 32-101 years (mean 71.8) were diagnosed with pernicious anemia. Referral was based on acute fracture of the spine or pelvis-41,RA-30, arthritis-30, osteoporosis-16, pain-15, autoimmune disease-9, SLE-7, psoriasis-2. There was a history of major osteoporotic fracture in 54, heartburn-73, past peptic ulcer disease-16, lower esophageal ring-3, thyroid disease-42, type 1 diabetes-13, and vitiligo-2. 12 patients were on proton pump inhibitors and 5 were on H-2 antagonists. The mean BMI was 27.3. 101 patients had a sensory deficit at the level of the ankle, including 38 with findings of a glove and stocking sensory loss. Only 25 patients were anemic with 2 patients having a MCV >100 fL and 5 with a low serum iron. Folic

acid was < 8 ng/mL in 19 patients with a predominance of intrinsic factor over anti-parietal cell antibody present (p=0.039). Vitamin D levels were < 12 ng/mL in 13. H. pylori was diagnosed on the basis of a positive urea breath test in 21 patients at the time of initial evaluation (Group 1). Paraproteinemia was identified with serum immunofixation in 19 (Group 2). Autoimmune disease diagnosis (Group 3) included RA-32, SS-a or SS-b positive Sjogren's 9, SLE -3, psoriatic arthritis-4, CREST-2, spondyloarthropathy-2,inflammatory bowel disease-2, anti-PLA2R+ glomerulonephritis-1. Patients with thyroid disease-42 constituted Group 4, with the remaining 51 in Group 5. Mean age of the groups was 65.8, 77, 66, 71.3, and 71.7 respectively. There was a statistically significant increase of autoimmune disease present in H. pylori + Group 1 compared to the remaining 129 patients without H. pylori (p=0.0295). No other statistically significant differences were noted between Groups 1-5 or between intrinsic factor and anti-parietal cell antibody positive patients.

Conclusion: Pernicious anemia is most likely to be found among rheumatology patients with fracture, primary Sjogren's ,thyroid disease, vitiligo and other features of APS as well as in patients with paraproteinemia. Patients with autoimmune disease and those with H. pylori infection present with pernicious anemia at a younger age. The statistically significant correlation among pernicious anemia patients between H. pylori infection and underlying autoimmune disease supports the hypothesis that H. pylori can act as a trigger of an autoimmune response in a genetically predisposed host.

Diagnosis of Behçet's Disease: Comparison of Two Sets of Classification Criteria. Application in 111 Patients of a Well-defined Population

David Martinez-Lopez[1], Alba Herrero Morant[2], Carmen Alvarez-Reguera[2], Lara Sanchez-Bilbao[2], Inigo Gonzalez-Mazon[3], José Luis Martín-Varillas[4], Guillermo Suarez-Amorin[2], Patricia Setien-Preciados[2], Cristina Mata-Arnaiz[5], Miguel Ángel González-Gay[6] and Ricardo Blanco[2], [1]Hospital Universitario Marques de Valdecilla, Santander (SPAIN), Spain, [2]Hospital Universitario Marques de Valdecilla, Santander, Spain, [3]Hospital Universitario Marques de Valdecilla, Bezana, Spain, [4]Hospital Sierrallana, Torrelavega, Spain, [5]Hospital de Laredo, Santander, Spain, [6]Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is a systemic, chronic, relapsing vasculitis with no pathognomonic diagnostic test. The most widely used classification criteria are those of the International Study Group (ISG) for BD. These criteria were repeatedly found to have low sensitivity. Therefore, the International Criteria for Behçet's Disease (ICBD) were published in 2014.

Objectives: To compare the ISG with ICBD diagnostic criteria for BD.

Methods: The study included all consecutive 111 patients diagnosed with definitive or possible BD by expert rheumatologists. They were diagnosed at a well-defined population in Northern Spain between 1980 and 2019. The ISG and ICBD diagnostic criteria for BD were applied to and compared among all patients.

TABLE 1

	Expert diagnosis (N=111)	ISG criteria (N=65)	ICBD criteria (N=86)
Age, mean (SD)	36.7 (13.2)	36 (12.8)	36.7 (13)
Gender, men/women, N (%)	49/62 (44.1/55.8)	29/36 (44.6/55.4)	38/48 (44.2/55.8)
Oral aphthosis	110 (99)	65 (100)	85 (100)
- Recurrent (3 times/year)	91 (87.2)	61 (93.8)	74 (86)
Genital aphthosis	59 (53.1)	42 (64.6)	56 (65.1)
Skin manifestations	76 (68.4)	56 (86.15)	71 (70.9)
- Pseudofolliculitis/ Erythema nodosum	51 (67.1)/ 27 (35.5)	38 (58.5)/ 21 (32.3)	42 (68.8)/ 22 (36.1)
Ocular lesions	39 (35.1)	32 (49.2)	39 (45.3)
- Anterior/ Posterior/ Panuveitis	17 (43.6);12 (30.8)/ 0	16 (50)/ 8(25)/ 7 (21.9)	17 (45.6); 0; 12 (30.8)
- Retinal vasculitis	4 (10.3)	1 (3.1)	4 (10.6)
Joint manifestations	76 (68.5)	43 (66.1)	58 (67.4)
- Arthralgias / Arthritis	69 (92.8)/ 45 (60)	39 (90.7)/ 24 (55.8)	52 (89.6)/ 33 (56.9)
Neurological manifestations	20 (18)	11 (16.9)	16 (18.6)
- Peripheral / Central	11 (55)/ 14 (70)	7 (63.6)/ 7 (63.6)	12 (75)/ 10 (62.5)
Vascular manifestations	9 (8.6)	7 (10.8)	10 (11.6)
- Arterial/ Vein thrombosis/ Phlebitis	0/ 5 (55)/ 1 (11.1)	0/ 4 (57.1)/ 1 (14.3)	1 (12.5)/ 5 (62.5)/0
Gastrointestinal features	4 (4.5)	4 (6.1)	4 (4.6)
Pathergy test positive (available data; %)	6 (28; 21.4)	4 (19; 21)	4 (25, 16)
HLA B51 positive (available data; %)	38 (86; 44.2)	19 (47; 40.4)	28 (63; 44.4)

Results: We studied 111 patients (62 Women/49 Men), mean age 36.8±13.2 years. BD was diagnosed in 65 (58.5%) by ISGBD criteria and in 86 (77.5%) by ICBD criteria. No significant differences were observed between both criteria ($p < 0.001$). The overall concordance was fair (Kappa 0.3; $p< 0.001$). Sensitivity was 58.6% for ICBD criteria and 80.2% for ISG. (TABLE-1)

Conclusion: ICBD criteria exhibit higher sensitivity than ISG criteria. Thus, the application of these new criteria can achieve a more correct and earlier diagnosis of BD.

Abstract Number: 0093

Review of Gastrointestinal Manifestations of Kohlmeier-Degos Disease

Samantha Sattler[1], Lee Shapiro[2] and Cynthia Magro[3], [1]Albany Medical College, Albany, NY, [2]Albany Medical College, Stillwater, NY, [3]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Kohlmeier-Degos disease is a rare obliterative vasculopathy that can present in a benign cutaneous form or with potentially malignant systemic involvement. While the benign form is restricted to cutaneous lesions, the malignant form involves visceral organs and may occur with or, rarely, without cutaneous lesions. In systemic cases, central nervous system, renal, respiratory, cardiac, and gastrointestinal manifestations have all been noted, in addition to other organs. Of these, the gastrointestinal tract is most commonly involved and mortality of systemic Kohlmeier-Degos is often related to bowel perforations. Given this, further characterization of this disease's gastrointestinal manifestations is essential to increasing awareness and recognition of this life-threatening entity.

Methods: Published case reports of gastrointestinal Kohlmeier-Degos disease were compiled by searching EBSCO*host* database. Case reports included are all those in which patients were diagnosed with Kohlmeier-Degos disease and reported at least one gastrointestinal symptom. Demographics, presentations, imaging, complications, and treatments were evaluated for approximately 40 cases. Novel pathophysiology of the gastrointestinal aspect of this disease was also elucidated.

Results: The average age of gastrointestinal Kohlmeier-Degos occurring in adults was 43, with a slight predilection for females. Infantile disease is present but rare. Bowel perforations occurred in roughly 40% of cases. Most perforations occurred in the small intestine, specifically the jejunum. Repeat perforations are possible, although not well documented due to the high risk of fatality. Various gastrointestinal visualization methods and treatments were employed across all cases. Pathology of the disease in the gastrointestinal tract is characterized as a purely arteriopathic and extravascular sclerosing process confined to the subserosal fat. Enhanced interferon alpha expression is likely involved in the obliterative arteriopathic process. Under the influence of a type I interferon microenvironment, there is an initial influx of monocytes into the intima. They undergo transdifferentiation into procollagen-producing cells with myofibroblastic properties, producing excessive collagen and hyaluronic acid that eventuates into the acellular plug that defines the final obliterative arterial lesion. A similar procollagen phenotype reminiscent of the scleroderma phenotype is encountered in the fibroblasts within the zone of serosal fibrosis; the fibroblasts express smooth muscle actin and show a noticeable absence of CD34 staining.

Conclusion: Gastrointestinal Kohlmeier-Degos remains a rare and elusive entity, but patterns can be seen in existing published cases. All gastrointestinal cases were preceded by characteristic skin lesions and the presence or histology of these cutaneous lesions often aided diagnosis. All cases of bowel perforation were preceded by at least one gastrointestinal symptom. Although underutilized, laparoscopy proves to be the most specific visualization and diagnostic technique. Presently, the combination of eculizumab and treprostinil is the most effective treatment option.

Validation Study of Proposed Diagnostic Criteria for Sympathetic Joint Effusion

Justin Levinson[1], Mali Jurkowski[2], Jasleen Kahlon[3], Hayoung Youn[4], Daohai Yu[3] and Irene Tan[5], [1]Section of Rheumatology, Lewis Katz School of Medicine at Temple University, Philadelphia, PA, [2]Temple University, Philadelphia, PA, [3]Temple University, Philadelphia, [4]Temple University Medical School, Philadelphia, [5]Albert Einstein Healthcare Network, Philadelphia, PA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Sympathetic joint effusion (SJE) is a rarely diagnosed rheumatologic entity characterized by painful yet non-inflammatory range synovial effusion. The condition was originally described in 1978 as a reactive joint effusion associated with adjacent pathology. Literature on the subject has remained scarce due to lack of clinician familiarity and diagnostic criteria, and remains markedly underdiagnosed.[1-3] A delay in diagnosis can lead to significant healthcare expenditure, unnecessary treatment and poor outcome.[1] A validated diagnostic criteria (Figure 1) would improve diagnostic certainty for clinicians and aid future studies and treatment.

Methods: Retrospective chart review was performed on diagnostic arthrocentesis with synovial fluid analysis between 1/31/2010 – 2/1/2019. Those with synovial fluid White Blood Cell (WBC) counts (< 2000 cells/mm3), with com-

Figure 1. Proposed Diagnostic Criteria for SJE

Definite SJE = Clinical features + Synovial Fluid features + Adjacent Pathological Process **Probable SJE = Clinical features + Synovial Fluid features**		
Clinical features (fulfill all 4 below):	**Synovial fluid analysis features (fulfill all 3 below):**	**Adjacent pathological process in same limb:**
1) Monoarticular (1 joint) 2) Joint or bursa effusion with evidence of inflammation on exam (Erythema, Pain, and/or Warmth) 3) Subacute onset of joint effusion (typically >24 hours and <1 month) 4) No history of concurrent osteoarthritis, recent direct trauma, or fracture.	1) Normal (<200 WBC/mm3) or non-inflammatory (<2,000 WBC/mm3) range 2) Culture negative for microbial growth 3) No intracellular crystals	Contiguous area, adjacent to, or in close anatomical proximity (either superficial or deep, proximal or distal) to the joint effusion. Includes, but not limited to, infection, DVT, soft tissue fluid collection, nearby trauma, recent orthopedic surgery, loosening of joint prosthesis, and ECMO catheter cannulation, e.g., knee SJE/SSE may be seen with foot infection.

Figure 1. Proposed Diagnostic Criteria for SJE

Table 1. Patients' Demographic and Clinical Features by Original Description

Clinical Feature	SJE (N=125)	Non-SJE (N=215)
Gender		
Male	81 (64.8%)	123 (57.2%)
Female	44 (35.2%)	92 (42.7%)
Age (years)		
Mean (STD)	57.5 (16.8)	58.6 (15.6)
Median (range)	59.0 (18-99)	58.5 (23-96)
Interquartile Range	47-67	48-68
WBC Count		
Median (range)	82.5 (0-2000)	291.5 (1-2000)
Interquartile Range	35-194	106-759.5
Joint Site		
Interphalangeal (finger) joint	1 (0.8%)	0
Wrist Joint	0	1 (0.5%)
Elbow Joint	7 (5.6%)	14 (6.5%)
Shoulder Joint	6 (4.8%)	9 (4.3%)
Lumbar Spine (disc)	0	1 (0.5%)
Hip Joint	6 (4.8%)	21 (9.8)
Knee Joint	93 (75.1%)	157 (72.9%)
Ankle joint	9 (7.2%)	12 (5.6%)
Metatarsal Joint	2 (1.6%)	0

Table 1. Patients' Demographic and Clinical Features

plete crystal and culture studies were included. A total of 1095 synovial fluid analyses were initially evaluated, with 340 having negative crystal and culture studies.

Results: Using the original SJE description, 125 cases were determined to have SJE with the remaining 215 cases as negative controls. The annualized incidence was 1.268%. Some of the adjacent pathologies found were infections (cellulitis, abscess), vascular manipulation (AV fistula, ECMO, line placement), and DVT.

Table 2. Independent and Joint Effects of Diagnostic Features for SJE Clinical Diagnosis

Independent Effects	N	(Raw) Odds Ratio (95% CI)	p-value
Effusion: Yes vs. No	324	4.37 (1.65, 11.55)	0.001
Erythema: Yes vs. No	300	4.00 (2.19, 7.29)	<0.0001
Warmth: Yes vs. No	293	1.63 (0.99, 2.67)	0.057
Pain/Tenderness: Yes vs. No	330	1.92 (0.74, 4.94)	0.20
WBC Count: <200 vs. ≥200 cells/mm3	340	4.61 (2.84, 7.48)	<0.0001
Adjusted/Joint Effects	**N**	**Adjusted Odds Ratio (95% CI)**	**p-value**
Effusion: Yes vs. No	297	4.69 (1.60, 13.75)	0.005
Erythema: Yes vs. No		4.92 (2.50, 9.71)	<0.0001
WBC Count: <200 vs. ≥200 cells/mm3		5.71 (3.24, 10.04)	<0.0001

Table 2. Independent and Combined Effects of Diagnostic Features for SJE Clinical Diagnosis

The sensitivity of monoarticular involvement was 38.1% while specificity was 75.8%. Eight of the SJE patients based on original description with adjacent pathology had complained of >1 joint involved. 65.7% of SJE cases presented with symptoms for greater than 1 day but less than 7, while 14.3% presented after day 7 but within the month. The odds of diagnosis increased 4-fold with erythema (Table 2). On multivariable analysis, erythema and WBC Count < 200 increased the odds of diagnosis 4.9 and 5.7-fold, respectively, after having adjusted for effusion and each other.

With the proposed diagnostic criteria, 59 cases would be considered "Definite" with 58 cases considered "Probable." Comparing cases on original description with intention to treat all "Definite" or "Probable" cases, the sensitivity of our proposed diagnostic criteria is 93.6% with specificity of 96.7% (PPV=94.4%,NPV=96.3%).

Conclusion: To our knowledge, this is the first proposed and validated diagnostic criteria of SJE. The sensitivity and specificity of our criteria are very high, driven by the use of exclusion diagnoses. Strong Odds Ratios for Erythema and WBC Count < 200 indicate the severity of physical symptoms yet minimal synovial inflammation. A weakness of our study is that data was collected retrospectively which is limited by history and exam included in the chart.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Monogenic autoinflammatory diseases (AID) are caused by mutations in innate immune signaling genes. The effect of these mutations on the risk of allergy is unknown. We previously reported results of our preliminary analysis, which indicated that allergy-associated features were rare in AID based on retrospective review [1]. We have now performed a full systematic analysis using a combination of retrospective chart review, standardized questionnaires, and T cell immunophenotyping. This revealed common and disease-specific correlations with allergy-associated clinical and immunologic phenotypes. This study was the first of its kind to investigate the prevalence of allergic features in multiple monogenic AID, and the first to do so within the U.S. population.

Methods: We investigated the prevalence of allergic clinical and immunologic phenotypes in AID caused by pathogenic mutations in *MEFV, TNFRSF1A, MVK, NLRP3, PSTPIP1,* proteasome genes, *STING, TNFAIP3*, and *ADA2*. We used retrospective chart review and questionnaires to assess clinical and laboratory features of patients enrolled on NIH protocol 94-HG-0105 or 17-I-0016. Questionnaires were developed by a panel of clinical allergists, clinical rheumatologists, and survey researchers. Six clinical syndromes were assessed (Table 1). Surveys were administered via the telephone, internet, and in the NIH Clinical Center. Informed consent was obtained from all participants. Comparator data was obtained from the National Center for Health Statistics and Chicago Food Allergy Research Surveys [2-6]. To determine if T helper 2 (Th2)/Th9 cells were expanded in AID, we stimulated peripheral blood mononuclear cells (PBMCs) and analyzed the data with flow cytometry.

Results: Allergic rhinitis, eczema, and eosinophilic gastrointestinal (GI) inflammation were prevalent in multiple AID (Table 1). Asthma was rare in patients with *MEFV* and proteasome mutations but common in patients with *NLRP3* mutations. A trend towards increased food allergy prevalence was seen in patients with *NLRP3*, *TNFAIP3*, and proteasome mutations. Median IgE was reduced in patients with *ADA2* and *MVK* mutations; median absolute eosinophil count (AEC) was reduced in patients with most AID but elevated in patients with *NLRP3* mutations (Figure 1). T helper 2 (Th2) cells were expanded in patients with *NLRP3, TNFRSF1A,* and *MVK* mutations; Th9 cells were expanded in patients with *TNFAIP3* mutations (Figure 2).

Disease (number of subjects)	**Allergic rhinitis**	**Asthma**	**Eczema**	**Food Allergy**	**Multiple food allergies**	**EGID**	**Flare-related urticaria**	**Flare-related angioedema**
General population (n = variable, from public datasets)	7.1%	12.9%	9.2%	9.2%	4.0%	0.0%	N/A	N/A

Table 1. Prevalence of atopic features in patients with autoinflammatory disease confirmed by genetic testing, and comparison data in the general population. Column shows prevalence in each population. FMF = Familial Mediterranean Fever; CAPS = Cryopyrin-Associated Periodic Syndrome; TRAPS = Tumor necrosis factor Receptor-Associated Periodic Syndrome (TRAPS); DADA2 = Deficiency of Adenosine Deaminase 2; HIDS = Hyper-IgD Syndrome; PAPA = Pyogenic Arthritis, Pyoderma gangrenosum, and Acne; HA20 = Haploinsufficiency of A20; CANDLE = Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated temperature; SAVI = STING-Associated Vasculopathy with onset in Infancy. *FDR<0.05 vs. general US population. #FDR<0.05 vs. FMF; Benjamini-Hochberg adjusted Fisher t-test.

Figure 1

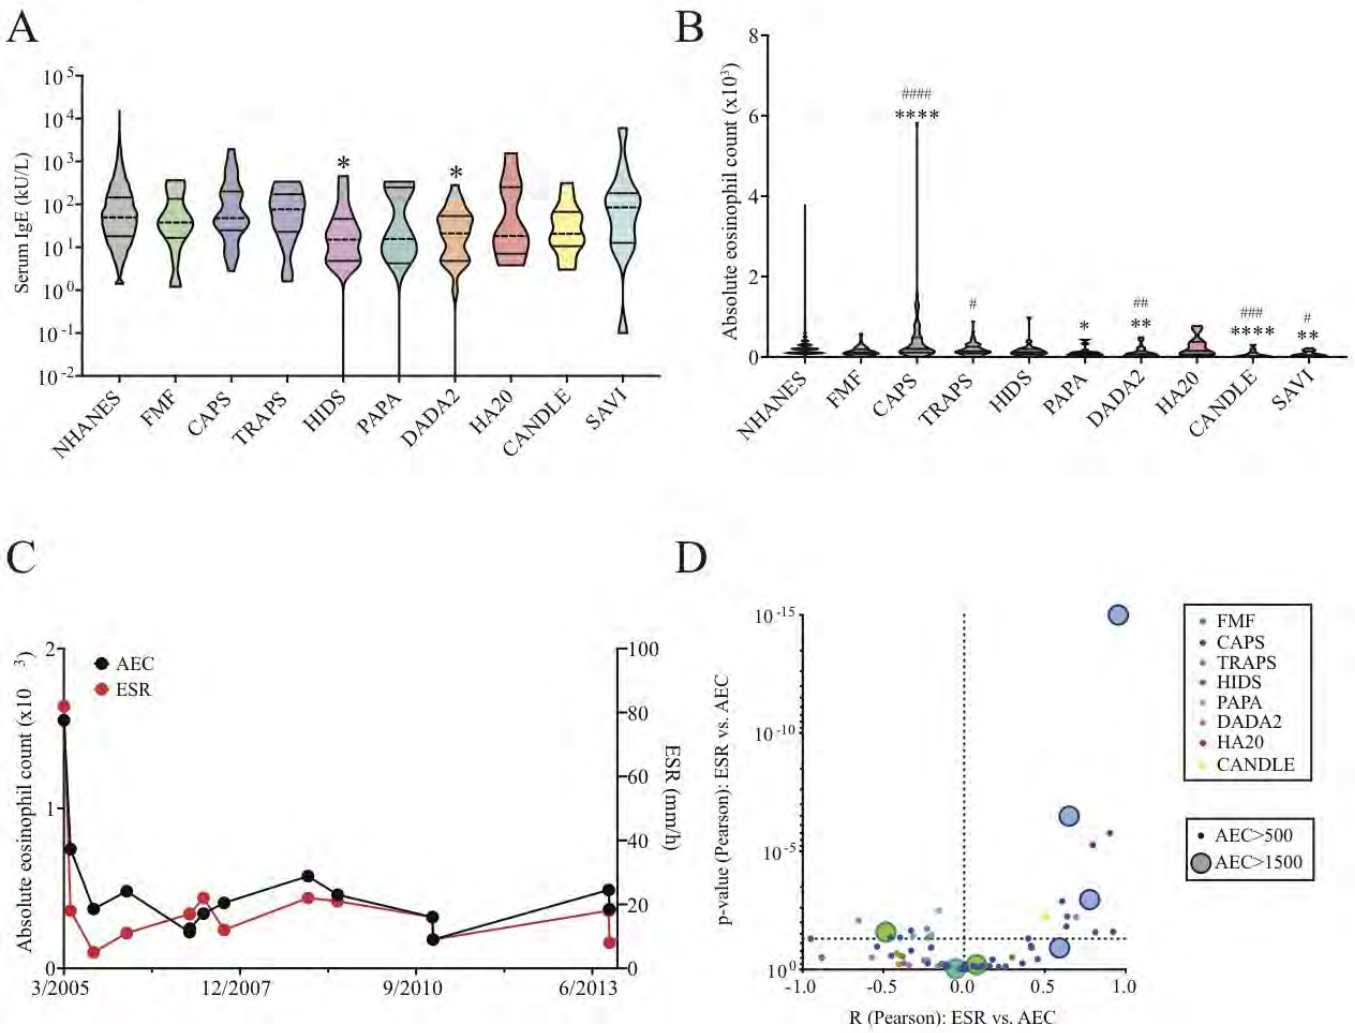

Figure 1. Eosinophilia and absolute eosinophil counts (AEC) in the general US population and in nine monogenic autoinflammatory diseases (AID). Data are shown for the general US population, Familial Mediterranean Fever (FMF); Cryopyrin-Associated Periodic Syndrome (CAPS); TNF-Receptor Associated Periodic Syndrome (TRAPS); Hyper-IgD Syndrome (HIDS); Pyogenic Arthritis, Pyoderma gangrenosum, and Acne (PAPA); Deficiency of ADA2 (DADA2); Haploinsufficiency of A20 (HA20); Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated temperature (CANDLE); and STING Associated Vasculopathy with onset in Infancy (SAVI). (A) Violin plot shows serum IgE levels for each population. (B) Violin plot shows serum IgE levels for each population. (C) Representative plots are shown for one CAPS patient with hypereosinophilia: dot plot of AEC and ESR values over a period of 8 years. (D) Volcano plot shows correlation (R, Pearson test) vs. p-value (Pearson test) of AEC vs. erythrocyte sedimentation rate (ESR, mm/h) for each AID patient with eosinophilia (AEC > 500). Colors of dots indicate specific AID (FMF, green; CAPS, dark blue; TRAPS, purple; HIDS, fuchsia; PAPA, teal; DADA2, orange; HA20, red; CANDLE, yellow). Size of dots distinguishes patients with eosinophilia (AEC > 500) from those with hypereosinophilia (AEC > 1500). *p<0.05, **p<0.01, ***p<0.005, ****p<0.001 vs. general US population. #p<0.05, ##p<0.01, ###p<0.005, ###p<0.001 vs. FMF; Benjamini-Hochberg adjusted Mann-Whitney (B).

Conclusion: Allergy-associated clinical and immunological phenotypes are prevalent in many AID, reinforcing a role for innate immunity in allergy pathogenesis. Further investigations are needed to determine the role of allergy-associated factors in AID pathology.

Figure 2

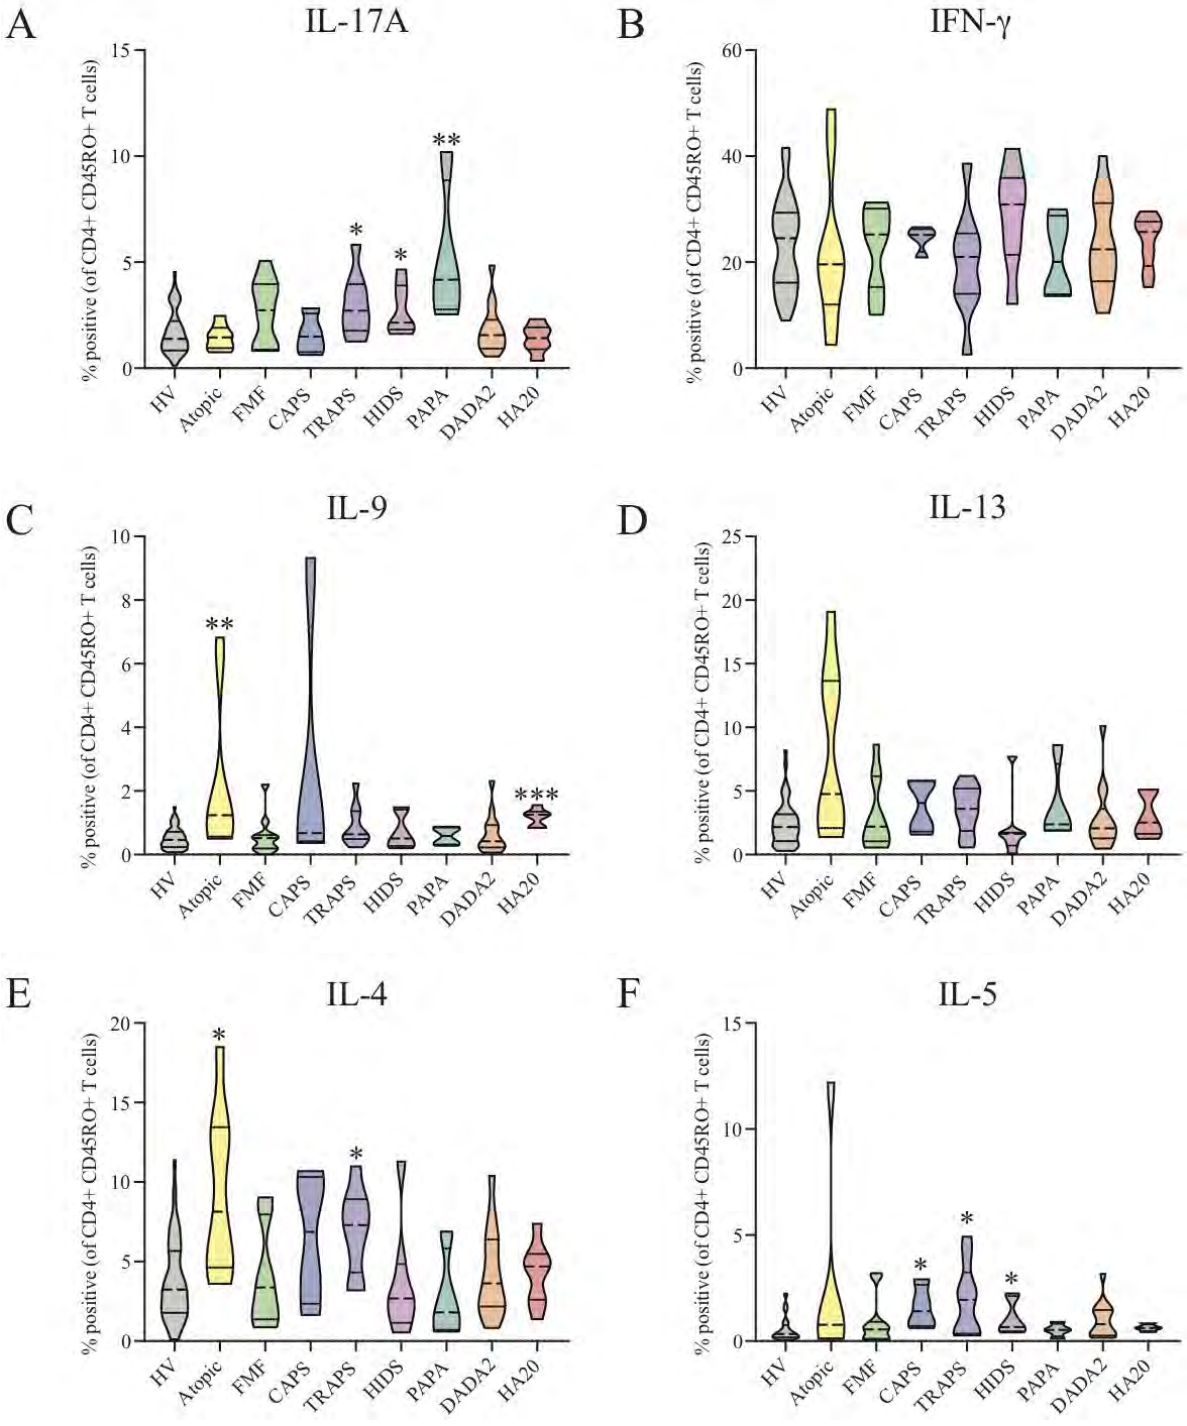

Figure 2. T helper immunophenotypes in seven monogenic autoinflammatory diseases (AID). Data are shown for healthy volunteers (HV); atopic dermatitis patients; Familial Mediterranean Fever (FMF); Cryopyrin-Associated Periodic Syndrome (CAPS); TNF-Receptor Associated Periodic Syndrome (TRAPS); Hyper-IgD Syndrome (HIDS); Pyogenic Arthritis, Pyoderma gangrenosum, and Acne (PAPA); Deficiency of ADA2 (DADA2); and Haploinsufficiency of A20 (HA20). Violin plots show percentage of memory T helper cells (CD3+ CD4+ CD8- CD45RO+) producing IL-17A (A), IFN-gamma (B), IL-9 (C), IL-13 (D), IL-4 (E), and IL-5 (F). *p<0.05, **p<0.01, ***p<0.005, ****p<0.001 vs. HC. #<0.05, ##p<0.01, ###p<0.005, ###p<0.001 vs. FMF; Benjamini-Hochberg adjusted Mann Whitney.

The Bicipital Stress Test: A Maneuver to More Accurately Diagnose Bicipital Tendinitis and Its Referred Pain Patterns

Meredith Thomley[1], David Spalding[2], Ana Preda-Naumescu[1] and Raymond Waldrop[1], [1]University of Alabama at Birmingham, Birmingham, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation of the bicipital tendon contributes heavily to shoulder joint morbidity. To date, diagnosis of bicipital tendinitis has relied on physical exam findings, particularly Yergason's sign and the Speed's test (ST). These tests have fallen out of fervent use due to their relative insensitivity. In this study, we introduce a novel diagnostic paradigm, the Bicipital Stress Test (BST), with improved sensitivity in comparison to previously standard tests.

Methods: This retrospective cohort study reviewed 151 patients over a six-month period. Patients were included who presented with upper body pain and whose exam demonstrated a positive ST and/or BST. Given a positive test, a treatment paradigm was utilized, and patients were reevaluated at four to six-week intervals for clinical improvement. Statistical analysis determined the sensitivity and specificity of the BST.

Results: The BST identified 248 positive upper extremities versus 71 for the traditional ST test. In every case that the ST test was positive, the BST was also positive.

Conclusion: Physical examination techniques of the upper extremity have been described but are infrequently utilized in clinical practice; this is due to the relative insensitivity of the most well-known tests for bicipital tendinitis, Yergason's sign (43%) and the ST (32%). The BST is a more sensitive test in diagnosing bicipital tendinitis. The clinical validity of the BST is supported by normalization of the physical exam and improvement in symptomatology following

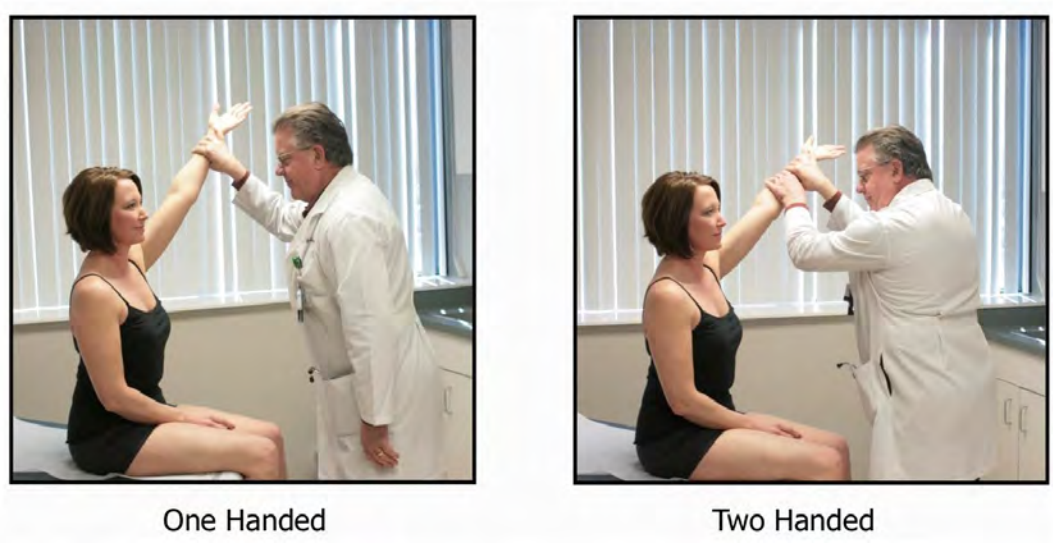

Figure 1. The Bicipital Stress Test. In the BST, the clinician faces the seated patient. The shoulder is forward flexed to 120 degrees, abducted to 30 degrees, and the arm is in the supinated position. The examiner then places direct downward force at the wrist. Inability to maintain position against forceful downward pressure is the key that determines a positive test.

treatment of a positive test. Implementation of the BST yields early detection, accurate diagnosis, and successful treatment of bicipital tendinitis and its referred pain patterns.

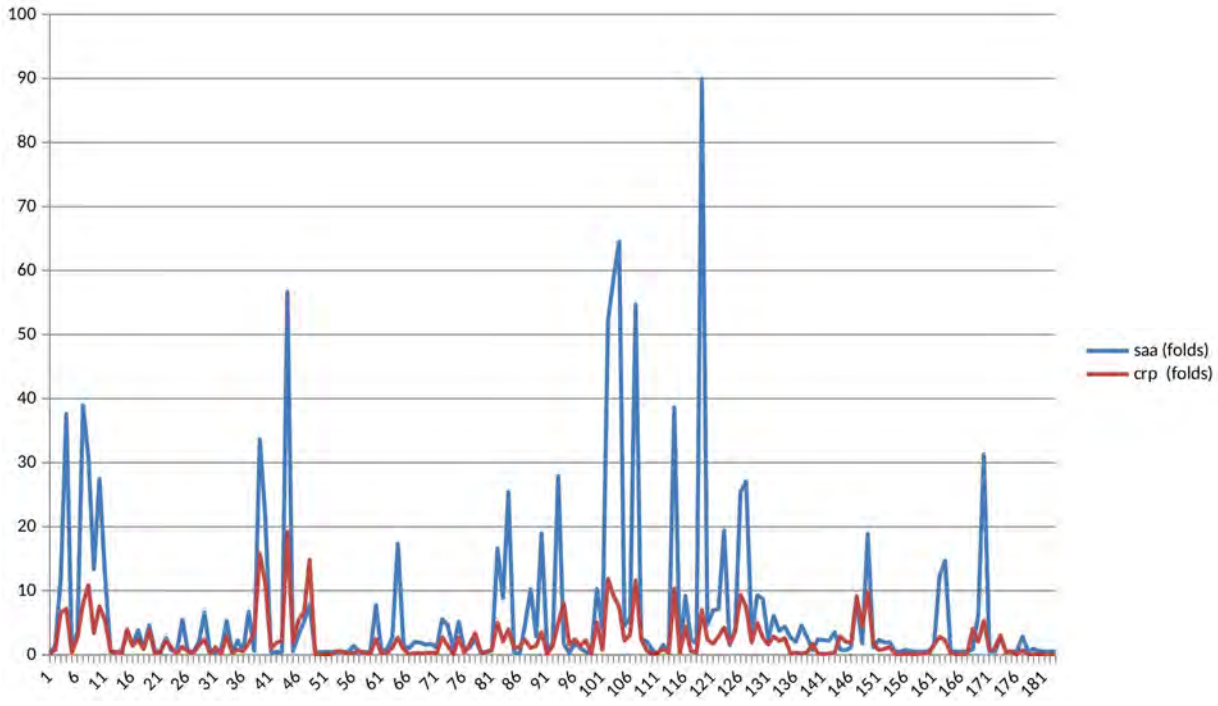
Does Testing for SAA Is More Beneficial Than CRP for the Follow-up of Patients with FMF?

Mert Oztas[1], Serdal Ugurlu[1], Oguzhan Selvi[2], Bilgesu Ergezen[1] and Huri Ozdogan[1], [1]Istanbul University-Cerrahpasa, Istanbul, Turkey, [2]Okmeydani Research and Training Hospital, Istanbul, Turkey

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In order to follow subclinical inflammation and adjust the therapy for an optimal disease control, clinicians seek for readily accessible, affordable and reproducible markers. C reactive protein (CRP) is widely used for this purpose. Some suggest that CRP measures are not conclusive in all cases, especially in initial stages of inflammation. It is suggested that Serum Amyloid A (SAA) may be more reliable and sensitive in predicting an ongoing inflammation.

Methods: In order to evaluate and to compare the sensitivity of SAA and CRP, 153 measurements from 28 patients M694V homozygous mutation and 31 measurements from 15 patients with M694V heterozygous mutation were obtained during a mean follow-up of 1 year. For the analysis, the folds of normal CRP and SAA values were used for correlation. Serum levels of the given markers were measured with nephelometric kits (normal CRP levels < 5 mg/L



The folds of the CRP and SAA in whole M694V homozygous and heterozygous mutant population

and SAA levels < 6,8 mg/L). More than one and half fold increasement of CRP and SAA was defined as an active inflammation.

Results: Except a patient, all patients in whole cohort were on prophylactic colchicine. Among 28 patients with M694V homozygous mutation, a patient with adalimumab, 12 patients with anti-IL-1 regimens. Of 15 patients with M694V heterozygous mutation, 4 were under anti-IL-1 treatment. There was a total of 183 measurements of CRP and SAA from 43 patients. Twenty-three measurements were obtained during the attack period in M694V homozygous group and the remaining 160 measurements were collected in attack free period. Figure demonstrates the correlation between CRP and SAA results ($r=0.745$, $p< 0.001$). Both acute phase reactants were increased in 69 measurements, while in 13 CRP was high but SAA was normal and in 31 SAA was high however CRP was within normal limits. The mean increase in CRP of the whole cohort was 2,37 ± 3,22-fold, whereas mean increase in SAA was 6,77 ± 13,23-fold of the normal.

Conclusion: According to these results, serial testing of SAA does not provide any additional advantages over CRP. Readily accessible and affordable bio-marker CRP seems to be sufficient for follow-up of patients with FMF

CCL2 and CCR2 in Adult Onset Still's Disease

Ju-Yang Jung[1], Ji-Won Kim[1], Chang-Hee Suh[1] and Hyoun-Ah Kim[1], [1]Ajou university school of medicine, Suwon, Republic of Korea

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Adult onset Still's disease (AOSD) is a rare systemic inflammatory disease characterized by a high spiking fever, evanescent rash, arthralgia, generalized lymphadenopathy, and leukocytosis. The activation of innate immune system is the main pathogenesis of AOSD. Chemokine C-C motif ligand (CCL) 2 and CC chemokine receptor (CCR) 2, a ligand of CCR2, have a chemical attractant activity and migrate monocyte and macrophages to the site of inflammation.

Methods: This study checked the serum levels of CCL2 and CCR2 in patients with AOSD and rheumatoid arthritis (RA), and healthy controls (HC), and analyzed their associations with clinical markers in patients with AOSD.

Results: The levels of CCL2 in serum were significantly increased in patients with AOSD (476.41 ± 689.06 pg/mL) compared in patients with RA (169.15 ± 118.71 pg/mL, $p = 0.007$) and HCs (135.14 ± 71.66 pg/mL, $p = 0.003$). The levels of CCR2 in serum were increased in AOSD patients rather than RA and HC, but it was not statistically significant because the large variation between individuals. The levels of CCL2 in serum was significantly increased in active group (589.49 ± 772.41 pg/mL) than inactive group (157.73 ± 71.02 pg/mL, $p < 0.001$) in patients with AOSD. The levels of CCL2 in serum correlated with systemic score ($r = 0.539$, $p < 0.001$), the counts of leukocyte ($r = 0.316$, $p = 0.041$) and neutrophil ($r = 0.316$, $p = 0.041$), C-reactive protein ($r = 0.321$, $p = 0.044$), ferritin ($r = 0.607$, $p < 0.001$), LDH ($r = 0.597$, $p < 0.001$) and albumin ($r = -0.428$, $p = 0.005$). However, the level of CCR2 in serum was not associated with any clinical markers of disease activity. After disease was resolved, the levels of CCL2 were significantly decreased in patients with AOSD ($p = 0.029$).

Conclusion: Circulating CCL2 was elevated in patients with AOSD and was associated with disease activity, suggesting that CCL2 might take a role in the inflammatory response of AOSD.

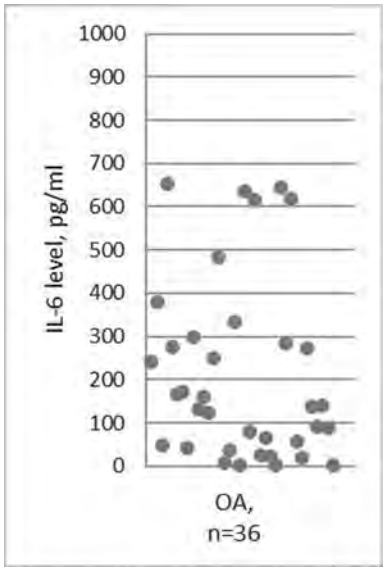
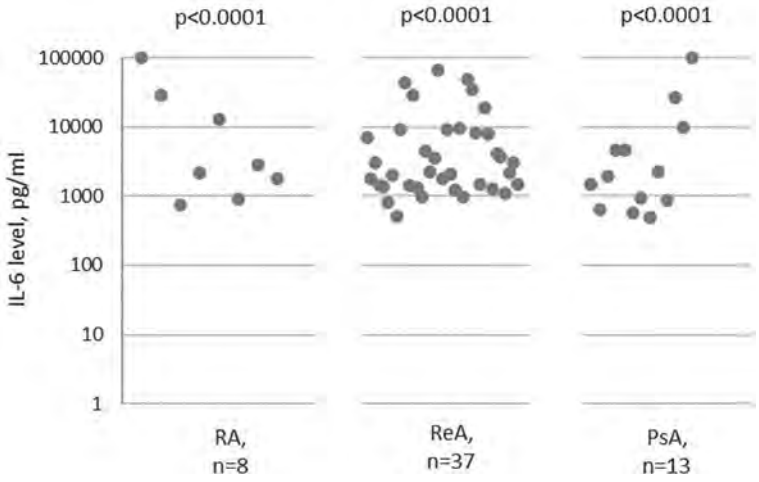
Interleukin 6 Concentration in Synovial Fluid of Patients with Different Types of Arthritis

Aleksandra Bukina[1] and **Anna Mihailova**[1], [1]Rigas Stradins university, Riga, Latvia

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM



IL-6 concentration in patients with osteoarthritis



IL-6 concentration in patient with inflammatory arthritis

Background/Purpose: Persistent synovitis without known markers such as rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA) as well as without genetic markers as HLAB27 is not uncommon. It is valuable to determine the presents of chronic inflammation and differentiate with age-related changes, what are especially relevant for middle-aged patients with mono- or oligo- arthritis, when dilemma to start disease modifying drugs for inflammatory disease often is present. Interleukin 6 (IL6) is a pleiotropic pro-inflammatory cytokine, which play significant role in the chronic inflammation and autoimmunity. IL6 concentration in synovial fluid was studied in different types of arthritis. The aim of present study to compare concentration of IL6 in synovial fluid in patients with known type of arthritis.

Methods: Synovial fluid was obtained from one hundred one patients with chronic synovitis, mostly from knee joints. IL6 concentration was determined by immunochemical luminescence method.

Results: The median IL6 concentration in synovial fluid in patients with osteoarthritis (OA) was 138.0 pg/ml (IQR 43.4 to 296.0) without any significant differences in primary and secondary osteoarthritis. In inflammatory arthropathies median IL6 level was 2194.0 pg/ml (IQR 1254.0 to 8625.0). Median IL6 concentration in patients with rheumatoid arthritis (RA) was 2516.5 pg/ml, (IQR 1136.0 to 25058.0). There was not significant differences found between seronegative and seropositive RA groups. In reactive arthritis (ReA) median IL6 level was 2281.0 pg/ml (IQR 1392.0 to 8652.0); psoriatic arthritis (PsA) - 1964.0 pg/ml (IQR 754.0 to 7300.0) and ankylosing spondylitis (AS) - 2776.0 pg/ml (IQR 514.7, 3944.0). In group of 19 patients with negative RF, ACPA and HLAB27 inflammatory arthritis (IA) median IL6 level was 2163.0 pg/ml (IQR 822.0 to 7875.0). The pairwise comparison of diagnosis by Kruskal-Wallis Test show statistically significant difference in OA and RA, OA and ReA, OA and PsA groups, $p< 0.0001$.

Conclusion: IL6 detection in the synovial fluid is useful in arthritis evaluation. The results show that IL6 level over 1000 pg/ml suggest diagnosis of inflammatory arthritis.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I: Diagnosis and Testing

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic diseases (RD) are at higher risk of latent tuberculosis infection (LTBI) reactivation. To detect and treat it before starting treatment, especially with biological therapies, decrease the reactivation risk. Diagnosis is carried out by the tuberculin skin test (TST) or interferon-gamma release assays (IGRAs), IGRAs might be more specific and sensitive. We aim to analyze the concordance between QuantiFERON-TB Gold In-Tube (QTF) and TST for the diagnosis of LTBI in patients with rheumatic diseases.

Methods: A retrospective observational study was conducted including patients diagnosed with RD screened for LTBI with both TST and QTF (2014-2018). Demographical and clinical variables at screening and at follow-up were collected. The concordance between both tests has been estimated as categorical variables using Cohen´s Kappa test, considering "poor" if it is $\leq 0,20$; “low” if $0,20 < k \leq 0,40$, “moderate” if $0,40 < k \leq 0,60$, “substantial” if $0,60 < k \leq 0,80$ and “optimal” if $k > 0,80$.

Table 1. Kappa concordance between QTF and TST.

	TOTAL SAMPLE	PATIENTS WITH GC AT LTBI SCREENING	PATIENTS WITHOUT GC AT LTBI SCREENING
Number of coincidences (p1)	147 (88.02%)	64 (83.12%)	83 (92.22%)
Number of randomly expected coincidences (p_e)	124.1 (74.28%)	62.9 (81.73%)	61.8 (68.62%)
Kappa = p1- p_e /1- p_e	**0,534**	**0,117**	**0.752**
IC 95%	(0.358-0.710)	(-0.154-0.305)	(0.579-0.926)

Results: 167 patients were included (57% women) with a mean age of 52±16 years. 42% of them had systemic autoimmune diseases, 22% spondyloarthropathies and 36% other RD. 2 had history of past active tuberculosis (TB). At the time of screening, 46.11% were treated with GC.

LTBI was diagnosed in 35 patients: 15 had both QTF and TST positive, 16 only QTF positive and 4 only TST positive. 12 from 31 QTF positive patients were treated with GC at the time of screening. 3 from 19 TST positive patients were treated with GC at the time of screening.

After LTBI screening 62 patients received biological treatment, 4 of them had both test positive, 6 only QTF positive and 2 only TST positive. 11 received LTBI treatment according to the hospital protocol (isoniazid for 6 to 9 months). 10 completed treatment, 1 did not because of intolerance and did not receive other treatment. 1 patient with only TST positive was considered a false positive and did not receive treatment. During follow-up no TB reactivation was reported.

23 patients with LBTI received treatment other than biological therapy during follow-up, of them 8 received LBTI treatment. There was no TB reactivation during follow up.

The Kappa concordance between QTF and TST was estimated: moderated in the whole sample, poor in the patients treated with GC at screening, and substantial when the patients treated with GC at screening were excluded. Results are shown in Table 1.

Conclusion: QTF seems to be the most appropriate LTBI screening test in patients with RD treated with GC. Screening and treatment of LTBI in patients with RD treated with or without biological agents was effective in reducing TB reactivation.

Romosozumab After Denosumab Improves Lumbar Spine and Maintains Total Hip Bone Mineral Density in Postmenopausal Women with Low Bone Mass

Michael R McClung[1], Michael A Bolognese[2], Jacques P Brown[3], Jean-Yves Reginster[4], Bente Langdahl[5], Norma Ruiz-Santiago[6], Yifei Shi[6], Maria Rojeski[6], Jen Timoshanko[7], Cesar Libanati[7], Helina Kassahun[6] and Mary Oates[6], [1]Oregon Osteoporosis Center, Portland, OR, [2]Bethesda Health Research Center, Bethesda, MD, [3]Laval University and CHU de Québec (CHUL) Research Centre, Québec City, Canada, [4]University of Liège, Liège, Belgium, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Amgen Inc., Thousand Oaks, CA, [7]UCB Pharma, Brussels, Belgium

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Romosozumab, an anti-sclerostin antibody that increases bone formation while decreasing bone resorption, reduces fracture risk within 12 months. Here we evaluate the effects of transitioning from denosumab to romosozumab in treatment-naïve patients.

Methods: This phase 2 trial (NCT00896532) enrolled postmenopausal women with a lumbar spine, total hip, or femoral neck T-score ≤ –2.0 and ≥ –3.5. Patients were randomized to placebo or various doses of romosozumab monthly or every 3 months from baseline to month (M) 24, were rerandomized to 12 months of denosumab 60 mg every 6

Treatment from M0–24: Treatment from M24–36: Treatment from M36–48:	Placebo Placebo Romosozumab 210 mg QM N = 12	Placebo Denosumab 60 mg Q6M Romosozumab 210 mg QM N = 16
Bone Mineral Density, mean % change (95% CI)		
Lumbar spine		
M0–24	2.7 (0.2, 5.1)	−0.8 (−2.8, 1.1)

M48	321.0 (276.5, 407.0)	532.0 (378.0, 661.0)

β-CTX = β-isomer of the C-terminal telopeptide of type I collagen, CI = confidence interval, M = month, P1NP = procollagen type 1 N-terminal propeptide, Q1 = quartile 1, Q3 = quartile 3, QM = monthly, Q6M = every 6 months.

Table

months or placebo (M24–36), and then all were to receive romosozumab 210 mg monthly for 12 months (M36–48). Results for the overall population have been previously published (McClung et al, J Bone Miner Res 2018; Kendler et al, Osteoporos Int 2019). Here we present data from a subset of patients who were randomized to placebo for 24 months, denosumab (n = 16) or placebo (n = 12) for 12 months, and then romosozumab for 12 months.

Results: In patients who were randomized to placebo followed by denosumab, romosozumab treatment for 12 months maintained BMD gained during denosumab treatment at the total hip (mean change from end of denosumab treatment, 0.9%) and further increased BMD gains at the lumbar spine (mean change from end of denosumab treatment, 5.3%) (Table). As expected, P1NP and CTX levels decreased with denosumab. Upon transition to romosozumab (M36–48), P1NP levels initially increased and gradually returned to baseline by M48 while CTX gradually increased to baseline levels.

In patients who transitioned to romosozumab after 36 months of placebo, BMD increased at the lumbar spine and total hip (Table). P1NP levels initially increased with romosozumab and gradually returned to baseline by M48 while median CTX level remained below baseline with romosozumab treatment.

Conclusion: BMD response in the placebo to romosozumab group was similar to that observed in other studies. Transitioning to romosozumab after 12 months of denosumab further improves lumbar spine BMD and maintains total hip BMD.

Bone Health in Patients with Psoriatic Arthritis in the National Swiss Cohort: A Cross-sectional Study

Diana Camelia Dan[1], Youssef Ibrahimy[2], Berengere Aubry-Rozier[3] and Daniel Aeberli[4], [1]Lausanne University Hospital, Lausanne, Switzerland, [2]University of Lausanne, Lausanne, Switzerland, [3]Hôpital orthopédique, Lausanne, Switzerland, [4]University Hospital of Bern, Bern, Switzerland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is much controversy surrounding the loss of bone mass in patients with psoriasis arthritis (PsA). We wanted to evaluate the prevalence of osteoporosis (OP) and fracture in patients with PsA in the Swiss Clinical Quality Management (SCQM) cohort, a large national database of patients with inflammatory arthritis; to study different factors influencing bone health and the correlation between disease activity, treatment and occurrence of densitometric osteoporosis or fracture.

Methods: We analyzed all PsA-patients included in the cohort from 2006 to April 2019. We evaluated demographic and clinical data: age, gender, BMI, disease duration, smoking/alcohol habits, patient's and physician's global as-

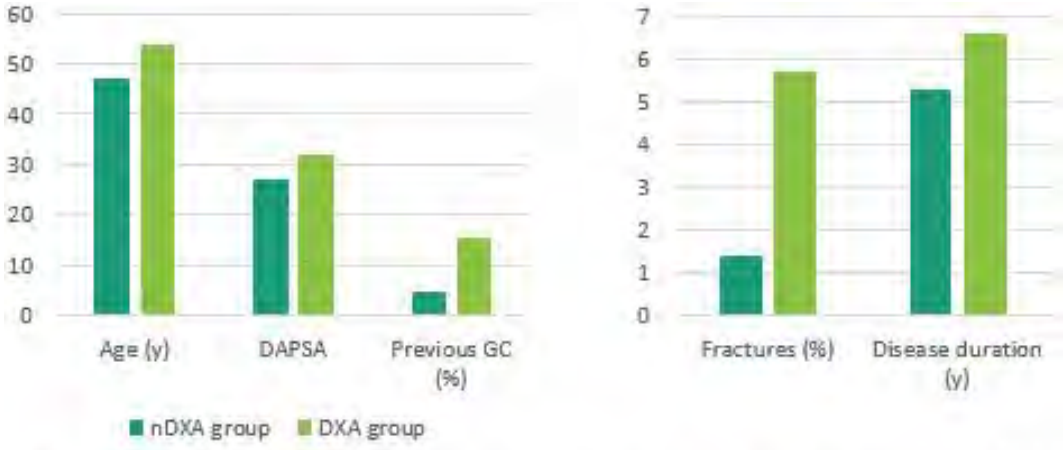

Figure 1: *Significant differences between patients with vs without DXA*

	NO OSTEOPOROSIS N=244	OSTEOPOROSIS N=51	P value
Age (years)	55 ± 9	59 ± 12	0,009*
Female (%)	67,6	68,6	0,89
Disease duration (years)	6,3 ± 8	7,7 ± 9,9	0,339
Body mass index	26,6 ± 5	22,7 ± 4,8	0,0001*
Smoking (%)	19,9	29	0.69
Alcohol consomption(%)	77,2	68,6	0,37
HAQ	0,7 ± 0,5	0,9 ± 0,7	0,03*
PGA	3,8 ± 2,2	4,1 ± 2,5	0,329
ESR (mm/1h)	16,6 ± 16,7	20,8 ± 20,9	0,2
CRP (mg/L)	9,1 ± 12,8	16,9 ± 36,2	0,001*
DAS28-ESR score	3,2 ± 1,4	3,6 ± 1,3	0,08
DAS28-CRP score	3,1 ± 1,2	3,4 ± 0,9	0,04*
DAPSA score	29,6 ± 23,6	37,8 ± 43,5	0,04*
Fracture history (%)	2	3,9	0,4
TNF inhibitors (%)	35,7	25,5	0,16
Prednisone (%)	15,2	13,7	0,069

Table 1: *Characteristics of DXA patient with and without OP. HAQ: health assessment questionnaire; PGA: Physician global assessment; *: significant.*

sessment, joint count, HAQ, medication and inflammatory activity measured by ESR, CRP, DAS 28 and DAPSA score. We compared patients with BMD measurement (DXA) with the group without DXA (nDXA). In DXA group we analyzed patients according to osteoporotic status and did subgroup analysis in premenopausal, menopausal women and men. We used STATA program vs 16, chi2-test, student's t-test and simple and multiple regression models for statistics. Statistical significance was set up at $p < 0.05$.

Results: Of the 2443 patients, 545 had a DXA. The age of scanned patients was 18-84 years. Only 295 BMD data were available for analysis. DXA patients were 6.4 years older (54.2±11,1 vs 47.8±12.4 years, p< 0.001), and were more female (67% vs 43%). Duration of the disease was longer (6.6±8.3 vs 5.3±7.1 y, p< 0.001) in the DXA group. DAS28-CRP and DAS28-ESR were higher in DXA group (3,1 ± 1,2 vs 2,9 ± 1,1, p< 0,04 and 3,2 ± 1,4 vs 3 ± 1,3, p< 0,002, respectively), as was the DAPSA score (32 ± 30 vs 27 ± 20 p< 0.04). Patients in DXA group were more exposed to prednisone and conventional DMARDs (15.4% vs 4.7%, p< 0.001 and 51.7% vs 43%, p< 0.01 respectively). There were more fractures in the DXA- than in nDXA-group (5.7% vs 1.4%, P< 0.001) (Figure 1).

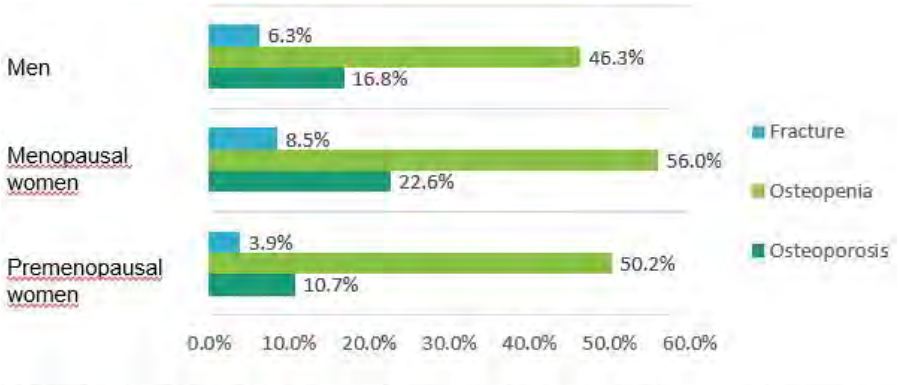

Figure 2: *Prevalence of fractures, osteopenia and osteoporosis in patient subgroups.*

In the DXA group 18.4% patients had OP and 50.2% osteopenia. Patient characteristics are shown in Table 1. We confirmed a positive correlation between femoral and lumbar T-score and BMI, and negative correlation between age and femoral T-score. Disease duration was inversely correlated with femoral, but not lumbar T-score. Interestingly, other variables, including disease activity, showed no correlation with T-score, but OP patients had higher disease activity.

Subgroup analysis (Figure 2) showed higher OP prevalence in postmenopausal women (22,6%) vs in men (16.8%) or premenopausal women (10.7%) in concordance with the fracture rate (8.3% vs 6.3% vs 3.9%). T-score was lower and the disease activity was higher in postmenopausal women compared to the others groups.

Conclusion: Our data suggest that Swiss clinician are aware of risk of poor bone-health in PsA patients and perform DXA in this population even in younger patients and in men. Interestingly, we describe that the patients with OP had higher disease activity and poorer functional status than patients without OP.

Longitudinal studies are needed to evaluate bone quality, fractures, and relationship between bone health in PsA and disease associated factors. They should integrate parameters of bone turnover and use an appropriate control group.

Abstract Number: 0103

The Association of Methotrexate, Sulfasalazine and Hydroxychloroquine Use with Incident Fractures in Postmenopausal Women with Rheumatoid Arthritis: Findings from the Women's Health Initiative

Rachel Elam[1], Sandeepkumar Gupta[2], Omar Tolaymat[2], Sowmya Vasan[3], Carolyn Crandall[4], Jean Wactawski-Wende[5], Karen Johnson[6] and Laura Carbone[2], [1]Augusta University, Evans, GA, [2]Augusta University, Augusta, GA, [3]WHI, Seattle, WA, [4]UCLA, Los Angeles, CA, [5]University of Buffalo, Buffalo, NY, [6]University of Tennessee Health Sciences Center, Memphis, TN

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: This study was conducted to evaluate the extent to which disease modifying antirheumatic medications (DMARDs) used as part of triple therapy for treatment of rheumatoid arthritis (RA) including methotrexate, sulfasalazine and hydroxychloroquine are associated with incident fractures in postmenopausal women with RA.

Methods: Of the 161,808 postmenopausal women who were enrolled in the Women's Health Initiative (WHI), all who self-reported at baseline a history of RA and had either a DMARD and/or a biologic use or presence of anti-cyclic citrullinated peptide (Anti-CCP) antibody were included as RA patients. There were too few users of standard triple therapy (methotrexate, sulfasalazine and hydroxychloroquine use (n=9)) to determine the association of standard triple therapy use with incident fractures. Therefore, incident fractures in postmenopausal women with RA following use of methotrexate, sulfasalazine and/or hydroxychloroquine alone or as "combination therapy" (methotrexate and sulfasalazine or methotrexate and hydroxychloroquine) were estimated by Cox proportional hazards models using hazard ratios (HR) and 95% confidence intervals (CI) after consideration of potential confounders.

Results: here were 1,201 postmenopausal women with RA enrolled in WHI included in these analyses, of which 74% were Caucasian, 17% were African American and 9% were of other or unknown race/ethnicity. Of the postmenopausal women with RA, 421 (35%) had not used either methotrexate, sulfasalazine or hydroxychloroquine while 519 (43%) had used methotrexate, 83 (7%) sulfasalazine and 363 (30%) hydroxychloroquine at some time during study follow-up. Over a median length of 6.46 years of follow-up, in multivariable adjusted models, no statistically significant association was found between methotrexate (HR 1.1 [95% CI 0.8-1.6]), sulfasalazine (HR 0.6 [95% CI 0.2-1.5]) or hydroxychloroquine use (HR 1.0 [95% CI 0.7-1.5]) and incident fractures or between combination therapy with methotrexate and sulfasalazine or methotrexate and hydroxychloroquine use (HR 0.9 [95% CI 0.5-1.6]) and incident fractures.

Conclusion: In conclusion, use of methotrexate, sulfasalazine or hydroxychloroquine alone or in combination is not associated with incident fractures in postmenopausal women with RA. Postmenopausal women with RA receiving any component of triple therapy should not be expected to have any substantial reduction in fracture risk from use of these medications.

Abstract Number: 0104

Bone Effects of One-year Tofacitinib Treatment in Rheumatoid Arthritis

Attila Hamar[1], Anita Pusztai[2], Edit Végh[1], Ágnes Horváth[1], Katalin Gulyás[1], Szilvia Szamosi[1], Zsófia Pethő[1], Nóra Bodnár[1], Boglárka Soós[1], Monika Czókolyová[1], Sándor Szántó[1], Gabriella Szűcs[1], Harjit Bhattoa[1], Gábor Nagy[1], Gábor Tajti[1], Andrea Domján[1], Katalin Hodosi[1] and **Zoltán Szekanecz**[1], [1]University of Debrecen, Debrecen, Hungary, [2]University of Debrecen Faculty of Medicine, Department of Rheumatology, Debrecen, Hungary

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Oral JAK inhibitor, tofacitinib appeared as a new therapeutic option, beside biological therapies, which has already proven its safety and effectivity in RA, but we lack of knowledge how it affects density of bone

structures and bone turnover markers. The aim of this study was to assess the effects of one-year tofacitinib therapy on bone metabolism in patients with RA.

Methods: Altogether 30 RA patients with active disease were recruited and treated with tofacitinib in this 12-months follow-up study. Mean age of patients were 52.8±10.0 years, duration of rheumatoid arthritis were 7.7±5.0 years. Half of the patients haven't received biological treatment prior tofacitinib therapy, other half of the patients switched to tofacitinib therapy after completing washout. 15 patients received 2x5mg and 15 patients received 2x10mg tofacitinib daily for 12 months. On both arms 2-2 patients have discontinued treatment and excluded from the study. Assessments were performed at baseline, month 6 and 12. Levels of CRP and IgM rheumatoid factor (RF) antibodies were measured by quantitaive nephelometry and levels of anti-CCP, sclerostin, osteocalcin (OC), P1NP were assesed by ELISA. Bone density was assesed by DXA (dual-energy X-ray absorptiometry, Lunar) and pQCT imaging techniques. Levels of DKK-1, OPG, RANKL were measured by multiplex microbead immunoassay (BioLegend LEGENDplex). In addition, disease activity (DAS28), age and disease duration were also measured. Correlations were determined by Spearman's analysis. Univariate and multiple regression analysis using the stepwise method was applied to investigate independent associations between DXA measurements (dependent variables) and laboratory parameters (independent variables).

Results: Tofacitinib significantly reduced DAS28 ($p< 0.001$) and HAQ values ($p=0.001$), also level of CRP ($p< 0.001$) and We ($p=0.014$). With respect to bone biomarkers we have experienced significant increase in levels of OC ($p=0.013$), OPG ($p=0.006$), sclerostin ($p=0.026$) and vitamin-D ($p=0.017$) at month 6, also in levels of OPG and vitamin-D ($p=0.004$, $p=0.003$) at month 12. We have found decrease in levels of CTX at month 6 ($p=0.009$) and 12 ($p=0.003$). When we examined the groups separately, we've found significant increase in levels of P1NP ($p=0.027$, $p=0.005$), OPG ($p=0.005$, $p=0.002$) and vitamin-D ($p=0.001$, $p=0.004$) at month 6 and 12, also in OC at month 6 ($p=0.027$) in Group A (2x5mg). In Group B (2x10mg) we've experienced a significant decrease in levels of phosphate and CTX at month 6 and 12 ($p=0.012$, $p=0.021$, and $p=0.005$, $p=0.007$).

Conclusion: One year tofacitinib treatment effectively stabilized bone density in patients with rheumatoid arthritis, and led to the increase of bone turnover markers, which is beneficial for ossification in long term.

Use of Peripheral Quantitative Computed Tomography in the Assessment of Bone Mineral Density in Anti-TNF-treated Rheumatoid Arthritis and Ankylosing Spondylitis Patients

Balázs Juhász[1], Katalin Gulyás[1], Ágnes Horváth[1], Edit Végh[1], Anita Pusztai[2], Ágnes Szentpétery[3], Zsófia Pethő[1], Nóra Bodnár[1], Attila Hamar[1], Levente Bodoki[1], Harjit Bhattoa[1], Éva Szekanecz[1], Katalin Hodosi[1], Andrea Domján[1], Szilvia Szamosi[1], Csaba Horváth[4], Sándor Szántó[1], Gabriella Szűcs[1], Hennie Raterman[5], Oliver FitzGerald[6] and **Zoltán Szekanecz**[1], [1]University of Debrecen, Debrecen, Hungary, [2]University of Debrecen Faculty of Medicine, Department of Rheumatology, Debrecen, Hungary, [3]Uppsala University Hospital, Uppsala, Sweden, [4]Semmelweis University, Budapest, Hungary, [5]Northwest Clinics, Alkmaar, Netherlands, [6]Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) have both been associated with generalized and localized bone loss. Inflammatory cytokines like tumor necrosis factor (TNF) have been implicated in bone resorption and, therefore, anti-TNF biologics may improve bone status. There have been very few observational or longitudinal data on the use of peripheral quantitative computed tomography (QCT) for determining changes in bone status in anti-TNF-treated RA and AS patients. Therefore, we assessed volumetric bone mineral density (BMD) by forearm QCT in conjunction with disease activity, dual-energy X-ray absorptiometry (DXA) and bone biomarker parameters in a mixed cohort of RA and AS patients.

Methods: ifty-three consecutive patients including 36 RA patients treated with etanercept (ETN) or certolizumab pegol (CZP) and 17 AS patients treated with ETN were included in a 12-month follow-up study. Volumetric (3-dimensional) and areal (2-dimensional) BMD were determined by peripheral QCT and DXA, respectively. Bone biomarkers, such as calcium, phosphate, PTH, osteocalcin, soluble RANKL, vitamin D3, P1NP, CTX, sclerostin, DKK-1 and cathepsin K (CATHK) were assessed by ELISA. DAS28 and BASDAI served as markers of disease activity in RA and AS, respectively. Determinants of volumetric BMD were investigated by uni- and multivariable regression analyses, as well as RM-ANOVA.

Results: One-year ETN or CZP therapy arrested further progression of bone loss in the radius in RA and AS as determined by peripheral QCT. Volumetric (QCT) and areal (DXA) BMD showed significant, variable correlations with each other ($p< 0.05$). The univariable analysis showed that total QCT BMD after 12 months was inversely determined by disease activity at baseline ($p=0.030$). Cortical BMD was negatively determined by baseline disease activity ($p=0.005$), as well as baseline ($p=0.025$) and 12-month CATHK levels ($p=0.033$). The negative associations of 12-month total ($p=0.030$) and cortical BMD ($p=0.012$) with baseline disease activity was also confirmed by multivariable analysis. The change in QCT trabecular BMD between baseline and 12 months was related to the anti-TNF treatment together with higher baseline vitamin D3 levels (VITD3-0) ($p=0.031$). In addition, TNF inhibition and lower cathepsin K determined cortical BMD changes over the one-year period ($p=0.006$).

Conclusion: QCT may be a suiTable methodology to measure volumetric BMD in various compartments (trabecular and cortical) of the radius. QCT confirmed that biologics may arrest generalized bone loss. Moreover, we identified baseline parameters, such as disease activity, CATHK and possibly VITD3 that may predict the effects of one-year anti-TNF treatment on volumetric BMD changes over time.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To discriminate osteoporosis and osteopenia using a quantitative computed tomography (QCT) radiomics signatures and clinical variables.

Methods: This retrospective study enrolled 635 patients with QCT images and clinical characteristics from November 2016 to November 2019. 851 radiomics features extracted from the QCT images of the third lumbar vertebra of each patients. Minimum redundancy and maximum relevance (mRMR) and least absolute shrinkage and selection operator (LASSO) were used for features selection. A radiomic nomogram was constructed based on the radiomics signatures and clinical characteristics for diagnosing osteoporosis and osteopenia. We systematically evaluated the diagnostic performance of the combined radiomics model, clinical model and radiomics model. Moreover, we investigated the value of the radiomics score in normal group and abnormal group.

Results: A total of 6 optimal radiomics features were selected to construct quantitative computed tomography (QCT) based signatures. The individualized nomogram included these features and 3 clinical characteristics (age, alkaline phosphatase, homocysteine) achieved good discrimination performance in both the training cohort (N=414; area under the curve (AUC) 0.96, 95% CI 0.95–0.98) and the validation cohort (N=176; AUC 0.96, 95% CI 0.92–1.00). The alone radiomics score also demonstrated significant differences in osteoporosis and osteopenia ($P < 0.001$).

Conclusion: This study presents a radiomics nomogram that incorporates the radiomics score and clinical risk factors, which can serve as a reliable and powerful tool for discriminating osteoporosis and osteopenia.

Abstract Number: 0107

Effects of Abaloparatide on Modeling and Remodeling Based Bone Formation

David W Dempster[1], Hua Zhou[1], Sudhaker D Rao[2], Chris Recknor[3], Paul D Miller[4], Benjamin Z Leder[5], Miriam Annett[6], Michael S Ominsky[6] and Bruce H Mitlak[6], [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, West Haverstraw, NY, [2]Bone & Mineral Research Laboratory, Henry Ford Health System, Detroit, MI, Detroit, MI, [3]United Osteoporosis Centers, Gainesville, GA, Gainesville, GA, [4]Colorado Center for Bone Research, Lakewood, CO, Lakewood, CO, [5]Mass General Hospital, Harvard Medical School, Boston, MA, Boston, MA, [6]Radius Health, Inc., Waltham, MA, Waltham, MA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

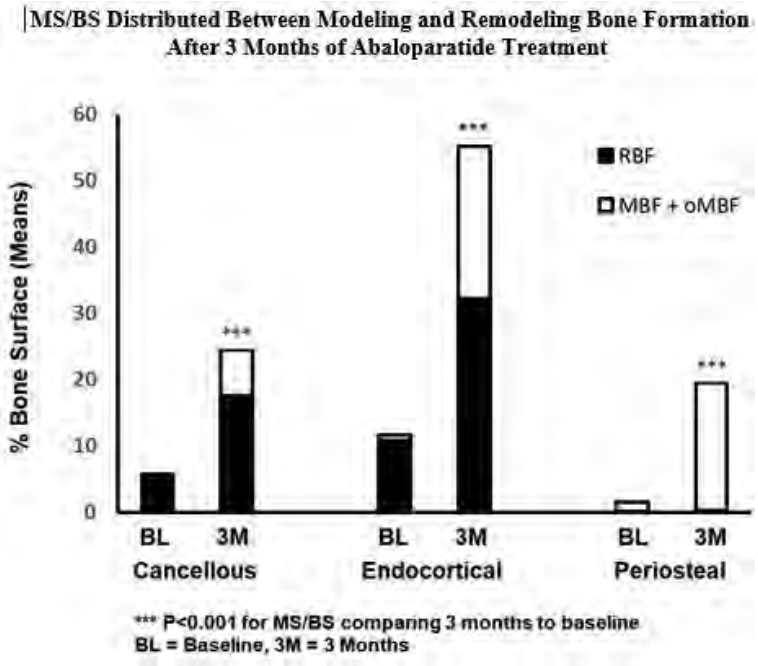
Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate abaloparatide-induced changes in the bone formation indices of mineralizing surface (MS), bone formation rate (BFR) and mineral apposition rate (MAR); and to assess the effect of abaloparatide on 3 types of bone formation: modeling-based formation (MBF), remodeling-based formation (RBF), and overflow MBF (oMBF) in transiliac bone biopsies.

Methods: Twenty-three postmenopausal women with osteoporosis were enrolled at 4 centers in the US; all received open label abaloparatide (80 µg/day SC) for 3 months in this phase 3 study. Subjects were administered double fluorochrome labeling at baseline and prior to biopsy at 3 months. Bone formation indices were evaluated by histomorphometry. Changes at 3 months from baseline were assessed for the indices on cancellous, endocortical, intracortical and periosteal bone envelopes. Sites of bone formation were designated as MBF if the underlying cement line was



Figure

smooth, RBF if scalloped, and oMBF if formed over smooth cement lines adjacent to scalloped reversal lines. Paired t-tests were used to compare the differences of the indices between baseline and 3 months in the 4 bone envelopes.

Results: Bone biopsies were obtained from 19 of the 23 subjects were enrolled in the study; all biopsies were evaluable. After 3 months of abaloparatide treatment, MS/ BS increased significantly from baseline in all of the 4 bone envelopes ($p < 0.001$), BFR/BS increased significantly in cancellous, endocortical and intracortical envelopes ($p < 0.001$); no significant change was observed in MAR in the 4 bone envelopes. Consistent with MS/BS, RBF/BS, MBF/BS and oMBF/BS increased significantly from baseline in the cancellous and endocortical envelopes ($p < 0.001$), as did MBF/BS in the periosteum ($p < 0.001$).

Conclusion: This study provides histomorphometric evidence that abaloparatide has a robust effect on bone formation in postmenopausal women with osteoporosis after 3 months of treatment. Both modeling- and remodeling-based bone formation were stimulated. This study also shows that abaloparatide has a favorable effect on cortical bone by increasing bone formation in endocortical and periosteal envelopes.

Abstract Number: 0108

The Relationship Between Body Fat Percentage and Bone Mineral Density in Rheumatoid Arthritis Patients

Anastasia- Vasiliki Madenidou[1] and Marwan Bukhari[2], [1]Rheumatology Department, University Hospitals of Morecambe Bay NHS Trust, Barrow-in-Furness, United Kingdom, [2]Rheumatology Department, University Hospitals of Morecambe Bay NHS Trust, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Currently, Dual-Energy X-ray Absorptiometry (DEXA) scans are used to determine fracture risk by calculating Bone Mineral Density (BMD). It is well established that body weight is one of the strongest predictors of bone mass, but there is ongoing controversy as to whether fat mass is a better predictor of bone density. Our research set out to find out whether there is association between body fat percentage and BMD in patients with rheumatoid arthritis stratified by steroid use.

Methods: Data were used from a cohort of rheumatoid arthritis (RA) patients referred for DEXA scan to a District General Hospital between 2004 and 2010. The following were recorded: age, sex, weight, height, body mass index (BMI), BMD at L1-L4, BMD at femoral neck (left and right) and BMD at hip (left and right). Multivariate linear regression was used to identify associations between body fat percentage and BMD at L1, L2, L3, L4, right neck of femur and left neck of femur in RA patient on steroids or not. Data was adjusted for age, sex, weight, height and BMI at scan.

Results: 1,527 patients were used in the study. 79% were female and mean age was 64.3 years (SD 11.6). Mean height was 1.62 m (SD 8.57), mean weight was 71.6 kg (SD 16.4 SD) and mean BMI was 26.8 kg/cm2 (SD 5.2). The

Table 1. The Bone mineral density (BMD) of lumbar spine, hips and femoral necks

Level	Mean BMD (SD)
L1	0.10 (0.19)
L2	1.08 (0.22)
L3	1.16 (0.23)
L4	1.16 (0.24)
Left Femoral Neck	0.85 (0.15)
Left Femur Total	0.90 (0.17)
Right Femoral Neck	0.85 (0.15)
Right Femur Total	0.90 (0.17)

Table 2. The linear relationship between BMD and body fat percentage (age-, sex-, weight, height- and BMI adjusted)

Level	On steroids β (95% CI) (Body Fat Percentage)	Not on steroids β (95% CI) (Body Fat Percentage)
L1	**0.34 (0.20, 0.48)**	0.10 (-0.08, 0.29)
L2	**0.39 (0.24, 0.55)**	0.03 (-0.18, 0.25)
L3	**0.31 (0.14, 0.49)**	0.02 (-0.20, 0.25)
L4	0.13 (-0.05, 0.32)	-0.07 (-0.31, 0.16)
Left Femoral Neck	0.07 (-0.03, 0.18)	-0.00 (-0.14, 0.13)
Left Femur Total	**0.18 (0.05, 0.32)**	0.07 (-0.07, 0.22)
Right Femoral Neck	0.05 (-0.07, 0.17)	-0.06 (-0.20, 0.07)
Right Femur Total	0.11 (-0.02, 0.25)	0.04 (-0.11, 0.20)

results of BMD are presented in **Table 1**. The results of the linear regression analysis of the relationships between fat percentage and BMD at each level are presented in the **Table 2**.

Conclusion: This study identifies that fat percentage is a predictor of the bone density at L1- L3 in RA patients on steroids. This association reflects how steroids affect the bone metabolism in different regions of the skeleton as bone loss is more marked in the trabecular bone (high content in vertebrae) in patients on steroids. The fat distribution may change in patients on steroids who can develop central obesity with the lower limbs spared and even wasted. This altered fat distribution may explain the association of fat percentage and bone density at a lumbar spine level and not at neck or hip level. Our results also suggest that the Fracture Risk Assessment (FRAX) tool underestimates the risk of fracture in patients on steroids as it takes into consideration the bone density at the femoral neck and not at the lumbar spine.We suggest further research in finding better tools for assessing fracture risk in glucocorticoid-induced osteoporosis.

Glucocorticoid-Induced Osteoporosis: Are We Practicing Prevention?

Eileen Rife[1], Emejuaiwe Nkechinyere[2] and Jose Leon de la Rocha[3], [1]Louisiana State University, Metairie, LA, [2]Department of Veterans Affairs, New Orleans, LA, [3]Louisiana State University, Auburn, AL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Descriptive study designed to assess compliance to evidence-based practice guidelines for the prevention of Glucocorticoid-Induced Osteoporosis (GIOP).

Methods: We queried the electronic database of the Department of Veterans Affairs Hospital in New Orleans and collected data on all veterans who filled systemic glucocorticoid (GC) prescriptions during a 2-year study period (January 1, 2016 - December 31, 2017). Data was collected on GC dosage and duration of therapy - with long term GC therapy defined as continuous treatment for ≥3 months (90 days). Data was also collected on demographics, specialty of the ordering prescriber, bone mineral density (BMD) testing, prescriptions for anti-osteoporotic therapy, and prescriptions for Vitamin D and/or Calcium supplementation. The recommendations followed were in accordance with the American College of Rheumatology, American Geriatrics Society, Institute of Medicine, and National Osteoporosis Foundation guidelines.

Results: During our study period, a total of 1,962 separate GC prescriptions were filled. Of those, 1,051 unique patients were identified. A total of 206 patients were prescribed GC for ≥90 days during the study window and they comprised our study population. Patients were predominately male (97%); 51% self-identified as Caucasian, and 46% as African American. A majority (68%) of prescriptions were for less than 10mg prednisolone-equivalent doses. Most prescriptions (63% n=130) were for >7.5mg prednisolone-equivalent doses for greater than 90 days. Primary care providers were the main prescribers of long-term GC (51%, n=105), followed by rheumatologists (24%, n=49). BMD testing was performed in 20% of patients (n=42). Of those tested, 14% (n=6) were found to have osteoporosis and 21% (n=9) had osteopenia. Approximately half of our study population (52%) were prescribed Vitamin D supplementation with 80% prescribed the guideline-recommended dose. Twenty-six percent of patients were prescribed supplemental Calcium, with 44% prescribed the guideline-recommended dose. Fewer than 10% of the patients taking greater than 7.5mg for ≥3 months (and meeting ACR treatment guidelines) were on primary prophylaxis with anti-osteoporotic therapy.

Conclusion: Our findings are overall worsethan previously published data. GIOP remains an under recognized and undertreated condition despite updated evidence-based practice guidelines. Bone mineral density screening rates remain low, as do Calcium/Vitamin D supplementation and primary prophylaxis with anti-osteoporotic therapy.

Does Urate Directly Influence Bone Turnover? Randomized Controlled Trial of Inosine Supplementation

Nicola Dalbeth[1], Anne Horne[2], Borislav Mihov[1], Tony Merriman[3], Gregory Gamble[1], Lisa Stamp[4] and Ian Reid[1], [1]University of Auckland, Auckland, New Zealand, [2]The University of Auckland, Auckland, New Zealand, [3]University of Otago, Dunedin, New Zealand, [4]University of Otago Christchurch, Christchurch, New Zealand

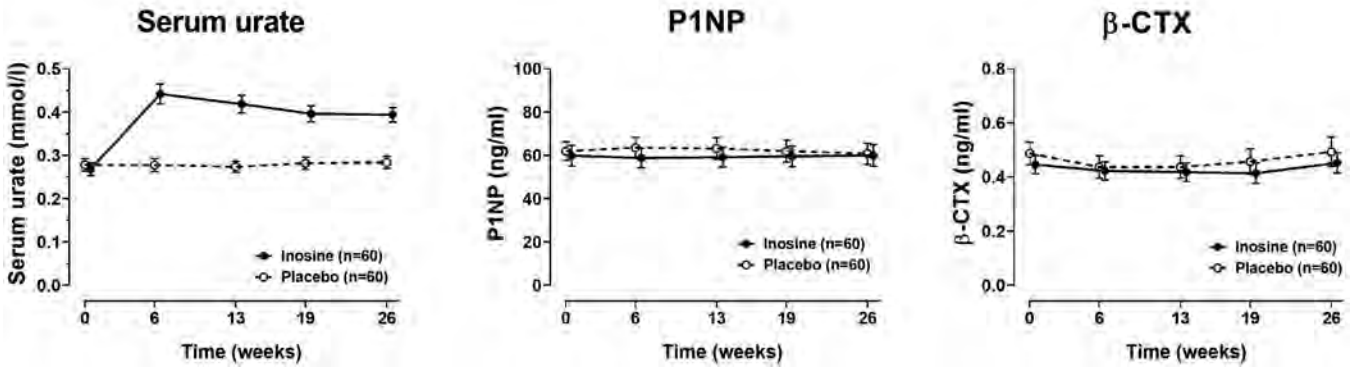
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Observational studies have reported that serum urate positively correlates with bone mineral density (BMD) and that hyperuricaemia is protective for the development of osteoporosis and risk of fragility fractures. In laboratory studies, urate has anabolic effects on bone through differential effects on osteoblast and osteoclast function. However, Mendelian randomization studies do not support a causal role for serum urate in BMD. Inosine is a purine nucleoside that increases serum urate concentrations. The aim of this study was to determine whether moderate hyperuricaemia induced by inosine supplements influences bone turnover markers over a six-month period.

Methods: Six month randomised, double-blind, placebo-controlled trial of 120 post-menopausal female participants. Key exclusion criteria were bone mineral density T-score below -2.5 at the total hip, femoral neck or lumbar spine, previous fragility fracture, bisphosphonate therapy, gout, kidney stones, and urine pH ≤5.0. Participants were randomised 1:1 to either placebo or inosine 500mg twice daily. The co-primary endpoints were change in procollagen type-I N-terminal propeptide (P1NP) and change in β-C-terminal telopeptide of type I collagen (β-CTX). Key secondary endpoints were measures of kidney function, blood pressure and other features of metabolic syndrome. Change in BMD measured by dual-energy x-ray absorptiometry was an exploratory endpoint. Data were analysed on an intention to treat basis, using a mixed models approach to repeated measures.

Results: Administration of inosine supplements led to a significant increase in serum urate over the study period (P< 0.0001 for all follow-up time-points, Figure). At week 26, the mean change in serum urate was +0.13 mmol/L (+2.2mg/dL) in the inosine group and 0.00mmol/L (0mg/dL) in the placebo group. There was no difference in P1NP or β-CTX

Figure. Serum urate, P1NP, and β-CTX over the study period. Data are presented as mean (95% CI).



between groups over the six months (false detection rate protected pairwise comparisons at each time point all P > 0.61 for P1NP and P=0.37 for β-CTX, Figure). No significant treatment by time interaction differences were observed in serum creatinine, systolic or diastolic blood pressure, body mass index, fasting lipids, or HbA1c over the study period (all P >0.13). Consistent with the bone turnover marker results, there were no significant changes in BMD between groups over the six months (P >0.48 for all sites). Adverse events and serious adverse events were similar between the two groups.

Conclusion: Although inosine supplementation leads to sustained increases in serum urate over a six month period, it does not alter markers of bone turnover. These findings do not support the concept that urate has direct biological effects on bone turnover.

Assessment and Treatment of Glucocorticoid-Induced Osteoporosis in a Rheumatology Clinic

Amanda Stefl[1], **Shikha Singla**[2], Jessica Michaud[1], Kama Thomas[2], Lisa Rein[2] and Mary Ellen Csuka[2], [1]Froedtert Hospital, Milwaukee, WI, [2]Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GC) are used as a long-term treatment option for an estimated 1% of the US population. The American College of Rheumatology has maintained guidelines to aid in the prevention and treatment of glucocorticoid-induced osteoporosis (GIOP). These recommendations include optimization of calcium and vitamin D intake and initiation of oral bisphosphonates based on age, fracture risk, and GC dose. The purpose of this study was to evaluate whether patients at the Rheumatology Clinic of Froedtert & the Medical College of Wisconsin's Froedtert Hospital who were prescribed chronic high-dose prednisone (> 7.5mg/day for ≥ 3 months) for a rheumatologic disease underwent a comprehensive assessment for GIOP.

Methods: This was a retrospective quality improvement study of 61 patients aged 40 to 90 years who were prescribed chronic high-dose prednisone by Froedtert Hospital Rheumatology Clinic providers between January 1, 2017 and December 31, 2017. The primary outcome was the percentage of patients who had a comprehensive assessment for GIOP, defined as assessment of calcium, vitamin D, dual-energy x-ray absorptiometry (DXA), and Fracture Risk Assessment Tool (FRAX™). Secondary outcomes included the percentage of patients with osteoporotic and non-osteoporotic fractures during the follow-up period; the percentage of patients starting an osteoporosis medication during the follow-up period; new osteopenia or osteoporosis diagnosis during the follow-up period; assessment of calcium, vitamin D, DXA and FRAX as individual measures; presence of calcium supplementation on the medication list; and appropriate vitamin D treatment.

Results: A comprehensive GIOP assessment including calcium, vitamin D, DXA imaging, and FRAX calculation was completed in 7% of the study population. Approximately 21% of patients had 0 factors assessed, 39% had one fac-

tor assessed, 16% had two factors assessed, and 16% had three factors assessed. The lowest rates were with FRAX calculation at 11% and DXA imaging at 26%. During the follow-up period, 8% of patients developed a new fracture, 8.5% were diagnosed with osteopenia or osteoporosis, and 14.9% were started on a new osteoporosis medication. The statistically significant results within the subgroup analyses included a higher rate of: calcium supplementation on the medication list (79% vs 32%, p=0.004) in patients with baseline diagnosis of osteoporosis; number of individual components of GIOP assessment completed (p=0.049) and DXA (33% vs 0%, p=0.026) in patients ≥ 50 years of age; comprehensive GIOP assessment (25% vs 2%, p=0.022), number of individual components (p=0.003), and FRAX (42% vs 4%, p=0.002) in patients who met with rheumatology clinic pharmacist; and number of individual components (p< 0.001), calcium assessment (77% vs 44%, p=0.016), and vitamin D level assessment (77% vs 41%, p=0.008) in patients taking very high-dose prednisone.

Conclusion: A comprehensive GIOP assessment was not routinely completed when patients were initiated on a high-dose GC. When evaluating the individual components of the assessment, DXA and FRAX were not completed as regularly as calcium and vitamin D assessments.

Abstract Number: 0112

Description of Risk Factors at Baseline and Need of Bone Agent According to Hadji Recommendations in Patients Taking Aromatase Inhibitors as Breast Cancer Therapy

David Montero-Seisdedos[1], Oihane Ibarguengoitia-Barrena[2], Lucía Vega-Álvarez[2], Carmen Lucía García Gomez[2], Itziar Calvo-Zorrilla[3], Juan M. Blanco-Madrigal[2], Maria Esther Ruiz-Lucea[2], María Luz García-Vivar[2], Eva Galindez-Agirregoikoa[2], Ana R. Inchaurbe-Pellejero[2], Olaia Fernandez-Berrizbeitia[2], Clara E. Perez-Velasquez[2], Eduardo Cuende-Quintana[4], Amaia Bilbao-González[3] and Iñaki Torre-Salaberri[3], [1]Basurto University Hospital, Bilbao, Pais Vasco, Spain, [2]Basurto University Hospital, Bilbao, Spain, [3]University Hospital of Basurto, Bilbao, Pais Vasco, Spain, [4]Basurto University Hospital, Madrid, Spain

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: A well-known adverse effect of aromatase inhibitors (AI) in the bone is the loss of mineral density with the consequent increased risk of fracture (fx).

A widely used algorithm for the management of bone agent treatment in patients taking AI is that of Hadji from 2011. Depending on the risk factors and densitometric values, patients would or would not be subsidiaries of receiving such treatment.

Methods: Retrospective cross-sectional study of 200 patients collected in the period between 2014 and 2019 on the monographic consultation of osteoporosis, referred by Medical Oncology to assess the risk of fracture at the start of AI treatment after being diagnosed with breast cancer. BMD and clinical risk factors for fractures are included, based on the 2011 Hadji algorithm, what percentage of patients required treatment with bone agents during follow-up.

Results: The average age of our sample is 64.8 years with a SD of 9.5 and a median of 64.5 (Q1 58 and Q3 72). Regarding the treatment, 56 patients (28%) took Anastrozole, 122 (61%) Letrozole and 22 (11%) Exemestane. The risk factors are: 28 patients (14%) were active smokers and 35 (17.5%) ex-smokers; 11 (5.5%) recognized daily alcohol intake at significant doses. 42 women (21%) had previous fx, of which 15 (35.71%) were on the wrist, 8 (19.05%) vertebral, 2 (4.76%) on the shoulder and 1 (2.38%) on the hip. 44 women (22%) recognized habitual falls and 15 (7.5%) had familiar history of hip fx. There were no patients on chronic steroid treatment and 9 (4.5%) had osteoporosis secondary to a chronic disease. The DXA at the baseline visit showed OP in 64 patients (32%), osteopenia in 108 (54%) and normality in the other 28 (14%). In the blood tests, all women except 1 had normal phospho-calcium levels. Regarding VitD, 13 patients (6.67%) had values < 10 ng/mL, 50 (25.64%) from 10 to 20, 68 (34.87%) from 20 to 30, and the remaining 64 (32.82%) over 30 ng/mL. PTHi levels were high in 15 women (7.69%) and the CTX was elevated in 34 (17.53%). Monitoring data is collected with the following interest: 12 patients (6%) suffer a new fx during AI treatment, 58% vertebral, 25% wrist, and 16% in other locations. 121 women in our sample (60.5%) received treatment for OP according to Hadji's protocol, 92 (76.03%) of them alendronate, 7 (5.79%) risedronate, 18 (14.88%) denosumab, and the remaining 4 (3.3%) zoledronate and ibandronate in equal proportion (1.65%).

Conclusion: 60.5% of the patients in our series required a bone agent based on the Hadji combining risk factors and BMD values. Highlight that only 30% of patients presented osteoporosis values in DXA at the initial assessment and that 21% had previous fractures, the most on the wrist. We consider the systematic assessment of the risk of fracture presented by patients with breast cancer who begin treatment with AI, assessing the need to prescribe bone agents using an algorithm as practical as that of Hadji.

Abstract Number: 0113

Improving Glucocorticoid-Induced Osteoporosis Screening and Management in Patients with Rheumatic Diseases Using the 2017 ACR Guidelines

Marielys Figueroa Sierra[1], Atefeh Vafa[1], Shu Cao[2], Yuanyuan Lu[3], Helen Bateman[4], John Carter[1], Yih Chang Lin[2], Raquel Cuchacovich[1], Marcos Maldonado[4], Joanne Valeriano-Marcet[1] and Gabriela Montes-Rivera[4], [1]University of South Florida, Tampa, FL, [2]University of South Florida, Morsani College of Medicine, Tampa, FL, [3]Biostatistician at Graduate Medical Education Department, Tampa, FL, [4]James A. Haley VA, Tampa, FL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoid-induced osteoporosis (GIOP) is a potentially prevenTable complication in those who are maintained on glucocorticoid (GC) therapy. It is imperative to identify these patients and initiate osteoporosis (OP) therapy to outweigh the potential harm from GC continuation. As per the ACR guidelines, those on ≥2.5mg/day of GC for ≥90 days should have baseline DEXA at initiation of GC therapy as well as repeat screening every 2-3 years if continued on GC. For those on >7.5mg/day of GC, the FRAX score should be increased by 1.15 for major osteoporotic fracture and 1.2 for hip fracture. Those identified as moderate to high risk or on ≥30mg/day of

GC with a cumulative dose of >5gm should be started on OP therapy. We aim to raise awareness of the 2017 ACR guidelines to increase appropriate screening and OP therapy initiation.

Methods: Retrospective chart review of 2,665 patients at 3 outpatient specialty clinics affiliated with the University of South Florida (James A. Haley VA, Tampa General Hospital Health Park, USF Morsani) between April 2018 and November 2019 was performed for baseline data. Included were those age ≥40 on ≥2.5mg for ≥90 days of GC (n=385). Excluded were those age < 40, on < 2.5mg/day of GC, on < 90 days of GC, or whose GC was not prescribed by our rheumatology group. Intervention consisted of educating our providers and having pre-visit chart reviews to identify patients at risk based on the ACR guidelines. Post-intervention, retrospective chart review of 925 patients was performed between November 2019 and April 2020. Of these, 230 patients met inclusion criteria. Chi-square and Student's t test were used for comparisons. Bonferroni correction was used for subgroup comparison. All analyses were conducted using the SAS System.

Results: A total of 385 patients composed the pre-intervention group compared to 230 in the post-intervention. Of these, 55.6% vs 47.0% were females and 44.4% vs 53.0% were males, respectively. Average age between groups was similar (63.9 vs 64.2). New GC prescription was higher in pre-intervention group (177 vs 56, p< 0.001). Rheumatoid arthritis (RA) was the most common disease between groups (39.7% vs 32.6%). Prednisone was the most prescribed steroid (93.5% vs 93.0%) at a frequent dose of >5mg to < 10mg daily (34.2% vs 33.1%).

Pre-intervention, appropriate DEXA was obtained in 56.9% (n=219) which increased to 68.3% (n=157) in the post-intervention group with an absolute difference of 11.4% (p=0.005). Overall screening amongst each condition increased, notably in RA (56.9% vs 61.3%) and vasculitis (58.7% vs 73.0%), but this was not statistically significant. Screening did not increase for those on ≥30mg/day (48.3% vs 48.0%). Appropriate OP treatment increased post-intervention (30.3% vs 48.1%, p=0.002). Modifying the FRAX risk score in pre- and post-intervention groups separately upgraded lower risk scores to higher risk (low: 50 to 45 vs 34 to 32; moderate: 69 to 63 vs 31 to 26; high: 70 to 81 vs 55 to 62).

Conclusion: Implementation of the 2017 ACR GIOP guidelines increased DEXA screening and OP therapy initiation in the post-intervention group by improving the identification of high-risk patients. Abiding by these guidelines will lead to a reduction in further OP complications.

Abstract Number: 0114

Incidence of Follow-Up Dual-Energy X-Ray Absorptiometry Scanner Error: A Contributor to Precision Error

Kevin Lee[1], Karam Al Jumaily[1], Mu Lin[2], Kerry Siminoski[3] and Carrie Ye[4], [1]Internal Medicine, University of Alberta, Edmonton, AB, Canada, [2]Alberta Health Services, Edmonton, AB, Canada, [3]Radiology, University of Alberta, Edmonton, AB, Canada, [4]Rheumatology, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is characterized by decreased bone tissue microarchitecture. This leads to reduced bone density and quality and is a significant contributor to morbidity, mortality, and resources. Current guidelines recommend serial BMD measurement with a DXA scan every 1 to 3 years and the latest position paper from International Society for Clinical Densitometry explicitly states the use of the same or cross-calibrated DXA scanners. Interpreting follow-up DXA scan results from different scanners that are not cross-calibrated may lead to erroneous clinical decisions. This retrospective study aims to determine the proportion of patients who had follow-up DXA scans done on different scanners that have not been cross-calibrated and to determine potential risk factors that may contribute to this type of error.

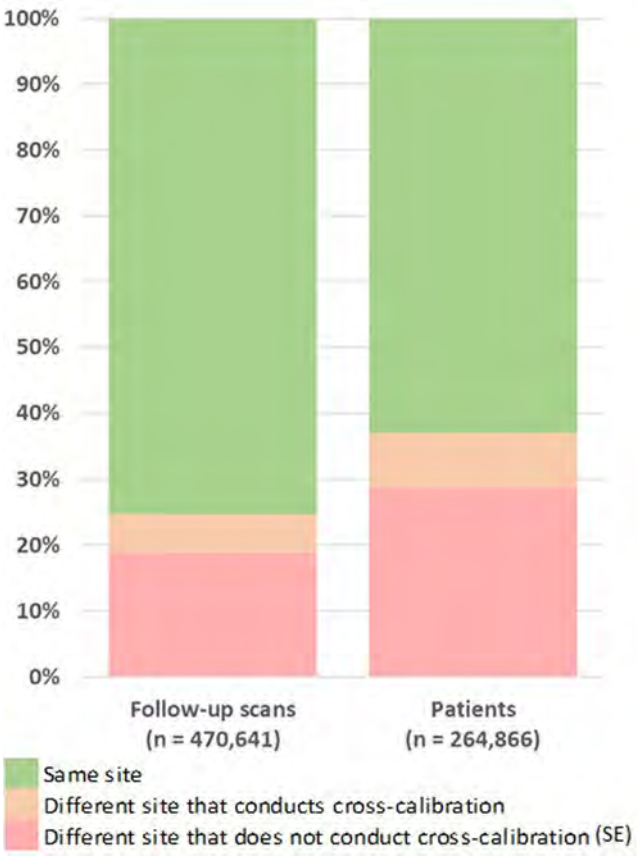
Methods: Service code X128 was used to extract DXA scan records from the Physician Claim Database (PCD) between 1 April 2009 and 31 December 2018, inclusively. Patients at least 18 years of age with at least 2 DXA scans completed during this period were included. Variables for each patient and DXA scan were obtained from the Pharmacy Information Network and PCD using pre-defined pharmaceutical, ICD-9, and ICD-10 codes.

The imaging facility identifier codes of all follow-up scans were compared to that of the immediately preceding scan. A follow-up scan was considered to have a scanner error (SE) if it was performed on different scanner that was not cross-calibrated. Logistic regression model with repeated measurements was used to calculate odds ratios for variables leading to SE.

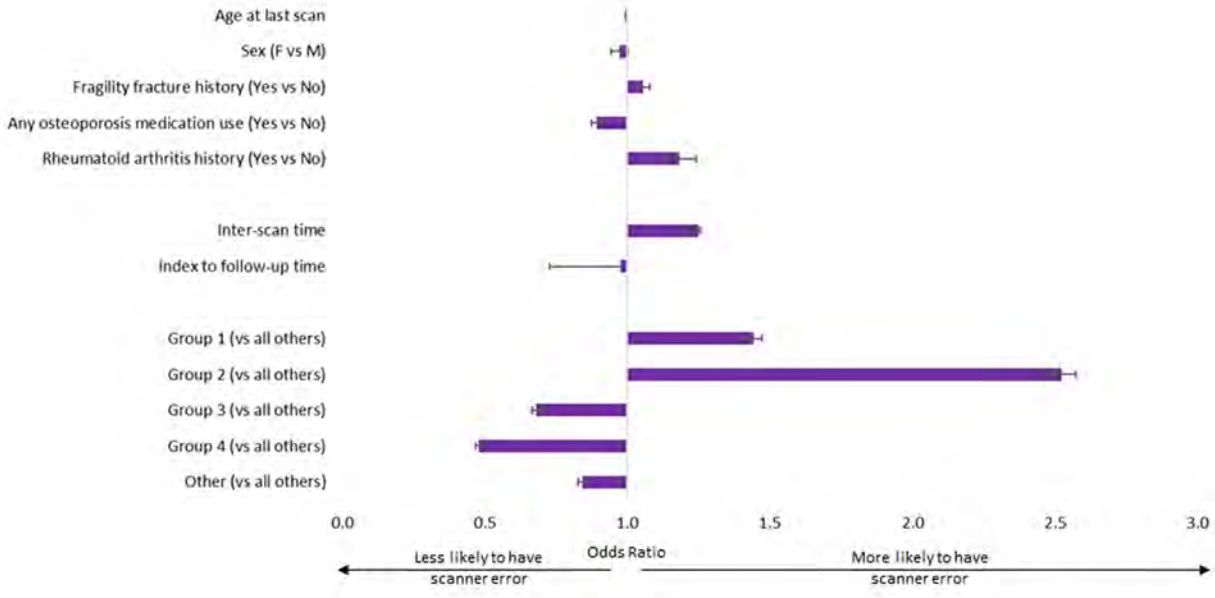
Results: At least 2 DXA scans were done by 264,866 patients for a total of 470,641 follow-up DXA scans. Of the follow-up DXA scans, 116,401 (25%) were done on a different scanner. With consideration of cross-calibrations done between these different scanners, 88,922 (19%) had a SE. Overall, 97,813 patients (37%) had at least one follow-up

Characteristics	n = 264,866 (%)
Age (mean ± stdev, in years)	
Index (First) DXA scan	61.3 ± 10
Last DXA scan	66.3 ± 10
Female	240,654 (90.9%)
Fragility fracture location	
Wrist	28,553 (10.8%)
Humerus	9,258 (3.5%)
Vertebra	8,241 (3.1%)
Hip	7,705 (2.9%)
Osteoporosis medication use	
Alendronate and Risedronate	69,980 (26.4%)
Zoledronic	3,846 (1.5%)
Denosumab	3,356 (1.3%)
Teriparatide	386 (0.1%)
Rheumatoid arthritis	7,195 (2.7%)

Baseline characteristics



Percentage of follow-up DXA scans and patients



Factors associated with scanner error

DXA scan done at a different facility. With cross-calibration considered, 75,928 (29%) of all patients experienced at least one SE.

Factors associated with SE include increasing time between consecutive DXA scans (OR 1.2502, CI 1.2435-1.2569), rheumatoid arthritis (OR 1.1830, CI 1.1277-1.2410), and fragility fractures (OR 1.0564, CI 1.0339-1.0794). Factors associated with less SE include use of osteoporosis medication (OR 0.8922, CI 0.8753-0.9095), increasing follow-up scan year (OR 0.9762, CI 0.7260-0.9798), and older age at time of last DXA scan (OR 0.9942, CI 0.9933-0.9950). Female sex did not significantly affect SE (OR 0.9725, CI 0.9433-1.0026). The imaging facility groups at which follow-up DXA scans were performed was also associated with differing risk of patients experiencing SE.

Conclusion: Proper management of osteoporosis requires interpretation of comparable DXA scans. This study found that a large proportion of follow-up DXA scans were of minimal clinical utility due to use of different DXA scanners that were not cross-calibrated. Using such results pose significant risk to patients and economic cost to the healthcare system. Interventions are needed to decrease this type of DXA scan error.

Improving Osteoporosis Screening in Men at a Resident-run Primary Care Clinic: A Quality Improvement Project

Khiem Vu[1], Chima Ohadugha[1], Kevin Dao[1], Rabih Nayfe[2] and Andrew Mangano[1], [1]Grand Strand Medical Center, Myrtle Beach, SC, [2]Carolina Health Specialists - Rheumatology, Myrtle Beach, SC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There are known indications for osteoporosis screening in women. However, osteoporosis also occurs in men and fragility fractures are linked to increased morbidity and mortality. Organizations as the National Osteoporosis Foundation, International Society for Clinical Densitometry, Endocrine Society, American College of Preventive Medicine, American College of Physicians, and American College of Rheumatology recommend that men ≥ 70 years old need universal screening for osteoporosis by dual energy x-ray absorptiometry. However, we have observed this recommendation to be underutilized in our resident clinic. The aim of this quality improvement project was to increase the documentation of osteoporosis screening in males ≥70 years old in our resident clinic (Grand Strand Primary Care) from the baseline 4-month average of 0% to ≥10% during the time period November 2019-May 2020.

Methods: Internal medicine residents were sent an educational email about osteoporosis screening in men ≥70 years old on November 1, 2019. It included the indications for screening in men, specific test to order, suggested diagnosis codes, references from literature, and solicited feedback regarding concerns about the project or clarification. Also, males ≥ 70 years old who were seen in clinic between July 1 and November 1, 2019 had their clinic notes reviewed for whether plans for screening was documented in the chart. Each resident was provided a customized list of patients (who had at least one scheduled follow-up in the next six months) for whom documentation about screening was lacking. Lastly, paper flyers were displayed in the clinic workspace similarly to those of other preventative health/screening recommendations for other medical conditions. On May 1, 2020 (six months later), charts were reviewed to evaluate the documentation rate of osteoporosis screening during the period November 1, 2019-May 1, 2020.

Results: Between July 1 and November 1, 2019, a total of 62 males ≥70 years old were seen in clinic among 26 residents. None of these patients had initial documentation regarding osteoporosis screening. Six months after our interventions (i.e. email sent on November 1, 2020, paper flyers displayed in clinic workroom), results were as follows: 11 patients were lost to follow-up (including one death), and 51 patients were seen at least once but osteoporosis screening was still not documented/discussed.

Conclusion: Our project did not meet the goal screening rate of at least 10% at six months. The results were humbling in that despite osteoporosis screening being recommended in men ≥70 years old by several medical organizations, screening rates remain exceptionally low, if not utilized at all. Although it is difficult to extrapolate our results to a broader scale, the major obstacles to screening most likely are limited life expectancy, prioritization of patients' other comorbidities, cost (i.e. lack of insurance coverage), or the perception that osteoporosis is a disease solely of women. Further discussion must be held to reevaluate whether this universal screening recommendation will still hold in the future, or whether it is rather a highly individualized decision best discussed between patient and physician.

The *in Vitro* 3D Fracture Gap Model: A Tool for Preclinical Testing

Moritz Pfeiffenberger[1], Alexandra Damerau[1], Paula Hoff[2], Annemarie Lang[1], Frank Buttgereit[3] and Timo Gaber[1], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Endokrinologikum Berlin, Rheumatologie, Berlin, Germany, [3]Charité University Medicine, Berlin, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 10% of fractures lead to significant fracture healing disorders. Of note, especially immunosuppressed patients with ongoing inflammation show difficulties in the correct course of fracture healing.

Current research has the focus on small animal models, facing the problem of translation towards the human system. In order to improve the therapy of fracture healing disorders, we have developed a human cell-based *in vitro* model to mimic the initial phase of fracture healing adequately. This model will be used for the development of new therapeutic strategies.

Our aim is to develop an *in vitro* 3D fracture gap model (FG model) which mimics the *in vivo* situation in order to provide a reliable preclinical test system for fracture healing disorders.

Methods: To assemble our FG model, we co-cultivated coagulated peripheral blood and primary human mesenchymal stromal cells (MSCs) mimicking the fracture hematoma (FH model) together with a scaffold-free bone-like construct (SFBC) mimicking the bony part of the fracture gap under hypoxia, to reflect the *in vivo* situation after fracture most adequately. To analyze the impact of the SFBC on the *in vitro* FH model with regard to its osteogenic induction capacity, we cultivated the fracture gap models in medium with or without osteogenic supplements. To analyze the impact of Deferoxamine (DFO, known to foster fracture healing) on the FG model, we treated our FG models with

either 250 µmol DFO or left them untreated. After incubation and subsequent preparation of the fracture hematomas, we evaluated gene expression of osteogenic (*RUNX2*, *SPP1*), angiogenic (*VEGF*, *IL8*), inflammatory markers (*IL6*, *IL8*) and markers for the adaptation towards hypoxia (*LDHA*, *PGK1*) as well as secretion of cytokines/chemokines using quantitative PCR and multiplex suspension assay, respectively.

Results: We found that both the fracture hematoma model and the bone-like construct had close contact during the incubation, allowing the cells to interact with each other through direct cell surface and signal molecules or metabolites. Additionally, we could show that the SFBCs induced the upregulation of osteogenic markers (*RUNX2, SPP1*) within the FH models irrespective of the supplementation of osteogenic supplements. Furthermore, we observed an upregulation of hypoxia-related, angiogenic and osteogenic markers (*RUNX2*, *SPP1*) under the influence of DFO, and the downregulation of inflammatory markers (*IL6*, *IL8*) as compared to the untreated control. The latter was also confirmed on protein level (e.g. IL-6 and IL-8). Within the bone-like constructs, we observed an upregulation of angiogenic markers (RNA-expression of *VEGF*, *IL8*), even more pronounced under the treatment of DFO.

Conclusion: In summary, our findings demonstrate that our established *in vitro* FG model provides all osteogenic cues to induce the initial bone healing process, which could be enhanced by the fracture-healing promoting substance DFO. Therefore, we conclude that our model is indeed able to mimic the human fracture gap situation and is therefore suiTable to study the influence and efficacy of potential therapeutics for the treatment of bone healing disorders in immunosuppressed patients with ongoing inflammation.

Abstract Number: 0117

Development of an *In Vitro* Trabecular Human Bone Model to Recapitulate Features of Glucocorticoid-induced Osteoporosis

Annemarie Lang[1], Karoline Diesing[1], Alexandra Damerau[1], Moritz Pfeiffenberger[1], Timo Gaber[1] and Frank Buttgereit[2], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Charité University Medicine, Berlin, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The bone matrix consists of inorganic and organic components and a variety of specialized cells such as osteoblasts, osteocytes and osteoclasts. The bone-forming osteoblasts are responsible for the production of organic matrix components; they differentiate later into osteocytes which is accompanied by matrix mineralization. Osteoclasts are multinuclear giant cells, which resorb bone. The healthy bone homeostasis is characterized by a balanced, dynamic and continuous remodeling process. Glucocorticoids (GCs) are commonly used to successfully treat patients with inflammatory rheumatic and other autoimmune diseases. However, long-term treatment with GC can potentially lead to several adverse effects such as the inhibition of osteoblast proliferation and the increase of osteoclastic activity resulting in osteoporosis. Hence, the aim of our project is to i) develop an *in vitro* trabecular human bone model, ii) integrate this bone model into a perfusion system to accelerate mineralization and provide biomechanical stimuli and iii) applying prednisolone to induce osteoporosis. Here we present our initial results describing

the successful differentiation of osteoblasts and osteoclast in a 3D environment, and the accomplished integration of the bone model into a perfusion system.

Methods: In a first step, different cultivation conditions were tested to allow optimal osteogenic or osteoclastic differentiation. To this end, a) human bone marrow derived mesenchymal stromal cells (hMSCs) were treated with osteogenic medium, and b) monocytes (isolated from buffy coats) were differentiated into osteoclasts using following protocol: incubation for 3 days with 25 ng/ml M-CSF followed by an 18-day incubation with M-CSF and 50 ng/ml RANKL. Calcification of hMSCs was evaluated via Alizarin-red staining. Osteoclasts were identified using immunofluorescence staining observing multinucleated (DAPI) giant (ß-Actin) cells with TRAP and Cathespin K activity. Additional gene expression analyses are currently conducted using qRT-PCR and looking for osteoclast-specific genes. In parallel to the monolayer cultures, cells were transferred on β-tricalcium phosphate (βTCP) – a suiTable bony-like scaffold. Furthermore, first experiments in a dynamic bioreactor platform (OSPIN GmH) were conducted to evaluate the influence of shear stress on the cells and model systems.

Results: We have been able to populate the βTCP scaffold with monocytes, which were differentiated into osteoclasts (morphological changes) without any effect on cellular viability as measured by Live/Dead staining. The morphological changes of those osteoclasts such as formation of filopodia could be demonstrated by scanning electron microscopy. In addition, the cultivation of βTCP populated with hMSCs in a perfusion system showed the upregulation of osteogenic marker (*RUNX2, OSX*) on mRNA-level.

Conclusion: These first results of our approach to develop an *in vitro* 3D model for glucocorticoid-induced osteoporosis are promising. Our next step will be the co-cultivation of osteoblasts and osteoclasts under dynamic and optimized cultivation conditions.

Indicators of Effectiveness After 6 Years of Follow-up in a Fracture Liaison Service

Antonio Naranjo Hernandez[1], Amparo Molina[2], Cristina Sepúlveda[2], Francisco Rubiño[3], Adrian Quevedo[3] and Soledad Ojeda[3], [1]Hospital Universitario Dr Negrin, Las Palmas, Canarias, Spain, [2]Hospital Universitario de Gran Canaria Dr Negrin, Las Palmas, Spain, [3]Hospital Universitario de Gran Canaria Dr Negrin, Las Palmas

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Data on the effectiveness of FLS in the medium and long term are needed. The objetive of this study was to analyze the indicators of long-term persistence to treatment, refracture and mortality in our Fracture Liaison Service (FLS)

Methods: We review the medical records of patients with an indication of treatment to prevent new fractures (bisphosphonate -BP- or equivalent) whose baseline visit took place between 2012 and 2016. The data included those of the baseline visit (age, sex, type of index fracture, FRAX scale and DXA results) and for the follow-up (death and date,

	(n = 896)
Women, n (%)	742 (83)
Age, mean (SD)	75.6 (10)
Primary fracture site, n (%)	
Femur	300 (33.4)
Forearm	245 (27.3)
Humerus	180 (20.0)
Vertebra	97 (10.8)
Other	74 (8.2)
Previous fragility fracture, n (%)	163 (18.1)
FRAX score, mean (SD)	
Major	15.4 (9)
Hip	7.3 (7)
Previous treatment with bisphosphonates, n (%)	180 (20.1)
Baseline DXA scan*, n (%)	
Normal	40 (5.3)
Low bone mass	306 (40.9)
Osteoporosis	401 (53.7)

Table 1. Baseline characteristics of patients Abbreviations: SD, standard deviation; DXA, dual energy X-ray absorptiometry , *analysed in 747 patients

refracture including revision of spine x-rays - it was considered only the first refracture and, in the case of several fractures the most serious was chosen-, prescribed treatment, persistence of treatment trough electronic prescription on the date of review or death, and MPR or proportion of days covered by treatment).

Results: 896 patients were included, with an average follow-up of 63,6 months (DE 29, range 42-90). Table 1 shows the baseline characteristics.

Follow-up.- The persistence of treatment was assessed in 888 patients; 618 patients (69.6%) were prescribed a treatment at any time, 480 of them (77,9%) with a MPR≥80% at the time of chart review or death (in that case). Therefore, 54% of the analyzed patients persist with the treatment defined as MPR > 80%.

When analyzing patients with prescribed treatment, in 378 cases (61.1%) it was a BP in a sustained manner, in 85 cases (13.7%) a BP was prescribed and subsequently changed to denosumab, while in 151 cases (24,4%) it was initiated and maintained denosumab, and 4 patients other treatments. The MPR > 80% was 75% in patients who started and maintained BP, 79% in those who started BP and switched to denosumab, and 87% in those who had denosumab throughout the analysis period.

138 of 891 pacients (15,4%) had a new fracture, 112 a major fracture (12,5%) and 50 hip fracture (5,6%). Taking the 6-year period, 42% of refractures occurred in the first two years after the index fracture.

In patients without a prescribed treatment, refracture ocurred in 15,1% (major and hip fractures in 12.9% and 8.5%). In patients with a prescribed treatment refractures ocurred in 15,7% (major and hip fractures in 12.5% and 4.3%). Compared to patients without treatment we found a significant lower incidence of hip fracture in patients wit a prescribed treatment (OR 0.49, CI 95% 0.20-0.79) but a similar incidence of major fracture, mean FRAX (15.8 vs 14.4) and age (75.4 vs 76.2).

212 patients (23.6%) died. Compared to those alive, in patients who died we found a higher age (81 vs 74), a higher frequence of hip fracture at baseline (52% vs 27%), a higher hip refracture (9.4% vs 4.4%) and a lower prescription of treatment (56.4% vs 73,6%).

Conclusion: 6 years after the assessment in an FLS, the persistence of treatment with MPR≥80% was 54%. We found an association with prescription of treatment with lower hip refracture.

Fracture Liaison Service at an Academic Center with an Open Health System: 30-month Outcomes

Donna Jose[1], Micah Yu[2], Karina Torralba[3], Christina Downey[4], Justin Dunn[5] and Vinicius Cabido[5], [1]Loma Linda University Medical Center, Ontario, CA, [2]Loma Linda University Medical Center, Loma Linda, CA, [3]Loma Linda University School of Medicine, Redlands, CA, [4]Loma Linda University Medical Center, Redlands, CA, [5]Loma Linda University Medical Center, Loma Linda

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis causes significant morbidity, mortality and healthcare burden. There continues to be a care gap in osteoporosis recognition, treatment and prevention. Several healthcare systems in the USA and worldwide have implemented a Fracture Liaison Service (FLS) aimed at secondary fracture prevention. Locally, a 2015-2016 study showed that up to 90% of elderly patients admitted to a tertiary academic center were not screened or treated for osteoporosis. An FLS was established fall 2017 to bridge the care gap in our population. The objective of this study is to longitudinally analyze the effectiveness of the FLS during the initial thirty-month period.

Methods: Data from the electronic health record (EHR) were analyzed to identify the number of inpatient FLS consults received between September 2017and February 2020 (30 months). The following metrics were recorded: demographics, anatomic location of fracture, any prior fractures, calcium and Vitamin D supplementation, pharmacotherapy initiation, DXA completion, transition to osteoporosis specialist and transition to any dependent living facilities. Current data was compared to 8-month data. Main target outcome was a 10% improvement in treatment initiation. Prior data noted that at month 8 and 18 transition to outpatient specialist was delayed, and a significant number of patients (25%) had a primary care provider outside of the academic health system. An FLS nurse practitioner (NP),

Descriptor	Result
Number of patients referred (N)	189
Sex	
Female	69.3% (131)
Male	30.7% (58)
Age	
<60	11.6% (22)
61-70	16.4% (31)
71-80	28.6% (54)
81-90	29.1% (55)
>90	14.3% (27)
Anatomic Location of Fracture	
Femoral	38% (72)
Vertebral	16.4% (31)
Had Prior Fracture	43.4% (82)
Primary Care Provider:	
Within academic health system	79.9% (151)
Outside academic health system	20.1% (38)
Never had DXA done pre-Fracture	60.0% (111)
Was not on Ca+, Vit D supplementation	64.8% (118), 52.7% (96)
Never been on Osteoporosis Treatment	79.6% (148)

Table 1. FLS Population at an Academic Medical Center associated with an Open Health System at 30 months Data Collection

Outcome Metric	8 months	30 months	p-value
Number of patients referred	65	124	N/A
Dual-Energy Bone Absorptiometry completed after discharge	17.5% (11)	19.8% (24)	0.697
Transitioned to outpatient osteoporosis specialist	27.4% (17)	32.5% (39)	0.482
Osteoporosis treatment initiation after discharge	18.8% (12)	15.3% (19)	0.548

Table 2. Outcome Metrics of a Fracture Liaison Service at an Academic Health System at 8 months and 30 months Data Collection

who also acted as an FLS coordinator, was hired at 18 months. A Chi-square test of independence was utilized to determine if there were proportional differences between those at the 8-month follow-up compared to those at the 30-month follow-up. Alpha was set equal to 0.05 for statistical significance.

Results: 189 patients were referred to the FLS service since initiation (Table 1). A 5% improvement in outpatient follow up was noted at the 30-month mark (32.5%) compared to the 8-month (27.4%) mark (Table 2). Treatment initiation rates that slightly decreased at the 30-month mark were noted to be largely due to patient refusal. This refusal in treatment initiation was noted to be due to patients' poor understanding of osteoporosis, fracture complications and risk aversion to use of medications. When a comparison was made between the 8-month group with the 30-month

group using the chi-square test, no proportional differences in DEXA completed after discharge, transition to outpatient osteoporosis specialist, or osteoporosis treatment initiation after discharge was seen (Table 2).

Conclusion: The number of patients transitioning to outpatient care has improved since the hiring of a NP/FLS Coordinator, even among patients who had a primary care provider outside of the academic health system. However, this number is not statistically significant. A study to analyze patient perceptions about osteoporosis and treatment risk aversion would be useful. Further education efforts are needed aimed at improving osteoporosis awareness not only among patients but also among Primary Care Providers.

Risk of Fracture in Patients with Different Glucocorticoid Requiring Diseases

Giovanni Adami[1], Angelo Fassio[2], Alessandro Giollo[2], Luca Idolazzi[2], Ombretta Viapiana[1], Davide Gatti[2] and Maurizio Rossini[2], [1]University of Verona, Verona, Italy, [2]Rheumatology Unit, University of Verona, Verona, Italy

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

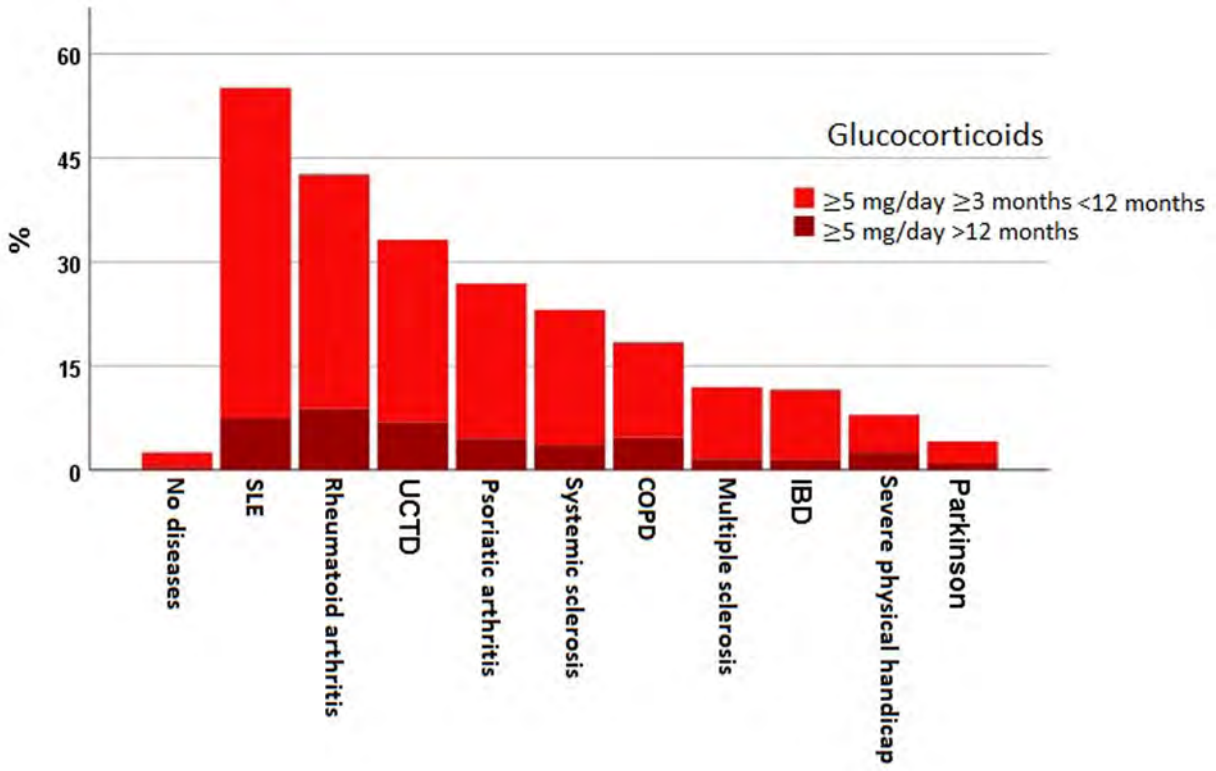

Figure 1. Glucocorticoid use in the cohort under analysis

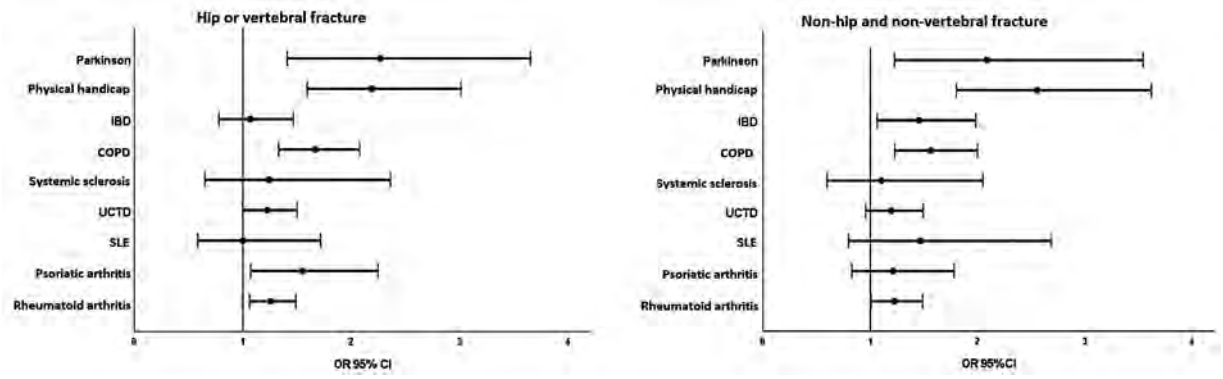

Figure 2. Odd ratios of vertebral and hip fracture and non-vertebral, non-hip fractures in the study population

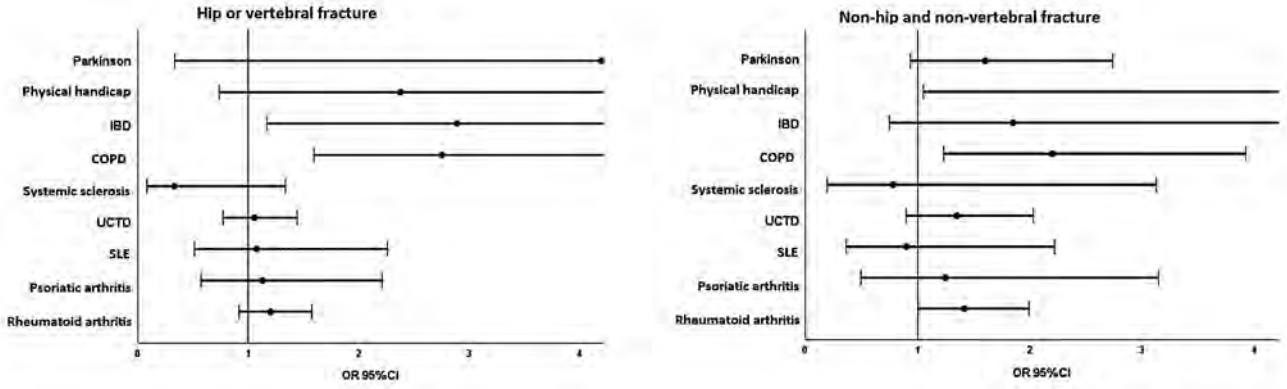

Figure 3. Odd ratios of vertebral and hip fracture and non-vertebral, non-hip fractures in the study population (excluding glucocorticoid users)

Background/Purpose: The aim of the present work is to determine the fracture risk associated with glucocorticoids requiring diseases

Methods: We conducted a retrospective analysis of a nation-wide cohort (DeFRACalc79 database). We collected many clinical variables, including the use of glucocorticoids, the presence of prior hip or vertebral and non-vertebral or non-hip fractures and the presence of comorbidities (rheumatoid arthritis, psoriatic arthritis, undifferentiated connective [UCTD], systemic lupus erythematosus [SLE], systemic sclerosis, chronic obstructive pulmonary disease [COPD], multiple sclerosis, chronic inflammatory bowel diseases [IBD], severe physical handicap, diabetes, Parkinson's and HIV). We generated age and T-score matched groups of patients with and without comorbidities via propensity score matching. After 1:1 matching we analyzed the prevalence of fragility fractures. We performed a sensitivity analysis by eliminating all patients who used glucocorticoids ≥5 mg/day for ≥3 months.

Results: 59950 women aged 65.1 years (SD 11.0), with total-hip T-score of -2.16 (SD 0.94) and lumbar spine T-score of –2.50 (SD 1.15) were included in the analysis. Among 13,546 women with comorbidity 3114 (23.0%) had diabetes; 3008 (22.2%) rheumatoid arthritis; 1910 (14.1%) UCTD; 1614 (11,9%) BPD; 942 (7,0%) IBD; 794 (5,9%) severe motor disability; 703 (5,2%) psoriatic arthritis; 412 (3,0%) Parkinson's. 294 (2,2%) LES; 277 (2,0%) systemic sclerosis; 243 (1,8%) multiple sclerosis and 235 (1,7%) had HIV. **Figure 1** shows the prevalence of glucocorticoid use stratified by disease. Glucocorticoid intake ≥5 mg/day for ≥3 months (after 1:1 matching by age and T-scores) was significantly

associated with vertebral fractures (aOR 1.5 95% CI 1.3-1.7) but not with non-femoral non-vertebral fractures (aOR 1.0 95% CI 0.9-1.2) while intake of ≥5 mg/day for ≥12 months was associated with fractures of all kind (aOR 1.3 95% CI 1.2-1.3 and 1.3 95% CI 1.1-1.8). **Figure 2** and **Figure 3** show the ORs for the presence of vertebral or hip fractures and non-vertebral or non-hip fractures (glucocorticoid users and non-users respectively). Diseases with increased risk of fracture, independently from glucocorticoid intake, were rheumatoid arthritis, COPD and severe physical handicap for non-vertebral and non-hip fractures and COPD and IBD for vertebral or hip fractures.

Conclusion: At a population level, glucocorticoid intake is still common, especially in patients with rheumatic diseases, and is associated with an increased risk of fractures, both vertebral, hip and non-vertebral non-hip fractures. Rheumatoid arthritis, COPD and severe physical handicap were independently associated with an increased risk of non-vertebral and non-hip fractures whereas only COPD and IBD were associated with vertebral or hip fractures.

Abstract Number: 0121

Association of Low Bone Density with Need for Early Revision After Elective Joint Replacement for Osteoarthritis in Postmenopausal Women

Rashmi Dhital[1], P. Daniel Nicholas[2], Gregory Emkey[3] and Anthony Donato[2], [1]Reading Hospital and Medical Center, West Reading, [2]Reading Hospital and Medical Center, West Reading, PA, [3]Reading Hospital and Medical Center, Reading, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Total joint replacement (TJR) is the standard surgical treatment for end-stage hip and knee osteoarthritis (OA). Patient optimization may limit the need for early revision surgeries. Low bone mineral density (BMD) may cause periprosthetic fractures, osteolysis and implant migrations which can affect postoperative outcomes, but the data is limited. There is also no standardized approach to assess bone health prior to TJR. Our primary objective was to study the prevalence of low bone mass and its relationship to early revision arthroplasty.

Methods: We performed a retrospective, case-control, single-center study using Reading Hospital Joint Database. We reviewed charts of postmenopausal women who underwent hip and knee arthroplasty from January, 2013 to December, 2019 and identified patients who underwent *early (within 5 years)* revision arthroplasty for aseptic indications ("cases"). We matched each of the cases to 2 postmenopausal women who did not undergo a revision surgery during the time period ("controls"), matched for age at index surgery (+/- 5 years), timing of initial TJR (+/- 6 months) and type of TJR. We identified patients with BMD testing with DEXA (dual-energy X-ray absorptiometry) within 2 years of the index TJR. We collected data on patient characteristics including age, body mass index (BMI), use of vitamin D and calcium, chronic glucocorticoid (prednisone equivalent of 5 mg/day for > 3 months) and anti-osteoporotic therapy use. Late revision surgeries and infectious indications were excluded.

	TJR for OA with need for early revision arthroplasty (n=25)	* Matched TJR for OA with no revision till date (n=50)
Mean Age (at index surgery), years	69.72	68
Mean BMI (at index surgery), kg/m^2	33.03	35.96
BMI categories		
Obesity (at index surgery)- n (%)	11 (44)	22 (44)
Morbid obesity (at index surgery)- n (%)	5 (20)	16 (32)
Bone density assessment with DEXA - n (%)	10 (40)	31 (60)
Osteoporosis by DEXA- n (%)	1 (10)	4 (12.90)
Osteopenia by DEXA- n (%)	6 (60)	13 (41.94)
Mention of fragility fracture- n (%)	4 (16)	8 (16)
Anti-osteoporotic medication use (in osteoporosis or fragility fractures)- n (%)	3/4 (75)	7/11 (63.63)
Calcium supplementation- n (%)	10 (40)	22 (44)
Vitamin D supplementation- n (%)	13 (52)	34 (68)
Steroid use for > 3 months - n (%)	2 (8)	4 (8)
Diabetes mellitus at index surgery- n (%)	11 (52)	37 (74)
Diabetes on insulin - n (%)	4 (36.36)	10 (27.03)

Table 1: Characteristics of postmenopausal women undergoing early joint revision (n=25) compared to those who did not undergo revision surgery during the study period (n=50)

*Matched by age at index surgery (+/- 5 years), timing of initial TJR (+/- 6 months) and type of TJR

Table 1. Characteristics of postmenopausal women undergoing early joint revision (n=25) compared to those who did not undergo revision surgery during the study period (n=50) *Matched by age at index surgery (+/- 5 years), timing of initial TJR (+/- 6 months) and type of TJR

Results: We identified 25 postmenopausal women with elective TJR for OA who underwent early revision hip (n=11) and knee replacement (n=14) for aseptic indications. The mean age for index TJR was 70 years. The average duration between index and revision surgery was 22 months (12 months for hip and 30 months for knee revision).

Each of the postmenopausal women who underwent early joint revision (n=25) were matched to 2 postmenopausal women who did not undergo early revision surgery (n=50) during the study period (**Table 1**). Forty percent patients in the early revision group had documentation of a screening DEXA compared to 60 % patients in the non-revision group. Among patients who had DEXA, 7/10 (70%) had low bone mass (osteopenia or osteoporosis) in the early revision group compared to 17/31 (55%) in the non-revision group. Of the 4 patients with a history of fragility fracture in the early revision group, 75% underwent revision surgery within the first 2 months of index TJR (two due to periprosthetic fracture and one due to femoral loosening). The use of calcium and vitamin D was identified in 40% and 52% in the early revision group compared to 44% and 68%, respectively, in the non-revision group.

Conclusion: Our study found a lower rate of DEXA screening and a higher prevalence of low bone mass in the early revision group, which may suggest a higher prosthetic failure in patients with low bone mass. We were unable to assess the role of anti-osteoporosis medication on the outcome due to the small sample size. Further studies are needed to explore the impact of osteoporosis and its treatment on postoperative outcomes, particularly in those with a history of a prior fragility fracture.

Osteoporosis Medication Utilization Patterns over Time in the ACR RISE Registry

Nitasha Khullar[1], Lang Chen[2], Jeffrey R Curtis[3], Joshua Baker[4], Huifeng Yun[3], Andreas Reimold[5] and Maria (Maio) Danila[6], [1]University of Alabama Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [4]University of Pennsylvania, Philadelphia, PA, [5]Veterans Affairs North Texas Healthcare System / UT Southwestern Medical Center, Dallas, TX, [6]University of Alabama at Birmingham (UAB), Birmingham, AL

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Many effective medications are available for osteoporosis treatment. However how rheumatologists use these therapies is not well understood, particularly in patients with concomitant rheumatologic conditions. The objective of this study was to examine the patterns of utilization of osteoporosis medications among rheumatologists reporting to the ACR's Rheumatology Informatics System for Effectiveness registry (RISE).

Methods: RISE is a national registry that passively collects data from real-world rheumatology practices. As of December 2018, RISE held validated data from 715 rheumatology providers in 226 practices, representing ~20% of the U.S. clinical rheumatology workforce. Patients included in this study were ≥18 years old and had osteoporosis based on ≥ 1 diagnosis code for osteoporosis or prescriptions/administrations of osteoporosis medications, each calendar

	Bisphosphonates (n= 70,904)	Denosumab (n= 35,046)	Teriparatide (n= 5,371)
Osteoarthritis	35.6%	35.6%	30.2%
Rheumatoid arthritis	20.7%	14.8%	15.1%
Long term steroid use	8.3%	3.9%	4.6%
Polymyalgia rheumatica	4.7%	2.4%	2.0%
Sjogren's	3.6%	3.0%	3.1%
Ankylosing spondylitis	3.2%	2.8%	3.4%
Systemic Lupus Erythematous	2.7%	2.1%	2.4%
Undifferentiated connective tissue disease	1.4%	1.0%	0.9%
Gout	1.1%	1.2%	0.7%
Scleroderma	0.8%	1.0%	1.2%
Mixed connective tissue disease	0.3%	0.3%	0.4%

year from 2015 to 2018. We identified autoimmune rheumatic disease type using ICD10 codes. We assessed osteoprosis medication use, including bisphosphonates, denosumab, and anabolics in each calendar year from 2015 to 2018, examining both prevalent use (i.e. any use) and separately, new osteoporosis medication initiation (i.e. use in that year, with no prior recorded use in RISE in any previous year).

Results: In 2018, we identified 251,620 eligible patients from 217 practices. Of these, 89.6% were female, 68.4% were white, 4.5% were black, and 7.5% were identified as Hispanic or Latino with an overall mean age of 73.0 +/- 11.3 years. The most common co-morbid autoimmune rheumatic disease in this cohort was RA (11.9%). The underlying rheumatic disease by first line osteoporosis medication choice is presented in the Table. In 2018, a nominally greater proportion (18.5%) of patients initiated denosumab, compared to bisphosphonate therapy (16.9%). Of patients who initiated denosumab in 2018, 34.6% had a prior recorded history of being on bisphosphonate therapy. Conversely, 9.0% of patients that started bisphosphonates in 2018 had a prior recorded history of being on denosumab previously. In patients who had never received any osteoporosis therapy, bisphosphonates remained the most frequently prescribed first-line treatment in 2018. Using the same definition of osteoporosis, compared to prior years, we observed a decline in proportion of registry participants initiating osteoporosis medications in each calendar year, decreasing from 47.9% in 2015 to 42.1% in 2016, 40.5% in 2017, and 36.5% in 2018, despite an increasing number of patients in the registry with osteoporosis (Figure).

Conclusion: Osteoporosis medication initiation in rheumatology practices declined over 2015-2018, however denosumab treatment appears to be gaining popularity. Bisphosphonate therapy remains favored as first line therapy for osteoporosis, but overall denosumab was initiated more frequently in 2018 compared to bisphosphonate therapy or anabolics.

(Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR)

Osteoporosis therapy initiated by U.S. rheumatologists participating in RISE in 2018 by patients' underlying rheumatologic diagnosis.

Abstract Number: 0123

Aromatase Inhibitor-Associated Bone Loss: Screening and Prevention

Matthew White[1] and Luke Barre[2], [1]Roger Williams Medical Center, Providence, RI, [2]Hawthorn Medical Associates, Dartmouth, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Aromatase inhibitors (AI) are frequently used in hormone receptor-positive breast cancer, which encompasses nearly 75% of all breast cancers. By preventing peripheral estrogen production, AIs magnify the effects of estrogen suppression during menopause causing accelerated bone loss at a rate 2-4 times higher than expected. Approximately 1 in 5 women treated with AI therapy will suffer from a fracture, increasing their risk of mortality. AI therapy is also used in men for the treatment of gynecomastia, but there is a lack of data regarding the effects of AIs on bone loss in men.

The American Society of Clinical Oncology recommends obtaining a baseline DXA in postmenopausal breast cancer survivors treated with an AI. Several studies have shown this screening is suboptimal but cost-effective in the U.S. The aim of this study was to assess our adherence to osteoporosis screening in patients on AI therapy and to understand factors that may influence screening.

Methods: In this retrospective cross-sectional study, clinic and hospital medical records were used to identify and analyze subjects on an aromatase inhibitor from January 2015 – January 2020. Descriptive and statistical analyses using Pearson's Chi-Square were used to compare the characteristics of subjects who received DXA screening to those who did not.

Results: We identified 4,340 subjects on AI therapy from 2,248,780 charts available in the medical record system, giving AI therapy a prevalence of 0.19%. Of those, 3,797 (87.4%) were female and 549 (12.6%) were male. A DXA was ordered in 818 (19%) subjects and was not ordered in 3,522 (81%) subjects. Ninety-eight percent of subjects who had a DXA ordered were females [X^2 (1, N=4340)=100.42, $p< 0.01$].

DXA screening was more likely to be ordered in subjects aged 65 years or older with a history of alcohol use [X^2(2, N=4340)=54.94, $p< 0.01$], rheumatoid arthritis [X^2(1, N=4340)=17.45, $p< 0.01$] , hypogonadism [X^2(1, N=4340)=70.60, $p< 0.01$], and fragility fracture [X^2(1, N=4340)=5.32, $p< 0.025$]. Among those who had DXA screening, the above fac-

Family History of Hip Fracture	1 (0.1%)	2 (0.05%)

Table 2. Descriptive Analysis of Osteoporosis (OP) Risk Factors

Variable	Pearson's Chi Square	Degrees of Freedom	p-value
Gender	100.42	1	<0.01
Age	2770.19	2	<0.01
Alcohol	54.94	2	<0.01
Rheumatoid Arthritis	17.45	1	<0.01
Hypogonadism	70.60	1	<0.01
History of Fragility Fracture	5.32	1	<0.025
Steroid Use	30.95	1	<0.01
Bisphosphonate Use	7.79	1	<0.01
Vitamin D Use	35.92	1	<0.01
Calcium Use	26.71	1	<0.01

Table 3. Pearson's Chi-Square Report of Statistically Significant Variables

tors were present in 51%, 5%, 2%, and 5%, respectively. Subjects with glucocorticoid [X2(1, N=4340)=30.93, p< 0.01], bisphosphonate [X2(1, N=4340)=7.79, p< 0.01], or vitamin D use [X2(1, N=4340)=35.92, p< 0.01] were also more likely to have DXA screening.

Conclusion: This investigation highlighted that osteoporosis screening for patients on AI therapy is low, despite the current guidelines. The osteoporosis risk factors associated with higher rates of screening were advanced age, alcohol use, rheumatoid arthritis, hypogonadism, and history of a fragility fracture. The rate of DXA screening was similar for patients with low BMI, tobacco use, type I diabetes mellitus, hyperthyroidism, liver disease, premature menopause, chronic malnutrition, and a family history of hip fracture. Males encompass nearly 13% of our population on AI therapy, and future studies are needed to understand the impact of AI treatment on bone health in men. More intense osteoporosis screening is needed for patients on AI therapy, especially for those with additional risk factors, and can be achieved through multidisciplinary collaboration.

Table 1. Characteristics of Denosumab Prescribing

administration or discontinuation without change to a different osteoporosis therapy, results in a subsequent decline in bone mineral density (BMD) and the development of new vertebral fractures (often multiple). Recent guidance recommends that a repeat dose of denosumab or an alternative osteoporosis therapy is administered no later than 7 months after the prior denosumab dose. Therefore, the aim of the present study was to identify current practices regarding the timing of denosumab administration as well as subsequent treatment of osteoporosis after denosumab discontinuation at an academic medical center.

Methods: Pharmacy records for a single academic medical center were accessed to identify all dispenses of denosumab between October 1, 2017 and March 5, 2020. Individuals between 18 and 100 years of age, who had had at least one dose of denosumab dispensed were included, except for those whose denosumab was prescribed by an Oncologist or Urologist. The electronic medical record was then reviewed for age, specialty of the prescribing physician, total number and dates of denosumab injections. If denosumab was discontinued, it was recorded whether or not an alternative osteoporosis therapy was prescribed. T-tests and chi-squared tests were utilized to assess for any differences between those treated by Endocrinologists and Rheumatologists.

Results: 389 individuals were initially identified of whom 249 (92% female) met inclusion criteria (Table 1). Mean (SD) age was 75 (10) years. In 175 (70%) individuals, denosumab was prescribed by an Endocrinologist, compared to Rheumatology (45 individuals, 18%) and 29 (12%) by other specialties. The median number of doses of denosumab

administered per individual was 3 (range 1-7) with the mean time between doses 6.4 months (SD 2.2 months). 446 (90%) of all subsequent denosumab doses were administered within 7 months. There was no significant difference in the mean time between doses nor the proportion of individuals receiving their denosumab dose within 7 months between Endocrinology and Rheumatology (p=0.5 and 0.09, respectively). For 99 (40%) individuals, greater than 7 months had elapsed since their last denosumab dose. Of those, only 7 (7%) were clearly transitioned to an alternative osteoporosis therapy, most commonly zolendronate (5 individuals).

Conclusion: 90% of denosumab doses were administered within the recommended timeframe of 7 months with no significant difference between Endocrinologists and Rheumatologists. However, where denosumab was discontinued, whether knowingly or not, only 7% were prescribed an alternative osteoporosis therapy. Given this, a considerable number of individuals may be at risk of decline in BMD and incident vertebral fracture. Moving forward, additional work is required to understand the reasons for both late administrations, but more importantly the lack of alternative therapy upon discontinuation before specific interventions can be implemented to address these deficiencies.Table 1: Characteristics of Denosumab Prescribing

A Resident-Led Interdisciplinary Quality Improvement Initiative to Increase Osteoporosis Screening in an Urban Clinic

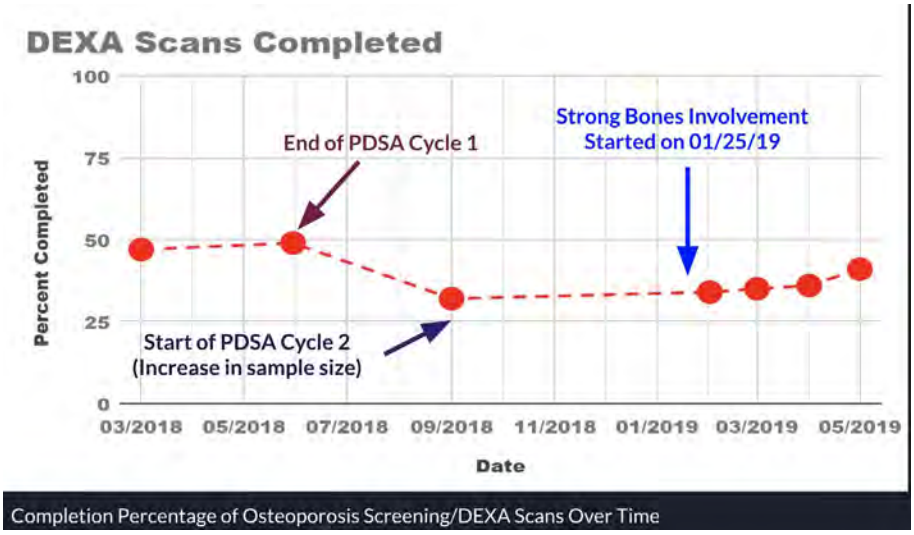
Catherine Teskin[1] and Hiba Sayed[2], [1]Christiana Care, Wilmington, [2]Christiana Care, wilmington, DE

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a major cause of morbidity and mortality in the United States. The USPSTF recommends screening all women age 65 and older or younger women with risk factors for osteoporosis.[2] Unfortunately, osteoporosis screening rates remain low nationwide.[3] In our residency clinic, the baseline screening rate for women age 65 and older was 47%. We aimed to increase this rate by 10% over a three month period.

Methods: Our root cause analysis identified provider, patient, and system level barriers to osteoporosis screening. Plan-Do-Study-Act (PSDA) cycle 1 targeted provider knowledge through didactic education and posters in the clinic space. PDSA cycle 2 identified patient barriers. We collaborated with an institutional nurse-led program called “Strong Bones” that has existing initiatives in place to detect and treat osteoporosis. We used a health registry embedded within our electronic medical record to identify patients from our clinic who were eligible for osteoporosis screening. A Strong Bones nurse then reached out to each patient to explain the need for screening and to help navigate barriers. We then tracked the rate of osteoporosis screening between PDSA cycles through the health registry and manually reviewed patient level data during a three month patient outreach period.

Results: After PDSA cycle 1, we saw a slight increase in our screening rate from a baseline of 46% (101/216) to 49% (106/216). During PDSA cycle 2, we identified and chose 138 patients eligible for osteoporosis screening to be contacted. 71 of these patients were called during the outreach period, and 11 scans were completed. Our screening rate



Completion Percentage of Osteoporosis Screening/DEXA Scans Over Time

at the beginning of cycle 2 was 34% (111/322) and increased to 36% (122/338). The most common barrier identified during this period was patient disinterest, though many were unreachable.

Conclusion: Results from PDSA-1 showed that resident education alone increased the number of DEXA scans ordered, but did not substantially increase completed screenings due to patient barriers. Furthermore, relying on "inreach" interventions targeting only the patients present at the office visit missed a large proportion the patient panel. PDSA cycle 2 addressed both of these issues. There was a substantial increase in DEXA completion and we were also able to quantify the barriers our patients faced in the process. Limitations included difficulty in obtaining reliable data. Additionally, ongoing changes to the health registry's patient attribution characteristics led to a lower rate of completed screening even though the total number of screenings increased. Although our intervention led to more patients having their screening completed, it was very time-intensive and would be difficult to sustain moving forward. Next steps consist of identifying ways to decrease system level barriers, such as through streamlined scheduling and same day appointments.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Avascular necrosis (AVN) is a musculoskeletal condition that can result in significant pain and compromised quality of life. The diverse etiologies of AVN have been described; glucocorticoid (GC) use is the most common cause for non-traumatic AVN. However, the pathogenesis of GC-induced AVN has yet to be fully elucidated. While a wide range of the immunomodulatory effects of GC has been reported, little is known of the changes in circulating cellular phenotype for patients with GC-induced AVN. This study investigated the linkage between GC-induced AVN and altered immune homeostasis. We hypothesized that GC may differentially affect the phenotype of immune cells in AVN patients, which may serve as a measure for the systemic status of AVN patients.

Methods: Fifty-four AVN patients (47.7 ± 14.5 yr [mean ± SD]; female 26 and male 29) were enrolled for the study. Twenty-nine patients had received GC therapy and 41.3% of GC-induced AVN patients had SLE. The maximum dose of glucocorticoid in the GC-induced AVN group was 56.8 ± 22.5 mg/day. Average cumulative glucocorticoid was 42.8 ± 54.5 g. The non-GC AVN group included twenty-five patients with idiopathic AVN (40.0%), heavy alcohol use (36.0%), osteoarthritis (16.0%), and trauma (8.0%). There were no significant differences in mean age and BMI between the two groups. The GC-induced AVN group had a higher female-to-male ratio. Serum cytokines were measured by multiplex assay. Circulating immune cells were defined by cell surface markers and measured by flow cytometric analysis. Gene expression profiles from macrophages and T cells were also measured and analyzed.

Results: As the composition of innate and adaptive immune cells reflects the systemic status of the host, we measured CD14+ macrophages, myeloid dendritic cells (DCs), plasmacytoid DCs, B cells, and T cells (CD4+ and CD8+ T cells) in blood from the GC-induced AVN and non-GC-induced AVN groups. There was no difference in the number of macrophages, dendritic cells (DCs), pDCs, and B cells between the two groups. There was also no difference in the number of CD4+ T cells between the two groups, but we found the number of CD8+ cells in the GC-induced AVN group to be significantly higher than that of the non-GC AVN group ($p = 0.0252$). To determine if the increased count of CD8+ T cells in the GC-induced AVN group resulted from GC therapy, we also compared the number of CD8+ T cells in the GC-induced AVN group to that of the GC-treated patients who did not have AVN. The number of CD8+ T cells was higher for GC-induced AVN patients ($p = 0.0008$). Accordingly, a CD4/CD8 T cell ratio was significantly lower for this group ($p = 0.0063$). In addition to the cellular phenotype, we also found that serum TNF-α and CXCL10 were significantly higher in the GC-induced AVN group compared to those of the non-GC induced AVN group.

Conclusion: Our findings revealed the status of circulating immune cells in GC-induced AVN patients and found that the subset of lymphocytes significantly increased in the GC-induced AVN group. Our study suggests that lymphocytes in the GC-induced AVN group may escape the immunosuppressive effect of GC, and we believe further study is needed to identify the mechanism of altered immune profiles in GC-induced AVN.

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Studies show a long diagnostic delay in Hypophosphatasia (HPP) and the accessibility for the genetic testing is not always possible. Our previous cross-sectional study (Tornero et al. OJRD (2020) 15:51) revealed alkaline phosphatase (ALP) levels < 25 IU/L seemed to be useful to identify individuals with *ALPL* variants

Table 1. Regression logistic models for the detection of genetic *ALPL* variants including ALP, PLP and PEA cut-off levels.

	Biochemical variables	R^2 Nagelkerke	B	Odds Ratio (95% CI:)	p-value	Diagnostic utility measures
Model 1:	ALP<25	0.161	ALP: 1.935 C: -0.325	6.923 (1.81-26.39)	0.005	S: 36.6 E: 92% PPV: 83% NPV: 58%
Model 2:	ALP<25 + PLP>180	0.461	ALP: 1.483 PLP 2.593 C: -1.283	4.407 (0.94-20.5) 13.364 (4.01-44.5)	0.059 0.000 0.001	S: 29% E: 97% PPV: 92% NPV: 56%
Model 3:	ALP<25 + PLP>180 + PEA>35	0.526	ALP: 1.875 PLP: 2.087 PEA: 1.486 C: -1.619	6.521 (1.07-39.6) 8.06 (2.18-29.9) 4.4 (1.03-18.9)	0.042 0.002 0.045 0.000	S: 22% E: 100% PPV: 100% NPV: 55%

Table 1

among subjects with persistent hypophosphatasaemia. These data highlight the importance of establishing a specific biochemical profile and the value of including TNSALP substrates is a matter of interest. First, to confirm our previous results in a one-year follow-up of a longitudinal study. Second, to determine the value of including TNSALP substrates (serum pyridoxal phosphate-PLP-and urinary phosphoetanolamine-PEA) in a specific biochemical profile to detect variants in *ALPL* in individuals with persistent low ALP levels.

Methods: Biochemical parameters of subjects included in a prospective longitudinal study conducted at La Paz Hospital were employed. Subjects were divided into two groups according to their genetics (+ GT or -GTgroup). Substrates were determined at baseline and at one-year visit and ALP levels also at six-months. To confirm the threshold, diagnostic utility measures were calculated at the 3 visits. ROC curves were employed to determine PLP and PEA best cut-off levels. Hierarchical binary logistic regression analysis was used to determine how well the different models fit (Nagelkerke R^2). Finally, diagnostic utility measures for each model were calculated.

Results: Using ALP data from the three visits, Specificity (E) ranged between 84-91%; positive predictive value (PPV), 76-87% and +LR 3-6.1%. The ROC curves revealed cut-off PLP levels with the best combination of S and E for PLP were 180 nmol/L (S: 72%, E:86%) and for PEA, 35 (S:58%, E89%) umol/g creat. The regression model showed an OR (95% IC) for ALP< 25 IU/L, PLP >180 and PEA >35 of 6.52 (1.07-39.6), 8.06 (2.2-29.9) and 4.4 (1.03-18.9). Compared to the model just including ALP, R^2 improved (0.161 to 0.526) when substrates were added (E and PPV:100% and S:22%), especially when PLP was included (Table 1).

Conclusion: This study confirms that ALP levels < 25 IU/L could be useful to identify individuals displaying *ALPL* variants. Additionally, the combination of this threshold with the proposed cut-off levels of its substrates, especially PLP, have shown a very high specificity to detect the disease and could help vigorously in the diagnostic work-up of HPP.

Short-Term Monitoring of Denosumab Effect in Breast Cancer Patients Receiving Aromatase Inhibitors Using Radiofrequency Echographic Multi-Spectrometry (REMS) Technology on Femoral Neck

Rosachiara Forcignanò[1], Fiorella Anna Lombardi[2], Mariangela Ciccarese[3], Eugenio Quarta[4], Antonella Grimaldi[5], Laura Quarta[5], Delia Ciardo[2], Ernesto Casciaro[2], Paola Pisani[2], Francesco Conversano[2], Maurizio Muratore[5] and Sergio Casciaro[2], [1]O.U. of Oncology, "Sacro Cuore di Gesù" Hospital, Gallipoli, Lecce, Italy, Gallipoli, Italy, [2]National Research Council, Institute of Clinical Physiology, Lecce, Italy, Lecce, Italy, [3]O.U. of Oncology, "Vito Fazzi" Hospital, ASL-LE, Lecce, Italy, Lecce, Italy, [4]O.U. of Rheumatology, "Galateo" Hospital, ASL-LE, San Cesario di Lecce, Lecce, Italy, San Cesario di Lecce, Italy, [5]O.U. of Rheumatology, "Galateo" Hospital, San Cesario di Lecce ASL-LE, Lecce, Italy, San Cesario di Lecce, Italy

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of the study was to carry out a short-term monitoring of the effect of aromatase inhibitors (AI) and Denosumab on bone health in post-menopausal women with breast cancer (BC) with positive estrogen receptor through a bone densitometry performed with Radiofrequency Echographic Multi-Spectrometry (REMS) and Dual-Energy X-ray Absorptiometry (DXA).

Methods: A group of patients (Group A) received AI adjuvant therapy annually and 60 mg Denosumab every 6 months. The other group (Group B) received annual AI therapy only. All patients underwent a femoral neck scan with REMS and DXA before receiving the first AI therapy (T0) and 12 months after (T1). Only REMS scans were repeated after additional 6 months (T2).

The results were analyzed in terms of relative changes in bone mineral density (BMD) compared to the basal value obtained at T0. The analysis of the results was carried out by balancing the two groups by age.

Results: The results of 200 patients were analyzed. As expected, for Group A (assuming Denosumab) an increasing trend in BMD was observed, whereas a decreasing trend in BMD was found for Group B both with REMS and DXA.

The difference between REMS and DXA obtained for patients in each group at each time point was not statistically significant. Instead, the difference between Group A and Group B is statistically significant for DXA (at T1) and REMS (at T1 and T2).

Conclusion: The effect of Denosumab in reducing the risk of fracture in BC patients treated with AIs is well known. The densitometric techniques currently available are not able to monitor BMD in the short term, since the minimum time between two consecutive measurements is at least 1 year [1]. REMS technology, on the other hand, has demonstrated high performance in terms of precision and repeatability of BMD measurement, and the consequent low least significant change (LSC) value [2]: consequently, it might overcome the limit of current densitometric techniques, allowing a repeated exam at 6 months. The results of this study demonstrate the feasibility of short-term follow-up using REMS technology with femoral neck scans.

Background/Purpose: Rheumatic diseases are associated with increased systemic bone loss and fracture risk related to chronic inflammation, disease-specific, general and demographic risk factors as well as treatment with glucocorticoids (GC). The purpose of this study was to investigate the prevalence of osteoporosis and fragility fractures in patients with inflammatory rheumatic diseases and to analyze the impact that treatment with GCs, other known risk factors and preventive measures have on bone health in these patients.

Methods: Rh-GIOP is an ongoing prospective observational study collecting and analyzing disease- and bone-related data from patients with chronic rheumatic diseases or psoriasis treated with GCs. In this cross-sectional analysis, we evaluated the initial visit of 1091 patients.

A multivariate linear regression model with known or potentially influential factors adjusted for age and sex was used to identify predictors of BMD as measured by dual-energy X-ray absorptiometry (DXA). Multiple imputation was applied for missing baseline covariate data.

The following T-scores were considered: i) minimum overall T-score, ii) minimum T-score of the lumbar spine and iii) minimum T-score of the femoral neck. P-values lower than 0.05 were considered significant; no adjustment for multiple testing was done.

Table 4: Variables with at least one significant result in one of the 3 models for minimal (min.) T-score at any site, min. T-score at the lumbar spine or min. T-score at the femoral neck in the multivariate linear regression model in all patients. Significant impact factors are highlighted in bold.

Hyperthyroidism	0.257 (-0.025;0.539)	*0.074*	0.126 (-0.277;0.529)	*0.540*	**0.351 (0.071;0.632)**	***0.014***
HAQ	-0.093 (-0.189;0.003)	*0.057*	-0.021 (-0.158;0.116)	*0.762*	**-0.132 (-0.227;-0.037)**	***0.007***

Results: In the total cohort of 1091 patients (75% female of which 87.5% were postmenopausal) with a mean age of 62.1 (±13.2) years, the prevalence of osteoporosis by DXA was 21.7%, while fragility fractures have occurred in 31.2% of the study population (6.7% vertebral, 27.7% nonvertebral). Current GC therapy was common (64.9%), with a median daily dose of 5.0mg [0.0;7.5], a mean life-time total GC dose of 17.7g (±24.6), and a mean GC therapy duration of 7.8 years (±8.5). Bisphosphonates were the most commonly used anti-osteoporotic drug (12.6%).

BMD as expressed by min T-Score at all measured sites was predicted by age, sex, menopause and BMI, Bisphosphonate and Denosumab treatment, as well as current GC therapy, proton pump inhibitor intake and use of NSAIDs. Current GC dose showed a positive correlation with BMD. Of measured bone-specific laboratory parameters, alkaline phosphatase levels and Gamma-GT were determinants of BMD. BMD was neither predicted by duration of GC treatment, GC cumulative dose nor by treatment with DMARDs or other factors relating to disease activity. Determinants for BMD varied slightly at the anatomical site with HAQ, hyperthyroidism and sun exposure affecting only femoral T-Score.

Conclusion: This cross-sectional analysis of our cohort study revealed a high prevalence of osteoporosis by DXA and fragility fractures. We identified and corroborated predictive variables of BMD that warrant consideration in the management of patients with rheumatic diseases.

Abstract Number: 0130

The Prevalence of Osteoporosis in Individuals with Osteoarthritis: A Systematic Review

Timothy Varghese[1], Ali Ahmadi Pirshahid[2], Dongkeun Kim[2] and Yueyang Li[2], [1]Schulich School of Medicine & Dentistry, Richmond Hill, ON, Canada, [2]Schulich School of Medicine & Dentistry, London, ON, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: There is controversy regarding the relationship between osteoarthritis (OA) and osteoporosis (OP). While OA may be associated with increased bone mineral density (BMD) due to increased weight, evidence exists that the incidence of OP may be increased in patients with OA.

Our purpose was to determine whether the prevalence of OP is increased in patients with OA, compared to age and sex-matched populations.

Methods: We conducted a systematic literature review using the databases PubMed, Embase, Scopus, and Web of Science, including articles that that analysed the frequency, rate, prevalence, incidence, risk, or excess risk of OP in patients with OA compared to age and sex-matched comparison groups (controls). Articles with fewer than 200 participants, and those without controls were excluded. Two reviewers conducted title and abstract screening.

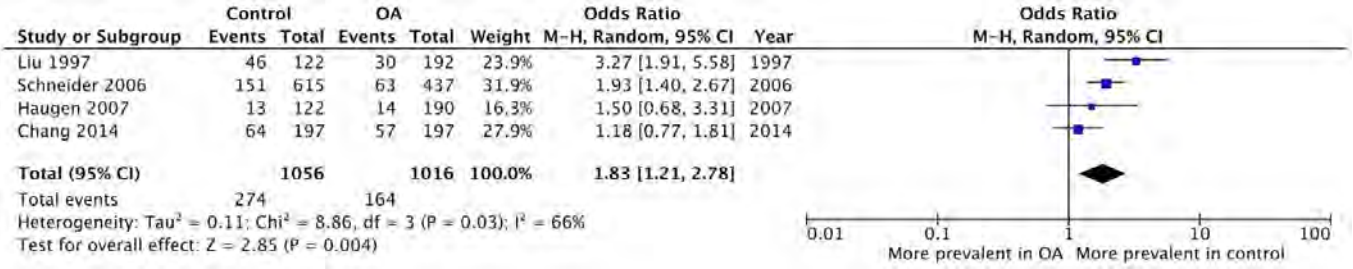

Figure 1. Prevalence of OP in OA vs. control in men and women with BMD measured at any site (lumbar spine, total hip, femoral neck) with confirmed diagnosis of OA at any site (lumbar spine, knee, hand)

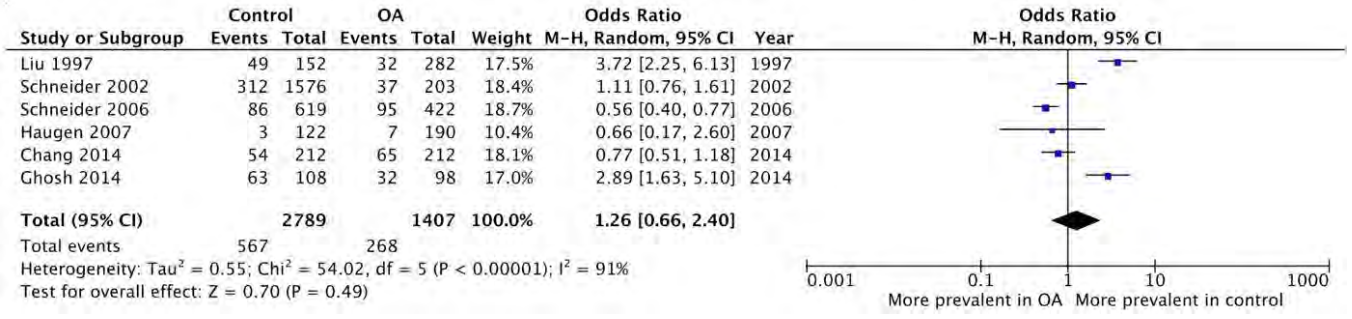

Figure 2. Prevalence of OP in OA vs. control in in men and women with BMD measured at the lumbar spine with OA at any site

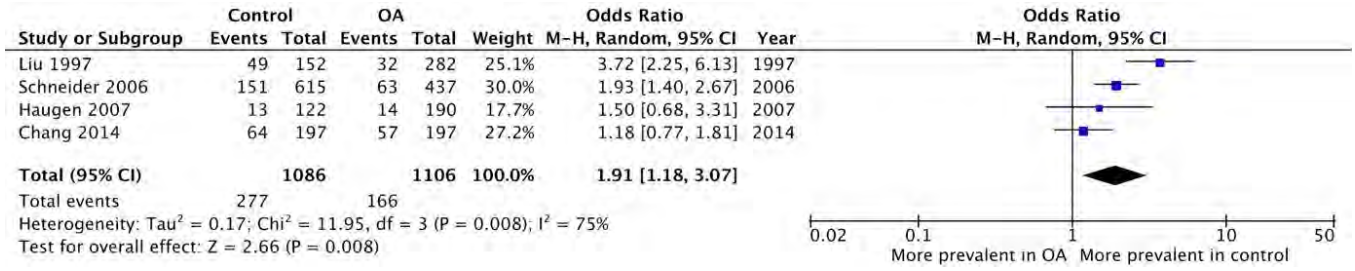

Figure 3. Prevalence of OP in OA vs. control in women with BMD measured at the lumbar spine with OA at any site

Results: Of 2772 unique articles, 49 articles were chosen for full article screening, and 6 articles met the inclusion criteria of our present study. These articles showed that there was no significant difference in prevalence of OP in the OA group compared to the respective control group in both men and women, when BMD was measured at femoral neck, hip or lumbar spine (Figure 1).

Subgroup analysis of both men and women whose BMD was measured at the lumbar spine showed higher prevalence of OP in the control group compared to the OA group (Figure 2). This difference remained significant in the subsequent subgroup analysis of only women whose BMD was measured at the lumbar spine (Figure 3).

Conclusion: Our findings suggest no significant difference in prevalence of OP in subjects with OA compared to those without OA; this suggests that OA may not have protective effects on development of OP. Therefore, diagnosis of OA should not preclude patients from being investigated for OP. OA may present with atrophic features associated with increased frequency of osteoporotic fractures compared to OA with osteophytosis; this distinction may be important to consider for future studies.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory arthritis in the elderly leads to greater comorbidity than that of the young patients, however, there are few data on body composition in this population.

Objective: To analyze the total body composition measured by dual-energy x-ray absorptiometry (DXA) in patients with arthritis in the elderly, its relationship with the activity disease scores and its evolution at 12 months.

Table 1: Total body composition parameters

Variable	RA		PMR		Control
	Baseline	12 months	Baseline	12 months	
Age (years)	74±7		77±5		73±8
Weight (kgs)	73±12	73±12	63±14 +	66±13	73±13
Size (cm)	161±8	159±9	153±8	153±8	161±13
BMI (Kg/cm2)	28±5	29±5	28±5	28±4	28±4
Abdominal perimeter (cm)	101±12	101±12	98±11	99±9	-
BMD total (g/cm2)	1,132±0,137	1,134±0,136	1,038±0,149 +	1,081±0,199	1,124±0,159
Fat mass (g)	29506±8391	29784±8697	28364±8331	32232±6215	28976±7274
Lean mass (gr)	40555±6836	39822±6798*	34459±6361 + ţ	36941±6273	41669±9927
Bone mass (gr)	2129±460	2206±459	2219±420	1928±410	2319±655

*p<0.05 compared to 12 months. + p< 0.05 compared to control group. ţ p<0.05 compared to patients with RA

Method: Prospective observational study of patients with elderly onset arthritis (> 65 years) recruited between January 2013 and December 2014 (ARTIEL cohort). Patients with previous known osteoporosis (OP) and/or antiosteoporotic treatment were excluded. We collected clinical-analytical variables, anthropometric data (weight, height , body mass index (BMI) and abdominal perimeter) and total body composition measures that include fat mass in grams (g), lean mass (g), and bone mineral density (BMD; g/cm2), at baseline (without treatment) and at 12 months. Data was compared with a control group without arthritis. The statistical study was performed using SPSS.

Results: We included 73 patients (37M: 36V), with a mean age of 75±7 years in the study. Most were diagnosed with rheumatoid arthritis (RA; n=43), followed by polymyalgia rheumatica (PMR; n=16) and others (n=14). 31.9% had densitometric OP at baseline and 31.3% at 12 months. When assessing comorbidities: 38.4% were diabetic and 33% were obese (BMI >30 Kg/cm2). Total body composition data is shown in the Table 1.

At the time of inclusion, patients with PMR had less lean mass than the control group, with no significant difference observed between the RA group and the control group. When comparing PMR vs RA, patients with PMR had lower weight, total BMD and lean mass than patients with RA.

When assessing the complete cohort (n=73), no significant changes were observed in the evolution of total body composition at 12 months. However, a significant loss of lean mass was observed in the subpopulation of RA patients at 12 months of follow-up (p=0.017), while patients with PMR showed no change in total body composition.

In the RA group, there was a negative correlation between lean mass and activity scores (DAS28PCR: r=-0.370, p=0.017; DAS28VSG: r=-0.401, p=0.009) at the time of patient inclusion in the study; while fat mass was positively correlated with DAS28VSG (r=0.429, p=0.005) and abdominal circumference (r 0.835; p< 0.001). In the group of patients with PRM, there was a positive correlation between fat mass and abdominal circumference (r=0.900; p< 0.001).

Conclusion: Patients with RA in the elderly present a significant loss of lean mass at 12 months. In addition, lean mass in these patients negatively correlated with disease activity scores, suggesting a relationship between inflammation and the changes in body composition. It should be noted that patients with PMR had a lower lean mass at the time of diagnosis, so we cannot rule out the possibility that they may have lost muscle mass before inclusion in the study.

Abstract Number: 0132

Prevalence of Osteoporosis and Fragitlity Fractures Is Not Different Between ACPA Positive Patients Compared to ACPA Negative Patients in a Real World Setting, Despite Longer Disease Duration and Glucocorticoid-Treatment

Edgar Wiebe[1], Desiree Freier[1], Dörte Huscher[2], Gloria Dallagiacoma[3], Sandra Hermann[1], Robert Biesen[4], Gerd Burmester[5] and Frank Buttgereit[6], [1]Charité University Medicine Berlin, Dep. of Rheumatology and Clinical Immunology, Berlin, Germany, [2]Charité University Medicine Berlin, Dep. of Biometry and Clinical Epidemiology, Berlin, Germany, [3]University of Verona, Dep. of Rheumatology, Verona, Italy, [4]Charité University Medicine, Dep. of Rheumatology and Clinical Immunology, Berlin, [5]Charité University Hospital Berlin, Berlin, Germany, [6]Charité University Medicine, Berlin, Germany

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Osteoporosis & Metabolic Bone Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased systemic bone loss, leading to a high risk for hip, vertebral and non-hip, non-vertebral fractures. Especially ACPA positivity is considered a risk factor for local bone erosions and systemic bone loss.

The purpose of this study was to compare ACPA positive versus ACPA negative RA patients in terms of the prevalence of osteoporosis and fragility fractures and to identify differences in underlying risk factors that influence bone health.

Methods: Rh-GIOP is an ongoing prospective observational study collecting and analyzing disease- and bone-related data from patients with chronic rheumatic diseases or psoriasis treated with glucocorticoids (GC). In this cross-sectional analysis, we performed a matched-pair analysis, matching 114 ACPA positive to 114 ACPA negative RA patients according to age (5-year-steps), sex, and body mass index (BMI, 2-unit-steps). Descriptive analyses were performed, with values displayed as mean ± standard deviation for continuous variables. Non-parametric tests were used at a two-sided significance level of 5% to compare differences in underlying and potential risk factors without adjustment for multiple testing.

Results: At same mean age (63.9 ±10.2 years) and BMI (27.9 ±5.6kg/m^2), the matched groups had a female proportion of 82.5%. APCA positive patients had a significantly longer mean disease duration (13.9 vs 9.9 years, $p< 0.001$), a higher mean cumulative GC-dose (22.3 vs 13.2g, $p< 0.01$) and mean duration of GC therapy (10.1 vs 6.6 years, $p< 0.01$). There was no significant difference in the prevalence of osteoporosis as defined by dual-energy X-ray absorptiometry (DXA) (18.4 vs 20.2%), nor in the prevalence of vertebral (7.0 vs 5.3%) or non-vertebral fractures (31.6 vs 29.8%). C-reactive protein levels as a marker of disease activity were significantly higher in ACPA positive patients (mean: 8.8 vs 4.3mg/l, $p= 0.02$), while mean disease activity score (DAS)28 levels were slightly lower in ACPA positive patients (2.4 vs 2.7, $p= 0.05$). No difference in health assessment questionnaire (HAQ) was found. RA-specific treatments were similar, especially concerning current daily GC-dose (8.6mg vs 7.1mg/day), except for Rituximab and targeted synthetic disease modifying anti-rheumatic drugs (DMARDs) which were more commonly used in ACPA

positive patients (9.6 vs 2.6%, p=0.05) and (5.3 vs 0%, p=0.029), respectively. ACPA positive patients did not differ significantly from ACPA negative patients in specific anti-osteoporotic treatment, nor in the prevalence of comorbidities or concomitant medication. There were no significant differences in bone-specific laboratory parameters.

Conclusion: In a cross-sectional analysis of our cohort, the prevalence of osteoporosis and fragility fractures was similar between ACPA positive and ACPA negative RA patients, despite longer disease duration and GC-treatment in ACPA positive patients. This is remarkable since it implies that ACPA negative patients are at a similar risk for osteoporosis and associated fractures.

Abstract Number: 0133

Pharmacist-Driven Clinic Development for Patients with Incidental Vertebral or Hip Fractures

Julie Ferm[1], Lanh Dang[1] and Gurjit Kaeley[2], [1]UF Health Jacksonville, Jacksonville, FL, [2]University of Florida College of Medicine - Jacksonville, Jacksonville, FL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Osteoporosis & Metabolic Bone Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-traumatic vertebral and hip fractures are detrimental complications of osteoporosis and those with a previous fracture have double the risk of subsequent fractures. The objective of this quality improvement (QI) project was to determine the baseline characteristics that may have contributed to the vertebral or hip fracture and determine if bone health was optimized subsequent to the fracture. Our institution determined the need for a pharmacist-driven clinic to assist patients with incidental vertebral and hip fractures receive appropriate follow-up care to prevent future fractures. This analysis completes the initial analysis that focused on patients who had an outpatient prednisone prescription prior to admission.

Methods: Data was retrospectively collected from the electronic health record for patients aged 45 and older admitted to UF Health Jacksonville for an active vertebral or hip fracture diagnosis between January 1, 2017 and January 31, 2019. Traumatic injuries were excluded. Retrospective chart review could occur dating back to January 2014 for completeness. Data on patient demographics, any medication that may affect bone health (e.g. steroids, calcium and vitamin D products, bisphosphonates, etc.), DXA scans, and pertinent labs were collected.

Results: A total of 287 patients were admitted 296 times between January 1, 2017 and January 31, 2019. Of these, 100 patients were screened and 33 patients were excluded. For the 67 hospitalized patients included in this analysis, 44 (65.7%) had a hip fracture and 23 (34.3%) had a vertebral fracture. A majority, 62.7%, were female with a mean age of 67 years old (range 46-97 years old). A total of 4 patients (6%) had a DXA scan prior to admission and 7 patients (10%) had a DXA scan after admission. No patient analyzed had chronic glucocorticoid dose ≥ 5 mg/day prednisone equivalent for greater than 3 months. A total of 17 patients had prednisone bursts with 23.5% of patients having cumulative burst doses between 10-100 mg, 52.9% patients between 101-500 mg, 5.9% patients between

501-1000 mg, and 17.7% patients > 1000 mg. Patients were also on other medications that may affect bone health with the highest rates of concomitant medication use being proton pump inhibitors 43.3%, antiepileptics 40.3%, serotonergic receptor inhibitors 31.3%, and levothyroxine 16.4%. Only 3% of patients were on a bisphosphonate prior to admission and 3% were newly started after admission. One patient was on denosumab prior to and after admission. Baseline vitamin D deficiency observed in 25.4% of patients.

Conclusion: In this convenience sample of patients with an active non-traumatic vertebral or hip fracture prior to admission, the rate of baseline DXA scan was low (6%) and after admission DXA (10%). The rate of pharmacologic antiresorprtive therapy after admission was 7.5%. The goal in development of this novel pharmacist – driven care pathway and clinic is to create a post-discharge process for patients admitted to the hospital for vertebral or hip fractures to optimize bone health by mitigating modifiable risk factors and increasing appropriate osteoporosis medication prescriptions to reduce the future risk of fractures.

The Impact of Exercise on Sleep in People with Rheumatoid Arthritis: A Pilot Randomised Controlled Trial

Sean McKenna[1], Laura Comber[2], Alan Donnelly[3], Alexander Fraser[4], Bente Appel Esbensen[5] and Norelee Kennedy[3], [1]University of Limerick, Mallow, Cork, Ireland, [2]HIQA, Limerick, Limerick, Ireland, [3]University of Limerick, Limerick, Limerick, Ireland, [4]University College Limerick, Limerick, Limerick, Ireland, [5]University of Copenhagen, Glostrup, Hovedstaden, Denmark

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Poor sleep quality and reduced sleep duration are prevalent complaints in people with RA. These in turn may further deteriorate functional ability and reduce exercise levels. Current rheumatology guidelines recommend exercise as a key component in the management of people with RA however, what is lacking is its impact on sleep. Purpose of this pilot randomised controlled trial was to obtain reliable estimates regarding recruitment rates; participant retention; protocol adherence and possible adverse events, in addition to producing estimates of the potential effect sizes of the intervention on changes in outcomes of sleep duration; sleep quality and disturbances; pain; depression; anxiety; functional limitation; disease activity and fatigue.

Methods: Participants were recruited in person at weekly rheumatology clinics at a University Hospital and through self-selected social networking. They were randomised to either a walking based exercise intervention consisting of 28 walking sessions, with 1 per week being supervised by a trained physiotherapist, spread over 8 weeks (2-5 times/week), or a control group who received advice on the benefits of exercise for people with RA. Ethical approval was received. Descriptive statistics and t-tests were used to analyse the data with SPSS v22.

Results: One hundred and one (101) people were identified, with 36 contacting through social networking. Of these, 24 met the eligibility criteria, with 20 being randomised (18% recruitment; 100% female; mean age 57 (SD 7.3 years). Ten exercise participants (100%) and 8 controls (80%) completed final assessments, with both groups being equivalent for all variables at baseline. Exercise participants completed 87.5% of supervised sessions and 93% of unsu-

pervised sessions. No serious adverse events were related to the intervention and through semi-structured interviews the intervention was highly accepTable to exercise participants. Pittsburgh Sleep Quality Index (PSQI) global score showed a significant mean improvement between exercise group -6.6 (SD 3.3) compared to control -0.25 (SD 1.1) (p=0.012); PSQI subcomponent sleep duration showed a significant improvement in mean hours between the exercise group 1.65 (SD 0.39) hours and control 0.56 (SD 0.46) hours (p=0.021); PSQI subcomponent sleep quality indicated those in exercise group improved their sleep quality from fairly bad/poor to fairly good/very good, while those in control reported no change at fairly bad/poor. Global rating of change indicated exercise participants reporting their sleep was minimally/much improved, while control participants reported no change/minimally worse, post intervention.

Conclusion: The walking based exercise intervention designed to improve sleep was feasible, safe and highly accepTable to study participants, with those in the exercise group reporting improvements in sleep duration and sleep quality compared to control group. Adverse events were predominantly mild. This pilot provides a framework for larger intervention studies and based on these findings a fully powered trial of walking as an exercise based intervention is recommended, preceded by focus groups to investigate methods to improve recruitment of males.

Abstract Number: 0135

Understanding the Rheumatologist-Patient Relationship in Treating Rheumatoid Arthritis

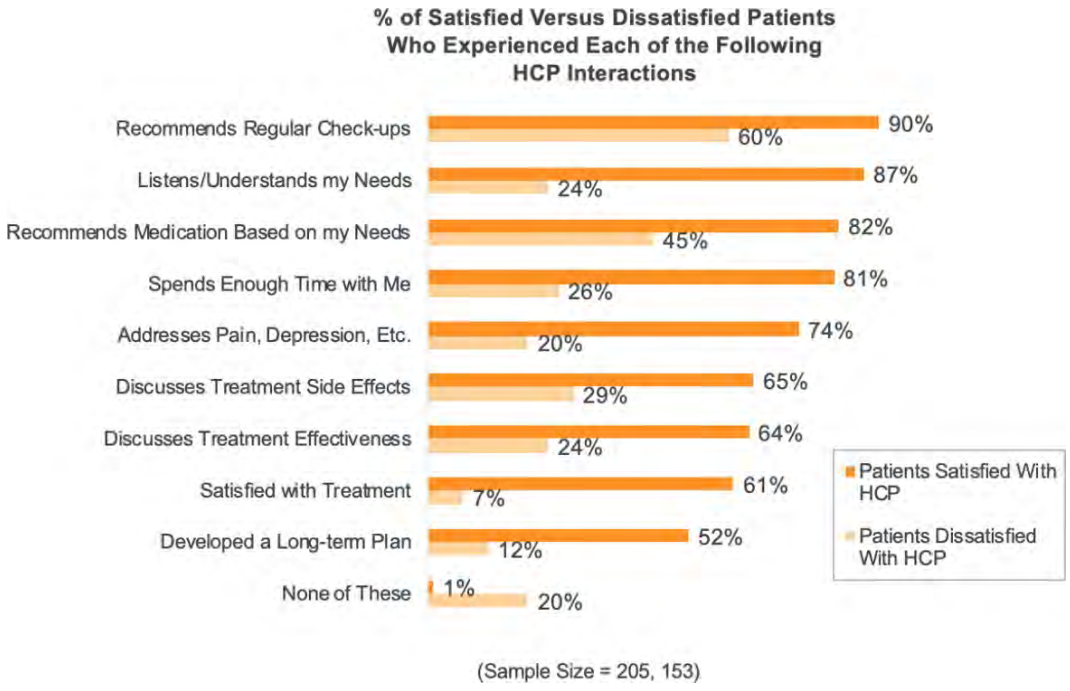
Beth Schneider[1] and Eric Peacock[1], [1]MyHealthTeams, San Francisco, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

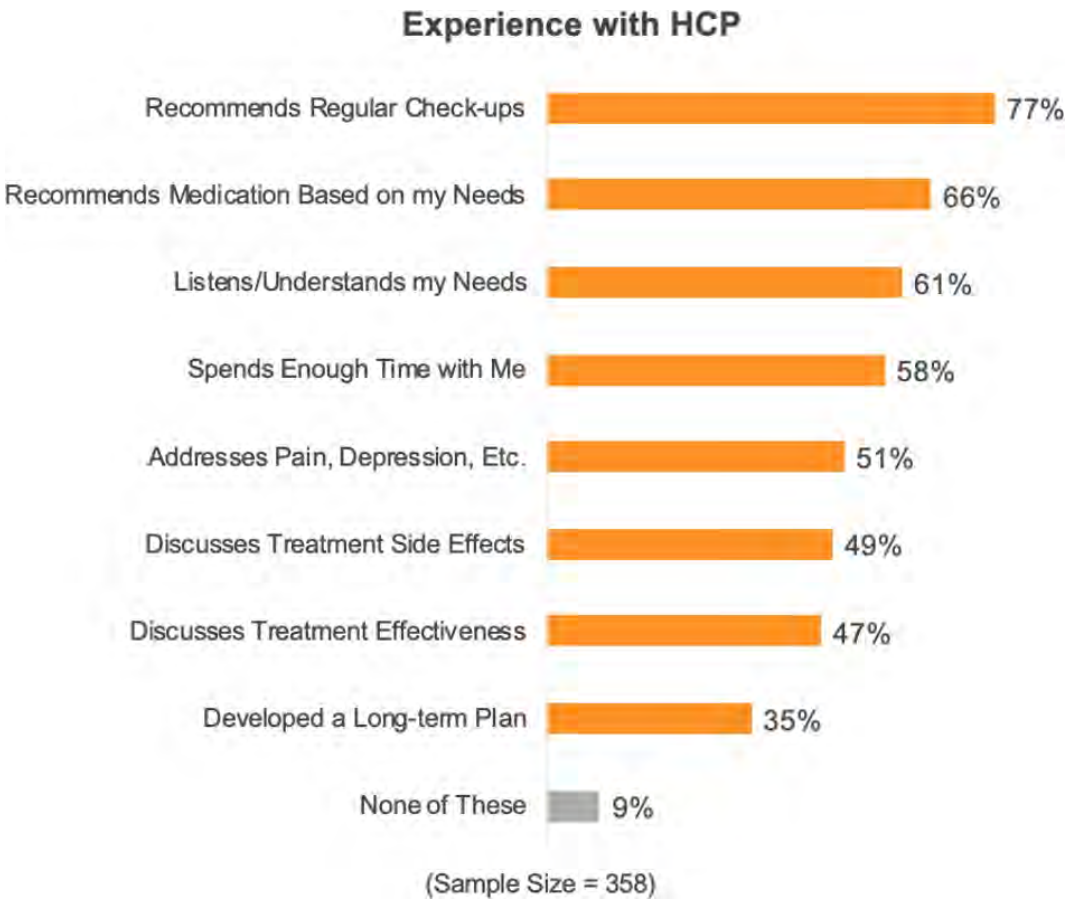
Background/Purpose: Understanding patient satisfaction with their rheumatologist and the drivers of satisfaction is crucial to improving doctor-patient interactions, helping patients get on the right treatment path to help slow progression and improving health outcomes overall.

Methods: In January 2020 an email invitation to an online survey was sent to US members of myRAteam, a social network of over 122,000 members. In total, 374 US members completed the 21-question survey regarding the HCP-patient experience.

Results: Over half of RA patients surveyed are satisfied with their HCP (57%) and 78% feel they are able to have meaningful conversations. The majority feel they're HCP is doing a good job of recommending regular checks-ups (77%) and medications (66%) based on the patient's unique needs. Slightly less than two-thirds feel they're doctor listens to them and truly understands what they are going through (61%) or spends enough time with them (58%). While biggest obstacles to managing RA are pain (80%), relentless fatigue (72%) and depression/anxiety (51%), only 51% of patients feel their HCP addresses these symptoms. Further, only 37% are satisfied with their current treatment and only 49% feel their HCP is adequately discussing potential side effects and 47% treatment efficacy. And only 35% feel their HCP has developed a long-term plan for treating this progressive disease. There is a significant



Experiences with HCPs



Satisfaction with HCP

delta in experiences among those who are satisfied versus dissatisfied with their HCP. 61% of satisfied patients feel their treatment is working versus only 7% who are dissatisfied with their HCP. 87% of satisfied patient feel their HCP listens to and understands them versus 24% of dissatisfied patients. Likewise, 81% of satisfied patients feel their HCP spends enough time with them versus 26% among dissatisfied patients. 74% of satisfied patients feel their doctor addresses symptoms like pain and depression versus 20% of dissatisfied patients.

Conclusion: Understanding the needs of RA patients provides significant opportunities for rheumatologists to better support and educate their patients. This includes offering a stronger recommendation on treatment path based on the patient's specific needs and goals, and specific information on diet/exercise approaches. It also means listening to patient concerns and addressing the mental health aspects of RA including pain, depression and fatigue, and not just disease progression.

Filgotinib Significantly Improved Patient-reported Health-related Quality of Life for Patients with Active Rheumatoid Arthritis: A Post Hoc Analysis of SF-36 and HAQ-DI from Phase 3 Studies

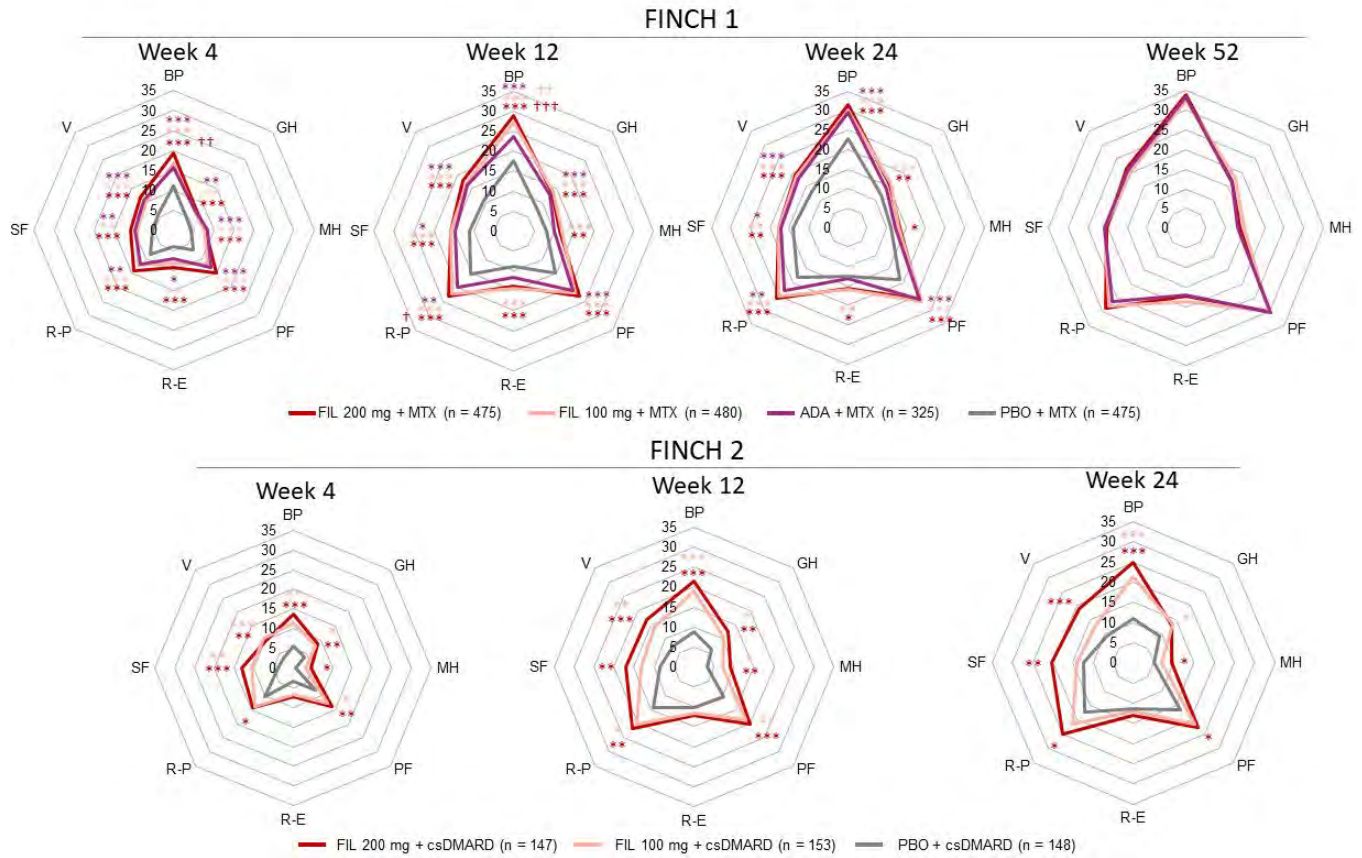
Clifton Bingham III[1], David Walker[2], Peter Nash[3], Susan Lee[4], Lei Ye[4], Hao Hu[4], Javaria Mona Khalid[5] and Bernard Combe[6], [1]Johns Hopkins University, Baltimore, MD, [2]Northumbria Healthcare NHS Foundation Trust, North Shields, United Kingdom, [3]School of Medicine Griffith University, Brisbane, Queensland, Australia, [4]Gilead Sciences, Inc., Foster City, CA, [5]Galapagos BV, Leiden, Netherlands, [6]University of Montpellier, Montpellier, France

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Reduction in pain and fatigue, maintenance of physical functioning, and improvement in health-related quality of life (HRQoL) are vital aspects of successful treatment for patients (pts) with RA. In phase 3 clinical trials, filgotinib (FIL)—a potent, selective, oral, small molecule Janus kinase 1 inhibitor—improved signs and symptoms of RA when used in combination with MTX in pts with inadequate response to MTX (MTX-IR; FINCH 1 study [F1]), or to a biologic (b)DMARD (bDMARD-IR; FINCH 2 study [F2]).[1,2] This is a post hoc analysis of functional status in both studies, with a focus on patient-reported outcomes using the Short Form-36 (SF-36) and HAQ-Disability Index (HAQ-DI).

Methods: All pts met 2010 ACR/EULAR criteria for RA. F1 pts were randomized 3:3:2:3 to receive once-daily FIL 200 mg, FIL 100 mg, adalimumab (ADA), or placebo (PBO) for up to 52 weeks (W) on a weekly sTable background dose of MTX; at W24, pts receiving PBO were rerandomized 1:1 to FIL 200 or 100 mg. F2 pts were randomized 1:1:1 to receive once-daily FIL 200 mg, FIL 100 mg, or PBO for up to 24W on a sTable background dose of permitted conventional synthetic (cs)DMARD(s). SF-36 was assessed at baseline and by visit on W4, 12, 24, 36, and 52. HAQ-DI was assessed at baseline and by visit on W2, 4, 8, 12, 14, 16, 18, 20, 24, 26, 30, 36, 44, and 52. The proportion of pts achieving HAQ-DI $\leq$0.5 was compared for FIL vs PBO (F1/F2) and FIL vs ADA (F1) using logistic regression with treatment groups and stratification factors in the model. Comparisons of change from baseline in SF-36 domains between FIL vs PBO and FIL vs ADA were conducted using mixed-effects model for repeated measures (MMRM)

Figure 1. LS-mean change from baseline in SF-36 individual domains by visit



including treatment group, visit, treatment group by visit interaction, stratification factors, and baseline value as fixed effects; and subjects as random effect. All analyses were exploratory without multiplicity adjustment, and nominal P values are reported.

Results: Improvements in SF-36 domains in all FIL arms were observed as early as W4 and were sustained or increased through end of study (Fig 1). Nominally statistically significant improvements across all SF-36 domain scores occurred for pts on FIL 200 mg vs PBO at W4, 12, and 24 in F1, and 7/8 domains at W4 and 12 in F2; substantial improvements were evident particularly for bodily pain, physical functioning, and role-functional (Fig 1). The proportion of pts with HAQ-DI ≤0.5 was nominally statistically significantly higher in each FIL arm vs PBO early in treatment (W2 for F1 and W8 for F2) and for FIL 200 mg vs ADA at W4, 8, 36, and 52 (F1) (Fig 2).

Conclusion: FIL provided rapid and sustained improvements across multiple aspects of pts' HRQoL captured by SF-36 and HAQ-DI when used in combination with csDMARD for treatment of MTX-IR or bDMARD-IR RA. Improvements in physical activities were observed with both HAQ-DI and SF-36. Furthermore, FIL meaningfully reduced HAQ-DI score to near-normal levels in relatively treatment-resistant bDMARD-IR patients, in addition to more MTX-IR pts on FIL 200 mg reaching this state by end of study when compared to pts on ADA. These results suggest that FIL can improve the daily lives of pts with advanced RA.

PROMIS-29 Scores Are Significantly Higher in Patients with Rheumatoid Arthritis Who Meet Criteria for Co-morbid Fibromyalgia (FM) Than in Those with Rheumatoid Arthritis and No FM

Kathryn Gibson[1], Geraldine Hassett[2] and Theodore Pincus[3], [1]Liverpool Hospital, Sydney, Australia, [2]Liverpool Hospital, Sydney, Liverpool BC, NSW, New South Wales, Australia, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The Patient-Reported Outcomes Measurement Information System short form 29 (PROMIS-29)[1] uses computer assisted technology (CAT) to derive patient assessments. High PROMIS-29 scores are seen in patients with rheumatoid arthritis (RA) with high disease activity, but may also reflect co-morbid FM. This problem is seen also in traditional indices used to assess patients with rheumatoid arthritis (RA), including DAS28, CDAI, and RAPID3 (routine assessment of patient index data 3). For example, a patient with no tender or swollen joints, a physician global assessment of 0, ESR of 20 mm/hr, but a patient global assessment of 80/100, would have a DAS28 of 3.2, suggesting moderate disease activity. Therefore, high scores may indicate high disease activity or co-morbid FM (or both) in RA patients.

	All patients (n=159)	FM 2011 positive (n=37)	FM 2011 negative (n=122)	P	FAST3P positive (n=46)	FAST3P negative (n=113)	P
PROMIS29							
Pain interference	58.0 (9.7)	66.3 (6.6)	55.5 (9.1)	<0.0001	66.3(6.7)	54.6 (8.7)	<0.0001
Depression/Sadness	50.9 (11.1)	62.0 (10.1)	47.5 (8.9)	<0.0001	60.0 (11.6)	47.1 (8.4)	<0.0001
Physical Function	42.2 (8.5)	36.0 (5.5)	44.1 (8.3)	<0.0001	35.1 (4.6)	45.0 (8.0)	<0.0001
Ability to Participate	48.0 (10.4)	39.8 (6.9)	50.4 (10.0)	<0.0001	39.6 (6.9)	51.4 (9.6)	<0.0001
Fatigue	52.5 (11.1)	62.6 (8.5)	49.5 (10.0)	<0.0001	62.5 (8.4)	48.5 (9.5)	<0.0001
Anxiety/Fear	52.0 (11.3)	62.7 (9.6)	48.8 (9.7)	<0.0001	60.6 (11.7)	48.5 (9.1)	<0.0001
Sleep disturbance	53.2 (9.4)	60.8 (8.0)	50.9 (8.6)	<0.0001	60.4 (8.7)	50.3 (8.1)	<0.0001
Pain (VNS)	4.7 (2.8)	7.3 (1.7)	3.9 (2.6)	<0.0001	7.4 (1.5)	3.6 (2.4)	<0.0001
RAPID3 (0-30)	11.5 (7.1)	18.7 (4.9)	9.3 (6.1)	<0.0001	19.2 (3.5)	8.4 (5.7)	<0.0001

PROMIS29 and RAPID3 in all patients and patients with and without FM by 2011 and FAST3P criteria. Higher scores indicate more of the concept being measured in PROMIS-29. In MDHAQ higher scores indicate more severe patient impact of the concept being measured.

Methods: All RA patients attending the Rheumatology clinic at Liverpool Hospital complete a MDHAQ at each visit, and were asked to complete a PROMIS-29 questionnaire,[1] and the 2011 modification of the criteria for Fibromyalgia (2011 FM criteria)[3] on paper. Two indices derived from MDHAQ scores RAPID3=0-30: (physical function=0-10 + pain=0-10 + patient global assessment=0-10) assesses clinical status, and FAST3-P (Fibromyalgia Assessment Screening Tool 3 (2/3=FM): pain≥6/10=1 + number of painful joints≥16/48=1 + number of symptoms≥16/60=1) provides a clue to the presence of FM. PROMIS-29 t-scores were obtained from the Assessment Center scoring service (https://www.assessmentcenter.net/ac_scoringservice). Cross sectional analysis of 159 patients with complete data was performed. Descriptive statistics and t-tests were derived using Stata/IC 16.1 (StataCorp. 2019. Stata Statistical Software: Release 16. College Station, TX: StataCorp LLC.)

Results: Patients had a mean (SD) age of 55.7 (15.2) years, were 67.3% female and had a mean education of 11.6 (4.0) years. 23.3% were found to have co-morbid FM by 2011 FM criteria and 28.9% by FAST3-P criteria. All PROMIS-29 t-scores indicated significantly poorer status in patients with co-morbid FM either by 2011 FM criteria or by FAST3-P criteria (Table). All scores for pain interference, depression/sadness, fatigue, anxiety/fear and sleep disturbance and poorer physical function and ability to participate were more than 0.5 SD from the population mean in the FM positive group, and within 0.5 SD of the population mean in those who did not have positive screening for FM (Table). All MDHAQ variables, including the components of RAPID3 indicated significantly poorer status in patients with co-morbid FM by either criterion (data not shown).

Conclusion: RA patients with comorbid FM by either the 2011 FM criteria or by FAST3-P had significantly higher PROMIS-29 t-scores, than RA patients who did not have FM. Interpretation of these scores in RA patients should consider whether there is coexisting FM in addition to any active inflammatory disease.

Alignment and Discordances in Treatment Perceptions and Shared Decision-Making Among RA Patients and Rheumatology Care Teams

Robert Levin[1], Christopher Parker[2], Kostas Botsoglou[3], Jigar Shah[4], Nimesh Dayal[5], Kristina Fajardo[6], Laura Simone[6], Jeff Carter[6] and Tamar Sapir[6], [1]University of South Florida, Clearwater, FL, [2]Austin Diagnostic Clinic, Austin, TX, [3]Rheumatology Center WNY, Buffalo, NY, [4]Arthritis and Rheumatology Center of South Florida, Margate, FL, [5]Arthritis Center of Orlando, Ocoee, FL, [6]PRIME Education, LLC, Fort Lauderdale, FL

SESSION INFORMATION

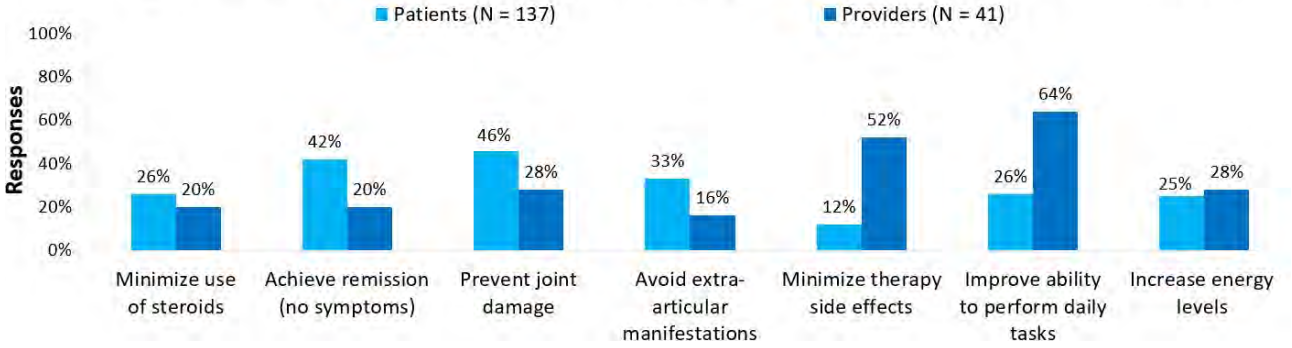
Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Figure 1. Provider and Patient Perspectives on Most Important RA Treatment Goals



Background/Purpose: Evidence-based guidelines for rheumatoid arthritis (RA) call for shared decision-making (SMD) as a method to personalize treatment decisions and achieve treat-to-target goals. We assessed alignment and discordances on treatment and SDM perceptions among RA patients and their rheumatology care teams.

Methods: Between 09/2019 and 06/2020, surveys were administered to RA patients and their health care professional (HCP) teams as part of in-clinic collaborative patient education sessions across 13 US-based rheumatology community practices. On 5-point Likert scales and multi-select questions, patients and HPs rated or indicated their perceptions, preferences, and concerns regarding RA treatment and SDM.

Results: Surveys were completed by 137 patients with RA (81% female, mean age 57 years) and 41 HCPs (52% physicians, 20% nurse practitioners, 4% physician assistants, 24% nurses) who reported 13 mean years of experience in rheumatology. Alignments were found in patients' and HCPs' perceptions of patients' current level of RA control (well or very well controlled: 50% patients vs 58% HCPs) and satisfaction with current therapy (high or very high: 68% patients vs 65% HCPs).

Discordances were found in patients' and HCPs' top goals for RA treatment (Figure 1), which included: prevent joint damage (46% patients, 28% HCPs), achieve remission (42% patients, 20% HCPs), avoid extra-articular manifestations (33% patients, 16% HCPs), improve ability to perform daily tasks (26% patients, 52% HCPs), and minimize therapy side effects (12% patients, 52% HCPs). Discordances were also observed in patients' and HCPs' main concerns about targeted therapy for RA (Figure 2), which included potential side effects (54% patients, 42% HCPs), efficacy (46% patients, 17% HCPs), cost (17% patients, 50% HCPs), and monitoring requirements (6% patients, 33% HCPs).

A high proportion of patients and HCPs reported often or always engaging in multiple components of SDM (Figure 3). However, compared with their patients' responses, HCPs underestimated how often they: explain goals of treat-

Figure 2. Provider and Patient Perspectives on Top Concerns on Targeted Therapies for RA

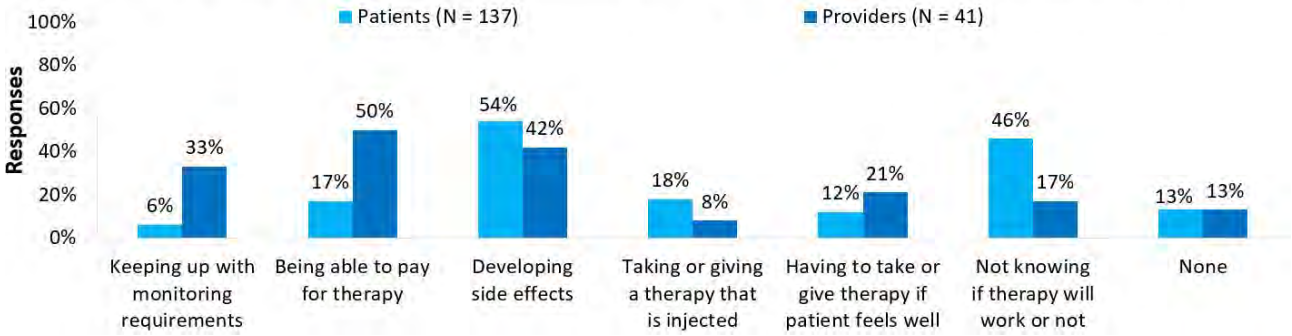


Figure 3. Provider and Patient Perspectives on the Frequency of Shared Decision-Making (SDM)

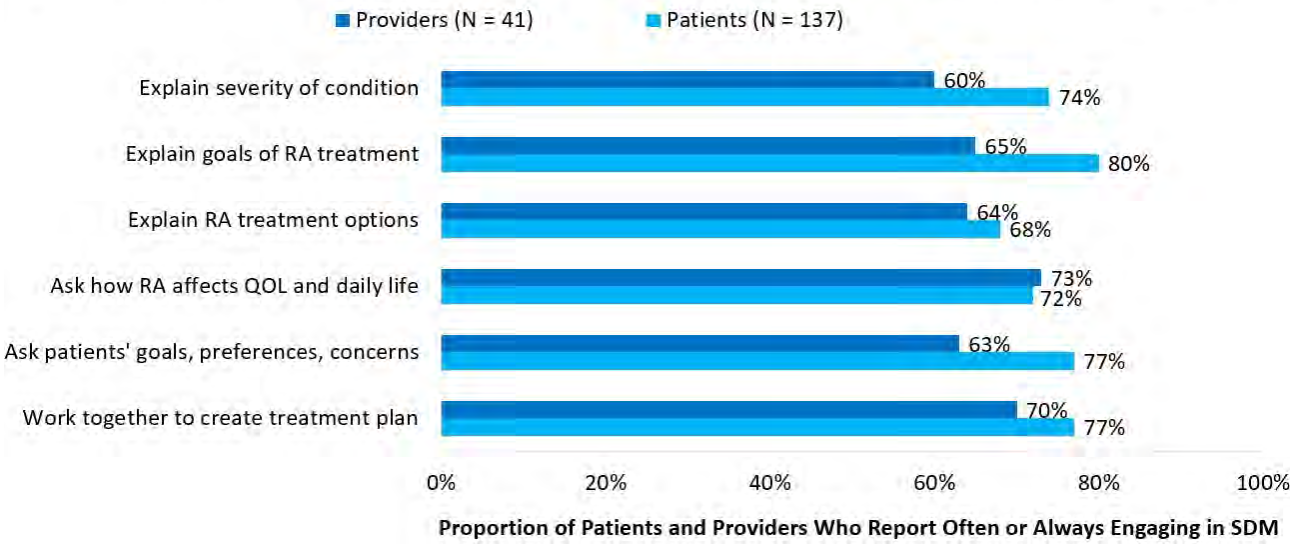

ment (80% patients; 65% HCPs), explain disease severity to patients (74% patients; 60% HCPs), and ask patients' treatment goals, preferences, and concerns (77% patients; 63% HCPs). When asked about the main barrier to SDM, patients reported not knowing enough about RA and available therapies (46%) while HCPs reported perceived patient resistance to SDM (57%).

Conclusion: Identifying alignments and discordances in perceptions of treatment and SDM can support rheumatology teams in individualizing treatment decisions and patient engagement for optimal RA care.

Routine Assessment of Patient Index Data (RAPID) 3 as a Predictor of Weight Reduction in Rheumatology Patients Undergoing Bariatric Surgery

John Byun[1], Meenakshi Jolly[2], Todd Beck[1] and Sobia Hassan[2], [1]Rush University, Chicago, [2]Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

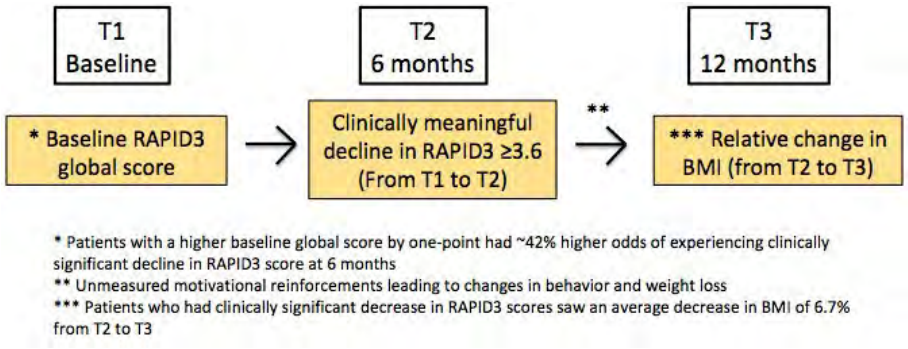
Background/Purpose: Obesity is associated with higher disease activity in many rheumatologic diseases with evidence of improvement following bariatric surgery. Despite the impressive average weight loss values that occur after surgery, 10–30% of patients will have suboptimal weight loss or weight-regain. The RAPID3 on Multidimensional Health Assessment Questionnaire (MDHAQ), is a patient-reported, disease monitoring index with 3 components:

Age at Surgery (mean ± SD) years	49.2 ± 8.9
Women (%)	97
Race (%)	
Caucasian	30.3
African American	48.5
Hispanic	21.2
Education (mean ± SD) years	14.0 ± 2.8
Osteoarthritis (%)	57.6
Fibromyalgia (%)	51.5
Average # of Medical Comorbidities	5.0
Type of Bariatric Surgery (%):	
Laparoscopic surgical gastrectomy	69
Lap band	9
Open surgical gastrectomy	3
Roux-en-Y gastric bypass	15
Unknown	3

Patient Baseline Characteristics Prior to Bariatric Surgery

Variable	T1 baseline/pre-surgical	T2 (6 months post-surgical)	T3 (12 months post surgical)
BMI (mean ± SD)	45.8 ± 7.1	37.6 ± 6.4	37.1 ± 6.6
% Change (decrease) in BMI		17.7	19.3
MDHAQ FN (mean ± SD)	3.4 ± 2.0	2.3 ± 1.5	2.8 ± 1.8
MDHAQ PN (mean ± SD)	6.4 ± 2.7	6.1 ± 2.9	5.8 ± 2.9
MDHAQ GL (mean ± SD)	5.2 ± 3.1	5.0 ± 2.7	5.2 ± 2.7
RAPID3 index (mean ± SD)	15.0 ± 6.4	13.4 ± 6.3	13.8 ± 6.4
Patients with Significant Decline in RAPID3 of at Least 3.6 compared to baseline (%)		30.3	21.4

Changes in BMI and RAPID3 Variables After Bariatric Surgery



Two-Stage Model Showing Longitudinal Relationship Between T1 RAPID 3 Global Score, Clinically Significant Decline in RAPID3 at T2, and Subsequent BMI decline from T2 to T3

Function (FN), Pain (PN), and Global Health (GL). This longitudinal study explored predictors of improvement in RAPID3 and weight loss in rheumatology patients before and after bariatric surgery.

Methods: Rheumatology patients evaluated between 2012-2019 with documented RAPID3 scores were enrolled. Variables collected included demographics, BMI, and MDHAQ components at baseline/pre-surgery (T1), 6 month post-surgery (T2) and 12 month post-surgery (T3). For Model 1, we conducted a univariate binary logistic regression analysis with clinically significant improvement in RAPID3 (defined as decline of ≥3.6) between T1 and T2 as the dependent variable (DV). Predictor variables (PV) tested include age, education, comorbidities, T1 BMI, and TI MDHAQ. For Model 2, we performed a linear regression analysis for % change in BMI between T2 and T3 as the DV, and clinically significant change in RAPID3 index as the PV. Change in BMI of 5% was considered clinically relevant. A P value of ≤0.05 was considered significant on two-tailed tests.

Results: 33 patients were enrolled (97% women). 30.3% were Caucasian, 48.5% African American, and 21.2% Hispanic (Table 1). Mean BMI and RAPID3 Index at T1 were 45.8 and 15.0, respectively. Changes in BMI and RAPID3 at T2 and T3 are shown in Table 2. There were no differences in BMI or RAPID3 by race. T1 RAPID3 GL predicted attainment of a clinically significant improvement in RAPID3 at T2 (OR 1.42, 95% CI 1.02-1.98, p=0.04). T1 BMI or % change in BMI were not predictive of a clinically significant change in RAPID3 at T2. Subjects with clinically significant decreases in RAPID3 scores at T2, saw a 7.5% greater decline in BMI from T2 to T3 compared to those without significant decrease (β 0.075, 95% CI 0.033-0.117, p=0.0015). Nearly 30% decline in % BMI change from T2 to T3 was explained by clinically significant decrease in RAPID3 index (R-Sq 0.29) at T2 (Figure 1).

Conclusion: Higher pre-surgical MDHAQ GL score predicted clinically relevant improvements in RAPID3 index at 6 months post-bariatric surgery. Attaining significant improvement in RAPID3 index at 6 months was further predictive of clinically relevant decline in BMI at 12 months. A plausible mechanism involves reinforcement in patients' behavioral changes as a result of perceptible health improvements. Longitudinal studies with larger numbers of patients will be required to see if improvements in RAPID3 leads to sustained weight loss, and whether this leads to improvement in their underlying rheumatological condition.

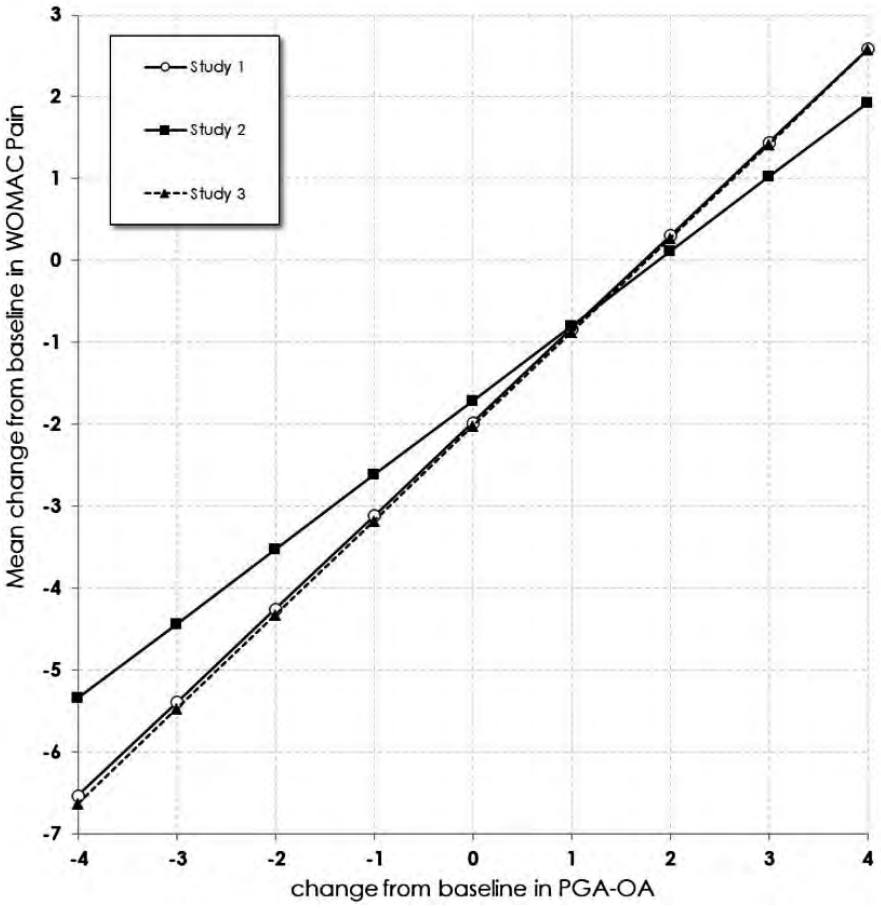
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) is a disease-specific measure of osteoarthritis (OA) symptoms (pain and stiffness) and functional impairment regularly used in clinical trials. To aid interpretation of the clinical meaningfulness of response to treatment, it is important to de-

Figure 1. Change in WOMAC Pain Domain (original units) versus change in PGA-OA in all 3 studies.



PGA-OA, patient's global assessment of osteoarthritis; WOMAC Western Ontario and McMaster Universities Osteoarthritis Index.

Table 1. Meaningful within-patient change by domain and study.

WOMAC domain	Study					
	1		2		3

Total	15.1	30.3	12.9	25.8	15.5	31.0

PGA-OA, patient's global assessment of osteoarthritis; WOMAC Western Ontario and McMaster Universities Osteoarthritis Index.

termine thresholds for WOMAC that would indicate meaningful within-patient change (MWPC), where an individual has experienced a meaningful clinical benefit. Our aim therefore was to define MWPC in WOMAC by examining the relationship between change in WOMAC domains and change in patient global assessment (PGA-OA) as an anchor (as recommended in recent FDA guidance[1]) in patients with moderate-to-severe OA.

Methods: WOMAC numerical rating scale (NRS) 3.1 Index[2] consists of 24 items measuring pain (5 items), stiffness (2 items) and physical function (17 items), assessed using a 0-10 NRS with higher scores indicating worse outcomes. Data were analyzed separately from three Phase 3 clinical trials of tanezumab, a novel treatment intended for the relief of signs and symptoms of moderate-to-severe OA, administered subcutaneously every 8 weeks. Studies 1 (NCT02697773) and 2 (NCT02709486) were 16- and 24-week placebo-controlled trials, respectively; study 3 (NCT02528188) was a 56-week active-controlled trial. Patients with moderate-to-severe OA of the hip or knee completed the WOMAC and PGA-OA at regular time points. A repeated measures model with change in WOMAC domain score as the outcome and change in PGA-OA as the anchor was used to establish MWPC for WOMAC domains.

Results: In the 3 studies there were 688, 844, and 2948 subjects available for analyses, respectively. Analysis showed that a linearity assumption for the relationship between changes in WOMAC domains and changes in PGA-OA was appropriate. Moreover, the relationships between these changes were very close for two trials and similar for the third (**Figure 1)**. The estimated MWPC for the three WOMAC domains were from 0.8 to 1.2 (NRS from 0 to 10) and from 12.5 to 16.2%, depending on study and domain, that corresponded to a 1- category change on PGA-OA (**Table 1**). For a 2-category change those values were from 1.7 to 2.3 and from 25.0 to 32.5%, respectively. Values were similar to and supportive of published results.[3] While the relationship between change in PGA-OA and change in WOMAC was approximately linear, the correspondence between, for example, ratings of 'no change' on the PGA-OA with changes in WOMAC pain may be a manifestation of their measuring similar but distinct concepts.

Conclusion: These results establish MWPCs for WOMAC domains, at the individual patient level, for patients with moderate-to-severe OA of hip or knee. The relationship between change in PGA-OA and change in WOMAC is the focus of ongoing evaluation.

These studies were sponsored by Pfizer and Lilly. Medical writing support was provided by Steven Moore, PhD, of Engage Scientific Solutions and was funded by Pfizer and Lilly.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is a potent oral selective janus kinase 1 inhibitor which is currently being investigated as an agent to treat rheumatoid arthritis (RA). In the FINCH 1 study (NCT02889796), FIL in combination with methotrexate (MTX) provided a rapid and meaningful clinical response in patients with inadequate response to MTX. Chronic inflammatory diseases such as RA substantially affects a broad range of aspects of the patient's health related quality of life including work participation.[1] The aim of this post-hoc analysis was to evaluate the rate and magnitude of change from baseline and assess the effect of treatment response on work productivity and activity scores in RA patients from the FINCH 1 study.

Methods: Patients with active RA were randomized to receive FIL 200 mg (n=475), FIL 100 mg (n=480), or subcutaneous adalimumab (ADA) 40 mg (n=325), or PBO (n=475) with concomitant MTX treatment in all groups for up to 52 weeks. At week 24, patients receiving PBO were randomized 1:1 to FIL 200 mg or 100 mg. The activity impairment, work productivity impairment, presenteeism, and absenteeism in the past 7 days were evaluated at baseline and then

Table 1. Baseline demographics and mean percentage change from baseline in WPAI scores at each visit.

**p <0.01, *p <0.05 for LS mean of the difference vs PBO. P values were not adjusted for multiplicity.

Decrease in score represents improvement. –, not measured at this time point because in FINCH 1, patients receiving PBO were rerandomized 1:1 to FIL 200 or 100 mg at week 24.

ADA, adalimumab; FIL, filgotinib; MTX, methotrexate; PBO, placebo.

at weeks 4, 12, 24, 36 and 52 on treatment, using the self-administered 6-item Work Productivity and Activity Impairment Questionnaire: Rheumatoid Arthritis (WPAI:RA). (employed patients only) The 4 subscale scores ranged from 0%-100%, with higher scores indicating greater impairment. changes from baseline in WPAI: RA score were analyzed using mixed effect models for repeated measures (MMRM), and missing data were not imputed. All analyses were exploratory without multiplicity adjustment, and nominal P values are reported.

Results: The baseline demographics were relatively consistent across all treatment arms. Patients were (mean ± SD) 35 ± 13 years old, 82% female and 40% employed. Statistically significantly greater improvement in WPAI scores from baseline compared to PBO was reported as early as week 4 with FIL 200 mg, and week 12 with FIL 100 mg for work productivity, presenteeism, and activity (**Table 1**). At 24 weeks, both doses of FIL resulted in 21.5-24.4% improvement in work productivity and presenteeism compared to 11.4-14.7% in PBO. Similarly, both doses of FIL improved activity impairment score by 31% from baseline compared to 21.7% in PBO. Improvement over baseline

persisted throughout treatment until week 52 for both FIL doses. WPAI scores were similar for both FIL doses and ADA throughout the study.

Conclusion: Improvement in overall work productivity, presenteeism, and daily activity was greater with both doses of FIL in combination with MTX compared to PBO + MTX in RA patients who had inadequate response to MTX.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is a potent oral selective janus kinase 1 inhibitor which is currently being investigated as an agent to treat rheumatoid arthritis (RA). In the FINCH 2 study (NCT02873936), FIL in combination with conventional synthetic (cs)DMARD therapy significantly improved the signs and symptoms of RA in patients with an inadequate response to a biologic (b)DMARD compared with placebo (PBO). Chronic inflammatory diseases such as RA substantially affects a broad range of aspects of patients' health related quality of life, including work participation.[1] The aim of this post-hoc analysis is to evaluate the rate and magnitude of change on work productivity and activity scores from the FINCH 2 study.

Methods: Patients with active RA were randomized to receive FIL 200 mg (n = 147), FIL 100 mg (n = 153), and PBO (n = 148) for 24 weeks. The activity impairment, work productivity impairment, presenteeism, and absenteeism in the past 7 days were evaluated at baseline and at weeks 4, 12 and 52 on treatment, using the self-administered 6-item Work Productivity and Activity Impairment Questionnaire: Rheumatoid Arthritis (WPAI:RA). The WPAI-RA contains

Decrease in score represents improvement.

csDMARD, conventional synthetic disease-modifying antirheumatic agent; FIL, filgotinib; PBO, placebo.

Table 1. Demographics

the activity impairment as a single item score evaluated among all subjects, while work productivity impairment (employed patients only) is absenteeism and presenteeism. The 4 subscale scores ranged from 0%-100%, with higher scores indicating greater impairment. Percentage changes from baseline in WPAI: RA score were analyzed using mixed effect models for repeated measures (MMRM), and missing data were not imputed. All analyses were exploratory without multiplicity adjustment, nominal P values are reported.

Results: Baseline characteristics were similar across all treatment arms. Patients were (mean ± SD) 56 ± 12 years old, 80% female, and 32% employed. Statistically significantly greater improvement in WPAI scores from baseline compared to PBO was reported as early as week 4 with both doses of FIL for work productivity and activity. Similar statistically significant improvement occurred as early as week 4 for presenteeism with FIL 200mg and as early as week 12 for FIL 100mg. (**Table 1**). At 12 weeks, FIL 200mg resulted in 21.5-24.7%% improvement in work productivity and presenteeism compared to 4.8-5.1% in PBO. Both doses of FIL improved activity impairment score by 19.6-25.8% from baseline compared to 11.7% in PBO at week 12 and was maintained through week 24.

Conclusion: Improvement in work productivity, presenteeism and activity was greater with both doses of FIL in combination with csDMARD compared to PBO + csDMARD in RA patients who had inadequate response to bDMARDs.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is a potent oral selective janus kinase 1 inhibitor currently being investigated as an agent to treat rheumatoid arthritis (RA). In the FINCH 3 study (NCT02886728), FIL in combination with methotrexate (MTX), demonstrated rapid and significant improvements in the signs and symptoms of RA vs MTX monotherapy in patients who were MTX-naïve. Chronic inflammatory diseases such as RA substantially affects a broad range of aspects of patient health related quality of life, including work participation.[1] The objective of this post-hoc analysis was to evaluate the rate and magnitude of treatment response on work productivity and activity scores in RA patients from the FINCH 3 study.

Methods: Patients with active RA and MTX-naïve were randomized 2:1:1:2 received FIL 200 mg + MTX, FIL 100 mg + MTX, FIL 200 mg (+ PBO), or MTX (+ PBO) for up to 52 weeks. The activity impairment, work productivity impairment, presenteeism, and absenteeism in the past 7 days were evaluated at baseline and at weeks 4, 12, 24, 36 and 52 on treatment, using the self-administered 6-item Work Productivity and Activity Impairment Questionnaire: Rheumatoid Arthritis (WPAI:RA). The WPAI-RA contains the activity impairment as a single item score evaluated among all subjects, while work productivity impairment (employed patients only) absenteeism and presenteeism. The 4 subscale scores ranged from 0%-100%, with higher scores indicating greater impairment. Percentage changes from baseline in WPAI: RA score were analyzed using mixed effect models for repeated measures (MMRM), and missing data were not imputed. All analyses were exploratory without multiplicity adjustment, and nominal P values are reported.

**p<0.01, *p <0.05 for LS mean of the difference vs MTX. P values were not adjusted for multiplicity.

Decrease in score represents improvement.

FIL, filgotinib; MTX, methotrexate.

Results: Baseline characteristics were similar across all treatment group. Patients were (mean ± SD) 53 ± 14 years old, 80% female, and 42% employed. Statistically significantly greater improvement in work productivity, presenteeism and activity from baseline was reported as early as week 4 with all FIL treatment group compared to MTX alone (**Table 1**). This improvement over baseline persisted through week 12 for both doses of FIL + MTX and throughout 52 weeks of treatment for FIL 200mg + MTX compared to MTX alone. At week 52, both doses of FIL + MTX resulted in 33.4-39.9% improvement in work productivity, presenteeism, and activity.

Conclusion: FIL monotherapy or with concomitant MTX led to earlier improvements in activity impairment, overall work productivity impairment and presenteeism in RA patients who were naïve to MTX compared to MTX alone.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this study is to understand experiences of empowerment in healthcare visits among US adults with arthritis, and key factors associated with discrepancies in empowerment, including sociodemographics and patient-reported health outcomes.

Items by Subdomain	Lead-in and Response Options*	
	During the last 6 months, did you feel that...	*During the last 6 months, how important is it that...*
Patient Information-Seeking	Not at all (1)	Not important at all (1)
You asked for explanations	Somewhat (2)	Slightly important (2)
You asked questions	Quite a bit (3)	Very important (3)
You asked for advice	Very much (4)	Extremely important (4)
Result of Self-Advocacy		
You were able to talk to a professional to answer your questions		
Your choices were respected		
You obtained all the information you wanted		
You got the help you needed		

Note: Respondents rated feeling and importance of each item. Scores are calculated by summing the cross-product of feeling and importance ratings for items within the subdomain. There are three items in the Involvement in Decision subdomains and four items in the Involvement in Interactions, so the possible ranges are 3-48 points and 4-64 points, respectively.

Table 1. Demographics

Methods: Data were collected through online surveys of a convenience sample of adults with arthritis in the United States from March 2019 to March 2020 through the Arthritis Foundation's LiveYes! INSIGHTS program. The primary outcome, patient empowerment, was measured by two domains of the Health Care Empowerment Questionnaire (HCEQ): Involvement in Decisions (6 items) which we call Patient Information Seeking, and Involvement in Interactions (8 items) which we call Result of Self-Advocacy. Additional patient-reported outcomes were measured using the PROMIS-29® and sociodemographic data were collected. We analyzed surveys in which individuals had seen a

	Patient Information Seeking			Result of Self-Advocacy

Table 2. Bivariate Analyses

doctor in the last 6 months, completed all HCEQ items, and provided key demographics. We tested for association between the dependent variables (Patient Information-Seeking and Result of Self-Advocacy) and independent variables using one-way Analysis of Variance (gender, race, education, income, rurality, arthritis type) or simple linear regression (age, number of arthritic conditions, years since diagnosis, and PROMIS-29 subscales) with the dependent variables (HCEQ scales). P-value < 0.050 was considered statistically significant; between groups, ≥10% differences in means of HCEQ scores were considered meaningful.

Results: 8,193 surveys were analyzed. Lower HCEQ scores for both Patient Information-Seeking and Result of Self-Advocacy were significantly and meaningfully associated with higher age (r^2=0.005, p< 0.001 and r^2=0.012, p< 0.001), lower educational attainment (F(4, 8188) = 29.39, p< 0.001, and F(4, 8188) = 31.47, p< 0.001), and lower income (F(5, 7543) = 21.73, p< 0.001, and F(5, 7543) = 44.55, p< 0.001), Respondents' HCEQ scores did not differ significantly and/or meaningfully based on gender, race, geographic area, time since diagnosis, or number of arthritic conditions (p >0.050). Respondents with Osteoarthritis (OA) only (compared to those with Rheumatoid Arthritis (RA) only or OA and RA only) reported significantly and meaningfully lower Result of Self-Advocacy (F(2, 2718) = 30.97, p< 0.001); their Patient Information-Seeking was significantly but not meaningfully lower (F(2, 2718) = 7.01, p< 0.001). Result of Self-Advocacy had a strong negative correlation with PROMIS subdomains of Anxiety (r^2=0.012, p< 0.001), Depression (r^2=0.022, p< 0.001), Pain Interference (r^2=0.007, p< 0.001), and Physical Function (r^2=0.010, p< 0.001); each of these domains had weak to moderate negative correlation with Patient Information-Seeking.

Conclusion: Results of Self-Advocacy was lower among those who were older, less educated, lower income, more anxious, more depressed, experiencing greater pain, or better physical function. Similar but muted trends were seen for patient information-seeking. The differences between patient information seeking and self-advocacy indicate that while patients may feel comforTable seeking information, they may still have unmet needs.

Treat-to-Target in Rheumatoid Arthritis: Rates of Treatment Changes in Patients Engaged with Care Management Services Compared to Historically Reported National Registry Based Estimates

Pranav Patel[1], Andrew Krueger[2], Aliza Lipson[3], **Michele Hamburger**[4] and Craig Hunter[5], [1]CVS Health, Toledo, OH, [2]Accordant Health Services, Greensboro, NC, [3]Emory University, Palmetto Bay, FL, [4]Frances Hamburger Institute, Hauppauge, NY, [5]CVS Health, Northbrook

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target is the foundation of rheumatoid arthritis (RA) management. Prioritizing routine measurement of patient-reported disease activity along with conventional physician, laboratory and imaging assessments is vital to achieving this target. However, in the practice setting, alliance with treat-to-target recommendations is often a challenge. A recent report published in Arthritis Care and Research demonstrates that only 35%-55% of patients change their treatment even when experiencing moderate to high disease activity as measured by either the Routine Assessment of Patient Index Data 3 (RAPID3) or Clinical Disease Activity Index (CDAI) RA assessment tools using data from a national registry. Previous research has indicated that nurse-led care management may improve adherence to treat-to-target recommendations. The purpose of this study is to assess the rate of treatment changes among patients with RA who are actively engaged in a care-management program, monitored using the modified Health Assessment Questionnaire (mHAQ), and results shared with the treating physician compared to historically reported national registry based estimates obtained from a recent study.

Age, years (mean, SD)	52.6 (9.5)
Age, n (%)	
18-39	115 (66.9%)

** cDMARD – Methotrexate, Sulfasalazine, Leflunomide, Hydroxychloroquine
*** bDMARD – Adalimumab, Certolizumab pegol, Etanercept, Golimumab, Infliximab, Abatacept, Rituximab, Sarilumab, Tocilizumab, Baricitinib, Tofacitinib

Table 1. Demographic Characteristics (N=172)

	Patients Experiencing Progressive Functional Losses*	Patients Undergoing Change in Therapy	Change in Therapy (%)
Total	88	60	68.2%
Normal to Mild	49	25	51.0%
Mild to Moderate	32	28	87.5%
Moderate to Severe	7	7	100.0%
	Treatment Naïve (n)	Therapy Initiation (n)	Therapy Initiation (%)
Total	43	18	41.9%
Normal to Mild	30	11	36.7%
Mild to Moderate	13	7	53.8%

*Progressive functional losses defined as transition from normal (mHAQ<0.3), mild (1.3<mHAQ<0.3), moderate (1.3<mHAQ<1.8), and severe (mHAQ>1.8)

Table 2. Rate of Therapy Changes/Initiations

Methods: This is a single arm retrospective study of patients engaged in care management services between 2016 and 2019. Adult patients (≥ 18 years), with RA (by International Classification of Diseases , Tenth Revision codes), and engaged with care-management services for at least 12 months from the index date (date of first mHAQ score) were included in this analysis. Treatment changes associated with progressive functional losses were documented and rates of change were assessed. Progressive functional losses were classified as transitioning from normal (mHAQ<

0.3), mild (0.3< mHAQ< 1.3), moderate (1.3< mHAQ< 1.8), and severe (mHAQ >1.8). Baseline regimens were classified based on utilization of cDMARD (MTX, SSZ, LEF, HCQ) and bDMARD (TNF-α inhibitors, Abatacept, Rituximab, Sarilumab, Tocilizumab, Baricitinib, Tofacitinib). Rates of treatment changes were compared to historically reported national registry based estimates obtained from a recent study.

Results: A total of 172 patients were included in the study, the majority were female (76.7%) and the mean age was 52.6 years (SD = 9.5). Baseline treatment regimens included cDMARD (59.3%), bDMARD (7%), combination (8.7%), and treatment naïve (25%). Depression (17.4%) and diabetes (12.8%) were the most commonly reported comorbidities. The rate of therapy change was 68% among those who were actively engaged and warranted a change in therapy based on progressive loss of functional status. Among the treatment naïve, 42% had initiated therapy during the observation period.

Conclusion: Utilization of patient-reported disease severity measures and shared decision making, in a nurse led care-management program appear to improve adherence to treat-to-target recommendations as compared to standard practice without care-management support. A limitation of this study – and potential value for future research – was the lack of a clinician-driven assessment, such as the CDAI, and its correlation to the findings herein based on patient-driven (mHAQ) assessments.

Patients' Perceptions and Expectations Towards the Role of Rheumatologists in the Recommendations of Physical Activity's Practice - A Cross-sectional Study Involving 308 Patients Living with Rheumatoid Arthritis in France

Anne-Christine Rat[1], Arnaud Constantin[2], Catherine Beauvais[3], Yannick Guillodo[4], Valérie Guay[5], Emilie Pain[6], Alexis Bombezin--Domino[6] and Florence E Lévy Weil[7], [1]Universite de Caen Normandie and Université de Lorraine, EA 4360, Caen, France, [2]Hospital Pierre Paul Riquet, Toulouse, France, [3]Saint-Antoine Hospital, AP-HP, Rheumatology Department, Sorbonne-Université, Paris, France, Paris, France, [4]La Cavale Blanche University Hospital, Rheumatology Department, Brest, France, Brest, France, [5]Argenteuil Hospital, Physiotherapist, Health executive, Argenteuil, France, Argenteuil, France, [6]Carenity, Online Patient Community, Paris, France, Paris, France, [7]Sanofi Genzyme, Gentilly, France, Gentilly, France

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatologists consider physical activity (PA) to be an important goal in the care for patients with rheumatoid arthritis (RA). However, there are very few studies on patients' perceptions of and expectations on the rheumatologist's role in the advising of PA practice.

The objective of this study was to describe the practice of PA in RA patients, in particular their perception of rheumatologist recommendations to engage in PA.

Methods: An online survey was conducted among French RA patients on Carenity.com, an online patient community. The survey was available from January 17th to February 25th, 2019. To ensure RA diagnosis, only patients who had declared being treated with at least one Disease Modifying Anti-Rheumatic Drug were included in the analysis.

Results: 308 patients participated in the study, 89% women; average age 53 years old (SD: 11.0); average time since RA diagnosis 9 years; 68% of patients were on methotrexate, 37% on biologics and 5% on JAK inhibitors.

97% of patients reported that they were engaged in a PA: domestic activities (77%), active transportation (i.e. walking or cycling) (73%), and sports (36%). However, 74% of patients reported a decrease in their PA level (both frequency and intensity) since their RA diagnosis.

Fatigue (64%), pain (54%) and lack of mobility (38%) were the main barriers to PA practice. Physician advice plays an important role in patients' motivation to engage in PA. In fact, after beneficial effects on mood (69%) and condition (44%), physician's advice (24%) was the third main motivation to engage in PA.

Physicians prescribed physiotherapy for 55% of patients. Despite the important role of doctors in patients' motivation, only 38% of patients were asked about their PA practice by their physician, 34% received advice and 9% were referred to PA sessions by their physician.

Moreover, half of the patients believed their rheumatologist did not know what type of PA to recommend in their case (median: 5.0/10, with 10="Totally agree"); a quarter of patients felt that their rheumatologist had limited knowledge of the impact of PA practice on joints and were not able to answer their questions on PA (third quartile: 5.0/10, with 10= "Totally agree").

When asked about their expectations regarding possible support in the practice of PA, patients spontaneously mentioned personalized advice/information and easier access to sport classes or specialized equipment. Brochures on recommended activities, exercise videos and brochures on the benefits of PA practice were considered useful by 52%, 45% and 42% of patients respectively.

Conclusion: Given that engagement in PA is considered an integral part of RA management, rheumatologists play an essential role in encouraging PA practice, along with other health professionals, including physiotherapists. As the study has shown, communication between physicians and RA patients about PA with personalized and practical information on PA practice should be encouraged.

Abstract Number: 0147

The Interpretation of Patient-reported Outcomes in Rheumatoid Arthritis: Do Clinical Trials Adequately Evaluate Meaningful Improvements for Patients?

Peter Taylor[1], Robin Dore[2], Kate Williams[3], Sarah Acaster[3], Jenya Antonova[4] and Mark Genovese[5], [1]Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Private practice, Tustin, CA, [3]Acaster Lloyd Consulting, London, United Kingdom, [4]Gilead Sciences, Foster City, CA, [5]Gilead Sciences, Inc., Foster City, CA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The importance of patient-relevant outcomes, such as pain, fatigue and physical functioning, has been long established in the field of rheumatoid arthritis (RA). Patient-reported outcomes (PROs) questionnaires evaluate these outcomes in RA clinical trials and can differentiate treatments. However, this ability depends on the interpretation of PRO endpoints. Measuring PRO changes that are meaningful to patients can help clinicians optimize the treatment selection and evaluate outcomes within the treat-to-target approach, recommended by ACR. For the incoming RA treatments within the Janus kinase inhibitors (JAKis) class, we aimed to evaluate the available metrics to capture meaningful individual-patient-level change in most common PROs.

Methods: A targeted PubMed literature search was conducted to identify RA clinical trials of JAKis published between 1st Jan 2009 and 1st April 2020 that included a PRO as an outcome. We reviewed relevant publications and conference abstracts to identify values used to interpret PROs. Follow-up literature searches were conducted to determine and critically appraise methods used to derive these values.

Results: Among 101 papers meeting the inclusion criteria, 35 reported the proportion of patients achieving a *minimal* (clinically) important difference [M(C)ID] on Health Assessment Questionnaire Disability Index (HAQ-DI), Pain visual analogue scale (VAS), Patient Global Assessment (PtGA), Short-Form 36 (SF-36), Functional Assessment of Chronic Illness–Fatigue (FACIT-Fatigue), Insomnia Severity Index (ISI), morning stiffness severity and duration. However, the secondary methodological search revealed no evidence supporting the application of these values to interpret individual-patient-level *meaningful* change (Table 1).

Conclusion: Despite common use of PROs MID/MCID thresholds in the RA clinical trials of JAKis, current methods lack evidence of the methodologically robust magnitude of change meaningful to individuals. These findings highlight a need to re-evaluate the patient-relevance of PRO metrics in RA clinical trials, and potentially explore other endpoints, such as the Patient AccepTable Symptom State. The availability of methodologically robust, patient-relevant,

	Values applied to individual patient-level change in RA clinical trials of JAKis		
PRO	**Value applied to individual patient-level change (and reference to source)**	**Sufficient evidence to define individual patient-level change?**	**Methods used to derive value**
HAQ-DI	≥0.22 or ≥0.3 (Wells et al, 1993)	No	Anchor-based, but not an established PRO of the same concept (i.e. physical functioning and disability)

Abstract Number: 0148

Perspectives on Treatment Burden for Methotrexate and TNF-inhibitors Among Psoriatic Arthritis and Rheumatoid Arthritis Patients: A Qualitative Study

Alexis Ogdie[1], Yomei Shaw[2], Michele Almonte[3], Ervant Maksabedian[4] and Kaleb Michaud[5], [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Forward, The National Databank for Rheumatic Diseases, East Lansing, MI, [3]University of Pennsylvania, Philadelphia, PA, [4]Amgen Inc., LOS ANGELES, CA, [5]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Physicians often consider adverse events when choosing therapies for PsA and RA but may give less attention to other ways in which treatments affect the well-being of patients, such as impacts on quality of life, barriers to access, and challenges with taking medications. In a previous study examining the prevalence of side effects to TNF inhibitors (TNFi) and methotrexate (MTX) in FORWARD, The National Databank for Rheumatic Diseases, we found that side effects were wide ranging and differed for PsA and RA and by treatment. The objective of this qualitative study was to consider patients' perspectives on the treatment burdens of MTX and TNFi's, the most commonly used therapies in PsA and RA.

Methods: We conducted semi-structured interviews with 24 patients with RA and 25 patients with PsA from 05/2019-03/2020 who were enrolled in FORWARD with documented use of MTX or TNFi. Participants were asked about their experiences with medications for their disease, specifically MTX and TNFi. Interviews were recorded and transcribed. Transcripts were analyzed using a grounded theory approach and NVivo software (v12.0). We coded concepts related to treatment burden, effectiveness of medications, decision-making, disease course, and impacts on daily life such as social relationships and work. We examined how medication type shaped patient experiences with treatment burdens.

Results: Participants were mostly female (72% in PsA, 88% in RA), all Caucasian, aged 45-85 years, and with disease duration of 4-51 years (Table 1). All participants had used MTX and 82% had used TNFi. We identified 9 types of treatment burdens (Table 2): side effects, managing side effects, psychological, daily functioning, taking medications, accessing medications, economic impact, work, and family planning/breastfeeding. For both patients taking MTX and TNFi, fewer than half of patients reported increased infections/cancer or seeking/receiving further medical atten-

Characteristic	PsA (N= 25)	RA (N=24)
Age, years, range	66.6 (46-80)	66.9 (45-85)
Female	72%	88%
Caucasian	100%	100%
Married	68%	58%
Disease duration, years (range)	27.1 (4-46)	27.2 (12-51)
Current Therapies		
MTX monotherapy	24%	20.8%
TNFi monotherapy	32%	25%
Non-TNFi biologic, no MTX	16%	12.5%
TNFi + MTX	12%	25%
Non-TNFi biologic+ MTX	12%	16.7%
Other or nothing	4%	0%
Previous (discontinued) therapies		
Prior TNFi	68%	72%
non-TNFi biologics	20%	21%
MTX	52%	38%

Table 1. Participant characteristics by diagnosis (mean (range) or %)

Treatment burden	MTX	TNFi
Side effects experienced	- Immunosuppressive effects (infections and cancer) -Nausea, fatigue, hair loss, mouth sores -Liver problems	-Immunosuppressive effects (infections and cancer) -Injection site reactions/allergic reactions -Painful injections
Management of side effects	-Getting medical attention or additional treatment to address side effects -Changing how MTX was taken (formulation, dose, timing) to alleviate side effects -Blood tests and avoiding alcohol to prevent liver damage	-Getting medical attention or additional treatment to address side effects -Dose reduction to reduce infections was only possible for certain TNFis
Psychological	-Worry about side effects -Fear of MTX as a 'cancer drug'	-Worry about side effects -Dread towards injections due to pain/fear of needles
Daily functioning	-Reduced ability to perform usual activities due to nausea/fatigue	—No issues reported—
Taking medications	-Taking MTX could be difficult because it induced nausea	-Self-injections were challenging—sometimes help from someone else was needed -Travel and time needed for infusions -Process of trying/switching biologics is lengthy
Accessing medications	— About one fifth of patients reported issues —	- Coordinating payment for medications (insurance issues, copay assistance) and delivery of medication was complicated -Insurance coverage issues could constrain choice of TNFi or interrupt receipt of effective treatment
Economic impact	— Fewer than one in every twenty patients reported issues —	-Costly and difficult to afford without insurance or copay assistance programs -Inability to pay for medications caused gaps in treatment -Patients preferred not to spend so much money on medication, but felt they had no choice
Work	-Side effects impacted ability to work	-Getting infusions required taking time off work
Family planning/ breastfeeding	-Have to stop MTX for pregnancy or breastfeeding	-Choice of TNFi was influenced by safety for pregnancy or breastfeeding

Table 2. Key Treatment Burdens Discussed by Participants

tion or care to address side effects. A majority of MTX users reported taking steps to manage the negative impacts of nausea, fatigue, mouth sores, or hair loss on quality of life, daily functioning or work. Three-quarters of TNFi users reported challenges with accessing, paying for, or taking medications. Consistent with previous research, discontinuing the use of medication because of lack of effectiveness was more common among participants with PsA than those with RA (data not shown).

Conclusion: Greater awareness of the treatment burdens experienced by patients may help healthcare providers better support patients with any medication-related challenges that they encounter. From the perspective of patients, we found that there are many treatment burdens associated with PsA and RA that are rarely addressed in clinical trials or observational studies.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: At RA onset, DMARDs are essential to controlling inflammation and preventing disability. In people with established RA, specific beliefs about the necessity of DMARDs and concerns about potential harm influence side effects and adherence. To examine how medication perceptions evolve over time, we evaluated the stability of RA medication beliefs around diagnosis and identified predictors of change 12 months later.

Methods: Data were from Early RA patients enrolled in the Canadian Early Arthritis Cohort (CATCH) March 2017 and January 2020 who completed the Beliefs about Medicines Questionnaire at 0 and 12 months. Necessity and Concerns scales each have 5 statements regarding the need for prescribed medication to control RA and concerns about potential harms of taking them. We used Pearson correlation and multivariable regression to examine associations and predictors of change at 12 months.

Results: The 362 Participants were mostly women (66%), of white racial background (83%), with a mean (SD) age of 56 (15) years, and symptoms of 6 (3) months. Compared with baseline, at 12 months (n=180), mean **Necessity** beliefs were slightly higher (18.1 vs. 18.9;p=.01) and **Concerns** were slightly lower (15.2 vs. 14.3; p< .01).

Table 1. Associations between RA medicine necessity and concern beliefs, individual characteristics, and HRQL at baseline and 12 months in early RA.

At baseline, weak (r< 0.30) associations were evident between **Necessity** beliefs and minority status, CDAI, MTX use, and all HRQL domains except sleep. At 12 months, sleep, depression, and pain were positively though weakly related, and participation was inversely and weakly related to **Necessity** beliefs (Table 1). At baseline, worse CDAI, symptoms, function, and participation were associated with higher **Concerns.** These relationships were somewhat stronger at 12 months, except physical function was no longer associated with **Concerns**.

In multivariable regression, when starting treatment **Necessity** scores were lower in minorities and increased with CDAI, MTX use, and fatigue but decreased as sleep improved (Table 2). No relationships were evident at 12 months. Higher **Concerns** when starting treatment were predicted by higher education, and greater depression and anxiety.

At 12 months, higher **Concerns** were predicted by minority status and MTX use, higher emotional distress, better function and lower participation in social activities.

Conclusion: Our data suggest that in people with early RA, there is an agreement that medicines are generally necessary, but also significant levels of concerns. Further, medication perceptions appear to be reasonably sTable over the first year and are influenced to some degree by some individual characteristics and RA and medication experiences. Findings suggest that specific interventions may be needed to systematically influence medication beliefs and concerns to improve acceptance, tolerance, and long-term adherence.

The Preparation Experience for Total Knee Arthroplasty of Patients with Osteoarthritis: A Cross-Sectional Survey

Aretina Leung[1], Geyanne Lui[2], Susan Goodman[3], Lisa Mandl[4], Peter Sculco[5], Mark Figgie[3] and Iris Navarro-Millan[1], [1]Weill Cornell Medicine, New York, [2]Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]Hospital for Special Surgery, New York, NY, [5]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously identified several barriers and facilitators of exercise before total knee arthroplasty (TKA) in a small qualitative study, as well as the existence of patient-reported anxiety in anticipation of TKA. We aim to further explore these domains in a larger group of patients who had TKA within 6 months in order to understand specific patient needs in the design of a pre-habilitation program for TKA.

Methods: We designed a cross-sectional survey deployed online with questions abstracted from the themes that emerged from our previous qualitative study. Patients were > 40 years old from a single center and had a primary

Table 1: Demographic characteristics of individuals surveyed who had total knee arthroplasty (TKA)

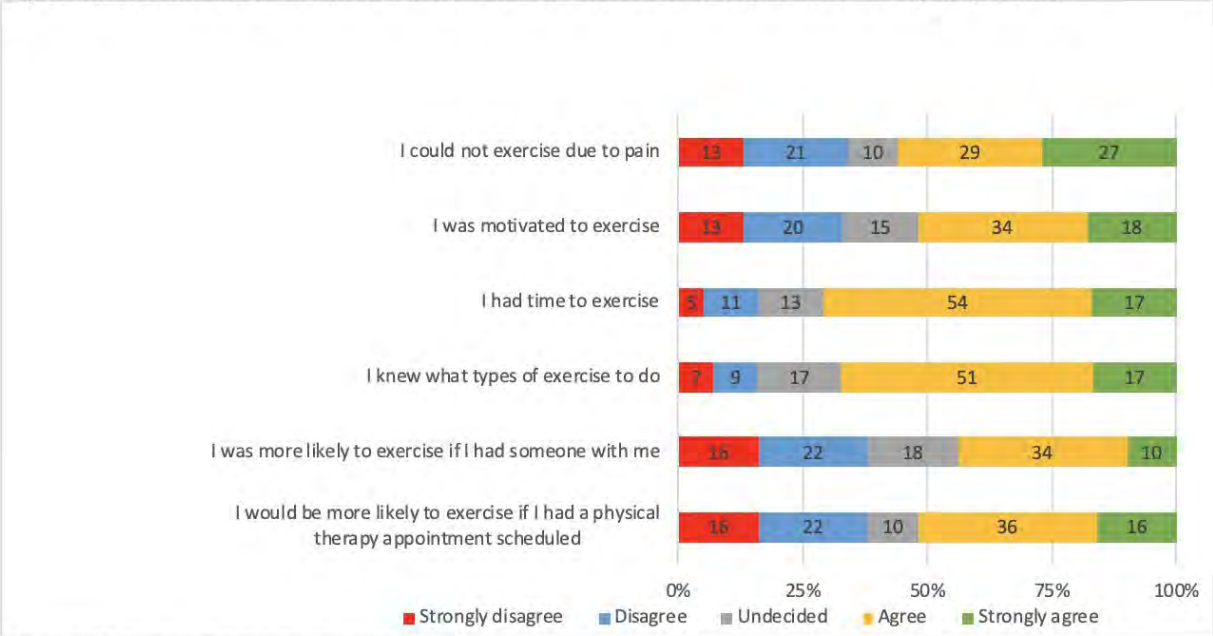
Patient Characteristics	Overall (N = 79) N (%)
Age (yrs)	
50-59	8 (10)
60-69	30 (38)
70-79	33 (42)
80-89	8 (10)
Female	50 (63)
Race/Ethnicity	
White	69 (87)
Black/African-American	6 (8)
Asian/Pacific Islander	1 (1)
Other	2 (3)
Prefer not to answer	1 (1)
Time between TKA and survey	
6-7 months	21 (27)
8-9 months	8 (10)
1 year or more	50 (63)
Physical preparation of patients with OA before TKA*	
Exercised regularly before TKA	45 (58)
Physician provided list of exercises in preparation for TKA	42 (55)
Referred to physical therapy in preparation for TKA	35 (46)
Exercised in preparation for TKA	43 (56)
Attended physical therapy in preparation for TKA	17 (22)

*Missing data from 2 respondents

TKA ≥ 6 months ago. We asked patients about barriers and facilitators to exercise before and after TKA, such as knee pain, knowledge about and motivation to exercise, time to devote to exercise, and peer support. We also examined the prevalence of anxiety in anticipation of TKA and coping mechanisms to alleviate that anxiety.

Results: 79 patients who met the inclusion criteria responded to the survey, age range 50 – 89. 30% had a primary TKA on both knees. 63% (N = 50) were women and 87% (N = 69) were White (**Table 1**). A majority of patients (56%) exercised in preparation for TKA, and 22% attended physical therapy. The most common barriers to exercise before TKA were pain (56%), lack of motivation (33%), lack of time (16%) and lack of knowledge (33%) on how to exercise. The main facilitators to exercise were presence of social support (44%) and scheduled physical therapy appointments (52%) (**Figure 1**). In the 48% of patients (N = 38) who reported anxiety before TKA, 95% sought reassurance from family/friends while 92% asked about the experiences of those who already had TKA (**Table 2**). Only 1 patient sought professional counseling for their anxiety.

Figure 1: Distribution of facilitators and barriers to exercise before total knee arthroplasty (TKA)*



*N = 77. Missing data from 2 respondents.

Table 2: Distribution of coping mechanisms of patients who reported anxiety in anticipation of total knee arthroplasty (TKA)

	Overall (N = 77) N (%)
Reported anxiety in anticipation of TKA*	38 (48)
Coping mechanisms for anxiety**	
Willingness to share concerns with physician	33 (87)
Referred to counseling services	1 (3)
Went to counseling services	0 (0)
Talked to family/friends	36 (95)
Sought others' experiences with TKA	35 (92)
Attended pre-operative education class	37 (97)

* Missing data from 2 respondents

** Answers based on the 38 (48%) patients who reported experiencing anxiety

Conclusion: Knee pain was the major barrier to exercise in preparation for surgery, while social support and physical therapy were the two major facilitators. Anxiety was common and interacting with family, friends or even another person who already had TKA were strategies used to alleviate anxiety in preparation for TKA. Similar leveraging of social support may motivate individuals to engage in physical activity in preparation for TKA.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Although DMARDs are essential for early aggressive control of RA to reduce symptoms and disability, medication adherence is variable. Beliefs about the necessity of medications and safety concerns predict adherence and are modifiable. Little is known about perceptions of RA medications in patients who are newly diagnosed. We examined associations among RA medication necessity beliefs and concerns, sociodemographics, RA characteristics, symptom levels and function in new RA patients around the time of diagnosis and starting medications.

Methods: Baseline data were analyzed from participants in the Canadian Early Arthritis Cohort (CATCH) who enrolled between 2017-2020 and completed the Beliefs about Medicine Questionnaire (BMQ) and PROMIS-29. All met ACR1987 or 2010 ACR/EULAR criteria and had active RA at enrollment. BMQ Necessity (N) and Concerns (C) scores were classified as **high** (≥20) or **low** (< 20) and categorized into: Accepting (↑N ↓C); Ambivalent (↑N↑C); Sceptical (↓N↑C); and 4) Indifferent (↓N↓C). Groups were compared using ANOVA and chi-square tests.

Mean(SD) or N(%)	Accepting	Ambivalent	Skeptical	Indifferent	p-Value

Table 3. Physical, emotional, and social function by BMQ attitudinal profiles.

Results: The 362 patients were mostly white (83%) women (66%) with a mean (SD) age of 56 (15), symptom duration of 6 (3) months, and 32% were obese (BMI≥30). More than half (56%) were DMARD-naive or minimally exposed. Mean N and C scores were similar between men and women; 54% were classified as **Indifferent**, 31% **Accepting**, 9% **Ambivalent,** and 6% **Sceptical** (Table 1). As compared to those classified as **Accepting**, more **Indifferent participants** smoked, had a healthy weight, lower TJCs, and trend for lower CDAI (Table 1). Groups were similar by sociodemographics, symptom duration, and DMARD/steroid use, except fewer **Indifferent** patients received MTX.

Most (67-100%) worried about the long-term effects of their medications (Table 2). **Indifferent** patients had statistically and meaningfully lower patient global, depression, anxiety, fatigue and pain interference, and higher function and participation scores (Table 3).

Conclusion: Most new RA patients worried about the long-term safety of their RA medications. Many had low medication necessity beliefs and concerns, and only 31% had high necessity beliefs and low concerns around diagnosis. Lifestyle and lower CDAI, TJCs, symptoms and functional impacts were associated with RA medication indifference. Exploring medication beliefs in newly diagnosed RA patients may help identify information gaps and provide opportunities to address concerns, potentially improving adoption and persistence over time.

Abstract Number: 0152

Veterans with RA and Gout Identify Their Goals and How They Can Work with Clinicians to Achieve Their Goals

Swathi Reddy[1], Aricca Van Citters[2], Rashmi Arora[1], Kyawt Shwin[1], Lisa Johnson[2], Jabeen Ahmad[2], Guy Eakin[3], Eugene Nelson[2], Andreas Reimold[1] and Salahuddin Kazi[1], [1]Veterans Affairs North Texas Healthcare System / UT Southwestern Medical Center, Dallas, TX, [2]The Dartmouth Institute for Health Policy & Clinical Practice, Lebanon, NH, [3]Arthritis Foundation, Atlanta, GA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding patient goals and concerns is essential for aligning treatment decisions with patient preferences and supporting effective patient-clinician partnerships. Yet, little is known about the goals and concerns of people with rheumatoid arthritis (RA) or gout. In this study, we aim to understand the primary goals and concerns expressed by veterans with RA and/or gout and how they envision working in partnership with their clinicians to achieve their goals or allay their concerns.

Methods: Veterans with RA and/or gout (n=283) at a busy rheumatology clinic completed a paper pre-visit survey immediately prior to a clinic visit. The survey included three open-ended questions: (1) What is your #1 concern or goal related to your arthritis?; (2) How can we help you achieve your goals?; and, (3) What steps can you take to help achieve your goals? Data were collected between April and September 2019. We conducted a content analysis of

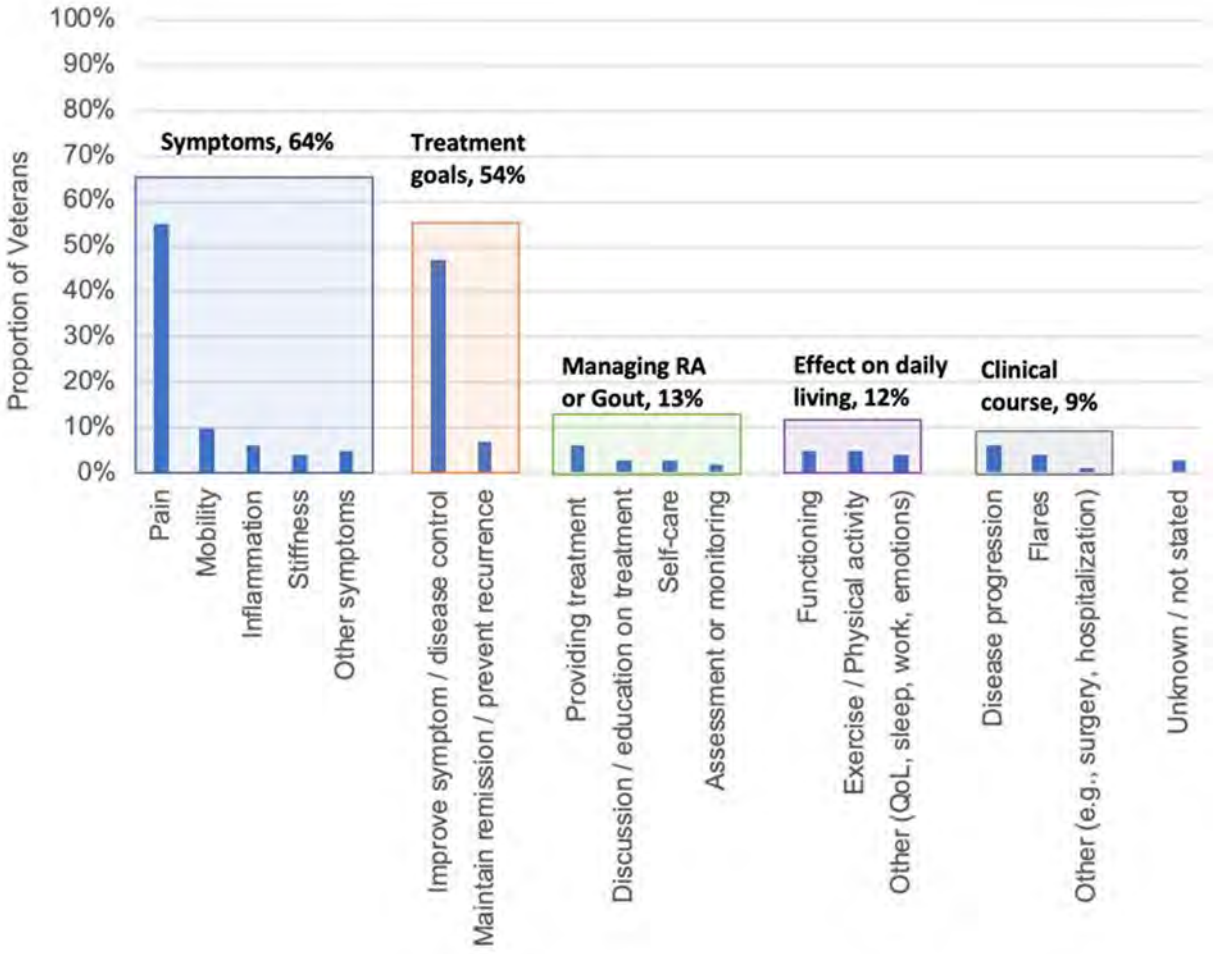

Figure 1. Frequency of Themes and Subthemes of 283 Responses to the Pre-Visit Survey: What is your number one concern or goal related to your arthritis?

patient responses. Codes were developed using grounded theory, with input from rheumatologists and adults with RA. If multiple themes were mentioned in response to any question, the response received multiple codes.

Results: We identified five domains of veteran's goals or concerns, including symptoms (64%), treatment goals (54%), managing RA or gout (13%), effect on daily living (12%), and clinical course of illness (9%). The most common themes in each domain were pain (55%), reducing symptoms or controlling disease (47%), accessing treatment (6%), functioning (5%), and disease progression or damage (6%), respectively (**Figure 1).** Veterans indicated that rheumatologists could help them achieve their goals by providing treatment (37%), discussing or educating around treatment options (18%), or monitoring and assessing disease status (9%) **(Figure 2)**. Veterans felt they (themselves) could achieve their goals through a combination of self-care activities (55%), such as exercising or being physically active (28%) and managing weight or eating a healthy diet (18%), and by following treatment recommendations (35%) **(Figure 2)**.

Conclusion: Veterans with RA and/or gout are largely concerned around improving pain. While they most often report that clinicians and patients can work together to meet goals (e.g., provide treatment/follow treatment recommendations), other important areas include provider education or discussion around treatment options and patient self-care (exercise and diet). Understanding patients' perceptions about their disease and what is most important to them can inform patients and clinicians working together to achieve shared treatment goals.

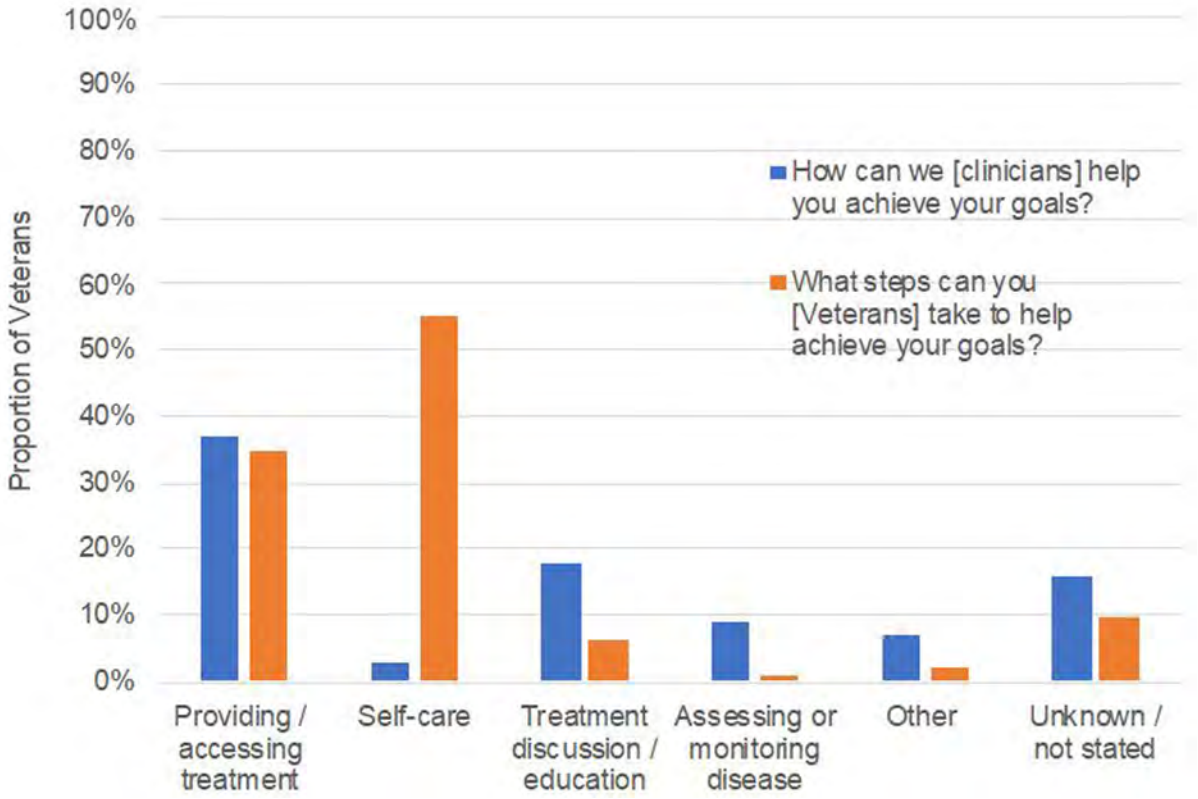

Figure 2. Frequency of Themes and Subthemes of 283 Responses to the Pre-Visit Survey Questions: "How can we help you achieve your goals?" and "What steps can you take to achieve your goals?"

Abstract Number: 0153

Counseling on Safe Driving Strategies in Patients with Osteoarthritis and Rheumatoid Arthritis

Anna Falls[1], Peta-Gay Ricketts[1], John Elliott[1] and Kim Jordan[1], [1]OhioHealth Riverside Methodist Hospital, Columbus, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) and rheumatoid arthritis (RA) cause functional impairments that impact daily life activities, including automobile driving. Radiographic presence of OA on knee and hip imaging significantly affects braking response time, and use of vehicle adaptations is common in patients with RA. There is little information on the correlation of functional disability scores, particularly the HAQ-DI score, with driving impairment in OA and/or RA patients. Limited studies suggested that an HAQ-DI score ≥ 1 correlated to driving difficulty, but driving

difficulties were also present in those with lower scores. Only three studies from Canada and Europe reported rates of physician counseling on driving difficulties (0-8%) in surveyed patients with RA. Rates of physician counseling on driving safety in OA and/or RA patients in the United States are unknown. Our study aims to address these information gaps by surveying patients with OA and/or RA on functional disability (HAQ-DI), driving habits and limitations, use of vehicle modifications, and whether counseling about driving safety by a healthcare professional has occurred. We hypothesize low rates of physician driving counseling, but suspect that patients with HAQ-DI scores ≥ 1 will have higher rates of counseling and vehicle modifications.

Methods: Participants were recruited and surveyed through the ResearchMatch Network, a national web-based recruitment tool maintained at Vanderbilt University Medical Center. A total of 4,435 patients with OA and/or RA were recruited; 304 (6.9%) respondents met screening criteria (held current US driver's license and were at least 18 years old) and completed the electronic HAQ-DI and study specific survey. Data was dichotomized with HAQ-DI ≥ 1 as a cut point and was analyzed using chi-squared analysis.

Results: Of the 304 completed surveys, 17.1% were male, 82.2% female, and 0.7% other; 65.1% reported OA, 16.8% RA and 18.1% both. The HAQ-DI score was ≥ 1 in 60.5%. Respondents with HAQ-DI ≥ 1 reported driving fewer miles each day that those with HAQ-DI ≤ 1 ($p = 0.001$), and greater level of difficulty with seven areas of driving activities ($p \leq 0.020$ for each activity). Physicians inquired about driving safety in 6.3% and other healthcare providers inquired in 8.6% respondents, with no significant differences based on HAQ-DI scores. Respondents with HAQ-DI ≥ 1 more frequently made the following vehicle modifications: seat supports (26.1% vs 10.8%; $p = 0.001$), extra mirrors (10.9% vs 3.3%; $p = 0.017$), and padded steering wheels (25% vs 5%; $p < 0.001$).

Conclusion: Survey respondents with HAQ-DI ≥ 1 indicated significant disability and impairment with driving related activities and were more likely to report vehicular assistive modifications. Despite this, physician and other healthcare provider rates of driving counseling remain low. Increased physician inquiry into driving safety is needed in patients with OA and RA. An HAQ-DI ≥ 1 could be considered as a screening tool to determine which patients may need more immediate counseling or vehicular modifications.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease-modifying antirheumatic drug (bDMARD) therapy has been shown to be effective in the treatment of axial spondyloarthritis (axSpA).[1,2] Little is understood about axSpA patients' treatment journey from their own perspective. The purpose of this study was to explore treatment decision-making of axSpA patients and to identify barriers and facilitators to treatment optimization.

Methods: This was an observational, cross-sectional study of participants (pts) in the ArthritisPower registry using a survey developed in partnership with patients and clinicians. Pts aged ≥ 19 years with physician-diagnosed axSpA and access to a computer/smartphone were invited to complete electronic patient-reported outcome measures and an online survey on treatment (tx) decision making. Pts' responses were classified into 2 groups based on whether or not currently on a bDMARD.

Results: 274 pts met inclusion criteria of whom 87.2% were female, 85.4% White, with mean age of 50 years (Table 1). The majority of pts (82.1%) had been diagnosed with axSpA by a rheumatologist. Of all pts, 56.9% (n=156) discussed a tx change at their most recent physician visit, 79.5% of whom researched the treatment change on their own, and 46.2% (n=72) of these pts reported having raised the issue with their clinician themselves. Half (51.3%) of tx

Table 1: Demographic and Clinical Characteristics (N=274)

Table 2: Treatment Change Behaviors and Rationale among axSpA Patients

	All Pts (n=156)	Pts on a bDMARD (n=77)	Pts not on a bDMARD (n=79)	p-value
What treatment change did your treating provider discuss with you? †				
Starting a new medication	80 (51.3)	34 (44.2)	46 (58.2)	0.08
Switching medications	61 (39.1)	40 (52.0)	21 (26.6)	<0.01*
Increasing the dose of the medication I am currently taking	46 (29.5)	33 (42.9)	13 (16.5)	<0.01*
Stopping a medication	38 (24.4)	15 (19.5)	23 (29.1)	0.16
Other	18 (11.5)	9 (11.7)	9 (11.4)	0.95
Decreasing the dose of the medication I am currently taking	10 (6.4)	4 (5.2)	6 (7.6)	0.54
What treatment change did you make? †				
Starting a new medication	58 (37.2)	28 (36.4)	30 (38.0)	0.84
Switching medications	40 (25.6)	25 (32.5)	15 (19.0)	0.05
Stopping a medication	34 (21.8)	11 (14.3)	23 (29.1)	0.02*
Increasing the dose of the medication I am currently taking	33 (21.2)	23 (29.9)	10 (12.7)	<0.01*
Other	24 (8.8)	9 (7.0)	15 (10.3)	0.34
None, I did not make a treatment change	23 (14.7)	11 (14.3)	12 (15.2)	0.87
Decreasing the dose of the medication I am currently taking	12 (7.7)	5 (6.5)	7 (8.9)	0.58
Why did you agree to the change? †	**All Pts (n=133) n (%)**	**Pts on a bDMARD (n=66)**	**Pts not on a bDMARD (n=67)**	**p-value**
My disease was not being controlled by the treatment I was previously on	73 (54.9)	39 (59.1)	34 (50.8)	0.33
Other (i.e., benefits of medication not worth cost, insurance coverage, disease inactive)	32 (24.1)	12 (18.2)	20 (29.9)	0.09
I experienced side effects with the treatment I was previously on	28 (21.1)	14 (21.2)	14 (20.9)	0.96
My disease was being controlled but I thought it could be better controlled on the new treatment	27 (20.3)	16 (24.2)	11 (16.4)	0.26
The benefits of the medication were not worth the risk of side effects	16 (12.0)	6 (9.1)	10 (14.9)	0.30
Why do you believe a treatment change was not discussed at your last visit? †	**All (n=118) n (%)**	**Pts on a bDMARD (n=51)**	**Pts not on a bDMARD (n=67)**	**p-value**
Other (Doctor does not listen to my concerns; Change in or lack of access; Changing is not an option / not needed; Tests or lack of results; Don't know)	47 (39.8)	17 (13.3)	30 (20.6)	0.11
My provider is happy with my current treatment	42 (35.6)	26 (51.0)	16 (23.9)	<0.01*
I am happy with my current treatment and I have told my provider this	36 (30.5)	23 (45.1)	13 (19.4)	<0.01*
I do not discuss treatment options with my provider	18 (15.3)	1 (2.0)	17 (25.4)	<0.01*

* Statistical significance between groups of pts who were on a bDMARD and not on a bDMARD, $p < 0.05$; t tests were performed for continuous variables and chi square tests for categorical variables; p values are nominal in nature and should be interpreted in an exploratory manner

†Pts could select more than one reason

changes discussed were related to initiation of a new medication, compared with stopping a medication (24.4%) and/or changing its dose (35.9%). The majority of pts (85.3%; n=133) who discussed a change agreed to the tx change and most pts agreeing to a change did so because they felt their disease was not being controlled (54.9%; n=73) or because they thought control could be better on new tx (n=27; 20.3%). Most pts (62.8%) reported agreeing to the suggested tx change by end of clinic visit, while 15.4% needed ≤ 1 week to decide. Pts on a bDMARD were more likely to discuss switching medications (52.0%) or increasing dose (42.9%) vs. non-bDMARD pts (26.6%, p=0.0012; 16.5%, p=0.0003) (Table 2). Among the pts (n=23) who declined a tx change, top reasons were pts not believing there were more efficacious options than their current tx (60.9%) and worries about potential side effects of a new tx (56.5%). For bDMARD pts whose tx change was not discussed at the last visit, pts felt it was because either they or their provider were happy with the current tx (Table 2); bDMARD-treated pts and their clinicians were more likely to report satisfaction with current tx as the reason a tx change was not discussed compared to non-bDMARD pts. Overall, factors that pts on bDMARDs (n=128) considered most important when making tx decisions were preventing other long-term consequences of untreated axSpA (92.2%), preventing damage from axSpA (89.1%), and advice from their doctor (87.5%) (Table 3).

Table 3. Factors* Considered Very Important to axSpA Patients on a bDMARD When Making Decisions about Their Treatment (n=128)

	N	%
Preventing other long-term consequences of untreated axSpA	118	92.2
Preventing damage from axSpA	114	89.1
Advice from my doctor	112	87.5
My doctor's availability to see me or talk to me to deal with problems or questions that come up	91	71.1
How good or bad the disease is making me feel at the time I make a treatment decision	84	65.6
Avoiding surgery	78	60.9
Possible drug interactions	77	60.2
Cost of the treatment	73	57.0
How affordable the treatment is	71	55.5
How easy it is to get the treatment	68	53.1
Wanting to get immediate relief	64	50.0
The newest research	62	48.4
Risk of addiction	56	43.8
Information I have found while doing my own research	54	42.2
Avoiding additional pills	52	40.6
Intuition or 'gut response' when I ask myself if this is the right thing to do	45	35.2
How easy the treatment is to use or do (such as taking a pill versus doing yoga)	41	32.0
Concern that the treatment will only work for a short time and I should save the treatment option for a later date when I feel worse	34	26.6
How often I have to take the treatment (daily versus weekly versus monthly)	30	23.4
How often I will need to get imaging tests (X ray, ultrasound) on this medication	27	21.1
How often I will need to get lab tests on this medication	25	19.5
Avoiding needles or injections	18	14.1
Whether people will judge me for my pain management strategy	11	8.6
Personal recommendations from family or friends	8	6.3
Whether the treatment is a natural remedy	6	4.7
Advertisements	1	0.8

*Not mutually exclusive

Conclusion: Most axSpA patients reported discussing tx changes with their provider at their most recent visit and had done their own research about it beforehand. Prevention of long-term damage and doctor's advice are major factors influencing patient decisions about tx.

Changes in Patient-Reported Outcome (PRO) Scores for Nausea and Fatigue Following Weekly Methotrexate Dose in a Real-World Sample of RA and PsA Patients in the ArthritisPower Registry

William Nowell[1], Elaine Karis[2], Kelly Gavigan[3], Laura Stradford[3], Scott Stryker[2], Huifeng Yun[4], Shilpa Venkatachalam[5], Gregory Kricorian[2], Lang Chen[4], Hong Zhao[6], Fenglong Xie[6] and Jeffrey R Curtis[4], [1]Global Healthy Living Foundation, New York City, NY, [2]Amgen Inc., Thousand Oaks, CA, [3]Global Healthy Living Foundation, Upper Nyack, NY, [4]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [5]Global Healthy Living Foundation, Upper Nyack, [6]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is frequently used in patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA) because of its beneficial effects in both populations. Despite the well-known benefits of MTX, it is associated with a number of potential side effects. These include nausea and fatigue, are often temporally related to

Figure 1. Nausea PROMIS Score Changes Among Patients Reporting Nausea as a Side Effect of MTX [n=64 observations (32 pairs) among 20 unique pts]

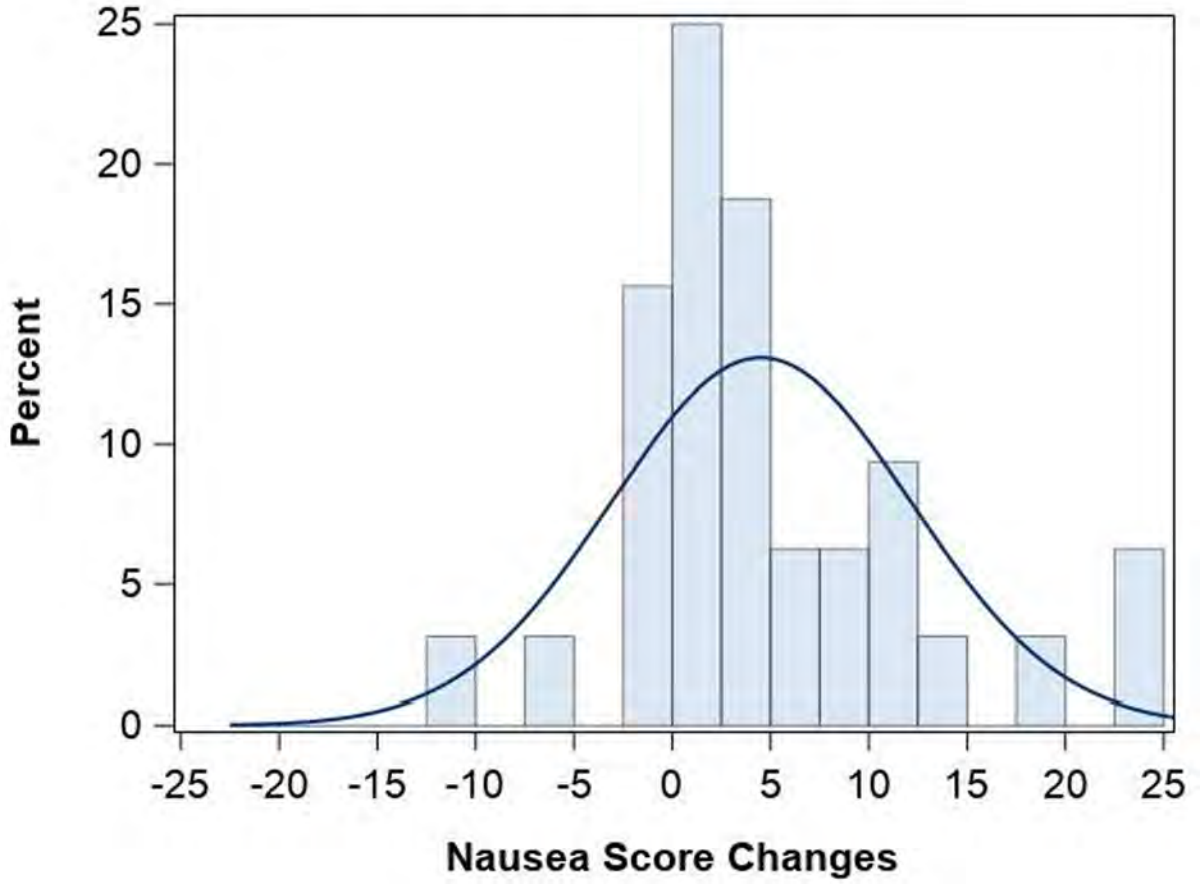

Figure 2. Fatigue PROMIS Score Changes Among Patients Reporting Fatigue as a Side Effect of MTX [n=96 observations (48 pairs) among 28 unique pts]

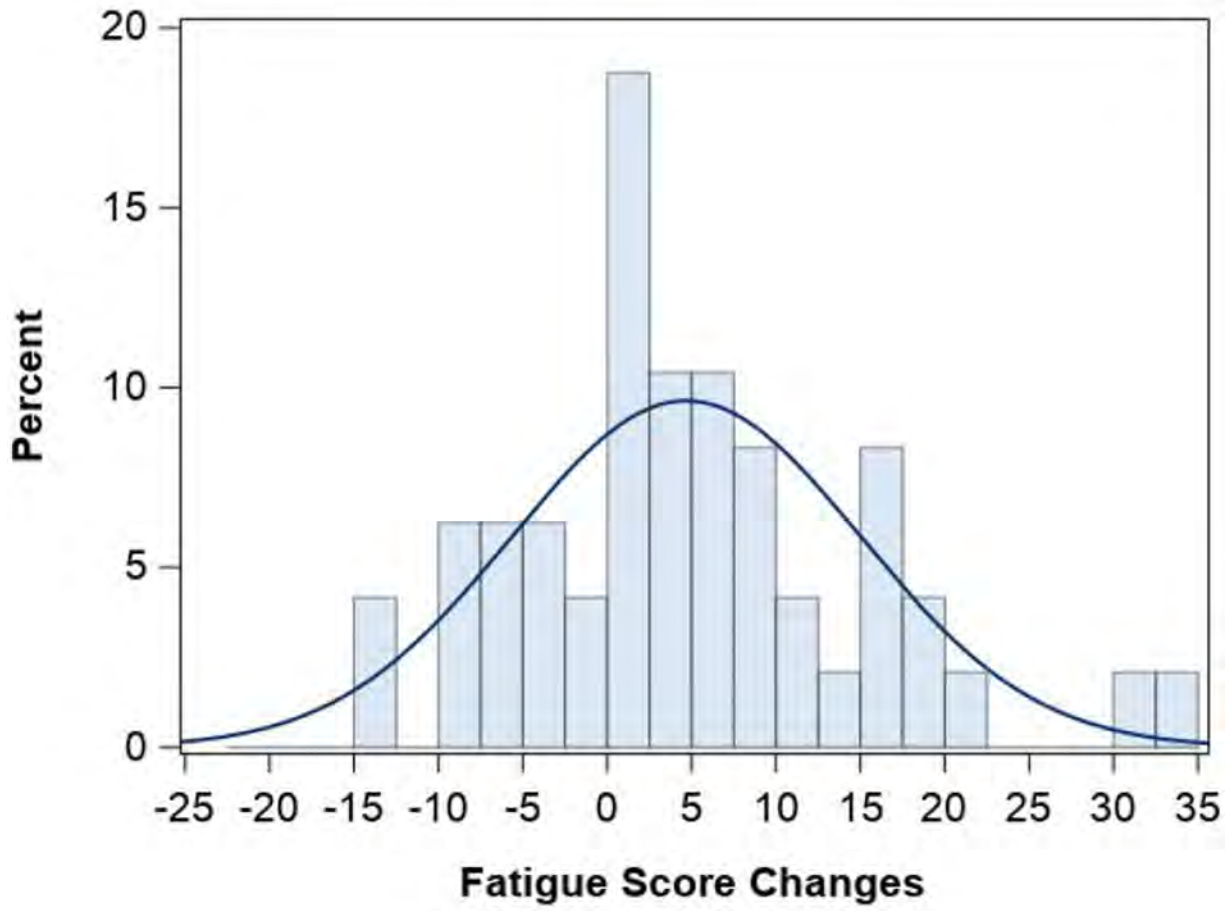

the timing of weekly MTX administration, and can be severe. The combined patient-reported side effects, along with potential of long term toxicity, may make use of MTX more burdensome. Currently, there is a gap in patient-centered studies that focus on patients' experience of fatigue and nausea relating to oral MTX therapy for the treatment of RA and PsA.

Methods: Adult US patients in the ArthritisPower registry with self-reported RA or PsA taking MTX for less than 10 years were invited to participate in the study via email invitation. Participants (pts) completed a screener and brief online survey. In an ancillary study to the ArthritisPower registry and using a self-controlled case series study design where pts serve as their own control to avoid between-person confounding, pts were asked to complete a set of up to 8 assessments within 6-36 hours ('risk') and 96-144 hours ('control') after taking their oral dose of MTX each week, for up to 4 weeks. Risk and control windows were selected based on the expected temporal relationship between MTX use and peak onset of these symptoms. Assessments included PROMIS short forms for same-day Fatigue, same-day Nausea/Vomiting, and Patient Global. Descriptive statistics were conducted using paired t-tests two-way comparisons. Within-person change in PROMIS scores between the risk (1-2 days after MTX) and control (4-6 days after MTX) windows were analyzed using mixed models for repeated measures, stratified on whether pts reported fatigue or nausea with MTX at baseline. Recruitment for this study is ongoing.

Results: As of December 2019, 91 pts had participated, of whom 76.9% were living with RA and 28.6% with PsA, with mean baseline PROMIS Patient Global score (SD) of 39.5 (7.1). Mean age (SD) was 50.9 (12.0) years, 84.6%

female, 92.3% White, with mean BMI 33.7 (8.8). Mean duration of MTX treatment among current users was 2.1 (2.8) years. Among pts, 41.8% were on a biologic DMARD and 58.2% on non-biologic DMARDs only. Among pts reporting baseline nausea (n=30, 33.0%) where paired within-week measures were observed (n=64 observations among 20 pts), the mean increase in the PROMIS Nausea score was 4.5 units (adjusted p=0.003). Among those reporting MTX-associated fatigue (n=39, 42.9%) as a side effect of MTX on their baseline survey where paired within-week measures were observed (n=96 observations among 28 pts), the mean increase in PROMIS Fatigue was 4.7 (adjusted p=0.004) units. In those pts, the proportion of pts with worsened nausea and fatigue with minimally important difference of >5 units was 40.0% (nausea), and 60.7% (fatigue) [Figures 1 and 2].

Conclusion: People taking MTX to manage RA or PsA commonly experience bothersome side effects, notably fatigue and nausea, that are temporally related to weekly MTX dosing. In this sample, one-third or more of pts were bothered by nausea or fatigue shortly after MTX dosing, many of them with clinically meaningful symptoms.

The Role of Biological Treatment in the Health-Related Quality of Life of Ankylosing Spondylitis Patients' Assessment - Meta-Analysis

Wojciech Tański[1], Mariusz Chabowski[2], Natalia Świątoniowska-Lonc[3] and Beata Jankowska-Polańska[3], [1]4th Military Teaching Hospital, Wrocław, Poland, [2]4th Military Teaching Hospital, Wroclaw Medical University, Wrocław, Poland, [3]Wroclaw Medical University, Wrocław, Poland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Spondyloarthritis (SpA) is a chronic inflammatory rheumatic disease involving the axial skeleton, entheses and peripheral joints, and may occur together with extra-articular manifestations, such as psoriasis, inflammatory bowel disease and uveitis. Patients with SpA are experiencing deterioration or bad quality of life. The most common symptoms are: physical limitations and limitations of motor activity, fatigue and sleep disturbances caused by the disease and inflammatory pain. Due to the young age of patients the sexual disorders, limitations or inability to work or to perform other social roles should be put into considerations.Since the last century in medicine it is considered that the regular quality of life assessment should complement the clinical efficacy assessment of the applied treatment. The efficacy of the biological treatment and its superiority to placebo has been proved in the newest research. There is scarcity of the studies which evaluate the efficacy of biological treatment regarding the quality of life. It is worth paying attention that the patients' satisfaction should be crucial in treatment selection and planning.

The main purpose of this meta-analysis was to evaluate the impact of biological treatment on the quality of life of the patients with ankylosing spondylitis.

Methods: A systematic literature search was performed on PubMed and Web of Science until May 2020 to obtain eligible studies. The used search terms were as follows: ("Quality of Life") OR ("patient-reported outcomes")

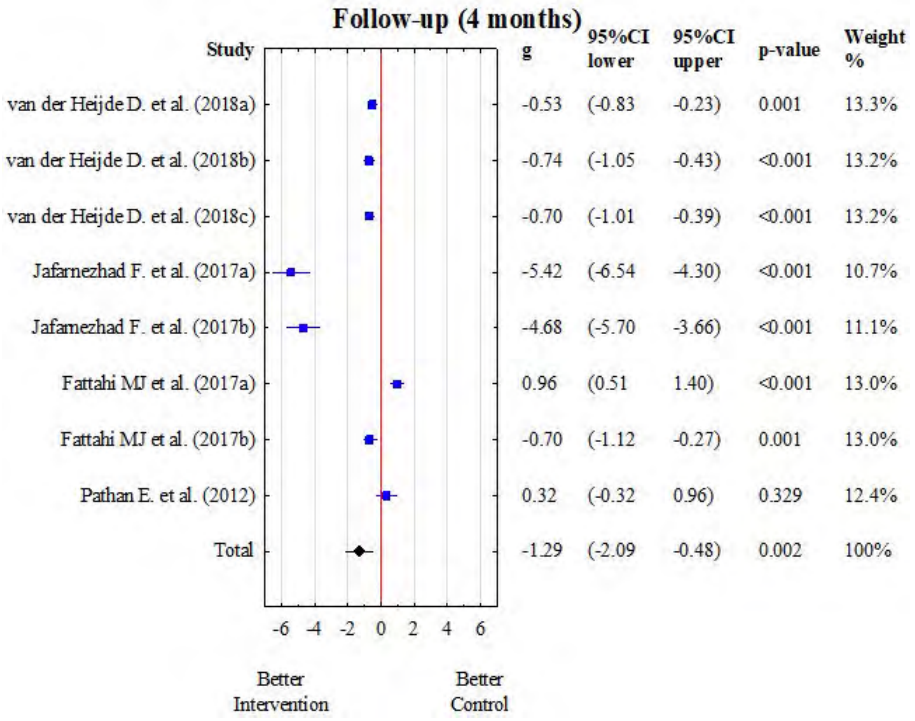

Figure.1 Quality of life in the control and intervention group after 4 months of treatment

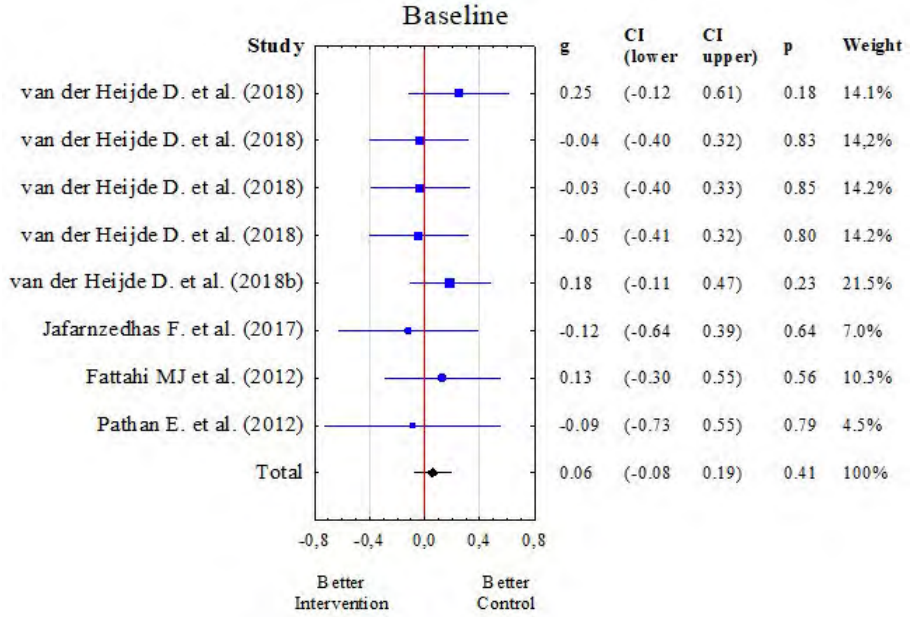

Figure.2 Quality of life in the control and intervention group at the beginning of treatment

OR (“well-being”) OR(“health related quality of life”) AND(“biological treatment ofankylosing spondylitis”) in this meta-analysis.

Results: Twenty-three papers were finally assigned to meta-analysis. Quality of life was evaluated using the questionnaires: SF-36, ASQoLS, FACIT-F: EQ-5D-5L, EQ-5D VAS. The results of the meta-analysis showed thatin baseline

study the quality of life of patients with AsS treated with biological drugs and the control group (placebo) did not differ (Q = 3.32, p = 0.854, I2 = 0.00%). However, after 16 weeks of the study the results were statistically different, and the group treated with biological drugs had better improvement in quality of life. The positive direction of the improvement of functioning was observed within the functional efficiency assessed with questionnaire BASFI.What is more, the significant decrease of CRP in the group with biological treatment was revealed, which confirmed the effectiveness of therapy.

Conclusion: (1) The biological treatment significantly improves the quality of life andfunctional efficiency as well as it decreases the inflammation markers in patients with SpA. (2) There is a need for introduction of the uniform study protocol andthe definition of a standard methodology for research tools in the evaluation of quality of life in patients with SpA in order to comparethe different results in differentscientific teams.

Early Arthritis Global Assesment: What Differences Exist Between Patients and Physicians?

Cristina Valero[1], Noelia Garcia[1], Juan Pablo Baldivieso[2], Ana Ortiz[3], Sebastian Rodriguez[2] and Isidoro González-Álvaro[3], [1]Hospital Universitario de la Princesa, IIS-Princesa, UAM, Madrid, Madrid, Spain, [2]Hospital de La Princesa, Madrid, Madrid, Spain, [3]Hospital Universitario de la Princesa, IIS-Princesa, Madrid, Madrid, Spain

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years there is increasing evidence of the relevance of including the assessment of the different aspects of rheumatoid arthritis (RA) from the patient's perspective through patient reported outcomes (PRO). Previous studies showed discrepancies in the disease global disease assessment reported by patients (PtGA) or physicians (PhGA).

Our aim was to evaluate differences between PtGA and PhGA and analyze the variables related to these differences in an early arthritis cohort.

Methods: Cross-sectional study analyzing data from the baseline visit of patients included in the PEARL study *(Princess Early Arthritis Register Longitudinal Study)* in which demographic, laboratory and clinical characteristics including PtGA and PhGA (0-100 mm) are systematically collected.

The main variable was the difference between PtGA and PhGA (ΔGA). The descriptive analysis was performed using the Kruskal-Wallis, Mann-Whitney or Pearson correlation tests as appropriate. Stadistical analysis was perfomed with STATA 14.

A multivariate linear regression model was developed with ΔGA as a dependent variable. All those predictors available at the baseline visit reaching a $p < 0.15$ in the univariate analysis were included in the initial model. The final one

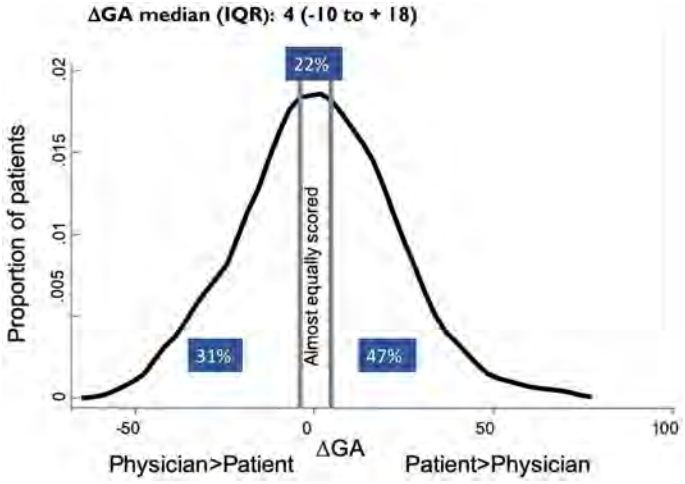

Figure 1. Representation of DGA distribution. DGA: difference between PtGA and PhGA; IQR: interquartile range.

was obtained through the progressive elimination of those variables not showing an improvement in the model as assessed by the adjusted R2 parameter. To categorize the dependent variable, we considered relevant differences between PtGA and PhGA greater than 5 mm.

Results: 530 patients were included, 422 (79.6%) were women with a mean age of 55.3 +/- 16 years, 21.2% current smokers, 54% and 50.4% rheumatoid factor and anti-CCP positive respectively. A 43.3% had moderate activity and 33.6% high, measured by DAS28-VSG.

The median of ΔGA was 4, (interquartile range; -10 to 18; see Figure1). In 22% of the cases patients and physicians scored the same, in 46.5% the patients' scores were higher and physicians' were so in 31.5% of the cases.

The variables that explained DGA after adjusting the multivariate model were pain [β=0.36 (95%CI 0.28 to 0.44)], number of swollen joints [β= -3.19 (95%CI -3.7 to -2.7)] and ESR [β=-0.11 (95%CI -0.2 to -0.03)]. Pain had a greater influence on patients' opinion while the number of swollen joints and ESR were more relevant for physicians. Other variables such as race, marital status, profession, sex, smoking, seropositivity or disease activity were not relevant in the prediction of ΔGA.

Conclusion: In our sample, disagreements between PtGA and PhGA were observed. Patients scored higher based on painful perception and physicians based on objective evidence of inflammation.Figure 1. Representation of DGA distribution. DGA: difference between PtGA and PhGA; IQR: interquartile range.

Session Time: 9:00AM–11:00AM

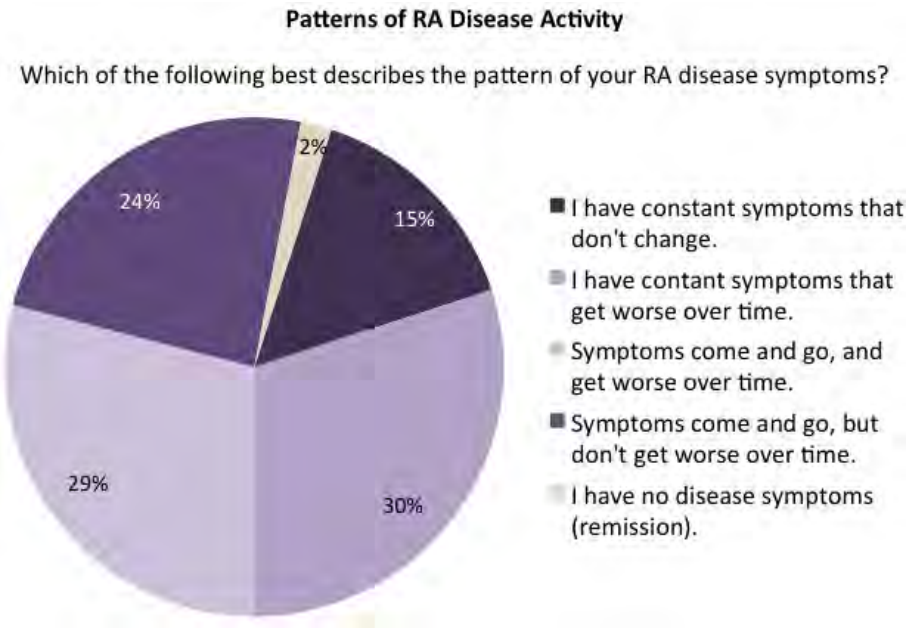

Fig.1 Patterns of RA Disease Activity

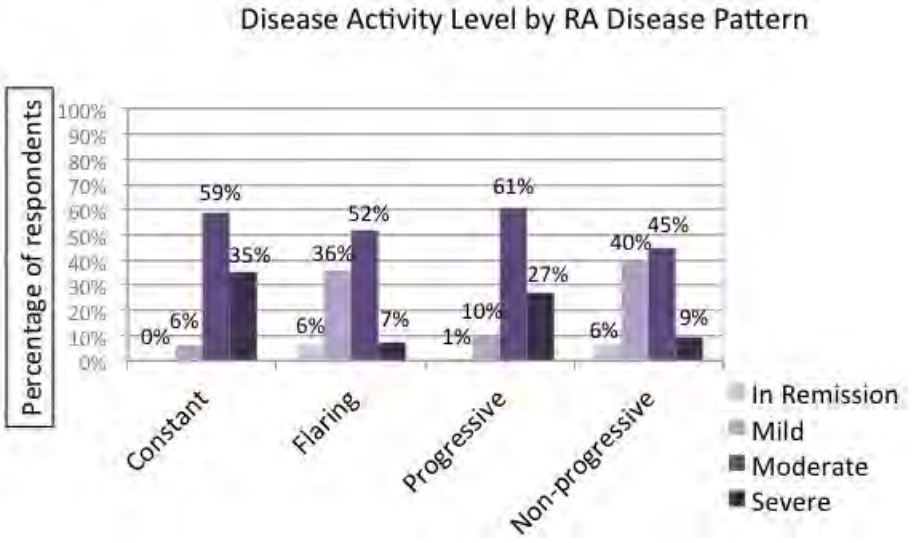

Fig.2 Disease Activity Level by RA Disease Pattern

Background/Purpose: We previously showed rheumatoid arthritis (RA) patients report diversity in disease activity (DA) patterns that may be associated with treatment response. Patients who describe their DA as a flaring or non-progressing pattern are more likely to experience high levels of DA improvement (≥70%). We aimed to better understand the relationship between RA disease activity patterns and rheumatology treatment experiences.

Fig.1 Current RA Disease Activity Level Versus Time to Diagnosis

Methods: An anonymous 28-item questionnaire was developed and pilot-tested by the study team and presented in 2019 on a secure online survey system. Eligible participants were U.S. residents age ≥18 years with a self-reported medical diagnosis of RA. They were asked questions about socio-demographics, RA disease activity, diagnosis and DMARD history, improvement from RA treatment, and RA treatment goals created with their provider. Further, patients were asked which of a list of disease patterns best described their DA (see Figure 1). The patterns were divided into 2 categories: constant vs flaring and remitting and progressive vs non-progressing.

Results: 907 people responded (90% women, 10% men), with a mean age of 58 years and 11.1 years since diagnosis (SD 10.1). Of the 886 people who responded to the disease pattern questions, 46% had constant and 54% were flaring/remitting. Similarly, 60% were progressive and 40% were non-progressing. Longer times from symptom onset to RA diagnosis associated with constant DA patterns (< 6mo 38%, >6mo to < 5yr 46%, >5yr 52%) and progressive DA patterns (< 6mo 50%, >6mo to < 5yr 60%, >5yr 70%).

Moderate-severe levels of DA were more common with constant and progressive patterns (constant 94%, flaring 59%, progressive 88%, non-progressing 54%). Those with constant disease were less likely to say they were in remission (constant 0%, flaring 6%) or have had their doctor say they were in remission (2% and 15%, respectively). Those with progressive disease gave similar responses for being in RA remission (progressive 1%, non-progressing 6%) or diagnosis of remission (6% and 14%, respectively). Those with constant or progressive DA were more likely to say they were in a poor/very poor state of health (constant 33%, flaring 12%, progressive 28%, non-progressing 14%).

Fewer people with constant or progressive disease were satisfied/very satisfied with their rheumatology treatment (constant 63%, flaring 79%, progressive 67%, non-progressing 76%). People with progressive disease were less likely to be asked by their providers about RA treatment goals (progressive 33%, non-progressive 42%). Respondents strongly supported the use of materials to enhance treatment goal discussions with their rheumatology providers.

Conclusion: This survey found previously unreported associations between patterns of RA disease activity and interfaces with rheumatology care including time to initiation of RA treatment, satisfaction with rheumatology care, and occurrence of shared treatment goal discussions as well as higher levels of DA and fewer remissions of disease. Further research should seek greater understanding of the significance of DA patterns in RA treatment and whether patients with more aggressive DA patterns should have adapted treatment recommendations.

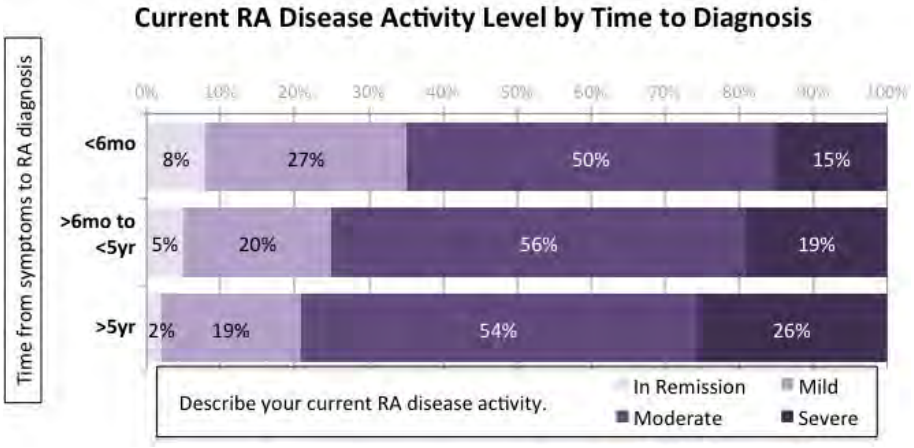

Fig.1 Current RA Disease Activity Level Versus Time to Diagnosis

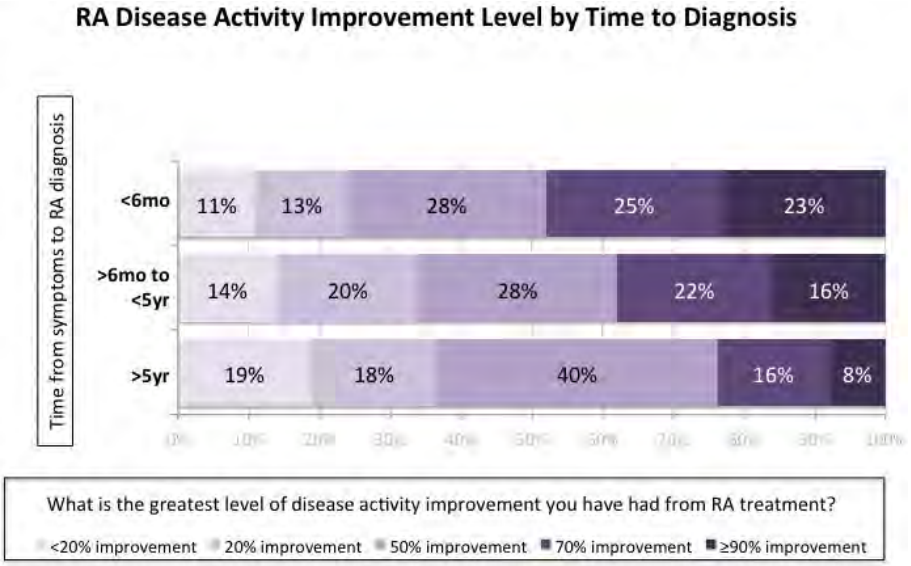

Fig.2 Disease Activity Improvement Level by Time to Diagnosis

Background/Purpose: Time from diagnosis to treatment has been well established to correlate with better outcomes in rheumatoid arthritis (RA). Treatment delays are often associated with worse outcomes and more difficult to treat disease, while early and aggressive treatment leads to better outcomes and increased levels of rheumatoid disease activity (DA) improvement. However time from symptom onset to diagnosis has been less discussed. Building on a collaboration between a non-profit organization and an academic rheumatology center, we aimed to gain greater understanding of the impact of time from symptom onset to diagnosis of RA.

Methods: An anonymous 28-item questionnaire was developed and pilot-tested by the study team and presented in 2019 on a secure online survey system. Eligible participants were U.S. residents age ≥18 years with a self-reported diagnosis of RA by a medical professional. They were asked questions about socio-demographics, RA disease activity, diagnosis and DMARD history, improvement from RA treatment, and RA treatment goals created with their provider. Analyses included descriptive statistics with chi-square and rank sum tests for comparisons.

Poor	33 (12%)	70 (16%)	39 (20%)	
Very good	17 (6%)	30 (7%)	6 (3%)	
Very poor	16 (6%)	22 (5%)	14 (7%)	

Table1. Responses by Time from Symptom Onset to RA Diagnosis

Results: The questionnaire was completed by 907 self-reported RA patients (90% women, 10% men), with a mean (SD) age of 58 years and a mean of 11.1 (10.1) years since diagnosis. According to patient self-reports, 5% were in remission, 22% reported mild DA, 54% moderate DA, and 19% severe DA.

The longer the time to diagnosis, the more likely people were to report moderate to severe DA levels (< 6mo 65%; >6mo-5yr 75%; >5yr 80%). Similarly, people with a shorter time to diagnosis were twice as likely to reach DA improvement levels ≥70% as those with long times to diagnosis (< 6mo 48%; >6mo-5yr 38%; >5yr 24%).

Longer times from symptom onset to diagnosis also associated with longer times between RA diagnosis and eventual treatment. When the time from symptom onset to diagnosis was < 6 months, time from RA diagnosis to treatment was only an additional 0.8 years. However for those whose diagnosis took >5 years, time from RA diagnosis to treatment initiation was an average of an additional 1.5 years.

The longer the time to diagnosis, the less satisfaction and greater dissatisfaction people with RA had with their rheumatology care (satisfied/very satisfied was reported in: < 6mo 76%; >6mo-5yr 71%; >5yr 65%). Additionally, those describing their health as poor/very poor tended to have longer times to diagnosis (< 6mo 18%; >6mo-5yr 21%; >5yr 27%).

Conclusion: This web-based survey found previously unreported associations between time from symptom onset to RA diagnosis and more severe disease activity and lower responses to treatment, independent of time to between RA diagnosis and treatment initiation. Our study is unique in that time to diagnosis and / or to treatment are reported by patients with RA. Further research should seek greater understanding of the significance of early RA diagnosis and investigate ways to decrease times from symptom onset to RA diagnosis.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The Patient-Reported Outcome Measure Information System (PROMIS) includes a set of instruments developed to measure physical, mental and social health. PROMIS measures have been studied in RA but have only recently been used in spondyloarthritis. In this study, we aimed to determine whether there are differences in five PROMIS measures across psoriatic arthritis (PsA), axial spondyloarthritis (axSpA) and rheumatoid arthritis (RA) that would affect differential use in these diseases.

Methods: A cross-sectional study was performed in the Forward database utilizing data from 2019 among patients who had PsA, axSpA or RA and completed at least one PROMIS measure (4-item short forms of PROMIS physical function, fatigue, pain interference, sleep disturbance, and ability to participate in social roles and activities). Score

	Social satisfaction	50 (9.9)	27.5 (2%)	64.2 (22%)	54.4 (9.3)	43.6 (7)	<0.001
axSpA	Physical function	44.7 (10.5)	22.9 (3%)	56.9 (36%)	49.6 (9.5)	36.8 (6.7)	<0.001
	Fatigue	52.2 (12.4)	33.7 (19%)	75.8 (4%)	48 (12.5)	59.2 (9.2)	<0.001
	Pain Interference	53 (10)	41.6 (39%)	75.6 (0%)	48.2 (8.5)	62.7 (4.3)	0.027
	Sleep disturbance	51.4 (9.2)	32 (7%)	73.3 (3%)	49.5 (9.2)	54.5 (8.7)	0.027
	Social satisfaction	49.9 (10)	27.5 (1%)	64.2 (23%)	53.8 (9.5)	43.6 (7.5)	<0.001
RA	Physical function	42.4 (9.5)	22.9 (3%)	56.9 (21%)	46.4 (8.5)	36.3 (7.5)	<0.001
	Fatigue	52.6 (11.1)	33.7 (12%)	75.8 (4%)	48.4 (9.8)	59.2 (9.8)	<0.001
	Pain Interference	57.1 (9.2)	41.6 (18%)	75.6 (5%)	53 (8.2)	62.6 (7.5)	<0.001
	Sleep disturbance	50.6 (9.1)	32 (5%)	73.3 (2%)	48.1 (8.4)	54.6 (8.7)	<0.001
	Social satisfaction	49 (9.5)	27.5 (3%)	64.2 (18%)	52.8 (8.6)	43 (7.6)	<0.001

*PROMIS scores increase with 'more' of the construct being measured. In other words, the score for physical function increases with better physical function (higher scores are good); likewise, more interference in life activities as a result of pain results in a higher pain interference scores (i.e., higher pain scores are bad).

**Min and max scores are provided as these are not typical scales

***Health status was defined using a question that asked patients "In general, would you say that your health now is: excellent, good, fair, poor." Responses were dichotomized as acceptable (excellent or good) or not acceptable (fair or poor). A student's t-test was used to calculate differences in the mean scores among those with an acceptable health status compared to those with fair or poor health status.

Table 2. Mean scores by disease

Table 3. Standardized differences* by contextual factors

Contextual Factor	Instrument**	PsA	axSpA	RA
Age≥65	Physical Function	-0.33	0.06	-0.12
	Fatigue	-0.35	-0.85	-0.39
	Pain Interference	0.02	-0.16	-0.22
	Sleep Disturbance	-0.35	-0.48	-0.40
	Social satisfaction	-0.02	0.38	0.13

	Fatigue	0.31	-0.04	0.43
	Pain Interference	0.08	-0.25	0.35
	Sleep Disturbance	0.18	0.08	0.26
	Social satisfaction	-0.36	-0.01	-0.44
Depression	Physical Function	-0.70	-0.39	-0.62
	Fatigue	1.07	0.43	1.12
	Pain Interference	0.30	-0.07	0.68
	Sleep Disturbance	0.40	1.10	0.67
	Social satisfaction	-0.75	-0.37	-1.05

*Standardized difference = (mean in patients with the factor – mean in patients without the factor)/standardized deviation. Standardized differences of greater than an absolute value of >0.10 are considered potentially important. The (-) indicates the direction of the score difference.
**PROMIS scores increase with 'more' of the construct being measured. In other words, the score for physical function increases with better physical function (higher scores are good); likewise, more interference in life activities as a result of pain results in a higher pain interference scores (i.e., higher pain scores are bad).
Abbreviations: axSpA = axial spondyloarthritis, PsA = psoriatic arthritis, RA = rheumatoid arthritis.

Table 3. Standardized differences* by contextual factors

distributions were examined (not shown) and floor and ceiling effects calculated. Differences in mean scores by disease were tested using Kruskal Wallis tests. Differences in scores among patients reporting an accepTable health status (current health status of excellent or good) compared to those rating health status as fair or poor were tested using student's t-tests. Differences in scores by potential contextual factors (age, sex, obesity and depression) were examined using standardized differences. We hypothesized that score distributions, floor and ceiling effects, discrimination between accepTable and not accepTable health status, and the impact of contextual factors on scores would be similar among the three diseases.

Results: In 2019, 3,243 patients completed the PROMIS29: 180 with PsA, 73 with axSpA and 2,990 with RA. Mean age was 63, 60, and 67 for PsA, axSpA, and RA respectively, and generally patients were more likely to be female, Caucasian and have long disease duration (Table 1). 63%, 60%, and 60% respectively rated themselves as having good or excellent health at the time of survey completion. Score distributions were similar across the three diseases. Mean scores for each instrument are shown in Table 2. Patients with PsA reported on average lower physical function compared to RA and axSpA (p=0.04), however there were not significant differences by disease for fatigue, pain interference, sleep disturbance, or social satisfaction (p >0.05). Patients with an accepTable health status had

better scores than those not in an accepTable state, and these differences were statistically significant for all instruments across all three diseases. Finally, contextual factors had an impact on the scores but the association between baseline characteristics and scores differed by disease (Table 3). For example, obese patients had worse physical function in all three diseases but impact on the other four measures was greater in PsA compared to axSpA. Similarly, depression had a significant effect on all scores but was particularly associated with worse fatigue in PsA and RA.

Conclusion: The PROMIS measures tested have similar score distributions and discrimination in PsA, axSpA and RA suggesting that they can be used across inflammatory arthritis. However, contextual factors may have differential influence on the scores in these three diseases.

Abstract Number: 0161

Validation of Patient-reported Outcomes (PRO) Lung Questionnaires for Systemic Juvenile Idiopathic Arthritis (SJIA) Patients at Risk for Lung Disease

Kim Nguyen[1], Christopher Towe[2], Shima Yasin[3], Alexei Grom[4], Hermine I Brunner[5] and Grant Schulert[5], [1]Veterans Affairs Cincinnati, University of Cincinnati Medical Center, Cincinnati, [2]Cincinnati Children's Medical Hospital Center, Cincinnati, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (SJIA) involves dysregulation of inflammation and innate immunity, and can cause life-threatening complications including lung disease (LD). However, there are no validated patient-reported outcomes (PRO) that measure SJIA-LD. The primary aims are to validate a lung symptom survey created by Cincinnati Children's Medical Health Center (survey A), and one based on existing Patient-Reported Outcomes Measurement Information System (PROMIS) measures (survey B). We hypothesize that patients with LD have higher scores compared to those without LD.

Methods: Parents or guardians of SJIA patients under 18 years of age, as identified through the CCHMC JIA database and Systemic JIA Foundation, were surveyed via mail or email, and responses stored in Research Electronic Data Capture. LD was divided into three subgroups of patients: interstitial lung disease (ILD) or pulmonary alveolar proteinosis (PAP); asthma; and pulmonary hypertension (PAH), hospital-acquired pneumonia (HAP), or recurrent pneumonia. Total scores were used for survey A. PROMIS survey B are represented by t-scores, defined as standardized scores with a mean of 50 and a standard deviation of 10. Correlation between surveys were made with Pearson coefficient, while between-survey comparisons were done with t-tests, and between-group comparisons with ANOVA. Severity for lung symptoms in survey B were determined by the PROMIS Scores Graph For Profile Domains.

Screening questions

1. Are you a parent of a child with SJIA under 18 years of age? □ Yes □ No
2. Have your child every been diagnosed with ANY lung disease, such as pneumonia, asthma, or interstitial lung disease? □ Yes □ No
   - Yes Check all the types of lung diseases your child has been affected with.
     □ hospital-acquired pneumonia □ asthma □ interstitial lung disease □ pneumonia more than once □ pulmonary hypertension
     □ pulmonary alveolar proteinosis (PAP) □ other
3. Has your child ever been diagnosed or hospitalized with early, subclinical, or occult macrophage activation syndrome (MAS)? □ Yes □ No □ Unsure
4. What SJIA medications has your child PREVIOUSLY been on?
   □ daily oral steroids □ monthly pulse intravenous steroids □ anakinra (Kineret) □ canakinumab (Ilaris) □ tocilizumab (Actemra)
   □ methotrexate □ cyclosporine □ tacrolimus (Astagraf XL, Envarsus XR, Prograf) □ rilonacept (Arcalyst) □ tofacitinib (Xeljanz)
   □ ruxolitinib (Jakafi/ Jakavi) □ baricitinib (Olumiant) □ other
5. What SJIA medications is your child CURRENTLY on?
   □ daily oral steroids □ monthly pulse intravenous steroids □ anakinra (Kineret) □ canakinumab (Ilaris) □ tocilizumab (Actemra)
   □ methotrexate □ cyclosporine □ tacrolimus (Astagraf XL, Envarsus XR, Prograf) □ rilonacept (Arcalyst) □ tofacitinib (Xeljanz)
   □ ruxolitinib (Jakafi/ Jakavi) □ baricitinib (Olumiant) □ other

Survey A*

1. Does your child have a cough lasting more than 2 weeks? □ No (1) □ Yes (2)
2. Does your child have trouble breathing? □ never (1) □ almost never (2) □ often (3) □ almost always (4)
3. Does your child breathe fast? □ never (1) □ almost never (2) □ often (3) □ almost always (4)
4. Does your child get short of breath (winded) at rest or easily? □ never (1) □ almost never (2) □ often (3) □ almost always (4)
5. Does your child have trouble breathing at night or when sleeping? □ never (1) □ almost never (2) □ often (3) □ almost always (4)
6. Does your child's breathing keep them from keeping up with their friends? □ never (1) □ almost never (2) □ often (3) □ almost always (4)
7. If you answered "yes" to any of these, how long has your child had these problems? □ <1 week □ 1-2 weeks □ 2-4 weeks □ >4 weeks

Survey B**

	Question identification
1. In the past 7 days, my child felt scared that he/she might have trouble breathing because of his/her SJIA... □ never (1) □ almost never (2) □ sometimes (3) □ often (4) □ almost always (5)	Pdisabasth10r
2. In the past 7 days, my child's chest felt tight because of his/her SJIA... □ never (1) □ almost never (2) □ sometimes (3) □ often (4) □ almost always (5)	Ppedsa2asth1r
3. In the past 7 days, my child felt wheezy because of his/her SJIA... □ never (1) □ almost never (2) □ sometimes (3) □ often (4) □ almost always (5)	Ppedsa2asth2r
4. In the past 7 days, it was hard for my child to play sports or exercise because of his/her SJIA... □ never (1) □ almost never (2) □ sometimes (3) □ often (4) □ almost always (5)	Ppaqlqasth1r
5. In the past 7 days, it was hard for my child to take a deep breath because of his/her SJIA... □ never (1) □ almost never (2) □ sometimes (3) □ often (4) □ almost always (5)	Ppedsa2asth7r

Figure 1. Patient-reported Outcomes Surveys. *Survey A- Cincinnati Children's Medical Health Center. Point designations in parentheses. Total score ranges (6-22). **Survey B- PROMIS Parent Proxy Item Bank v2.0- Asthma Impact- Short Form 8a. Total scores (5-25) converted to t-scores. Modifications- "asthma" changed to "SJIA," excluded questions Ppedsdiaryasth4r, Ppaqlqasth3r, and Ppedsdiaryasth5r.

Results: Out of 139 participants, 40.3% (n=56) reported at least one LD including 12.9% (n=18) with ILD or PAP; 15.1% (n=21) with asthma; and 15.1% (n=21) with PAH, HAP, or recurrent pneumonia. There was high correlation (r=0.64) between both surveys. In survey A, the < 1 week group (n=21) had a median of 8 (IQR 7-10.5), and >4 weeks (n=51) had a median of 11 (IQR 9-14; p=0.0006). All patients with LD had significantly higher total scores than patients without known LD, with ROC curve showing an area of 0.73. A total score of >6.5 (range 6-22) had moderate sensitivity of 80.4% but poor specificity of 51.8% for identifying LD. However, patients with ILD and PAP had similar scores to those with asthma.

For survey B, patients with LD had significantly higher scores than patients without LD, although the median score was in the normal range. Further evaluation of LD subgroups showed that survey B was only significant for asthma, likely as the survey was based on existing asthma measures. For lung symptom clinical severity t-score thresholds, 95% was normal and 5% was moderate. The questions for survey B were further scrutinized; questions 1, 2, and 5 were significant when comparing no LD vs LD. Question 1 and 2 were significant when comparing no LD and all lung subgroups. The significant range differences between the questions can be helpful in creating future surveys with meaningful change.

Conclusion: While PROs based on lung disease symptoms showed higher scores in children with SJIA and LD, they could not discriminate between asthma and ILD/PAP. This is in agreement with prior work that most patients with

Identifying Sleep Problems in Systemic Juvenile Idiopathic Arthritis (SJIA) Patients with Patient-reported Outcomes (PRO) Questionnaires

Kim Nguyen[1], Christopher Towe[2], Shima Yasin[3], Alexei Grom[4], Hermine I Brunner[5] and Grant Schulert[5], [1]Veterans Affairs Cincinnati, University of Cincinnati Medical Center, Cincinnati, [2]Cincinnati Children's Medical Hospital Center, Cincinnati, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (SJIA) can cause severe and chronic multisystem involvement. Medical therapies including high-dose corticosteroids can have significant side effects affecting sleep. The primary aims are to validate Patient-Reported Outcomes Measurement Information System (PROMIS) surveys-sleep disturbance (survey A) and sleep impairment (survey B). Our hypothesis is that current steroid drug treatment cause worse sleep.

Screening questions

1. Are you a parent of a child with SJIA under 18 years of age? □ Yes □ No
2. Have your child every been diagnosed with ANY lung disease, such as pneumonia, asthma, or interstitial lung disease? □ Yes □ No
   - Yes Check all the types of lung diseases your child has been affected with.
     □ hospital-acquired pneumonia □ asthma □ interstitial lung disease □ pneumonia more than once □ pulmonary hypertension
     □ pulmonary alveolar proteinosis (PAP) □ other
3. Has your child ever been diagnosed or hospitalized with early, subclinical, or occult macrophage activation syndrome (MAS)? □ Yes □ No □ Unsure
4. What SJIA medications has your child PREVIOUSLY been on?
   □ daily oral steroids □ monthly pulse intravenous steroids □ anakinra (Kineret) □ canakinumab (Ilaris) □ tocilizumab (Actemra)
   □ methotrexate □ cyclosporine □ tacrolimus (Astagraf XL, Envarsus XR, Prograf) □ rilonacept (Arcalyst) □ tofacitinib (Xeljanz)
   □ ruxolitinib (Jakafi/ Jakavi) □ baricitinib (Olumiant) □ other
5. What SJIA medications is your child CURRENTLY on?
   □ daily oral steroids □ monthly pulse intravenous steroids □ anakinra (Kineret) □ canakinumab (Ilaris) □ tocilizumab (Actemra)
   □ methotrexate □ cyclosporine □ tacrolimus (Astagraf XL, Envarsus XR, Prograf) □ rilonacept (Arcalyst) □ tofacitinib (Xeljanz)
   □ ruxolitinib (Jakafi/ Jakavi) □ baricitinib (Olumiant) □ other

Survey A- PROMIS Parent Proxy Item Bank v1.0- Sleep Disturbance- Short Form 4a	Question identification

4. In the past 7 days, my child had problems during the day because of poor sleep □ never (1) □ almost never (2) □ sometimes (3) □ almost always (4) □ always (5)	w029p_r

Figure 1. **Survey questions.**

Methods: Patients were identified through the CCHMC JIA database and Systemic JIA Foundation, and included parents or guardians of SJIA patients under 18 years of age at the time of the survey. Survey invitations were mailed or e-mailed, and de-identified data were stored in Research Electronic Data Capture. The two surveys are listed in Figure 1 and include demographic screening questions and past and current drug treatments. In performing descriptive statistical analyses, PROMIS surveys are represented by t-scores, defined as standardized scores with a mean of 50 and a standard deviation (SD) of 10. Between-group comparisons were done with t-tests. Severity of sleep problems were determined by the corresponding PROMIS Scores Graph For Profile Domains (Figure 3).

Results: 139 participants were included in the survey. There was reasonable correlation between survey A and B (r=0.5175). For survey A, 51.1% (n=71) of patients reported some level of sleep disturbance; 12.9% were mild, 14.4% were moderate, and 23.8% were severe. For survey B, 53.2% (n=74) of patients reported sleep impairment; 15.8% were mild, 19.4% were moderate, and 18% were severe. For survey A, the steroid treatment group showed a mean of 58.43 (SD 12.01), a median of 57.7 (IQR 47.65-69.4), and a range of 41.4 to 78.9. The no steroid treatment group had a mean of 55.16 (SD 11.72), a median of 54 (IQR 41.4-64.6), and a range of 41.4 to 78.9. T-test treatment group comparison was not significant (p=0.13). In survey B, patients treated with steroids showed a mean of 55.18 (SD 11.79), a median of 51.2 (IQR 46.2-66.13), and a range of 40 to 84.4. The no steroid treatment group had a mean of 54.85 (SD 11.76), a median of 56.1 (IQR 40-63.6), and a range of 40 to 84.4 There was not statistical significance between treatment groups (p=0.88) (Figure 2).

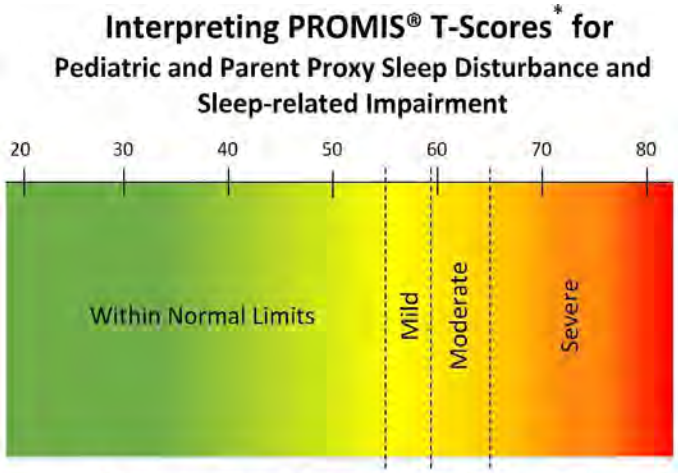
mean	55.18 (SD 11.79)	54.85 (SD 11.76)
t-test (*p* value)	*t*= 0.1533 (*p*=0.8784)	

Figure 2. **PROMIS Scores For Profile Domains and Descriptive Statistical Analyses.**



Parent proxy	normal	mild	moderate	severe
Sleep disturbance	≤ 55	56-58	59-65	≥ 66
Sleep-Related Impairment	≤ 54	55-58	59-65	≥ 66

Figure 3. PROMIS Scores Graph For Profile Domains

Conclusion: In conclusion, a majority of patient with SJIA have clinically significant sleep disturbance and/or impairment. However, current steroid treatment did not have statistical significance for causing worse sleep. Sleep problems interfere with quality of life and future endeavors include identification of factors that correlate with higher scores.

Cost of Non-Persistence in the Treatment with Subcutaneous Tumor Necrosis Factor-Alpha Inhibitors of Inflammatory Arthritis: A Propensity Score Matching Approach

Johan Dalén[1], Karin Luttropp[1], Tor Olofsson[2], Christopher Black[3] and Amy Puenpatom[4], [1]ICON plc, Stockholm, Sweden, Stockholm, Sweden, [2]Department of Clinical Sciences, Lund, Rheumatology, Lund University, Sweden; Department of Rheumatology, Skåne University Hospital, Lund, Sweden, Lund, Sweden, [3]Merck & Co., Inc., Kenilworth, NJ, USA, Rahway, NJ, [4]Merck & Co., Inc., Kenilworth, NJ, USA, North Wales, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Few studies have explored cost consequences of non-persistence in the treatment with Subcutaneous Tumor Necrosis Factor-Alpha Inhibitors (SC-TNFi) in Inflammatory Arthritis (IA; rheumatoid arthritis [RA], psoriatic arthritis [PsA] and ankylosing spondylitis [AS]). Hence, the aim of this study was to estimate the costs associated with non-persistence among biologics-naïve patients treated with SC-TNFi for IA.

Methods: An adult and biologic treatment-naïve population initiating treatment for IA with any available SC-TNFi (adalimumab, etanercept, certolizumab, and golimumab) between May 1, 2010 and December 31, 2017, was identified in the Swedish Health Data Registers. Treatment persistence was derived based on information from filled prescriptions and a grace period of 60 days. Patients not reaching the specified treatment maintenance period (i.e. persistent < 6 months) or with insufficient follow-up data were excluded. Patients were deemed non-persistent if treatment was discontinued or if they switched to another novel synthetic or biologic disease-modifying anti-rheumatic drugs (DMARDs). Costs of non-treatment related Health Care Resource Utilization (HCRU) were captured and compared 12-months before and after the date of non-persistence (i.e. index date). Resources comprised specialized outpatient care, inpatient stays, and medication other than DMARDs. The analysis was conducted on a propensity score matched cohort based on the predicted probability of non-persistence, within two years from treatment initiation; controlling for baseline characteristics collected 12 months before treatment initiation (e.g. age, gender, diagnosis, and level of education). Non-persistent patients (cases) were matched 1:1, without replacement, to persistent patients with at least 12 months additional time on treatment (controls). The number of days on treatment in cases was also used to identify the index date in controls, enabling comparisons across the same time period in relation to treatment initiation.

Results: A total of 9,976 eligible patients initiating SC-TNFi treatment for IA were identified. A PSM cohort was derived with 2,969 cases and an equal number of controls. In this cohort overall, 63% were female, the mean age was

	Persistent patients n = 2,969			Non-persistent patients n = 2,969

CI – confidence interval; HCRU – health care resource use; DMARDs – disease,modifying anti-rheumatic drugs; index – index date; SC,TNFi – subcutaneous tumor necrosis factor-α inhibitor; SD – standard deviation; USD – US dollars

** Bootstrapped 95% confidence intervals*

† Costs are presented in 2018 US-dollars.

Table 1. Costs of non-treatment related health care resource utilization 12-months before and after index date in, propensity score matched, persistent and non-persistent patient's treated with SC-TNFi for IA

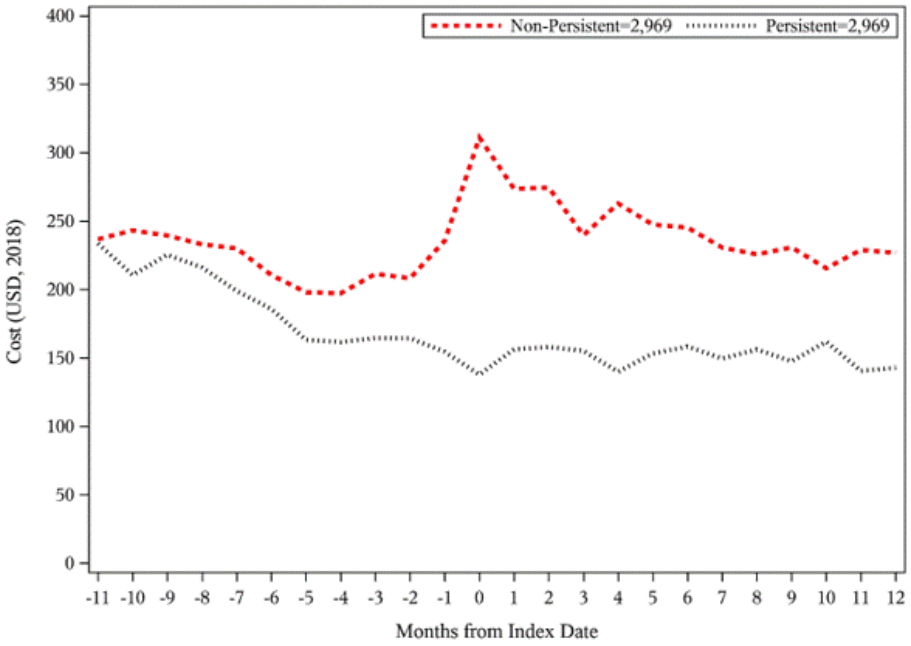

Figure 1. Development of costs for non-treatment related health care resource utilization 12-months before and after index date in, propensity score matched, persistent and non-persistent patient's treated with SC-TNFi for IA

50 years, and 52%, 22%, and 26% were diagnosed with RA, PsA and AS, respectively. While non-persistent patients increased their total non-treatment related cost of HCRU from the 12-month period before to the 12-month period after the index date, persistent patients decreased their costs between the same time periods (Table 1). Figure 1 shows the monthly development of total non-treatment related HCRU costs from 12 months before to 12 months after the index date. Costs were more similar before the index date and the differences increased for non-persistent patients in conjunction with their treatment discontinuation.

Conclusion: Among patients initiating SC-TNFi treatment for IA, non-persistent patients incurred significantly higher non-treatment HCRU costs compared to those who were persistent during the year following index date. This highlights the impact of therapy persistence from an economic point of view, adding further aspects to the clinical perspective.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The childhood inflammatory disorder systemic juvenile idiopathic arthritis (SJIA) has historically had several names, including Still's disease and systemic juvenile rheumatoid arthritis. While its current name reflects its classification as a subtype of JIA, SJIA is genetically and pathogenically distinct from the other subtypes of JIA. To complicate things further, SJIA and adult onset Still's disease (AOSD) may be the same disorder with different ages of onset. Scant data exists regarding how the name "SJIA" is perceived by patients and families as well as its implications for the patient experience.

Methods: A qualitative study of self-reported online survey of patients with SJIA was developed by the non-profit organizations, the Autoinflammatory Alliance, KAISZ/VAISZ, and SJIA Foundation in English and translated to Dutch. Respondents were recruited by convenience sampling through online social media posts. Respondents were asked if they considered that SJIA adequately described their disease, followed by an open-ended question on what they thought about the name, "Systemic Juvenile Idiopathic Arthritis".

Table 1: Representative patient comments by theme area

Theme areas	Representative comments
1) Insurance reasons	Our insurance company (Tricare) requires "step-wise" therapy. For example: first use steroid, next use MTX and then Humira and after that use Anakinra.
	Other people and insurance see it as just joint pain and nothing else.
2) Gets confused with rheumatoid/osteoarthritis or other forms of JIA	Many people have a misconception about arthritis. They feel that only elderly people are affected by arthritis within their joints.
	People hear "arthritis" and think of the arthritis an old person has, and that isn't an accurate picture of my child.
	When I explain what my daughter has and say the name they only hear "arthritis" and then to proceed to say they know exactly how they feel cause they have arthritis in their finger
3) Other disease features more pronounced than the arthritis	My child is more affected by systemic inflammation and organ involvement than arthritis in her joints (though she has that, as well).
	(we) know that the Systemic subset is made up of so many more symptoms than just inflammation of the joints. I know of patients who are diagnosed with SJIA but have not had inflammation in any joints, therefore arthritis does not cover their experience with this diagnosis
	My daughters main symptoms 3 years after diagnosis are still systemic. Over the years she has had major organ involvement and MAS (needing care in ICU). I find people see the word arthritis and think that's all that's wrong with her
4) Make the name easier to understand to lay people	I would prefer a name that gives laypersons an accurate perception of what is going on inside my child's body.
	We understand it because we live it. But to say it and explain it is difficult for others to understand.
5) The name makes the disease seem less serious than it is	It difficult emotionally to have people not understand why this disease is so dangerous and life altering
	No one understands that it's far more serious than sore joints.
6) Name is difficult to remember/pronounce/ understand	People shut down often with longer names and with arthritis.
	I just know when she was diagnosed five years ago I could not even tell people her disease because I had a hard time remembering SJIA
7) Possibility for subclassification if it has a separate name	I think that this name will be an even bigger issue as discoveries are made about the pathogenesis of this disease and we see indicators of why different subsets of children have differing symptoms. It would be easier to change it now so that subsets could be created later on, if needed."
	I also don't think it should be group together with the other "Juvenile Arthritis" categories. It should be it's own classification with it's own subcategories.
8) Seems to affect only children	By its title one believes it concerns only children. I had my first attack at 4, now 57.. came and went all my life until I was 35 and my disease process came to stay.
9) More similar to period fever syndromes	Since joining the auto inflammatory rare disease but not alone page I have discovered my daughters SJIA presents much more like a periodic fever syndrome than juvenile idiopathic arthritis.

Results: Between 2017 and 2019, there were 72 responses, 54 from parents of children with SJIA and 18 from adults with SJIA. Thirty six (51%) answered that they did not think the name adequately represented the disease, including 61% of adults with SJIA. Responses were grouped into several themes. The most frequent responses were that the name confuses the condition with more common types of arthritis. Several noted this minimizes the disorder as “just

sore joints." Hindrance to appropriate treatment was also noted due to lack of insurance coverage because they had to try and fail treatments for other forms of arthritis. Similarly, many noted that the name does not reflect the most common clinical features of their own disease- "(its) difficult emotionally to have people not understand why this disease is so dangerous and life altering because … Arthritis is only a piece of it". Adult patients with SJIA noted that the name implies it only affects children when they have had life-long symptoms. Finally, several noted the name was too long and complicated to explain to people: "We understand it because we live it, but to say it and explain it is difficult for others to understand".

Several themes also reflected what patients would like to see in a disease name, including: 1) something that is easier to explain to lay people, 2) greater reflection of autoinflammatory disease, rather than a form of JIA, and 3) that there is a wide variety of clinical features, which might benefit from subtypes.

Conclusion: Over half of the SJIA patients and caregivers do not agree with the name. They highlighted many areas where the disease name can negatively impact the perception of their disease. The study is limited by being a convenience sample of parents engaged in social media and may not be representative of the general population of patients with SJIA. However, these responses regarding the limitations of the name and how it could be improved will serve as the basis for a larger and more structured survey, including patients with AOSD, to provide patient and family input on the future classification of SJIA.

Work Disability and Predictors of Poor Work Outcome in Patients with Axial Spondyloarthritis

Elif Ediboglu[1], Dilek Solmaz[2], Hande Ece Oz[3], Gokhan Kabadayı[4], Haluk Cinaklı[4], Eda Otman Akat[3], Mustafa Ozmen[4] and Servet Akar[3], [1]Izmir Katip Celebi University, Izmir, Izmir, Turkey, [2]Izmir Katip Celebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, TURKEY, Izmir, Turkey, [3]Izmir Katip Celebi University, Izmir, Turkey, [4]Izmir Katip Celebi University, Izmir

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease which may lead substantial functional limitation. The disease more commonly affects men in their third decade of life. For patients with chronic disease participation in paid work may be the result of series factors like disease severity, effectiveness of the health care, availability and the type of work. Previously it was reported that ankylosing spondylitis may cause adverse work outcome.

To understand the impact of axSpA on work disability and the factors associated with poor work outcome.

Table. Demographics and diseases related characteristics of study population

Variables	All population (n=219)	No work disability (n=172)	Work disability (n= 47)
Male, n (%)	161 (73.5)	122 (70.9)	39 (83)
Age, years*		41.5 (9.4)	43.1 (12.4)
Ever smoking, n (%)	155 (71.4)	115/171 (67.3)	40/46 (87)
Education duration ≤8 years, n (%)	82/212 (61.3)	53/165 (32.1)	29/47 (61.7)
Disease duration, years	6.7 (8.3)	5.5 (6.3)	10.7 (12.6)
BASDAI*	4.3 (2.4)	4 (2.3)	5.3 (2.6)
BASFI*	3.4 (2.8)	2.9 (2.5)	5.4 (3.0)
ASDAS-CRP*	2.8 (1.2)	2.7 (1.1)	3.3 (1.4)
BASMI*	2.3(2.0)	2 (1.8)	3.5 (2.4)
ASQOL*	9 (5.5)	8 (5.3)	12 (4.9)
Peripheral arthritis, n (%)	81/207 (39.1)	54/163 (33.1)	27/44 (61.4)
Hip arthritis, n (%)	39/205 (19)	26/163 (16)	13/42 (31)
Presence of syndesmophyte, n (%)	92/164 (56.1)	63/125 (50.4)	29/39 (74.4)

* Variables presented as mean (SD).

Methods: A cross-sectional survey was performed among323 patients withaxSpA according to ASAS classification criteriafrom one tertiary center. In total 219 (67.8%) patients were working age at the time study. The others were student, housewife or retired. Demographic, social and disease related characteristics were collected. Characteristic that might be associated with premature work loss were evaluated byunivariable and multivariable logistic regression analysis.

Results: Out of 219 axSpA patients (155 [71%] r-axSpA and 64 nr-axSpA, 69% HLA-B27 positive) who have a work at least once 47 (22%) was either withdrawn from work (n=35) or retired due to disability (n=12) during median (IQR) 12 (12) years symptom duration. Demographic and disease related characteristics of the patients with or without work diasbilitywere summarized in the Table. In univariate analysis gender, smoking, education levels, the presence of peripheral arthritis, BASMI score and radiographically presence of syndesmophyte and hip involvement were found to be associated with poor work outcome. However poor work outcome were similar between r- and nr-axSpA patients. In regression analysis low education level (HR:3.4 [95%CI:1.4-8.6], P=0.007), peripheral arthritis (HR:2.7[95%-CI:1.07-6.8], P=0.035), and ever smoking (HR:4.9 [95%CI :1.3-18.0], P=0.02) were independent predictors of work disability.

Conclusion: Our results suggest that there is still remarkable poor work outcome among axSpA patients and work disability might be similar in r- and nr-axSpA. Patients who are smoker, with low education levels, and peripheral arthritis seem to be at risk for premature work loss.

Prevalence and Impact of UnaccepTable Symptom State Among Patients with Psoriatic Arthritis: Results from the National Psoriasis Foundation's 2019 Annual Survey

Alexis Ogdie[1], George Gondo[2], Joseph Merola[3], Stacie Bell[4] and Alice Gottlieb[5], [1]University of Pennsylvania, Philadelphia, PA, [2]National Psoriasis Foundation, Portland, OR, [3]Brigham and Women's Hospital, Harvard Medical School, Newton, MA, [4]National Psoriasis Foundation, Portland, [5]Department of Dermatology, Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite many efficacious therapies for PsA, many patients do not achieve remission. Ongoing disease activity leads to many downstream effects including diminished functional ability, reduction in social interaction and in some cases depression. Furthermore, depression may be associated with ongoing symptoms that can be attributed to PsA. The objective of this study was to determine the prevalence of 'unaccepTable' symptom states among patients with PsA and to examine the association with being in an unaccepTable symptom state with depression and impaired social interaction.

Methods: The National Psoriasis Foundation (NPF) surveyed a random, stratified sample of individuals with psoriatic disease in the US from the NPF's constituent database. Patients were active members of the NPF within the past 2 years, age >=18, carried a self-reported diagnosis of psoriasis or PsA and had an active email address or phone number. The presence of accepTable vs unaccepTable level of disease impact of PsA was assessed using the established patient accepTable symptom state for the PsAID-9 (< =4 on a scale of 0-10). Severity of psoriasis was defined by body surface area (BSA, Mild < 3%, Moderate to Severe ≥ 3%) as reported by patients using the Patient Report of Extent of Psoriasis Involvement (PREPI). Linear regression analyses were conducted to compare outcomes of individuals with accepTable level of PsA activity with those who have unaccepTable level of PsA activity while adjusting for severity of PsO. Outcomes of interest were depression and ability to participate in social roles and activities. Depression was assessed by a two-stage assessment process utilizing the PhQ-2 and PhQ-9. The PhQ-2 is utilized in this analysis. Ability to participate in social roles and activities was assessed by the PROMIS Ability to Participate in Social Role and Activities-SF4a. Descriptive statistical analyses were conducted with SPSS Ver 26 and ANOVA and linear regression analyses were conducted in STATA SE Ver 9.

Results: Among 23,340 patients sent a survey, 1,570 individuals completed the survey, including 834 who reported being diagnosed with PsA by a healthcare provider and 801 (96.0%) completed the PSAID. Among individuals who self-reported diagnosis of PsA and completed the PsAID-9, 59.6% reported unaccepTable level of disease activity (PSAID >4) and 40.4% reported accepTable level of disease activity. After adjusting for age, sex, and severity of PsO, statistically significant differences were found between individuals with unaccepTable level of PsA activity and accepTable level of PsA activity for depression [2.56 (SD 2.00) vs 0.08 (SD 1.25, p≤.001] and ability to participate in social roles and activities [mean T-scores 44.56 (SD 6.83) vs 55.46 (SD 6.99), p≤.001].

Conclusion: Not being in a patient accepTable symptom state is common in this US-based population of patients with PsA and is associated with significant decrements in social activity and increase prevalence of depression. Being monitored by a dermatologist or rheumatologist was associated with an increased likelihood of being in a patient accepTable symptom state.

Rheumatoid Arthritis Patient Phenotypes from a Digital Health Coaching Engagement Program

Jonathan Patterson[1], Kirby Magid[2], Dhiren Patel[3] and **Matt Allison**[3], [1]Pack Health, Birmingham, AL, [2]University of North Carolina at Charlotte, Charlotte, [3]Pack Health, Birmingham

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The goal of this study was to examine whether cluster analysis could be used to identify homogeneous subgroups of engagement in RA patients enrolled in a digital health coaching program. The novelty of this approach was our attempt to identify actual user engagement behaviors, as opposed to employing engagement benchmarks derived from a trial protocol. These findings can help clinical staff stratify the RA population for digital health interventions between clinic visits for disease monitoring, self-management, and other efforts.

Methods: A longitudinal, retrospective analysis was conducted in a sample of RA members enrolled in Pack Health digital health coaching program (n = 66). Members reported the primary measures of RA disease severity (RAPID3) and physical and mental health quality of life (PROMIS) upon enrollment. Digital engagement data was measured using the frequency of outbound calls to a health coach, inbound calls from a health coach, the average call length, email open rate, frequency of outgoing patient text messages to a health coach, and incoming member text messages over the initial 12 weeks of the program. An agglomerative hierarchical cluster analysis was performed using Ward's method to link and identify subgroups of members with similar profiles. Dismarilarity between RA members was calculated by the Minkowski distance in nine-dimensional space.

Results: Three clusters were identified with a Minkowski dissimilarity measure greater than 100. Cluster 1 (poor health, highly engaged) consisted of 28 patients with below-average PROMIS mental health (45.15), poor PROMIS physical health (38.70), and moderate to severe RA (RAPID3 4.90). This highly engaged cluster averaged 11.29 connected outbound calls or a 94% call success rate along with the highest volume of total text messages (56.75). Cluster 2 (better health, moderately engaged) consisted of 23 patients with below-average PROMIS mental health (46.50), above-average PROMIS physical health (52.49), and low RA severity (RAPID3 2.61). Cluster 2 averaged 8.48 total calls out of a possible 12 along with 16.3 total text messages. Cluster 3 (poor health, minimally engaged) consisted

Cluster	PROMIS Physical	PROMIS Mental	RAPID3	Inbound Calls	Outbound Calls	Avg Call Length	Inbound Text Messages	Outbound Text Messages	Email Open Rate
1: Poor Health, Highly Engaged	38.70	45.15	4.07	11.29	1.54	11.36	36.25	20.50	63.10%
2: Better Health, Moderately Engaged	46.50	52.49	2.61	7.39	1.09	9.27	13.87	2.43	55.39%
3: Poor Health, Minimally Engaged	32.03	36.35	4.90	3.07	0.53	6.44	12.33	2.87	58.22%

Table1. Cluster Descriptive Statistics

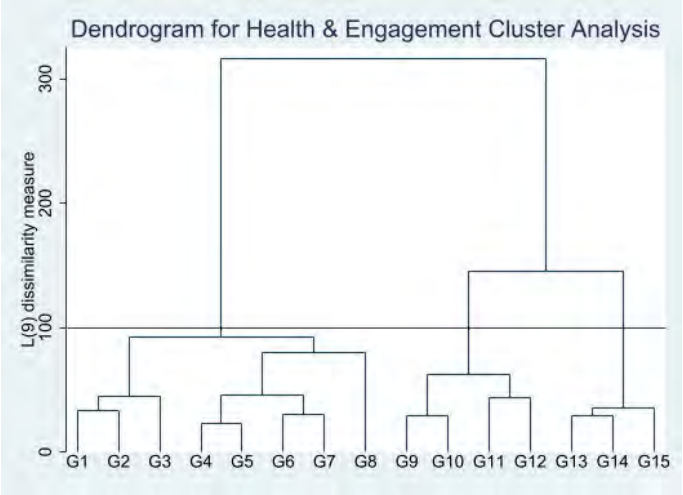

Figure 1. Dendrogram for Hierarchical Cluster Analysis

of 15 members with poor PROMIS mental health (32.05), poor PROMIS physical health (36.35), and high severity RA (RAPID3 4.90). This minimally engaged cluster averaged 3.07 successful calls and 15.2 total text messages. Complete health and engagement cluster data are shown in Table 1.

Conclusion: Results indicated that distinct patterns of engagement exist among RA patients in a digital health coaching program. The demographics and patient attributes identified in each subgroup may be helpful in (a) predicting RA patients' participation and engagement in digital health interventions between clinic visits, and (b) enhancing patient engagement in digital health coaching programs for RA by tailoring treatment to the patient's particular disease severity and engagement phenotype.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Figure 1. Proportion of patients who achieved quiescence and proportion of patients who maintained response (quiescence achieved at prior visit and no flare at current visit) at any visit during the follow-up.

*Quiescence: no new active chorioretinal inflammatory lesions and AC cells and VH grade ≤0.5+ in both eyes.

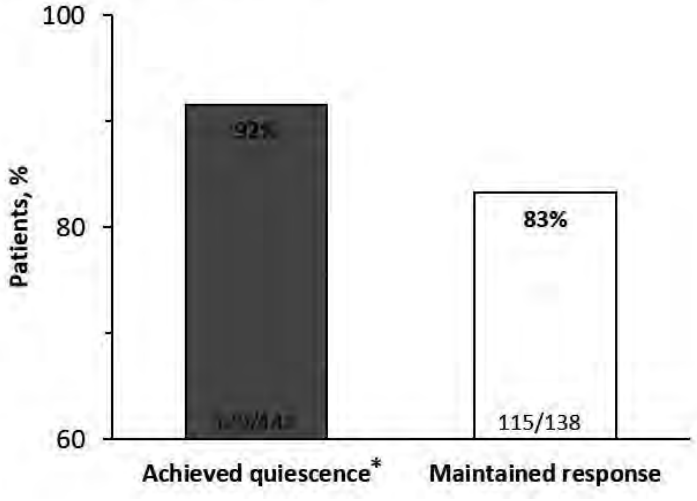

Figure 2. Proportion of patients who achieved quiescence and proportion of patients who maintained response (quiescence achieved at prior visit and no flare at current visit) at separate follow-up visits. Visit schedule included baseline (V0) and 4 follow-up visits over 12 months at 3-month intervals (V1, V2, V3, and V4).

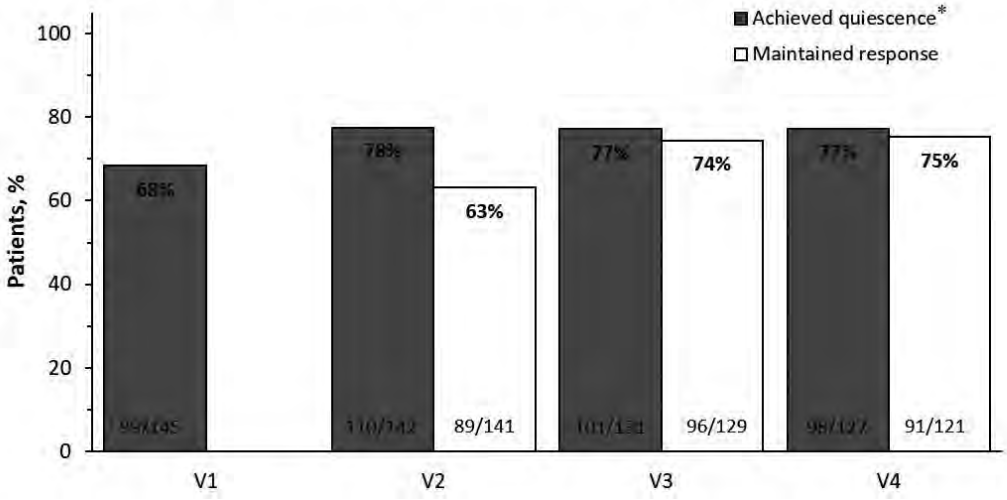
*Quiescence: no new active chorioretinal inflammatory lesions and AC cells and VH grade ≤0.5+ in both eyes.



Background/Purpose: VISUAL clinical trials demonstrated efficacy and safety of adalimumab (ADA) in patients with active and inactive non-infectious, intermediate, posterior, or panuveitis (NIIPPU).[1-3] The purpose of this study (HOPE) was to evaluate disease characteristics and assess real-world effectiveness of ADA, including effects on treatment response (quiescence) and health resource utilization in patients with active NIIPPU.

Methods: HOPE was a post-marketing, prospective, observational study conducted in 15 countries. Included in the study were patients ≥18 years old with active NIIPPU (active, inflammatory, chorioretinal, and/or inflammatory retinal

vascular lesion; or anterior chamber [AC] cells grade ≥2+; or vitreous haze [VH] grade ≥2+) despite high-dose corticosteroid therapy. Patient visits included baseline (V0) and follow-up at month 3 (V1), 6 (V2), 9 (V3), and 12 (V4). Patients received ADA per local prescription guidelines and signed informed consent. Excluded were patients with prior ADA treatment, participating in other clinical studies, or unwilling or unable to complete patient-reported questionnaires. Primary endpoint was proportion of patients in quiescence (no new active chorioretinal inflammatory lesions and AC cells and VH grade ≤0.5+ in both eyes) at any of the follow-up visits. Secondary endpoints were proportion of patients in quiescence at each visit; proportion of patients who maintained response (quiescence achieved at prior visit and no flare at current visit); and proportion of patients with flares (new active inflammatory lesions, AC cells grade ≥2+, or VH grade ≥2+ in ≥1 eye) at any visit. Visual function was assessed with National Eye Institute 25-Item Visual Function Questionnaire (VFQ-25). Serious adverse events (SAEs) were recorded at all visits.

Results: Patients in the full analysis set were assessed at V0 (n=149), V1 (n=147), V2 (n=143), V3 (n=133), and V4 (n=127). Of 149 patients, 62% were female, 43% had panuveitis, and 50% had idiopathic etiology; mean age was 42.3 years (**Table**). Quiescence was achieved by 92% of patients, and response was maintained in 83% of patients at any of the follow-up visits (**Figure 1**)**.** Most patients achieved quiescence and maintained response at each visit (**Figure 2**). Flares occurred in 32% of patients at any of the follow-up visits. Proportion of patients with medical visits

for uveitis during the preceding 6 months or since last visit decreased from 89% (132/149) at V0 to 39% (55/142) at V2 and 21% (27/126) at V4. Median change in overall VFQ-25 score from V0 to V2 and V4 was 3.3 (interquartile range [IQR], 0.4–13.4) and 5.1 (IQR, 0.4–15.7), respectively. SAEs were reported for 14 patients (9%).

Conclusion: In patients with active NIIPPU treated in routine clinical practice, ADA showed effectiveness in improving ocular inflammation, achieving quiescence, improving quality of life, and decreasing healthcare resource utilization. No new safety signals were identified.

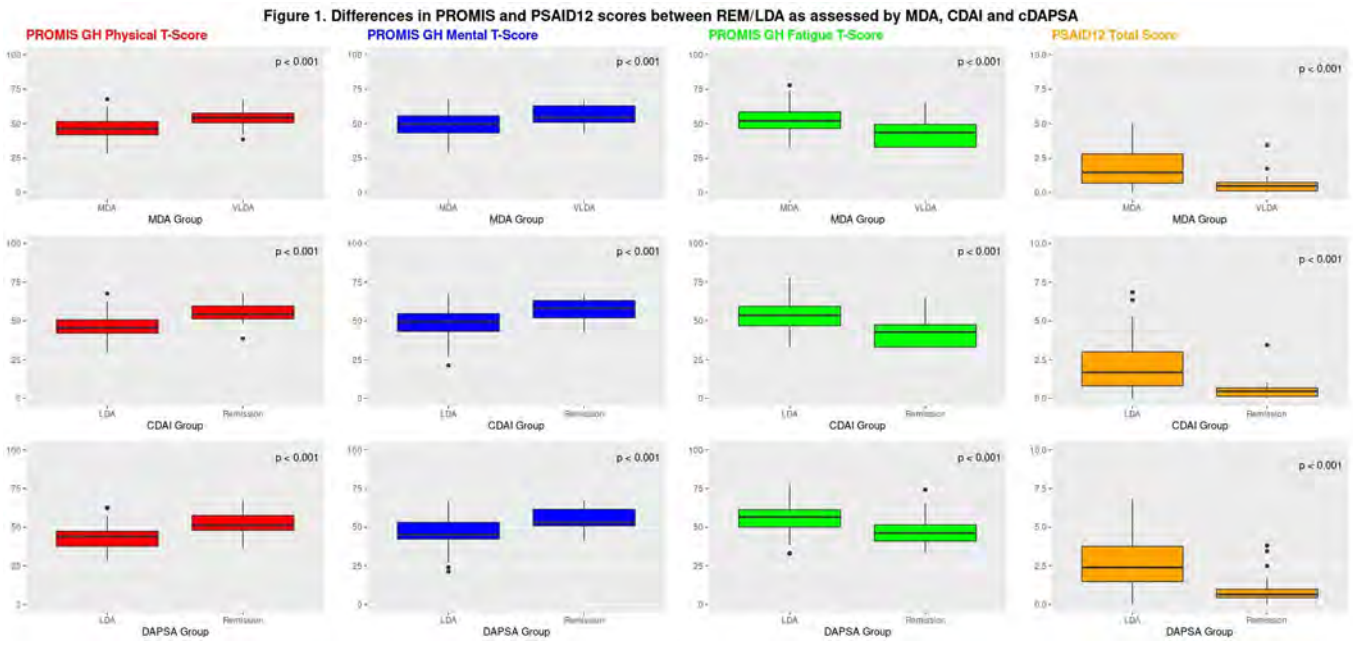
Patient-Reported Outcomes Differentiate Between Remission and Low Disease Activity in Psoriatic Arthritis

Juliette Yedimenko[1], Jessica Walsh[2], Alexis Ogdie[3], Yuxuan Jin[1], Soumya Reddy[4], Jose Scher[5] and M. Elaine Husni[1], [1]Cleveland Clinic, Cleveland, OH, [2]University of Utah School of Medicine, George E. Wahlen Veteran Affairs Medical Center, Salt Lake City, UT, [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [4]NYU School of Medicine, New York, NY, [5]NYU School of Medicine, New York City

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: For psoriatic arthritis (PsA), several different composite instruments are available to define low disease activity (LDA) and remission (REM) targets for treatment. Patient-reported outcomes (PROs) may also be useful in assessing disease activity and may be more practical than composite indices in some settings. In this study, we examined the ability of PROs to differentiate between states of low disease activity and remission treatment targets (LDA and REM), using composite indices as the reference standards.

Methods: This cross-sectional study was performed with the Psoriatic Arthritis Research Consortium between 2016-2019. PROs included Patient-Reported Outcomes Measurement Information System [PROMIS] instruments, EULAR Psoriatic Arthritis Impact of Disease [PSAID12], and Routine Assessment of Patient Index Data 3 [RAPID3]). Participants (pts) were classified as LDA if they fulfilled composite index criteria for Minimal Disease Activity (MDA), Clinical Disease Activity Index (CDAI)-LDA, or Disease Activity in Psoriatic Arthritis (cDAPSA)-LDA and REM if they fulfilled



composite index criteria for Very Low Disease Activity (VLDA), CDAI-REM, or cDAPSA-REM. PROs were evaluated by determining 1) score differences between pts in LDA vs. REM, 2) correlations with composite indices scores, and 3) percentages of pts in LDA and REM who fulfilled PRO criteria for low disease states (in PROs with previously established low disease state criteria). PROs were compared between groups using t-tests or Wilcoxon rank sum test, depending on their distributions. The categorical versions of RAPID3 and PSAID12 were compared between groups using Chi-Squared test or Fisher's exact test, when appropriate. Correlations were calculated with Spearman's rank correlation. Data was analyzed using R software (Version 3.5; Vienna, Austria).

Results: 227 PsA pts were included (52.2% female, average age 52.7±14 years). Compared to pts in LDA, pts in REM had significantly more favorable PROMIS Physical, PROMIS Mental, PROMIS Fatigue, and PSAID12 scores (Figure

p-values: a=Fisher's Exact Test; b=Pearson's chi-square test

PSAID12 patient acceptable state = score ≤4; PSAID12 not patient acceptable state = score >4

1). Correlations were strong between the composite indices and PROMIS GH physical health (r=0.65- 0.69) and between the composite indices and PSAID12 (r=-0.77- 0.79) (Figure 2). RAPID3 Low Severity and Near-Remission were reported by >98% of patients in REM, but only up to 54% of patients in LDA (Table 1). PSAID12 Patient AccepTable State occurred more frequently in pts in DAPSA-REM than pts in DAPSA-LDA (Table 1).

Conclusion: PROMIS and PSAID12 instruments correlated well with composite indices and differentiated between states of LDA vs REM. RAPID3 Near-Remission may be the most rigorous PRO criteria (including only the lowest states of disease activity), while PSAID Patient AccepTable State may identify a broader range of low states of dis-

ease activity. These data contribute to the construct validity of using PROs to measure low states of disease activity that may be considered for additional treatment targets in PsA.

Abstract Number: 0170

Utilizing Design Thinking to Develop a Decision Aid for Patients with Psoriasis and Psoriatic Arthritis

Marilyn Wan[1], Michele Almonte[2], Joel Gelfand[1] and **Alexis Ogdie**[2], [1]University of Pennsylvania, Philadelphia, [2]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: RA, Spondyloarthritis, & OA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Given the complexity of available treatment recommendations, patients with psoriatic disease would benefit from a process fostering shared decision-making using a patient-centered approach. True shared decision-making is challenging during short visits but patient decision aids (DAs) can assist this. This study aimed to understand patient and clinician needs in the process of starting/switching therapy and use design thinking to develop a patient-centered DA that addresses these needs.

Methods: Design thinking, a method adopted from engineering, first seeks to understand user needs to develop a prototype which is then iteratively revised based on user input. Semi-structured interviews of ten patients and two focus groups with rheumatologists (n=7), dermatologists (including one nurse practitioner) (n=5) and specialty pharmacists (n=2) were conducted to inform the first prototype. Follow-up focus groups with the same healthcare providers and semi-structured interviews with an additional eight patients were conducted to revise the prototype. Interview transcripts were independently coded by two research team members using NVivo12 to elicit pertinent themes. Participants were continually interviewed until saturation of themes was reached where no new themes emerged.

Results: Themes were identified from clinicians and patients (representative quotes in Table 1). Interrater reliability of the two coders surpassed the *a priori* kappa threshold of 0.80 to ensure consistency in coding. Clinicians felt that a DA was most useful for patients initiating or switching therapies and should include basic information about the disease, managing flares, and individual therapies. Clinicians suggested that treatment options should be identified using an algorithm that considers patient characteristics (e.g., comorbidities) and then select 2-3 therapies for patients to learn about. Patients desired a DA that would give them access to all information about therapies including lifestyle alterations from medications, efficacy rates, side effects, insurance coverage, and personal testimonials from other patients. Patients and clinicians noted readability and easy navigation as necessary. Patients desired more detailed information than anticipated by clinicians or would typically be provided in a short encounter. The final decision aid prototype can be found at psoriasisdecisionaid.com.

Theme	Representative Quote
Available treatments for a given circumstance	"I mean, basically it was we discussed whatever all the options and based on my circumstance at that time, which was that I was a young mother with a newborn nursing, I wasn't going to do anything that was systemic because I didn't want to stop nursing and I didn't want to hurt my baby."
Lifestyle	"There were also concerns, like I said, about certain treatments would require me to stop drinking, and it's just because that sort of cuts down on your ability to socialize, that sort of thing."
Novelty	"Well, yeah. I mean, I guess, it's also not knowing really what effects I would have from being on medication like that long-term which isn't something that has been around for a while. Some of the newer medications that I guess there wasn't a whole lot of research on at that time seemed I wasn't sure about."
Side effects	"And I knew, like we had talked about other options like different medications, but the risks associated with them just weren't worth it to me. Like I would rather have the psoriasis that I have than like be on a medication that could maybe cause side-effects like depression or something like that. That just really scared me." "I was willing to try something different because it was, again, if there are long-term effects – if we discover that the biologic drugs do something awful to you for 20 years, I'll be in my 80s by then so that's okay, I'll take it." "I think drug interactions are a key thing."
Risk-benefit Analysis	"I think just making sure everything is in balance. Like I said, I know how badly my psoriasis could be and it's really – it is manageable. So I think just balancing out like, okay, how much do I really hate having these spots versus like what am I really – like what lengths am I willing to go to get rid of them or to have it completely clear. So I just think finding that in between …" "But it was just a question of weighing these different things. Is it time? Have I reached the tipping point, as they would say?"
Efficacy	"I think what's most important is that is that it's effective."
Main concern	"Just because I was in so much pain, I wasn't really mobile, so being able to get up and get exercising again and being more active was important to me." "Also, with the skin lesions, I was also embarrassed. I was self-conscious about it as well." "It always has been the pain, but there's also the sub-issue of the skin lesions on the face. I don't really care about the skin lesions on my legs because nobody really sees those." "…what would be helpful to me as a provider is if I could understand what are the two or three major concerns a patient has that I can address for them"

Figure 2: Circos plot comparing clinical LS subtype to immune-phenotype clustering.

Conclusion: Design thinking was an effective method of creating a comprehensive decision aid; including patients, clinicians and pharmacists was of critical importance in arriving at a final decision aid that serves the needs of all stakeholders. Next steps include testing how the decision impacts treatment decisions and whether it reduces decision conflict.Table 1. Themes identified and representative quotes.

Interferon Response Gene Expression Differs in Whole Blood, Peripheral Blood Mononuclear Cells, Monocytes, T Cells, B Cells, and NK Cells in Patients with the Autoinflammatory Interferonopathies, CANDLE and SAVI

Jacob Mitchell[1], Sara Alehashemi[2], Bernadette Marrero[3], Yan Huang[4], Sofia Torreggiani[1], Lena Bichell[1], Gina Montealegre Sanchez[5], Raphaela Goldbach-Mansky[6] and Adriana de Jesus[7], [1]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, MD, [2]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Clarksville, MD, [3]Computational Systems Biology Section/NIAID/NIH, Bethesda, MD, [4]NIH, Bethesda, [5]NIAID/NIH, Rockville, MD, [6]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Potomac, MD, [7]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Silver Spring, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The disease progression of patients (pts.) with type-I interferon (IFN)-mediated diseases undergoing treatment with JAK1 and JAK2 inhibitors is monitored in part by measuring the transcription of a 28 IFN response gene (IRG) signature in whole blood with Nanostring technology to calculate a 28-gene IFN score. We sought to determine the differences in 28-gene IFN scores and in the patterns of IRG signatures among peripheral blood mononuclear cells (PBMCs), monocytes, CD4 and CD8 T cells, B cells, NK cells, and neutrophils in the type-I IFN-mediated diseases CANDLE (chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperatures) and SAVI (STING-associated vasculopathy with onset in infancy).

Methods: All patients (pts.) were enrolled into an IRB-approved natural history protocol (NCT02974595). RNA was extracted from pts. and healthy control whole blood, PBMCs, monocytes, CD4 and CD8 T cells, B cells, NK cells, and neutrophils. Transcript counts for 28 IRGs and 4 additional genes were measured with a NanoString instrument and compared to expression in the same cells or tissues in a cohort of healthy controls (HCs).

Results: Both CANDLE (p=0.065) and SAVI pts. (p=0.004) had greater 28-gene standardized IFN scores in whole blood and PBMCs compared to HCs. Significantly higher IFN scores were seen in SAVI PBMCs as compared to SAVI whole blood (p=0.035) while CANDLE PBMC IFN scores were not significantly different compared to CANDLE whole blood. SAVI PBMCs expressed more *IFNA2* and *IFNB1* than PBMCs from CANDLE pts. (p=0.0023; p=0.0012) or HCs (p=0.0097; p=0.0004). One family of SAVI pts. with a novel STING missense variant was found to have elevated IFN scores in their PBMCs while their whole blood IFN scores were not elevated. In cell subsets isolated from PBMCs, CANDLE and SAVI pts. had elevated IFN scores in monocytes and T cells, but the IFN scores in B cells and NK cells were not significantly different from HCs. SAVI pts. had significantly high IFN scores than CANDLE patients in the monocyte (p=0.02) and CD4 T cell (p=0.002) subsets. Within the 28 IRGs of the IFN score, SAVI and CANDLE mono-

cytes had the highest relative expression of *IFIT3* and *LY6E*, respectively. Preliminary studies in neutrophils have also shown that SAVI neutrophils have a greater induction of IRG transcription compared to CANDLE pts.

Conclusion: High expression of type-1 IFNs and IRGs in the PBMCs of SAVI pts. further demonstrate the role of these cells in the amplification of constitutive IFN signaling in this disease. Monocytes make a substantial contribution to the elevated IRG signature in peripheral blood found in both diseases and to a greater extent in SAVI. In addition, pts. with a SAVI phenotype and genotype but a negative IRG signature in whole blood may present an IRG transcription signature when investigating the PBMC fraction.

Funding for this study was provided in part by the Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health. All patients were enrolled into an IRB-approved natural history protocol.

Early Treatment and *IL1RN* Single Nucleotide Polymorphisms Affect Response to Anakinra in Systemic Juvenile Idiopathic Arthritis

Marianna Nicoletta Rossi[1], Manuela Pardeo[2], Denise Pires Marafon[2], Emanuela Sacco[2], Chiara Passarelli[3], Claudia Bracaglia[2], Chiara Perrone[3], Anna Tulone[4], Giusi Prencipe[5] and Fabrizio De Benedetti[6], [1]Laboratory of Immuno-Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Lazio, Italy, [2]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, Italy, [3]U.O.C. SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) represents 10-20% of all chronic arthritis during childhood. The interleukin 1 (IL-1) play a pivotal role in the pathogenesis of the disease. Indeed, several studies confirmed the therapeutic efficacy of anakinra (recombinant IL-1 receptor antagonist) in a significant portion of patients with sJIA, especially in the first phase of disease. The use of anakinra as first-line therapy can benefit from the so-called "window of opportunity", for which the evolution of the disease can be modified preventing the onset of chronic arthritis. Despite a good response to anakinra in a high percentage of patients, there is a subset of non-responders. The early identification of non-responder patients is of primary importance to avoid the progression towards chronic arthritis. Some single nucleotide polymorphisms (SNPs) in *IL1RN* gene have been found associated with sJIA, and recently, a cluster of SNPs in the *IL1RN* non-translated region has been suggested as a possible predictor of non-response to anakinra. The aim of this study was to evaluate the impact of early treatment and genetic variants in *IL1RN* gene on the response to anakinra in sJIA.

Methods: Response to anakinra was considered as clinically inactive disease (CID) at 6 months, without glucocorticoids treatment. Demographic, clinical and laboratory characteristics of 56 patients were analyzed in univariate and

multivariate analysis as predictors of response to treatment. Six SNPs in *IL1RN* gene were genotyped by qPCR or Sanger sequencing. Haplotype mapping was performed with Haploview software and *IL1RN* mRNA expression in whole blood from patients before anakinra initiation was assessed by qPCR.

Results: After 6 months of treatment, 73.2% of patients met the criteria for CID off glucocorticoids. In univariate analysis the variable strongly related with the response was disease duration from onset to anakinra initiation, with an optimal cut-off at 3 months. Patients who started anakinra after 3 months from disease onset had an 8-fold higher risk of non-response at 6 months. We confirmed that the 6 *IL1RN* SNPs were inherited as a common haplotype in our cohort of patients. We found that homozygosity for at least one high expression SNP correlates with higher *IL1RN* mRNA levels and was associated with a 6 fold higher risk of non-response, independently of disease duration.

Conclusion: Our results confirm the important role of early IL-1 inhibition and suggest that genetic *IL1RN* variants predict non-response to therapy with IL-1 blockade in patients with sJIA.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is potentially life-threatening disease characterized by prolonged fever, systemic inflammation and skin rash in addition to joint inflammation. Aberrant activation of the innate immune system driven by interleukin (IL)-1 and IL-6 is thought to be responsible for the initial phase of systemic inflammation. Monocytes propagate the inflammatory process in sJIA and their numbers are greatly increased in patients with active disease. Using mice deficient of IL-1 receptor antagonist (Il1rn$^{-/-}$) to model sJIA, we studied the role of the central metabolic regulator mTORC1 (mechanistic target of rapamycin complex 1) in the development of monocytosis and arthritis.

Methods: We analyzed myeloid cell populations in the bone marrow and peripheral blood of Il1rn$^{-/-}$ mice and wild-type (WT) BALB/c controls (8-10 weeks of age). mTORC1 signaling was quantified by intracellular phospho-flow cytometry. Mice were treated with the recombinant IL1 receptor antagonist anakinra, the mTORC1 inhibitors rapamycin or vehicle control for two weeks to study the impact on monocytosis and arthritis. Monocyte count was analyzed in sJIA patients pre- and post-treatment with anakinra.

Figure 1. Anakinra treatment reversed monocytosis in IL1rn $^{-/-}$ mice

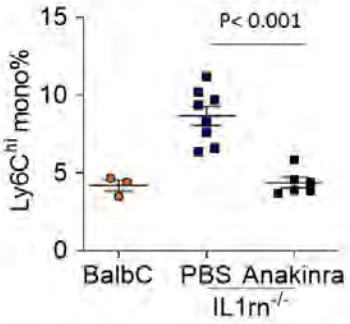

Figure 2. Anakinra treatment reversed monocytosis in sJIA patients (n = 8)

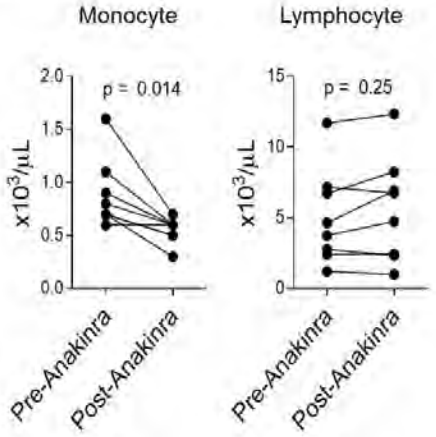

Figure 3. Rapamycin treatment ameliorates arthritis in IL1rn $^{-/-}$ mice

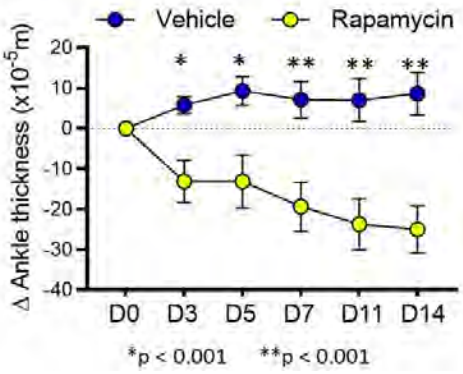

Results: IL1rn$^{-/-}$ mice spontaneously developed severe arthritis by 6–8 weeks of age accompanied by monocytosis in the peripheral blood (Figure 1). Bone marrow cells from IL1rn$^{-/-}$ mice produced a greater number of monocyte-derived macrophages in vitro with or without the addition of macrophage colony stimulating factor. Analysis of hematopoietic stem and progenitor cells by flow cytometry revealed expansion of myeloid progenitors and increased monocyte production in the bone marrow of IL1rn$^{-/-}$ mice. Transcriptomic analysis of IL1rn$^{-/-}$ myeloid progenitors by RNA-sequencing revealed enrichment of genes associated with IL-1 and mTORC1 signaling. Intracellular flow cytometry confirmed increased phosphorylation of the mTORC1 targets S6 and 4E-BP1 in monocytes from IL1rn$^{-/-}$ mice compared to WT controls. Daily treatment of IL1rn$^{-/-}$ mice with anakinra for two weeks reduced circulating monocytes and mTORC1

signaling to levels seen in WT (Figure 1). A similar reduction in monocyte count was observed in sJIA patients after anakinra treatment (Figure 2). Confirming the pathogenic role of mTORC1 activation, rapamycin treatment corrected the monocytosis and reduced the severity of arthritis in $IL1rn^{-/-}$ mice (Figure 3).

Conclusion: mTORC1 activation downstream of IL-1 signaling drives the development of monocytosis and arthritis in $IL1rn^{-/-}$ mice. Inhibition of mTORC1 may be a promising approach for the treatment of sJIA.

Dense Genotyping of Immunologic Loci Identifies *CXCR4* as a Novel Susceptibility Locus for Systemic Juvenile Idiopathic Arthritis

Emily Shuldiner[1], Elaine Remmers[2], Miranda Marion[3], Marc Sudman[4], Colleen Satorius[5], Patricia Woo[6], Sampath Prahalad[7], Carl Langefeld[8], Susan Thompson[9], Wendy Thomson[10] and **Michael Ombrello**[11], [1]NIAMS, NIH, Bethesda, [2]National Human Genome Research Institute (NHGRI), NIH, Bethesda, MD, [3]Wake Forest School of Medicine, Winston-Salem, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, [5]NHGRI, NIH, Bethesda, [6]Great Ormond Street Hospital, London, United Kingdom, [7]Emory + Children's Pediatric Institute, Atlanta, GA, [8]Wake Forest School of Medicine, Winston Salem, NC, [9]Cincinnati Children's Hospital Medical Center/Univ of Cincinnati College of Medicine, Cincinnati, OH, [10]Centre for Genetics and Genomics Versus Arthritis, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [11]Translational Genetics and Genomics Unit, NIAMS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a severe, potentially lethal inflammatory condition. It accounts for a disproportionate share of morbidity and mortality among childhood arthritidies. Despite recognition of excessive innate immune activation, specific host or environmental factors that underlie sJIA have eluded detection. Genomic investigations are an important tool for identifying new disease associated genes and pathways, and recent genomic studies of sJIA have yielded important new insights. Here, we examine sJIA with the Immunochip, a single nucleotide polymorphism (SNP) array that generates exceptionally dense genotyping at 186 immunologic loci, many of which are putatively relevant to sJIA.

Methods: Immunochip genotype data were generated in 889 sJIA cases from the International Childhood Arthritis Genetics Consortium and the Juvenile Arthritis Consortium for Immunochip and 16,144 geographically-matched control subjects. All cases fulfilled the ILAR criteria for sJIA. Genotyping/genotype calling were performed according to the manufacturer's protocols. The dataset was subjected to stringent quality control operations (QC) to exclude poor quality samples and markers. The study population was systematically restricted to subjects of northern European ancestry using principal components analysis (PCA). The full dataset was expanded with 1000 Genomes Project (1KG)-based SNP imputation. Haplotypic analysis was performed for novel risk loci and association testing of markers and haplotypes was performed by logistic regression, corrected for sex and ancestry. The effect of sJIA-associated variables on gene expression was examined in paired whole genome (WGS) and RNA sequencing data from lymphoblastoid cell lines (LCL) of 373 European 1KG subjects.

Results: SNP genotyping, imputation and QC produced a panel of 841,043 SNPs in a collection 579 sJIA cases and 12,930 healthy subjects of northern European ancestry (λGC=1.000). Association testing identified a novel, highly-significant susceptibility locus on chromosome 2 that contained *CXCR4*, encoding C-X-C chemokine receptor type 4. The strongest risk factor for sJIA in the study was a 124kb 6-SNP haplotype (case frequency 0.21, control frequency 0.13, p=4.3E-10, OR=1.7 [1.5, 1.9]). Analysis of paired WGS and RNAseq data identified positive correlation between the sJIA risk haplotype and *CXCR4* expression in LCLs (p=4.0E-4). Examination of the risk haplotype in public databases revealed that it 1) intersects with a lymphocyte super-enhancer that regulates *CXCR4*; and 2) engages in 3 distinct chromatin loops with the promoter of *CXCR4* in LCLs.

Conclusion: This study has identified *CXCR4* as a novel risk locus in sJIA. CXCR4 is an immunologically important molecule that is involved immune cell development and migration, particularly that of B lymphocytes. The correlation of the sJIA risk haplotype with increased *CXCR4* expression in LCLs, its intersection with a lymphocyte-specific super-enhancer and its formation of chromatin loops with the *CXCR4* promoter in LCLs may indicate that this haplotype influences sJIA risk through B lymphocytes. Further studies are necessary to systematically evaluate this hypothesis.

Abstract Number: 0175

Identifying Immuno-phenotypes in Juvenile Localized Scleroderma with RNA Sequencing

Christina Schutt[1], Emily Mirizio[2], Kaila Schollaert-Fitch[2], Claudia Salgado[3], Miguel Reyes-Mugica[3] and Kathryn Torok[2], [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh Medical Center, Pittsburgh

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile localized scleroderma (jLS) is an autoimmune disease of the skin and underlying tissue characterized by an early inflammatory infiltrate followed by fibrosis and collagen deposition leading to atrophy. Uncontrolled jLS results in significant disFigurement and functional disability. Our goal was to determine the transcriptome within inflammatory and fibrotic LS tissue vs. healthy controls and identify potential molecular targets using RNA sequencing (RNAseq). Differentially expressed genes (DEGs) identified in jLS patients were compared to histopathological features to determine correlation and were used to cluster LS patients according to common expression pathways.

Methods: RNAseq was performed on paraffin-embedded skin (n=28 jLS, n=10 pediatric healthy) using the Illumina HTS and TrueSeq Access library preparation. Paired-end RNAseq data was aligned using STAR, corrected for batch effect and analyzed for DEGs using DESeq2. Genes were analyzed using DEG cutoffs of log fold change > ±2.0, adjusted p< 0.05, and a false discovery rate (FDR) cutoff of < 0.05 for Reactome and enrichment software (GSEA©). Standardized scoring was developed for inflammation and collagen deposition and was completed between 2 blinded pathologists. Spearman's correlation was used to determine significance between DEGs and histology scoring.

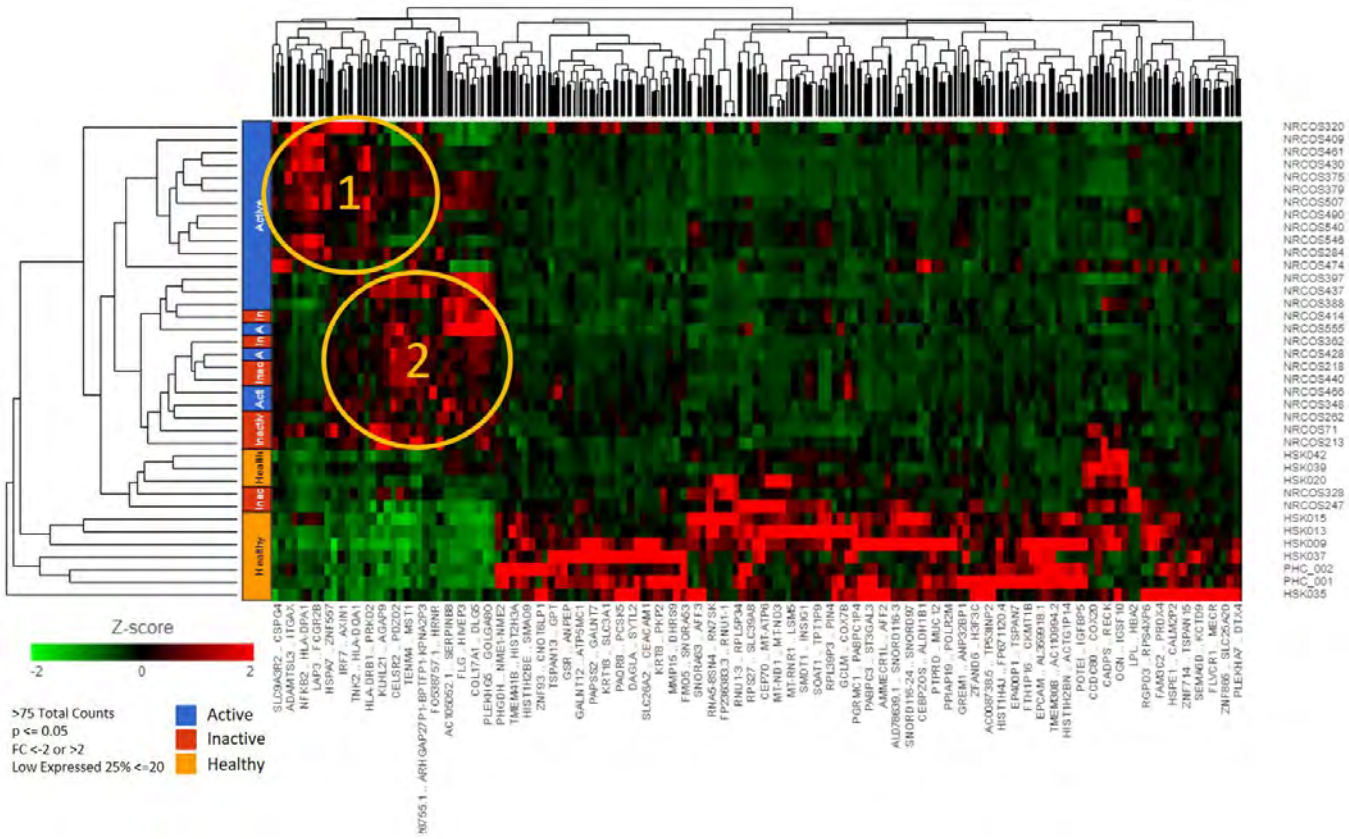

Figure 1. Hierarchical Clustering using complete linkage of Euclidean Distance

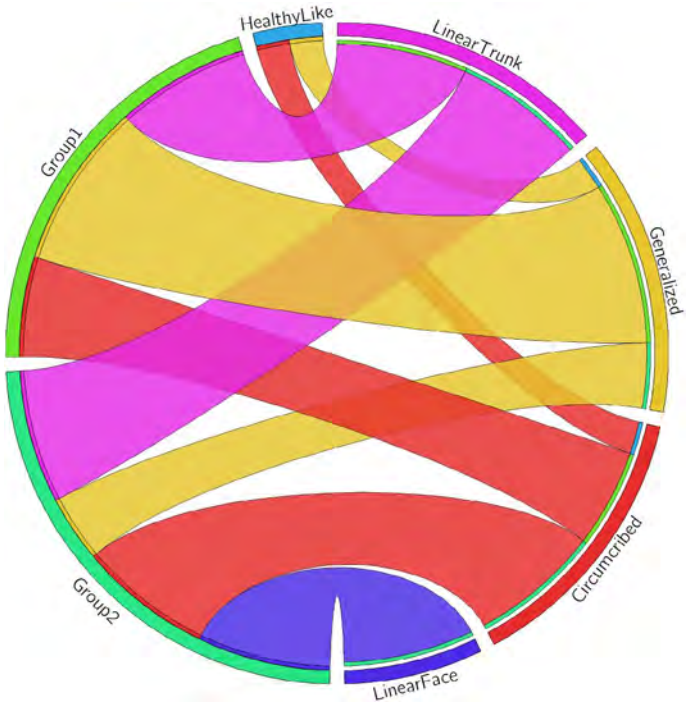

Figure 2. Circos plot comparing clinical LS subtype to immune-phenotype clustering.

Results: We found 589 significant DEGs between jLS vs. pediatric healthy controls with the above cutoffs. Hierarchical clustering using complete linkage of Euclidean distance demonstrated three distinct jLS groupings; Group 1, Group 2 and Healthy-Like (Figure 1). In Group 1, 61 DEGs were identified which associate with interferon gamma signaling, MHC class II antigen presentation, and TCR signaling ($p< 0.01$). Specifically, five are HLA class II genes, HLA-DQA1, HLA-DQB1, HLA-DRB5, HLA-DPA1, and HLA-DRB1 ($p< 0.01$, FC >2, FDR< 0.05). Degree of inflammatory cell infiltrates significantly correlated with HLA-DPB1, HLA-DQA2, HLA-DRA, and STAT1 ($rs > 0.5$, $p< 0.01$). Collagen thickness in upper reticular dermis had a positive correlation with HLA-DQA1 ($rs=0.46$, $p=0.03$). In Group 2, 76 DEGs were identified, which associate with pathways of FGFR1 amplification, collagen formation and keratinization ($p< 0.05$).

Conclusion: The identified groupings of jLS patients showed two distinct genetic signatures, one with upregulated inflammatory-related pathways, which corresponded to inflammatory infiltrate score, and a second group with upregulated fibrosis-related pathways. HLA Class II gene upregulation was observed within the inflammatory group, which has also been described for systemic sclerosis. Interestingly also the immune-phenotype groups did not directly correspond with the patients clinical phenotype. Further investigation into the relationship and functions of these genes in jLS tissue is underway.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The NF-kB essential modulator (NEMO) is a scaffolding protein with a broad immune cell and tissue expression profile. Hypomorphic mutations in *IKBKG* encoding NEMO typically present with immune deficiency. However, we previously showed that the absence of the NEMO C-terminus zinc finger domain (NEMO-ΔCT), encoded by exon 10, leads to impaired negative regulation of the canonical IKK kinase and additional inflammatory

disease phenotypes. Other functional NEMO domains are likely important for the regulation of NF-κB activation and type I IFN induction.

Methods: Patients and healthy controls enrolled in an IRB-approved natural history protocol provided blood and skin samples that were used for genetic and functional analyses. These studies included WGS/WES, minigene cDNA analysis, primary cell line gene reconstitution and knockdown experiments, signal transduction by microscopy, Western blot (WB), and intracellular flow cytometry, transcriptome, cytokine release, co-immunoprecipitation and WB, and in vitro viral infection models.

Results: Here we describe the diagnosis, disease features and molecular mechanism underlying enhanced NF-κB and Interferon induction due to expression of the alternative NEMO isoform lacking the domain encoded by exon 5 (NEMO-Δex5). We demonstrate that the NEMO Deleted exon 5 Autoinflammatory Syndrome (NDAS) is distinct from the immunodeficiency syndrome resulting from loss-of-function *IKBKG* mutations clinically. Dermal fibroblasts from NDAS patients uniquely activate NF-κB in response to TNF, but not TLR3 or RLR stimulation, and type I IFN and antiviral responses are blunted in vitro. By contrast, T cells, monocytes and macrophages expressing NEMO-Δex5 express a strong Type I Interferon and NF-κB transcriptional signature that correlates highly with alternative isoform expression. We utilized these cell specific differences to dissect the roles of TNF and the atypical IKK kinases, TBK1 and IKKε, in altered NEMO-Δex5 signaling and antiviral cell function. NEMO-Δex5 expression in both immune cells and TNF-stimulated dermal fibroblasts specifically protected IKKε from stimulation-induced protein destabilization, promoting type I IFN induction and enhanced antiviral responses in vitro.

Conclusion: NEMO-NDAS represents a distinct disease phenotype with unique cellular gene expression and functional profiles. Ongoing work is directed at understanding the regulation and function of NEMO-Δex5 in host defense and in both monogenic and complex genetic rheumatic diseases.

Association of Hydroxychloroquine Use with Development of Non-Alcoholic Fatty Liver Disease in Rheumatoid Arthritis

Nicholas Wiemer[1], Rebecca Schorr[2], Mary Chester Wasko[3] and Tarun Sharma[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]Highmark, Pittsburgh, PA, [3]Allegheny Health Network, West Penn Hospital, Pittsburgh, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-alcoholic fatty liver disease (NAFLD), the most common form of liver disease, refers to a spectrum of conditions which includes non-alcoholic fatty liver (NAFL), non-alcoholic steatohepatitis (NASH), and fibrosis. Progression of NAFL to cirrhosis via inflammatory pathways has been associated with low levels of adiponectin. Hydroxychloroquine (HCQ) is concentrated in the liver, has been shown do increase adiponectin levels,

Table 1: Risk of NAFLD According to HCQ Use

Variable	HCQ Users (n=1285)	Non-HCQ Users (n=4332)	P-value
Age, yrs (± SD)	67 (±12)	69.35 (±12.4)	0.297
Female sex, n (%)	1044 (81.2%)	3234 (74.5%)	0.925
Caucasian, n (%)	1147 (89.3%)	3775 (87.1%)	0.572
Mean BMI, kg/m^2	29 (±7.5)	30.2 (±6.9)	0.282
Alcohol use (%)	496 (38.6%)	1600 (36.9%)	0.438
Duration of RA, mean, yrs (n=95)	6.37(±7.2)	5.02(±5.8)	0.397
Hypertension (n=95) (%)	12/20 (60%)	25/75 (33.33%)	0.0221
Dyslipidemia (n=95) (%)	12/20 (60%)	33/75 (44%)	0.162
Diabetes (n=95) (%)	6/20 (30%)	17/75 (22.67%%)	0.684
Metabolic Syndrome (n=95)	8/20 (40%)	20/75 (26.67%)	0.421
HCQ dose, mean, mg (n =20)	350 (±85.49)	n/a	--
HCQ duration, mean, yrs (n=20)	2.32 (±3.09)	n/a	--
Statin use (n=95) (%)	7/20 (35%)	7/75 (9.33%)	0.0032
MTX use (n=95) (%)	9/20 (45%)	16/75 (21.33%)	0.0743
MTX dose, mean, mg (n=95)	18.61 (±4.17)	15.78 (±4.58)	0.0579
MTX duration, mean, years (n=95)	2.33 (±1.51)	4 (±3.54)	0.657
Transaminitis (n=95) (%)	7/20 (35%)	24/75 (32%)	0.914
Incident NAFLD (%)	5/1285 (0.39%)	19/4332 (0.43%)	0.773
Unadjusted Odds Ratio	0.89 (95% CI: [0.33, 2.38], p=0.81)		
Age, Sex, and Race Adjusted OR	0.76 [0.22, 2.6], p=0.24		

NAFLD=non-alcoholic fatty liver disease, HCQ=hydroxychloroquine, BMI=body mass index, MTX=methotrexate, CI=confidence interval

Table 1. Risk of NAFLD According to HCQ Use

and, per one animal study, shown to improve hepatic steatosis. The role of HCQ in the prevention of NAFLD has not been explored.

Methods: A retrospective review of adult patients with RA (ICD 10 M05 and M06) seen at a tertiary academic rheumatology practice from 12/1/2014 to 5/30/2017 was constructed. Electronic health records (EHR) of patients with any history of liver disease were manually reviewed to confirm eligibility. The primary outcome was incident NAFLD during the observation period. RA diagnoses were confirmed using a previously validated algorithm with greater than 90% accuracy. The diagnosis of NAFLD, according to the American Association for the Study of Liver Disease (AASLD) criteria, was validated by reviewing right upper quadrant ultrasound, abdominal CT imaging, and/or liver biopsy results. History of prior NAFLD, alcohol abuse, alcoholic cirrhosis, infectious hepatitis, hemochromatosis, Wilson disease, alpha-1 antitrypsin deficiency, acetaminophen toxicity were exclusion criteria. Multivariate regression analysis was performed to determine the association between HCQ use and the development of incident NAFLD, after adjusting

for relevant confounders, including demographics (age, sex, body mass index (BMI)), medications (dose and duration of HCQ use, concomitant MTX, and statin use), comorbidities (diabetes, metabolic syndrome, dyslipidemia, hypertension, alcohol use), and laboratory values (AST, ALT).

Results: Our study included 5617 patients with RA, including 1285 HCQ users. 95 patients were found to have history of liver disease in our database (20 in HCQ users and 75 in non-users) and underwent EHR review to screen for incident NAFLD. During the observation period, 5 incident NAFLD events were found in the HCQ users (0.39%) and 19 in the non-users (0.43%). The unadjusted odds ratio (OR) for incident NAFLD was calculated at 0.89 (95% CI 0.33-2.38, p=0.81). When adjusted for age, sex, and race, the OR for incident NAFLD is 0.76 [0.22, 2.6], p= 0.24. Metabolic syndrome, diabetes, hypertension, and MTX use were more prevalent in the HCQ user group. Hypertension and statin use were significantly different between the HCQ group and non- HCQ group.

Conclusion: In this exploratory study, HCQ use was associated with a 24% decrease in incident NAFLD. The higher prevalence of metabolic syndrome and related risk factors in our HCQ user group is unexpected, given the favorable relationship that others and we have described previously. This is the first study to examine the association of HCQ with NAFLD. Given the observational design and small number of events, our findings warrant confirmation in larger studies.Table 1: Risk of NAFLD According to HCQ Use

Abstract Number: 0178

Associations of Multimorbidity with DMARD Initiation and Achieving Target Disease Activity Thresholds in Active Rheumatoid Arthritis: A Cohort Study Using the Rheumatology Informatics System for Effectiveness (RISE) Registry

Bryant England[1], Huifeng Yun[2], Lang Chen[3], Kaleb Michaud[1], Ted Mikuls[1] and Jeffrey R Curtis[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Although a treat-to-target strategy is endorsed in rheumatoid arthritis (RA) treatment guidelines, its routine implementation in real-world settings, particularly in the context of multimorbidity, is not well understood. In this study, we examined whether multimorbidity is associated with DMARD initiation and the achievement of target disease activity thresholds in patients with RA using the largest Electronic Health Record-enabled rheumatology registry in the U.S.

Methods: We conducted a retrospective cohort study within the Rheumatology Informatics System for Effectiveness (RISE) registry. We selected patients >18 years of age, with ≥2 encounters for RA based on ICD-10 codes, and who had 2 consecutive visits in moderate or high disease activity (by Clinical Disease Activity Index [CDAI] or Routine Assessment of Patient Index Data 3 [RAPID3]) without treatment changes between visits. For inclusion in analyses assessing treatment response, we additionally required initiation of a new DMARD at or immediately following the

2nd visit and ≥1 additional visit in the following 365 days. Demographics, seropositivity, disease activity, and medications were obtained from the RISE registry. Multimorbidity was measured using RxRisk, a medication-based index of chronic disease, and modeled both as a continuous variable and categorized into quartiles based on the number of RxRisk categories using all available prior medication data. We used multivariable logistic regression models to assess the independent associations of multimorbidity with 1) the odds of initiating a new DMARD in active RA; and

Models adjusted for age, sex, race, U.S. region, insurance status, seropositivity, number of visits, baseline oral steroid use, # prior cDMARDs, #prior bDMARDs, # prior tsDMARDs, baseline disease activity category, treatment being initiated (cDMARD, TNFi, non-TNFi bDMARD, and tsDMARD). Continuous and categorical multimorbidity variables tested in separate models.		

Table 3. Associations of Multimorbidity with Achieving Treatment Target Following New Treatment Initiation in Active RA

2) among those initiating a new DMARD, the odds of achieving low disease activity or remission. Separate models were constructed for CDAI and RAPID3 cohorts.

Results: We identified 15,626 (RAPID3) and 5,733 (CDAI) patients with active RA, of which 1,558 (RAPID3) and 834 (CDAI) initiated a new DMARD and had ≥1 follow-up visit within 365 days. Patients were middle aged, female and Caucasian predominant, and frequently received medications from ≥5 RxRisk categories (**Table 1**). Multimorbidity was not independently associated with the odds of initiating a new DMARD in the setting of active RA in either the RAPID3 or CDAI cohorts (**Table 2)**. However, among RA patients with active disease initiating a new DMARD, greater multimorbidity burden was associated with a lower likelihood of achieving low disease activity or remission (**Table 3**). Patients with the highest burden of multimorbidity (≥12 RxRisk categories) had approximately half the odds of achieving target RA disease activity (OR=0.48 RAPID3; OR=0.55 CDAI) compared to those with ≤5 RxRisk categories.

Conclusion: After initiating a new therapy for active RA, patients with greater multimorbidity were less likely to achieve target RA disease activity. These findings from a large, real-world registry illustrate the potential impact of multimorbidity on treatment response and indicate that broader management efforts targeted at multimorbidity may be needed to optimize RA disease control in these patients. Comparative effectiveness studies in multimorbid RA patients are needed since the risks and benefits of therapies may differ in this population.

Table 2. Multimorbidity patterns identified through factor analysis within the Veterans Health Administration

the overall burden of multimorbidity afflicting patients with RA is not well understood. We aimed to identify patterns of multimorbidity in RA using unsupervised machine learning.

Methods: We constructed RA and age-, sex-, and year-matched (1:1) non-RA cohorts within a large commercial insurance database (MarketScan, 2006-2015) and the Veterans Health Administration (VHA, 2001-2015) using validated administrative algorithms for RA. Chronic conditions (n=44, selected based on relevance to multimorbidity in the general population and RA) were identified using diagnosis codes from outpatient and inpatient encounters. Unsupervised machine learning was conducted separately in both databases and stratified by RA status and sex, to identify patterns of multimorbidity. Tetrachoric correlation coefficients were calculated between pairs of chronic conditions. Factor analysis was performed on this correlation matrix using the principal factor method. Factors with Eigenvalues $^{3}1$ were retained and an orthogonal rotation was executed on the extracted factors. Conditions with a factor loading >0.3 were considered relevant to the extracted factor, and patients were considered to have the multi-

Metabolic	24,629 (45.9)	19,544 (36.5)	1.48 (1.44, 1.52)
Patterns are those derived in RA patients; patterns considered present if patients had at least 2 conditions with loading values >0.3. *Conditional odds ratio for multimorbidity pattern among RA vs non-RA, matched on age, sex, and calendar year			

Table 3. Prevalence of multimorbidity patterns in RA and non-RA patients

morbidity pattern specified by that factor if they had at least 2 conditions with factor loadings >0.3 for that factor. The prevalence of the derived multimorbidity patterns was compared between RA and non-RA patients using conditional logistic regression.

Results: We studied 226,850 patients in MarketScan (76% female, mean age 53 [female] and 58 [male] years) and 120,780 patients in the VHA (89% male, mean age 53 [female] and 64 [male] years). In both MarketScan (**Table 1**) and the VHA (**Table 2**), cardiovascular, metabolic, cardiopulmonary, mental health, and pain disorders were the primary patterns of multimorbidity identified in RA and non-RA populations. Similar multimorbidity patterns were also derived separately in men and women. The frequency of each multimorbidity pattern was significantly higher in RA (odds ratios ranging from 1.17 to 2.96), with cardiopulmonary, mental health, and pain disorder related multimorbidity patterns most closely associated with RA (**Table 3**).

Conclusion: Using two independent, large, real-world datasets and unsupervised machine learning, we identified cardiometabolic, cardiopulmonary, and mental health/pain disorders as the predominant patterns of multimorbidity in RA. Patterns of multimorbidity are similar between RA and non-RA populations, suggesting the interrelationships of chronic conditions is similar in RA as in the general population. However, because the prevalence of these overlapping disease processes is significantly higher in RA, it is imperative for clinicians to recognize and address these patterns of multimorbidity to achieve optimal long-term outcomes for patients with RA.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Lymphoproliferative disorders (LPDs) in patients with rheumatoid arthritis (RA) are one of potentially life-threatening complications. However, the diagnosis of LPDs is complicated by the diversity in clinical, laboratory, and pathological manifestations. As the data on LPDs in RA patients are limited to small-scale studies, we aimed to clarify their clinicopathological characteristics in a large multicenter study.

Methods: We retrospectively reviewed the clinical, laboratory, and pathological data of adult patients with RA who were newly diagnosed as having LPDs between January 2000 and March 2017 in eight tertiary hospitals in Japan. In addition to patients with biopsy-proven LPDs, we included patients clinically diagnosed as having LPD (clinical LPD) without biopsy because of prompt regression of clinical manifestations after withdrawal of immunosuppressive therapy.

Results: Of the 232 patients with LPDs, the median age was 67 years (IQR 60–73 years), and 77.1% were female. At the time of LPD diagnosis, 94.4% of the patients received methotrexate. The development of LPDs was observed from early to long-standing RA, irrespective of disease duration (Table 1). Approximately 60% of patients were in remission or low disease activity status based on the DAS28-CRP with three variables. B symptoms, lymphadenopathy, and extranodal involvement were present in 30.6%, 77.3%, and 50.7% of the patients, respectively (Table 2). Of the 230 patients with available data, 55 (23.9%), 54 (23.5%), 47 (20.4%), and 74 (32.2%) were in the Ann Arbor stages I, II, III, and IV, respectively. Of the 116 patients with extranodal involvement, the most frequently involved sites were the lungs (36 [30.2%]), oropharyngeal mucosa (19 [16.4%]), bone marrow (14 [12.1%]), skin (13 [11.2%]), and gastrointestinal tract (12 [10.3%]). Lymphocytopenia (≤1,000/mm^3) was present in 44.7% of the patients, elevated lactate dehydrogenase (≥230 U/L) in 53.4%, elevated C-reactive protein (≥0.30 mg/dL) in 75.2%, and elevated soluble interleukin-2 receptor (≥500 U/mL) in 82.9%. Biopsy was performed in 195 patients (84.1%). The most common LPD pathological subtype was diffuse large B-cell lymphoma (79 [40.5%]), followed by classic Hodgkin lymphoma (21 [10.8%]), Epstein-Barr virus-positive mucocutaneous ulcer (EBVMCU) (15 [7.7%]), reactive lymphoid hyperplasia (12 [6.2%]), unclassifiable B-cell lymphoma (11 [5.6%]), and follicular lymphoma (10 [5.1%]). The clinical and laboratory characteristics were diverse across the pathological subtypes (Table 3).

Pathological characteristics										
EBER positivity — no./total no. (%)	74/136 (54)	19/50 (38)	12/17 (71)	15/15 (100)	6/10 (60)	8/10 (80)	1/4 (25)	1/5 (20)	5/5 (100)	NA

Unclassifiable B-cell lymphoma, lymphomatoid granulomatosis, composite lymphoma, polymorphic LPD, extranodal natural killer/T-cell lymphoma, lymphoplasmacytic lymphoma, and other LPDs are excluded from this table because of the small number of patients.

*MZL includes seven patients with extranodal MZL of mucosa-associated lymphoid tissue (MALT lymphoma) and two patients of nodal MZL.

Abbreviation: CHL, classic Hodgkin lymphoma; DLBCL, diffuse large B-cell lymphoma; EBER, Epstein-Barr Virus-encoded small RNA; EBVMCU, Epstein-Barr virus -positive mucocutaneous ulcer; FL, follicular lymphoma; HLL, Hodgkin-like lesion; LPD, lymphoproliferative disorder; MZL, marginal zone lymphoma; NA, not applicable; PTCL, peripheral T-cell lymphoma; RLH, reactive lymphoid hyperplasia.

Clinical characteristics, laboratory findings, and EBV-encoded small RNA (EBER) positivity in each pathological subtype of LPDs in patients with RA

Conclusion: LPDs occurred mainly in patients aged 50 years or older who were receiving methotrexate. Although the clinical manifestations of LPDs vary depending on the pathological subtypes, lymphadenopathy, extranodal mass, and mucocutaneous ulcer should be recognized as possible early signs of LPDs in combination with laboratory abnormalities in patients with RA.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: We aimed to determine whether methotrexate (MTX) treatment in patients with rheumatoid arthritis (RA) leads to the development of nonalcoholic fatty liver (NAFL).

Methods: Data were derived from records of all patients with RA who underwent abdominal ultrasonography at Jeonbuk National University Hospital. Patients with ultrasound-proven NAFL were identified, and those without NAFL were matched by age and sex using the propensity score matching method at 1:3 ratio. We also analyzed the Health Insurance Review and Assessment Service-National Patient Samples, a nationwide cohort database, to determine the association between MTX use and NAFL in a large number of patients (n = 24,653).

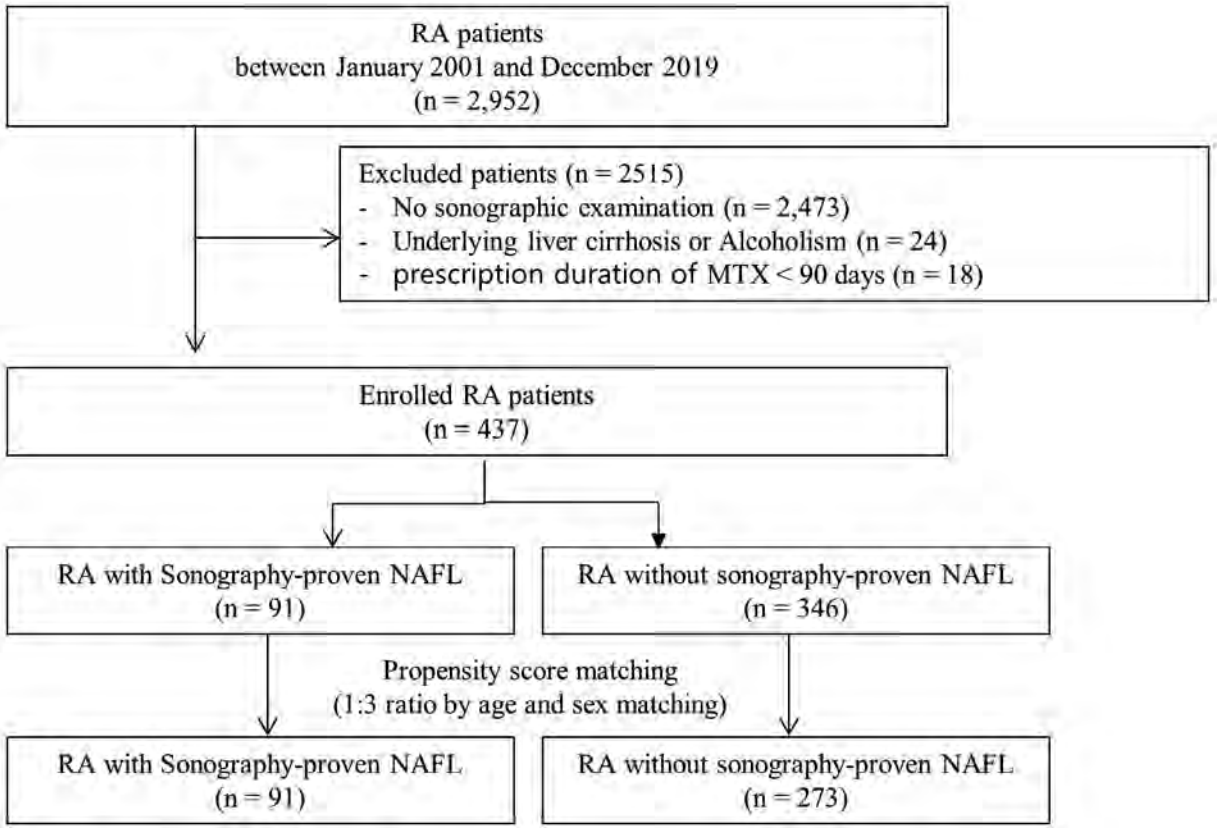

Figure 1. Flow chart of the study design MTX, Methotrexate; NAFL, Non-alcoholic fatty liver; RA, Rheumatoid arthritis

MTX	1.33	0.64-2.74	0.443			
Tacrolimus	3.39	0.56-20.66	0.185			
Leflunomide	1.07	0.61-1.87	0.807			
Sulfasalazine	1.71	0.70-4.17	0.237			
Hydroxychloroquine	1.07	0.71-1.61	0.744			
Prednisone equivalent	1.79	1.06-3.02	0.029	1.16	0.86-1.57	0.310

Table 1. Risk factors influencing the development of NAFL among RA patients (n=368) BMI, Body mass index; HbA1c, hemoglobin A1c; HDL, High-density lipoprotein cholesterol; LDL, Low-density lipoprotein cholesterol; MTX, Methotrexate; NAFL, Nonalcoholic fatty liver 95% C.I., 95% Confidence Interval

Results: In the hospital cohort, 92 patients with NAFL did not show significant differences in the cumulative MTX dose when compared with the no-NAFL group (n = 276) (1,908.5 ± 1,757.5 vs. 1,948.6 ± 2,118.8 mg, $p = 0.911$). The prevalence of NAFL was not significantly different across strata of cumulative MTX dose. Multiple logistic analyses identified hypertriglyceridemia (OR, 4.88 [95% CI, 1.13–20.93]) and higher body mass index (OR, 1.22 [95% CI, 1.05–1.41]) as being associated with an increased risk of NAFL. In the nationwide cohort, the MTX exposure rate between the NAFL and no-NAFL groups was not significantly different.

Conclusion: Collectively, no significant association between NAFL development and administration of MTX was detected in this study. Our results suggest that it is more efficient to adjust for individualized risk factors for NAFL prevention rather than discontinuation of MTX in patients with RA.

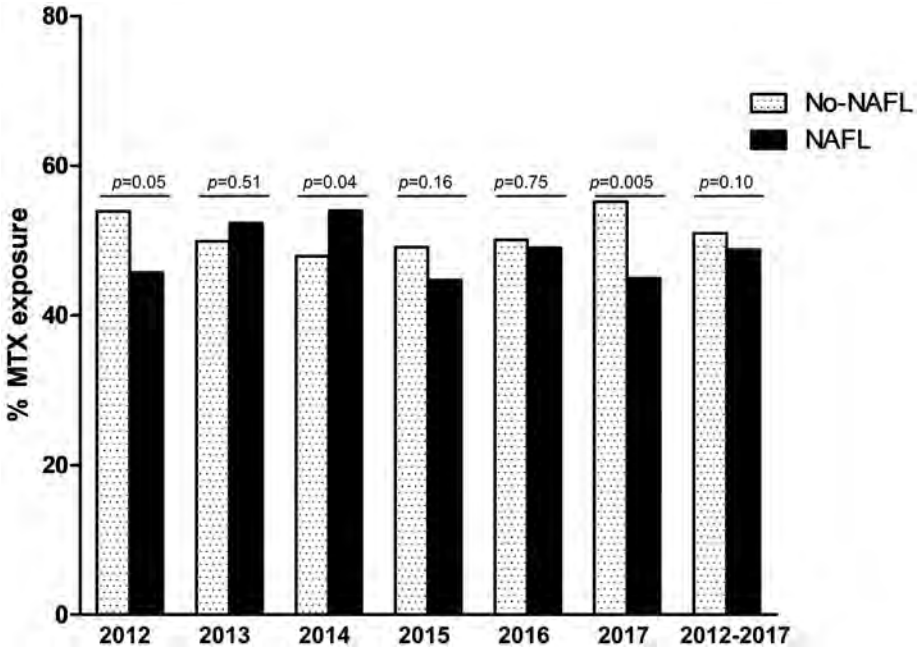

Figure 2. Prescription rate of MTX in RA patients with or without NAFL based on HIRA-NPS data Prescription rate of MTX in RA patients with or without the diagnosis code of NAFL was analyzed and compared using HIRA-NPS data for 6 years, from 2012 to 2017. HIRA-NPS, Health Insurance Review and Assessment Service-National Patient Samples; MTX, Methotrexate; NAFL, Non-alcoholic fatty liver; RA, Rheumatoid arthritis

Table 1. Patients' characteristics with different rheumatic diseases (GFR: Glomerular filtration rate; FFbH: Funktionsfragebogen Hannover, range 0-100 (100 normal function), equivalent to Health assessment questionnaire (HAQ-DI) range 3-0)

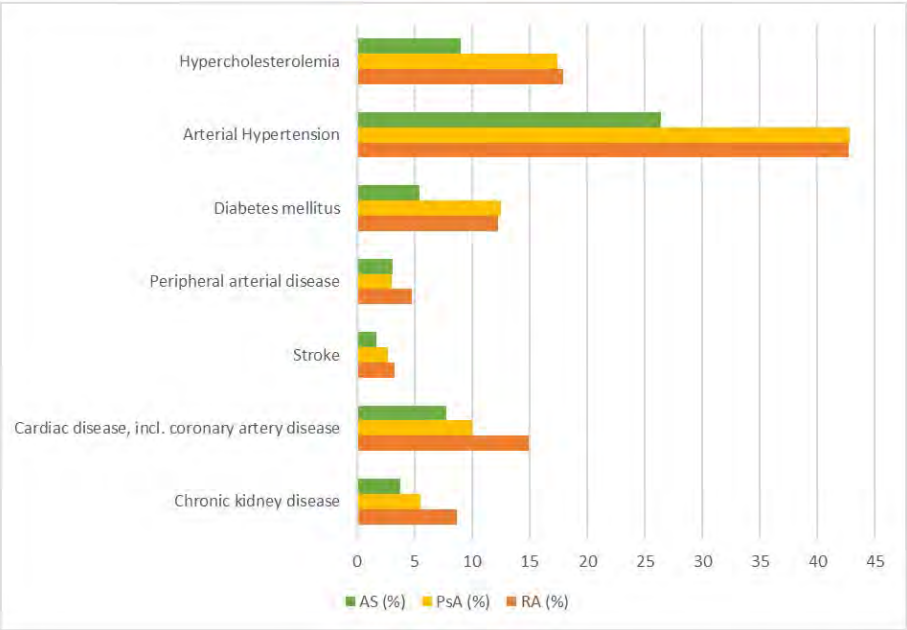

Figure 1. Cardiovascular and renal comorbidities in patients with RA, PsA, and AS as documented by the treating physician.

Chronic kidney disease - G1-5 by glomerular filtration rate (GFR)	RA (n)	RA (%)	PsA (n)	Ps (%)	AS (n)	AS (%)
G 1: Normal (GFR ≥ 90)	1098	36,7	288	48,1	337	64,3
G 2: Mildly decreased (GFR 60-89)	1487	49,7	279	46,6	167	31,9
G 3a: Mildly to moderately decreased (GFR 45-59)	286	9,6	23	3,8	19	3,6
G 3b: Moderately to severely decreased (GFR 30-44)	103	3,4	6	1	1	0,2
G 3 total (GFR 30-59)	389	13	29	4,8	20	3,8
G 4: Severely decreased (GFR 15-29)	14	0,5	2	0,3	0	0
G 5: Kidney failure (GFR <15)	2	0,1	1	0,2	0	0
Total documented	2990	100	599	100	524	100

Table 2. Chronic kidney disease analysed by using the laboratory value “estimated glomerular filtration rate”.

Methods: The RHADAR framework is a network of currently 25 rheumatologists in Germany supplying pseudonymized data for aggregation into a joint database. Every patient, except the patients not consenting, is documented. The growing data input is conducted by physicians, nurses and patients using personal computers, Tablets, and apps. Laboratory values are included (semi)automatically. Comorbidities are documented using the diagnoses in the patients’ records. The database is regularly analysed, lastly after March 31st 2020, using statistical software R and RStudio. (1, 2)

Results: 4962 patients had rheumatoid arthritis (RA), 1009 psoriatic arthritis (PsA), and 1013 axial spondyloarthritis (axSpA). The minimum data set consisted out of age, sex, and symptom duration. Different disease specific scores were present in subsets of patients (Table 1).

Chronic renal disease was documented in 252 (8.7%) RA patients, 33 (5.5%) PsA patients, and 16 (3.8%) of axSpA patients. Further cardiovascular diseases and risk factors are displayed in Figure 1.

Laboratory results regarding estimated renal function (GFR) by the CKD-EPI equation (3) revealed a higher percentage of renal impairment (Table 2) in RA patients, but not in SpA or PsA patients. A grad 3 renal impairment was present in 389 (13 %) RA patients, 29 (4.8 %) PsA patients, and 20 (3.8%) of axSpA patients

Conclusion: Real world data revealed a higher percentage of chronic kidney disease by laboratory values than recognized by the treating physician in RA patients..

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with RA have an increased risk of some malignancies compared with the general population, and this can vary by region/race.[1,2] Epidemiologic data on the incidence of malignancies in Japanese pts with RA are limited. There are also limited data reporting the impact of biologic (b)DMARDs and targeted synthetic (ts)DMARDs, such as JAK inhibitors, on the incidence of malignancies in Japanese pts with RA. The National Database of Rheumatic Diseases in Japan (NinJa) is one of the largest RA registries in Japan. This study evaluated the incidence of malignancies in Japanese pts with RA using NinJa registry data.

Methods: This retrospective observational study analyzed NinJa registry data for Japanese pts with RA aged ≥ 18 years with ≥ 1 data entry between 2013 (first JAK inhibitor approval for RA in Japan) and 2018. The overall cohort included all pts with RA, and two sub-cohorts were analyzed: pts exposed and unexposed to bDMARDs (exposure defined as ≥ 1 bDMARD reported in the database). Crude incidence rates (IRs) for malignancies (including non-melanoma skin cancer) were calculated as the number of events per 100 pt-years of follow-up (time between start of follow-up and end of the observation period, or withdrawal from the database). The most recent data for incidence of

Table 1. Cross-sectional analysis of the incidence of malignancies[a] in Japanese pts with RA from 2013–2018

[a]Including non-melanoma skin cancer; [b]IR was calculated as the number of events per 100 PY of follow-up; [c]Standardized using data from a Japanese general population database of malignancy incidence from 2013–2015, provided by the Center for Cancer Control and Information Services, National Cancer Center, Japan
ASR, age- and sex-adjusted-standardized rate; bDMARD, biologic disease-modifying antirheumatic drug; CI, confidence interval; IR, incidence rate; JAK, Janus kinase; N, total number of pts evaluated; n, number of events; pts, patients; PY, pt-years; RA, rheumatoid arthritis; SIR, standardized incidence ratio

Table 2

malignancy in the Japanese general population (2013–2015 data from the National Cancer Center, Japan) were used to calculate standardized incidence ratios (SIRs) and age- and sex-adjusted standardized rates (ASRs) for malignancies. Cross-sectional (per calendar year) and cumulative analyses were performed for the overall cohort. Cumulative rates were also calculated for the sub-cohorts, and all cumulative analyses were repeated excluding pts exposed to JAK inhibitors (ie ≥ 1 JAK inhibitor reported in the database).

Results: Data were collected for 26,607 Japanese pts with RA from 2013–2018. In the cross-sectional analysis (Table 1), the SIR and ASR for malignancies in all pts with RA were generally consistent from 2013–2018. In the cumulative analysis (Table 2), the SIR (95% confidence interval [CI]) for malignancies from 2013–2018 was 1.00 (0.94, 1.06) in all pts with RA, and 0.95 (0.85, 1.07) and 1.02 (0.94, 1.09) in pts exposed and unexposed to bDMARDs, respectively. Adjusting for age and sex, the cumulative ASR (95% CI) for malignancies from 2013–2018 was 0.81 (0.74, 0.88) in all pts with RA, and 0.79 (0.67, 0.91) and 0.85 (0.75, 0.94) in pts exposed and unexposed to bDMARDs, respectively (Table 2). In all cohorts, the cumulative SIR and ASR were similar when pts exposed to JAK inhibitors were excluded (Table 2).

Conclusion: The incidence of malignancies in Japanese pts with RA, registered in the NinJa database from 2013–2018, was similar to that in the Japanese general population. The SIR and ASR for malignancies were comparable in pts exposed and unexposed to bDMARDs. In all cohorts, rates did not increase when pts exposed to JAK inhibitors were included.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of non-Hodgkin B-cell lymphoma (B-cell NHL).

The objectives of this work were:

- To study the characteristics of B-cell NHL complicating RA
- To identify the factors associated with their occurrence.
- To identify single nucleotide polymorphisms (SNP) associated with their occurrence.

Methods: A multi-centre retrolective case-control study was performed in France. Cases were patients with RA fulfilling the ACR-EULAR 2010 criteria, who developed a B-cell NHL after the diagnosis of RA. Cases were reported following a call for observations by the CRI-Imidiate network, registries from the French society of Rheumatology and the ESPOIR cohort. For each case, 2 control patients were drawn at random from patients fulfilling ACR-EULAR 2010 criteria in the ESPOIR cohort; cases and controls were matched on age (age at lymphoma diagnosis for cases and age at the 10-year ESPOIR visit for controls). Patients with associated Sjögren's syndrome were excluded. Cases and controls characteristics were compared for parameters associated with the occurrence of lymphoma. Blood or saliva samples were collected whenever possible for genotyping, looking for 24 SNP of known interest for their association with lymphomas and/or for their implications in B-cell control pathways.

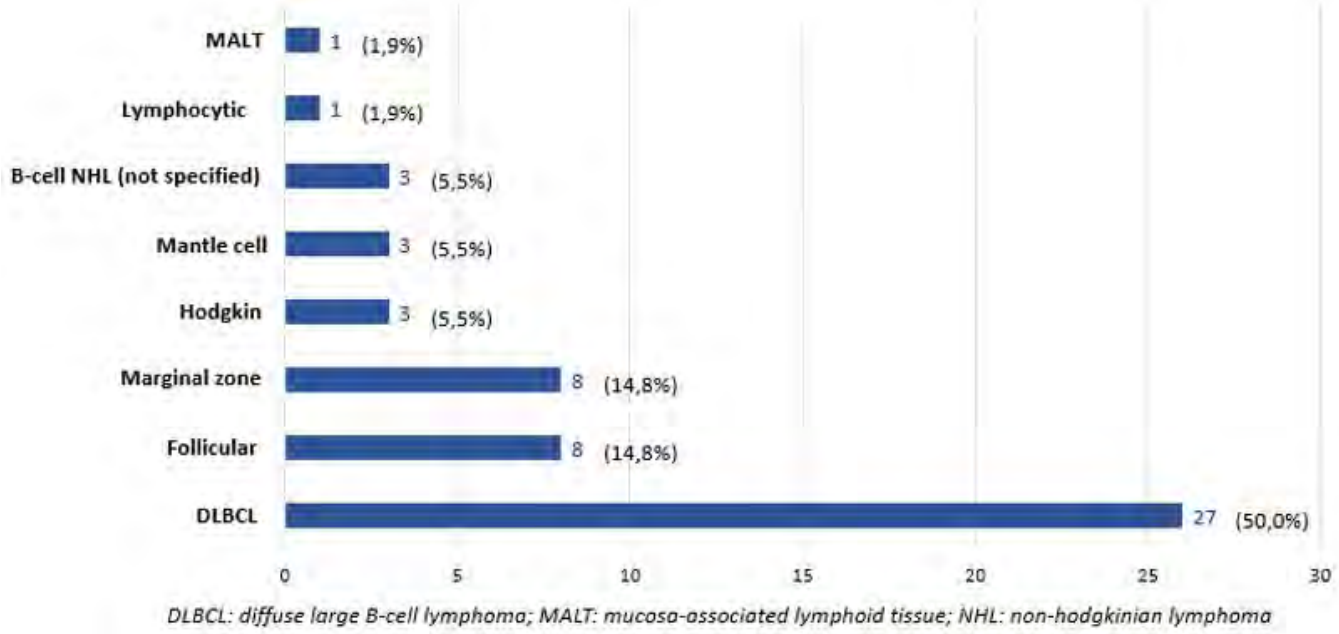

Figure 1. lymphomas histology

**B-cell NHL diagnosis for cases, 10th year visit for controls*

Table 1. association between RA characteristics and B-cell NHL in univariate and multivariate analysis

Results: A total of 54 cases were included and matched to 108 controls. Lymphomas were mostly diffuse large B-cell lymphomas (n=27, 50.0%) *(Figure 1)*. EBV positivity was found in 4 cases among 27 tested (14.8%). Cases had a mean age of 63.5 years (SD=10.9) and had a mean RA duration of 12.4 years (SD=10.5) at the time of diagnosis of

	Cases (N=54)	Controls (N=108)	OR (95% CI%)	p-value

Table 2: association between RA treatments and B-cell NHL in univariate analysis

lymphoma; there was no significant difference with controls (p=0.47 and p=0.40 respectively). The mean duration of follow-up after the diagnosis of lymphoma was 5.2 years (SD=5.8).

In univariate analysis, factors associated with occurrence of B-cell NHL were: male gender (OR=3.3, 95%CI: 1.7-6.7), positive ACPA (OR=5.1, 95%CI: 2.0-15.7), positive Rheumatoid Factor (RF) (OR=3.9, 95%CI=1.6-12.2), erosions on X-rays (OR=15.4, 95%CI: 6.9-37.7) and DAS28 (OR=2.0, 95%CI: 1.5-2.7). Erosions and DAS28 remained significant in multivariate analysis, and there was a trend for ACPA positivity *(Table 1)*. Methotrexate, TNF-blockers and the number of previous biologics were not associated with the occurrence of B-cell NHL *(Table 2)*. Previous use of hydroxychloroquine and sulfasalazine were more frequent in cases versus controls, which could be linked to a date bias; since the mean year of RA diagnosis was earlier in cases than in controls (1997±10.6 vs 2003±0.7, p< 0.0001), they were more susceptible to have received these drugs than more recent RA.

The exploratory genetic analysis suggested an association of the *BLK* rs2736340 minor allele (encoding for B-cell lymphocyte kinase BLK) with B-cell NHL (OR=1,8, 95%CI: 1.0-3,2, crude p=0.03).

Conclusion: B-cell NHL complicating RA are mostly DLBCL. This study revealed an association between markers of activity (DAS28), severity (erosions) and the risk of B-cell NHL in patients with RA, and suggested the possible

role of B-cell activation (RF, ACPA, *BLK* gene), supporting the paradigm of a continuum between autoimmunity and lymphomagenesis in RA.

Abstract Number: 0185

Prevalence of Migraine and Neuropathic Pain in Rheumatic Disease

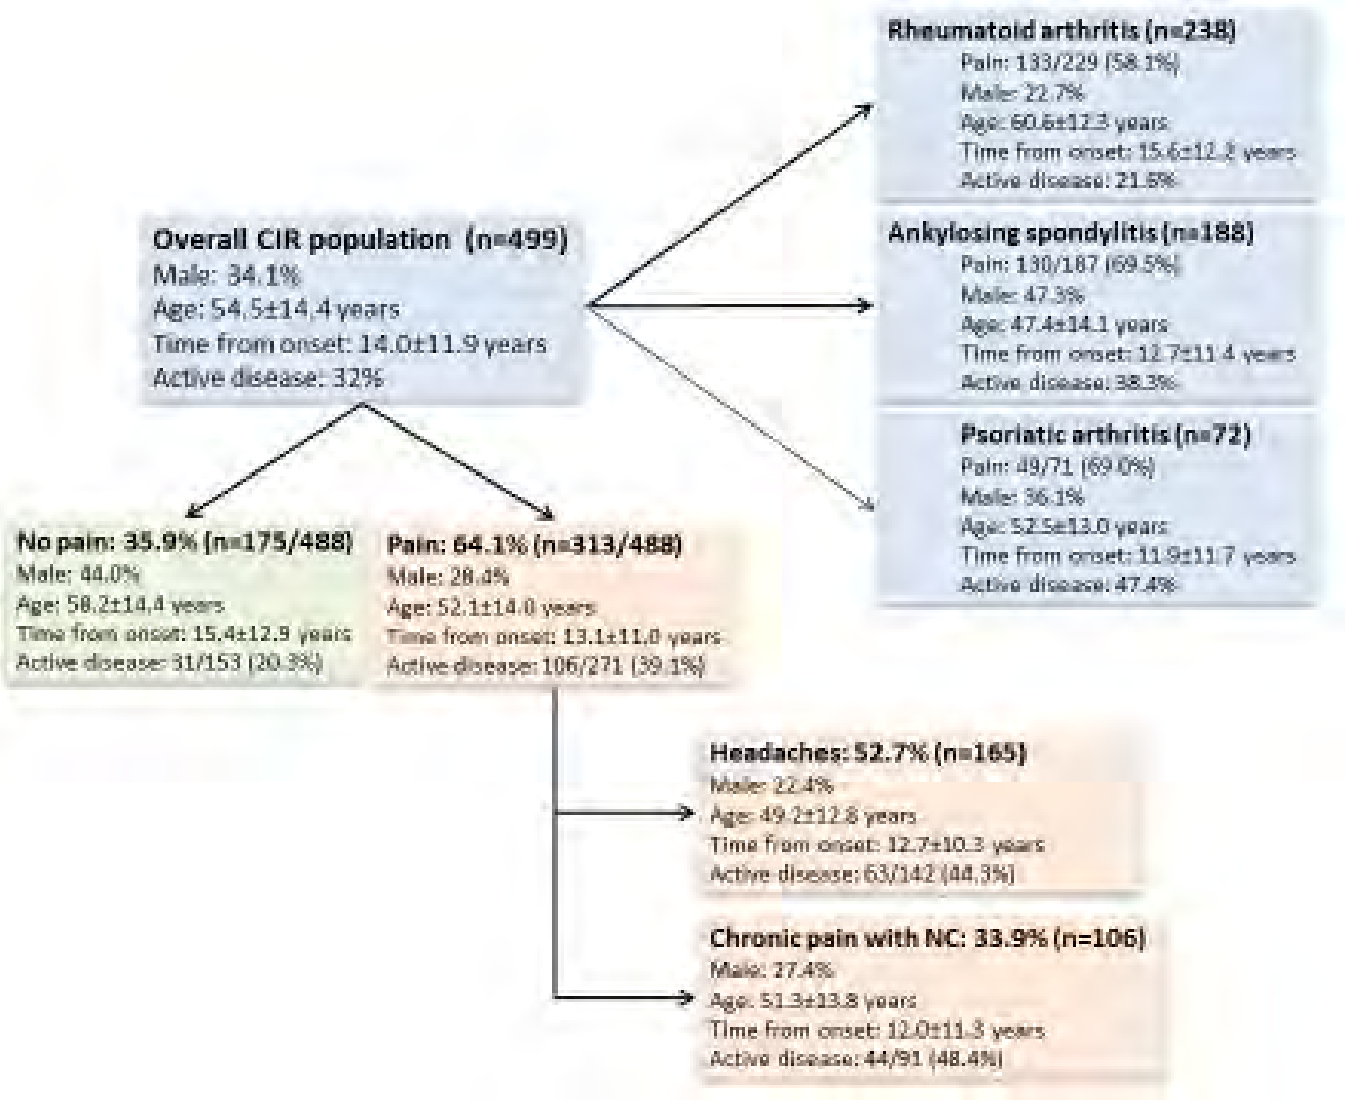
Sylvain Mathieu[1], Marion Couderc[1], Bruno Pereira[1], Jean-Jacques Dubost[1], Sandrine Malochet-Guinamand[2], Anne Tournadre[2], Martin Soubrier[1] and Xavier Moisset[2], [1]CHU Gabriel Montpied, Clermont-Ferrand, France, [2]CHU Gabriel Montpied, Clermont-Ferrand

SESSION INFORMATIONSession Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of our study was to assess the prevalence of migraine and neuropathic pain in a sample of patients with chronic inflammatory rheumatism (CIR) routinely followed in Rheumatology and to compare it with that found in the general French population.

Methods: Patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) were invited to complete a validated self-assessment questionnaire. Migraine was diagnosed according to the IHS migraine diagnostic criteria. Neuropathic pain was retained in case of a total score at 3 or more at DN4-interview questionnaire. Continuous parameters were compared between independent groups (RA/AS/PsA, with/without migraine, with/without neuropathic pain) with the ANOVA or Student *t*-test. Categorical data were compared between groups with the chi-squared test or Fisher's exact test. Binary variables of particular interest, like the presence/absence of migraine or pain, were evaluated with generalized linear models (i.e., logistic regression). Differences between our cohort and the French general population were expressed as ORs, based on the Mantel-Haenszel method.

Results: A total of 499 patients with CIR were included (238 RA, 188 AS and 72 PsA and one patient not classified). We found a prevalence of migraine of 34% (165/484). This prevalence was higher in PsA patients (32/71: 45.1%). Parameters associated with a higher prevalence of migraine were a higher level of anxiety (OR=1.14 [1.05-1.23]), female sex (OR=4.03 [2.24-7.52]), younger age (OR=0.97 [0.95-0.99]), TNF alpha inhibitors treatment (OR=1.91 [1.14-3.23])



Distribution of rheumatic diseases, migraine, and neuropathic pain among study participants.

in the entire population and a high disease activity in AS patients. Systemic inflammation was never significantly associated. Among the 165 patients with migraine, 124 (75.2%) had HIT-6 scores above 55, which indicated that headache had an important impact on these patients.

Chronic pain with neuropathic characteristics was found in 21.5% of 493 patients with CIR. The intensity of pain was moderate (5.0 ± 1.5). Prevalence was significantly higher in the AS group (26.7%) than in the PsA (19.4%) and RA (17.6%) groups (p = 0.02). Active disease (OR = 1.00, 95%CI: 1.00-1.03), and salazopyrine treatment (OR = 1.91. 95%CI: 1.08-12.9) were associated with a higher risk of neuropathic pain.

Compared to the general population, our cohort showed significantly higher rates of migraine (OR = 1.91, 95%CI: 1.57-2.32) and neuropathic pain (OR = 3.71, 95%CI: 2.97-4.62), based on the Mantel-Haenszel method. We observed significant differences in strict and probable migraine rates between the general population and our cohort, when we performed separate analyses, according to gender and age. The higher frequency of neuropathic pain in our sample compared to the general population was more dramatic among younger patients but was not different between the sexes.

Conclusion: We found a high prevalence of migraine and neuropathic pain in our sample of patients with rheumatic disease. It seems therefore important to check the presence of migraine or neuropathic pain in rheumatic disease patients with residual pain despite a clinically well-controlled rheumatic disease.

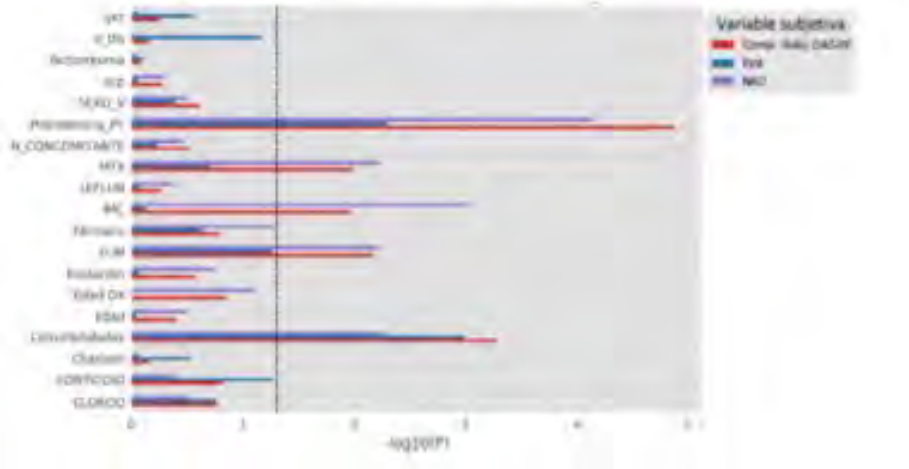
DASDBC disease activity score 28 complete, ODASDB objective component of DAS28 formula SDAS28 subjective component of DAS28, SJC swollen joint count, TJC tender joint count, ESR: erythrosedimentation rate, ptVAS: patient global health Visual analog scale, CRP, C reactive protein

scores is DAS28, which is composed of subjective and objective variables. The subjective component is derived from the patient evaluation of global health by visual analog scale (ptVAS) and the number of tender joints (TJC). Previous studies have reported the impact of comorbidities like fibromyalgia, and depression on TJC ,ptVAS, and DAS, but less is known of how non-pain related comorbidities impact DAS..

Methods: A retrospective, observational study was conducted. Patient data was abstracted from BIOBADAGUAY registry, which prospectively collects data for rheumatologic patients undergoing biologic therapy in Paraguay and Uruguay. Entries for adult patients with RA and complete data for DAS28/TJC/ptVAS scores were used. The DAS28 formula was separated into an objective component (0.28√SJC+ 0.70 ln ESR, called oDAS28) and a subjective component (0,56√TJC + 0,√014 ptVAS, called sDAS28).Descriptive analysis of DAS28, sDAS28, oDAS28 and their individual components, as well as for reported Charlson index comorbidities was done for both populations. Patients were grouped as having 0, 1 or 2+ concomitant comorbidities besides RA. Linear regression analysis was performed

Graphic 1.

Univariate Analysis of Subjective Disease Activity Components and Clinical, demographic and serological variables.



CRP: c reactive protein, treatmeat number (first line or second line) , RF: rhumatoid factor, CCP: cyclic citrulinated peptide, PY: Paraguay, tx: treatment, MTX: metotrexate, Leflu:leflunomide, BMI: body mass index; dx: diagnosis, Charlson: Charlson comorbidity index, HCQ:hidroxychloroquine

to see the impact of different clinical, demographic and serologic variables on the sDAS28 and on ptVAS and TJC independently. Multivariate analysis was used to confirm associations using variables that had reached a p< 0,01 in the univariate analysis.

Results: Significant differences in DAS28 scores were noticed. Patients from Uruguay had significantly higher mean DAS28 scores than Paraguayan patients (5.72 vs. 5.41, p 0.007 respectively), despite having no difference in mean SJC, ESR, or CRP. The difference in DAS28 scores between Uruguay and Paraguay were secondary to differences in the mean ptVAS (70 mm vs. 64 mm respectively, p 0.003) and the TJC (10.4 vs. 8.0 respectively, p 0.00001). Significant differences were also noted in the distribution of number of reported concomitant comorbidities. Paraguayan patients reported a higher number of patients with no concomitant comorbidities (58.1% for Paraguay vs. 26.7% in Uruguay) and a lower number of patients with 2 + comorbidities (8.4 % for Paraguay vs. 34.5% in Uruguay). Linear regression analysis revealed that, despite both TJC and ptVAS being associated with the number of comorbidities, the impact of ptVAS on the sDAS28 was greater. Multivariate analysis confirmed the association of ptVAS with number of comorbidities (p 0.046) , but not for TJC.

Conclusion: The number of Charlson index concomitant comorbidities in Latin-American RA patient can impact their perception of global health and therefore their final DAS28 score. Evaluation of these patients should be personalized. Decisions on therapeutic escalation should take patient characteristics into account and not based solely on DAS28 scores.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Persistent pain can occur in early RA patients, despite improvement in synovitis and may be due to coexisting non-articular pain (NAP). Though NAP is often attributed to fibromyalgia and widespread NAP, regional NAP syndromes may be more common and under-recognized. The purpose of this study is to describe patterns of NAP, predictors of persistent NAP and impact on outcomes in the first year following early RA diagnosis.

Methods: Data were from participants enrolled in the Canadian Early Arthritis Cohort (CATCH) between *2017-2019* who completed 0,6,12-month evaluations with patient-reported outcomes [PROs] and clinical data available. We used the McGill Body Pain Diagram (BPD) to classify patients as experiencing no NAP, regional (RP:1-2 regions) or widespread NAP (WP:3-5 regions). Multinomial regression was used to identify baseline predictors of persistent RP and WP at 12-months. Multi-adjusted GEE with linear and logit links were used to estimate time-varying associations of NAP patterns with outcomes updated at each time point.

Results: Study included 421 participants: 66% were female, with a mean(sd) age 56 (14); 72% were seropositive and 90% were treated with MTX ± csDMARDs as initial therapy. NAP at baseline was common (55%), with majority

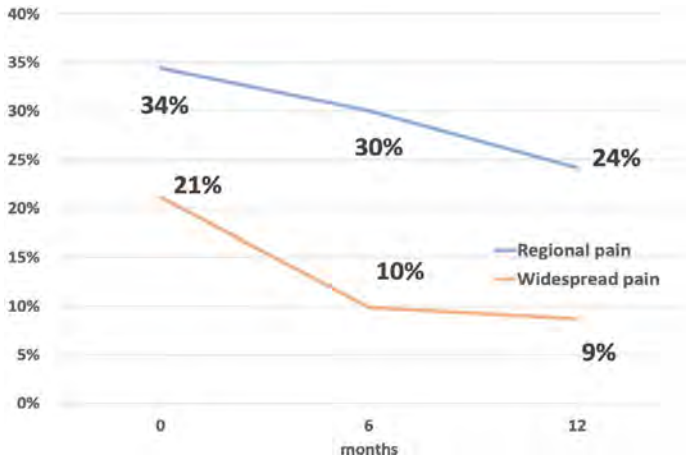

Figure. Point prevalence of regional and widespread NAP at baseline, 6 and 12 months.

Table. Results of Multi-Adjusted GEE Logistic Regression showing Regional and Widespread NAP is associated with a reduced likelihood of achieving Stringent Remission Targets

(62%) reporting regional NAP. NAP prevalence was 33% at 12 months (Figure). Female sex and baseline depressive symptoms were independent predictors of widespread NAP at 12 months while poorer function and lack of early MTX treatment independently predicted regional NAP, at 12 mos. Regional and widespread NAP were associated with lower likelihood of remission in adjusted models that accounted for changes in NAP and remission over time (Table).

Conclusion: NAP is commonly reported in early RA pts seen in real world settings. Regional NAP was more common than WSP at all time-points, but both NAP patterns were associated with lower odds of achieving remission targets by 12 months. These data support considering the role of NAP when assessing RA treatment efficacy during clinical visits and warrant different treatment approaches to reduce symptoms in RA patients receiving target-based care.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) has been associated with increased risk of osteoporosis and fractures. We have recently presented results on DXA measurements over 10 years in patients with newly diagnosed RA, where women were shown to retain their bone mineral density (BMD) fairly well compared with the reference population whereas men with early RA had reduced BMD in the femoral neck at diagnosis and after 5 years of follow-up [1]. To what extent such patterns have an impact on fracture risk in established RA is an issue of major clinical importance. The aim of this study was to survey the risk of fragility fractures in a community-based sample of patients with RA, compared with controls without RA from the same area.

Methods: A dynamic community-based cohort of patients with RA (n=1928) was investigated. Prevalent cases identified in 1997, and incident cases from 1997-2006 were included. Four controls per patient were matched for age, sex and residential area. Information on fractures in patients and controls during the period 1. July 1997 to 31. December

Table 1. Number of fractures and incidence per 1000 person years for the specific fractures and overall, in RA patients and controls

	Men		Women	
	RA patients	Controls	RA patients	Controls
Hip fracture (n)	43	93	147	465
Hip incidence/1000 PY (95% CI)	6.56 (4.75; 8.84)	3.67 (2.96; 4.50)	8.16 (6.89; 9.59)	6.24 (5.69; 6.84)
Vertebral column fractures (n)	5	12	16	50
Vertebral column incidence/1000 PY (95% CI)	0.75 (0.24; 1.74)	0.46 (0.24; 0.82)	0.85 (0.49; 1.38)	0.65 (0.48; 0.86)
Upper arm fracture (n)	5	11	46	107
Upper arm incidence/1000 PY (95% CI)	0.75 (0.24; 1.75)	0.43 (0.21; 0.77)	2.46 (1.80; 3.28)	1.40 (1.15; 1.69)
Forearm fracture (n)	4	14	27	105
Forearm incidence/1000 PY (95% CI)	0.60 (0.16; 1.53)	0.55 (0.30; 0.92)	1.43 (0.94; 2.08)	1.38 (1.13; 1.67)
Fractures in total (n)	51	119	202	604
Fractures in total incidence/1000 PY (95% CI)	7.86 (5.85; 10.33)	4.73 (3.92; 5.67)	11.6 (10.0; 13.3)	8.29 (7.64; 8.98)

RA: Rheumatoid Arthritis, n: number, PY: person years, CI: Confidence Interval.

Table 2. Risk of fractures in RA patients compared with matched controls

	Men HR (95% CI)	Women HR (95% CI)
Hip	1.68 (1.05; 2.68)	1.41 (1.14; 1.75)
Vertebral column	NA	1.55 (0.85; 2.83)
Upper arm	NA	2.11 (1.43; 3.12)
Forearm	NA	1.10 (0.69; 1.75)
Fractures in total	1.55 (1.03; 2.34)	1.52 (1.27; 1.83)

HR: Hazard Ratio, CI: Confidence Interval.
NA: Not applicable due to <10 events in men with RA

2017 was obtained by linkage to the Swedish National Patient Register and the Cause of Death Register. Fractures of the hip, upper arm, forearm and vertebra were identified based on ICD-9 and ICD-10 diagnostic codes. Patients and controls with identified fractures before study start were excluded. The incidence of fractures was estimated in RA patients and controls, stratified by sex. The relation between RA and the risk of fractures in women and men was assessed using Cox regression models.

Results: Of the patients included, 73 % were women and 73 % were rheumatoid factor positive. The mean age at inclusion in men was 61 years and in women 60 years. Mean duration of disease was 8 years in men and 9 years in women. A total of 51 (9.7%) men and 202 (14.4%) women with RA suffered from at least one of the studied fractures during the study period, compared to 119 (5.6%) male and 604 (10.8%) female controls (Table 1). Men with RA had increased risk of fragility fractures overall (hazard ratio (HR) 1.55, 95% Confidence Interval (CI) 1.03; 2.34) and of fractures in the hip (HR 1.68, 95% CI 1.05; 2.68). Women with RA also had increased risk of fragility fractures overall (HR 1.52, 95% CI 1.27; 1.83), of fractures in the hip (HR 1.41, 95% CI 1.14; 1.75) and in the upper arm (HR 2.11, 95% CI 1.43; 3.12). There was a similar trend in the vertebral column but not in the forearm (Table 2).

Conclusion: In this cohort of patients with RA, the risk of fragility fractures was increased in both men and women compared with controls without RA. For men the results are in line with previous findings of reduced femoral neck BMD in early RA. For women with RA, long term changes in BMD in established disease, or other disease related factors, may be of importance in the assessment of fracture risk.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory disease that primarily affects synovial tissues. While the exact etiology is unknown, it is hypothesized that RA is caused by a combination of environmental and genetic factors. One possible etiology of RA is *Mycobacterium avium subspecies paratuberculosis* (MAP), a bacterium found in cattle and cow's milk. MAP is known to cause Johne's disease in cattle and has implications in human autoimmune diseases such as type 1 diabetes, Crohn's disease, and recently RA.[1-2] It is unknown if RA patients who are MAP positive have different dietary habits and medication use. This study examines the relationships between MAP serostatus, RA medication use, dietary habits, and perceived levels of joint pain in patients with RA.

Methods: Patients at the UCF Health Clinic with confirmed RA diagnosis according to the ACR classification criteria had blood samples drawn to determine MAP serostatus and were surveyed regarding their dietary habits, perceived levels of joint pain, and RA medication regimen. A total of 69 patients were included in the final analysis. Fisher's exact test was used to explore relationships and p-values < 0.05 were considered statistically significant. All statistical tests were conducted in SPSS 24.0 (IBM Corp. Armonk, NY).

Results: Fisher's exact test revealed a significant association between use of adalimumab and MAP serostatus (p-value for 2-sided test 0.025, p-value for 1-sided test 0.017). There was a significant association between using at least one biologic medication and MAP serostatus (p-value for 2-sided test 0.010, p-value for 1-sided test 0.006). Compared to those that are not on adalimumab, those that are on it have 8.667 times the odds of being MAP+ (95% CI = 1.057-71.077). Compared to those that are on no biologic medications, those that are on at least one biologic medication have 4.680 times the odds of being MAP+ (95% CI = 1.482-14.774). There were no other significant associations between MAP serostatus, medication use, dietary habits, and patient-perceived joint pain. However, 50.7% of patients surveyed (34/67) reported that diet influences their level of joint pain, 25% (17/68) reported that dairy consumption increases their joint pain, and 25.8% (17/66) reported that red meat consumption increases their joint pain.

Conclusion: There is a significant association between adalimumab use and MAP serostatus and using at least one biologic medication and MAP serostatus. Additionally, dietary habits in RA patients may play a role in patient-perceived joint pain.

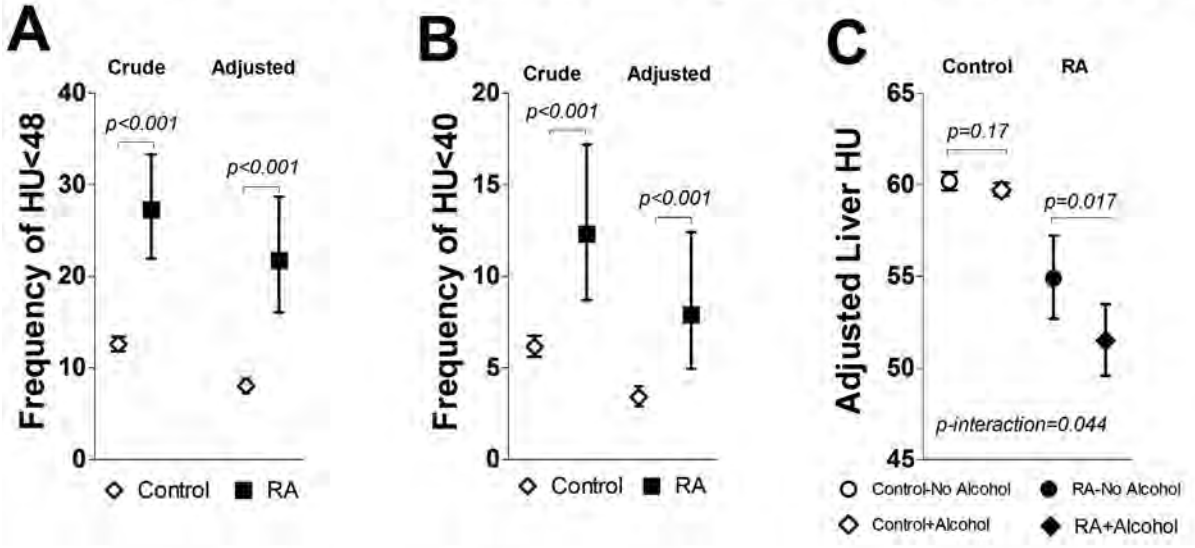
Hepatic Steatosis in Rheumatoid Arthritis: Frequency and Disease-Related Contributors

Jun Lee[1], Galina Lagos[2], Joan Bathon[1] and Jon Giles[1], [1]Division of Rheumatology, Columbia University Vagelos College of Physicians and Surgeons, New York, NY, [2]Columbia University Vagelos College of Physicians and Surgeons, New York

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Figure. Measures of Hepatic Steatosis Were More Frequent in RA vs. Control, Particularly Among Current Alcohol Users



Means±95% CIs depicted. Adjusted for age, gender, race, education, BMI, diabetes, smoking, triglycerides, CRP, and IL-6

Background/Purpose: Nonalcoholic fatty liver disease (NAFLD), a spectrum of disorders characterized by the presence of hepatic steatosis, is the most common liver disorder in western countries. Risk factors, such as obesity, hypertension, dyslipidemia, insulin resistance, and elevated inflammatory cytokines, are frequent in RA. However, few prior studies have explored the prevalence and contributors to hepatic steatosis in RA.

Methods: A total of 235 RA patients underwent abdominal computed tomography (CT), with attenuation of hepatic parenchyma (away from hepatic vasculature) measured in Hounsfield units (HU). A cohort of 6615 non-RA controls underwent similar scanning and liver HU assessment. Any steatosis was defined as HU< 48. Moderate/severe hepatic steatosis was defined as HU< 40, a standard that correlates histologically with ≥30% fatty deposition. Generalized linear models were used to compare the prevalence of steatosis between the RA and control groups, adjusted for pertinent confounders, and to assess the associations of RA characteristics and other risk factors with steatosis within the RA group.

Results: Mean hepatic attenuation was 15% lower in the RA group compared with controls (51 vs. 60 HU, respectively; p< 0.001). The prevalence of any steatosis in RA was more than double that of controls (27 vs. 13%, respectively; p< 0.001) and remained significantly higher after adjusting for relevant confounders (adjOR=3.2; p< 0.001) (Fig 1A). The prevalence of moderate/severe steatosis was double that of the controls (12 vs. 6%, respectively; p< 0.001) and also remained significantly higher after adjustment (adjOR=2.5; p< 0.01) (Fig 1B). Alcohol consumption was more strongly linked to steatosis in the RA group compared with the control group (Fig 1C). RA patients with any steatosis had significantly higher CRP levels, on average, compared with RA patients without steatosis (9.3 vs. 4.4 mg/L, respectively; p< 0.001). Rheumatoid factor was more frequent among RA patients with any steatosis (84 vs. 66%, respectively; p=0.01). However, steatosis was not associated with articular disease activity nor current use of corticosteroids, or biologic and non-biologic DMARDs, including methotrexate and leflunomide.

Conclusion: Hepatic steatosis was more frequent in RA compared with controls, even after adjusting for relevant confounders, and was linked with autoimmunity and systemic inflammation. Current use of DMARDs was not associ-

ated with hepatic steatosis. Prospective studies will help elucidate the consequences of increased hepatic steatosis in RA patients and define whether intervention is warranted.

Increased Frequency of Lower Limb Arterial Obstruction in Rheumatoid Arthritis

Ahmed Oglah[1], Ali Hussein[2], Jose Felix Restrepo[3], Carlos Lorenzo[3], Agustin Escalante[3] and Inmaculada Del Rincon[3], [1]University of Texas Health Science Center at San Antonio/ Internal Medicine Residency program, San Antonio, TX, [2]University of Texas Health Science Center at San Antonio/ Department of Internal Medicine/ Rheumatology, San Antonio, TX, [3]University of Texas Health Science Center at San Antonio/ Department of Medicine/ Rheumatology, San Antonio, TX

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite a high frequency of cardiovascular disease in rheumatoid arthritis (RA), peripheral arterial disease in RA has received little attention. The objective of the present analysis was to examine the frequency of impaired lower limb arterial function in members of an RA cohort, compared to a control group without RA.

Methods: Patients meeting diagnostic criteria for RA were recruited consecutively from private and public rheumatology practices, from 1996 through 2011. For comparison, we studied participants in the Insulin Resistance and Atherosclerosis Study (IRAS), who were recruited from four clinical centers based on blood glucose tolerance status indicating normal glucose tolerance, impaired glucose tolerance, or diabetes mellitus. The clinical centers were in Los

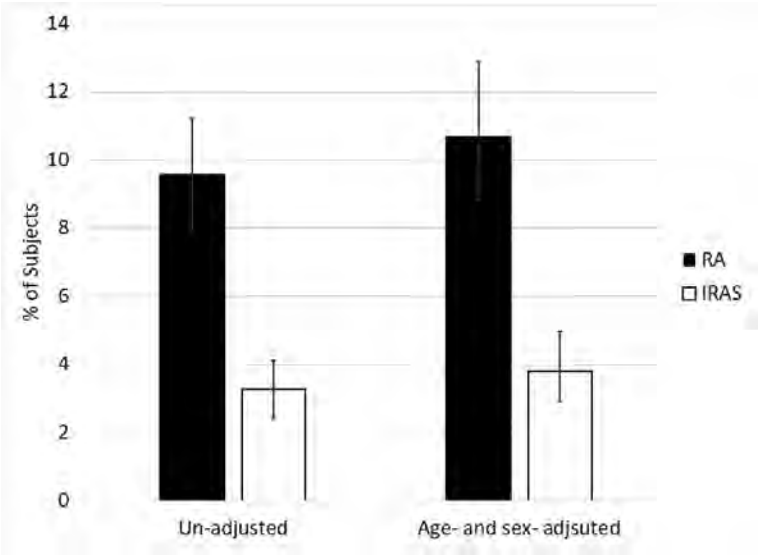

Figure. Unadjusted and adjusted frequency of obstructed ankle brachial index in rheumatoid arthritis and controls. Error bars represent 95% confidence intervals.

Angeles, Oakland, San Antonio and the San Luis valley in Colorado. The ABI was measured using a blood pressure cuff and a doppler ultrasound probe to measure the systolic blood pressure (SBP) in all four extremities. The ABI was calculated for each ankle provided as the ratio of highest SBP in the ankle to the highest SBP in the upper extremities. The ABI was considered obstructed if ≤0.9, normal if >0.9 but ≤1.3, and incompressible if >1.3. Logistic regression was used to compare the frequency of obstruction or incompressibility between RA and controls, adjusting for age, sex, smoking, diabetes mellitus and hypertension.

Results: We recruited 1328 RA patients, of whom 1182 had an ABI measurement. Their mean age was 58 (range 19-91), and 887 (75%) were women. They were compared to 1624 IRAS study participants, whose mean age was 55 (range 39-69), and 905 were women (55%). An obstructed ABI was present in 113 of the RA patients (9.56%), and in 53 of the IRAS participants (3.26%), odds ratio (OR) 3.09, CI 95% 2.18, 4.41, p< 0.0001. Adjusting for age, sex, smoking, diabetes and hypertension, the frequency of obstruction remained higher in the RA group with an OR of 3.74, CI 95% 2.5, 5.59, P < 0.0001. (Figure) An incompressible ABI was present in 183 of the RA patients (15.48%), and in 286 of the IRAS participants (17.6%), OR 0.92, CI 95% 0.75, 1.14. P 0.47. Multivariable adjustment did not alter the odds of incompressibility between the two groups.

Conclusion: Our findings suggesting an increased frequency of peripheral arterial obstruction in RA patients broadens the scope of cardiovascular morbidity in RA. The clinical significance of the increased frequency of peripheral arterial obstruction in RA deserves further study.Figure: Unadjusted and adjusted frequency of obstructed ankle brachial index in rheumatoid arthritis and controls. Error bars represent 95% confidence intervals.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the profile of adult-onset diabetes in patients with rheumatoid arthritis (RA) or osteoarthritis (OA), two chronic diseases leading to disability differing by their joint and systemic inflammation levels, and identify the disease characteristics associated with insulin resistance and metabolic control.

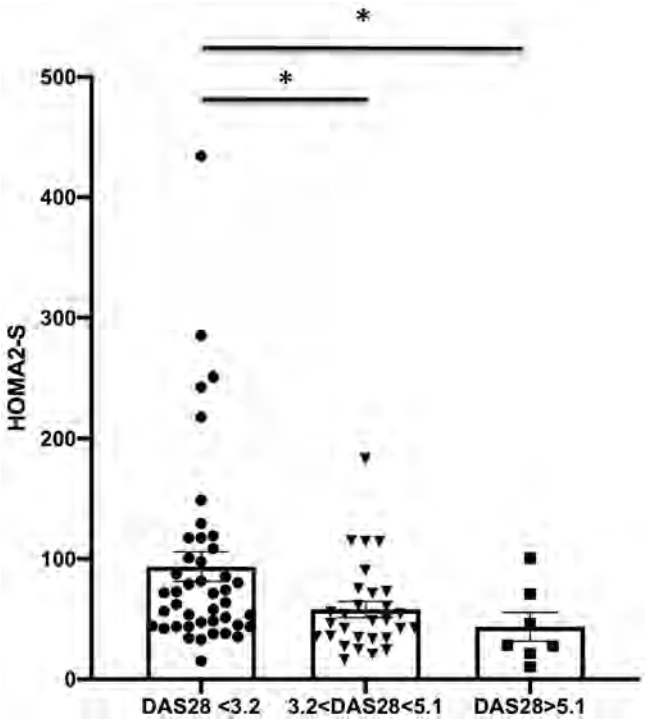

Figure 1. Insulin sensitivity assessed by the HOMA2-S according to the disease activity score (DAS)-28 HOMA2-S was evaluated in these subgroups after excluding patients with Latent Autoimmune Diabetes in Adults and T2D patients treated with insulin. Statistical test: Kruskal-Wallis test with Dunn correction, *p<0.05

Methods: Observational, multicenter, cross-sectional usual-care study, including 7 rheumatology centers. This study included over a 24-month period consecutive patients with type-2 diabetes (T2D) and RA, fulfilling the 2010 ACR / EULAR criteria, and diabetic patients with osteoarthritis (OA). The following data were collected: demographics, disease activity and severity indices, current treatment for RA and diabetes, history and complications of diabetes. A systematic blood test was performed, assessing inflammatory (CRP levels) and metabolic (fasting glycemia and insulin levels, HbA1c) parameters. The HOMA2%B (insulin secretion) and HOMA2%S (tissue insulin sensitivity) indices (HOMA calculator, © Diabetes Trials Unit, University of Oxford) were used to assess insulin resistance.

Results: We included 122 RA patients (74% women, mean age 64±11 years, mean disease duration 15±11 years, 75% with positive ACPA antibodies and 64% with erosive disease). 64% of RA patients were treated with oral corticosteroids < 10 mg/day, 65% received Methotrexate and 53% received targeted biological therapies. We recruited 54 diabetic controls (75% women) with OA (33 knee OA and 21 hip OA), who were significantly older (68.5±11.9 years, p=0.031) and had a significantly higher BMI (31.5±6.3 kg/m2 vs. 27.7±5.5 kg/m2, p< 0.001) than patients with RA.

OA and RA patients had severe T2D with suboptimal metabolic control (mean HbA1c: 7.3%±1.29% and 7.0% ± 1.19%, respectively) and a biological profile of insulin resistance.

Insulin resistance was significantly higher in RA than OA patients after stratification on age and body mass index (HOMA2-S: 69.4±31.6 vs. 98.4±69.2, p=0.002).

The DAS28 negatively correlated with HOMA2-S (r=-0.29, p=0.011) and patients with moderate or high disease activity, had significantly decreased HOMA2-S (Figure 1). In multivariate analysis, HOMA2-S was independently associated with DAS28 (OR: 3.93, 95% CI 1.02-15.06). T2D metabolic control was not related to disease activity and functional impairment, but HbA1c levels were independently associated with bone erosions (OR: 4.43, 95% CI 1.18-16.61). Treatment with low-dose corticosteroids was not associated with decreased insulin sensitivity or increased

HbA1c levels. Treatment with TNF-α inhibitors was associated with increased insulin sensitivity compared to patients not receiving biologics (101.3±58.71 vs. 60.0±32.5, p=0.001).

Conclusion: OA and RA patients with adult-onset diabetes display a clinical profile of severe T2D with suboptimal metabolic control. RA patients displayed a biological profile of insulin resistance associated with joint and systemic inflammatory inflammation. These findings may have therapeutic implications, with the potential targeting of insulin resistance through the treatment of joint and systemic inflammation.

Patients with Asthma Have a Higher Risk of Rheumatoid Arthritis: A Systematic Review and Meta-analysis

Nipith Charoenngam[1], Ben Ponvilawan[1], Thanitsara Rittiphairoj[1], Surapa Tornsatitkul[1], Phuuwadith Wattanachayakul[1], Pongprueth Rujirachun[1] and **Patompong Ungprasert**[2], [1]Mahidol University, Bangkok, Thailand, [2]Cleveland Clinic, Cleveland, OH, Cleveland Heights, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies have reported the association between asthma and elevated risk of several chronic diseases, such as inflammatory bowel disease, diabetes mellitus and coronary heart disease. Additionally, there are data on the association between asthma and risk of rheumatoid arthritis (RA), although the results from existing studies are largely inconsistent. The current systematic review and meta-analysis was conducted in order to investigate whether patients with asthma have an increased risk of rheumatoid arthritis by identifying all available studies and summarizing their results together.

Methods: Potentially eligible studies were identified from Medline and EMBASE databases from inception to November 2019 using search strategy that comprised of terms for “Asthma” and “Rheumatoid arthritis”. Eligible cohort study must consist of one cohort of patients with asthma and another cohort of individuals without asthma. Then, the study must report relative risk (RR) with 95% confidence intervals (95% CIs) comparing incident RA between the groups. Eligible case-control studies must include cases with RA and controls without RA. Then, the study must explore their history of asthma. Odds ratio (OR) with 95% CIs of the association between RA and prior history of asthma must be reported. Point estimates with standard errors were retrieved from each study and were combined together using the generic inverse variance method of DerSimonian and Laird.

Results: A total of 21,824 articles were identified. After two rounds of independent review by three investigators, 5 cohort studies and 11 case-control studies met the eligibility criteria and were included into the meta-analysis. Patients with asthma had a significantly higher risk of incident RA compared with individuals without asthma with the pooled RR of 1.48 (95% CI, 1.20 – 1.82; I^2 92%).

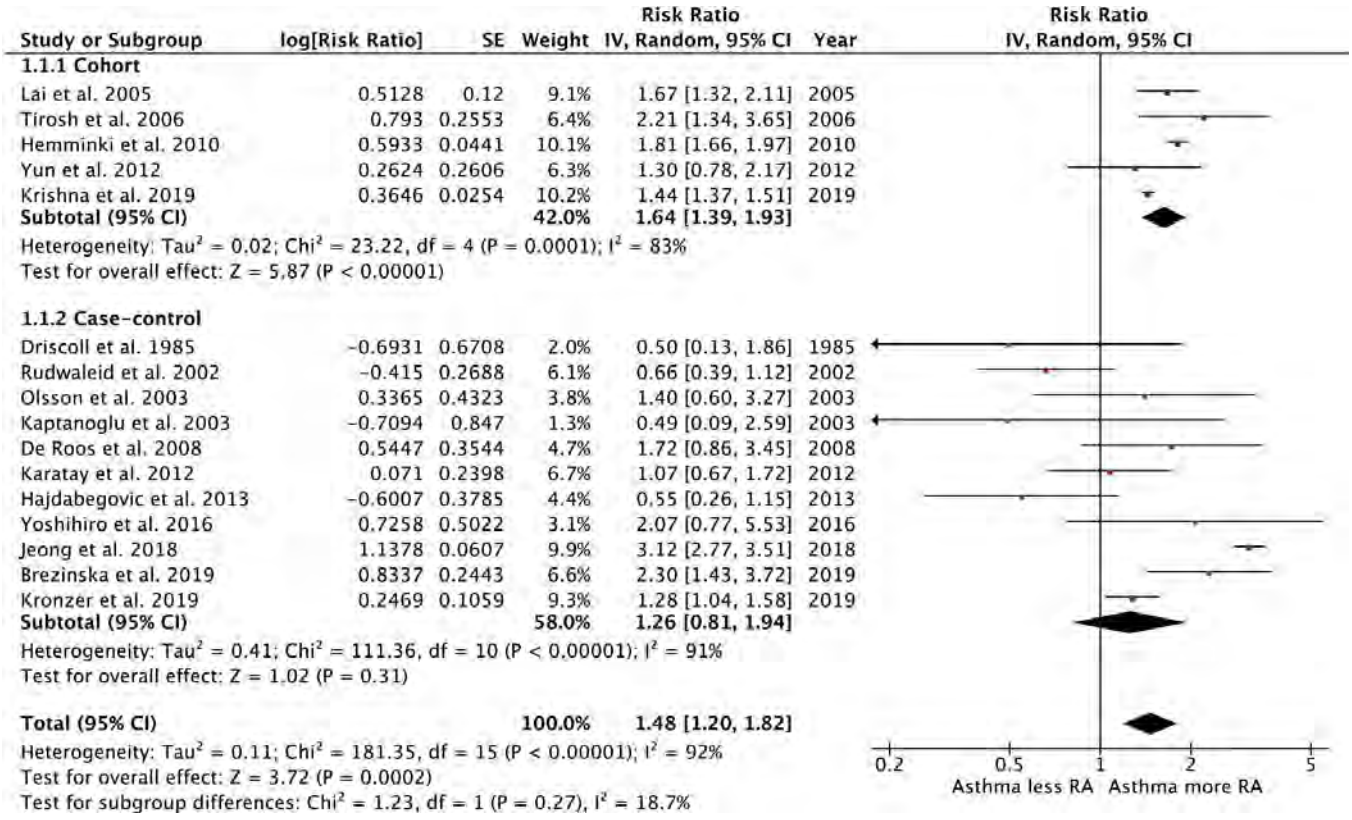

Figure 1. Forest plot of the meta-analysis of risk of RA in individuals with asthma versus individuals without asthma

Conclusion: This systematic review and meta-analysis found a significant association between asthma and a higher risk of incident RA.

Abstract Number: 0194

Depression Symptoms but Not Clinically Diagnosed Depression Predict Mortality in Rheumatoid Arthritis

Jose Felix Restrepo[1], Inmaculada Del Rincon[1] and Agustin Escalante[1], [1]University of Texas Health Science Center at San Antonio/ Department of Medicine/ Rheumatology, San Antonio, TX

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Depression and depressive symptoms are common but under-recognized in rheumatoid arthritis (RA). Few studies have examined depression symptoms in RA patients compared to clinically diagnosed depression, and their role as mortality predictors. The objectives of the present study were to examine the prevalence

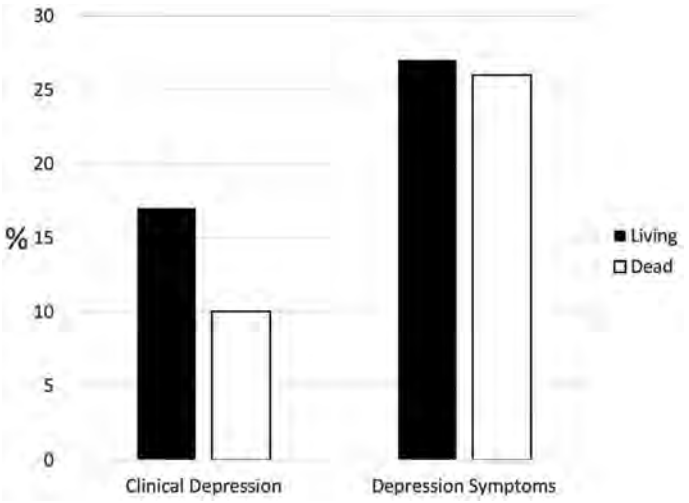

Figure. Significant depression symptoms were more frequent than clinically diagnosed depression in both patients who survived as well as in those who died (P < 0.001)

of depression symptoms compared to clinically diagnosed depression and to examine the association of depression with mortality in RA patients.

Methods: We studied a cohort of RA patients who met the 1987 classification criteria, recruited from 1996 through 2011. All underwent a comprehensive clinical and psychosocial evaluation using standardized instruments. Depressive symptoms were measured with the Center for Epidemiologic Studies Depression Scale (CESD), adjusted for RA (CESD-RA) by eliminating items that may overlap with symptoms of RA. We considered depression as present when the CESD score was ≥ 16. To quantify RA disease activity, we used the DAS28 ESR (DAS28). All deaths were confirmed with a death certificate. Multivariable logistic regression models were fit to examine the combined influence of independent variables on the outcome

Results: We studied 1328 RA patients, 981 of whom were women (74%). A clinical diagnosis of depression was found in the medical records of 220 patients (17%), significantly fewer than the 361 (27%) with significant depression symptoms on the CESD (P < 0.0001). There were 305 deaths during the study period. Of the patients who died, 31 had been diagnosed clinically with depression (10%), but 75 had significant depression symptoms on the CESD (26%). Patients with depression or significant depression symptoms were younger than patients without them, mean age 53 years (95% CI 52, 54) vs. 58 years (95% CI 57, 59), P < 0.0001, and more likely to be women, 82% vs. 69%, OR 1.97, (95% CI 1.48, 2.63), P < 0.0001. Patients with significant depression symptoms had greater disease activity than those without them, mean DAS28ESR 5.1 (95% CI 5.0, 5.3) vs. 4.0 (95% CI 3.9, 4.1), P < 0.001).

Logistic regression analysis adjusted for age and sex revealed that significant depression symptoms predicted all-cause mortality, OR 1.77 (95% CI 1.49, 2.12), P < 0.001, but clinically diagnosed depression did not.

Conclusion: Significant depression symptoms in RA are more frequent than depression diagnosed clinically, suggesting that some patients with depression may go undiagnosed. Depression symptoms predicted mortality in RA patients, while a clinical diagnosis of depression did not. Our findings suggest that strategies to improve the recognition of depression in RA should be studied further.

Epidemiology and Characteristics of Incident Rheumatoid Arthritis in Persons with and Without HIV

Jennifer Hanberg[1], Kathleen Akgun[2], Liana Fraenkel[3], Evelyn Hsieh[2] and Amy Justice[4], [1]Yale University School of Medicine; West Haven VA, Boston, MA, [2]Yale University School of Medicine; West Haven VA, New Haven, CT, [3]Yale School of Medicine; West Haven VA; Berkshire Medical Center, Lenox, MA, [4]Yale University School of Medicine; Yale School of Public Health; West Haven VA, West Haven, CT

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most common chronic inflammatory arthritis, affecting 1-2% of the population. Estimates of the incidence of RA in patients with HIV (PWH) are sparse, as are data regarding the presentation of RA in PWH.

Methods: Patients were selected from the Veterans Aging Cohort Study, a longitudinal cohort of Veterans with HIV and age, sex, race, and site-of-care-matched 1:2 to uninfected Veterans. Between 1997-2017, we searched all International Classification of Diseases (ICD) codes starting from each patient's first entry into the medical record, or in cases of PWH, from the time of diagnosis of HIV. We identified patients with ≥1 outpatient rheumatology clinic ICD code for RA and a positive or negative rheumatoid factor (RF) or anti-CCP antibodies. Charts were reviewed using the 2010 RA Classification Criteria; a score of ≥6 was classified as incident RA if there was no evidence of prior diagnosis, such as listing of RA as past medical history. We recorded conventional and biologic disease-modifying anti-rheumatic drug (DMARD) use, and reasons for changes in therapy during the first contiguous course of therapy (period with no interruption greater than 6 months).

Results: We included 56,250 PWH and 116,944 uninfected persons over 2,384,541 person-years. Of 2,748 patients with an ICD code for RA, 1,030 (37%) had at least one rheumatologist-generated ICD code and 881 (32%) had serology available. "Definite" incident RA was identified in 215 cases, 21 of whom were PWH at the time of RA diagnosis. The crude incidence of RA was 0.33 cases per 10,000 person-years (95% CI, 0.21-0.51) in PWH vs. 1.11 (0.96-1.28) in patients without. The incidence rate ratio of RA in PWH vs. uninfected was 0.29 (95% CI 0.19-0.48, p< 0.0001). Among PWH with incident RA, the median CD4 count closest to diagnosis was 487 cells/mm3 (25th-75th percentile, 367-650), and 81% of patients with recent HIV-1 viral titers available had levels less than 500 copies/mL. Most patients (88%) with incident RA were seropositive. However, high antibody titers were found less frequently in PWH: 5% of PWH had both a high (≥3 times upper limit of normal) anti-CCP titer and a high RF titer, compared to 41% of persons without HIV (Table). DMARDs were prescribed for 71% of PWH with "definite" RA, compared to 94% of uninfected Veterans (p=0.0002). The most commonly used DMARD among PWH was HCQ (57%) while methotrexate was more common in uninfected Veterans (66%). PWH were significantly less likely to be prescribed methotrexate (33% vs. 66%, p=0.004), leflunomide (0% vs. 12%, p=0.01), and biologic or small molecule drugs (10% vs. 32%, p=0.02).

Conclusion: Incident RA was less common in PWH than in matched uninfected persons. PWH with incident RA were less likely to have strongly positive autoantibody profiles than uninfected individuals.

		PWH (n=21)	Uninfected (n=194)	p-value
Serology (N (%))				
	Rheumatoid Factor			0.0002
	High positive	6 (29)	116 (60)	
	Low positive	5 (24)	47 (24)	
	Negative	9 (43)	19 (10)	
	Not tested	1 (5)	12 (6)	
	Anti-CCP			0.01
	High positive	5 (24)	116 (60)	
	Low positive	5 (24)	18 (9)	
	Negative	9 (43)	44 (23)	
	Not tested	2 (10)	16 (8)	
	Overall pattern			0.002
	Both (anti-CCP and RF) high positive	1 (5)	81 (42)	
	One high positive/ One low positive	2 (10)	31 (16)	
	Both low positive	1 (5)	4 (2)	
	One positive/ One negative	11 (52)	43 (22)	
	One positive/ One not nested	2 (10)	22 (11)	
	Seronegative	4 (19)	13 (7)	

Table: Anti-CCP and Rheumatoid Factor Serologies Were More Strongly Positive in Uninfected than in PWH with Incident RA. High positive was defined in accordance with the 2010 RA Classification Criteria as at least 3 times the upper limit of normal per the local laboratory value. Low positive was defined as a result greater than the upper limit of normal but less than 3 times this value, or an unquantified positive result.

Objectively-Measured Obstructive Sleep Apnea Is Frequent Among Individuals with Rheumatoid Arthritis

Stephanie Rush[1], Sarah Morsi[2], Jose Pinzón Tirado[2], Laura Trupin[2], Katie Stone[3] and Patricia Katz[4], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA, [3]California Pacific Medical Center Research Institute, San Francisco, CA, [4]University of California, San Francisco, Novato, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite frequent reports of sleep problems, accurate information on sleep disturbance in rheumatoid arthritis (RA) is not available. Studies using objective measures of sleep in RA are rare, but are needed to provide greater accuracy than classifications based on self-report. We examined the presence and severity of obstructive sleep apnea (OSA) using a validated home-monitoring device among Individuals with RA.

Methods: Data were from the RA Sleep Study, in which participants were recruited from an academic medical center and a safety-net hospital clinic. They completed in person visits and questionnaires every 6 months over an 18-month period and interviews were conducted in Spanish and English. All have physician-diagnosed RA; current use of a CPAP device was an exclusion criterion. At baseline, participants were provided with a WatchPAT™ device (Itamar Medical, Ltd) to wear for two consecutive nights at home. The WatchPAT™ is a validated diagnostic wrist-worn device which measures multiple channels of data (peripheral arterial tone, oximetry, actigraphy, heart rate and chest motion) with 3 points of contact (wrist, finger, and chest sensor). It yields estimates on a variety of measures, including the apnea-hypopnea index (AHI), reflecting the number of apnea or hypopnea episodes per hour of sleep. AHI was categorized as normal (< 5), mild OSA (5- < 15), moderate OSA (15-< 30), or severe OSA (≥30). The STOP-BANG questionnaire[1], a validated measure of OSA risk was also administered and physician diagnoses of OSA were queried. Potential predictors of the presence and severity of OSA were identified through chi-square test and analysis of variance with post-hoc means comparisons, and included age, sex, race/ethnicity (white non-Hispanic vs.

Table 1. Factors associated with obstructive sleep apnea severity

Table 2. Report of physician-diagnosed OSA and risk of OSA from STOP-BANG questionnaire, by Apnea-hypopnea Index (AHI) Category

		AHI (apnea-hypopnea index)			
	Total	Normal (n=6)	Mild (n=22)	Moderate (n=24)	Severe (n=11)
			n (%)		
OSA diagnosed by doctor	9	0 (0)	1 (4.6)	4 (16.7)	4 (36.4)
High risk OSA (STOP-BANG)	13	0 (0)	4 (18.2)	4 (16.7)	5 (45.5)

all others), smoking, low income, BMI, obesity (BMI ≥ 30 kg/m^2), morbid obesity (BMI ≥ 35), glucocorticoid use, and self-reported RA disease activity (Rheumatoid Arthritis Disease Activity Index, RADAI).

Results: Participants (n=63) were 79% female, 38% white non-Hispanic, 16% low income and mean age was 58 ± 13 years. Using AHI, OSA was frequent: 35% had mild OSA, 38% moderate, and 17% severe. Participants with normal AHI were significantly younger, and those with severe OSA had significantly higher BMI (Table 1). Among 13 (21%) participants identified as high risk for OSA in the STOP-BANG questionnaire, 6 (10%) reported a physician's diagnosis of OSA. None of the participants with normal AHI had either a diagnosis of OSA or identified as high risk for OSA. (Table 2).

Conclusion: Some degree of sleep apnea was identified in 90% of this group of individuals with RA, with over half having moderate to severe OSA. Most OSA was unrecognized and would not be identified with current screening measures. OSA is linked to multiple health problems, including cardiovascular disease and fatigue, both of which are common in RA. Results highlight the importance of future objective studies of sleep as well as the importance of considering OSA as a risk factor for poor outcomes in RA.

Background/Purpose: Patients with elderly onset rheumatoid arthritis(RA) have been reported to be less positive for RF(rheumatoid factor) and ACPA(anti-cyclic citrullinated peptide antibody), and have a higher risk of malignancy than young onset RA. The aim of this study was to investigate the relationship between seronegative RA and malignancy, and to examine the clinical and laboratory features of those with and without malignancy.

Methods: We retrospectively examined consecutive patients diagnosed with seronegative RA in our hospital from 2007 to 2019. Patients with seronegative RA were negative for both RF and ACPA and met the EULAR/ACR 2010 criteria. The patients who were diagnosed with remitting seronegative symmetrical synovitis with pitting edema syn-

drome or polymyalgia rheumatica at first and then diagnosed with seronegative RA afterward were included in seronegative RA. The first analysis was performed on the affected joints, C-reactive protein(CRP), erythrocyte sedimentation rate(ESR), hemoglobin(Hb), albmin(Alb), immunoglobulin G(IgG), fibrinogen, lactate dehydrogenase(LDH), matrix metalloproteinase 3(MMP-3), image findings(ultrasound, X-ray, and MRI), and the history of malignancy 2 years before and after the diagnosis with seronegative RA. The affected joints were large joints(shoulders, elbows, hips, knees, and ankles), wrists, finger joints (MCP, and PIP joints), and toe joints (MTP and PIP joints). The secondary analysis was performed on the above evaluations with a propensity score (PS) matching for sex.

Results: In the first analysis, 124 patients with seronegative RA were enrolled. Eight patients had malignancies, and 116 patients did not have malignancy. Table 1 shows the types of malignancy. The median time for the diagnosis of malignancy was 10 months after the diagnosis of RA. Table 2 shows the baseline characteristics at the diagnosis of seronegative RA. The mean ages with and without malignancy were 73.4±10.1 and 66.1±14.8 years old, respectively(p= 0.18). Males were 62.5% and 35.3%(p=0.12). The mean numbers of large swollen joints were 0.6± 0.7, 1.5±1.4(p=0.04). There was no difference in the levels of CRP, ESR, Hb, Alb, IgG, fibrinogen, LDH between seronegative RA with and without malignancy. The levels of MMP-3 were 120.8±109.1 and 408.6±564.9 ng/mL(p=0.04). The patients with only tenosynovitis were 40.0% and 7.5%(p=0.03).

In the secondary analysis with PS, 8 patients with malignancy and 8 patients without malignancy were enrolled(Table 3). The mean numbers of large swollen joints were 0.6± 0.7, 1.5±1.4(p=0.04). The mean levels of MMP-3 were 120.8±127.1 and 425.8±127.1 ng/mL (p=0.07).

Conclusion: In seronegative RA, the patients with malignancy had lower levels of MMP-3 and fewer numbers of large swollen joints at the time of RA diagnosis than those without malignancy. The patients with only tenosynovitis were

more common in the patients with malignancy than in those without malignancy. Furthermore, among seronegative RA patients, it was considered that the patients with lower levels of MMP-3 and fewer numbers of large swollen joints should pay attention especially to the complication of malignancy.

Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Multimorbidity
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Automobile driving is an instrumental activity of daily living. Owing to symptoms and functional impairment, patients with rheumatoid arthritis (RA) rely disproportionately on driving for the preservation of health, well-being, and quality of life[1]. To date, there have been no rigorously designed prospective studies examining driving performance in patients with RA. This prospective cohort study compared variability in longitudinal (acceleration/braking) and lateral (steering) vehicle acceleration as measures of vehicle control between drivers with RA and healthy controls (HC).

Methods: Patients with RA were recruited from an academic rheumatology practice and were required to have at least one swollen joint and a CDAI score ≥6 to participate. HCs were recruited using advertisements and a pool of

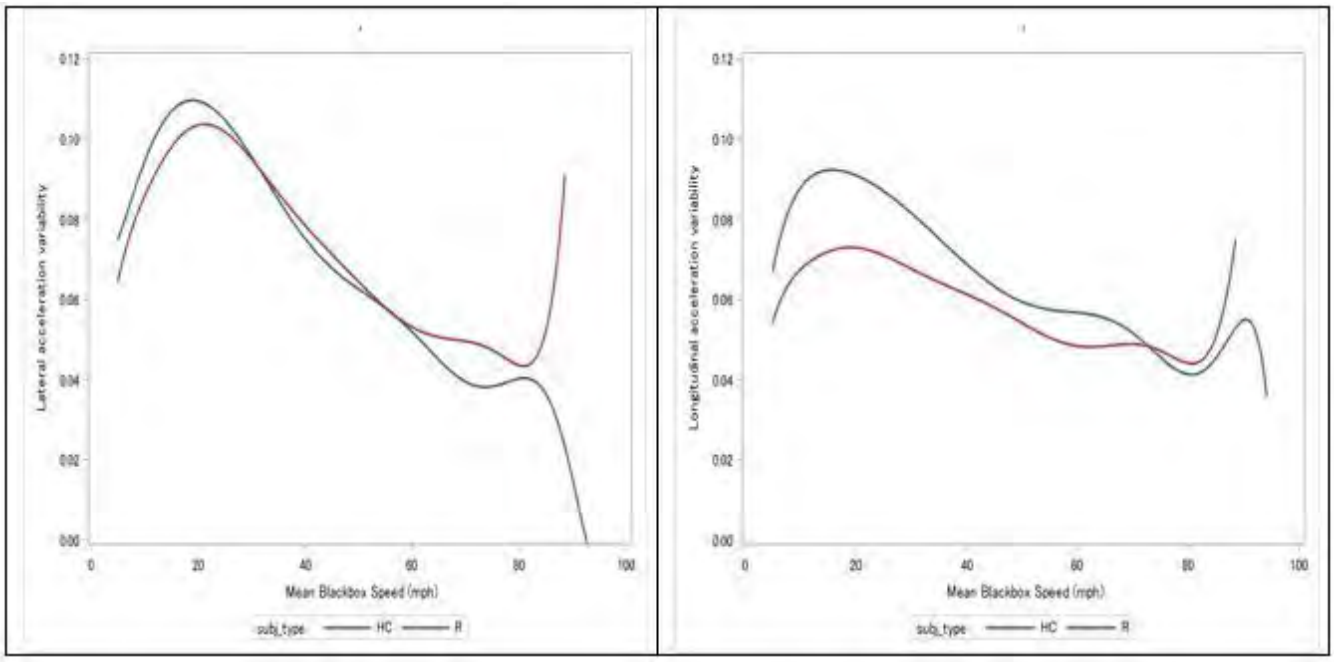

Figure 1. Plot of variability in lateral (left panel) and longitudinal (right panel) acceleration by vehicle speed

local study volunteers. Data collection occurred over 2, 4-week periods (separated by 2 months) of continuous naturalistic driving observation. Driving data were collected using instrumentation installed in participants' own vehicles, collecting video, audio, GPS, speed, acceleration and engine data. Data were aggregated into 45-second segments (from start-to-end) of uninterrupted driving. Segments with >20 seconds of missing data or mean speeds < 5 mph were excluded. Associations of disease status (RA vs. HC) and disease activity (CDAI score, RA only) with acceleration variability (standard deviations, SDs) were examined using mixed-effect linear regression models, accounting for between-patient variability.

Results: Characteristics of RA and HC subjects are shown in **Table 1**. There were 232,538 driving segments (2,906 driving hours) analyzed. Factors associated with variability in longitudinal and lateral acceleration included RA disease status, higher disease activity in RA, study period, season, and mean vehicle speed (**Table 2, Figure 1**). Increases in disease activity between periods 1 and 2 tended to produce more erratic braking/accelerating (increased longitudinal variability; estimate = 0.0004; p = 0.05) without affecting steering.

Conclusion: To our knowledge, this is the first study quantifying naturalistic driving in the real world in patients with RA. These results link RA and heighted arthritis disease activity with aberrant vehicle control. Specifically, increased RA disease activity reduces steering variability while simultaneously increasing erratic/harsh braking and accelerating. These findings support the need for further research to map these observed patterns in vehicle control to metrics of driver risk, and, in turn, to link patterns of real world driving behavior to diagnosis and disease activity.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: CT-P17 is a recombinant human monoclonal antibody that was developed as the first biosimilar adalimumab with high concentration (100 mg/mL) and citrate-free formulation. The purpose of this study was to compare the pharmacokinetics (PK), safety, and immunogenicity of the CT-P17 auto-injector (AI) and CT-P17 pre-filled syringe (PFS) after a single subcutaneous (SC) injection of 40 mg (100 mg/mL) in healthy subjects.

Methods: Healthy subjects aged 18 to 55 years (N=193) were randomized in 1:1 (98 subjects in the CT-P17 AI and 95 subjects in the CT-P17 PFS treatment groups) to receive 40 mg of either CT-P17 by AI or PFS. The primary objective of this study was to demonstrate PK similarity in terms of area under the serum concentration-time curve (AUC) from time zero to infinity (AUC0-inf), AUC from time zero to the last quantifiable concentration (AUC0-last), and maximum

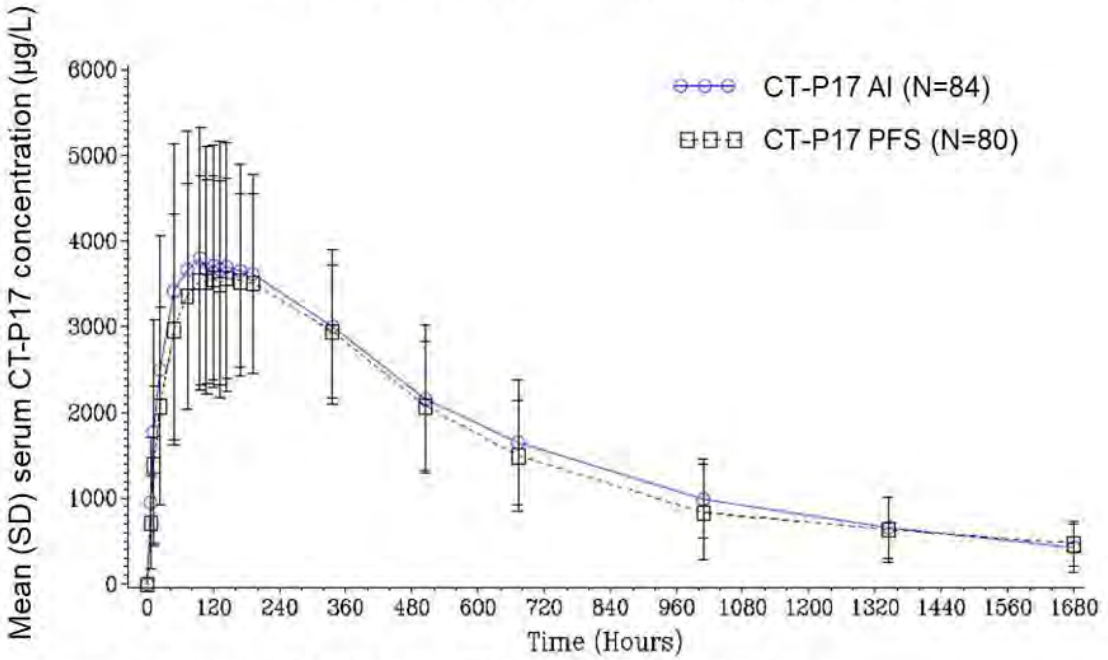
Table 1 Statistical Analysis of the Primary PK Endpoints (Pharmacokinetic Population)

Parameter (units)	Treatment	gLSM	Ratio of gLSMs (90% CI)[a]	P-value[a]
C_{max} (µg/mL)	CT-P17 AI CT-P17 PFS	3.801 3.705	102.60 (94.08–111.90)	0.6244
AUC_{0-inf} (h·µg/mL)	CT-P17 AI CT-P17 PFS	2,606.4 2,514.8	103.64 (93.98–114.29)	0.5459
AUC_{0-last} (h·µg/mL)	CT-P17 AI CT-P17 PFS	2,110.7 2,003.4	105.36 (91.09–121.86)	0.5537

Abbreviations: AI, auto-injector; ANCOVA, analysis of covariance; AUC_{0-inf}, area under the concentration–time curve from time zero to infinity; AUC_{0-last}, area under the concentration–time curve from time zero to the last quantifiable concentration; CI, confidence interval; C_{max}, maximum serum concentration; gLSM, geometric least squares mean; PFS, pre-filled syringe; PK, pharmacokinetic.

[a]Determined by ANCOVA performed with the natural log-transformed PK parameters as the dependent variable, treatment as a fixed effect and stratification factors (sex [male versus female], study center and Day –1 body weight) as covariates.

Figure 1 Mean (± SD) Serum Concentrations of CT-P17 for CT-P17 AI and CT-P17 PFS (Pharmacokinetic Population)



Abbreviations: AI, auto-injector; PFS, pre-filled syringe; PK, pharmacokinetic; SD, standard deviation.

[a]Six and seven subjects in the CT-P17 AI and CT-P17 PFS treatment groups, respectively, were excluded due to absence of ≥1 post-treatment serum concentration above the lower limit of quantification for CT-P17 and ≥3 time points following C_{max}. Three subjects (CT-P17 AI) were excluded due to major protocol deviations (whole volume of study drug was not administered successfully [n=2] and dosing with morphine in a previous clinical study [n=1]).

Figure 1. Trial profile. The SHR0302 8 mg group was added in protocol v2.0 to explore the maximum safe and effective dose according to latest preclinical data. AE, adverse events; INV, investigator; PD, progressive disease; DC, discontinuation.

serum concentration (Cmax) of CT-P17 via AI versus CT-P17 via PFS in healthy subjects. Secondary objectives were to evaluate additional PK parameters, safety and immunogenicity.

Results: Demographics and baseline characteristics were similar between the 2 treatment groups. Following a single SC administration of CT-P17 via AI in healthy subjects, mean peak and total systemic exposure (Cmax, AUC0-inf, and AUC0-last) were equivalent with those of CT-P17 via PFS, since the 90% CIs of the geometric least squares mean

Table 2 Summary of Adverse Events (Safety Population)

	CT-P17 AI (N=93)	CT-P17 PFS (N=87)
Subjects with ≥1 TEAE, n (%)[a]	56 (60.2)	45 (51.7)
Grade 1	44 (47.3)	39 (44.8)
Grade 2	10 (10.8)	6 (6.9)
Grade 3	2 (2.2)[b]	0
Subjects with ≥1 TESAE, n (%)	2 (2.2)[b]	0
Subjects with ≥1 TEAE due to hypersensitivity/allergic reactions, n (%)[c]	3 (3.2)	1 (1.1)
Subjects with ≥1 TEAE due to ISR, n (%)[d]	8 (8.6)	6 (6.9)
Subjects with ≥1 TEAE due to infection, n (%)	10 (10.8)	6 (6.9)
Serious infection	1 (1.1)[e]	0

Abbreviations: AI, auto-injector; ISR, injection site reaction; PFS, pre-filled syringe; SAE, serious adverse event; TEAE, treatment-emergent adverse event; TESAE, treatment-emergent serious adverse event.

[a]No subjects experienced TEAEs led to study drug discontinuation or death or TEAEs due to malignancy.
[b]The TESAEs were viral meningitis and rhabdomyolysis; both were grade 3 in intensity and considered related to study drug. Both subjects recovered and completed the study. These were the only grade ≥3 TEAEs reported.
[c]All TEAEs classified as hypersensitivity/allergic reactions were considered study drug-related and were Grade 1–2 in intensity.
[d]All TEAEs classified as ISR were considered study drug-related and were Grade 1 in intensity.
[e]Grade 3 viral meningitis (n=1) reported as a TESAE

ratios were within the predefined equivalence margin of 80% to 125% (Table 1). Median Tmax occurred at 132 hours for both treatment groups. Means of secondary PK parameters (t1/2, λz, CL/F, Vz/F and %AUCextrap) were also comparable between the treatment groups.

Mean serum CT-P17 concentrations observed through 71 days post-dose were comparable between the treatment groups (Figure 1).

Overall, 56 (60.2%) and 45 (51.7%) subjects reported ≥1 treatment-emergent adverse event (TEAE) in the CT-P17 AI and CT-P17 PFS treatment groups, respectively (Table 2). TEAEs considered to be related to study drug were reported by 47 (50.5%) and 38 (43.7%) subjects, respectively. The most frequently reported TEAEs were headache (11 [11.8%] and 8 [9.2%] subjects) and injection site reactions (8 [8.6%] and 6 [6.9%] subjects) in the CT-P17 AI and CT-P17 PFS treatment groups, respectively).

Overall, 91 (97.8%) and 85 (97.7%) subjects in the CT-P17 AI and CT-P17 PFS treatment groups, respectively, had ≥1 positive result post-treatment for anti-drug antibodies (ADA) and 81 (87.1%) and 75 (86.2%) subjects, respectively, had ≥1 positive result post-treatment for neutralizing ADA. ADA titers were similar between the treatment groups. In both treatment groups, higher ADA titers were significantly associated with decreased AUC0-inf and AUC0-last (Fisher's z transformation; p-value <0.0001). Cmax did not correlate significantly with ADA titer.

Conclusion: Mean peak and total exposure were equivalent following administration of high concentration formulation CT-P17 via AI or PFS. Secondary PK parameters and safety, including immunogenicity, were also comparable between the two delivery methods.

Abstract Number: 0200

Predictors of Durable Clinical Response to Tofacitinib 11 Mg Once Daily with or Without Methotrexate in Patients with Rheumatoid Arthritis: Post Hoc Analysis of Data from a Phase 3b/4 Methotrexate Withdrawal Study

Kunihiro Yamaoka[1], Stanley B Cohen[2], Naonobu Sugiyama[3], Harry Shi[4], Jose L Rivas[5], Annette Diehl[4] and Josef Smolen[6], [1]Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan, [2]Metroplex Clinical Research Center, Dallas, TX, [3]Pfizer Japan Inc, Tokyo, Japan, [4]Pfizer Inc, Collegeville, PA, [5]Pfizer SLU, Madrid, Spain, [6]Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: ORAL Shift, a global Phase 3b/4 non-inferiority study, demonstrated sustained efficacy/safety of tofacitinib modified-release (MR) 11 mg QD following MTX withdrawal in patients (pts) with RA who achieved CDAI low disease activity (LDA) after treatment with tofacitinib + MTX.[1] Here, we assessed predictors of durable clinical response in pts receiving tofacitinib MR 11 mg QD in ORAL Shift.

Methods: ORAL Shift (NCT02831855) enrolled pts aged ≥ 18 years with moderate to severe RA and an inadequate response to MTX. Pts received open-label (OL) tofacitinib MR 11 mg QD + MTX for 24 weeks. Pts achieving LDA (CDAI score ≤ 10) at W24 entered the 24-week double-blind (DB) MTX withdrawal phase and were randomized 1:1 to receive tofacitinib MR 11 mg QD + placebo (PBO) (tofacitinib monotherapy; ie blinded MTX withdrawal) or continue tofacitinib + MTX. In this post hoc analysis of randomized pts, we assessed predictors of durable response (maintenance of response from W24–48) per CDAI LDA and remission criteria (CDAI score ≤ 2.8). All covariates were initially assessed for significance in a univariate logistic regression. Highly correlated covariates were reviewed to assess which would be removed prior to modeling in a multivariable logistic regression. Remaining significant ($p \leq 0.10$) covariates in the univariate regression were selected in the model using a stepwise selection process with $p \leq 0.15$ entry and $p \leq 0.05$ stay criteria. From the final model, estimated odd ratios (ORs) with 95% confidence intervals (CIs) are presented.

Results: In the DB phase of ORAL Shift, durable CDAI LDA and remission rates were: 66.2% and 14.7%, respectively, with tofacitinib + MTX (N=266); and 55.3% and 11.0%, respectively, with tofacitinib + PBO (N=264) (Table). In the

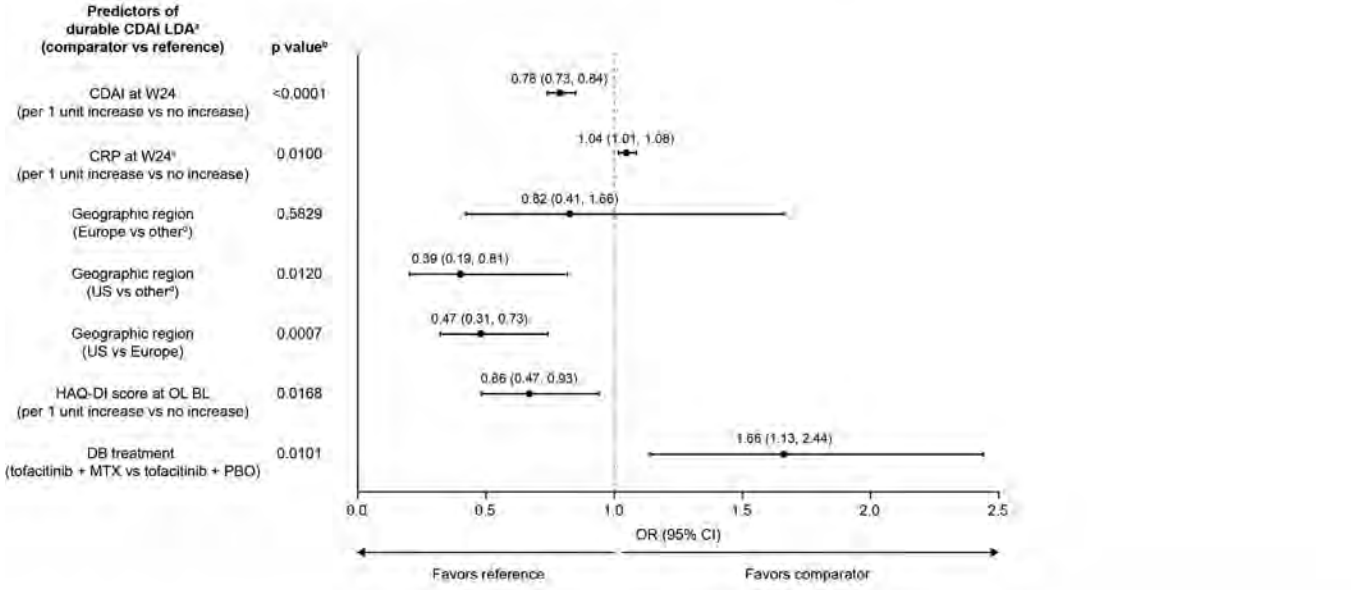
Table. Durable CDAI LDA and remission[a] in pts receiving tofacitinib MR 11 mg QD with MTX or PBO in the DB phase of ORAL Shift

	Tofacitinib + MTX (N=266)	Tofacitinib + PBO (N=264)
Durable CDAI LDA, n (%)	176 (66.2)	146 (55.3)
Durable CDAI remission, n (%)	39 (14.7)	29 (11.0)

[a]Durable CDAI LDA or remission was defined as achievement of LDA (CDAI score ≤10) or remission (CDAI score ≤2.8), respectively, at W24-48

CDAI, Clinical Disease Activity Index; DB, double-blind; LDA, low disease activity; MTX, methotrexate; MR, modified-release; N, number of patients in each group; n, number of patients achieving outcome; PBO, placebo; pts, patients; QD, once daily; W, week

Figure. Multivariable regression results for predictors of durable CDAI LDA[a] in pts receiving tofacitinib MR 11 mg QD with MTX or PBO in the DB phase of ORAL Shift



[a]Durable CDAI LDA was defined as achievement of LDA (CDAI score ≤10) at W24-48; [b]The Wald chi squared test p value for that comparison; [c]Mean CRP levels at W24 (randomization) were 25.6% higher in the tofacitinib + MTX group (mean CRP=5.05 mg/L) vs tofacitinib + PBO group (mean CRP=4.02 mg/L). During the DB phase, CRP stabilized with tofacitinib + MTX but increased with tofacitinib + PBO. The CRP differences between treatment groups may have impacted the CDAI LDA durability outcome; [d]'Other' refers to Australia, Korea, Philippines, Mexico, and South Africa

BL, baseline; CDAI, Clinical Disease Activity Index; CI, confidence interval; CRP, C-reactive protein; DB, double-blind; HAQ DI, Health Assessment Questionnaire-Disability Index; LDA, low disease activity; MR, modified-release; MTX, methotrexate; OL, open-label; OR, odds ratio; PBO, placebo; pts, patients; QD, once daily; US, United States; W, week

multivariable analysis, five pt covariates significantly predicted durable CDAI LDA (Figure; discussed hereafter). Each unit increase in CDAI score at W24 reduced the likelihood of maintaining CDAI LDA by 22.0%. Each unit increase in CRP at W24 increased the likelihood of maintaining CDAI LDA by 4.0%; this may have been due to imbalanced CRP levels at W24 (randomization) between treatment groups (Figure, footnote d). The odds of durable CDAI LDA were 53.0% lower in the US vs Europe and 61.0% lower in the US vs 'other' regions. Each unit increase in baseline (BL)

HAQ-DI score reduced the odds of durable CDAI LDA by 34.0%. Pts receiving tofacitinib + MTX had 66.0% greater odds of durable CDAI LDA vs pts receiving tofacitinib + PBO. CDAI at W24 was the only significant predictor of durable CDAI remission in the multivariable analysis: OR (95% CI) 0.32 (0.24, 0.43); p< 0.0001. Each unit increase in CDAI score at W24 reduced the odds of durable CDAI remission by 68.0%.

Conclusion: This post hoc analysis of data from ORAL Shift found that CDAI and CRP at W24, geographic region, BL HAQ-DI, and treatment could be predictors for durable CDAI LDA. As the findings of this post hoc analysis were limited to pts who achieved CDAI LDA at W24 with tofacitinib MR 11 mg QD + MTX, additional data in the general pt population need to be investigated.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Proinflammatory cytokine activation of JAK/STAT signal pathway is critical in the pathogenesis and progression of RA. SHR0302, a potent and selective inhibitor of JAK1, demonstrated promising anti-inflammatory effects for RA in both preclinical and phase 1 studies. A multicenter, randomized, placebo-controlled, double-blind phase 2 study was performed to evaluate the efficacy and safety of SHR0302 in Chinese subjects with RA.

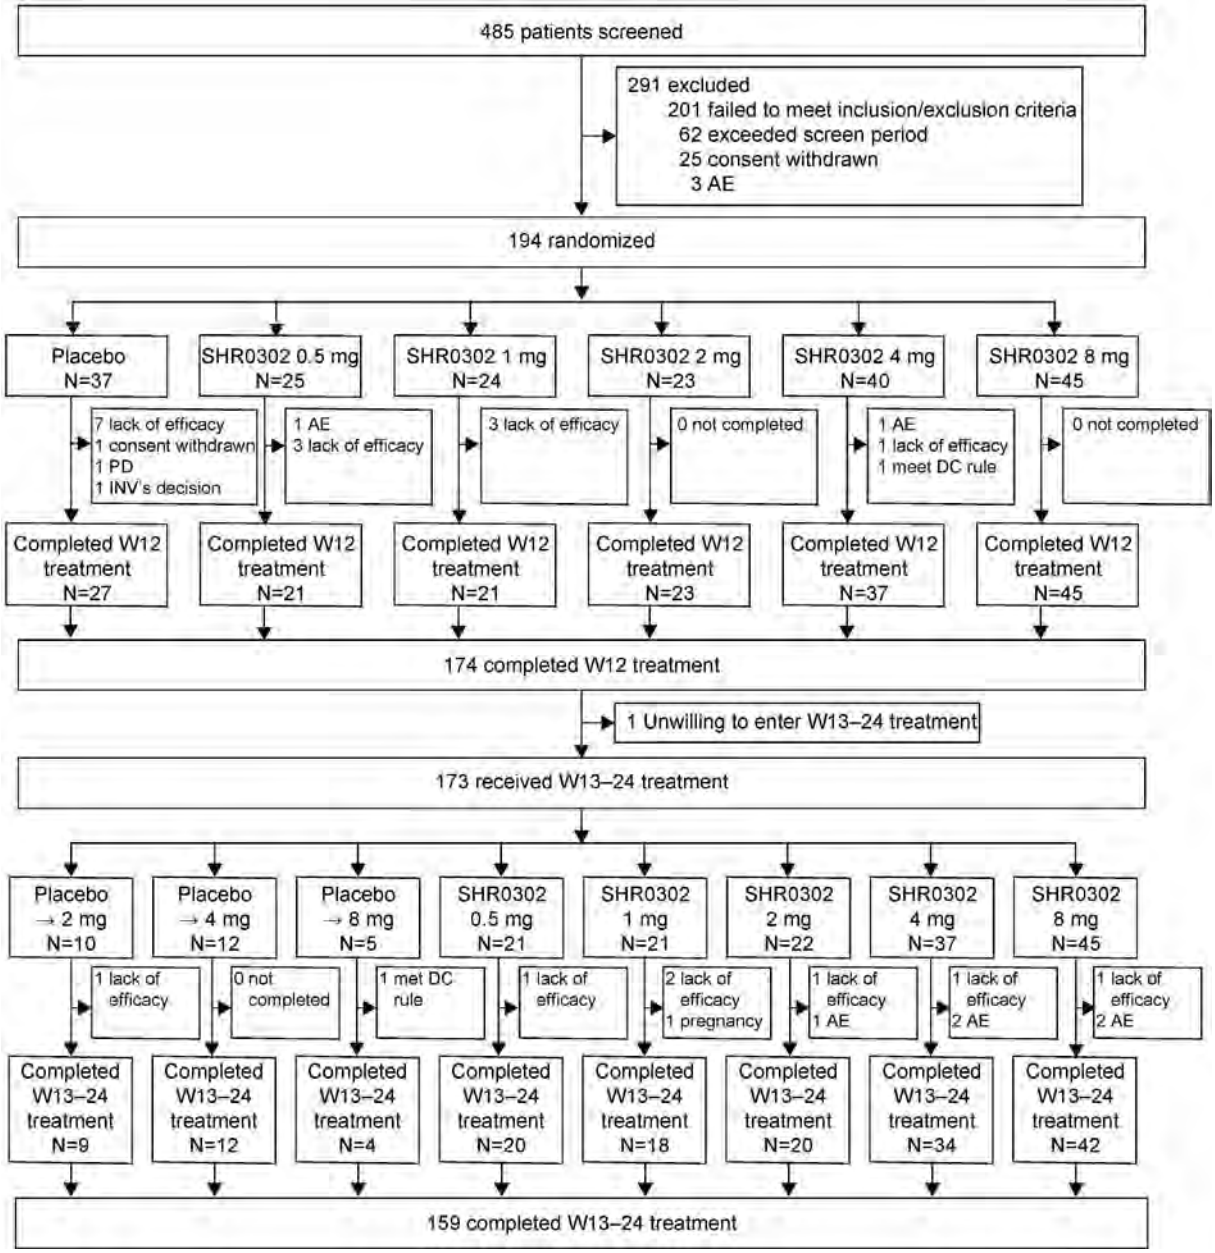

Figure 1. Trial profile. The SHR0302 8 mg group was added in protocol v2.0 to explore the maximum safe and effective dose according to latest preclinical data. AE, adverse events; INV, investigator; PD, progressive disease; DC, discontinuation.

Methods: Eligible subjects were 18–70 years; had a diagnosis of RA according to 2010 ACR/EULAR RA criteria; had moderately to severely active disease defined by ≥6 tender joints, ≥6 swollen joints (out of 68- or 66-joints examined), and ESR > 28 mm/h or CRP > 1.2 times upper limit of normal; were either treatment-naive or inadequately responded or intolerant to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs). Subjects who had prior treatment with JAK inhibitor or biologics were excluded. Eligible subjects were randomized to receive placebo or 0.5, 1, 2, or 4 mg SHR0302 in 1:1:1:1:1 (per protocol v1.1) or to receive placebo, 4 or 8 mg SHR0302 1:1:3 (per protocol v2.0) once daily (oral) for 12 weeks. Afterwards, subjects who initially assigned to placebo were re-assigned to take 2, 4 mg or 8 mg SHR0302 daily for additional 12 weeks, while subjects initially assigned to SHR0302 remained on the same treatment. The primary endpoint was the proportion of subjects who achieved ≥20% improvement according to the American College of Rheumatology response criteria (ACR20) at week 12.

Table 1. Efficacy results. †: P< 0.05; ‡: P< 0.01 vs PBO; *: adjusted for baseline HAQ-DI score and previous inadequate response to csDMARDs or not; Data are n (%), unless otherwise specified; PBO, placebo; DAS28-3 (CRP), 3-variable 28-joint Disease Activity Score using C-Reactive Protein; HAQ-DI, Health Assessment Questionnaire Disability Index.

Results: Between Sep 2017 to Oct 2019, 194 eligible subjects were randomized (Figure 1). The ACR20 response rates at week 12 for subjects receiving SHR0302 2 mg (56.5%, p=0.02), 4 mg (67.5%, p< 0.001), and 8 mg (77.8%, p< 0.001) were significantly greater than those of placebo (27.0%). ACR50/70 response rates at week 12 were generally consistent with ACR20 (Table 1). Mean changes from baseline in DAS28-3 (CRP) were numerically greater with the treatment of SHR0302 in comparison with placebo at week 12 (Table 1), and significantly more subjects in 4 mg (25.0%, p=0.02) and 8 mg (33.3%, p=0.002) groups achieved a DAS28-3 (CRP) < 2.6 versus placebo (5.4%) at week 12. SHR0302 2, 4, and 8 mg groups had significantly greater changes from baseline in HAQ-DI scores at week 12 (adjusted mean change: 2 mg, -0.68, p=0.02; 4 mg, -0.48, p=0.048; 8 mg -0.75, p< 0.001) as compared with placebo (-0.30). Above-mentioned improvements were sustained at week 24 (Table 1). The proportion of subjects with any treatment emergent adverse events was higher for SHR0302 (73.9%) vs placebo (62.2%) through week 12, particularly infection (Table 2). A total of four cases of herpes zoster and one case of opportunistic infection (cryptococcal pneumonia) were reported, all in SHR0302 8 mg group. No tuberculosis, malignancy, important cardiovascular events or death were reported. Safety results were presented in Table 2.

Conclusion: SHR0302 showed sustained efficacy in improving signs and symptoms of rheumatoid arthritis in a dose-dependent manner and had a generally accepTable safety profile. Further confirmatory studies with SHR0302 in RA will be planned accordingly.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib (bari) is an oral selective Janus kinase (JAK)1/JAK 2 inhibitor approved for the treatment of moderately to severely active rheumatoid arthritis (RA) in adults. The objective of this study was to update bari's safety profile with data up to 8.4 years of treatment.

Table. Safety summary among patients with RA treated with at least one dose of baricitinib through 1-Sep-2019 (All-Bari-RA analysis set).

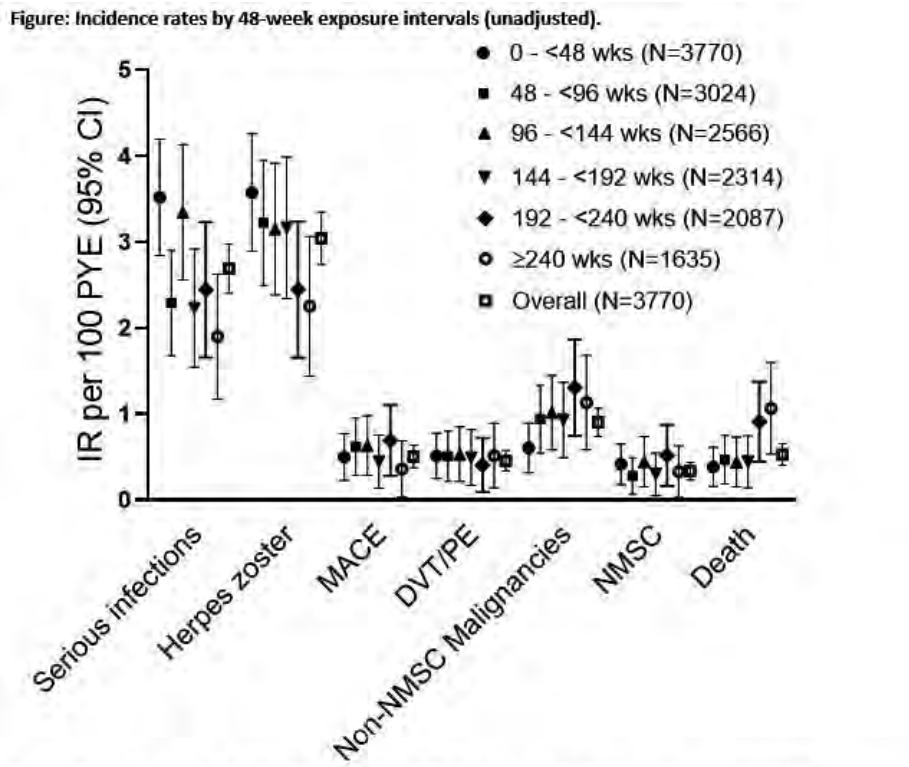
	n/N	IR
Treatment-emergent AE	3391/3770	25.8
Serious AE (including death)	940/3770	7.2
Temporary d/c because of AE	1241/3647	9.5
Permanent d/c because of AE	644/3770	4.8
Death	70/3770	0.5
Serious infection	344/3770	2.7
Opportunistic infection (excluding tuberculosis, including multidermatomal herpes zoster)	61/3770	0.5
Herpes zoster	384/3770	3.0
Tuberculosis	20/3770	0.2
Major adverse cardiovascular events*	63/3251	0.5
DVT	41/3770	0.3
PE	32/3770	0.2
DVT and/or PE	60/3770	0.5
Malignancies excluding NMSC	122/3770	0.9
NMSC	44/3770	0.3
Lymphoma	8/3770	0.06
Gastrointestinal perforation	6/3770	0.04

*positively adjudicated events in studies with adjudication (5 Phase 3 studies and 1 long-term extension study). AE = adverse event; D/C = discontinuation; DVT = deep vein thrombosis; IR = incidence rate; n = number of patients with the event of interest; N = number of patients in the safety analysis set; NMSC = non-melanoma skin cancer; PE = pulmonary embolism.

Methods: Long-term safety of bari was assessed from 9 completed randomized trials (5 Phase 3, 3 Phase 2, 1 Phase 1b) and one ongoing long-term extension (LTE) study. Incidence rates (IR) per 100 patient-years of exposure (PYE) were calculated for all patients treated with ≥1 dose of bari through 1-Sep-2019 (All-Bari-RA analysis set). IRs for deep vein thrombosis (DVT), pulmonary embolism (PE), and DVT and/or PE (DVT/PE) were also calculated for groups of patients while receiving bari 2mg or bari 4mg within All-Bari-RA. Major adverse cardiovascular events (MACE) were adjudicated in 5 Phase 3 studies and the LTE. IRs for serious infections were evaluated by age group (< 65 vs. ≥65) through Week 24 for patients randomized to placebo and bari 4 mg in 7 Phase 2/3 trials (Bari-RA-PC analysis set) as well as within All-BARI-RA. Within All-Bari-RA, events of interest were assessed over time in 48-month intervals. In addition, to account for aging of the cohort, IRs for death and malignancy (excluding non-melanoma skin cancer [NMSC]) were directly standardized to the WHO world population 2000-2025 within each time interval.

Results: A total of 3770 patients received bari for 13,148 PYE, with a median and maximum exposure of 4.2 and 8.4 years, respectively. Overall IRs per 100 PYE for any treatment-emergent adverse event (AE) and serious AE (including death) were 25.8 and 7.2, respectively (Table). Within All Bari-RA, IRs (95% confidence intervals [CI]) for patients while receiving bari 2mg (N=1077) or bari 4mg (N=3400), respectively, were 0.4 (0.2, 0.7) and 0.3 (0.2, 0.4) for DVT, 0.3 (0.1, 0.6) and 0.3 (0.2, 0.4) for PE, and 0.5 (0.2, 0.8) and 0.5 (0.3, 0.6) for DVT/PE. In All-Bari-RA, IRs (95% CI) of serious infections for patients age < 65 and ≥65 were 2.1 (1.9, 2.4) and 4.8 (4.0, 5.7), respectively. In Bari-RA-PC, IRs (95%

Figure: Incidence rates by 48-week exposure intervals (unadjusted).



CI = confidence interval; IR = incidence rate; DVT/PE = deep vein thrombosis and/or pulmonary embolism; MACE = positively adjudicated major adverse cardiovascular events; N = number of patients with any data reported in window; NMSC = non-melanoma skin cancer; PYE = patient-years of exposure; wks = weeks.

CI) of serious infections for placebo (N=1215) and bari 4mg (N=1142) treatment groups, respectively, were 3.1 (1.6, 5.4) and 3.3 (1.8, 5.6) among patients < 65 and 9.9 (4.0, 20.4) and 7.0 (2.6, 15.2) among those ≥65. For MACE, DVT/PE, and NMSC, IRs generally remained sTable over time (Figure). There were no increases in rates of death or non-NMSC malignancy after adjustment for aging of the cohort. Across safety topics, IRs were consistent with previous analyses[1,2].

Conclusion: In this update with 13,148 PYE, bari maintained a safety profile similar to that previously reported,[1,2] with no increase of IRs across safety topics through exposures up to 8.4 years.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the safety of baricitinib in rheumatoid arthritis (RA) patients in clinical use.

Methods: An all-case post-marketing study of baricitinib, started in September 2017, collects safety and effectiveness for the first 24 weeks of treatment and continues to collect serious adverse events (SAEs) for 3 years. We report patients baseline demographics and adverse events (AEs) for patients completing the 24 weeks case report or discontinued before 24 weeks, as of December 2019.

Results: Data from 1992 patients were collected (females 80%). At dosing, the mean age was 64 years (median: 66 years), ≥65 years 54%; the mean RA duration was 11 years (median: 9 years), baricitinib dose regimen 4 mg 62%, 2 mg 27%, 4 mg → 2 mg 5%, 2 mg → 4 mg 4%, and others 3%. Pre-use of biologic DMARDs was 75% and targeted synthetic DMARDs was 21%; concomitant use of MTX was 55% and corticosteroid was 43%. 73% continued treatment for 24 weeks.

Totally, 536 patients (27%) had AEs. 4 patients died of adenocarcinoma, aspiration pneumonia, bacterial pneumonia, and pulmonary hypertension. The SAEs were 79 patients (4%): pneumonia (9), herpes zoster (5), bacterial pneumonia (4), osteonecrosis (3), anemia (3), aspiration pneumonia (3), fall (3), and femur fracture (3). The major adverse event of special interests were herpes zoster (58), serious infections (29), low hemoglobin or anemia (26), liver dysfunction (68), high lipid or hyperlipidemia (27), cardiovascular event (15), interstitial pneumonia (5), malignancy (7), and venous thromboembolism (2).

Conclusion: No new safety concern has been indicated. Encourage guideline-compliant use of baricitinib, as SAEs, including infections, have been reported.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

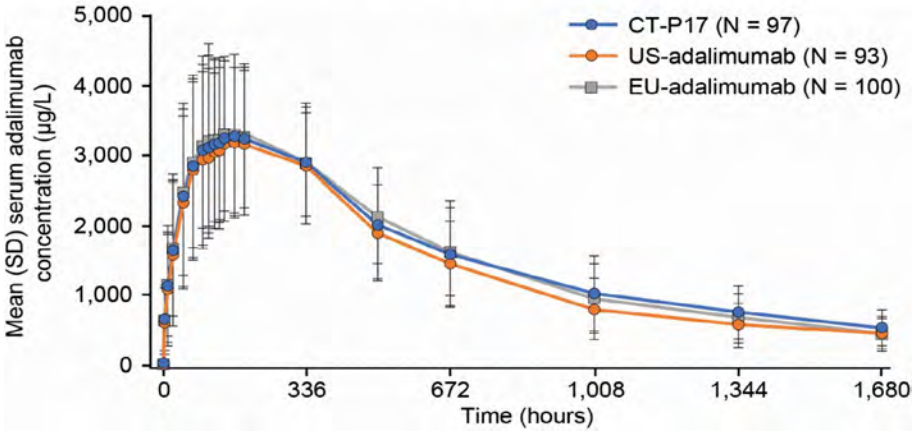
Background/Purpose: CT-P17 was developed as the first biosimilar of the high concentration (100 mg/mL), citrate-free formulation of reference adalimumab. The purpose of this study was to compare the pharmacokinetics (PK), safety, and immunogenicity of CT-P17 to EU-approved adalimumab (EU-adalimumab) and US-licensed adalimumab (US-adalimumab) up to Day 71 after a single subcutaneous (SC) injection of 40 mg (100 mg/mL) of each product in healthy subjects.

Table 1 Primary Pharmacokinetic Endpoints (Pharmacokinetic Population)

Treatment and Comparison	C_{max} (µg/mL) gLSM (n)	AUC_{0-Inf} (h·µg/mL) gLSM (n)	AUC_{0-last} (h·µg/mL) gLSM (n)
CT-P17	3.008 (96)	2,165.0 (80)	1,949.2 (96)
US-adalimumab	2.952 (93)	2,046.5 (86)	1,816.6 (93)
EU-adalimumab	3.006 (98)	2,209.3 (89)	1,933.9 (98)
Ratio (90% CI)*			
CT-P17 vs US-adalimumab	101.89 (95.33–108.89)	105.79 (97.19–115.16)	107.30 (98.29–117.13)
CT-P17 vs EU-adalimumab	100.05 (93.69–106.85)	98.00 (90.06–106.63)	100.79 (92.42–109.92)
US-adalimumab vs EU-adalimumab	98.20 (91.91–104.92)	92.63 (85.29–100.61)	93.93 (86.08–102.50)

Abbreviations: AUC0–inf, area under the concentration–time curve from time zero to infinity; AUC0–last, area under the concentration–time curve from time zero to the last quantifiable concentration; CI, confidence interval; Cmax, maximum serum concentration; EU adalimumab, European Union-approved adalimumab; gLSM, geometric least squares mean; US-adalimumab, United States-licensed adalimumab. *Ratio of geometric least squares mean and 90% CIs for the ratios

Figure 1 Mean (±SD) Serum Concentrations of Adalimumab (Pharmacokinetic Population)



Abbreviations: EU-adalimumab, European Union-approved adalimumab; SD, standard deviation; US-adalimumab, United States-licensed adalimumab.

Methods: 312 healthy subjects aged 19 to 55 years were randomly assigned 1:1:1 to receive either CT-P17, EU-adalimumab or US-adalimumab. The primary objective was to evaluate PK equivalence based on area under the concentration-time curve (AUC) from time zero to infinity (AUC_{0-inf}), AUC from time zero to the last quantifiable concentration (AUC_{0-last}), and maximum serum concentration (C_{max}). Secondary objectives were to assess additional PK parameters, safety, and immunogenicity.

Results: Demographics and baseline characteristics were well balanced among the 3 treatment groups. The 90% confidence intervals (CI) for the geometric least squares mean ratios of each of the primary PK parameters (AUC_{0-inf}, AUC_{0-last}, and C_{max}) were within the predefined equivalence margin of 80% to 125% (Table 1). Secondary PK parame-

Table 2 Summary of TEAEs (Safety Population)

Overall Adverse Events, n (%)	CT-P17 (N=102)	US-adalimumab (N=102)	EU-adalimumab (N=104)
Number of subjects with at least 1:			
TEAE	56 (54.9)	65 (63.7)	60 (57.7)
Study drug-related	45 (44.1)	49 (48.0)	49 (47.1)
TESAE	2 (2.0)	0	1 (1.0)
TEAE leading to study discontinuation	1 (1.0)	0	0
Death	0	0	0
TEAE classified as hypersensitivity/allergic reaction	1 (1.0)	0	1 (1.0)
TEAE classified as injection site reaction	20 (19.6)	16 (15.7)	19 (18.3)
TEAE classified as infection	10 (9.8)	19 (18.6)	13 (12.5)
Study drug-related	9 (8.8)	16 (15.7)	12 (11.5)
TEAE classified as malignancy	0	0	0

Abbreviations: EU-adalimumab = European Union-approved adalimumab; TEAE = treatment-emergent adverse event; TESAE = treatment-emergent serious adverse event; US-adalimumab = United States-licensed adalimumab.

ters (T_{max}, $t_{1/2}$, λ_z, CL/F, V_z/F, and $\%AUC_{extrap}$) were similar among the 3 treatment groups. Mean serum concentrations of adalimumab to Day 71 were comparable among the 3 treatment groups (Figure 1).

The overall safety profile was comparable among the 3 treatment groups (Table 2). The most frequently reported treatment-emergent adverse event (TEAE) was injection site reaction. Overall, most TEAEs were Grade 1 or 2 in intensity. There were 3 treatment-emergent serious adverse events (TESAEs), each of which was assessed as being unrelated to study drug.

Similar numbers of subjects among the 3 treatment groups tested positive for anti-drug antibodies (ADA) and neutralizing ADA (NAb). Overall, 99 (97.1%), 96 (94.1%) and 99 (95.2%) subjects in the CT-P17, US-adalimumab and EU-adalimumab groups, respectively, had ≥1 positive ADA result post-treatment and 79 (77.5%), 85 (83.3%) and 84 (80.8%) subjects in the CT-P17, US-adalimumab and EU-adalimumab groups, respectively, had ≥1 positive NAb result post-treatment. ADA titers were similar across the 3 treatment groups. AUC_{0-inf} and AUC_{0-last} each correlated negatively with ADA titer in all treatment groups (P-value < 0.0001; calculated using Fisher's z transformation). There was no statistically significant correlation of C_{max} with ADA titer.

Conclusion: This study demonstrated PK equivalence of CT-P17 to the high concentration (100 mg/mL), citrate-free formulation of both US- and EU-sourced reference adalimumab in healthy subjects. Safety profiles, including immunogenicity, were comparable among the 3 treatment groups.

Abstract Number: 0205

Methotrexate Therapy Is Not Associated with an Increased Risk of Liver Fibrosis Assessed by the Fibrosis-4 Index

Jerome Avouac[1], Raphael Degrave[2], Helene Vergneault[1] and Yannick Allanore[1], [1]Service de Rhumatologie, Hôpital Cochin, AP-HP.CUP, Paris, France, [2]Service de Rhumatologie, Hôpital Cochin, AP-HP.CUP, Paris, Ile-de-France, France

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) holds a unique place in the management of rheumatoid arthritis (RA) given its favorable balance between efficacy and safety. However, conflicting data still suggest a potential risk of MTX-induced long-term liver fibrosis. The fibrosis-4 (FIB-4) index was originally proposed as a simple and non-invasive marker of liver fibrosis in HIV/HCV co-infection. In patients with RA, FIB-4 values have been correlated to the amount of histologic liver lesions, suggesting that this index may be a valuable marker to diagnose liver disease in RA patients. Our objective was to estimate the amount of scarring in the liver with the FIB-4 index in RA patients on maintenance therapy with MTX.

Methods: We performed a cross-sectional study including successive RA patients hospitalized in the Rheumatology department of Cochin Hospital for a 12-month period. Data on liver function, disease activity, hepatotoxic and cardiovascular risk factors were systematically collected. The FIB-4 index was calculated according the following formula: (age(years) ×AST(U/L)/platelet (PLT) (109/L) × √ALT(U/L)). Using a lower cutoff value of 1.45, a FIB-4 score < 1.45 had

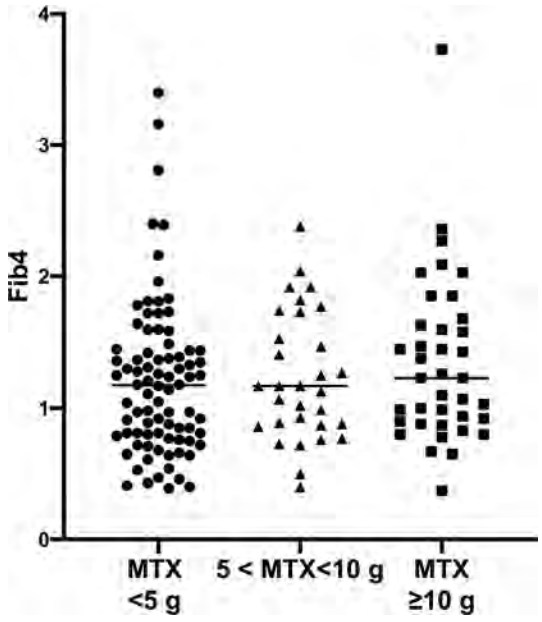

Figure 1. Fibrosis-4 index according to the cumulative dose of methotrexate in patients with rheumatoid arthritis

a negative predictive value of 90% for advanced fibrosis in the patient cohort in which this formula was first validated. In contrast, a FIB-4 >3.25 had a 97% specificity and a positive predictive value of 65% for advanced fibrosis.

Results: We included 170 patients with established RA: 141 (83%) were women, the mean age was 59±12 years and the mean disease duration was 15±11 years. Positive rheumatoid factors and anti-CCP antibodies were detected in 134 patients (79%). 102 patients (60%) were treated with methotrexate, with a mean dose of 10.0±8.4 mg/week, a mean treatment duration of 9.5±10.3 years and a cumulative dose of 5.3±5.1g. 23 patients (13.5%) received conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) other than MTX, 112 (66%) corticosteroids (99 with a dose < 10 mg/day) and 85 targeted biologic DMARDs (bDMARDs) (50%).

The mean FIB-4 value was 1.24±0.57, with 120 patients (71%) with value < 1.45, 49 (29%) with values ranging from 1.45 to 3.25 and a single patient with FIB-4 >3.25. The FIB-4 was low and not significantly different between patients receiving MTX, patients previously treated with MTX and patients never treated with MTX (median 1.1, 1.25 and 1.18, respectively, p=0.709). This result was not modified after adjustment on treatments with other csDMARDs, corticosteroids, and bDMARDs. No correlation was observed between FIB-4 values and the cumulative dose of MTX (r=0.09, p=0.271). The FIB-4 index was low and similar between patients receiving cumulative MTX doses < 5g, between 5 and 10g and 10g (Figure 1). The cumulative dose of MTX was not significantly higher in patients with a FIB-4 index >1.45 (median cumulative MTX dose 5.5g vs. 3.5g, p=0.302).

No association was detected between the FIB-4 index and parameters of disease activity (DAS28, ESR and CRP levels), the body mass index, traditional cardiovascular risk factors and metabolic syndrome.

Conclusion: RA patients with long-term maintenance MTX therapy have low FIB-4 values suggesting that MTX is not associated with an increased risk of advanced liver fibrosis.

J-HAQ (0-3)	1.16 ± 0.74	0.94 ± 0.78	< 0.01	1.24 ± 0.77	1.19 ± 0.81	< 0.01
EQ-5D (0-1)	0.66 ± 0.15	0.75 ± 0.17	< 0.01	0.62 ± 0.13	0.65 ± 0.16	< 0.01

Both groups were adjusted by propensity score matching (sex, age, disease duration, SDAI, J-HAQ, MTX use, history of biologics use, corticosteroid use and comorbidity). 95%CI means 95% Confidence Interval.

Table 3. Safety Information up to Week 52 after ABA Administration

Event	ABA (N=298)	
All AEs, n (%)	151 (50.7)	
All ADRs, n (%)	68 (22.8)	
Death, n (%)	2 (0.7)	
Serious AEs, n (%)	36 (12.1)	
Serious ADRs, n (%)	14 (4.7)	
Event	**Serious AEs**	**Serious ADRs**
Infections, n (%)	7 (2.3)	7 (2.3)
Malignancies, n (%)	9 (3.0)	3 (1.0)
Fractures, n (%)	5 (1.7)	0 (0.0)
Cardiovascular diseases, n (%)	6 (2.0)	2 (0.7)
Interstitial pneumonia, n (%)	0 (0.0)	0 (0.0)
Other, n (%)	12 (4.0)	4 (1.3)

AE, adverse event; ADR, adverse drug reaction.

Background/Purpose: Long-term clinical benefit and patient-reported outcomes (PRO) of subcutaneously-injected abatacept (ABA) in patients with RA in a real-world setting are of therapeutic interest. We conducted a non-interventional, prospective, five-year observational study (ORIGAMI study) to evaluate long-term effectiveness, safety, and PRO of ABA in Japanese patients with RA. We herein report the one-year interim results with the simplified disease activity index (SDAI) remission rate at week 52 as the primary outcome.

Methods: Biologic-naïve patients with RA who showed inadequate responses to conventional synthetic DMARDs (csDMARDs) and had SDAI-moderate disease activity were eligible. A total of 325 patients who started ABA treatment were enrolled at 64 facilities in Japan from June 2016 to October 2018. Clinical outcomes, including SDAI and PRO, were evaluated at weeks 0, 4, 24, and 52. Adverse events (AEs) were assessed during the observational period. Some of the outcomes were compared to those of csDMARDs-treated patients without concomitant biologics therapy and with SDAI-moderate disease activity. These patients were enrolled during the same period in the IORRA registry, which is a prospective, large cohort study for RA in Japan. The propensity score weighting method was used to compare the two groups.

Results: Overall, 279 patients with RA were eligible for effectiveness analyses. The mean age was 66.9 years old and the mean SDAI was 19.7. The proportions of patients with disease durations of < 2, 2 to < 10, and ≥ 10 years were 39.1%, 31.9%, and 29.0%, respectively (Table 1). The proportion of patients with SDAI remission (≤ 3.3) at week 52 was 18.9%. SDAI-low disease activity (LDA, ≤ 11) was achieved in 53.3% of the patients (Table 2). The mean score of SDAI significantly decreased from week 4 and the proportions of LDA at weeks 4, 24, and 52 were 44.6%, 68.6%, and 79.0%, respectively. Similar improvements were observed in other variables such as clinical disease activity index and DAS28-CRP. Treatment with ABA significantly lowered the J-HAQ score. The proportions of patients who achieved HAQ remission (J-HAQ ≤ 0.5) at weeks 4, 24, and 52 were 27.9%, 33.2%, and 36.2%, respectively. These represent a significant increase from 19.4% at baseline. Furthermore, improvement of EuroQol 5 Dimension (EQ-5D) was observed at week 4 and onward. The ABA group showed numerically-higher proportions of patients with SDAI remission and SDAI-LDA, as well as better control of disease activity, J-HAQ score, and EQ-5D score at week 52 than the csDMARDs group (Table 2). The safety of ABA was evaluated in 298 patients. AEs and serious AEs were reported in 151 (50.7%) and 36 (12.4%) patients, respectively. Among patients with serious AEs, malignancy and serious infection were observed in 9 (3.0%) and 7 (2.3%) patients, respectively (Table 3).

Conclusion: ABA significantly improved disease activity, physical disability, and quality of life in as early as 4 weeks of treatment, for up to 52 weeks, in patients with RA in a real-world setting. Moreover, these clinical benefits from ABA, such as improved SDAI and PRO, were apparently better than csDMARDs.

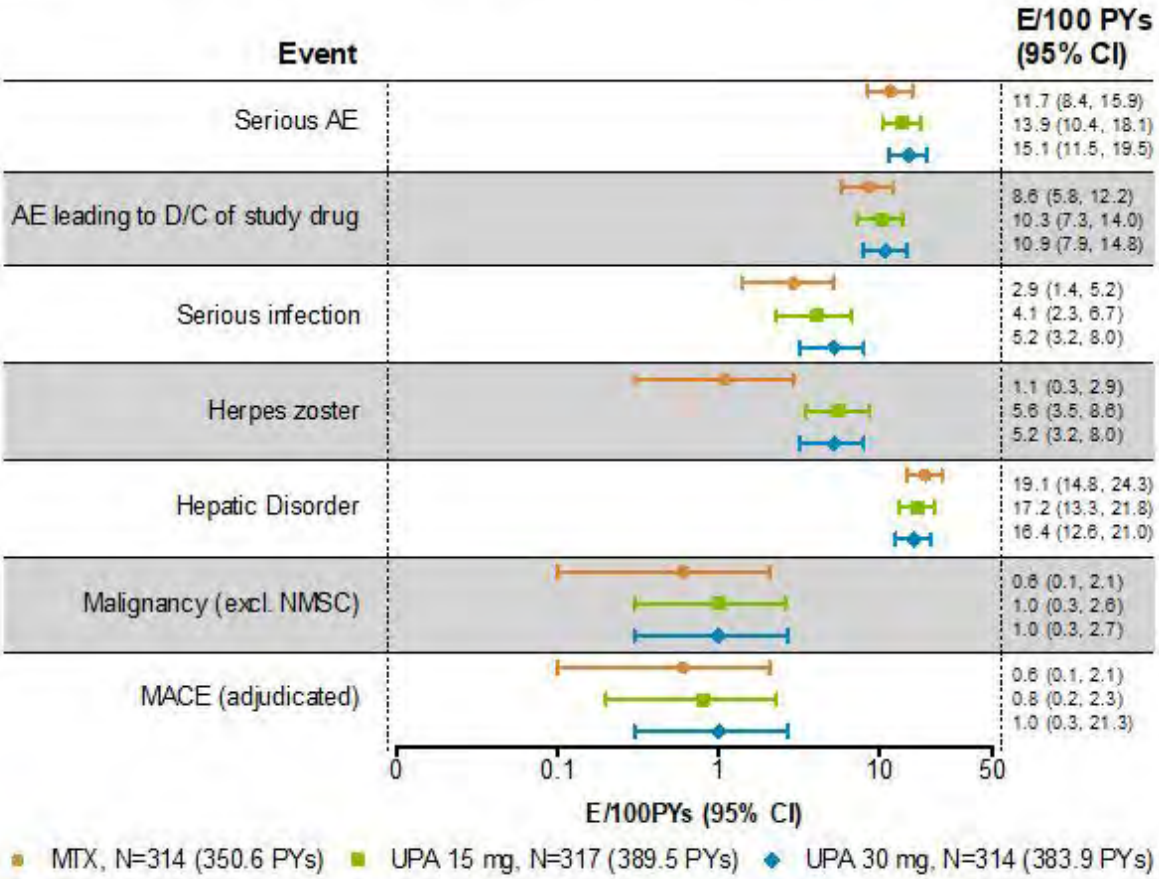
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor, demonstrated significant improvements in signs, symptoms, and structural inhibition as monotherapy vs methotrexate (MTX) in a randomized, controlled trial (RCT) of MTX-naive RA patients (pts) through 48 weeks (wks)**.**[1] We present the safety and effectiveness of UPA through 72 wks in an ongoing long-term extension (LTE) of the SELECT-EARLY RCT.

Methods: SELECT-EARLY included 2 study periods: (1) a 48-wk double-blind, active comparator-controlled, with pts randomized to UPA monotherapy 15 or 30 mg once daily or MTX (titrated to 20 mg/wk by Wk8); (2) an LTE, up to 4 years. Pts received open-label treatment once the last pt reached Wk48. Rescue therapy was added (MTX, for UPA groups; UPA, for MTX group) to pts not achieving CDAI remission (≤2.8) at Wk26. Non-responder imputation (NRI) was used for missing data as well as for pts receiving rescue therapy. Treatment-emergent adverse events (TEAEs) are summarized per 100 pt yrs (PY) through the cut-off date of 21 Feb 2019, when all pts had reached Wk72. Data are censored at the time of MTX or UPA addition among rescued patients.

Table. Proportion of Patients at Week 72 (NRI)			
Parameter (%)	MTX Monotherapy	UPA 15 mg QD Monotherapy	UPA 30 mg QD Monotherapy
ACR20/50/70	50/39/26	71***/62***/47***	72***/67***/54***
DAS28(CRP) ≤3.2/<2.6	38/28	63***/52***	69***/61***
CDAI ≤10/≤2.8	42/19	60***/35***	69***/44***
Boolean Remission	13	29***	33***
***, *P* <0.001 for differences between MTX and UPA 15 and UPA 30 mg groups. MTX, methotrexate; UPA, upadacitinib; QD, once daily; ACR, American College of Rheumatology; DAS28(CRP), 28-joint disease activity index based on C-reactive protein; CDAI, clinical disease activity index.			

Figure. Treatment-emergent Adverse Events Through ≥72 Weeks (E/100 PYs, 95% CI).



Results: Of 945 pts randomized and treated, 781 (83%) completed Period 1. Of these, 775 entered the LTE, including 57 rescued pts (MTX, 33; UPA 15 mg, 17; UPA 30 mg, 7). A total of 52 (7%) pts discontinued during the LTE through the cut-off date (primary reasons: AEs [n=16, 2.1%]; consent withdrawal [n=12, 1.5%]; lost to follow-up [n=10, 1.3%]). Cumulative exposures to monotherapy with MTX, UPA 15 mg, and UPA 30 mg were 350.6, 389.5, and 383.9 PYs, respectively. Both UPA 15 mg and 30 mg as monotherapy was associated with continued statistically significant improvements in disease activity measures vs MTX monotherapy observed at Wk 24, and maintained responses through 48 and 72 wks (**Table**). The safety profiles of the UPA 15 and 30 mg groups were comparable for total TEAEs and numerically higher than MTX. Serious TEAEs and TEAEs leading to discontinuation of study drug were comparable across all groups (**Figure**). Most AEs of special interest were comparable across MTX and UPA groups, with the exception of higher rates of herpes zoster, opportunistic infections, and elevated creatine phosphokinase among the UPA groups. Two pts receiving MTX monotherapy experienced

a venous thromboembolic event, with one event reported on UPA 30 mg and none on UPA 15 mg. There were 12 deaths (including 3 non-treatment-emergent) due to varied causes.

Conclusion: Long-term UPA monotherapy was associated with maintained improvements in RA signs and symptoms vs MTX monotherapy through 72 wks, and only a small proportion of pts required MTX addition at Wk26. Through 72 wks of treatment, the safety profile of UPA monotherapy remained consistent with data reported through 48 wks.[1]

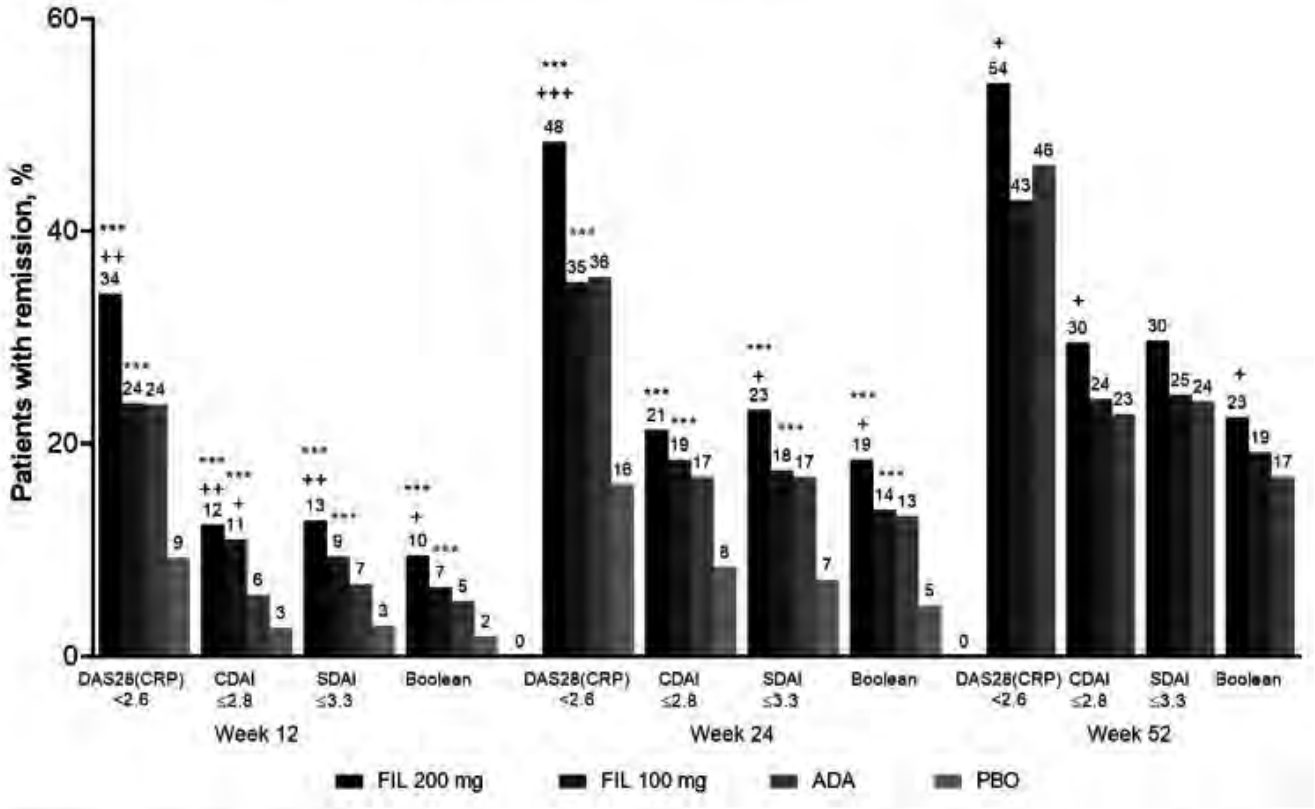
ADA, adalimumab; AE, adverse event; FIL, filgotinib; MACE, major adverse cardiac events; NMSC, nonmelanoma skin cancer; PBO, placebo; SAE, serious AE; TE, treatment-emergent; TEAE, treatment-emergent AE; VTE, venous thromboembolism.

Background/Purpose: Filgotinib (FIL) is an oral, potent, selective Janus kinase 1 (JAK1) inhibitor. FINCH 1 (NCT02889796) assessed FIL efficacy and safety in patients (pts) with rheumatoid arthritis (RA) with an inadequate response to methotrexate (MTX-IR); primary outcome results at week (W)12 and W24 were previously reported.[1] This analysis presents results from the FINCH 1 study through 52 weeks.

Methods: This global, phase 3, double-blind, active- and placebo (PBO)-controlled study randomized MTX-IR pts with active RA on a background of sTable MTX 3:3:2:3 to oral FIL 200 mg or FIL 100 mg once daily, subcutaneous adalimumab (ADA) 40 mg every 2W, or PBO up to W52; pts receiving PBO at W24 were rerandomized to FIL 100 or 200 mg. Efficacy was assessed using clinical, radiographic, and pt-reported outcomes; W52 comparisons were not adjusted for multiplicity, and nominal p-values are reported. Safety endpoints included types and rates of adverse events (AEs) and laboratory abnormalities.

Results: Of 1755 treated pts, 1417 received study drug through W52. The majority (81.8%) were female, mean (standard deviation [SD]) RA duration was 7.8 (7.6) years, and baseline mean (SD) DAS28(CRP) was 5.7 (0.9). FIL ef-

Figure 1. Patients in remission at weeks 12, 24, and 52



***, p vs PBO <0.001, not adjusted for multiplicity except DAS28(CRP) at week 12; +, p vs ADA <0.05; ++, p vs ADA <0.01; +++, p vs ADA <0.001; not adjusted for multiplicity. ADA, adalimumab; FIL, filgotinib; PBO, placebo.
Non-responder imputation. Logistic regression model with treatment groups and stratification factors for treatment comparisons.

ficacy was sustained through W52; 54%, 43%, and 46% of pts receiving FIL 200 and 100 mg and ADA, respectively, had W52 DAS28(CRP) < 2.6 (nominal p for FIL 200 vs ADA = 0.024) (**Figure 1, Table 1**). FIL safety profile through W52 was consistent with W24 data. AEs of interest were infrequent and balanced among treatments (**Table 2**).

Conclusion: Through W52, both FIL 200 and 100 mg showed sustained efficacy based on clinical and pt-reported outcomes and radiographic progression and were well tolerated in MTX-IR pts with RA.

Upadacitinib as Monotherapy in Patients with Rheumatoid Arthritis and Prior Inadequate Response to Methotrexate: Results at 84 Weeks

Josef Smolen[1], Paul Emery[2], William Rigby[3], Yoshiya Tanaka[4], Juan Vargas[5], Nemanja Damjanov[6], Manish Jain[7], Yanna Song[8], Nasser Khan[9], Jeffrey Enejosa[9] and Stanley Cohen[10], [1]Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds, United Kingdom, [3]Dartmouth College, Norwichi, VT, [4]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, [5]Quantum Research, Puerto Varas, Chile, [6]University of Belgrade Medical School, Belgrade, Serbia, [7]Great Lakes Clinical Trials, Chicago, IL, [8]AbbVie Inc., North Chicago,, IL, [9]AbbVie Inc., North Chicago, IL, [10]Metroplex Clinical Research Center, Dallas, TX

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In the SELECT-MONOTHERAPY trial, upadacitinib (UPA), an oral JAK inhibitor, demonstrated significantly greater efficacy compared to continuing methotrexate (MTX) when used as monotherapy over 14 weeks (wks) in patients (pts) with rheumatoid arthritis (RA) and prior inadequate response to MTX.[1] Here we describe the long-term safety and efficacy of UPA monotherapy in an ongoing long-term extension (LTE) of the SELECT-MONOTHERAPY trial.

Methods: Pts on sTable MTX were randomized to either continue MTX (cMTX, given as blinded study drug) or switch to once-daily (QD) UPA 15 (UPA15) or 30 (UPA30) mg monotherapy for 14 wks. From Wk14, pts could enter a blinded LTE and continue to receive UPA15 or UPA30; pts randomized to cMTX were switched to UPA15 or UPA30 per pre-specified assignment at baseline. Treatment-emergent adverse events (TEAEs) per 100 pt yrs (PYs) of exposure are summarized up to a cut-off data of 5 February 2019, when all pts had reached Wk84. Efficacy outcomes through Wk84 are reported as observed and using non-responder imputation.

Results: Of 648 pts randomized, 598 (92%) completed 14 wks and entered the LTE on blinded UPA. By the cut-off date, 20% in total had discontinued due to the following: AE (6%), consent withdrawal (4%), lost to follow-up

Figure. Treatment-emergent Adverse Events Through ≥84 Weeks (E/100 PYs, 95% CI).

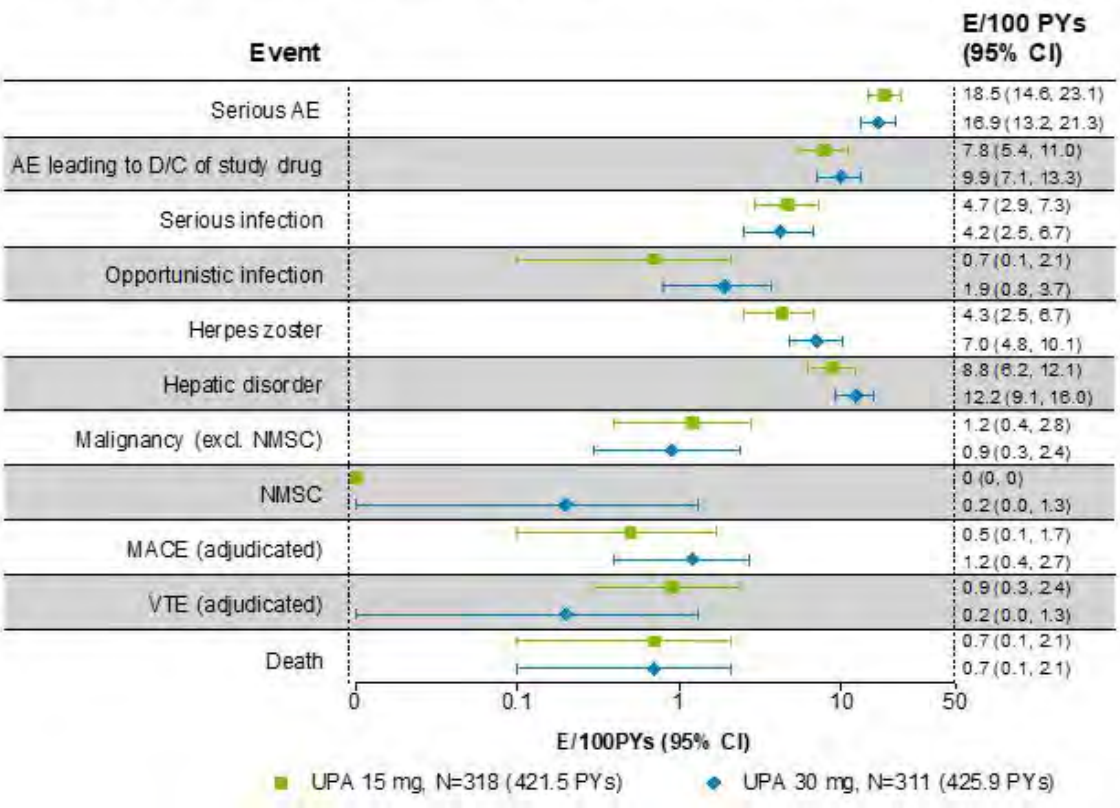

Table. Proportion of Patients at Week 84

Parameter (%)	cMTX→UPA 15 mg n=108		cMTX→UPA 30 mg n=108		UPA 15 mg n=217		UPA 30 mg n=215

AO, as observed; NRI, non-responder imputation.

(2%), lack of efficacy (1%), or other reasons (7%). Cumulative exposures were 421.5 and 425.9 PYs for UPA15 and UPA30, respectively. The most frequently reported TEAEs were urinary tract infection, creatine phosphokinase (CPK) increase, upper respiratory tract infection, nasopharyngitis, worsening of RA, bronchitis, herpes zoster (HZ), and alanine aminotransferase increase; the most common serious AE was pneumonia. Events of HZ, hepatic disorder, and CPK elevations were higher among pts receiving UPA30, while rates of serious infection and malignancy appeared comparable between doses (**Figure**). Most HZ events involved 1-2 dermatomes, with a single disseminated cutaneous event (UPA30) and none with CNS involvement. Five patients experienced MACE, and there were 5 VTE events (UPA15: 4; UPA30: 1). All MACE and VTE events occurred in pts with underlying risk factors. Pts continuing to receive UPA15 and UPA30 achieved stringent endpoints at Week 84 (**Table**). Pts who switched from cMTX to UPA15 or UPA30 demonstrated comparable efficacy responses to those initially randomized to UPA.

Conclusion: The adverse event profile associated with long-term exposure to UPA15 or 30 as monotherapy was consistent with an integrated analysis of UPA safety across the entire phase 3 program, with no new safety signals identified. Further, UPA15 or 30 monotherapy resulted in continued and sustained improvements in RA signs and symptoms through 84 wks.

Abstract Number: 0210

Long-term Safety and Efficacy of Sarilumab over 5 Years in Patients with Rheumatoid Arthritis Refractory to Tumor Necrosis Factor Inhibitors

Roy Fleischmann[1], Karina Maslova[2], Henry Leher[3], Amy Praestgaard[2] and Gerd Burmester[4], [1]Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX, [2]Sanofi, Cambridge, MA, [3]Regeneron Pharmaceuticals, Inc, Tarrytown, NY, [4]Charité University Hospital Berlin, Berlin, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarilumab is a human IL-6 receptor (IL-6R) inhibitor approved for the treatment of adults with moderate to severely active RA. In the TARGET study (NCT01709578), sarilumab significantly improved signs and symptoms of RA and physical function versus placebo in patients refractory to TNF inhibitors who were receiving background treatment with conventional synthetic DMARDs. Here we report the long-term safety and efficacy of subcutaneous (SC) sarilumab over 5 years in patients who continued treatment in the open-label extension (OLE) study, EXTEND (NCT01146652).

Methods: Patients who received double-blind placebo, sarilumab 150 mg, or sarilumab 200 mg every 2 weeks (q2w) in the 24-week randomized controlled trial TARGET were eligible to receive open-label sarilumab 200 mg q2w during EXTEND, with dose reduction to 150 mg q2w permitted to manage laboratory abnormalities or per investigator's dis-

[a]Including placebo patients from the double-blind phase who switched to sarilumab 200 mg in the OLE; [b]Any dose includes exposure on all sarilumab doses; [c]In summary, rates (AEs/100 PY) were calculated over time to first event; [d]The TEAEs associated with the 5 instances of death were septic shock, acute pulmonary edema, myocardial infarction, pneumonia, and metastatic gallbladder cancer; [e]Includes cardiovascular death, myocardial ischemia, stroke, hospitalization for unstable angina, or hospitalization for transient ischemic attack; [f]Upon medical review, the 4 cases of diverticulitis/potential GI perforation were determined to be colonic abscess (n=1), peritonitis (n=1), and diverticulitis (n=2); AE=adverse event; GI=gastrointestinal; OLE=open-label extension; PY=patient-years; q2w=every 2 weeks; SAE=serious AE; TEAE=treatment emergent AE

Table 1

cretion. Safety outcomes are presented for the EXTEND population for the follow-up from TARGET baseline through EXTEND cut-off date (January 15, 2019). Efficacy assessments included Clinical Disease Activity Index (CDAI) score and the proportion of responders (CDAI ≤10 and ≤2.8) over time.

Table 2. Proportion of responders*

	Assigned TARGET Treatment		
	Placebo + DMARD	Sarilumab 150 mg + DMARD	Sarilumab 200 mg + DMARD
	EXTEND Treatment		
	Sarilumab 200 mg + DMARD (n=156)	Sarilumab 200 mg + DMARD (n=145)	Sarilumab 200 mg + DMARD (n=153)
CDAI ≤2.8, n (%)			
OLE baseline	21 (13)	26 (18)	23 (15)
After 192 weeks' follow-up	17 (11)	28 (19)	28 (18)
CDAI ≤10, n (%)			
OLE baseline	62 (40)	75 (52)	76 (50)
After 192 weeks' follow-up	57 (37)	61 (42)	66 (43)

*Nonresponder imputation; ITT values used as denominators. CDAI= Clinical Disease Activity Index; ITT=intent to treat; OLE=open-label extension

Table 2

Results: Of the 546 patients randomized in TARGET, 454 (83%) entered EXTEND and were treated with open-label sarilumab 200 mg (original placebo group, n=156; sarilumab 150 mg, n=145; sarilumab 200 mg, n=153). At EXTEND baseline, demographic and clinical characteristics were similar between previous treatment groups from TARGET. Overall, 81% of patients in EXTEND were women, mean age was 53 years, and mean RA duration was 12 years. At the time of data cut-off, 199 (36%) patients had discontinued treatment, of whom 100 (18%) had discontinued due to treatment-emergent adverse events (AEs), 27 (5%) due to lack of efficacy, and 68 (13%) due to other reasons. Cumulative exposure to sarilumab through TARGET and EXTEND (n=521) was 1655 patient-years (PY), with 268 (51%) patients having ≥4 years' exposure (Table 1). Overall, there were 160 TEAEs/100 PY, 10 serious AEs/100 PY, 8 AEs/100PY leading to discontinuation, and 0.3/100 PY leading to death (Table 1). The most common AEs were neutropenia (15/100 PY) and injection site erythema (12/100 PY; Table 1). Absolute neutrophil count < 1000 cells/mm^3 (Grade 3–4 neutropenia) was observed in 74 (14%) patients, and normalized on treatment in 65% (48/74) of those patients. Alanine aminotransferase above 3-fold the upper limit of normal was observed in 46 patients (9%) and normalized on treatment in 54% (25/46) of those patients. Infections and serious infections occurred at rates of 58/100 PY and 4/100 PY, respectively. Clinical efficacy was sustained through 5 years of EXTEND (Table 2). At EXTEND Week 240 (n=95), mean ± SD change in CDAI score from TARGET baseline was –31 ± 15.

Conclusion: The safety profile of sarilumab was consistent with results of phase 3 trials, IL-6R inhibition, and SC administration, and no new safety signals were identified over 5 years of follow-up in patients with RA refractory to TNF inhibitors. Clinical efficacy was sustained through 5 years' follow-up.

Abstract Number: 0211

Efficacy and Safety of Upadacitinib in Patients from China, Brazil, and South Korea with Rheumatoid Arthritis Who Have Had Inadequate Response to Conventional Synthetic Disease-modifying Antirheumatic Drugs

Xiaofeng Zeng[1], Dongbao Zhao[2], Sebastiao Radominski[3], Mauro Keiserman[4], Chang Keun Lee[5], Sebastian Meerwein[6], Jeffrey Enejosa[7], Yunxia Sui[7], Mohamed-Eslam Mohamed[7] and Won Park[8], [1]Department of Rheumatology, Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Beijing, China (People's Republic), [2]Shanghai Changhai Hospital, Shanghai, China (People's Republic), [3]Universidade Federal do Paraná, Curitiba, Brazil, [4]Pontificial Catholic University, Porto Alegre, Brazil, [5]Asan Medical Center, Seoul, Republic of Korea, [6]Pharmaceutical Development, AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany, [7]AbbVie Inc., North Chicago, IL, [8]Inha University, Incheon, Republic of Korea

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: This Phase 3, randomized, double-blind, placebo (PBO)-controlled study assessed the efficacy and safety of upadacitinib (UPA) in combination with csDMARDs in patients with rheumatoid arthritis (RA) from China, Brazil and South Korea who had an inadequate response to csDMARDs (csDMARD-IR).

Table 1. Efficacy endpoints at Week 12

Endpoint[a]	UPA 15 mg QD (n=169)	PBO (n=169)
Primary endpoint		
ACR20, %	71.6***	31.4
Secondary endpoints		
Δ DAS28(CRP)	-2.56***	-0.95
Δ HAQ-DI	-0.62***	-0.18
Δ SF-36 PCS	8.93[c]***	3.36[d]
DAS28(CRP) ≤3.2, %	46.2***	13.6
DAS28(CRP) <2.6, %	29.6***	5.3
CDAI ≤10, %	35.5***	11.2
ACR50, %[b]	40.8***	8.3
ACR70, %[b]	21.3***	3.6
ACR20 at Week 1, %[b]	25.4***	5.9

***p<0.001 versus PBO

[a]NRI for binary endpoints; ANCOVA with multiple imputation for DAS28(CRP) and HAQ-DI; mixed model repeated measures for other continuous endpoints.

[b]Unranked secondary endpoint. [c]n=143 [d]n=149

Methods: Patients were randomized 1:1 to receive UPA 15 mg once daily (QD) or PBO in combination with csDMARDs. The primary endpoint was ACR20 response at Week 12, using non-responder imputation.

Results: 338 patients were randomized, and 310 (91.7%) completed Week 12. At Week 12, statistically significantly more patients receiving UPA vs PBO achieved the primary endpoint of ACR20 (71.6% vs 31.4%, $p< 0.001$). UPA also demonstrated statistically significantly improvements in all ranked secondary endpoints vs PBO at Week 12 (Table 1), including mean change in DAS28(CRP), HAQ-DI, and SF-36 PCS, and patients achieving DAS28(CRP) ≤3.2, DAS28(CRP) < 2.6 and CDAI≤10. Greater responses were also seen with UPA vs PBO for other key secondary endpoints including ACR50 and ACR70. Onset of UPA action was rapid with more patients on UPA achieving ACR20 by Week 1 (25.4% vs 5.9%, $p< 0.001$). The frequency of AEs (61.5% vs 49.1%) and serious AEs (7.1% vs 3.0%) was higher with UPA versus PBO. The frequency of AEs of special interest was generally similar between UPA and PBO, with the exception of herpes zoster (1.8% vs 0.6%), hepatic disorders (9.5% vs 7.1%), neutropenia (3.0% vs 0%), and elevated creatine phosphokinase (1.8% vs 0.6%), which were higher with UPA. One case of breast cancer (on Day 1 of study) and one VTE (pulmonary embolism and deep vein thrombosis in a patient with history of deep vein thrombosis) were reported with UPA treatment.

Conclusion: Efficacy of UPA was demonstrated in this csDMARD-IR population from China, Brazil, and South Korea. The safety of UPA was comparable with the global Phase 3 program.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: We report safety/efficacy of upadacitinib (UPA) vs adalimumab (ADA) up to 72 weeks (wks) in patients (pts) with rheumatoid arthritis from the ongoing long-term extension (LTE) of SELECT-COMPARE.

Methods: Pts were randomized to once-daily UPA 15mg, placebo (PBO), or ADA 40mg every other wk. Pts were rescued at Wks 14/18/22 from UPA to ADA, ADA to UPA or PBO to UPA if they met protocol-specified rescue criteria; at Wk26 all remaining patients with CDAI >10 were rescued as above with all remaining PBO pts switched to UPA. Pts continued UPA or ADA in a blinded manner until the last pt completed the Wk48 visit. Completers entered the LTE. Treatment-emergent adverse events (TEAEs)/100PY were summarized up to December 26 2018. Efficacy was analyzed by randomized group. NRI was used for binary endpoints for rescue prior to Wk26.LOCF was used for continuous and binary endpoints for rescue at Wk26.

Results: 1629 pts were randomized (UPA: 1209 [399 non-switched; 159 switched from ADA; 651 from PBO]; ADA: 420 [168 non-switched; 252 switched from UPA]); 1403 entered the LTE. Cumulative exposures were 1396.7 and 515.1 PYs for UPA and ADA, respectively. TEAEs/100PY of any AEs and serious AEs for UPA vs ADA were 266.3 vs 299.4 and 12.7 vs 15.9, respectively. AE of special interest (AESIs)/100PY for UPA vs ADA were 3.7 vs 4.3 for serious infections, 0.9 vs 0.6 for opportunistic infections, 0.7 vs 1.0 for malignancy, 0.4 vs 0.6 for adjudicated MACE, 0.3 vs 1.0 for VTE, and 0.6 vs 1.2 for deaths. The event rates were numerically higher with UPA vs ADA for herpes zoster (3.1 vs 1.2), hepatic disorder (17.3 vs 14.0), and CPK elevation (5.6 vs 2.1). At Wk72, ACR20/50/70 was achieved by 64/51/38% vs 53/38/25% of pts on UPA and ADA ($p< .01/.001/.001$), DAS28-CRP$\leq$3.2/$<$ 2.6 by 49/41% vs 32/26% ($p< .001$), and CDAI$\leq$10/$\leq$2.8 by 46/28% vs 33/17% ($p< .001$), respectively.

Conclusion: UPA continued to demonstrate a safety profile consistent with observations through 48 wks and durable clinical efficacy.[1]

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

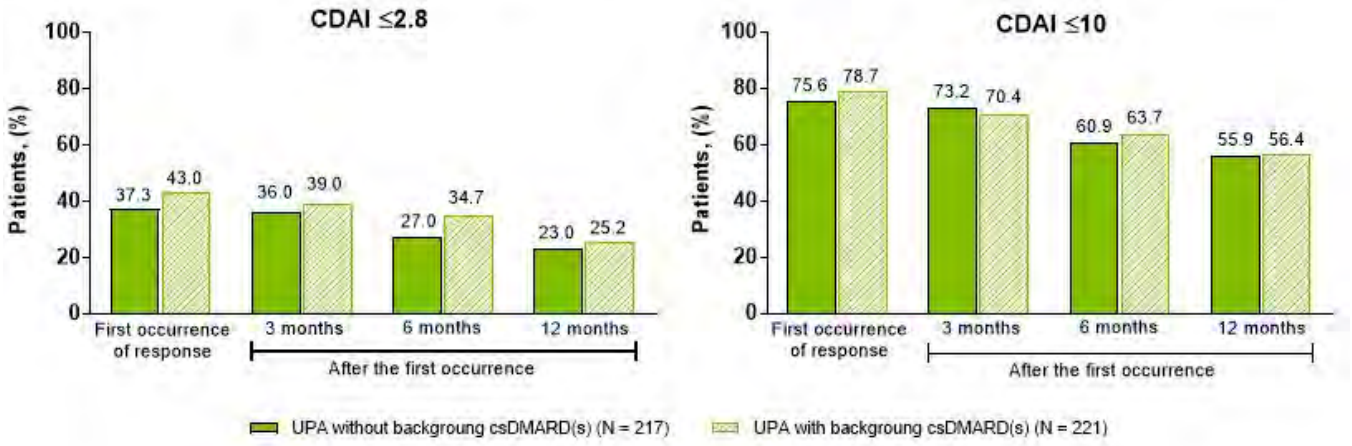
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To assess long-term sustainability of responses to upadacitinib (UPA), a JAK inhibitor, with or without background csDMARD(s) in patients (pts) with rheumatoid arthritis (RA).

Methods: Data are from two phase 3 trials of UPA in RA pts with roughly similar baseline disease characteristics: SELECT-NEXT enrolled pts with inadequate response (IR) to csDMARD(s) on background sTable csDMARD(s) receiving UPA 15 or 30 mg once daily or placebo for 12 wks; SELECT-MONOTHERAPY enrolled methotrexate (MTX)-IR pts receiving UPA 15 or 30 mg monotherapy or blinded MTX for 14 wks. After 12/14 wks, pts could receive UPA 15 or 30 mg up to 5 years in a blinded long-term extension. This post hoc analysis evaluated clinical remission (REM:CDAI ≤2.8; SDAI ≤3.3), low disease activity (LDA:CDAI≤10; SDAI≤11), and DAS28(CRP) < 2.6/≤3.2 at first occurrence before Wk 84; these were also evaluated at 3, 6, and 12 months after the first occurrence for total number of pts

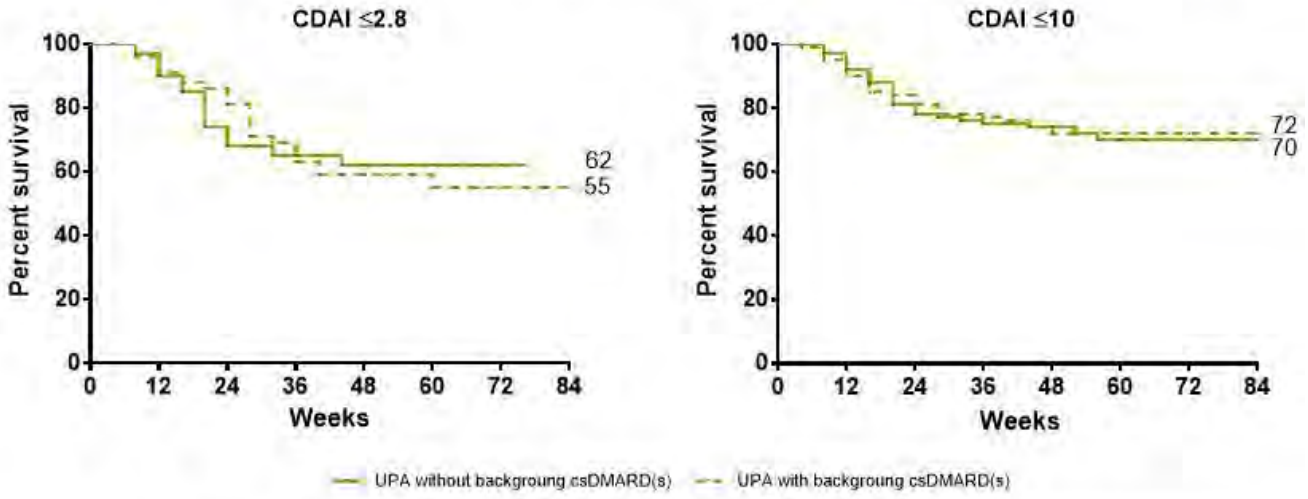
Figure 1. Proportion of patients sustaining CDAI remission or low disease activity at 3, 6, and 12 months after the first occurrence of response among the total randomized population



UPA, upadacitinib; csDMARD, conventional synthetic disease-modifying anti-rheumatic drugs; CDAI, Clinical Disease Activity Index; N, total number of patients randomized to UPA with or without background csDMARD(s).

Data for patients who maintained response through the cut-off (22 March, 2018 for SELECT-NEXT and 25 May, 2019 for SELECT-MONOTHERAPY, when all patients had reached Week 84 visit) were censored. Data are summarized, with no adjustments applied to account for between-study differences. Non-responder imputation was used for missing data.

Figure 2. Kaplan-Meier analysis of time to loss of CDAI remission or low disease activity after the first occurence of response



UPA, upadacitinib; csDMARD(s), conventional synthetic disease-modifying anti-rheumatic drugs; CDAI, Clinical Disease Activity Index; N, number of patients who had achieved CDAI remission or low disease activity.

Results are for patients who had achieved CDAI remission or low disease activity. UPA without backgroung csDMARD(s): CDAI ≤2.8: n = 81;CDAI ≤10: n = 164. UPA with backgroung csDMARD(s): CDAI ≤2.8: n = 95; CDAI ≤10: n = 174.

Data for patients who maintained response through the cut-off (22 March, 2018 for SELECT-NEXT and 25 May, 2019 for SELECT-MONOTHERAPY, when all patients had reached Week 84 visit) were censored. Data are summarized, with no adjustments applied to account for between-study differences. Non-responder imputation was used for missing data. Week 0 indicates the first occurrence of response.

2. ACR: Singh et al. Arthritis & Rheumatology Vol. 68, No. 1, January 2016, pp 1–26.
   Original abs: *Ann Rheum Dis.* 2020; 79(S1):323.

randomized to UPA 15 mg. Sustainability was evaluated by Kaplan-Meier for pts who achieved REM/LDA and was defined as time to the earliest date of losing response at two consecutive visits or discontinuation of study drug. Predictive ability of time to clinical REM/LDA was assessed using Harrell's concordance (c)-index (~ 0.5, no ability to predict; closer to1 or -1, perfect prediction). Last follow up dates were 22 March 2018 (SELECT-NEXT) and 25 May, 2019 (SELECT-MONOTHERAPY), when all pts reached the Week 84 visit.

Results: Through Wk 84, CDAI REM/LDA was achieved in 43%/79% of pts receiving UPA 15 mg with background csDMARD(s) (SELECT-NEXT) and 37%/76% without background csDMARD(s) (SELECT-MONOTHERAPY). 35%/25% of pts randomized to UPA 15 mg with background csDMARD(s) and 27%/23% without background csDMARD(s) achieved sustained CDAI REM through 6/12 months after first occurrence. 64%/56% of pts randomized to UPA 15 mg with background csDMARD(s) and 61%/56% without background csDMARD(s) achieved sustained CDAI LDA through 6/12 months after first occurrence (**Figure 1**). Time to initial clinical REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15 mg with background csDMARD(s) and without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15 mg with background csDMARD(s) and 62% without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CDAI LDA, respectively (**Figure 2**). Similar results were observed across other disease activity measures (SDAI REM/LDA and DAS28(CRP) < 2.6/≤3.2).

Conclusion: More than a quarter and more than a half of pts with RA and prior IR to csDMARD(s) receiving UPA with or without background csDMARD therapy achieved sustained clinical REM and LDA, respectively, across disease

activity measures. Sustainability of responses appeared comparable among pts receiving UPA with or without background csDMARDs through up to 84 wks.

   Original abs: *Ann Rheum Dis.* 2020; 79(S1):643.

Background/Purpose: The primary treatment goal for patients(pts) with rheumatoid arthritis(RA) is a state of sustained clinical remission(REM) or low disease activity(LDA).[1,2] W**e** assess long-term sustainability of response to upadacitinib(UPA), a JAK inhibitor, and adalimumab(ADA), both with background methotrexate(MTX), among pts with RA and prior inadequate response to MTX.

Methods: In the phase 3, randomized, placebo(PBO) and active-controlled SELECT-COMPARE trial, pts on sTable background MTX received UPA 15 mg once daily, PBO, or ADA 40mg every other week. Pts not achieving 20% improvements in tender/swollen joint counts(Weeks 14-22) or LDA(CDAI ≤10 at Week 26) were rescued from UPA to ADA or PBO/ADA to UPA; all non-rescued PBO pts were switched to UPA at Week 26. This post hoc analysis evaluated clinical REM(CDAI ≤2.8; SDAI ≤3.3), LDA(CDAI≤10; SDAI≤11), and DAS28(CRP) < 2.6/≤3.2 at first occurrence before Week 72 or prior to treatment switch; additionally, these measures were evaluated at 3, 6, and 12 months after the first occurrence for total number of pts randomized to UPA(n=651) or ADA(n=327). Sustainability of response was evaluated by Kaplan-Meier only for pts who achieved REM/LDA and was defined as time to the earliest date of losing response at two consecutive visits, discontinuation of study drug, or losing response at time of rescue. The predictive ability of time to clinical REM/LDA was assessed using Harrell's concordance (c)-index (for reference, an index ~ 0.5, indicates no ability to predict; an index of 1 or -1 would be a perfect prediction). The date of last follow up was 6 July, 2018, when all pts reached the Week 72 visit.

Results: Through Week 72, a significantly higher proportion of pts receiving UPA + MTX vs ADA + MTX achieved CDAI REM(41% vs 31%, p=.0035) as well as CDAI LDA(70% vs 59%, p=.0007). 26%/22% of pts randomized to UPA + MTX and 16%/14% of pts randomized to ADA + MTX achieved sustained CDAI REM at 6/12 months after the first occurrence. Additionally, 49%/46% of pts randomized to UPA + MTX and 36%/34% of pts randomized to ADA + MTX achieved sustained CDAI LDA at 6/12 months after the first occurrence(**Figure 1**). Time to initial clinical REM/LDA did not appear to be associated with sustained disease control. The c-indices (95% CI) for CDAI REM in the UPA +MTX and ADA + MTX groups were 0.528(0.48, 0.58) and 0.510(0.43, 0.59) and that of LDA were 0.601(0.56, 0.64) and 0.555(0.50, 0.61), respectively. Through last follow-up visit, 51% of UPA + MTX pts and 45% of ADA + MTX pts remained in CDAI REM while 65% of UPA + MTX pts and 58% of ADA + MTX pts remained in CDAI LDA, respectively(**Figure 2**). Similar results were observed across other disease activity measures(SDAI REM/LDA and DAS28(CRP) < 2.6/≤3.2).

Conclusion: A significantly greater proportion of pts with RA and prior inadequate response to MTX receiving UPA + MTX vs ADA + MTX achieved clinical REM or LDA across disease activity measures. REM and LDA were sustained through Week 72 in both treatment arms, with numerically higher proportions retaining response among UPA-treated pts.

population (~2-fold increase).[1] Beyond RA, additional risk factors have been described, with prior history of VTE and obesity posing particular risk. VTE events have been observed in pts receiving JAK inhibitors, including upadacitinib (UPA). We describe the incidence of VTE in pts with RA receiving UPA relative to active comparators in the phase 3 clinical trial program and to evaluate potential risk factors.

Methods: Adjudicated events of treatment-emergent VTE were determined in pts receiving UPA in an integrated analysis (data cut-off, 30 Jun 2019) of five randomized phase 3 trials (SELECT-EARLY, SELECT-MONOTHERAPY, SELECT-NEXT, SELECT-COMPARE, and SELECT-BEYOND), of which 4 evaluated both the UPA 15 mg and 30 mg QD doses and 1 (SELECT-COMPARE) evaluated only UPA 15. Incidence of VTE was also determined in pts receiving adalimumab (ADA) + methotrexate (MTX) in SELECT-COMPARE and MTX monotherapy in SELECT-EARLY. Events are attributed to treatment received at time of event and are summarized per events/100 patient yrs. VTE risk factors were assessed using univariate Cox regression models.

Results: A total of 35 VTE events were observed across treatment groups. The exposure-adjusted treatment-emergent event rates (E/100 PYs, 95% CI) of VTE were 0.5 (0.3, 0.7) for UPA 15, 0.3 (0.1, 0.7) for UPA 30, 0.5 (0.1, 1.3) for ADA + MTX, and 0.4 (0.1, 1.6) for MTX, with no pattern to event onset across treatments. Events of PE, DVT, or both PE and DVT were reported across treatment groups (**Table**). Pts who experienced VTE, across all treatment groups, on average, were older than pts who did not (62/59/58/61 yrs vs 54/55/54/53 yrs for UPA 15, UPA 30, ADA + MTX, and MTX, respectively). The mean body mass index (BMI) of pts with VTE tended to be higher (34–40 for pts with VTE vs 28-29 kg/m^2 for those without). Across UPA treatment groups, 135/2629 (UPA 15) and 62/1204 (UPA 30) pts had a prior history of VTE; of these pts, 5 (3.7%) and 2 (3.2%) experienced VTE on UPA 15 and UPA 30, respectively. Univariate Cox regression models identified BMI and prior history of VTE as factors associated with VTE in the UPA 15 and 30 mg groups (**Figure**). Age and NSAID use were shown to be associated with VTE risk among pts in the UPA 15 but not 30 mg group.

Conclusion: VTE event rates appeared balanced across UPA doses and active comparator groups in pts with RA. Risk factors for VTE events identified through univariate analyses in pts who received UPA included prior history of VTE and BMI, two factors previously known to be associated with VTE risk. One limitation is the small sample size, limiting the analysis to univariate. Continued follow-up of pts receiving UPA is ongoing to further contextualize the risk of VTE in the clinical trial program.

Figure: VTE Risk Factors in Patients Receiving UPA 15 or 30 mg QD Through Univariate Cox Regression

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite effective treatments, many patients (pts) with rheumatoid arthritis (RA) have inadequate responses to biologic DMARDs (bDMARD-IR), highlighting an unmet need. It is unclear whether prior bDMARD use affects efficacy of the oral, selective JAK-1 inhibitor filgotinib (FIL). This analysis explored the clinical response to FIL in bDMARD-IR pts stratified by mode of action (MOA) and number of prior bDMARDs.

Methods: The global, phase 3 FINCH-2 (NCT02873936) study treated 448 bDMARD-IR pts with active RA.[1] Pts were randomized 1:1:1 to once-daily FIL 200 mg, FIL 100 mg, or placebo (PBO) for 24 weeks. Efficacy was assessed by percent of pts achieving low disease activity (LDA) or remission at week (W)24 as measured by CDAI and DAS28(CRP)

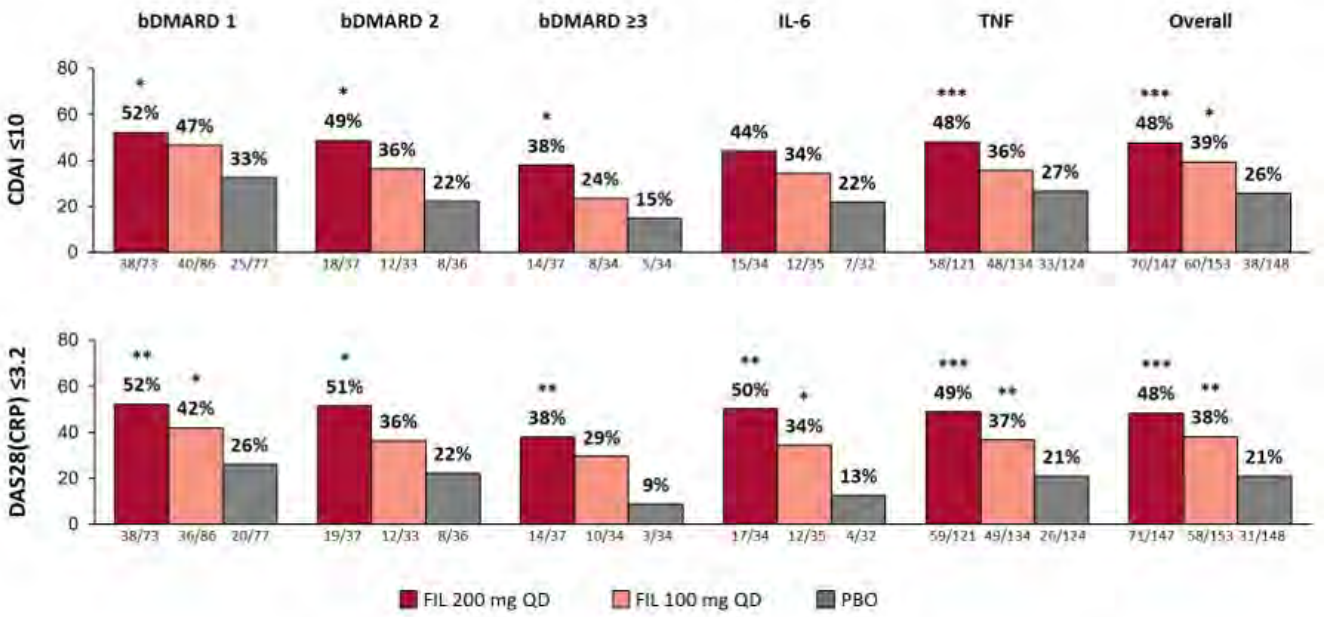
Table. Number and MOA of prior bDMARDs

	FIL 200 mg = 147	n FIL 100 mg n = 153	PBO n = 148	Total N = 448
Prior bDMARDs				
1	73 (49.7)	86 (56.2)	77 (52.0)	236 (52.7)
2	37 (25.2)	33 (21.6)	36 (24.3)	106 (23.7)
≥3	37 (25.2)	34 (22.2)	34 (23.0)	105 (23.4)
LOE ≥1 bDMARD	125 (85.0)	129 (84.3)	126 (85.1)	380 (84.8)
Intolerance ≥1 bDMARD	36 (24.5)	34 (22.2)	32 (21.6)	102 (22.8)
Prior TNFi	121 (82.3)	134 (87.6)	124 (83.8)	379 (84.6)
LOE ≥1 TNFi	97 (66.0)	113 (73.9)	103 (69.6)	313 (69.9)
Intolerance ≥1 TNFi	25 (17.0)	24 (15.7)	24 (16.2)	73 (16.3)
Prior non-TNFi	73 (49.7)	62 (40.5)	75 (50.7)	210 (46.9)
LOE ≥1 non-TNFi	52 (35.4)	43 (28.1)	56 (37.8)	151 (33.7)
Intolerance ≥1 non-TNFi	13 (8.8)	13 (8.5)	11 (7.4)	37 (8.3)
Prior IL-6i	34 (23.1)	35 (22.9)	32 (21.6)	101 (22.5)
LOE ≥1 IL-6i	25 (17.0)	22 (14.4)	21 (14.2)	68 (15.2)
Intolerance ≥1 IL-6i	5 (3.4)	10 (6.5)	5 (3.4)	20 (4.5)

Data presented as n (%).

i, inhibitor; LOE, lack of efficacy.

Figure 1. Low disease activity at week 24



***P<0.001 vs PBO; **P<0.01 vs PBO; *P<0.05 vs PBO bDMARD, biologic disease-modifying antirheumatic drug; CDAI, Clinical Disease Activity Index; DAS28(CRP), Disease Activity Score with C-reactive protein; FIL, filgotinib; IL, interleukin; PBO, placebo; QD, once-daily; TNF, tumour necrosis factor.

stratified by number and MOA of prior bDMARDs. Comparisons were not adjusted for multiplicity. Non-responder imputation was used.

Results: In total, 448 bDMARD-IR pts were included, 105 with prior experience with ≥3 bDMARDs (**Table**). At W24, pts receiving FIL were in LDA at a higher proportion vs PBO, irrespective of number of prior bDMARDs or MOA (**Figure 1**). For pts receiving FIL 200 vs PBO, DAS28(CRP) ≤3.2 was achieved at W24 by 52% vs 26%, 51% vs 22%, and 38% vs 9% of pts with 1, 2, or ≥3 prior bDMARDs, respectively, and 49% vs 21% and 50% vs 13% of pts exposed to TNF or IL-6 inhibitors; for all subgroups, rates were significantly higher vs PBO (**Figure 1**). Delta between FIL 200 mg and PBO was maintained irrespective of number or type of prior bDMARDs. At W24, pts receiving FIL achieved remission at numerically higher rates vs PBO (**Figure 2**). For pts receiving FIL 200 mg vs PBO, DAS28(CRP) < 2.6 was achieved at W24 by 36% vs 14%, 30% vs 14%, and 22% vs 6% of pts with 1, 2, and ≥3 prior bDMARDs, respectively, and 31% vs 14% and 29% vs 9% of pts exposed to TNF or IL-6 inhibitors (**Figure 2**). Delta between FIL 200 mg and PBO was maintained irrespective of number or type of prior bDMARDs. Treatment-emergent adverse events across subgroups were consistent with overall study population.

Conclusion: Treatment with FIL vs PBO led to higher rates of LDA and remission in pts with IR to IL-6 or TNF inhibition, or to 1, 2, or ≥3 prior bDMARDs, with a similar safety profile to the overall study population. A significantly higher proportion of pts overall receiving FIL 200 mg vs PBO were in LDA at W24. Improved efficacy of FIL vs PBO in pts who previously failed multiple bDMARDs indicates distinct benefits of selective JAK-1 inhibition with FIL.

Figure 2. Remission at week 24

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an oral, potent, selective JAK 1 inhibitor. FINCH 3 assessed FIL efficacy and safety in methotrexate (MTX)-naïve patients (pts) with rheumatoid arthritis (RA); week (W)24 primary outcome results were previously presented.[1] These analyses report FINCH 3 (NCT02886728) results through W52.

Methods: This global, phase 3, double-blind, active-controlled study randomized MTX-naïve pts with moderately to severely active RA 2:1:1:2 to oral FIL 200 mg once daily + MTX ≤20 mg weekly, FIL 100 mg + MTX, FIL 200 mg monotherapy (mono) + placebo (PBO), or PBO + MTX up to W52. Comparisons at W52 were not adjusted for multiplicity. Safety was assessed from adverse events and laboratory abnormalities.

Results: Of 1249 treated pts, 975 received study drug through W52. FIL efficacy was sustained up to W52. Treatment with FIL + MTX or FIL mono increased proportions of pts achieving ACR20/50/70 and clinical disease remission by DAS28(CRP) < 2.6 (FIL 200 mg + MTX, 53%; FIL mono, 46%), CDAI, SDAI, and Boolean criteria; improved HAQ-DI; and halted radiographic progression vs MTX alone (**Table 1** and **Figure**). Safety was consistent with W24 data (**Table 2**).

Table 1. Efficacy outcomes at week 52

	FIL 200 mg + MTX (n = 416)	FIL 100 mg + MTX (n = 207)	FIL 200 mg (n = 210)	MTX (n = 416)

Clinical Outcomes of Earlier versus Delayed Treatment of Iraqi Patients with Rheumatoid Arthritis with Etanercept

Nizar Abdulateef[1], Faiq Gorial[1], Yasameen Humadi[2], Dina Yasiry[3], Fadya Al Derwibee[3], Nancy Sunna[4] and Ali AlJabban[5], [1]Rheumatology Unit, Department of Medicine, College of Medicine, University of Baghdad, Iraq, Baghdad, Iraq, [2]Baghdad Teaching Hospital, Rheumatology Department, Baghdad, Iraq, Baghdad, Iraq, [3]Baghdad Teaching Hospital, Rheumatology Department, Baghdad, Iraq, Baghdad, Iraq, [4]Pfizer Inc., Amman, Jordan, [5]Pfizer Inc., Baghdad, Iraq

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The management of patients with early rheumatoid arthritis (RA), defined by the American College of Rheumatology (ACR) guidelines as patients who have had RA disease or symptoms for < 6 months, can improve prognosis and long-term clinical outcomes and reduce joint damage. In the Middle East, available evidence suggests that the management of patients with RA may be suboptimal, indicating a need for guidelines supporting the early use of biologic DMARDs.

Methods: This observational, retrospective study assessed real-world patient data entered in the National Center of Rheumatology database in Iraq from 2012 till 2018. Patients included in the study after they met ACR/EULAR 2010 criteria for Rheumatoid Arthritis with 1 year of follow up after starting their first etanercept therapy. Patients are excluded from the study if previously or currently treated with other biological therapies. Patients were categorized into two separate groups:

- Patients were stratified based on the disease duration before initiation of treatment with etanercept (≤1 year, >1 to ≤4 years, >4 to ≤10 years, >10 to ≤20 years, and >20 years) (group A).
- Patients were stratified based on the mean duration of RA: early and delayed treatment initiation were defined as having a RA diagnosis below or above mean of RA duration, before initiation of treatment with etanercept (group B).

VARIABLES	VALUES (N=979)
TOTALL POPULATION	
WOMEN, N (%)	813 (83)
AGE, YEARS, MEAN ± SD	48.06 ± 12.08
DISEASE DURATION, YEARS, MEAN ± SD	10.08 ± 8.27
PATIENTS STRATIFICATION N (%)	
≤1 YEAR	69 (7.05%)
>1 TO ≤4 YEARS	211 (21.55%)
>4 TO ≤10 YEARS	306 (31.26%)
>10 TO ≤20 YEARS	262 (26.76%)
>20 YEARS	131 (13.38%)
CDAI SCORE, MEAN ± SD	27.65 ± 11.63
DAS28 SCORE, MEAN ± SD	5.68 ± 1.2
METHOTREXATE TREATMENT, N (%)	
YES	535 (54.6%)
NO	444 (45.4%)

Table 1. Summary of baseline characteristics

Results: A total of 979 Iraqi patients with RA (of whom 813 [83%] were female) were included in the analysis, with a mean RA duration at baseline of 10 years and mean Clinical Disease Activity Index (CDAI) and Disease Activity Score 28 (DAS28) scores of 27.65 ± 11.63 and 5.68 ± 1.2, respectively **(Table 1).** Based on the stratified group (A), Patients who had RA symptoms for ≤1 year before etanercept initiation had the greatest CDAI change from baseline (10.9-point) and it was significantly lower in comparison to another stratified group (P=0.01). The change from baseline for >1 to ≤4 years, >4 to ≤10 years, >10 to ≤20 years, and >20 years group were (7.32-, 7.69-, 6.41-, and 6.62- point decrease respectively) [**Figure 1A**]. The mean change in DAS28 score was 1.1- point decrease for patients who had RA symptoms for ≤1 year and >1 to ≤4 years before etanercept initiation, while other patients (>4 to ≤10 years, >10 to ≤20 years, and >20 years groups) showed mean change of (1-, 0.83-, and 0.9- point decrease respectively) [**Figure 1B**]. In group B, at the last follow-up visit, patients with early etanercept initiation (≤10 years) had a higher decrease in CDAI and DAS28 scores from baseline compared with patients with delayed initiation (>10 years) (CDAI 7.9-point and CDAI 6.4-point decrease, respectively) [**Figure 2A**], (DAS28 1.05-point and DAS28 0.88-point decrease, respectively) [**Figure 2B**].

Conclusion: Patients who received earlier etanercept treatment appear to have a better clinical outcome compared with patients with delayed treatment.

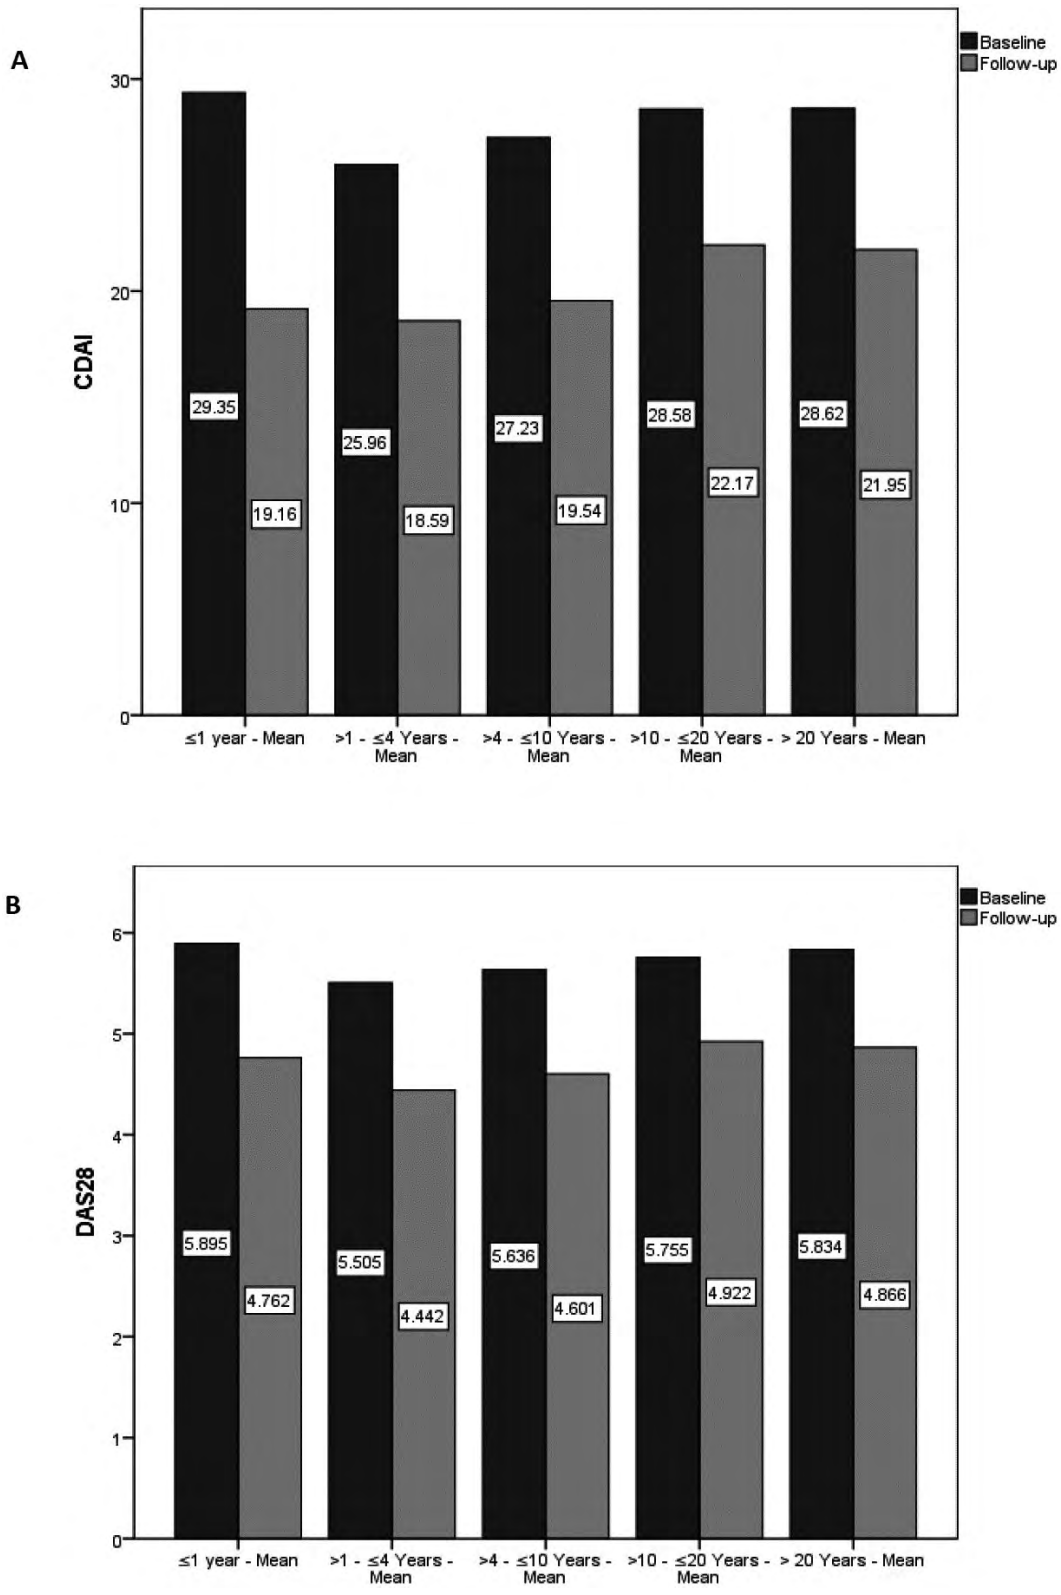

Figure 1. Changes in CDAI (A) and DAS28 (B) scores from baseline in patients stratified by RA duration before initiation of treatment with etanercept

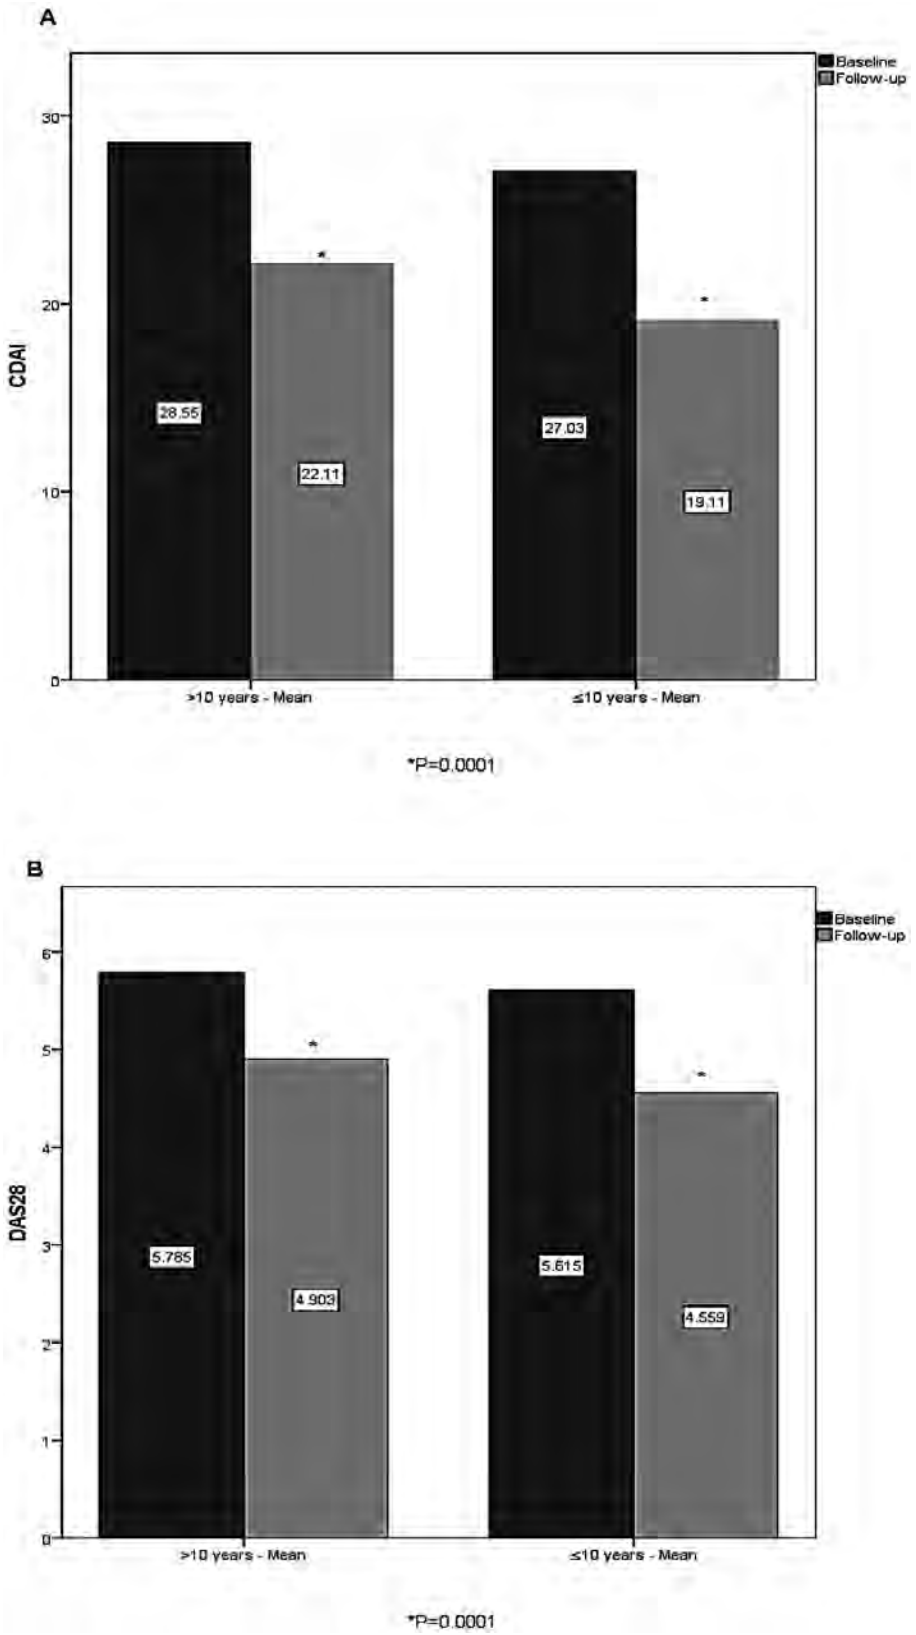

Figure 2. Changes in CDAI (A) and DAS28 (B) scores from baseline in patients with early (≤10 years) versus delayed (>10 years) management with etanercept

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids are widely used in the treatment of rheumatoid arthritis (RA) patients. It is internationally recommended to taper and stop glucocorticoids as rapidly as clinically feasible, but there are little data regarding this strategy. In two previous clinical trials (BeSt and IMPROVED) patients were treated with methotrexate (MTX) and a temporary course of oral prednisone (60 mg/day, tapered in 7 weeks to 7.5 mg/day). If the treatment target (TT, DAS≤2.4 in BeSt, DAS< 1.6 in IMPROVED) was achieved, prednisone was stopped, but in case of flare it was restarted. We present percentages of successful stopping and looked for potential predictors.

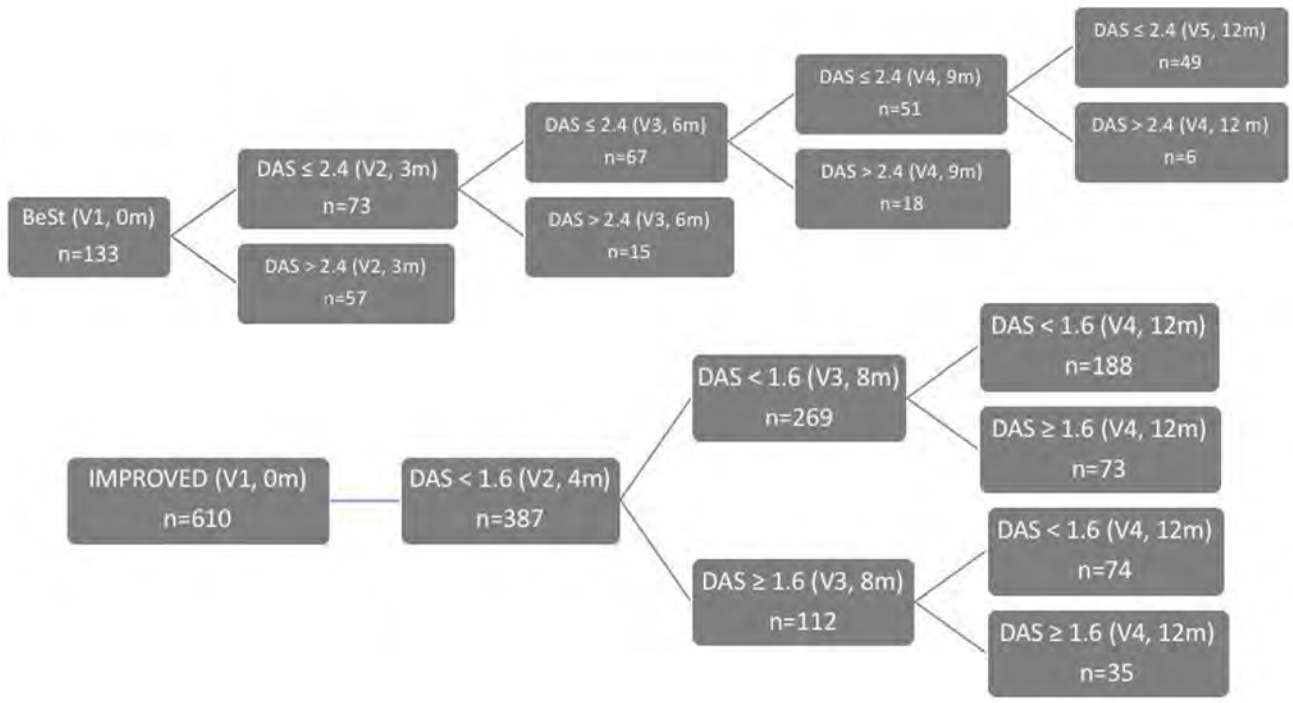

Figure 1. flow chart of the patient selection in BeSt and IMPROVED studies. m (month), DF (drug-free).

Table 2. univariable and multivariable analysis of predictors for successful GC stopping (OR 95% CI) in the BeSt and IMPROVED studies. RF (Rheumatoid Factor), ACPA (Anti-Citrullinated Protein Antibodies), bDAS (baseline DAS), pDAS (previous visit DAS), CRP (C-Reactive Protein, mg/dl), ΔDAS (difference between DAS at current visit and DAS at baseline), bVASGH (basal Visual Analogue Score Global Health).

Methods: 508 early RA patients were recruited for the BeSt study, from those 133 patients were randomized into the third arm of treatment (MTX+Sulfasalazin+Prednisone). 610 early RA or undifferentiated arthritis patients were enrolled into the IMPROVED study, all receiving MTX+Prednisone. Disease Activity Score was measured each 3 and 4 months, respectively. Stepwise tapering was slow in BeSt (prednisone tapered only after repeated treatment target achieved, earliest stop at week 35) and more rapid in IMPROVED (prednisone stop as soon as treatment target achieved, earliest at week 16), with a restart in case of flare 3 (BeSt) or 4 months (IMPROVED) after stop, respectively. Percentages still on treatment target after stopping of prednisone were compared in BeSt and IMPROVED. Univariable logistic regression was performed to identify potential predictors of successful stopping. Predictors with $p< 0.2$ were included in multivariable logistic regression analyses.

Results: In the BeSt study, 67/133 (50%) could stop initial prednisone due to sustained low disease activity (Figure 1). After prednisone stop, 51/67 (76%) patients remained on TT, but 18 flared. In the IMPROVED study, 387/610 (63%) patients stopped prednisone because of DAS-remission at 4 months (Figure 1). Of those, 269/387 (70%) remained on TT after stopping prednisone, while 112 flared. Baseline patient and disease characteristics between patients who did or did not flare after prednisone stop in both studies are shown in Table 1. In the BeSt study, DAS at previous visit was an independent predictor for successful secondary stopping of prednisone ($p=0.005$, Table 2). In the IMPROVED multivariable testing showed female gender and lower DAS at previous visit as independent predictors of successful secondary stopping prednisone ($p< 0.03$) Fulfilling the 2010 classification criteria for RA was not associated with the outcome after PRD stop (Table 2).

Conclusion: In these treat-to-target studies, where initial co-treatment with prednisone was stopped after the treatment target was (repeatedly, in BeSt) achieved, a lower DAS at the visit before stopping, was predictive of remaining on treatment target without flare. In IMPROVED, female patients also could more often successfully stop prednisone. Successful stopping of initial co-treatment with prednisone appears to be irrespective of treatment duration and treatment target. The data suggest that in patients with early RA the duration of temporary 'bridging' treatment of prednisone should be individually timed.

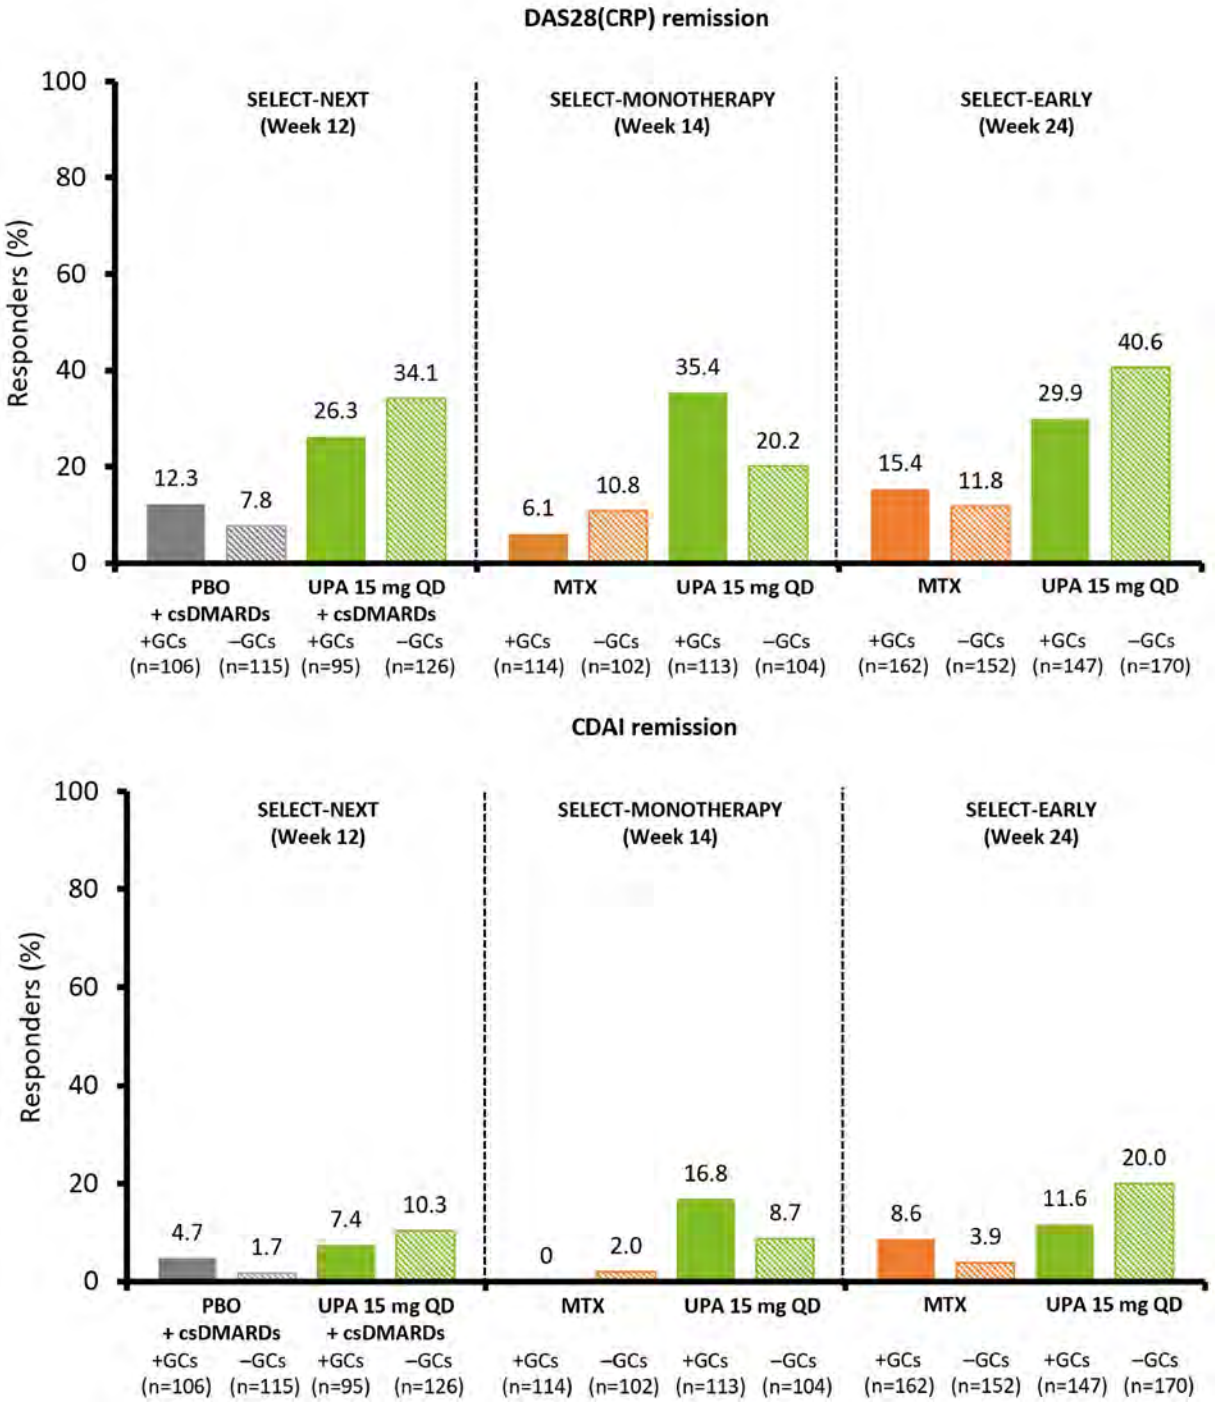
[a]Includes non-treatment-emergent deaths. [b]One death, caused by hemorrhagic stroke due to ruptured aneurysm. [c]One sudden CV death. [d]One CV death. [e]One death, caused by metastatic malignant melanoma. AE, adverse event; AESI, adverse event of special interest; csDMARD, conventional synthetic DMARD; CV, cardiovascular; GC, glucocorticoid; HZ, herpes zoster; MACE, major cardiovascular event; PBO, placebo; QD, once daily; UPA, upadacitinib; VTE, venous thromboembolic event.

Background/Purpose: Glucocorticoid (GC) therapy has strong anti-inflammatory effects and helps slow radiographic progression in RA[1]; however, GCs can be associated with adverse events (AEs) such as infection, especially with long-term use and higher doses. This ad hoc analysis of three Phase 3 studies of upadacitinib (UPA) in RA (SELECT-NEXT, SELECT-MONOTHERAPY, and SELECT-EARLY) aimed to evaluate the impact of baseline GCs on the efficacy and safety of UPA with or without concomitant conventional synthetic DMARDs (csDMARDs).

Methods: Patients with inadequate response to MTX (MTX-IR) receiving UPA 15 mg once daily (QD) or placebo (PBO) + csDMARDs in SELECT-NEXT, and MTX-IR/MTX-naïve patients receiving UPA 15 mg QD monotherapy or MTX monotherapy in SELECT-MONOTHERAPY/SELECT-EARLY, respectively, were included in the analysis. Efficacy outcomes, including measures of remission and low disease activity (LDA) determined by DAS in 28 joints using CRP (DAS28[CRP]; < 2.6/≤3.2) and Clinical Disease Activity Index (CDAI; ≤2.8/≤10), were assessed and stratified by baseline GC use. Patients were permitted to receive oral GCs ≤10 mg/day (prednisone equivalent) at baseline with no adjustment permitted until Week 24/26/48. Safety was reported as number and proportion of patients with AEs. Data were analyzed descriptively with no statistical comparisons between groups or doses.

Results: Of 1,506 patients included in the analysis, 737 (48.9%) were receiving baseline GCs (mean dose 6.2 mg/day). Baseline characteristics were broadly similar across treatment groups; SELECT-EARLY, which enrolled MTX-naïve patients, generally had the shortest duration of RA and higher CRP levels. Across UPA treatment groups, concomitant GCs generally did not influence the proportions of patients achieving remission (**Figure 1**). In SELECT-NEXT, clinical responses with UPA 15 mg in combination with csDMARDs were similar irrespective of concomitant GC use (**Figure 1**). Within SELECT-MONOTHERAPY, responses in patients receiving UPA 15 mg without concomitant csDMARDs or GCs were higher than those in patients receiving MTX alone, but were numerically lower than in those receiving UPA 15 mg with GCs (**Figure 1**). However, this was not observed within SELECT-EARLY, where clinical

Figure 1. Efficacy in patients receiving UPA or PBO with/without csDMARDs, and with/without GCs[a]



[a]Non-responder imputation. CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic DMARD; DAS28(CRP), Disease Activity Score in 28 joints using CRP; GC, glucocorticoid; PBO, placebo; QD, once daily; UPA, upadacitinib.

responses in patients receiving UPA 15 mg monotherapy without GCs were higher than in those patients receiving UPA 15 mg with GCs for both DAS28(CRP) < 2.6 (40.6% vs 29.9%, respectively) and CDAI ≤2.8 (20.0% vs 11.6%, respectively) (**Figure 1**). A similar trend was observed for LDA. Serious AEs, AEs leading to discontinuation, and AEs

of special interest, including infections (such as herpes zoster), were broadly similar in the UPA groups irrespective of concomitant GC use (**Table 1**).

Conclusion: UPA 15 mg in combination with csDMARDs or as monotherapy was effective in achieving remission and LDA, irrespective of concomitant GC use. Safety of UPA, including incidence of infection, appeared largely unaffected by concomitant GC use.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Early effective treatment has led to major improvements in patients with rheumatoid arthritis (ERA). Low disease activity and remission are achieved earlier and in higher frequency when the initial treatment in rheumatoid arthritis includes a combination of methotrexate (MTX) with a bDMARD compared to MTX alone.

The aim of this study is to retrospectively analyse and compare the benefit of a treatment with methotrexate (MTX) alone or combined with a bDMARD as an induction therapy during 5 years of follow-up in early rheumatoid arthritis (ERA) patients.

Methods: We included ERA patients from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 classification criteria and were naïve to DMARDs. Treatments were initiated based on the decision of a senior rheumatologist. bDMARDs induction therapy was usually limited to 6 or 12 months. We collected patient characteristics at baseline and clinical response was analysed at 6 months, 1 year, 3 years and 5 years.

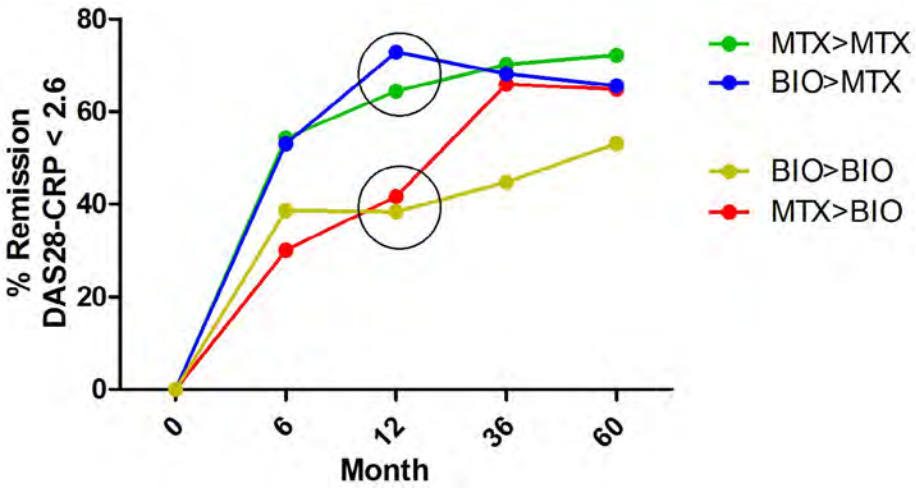

Figure 1. DAS28-CRP remission rate during time in each of the four groups (MTX->MTX (n=134), MTX->BIO (n=103); BIO->MTX (n=95), BIO->BIO (n=59).

Results: Data from 470 eligible ERA patients were collected. The average age of the population is 48.9 years; 70.5% of the patients are women; 27.3% are smokers and 68.8% are positive for anti-citrullinated protein antibody (ACPA). 281 patients (59.8 %) initiated MTX as a monotherapy (MTX group) compared to 189 patients (40.2%) who received a bDMARD (Bio group).

At baseline, the disease activity is the main factor that favors the initiation of bDMARDs (DAS28-CRP 5.2 vs 4.5, p< 0.001) followed by HAQ (1.32 vs 1.15, p=0.009), ACPA positivity (77.8% vs 62.5%, p=0.0006), rheumatoid factor positivity (71.5% vs 60.2%, p=0.0134). Other parameters such as age, gender, smoking habits or baseline erosion were similar between groups.

391 patients were followed up to 5 years. We then divided each of the two groups into two subgroups according to the last treatment they received at 5 years. Figure 1 shows the percentage of DAS28-CRP remission during time in each of the four groups (MTX- >MTX (n=134), MTX- >BIO (n=103); BIO- >MTX (n=95), BIO- >BIO (n=59);

At 12 months, DAS28-CRP response rate was statistically significantly higher in MTX >MTX and BIO >MTX groups compared to the two other groups. As expected, the remission rate was rescued in the group MTX- >Bio after 12 months.

Interestingly, ERA patients initially treated by a bDMARD followed by a MTX maintenance therapy experienced a sTable and sustained rate of remission.

Conclusion: Longterm remission is an achievable goal in ERA followed in daily clinic. Our results suggest that a bDMARD induction therapy followed by MTX maintenance therapy could be a good option in severe case of ERA.

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The Tool for Administrative Reimbursement Drug Information Sharing (TARDIS) is an electronic platform combining the collection of data from all Belgian patients with Rheumatoid Arthritis (RA) on biologic (b) and targeted synthetic (ts) DMARDs, together with the submission of a request for reimbursement of this medication. Therapy choice after failure of 2 classical synthetic (cs) DMARD is left at the discretion of the treating physician in Belgium. Therapy is prolonged after 3 months for tsDMARDS and after 6 months for bDMARDs if treatment is effective.

Table 1: Baseline characteristics of TARDIS patients

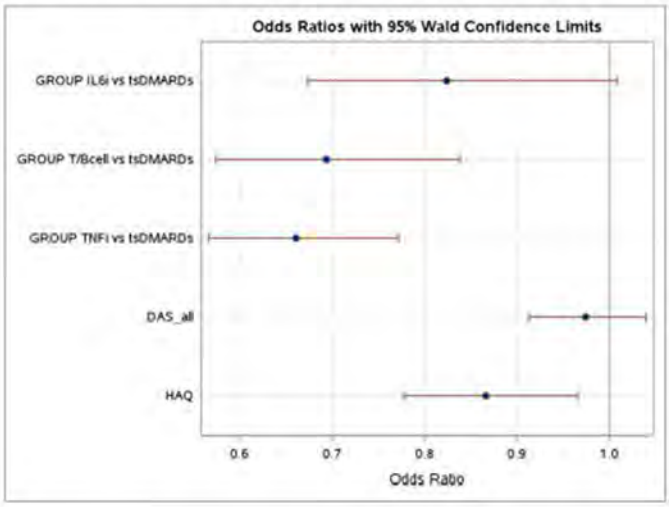
TNFi = tumour necrosis factor inhibitor, ts= targeted synthetic, HAQ= health assessment questionnaire, PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJC= tender joint count; SJC= Swollen joint Count; DAS28 = disease activity score based on the 28joints, Therapy prolongation = patient received same therapy at next visit

Fig1: Multivariate logistic regression predicting prolongation of therapy



Our aim was to investigate which factors are associated with a successful prolongation of therapy in the TARDIS-RA registry.

Methods: The Tool for Administrative Reimbursement Drug Information Sharing (TARDIS) is an electronic platform combining the collection of data from all Belgian patients with Rheumatoid Arthritis (RA) on biologic (b) and targeted synthetic (ts) DMARDs, together with the submission of a request for reimbursement of this medication. Therapy choice after failure of 2 classical synthetic (cs) DMARD is left at the discretion of the treating physician in Belgium. Therapy is prolonged after 3 months for tsDMARDS and after 6 months for bDMARDs if treatment is effective. Our aim was to investigate which factors are associated with a successful prolongation of therapy in the TARDIS-RA registry.

Results: We could include 6355 drug observations in 5471 unique patients. Table 1 describes this population in detail. In univariate logistic regression, prolongation of therapy was associated with lower baseline Patient Global Assessment ($p=0.032$), lower baseline disease activity score ($p=0.036$), lower baseline Health Assessment Questionnaire (HAQ) score ($p=0.003$) and starting at baseline tsDMARD therapy instead of either TNFi ($p< 0.001$), T/B cell ($p< 0.001$) or IL6 inhibition therapy ($p=0.049$) therapy. In multivariate logistic regression, prolongation of therapy remained associated with lower baseline HAQ score ($p=0.022$) and starting at baseline tsDMARD therapy instead of either TNFi ($p< 0.001$) or T/B cell ($p< 0.001$) therapy (Figure 1). Sensitivity analyses in advanced therapy naïve patients confirmed these results, but in advanced therapy experienced patients, baseline HAQ score became statistically insignificant ($p=0.780$).

Conclusion: TsDMARD therapy and lower baseline HAQ scores seem to be associated with more prolongations of therapy, even after adjusting for other confounding factors. However, the absolute difference between groups is small as all therapies show high rates of therapy prolongation, indicating effective initial therapy choices by Belgian rheumatologists.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased awareness of the importance of MTX in rheumatic disease is leading to more MTX use in patients from TB-endemic areas. Current management guidelines for rheumatic disease address TB in the context of biologics but not MTX use. We aimed to systematically review the published literature on TB rates with MTX < 30 mg per week.

Methods: We searched CINAHL, Embase, Global, MEDLINE and World of Science databases (Jan 1990 to May 2018) for terms including 'methotrexate' and 'tuberculosis'. We also searched citations from review articles. Titles, abstracts or full manuscripts of the 4707 reports identified were screened independently by 2 reviewers to identify studies reporting TB in patients taking MTX. Study quality was assessed using the McGill Mixed Methods Appraisal Tool (MMAT). Data was extracted on TB incidence (new TB diagnosis vs reactivation of latent TB), and outcomes

Region (Year)	Diagnosis	TB with MTX	TB without MTX	Odds Ratio
Mexico (1999)	Mixed (4 RA)	1/6	5/75	2.76
Japan (2004)	RA	3/47	17/154	0.56

Case Contro1l Studies

(pulmonary, dissemination, death) and safety of isoniazid, INH. Descriptive summaries are presented on studies providing outcomes in patients taking MTX < 30 mg per week.

Results: After removing duplicates and studies not meeting criteria or providing sufficient information, 31 studies were included (8 cohort, 7 case-control, 1 clinical trial, 15 case reports/case series). Only 27% of articles reported data from low to moderate human development index countries. Studies were of moderate quality. Seven case control studies were heterogeneous but most demonstrated a modest increased risk of TB with MTX (Table). Five cohort studies reported TB incidence rates in rheumatic disease (treated with MTX +/- biologics) ranging from 102-367.9/100,000 patient-years. These rates were generally higher than comparator general population rates. Two cohort studies of MTX in RA (without biologic) reported cumulative TB incidence in Maldova (12 TB cases in 44 RA patients, 27%) and in China (9/114, 7.9%). Other cohort studies generated rates of overt infection (143/100,000 patient years in Spain, higher if co-prescribed with corticosteroids and other immunosuppressants in South Africa), and latent TB rates detection (16/922 RA screened, 1.7%, in Canada). When reported, rates of extra-pulmonary TB were higher than comparator general population rates. One clinical trial (China), 2 cohorts (Japan, USA) and 2 case series (Belgium, USA) evaluated safety of INH and MTX. Isoniazid-related hepatotoxicity and neutropenia were generally more common when taken with MTX, but were usually reversible.

Conclusion: Despite a paucity of high-quality data, this review confirms that TB screening and clinical surveillance are needed in patients from TB-endemic areas who are prescribed MTX, particularly with co-administration of corticosteroids or other immunosuppressants. Isoniazid, if monitored, appears safe and prevents TB reactivation.

Abstract Number: 0224

Efficacy of Long-term Treatment with Baricitinib 2 Mg in Patients with Active Rheumatoid Arthritis

Alvin Wells[1], Bochao Jia[2], Li Xie[2], Guillermo Valenzuela[3], Edward C Keystone[4], Zhanguo Li[5], Amanda Quebe[2], Kirstin Griffing[2], Susan Otawa[2] and Boulos Haraoui[6], [1]Aurora Rheumatology and Immunotherapy Center, Franklin, [2]Eli Lilly and Company, Indianapolis, IN, [3]Integral Rheumatology & Immunology Specialists, Plantation, FL, [4]Mount Sinai Hospital, Toronto, ON, Canada, [5]Peking University People's Hospital, Xicheng, Beijing, China (People's Republic), [6]Institut de Rhumatologie de Montréal, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The short-term efficacy of baricitinib was demonstrated previously.[1,2] The objectives of this post-hoc analysis were to evaluate long-term efficacy of once-daily baricitinib 2 mg in patients with active rheumatoid arthritis (RA) who were inadequate responders (IR) to conventional synthetic disease-modifying antirheumatic drugs (csDMARD) or biologic DMARDs (bDMARD).

Methods: Data from patients in two 24-week, phase III studies, RA-BUILD (NCT01721057, csDMARD-IR) and RA-BEACON (NCT01721044, bDMARD-IR), and one long-term extension (LTE) study (RA-BEYOND, NCT01885078) were analyzed (120 total weeks); all patients had a diagnosis of adult-onset RA as defined by the American College of

Rheumatology/European League Against Rheumatism 2010 Criteria for the Classification of RA.[3] The main outcomes of this analysis were achievement of low-disease activity (LDA; Simple Disease Activity Index [SDAI] ≤11), clinical remission (SDAI ≤3.3), Health Assessment Questionnaire Disability Index ≤0.5, and safety. Non-responder imputation (NRI) and completer analyses were conducted on the modified intention-to-treat (mITT) population, which included patients who were randomized to baricitinib 2 mg in the RA-BUILD and RA-BEACON studies and who had received ≥1 dose of the study drug after randomization.

Results: A total of 684 patients in RA-BUILD and 527 patients in RA-BEACON were randomized. In RA-BUILD, 229 patients were randomized to baricitinib 2 mg; 180 of whom completed the study and entered RA-BEYOND. In RA-BEACON, 174 patients were randomized to baricitinib 2 mg; 117 of whom completed the study and entered RA-BEYOND. At week 120, based on the mITT population with data up to rescue, 27.5% of csDMARD-IR and 18.4% of bDMARD-IR patients treated with baricitinib 2 mg were in SDAI LDA; 13.1% of csDMARD-IR and 5.2% of bDMARD-IR patients were in SDAI remission (NRI). At week 120, 20.1% of csDMARD-IR and 10.9% of bDMARD-IR patients treated with baricitinib 2 mg met or exceeded the population normative value for physical function (NRI). The completer analysis results are not shown. Rates of adverse events of special interest were consistent with previous reports.

Conclusion: This analysis supports the long-term treatment sustained efficacy and safety of baricitinib 2 mg for up to 120 weeks.

*Significant according to a significance level of 0.05.

Table 2. Binary logistic regression and corresponding adjusted odds ratio for the prevalence of ADRs in different IV originator biologics

(ADRs) in RA patients treated with intravenous (IV) originator biologics[2]. Moreover, none of these studies utilized Naranjo[3] probability assessment for ADRs and compared all IV biologics in one setting.

Methods: A retrospective cohort study of adult RA patients receiving IV abatacept, tocilizumab, infliximab, or rituximab from January 2015 to January 2020 in a tertiary hospital located in Riyadh, Saudi Arabia was conducted. After Naranjo probability assessment [1]of ADRs, data including demographics, comorbidities, and concomitant medications were retrieved and their contribution to ADRs was analysed by logistic regression. Time to develop ADR for each biologic was plotted using Kaplan Meier graph.

Results: A total of 129 eligible patients were included in the study taking tocilizumab, rituximab, abatacept and infliximab (38.76%, 38.76%,13.95% and 8.53%, respectively) with a total of 1963 doses administered over five years. Patients had a mean (±SD) age of 54 (±13) years and were mostly females (87.6%). In addition to biologics used, 72 patients (55.8%) were receiving methotrexate, and 29 (22.5%) were receiving other disease modifying anti-rheumatic drugs (DMARDs). A total of 282 ADRs with Naranjo score≥1 was experienced by 103 patients (79.84%). The most common ADRs were infections (26.6%), skin and mucous membrane disorders (14.18%), and gastrointestinal disorders (11.7%) with predominance of probable ADRs using Naranjo classification (Table 1). Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) for biologics and other factors are available in Table 2. Experiencing multiple ADRs

was significant with abatacept users with an AOR of 3.15 [95% CI: 1.004-9.854, p= 0.049]. The time to experience ADRs was ranging from day zero to three years (Figure 1).

Conclusion: Intravenous biologics use is limited by the prevalence of ADRs globally. Knowledge of different types of ADRs and their expected occurrence aids with clinical decision making and provides a database for future comparison with biosimilars. Although this study had a small number of participants for some IV biologics, the longitudinal nature of study methods provides an insight on the safety profile while managing RA patients.

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarilumab, as monotherapy or in combination with conventional synthetic DMARDs like methotrexate (MTX) has demonstrated improvement in symptomatic and functional outcomes in patients (pts) with RA. Comparison of efficacy between monotherapy and combination therapy is important due to suboptimal adherence and persistence to MTX in patients with RA and lack of direct comparison studies. Here, we report the results from a *post hoc* analysis that compared the efficacy of sarilumab monotherapy (MONARCH study; NCT02332590) vs sarilumab and MTX combination therapy (MOBILITY study; NCT01061736).

Methods: MONARCH and MOBILITY were phase III, double-blind randomized controlled studies in pts with RA who showed inadequate responses to or were intolerant to MTX. In MONARCH, pts (enrolled based on 2010 ACR/EULAR criteria) were randomized to receive sarilumab or adalimumab in combination with placebo for 24 weeks. In MOBILITY, pts (enrolled based on 1987 ACR revised classification criteria) were randomized to receive sarilumab or

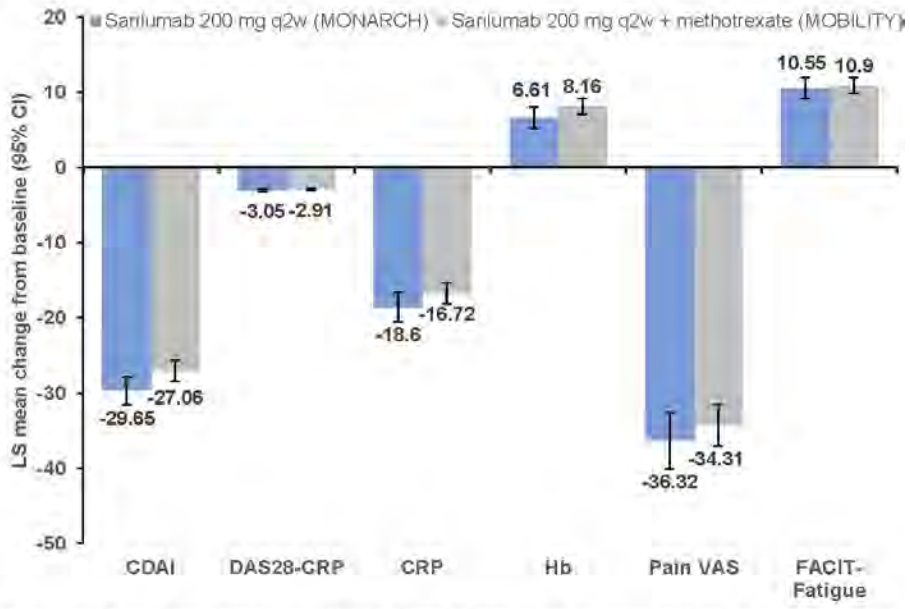
[a]*P*-value was obtained using t test for equality of variance. In case equality of variance assumption was not met, Satterthwaite's p-value was provided; [b]*P*-value was obtained using chisquare test. In case expected cell frequency was < 5, Fisher's exact test was used; [c]N=398 for the "sarilumab plus MTX" treatment arm; [d]N=178 for the "sarilumab" treatment arm and N=397 for the "sarilumab plus MTX" treatment arm. Anti CCP, Anti-cyclic citrullinated peptide; BMI, body mass index; CDAI, Clinical Disease Activity Index; CRP, C-reactive protein; DAS28-CRP, 28-joint Disease Activity using C reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; MD-GA, physician's global assessment of disease activity; MTX, methotrexate; N, number of patients assessed; Pt-GA, patients global assessment of disease activity; q2w, every 2 weeks; RA, rheumatoid arthritis; SD, standard deviation

placebo in combination with weekly MTX for 52 weeks. The primary objective of this analysis was to compare the efficacy of sarilumab (200 mg q2w) as monotherapy and in combination with MTX, at Week 24. The endpoints were mean change from baseline in Clinical Disease Activity Index (CDAI), 28-joint Disease Activity using CRP (DAS28-CRP), CRP, hemoglobin (Hb), pain visual analogue scale (VAS) and Functional Assessment of Chronic Illness Therapy

Figure 1. Adjusted Comparisons of Efficacy Between Sarilumab Monotherapy vs Sarilumab and Methotrexate Combination Therapy Using MMRM[a]



All values are LS mean change from baseline (95% CI) at Week 24. Patients with non-missing endpoint values were considered.
[a]MMRM assuming an unstructured covariance structure. Ethnicity, region, baseline BMI Group, rheumatoid factor, anti CCP antibody, SJC at baseline, CDAI at baseline, CRP at baseline, endpoint value at baseline, sarilumab group, visit and sarilumab group-by-visit interaction were used as covariates in this model.

Anti CCP, Anti-cyclic citrullinated peptide; CDAI, Clinical Disease Activity Index; CI, confidence interval; CRP, C-reactive protein; DAS28-CRP, 28-joint Disease Activity using C reactive protein; FACIT, Functional Assessment of Chronic Illness Therapy; Hb, hemoglobin; LS, least square; MMRM, Mixed-effect model repeated measure; q2w, every 2 weeks; SJC, swollen joint count; VAS, visual analogue scale.

(FACIT)-Fatigue. For unadjusted comparisons of efficacy between monotherapy and combination therapy treatment arms, mean change from baseline (95% confidence interval [CI]) at Week 24 in end points was compared between the treatment arms. For adjusted comparisons, continuous change from baseline in endpoints were set as dependent variables and pt baseline characteristics that differed significantly ($P< 0.05$) between the two trials were set as covariates in mixed-effect model repeated measure (MMRM) models; least square (LS) mean change from baseline (95% CI) at Week 24 in end points was compared between the treatment arms.

Results: This analysis included 184 pts from the sarilumab monotherapy arm (MONARCH) and 399 pts from the sarilumab plus MTX treatment arm (MOBILITY). Among the baseline characteristics of pts in these two trials, differences ($P< 0.05$) were observed in ethnicity, region, body mass index group, rheumatoid factor, anti-citrullinated peptide antibodies, swollen joint count, CRP, and clinical disease activity index between the treatment arms (**Table 1**). After adjusting for these differences in MMRM, LS mean change from baseline at Week 24 for all assessments was similar between the treatment arms with overlapping confidence intervals (**Figure 1**). Results of unadjusted comparisons were similar to adjusted comparisons (data not shown). The safety profile of sarilumab was previously reported.

Conclusion: Findings from this *post hoc* analysis of combined data demonstrated that the efficacy of sarilumab as monotherapy was similar to its efficacy as a combination therapy with MTX. These data support previous observations that interleukin (IL)-6R blockade with or without concomitant conventional synthetic DMARDs have similar efficacy.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Infections are one of the main complications among patients with rheumatoid arthritis (RA) with immunosuppressive treatment. The differences between treatments and the influence of other factors is unclear.

The objective of this study was to evaluate the frequency and factors associated with serious infections in patients with RA treated with biological therapy (BT) and JAK inhibitors (JAKi) and the differences between treatments.

Methods: Descriptive and retrospective study (January 2015-May 2020) of patients with RA treated with BT (TNFi, non-TNFi) and JAKi (tofacitinib, bariticinib) in a single center. RA diagnosis was performed according to ACR classification criteria. Severe infection was considered a life-threatening infection or one that required hospitalization and intravenous treatment. Epidemiological variables, clinical characteristics, Charlson comorbidity index, type of BT or JAKi and concomitant treatment were collected. For the analysis frequencies and percentages are used in qualitative variables, and mean ± SD in the quantitative ones. Statistical analysis was performed with IBM SPSS v 23.

Results: We registered 246 patients (85% women) mean aged 56±13.5 years. RF was positive in 87%, anti-CCP in 75.6% and 15.4% presented extra-articular manifestations (nodulosis 8.9%, intersticial lung disease 5.3%, other 1.2%). At the start of the study 149 patients (60.6%) were with TNFi, 79 (32.1%) non-TNFi and 18 (7.3%) with JAKi. Conventional synthetic DMARDs (csDMARDs) were used in 84.1% of cases (methotrexate 71%, leflunomide 21.3%, other 7.7%).

During the study, 165 patients (67.1%) continued with the same treatment and in 81 (32.9%) it was changed at least once. Four patients discontinued the treatment. At the end of the study, 119 patients (49.2%) were with TNFi, 79 (32.6%) non-TNFi and 44 (18.2%) with JAKi.

TABLE 1. CHARACTERISTICS OF PATIENTS WITH INFECTION VS. WITHOUT INFECTION

	INFECTION		
	YES n:23	**NO** n:223	**p**
FEMALE, n (%)	19 (82.6)	190 (85.2)	0.759
AGE years, (mean±SD)	60.2 ± 13	55.6 ± 13.4	0.116
AGE ≥ 65 n (%)	10 (43.5)	63 (28.3)	0.151
RF +, n (%)	21 (91.3)	193 (86.5)	0.748
ANTI-CCP +, n (%)	17 (73.9)	169 (75.8)	0.803
INTERSTICIAL LUNG DISEASE, n (%)	1 (25)	12 (35.3)	0.708
ALCOHOL, n (%)	2 (8.7)	18 (8.1)	1.00
SMOKER, n (%)	6 (26.1)	59 (26.5)	0.731
COPD, n (%)	6 (26.1)	23 (10.3)	**0.038***
DM, n (%)	7 (30.4)	19 (8.6)	**0.005***
SEVERE LIVER DISEASE, n (%)	2 (8.7)	1 (0.4)	**0.024***
CEREBROVASCULAR ACCIDENT, n (%)	2 (8.7)	2 (0.9)	**0.045***
RENAL INSUFFICIENCY, n (%)	2 (8.7)	3 (1.4)	0.071
PERIPHERAL VASCULAR DISEASE, n (%)	8 (34.8)	24 (10.8)	**0.004***
CHARLSON INDEX (mean±SD)	1.83 ± 2	0.67 ± 1.2	**<0.001***
TNFi, n (%) **NON-TNFi** n (%) **JAKi**, n (%)	12 (52.2) 7 (30.4) 4 (17.4)	107 (48.8) 72 (32.9) 40 (18.3)	
csDMARDs, n (%)	18 (78.3)	151 (67.7)	0.353
GLUCOCORTICOIDS, n (%)	14 (60.9)	111 (49.8)	0.383

Severe infection was developed in 23 (9.3%) patients (respiratory 11, sepsis 4, cellulitis 4, urinary 3, osteomyelitis 1). Two patients had severe infection and herpes zoster and 3 developed a second infection. Twelve patients were with TNFi (52.2%), 7 non- TNFi (30.4%) and 4 JAKi (17.4%).**Table 1**

The inflammatory activity of RA was mild at the time of infection (DAS28: 2.6±1.1). The median time until infection was: TNFi 21.65 [7-60.8] months, non- TNFi 20.09 [17-37.7] and JAKi 28.19 [15.1-28.7]. The Charlson index, chronic obstructive pulmonary disease (COPD), diabetes mellitus (DM), severe liver disease, cerebrovascular accidents and peripheral vascular disease were statistically significantly associated with infection. The infection developed in 60.9% and 78.3% of patients who were on concomitant treatment with corticoid and csDMARD respectively. **Table 1**

Conclusion: In our study, 9.3% of patients with RA treated with BT or JAKi developed severe infection during 4.5 years of follow-up. Comorbidity, especially DM, increased the risk of presenting this complication. Concomitant treatment with corticoid and csDMARDs was not statistically significantly associated with infection.

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

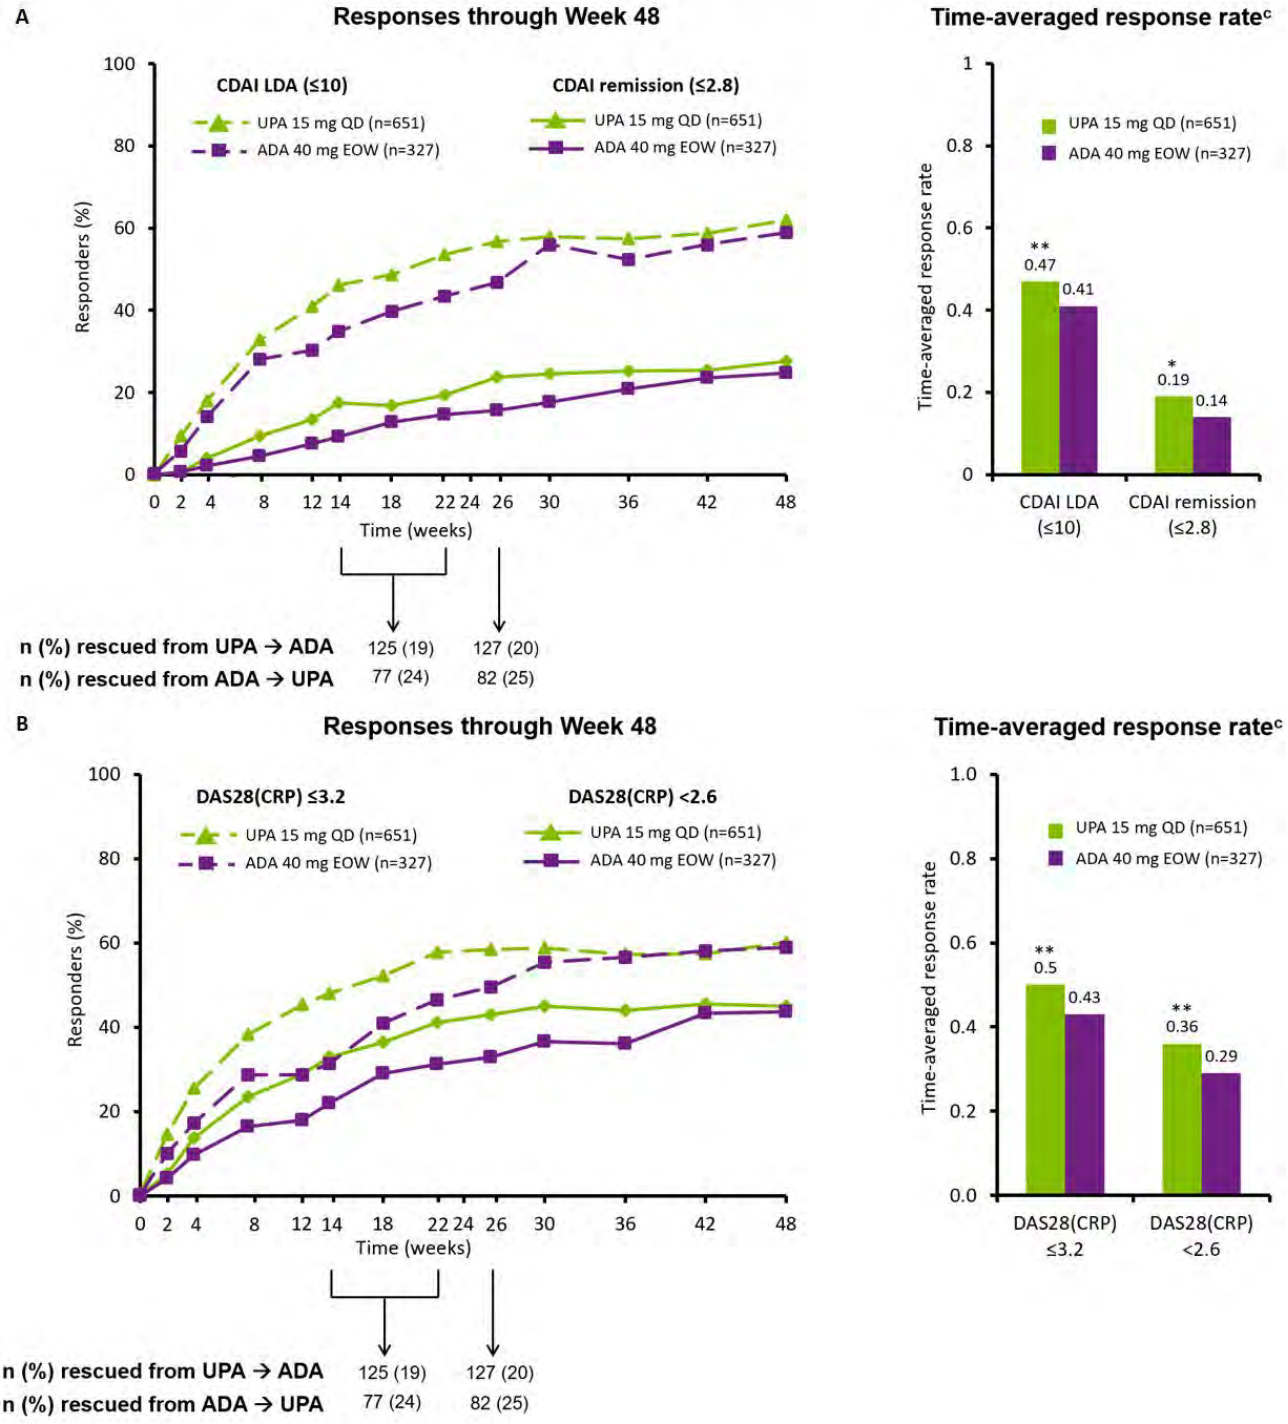
Session Time: 9:00AM–11:00AM

Background/Purpose: In the randomized, double-blinded, Phase 3 SELECT-COMPARE study, upadacitinib (UPA) + MTX demonstrated greater clinical and functional responses vs adalimumab (ADA) + MTX in patients with RA and inadequate response to MTX.[1,2] In SELECT-COMPARE, patients with an insufficient response to their initial therapy were switched from UPA to ADA (and vice versa) according to treat-to-target (T2T) principles. To assess the effectiveness of such a strategy, we analyzed 1-year treatment outcomes in SELECT-COMPARE according to initial randomization group, regardless of whether or not patients subsequently switched therapy.

Methods: Patients initially randomized to UPA 15 mg once daily (QD) or ADA 40 mg every other week (EOW; both + MTX) for up to 48 weeks in SELECT-COMPARE were included in the analysis. As per the protocol-directed rescue strategy, patients experiencing < 20% improvement in tender or swollen joint counts at Week 14, 18, or 22, or Clinical Disease Activity Index (CDAI) >10 at Week 26, were switched from UPA to ADA or ADA to UPA in a blinded fashion. Efficacy outcomes included CDAI remission (≤2.8) and low disease activity (LDA; ≤10), DAS of 28 joints using CRP (DAS28[CRP]) < 2.6 and ≤3.2, and a composite of "deep response" (CDAI remission, HAQ-Disability Index < 0.5, and pain score < 20). Data are presented and attributed to initial randomized group (UPA or ADA) regardless of any subsequent switch in therapy. Time-averaged response rates were calculated as area under the curve of response rate standardized by 48 weeks. The proportions of patients who maintained Week 26 responses through 6 months of follow-up are also reported.

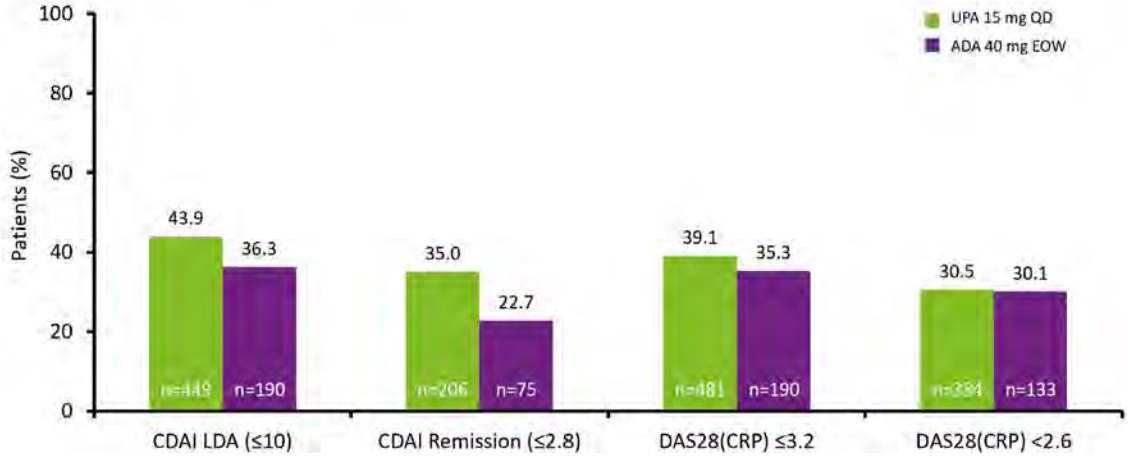
Results: This analysis included 651 patients initially randomized to UPA (of whom 245 switched to ADA) and 327 patients initially randomized to ADA (of whom 157 switched to UPA). Baseline characteristics including age, sex, and BMI were generally well balanced between randomized groups. At Week 48, similar proportions of patients initially randomized to UPA or ADA therapy achieved CDAI remission/LDA (27.6%/61.9% vs 24.8%/59.0%) and DAS28(CRP) < 2.6/≤3.2 (45.0%/60.2% vs 43.7%/59.0%) (**Figure 1**). However, a small but significantly greater proportion of patients achieved a deep response with initial UPA vs initial ADA therapy (17.8% vs 12.8%; p< 0.05). In addition, time-averaged response rates over 48 weeks were higher for initial UPA vs initial ADA therapy across efficacy outcomes (**Figure 1**). Similar trends were observed for other outcomes. Additionally, similar proportions of patients

Figure 1. Achievement of CDAI (A) and DAS28(CRP) (B) responses corresponding with time-averaged response rates over 48 weeks by initial therapy with UPA or ADA in SELECT-COMPARE[a,b]



**p<0.01,*p<0.05 vs ADA. [a]Non-responder imputation. [b]Blinded rescue from UPA to ADA or ADA to UPA was permitted at Weeks 14, 18, and 22 for <20% improvement in TJC/SJC and at Week 26 for CDAI <10. Data are presented and attributed to original randomized group (UPA or ADA) regardless of any subsequent switch in therapy. [c]Calculated as area under the curve of response rate standardized by length of study (48 weeks). ADA, adalimumab; CDAI, Clinical Disease Activity Index; DAS28(CRP), DAS of 28 joints using CRP; EOW, every other week; QD, once daily; SJC, swollen joint count; TJC, tender joint count; UPA, upadacitinib

Figure 2. Proportion of patients maintaining Week 26 CDAI and DAS28(CRP) responses during 6-month follow-up by initial therapy with UPA or ADA in SELECT-COMPARE[a–c]



[a]As observed. [b]Blinded rescue from UPA to ADA or ADA to UPA was permitted at Weeks 14, 18, and 22 for patients with <20% improvement in TJC or SJC and at Week 26 for patients with a CDAI <10. Data are presented and attributed to original randomized group (UPA or ADA) regardless of any subsequent switch in therapy. [c]Maintaining response defined as never losing response at any visit during ~6 months (22–26 weeks) follow up after first achieving response before or at Week 26. ADA, adalimumab; CDAI, Clinical Disease Activity Index; DAS28(CRP), DAS of 28 joints using CRP; EOW, every other week; QD, once daily; SJC, swollen joint count; TJC, tender joint count; UPA, upadacitinib

maintained Week 26 responses with initial UPA vs initial ADA therapy based on CDAI remission/LDA and DAS28(CRP) < 2.6/≤3.2 during 6-month follow-up (**Figure 2**).

Conclusion: Using a stringent T2T approach to RA management, rates of LDA or remission at 1 year were similar, regardless of whether patients were initially randomized to UPA or ADA. However, initial UPA therapy led to more frequent deep responses and higher time-averaged response rates vs initial ADA therapy.

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The oral, selective Janus kinase-1 inhibitor filgotinib (FIL) significantly improved RA signs and symptoms in patients (pts) with MTX-naïve and MTX- and biologic-refractory RA.[1–5] In 52-week (W) active controlled trials, FIL safety was comparable to adalimumab and MTX.[1,2] Updated integrated analysis of FIL safety is needed.

Methods: Data were integrated from 3 phase 3 (FINCH 1–3; NCT02889796, NCT02873936, NCT02886728), 2 phase 2 (DARWIN 1, 2; NCT01668641, NCT01894516), and 2 long-term extension (DARWIN 3, NCT02065700; FINCH 4, NCT03025308) trials including up to 5.5 years (y) FIL exposure. Pts were ≥18 y with active RA per ACR criteria. DARWIN 3 and FINCH 4 data through April 26, 2019, and Sept 16, 2019, respectively, were included; other trials are complete. Placebo (PBO)-controlled analysis set included pts from 4 PBO-controlled trials receiving FIL 200 or 100 mg once-daily (QD) or PBO for 12W. Long-term as treated analysis set included all available data for pts receiving ≥1 dose FIL 200 or 100 mg QD from 7 trials, including after treatment conversion. Incidence (n [%]) and exposure-adjusted incidence rates (EAIR) per 100 pt-years exposure (PYE) of treatment-emergent adverse events (TEAEs; onset after first dose and no later than either 30 days after last dose or new drug first dose date –1 day) and TEAEs of special interest (AESIs) are presented. EAIR and 95% confidence intervals were estimated with Poisson models with treatment

Table 1. Summary of exposure

	PBO-controlled			Long-term (as treated)		
	FIL 200 mg	FIL 100 mg	PBO	FIL 200 mg	FIL 100 mg	Total FIL
N	777	788	781	2267	1647	3691

Data are n (%) unless otherwise indicated. EAIR are per 100 PYE.
[a]Grade ≥3 TEAEs were determined by the investigator to be severe, life-threatening, or fatal
[b]EAIR and 95% CI were estimated using Poisson models with treatment as covariate and an offset of natural log of exposure.
[c]Including non-TE deaths.
[d]For the PBO-controlled analysis set, FIL 200 mg PYE = 180.3, FIL 100 mg PYE = 181.9, and PBO PYE = 178.8.
CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL, filgotinib; PBO, placebo; PYE, patient-years exposure; SAE, serious adverse event; TE, treatment-emergent; TEAE, treatment-emergent adverse event.

Table 2. Overall summary of treatment-emergent adverse events

and study covariates and natural log of exposure offset, unless otherwise specified for infrequent events. Positively adjudicated major adverse cardiovascular events (MACE) and venous thromboembolisms (VTE) were included.

Results: In long-term as treated set, 74.2% of pts received FIL for ≥52W (**Table 1**). In 12W PBO-controlled set, rates of TEAEs, TEAEs Grade ≥3, serious AEs (SAEs), and TEAEs leading to discontinuation or death were comparable for both FIL doses vs PBO (**Table 2**). EAIR for TEAEs were lower with FIL 200 vs 100 mg in as treated set but comparable between doses for TEAEs Grade ≥3, SAEs, and TEAEs leading to discontinuation or death. All and serious infection incidences were numerically higher for FIL vs PBO in the PBO-controlled set; herpes zoster occurred in 0.1%/0.3%/0.3% receiving FIL 200 mg/100 mg/PBO (**Table 3**). In as treated set, EAIR of all and serious infections were numerically higher for FIL 100 vs 200 mg, and herpes zoster EAIR was numerically higher for FIL 200 vs 100 mg. In PBO-controlled set, 0/3/2 cases of MACE occurred with FIL 200 mg/100 mg/PBO. In as treated set, MACE EAIR were comparable for FIL doses. No VTE occurred in 12W PBO-controlled set. In as treated set, VTE EAIR were 0.2 and 0.0/100 PYE for FIL 200 and 100 mg, respectively. Malignancies were uncommon and comparable for FIL doses.

Conclusion: FIL was well tolerated; no consistent dose dependent effect was observed for AESIs. VTE and other AESIs were infrequent. No new safety signals were identified with FIL dosing up to 5.5 y.

CDAI, Clinical Disease Activity Index; DAS28, Disease Activity in 28 Joints; LDA, low disease activity; SDAI, Simple Disease Activity Index.

*Dose escalation from TCZ-SC q2w to qw at week 12 in COMP-ACT. Logistic regression model included protocol, week, week × week, age, sex, baseline weight group (< 80 kg, 80-100 kg), baseline DAS28, DAS28 at week 12 and interactions of protocol with baseline weight group, protocol with DAS28 at baseline, protocol with week and protocol with DAS28 at week 12.

†All patients in the COMP-ACT trial were from the United States.

‡North American patients included those from the United States and Canada.

Background/Purpose: In patients with rheumatoid arthritis (RA), subcutaneous tocilizumab (TCZ-SC) is administered every 2 weeks (q2w) or every week (qw), based on the patient's weight and clinical response. This study evaluated the effects on disease activity at week 24 when the dosing schedule of TCZ-SC was escalated from q2w to qw in patients who did not achieve low disease activity (LDA; Disease Activity Score in 28 Joints [DAS28] > 3.2) at week 12 in COMP-ACT compared with patients who did not achieve LDA and did not escalate dosing in SUMMACTA and BREVACTA.

Methods: US patients in COMP-ACT who weighed < 100 kg at baseline and who received TCZ-SC 162 mg q2w + methotrexate escalated to qw if they did not achieve LDA at week 12. In the primary analysis, DAS28 remission (< 2.6) and LDA (≤ 3.2), Clinical Disease Activity Index (CDAI) remission (≤ 2.8) and LDA (≤ 10) and Simple Disease Activity Index (SDAI) remission (≤ 3.3) and LDA (≤ 11) at week 24 were compared between patients who switched from q2w to qw and North American patients in SUMMACTA who initiated TCZ qw + conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and continued a qw dose (baseline body weight < 100 kg and DAS28 > 3.2 at week 12). A secondary analysis compared COMP-ACT patients who escalated from q2w to qw with all SUMMACTA patients who continued a qw dose and all patients in BREVACTA who initiated a TCZ-SC q2w dose + csDMARDs and continued a q2w dose (baseline body weight < 100 kg and DAS28 > 3.2 at week 12). DAS28 was standardized to DAS28-ESR, and comparisons were calculated using a mixed model with repeated-measures logistic regression, including the following covariates: CDAI, SDAI and/or DAS28 at the reference visit (week 12), as well as study baseline values of CDAI, SDAI and/or DAS28, baseline age, sex, tumor necrosis factor inhibitor use prior to the study (yes or no) and weight category.

Results: A total of 328 US patients in COMP-ACT did not achieve LDA at week 12 and escalated from q2w to qw TCZ-SC. In SUMMACTA, 285 patients did not achieve LDA at week 12 and continued TCZ-SC qw, of whom 71 were from North America. Baseline demographic and clinical characteristics were comparable between patients in COMP-ACT and North American patients in SUMMACTA (**Table 1**). A significantly higher proportion of patients in COMP-ACT achieved DAS28, CDAI and SDAI remission and LDA 12 weeks after TCZ dose escalation (week 24) than North American SUMMACTA patients (**Table 2**). In the secondary analysis, similar results were seen when the proportion of patients who achieved DAS28 remission and LDA was compared at week 24 between patients in COMP-ACT and patients from all geographic regions who did not escalate dosing in SUMMACTA and BREVACTA (N = 196) (**Table 2**). Comparable clinical responses were seen with CDAI and SDAI when the COMP-ACT patients and patients from all geographic regions in SUMMACTA were analyzed.

Conclusion: US patients with RA who did not achieve LDA and escalated from q2w to qw TCZ-SC at week 12 in COMP-ACT had better outcomes at week 24 than North American patients who did not achieve LDA and continued qw dosing in SUMMACTA. These results provide evidence that escalation from q2w to qw has more effect than would be expected without dose change for patients who do not achieve LDA by week 12.

Treatment Patterns of Biologic/Targeted Synthetic DMARDs for the Management of Rheumatoid Arthritis in Australia: An Analysis of the OPAL Dataset

Helen Cooley[1], Tegan Smith[2], Peter Youssef[3], Kathleen Tymms[4], David Mathers[5], Sabina Ciciriello[6], Hedley Griffiths[7], Catherine OSullivan[2] and Geoffrey Littlejohn[8], [1]Hobart Private Hospital, Hobart, TAS, Taroona, Australia, [2]OPAL Rheumatology Ltd, Sydney, NSW, Kogarah, New South Wales, Australia, [3]University of Sydney, Sydney, NSW; Royal Prince Alfred Hospital, Camperdown, NSW, Camperdown, New South Wales, Australia, [4]Canberra Rheumatology, Canberra, ACT, Canberra, Australian Capital Territory, Australia, [5]Georgetown Rheumatology, Georgetown, NSW, Georgetown, New South Wales, Australia, [6]Royal Melbourne Hospital, Melbourne, VIC, Melbourne, Victoria, Australia, [7]Barwon Rheumatology Service, Geelong, VIC, Geelong, Victoria, Australia, [8]Monash Rheumatology, Clayton, VIC; OPAL Rheumatology Ltd, Sydney, NSW, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In Australia the cost of biological/targeted synthetic DMARDs (b/tsDMARDs) for treatment of RA is subsidized if the patient has documented high levels of clinical/laboratory disease activity and has not responded to a pre-specified combination of conventional synthetic DMARDs, including methotrexate. Once eligible for subsidy the clinician can then prescribe the b/tsDMARD deemed most clinically appropriate until the desired level of disease control has been reached, with the available options being adalimumab, etanercept, certolizumab pegol, golimumab, infliximab, abatacept, tocilizumab, rituximab, tofacitinib, baricitinib and upadacitinib. The aim of this analysis was to explore b/tsDMARD treatment patterns and clinical priorities when managing RA in real-world rheumatology practice

Methods: Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record at the time of the consultation[1] by 110 rheumatologists in Australia. Prescribing patterns for patients >18 years with RA treated with a b/tsDMARD between Jan 2010-Dec 2014 and Jan 2015-Dec 2019 were included in the analysis. The software program Tableau® was used to display data on medication initiation and cessation dates, and reasons for starting and stopping b/tsDMARDs, which is recorded at the time of the decision.

Results: At Dec 2019, there were 46,412 patients with RA in the dataset and 27% were prescribed b/tsDMARDs. Between 2010-2014, 63% of patients were prescribed a TNF inhibitor (TNFi), and 16%, 15% and 5% prescribed tocilizumab, abatacept and rituximab, respectively. Between 2015-2019, 46% of patients were prescribed a TNFi, followed by JAK inhibitors (JAKi) (28%), tocilizumab, abatacept, and rituximab (12%, 11% and 3%, respectively). TNFi cycling was frequently observed during 2010-2014 with 58% of patients receiving a TNFi in 1st line switching to another TNFi in 2nd line, which reduced to 40% between 2015-2019; however, TNFi cycling was still frequently observed despite the first TNFi being stopped due to lack of efficacy. From 2015, 33% of patients switched from a TNFi in 1st line to a JAKi, and 57% switched from a JAKi in 1st line to a TNFi. 20% of patients receiving a JAKi in 1st line switched to another JAKi, which increased to 31% between Jan 2019-Dec 2019, citing lack of efficacy, AEs and better alternative.

Conclusion: Real-world treatment patterns for b/tsDMARDs are increasingly complex as more drugs with different modes of action (MOA) become available. There is a trend for earlier introduction of drugs with different MOA; however, TNFi cycling is still frequently observed despite evidence supporting increased persistence after switching MOA. Outcomes of JAKi cycling are uncertain and require further investigation.

Abstract Number: 0232

Safety and Effectiveness of Tocilizumab in Patients with Renal Insufficiency in the Non-interventional Study ICHIBAN

Christof Specker[1], Martin Aringer[2], Gerd Burmester[3], Johannes Gerlach[4], Michael Hofmann[5], Herbert Kellner[6], Frank Moosig[7], Hans-Peter Tony[8] and Gerhard Fliedner[9], [1]Clinic Essen-Mitte, Essen, Germany, [2]Rheumatology, Medicine III, University Medical Center & Faculty of Medicine, TU Dresden, Dresden, Germany, Dresden, Germany, [3]Charité University Hospital Berlin, Berlin, Germany, [4]Roche Pharma AG, Grenzach-Wyhlen, Germany, [5]Chugai, Frankfurt am Main, Germany, [6]Rheumatology and Gastroenterology Specialty Practice, Munich, Germany, [7]Rheumatology Center Schleswig-Holstein Middle, Neumünster, Germany, [8]Rheumatology/Clinical Immunology, Department of Internal Medicine II, Würzburg, Germany, [9]Rheumatology Practice, Onsabrück, Germany

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: RA increases a patient's systemic inflammatory burden, which has been associated with development of chronic kidney disease (CKD), especially in patients with comorbid hypertension, diabetes, or cardiovascular events[1,2]. Propensity-matched real-world cohorts show that treatment of RA with biologic therapies lowers the risk of glomerular filtration rate decline[1]. In the ICHIBAN study, tocilizumab (TCZ) was effective and well tolerated in clinical practice in Germany over up to 2 years[3]. Here, we present a post-hoc analysis of ICHIBAN patients with baseline renal insufficiency (RI; assessed as comorbidity by the study physician).

Methods: ICHIBAN was a prospective, multi-center, non-interventional study (NCT01194401; ML22928) that included adults with active, moderate-to-severe RA who received TCZ according to the local label in Germany. Safety was analysed in all patients who received one dose of TCZ (SAF). Effectiveness outcomes (SAF patients with no prior TCZ analyzed) included DAS28-ESR, CDAI, HAQ, and patient-reported outcomes (PROs) assessed via visual analogue scales (VAS; 0=best; 100=worst).

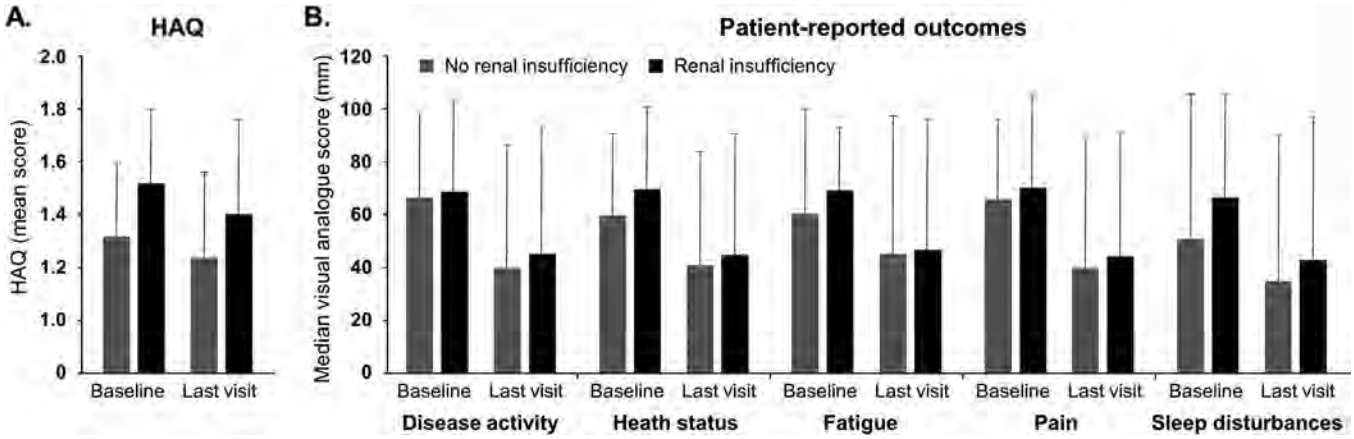

Figure 1. HAQ and patient-reported outcomes (PRO) at baseline and last visit in patient with and without renal insuffciency. A) Mean HAQ score and B) PROs accoring to the visual analogue scale, median mm. Error is presented in standard deviation for HAQ score and interquartile range for PROs. In case of discontinuation of tocilizumab treatment, the last available value was taken and carried forward (last observation carried forward, LOCF). Only patients with data at baseline and last visit under tocilizumab (or LOCF). 9 patients with missing renal status were not analyzed.

Osteoporosis	41.1 (37)	16.5 (505)

DMARDs: disease modifying anti-rheumatic drugs; SD: Standard deviation. 9 patients with missing renal status were not analyzed.

Table 2. Effectiveness after two years of observation

Results: Of the 3164 patients in the SAF, 90 (2.84 %) had RI at baseline. These patients were on average 12.8 years older; had a higher frequency of additional comorbidities, such as diabetes, hypertension and coronary heart disease (**Table 1**); and generally worse baseline physical functioning and PROs (especially sleep disturbances) (**Table 2**) than those without RI.

The mean treatment duration was similar patients with and without RI. At baseline, patients with RI less frequently received csDMARDS (**Table 1**), and slightly more frequently glucocorticoids (GCs; 85.4 vs 81.4%) than patients without RI. At last visit however, both groups showed identical proportions of GC therapy (74.4 vs 74.4%).

Importantly, TCZ treatment led to similar improvements in DAS28-ESR, CDAI, HAQ and PROs regardless of RI (**Table 2; Figure 1**).

The rates of adverse events (AEs) and serious AEs per 100 patient years were higher in patients with RI than in those without (169.3 vs 106.8, and 53.6 vs 23.1, respectively). The rate of infections was similar in both groups (23.3 vs 21.1) while the rate of serious infections was higher in patients with RI (11.3 vs 3.7). The rate of gastrointestinal perforations per 100 patient years was 1.9 in patients with RI and 0.2 in those without. The rate of treatment discontinuations due to AE was similar in both groups (9.4 vs 9.2).

		Patients with renal insufficiency	Patients without renal insufficiency
N		82	2814

Sleep disturbances; Median (IQR)	BL	66.5 (39.0)	51.0 (55.0)
	Last Visit	43.0 (54.0)	35.0 (55.0)

SD: Standard deviation; IQR: Inter quartile range.
In case of discontinuation of tocilizumab treatment, the last available value was taken and carried forward (last observation carried forward, LOCF). Only patients with data at baseline and last visit under tocilizumab (or LOCF).

Table 1. Baseline characteristics of patient with and without renal insufficiency

Conclusion: In the non-interventional ICHIBAN study, despite worse baseline disease in affected patients, the effectiveness of TCZ was similar in patients with and without RI. GC sparing was even more pronounced in patients with CKD compared with those without. As expected, higher rates of baseline comorbid risk factors, such as diabetes and hypertension, and age-dependent serious infections were observed in patients with RI. However, TCZ discontinuation due to an AE was not increased. Overall, this analysis supports the effectiveness and tolerability of TCZ in patients with RA and RI in real-world clinical practice.

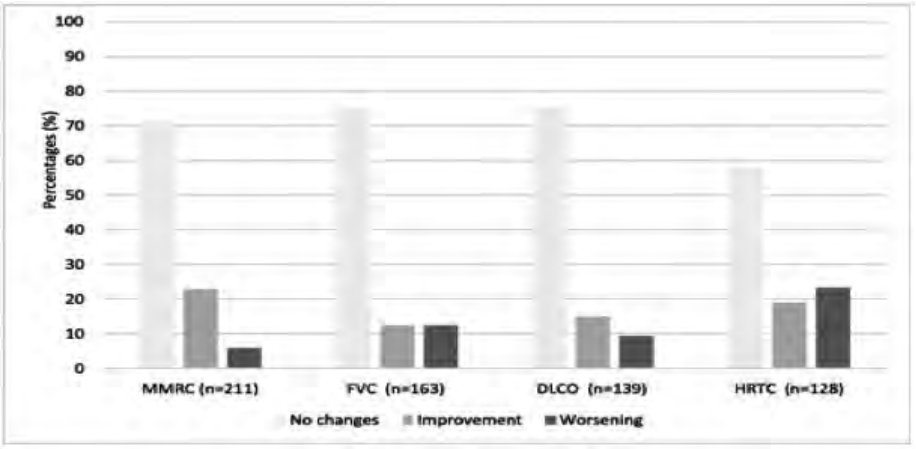
SESSION INFORMATION

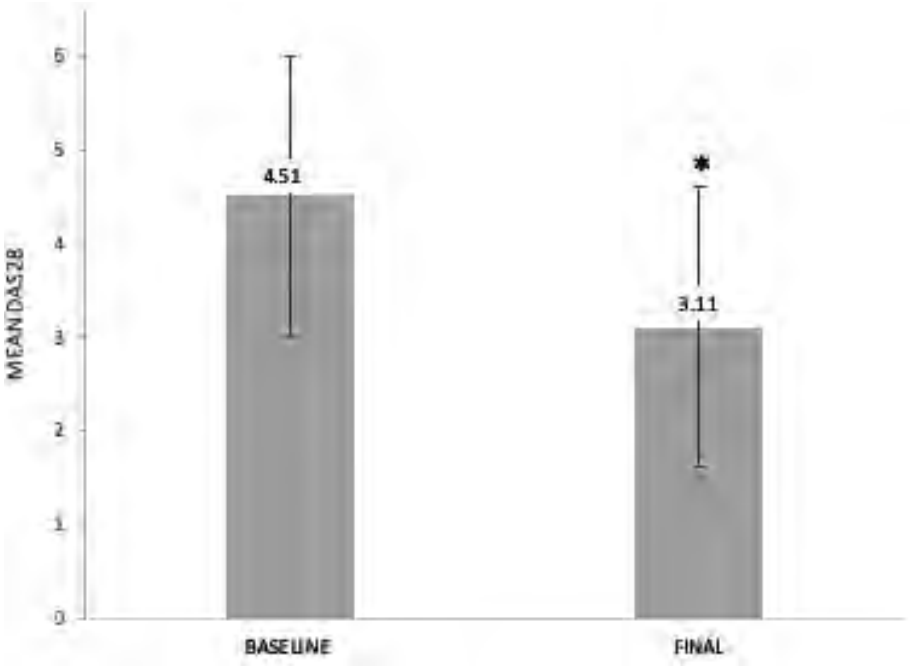
Session Date: Friday, November 6, 2020

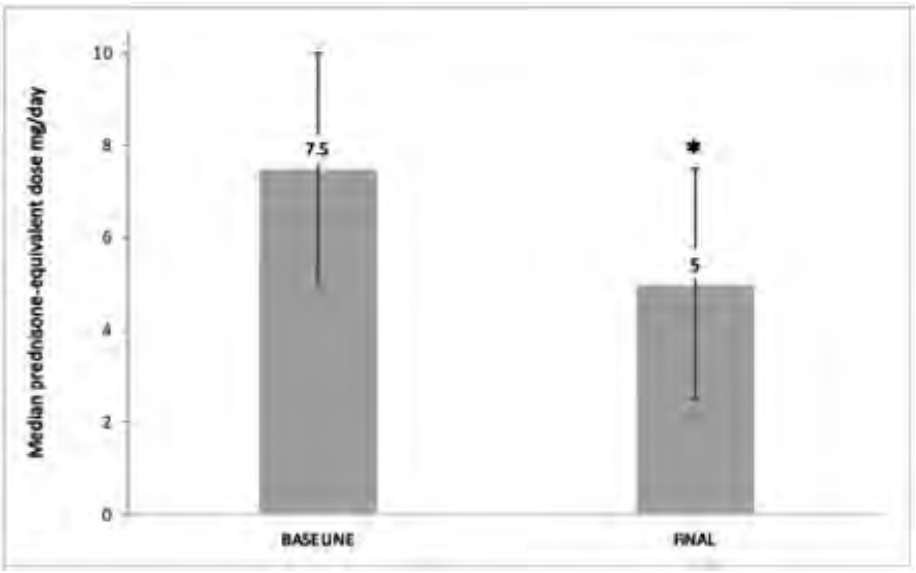
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM







Background/Purpose: To assess the efficacy of abatacept (ABA) in Rheumatoid Arthritis (RA) patients with Interstitial Lung Disease (ILD) (RA-ILD).

Methods: Observational multicenter study of RA-ILD patients treated with at least 1 dose of ABA. ILD was diagnosed by high-resolution computed tomography (HRCT). We analyzed the following variables at baseline (ABA initiation), 12 months, and at the end of the follow-up: **a)** Modified Medical Research Council (MMRC) scale (1-point change), **b)** Forced Vital Capacity (FVC) or Diffusion Lung Capacity for Carbon Monoxide (DLCO) (improvement or *worsening* ≥10%), **c)** HRCT, **d)** $DAS28_{ESR}$, and **e)** corticosteroid sparing effect

Results: We studied 263 RA-ILD patients (150 women/113 men; mean age 64.6±10 years). At baseline, they had a median duration of ILD of 1 [0.25-3.44] years, moderate or severe degree of dyspnea (MMRC grade 2, 3 or 4) (40.3%), FVC (% of the predicted) mean±SD 85.9±21.8%, DLCO (% of the predicted) 65.7±18.3, and $DAS28_{ESR}$: 4.5±1.5. The ILD patterns were: Usual Interstitial Pneumonia (UIP) (40.3%), Non-Specific Interstitial Pneumonia (NSIP) (31.9%), and others (27.8%). ABA was prescribed at standard dose, intravenously (25.5%) or subcutaneously (74.5%). After a median follow-up of 12 [6-36] months the following variables did not show worsening: dyspnea (MMRC) (91.9%); FVC (87.7%); DLCO (90.6%); chest HRCT (76.6%). A significant improvement of $DAS28_{ESR}$ from 4.5±1.5 to 3.1±1.3 at the end of follow-up ($p< 0.001$) and a corticosteroid sparing effect from a median 7.5 [5-10] mg/day to 5 [2.5-7.5] mg/day at the end of follow-up; $p < 0.001$ was also observed. ABA was withdrawn in 62 (23.6%) patients due to adverse events (n=30), articular inefficacy (n=27), ILD worsening (n=3), and other causes (n=2).

Conclusion: ABA may be an effective and safe treatment for patients with RA-ILD.

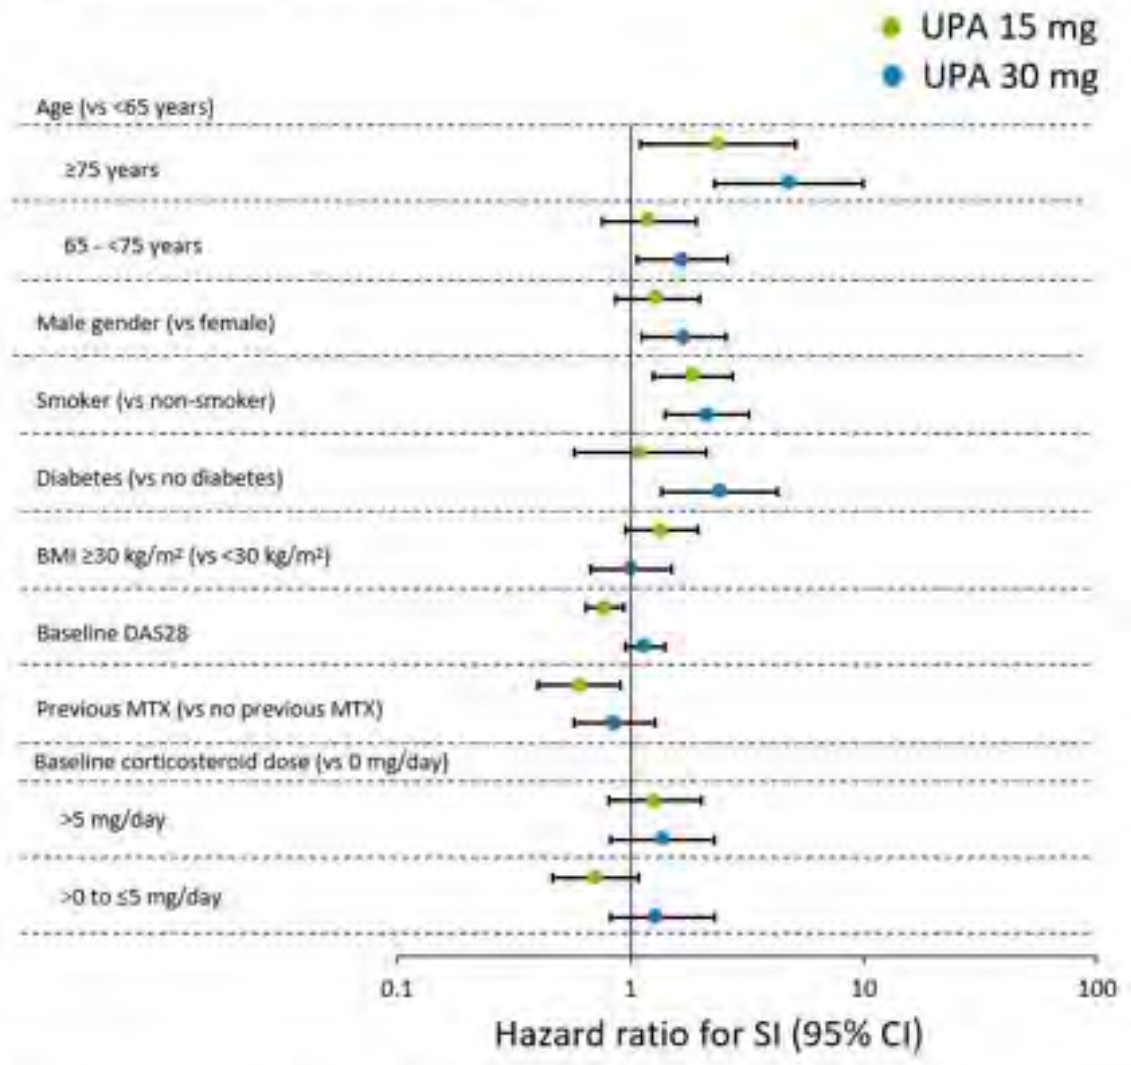
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) is a selective and reversible Janus kinase (JAK) inhibitor with an approved dose of 15 mg once daily (QD) for the treatment of rheumatoid arthritis (RA). Patients (pts) receiving JAK inhibitors have been reported to be at increased risk of developing serious infection events (SIE) and opportunistic infections (OI). We evaluate the incidence of SIEs and OIs in pts with RA receiving UPA and active comparators in the Phase 3 SELECT clinical trial program.

Figure. Univariate analysis of SIE risk factors



BMI, body mass index; DAS28, 28-joint disease activity score.

Methods: The exposure-adjusted event rate (EAER) per 100 patient-years (E/100 PY) of SIEs and OIs was determined in pts receiving UPA in five randomized Phase 3 trials (SELECT-EARLY, SELECT-MONOTHERAPY, SELECT-NEXT, SELECT-COMPARE, and SELECT-BEYOND), of which four evaluated both UPA 15 mg and 30 mg QD doses and one (SELECT-COMPARE) evaluated only UPA 15 mg QD. Incidences of SIEs and OIs were also determined in pts receiving adalimumab (ADA) + methotrexate (MTX) in SELECT-COMPARE and MTX monotherapy in SELECT-EARLY. Data were analyzed descriptively, with no statistical comparisons between groups or doses. Risk factors for SIEs were determined using a univariate Cox regression model. The data cut-off was June 30, 2019.

Results: Overall, 2629 pts who received UPA 15 mg, 1204 pts who received UPA 30 mg, 579 pts who received ADA + MTX, and 314 pts who received MTX monotherapy were included in this analysis. The EAERs (E/100 PYs [95% CI]) of SIEs were 3.2 (2.7–3.7) in the UPA 15 mg group, 5.7 (4.8–6.8) in the UPA 30 mg group, 3.9 (2.6–5.6) in pts receiving ADA + MTX, and 3.1 (1.7–5.2) in pts receiving MTX monotherapy. Pneumonia was the most common SIE, with EAERs (E/100 PYs [95% CI]) of 0.7 (0.5–1.0), 1.3 (0.9–1.9), 0.7 (0.2–1.5), and 0.7 (0.1–1.9) in the UPA 15 mg, UPA 30 mg, ADA

+ MTX, and MTX monotherapy groups, respectively. Rates of OIs (including oral candidiasis and disseminated herpes zoster [HZ]) (E/100 PYs [95% CI]) were 0.7 (0.5–1.0), 1.3 (0.9–1.9), 0.4 (0.1–1.1), and 0 (0–0) in the UPA 15 mg, UPA 30 mg, ADA + MTX, and MTX monotherapy groups, respectively. Oral candidiasis was the most frequent OI with EAERs (E/100 PYs [95% CI]) of 0.4 (0.2–0.6) in the UPA 15 mg group, 0.6 (0.3–1.0) in the UPA 30 mg group, 0.4 (0.1–1.1) in the ADA + MTX group, and 0 (0–0) in the MTX monotherapy group. Serious adverse events of HZ were only reported in the UPA groups (0.2 E/100 PYs [95% CI: 0.1–0.3] and 0.6 E/100 PYs [95% CI: 0.4–1.1] in the UPA 15 mg and 30 mg groups, respectively). Overall, there were 3 (4 coded events), 3, 1, and 0 pts who had active tuberculosis events in the UPA 15 mg, UPA 30 mg, ADA + MTX, and MTX monotherapy groups, respectively. Risk factors for SIEs are shown in the Figure. For both UPA doses, age ≥75 years and smoking were noted to have hazard ratios >1.

Conclusion: The incidence rate of SIEs and OIs was higher in the UPA 30 mg group than the UPA 15 mg group. SIEs observed with UPA 15 mg were similar to that seen with ADA although the rates of HZ were higher on UPA. Pts with RA who are ≥75 years old and/or smokers may be at higher risk than other pts with RA for SIEs while receiving UPA.

Safety and Biological Activity of Rozibafusp Alfa in Subjects with Rheumatoid Arthritis: Final Results of a Phase 1b Randomized, Double-blind, Placebo-Controlled, Multiple Ascending Dose Study

Lubna Abuqayyas[1], Laurence Cheng[1], Kyong Park[1], Marcia Teixeira dos Santos[1], Barbara Sullivan[1], Hui Wang[1], Yanchen Zhou[1], Vishala Chindalore[2], **Stanley Cohen**[3], Alan Kivitz[4], Maximilian Posch[5] and Jane Parnes[1], [1]Amgen Inc., Thousand Oaks, CA, [2]Pinnacle Research Group, Anniston, AL, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Altoona Center for Clinical Research/Altoona Arthritis and Osteoporosis Center, Duncansville, PA, [5]Charité Research Organisation, Berlin, Germany

SESSION INFORMATION

Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

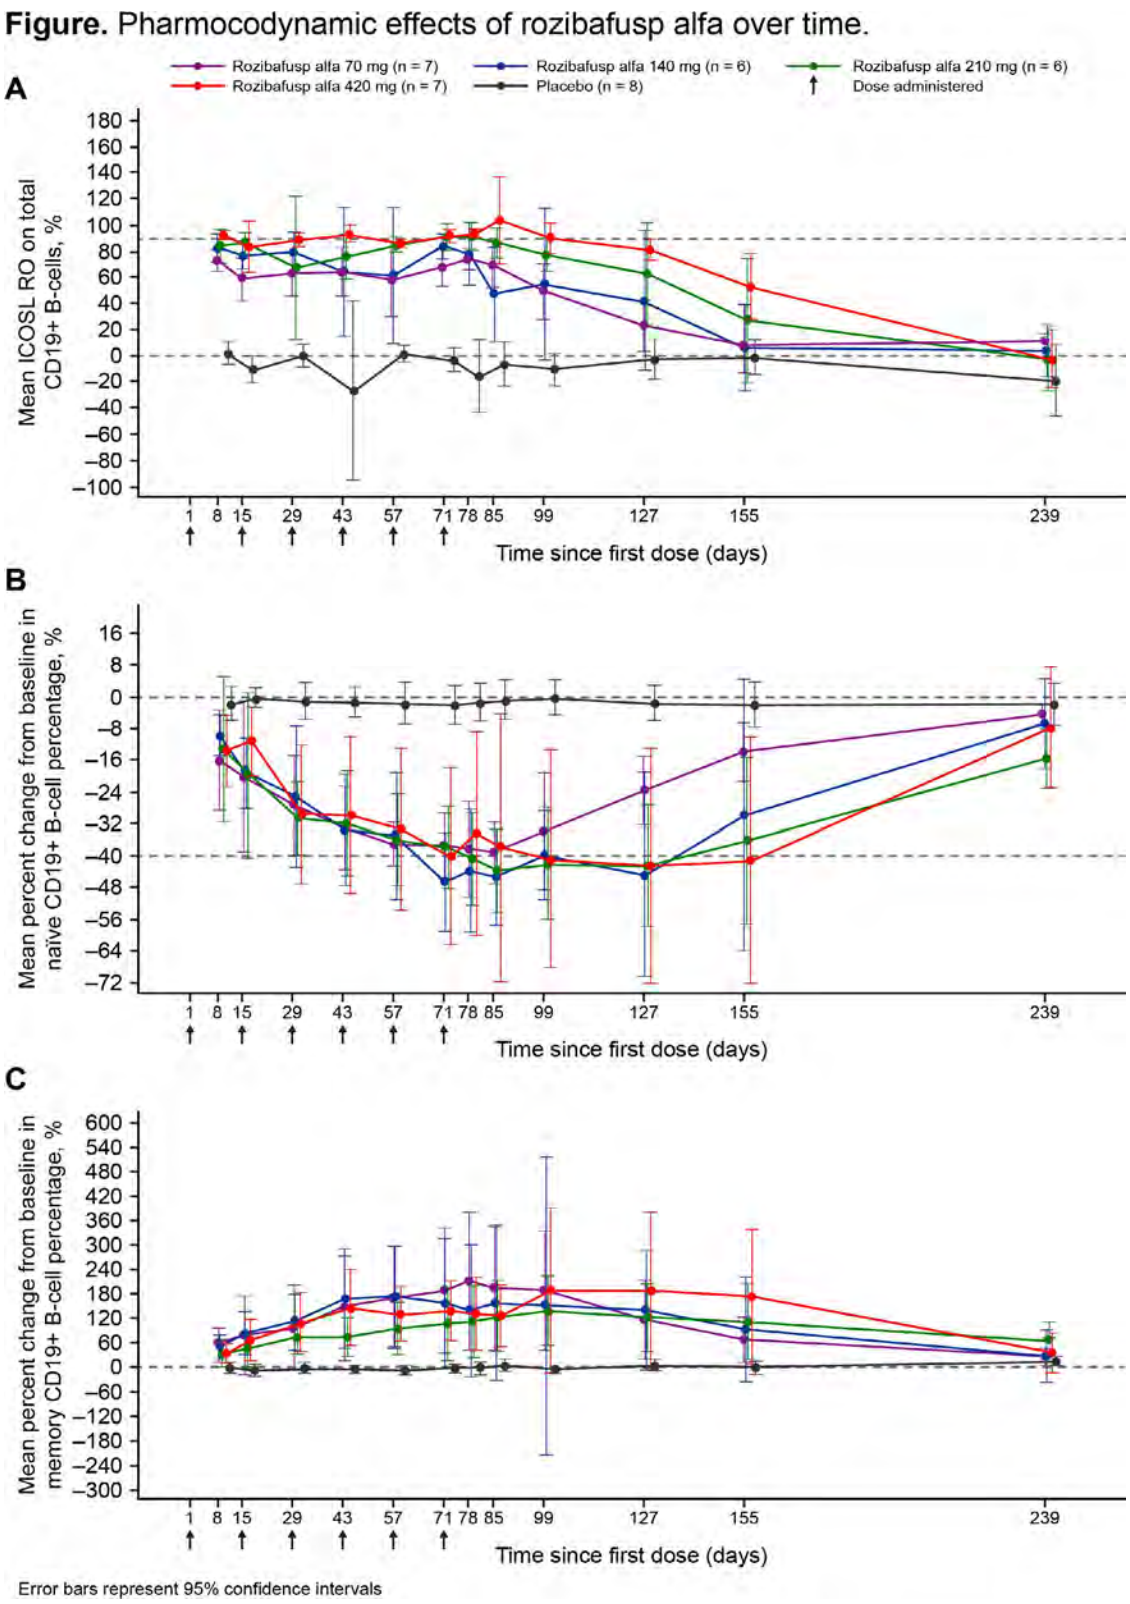

Figure. Pharmacodynamic effects of rozibafusp alfa over time

Background/Purpose: B-cell activating factor (BAFF) and inducible costimulator ligand (ICOSL) are implicated in autoimmune disease pathogenesis, and clinical findings support their utility as drug targets in autoimmune disease (Navarra SV *Lancet* 2011; Cheng LE *Arthritis Rheumatol* 2018). Rozibafusp alfa is a first-in-class bispecific

antibody-peptide conjugate that inhibits BAFF and ICOSL and is currently in phase 2 clinical development for the treatment of SLE. This final analysis of a phase 1b study (NCT03156023) reports the safety, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity, and effect of rozibafusp alfa on disease control in subjects with RA.

Methods: A total of 34 subjects (age 42–75 years; 82.4% female) with active RA, defined as a disease activity score (DAS28-CRP) >2.6, were randomized 3:1 to receive rozibafusp alfa (N=26, divided into 4 multiple ascending dose cohorts of 70, 140, 210, and 420 mg) or placebo (N=8) subcutaneously every 2 weeks for 10 weeks (6 doses), with 24 weeks of follow-up. All subjects were maintained on a sTable dose of MTX. The primary endpoint was the subject incidence of treatment-emergent adverse events (TEAEs). Additional assessments included serum PK profiles, PD (eg, ICOSL receptor occupancy (RO), changes in peripheral blood B-cells), incidence of anti-rozibafusp alfa antibodies (ADA), and Patient and Physician Global Assessments (PtGA and PhGA) of disease activity.

Results: TEAEs occurred in 96.2% and 87.5% of subjects receiving rozibafusp alfa and placebo, respectively. Two rozibafusp alfa-treated subjects (7.7%) reported serious adverse events; none were considered related to treatment by the study investigator. Rozibafusp alfa demonstrated nonlinear PK and a mean terminal half-life of 4.6–9.5 days, with longer half-lives at higher doses. ICOSL RO on circulating B-cells was dose-related and reversible; >90% mean RO was observed for the 210 and 420 mg dose cohorts (**Figure**). Treatment with rozibafusp alfa reduced the percentage of naïve B-cells and increased the percentage of memory B-cells in all cohorts (**Figure**). Five (20%) subjects developed ADA with no associated AEs, but 1 subject had lower PK and reduced ICOSL RO at day 57. RA disease activity showed greater numerical improvement from baseline in PtGA and PhGA with rozibafusp alfa vs. placebo in the 210 and 420 mg cohorts; maximum score reduction for PtGA and PhGA was achieved after 10 and 6 weeks of rozibafusp alfa treatment, respectively, in both cohorts and persisted through day 183 in the 420 mg cohort.

Conclusion: Multiple ascending doses of rozibafusp alfa were safe and generally well tolerated, with exploratory efficacy results observed in the highest dose cohorts. PK/PD analysis demonstrated nonlinear, target-mediated disposition consistent with cell surface target interaction and PD activity consistent with dual ICOSL/BAFF neutralization. These findings informed the design and dose selection of an ongoing phase 2, randomized, placebo-controlled study to assess the efficacy and safety of rozibafusp alfa in subjects with active SLE and inadequate responses to standard of care therapy.Figure. Pharmacodynamic effects of rozibafusp alfa over time

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The subcutaneous (SC) formulation of CT-P13 received marketing authorization for RA from the EMA by demonstrating non-inferiority compared to CT-P13 intravenous for efficacy in RA patients[1]. CT-P13 SC can provide a clinically meaningful improvement in the quality of life, convenience in treatment and use, as well as enable patients to gain better control over their condition. To provide patients with more comforTable administration

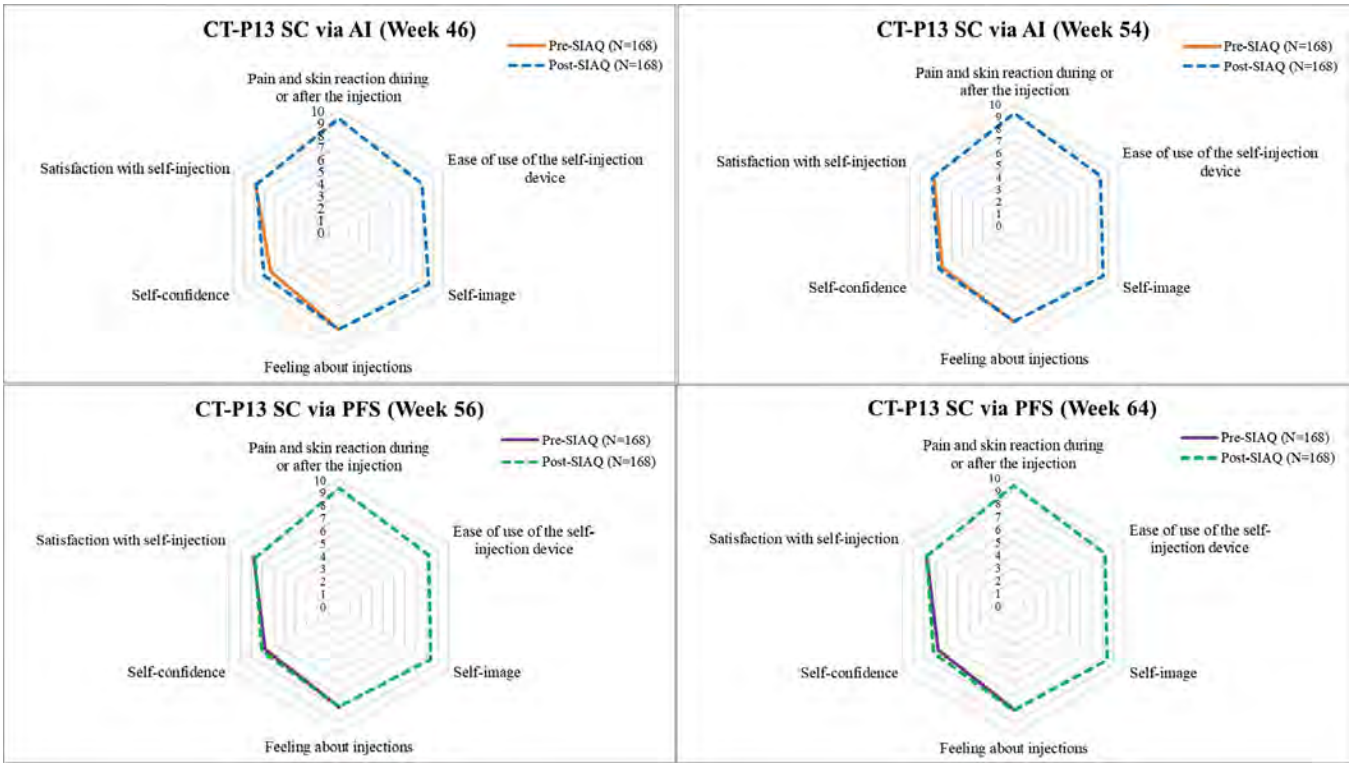

Figure 1. Spidergram of Pre- and Post-Self Injection Assessment Questionnaire

Criteria	Device	Visit	Proportion of patients (%)
Patients with "No" in all items on the Potential Hazard Checklist	AI	Week 46	158/167 (94.6%)
		Week 54	162/165 (98.2%)
	PFS	Week 56	163/164 (99.4%)
		Week 64	158/159 (99.4%)

Note: Percentages were calculated by using the number of patients who self-injected at least one CT-P13 SC via AI or PFS with at least one usability assessment performed and who had hazard-free self-injection assessment as the denominator.

Table 1. Summary of Proportion in Hazard-free Self-Injection

Number of patients, n (%)	**Usability population (N=168)**
Any TEAEs	67 (39.9%)
TEAEs related to the study drug	48 (28.6%)
TEAEs leading to the study drug discontinuation	3 (1.8%)
Localized injection site reaction	1 (0.6%)
Urinary tract infection	1 (0.6%)
Delayed hypersensitivity	1 (0.6%)
Serious TEAEs	1 (0.6%)
Localized injection site reactions	30 (17.9%)
Injection site pain	21 (12.5%)
Injection site erythema	18 (10.7%)
Injection site pruritus	11 (6.5%)
Injection site swelling	10 (6.0%)
Injection site induration	9 (5.4%)
Injection site bruising	3 (1.8%)
Injection site coldness	3 (1.8%)
Injection site irritation	2 (1.2%)
Injection site oedema	2 (1.2%)
Injection site paraesthesia	2 (1.2%)
Injection site haematoma	1 (0.6%)
Injection site ulcer	1 (0.6%)
Injection site urticaria	1 (0.6%)
Scab	1 (0.6%)

Table 2. Summary of Adverse Events during the Usability Assessment

of CT-P13 SC, an AI was developed and this study is to investigate the usability and safety including localized injection site reactions (ISRs) of the AI versus PFS for SC delivery of CT-P13 in RA.

Methods: Usability assessment was conducted as a sub-study of the pivotal CT-P13 SC study in RA patients. Patients self-injected CT-P13 SC every 2 weeks via AI from Weeks 46 to 54 and via PFS from Weeks 56 to 64. The usability of both devices was determined by the observer (healthcare professional) rating of successful, hazard-free self-injection and patient reporting of device experience using the Self-Injection Assessment Questionnaire (SIAQ). Safety, including localized ISRs, was recorded during the usability assessment period.

Results: Patients (N=168) self-injected at least one dose of CT-P13 SC via AI or PFS and had at least one usability assessment performed. The results of usability for CT-P13 SC via AI and PFS were both high (Figure 1), as rated by the patients based on the mean scores ranging from 7.09 to 9.37 for AI and 7.03 to 9.41 for PFS on a scale of 0 (worst experience) to 10 (best experience) for all post SIAQ domains. Following the use of both devices, patients rated their self-confidence higher; 6.47 to 6.97 before using AI, but changed to 7.09 to 7.30 after using AI; 6.73 to 6.84 before

using PFS but changed to 7.03 to 7.20 after using PFS. Except for 11 patients who missed assessment or discontinued from the study, all patients were able to successfully self-administer the injections and completed all instructions from the self-injection assessment checklist for both AI and PFS. The number of patients with the hazard (experiencing a needle stick in the non-critical area) was decreased from 9 patients at Week 46 to 3 patients at Week 54 with AI showing that AI improved in terms of safety by reducing the risk of injury and improper administration. Only 1 patient was with hazard at Weeks 56 and 64, and therefore there was no increase in potential hazard after switching from AI to PFS (Table 1). At least one treatment-emergent adverse event was reported in 67 (39.9%) patients during the usability assessment period. CT-P13 administered by either AI or PFS was generally safe, demonstrating consistency with the known safety profile of infliximab (Table 2).

Conclusion: Infliximab delivered by both AI and PFS was generally well-tolerated and the results demonstrated that there were no differences in usability between AI and PFS. The availability of both AI and PFS will allow patients to select a device based on their own preferences and experiences and will lead to increased adherence during long-term therapy.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The safety and efficacy of upadacitinib (UPA), an oral JAK inhibitor, was evaluated in the phase 3 SELECT clinical program, which included 5 randomized, double-blind, controlled trials across a spectrum of rheumatoid arthritis (RA) patients (pts)[1-5]. We describe the long-term integrated safety profile of UPA relative to active comparators in pts with RA treated in the SELECT program up to a cut-off date of 30 June 2019.

Table. Overall TEAEs for UPA and Active Comparators (E/100 PYs [95% CI])				
	MTX n=314 (456.0 PYs)	ADA 40 mg eow n=579 (768.6 PYs)	UPA 15 mg QD n=2629 (4565.8 PYs)	UPA 30 mg QD n=1204 (2309.7 PYs)
Any AE	271.7 (256.8, 287.3)	242.3 (231.4, 253.5)	247.7 (243.2, 252.3)	310.6 (303.5, 317.9)
Any SAE	12.7 (9.7, 16.4)	14.6 (12.0, 17.5)	12.9 (11.9, 14.0)	19.8 (18.0, 21.7)
Any AE leading to discontinuation	7.7 (5.3, 10.7)	8.2 (6.3, 10.5)	6.3 (5.6, 7.1)	10.0 (8.8, 11.4)
Deaths[a]	0.4 (0.1, 1.6)	0.8 (0.3, 1.7)	0.4 (0.2, 0.6)	0.7 (0.4, 1.1)
[a]Deaths included non-treatment emergent deaths: ADA, 1; UPA 15 mg, 3; UPA 30 mg, 3.				

Methods: Treatment-emergent adverse events (TEAEs: AE onset ≥first dose and ≤30 days after last dose) were summarized for the following: methotrexate (MTX, 1 trial, mean exposure 76 wks); adalimumab (ADA, 1 trial, mean exposure 69 wks); pooled UPA 15 mg (5 trials, mean exposure 90 wks); pooled UPA 30 mg (4 trials, mean exposure 100 wks). TEAEs are reported as exposure-adjusted event rates (EAERs; events/100 patient years [E/100PYs]).

Results: 3833 pts received ≥1 dose of UPA 15 mg [n=2629, 4565.8 PYs] or 30 mg [n=1204, 2309.7 PYs] QD, with no option to switch doses. More than half of pts received UPA for ≥96 wks (median: UPA 15, 101.9 wks; UPA 30: 111.7 wks). The EAERs of overall SAEs and AEs leading to discontinuation on UPA 15 mg were comparable to MTX and ADA; rates on UPA 30 mg were numerically higher than UPA 15 mg (**Table**). The most common AEs (≥5 E/100 PYs) reported with UPA 15 mg were upper respiratory tract infection (URTI), nasopharyngitis, urinary tract infection (UTI), bronchitis, increased CPK, and increased ALT. For UPA 30 mg, the most common AEs reported were URTI, UTI, increased CPK, nasopharyngitis, bacterial bronchitis, and herpes zoster (HZ). Overall rates of serious infections and opportunistic infections were comparable between UPA 15 mg, MTX, and ADA groups but were higher on UPA 30 mg (**Figure**). Rates of HZ were higher in both UPA groups (30 mg higher than 15 mg) vs MTX and ADA. The majority of HZ cases were non-serious (96%) and involved a single dermatome (74%). Rates of VTE were comparable across treatment groups (0.3-0.5/100 PYs), as were rates of adjudicated MACE and malignancies (excluding NMSC). Rates of NMSC in UPA 15 mg and ADA were similar, with numerically higher rates on UPA 30 mg. SMR analysis demonstrated that the number of deaths in pts with RA exposed to UPA was not higher than what would be expected for the general population.

Conclusion: Through long-term follow-up, the integrated safety profile of UPA remained consistent with previous analyses, with no new signals identified.

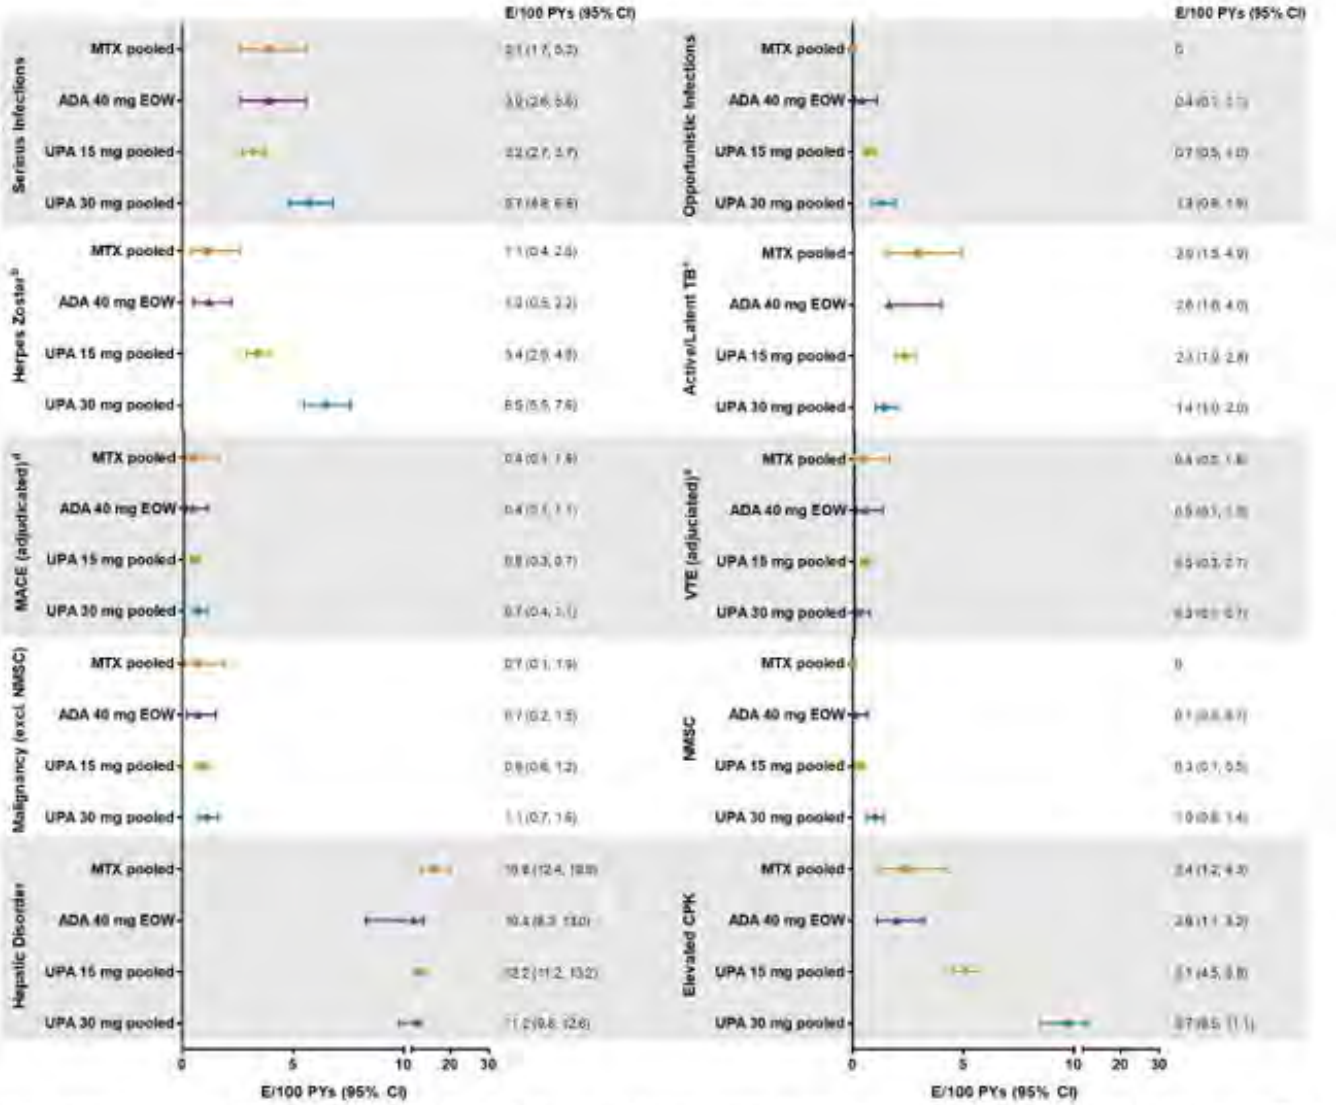
Figure. Overall AESIs in Patients Treated with Upadacitinib Compared to Active Controls[a]



MTX pooled: N=314, PYs=456.0; ADA 40 mg EOW: N=579, PYs=768.6; UPA 15 mg pooled: N=2629, PYs=4565.8; UPA 30 mg pooled: N=1204, PYs=2309.7

[a]Patients who switched from PBO, ADA, or MTX to UPA were included in the UPA analysis set from the start of UPA, while those who switched from upadacitinib to ADA were included in the ADA dataset from the start of ADA. There was no switch between UPA doses in any study. MTX monotherapy censored at time of rescue to combination therapy (either UPA + MTX or addition of csDMARD).

[b]Most HZ cases were non-serious (95.9%) and single dermatome (74.4%).

[c]There were 6 cases of active TB on UPA (0.1 E/100 PYs) and 1 on ADA.

[d]MACE was defined as CV death, non-fatal MI, and non-fatal stroke.

[e]VTE was defined as deep vein thrombosis and pulmonary embolism

ADA, adalimumab; AE, adverse event; CPK, creatine phosphokinase; CV, cardiovascular; E, events; EOW, every other week; MACE, major adverse cardiovascular event; MI, myocardial infarction; MTX, methotrexate; NMSC, non-melanoma skin cancer; PBO, placebo, PYs, patient-years; QD, once daily; TB tuberculosis; TEAE, treatment-emergent adverse event; UPA, upadacitinib; VTE, venous thromboembolism.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: INTRODUCTION The use of biological therapies during pregnancy has been contraindicated since the beginning of the use of these drugs. In recent years several studies have demonstrated the minimal-to-no transfer of certolizumab pegol (CZP) to the placenta and breast milk, which has allowed its approval for use in pregnancy and breastfeeding if clinically necessary. However, there are no studies evaluating the use of CZP during this period in real life or the characteristics of this subgroup of patients. OBJECTIVE: To describe the profile of women of childbearing age diagnosed with chronic inflammatory rheumatic disease (CIRD): Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and axial Spondyloarthritis (axSpA), who initiate CZP by gestational desire using the GESTAMAD registry (multicenter study of women with chronic inflammatory rheumatic disease of childbearing age who are initiated on CPZ by gestational desire from the Madrid community).

Methods: Prospective multicenter study that aims to know the characteristics of women of childbearing age diagnosed with CIRD and gestational desire to which CZP is initiated for this reason. The comorbidities of the patients such as hypertension, diabetes and cardiovascular disease were collected. Disease activity was measured by DAS28 using CRP in RA and PsA and BASDAI in axSpA. The present study presents preliminary data from the initial cohort and will be followed prospectively for 24 months to assess the efficacy and safety of the drug during pre-conception, pregnancy and lactation.

Results: A total of 48 patients have been recruited in 6 Madrid hospitals from June 2019 to May 2020. Patients had a mean age of 35.6, (36.3 in RA, 35.2 in PA and 34.9 in SPA). 52.1 percent had RA, 29.2 percent had PA and 18.7

percent had SPA. The mean disease duration for RA, PA and SPA was 9.5, 7.5 and 6.8 years, respectively. 50.0% of women were nulliparous. The abortion rate of patients diagnosed with spondyloarthropathy was 21.8%. 33.3% of the patients had been treated with previous biologicals, with gestational desire/pregnancy being the reason for the change. 78.1 % of the patients had been treated with synthetic disease modifying antirheumatic drugs (DMARD) previously. With regard to disease activity, the mean DAS 28 at the start of treatment was 4.5 in RA and 3.8 in PA and BASDAI 7.0 in axSPA. In RA the highest values of CRP and ESR were found prior to initiation with CZP, but this difference was not statistically significant (p=0.632 and 0.621, respectively). 22.9% of patients had previous comorbidities.

Conclusion: CONCLUSIONS: The mean age of patients with gestational desire in CIRD is high. Women diagnosed with PsA and axSpA have a high rate of previous abortions, upper than 25%. The duration of the disease is equally long at the time of manifesting gestational desire. The use of treatments such as CZP, compatible with pregnancy and lactation would allow a better control of inflammatory joint disease in this period of life, encouraging patients not to postpone their gestational desire.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Treatments Poster I: RA Treatments & Their Safety
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL)—an oral, selective Janus kinase 1 inhibitor (JAKi)—improved RA signs and symptoms in three phase 3 trials. Despite the efficacy of FIL and other JAKi, there are some concerns regarding potential for venous thromboembolism (VTE); major adverse cardiac events (MACE); and elevated platelet levels, which may result from JAK2 inhibition and modulation of thrombopoietin and could be causally related to VTE.

Methods: Patients (pts) meeting 2010 ACR/EULAR criteria for RA who participated in the phase 2 DARWIN 1–2 (D1–2), phase 3 FINCH 1–3 (F1–3), and long-term extension studies (DARWIN 3 [D3] and FINCH 4 [F4]) and received

Table 1. Prevalence of factors associated with cardiovascular risk at baseline in patients receiving FIL 200 mg or FIL 100 mg in pooled phase 3 studies (F1, 2 and 3)

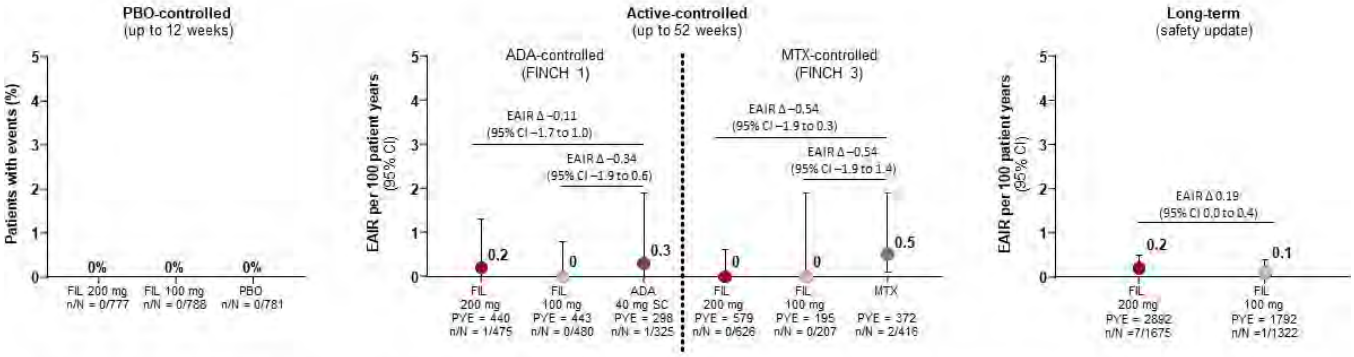
FIL 100 mg, FIL 200 mg, adalimumab (ADA), or placebo (PBO) with or without MTX were included. Events were analyzed as-exposed according to treatment received.

The week (W)12 PBO-controlled safety analysis included data from pts who received FIL 100, FIL 200, or PBO for ≤12W (D1–2, F1–2); some PBO-treated pts had additional data through W24 (F1–2). The active-controlled analysis included data from pts who received FIL 100, FIL 200, or ADA with background MTX (F1) and pts who received FIL 100 + MTX, FIL 200 + MTX, FIL 200, or MTX (F3) for ≤52W. The FIL 200 vs FIL 100 analysis included data from pts (D1–3, F1–4) for ≤5.5 years.

Data were analyzed based on whether pts did/did not experience a MACE or VTE event. For active-controlled analysis sets (except MACE in the MTX-controlled analysis set), exposure-adjusted incidence rates (EAIRs) and 95% confidence intervals (CIs) were calculated using the exact Poisson method, and treatment differences were provided with corresponding CIs based on the confidence limits of individual point estimates. For FIL 200 vs FIL 100 analyses and MACE in the MTX-controlled analysis set, EAIRs, difference in EAIRs, and 95% CIs were calculated using Poisson regression with treatment group as a covariate. Suspected MACE (cardiovascular [CV] death, myocardial infarction,

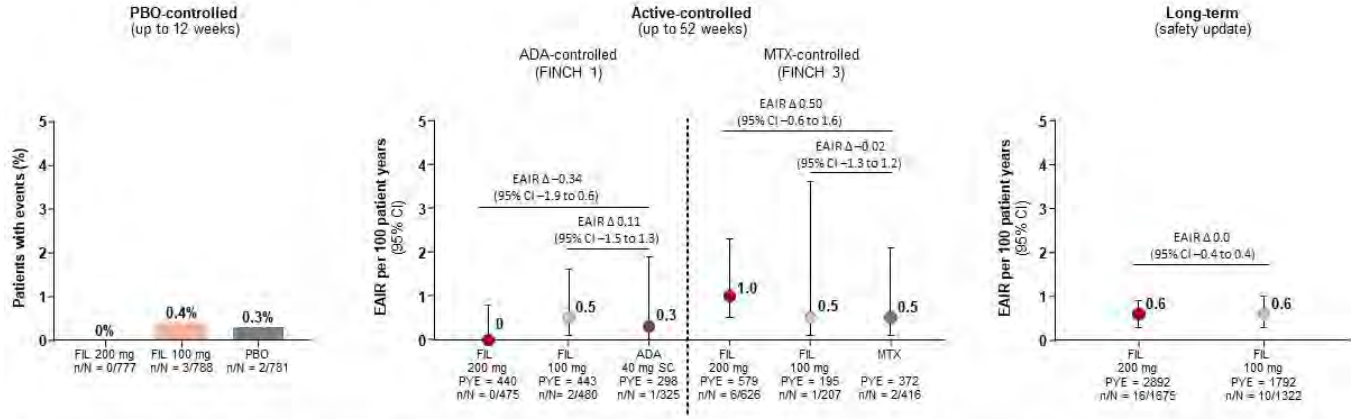
Figure 1. VTE events during the PBO-controlled, active-controlled, and long-term periods



All analyses include all data from the patient's original assigned study treatment but censor data after subjects were rerandomized or assigned to a different treatment; long-term analysis also includes data from patients rerandomized from PBO to FIL.
EAIR for ADA-controlled and MTX-controlled: Exact Poisson method.
EAIR for long-term: Poisson regression with treatment and log exposure as offset.
Two additional events occurred in PBO-treated patients between week 12 and week 24.
Δ, change; ADA, adalimumab; CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL, filgotinib; n/N, number of events per total number of patients; PBO, placebo; PYE, patient-years of exposure; SC, subcutaneous; VTE, venous thromboembolism.

Figure 1. VTE events during the PBO-controlled, active-controlled, and long-term periods

Figure 2. MACE during the PBO-controlled, active-controlled, and long-term periods



All analyses include all data from the patient's original assigned study treatment but censor data after subjects were rerandomized or assigned to a different treatment; long-term analysis also includes data from patients rerandomized from PBO to FIL.
EAIR for ADA-controlled: Exact Poisson method.
EAIR for MTX-controlled and long-term: Poisson regression with treatment and log exposure as offset.
One additional event occurred in a PBO-treated patient between week 12 and week 24.
Δ, change; ADA, adalimumab; CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL, filgotinib; MACE, major adverse cardiovascular event; n/N, number of events per total number of patients; PBO, placebo; PYE, patient-years of exposure; SC, subcutaneous.

Figure 2. MACE during the PBO-controlled, active-controlled, and long-term periods

and stroke) and VTE (deep vein thrombosis and pulmonary embolism) were adjudicated by a blinded independent CV safety endpoint adjudication committee.

Results: CV risk factors were common at baseline (**Table 1**). No VTE occurred in the 12W PBO-controlled safety analysis (**Figure 1**). There were 13 total VTE events. EAIR/100 patient-years of exposure (PYE) were comparable for all treatments (EAIR [n]: FIL 200, 0.2 [7]; FIL 100, 0.1 [1]; ADA, 0.3 [1]; MTX, 0.5 [2]; PBO (up to W24), 0.7 [2]; **Figure**

1). Crude incidence of MACE in the PBO-controlled safety analysis is shown in **Figure 2**. There were 32 MACE events overall. EAIRs were comparable for all treatments (EAIR [n]: FIL 200, 0.6 [16]; FIL 100, 0.6 [10]; ADA, 0.3 [1]; MTX, 0.5 [2]; PBO (up to W24), 1.0 [3]; **Figure 2**). Platelet counts did not increase during the study; at W52, mean platelet counts slightly decreased in all treatment arms.

Conclusion: No safety signal for VTE or MACE was observed in the filgotinib RA program. EAIRs of positively adjudicated VTE and MACE were low and consistent with expectations in patients with RA (EAIR 0.4/100 PYE for VTE and 1.0/100 PYE for MACE).[1,2]

Long-term Safety and Efficacy of Sarilumab over 5 Years in Patients with Rheumatoid Arthritis with 1 or >1 Prior Tumor Necrosis Factor Inhibitor Failures

Roy Fleischmann[1], Karina Maslova[2], Henry Leher[3], Amy Praestgaard[2] and Gerd Burmester[4], [1]Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX, [2]Sanofi, Cambridge, MA, [3]Regeneron Pharmaceuticals, Inc, Tarrytown, NY, [4]Charité University Hospital Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Treatments Poster I: RA Treatments & Their Safety

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: A proportion of adult patients with RA are refractory to TNF inhibitors (TNFi), and treatment with subsequent biologics may be associated with reduced response. Sarilumab is a human IL-6 receptor inhibitor approved for the treatment of adults with moderate to severely active RA. In the phase 3 TARGET study (NCT01709578), significant improvements in the signs and symptoms of RA and physical function were shown with sarilumab versus placebo in patients refractory to TNFi who were receiving background conventional synthetic DMARDs. Here we investigate the long-term safety and efficacy of subcutaneous sarilumab over 5 years in patients with 1 or >1 TNFi treatment failure prior to their enrollment in TARGET, who continued onto the open-label extension (OLE) study, EXTEND (NCT01146652).

Methods: In the 24-week, randomized, controlled trial TARGET, patients received placebo, sarilumab 150 mg, or sarilumab 200 mg every 2 weeks (q2w), and were eligible to receive open-label sarilumab 200 mg q2w in EXTEND. Dose reduction to 150 mg q2w was permitted per investigator's discretion, or to manage laboratory abnormalities. Safety outcomes are presented for the entire follow-up period from TARGET baseline through EXTEND. Efficacy was assessed using Clinical Disease Activity Index (CDAI) score. Data cut-off date was January 15, 2019.

Table 1. Summary of TEAEs by treatment allocation during TARGET and by TNFi failure status, number of events (events per 100 PY)

	Placebo + DMARD		Sarilumab 150 mg q2w + DMARD		Sarilumab 200 mg q2w + DMARD		All	
Prior TNFi, n	**1**	**>1**	**1**	**>1**	**1**	**>1**	**1**	**>1**

Table 1

Table 2. Mean CDAI and proportion of CDAI responders

Treatment allocation in 24-week RCT	Placebo + DMARD (n=156)		Sarilumab 150 mg + DMARD (n=145)		Sarilumab 200 mg + DMARD (n=153)	
TNFi failures	**1**	**>1**	**1**	**>1**	**1**	**>1**
CDAI, mean (SD)						
RCT baseline	43.7 (12.7)	42.5 (10.3)	42.0 (13.0)	44.3 (13.5)	42.1 (13.5)	48.5 (13.0)
Change after 216 weeks' follow-up	−30.9 (17.5)	−32.6 (15.2)	−33.3 (15.8)	−33.1 (12.7)	−30.3 (13.6)	−36.0 (18.1)
CDAI ≤10, n (%)*						
OLE baseline	48 (42)	14 (33)	59 (53)	16 (47)	56 (49)	20 (51)
After 216 weeks' follow-up	24 (21)	10 (24)	29 (26)	7 (21)	29 (25)	8 (21)

*Nonresponder imputation; ITT values used as denominators. CDAI=Clinical Disease Activity Index; ITT=intent to treat; OLE=open-label extension; RCT=randomized controlled trial; TNFi=TNF inhibitor

Table 2

Results: Of the 546 patients randomized in TARGET, 454 (83%) entered EXTEND; of those, 339 had 1 TNFi failure and 115 had >1 TNFi failure. Patients with >1 TNFi failure were older and had a longer duration of RA than patients with 1 TNFi failure (mean ± SD age: 55 ± 13 years vs 52 ± 12 years; RA duration: 14 ± 9 years vs 11 ± 9 years). Kaplan-Meier estimates of the probability of continuation at 5 years were similar between groups: 48% and 54% for patients with >1 and 1 TNFi failure, respectively. By the cut-off date, 36% (199/546) of patients had discontinued treatment during TARGET and EXTEND. In patients with >1 and 1 TNFi failure, there were 291 and 198 treatment-emergent adverse events (AEs) per 100 patient-years (PY), respectively, and 6 and 8 AEs/100 PY leading to discontinuation (Table 1). Clinical efficacy of sarilumab was sustained through 5 years in EXTEND, regardless of initially assigned treatment in TARGET (Table 2).

Conclusion: The long-term safety and efficacy of sarilumab were similar in patients with 1 or >1 prior TNFi failure over 5 years' follow-up. Clinical efficacy could be sustained through 5 years of treatment.

ular cartilage and the juxtaarticular bone. Initiating disease-modifying anti-rheumatic drugs (DMARDs) within three months of diagnosis is currently recommended to prevent the potential effects of untreated synovitis (i.e., joint destruction, loss of joint function, and pain). Patients taking DMARDs commonly experience medication adverse events. The purpose of this study is to report factors predictive of medication adverse events in patients with RA over time.

Methods: We conducted a secondary analysis of a prospective study (baseline, 1 week, 8 weeks, 16 weeks and 24 weeks) in a sample of 143 RA patients at one University health system. Trust in provider was measured with the *Trust in Physician Scale*, an 11-item scale using a 5-point Likert scale (1 = *strongly disagree* – 5 *strongly agree;* Cronbach's α = .87). Disease activity was measured with the *Routine Assessment of Patient Index Data 3* (RAPID3) on three domains: physical function, pain, and patient global assessment on a scale of 0 to 10 (range 0 - 30). The RAPID3 has been significantly correlated with other measures of disease activity. Adverse events and demographic factors were self-reported. We used repeated measures models using last observation carried forward for participants with missing follow-up data.

Results: In the sample of 143 participants, the average age was 52 years (SD=10.8). The majority of participants were female (81%) and White (91%). Disease activity scores were low (mean 2.6; SD=0.6) and trust in the provider scores were high (mean 87.4; SD=9.9; Table 1). Approximately half of the sample experienced an adverse event. For the adverse events model, the only significant predictor in the model was gender. Females compared to males (Odds ratio [OR] = 0.13, 95% confidence interval [CI] for OR: 0.03 – 0.47; p = .002; see Table 2) were more likely to report adverse

events. Time was significantly associated with decreased experiences of adverse events (OR = 0.12-0.16, 95% CI for OR: 0.04 – 0.41; $p < .001$). Trust in the provider and disease activity were not significant predictors.

Conclusion: Females were more likely to report adverse events suggesting either an increased likelihood of experiencing an adverse event or this group is more likely to report the adverse event if it occurs. Identifying this high risk group could facilitate targeted interventions to decrease medication adverse events, and in turn, improving treatment effectiveness.

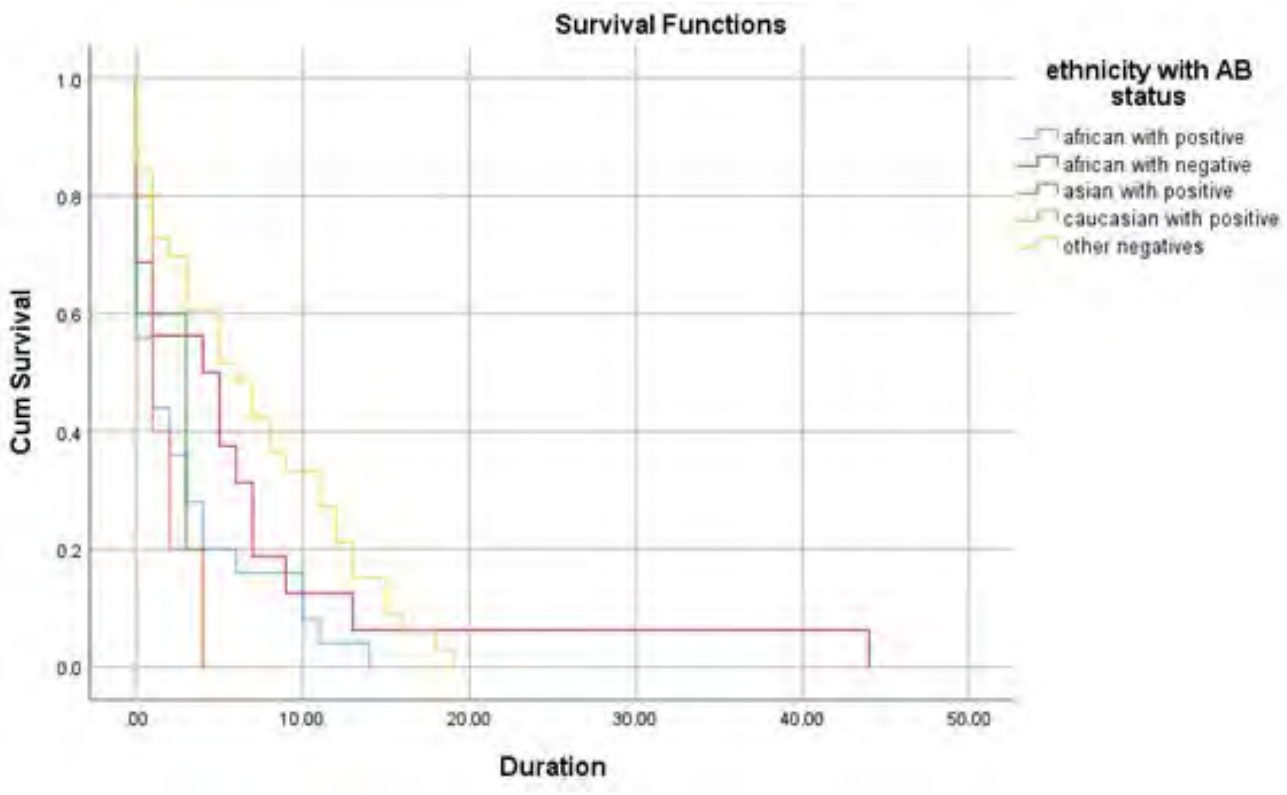
ancestry with the unusual autoantibody combination of anti-Sm, Ro & RNP antibodies (AB) were at increased risk of developing LN (1).

Our aim was to determine the correlation between autoantibody profile: Sm, Ro and RNP as a combination in the development of LN in patients with African ancestry. We investigated time to the development of LN from SLE onset.

Methods: A retrospective case-control study was conducted at Guys and St Thomas NHS Trust, London, United Kingdom.

84 patients with confirmed LN meeting the ACR classification criteria for SLE and Nephritis, were included: African (n=41), Caucasian (n=25) and Asian (n=18) ancestry. LN patients with the combination of Sm, Ro and RNP antibodies (Group 1) were compared to LN patients without this autoantibody combination (Group 2). Demographic data, pathology results and laboratory findings were collected.



Graph.1 Kaplan-Meier survival plot

P-values < 0.01 were considered statistically significant. All Anonymized data was analyzed using Statistical Package for Social Sciences (SPSS). Left censorship bias was reduced by use of a database of confirmed LN in our cohort of patients. Research and Development Office approval was obtained for this study.

Results: 84 patients were analyzed, females accounted for 75(89.3%) while males accounted for 9(10.7%), the median range was 44 y.o.

We stratified our population based on their antibody status: Of the 84 (100%) patients, 35 (41.7%) patients had the combination of Sm, Ro & RNP antibodies (Group 1) while the remaining 49 (58.3%) patients did not (Group 2).

In Group 1, regardless of ethnicity, 30 (85.7%) patients developed LN within 5 years or less from the onset of SLE symptoms, while the remaining 5 (14.3%) developed LN after 5 years. In contrast, in Group 2, 26 (53.06%) patients developed LN within 5 years or less while 23 (46.93%) developed LN after 5 years. (P value = 0.002)

Further stratification was based on ethnicity and antibody (AB) status to investigate the time to develop LN from SLE symptom onset: African ancestry with positive AB, African with negative AB, Asian with positive AB, Caucasian with positive AB and Asian & Caucasian with negative Ab. Analysis showed that out of 84 (100%) patients, 20(35.7%) African ethnicity patients with the positive autoantibody combination have developed LN in less than 5 years exceeding the number of those of other ethnic backgrounds. (P value = 0.01).

Conclusion: Patients with the unusual autoantibody combination of Sm, Ro & RNP developed LN significantly earlier than patients who did not have this combination. This autoantibody combination was significantly over represented in the African ancestry patients. Our data suggests that African ancestry patients with this autoantibody combination

are at increased risk of developing LN soon after SLE symptom onset and merit close monitoring for the development of renal disease.

The Role of Anti-dsDNA Antibodies in Predicting Incident Lupus Nephritis in Newly Diagnosed Lupus

Pooja Kumari[1], Viswanathan Ramakrishnan[2], Jihad Obeid[2], Diane Kamen[3] and Jim Oates[4], [1]The university of Tennesse Health Science center, Memphis, TN, [2]medical university of south carolina, south carolina, [3]Medical University of South Carolina, Charleston, SC, [4]Medical University of South Carolina, Charleston, SC, Charleston, SC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a severe manifestation of systemic lupus erythematosus (SLE) that leads to significant morbidity and mortality. Therefore, it is essential to identify biomarkers that predict incident LN in a newly diagnosed SLE patient. Anti-double stranded DNA antibodies (dsDNA) serve as a standard of care disease activity marker in patients with LN. However, the evidence for a predictive role of anti-dsDNA for incident LN is limited. To fill these knowledge gaps, we performed a case-control study to look at the association of anti-dsDNA in newly diagnosed SLE for future incident LN. We determined that the presence of and high titers of anti-dsDNA in newly diagnosed SLE are a significant predictor of future incident LN. Additionally, we found that the presence as well as the titers of anti-dsDNA at the time of SLE diagnosis predict earlier onset of LN. These results provide a roadmap

Baseline characteristics of SLE patients with and without lupus nephritis

Characteristics	SLE with Nephritis (N=300)	SLE without Nephritis (N=94)	p value
Age, median (IQR)	40 (31-52)	42 (33-60)	<0.001
Age at SLE diagnosis, median (IQR)	24 (17-34)	28 (20-41)	<0.001
*Race, N (%)			
African Americans	263 (89)	59 (64)	
Caucasians	24 (8.1)	26 (28)	<0.001
Other	9 (3)	7 (8)	
Females, N (%)	263 (88)	86 (91)	0.09
dsDNA (positive), N (%)	195 (65)	44 (47)	0.002
Age at biopsy mean (SD)	31 (13.8)	NA	
Years of follow up, mean (SD)	4.5 (6.5)	11.6 (10.4)	
Months to first anti-dsDNA, median (IQR) (after SLE onset)	0 (0-2)	1 (0-5)	<0.001

*Race could not be determined for 6 patients

Baseline characteristics of SLE patients with and without lupus nephritis

Cox proportional analysis for incident LN by dsDNA titers

Variables	Hazard Ratio	95% Confidence Interval	p value
A. Univariate Cox proportional analysis for the titers of anti-dsDNA			
dsDNA titers	1.112	1.04-1.19	0.001
B. Multivariate Cox proportional analysis for the titers of the anti-dsDNA			
dsDNA titers	1.083	1.02-1.16	0.022
Other race	6.296	2.67-13.8	<.0001
African American	1.363	0.90-2.20	0.177
Age	0.976	0.97-0.99	<.0001
Male	1.320	0.90-1.88	0.133

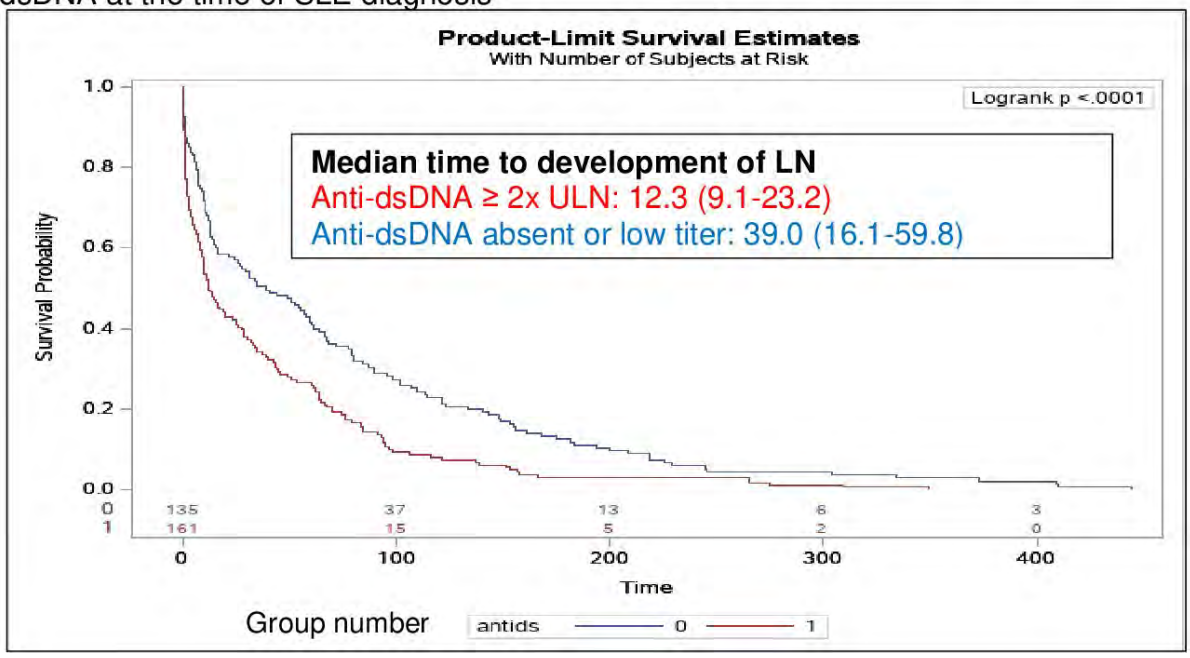
Cox proportional analysis for incident LN by dsDNA titers

Kaplan-Meier survival curve for the incident lupus nephritis based on the titers of anti-dsDNA at the time of SLE diagnosis



Kaplan-Meier survival curve for the incident lupus nephritis based on the titers of anti-dsDNA at the time of SLE diagnosis

for the use of anti-dsDNA levels to risk stratify newly diagnosed SLE patients. This stratification could guide disease activity monitoring to diagnose LN at an earlier stage.

Methods: In a prospective, observational case-control study, patients with the diagnosis of SLE were divided into cases (SLE patients with a biopsy proven LN) and controls (without LN). A logistic regression model was utilized to identify the predictive value of the presence of and high titers of anti-dsDNA for future incident LN. A survival analysis was performed to identify the time to new development of LN in relation to the presence of and high titers of anti-dsDNA.

Results: Of 394 SLE patients included in this study, 300 had LN, and 94 did not have LN. In univariate logistic regression analysis, the presence of and high titers of anti-dsDNA were associated with a significantly higher risk for incident LN. In a multivariate logistic regression model, the risk of incident LN was 2-fold with the presence of anti-dsDNA antibodies at the time of SLE diagnosis, adjusting for age, gender and sex (OR 2.1, CI 1.2- 3.4, p 0.005). In comparison to Caucasians the African Americans had a 5-fold risk of developing LN. In a multivariate Cox proportional hazard model, the adjusted risk for the early development of LN was 44% higher in those with anti-dsDNA. The

adjusted risk was about 5-fold for other races in comparison to Caucasian race. By utilizing titers as a continuous variable in the multivariate model, the adjusted risk for early development of LN increased by 8.3% for each doubling of anti-dsDNA. In Kaplan Meier analysis, the median time(month) to development of LN among patients who had a positive anti-dsDNA with new onset SLE was much shorter than patients who did not have anti-dsDNA with new onset SLE (14.4 vs 34.4, p 0.003).Similarly, the median time to incident LN among patients with high anti-dsDNA titers (≥2 times the upper limit of normal) was significantly lower compared to those with lower anti-dsDNA titers (12.3 vs 39.0,$p < 0.001$).

Conclusion: Younger age, African American race, presence of anti-dsDNA and high titers of anti-dsDNA at the time of SLE diagnosis are significant predictors for the incident LN.

Younger age, Hispanic ethnicity, non-Caucasian race, and presence of anti-dsDNA antibody at the time of SLE diagnosis increased the likelihood of a more rapid progression to LN.

What Are the Early versus Late Predictors for Systemic Lupus Erythematosus (SLE) Diagnosis?

Yiting Wang[1], Kirsten Lum[2], **Karen Costenbader**[3], Grace Wang[4], Jennifer Lofland[5], Dominik Naessens[6], Yihan Zhao[7], Kourtney Davis[8] and Chetan Karyekar[9], [1]Janssen Research & Development, LLC, Newark, DE, [2]Janssen Pharm Technology - Data Sciences and Data Management, Horsham, PA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Janssen Pharmaceuticals, Horsham, [5]Janssen Global Market Access, horsham, PA, [6]Jassen Global Market Access, Beerse, Belgium, [7]Janssen Pharm Technology - Data Sciences and Data Management, Horsham, [8]Janssen R&D, LLC, Titusville, NJ, [9]Janssen Global Services, LLC, Horsham, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is clinically heterogenous and its diagnosis is often difficult or delayed. The length of time from symptom onset or from when patients seek care for symptoms to SLE diagnosis has been reported to average 2-3 years. Early recognition and diagnosis provide the chance for timely treatment to minimize organ damage and improve outcomes. We aimed to develop predictive models for SLE diagnosis and to identify differences and overlap between early versus late predictors for SLE.

Methods: A case-control sample was created using the IBM MarketScan® Commercial Claims and Encounters database (2009-2019), which represents data from individuals enrolled in US employer-sponsored insurance health plans. Patients were classified as SLE cases if there were ≥3 outpatient diagnosis records (dx) that spanned at least 60 days, or ≥1 inpatient dx with ≥1 SLE medication records, or ≥1 SLE dx with ≥1 belimumab prescriptions. The first date of SLE dx code or belimumab prescription was designated as the index. Controls were 1:1 matched to each case by age, sex, and latest healthcare visit date (with any diagnosis) within 90 days of the case' index date. All subjects were required to have ≥3 years of pre-index records with the 1.5-3 years and < 1.5 years pre-index periods defined as the early versus late time-window (Figure 1). A set of 171 candidate predictors from existing SLE classification criteria and the literature was observed in both time-windows and used to build 4 machine-learning models for

Table 2. Machine learning model results. *AUC: area under the receiver operating characteristic curve; accuracy: weighted arithmetic mean of positive predictive value (PPV) and Inverse PPV (weighted by Bias), where PPV was % true SLE case among those predicted as SLE case; recall: % of true SLE cases that were predicted as SLE case.

each time window: regularized (L1) logistic regression, gradient boosted trees (GBT), XGBoost, and random forest. The models were trained and validated using 5-fold cross-validation in Dataiku DSS 5.0. Model performance was assessed by area under the receiver operating characteristic curve (AUC), accuracy and recall rate.

Results: A total of 13781 incident cases of SLE were identified and matched to the same number of controls. Mean age was 45 (median 47) years, and 87% were female. Table 1 describes the subjects' characteristics: SLE cases had overall higher frequency of health care utilization (HU) than the controls, and generally higher frequency of HU in the late than the early time-window. Based on the same set of 171 candidate features, the top-performing machine learning model in the early and late time-windows was GBT, with AUC 0.82 and 0.90, accuracy 0.72 and 0.83, recall of 0.82 and 0.81, respectively. The other three models performed similarly. Predictors with the highest importance factor included blood metabolic panel, urinalysis, prescriptions for benzodiazepines, opioids and macrolides; and diagnoses of chronic pain, osteoarthritis, rheumatoid arthritis, and hypertension. The top 10 predictors for both windows were very similar (Table 2) though generally higher in frequency of occurrence in the late window (Table 1).

Conclusion: All 4 machine-learning models had good predictive performance, especially using predictors in late time-window. The set of predictors identified in the early window (1.5-3 years pre-index) overlapped substantially with that of the late window (< 1.5 years pre-index), indicating opportunities for earlier diagnosis.

Abstract Number: 0245

Systemic Lupus Erythematosus Phenotype Risk Score Identifies Undiagnosed Cases in a Large Electronic Health Record

April Barnado[1], Robert Carroll[1] and Lee Wheless[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous disease with patients often presenting with non-specific symptoms that can cause delays in diagnosis. Phenotype risk scores measure the degree to which a patient's symptoms, as assessed by billing codes, overlap with defined disease criteria. Phenotype risk scores have identified patients with unrecognized Mendelian genetic disorders successfully and may help identify patients earlier with rare diseases. We developed and validated a phenotype risk score for SLE in a large electronic health record (EHR) cohort using billing codes to capture SLE criteria

Methods: We identified 837 SLE cases from a de-identified EHR with over 3 million subjects with decades of follow-up using a previously validated and published algorithm. Subjects were required to have a SLE diagnosis by a rheumatologist. We identified 3,149 age, sex, and race-matched controls with no known autoimmune disease diagnoses. Billing codes that correspond to SLE disease criteria were used in the phenotype risk score (Table 1). The SLE phenotype risk score was the sum of these codes in a given patient weighted by the log inverse prevalence of that code in the entire EHR. Billing codes specifically for SLE (i.e. 710.0 and M32*) were excluded. We compared phenotype risk scores in SLE cases vs. matched controls and evaluated phenotype risk scores in different SLE subgroups. Chart review was conducted on 50 of the controls with the highest SLE phenotype risk scores. We performed logistic regression to estimate the association of SLE case status with phenotype risk score adjusting for demographics. Lastly, we examined phenotype risk scores over time in SLE cases.

Results: SLE cases had a significantly higher SLE phenotype risk score compared to controls (7.2 ± 5.6 vs. 1.7 ± 2.5, $p < 0.001$) (Figure 1). The SLE phenotype risk score was significantly associated with case status after adjusting for age, sex, and race ($p < 0.001$). Of the 50 controls with the highest phenotype risk score, the two controls with the highest score had SLE by ACR SLE and SLICC criteria with an additional 4 patients having incomplete or probable SLE and another 8 having other autoimmune diseases including discoid lupus, Crohn's, and inflammatory arthritis. Comparing subgroups of SLE patients, females and males had similar scores (7.1 ± 5.6 vs. 7.3 ± 5.3, $p = 0.75$). African Americans with SLE had significantly higher scores compared to Caucasians (9.6 ± 6.7 vs. 6.4 ± 5.0, $p < 0.001$). Figure 2 shows trends of SLE phenotype risk scores over time. There was a small cluster of 57 SLE patients who had phenotype risk scores ≥ 50th percentile before their first SLE billing code.

Conclusion: Due to its heterogeneity, SLE can be a difficult disease to diagnose leading to delays in diagnosis and treatment that impact patient morbidity and mortality. We developed a SLE phenotype risk score in a large EHR

Dermatitis due to solar radiation	2.08	692.70, 692.72, 692.74, 692.79, 692.82	L56.8, L56.9, L59.8, L59.9

*These codes most closely aligned with SLE ACR and SLICC disease criteria and were used to create the SLE phenotype risk score. SLE ICD-9 (i.e. 710.0) and ICD-10-CM (i.e. M32.12, M32.14, M32.15) codes were excluded.
**Determined by the prevalence of that particular code in the entire electronic health record.

cohort that identifies missed SLE diagnoses. We propose that phenotype risk scores could serve as a clinical tool, potentially coupled with genetic data, to make earlier and more accurate SLE diagnoses.

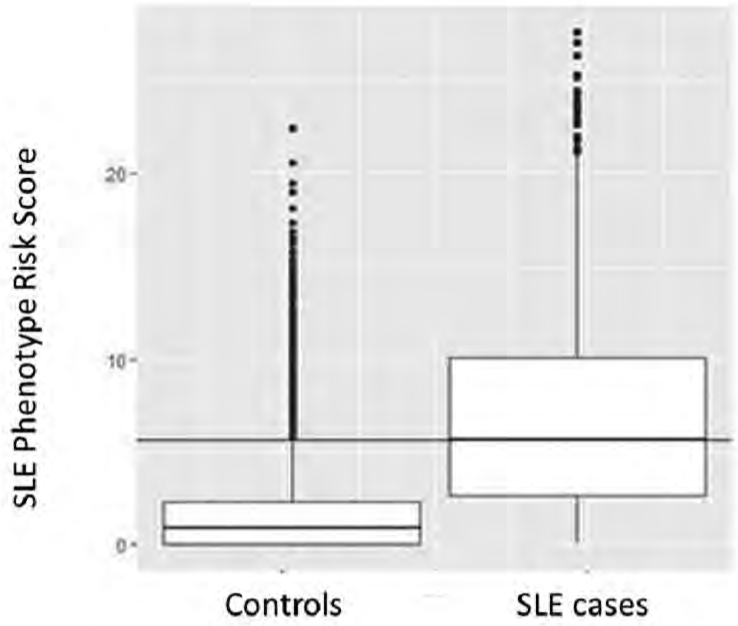

Figure 1. Boxplot of Systemic lupus erythematosus (SLE) phenotype risk scores in SLE cases vs. matched controls. We identified 837 SLE cases, all who had a SLE diagnosis by a rheumatologist. We identified 3,149 age, sex, and race-matched controls with no known autoimmune disease diagnoses. The horizontal line indicates the median SLE phenotype risk score for SLE cases.

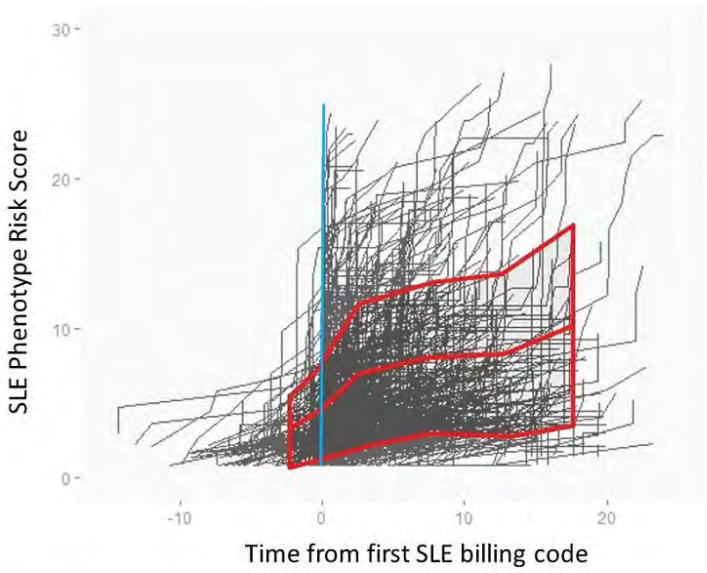

Figure 1. Phenotype risk scores over time. The x axis shows time in years in the electronic health record (EHR). Year 0 designates first SLE code in the EHR and is shown with a vertical blue line. The y axis shows phenotype risk score. The red lines indicate 25th, 50th, and 75th percentiles of the SLE phenotype risk score at each time point.

Extreme Fatigue in Patients with Systemic Lupus Erythematosus and Neuropsychiatric Symptoms

Rory Monahan[1], Rolf Fronczek[1], Jeroen Eikenboom[1], Huub Middelkoop[1], Liesbeth Beaart-van de Voorde[1], Gisela Terwindt[1], Nic van der Wee[1], Thomas Huizinga[1], Margreet Kloppenburg[1] and Margreet Steup-Beekman[1], [1]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is commonly described in chronic illnesses, especially in auto-immune disorders such as systemic lupus erythematosus (SLE). We aim to study the prevalence of fatigue in SLE patients with NP symptoms attributed to major nervous system involvement in SLE and other attributions.

Methods: All patients visiting the tertiary referral center for NPSLE in the LUMC between 2007-2019 with the clinical diagnosis of SLE and age >18 years that signed informed consent were included in this study. Patients underwent a standardized multidisciplinary assessment, including two questionnaires: SF-36 (2007-2019) and multidimensional fatigue index (MFI, 2011-2019). Patients were classified as NPSLE in this study if NP symptoms were attributed to SLE and immunosuppressive or anticoagulant therapy was initiated, otherwise patients were classified as minor/non-NPSLE. The vitality (VT) domain of the SF-36 domain was used to assess fatigue, which generates a score from 0-100, 100 representing the complete absence of fatigue. Patients with a score more than one standard deviation (SD) removed from age-related controls of the Dutch general population were classified as fatigued; patients more than two SD removed were classified as extremely fatigued[1]. The MFI was also assessed, which consists of five sub-domain scores between 0-20, leading to a total score between 0-100, 100 representing the most extreme fatigue. All scores are presented as mean and SD.

	NPSLE *(n = 65)*	**Minor/non-NPSLE** *(n = 167)*
MFI (mean, sd)		
General Fatigue	10.8 (1.8)	11.3 (2.3)
Physical Fatigue	11.4 (2.4)	12.4 (2.2)
Reduced Activity	9.6 (2.9)	10.7 (2.2)
Reduced Motivation	10.7 (2.6)	11.1 (1.9)
Mental Fatigue	9.6 (3.0)	9.9 (2.9)
Total score	51.8 (9.9)	56.2 (9.0)
SF-36 Vitality (mean, sd)	35.9 (20.6)	33.6 (18.6)

Fatigue in patients with NPSLE and minor/non-NPSLE

Results: 373 patients fulfilled the inclusion criteria and SF-36 questionnaires of 335 patients were available (90%). The majority of these patients was female (87%) and 97 were classified as NPSLE (29%). In NPSLE patients, average age was 41 years (SD: 13) and in minor/non-NPSLE the average age was 44 years (SD: 14). The average score of the SF-36 vitality domain was 35 (SD: 21) in NPSLE vs 34 (SD: 19) in minor/non-NPSLE. Overall, 75% of the patients were fatigued and 49% extremely fatigued in NPSLE vs 79% fatigued and 47% extremely fatigued in minor/non-NPSLE.

The MFI questionnaire was available for 230 patients, of which 65 patients were classified as NPSLE (28%). *Table 1* depicts the scores of NPSLE and minor/non-NPSLE patients on the MFI subdomains.

Conclusion: Nearly half of all patients with SLE and NP symptoms are extremely fatigued compared to only 2.5% of the general Dutch population. Extreme fatigue is irrespective of NP attribution to SLE.

General characteristics and treatments of pregnant women with systemic lupus erythematosus

Background/Purpose: This study aimed to examine the frequency and risk factors of complications during pregnancy in women with systemic lupus erythematosus (SLE).

Methods: The medical records of patients with SLE and age-matched controls at Ajou University Hospital were collected. Clinical features and pregnancy complications in women with SLE were compared to those in controls. Multivariate logistic regression analysis was performed to determine the predictors of adverse maternal and fetal outcomes.

Results: We analyzed 163 pregnancies in patients with SLE and 596 pregnancies in the general population; no significant differences regarding demographic characteristics were noted. Lupus patients experienced a higher rate of stillbirth (odds ratio [OR], 13.2), pre-eclampsia (OR, 4.3), preterm labor (OR, 2.6), intrauterine growth retardation (OR, 2.5), admission to neonatal intensive care unit (OR, 2.2) and emergency cesarean section (OR, 1.9) than control group. Multivariate regression analysis revealed that thrombocytopenia, low complement, high proteinuria, high SLE Disease Activity Index (SLEDAI), low Lupus Low Disease Activity State (LLDAS) achievement rate, and high corticosteroid dose were associated with adverse pregnancy outcomes. In the receiver operating characteristic curve analysis, the optimal cut-off value for the cumulative and mean corticosteroid doses were 3,500 mg and 6 mg, respectively.

	Maternal complications					
	Univariate analysis			Multivariate analysis		
	OR	95% CI	P-value	OR	95% CI	P-value
Hemoglobin < 10g/dL	17.7	3.63 – 86.25	< 0.001*	4.38	0.4 – 47.71	0.182

LLDAS	0.14	0.07 – 0.29	< 0.001*	0.21	0.06 – 0.65	0.01*
Mean steroid dose during pregnancy > 6 mg/day	3.59	1.63 – 7.92	0.035*	0.98	0.15 – 1.75	0.281

Potential risk factors of complications in pregnancies with SLE

Conclusion: Pregnant women with SLE have a higher risk of adverse pregnancy outcomes. Pregnancies should be delayed until achieving LLDAS and closely monitored with the lowest possible dose of corticosteroids.

Assessment of Lupus Knowledge Through Creation of the Lupus Knowledge Assessment Test (LKAT)

Mithu Maheswaranathan[1], Amanda Eudy[1], Jayanth Doss[1], Rebecca Sadun[1], Lisa Criscione-Schreiber[2], Kai Sun[1], Stacy Bailey[3], S. Nicole Hastings[1], Megan Clowse[4] and Jennifer Rogers[5], [1]Duke University, Durham, NC, [2]Duke University School of Medicine, Durham, NC, [3]Northwestern University, Chapel Hill, NC, [4]Duke University, Chapel Hill, NC, [5]Duke, Durham, NC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an inherently complex disease to manage with heterogenous clinical manifestations and complicated medication regimens. The complexity of lupus self-management combined with low health literacy may contribute to poor outcomes. Nationally, over 33% of American adults have low health literacy. The objective of this project was to determine the level of comprehension of SLE specific knowledge amongst patients with SLE and determine whether this was associated with existing validated measures of health literacy and numeracy.

Table 1: Lupus Knowledge Assessment Test (☑ indicates correct answer)

Question	% Correct
(1) My doctor does blood work and urine to check for: ❑ Lupus Activity ❑ Side effects from lupus medications ☑ Both lupus activity and side effects from medication	85%
(2) Plaquenil (hydroxychloroquine) helps prevent lupus flares. ☑ True ❑ False	89%
(3) In lupus patients, fatigue can be caused by which of the following? Check all that apply: ☑ Lupus ☑ Depression ☑ Trouble sleeping (insomnia)	67%
(4) Which of the following UPC lab ratios is **>1000** (mg/g), a sign that may indicate that a patient has active lupus nephritis? ❑ 300 mg/g ❑ 800 mg/g ☑ 2300 mg/g ❑ Not sure	21%

Table 2: Association of Lupus Knowledge Assessment Test, LKAT and Proteinuria Question with Health Literacy and Numeracy Assessments

Health Literacy Measure			LKAT Score mean (sd)	p-value	Nephritis Q	p-value
Self-Reported	Basic Health Literacy Screen (BHLS)	Adequate (n=148)	2.6 (0.9)	0.01*	21% (24/115)	0.09
		Low (n=24)	1.9 (1.1)		0% (0/20)	
	Subjective Numeracy Scale (SNS-3)	Adequate (n=88)	2.7 (0.9)	0.07	26% (18/68)	0.01*
		Low (n=82)	2.4 (0.9)		9% (6/65)	
Objective	Rapid Estimate of Adult Literacy in Medicine (REALM)	Adequate (n=75)	2.7 (0.8)	0.19	30% (25/82)	0.03*
		Low (n=13)	2.4 (0.6)		0% (0/12)	
	Numeracy Understanding in Medicine Instrument, short version (S-NUMI)	Adequate (n=23)	3.1 (0.7)	<0.001	44% (11/25)	0.03*
		Low (n=62)	2.4 (0.8)		20% (13/66)	

Legend:
LKAT = Lupus Knowledge Assessment Test, **average score** from 0-4 (sd)
Nephritis Q = proteinuria question [Question 3 of the LKAT], **%** who answered correctly
BHLS = Basic Health Literacy Screen
SNS3 = Subjective Numeracy Scale 3
REALM = Rapid Estimate of Adult Literacy in Medicine
S-NUMI = Numeracy Understanding in Medicine Instrument, short version

Methods: SLE patients meeting SLICC criteria were recruited from an academic university clinic from March 2019 through January 2020. A four-item questionnaire, the Lupus Knowledge Assessment Test (LKAT, Table 1), was developed and reviewed by six rheumatologists who see patients in a tertiary center lupus clinic. Health literacy was assessed using the self-reported Basic Health Literacy Screen (BHLS) and numeracy by the 3-item Subjective Numeracy Scale (SNS-3). Additionally, we collected objective health literacy assessments in a subset of patients including the Rapid Estimate of Adult Literacy in Medicine (REALM) and the Numeracy Understanding in Medicine Instrument, short form (S-NUMI).

We defined low health literacy as BHLS < 12 and low numeracy as SNS3 ≤ 14. The LKAT and health literacy assessments were administered during routine clinic visits. Additional patient demographics were gathered by survey. Data was analyzed using descriptive statistics.

Results: 225 SLE patients completed the questionnaire, of which 172 had correlating self-reported health literacy assessments and 89 had objective health literacy assessments. 95% of participants were female; 61% were African American. **Table 1** shows the questions comprising the LKAT questionnaire and percentage of correct answers for each question. The majority of patients knew reasons for routine blood and urine monitoring (85%); 67% were able to identify factors contributing to fatigue in SLE. Only 21% were able to answer which urine protein to creatinine (UPC) value was greater than 1000 mg/g correctly (from 300, 800, 2300 mg/g and not sure as choices).

Patients with low health literacy (by BHLS) and low numeracy (by S-NUMI) had lower LKAT scores ($p=0.01$, $p< 0.001$). Those with low health literacy (by REALM) and low numeracy (by SNS3 or S-NUMI) were more likely to miss the proteinuria question ($p \leq 0.03$, **Table 2**).

Conclusion: Patients with lower health literacy and numeracy have less knowledge about SLE, as measured by the LKAT (Lupus Knowledge Assessment Test). Patients had specific deficits recognizing factors contributory to fatigue in SLE and understanding proteinuria; only 21% of patients were able to answer which numerical UPC value is greater than 1000 mg/g correctly. This suggests many patients with low numeracy may have difficulty in functional understanding and interpretation of lab results. Further studies are needed to identify association of decreased lupus knowledge and low health literacy with other health outcomes.

Validation of the SIMPLE Index for Disease Activity of Systemic Lupus Erythematosus in Chinese Patients

Chi Chiu Mok[1], Ling Yin Ho[1], Kar Li Chan[2] and Meenakshi Jolly[3], [1]Tuen Mun Hospital, Hong Kong, China (People's Republic), [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The SIMPLE (SIMple Disease Assessment for People with Lupus Erythematosus) index is a composite numeric tool that captures disease activity from patients' self-assessment with minimal physicians' input. The SIMPLE index consists of 2 components: patient self-reported survey questionnaire (3 items from the lupus symptoms domain from the validated LupusPRO, 10 items from Lupus Impact Tracker [LIT], change in the health status and current glucocorticoids use [and dose]) and two laboratory tests (low complements [C3/C4] and urine protein-creatinine ratio >0.5). The values are put in an equation to derive a number, which is transformed to a 0- to 100-point scale by a formula using weighted scores of the above parameters. The SIMPLE index has been validated in US with good correlation with physicians' assessment of disease activity.

Objective: To validate the SIMPLE index for systemic lupus erythematosus (SLE) disease activity assessment in Chinese patients.

Methods: Adult patients (age ≥18 years) who fulfilled the 2013 SLICC criteria for SLE and were followed in the Rheumatology clinics of Tuen Mun Hospital, Hong Kong were recruited in a cross-sectional study. Participants were invited to complete the SIMPLE questionnaire before seeing doctors on the same day. The two laboratory results were supplemented by research nurses. Physicians, who were blinded to the SIMPLE results, were asked to complete disease activity assessment by the SELENA-SLEDAI and physicians' global assessment (PGA) after consultation. Correlation was made between the SIMPLE score and the SLEDAI/PGA scores by Spearman's rank correlation test. Receiver operating characteristic (ROC) analysis was performed to find the best cut-off SIMPLE score that predicted a clinical SLEDAI score of 1-6 (mild SLE activity) and ≥7 (moderate/severe activity).

Results: 364 SLE patients were studied (94% women; age 45.4±13.4 years; disease duration 13.2±8.0 years). The proportion of patients having a history of neuropsychiatric and renal disease that required immunosuppressive therapies was 9.3% and 56%, respectively. At the time of questionnaire completion, 69 (19%) patients had SLEDAI ≥6 and 192 (53%) had SLEDAI 1-5. The mean SLEDAI was 3.04±2.85 and PGA score was 0.62±0.55. A total of 161 (44%) had SDI score ≥1. The mean SIMPLE index was 26.0±12.9. SIMPLE index correlated significantly with SLEDAI (ρ=0.76; p< 0.001) and PGA score (ρ=0.48; p< 0.001). ROC analysis showed that a SIMPLE index of >27 points best predicted a clinical SLEDAI score of 1-6 (area under the curve [AUC] 0.78[0.73-0.84]; sensitivity 0.75; specificity 0.71), and >36.8 points best predicted a clinical SLEDAI score of ≥7 (AUC 0.87[0.69-1.00]; sensitivity 0.88, specificity 0.85).

Conclusion: SIMPLE shows a good correlation with SELENA-SLEDAI and PGA. It is a simple tool that enables patients to self-report disease activity and communicate with the health care team more efficiently.

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The Accelerating Medicines Partnership (AMP) will use multi-omics modalities including single cell RNA sequencing to understand lupus nephritis with the ultimate goal to devise novel and personalized treatment strategies. African-Americans have more lupus nephritis and worse outcomes in terms of end stage renal disease. We report here the clinical findings to date on African-American patients in the AMP cohort.

Methods: We included 118 patients with urine protein-to-creatinine ratio (UPCR) ≥ 1 and biopsy proven class III, IV, V or mixed lupus nephritis at time of enrollment. All patients met revised ACR or SLICC classification criteria. Clinical data were obtained at baseline, 12, 26, and 52 weeks after the renal biopsy. Response status at week 52 was defined as follows. Complete: UPCR ≤ 0.5, normal serum creatinine (sCr) or < 25% increase from baseline if abnormal, and prednisone < 10mg daily; partial: UPCR > 0.5 but ≤ 50% of the baseline value and same sCr and prednisone rules as complete response; no response: UPCR > 50% of baseline value or new abnormal elevation of sCr or ≥ 25% from baseline or prednisone ≥ 10mg daily.

Results: Table 1 shows that African Americans were more likely to have class V lupus nephritis (38% vs 22.5%, p=0.06), were less serologically active (low C3 50% vs 77.5%, p=0.002; anti-dsDNA 63% vs 79%, p=0.006), and were more likely to have elevated serum creatinine (55% vs 30%, p=0.03). Caucasians were older (47 vs 34 years, p=< 0.001) and more likely to be at their first biopsy (64% vs 31%, p=0.04). Table 2 shows the differences based on the first biopsy versus a repeat biopsy. African-Americans were significantly less likely to have a treatment response

Table 2. Comparison of clinicodemographic features between African-American and non African-American patients at first or repeat biopsy. Data are presented as n (%) or mean (SD). P values > 0.1 are indicated as ns.

	Any response vs. no response		Complete vs. non-responders	
African-Americans vs. non African-Americans	OR (95% CI)	p-value	OR (95% CI)	p-value
Model 0: unadjusted	0.2 (0.05, 0.79)	**0.021**	0.14 (0.03, 0.69)	**0.016**
Model 1: adjusted for biopsy class	0.23 (0.06, 0.91)	**0.037**	0.16 (0.03, 0.8)	**0.026**
Model 2: adjusted for activity (n=25)	0.24 (0.04, 1.55)	0.133	0.09 (0.01, 1.11)	0.06
Model 3: adjusted for chronicity (n=25)	0.12 (0.01, 0.94)	**0.044**	0.06 (0.01, 0.75)	**0.029**

Table 3. Multivariable models of response status in African-American and non African-American patients. Only patients at their first biopsy were included.

at the first biopsy. Regardless of first or later biopsy, they were less likely to have low C3. Table 3 shows multi-variate models. African-American patients at their first episode of lupus nephritis were less likely to respond to treatment (37.5% vs 75%, p=0.018) independently of histological features including class, activity and chronicity.

Conclusion: The AMP cohort demonstrates the current unmet clinical need to improve treatment of lupus nephritis in the United States. African-American lupus nephritis is different in terms of ISN class, serologies, first biopsy, and worse in terms of response status even after adjusting for activity and chronicity. Personalized treatments should be developed to improve outcomes in high risk populations such as African-Americans.Table 1. Patients characteristics by race / ethnicity. Data are presented as n (%) or mean (SD). Two patients identified as "Other" and are not shown in this Table. P values > 0.1 are indicated as ns.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: ANA testing as an approach to diagnosing and classifying SLE, now embedded in the EULAR/ACR Criteria, is more important than ever. Cross-sectional studies indicate that as few as 70% are ANA-positive, although ANA status may change over time. There are limited previous attempts to look at alterations in longitudinal ANA status in newly diagnosed SLE (1). We examined the dynamics of ANA tests in a longitudinal analysis using the SLICC Inception Cohort.

Methods: We evaluated demographic, clinical, and serological data from SLICC patients who fulfilled the 1997 Updated ACR SLE Classification Criteria and were within 15 months of diagnosis at enrolment. We performed two FDA-approved ANA tests: HEp-2 indirect immunofluorescence assay (IFA) and enzyme-linked immunosorbent assay (ELISA) (both from

Table 1. Number of patients with different ANA trajectories using indirect immunofluorescence assay (IFA) and enzyme-linked immunosorbent assay (ELISA)

Trajectory	ANA status at each time point			ANA assay used at each time point			
	Enroll	Year 3	Year 5	IFA only n (%)	ELISA only n (%)	ANA (+) at all three time points on both IFA and ELISA n (%)	ANA (-) at least once on IFA or ELISA n (%)
1	+	+	+	730 (96.2)	658 (86.7)	644 (84.8)	N/A
2	+	+	-	7 (0.9)	30 (4.0)	N/A	32 (4.2)
3	+	-	+	8 (1.1)	25 (3.3)	N/A	27 (3.6)
4	+	-	-	1 (0.1)	20 (2.6)	N/A	20 (2.6)
5	-	+	+	11 (1.4)	8 (1.1)	N/A	13 (1.7)
6	-	+	-	0 (0.0)	7 (0.9)	N/A	8 (1.1)
7	-	-	+	1 (0.1)	1 (0.1)	N/A	3 (0.4)
8	-	-	-	1 (0.1)	10 (1.3)	N/A	12 (1.6)

Abbreviations: ANA, antinuclear antibody; Enroll, enrolment; N/A, not applicable

Inova Diagnostics, San Diego, CA) for each patient at enrolment and follow-up at years 3 and 5, at one central laboratory (Calgary, AB). A positive test was defined as a titer ≥1:80 for IFA and ≥20 units by ELISA. SLE-specific autoantibodies were performed using a commercially available autoantigen array (FIDIS Connective Profile-13, TheraDiag, Paris) in an addressable laser bead immunoassay. Anti-dsDNA positivity and titers were confirmed by chemiluminescent assay (Bio-Flash: Inova Diagnostics). Demographic and clinical characteristics of patients with a negative ANA test at any time point over the 5 years of disease were compared to patients with consistently positive ANA tests.

Results: Overall, 759 patients were included; 88.5% were female and the mean age at diagnosis was 35.2 (SD 13.5) years. There were 8 different ANA trajectories over 5 years; 29 (3.8%) tested negative at least once by ANA IFA and 101 (13.3%) by ELISA (**Table 1**). Compared to patients with a positive ANA at all 3 time points (n=644), those with any negative ANA (either IFA or ELISA, n=115) were diagnosed at an older age (37.9 vs 34.7 years), were more likely to be of white ethnicity (67.8% vs 49.8%), less likely to use steroids at enrolment (60.9% vs 71.0%), less likely to have ever used immunosuppressants/biologics at 5 years (57.4% vs 68.0%) (**Table 2**), and less likely to have other SLE-related antibodies at enrolment and year 5 (**Table 3**). The SLEDAI-2K of patients with a negative ANA (vs those with a persistently positive ANA) was lower (4.2 vs 5.9 at enrolment, 2.0 vs 3.3 at year 5) with less mucocutaneous (28.7% vs 39.0% at enrolment), immunological (38.3% vs 59.5% at enrolment and 31.3% vs 53.4% at year 5), and hematological (3.5% vs 11.8% at enrolment and 2.6% vs 10.1% at year 5) involvement.

Conclusion: Most of the 759 cases (84.8%) in the SLICC inception cohort remained ANA positive on both IFA and ELISA at each time point over the first 5 years of follow-up. The proportion of consistently ANA-positive patients was higher by IFA (96.2%) than ELISA (86.7%). Patients with at least one negative ANA over the first 5 years had features suggestive of milder disease (i.e. lower SLEDAI-2K, less steroid and immunosuppressive use, fewer autoantibodies) compared to patients with persistently positive ANAs, but differences in other disease features, e.g. nephritis and SLICC/ACR Damage Index, were not observed.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is managed by variable combinations of five drug classes: antimalarials, biologics, corticosteroids, non-steroidal anti-inflammatory agents, and immunosuppressants. Opioids are commonly prescribed to SLE patients despite not being effective for the management of long-term musculoskeletal pain.[1] The aim was to describe corticosteroid and opioid use among SLE patients in the United States, and the impact of belimumab initiation on prescribing patterns.

Methods: This retrospective study used MarketScan administrative claims databases to select insured adults, age ≥18, with a diagnosis (International Classification of Diseases (ICD)-9/10 710.0 & M32) of SLE between 1/1/2012 and 5/31/2018 (earliest SLE diagnosis = index date). Patients were followed from index through the earliest of health plan disenrollment or 5/31/2019 (minimum of 12 months). Corticosteroid use was measured in the 12 months following SLE index date. Average daily dose of oral corticosteroids in prednisone equivalents was measured for 12 months after corticosteroid initiation. Opioid use was measured overall, and by strength and length of treatment (chronic use defined as >90 days of supply). Oral corticosteroid and opioid use were compared in the 6 months before and after initiation of belimumab.

Results: Of 49, 413 SLE patients eligible for analysis, mean [SD] age was 50.1 [14.0] years, 90.2% were female, and average follow-up was 3.6 [1.9] years. 89.8% of patients received any SLE treatment and 68.5% received corticosteroids. The average number of corticosteroid prescriptions was 4.6 [4.1] during 12 months of follow-up. 52.6% of patients had ≥1 claim for an opioid prescription in the 12 months after SLE index and 34.6% were identified as having chronic opioid treatment. Among patients with oral corticosteroid treatment and 12 months of study enrollment post-corticosteroid initiation, the average daily dose for oral corticosteroids was 19.4 [14.2] mg and 59.6% had a high average daily dose of >15 mg (Figure 1). Among 1,710 patients with belimumab treatment and 6 months of study enrollment after the first prescription, use of oral corticosteroids decreased by 9.1% (p=0.001), average daily dose decreased from 14.5 [18.4] mg to 11.9 [18.0] mg (p< 0.001) in the 6 months post initiation as compared to the 6 months prior. However, 48.6% of patients remained on a medium (7.5 mg – < 15 mg) or high dose (≥15 mg). Initiation of belimumab resulted in no change in opioid use (Table 1).

Conclusion: These results suggest that a strikingly high proportion of patients with SLE are treated with corticosteroids to control the disease, and opioid therapy to manage chronic pain. While there was no change in opioid use, corticosteroid use decreased following initiation of belimumab.

Table 1

	Before Belimumab (N = 1,710)		After Belimumab (N = 1,710)		p-Value, pre- vs. post-Belimumab
Patients with an oral steroid prescription (N, %)	**1,242**	**72.6%**	**1,086**	**63.5%**	**0.001**
Number of prescriptions (Mean, SD)	2.3	2.3	2.1	2.3	**<0.001**
Average daily dose (Mean, SD)	14.5	18.4	11.9	18.0	**<0.001**
Low average daily dose (>0 to <7.5 mg; N, %)	210	12.3%	255	14.9%	**0.037**
Medium average daily dose (7.5 - <15 mg; N, %)	389	22.7%	334	19.5%	**0.041**
High average daily dose (15 mg or more; N, %)	643	37.6%	497	29.1%	**<0.001**
Patients with an opioid prescription (N, %)	901	52.7%	861	50.4%	0.341
Weak opioids	356	20.8%	312	18.2%	0.089
Strong opioids	699	40.9%	695	40.6%	0.915
Acute opioid use	538	59.7%	486	56.4%	0.165
Chronic opioid use	363	40.3%	375	43.6%	0.165

Serum Albumin as a Predictor of Proteinuria Recovery in Lupus Nephritis

Tara Tofighi[1], Heather Reich[2], Jiandong Su[3] and Zahi Touma[4], [1]Department of Medicine, University of Toronto, Toronto, Canada, [2]Division of Nephrology, University of Toronto, Toronto, Canada, [3]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [4]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network; Krembil Research Institute, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical trials and observational studies in lupus nephritis (LN) have shown that proteinuria level at 12 months is the best predictor of long-term renal outcomes (adequate renal function and no dialysis/ transplant), although proteinuria can be a slowly changing parameter with a recovery time often beyond 2 years. Given the high morbidity of LN, an accessible, rapidly responsive biomarker may serve as a useful adjunct to proteinuria in assessing early treatment response.

The aim of this study was to determine if serum albumin can serve as predictor of complete (CPR) and partial proteinuria recovery (PPR) at 6-9 and 18-21 months in LN patients receiving standard treatment.

Methods: We studied all patients followed at the Lupus Clinic from 1990 onwards with baseline and follow-up visits at 6-9 and 18-21 months. Patients were diagnosed with LN based on 24-hour urine proteinuria > 0.5 g/24 hours or a spot urinary protein/creatinine ratio (UPCR) > 0.5 g/g associated with a prednisone start of ≥ 10 mg or a dose escalation of ≥ 5 mg.

CPR was defined as UPCR < 0. 5 g/g. PPR was defined as UPCR < 1.0 g/g (if baseline ≤ 3.0 g/g) or UPCR ≤ 3.0 g/g (if baseline PCR > 3.0 g/g) as defined by Rovin [LUNAR] criteria. We compared this to SLE Disease Activity Index-2000 (SLEDAI-2K) which defines CPR as proteinuria < 0.5g/24 hours and the SLEDAI-2K Responder Index-50 (SLEDAI-2K RI50) which defines PPR as a ≥ 50% decrease in proteinuria from baseline. Complete recovery of serum albumin was defined as ≥ 35 g/L from a baseline of < 30 g/L, with partial recovery defined as ≥ 30 g/L but < 35 g/L from a baseline of < 30 g/L.

Receiver operating characteristic (ROC) curves were generated to test if serum albumin is a predictor of combined proteinuria recovery endpoint (PPR+CPR as defined by Rovin criteria) at 6-9 and 18-21 months. Area under curve (AUC) was analyzed for (a) albumin level at baseline (b) absolute change from baseline to 6-9 and 18-21 months, and (c) percent change between baseline to 6-9 and 18-21 months.

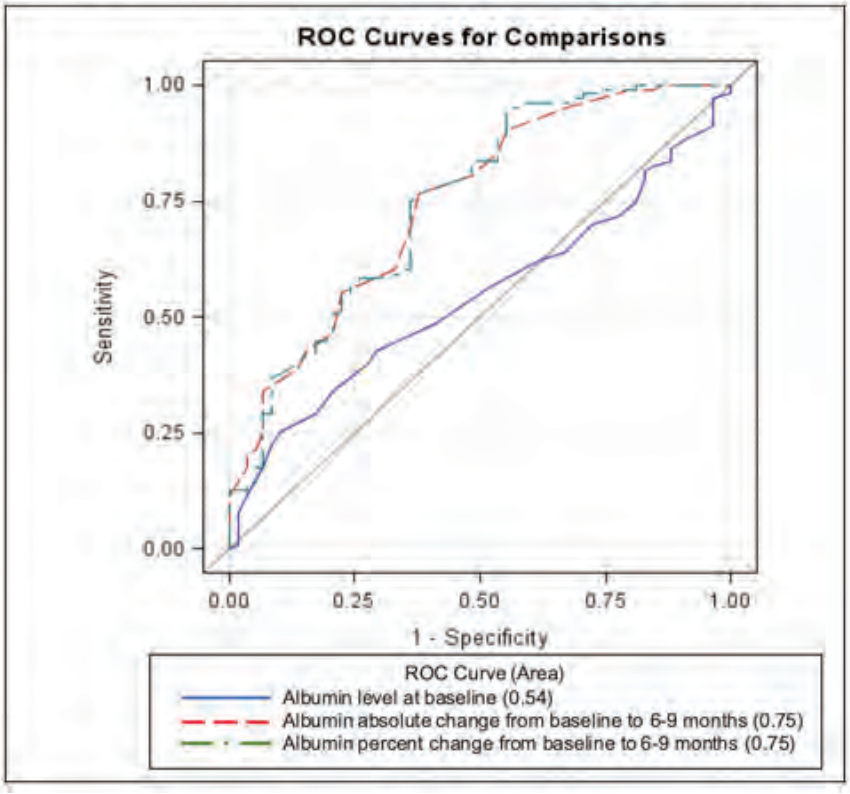
Results: 161 patients with 6-9 month visits (83.9% female) were identified. The mean age and duration of lupus at the start of the study was 34.7 ± 12.6 and 5.2 ± 5.6 years.

At the 6-9 month visit, 22% of patients achieved PPR and 42% of patients achieved CPR (64% combined). Of the 161 patients, 31 (19.3%) had a baseline albumin < 30 g/L. Of the 94 patients with an 18-21 month visit, 17% achieved

Table 1. Percent of patients with proteinuria recovery based on Rovin [LUNAR] and SLEDAI-2K/SLEDAI-2K RI-50 criteria

Definitions of LN recovery	Percent of patients with proteinuria recovery			
	6-9 month visit (n=161)		18-21 month visit (n=94)	
	Rovin [LUNAR]	SLEDAI-2K/ SLEDAI-2K RI-50	Rovin [LUNAR]	SLEDAI-2K/ SLEDAI-2K RI-50
Partial recovery [PPR]	22%	21%	17%	10%
Complete recovery [CPR]	42%	42%	54%	54%
Partial or complete recovery [PPR+CPR]	64%	63%	71%	64%

Figure 1. ROC predicting 6-9 month proteinuria recovery (defined as PPR+CPR by Rovin criteria) using increase of serum albumin from baseline to 6-9 months (n= 161)



PPR and 54% achieved CPR (71% combined). Both Rovin and SLEDAI-2K RI-50 criteria identified similar percentage of responders.

Figure 2. ROC predicting 18-21 month proteinuria recovery (defined as PPR+CPR by Rovin criteria) using increase of serum albumin from baseline to 18-21 months (n= 94)

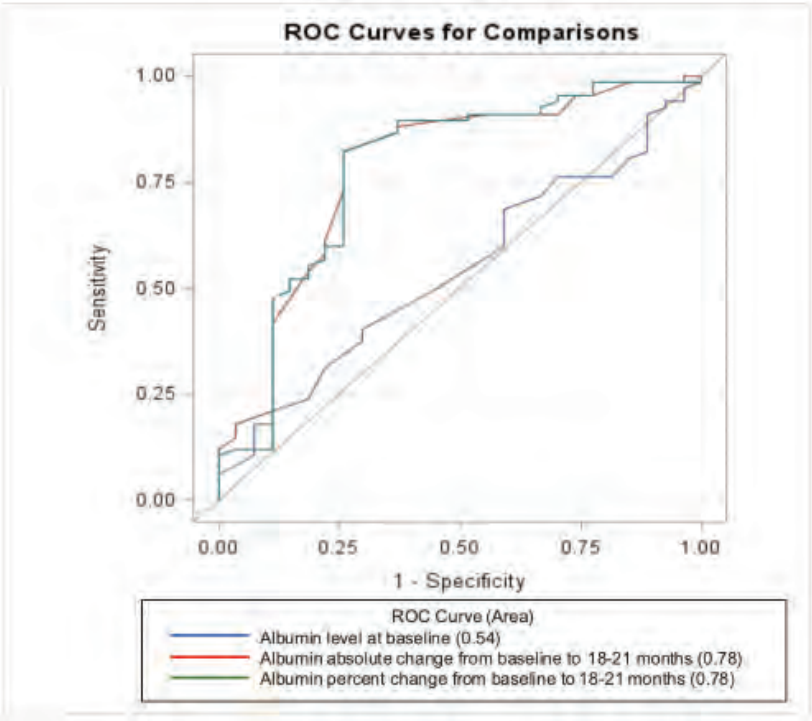


Figure 2. ROC predicting 18-21 month proteinuria recovery (defined as PPR+CPR by Rovin criteria) using increase of serum albumin from baseline to 18-21 months (n= 94)

ROC curves showed serum albumin absolute change (AUC= 0.75) and percent change (AUC=0.75) from baseline to 6-9 months predicted 6-9 month proteinuria recovery. Similarly, serum albumin absolute change (AUC= 0.78) and percent change (AUC=0.78) from baseline to 18-21 months predicted proteinuria recovery at 18-21 months. Serum albumin levels at baseline were not predictive of proteinuria recovery at 6-9 months or 18-21 months (AUC 0.54).

Conclusion: Absolute and percent change in serum albumin from baseline to 6-9 and to 18-21 months is a good predictor of proteinuria recovery. Serum albumin may serve as a readily accessible adjunct to proteinuria in assessing clinical course and treatment response in LN.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: LLDAS and remission have been proposed as treatment goals for SLE patients. However, their impact on damage prevention in patients from Latin America has been scarcely evaluated. The aim of this study was to determine if achieving LLDAS or remission prevents the occurrence of damage accrual.

Methods: SLE patients from a single center cohort with at least two visits were included. Visits were performed every six months. Remission was defined as a SLEDAI-2k (excluding serology) =0, physician global assessment (PGA)< 0.5, prednisone daily dose≤5 mg/d and immunosuppressive drugs on maintenance dose. LLDAS was defined as a SLEDAI-2k≤4 with no activity in major organ systems, with no new features of lupus disease activity compared to the previous assessment, PGA≤1.0, prednisone daily dose≤7.5 mg/d and immunosuppressive drugs on maintenance dose. Damage accrual was ascertained with the SLICC/ACR damage index (SDI). Univariable and multivariable interval-censored survival regression models were used. Two models were done: 1. Remission vs Not on remission; 2. LLDAS/Remission vs Active. Possible confounders included in the multivariable analyses were gender, age at diagnosis, socioeconomic status, educational level, disease duration, antimalarial use and SDI. Confounders were determined at the same visit than disease activity state but the SDI was assessed at the subsequent visit.

Results: Two hundred and eighty-one patients were included, 260 (92.5%) were female, median age at diagnosis was 34.4 (25^{th}-75^{th} percentile: 27.1-42.4) and a median disease duration at baseline was 7.9 (25^{th}-75^{th} percentile: 3.9-12.8) years. Patients had median of 5 (25^{th}-75^{th} percentile: 2-6) visits and a median follow-up of 3.0 (25^{th}-75^{th} percentile: 1.8-3.5) years. Eighty-three patients (29.5%) increased their SDI during the follow-up. Based on remission, 580 visits (54.6%) were categorized as being on remission, 482 (45.4%) as not on remission. Based on LLDAS, 726 (68.4%) as being on LLDAS and 336 (31.6%) as active. In the analyses of remission, in the multivariable model, being on remission predicted a lower probability of damage (HR=0.586; 95%CI: 0.368-0.933; p=0.024). In the analyses of LLDAS, in the multivariable model, being on LLDAS predicted a lower damage (HR=0.590; 95%CI: 0.358-0.972; p=0.038). These analyses are depicted in Table 1.

	Model 1		Model 2	
Not on remission	Ref.			
Remission	0.586 (0.368-0.933)	0.024		
Active			Ref.

Past	0.908 (0.392-2.103)	0.822	0.903 (0.389-2.095)	0.812
Never	0.984 (0.209-4.645)	0.984	0.958 (0.202-4.544)	0.957
SDI	1.073 (0.935-1.230)	0.317	1.080 (0.939-1.032)	0.253

Table 1. Impact of disease activity states on damage accrual. Multivariable models.

Conclusion: LLDAS and Remission predicted less damage accrual. Although Remission is the desirable endpoint on the treatment of lupus, LLDAS also exerts some protective effect and thus could be an alternative endpoint in the management of these patients.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The Lupus Low Disease Activity State (LLDAS) has recently undergone prospective longitudinal validation in a multinational cohort, demonstrating the association of attaining LLDAS with protection from damage accrual and flare, results that have been replicated in numerous other observational cohorts. Domain 1 of the original LLDAS operational definition captured the absence of significant disease activity by requiring SLEDAI-2K ≤4, the absence of SLEDAI activity in major organs, and also the absence of haemolytic anaemia (HA) and gastrointestinal (GI) activity, manifestations not accounted for in the SLEDAI-2K. The requirement for absence of these infrequent clinical features creates the potential to misclassify patients' LLDAS status, as there is no formal definition of HA and GI activity. This has in turn limited regulatory approval of LLDAS as a clinical trial endpoint. To determine the requirement for capture of HA and GI activity in the LLDAS definition we performed a sensitivity analysis.

Methods: We analysed the prospective LLDAS longitudinal validation dataset. To evaluate whether HA and GI activity were captured by the physician global assessment (PGA) criterion of LLDAS, we compared patients with and without

Table 1 - PGA, stratified by HA and GI activity

	No HA or GI activity	HA &/or GI activity present	p-value
N visits (%)	12,570 (99.21)	100 (0.79)	
PGA, *median [IQR] (range)*	0.4 [0.2, 0.9] (0, 3)	0.7 [0.4, 1.7] (0, 3)	<0.001
PGA>1, *n(%)*	1,939 (15.5%)	34 (34.0%)	<0.001

HA and GI with respect to median PGA and the proportion of patients with PGA >1. The impact on subsequent damage accrual and flare of time-dependent associations of criterion 1 of the LLDAS definition, with and without inclusion of HA and GI activity, were assessed using Cox regression analysis.

Results: Data on 1,707 patients, with 12,689 visits over 2.2 years were analysed. HA and GI activity were recorded in 28 and 73 visits, respectively. The median PGA, and the proportion of patients with PGA >1, were significantly higher in patients with either HA or GI activity (Table 1). Omitting the requirement for absence of HA and GI activity from criterion 1 of the LLDAS definition had no meaningful impact on the protective association with damage accrual in either visit by visit analysis (SLEDAI≤4 ignoring HA&GI: HR 0.55, 95% CI 0.43,0.70, p< 0.001; original definition: 0.55, 95% CI 0.43,0.71, p< 0.001). A similar lack of effect was observed for cumulative time effects of LLDAS (≥50% of time) on reducing damage accrual, and of LLDAS status on disease flare, when the requirement for absence of HA and GI activity was removed.

Conclusion: In data from a large prospective SLE cohort, the PGA adequately captures HA and GI activity. Removing the requirement for 'absence of HA and GI activity' in criterion 1 of the LLDAS definition is without effect on the protective associations of LLDAS attainment. Therefore, the definition of LLDAS does not require specification of HA and GI activity, improving its applicability to datasets where this information is not available and simplifying the use of LLDAS as a clinical trial endpoint. Together with published sensitivity analysis of the SLEDAI-2K and prednisolone dose cut-offs, this completes validation of the LLDAS endpoint.

Patient Perspective of the Type 1 and 2 SLE Model: A Qualitative Study

Amanda Eudy[1], Amy Corneli[2], Kevin McKenna[2], Mithu Maheswaranathan[1], Bryce Reeve[2], David Pisetsky[3] and Megan Clowse[4], [1]Duke University, Durham, NC, [2]Duke University, Durham, [3]Duke University Medical Center, Durham, NC, [4]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To better characterize the signs and symptoms of systemic lupus erythematosus (SLE) we have developed a conceptual model to characterize SLE activity into two dimensions: Type 1 SLE consists of inflammatory manifestations like arthritis, nephritis, and rashes; Type 2 SLE includes symptoms of fatigue, myalgia,

mood disturbance, and cognitive dysfunction. The objective of this study was to assess how the Type 1 and 2 conceptual model fits within the disease experience of individuals living with SLE.

Methods: We conducted semi-structured interviews among purposefully selected adult participants meeting SLICC criteria for SLE. High Type 1 symptoms were defined as SLEDAI ≥6, and high Type 2 symptoms were defined as a fibromyalgia severity score ≥12. Participants with a history of high Type 1 and 2 SLE in the prior year were classified as Mixed SLE. All interviews were audio-recorded and transcribed, with subsequent qualitative thematic analysis.

Results: Thirty-seven patients were interviewed (12 with Type 1 SLE, 12 with Type 2 SLE, and 13 with Mixed SLE); 73% were aged ≤55 years, 84% had disease duration ≥5 years, 49% were black or African American, and 35% had a history of nephritis.

Self-Classification: Most patients endorsed some degree of Type 2 symptoms and self-identified as Mixed SLE (n=24), n=8 as Type 2 SLE, and n=5 as Type 1 SLE.

Most Bothersome Symptoms: In every patient sub-group, participants were split on whether Type 1 symptoms (n=16), Type 2 symptoms (n=14), or the combination of both (n=7) were most bothersome. Fatigue, followed by joint pain and rash, were the most bothersome symptoms. The prevalence and severity of these symptoms, as well as their impact on physical and social functioning (fatigue and joint pain) and appearance or self-esteem (rash) made these symptoms most problematic.

Treatment: The type of symptoms the patient wanted to be the focus of therapy was different based on the patient's experience with Type 1 and 2 symptoms: 8/12 Type 1 participants identified Type 1 symptoms, 7/12 Type 2 participants identified Type 2 symptoms, and 7/13 Mixed participants identified both Type 1 & 2 symptoms.

Ignoring Type 2 Symptoms: Participants in all three groups (n=22/31) wanted their rheumatologist to discuss Type 2 symptoms during clinic appointments in order to address their full symptom experience (n=18). Several participants (n=5) stated they would find a new rheumatologist if their Type 2 symptoms were not addressed. Conversely, some participants (n=9) said they accept rheumatologists' emphasis on Type 1 symptoms, primarily because the patient themselves would still bring up their Type 2 symptoms. Three participants felt Type 1 symptoms were more severe and should be addressed first.

Conclusion: The Type 1 and 2 conceptual model appeared to be reflective of most participants' experience, with Type 2 symptoms most frequently reported and both Type 1 and 2 symptoms being bothersome and warranting treatment. Despite their disease classification, almost all participants reported some degree of Type 2 symptoms and most felt discussing and treating these symptoms should be an important component of their lupus care.

Application of Text Mining Methods to Identify Lupus Nephritis from Electronic Health Records

Milena Gianfrancesco[1], Suzanne Tamang[2], Gabriela Schmajuk[3] and Jinoos Yazdany[4], [1]University of California, San Francisco, San Francisco, CA, [2]Stanford Center for Population Health Sciences, Redwood City, CA, [3]University of California, San Francisco, Atherton, CA, [4]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a frequent complication of SLE and associated with higher morbidity and mortality. Accurate estimates of the prevalence of LN in the population remain limited due to the inability to capture this information through structured data fields such as ICD codes in electronic health records (EHR). We developed a text mining pipeline to extract information on LN and class from clinical notes in the EHR of a large, racially/ethnically diverse university health system.

Methods: Individuals with a single diagnosis code for SLE in the EHR between June 2012 – February 2019 were included. All available clinical notes (including physician ambulatory and hospital progress reports, and biopsy reports)

Table 1. Individuals with a single diagnosis code for SLE from electronic health records of a university health system, June 2012 – February 2019

	N (%) or Mean (SD)
Female	2,425 (87)
Age	46.9 (17.9)
Race	
White	945 (38)
Asian	310 (12)
Black	393 (16)
Other/Mixed Race	560 (22)
Unknown/Declined	300 (12)
Ethnicity	
Non-Hispanic or Non-Latino	2,020 (73)
Hispanic or Latino	526 (19)
Unknown/Declined	236 (8)

Table 2. Comparison of positive and negative annotations of lupus nephritis using text-mining of clinical notes and a published structured data algorithm

	Text-Mining using CLEVER		
Algorithm Using Structured Data*	Negative	Positive	Total
Negative	1,897	631	2,506
Positive	37	217	274
Total	1,934	848	2,782

*Chibnik LB, Massarotti EM, Costenbader KH. Identification and validation of lupus nephritis cases using administrative data. *Lupus* 2010;19(6):741-743.

were extracted and annotated using an open source clinical text-mining tool, the Clinical Event Recognizer (CLEVER). CLEVER is a hybrid information extraction approach that combines rule-based (semantic) and statistical components to annotate and extract information from millions of clinical notes efficiently. A custom-built dictionary that included "lupus nephritis," "class," and various associated terms referring to nephritis was built. Performance of the text-mining tool in identifying LN was assessed by calculating the sensitivity and specificity against a gold-standard subset of SLE patients for whom ACR criteria were assessed through chart review. We also compared our findings to a published algorithm in which LN is identified using structured data only.

Results: We included 2,782 SLE patients; these patients had a total of 614,683 clinical notes. Most patients were female (87%), with a mean age of 46.9 years (± 17.9), and the sample was racially/ethnically diverse (Table 1). A total of 18,354 positive and 9,293 negative mentions of LN were detected using CLEVER. Positive mentions were captured for 848 unique individuals with SLE, indicating that 30% of our SLE population had LN, similar to previously published estimates. When compared to a gold-standard set of chart-reviewed cases (n=152), our text mining tool detected LN with 96% sensitivity and 94% specificity. Compared to a previous algorithm of LN detection based on structured data fields (such as ICD codes) alone, our text-mining pipeline identified 631 additional cases of LN that would have otherwise not been captured (Table 2). Chart review of notes for a random sample of 50 cases from these 631 additional cases indicated that 86% were true positives. Thirty-seven cases that were not tagged by CLEVER, but positive according to the structured data algorithm, were found by chart review to be true negatives, with phrases such as "unclear," "possible," "to be evaluated," or "no evidence." Additionally, of those with LN, CLEVER was able to detect the specific class of LN (I-VI) in 415 (50%) cases.

Conclusion: We developed the first text-mining strategy to extract SLE LN status and class from clinical notes. Additional evaluation on clinical notes from the EHRs of additional institutions is ongoing to examine the generalizability of this algorithm. Further refinement of the pipeline will allow us to determine factors associated with this important disease outcome.

Using Patient-Reported Outcomes Measures to Classify Patients with Systemic Lupus Erythematous

Amanda Eudy[1], Bryce Reeve[2], Theresa Coles[2], Li Lin[2], Jennifer Rogers[3], Lisa Criscione-Schreiber[4], Jayanth Doss[1], Kai Sun[1], Rebecca Sadun[1], Patricia Katz[5], David Pisetsky[6] and Megan Clowse[7], [1]Duke University, Durham, NC, [2]Duke University, Durham, [3]Duke, Durham, NC, [4]Duke University School of Medicine, Durham, NC, [5]University of California, San Francisco, Novato, CA, [6]Duke University Medical Center, Durham, NC, [7]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Because systemic lupus erythematosus (SLE) is a complex and heterogeneous disease, we have developed a conceptual model that divides SLE activity into two dimensions: Type 1 SLE consists of inflamma-

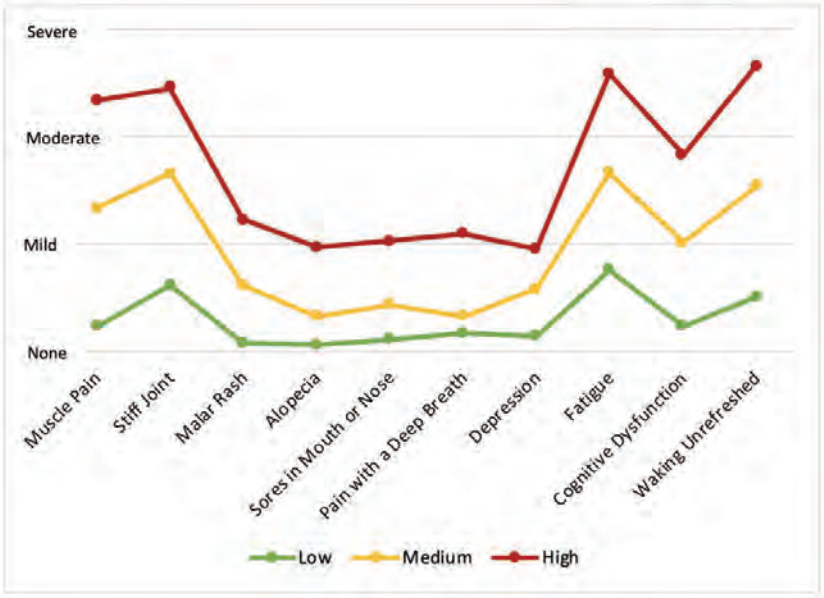

Figure 1. Average patient-reported symptoms by severity class.

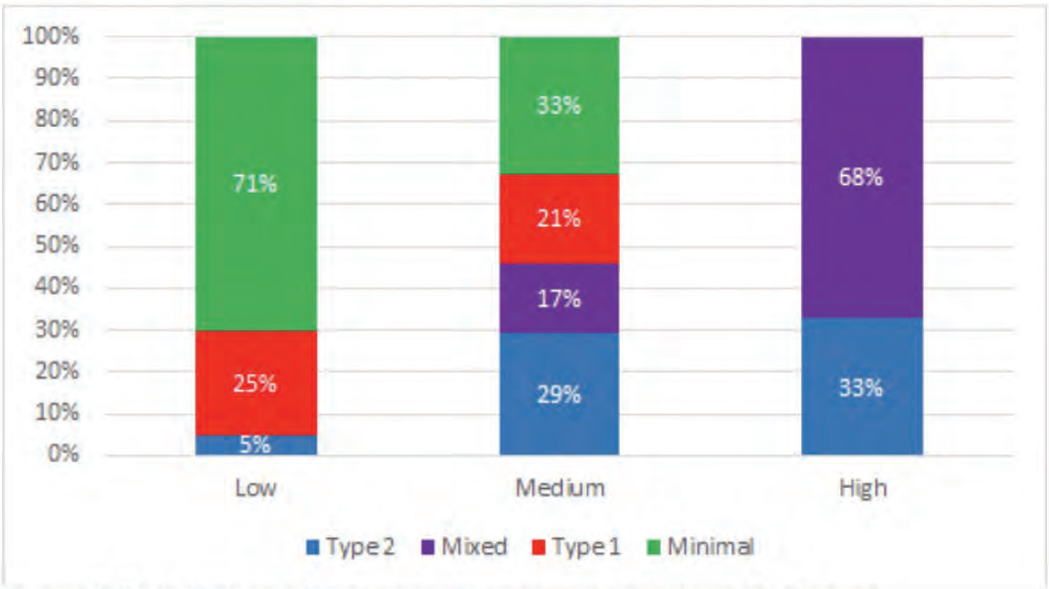

Figure 2. Distribution of Type 1 and 2 groups across severity classes.

tory activity, including arthritis, nephritis, and rashes; Type 2 SLE includes fatigue, myalgia, mood disturbance, and cognitive dysfunction. We theorize that different treatment paradigms may be needed for each dimension because of differences in underlying pathogenesis. In this study, we assessed whether distinct patterns of patient-reported symptoms could provide meaningfully distinguish between Type 1 and Type 2 SLE activity.

Methods: Consecutive SLE patients meeting SLICC criteria in a university lupus clinic registry completed two questionnaires: the Systemic Lupus Activity Questionnaire (SLAQ) and the ACR Fibromyalgia Severity Score (FSS). SLEDAI and physician global assessment (PGA; 0-3) were also recorded. High Type 1 SLE activity was defined as SLEDAI

≥4 (scored without labs), SLEDAI ≥6, active nephritis, or PGA ≥1.5. High Type 2 SLE activity was defined as FSS ≥8. Patients with both high Type 1 and 2 activity were defined as Mixed SLE, and patients with low Type 1 and 2 activity were defined as Minimal SLE.

Latent class analysis (LCA) was used to identify classes of SLE patients based on SLAQ symptoms (muscle pain, stiff joint, malar rash, alopecia, oral or nasal ulcers, chest pain with a deep breath, depression, and a patient global assessment of disease activity) and FSS symptoms (fatigue, cognitive dysfunction, waking unrefreshed, and total areas of widespread pain). Latent classifications were then compared to the clinically defined Type 1 and 2 SLE classification groups to determine if the PRO-derived classes could identify the Type 1/2 disease classifications.

Results: The study included 225 SLE patients. A 3-class solution provided the best fit of the data (entropy >0.90) and classified patients into low (n=85, 38%), medium (n=110, 49%), and high (n=40, 18%) PRO severity classes.

Patients in the low PRO severity class were primarily asymptomatic (Figure 1). While most patients were classified as Minimal SLE, 29% had Type 1 activity, half of whom had active nephritis (Figure 2).

The medium PRO severity class was characterized by mild-moderate fatigue (85%), stiff joints (84%), and waking unrefreshed (70%). Patients in this class were evenly distributed across the *a priori*-defined Type 1 and 2 SLE groups.

The high PRO severity class reported the most severe symptoms, including moderate-severe fatigue (100%), waking unrefreshed (95%), stiff joints (93%), muscle pain (92%), and cognitive dysfunction (65%), as well as high patient-global assessment scores (average: 7.3) and areas of widespread pain (average: 10.4). All patients in this class had active Type 2 SLE, with 33% having inactive and 68% having active Type 1 SLE.

Conclusion: While the LCA was able to classify SLE patients based on the severity of Type 2 SLE activity, this approach was unable to yield a class that was exclusive to Type 1 SLE activity. Ongoing research will explore whether including clinician-reported or laboratory data will better distinguish between these four SLE groups.

Guillain-Barré Syndrome in Systemic Lupus Erythematosus - Results of a Nationwide Analysis

Shilpa Arora[1], Ehizogie Edigin[2] and Augustine Manadan[1], [1]Rush University Medical Center, Chicago, IL, [2]John H Jr. Stroger Hospital of Cook County, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Guillain-Barré Syndrome (GBS) is a rare autoimmune polyneuropathy well described following viral illness, vaccination, or surgery. Systemic Lupus Erythematosus (SLE) has been associated with several neuropsychiatric syndromes including GBS. This study aims to i) Compare the risk of being hospitalized for GBS in

Table 1. Weighted descriptive characteristics of adult GBS hospitalizations with and without SLE in 2016 and 2017

Hospitalization Characteristics	GBS with SLE (n=130)	GBS without SLE (n=15,975)	P-value
Number of hospitalizations no. (%)	130 (0.8)	15,975 (99.2)	
Females, number (%)	88.5	43.6	<0.001
Age, mean in years	44.7	53.8	0.003
Number (%) hospitalizations by age Age 18-40 years Age 40-60 years Age 60-80 years Age > 80 years	 50 (38.5) 55 (42.3) 25 (19.2) 0 (0)	 3,765 (23.6) 5,520 (34.6) 5,865 (36.7) 825 (5.2)	
Race, Number (%) a) White	70 (56)	10,885 (71.5)	Reference
b) African American	40 (32)	1,360 (8.9)	0.002
c) Hispanic	10 (8)	1,755 (11.5)	0.873
d) Asian or Pacific Islander	5 (4)	560 (3.68)	0.752
e) Native American	0 (0)	85 (0.56)	-
f) Other	0 (0)	580 (3.81)	-

Table 2. Treatment and clinical outcomes of GBS hospitalizations with and without SLE in 2016 and 2017

Variable	GBS with SLE (n=130)	GBS without SLE (n=15,975)	Adjusted odds ratio (AOR)	P value
PLEX, number of patients (%)	35 (26.9%)	1965 (12.3%)	3.06 (1.27-7.35)	0.012*
IVIG, number of patients (%)	15 (11.5)	3,170 (19.8)	0.48 (0.11-2.15)	0.338
			Adjusted mean difference	
LOS, mean days	9.0	11.4	-3.46 (- {6.37-0.54})	0.02*
Total charge, mean USD	140,095	142,977	-1,989 ({-62,285}-58,308)	0.948
In hospital mortality, number (%)	0	215 (1.3%)	-	-

Abbreviations: LOS: Length of stay, C.I: Confidence Interval, PLEX: Plasmapheresis, GBS: Guillain-Barré Syndrome, SLE: Systemic Lupus Erythematosus, USD: United states dollars, *statistically significant

patients with SLE compared to patients without SLE and ii) Compare the characteristics and outcomes of patients primarily admitted for GBS with and without a secondary diagnosis of SLE.

Methods: Data were abstracted from the National Inpatient Sample (NIS) Database. The numbers in the databases are weighted to optimize national estimates. The NIS 2016 and 2017 database was searched for hospitalizations of adult patients with a principal discharge diagnosis of GBS (ICD-10 code G61.0) with and without a concomitant secondary discharge diagnosis of SLE (codes M32, M32.1, M32.10, M32.11, M32.12, M32.13, M32.14, M32.15, M32.19, M32.8, and M32.9). Multivariate logistic regression model was used to calculate the adjusted odds ratio of principal discharge diagnosis of GBS and a secondary diagnosis of SLE. Age, gender and ethnicity distribution, treatment

rates of plasmapheresis and IVIG, outcomes in terms of length of stay (LOS), mortality and total hospital charges were recorded and compared between the two groups. Multivariable logistic and linear regression analyses were used to adjust for confounding variables.

Results: There were over 71 million discharges documented in the combined 2016 and 2017 NIS database. A total of 16,105 hospitalizations were for adults with a principal discharge diagnosis of GBS. Of those, 130 (0.8%) had a secondary diagnosis of SLE and 15,975 (99.2%) did not have a secondary diagnosis of SLE. GBS hospitalizations with a secondary diagnosis of SLE had an adjusted odds ratio (AOR) of 2.06 (95% CI 1.35-3.12, P=0.001) compared to GBS without SLE. Characteristics of GBS patients with and without SLE are displayed in Table 1. The SLE patients were more likely to be female (88.5% vs 43.6%, p< 0.0001) and younger (44.7 vs 53.8, p=0.003). GBS with concomitant SLE was much more common in African American population compared to GBS without SLE (32% vs 8.9%, p 0.002). Total of 2,000 (12.4%) patients received PLEX. GBS with SLE patients were more likely to have received PLEX (26.9% vs 12.3%, AOR: 3.06, 95% CI 1.27-7.35, p=0.012) and had shorter length of stay (9.0 vs 11.4 days, p=0.02) in comparison to GBS patients without SLE. 3,185 (19.8%) patients received IVIG and rates of IVIG treatment were similar between the two groups (11.5% vs 19.8%, AOR: 0.48, 95% CI 0.11-2.15, p=0.338). (Table 2). From all GBS hospitalizations, 215 (1.3%) resulted in inpatient death and all of these occurred in patients without SLE.

Conclusion: Patients with SLE had 2 times the odds of being admitted for GBS compared to non-SLE patients. The inpatient prevalence of GBS in SLE in the United States was 2 cases per 1,000,000 hospitalizations. No mortality was seen in patients with GBS and SLE. Physicians should be aware of this association between SLE and GBS, and should have a high index of suspicion, when SLE patients present with neurologic manifestations suggestive of GBS.

Does Higher Quality of Care in SLE Improve Quality of Life?

Shilpa Arora[1], Patricia Katz[2], Jinoos Yazdany[3], Joel Block[1], Edward Yelin[4] and Meenakshi Jolly[5], [1]Rush University Medical Center, Chicago, IL, [2]University of California, San Francisco, Novato, CA, [3]University of California, San Francisco, San Francisco, CA, [4]UCSF, San Francisco, CA, [5]Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease activity, damage and quality of life (QOL) are core outcomes in Systemic lupus erythematosus (SLE). ER visits and hospital admissions (non-routine health care utilization, HCU) can be surrogates for higher disease related morbidity. Quality of care (QOC) measured by validated quality measures (QM) is associated with decreased accrual of damage in SLE. We aimed to study the association between high QOC and QOL and non-routine HCU in SLE.

Methods: Data was obtained from 814 participants from Lupus Outcomes Study Sample (LOS), a large observational cohort of individuals with ACR criteria confirmed SLE at University of California, San Francisco. Data on socio-demographics, disease status, medications and healthcare variables were collected through annual interviews beginning in 2003. QOC was available on self-report of 13 QMs. Baseline QOC for this study was measured in Year 10 interviews

Outcome variables	Univariate analysis			Multivariate analysis		
MCID increase in SF 36 domains n (%)			P-value	High QOC	95% CI	P-value
	OR	95% CI		(OR)		
Physical component score (PCS)	1.41	1.05,1.90	0.022	0.981*	0.709, 1.358	0.91
Mental component score (MCS)	1.46	1.09, 1.97	0.012	0.891*	0.643,1.234	0.49
Any ER visit	1.83	1.35,2.47	0.0001	1.073**	0.752, 1.531	0.7
Any hospitalization	1.81	1.33,2.46	0.0002	1.375**	0.945,2.000	0.096

MCID cut off for improvement in PCS: +2.3; MCS: +2.2.

* Multivariate model accounting for baseline disease activity, damage and quality of life, below poverty line and fibromyalgia.

** Multivariate model accounting for demographics, co-morbidities, baseline damage and quality of life, renal involvement, steroid use, disease duration.

Table 1 Relationship between high QOC (at baseline) and (MCID) increase in QOL and non-routine HCU at follow up in Lupus Outcomes Study sample

and follow up QOL and non-routine HCU in Years 11 and 12. We considered a performance on QMs of ≥67% (top quartile) as high QOC. QOL was measured by the Short Form (SF)-36 (Physician Component Summary PCS, mental component summary MCS score). Patient-reported disease activity and damage were measured with the Systemic Lupus Activity Questionnaire (SLAQ) and Brief Index of Lupus Damage (BILD). Chi square and T tests identified co-variates of high QOC at baseline. Univariate and multivariate regression analyses evaluated high QOC at baseline as predictor of minimal clinically important difference (MCID) improvements in SF-36 summary scores, ER visits and hospitalizations at follow up.

Results: Mean age was 53 years, 93% were women. Income below poverty and use of steroids were inversely associated with high QOC while presence of diabetes, lupus nephritis, fibromyalgia, hydroxychloroquine use, a primary care provider, and higher disease activity were directly associated with high QOC. High QOC was associated with worse QOL at baseline (PCS). High QOC at baseline was predictive of MCID based improvements in SF-36 PCS and MCS, and higher non-routine HCU (ER visits and Hospitalizations) at follow up on univariate analyses (Table 1). However, after adjusting for baseline covariates (income below poverty line, disease activity, damage, quality of life, and fibromyalgia), high QOC did not remain an independent predictor of improvement in QOL or non-routine HCU.

Conclusion: High QOC was predictive of subsequent clinically meaningful improvements in QOL. However high QOC did not remain an independent predictor of subsequent QOL or non-routine HCU on adjusting for other baseline covariates, suggesting that the effects may be mediated through one or more of the covariates (such as disease activity).

*Statistically Significant
**Average effect of change in the explanatory variables on the change in probability of outcome (repeat renal biopsy)

Table 2. Descriptive Tabulation of Explanatory Variables in Logistic Regression

has been debated. We assessed biochemical, pathological and demographic factors and evaluated their impact on risk of repeat renal biopsies. The role of repeat biopsies in further management of LN flares was also assessed.

Methods: Of the 66 biopsy-proven LN patients identified at two institutions in New York from 2000-2019, 16 were identified to have repeat renal biopsies. LN classes were identified based on the 2003 ISN/RPS Classification and tubulointerstitial pathology was defined by use of NIH LN Activity and Chronicity Indices. A logistic regression model and Wilcoxon signed-rank test were used to analyze the data. P value < 0.05 was deemed to be statistically significant.

Results: Repeat renal biopsies showed that a majority of patients (81%) did not transition between proliferative (class III, IV) and non-proliferative (class II, V) classes of LN. Only 18% of patient's showed a transition from non-proliferative to proliferative class and none of the patient's transitioned from proliferative to non-proliferative class of LN. All patients with a class switch to a proliferative type of LN were seen to have an escalation in immunosuppressive therapy. Escalation of immunosuppressive therapy was seen in 77.7% of patients with LN flares having no class switch between non-proliferative and proliferative. There was a statistically significant progression of chronicity index (mean ± SD) from initial (4.2 ± 2.77) to repeat (7.2 ± 2.58) biopsy, $P = 0.043$.

The logistic regression model had a 96.9% correct prediction, indicating that the model is highly successful in predicting the outcome. The Chi-square probability value was < 0.0005 and McFadden Pseudo R^2 value >0.5, indicating

the model is a good fit. The results indicated that sex, age at SLE diagnosis, quality of first biopsy, urine protein creatinine ratio (UPCR) at time of biopsy or Class III LN on initial biopsy influenced either positively or negatively the probability of a repeat renal biopsy. Females are 10% less likely to have repeat biopsies than their male counterparts, P = 0.022. Patient risk of repeat biopsy increased by 0.29% with every 10 year increase of age at SLE diagnosis, P = 0.029 and reduced with increase in number of glomeruli in initial biopsy, P = 0.042. Identification of Class III LN on initial biopsy decreased risk of repeat by 96.9% when compared to Class II and V (P = 0.03); Class IV LN showed no significant correlation. Higher UPCR at time of biopsy increased the risk of repeat biopsy, P = 0.037.

Conclusion: Demographic, serological and pathological factors can be used to assess likelihood of patients requiring repeat renal biopsies in the future. A majority of patient's did not switch between non-proliferative and proliferative classes of LN on repeat biopsy, however most of these patient's still had an escalation of immunosuppressive therapy. This study shows that there is little relation between repeat renal biopsy findings in LN flares and its use as a tool in determining further management in LN flares

T3	9/11 (82%)	33/109 (30%)	*0.001*

Background/Purpose: SLE pregnancies have an increased risk of Adverse Pregnancy Outcomes (APO). In clinical practice, low C3 and C4 levels are associated with active disease and, during pregnancy, complement activation products are shown to be associated with APO. Our aim was to analyse C3 and C4 variations during SLE pregnancies, focusing on APO and disease flares.

Methods: Data on SLE pregnancies prospectively-followed by a multidisciplinary team from 1987 to 2017 were analysed. Serum C3 and C4 levels were recorded at preconception visit (T0) and each trimester (T1, T2, T3). Hypocomplementemia was defined according to the normality range calculated in healthy pregnancies by Reggia et al. APO were defined as: early miscarriage (< 10^{th}week), intrauterine fetal death (IFD, >10^{th}week), perinatal death (< 30^{th}day of life), pre-eclampsia (PE), severe preterm birth (< 34^{th}week).

Results: 153 pregnancies in 106 SLE patients were analysed. APO occurred in 25 (16%): 13 early miscarriages, 4 IFD, 3 severe preterm births, 7 PE (hesitated in 2 IFD and 7 live births); 13 flares (2 renal, 4 articular, 6 cutaneous and 1 neurological) were recorded in 11 (7%) pregnancies.

In pregnancies with flares C3 was lower at T2 and T3 as compared with pregnancies without flare while C4 was lower at T0 and T3 (fig 1). There was no difference between pregnancies with and without APO.

Considering the overall pregnancies, C3 progressively increased from T0 to T3, while it remained stable between T2-T3 in the flare group and between T0-T1 and T2-T3 in the APO group (tab1).

In the flare group, C4 increased only between T0-T1 while in the APO group it remained stable throughout pregnancy. Notably, in pregnancies without APO, C4 increased from T0 to T2.

In pregnancies with APO, the variation of C4 levels between T2-T3 trimester was lower than in pregnancies without APO (mean: -2.98 [SD 0.05] vs 0,4 [SD 3.05]; p=0.03).

The frequency of low C4 was higher in pregnancies with flare at T0 and at each trimester as compared with pregnancies without flares (tab2).

Conclusion: Low C4 at pre-conceptional visit seems to predict flares during pregnancy. Lower increase of C4 levels between the 2nd and the 3rdtrimester could predict APO.

Factors Associated with Disease Activity Remission and Recurrence in Cutaneous Lupus Erythematosus

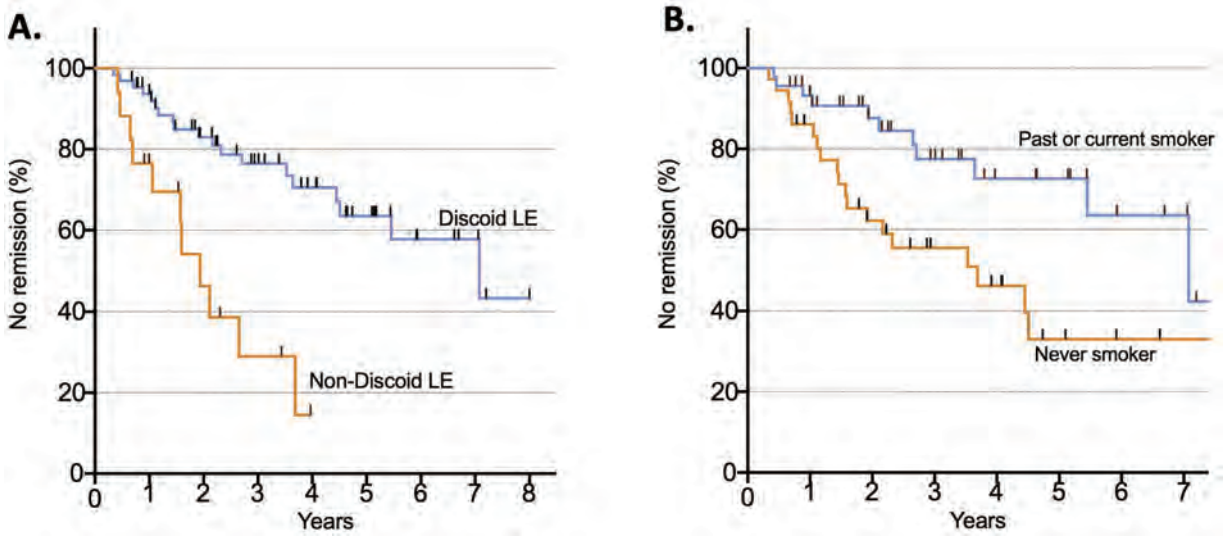
Stephanie Florez-Pollack[1], Syed Rizvi[2], Benjamin Chong[2] and Linda Hynan[2], [1]University of Pennsylvania, PHILADELPHIA, PA, [2]University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is a photosensitive skin disorder that can occur with systemic lupus erythematosus. As CLE often fluctuates in disease activity, little is known about the rates of disease remission and recurrence in patients with CLE. In this retrospective study, we assessed the rates of remission and recurrence in a longitudinal cohort study of 97 CLE patients, and identified clinical factors associated with each of these outcomes.

Methods: Inclusion criteria included CLE patients with at least three study visits spanning at least six months. The primary outcomes were remission and recurrence of disease activity. The secondary outcomes were time to remission from the baseline visit, and time to recurrence from documented remission. Disease remission was defined as reaching Cutaneous Lupus Erythematosus Activity and Severity Index activity (CLASI-A) equal to 0. Disease recurrence was defined as having a CLASI-A≥1 after remission. Univariate and multivariable analyses were performed to identify clinical and demographic risk factors associated with disease remission and recurrence. Time to remission and recurrence of activity was calculated by survival curve analyses. Significant variables associated with disease remission based on survival curve analyses were then used to perform a Cox proportional hazards model to identify variables that are predictive of shorter time to remission.

Results: 46 patients (48%) reached remission of CLE activity. Median time to remission was 5.45 years from the initial visit. Patients who achieved remission less likely to have discoid lupus erythematosus (DLE) (OR:0.20 (95% CI: 0.05-0.70), p=0.01) and more likely to have milder baseline disease activity (OR:1.75 (1.30-2.38), p< 0.001). Cox proportional hazards regression model showed that the absence of DLE (HR:4.20 (1.98-8.92) and lifetime non-smoker history (HR:2.57 (1.22-5.43)) were predictors of shorter time to remission (**Figure 1**). 29 patients (63%) of participants experienced disease recurrence within a median of 2.1 years from their remission date. Univariate analyses showed patients with recurrence of CLE activity had a longer disease duration prior to their baseline visit (p=0.002), and were more likely to have DLE (72% v. 29%, p=0.005), but were not significant in the multivariable analyses.



Conclusion: We found that CLE patients with mild baseline disease activity and do not have DLE are more likely to attain disease remission. The presence of discoid lesions and positive smoking history are associated with longer time to remission on standard-of care therapies. These findings can be helpful for clinicians to guide CLE patients on their potential disease course.

Factors associated with remission of disease activity in patients with cutaneous lupus. Patients without discoid rash (A) (HR:4.20 (1.98-8.92) and without a smoking history (HR:2.57 (1.22-5.43) (B) have a significantly shorter time to disease remission.

Prevalence and Risk Factors Associated with Isolated Neutropenia in Outpatients with Systemic Lupus Erythematosus

Nouf Alhammadi[1], Murray Urowitz[2] and Dafna Gladman[3], [1]University of Toronto, Toronto, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Leukopenia in SLE is defined as leukocyte count below 4,000/mm3 on two or more occasions according to the ACR criteria and may include a combination of lymphopenia and neutropenia or either of these alone. Neutropenia may be mild/moderate or severe and may be associated with increased susceptibility to infection. Our objective was to determine the prevalence and factors associated with isolated neutropenia in outpatients with SLE.

Methods: Retrospective analysis of prospectively collected data. Setting: Patients in our cohort are followed regularly at 2-6 months' intervals according to a standardized research protocol which captures demographic, clinical, laboratory and therapeutic variables along with the major co-morbidities. All data are entered and stored in an electronic database. Neutropenia was defined as absolute neutrophil count (ANC) below 1,500/mm3. Mild/moderate neutropenia was defined as neutropenia ≥ 1000/mm3 and < 1500 /mm3) and severe neutropenia was a neutrophil count < 1000 / mm3. Patients with isolated neutropenia on at least 2 consecutive visits with gap between visits of ≤ 24 months were identified. The baseline characteristics of the patients were compared between patients who experienced isolated neutropenia and those with combined neutropenia and lymphopenia. The percent of infections and the rate of infection in the 2 groups was determined. Mean with standard deviation and median with interquartile ranges were used to describe continuous variables, counts with percentages were use to describe categorical variables, then variables were compared by Student's t-test or Chi-Square test between groups.

Results: Of 2045 patients in the database, 170 (8.3%) were found to have neutropenia on 2 consecutive visits (visit gap ≤24 months) of whom, 30(1.4%) had severe neutropenia and the rest was mild to moderate. Isolated neutropenia was found in 35(1.9%) patients, 29 (82.9%) with mild moderate and 6 (17.1%) with severe neutropenia. Patients with

Table 1. Characteristics of patients with neutropenia.

VARIABLE	VALUE	Isolated Neutropenia	with Lymphopenia	p value
		N=35	N=135	
By neutropenia severity	Severe	6 (17.1%)	24 (17.8%)	0.93
	Mild/Moderate	29 (82.9%)	111 (82.2%)	
Age at index date	Mean ± SD	38.5 ± 12.1	38.7 ± 12.7	0.913
Disease duration in years	Mean ± SD	8.8 ± 8.6	10.4 ± 8.9	0.33
Female Gender	Yes (%)	32 (91.4%)	121 (89.6%)	0.752
Race/Ethnicity	Black	19 (54.3%)	45 (33.3%)	0.135
	Caucasian	11 (31.4%)	64 (47.4%)	
	Chinese	1 (2.9%)	9 (6.7%)	
	Others	4 (11.4%)	17 (12.6%)	
Black ethnicity	Yes (%)	19 (54.3%)	45 (33.3%)	0.023
SLEDAI-2K Score	Mean ± SD	4.0 ± 3.8	5.2 ± 4.5	0.169
low COM or dsDNA+	Yes (%)	23 (65.7%)	91 (67.4%)	0.849
Azathioprine	Yes (%)	3 (8.6%)	37 (27.4%)	0.019
Cyclophophamide	Yes (%)	0 (0.0%)	0 (0.0%)	N/A
Methotrexate	Yes (%)	0 (0.0%)	7 (5.2%)	0.169
Mycophenolate	Yes (%)	7 (20.0%)	21 (15.6%)	0.528
Infection	Yes (%)	3 (8.6%)	12 (8.9%)	0.953
Bacterial infection	Yes (%)	1 (2.9%)	5 (3.7%)	0.809
Viral infection	Yes (%)	2 (5.7%)	6 (4.4%)	0.752

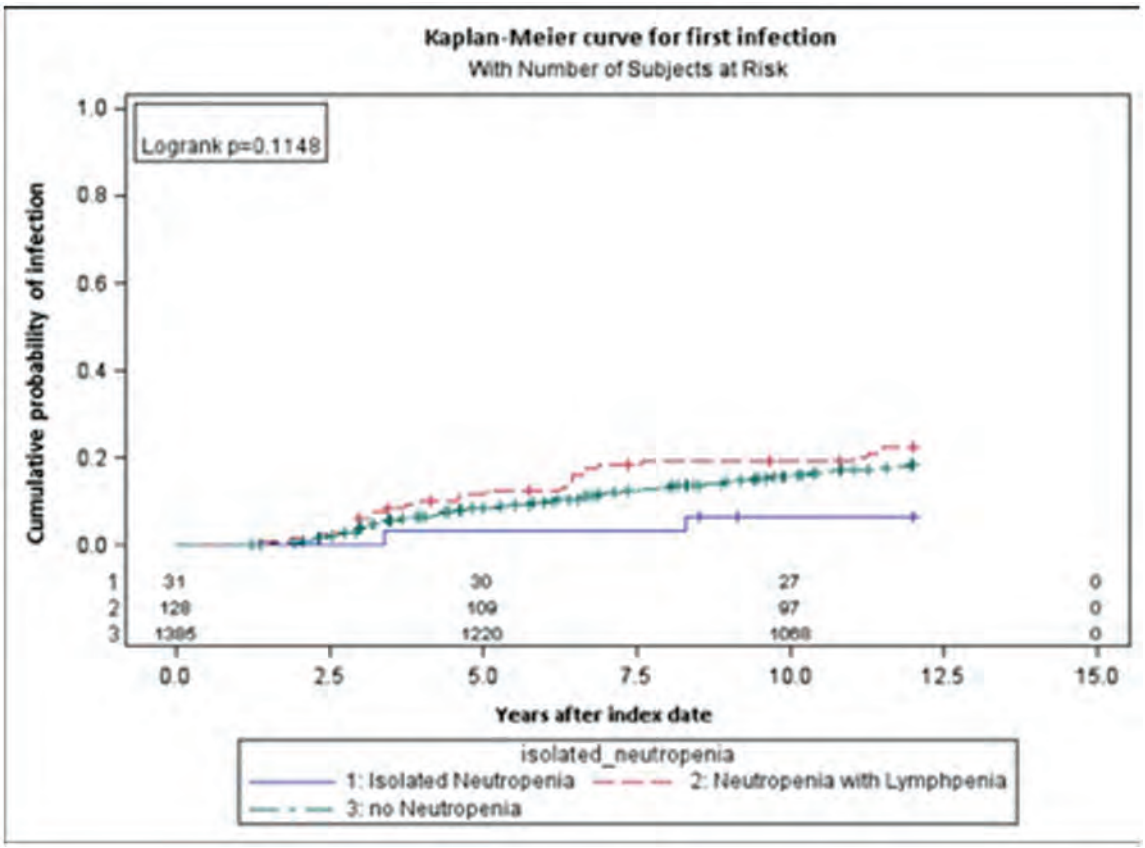

Figure 1. Kaplan Meier curve for first infection.

isolated neutropenia and neutropenia with lymphopenia were similar except for Black ethnicity which was more common in isolated neutropenia and more patients taking azathioprine had neutropenia/lymphopenia (Table 1)

Infections occurred in 17,6% with no neutropenia, 6.5% with isolated neutropenia and 21.9% with neutropenia/lymphopenia**.** Kaplan Meier survival curves showed higher cumulative incidence of infection with no neutropenia and neutropenia/lymphopenia likely due to low numbers (Fig 1)

Conclusion: Isolated neutropenia is not prevalent in SLE patients in general but is more common in Blacks. Risk of infection didn't increase in isolated neutropenia group compared to combined leucopenia and SLE patients without neutropenia.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple indices are available to measure disease activity in SLE patients, but are often considered too complex and time consuming for use in routine clinical practice. The Lupus Foundation of America-Rapid Evaluation of Activity in Lupus (LFA-REAL)[1] is a simplified assessment which provides multiple anchored visual analog scales (range 0–100 mm) for individual symptoms, the sum of individual scores derives an overall disease activity assessment. Moreover, it includes both a clinician- and a patient-reported outcome component for tandem assessments of disease activity. The aim of this study was to analyze the performance of the LFA-REAL as an SLE disease activity measure and to compare it with other clinician- and patient-reported outcome measures in a single-center Italian cohort.

Methods: This is a cross-sectional study that enrolled SLE patients (diagnosed based on 1997 ACR criteria). Disease activity was evaluated using the SELENA-SLEDAI score and organ damage using the SLICC/DI. During the visit, both the clinician and the patient completed the LFA-REAL for the assessment of disease activity. Moreover, each patient completed the following patient reported outcome measures (PROs): SLAQ, SF-36, FACIT-Fatigue, LIT. We evaluated the correlation between clinician LFA-REAL and SELENA-SLEDAI and between patient LFA-REAL and the PROs. ROC curve analysis was applied to compare LFA-REAL with the definition of active disease (SELENA-SLEDAI >4) and low disease activity state (LLDAS)[2].

Results: We enrolled 110 consecutive adult SLE patients (90.9% female, 97.3% Caucasian, mean age 45.06±11.8 years, median disease duration 14 years (IQR 7-21)). Median SELENA-SLEDAI at enrollment was 2 (IQR 0-3). Baseline characteristics of the cohort are summarized in Table 1. The mean clinician total LFA-REAL was 15±27.7 mm, while the mean patient total LFA-REAL was 127.3±114.0 mm; clinician and patient LFA-REAL were significantly correlated ($r= 0.36$, $p< 0.001$). We found a moderate correlation between clinician LFA-REAL and SELENA-SLEDAI ($r=0.31$, $p< 0.001$), while patient LFA-REAL was strongly associated with the SLAQ score ($r= 0.88$, $p< 0.0001$) and with the scores of all other PROs, as reported in Table 2. Clinician LFA-REAL was highly accurate in defining active disease (SELENA-SLEDAI >4) by ROC analysis (area under the curve 0.929). A clinician LFA-REAL of at least 33 mm demonstrated the optimal trade-off of sensitivity (83.33%) and specificity (81.73%) in detecting active disease. Conversely, we found that clinician LFA-REAL performed less well against the definition of LLDAS (area under the curve 0.690).

Table 1. Baseline characteristics of the cohort.

Table 1. Baseline characteristics of the cohort.

N. of patients	110
Mean age (years)	45.1±11.8
Median disease duration (IQR)	14 (7-21)
Median SELENA-SLEDAI (IQR)	2 (0-3)
SLICC-DI>0 (% of patients)	50/110 (45.4%)
Median SLICC-DI among patients with SLICC-DI>0 (IQR)	1 (1-3)
Active lupus arthritis (% of patients)	10/110 (9.1%)
Active muco-cutaneous lupus (% of patients)	4/110 (3.6%)
Active lupus nephritis (% of patients)	4/110 (3.6%)
Active hematologic manifestations (% of patients)	9/110 (8.2%)
Active neuropsychiatric lupus (% of patients)	1/110 (0.9%)
Ongoing GC therapy (% of patients)	50/110 (45.4%)
Mean GC daily dose (mg of prednisone)	1.7±2.7
Ongoing conventional immunosuppressants (% of patients)	42/110 (38.2%)
HCQ therapy (% of patients)	88/110 (80%)
Ongoing biologic DMARDs* (% of patients)	16/110 (14.5%)
Fibromyalgia (% of patients)	14/110 (12.7%)

*Disease Modifying Anti-Rheumatic Drugs

Table 2. Correlation between patient LFA-REAL and PROs.

Table 2. Correlation between patient LFA-REAL and PROs.

SLAQ	r= 0.886 p<0.0001
FACIT-Fatigue	r= -0.817 p< 0.0001
LIT	r= 0.871 p< 0.0001
SF-36 PCS	r= -0.753 p< 0.0001
SF-36 MCS	r= -0.654 p< 0.0001

Conclusion: In our SLE cohort, clinician LFA-REAL demonstrated a good correlation with SELENA-SLEDAI and patient LFA-REAL showed strong correlations with multiple PROs, including the SLAQ score. Therefore, the LFA-REAL may be a valuable simplified screening tool to rapidly identify active patients in routine clinical practice.

Abstract Number: 0266

The Correlation Between Pregnancy, Disease Activity and Adverse Pregnancy Outcomesin Patients with Systemic Lupus Erythematosus

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) can present with acute disease flares/exacerbations during pregnancy and postpartum period[1]. These flares can cause adverse pregnancy outcomes (APO).

In this study, our pregnant SLE cohort, which was under medical surveillance of both our Rheumatology and Gynecology and Obstetrics departments was analyzed. We intended to determine the effects of pregnancy on disease activity and the correlation between disease flares and adverse pregnancy outcomes.

Methods: 168 pregnancy data involving 136 patients with SLE meeting the ACR criteria were examined. Cumulative clinical, laboratory and serological parameters were described and disease activity and flares were calculated using SLEDAI-2K disease activity index during preconceptional six month period, during all trimesters of pregnancy, and during postpartum six month period. Patients with low lupus disease activity scores (LLDAS) during each of these periods were identified. Fetal/neonatal death, premature birth due to preeclampsia, eclampsia or HELLP syndrome, neonates small for gestational age were determined as adverse pregnancy outcomes. Relationship of APO with disease activity was studied and patients with APO were compared to patients without APO.

Results: Mean SLEDAI-2K scores was 1.3±2.2 (0-16) during preconceptional six month period, 1.3±2.6 (0-16) during conception period, 1.7±3.2 (0-22) during first trimester, 1.4±2.7 (0-16) during second trimester, 1.5±3.3 (0-20) during third trimester and 3.5±5.4 (0-26) during postpartum six month period. Mean postpartum six month period SLEDAI-2K score was higher compared to the mean pregnancy SLEDAI-2K score ($p< 0.05$). LLDAS was sustained in 79% of all pregnancies. 19% of pregnancies resulted in flares. 42% of these flares were severe and 58% were mild or moderate. 49% of severe flares occurred during the postpartum six month period and this percentage was significantly higher compared to each trimester ($p< 0.05$). Most of the flares during pregnancy and postpartum period had mucocutaneous (37%), renal(35%) and hematological(25%) involvement.

APO was observed in 34% of pregnancies (n=57). APO (+) group was characterized by significantly longer disease duration and higher disease activity in all periods compared to APO (-) group (142±70 vs 170±88 months, $p< 0.05$). In APO (-) group, the proportion of patients with severe disease activity during all pregnancy periods and postpartum period was significantly low (%18 vs 35, $p< 0.05$), while the proportion of patients with sustained LLDAS was much higher (%88 vs 70).

Conclusion: Postpartum six-month period appears to have the highest risk for disease flares during SLE pregnancies. Disease activity during pregnancy increases the risk of APO. Patients with sustained LLDAS have significantly lower APO rates. In order to achieve a positive pregnancy outcome and lower maternal morbidity, regular follow up of patients during pregnancy and postpartum period by Rheumatology and Gynecology and Obstetrics Departments is necessary.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To describe the GI manifestations of SLE in the RELESSER (Registry of Systemic Lupus Erythematosus Patients of the Spanish Society of Rheumatology) cohort and to determine if those are associated with a more severe disease, damage accrual and a worse prognosis.

Methods: We conducted a nationwide, retrospective, multicenter, cross-sectional cohort study of 3658 SLE patients who fulfill ≥ 4 ACR-97 criteria. Data on demographics, disease characteristics, activity (SELENA-SLEDAI), damage (SLICC/ACR/DI) and therapies were collected. **Table 1** shows the different gastrointestinal manifestations among the RELESSER cohort. Demographic and clinical characteristics were compared between lupus patients with and without GI damage to establish whether GI damage is associated with a more severe disease (**Table 2**). $\chi 2$ tests for categorical variables and Student t-test for continuous variables were used. For non-continuous variables, either Mann-Whitney U test or logarithmic transformation were used (data expressed as median and interquartile range - IQR). Univariate linear and multivariate logistic regression analyses were performed to establish the relation of demographics, different SLE clinical manifestations, damage and GI manifestations.

Table 1. GI manifestations in the RELESSER cohort

	Total (%)
GI damage	**131 (3.7)**
-Mesenteric Insufficiency	6 (0.2)
-Infarction o bowel resection, spleen, liver	101 (2.8)
-Pancreatic Insufficiency	12(0.3)
-Chronic Peritonitis	6 (0.2)
-Stricture or Upper GI Tract Surgery	12 (0.3)
Other GI manifestations	
- Oral ulcers	1603(46.3)
- Splenomegaly	118 (3.4)
- Abdominal serositis	60 (1.7)
- Lupus hepatitis	91 (2.6)
- Protein-losing enteropathy	18 (0.5)
- Gastroduodenal ulcers	128 (3.9)
- Hepatopathy	35 (1.0)
- HCV Infection	48 (1.4)
- Inflammatory bowel disease	7 (0.2)
- Autoimmune hepatitis	6 (0.2)
- Celiac disease	4 (0.1)
- GI solid tumors	11 (0.3)

Results: From 3654 lupus patients, 3.7% developed GI damage (**Table 1**). Patients in this group (group 1) were older (53.1 vs 46 years; p< 0.001), they had longer disease duration (16.4 vs 11.7 years; p=0.001) and were more likely to have vasculitis (14.1% vs 8.7% p=0.056), renal disease (56.1% vs 42.4% p=0.003) and serositis (40.5% vs 28.5% p=0.005) than patients without GI damage (group 2). With regard to treatment, there were statistically significant differences between both groups in terms of glucocorticoids (96.9% vs 88.6% p=0.001), azathioprine (44.2% vs 33.9% p=0.01), mycophenolate mofetil (23.7% vs 14.9% p=0.009) and cyclophosphamide (37.4% vs 21.8% p< 0.001).The use of hydroxychloroquine was more common among SLE patients with no GI manifestations related to damage (83.4% vs 75.2%, p=0.022). Hospitalizations and mortality were significantly higher in group 1 suggesting that having GI damage is linked to a worse prognosis. Moreover, patients in group 1 had higher modified SDI (2; IQR 1-4; p< 0.001) (**Table 2**). After the multivariable analysis, older age, high daily dose of glucocorticoids (≥ 30 mg prednisone) and higher SDI remained significant. Interestingly, even the prevalence of oral ulcers was slightly similar in both groups, the multivariable analysis revealed that the presence of oral ulcers reduced risk of developing damage in 30% of patients (**Table 3**).

Conclusion: Having GI damage is associated with clinical involvement of other target organs in lupus and with a worse prognosis. Patients on high dose of glucocorticoids are at higher risk of developing GI damage which reinforces the strategy of minimizing glucocorticoids. Oral ulcers are common in SLE and seem to be protective from GI damage.

Table 2. Demographics and clinical characteristics. *Modified SLICC/SDI was calculated excluding gastrointestinal damage manifestations

	SLE patients with GI damage (Group 1)	SLE patients without GI damage (Group 2)	P Value

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The effect of flares on healthcare resource usage and patient-reported outcome scores in SLE patients is not well quantified.

To understand how flares impact healthcare resource utilization (HCRU) and patient-reported outcomes amongst an international real-world dataset of SLE patients.

Methods: The Adelphi Real World 2015 Lupus Disease Specific Programme (DSP) is a cross-sectional study of 263 rheumatologists in the US and EU5. Rheumatologists were asked to complete patient record forms (PRFs) for the next 5 prospectively consulting SLE patients; the same patients were asked to complete patient self-completion (PSC) forms describing how SLE affected them. PRFs collected data pertaining to the patient's diagnosis, disease history, current clinical outcomes, treatment and management history. PSCs collected similar data and included patient-reported outcome measures (PROs) to assess humanistic burden. Propensity score matching was used to assess differences in HCRU and health status between SLE patients who had flared (physician defined) in the last 12 months and those who had not. Matching variables were patient ethnicity, time since diagnosis, and severity at diagnosis. Data were extracted from 1134 PRFs, and 635 PSCs. Propensity score matching was carried out on two matched groups of 408 patients.

Results: Demographic data are reported in Table 1. Propensity score matching showed patients who flared in the last 12 months were significantly more likely to have been hospitalized, visited the ER, and had greater total HCP consults in the last 12 months. Significantly greater drug burden lower physician and patient satisfaction, lower EQ-5D score (worse health status), lower FACIT Fatigue score (greater fatigue), and greater overall work impairment (Table 2) were also observed.

Conclusion: The analysis of international real-world data confirmed that SLE patients who flared in the last year represent a greater burden on healthcare resource and demonstrate significantly worse health status, greater fatigue, lower patient and physician satisfaction and greater overall work impairment compared with non-flaring patients. There is a need for more effective treatments in this patient population to reduce patient and healthcare burden.

Table 1 Demographic data

Variable	Flared in last 12 months	Not flared in the last 12 months
Mean age (years)	41.8	42.4
% Female	86.0	87.0
% White/Caucasian	66.2	76.3
Mean years diagnosed	5.9	5.4

Table 2 Propensity score matching results

Outcome variable	Flared mean	Not flared mean	Coefficient	95% CI	p-value
Hospitalized in last 12 months	24.26	7.63	0.17	[0.12 – 0.21]	<0.001
Emergency department visit in last 12 months	20.83	4.19	0.17	[0.12 – 0.21]	<0.001
Number of tests in last 12 months	46.49	38.90	7.59	[3.74 – 11.44]	<0.001
Number of current medications	2.76	2.19	0.57	[0.43 – 0.72]	<0.001
Physician satisfied	64.46	86.63	-0.22	[-0.28 – -0.17]	<0.001
Patient satisfied	69.29	85.09	-0.16	[-0.24 – -0.08]	<0.001

Systemic Lupus Erythematosus with Libman-Sacks Endocarditis Increases Inpatient Mortality

Ehizogie Edigin[1], Precious Eseaton[2], Pius Ojemolon[3] and Augustine Manadan[4], [1]John H Stroger Jr. Hospital of Cook County, Chicago, IL, [2]University of Benin Teaching Hospital, Benin, [3]St. George's University, St. George's, Grenada, [4]Cook County Hospital/Rush University Medical center, Chicago, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Libman-Sacks endocarditis characterized by thrombotic and/or non-infective sterile inflammatory vegetations are common in Systemic Lupus Erythematosus (SLE) and associated with increased morbidity. These vegetations can be complicated with superimposed infective endocarditis, embolic cerebrovascular disease,

severe valvular regurgitation, and need for high-risk valve surgery. The study aims to compare the outcomes of SLE hospitalizations with and without Libman-Sacks endocarditis. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. This database is the largest collection of inpatient admission data in the USA. It is a nationally representative sample of 20% of hospitalizations from approximately 1,000 hospitals. The numbers in the databases are weighted to optimize national estimates. The NIS was searched for SLE hospitalizations with Libman-Sacks endocarditis ("M32.11") and SLE without endocarditis (remaining M32 ICD-10 codes) as principal or secondary diagnosis. SLE hospitalizations for adult patients (age≥ 18 years) from the above groups were identified. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. Confounders adjusted for include age, sex, race, median income expected for zip code, Charleston comorbidity index, insurance status, and hospital location/region/teaching status and bed size. STATA software was used to analyze the data.

Results: There were combined 71 million discharges included in the 2016 and 2017 NIS database. 355,740 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE. 680 (0.19%) and 355,060 (99.81%) of these hospitalizations were for SLE with and without Libman-Sacks endocarditis respectively. The mean age for SLE with Libman-Sacks endocarditis was 43 vs 52 years without endocarditis (P< 0.001). 7,060 adult SLE hospitalizations (2%) resulted in inpatient mortality. 45 (6.6%) deaths occurred in SLE with Libman-Sacks endocarditis vs 7,015 (2%) without endocarditis (P=0.0001). The adjusted odds ratio (AOR) for inpatient mortality for SLE with Libman-Sacks endocarditis compared to those without endocarditis was 3.64 (95% CI 1.63-8.12, P=0.002). SLE with Libman-Sacks endocarditis hospitalizations had an increase in mean adjusted LOS of 5.22 days (95% CI 1.54-8.90, P=0.005) compared to SLE without endocarditis. Hospitalizations for SLE with Libman-Sacks endocarditis had an increase in mean adjusted total charges by $53,507 compared to SLE without endocarditis (95% CI 10,611-96,404, P=0.015).

Conclusion: Hospitalizations for SLE with Libman-Sacks endocarditis have more than 3 times the risk of in-hospital death compared to those without endocarditis. Hospitalizations for SLE with Libman-Sacks endocarditis have statistically and clinically significant increase in LOS and mean total hospital charges compared to those without endocarditis.

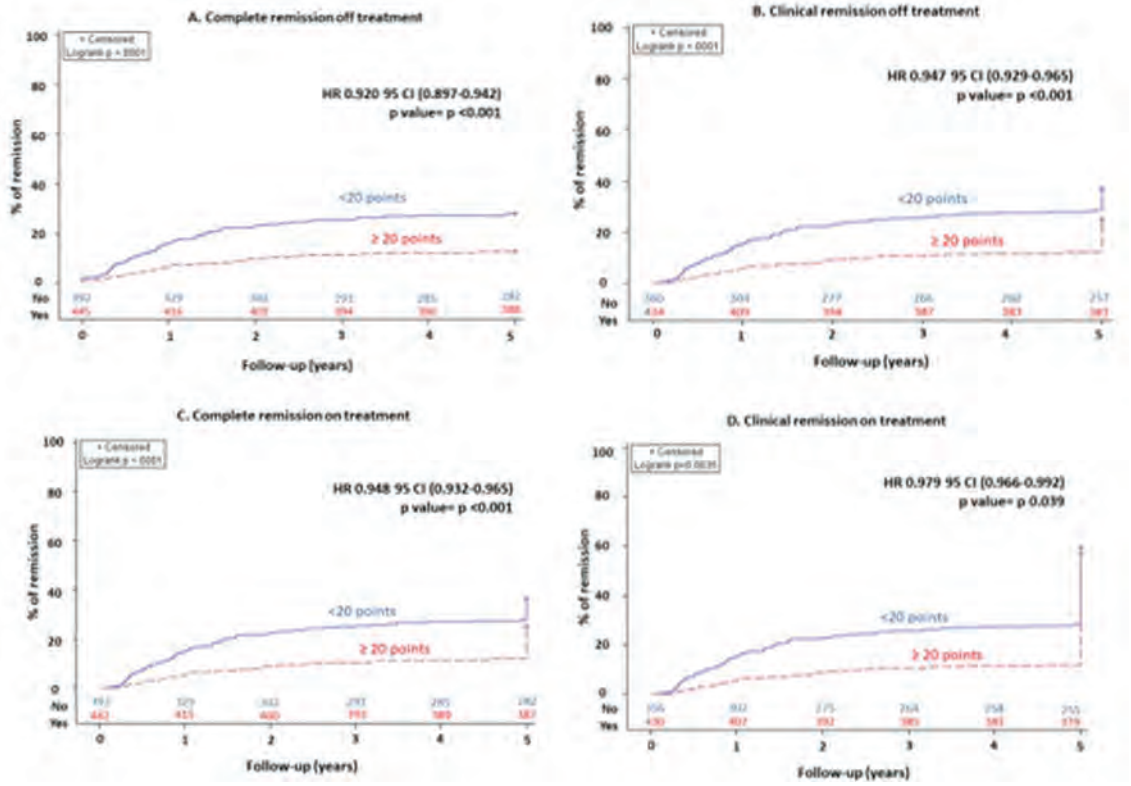
Figure 2 (A, B, C, D). Remission according to the 4 DORIS definitions. Kaplan-Meier survival curves stratified by EULAR/ACR criteria score of ≥ 20 and < 20. Hazard ratios and 95% confidence intervals of higher score group vs. low score group on the outcome of four types of remissions.



Background/Purpose: SLE is characterized by different patterns of disease activity throughout its course. Overall, a higher disease activity is an important predictor of mortality and damage accrual.

Recently, a new set of classification criteria for SLE using an additive point system has been introduced, the 2019 EULAR/ACR classification criteria (EULAR/ACR) which have proven to be sensitive and specific. Furthermore, these criteria have correlated with SLEDAI and SLAM-R scores at diagnosis. In a different cohort, higher EULAR/ACR scores were associated with higher rates of organ damage.

We aimed to determine the ominosity of the EULAR/ACR by determining their potential predictive role for disease severity in the first 5 years of disease course.

Methods: Inception SLE patients (recruited in the first 12 months after diagnosis) were included.

For each patient a score of the EULAR/ACR was calculated based on the baseline clinical and laboratory information. The baseline information was obtained from the first 2 visits as some of the data and therapies ordered at the first visit were recorded only at the second visit.

To determine the ominosity of the EULAR/ACR, we used outcomes to establish disease severity over the first 5 years after diagnosis including Adjusted mean SLEDAI-2K (AMS), flares, remission and use of immunosuppressive treatment.

Results: A total of 867 inception patients were included, 87.5% were woman, with a mean age of 36.2 years at baseline. Most patients were Caucasians (66.7%), followed by Blacks (14.2%).

The mean disease duration (time between diagnosis and first visit) was 0.2 years, the median time between the first visit and the second visit was 3.3 months.

The median EULAR/ACR score was 20. We used this score as a threshold to compare demographic, clinical characteristics and outcomes between groups. **Fig 1.**

Blacks more frequently presented with a score ≥ 20 compared to Caucasians. At baseline patients with a score ≥ 20 were younger, had higher SLEDAI-2K scores and were more likely to receive immunosuppressive therapy. **Table 1.**

In the first 5 years of disease course, patients with a score ≥ 20 had higher AMS scores. Every increase of 10 points in the score increased the AMS by 2.2 units (Univariate Linear regression, beta = 0.22, p< .0001). Likewise, patients with a higher score were more likely to ever present with a flare and more frequently experienced ≥2 flares. Every 10 points increase in the score increased the risk of a flare by 32% (RR: 1.32 95%CI: 1.173, 1.485, p < .0001) **Table 1**. Looking at specific organ flares this group presented more renal (31.6% vs 12.8%, ≥20 vs < 20, p=< 0.001) and hematologic (8% vs 2.2%, ≥20 vs < 20, p=0.007) flares**.**

In addition, these patients were less likely to achieve remission, **Fig. 2** and had higher requirements for immunosuppressive therapy. **Table 1.**

Conclusion: Overall, EULAR/ACR score ≥20 is an indicator of ominosity in the SLE disease course. SLE patients with a score ≥20 were characterized by higher disease activity throughout the first 5 years after diagnosis. Thus, the new classification criteria could be helpful not only in classifying SLE cases but could also provide prognostic information regarding the disease course in the first 5 years following diagnosis.

External Validation of the Systemic Lupus International Collaborating Clinics Frailty Index (SLICC-FI) as a Predictor of Mortality and Organ Damage Accrual in Systemic Lupus Erythematosus

Alicia Malone[1], **Alexandra Legge**[1] and John Hanly[1], [1]Dalhousie University, Halifax, NS, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Using data from the Systemic Lupus International Collaborating Clinics (SLICC) inception cohort, a frailty index (FI) was recently developed as a measure of susceptibility to adverse health outcomes among individuals with SLE. In this work, higher baseline SLICC-FI values were associated with increased organ damage accrual and mortal-

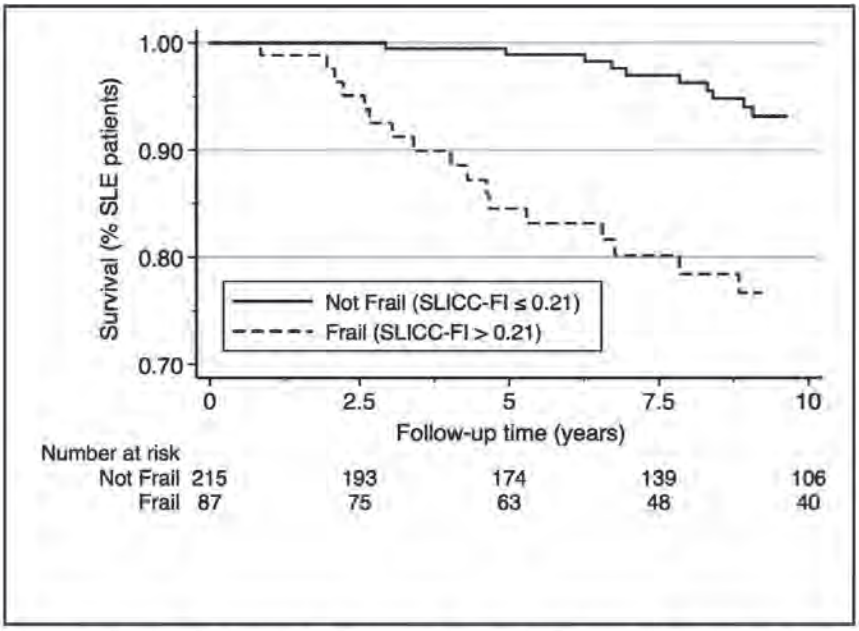

Figure 1. Kaplan-Meier survival curves for the risk of mortality during follow-up among SLE patients, stratified by baseline frailty status. Mortality risk was higher among frail individuals compared to those who were non-frail at baseline (Hazard Ratio 4.01; 95% CI 2.13-7.54).

Table 1. Univariable and multivariable Cox regression models for the association of baseline SLICC-FI values with the risk of mortality during follow-up among patients with SLE.

	Univariable model		**Multivariable model [a]**	
	Hazard Ratio (95% CI)	**p value**	**Hazard Ratio (95% CI)**	**p value**
Main analysis (n=302)				
SLICC-FI (per 0.05 increase)	1.61 (1.34 - 1.94)	<0.001	1.42 (1.14 – 1.78)	0.002
Excluding inception patients [b] (n=168)				
SLICC-FI (per 0.05 increase)	1.52 (1.25 – 1.85)	<0.001	1.31 (1.01 – 1.70)	0.040
Excluding organ damage from the SLICC-FI (n=302)				
Modified SLICC-FI [c] (per 0.05 increase)	1.29 (1.12 – 1.48)	<0.001	1.27 (1.07 – 1.50)	0.006

[a] Models adjusted for the following baseline characteristics: age, sex, corticosteroid use, antimalarial use, immunosuppressive use, education, disease duration, SLICC/ACR damage index (SDI), and cigarette smoking status.

[b] Excludes patients with SLE disease duration < 15 months at study enrolment.

[c] Excludes the 16 health deficits related to organ damage. Baseline SLICC-FI scores re-calculated using the remaining 32 health deficits.

Abbreviations: SLICC = Systemic Lupus International Collaborating Clinics; FI = Frailty Index.

ity risk during follow-up. While promising, these results require external validation. The objective of the current study was to evaluate the properties of the SLICC-FI in a prevalent cohort of individuals with more longstanding SLE.

Methods: This was a secondary analysis of data from a prospective cohort of adult SLE patients at a single academic medical center. All participants met the 1997 revised ACR classification criteria for SLE and were assessed annually for medication use, comorbidities, disease activity (SLEDAI-2K), organ damage [SLICC/ACR Damage Index (SDI)], health-related quality of life [Short-Form 36 (SF-36)], and other measures.

For this analysis, we defined the baseline visit as the first visit at which both SDI and SF-36 data were available. We created an adapted version of the original SLICC-FI by modifying the definitions of individual health deficits based on data availability. Using 48 health deficits, we calculated a baseline SLICC-FI score for each patient. Vital status and SDI score at last follow-up were recorded.

Cox regression was used to estimate the association between baseline SLICC-FI values and mortality risk. Negative binomial regression was used to estimate the association of baseline SLICC-FI values with the rate of change in SDI scores per patient-year of follow-up. Multivariable models adjusted for relevant baseline variables.

Results: The 329 eligible SLE patients (96% of cohort) were mostly female (88%) with mean (SD) age 43.9 (14.4) years and median (IQR) disease duration 3.4 (1.2-13.3) years at baseline. Mean (SD) baseline SLICC-FI score was 0.17 (0.08), with 94 patients (28.6%) classified as frail (SLICC-FI > 0.21).

Table 2. Negative binomial regression models for the association of baseline SLICC-FI scores with the rate of change in the SDI per patient-year of follow-up among patients with SLE.

	Univariable model		Multivariable model [a]	
	IRR (95% CI)	**p value**	**IRR (95% CI)**	**p value**
Main analysis (n=292)				
SLICC-FI (per 0.05 increase)	1.33 (1.23 - 1.45)	<0.001	1.19 (1.09 – 1.31)	<0.001
Excluding inception patients [b] (n=163)				
SLICC-FI (per 0.05 increase)	1.31 (1.21 – 1.43)	<0.001	1.18 (1.07 – 1.29)	<0.001
Excluding organ damage from the SLICC-FI (n=292)				
Modified SLICC-FI [c] (per 0.05 increase)	1.18 (1.10 – 1.26)	<0.001	1.11 (1.04 – 1.19)	0.003

[a] Models adjusted for the following baseline characteristics: age, sex, corticosteroid use, education, disease duration, baseline SDI score, and cigarette smoking status.

[b] Excludes patients with SLE disease duration < 15 months at study enrolment.

[c] Excludes the 16 health deficits related to organ damage. Baseline SLICC-FI scores re-calculated using the remaining 32 health deficits.

Abbreviations: SLICC = Systemic Lupus International Collaborating Clinics; FI = Frailty Index; SDI = SLICC/ACR damage index; IRR = incidence rate ratio.

Forty deaths occurred during mean (SD) follow-up of 10 (5.5) years. Mortality risk was significantly higher among frail individuals (Figure 1). Higher baseline SLICC-FI values (per 0.05 units) were associated with increased mortality risk (Hazard Ratio 1.42; 95% CI 1.14-1.78), after adjusting for age, sex, education, SLE medication use, disease duration, smoking status, and baseline SDI (Table 1).

There were 133 patients with an increase in SDI score during follow-up. Higher baseline SLICC-FI values (per 0.05 units) were associated with increased damage accrual over time (Incidence Rate Ratio 1.19; 95% CI 1.09-1.31), after adjusting for age, sex, corticosteroid use, disease duration, smoking status, and baseline SDI (Table 2).

These associations between baseline SLICC-FI values and adverse health outcomes persisted when inception patients (disease duration < 15 months at enrolment) were excluded, and when items related to organ damage were omitted from the SLICC-FI.

Conclusion: Frailty, measured using the SLICC-FI, predicts organ damage accrual and mortality risk among individuals with established SLE. This external validation study provides additional support for the SLICC-FI as a useful prognostic tool in SLE.

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target (T2T) approaches to rheumatic disease require the definition and validation of low disease activity and remission endpoints that should be concentrically more stringent. The Lupus Low Disease

Activity State (LLDAS) has been established as a low-disease activity endpoint for SLE, but multiple possible definitions for remission arise from the Definition of Remission in SLE (DORIS) framework. LLDAS and all remission definitions are associated with improved long term outcomes in terms of damage accrual and flare, but previous analyses suggested that Clinical Remission on Treatment (CROT) allowing 5mg/day prednisolone was insufficiently different from LLDAS (≤7.5 mg/day) to be used separately. Therefore, we examined a more stringent threshold, requiring daily prednisolone < 5mg (CROT< 5), a dose which requires physician and patient to change from standard 5 mg tablets.

Methods: Data from a prospective multinational cohort study of patients with SLE (ACR or SLICC criteria) undertaken in 17 centres between 2013-2017 were used. Time-dependent Cox proportional hazards models were used to compare LLDAS and DORIS definitions of remission in terms of impact on flares (SELENA flare index) and organ damage (SLICC damage index (SDI)). LLDAS and DORIS CROT were defined as described in Golder *et al*, 2019: CROT requires clinical SLEDAI-2K = 0 and physician global assessment (PGA) (0-3) < 0.5; CROT allows prednisolone ≤5 mg/day; whereas CROT< 5 excludes patients taking 5mg/day. LLDAS allows SLEDAI-2K ≤4 with no new/major organ activity, PGA ≤1, and prednisolone ≤7.5 mg.

Results: 18.659 visits of 2,384 patients collected over a mean (SD) 2.26 (1.34) years were analysed. LLDAS was attained in 8,883 (47.6%) visits, CROT in 6,521 (35.0%) and CROT< 5 in 4,373 (23.4%; mean (SD) daily prednisolone 1.16 (1.32) mg)), confirming that lowering the prednisolone threshold resulted in a more stringent remission definition compared to CROT. LLDAS was protective from flare and damage accrual whether assessed visit by visit or cumulatively using a 50% of time exposed threshold. Visit by visit analysis revealed that CROT< 5 was associated with slightly greater protection from future flare (HR (95% CI) 0.48 (0.42,0.54)) than CROT (HR 0.54 (0.49,0.60)). Similarly, future damage risk was slightly less with CROT< 5 (HR 0.60 (0.47,0.78)) than CROT (0.62 (0.50,0.78)). When measured cumulatively using a 50% of time exposed threshold, CROT < 5 was more protective from flare (HR 0.40 (0.35,0.46)) than CROT (0.45 (0.40,0.50)) but not from damage. The effect of cumulative LLDAS on damage accrual overtime remained significant after excluding patients in CROT< 5 (HR 0.74 (0.57,0.96), p=0.022) but not after excluding CROT. Cumulative LLDAS was independently associated with flare excluding either CROT or CROT< 5.

Conclusion: A remission definition requiring a ceiling dose of prednisolone less than 5 mg (CROT< 5) is more stringent than CROT (allowing 5 mg/day) and its effects are independent of LLDAS, while CROT is insufficiently distinct from LLDAS. Confirmation in other cohorts should be undertaken prior to agreeing on a definition of remission for SLE.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE have poor health related quality of life (HRQoL), however the differences in the predominant causes of decreased HRQoL across subgroups of SLE are not known. Features of fibromyalgia including fatigue, widespread pain, depression, sleep and cognitive dysfunction are prevalent in SLE affecting 20-65% of patients and often contribute to disability and poor HRQoL. These aspects of fibromyalgia have not been well described in patients with lupus nephritis (LN). We evaluated self-reported symptoms of fibromyalgia and mood disorders in patients with and without lupus nephritis.

Methods: This was a cross sectional study of SLE patients (ACR 1997 or SLICC 2012 criteria) enrolled in a university registry from June 2018 to November 2019. All patients completed Systemic Lupus Activity Questionnaire (SLAQ), Patient Health Questionnaire-9 (PHQ9), and 2016 ACR Fibromyalgia criteria surveys. Active nephritis was defined as UPC >500mg and/or active urinary sediment excluding other causes. Fibromyalgia was defined as ≥7 widespread pain index (WPI) with ≥5 symptoms severity score (SSS) or ≥4 WPI with ≥9 SSS. Differences across groups were analyzed by Fisher's exact test and ANOVA.

Results: Two hundred and twenty-four patients completed patient-reported outcome measures (93% female, mean age 40 years, 67% Black). In our cohort 11% had active nephritis, 35% had nephritis in remission and 54% had no history of nephritis. Of nephritis patients, 22% had membranous class V, 48% had proliferative or proliferative/mixed LN, 3% class I/II, 5% post-transplant, 6% ESRD on dialysis, and class was unknown in 28%.

Active nephritis patients were younger, more often of Black race, and reported greater social support than non-nephritis patients. There were no differences in sex, disease duration, education, income, disability, insurance, or serologies. The use of plaquenil, anti-depressants, gabapentinoids, muscle relaxers, and narcotics were similar between groups. Active nephritis patients were more often prescribed prednisone (Table 2).

Table 1. Patient demographics and socioeconomic factors of active nephritis, nephritis in remission and non-nephritis SLE patients

	Active Nephritis n=24	Nephritis in Remission n=78	Non-nephritis n=122	p-value
Mean age (SD), years	34.0 (10.6)	38.9 (11.6)	47.1 (14.4)	<0.0001

The prevalence of fibromyalgia was 13% in active nephritis, 3% in nephritis remission and 21% in non-nephritis patients (p=0.001). LN patients had significantly lower fibromyalgia severity, symptom severity, areas of pain, fatigue, cognitive, and sleep dysfunction. Patient-reported disease activity was significantly lower in patients with LN remission. Rates of anxiety and depression were similar across active LN and non-nephritis groups.

Conclusion: Patients with active and inactive LN report less fatigue, fibromyalgia, sleep, and cognitive dysfunction compared to non-nephritis patients. There were differences in demographics as well as greater social support in nephritis patients. Differences in social support could potentially mitigate fatigue and fibromyalgia in nephritis patients. There was no difference in anxiety or depression, suggesting fibromyalgia can occur independently of mood disorders. The drivers of low HRQoL may be distinct across SLE subgroups. Lupus nephritis patients have high rates of disability and poor HRQoL; however, the mechanism underlying these outcomes is nephritis is less likely related to features of fibromyalgia.

The Rising Incidence of Lupus Nephritis: A Population-Based Study of Four Decades

Mehmet Hocaoglu[1], Shirley-Ann Osei-Onomah[2], Jesse Dabit[3], Rachel Giblon[3], Thomas O'Byrne[3], Fernando C. Fervenza[3], Cynthia Crowson[4] and Ali Duarte-Garcia[3], [1]University of Maryland Medical Center Midtown Campus, Baltimore, MD, [2]Mayo Clinic, Rochester, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Estimating the incidence of lupus nephritis (LN) is important to understand disease burden, particularly since patients with LN have a higher morbidity and mortality than other patients with systemic lupus erythematosus (SLE). Population-based studies that investigate the incidence of LN are lacking, and changes over time remain uncertain. We aimed to estimate the incidence of LN and its secular trends in a well-defined geographic region between 1976 and 2018.

Methods: All patients who had an SLE related diagnostic codes or the following laboratory measures: anti-nuclear antibodies, anti-double stranded DNA, anti-Sm, anti-cardiolipin, anti-beta 2 glycoprotein 1antibodies, complement, coombs and lupus anticoagulant were identified using a population-based research infrastructure. Medical records were thoroughly reviewed from 1976-2018. LN was defined as patients who had either 1) biopsy proven LN in the presence of a positive ANA or ds-DNA antibody, or 2) meeting one of the following SLE criteria: ACR97, SLICC or ACR/EULAR 2019 and developing proteinuria (500 mg in 24hrs urine collection or protein/creatinine ratio > 0.5) that did not have a better explanation. Patients with diabetes or other causes of proteinuria were excluded.

Incident cases were defined as a patient who had been a resident of our geographic region for at least one year prior to meeting the case definition for LN. The incidence date was the earliest date that the patient fulfilled either case definition. LN class data was obtained from biopsy reports. Age- and sex- specific incidence rates were adjusted to the 2010 US white population. The 95% Confidence intervals for incidence rates were calculated by assuming the data follows a Poisson distribution.

Table 1. Demographics and Clinical Characteristics of Incident Lupus Nephritis cohort

Characteristics	Timeframe 1976 to 1988 (N=7)	1989 to 1998 (N=9)	1999 to 2008 (N=13)	2009 to 2018 (N=19)	Total (N=48)

50-59	4	1.4	2	0.7	6	1.1
60-69	1	0.5	0	0.0	1	0.3
70-79	3	2.1	1	0.9	4	1.6
Total	38	1.3* (0.9, 1.7)	10	0.4* (0.2, 0.7)	48	0.9** (0.6, 1.1)

*Age-adjusted to the US White 2010 population
**Age- and sex- adjusted to the US White 2010 population

Results: We identified 48 incident cases between the years 1976 and 2018. As detailed in Table 1, the mean age was 38.6 years (SD15.5), 79% were female and 21% male. The racial distribution was 6% Black, 23% Asian, 68% Caucasian while 8% were Hispanic. There was a decrease in the proportion of Caucasians over the decades.

The overall LN incidence was 0.9 (95%CI: 0.6, 1.1) per 100,000 (Table 2). The incidence rate in females was 1.3 (95%CI: 0.9, 1.7) while in males was 0.4 (95%CI: 0.2, 0.7) per 100,000. Age- and sex- specific incidence peaked at 30-39 years for females and 40-49 for males with rates of 2.3 and 0.9 per 100,000 respectively.

The incidence of LN doubled from 0.6 (95%CI: 0.1, 1.2) in 1976-1988 period to 1.2 (95%CI: 0.7, 1.8) in 2009-2018 period per 100,000 (Table 2).>

For patients who had a biopsy, the LN class distribution was 6% class II, 25% class III, 47% class IV and 22% class V.

Conclusion: Our report provides a population-based estimate on the incidence of LN in the United States previously unavailable. Furthermore, our data shows that the incidence of LN has doubled in the last four decades. Future studies are needed to explain whether these changes are due to increases in racial and ethnic diversity, better detection or environmental influences.

Abstract Number: 0275

Paradoxical Relationship Between Disease Activity and Satisfaction with Care in Lupus

Sana Afroz[1], Ailda Nika[2], Winston Sequeira[3], Joel Block[4], Patricia Katz[5] and Meenakshi Jolly[2], [1]RUMC, chicago, IL, [2]Rush University, Chicago, IL, [3]Rush University Medical Center, Oak Brook, IL, [4]Rush University Medical Center, Chicago, [5]University of California, San Francisco, Novato, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Satisfaction with care (SC) is increasingly being used as a surrogate of QOC, with growing emphasis on optimizing SC/patient experience in health care. We previously reported higher disease activity in systemic lupus erythematosus (SLE) to be associated with better SC in a large International study with cross sectional data. However, health care systems differ across regions and countries which could impact SC. Herein, we aimed to study association of disease activity and SC with disease activity (SLEDAI and Treat to Target T2T) at baseline and longitudinally in a single center.

Methods: Baseline (Time 1) data on 147 consenting SLE patients, meeting ACR criteria, were used from the Rush Lupus data repository. Patients completed assessments of demographics, PROs (LupusPROv1.8 and MDHAQ) at routine clinic visits. Other data collected included disease duration, SLE medications, disease activity (SELENA-SLEDAI), Treat to Target category (T2T-Nonoptimal, Low disease activity state -LDAS, Remission on therapy [RONT] and Remission Off therapy [ROFT]), damage (SLICC-SDI/ACR) and other comorbidities. SC was measured using the LupusPRO SC domain items. Univariate and multivariate regression analyses was done, with SC as a dependent variable and demographics, disease activity/duration, comorbidities, and PROs (Lupus-PRO and MDHAQ) as independent variables.

Table 1. Predictors of Satisfaction with Care

Variable	Univariate Analyses			Multivariate analysis, R^2=0.12		
	β	95% CI	*P*	β	95% CI	P
Demographics						
Education	-5.63	12.27 to 1.01	0.1			
Hispanic vs Non-Hispanic	14.01	1.31to 26.7	**0.03**	11.69	-0.70 to 24.08	0.06
Disease features						
Disease duration	0.288	-.35 to 0.93	0.38			
ROFT	-14.06	-25.65 to -2.48	**0.018**	-12.4	-23.7 to -1.03	**0.03**
Comorbidities						
HTN	6.228	-3.7 to 16.2	0.22			
LupusPRO						
LMED	0.126	0.01 to 0.15	0.028			
PRF	0.147	−0.22 to −0.08	0.12			
BI	0.133	0.33 to 0.43	0.1			
SS	0.202	0.05 to 0.35	**0.008**	0.186	0.04 to 0.33	**0.01**
CO	0.107	0.49 to 0.62	0.277			

We developed a conceptual model based on Time 1 data. Longitudinal (Time 2) paired data on T2T and SC were available for 72 patients. We performed univariate linear regression with SC at Time 2 as the dependent and ROFT (Yes/No) T2T Time 1 as the independent variable. P value of ≤0.05 was considered significant.

Results: Mean (SD) age was 43.8 (13.4) years; 90% were female. Median (IQR) SLEDAI was 2(4; 0-14) and SLEDAI was ≥ 4 in 35%. Current prednisone use was observed among 35% patients. T2T category distribution were: Non-Optimal 25%, LDAS 34%, RONT 18% and ROFT 22%. Mean (SD) SC was 86.9±26.8. Total SLEDAI was not correlated with SC.

On univariate analysis, Hispanic ethnicity, and LupusPRO domains of Lupus Medications, and Social Support were directly associated with SC while ROFT (Yes/No) status was inversely associated with SC. On multivariate analysis, LupusPRO-Social Support and ROFT remained independent predictors of SC cross-sectionally (Table 1).

Longitudinal analysis also showed ROFT status at T1 to be a predictor of lower SC at T2 (β -15.56, 95% CI -30.2, -0.92, p 0.038).

Conclusion: SLE Patients in remission off therapy have worse satisfaction with care (as compared to those without ROFT) both at baseline and longitudinally. It is plausible that greater interaction with the care providers or health care system due to either active disease or use of immunosuppressive medications contributes to greater SC among those not in remission off therapy. Satisfaction with care may not be an appropriate surrogate to use for QOC in the context of attainment of disease activity status.

Type 2 SLE Symptoms Persist Despite Type 2 Medication Polypharmacy

Raeann Whitney[1], Amanda Eudy[2], Cynthia Coffman[3], Megan Clowse[4], Lisa Criscione-Schreiber[5], Jayanth Doss[2], Rebecca Sadun[2], Kai Sun[2] and Jennifer Rogers[6], [1]Duke University Medical Center, Durham, NC, [2]Duke University, Durham, NC, [3]Duke University, Durham, [4]Duke University, Chapel Hill, NC, [5]Duke University School of Medicine, Durham, NC, [6]Duke, Durham, NC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Management of Type 2 SLE (widespread pain, fatigue, depression, sleep distrubance, and cognitive dysfunction) is challenging and often requires multiple medications to ameliorate symptoms. Polypharmacy can increase the risk of drug interactions, side effects, adverse reactions, non-adherence, and lead to greater healthcare costs. Many medications used for Type 2 SLE are associated with QTc interval prolongation. The purpose of this study was to examine symptoms and Type 2 medication polypharmacy.

Methods: This was a cross-sectional study of SLE patients (SLICC 2012 criteria) enrolled in a university registry from May 2018-March 2019. All patients completed the Systemic Lupus Activity Questionnaire (SLAQ), Patient Health

Table 1. Characteristics of SLE patients by Type 2 medication use

	No Type 2 Medications	One Type 2 Medication	Two or More Type 2 Medications	p-value
	n=79	n=39	n=41	
Socioeconomic Factors				
Age n(SD)	38.7 (12.5)	45.0 (13.3)	47.5 (12.6)	0.001
Disease Duration (yrs) (n=148)	12.3 (7.5)	17.2 (8.4)	17.1 (8.8)	0.002

Historical nephritis	35 (44.3%)	20 (51.3%)	21 (51.2%)	0.7
Historical arthritis	25 (31.6%)	9 (23.1%)	10 (24.4%)	0.6
Clinical SLEDAI Mean(SD)	1.3 (2.5)	1.7 (2.5)	1.6 (2.3)	0.7
Full SLEDAI Mean (SD)	3.7 (4.3)	4.2 (4.3)	2.5 (3.0)	0.13
QTc Interval Prolonging Type 2 Medications				
QTc Type 2 Meds		23(59%)	35(85.4%)	0.009
Qtc interval prolonging medications: TCA, SNRI, SSR, mirtazapine, tramadol, trazodone				

Questionnaire-9 (PHQ-9), and 2016 ACR Fibromyalgia criteria questionnaires. Type 2 SLE was defined as a polysymptomatic distress (PSD) score ≥8. Type 2 medications included antidepressants (serotonin and norepinephrine reuptake inhibitors (SNRIs), selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (TCAs), mirtazapine, bupropion, muscle relaxers (cyclobenzaprine, baclofen, metaxalone), gabapentinoids (gabapentin, pregabalin), topiramate, zolpidem, trazodone, tramadol, anxiolytics, stimulants, and DHEA. Relationships between clinical variables and medications in different groups were analyzed using ANOVA and Fisher's exact test.

Results: One hundred and fifty-nine patients completed surveys (96% female, 66% Black, 42% Type 2 SLE.) Type 2 medications were prescribed in 50% of patients. Patients on Type 2 medications were older and had longer duration of SLE (Table 1). Multiple Type 2 medication use was more frequent in Type 2 SLE patients than non-Type 2 patients (43% vs 25.7%). The average number of Type 2 medications was 1.9. Of patients taking Type 2 medications, 72% were taking at least one QTc interval prolonging Type 2 medications (mean 1.3 medications).

Despite pharmacologic therapy, 58% of SLE patients had active Type 2 SLE (Table 2). The number of patients with depression and Type 2 SLE activity was greater in those on multiple medications. Moreover, the severity of nearly all Type 2 SLE symptoms including widespread pain, fatigue, depression, forgetfulness and sleep dysfunction was greatest in those on more than one Type 2 medication compared to no Type 2 medications or one Type 2 medication.

Table 2. Type 2 SLE symptoms and Type 2 medication polypharmacy

	No Type 2 Medications	One Type 2 Medication	Two or More Type 2 Medications	p-value
	n=79	n=39	n=41	
Active Type 2 SLE (PSD ≥8)	21 (26.6%)	17 (43.6%)	29(70.7%)	<0.001
2016 ACR Fibromyalgia Criteria				
Fibromyalgia Severity Score	6.0 (4.4)	9.3 (5.9)	13.0 (6.8)	<0.0001
Widespread Pain Index	2.2 (2.4)	3.6 (3.8)	6.4 (4.9)	<0.0001
Symptom Severity Score (SSS)	2.8 (2.2)	4.1 (2.4)	5.2 (2.3)	<0.0001
SSS Elements (moderate-severe)				
Cognitive dysfunction	10 (12.7%)	29 (74.4%)	29 (70.7%)	0.05
Fatigue	29 (36.7%)	22 (56.4%)	30 (73.2%)	0.001
Sleep dysfunction	25 (31.6%)	18 (46.2%)	27 (65.9%)	0.002
PHQ-9				
Depression criteria (n=20)	3 (3.8%)	5 (12.8%)	7 (17.1%)	0.02
Depression severity (PHQ-9 score)	3.9 (3.6)	6.7 (5.3)	8.3 (4.7)	<0.0001
SLAQ (moderate or severe)				
Forgetfulness	8 (10.1%)	32 (82.1%)	25 (61.0%)	0.001

Conclusion: SLE patients have distressing Type 2 symptoms that often require complex pharmacologic interventions. Although the majority of patients with Type 2 SLE activity take therapies aimed at these symptoms, they continue to have a multitude of symptoms. Furthermore, severe symptoms persist despite nearly half of patients taking multiple medications. Several Type 2 medications can prolong the QTc interval, which when combined with other QTc prolonging medications such as hydroxychloroquine, can augment the risk of arrhythmia. The average number of Type 2 SLE medications is similar to the number used for Type 1 SLE, highlighting the difficulty managing Type 2 SLE, the need for targeted Type 2 therapeutics, and the importance of non-pharmacologic management.

manifestations such as Systemic Lupus Erythematosus (SLE). Recently the 2019 European League Against Rheumatism/American College of Rheumatology classification criteria for SLE was published. The sensitivity and specificity of the 2019 EULAR/ACR criteria are different from the 1997 ACR criteria and the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria. The effect on the incidence estimations of the disease using different criteria has not been studied. A reason to develop the new EULAR/ ACR criteria was to classify patients earlier in their disease process; however it has not been proven if this was indeed accomplished. We aimed to 1) estimate the incidence and time-to-classification of SLE using the 1997 ACR, 2012 SLICC and 2019 EULAR/ACR criteria.

Methods: We identified potential incident SLE cases from 2000-2018 in a geographically well-defined population using diagnostic codes for cutaneous and systemic lupus and the following laboratory measures: anti-nuclear antibodies, anti-double stranded DNA, anti-Sm, anticardiolipin, anti-beta 2 glycoprotein 1 antibodies, complement, coombs and lupus anticoagulant. Clinical data included in the 1997 ACR, 2012 SLICC and 2019 EULAR/ACR criteria were abstracted through chart reviews. If a disease manifestation could be better explained by another condition rather than SLE, it was not counted towards the criteria. We defined the time-to-classification based on the first lupus-attributable disease manifestation ever documented in the record to the time meeting criteria by each of the three definitions. Incidence rates were age and/or sex adjusted to the estimated 2010 white population of the US. To compute 95% confidence intervals for incidence rates, it was assumed that the number of incident cases followed a Poisson distribution. Time-to-classification among different criteria was compared using signed rank test.

Results: There were 127 incident cases that met the EULAR/ACR 2019 criteria, corresponding to an adjusted incidence of 4.7 per 100,000 (95% CI, 3.9-5.5). The incidence was higher than that of the 1997 ACR (91 cases; 3.3 per

100,000 [95%CI 2.6 - 4], p=0.015) but similar to 2012 SLICC criteria (114 cases; 4.2 per 100,000 [95%CI, 3.4 - 4.9], p=0.40). (Table 1)

The median time from first disease manifestation to criteria fulfillment was shorter for the EULAR/ACR 2019 criteria (28.47 months) than the 1997 ACR criteria (45.3 months, p< 0.001) and similar to the SLICC 2012 criteria (33.2 months, p=0.89).

The demographic characteristics are detailed in Table 2. Female: male ratio, mean age at classification and the proportion across different races/ethnic groups were similar across the three criteria.

Conclusion: In this population-based study, the incidence of SLE was higher and time to criteria fulfillment sooner by 2019 EULAR/ACR criteria compared to the 1997 ACR but not significantly different than the 2012 SLICC criteria.

Trends in Incidence of Cutaneous Lupus Erythematosus from 1976 to 2018: A Population-Based Study

Mehmet Hocaoglu[1], Mark Denis P. Davis[2], Shirley-Ann Osei-Onomah[3], Jesse Dabit[2], Rachel Giblon[2], Thomas O'Byrne[2], Cynthia Crowson[4] and Ali Duarte-Garcia[2], [1]University of Maryland Medical Center Midtown Campus, Baltimore, MD, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Rochester, [4]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is a heterogeneous chronic disease with potential for long lasting morbidity. Studies that provide incidence data on the entire spectrum of CLE are needed to better estimate the disease burden. Furthermore, it is unclear whether secular changes in risk factors such as smoking over the decades have had an impact in CLE incidence. We aimed to investigate the incidence of CLE and its secular trends from 1976 to 2018.

Methods: All patients in a geographically well-defined area who received a SLE or CLE diagnostic codes or the following laboratory measures: ANA, anti-double stranded DNA, anti-Sm, complement, and antiphospholipid antibodies underwent a thorough review of clinical notes, pathology and medical photography.

Incident cases were defined based on the criteria by Sontheimer. We categorized CLE as follows: discoid lupus erythematosus (DLE), lupus panniculitis (LP), lupus tumidus (TL), chilblain lupus (CHLE) and subacute cutaneous lupus (SCLE). Those with uncertain diagnosis or subtype were reviewed by a CLE expert dermatologist. The incidence date was when the skin lesion was first described in the medical record. We included both patients with CLE as well as those with systemic lupus erythematosus (SLE) with cutaneous manifestations. We considered chronic CLE in patients who did not have a concurrent (within one year of cutaneous manifestations) or previous diagnosis of SLE.

Table 1. Demographics and Clinical Characteristics of Cutaneous Lupus Erythematosus

Characteristic	Timeframe				
	1976 to 1988 (N=36)	1989 to 1998 (N=49)	1999 to 2008 (N=58)	2009 to 2018 (N=66)	Total (N=209)

Multiple subtypes	1 (3)	1 (2)	1 (2)	0 (0)	3 (2)

Age and sex specific incidence rates were adjusted to the 2010 US white population. The 95% confidence intervals for incidence rates were computed assuming that the data follows a Poisson distribution.

Results: We identified a cohort of 209 incident CLE cases between 1976 and 2018. Mean age was 50.3 (SD 17.2). 72% were female. The racial make-up was 5% Asian, 7% Black, 87% Caucasian, 1% Native American. 2% percent were Hispanic. The proportion of Caucasians decreased over the years.

Out of 209 patients, 13 (6.2%) had a previous or concurrent diagnosis of SLE by the ACR 97 criteria and 94% were considered chronic CLE.

Table 2. Age- and sex-specific incidence rates for CLE

	Female		Male		Total	
Age	N	Rate per 100,000 (95% CI)	N	Rate per 100,000 (95% CI)	N	Rate Per 100,000 (95% CI)
0-17	2	0.3	1	0.1	3	0.2
18-29	19	3.2	4	0.8	23	2.1
30-39	22	5.1	11	2.8	33	4.0
40-49	31	8.8	12	3.7	43	6.4
50-59	29	9.9	14	5.2	43	7.7
60-69	24	11.8	10	5.6	34	8.9
70-79	12	8.3	6	5.5	18	7.1
>80	12	10.7	0	0.0	12	7.1
Total	151	6.2* (5.2, 7.2)	58	2.7* (2.0, 3.5)	209	4.5** (3.9, 5.2)

*Age-adjusted to the US White 2010 population
**Age- and sex- adjusted to the US White 2010 population

Figure 1. Trends in age-adjusted Cutaneous Lupus Erythematosus incidence over time by Sex (female is solid line and male is dashed line)

The distribution of the CLE subtypes was: 23% SCLE, 63% DLE, 1% LP, 3% CHLE, 7% TL. 1% of the cases had more than one subtype. The proportion of LT, CHLE and LP increased over the decades. (Table 1)

The overall incidence rate of CLE between 1976 and 2018 was 4.5 (95%CI: 3.9, 5.2) per 100,000. Females had a higher incidence than males: 6.2 (95%CI: 5.2, 7.2) and 2.7 (95%CI: 2.0, 3.5) per 100,000, respectively. Age- and sex-specific incidence rates peak at the 60-69 age group in both females and males, 11.8 and 5.6 per 100,000, respectively. (Table 2) There was an increase in CLE incidence during 1985-1995 that was observed in both sexes and posteriorly trended downwards. (Figure 1)

Conclusion: Our data shows that the overall incidence of CLE has remained stable over the decades with a sudden increase in 1985-1995 with posterior return to prior rates. The majority of the CLE cases do not have SLE prior or concurrent to diagnosis. The clinical characteristics of CLE changed with rising proportion of TL, SCLE, CL, LP cas-

es. More studies are needed to investigate whether these changes are due to rising awareness of rare subtypes or changes in environmental or demographic factors.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of SLE pulmonary involvement varies depending on several factors, including diagnostic methods. In this study, we sought to determine the frequency of involvement with different diagnostic methods in a single-center cohort.

Methods: 300 randomly chosen patients with SLE were included. Chest x-ray (CXR), lung spirometry, carbon monoxide diffusion test (DLCOc), and echocardiography were performed. High-resolution thorax computed tomography (HRCT) was done for a definite diagnosis of interstitial lung disease (ILD) whilst diagram electromyography (EMG), ultrasonography (USG), and magnetic resonance imaging (MR) were utilized to diagnose shrinking lung syndrome (SLS).

Results: 88,3 % of the cohort was female. The mean age and follow-up time were 43 and 11,5 years respectively. Of 300 patients, 16 % had ILD, 6,7 % had pulmonary hypertension (PHT), 3 % had SLS, 0,3 % had pulmonary infarction. At the start of the study, the prevalence of these involvements obtained from the patients' records showed that 4 % had ILD, 5 % PHT, 0,3 % SLS, and 0,3 % pulmonary infarction. The median age, mean duration of disease, and follow-up time were significantly higher and longer in patients with ILD compared to patients without ($p< 0.05$). Forced expiratory volume (FEV1), forced vital capacity (FVC), DLCOc, and total lung capacity (TLC) were significantly lower in patients with ILD and with SLS ($p< 0,001$). Patients with ILD had a significantly higher frequency of arthritis, serositis, Raynaud myositis, and anti-Scl70 positivity. Neuropsychiatric damage, avascular necrosis, diabetes, and malignancy were significantly more frequent in those patients. All patients with suspected SLS has undergone diagram EMG, USG, and MR. Out of 10 suspected cases, in 6 EMG, in 5 USG and in 9 MR was compatible with SLS diagnosis(table 1). 5 patients had 3 of the diagnostic methods positive to diagnose SLS. Patients with SLS had a higher frequency of pleuritis, pericarditis, leukopenia, anti-Ro, and anti-La antibodies. Muscle atrophy and weakness, avascular necrosis were more frequent in this group of patients ($p< 0.05$). There were more patients treated with mycophenolate mofetil (MMF) and cyclophosphamide in the SLS group whilst more with MMF in the ILD group. Significantly higher frequency of patients had stopped using hydroxychloroquine (HCQ) in the ILD group ($p=0,04$).

Table 1. Spirometry, DLCO, diaphragm EMG, diaphragm USG and MR results of patients with Shrinking Lung Syndrome.

6/60/F	62	70	55	64	3,06	2,17	1,59	1,31			0,4	8	0,6	6
7/58/F	71	72	47	54	5,73	4,67	2,09	1,79	R	2,45	0,1	6,15	0,3	6
8/37/F	53	55	65	63	4,17	2,83	3,18	1,97	R	1,73	0,8	4,75	1,2	4,35
9/66/F	70	62	62	62	2,12	4,62	1,62	2,08	L	0,95	0,9	6	0,5	5,2
10/28/F	39	37	45	45	1,59	2,49	1,44	1,63	L	0,78	0,7	5,8	0,5	6,15

Conclusion: Interstitial lung disease is common in patients with SLE and a considerable number of patients have SLS. Spirometry, diffusion tests, and chest x-ray are simple but valuable tools to shape a diagnostic approach for pulmonary involvement in patients with SLE. Diagram MR, USG, and EMG are complementary methods for a definite diagnosis in SLS. Considering the significant difference in prevalence between the start and the end of the study, one of the possibilities is the underrecognition of SLE pulmonary disease due to its being part of a multisystemic presentation. Moreover, the higher usage of immunosuppressives in these patients may support a multisystemic active disease. Although the drug effect is another concern, it is hard to establish a causal relationship due to the study's cross-sectional design. HCQ may have a role in ILD prevention.

Abstract Number: 0280

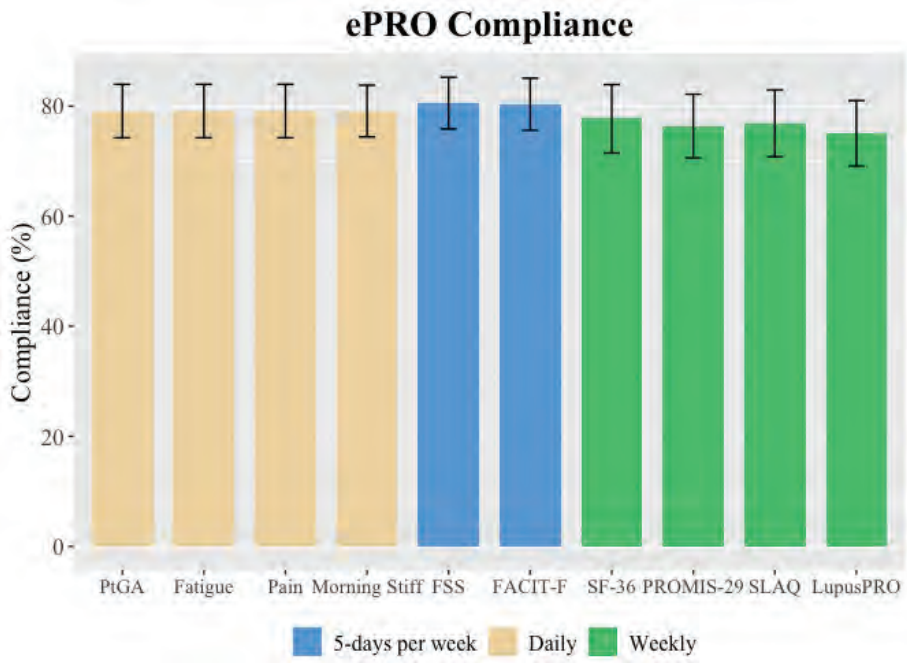
Compliance and Validation of Patient Reported Outcome Information Collected from Lupus Patients Using a Mobile Application

Kristy Bell[1], Claire Dykas[1], Hope Rainey[1], Maggy Comberg[1], Mary Mora[1] and Peter Lipsky[1], [1]AMPEL BioSolutions LLC., Charlottesville, VA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient Reported Outcomes (PROs) can provide critical data in measuring the impact of a disease on an individual as well as the quality of response to treatment. However, PROs are oftentimes recorded intermittently and require patients to recall a period of several weeks or months. As a result, important PRO information may not always be representative of the complete recall period. The development of mobile technology to collect PRO data in an electronic format (ePRO) allows for more frequent assessment in real time and in the person's regular environment. The goal of this study was to assess the compliance and equivalence of a smart phone application (app) in collecting PRO data in individuals SLE.

Methods: A smart phone app was developed that collects ePRO data from various instruments, including the Fatigue Severity Scale (FSS), Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F), Short Form Health Survey (SF-36), Patient Reported Outcome Measurement Information System (PROMIS-29), Systemic Lupus Activity Questionnaire (SLAQ), and LupusPRO. Additionally, the duration of morning stiffness as well as patient global assessment (PtGA), pain and fatigue using a 10 cm visual analog scale were collected. Information was collected as part of a multicenter randomized interventional clinical trial of patients who met ACR criteria for the classification of



Compliance with PRO instruments collected with a mobile app.

Top 15 intraclass correlation coefficients (ICCs) and respective 90% confidence intervals.

SLE (NCT03098823). ePRO information was collected daily (PtGA, fatigue, pain, morning stiffness), 5-days per week (FSS, FACIT-F), or weekly (SF-36, PROMIS-29, SLAQ, LupusPRO), and biometric data (steps, sleep and location) was recorded daily with the app or a linked smart watch. Additionally, all PRO instruments were completed on seven occasions at the clinical sites utilizing both the app and standard paper forms separated by a distraction. To determine agreement between information collected with the app and the paper-administered PROs, intra-class correlation coefficients (ICCs), paired student's t-tests, and Bland-Altman plots for data collected at each of the seven site visits were evaluated. Compliance, demographic information and Cronbach's alpha as a measure of survey reliability were also assessed.

Results: For the 62 subjects from diverse ancestral backgrounds, compliance with ePRO completion was high for all PRO surveys (>75%; Figure 1). Cronbach's alpha values for each PRO ranged from 0.74 to 0.96 for the ePROs, and 0.70 to 0.96 for the paper versions, suggesting moderate to high inter-survey reliability in measuring the targeted concepts. Of the 168 ICC values computed from each site visit for each survey, 41 were indicative of moderate (0.5 to 0.75), 69 good (0.75 to 0.9) and 55 excellent (>0.90) reliability between measurement methods (Table 1). Bland-Altman plots verified method agreement with 151 of the pairwise comparisons yielding an insignificant difference.

Conclusion: The high rate of compliance in collecting ePROs and the high level of consistency between data collected by paper and electronic methods of administration indicate that the app provides highly reliable information capable of cataloging real-time changes in PROs in SLE patients.

ANCA in SLE: Prevalence and Predictor Factors

Reza Mirza[1], Murray Urowitz[2], Jiandong Su[3] and Dafna Gladman[4], [1]University of Toronto, Toronto, ON, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [4]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Clinical Manifestations
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a systemic autoimmune disease notable for the ability to affect nearly every tissue, and is associated with a breadth of auto-antibodies. Anti-neutrophilic cytoplasmic antibodies (ANCA) are strongly associated with small-vessel vasculitis, specifically the ANCA-associated vasculitides, but their role in SLE is less clear.

Purpose: To determine whether ANCA are associated with disease features including vasculitis in SLE.

Methods: Patients with 4 or more of the 1971 or 1982 ACR classification criteria, or 3 criteria and a typical biopsy of SLE are registered in the database and are followed longitudinally, with clinical and laboratory information collected at 2-6-month intervals.

SLE patients with at least 2 ANCA tests, between Aug 1979 (when ANCA became locally available) and Nov 2019 were included. Patients with 2 consecutive ANCA (both C and P ANCA) were considered exposed in this study. Controls were patients who never had a positive ANCA. Index date was the time of the second ANCA. Vasculitis was defined by the SLEDAI-2K: ulceration, gangrene, tender finger nodules, periungual infarction, splinter hemorrhages, and biopsy/angiogram. Descriptive statistics were used to show patients' characteristics at ANCA positive or negative in patient groups, Kaplan-Meier survival curves were plotted for outcomes of first vasculitis, Weibull parametric survival regression was applied to evaluate the effects of ANCA positivity on the outcome of vasculitis adjusting other confounding variables.

Results: Of the 1426 patients tested for ANCAs on two occasions, 1091 (77%) had never tested positive, 145 (10%) tested positive twice and 190 (13%) tested positive once. Those that tested positive twice or more included 92 with only p-ANCA, 24 with only c-ANCA, and 29 with both. Median time between first and second ANCA was 12 months. Patients' demographics, clinical measurements, treatments are presented by ANCA subtype in table 1. Patients with either two positive ANCA-C or two positive ANCA-P had lower proportions of steroid treatment compared to 29 patients with both ANCA-C and ANCA-P positive, but were otherwise largely similar to those with both ANCA-C and ANCA-P positivity. Kaplan-Meier survival curves show significantly higher cumulative index of vasculitis in the 145 patients with any ANCA positive compared to none (p=0.0491, Figure 1). Survival regression models revealed that two or more ANCA-P positive (vs. normal ANCA patients) predicted the outcome of vasculitis after adjusting for SLE-

Table 1: Demographics: ANCA positive by subtype versus ANCA negative controls

VARIABLE	VALUE	pure ANCA-C patients	pure ANCA-P patients	both ANCA-C and ANCA-P patients	No ANCA positive
		N=24	N=92	N=29	N=1,091
Age at Index date	Mean ± SD	41.9 ± 15.2	41.3 ± 13.9	38.0 ± 16.2	37.7 ± 13.8
Sex	F	20 (83.3%)	88 (95.7%)	26 (89.7%)	965 (88.5%)
	M	4 (16.7%)	4 (4.3%)	3 (10.3%)	126 (11.5%)
Ethnicity	Black	2 (8.3%)	13 (14.1%)	1 (3.4%)	171 (15.7%)
	Caucasian	16 (66.7%)	65 (70.7%)	18 (62.1%)	663 (60.8%)
	Chinese	1 (4.2%)	8 (8.7%)	4 (13.8%)	113 (10.4%)
	Others	5 (20.8%)	6 (6.5%)	6 (20.7%)	144 (13.2%)
Disease duration at index	Mean ± SD	11.3 ± 12.1	11.5 ± 9.4	9.9 ± 9.8	6.9 ± 7.9
Follow up duration from index date to last visit	Mean ± SD	6.2 ± 7.0	6.9 ± 8.3	7.1 ± 7.4	9.7 ± 7.2
SLEDAI-2K score at index date	Mean ± SD	6.0 ± 5.7	4.7 ± 4.0	5.0 ± 5.6	6.9 ± 6.8
Adjusted Mean SLEDAI within 3 years prior to index	Mean ± SD	5.8 ± 5.1	5.0 ± 4.0	5.9 ± 5.5	7.2 ± 6.6
SLICC score at index date	Mean ± SD	1.2 ± 1.9	1.1 ± 1.4	0.8 ± 1.2	0.5 ± 1.1
Treated with steroids at index *	Yes (%)	11 (45.8%)	54 (58.7%)	25 (86.2%)	722 (66.2%)
Steroid dose (mg/day) at index	Mean ± SD	14.5 ± 10.3	12.0 ± 9.0	13.9 ± 12.4	18.1 ± 16.1
Cumulative steroid dose (gram) within 3 years prior to index	Mean ± SD	20.9 ± 25.8	28.8 ± 39.4	29.2 ± 48.4	13.1 ± 28.5
Treated with antimalarials at index	Yes (%)	13 (54.2%)	43 (46.7%)	15 (51.7%)	613 (56.2%)
Treated with Immunosuppressives at index	Yes (%)	9 (37.5%)	26 (28.3%)	9 (31.0%)	427 (39.1%)

Note that there were no statistical significance differences among the three mutually exclusive ANCA positive groups except the following:
* both ANCA-C and ANCA-P positive patients had statistically higher percentage of patients treated with prednisone, even after Bonferroni multiple comparison adjustment (p = 0.02 and p = 0.005 for ANCA-C and ANCA-p comparing with 29 patients with both ANCA-C and ANCA-P positive).

DAI-2K and prednisone treatment at index date (HR 1.78, 95% CI: 1.15-2.79) in the best fit multivariable model, while two or more ANCA-C positive did not reach significance in the other regression model. Looking into the nature of vasculitis, the proportion of patients with vasculitis within each of the ANCA subgroups were similar (p-ANCA 20.1%, c-ANCA 16.7%, mixed ANCA 20.7%), but only the p-ANCA group was significantly higher than those with no ANCA positivity (12.4%; Table 2) partially due to sample sizes.

Conclusion: In our cohort, approximately 10% of SLE patents have persistent ANCA positivity, predominantly p-ANCA. The presence of p-ANCA was associated with significantly more vasculitis predominantly skin vasculitis.

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Inappropriate sensing of nucleic acids leading to enhanced type I interferon (IFN) induction is a hallmark of SLE, contributing to breakdown of immune tolerance and driving pathology. Cytosolic DNA is sensed by cyclic GMP-AMP synthase (cGAS), which synthesizes cyclic GMP-AMP (cGAMP), a potent second messenger that activates STING-dependent type 1 IFN (R Zhou *et al.*, 2019). Recently, the cGAS-STING pathway has been implicated in SLE by the observation that cGAS expression and cGAMP levels were elevated in SLE PBMCs compared to healthy controls (J An *et al.*, 2017). Also, it has emerged that cGAMP can be transported across the cell membrane by SLC19A1, a reduced folate transporter that is found on myeloid cells, leading to direct activation of STING. Interestingly, methotrexate (MTX) is a potent inhibitor of SLC19A1 import of cGAMP in monocytes (RD Luteijn *et al.*, 2019). Here we explore the potential that altered SLC19A1 expression may contribute to increased IFN responses in SLE.

Methods: Peripheral blood samples from SLE patients (meeting ACR classification criteria for SLE) and healthy controls (HC) were collected via a protocol approved by the local institutional review board. Monocytes were isolated from peripheral blood using CD14+ immunomagnetic bead isolation (StemCell Technologies). For gene expression analysis, qPCR analysis was performed using ddCt method, and statistical analyses were performed using GraphPad Prism 5. Four interferon stimulated genes (ISG) RSAD2, IFI44, IFI44L, IFI27 were used to calculate IFN scores, which are associated with increased disease activity in SLE patients (X Feng *et al.*, 2006).

Results: A total of 28 HCs and 89 SLE patients were enrolled in an independent cohort. 95% of the patients were female, with a mean age of 44 (SD ± 13 years). In keeping with cGAS as an ISG, its expression was significantly higher in the peripheral blood of SLE patients compared to HC ($p < 0.0001$) (figure 1a) and correlated positively with IFN score measured in the same samples (figure 1b). Expression of SLC19A1 was also significantly higher ($p=0.0325$) in SLE patient blood compared to HC (figure 1c). In examining the level of expression on patient monocytes compared to those from HC, SLC19A1 was found to be increased on the surface of cells as determined by flow cytometry (data not shown). In assessing how methotrexate (MTX) use altered SLC19A1 at the mRNA level, no difference was seen between those taking MTX (32.9%) and those not. Our preliminary data also indicates that cGAMP and type I IFN can also regulate SLC19A1 expression in whole blood but as to whether there are differences between responses in HC and SLE patient cells is currently been assessed.

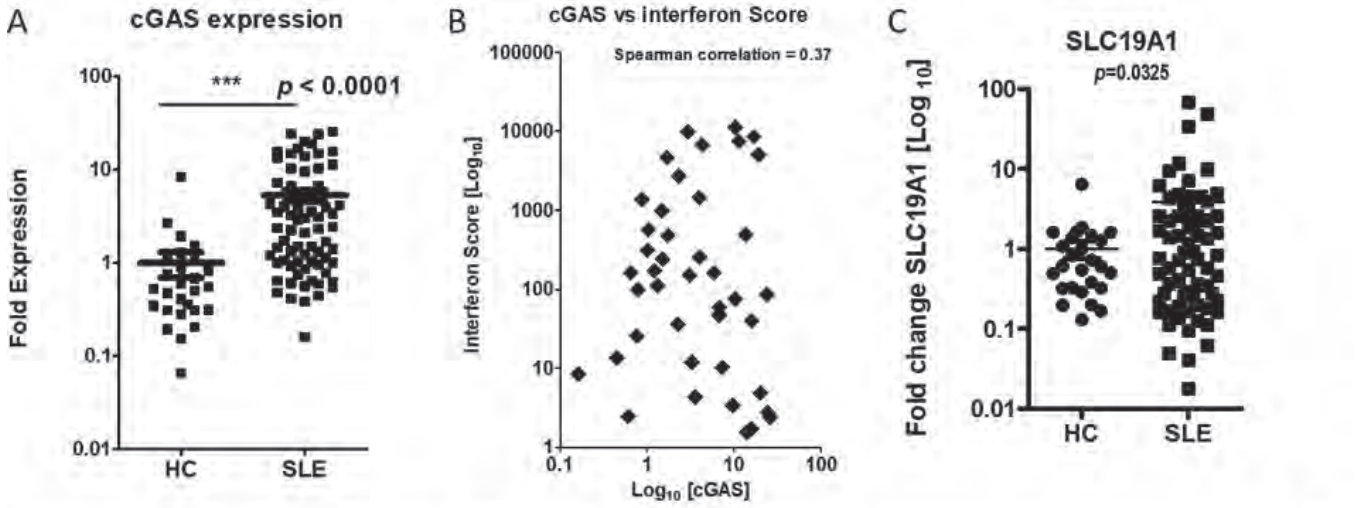

Figure 1: Whole blood from healthy controls (n=28) and SLE patients (n=89) was analyzed for expression of cGAS, ISGs (RSAD2, IFI44, IFI44L, IFI27) and SLC19A1 by qPCR. Between group differences were analyzed by unpaired *t*-test and Spearman's rank correlation used to analyze the correlation between cGAS and IFN score. All statistical analysis was carried out using GraphPad Prism

Conclusion: Increased cGAS expression in SLE patients was consistent with previous reports, in keeping with it being an ISG. Our observation that the cGAMP transporter SLC19A1 is increased is in keeping with the observed elevation of cGAMP levels detected previously in SLE patient serum (J An *et al.*, 2017). This suggests that altered SLC19A1 expression may contribute to enhanced IFNβ expression via direct uptake and activation of STING. Whether enhanced SLC19A1 expression on cells correlates with enhanced cGAMP uptake and STING activation is currently been assessed.

Genome-wide DNA Methylation Analysis in Lupus Keratinocytes Identifies Differential Methylation of Genes That Regulate Apoptosis

Grace Hile[1], Patrick Coit[1], Chang Zeng[1], Rachael Wasikowski[2], Alex Tsoi[2], Allison Billi[2], Johann Gudjonsson[3], Amr Sawalha[4] and J. Michelle Kahlenberg[5], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann ARbor, [3]University of Michigan, Ann ArborUniversity of Michigan, [4]University of Pittsburgh, Pittsburgh, [5]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous lupus erythematous (CLE) is a disfiguring manifestation of systemic LE (SLE), and the pathogenesis remains unclear. However, epidermal regulation of skin inflammation and cell death contribute, potentially in a female-biased manner. Differential DNA methylation is important in the organ-specific manifestations of SLE but has not been studied in the skin. Thus, we explored the genome-wide DNA methylation changes in keratinocytes (KC) to investigate the functional relevance in CLE.

Methods: Eight SLE skin biopsy samples were taken from non-sun-exposed, unaffected skin from participants of the Michigan Lupus Cohort as well as age (+/- 6 years), sex, and ethnicity-matched healthy control subjects. Freshly cultured KC (at passage 2) were used to isolate DNA using DNeasy Blood and Tissue Kit. DNA was bisulfite converted for DNA methylation studies using the EZ DNA Methylation Kit. Genome-wide DNA methylation analysis was performed using the Infinium HumanMethylation450 BeadChip Kit. Differentially methylated loci were mapped to genes or gene regions and subject to gene ontology and pathway analysis using the Database for Annotation, Visualization, and Integrated Discovery (DAVID).

Results: We identified 1443 differentially methylated sites with 924 hypomethylated genes and 519 hypermethylated genes in lupus KC compared to controls. Pathway analysis revealed Hippo signaling as the top canonical pathway associated with the DNA methylation profile of primary lupus KCs. TEA Domain Transcription Factor 1 (TEAD1), a key transcription factor in the Hippo pathway, was significantly hypomethylated in lupus compared to control ($\Delta\beta$ =-0.17, P= 4.36 X 10^{-9}). Further, methylation of LATS1/2, which contributes to inactivation of Hippo pathway effector proteins TAZ and YAP, was significantly increased ($\Delta\beta$= 0.11, P= 3.82 X 10^{-4}). YAP and TAZ were both hypermethylated ($\Delta\beta$= 0.11 (P= 1.53 X 10^{-3}) and 0.12 (P= 2.20 X 10^{-4}), respectively), thereby increasing TEAD1 activity.

Conclusion: SLE KCs display methylation changes in the Hippo pathway that may contribute to dysregulated apoptosis, a known feature that contributes to photosensitivity in CLE. Vestigial like family member 3 (VGLL3) has recently been identified as a putative transcription factor and master orchestrator of sex bias in autoimmune diseases, including SLE and CLE. Importantly, studies have shown VGLL3 operates through TEAD1 in other cell types and may be a key upstream regulator in the skin. Overall, these results suggest that differential methylation in KC may underlie dysregulated apoptosis and female bias of CLE.

Oxidative DNA Damage Accelerates Skin Inflammation in Pristane-induced Lupus Model

Gantsetseg Tumurkhuu[1], Shuang Chen[2], Erica Montano[1], Malcolm Lane[2], Michifumi Yamashita[2], Janet Markman[2], Luz Blanco[3], Mariana Kaplan[4], Kenichi Shimada[2], Timothy Crother[2], Mariko Ishimori[2], Daniel J Wallace[1], Caroline Jefferies[5] and Moshe Arditi[2], [1]Cedars-Sinai Medical Center, Los Angeles, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Centreville, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [5]Cedars-Sinai Medical Center, West Hollywood, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory autoimmune disease in which type I interferons (IFN) play a key role. The IFN response can be triggered when oxidized DNA engages the cytosolic DNA sensing platform cGAS-STING, but the repair mechanisms that modulate this process and govern disease progression are unclear. To gain insight into this biology, we interrogated the role of oxyguanine glycosylase 1 (OGG1), which repairs oxidized guanine 8-Oxo-2′-deoxyguanosine(8-OH-dG), in the pristane-induced mouse model of SLE.

Methods: C57/Bl6 (WT) and Ogg1 KO mice were injected i.p. with 0.5ml of pristane or PBS as control (WT-PBS). In order to observe the effects of Ogg1 deficiency in fully developed SLE, we analyzed the mice 10 months after induction. Histological features of skin and kidney were quantified by an image analysis system. Serum total IgG, IgG subtypes (IgG1 and IgG2a), and autoantibodies (anti-dsDNA and anti-RNP) were measured by ELISA. Gene expression analysis for IFN and ISG genes was performed by RT-PCR using SYBR green.

Immune cell types were analyzed separately for each mouse by standard FACS procedures. Peripheral blood mononuclear cells (PBMCs) were separated from whole blood by density-gradient centrifugation with Ficoll-Paque Plus (GE Healthcare). $CD14^+$ monocytes were purified from fresh PBMCs by positive selection using magnetic $CD14^+$ beads (Miltenyi Biotec) according to the manufacturer's protocol

Results: *Ogg1*$^{-/-}$ mice developed an exacerbated disease profile, characterized by aggravated skin pathology, increased auto-antibodies, higher total IgG, and higher splenic cell number. Neutrophils from pristane-treated *Ogg1*$^{-/-}$ mice exhibited earlier NETosis compared to WT. BMDMs from *Ogg1*$^{-/-}$ mice produced increased basal and cGAMP-driven IFN-β expression, which was diminished by treatment with the STING inhibitor H151, and skin lesions

from pristine-treated *Ogg1*$^{-/-}$ mice had significantly higher expression of type I IFN genes than lesions in WT mice. Finally, expression of *OGG1* was significantly lower in lesioned skin compared with non-lesioned skin in Discoid Lupus patients.

Conclusion: In conclusion, our study clearly supports a crucial role for OGG1 in protecting against IFN production and SLE skin disease.

Abstract Number: 0285

CXCL13 Neutralization Reduces Neuropsychiatric Manifestations in MRL/*lpr* Mice

Michelle Huang[1], Ariel Stock[1] and Chaim Putterman[1], [1]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Targeted treatments for neuropsychiatric systemic lupus erythematosus (NPSLE) remain challenging to develop due to the unclear pathogenesis of the disease. Our laboratory has previously identified tertiary lymphoid structure (TLS) (a.k.a. ectopic germinal center) formation in the brains of MRL/*lpr* mice, a classic SLE mouse model with neuropsychiatric manifestations. TLS form at sites of chronic inflammation and functionally perform like other lymphoid follicles to create clonotypic immune responses in a localized fashion. This specialized immune response may target self-antigens in autoimmune conditions and perpetuate pathogenesis of disease. CXCL13 is a key chemokine in lymphoid follicle formation and maintenance; in this study, we inhibited CXCL13 in MRL/*lpr* strain and examined the effect of this intervention on TLS formation and the development of neurobehavioral deficits.

Methods: MRL/*lpr* mice share several important similarities with human lupus, including ANA production, widespread immune complex deposition, nephritis, and skin disease. Importantly for this study, this strain also exhibits early onset of cognitive and affective disease similar to that seen in NPSLE patients. Female MRL/*lpr* mice were injected with a CXCL13-neutralizing monoclonal antibody (Vaccinex), an IgG1 isotype control antibody, or PBS intraperitoneally (IP) three times a week for 12 weeks starting at 6-8 weeks of age (n=13-19 per group), or continuously intracerebroventricularly (ICV) with an osmotic pump, over a two-week period starting at 15 weeks of age (n=4-5 per group). Cognitive dysfunction and affective deficits were tested for at the end of treatment using object placement (OP) and object recognition (OR) tasks to evaluate spatial and recognition memory, respectively, and using Porsolt swim test to evaluate depression-like behavior. Anti-DNA antibody titers and serum blood urea nitrogen (BUN) levels were assessed to measure systemic disease progression at the time of the behavioral tests.

Results: MRL/*lpr* mice treated with anti-CXCL13 antibody IP showed significant improvement in spatial memory, recognition memory, and despair-like behavior compared to the two control groups (Figure 1). Mice that received the treatment via ICV pump showed similar results (vs PBS: OP: p=0.059, OR: p=0.090, Porsolt swim: p=0.018; vs isotype control: OP: p=0.029, OR: p=0.19, Porsolt swim: p=0.80). However, antibody titers (indicating systemic disease),

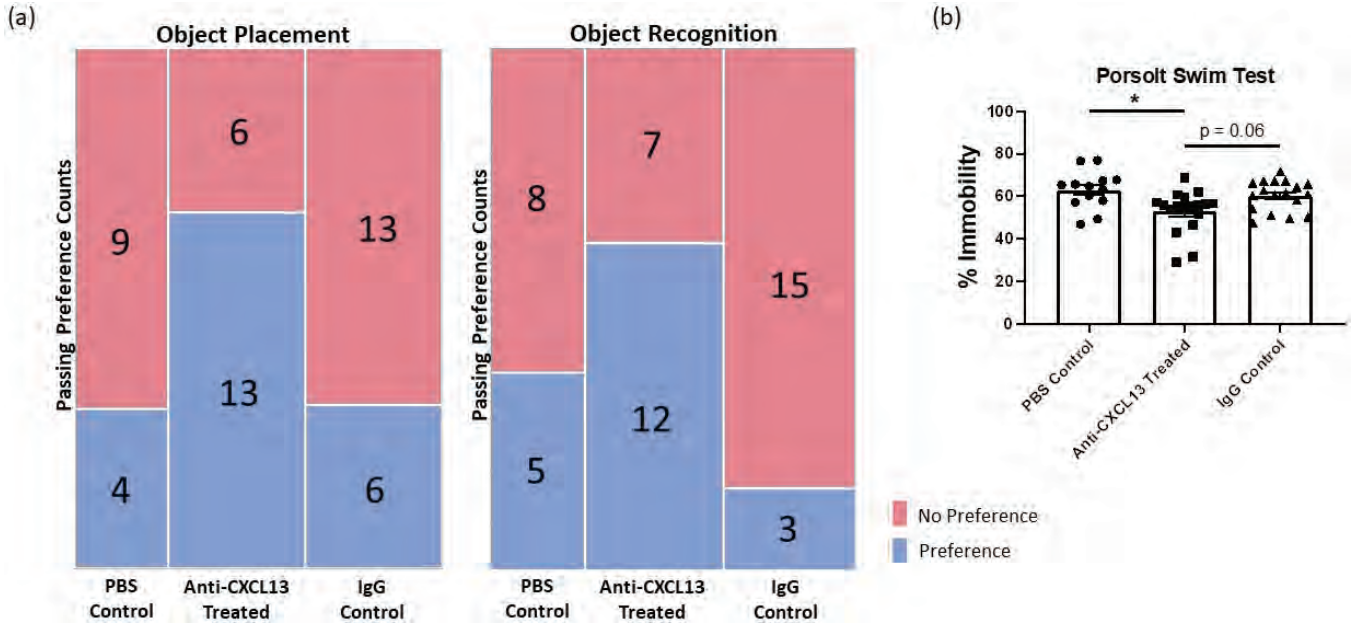

Figure 1. Behavioral Test Results (for IP cohorts). (a) Object placement (OP, left) and object recognition (OR, right) tasks are measured by animals showing over a 55% preference to a novel object. Counts of mice separated into either showing a preference (blue) or no preference (red). Both tasks showed that the treatment group performed significantly better than both the PBS control group (OP: p=0.034; OR: p=0.17) and the IgG control group (OP: p=0.022; OR: 0.0031). (b) Depression-like behavior is measured by percent time spent immobile over the total time in the Porsolt swim test. The treatment group demonstrated significantly less despair-like behavior than both groups (vs PBS: p=0.012; vs IgG: p=0.063; error bars: SEM).

and BUN levels (reflecting renal disease), showed no difference among groups, with any of the two antibody delivery methods. Further analysis of brain histology and cellular infiltration to evaluate for TLS and determine whether germinal center formation was disrupted are ongoing.

Conclusion: Our results suggest that inhibition of TLS formation affects the behavioral phenotype but not systemic or renal disease in the lupus prone MRL/*lpr* strain. Therefore, CXCL13 overexpression contributes to the pathogenesis of murine NPSLE and suggests that neutralizing this chemokine, if it can be done locally and safely, may be a novel therapeutic approach to the treatment of this manifestation.

An SLE-linked ITGAM Gene Variant Changes Mac-1 Structure, Signaling, and Surface Expression and Enhances IFNg Production and Antigen Presentation by B Cells

Joseph Blake[1], Alexander Szalai[2], Jeffrey Edberg[3] and James Mobley[3], [1]UAB, Birmingham, [2]University of Alabama at Birmingham, birmingham, AL, [3]UAB, Birmingham, AL

SESSION INFORMATION

Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic and debilitating disease; in the USA with an estimated incidence of 3-10 per 100,000 people and currently affecting an estimated 300,000 people. The exact pathogenesis of SLE remains unknown, but there is a growing body of evidence that various genetic, hormonal, and environmental factors contribute to its occurrence and severity. Each is thought to modulate the activation and regulation of innate and adaptive immunity in ways that drive autoimmunity, the underlying cause of SLE. The hallmark of autoimmunity in SLE is B cell hyperactivity leading to the generation of autoantibodies, which together drives the deposition of deleterious immune complexes. SLE has strong familial clustering, high heritability, and high concordance rates between monozygotic versus dizygotic twins, suggesting it's a polygenic disease. Among the many different gene variants reportedly associated with SLE risk or severity are single nucleotide polymorphisms (SNPs) in the integrin alpha-M (*ITGAM*) gene, which are present in more than 1/3 of SLE patients. *ITGAM* encodes the protein CD11b, which pairs with CD18 and forms the Mac-1 receptor. Among the *ITGAM* SNPs associated to SLE is SNP rs1143678, encoding a P1146S amino acid substitution in the cytoplasmic tail of CD11b. Mac-1 is widely expressed by myeloid cells, and it is reported that SNP rs1143678 alters myeloid cell functions in ways that could propel SLE. Mac-1 is also expressed on lymphocytes, but comparatively little is known about its role in B cells or whether SNP rs1143678 has any impact on B cell biology. To fill this gap in knowledge we are investigating the impact of *ITGAM* SNP rs1143678 on Epstein-Barr Virus (EBV) transformed B cells from healthy human donors.

Methods: N/A

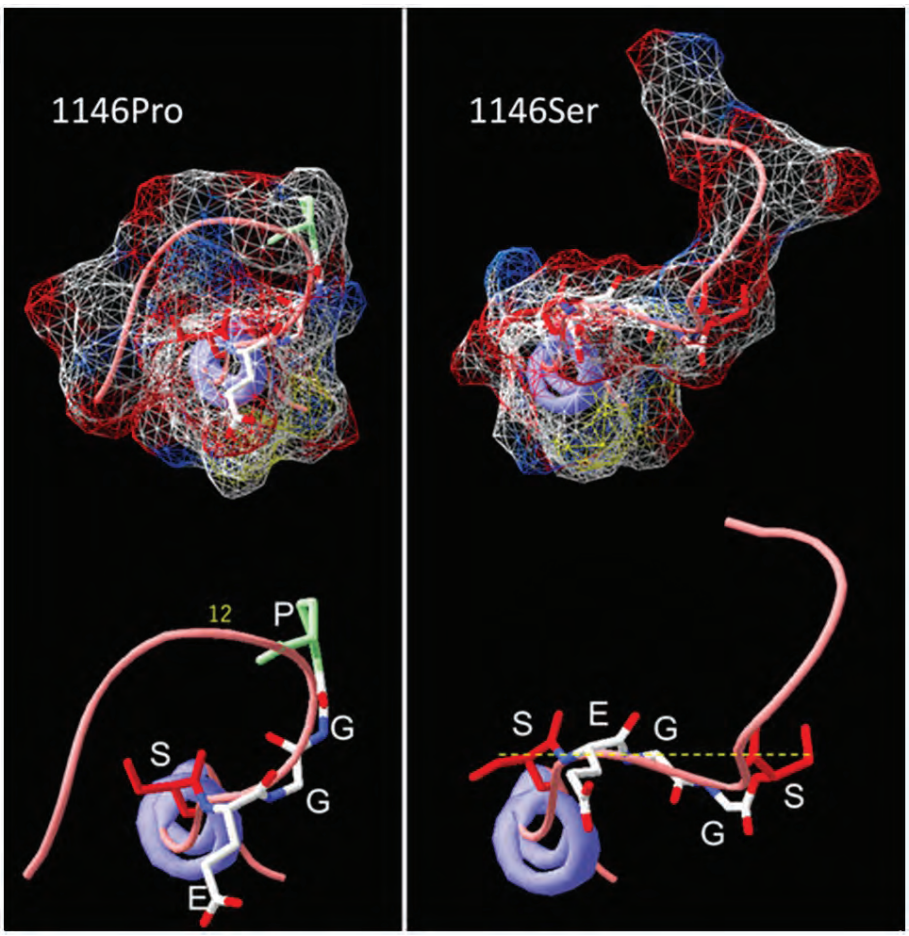

Figure 1. Space filling (top) and ribbon models (bottom) of the cytoplasmic tail of CD11b, viewed from inside the cell looking upwards at the receptor. For individuals carrying the SNP rs1143678 (right) the modelling predicts a 12-angstrom-wide space between the invariant 1142SER and the SNP variant 1146Ser residues (dashed yellow line).

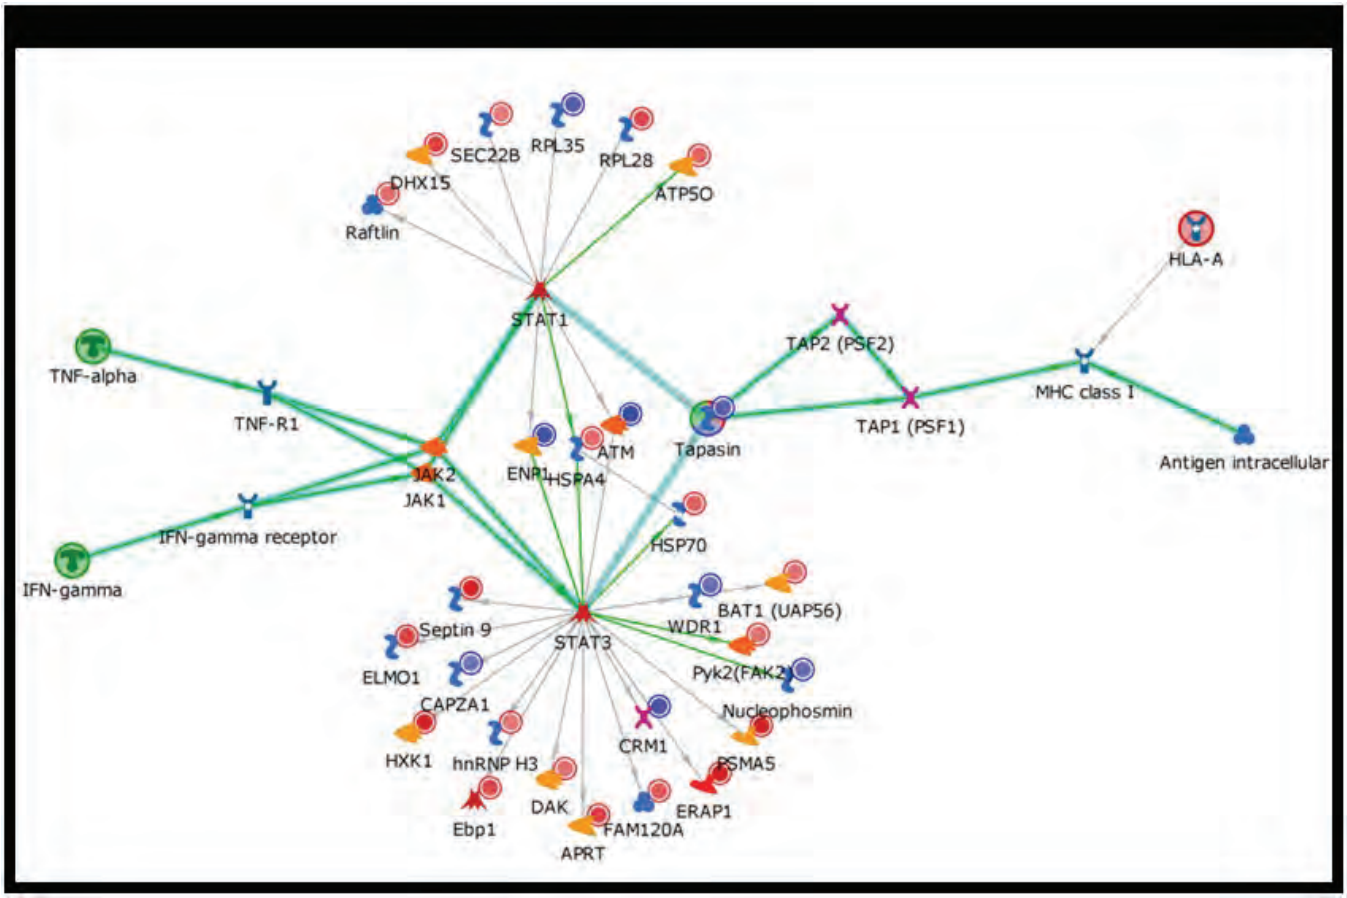

Figure 2. B cells from healthy donors homozygous for the ITGAM SNP rs1143678 or the major allele were transformed with Epstein Bar Virus. The cells were lysed and whole proteome analysis was done by LC MS/MS. Protein expression differences were determined and over-represented pathways in the SNP samples were mapped by Clarivate Analytics pathway analysis software. B-cells expressing the ITGAM SNP rs1143678 had high levels of IFNg induced MHC-1 presentation.

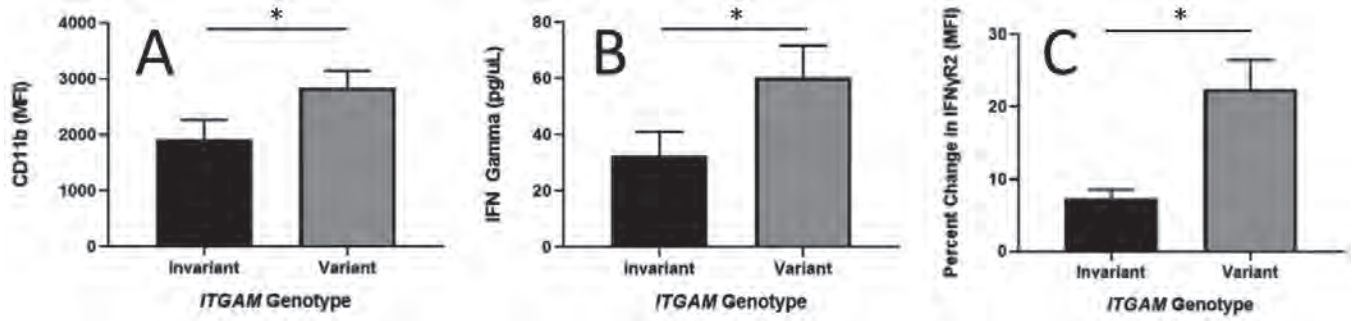

Figure 3. A) B-cells expressing the SLE associated SNP have a higher basal expression of CD11b. B) B-cells expressing the SLE associated SNP spontaneously secrete higher amounts of IFNg. C) Upon stimulation with exogenous IFNg, B-cells expressing the SLE associated SNP increase their surface expression of IFNgR2 to a higher degree than contol. A * indicates $p < 0.05$ by T test.

Results: We report here three of our main findings. First, juxtaposition of the cytoplasmic tails of CD11b and CD18 - and their activation induced separation - are thought to be required for Mac-1-mediated cell signaling. Our *in silico* structural modelling (Fig. 1) predicts that the SLE-associated P1146S substitution significantly changes the conformation of CD11b's cytoplasmic tail. This shape-shift should allow CD11b to accommodate additional or new cytoskeletal/cytoplasmic binding partners, and thereby could influence Mac-1 signaling. Second, phosphorylation of

1142Ser (an invariant residue in CD11b) is thought to be required for Mac-1 signaling, but using *in vitro* kinase assays and Western blots we provide the first direct evidence that the SLE-associated 1146Ser residue is also phosphorylated (data not shown). Third, by mass-spectrometry combined with proteomics and network analyses, we obtained evidence that both IFNγ and antigen presentation pathways are enriched in B cells from donors expressing the *ITGAM* SNP variant (Fig 2). Indeed, compared to B cells from *ITGAM* invariant donors, B-cells from donors carrying the *ITGAM* SNP showed increased expression of CD11b, increased spontaneous secretion of IFNγ, and increased expression of the IFNγR2 receptor following stimulation (Fig 3). This trio of new findings together suggests that the *ITGAM* SNP rs1143678 significantly alters the biology of B cells, which might explain the strong association rs1143678 to SLE.v

Conclusion: N/A

RNA Externalized by Neutrophil Extracellular Traps Promotes Inflammatory Pathways in Endothelial Cells

Xinghao Wang[1], Philip Carlucci[2], Jorge Romo-Tena[1], Jose Torres-Ruiz[1], Hong-Wei Sun[1], Markus Hafner[1], Mariana Kaplan[3] and **Luz Blanco**[4], [1]NIAMS, National Institute of Health, Bethesda, [2]New York University School of Medicine, New York, NY, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Centreville

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophil extracellular traps (NETs) are extracellular lattices composed of nucleic material bound to neutrophil granule proteins. NETs may play pathogenic roles in development and severity of autoimmune diseases such as systemic lupus erythematosus (SLE), at least in part, through induction of type I interferon (IFN) responses via externalization of oxidized immunostimulatory DNA. A distinct subset of SLE proinflammatory neutrophils (low density granulocytes; LDGs) displays enhanced ability to form proinflammatory NETs that damage the vasculature. We assessed whether NET-bound RNA can contribute to inflammatory responses in endothelial cells and the pathways that mediate this effect.

Methods: Expression of newly-synthesized RNA was quantified if healthy control and lupus NETs. The ability of endothelial cells to take up NET-bound RNA and downstream induction of type I IFN responses was quantified. RNAs present in NETs were sequenced and specific small RNAs were tested for induction of endothelial type I IFN pathways.

Results: NETs extruded newly-synthesized RNA that was internalized by endothelial cells and this was enhanced when NET nucleic acids were oxidized, particularly in lupus LDG NETs. Internalization of NET-bound RNA by endothelial cells was dependent on endosomal TLRs and the actin cytoskeleton and induced type I IFN stimulated genes (ISGs). This ISG induction was dependent on NET-associated miR-let7b, a small RNA expressed at higher levels in LDG NETs, which acted as a TLR7 agonist.

Conclusion: These results highlight underappreciated roles for small RNAs externalized in NETs in the induction of proinflammatory responses in vascular cells, with implications to lupus vasculopathy.

Targeted Sequencing Revealed Novel Candidate Genetic Contributions to Lupus Nephritis in a Cohort of Swedish Patients with Systemic Lupus Erythematosus

Sule Yavuz[1], Pascal Pucholt[2], Dag Leonard[2], Juliana Imgenberg-Kreuz[2], Matteo Bianchi[2], Johanna Sandling[2], Iva Gunnarsson[3], Swedish Sle Network[2] and Lars Ronnblom[2], [1]Uppsala University Rheumatology, Doral, FL, [2]Uppsala University, Uppsala, Sweden, [3]Karolinska Institute, Stockholm, Sweden

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a common debilitating manifestation of Systemic Lupus Erythematosus (SLE). Despite improved understanding of underlying mechanisms driving to LN and early treatment strategies, yet 10% of LN patients progress to end-stage renal disease (ESRD) in 5 years after the onset of LN[1]

Methods: To explore novel genetic associations, we performed a case-case analysis in a quality-controlled dataset of 958 Swedish patients with SLE (337 with LN) and 1030 healthy individuals. We stratified patients based on their histopathologic phenotype as proliferative, pure membranous LN, and ESDR. Mixed phenotypes were excluded. Targeted capture and enrichment was performed using a NimbleGen array, including 1853 genes selected based on their known involvement in systemic inflammatory autoimmune diseases. Variant and gene-level aggregate association testing were performed separately using Plink and SKAT-O respectively[2].

Results: We identified seven candidate loci ($P \leq 1\times 10^{-5}$) associated with proliferative nephritis, five with membranous nephritis, and seven with ESRD. The strongest associations with proliferative nephritis, membranous nephritis, and ESRD corresponded to *chr14q23.3 (*$p=5.58\text{x}10^{-6}$), LTF ($p =1.64\text{x}10^{-6}$), and MERTK($p=9.52\text{x}10^{-6}$), respectively. The gene-based aggregate association, which potentiates the power to detect gene regions with aggregation of functional common and rare variants revealed two additional potentially novel genes, CTF1 ($p= 2.97\text{x}10^{-5}$, FDR=0.03) and FBXL19 ($3.14\text{x}10^{-5}$, FDR=0.03), that were associated with membranous nephritis.

Conclusion: We revealed novel genetic risk loci in association with ESRD and candidate genes in association with membranous nephritis in Swedish SLE patients.

Endogenous Interferon-β and Low IL-4R on Transitional B Cells Promotes Lupus Nephritis

Fatima Alduraibi[1], Huma Fatima[1], W. Winn Chatham[1], Hui-Chen Hsu[1] and John Mountz[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University Alabama at Birmingham and Birmingham VA Medical Center, Birmingham, AL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously showed that B-cell endogenous interferon-beta (IFNβ) at the transitional (Tr) stage correlates with development of anti-Smith (anti-Sm) and renal disease as well as African American (AA) race. We recently identified that down regulation of IL-4 receptor (IL-4R$^-$), a resting B-cell marker, is another phenotype of pathogenic B cells in SLE. This study determined if the Tr B-cell activation phenotype characterized as "IFNβ$^+$IL-4R$^-$" correlated with anti-Sm and can be a useful prognostic marker for autoantibody, renal disease (RD), and histopathologic features of lupus nephritis (LN).

Methods: The expression of IL-4R and interferon beta (IFNβ) in subsets of B cells was analyzed using flow cytometry analysis in 47 patients diagnosed with SLE. Plasma was assayed for IgG anti-Sm/RNP and anti-DNA using a standard ELISA method. Charts of 32 patients among these were reviewed and included in this analysis (30 were female and 21 patients were AA). Serologic manifestations of SLE included anti-DNA, anti-Sm, C3, and C4. Clinical laboratory manifestations of RD included creatinine and urine protein/creatinine ratio. RD classification was diagnosed based on the revised ISN/RPS (2004) criteria (16 patients) and included renal histopathology microscopy findings on light, electron microscopy and immunofluorescence (IF) for deposit of IgM, IgG, IgA, light chain, C1q and C3 (9 patients).

Results: Higher expression of IFNβ and lower expression of IL-4R at the Tr stage correlated with their expansion in naïve B cells and plasma levels of anti-Sm/RNP. Among the 32 patients analyzed 17 (53%) patients were diagnosed with LN. At the time of B cell phenotype analysis, 8 (25%) of patients were positive with anti-DNA, and 20 (62%) of patients were positive with anti-Sm. Multivariate regression analysis indicated a significant positive correlation between the IFNβ$^+$IL-4R$^-$ phenotype with anti-Sm (p=0.0035), anti-DNA (p=0.0234), low C3 (p=0.0360) and high protein creatinine ratio (p=0.0246). RD classification revealed Class II in 5 (29%) patients, Class III or IV in 5 (29%) patients, Class III or IV with Class V in 2 (12) patients and Class V only in 4 (23 %) patients. Direct IF examination of LN biopsies revealed that patients with higher percentage of the Tr B cell IFNβ$^+$IL-4R$^-$ phenotype also exhibited increased deposition of IgM, IgA, and C1q, but not IgG and C3 especially in glomerular mesangium compared to tubular basement membranes and arteries.

Conclusion: These results suggest a sequence for immunopathogenesis in SLE which is initiated as IFNβ$^+$IL-4R$^-$ activated B cells at the earliest Tr stage of development. These B cells are predisposed to undergo tolerance loss, especially to the Sm autoantigen. This is highly correlated with development of renal disease and low C3 consistent with previous studies. Association of the circulating IFNβ$^+$IL-4R$^-$B cell phenotype with immunofluorescence staining for IgM, IgA, C1q, but not IgG or C3 suggest distinct mechanisms of inflammation in the kidney compared to system-

Role of Protein Tyrosine Phosphatase 1B (PTP1B) in Endothelial-to-Mesenchymal Transition (EndoMT) Promoted by Inflammation: Implications for SLE

Jorge Romo-Tena[1], José Esparza-López[2], Carmelo Carmona-Rivera[3], Luz Blanco[4], Mariana Kaplan[3] and María de Jesús Ibarra-Sánchez[2], [1]NIAMS, National Institute of Health, Bethesda, [2]INNSZ / UNAM-RAI, Mexico City, Mexico, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Centreville

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The endothelial-to-mesenchymal transition (EndoMT) transdifferentiation process can be promoted by several proinflammatory mediators in many pathological conditions. Recently, it was suggested a crucial role of EndoMT in the pathogenesis of vasculopathy in systemic lupus erythematosus (SLE). However, it remains unclear which proinflammatory mediators and signaling pathways promote EndoMT. Phosphatase Tyrosine Protein

1B (PTP1B) regulates signaling pathways of proinflammatory cytokines that are known to be involved in EndoMT. Previous works have shown that type I Interferons (IFNs) are key players in the progression of vascular damage and atherogenesis in SLE, but the role of proinflammatory cytokines such as TNF-α in EndoMT remains to be investigated.

Objective: To elucidate the capacity of TNF-α as EndoMT inducer and the putative role of PTP1B in this process.

Methods: Human aortic endothelial cells (HAEC) and human glomerular microvascular endothelial cells (HGMVEC) were used as model for *in vitro* induction of EndoMT. These endothelial cells (ECs) lines were incubated with human recombinant TNF-α (25 ng/ml) for 2 and 4 days. Expression of specific endothelial markers (eNOS, PECAM-1, VE-cadherin) and mesenchymal (SNAIL1, N-cadherin, α-SMA) markers were analyzed by Western blot (WB). Canonical activation of TNF-α-induced NF-κB pathway in EndoMT was assessed by phosphorylation of p65-Ser536, degradation of IkBa and nuclear translocation of p65 by WB and immunofluorescence (IF), respectively. PTP1B expression changes during EndoMT were evaluated by WB. CRISPR-Cas9 gene editing assay will be performed to generate *PTPN1* knockdown ECs *in vitro* and corroborate its role in EndoMT.

Results: TNF-α induced EndoMT in both HAEC and HGMVEC by downregulation of endothelial markers (eNOS, PECAM-1, VE-cadherin) and upregulation of mesenchymal markers (SNAIL1, N-cadherin, α-SMA). TNF-α induced phosphorylation of NF-κB (p65-Ser 536) and degradation of IkB-α. Nuclear translocation of p65 was observed as early as 5 min after treatment and remained in the nucleus up to 1 h. TNF-α-induced EndoMT provoked an increase in PTP1B levels during the 4 days of EndoMT process. Additionally, PTP1B inhibition by CRISPR-Cas9 system is going to be investigated.

Conclusion: We established a model of TNF-α-induced EndoMT in the HAEC and HGMVEC endothelial cell lines. We observed decreased of endothelial markers and upregulation of mesenchymal markers. Concomitant with these changes of EndoMT markers, we found that PTP1B increases its expression. Furthermore, we found that NF-κB canonical signaling pathway is activated during this process. These findings unveil a putative important pathway in SLE vasculopathy and suggest novel avenues for intervention.

SLAMF7 and CD38 on NK Cells Represent Potential New Therapeutic Targets for Systemic Lupus Erythematosus

Morgane Humbel[1], Florence Bellanger[2], Craig Fenwick[2], Alice Horisberger[2], Camillo Ribi[2] and Denis Comte[2], [1]CHUV, Lausanne, Vaud, Switzerland, [2]CHUV, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by the production of autoantibodies. For this reason, anti-B cell therapy seems to be a promising approach. However, B cell depletion with Rituximab, an anti-CD20 monoclonal antibody (mAb), failed to meet the primary endpoint in large

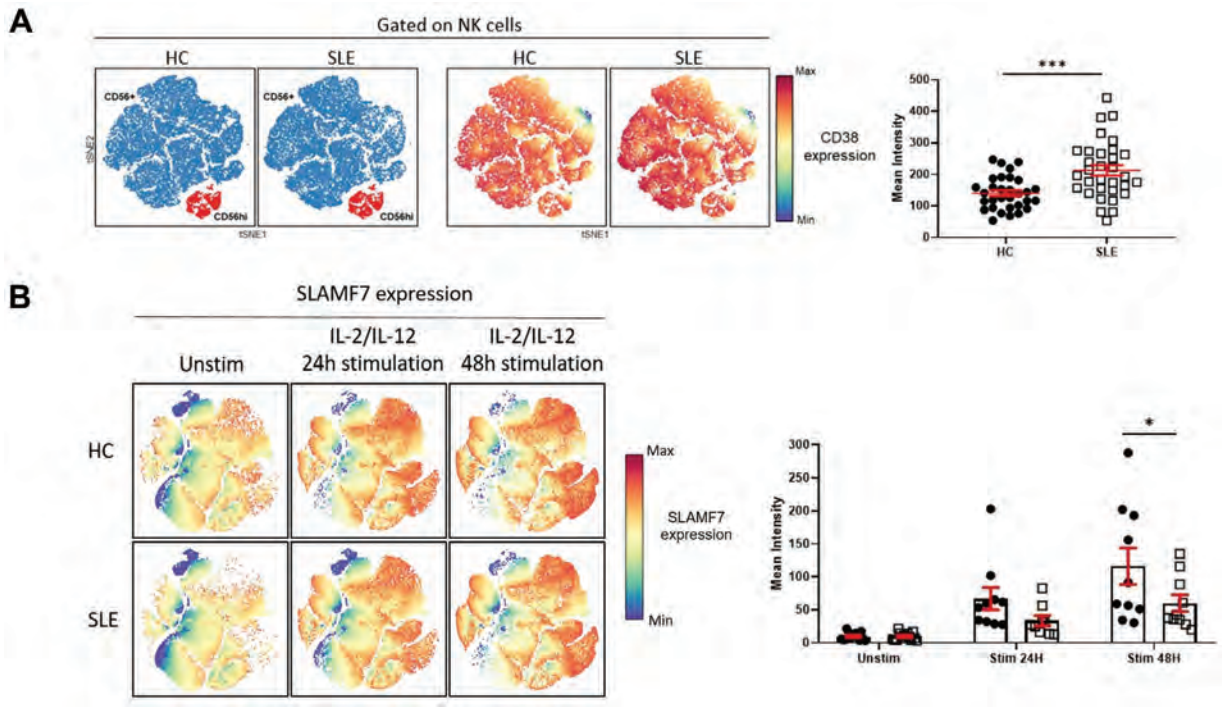

Figure 1. CD38 and SLAMF7 expression is increased on NK cells from SLE patients A. tSNE representation of NK cells distribution and CD38 expression (blue: CD56+; red: CD56hi) in healthy controls (HC) and SLE patients (left panel). Mean intensity of CD38 on total NK cells is significantly increased in SLE patients (right panel, shown as mean±SEM, Welch's t test, $p<0.001$). B. tSNE representation of SLAMF7 expression in NK cells in HC and SLE patients following 24H and 48H cytokine stimulation (left panel). SLE NK cells lack the ability of increasing the expression of SLAMF7 following cytokine stimulation (right panel, shown as mean±SEM, Two way ANOVA, Sidak's multiple comparison, $p<0.05$).

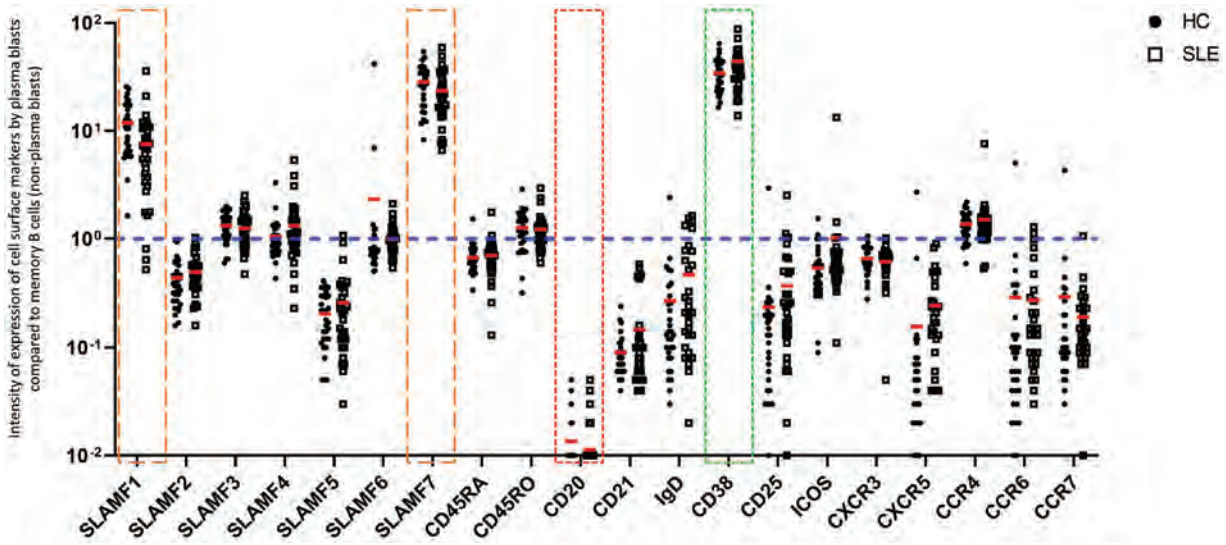

Figure 2. Expression of cell surface markers by plasma blasts from the peripheral blood of SLE patients The intensity of expression of cell surface markers is represented as an expression ratio of circulating plasma blasts (CD19+ CD27+ CD38+ CD20-) on memory B cells (non-plasma blasts) (CD19+ CD27+ CD38-). Accordingly, CD38 represents a positive control (in green) and CD20 represents a negative control (in red). These data show that SLAMF1 and SLAMF7 (in orange) are strongly expressed by plasma blasts compared to other populations of memory B cells. No difference was observed in the expression of these receptors between HC and SLE patients.

clinical trials, possibly because antibody-producing plasma blasts/cells express low levels of CD20. Therefore, strategies that specifically target the depletion of plasma blasts/cells may be effective in treating SLE. Moreover, Natural killer (NK) cells are dysfunctional in patients with SLE, and restoration of NK cell immunity has been shown to promote

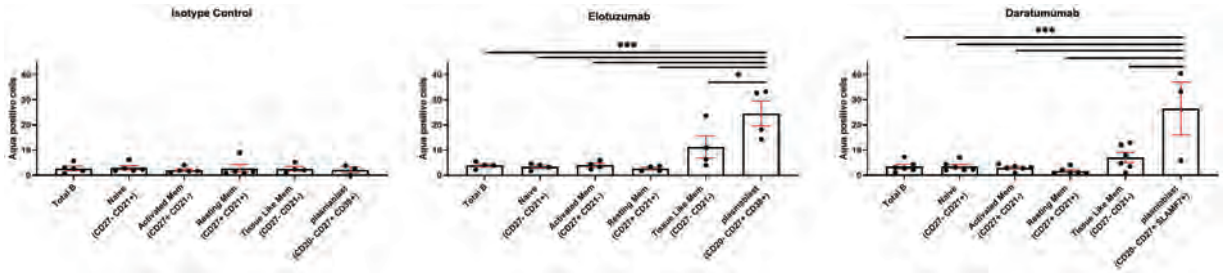

Figure 3. NK stimulation with Elotuzumab and Daratumumab promotes plasmablast killing. The engagement of NK cells with Elotuzumab and Daratumumab predominantly promotes the killing of plasmablasts compared to other B cell subpopulations (One way ANOVA Sidak's multiple comparison, *p<0.05, **p<0.005,***p<0.0001).

the destruction of plasma cells in other diseases such as multiple myeloma. Herein, we hypothesize that alterations in NK cells contribute to the pathophysiology of SLE and the restoration of NK cell immunity may promote the killing of autoantibody-producing plasma blasts/cells.

Methods: The extracellular phenotype of cryopreserved peripheral blood mononuclear cells (PBMC) from 31 SLE patients and 31 gender-, age- and ethnicity-matched healthy controls (HC) was examined by mass cytometry (CyTOF). Functional assays (cytolytic enzyme expression, cytokine production, degranulation, depletion assay) and signaling (calcium influx, phosphoprotein measurements) were examined by flow cytometry. NK cells were pre-treated with anti-SLAMF7 (Elotuzumab) or anti-CD38 (Daratumumab) mAb and were then co-cultured with B cells, to evaluate the killing of plasma blasts by activated NK cells.

Results: Our data shows that SLE NK cells are reduced in number and in function (IFNγ and TNFα production after activation with cytokines). SLE NK cells exhibit phenotypic alterations with respect to HC: (1) SLE NK cells express increased levels of CD38 and (2) fail to upregulate SLAMF7 upon activation with exogenous cytokines (**Figure 1**). In addition, circulating SLE plasma blasts are increased in the peripheral blood compared to HC. Moreover, plasma blasts express very high levels of CD38 and SLAMF7 (**Figure 2**). The engagement of SLAMF7 and CD38 with mAb partially restores the function of SLE NK cells (production of IFNγ and TNFα, degranulation). Furthermore, commercially available mAb directed against SLAMF7 (Elotuzumab) and CD38 (Daratumumab) promote the immunogenicity of NK cells to specifically kill plasma blasts (**Figure 3**).

Conclusion: We showed that SLAMF7 and CD38 are aberrantly expressed or regulated on the surface of NK cells of SLE patients. The engagement of SLAMF7 or CD38 with mAb restores the function of SLE NK cells and promotes the killing of plasma blasts by NK cells. Our data indicates that targeting these receptors may represent future therapeutic options in SLE to eliminate autoantibody-producing cells.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

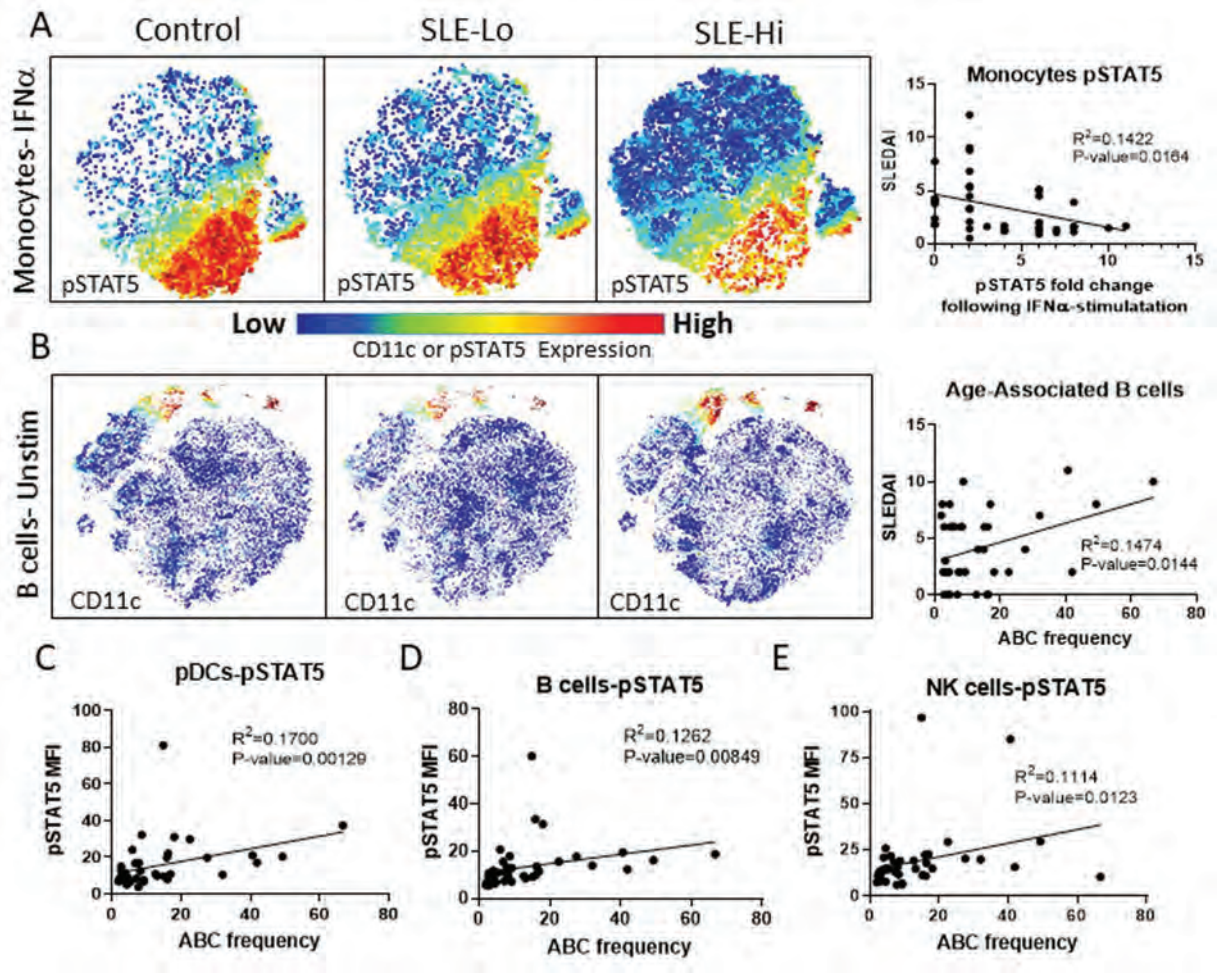

Figure 1. pSTAT5-IFNa signaling pathways are associated with age-associated B cells (ABCs). Whole blood of 58 subjects, either controls or SLE patients with variable disease activity, were used for phenotype analysis by mass cytometry. T-distributed stochastic neighbor embedding (tSNE) was used to visualize and cluster cells that were most similar using 28 surface markers. B cells or monocytes were gating and a second tSNE visualization was rendered to cluster and differentiate B cells or monocytes (A, B). pSTAT5 signaling was strongly reduced in monocytes following IFNa stimulation suggesting exhaustion of this pathway from persistent activation, and this was positively correlated with SLEDAI (A). CD11c+ ABC frequencies were higher in SLE patients, and correlated with lupus disease activity (B). Basal levels of pSTAT5 in pDCs (C), B cells (D), and NK cells (E) were correlated with ABC frequencies.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by periods of elevated and suppressed clinical symptoms. Specific cell subsets, such as CD11c+ age-associated B cells (ABCs) have been associated with SLE pathogenesis. While TLR7 and TLR9 are thought to be prerequisites for ABC differentiation, the signaling pathways involved in driving SLE disease activity and ABC generation are still unclear.

Methods: Peripheral whole blood of healthy controls (n=18) and SLE patients with variable disease activity (n=40) were stimulated for 15 minutes with either interferon-α (IFNα), PMA and ionomycin, or Toll-like receptor (TLR) ligands for TLR4, TLR7/8 or TLR9 for phospho-protein analysis. Phenotype and phospho-protein markers were assessed by mass cytometry and cell heterogeneity was analyzed using t-SNE and manual gating. Plasma cytokines were assessed by 37-plex xMAP assays and ELISAs. SELENA-SLEDAI scores were used to correlate phenotype and functional differences with disease activity. All SLE patients met ACR classification criteria.

Results: Basal levels of pSTAT5 in CD4+ (p=0.0094) and CD8+ T cells (p=0.0289), pSTAT1 in B cells (p=0.0246), and cCASP3 in NK cells (p=0.0155) were elevated in SLE patients compared to controls. Following whole blood stimulation, a reduced fold change in pSTAT5 expression following IFNα whole blood stimulation was the primary signaling marker altered in SLE patients with high disease activity (SLEDAI≥4) compared to low disease activity (SLEDAI< 4) (p< 0.05). Most significantly, monocyte pSTAT5 IFNα-induced fold change in expression was negatively correlated with disease activity scores in SLE patients (p=0.0164) (Figure 1A). CD11c+ age-associated B cells had the strongest positive correlation with SLEDAI out of all 45 cell phenotypes assessed (p=0.0144) (Figure 1B), followed closely by HLA-DR+ CD4+ T cells (p=0.0186). A reduced fold change of pSTAT5 IFNα-induced expression in pDCs (p=0.0058), B cells (p=0.0116), and monocytes (p=0.0214) was negatively correlated with ABCs frequencies, while basal levels of pSTAT5 in pDCs, B cells, and NK cells were positively correlated with ABCs (Figure 1C, D, and E). Basal pSTAT1 levels and pSTAT1 IFNα-induced fold changes were not correlated with ABCs. Basal pSTAT5 expression in whole blood was associated with higher plasma levels of BLyS (p=0.02 $x10^8$), TNFα (p=0.02$x10^7$), IL-8 (p=0.01$x10^3$), IL-10 (p=0.00010), IL-6 (p=0.00011), SCF (p=0.0006), IL-22 (p=0.0007), and IL-31 (p=0.0018). ABCs frequencies were also strongly correlated with TNF-β (p=0.0019) plasma levels in SLE.

Conclusion: ABCs are highly correlated with disease activity and exhausted pSTAT5 IFNα-induced signaling in pDCs and other antigen-presenting cells suggesting an important role for this pathway in lupus pathogenesis and ABC differentiation.

Contraction of the Stool Taxa *Clostridia* Is Associated with the Development of Clinical Disease Among Anti-Ro+ Mothers of Children with Neonatal Lupus

Robert Clancy[1], Miranda Marion[2], Peter Izmirly[3], Mala Masson[4], Hannah Ainsworth[2], Timothy Howard[5], Jill Buyon[6] and Carl Langefeld[7], [1]NYU School of Medicine, New York, [2]Wake Forest School of Medicine, Winston-Salem, [3]Department of Medicine, New York University School of Medicine, New York, NY, [4]New York University School of Medicine, New York, [5]Wake Forest School of Medicine, Winston-Salem, NC, [6]Department of Medicine, NYU School of Medicine, New York, NY, [7]Wake Forest School of Medicine, Winston Salem, NC

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Ro autoantibody production often precedes the development of systemic lupus erythematosus (SLE) or Sjögren's syndrome (SS) by years. Anti-Ro+ mothers of children with manifestations of neonatal lupus such as congenital heart block are a unique cohort at risk for pathologic autoimmunity; many are asymptomatic or have an undifferentiated autoimmune syndrome with vague symptoms (Asym/UAS) and become aware of autoantibodies solely based on identification of disease in the fetus or infant. Over time, a third may progress to established diseases such as SLE or SS (SS/SLE). This study was initiated to investigate the hypothesis that stool microbiome compositional variation and taxa-specific interactions with class II HLA alleles may correlate with transition to SS/SLE.

Methods: The stool microbiome of 125 anti-Ro+ women (Asym/UAS, N=43; SS/SLE, N=82) and 23 healthy controls (HC) were 16S ribosomal RNA sequenced and assigned to taxa (SILVA). At each taxonomic level, the ranks of the centered log ratio transformed relative abundances were compared, adjusting for batch, to test for differences among groups (HC vs. Asym/UAS vs. SS/SLE); false discovery rate (FDR) adjusted p-values were computed. Class II HLA at DRB1 and DQB1 four-digit alleles were assigned by imputation (HIBAG) or sequencing and tested for an interaction between FDR-significant genera and HLA allele (cumulative logit models).

Results: There were reductions in genera and species diversity (Shannon Index) for the SS/SLE patients (g. 2.62±0.53; spp. 2.36±0.43) compared to Asym/UAS (g. 2.74±0.44; spp. 2.53±0.43) and HC (g. 2.77±0.36; spp 2.50±0.52) ($p< 0.05$). There were also differences in the microbial relative abundances among the three groups. Of note, the majority (76.9%) of taxa with significant differences among the three groups were in the class *Clostridia*, which includes the genera *Romboutsia* and *Coprococcus 3*. Specifically, by ranking the conditions by disease severity (HC < Asym/UAS < SS/SLE), there was a reduction in the relative abundance of *Romboutsia* and *Coprococcus 3* (P=2.38E-06 and P=1.58E-3, respectively). Given the overall sample size, HLA allelic frequencies and genus-HLA allele interactions (i.e., differential effect of genus depending on which HLA allele was present) were not significant (FDR P >0.05). However, notable findings include the allele frequencies of the DQB1*0602 allele in Asym/UAS, SS/SLE and HC were 22%, 17% and 10%, respectively (P=0.03). DQB1*0602 taxa by HLA-genus interaction analysis revealed that 70% of the top 20 taxa were contained within *Clostridia*, including *Romboutsia* and the 5 taxa below. Suggestive interactions between taxa within *Clostridia* and DQB1*0602 were *Lachnospiraceae UCG-010* (OR=0.52, P=0.006), *Oscillibacter* (OR=0.57, P=0.01), *Intestinimonas* (OR=0.60, P=0.02) and *Lachnospiraceae_NK4A136* (OR=0.65, P=0.03), and *Anaerotruncus* (OR=0.61, P=0.05).

Conclusion: Given *Clostridia's* critical role in gut homeostasis, including immune functions, reductions in this taxa combined with autoimmune related HLA alleles may serve as harbingers of a shift toward a pathologic gut microbiome that may, in part, explain progression from benign to pathologic autoimmunity and overt SLE and/or SS.

Tired T-Cells and Monocytes with Malaise: Investigating the Links Between Cellular Iron Deficiency and Mitochondrial Dysfunction in Systemic Lupus Erythematosus

Chris Wincup[1], Thomas McDonnell[1], George Robinson[2], Filipa Farinha[1], Anna Radziszewska[1] and Anisur Rahman[1], [1]University College London, London, United Kingdom, [2]University College London, Hertford, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Iron is vital for many physiological processes and is found within respiratory complexes of the mitochondrial electron transport chain, the key site of oxidative phosphorylation ATP energy production.

Previously we demonstrated that patients with SLE are at risk of absolute Iron deficiency, which occurs when stores of iron within the body become deplete. Patients are also at risk of a state of functional iron deficiency, in which there is adequate supplies of iron within the body but there is an inability to mobilise or release iron from stores. At a cellular level, upregulation of the transferrin receptor is consistent with cellular iron deficiency and this has not previously been studied in SLE.

Given that preliminary findings suggest patients are at risk of iron deficiency, this study aimed to identify evidence of cellular iron deficiency and study the impacts on mitochondrial function.

Methods:

1. *Investigating for evidence of cellular iron deficiency and changes in mitochondrial mass in SLE.* Flow cytometry was used to identify cell surface lineage markers of B-cells, T-cells and Monocytes. Cellular transferrin receptor was measured using median fluorescence intensity to quantify cell surface expression of the key iron receptor. Mitochondrial mass was measured using the dye MitoTracker Green.
2. *Studying mitochondrial function in iron deficiency and SLE*. Peripheral blood mononuclear cells (PBMCs) from healthy controls (HCs) and patients with SLE were analysed using Seahorse Respirometry, which measures mitochondrial oxygen consumption rate (a measure of energy metabolism dependent upon oxidative phosphorylation). To assess differences between health, iron deficiency and SLE, 3 groups were assessed; 1. PBMCs derived from HCs; 2. PBMCs from patients with SLE; 3. Healthy PBMCs cultured in iron deficient condition, in which cells were treated with the potent iron chelator, Deferiprone. Following analysis of PBMCs, magnetic bead isolation was used to specifically study monocytes (CD14+) and T-helper cells (CD4+).

Results: Figure 1 highlights that SLE CD4+ T-cells, monocytes and B-cells show increased cell surface transferrin receptor expression compared with HCs thus suggesting these cells are iron deficient.

Figure 2a demonstrates that PBMCs derived from healthy controls grown in iron deficient conditions (with Deferiprone) show both basal and maximal mitochondrial respiration is reduced. PBMCs derived from patients with SLE show similarly reduced respiration at a level comparable to iron deficient healthy cells. Figure 2b shows that monocytes from patients with SLE have reduced basal and maximal respiration when compared with those from HCs whilst Figure 2c shows that T-cells show reduced basal but not maximal respiration.

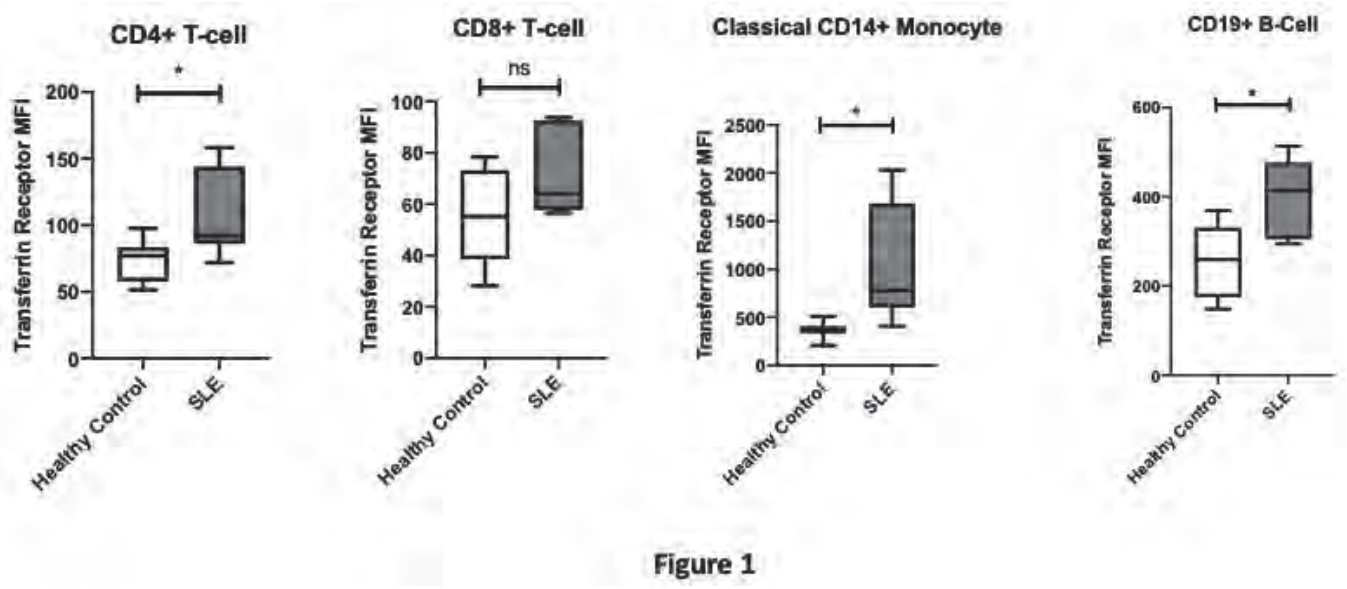

Figure 1. Transferrin Receptor Expression

Figure 3 reveals that both CD4+ and CD8+ T-cells have significantly lower mitochondrial mass when compared with HCs.

Conclusion: These findings suggest that patients with SLE display evidence of cellular iron deficiency in a number of immune cells. In addition, CD4+ T-cells and monocytes derived from SLE patients show reduced mitochondrial

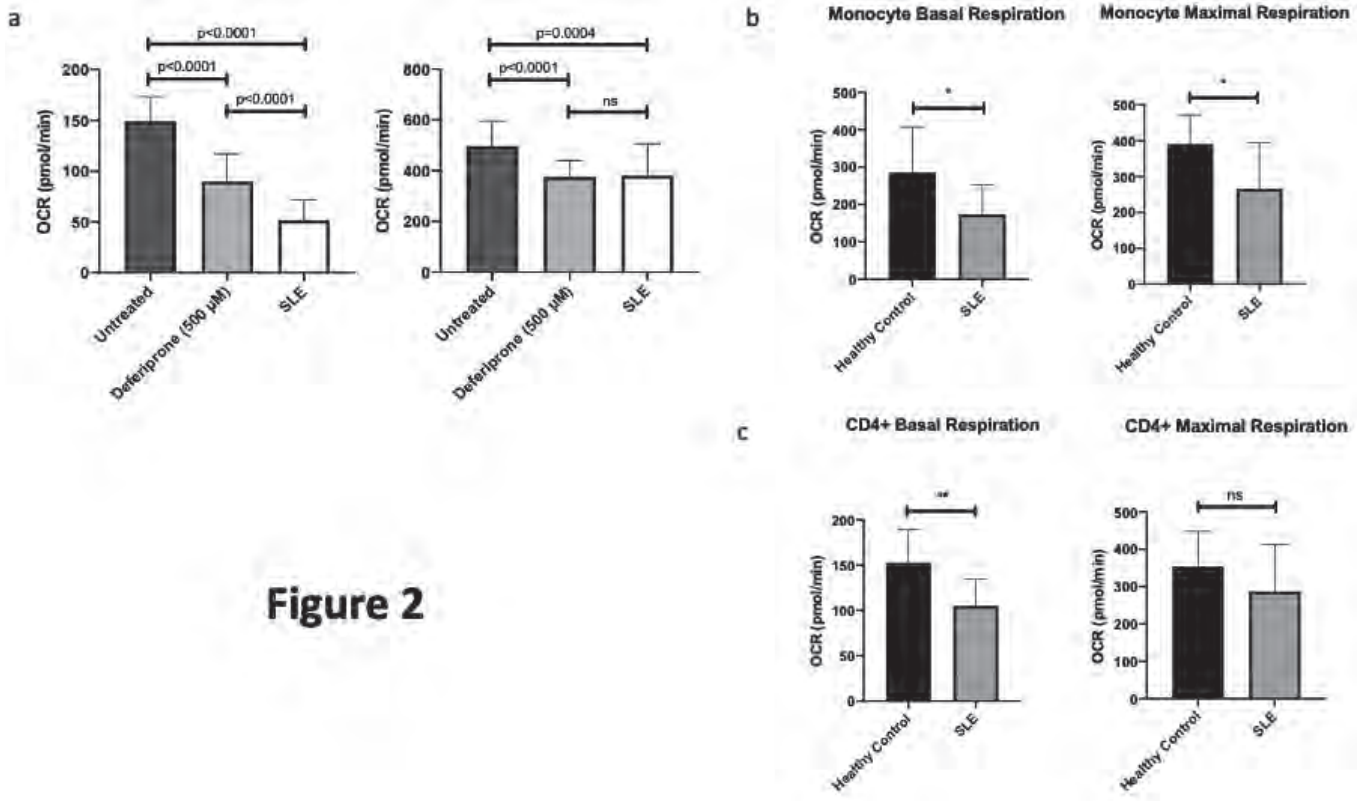

Figure 2. Basal and Maximal Mitochondrial Respiration

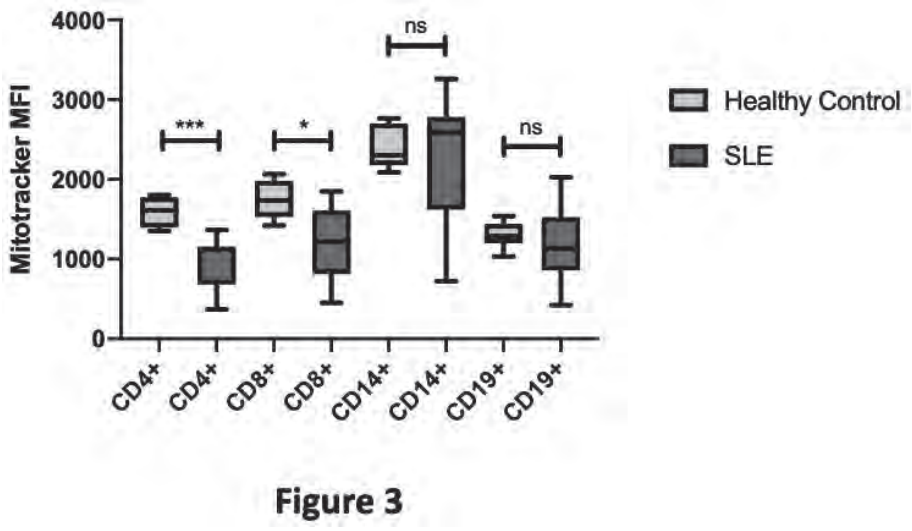

Figure 3. Differences in Mitochondrial Mass between Healthy Controls and SLE

respiration and T-cells from patients with SLE have lower mitochondrial mass, which may be a result of mitochondrial damage due to iron deficiency.

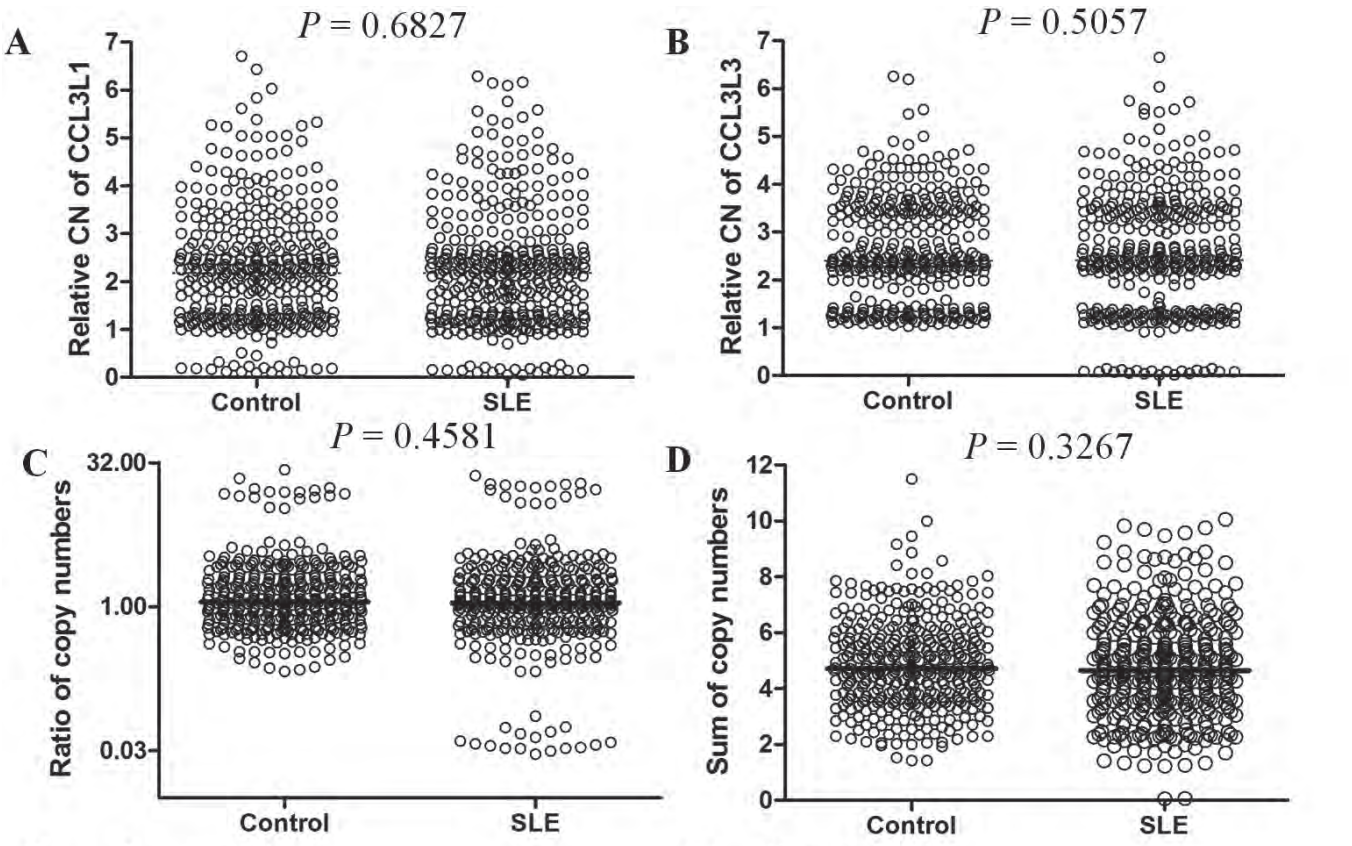
CCL3L3–null Status May Predispose to Systemic Lupus Erythematosus and Non-scarring Alopecia

Eunyoung Lee[1], Young-Ho Kim[2], Hye Won Sim[2], Eun-Kyung Kang[2], Yoon-Ho Won[2], Esther Park[2], Yeong-Wook Song[3] and Kyeong-Man Hong[2], [1]Seoul National University Hospital, Seoul, Republic of Korea, [2]National Cancer Center, Ilsan, Kyonggi-do, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Seoul, Korea, Republic of Korea

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The correlation between the copy number variation of *CCL3L1* and susceptibility to systemic lupus erythematosus (SLE), rheumatoid arthritis, Kawasaki disease, and HIV infection has been reported. However, the high level of homology (50 – 99%) within the *CCL3L* gene family has raised questions on the previously reported associations.

Methods: A modified real competitive PCR (mrcPCR) assay for the specific detection of *CCL3L1* and *CCL3L3* was developed with consideration of high homology within the *CCL3L* gene family. The *CCL3L1* and *CCL3L3* copy numbers were determined in 373 SLE patients and 358 age- and sex-matched controls by the mrcPCR assay and their associations with SLE or SLE manifestations were analyzed.



E $P = 1.000$

CN of CCL3L1	Control	SLE patients
CN > 0.45	341	356
CCL3L1-null (CN < 0.35)	17	17

F $P < 0.0001$

CN of CCL3L3	Control	SLE patients
CN > 0.8	358	354
CCL3L3-null (CN < 0.2)	0	19

Results: *CCL3L1* or *CCL3L3* copy numbers did not have any significant correlation with the prevalence of SLE. However, the absence of the *CCL3L3* gene or *CCL3L3*-null status was observed only in SLE patients (N = 19, $P < 0.0001$), whereas *CCL3L1*-null status was not significantly associated with SLE ($P = 1.000$). In addition, *CCL3L3*-null status was marginally associated ($P = 0.053$), and lower *CCL3L3* copy status (0 or 1) was significantly associated ($P = 0.013$) with non-scarring alopecia in patients with SLE.

Conclusion: The *CCL3L3*-null status may predispose to SLE, and low *CCL3L3*-copy status was significantly associated with non-scarring alopecia in SLE patients.

Association of CCL3L3-null status with SLE. A. No significant association of CCL3L1 copy number with SLE. B. No significant association of CCL3L3 copy number with SLE. C. No significant association of the copy number ratio of CCL3L3/CCL3L1 with SLE. D. No significant association of the copy number sum of CCL3L3 and CCL3L1 with SLE. Statistical tests for A-D were performed by the Mann-Whitney test. E. No significant association of CCL3L1-null status with SLE (Fisher's exact test) F. Significant association of CCL3L3-null status with SLE (Fisher's exact test).

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Within the Anti-Nuclear Antibody (ANA) associated Systemic Autoimmune Rheumatic Diseases (SARD), such as Systemic Lupus Erythematous (SLE), Sjögren's Syndrome (SS), and Systemic Sclerosis (SSc), changes in the quantity and/or abundance of specific auto-antibodies (auto-Ab) occur as individuals progress towards SARD. However, previous studies have examined only a small number of ANAs. Thus, additional changes in the auto-Ab profile may accompany and predict disease progression that have not yet been appreciated. To address this, we examined the auto-Ab profile for a broad range of auto-antigens (auto-Ag) across 245 ANA^+ asymptomatic and symptomatic individuals.

Methods: A microarray was used to simultaneously measure 144 auto-Ab specificities across six patient groups: ANA^- healthy controls (HC, n=38); ANA^+ (≥1:160 by IF) individuals lacking SARD criteria (ANA^+ NS, n=83); individuals with ≥ 1 SARD criteria but with insufficient evidence for a diagnosis (undifferentiated connective tissue disease; UCTD, n=52); early untreated (except anti-malarial) SARD patients (n=26 SLE, n=30 SS, and n=16 SSc, classified according to the 1997 ACR criteria, 2013 ACR-EULAR criteria, and the 2016 ACR-EULAR criteria, respectively). ANA^+ NS and UCTD patients were followed yearly for up to 4 years, 12 of which demonstrated symptom progression. Eleven specific ANAs were detected using the Bioplex 2200 ANA-Screen and the expression levels of five IFN-α induced genes were measured and summed to generate an IFN5 score.

Results: Following unsupervised hierarchical clustering, IgG but not IgM auto-Ab showed clear patterns by diagnosis (heat map for IgG shown in Figure 1). A subset of ANA^+ NS and UCTD individuals were admixed with SLE and SS patients, which included the majority of progressors. In general, there was a moderate positive correlation between the levels of the auto-Ab detected by Bioplex and the corresponding auto-Ab in the microarray, however, using 2 standard deviations above the mean for ANA^- HC as a cut-off, elevated levels of auto-Ab were seen more frequently in ANA^+ individuals by microarray than by Bioplex. Furthermore, the microarray was able to detect differences in au-

Figure 1

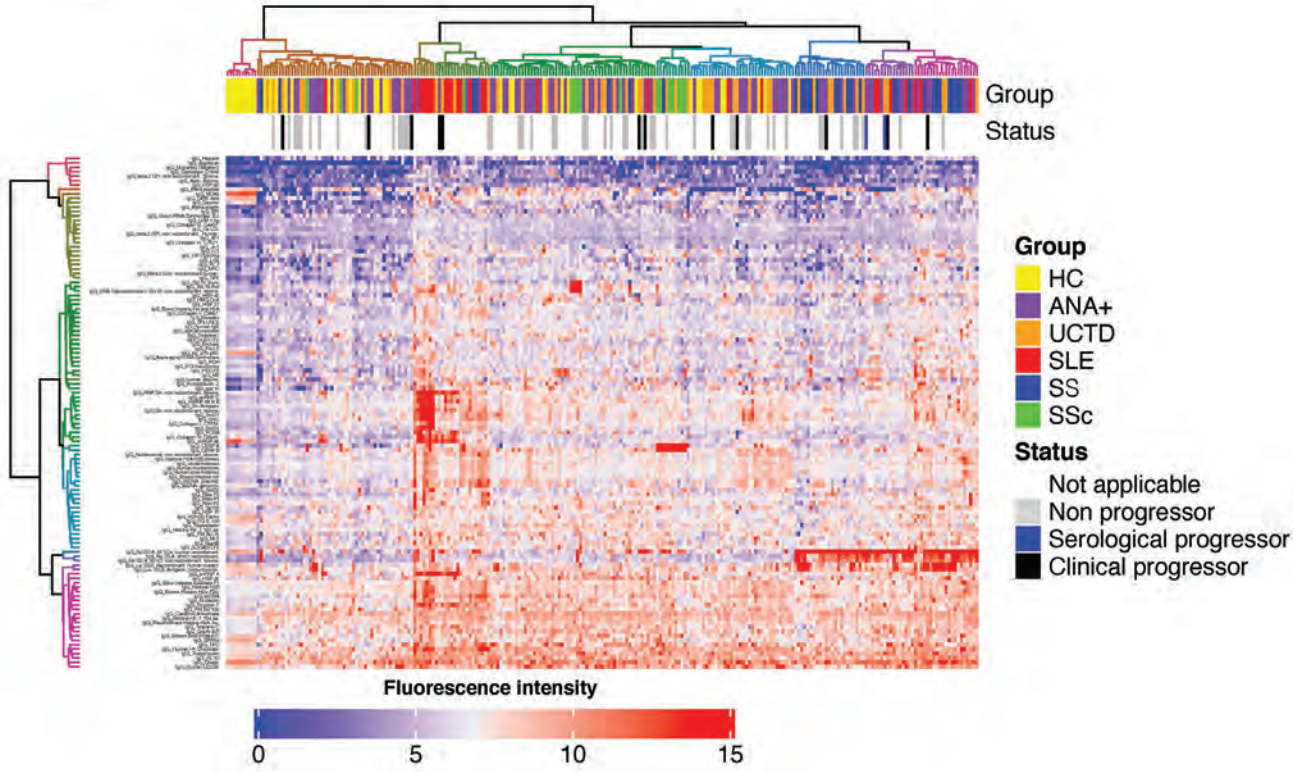

Figure 2

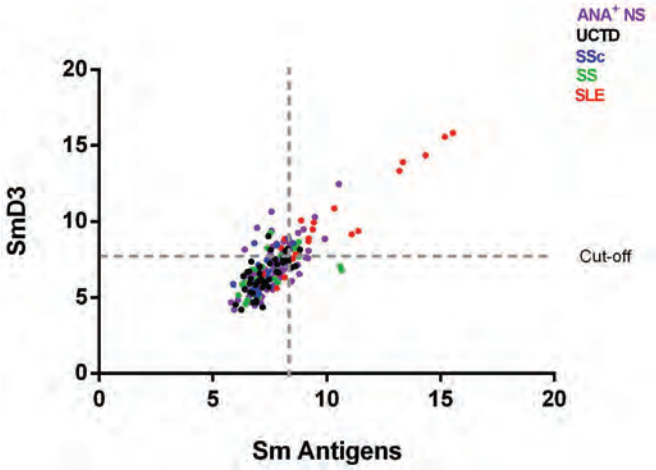

Figure 3

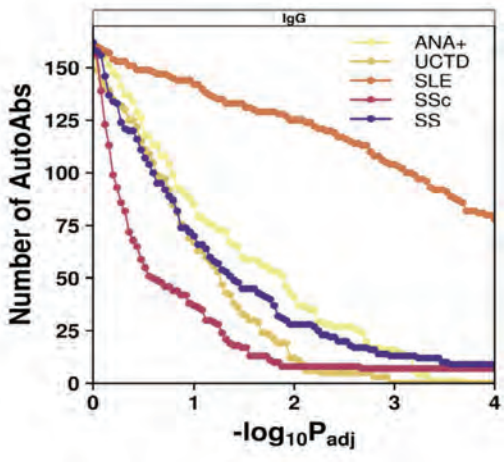

Figure 1. Heat Map of selected antigens following unsupervised clustering. IgG auto-Ab levels in red are high and those in blue are low. Controls are clustered on the left. Note the admixture of asymptomatic ANA+ and UCTD individuals with the early SARD patients, indicating similar auto-Ab profiles. Figure 2. Representative plot showing the levels of auto-Ab (Sm antigen and SmD3 subcomponent in this example) determined by microarray. Note that very high levels are restricted to SLE patients. Figure 3. P-value sensitivity plot examining the number of significantly differentially abundant probes relative to healthy controls, where it can be appreciated that many more IgG auto-Abs are elevated in SLE than in the other ANA+ groups.

to-Ab levels above the upper limit of detection on Bioplex, with very high levels restricted to SARD patients (Figure 2). Many more auto-Ag were recognized by IgG auto-Ab in SLE than in the other ANA$^+$ groups indicating that self-tolerance is significantly more disrupted in SLE (Figure 3). Interestingly, although anti-Ro60 had the strongest correlation with IFN-induced gene expression, only the presence of IgG anti-Ro52 at baseline was associated with progression in ANA$^+$ individuals lacking a SARD diagnosis. Strikingly, the types and levels of auto-Abs remained remarkably stable over time in these individuals regardless of whether they progressed or not.

Conclusion: ANA$^+$ individuals have auto-Ab to many self-antigens that are not being captured by current screening techniques. Measurement of these additional auto-Ab specificities, together with the larger dynamic range of the microarray, may help to identify individuals at high risk of progression.

Towards a Glucocorticoid Exposure Signature in SLE: Effects of Type I Interferon

Melissa Northcott[1], Linden Gearing[2], Hieu Nim[3], Champa Nataraja[3], Sarah Jones[1] and Eric Morand[4], [1]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Victoria, Australia, [2]Hudson Institute of Medical Research, Clayton, Victoria, Australia, [3]Monash University, Clayton, Victoria, Australia, [4]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GC), utilised in SLE for their broad immunosuppressive actions, predominantly mediate these effects by interaction with the cytoplasmic GC receptor (GR) to modulate gene transcription. Interactions of GC with many pathways in SLE, including the type 1 interferon (IFN) program, are poorly understood, with some evidence that IFN program is GC resistant. Minimising GC exposure is a treatment goal in SLE, however evidence-based treatment guidelines are lacking and no pharmacodynamic measure has been established. We aimed to evaluate GC regulated genes for their potential to be used as biomarkers of GC exposure in SLE.

Methods: A previously described set of 80 GC induced genes (Hu *et al*, Arthritis and Rheumatology, 2018) was measured using Fluidigm Biomark HD in peripheral blood mononuclear cells (PBMC) from patients meeting ACR criteria for SLE. Public data sets GSE49454 and GSE 88884 were accessed; clinical data correlating to GSE88884 were provided by Eli Lily. IFN status was determined using a validated 4 gene signature (IFI44, IFI44L, IFI27, RSAD2). RNAseq was performed on RNA extracted from healthy donor PBMC (n=4) treated with dexamethasone 10^{-7}M (DEX) and/or IFN 1000IU/mL. The HALLMARK_INTERFERON_ALPHA_RESPONSE gene set was extracted from the Broad Institute Molecular Signature Database.

Results: 80 GC-regulated genes were analysed in our cohort (n=18) and GSE49454 (n=62). Five genes (VSIG4, ALOX15B, CD163, AMPH, IL1R2) correlated with daily oral GC dose in both cohorts; these were combined to make a 5-gene GC signature (5GGCS) and this was analysed in GSE88884 (n=1,756). Although a dose-dependent asso-

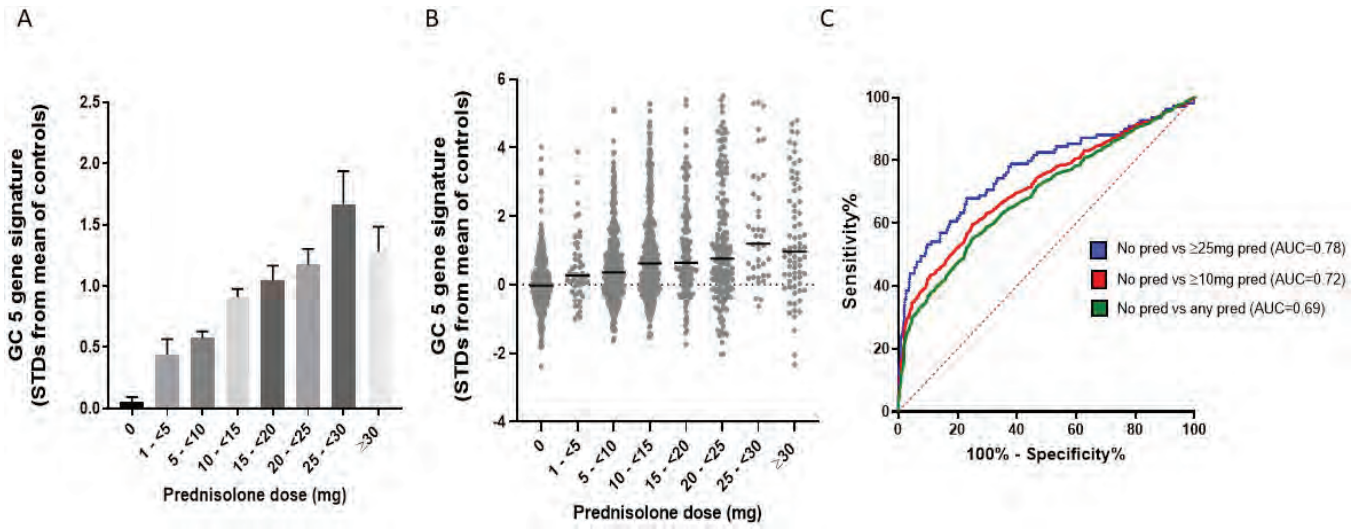

Figure 1. Correlations between 5-gene GC signature and prednisolone (pred) dose in dataset GSE888884. Mean GC signature scores increased with increasing GC dose (A, p for trend <0.0001) but exhibited large interpatient variation (B) and only modest benefit in differentiating patients taking/not taking prednisolone (C).

ciation of 5GGCS expression with GC doses was observed ($p < 0.0001$) (Fig 1A), high interpatient variation (Fig 1B) meant GC signature had only modest ability to distinguish patients taking/not taking GC overall (AUC = 0.69) (Fig 1C). We next examined whether IFN status impacted on GC signatures in SLE. In GSE88884 there was no effect of GC dose on ISG expression. In contrast, we observed a stronger correlation of 5GGCS with GC dose in IFN low patients (R=0.42, p< 0.0001) compared to IFN high patients (R=0.29, p< 0.0001) and IFN low patients had increased 5GGCS expression compared to IFN high patients matched for GC dose ($p < 0.05$), suggesting GC-induced genes are suppressed by IFN. RNAseq on IFN and DEX-treated PBMC confirmed that IFN significantly altered the expression of 29/80 GC-regulated genes, while DEX had minimal impact on ISG expression. We identified 61 genes regulated by DEX but not affected by IFN. Only 9/61 correlated with GC dose in GSE88884. Combined signatures using these genes showed modest ability to distinguish patients taking/not taking GC (AUC=0.63) (Figure 2), with slightly better performance for negatively regulated genes when prednisolone ≥ 25 mg/day (AUC=0.71).

Conclusion: A signature for GC exposure was identified, but interpatient variation and effects of IFN status may limit application in IFN-driven diseases such as SLE. These data confirm insensitivity of IFN-regulated genes to GC, but substantial impact of IFN on GC induced genes, strongly supporting the concept that IFN plays a role in GC resistance in SLE.

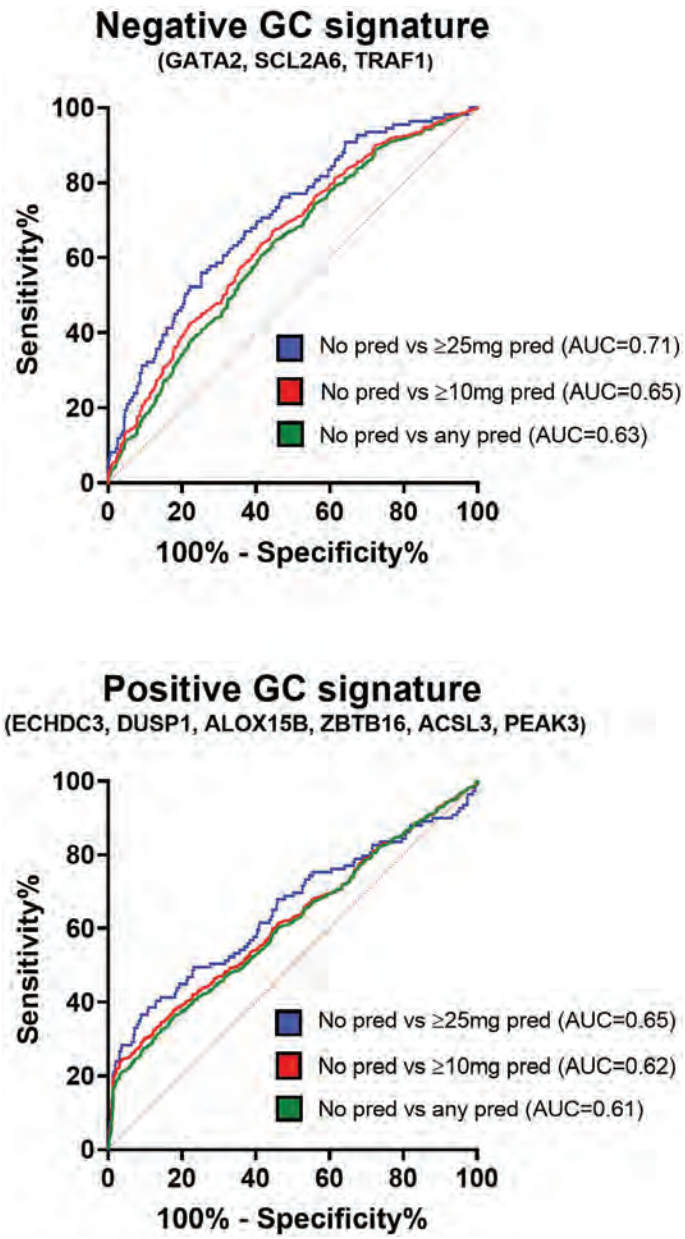

Figure 2. ROC curve analysis for negative and positive GC gene signatures to distinguish patients taking/not taking GC prednisolone (pred).

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with heterogeneous clinical manifestations which are known to vary in severity by race. Health disparities in prognosis and and presentation of SLE place a disproportionate burden on underrepresented populations as non-white populations with SLE are more likely to have features indicative of more severe disease. Prior analyses have shown global ancestry is associated with SLE risk and SLE features such as lupus nephritis; however, it is not yet known if local genetic ancestry is associated with specific SLE manifestations.

Methods: We evaluated local ancestry in multi-ethnic SLE cohorts from the UCSF Lupus Genetics Study and the California Lupus Epidemiology Study (CLUES). Genetic and phenotype data were available for 250 African American, 288 Asian, and 232 Hispanic subjects. All subjects satisfied the American College of Rheumatology criteria for SLE. DNA was extracted from blood or saliva samples and genotyped on the Affymetrix LAT1 World Array, which is designed specifically for diverse ethnic populations. Genotype data were imputed using *IMPUTE4* and phased using *BEAGLEv5.1*. We inferred local ancestry using *RFMix2.0*, which assigns local ancestry proportions to windows of the genome, and analyzed differences in local ancestry within each population. We used a non-parametric test statistic (Montana and Pritchard) to assess the difference in local ancestry between cases and controls at a SNP while adjusting for global ancestry differences. We assessed differences for two key features of SLE including if a subject had been diagnosed with lupus nephritis and age of symptom onset. We conducted tests both genome-wide and for candidate SLE SNPs previously identified to be associated with SLE and lupus nephritis risk.

Results: Although results did not remain significant after adjustment for multiple testing, top results (nominal $p < 0.01$) for differences in African Americans with lupus nephritis showed increased African ancestry at SNPs located in *TTYH2*, which functions in chloride anion channels and may play a role in kidney tumorigenesis. SNPs located in *SGCN,* which encodes a calcium binding protein, showed increased African and Asian ancestry in both African American and Asian subjects with lupus nephritis, respectively. In Hispanic subjects, increased Amerindian ancestry at a SNP previously associated with SLE risk in *DGKQ* was associated with an earlier age of onset.

Conclusion: These results warrant further investigation into local genetic ancestry differences to determine if these differences may contribute to health disparities for admixed patients with SLE.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a clinically heterogenous autoimmune disease characterized by autoantibody- and complement-mediated inflammatory damage to multiple organ systems. We previ-

ously showed that the single-nucleotide polymorphism (SNP) rs1876453, located in the first intron of complement receptor 2 (CR2/CD21), is associated with decreased risk of lupus, with a preferential effect on anti-double stranded (ds) DNA antibodies. Since anti-dsDNA antibodies develop prior to clinically apparent disease, we hypothesized that the minor A allele at rs1876453 would delay lupus onset.

Methods: DNA from individuals recruited from multiple sites was processed with institutional review board approval. All patients with SLE met the 1997 American College of Rheumatology revised classification criteria. Age of onset was collected by chart review. Genotyping was performed on the OMRF Illumina iSelect platform. Global ancestry was estimated based on the genotype of ancestry informative markers (AIMs), using principal components analysis and ADMIXMAP, and genetic outliers removed. Final clean data were from European Americans (EA), African Americans (AA; 7.5% Gullahs), Asians (AS; 74.6% Koreans, 16.1% Chinese, 9.3% Japanese and Singaporeans) and Hispanics (HS) enriched for Amerindian–European admixture. Kruskal-Wallis and Mann-Whitney tests were used to detect differences between groups. A p value of < 0.05 was considered significant. Statistics and graphs were generated using GraphPad Prism software.

Results: The median age of lupus onset for subjects with AG or AA at rs1876453 was significantly higher than subjects with GG [median (interquartile range[IQR]) 40 (21) for AA (n=31), 32 (17) for AG (n=488), and 30 (19) for GG (n=5175), $p < 0.0001$]. When stratified based on sex, both females and males with the protective allele had significantly delayed disease onset [median (IQR) 40 (21.75) for AA (n=30), 32 (17) for AG (n=439), and 30 (18) for GG (n=4775) for females, $p = 0.0006$; median (IQR) 37.5 (21) for AA + AG (n=50) and 30 (23.75) for GG (n=400) for males, $p = 0.0083$].

Conclusion: The minor allele at rs1876453 delays lupus onset by 2-10 years. These data provide further support for a protective role for this SNP in lupus pathogenesis and suggest that novel therapies designed to mimic its mechanisms may prevent disease development in at-risk individuals.

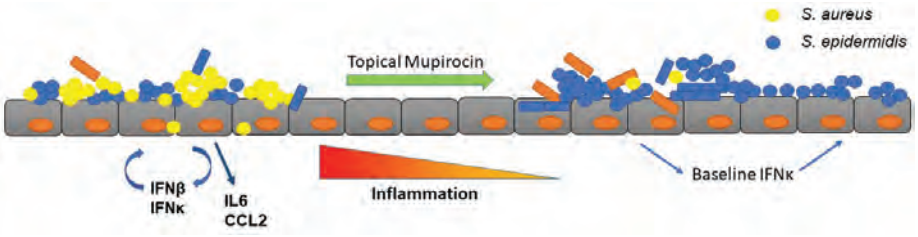
Exposure to Topical Antimicrobials Reduces Inflammatory Gene Expression in Cutaneous Lupus Lesional Skin

Sirisha Sirobhushanam[1], Allison Billi[2], Alex Tsoi[2], Celine Berthier[2], Johann Gudjonsson[3] and J. Michelle Kahlenberg[4], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, [3]University of Michigan, Ann ArborUniversity of Michigan, [4]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM



Background/Purpose: Lupus lesional skin has elevated interferon expression, is highly colonized with *Staphylococcus aureus* (50%) and has no FDA-approved treatment options. *S. aureus* is known to induce proinflammatory responses such as cytokine expression and infiltration of immune cells to the affected area. Thus dysbiosis of the cutaneous microbiota could negatively affect the cutaneous immune response. Here we investigated the effect of topical antibiotic on lupus lesional skin to determine whether it affects inflammatory gene expression.

Methods: Adult Systemic Lupus Erythematosus (SLE) patients with skin inflammation (discoid or subacute cutaneous lupus erythematosus lesions) were recruited for this study from the Michigan Lupus cohort. The study was approved by the University of Michigan IRB and all patients gave informed consent. Lesions were swabbed to determine *S. aureus* colonization and then 4 mm skin biopsies were collected from the affected area. Patients were then randomized for either mupirocin treatment or petroleum jelly as the control (3x each). Mupirocin is a topical antibiotic that reduces bacterial load in the treated area. Product was applied to the lesion thrice daily for 7 days followed by repeat swab and biopsy. Biopsies were saved at -80 °C until use. RNA was isolated from the biopsies, checked for quality, and sequenced to determine transcriptomic changes.

Results: Mupirocin treatment results in a greater reduction of differentially-expressed genes (DEGs) (184) when compared to treatment with petroleum jelly (133). Functional enrichment analysis of the differentially regulated genes with each treatment showed that antibiotic treatment resulted in downregulation of genes that were significantly enriched in cytokine pathways including genes such as CCL19, CCL2, CXCL10, FPR1, and PTGS2 and genes such as STAT1, OAS3, SOCS3, ICAM1 and IL6 that are interferon (IFN) regulated. In contrast, downregulated genes post petroleum jelly treatment were enriched in cell communication and extracellular matrix pathways. Importantly, a scatter plot of the data to compare the effects of the two treatments showed that DEGs from the two treatments were almost completely independent with only a few that were DE in both treatments.

Conclusion: Inflammatory signaling can be reduced in lupus lesional skin by reducing Gram-positive bacterial load by topical antibiotic treatment. CCL19 is an interferon regulated gene that mediates ectopic lymphoid aggregates in non-lymphoid tissues. CCL2, a chemokine highly expressed in CLE, and CXCL10 are known to recruit monocytes, memory T cells and dendritic cells to sites of inflammation, resulting in Th1 oriented inflammation in CLE. Thus, modulation of the lesional microbiota may facilitate reduction in inflammation. This may be particularly helpful in patients who are recalcitrant to typical treatment protocols for skin inflammation. Further study of additional patients is underway to confirm this finding.

Graphical representation of lesional skin showing high IFN production that contributes to further inflammation, as well as high S. aureus colonization and low microbial diversity. Mupirocin treatment could reduce the proliferation and density of S. aureus thereby improving microbial diversity as well as reducing inflammation.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with incomplete lupus erythematosus (ILE) have features of lupus, but have insufficient criteria for SLE classification. Some ILE patients transition to classified SLE, but the majority remain ILE without major organ involvement. ILE presumably shares genetic associations with SLE, while unique ILE variants or reduced genetic load may influence a more mild disease course. This study aims to identify variants associated with ILE through genome-wide association study (GWAS) and compare genetic load of ILE patients, SLE patients, and unaffected individuals.

Methods: ILE was defined as 3 ACR-1997 SLE criteria (ILE^{ACR}) and SLE as ≥4 ACR-1997 criteria by standardized medical record review. The subset of ILE^{ACR} who also did not meet SLE classification by *SLICC* criteria were designated ILE^{SLICC}. Study participants were genotyped on the Infinium Global Screening Array (GSA). After quality control, association testing included 335 ILE^{ACR} patients and 236 controls of diverse ancestry without self-reported lupus manifestations (Table). Principal components were included as logistic regression covariates. For genetic load

Table 1. Demographic Information and Genetic Load for the samples passing quality control for GWAS and genetic load calculations. n/a: not applicable. *p<0.05, **p<0.01, ***p<0.001 vs. control. For ILE vs. SLE comparisons, p>0.05.

Parameter	GWAS		Genetic Load			
	ILE^{ACR} (n=335)	Control (n=236)	ILE^{ACR}	ILE^{SLICC}	SLE	Control
Female, *n* (%)	296 (88.4)	208 (88.1)	159 (86.8)	109 (87.9)	203 (89.8)	134 (86.5)
Ancestry, n						
European American	183	155	183	124	226	155
African American	84	65				
American Indian	7	4				
Asian	8	1				
Hispanic	17	5				
Multiple	34	5				
Other/Unknown	2	1				
Unweighted genetic load, mean (range)	n/a	n/a	631.8*** (92.0)	630.7** (85.0)	632.8*** (104.0)	624.9 (93.0)
Weighted genetic load, mean (range)	n/a	n/a	77.0*** (15.8)	76.7** (11.8)	77.2*** (16.3)	75.9 (13.0)

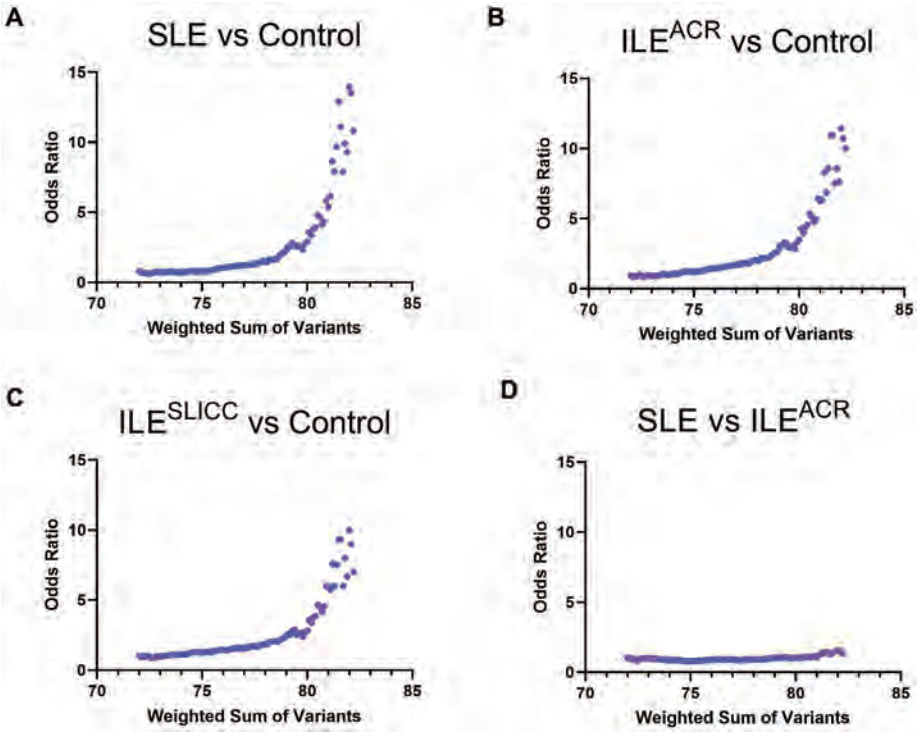

Figure 1. Odds ratio across genetic load range. The odds ratio represents the odds that an individual with a given genetic load (+/-2.0) will have SLE vs control (A), ILE(ACR) vs control (B), ILE(SLICC) vs control (C), or SLE vs ILE(ACR) (D), compared to a baseline comparison group of individuals in the lowest decile for weighted genetic load.

calculations, genotypes were pre-phased and imputed against 1000 Genomes Project haplotypes. Risk alleles that showed association with European SLE in Langefeld, et al (Nat Comm, 2017) (pFDR< 0.05) were identified in unrelated European American (EA) patients with SLE, ILE^{ACR}, ILE^{SLICC}, and controls (Table). Genetic loads were computed for each person as the number of risk alleles (unweighted) and allele sum with each allele weighted by its beta coefficient (weighted).

Results: Through GWAS in the ancestrally diverse population of ILE^{ACR} and controls, 12 variants exceeded the suggestive level of significance ($p < 1 \times 10^{-5}$). Eight were not previously reported in SLE (DPP10-DDX18, LRP1B, HMHB1-YIPF5, PHF14-THSD7A, ABCA1, DMRTA1-LINC01239, LOC105369443-CNTN5, and MIR3649-ADIPOR2), involving genes associated with phospholipid metabolism, asthma, Behçet disease, and cancers. No variants reached genome-wide significance ($p < 5 \times 10^{-8}$) in this small study. EA ILE^{ACR}, ILE^{SLICC}, and SLE patients had significantly greater unweighted and weighted genetic load than controls ($p < 0.001$) ($p < 0.001$) and ($p < 0.01$) (Table), respectively. There was no significant difference between mean genetic load (weighted or unweighted) in ILE and SLE, and weighted genetic load did not significantly differentiate between ILE^{ACR} and SLE in receiver operator characteristics analysis (area under the curve = 0.52). Further, those with a weighted genetic load of 81.0 (+/-2.0) or higher had greater odds of being SLE or ILE vs. healthy control (odds ratios >5.4-6.3), compared to individuals in the lowest weighted genetic load decile (Figure 1-C). However, weighted genetic load did not significantly affect odds of having SLE vs. ILE^{ACR} (Figure 1D).

Conclusion: ILE and SLE patients have similar genetic loads of SLE risk loci, suggesting a similar genetic predisposition between these conditions. Suggestive associations for novel loci are identified in ILE patients which require replication and validation. Phenotypic differences may be influenced by novel ILE variants and gene-environment interaction.

Longitudinal Study of Acute SLE Flare Reveals Dynamic Changes in Multiple Immune Cell Subsets

Kieran Manion[1], Dennisse Bonilla[2], Dafna Gladman[1], Murray Urowitz[3], Zahi Touma[4] and Joan Wither[2], [1]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In SLE, periods of relative quiescence are punctuated by flares in disease activity that can lead to extensive tissue damage and morbidity. Existing studies suggest that flare onset is linked to immune cell subsets involved in ANA production, including activated memory T helper cells, plasma cells, and age-associated B

Table 1. There are significant differences between healthy controls and lupus patients in multiple immune cell subsets at baseline; however, many of these populations do not show further differences between flare and inactive patients.

Immune Cell Subsets	Healthy Control (n=16)	Lupus (n=72)	*p value*	Acute Flare (n=47)	Inactive (n=25)	*p value*

cells (ABCs); however, it is largely unknown how these and other immune subsets differ between flare and inactive disease, particularly in the period post-flare.

Methods: Healthy controls (HC, n=16) and acute flare (n=47) or inactive (n=25) SLE patients were recruited, with patients diagnosed based on the 1997 ACR criteria. Flare patients were within 1 month of flare onset (a clinical SLEDAI-2K >0 requiring a change in therapy) while inactive patients had to be inactive for ≥1 year (clinical SLEDAI-2K=0) and on ≤10mg prednisone at recruitment. All patients had blood collected at first visit as well as at 6M and 12M follow-ups. Freshly isolated PBMCs were stained with various fluorochrome-conjugated antibodies to identify immune cell populations by flow cytometry. Statistical significance was determined using Mann-Whitney U tests to compare baseline groups and Wilcoxon matched-pairs signed rank tests to compare baseline and follow-up visits.

Results: SLE patients differed significantly from HC in multiple immune cell subsets at baseline, with higher proportions of ABCs, T peripheral helper (T_{ph}) cells, regulatory T (T_{reg}) cells, and pro-inflammatory monocytes, as well

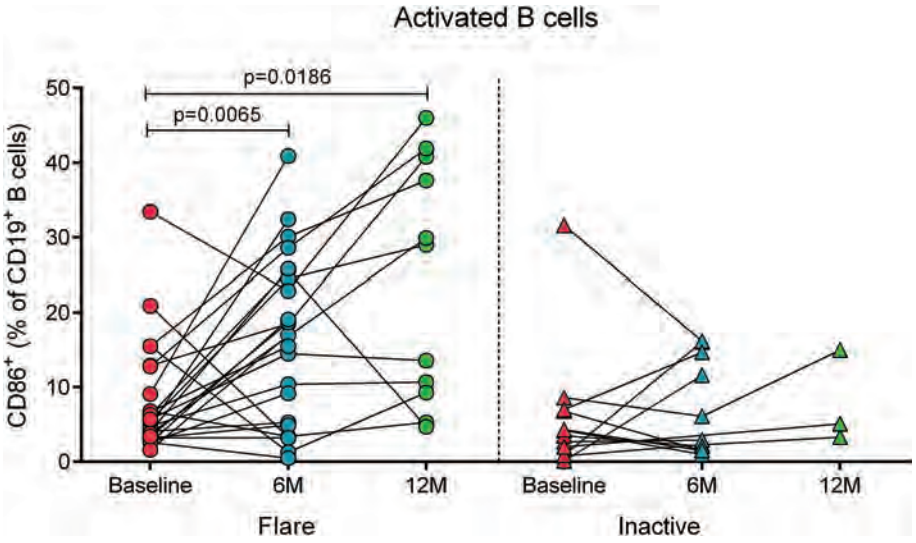

Figure 1. Flare patients show significant increases in the proportions of activated B cells in the blood at 6M and 12M post-flare, while levels remain stable in inactive patients over time.

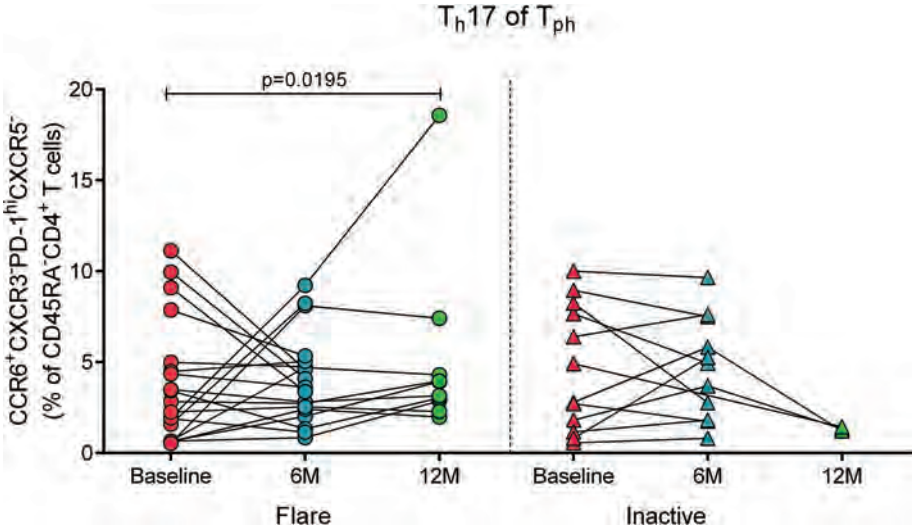

Figure 2. Flare patients show significant increases in the proportions of Tph Th17 cells in the blood at 12M post-flare, while levels remain stable in inactive patients over time.

as a trend to higher plasmablasts (see Table 1). However, stratification of SLE patients into acute flare and inactive groups revealed limited differences between these groups at baseline. While flare patients had significantly higher proportions of ABCs as well as significantly lower proportions of NK cells, pDCs and mDCs as compared to inactive patients, the majority of monocyte, B, T, and antibody-producing cell subsets did not differ between flaring and inactive patients, suggesting that these populations are not enriched in the blood during flare. In contrast, flare patients diverged significantly from inactive patients in multiple immune subsets at 6M and/or 12M following flare treatment, showing significant increases in B cell activation ($p=0.0118$), $CD16^{+}$ monocytes ($p< 0.0001$), transitional B cells ($p=0.0006$), T_{regs} ($p=0.0093$), T_{ph} cells ($p=0.0385$) and $T_{ph}17$ cells ($p=0.0055$). These differences appeared to stem from increases in these populations in flare patients during the post-flare period, while inactive patients remained relatively stable over the same time frame (see Figures 1 and 2 for representative results).

Conclusion: Our results suggest that at the time of acute flare many of the activated immune cell populations that are proposed to participate in flare are absent from the peripheral blood. Instead, differences between flaring and inactive patients become more apparent in the months following flare treatment, as activated immune cells are not recruited into and/or migrate out of inflamed tissues. These findings highlight the importance of longitudinal studies of flare in SLE.

SLE Patients Stratify into Distinct Clusters Based on Their Peripheral Blood Immunologic Phenotype During Acute Flare

Kieran Manion[1], Carolina Munoz-Grajales[2], Michael Kim[3], Kirubel Goliad[4], Dennisse Bonilla[5], Dafna Gladman[1], Murray Urowitz[6], Zahi Touma[7] and Joan Wither[5], [1]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto-UHN, Toronto, ON, Canada, [3]Krembil Research Insitute, Toronto, ON, Canada, [4]University of Toronto-UHN, Toronto, Canada, [5]University of Toronto Lupus Clinic, Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [6]University Health Network, University of Toronto, Toronto, ON, Canada, [7]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic autoimmune disease in which periods of quiescence are interspersed with acute flares of disease activity that produce much of the associated tissue and organ damage. Current literature suggests that flares can be induced by multiple environmental triggers and are mediated by pro-inflammatory and ANA-producing immune cell subsets; however, the specific immune response that characterizes acute flare as opposed to disease quiescence in the disease course of an individual with SLE is largely unknown.

Methods: Healthy controls (n=16) and acute flare (n=47) or inactive (n=25) SLE patients were recruited. All SLE patients were diagnosed based on the 1997 ACR criteria. For acute flare, patients had to be within 1 month of flare onset (clinical SLEDAI-2K >0 requiring a change in therapy); inactive patients had to be ≥1 year without flare (clinical SLEDAI-2K=0) and on ≤10mg prednisone. Freshly isolated PBMCs were stained for various immune cell subsets and

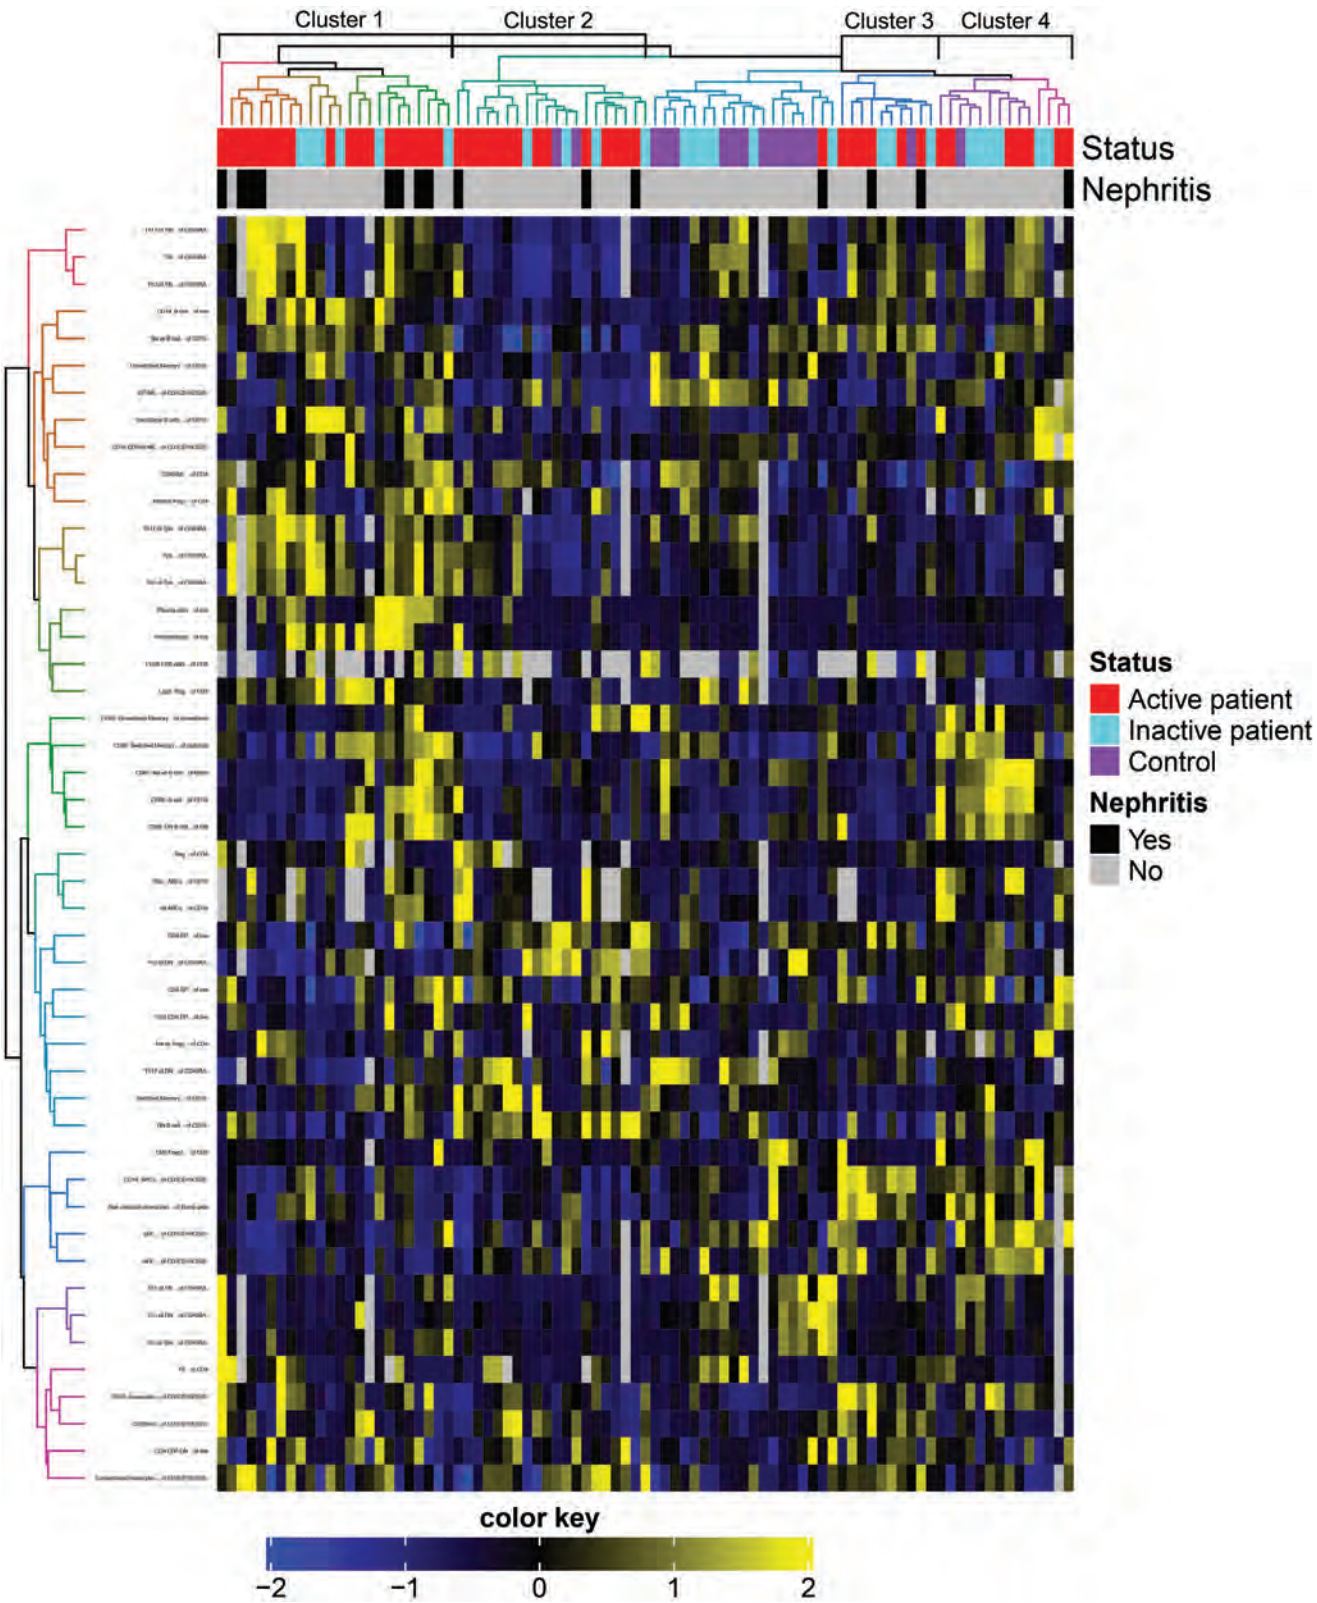

Figure 1. Heat map depicting the clustering of Z-scores for immune cell populations from healthy controls, acute flare and inactive SLE patients.

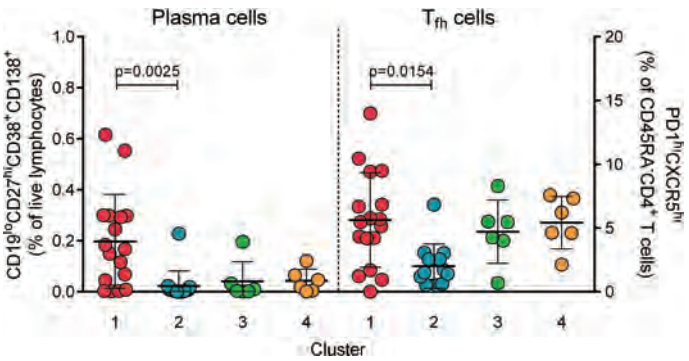

Figure 2. Plasma cells (left axis) and Tfh cells (right axis) are significantly elevated in cluster 1 of flare patients as compared with cluster 2.

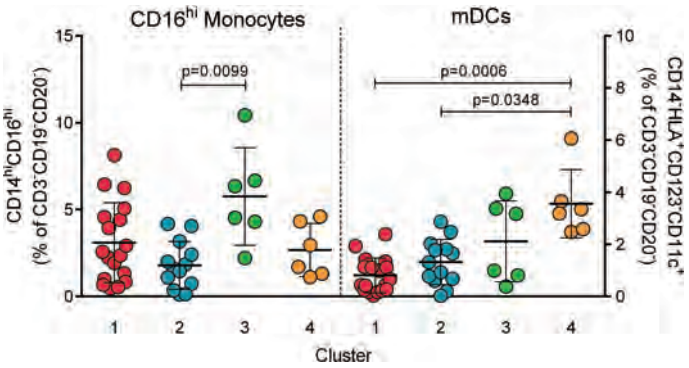

Figure 3. CD16hi monocytes (left axis) are significantly higher in cluster 3 of flare patients compared with cluster 2, while mDCs (right axis) are significantly higher in cluster 4 than in clusters 1 and 2.

examined by flow cytometry. Z-scores were calculated for the proportions of immune cell subsets from HC, flare and inactive patients. A heat map displaying immune cell subsets was generated using the ComplexHeatmap package in R (v3.6.1). For comparisons between groups, statistical significance was determined using Kruskal-Wallis non-parametric tests.

Results: While HC mostly clustered together on the heat map, flare patients stratified into four predominant clusters and inactive patients were admixed with both HC and flare groups. Looking at flare patients alone, cluster 1 had significantly elevated plasma cells ($CD19^{lo}CD27^{hi}CD38^{+}CD138^{+}$; 1 vs 2: p=0.0025), T follicular helper (T_{fh}) cells ($CD4^{+}CD45RA^{-}PD\text{-}1^{hi}CXCR5^{hi}$; 1 vs 2: p=0.0154) and $T_{fh}17$ cells ($CD4^{+}CD45RA^{-}PD\text{-}1^{hi}CXCR5^{hi}CCR6^{+}CXCR3^{-}$; 1 vs 2: p=0.0037), as well as trends to increased T peripheral helper (T_{ph}; $CD4^{+}CD45RA^{-}PD\text{-}1^{hi}CXCR5^{-}$) and regulatory T cells (T_{reg}; $CD4^{+}CD45RA^{-}CD25^{+}CD127^{-}$). Cluster 2 had similar or decreased proportions of immune subsets compared to the other groups, with the exception of expanded double negative B cells ($IgD^{-}CD27^{-}CD19^{+}$; 2 vs 1: p=0.0013, 2 vs 3: p=0.0010). In contrast, clusters 3 and 4 exhibited a more innate phenotype, with significant elevations in $CD16^{hi}$ ($CD14^{hi}CD16^{hi}CD3^{-}CD19^{-}CD20^{-}$; 3 vs 2: p=0.0099) and non-classical monocytes ($CD14^{int}CD16^{+}CD3^{-}CD19^{-}CD20^{-}$; 3 vs 2: p=0.0090), or in mDCs ($CD14^{-}HLA^{+}CD123^{-}CD11c^{+}CD3^{-}CD19^{-}CD20^{-}$; 4 vs 1: p=0.0006, 4 vs 3: p=0.0348) and NK cells ($CD16^{+}CD56^{+}CD14^{-}CD3^{-}CD20^{-}CD19^{-}$; 4 vs 3: p=0.0196), respectively. While there was no difference between the clusters with regard to age, dsDNA, complement or SLEDAI-2K score, patients in cluster 1 trended towards a longer disease duration and were more likely to have nephritis.

Conclusion: Our findings suggest that significant variations in the immune mechanisms that promote flare may exist between patients, with some patients demonstrating a more adaptive immune response in flare while others have a more innate immune response. Thus, effective treatment of SLE flare may require a more targeted approach tailored to the specific flare mechanism in each patient.

Type I Interferon Inhibits Glucocorticoid-Induced Leucine Zipper (GILZ) Expression and Upregulation by Glucocorticoids

Wendy Dankers[1], Melissa Northcott[2], Taylah Bennett[3], Brendan Russ[3], Jacqueline Flynn[1], Sarah Jones[2] and Eric Morand[1], [1]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, [2]Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Victoria, Australia, [3]Department of Microbiology, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GC) are broadly used in the treatment of inflammatory diseases, including systemic lupus erythematosus (SLE). Despite their widespread use, most SLE patients do not reach a state of low disease activity on GC treatment. Currently it is not completely understood what factors play a role in the response to this treatment. It is thought that many anti-inflammatory effects of GC are mediated through upregulation of glucocorticoid-induced leucine zipper (GILZ). GILZ expression is decreased in the blood of SLE patients compared to healthy controls. Interestingly, we have previously shown that this is inversely correlated with the interferon (IFN) signature induced by type I IFN, including IFNα and IFNβ. Given the important role of type I IFN in SLE pathogenesis, we studied whether IFNα could suppress GILZ and thereby reduce the effectiveness of GC.

Methods: Human peripheral blood mononuclear cells (PBMC) were isolated from healthy individuals and treated with 1000 IU IFNα2a, 100 nM dexamethasone (DEX) or both, with or without the Jak1/Tyk2 inhibitor tosylate salt (TS). GILZ expression in these cultures was analysed using RT-PCR. STAT1 binding sites were analyzed from public datasets and using chromatin immunoprecipitation followed by RT-PCR. Public datasets were also used to study the effect of IFNα and the interplay between GC and IFNα on GILZ expression in SLE patients.

Results: IFNα treatment reduces the expression of GILZ in human PBMC in a dose- and time-dependent manner. Interestingly, it also reduces the DEX-induced upregulation of GILZ. This corresponds to data in SLE patients, where GC treatment is less effective at inducing GILZ in patients with a high IFN score than in patients with a low IFN score. Mechanistically, we found that IFNα2a reduces GILZ expression via the Jak1/Tyk2 signalling pathway, as treatment with the specific inhibitor TS reversed the effects of IFNα2a. In public datasets, and then confirmed via ChIP, we subsequently found that the transcription factor STAT1, downstream of Jak1/Tyk2, has multiple DNA binding sites surrounding the GILZ locus. These STAT1 binding sites coincide with binding sites of the glucocorticoid receptor (GR), which may explain the mechanism by which IFNα2a reduces the DEX-induced GILZ upregulation.

Conclusion: In human PBMC, IFNα2a reduces GILZ expression and the DEX-induced upregulation of GILZ via the Jak1/Tyk2 signalling pathway and direct DNA binding of STAT1 to the GILZ locus. These data reveal a potential mechanism by which type I IFN suppress the effectivity of GC, which could be targeted to improve therapeutic efficacy in SLE.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

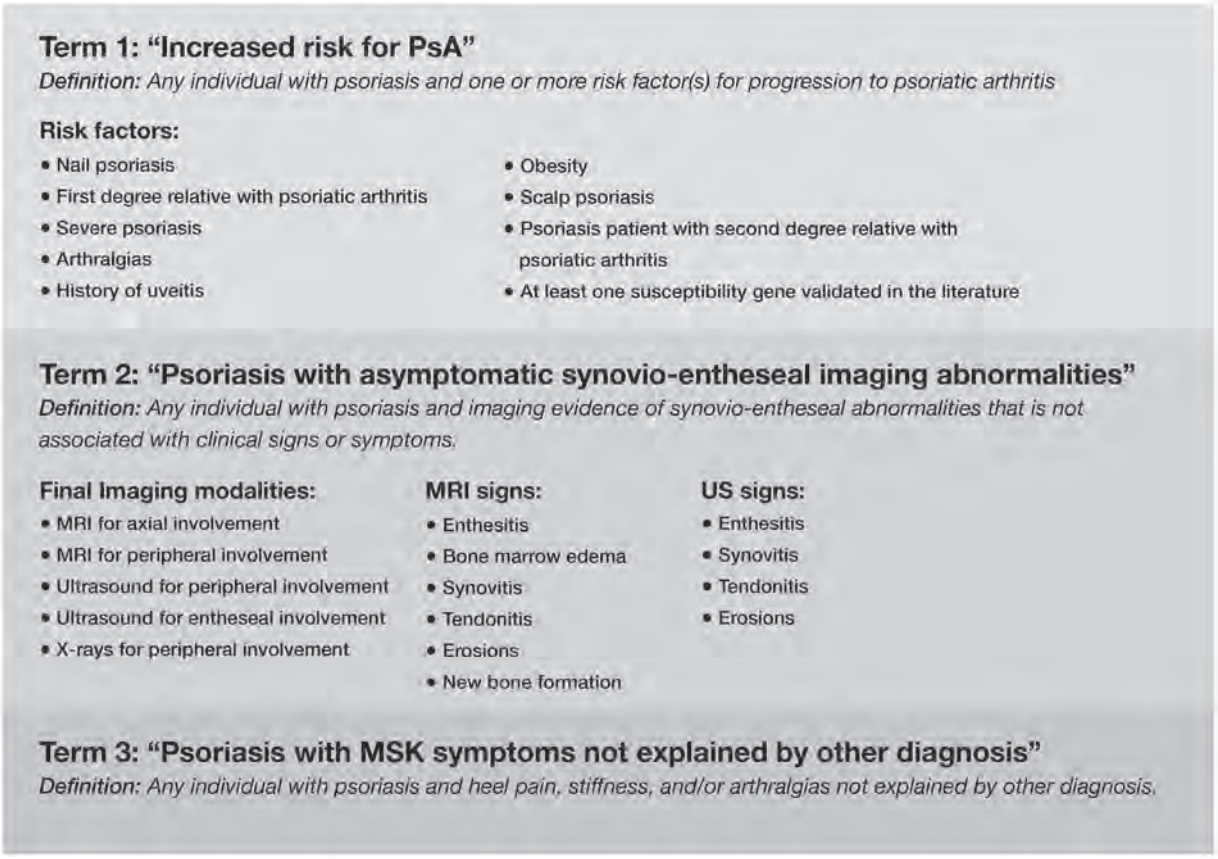
Session Time: 9:00AM–11:00AM

Background/Purpose: The concept of prevention of psoriatic arthritis (PsA) has gained increased interest given the physical limitation and poor quality-of-life experienced by PsA patients coupled with low remission rates observed with the use of currently available therapies. The transition from psoriasis to PsA offers a unique window of opportunity to identify individuals at increased risk for PsA, to study and implement preventive strategies. Herein, we propose terminology to define specific subgroups during the pre-clinical and early clinical phases of PsA to facilitate and harmonize recruitment for research studies.

Methods: We conducted a 3-round online Delphi exercise including international experts in psoriatic disease. Experts were recruited from the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) and the Psoriasis and Psoriatic Arthritis Clinics Multicenter Advancement Network (PPACMAN). Participants were asked to vote on and rank their preferred (a) terms and (b) definitions to describe pre-clinical PsA populations. Consensus for multiple choice and ranking questions was defined *a priori* as ≥ 70%. For questions based on a visual analogue scale, items were retained if the median was ≥ 70. Delphi items that had < 15% of the votes or the median was < 15 were removed. If consensus was not reached, the question was carried through to the next round.

Results: A total of 29, 33, and 35 experts participated in the first, second and third Delphi round, respectively. Consensus was met for the following terms and associated definitions: "Increased risk for PsA"**,** "Psoriasis with asymptomatic synovio-entheseal imaging abnormalities", and "Psoriasis with musculoskeletal symptoms not explained by other diagnosis" (Figure). Risk factors for progression to PsA that met consensus included obesity, presence of arthralgia, severe psoriasis, history of uveitis, nail psoriasis, scalp psoriasis, and first-degree relative with PsA. Specific imaging modalities to evaluate these populations were also included in the exercises and consensus was achieved.

Conclusion: In these Delphi exercises, there was agreement on three terms and definitions that characterize the psoriasis-to-PsA transition that can to be used for research purposes. The adoption of standardized nomenclature and common definitions for research in this area should improve the communication of ideas in the field and help to enroll well-defined, homogenous cohorts of psoriasis patients, for comparison across future studies. These terms



and definitions may evolve as increasing evidence regarding the molecular, clinical, and imaging features of the psoriasis-to-PsA continuum emerges.

Characteristics of Patients with Early Oligoarticular Psoriatic Arthritis in the Corrona Psoriatic Arthritis/Spondyloarthritis Registry

Alexis Ogdie[1], Taylor Blachley[2], Kelechi Emeanuru[2], Sven Richter[3], Benoit Guerette[3] and Philip Mease[4], [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Corrona, LLC, Waltham, MA, [3]Amgen Inc., Thousand Oaks, [4]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The efficacy of apremilast vs placebo for the treatment of oligoarticular PsA of ≤2 years duration is being investigated in the FOREMOST trial (NCT03747939). There is a paucity of real-world data characterizing patients (pts) with oligoarticular PsA. The Corrona PsA/SpA Registry, a prospective, observational cohort study, collects real-world data on US pts with PsA. The current analysis compared characteristics of pts with early oligoarticular PsA in the Corrona PsA/SpA Registry who would generally meet eligibility criteria for FOREMOST with the remainder of the PsA registry population.

Methods: Pts ≥18 years of age diagnosed with PsA who enrolled in the registry from March 2013 to February 2020 were included in the analysis. The FOREMOST-eligible group consisted of pts diagnosed with PsA within 2 years prior to enrollment who were naive to biologic DMARDs or targeted systemic DMARDs (apremilast or tofacitinib), had a history of ≤1 prior conventional synthetic DMARD (csDMARD [methotrexate, hydroxychloroquine, sulfasalazine, leflunomide]), and had swollen joint counts (0-66) of 2 to 4 and tender joint counts (0-68) of 2 to 4. The remainder of the PsA registry population included pts with PsA who did not meet these criteria. Data on patient demographics, clinical characteristics, treatment, disease activity, and patient-reported outcomes at enrollment are summarized descriptively.

Results: Of the 3,556 pts with PsA enrolled in the registry, 109 (3.1%) were included in the FOREMOST-eligible group and 3,447 (96.9%) comprised the remainder of the PsA registry population. Baseline characteristics among the 2

Table 1. Patient Characteristics and Treatment Experience at Time of Enrollment

Outcome	FOREMOST-Eligible (n = 109)	Remainder of PsA Registry Population (n = 3,447)
Age, mean (SD), years	50.1 (13.6)	53.7 (13.1)
Women, n (%)	65 (59.6)	1,855 (54.3)
Body mass index, mean (SD), kg/m^2	31.4 (7.4)	31.9 (7.6)
Years since PsA diagnosis, mean (SD)	0.5 (0.6)	7.6 (8.5)
Duration since onset of PsA symptoms, mean (SD), years	2.3 (3.2)	11.1 (10.3)
Prior csDMARD use, n (%)		
0	101 (92.7)	1,751 (50.8)
1	8 (7.3)	786 (22.8)
Current csDMARD therapy, n (%)	37 (37.8)	1,368 (58.7)

csDMARD = conventional synthetic DMARD; PsA = psoriatic arthritis; SD = standard deviation.

Table 2. Clinical Assessments and Disease Activity at Time of Enrollment

Outcome	FOREMOST-Eligible	Remainder of PsA Registry Population
SJC (0-66), mean (SD)	2.8 (0.9)	2.2 (4.4)
TJC (0-68), mean (SD)	2.8 (0.9)	5.2 (9.0)
Dactylitis, n (%)	28 (25.7)	359 (10.4)
Enthesitis, n (%)	13 (11.9)	796 (23.1)
Pain VAS (0-100 mm), mean (SD)	51.1 (27.1)	41.0 (30.0)
Fatigue VAS (0-100 mm), mean (SD)	47.8 (29.4)	43.3 (29.8)
PtGA of PsA VAS (0-100 mm), mean (SD)	42.5 (26.1)	40.9 (29.5)
PtGA of PsA and psoriasis VAS (0-100 mm), mean (SD)	42.4 (27.8)	40.7 (29.4)
PhGA of PsA VAS (0-100 mm), mean (SD)	35.4 (20.5)	22.3 (22.8)
Minimal disease activity, n (%)	8 (8.1)	1,186 (38.5)
cDAPSA, mean (SD)	14.9 (5.4)	15.6 (14.4)
cDAPSA category, n (%)		
Moderate disease activity, cDAPSA >13 to ≤27	66 (63.5)	944 (29.7)
High disease activity, cDAPSA >27	NA	NA
DAPSA, mean (SD)	16.3 (6.0)	16.9 (14.9)
DAPSA category, n (%)		
Moderate disease activity, DAPSA >14 to ≤28	44 (65.7)	620 (29.8)
High disease activity, DAPSA >28	NA	NA
PASDAS, mean (SD)	4.6 (1.0)	3.7 (1.6)
PASDAS category, n (%)		
Moderate disease activity, PASDAS ≥3.2 to <5.4	48 (44.0)	949 (27.5)
High disease activity, PASDAS ≥5.4	13 (11.9)	313 (9.1)
RAPID3, mean (SD)	11.0 (5.8)	9.4 (6.1)

NA refers to parameters with n <5. cDAPSA = Clinical Disease Activity Index for Psoriatic Arthritis; DAPSA = Disease Activity Index for Psoriatic Arthritis; PASDAS = Psoriatic Arthritis Disease Activity Score; PhGA = Physician's Global Assessment; PsA = psoriatic arthritis; PtGA = Patient's Global Assessment; RAPID3 = Routine Assessment of Patient Index Data 3; SD = standard deviation; SJC = swollen joint count; TJC = tender joint count; VAS = visual analog scale.

populations were generally similar, with slightly younger pts and proportionally more women in the FOREMOST-eligible group than in the remainder of the PsA registry population (Table 1). FOREMOST-eligible pts had shorter duration of PsA and shorter time to PsA diagnosis than the remainder of the PsA registry population (Table 1). Prior and current csDMARD use in the FOREMOST-eligible pts was lower than in the remainder of the PsA registry population (Table 1). FOREMOST-eligible pts had higher mean scores for patient-reported pain visual analog scale (VAS) and the Physician's Global Assessment (PhGA) of PsA VAS, in the context of comparable overall mean DAPSA, cDAPSA, PsA Disease Activity Score (PASDAS), and Routine Assessment of Patient Index Data 3 (RAPID3) scores (Table 2). Compared with the remainder of the PsA registry population, FOREMOST-eligible pts were less likely to be in minimal disease activity and more likely to have moderate disease activity based on the cDAPSA, DAPSA, and PASDAS (Table 2). Prevalence of dactylitis was higher in the FOREMOST-eligible group, whereas prevalence of enthesitis was higher in the remainder of the PsA registry population.

Conclusion: In the Corrona PsA/SpA Registry, pts with early oligoarticular PsA based on approximating FOREMOST trial criteria were the minority of the enrolled pts. Descriptive statistics of this small but understudied population indicated a higher burden of patient-reported pain and PhGA of PsA compared with the remainder of the PsA registry population, suggesting there is unmet need in this population.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

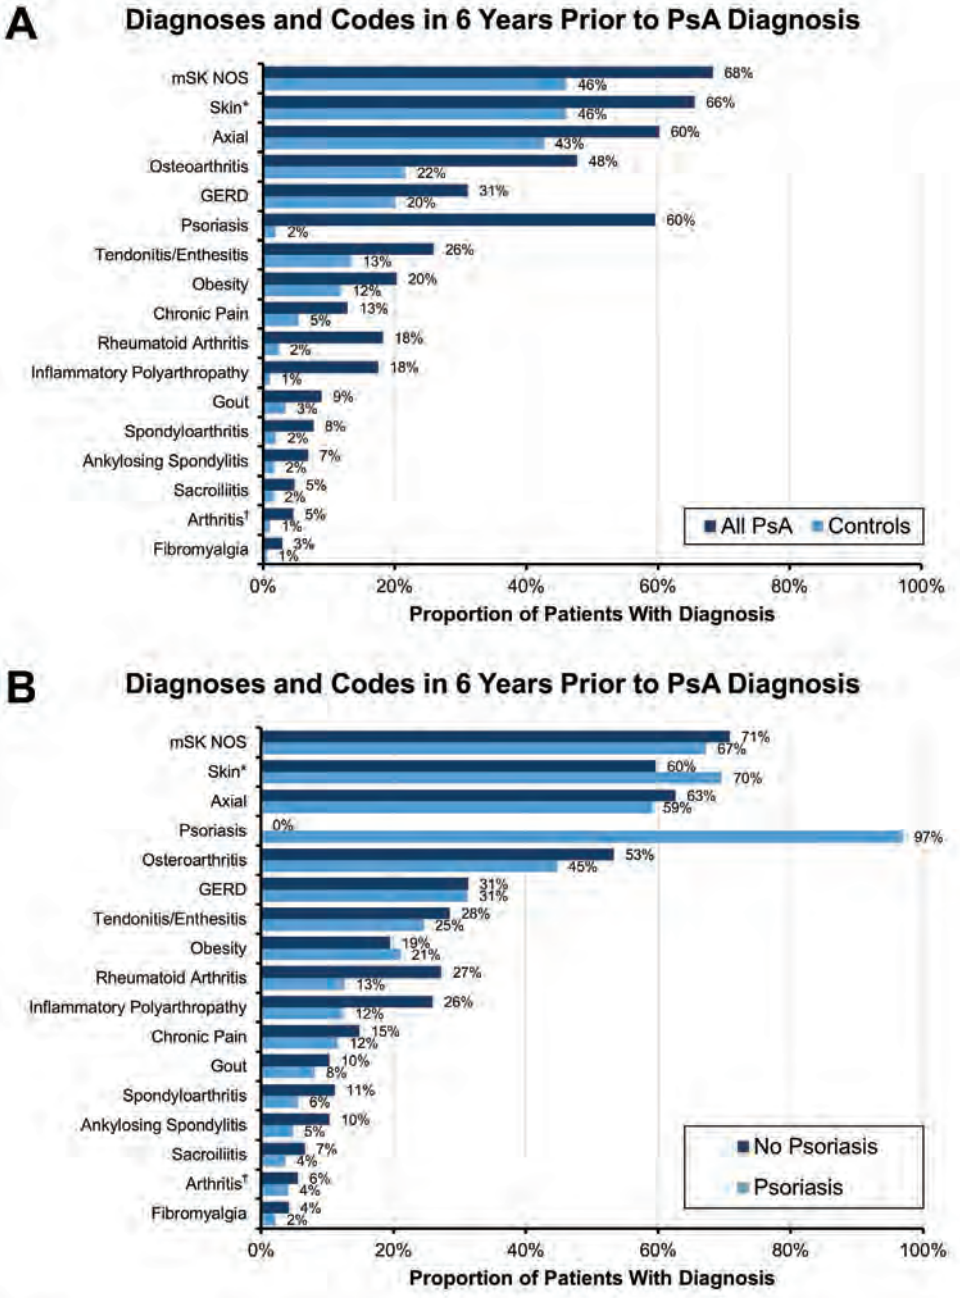
Background/Purpose: In developing algorithms within claims databases that may inform how to find patients with psoriatic arthritis (PsA) prior to diagnosis, it is important to identify meaningful potential predictors that appear prior to diagnosis. This study aims to better understand PsA patient pathways by examining the sequences of health events over the 6 years prior to PsA diagnosis, as well as differences in patients with and without PsA.

Methods: This retrospective cohort study used administrative claims data from patients in the Truven Health MarketScan® Commercial and Medicare Supplemental Databases from January 2006 to April 2019. The PsA population included all patients aged ≥ 18 years with ≥ 2 diagnoses of PsA (ICD-9-CM/ICD-10-CM) ≥ 30 days apart who had ≥ 6 years of continuous enrollment prior to first PsA diagnosis. Control (non-PsA) patients were matched 2:1 to patients with PsA by age, sex, geographic location, insurance, and enrollment duration. Sequences of health events as described by diagnosis codes, procedures performed, drugs prescribed, and physician types were examined over the 6 years prior to PsA diagnosis and for controls; results were also stratified by psoriasis vs no psoriasis prior to PsA diagnosis.

Results: Among 13,661 patients who met the inclusion criteria for diagnosis of PsA, the mean age was 55.8 years and 60.2% were women. Compared with controls, patients with PsA had an increased history of coding for arthritis and skin issues including osteoarthritis (OA; 48% vs 22%), rheumatoid arthritis (RA; 18% vs 2%), inflammatory polyarthropathy (IA; 18% vs 1%), and psoriasis (60% vs 2%) (**Figure 1A**). PsA patients without a prior diagnosis of psoriasis had higher levels of coding for other forms of arthritis compared to PsA patients with psoriasis including OA (53% vs 45%), RA (27% vs 13%), and IA (26% vs 12%) (**Figure 1B**). For many patients, diagnoses of different types of arthritis, axial symptoms, and tendonitis/enthesitis steadily increased over time prior to their PsA diagnosis (**Figure 2A**). In particular, there was a sharp rise in psoriasis diagnoses preceding the diagnosis of PsA and smaller increases in diagnoses of OA and IA prior to PsA diagnosis. Rheumatology visits were much more common just before the diagnosis of PsA (**Figure 2B**). Diagnoses made prior to diagnosis of PsA differed by the type of provider patients seen. Dermatologists were less likely than other providers to enter codes for arthritis and musculoskeletal issues, while rheumatologists were unlikely to code for psoriasis but had a fairly even distribution across different types of arthritis. General practitioners focused more on axial symptoms and general musculoskeletal codes than arthritis diagnoses (**Figure 3A**). PsA was most commonly diagnosed by rheumatologists (40%) but was diagnosed in 22% and 7% of cases by general practitioners and dermatologists, respectively (**Figure 3B**).

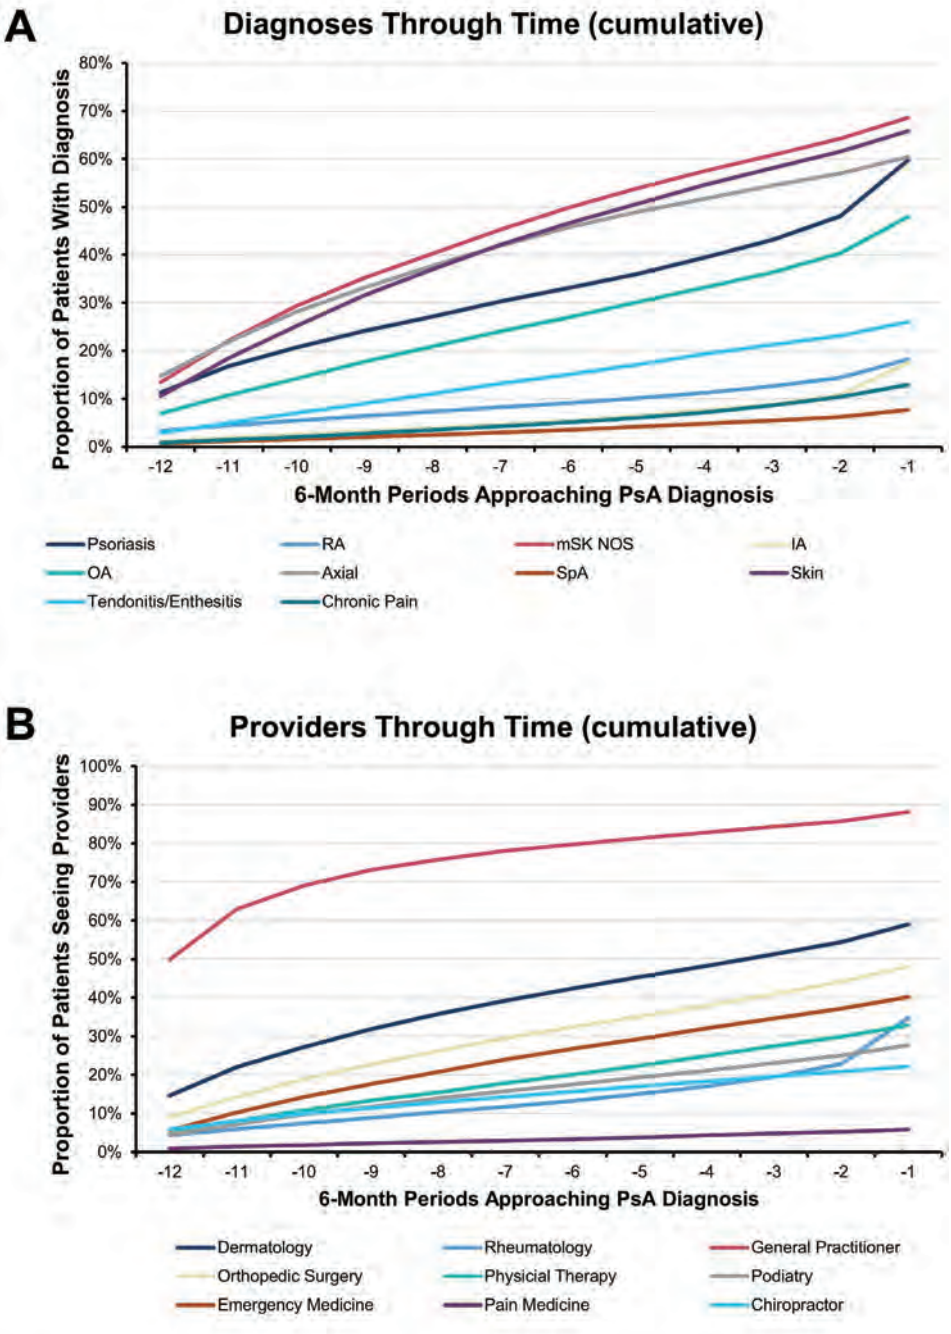
Conclusion: Rheumatologists, general practitioners, and dermatologists were responsible for diagnosing two-thirds of patients with PsA. Musculoskeletal symptoms and potential misdiagnoses are common in the years preceding diagnosis of PsA and the diagnoses and codes entered prior to PsA diagnosis varied by provider type.

Figure 1. Diagnoses and Codes in 6 Years Prior to PsA Diagnosis Among **(A)** Patients With PsA vs Controls **(B)** PsA Patients With Prior vs No Prior Psoriasis Diagnosis



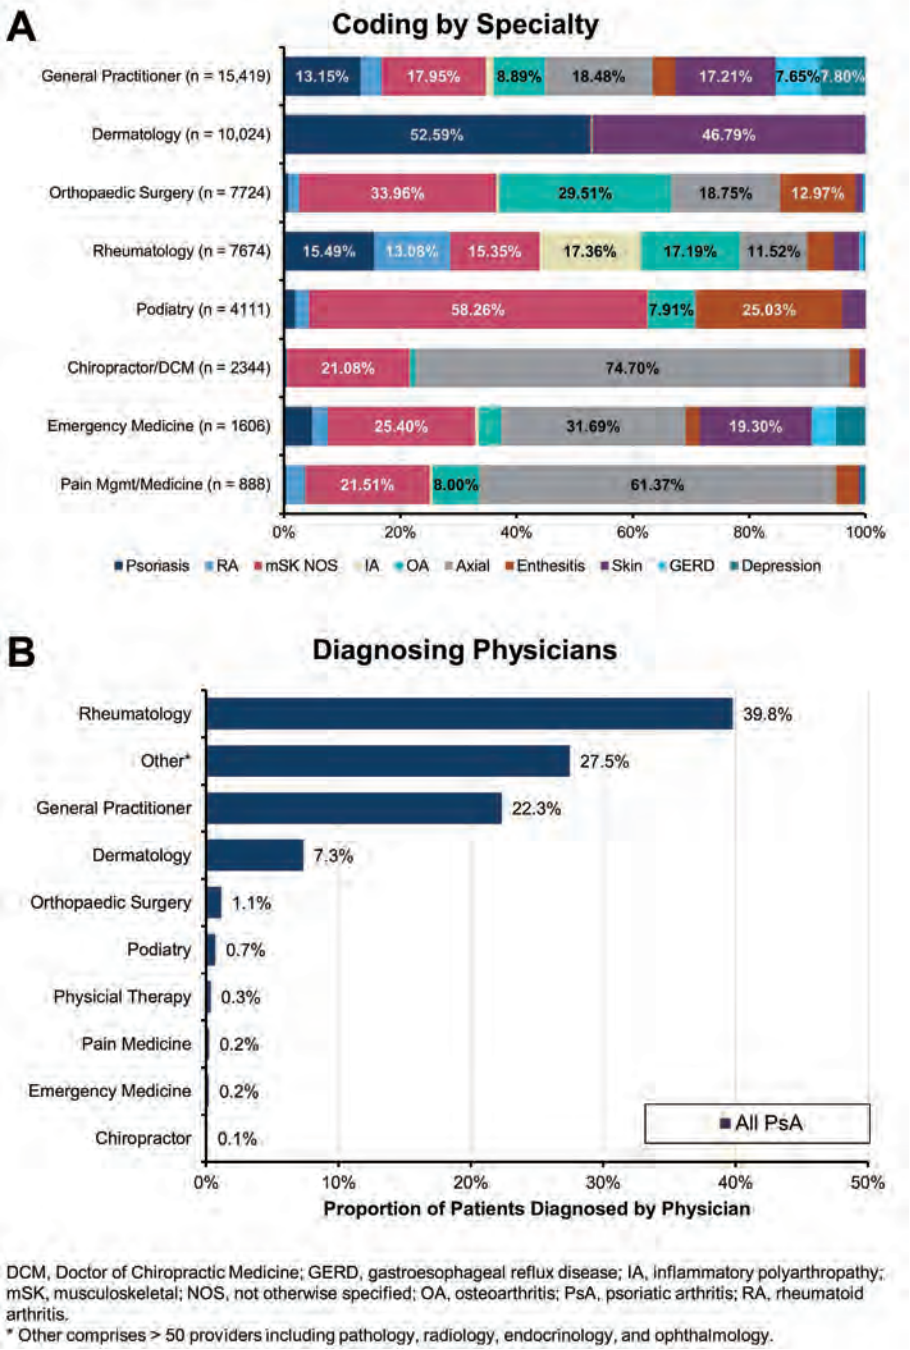
GERD, gastroesophageal reflux disease; mSK, musculoskeletal; NOS, not otherwise specified; PsA, psoriatic arthritis.
* Skin comprises 43 codes including various forms of dermatitis, rash, acne, and keratosis.
† Arthritis codes include chronic postrheumatic arthropathy (714.4); synovitis and tenosynovitis, unspecified (727.00); synovitis and tenosynovitis in diseases classified elsewhere (727.01); and secondary multiple arthritis (M153).

Figure 2. Cumulative Patient Journey Through Different **(A)** Diagnoses and **(B)** Providers in the 6 Years Prior to PsA Diagnosis



IA, inflammatory polyarthropathy; OA, osteoarthritis; PsA, psoriatic arthritis; RA, rheumatoid arthritis; SpA, spondyloarthritis.

Figure 3. (A) Coding Patterns by Specialty—Relative Fraction of Codes Given out by Each Specialty in the 6 Years Prior to PsA Diagnosis and **(B)** the Fraction of PsA Diagnosing Physicians



DCM, Doctor of Chiropractic Medicine; GERD, gastroesophageal reflux disease; IA, inflammatory polyarthropathy; mSK, musculoskeletal; NOS, not otherwise specified; OA, osteoarthritis; PsA, psoriatic arthritis; RA, rheumatoid arthritis.
* Other comprises > 50 providers including pathology, radiology, endocrinology, and ophthalmology.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease which may precede, occur concurrently or after the development of psoriasis. In order to better understand the natural history of the disease we aimed to identify demographic and clinical characteristics associated with delay in transition from psoriasis to PsA.

Methods: A retrospective, population-based cohort of incident PsA patients ≥18 years of age from a geographically-defined area meeting ClASsification of Psoriatic ARthritis (CASPAR) criteria for PsA (2000-17) was identified. Onset of psoriasis was defined as confirmatory diagnosis of psoriasis by a dermatologist or rheumatologist. Date of fulfillment of CASPAR criteria was considered as the time of onset of PsA. PsA patients were divided into two groups: patients with concurrent psoriasis and PsA (within one year of each other) and patients with psoriasis onset before PsA (>1 year). Those patients with psoriasis development after PsA onset (>1 year) or only family history of psoriasis were excluded. Logistic regression models adjusted for age and sex were performed to identify factors associated with delay in transition from psoriasis to PsA.

Results: There were 157 incident cases of PsA, mean age at diagnosis was 46.3 (SD=12.0) years and 46% were females. Median lag time from psoriasis onset to PsA was 263 days (interquartile range=0, 2889). 51% (n=80) of patients had concurrent psoriasis and PsA while 49% (n=77) had onset of psoriasis before PsA (Table 1). Family history of psoriasis (OR= 2.71, 95% CI 1.24 - 5.90) and psoriasis severity (OR=1.96, 95% CI 1.26 -3.06) were more likely in those who had a delay in transition from psoriasis to PsA than those who had a concomitant diagnosis (Table 2). There were no statistically significant differences in demographic features, or any of the other psoriasis or PsA related factors between the 2 groups. Similarly, no difference in radiographic outcome was noted for the 2 groups.

Conclusion: In this population-based study, approximately half of the patients had psoriasis onset before PsA, and the other half had concurrent psoriasis and PsA. Patients with a family history of psoriasis and severe psoriasis were more likely to have a delay in transition from psoriasis to PsA. Whether this difference is secondary to earlier detection of psoriasis in patients with a family history of psoriasis and severe psoriasis or a true phenotypic difference will require further studies.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of psoriatic arthritis (PsA) is important for improving long-term outcomes. Trends in diagnostic delay of PsA in the US and factors associated with delay in diagnosis have not been well studied. The aim of our study was to 1) examine the diagnostic delay in PsA in residents of a geographically defined area from 2000-17, and 2) identify demographic and clinical characteristics associated with diagnostic delay in PsA.

Methods: A retrospective, population-based cohort of incident PsA patients ≥18 years of age from a geographically defined area meeting CIASsification of Psoriatic ARthritis (CASPAR) criteria for PsA (2000-17) was identified. Disease onset was taken as onset of any PsA related joint symptom as reported by the patient and documented by a physician in the medical records. PsA diagnosis date was the date of confirmatory diagnosis of PsA by a physician/rheumatologist. Diagnostic delay was defined as the time from disease onset to a diagnosis of PsA. Logistic regression models adjusted for age and sex were performed to identify factors associated with delay in PsA diagnosis.

Results: There were 162 incident PsA cases from 2000-17. Mean age was 41.5 (SD=12.6) and 46% were females. Median lag time from disease onset (PsA related joint symptoms) to first confirmatory diagnosis by a physician was 2.5 years (interquartile range=0.5, 7.3). At six months 23% (n=38) of the cohort received a confirmatory diagnosis of PsA, 35% (n=56) at one year and 45% (n=73) at two years of symptom onset respectively. No significant trend in diagnostic delay were observed. PsA patients with younger age at diagnosis, higher body mass index (BMI), and enthesitis before diagnosis, were associated with a diagnostic delay of greater than one and two years, while sebopsoriasis at diagnosis was associated with a lower likelihood of delay (Table 1). No significant association with sex, education level, smoking status, alcohol intake, psoriasis severity or location, nail involvement, family history of psoriasis or PsA, history of extra-articular manifestations (i.e., uveitis, inflammatory bowel disease), or high inflammatory markers at the time of diagnosis was found. Logistic regression models adjusted for age and sex showed a higher likelihood of radiographic damage at PsA diagnosis with a delay in diagnosis of six months, one year and two years, however these associations did not reach statistical significance (Table 2).

Conclusion: In this population-based study, more than half of PsA patients had a delay in diagnosis two or more years, and no significant improvement in time to diagnosis was noted from 2000-17. Patients with younger age at diagnosis, higher BMI, or enthesitis before diagnosis were more likely to have a diagnostic delay of more than two years while patients with sebopsoriasis were less likely to have a diagnostic delay. Radiographic damage may be associated with diagnostic delay, but this association did not reach statistical significance, perhaps due to the limited sample size of the cohort.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: A simple, scalable tool that identifies psoriasis patients at high risk for developing PsA could improve early detection and facilitate early intervention. Our overall objective is to develop an accurate risk prediction model for the development of PsA in patients with psoriasis. This analysis focused on clinical predictors.

Methods: In this longitudinal cohort study we analyzed data from the *International Psoriasis and Arthritis Team (IP-ART) study,* a prospective cohort of psoriasis patients without PsA at the time of enrollment. The participants have been followed prospectively and their PsA status has been assessed annually by a rheumatologist. Information about their demographics, psoriasis characteristics, co-morbidities and musculoskeletal symptoms, was used to develop prediction models for PsA. Serial logistic regression models were fitted with a defined set of time-varying covariates in order to identify the optimal combination of covariates to construct risk prediction models. Prediction models were

*Adjusted for psoriasis duration N=635; 71 events			

Figure 2 The Risk of Developing PsA within 5 years – Cox Proportional Hazards Model

set to estimate the risk of developing PsA over 1 and 5 years respectively. Each model was adjusted for psoriasis duration. Model selection was based on backward elimination approach ($p< 0.10$). Receiver operating characteristics curves were plotted and the predictive performance was summarized by the area under the curve (AUC).

Results: A total of 635 psoriasis patients, followed from 2016 to 2020, were analyzed (mean duration of follow up 7.7 years). 75 patients developed PsA during the study period. Univariate analysis identified various candidate predictors of PsA including the severity of musculoskeletal symptoms, psoriatic nail lesions, iritis, psoriasis type, location and severity and the use of non-biologic systemic medications or phototherapy (Table 1). The risk of developing PsA within 1 year was predicted by younger age, patient global health and pain severity (AUC 76.8, 95% confidence interval (CI) 68.5, 85.1, Figure 2). The risk of developing PsA within 5 years was predicted by psoriatic nail lesion, health as-

sessment questionnaire disability index (HAQ-DI), Functional Assessment of Chronic Illness Therapy (FACIT) fatigue scale and use of systemic non-biologic medication or phototherapy (AUC 71.9, 95% CI 65.2, 78.6, Figure 3).

Conclusion: The development of PsA within clinically meaningful time frames can be predicted with reasonable accuracy for psoriasis patients. Additional work is underway to optimize the current models and validate them in external cohorts of psoriasis patients.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study is to explore the link between the severity of the joint and entheses involvement in psoriatic arthritis (PsA) using musculoskeletal ultrasound (US).

Methods: PsA patients from 2 centers in the Psoriatic Arthritis- International Database (PsArt-ID) (n=126) underwent an ultrasound assessment of 46 joints and 12 large entheses. The correlation between joint and enthesitis scores on the US was analyzed in addition to the clinical indices versus the US.

Results: Fifty-six of the 126 patients (44.4%) were male and the mean (SD) age was 54.8 (14.6) years. The mean PsA duration was 7.6 (8.3) years. Greyscale (GS) synovitis score for the joints was moderately correlated with the total enthesitis score ($r=0.410$, $p< 0.001$) (Table). The Global Outcome Measure in Rheumatology in Clinical Trials-European League Against Rheumatism Synovitis Score (GLOESS) score was also found in correlation with the total enthesitis score ($r=0.400$, $p< 0.001$) (Table). The link between the US and clinical examination findings only showed a poor correlation between swollen joint counts (SJC) and joint-US scores ($r=0.298$, $p=0.001$ for GLOESS). Assessment of the entheses on US showed a poor-moderate correlation between the entheseal damage scores and tender joint counts

	Total Enthesitis Score (A+B)	0.410	**<0.001**	0.101	0.264	0.400	**<0.001**

GS: Gray Scale, PD: Power Doppler, GLOESS: Global omeract/eular ultrasound synovitis score,

Inflammation score= Hypoechogenecity+Thickness+Power Doppler Score (0-108)

Damage Score= Calcification+Erosion+Enthesophyte (0-108)

(TJC) (r=0.217, p= 0.018) and SJC (r=0.326, p= p< 0.001). In terms of the clinical examination and activity parameters, none of the clinical parameters and acute phase reactants were correlated to Leeds Enthesitis Index.

Conclusion: Our study showed a link between the severity of the sonographic findings in the joints and the entheses. The link between these two anatomical structures supports the synovio-entheseal complex theory.

Dactylitis Is Associated with Greater Disease Severity, Ultrasound Synovitis, and Erosive Damage, in Very Early DMARD Naïve Psoriatic Arthritis

Sayam Dubash[1], Oras Alabas[2], Xabier Michelena[2], Gabriele De Marco[3], Leticia Garcia-Montoya[2], Richard Wakefield[2], Ai Lyn Tan[2], Philip Helliwell[4], Paul Emery[5], Dennis McGonagle[2] and Helena Marzo-Ortega[2], [1]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, England, United Kingdom, [2]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom, [3]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Treviglio, Italy, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Dactylitis is a hallmark feature of Psoriatic arthritis (PsA), defined as a uniform swelling of a finger or toe ("sausage digit"). It is associated with radiographic damage in chronic PsA. However, there are paucity of data on its characterisation, phenotypical significance, and disease burden in very early PsA. The objective of this study was to characterise a very early DMARD naïve PsA cohort based on the clinical presence or absence of dactylitis.

Methods: Very early PsA patients fulfilling CASPAR criteria were recruited into a prospective observational study; the Leeds Spondyloarthritis Register for Research and Observation (SpARRO). The cohort was evaluated based on presence/absence of dactylitis. Dactylitis was recorded per digit as tender ("hot") or non-tender ("cold"). Statistical differences between mean, medians, and proportions were calculated using student's t-test, quantile regression, one-sample tests, and Pearson Chi-squared test. Ultrasonography (US) of joints was conducted by trained sonog-

Table 1. Baseline characteristics of the PsA cohort by the presence or absence of dactylitis.

Variables	PsA without dactylitis (n=96)	PsA with dactylitis (n=81)	Mean/median difference
Age, mean (SD), years	44.4 (12.8)	43.7 (13.3)	0.7 (-3.2 to 4.5)
Male	38 (39.6%)	42 (51.9%)	-12.3 (-34.0 to 9.4)

*p<0.05, **p<0.01, ***p<0.001.			

Table 2 Significantly greater synovitis and erosions in ultrasound scanned joints in PsA with dactylitis compared to PsA without dactylitis.

US	No dactylitis (n=86/155)	Dactylitis (n=69/155)	Mean difference/ Pearson Chi-squared test	P value
GS≥2	551/3422 (16.1%)	642/2721 (23.6%)	-7.5 (-12.0 to -3.0)	<0.001
PD≥1	114/3422 (3.3%)	198/2721 (7.3%)	-4.0 (-8.8 to 0.9)	<0.001
GS≥2 & PD>1	89/3422 (2.6%)	171/2721 (6.3%)	-3.7 (-4.7 to -2.6)	<0.001
Total number of US erosions	15/3206 (0.5%)	33/2557 (1.3%)	-0.8 (-1.3 to -0.3),	<0.001
Patients with US erosions	11/86 (12.8%)	22/69 (32.9%)	Pearson Chi-squared test=8.3	p=0.004

raphers blinded to clinical details. Synovitis was graded for grayscale (GS) and power Doppler (PD) using the semi-quantitative method (0-3) at 48 joints: wrists, MCP1-5, PIP1-5, DIP2-5, MTP1-5, knees, ankles, subtalar and talonavicular joints. Bone erosions were determined by US if cortical bone discontinuity was present in two perpendicular planes (longitudinal/transverse).

Results: A total of 177 patients were recruited. Dactylitis patients recorded significantly higher median difference in TJC ($p< 0.01$), SJC ($p< 0.001$), and CRP ($p< 0.01$) compared to PsA without dactylitis. Table 1 outlines the characteristics of the cohort. Dactylitis was present in 81/177 (46%) patients and 214 digits. Multiple digits (>1) were involved in 51/81 (63%) patients, asymmetrical in 52/81 (64%). Dactylitis was more prevalent in toes (146/214; 68.2%) than fingers (68/214; 31.8%). “Hot” dactylitis was more prevalent (179/214; 83.6%) than “cold” dactylitis (35/214; 16.4%). The most frequent sites for “hot” dactylitis were 2nd finger (23/179; 12.8%), 4th toe (40/179; 22.3%) and for “cold” dactylitis, 3rd finger (2/35; 8.5%), 4th toe (10/35; 28.5%). Significantly greater US synovitis was identified in PsA with dactylitis ($p< 0.001$) determined by either GS≥2, PD≥1, or GS≥2+PD≥1 as shown in table 2. Ultrasound defined erosions were also significantly greater in joints of patients with dactylitis ($p< 0.001$) overall and were identified in significantly more patients with dactylitis compared to patients without dactylitis [22/69 (31.9%) versus 11/86 (12.8%) patients; p=0.004] (table 2). Sites most prone to erosive damage were MCP2 (9/33, 27.3%), MTP5 (11/33, 33.3%).

Conclusion: This study identifies dactylitis as a clinical indicator for an aggressive phenotype with significantly greater TJC, SJC, CRP, US synovitis and US defined erosions in very early DMARD naïve PsA, compared with PsA without dactylitis. Longitudinal follow-up will determine if dactylitis represents poor prognosis at this very early disease stage. Dactylitis may be a useful discriminator for risk stratification in future PsA management strategies and clinical trials.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

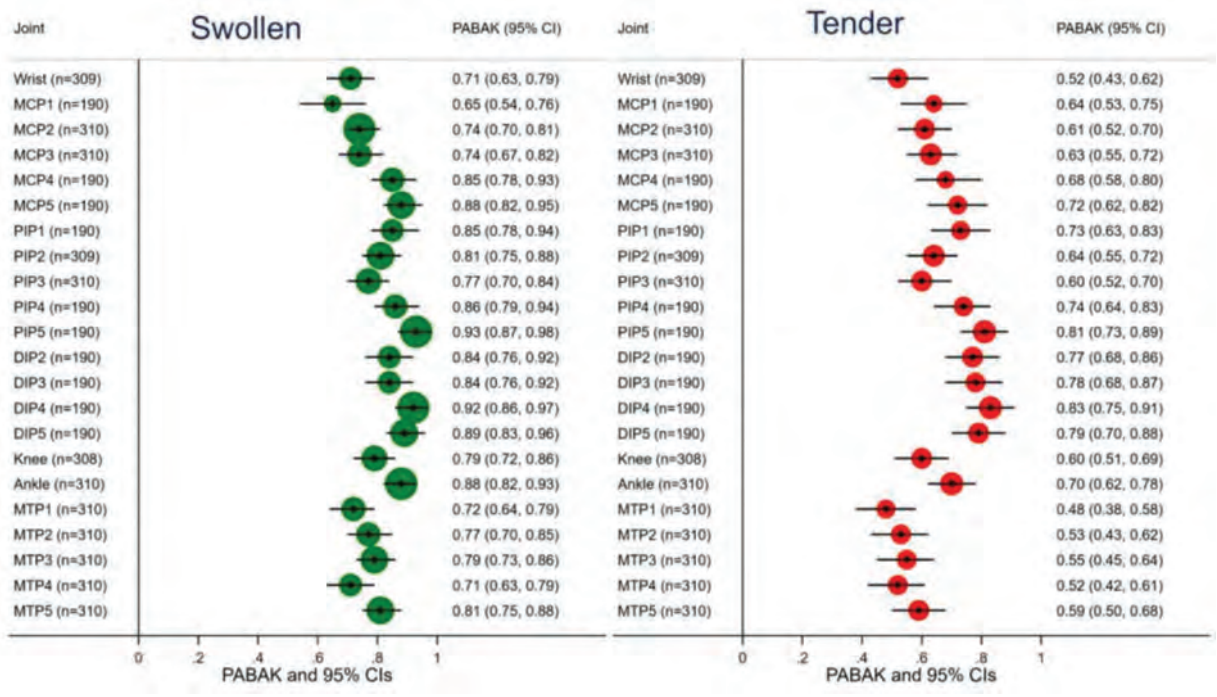

Figure 1. Percentage agreement (%) and adjusted kappa (PABAK) with 95% CIs between tender/swollen joints and ultrasound power Doppler Synovitis per joint.

Background/Purpose: Clinical tender and swollen joint counts are used for biologic drug eligibility and clinical trial inclusion criteria. Ultrasonography (US) adds to clinical examination as it is a sensitive imaging modality in the assessment of inflammatory arthritis, yet its relationship with tender and swollen joints is not fully understood. The objective of this study was to explore the relationship between clinical examination and US determined synovitis in very early, DMARD naïve psoriatic arthritis (PsA).

Table 1. Individual joint level correlation (rho) between tender non-swollen joints versus tender and swollen joints. Lack of correlation was determined by the absence of swelling.

*p<0.05, **p<0.01, ***p<0.001

Methods: Eligible PsA patients determined by CASPAR criteria underwent matched clinical and US joint assessments (44 joints). Disease activity per joint was determined by tender/swollen joints (TJ/SJ) and US synovitis defined by power Doppler (PD) ≥1. Agreement between TJ/SJ and PD≥1 was conducted at the individual joint level and patient level (TJC/SJC). Statistical agreement between clinical and US assessments was calculated using prevalence-adjusted and bias-adjusted kappa (PABAK), and the association was determined using the Spearman's rank test (rho/ρ).

Results: A total of 5,616 joints were assessed using US in 155 patients [median disease duration (interquartile range (IQR)) 1.1 months (0-3.0) from diagnosis; median symptom duration (IQR) 12 months (7-30)]. Grayscale (GS) was identified in 2273/5616 (40.4%) and PD≥1 in 292/5616 (5.2%) joints. Agreement between SJ and PD was very high at the individual joint level (82.6 - 96.3%, PABAK 0.65- 0.93) and patient level (SJ and PD≥1: 89.9%, PABAK 0.80), as per figure 1. Joints that were tender and swollen (T+ S+) demonstrated weak/moderate correlation (r=0.28, p< 0.001) with PD≥1 synovitis at the patient and individual levels. However, tender joints in the absence of swelling (T+ S-) did not correlate with PD synovitis (r=0.01) at the patient level, with negligible correlation at individual joint level (table 1).

Conclusion: In very early, DMARD naïve PsA, clinically swollen joints are associated with PD synovitis, but tender, non-swollen joints are not. Further understanding of the aetio-pathology of joint tenderness may disentangle its complex relationship in early PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study to explore the comparison of physical examination (PE) and ultrasound (US) detected synovial and extra-synovial pathologies of the hands in psoriatic arthritis (PsA).

Methods: Twenty-nine PsA patients who had hand pain included the study. A detailed PE was performed to differentiate pain due to joint, tendon, and entheseal disease. At the same visit US scans of MCP (Metacarpophalangeal), PIP (Proximal Interphalangeal), DIP (Distal Interphalangeal) joints (total 696 joints), extensor and flexor tendons (464)

Table. Agreement of Physical Examination and Ultrasound in Joints, Enthesis and Tendons

US: Ultrasound, PABAK: Prevalence Adjusted and Bias Adjusted Kappa, PE: Physical Examination
MCP: Metacarpophalangeal, PIP: Proximal Interphalangeal, DIP: Distal Interphalangeal
EE: Extensor Enthesis, FF: Flexor Enthesis, ET: Extensor Tendon, FT: Flexor Tendon
*Results are only given for the insertions of the tendons to the basis of distal phalanx.

and enthesis (696) of 2nd to 5th fingers of both hands were done by an investigator blinded to the clinical assessment. The agreement between PE and US findings was calculated with Kappa and Prevalence Adjusted and Bias Adjusted Kappa (PABAK).

Results: Fifteen of the patients were male, the mean age was 54.8 (8.4) and the mean PsA duration was 15.3 (10) years. Tender joint count was detected highest in MCP joints [n=122 (52.5%)] in 27 (93%) patients and swollen joint count was highest in PIP joints [n=79 (34%)] in 23 (79%) patients. Power Doppler (PD) positivity rate was similar in MCP (n=15, 6.5% of the joints; 7/29, 24% of the patients) and PIP joints (n=16, 7% of the joints; 8/29, 27.5 %) of the patients), but Gray Scale (GS) positivity was found highest in MCP joints [n=89, (38.4%)] and in 24 (83%) patients. Overall DIP joints had low GS and PD positivity rates (1.3% and 0.9%, respectively). Strongest agreement for joints was between "swollen joints", "tender and swollen joints" and PD in the MCP joints and GS in the PIP joints (Table). The agreement of tender entheses on PE and inflammation on US (hypoechogenicity, thickening and/or PD signals) was poor for both extensor (Kappa= -0.027 PABAK= 0.344) and flexor compartments (Kappa= 0.039 PABAK= 0.569). Similar to enthesitis, for the tendons, comparison of any PE and US findings showed a poor agreement at the extensor and flexor regions (extensor: Kappa= 0.123, PABAK= 0.448 and flexor: Kappa= 0.171, PABAK= 0.431).

Conclusion: Our study showed that there is a poor to fair agreement of PE and US findings of hands, for the joints, tendons, and entheses which may all be involved in PsA. US can add value when determining the source of pain in PsA in the small joints.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of fibromyalgia (FMS) in psoriatic arthritis (PsA) patients increases the scores of the clinical measures of disease activity.

The aim of this study is to examine whether ultrasound (US) can be used in the evaluation of disease activity in PsA patients with concomittant FMS as an objective tool that is not influenced by the presence of FMS

Methods: The study population included consecutive PsA patients that were recruited prospectively and fulfilled the CASPAR criteria. The assessment of the patients included, complete medical history and physical examination including assessment of joints (66/68 joint count), enthesitis (LEEDS and SPARCC), and fibromyalgia tender points. All the patients were assessed by the widespread pain index (WPI) and symptom severity score (SSS) for fibromyalgia criteria. Patients were classified with FMS if they fulfilled the 2016 fibromyalgia classification criteria. All the patients underwent a detailed US evaluation (gray scale and Doppler) including 52 joints, 40 tendons and 14 points of en-

*<0.01, GS – Gray scale, PD – Power Doppler

theses (according to MASES index plus lateral epicondyles). The score of the US was based on the summation of a semi-quantitative score (0-3) for synovitis (based on the EULAR-OMERACT definition), tenosynovitis, and enthesitis score. All the evaluations occurred in the same day and the sonographer was blinded to the clinical data.

Results: 156 patients completed the study. Overall 7540 joints, 5800 tendons and 2030 entheses were scanned by the US. 42 patients (26.9%) classified with both PsA and FMS were compared to 114 (73.1%) PsA patients without FMS. Patients with PsA and FMS had significantly increased scores for almost all the clinical measures, including non-MDA (97.6% vs. 54.4%, p< 0.001), mean CPDAI (11.6 vs. 6.8, p< 0.001), mean DAPSA (35.1 vs. 15.9, p< 0.001) and mean PASDAS (5.8 VS. 2.7, P< 0.001). On the other hand, the total US score and its' subcategories (US synovitis, tenosynovitis and enthesitis) did not demonstrate significant differences between those with to those without FMS (Table 1). The US score significantly correlated with each clinical score (CPDAI, DAPSA and PASDAS, p< 0.01) in the PsA without FMS but not in the PsA and FMS group (Table 2). Furthermore, these correlations were significantly

Table 3. Multivariable linear regression model for association with clinical scores (DAPSA, CPDAI, PASDAS) & Total US score

Table 3: Multivariable linear regression model for association with clinical scores (DAPSA, CPDAI, PASDAS) & Total US score

Variables	DAPSA Regression coefficient	P-value	CPDAI Regression coefficient	P-value	PASDAS Regression coefficient	P-value	US Score Regression coefficient	P-value
Age	0.06	0.37	0.01	0.57	0.07	0.50	0.36	0.005
Gender	-0.52	0.78	0.68	0.20	0.05	0.86	2.4	0.44
BMI	0.39	0.03	0.08	0.11	0.04	0.09	0.24	0.41
Psoriasis duration	0.01	0.83	0.03	0.11	0.001	0.87	0.18	0.11
Fibromyalgia presence	17.6	<0.001	4.42	<0.001	2.93	<0.001	-3.5	0.31
PASI	0.09	0.7	0.11	0.11	0.05	0.16	0.04	0.9
CRP	1.77	0.02	0.13	0.55	0.19	0.09	5.14	<0.001
SJC	2.42	<0.001	0.38	<0.001	0.31	<0.001	3.4	<0.001

BMI – Body Mass Index, SJC – Swollen Joint Count

higher for the CPDAI and PASDAS in the PsA without FMS compared to PsA with FMS ($p< 0.05$). Multivariable linear regression model showed that FMS was significantly associated with higher clinical scores ($p< 0.001$) but not with the US score (Table 3).

Conclusion: Patients with PsA and FMS had increased scores of clinical measures compared to those without FMS. US scores were similar between the groups, independently of the presence of FMS**.** Hence, US has a significant additional value over composite clinical scores in the assessment of disease activity in PsA patients with fibromyalgia.

High-sensitivity ^{18}F-FDG PET/CT: A Diagnostic Tool for Psoriatic Arthritis

Siba Raychaudhuri[1], Yasser Abdelhafez[2], Soumajyoti Sarkar[3], Smriti Raychaudhuri[4] and Abhijit Chaudhari[2], [1]Division of Rheumatology, Allergy & Clinical Immunology, University of California School of Medicine, Davis, and VA Medical Center Sacramento, Sacramento, CA, [2]University of California, Davis, Sacramento, CA, [3]University of California, Davis, Davis, [4]VA Sacramento Medical Center, Davis, CA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To validate high-sensitivity PET/CT as a diagnostic test we have explored the association of total-body and extremity PET/CT measures with the standardized psoriatic arthritis (PsA) outcome measures (DAPSA, Leeds Enthesitis Index, etc). The *objective of our study* is to determine the association of *in vivo* PET/CT measures, and use these data to create a catalog of systemic PsA musculoskeletal pathologies and compare with that of RA and OA.

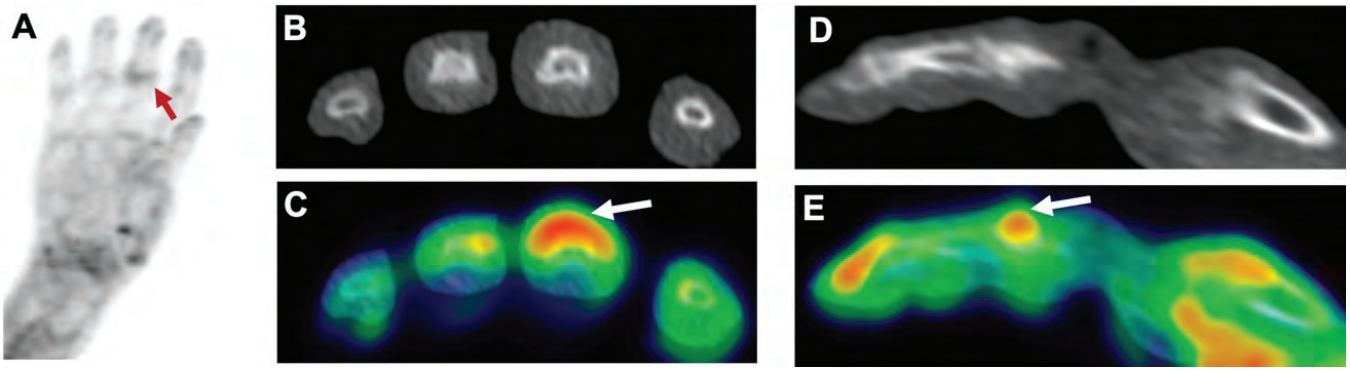

Figure 1. Enthesitis on PET/CT in PsA: Extensor digitorum tendon uptake at the central slip, showing enthesitis; (A) Maximum-intensity projection through the PET scan of the right hand of a participant with PsA showing entheseal uptake at the third PIP joint; axial (B) and sagittal (D) sections through the CT scan of the third PIP joint (grayscale); and axial (C) and sagittal (E) section from the overlay of PET (color) on CT (grayscale).

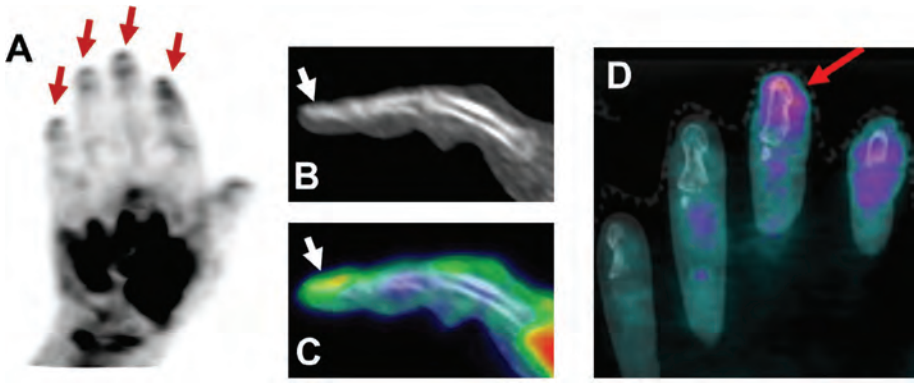

Figure 2. Nail matrix involvement in PsA: (A) Maximum-intensity projection through the PET scan of the left hand of a participant with PsA showing nail involvement; sagittal (B) CT and (C) PET/CT (PET in color, CT in grayscale) of the second digit showing nail bed inflammation. (D) shows nail bed involvement in a participant with PsA from our previous study for comparison.

Methods: Patients with RA, PsA or OA were enrolled in IRB-approved studies. All subjects underwent a single-time-point PET/CT scan on either the total body uEXPLORER scanner or the UC Davis extremity PET/CT scanner for 20 minutes starting at either 40 or 70 minutes after IV injection of ^{18}F-FDG (~1/4th of the conventional dose). Qualitative findings and different patterns for the three conditions were evaluated. We quantified the degree of inflammation in the extremities and whole-body, respectively and determine pathologic predilection for anatomical domains of bones/ligaments of hands in PsA, RA and OA.

Results: Here we will share data from recruited 20 patients, all males, with RA (n=7; median age: 67 years), PsA (n=10; median age: 68 years), OA (n=3; median age: 60 years). The RA patients had symmetric joint involvement, most commonly in the hands/knees. The following sites were involved: radio-and/or ulno-carpal compartments (n=5), MCP (n=4), PIP (n=5) joints. Joints of the feet appeared to be less frequently affected. All PsA patients demonstrated multiple sites of enthesitis (n=10/10), affected the tendons of the hands/fingers and seemed more active on the extensor side (n=5). Increased nail matrix/fingernail FDG uptake was observed to be a distinct feature (n=8/10). Several large joints showed positive findings in all patients. Less frequent features included sausage finger (n=2), plantar fasciitis (n=3); sacroiliac joint (n=2). Involvement of the interspinous ligament (n=2) and facet joints (n=2) was also noted. Patients with OA showed unilateral enhanced FDG uptake at least one big joint (shoulder, n=3; elbow, n=1; knee, n=2), and small joints of the hand/feet (1st CMC/1st MTP).

Conclusion:

1. Asymmetric synovitis of small joints of hands/feet, enthesitis, nail matrix inflammation, dactylitis and spondylitis stands out to be pathologic features for PsA.
2. There appeared to be an overall concurrence between degree of inflammation by imaging and clinical outcome measures of PsA such as DAPSA and Leeds Enthesitis Index.
3. We expect at the completion of this study these clinico-radiologic domains will provide for unique quantitative diagnostic imaging biomarkers for PsA and a single PET imaging scan will be able to differentiate from other inflammatory/non-inflammatory conditions like RA and OA.

Axial Involvement in Psoriatic Arthritis in a Comprehensive Rapid Diagnosis Program (Reuma-check PsA). Analysis of Its Characteristics

Rodrigo Garcia Salinas[1], Santiago Ruta[2], Jessica Torres Chichande[1], Einer Sanchez Prado[1], Facundo Salvatori[1] and Sebastian Magri[1], [1]Hospital Italiano La Plata, La Plata, Argentina, [2]Hospital Italiano La Plata, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To date, there is no consensus that allows an appropriate definition of axial involvement in PsA, that ranges between 25 to 70%. To estimate the prevalence of axial involvement in patients with newly diagnosed PsA and to describe their characteristics and differences.

Methods: An observational study included patients older than 18 who entered the fast track evaluation program (Reuma-check APS) according to the following criteria: arthritis, dactylitis or enthesitis, associated with psoriasis. Those admitted to the circuit underwent: blood test (VSG and PCR), x-ray and joint and enthesis ultrasound. Socio-demographic data, level of education and habits, DAPSA and HAQ were also recorded. If the patient reported axial symptom was re-entered into an "axial" circuit to collect: date and age of onset, characteristic of low back pain, received NSAIDs and response, VAS of pain, morning stiffness, x-ray and MRI of the sacroiliac, HLA B27, BASDAI and BASFI. The clinical assessor was blinded for the complementary studies that were collected by another observer. Statistical analysis: descriptive statistics was performed and in the low back sample, Chi2 test and Fisher's exact test and Student or Mann Whitney test was applied, logistic regression.

Results: 75 patients were diagnosed with PsA in the circuit between 2018 and 2019, 55% were women, mean age was 49 (SD 12.5), with a median duration of symptoms until the diagnosis of 3 years (RIC: 5-8).

37% (CI: 25-49) presented clinical axial involvement. The characteristics of low back pain were: inflammatory 76%, sacroiliac test 70%, HLA B27 21%, positive x-ray 40%, MRI 56%, good response to NSAIDs 55%, morning stiffness: 30 mint (15- 40), BASFI 5 (3.8-5.6), BASDAI 4.1 (3-5.8), age of onset 44 (36-50), the time between low back pain and the diagnosis of PsA 4 years (1 -9.7).

In patients with PsA and axial involvement, a higher number of enthesitis was observed median 2 (0-1) vs 0 (0-1) p 0.001, higher DAPSA: median 17 (14-19) vs 12 (5-16) p 0.02, and greater functional alteration: HAQ of 0.8 (0.5-1) vs. 0.5 (0.1-1.2). No difference was found regarding sex, smoking, peripheral ultrasound abnormalities, or acute phase reactants. In the logistic regression analysis, only the enthesitis was associated independently.

Conclusion: The prevalence of axial symptoms in our cohort was 37%, the characteristics were mostly inflammatory and with activity by BASDAI. Patients with axial symptoms had more severe PsA characteristics, with greater activity (DAPSA), functional alteration due to HAQ and enthesitis.

Oxylipin Profile Is Associated with Skin Disease and Enthesitis in Psoriatic Disease

Roxana Coras[1], Arthur Kavanaugh[2], Angela Kluzniak[3], Dustina Holt[3], Amy Weilgosz[3], Oswald Quehenberger[1], Christopher Ritchlin[4] and Monica Guma[5], [1]University of California San Diego, La Jolla, CA, [2]Division of Rheumatology, Allergy, & Immunology, University of California San Diego Medical School, San Diego, CA, [3]University of Rochester Medical Center, New York, NY, [4]Department of Medicine, University of Rochester Medical Center, Rochester, NY, [5]Division of Rheumatology, University of California San Diego, Department of Medicine, Autonomous University of Barcelona, La Jolla, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA), a systemic inflammatory disease, occurs in about 25% of patients with psoriasis (PsO). At present, there are no biomarkers that reliably identify patients with PsO who will go on to develop PsA. In addition to peripheral and axial arthritis, enthesitis is common in PsA. Oxylipins are biological lipids that have been implicated in various pathological processes, including inflammation. We previously found that certain oxylipins correlated with joint disease and skin disease in a cohort with PsA patients. Here, we compare the oxylipin profile in two different cohorts of PsO patients without joint disease and PsA patients.

Methods: Patients with PsA and PsO, diagnosed based on the CASPAR criteria were recruited from the Rheumatology Outpatient Clinic at the University of Rochester, NY. A thorough clinical examination was performed, including enthesitis (using Leeds index). Patients completed a health assessment questionnaire. DAS (disease activity score) 44, Psoriasis Area and Severity Index (PASI) and body surface area (BSA) of psoriasis were also calculated. Serum oxylipins were determined by Mass Spectrometry and were classified into groups according to their precursor: arachidonic acid (AA), linoleic acid (LA), a-Linolenic acid, Docosahexaenoic acid (DHA), eicosapentaenoic acid (EPA) and Dihomo-g-linolenic acid. Data were analyzed using R version 3.6.1.

Results: Sera from 20 PsO patients were analyzed (average age 51.95 (10.83), 55% males, average body mass index BMI; 33.73 (6.84)). The average PASI was of 3.87 (4.25) and there was an average BSA of 4.5 (4.77). PsO patients were classified in 2 groups, based on the PASI. The group with higher PASI score (>2.5) had significantly lower serum concentrations of pro-inflammatory oxylipins, most of them being derived from AA. 19 PsA patients were analyzed

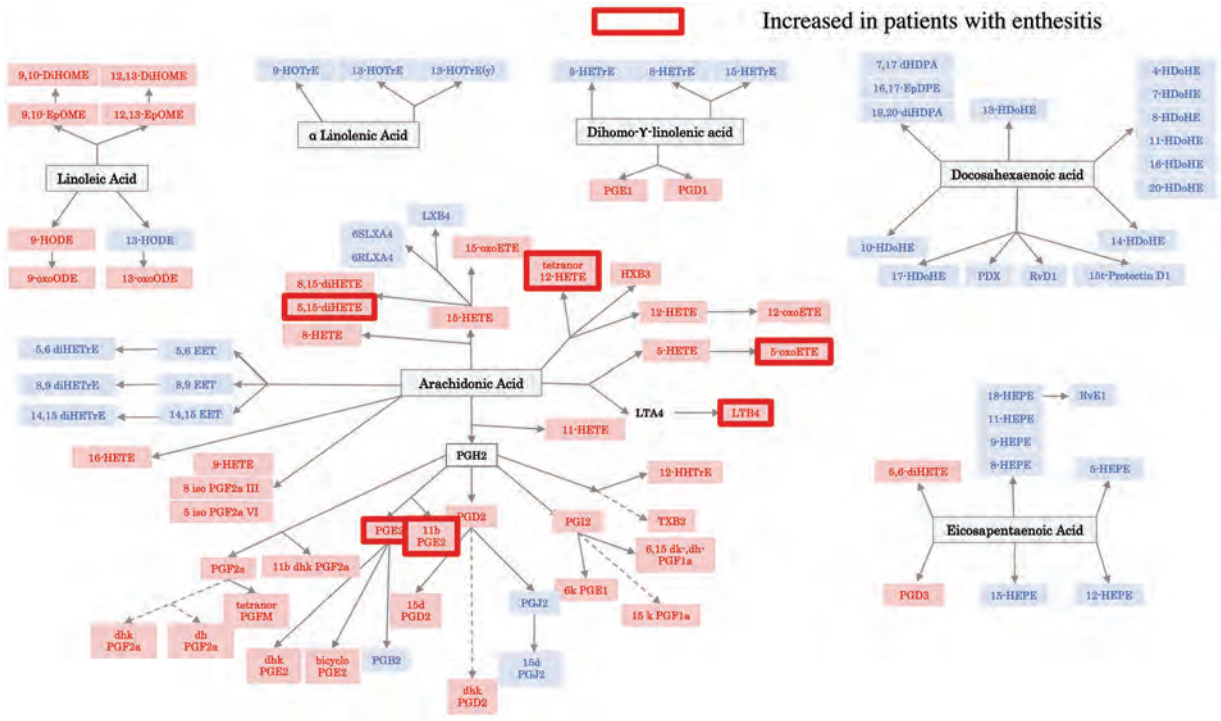

Figure 1. Oxylipins that are decreased in PsO patients with higher PASI (> 2.5) compared to lower PASI (≤ 2.5) are marked with blue squares. Red background – pro-inflammatory; blue background – anti-inflammatory.

(average age 60.5 years old (11.41), 63.15% males, with an average BMI of 31.96 (5.64)). The average number of TJC was 9.38 (10.41) and of SJC 3.77 (4.23). 63.15% patients had enthesitis (average of 2.21 (3.08)) and psoriasis (average PASI 3.02 (5.09)). Oxylipins profiling in the PsA patients with higher PASI score (>2.5) also had lower AA-derived oxylipins compared to PASI ≤ 2.5 . Oxylipin profiling did not associate with the number of SJC nor TJC. Yet, interestingly, several AA-derived oxylipins (8,15 di-HETE, 5-oxoETE, PGE2, 11bPGE2, 5-oxoETE, LTB4) were significantly associated with enthesitis. PsA patients with enthesitis had higher concentrations of oxylipins compared to PsA patients without enthesitis (Figure 1).

Conclusion: The AA-derived proinflammatory oxylipins were lower in both PsO and PsA patients with higher skin scores. Joint disease activity didn't have an effect on the concentrations of oxylipins. Yet, enthesitis was associated with an increase of AA derived pro-inflammatory oxylipins. Further studies are needed to determine whether oxylipin profiling can be a good biomarker of enthesitis in PsO patients.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) treatment should aim to achieve robust improvement of arthritis as well as control of extra-articular manifestations like the skin. SPIRIT-H2H evaluated the efficacy of ixekizumab (IXE)

Table: Efficacy endpoints at Week 24

	ACR50 and PASI100 n=181	ACR50 only n=94	PASI100 only n=121	Neither ACR50 nor PASI100 n=170
ACR20	100.0 [b,c]	100.0	53.7	34.7
ACR70	64.6 [a,b,c]	48.9	0.0	0.0
MDA	75.7 [a,b,c]	60.6	23.1	12.4
VLDA	32.6 [a,b,c]	13.8	3.3	1.8
DAPSA LDA or Remission (≤14)	92.3 [a,b,c]	81.9	43.0	28.8
DAPSA Remission (≤4)	44.8 [b,c]	35.1	6.6	2.4
HAQ-DI score ≤0.5	75.7 [b,c]	64.9	30.6	27.4
PASI75	100.0 [a,c]	60.6	100.0	37.1
PASI90	100.0 [a,c]	36.2	100.0	14.7
SF-36 PCS change from baseline[§]	12.3±0.53 [b,c]	12.3±0.74	5.4±0.66	4.0±0.55

Data are presented as %; [§]mean±standard error.
[a] p<0.05 vs. ACR50 only; [b] p<0.05 vs. PASI100 only; [c] p<0.05 vs. Neither ACR50 nor PASI100.
ACR=American College of Rheumatology; DAPSA=Disease Activity in Psoriatic Arthritis; HAQ-DI=Health Assessment Questionnaire Disability Index; LDA=low disease activity; MDA=minimal disease activity; PASI=Psoriasis Area and Severity Index; SF-36 PCS=36-item Short Form health survey and physical component summary; VLDA=very low disease activity.
Nine patients with active psoriasis and body surface area (BSA) ≥3% were assessed as PASI=0 at baseline, a medical inconsistency that was resolved using medical judgement. These patients were considered PASI100 responders if PASI=0 and BSA=0 at post baseline visits.

and adalimumab (ADA) in patients with active PsA and psoriasis, and naïve to biologic Disease-Modifying Anti-Rheumatic Drugs (bDMARDs). At Week 24, IXE showed superiority to ADA in simultaneous achievement of ACR50 and Psoriasis Area and Severity Index (PASI) 100 as well as significant improvement of treat-to-target and other extra-articular outcomes. The objective is to examine and to compare PsA efficacy outcomes in patients beyond achievement of the primary endpoint of the SPIRIT-H2H trial at Week 24, irrespective of treatment allocation.

Methods: All patients recruited had active PsA (defined as tender joint count ≥3/68, swollen joint count ≥3/66 and body surface area [BSA] ≥3%), and inadequate response to conventional synthetic (cs)-DMARDs. Patients were randomized 1:1 to open-label, assessor-blinded IXE or ADA. We conducted post-hoc analysis of SPIRIT-H2H (NCT03151551), categorizing patients into four independent groups based on the achievement of the primary outcomes (ACR50 and PASI 100), ACR50 only, PASI 100 only or none of them, after 24 weeks of treatment. Statistical analyses consisted of mixed model for repeated measurement and logistic regression models using non-response imputation.

Results: At Week 24, patients reaching simultaneously ACR50 and PASI 100 had a statistically significant higher response in most treat-to-target endpoints than those meeting ACR50 only ($p< 0.05$). In this latter group, a high response rate was observed in ACR70, minimal disease activity (MDA), Disease Activity in Psoriatic Arthritis (DAPSA) remission and PASI 90 response (48.9%, 60.6%, 35.1%, 36.2%, respectively). In patients that did not achieve either ACR50 or PASI 100, up to 1/3 of the patients did achieve ACR20, DAPSA score ≤14, or no physical impairment.

Conclusion: Reflecting the complexity of PsA, different degrees of improvement were observed across all treat-to-target outcomes with greater improvements in patients that met ACR50 response regardless of skin resolution. These findings at Week 24 need to be confirmed with a longer duration of treatment.

Assessment of Implementation of Treat to Target Concept Using Validated Composite Scores in Psoriatic Arthritis Patients

Tal Gazitt[1], Muhanad Abu Elhija[1], Amir Haddad[1], Idit Lavi[1], Muna Elias[1] and Devy Zisman[1], [1]Carmel Hospital, Haifa, Israel

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To assess the implementation of the "Treat-to-Target" (T2T) concept using validated composite disease activity scores in daily management of psoriatic arthritis (PsA).

Methods: A retrospective analysis of 117 consecutive PsA patient visits during 2016-2017 was performed including patient demographics, clinical disease parameters used in the Minimal Disease Activity (MDA) and Disease Activity Index for PSoriatic Arthritis (DAPSA) composite scores, medication use, comorbidities including osteoarthritis (OA) and fibromyalgia syndrome (FMS) and treatment changes as recorded by the treating physicians. Medical records were reviewed to assess whether T2T concept was implemented. All associations were assessed using Chi square test, or Students' t-test, as appropriate. Pearson's correlation, McNemar and Cohen's kappa measures test were used to evaluate association and agreement between MDA and DAPSA parameters.

Results: Patient visits with complete data for MDA and DAPSA (116 and 114 visits, respectively) were analyzed with mean age 58.4±13 years, 65.5% women. T2T approach was implemented in 76 (65.5%) and 74 (64.9%) patient visits using MDA and DAPSA, respectively (Pearson's correlation -0.695). There was no correlation between T2T implementation and patient age, gender, alcohol and tobacco use, disease activity parameters and the various treatment regimens chosen. Physician assessment of disease activity and treatment changes did not correlate with the MDA score in 40 (34.5%) patients. In 30 of these cases (75%), the MDA status was over-estimated due to disregard of patient reported outcomes (PRO). Underestimation of the MDA status occurred in 10 cases (25%) and could be attributed to treatment changes made in patients having < 2 active joints or entheses. Underestimation of disease activity using DAPSA score occurred in 22 (19.3%) patients and could be attributed to disregarding tender joint count, patient pain visual analogue scale and C-reactive protein level. The co-existence of FMS or OA was associated with worse DAPSA scores in PsA patients (p=0.031, p=0.026, respectively), but did not affect MDA status. Achieving disease remission as a goal using the MDA score was more difficult compared to the use of the DAPSA score (Cohen's kappa=0.489).

Conclusion: In our cohort, T2T concept was implemented in about 65% of patients. The main obstacle observed in T2T implementation was the lack of use of validated, practical disease activity scores such as MDA or DAPSA and physicians' overlooking "subjective" components of these scores in daily practice. Efforts should be made in order to increase physician reliance and use of validated composite scores in PsA patient management.

Outcome Measures in Psoriatic Arthritis Registries Are Very Heterogeneous: A Systematic Literature Review of 27 Registries, or 16183 Patients

Krystel Aouad[1], Georgia Moysidou[1], Antsa Rakotozafiarison[1], Bruno Fautrel[2] and Laure Gossec[1], [1]Sorbonne University, INSERM; Pitié-Salpêtrière Hospital, Paris, Ile-de-France, France, [2]Sorbonne University, INSERM, IPLES; Pitié-Salpêtrière Hospital, Paris, Ile-de-France, France

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Table 1. Description of 27 ongoing PsA registries or PsA cohorts

Table 1. Description of 27 ongoing PsA registries or PsA cohorts

	Total N =16183 patients (n=27 registries)
Age of patients, weighted mean, years(SD)	49.7(9.3)
Diagnosis criteria based on Caspar, N(%)	21(78)
Gender, female, N(%)	7959(49)
Disease duration, weighted mean, years(SD)	6.8(0.2)
Study involving a single center, N(%)	12(44)
Number of patients per study, mean (SD)	599(578)
Inception cohorts for early disease (≤3years), N(%)	4/26(15)

Background/Purpose: Psoriatic arthritis (PsA) is a multidimensional inflammatory disease for which multiple outcome measures can be used, to assess disease activity e.g. through composite scores, and to assess other aspects of disease such as patient-reported outcomes (PROs)[1]. In trials, outcome measures were varied in 2012, as evi-

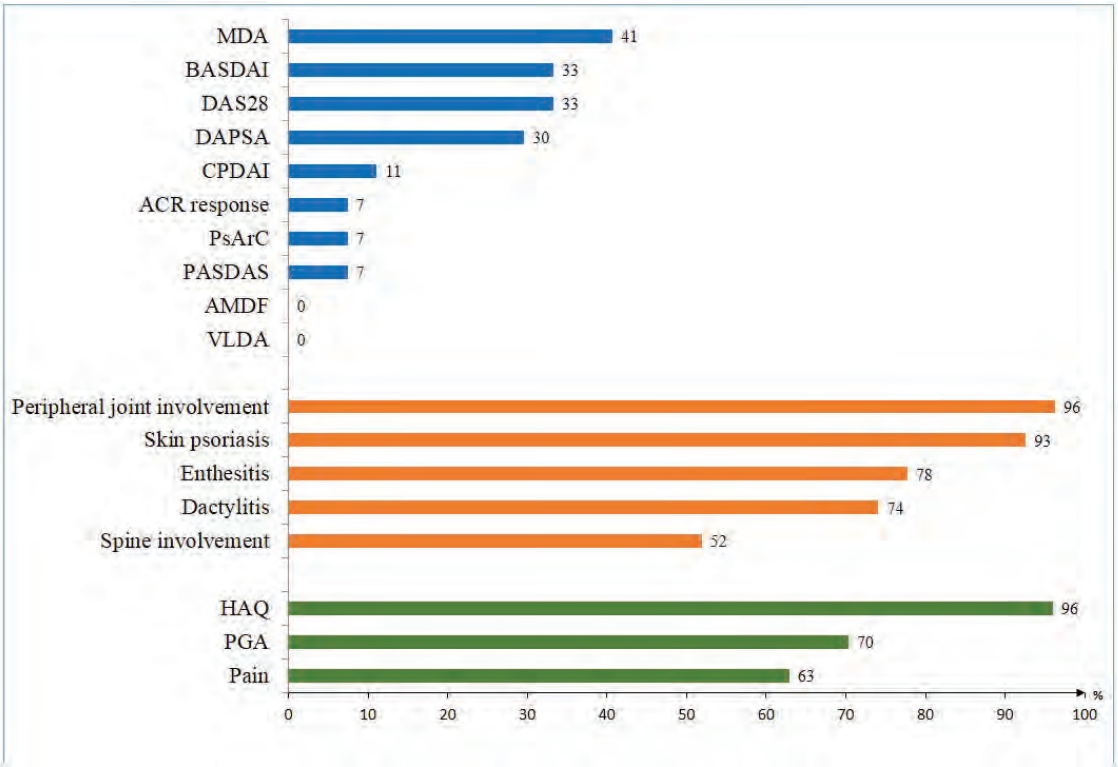

Figure 1. Outcomes reported in 27 PsA cohorts and registries. AMDF: Arithmetic Mean of the Desirability Function; ACR response: American College of Rheumatology response; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CPDAI: Composite Psoriatic Disease Activity Index; DAS28: Disease Activity Score 28; HAQ: Health assessment Questionnaire; PASDAS: Psoriatic Arthritis Disease Activity Score; PASI: Psoriasis Area Severity Index; PGA: Patient's global assessment; PsArC: Psoriatic Arthritis Response Criteria; VLDA: Very Low Disease Activity

denced in a systematic literature review [2]. Since 2012, much work has been performed on outcome measures in PsA [3]. Furthermore, registries reflect more closely real-world data than trials.

The purpose of this study was to assess outcome measures collected in ongoing PsA registries or longitudinal cohorts, through a systematic literature review.

Methods: We performed a systematic literature review in Pubmed Medline (PROSPERO CRD42020175745) to identify all studies reporting either registries or longitudinal cohorts in PsA, published between 2010 and March 2020. Registries centered on drugs or not centered on PsA (e.g., reporting outcomes for several rheumatic diseases), trials and long term extension studies were excluded. The registry principal investigators were contacted by email as needed. All publications for a single registry were analyzed together. The data collection comprised the clinical outcome measures reported, and patient characteristics, based on the largest published population for a given registry. Outcomes were classified as disease activity scores, assessments for the different domains of PsA [3], or PROs. The analysis was descriptive.

Results: Of 673 articles, 73 were relevant for analysis, corresponding to 27 registries or PsA-specific cohorts. The overall number of patients was 16,183 with a mean of 599 per study (**Table 1**). Overall, 51% were men, weighted mean age was 49.7±9.3 years and weighted mean disease duration was 6.8±0.2 years. Most of the studies (78%) were performed in Europe or the United States.

Overall, 58 different clinical outcome measures were collected. Disease activity composite scores were used in 20 registries (74%): of these, 41% reported Minimal Disease Activity, 33% DAS28 and 30% DAPSA (**Figure 1**). Regarding the different domains of PsA, joint involvement was reported in 96% (using variable joint counts, most frequently the 66/68 joint count, in 85%) and 93% of the registries reported skin psoriasis (most frequently through PASI, in 72%), whereas enthesitis, dactylitis and axial involvement were less often reported, also using variables outcome measures (**Figure 1**). Among PROs, 96% of the registries reported HAQ, and the other frequently reported PROs were patient global assessment and pain (**Figure 1**).

Conclusion: Data collection in PsA is very heterogeneous, reflecting the lack of international consensus on outcome measures. Experts need to define a core set of feasible and practical outcome measures for the clinical follow up with patients with PsA.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic has increasingly driven clinical care into remote settings, where patients with immune-mediated and inflammatory diseases struggle to convey symptom severity to their health providers. Smartphone sensor technology has demonstrated the ability to quantitatively measure disease symptoms, however, similar tools for psoriatic arthritis (PsA) are lacking. Here, we describe preliminary data on the performance of 3 novel tools that can be self-administered by patients using the *Psorcast* iOS app to measure PsA symptoms.

Methods: Three novel smartphone sensor-based measurement tools were developed as part of *Psorcast* to assess PsA symptoms affecting joints domains (Fig 1). Patients with PsA and controls are being recruited at PPACMAN clinical sites to perform the digital measurements while being concurrently assessed by a rheumatologist.

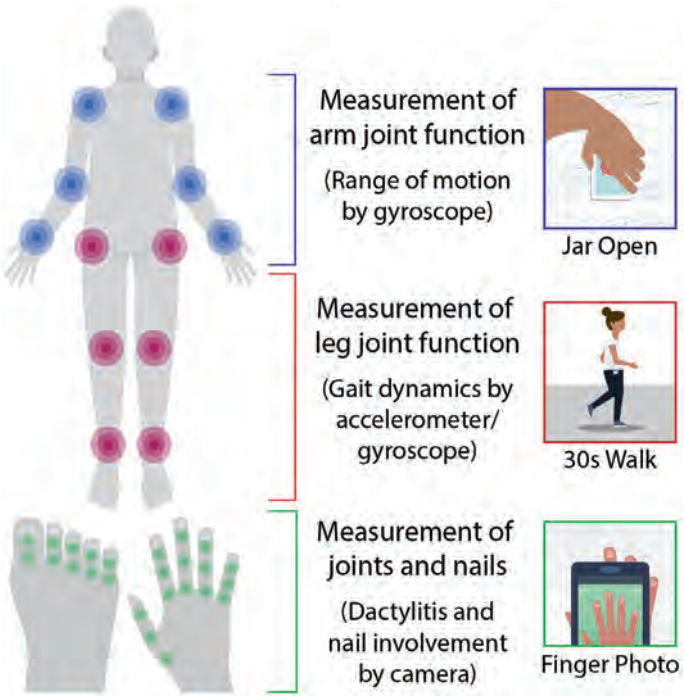

Figure 1. Interactive smartphone sensor-based measures of PsA symptoms from the Psorcast app and the joints that are assessed in each.

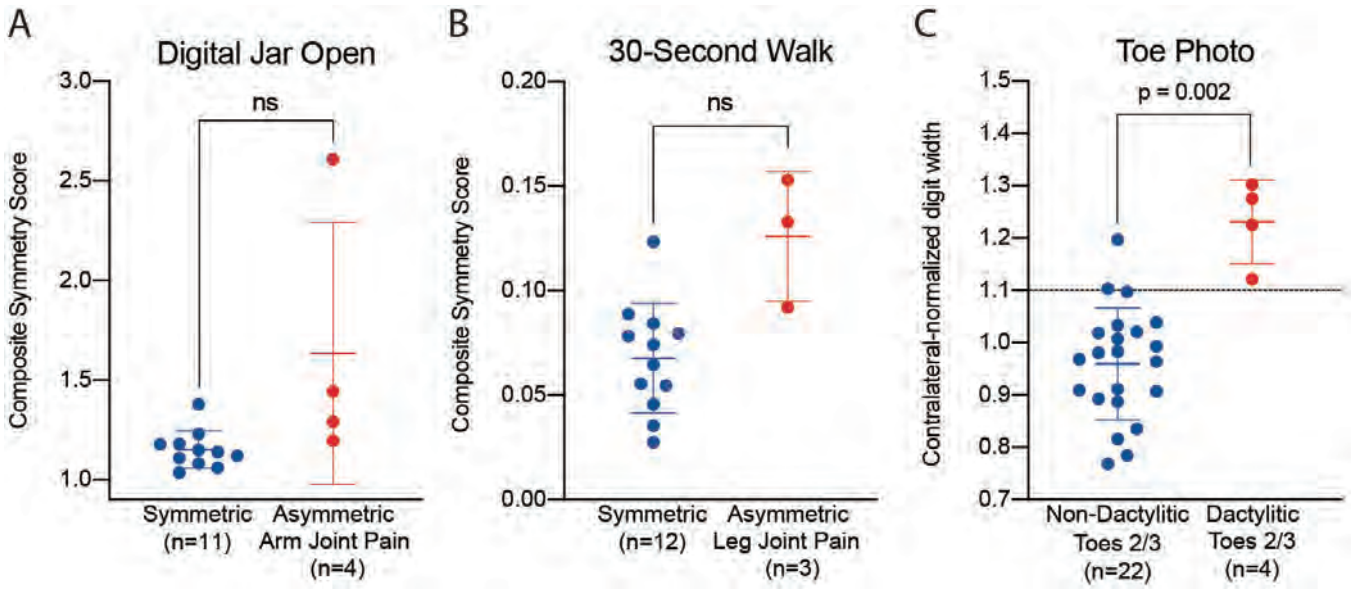

Figure 2. Preliminary results from Psorcast measures. (A) Detection of asymmetric upper extremity joint pain, (B) Detection of asymmetric lower extremity joint pain, (C) Detection of dactylitis in toes 2 and 3. All statistical comparisons use Welch's t-test.

The *Digital Jar Open* tool uses the gyroscope to measure inward and outward rotation of each arm to generate an inward symmetry score and outward symmetry score that are normalized within each participant. The *30-Second Walk* tool measures gait with the smartphone in a pocket during a walk to generate a symmetry score using PDKit. The *Finger/Toe Photo* captures finger and toe images, normalizing them with the contralateral nail bed width to measure relative digit widths.

To assess preliminary validity, *Digital Jar Open* composite symmetry scores were compared between participants with asymmetric upper extremity tenderness as determined by the examining physician and those with none. Triaxial gait asymmetry from the *30-Second Walk* was compared between participants with diagnosed asymmetric lower extremity joint tenderness and those with none. The relative widths of digits captured by the *Finger/Toe Photo* were compared to matching digits from the rest of the cohort with this data, and the resulting data was grouped by physician diagnosis of dactylitis.

Results: In all, 26 patients have been recruited to date. Of these, 15, 15, and 7 provided data to assess the *Digital Jar Open*, *30-Second Walk, and Finger/Toe Photo* tools, respectively. Results from both the *Digital Jar Open* test and *30-Second Walk* demonstrated that the asymmetric joint pain groups are markedly different from controls, but neither of these findings reach statistical significance (Fig. 2A). Finally, 3 individuals in our cohort had dactylitis, all in toes 2 and 3. The relative widths of these digits compared to the rest of the cohort showed a statistically significant separation between the two groups near the 10% difference mark (Fig. 2C). Interestingly, this is the validated cutoff for diagnosing dactylitis from the Leeds Dactylometer.

Conclusion: While validation of *Psorcast* measurements will require an expanded cohort and analysis beyond symmetry-related features, we observed that the 3 sensor-based measurements described here can distinguish some clinical features of PsA. If validated, these and other *Psorcast* tools may provide for remote self-assessment when clinical visits cannot be performed. Importantly, longitudinal and frequent symptom measurement could be of high value to study disease progression and assessing treatment response.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Discrepancy between patient and provider assessments of disease activity is well described in psoriatic arthritis (PsA) and other inflammatory arthritides. Patients often have low tender (TJC) and swollen joint counts (SJC) but continue to have symptoms they ascribe to their PsA. Limited data exists on the specific residual symptoms that patients describe in discordance with physician assessments of very low disease activity (VLDA). Targeting these additional symptoms could improve patient outcomes without escalation of therapy. The objective of this study was to describe the residual symptoms among patients with low TJC, SJC, and enthesitis counts.

Methods: A cross-sectional observational study was conducted of consecutive PsA patients in the Psoriatic Arthritis Research Consortium (PARC) cohort between 2017-Jan 2020. Participants (pts) who started a new therapy and completed a global assessment of response to treatment, the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and Psoriatic Arthritis Impact of Disease (PsAID) questionnaire were included. We examined the prevalence of BASDAI and PSAID item scores ≥ 4 (score ≥ 4 is considered active disease) among pts with very low physician-assessed disease activity as defined by the provider portions of the VLDA criteria: SJC (0-66) of ≤ 1, TJC (0-68) of ≤ 1, and enthesitis count (Leeds + plantar fascia, 0-8) ≤ 1. Pts global assessment of response to treatment was recorded as improvement, no change, or worsening of symptoms.

Results: 244 PsA pts (mean age 51.1yrs (SD 13.9), 53% female, mean BMI 30.0 (SD 6.6) were identified with the required assessments at baseline and follow up after initiating a new therapy. Therapies initiated (pts could start more than one) included: TNFi (134), IL-17i (50), oral small molecule (88), and other (14). Mean PSAID and BASDAI scores at follow-up were significantly lower for pts in physician-assessed VLDA compared to those not in VLDA ($p< 0.001$ for almost all comparisons. Table 1); however, 47% of pts in physician-assessed VLDA had at least one residual symptom (score >=4 on BASDAI or PSAID item) compared to 85% not in physician-assessed VLDA using the PsAID. Pts global assessment of response to treatment demonstrated improvement in 42%, no change in 45%, and worsening in 12%. The most common residual symptoms were fatigue (33%), spine pain (30%), peripheral joint pain/swelling (26%), stiffness (23%), disrupted sleep (24%), and tenderness to touch (19%). Many of these symptoms

Table 1. Mean differences in patient reported outcomes by physician-assessed very low disease activity

	PhA-VLDA No. or Mean (% or SD)	Not in PhA-VLDA No. or Mean (% or SD)	p-value
Patient global assessment of response to treatment	n=91	n=153	
Improvement	39 (43%)	31 (20%)	<0.001
No change	41 (45%)	67 (44%)	
Worsening	11 (12%)	55 (36%)	
PsAID (each symptom specifically attributed to PsA)	n-=91	N=153	
Pain	2.4 (2.4)	4.9 (2.3)	<0.001
Fatigue	2.6 (2.6)	5.1 (2.6)	<0.001
Skin	1.7 (2.1)	2.5 (2.6)	0.03
Work	1.4 (2.1)	4.1 (2.8)	<0.001
Function	1.4 (1.9)	3.9 (2.7)	<0.001
Discomfort	2.3 (2.5)	4.9 (2.5)	<0.001
Sleep	2.1 (2.7)	4.3 (3)	<0.001
Coping	1.1 (2)	3.3 (2.8)	<0.001
Anxiety	1.2 (2.1)	2.9 (2.9)	<0.001
Embarrassment	0.7 (1.4)	2.1 (2.9)	<0.001
Social	0.8 (1.6)	2.7 (3)	<0.001
Depression	0.7 (1.7)	2.8 (2.9)	<0.001
BASDAI (symptoms *not* specifically attributed to PsA)	n=53*	n=90*	
Fatigue	2.9 (2.3)	5.4 (2.2)	<0.001
Spine pain	2.6 (2.3)	4.9 (2.6)	<0.001
Peripheral joints pain/swelling	2.3 (2)	4.6 (2)	<0.001
Tender to touch	1.7 (1.9)	4.8 (2.5)	<0.001
Stiffness severity	2.3 (2.2)	4.7 (2.3)	<0.001
Stiffness duration	1.8 (2.3)	3.7 (3)	<0.001

*BASDAI was added later than PsAID and thus not all patients in this cohort had an available BASDAI score
Abbreviations: BASDAI-Bath Ankylosing Spondylitis Disease Activity Index; PhA- Physician Assessed; PsAID-Psoriatic Arthritis Impact of Disease; VLDA- very low disease activity

were ascribed to PsA (PsAID items include the phrase “due to my PsA”). Furthermore, more than 10% of pts in physician-assessed VLDA still reported difficulty with function, work, and skin symptoms. Mean BMI was not significantly different between those in and not in physician-assessed VLDA.

Conclusion: Among PsA patients in VLDA according to physician measures, approximately half continue to have residual symptoms. Further studies are needed to develop comprehensive, evidence-based, patient-focused treatment plans to address these residual symptoms.

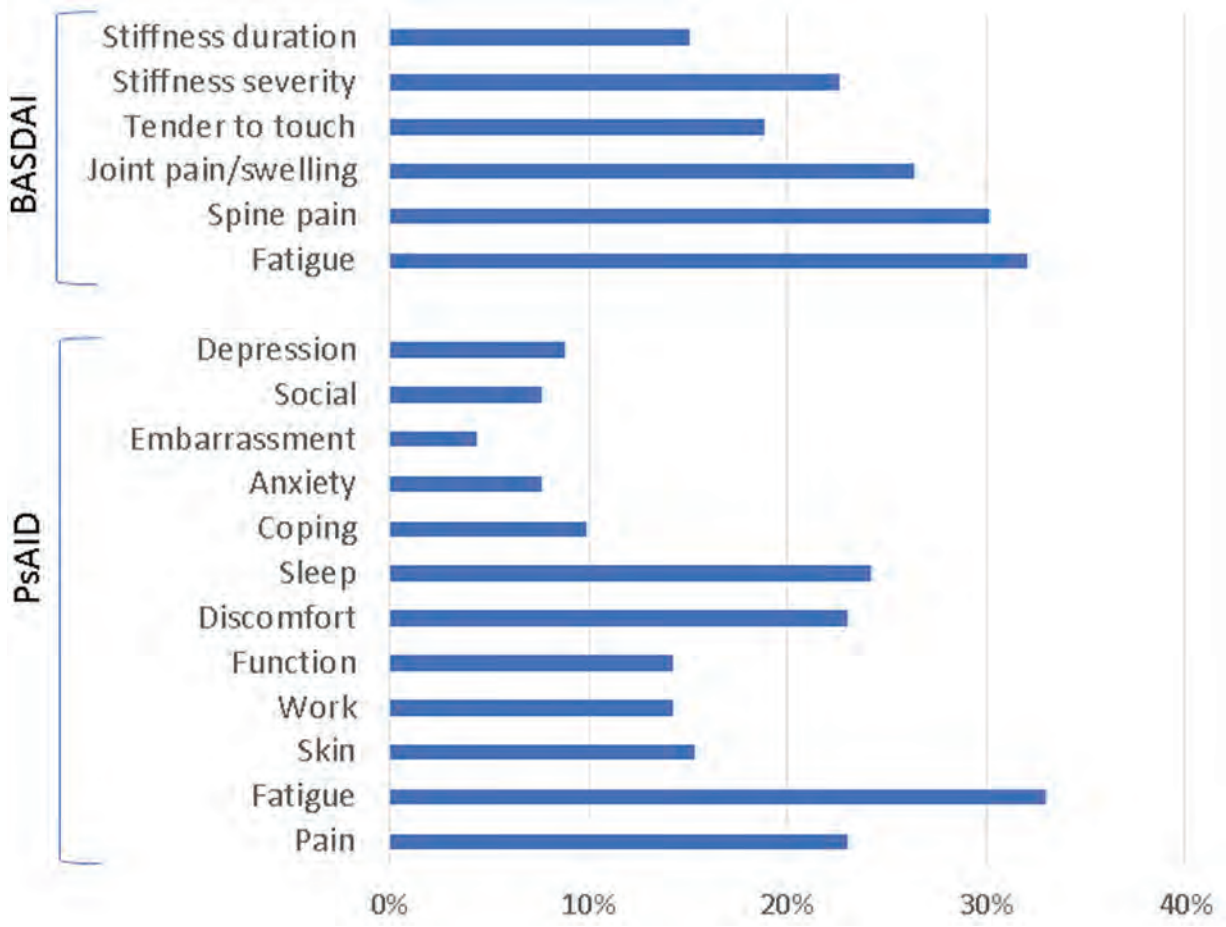

Figure 1. Residual symptoms among patients in physician-assessed very low disease activity

cDAPSA	Both	234	17.29 (12.87)	225	-2.26 (12.36)

Abbreviations: RAPID3= Routine Assessment of Patient Index Data; HAQDI=Health Assessment Questionnaire Disability Index; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; PROMIS PH= PROMIS Physical Health; PROMIS MH= PROMIS Mental Health; PSAID=PsA Impact of Disease; MDHAQ=Multidimensional Health Assessment Questionnaire; MD global= physician's global assessment; SJC=swollen joint count; TJC=tender joint count; cDAPSA=clinical Disease Activity of PsA

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous condition; this presents a challenge in how to best measure disease activity for all patients. While several outcome measures have been studied for use in traditional randomized clinical trials (RCT) of PsA, this has been done in the context of pre-defined inclusion criteria derived from a relatively homogenous population with a polyarticular phenotype and higher disease activity than is typically encountered in "real world" practice. There remains a need to determine the ideal outcomes for PsA pragmatic trials that enroll patients representative of those seen in routine care in the clinics. We aimed to investigate the responsiveness of outcome measures among patients with PsA initiating therapy in clinical practice.

Methods: Patients were enrolled in the Psoriatic Arthritis Research Consortium (PARC), a multi-center longitudinal observational cohort study, between 2017-2020. We collected data at initiation of a new treatment for PsA, including a switch in treatment, and follow-up at approximately 16 weeks. At both visits, patients completed patient-reported outcome assessments (PROs) and rheumatologists completed a comprehensive musculoskeletal exam. Change in scores were calculated for the following measures between both timepoints: Routine Assessment of Patient Index Data (RAPID3), clinical Disease Activity of Psoriatic Arthritis (cDAPSA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), PsA Impact of Disease (PSAID), Multi-Dimensional Health Assessment Questionnaire (MDHAQ), Health Assessment Questionnaire (HAQDI), Patient Reported Outcome Measure Information System (PROMIS) physical health (PH) subscore, PROMIS mental health (MH) subscore, PROMIS fatigue, PROMIS depression, patient pain assessment, patient global assessment, physician global assessments of joints and overall, and tender (68) and swollen (66) joint counts. Standardized response means (SRMs) were calculated as the mean change between two visits divided by the standard deviation. Responsiveness cutoffs are debatable, but SRMs may roughly be considered large at >0.8, moderate 0.5-0.8, and small < 0.5.

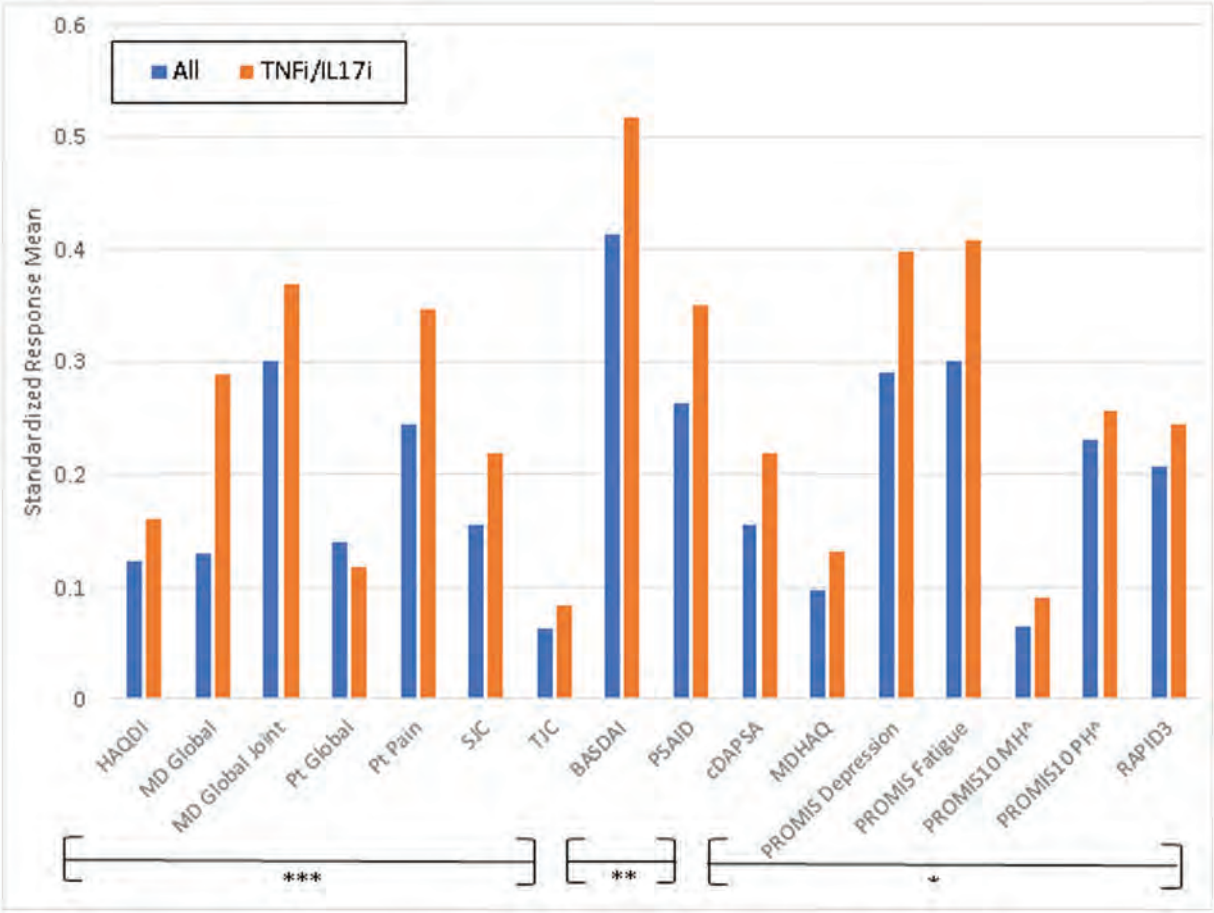

Figure 1. Standardized Response Means of Instruments Tested. ***=Outcome measures frequently used in randomized controlled trials (RCTs) for PsA **= Outcome measures sometimes used in RCTs for PsA *= Outcome measures rarely used in RCTs for PsA Abbreviations: HAQDI=Health Assessment Questionnaire Disability Index; MD global= physician's global assessment; SJC=swollen joint count; TJC=tender joint count; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; PSAID=PsA Impact of Disease; ; cDAPSA=clinical Disease Activity of PsA; MDHAQ=Multidimensional Health Assessment Questionnaire; PROMIS MH= PROMIS Mental Health; PROMIS PH= PROMIS Physical Health; RAPID3= Routine Assessment of Patient Index Data

Results: Among 177 unique patients, 266 therapy courses met inclusion criteria. The mean age was 51 years, 53% were female, mean BMI was 29.9, and 16% had axial disease. Among the 266 visits, 145 initiated a TNFi, 55 an IL17i, 96 an OSM, and 14 started another biologic or JAKi. Mean swollen and tender joint counts (66/68) at therapy initiation were 2.9 and 5.8. Responsiveness for all measures was small to moderate (Figure 1.) BASDAI was the most responsive, and tender joint count the least responsive; SRMs were similar among those initiating a biologic therapy vs. any therapy.

Conclusion: Patients with PsA switching or starting therapy in this patient population had different clinical characteristics compared to those usually enrolling in a RCT. Similarly, responsiveness of outcome measures in clinical practice looks different than traditional PsA clinical trials, with SRMs that are generally lower. This data will be useful for selecting outcome measures and calculating sample size for pragmatic trials in PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient satisfaction associated with disease control status among PsA patients has not been extensively studied in a real-world setting. The objective of this study was to assess the impact of PsA disease control status on patient-perceived satisfaction with treatment.

Methods: A cross-sectional survey of PsA patients recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, the UK and US. Data were collected from Jun–Aug 2018 via physician- and patient-completed forms. Physicians reported if patients were currently improving, stable, unstable or deteriorating. Unstable and deteriorating patients were grouped together for this analysis. Patients reported their satisfaction with their current treatment. Patients were compared according to disease status (improving vs. unstable/deteriorating vs. stable) using parametric and non-parametric tests. Multiple ordered logistic regression analyses examined the impact

Table 1. Comparison of patient demographic and disease characteristics by physician-reported PsA disease status. *Calculated on available data: Swollen Joint Count=354, Tender Joint Count=335. Abbreviations: BMI, Body Mass Index; BSA, Body Surface Area; SD, standard deviation; tx, treatment.

	Stable (n=1,530)	Improving (n=1,018)	Unstable/Deteriorating (n=319)	p-value
Age, years, mean (SD)	49.1 (12.8)	47.1 (12.8)	48.4 (13.6)	**<0.01**
Female, n (%)	666 (43.5)	488 (47.9)	161 (50.5)	**0.02**
BMI, kg/m^2, mean (SD)	26.9 (5.1)	26.6 (6.3)	27.5 (5.3)	0.08

Full-time employment, n (%)	370 (58.5)	280 (65.1)	56 (46.3)	**<0.01**
Biologic tx, n (%)	998 (65.2)	658 (64.6)	172 (53.9)	**<0.01**
No. of lines of biologic tx, mean (SD)	0.49 (0.89)	0.48 (0.93)	0.91 (1.42)	**<0.01**
Months since diagnosis, mean (SD)	68.8 (72.6)	46.5 (57.4)	57.9 (89.3)	**0.01**
Current BSA %, mean (SD)	4.3 (7.8)	6.5 (9.2)	10.3 (11.8)	**<0.01**
*66 Swollen Joint Count, mean (SD)	3.1 (7.8)	2.7 (6.2)	6.3 (6.3)	**<0.01**
*68 Tender Joint Count, mean (SD)	3.2 (5.3)	3.5 (6.4)	8.7 (7.3)	**<0.01**
No. of joints affected, mean (SD)	2.4 (3.7)	3.3 (4.9)	6.9 (6.4)	**<0.01**
Charlson Comorbidity Index score, mean (SD)	1.1 (0.5)	1.1 (0.5)	1.2 (0.7)	0.06

Table 2. Multivariate logistic regression model for patient satisfaction with treatment as a function of PsA disease status. Abbreviations: BMI, Body Mass Index; BSA, Body Surface Area affected by psoriasis.

Covariate	Odds ratio of patient dissatisfaction	p-value
Disease status - Stable (reference) - Improving - Unstable/deteriorating	 1.00 0.95 3.67	 0.77 **<0.01**
Variables adjusted for		
Age	1.01	0.13
Sex - Female (reference) - Male	 1.00 0.74	 **0.02**
BMI	1.01	**<0.05**
BSA	0.99	0.57
No. of joints affected	1.02	0.21
Charlson Comorbidity Index score	1.36	0.07
No. of treatment lines	0.96	0.64
No. of symptoms	1.16	**<0.01**

of disease status on patient-reported satisfaction with treatment. The model controlled for gender, age, Body Mass Index (BMI), current advanced treatment line, pain, body surface area affected by psoriasis (BSA), number of joints affected, total number of symptoms experienced and Charlson Comorbidity Index score.

Results: Of 2867 patients (638 US, 2229 EU), 53% of patients were stable, 36% of patients were improving and 11% of patients were unstable/deteriorating.

Patients who were improving or stable more commonly received a biologic treatment than those who were unstable/deteriorating. Those who were unstable/deteriorating had a worse clinical profile than those who were improving (Table 1). After controlling for demographic and disease characteristics and treatment status regression analysis showed that patients who were unstable/deteriorating were at a significantly increased risk of being dissatisfied with treatment. There was no observed difference between patients who were stable and improving (Table 2).

Conclusion: After controlling for demographic and disease characteristics, and treatment status, PsA patients who were unstable/deteriorating had greater odds of being dissatisfied with treatment than stable/improving patients. Patient satisfaction was associated with therapy that provides highest degree of disease control stability. Given the importance of disease control stability for patient satisfaction, physicians should prioritise therapy that will ensure patients' disease control stability in the long term.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Flares in PsA, presenting as periods of acute disease activity, are thought to negatively impact patients' lives. This has not been extensively studied in a real-world setting. The objective of this study was to describe frequency of flares, assess flare impact on quality of life and work productivity, and explore predictors of flares.

Methods: A cross-sectional survey among patients with PsA recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, UK and US. Data were collected Jun-Aug 2018 via patient record forms and patient self-complete forms. Flares, by definition, could involve joints or skin or both simultaneously. Physicians recorded flare status (in flare currently/flared in last 12 months/longer than 12 months or never), demographics, physician perceived severity, and clinical outcomes. Patients reported quality of life [QoL] (EQ5D-5L), work productivity (WPAI), disability (HAQ-DI), pain (PsAID12 pain scale). Patients were compared by flare status using parametric or non-parametric tests. Logistic regression was used to explore predictors of flare. Multivariate regression was used to assess the impact of flare status on patient reported outcomes (PRO). The multivariate model was adjusted for gender, age, BMI, physician speciality.

Results: Data was collected for 2,238 patients (586 US, 1,652 EU). Mean age was 48.7 years (13.2 SD), 53.8% were male. Physicians reported 7.5% of patients were currently in flare and 22.0% had flared in the last 12 months. Patients had experienced 2.2 mean flares in the last 12 months (4.9 SD), lasting a mean 16.4 days (16.2 SD). Patients in

Table 1. Clinical characteristics of patients by flare status

	Currently in flare (n=168)	Flared in last 12 months (n=492)	Not flared in last 12 months/never flared (n=1578)	p-value
In remission, n (%)	4 (2.4)	157 (33.2)	799 (53.5)	<0.01
*Current BSA affected, mean (SD)	10.3 (12.0)	6.5 (7.6)	5.0 (7.7)	<0.01
*66 SJC, mean (SD)	5.4 (4.6)	4.5 (7.3)	2.4 (6.9)	<0.01

Physician-perceived severity, n (%)				
-Mild	35 (20.8)	346 (70.3)	1297 (82.2)	<0.01
-Moderate	101 (60.1)	139 (28.3)	261 (16.5)	
-Severe	32 (19.0)	7 (1.4)	20 (1.3)	

*Calculated on available data: Total base sizes: BSA=1665; SJC=514; TJC=493; Satisfaction=931

flare were comparable demographically with those not; however, those in flare were less likely to work full time (43.6 vs. 59.3%, p< 0.01). Patients not in flare had clinically active disease (Table 1).

Results showed that flare status significantly impacted QoL, work productivity, disability, and pain (Table 2). Exploring predictors of flare in the last 12 months showed that demographic characteristics were not predictive of flare status, however patients presenting with any skin involvement or enthesitis at diagnosis were at greater risk of flare. Patients who were prescribed a bDMARD at diagnosis were at lower risk (Figure 1).

Conclusion: One third of patients surveyed were either currently in flare or had flared in the last 12 months. Being in flare adversely impacted QoL, disability and work productivity. Flare may be predicted by any degree of skin involvement or enthesitis at diagnosis.

Table 2. Impact of flare status on PROs

	Current flare status	Change in predicted PRO values	P value

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The degree of joint and skin involvement varies across patients with PsA. Differences in patient outcomes with active joint only vs. joint plus skin involvement have not been extensively studied in a real-world setting. The objective of this study was to assess prevalence of joint-only and joint-plus-skin disease in a real-world clinical setting, and to assess the incremental impact of skin symptoms on quality of life (QoL), disability and work productivity.

Methods: A cross-sectional survey in patients with PsA recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, UK and US. Data were collected Jun-Aug 2018 via physician-completed forms and patient-completed forms. Patients were compared by joint and skin involvement (joint only, joints plus

1-3%, >3-10%, and >10% body surface area [BSA]) using parametric and non-parametric tests. Multiple linear regression analyses examined impact of incremental BSA on patient reported outcomes (PROs) (EQ5D, HAQ-DI, PsAID12, WPAI). Models controlled for gender, age, time since diagnosis, employment status, biologic DMARD use, BMI, number of joints affected.

Results: Of 1,909 patients (539 US, 1,370 EU), 35% of patients had joint-only disease, while 26%, 23%, and 16% experienced joint disease plus 1-3%, >3-10%, and >10% BSA respectively (Figure 1). Patients were comparable

demographically (Table 1). After controlling for demographics and number of joints involved, results showed BSA independently and significantly impacted QoL, work productivity, disability (Table 2).

Conclusion: Two thirds of this sample of actively treated PsA patients had skin involvement. Over half had moderate-severe psoriasis (BSA >3%). Joint counts increased with BSA. After controlling for joint counts, increasing skin involvement adversely impacted QoL, disability and work productivity.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The costs of psoriasis and psoriatic arthritis (PsA) are substantial for both patients and the United States healthcare system. This study compared healthcare resource utilization and costs across three groups: patients with psoriasis, patients with PsA, and matched controls with neither psoriasis nor PsA in the United States.

Methods: The IBM MarketScan Commercial Database was used to identify three adult patient groups from 1/1/2009 through 2/29/2020: 1) Psoriasis patients: ≥ 1 inpatient or 2 outpatient psoriasis diagnoses and no PsA diagnoses; 2) PsA patients: ≥ 1 inpatient or 2 outpatient PsA diagnoses; 3) Control: absence of psoriasis and PsA diagnoses. Controls were matched 1:1 to psoriasis and PsA patients based on age, gender, and comorbidities. Healthcare resource utilization and costs (in 2019 USD) were evaluated descriptively and through mixed models for five years of follow-up.

Results: 208,434 psoriasis patients and 47,274 PsA patients were matched to the control group (N=255,708). Annual all-cause healthcare costs per patient were $7,542, $11,856, and $29,621 for the control, psoriasis, and PsA group, respectively. All-cause healthcare costs were significantly greater among patients with PsA and patients with psoriasis than controls at one year ($p< 0.0001$). These costs were also significantly greater for PsA patients than psoriasis

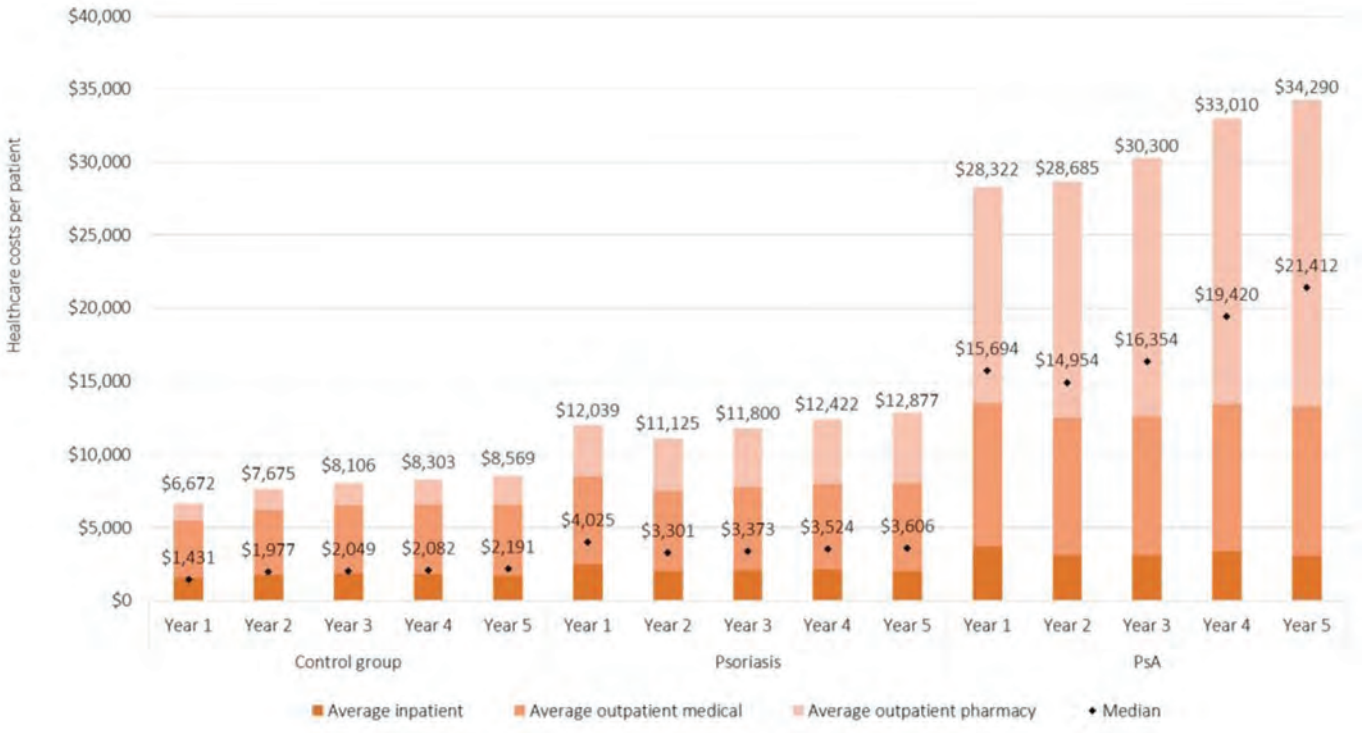

Figure 1. Mean and median all-cause healthcare costs per patient per follow-up year

patients at one year ($p < 0.0001$). This trend of increased costs for patients with PsA compared with the other groups was sustained throughout the five years of follow-up (Figure 1). Across all categories of healthcare resources, utilization was greatest among patients with PsA and lowest in the control group (Table 1). Categories included inpatient hospitalizations, physician office visits, and hospital outpatient, radiology, emergency room, laboratory, and outpatient pharmacy services.

Conclusion: Annual healthcare costs and resource utilization were significantly higher for PsA patients compared with psoriasis patients and the control group. The cost and resource utilization differences between these patient groups highlight the higher burden of illness for PsA patients as compared to patients with psoriasis, or patients without either of these diseases.

Table 1. Healthcare resource utilization during follow-up

	Control group	Psoriasis	PsA

Session Time: 9:00AM–11:00AM

Table 1. Demographics, Clinical Characteristics and Disease Activity Among Patients With PsA Who Completed ≥ 1 HAQ-DI Questionnaire

Characteristic	Patients With PsA (n = 828)
Age, mean (SD), years	58.5 (13.5)
Female, n (%)	599 (72.3)
White, n (%)	697 (92.3)
Education (highest year of education), n (%)	n = 753
High school graduate or less	181 (24.0)
College graduate	229 (30.4)
Master or doctorate degree	343 (45.6)
Insurance status, n (%)	n = 828
Private	263 (31.8)
Medicare	362 (43.7)
Medicaid	68 (8.2)
Other	120 (14.5)
None	15 (1.8)
Geographic location, n (%)	n = 806
Urban	638 (79.2)
Rural	168 (20.8)
Disease duration, mean (SD), years [n]	17.5 (12.4) [759]
Rheumatic disease comorbidity index (0-9), n (%)	n = 828
0	136 (16.4)
1	215 (26.0)
2	176 (21.3)
≥ 3	301 (36.4)
Smoking status, n (%)	n = 828
Never smoker	439 (53.0)
Ever smoker	318 (38.4)
Current smoker	71 (8.6)
PsA treatment history (current and past use), n (%) [n]	
DMARDs	413 (49.9) [801]
Biologics	376 (45.4) [801]
Prednisone	93 (11.2) [735]
NSAIDs	298 (36.0) [801]
Opioids	218 (26.3) [828]
PsA disease activity and quality of life, mean (SD) [n]	
HAQ-DI	0.9 (0.7) [828]
PsAID-12	3.1 (2.3) [196]
BASDAI	3.7 (2.4) [204]
EQ-5D	0.7 (0.2) [766]
Pain VAS	4.2 (2.8) [827]
Patient global assessment	4.0 (2.6) [817]

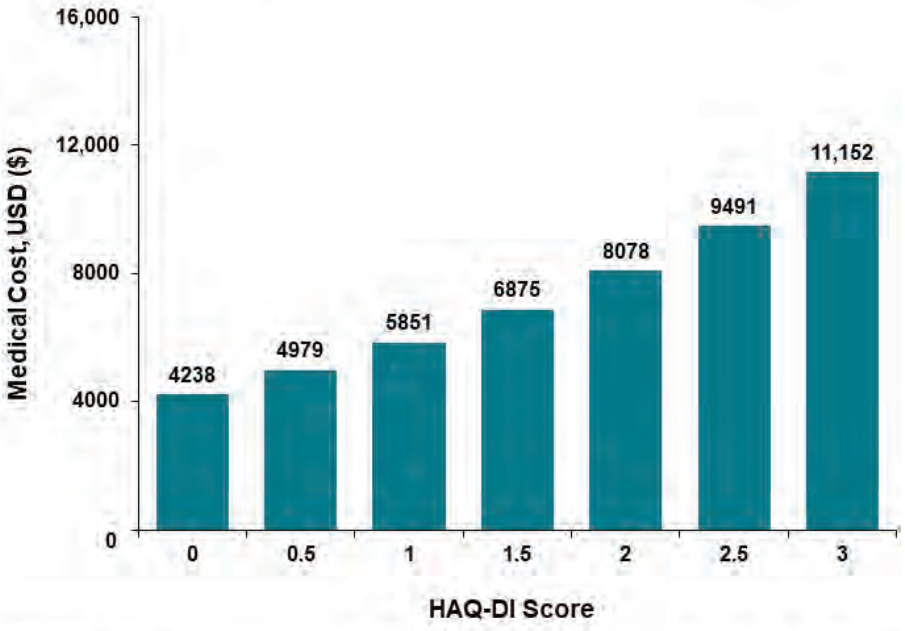
Figure 1. Average Annualized Patient Medical Costs Across HAQ-DI Scores in Patients With PsA*



HAQ-DI, Health Assessment Questionnaire Disability Index; NSAID, nonsteroidal anti-inflammatory drug; PsA, psoriatic arthritis.
* Adjusted for age, disease duration, comorbidity index, biologic use, NSAID use, and opioid use.

Background/Purpose: The Health Assessment Questionnaire Disability Index (HAQ-DI) has been validated and widely used in psoriatic arthritis (PsA) clinical trials for the assessment of patient functional status. Few US studies have evaluated the economic impact of functional disability in patients with PsA. The purpose of this study was to evaluate the association of functional status with healthcare resource utilization (HCRU) and medical costs in US patients with PsA in a national data registry.

Methods: FORWARD is a longitudinal observational databank for rheumatic diseases that collects patient-reported data through questionnaires administered every 6 months. Data collected include demographics, clinical characteristics, symptoms, health and functional status, health-related quality of life, and HCRU. This cohort study included adult patients with PsA enrolled in FORWARD between July 2009 and June 2019 who completed ≥ 1 questionnaire, including the HAQ-DI, between January 2010 and December 2019. Patient demographics, clinical characteristics, and patient-reported outcomes were collected from the most recent questionnaire. HCRU and medical costs (USD 2019) for all hospitalizations, emergency department (ED) visits, outpatient visits, diagnostic tests, and procedures were assessed for the 6 months prior to survey completion. Negative binomial regression models (HCRU outcomes) and generalized linear models with gamma distribution and log-link function (cost outcomes) were used to assess the relationship between HAQ-DI and HCRU and cost outcomes adjusted for confounders.

Results: A total of 828 patients with PsA who completed HAQ-DI questionnaires were included. The mean (SD) age was 58.5 (13.5) years, 72.3% were female, and 92.3% were white. The mean (SD) disease duration was 17.5 (12.4) years, and the mean (SD) HAQ-DI score at the time of the patients' most recent questionnaire was 0.9 (0.7) (**Table 1**). Increasing HAQ-DI score was significantly associated with increased risk (relative risk [95% CI]) of hospitalizations (1.68 [1.11-2.55]), ED visits (2.09 [1.47-2.96]), outpatient visits (1.14 [1.05-1.24]), and diagnostic tests (1.42 [1.16-1.74]) (**Table 2**). There was also a significant positive association between greater HAQ-DI score and increased medical costs (coefficient [95% CI], 1.38 [1.13-1.69]) (**Table 2**). Overall, adjusted average patient medical costs increased with increasing HAQ-DI score (**Figure 1**).

Conclusion: Among patients with PsA, higher HAQ-DI scores were associated with greater HCRU and increased medical costs. These results suggest that interventions that improve functional status may reduce economic burden for patients and healthcare systems throughout the course of disease.

Musculoskeletal Surgery in Psoriatic Arthritis: Prevalence and Risk Factors

Timothy Kwok[1], Mitchell Sutton[2], Daniel Pereira[2], Vinod Chandran[3] and Dafna Gladman[3], [1]University of Toronto, Toronto, ON, Canada, [2]Centre for Prognosis Studies in the Rheumatic Diseases, Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, Canada, [3]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite optimal medical therapy, joint space disease and skeletal damage persists in a subset of patients with PsA, many of whom requiring musculoskeletal (MSK) surgery for disease related morbidity. The purpose of this study was to determine the prevalence of MSK surgery in PsA patients, describe the type/indications for surgery and associated risk factors that increase the likelihood of undergoing MSK surgery.

Table 1. Distribution and descriptions of MSK surgeries performed attributable to PsA (n=379)

Type of Surgery	N (%)	**Anatomical Location**	N (%)	**Surgical Indication**	N (%)	**Joint retaining/ sacrificing**	N (%)
Arthrodesis	102 (27%)	Knee	106 (28%)	Deformities	161 (42%)	Joint sacrificing	224 (59%)
Arthroplasty	102 (27%)	Finger	80 (21%)	Inflammation/ synovitis	156 (41%)	Joint retaining	155 (41%)
Arthroscopic synovectomy	59 (16%)	Foot	70 (18%)	Failed implant	24 (6%)		
Tendon/ ligament repair	28 (7%)	Hip	37 (10%)	Infection	9 (2%)		
Osteotomy	18 (5%)	Wrist	26 (7%)	Pain	9 (2%)		
Arthroscopic debridement/ meniscectomy	17 (4%)	Hand	17 (4%)	Avascular necrosis from corticosteroids	5 (1%)		
Revision arthroplasty	14 (4%)	Shoulder	12 (3%)	Secondary degenerative disease	5 (1%)		
Diagnostic arthroscopy	12 (3%)	Ankle	12 (3%)	Trauma/injury	4 (1%)		
Implant removal	10 (3%)	Elbow	7 (2%)	Ankylosis	3 (1%)		
Amputation	5 (1%)	Jaw	8 (2%)	Carpal tunnel syndrome	3 (1%)		
Carpal tunnel release	4 (1%)	Spine	3 (1%)				
Irrigation and debridement	3 (1%)	Pelvis	1 (1%)				
Laminectomy/ discectomy	2 (1%)						
Soft tissue excision/ debridement	2 (1%)						
Revision arthrodesis	1 (1%)						

Table 2. Multivariate cox proportional-hazards model for predictors at initial clinic visit of undergoing first MSK surgery adjusted for sex, age and duration of PsA at baseline

Variable	HR	95% CI	p-value
Male sex	0.851	(0.567, 1.279)	0.438
Age at baseline visit	1.043	(1.027, 1.059)	<0.001
PsA disease duration at baseline visit	0.989	(0.966, 1.013)	0.382
Biologic use	1.453	(0.768, 2.751)	0.251
DMARD use	1.291	(0.858, 1.941)	0.220
Elevated ESR	1.322	(0.873, 2.000)	0.187
Total active joints	1.011	(0.993, 1.030)	0.233
Total digits with dactylitis	0.973	(0.850, 1.114)	0.692
Total damaged joints	1.047	(1.024, 1.070)	<0.001
HR, hazard ratio; CI, confidence interval; MSK, musculoskeletal; PsA, psoriatic arthritis; DMARD, disease-modifying antirheumatic drug; ESR, erythrocyte sedimentation rate			

Table 3. Multivariate cox proportional-hazards model using time-dependent covariates for predictors of undergoing first MSK surgery adjusted for sex, age and duration of PsA at baseline

Variable	HR	95% CI	p-value
Male sex	0.902	(0.575, 1.413)	0.651
Age at baseline visit	1.073	(1.055, 1.090)	<0.001
PsA disease duration at baseline visit	1.020	(0.998, 1.042)	0.075
Biologic use	2.890	(1.784, 4.681)	<0.001
DMARD use	0.887	(0.569, 1.384)	0.599
Elevated ESR	1.408	(0.913, 2.171)	0.121
Presence of nail lesions	2.482	(1.530, 4.029)	<0.001
NSAID use	2.623	(1.577, 4.362)	<0.001
Total active joints	1.032	(1.011, 1.053)	0.002
Total digits with dactylitis	1.078	(0.867, 1.339)	0.499
HR, hazard ratio; CI, confidence interval; MSK, musculoskeletal; PsA, psoriatic arthritis; DMARD, disease-modifying antirheumatic drug; ESR, erythrocyte sedimentation rate; NSAID, nonsteroidal anti-inflammatory drug			

Methods: A longitudinal single center cohort was analyzed to identify PsA patients who had MSK surgery from January 1973 to December 2019 inclusive. All cohort patients fulfilled the 2006 CASPAR criteria. Data from all MSK surgeries were collected using a web-based database. Patient charts were reviewed to confirm individual surgeries were MSK related and attributable to PsA by cross-referencing to clinical records and pre and post-operative diagnoses. Descriptive statistics determined the prevalence of MSK surgeries attributable to PsA, in addition to categories, indications and anatomical locations for surgery. A cox proportional-hazards model determined predictors at initial clinic visit for undergoing first MSK surgery. Lastly, a cox proportional-hazards model using time-dependent covariates evaluated the cumulative effect of PsA disease burden on undergoing MSK surgery. All models were adjusted for sex, age and duration of PsA at baseline.

Results: Of the 1574 patients in the cohort, 185 patients had 379 MSK surgeries related to PsA (Table 1). Common surgeries were arthrodesis (27%) and arthroplasty (27%). Common anatomical locations included the knee (28%) and finger (21%) with surgical indications representing deformities (42%) and inflammation/synovitis (42%). 59% of surgeries were joint sacrificing while 41% were joint retaining. Complete covariate data for the cox proportional-hazards model at initial clinic visit and the time-dependent covariate cox proportional-hazards model was present in 97 and 90 patients respectively. At baseline visit, higher age (hazard ratio, 1.043; $p< 0.001$) and total damaged joints (hazard ratio 1.047, $p< 0.001$) were predictors for undergoing first MSK surgery (Table 2). In time-dependent covariate analysis, biologic use (hazard ratio 2.890, $p< 0.001$), nonsteroidal anti-inflammatory drug (NSAID) use (hazard ratio 2.623,

p< 0.001), the presence of nail lesions (hazard ratio 2.482, p< 0.001), higher age at baseline visit (hazard ratio 1.073, p< 0.001) and higher total actively inflamed joint count (hazard ratio 1.032, p< 0.002) were predictors for undergoing first MSK surgery (Table 3).

Conclusion: 11.8% of patients in our cohort had at least one MSK surgery attributable to PsA, with most surgeries being joint sacrificing in nature (59%). Older age at presentation and more severe disease evidenced by damaged joints at presentation, active inflammation, nail lesions and use of biologic therapy were associated with a higher risk of MSK surgery. Despite medical therapy, a significant number of patients still require surgical intervention for mainly deformities (42%) or inflammation/synovitis (42%).

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Absenteeism and work disability substantially contribute to the economic burden of psoriasis and psoriatic arthritis (PsA). This study compared work absenteeism and short-term disability among adults with psoriasis, PsA, and controls with neither psoriasis nor PsA in the United States.

Methods: Adults eligible for work absenteeism and/or short-term disability benefits between 1/1/2009 and 2/29/2020 were screened in the IBM MarketScan Commercial and Health and Productivity Management Databases. The following groups were defined: 1) Psoriasis: ≥ 1 inpatient or 2 outpatient psoriasis diagnoses and no PsA diagnoses; 2) PsA: ≥ 1 inpatient or 2 outpatient PsA diagnoses; 3) Control: absence of psoriasis and PsA diagnoses. Controls were matched 3:1 to psoriasis and PsA patients based on age, gender, and comorbidities. Absenteeism, short-term disability, and corresponding costs (in 2019 USD) were evaluated descriptively and through mixed models.

Results: 5,785 psoriasis and 1,245 PsA absentee-eligible and 35,512 psoriasis and 7,434 PsA short-term disability-eligible patients were matched to the control group. During the first year of follow-up, 9.7% of patients with PsA had short-term disability leave compared with 6.2% of patients with psoriasis and 4.8% of controls (Table 1). The

Table 1. Work absenteeism and short-term disability during follow up

	Control group	Psoriasis	PsA
Number of absentee-eligible patients	21,090	5,785	1,245
Patients with work absence during 1st follow-up year - N (%)			
Non-recreational	12559 (59.5%)	3982 (68.8%)	876 (70.4%)
Sick leaves	9422 (44.7%)	3208 (55.5%)	728 (58.5%)
Absenteeism days during follow-up - Mean (SD)			
Non-recreational (PPPY)	6.29 (13.11)	7.82 (15.53)	8.78 (17.97)
Sick leaves (PPPY)	3.37 (7.62)	4.43 (9.24)	5.10 (10.95)
Costs from hours missed from work - Mean (SD)			
Non-recreational (PPPY)	1333.04 (2778.51)	1680.40 (3350.64)	1890.88 (3878.78)
Sick leaves (PPPY)	714.90 (1614.39)	953.39 (1999.70)	1099.64 (2377.68)
Number of short-term disability-eligible patients	128,838	35,512	7,434
Patients with short-term disability during 1st follow-up year - N (%)	6217 (4.8%)	2190 (6.2%)	722 (9.7%)
Short-term disability days during follow-up - Mean (SD)	2.76 (18.21)	3.38 (21.26)	5.15 (25.71)
Costs associated with short-term disability (PPPY) - Mean (SD)	352.88 (2323.59)	436.03 (2736.99)	664.58 (3315.59)

PPPY: per patient per year

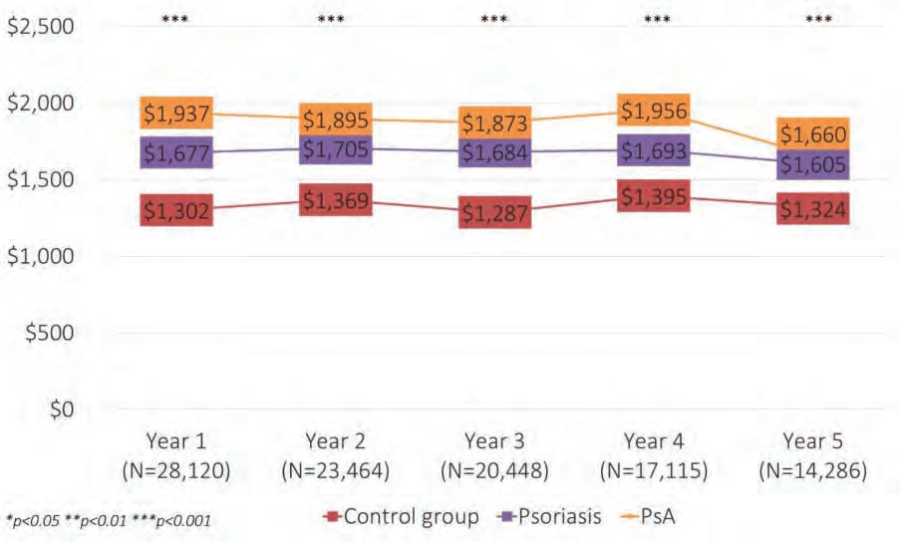

Figure 1. Average costs from non-recreational hours missed from work per patient per year

odds of short-term disability at one year were significantly greater among patients with PsA than psoriasis (OR: 1.56, 95% CI: 1.45-1.69) and controls (OR: 1.95, 95% CI: 1.82-2.10). Average costs from non-recreational work absences were $1,891, $1,680, and $1,333 per patient per year for the PsA, psoriasis, and control group, respectively. Costs associated with non-recreational work absences and short-term disability were significantly greater for patients with PsA and patients with psoriasis than controls at one year ($p< 0.0001$ for all comparisons). These costs were also significantly greater for PsA than psoriasis at one year ($p=0.001$ and $p< 0.0001$, respectively). This trend of increased costs for patients with PsA compared with the other groups was sustained throughout the five years of follow-up (Figures 1 & 2).

Conclusion: Work absenteeism and short-term disability were greater among both the psoriasis and PsA groups than the control group. Absenteeism and short-term disability were greater among patients with PsA than psoriasis. These findings demonstrate the substantial impact that psoriatic disease has on patients' work related outcomes, and highlight remaining unmet needs for patients with psoriatic disease.

Methods: Bio-naïve adults with active PsA despite nonbiologic DMARDs &/or NSAIDs received subcutaneous GUS 100 mg every (q) 4 weeks (W); GUS 100 mg Week 0, Week 4, q8W; or placebo (PBO). WPAI-PsA assesses, due to PsA over the previous week, work time missed (absenteeism), impairment while working (presenteeism), and impaired overall work productivity (absenteeism + presenteeism) and daily activity. Percentage change from baseline was analyzed for WPAI-PsA domains using mixed-effect model repeated measure (MMRM). Indirect savings from improved overall work productivity were estimated with 2018 US mean yearly wage estimate (all occupations).[2]

Results: At Week 24, impaired overall work productivity and daily activity were improved 20-22% in GUS-treated and 10-11% in PBO-treated patients (Table). Potential yearly indirect savings from improved overall work productivity was $10,242 with GUS q8W and $10,404 with GUS q4W vs $5,648 with PBO; $4,594 and $4,756 difference, respectively.

Conclusion: Improvement in overall work productivity and daily activity was greater with GUS versus PBO among patients with moderate-to-severe PsA, resulting in potential annual incremental economic gains.

Comparative Effectiveness of Secukinumab, Adalimumab and Other Tumor Necrosis Factor Inhibitors Used with or Without Methotrexate in the Treatment of Psoriatic Arthritis

Denis Choquette[1], Loïc Choquette Sauvageau[2], Louis Bessette[3], Isabelle Ferdinand[2], Boulos Haraoui[4], Frédéric Massicotte[2], Jean-Pierre Pelletier[1], Jean-Pierre Raynauld[1], Marie-Anaïs Rémillard[2], Diane Sauvageau[2], Édith Villeneuve[2] and Louis Coupal[2], [1]Institut de Rhumatologie de Montréal, Montreal, Canada, [2]Institut de Rhumatologie de Montréal, Montréal, QC, Canada, [3]Laval University, Quebec, Canada, [4]Rheumatology Institute of Montréal, Montreal, Canada

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

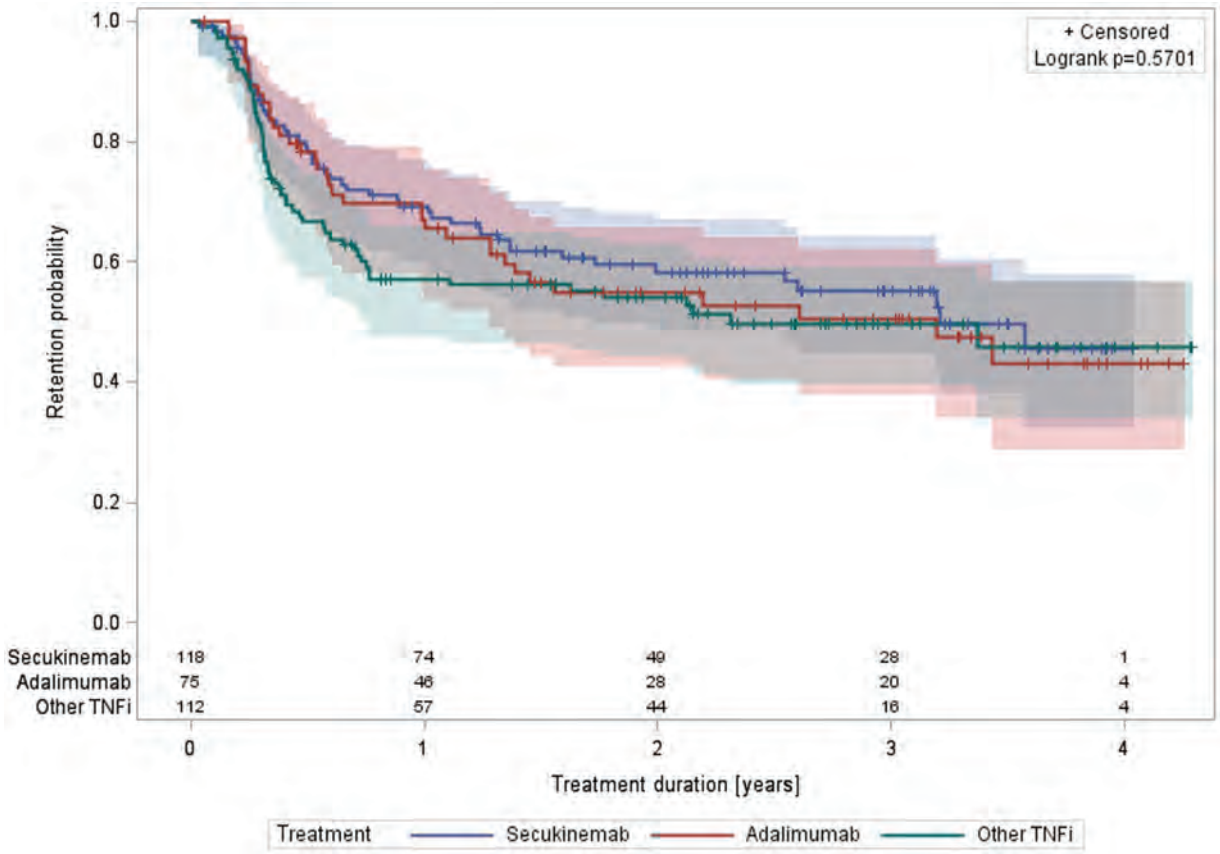
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment of psoriatic arthritis has evolved with the addition of agents targeting a different cytokine, Il-17 introduced in 2016. It has proven to be more effective than anti-TNF in controlling the cutaneous manifestation of psoriasis. Recent data have not shown clear superiority on the articular manifestations [EXCEED Study].

Methods: Patients diagnosed with PsA enrolled in RHUMADATA® were selected if they gave informed consent and were treated with secukinumab (SEC), adalimumab (ADA) or other TNF inhibitors (TNFi) on or after January 1, 2016. RHUMADATA® provides socio-demographics, comorbidities, patient-reported outcomes, disease activity indices, laboratory variables, rheumatologist exam report data, use of concomitant medications and PsA treatment. Kaplan-Meier survival curves and proportional hazard models were used to analyze time to treatment cessation.

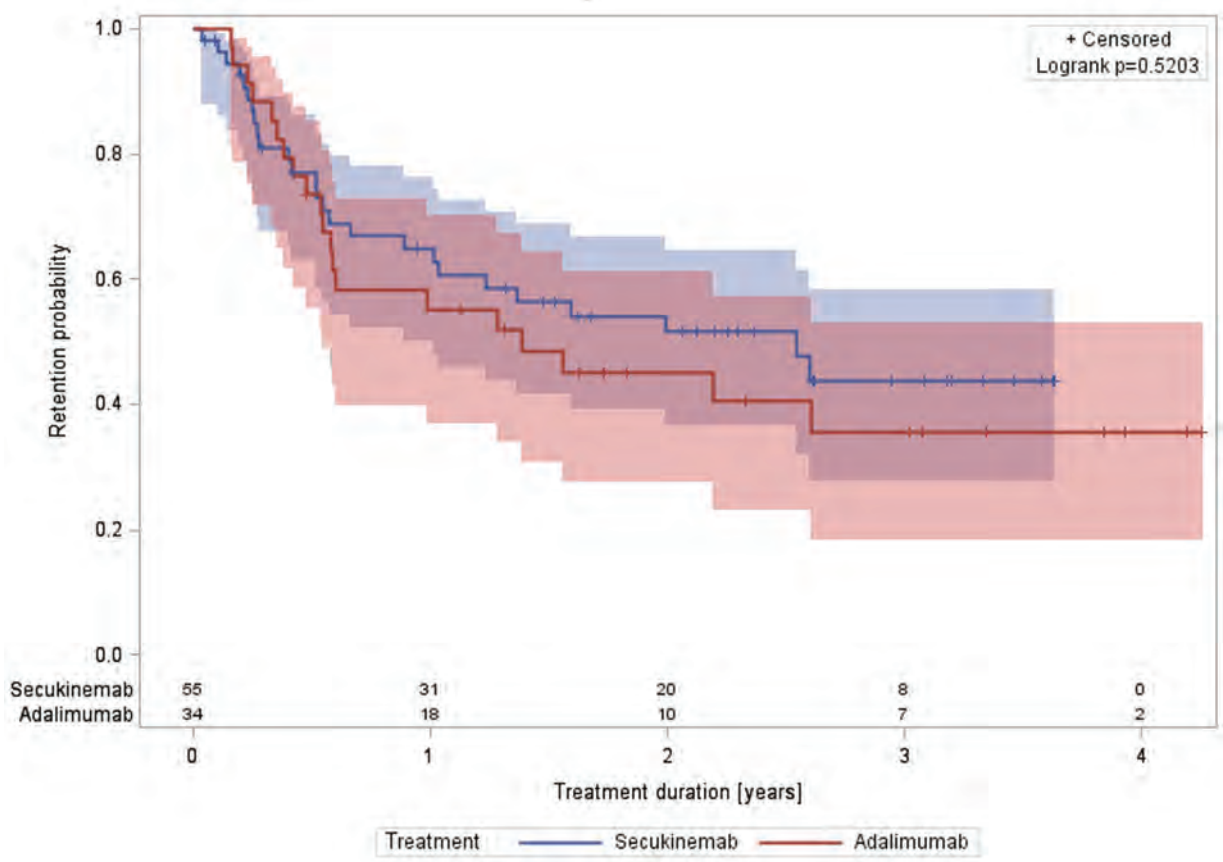
Results: A total of 305 patients with PsA were extracted from RHUMADATA®. One hundred and eighteen were treated with SEC, 75 with ADA and 112 with other TNFi (certolizumab, golimumab or infliximab. etanercept was not included



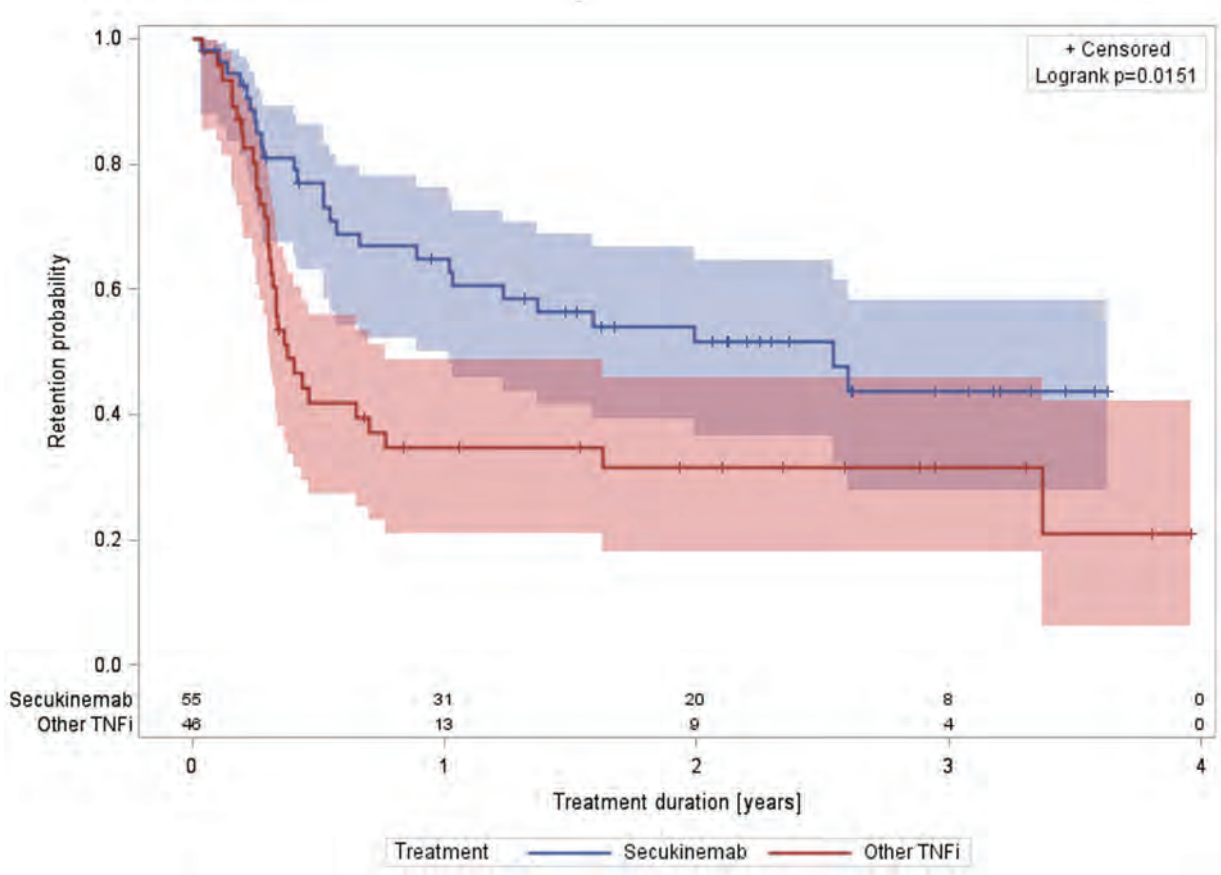
Retention of SEC, ADA and TNFi (all intentions).

as it is not an atibody targetting TNFi). Overall, 54.1% were women, average age at diagnosis and disease duration at treatment initiation were respectively 44.3 (±standard deviation (STD)=12.4) and 6.3 (7.9) years. The age-adjusted Charlson Comorbidity Index (aCCI) was 1.4 (1.8). The proportion of patients diagnosed or treated for diabetes and hypertension were 13.4% and 37.7%. The patient's assessment of disease activity, pain and fatigue were 5.5 (2.7), 6.0 (2.8) and 5.5 (3.1). Overall, BASDAI and BASFI scores were 5.6 (2.5) and 4.4 (2.8). The mean number of affected fingers and toes (dactylitis) and enthesitis were 0.9 (1.5) and 0.9 (1.7), respectively. SEC, ADA and TNFi were used in first intention in 25.4%, 61.3% and 37.5% of patients, respectively. CDAI at treatment initiation was 18.5 (11.0), 21.0 (10.2) and 16.6 (8.8) in the SEC, ADA and TNFi groups, respectively. At one-year CDAI, values were 6.1 (7.5), 5.0 (5.4) and 4.9 (3.1). Kaplan-Meier log-rank p-values comparing the three groups in all (Figure 1), first and second, and third+ intentions were 0.5701, 0.6631 and 0.3246, respectively. No pairwise comparisons of treatment (SEC vs. ADA, SEC vs. TNFi, ADA vs. TNFi) showed better retention for any agent. Pairwise comparison of these agents in monotherapy numerically favored SEC over ADA (Figure 2) but failed to reach statistical significance (log-rank p-value=0.5203), and SEC over TNFi (Figures 3) statistically favored SEC over ADA (log-rank p-value=0.0150). A Cox proportional hazard model adjusting for age at diagnosis, disease duration, aCCI, the number of prior advanced therapies, and concomitant use of MTX at treatment initiation as well as selected treatment demonstrated a statistically better retention among patients treated with MTX (Adjusted hazard ratio and 95% confidence interval: 0.487 [0.347, 0.683]. Adjusted treatment-MTX interaction terms were non-significant.

Conclusion: Secukinumab in observational data have shown similar efficacy over ADA and other TNFi. The use of these treatments in monotherapy showed similar retention for SEC over ADA , and impreoved retention for SEC over TNFi.



Retention of SEC and ADA in monotherapy (all intentions).



Retention of SEC and TNFi in monotherapy (all intentions).

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

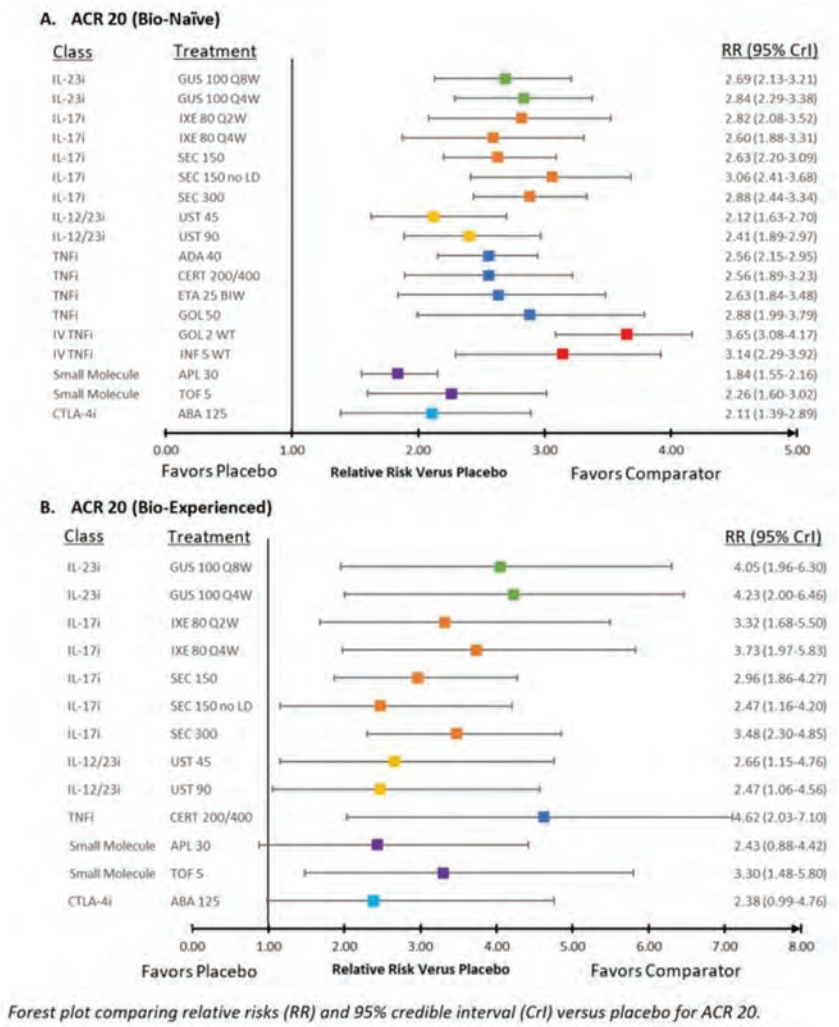

Figure 1. Forest Plot of ACR 20 Response Versus Placebo In Bio-Naïve and Bio-Experienced Populations

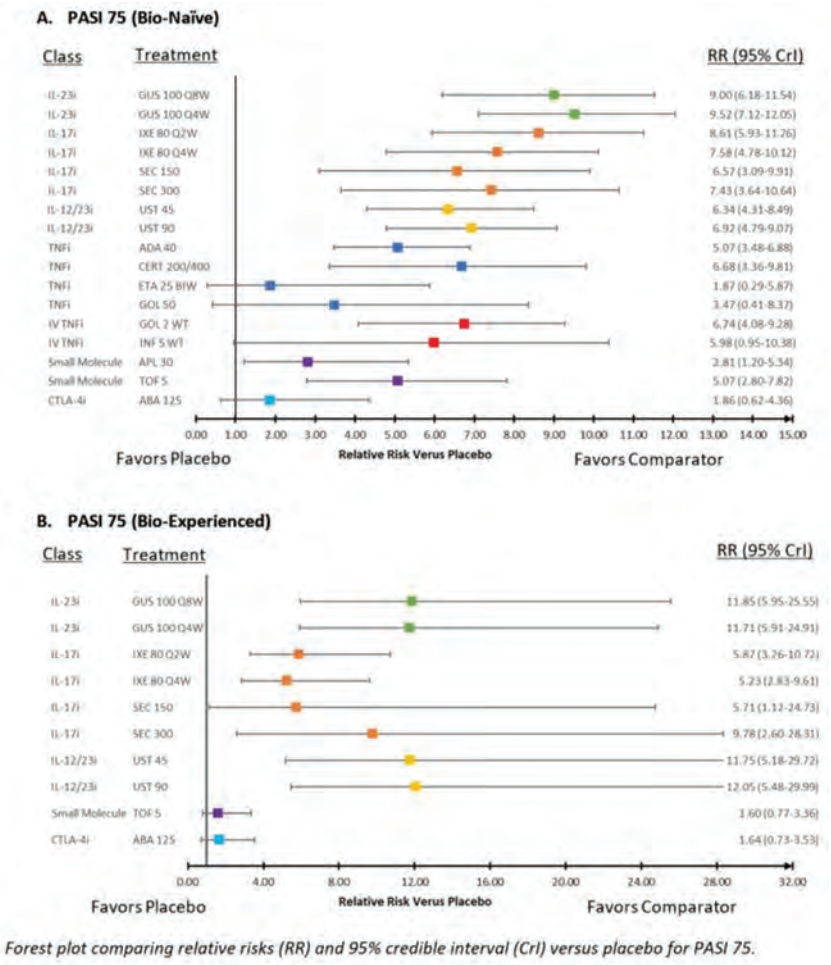

Figure 2. Forest Plot of PASI 75 Response Versus Placebo In Bio-Naïve and Bio-Experienced Populations

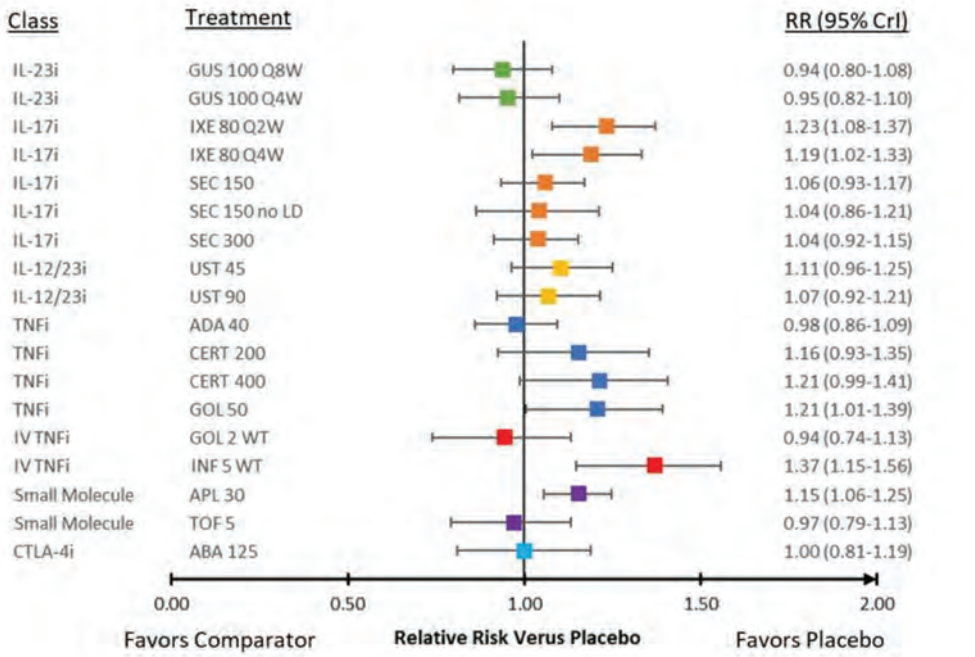
Background/Purpose: The efficacy of the interleukin (IL)-23 subunit p19 inhibitor guselkumab (GUS) for psoriatic arthritis (PsA) has recently been demonstrated in two Phase 3 trials (DISCOVER-1 & -2) but has not been evaluated versus existing targeted therapies for PsA. The objective of this study was to compare GUS to targeted therapies for PsA through network meta-analysis (NMA).

Methods: A systematic literature review was performed to identify PsA randomized controlled trials from 2000 to 2018. Bayesian NMAs were performed to compare treatments on American College of Rheumatology (ACR) 20/50/70 response, Psoriasis Area Severity Index (PASI) 75/90/100 response, Health Assessment Questionnaire Disability Index (HAQ-DI) score, modified van der Heijde-Sharp (vdH-S) score, adverse events (AEs) and serious adverse events (SAEs). For ACR 20 and PASI 75 response outcomes, analyses stratified according to previous exposure to biologics. Analyses adjusted for placebo response via meta-regression on baseline risk when feasible. Results are summarized by ranking treatments according responses derived from NMAs, with conclusions (ie, comparable or better/worse) derived from overlap of pairwise 95% credible intervals (CrI) between treatments.

Results: Twenty-four Phase 3 studies were included in NMAs. Studies were placebo-controlled up to 24 weeks and evaluated 13 targeted therapies for PsA. Forest plot of relative risks (RR) versus placebo for ACR 20 and PASI 75 according to previous exposure to biologics are presented in *Figure 1* and *Figure 2*, respectively. Forest plot of RRs versus placebo for AEs are presented in *Figure 3.* For ACR 20 response in the bio-naïve population, GUS 100 mg every 4 weeks (Q4W) and every 8 weeks (Q8W) ranked 5th and 8th out of 19 interventions and were comparable to



Forest plot comparing relative risks (RR) and 95% credible interval (CrI) versus placebo for patients with adverse events.

Figure 3. Forest Plot of Adverse Events Versus Placebo

IL-17 inhibitor (IL-17i) and subcutaneous tumor necrosis factor inhibitor (TNFi) agents. For ACR 20 response in the bio-experienced population, GUS Q4W and Q8W ranked 2nd and 3rd out of 14 interventions and were considered comparable to other active agents. Similar results were seen in mixed analyses of ACR 50 & 70. For PASI 75 response in the bio-naïve population, GUS Q4W and Q8W ranked 1st and 2nd out of 18 interventions and were better than most other agents. For PASI 75 in the bio-experienced population, GUS Q4W and Q8W ranked 3rd and 2nd out of 11 interventions and were better than several other agents. Similar results were seen in mixed analyses of PASI 90 & 100. For HAQ-DI score, GUS Q4W and Q8W ranked 6th and 11th out of 20 interventions and were comparable to IL-17i and subcutaneous TNFi agents. For vdH-S score, GUS Q4W and Q8W ranked 3rd and 10th out of 18 interventions, with Q8W comparable to most IL-17i and TNFi agents and Q4W likely to provide a benefit over IL-17i agents and most TNFi agents. For both AEs & SAEs, GUS Q4W and Q8W were comparable to most other agents.

Conclusion: GUS provides joint arthritis efficacy (ACR responses and modified vdH-S score), physical function (HAQ-DI score), and safety outcomes that is comparable to most targeted PsA treatments. For PASI outcomes, GUS is considered better than most other targeted PsA treatments.

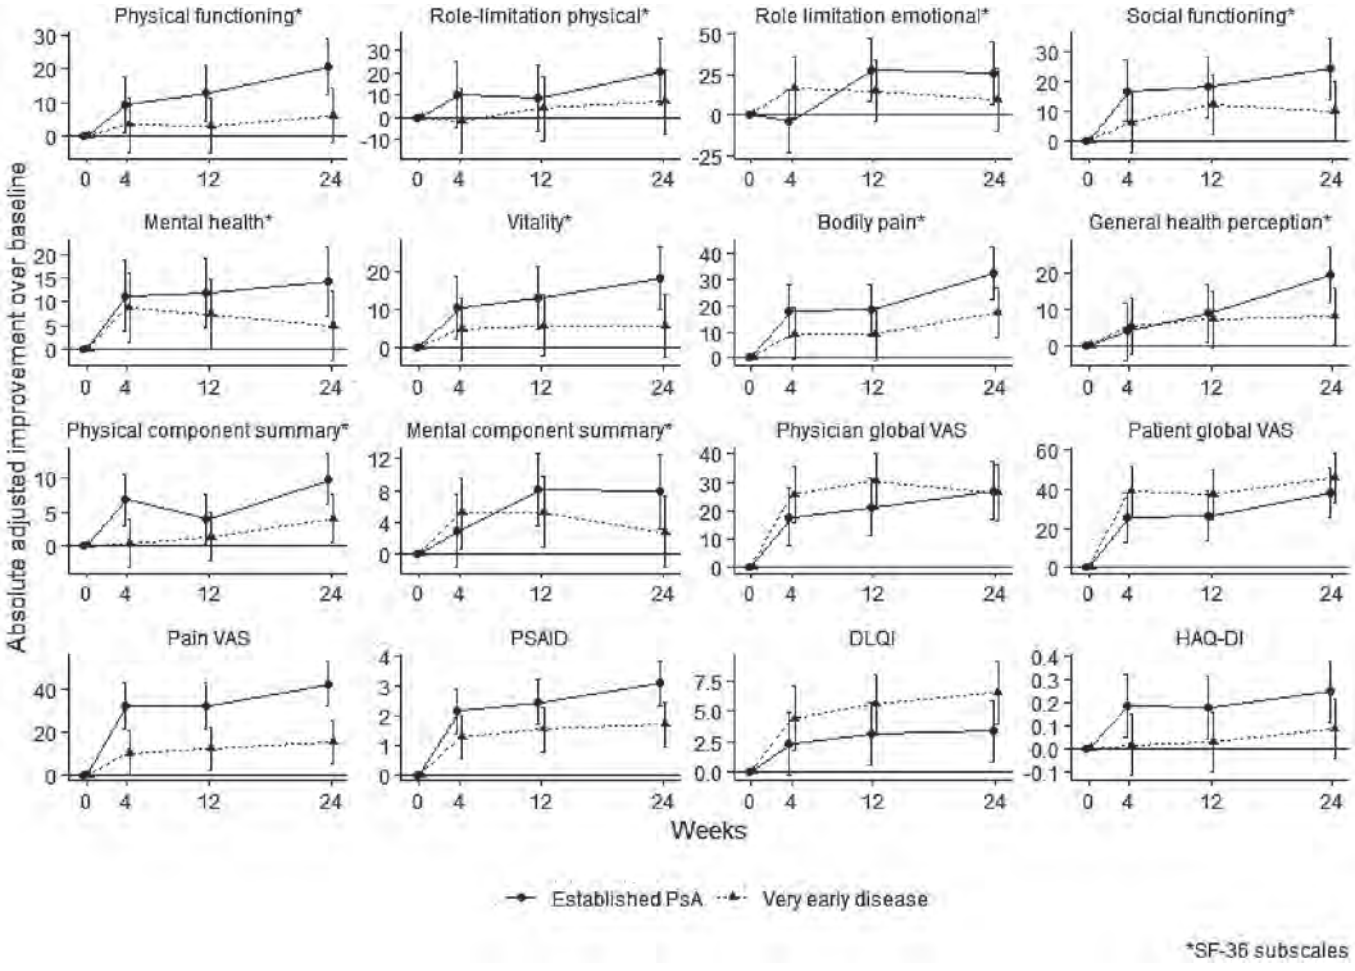
SESSION INFORMATION

Session Date: Friday, November 6, 2020

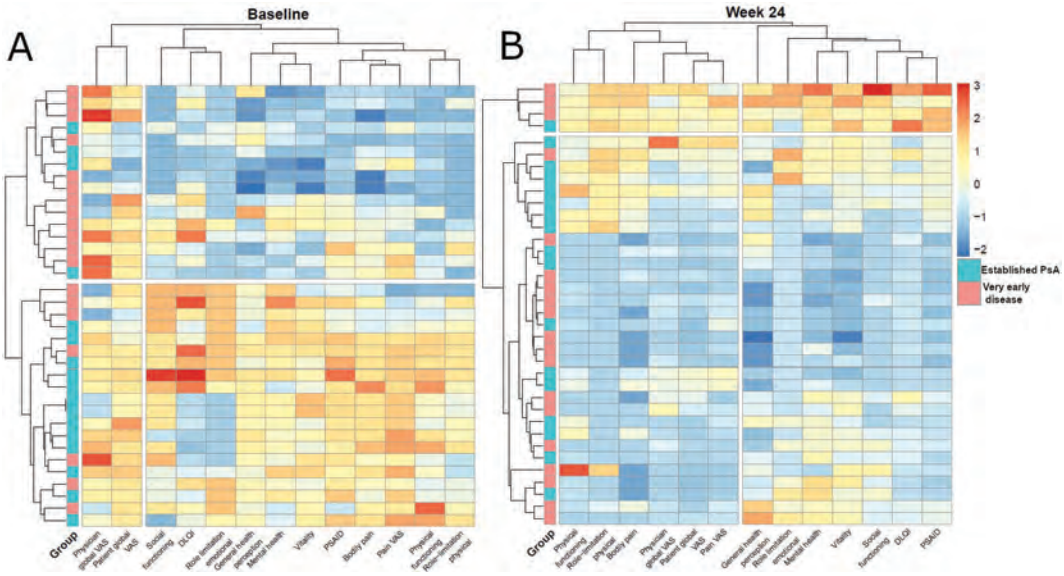
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM



Effects of secukinumab on patient-related outcomes in patients with very early disease and established psoriatic arthritis



Pre- and post-treatment patient-related outcome based cluster analysis

Background/Purpose: Limited information exists about the very early forms of psoriatic arthritis (PsA). In particular, differences and responsiveness of patient-reported outcomes (PROs) in very early disease as compared to established PsA have not been investigated to date.

Methods: Cross-sectional and prospective longitudinal evaluation of PROs related to pain (VAS pain score), physical function (HAQ-DI, SF-36 physical), mental function (SF-36 mental), impact of psoriatic skin (DLQI), joint (PsAID) and global disease (VAS global) in two small prospective observational studies on secukinumab 300 mg therapy over 6 months in 20 very early disease patients (1) and 20 established PsA patients (2). Adjusted changes from baseline were estimated using linear mixed models. We performed a cluster analysis of centered and scaled PROs at baseline and 24-weeks of follow-up using Euclidean distances.

Results: While responses in pain and physical activity-related PROs to secukinumab were more pronounced in established PsA than very early disease, effects on PROs related to general health perception, as well as those related to emotional and mental well-being, were modified in a similar way in very early disease and established PsA. The absolute adjusted improvement over baseline for the specific PROs for the 2 groups of patients is presented in figure 1. Cluster analysis based on global disease activity assessment and PROs showed that baseline clusters reflected very early disease and established PsA, while during interleukin-17 inhibition these clusters were abolished and new clusters based on differential responses to physically and mentally-oriented PROs formed (figure 2).

Conclusion: Inhibition of IL-17A leads to comprehensive improvement of PROs in patients with very early musculoskeletal involvement in PsA. Most importantly, treatment restructures original clusters based on the stage of psoriatic disease and leads to the formation of clusters that reflect their post-treatment state in physical and mental-orientated PROs.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anxiety and depression are comorbidities among PsA patients. The impact of anxiety and depression on outcomes in PsA patients has not been characterized in a real-world clinical setting. The objective of this study was to describe the prevalence of anxiety and/or depression in PsA patients, assess concordance in reported anxiety and/or depression between patients and physicians, and compare clinical and patient reported outcomes (PROs) in patients who report anxiety and/or depression and those who do not.

Methods: A cross-sectional study among patients with PsA recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, UK and US. Data were collected Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Physicians reported patient demographic, disease characteristics and diagnosed anxiety and/or depression. Patients reported experience of PsA-related anxiety and/or depression, quality of life [QoL] (EQ5D-5L), work productivity (WPAI), disability (HAQ-DI), and disease impact

Table 1 Demographic and clinical characteristics by patient-reported anxiety and/or depression

	No anxiety and/or depression (n=436)	Anxiety and/or depression (n=252)	P value
Demographic characteristics			
Age, mean (SD)	47.7 (12.1)	49.1 (12.6)	0.13
Female, n (%)	196 (45.0)	146 (57.9)	<0.01
BMI, mean (SD)	26.7 (5.1)	26.9 (4.4)	0.57
Caucasian, n (%)	408 (93.3)	238 (94.4)	0.46
Working full time, n (%)	293 (68.6)	107 (44.8)	<0.01
Biologic tx, n (%)	257 (58.9)	160 (63.5)	0.26
Disease characteristics			
Years since diagnosis, mean (SD)	5.7 (6.0)	6.9 (7.7)	0.04
Physician-perceived Current overall severity*, n (%) -Mild -Moderate -Severe	 277 (63.5) 145 (33.3) 14 (3.2)	 137 (54.4) 106 (42.1) 9 (3.6)	0.02
Current BSA %, mean (SD)	8.7 (12.3)	6.4 (8.2)	0.02
66 swollen joint count, mean (SD)	2.7 (3.6)	5.6 (10.4)	<0.01
68 tender joint count, mean (SD)	3.8 (4.3)	6.0 (6.2)	<0.01

Table 2. Impact of anxiety or depression on PROs*

	With or without anxiety and/or depression	Difference in predicted PRO value with anxiety and/or depression [α]	P value
EQ5D utility score, mean N=488	Without (ref) With	0.83 -0.10	<0.01
WPAI percentage overall work impairment, mean N=262	Without With	22.3 +7.4	<0.01
HAQ-DI score, mean N=480	Without With	0.53 +0.26	<0.01
PsAID12 score, mean N=482	Without With	2.32 +1.78	<0.01

* Adjusted for age, gender, employment status, BMI, no. of joints affected and BSA

[α] PRO key for worse outcome (range): EQ5D utility (0-1.0) = lower; EQ5D VAS (1-100) = lower; WPAI (0-100) = higher; HAQ-DI (0-3) = higher; PsAID12 (0-10) = higher.

(PsAID12). Patients were compared according to patient reported anxiety and/or depression using parametric tests and non-parametric tests. Multivariate regressions explored impact of anxiety and/or depression on PROs. Models adjusted for age, gender, employment status, BMI, no. of joints affected, body surface area (BSA).

Results: Data were collected from 688 physician-patient pairs (524 EU; 164 US). Physicians reported anxiety and/or depression in 14.2% of patients (EU 13.3%; US 16.2%), while 36.6% (EU 36.3%; US 37.8%) of patients self-reported anxiety and/or depression. 71.4% of physician-patient pairs agreed on anxiety and/or depression presence

or absence (Kappa = 0.31, fair agreement). Patients with anxiety and/or depression had worse QoL, higher work impairment, and greater disability (Table 2).

Conclusion: After adjusting for demographic and clinical factors, patients with anxiety and/or depression were found to have worse QoL, work productivity, and disability outcomes than those without. Differences between patient and physician reports of anxiety and/or depression suggest that physicians may not be aware of the extent to which PsA patients experience anxiety and/or depression.

Similar Impact of Psoriatic Arthritis and Rheumatoid Arthritis on Objective and Subjective Parameters of Hand Function

Anna-Maria Liphardt[1], Eva Manger[2], Sonja Liehr[2], Lisa Bieniek[2], Arnd Kleyer[3], David Simon[3], Koray Tascilar[3], Michael Sticherling[4], Juergen Rech[3], Georg Schett[5] and Axel Hueber[6], [1]Friedrich-Alexander-University Erlangen-Nuremberg, Internal Medicine 3 - Rheumatology & Immunology, University Hospital Erlangen, Erlangen, Bayern, Germany, [2]Departement of Internal Medicine 3 - Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nuremberg and University Hospital Erlangen, Erlangen, Bayern, Germany, [3]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Bayern, Germany, [4]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany, [5]Friedrich-Alexander-Universität Erlangen- Nuremberg, Erlangen, Germany, [6]Sozialstiftung Bamberg, Sektion Rheumatologie, Bamberg, Germany

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the impact of psoriatic arthritis (PsA) and rheumatoid arthritis (RA) on objective and subjective parameters of hand function.

Methods: Hand function was assessed by (i) vigorimetric grip strength, (ii) Moberg picking up test (MPUT) and (iii) self-reported hand function (Michigan Hand Questionnaire, MHQ). Mixed effects linear regression models were used to test the relation of hand function with age, sex and disease group.

Results: 299 subjects were tested, 101 with RA (Age: 59.1 ± 13.3 years, BMI: 27.2 ± 5 kg/m^2), 92 with PsA (Age: 58.8 ± 11.6 years, BMI: 29 ± 6.1kg/m^2) and 106 non-arthritic controls (51 with Pso (Age: 47.3 ± 14.1 years, BMI: 29.8 ± 7.3 kg/m^2) and 55 healthy controls (HC, Age: 54.6 ± 16.5 years, BMI: 25.2 ± 3.3 kg/m^2). Grip strength as a measure of muscle force (lbf) was lowest in RA patients (57.9(31)), followed by PsA (72.8(34.7)), Pso (80.4(34.1) and HC (84.1(24.9)) respectively. MPUT (seconds) of the dominant hand was best in HC (11.5(2.3)), followed by Pso patients (14.7(4.6)), PsA (16.4(8.5)) and RA (18.2(21.6)). Group means for self-reported hand function score by MHQ ranged

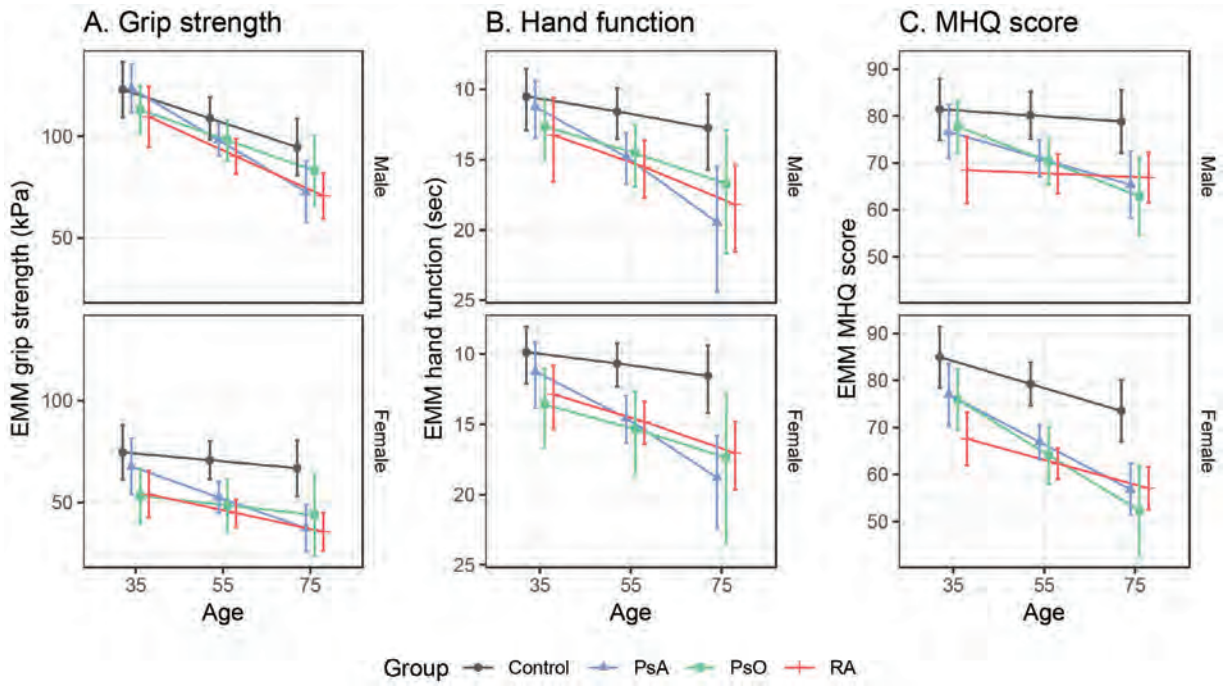

Figure 1. Estimated marginal means with multiplicity-adjusted 95% confidence intervals for psoriatic arthritis patients (PsA), rheumatoid arthritis patients (RA), psoriasis patients (PsO) and healthy controls (HC) at ages 35, 55 and 75 by gender and dominant hand.

between 77.2 (HC) and 63.8 for RA patients. Regression analysis showed that grip strength was affected by sex, age and disease group ($p < 0.001$ for all) with higher values but also greater decline with increasing age in male individuals (Figure 1A). PsA, RA and unexpectedly also psoriasis lowered grip strength in females, while in males only modest disease-related reductions of grip strength were observed. Fine motor skills as assessed by MPUT remained remarkably stable in healthy subjects during age. However, they significantly dropped with age in RA, PsA and interestingly also in psoriasis patients ($p < 0.001$ for the interaction of MPUT with age and disease Group, Figure 1B). Self-reported hand function was assessed by MHQ. Regression analysis showed that MHQ is significantly affected by age, disease status and hand dominance ($p < 0.001$ for all). The effect of disease on the MHQ increased with age and was more pronounced in females. Estimated marginal mean MHQ incrementally deviated from controls in PsA and psoriasis with increasing age, whereas in RA self-reported hand function was already low in younger subjects (Figure 1C).

Conclusion: In conclusion, the impact of PsA on hand function is similar to RA and affects muscular force, fine motor skills and self-perception of hand function. The burden of disease on hand function increased with age and affects both sexes and both hands. In addition, hand function is impaired already in psoriasis patients suggesting intrinsic functional musculoskeletal alterations in psoriatic disease, which occur independently from PsA.

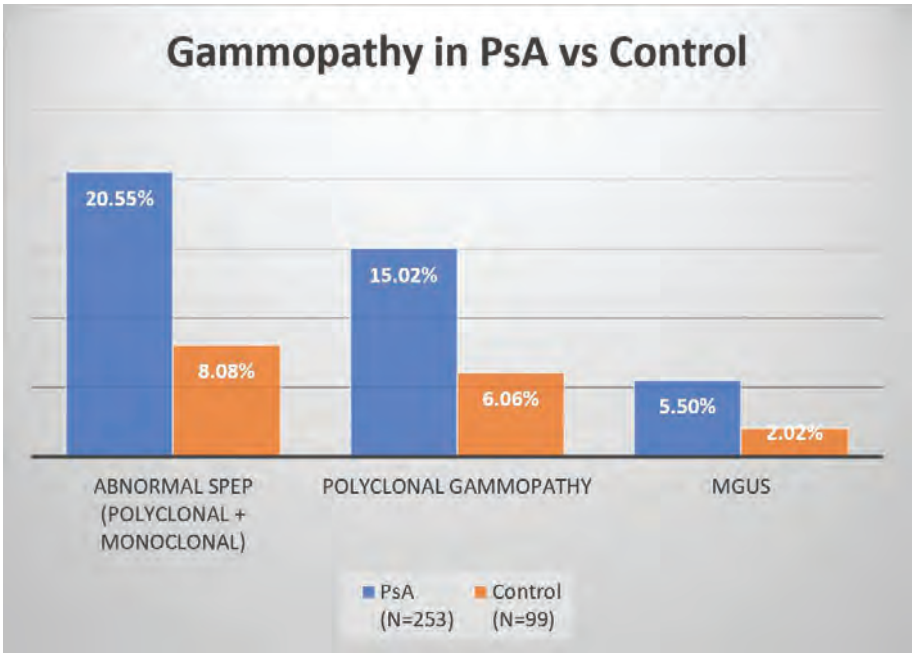
Increased Risk of Lymphoproliferative Disorders in Psoriatic Arthritis

Eugenia Chen[1] and Maida Wong[2], [1]Department of Medicine, University of California Irvine, Orange, CA, [2]Division of Rheumatology, Department of Medicine, VA Long Beach Healthcare System, Long Beach, CA

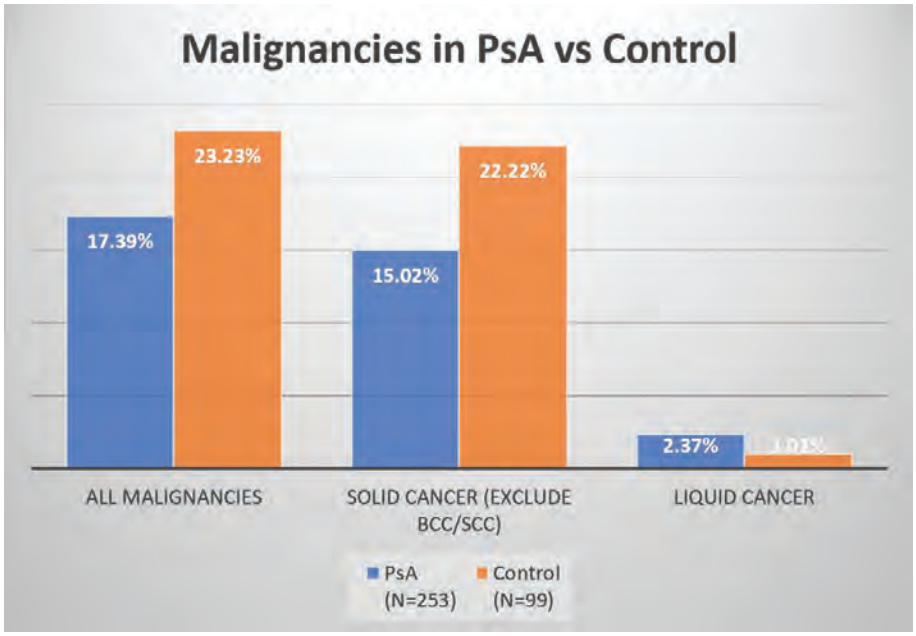
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a systemic inflammatory disease that involves musculoskeletal and skin manifestations. Such autoimmune disease has been associated with increased lymphoproliferative disease risk, which is thought to be due to abnormal immune activation and/or continual exposure of systemic immunosuppressive therapies. Such risk is well established in psoriasis but is still unclear in PsA. This study was undertaken to investigate the risk of developing lymphoproliferative disorders among patients with PsA.

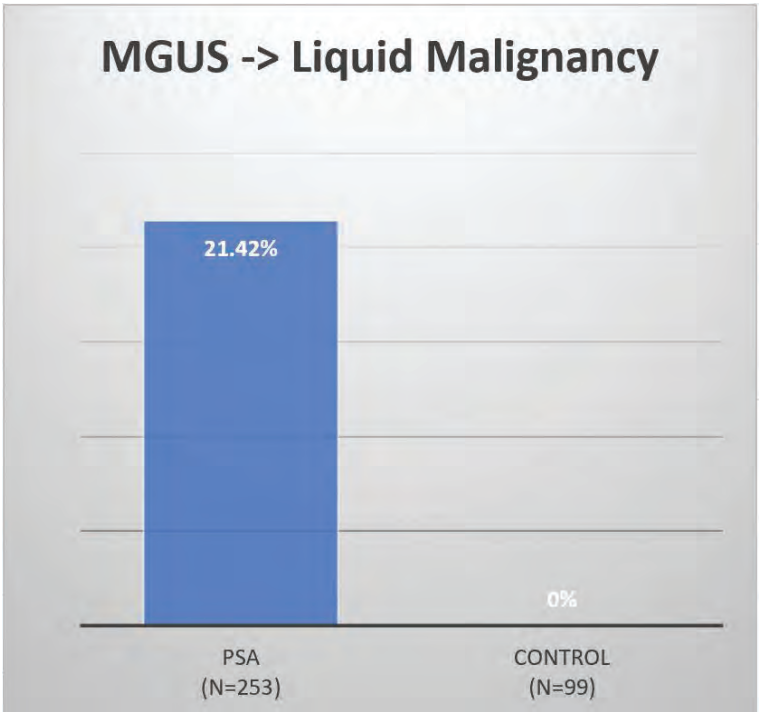
Methods: A multicenter retrospective study involving two Veterans Affairs (VA) Hospitals in Southern California, namely Long Beach and Greater Los Angeles, was performed. Patients with PsA were assembled using the ICD 9 and 10 coding from 2000 to 2019 (n=253) compared against controls (n=99) without autoimmune diseases that were matched in age, sex and race. Outcome measures were the number of patients who developed malignancies (excluding skin basal cell carcinoma and squamous cell carcinoma) and the number who had abnormal serum protein electrophoresis (SPEP). The Odds Ratio (OR) for developing abnormal SPEP, including polyclonal and monoclonal gammopathy (MGUS), as well as solid and liquid cancers (lymphoma or leukemia) were calculated. Additionally, the percentage of MGUS patients progressing to develop lymphoproliferative malignancies was compared.



The risk of developing abnormal SPEP and polyclonal gammopathy were both significantly higher in PsA patients compared to controls with $p<0.05$. The prevalence of MGUS was 5.5% among PsA patients, while 2% among controls, with p value close to but not statistically significant.



There was no significant difference in the risk of developing malignancies in PsA patients vs controls. However, we observed a trend of slightly higher liquid cancer risk in PsA patients, but not solid tumors.



Among PsA patients with MGUS, approximately 20% eventually developed lymphoproliferative cancers but none in the controls. However, the sample size was too small to reach statistical significance.

Results: PsA patients were at least twice more likely to develop abnormal SPEP (OR 2.36, CI 1.08-5.15), and in particular, polyclonal gammopathy (OR 2.74, CI 1.12-6.70), compared to controls. The prevalence of MGUS was 5.5% in PsA patients versus 2.0% in controls (OR 2.84, CI 0.63-12.74). There was no significant difference in the risk of developing any kind of malignancies, however there was a trend of a slightly higher number of PsA patients with liquid

cancers than solid tumors. Among PsA patients with MGUS, approximately 20% eventually developed lymphoproliferative cancers but none in the controls. However, the sample size was too small to reach statistical significance.

Conclusion: PsA patients have a higher risk of developing polyclonal gammopathy, likely due to abnormal immune activation of the disease and chronic inflammation. More PsA patients developed MGUS, and possibly with an increased propensity to progress to lymphoproliferative malignancy, which requires validation with a larger cohort. Additional studies on immunosuppressive therapies, disease activity and inflammatory markers are underway to elucidate their correlation with lymphoproliferative cancer risk in PsA patients. Malignancy screening by SPEP on a regular basis may be beneficial to PsA patients, especially for those who have MGUS.

Is Sex-adjusted Treatment in Early-PsA Justified?

Evangelia Passia[1], Jolanda Luime[1], Marc Kok[2], Ilja Tchetverikov[3], Marijn Vis[4], Fouchia Fodili[5], Yvonne Ruiterman[6] and Lindy-Anne Korswagen[7], [1]Erasmus MC, Rotterdam, [2]Maasstadziekenhuis, Rotterdam, [3]Albert Schweitzer Ziekenhuis, Dordrecht, [4]Erasmus UMC, Rotterdam, Netherlands, [5]RZWN, Roosendaal, [6]HAGA ziekenhuis, Den Haag, [7]Franciscus Gasthuis, Rotterdam

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: According to existing knowledge, the prevalence of psoriatic arthritis (PsA) is equal in men and women, however, women experience a higher burden of disease (pain, disability and fatigue). Recently we showed that women with newly diagnosed PsA present higher disease activity, pain and functional impairment compared to men at baseline but also at one year of follow up. Several reasons could be incriminated for the observed differences and their persistence over time. One of them could be a different therapeutic approach, maybe less aggressive, in women compared to men.

To compare applied treatment in female and male patients with early PsA.

Methods: Data were used from the Dutch south west Psoriatic Arthritis Cohort (DEPAR) which includes newly diagnosed PsA patients. Data on disease activity, medication use and patient reported outcomes is gathered at baseline and from then, during the first year, every 3 months. Exposure time (days), cumulative and mean dose per dosing interval during the first year were calculated for each conventional DMARD (csDMARD). Exposure time for biological DMARDs (bDMARDs), as a group was also calculated. T-tests and Kruskal Wallis tests were used for the comparison across sexes. Stata 16 was used for statistical analysis.

Results: In February 2019, 615 patients were available for analysis, 304 men and 311 women (51%), average age of 50 (SD 13.6) years. Oligoarthritis was the most frequent phenotype (39%), more frequently present in men (44%) than in women (33%). Polyarthritis (23%) was more prevalent in women. 523 patients had 12 months of follow-up, while the remaining 92 participated a mean 223 days in the study. Over the first year, 75% of the patients received one or more DMARDs for which the majority (82%) started within the first month after diagnosis. Not using DMARDs was equally present in both sexes. Monoarthritis was the phenotype less frequently treated by DMARDs (50%).

		Men (n=304)				Women (n=311)				
		n	p25	p50	p75	n	p25	p50	p75	p-value

	dose		10	20	20		10	17	20	0.59
Prednisone	days	32	34	98	171	51	38	89	183	0.66
	cumulative dose (mg)		648	1208	1820		420	814	1480	0.20
	dose		8	11	20		7	8	15	0.06

Table 1. DMARD medication frequency, median days of exposure, cumulative dose and dose per dosing interval in the first year after PsA diagnosis stratified by sex. *non-parametric comparison between men and women. t parametric t-test for comparison between men and women

Results are shown in table 1. Methotrexate was the most frequently used drug during the first year. Its frequency (70%) and dosing (median 20 mg/week) were similar for men and women.. Women received methotrexate for a shorter period (median 270 vs 290 days) and subsequently had a lower cumulative dose compared to men. Sulfasalazine, leflunomide, hydroxychloroquine and corticosteroids were more frequently prescribed in women compared to men. Retention time of sulfasalazine was substantial shorter in women. Number of days on bDMARDs was lower for women (n=39, median 160 days), but not significantly different from men(n=42, median 212 days), mainly caused by a later start of bDMARDs in women.

Conclusion: 75% of early Psoriatic Arthritis patients in DEPAR were treated by DMARDs in the first year after diagnosis. Initial treatment strategies were similar in both sexes. However, over time women received methotrexate for a shorter period, were more often switched to other csDMARDs and started later with bDMARDs. Retention time for the other csDMARDs was shorter in women. These observations raise the question whether optimal therapeutic strategies are in place for women with early PsA.

Neuropathic Pain Relationship with Comorbidity in Psoriatic Arthritis Patients and Its Influence on Disease Activity

Maria Elisa Acosta[1], Olga Compán[2], Sonia Pastor[1], Guadalupe Manzano Canabal[1], Luis Gomez-Lechon Quiros[3], Cristina Hidalgo Calleja[4], Olga Martinez Gonzalez[5], Ana Isabel Turrión[1], Javier Del Pino-Montes[1] and Carlos Montilla Morales[1], [1]Hospital Universitario de Salamanca, Salamanca, Spain, [2]Hospital Universitario de Salamanca, ´Salamanca, Spain, [3]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain, [4]Hospital Universitario Salamanca, Salamanca, Spain, [5]Hospital Universitario de Salamanca, Zamora, Spain

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In psoriatic arthritis (PsA) peripheral nociceptive pain is characteristic, and is trigger by the activation of the afferent sensory fibers in the inflamed synovial membrane. The greatest ability to respond to pain in the presence of inflammation is physiological, however, pain hypersensitivity may persist after inflammation has resolved and perpetuate itself as chronic pain, a mechanism in which central hypersensitivity is involved. Inflammatory activity indices include subjective variables related to pain perception, so central hypersensitivity can overestimate disease activity. For this reason, identifying possible underlying pain mechanisms can be of great importance in clinical decision-making. Purpose: To relate the presence of neuropathic pain with disease activity and impact, and to analyze the influence of comorbidity on neuropathic pain.

Methods: Cross-sectional study of 246 PsA patients (diagnosed with CASPAR criteria). Patients with fibromyalgia, depression, anxiety or diabetes were excluded. The PAINDETECT questionnaire was used to identify neuropathic pain and to classified patients into 3 groups: a score ≥ 19 indicated a high probability of pain with a neuropathic component, between 18 and 13 was ambiguous and ≤ 12 possibly ruled out this type of pain. Disease activity was measured by DAPSA index, ESR and CRP. The therapeutic objective was the minimal disease activity (MDA) and to assess disease impact PsAID questionnaire was used. Regarding comorbidities anxious and/or depressive habit were assessed using the Hospital Anxiety and Depression Scale (HADS), fatigue (item 2 of PsAID), sleep quality by the Insomnia Severity Index (ISI) and waist-to-hip ratio, apolipoprotein A, apolipoprotein B, lipoprotein A, C-peptide, insulin, insulin resistance (HOMA) and leptin were also measured.

Results: Of the 246 patients 44.7% were female and the mean of age was 53.45 years (SD: 11.00). The average disease duration was 10.3 years (SD: 7.47). 64.6% were taking synthetic DMARDs and 14.6% were receiving biological therapy. 24.8% were in remission by DAPSA and 39.4% achieved MDA. According to the PAINDETECT questionnaire

Table 1.

	PAINDETECT≥19	PAINDETECT≤12	P
Gender (M/F)	12/30(28,6%)	104/60(63,4%)	0,001
MDA (Yes/No)	8/34(19%)	83/81(53%)	0,001
DAPSA(≤4) (Yes/No)	1/41(2,4%)	40/123(24,5)	0,001
Pain	6,26(2,28)	2,50(2,39)	0,001
HAQ	1,16(0,59)	0,47(0,53)	0,001
Tender joint count	2,73(2,42)	1,40(1,94)	0,002
MASES Index	2,52(2,71)	0,82(1,44)	0,001
Fatigue	6,26(2,26)	3,70(2,49)	0,001
ISI	14,54(6,12)	7,34(4,99)	0,001
Anxiety	9,85(3,71)	5,89(3,97)	0,001
Depression	7,61(4,10)	3,99(3,46)	0,001
PsAID	6,13(1,75)	2,66(1,95)	0,001
Leptin (ng/mL)	34,26(36,20)	14,21(13,56)	0,001

17.1% of patients had neuropathic pain and 66.7% didn't. Table 1 shows the significant variables related to neuropathic pain.

In the multivariate analysis composed of gender, ISI, HADS, fatigue, leptin and obesity, the variables that influenced the presence of neuropathic pain were fatigue $p < 0.003$ (OR: 1.34, 95% CI: 1,10-1.62), sleep quality $p < 0.001$ (OR: 1.20; 95% CI: 1.10-1.32) and leptin $p < 0.008$ (OR: 1.03; 95% CI: 1.008-1.052). Nagelkerke's $R2 = 0.51$.

Conclusion: PsA patients with neuropathic pain have higher probability of not achieving MDA or remission measured by DAPSA. More intense pain, greater number of entheses and tender joints were the main reasons. Therefore, neuropathic pain assessment in our patients may have therapeutic implications. Sleep quality and fatigue influenced the presence of neuropathic pain, and these processes (secondary to central hypersensitivity) were associated to PsA and not to other diseases such as fibromyalgia. As described in animal models, leptin levels could mediate in the presence of chronic pain.Table 1.

Metabolomics Profiling of Human Serum for Discovering Biomarkers to Diagnose Psoriatic Arthritis and Ankylosing Spondylitis with High Specificity

Wei Han[1], Xiaohang Wang[1], Liang Li[1], Stephanie Wichuk[2], Edna Hutchings[3], Rana Dadashova[3], Joel Paschke[3] and Walter Maksymowych[2], [1]Department of Chemistry, University of Alberta, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]CARE Arthritis, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In this work, we applied a high-performance chemical isotope labeling (CIL) LC-MS platform to search for biomarker candidates of PsA and AS in human serum samples. We aimed to identify metabolite biomarkers with high discriminatory power for PsA and AS versus rheumatoid arthritis and healthy controls.

Methods: Serum samples were collected from 331 subjects, including 100 healthy controls, 48 PsA patients, 52 AS patients and 131 RA patients. The average age of each group was: 52.6 (control), 50.7 (PsA), 51.8 (AS) and 53.1 (RA) years. After pre-treatment, each sample was incubated with ^{12}C-dansyl chloride, which can label the amine/phenol-containing metabolites. The reference sample for relative quantification was prepared by mixing all individual samples and then labeled by ^{13}C-dansyl chloride. With this normalization, the individual samples and the reference sample were mixed at an equal amount. Finally, we used an LC-QTOF-MS platform to analyze the mixtures and measure the ^{12}C/^{13}C peak pairs.

Results: We detected 1,149 peak pairs commonly existing in the serum samples. Using our dansyl-library of 700 dansyl-labeled standards and a prediction library, which contains the predicted retention times and mass values of

3,431 dansylated human metabolites, we identified 134 and 141 peak pairs, respectively. The relative concentrations are calculated from the intensity ratios of $^{12}C/^{13}C$ peak pairs. We first visualized the entire amine/phenol-submetabolome for all phenotypes using the partial least squares discriminant analysis (PLS-DA). We found that the most significant between-group separation was between healthy controls and all the patients. No significant sex or age effect was observed. Furthermore, among the three diseases, PsA and AS samples were closely clustering, while the RA group was well separated from them. Therefore, we chose a two-step diagnosis approach that first differentiates PsA patients from controls/RA patients and then filters out the AS patients wrongly classified as PsA in the first step. The same strategy was conducted for AS. Stipulating a fold change larger than 1.5 with the false discovery rate lower than 5%, we found 74 metabolites having significantly higher or lower concentrations in the PsA group compared to the control or the RA group. We selected two of these significant metabolites to build a classification model based on the linear support vector machine (SVM) method, and the area-under-the-curve (AUC) value of the resulting receiver operating characteristic (ROC) curve was 0.929 (95% confidence interval: 0.899-0.956). Similarly, 37 metabolites could differentiate AS samples from RAs and controls. A proposed diagnostic panel containing four metabolites demonstrated an AUC value of 0.890 (0.843-0.934). For the last step, distinguishing between PsA and AS, there were 15 significantly increased metabolites and 9 lowered ones. The biomarker panel consisting of the top three metabolites also achieved good discriminatory power with AUC = 0.827 (0.717-0.919).

Conclusion: Isotope-labeling-LC-MS-based metabolomics has revealed biomarker candidates that can specifically differentiate PsA or AS patients from control populations.

Multimorbidity Clusters in Psoriatic Arthritis: A Population-Based Study

Paras Karmacharya[1], Dilli Poudel[2], Cynthia Crowson[3], John Davis[4], Kerry Wright[4] and Alexis Ogdie[2], [1]Mayo Clinic, Rochester MN, ROCHESTER, MN, [2]University of Pennsylvania, Philadelphia, PA, [3]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN, [4]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) patients have a higher prevalence of cardiometabolic and other morbidities compared to the general population. Studies suggest that a single clinical variable cannot adequately predict which PsA patients will have worse outcomes; therefore studying these morbidities together will provide better insight. Multimorbidity refers to the simultaneous presence of ≥2 morbidities, and certain morbidities are more likely to cluster than others. We used The Health Improvement Network (THIN) database to identify prevalent multimorbidity clusters in PsA.

Methods: We used the THIN database (2000-14) to identify adults (aged 18–89 years) with PsA using the Read code for PsA (positive predictive value- 85%). THIN contains systematically and prospectively recorded data by general practitioners in the UK. Morbidities in PsA were selected by clinical relevance and by previous reports, and only those occurring ≥1% were included. Multimorbidity clusters were identified using K-median clustering, which is an

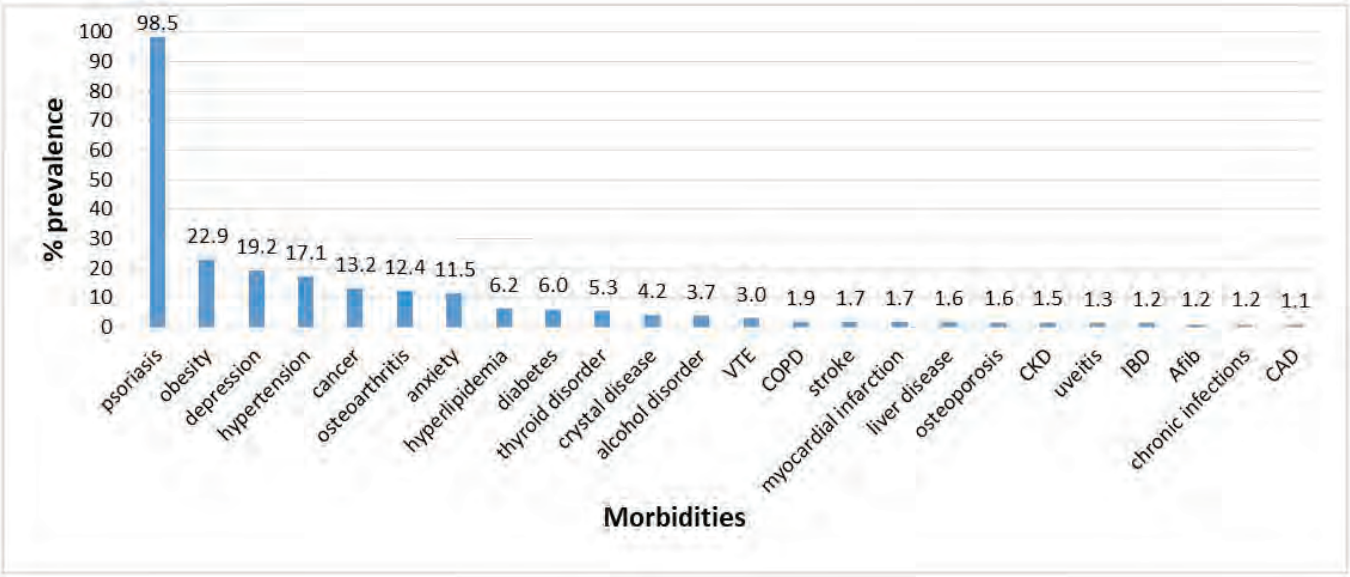

Figure 1. Prevalence of morbidities in psoriatic arthritis

unsupervised machine learning algorithm which groups data into a user-specified number (k) of clusters based on a set of variables (here morbidities). The optimal number of clusters was determined using the elbow method. K-median clustering was run on the dataset for a range of values of k (e.g., k from 1 to 10); and for each value of k, sum of squared errors (SSE) was calculated. In a scree plot of the SSE for each value of k, we identified the "elbow" on the arm (graph line), which was taken as the best value of k.

Results: There were 14,560 PsA patients identified in the THIN database from 2000-14, with a mean age of 47 ±15 years and 50% males. Psoriasis was the most prevalent morbidity (98.45%), followed by obesity (22.9%) and depres-

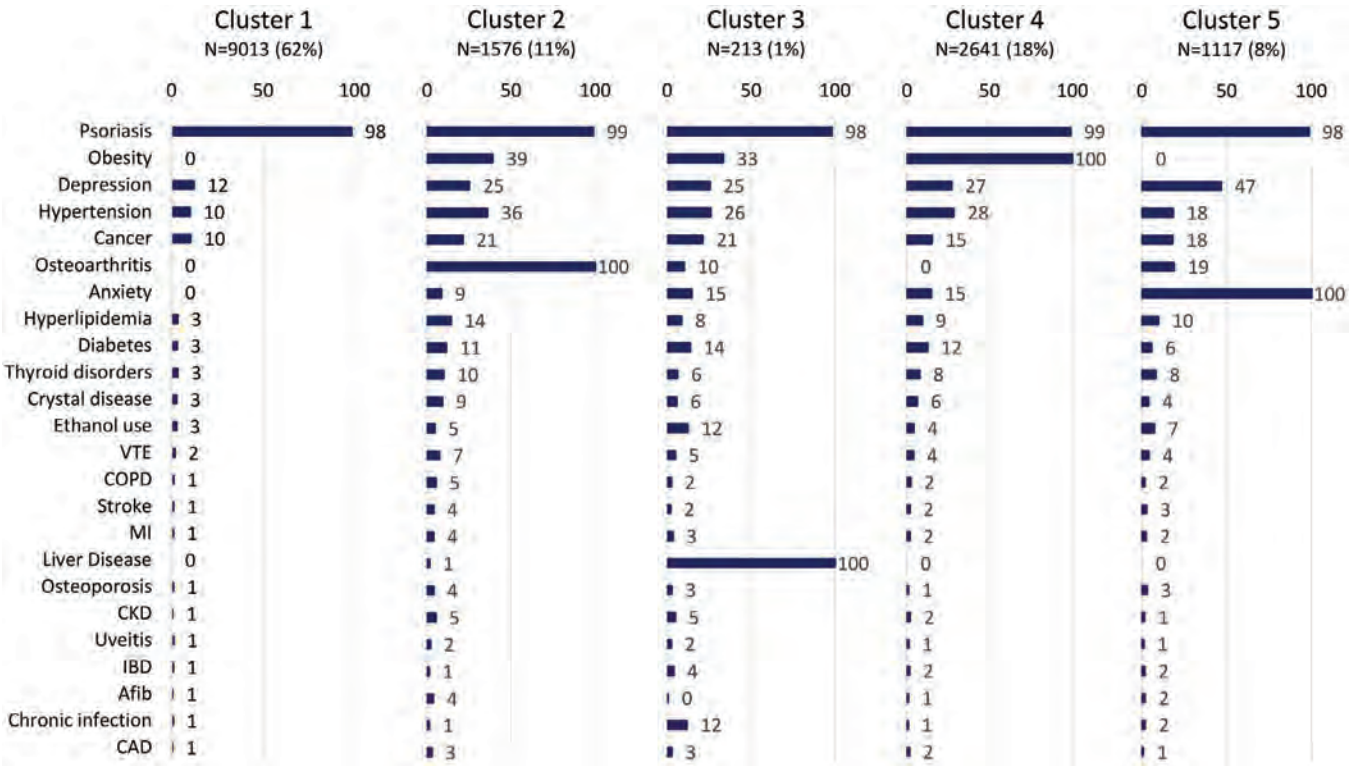

Figure 2. Multimorbidity clusters in psoriatic arthritis

sion (19.2%) (Figure 1). The optimal number of clusters determined using the elbow method was 5. The five clusters included relatively healthy (62%), osteoarthritis (11%), liver disease (1%), obesity (18%), and anxiety/depression (8%) (Figure 2). Males had higher odds of being in the anxiety/depression (OR=2.11, 95% CI 1.86 to 2.40), obesity (OR=1.54, 95% CI 1.41 to 1.68), and osteoarthritis (OR=1.47, 95% CI 1.32 to 1.64) clusters compared to the healthy cluster.

Conclusion: Distinct multimorbidity clusters were identified in PsA patients in the THIN database. Further research is needed to look for common pathophysiologic mechanisms within each clusters and comparison with the general population. The identified clusters could have different effects on important outcomes in PsA.

Co-expression of DC-STAMP and CX3CR1: Biomarkers for Tissue Resident Osteoclasts in Psoriatic Arthritis

Maria de la Luz Garcia-Hernandez[1], Javier Rangel-Moreno[2], Ananta Paine[3], Benjamin Korman[3], Marc Nuzzo[4], Lihi Eder[5] and Christopher Ritchlin[3], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY, [3]Department of Medicine, University of Rochester Medical Center, Rochester, NY, [4]Department of Medicine, University of Rochester Medical Center, Rochester, [5]Women's College Research Institute, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) patients often experience joint damage mediated by osteoclasts (OC). Although PsA pathogenesis is poorly understood, the production of the cytokines IL-17, IL 23, and TNF are implicated in disease initiation and progression. TNF and IL-17 induce the expression of CX3CR1 and the CX3CR1-Fractalkine (FKN) axis promotes inflammation and bone damage in rheumatoid arthritis (RA). In addition, a tissue-resident OC that expresses CX3CR1 was identified in murine arthritis and RA synovial tissue[1]. Dendritic Cell-Surface Transmembrane Protein (DC-STAMP) is expressed on OC precursors (OCP). We found that DC-STAMP$^{-/-}$ mouse fibroblasts exposed to TNF do not secrete FKN and that DC-STAMP$^{-/-}$ x TNFTg arthritic mice show impaired migration of CX3CR1^{+} monocytes to joints. The purpose of this study is to identify whether DC-STAMP and CX3CR1 are co-expressed on OCP in the blood and synovial tissue of PsA patients.

Methods: We collected blood from 23 psoriatic (Ps) and 10 PsA patients to measure serum IL-17 and TNF by multiplex assay. We assessed the frequency of CD14^{+}CX3CR1^{+}DCSTAMP^{+} monocytes in the blood of Ps and PsA patients and controls. We used immunofluorescence to enumerate TNF and IL-17-producing cells in biopsies of non-lesional (NL) and lesional (L) skin of Ps and PsA patients, and qPCR to calculate fold changes in TNF and IL-17 mRNA expression in skin biopsies (L, NL). We enumerated DC-STAMP^{+}CX3CR1^{+} monocyte subsets in 3 synovial and 5 PsA L skin biopsies.

Results: We found low serum TNF levels (Ps, 4.6 ± 1.05 vs PsA, 13.98 ± 6.8, p=0.04), high IL-17 mRNA expression (Ps, 40-fold ± 7.6 vs PsA, 4.6-fold, p = 0.04) and an increased number of IL-17$^+$ cells in L skin of Ps patients (Ps, 31.5 ± 3.3 vs PsA, 7.0 ± 2.6, p = 0.0001). In contrast, PsA patients had higher systemic levels of TNF, lower IL-17 mRNA expression, and poor infiltration of IL-17$^+$ cells in L skin. Interestingly, we visualized higher numbers of TNF-expressing cells in PsA synovial tissue than skin. Flow cytometry analysis showed an increased frequency of CD45$^+$CD14$^+$DC-STAMP$^+$CX3CR1$^+$ circulating monocytes in PsA (2.3%), compared to Ps (0.6%) and controls (0.001%). Intriguingly, DC-STAMP$^+$CX3CR1$^+$CD14$^+$ and DC-STAMP$^+$CX3CR1$^+$ CD14$^-$ monocytes were present only in synovial tissue, while a unique subset of CX3CR1$^-$DC-STAMP$^+$CD14$^+$ cells was present in PsA but not psoriasis skin biopsies.

Conclusion: These findings highlight the divergence of TNF and IL-17 expression in the serum and skin of psoriasis and PsA patients. The co-expression of CX3CR1 and DC-STAMP present only in synovial cells supports the presence of a tissue-resident OC that arises from precursors in the skin and blood.

SESSION INFORMATION

Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: Psoriatic Arthritis
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is increasingly being used to assess the activity of axial disease in patients with psoriatic arthritis (PsA). However, five out of six BASDAI questions are not specific to axial disease. The objective of this study was to evaluate the specificity of BASDAI for axial disease in PsA compared to PsA without axial disease by examining differences in baseline scores, change in scores after therapy initiation, and responsiveness between the two groups.

Methods: Participants (pts) were enrolled in the Psoriatic Arthritis Research Consortium (PARC) longitudinal observational study between 2017-Jan 2020. In this study we included PsA pts initiating therapy with a BASDAI score at baseline and follow up. Pts were classified as having axial disease if they a) fulfilled the ASAS axial spondyloarthritis (axSpA) classification criteria or b) had imaging (MRI, X-ray, or CT) features of axial disease (sacroiliac joints or spine). We descriptively report scores (BASDAI, individual BASDAI items, patient global, patient pain, and the Routine Assessment of Patient Index Data (RAPID3)) at baseline and change in scores following therapy initiation by presence or absence of axial disease.

Table 1. Baseline characteristics and disease activity measures by presence or absence of axial disease in psoriatic arthritis.

Table 1. Baseline characteristics and disease activity measures by presence or absence of axial disease in psoriatic arthritis.

	All	Peripheral only	Axial* +/- Peripheral	p-value
Age (yrs)	49 (13.7)	49.5 (13.1)	48 (15)	NS
Sex (male)	55%	49%	65%	NS
Body mass index	29.7 (6.2)	29.6 (6.1)	29.8 (6.7)	NS
Body Surface Area	1.9% (3.8)	1.2% (1.7)	3.3% (6.1)	0.04
Swollen Joint Count (0-66)	4.1 (5.2)	3.6 (4.2)	4.9 (6.8)	NS
Tender Joint C (0-68)	6.5 (7.3)	6.6 (7.1)	6.4 (7.6)	NS
Enthesitis count (0-8)**	0.7 (1.1)	0.6 (1)	0.9 (1.3)	NS
Dactylitis count (0-20)	0.2 (1.1)	0.3 (1.3)	0.2 (0.6)	NS
BASDAI (0-10)	4.9 (2.1)	4.8 (2)	5.5 (2.6)	NS
Item 1 (Fatigue)	5.3 (2.5)	5.2 (2.4)	5.4 (2.6)	NS
Item 2 (Spinal Pain)	4.8 (2.7)	4.5 (2.7)	5.2 (2.8)	NS
Item 3 (Peripheral joints)	5.2 (2.5)	5.2 (2.4)	4.5 (2.9)	NS
Item 4 (Enthesitis)	4.6 (2.7)	4.7 (2.6)	5.4 (2.7)	NS
Item 5 (AM stiffness duration)	5.2 (2.5)	5.1 (2.4)	5.7 (3.2)	NS
Item 6 (AM stiffness severity)	3.6 (3.1)	3.6 (3)	5 (2.2)	NS
Patient Global (0-10)	4.5 (2.4)	4.3 (2.3)	4.9 (2.6)	NS
Patient Pain (0-10)	5.2 (2.4)	5 (2.3)	5.7 (2.6)	NS
RAPID3 (0-30)	11.7 (5.3)	11.2 (5.2)	12.8 (5.4)	NS

*Axial PsA is defined as having met ASAS classification criteria for axSpA or having an imaging finding consistent with axial PsA.

**Enthesitis count was the Leeds Enthesitis Index plus plantar fascia insertion

Patient Global	-0.60 (2.7)	-0.22	-0.46 (2.4)	-0.19	-0.90 (3.3)	-0.27
Patient Pain	-1.06 (2.7)	-0.39	-0.85 (2.5)	-0.33	-1.51 (3.0)	-0.51
RAPID3	-1.78 (5.4)	-0.33	-1.38 (5.2)	-0.27	-2.7 (5.8)	-0.46

*Axial PsA is defined as having met ASAS classification criteria for axSpA or having an imaging finding consistent with axial PsA.

Abbreviations: BASDAI = Bath Ankylosing Spondylitis Index; Chg = Change; RAPID3 = Routine Assessment of Patient Index Data; SD = standard deviation; SRM = standardized response mean.

Results: Among 117 PsA pts who initiated therapy with a BASDAI at baseline and follow up, the mean age was approximately 49 years, 55% were female, and the mean BMI was 29.7 (Table 1). Among these pts, 30 (26%) had imaging evidence of axSpA, 33 (30%) met ASAS classification criteria (7 had missing data for axSpA criteria), and 40 (34%) met one or both of these criteria. The mean baseline BASDAI score at the time of therapy initiation was 5.5 among those with axial disease by either definition and 4.8 among those without axial disease. This was similar when using either ASAS criteria or imaging evidence of axSpA. Item 2 on the BASDAI, which asks about spine pain, was higher in those with axial disease (5.2) compared to those without (4.5). Item 5 (stiffness) was higher in those without axial disease compared to those with axial disease (5.1 vs 3.7). Patient pain, patient global and the RAPID3 were slightly higher in those with axial disease.

The mean change for BASDAI was -0.81 (SD 2.0) among all pts initiating therapy and similar among axial vs peripheral only (-0.75 vs -0.83). Among the subgroup of 95 pts initiating a TNFi or IL17i, mean change in BASDAI was -0.93 (SD 2.0) with similar differences in SRMs compared to the entire group (-0.47 vs -0.41 respectively) thus only the full cohort of therapy initiators is presented. The SRMs for the individual BASDAI items varied from 0.12 (item 6) to 0.41 (item 5) (Table 2). SRMs were similar across axial vs peripheral only disease for BASDAI (-0.37 vs -0.44 respectively) and individual items. The SRMs for the patient global, patient pain, and RAPID3 however were greater among pts with axial disease (Table 2).

Conclusion: While BASDAI was initially developed as an axial disease measure and works well in axSpA, it is a broad measure of disease activity and current symptoms. The BASDAI has similar scores, change in scores, and responsiveness in PsA regardless of the presence of axial disease.
